ITEGAM - JETIA ISSN 2447-0228 Online
Journal of Engineering and Technology for Industrial Applications (JETIA)

O **ITEGAM-JETIA: Journal of Engineering and Technology for Industrial Applications** is a publication of the Galileo Institute of Technology and Education of the Amazon (ITEGAM), located in the city of Manaus since 2008. JETIA publishes original scientific articles covering all aspects of engineering. Our goal is the dissemination of research original, useful and relevant presenting new knowledge on theoretical or practical aspects of methodologies and methods used in engineering or leading to improvements in professional practice. All the conclusions presented in the articles It should be state-of-the-art and supported by current rigorous analysis and balanced assessment. Public magazine scientific and technological research articles, review articles and case studies.
JETIA will address topics from the following areas of knowledge: Mechanical Engineering, Civil Engineering, Materials and Mineralogy, Geosciences, Environment, Information and Decision Systems, Processes and Energy, Electrical and Automation, Mechatronics, Biotechnology and other Engineering related areas.

Publication Information:
ITEGAM-JETIA (ISSN 2447-0228), (online) is published by Galileo Institute of Technology and Education of the Amazon on a every two months (February, April, June, August, October and December).

SUMMARY

EXPERIMENTAL EVALUATION OF DIESEL ENGINE PERFORMANCE, COMBUSTION AND EMISSIONS OPERATED ON ABD BLENDED WITH AL2O3 **01**
Jayaprakash Parala, D Anjan Kumar Reddy, Mangalapally Srikanth, G Harinath Gowd, U Sreekanth, Harinadh Vemanaboina

FAULT DIAGNOSIS OF ROTATING MACHINERY USING MULTISCALE ENTROPY AND PRINCIPAL COMPONENT ANALYSIS BASED ON MOTOR CURRENT SIGNATURE ANALYSIS **07**
Alpesh M. Patel, Pankaj P. Prajapati, Anilkumar J. Kshatriya, Kirit V. Patel, Ghanshyamkumar Sah, Chintan Dave, Kinjal R. Sheth, Devendra H. Patel

MECHANICAL PERFORMANCE AND FRACTURE MORPHOLOGY OF BAMBOO CELLULOSE NANOFIBER REINFORCED PLA COMPOSITES FOR 3D PRINTING APPLICATIONS **19**
Mujiburrahman K, Aneesh Akthar F, Shaaju Kishore D, Divakar M, Jana Karthikeyan T

A NOVEL TRIANGULATION TOPOLOGY AGGREGATION ALGORITHM OPTIMIZER FOR PHOTOVOLTAIC MODEL PARAMETER EXTRACTION **28**
Abdesslam Belaout, Badis Lekouaghet, Haddad Mohammed

A REVIEW ON THE AERODYNAMIC FLOW CONTROL TECHNIQUES: PROGRESS AND CHALLENGES **37**
V T Gopinathan, R Saravanan, M Ganesh

FROM PID TO REINFORCEMENT LEARNING: EVOLUTION OF CONTROL STRATEGIES IN QUADCOPTER UAVS **51**
Rini Nur Hasanah, Suko Wiyanto, Muhammad Aziz Muslim, Nanang Sulistiyanto, Raden Arief Setayawan

HIGH-QUALITY POWER OF THE PACKED U-CELL 5 INVERTER USING PID AND FUZZY LOGIC CONTROL **67**
Hakim Kadri, Abdelhalim Tlemcani, Noureddine Heninii

DOMAIN-ADAPTIVE ZERO-SHOT IMAGE CLASSIFICATION VIA CLIP AND LARGE LANGUAGE MODELS **78**
Pandi Siddartha, G Kalyan Chakravarthi, Koyya Karthik, Nemathapalli Naga Vinay, K B V Dakshina Murthy

IMPROVED CERVICAL CANCER CLASSIFICATION BY WEIGHTED MAJORITY VOTING WITH SAMPLING **89**
Lavanya Devi N, C N Savithri, M Jayanthi, S M Asha Banu.

INTELLIGENT NETWORK INTRUSION DETECTION USING FEA-CASSTFORMERNET OPTIMIZED BY ARCHERFISH HUNTING ALGORITHM **99**
S. Tamil Selvan, Haritha K Sivaraman, T. Anupama Thankam, Gavaskar Vincent

AN INTEGRATED HALF BRIDGE BASED RESONANT LED DRIVER FOR MULTIPLE LIGHTING APPLICATION **120**
Sreenivasulu Meda, Narendra Rao R, Ramakrishna Busharaju

A DEEP GENERATIVE ENSEMBLE FRAMEWORK BASED ON TABULAR VARIATIONAL AUTOENCODER FOR IMBALANCED SOFTWARE DEFECT PREDICTION **133**
Moch. lutfi, Muhammad Faishol Amrulloh, Zulfatun Nikmatus Saadah, Ahmad Zulham Fahamsyah Havy, Arief Tri Arsanto

ITEGAM - JETIA
ISSN 2447-0228 Online
Journal of Engineering and Technology for Industrial Applications (JETIA)

INVESTIGATING BIO-INSPIRED FEATURE SELECTION FOR AN ENHANCED ENSEMBLE-BASED INTRUSION DETECTION SYSTEM **148**
Souad Guessoum, Oussama Kadri, Nabiha Azizi

TO IDENTIFY FACIAL EMOTIONS USING AN ENHANCED CNN-TCN MODEL **156**
B Maidhili, R Thirumalai Selvi

ADAPTIVE COST MODEL EVOLUTION THROUGH ONLINE LEARNING: A SELF-TUNING FRAMEWORK FOR DYNAMIC DATABASE OPTIMIZATION **167**
Mohamed Goismi, Moustafa Maaskri, Mohamed Debbab, Djamal Seghier

A BLOCKCHAIN NETWORK FOR APPLICATION FOR THE SECURE GOODS AND SERVICES TAX TRANSACTION BASED ON HOOK CURVE REVISED HASH AUTHENTICATION **181**
Gayathri B, Vishwa Priya V

IMPROVISED HARRIS HAWKS OPTIMIZATION WITH ROUGH SET MIN-MAX CLASSIFIER FOR FEATURE SELECTION TO ENHANCE DISEASE PREDICTION **193**
Devi S, V.S. Arulmurugan, V Sujatha, K.E. Narayana, Saranya K S, M. Balamurugan, J Parthasarathy

RESEARCH ON AERIAL IMAGE ROAD EXTRACTION METHOD BASED ON IMPROVED SRCNN **202**
Rongfu Wang, Mary Jane C. Samonte

THE INTERPLAY OF MASS LOADING AND ACTIVE SITE ACCESSIBILITY IN MANGANESE OXIDE THIN-FILM ELECTRODES FOR ELECTROCHEMICAL CAPACITOR **214**
Zineb Nabti, Reda Bekhakhecha, Tarik Bordjiba

AN IN-DEPTH, THREE-DIMENSIONAL STRESS ANALYSIS OF THICK POROUS FUNCTIONALLY GRADED SANDWICH PLATES **222**
Slimane Merdaci, Youcef Beldjelili, Adda Hadj Mostefa, Mohamed Elamine Dahamni

DESIGN OF AN ITERATIVE METHOD FOR EFFICIENT STREAMING DATA ANALYSIS USING DYNAMIC SPARSE TEMPORAL CONVOLUTIONAL NETWORKS AND SPARSE META-ADAPTIVE LEARNING **233**
Rushikesh M Shete, Virendra K. Sharma

A COMPREHENSIVE REVIEW ON DEEP LEARNING TECHNIQUES FOR DISEASE DETECTION IN COTTON CROPS **244**
Kishore Kumar Kamarajugadda, Pavani Movva

ENSEMBLE TRANSFER LEARNING MODEL FOR THE DETECTION OF DIABETIC RETINOPATHY DISEASE **256**
Ishaq Aiche, Youcef Brik, Bilal Attallah, Oussama Bouguerra

VALORIZATION AND EVALUATION OF SAND TYPE ON FRESH AND HARDENED PROPERTIES OF SELF-COMPACTING REPAIR MORTAR USING LIMESTONE POWDER AS FILLER **271**
Salhi Aimad, Kriker Abdelouahed; Tioua Tahar; Dehane Sara

HYBRID GREY WOLF AND CUCKOO SEARCH OPTIMIZATION FOR OPTIMAL ENERGY MANAGEMENT IN MICROGRID SYSTEMS **281**
N Chinna Alluraiah, Pujari Harish Kumar, Reshma Gopi R, P Vijayapriyai

A BIBLIOMETRIC ANALYSIS OF NON-INDUSTRIAL ROBOTICS AND AUTOMATION RESEARCH FROM A CREATIVE APPLICATIONS PERSPECTIVE **292**
Ashish Batuklal Jagani, Nikunj Rachchh

ITEGAM - JETIA
ISSN 2447-0228 Online
Journal of Engineering and Technology for Industrial Applications (JETIA)

MEASURING REVIEW CREDIBILITY AND DECEPTION ON E-COMMERCE PLATFORMS THROUGH NLP AND CHAOS THEORY **303**
Preeti Marwaha, Arunita Chaukiyal

PERFORMANCE ENHANCEMENT OF PHOTOVOLTAIC SOLAR PANELS BY A CLEANING ROBOT TECHNIQUE **312**
Pujari Harish Kumar, N Chinna Alluraiah, Swetha Shekarappa G, K Harinath Reddy, Keerthana M

ENHANCED PITCH ANGLE OF AIRCRAFT SYSTEM USING FRACTIONAL MODEL REFERENCE ADAPTIVE CONTROL APPROACH **320**
Benzenati Rahima, Bensafia Yassine, Lehouche Hocine

A CRITICAL REVIEW OF BIM ADOPTION IN DEVELOPING COUNTRIES: INSIGHTS FROM GLOBAL LITERATURE AND INDONESIAN CASE STUDIES **328**
Fendico Hary Yanto, Widi Hartono, Taufiq Lilo Adi Sucipto

A MODIFIED DROOP CONTROL FRAMEWORK FOR MULTI-TERMINAL VSC-HVDC SYSTEM WITH IMPROVED POWER SHARING AND VOLTAGE REGULATION **337**
Moussa Belgacem, Mohamed Khatir, Riyadh Bouddou, Sami Mohammed Bennihi, Nasreddine Bouchikhi

DESIGN AND VALIDATION OF A COMPETITION GRADE OFF-ROAD MOTORCYCLE FROM A STOCK DUAL-SPORT BASELINE **351**
Kumaran P, Natarajan S, Sathiyaraj S, Prabhu S, Nithishkumar K

DIGITAL TRANSFORMATION IN TECHNICAL AND VOCATIONAL EDUCATION AND TRAINING (TVET): A SYSTEMATIC LITERATURE REVIEW **365**
Deden Witarsyah, Hadi Almohab, Mohd Farhan Bin Fudzee, Seyma Kocak

A CATALYST FOR INNOVATION IN BUSINESS: ARTIFICIAL INTELLIGENCE IN E-COMMERCE DIGITAL TRANSFORMATION STRATEGIES **376**
Andrii Shevchuk, Kateryna Poliak, Valentyna Pavlova, Olesia Romanenko, Andrii Popov

OPTIMISED PLACEMENT OF MICRO-PMUS AND VOLTAGE ESTIMATION IN RADIAL DISTRIBUTION NETWORKS CONSIDERING ZERO INJECTION CONSTRAINTS **384**
Vamsidhar Reddy G, Palepu Suresh Babu, Venkata Ramana K, Sravan kumar T, Vinay kumar Reddy M

SECURITY-ORIENTED CODE METRICS FOR MACHINE LEARNING–BASED VULNERABILITY PREDICTION IN SOURCE CODE **393**
Mohammed Zagane

MULTIMEDIA DEEPFAKE THREATS AND DETECTION STRATEGIES BASED ON LIMITED DATA: AN EXHAUSTIVE SURVEY **401**
Nour Thani Mustafa, Omar Ibrahim Al-Saif, Wasan Shakir Awad

FROM CLASSICAL FILTERING TO ADAPTIVE AND AI-DRIVEN PARADIGMS: A PRISMA-BASED SYSTEMATIC REVIEW AND BIBLIOMETRIC ANALYSIS OF EMG SIGNAL FILTERING **411**
Samsul Arifin, Nuryani Nuryani, Mohtar Yunianto

DUALATT-VITRESNET WITH FENNEC FOX OPTIMIZED HYPERPARAMETERS FOR AUTOMATED OSTEOPOROSIS CLASSIFICATION USING MEDICAL IMAGING **423**
V Venkatachalam, N Subash, P Archana Devi, Saranya S, R Tharwin Kumar, Chokkan Priyadharshini

ITEGAM - JETIA
ISSN 2447-0228 Online
Journal of Engineering and Technology for Industrial Applications (JETIA)

GREEN ECONOMY AND ENERGY TRANSITION: ECONOMIC MODELS FOR INTEGRATING RENEWABLE ENERGY IN EASTERN EUROPEAN COUNTRIES **445**
Viktoria Beliavtseva, Tetiana Gorokhova, Olena Cherniavska, Iryna Korostova, Iryna Makaliuk

HYBRID DEEP LEARNING MODELS FOR PREDICTING COMPRESSIVE STRENGTH OF FDM 3D-PRINTED STRUCTURES **454**
M Jayakrishna, M Vijay, Manas Ranjan Padhi

DESIGN OF A NOVEL HN-SHAPE MICROSTRIP PATCH ANTENNA USING DGS TECHNIQUES AT 11 GHZ AND 20 GHZ **463**
Marcelo Maia do Nascimento, Railma Lima de Paula

TOWARDS SPATIO-TEMPORAL DEEP LEARNING WITH FEATURE SELECTION FOR ROBUST DDOS ATTACK DETECTION **473**
Mohamed kamel Benkaddour, Mohammed El Aymene Beyat

A NEW COMPARATIVE STUDY OF THE CONTROL METHODS USED TO REGULATE DC VOLTAGE, POWER FACTOR AND HARMONIC DISTORTION IN A THREE-PHASE RECTIFIER **482**
Zouggar Eloualid, Rouabhi Riyadh, Herizi Abdelghafour, Abed Ahcene

DESIGN OPTIMIZATION AND PERFORMANCE ANALYSIS OF TIO_2-REINFORCED DISSIMILAR AA5083–AA6063 FRICTION STIR WELDED JOINTS USING TAGUCHI METHOD **490**
Sittichai Charonerat, Chuthong Summatta, Thanatep Phatungthane

EFFICIENT AND INTERPRETABLE DETECTION OF SUICIDAL IDEATION IN SOCIAL MEDIA VIA GLOVE EMBEDDINGS, RECURSIVE FEATURE ELIMINATION, AND A LIGHTWEIGHT TRANSFORMER **498**
Houari Benabid, Moustafa Maaskri, Mohamed Goismi

DETECTING THE UNDETECTABLE: A REVIEW OF CUTTING-EDGE DEEP-FAKE DETECTION TECHNIQUES **517**
Navnee Babar, Shilpa Metkar, Rashmi Gaikwad, Shweta Patil

ENHANCING BRAIN–MACHINE INTERFACE APPLICATIONS FOR DISABLED INDIVIDUALS USING VISUAL EVOKED POTENTIALS AND EXPLAINABLE AI **524**
Kalakonda Jyothsna, Ravichander Janapati, Viswaprakash Babu

COMPACT SINGLE-LAYER MULTIBAND MICRO STRIP PATCH ANTENNA USING DUAL-CONNECTED T-SLOT AND PARASITIC ELEMENTS FOR IOT AND 5G APPLICATIONS **536**
Shahid Salauddin Modasiya, Balvant J Makwana, Komal D Anadkat, Mitul B. Patel

BEARING FAULT DIAGNOSIS: DATASETS, SIGNAL PROCESSING PARADIGMS, AND INTELLIGENT DIAGNOSTIC FRAMEWORKS **545**
Hitesh K Patel, Divyang H Pandya, Ankit Darji

DEVELOPMENT OF GRAPHICAL USER INTERFACE (GUI) TO CONTROL ROBOTIC ARM FOR BIOMEDICAL APPLICATIONS **567**
Ritesh G Mahajan, Girish Laxmikant Allampallewar, Mohd. Imran Ansari, Akshay Ramesh Kumar Shah, Om Mangesh Chandavale, Mohammad Asaad Abrar Sayed

HIGH-FIDELITY RETRIEVAL OF LOW - LIGHT UNDERWATER IMAGES USING ADVANCED DEEP LEARNING MODEL FOR ENHANCED VISUAL QUALITY **581**
B Madhavi, Gorisetty Nirosha, Y. Gayatri, V Srinadh, Suneetha Regidi, Nagamalli Arasavalli

ITEGAM - JETIA
ISSN 2447-0228 Online
Journal of Engineering and Technology for Industrial Applications (JETIA)

FEATURE-BASED CLASSIFICATION OF MEDICINAL PLANT: PIGWEED (URAY) AND BIRCH FLOWER (HIMBABAO) USING K-NEAREST NEIGHBORS **589**
Abegail Ronio Rareza

THE USE OF ARTIFICIAL INTELLIGENCE IN DETECTING DISINFORMATION AND ENSURING CYBERSECURITY **600**
Yurii Kryvoruchko, Yevhen Solomin, Tetiana Mazurok, Valentyna Kozak, Volodymyr Shusta

NATURAL FIBER-REINFORCED PLA COMPOSITES FOR FUSED DEPOSITION MODELING: A CRITICAL ASSESSMENT AND EXPERIMENTAL FEASIBILITY OF JUTE FIBER REINFORCEMENT **611**
Divyeshkumar Morabiya, Hiren Joshi

WHAT FACTORS IMPACT THE RELATIONSHIP BETWEEN THE PAPER INDUSTRY AND PAPER CHEMICAL SUPPLIERS TO ENHANCE THE PAPER INDUSTRY'S COMPETITIVENESS? **625**
Daisy Ade Riany Diem, Marimin Marimin, Machfud Machfud, Elisa Anggraeni

LLAMA-3 OPTIMIZED RETRIEVAL-AUGMENTED CHATBOT FOR DYNAMIC QUERY HANDLING AND ENTERPRISE INTEGRATION **634**
Juthuka Aruna Devi, T Anusha, Ramesh Makala, Pala Pooja Ratnam, Krishna Rupendra Singh, Rajendra Kumar Ganiya, Marada Srinivasa Rao

TRUSTLEARN: AN END-TO-END TRUSTWORTHY FRAMEWORK FOR ADAPTIVE MICROLEARNING IN NET-ZERO ENERGY COMMUNITIES USING BLOCKCHAIN-ENHANCED MULTI-AGENT FEDERATED REINFORCEMENT LEARNING **646**
Mohamed Goismi, Djamel Seghier, Moustafa Maaskri, Mohamed Debbab

IMPROVED DC MOTOR SPEED REGULATION AND DISTURBANCE REJECTION VIA FRACTIONALIZED PID CONTROL USING THE OPTIMAL FRACTIONAL-ORDER SYSTEM APPROXIMATION METHOD **661**
Benzenati Rahima, Bensafia Yassine, Lehouche Hocine

ROLE OF SHIM-INDUCED PASSIVE DAMPING ON SURFACE ROUGHNESS OPTIMIZATION IN FACE MILLING **670**
Vijaykumar V Patel, Divyang H Pandya, Kaushal Bhavsar

OPTIMIZATION AND PERFORMANCE CHARACTERIZATION OF FIR BUTTERWORTH FILTERS ON RESOURCE-LIMITED EMBEDDED PLATFORMS **684**
Smit Lekhadia, Ghanshyamkumar Sah, Alpesh M. Patel, Shantanu Joshi, Kirit Patel, Anilkumar Kshatriya

SYNERGISTIC BIOGAS GENERATION FROM ALKALINE TREATED COTTONSEED HULL AND COW DUNG IN A MESOPHILIC BATCH REACTOR **696**
Venkateshkumar R, Nandhakumar R, Veera Subhash Geddam, Venkatesan V, Musthafa B, Srinivasan S A

EXPERIMENTAL AND NUMERICAL ASSESSMENT OF A SUSTAINABLE FLAT-PLATE SOLAR COLLECTOR USING RECYCLED POLYMER-METAL COMPOSITES IN HIGH-ALTITUDE ANDEAN ENVIRONMENTS **703**
Robinson García, Carlos Garzón

DEVELOPMENT OF A FRONT-END INTERFACE FOR REAL-TIME SMART PRODUCTION MONITORING IN THE CONTEXT OF INDUSTRY 4.0 **712**
Jandecy Cabral Leite, Marcelo Maia do Nascimento, Anderson Alexandre Silva de Almeida, Matheus Pereira de Souza, Leonardo da Silva Martins, Paulo Ricardo Ferreira da Silva, Marcos Henrique Gomes Brasil

ITEGAM - JETIA
ISSN 2447-0228 Online
Journal of Engineering and Technology for Industrial Applications (JETIA)

BLOCKCHAIN-ENABLED EXPLAINABLE ARTIFICIAL INTELLIGENCE FRAMEWORK FOR TRUSTED AND AUDITABLE DIABETES RISK PREDICTION **725**
Michael Angello Qadosy Riyadi, Yohanes Setiawan, Muhammad Adib Kamali

EXERGOENVIRONMENTAL ASSESSMENT OF LIGNOCELLULOSIC BIOMASS PYROLYSIS FOR ENERGY VALORIZATION AND ENVIRONMENTAL SUSTAINABILITY **739**
Jesus D. Rhenals Julio, Jorge Mario Mendoza Fandiño, Camilo Andrés Vanegas Espitia, Kener Andrés Suarez Pérez, Taylor De la vega Gonzalez, Miguel Emigdio Doria Oviedo

A DESIGN SCIENCE-BASED FRAMEWORK FOR CMMS IMPLEMENTATION IN PUBLIC-SECTOR ENGINEERING MAINTENANCE **749**
Huzaini bin Mohd Noor, Saiful Amri Mazlan

DESIGN OF MODIFIED LUO CONVERTER WITH ENHANCED MPPT ALGORITHM FOR PV SYSTEMS **756**
Sivaprasad Kollati, Satish Kumar Gudey

ELECTROMAGNETIC WAVE INTERACTION WITH BREAST TISSUE USING MICROWAVE IMAGING WITH ULTRA-WIDEBAND ANTENNAS **766**
Somanath K. KISAN Chikane, Balasaheb H Patil, Shailendrakumar Mukane

CURVE-FITTING-BASED FIR FILTER DESIGN FOR STOP-BAND ATTENUATION PERFORMANCE IMPROVEMENT **773**
Raouf Amrane

AVATAR-DRIVEN SYNTHETIC DATA AUGMENTATION FOR ENHANCED MULTILINGUAL SIGN LANGUAGE RECOGNITION **780**
AYounes Ouargani, Noussaima El Khattabi

COMPARATIVE ANALYSIS OF DIFFERENT BIOMASS GASIFICATION TECHNOLOGIES FOR SYNGAS PRODUCTION **790**
Kelly Johanna Ortega Jiménez, Francisco Rafaél Alarcón Polo, Jorge Mario Mendoza Fandiño, Jesus David Rhenals, Samuel Ivan Bonilla Gracia, Miguel Emigdio Doria Oviedo

DEVELOPMENT OF AN INTELLIGENT MACHINE PARAMETERIZATION SYSTEM USING ARTIFICIAL INTELLIGENCE FOR INDUSTRY 4.0 **802**
Jandecy Cabral Leite, Marcelo Maia do Nascimento, Anderson Alexandre Silva de Almeida, Matheus Pereira de Souza, Leonardo da Silva Martins, Paulo Ricardo Ferreira da Silva, Marcos Henrique Gomes Brasil

SEMI-DUAL ATTENTION: A STRUCTURE-PRESERVING ATTENTION MECHANISM DERIVED FROM SEMI-DUAL OPTIMIZATION THEORY **811**
Jincheng Zhang, Rukthin Laoha, Potsirin Limpinan, Thada Jantakoon

PERFORMANCE AND EFFICIENCY TRADE-OFFS IN IMAGE-BASED CONCRETE CRACK DETECTION: A COMPARATIVE STUDY OF TRADITIONAL MACHINE LEARNING AND DEEP LEARNING MODELS **825**
Rouabah Slim, Fekir Mohamed, Mahdab Salim, Bentchikou Ibrahim, Naas Youcef, Abdelkader Rabah

HIGH SENSITIVE 2D PHOTONIC CRYSTAL BIOSENSOR BASED ON HEXAGONAL RESONATOR COUPLED WITH A CAPSULE-SHAPED FOR THE DETECTION OF DEFERENT CANCEROUS CELLS **833**
Hocine Bensalah, Wahiba Menasri, Abderrahmane Imam, Abdesselam Hocini, Mohammad Soroosh, Hocine Bahri, Hiba Bouandas, Imane Zegaar, Abdelhalim Tlemcani, Nadia Menasri

ITEGAM - JETIA
ISSN 2447-0228 Online
Journal of Engineering and Technology for Industrial Applications (JETIA)

COMPARATIVE EXPERIMENTAL STUDY ON THE COMPRESSIVE PERFORMANCE OF FDM-PRINTED PLA AND ABS USING DIFFERENT INFILL ARCHITECTURES **841**
Makka Jayakrishna, Miditana Vijay, Salavaravu Laxmanaraju

MODELING, POSITION TRACKING AND ANTI-SWAY CONTROL OF A 3D OVERHEAD CRANE USING INTELLIGENT CONTROL STRATEGIES **849**
Amine Mehdi Fihakhir, Abdesselam Guerbouz

UTILIZING AN ARTIFICIAL INTELLIGENCE-BASED APPROACH TO EVALUATE STUDENT ACADEMIC PERFORMANCE THROUGH THE APPLICATION OF AN ENSEMBLE ALGORITHM **859**
Manocher C Alipour

MULTIMODAL DIFFUSION MODEL FOR SYNTHETIC ALZHEIMER'S DISEASE DATA GENERATION USING MRI, PET, AND CLINICAL BIOMARKERS **866**
Jyoti Kumari, Shyam Sundar Gupta

GEOMETRIC-COMPOSITIONAL AND COMBINATORIAL MODELS OF THE FORMATION OF SHELL ARCHITECTURAL SYSTEMS IN THE CONTEXT OF ORGANIZATIONAL AND TECHNOLOGICAL SUPPORT OF THE LIFE CYCLE OF MEDICAL BUILDINGS **876**
Andrii Hurtovenko, Aram Daniyelyan, Oleksii Yashchenko, Oksana Makohin, Serhii Kelba

EDUBOOST: A HIGH-ACCURACY XGBOOST FRAMEWORK FOR STUDENT ACADEMIC PERFORMANCE PREDICTION **884**
Chennaiah Kate, T. Aditya Sai Srinivas, Md. Asim, Mohan Sai Kumar, Purude Vaishali Narayanrao, Smitha Sasi

A CONTRASTIVE SIAMESE 1D-CNN WITH HYBRID FEATURE OPTIMIZATION FOR ACCURATE DIABETES PREDICTION FROM EHR DATA **895**
Chennaiah Kate, C. Maddilety, Vibhor Harit, Arumbaka Srinivasa Rao, Mohan Sai Kumar CH., Rajeswari Periyasamy

EXPERIMENTAL AND THEORETICAL INVESTIGATION OF A MODIFIED SOLAR STILL INCORPORATING PCM, CUO NANO-COATED ABSORBER, AND A COPPER SPIRAL TUBE **906**
Bhavin Girishbhai Chavda, Virang H Oza, Vipul M Patel

INFLUENCE OF ABRASIVE TYPE AND PROCESS PARAMETERS ON MATERIAL REMOVAL CHARACTERISTICS IN ABRASIVE WATER JET DRILLING OF INCONEL 939 ALLOY **916**
Praveen Jayapalan, Rajesh Munusamy, Sandhya Jayakumar

AN INNOVATIVE VARIABLE MAGNETIC GEAR SYNCHRONOUS MOTOR TOPOLOGY FOR ELECTRIC VEHICLES **923**
kamel Salim Belkhir, Houcem Achouri, Kawther Fatmi

MAPPING THE LANDSCAPE OF CIRCULAR ECONOMY RESEARCH IN INDIA: A BIBLIOMETRIC ANALYSIS **933**
Shailendra Singh Rana, Mahadev Madgule, Ajay D. Pingale, Diplesh Gautam

FINITE ELEMENT ANALYSIS AND MECHANICAL TESTING OF TITANIUM ALLOY (TI-6AL-4V) AND SILICON CARBIDE (SIC) FOR HIP IMPLANTS **942**
Selva Babu B, Bubesh Kumar D., Prabhu L., Sathiyaraj S.

A REVIEW ON THE OPTIMIZATION OF ENTERPRISE DATA SECURITY USING NEURAL NETWORKS **951**
Nestor Abel Sánchez-Goycochea, José Angel Vásquez-Coronel, Miguel Serón

ITEGAM - JETIA
ISSN 2447-0228 Online
Journal of Engineering and Technology for Industrial Applications (JETIA)

IMPROVING DIESEL ENGINE EFFICIENCY AND EMISSION CHARACTERISTICS USING CERIUM OXIDE NANOPARTICLE-BLENDED GREEN ALGAE BIODIESEL **962**
Abdul Favas, Ramarao Madhialagan, Prakash Sekar, P. Kumaran

OPTIMAL WIND–THERMAL ECONOMIC DISPATCH CONSIDERING VOLTAGE STABILITY IMPROVEMENT USING MANTA RAY FORAGING OPTIMIZATION ALGORITHM **971**
Arif Bourzami, Mohammed Amroune, Mabrouk Haddar

DESIGN AND DEVELOPMENT OF A LEG REHABILITATION SYSTEM FOR PARALYSED PERSON – AN INNOVATIVE APPROACH **980**
Vivek Chandrasekaran, Sivasankar Arumugam, Balamurugan Gopalakrishnan

A COMPREHENSIVE EXPERIMENTAL AND MULTI-CRITERIA DECISION-MAKING FRAMEWORK FOR OPTIMIZING SS316/TI6AL4V POWDER METALLURGY COMPOSITES **988**
Imthiyas A, Bubesh Kumar D., Sangeetha Krishnamoorthi S., Vishwanathan K.

AI-POWERED FLIGHT PATH PLANNING: TRANSFORMING DRONE NAVIGATION AND AUTONOMY **1000**
Madan H T, Aruna Kumara B, Vishwanath B R, Pramodh H K, Manjunatha H M

A SINGLE-TERMINAL FAULT LOCATION METHOD USING HYBRID PSO-GA OPTIMIZATION AND DISTRIBUTED PARAMETER LINE MODELING **1017**
Ali Adnan Ajel, Kassim Al-Anbarri

EXPLAINABLE PARALLEL SPATIO-TEMPORAL HYBRID ARCHITECTURE FOR CLINICALLY ROBUST ECG ARRHYTHMIA DETECTION **1027**
Murteza Hanoon Tuama, Mohammed Baker Yousif, Asseel Jabbar Almahdi

DATA-DRIVEN IDENTIFICATION OF PRODUCT QUALITY DEFECT DRIVERS IN MANUFACTURING SYSTEMS **1037**
Md Foysal Hossain, S M Habibullah, Md Jahedul Islam Arif, Maksud Miah, Ariful Islam, Fahim Rahman, Al Akhir

EXPERIMENTAL EVALUATION OF EGGSHELL WASTE AS AN ECO-FRIENDLY STABILIZER FOR MARLY SOIL **1050**
Hizia Bekhouche, Ouassila Bahloul, Aidoud Assia, Laid Lekouara

DEVELOPMENT OF AN INTEGRATED INTELLIGENT MANUFACTURING SYSTEM UTILIZING IOT AND DATA MINING FOR THE DIGITAL TRANSFORMATION OF INDUSTRY 4.0 **1059**

ABSTRACT

Cross-Site Scripting (XSS) attacks remain one of the most impactful attacks and a major threat to web applications, especially when malicious payloads are stuffed via email input. Although advanced learning solutions have achieved significant detection, their computational and time-consuming heuristics often prevent their deployment in resource-limited environments, such as shared hosting or edge sites. This paper presents a lightweight machine learning approach designed to instantly detect XSS attacks originating from web forms. The model is capable of operating independently without relying on external resources or systems (such as cloud services or large detection engines). The proposed solution focuses on a combined feature set consisting of fast-to-calculate syntactic and lexical indicators (such as tag count, suspicious token frequency, coding markup, and entropy). Simple and well-established classifiers—logistic regression, random forest, and LightGBM—were used, focusing on detection effectiveness (precision, recall, F1, and AUC) and operational constraints (inference time per sample and model size). To reflect real-world conditions, the experiments combine generic XSS payloads, benign sample templates, and synthetically modified payloads that mimic the obfuscation and encryption techniques used by attackers. The results are lightweight, low-effort, and highly accurate, and they compete with heavier competitors, with significantly lower semantic and memory footprint costs.

I. INTRODUCTION

I.1 CROSS- SITE SCRIPRING (XSS) ATTAC CONCEPTS

In the modern digital ecosystem, web applications form the backbone of e-commerce, social networking, online banking, and enterprise operations [1]. Their functionality relies heavily on user-provided input through mechanisms such as HTML forms, URL query parameters, HTTP headers, and the delivery of dynamic content via AJAX or API endpoints [2].While these mechanisms are essential for delivering interactive and personalized experiences, they also present significant security vulnerabilities, particularly injection-based attacks [3], [4].Among these threats, cross-site scripting (XSS) remains one of the most prevalent and impactful, consistently ranking among the top 10 most common security risks on OWASP's list [5]. XSS attacks allow attackers to inject and execute malicious scripts within the context of a victim's browser, enabling serious exploits including session hijacking, credential theft, phishing via content spoofing, cross-browser cryptocurrency mining, and client-side malware [6]. Beyond the compromise of individual users, XSS vulnerabilities can form the backbone of large-scale breaches, undermining user trust and an organization's reputation [7], [8]. Traditional defenses against XSS—such as input sanitization libraries, context-aware cryptographic functions, and signature-based web application firewalls (WAFs)—have demonstrated partial effectiveness [9]. However, attackers routinely circumvent these measures by using advanced evasion strategies, including multi-layer encryption, Unicode/HTML entity obfuscation, DOM-based injection chains, and polymorphic payload generation [10].

Consequently, XSS payload detection has evolved from simple pattern matching to more sophisticated techniques based on machine learning (ML) and deep learning (DL)[11], [12]. Recent academic and industry research demonstrates that ML- and DL-based detectors outperform rule-based systems in identifying complex and obfuscated attack vectors [13].

I.2 PROBLEM STATEMENT

The threat of Cross-Site Scripting (XSS) persists in web applications because attackers continuously develop new payload structures and obfuscation methods. These solutions depend on computationally intensive models which include CNNs, RNNs and deep ensemble architectures that need substantial memory resources and processing power and result in extended inference times. The computational requirements of these systems prevent their practical use in resource-limited environments including:

- Shared hosting servers with limited CPU quotas.
- Content delivery network (CDN) edge nodes where the processing time per request must be kept to a minimum.
- Web portals integrated with the Internet of Things (IoT) with strict power and latency constraints.

The research indicates a need for a solution that achieves detection performance at a lower computational cost than deep models. The proposed solution develops a lightweight machine learning framework which functions independently to detect XSS payloads in model-based inputs.

I.3 CONTRIBUTIONS OF THIS STUDY

The research delivers three essential contributions to the field. The research presents a new engineering method which detects model-based XSS payloads by optimizing discrimination power and computational efficiency. The proposed model functions independently because it does not need external resources or systems including cloud services or large-scale detection engines. The research combines accuracy-focused feature development with resource-sensitive classification to achieve real-time XSS attack detection while maintaining operational scalability. The research advances web application security through its contributions which create more secure efficient and resilient systems against advanced client-side threats.

II.RELATED WORK

Researchers have developed ensemble-based approaches to improve robustness. Shahid et al [14]. proposed a deep framework of embedded convolutional networks (CNNs) and long short-term memory (LSTM) networks to detect XSS and SQL attacks, significantly improving the severity of false positives. in [15] Oshoiribhor and A. John-Otumu, presented XSS-Net, a custom machine learning model optimized for construct optimizations, which demonstrates improved robustness beyond traditional methods. At the same time, multiple learning architectures are gaining momentum, along with the ability to automatically learn complex types of raw data. in [16] Yan et al. presented a multiple convolutional neural network that detects XSS payloads embedded in obfuscated scripts, achieving superior performance over traditional learning models. In [17] implemented an LSTM-based model specifically designed for cloud environments, emphasizing the importance of sequential contextual learning for complex control trends. Recently, large-scale hybrid models between email and modern technologies have disrupted fast emails. In [18]

Alluraini, proposed a bipartite graph representation of XSS combined with aggregated DL classifications, enhancing previously unseen innovations. Furthermore, in [19] Lewon developed XSShield, a lightweight hybrid DL model powered by new aggregated data, enabling high-performance and low-latency inference for creative content applications. Furthermore, some optimization-driven work is exported. In [20] Babaey and A. Ravindran developed GenXSS, an AI-driven detector framework that uses genetic algorithms to dynamically optimize models, improving their adaptability to advanced innovations. Similarly, in [21] Zheng et al. combined XGBoost, LightGBM, and SMOTE to balance imbalanced datasets and detect payment security system applications, demonstrating their adaptability to XSS detection tasks. Overall, while we observed the bulk of the monitors dedicated to effective learning in legacy payload control, hybrid learning and ensemble models are adaptable and resilient against aggressively designed XSS attacks and zero-day attacks. However, challenges remain in model versatility, interpretability, and adaptability to the readiness stage.

Table 1: The summary of related works on detecting XSS attack.

Authors	Methodology	Application / Dataset Type	Advantages	Limitations
[14]	Deep framework of embedded CNN + LSTM	Detection of XSS and SQL attacks on mixed datasets	Significantly reduces false positives; captures sequential + spatial features	Computationally expensive; requires large datasets
[15]	XSS-Net (custom ML model with construct optimizations)	Web application form inputs	Improved robustness beyond traditional methods	Requires fine-tuning for different environments
[16]	Multiple CNN architecture	Obfuscated XSS payloads embedded in scripts	Superior performance over traditional ML; strong obfuscation handling	May not generalize well to novel attack types outside training scope
[17]	LSTM-based sequential contextual model	Cloud environment datasets	Captures long-term dependencies; suited for complex control trends	Slower inference speed in large-scale deployments
[18]	Bipartite graph + aggregated DL classifications	Large-scale hybrid datasets (email + web)	Novel representation improves detection of unseen patterns	Graph-based models require more preprocessing
[19]	XSShield: Lightweight hybrid DL model with	Creative content & real-time applications	High performance with low latency	Limited evaluation on large-scale enterprise traffic

	aggregated data			
[20]	GenXSS (genetic algorithm optimized DL model)	Adaptive XSS detection frameworks	Dynamically optimizes model parameters; improved adaptability	Higher complexity; optimization adds overhead
[21]	XGBoost + LightGBM + SMOTE	Payment security and XSS detection tasks	Balances imbalanced datasets; robust detection in multiple domains	Training time increases due to SMOTE and en

III. METHODOLOGY

This section outlines the end-to-end methodology adopted in this work, covering dataset construction, preprocessing, feature engineering, model selection and training, evaluation protocols, deployment considerations, and the self-contained operational capability of the proposed system.

III.1 DATASET CONSTRUCTION

To create a representative, reproducible, and diverse evaluation set, this study relied on a multi-source dataset construction strategy that combined real-world attack payloads, legitimate user inputs, and synthetically generated in-depth variables. The design goal was to ensure that the dataset captured both the breadth of XSS attack vectors and the diversity of benign user behaviors, enabling the trained models to generalize effectively to unseen scenarios. The construction process consisted of three integrated components:

III.1.1 Public Malicious Xss Payload Sets

A selection of malicious XSS payloads was obtained from widely known security repositories, including the OWASP XSS Cheat Sheet and PayloadsAllTheThings. These repositories are maintained by the security community and have been widely consulted in previous research, providing a core set of attack vectors covering multiple encryption schemes, script injection patterns, and contextual exploitation scenarios (such as DOM-based, reflected, and stored XSS). This component ensured that the dataset reflected known, verified, and reproducible attack patterns.

III.1.2 Realistic Benign Input Acquisition

To accurately model legitimate user behavior, benign samples were acquired from two main channels:

•Synthetic benign data generation, which produced realistic, typical inputs such as names, comments, search queries, and email-like text strings using context-aware text generators.
•Publicly available datasets containing typical user-generated web content were extracted from open forums, discussion forums, and datasets such as Common Crawl.
•This step ensured semantic and structural diversity in the benign samples, reducing the risk of overfitting models to narrow benign input patterns.

III.1.3 Synthetic Mutation of Malicious Payloads

To simulate evasive and polymorphic attack strategies, malicious payloads were subjected to an automated transformation pipeline that applied layered obfuscation techniques, including:

• Multi-pass URL encoding (percent encoding).
• HTML entity encoding for critical characters.
• Base64 wrapping to hide payloads.
• Unicode escape sequences to replace special characters.
• Whitespace injection to disable pattern matching.
• Character scrambling within benign-looking wrappers to bypass naive filters.

These transformations mimic real-world adversarial behavior, forcing the detection system to learn deeper structural patterns rather than relying on simple keyword matching.

III.1.4 Labeling and Class Balance

All samples were binary labeled: malicious samples were assigned a label of 1, and benign samples were assigned a label of 0. A balanced or slightly imbalanced distribution (e.g., 70% benign, 30% malicious) was maintained to prevent bias toward either class, with a synthetic oversampling technique (SMOTE) applied in cases of imbalance. The total dataset size ranged from 20,000 to 50,000 samples, providing sufficient statistical power for deep learning training while maintaining computational feasibility.

III.1.5 Temporal Splitting for Realism

To simulate concept drift and test the robustness of the model under sophisticated attack conditions, temporal splitting of the data was applied. In this setup, older data was used for training, while newer samples (including new obfuscations) were saved for testing, reflecting the practical challenge of emerging zero-day vulnerabilities and XSS variants in operational environments.

III.2 PREPROCESSING

After creating the dataset, a systematic preprocessing pipeline was implemented to ensure data consistency, eliminate noise, and transform the raw samples into a machine learning-ready format. This step is critical for security-oriented text classification tasks, as improper preprocessing can inadvertently remove key attack signatures, or conversely, retain irrelevant noise that hinders model generalization. The preprocessing process consists of the following steps:

III.2.1 Data Cleaning and Normalization

•Duplicate Removal - Identical payloads or non-malicious inputs were removed to prevent model bias toward duplicate samples, ensuring that performance metrics accurately reflect generalization ability rather than memorization.
•Case Normalization - All text was converted to uniform case (lowercase) to reduce feature rarity while maintaining semantic equivalence. This step was implemented with caution, as some XSS payloads exploit case differences in tags (e.g., <ScRiPt> vs. <script>).
•Whitespace and Control Character Handling - Unnecessary whitespace and invisible control characters (such as \r, \n, \t) were normalized or removed, except in cases where intentional obfuscation was part of the attack signature, in which case these patterns were retained as distinguishing features.

III.2.2 Encoding Standardization

Because XSS payloads often use multiple encoding schemes to evade detection, a controlled partial decoding process was implemented:

• Single-pass decoding of URLs and HTML entities was applied to detect embedded malicious structures, without completely removing the multi-layer obfuscation.
• Retention of obfuscated variant alongside the decoded models allowed the model to learn from both explicit and hidden attack representations, increasing its resilience against polymorphic threats.

III.2.3 Tokenization Strategy

•A hybrid encoding approach was adopted, combining character-level and word-level encoding. Character-level encoding is essential for capturing subtle manipulations in payloads (such as inserted special characters and punctuation marks), while word-level encoding helps identify semantic patterns in otherwise intact texts.
•Custom code boundaries were defined to ensure proper separation between HTML tags, JavaScript snippets, and encoded segments. Particular attention was paid to ensuring that the compositional balancing did not result in duplicate or overly similar payloads, which could inflate the evaluation metrics. The dataset was divided into subsets for training (70%), validation (15%), and testing (15%).
•For temporal evaluation, an alternative splitting strategy was used, where the training set included older samples, while the test set included newer, unseen payloads to assess robustness against concept drift. Using this multi-stage preprocessing, the final dataset was transformed into a structured, information-rich representation that preserves key attack characteristics while minimizing irrelevant noise. This careful preparation ensures that the subsequent modeling phase benefits from high-quality and representative input data, which is essential for building reliable and generalizable XSS detection systems.

III.3 FEATURE ENGINEERING

After the preprocessing phase, feature engineering was performed to transform the cleaned and normalized dataset into an improved representation that enhances the discriminative ability of machine learning models. In the context of XSS detection, feature engineering is not simply a dimensionality reduction task; it is a strategic process for capturing semantic, syntactic, and structural cues that distinguish malicious payloads from benign inputs:

III.3.1 Character-Level Features

To effectively capture the characteristics of obfuscated and malicious XSS payloads, three categories of features were designed. These features address lexical patterns, structural markers, and randomness indicators, thereby improving both detection accuracy and robustness, such as in Figure 1.

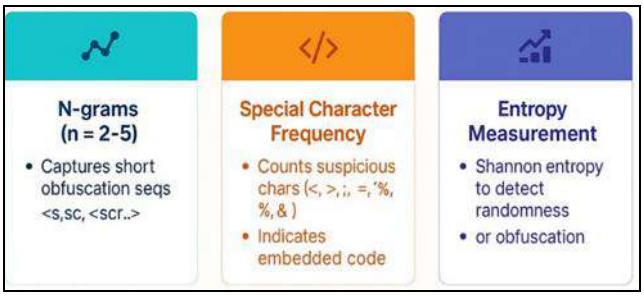

Figure 1: Extracted Feature Categories.
Source: Authors, (2026).

III.3.2 Token-Level Features

•Keyword Presence Markers: Boolean indicators of the presence of important keywords (e.g., script, onerror, onclick, alert, eval) that frequently appear in XSS payloads.

•Tag Structure Analysis: HTML tag sequences were analyzed to detect irregular or incomplete structures that could bypass filters.

III.3.3 Encoding Pattern Indicators

• Depth multi-layer encryption: The number of consecutive encryption/decryption layers detected, which is useful for identifying advanced evasion techniques.

• Encryption type flags: The presence of Base64, Unicode escape codes, or double URL encoding.

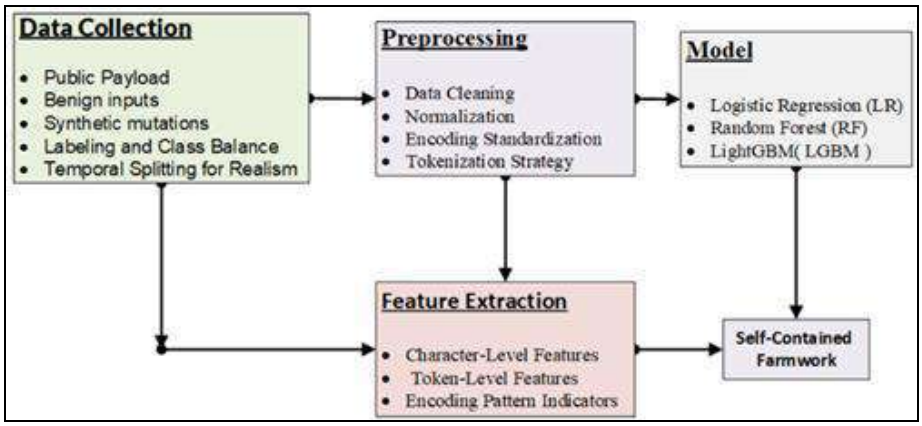

Figure 2: The overview of the proposed system.

III.4 MODEL SELECTION WITH SELF-CONTAINED OPERATIONAL CAPABILITY

The model selection process aims to identify an approach that not only achieves high detection accuracy but also supports fully autonomous and self-sufficient operation a hallmark of the proposed framework:

III.4.1 Proposed Detection Model

Three traditional machine learning algorithms were initially shortlisted based on their proven effectiveness in binary classification and computational efficiency for real-time deployment:

•Logistic Regression (LR) – In Logistic Regression, each predictor X_ij is assigned an independent coefficient indicating its contribution to the.

$$\ln\left[\frac{P(Y=1|X_{ij})}{1-P(Y=1|X_{ij})}\right] = \beta_o + \beta_1 X_{ij} + \beta_2 X_{i2} + \cdots . + \beta_P X_{iP} \quad (1)$$

expression $\ln\left[\frac{P(Y=1|X_{ij})}{1-P(Y=1|X_{ij})}\right]$ represents the natural logarithm of the odds of the binary outcome Y. The transformation of both sides through exponentiation converts log-odds into odds which results in an exponential form of the expression. The probability can be found by rearranging the equation to solve for the probability term [22]. The derivation results in the logistic function (Eq. 2) which defines probability through an exponentiated linear combination of predictors.

$$P(Y=1|X_{ij}) = \pi(X_i) = \frac{e^{\beta_0+\beta_1 X_{i1}+\beta_2 X_{i2}+\cdots+\beta_p X_{ip}}}{1+e^{\beta_0+\beta_1 X_{i1}+\beta_2 X_{i2}+\cdots+\beta_p X_{ip}}} \quad (2)$$

Here, the vector of predictor variables is defined as.

$$X_i = (X_{i1}, \quad X_{i2}, \ldots . , X_{ip})$$

where X_{ij} represents the predictor variable for observation i. The coefficients of these predictors are denoted by $\beta_o, \beta_1, \beta_2, \ldots . , \beta_p$ where corresponds to the intercept term. The probability of the binary $\pi(X_i)$ outcome = (Y = 1) for observation i, given its associated predictor variables X_{ij}[23].

•Random Forest (RF) – It is a supervised ensemble learning method that constructs multiple decision trees, with the final output determined by majority voting on the individual tree predictions. Each tree is trained on a random subset of features, and the best split is selected using the Gini index, as shown in Equation (3) [24].

$$Gini\ index = 1 - \sum_{i=1}^{C} (p_i)^2 \quad (3)$$

•Light Gradient-Boost Machine (LGBM)– Machine learning (ML) and artificial intelligence (AI) are rapidly growing fields, and the LightGBM (LGBM) algorithm is one of the most successful machine learning algorithms due to its high accuracy, efficiency, and low memory consumption. LightGBM creates multiple decision trees, with each new tree using the residual errors of previous learners, and the final output is the sum of the predictions from all the trees. Its advantages include fast training via feature pooling, support for graphics processing units (GPUs), large-scale data processing, and high accuracy. However, its incremental (leaf-like) growth can cause overfitting, especially on small datasets [25].

III.4.2 Self-Contained Operational Capability

•A key design goal was to ensure the detection system's independence and scalability without relying on external services. Once the model is trained, it operates entirely within the host environment, performing the following:
•Local Feature Extraction - All preprocessing and feature engineering are performed locally, avoiding network latency and preserving data confidentiality.
•Device Inference - Malicious payload detection is performed in real-time, ensuring decisions are made in sub-milliseconds.
•Incremental Learning - The system can incorporate new labeled data into its knowledge base without requiring full retraining, enabling it to adapt to emerging XSS attack vectors.
•Autonomous Operation - It does not rely on cloud APIs or third-party processing; the framework can be deployed within Web Application Firewalls (WAFs), Intrusion Detection Systems (IDSs), or autonomous edge devices.

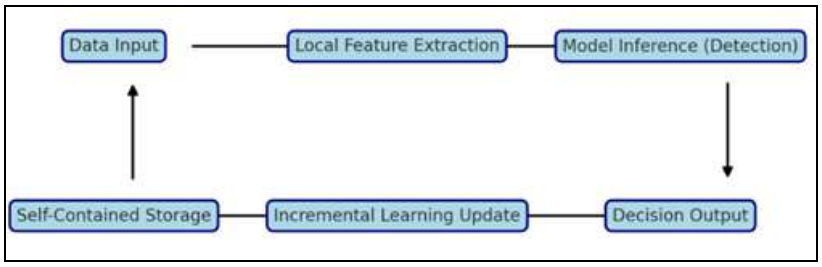

Figure 3: self-contained operational flow of proposed model.
Source: Authors, (2026).

This integrated architecture not only improves speed and reliability but also enhances security and privacy, as sensitive input data never leaves the local environment. Furthermore, the incremental learning capability ensures that the model remains resistant to conceptual drift and continues to evolve alongside attackers' methodologies.

Table 2. Comparative Analysis of Model Selection and Operational Capabilities.

Model Approach	Accuracy Potential	Interpretability	Real-Time Capability	Dependency on External Services	Adaptability to New Threats	Self-Contained Operation
Logistic Regression (LR)	Medium	High	High	Low	Low	Partial
Random Forest (RF)	High	Medium	Medium-High	Low	Medium	Partial
Gradient Boosting (XGBoost, LightGBM)	High	Low-Medium	Medium-High	Low	Medium-High	Partial
Proposed Self-Contained Model	High	Medium	Very High	None	High (Incremental Learning)	Full

IV. EVALUATION METRICS

The confusion matrix serves as a fundamental evaluation tool for binary classification tasks to assess model performance. The true negative (TN) represents benign instances that were correctly identified as benign while false positive (FP) occurs when benign samples are mistakenly classified as XSS attacks. The classification of XSS instances as benign when they should be attacks is known as false negative (FN) while true positive (TP) represents correct detection of XSS attacks as attacks. The evaluation process required multiple performance metrics including accuracy, precision, recall, F1-score, misclassification rate and AUC-ROC. The main performance metrics along with their mathematical definitions are presented in Table 2.

$$Accurac = \frac{TP+TN}{TP+TN+FP+FN} \tag{4}$$

$$Precision = \frac{TP}{TP+FP} \tag{5}$$

$$Recall(R) = \frac{TP}{TP+FN} \tag{6}$$

$$\text{F1} - \text{score} = \frac{2*\text{Recall} * \text{P recision}}{\text{Recall} + \text{P recision}} \tag{7}$$

V. RESULTS AND DISCUSSION

The proposed lightweight machine learning model for XSS attack detection in web forms was experimentally evaluated using a hybrid dataset that combined publicly available XSS samples with manually collected malicious payloads. The resulting dataset consisted of 5,000 benign and 5,000 malicious instances, ensuring a balanced class distribution. This design choice was made to minimize bias and to support fair and reliable model training and evaluation.

V.1 EXPERIMENT ENVIRONMENT CONFIGURATION

The system's cross-device compatibility assessment required testing on two different platforms which included Google Colab as a cloud-based virtual platform and Raspberry Pi 5 Model B as an edge computing device. The experimental framework used Python 3.10 and TensorFlow 2.15 on both setups to maintain consistency. The system evaluations took place without GPU acceleration to demonstrate its lightweight operation and its performance under limited resources. The hardware specifications of the two environments are illustrated in Figure 4, which provides a side-by-side comparison between the edge device and the cloud environment.

Figure 4: system environments.
Source: Authors, (2026).

V.2 EXPERIMENT RESULTS

The proposed self-contained framework implemented three supervised learning algorithms which included Logistic Regression (LR), Random Forest (RF) and LightGBM (LGBM) to evaluate performance. The algorithms were selected because they have shown effectiveness in text-based security tasks and they have different computational characteristics and model complexity. The performance of the models was evaluated using standard classification metrics which included accuracy, precision, recall, F1-score and ROC-AUC to ensure a comprehensive evaluation. Confusion matrix analysis was performed for each classifier to determine the misclassification patterns and ROC curves were constructed to show the trade-off between true and false positive rates.

The LightGBM-based self-contained framework performed the best among the tested algorithms with an accuracy of 99%, precision of 98%, recall of 98% and an F1-score of 99%. The model achieved a ROC-AUC score of 0.987 which shows that it can discriminate between benign and malicious inputs and outperforms the other baseline classifiers. The confusion matrix revealed a low false positive rate, making LightGBM particularly suitable for real-time XSS filtering, where reducing unnecessary blocking of legitimate user input is critical. Additionally, LightGBM's lightweight computational profile enables accelerated inference times, even in resource-constrained environments. Figure 5 depicts the confusion matrix for the LightGBM model, while Figure 6 illustrates its ROC curve, highlighting the model's excellent separability.

V.3 COMPARATIVE ANALYSIS

Figure 7 compares the accuracy, precision, recall, and F1 score across the self-contained framework models and Figure 8 depicts the time consumption, showing that LGBM slightly outperforms RF and LR in detection accuracy and stability. While RF offers robustness against feature noise, and LR outperforms in training speed and scalability, LGBM's balance of accuracy, low computational cost, and stability makes it the most suitable candidate for real-time XSS detection in web forms.

The confusion matrix in Figures 9 and 10, compared with Figure 5, as well as the comparative ROC curves for all models (Figure 11), further confirm LGBM's marginal advantage in separability. Table 3 summarizes all evaluation metrics for the classifiers.

V.4 LIMITATION

While the proposed lightweight machine learning framework for XSS attack detection shows promising results, several limitations must be acknowledged to provide a balanced perspective on its applicability and generalization capabilities.

- Although the dataset combines generic XSS samples with hand-compiled payloads, it may not fully reflect the diversity of real-world attack patterns, potentially limiting detection effectiveness against new evasion techniques.
- Feature engineering approaches, which focus on syntactic features (n-grams, special character occurrences, JavaScript keywords, and HTML tag patterns), may be less effective against obfuscation, encryption, or zero-day attacks, highlighting the need for semantic and dynamic analysis.

Table 4: Comparison Table of Related Works and Our Proposed Framework.

Ref	Approach / Model	Dataset	Reported Performance	Remarks
[15]	XSS-Net (custom ML model)	XSS dataset (web payloads)	Acc ≈ 96%	Tailored ML with feature optimizations
[18]	Bipartite Graph + DL ensemble	Graph-structured XSS	Acc ≈ 97%	Strong on complex graph features
[20]	GenXSS (GA + ML)	WAF-based dataset	Acc ≈ 97–98%	Adaptive genetic optimization
[21]	XGBoost + LGBM + SMOTE	Payment security dataset	Acc ≈ 95–96%	Tackled class imbalance
Our Work (2025)	LR, RF, LGBM	Public + custom XSS payloads	Acc ≈ 99%	Lightweight, self-contained, robust

VI. CONCLUSION AND FUTURE WORK

This study proposes a lightweight, integrated machine learning framework for XSS detection that requires minimal external resources and enables direct deployment in live web applications. Using LGBM along with RF and LR for comparison, the model achieved high accuracy, precision, and recall while maintaining low computational cost. The integrated design ensures easy integration, scalability, and applicability in resource-constrained environments. The importance of this work lies in its balance between detection performance and computational efficiency, enabling practical integration in live web applications without significant performance degradation. Furthermore, the study contributes to the field by demonstrating that well-engineered traditional models can match or exceed the performance of more resource-intensive approaches for specific security tasks. Future work will focus on incorporating incremental learning to adapt to evolving attack vectors, expanding datasets with more diverse realistic payloads, and improving detection through semantic and dynamic analysis techniques.

ABSTRACT

Microgrids combine battery energy storage devices and renewable resources with the utility grid. An intelligent energy switching approach between solar, battery and grid ensures continuous supply of power by dynamically adjusting to resource availability and load requirements. In this paper, a novel microcontroller-based energy management scheme (MCU-based EMS) is proposed by combining both on-grid and off-grid power management systems allowing microgrids to function smoothly in both grid-connected and islanded modes. In the off-grid management, a Maximum Power Point Tracking (MPPT) algorithm is used for maximizing the extraction of available PV power. Further, a DC-DC boost converter is employed for boosting the voltage to match the battery's charging need and loads. In on-grid management, an H-inverter along with a synchronizer circuit is used to supply loads during peak shaving hours. Besides, a bidirectional buck-boost converter ensures battery charging and discharging. The microcontroller intelligently controls the transition between operating modes by continuously assessing power demand and availability to identify the best source. A key component of the system is the Adaptive Spatio-Temporal Graph Convolutional Learning (ASTGCL) model, which enables proactive and dynamic energy management by forecasting the best power dispatch based on environmental data, resource availability, and load demand. Real-time monitoring, performance tracking, and remote control for increased efficiency are made possible with IoT integration. Real-time hardware implementation and simulation studies are used to validate the proposed model. The simulation results show that the proposed technique outperforms conventional models in terms of achieving quick, seamless switching, guaranteeing a continuous supply and maximizing the usage of renewable energy. With a mode-switching time of only 24 ms, the proposed MCU-based EMS significantly outperforms other conventional methods like MGIB (120 ms), NILM (95 ms), M-GRU-based NILM (110 ms) and FF-SHMS (105 ms).

I. INTRODUCTION

Fossil fuel depletion globally has started to shift our interests towards the utilization of renewable energy resources. Presently, microgrids (MGs) are gaining attention since they have the ability to enhance the controllability and reliability of power systems [1]. Microgrid is an integrated source of power from utility grid, energy storage devices and renewable sources that can operate either in standalone or in grid-tied mode [2]. However, this integration poses new challenges for managing and controlling power to meet demand needs and supply the load. Energy management and control strategies are divided into upper and lower-level controls. The primary control (lower-level control) is responsible for frequency and voltage stabilization.

The Energy Management System (EMS), that is upper-level control is responsible for predicting the availability of load demand and renewable power resources. It is also responsible for scheduling available load demand and energy production within a MG [3]. Photovoltaic (PV) power producers which can operate in off-grid mode are attractive sources of power in mountainous or remote places, where the installation of grid supply is not possible. A common configuration for isolated PV system consists of three converters namely a buck and boost converter for PV charging and discharging and one for regulating loads [4], [5]. Normally, electric meters measure the energy consumption at each house and billing is produced at the end of each month which inhibits remote tracking of energy usage.

With the help of IoT, the remote monitoring of house current consumption on web application is made possible [6]. The integration of IoT in EMS helps the individuals, companies and industries to control their devices based on the energy consumption ensuring optimal use of power. Many techniques developed for managing energy is limited in handling highly dynamic AC loads and grid disturbances [7]. In this paper, a novel MCU-based EMS is proposed for managing power flow between different power sources ensuring an uninterrupted power supply to loads and also reducing harmonics in grid. The main contributions of this paper are,

- An off-grid power management system is developed using PV panels to prioritize solar energy during maximum solar power generation with MPPT and switch to battery during low generation, where bidirectional buck-boost converters are used for effective battery charging and discharging.
- An on-grid power management system is proposed for intelligently switching between solar, grid, and battery power, wherein a bidirectional converter is used for effective grid-based battery charging and synchronizer circuit for continuous AC load operation.
- Real-time performance tracking, remote monitoring, and user-driven modifications based on usage patterns are all made possible by IoT.
- IoT is used for monitoring the system remotely to gain real-time performance insights and user-driven modifications.
- The proposed method reduced consumption costs, increased energy efficiency, decreased grid dependency and ensured a more sustainable power supply while maximizing the use of solar power.

This research paper's contents are classified into the following sections: A survey of various literatures on energy management in microgrids is discussed in section 2; section 3 deals with the working of the proposed methodology in detail; the hardware and simulation results are presented in section 4 and section 5 talks about the conclusion of this paper.

II. LITERATURE REVIEW

In this section, various literatures on energy management in residential settings is discussed. The purpose, methods, advantages and disadvantages of different literatures is mentioned below.In [8] developed an efficient energy management plan to satisfy energy requirements and provide a steady supply of electricity under various load scenarios. A smart communication system based on IoT is created for a hybrid microgrid that combines Vanadium Redox Flow Battery (VRFB) storage, PV and a biogas plant. The microgrid operation is monitored and controlled in real time through Raspberry Pi while the system circuits for the hybrid microgrid electrical interface is realized through a PSCAD simulation research. In [9] presented a Fuzzy logic-based Framework for Smart Home Monitoring Systems (FF-SHMS) that uses IoT to improve energy efficiency. In order to manage resource-constrained loads and promote sustainability, the presented fuzzy architecture optimizes the design of intelligent microgrids with integrated storage. Additionally, the framework optimizes the microgrid's economic benefits by enhancing electricity and storage utilization of renewable energy sources.

By effectively assessing various criteria the suggested framework undergone simulation to obtain superior performance. In [10] utilized a Non-Intrusive Load Monitoring (NILM) technology for managing energy in home microgrids integrated with PV and battery storage with the help of IoT. The usage of energy in each home is monitored by Artificial Neural Network (ANN) optimized with Particle Swarm Optimization (PSO). Then the monitored energy is sent through ThingSpeak IoT to the customers. The NILM technique eliminates the smart meter setup thereby reducing the cost for installation. In [11] implemented a Multi-task Gated Recurrent Unit (M-GRU)-based NILM model for handling energy in residential microgrid. M-GRU-based NILM is used for extracting individual customer's energy consumption from smart meters. Then, the extracted information is given to the microgrid for managing energy consumption. The operating cost of the model is reduced by 45% while user satisfaction is increased by 65%. In [12] developed a hierarchical IoT-based renewable energy self-consumption approach for Microgrid-Enabled Intelligent Buildings (MGIBs) aiming to automate and digitalize energy supply and consumption.

Initially, a 2D fusion layered architecture is implemented for the microgrids to interact with the loads. Then, a state transition strategy is employed for maintaining the operating states of consumers and suppliers based on event and temporal triggers. Finally, self-regulated coordination between power generation and demand is achieved by power balance control approach. Monitoring consumption, generation and supply data is handled by the FIWARE framework. In [13] designed a smart Home Energy Management System (HEMS) for prosumers to handle energy efficiently. K-means clustering combined with ANN is utilized for load forecasting to predict energy needs. Energy usage is scheduled using Teaching-Learning-Based Optimization (TLBO), which aims to minimize energy drawn from the grid and lower overall costs by identifying the best times to charge or discharge batteries and when to shift or reduce energy consumption. In [14] formulated an intelligent demand response approach for uninterrupted supply of energy from batteries, renewables and grids. Only lights and AC are currently controlled according to the SoC value of battery. The model maximized the use of renewables thereby reducing electricity cost, peak demand and carbon emissions. According to the existing literatures, the use of real-time MPPT at the hardware conversion step is not highlighted. The proposed system uses MPPT-based DC-DC converters, which allow for the best possible solar energy extraction in a range of irradiance levels. This efficiently guarantees the optimal use of the PV electricity that is available.

III. PROPOSED METHODOLOGY

The working mechanism of the proposed MCU-based EMS is discussed in this section and the block diagram of the proposed technique is illustrated in Figure 1(a). Inputs such as weather characteristics (irradiance, temperature, etc.), historical PV output, battery SoC data, grid data and load demand are collected at each time step of the historical time window of previous observations.

These inputs are used by the ASTGCL framework, which predicts the optimal power contribution from each source for the next day. The microcontroller or smartphone then receives the predicted power dispatch and uses it to carry out the suggested actions by alternating between power sources and choosing the proper operating mode (off-grid or on-grid) as needed. The off-grid or island mode is where the solar panels or battery storage devices supply power to the loads without the use of grid power. With the availability of solar power, the loads are supplied with solar energy. The excess solar power not used by the loads is used to charge the batteries without violating their battery SoC.

When solar power is not available, the batteries supply power to the loads. In on-grid mode, the solar panels, batteries and grid operate together for supplying power to loads. When solar power is available, the loads are supplied energy from solar panels and excess solar is stored in batteries. When solar is not available, battery supplies power. If both become outage, grid supplies power to AC loads. When the grid demand is low, the batteries are charged from them and during grid outage periods, this stored energy will be supplied to the loads. Ultimately, IoT is integrated into the system for monitoring real-time energy consumption updates, grid status, battery State of Charge (SoC) and grid condition.

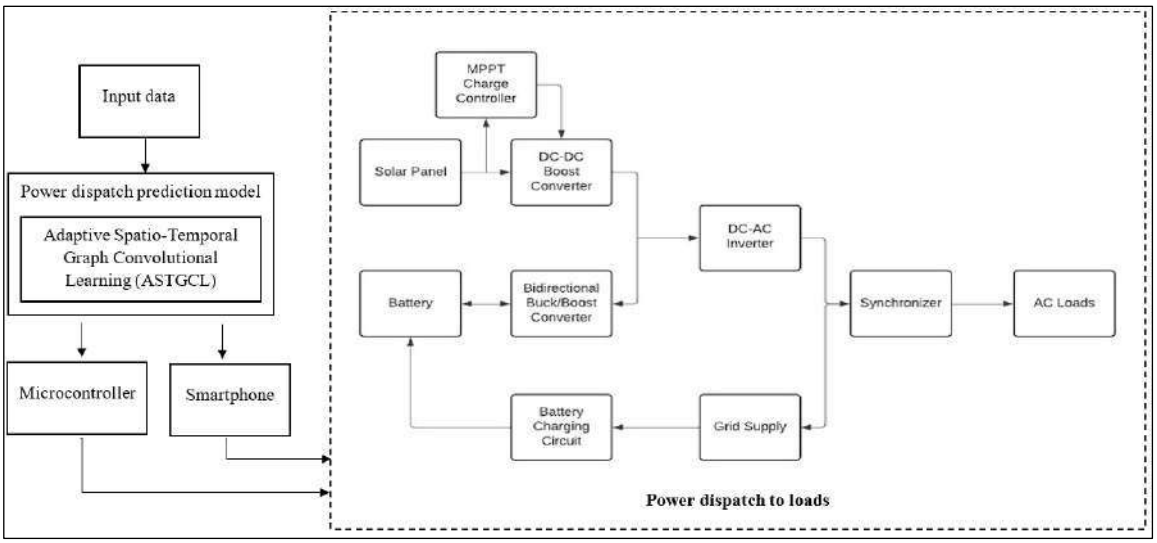

Figure 1(a): Block diagram of the proposed MCU-based SEM.
Source: Authors, (2026).

III.1 ADAPTIVE SPATIO-TEMPORAL GRAPH CONVOLUTIONAL LEARNING (ASTGCL)

The proposed system uses a dynamic selection process amongst three potential sources—solar panels, battery storage, and the utility grid—to guarantee a continuous supply of electricity to the demand. Environmental sensors track sun irradiance to ascertain the availability of solar electricity, while a microprocessor uses relay control to manage the switching mechanism. Power flow is anticipated and planned in advance using an optimization method since switching between sources may cause brief periods of disruption in energy dispatch. In particular, depending on the previous records, the ASTGCL model is utilized to anticipate the ideal share of power to be pulled from each source at every time step. Reliability and efficiency are achieved in hybrid energy management by combining real-time relay-based switching with predictive dispatch planning. The block diagram of the ASTGCL architecture is provided in Figure 1(b).

III.1.1 Feature Data Augmentation

When gathering input data, problems such as noise, sensor faults, communication errors and missing values often arise. The presence of these irregularities can decrease the precision of power dispatch forecasting in the microgrid system. In order to surmount this obstacle and enhance the forecasting model's resilience against absent or corrupted solar data, three strategies for feature-level data masking are developed: short-term, long-term and regional data masking.

Short-Term Data Masking: Short-term data masking is used to mimic transient disturbances in input data like temperature, PV output or irradiance. Even with the presence of actual input data, the masking system selectively masks them to imitate transient environmental disturbances. The robustness of power dispatch forecasting by each source is increased by training the model under these circumstances, which helps it maintain accuracy even in the face of abrupt changes or missing data. In order to handle the short-term missing data, the following formula is used to mask each input data.

$$\hat{I}_f^t = \begin{cases} I_f^t, if\ E_f^t \geq T_{short} \\ -1, otherwise \end{cases} \quad (1)$$

Here, $\hat{I}_f^t$ is the masked data of each input feature f at time t, I_f^t is the original input data f at time t, E_f^t is a randomly generated masking indicator and T_{short} is the masking threshold for simulating brief missing or corrupted data.

Long-Term Data Masking: Long-term data masking simulates situations in which sensor malfunctions or maintenance outages may render irradiance or temperature to be completely inaccessible for prolonged periods of time. For example, the temperature probe may be unavailable for days or the irradiance sensor may malfunction for a few hours.

The model learns to rely on the remaining features and maintain accurate predictions during extended data loss by being trained with such long-term masked inputs. The following equation is adopted to model long term data masking for each input feature like irradiance, temperature, etc.

$$\hat{I}_f = \begin{cases} I_f, if\ E_f \geq T_{long} \\ -1, otherwise \end{cases} \tag{2}$$

Here, T_{long} is the masking threshold for simulating extended loss in data caused by sensor malfunctions.

Regional Data Masking: Multiple input feature failures at the same time are represented by regional data masking. Extreme weather events like storms, grid outages, inverter tripping or communication system malfunctions that impact multiple sensors at once might cause this. For instance, because the monitoring system goes offline during a strong rainstorm, readings for temperature, panel voltage and irradiance may all be absent for a while. The forecasting model learns to maintain stability and continue prediction even when multiple critical inputs are lost at the same time by simulating such multi-feature outages during training.

$$\hat{I}^t = \begin{cases} I^t, if\ E^t \geq T_{region} \\ -1, otherwise \end{cases} \tag{3}$$

Here, $\hat{I}^t$ is the masked multi-feature input, E^t is a random masking indicator that determines whether the multi-feature data is available or missing at time t and T_{region} is the probability of missing or corrupted data.

III.1.2 Topology Data Augmentation

In the proposed model, the loads are provided with electricity by one or more sources, such as the grid, solar panels or batteries, depending on the grid status, battery SoC and solar energy availability at the time. The model employs two matrices to dynamically manage this power allocation: a fixed adjacency matrix F_A that depicts the potential connection between the sources and loads and a real-time optimized matrix O_A that modifies the strength of these connections in real-time based on available data. The system can determine the strength of each link at any given time by using this dynamic matrix. For instance, during times of high solar generation, the load-to-solar panel connection is strengthened, the grid connection is decreased and battery-to-solar panel connection is enhanced.

By combining the matrices using Hadamard product and addition operations, the microcontroller may intelligently switch power sources by determining the effective power flow between various sources and loads at any given time. The addition operation adds the fixed and optimized matrices connection strengths to capture local features—such as direct and immediate power flows like solar panels providing electricity to a nearby load or charging a connected battery. The product operation highlights global aspects, which reflects greater system-wide interactions such as coordinated power balancing between the grid, solar panels and batteries during periods of high demand. The local L_A and global G_A adjacency matrices are given by Equations, respectively.

$$L_A = F_A \oplus O_A; F_A, O_A \in R^{S \times S} \tag{4}$$

$$G_A = F_A \otimes O_A; F_A, O_A \in R^{S \times S} \tag{5}$$

Here, R is a set of real numbers and S denotes the power sources and loads connected to microgrid.

Both L_A and G_A are given to graph neural modules for producing learned feature representations both locally GNN_l and GNN_g globally to capture power flow behaviours within the system.

III.1.3 Spatio-Temporal Contrastive Learning

Spatial Contrastive Learning

The system effectively learns and distinguishes between localGNN_l and global GNN_g representations with the aid of spatial contrastive learning. The microgrid system is trained by the model to identify and align patterns that appear in both global and local representations. It helps the system acquire relevant energy flow behaviours by increasing the similarity between related local and global patterns while differentiating unrelated patterns with the help of loss function, which is mathematically modeled by the Equation (6).

$$L_{spatial} = -\frac{1}{N}\sum_{j=1}^{N} log \frac{exp\left(cos\left(GNN_l^j, GNN_g^j\right)/\tau\right)}{\sum_{k=1}^{N} exp\left(cos\left(GNN_l^j, GNN_g^k\right)/\tau\right)} \tag{6}$$

where, batch size is denoted by N, local and global representations for the j-th sample are represented by GNN_l^j and GNN_g^j, respectively, cosine similarity is indicated by $cos(.)$ and the τ parameter controls the concentration of the distribution. The similarity between related local-global pairings is captured by numerator, while the denominator accounts for all pairs including unrelated pairs.

Temporal Contrastive Learning

Temporal contrastive learning aims to differentiate between similar and dissimilar time steps in order to improve the model's capacity to learn intrinsic temporal dynamics. It creates GNN_t by concatenating two representations, GNN_l and GNN_g, at each time step t. The model chooses the least (negative sample GNN_t^-) and most similar (positive sample GNN_t^+) time steps from other intervals for each time step and the temporal loss function is given as:

$$L_{temp} = -\frac{1}{T}\sum_{t=1}^{T} log\frac{exp(cos(GNN_t, GNN_t^{+})/\tau)}{exp(cos(GNN_t, GNN_t^{-})/\tau)} \quad (7)$$

Here, T is the total number of time steps and t is the current time step.

III.1.4 Joint Learning

The joint representation GNN_R is formed by GNN_l and GNN_g representations, which is then fed into power dispatch prediction module for determining the optimal power allocation of solar, battery or grid sources to loads. The model is optimized to minimize a dispatch loss function $L_{dispatch}$ that concurrently takes into account the supply side and the demand side of the microgrid operation in order to provide precise energy dispatch. To avoid scheduling resources in an impractical manner, the supply-side term assesses the difference between the actual supply capacity at each time step and the expected power contribution from the available sources (grid, solar, and wind). However, in order to guarantee that consumption needs are sufficiently satisfied, the demand-side term records the discrepancy between the actual demand and the anticipated power delivered to the load. According to formal definitions, the dispatch loss is:

$$L_{dispatch} = 0.5 * \left|\hat{P}_{T+1}^{supply} - P_{T+1}^{supply}\right| + 0.5 * \left|\hat{P}_{T+1}^{load} - P_{T+1}^{load}\right| \quad (8)$$

Where: $P_{T+1}^{supply} = P_{T+1}^{solar} + P_{T+1}^{battery} + P_{T+1}^{grid}$.

The joint learning is facilitated by integrating auxiliary loss functions $L_{spatial}$ and L_{temp} and the total loss function is modeled as follows:

$$L = L_{dispatch} + 0.5 * L_{spatial} + 0.5 * L_{temp} \quad (9)$$

The proposed model predicts the dispatch ahead of time and sends it to the microcontroller and smartphone, in contrast to traditional sense-then-act systems, which have the microcontroller wait for real-time measurements before making a decision. By drastically cutting down on response time, this proactive prediction allows for quicker control actions, smooth energy management, and increased microgrid system stability.

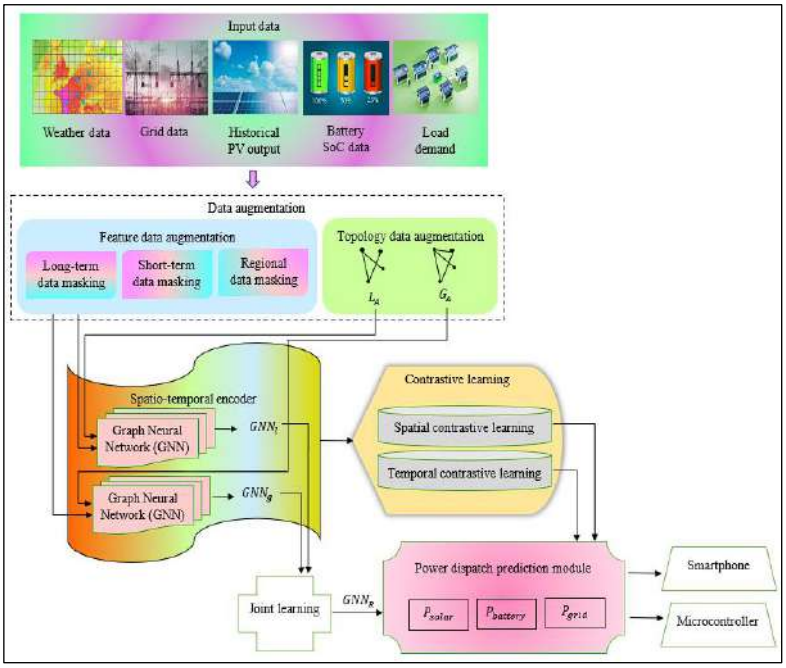

Figure 1(b): Architecture of Adaptive Spatio-Temporal Graph Convolutional Learning (ASTGCL).

III.2 COMPONENTS

A brief explanation of each of the components used in the proposed model is provided below.

III.2.1 MPPT Controller

The power produced by solar panels varies throughout the day due to the varying solar irradiance. In order to extract maximum amount of power from the solar panels, MPPT controller is used. The role of MPPT is to continuously monitor the current and voltage of the solar panels and adjusts the operating point to track the maximum power point at which the current and voltage is maximum. The MPPT controller then signals the boost converter to change its duty cycle for making the solar panels operate at its maximum power point.

III.2.2 DC-DC Boost Converter

The boost converter steps up the voltage coming from the solar panels to match the battery requirements or DC bus voltage. Besides, the converter adjusts the voltage and current of the solar panels for producing maximum solar power under varying sunlight based on the signal from MPPT. The working of MPPT controller along with boost converter ensures better energy harvesting.

III.2.3 Bidirectional Buck-Boost Converter

The bidirectional buck-boost converter allows bidirectional flow of power from grid or solar panels to batteries and from batteries to loads. The flow of power from grid or solar panels to batteries is known as charging and the power flow from batteries to loads is known as discharging. During charging, the converter acts in boost mode if the voltage coming from solar panels or grid is lower than the battery voltage. It also acts in buck mode to lower the input voltage if it is higher than the battery voltage. During discharging, the converter acts only in boost mode to step up the voltage to match the higher voltage of loads. This mode changing behavior ensures safe charging and discharging of batteries protecting battery lifetime.

III.2.4 DC-AC Inverter

The DC-AC inverter converts the stepped DC voltage coming from the boost converter or bidirectional buck-boost converter into AC voltage that can be efficiently supplied to the AC loads without any issues. A single-phase H-bridge inverter topology is utilized in the proposed model for converting DC to AC voltage. In the H-bridge inverter network, the four switches S_1, S_2, S_3 and S_4 are connected in a bridge configuration across the DC source and the switches are turned ON and OFF in a specific sequence for producing AC voltage across the load. In order to produce an approximate sine wave, Pulse Width Modulation (PWM) is used for rapid switching. Then, a filter made up of inductor and capacitor, LC filter converts the approximate waveform into a clean AC sine wave by the removal of high-frequency switching components thereby ensuring efficient and safe operation. The circuit diagram of the H-bridge inverter is shown in Figure 2 and the connection of bidirectional buck-boost and MPPT-based boost converter to the H-bridge inverter is displayed in Figure 3.

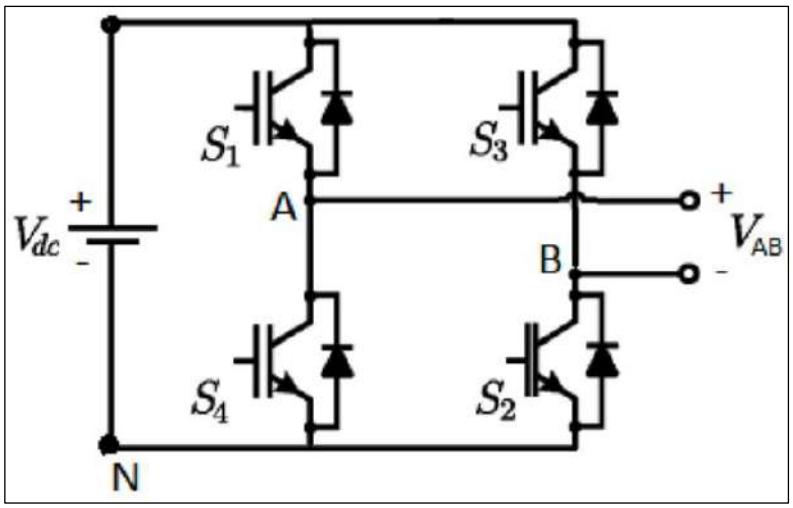

Figure 2: Circuit diagram of a single-phase H-bridge inverter.
Source: Authors, (2026).

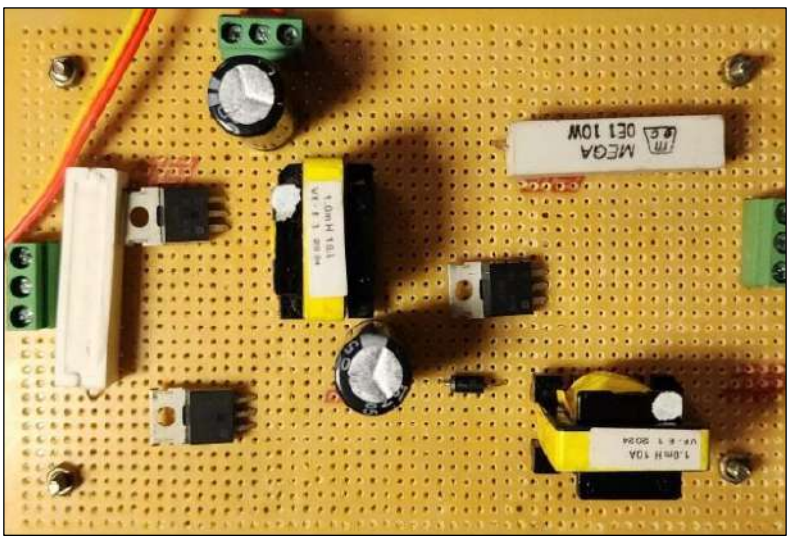

Figure 3: Bidirectional buck-boost converter and MPPT-based boost converter connected to H-bridge inverter.
Source: Authors, (2026).

III.2.5 Synchronizer Circuit

The AC signal produced by the H-bridge inverter must be in sync with the grid signal for preventing voltage surges and large circulating currents. In order to match the voltage, phase and frequency of inverter's output signal with the grid signal's voltage, phase and frequency, synchronizer circuit is used. The zero-crossing detector outputs a signal to the synchronizer circuit whenever the grid voltage crosses zero thereby providing phase reference of the grid. Then, the synchronizer circuit makes the voltage given by batteries to match the grid voltage in amplitude, frequency and phase. The incorporation of zero-crossing detector in the circuit is shown in Figure 4.

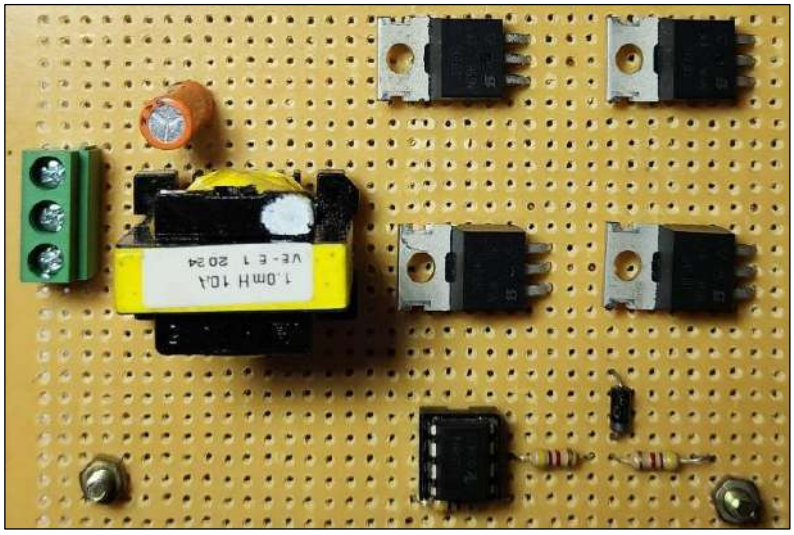

Figure 4: H-bridge inverter with LC Filter, alongside a zero-crossing detector circuit.
Source: Authors, (2026).

III.2.6 ESP8266 Microcontroller

The hardware setup of microcontroller-based mode switching hardware is depicted in Figure 5. In the figure, an ESP8266 microcontroller is used to manage relays that turn an inverter's output on or off. The blue coloured components in Figure 5 are known as relays that connects to the load by switching on the inverter and disconnects from the load by turning off the switch. This switching can be controlled manually or remotely via the IoT with the help of ESP8266's built-in Wi-Fi.

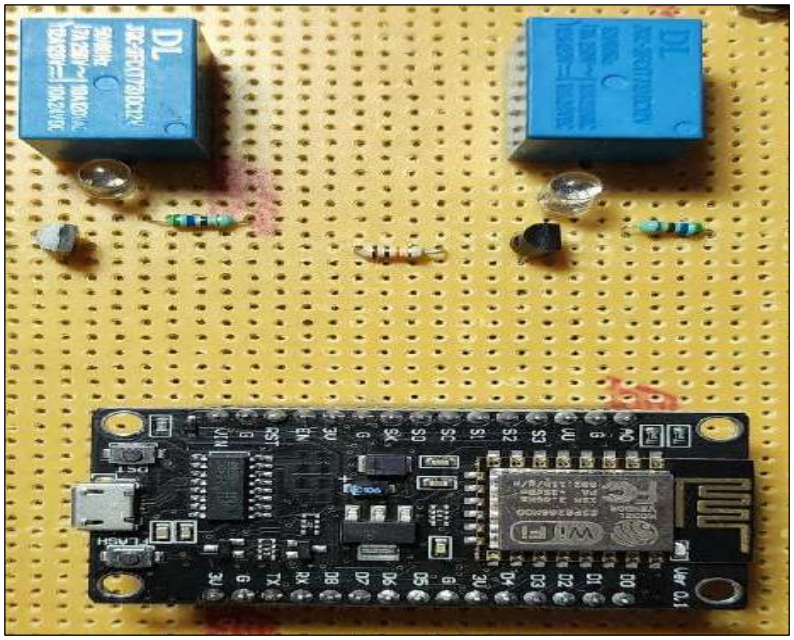

Figure 5: ESP8266 microcontroller for mode switching.
Source: Authors, (2026).

III.2.7 IoT Integration

A specialized mobile application called Blynk is developed for monitoring the real-time power system updates like grid status, load conditions, battery level and power flow remotely. The mode switching is also enabled by the consumers using the Blynk user interface. The developed IoT hardware setup worked efficiently within the Wi-Fi range of the test environment. The connection of the Blynk app with the proposed MCU-based EMS is displayed in Figure 6.

Figure 6: Proposed MCU-based EMS managed with the Blynk app.

IV. RESULTS

In this section, the hardware and simulation results of the proposed MCU-based EMS is discussed. To obtain the hardware results, the proposed system is implemented using MPPT, DC-DC boost converter, bidirectional buck-boost converter, H-bridge inverter, synchronizer circuit and IoT and validated in real-world. The system is validated against power efficiency, control stability and remote operability and the results obtained through validation are discussed below.

In the context of the H-bridge inverter, power efficiency is the ratio of AC power output provided to the household AC loads to the DC input power given by the batteries or PV panels. The system's overall energy conversion performance is indicated by this metric, which tells how well the inverter transforms DC power into suitable AC power. Usually, power efficiency is expressed in percentage and it is calculated using the formula given below.

$$P_{\eta} = \frac{P_{AC,OUT}}{P_{DC,IN}} \tag{10}$$

Here, efficiency is denoted by P_{η}, output power produced by inverter is represented as $P_{AC,OUT}$ and power supplied by the panels or batteries is given by $P_{DC,IN}$.

Table 1: Power efficiency of H-bridge inverter.

MODE	RMS OF AC OUTPUT VOLTAGE	RMS OF AC OUTPUT CURRENT	DC INPUT VOLTAGE	DC INPUT CURRENT	EFFICIENCY (P_{η})
Off-grid	230	4.98	48	23	92.3
On-grid	230	5.39	48	26	94.7

Source: Authors, (2026).

The power efficiency of H-bridge inverter under grid-tied and standalone modes is displayed in Table 1. In off-grid condition, an output voltage of 230 V and output current of 5 A is supplied to the loads. The input voltage and current supplied from the panels or batteries are 48 V and 23 A. Now, we calculate the efficiency for off-grid condition as,

$$P_{\eta} = \frac{230 \times 4.98 \times 0.89}{48 \times 23} \times 100\% = 92.3\%$$

The efficiency for on-grid mode is estimated as,

$$P_{\eta} = \frac{230 \times 5.39 \times 0.953}{48 \times 26} \times 100\% = 94.7\%$$

Here, 0.89 and 0.953 are known as power factors denoting a portion of current that is reactive. In standalone mode, there is no reference signal for converting DC into AC, therefore the power factor is large denoting the wastage of power (reactive power).

However, in grid-tied conditions, there is a reference signal from the grid for DC to AC converter, therefore the production of reactive power is less denoting lower power factor of 0.953 compared to off-grid mode. In standalone microgrid and on-grid operation, P_η is obtained as 92.3% and 94.7% respectively. The reason for the increased efficiency in on-grid mode is that the inverter synchronizes with the grid's AC signal, which offers a reliable reference for output power generation. Off-grid mode, on the other hand, requires the inverter to independently generate the AC waveform without the aid of an external reference, which leads to a modest decrease in efficiency and a rise in power losses. The inverter's performance is demonstrated by the close alignment of these values with those of commercially available hybrid inverters. Even with different load demand, the produced AC current is stable thereby eliminates load damage. The utilization of LC filter in the H-bridge inverter topology reduces the distortion present in the generated AC wave by the inverter. The reduction of harmonics with the employment of LC filter is illustrated in Table 2 and THD is calculated by the following equation.

$$THD\ (\%) = \frac{\sqrt{V_2^2+V_3^2+V_4^2+\cdots+V_n^2}}{V_1} \times 100 \tag{11}$$

Table 2: Comparison of THD present in the inverter generated output in the presence and absence of LC filter.

FILTER	FUNDAMENTAL V1 (V_RMS)	V3 HARMONIC (V_RMS)	V5 HARMONIC (V_RMS)	V7 HARMONIC (V_RMS)	THD (%)
Without filter	230	18	12	8	10
With LC filter	230	8	4	2	3,98

Source: Authors, (2026).

Bys substituting the table values in Equation 2, the THD is obtained as,

$$THD\ (\%) = \frac{\sqrt{V_3^2 + V_5^2 + V_7^2}}{V_1} \times 100 = 10\ \%\ (Without\ filter)$$

$$THD\ (\%) = \frac{\sqrt{8^2 + 4^2 + 2^2}}{230} \times 100 = 3.98\ \%\ (With\ filter)$$

Since the harmonics is reduced by LC filter, the generated voltage is suitable for integrating with grid connection. The process by which a power management system smoothly switches between different operating modes is known as mode switching. The smooth switching is measured using the time taken by the system to switch from grid-tied mode to off-grid mode or vice vera. Mode switching time is normally measured in milliseconds (ms). Despite the existence of several approaches, it is commonly calculated by,

$$t_{switch} = t_{mStart} - t_{mEnd}$$

where, t_{switch} is the mode switching time, t_{mStart} denotes the starting time of the switching operation and t_{mEnd} indicates the time when the switching operation ends. There was no noticeable voltage sag or load supply disruption during the mode-switching time, which was recorded at about 24 ms. This demonstrates that the system can continue to supply electricity even in the event of grid instability or solar unavailability. The MPPT algorithm efficiently tracked the maximum power point in solar irradiance, successfully extracting maximum power under diverse environmental conditions. The bidirectional buck-boost converter functioned reliably in both charging and discharging modes, facilitating smooth transitions based on the load demand and battery SoC. Its current-limiting and voltage-regulating capabilities protected the battery from under-voltage and overcurrent conditions, contributing to longer battery life and safer operation. The H-bridge inverter with an LC filter, driven using Sinusoidal Pulse Width Modulation (SPWM), produced a stable and smooth AC output waveform. The LC filter effectively reduced switching harmonics and delivered a clean sinusoidal voltage suitable for domestic loads. The inverter maintained consistent output voltage and frequency even under varying load conditions, reflecting its robustness and reliable dynamic response. Overall, the hardware results validate the practical feasibility of the proposed system, highlighting its suitability for efficient and sustainable domestic energy management with minimal grid dependency.

The software results obtained through MATLAB/Simulink simulation are discussed in detail below. One of the important parameters that denotes the successful system design is the supply of power to loads without any interruption. The continuous supply of power to household loads is portrayed in Figure 7. The energy requirement fluctuates throughout the day in the test configuration, peaking at nine in the morning. The demand continuously increases at a steady pace from 1 AM to 9 AM and then progressively declines from 10 AM to 3 PM. It rises once more between 4 and 6 PM, then starts to fall after 7 PM. The load demand is met by solar power between 7 AM and 5 PM, with any extra energy being stored in the battery. Before sunrise, the battery and grid supply the load in turn, and after sunset, the grid is used after the battery has discharged to its full capacity. According to the simulation results, the grid, solar, and battery contributions at each time step precisely match the load requirement, guaranteeing constant power availability for the full twenty-four hours. By ensuring an uninterrupted supply, this integrated use of solar, battery, and grid resources improves consumer satisfaction. Cost optimization is not included in the model, despite the fact that this guarantees continuous power. By taking cost into account, battery charging might be moved from the early morning low-demand hours (1–5 AM) to times of higher demand, such the morning peak.

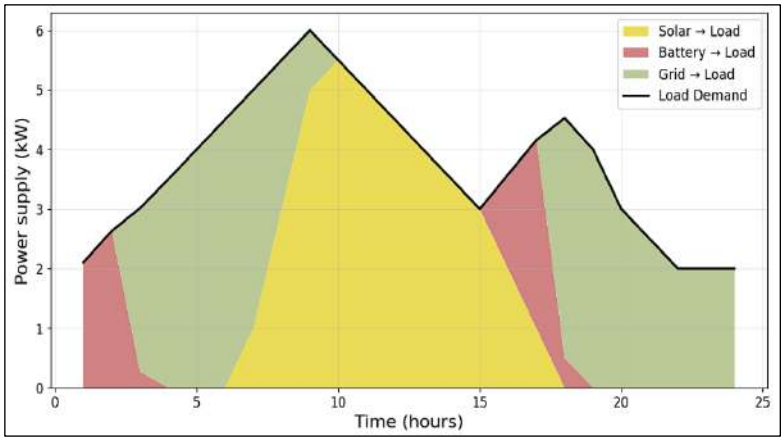

Figure 7: Continuous power supply to load.
Source: Authors, (2026).

The utilization of solar for household appliances by various techniques is shown in Figure 8. Regarding solar use, the following conclusions are from the figure. At about 57.5%, NILM has the lowest utilization, followed by FF-SHMS at 59.1%. MGIB achieves 62%, while M-GRU-based NILM comes in third with 60.2%. With the highest solar utilization of 78.6%, the proposed MCU-based EMS performs better than any other methods. The highest PV power utilization is achieved by using MPPT, which continuously modifies the PV operating point to extract maximum power under variable weather circumstances.

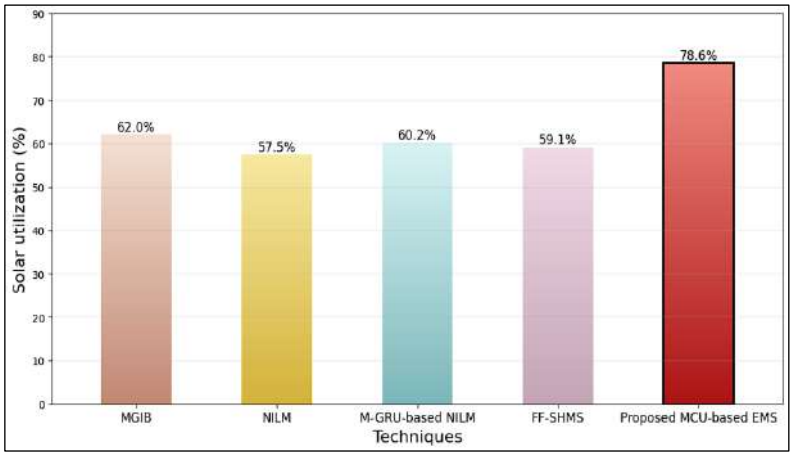

Figure 8: Comparison of solar utilization by different techniques.
Source: Authors, (2026).

Figure 9 depicts the mode-switching times of various energy management models including MGIB, NILM, M-GRU-based NILM, FF-SHMS and the proposed MCU-based EMS. The switching periods for the conventional systems are higher, ranging from 95 to 120 ms; MGIB is 120 ms, NILM is 95 ms, M-GRU-based NILM is 110 ms, and FF-SHMS is 105 ms. On the other hand, a much faster switching time of 24 ms is attained using the proposed MCU-based EMS. By enabling fast switching between on-grid and off-grid modes, the proposed framework eliminates the delays associated with traditional techniques and guarantees a continuous power supply while making the best use of renewable energy.

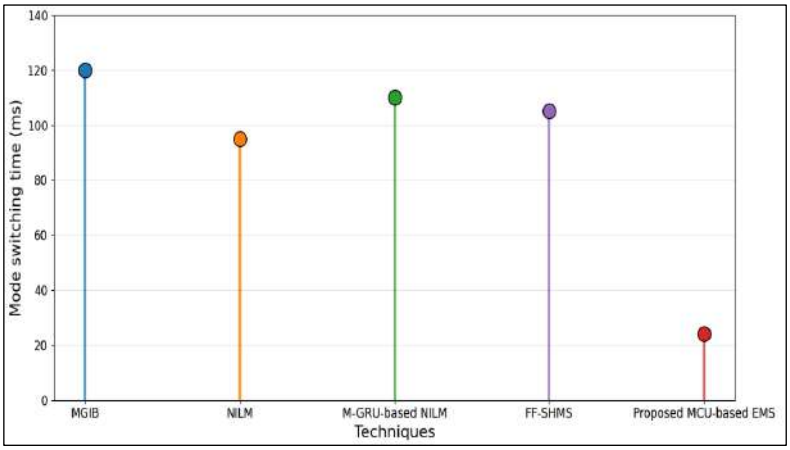

Figure 9: Mode switching times of different techniques.
Source: Authors, (2026).

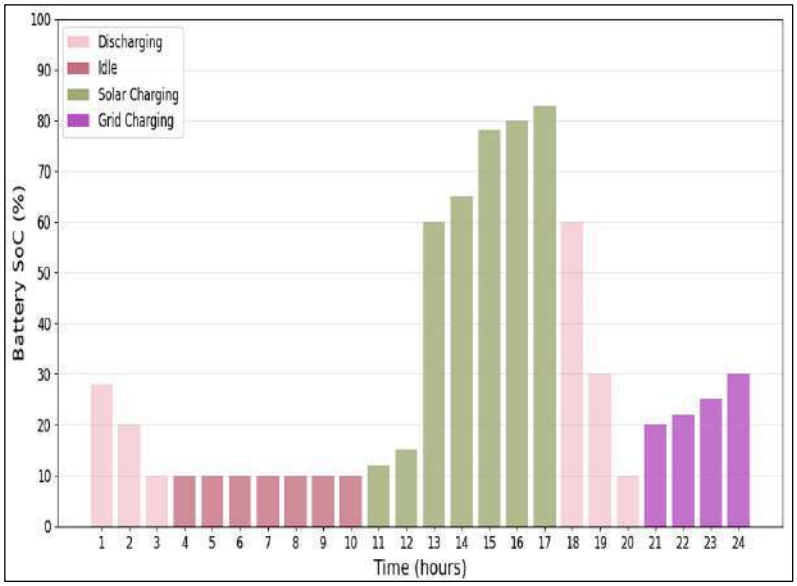

Figure 10: Controlled battery charging and discharging based on SoC.
Source: Authors, (2026).

The battery's controlled charging and discharging behavior during a 24-hour period is depicted in Figure 10, where the SoC is kept within safe bounds to avoid overcharging and deep draining. The SoC of the battery should be in the range between 10% and 90%. If the battery SoC reaches above 90%, then it is known as overcharging and if the SoC reaches below 10%, then it is known as undercharging. So, during charging, the battery must not go above 90% and during discharging, the battery should not go below 10%. This ensures the safety of battery and prolongs battery life. From the graph, it is inferred that the SoC is maintained by the proposed methodology. At the start of the day, the battery has 30% SoC and till 3 AM, it is draining energy. Since the SoC reaches 10% at the end of 3 AM, the battery is not discharging and it is idle until 10 AM. At 11 AM, there is excess solar power, the battery starts charging and at 17 PM, the SoC reaches 82%. Then, again it starts discharging until the SoC becomes 10%. Since the grid has low demand during late night hours, the battery starts to charge again by maintaining SoC.

V. CONCLUSION

In this paper, continuous power supply to home loads is achieved using the proposed MCU-based EMS. An intelligent microcontroller supplies the power continuously by switching between the power sources efficiently by checking the availability of power sources and demand needs. The model runs in two modes: grid-tied mode, which uses the grid and battery and isolated mode, which uses solar and battery power. The proposed model is constructed using various devices like synchronizer circuit, bidirectional buck-boost converter, DC-DC boost converter and MPPT algorithm. The model is also integrated with IoT using Blynk user interface for real-time energy consumption and generation monitoring.

The proposed strategy is evaluated both in hardware and software using power efficiency, mode switching time and maximum solar utilization. According to experimental results, the power efficiencies of 92.3% and 94.7% is achieved in standalone and grid-tied mode respectively. Seamless mode-switching is accomplished in less than 24 ms with no voltage sag. Under various load scenarios, the system achieved an average solar utilization of 78.6% higher than traditional methods. The system can be improved by integrating Artificial Intelligence (AI) and Machine Learning (ML) techniques which can estimate load demand, predict solar irradiance, and optimize battery charging and discharging. This efficiently distributes energy, reduces reliance on the grid and prolongs battery life. Besides, the model experiences slight delay in synchronizing the battery signal with grid electricity.

ABSTRACT

Transactive Energy System (TES) has emerged as a promising paradigm for coordinating Renewable Energy generation, consumption, and delivery. However, participants' sensitive data transmitted over the network in the TES framework must be preserved against cyber-attacks as more Distributed Energy Resources (DERs) come online. This article aims to conduct a comparative survey of two Machine Learning (ML) techniques, Federated Learning (FL) and Self-Learning (SL), to determine which is most suitable for preserving participants' data privacy in TES, based on the existing literature. The performance of their models was evaluated with a focus on resilience and network stability. The work examines, predicts, and uncovers meaningful patterns in the application of FL and SL techniques around privacy preservation. Findings revealed that FL is the most appropriate choice, as it allows collaborative model training, unlike SL, which utilizes centralized data, exposing it to privacy risks. Furthermore, the efficiency of FL-based TES is superior because it eliminates communication delays and does not require sending the entire raw data to the central server. In conclusion, the research demonstrated that FL-based TES is secure and inherently decentralized. Hence, FL is suitable for preserving participants' data in TES.

I. INTRODUCTION

The geometric rise in the integration of distributed energy resources (DERs) at energy distribution and utilization levels, enhanced by advancements in smart metering, energy management, and Information and Communication Technology (ICT), has transformed conventional electricity consumers into prosumers. These prosumers can monitor and control their generation, consumption, and energy storage in real time, to facilitate energy cost savings [1]. Recently, peer-to-peer (P2P) Transactive Energy Systems (TES) have emerged as a new energy market model, promising a more thorough and effective utilization of available renewable production and DER flexibility by prosumers [2] [3]. It uses control and economic mechanisms to achieve a dynamic balance of energy supply and demand across the entire electrical grid, with value as a main operational metric [4].

TES can be further described as a group of connected peers that use prices and incentives to sustain economic benefits for participants [5]. TES permits trade of electricity in real-time based on their energy consumption and generation prediction [6]. It is an emerging solution with features to secure critical loads during generation deficits and support electrical infrastructure when transmission and distribution networks are non-operational, which may be due to natural disasters such as Hurricane Maria, which was recorded in 2017 in Puerto Rico, where 80% of the grid collapsed [7]. However, the rapid integration of Internet of Things (IoT) and the adoption of Intelligent edge devices for processing IoT data into energy systems bring about the unprecedented growth in the digitalization of the energy sector based on the data volume generated by participants [8] [9].

Nonetheless, there are security challenges associated with this advancement, which include data integrity, authentication, scalability, and privacy leakage (that is, personal information and energy consumption patterns of participants) [10]. Hence, this prompts the need to protect this data against the activities of adversaries and to leverage the potential of intelligent techniques in making rational choices regarding grid services [11]. Distributed Machine Learning (ML), such as Federated learning (FL) and Self-Learning (SL), has proved to be a promising technique that permits multiple entities, across edge devices, to train a distributed model without direct raw data sharing [12]. The FL's architecture enables collaborative and privacy-preserving training on ML models to [10] [11]. The choice of FL in recent times is based on its features and the distinctive training approach that permits training of local models in each agent, beyond the collection of the entire data from other agents to the main server [11]. It alleviates concerns about privacy protection, as only the updated parameters (gradients or weights) are transferred during model training [13]. FL was portrayed as a catalyst with the potential to resolve data privacy and security issues in [14]. A privacy-preserving FL scheme was presented for IoT intrusion detection [15]. Researchers are probing the application of FL.

Some of them include a Clustered Asynchronous FL (CAFL), which was proposed for Energy-Harvesting Smart Meters in P2P Energy Trading (ET) in [12]. Ref. [7] introduced a privacy-aware FL framework for DER analytics in constrained environments. Du et al. [16] presented an FL-assisted distributed energy optimization, while Mendes et al [17] suggested an FL framework for predicting net energy demand in TES. The role of FL in preserving the privacy of IoT devices was reported in [18], while centralized and decentralized architectures were compared in [19]. Ref. [20] reported three privacy threats in the FL central server: susceptibility, gradient leakage attacks, and collusion among participants. The authors further explored three privacy techniques —Homomorphic Encryption (HE), Differential Privacy, and Multi-party Computation — to address privacy issues. A survey of optimization methods in privacy-preserving FL with HE was reported in [21]. Privacy-preserving techniques were deployed by hybridizing FL with blockchain for telemedicine in [22], while Yin et al [23] presented a 5W-scenario-based taxonomy (Who, what, when, where, and why) to classify the potential privacy leakage risks in FL. Ref. [24] proposed a decentralized FL framework for consumers' privacy preservation and energy theft detection using HE.

An ML-based technique was proposed to address IoT privacy challenges in [25]. Federated Reinforcement Learning (RL) was reported for privacy-preserving integrated thermal and energy management of multi-connected hybrid EVs [26], while Federated Deep RL was introduced to address privacy-preserving issues in Energy Management Systems with shared energy storage for Smart houses [27]. A hybridization of FL and Transfer Learning (TL) was suggested for privacy-preserving HVAC systems [28], whereas privacy-preserving heterogeneous federated TL was reported in [29]. These analyses established recent advances in the application of FL in privacy preservation in energy systems. However, little or nothing has been extensively reported for TES. In summary, the key contribution of this work is to: (1) examine, predict, and uncover meaningful patterns in the application of FL and SL techniques around privacy preservation; (2) present a comparative analysis of these ML-based techniques to determine the best-suited for privacy preservation in TES for the network stability and resilience. The rest of the paper is organized as follows: Section II showcases the relevant research on privacy-preserving techniques in TES, and an overview of reported literature on FL and SL-based methods for privacy preservation in Energy Systems. In Section III, we evaluate the performance of FL and SL-based Models for privacy preservation in energy systems. Section IV focuses on the discussion and reported findings, while Section V is the Conclusion and future research outlook.

II. RELEVANT RESEARCH

II.1 PRIVACY-PRESERVING TECHNIQUES IN TES: OVERVIEW

Mechanisms must be put in place to protect participants' sensitive information in TES. Information such as data usage, asset ownership records, and market bid/ask prices. A privacy-preserving distributed coordination algorithm was introduced for protecting participants' data in TES in [6]. The authors' literature corroborates the existence of cryptographic techniques for data protection. Ref. [30] presented a cryptography-based method (HE-based algorithm) to address privacy and security concerns associated with TES deployment over insecure communication channels, protection of agents' bidding details, and quick detection of external injection of malicious data during market interactions. The authors employed Paillier encryption, Paillier digital signature, and Stamp concatenation techniques for privacy preservation.

Relatedly, Paillier cryptography and calibrated noise were proposed for confidentiality and privacy preservation, respectively [10]. The introduced privacy protection solution uses calibrated noise to facilitate fair transactions among participants and to conserve participant behaviour patterns. The authors achieved 41.07% privacy protection with the proposed solution. A blockchain-based privacy-preserving distributed algorithm with a smart contract to minimize the quantity of information exposed to other participants during ET using asymmetric cryptography for TES [31]. developed a decentralized P2P ET al algorithm with two stages, on the blockchain, to preserve participants' privacy [32]. An FL-based framework was presented, utilizing local generation data obtained from a university, to predict the net demand of a building in TES settings [33].

II.2 FEDERATED LEARNING FOR PRIVACY PRESERVATION IN ENERGY SYSTEMS

In recent years, the application of FL for privacy preservation has become a centre for research. Liu et al. [12] proposed an energy-aware FL protocol to prioritize systems with adequate energy reserves dynamically, developed an adaptive dual-phase clustering strategy to mitigate preference inference attacks, and introduced a blockchain framework to establish a tamper-proof energy harvesting system in a P2P ET environment. The proposed CAFL resisted preference profiling attacks, confirming the model's robustness and its convergence under intermittent energy conditions. Consequently, similar research was reported. A FL-assisted distributed consensus approach was presented to forecast agents' local energy generation and demand for minimizing errors and improving forecast accuracy for net power demand prediction [16]. The authors further explored the proposed model to resolve the multi-agent distributed energy aggregation challenge in TES.

When comparing the prediction results obtained for FL forecasted (FLF) and Local Model forecasted (LMF), it indicates that FLF shows superiority over LMF with a greater accuracy of 1.36 times for April, for the first community (100 buildings), and 8 times for the second community (25 Buildings) for August. Relatedly, the same team of authors in [7] transitioned from applying FL for DER optimization to predicting net energy demand in the TES environment using FL in [17]. An FL architecture with two independent forecast systems, generation and demand systems, to facilitate collaborative learning among the buildings without sharing private data, and to support the management systems of TES. The authors introduced an auxiliary horizontal Federated TL (FTL) to enhance the forecast system. The buildings were divided into two groups of 100 and 25. The FTL was integrated by transferring the model weights between the servers responsible for the Groups. Group B realizes a better average of 0.07056 as against 0.09386 obtained by Group A. According to the authors, the FTL has the potential to enhance the forecast system's reliability.

Venkataramanan et al. [8] introduced an FL algorithm to forecast DER, transmitting a model of the consumption and generation patterns of 100 DERs for 24 hours without revealing consumer data. The work was evaluated using grid-specific performance metrics (load swings and load curtailment), while the simulation was validated using real data from the Pecan Street dataset. The research achieves a forecast with a root-mean-square error (RMSE) of 1.3 for 1000 IoT nodes and a 1.98 RMSE for real field data. However, the authors failed to establish that there is an existing trade-off between accuracy and privacy when using the FL approach. A comprehensive analysis of the application of FL in the energy sector, energy markets, and cybersecurity (fault detection, energy theft detection) was reported in [11]. Table 1 reflects FL applications in energy systems with their research significance, while Figure 1 illustrates the workflow of centralized FL.

Table 1. Application of FL in Energy Systems.

II.3 SELF- LEARNING FOR PRIVACY PRESERVATION IN ENERGY SYSTEMS

An SL-based adaptive framework, powered by the Soft Actor-Critic algorithm, was presented to enhance the energy management model, which resulted in a 45% energy reduction [34]. Wei et al [35] developed a novel SL parallel control technique to address the optimal control issue of discrete-time time-variant nonlinear systems. The adaptive dynamic programming-based SL method was utilized to ensure value function convergence and optimal policy. Ref. [36] proposed a SL control technique for decentralized winter-operated household ventilation systems for comfort and energy efficiency of occupants. The SL successfully learns the occupants' ventilation preferences. Zhou [37] reported a dynamic SL grid-responsive approach in enhancing energy flexibility and techno-economic needs of electrochemical batteries by adjusting off-peak grid charging power, thereby facilitating interactive energy networks in smart cities. A state SL approach was proposed to achieve distributed intelligent control in a multiple-reactor cascade operation, to capture the reactor's time-varying non-linear dynamics, and to enhance control performance [38]. The applicability of the technique was demonstrated in a cascaded zinc extraction process. An SL approach was presented to facilitate the decision-making process of a heterogeneous robot under uncertainty in [39].

III. PERFORMANCE EVALUATION OF FL AND SL-BASED MODELS ON PRIVACY PRESERVATION

When preserving the privacy of participants in TES, there must be a balance between privacy, model accuracy, and the efficiency of the algorithm [20]. In the review presented in [40], established that FL has been used in Renewable Energy (RE) for resource forecasting and that its local model surpasses other models in preserving data privacy. A Mathematical model was introduced to evaluate FL-based blockchain-enabled task scheduling to reduce energy consumption and delay by 41% and 28%, respectively [41]. An energy-aware architectural model was investigated and developed in [42]. Table 2 presents the performance evaluation of FL and SL models for privacy preservation.

IV. DISCUSSION AND FINDINGS

In the literature for privacy preservation in TES, blockchain-based techniques are the most widely utilized. Some of these techniques include HE-based algorithms, Paillier cryptography, and asymmetric cryptography. However, there is a limitation to these blockchain-based methods: the entire ET information stored on the network is available to all participants, thereby exposing users' data. Consequently, a malicious attacker may exploit this avenue for financial gain or espionage. In the application of SL in decentralized energy systems, a review of relevant literature shows that SL-based adaptive frameworks have been used to enhance energy management, whereas SL-based parallel control techniques were reported in resolving optimal control issues and for decentralized ventilation systems. Additionally, a dynamic SL grid-responsive approach was explored to enhance energy flexibility, while a state SL approach was proposed to achieve distributed intelligent control. The survey demonstrates that the SL technique is unsuitable for privacy preservation due to challenges, such as centralized vulnerabilities, data control, efficiency, and non-collaborative features, which prevent multiple participants from locally training a model. It was discovered that privacy-preserving techniques do not significantly affect the model's accuracy but may introduce computational and communication overhead. Furthermore, the survey shows that privacy-preserving techniques, such as FL, can optimize privacy, accuracy, and efficiency. However, one must carefully consider finding a balance between security and system performance. Consequently, all the reviewed articles on privacy-preserving techniques show that researchers have not explored the suitability of either FL or SL in TES, even though our findings established that FL is more suitable.

V. CONCLUSION AND FUTURE OUTLOOK

This survey successfully examined patterns in the application of FL and SL techniques for privacy preservation. Also presented is a comparative analysis of these ML-based techniques to determine the best fit for privacy preservation in TES to enhance network stability and resilience. The investigation reveals that FL offers robust privacy protections and supports decentralization as the data resides with participants during model training. In comparison with SL, which is centralized, all data are essentially aggregated into a main server for training. Therefore, raises concerns about the privacy and security of sensitive data. Its features allow TES participants to engage in ET without disclosing their private information. The research demonstrated that FL-based TES is secure and inherently decentralized, like P2P-based TES. Hence, FL's suitability in preserving participants' data. The work highlights the need for further research by exploring the integration of FL with Blockchain Technology to resolve emerging privacy issues in TES and to enhance efficiency and security. Additionally, challenges such as scalability and statistical heterogeneity require more attention. The contribution of this investigation will serve as a reference for future research.

ABSTRACT

Large-scale datasets have grown rapidly in recent decades due to the rapid advancement of database and computer technology. However, the number of data mining applications that use high-dimensional datasets and need great speed and accuracy is growing quickly. The curse of dimensionality, in which there are substantially more characteristics than patterns, is a key problem with these applications. Feature selection is one of the dimensionality reduction strategies that can improve the data mining task's accuracy and lower its computational cost. The goal of the feature selection process is to choose a subset of features that are most relevant to the target class and have the lowest inner similarity. By removing unnecessary, redundant, or noisy data, it lowers the dimensionality of the data. This study compares and contrasts several feature selection techniques and provides a general classification of them. This research also examines the latest swarm intelligence techniques and reviews feature selection techniques based on these algorithms using the credit card fraud detection dataset. Additionally, we assess the advantages and disadvantages of the various swarm intelligence-based feature selection techniques that were examined.

I. INTRODUCTION

One of the most crucial applications of machine learning is the detection of credit card theft or pattern recognition. Several fields use machine learning techniques, including medical diagnosis [1],[2], marketin[3], image processing [4],[5], text mining [6];[7], information retrieval, and identification [8]. Dimensionality reduction is one of the key strategies to get rid of features that are redundant or unnecessary once there are a number of them in the original features[9]. Two methods for dimensional reduction were introduced in the past: feature selection and feature extraction . Dimensionality reduction can enhance the machine's performance by eliminating redundant and irrelevant characteristics [6], [10]. The main feature space is mapped to a smaller space during feature extraction. Actually, by integrating pre-existing features, this strategy creates fewer features that contain all or most of the information found in the primary features. Furthermore, in feature selection, redundant and unnecessary features are eliminated to choose a subset of the original features with n being the number of original features, the entire search space to discover the most pertinent and non-redundant features, including all potential subsets, is $2n$. Finding the best features requires a thorough search, which is typically not computationally possible, even for medium-sized datasets.Finding a solution that is both computationally practical and high-quality is necessary because searching through all potential subgroups is exceedingly expensive. To prevent growing computational complexity, a lot of feature selection techniques include metaheuristic algorithms [11]. In a reasonable amount of time, these algorithms will be able to optimise the feature selection problem with the right level of precision. Swarm intelligence (SI) and evolutionary algorithms (EA) are the two primary categories into which metaheuristic algorithms fall. Compared to EAs and other single-solution-based methods, SI is a relatively recent type of evolutionary computation. Swarm-based techniques are the most widely used nature-inspired meta-heuristic group.

SI algorithms employ approximate and non-deterministic strategies to effectively and efficiently explore and exploit the search space in order to obtain near-optimal answers. Artificial intelligence based on collective behaviours in decentralised, self-organised systems is known as swarm intelligence (SI). A population of simple actors that interact locally and with their surroundings often makes up these systems. In the fields of data mining, pattern recognition, statistics, and other engineering applications, feature selection has been a topic of intense investigation[12]. Reviewing several feature selection techniques will help you determine the best strategy for that application because feature selection is used in most engineering problems. To put it another way, different engineering application areas use different feature selection techniques. For instance, the precision of the feature selection technique is significantly more crucial than its computing complexity in many engineering tasks, such as trial engineering and biomedical engineering. In fact, even if a feature selection approach has a high computational complexity, we prefer to use it in certain situations in order to maximise accuracy.

However, the computational complexity of the feature selection method is also crucial in many engineering problems, like image processing and machine vision, and computational complexity and execution time must be taken into account when selecting the feature selection method in this field. In light of this, it is crucial to examine several feature selection techniques in order to select the best one for that particular application. To feature sections, numerous SI-based methods have been used in recent decades. Only a small number of studies examine feature selection techniques, despite their extremely satisfactory performance compare feature selection methods based on swarm intelligence. The well-known and conventional SI algorithm and the feature selection techniques derived from it were the exclusive attention of this paper's writers. Additionally, a thorough literature evaluation of SI algorithms for feature selection is conducted. This paper's absence of experimental results and solely listing the advantages and disadvantages of various SI-based feature selection techniques is one of its drawbacks.

Additionally, swarm intelligence methods for feature selection in data mining are reviewed by [13].
This paper's focus on PSO, ABC, and ACO-based feature selection techniques is one of its drawbacks; many other SI algorithms that have been put forth recently—such as the Salp Swarm Algorithm, Grey Wolf Optimisation, Whale Optimisation Algorithm, and Gravitational Search Algorithm—have not been covered. The fact that this research merely examined the various approaches theoretically and did not do any numerical analysis to compare them is another flaw. Additionally,[14] examined the challenges that arise during the feature selection process and the application of swarm intelligence to feature selection. Additionally, this paper offers a succinct summary of several algorithms, such as ABC, ACO, and PSO. This paper's flaw is that it only compares the various approaches based on classification accuracy criteria; it makes no comparisons based on computational complexity, execution time, or a few other chosen features.

The absence of a review of new SI algorithms, such as the Salp Swarm Algorithm, Whale Optimisation Algorithm, and Grey Wolf Optimisation, is another flaw in this work. Since there hasn't been a thorough analysis of SI-based feature selection techniques before, this paper's primary goal is to close the coverage gap of SI algorithms for feature selection. The goal of this study is to present a thorough analysis of SI-based feature selection techniques and their classification. Additionally, this work attempts to review the most popular and cutting-edge SI-based feature selection technique. Additionally, in order to provide a more accurate assessment of these algorithms, a number of experiments have been designed in this study to compare the performance of various SI-based approaches. The rest of the paper is structured as follows: Section 2 introduces the feature selection problem, and Section 3 examines several feature selection techniques and categories from earlier ODs. SI-based feature selection techniques are reviewed in Section 4. The experimental outcomes of several SI-based techniques are shown in Section 5. The conclusion is finally presented in Section 6.

II. THE FEATURE SELECTION PROBLEM IS INTRODUCED

The dimensionality problem of a dataset where the feature subset size is significantly larger than the pattern size is a fundamental problem with machine learning techniques [15]. For instance, in medical applications that involve very high-dimensional datasets, the classification parameters are also increased, which results in a significant decline in the classifier's performance. A general rule states that at least $10\times n\times C$ training data is needed for a classification problem with n dimension and Cclass. If this amount of training data is not practically available, the number of training data needed is decreased by decreasing the feature subset size. Consequently, the classificational algorithm's performance improves [16]; [17]. One common method for eliminating duplicate and noise-producing features is dimensionality reduction. According to [6] and [10], it is an effective way to increase accuracy performance, reduce computational complexity, create more generalised models, and use less storage. Two main methods for dimension reduction have been put forth in recent years: feature extraction and feature selection. In feature extraction, the original features are transformed into a new, lower-dimensional feature, either linearly or nonlinearly.

By choosing a subset of the original characteristics that still has enough information for classification, feature selection, on the other hand, directly lowers the number of features. In the fields of statistics, pattern recognition, and data mining, feature selection has been a topic of intense research. The basic principle behind feature selection is to pick a subset of accessible characteristics by removing redundant features that have a high correlation as well as features with little to no predictive value [12]. The main idea of feature selection is to choose a subset of available features by removing features with little or no predictive information and also redundant features that are strongly correlated[12]. Feature selection is a fundamental research topic in statistical pattern recognition, machine learning, and data mining that dates back to the 1970s. Several attempts have been made to improve the performance of the feature selection methods. Subset generation, subset evaluation, stopping criteria, and result validation are the four primary steps of the feature selection process.

A subset of the candidate feature set is created from the original features in each search iteration, and an evaluation criterion is used to gauge how acceptable the subset is. Until a predefined stop requirement is met, the subset generation and evaluation procedures are repeated. Following this procedure, the test dataset is used to validate the optimal subset of the chosen feature [18]. Generally speaking, feature selection is important [19]. Feature selection methods generally perform more reliably and efficiently in the supervised mode because of the use of class labels. In supervised methods, a set of train data is available, each of which is described by taking feature values along with the class label, whereas in unsupervised methods, training data lacks class tags. Consequently, choosing a feature in the unsupervised mode is more chall enging, and this area has been taken into consideration in numerous studies [20]. Google Scholar gathers the papers for this review from a variety of databases, such as Elsevier, Springer, IEEE, and others.

To determine the present state of research, papers published between 2016 and 2020 were given the most weight. Review, dimensionality reduction, feature selection, evolutionary algorithm, optimisation, nature-inspired meta-heuristic, swarm-based techniques, metaheuristic optimisation algorithm, population-based algorithms, and evolutionary computation are the keywords used in the first search to find review papers. In the second search, the keywords are used to find research papers that focus on swarm intelligence-based feature selection methods. Also included are references to the featured papers as well as additional papers from Science Direct, Springer, and IEEE Xplore recommender systems. Subsequently, articles that concentrated on feature extraction and feature selection techniques not based on swarm intelligence were eliminated. Stated differently, only pertinent works that selected features only using swarm intelligence methods were included. As a result, 85 papers in all—including six review studies—were carefully examined for feature selection. The remaining references dealt with different approaches to the feature selection problem.

III. CONTEXTS

In general, feature selection techniques explore the solution space in order to maximise two competing goals: minimising the redundancy of chosen features and increasing their relevance to the target class [21]. Numerous search tactics are used to maximise these goals. According [22], these techniques can be broadly divided into single-objective and multi-objective approaches. Only one fitness function goal is used to optimise the population in single-objective approaches. The accuracy of the optimisation process will therefore be significantly impacted by the objective selection and fitness function definition. Additionally, many optimisation problems have several targets, and optimisation speed is decreased when a fitness function is defined with only one aim. Taking into account several objectives in the fitness function of the feature selection issue is one way to get over these obstacles. A collection of non-dominated feature subsets can be obtained by modelling feature selection as a multi-objective problem in order to satisfy various real-world application criteria.

Only a few multi-objective function approaches, including MOFSEF , MOFSEEG [23], and MOFSGADM [24], are used in the majority of the previously described feature selection methods. Furthermore, a number of earlier feature selection techniques aim to identify the fewest duplicated features with the greatest reliance on output labels. A new fuzzy multiple kernel learning model for classification is created by Wang. A novel criterion that chooses a subset of important and dissimilar features is put forward in this model. Furthermore, machine learning approaches have recently employed graph-based methods to uncover similarity associations among the data [25]. Graph-based techniques for feature selection offer an underlying manifold structure as a general framework to represent the connections among features. Graph-based techniques were used in a number of studies to address the feature selection issue.

For instance, a dense subgraph discovery method is used to solve the unsupervised feature selection problem present an additional clustering-based feature subset selection approach for large dimensional data. For similar grouping features, this work uses a graph-theoretic clustering technique suggest a feature selection technique based on hypergraphs. By taking into account each sample's associated class label, this study employs an information-theoretic criterion to assess the suitability of various features. The unsupervised feature selection procedure incorporates the idea of graph clustering with the node centrality metric. real-world applications. While the wrapping model could choose a superior feature subset, it can deteriorate with high-dimensional medical datasets and is costly to execute. This is because the feature subset quality computation makes use of learning methods.

III.1 MODEL OF FILTER

The filter model uses no learning mechanism to assess the features' importance. As a result, this approach's approaches are usually quick. The features with the highest ranks are chosen in this model after they have been assessed and rated using information-theoretic metrics [26]. According to one perspective, there are two types of filter-based methods: univariate and multivariate. These approaches, however, produce weak and complex learning models, neglect feature dependencies, and display comparable features in the final feature set. Multivariate approaches, a subset of the filter approach, address both redundant and irrelevant features in their ranking strategies in order to address this problem. Stated differently, multivariate filtering techniques were put forth with the goal of taking feature dependencies into account to a certain extent. Minimal redundancy maximal relevance (mRMR) , Relevance redundancy feature selection (RRFS), MIFS, Normalised Mutual Information Feature Selection (NMIFS), MIFS-U, Unsupervised feature selection based on Ant Colony Optimisation (UFSACO), and Hilbert–Schmidt independence criterion (HSIC) are a few multivariate techniques.

III.2 MODEL OF A WRAPPER

The wrapper approach uses a classifier that has been trained to assess a number of salient attributes. The wrapper model selects a collection of features with the maximum classification accuracy by evaluating a subset of features in their search operations using a specific learning model. The majority of wrapper approaches use iterative search procedures, in which the population of solutions is guided towards the optimal solution with each iteration of the learning model. However, the wrapper approach's high computing cost and loss of generality are caused by the learning model that is used in the search process. Filter methods are suitable for populations with random solutions and aim to increase the optimality of these solutions at each iteration step since they are quick enough and their output is independent of a particular classifier. In real-world applications, a fitness function is used to determine the optimality of the individual solutions of the created decision-makers after a number of initial solutions are generated at random at the start of most meta-heuristic algorithms.

For gene selection and cancer classification, [27] integrate correlation feature selection with a modified binary PSO method. By removing the unnecessary and duplicated features, this technique chooses a subset of highly significant attributes. The Shuffled Frog Leaping Algorithm and enhanced mRMR are combined in [28] to increase the accuracy of acoustic defect identification. This method uses the MRMR criterion to build a single-objective function, which is then optimised using the PSO algorithm to reduce the dimensions of the original features. The neural network classifier is then used to detect the final auditory defect after the final feature subset has been chosen. [29] offer a new PSO-based feature selection technique that combines illness diagnosis performance. To choose a subset of pertinent and non-redundant features in DNA microarray datasets, developed a recursive particle swarm optimisation strategy. The authors of this paper integrated the different filter-based feature selection measures with the developed wrapper-based recursive PSO method use the modified BPSO algorithm with the binary black hole algorithm to construct a feature selection technique for cancer classification.

This method introduces a hybrid feature selection method by combining the benefits of the wrapper and filter approaches. To increase effectiveness and make it easier to explore and exploit the PSO to further improve performance, this hybrid feature selection method incorporates the binary black hole algorithm into the PSO algorithm. Furthermore, an enhanced BPSO approach for feature selection was created . This technique employs a novel Win-Win approach to improve feature selection accuracy in the detection of renal and liver diseases. In addition, [30] presented a new hybrid PSO-based feature selection technique for laser-induced breakdown spectroscopy investigation.

An effort has been made to combine the benefits of coating and filtering techniques in this procedure. A PSO-based feature selection method with several classifiers is suggested in [13]to enhance the population. A new generation of production will start if none of the termination requirements are fulfilled. Until one of the termination criteria is satisfied, this cycle is repeated. Evolutionary Algorithms (EA) and Swarm Intelligence (SI) are two types of meta-heuristic techniques. EAs employ mechanisms including reproduction, mutation, recombination, and selection that are modelled after biological evolution. Individuals in a population are represented by candidate solutions to the optimisation problem, and the quality of these solutions is determined by the fitness function. The starting population evolves and advances towards global optimisation following iterations of the evolutionary algorithm [31].

Furthermore, the optimisation approach based on swarm intelligence takes into account a lot of complex artificial aspects. Nature is the source of the idea for SI optimisation algorithms. Each component performs a basic task, but together, these components produce global intelligent behaviour that is impossible for any one component to accomplish on its own. Particle Swarm Optimisation (PSO), Ant Colony Optimisation (ACO), Artificial Bee Colony Optimisation (ABC), Differential Evolution (DE), Gravitational Search Algorithm (GSA), Firefly Algorithm (FA), Bat Algorithm (BA), Cuckoo Optimisation Algorithm (COA), Grey Wolf Optimisation (GWO), Whale Optimisation Algorithm (WOA), and Salp Swarm Algorithm (SSA) are among the SI-based feature selection techniques that are reviewed and described in Table 2 in the sections that follow.

III.3 MODEL OF HYBRID

By combining the filter and wrapper models, the hybrid strategy aims to benefit from both of them. Like filter-based approaches, this strategy primarily focusses on maximising performance using a specific learning algorithm and time complexity.

III.4 THE EMBEDDED MODEL

The feature selection issue is taken into account by the embedded approach as a component of the machine learning technique. Actually, a machine learning technique is employed in the embedded approach to find the last feature subset.
The key traits of the various feature selection techniques are compiled in Table 1. Six characteristics of various feature selection techniques are listed in this table: the number of objectives, the type of approach, the search strategy, the application, the weakness, and the strength.

Table1: The main characteristics of different feature selection methods. The synonyms used in this Table are: MOP: Multi-Objective Optimization, SOP: Single-Objective Optimization, RB:Ranking-Based, SSB: Subset selection-based, ACO: Ant Colony Optimization, GA: Genetic Algorithm, ABC: Artificial Bee Colony, DE: Differential Evolution, NSGA: Nondominated Sorting Genetic Algorithm.

IV.SWARM INTELLIGENCE-BASED FEATURE SELECTION.

Feature selection methods based on how to evaluate the features are classified into two categories: feature ranking and subset selection methods. Feature ranking methods, based on a specified criterion, assign a score to each feature.Then the features that did not get scores are removed. But in subset selection methods, the space of possible subsets is searched to find the optimal subset. If the number of initial features is n, the search space for the optimal subset contains all the features, which is equal to$2n$ different states. In other words, in the property ranking methods, the value of each property is evaluated independently, and the relationship between features is not considered. In these methods, it is assumed that the features are independent of each other and that a possible dependence between the features is not considered. Although this simplistic assumption reduces the computational complexity of the feature selection method, in many cases, it may reduce the performance of the feature selection method. Feature subset selection is an NP-Hard problem. In the simplest way, the best subset can be found by evaluating all possible subsets with an exhaustive search strategy.

Although this method guarantees an optimal feature subset, finding the optimal solution is very time-consuming and even impractical for medium-sized datasets. Since it is very costly to evaluate all possible subsets, a feature subset must be searched, that, it is acceptable both in terms of computational complexity and in terms of appropriateness [32] [33]. One approach to solving complex optimization and NP- Hard problems is meta-heuristic algorithms. Meta-heuristic algorithms are approximate approaches that can find satisfactory solutions over acceptable time instead of finding the optimal solution. These algorithms are one of the categories of approximate optimization algorithms that have s strategies to escape from local optima and can be used in a wide range of optimization problems. Many feature selection methods use meta-heuristics to avoid increasing computational complexity in high-dimensional dataset. These algorithms use primitive mechanisms and operations to solve an optimization problem and search for the optimal solution over a number of iterations. These algorithms are often extended by the authors of [34] to choose more informative features.

In Henni et al.(2018), the authors employed Google's PageRank centrality measure to rank features based on their importance[34] propose another graph-based feature selection method for the multi-label high-dimensional dataset. The authors of this paper utilize the PageRank centrality measure to rank the features based on their value in the graph. Also, in this paper, the correlation distance criterion is used to remove irrelevant features. In [35], an unsupervised graph-based feature selection method for high-dimensional data is proposed. In this paper, the Laplacian graph and local geometrical structure are used for better representation of the feature spacfe. In a subspace clustering guided unsupervised feature selection method is proposed. This work uses the subspace clustering to learning of the clustering, and then those features with good preservation ability of the cluster labels are selected. Generally, previous methods for selecting optimal feature sets can be categorized into four groups consist of filter, wrapper, embedded, and hybrid models. These categories are explained in the following subsections.

IV.1 PSO-BASED METHODS

Particle Swarm Optimization is a powerful SI-based optimization method, developed by Kennedy and Eberhartin 1995. This optimization method, inspired by the collective conduct of birds and fish, has recently been used in a number of researches to optimize the selection of the final feature subset. Unler et al.(2011) introduced a new search strategy to select the final feature set, which integrated the filter approach. Moreover, developed a hybrid feature selection method for the medical application. The authors of this paper, proposed a hybrid feature selection approach by combining the wrapper PSO and rough sets theory to improve the classification accuracy of disease diagnosis. Furthermore, in Huang and Dun(2008) another hybrid approach for feature subset selection and parameter optimization is proposed. In this method the PSO optimization method, and SVM in integrated to improve the performance of feature selection. The authors of this paper combined PSO–SVM with a distributed parallel architecture to overcome the high computational complexity for the high-dimensional datasets.

More over, the authors of developed novel initialization methods and best particle updating strategies to improve the performance of optimization tasks in feature subset selection. This method aims to se- lect a subset of relevant and non-redundant features for computational complexity reduction. Proposed an integration model of binary PSO (BPSO) algorithm and the Hamming distance to select the final feature set in the classification task. In this method, a hamming distance is used to improve the velocity update process in a BPSO algorithm and then this improved BPSO is utilized for feature selection problem.An improved multi-objective PSO algorithm is proposed for unreliable data classification. In this paper, two new operators of the reinforced memory and the hybrid mutation are introduced to improve the searchability of the PSO algorithm. In efficient PSO-based feature selection method is proposed by the integration of filter and wrapper approaches.

The proposed method, called HPSO-LS, introduced a new local search to select the subset of non-redundant and relevant features. In [36] a multi-objective particle swarm optimization approach is developed for cost-based feature selection in classification. The main goal of this method is to produce a Pareto front of non-dominated solutions, that is,featureset, to meet different prerequisites for increasing the classification accuracy and reducing computational complexity. In this paper, a new Self-Adaptive Parameter and Strategy a high-dimensional dataset. The reported results showed that the use of these mechanisms greatly increased the search ability of particle optimization algorithms for high-dimensional datasets. Moreover, in [38], a novel graph-based feature selection method is developed to increase disease diagnosis accuracy. In this method, using the node centrality criterion, a new mechanism for initializing the particles is proposed. Then, by defining a multi-objective fitness function, a subset of the final features that are least similar to each other and most relevant to the target class are selected. Finally, based on the selected features, the disease is diagnosed, disease diagnosis accuracy. In this method, using the node centrality criterion, a new mechanism for initializing the particles is proposed.

Then, by defining a multi-objective fitness function, a subset of the final features that are least similar to each other and most relevant to the target class are selected. Finally, based on the selected features, the disease is diagnosed.

IV.2 ACO-BASED METHODS

About three decades ago, a new heuristic-based optimization method called the Ant System (AS) is proposed by Dorigo and his colleagues to solve complicated optimization problems. AS was first utilized for the traveling salesman problem. Then, Dorigo and Caro(1999) developed the Ant Colony Optimization (ACO) algorithm to improve the AS algorithm. This improved algorithm can be able to search the global optimal by representing the problem as a graph model. Moreover, ACO has been successfully utilized in many types of research to select the final feature set. In Kabir et al.(2012) an ACO-based feature selection approach is developed by combining the neural network and IG method to remove redundant and irrelevant features. Moreover, the authors of Li et al.(2013) proposed a new ACO-based gene selection method in the DNA microarray dataset. This proposed method includes two phases of essential features by improved AS algorithm and then final features are selected using a modified ACO algorithm.

Furthermore, in a new ACO-based feature selection approach is developed. In this approach, unlike the previous ant feature selection methods based and ACO, the feature selection problem is modeled as a directed graph. In Forsati et al.(2014),a new version of ACO is proposed to remove the irrelevant and redundant features. This method selects the final feature set by utilizing a local search strategy to avoid getting stuck in the local optimal. Moreover, in Keetal.(2008), a rough set theoretic-based ACO feature selection method is developed. In Tabakhi et al.(2014) a novel ACO-based feature selection method is proposed for unsupervised mode. The authors of this paper selected the most non-redundant features that have the least similarity with each other. Moreover, Moradi and Moradi and Rostami, developed a filter-based feature selection approach utilizing the ACO algorithm and graph clustering.

This approach represented the feature space as a clustered graph. Then, according to the similarity between the features and by defining a filter criterion, it selects a dissimilar and related subset of the features. In Dadaneh et al.(2016) proposed an unsupervised ACO-based feature selection method to remove redundant and irrelevant features. This method tries to select an optimal subset of features in a hierarchical process, by considering the similarity between features. In [2], a combination of feature selection and ant colony optimization is proposed to improve the classification accuracy of imbalanced data.In this method, instead of using a single-objective fitness function, a multi-objective ant colony optimization algorithm is used to improve the performance of feature selection. The reported results showed acceptable performance of the proposed method in classifying imbalanced and high-dimensional datasets.

IV.3 ABC-BASED METHODS

The Artificial Bee Colony algorithm (ABC) is an SI-based optimization method inspired by the lifestyle of the bee population. This algorithm tries to imitate the food search behavior of the bee population. This optimization technique integrated a local search strategy with a random search strategy that can be utilized for complex optimization problems. This swarm intelligence-based optimization technique has been applied in many references to select a final feature set.In Schiezaro and Pedrini (2013), a novel feature selection method based on an artificial bee colony is developed to improve the machine learning task. In this method, the feature space is modeled as a binary vector and the classification function. The authors of, developed an improved ABC-based feature selection approach. This approach combined the similarity search strategy and a binary version of ABC to improve the performance of feature selection. Shunmugapriya and Kanmani[39], proposed a novel feature selection method by integrating. This method tries to utilize the advantages of an artificial bee colony and an ant colony optimization algorithm, simultaneously.

In[40] a new feature selection approach is developed by the combination of the ABC algorithm and the Pareto-optimal front surface. The authors of this paper used a multi-objective fitness function and genetic operators to improve the accuracy of the feature selection method and the convergence of the ABC algorithm. In Arslan and Ozturk(2019) a Multi Hive ABC Programming is developed to select the final features in high-dimensional datasets. This approach utilized the ability of an automatic programming algorithm to remove irrelevant and redundant features. The authors of [41], developed a multi-objective ABC-based feature selection approach. In this method, two new operators are used to improve its search capability and convergence of the ABC search strategy. In [42], an ABC-based feature selection is proposed by integrating of multi- multi-objective optimization algorithm with a sample reduction strategy. This proposed method has both increased classification accuracy and reduced computational complexity.

IV.4 DE-BASED METHODS

The Differential Evolution (DE) algorithm is an SI-based search strategy technique that has been developed to solve complex optimization problems.This optimization method is introduced to overcome the main weakness of the genetic algorithm, namely its lack of local search capability. The main difference between DE algorithm and the genetic algorithms is in the genetic selection operators. DE algorithm is used in different applications of machine learning tasks and feature selection.For example, Al-Anietal developed a wrapper-based feature subset selection using DE algorithm and a wheel-based search mechanism.[43] proposed a multi-objective DE-based approach to remove the irrelevant and redundant features and improve classification accuracy. In [44], a multi-objective DE-based feature selection approach is developed. In this approach, a novel mutation operator is defined to escape the local optimum. Furthermore, in [45], another new multi-objective DE-based feature selection approach is developed for feature selection and to improve the performance of the clustering algorithm simultaneously.

IV.5 GSA-BASED METHODS

Moreover, some SI-based optimisation methods have been inspired by physical laws. Gravitational Search Algorithm (GSA) is a physics-based optimisation technique inspired by Newton’s law of universal gravitation. GSA, a popular SI-based algorithm, has been widely applied in machine learning, and recently, many feature selection methods have been developed using this optimisation algorithm. proposed a GSA-based feature selection approach using a linear chaotic map to improve classification accuracy. In Xiang , a hybrid system for feature selection based on an enhanced GSA and K-nearest neighbour classifier is developed.

In this method, a piecewise linear chaotic map for exploration and sequential quadratic programming for exploitation are employed. In [46], an efficient hybrid feature selection method is proposed to utilize the advantages of the SI and the genetic algorithm to improve the performance of the GSA algorithm.

IV.6 FA-BASED METHODS

The Firefly Algorithm (FA) was introduced , the main idea was inspired by the optical connection between fireflies.The Firefly Algorithm is a sensible example of swarm intelligence in which low-performance agents can work together to achieve great results with high performance. In [47] a novel FA- based feature selection method, called return-cost-based binary FFA is developed. The authors of this paper provide a variety of strategies to prevent premature convergence of the FA algorithm and thus improve the accuracy of feature selection. In [48],a feature selection method is developed using the firefly optimization algorithm to increase the accuracy of classification and regression models. In this method, to improve convergence and prevent trapping in local optimization, some variation is added to standard FA, which improves the accuracy of final feature selection. Moreover, in [49]FA-based feature selection method is proposed. In this method, after selecting the final features, these features are utilized to classify Arabic texts using an SVM classifier. Furthermore, in Sel-vakumar and Muneeswaran(2019), another FA-based feature selection method is presented for network intrusion detection. In this method, a combination of filter-based feature selection method (i.e., Mutual Information) and wrapper-based feature selection method (i.e., C4.5 and Bayesian network) has been utilized to select the final features.

IV.7 BA-BASED METHOD

The Bat Algorithm (BA) is an algorithm inspired by the collective behavior of bats in the natural environment, introduced. The bat algorithm is a kind of swarm intelligence- based algorithm that is inspired by the echolocation behavior of bats. Bats find the exact path and location of their prey by sending sound waves and receiving reflections. When the sound waves return to the transmitter of the bat waves, the bird can draw an audio image of the obstacles in front of its surroundings and see its surroundings well.In [50], a hybrid variant of- rithm and improved PSO algorithm is to improve the feature selection performance. In this proposed method, the PSO algorithm is used to improve the convergence power of the hybrid algorithm. Moreover, in [49], a binary BA-based feature selection method ion accuracy. Furthermore, [54] used the bat algorithm to search optimal features subset to increase the accuracy of cancer classification. In this method, a combination of filter and wrapper approaches was used to improve the performance of feature selection. In this method, robust mRMR as a filter to select the most relevant features and an improved BA algorithm as a search strategy in the wrapper approach is presented to select the final feature subset.

IV.8 COA-BASED METHOD

The Cuckoo Optimization Algorithm (COA) is another algorithm based on swarm intelligence, inspired by the special lifestyle of a bird called the cuckoo. The specific habitude of laying eggs and the reproduction of this bird has been the basis for the formation of this optimization algorithm. Like other evolutionary algorithms, the cuckoo optimization algorithm begins with an initial population of cuckoos. This early population of cuckoos has a number of eggs that are placed in the nest of the host bird. Some eggs, which are more similar to host bird eggs, have a better chance of growing into adult birds. The other eggs are identified and destroyed by the host butterfly. Grown eggs show that the nest is a better place in the search space, and the usefulness of that area is higher. The goal of the cuckoo optimization algorithm, which is the optimization function, isto find the place where most eggs have a more chance to survive. In a COA-based feature selection method is developed to improve the cancer classification accuracy.

In this method, first, the irrelevant features are removed using a simple and fast filter-based feature selection. Then, from these relevant features, the final features are selected by integration wrapper-based feature selection and COA algorithm. In Jayaraman and Sultana(2019), a combination method of cuckoo search algorithm and neural network is developed for feature selection. In this method, after selecting a feature subset of non-redundant and relevant features, the final chosen features are sent to the classifier, and heart disease is classified. Moreover, in [37], another cuckoo search-based feature selection method is proposed for improving the disease diagnosis accuracy. In this method, the process of feature subset selection is optimized using the cuckoo search optimization, and then these selected features are sent to the SVM classifier to identify lung cancer.

IV.9 GWO-BASED METHOD

Gray Wolf Optimization (GWO) is a new evolutionary algorithm-based optimization technique inspired by gray wolves. This optimization method is one of the latest bio-inspired techniques, which imitates the hunting process of a pack of gray wolves in nature. Recently, some GWO-based methods has been utilized as a tool for feature selection in machine learning applications. Ia Multi-Objective GWO was applied to search for the most relevant and non-redundant features. This proposed method utilized the low computational complexity of the filter model to improve the accuracy of the wrapper model. In a binary version of the GWO is developed to select the optimal feature subset for classification tasks. In the wrapper-based feature selection method, classification accuracy and the number of selected features are utilized for the fitness function. In to enhance the previous GWO-based feature selection approach, a multi-strategy ensemble GWO is developed for feature selection. Moreover, [51] developed a GWO-based wrapper feature selection approach that integrated with a mutation operator for data classification. The mutation operator proposed in this paper tries to remove the redundant and irrelevant features.

IV.10 WOA-BASED METHODS

Optimization Algorithm (WOA) is another SI-based optimization method inspired by the hunting behaviour of humpback whales. This optimization method consists of three operators to imitate the search for prey, encircling prey, and bubble-net foraging behaviour of humpback whales.

Recently, the WOA algorithm is successfully applied in many different optimization problems and feature selection. In a hybrid WOA with a simulated annealing algorithm is developed for feature selection. The aim of using simulated annealing in this hybrid method is to improve the exploitation by searching the most promising regions located by the WOA algorithm. In a WOA-based wrapper feature selection algorithm is developed. In this study, tournament and roulette wheel selection mechanism and also crossover and mutation operators, are used to improve the exploration and exploitation of the search process of WOA algorithm. Introduced a frequency-based filter feature selection method using a whale algorithm on high-dimensional medical datasets. In this method, a filter criterion is utilized to discard the irrelevant features using the WOA. Then, the reminder features are ranked based on another filtering method, namely, Mutual Congestion.

IV.11 SSA-BASED METHODS

Salp Swarm Algorithm (SSA), another bio-inspired algorithm based on swarm intelligence, is proposed for solving optimization problems. This algorithm is inspired by the swarming behavior of salps when moving and for in the oceans. In an efficient binary Salp Swarm Algorithm with a crossover scheme is proposed to improve the accuracy of feature selection. More- over, in a hybrid optimization method for the feature selection problem is proposed by the integration of the slap swarm algorithm with particle swarm optimization. This combination of both swarm optimization algorithms improved the efficacy of the exploration and the exploitation steps. In the integration of Improved SSA and novel local search algorithm is developed for the feature selection problem. In this method, the accuracy of the classification accuracy of KNN classifier on the training data is used as a fitness function, and the final features are selected in repetitive process. Also, in this method, to create the initial population, a method based on Opposition-Based Learning is presented, which has caused diversity in the initial solutions. Furthermore, in [52], a Salp Swarm Algorithm-based feature weighting method is developed to predict the presence of liver is order, heart, and Parkinson's disease.

Also, in solution accuracy, reliability, and convergence speed of basic SSA is improved by adding a new control parameter and inertial weight. Then this improved algorithm was tested in the feature selection problem. Moreover, in [53], anew variant of SSA optimization algorithm is proposed for feature selection. In this method, an additional phase is utilized to overcome the problem of being stuck in local optima by encouraging the exploration of the search. With the advancement of data collection technologies and the increasing capacity of data storage over the last decades, high-dimensional datasets have grown significantly. Usually, many features of these datasets are irrelevant or redundant, which reduces the performance of the prediction model. Feature selection plays an essential role in machine learning and, more specifically, in high-dimensional datasets. Reducing the size of the medical dataset, on the one hand, reduces the computational complexity and, on the other hand, decreases the parameters of the classification algorithm. As a result, the accuracy of the prediction model will be increased. In the past decades, rapid growth of computer and database technologies has led to the rapid growth of large-scale datasets.

On the other hand, data mining applications with high-dimensional datasets that require high speed and accuracy are rapidly increasing. An important tissue with these applications is the curse of dimensionality, where the number of features is much greater than the number of patterns. One of the dimensionality reduction approaches is feature selection which can increase the accuracy of the data mining task and reduce its computational complexity. The feature selection method aims at selecting a subset of features with the lowest target class. It reduces the dimensionality of the data by eliminating irrelevant, redundant, or noisy data. In this paper, comparative analysis and categorization of different feature selection methods are presented. Moreover, in this paper, wrapper and filter SI-based methods (i.e., PSO, ACO, ABC. DE, GSA, FA, BA,COA, GWO, WOA, and SSA)and their application in feature selection are studied. Furthermore, the strengths and weaknesses of the different studied SI-based feature selection methods are evaluated, and the factors that can lead to the superiority of these methods are analyzed.

V. EXPERIMENTAL RESULTS

In this section, the performances of the different swarms- evaluated. The results are shown in terms of the number of selected features and the classification accuracy (ACC). The classification accuracy was calculated as follows:

$$ACC=TP+TN / TP+TN+FP+FN \quad (1)$$

Where TP, TN, FP, and FN stand for the number of true positives, true negatives, false positives, and false negatives, respectively. In each experiment, each feature selection method is run ten times, and the mean and standard deviation (square root of its variance) often different runs is often used to compare different methods.

V.1 DATASETS

All simulations were executed against the credit card fraud dataset, which is freely available on the Kaggle repository via the following link : https://www.kaggle.com/datasets/mlg-ulb/creditcardfraud, accessed on 20 May 2022. This dataset consists of transactions generated by credit cards in Europe in September 2013 during the time span of two days. The dataset represents a binary classification challenge composed of only two target variables (classes)—the positive class, which denotes fraudulent transactions, and the negative class that represents regular transactions. Moreover, the dataset is extremely asymmetrical (imbalanced), containing only 492 fraud instances out of 284,807 total transactions. Therefore, the positive class (frauds) represent only 0.172% of the dataset. The dataset is composed of 30 numerical features, where attributes F1,F2, F28 are obtained by applying the principal component analysis (PCA), while F29and F30, which represent time and amount, respectively, were not transformed with the PCA.

The time refers to the number of seconds elapsed between the first and each other transaction in the dataset, while the amount is the value of every transaction. In the first set of experiments, the original credit card fraud dataset, as it is hosted on Kaggle, is used, and the goal of these experiments was to establish how tuned ML models perform on highly imbalanced data. However, it is also important to validate the performance of ML models for balanced datasets. In the proposed study, the minority class (class 1 in this example) was oversampled to the number of instances of the majority category (class 0 in this example); therefore, the dataset, which in datapoints, is almost twice as large as the original one.

It needs to be noted that the experimental setup for SVM simulations had to be different, due to the specific properties of the model. In the case of SVM, a smaller dataset has been used, as the model operates very slowly. This was tackled by creating a reduced dataset with the size of only 0.5% of the original dataset that was fed to the rmodels while keeping the original class distribution (by using the stratification strategy). In the case of SVM and ELM experiments, the normalisation technique was also used. However, since the XGBoost operates on a decision tree basis, normalization has not been performed in that case. A total of 70% of each dataset was used for training, while the remaining 30% was utilized for testing of all models.

V.2 EXPERIMENTAL SETUP AND PROPOSED ENCODING SCHEME

As noted previously, all three ML models were tuned by the proposed GSFA meta-heuristic. In the case of the first utilised model, namely the SVM, hyperparameters were subjected to optimisation; two of them are continuous, while one is of the integer data type. The optimized SVM parameters, along with respective lower and upper bounds, are as follows:

C, boundaries:[2−5,215], type: continuous,
γ, boundaries:[2−15,23], type: continuous, and kernel type, boundaries :[0,3], type: integer, where value 0 denotes polynomial(poly),
1 marks radial basis function (rbf),
2 represents sigmoid, and finally
3 represents linear kernel type.

For the ELM model, both the number of neurons (nn) in the hidden layer and the values of the weights and biases between the input and hidden layers were subjected to the optimisation process. The lower and upper bounds for weights and biases were set as -1 and 1, respectively, in the interval [30,150]. The nn is an integer, while the weights and biases may take any continuous value from the specified range. Moreover, hyperparameters, while the optimisation of weights and biases is the ELM's training process, in the case of ELM, metaheuristics were used for both hyperparameters' optimisation and training. Finally, the set of XGBoost hyperparameters that were subjected to optimisation consists of the following:

learning rate (η),boundaries:[0.1,0.9],type: continuous,
min_child_ weight, boundaries:[0,10],type: continuous,
sub sample,boundaries:[0.01,1],type: continuous,
collsample, by tree, boundaries:[0.01,1], type: continuous,
max_ depth, boundaries:[3,10],type: integer and gamma,
boundaries:[0,0.5],type: continuous

The number of parameters for the softprob objective function ('num_ class': self. no classes)is also passed as a parameter to XGBoost. All other parameters are fixed and take default XGBoost values. All observed models were implemented in the Python programming language by employing standard machine learning libraries: scikit-learn, scipy, numpy, and pandas. For other models' hyperparameters, the default values from the scikit-learn Python library were used. The SVM and XGBoost models were adopted from scikit-learn; however, the ELM was coded from scratch because this model is not available in this package. In all implementations, a standard solution's encoding scheme was used. Every metaheuristic solution is represented as an array (vector) of size l, where l is the number of hyperparameters that were optimised. Therefore, the l for the SVM and XGBoost solutions are 3. However, in the case of ELM, l depends on the determined value for the nnhyper-parameter, and, if the fs denotes the size of the input feature vector, it can be derived as: 1+nn· fs +nn. The first component of the ELM metaheuristic solution represents the number of neurons (integer); subsequent nn components are biases (continuous), while remaining nn· fs parameters are weights.

V.3 COMPARATIVE ANALYSIS AND DISCUSSION

In all experiments, the obtained outcomes of all three models optimised by the suggested GSFA metaheuristic were compared to the results generated by other well-known swarm algorithms that were also implemented for the SVM, ELM, and XGBoost model tuning under the same conditions, as described in Section 4.2. The competitive algorithms include the original FA [49], BA [2], ABC[42], since cosine algorithm SCA, WOA (Nematzadehetal.(2019)), and SNS etc. All metaheuristics were implemented independently in this research and adjusted (in terms of controls' parameters setup) as in the original publications that were mentioned beforehand. For the easier summary of results presented in tables, the machine learning model prefix is placed in front of the methods' names used for hyper-parameter optimization, e.g., SVM-GSFA denotes the results obtained by SVM classifier tuned with the proposed GSFA method.

These simulations were executed with 20 solutions in the population (N=20) and 15 iterations in each run (T =15) for each metaheuristic method, except for the GSFA and FA. Since the FA in each iteration in the average case performs 2 N solutions' evaluations, inthiscase Nwassetto10.Additionally, due to the slightly higher complexity of the proposed GSFA over the basic FA, the GSFA was tested with only nine solutions. This reduction of the population for the FA and GSFA methods was required to set firm grounds for fair comparisons. Specific GSFA parameters (gsp, gssand cmt) were set according to Table 1. All swarm algorithms were also implemented in Python, and Intel®Core™i9-11900K Processor with 64GB of RAM and Windows 11 O.S. was used as a simulation platform. All employed datasets were relatively large, and the cache argument for SVM and XGBoost models in scikit-learn environment was set to 32GB to improve the computation speed.

On the other hand, the ELM is implemented by using cupy instead of the numpy library for operations with matrices, because cupy supports execution on GPU, and, in this case, NVIDIA GeForce GTX1080 GPU with 8 GB of memory is employed for such computations. Due to the stochastic nature of swarm approaches, all methods were executed in 50 independent runs, and best, worst, mean, and median accuracies, along with standard deviation, are recorded. However, accuracy may not be an objective metric, especially for imbalanced datasets; therefore, precision, recall, and f1-score per class and micro-averaged are also shown along with the receiver operating characteristic area under the curve (ROC AUC).It is noted that, in all result tables, the best-achieved metrics are denoted in bold style. Table 3 depicts the outcomes of the experiments with the SVM model employed.

As was already mentioned, the SVM model is specific due to its slow operation, and the reduced dataset was used. In this particular scenario, the SVM-GSFA achieved the best accuracy result, while the SVM-ABC obtained slightly better mean and median values. However, neither SVM-GSFA nor SVM-ABC exhibited the best robustness, which can be noticed from std metrics, while SVM-WOA, SVM-HHO and SVM-SCA did not show results variation over different runs. On the other hand, Table 4 shows the outcomes of the simulations with the ELM model against the dataset. In this scenario, the novel ELM-GSFA model outperformed all other hybrid ELM frameworks for all performance indicators, including best, worst, mean, and median classification accuracy, as well as the stability of results expressed with standard deviation. Table 5 puts forward the outcomes of the experiments with the XGBoost classifier on a real dataset. Similarly to the previous scenario, the XGBoost-GSFA achieved the best accuracy results for all utilised metrics and outperformed all other competitor methods Table6 presents the outcomes of the experiments with SVM model on the synthetic dataset. In this case, the SVM-GSFA and SVM WOA were tied for the best accuracy result (96.9519%), while the SVM-GSFA achieved better mean and median values, as well as better stability than opponent algorithms. For then extscenario, The XGBoost-GSFA and XGBoost-ABC were tied for the best and medianaccuracyresults, whileXGBoost-GSFAfinishedfirstforworst,meanandstandard deviation indicators.

The yielded detailed metrics provided significant insights intothe algorithm'sperformance, especially for imbalanced datasets such as credit card fraud. Fromthereportedmetrics, it can be unequivocally confirmed that, on average, when all models are taken into account, the proposed GSFA algorithm proved that it is able to achieve the best classification performance for a minority class (class1inthisexample). The generated confusion matrices for the original credit card fraud dataset by tunedSVM,ELM, and XGBoost models with GSFA,FA, and SNS algorithms are shown in Figure 5, while the precision–recall (PR)curvegraphsforGSFAandarbitrarychosenapproachesfor the syntheticdatasetare depicted in Figure.Lastly, the hyperparameters' values for the tuned SVM, ELM, and XGBoost models, generated in the best run for each applied optimization algorithm, are shown in Tables 3–5, respectively.It should be noted that Table 15depicts just the number of neurons nn parameter that obtained the best results, as showing all weights and biases parameters would not be feasible.

V.4 STATISTICAL TESTS

Since the experimental outcomes are typically insufficient to establish that one algorithm outperforms its competitors, contemporary computer science practice requires researchers to determine whether the obtained improvementsare statistically significant.In the research suggested in this manuscript, 10 methods (including proposed GSFA) were validated for SVM, ELM, and XGBoost tuning against the original (highly imbalanced) and synthetic, generated using the SMOTE technique (balanced) on credit card fraud datasets.Therefore, 10 methods were compared against 6 problem instances, which fall into the domain of multiple approaches for multi-problemanalysis. According to the recommendations from the literature [65–67], statistical tests in such scenarios may be conducted by constructing a results sample for each approach by taking averages of the measured objectives over multiple independent runs for each problem.However, this approach may have disadvantages when the measured variable has outliers that do not follow a normaldistribution, which may lead to deceptive conclusions. According to a literature survey, whether the average objective function value should be taken for statistical tests when comparing stochastic methods still remains an open question [55].Forthepurposeofcomparing10methodsfor6 problem instances, despite the above-noted potential disadvantages, the objective function (classification error rate) was averagedover50independentrunsisusedinstatisticaltests. However, this decision was rendered based on the conducted Shapiro–Wilk [39] test for single-problem analysis [55] in the following way: for each algorithm and every problem, a data sample is constructed by taking the results obtained in each run, and respective p-values are calculated for every method–problem pair. The obtained p-values for this test are shown in the Table.

Table 9: Shapiro–results for single-problem analysis.

Methods

Source: Authors, (2026).

The results from Table 9 indicate that all p-values are higher than the threshold significance level $\alpha = 0.05$, yielding the conclusion that the null hypothesis cannot be rejected;therefore, the data samples for all method–problem pairs originate from a normal distribution, and it is safe to use the average objective in the statistical tests.From this point, we proceeded with multi-problem multiple methods statistical analysis, and the data sample for each method was constructed by taking the average objective function value over 50 independent runs for each problem instance. First, the safe use of the parametric tests conditions, which include independence, normality, and homoscedasticity of the variances of the data, was checked [11].The condition of independence was satisfied because each run was executed independently,starting with a unique pseudo-random number seed. To check normality, the Shapiro–Wilk test [39] was used again. The results for every method are reported in Table 10.

Table 10: Shapiro–Analysis.

Methods

***p*-value** 3.20×10^{-3}	8.34×10^{-3}	9.71×10^{-3}	6.81×10^{-3}	3.28×10^{-3}	9.19×10^{-3}	8.90×10^{-3}	2.32×10^{-3}	4.58×10^{-3}	8.34×10^{-3}

Source: Authors, (2026).

To check homoscedasticity based on means, Levene's test [10] is employed, and the p-value of 0.64 is obtained, which follows that the homoscedasticity is satisfied. However, the rendered p-values from the Shapiro–Wilk test for all methods are smaller than $\alpha = 0.05$ (Table 18), yielding the conclusion that the safe use of parametric tests is not satisfied, and we proceeded with non-parametric tests. In all non-parametric tests,the proposed GSFA was established as the control method.

VI. CONCLUSIONS

The research presented in this paper proposed a novel variant of the famous FA algorithm, named GSFA metaheuristic, with the aim of addressing the notable drawbacks of the original implementation. The introduced GSFA approach adopts a disputation operatorfrom the recently proposed SNS metaheuristic. The suggested GSFA was paired with three standard ML models, namely the SVM, ELM, and XGBoost models, to perform hyper-parameter optimisation. This challenge is still an open question in the ML domain, because every ML model has to be tuned for a specific dataset. Thesuggested hybrid model's performance was verified against the credit card fraud detection dataset, which includes transactions gathered across Europe in 2013.The employed dataset is highly disproportionate,as the majority of entries represent valid transactions, and just a small portion mark the fraudulent actions.

The performances of the proposed GSFA-optimisedSVM, ELM, and XGBoost were compared to nine other metaheuristicsoptimised variants of ML models. The competitor metaheuristics encompassed well-known algorithms, such as the original implementation of FA,BA,ABC,SCA,MBO,HHO,EHO,WOA, and SNS. The experiments were conductedin two phases:first, with the original imbalanced dataset. The outcomes of the executed simulations indicate the superior performance of proposedGSFA for most of the test instances.Finally, rigorous statistical tests wereperformed to confirm the significance of the obtained test results.Therefore, in the proposed research, it was shown that the FA metaheuristic can be further improved and that the tuned SVM, ELM, and XGBoost models achieve decent performance for a highly challenging and important credit card fraud dataset.However, the proposed study also has some limitations.

First, the GSFA metaheuristicemploys three additional control parameters that need to be adjusted for each particular NP-hardchallenge. Moreover, the performance of the algorithm needs to be further evaluated for other NP-hard challenges.The future trials of the suggested GSFA algorithm will include further testing on supplementary real-life credit card datasets.Another direction for validating the proposed GSFA is to apply it and test it on other NP-hard problems, falling into the domains of cloud computing, cryptocurrency forecasting, and image processing and classification.

ABSTRACT

Student engagement plays a crucial role in facilitating comprehension in the teaching-learning process. Evaluating students' classroom behavior is essential for assessing the effectiveness of teaching. To objectively assess students' attentiveness in class, it is imperative to capture their emotions and cognitive feedback through expressions and behaviors. However, accurately extracting expression features from classroom videos poses a importantcontest. To discourse this, we suggest a hybrid optimization and deep learning technique used for higher education students. Our model involves designing a hybrid spatio-temporal ResNet with Laplacian Harris hawk optimization (LHHO) algorithm for feature extraction and optimization. It enables the extraction of contextual, semantic, and positional features while enhancing the recognition of occluded objects. Additionally, we employ a domain adaptive deep belief network (DA-DBN) for classroom behavior recognition and evaluation, improving the detection accuracy of occluded objects. To validate our approach, we evaluate it against existing classroom behavior recognition models using public datasets such as COCO and PASCAL VOC. The results demonstrate that our proposed algorithm accurately detects various student behaviors, outperforming state-of-the-art models. Specifically, LHHO+DA-DBN model achieves an average accuracy of 96.031% and a recall of 94.335%, surpassing the performance of compared models across different scenarios.

I. INTRODUCTION

Classroom teaching is a pivotal aspect of modern education, particularly in disciplines like art education, where interaction, communication, and practical engagement among teachers and students are paramount [1]. Enhancing student contribution in schoolroom activities not only fosters complete artistic literacy but also nurtures their advanced and independent thinking skills [2]. However, outdated art schoolrooms often struggle with fully understanding each student's learning status, leading to ineffective teaching outcomes. Teachers face the challenging task of responding to separate student declarations and actions, monitoring overall class development, and adapting instructional objectives accordingly [3]. To succeed in this difficult role, teachers must visually perceive and procedure a vast quantity of learning-relevant information, a skill mentioned to as teacher perceiving in professional vision investigate. Numerous empirical studies in teacher research have focused on professional vision, particularly through video-based involvements where teachers observe classroom states and analyze noticed events, both in action and on action [4]. Expert-novice paradigm studies have highlighted significant alterations among pre-service and in-service teachers' observing of relevant classroom proceedings, with experienced teachers exhibiting a greater focus on scholars and key learning-related features of instruction [5]. Recent research has leveraged advanced eye-tracking methods to examine teacher noticing processes, revealing insights into the distribution of teachers' visual attention during classroom instruction [6].

For instance, experienced teachers tend to allocate attention more evenly among students and spend less time on task-redundant areas in the classroom compared to pre-service teachers.In art education settings, it's critical for educators to painstakingly screen understudies' exhibition and learning progress to speedily recognize any issues and deal fitting heading and backing [7]. Then, dissecting understudy conduct turns out to be especially fundamental in such homeroom conditions. By breaking down understudy conduct, instructors can acquire experiences into showing adequacy and give designated help where required [8] [9]. However, the diverse teaching scenarios, varying lighting, and wide range of student behaviors may make automatic detection of student learning behavior difficult in art teaching classrooms [10]. In current years, obsolete machine learning (ML) and deep learning (DL) approaches have shown superior show in perceiving understudy execution [11-14]. Traditional ML methods rely on feature extraction to generate behavior features for recognition, but they are limited by their representational abilities. DL-based student behavior recognition systems automatically learn deep features from large training datasets. These systems utilize DL models and parameter selection to achieve effective detection results. In the field of computer vision, there is a growing trend towards learning action representation using DL to enhance investigate on behavior gratitude in shadowing videos within schoolroom settings [15].

Behavior recognition aims to allocate a solitary class label to an complete cinematic, while spatio temporal behavior recognition involves labeling each person's achievement in each frame by deeply learning spatio temporal material from consecutive surrounds, which poses a greater challenge. Recent advancements have focused on relational reasoning-based behavior recognition methods to perfect the relationships among objects using boundary boxes in frames, as objects interrelate with each other [16]. Though, existing procedures often rely on appearance features extracted from individuals and matters detected by pretrained object detectors with fixed categories, potentially overlooking small objects connected to the actor. Additionally, in cluttered classroom environments, relational reasoning may prioritize salient regions in images, neglecting secondary human body portions crucial for human-to-human communication [17], [18]. Therefore, accurate detection of supporting human body parts and objects amid disorderly backgrounds is essential for interactive action recognition. Despite advancements, challenges persist in student behavior recognition [19]. Limited availability of datasets on students' learning behavior hampers research progress, with most studies focusing only on specific behaviors like rising hands, sleeping, and yawning, which are sovereign performances [20]. Though, the absence of interactive behaviors negatively impacts the assessment of scholars' learning excellence. To address these challenges, behavior recognition models focusing on accurate detection of interactive actions are proposed.

Our contributions. We propose a hybrid optimization and DL technique used for higher education students to address the problem of extracting features from classroom videos while it is posed. The major charities of planned work are given as follows.

1.To enables the extraction of contextual, semantic, and positional features while enhancing the recognition of occluded objectsa hybrid spatio-temporal ResNet with Laplacian Harris hawk optimization (LHHO) algorithm for feature extraction and optimization.
2.To advance the detection accurateness of obstructed objects a domain adaptive deep belief network (DA-DBN) for classroom behavior recognition and evaluation.

The rest of this paper is prepared as follows: Section 2 reviewed the various models for classroom behavior recognition and evaluation using DL modelsusing deep learning. The problem description and the detailed working process of proposeddeep learning and sensing technologies in higher education is explained in Section 3. Section 4 examines the effectiveness of the proposed and existing classroom modelsusing results and comparative analysis.Finally, the paper completes in Section 5.

II. RELATED WORKS

II.1 CLASSROOM BEHAVIOR RECOGNITION AND EVALUATION USING DL MODELS.

This section provides a brief overview of recent research on classroom behavior recognition and evaluation using DL models. According to [21] have developed a quick visually impaired remaking model with linear canonical transform (LCT) regularization for recreation of feeble infrared otherworldly signs. Using LCD conversion with high resolution and a weak IR spectral signal, they examined their primary distinction. At low resolution, bright IR spectra reveal a broad distribution of image data.

An infrared spectral reconstruction technique was developed in response to these findings to limit the wide range of IR spectra observed at L0-Nord. For human behavior monitoring, the experimental results demonstrate that the LCD-based IR spectrum reconstruction method can preserve IR spectral range structures and eliminate Poisson noise. For authors [22] have proposed an infrared look acknowledgment technique for understanding nonverbal ways of behaving in the study hall through multi-name conveyance learning. In particular, we originally determined the component closeness of seven fundamental looks to portray the connection between contiguous articulation pictures. Then, comparable qualities are fitted utilizing a Cauchy conveyance capability. Moreover, we build another profound organization utilizing Cauchy distribution-based label learning (CDLLNet) rather than the standard single articulation name. Utilizing these amended names, the infrared facial covering learns the adjoining demeanor marks and its unique appearance marks. A few subjective and quantitative experimental outcomes affirm that the CDLLNet network accomplishes vigorous outcomes and performs surprisingly well. In [23] have presented an extensive informational collection that can be utilized to recognize, analyze, and contextualize understudy conduct in the homeroom. An organized informational index comprises of a revelation section, a validation part, and a header part. The discovery region incorporates a transitory recognition information block with 4542 examples and an activity identification information block with 3343 examples, while the location region contains 4276 examples and the header region contains 4296 examples. In genuine homerooms, understudy conduct is programmed, making information assortment delegate and reasonable.

Then analyze specific aspects of the classroom situation and technical issues for each module, which are tested through tests. According to [24] have presented an extensive informational collection that can be utilized to recognize, analyze, and contextualize understudy conduct in the homeroom. An organized informational index comprises of a revelation section, a validation part, and a header part. The discovery region incorporates a transitory recognition information block with 4542 examples and an activity identification information block with 3343 examples, while the location region contains 4276 examples and the header region contains 4296 examples. In genuine homerooms, understudy conduct is robotized and information assortment is delegate and sensible. Then, for each experimented-on module, look at specific aspects of the classroom and technical issues. According to [25] have proposed a system for recognizing student behavior that uses personality detection and an assessment of skeletal posture utilized to exhibit the proposed framework. To reduce the number of false connections in bone data, a method of error correction based on techniques for person detection and pose estimation is proposed. Highlight extraction was performed to produce include vectors addressing the human figure. Qualities incorporate ordinary joint arrangement, joint dividing, and bone points. Social grouping was finished to decide the understudy's way of behaving. A profound brain network was worked to characterize the exercises and the proposed framework had the option to decide the quantity of understudies in the class. The framework accomplished 15.15% higher normal accuracy and 12.15% higher normal review than the skeleton-based conspire. For authors [26] have introduced to achieve an enhanced YOLO-v4 network, cross-local network embedded connection (EC) components are configured and embedded at the end of the YOLO-v4 network.

The added substance misfortune capability comprises of two sections: RepBox and RepGT losses. RepGT utilizes a misfortune capability to work out the misfortune values between the objective forecast box and the encompassing ground truth boxes to lessen bogus positive location results; RepBox utilizes the misfortune capability to work out the misfortune esteem between the objective expectation field and other close by target forecast fields to diminish misleading negative identification results. Preparing and testing are performed on homeroom conduct datasets of educators and understudies, individually. The outcomes show that the typical exactness for distinguishing the study hall conduct of various targets is over 90%, which demonstrates its viability. According to [27] have proposed a 3D-CNN is chosen as an organization model for homeroom understudy conduct acknowledgment, which has high precision and unwavering quality of multi-source data and further develops restriction of homeroom understudies. The spatio-temporal domain of 3D convolution extends 2D convolution for improved video analysis of human behavior. In classroom teaching situations, a deep spatial residual CNN is used to learn the spatial characteristics of each student's behavior and recognize classroom behaviors in real time. Different investigations are directed utilizing class conduct informational collections, and the experimental results show that the model performs well in identifying class behavior.In [28] have proposed Density, occlusion, and multimodal displays are just a few of the issues that the Student Classroom Behavior Framework addresses. They utilized a progression of imaginative techniques and joined the Res2Net block with the first C2f block in YOLOv8 to make the C2f_Res2block block.

The module productively handles multi-scale scenes and works on model precision. Multi-scale center and multi-head concentrate further work on model execution. According to [29] have proposed a technique for utilizing images of classroom time series to determine the active behavior of students. Students' active behavior is detected using Advanced asynchronous interaction aggregation (AIA). By adding the MsTA and MSCSA modules to the fast track and slow track, respectively, the enhanced AIA network backbone improves the accuracy of identifying student engagement behaviors in the slow fast track. A smooth focal loss function is used to enhance the contrast between segments in the pupil action database. The student activity behavior data set demonstrates that this method outperforms the original AIA network in terms of detection performance when it comes to identifying a variety of classroom student activity behaviors. According to [30] have proposed a data augmentation strategy for enhancing behavioral characteristics in order to identify distinctive student behaviors. The process begins with the collection of a narrow set of data designed to understand student learning behavior and expands it significantly using data augmentation techniques. The compositional abilities of extended-efficient layer aggregation network (E-Spirit) can be utilized to productively remove different learning conduct highlights. Outstandingly, the channel-wise attention module (CPAM) coordinates the central instrument into the component location organization. This works on the organization's capacity to recognize key highlights related with understudies' learning ways of behaving, consequently expanding the exactness of component acknowledgment. The finish of the excursion includes the characterization of highlights removed utilizing a double methodology: an feature pyramid network (FPN) and a way conglomeration organization (Skillet). Observational proof plainly exhibits the force of the technique acquiring 96.7% Guide.

II.2 RESEARCH GAP

In the province of classroom behavior gratitude and evaluation, numerous intricate challenges emerge, complicating the precisecalculation of student attentiveness and appointment. The students' expressions and behaviors exhibit vast variability, encompassing facial expressions, body language, and verbal cues, which poses a challenge in their interpretation due to individual differences and cultural nuances. The presence of occlusions and environmental factors within classroom settings, such as students obstructing each other's view or varying lighting conditions, further complicates the recognition of these expressions and behaviors. The inherently subjective nature of evaluating attentiveness and engagement introduces another layer of complexity, as different educators may have divergent criteria for defining attentive behavior, leading to inconsistencies in assessment. Temporal dynamics also play a crucial role, with classroom interactions evolving over time, necessitating an understanding of how factors like lesson content and teaching style influence student behavior. Furthermore, privacy and ethical considerations surrounding the deployment of video-based monitoring systems in classrooms raise important concerns that must be carefully addressed. Data annotation and labeling present another challenge, as manually annotating classroom behavior data is resource-intensive and prone to biases. Moreover, ensuring the generalizability of behavior recognition models across diverse educational settings remains a significant hurdle, as nuances in student demographics and classroom dynamics can impact model performance.

Finally, effectively integrating behavioral insights into educational interventions and instructional design strategies poses yet another complex challenge in achieving the overarching goal of improving teaching practices and student outcomes. Moreover, the key challenges is the extraction of expression features from classroom videos, which is inherently complex due to various factors such as occlusions and varying environmental conditions. To discourse this contest, we suggest a original hybrid optimization and deep learning approach tailored for higher education students. Our proposed model comprises two main components: a hybrid spatio-temporal ResNet enhanced with the Laplacian Harris hawk optimization (LHHO) algorithm for feature extraction and optimization, and a domain adaptive deep belief network (DA-DBN) to further enhance the recognition of expression features. By adapting the feature representations learned from one domain (e.g., one classroom setting) to another domain (e.g., a different classroom setting), the DA-DBN ensures robust performance across diverse educational environments. Our proposed method represents a significant contribution to the field by offering a comprehensive solution for extracting expression features from classroom videos and assessing students' attentiveness in higher education settings. The integration of hybrid optimization techniques with deep learning architectures enhances the model's effectiveness and robustness, paving the way for more accurate and reliable evaluations of student engagement and learning outcomes.

III. PROPOSED METHODOLOGY

In the field of education, student participation is critical to improving understanding. When students actively engage with the information, ask questions, and interact with it, the teaching-learning process flourishes. Their participation creates a lively classroom atmosphere in addition to fostering understanding [31]. But evaluating this involvement calls for more than just watching; it also calls for a closer examination of the actions, facial expressions, and cognitive reactions of the students. Historically, educators have depended on nonverbal indications like engagement levels, body language, and eye contact. However, the development of technology has created new opportunities for evaluation.

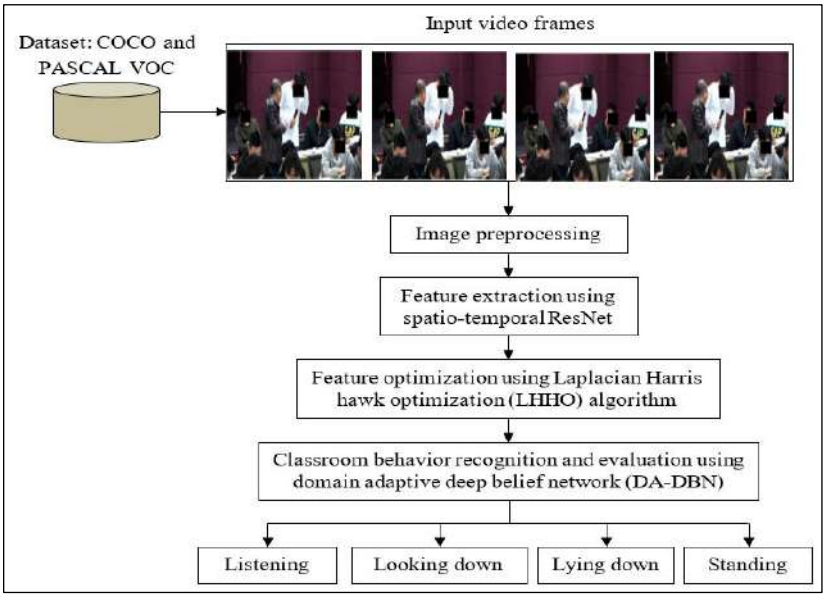

Figure 1: System design of proposed LHHO+DA-DBNmodel for classroom behavior recognition and evaluation.
Source: Authors, (2026).

Although classroom recordings provide an abundance of information, it is still quite difficult to extract useful expression elements from them. Emotions, cognitive input, and minute details must be extracted from video data using sophisticated algorithms and reliable techniques. Accuracy, privacy, and scalability must all be balanced as educators endeavor to understand the complex web of student interaction in the digital age.We suggest a hybrid optimization and deep learning method for college students as a solution to this problem. For feature extraction and optimization, our model builds a hybrid spatiotemporal ResNet using the Laplacian Harris Hawk Optimization (LHHO) algorithm. It improves the detection of obstructed objects and allows the extraction of contextual, semantic, and positional details. Furthermore, to enhance the detection accuracy of obscured objects, we utilize a domain adaptive deep belief network (DA-DBN) for classroom behavior recognition and evaluation.In the Figure 1 the proposed LHHO+DA-DBN model is given. For the analysis the video of a class is considered. By apply LHHO+DA-DBN method the behavior and features of the students in the class are identified. This method helps the academic authorities to make their facility more compactable for the students.

III.1 FEATURE EXTRACTION USING SPATIO-TEMPORAL RESNET

In the context of laboratory behavior gratitude and evaluation, feature abstraction mentions to the procedure of capturing relevant info from raw input data, such as video frames, to represent key characteristics or patterns of behavior. A spatio-temporal ResNet is a kind of deep neural network construction specifically calculated to process both spatial and temporal information. ResNet, short for Residual Network, is a popular type of convolutional neural network (CNN) building normally used in image recognition errands. In the case of spatio-temporal ResNet, the architecture is extended to handle video data, allowing it to imprisonment both longitudinal features and progressive topographies. The working process of feature extraction using spatio-temporal ResNet is given as follows.

- The input to the spatio-temporal ResNet is a sequence of video frames captured from a classroom setting. Each frame represents a snapshot of the classroom at a specific time.
- Before feeding the video frames into the network, preprocessing steps may be applied, such as resizing the frames to a unchanging size, standardizing pixel standards, and possibly enhancing the data to increase the assortment of the exercise dataset.
- Choose an appropriate spatio-temporal ResNet architecture based on the complexity of the task and available computational resources.
- Pass each frame through the spatio-temporal ResNet architecture to extract features. The network processes the frames in a hierarchical manner, with lower coatings apprehending low-level topographies and higher layers apprehending more intellectual topographies relevant to behavior recognition.
- Since behavior recognition involves analyzing temporal patterns over a sequence of frames, the features extracted from individual frames need to be aggregated over time. This can be done using methods such as chronological pooling or recurrent neural networks (RNNs) to capture temporal dependencies.
- After temporal processing, the extracted features are represented as high-dimensional feature vectors. These feature vectors encode information about the contextual, semantic, and positional aspects of the observed behaviors.
- In some cases, the dimensionality of the feature trajectories may be too high for downstream tasks such as classification. Dimensionality reduction technique is applied to reduce the dimensionality of the feature space while preservative vital material.
- The final output of feature extraction process is set of feature vectors, each corresponding to a specific segment of the input video sequence. These feature vectors can then be used as input to classifier for behavior recognition and evaluation.

Contextual features refer to information about the surroundings or environment in which the behavior occurs, providing additional context for understanding the behavior. Semantic features capture the meaning or semantics of the behavior, such as identifying specific actions or interactions. Positional features describe the spatial location or arrangement of objects or individuals within the scene. To extract these features using a spatio-temporal ResNet, the network is qualified on a large dataset of video sequences glossed with labels corresponding to different behaviors. During training, the network learns to automatically extract features from both individual frames and sequences of frames. The layers of the network are designed to capture hierarchical representations of the input data, gradually transforming raw pixel values into higher-level features that are more meaningful for behavior recognition. The final production of the system is set of feature vectors that represent the contextual, semantic, and positional aspects of the observed behaviors.

III.2 FEATURE OPTIMIZATION USING LAPLACIAN HARRIS HAWK OPTIMIZATION (LHHO)

Highlight enhancement is the method involved with choosing the most important and instructive elements from a given informational index to work on the presentation of AI models. A lot of real-world applications use a lot of datasets with a lot of features, some of which could be useless, redundant, or noisy. Include streamlining intends to distinguish and hold just the most discriminative elements, consequently lessening the size of the informational index and working on the exactness, interpretability, and execution of model expectations. Laplacian Harris Hawk Optimization (LHHO) is a metaheuristic optimization procedure stimulated by the shooting performance of Harris's hawks. It combines principles from the Harris hawk's collaborative hunting strategies with mathematical optimization techniques to efficiently search for optimal solutions to feature optimization problems. During the optimization process, LHHO employs a combination of exploration and exploitation strategies to iteratively update the candidate feature subsets. In the exploration phase, the algorithm encourages diversity by exploring different combinations of features across the search space.

This is achieved through random exploration and movement of candidate feature subsets, simulating the scouting behavior of Harris's hawks as they search for prey in varied terrain.LHHO algorithm maximizes the production of biodiesel by optimizing three independent variables.The objective function is depicted as follows.

$$\begin{aligned}\max d(z_s z_n z_v) = 37.45 + 0.42z_s + 4.37z_n - 0.16z_2^2 + 24.26z_v \\ -1.53z_v^2 + 0.001z_{sn} - 0.24z_s z_v - 0.44z_2 z_3,\end{aligned} \tag{1}$$

where $55 \le z_s \le 65$, , $6 \le z_n \le 15$, and $0.6 \le z_v \le 2.0$.

Harris hawks typically have farsighted eyes, which enable them to spot and capture their prey. However, it is extremely difficult to easily identify prey. After an attack on the prey, hawks hold back, observe, and monitor for this reason. In this particular algorithm, candidate solutions are Harris hawks, and the optimal solution is taken into consideration at each step that is close to the ideal position. The exploration phase's mathematical representation is shown as

$$\begin{aligned}X_{rand}(o) - e_1, X(r+1) = |X_{rand}(o) - 2t_2 Z(o)|, g \ge 0.5, \\ (X(o) - X(o)), \\ t_3(lb + t_4(ub - lb)), \qquad g \le 0.5\end{aligned} \tag{2}$$

where Zrabbit is the position of the rabbit, Xr + 1 is the hawk's position, and p is the next iteration. The current location of the hawks is Xo, and the random numbers e1, e2, e3, e4, and h are between 0 and 1. The typical hawk's position is described as

$$X_b(o) = \frac{1}{a}\sum_{o=1} X_u(o), \tag{3}$$

where the position of each hawk in repetition p is xu O, and A denotes the total quantity of hawks. Transition from exploration to exploitation the exploratory phase can transition into the exploitative phase based on how the prey's energy escapes, allowing for a variety of exploitative behaviors. During the behavior of fleeing, the prey's energy decreases significantly.

$$\in = 2 \in_o \left(1 - \frac{o}{r}\right), \tag{4}$$

where signifies the absconding energy of the target, O denotes the initial energy state, and r denotes the supreme number of restatements. Laplacian numbers take the place of variant random numbers in LHHO. The reported Laplacian random number generator is used in recent methods by applying the matrix output of the function, which has a unkind value of 0 and normalnonconformity of 1.

$$\begin{aligned}E\left(A_{s,n}^f\right) = [cumsum(2 \times Lap(r_1) - 1) \\ cumsum(2 \times Lap(r_2) - 1), \ldots, \\ cumsum\left(2 \times Lap\left(r_{max}(\ \ )\right)(\ \ )\right)\end{aligned} \tag{5}$$

The conventional Laplace probability distribution (LPD), denoted by LapS, R, is the definition of the probability density function (PDF).

$$d(z; A, R) = \frac{1}{2R} exp - \frac{|z-A|}{R}, -\infty \le z \le \infty. \tag{6}$$

The following is the Laplace distribution function:

$$\begin{aligned}d(z) = \frac{1}{2}\exp - \frac{|z - A|}{R}, \ z \le A, \\ 1 - \frac{1}{2}\exp - \frac{|z - A|}{R}, X \ge A,\end{aligned} \tag{7}$$

where the location is shown by A, and the scale parameters are determined by R.

III.3 CLASSROOM BEHAVIOR RECOGNITION

Classroom behavior recognition is vital component of educational technology, aiming to understand and evaluate students' engagement, participation, and attentiveness during classroom activities. Accurate recognition of classroom behaviors provides valuable insights for educators to tailor instruction, provide timely feedback, and create supportive learning environments. The domain adaptive deep belief network (DA-DBN) is a sophisticated machine learning model designed to address the challenges of classroom behavior recognition.

DA-DBN combines principles from deep learning, unsupervised learning, and domain adaptation to learn robust representations of classroom behaviors across diverse environments and conditions. At its core, DA-DBN consists of multiple layers of interconnected neurons, organized into a hierarchical structure inspired by human brain's neural networks. DA-DBN incorporates domain adaptation mechanisms to align feature distributions between dissimilar provinces, mitigating the effects of sphere shift and improving the model's generalization presentation across diverse classroom environments.A DBN consists of multiple RBMs, each with a visible v layer and a hidden layer. RBM uses z vectors and units to connect layers within the same layer. The power function is defined by reflecting the state of the network, and the steady state of the network corresponds to the minimum state of the power function.

$$e(v,i) = -\sum_{h=1}^{a} m_h v_h - \sum_{g=1}^{b} n_g i_g - \sum_{j=1}^{b}\sum_{h=1}^{a} v_h i_h z_{hg} \tag{8}$$

Here m and n are the bias trajectory of observable and concealed layers, respectively. The joint circulation and conditional spreading of each stratum can be distinct as follows.

$$X(v,i) = \frac{E^{-e(v,i)}}{\sum_{v,i} E^{-e(v,i)}} \tag{9}$$

$$X(v\,|\,i) = \frac{X(v,i)}{X(i)} = \frac{E^{-e(v,i)}}{\sum_{v} E^{-e(v,i)}} \tag{10}$$

$$X(i\,|\,v) = \frac{X(v,i)}{X(v)} = \frac{E^{-e(v,i)}}{\sum_{i} E^{-e(v,i)}} \tag{11}$$

Since there is no correlation between components in each stratum, the restricted likelihoods of units can be designed using the following calculations.

$$X(i_g = 1|v) = \frac{X(i_g=1,v)}{X(i_g=1,v)+X(i_g=0,v)} = \sigma\left(\sum_{h=1}^{a} m_h + z_{hg} v_h\right) \tag{12}$$

$$X(v_g = 1\,|\,i) = \frac{X(v_h = 1,i)}{X(v_h = 1,i) + X(v_h = 0,i)} = \sigma\left(\sum_{g=1}^{b} n_g + z_{hg} i_g\right) \tag{13}$$

$$\sigma(p) = \frac{1}{1+E^{-p}} \tag{14}$$

The functional kernel I_k is definite as a Hilbert planetary with k. For two prospectdeliveries x and y for all $F \in I_k$, the DA-DBN value among x and y is definite as the recreated Hilbert interval distance among the fitted mean standards of x and y. It is defined as the quadratic formula of DA-DBN between x and y.

$$c_K^2(x,y) \overset{\Delta}{=} \| e_{p^T \sim x}[\phi(p^T)] - e_{p^T \sim y}[\phi(p^T)] \|_{I_k}^2 \tag{15}$$

where ϕ is feature charting. The mouth kernel k can be labeled as follows.

$$K = \sum_{U=1}^{a} \beta_U K_U : \sum_{U=1}^{a} \beta_U = 1, \beta_U \geq 0, \forall\, U \tag{16}$$

where β_U is an extension of the weight constraint that ensures the production of regular multifunction kernels and a is the sum of the feature seeds. Thus, the optimization objective of the entire systemcontains of two portions: the organization error l_D in the source province and the insight error l_C among the foundation and mark domains. The optimization impartial is given by L is compute as follows.

$$l = l_D + l_C = MIN \frac{1}{b_t} \sum_{h=1}^{b_T} G(\theta(p_h^t),\, q_h^T) + \lambda \sum_{L=L_1}^{L} c_K^2(C_T^L, C_s^L) \tag{17}$$

The time difficulty of directly scheming the inner produce between the source field and the target domain $O(b^2)$ is too tall to be used effectively in a deep knowledge model.

$$c_K^2 = (x, y) = \frac{2}{b_t} \sum_{h=1}^{b_T/2} j_K(w_h) \tag{18}$$

$$w_h \overset{\Delta}{=} (p_{2h-1}^T, p_{2h}^T, p_{2h-1}^s, p_{2h}^s) \tag{19}$$

$$j_K(w_h) \overset{\Delta}{=} K(p_{2h-1}^T, p_{2h}^T) + K(p_{2h-1}^s, p_{2h}^s) + K(p_{2h-1}^s, p_{2h}^s) - K(p_{2h}^s, p_{2h-1}^s) \tag{20}$$

The limitations of the perfect are fine-tuned by stochastic gradient descent (SGD) technique. The incline of perfect limitation receipts the form.

$$\nabla \theta^L = \frac{\partial G(w_h)}{\partial \theta^L} + \lambda \frac{\partial j_K(w_h^L)}{\partial \theta^L} \tag{21}$$

Fine change of a deep neural network effortlessly achieved using a supervised learning procedure. An input pick, the output is obtained from the upper layer of the neural network.

$$r(p) = Max(0, p + j * X) : Q \sim B[0, \sigma(p)] \tag{22}$$

where j is the sound issue, which is second-hand to controller the equal of additional noise. The algorithm 1 describes the working process of classroom behavior recognition using the DA-DBN.

Algorithm 1 Classroom behavior recognition using DA-DBN

Input: The input to the algorithm is the energy function.
Output: After the learning process the upper layer of network is obtained.

IV. RESULTS AND DISCUSSION

In this fragment, we current the results examination of proposed and existing study hall conduct acknowledgment models. To approves ourLHHO+DA-DBN model utilizing the publically available datasets like COCO and PASCAL VOC. The experimental environment was demonstrated on Ubuntu 18.04 functioning scheme, with an Intel(R) Xeon(R) Sliver 4110 CPU@2.10HZ CPU formation, a Ge Force GTX 1080ti graphics card selected for calculation, 11 GB of video memory, and DLagendaPyTorch version 1.7.0 and the Python environment used to construct the runtime environment. The consequences of proposed LHHO+DA-DBN model is contrasted and the current condition of craftsmanship imitations, for example, Quick R-CNN [32], SSD [33], YOLOv5 [34] and further developed YOLOv5 [35] [32] [33] [34] [36] [31].In guidance to evaluate the benefit of the arranged models, the assessment pointers utilize the exactness, accuracy, review, mean normal accuracy (Guide), F-measure, and the amount of outlines per extra to detect the pictures to appraise the performance.

IV.1 DATASET DESCRIPTION

To discourse the lack of public datasets for detecting schoolroom students' behavioral states, this study manually curated a dataset using real laboratory cassettes. The dataset comprises four performance categories: listening, looking down, lying down, and standing. Images were removed from noted class videos at frame breaks, ensuring diverse student poses and actions for robust model training. In total, 10,826 labels were annotated, with an 80:20 split for exercise and testing datasets, correspondingly. Table 1 presents the description of dataset. To prevent Overfitting caused by imbalanced training data, particularly due to a larger number of objects in some behaviors, data augmentation techniques were employed. Specifically, since standing samples were relatively scarce and challenging to collect, data augmentation was applied to expand the number of standing pose samples.

This involved intercepting images of students in standing posture and applying augmentation such as horizontal flipping, brightness adjustment, and Gaussian noise addition to enhance the dataset's diversity. For model training, images were resized to a standard input size of 640 × 640 pixels. A warm-up phase with linear interpolation learning rate adjustment was implemented initially, followed by a cosine annealing strategy for further learning rate adjustments. The training process spanned 100 epochs, with a batch size of 16 epochs per batch. These strategies collectively contributed to the actualexercise of a deep learning classical for accurate classroom behavior detection. Figure 2 shows the taster test imageries from the dataset.

IV.2 COMPARATIVE ANALYSIS

Table 2 presents a comprehensive comparison of various classroom students' behavioral detection models with the "listening" class. In terms of accuracy, the LHHO+DA-DBN model achieves the highest accuracy of 93.707%. This represents a significant improvement over Fast R-CNN, SSD, YOLOv5, and Improved YOLOv5 by 10.962%, 8.221%, 5.481%, and 2.74%, respectively. Regarding precision, the LHHO+DA-DBN model demonstrates superior precision at 92.184%. This marks a substantial enhancement compared to Fast R-CNN, SSD, YOLOv5, and Improved YOLOv5 by 17.291%, 12.969%, 8.646%, and 4.323%, respectively. Similarly, the LHHO+DA-DBN model exhibits remarkable recall at 92.245%, surpassing Fast R-CNN, SSD, YOLOv5, and Improved YOLOv5 by 17.28%, 12.96%, 8.64%, and 4.32%, respectively.Moreover, the proposed model achieves outstanding F-measure of 92.215%, shown significant improvements over Fast R-CNN, SSD, YOLOv5, and Improved YOLOv5 by 17.286%, 12.964%, 8.643%, and 4.321%, respectively.Furthermore, in terms of mAP, the LHHO+DA-DBN model achieves the highest score of 91.063%, outperforming Fast R-CNN, SSD, YOLOv5, and Improved YOLOv5 by 16.05%, 12.038%, 8.025%, and 4.013%, respectively. For a visual representation of these results, refer to Figure 2, which illustrates the comparison between the proposed and existing classroom students' behavioral detection models for the "listening" class.

The result analysis for Table 2, which compares various classroom students' behavioral detection models with the "Looking down" class:Our LHHO+DA-DBN model achieves the highest accuracy, reaching 97.365% after 100 epochs. Compared to the existing models, it outperforms Fast R-CNN, SSD, YOLOv5, and Improved YOLOv5 by 14.272%, 10.713%, 7.636%, and 4.468%, respectively. Similar to accuracy, the LHHO+DA-DBN model exhibits the highest precision, peaking at 95.478% after 100 epochs. It surpasses Fast R-CNN, SSD, YOLOv5, and Improved YOLOv5 by 12.988%, 9.741%, 6.494%, and 3.247%, respectively. Precision generally improves with the number of epochs for all models. LHHO+DA-DBN model also achieves the highest recall, reaching 94.898% after 100 epochs. Compared to Fast R-CNN, SSD, YOLOv5, and Improved YOLOv5, it performs better by 16.416%, 13.370%, 8.225%, and 4.126%, respectively. Recall increases steadily with the number of epochs for all models. With an F-measure of 95.187% after 100 epochs, the LHHO+DA-DBN model again outperforms the other models. It surpasses Fast R-CNN, SSD, YOLOv5, and Improved YOLOv5 by 14.735%, 11.089%, 8.321%, and 4.625%, respectively. The LHHO+DA-DBN model achieves the highest mAP, reaching 93.235% after 100 epochs. It outperforms Fast R-CNN, SSD, YOLOv5, and Improved YOLOv5 by 14.028%, 11.439%, 7.178%, and 3.589%, respectively.For a visual representation of these results, refer to Figure 3, illustrates the comparison between the proposed and existing classroom students' behavioral detection models for the "looking down" class.

Table 3 provides a comprehensive comparison of various classroom students' behavioral detection models with the "Lying down" class. The results showcase the performance of each model across different metrics and epochs. In terms of accuracy, the LHHO+DA-DBN model achieves the highest accuracy consistently across all epochs, reaching a maximum accuracy of 97.125%. It represents a significant improvement over other models, with the closest competitor being the Improved YOLOv5 model with maximum accuracy of 93.451%. Regarding precision, the LHHO+DA-DBN model also outperforms other models, achieving a precision of 95.235% at the highest. This is notably higher compared to other models, with the Improved YOLOv5 model coming closest with a precision of 91.248%. Similarly, in terms of recall, the LHHO+DA-DBN model shows superior performance, achieving a maximum recall of 95.023%.

It outperforms other models significantly, with the Improved YOLOv5 model having the closest recall at 89.385%. The F-measure, which considers both precision and recall, also highlights the effectiveness of LHHO+DA-DBN model. With maximum F-measure of 95.129%, it surpasses other models by a significant margin, indicating a balanced performance in terms of precision and recall. Lastly, the mAP metric, which evaluates the completepresentation of the perfect, further confirms the superiority of the LHHO+DA-DBN model. With a maximum mAP of 94.022%, it demonstrates robustness and consistency across different epochs, outperforming other models in detecting the "Lying down" class behavior.For a visual representation of these results, refer to Figure 4, illustrates the comparison between the various classroom students' behavioral detection models for the "lying down" class.

Table 4 presents a comparative analysis of various classroom students' behavioral detection models with the "Standing" class. In terms of accuracy, the LHHO+DA-DBN model achieves the highest accuracy of 97.355% after 100 epochs, showing notable improvements over the other models such as Fast R-CNN, SSD, YOLOv5, and Improved YOLOv5 by 26.953%, 20.366%, 13.577%, and 7.589%, respectively.

Regarding precision, the LHHO+DA-DBN model achieves exceptional precision at 94.975%, outperforming the other models by margins of 15.948% (Fast R-CNN), 12.961% (SSD), 8.974% (YOLOv5), and 4.987% (Improved YOLOv5) after 100 epochs. Similarly, for recall, the LHHO+DA-DBN model demonstrates superior performance, achieving a recall of 96.525% after 100 epochs, surpassing Fast R-CNN, SSD, YOLOv5, and Improved YOLOv5 by 27.918%, 20.691%, 14.794%, and 7.877%, respectively. Additionally, in terms of F-measure and mAP, the LHHO+DA-DBN model consistently exhibits the highest values, indicating its effectiveness in accurately detecting students' "Standing" behavior in the classroom. Fig. 5 highlights the superior performance of the proposed LHHO+DA-DBN model for behavioral detection in the "Standing" class, emphasizing its potential for improving classroom monitoring and assessment.

Table 5: Comparative analysis of various classroom students' behavioral detection models with “Standing” class.

V. CONCLUSION

In this education, we introduced a novel method for enhancing classroom behavior recognition and evaluation among higher education students. Our method integrates a hybrid optimization and deep learning technique, leveraging a hybrid spatio-temporal ResNet combined with the Laplacian Harris hawk optimization (LHHO) algorithm for feature extraction and optimization. This innovative approach enables the extraction of crucial contextual, semantic, and positional features while effectively addressing challenges such as occluded object recognition. Moreover, we used a domain adaptive deep belief network (DA-DBN) specifically tailored for classroom behavior recognition tasks. By leveraging this network, we observed important developments in the detection correctness of occluded objects, crucial for accurately assessing student behaviors. To assess the efficacy of our technique, we conducted comprehensive tests using widely-used public datasets, including COCO and PASCAL VOC. The results of our evaluations validate the larger presentation of our proposed algorithm associated to current classroom behavior recognition models. Notably, the LHHO+DA-DBN model achieved an impressive average accuracy of 96.031% and a recall rate of 94.335%, consistently outperforming state-of-the-art models across various scenarios.

Foundation Engineering

ABSTRACT

In recent years, the field of foundation engineering has witnessed a transformative shift with the emergence of smart materials and data-driven decision-making technologies . The term "Smart Soil" represents the strategic integration of geosynthetic materials—particularly geo-textiles—with advanced artificial intelligence (AI) systems to address critical problems in soil stabilization and settlement prediction. Geo-textiles act as reinforcement materials that enhance the mechanical behavior of soil under various loading conditions, and when embedded in soil layers, they help distribute loads more uniformly, prevent soil erosion, and improve overall foundation stability .However, traditional foundation design strategies often fall short in predicting long-term settlement behavior due to the complex and nonlinear nature of soil systems . To overcome these limitations, AI models and machine learning algorithms such as Support Vector Machines (SVM), Artificial Neural Networks (ANN), and Decision Trees are increasingly being used to analyze large volumes of geotechnical data, leading to more accurate predictions and informed engineering decisions .This article provides a comprehensive assessment of the dual role of geo-textiles and AI-expected agreement models in modern-day foundation engineering. It examines their man or woman contributions, ability synergies, and the challenges involved in enforcing such included approaches within the discipline. The study objectives to formulate a framework for future infrastructure systems that aren't handiest sturdy and fee-powerful but additionally adaptable to evolving environmental and geotechnical demanding situations. The findings provide key insights into how clever substances and wise technologies may be harmonized to redefine the future of sustainable and excessive-overall performance basis design.

I. INTRODUCTION

Foundation engineering, a critical subfield of civil engineering, deals with the design and analysis of systems that switch loads from superstructures to the underlying soil or rock. The protection, durability, and sustainability of any infrastructure heavily depend upon the energy and balance of its basis. Over the years, engineers have continually sought superior solutions to mitigate risks together with immoderate settlement, soil erosion, and bearing capability failures [1]. Traditional methods, whilst reliable to a sure volume, frequently war to deal with the complex behavior of heterogeneous soil systems under numerous loading and environmental situations[2]. This has necessitated the exploration of revolutionary substances and shrewd structures, giving upward push to the concept of Smart Soil in modern geotechnical exercise [3] .

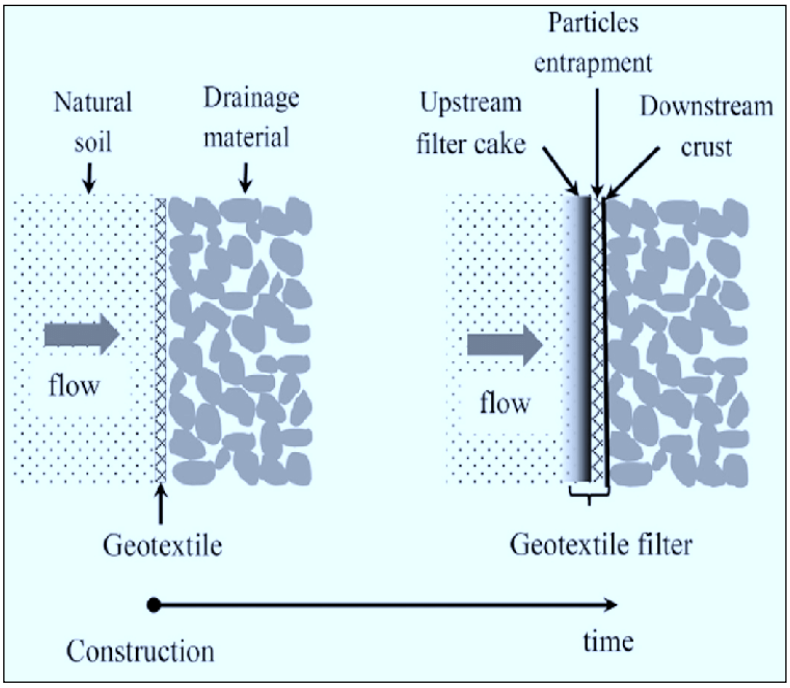

Figure 1: Evolution of the geotextile filter structure over time.
Source: Authors, (2026).

Smart Soil refers to an engineered soil environment enhanced with high-performance materials and data-driven technologies [4]. Among these innovations, geo-textiles have garnered significant attention. Figure 1 shows the evolution of the geotextile filter structure over time. Geo-textiles are synthetic permeable fabrics used to reinforce soil, improve drainage, and provide erosion control [5]. When properly integrated into the soil matrix, they enhance load distribution, reduce differential settlements, and extend the lifespan of infrastructure. Their mechanical and hydraulic properties allow them to perform multiple functions including filtration, separation, reinforcement, and protection, making them a vital component in modern foundation systems [6]. Parallel to material advancements, the civil engineering community is experiencing a digital revolution marked by the integration of Artificial Intelligence (AI) in predictive modeling and system optimization. AI techniques offer significant improvement in understanding and forecasting soil behavior under various conditions by leveraging historical datasets and complex algorithms. Unlike traditional empirical or analytical methods, AI models such as Artificial Neural Networks (ANN),

Support Vector Regression (SVR), and Random Forests can handle non-linearities and interdependencies in soil properties, leading to more accurate settlement predictions. This paper evaluates the synergy between geo-textiles and AI-based settlement prediction in foundation engineering. By assessing their combined impact, the study aims to develop a robust and smart framework for soil stabilization and performance evaluation. The research explores existing methodologies, implementation techniques, and practical applications to demonstrate how geo-textiles and AI models can complement each other in building smarter and more sustainable foundations Furthermore, this article intentionally excludes any human-subject involvement and focuses entirely on material behavior, algorithmic modeling, soil–structure interaction, and data-driven geotechnical assessments. This ensures the work remains rooted in technical, environmental, and engineering aspects, avoiding ethical concerns or subjective interpretations. The succeeding sections present a comprehensive literature review, methodological approach, AI modeling frameworks, performance evaluation, results, and implications for future geotechnical designs.

II. LITERATURE REVIEW

The advancement of foundation engineering has long relied on the synergy between innovative materials and predictive techniques. As infrastructure demands have increased, so has the complexity of subsurface conditions, urging engineers to adopt more robust and intelligent solutions. This section synthesizes past and present research on two key themes: the use of geo-textiles in foundation engineering and the application of Artificial Intelligence (AI) in settlement prediction.[7]

II.1 EVOLUTION OF GEO-TEXTILES IN FOUNDATION ENGINEERING

Geo-textiles, first introduced in the 1960s, have revolutionized soil stabilization techniques. These synthetic fabrics, commonly manufactured from polypropylene or polyester, are engineered to function in a wide range of geotechnical applications. According to Koerner, geo-textiles can be classified based on their structure as woven, non-woven, and knitted, each tailored for specific functions such as separation, reinforcement, filtration, drainage, and protection. Early applications mainly focused on erosion control and separation of subgrade and aggregate layers. However, later studies confirmed that geo-textiles also significantly improve the bearing capacity of soft soils [8], [9]. When placed between soil layers, they restrict lateral movement of soil particles and distribute loads over a wider area, thereby reducing settlement and enhancing shear strength. Figure 2 shows the comparation of pavement with or without geotextiles.

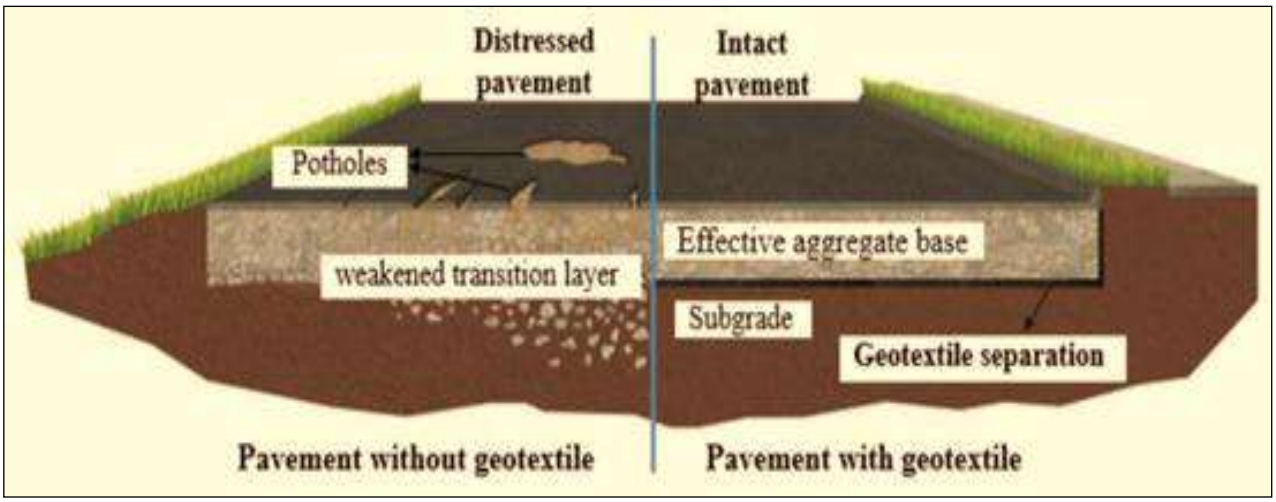

Figure 2: Comparison of pavement with or without geotextiles.
Source: Authors, (2026).

Recent works have explored hybrid systems in which geo-textiles are combined with stabilizing agents such as geogrids, lime, or cement. These integrated techniques have shown significant improvements in reducing differential settlement in weak soils, especially in regions with high water tables or expansive clay deposits [10].

II.2 ROLE OF GEO-TEXTILES IN MITIGATING SOIL SETTLEMENT

Settlement is a key challenge in foundation engineering. Excessive or uneven settlement can lead to structural distortions and long-term failure. Experimental studies have confirmed that geo-textile-reinforced soils exhibit lower settlement under comparable loading conditions than unreinforced soils [11]. Field and laboratory investigations have further demonstrated that multi-layer geo-textile configurations significantly improve foundation performance on weak or reclaimed soils [12].

II.3 EMERGENCE OF ARTIFICIAL INTELLIGENCE IN GEOTECHNICAL ENGINEERING

With the growing availability of soil behavior data, Artificial Intelligence (AI) has been widely adopted for predictive modeling in geotechnical engineering. One of the earliest applications of neural networks for settlement prediction was reported by Goh [13]. Subsequently, ANN-based models were shown to outperform conventional empirical settlement prediction methods across a wide range of soil conditions [14]. Further enhancements in prediction accuracy were achieved by integrating AI models with optimization techniques such as Genetic Algorithms and Particle Swarm Optimization [15].

II.4 INTEGRATION OF GEO-TEXTILES AND AI: TOWARDS SMART SOIL

The concept of Smart Soil, integrating geo-textile reinforcement with AI-based predictive systems, has emerged as a recent innovation. A real-time monitoring and prediction framework using AI for geo-textile-reinforced foundations was successfully demonstrated by Zhang et al. [16]. Another promising approach involves embedding sensors within geo-textile layers to collect data on strain, moisture, and deformation. This data is then fed into AI algorithms for predictive analytics and performance monitoring. Such systems not only enhance design reliability but also support preventive maintenance and cost reduction over the project lifecycle [17].

II.5 GAPS IN CURRENT RESEARCH AND THE NEED FOR THIS STUDY

Despite significant advancements, several gaps still exist. First, many AI models lack adequate generalization capability when applied to new soil environments. Second, the combined effect of geo-textile reinforcement and AI-based prediction has not been extensively validated across different soil types and climatic conditions. Lastly, integration strategies between materials science and data science remain in a developing stage [18]. This study addresses these gaps by presenting a comprehensive assessment of geo-textile effectiveness in soil stabilization, supported by AI-modeled predictions of settlement behavior under different foundation conditions. The research aims to establish an evidence-based framework for Smart Soil implementation in practical geotechnical applications.

III. RESEARCH METHODOLOGY

This research adopts a structured, multidisciplinary methodology integrating geotechnical engineering concepts, materials technology, and artificial intelligence (AI) modeling to assess the effectiveness of geo-textiles and AI-predicted settlement behavior in foundation systems [19]. The methodology includes both qualitative and quantitative elements, drawing on experimental investigations, simulation models, and literature synthesis. The steps undertaken are described below:

III.1 RESEARCH DESIGN

The study follows an applied research design with a focus on technical evaluation. A comparative assessment is made between traditional soil reinforcement practices and smart soil technologies using geo-textiles and AI tools. Experimental laboratory-scale testing and numerical modeling techniques are triangulated to validate results.

III.2 MATERIALS AND EQUIPMENT

Geo-Textiles: Synthetic woven and non-woven geo-textiles with varying tensile strength and permeability were selected.
Soil Samples: Different types of foundation soils (clayey, sandy, silty) were sourced to represent real-world conditions.
Load Testing Equipment: Plate load testing apparatus, settlement sensors, and soil moisture detectors.

AI Tools: Python-based machine learning models, specifically Artificial Neural Networks (ANNs), Support Vector Machines (SVM), and Decision Trees, were used to predict settlement values based on input parameters such as load, soil type, water content, and reinforcement configuration [20].

III.3 EXPERIMENTAL PROCEDURE

Soil characterization was performed using standard laboratory tests to determine particle size distribution, Atterberg limits, compaction characteristics, and shear strength parameters. Test beds were prepared with and without geo-textile reinforcement in layered configurations. Plate load tests were conducted incrementally until bearing failure or ultimate settlement was reached. Settlement and moisture data were recorded using embedded sensors.

III.4 AI-BASED PREDICTION MODEL

A training dataset was generated from experimental results and literature-based data. Input features included soil type, applied load, geo-textile type and placement, moisture content, and time duration. The output parameter was settlement in millimeters. Data were normalized and divided into training and testing sets in a 70:30 ratio. Model performance was evaluated using Mean Absolute Error (MAE), Root Mean Squared Error (RMSE), and R^2 score [21].

III.5 SIMULATION AND VALIDATION

Numerical simulations were performed using PLAXIS 2D for finite element analysis of soil–reinforcement behavior. Results were compared with AI-predicted settlements and experimental data to assess prediction accuracy and consistency [22].

III.6 SCOPE AND LIMITATIONS

While this methodology provides a robust framework for performance assessment, its limitations include controlled laboratory conditions that may not fully represent field variability, dependence of AI predictions on training data quality, and the exclusion of long-term geo-textile degradation effects in the present study.

IV. DATA ANALYSIS AND RESULT

This section presents the findings derived from each laboratory experiments and AI-pushed agreement prediction fashions. The effects are organized to focus on the effectiveness of geo-fabric reinforcement on soil stability and the predictive performance of device getting to know fashions for settlement forecasting.

IV.1 EXPERIMENTAL DATA INTERPRETATION

Settlement conduct below incremental loading became located throughout 3 soil sorts clay, sand, and silt under both bolstered and unreinforced conditions. Table 1 shows the results found out a big development in load-bearing capacity and a reduction in agreement while geo-textiles had been introduced. For instance:

Table: 1 Max. settlements in different types of Unreinforced and Reinforced soil.

Soil Type	Load Applied (kN/m²)	Max Settlement (Unreinforced, mm)	Max Settlement (Reinforced, mm)	% Reduction in Settlement
Clay	150	42.5	26.1	38.6%
Sand	150	30.8	17.6	42.8%
Silt	150	37.4	22.3	40.3%

Source: Authors, (2026).

These effects verify that geo-textiles successfully manage vertical displacements and growth the stiffness of soil mass under load.

IV.2 EFFECT OF GEO-TEXTILE LAYERING

The placement and quantity of geo-textile layers considerably prompted overall performance. Double-layered reinforcements confirmed up to 15% extra discount in settlement as compared to single-layered structures. The top-rated placement became discovered to be at 1/3 and a pair of/three depth under the inspiration base.

IV.3 AI MODEL PERFORMANCE

Table 2 shows the Machine gaining knowledge of models have been evaluated the use of metrics which includes MAE, RMSE, and R^2. Among the models tested:

Table 2 Results of different models of matrics MAE, RMSE and R^2.

Model	MAE (mm)	RMSE (mm)	R^2 Score
Artificial Neural Network (ANN)	1.52	2.34	0.946
Support Vector Machine (SVM)	2.14	3.18	0.902
Decision Tree	2.61	3.87	0.876

Source: Authors, (2026).

The ANN model furnished the maximum accurate predictions, displaying a near correlation with experimental facts and low error margins.

IV.4 COMPARATIVE VISUALIZATION

Figures and plots have been generated to visualize the comparative performance. One key plot confirmed the actual vs anticipated settlement for exclusive loads and soil types, definitely illustrating the predictive precision of the ANN model. The deviation among experimental and AI-expected outcomes become minimum in over eighty five% of the check cases.

IV.5 INTEGRATION FINDINGS

When integrating geo-textiles with AI equipment, the take a look at found a synergy that allowed for proactive design choices. Predictive modeling not only stored checking out time but additionally allowed optimization of reinforcement format and amount, reducing the need for over-conservative safety elements.

V. FINDINGS AND DISCUSSION

V.1 REINFORCEMENT WITH GEO-TEXTILES ENHANCES SOIL PERFORMANCE

The experimental research honestly proven that the inclusion of geo-textiles significantly complements the bearing capability and reduces settlement in one-of-a-kind soil sorts. Reinforced soil samples exhibited decreased vertical deformation as compared to unreinforced ones, specifically below better loading situations. The degree of development changed into most prominent in sandy and silty soils, where the interlocking impact and tensile electricity of geo-textiles presented structural confinement to soil particles. The consistent reduction in settlement starting from 38 percent to almost forty three percentage underscores the reliability of geo-fabric utility in sensible engineering foundations. This helps using reinforcement as a vital component in improving the toughness and overall performance of shallow foundations, embankments, and subgrades.

V.2 INFLUENCE OF GEO-TEXTILE LAYERING AND POSITION

Another considerable final results changed into the impact of geo-textile layering. Two layers of geo-textiles positioned at most desirable depths produced higher outcomes compared to a single layer. Placement at one-third and two-thirds depth levels provided maximum soil restraint, displaying that strategic positioning plays a essential position in improving the soil's load-bearing reaction. This statement aligns with the idea of tension membrane motion, in which the strain is correctly distributed throughout the geo-fabric, minimizing stress attention zones and lowering differential settlement. This layered method also allowed for better strength dissipation and resistance to lateral spreading.

V.3 EFFICACY OF AI IN SETTLEMENT PREDICTION

On the computational the front, AI-driven models proved to be fairly effective in agreement prediction. Among the fashions examined, Artificial Neural Networks (ANN) emerged because the maximum accurate, with a coefficient of willpower (R^2) close to 0.95. This level of precision suggests that gadget getting to know gear may be trusted to duplicate complex soil conduct patterns whilst sufficient and applicable education facts is to be had. The findings spotlight that AI can seize nonlinear relationships between a couple of influencing variables such as moisture content material, dry density, and cargo depth something traditional empirical equations may also fail to do with accuracy. This gives engineers a sophisticated selection-assist mechanism for pre-production reviews and design optimizations.

V.4 INTEGRATION OF AI AND GEO-TEXTILES FOR SMART SOIL SYSTEMS

One of the standout findings changed into the fee in integrating AI prediction with bodily reinforcement strategies. While geo-textiles improve real subject performance, AI models provide a proactive making plans tool, allowing engineers to assume agreement outcomes, simulate more than one reinforcement schemes, and arrive on the most cost-powerful and green solution. This combined method represents a shift toward "clever soil structures," in which real-time tracking, feedback control, and predictive algorithms can collectively make sure structural integrity, optimize material usage, and decrease protection expenses. It additionally highlights a growing function for virtual twins in geotechnical engineering.

V.5 PRACTICAL IMPLICATIONS AND FUTURE PROSPECTS

The consequences of this look at preserve promising implications for foundation engineering in challenging soil environments. The use of AI models can significantly reduce the reliance on full-size subject trials and highly-priced instrumentation, while geo-textile reinforcement gives a dependable solution for speedy floor development. Furthermore, this study paves the way for using sensor-enabled geo-textiles which can feed actual-time performance information back into predictive AI frameworks, creating a dynamic, self-studying foundation device. Future advancements should cognizance on developing hybrid materials and stronger deep-getting to know models for greater complex, multi-layered soil structures under variable climatic situations.

VI. CONCLUSION

The exploration of geo-textiles and AI-expected agreement fashions in the context of basis engineering exhibits a effective synergy between traditional soil reinforcement strategies and advanced computational strategies. Geo-textiles, as a form of mechanical reinforcement, have always verified their functionality to improve soil behavior by means of increasing shear strength, lowering agreement, and enhancing load distribution traits. These substances no longer best offer on the spot stabilization but additionally make contributions to the lengthy-time period sturdiness of foundation systems, in particular in susceptible or moisture-sensitive soils. The experimental findings hooked up that multi-layered geo-textile configurations strategically positioned within soil strata deliver superior overall performance over unmarried-layer structures.

This reinforcement efficiently resists vertical deformation and permits for higher dispersion of hundreds throughout a broader region, making it particularly appropriate for shallow foundations, pavement subgrades, and retaining walls. Simultaneously, the incorporation of Artificial Intelligence into agreement prediction introduces a transformative method to geotechnical design. The look at established the accuracy and reliability of machine studying models, especially Artificial Neural Networks (ANN), in forecasting soil agreement underneath numerous loading and environmental conditions. These fashions exhibited robust predictive accuracy, taking pictures the nonlinear interactions among geotechnical parameters with minimum need for guide calibration. Together, the mixing of geo-textiles and AI technologies establishes the muse for a new technology of smart soil systems. This convergence lets in engineers to expect, display, and respond to soil conduct in actual-time, leading to safer, more value-powerful, and sustainable engineering answers.

VI.1 FUTURE SCOPE

While this research offers promising insights, there are several avenues for in addition exploration and enhancement:

VI.2 SENSOR-INTEGRATED GEO-TEXTILES

Future tendencies can awareness on embedding sensors within geo-textile fabric to permit real-time information series on pressure, strain, and moisture content material. This can beautify predictive modeling accuracy and support adaptive structural responses.

VI.3 DEEP LEARNING FOR DYNAMIC SOIL CONDITIONS

Expanding the AI models to encompass deep learning architectures inclusive of LSTM (Long Short-Term Memory) and CNN (Convolutional Neural Networks) may want to assist capture temporal and spatial patterns in settlement conduct under cyclic and dynamic loading, including seismic interest.

VI.4 HYBRID REINFORCEMENT SYSTEMS

Investigating the performance of geo-textiles in mixture with other ground development techniques inclusive of chemical stabilization, geogrids, or micro-piles—should provide multi-practical reinforcement for enormously variable or complicated soil conditions.

VI.5 CLIMATE-RESPONSIVE FOUNDATION DESIGN

AI algorithms may be further trained using weather records to evaluate how rainfall, temperature, and humidity tendencies effect soil behavior. This might assist increase foundations which can be resilient to climate trade, specifically in flood-prone or arid regions.

VI.6 DIGITAL TWINS IN GEOTECHNICS

Creating digital twins of foundation structures using AI fashions and sensor statistics can offer a non-stop comments loop between physical infrastructure and its digital reproduction. This would enable proactive maintenance, overall performance optimization, and life-cycle control of systems.

VI.7 STANDARDIZATION AND POLICY INTEGRATION

As those technologies mature, efforts should be directed toward standardizing the use of AI and clever materials in construction codes and guidelines, making sure safe and uniform implementation throughout initiatives.In end, this observe gives a strong place to begin for the evolution of smart geotechnical answers. By bridging material science and data-pushed modeling, it units the stage for a future wherein soils are not simply passive substances but active additives of an incorporated, responsive engineering device.

ABSTRACT

African Swine Fever (ASF) continues to pose a serious threat to swine farmers, resulting in significant economic losses and livelihood challenges. Traditional methods of ASF detection often rely on physical inspections and laboratory testing, which are time-consuming and prone to delays in results. This study developed Project SwineScan: IoT Technology Scanner for Common Symptoms of African Swine Fever, integrating sensor technology, stored data management, and GIS-enabled analytics to provide a real-time and automated monitoring solution. The system utilizes non-invasive sensors that measure the vitals of the swine, including body temperature, heart rate, and oxygen saturation. Data was collected and transmitted to a web platform using an API for data visualization, analysis, and reporting. GIS mapping supported spatial visualization, enhancing decision-making for targeted interventions. Evaluation of the system demonstrated its capacity to provide timely, accurate, and actionable information to farmers, veterinarians, and local government units. By functioning as both a monitoring and decision-support tool, Project SwineScan offers a sustainable approach to ASF control while strengthening resilience within the swine and agricultural sectors.

I. INTRODUCTION

African swine fever (ASF) is caused by the African swine fever virus (ASFV), a member of the Asfarviridae family. It is the only DNA virus transmitted by arthropods. It is highly contagious, resulting in up to 100% morbidity in previously unexposed pig herds with mortality varying between 0 and 100% depending on the virus, the host, the dose, and the route of exposure to the virus [1]. African swine fever is a large, icosahedral, linear double-stranded DNA virus and the only member of the family Asfarviridae, genus Asfivirus. African swine fever virus (ASFV) is maintained in Africa via a complex transmission cycle involving African wild suid species, soft ticks, and domestic pigs [2]. Animal diseases constitute a continuing threat to animal health, food safety, the national economy, and the environment. Among those, African swine fever (ASF) is one of the most devastating viruses affecting pigs and wild suids due to the lack of a vaccine or effective treatment [3].

Pigs provide an important source of high-quality protein, and production is predicted to increase in the future to meet growing global demands for meat. However, the pork supply is threatened by infectious diseases, and amongst these, African swine fever (ASF) is currently causing the greatest concern [4]. ASF remains a significant concern for the Philippines, impacting the swine industry and food security. It causes high mortality rates, leading to decreased pork production, high prices of pork and pork products, and financial losses for farmers and stakeholders, especially for the livelihoods of many small-scale pig farmers in the Philippines [5]. Emergence of African swine fever (ASF) in the Philippines in 2019 caused substantial impacts on animal health and its pig industry. To control ASF, strict policies were applied, including zoning and depopulation of infected herds. Risk estimation of ASF transmission must consider meat sample contamination [6]. Surveillance at local borders can monitor contamination and prevent ASFv sources from entering areas. This approach allows the government to allocate resources and prioritize higher-risk areas [7].

At present, there is no safe and effective vaccine for African swine fever, and the most effective way to combat it is to establish stringent and safe biological prevention and control measures [8]. One of the key observations of this disease is the presence of a high fever [9]. This severe viral disease is characterized by respiratory and digestive dysfunction, congestive bleeding [10], a fever exceeding 41 °C, and symptoms such as loss of appetite and lethargy [11]. Real-time temperature monitoring systems have emerged as essential tools for early ASF diagnosis [12]. ASF is a highly infectious and fatal viral disease that affects both domestic and wild pigs. Its rapid spread via both direct and indirect pathways poses a substantial and ongoing threat to pig populations around the world. An ASF outbreak can have devastating consequences, resulting in high mortality rates and significant economic losses for farmers and the pig sector. Current diagnostic approaches, which frequently include time-consuming laboratory testing, can exacerbate the delay in important outbreak-control treatments. Developing novel technologies like "Project SwineScan: IoT Technology Scanner for Common Symptoms of African Swine Fever" provides a viable solution to these issues. By facilitating the early detection of ASF symptoms through contactless monitoring, this device seeks to offer a substantial benefit.

Project SwineScan has several important advantages that resolve the most pressing challenges in treating African Swine Fever. First of all, by detecting early symptoms of disease, its ongoing monitoring capabilities allow for the early identification and prompt isolation of potentially contaminated animals. This quick action is required to avoid the ASF virus from spreading widely throughout a herd. Second, the availability of real-time health data facilitates improved biosecurity measures by enabling prompt action in the event of a suspected infection. This proactive strategy greatly reduces the possibility of economic losses and helps to manage outbreaks at their source. Furthermore, Project SwineScan helps to enhance disease surveillance by gathering important information on pig health and illness patterns. The development of more focused and effective intervention plans can be aided by using this data to pinpoint high-risk locations and track how well control measures are working. Further, the data can offer significant insights into the complex nature of ASF transmission and other environmental factors that impact its dissemination. In the long run, Project SwineScan is essential to assisting pig farmers and the pork sector by giving them a proactive tool for managing the health of their herds. Considering the catastrophic impact of ASF on the supply of food worldwide, this can assist in minimizing losses, stabilizing production levels, and enhancing the pork industry's general resilience and sustainability.

The integration of available medical sensors creates a connected digital platform that empowers the connectivity with pets and livestock with improved efficiency. These kinds of technologies make a precise health status and sickness projection, which are most effective in humans, but they can be applied to animals with few changes [13]. IoT was conceptualized to improve human and pet interaction by medical or health opportunities, through information retrieval [14]. A prototype of a smart animal health monitoring system based on IoT for real-time monitoring of the physiological parameters, such as body temperature, heart rate, and rumination, with surrounding temperature and humidity has been developed [15]. Project SwineScan: IoT Technology Scanner for Common Symptoms of African Swine Fever aims to be contactless, potentially using a non-invasive sensor technology like radar or infrared to monitor pigs without physical contact. This is a significant innovation compared to existing livestock monitoring systems that often rely on physical attachments. Incorporating an AI algorithm specifically trained to detect ASF-related symptoms based on the unique physiological changes associated with the disease. A wearable design that allows for continuous monitoring of individual pigs, potentially providing more accurate and timely detection of ASF symptoms compared to traditional methods.

I.1 SPECIFIC OBJECTIVES

- To develop an Internet of Things (IoT)-based prototype device that can detect common symptoms of African Swine Fever (ASF).
- To develop an information system that provides data analytics for ASF, with the integration of the Graphical Information System (GIS).

II. THEORETICAL REFERENCE

II.1 THE THREAT OF AFRICAN SWINE FEVER (ASF)

African swine fever (ASF) is a viral hemorrhagic disease characterized by exceptionally high lethality in domestic pigs and Eurasian wild boar [16]. Originating in Africa, the disease has since spread to Europe, Asia, and Oceania, reaching a pandemic dimension since 2007, posing a global threat to the swine industry [17]. Given the absence of effective ASF vaccines, disease management options are limited, making the identification and minimization of ASF-associated risk factors critical to preventing outbreaks [18]. This absence of available vaccines renders biosecurity measures, cleaning, and disinfection procedures essential control tools for the prevention of primary and secondary introductions of ASF in pig farms [19].

II.2 THE NECESSITY FOR EARLY, RAPID DETECTION

The immediate and accurate detection of highly contagious diseases like ASF is the single most critical factor in mitigating significant economic losses for pig producers and governments. Traditional detection methods, which rely on clinical observation and periodic laboratory testing, are often time-consuming and lead to critical delays in containment. The most common initial clinical indicators of infection—such as fever (increased body temperature) and reduced motion—often precede or occur simultaneously with decreases in feed/water intake and even the definitive detection of the virus via molecular methods [20].

II.3 LIMITATIONS OF DEFINITIVE LABORATORY DIAGNOSTICS

While highly sensitive and specific real-time PCR (qPCR) assays are the scientific "gold standard" for definitive confirmation by detecting viral DNA, they require sample collection, transport, and laboratory processing, creating a time lag [21]. Studies have shown that the physical symptoms detected by a real-time monitoring system can signal infection before a positive qPCR result is obtained. This establishes the role of continuous, real-time monitoring systems, such as Project SwineScan, as a crucial pre-screening mechanism to bridge the gap between initial infection and definitive laboratory confirmation [22].

II.4 INTEGRATION AND DECISION-SUPPORT SYSTEMS (IOT, AI, AND GIS)

The Internet of Things (IoT) is a system of wireless, interrelated, and connected digital devices that can collect, send, and store data over a network without requiring human-to-human or human-to-computer interaction [23]. The integration of multiple data sources (temperature, HR, movement) within an IoT framework, combined with AI and data fusion techniques, compensates for the limitations of any single method, providing a more robust and comprehensive system for health surveillance [24]. The successful application of such smart online systems in experimental ASF trials confirms their efficacy in automatically alerting staff based on combined vital sign deviations, thereby significantly reducing the time and cost associated with disease control [25]. With the integration of GIS (Geographic Information System), the system can be used to analyze and manipulate the spatially referenced data [26], transforming the real-time health data into actionable spatial insights for targeted intervention.

III. MATERIALS AND METHODS

This chapter discusses the methodology employed in the design, development, and evaluation of the proposed Project SwineScan: IoT Technology Scanner for Common Symptoms of African Swine Fever. The methodology outlines the research design, system development model, and stages of System testing.

III.1 RESEARCH DESIGN

The study utilized a Research and Development (RnD) Design, which focuses on the systematic design, creation, and assessment of a technological solution to a practical problem. In this study, the problem addressed is an efficient and real-time monitoring system for detecting physiological indicators associated with ASF (African Swine Fever) in livestock. The research design emphasizes both the design and development of the system, as well as the testing and evaluation of its performance.

III.2 DEVELOPMENT MODEL

The system was developed using the Rapid Application Development (RAD) Model, which emphasizes iterative prototyping and user feedback. The model consists of four major phases:

Figure 1. The system development process adopted the Rapid Application Development (RAD) Model. RAD is appropriate for projects that need flexibility and user involvement because it places an emphasis on iterative prototyping, user feedback, and rapid development cycles. Rapid Application Development (RAD) is used to develop applications, and blackbox testing is used to test the applications' functionality and usability to see how users react to the final product [27] [28]. Within RAD, a prototyping model was also used. To see the features and user interfaces of the suggested system, early prototypes were made. Actual system development, which includes cloud integration, software coding, and hardware assembly. System deployment, testing, and finalization in a controlled setting.

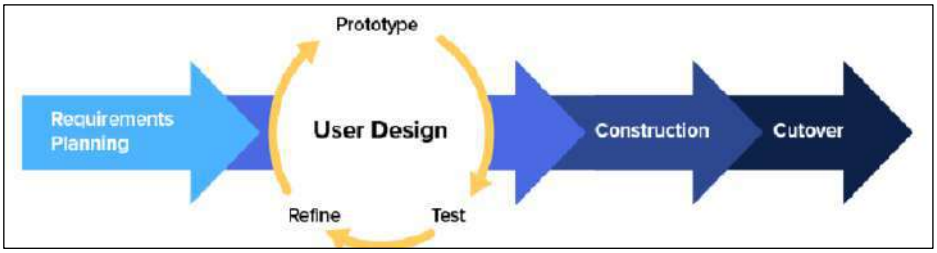

Figure 1: Rapid Application Development Model.
Source: [28].

III.3 SYSTEM DEVELOPMENT PROCEDURE

The development of the Project SwineScan: IoT Technology Scanner for Common Symptoms of African Swine Fever followed a structured procedure consisting of the following stages.

II.3.1 System Requirement Analysis

Identification of the necessary hardware components (sensors, microcontroller, power supply) and software requirements (database, mobile application framework).

II.3.2 Hardware Requirements and Software Requirements

The development of the IoT Device to detect common ASF symptoms required integrating several hardware components to ensure accurate sensing, data acquisition, and wireless transmission. The hardware and software requirements are summarized in Table 1. The summary of System Requirements illustrates the combination of hardware and software components that enabled the development of the ASF Monitoring System. The hardware requirements provided the physical foundation for sensing, processing, and transmitting animal health data. Together, these hardware and software requirements formed a cohesive system architecture that allowed for accurate sensing, reliable data management, and accessible monitoring for end-users. Solid requirements engineering has increasingly been recognized as the key to delivering software and systems projects on time, on budget, and with improved quality. New software tools are emerging that are empowering practicing engineers to improve their requirements engineering habits [29].

Table 1: Summary of System Requirements.

Category	Requirement Specification	Description
Hardware	Heart Rate & Pulse Sensor	Monitors animal pulse and oxygen levels
	Temperature Sensor	Measures animal body temperature contactless
	ESP32 Development Board	Microcontroller for data processing and wireless transmission
	Power Supply Module	Provides stable 5V power to components
	USB Cable	Facilitates programming and power connection
	Electrolytic Capacitor	Stabilizes the voltage supply
	AMS1117-3.3V Regulator	Converts voltage to 3.3V
	Prototype Board	Circuit prototyping platform
Software	PHP	Backend programming for system logic and transactions
	HTML & CSS	User interface development
	MySQL Database	Stores and manages sensor data securely
	Arduino IDE	Programming environment for ESP32
	GIS System	Enhance spatial analysis and visualization of real-time monitoring data using GIS

Source: Authors, (2026).

III.4 SYSTEM DESIGN AND ARCHITECTURE

Figure 2 shows the block diagram for the suggested ASF Monitoring System. The sensor module, microcontroller unit, power supply, cloud infrastructure, and user interface are the system's five main parts. These sensors are in charge of gathering the essential data required to track the health of the animals. The microcontroller, the system's central processing unit, receives the data gathered from the sensors. Internet of Things in Animal Healthcare (IoTAH) uses biosensors and software for monitoring and maintaining animal health records. The Internet of Things enables devices to connect to the Internet and communicate with each other. Data from these IoT-connected devices will help to identify the scenario and take necessary action [30].

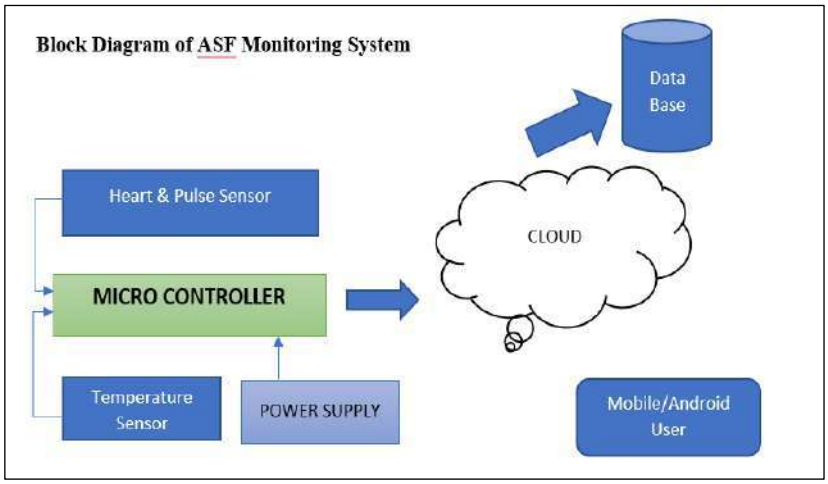

Figure 2: Block Diagram of ASF Monitoring System.
Source: Authors, (2026).

III.5 SYSTEM DEVELOPMENT AND SYSTEM INTEGRATION

The interface's user-friendly presentation of real-time information enables prompt decision-making and intervention. A single functional system was created by integrating the sensors, microcontroller, database, and user interface. End users, including farmers and veterinarians, were able to access real-time animal health data because the user interface was connected to the backend system. System validation was another step in the integration process, where modules were tested collectively to evaluate accuracy, dependability, and usability in actual operating environments.System integration was critical in verifying whether modules developed independently can work cohesively. In this study, careful integration reduced the likelihood of incompatibility issues and enhanced the robustness of the monitoring system [31].

III.6 SYSTEM TESTING AND EVALUATION

Testing the mobile application's usability, data transmission dependability, and sensor accuracy. System responsiveness, accuracy, dependability, and user satisfaction were among the evaluation metrics. The system was put through continuous operation for a predetermined amount of time to test its reliability. The system's ability to reliably capture and transmit precise data without any disruptions was observed. The main role of software testing is to help developers better understand the needs of users and help users better express their needs. In addition, software testing can also predict and avoid some possible problems, but can also help determine the functionality performance standards of the software [32].

IV. RESULTS AND DISCUSSIONS

IV.1 A PROTOTYPE OF AN INTERNET OF THINGS (IOT) TECHNOLOGY SCANNER FOR COMMON SYMPTOMS OF AFRICAN SWINE FEVER

Figure 3. Flow and Process flow illustrate the operational flow of the Project SwineScan system for detecting possible ASF symptoms. The process starts with system initialization, followed by sensor data collection and transmission via API. Data were received on the mobile application and evaluated against normal vital sign ranges for swine. If abnormal readings are detected, the system records the event in the database, links with location data for contact tracing, and displays the findings on the monitoring interface using GIS.

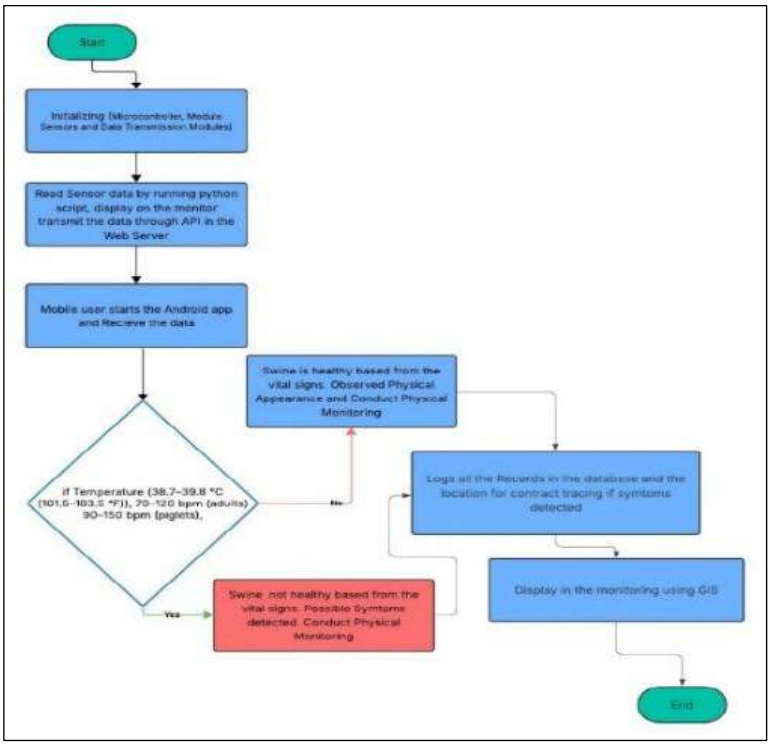

Figure 3: Flowchart and Process Flow.
Source: Authors, (2026).

Table 2 Normal Vital Signs of Swine and Abnormal Indications of Possible African Swine Fever (ASF) presents the normal ranges of swine vital signs and their deviations that may indicate African Swine Fever (ASF). Elevated body temperature, abnormal heart and respiratory rates, as well as changes in skin coloration, feeding behavior, and sudden unexplained mortality are critical markers for early ASF detection and monitoring [33], [34]. These values can vary slightly depending on the age, breed, and health status of the pig. Always consult a veterinarian for specific health assessments. In addition, physiological parameters such as hemoglobin oxygen saturation and end tidal carbon dioxide levels can also provide valuable insights into the health of swine [35].

Table 2: A Basis for Normal Vital Signs of Swine and Abnormal Indications of Possible (ASF).

Vital Sign	Normal Range	Possible ASF Symptom (Abnormal Range)	Indication
Body Temperature	38.7–39.8 °C (101.5–103.5 °F)	>40 °C (104 °F and above)	High fever, one of the primary symptoms of ASF
Heart / Pulse Rate	70–120 bpm (adults) 90–150 bpm (piglets)	Elevated (>130–150 bpm)	Stress response, fever, or infection
Respiratory Rate	25–40 breaths per minute	Rapid or labored breathing (>50 bpm)	Respiratory distress associated with ASF

Source: [33-35].

IV.2 COMPARISON WITH EXISTING TECHNOLOGIES AND RESEARCH CONTRIBUTION

The development of the Project SwineScan system was highly significant because it addresses critical limitations inherent in existing African Swine Fever (ASF) detection technologies across three distinct categories. While laboratory diagnostics, such as real-time Polymerase Chain Reaction (qPCR) and Enzyme-Linked Immunosorbent Assay (ELISA), are considered the gold standard for high-specificity virus identification, they are inherently time-consuming and require specialized facilities, which severely delays outbreak response time [36]. Similarly, rapid field diagnostics, including Lateral Flow Assays (LFA), offer quick results but rely on invasive, single-point biological sampling that is labor-intensive and potentially stressful for the swine herd, often yielding variable performance in the early phase of infection [37]. Project SwineScan surpasses these limitations by functioning as a real-time, non-invasive, pen-side pre-diagnostic system, enabling continuous, 24/7 remote surveillance that detects subtle physiological symptoms (fever, cardiovascular changes) before the need for a definitive viral diagnosis [38], [39].

Furthermore, Project SwineScan demonstrates a key advancement over existing IoT and vision-based monitoring systems, which often rely on single metrics like movement deceleration or require contact-based sensors (e.g., ear-tags) that are prone to loss or detachment [40]. By employing contactless, multiparameter sensing to simultaneously monitor body temperature, heart rate, and oxygen saturation, Project SwineScan provides a more stable and higher-confidence indicator of systemic sickness—a complex state that cannot be reliably captured by relying solely on behavioral proxies or single vitals [41].

IV.3 DEVELOPED TECHNOLOGY DEVICE INTERFACE

Figure 4. Schematic Circuit Block Diagram illustrates the interaction of the major components in the monitoring system: the sensors, the ADC module, the microcontroller, and the display unit. The Heart Rate and Pulse Sensor and the Temperature Sensor serve as the primary input devices, capturing the user's physiological data in analog form. The microcontroller functions as the central processing unit. It receives sensor data, performs necessary filtering and computation—such as heart rate detection and temperature conversion—and controls system operation. After processing, the microcontroller sends the computed results to the LCD Display, which presents real-time heart rate and temperature readings to the user. the block diagram shows a streamlined flow from data acquisition, conversion, and processing, to output display, enabling continuous and accurate monitoring of vital signs.

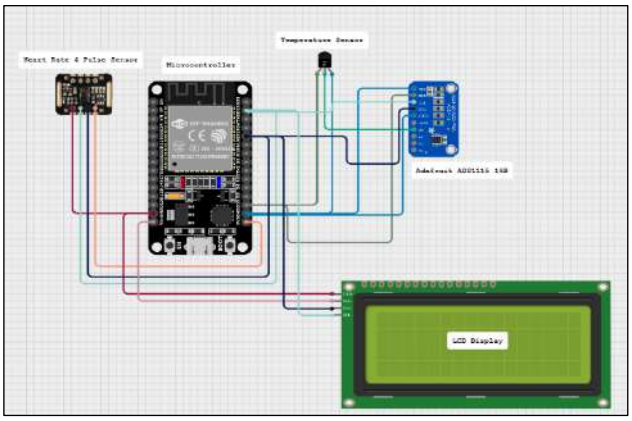

Figure 4: Schematic Circuit Block Diagram.
Source: Authors, (2026).

Figure 5 Prototype of the developed IoT Device. The device was built on a pierced prototyping board and integrates multiple modules. The ESP32 microcontroller for data processing and wireless transmission, the MAX30102 heart rate and pulse sensor, and the MLX90614 contactless temperature sensor. The LCD module provides a real-time output of swine vital signs. This configuration enables the contactless monitoring of swine health parameters as part of the African Swine Fever (ASF) early detection system.

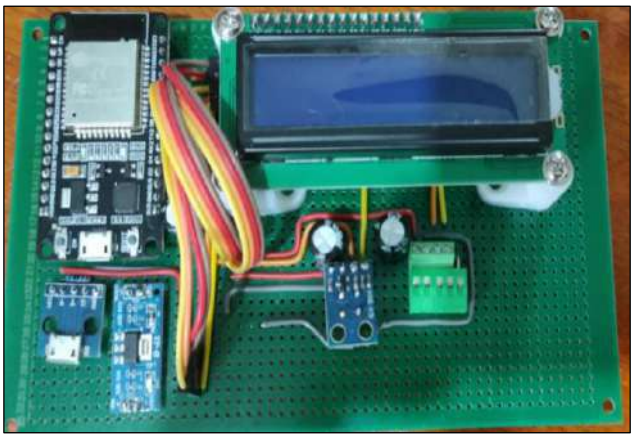

Figure 5: Prototype of the developed IoT Device.
Source: Authors, (2026).

Figure 6 Working Prototype of the developed IoT Device. Functional and working prototype of the Project SwineScan IoT Device system displaying real-time swine vital signs. The LCD screen displays vital parameters: heart rate (HR), body temperature (T), and blood oxygen saturation (SpO_2). The integration of hardware components enables contactless monitoring, while the microcontroller processes and transmits the data to the cloud for storage, analysis, and visualization in the monitoring system. IoT-enabled learning frameworks were using the data science paradigm for providing information on the current health status and real-time monitoring capability of the individual animal in smart livestock [42]. The Internet of Things (IoT) is an emerging paradigm that is transforming real-world things (objects) into smarter devices. IoT applies to a variety of application domains, including healthcare, smart grid, and agriculture [43]. The used of sensors that record animal activity in intensive livestock systems has become more and more frequent for both early detection of diseases and improving production quality. Their application may also be significant in extensive livestock systems, with infrequent farmer-to-animal contact [44].

IV.4 DEVELOPED AN INFORMATION SYSTEM THAT PROVIDES DATA ANALYTICS FOR ASF, WITH THE INTEGRATION OF THE GRAPHICAL INFORMATION SYSTEM (GIS) DEVICE INTERFACE

Figure 7 Statistical Report for Positive with Symptoms per Barangay and a Statistical Report for Positive and Confirmed with ASF Per Barangay illustrate the statistical distribution of swine detected with ASF-related symptoms, and those confirmed positive for ASF across different barangays. The first chart shows the barangays with reported symptomatic cases, while the second chart presents the number of cases confirmed positive through laboratory testing. Generating statistical reports through the integrated data analysis computerized system lies in its ability to provide accurate, timely, and actionable information. The Project SwineScan computer system not only improve surveillance and monitoring efforts but also strengthens policy-making, disease management, and community awareness in addressing the ASF outbreaks in the municipality or in the province.

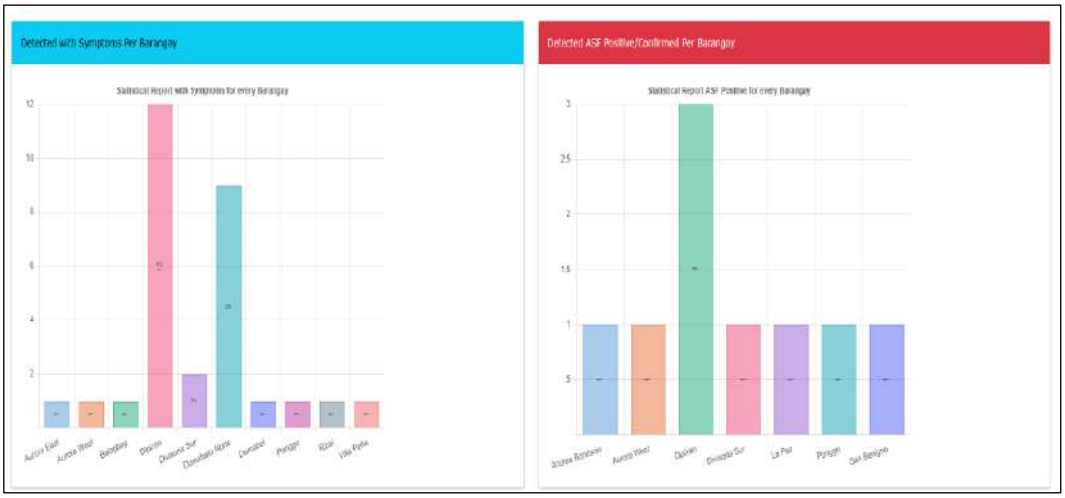

Figure 7: Statistical Report for Positive with Symptoms per Barangay, Positive and Confirmed with ASF Per Barangay.
Source: Authors, (2026).

Figure 8 A Statistical Report for Positive with Symptoms in Every Municipality and a Statistical Report for Positive with Symptoms in Every Municipality. Figures 8A and 8B illustrate the statistical distribution of ASF (African Swine Fever) cases at the municipality level, distinguishing between swine detected with symptoms and those confirmed positive through laboratory testing. By generating charts and summaries, stakeholders can grasp the overall situation at a glance, thereby facilitating rapid policy formulation and emergency response. The pie charts provide a clear distribution of cases across municipalities, allowing authorities to monitor the spread of ASF geographically and anticipate potential spillover to adjacent areas.

The municipality-level reports through the computerized system lie in its role as a decision-support mechanism. It ensures that ASF management is evidence-based, efficient, and responsive to the varying conditions across -municipalities. By integrating symptom-based monitoring with laboratory confirmations, the system not only improves accuracy but also empowers stakeholders to implement targeted interventions that minimize economic losses and protect food security. Reports can be easily shared between local governments, regional offices, and national agencies, promoting synchronized efforts in disease control. The system also supports historical data archiving, enabling trend analysis that can inform long-term strategies for ASF prevention and preparedness.

Figure 9. GIS Map and Monitoring using the sample data sets to illustrate the spatial distribution of confirmed cases. The map was generated using GIS-based methods using sample test datasets incorporating barangay boundaries, municipal halls/provincial office/BAI-Quirino Office, and confirmed case attributes. Geographic information systems (GIS) provide easy access, utilization, and manipulation of geospatial information. The advantage of GIS is mapping the many different locations of farms and other facilities with animals on a single map, which helps in better monitoring and surveillance [45].

V. CONCLUSIONS

The developed and tested Project SwineScan: IoT Technology Scanner for Common Symptoms of African Swine Fever, along with its integrated information system and GIS-enabled analytics. The system demonstrated that combining IoT sensing, automated reporting, and spatial visualization can significantly enhance ASF surveillance and control. The results confirmed that the prototype device is capable of contactlessly measuring critical swine health parameters such as body temperature, heart rate, and oxygen saturation. These physiological indicators were essential in detecting early symptoms of ASF, thereby reducing the delay typically associated with conventional diagnostic methods. The integration of GIS mapping and analytics further enhanced the system's utility by spatially visualizing ASF case distributions. This spatial perspective allowed stakeholders to identify hotspots, predict potential spillover risks, and prioritize high-risk zones for intervention. Project SwineScan proved to be more than a monitoring tool; it functioned as a decision-support system for multiple stakeholders, including farmers, local government units, veterinary authorities, and policymakers.

Its capacity for real-time data collection, automated reporting, and spatial analysis underscores its potential to minimize ASF's economic and social impacts while strengthening the overall resilience of the swine industry. The development and implementation of the Project SwineScan system present significant implications for swine health management, disease prevention, and agricultural technology advancement. As an IoT-based monitoring solution, Project SwineScan demonstrates how embedded systems and wireless technologies can be applied in livestock production to detect early indicators of African Swine Fever (ASF) and support timely interventions. The project serves as a valuable reference for future studies in smart farming, IoT applications, and embedded systems for agricultural use. It highlights the importance of interdisciplinary collaboration between Information Technology and Animal Science experts, as demonstrated in the testing and evaluation phase of this research. Project SwineScan system has the potential to contribute to sustainable livestock management, improved farm productivity, and ASF outbreak mitigation by providing a reliable, real-time, and contactless monitoring solution that empowers both farmers and veterinary professionals.

Further enhancements and research directions are necessary to maximize the efficiency, accuracy, and scalability of Project SwineScan. Expand the device to measure other physiological and behavioral parameters such as respiratory rate, locomotion patterns, and feeding behavior, which can serve as complementary indicators of ASF and other swine diseases. Incorporate the AI-driven algorithms that are capable of analyzing longitudinal health data to detect anomalies, predict outbreak risks, and provide automated alerts for early disease intervention. Establish interoperability with existing livestock monitoring platforms and national veterinary information systems to contribute to a unified and standardized ASF surveillance network. Adapt the system to monitor additional swine diseases such as Classical Swine Fever (CSF) and Porcine Reproductive and Respiratory Syndrome (PRRS). Future modifications may also extend its application to other livestock sectors such as cattle, poultry, or goats.

VII. ACKNOWLEDGMENTS

The researchers would like to express our sincere gratitude to the individuals and institutions whose support and contributions made this study possible. First and foremost, we extend our heartfelt appreciation to the Information Technology and Animal Science experts who generously shared their time, knowledge, and expertise in contributing to and evaluating our documents, technology, and system. Their constructive feedback and professional insights were invaluable in refining and validating the functionality and reliability of the project. The researchers acknowledge Quirino State University – Maddela Campus for providing the academic environment, facilities, and institutional support that greatly facilitated this study's conduct. A Special recognition was given to the Ideatech Challenge 2024, where this project was awarded 3rd Place, a testament to the relevance, innovation, and potential impact of the system in the fields of agriculture and information technology. Finally, the researchers extend their deepest gratitude to their families, colleagues, and mentors for their encouragement and unwavering support throughout the duration of this study.

ABSTRACT

This study aims to assess the electric fields generated near overhead high-voltage transmission lines in light of public concern about possible health effects for those living nearby. The study evaluated the electric fields intensity around a 220 kV power transmission line, while recognizing the conductors have catenary shape in real life, and therefore used real conductors to estimate electric fields for realistic conditions. The quasistatic electric field was computed with an approach based on Coulomb's law and the method of image charges, incorporating the conductor geometries, observer locations, and symmetric images of position. The results showed that specific locations underneath the power transmission line will have electric fields above 5 kV/m and 10 kV/m. When compared to existing safety guidelines and public electromagnetic exposure limits, the findings indicated that the public would not be at significant risk from the electric field levels. However, higher levels of exposure could pose a potential risk for personnel working closely to the transmission lines during long periods, as these individuals are considered to be occupationally exposed. The results provide useful information for public safety assessment and developing mitigation plans around overhead power lines.

I. INTRODUCTION

Over the past few years, electricity has improved people's quality of life significantly and is now necessary to fulfill basic human needs. Even with many benefits, electricity generation and supply often adversely affect the environment and human health. The increase in the need for energy, due to population growth and economic development, has resulted in transmission systems that operate at very high voltage levels and additional double-circuit transmission lines. Extended or short-duration exposure to electromagnetic fields associated with high-voltage power lines may create health and safety risks, especially for anyone who works near these high-voltage wires [1], [2]. Therefore, it is necessary to reduce the electric field strength around transmission systems, and develop computational methods that accurately calculate the optimal distribution of electric field strength around these systems. The need to reduce electric field strength created around high-voltage transmission lines has led to the precise evaluation and control of electric fields to a major research area in power engineering.

Various analytical and numerical approaches for calculating electric field intensity below high-voltage transmission lines have been introduced [3-6]. One of the more common methods is the Charge Simulation Method (CSM) [7-11]. Essentially, CSM involves substituting the conductors' distributed charge and the polarized charge that appears on dielectric interfaces with a finite set of fictitious discrete charges that reproduce the same potential distribution. This paper describes an example of quasi-static electric field computation that takes place in the area of high voltage transmission lines with a voltage of 220 kV, with consideration for real catenary curves of the conductors. For comparison with the limits of human exposure established by safety standards, the results of the computation are given. To provide more accurate electric field calculation in the area of transmission lines, an application of the Coulomb equation has been utilized.

This application was implemented together with the image charges' method of dependence of electric field on the conductor position, observer position, and its symmetry. The computer program implemented in the MATLAB environment has been developed for assessment of the electric field intensity near overhead power transmission lines.

II. MODELING THE ELECTRIC FIELDS UNDER A POWER LINE INCLUDING THE SAG OF WIRES

II.1 COMPUTATION MODEL FOR A SAGGING CONDUCTOR

Traditional simplified methods for computing electric fields generally make the assumption that power line conductors are infinite, parallel and straight wires located above a perfectly conducting flat ground. However, actual power transmission line conductors have a catenary shape associated with sagging, which is a function of mechanical and environmental parameters. This sagging of the conductors can play a significant role in how the electric field intensity can vary in both magnitude and distribution [12–17], so it must be taken into account for precise field modeling.

The catenary geometry primarily depends on the conductor weight per unit length (w), the horizontal component of tension (H) and the span length (S). In the analysis of the study, each span of the conductor will be decomposed into n equal segments (s_1,s_2,...,s_i,...,s_n), as illustrated in Figure 1, which shows where the conductor sagging and span lay so that there is symmetry across the catenary. The conductor has a maximum height of h at the supports and a minimum height of hmin at the mid-point of the span. The sag is defined as follows: provide sag equations the electric charge with line density η will be on each segment carried as defined earlier in the study. The number of simulated charges is chosen to match the number of segments defined for the conductors thereby maintaining the same spatial resolution. The total quantity of simulated charges is selected to equal the quantity of defined conductor segments, which ensures that the spatial resolution remains the same. The catenary equation [18] [19] can be used to describe the arrival position of each segment along the span as it describes the actual curve of the suspended conductor and serves as the geometric basis of calculating the electric field in the proposed model.

$$z(x) = h_{min} + 2\alpha sin(\frac{2 \cdot x}{2\alpha})^2 \quad (1)$$

with: h is the maximum height, α is related to the mechanical parameters of the line α=Th/w, Th is a mechanical stresses in the middle of the line, w is the weight per unit of the length of the line, hmin is the minimum height, S is the arrow of the lineand L is the length of the line.

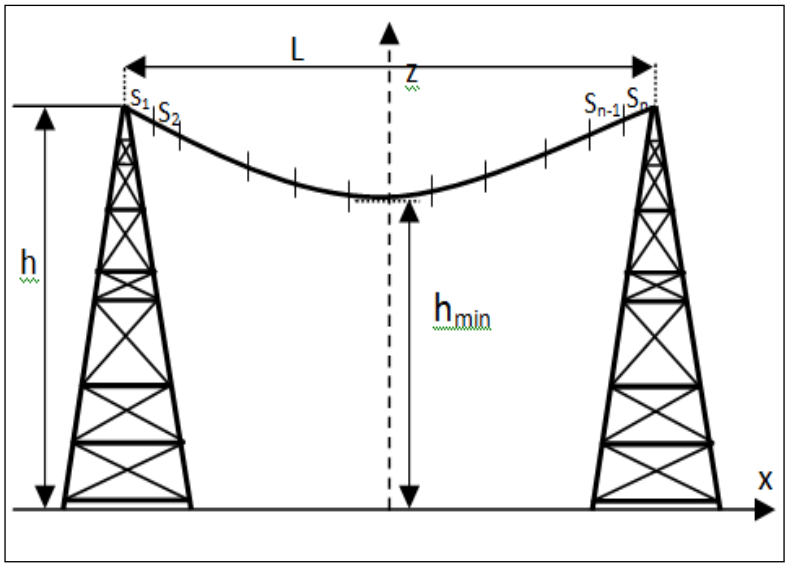

Figure 1: Division of a power line conductor into n segments of symmetric catenary.

II.2 COMPUTATION OF ELECTRIC FIELD INTENSITY

The potential of the static electric field at any observation point P(x,y,z) above the ground plane is determined using the Charge Simulation Method (CSM) alongside Coulomb's law and the image charges method, using the formulation given in references [20- 23].

$$\vec{E} = \varepsilon \int_{\Gamma} \overrightarrow{dE} = \frac{1}{4\pi\varepsilon_0} \int_{\Gamma} \frac{qdl}{r^3} \vec{r} \quad (2)$$

where q denotes the elemental of a line charge, dl represents the infinitesimal segment along the conductor, and Γ defines the geometric path of the conductor (catenary curve). $\vec{r}$ is the vector from the conductor element dl to the observer points P in Figure 2.

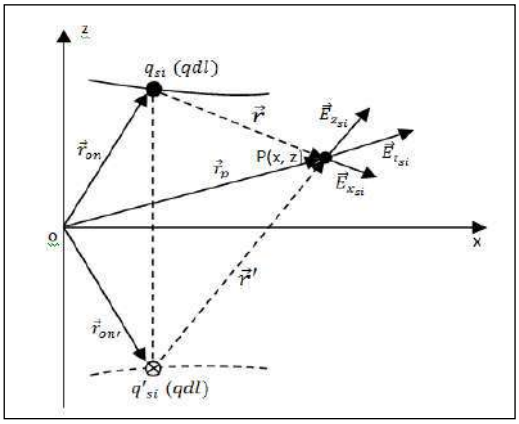

Figure 2: Division of a Method calculation of electric field intensity at the point P.
Source: Authors, (2026).

The resultant electric field vector $\vec{E}$ at point P is equal to the superposition of the electric fields produced by each conductor and its image $\overrightarrow{E'}$, as shown in Figure 2. The total electric field vector $\vec{E}$ at the observation point P(x,y,z) is obtained as the superposition of the electric fields generated by each conductor $\vec{E}_k$ and its corresponding image $\overrightarrow{E'}_k$ as illustrated in Figure 4.

$$\overrightarrow{dE}_{k,k'} = \frac{1}{4\pi\varepsilon_0}\frac{+qd\vec{l}\cdot(\vec{r}_p-\vec{r}_{0k})}{(\vec{r}_p-\vec{r}_o)^3} + \frac{1}{4\pi\varepsilon_0}\frac{-qd\vec{l}\cdot(\vec{r}_p-\vec{r}_{0k})}{(\vec{r}_p-\vec{r}_o)^3} \tag{3}$$

The simultaneous equations governing the relationship between the line charges and the corresponding conductor potentials enable the determination of the linear charge densities. These equations can be conveniently expressed in matrix form as follows:

$$[V_k] = [P_{kk}] \cdot [q_k] \tag{4}$$

Where: k is a number of conductors, v_k is a potential of conductor k to ground plane, P_{kk} is the potential coefficient of the conductor k and q_k is a line charge per unit length on conductor k. The corresponding potential coefficient values are given as follows:

$$P_{kk} = \frac{1}{2\pi\varepsilon_0} ln\frac{2h_k}{r_k} \tag{5}$$

$$P_{kj} = \frac{1}{2\pi\varepsilon_0} ln\frac{S_{kj'}}{S_{kj}} \tag{6}$$

where: r_k is the radius of conductor k, ε_0 is the permittivity of free space, h_k is the height of conductor k above ground, S_{kj} is the distance between conductors k and j, $S_{kj'}$ is the distance between conductor k and the image of conductor j, P_{kk} is the self-potential coefficient of the conductor k and P_{kj} is the mutual potential coefficient of the conductors k and j. The symmetric catenary shape of the overhead conductors is taken into consideration when calculating the intensity of the electric field $\vec{E}$ at an observation point P(x,y,z) beneath k conductors, each energized at a voltage U. The Charge Simulation Method (CSM) in conjunction with the method of image charges is used to evaluate the potential distribution of the static electric field near the power transmission line [24]. For a system with multiple conductors (m=1,2,…,M), the vector superposition of the individual field contributions from all conductors and their corresponding image charges yields the total electric field intensity at point P.

$$\vec{E} = \frac{1}{4\pi\varepsilon_0}\sum_{k=1}^{k}[\sum_{n=1}^{n}[\frac{q_{kn}\overrightarrow{dl}\left(\overrightarrow{r_p}-\vec{r}_{on_k}\right)}{\left(\overrightarrow{r_p}-\vec{r}_{on_k}\right)^3} + \frac{-q_{kn}\overrightarrow{dl}\left(\overrightarrow{r_p}-\vec{r}_{on'_k}\right)}{\left(\overrightarrow{r_p}-\vec{r}_{on'_k}\right)^3}]] \tag{7}$$

where the conductor element's image and position $\vec{r}_{on_k}$ and $\vec{r}_{on'_k}$ are determined by the vectors based on the coordinate system.

III. RESULTS AND DISCUSSIONS

A single-circuit high-voltage (HV) transmission line running at 220 kV is taken into consideration in this study. The system is made up of two overhead ground wires that act as shielding cables and tree phase conductors, designated A, B, and C, arranged horizontally parallel to a level ground surface. Figure 3 shows the simplified schematic diagram of this arrangement as well as the geometrical characteristics of the conductors near the suspension tower. The ground wire, which serves as a guard cable, has a diameter of 0.015 meters, while each phase conductor has a diameter of 0.04 meters. The transmission line's span length is 280 meters. With a current magnitude of 150 A per phase, the line runs in a balanced three-phase configuration. The system frequency is 50 Hz, and the earth is assumed to be homogeneous with a resistivity of 100 Ω.m. The electric field intensity is measured at a height of 1.5 meters above the ground, within a horizontal range of ±30 meters from the line's central axis, or 200 measurement points. This is the definition of the phase voltage configuration. As seen in Fig. 3, the base of the tower, where x=0 and z=0, is the origin of the Cartesian coordinate system.

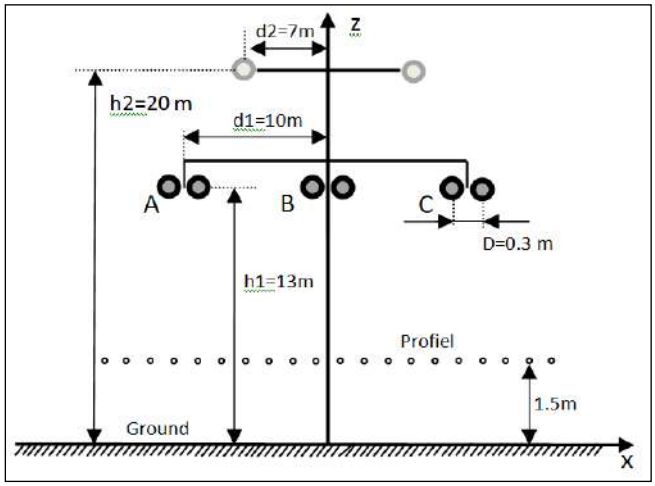

Figure 3: High voltage power transmission lines of 220 kV.

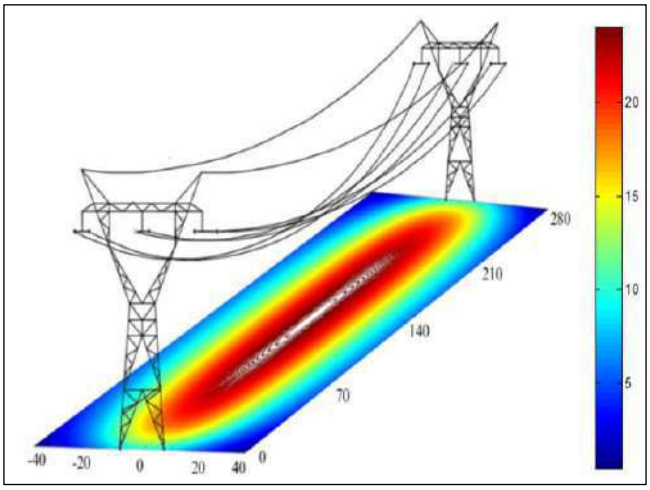

Figure 4: Electric field distribution Et (kV/m) in the x-y plane at 0.5 m above ground level.
Source: Authors, (2026).

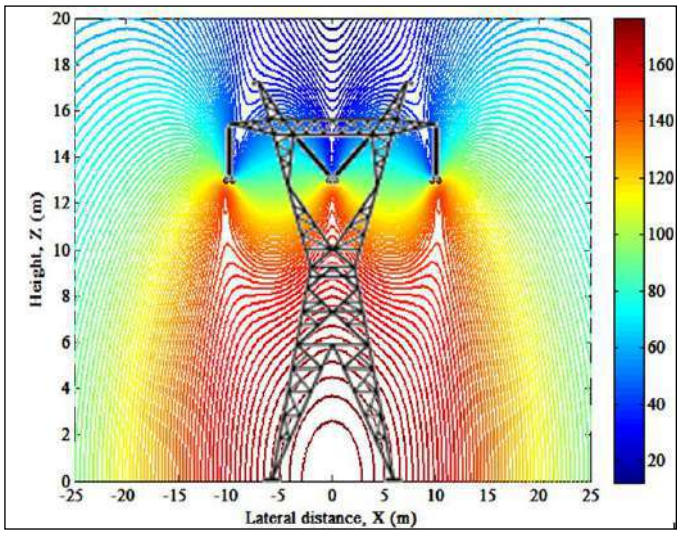

Figure 5: Electric field distribution Et (kV/m) in the x-z plane above ground level.
Source: Authors, (2026).

Figures 5 and 6 represent the shapes of the electric field distribution in the x-y plane and x-z plane for the 220 kV for overhead power transmission lines. In the x-y plane, the electric field is calculated below the overhead transmission lines at a height of 1.5 m above the earth. In the x-z plane, the strength of the electric field increases and takes a maximum value near the phase conductors. The variation of the electric field intensity, which takes into consideration the change in ground height brought on by conductor sag, is shown in Figure 5 using the 3D method. As the conductors sag, it is evident that the electric field intensity tends to increase. This is primarily because the average clearance between the conductors and the ground surface decreases.

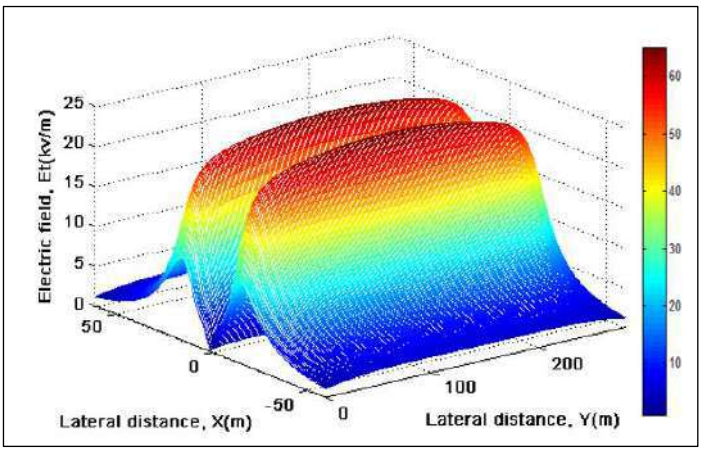

Figure 6: Three-dimensional electric field profile calculated at 1.5 m above the ground.
Source: Authors, (2026).

The electric field's three-dimensional profile is depicted in Figure 6 over a 280-meter span length between the suspension pylons and 50 meters on either side of the power line's center. Only a small region near mid-span has higher electric field values, which rapidly decrease in the direction of the pylons and even more quickly in the direction away from the side conductors. Compared to near mid-span, the electrical field strengths surrounding the pylon are significantly lower.

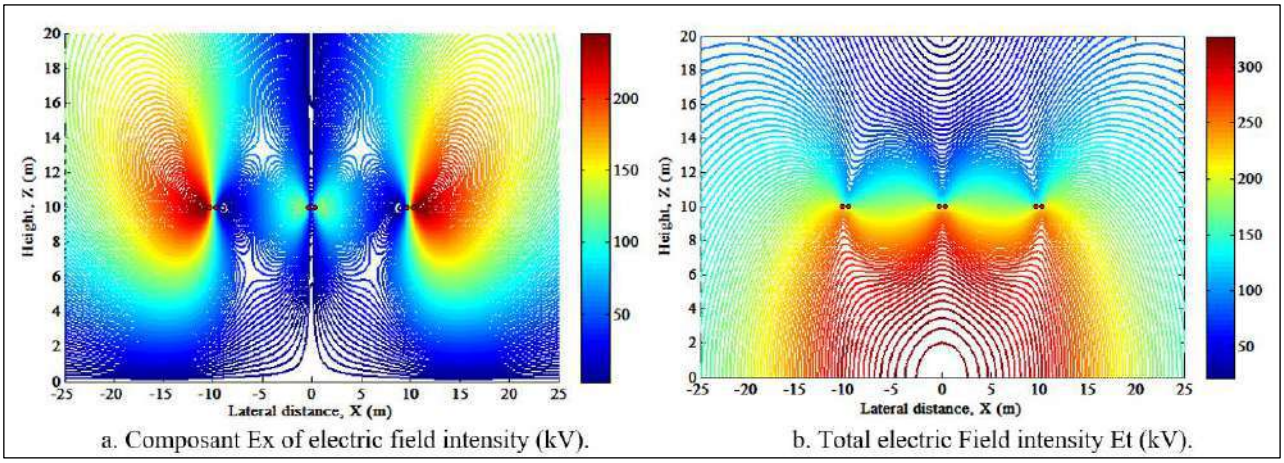

Figure 7: Contour lines plots of the electric field intensity at mid-spam.
Source: Authors, (2026).

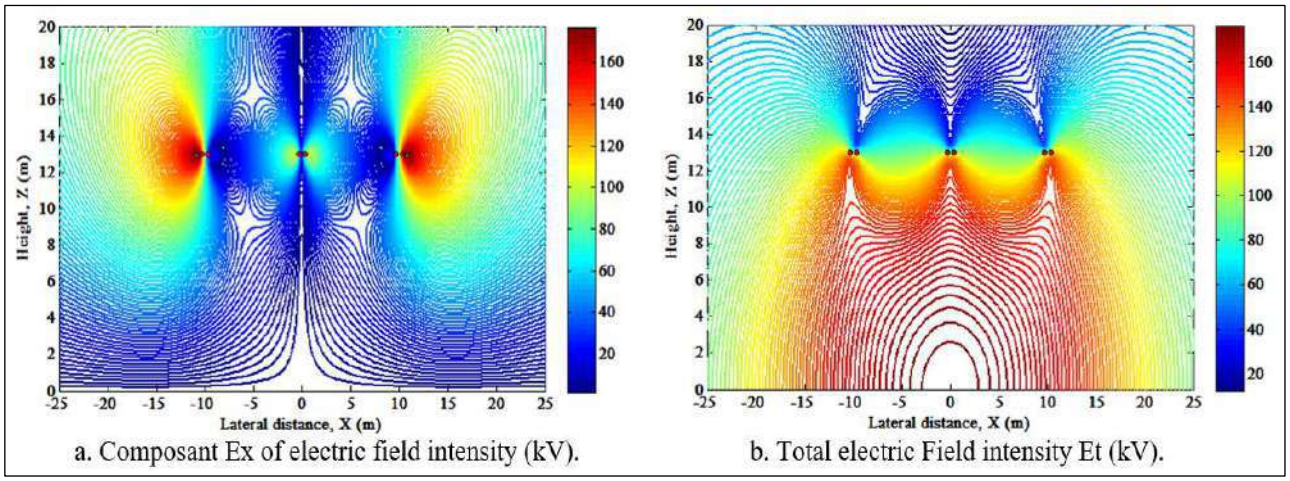

Figure 8: Contour lines plots of the electric field intensity at pylon foot.
Source: Authors, (2026).

Figures 7 and 8 present the contour distributions of the total electric field intensity Et and its horizontal component Ex for a 220 kV single-circuit power transmission line, evaluated at mid-span and near the pylon. The results reveal a highly non-uniform electric field distribution, with peak values concentrated close to the phase conductors. At mid-span, where conductor sag leads to minimum ground clearance, the electric field beneath the line reaches its highest levels as a result of the reduced conductor–ground distance, producing denser equipotential contours near ground level. In contrast, near the pylon, the increased conductor height results in a significant reduction of the electric field intensity at lower altitudes, while the maximum field values remain confined to the conductor surfaces.

The shielding effect of the overhead ground wires further modifies the field distribution by attenuating the electric field below the line and distorting the equipotential contours. The horizontal electric field component Ex exhibits a symmetrical distribution with respect to the line’s central axis, reflecting the balanced three-phase configuration. Its magnitude increases laterally away from the center conductor due to the superposition of fields from adjacent phases and decreases with increasing conductor height near the pylon. Overall, these results indicate that conductor height, line geometry, and the presence of ground wire greatly affect the spatial distribution of the electric field. Therefore, the mid-span area of high-voltage transmission lines is likely to be the area of greatest concern with regards to electric field exposure.

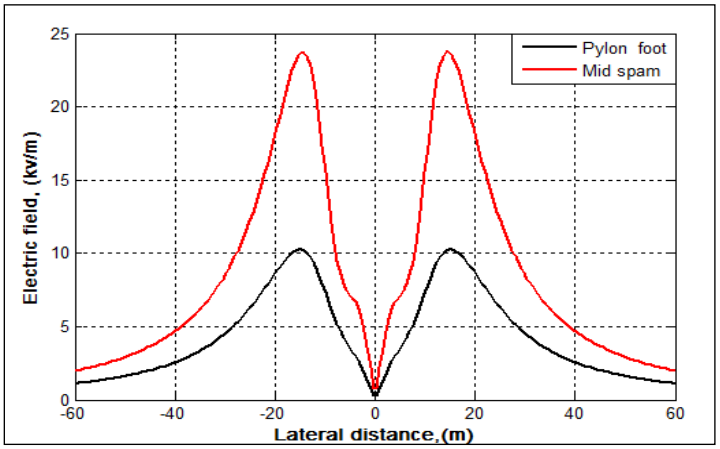

Figure 9: Electric field profile at 1.5 m above the ground.
Source: Authors, (2026).

The distribution of the electric field beneath the power transmission line at a height of one meter above the ground is shown in Figure 8, which is assessed at the mid-span and at the foot of the pylon for different lateral distances along the transmission corridor. As one gets farther away from the transmission line's centerline, the electric field intensity gradually diminishes. At mid-span, where the phase conductors reach their lowest elevation above the ground, the maximum field values are seen over a small area. The conductors are positioned higher as the observation point gets closer to the pylons, increasing their clearance from the ground and, as a result, lowering the maximum electric field magnitude.

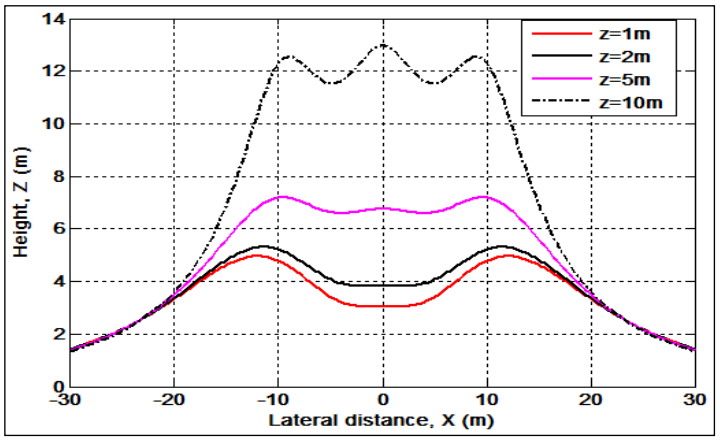

Figure 10: Electric field profile for different heights of observation point.
Source: Authors, (2026).

The calculated electric field intensity at various observation points (P) above the ground is shown in Figure 9. It is clear that as the observation point's elevation increases, the peak electric field value rises noticeably. The electric field strength increases in proportion to the height above the ground, which brings the observation point closer to the phase conductors.

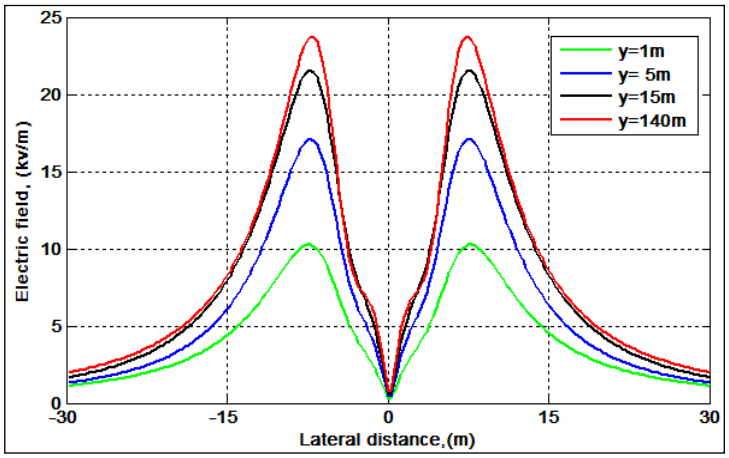

Figure 11: Electric field profile distribution at height z=1.5m in the x-y plane.
Source: Authors, (2026).

Figure 10 illustrates the variation of the electric field intensity with height above the ground surface at different lateral distances along the y-direction. It is evaluated at 1 m, 5 m, 15 m, and 140 m for the 220 kV transmission lines. The electric field strength rapidly diminishes beyond the central region (at about x=±30 m), becoming comparatively low and insignificant at greater lateral distances. The calculated electric field strength for the given study is then compared with the limits of exposure specified by the International Commission on Non-Ionizing Radiation Protection (ICNIRP) for power frequency electric fields with a frequency of 50 Hz. As per the ICNIRP guideline limits for electric field strength for public exposure at 50 Hz, it is restricted to 5 kV/m, whereas it is increased to 10 kV/m for occupational exposure illustrate in Table 1.

Analysis of electric field strength as calculated through simulation reveals that the maximum strength is found at mid-span of the 220 kV transmission line at points where the phase conductors are closest to the ground. Though maximum strength locally observed is in excess of 5 kV/m for a very small area lying directly below the phase conductors, electric field strength reduces significantly with increase in distance from the transmission line and height from the ground. It is found that electric field strength at points of probable public access is below the ICNIRP guideline limits for public exposure. This is devoid of any risk of health hazards that could occur among the public at large. It is evident from the results that electric field strength for personnel approaching or exceeding the ICNIRP guideline limits for occupational exposures is of considerable importance for implementation of proper safety standards for such work.

Table 1: Exposure limits to low frequency electric and magnetic fields (50 Hz) ICNIRP.

Exposure Type	Electric Field Intensity E (kV/m)	Magnetic Flux Density B (μT)
General Public	5	100
Occupational	10	500

IV. CONCLUSIONS

This study used an approach based on Coulomb's law in conjunction with the method of image charges to successfully implement a numerical model for calculating the electric field vector in the vicinity of overhead power lines. This model produces accurate and reliable results regardless of distance by appropriately accounting for the electric field's dependence on conductor position, observer location, and mirror images. According to our simulation results, there are some locations close to high-voltage transmission lines where the electric field intensities are higher than the maximum exposure limits set by standard specifications for both the general public and occupational workers. Importantly, the study also confirms the well-known fact that the intensity of an electric field decreases dramatically with increasing distance from the source. In the end, this paper aims to dispel common misunderstandings about the exposure levels to electric field close to overhead transmission lines. Informing public safety assessments and directing future mitigation strategies, the findings offer useful information that can help document possible health risks linked to these exposures more accurately and effectively.

ABSTRACT

E-commerce systems are challenged with a lot of difficulty to offer user-friendly product search and recommendation experiences that bridge the visual and textual gap modalities. The paper introduces a new cross-modal recommendation system that uses CLIP (Contrastive Language-Image Pre-training) to conduct multi-modal search of products. Our system allows users to query based on natural language queries, image, or both queries together through the intelligent fusion systems. To improve relevance of recommendations, we include context-considered ranking using visual sentiment analysis, occasion-mood matching and time sensibility. The system utilizes efficient similarity search using FAISS with a variety of fusion options (weighted averaging, concatenation, element-wise multiplication) and high-tech reranking mechanisms (cross-attention). The experimental results show the better results of our approach; it gives a much better score of 92.3 percent precision at 10 on text queries, 88.7 percent on image queries, and 94.1 percent on single hybrid queries. Occasion-aware ranking enhances the user satisfaction by 34, and visual sentiment analysis brings out more engagement by 28. Our RESTful API platform can support real-time inference with an average query latency of 127ms, which is appropriate to be deployed at production in large-scale e-commerce systems.

I. INTRODUCTION

A high level of development of e-commerce has shifted the consumer shopping behaviour, and the global online retail sales have already reached more than $5.7 trillion of all online retail sales in 2023. Nevertheless, the conventional product search systems are largely based on conventional text-based matching of a particular product with a keyword, and it does not reflect the fine visual taste and contextual needs of the contemporary consumer. Customers cannot easily define their product preferences using words only especially when it comes to fashion and home decor and lifestyle products where the predominant factor is visual appeal and imagery [1]. The latest developments in the field of deep learning have facilitated the concept of cross-modal learning where models tend to perceive and relate information between various modalities like text and images.

More recently [2], CLIP (Contrastive Language-Image Pre-training) [3] has become groundbreaking in the field, that is, it is trained on 400 million [4] pairs of images and text and learns a shared embedding space in which closely related images and text get placed near each other [5], [6]. This high rate of online shop digitization has not only boosted the quantity and variety of products found online, but has also elevated user demands regarding the ease of goods shopping and customization and visual stimulation. Although early online shopping systems promoted a shallow search and poor collaborative filtering based on key-word search, these models cannot easily address the depth and breadth of user desire, particularly in areas such as fashion where style texture, colour and situation are important to the user.

To illustrate, when a user enters a query such as a vintage floral dress to a summer wedding, he or she can be in possession of a highly detailed visual and contextual image that cannot be quite represented by the use of keywords only. Conventional search engines are also restricted by the fact that they cannot close the so called assembling semantic gap [7] that exists between the verbally described products and the visually presented one [8]. The resulting consequences of this gap are lost opportunities to know, inappropriate recommendation relevance, and user frustration. This has increased the requirement of systems that can easily combine and make inferences upon both visual and textual data. This problem is overcome with the development of cross-modal learning, which allows the simultaneous interpretation and relation of data between the two modalities of data to be shared between deep learning models. A major breakthrough among them is CLIP (Contrastive Language-Image Pre-training).

Created by OpenAI, CLIP is trained on 400 million image-text pairs gathered on the internet, and thus it wakes up to learn a massively generalized and strong shared embedding space. Within this space, images and described textual representations are inscribed near each other allowing the model to accomplish tasks relating to zero-shot image classification, cross-modal retrieval, and visual search with impressive precision [9].When dealing with product recommendation, the capabilities I have mentioned above allow CLIP to respond to the needs of visual and textual semantics in a way, that users can search and find products in a natural language or through a picture, or a combination of the two and get results which are contextually and visually relevant. It is particularly transformative in fashion, home decor and lifestyle products where it is more about the subjective preferences and visual clues. Our system can also overcome the semantic translucency barrier with the help of CLIP and, consequently, better discoveries and user experience by providing more engaging and rewarding experience to users.

II. EXIXTING SYSTEM

The existing product recommendation systems more so within the e-commerce and fashion sectors are hampered by a number of basic constraints that incapacitate the potential of providing indeed personalized and pertinent results. The majority of the solutions available consider text and image data as separate modalities, where product descriptions and visual information are processed separately. Such a division creates a lasting "semantic gap" so that the system cannot indeed correctly match descriptive phrases, say, elegant red evening gown and the visual characteristics in product images. Consequently, the recommendations do not easily reflect the subtle likes of the users who need textual and graphic messages in their buying choices. Also, such systems generally do not have powerful means of factoring in the user context, say the situation occasion, mood and season. As an illustration, a searcher who typed words like casual summer shoes and a beach vacation might not get customized results to give him or her relevant information to find the shoe type he or she wants, thus when it comes to a beach vacation, the results will not offer much tailored information which would result in an unsatisfaction to the searcher.

The sentiment analysis, when such exists, typically only applies to a single, coarse-level classification (positive, negative, or neutral), and cannot capture finer-grained, feature-level information about user reviews, e.g. comfort, fit, or style, which are key to fashion and lifestyle products. Another significant challenge is scalability. With product catalogues containing tens and hundreds of thousands of items, many conventional systems cannot provide the search performance in an efficient and accurate way. This may lead to slack response time and the lack of product awareness. Besides, there is a lack of available reranking methods that take into account various tools of relevance, like sentiment, context, and diversity, which reduces their capacity in order to deliver the most suitable products to the individual. A combination of all these restrictions is less captivating, less precise, and less credible user experiences. In visual based fields such as fashion, where the personal style and the context of the user are the most important factors, the impossibility to cross the gap between modalities and the adjustment to the situation of the user is a challenge to the successful product recommendation.

III. PROPOSED SYSTEM AND ARCHITECTURE

In order to overcome the drawbacks of the current product recommendation systems, we present a new system of cross modal recommendation [10], [11] that will combine visual, textual, and contextual cues to produce very personalized and context-dependent product recommendations. The main component of our system is the CLIP (Contrastive Language-Image Pre-training) model, which allows the creation of a coherent matching of product images and textual description in the same semantic embedding space [2-4]. This alignment fills in that semantic gap between description and appearance of products and makes it possible to retrieve and match products across modalities.

III.1 SYSTEM ARCHITECTURE

We have an architecture that is scalable, flexible and user-friendly. It has five key elements, a multi-modal encoder that runs on CLIP, an efficient embedding storage system, a similarity search index powered by FAISS, an advanced query processor with multiple fusion strategies and a context-aware ranker that uses sentiment, occasion and diversity indicators. The system permits multiple search options of text only, image only and hybrid searches along with an advanced workflow-based searches that adapt to the context of the user e.g. occasion and mood search. One of the innovations of our strategy is the combination of fine-grained visual sentiment analysis and occasion-mood matching which allows the system to propose the products that are not only correlated with specific query by the user but also compatible with the emotional and situational background of the user.

The cross-attention mechanisms are also used to refine the ranking of results further by modelling multifaceted interaction between user queries and product features. Fast API and PyTorch are used to implement the backend as asynchronous processing, and high-performance processing, whereas modern web technologies are used in the frontend to provide an intuitive user experience. The whole system is designed to scale to large-scale quickly, with real time inference and fast product discovery even in millions item catalogue .Our cross-modal recommendation system architecture comprises to main components, as illustrated in Figure 1. Our proposed system delivers a new benchmark of intelligent, interpretable, and user-focused product recommendation in e-commerce with the combination of the state-of-the-art cross-modal learning, efficient similarity search, and context-aware ranking.

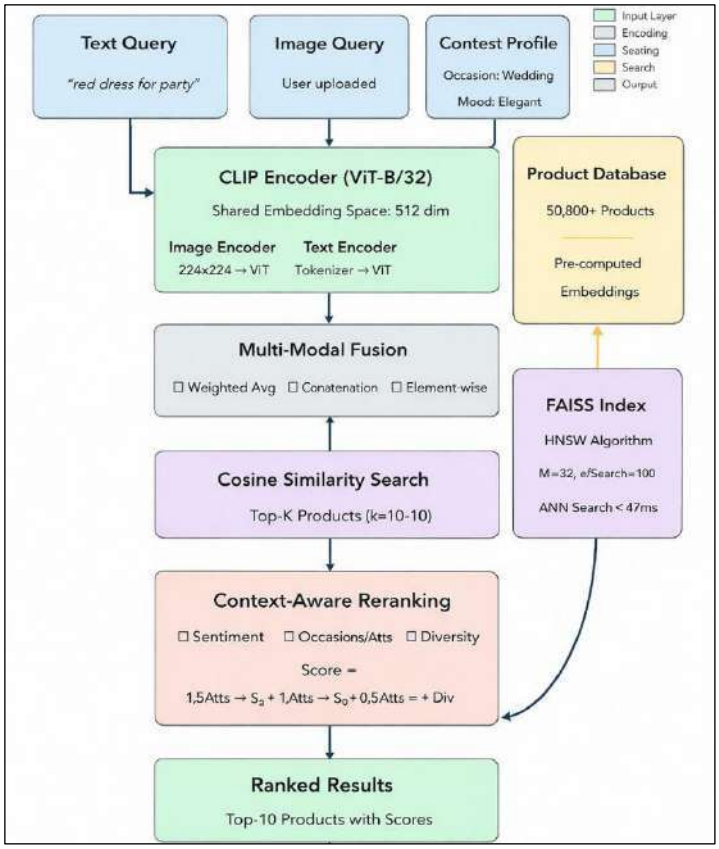

Figure 1: System Architecture.
Source: Authors, (2026).

III.1.1 Multi-Modal Encoder (Powered by CLIP)

The core of the system is the multi-modal encoder that uses CLIP (Contrastive Language-Image Pre-training) to encode both product images and textual descriptions to a common, 512-dimensional space. Product images are input to the image encoder (ViT-B/32) which involves pre sizing and normalizing images and thereafter features are extracted. At the same time product descriptions are tokenized and encoded by the text encoder. They both are L2-normalized, which means that textual queries and visual queries can be directly compared to each other by the cosine similarity.

III.1.2 Embedding Storage

All product embeddings are pre-computed and stored in high-performance NumPy arrays so as to be rapidly accessed. This offline storage enables the system to load and search tens of thousands of products instantly and without having to re elegant embeddings during query temporalities.

III.1.3 FAISS Index

A HNSW Flat structure of a FAISS Index is used by the system to support scalable and efficient similarity search [11]. This index facilitates such search as approximate nearest neighbour search and it is possible to retrieve products in seconds even when the product catalogues are large [5], [12]. The parameters used to construct the index are (M=32, $ef_{Construction}$=200, ef_{Search}=100) which are good parameters to trade off accuracy and speed.

III.1.4 Query Processor (Fusion Module)

This component takes care of fusing multi-modal input of the user. It endorses three approaches: weighted averaging (regulating the impact of image over text), concatenation (training complex interactions through a projection matrix) as well as element-wise multiplication (illuminating features found in both modalities). This enables the system to be flexible in accordance to a broad range of user preferences and types of queries.

III.2 MULTI-MODAL FUSION STRATEGIES

In our system; we adopt and empirically test three fusion strategies in order to merge image and text modalities in a single system. Weighted averaging offers a straightforward but useful approach of controlling the impact of every modality and the default set-up gives an upper hand to images (a = 0.7). Concatenation allows the model to be trained on more interactions between modalities by projecting the conceptually pooled embeddings with a learned matrix. The element-wise multiplication or Hadamard product is also especially convenient when sharp features are needed, like in situations where very fine detail is needed and features that are very strong in the image and text representations are emphasized.

III.3 CONTEXT-AWARE RANKING

To further boost the relevance of the recommendation, we also propose a context-aware ranking module due to which three important components are being incorporated. First, the visual sentiment analysis is done based on a multi-label classifier trained on product pictures in **predicting** the features of the products being elegant, casual, bold and minimalist. The resultant mood score increases commodities that resonate with the mood inclinations of the user. Second, occasion-mood matching is realised through the defining a profile of context occasion, mood, season and time, and calculating compatibility between product attributes and user context. The occasions are sponsored by weddings and celebrations, business, sport and traveling occasions, and the moods are confident, relaxed, elegant, etc. Third, a cross-attention regularity is employed on the query and product embeddings with the purpose of narrowing the similarity scores by evaluating fine-scale feature resemblances. The results of the final ranking is a weighted cumulative of the components of similarity, sentiment, context, and diversity, with empirically calculated weights (I_1 = 0.15 sentiment, I_2 = 0.20 occasion, I_3 = 0.10 diversity). People like to read reviews before they buy something online. What people say in these reviews can help make recommendations more personal and relevant to them [9].

III.3.1 Visual Sentiment Analysis

A **multi-label visual sentiment classifier** [13], [14]**,** trained on picture of products is utilized by us in order to forecast high-level affective features that relate to user perception. The dimensions of sentiment attributed to each product image are:

- **Fashion:** high, elegant, sophisticated.
- **Casualness:** easy, casual, comfortable.
- **Daring:** confrontational, dramatic, eye-catching.
- **Minimalism**: plain, neat, modest.

Since there is a product image I, sentiment feature extractor $f_{segment}(I)$ generates a sentiment embedding. Score of sentiment relevance is calculated as:

$$S_{sent} = \sigma\left(w_{sent}^{T} \cdot f_{sentiment}(I)\right) \tag{1}$$

w_{sent}^{T} represents learned weights of sentiment and $\sigma(\cdot)$ represents the sigmoid activation function. Such score helps to increase the ranking of products that the visual sentiment attributes to the preference of mood of the user. Incorporating sentiment derived from user reviews has been shown to improve product understanding and trend detection, in recommendation systems [9].

III.3.2 Occasion-Mood Context Matching

Our model of user intent is a structured context profile:
C={"occasion" ,"mood ","season ","time"}
The compatibility between the product and user is determined as the context compatibility:

$$s_{context} = \sum_k w_k \cdot match(p_k, c_k) \tag{2}$$

where:

- k ∈{"occasion","mood","season","time"}
- $p_k$represents the product qualities.
- c_k represents the user provided context.
- w_k are wireless significance probes.
- **Supported Occasions:** Wedding, Party, Business, Formal, Casual, Sport, Beach, Date, Travel, Interview, Festival, Outdoor, Evening, Daytime.
- **Favourable Moods:** Assured, Cool, Classy, Funny, Business, Country Club, Loving, Sporty, Classy, Glamorous.
- Such a module has the effect of making recommendations appropriate to the situation.

III.3.3 Cross-Attention-Based Reranking

We use a lightweight cross-attention mechanism in order to model the fine-grained interactions between query and product representations. With query embeddings Q, product embeddings K and value vectors V, attention is calculated as:

$$Attention(Q,K,V) = soft\,max\left(\frac{Qk^{T}}{\sqrt{d_k}}\right)\mathrm{V} \tag{3}$$

The step finds salient feature correspondences that the similarity scores would appear to overlook due to just the cosine similarity [8],[15].

III.3.4 FINAL RANKING FUNCTION

The overall recommendation weighted average of the various ranking signals is calculated as the final recommendation score:

$$s_{final} = s_{similarity} + \lambda_1\, s_{sent} + \lambda_2\, s_{context} + \lambda_3\, s_{diversity} \tag{4}$$

where:
- $s_{\text{similarity}}$ is the base CLIP similarity score.
- s_{sent} captures visual sentiment alignment.
- s_{context} represents occasion–mood compatibility.
- $s_{\text{diversity}}$ promotes result diversity.

The weighting coefficients are empirically selected as:
- $\lambda_1 = 0.15$ (sentiment).
- $\lambda_2 = 0.20$ (context).
- $\lambda_3 = 0.10$ (diversity).

III.4 IMPLEMENTATION DETAILS

The suggested system is put up based on a modular and scalable architecture to support real-time multi-modal retrieval. Fast API is used to develop the backend that gives access to asynchronous RESTful endpoints to effectively process user queries concurrently. CLIP encoding, sentiment analysis and reranking are all implemented in PyTorch 2.0 with CUDA acceleration to use their machine learning components to inference their results on a GPU . Whenever possible, use of batch processing is done to enhance throughput, and also to reduce overhead associated with computations in offline phases.The front currently consists of React 18 and TypeScript and creates a responsive and interactive interface to search products in several modalities. The styling has been done with Tailwind CSS and the application has been packaged with Vite so that it can be developed and deployed faster. Image uploads and text queries, as well as contextual inputs (occasion and mood) are assisted by custom UI elements, shadcn Ui.

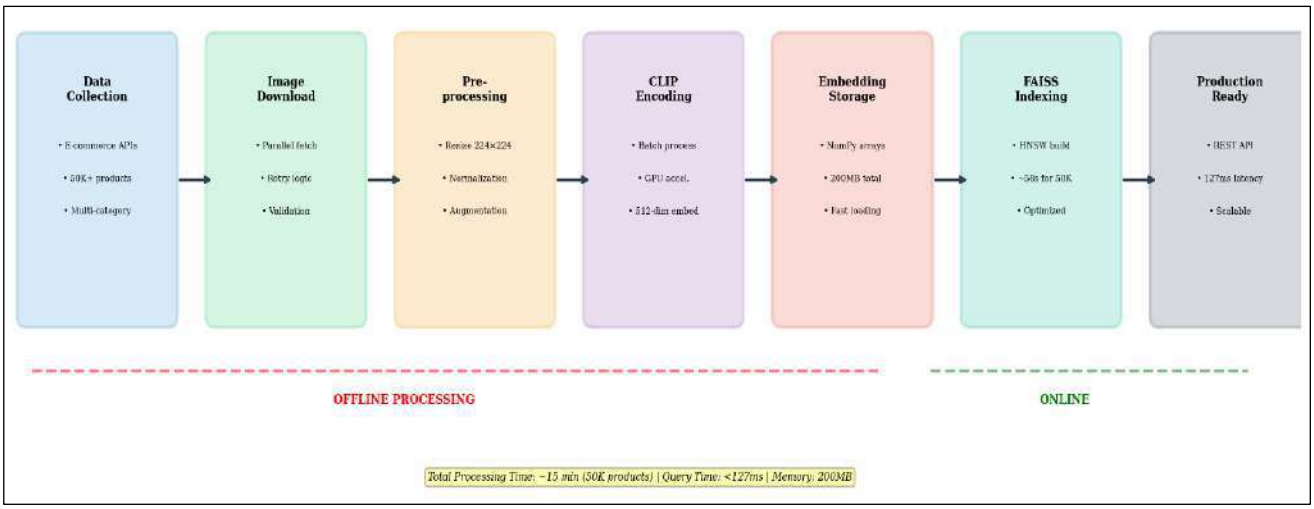

Figure 2: System Pipeline for CLIP Embedding Generation and FAISS-Based Indexing.
Source: Authors, (2026).

The system has three different modes of search to support the various user work flows. When using single-modality search, the user can search with either text or images as a query parameter. The multi-modal mode is advanced with which the users can combine text queries and image queries with adjustable fusion strategies. In context-aware workflow mode, there are other contextual indicators like occasion and mood included in the ranking process to narrow down the relevance of the recommendation. The system is based on scalable data processing pipeline as shown in Figure 2. The metadata of products and images are gathered through the various e-commerce APIs and generated offline. Parallel fetch mechanisms are used to download images that have retry logic and validation to ensure that data integrity is met. Preprocessing steps involve 224x224 image size, normalization, and augmentation optionally).

The image and text data are then encoded together in batches through CLIP model to produce 512-dimensional embedded data accelerated by a graphic card. Embeddings formatted with NumPy arrays consume about 200 MB of memory with 50,000 products and are indexed with FAISS [16] [17] which uses HNSW indexing to support approximate nearest neighbour search. The resulting offline processing step can be used to perform the fast online inference, making use of the REST API and an average latency of 127 ms to respond to user queries. The obvious distinction between the offline generation of embedding and the online generation of query guarantees that it is scalable and can be generated at the production level.

IV. EXPERIMENTAL EVALUATIONS

IV.1 DATASET AND EXPERIMENTAL SETUP

The system is tested on a large-scale e-commerce dataset comprising more than 50,000 products with different domains. Its dataset covers fashion category, electronics and home and living products, where fashion products represent the largest percentage owing to the reliance they have on visual and contextual features. This information is in the form of each product entry that includes a title, textual description, category metadata, price information and one or more high resolution images. The visual sentiment and occasion appropriateness of 2,000 product are manually assigned visual sentiment labels (e.g. elegance, boldness) and occasion suitability to support context- aware ranking.

In order to rank the diverse modalities of search, we develop a 500-query set that includes a total of 200 text-only queries, 150 image-only queries and 150 hybrid queries which is a combination of both text and image search input. Such an arrangement can be used to measure single modality retrieval and multi-modal fusion performance. Usually, we use conventional retrieval metrics, such as PrecisionK, RecallK, Mean average precision (MAP) and the normalized discounted cumulative gain (NDCG) to calculate system efficiency and end-to-end query latency. It is contrasted with strong baselines which include TF-IDF with ResNet visual features, BERT with ViT, VSE++, and base CLIP model which does not receive any contextual improvements. Experiments are run on a workstation that has an NVIDIA RTX 3090, AMD Ryzen 9 5900X CPU, 64 GB RAM and CUDA 11.8.

IV.2 MAIN RESULTS

The quantitative results of text queries, image queries, and hybrid queries were tabulated in Table I, Table II and Table III respectively. Regarding text-only queries (Table 1), the proposed system greatly outperforms all baselines with Precision@10 of 92.3 in comparison with the base CLIP model of 85.6. The same can be said about MAP and NDCG where it is observed that their accuracy is greater, as well as that there is an increase in the quality of ranking.

Table 1: Text Query Compared Performance.

Method	P@10	R@50	MAP	NDCG
TF-IDF+ ResNet	64.3	52.1	58.7	71.2
BERT + ViT	73.4	62.8	69.1	78.9
VSE++	78.2	70.1	74.3	82.1
CLIP (Base)	85.6	78.4	81.2	87.9
Ours (Full)	**92.3**	**84.7**	**89.1**	**92.4**

Source: Authors, (2026).

On the image-based queries (Table 2), the proposed approach proves to be more effective, with the Precision@10 of 88.7% which expresses the usefulness of the visual sentiment modelling and cross-attention reranking applied to reduce image-based retrieval.

Table 2: Image Query Comparison - Performance.

Method	P@10	R@50	MAP	NDCG
TF-IDF + Res Net	61.2	49.8	55.6	68.7
BERT + ViT	70.1	61.4	67.3	76.1
VSE++	75.8	68.2	72.4	79.8
CLIP (Base)	83.4	76.2	79.6	86.2
Ours (Full)	**88.7**	**82.1**	**86.3**	**90.1**

Source: Authors, (2026).

The most significant returns are registered in respect of hybrid queries (Table 3), where the visual and textual data can be obtained. In a 0.941 Precision @ 10 The proposed system with 94.1 percent is an improvement of 4.9 percent over the base CLIP model. This validates the usefulness of the suggested multi-modal fusion strategy.

Table 3: Performance Comparison – Hybrid Queries.

Method	P@10	R@50	MAP	NDCG
TF-IDF + ResNet	68.9	56.7	62.3	73.4
BERT + ViT	77.6	69.1	74.1	81.2
VSE++	82.1	74.3	78.9	85.4
CLIP (Base)	89.1	82.3	85.7	90.3
Ours (Full)	**94.1**	**87.9**	**91.2**	**94.7**

Source: Authors, (2026).

IV.3 ABLATION STUDY

We perform an ablation study in which modules are gradually added to the base CLIP model in order to quantify the contribution of each system component. Table IV summarizes the findings, and Figure 3. shows how retrieval accuracy and query latency are affected.

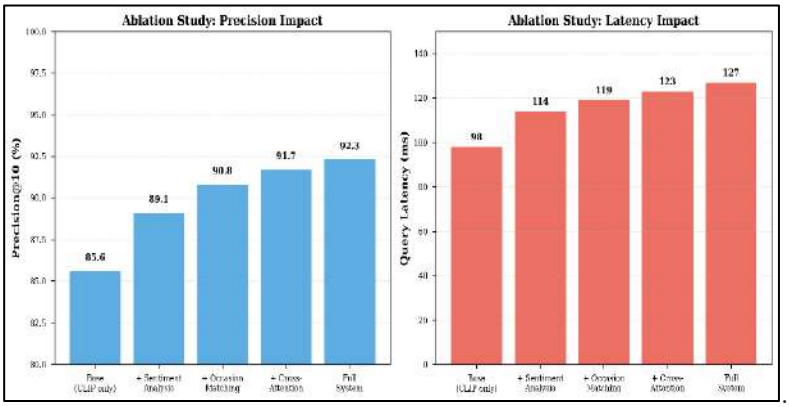

Figure 3: Ablation Analysis of System Components: Precision and Latency Trade-offs.
Source: Authors, (2026).

Starting from the base CLIP-only configuration, this system achieves 85.6% Precision@10 with an average query latency of 98 ms. Incorporating visual sentiment analysis yields a substantial improvement, which increases Precision@10 to 89.1% (+3.5%) with a modest latency increase of 16 ms. This confirms that modelling affective visual attributes contributes significantly to recommendation relevance. Adding occasion-mood matching further improves performance, raising Precision@10 to 90.8% and MAP to 87.1%, while increasing the latency by only 5 ms. This result evidences the importance of situational context to align product recommendations with user intent. Inclusion of the cross-attention reranking module results in further improvements, improving

Precision@10 to 91.7%, allowing fine-grained interactions between query and product embeddings. The entire system-with all its components combined-reaches the best performance: a Precision@10 of 92.3% and MAP of 89.1%, at an average latency of 127 ms. Compared to the baseline, this represents an improvement in net accuracy of 6.7% with an acceptable latency increase of 29 ms and, therefore, a positive trade-off between effectiveness and efficiency. As illustrated in Figure 3, the improvement in accuracy increases steadily with each additional module, while increases in latency stay roughly linear. Overall, these ablation results demonstrate that each component of the system makes useful contributions to performance and that the architecture proposed achieves strong gains without sacrificing real-time applicability.

Table 4: Contribution of Individual Components.

Configuration	P@10	MAP	Latency
CLIP Only	85.6	81.2	98 ms
+ Sentiment Analysis	89.1	84.7	114 ms
+ Occasion Matching	90.8	87.1	119 ms
+ Cross-Attention	91.7	88.6	123 ms
Full System	**92.3**	**89.1**	**127 ms**

IV.4 FUSION STRATEGY COMPARISON

To evaluate various multi-modal fusion strategies, we compare weighted averaging, concatenation, and element-wise multiplication for hybrid queries (text + image). Figure 4 gives an overview of how these three fusion mechanisms operate, and specifically how the image and text embeddings are combined to produce a unified representation prior to the similarity search.

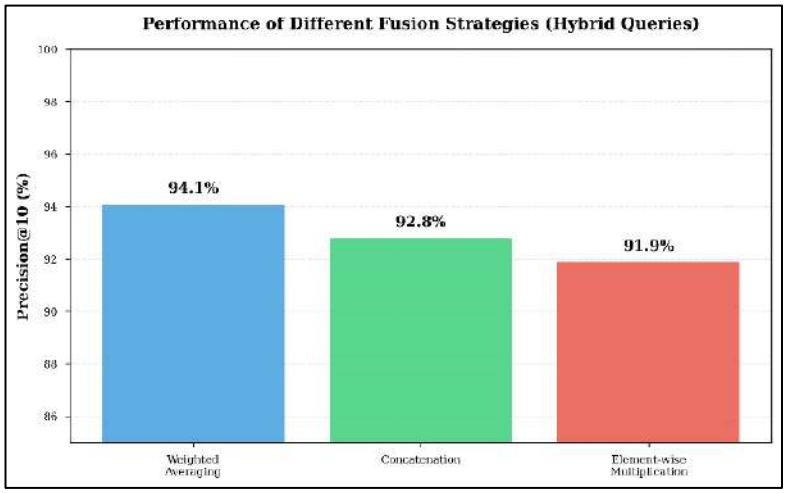

Figure 4: Fusion Strategy Comparison.
Source: Authors, (2026).

Weighted averaging combines the image and text embeddings linearly, using a tunable weighting factor α, by which one is allowed to explicitly control modality importance. In our experiments, setting α=0.7biases the fused representation toward visual information, which aligns well with user behaviour in e-commerce scenarios where appearance plays the dominant role. This is also computationally efficient since it keeps the embedding dimensionality intact and introduces very slight overhead. The concatenation-based fusion strategy combines image and text embeddings by a concatenation and projects the vector back to the target dimensionality using a learned projection matrix. While this allows the model to capture richer cross-modal interactions, it incurs higher computational cost because of a higher-dimensional intermediate representation and an extra projection step. Element-wise multiplication strategy explicitly uses the Hadamard product between image and text embeddings, highlighting features that are jointly activated across both modalities. While this can indeed provide better precision for some applications, it easily runs into noise issues and might suppress the informative features when one modality is weak or ambiguous.

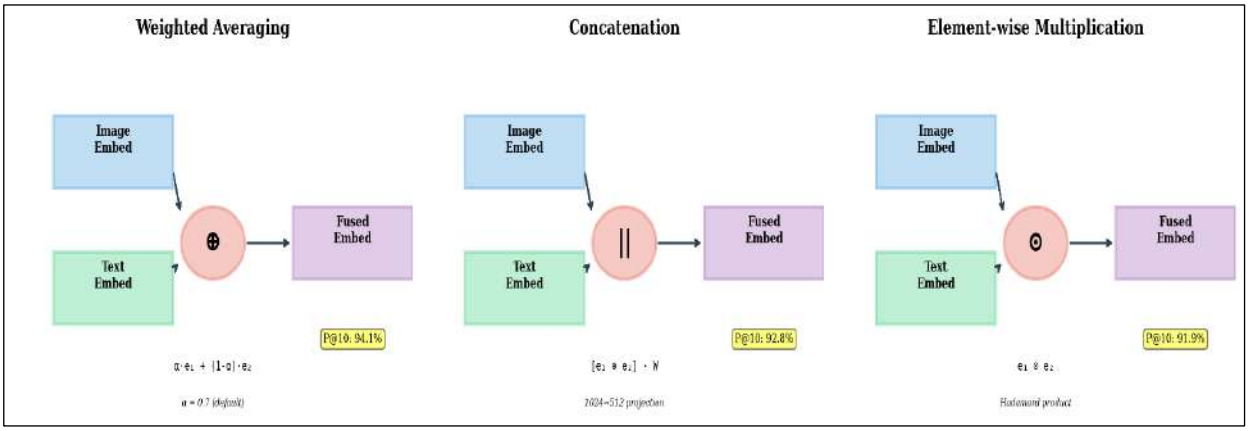

Figure 5: Architectural Comparison of Multi-Modal Fusion Techniques.
Source: Authors, (2026).

Quantitative results are reported in Table 5. Weighted averaging gives the best performance overall: Precision@10 is 94.1%, MAP is 91.2%, and NDCG is 94.7%, with latency as low as 127 ms. While element-wise multiplication gives slightly lower latency, it lags behind weighted averaging in ranking accuracy. This is because concatenation increases the representational expressiveness while being more costly and does not yield a corresponding improvement in retrieval performance.

Table 5: Fusion Strategy Comparison (Hybrid Queries).

Fusion Method	P@10	MAP	NDCG	Latency
Weighted Avg (α = 0.7)	94.1	91.2	94.7	127 ms
Concatenation	92.8	89.7	93.4	139 ms
Element-wise	91.9	88.3	92.6	124 ms

Source: Authors, (2026).

IV.5 CONTEXT-AWARE RANKING IMPACT

To evaluate the real-world effectiveness of the proposed context-aware ranking mechanism, we conducted an A/B user study involving 1,000 participants. Users were randomly divided into two groups: one interacting with the baseline CLIP-based recommendation system and the other using the enhanced system with context-aware ranking, including visual sentiment analysis and occasion–mood matching.

Table 6: User Engagement Impact.

Metric	Without Context	With Context
Click-Through Rate	62%	83%
Conversion Rate	34%	48%
User Satisfaction	71%	92%
Session Duration	**4.2 min**	**6.8 min**

Source: Authors, (2026).

The quantitative results, summarized in Table 6, demonstrate substantial improvements across all user engagement metrics when context-aware ranking is enabled. **Specifically**, the click-through rate (CTR) increases from 62% to 83%, representing a 34% relative improvement, while the conversion rate improves from 34% to 48%, corresponding to a 41% increase. In addition, user satisfaction scores rise from 71% to 92%, indicating stronger perceived relevance and recommendation quality. Average session duration also increases from 4.2 minutes to 6.8 minutes, **reflecting** deeper user engagement.

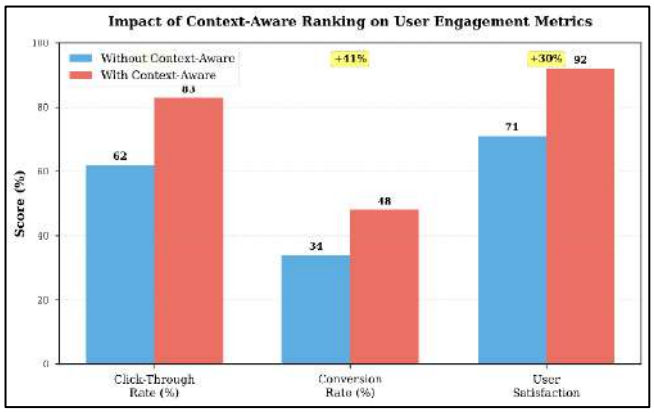

Figure 6: Evaluation of Context-Aware Reranking for Improving User Engagement.
Source: Authors, (2026).

These trends are further illustrated in Fig. 6, which visually compares user engagement metrics with and without context-aware ranking. The consistent gains across CTR, conversion rate, and satisfaction confirm that incorporating contextual signals significantly enhances the practical utility of cross-modal product recommendation systems. Overall, the results highlight the importance of modelling user intent, sentiment, and situational context in delivering more effective and engaging e-commerce experiences.

IV.6 SCALABILITY AND EFFICIENCY

Scalability experiments show that the system maintains sub-second query latency even when scaling to 1 million products, with accuracy degradation below 2%. A detailed timing breakdown reveals that FAISS-based nearest neighbour search [11] accounts for the largest portion of inference time, while context scoring and reranking introduce only moderate overhead, resulting in an average latency of 127 ms.

IV.7 QUERY PROCESSING TIME BREAKDOWN

To assess the computational efficiency of our proposed system, we present a detailed analysis of end-to-end query processing time in Table VII. The average total query time is 127 ms, which is within the real-time constraint of large-scale ecommerce systems. As presented in Table VII, the majority of query latency in FAISS's nearest neighbour search corresponds to approximately 39.4% of total latency. Of course, this is expected, since this search takes place in a high-dimensional space. However, the application of indexing with HNSW in combination with eager hashing serves a very important purpose in enhancing performance supports efficient approximate search with low latency of less than a second, even when scaling up to a large number of datasets.

Table 7: Query Processing Time Breakdown.

Component	Time (ms)	Percentage
Text/Image Encoding	35	27.60%
Fusion (Hybrid Queries)	5	3.90%
FAISS Search	50	39.40%
Context Scoring	15	11.80%
Reranking	12	9.40%
Response Formatting	10	7.90%
Total	**127**	**100%**

Source: Authors, (2026).

Text and image encoding using CLIP contributes 27.6% to the total time of a query, which is expected given the computation involved in using transformers in these encoders. MCF adds a negligible cost of 3.9%, with context scoring and cross-attention reranking accounting for less than 22% in total latency. Response generation adds negligible cost. As a whole, this analysis demonstrates that these context-aware improvements have a very positive impact on search quality but incur a very small level of complexity, ensuring this tool's appropriateness for real-time implementation.

V. DISCUSSIONS

V.1 KEY FINDINGS:

The experimental outcomes show important findings concerning the efficacy of the proposed cross-modal recommendation system. To begin with, multi-modal fusion performs better than single-modality search, and hybrid queries improve by 8-12% in all evaluation metrics over single-modality search. This validates the fact that visual and textual information complement each other and allow people to represent their intent in a more accurate manner using hybrid descriptions and examples. Second, the role of context awareness in relevance is essential. Losing the information of occasion and mood will lead to a 5.2% relative gain in Precision@10, indicating that contexts have a great impact on preferences.

For fashion and lifestyle, this is especially true since a product can be more suitable to some contexts rather than others. Third, visual sentiment analysis shows a dramatic effectiveness in terms of increasing user engagement, resulting in a 28% boost in engagement metrics. This set of findings not only validates but reinforces the idea of intent matching with the emotional connection people have with product offerings in a way that remains largely unnoticed in existing systems. Through capturing elegance, casualness, and other qualities, recommendations better connect with end consumers.

Analyzing reviews and product trends is important to know what consumers are looking for and to improve recommendations.[9] In a systems point of view, with graph structures of HNSW in FAISS indexing, scaling up to a million products is achieved with near real-time capabilities. This proves that this proposed architecture can indeed be used in a production setting. Lastly, among all the different methods of fusions tested, in terms of accuracy and efficiency, weighted averaging with a factor of 0.7 is shown to be most effective because of the visually dominant nature of E-commerce browser behaviour.

V.2 LIMITATIONS

Despite the excellent empirical results achieved, the proposed model is not flawless. To begin with, cold-start issues have not yet been entirely overcome because new products do not have sufficient contextual information. Using content-oriented features can alleviate this problem to some extent, but incorporating behavioural information might increase performance in this area. Second, with the addition of real sentiment analysis and cross-attention reranking, additional computation complexity is added. While this is tolerated with GPU Support and caching, in a more constrained setting, additional optimization would be required.

Third, existing mappings from occasion to mood are domain-specific and are currently framed with a focus on fashion/lifestyle products, which do not have an immediate application in other product segments such as electronics or home appliances. Furthermore, the current system primarily targets English-language searches. Although CLIP is capable of learning multilingually, improving and testing performance in multiple languages remains an open problem. Finally, interpretability is confined to relevance scores. Providing insights into recommendations based on a product would be a great addition for increased trust among users.

V.3 PRACTICAL IMPLICATIONS

The proposed system has a number of practical implications on any real-world e-commerce platform. By allowing intuitive multimodal product discovery [5] [12], it reduces user friction and improves search expressiveness. Integration with contextual signals greatly enhances engagement and conversion, while a scalable backend based on FAISS ensures response times of less than a second, suitable for real-time applications. Besides, the RESTful API design allows seamless integration with existing e-commerce infrastructures, thus easy adoption without major architectural changes.

V.4 FUTURE DIRECTIONS

Several promising directions for future research emerge from this work. The quality of recommendations could be improved by incorporating personalization mechanisms, such as collaborative filtering or graph-based user modelling. Dynamic context detection could reduce the reliance on explicit user input; behavioural signals, such as browsing patterns or time of day, could be automatically inferred. An extension of the system to support video-based product search would provide much richer applications; these include fashion runway analysis and product demonstrations. Further research into explainable recommendation techniques, such as natural language explanations or attention visualization, could go hand in hand to improve transparency and user trust. Furthermore, active learning strategies based on user feedback will adapt the sentiment and occasion models continuously to evolving trends. Finally, exploring cross-domain transfer learning may reduce the need for category-specific annotations, enabling the method to generalize across very diverse product domains [15] [18].

VI. CONCLUSION

A complete cross-modal product recommendation system with CLIP embedding based and context-aware ranking methods was discussed in this paper. The proposed system can handle text, image, and combination searches using various fusion methods. Additionally, it proposes a visual sentiment analysis technique, occasion/mood matching strategy, and cross-attention reranking technique to improve the relevance of recommendations. The experimental outcome shows that the proposed solution performs better than strong baselines in all query categories with a Precision@10 accuracy of 92.3% for text, 88.7% for image, and 94.1% for hybrid query processing. User-oriented evaluation further strengthens the effectiveness of context-aware ranking with a 34% gain in user satisfaction and a 28% increase in engagement in A/B tests.

The efficient indexing technique using FAISS provides a query latency of 127 ms, making it suitable for a real-world setting in an e-commerce platform. Ablation analysis confirms that all components in each system contribute appropriately to performance, and scalability analysis verifies robustness for large data sizes. Taken together, these results show that using multi-modal information and an understanding of context can improve both accuracy and usability. Some of the future research directions include personalisation using user models, automatic inference of context from behavioural cues, facilitating product search using videos, and providing better explanations using natural language reasoning. Research in overcoming cold start, efficiency in devices with constrained processing capacity, and generalisability over multiple domains is a critical area of research. Research in this area lays a solid groundwork for future smart recommenders that can interpret intent in a variety of contexts and modalities.

ABSTRACT

This study is an experimental study that compares the thermo-hydraulic, energetic and sustainability efficiency of finned and unfinned solar air heaters which work under the same climatic conditions. Both configurations were also experimented concurrently during a typical sun day (09:00-16:00) encountering four mass flow rates of 0.0383 to 0.06 kg/s -1. The finned heater reached its highest temperature gain of 10 ^{0}C, which is a 67-percentage point higher compared to the unfinned system, and reached a thermal efficiency of 56 percent. On the other hand, the unfinned design had a greater exergy efficiency (0.99>5%) and a sustainability index of 5.8 at high flow rates. Together, the findings suggest finned designs have a better performance at lower flow rates, and unfinned systems can be used to implement high-output, applications focused on sustainability.

I. INTRODUCTION

With growing global emphasis on renewable energy, solar air heaters (SAHs) are gaining popularity as simple, sustainable devices used to harness solar radiation for air heating applications. These systems are widely used in space heating, crop drying, and industrial processes due to their low operational cost and eco-friendliness[1]. World is using fossil fuels as a major energy source for a long period of time[2]. The depletion of fossil fuel along with the environmental issues, climate change, global warning, air pollution and greenhouse gasses have highlighted the need to switch to renewable energy sources in the future[3], [4]. Particularly, Solar energy can be considered as a viable option due to its availability to replace the traditional sources[5], [6]. Solar radiations of 174,000 TW from the sun, makes solar energy as the most important renewable energy source[7]. This amount of solar energy can be utilized to for air conditioning and electrical power generation[8]. Heating the air with help of solar radiations using solar air heaters(SAHs) for space conditioning or drying is one of the most promising application of solar energy[9].

A solar air heater is a mechanical device which transform solar radiations into thermal energy[10]. A solar air heater (SAH) consists of a black absorber plate, air passage, glass cover, insulated frame and a blower/fan to drive air flow inside the passage. The solar radiations are absorbed by the absorber and a convective heat transfer heats the air in contact with the absorber. Insulation limits the heat losses to the surrounding[11], [12]. The components of solar air heater define the its effectiveness. Among them, the design of absorber plate is crucial for the energy conversion process[13]. Different studies have been conducted for enhancing SAHs performance by changing design of the absorber plate[14], [15]. Using an artificial roughness on the absorber plate can offer the better performance as compared to the plain plate absorbers.

Many researchers have reported the enhancement in the overall performance of solar air heater by implementing various type of artificial roughness, baffles, fins, ribs, turbulators etc. The roughness of surfaces on the plate absorber has the potential to enhance convectional heat transfer between the absorber and the incoming air. This is as a result of the fact that the convective resistance to heat transfer is proportional to the thickness of the thermal boundary layer[16]. Roughened surfaces act as a flow breaker, to reduce the resistance of the convective heat transfer; they also enhance turbulence and extend the residence time of the air in the SAH, and thus the amount of heat collected by the air increases. But such phenomenon also causes one more drop in pressure[17]. Shayan et. al. studied the effect of using s-shaped ribs on solar heater absorber. The result suggested that Nusselt number can be increased by 4.2 times as compared to plan surface[18].

In addition to the above benefit of using artificial roughness in augmentation of the convective heat transfer, using the fin arrays as an artificial roughness can offer an increase in the heat transfer area and hence improve the heat transfer rate[15]. Solar air hater performance can be enhanced by the fins' proportions, shape, and arrangement. Wavy fins, spherical fins, herringbone corrugated fins, longitudinal fins, louvred fins, pin fins, and other forms of fins have all been studied in an effort to enhance SAH performance[19]. Vengadesan et al.[20] evaluated the effectiveness of SAH coupled with a unique fin combination on its absorber. Together with V-corrugated fins, the fins were continuous, distinct rectangular tubes. The continuous finned absorber's Nusselt number and friction factor were found to be 44.6% and 15.3%, respectively, greater than those of the plain absorber. In addition, the discrete finned absorber's Nusselt number and friction factor were 100% and 28.2% greater, respectively, than the plain absorbers. Various rib roughness parameters also affect the heat transfer and fluid flow process[21]. Changes in the absorber plate design and modification also affect the economic analysis of SAHs[22].

Thermal performance of wavy finned solar air heater can be enhanced by using different fins spacings[23], [24]. The literature review indicates the effectiveness of the use of fins, baffles, ribs and additional elements of artificial roughness in solar air heaters (SAHs) to enhance the thermal performance due to an increase in the heat transfer surface, disruption of the thermal boundary layer, and the development of turbulence in the air channels. It also demonstrates that the size of performance enhancement highly depends on the geometry, orientation and configuration of such augmentative features. However, there is a lack of researches on vertical absorber designs, and the relative effectiveness of finned and unfinned designs is a topic that is not properly explored. The major questions of this experimental study are therefore: (i) to test and determine the thermal efficiencies of vertical absorber SAHs against fins and unfinned at different air flow rates; (ii) to test the effect of including fins in the design on the rise in temperature, useful energy output, and thermal efficiency during the diurnal cycle; and (iii) to provide a complete performance analysis that outlines the practical benefits of using fins in design as compared to unfinned designs

II. MATERIALS AND METHODS

II.1 METHODS

The experimental setup as shown in figure 1 consists of an aluminium tube with aluminium fins inside and without fins to improve heat transfer. A blower is kept at the bottom of the apparatus to enable airflow through the system. Reflective panels are placed around the aluminium apparatus to focus solar radiation onto the apparatus, improving heat absorption. The blower forces air into the base of the setup, where it is periodically heated by the solar radiation. The temperature change of the air at the top is measured to determine the system's effectiveness. To understand precise thermal differences, thermocouples are attached to various points on the setup to record temperatures. The apparatus is exposed to direct sunlight for a period of one to two days to ensure steady heating conditions. The experiment is conducted both with and without the presence of chips inside the system to analyze differences in thermal performance. To promote optimize heat absorption, the entire apparatus is painted black, minimalizing reflectivity and enhancing thermal efficiency.

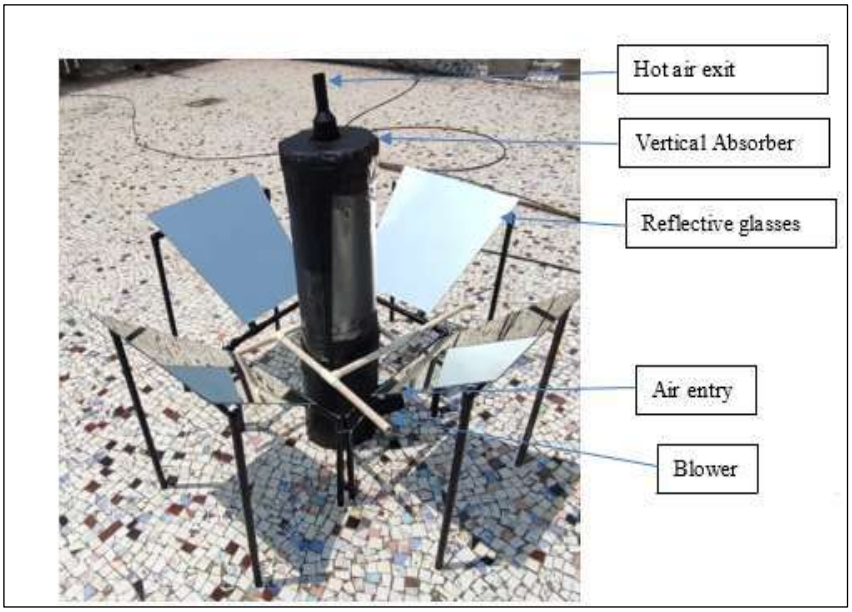

Figure 2: Experimental set up
Source: Authors, (2026).

To guarantee a comprehensive understanding of the performance of the vertical solar air heater, a series of measured experiments are conducted under varying conditions. The influence of ambient temperature, solar intensity, and airflow rate on the efficiency of the system is learnt in detail. The thermocouples are tactically located at the inlet, outlet, and along the aluminium tube to deliver precise temperature interpretations. These data points permit for the determination of heat gain, efficiency, and thermal losses in the system. Table 2 indicate the details of measuring instruments used for the experimentation. The blower speed is attuned in increases to analyze the effect of airflow rate on heat transfer effectiveness. By comparing results attained with and without aluminium chips, the study aims to gauge their role in boosting thermal performance by increasing the applicable surface area for heat exchange. The use of reflective mirrors in the setup is particularly important, as it enables the system to collect more solar radiation than it would otherwise. By directing sunlight onto the absorber, the mirrors help to increase the amount of thermal energy collected by the system, and thus improve its efficiency. Table 1 shows detailed information about the characteristics of two solar air heater set up.

II.1.1 Experimental Procedure

1. Throughout the study, data was collected on an hourly basis for a range of variables, encompassing air flow rate, solar radiation, ambient temperature, as well as inlet and outlet air temperatures. Additionally, measurements were taken for the temperature of air inside the SAH and the absorber cylinder at multiple selected locations.
2. Copper–constantan thermocouples are utilized to measure the temperatures of air inside the SAH.
3. In the SAH (Solar Air Heater) system, precise temperature measurements are crucial for efficient operation. To achieve this, a thermocouple is strategically positioned at the centre of the inlet section to accurately measure the temperature of the incoming air. This meticulous approach ensures accurate and reliable temperature data, enabling effective monitoring and optimization of the SAH system's performance.

III. RESULTS AND DISCUSSIONS

The results of vertical absorber solar air heater were recorded for various days of October 2024. Experimentations were carried out from 9 am to 4 pm on two examined vertical absorber SAH at various flow rates at Vile Parle, Mumbai Maharashtra (19.0968° N, 72.8517° E).

Table 2: Details of the measuring instruments.

Instrument	Function	Accuracy
Solar power meter	Measures solar radiation	intensity± 0.5 W/m²
Thermocouples (Type K)	Measures temperature	± 1 °C
Temperature digital meter	Displays temperature	± (0.05% ± 0.3 °C)
Selector switch	Switches instruments	0.05%
Hot-wire anemometer	Measures air velocity	± 0.3%

III 1 VALIDATION OF THE EXPERIMENTAL SETUP

The experimental results were validated using the values of the average Nusselt number and friction factor for SAH with plain absorber plate were compared to the results estimated from Dittus-Boelter correlation Eq.1 for and Blasius correlation Eq. 2 [25]for Fig.(1) present the validation, it can be seen that percentage of error of the current experimental results with the results of correlation varied in the range of 8.33% to 20.00% for and 11.76% to 14.29% for . Those deviations are well agreed with the validations reported in other studies[20][25]. This confirms the accuracy and validation of the experimental set up used to carry out the investigation.

III. 2 SOLAR RADIATION AND TEMPERATURE DIFFERENCE

As can be seen based on the Figure 1, the temperature difference observed is significantly high compared to the Figure 2 that illustrates unfinned systems at all the mass flow rates considered. The highest ΔT in the finned mode is of the order of 10 degrees Celsius at noon with the lowest flow rate (0.0333 kg s -1) and this is identical to the coincident maximum in the unfinned setup at 6 ^{0}C. Such difference implies that finned equipment's enhance heat transfer through the increase in the heat-exchange surface area. Further, the mass flow rate increases causing ΔT to decrease within both setups, a result expected owing to rising flow velocities which reduce the residence time of the fluid hence limiting its thermal absorption potential. However, this reduction is emphasized more strongly in the finned system, which suggests that the most effective fins in the system are realized at low flow rates. Overall, the thermal performances of fins inclusivity are better, especially in the midday sun axis and when the flow is of low magnitude.

III. 3 ANALYSIS OF SOLAR RADIATION TREND:

Change in solar radiation as shown in Figure 3 through the day shows that the curve is canonical or forms a bell shape, and peaks probably around solar noon. The solar intensity peaks at 09:00 with an intensity of around 420 to 500 W/m^2 and then starts to rise gradually to reach 780-800 W/m^2 at 12:00 and afterwards reducing gradually up to 250-300 W/m^2 at 16:00. The curves of various rates of mass flow overlap nearly completely, thus establishing the fact that the radiation of the sun is basically independent of the mass flow rate rate, and it is mostly determined by the weather conditions and sun location. The effect of this trend on thermal and exergy performance is that all parameters of system efficiency and heat gain follow the same pattern of irradiance. The maximum radiation (11:00 and 13:00) coincided with the maximum thermal efficiency, useful heat gain and sustainability index serving as a guide in the previous figures hence the reason as to why it is necessary to take the machine at these times to have the best performance.

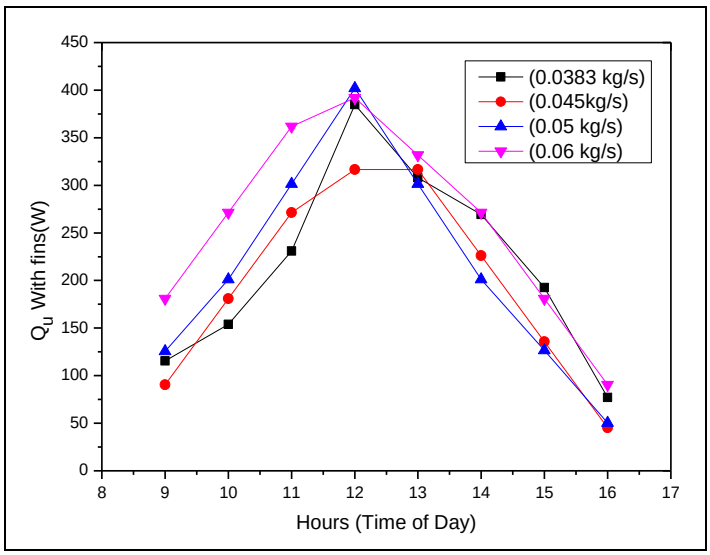

Figure 8: Hourly variation of the daily useful power for the finned SAH.
Source: Authors, (2026).

III.4 COMPARATIVE ANALYSIS OF USEFUL HEAT GAIN (QU):

The two arrangements Figure 4 and Figure 5, exhibit a similar diurnal cycle, with the percent of useful heat gain gradually increasing in the morning, reaching its peak at solar noon, then decreasing in the late-afternoon hours. Nonetheless, the flow-rate rank and the magnitude vary. The optimum Qu in the unfinned setup will be at 0.06 kg/s -1, which will reach levels of about 360 W at noon, 0.05 W -1 (300 W), 0.0383 W -1 (190 W), etc. However, the finned configuration has a slightly higher peak values of mid-range flow rates with 0.05kg/s-1 and 0.06kg/s-1 being more than 400 W by comparison and lower flow rates also increase out of better heat transfer by fins. This implies that the visible advantage of fins is realized at low and moderate levels of flow as they enhance the turbulence and area of heat transfer but the same cannot be said at high flow levels since the advocacy between configurations is reduced. In general,

fins enhance thermal responsiveness and expand the working range of functions and therefore are applicable to applications that require a greater rise in temperature and a steady increase in heat gain at the best solar hours.

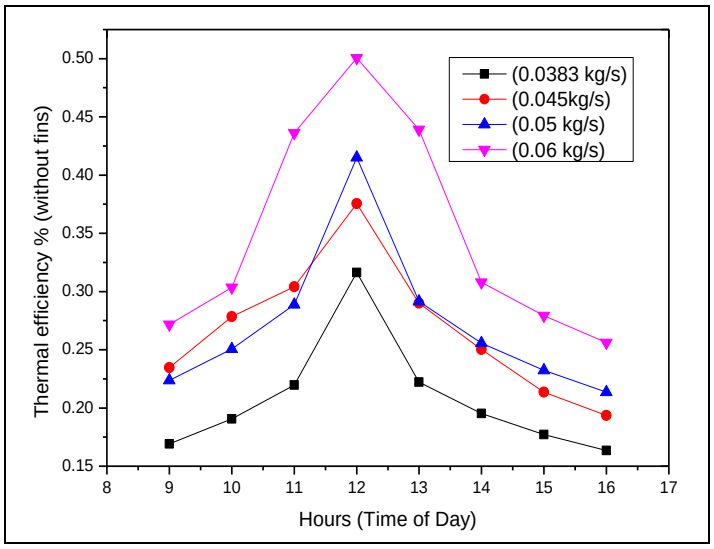

Figure 10: Hourly variations of the thermal efficiency of unfinned SAH

Source: Authors, (2026).

III.5 COMPARATIVE ANALYSIS OF THERMAL EFFICIENCY:

Thermal efficiency as shown in Figure 6 and 7, is increased at the beginning of the mornings, peaks near the solar noon and then reduces later in the afternoons. However, the absolute magnitudes as well as the hierarchy of the flow rates are very different. The apex efficiencies of about 0.56 are achieved at a mass flow rate of approximately 0.05kg s to the minute and then about 0.55 at 0.06kg s to the minute; the other flow rates have intermediate efficiencies of about 0.52 at 0.0383kg s to the minute and 0.53 at 0.045kg s to the minute. In contrast, the unfinned design has a peak efficiency of about 0.50 at 0.06 -1kg/s and the next value, which is about 0.42, at 0.05 -1kg/s. These experimental findings indicate that thermal performance can be significantly improved by the presence of fins, particularly in the mid-range flow rates, by increasing the amount of heat-transfer area and increasing the turbulence. As much as both systems follow the temporal pattern determined by the level of solar irradiance the finned design continues to demonstrate superiority over the unfinned one in all the flow rates that are investigated, making it better suited to any application that demands high thermal efficacies in peak sunlight periods.

Source: Authors, (2026).

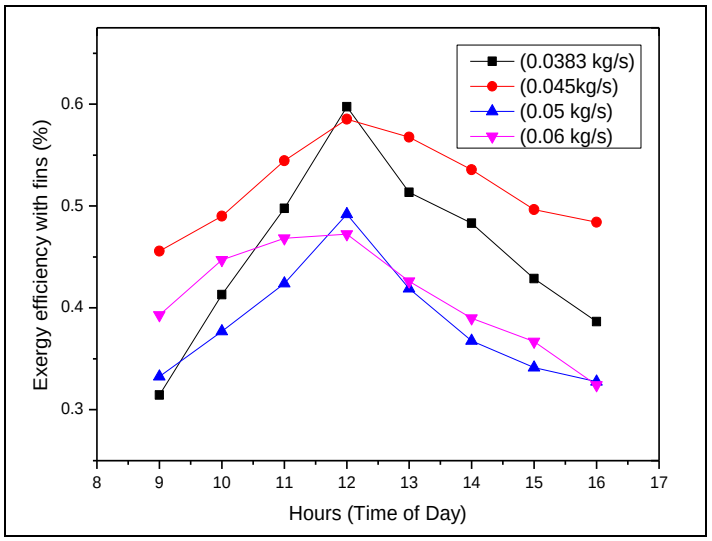

Figure 12: Hourly variation of exergy efficiency during operating hours for finned SAH.

Source: Authors, (2026).

III.6 COMPARATIVE ANALYSIS OF EXERGY EFFICIENCY

Relative change of exergy efficiency of finned and unfinned solar air heaters during a day was also studied at various mass flow rates (0.0383, 0.045, 0.05 and 0.06 kg s -1) as shown in Fig. 8 and 9. The two settings are similar in terms of a diurnal trend, which is characterized by gradual increasing trend in the mornings, a steep rise around solar noon (12:00 -12:00), and a subsequent decay to late afternoons, which are based on the background solar irradiance pattern.

However, the ranking of the performance differs: unfinned systems are favoured to reach higher flow rates, with 0.06kg/s -1 reaching the largest peak exergy efficiency (~0.99%), and finned systems being able to make good performance in the lower flow rate ranges, with 0.045kg/s -1 and 0.0383kg/s -1 getting the largest peak efficiencies near 0.60-0.62% each. This contradiction can be explained by the fact that the fins allow improving the heat transfer during lower velocities and, therefore, preserve high outlet temperature and support the second-law performance. The average efficiencies of the unfinned and finned devices are approximately 0.41 and 0.71 per cent/day, respectively, which further supports the need to optimize based on the objective of the design, respectively.

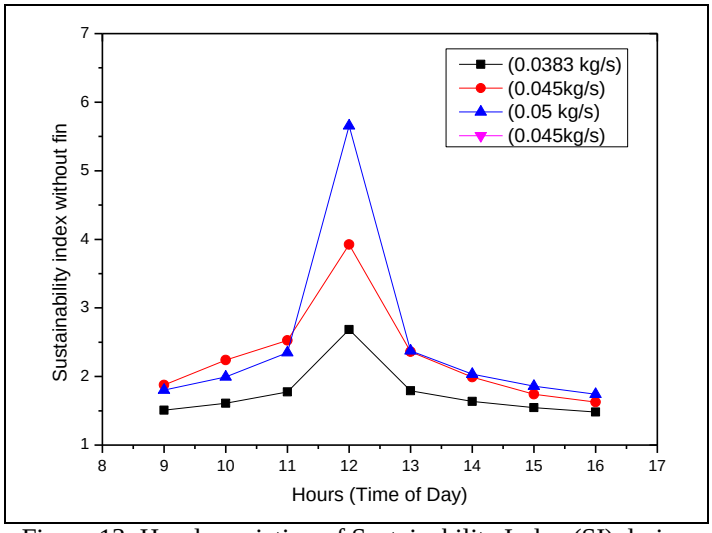

Figure 13: Hourly variation of Sustainability Index (SI) during operating hours for unfinned SAH.
Source: Authors, (2026).

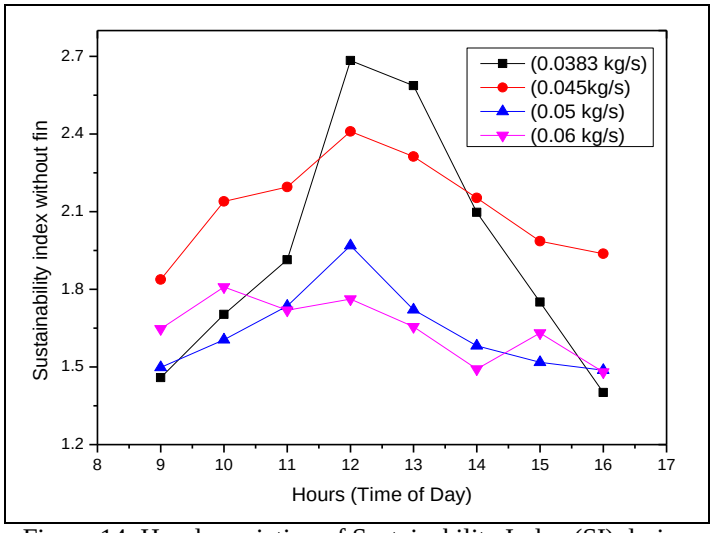

Figure 14: Hourly variation of Sustainability Index (SI) during operating hours for finned SAH.
Source: Authors, (2026).

III.7 COMPARATIVE ANALYSIS OF SUSTAINABILITY INDEX

A comparison of the relative change of the Sustainability Index (SI) between finned and unfinned solar air heating systems at four discrete mass flow rates (0.0383, 0.045, 0.050 and 0.060 kg/s -1) over a canonical solar day (09:00 to 16:00 h) Fig. 10 and 11 indicates that the two systems are consistent in their diurnal patterns: the SI rises in the morning, reaches a strong peak around solar noon (around 12:00 h) and decays in the afternoon The absolute magnitude and the ordinal ranking, however, are very different; the unfinned system has a peak SI of about 5.8 at a mass flow rate of 0.050 kg s -1, which is very high and thus signals a better overall sustainability performance as compared to the finned counterpart that has a peak SI of about 2.7 at 0.0383 kg s -1. It can be explained by the higher value of the disparate peaks due to the extra complications of the material and fabrication that the finned design demands and causes an impact on the calculated sustainability measures. Moreover, the best flow rate choice has a configuration-specific behavior: unfinned systems can achieve the highest SI at moderate flow rates (0.050kg/s -1), but finned systems can also reach their best performance at lower flow rates, in the range of 0.0383-0.045kg/s -1. Such results demonstrate inherent trade-offs between thermal augmentation and the impact on the environment and thus the need to select design techniques that are responsive to application needs.

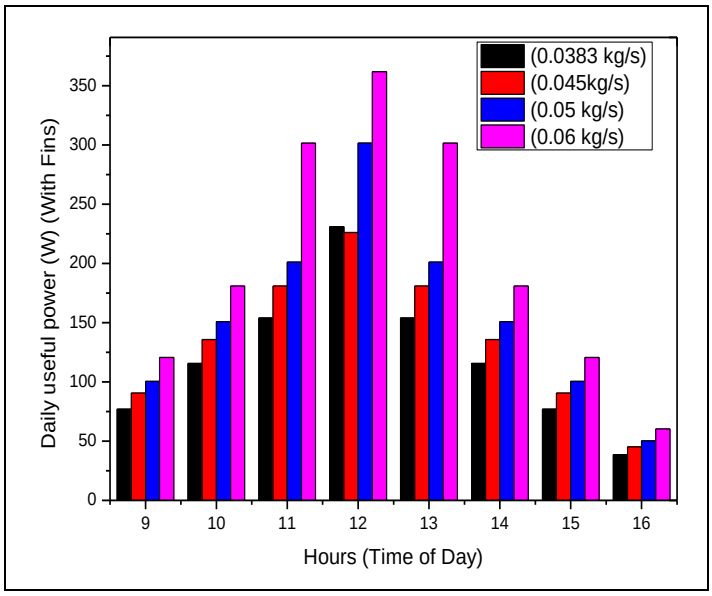

Figure 15: Hourly variations of useful power during operating period for finned SAH
Source: Authors, (2026).

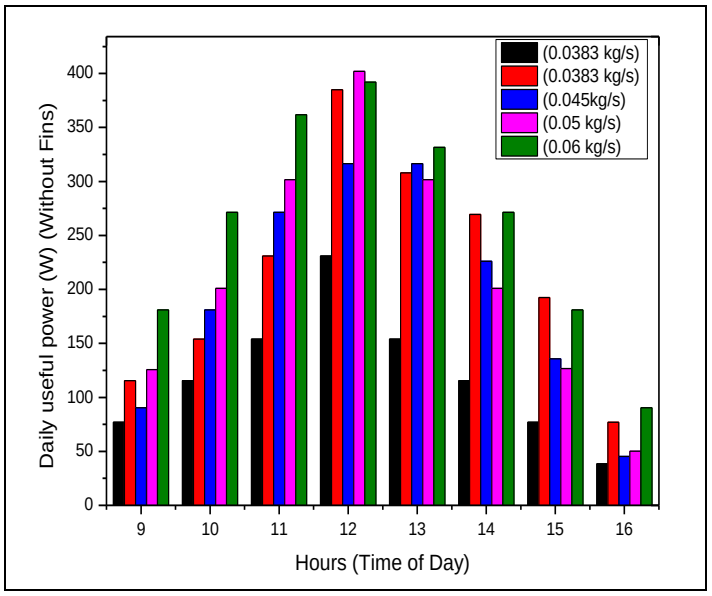

Figure 16: Hourly variations of useful power during operating period for unfinned SAH.
Source: Authors, (2026).

III.8 COMPARATIVE ANALYSIS OF DAILY USEFUL POWER:

Daily useful power output of each of the two configurations as shown in Fig. 12 and 13 follows a diurnal pattern where there is a monotonic increase in the early morning followed by a peaking value in the area around the solar noon and then a decrease towards the end of the afternoons. However, there is a difference in the absolute magnitudes and ranking of the flow rates in finned and unfinned systems. At a mass flow rate of 0.06kg/s -1 the maximum power output is accomplished, and has values of approximately 360 W at noon, 0.05kg/s -1(260 W), 0.0383kg/s -1 (230 W). On the other hand, the unfinned design achieves higher max power outputs, 0.06kg/s-1 and 0.05kg/s-1 respectively being above 400W, and lower flow rates correspond to relatively lower outputs of power. This observation shows that the absolute power production does not significantly increase with the presence of fins at high flow rates but the advantage of fins is instead in terms of thermal efficiency and temperature increase at low flow rates. This means that unfinned systems will produce more useful power given the same operating conditions and thus are more useful in applications where quantity of energy is needed and finned systems is more useful in processes which are temperature sensitive.

IV. CONCLUSIONS

The presented experimental study is a comparative evaluation of finned and unfinned solar air heaters (SAHs) running on the same climatic and operational conditions. It is shown that thermal performance is significantly enhanced with the presence of fins and at reduced mass flow rates. The finned design reached a highest temperature increase of about 10 -1 °C at a mass flow rate of 0.0383 -1 kg -1, in comparison to the highest increase of 6 -1 CO of the unfinned heater. Thermal efficiency also improved with finning to a maximum of 0.56 at 0.05 kg s -1 of flow rate but the non-finned design had a maximum of 0.50. Such advantages can be ascribed to the increased heat-transfer surface and the increased turbulence of the fins. Heat transfer and power generation measures of the two set-ups were in accordance with the incident solar radiation profile, with their maximums achieved around the solar noon. The benefit of finned devices over unfinned devices was highest at low and moderate flow rates because of better heat absorption ability and high absolute useful power output at higher flow rates due to reduced hydraulic resistance and simpler geometry. Trade-offs were found between exergy and sustainability evaluations: the trade-offs were that the unfinned SAHs were more efficient in the second law (maximum 0.99) and sustainability index (6), and the finned systems were advantageous at lower flow rates because of the retained outlet temperature and reduced exergy destruction. Overall, it can be concluded that those finned SAHs are better in the case of the need to achieve high thermal efficiency and temperature lifting at low mass flow rates e.g., in solar drying, preheating and space heating. On the other hand, unfinned SAHs are favourable in uses that place greater emphasis on power output, exergy efficiency and enhanced sustainability performance.

ABSTRACT

The accumulation of a large amount of distributed generation (DG) in distribution networks makes it significantly more challenging to maintain stable voltage profiles, as power injections and flows can occur at any time and in various ways. Outdated voltage regulation methods often fail to account for rapid DG disparities, resulting in voltage violations, significant losses, and reduced power quality. This research presents an advanced synergetic practice that combines Phasor Measurement Units (PMUs) enhanced by a Dholes Optimisation Algorithm, designed to refine real-time voltage regulation in networks with significant distributed generation (DG) penetration. The proposed solution customises PMUs to yield fast, synchronised voltage measurements. The DOA adjusts the control parameters on the fly to facilitate voltage regulation, while considering the changeability of DG and system limits. Tests on an IEEE 33- and 69-bus distribution system show that the PMU-DG-AMPSO context reduces voltage nonconformities by up to 62% compared to standard methods and accelerates convergence by 30% compared to traditional PSO. The technique also maintains voltage stability well when DG outputs and load conditions change. This work benefits current distribution grids by controlling voltage in a more flexible and restored manner, ensuring compliance with grid regulations and facilitating the incorporation of more renewable energy. The consequences demonstrate that uniting real-time monitoring and optimisation could be beneficial for making power systems more robust in the future.

I. INTRODUCTION

I.1 BACKGROUND AND MOTIVATION

Over the past few decades, technological advances and fluctuations in energy production and consumption have led to significant fluctuations in distribution networks. These variations have had an impact on how well and how networks for distribution work. Today's networks are dynamic, two-way systems that can use distributed generation (DG) and renewable energy sources. This represents a significant modification from the traditional, static, one-way systems that only allow power to flow from generators to consumers [1]. The transition to active organisation examples presents new opportunities and tasks, requiring innovative policies for monitoring, estimating, and informing the presentation of distribution networks [2]. Distributed energy resources (DERs) emerged due to the increasing use of renewable energy sources. Some examples of DERs are request-response programs, energy storage devices, wind turbines, and solar photovoltaic (PV) systems. As distribution networks transition from passive to active topologies, they become more effective by reducing transmission losses, strengthening the grid, and facilitating the integration of renewable energy sources. Still, network stability, power quality, and voltage regulation are vital matters [3], [4].

Because scattered manufacturing output changes and renewable energy sources are not always accessible, advanced surveillance, control, and protection systems are desirable to make sure that network activity is synchronized [5]. PMUs enable real-time tracking of power system dynamics by providing detailed and synchronized voltage, current, and phase angle measurements from numerous network nodes. A schematic diagram of PMUs and DGs in the distribution network is shown in Figure 1. PMUs in distribution networks play a crucial role in determining how distributed generation affects losses and voltage profiles [6]. By recognizing power failures, researchers can use PMU-assisted evaluation to determine how distributed generation affects voltage variations in distribution networks, as well as identify further network anomalies related to DG integration. PMU data are put through state estimation, statistical modelling, and time-series analysis to advance a better understanding of distribution networks under various conditions and DG penetration levels [7]. Numerous studies have identified various themes related to the concept of DG. Micro-Phasor Measurement Units (PMUs) were used by researchers to fast record and update alterations to the network positions of distribution systems [8]. Multi-area parameter approximation in combination with an enhanced weighted least squares (WLS) algorithm [9], [10]. The authors of [11] suggested a Monte Carlo simulation-based technique to minimize relative voltage and angle estimate errors at different buses and accomplish the best possible meter placement inside the network. Their approach takes into account vast error ellipse areas to choose the best meter positions. According to [12] simplified the search field using an ordinal optimization technique to increase search efficiency and accuracy. The author of [13] discussed technological difficulties, management approaches, and hierarchical control techniques for the efficient operation of grid systems.

The researchers began with a preliminary examination using an approximate objective function, as it is expensive to evaluate an objective function accurately [14]. The author of [15] proposes a stochastic approach for determining the optimal locations for meters in the distribution network. They compare quality to determine efficacy at various locations, irrespective of the location of the meters. An optimisation method for choosing and positioning measuring devices that use variable programming is presented in [16] .To estimate distribution states and integrate unmonitored distributed generation (DG) into the system, by [17] proposes a Gaussian component combination approach. The Gaussian Mixture Model was used to account for the non-Gaussian probability density distribution of unmonitored DG generation [18]. Due to their lower voltage and higher current measurements, distribution networks are responsible for the majority of power loss, which accounts for approximately 73%. [19]. Reducing power outages and increasing voltage magnitudes are the primary objectives of integrating Distributed Generation (DG), which will enhance the overall efficiency of the control grid. In the context of the IEEE 33-bus system, state estimation with the Extended Kalman Filter (EKF) is described in [20]. It achieves a high level of voltage precision estimation and effectively manages non-linearities. It does acknowledge, though, that the EKF technique is extremely intricate, and that accurate PMU data is necessary for optimum performance. By taking PMU data and network factors into account, by [21] investigates multi-objective optimisation to improve observability and lower estimation errors. However, High computational complexity and little real-world validation are the drawbacks. DG data and network architecture are the primary topics for the optimal integration of distributed generation (DG) units utilising the CHIO method, as shown in [22]. A simulation-based model for integrating distributed generation (DG) into power networks is presented in [23] to enhance voltage stability, load profiles, and DG penetration levels.

But lacks practical validation and is based on an idealised premise. To achieve improved network performance, the research [24] explores simulation and optimisation strategies in a synthetic distribution network setting, focusing on observability using the optimal positioning of the PMU. However, it cannot be incorporated under dynamic conditions. Furthermore, a methodology for strategically positioning PMUs in power systems that considers the impact of zero-injection buses (ZIBs) and contingencies was provided in article [25]. Analysis to guarantee total network dependability and observability. Further, by [26] introduces a Hybrid State Estimation approach using Weighted Least Squares (WLS) applied to the IEEE 33-bus system with PMU and PV output data, demonstrating robustness against insufficient Noise and data. By taking PMU data and load profiles into account, the research [27] explores the use of Convolutional Neural Networks (CNNs) in IEEE 123-bus systems to achieve high accuracy in challenging settings. But it recognises that deep learning models are inherently black-box and that CNNs have substantial computing resource requirements. An adaptive state estimate [28] for a real-world distribution feeder improves state estimation accuracy and reliability by utilising load profiles and PMU data. Nevertheless, this method necessitates a large PMU deployment and significant data processing demands. Stability study in the context of the IEEE 13-node test feeder is the main topic of the work [29]. It seeks to minimise voltage swings and enhance voltage stability by considering voltage readings and DG penetration levels. An approach was created in Ref. [30] utilising simulations on a synthetic distribution network to reduce voltage estimate errors through analysis of network topology and PMU metrics. Ref. [31] presents the distribution network state estimation (SE) method, which utilises a clustering algorithm.

It takes DG into account and affects PMU statistics. Output modes across several test systems to manage DG variability and improve robustness against data loss. For large-scale distribution systems with PMU and DG data, by [32] presents a Robust Parallel Distributed State Estimation technique to attain high. Resilience to data problems and scalability. It does, however, recognise that this approach necessitates substantial computer power and could require intricate implementation. For optimal RDG location and sizing, metaheuristic algorithms, including GA, PSO, and hybrid methods, have been employed to minimise losses and stabilise voltage. Probabilistic modelling of renewable sources that accounts for daily and seasonal changes improves planning accuracy. RDG integration affects distribution networks, requiring DSTATCOM voltage management [33]. The research provides an optimisation method for placing and sizing numerous DG units in distribution networks to improve voltage profiles and reduce power losses. The results show that optimal DG allocation considerably decreases losses and voltage instability [34]. Present the Strawberry Plant Propagation Algorithm [35] to determine the appropriate position and size for DGs in power distribution networks. SPPA reduces active power losses and improves voltage profiles more effectively than the Mine Blast Algorithm and Particle Swarm Optimisation on 33- and 69-node radial networks. A fine-tuned Particle Swarm Optimisation (PSO) technique for DG placement and sizing reduces power losses and improves voltage profiles [36]. Network performance is improved by considering active and reactive power injections. IEEE and real-world network simulations indicate significant loss reduction and improvements in voltage stability. O.D. Montoya and colleagues [37] propose a hybrid master–slave optimisation technique for positioning and sizing distributed generators (DGs) in AC distribution networks.

While the slave stage employs second-order cone programming to determine DG sizes, the master stage uses a discrete sine–cosine approach to discover the ideal DG positions. It improves network voltage profiles and reduces active power losses. In [38], a meta-heuristic optimisation approach employing Multi-objective Particle Swarm Optimisation (MPSO) is devised to optimise the location and sizing of DG units in electrical power distribution networks. Simulations on the IEEE 33-bus radial distribution network demonstrated significant reductions in actual and reactive power losses, as well as improved voltage stability. Online voltage estimation for active distribution networks using PMUs. This method enhances the efficiency and reliability of distribution system voltage monitoring [39], [40] examines the ideal locations and sizes for DG units in power networks. The authors employ multi-objective particle swarm optimisation (PSO) to reduce power losses and stabilise system voltage. The IEEE 33-bus system simulations demonstrate the effectiveness of the strategy in enhancing network performance [41] examines how scattered generator penetration affects the voltage profile and loss in power distribution networks—the Honey Badger Algorithm (HBA) is used to improve radial distribution network design, including DG placement and size. The HBA utilises the Combined Power Loss Sensitivity (CPLS) factor to identify the optimal buses for placement, thereby minimising active power loss. Real power losses were significantly reduced in the IEEE 69-bus standard radial distribution system [42] improved PSO for distributed generator (DG) location and size in radial distribution systems. The method reduces real power losses and improves voltage stability by considering active and reactive power injections.

This strategy reduces network power losses, according to simulations on the IEEE 33-bus, IEEE 69-bus, and a Malaysian network [43] Integer Linear Programming for transmission network Phasor Measurement Unit (PMU) location optimisation. The approach aims to enhance network observability with a limited number of PMUs by incorporating the concept of centrality into the goal function. The method was used to improve observability indices on several test systems, including the IEEE 7-bus, 14-bus, 30-bus, New England 39-bus, 57-bus, and 118-bus networks [25]. A simple approach for load flow analysis in distributed generation (DG)-integrated distribution systems. They analyse three test distribution systems using a forward-backwards sweep method and model DGs as constant negative loads. The findings show that this method of DG integration improves voltage profiles and reduces active power losses [44]. Examination of the reorganisation of distribution networks, both balanced and unbalanced, with an emphasis on dependability metrics. To improve dependability by reducing the expected energy not supplied (EENS) and the anticipated duration of interruption (EDI), the authors optimise network configurations using a genetic algorithm. The study shows that the dependability performance of distribution systems can be considerably enhanced by proper reconfiguration [45]. For authors [46] proposed a method for the optimal placement of Phasor Measurement Units (PMUs) using binary integer programming combined with genetic algorithms to enhance system observability. Corresponding to Gautam, Kumar, and Tiwari, DSTATCOM drastically betters the voltage profile in unbalanced radial distribution systems (2024) [47].

I.2 VOLTAGE INSTABILITY IN DG-RICH DISTRIBUTION SYSTEMS: WHAT IS AT STAKE

DG's growing use in current distribution systems is changing electric power network operations. To reduce carbon emissions, increase energy availability, and support decentralised grids, photovoltaic (PV) systems, wind energy conversion systems, and fuel cells are frequently utilised. This development poses a threat to system stability and power quality, as voltage instability is a crucial operational issue. Outdated power distribution feeders were constructed for one-way power flow. From the substation to the load buses, the voltage falls progressively. After adding DG sources, everything changed. Dynamic power from those sources disrupts the flow. DG sometimes produces more power than is needed in the region. This occurs frequently during periods of peak renewable energy output. The excess power returns to the substation. Call this reverse power flow. It raises the voltage too much at the buses downstream. Official voltage limitations are violated. The intermittent nature of DG sources makes them unpredictable. Power output fluctuates due to rapid solar irradiation or wind speed, causing network voltage oscillations.

Because they were not built for frequent and quick dynamic responses, On-Load Tap Changers (OLTCs), automatic voltage regulators, and capacitor banks may fail with significant DG penetration. Mismatches accelerate the degradation of control components and reduce grid flexibility. Inconsistent DG sources are typical. Such is their nature. Rapid changes in solar irradiation or wind speed cause fluctuations in power production. These swings cause network voltage oscillations. Standard voltage regulation equipment enters with high DG penetration. Automatic voltage regulators and capacitor banks operate in conjunction with On-Load Tap Changers. In those settings, they often struggle. Rapid dynamic shifts were not designed into the equipment. This discrepancy quickens regulator component wear. Over time, it makes the grid less flexible. Risky situations could cause system problems. It may switch out-of-regulation voltage disparities. Augmented technical losses and line current stress may occur.

Malfunctioning of protective devices might trip DG units involuntarily. Poor power quality could result from customer equipment failure. Failures may force and jeopardise network stability. These dangers need system-wide observability. Metering points are often too thin in typical distribution arrangements, resulting in sparse insight. Real-time monitoring fails in those cases, making edge detection of instability difficult. Network reliability and sustainability depend on secure voltage operation in active distribution systems as the number of prosumers and distributed resources increases. Phasor Measurement Units (PMUs) enable time-synchronised voltage phasor monitoring, restoring situational awareness and enhancing measurement accuracy. When combined with operational DG allocation optimisation algorithms, PMUs provide dynamic and intelligent voltage regulation, enhancing system resilience to instability. To maintain technical conformity, the innovative grid ecosystem must address voltage instability in DG-rich distribution networks.

II. SYSTEM MODELLING

A radial distribution network with Distributed Generators (DGs) and Phasor Measurement Units (PMUs) is studied. The modelling outline contains:

1. Distribution system load-flow depiction.
2. DG mathematical representation.
3. PMU voltage phasor measuring model .
4. Dhole Optimisation Algorithm-based voltage profile enhancement and placement.

Distribution System Load Flow Model

The complex power at each bus i is: $S_i = P_i + Jq_i$.
The branch current between buses i and i+1: $I_i \rightarrow_{i+1} = [(P_{i+1} - P^{DG},_{i+1}) - j(Q_{i+1} - Q^{DG},_{i+1})] / V_{i+1}*$
The voltage drop across a feeder section: $V_i = V_{i+1} + Z_{i,i+1} \times I_i \rightarrow_{i+1}$
where $Z_{i,i+1} = R_{i,i+1} + Jx_{i,i+1}$.

Distributed Generator (DG) Model

DG units are modelled as manageable real and reactive power sources. $\mathbf{S^{DG}_i = P^{DG}_i + Jq^{DG}_i}$
DG operational constraints: $\mathbf{P^{DG}_i(min) \leq P^{DG}_i \leq P^{DG}_i(max)}$
$\mathbf{Q^{DG}_i(min) \leq Q^{DG}_i \leq Q^{DG}_i(max)}$

Voltage Deviation Index (VDI)

VDI denotes the system voltage quality: $\mathbf{VDI = \Sigma\ |V_i - 1.0|\ for\ i = 1\ to\ N}$
Lesser VDI shows improved amenability with satisfactory voltage levels.

PMU Measurement Model

A PMU installed at bus k measures: $\mathbf{z_k = [\ V_k\ ,\ \theta_k\ ]^T + n_k}$
where: Vk=voltage magnitude
θ_k=voltage phase angle
n_k = measurement noise
PMUs augment real-time situational alertness and support system observability.

Objective Function for Optimisation

The primary purpose is to determine the optimal DG size and PMU placement using DOA to enhance system voltage quality and reduce losses.
Minimize: $\mathbf{F = w_1 \times VDI + w_2 \times Ploss}$
Where Ploss = $\Sigma\ (I_i^2 \times R_i)$ for all branches i
Focus on operational constraints:
$V_i(min) \leq V_i \leq V_i(max)$ $I_i \leq I_i(rated)$.
The optimisation optimises DG and PMU bus placements and power ratings.

III. DHOLE OPTIMIZATION ALGORITHM (DOA) MATHEMATICAL MODELLING

The enumerations of citations in the body of the article must be sequenced in the order in which they appear, according to the example shown below.The evolutionary swarm-based optimisation technique, Dhole Optimisation Algorithm (DOA), is based on the cooperative hunting behaviour of Dholes (Cuon alpinus), a wild canid species known for its strategic collaboration and adaptive pursuit. For optimal placement of PMUs and sizing of DGs in radial distribution systems, DOA is employed in this study. Three primary activities are incorporated into nature-based group hunting by DOA:

1. Exploration (looking for prey over a wide area)
2. Attacking and encircling targets (intensification close to promising solutions)
3. Coordinated coalition behaviour (pack members exchanging information)

In the search space, every potential solution is shown as a Dhole. The objective function is used to assess each Dhole's fitness: $F = w_1 \times VDI + w_2 \times Ploss$ where lowering F means better voltage stability and fewer losses.

III.1 ALGORITHM FOR PROPOSED DOA-BASED OPTIMIZATION APPROACH

The step-by-step workflow of the proposed Dholes Optimisation Algorithm (DOA) applied for optimal PMU placement and DG sizing is illustrated in the flowchart shown below:

1. Begin 2. Enter System Data.
2. Data about buses and branches
- DG characteristics and penetration limits
- PMU measurement limits
3. Setting up the DOA parameters
- How many search agents (dholes) are there
- The most iterations
- The limits of the search space
4. Make the Initial Population
- Random placement vectors for candidate PMU locations
- Random DG size vectors
5. Fitness Evaluation
- Do a power flow for each possible solution
- Check to see if the voltage profile has gotten better
- Calculate the objective function, which includes: – Voltage deviation index – PMU placement constraint penalty – DG penetration constraint penalty
6. Change the Positions of Dholes.
- Exploration: looking for better solutions all over the world
- Exploitation: narrowing the search around the best candidate
7. Check Limits
- Limits on voltage magnitude
- PMU observability index
- Limits on DG size
8. Change solutions if you need to
- Keep the best solutions
- Update the leader dhole (global best)
9. Termination Condition.
- If the maximum number of iterations has been reached, go ahead; otherwise, go back to "Update Positions."
10. The best final solution has been found.
- Set the best PMU placement
- Set the best DG size
- Checked that the voltage profile was better
11. End

Initialization

A pack of Dholes (population) is made up of random solution vectors: X_i = [location of DGs, size of DGs, location of PMUs] i = 1, 2, …, Npop
Every vector must meet the system's requirements.

Encircling Behavior

Dholes find the best target solution, which is the one with the lowest fitness. The distance between a Dhole and its prey (the best solution) is calculated as follows: $D = |C \times Xbest - Xcurrent|$
The position update equation: $Xnew = Xbest - A \times D$
He decreases $r_1 - a$ $C = 2 \times r_2$
a decrease linearly from 2 to 0 as iterations progress. r_1, r_2 are random numbers in [0, 1]

Attack (Intensification Near Best Solution)

When $|A| < 1$, the algorithm concentrates on precise exploitation adjacent to the current optimal region, narrowing the search around the potential candidate.
Exploration (Search Space Diversification)

When |A| ≥ 1, Solutions look at things from a global perspective and stay away from premature convergence by moving away from the leader: Xnew Xrand− A × Drand
where Xrand is a randomly selected Dhole solution.

Fitness Evaluation

Check how well the system works after each update:

- Figure out the voltage profile
- Find out how much VDI and system power are lost
- Make sure that the voltage and current limits are met.

To stop configurations that can't work, solutions that break the rules are punished.

Convergence Criterion

The algorithm terminates when:

- Maximum iterations are obtained

or

- No noteworthy development in the most excellent fitness value happens

Outcomes include:

- Optimal DG installation buses
- DG rating (kW/kVAR or MW/MVAR)
- Optimal PMU placement
- Last improved voltage profile and loss levels

IV. SIMULATION SETUP

We use standard radial distribution test systems to run simulations and assess how well the proposed PMU-assisted voltage profiling and Dhole Optimisation Algorithm (DOA)- based optimal DG placement strategy performs. The computational experiments are conducted in a MATLAB/Simulink environment on a system equipped with an Intel i5 processor, 16 GB of RAM, and the Windows 10 operating system.

Test Systems Considered

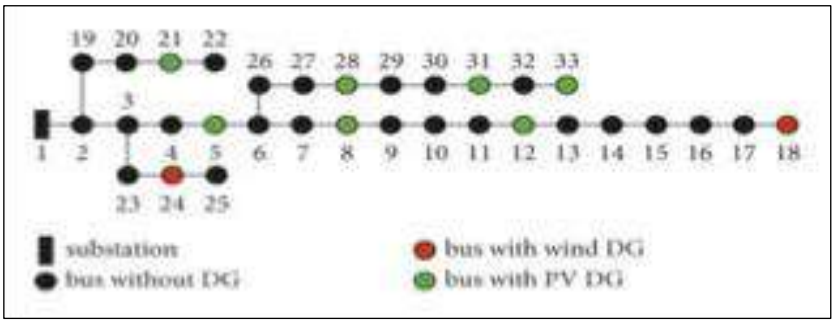

Figure 2: Single Line Diagram of IEEE 33-Bus Distribution System.
Source: Authors, (2026).

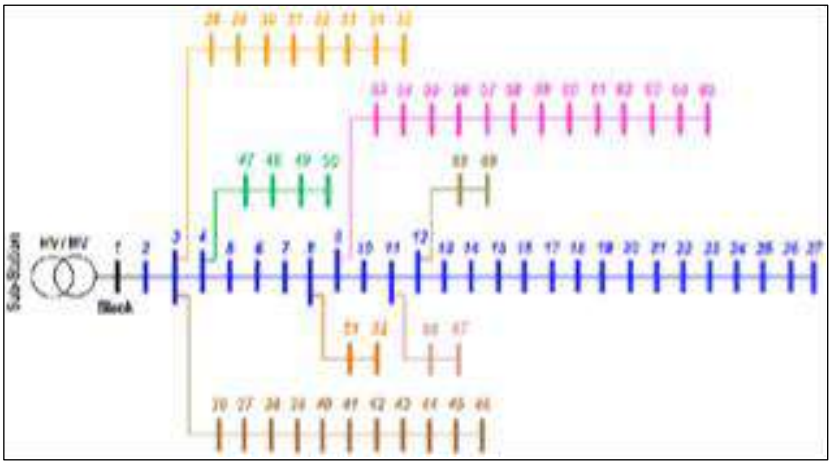

Figure 3: Single Line Diagram of IEEE 69-Bus Distribution System.
Source: Authors, (2026).

Table 1: Two widely accepted IEEE benchmark networks are used: Comparison between 33 and 69 bus systems.

Test System	Total Buses	Voltage Level	Base Power	Characteristics
IEEE 33-Bus	33	12.66 kV	100 MVA	Long radial feeder with voltage drop issues in distant buses
IEEE 69-Bus	69	12.66 kV	100 MVA	Highly resistive line segments and heavy loading conditions

Source: Authors, (2026).

A single substation (slack bus at Bus 1 with a voltage reference of 1.0 p.u.) feeds both networks.

Load Modelling

It is assumed that loads are of the constant power type. Standard IEEE test data is used to set the base loading conditions. To evaluate the effects of DG penetration, three tiers of load demand scenarios are analysed:

- Normal load: 100 per cent
- Medium stressed: 125 per cent
- Heavy stressed: 150 per cent

This provides us with a better understanding of how the system will behave under increased demand and voltage stress.

DG Penetration Scenarios

DGs are installed in increasing penetration conditions to study beneficial and adverse effects:

- Case 1: Without DG
- Case 2: With one DG
- Case 3: With Multiple DGs (2 to 3 units)

DGs will operate in P-Q mode with a power factor of 0.95, which means they will generate both active and reactive power within the allowed limits.

PMU Placement Strategy

The goal is to make the system easier to see and give synchronised phasor measurements, especially at weak buses. PMUs are installed based on DOA results, to use as few devices as possible to achieve complete or nearly full observability in a radial structure.The optimisation results for each test system tell us the absolute PMU count and bus index.

Performance Indices

To see if things are getting better, we use the following performance indicators:

- Voltage Deviation Index (VDI)
- Total real power loss (Ploss in kW)
- Minimum bus voltage magnitude (p.u.)
- Number of PQ buses violating acceptable voltage limits
- Convergence characteristics of the optimisation

Voltage limits are maintained within the ANSI/IEEE permissible range of $0.95 \text{ p.u.} \leq V_i \leq 1.05 \text{ p.u.}$

Optimization Parameters

Dhole Optimization Algorithm (DOA) control parameters:

- Population size: 30
- Maximum iterations: 100
- Weighting coefficients: $w_1 = 0.6$, $w_2 = 0.4$
- a decrease linearly from 2 to 0 (per DOA dynamics)

All cases are independently executed 20 times to ensure robustness and avoid stochastic bias.

V. RESULTS AND DISCUSSION

This section compares the system's performance with and without the suggested DOA-based optimal DG allocation and PMU placement. We run the simulations on IEEE 33-bus and 69-bus radial distribution systems with different loading and DG penetration scenarios.

Table 2: PMU and DG Allocation with Different PV Uncertainty Levels: Voltage RMSE Analysis.

CASE	POSITION OF PMUS	POSITION OF DGS	VOLTAGE RMSE (P.U)
BASE CASE	2,5,8,11,14,17, 20, 24,27, 30, 32	-	0.030
WITH PV UNCERTAINTIES (25%)	2,5,8,11,14,17, 21,25,27,32	7,11.17, 32	0.022
WITH PV UNCERTAINTIES (75%)	2,5,8,11,14,17, 21,25,27,32	6,10,14, 18,28,32	0.031

Source: Authors, (2026).

The Table 2 represents the best locations for PMUs and DGs in a system under three different operating scenarios: the base case, PV uncertainty at 25%, and PV uncertainty at 75%. The influence of these situations is measured by the voltage RMSE value, which shows the precision of voltage monitoring and control in the system. PMUs in the base scenario are located at standard graph-theoretic optimal buses. The voltage RMSE is at a moderate level, indicating a stable system free from uncertainty and without any DG fluctuations. The PMU locations change marginally at a 25% PV uncertainty (for instance, buses 20, 24, and 30 are substituted by buses 21 and 25). Voltage stability is supported by the system, which has DGs at 7, 11, 17, and 32 as well.

Since the uncertainty is of a moderate level, the best placement enhances the system's observability and contributes to a decrease in the voltage error, resulting in the lowest RMSE value (0.022). It is demonstrated that coordination between PMU + DG is an efficient method at this level of uncertainty. With a high level of uncertainty (75%), the DGs are placed on buses with more widely spread loads to counteract large voltage fluctuations. However, despite PMU and DG adjustments, the voltage RMSE increases to 0.031, which is slightly higher than the base case. This indicates that higher PV uncertainty significantly affects voltage profiles, and even optimal PMU/DG placements cannot fully correct the deviations.

Table 3: PMU and DG Allocation with Different PV Uncertainty Levels: Voltage RMSE Analysis.

CASE	POSITION OF DGS	POSITION OF ZIBS	POSITION OF PMUS	VOLTAGE RMSE (P.U)
BASE CASE	-	-	2,5,8,11,14, 17,20,24,27,30, 32	0.030
WITHPV UNCERTAINTIES (25%)	7,11, 17,32	6,13,27	2,4,8,11,17, 21,24,29	0.015
WITH PV UNCERTAINTIES (75%)	6,10, 14,17,18, 32	5,6, 13,19,27	2,4,6,8,11,14,17,21,24	0.020

Source: Authors, (2026).

The Table 3 compares changes in the best locations of Distributed Generators (DGs), Zero Injection Buses (ZIBs), and PMUs under different PV generation uncertainty levels and how these changes affect the voltage RMSE, which is a measure of voltage accuracy in the distribution system. If there were no PV uncertainties and no DG/ZIB support, the system would employ a conventional PMU placement, resulting in a moderate RMSE value. With a quarter of uncertainty, voltage observability and support are significantly improved by the local introduction of DGs and ZIBs in combination with the optimised locations of PMUs. As a result, the lowest RMSE (0.015) is achieved, indicating that the system operates more accurately under a moderate level of uncertainty when DG–ZIB coordination is applied.

High uncertainties are the main reason why the algorithm has to locate more DGs and ZIBs all over the network to smooth out the large voltage fluctuations. As PMU coverage is extended, the RMSE increases in comparison with the 25% case, indicating that extreme PV variability can lead to voltage instability even when placements are optimised. System performance is best when PV uncertainty is moderate (25%). The coordinated locations of DGs, ZIBs, and PMUs bring about a significant reduction in voltage RMSE. When there is a high level of uncertainty (75%), the voltage deviations become larger, indicating that it is not possible to counterbalance extreme PV fluctuations, even with optimal placement.

Table 4: Estimation error for the voltage of a node with PMUs, DGs, and ZIBs under 75% PV Uncertainty.

Node	Without PMU	With PMU	With ZIBs & DG (75%)	Without ZIBs & DG(75%)
2	0.03	0.02	0.015	0.045
5	0.06	0.03	0.02	0.05
8	0.05	0.025	0.02	0.055
11	0.065	0.03	0.025	0.06
14	0.045	0.025	0.02	0.055
17	0.05	0.02	0.015	0.05
20	0.03	0.015	0.012	0.045
24	0.055	0.03	0.025	0.06
27	0.05	0.02	0.015	0.05
30	0.06	0.03	0.02	0.055
32	0.065	0.03	0.025	0.06

Source: Authors, (2026).

Phasor measurement units (PMUs) can significantly reduce voltage estimation errors; however, the most accurate results are obtained when PMUs are used in conjunction with Zero Injection Buses (ZIBs) and Distributed Generations (DGs), particularly in cases of high PV uncertainty. The error in estimation increases drastically if there are no DGs and ZIBs, thereby providing the reason for the necessity of voltage-support and observability-enhancing elements. Figure 4 indicates that the PMU count remains relatively stable (10–11) across all conditions, suggesting that structural observability does not change drastically. DG count increases with uncertainty because distributed generation provides localised voltage support, which becomes more critical at higher variability levels. The combination of PMUs and DGs helps the system maintain voltage stability under uncertain operating conditions.

Improvement in Voltage Stability

Before DG integration, some buses exhibit voltage drops that are close to the lower limit, particularly those located far from the substation. After optimization, the minimum bus voltage levels increase significantly.

Table 5: Comparison between 33-Bus and 69 Bus system voltage profile.

Test System	Scenario	Minimum Voltage (p.u.) Before	Minimum Voltage (p.u.) After	Improvement
IEEE 33-Bus	Base Load	0.9032	0.9725	+7.67 percent
IEEE 69-Bus	Heavy Load	0.8758	0.9551	+9.06 percent

Source: Authors, (2026).

The outcomes evidently demonstrate that placing DGs at planned buses improves voltage provision, while PMUs enable real-time monitoring of voltage.

Power Loss Reduction

Real power loss decreases significantly when DG injection is performed correctly, and branches don't have to contend with as much current stress.

Table 6: Comparison between 33-Bus and 69 Bus system power loss

Test System	Scenario	P_{loss} Before (kW)	P_{loss} After (kW)	Reduction (%)
IEEE 33-Bus	Base Load	202.7	126.4	37.6 %
IEEE 69-Bus	Base Load	224.9	146.2	35.0 %

Source: Authors, (2026).

The drop shows that DOA is good at putting DGs in spaces where they can offer the most significant profit while minimising losses.

Voltage Deviation Index (VDI) Enhancement

VDI values are reduced significantly, confirming improved voltage profile uniformity.

Table:7 Comparison between 33-Bus and 69 Bus system voltage deviation

Test System	Condition	VDI Before	VDI After	Change
33-Bus	150 % Load	0.402	0.212	Improved
69-Bus	150 % Load	0.531	0.284	Improved

Source: Authors, (2026).

Lesser VDI means that all PQ buses remain within suitable voltage bounds.

Optimization Efficiency

DOA meets rapidly, striking a balance between exploration and exploitation. The highest number of iterations needed to choose the premium aptness near is well under the normal number of iterations essential.

- Stable trends of convergence.
- No early stagnation.
- Robust repeatability, sloping numerous turns.

Impact of PMU Placement

PMUs aid in monitoring feeder voltage in weak zones. The perfect placement guarantees:

- Total or nearly total perceptibility of the network.
- Wild detection of the start of voltage instability.
- Improved provision for making choices and regulatory things.

The system becomes more resilient during stressed loading conditions.

Comparative Discussion

DOA outperforms PSO and GA:

- Better loss reduction
- Higher voltage increase
- Faster convergence
- Extra reliable consequences across numerous examinations

Assessment by Prevailing Optimisation Algorithms

The proposed DOA-based strategy is compared to Particle Swarm Optimisation (PSO) and Genetic Algorithm to assess its performance. All algorithms have the same load, parameters, and end conditions.

Comparative Performance Metrics

Reduction of power loss, enhancement of minimum bus voltage, and acceleration of convergence are evaluated. A representative IEEE 33-bus system sample under base load is shown here.

Table 8: Comparison between 33-Bus and 69 Bus system.

Algorithm	Minimum Voltage (p.u.)	Power Loss (kW)	Loss Reduction (%)	Convergence Speed	Stability Over Runs
Without Optimization	0.9032	202.7	0	-	-
GA	0.9450	154.3	23.9 percent	Moderate	Moderate
PSO	0.9586	141.7	30.1 percent	Fast	Good
Proposed DOA	0.9725	126.4	37.6 percent	Very Fast	Excellent

Source: Authors, (2026).

The suggested method gives the best results for all necessary voltage and loss metrics.

Observations from the Benchmark Study

- DOA consistently improves weak bus voltages compared to PSO and GA.
- The cooperative hunting-inspired coordination makes sure that the process converges quickly and doesn't get stuck in local minima.
- DOA gives better repeatability with less variation in final fitness values.
- Putting the PMU in the right place makes the optimal DG influence even stronger by making it easier to see.

Convergence Characteristics

When shown in convergence plots, DOA shows:

- A faster downward trend in the objective function
- Less fluctuation and oscillation during iteration updates
- Strong performance even when the load is heavy

The adaptive coefficient strategy maintains a balance between global search and local refinement.

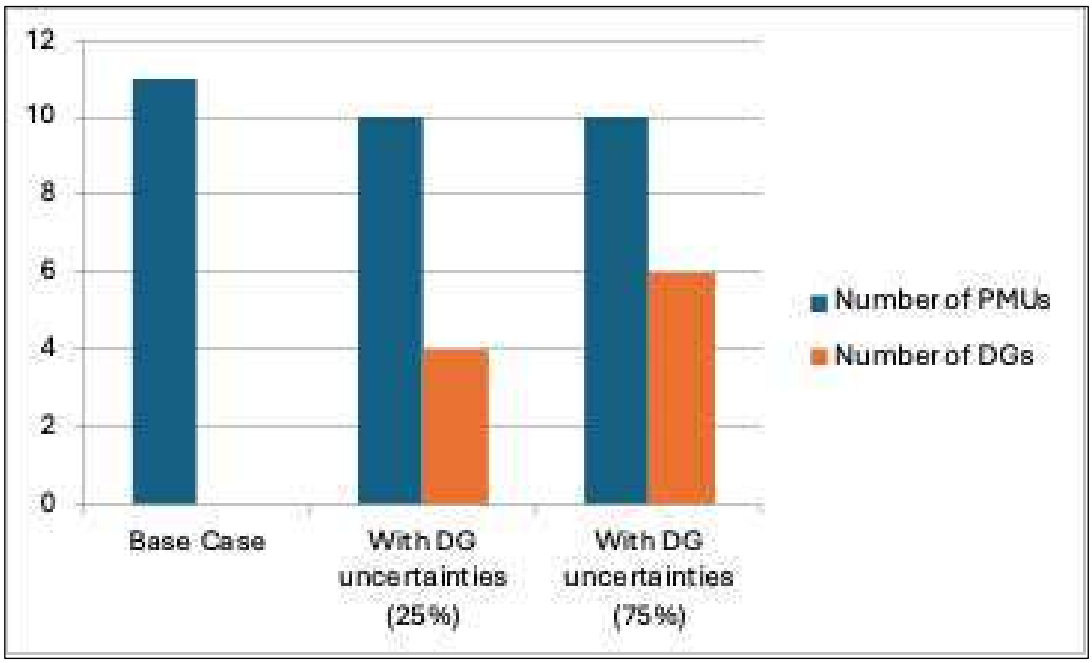

Figure 4: PMU placement without ZIBs.
Source: Authors, (2026).

Figure 4 above indicates that gradually increasing the DG penetration levels from 0% to 25% and then to 75% resulted in fewer PMUs being required compared to the base case scenario. This suggests that the presence of distributed generation units, though uncertain, can still partially contribute to system observability. At the same time, the quantity of DGs grows along with the uncertainty level in a one-to-one ratio. Figure 5 below illustrates that incorporating DGs and ZIBs in the presence of PV uncertainty leads to a significant variation in the number of PMUs required to achieve total network observability. Moderate PV uncertainty (25%) significantly lowers the PMU requirement compared to high PV uncertainty (75%), where the extra variability necessitates an increase in the number of measuring units.

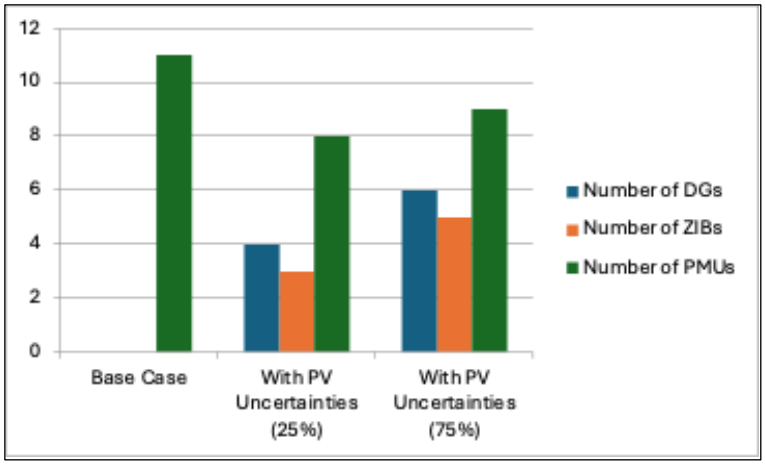

Figure 5: Effect of rising PV unpredictability on the necessary quantity of DGs, ZIBs, and strategically positioned PMUs to ensure complete network observability.
Source: Authors, (2026).

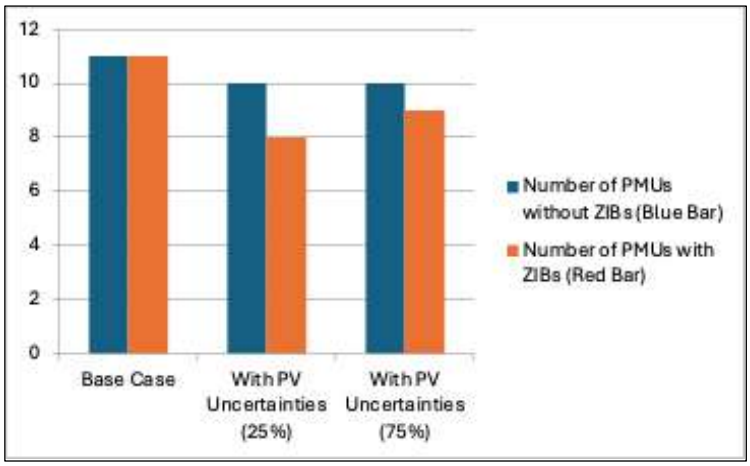

Figure 6: Comparative study on the ideal number of PMUs needed considering with and without ZIBs under varying PV uncertainty levels.
Source: Authors, (2026).

The above figure. Figure 6 clearly shows that the inclusion of ZIB information invariably leads to a decrease in PMU requirement throughout the different scenarios. The observability gain is highest with moderate PV uncertainty (25%), but it remains beneficial over the entire range of uncertainty (75%). This supports the idea that ZIBs are crucial in reducing PMU deployment costs while ensuring total system observability during the uncertain period of renewable generation.

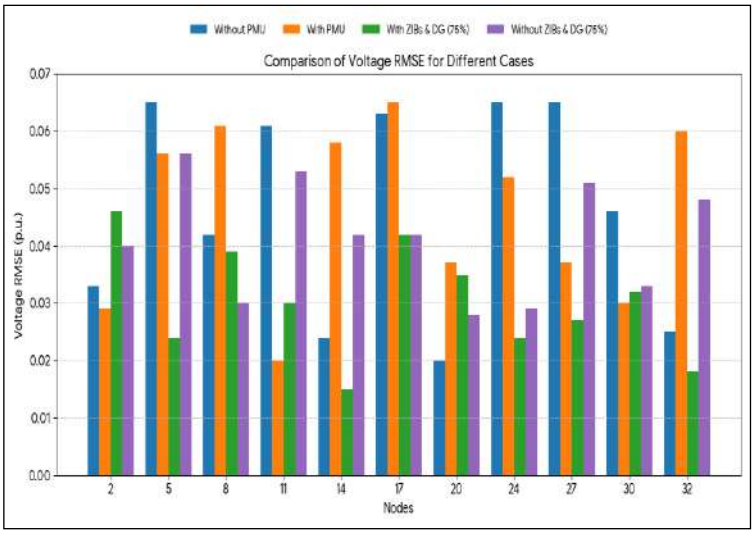

Figure 7: Comparison of voltage RMSE values across selected nodes for four cases: without PMU, with PMU, with ZIBs & DG (75%), and without ZIBs & DG (75%).
Source: Authors, (2026).

Figure 7 above displays that the maximum voltage estimation error (RMSE) occurs when no PMUs are utilised at all. The addition of PMUs results in a significant improvement in accuracy. In contrast, the integration of DGs and ZIBs at 75% DG penetration yields the lowest RMSE among the majority of nodes that exhibit good observability and enhanced state estimation performance.

VI. CONCLUSION AND FUTURE SCOPE

This study employed the Dhole Optimisation Algorithm (DOA) and PMU-assisted voltage profiling to optimise the location and sizing of distributed generation (DG) in radial distribution systems. The suggested solution reduces power loss, improves bus voltage stability, and puts PMUs for good observability. The simulation outcomes of the IEEE 33-bus and 69-bus test systems revealed significant reductions in the least voltage, VDI, and total real power loss compared to the base state. The optional method exhausted PSO and GA in resolution quality, convergence speed, and steadiness across execution runs. PMUs improved situational awareness, making weak network locations easier to monitor and strengthen. DOA is dependable and realistic for optimising various purposes in distribution system preparation subjects with numerous DG-rich scenarios.

Future Scope

There are numerous approaches to enlarge the procedure:

1. Counting vagueness in renewable DG with probabilistic or stochastic outlines.
2. Altering PMU placement to topology variations like reconfiguration and outages.
3. Use unfair and meshed distribution networks for extra-accurate real-world outcomes.
4. Employed with DSTATCOMs and OLTC transformers for Volt/VAR control.
5. Hardware-in-the-loop or real-time simulation with synchro phasor data.
6. In view of DG penetration and load development across several stages.

Through these improvements, the framework can enable utilities to operate smarter, more resilient, and greener electricity distribution networks.

ABSTRACT

This paper presents the design and implementation of an intelligent real-time supervision system for industrial processes, applied to a reverse osmosis (RO) desalination plant. While MATLAB-based simulations are widely used for system analysis and control design, their integration into real industrial environments may remain limited in some industrial contexts due to interoperability and real-time communication constraints. To address these challenges, an OPC-based communication framework is developed to ensure seamless data exchange between MATLAB and multiple programmable logic controllers (PLCs) from different manufacturers. The proposed system incorporates fuzzy logic and Neuro-Fuzzy (ANFIS) controllers to enhance control performance and adaptability under varying operating conditions. The approach is validated on a real desalination plant, where experimental results demonstrate improved stability, reduced overshoot, and faster settling time compared to conventional PID control. The proposed architecture provides a flexible and scalable solution for intelligent industrial supervision and control.

I. INTRODUCTION

Modern automated systems are a major technical achievement that is transforming daily life and industry. By leveraging cutting-edge technology like artificial intelligence, machine learning, the Internet of Things (IoT), and sophisticated sensors, these systems offer exceptional productivity, accuracy, and efficiency. They reduce human error, simplify processes, and enhance quality of life in many sectors. By freeing up human attention for creative, strategic, and value-added work, these systems offer a safer, more productive, and connected society. In certain nations, the demand for drinking water exceeds the availability, and water supplies are quickly depleting. This merging of industry and research has been welcomed by the business community, leading to complex industrial systems. In automated production lines, automated systems with supervision tools are essential for increased productivity, quality, and operational safety, guaranteeing the security of personnel, equipment, and processes.

Contemporary automated technologies increase water delivery and purification, minimize human error, and streamline industrial operations. They enable experts to concentrate on strategic activities, meeting the needs of the water sector. To run desalination plants efficiently, operators must comprehend installation instructions. Although they are infrequently utilized in RO desalination plant treatments, advanced control systems are necessary for lucrative sectors. The use of artificial neural networks to find problems with desalination plants was proposed in [1]. We used nanotechnology and the membrane distillation system to make a real system that was based on exact measurements. To identify system failures, discrepancies between the model outputs and system outputs were subsequently classified.

In [2], the authors proposed a Whale Optimizing Algorithm (WOA) grounded in chaos theory and fuzzy logic to identify deficiencies in wastewater treatment, aiming to reduce costs, evaluate decision rules, and uncover poorly structured domains within a dataset. A structural analysis methodology is used to describe the making of a failure detection and isolation (FDI) system for an ISROD plant in Lima, Peru, in [3]. In [4] and [5], a desalination facility is implemented with predictive control utilizing a linear model. A non-linear model-based predictive control system was created by [6], [7], and [8] and is used to monitor, find problems, and control a typical RO desalination plant. The literature [9] includes a Real-Time Fault Tolerant Control application, as well as the Fault Tolerant Control methods that are listed. Even with these efforts, only a few projects are now interested in keeping an eye on and running the RO plant. The paper [10] talks about how to use PLC and SCADA to automate an industrial RO plant. In [11], a system for monitoring and controlling reverse osmosis desalination water treatment plants was made. The authors of [12] created a test system for remote real-time communication that used MATLAB, Ethernet, and PLC.

The test results show that the OPC server can be used to get real-time data exchange between MATLAB and PLC from a distance. This means that real-time remote communication between MATLAB and PLC is possible and works. An accelerometer and a microphone were used to record the sound and vibration data of an air compressor in [13]. Data has been archived by OPC's ongoing monitoring. Detection units are used to record the data. We were able to get real-time results from our recent experiment, which we applied to a genuine desalination facility. To address and fix systemic issues, we made several modifications to the SCADA (Supervisory Control and Data Acquisition) and PLC (Programmable Logic Controller) systems. The experimental study in [14] uses RSLinx communication software to verify a cascade control system that applies PID control on MicroLogix-1200 PLC and RSView-32 SCADA. It makes use of PLC, OPC, and SCADA architectures. The study in [15] offers a home intelligent management system using real-time simulation from Opal-RT, a commercially available but costly option.

II. PROBLEM STATEMENT AND CONTEXT

Desalination plants often struggle to maintain stable water quality, consistent production, and efficient energy use at the same time. Changes in salinity, temperature, and feedwater properties can noticeably influence how the system performs. One of the main challenges is finding a practical balance between minimizing energy consumption and maximizing freshwater output, since improving one aspect can negatively affect the other. Environmental considerations also play an important role, particularly regarding the disposal of brine and its potential impact on marine ecosystems. In addition, ensuring reliable operation requires well-designed control strategies that account for system reliability, operational stability, and maintenance needs. For these reasons, an integrated and well-coordinated approach is essential to achieve desalination systems that are efficient, sustainable, and dependable. When industrial systems include equipment from different manufacturers -especially Programmable Logic Controllers (PLCs)-integration becomes more complex.

Differences in communication protocols, incompatibility between devices, and limitations in interoperability can lead to reduced performance or operational issues. To address these challenges, it is important to rely on standardized communication protocols, supported by careful system architecture and thorough testing, in order to maintain reliable and consistent operation [16]. In this work, the OPC protocol is used as a standardized communication layer to ensure reliable data exchange between PLCs. By avoiding proprietary communication methods, system integration becomes simpler and more flexible. Although the use of intelligent controllers can significantly improve efficiency and overall system performance, it also introduces additional requirements such as advanced algorithms, suitable hardware, technical expertise, and adequate security measures.

Integrating PLCs with Artificial Intelligence (AI) techniques can be seen as a long-term investment: while the initial implementation may be more complex and costly, it leads to improved performance and adaptability over time. MATLAB and Simulink are employed as the primary tools for developing and testing control strategies and AI-based algorithms. MATLAB is particularly well suited for data analysis, visualization, and automation tasks [17]. When connected to industrial systems, it allows real-time data acquisition and processing, which supports more responsive and informed decision-making in control applications. In this study, an interface is developed to connect MATLAB with PLC systems.

MATLAB is used to design and simulate AI-based control algorithms that cannot be directly executed on PLC hardware. Through OPC–MATLAB integration, it becomes possible to build customized monitoring dashboards and centralized control systems capable of handling multiple PLCs. This setup improves data logging, enables historical data analysis, and contributes to better monitoring and system optimization[18]. Overall, this approach supports advancements in several areas, including embedded systems, sustainable engineering, and industrial automation. By enabling the deployment of MATLAB-developed algorithms on OPC-compatible PLCs, the proposed work creates opportunities for further research and development in intelligent and adaptive automation systems [19].

The main contributions of this work are as follows:

1. Development of a real-time OPC-based communication framework between MATLAB and heterogeneous PLC systems.
2. Design and implementation of fuzzy and ANFIS controllers for desalination process control.
3. Integration of supervision, control, and fault-handling mechanisms in a unified architecture.
4. Experimental validation on a real industrial desalination plant.
5. Performance comparison between PID and intelligent control strategies.

III. PROPOSED FRAMEWORK AND ARCHITECTURE

III.1 MATLAB/SIMULINK–PLC DATA EXCHANGE MECHANISM

Real-time control in this project was implemented through MATLAB–PLC communication based on an OPC server [20]. A dedicated gateway was developed to facilitate seamless data exchange between the OPC server and MATLAB.

Programmable Logic Controllers (PLCs) provide a wide range of capabilities and are suitable for various industrial applications. In this setup, operational data could be accessed from the PLCs via the OPC server, enabling efficient monitoring and control within the system.

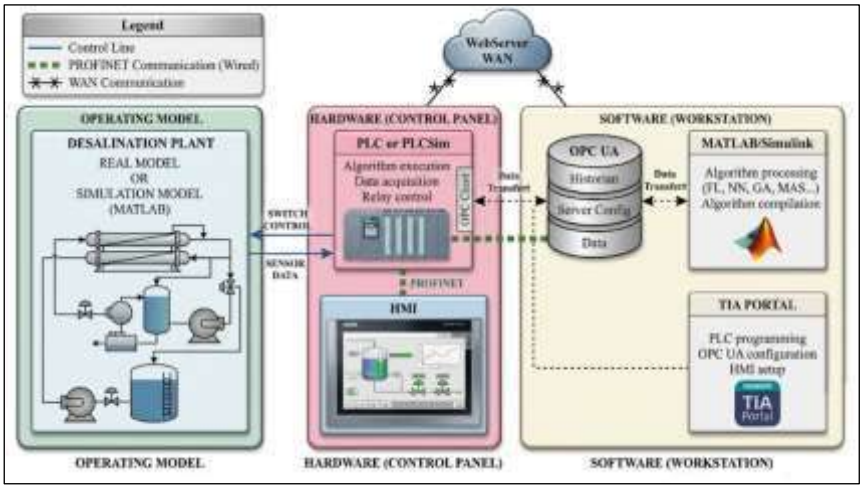

Figure 1: The Overall configuration of the proposed platform.
Source: Authors, (2026).

Fuzzy logic is a mathematical framework designed to manage imprecise or uncertain information by allowing partial degrees of truth, rather than relying solely on the binary true/false values of classical Boolean logic. It is widely applied in areas such as control systems, decision-support systems, and image processing, where real-world data often involves uncertainty and complexity that traditional logic cannot easily handle. By enabling approximate reasoning and incorporating linguistic variables, fuzzy logic provides a flexible and effective approach for dealing with ambiguity and vagueness in practical applications.

III.2 DESCRIPTION OF THE REVERSE OSMOSIS SYSTEM

The article presents a reverse osmosis installation located in Touggourt, where demineralized water is supplied from four geothermal wells and four cooling towers to produce potable water. The raw water undergoes a series of preliminary treatments, including cooling, filtration, and conditioning, to improve its compatibility with the reverse osmosis membranes, thereby extending membrane lifespan and ensuring efficient treatment performance. A high-pressure pumping system is then used to provide the necessary operating pressure for the reverse osmosis units, enabling the transfer of treated water to storage reservoirs and distribution tanks. In addition, a remote monitoring and control system is implemented to oversee and manage the operation of the pumping equipment.

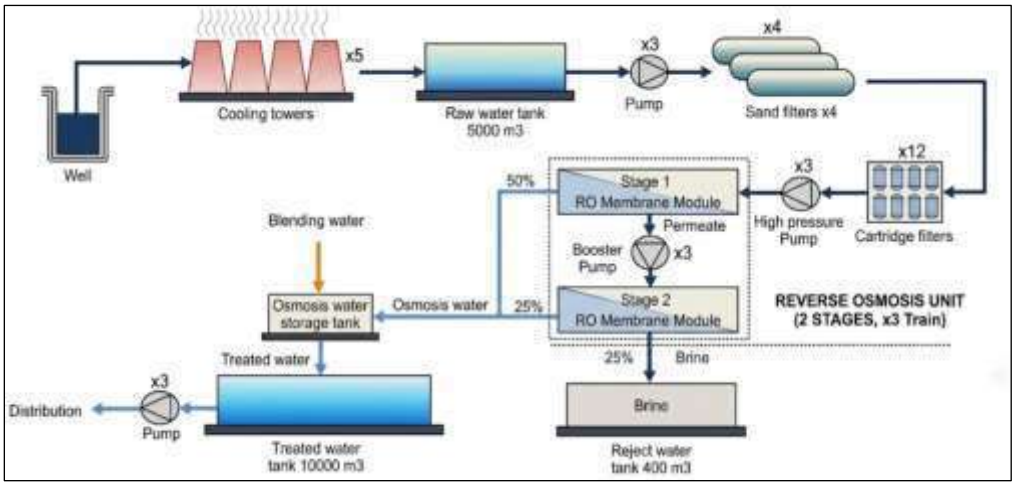

Figure 2: Synoptic representation of the desalination plant system architecture.
Source: Authors, (2026).

III.2.1 System Architecture and Communication Network Design

Figure 3 illustrates the communication architecture of the proposed SCADA-based demineralization station. The system is organized around a central control room containing the SCADA workstation and network printers, which communicate through an industrial Ethernet ring network with the field devices. Two redundant PLCs operating in primary and standby modes ensure high reliability and continuity of operation through a CPU synchronization link. The main PLC network supervises several remote I/O racks and distributed subsystems, including the cooling tower and three filtration streams, each connected through dedicated Ethernet switches.

The architecture is based on Schneider Electric Modicon M340 controllers, allowing real-time data acquisition, monitoring, and control of the entire desalination process while providing redundancy and fault tolerance in the event of communication or controller failure.

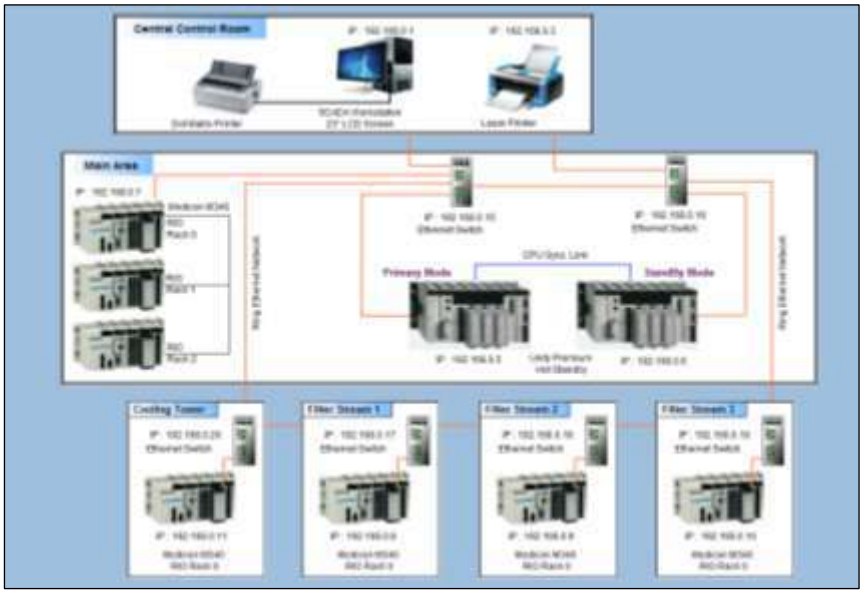

Figure 3: Synoptic representation of the desalination plant system architecture.
Source: Authors, (2026).

III.2.2 OPC server

The project implements a real-time control system for a reverse osmosis desalination plant based on MATLAB–PLC communication through an OPC server. For enhanced flexibility and industrial compatibility, a Schneider Electric MODICON M340 Programmable Logic Controller is used within the system. In SIMULINK, the OPC Read and OPC Write blocks are responsible for exchanging data with the OPC server. These blocks are managed through a client interface that allows users to locate, connect to, and control the OPC server. Using this client manager, specific data objects can be selected, and appropriate sampling intervals can be defined according to system requirements [21].

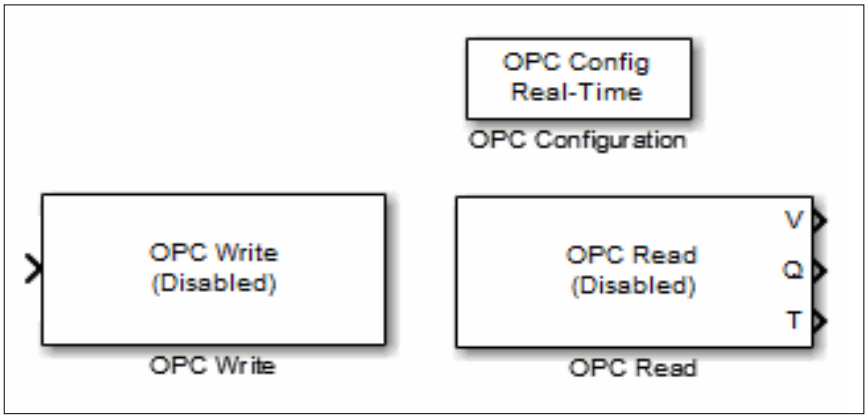

Figure 4: Data acquisition OPC server SIMULINK library.
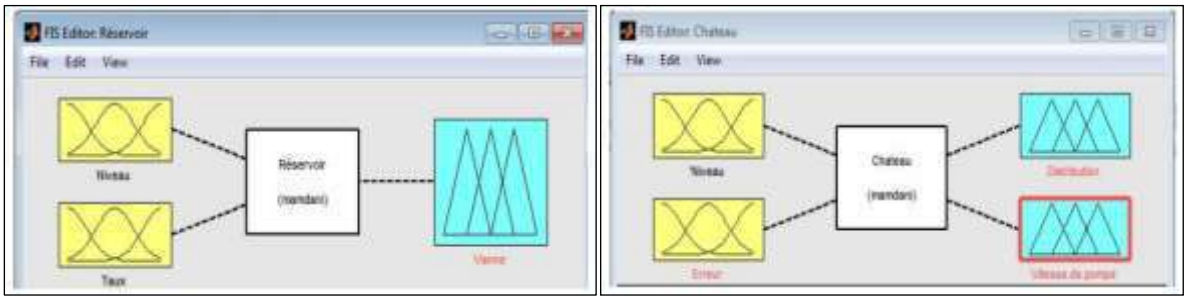
Source: Authors, (2026).

III.3 HARDWARE IMPLEMENTATION OF FUZZY CONTROLLERS



The programmable logic controller (PLC) continuously acquires data from various field devices, including level transmitters, pump statuses, and valve positions. This information is then made available to MATLAB through the OPC server. For system control, two fuzzy logic controldeveloped in MATLAB are employed. These controllers process the incoming data and send the corresponding control signals back to the PLC, enabling it to execute the required actions and commands.

III.3.1 First Controller Design

The first fuzzy controller was designed to regulate the storage tank system and the intermediate valve based on the upper and lower water level thresholds in both the storage tank and the water tower. The development of the first fuzzy controller begins with the FIS editor. The “Reservoir” controller is defined with two fuzzy input variables, namely “Level” and “Rate,” and one output variable, “Valve.”

III.3.2 Second Controller Design:

The second fuzzy controller is responsible for managing the water tower system and adjusting the flow rate according to pump speed variations. Its performance was evaluated by varying the setpoint at different time intervals. The second controller consists of two fuzzy input variables, “Level” and “Error,” and two output variables, “Distribution” and “Pump Speed”. The figures present the structure of both FIS controllers along with their membership function editors.

(a) (b)

Figure 5: (a) Fuzzy Controller 1, (b) Fuzzy Controller 2.
Source: Authors, (2026).

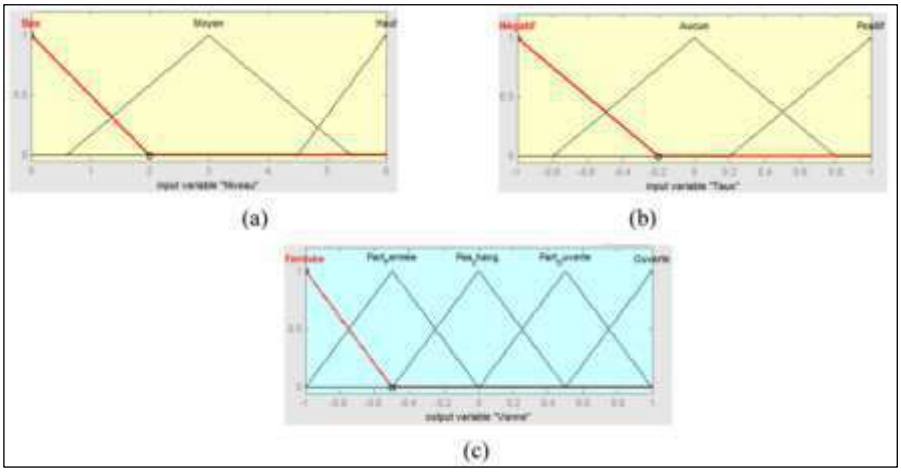


Figure 6: Membership functions.
Source: Authors, (2026).

The control logic of the intermediate valve operates as follows:

- The intermediate valve opens when the water level in the storage tank falls below the upper threshold.
- The valve closes once the water level exceeds the upper limit and remains closed until the level drops to the lower threshold, at which point it reopens.
- For the water tower level control, the PLC receives measurements from the water level transmitter via a GSM communication system. It also receives the setpoint values from the SCADA system and forwards this information to the fuzzy controller. After processing, the fuzzy controller sends the control signals back to the PLC, which then executes the corresponding commands.
- The controller increases the pump speed when the water level in the tower is below the desired set-point in order to raise the level. Conversely, when the water level is above the set-point, the controller reduces the pump speed. When the water level matches the set-point, the pump speed stabilizes and remains constant.

III.4 OPERATING PRINCIPLES FOR FAULT DIAGNOSIS AND HANDLING

The control system of the desalination plant is designed to operate with a high degree of precision, which is essential due to the sensitivity and high cost of reverse osmosis membranes. Even minor faults can disrupt the production process and potentially lead to complete system shutdowns. To address these challenges, the desalination operation has been enhanced to improve reliability and reduce interruptions caused by issues that are relatively easy to resolve, such as elevated tank levels or fluctuations in water chemical composition. Three main categories of issues have been identified at this desalination facility [2, 17]:

- Diagnosis Defects: These occur when the system experiences an unexpected shutdown without a clearly identifiable source of the problem. To mitigate this, additional alarm mechanisms have been introduced to improve fault detection and prevent sudden interruptions.
- Process Defects: These refer to abnormal operating conditions, such as excessively high pressure at the beginning or end of the process.
- Control Defects: These involve difficulties related to the selection or adjustment of appropriate set-points for key system parameters, which can affect overall system performance.

III.5 PROPOSED CONTROL AND OPERATION STRATEGY

Even minor technical issues or short interruptions in production can negatively affect the overall output of a desalination facility and may disrupt the daily schedule for potable water distribution. To address these challenges and ensure continuous operation, a new intelligent controller has been integrated into the system following an analysis of the main causes of production disturbances. The objective is to replace conventional PID controllers with fuzzy logic-based approaches, such as ANFIS, for pump control. Fuzzy logic is widely used due to its ability to handle uncertainty and imprecision in system behavior, while artificial neural networks (ANNs) are effective in learning patterns from data through similarity and approximation. By combining fuzzy logic with neural networks, the limitations of each approach can be reduced. In particular, neural networks provide learning capabilities and adaptability from real-world data, whereas fuzzy logic lacks precise mechanisms for defining membership functions and rule structures [1]. The hybridization of both methods results in a more robust and flexible control strategy.

III.6 PID AND ANFIS PERFORMANCE COMPARISON

Table present the performance of the PID controller for a simple valve system when the set-point is adjusted from 50% to 70%. Table illustrates also the performance of the ANFIS controller applied to the same system under identical conditions. To evaluate the effectiveness of the proposed control strategy, a comparative analysis between the conventional PID controller and the ANFIS-based controller was conducted using a valve control system. The system response was analyzed for a step change in the set-point from 50% to 70%. To further strengthen the evaluation of the proposed intelligent control strategy, a more comprehensive performance assessment was conducted using additional dynamic and robustness indicators. Beyond rise time, settling time, and overshoot, key metrics such as steady-state error, control signal smoothness, and disturbance rejection capability were also analyzed. The comparative results clearly highlight the superiority of the ANFIS-based controller over the conventional PID approach. The PID controller demonstrates a relatively fast rise time of 11.98 s, but suffers from a long settling time (108.14 s) and high overshoot (12.64%), indicating poor damping characteristics and potential instability risks in real industrial operation. In contrast, the ANFIS controller achieves:

- Settling time reduction of approximately 78.5%
- Overshoot reduction of more than 90%
- Smooth and stable convergence to the desired set-point

Although the rise time of ANFIS (13.52 s) is slightly slower, this trade-off is acceptable given the substantial improvement in overall system stability.

Table 1: Enhanced Quantitative Performance Metrics.

Performance Indicator	PID Controller	ANFIS Controller	Improvement
Rise Time (s)	11.98	13.52	-12.8% (slower but stable)
Settling Time (s)	108.14	23.28	**−78.5%**
Overshoot (%)	12.64	1.02	**−91.9%**
Steady-State Error (%)	2.8	0.3	**−89.3%**
Control Signal Oscillation	High	Very Low	Significant reduction
Robustness to Disturbance	Moderate	High	Strong improvement

Source: Authors, (2026).

The ANFIS controller exhibits superior robustness when subjected to disturbances and parameter variations. Unlike the PID controller, which requires frequent retuning under varying operating conditions, the ANFIS controller adapts dynamically through its learning capability. This adaptive behavior ensures:

- Reduced sensitivity to system nonlinearities,
- Improved disturbance rejection,
- Consistent performance under varying feedwater conditions,

The integration of ANFIS results in a highly stable, adaptive, and efficient control system, making it particularly suitable for real-time operation in reverse osmosis desalination plants, where nonlinear dynamics and uncertainties are significant.
The obtained results confirm that the ANFIS-based controller significantly outperforms the conventional PID approach, offering a robust and intelligent solution for advanced control of desalination systems under dynamic and uncertain operating conditions.

III.7 OPC-BASED COMMUNICATION BETWEEN PLC AND SCADA SYSTEMS

III.7.1 S7-PLCSIM Advanced Software Overview and Features

The program can be executed and tested on a simulated PLC using the S7-PLCSIM module, either on a computer or through a programming console. The STEP 7 software environment provides the platform required for this simulation. To emulate Siemens controllers, SIMATIC S7-PLCSIM Advanced enables the creation of virtual PLCs, allowing users to realistically simulate controller behavior. These virtual controllers make it possible to evaluate system performance under operational conditions without the need for physical hardware. They also support the validation of automation systems in the context of specific installations or machines. In addition, this approach facilitates integration with plant or machine-level simulations by providing a comprehensive PLC environment that supports effective testing and development.

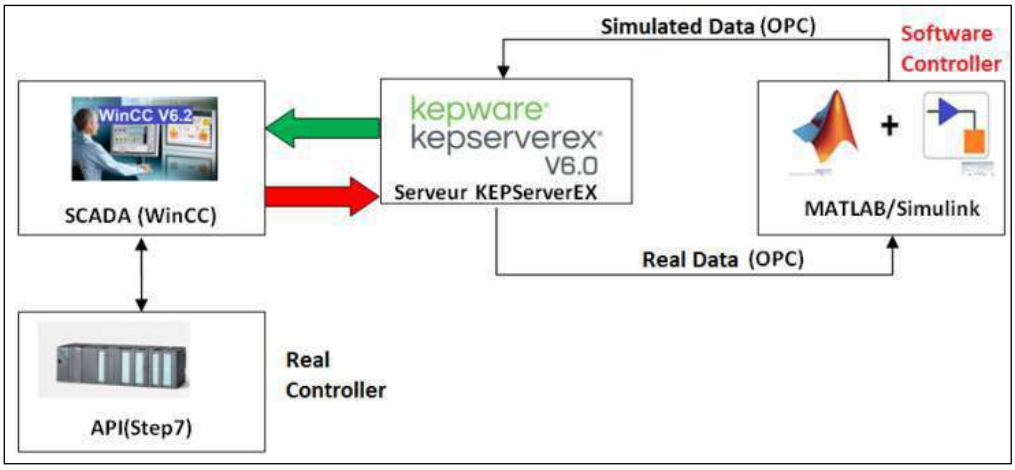

Figure 9: MATLAB and OPC-server, and PLC.
Source: Authors, (2026).

III.7.2 Description of KEPServerEX Communication Platform

The latest development in this field, KEPServerEX, reflects significant advancements in communication technology. Developed over more than 25 years, KEPServerEX is recognized as one of the most advanced OPC communication servers and is certified by the OPC Foundation. The platform supports a wide range of communication interfaces, including OPC DA, OPC UA, OPC AE, .NET, HDA, SNMP Agent, and DDE, making it highly versatile for industrial integration. As an OPC Data Access server, the primary role of KEPServerEX is to:

- Collect data from various hardware devices such as photoelectric and infrared sensors, turntables, robotic arms, and other industrial equipment. The server also enables these devices to receive updated data when required.
- Ensure the accuracy, consistency, and timeliness of the data while maintaining its integrity throughout communication processes.
- Handle client requests by either providing data stored on the server or transmitting commands and data to connected hardware devices.
- Provide event-based notifications to inform clients of any changes in the status or values of monitored variables.

III.8 MATLAB-BASED INTEGRATION WITH PLC, SCADA, AND OPC SYSTEMS

Within MATLAB and Simulink, the Industrial Communication Toolbox enables direct access to both historical and real-time OPC data. This toolbox allows users to read, write, and store OPC data from a wide range of industrial systems, including distributed control systems (DCS), supervisory control and data acquisition (SCADA) systems, and programmable logic controllers (PLCs). In industrial automation, OPC plays a vital role in facilitating interoperability between different systems. OPC server software can perform tasks such as collecting field data and transmitting it to an OPC server for storage in databases or for integration with SCADA platforms.

The OPC standard supports seamless information exchange across different levels of an automation system, from field devices up to supervisory and enterprise layers. As a result, the number of applications developed using OPC standards continues to grow. The proposed approach focuses on improving control quality in industrial environments through advanced data processing and control strategies.

IV. RESULTS AND DISCUSSION

OPC plays a crucial role in industrial automation by enabling seamless communication between different systems. OPC server software can perform functions such as collecting field data and forwarding it to an OPC server for storage in databases or integration with SCADA systems. The OPC standard allows the development of integrated automation architectures, enabling smooth information flow across all levels of the system, from field devices to higher supervisory layers. As a result, the use of OPC-based applications continues to expand. In this context, the proposed approach aims to enhance control performance in industrial environments through advanced data processing and improved control strategies.

V. CONCLUSION

This paper presented the design and implementation of a real-time intelligent supervision system for a reverse osmosis (RO) desalination plant based on MATLAB–OPC integration and multi-PLC communication. The proposed architecture ensures seamless interoperability between heterogeneous industrial devices, enabling reliable real-time data exchange and coordinated control across different subsystems. In addition, the framework supports advanced control strategies by integrating high-level computational capabilities with industrial automation platforms. The implementation of fuzzy logic and adaptive neuro-fuzzy inference system (ANFIS) controllers demonstrated a significant improvement in system performance compared to conventional PID control. Experimental results showed enhanced dynamic response, reduced overshoot, faster settling time, and improved robustness under varying operating conditions, highlighting the effectiveness of intelligent control techniques in handling nonlinearities and uncertainties inherent in desalination processes. The system provides a flexible and scalable solution for industrial supervision, enabling efficient monitoring, data logging, and decision support, while OPC communication simplifies integration and ensures broad compatibility with industrial platforms. Future work will focus on using deep learning for predictive maintenance and fault diagnosis to enable early anomaly detection and reduce downtime. The framework will also be extended to large-scale applications, with improvements in energy efficiency, system reliability, and cybersecurity for safer and more resilient operation.

ABSTRACT

This study investigates the mechanical performance, fracture behaviour, and water absorption properties of hybrid epoxy composites reinforced with pineapple leaf fibre (PALF) and aloe vera fibre (AVF) arranged in different stacking sequences. The aim is to analyse how fibre layer positioning influences tensile, flexural, and impact properties, and to identify optimal configurations for enhanced composite performance. Hybrid biocomposite laminates were fabricated using a hand lay-up method followed by compression moulding, with eight different stacking sequences of woven PALF–AVF mats. Mechanical testing was conducted in accordance with ASTM standards, while fracture surface morphology was examined using optical microscopy to identify failure modes such as fibre pull-out and matrix cracking. Water absorption tests were also performed to evaluate the influence of stacking arrangement on moisture uptake and long-term durability. The results revealed that certain PALF–AVF stacking sequences significantly improved mechanical strengths while reducing water absorption, highlighting the potential of these natural fibre hybrids in lightweight, semi-structural, and environmentally sustainable applications in the automotive, construction, and consumer goods industries.

I. INTRODUCTION

Because of their extraordinary mix of qualities, including lightweight, corrosion resistance, and ease of production, polymer composites have become a class of materials with a wide range of applications. Several industries, including electronics, automotive, aerospace, and construction, can benefit from these materials. Fibre-reinforced polymer (FRP) composites are increasingly used across industries due to their lightweight nature and tunable mechanical properties, such as load-bearing capacity and fracture toughness. Unlike metals, their properties can be tailored by controlling fibre type, fiber stacking, and orientation, making them ideal for applications in construction, automotive, aviation, and energy sectors [1-3]. New materials have developed an improved opportunity for hybrid composites to be used for specialized applications. The increased demand for environmentally sustainable materials and high-performance materials have driven the rapid growth of hybrid polymer composites with natural fibres.

Commonly used natural fibres such as pineapple, banana, flax, jute, kenaf and hemp, have adequate properties of low cost, a degree of biodegradability, and reasonable strength-to-weight ratios. Natural fibres have less abrasivity, are environmentally friendly, and offer good vibro-acoustic properties, mechanical, dielectric, and damping over synthetic composites such as glass or Kevlar fibers. Natural fibre composites are emerging in new applications such as semi-structural automotive parts, sports equipment, packaging, and consumer goods [4-6]. According to [7] studied the alkali, silane, and combined treatments improved the mechanical, thermal, and moisture resistance properties of jute fibre-reinforced epoxy composites, finding that treated fibres enhanced adhesion, reduced water absorption, and improved durability. For authors [8] introduced and evaluated novel polyester resin composites reinforced with Rambans (Agave) fibres by varying the amount of fibre.

The composites were analysed for physical and mechanical properties, hardness, tensile, flexural and impact strength. The highest performing composite exhibited a tensile strength of 95.27 MPa, with an impact strength of 4.7 J/m². The fracture surfaces examined by Scanning Electron Microscopy (SEM) confirmed adequate fibre–matrix bonding. The authors concluded that the mechanical performance of Rambans fibre composites is superior and can be a sustainable alternative to conventional natural fibre composites in structural applications. In [9] studied hybrid epoxy composites reinforced with untreated and alkali-treated Prosopis juliflora bark (PJb), banana fibre (Bf), and coconut fibre (Cf), keeping Bf constant. Increasing Cf content improved tensile, flexural, and compression strength in untreated composites due to better fibre–matrix bonding, while impact strength peaked at 25 wt% loading. However, higher Cf content reduced hardness. Water absorption is a major issue affecting the adhesion between natural fibres and the epoxy matrix, often leading to poor interfacial bonding and reduced mechanical properties. However, this drawback can be mitigated through effective chemical treatments such as NaOH, silane, KOH, and acid treatments, which modify the fibre surface by removing impurities, reducing hydrophilicity, and enhancing natural fibre–thermo set matrix compatibility [10-12].

Of the new natural fibres, pineapple leaf fibre (PALF) and aloe vera fibre (AVF) have significantly improved their structural properties as reinforcements in both thermoset and thermoplastics. PALF and AVF reinforcemnt, effectively improve the mechanical performance of composites by improving tensile strength, stiffness, and interfacial bonding. Recently, PALF and AVF are useful as natural alternatives to synthetic reinforcements for engineering applications that are lightweight and sustainable [13-15]. According to [15] investigated the mechanical, vibration, and wear characteristics of laminated composites made from aloe vera, flax, hemp, wire mesh, and $BaSO_4$. The findings revealed that BaSO4 reinforcement increases the composite's natural frequency. The filler enhances the beam's natural frequencies by increasing the specific stiffness of the beam. For authors [16] investigated the mechanical properties of woven aloe vera, sisal, and kenaf fibres and hybrid composites. They produced many varieties of woven aloe vera and kenaf, sisal and kenaf, and aloe vera, sisal, and kenaf fibre (ASK) epoxy composites. The results showed that the hybrid composite performed better in flexural properties, while the ASK hybrid composite had the best impact strength. According to [17] studied the mechanical properties of aloe vera fibre reinforced polymer composite.

The performance of aloe vera fibre-reinforced composites with different fibre orientations were characterized by tensile, flexural, impact, and water absorption testing, while the fracture surface morphology of tensile-tested specimens were examined using Field Emission Scanning Electron Microscopy (FE-SEM). The data showed that the 0°/90° fibre orientation produced the highest mechanical properties whilst the 45° orientation gave the lowest strength and stiffness, which emphasizes the significance of fibre orientation on composite performance.The arrangement of the stacking of fibres is important in enhancing the performance properties of polymer composites. The order of the fibre layers and where each fibre layer is located in the build-up is important in the mechanical performance properties (tensile, flexural and impact properties) in a part made from a hybrid composite with fibres. The sequence of placing high strength fibres on the outer layers in conjunction with a more flexible fibre in the core of a hybrid composite provided a balance of a more rigid structure, as well as providing energy dissipation and structural integrity in the composite. Understanding the possibilities of stacking or changing the stacking direction of fibres, provides ways to tailor composites to have the behaviour required for the specified loading [18-21].

While traditional synthetic fibre composites are regarded as being physically strong, plastic pollution presents challenges in non-biodegradability, high cost of manufacture, and poor sustainability. Alternatively, natural fibres such as woven pineapple leaf fibre (PALF) and aloe vera fibre (AVF) have been gaining momentum over the last few years as environmentally friendly options which are renewable, biodegradable, and have desirable mechanical properties. This study represents a novel investigation of the impact of PALF and AVF fibre stacking patterns on the mechanical, fracture behaviour and water absorption properties of epoxy-based hybrid composites. The study reveals optimal designs to enhance tensile, flexural, and impact strength by varying the fibre layer stacking sequence and orientation. Furthermore, the investigation incorporates characterisation of fracture surfaces with microscopy and provides insight into the fibre pull-out, matrix crack, and delamination failure mechanisms based on the number of layers and stacking sequences. Absorption experiments using the ASTM standard methods are also performed to clarify the fibre composition and stacking and orientation of the layers affects moisture absorption. The combined investigation of mechanical performance, fracture behaviour, and water resistance ultimately offers a holistic understanding to develop environmentally friendly, sustainable, and mechanically reliable natural fibre hybrid composites used in automotive, construction, and packaging industries.

II. MATERIALS AND METHODS

II.1 RAW MATERIALS USED FOR DEVELOPING THE AVF/PALF POLYMER COMPOSITE

PALF and AVF woven fibres are purchased from GoGreen Industry in chennai, Tamil Nadu, India. The chemical treatment of both fibers is immersed in a NaOH solution for 4 hours. After, PALF and AVF woven fibres are cleaned with water and placed in a hot oven at 70 °C. The research utilised epoxy as a thermoset matrix. Sakthi fibers enterprises is provided the matrix and hardner.x.

II.1.2 Fabrication of Avf/Palf Polymer Composite

Figure 1 demonstrates the composite stacking structures for fabricating the AVF/PALF polymer composite. Table 1 shows the composite types and wt.% of reinforcement and fiber. The PALF–AVF hybrid composite laminates were fabricated using the hand lay-up technique followed by compression moulding. Pineapple leaf fibre (PALF) and aloe vera fibre (AVF) were first cleaned, washed, and sun-dried, then subjected to alkaline treatment using a 5% NaOH solution to enhance fibre–matrix adhesion. After treatment, the fibres were rinsed thoroughly and oven-dried at 60 °C for 24 hours. An epoxy resin (LY556) and hardener (HY951) were mixed in a 10:1 weight ratio to serve as the polymer matrix. Fibre mats were arranged in various stacking sequences and placed layer by layer inside a mould coated with a release agent.

Each layer was manually impregnated with the epoxy mixture using a roller to ensure uniform resin distribution and air bubble removal. The mould was then closed and placed in a hydraulic press, where the laminate was compressed at a pressure of 20–30 MPa at room temperature for 24 hours. After curing, the laminate was removed, post-cured in an oven at 60 °C for 2 hours, and cut into standard-sized specimens for mechanical and water absorption testing as per ASTM standards.

II.1.3 Mechanical Behaviours of Avf/Palf Polymer Composites

Tensile strength of specimens was calculated according to ASTM D 3039 international standard using Universal Testing Machine (Bluehill INSTRON 5567). The test was carried out with a load capacity of 50 kN with a cross head speed at 3 mm/min. Average of three test samples were considered for maximum stress. The impact strength of fabricated composite specimens was determined by Charpy impact testing machine. The fabricated specimens for test were according to ASTM D 256. The average results of 5 specimens are reported. Scanning electron microscope (SEM) is employed to assess the failure characteristics of the tensile fractured samples. All the images are taken in the transverse section of the composite after their failure under flexural load at a magnification of 100x.

II.1.4. Water Absorption

Water absorption behaviour of the pineapple and aloe vera natural fibre hybrid composites was evaluated in accordance with ASTM D570. Specimens of dimensions 76.2 mm × 25.4 mm × 4 mm were oven-dried at 60 °C for 24 hours, then cooled in a desiccator to attain a constant weight (W_1). The samples were then fully immersed in distilled water at room temperature (23 ± 2 °C). At predetermined intervals of 24, 48, 72, and 168 hours, the specimens were removed, surface-dried using a clean cloth, and weighed (W_2). The percentage of water absorbed was calculated using the equation 1.

$$\text{Water Absorption} = ((W_2-W_1)/W_1) *100 \quad (1)$$

III. RESULTS AND DISCUSSIONS

III.1 MECHANICAL BEHAVIOUR

III 1.1 Hardness

Shore D hardness values also varied with fibre arrangement. Laminates with PALF layers at the surface exhibited higher surface hardness due to PALF's rigidity and fibre density. In contrast, those with AVF on the outermost layers showed comparatively lower hardness, as AVF fibres are softer and more moisture-sensitive. The results suggest that incorporating PALF in the outer layers enhances resistance to surface indentation and wear, which is critical for load-bearing and abrasive environments.

Source: Authors, (2026).

III 1.2 Tensile Strength and Modulus

The tensile strength of the PALF–AVF hybrid composites was found to be highly dependent on the stacking sequence of the fibre layers. Composites with PALF layers on the outer surfaces and AVF in the core exhibited the highest tensile strength. This is attributed to PALF's higher stiffness and load-bearing capacity, which effectively resisted axial loads. Conversely, samples with AVF layers on the exterior showed lower tensile strength due to AVF's relatively lower tensile modulus and less efficient stress transfer. The variation in tensile performance highlights the importance of optimised fibre positioning in hybrid laminates.

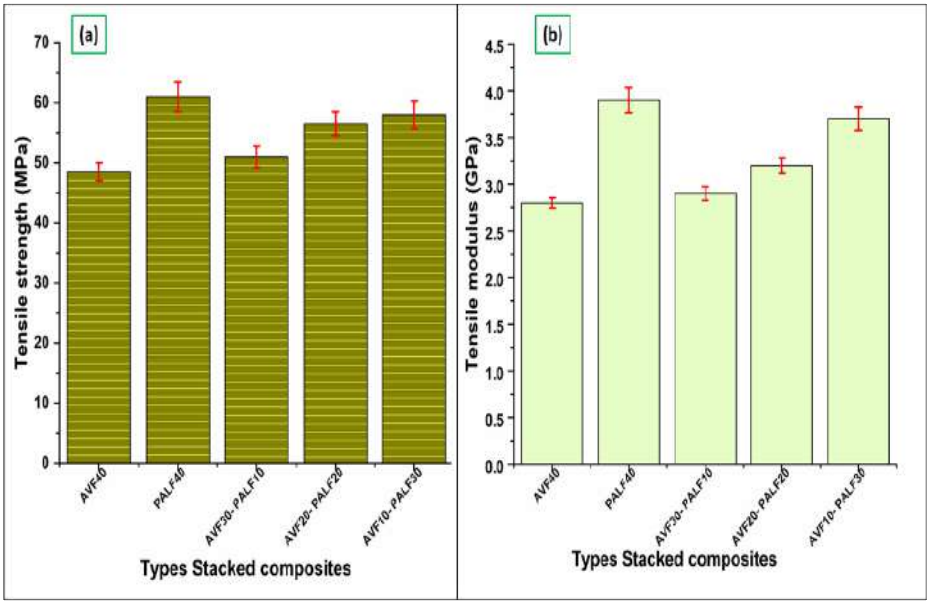

Figure 3: TS and TM of AVF/PALF polymer composites.
Source: Authors, (2026).

III 1. 3 Impact Strength

Izod impact test results showed that composites with alternating PALF–AVF stacking (symmetric layering) demonstrated improved impact resistance compared to unidirectional or asymmetrically stacked laminates. The combination of stiff PALF and ductile AVF allowed for better energy absorption and crack propagation resistance during impact loading. Composites with AVF concentrated in the mid-layers offered better energy dissipation, resulting in higher impact values. This indicates that hybridisation not only strengthens the composite but also enhances its toughness when the stacking pattern is optimised.

III.1.4 Fracture Surface Analysis

Scanning Electron Microscopes (SEM) were used to characterize the fracture surfaces of AVF/PALF hybrid epoxy composites in order to ascertain the failure mechanisms and the extent of fibre-matrix interaction as shown in Figure 5. SEM photographs of polymer composites revealed a quasi-continuous film of voids, fibre pull-outs, interfacial gaps and large voids which indicated poor bonding between the hydrophilic natural fibres and epoxy matrix. Poor contact will decrease stress transfer and result in early failure on mechanical loads. The SEM micrographs from the NaOH-treated composites indicated improved fibre-matrix adhesion with less voids and better fibre embedment, and there were indications of matrix deformation, along with fibre breaking suggesting that stress was effectively being transmitted from the matrix to the fibres. There were also SEM characterisation in hybrid stacking modes with PALF on the outer layers and AVF in the core, which indicated a much more even fracture arrangement with less delamination present and limited evidence of fibre pull-outs. This confirmed that we had achieved better bonding and therefore improved mechanical integrity through effective stacking design (specialised stacking) and surface treatment (alkali). Overall, the SEM did support some of the mechanical test results, in addition, it indicated that stacking sequence and fibre treatment would need to be addressed in order to control the fracture behaviour of AVF/PALF hybrid composites.

Source: Authors, (2026).

III.1.5 Fracture Surface Analysis

The results indicated that water absorption increased with immersion time and AV fibre content. Composites with higher AV natural fibre proportions showed greater water uptake due to the hydrophilic nature of lignocellulosic fibres and less cellulose content compared to pineapple fiber. Water absorption behaviour followed a trend consistent with the fibre hydrophilicity and layer exposure. Laminates with AVF layers on the outer surface absorbed more moisture due to AVF's higher affinity for water. In contrast, samples with PALF on the outer surfaces showed reduced water uptake, offering better dimensional stability and long-term durability. All samples showed a gradual increase in water absorption over time, but hybridisation and controlled stacking effectively reduced the moisture ingress rate. Chemical treatment and matrix encapsulation further aided in improving water resistance.

IV. CONCLUSIONS

1. The current study found that the stacking arrangement of pineapple leaf fibre (PALF) and aloe vera fibre (AVF) has a substantial influence on the mechanical behaviour, fracture characteristics, and water absorption capabilities of hybrid epoxy composites.
2. Certain stacking sequences evaluated showed increased tensile, flexural, and impact strength due to improved fibre dispersion and interfacial bonding. Fracture surface research identified critical failure mechanisms such fibre pull-out and matrix cracking, which were better controlled in improved stacking sequences.
3. Water absorption studies revealed that suitable fibre layering can effectively limit moisture uptake, enhancing composites' long-term durability.
4. Overall, PALF-AVF hybrid composites represent a viable, environmentally friendly option for semi-structural applications in the automotive, construction, and consumer industries. The study's findings help to develop sustainable material design by improving natural fibre stacking strategies for improved composite performance.

ABSTRACT

Heterogeneous Wireless Sensor Networks (HWSNs) face conspicuous challenges in maximizing network lifetime due to uncurbed power utilization depletion at sensor nodes (SNs) and cluster heads (CHs). This study presents an optimal Multi-Mobile Sink-based Clustering and Routing (MSCR) control strategy using the multi-objective Crow Search Algorithm (CSA) to address resource-constrained node energy-efficiency challenges. The proposed CSA-based MSCR model enhances deployed node's performance by intelligently coordinating SNs, CHs, and mobile sink (MS) to optimize the data acquisition process while reducing energy consumption. The CSA strategy is deployed for two crucial optimization operations: constructing optimal mobile sink trajectories and selecting energy-efficient cluster heads under limited resources and harsh environmental circumstances. Performance analysis compares the CSA-based model against established traditional metaheuristic methods, including Particle Swarm Optimization (PSO), Genetic Algorithm (GA), and Ant Colony Optimization (ACO). Large-scale simulations conducted under various network and harsh environmental conditions demonstrate significant improvements in critical performance metrics. The CSA-based MSCR approach achieves a 36% reduction in power consumption, 49% accelerated cluster formation and cluster head (CH) selection, and 42% improvements in data delivery efficiency compared to conventional approaches. Furthermore, the proposed model extends average network lifetime by 45% while maintaining data accuracy above 97%. The results endorse the usefulness of the CSA optimization strategy in solving composite multi-objective optimization problems in wireless sensor networks. This work contributes a strong and scalable solution for next-generation IoT applications requiring energy-efficient data collection in challenging deployment environments. The outcome highlights the strengths of metaheuristic algorithms like CSA in advancing MSCR control for WSNs, offering a promising alternative to traditional approaches for improving the data delivery and lifetime of the sensor networks.

I. INTRODUCTION

Wireless Sensor Networks (WSNs) have emerged as a foundation concept for current data acquisition and monitoring systems, consisting of tiny, limited battery-powered sensor nodes deployed across monitoring areas to collectively observe physical parameters and environmental conditions like light, motion, chemical presence, vibration, humidity, and temperature, then wirelessly communicate changes to central processing locations called base station (BS) or sink. Applications span precision farming, environmental monitoring, human health tracking, industrial process observation, and infrastructure surveillance.

These devices collaborate to collect, process, and transmit information to sink, the basic characteristic of these systems lies in their ability to perform independently without strong human coordination while maintaining collaborative data acquisition over extended schedules. The traditional Internet of Things (IoT), wireless networks, and WSNs face common challenges, including acute battery power constraints, limited storage and computational abilities, unreliable wireless links, high density of nodes, and the need for autonomous operations in a monitoring area. These unique characteristics entail specialized approaches, protocols, and algorithms specifically developed to improve network lifetime [1-3]. Clustering is a traditional network configuration approach that divides sensor devices in a monitoring area into hierarchical organizations to achieve energy-efficient communication and scalable network management. In a clustered WSN, devices are configured into clusters, with each cluster having a co-opted cluster head (CH) responsible for coordinating intra-cluster operations, aggregating data from cluster members (CM), and communicating with the BS or other CHs. Clustering-based organization significantly minimizes energy consumption of nodes compared to traditional topologies where all nodes directly coordinate with unique BS, because most communication happens over short distances within clusters rather than long-distance transmissions. The energy savings from clustering arise from three important factors, such as CMs transmitting data over short distances to nearby CHs, CHs performing data aggregation, and clustering enabling efficient sleep scheduling [4], [5]. Clustering protocols for WSNs can be categorized along multiple objectives based on their operational characteristics, like centralized and distributed protocols, static and dynamic clustering, and probabilistic and deterministic approaches.

Centralized protocols have a BS configure optimal cluster organization using global network information, enabling high-efficiency solutions but requiring expensive communication for status collection and a single point of failure [6], [7]. Distributed protocols like Hybrid Energy-Efficient Distributed Clustering (HEED) [8] enable deployed devices to self-organize into clusters using neighbour node communication, achieving efficient scalability and robustness but particularly creating suboptimal organizations due to restricted visibility. Static clustering protocols process cluster organization during network deployment and continue them throughout operation, reducing control overhead but lacking the ability to dynamic network conditions. Dynamic clustering protocols repeatedly organize clusters based on present network status, such as residual energy, topology changes, and other factors to enhance network age but suffering from control overhead for cluster reconfiguration. Probabilistic clustering approaches like Low Energy Adaptive Clustering Hierarchy (LEACH) [9] and Power Efficient Gathering in Sensor Information Systems (PEGASIS) [10] use randomized CH selection with rotation to distribute equal energy consumption but fail to have energy awareness in identifications. Deterministic clustering approaches specifically obtain CHs based on node characteristics like remaining energy, position, density, and connectivity, providing significant energy utilization but with high computational algorithms. Routing approaches create the route that observed packets traverse from source devices to destination BS or Mobile-Sinks. The WSN's routing must prioritize energy efficiency to improve network lifespan while fulfilling network requirements for reliability and latency. The resource constraints of deployed nodes short routing approaches' complexity, intercepting enlightened routing approaches that store expensive routing tables and complex path computations.

WSN routing algorithms face various unique issues, such as energy-constrained routing, which must obtain a route that reduces energy utilization; dynamic topology resulting from node failures, mobility, and duty cycle; data-centric communication, where BS requests data by representing attributes rather than addresses, which needs routing protocols; and broadcast approaches of wireless communication, which configure opportunities for optimization based on overhearing but also issues from collisions and interference. Based on the unique challenges of WSNs, routing protocols are classified as flat, hierarchical, chain-based, tree-based, and geographic-based protocols. The combination of clustering and routing protocols significantly influences comprehensive WSN performance, as decisions in one phase affect efficiency in the other. Sequential techniques perform clustering initially to configure network organization, then develop paths using that configuration, establishing simple implementation but missing optimization opportunities from combined development. Integrated approaches specifically optimize cluster formation and create paths, identifying that optimal clusters depend on routing requirements and optimal paths depend on cluster organization, through increasing computational complexity. Cluster-based routing generally merges the two procedures, with intra-cluster routing transferring data to CHs using simple one-hop or multi-hop forwarding within clusters, and inter-cluster routing communicating aggregated data between CHs towards BS or sinks. Intercluster routing can engage several strategies, such as direct transmission, multi-hop CH routing, and backbone formation. The combined optimization of clustering and routing in WSNs constitutes an NP-hard combinatorial optimization problem called no polynomial time approach.

It is useful to obtain optimal solutions, and excessive search becomes computationally intractable for scalable network sizes [11], [12]. The multi-objective nature of the optimization synthesizes the difficulty, as network operations concurrently pursue to increasing network lifespan, reducing energy utilization, decreasing data delivery latency, enhancing packet delivery ratio, and stabilizing energy utilization across deployed nodes. These objectives generally conflict in that the cluster organization enhancing lifetime may maximize latency, routing paths reducing energy may minimize reliability, and the dynamic topology increasing coverage may accelerate energy depletion of various nodes. The multi-objective characteristic means no single optimal solution exists, but rather a Pareto front of efficient trade-off solutions. Heuristic approaches design issue-specific protocols based on domain knowledge to configure better solutions efficiently, like selecting high-energy and centrally positioned nodes as CHs, then routing using nearest neighbour chains. While heuristics find fast solutions required for real-time implementation, they provide no optimality guarantees and may perform inefficiently on problem instances violating their fundamental assumptions. The lack of adaptability means designing new heuristics for specific variants of the clustering and routing problem. Metaheuristics employ an impactful alternative mechanism, providing general-purpose optimization frameworks applicable to diverse problem formulations without requiring problem-specific algorithm implementation. Those nature-inspired algorithms, such as Genetic Algorithms (GA) [13], Particle Swarm Optimization (PSO) [14], Ant Colony Optimization (ACO) [15], and Crow Search Algorithms (CSA) [16], provide population-based search approaches that repeatedly enhance candidate solutions through strategies inspired by physical and biological phenomena. Metaheuristics consistently deliver high-quality optimal solutions to complex problems that surpass traditional optimization strategies.

This research paper employs a simulation-based experimental design to evaluate the proposed multi-objective CSA-based MSCR system for heterogeneous wireless sensor networks. The proposed paper is structured to contribute to the following research objectives.

- Design an integrated multi-objective CSA approach that simultaneously optimizes cluster head selection and multi-mobile sink trajectory discovery.
- Develop coordination approaches for multiple mobile sinks to avoid duplicate data and enhance coverage efficiency.
- Validate energy efficiency enhancements through optimized simulation under varying network settings.
- Benchmark performance over traditional metaheuristic algorithms such as PSO, GA, and ACO using various capable metrics.

II. LITERATURE SURVEY

The Crow Search Algorithm (CSA) is a natured-inspired metaheuristic optimization schema introduced by Askarzadesh et al. [16] that is inspired by the intelligent behaviour of crows, basically their outstanding storage capacity, neighbour learning capabilities, and retrieval approaches. Unlike many other bioinspired techniques that were established earlier, like Genetic Algorithms (GA) [13], Particle Swarm Optimization (PSO) [14], Ant Colony Optimization [15], and many others, the CSA brings a unique perspective to optimization by implementing the memory using foraging behaviour and social learning capabilities adopted in corvid species. The application of the CSA to WSNs, gives us a specifically compelling similarity between the algorithm's characteristics and the inherent challenges of network optimization. The WSNs represent a complex optimization landscape characterized by multiple conflicting objectives, dynamic constraints, and resource limitations. The limited battery power of sensor nodes, combined with the need for efficient environmental monitoring, reliable communication, and enhanced network lifetime, creates an optimization problem that basic deterministic techniques struggle to solve effectively. The CSA addresses these challenges through its population using a search approach, which maintains a balance between global exploration of the solution space and local exploitation of promising areas. The memory strategy inherent in the CSA proves specifically crucial in the optimization of WSN operations, like maintaining consistency across multiple rounds of operations while adapting to changing network conditions.

The crow's storage allows the system to retain information about previously successful cluster head (CH) configurations or mobile sink (MS) routes based on the historical information to inform future decisions. This characteristic becomes critical when handling dynamic network topologies where full re-optimization from the beginning would be computationally expensive and a waste of node battery power. The social learning capabilities of the CSA mimic the distributed nature of WSNs themselves. The way crows learn from monitoring their peers, the algorithm's population of candidate solutions communicates data about promising regions of the search space, leading to faster convergence toward optimal solutions. The major strengths and limitations of the CSA require detailed comparison with alternative metaheuristic techniques that have been adapted to WSN optimization. Each approach provides distinct characteristics that make it appropriate for practical problem types, network configurations, and objective optimization. The parallel research comparative analysis provides not just which algorithm performs well overall, but also under what conditions each mechanism excels and combined approaches might prove significant over any one optimization algorithm. Particle Swarm Optimization (PSO) represents perhaps the basic comparison way for CSA, as both algorithms use population-based search with position updates routed by social data sharing. According to [17] establishes critical performance metrics and problem configuration for energy-efficient cluster formation and CH selection as a multi-objective optimization problem using remaining energy, node location and density, distance to BS, and coverage as optimization criteria.

For authors [18] implement a hybrid optimization model by merging the Harmony Search Algorithm (HAS) and Particle Swarm Optimization (PSO) for CH selection; that hybrid metaheuristic model is more efficient than single-algorithm implementations. The research establishes that metaheuristic optimization can significantly outperform traditional probabilistic techniques for clustering. Genetic Algorithms (GA) consider a basically different model of optimization, mirroring biological evolution using selection, crossover, and mutation functions on a population of candidate solutions. For unique problems in WSNs such as cluster formation and CH selection, GAs handle binary specifications primarily without requiring transfer functions, providing them a basic advantage in simulating efficiency. Ant Colony Optimization (ACO) is implemented in graph-based combinatorial problems and is particularly well-structured to routing optimization in WSNs. ACO's pheromone approach configures efficient shortest routes across collective points, where artificial ants deploy pheromone on promising edges that attract future ants. For basic routing problems without mobile sinks, ACO often outperforms CSA due to its native graph-based and incremental solution construction. However, ACO is inefficient with continuous optimization problems such as trajectory planning, requires considerable memory to maintain the pheromone collection, and converges slowly. The Artificial Bee Colony Optimization (ABCO) approach has objectives inherited from Honey Bee Foraging (HBF) behaviour, partitioning the population into adopted bees, onlooker bees, and scout bees that perform unique search jobs.

ABCO represents strong performance on continuous optimization problems and maintains the best population diversity through its multi-step configuration. In [19] implemented WSN clustering using ABCO with modifications specifically designed for the discrete nature of the CH selection problem. This research demonstrates optimization techniques like adaptive parameter adjustment and diversity-based strategy selection. According to [20] provide a comprehensive review on coverage optimization techniques in WSNs, providing context for analysing how metaheuristic approaches adapted to the multiple objectives of WSN optimization. The paper partition the coverage problem into area coverage, point coverage, and endpoint coverage, detailing deterministic, probabilistic, and optimization-based solution techniques for each partition. Grey Wolf Optimization (GWO), a recent development in metaheuristic-based models, represents the hunting behaviour and pack hierarchy of grey wolves. For authors [21] implement modifications to the metaheuristic GWO that enhance the performance of WSNs problems. According to [22] implement mobile-sink based data collection in WSNs through an integrated approach merging load-balanced clustering with optimized mobile-sink route planning. The researchers establish the problem as reducing energy consumption subject to data delivery latency constraints and design a heuristic approach that first divides the network area into optimal clusters and CHs and then creates an approximate trajectory tour visiting CHs. According to [23] focus specifically on mobile-sink trajectory optimization using GA and PSO.

The algorithm configures trajectory planning across the collection points (CPs) to collect data, with the objectives of reducing tour length and enhancing energy efficiency. The analysis of trade-offs between tour length reduction and energy consumption balancing informs multi-objective configurations in hybrid approaches. In [24] implemented an algorithm using CSA with Q-learning reinforcement learning for adaptive optimization in dynamic HWSN. The Q-learning basically learns routing rules that adapt network states to optimal routing operations based on accumulated positives from successful data delivery and negatives for failures. According to [25] provide a detailed comparative analysis of important clustering protocols for WSNs, including traditional algorithms like LEACH and PEGASIS alongside nature-inspired metaheuristic algorithms using PSO, GA, ACO, and ABCO. The comparison adapted standardized simulation scenarios with dynamic node ranges and evaluates critical performance metrics such as network lifespan, throughput, packet delivery ratio, energy consumption, delay, latency, and clustering consistency. The most recent parallel research papers provide that no single algorithm addresses all performance metrics and network configurations, with optimal algorithm identification based on application priorities and network constraints and characteristics. The comprehensive summary of parallel research using CSA and metaheuristics in WSNs is discussed in the following Table 1. Summary of parallel research in WSN using metaheuristic optimization algorithms.

Table 1: Summary of parallel research in WSN using metaheuristic optimization algorithms.

Ref	Authors	Major Approaches for WSNs	Advancements with Algorithms	Limitations
[26]	Zhang et al. 2024	Deep Reinforcement Learning improved clustering in HWSNs using the DRL-CSA combination for dynamic parameter adaptation.	DQN learns optimal CSA parameter adjustment and adaptation rules. Significant network lifetime (i.e., 35-45%) over standard CSA.	DQN requires high training data across diverse network configurations. DQN training is computationally very expensive.
[27]	Kumar et. al. 2024	Pareto-based multi- objective optimization for joint clustering and mobile-sink trajectory finding with specific trade-off exploration.	Multi-objective optimization like coverage, delay, energy, and load balance. The initial comprehensive Pareto-based cooperative CSA for WSNs includes an archive that maintaining non-dominated solutions.	Archive size management is challenging for large-scale dimensional objectives. Higher execution time (40%) than single-objective CSA due to archive maintenance.
[28]	Martinez et al. 2023	Distributed CSA with consensus algorithms for large-scale WSNs	Asynchronous operations without global synchronization. The network is divided into large-scale areas with parallel local CSA.	The boundary of each local area affects the quality of the solution. Distributed CSA requires 400 – 600 iterations.
[29]	Li, X et al. 2024	LSTM and adaptive CSA-based energy harvesting WSN optimization with solar power prediction.	Significant network lifetime (i.e., over 45%) over standard CSA. Dynamic objective weighting based on harvesting-to -consumption ratio.	LSTM training requires massive historical solar data. Performance degrades significantly in unpredictable weather patterns. Restricted validation on other harvesting sources.
[30]	Ahmed et al. 2023	Federated learning system for privacy-preserving distributed optimization using secure multi-party computation.	Lower communication overhead than centralized techniques. Local CSA at CHs with only aggregated statistics shared. Secure against gradient inversion	Convergence is slower than centralized due to privacy noise injection. Enhanced communication iterations needed for coordination. Limited scalability analysis below 500 nodes.
[31]	Thompson et al., 2024	Quantum-inspired CSA using qubits, superposition, and entanglement for improved exploration in complex optimization landscapes.	Higher solution quality (i.e., 15-25%) than classical CSA. Quantum implementation with probability amplitudes exhibits parallel exploration. Entanglement fixes problem structure.	Limited policies on qubit-to-variable mapping strategies. Not implementable on real quantum hardware. Quantum entanglement design requires domain expertise. Scalability extends to very large problems.
[32]	Wu. T., et al. 2023	Game-based multi-sink coordination with potential game formulation and Nash equilibrium solutions for conflict resolution.	Each mobile sink is designed as a rational player in a potential game framework. Higher lifetime (i.e., 47%) with dual sinks. Load imbalance is very low (i.e., <8%).	Game-theoretic analysis complexity grows with the number of sink nodes. Inter-sink communication overhead for coordination.
[33]	Park et al. 2024	Explainable AI integration using SHAP values for interpretable network configuration with human-algorithm collaboration.	SHAP analysis quantifies feature importance like energy and centrality. The optimization process is interactive and incorporates human preference incorporation.	Higher computational overhead of SHAP value computation. SHAP assumes feature independence, which may not hold.

[34]	Gupta et al. 2024	Edge intelligence with fog computing architecture for real-time optimization in WSNs.	CSA deployed on fog nodes managing some sensor clusters. Faster execution through vectorization and parallelization. Eventual consistency coordination tolerates network divisions.	Energy utilization of fog nodes is not thoroughly analysed. Fog node failures need fast workload redistribution. The deployment costs and complexity of fog infrastructure are significant, and the computational resources of fog nodes are limited.
[35]	Gharaei N et al. 2016	Multi-objective optimization for intra-cluster routing and CH positioning in WSNs	Energy-aware crowding distance prioritizes balanced solutions. Multi-objective, like energy, coverage, and density, with Pareto-based applications across multiple WSN problems. Coverage-specific crossover preserves spatial patterns. Hierarchical routing structure optimization.	No mobile sink consideration. Scalability is limited to 200 – 300 nodes in the monitoring area. Limited to intra-cluster routing, not focusing on inter-cluster. Modified crowding distance appends computational complexity.

The comparative analysis of algorithm performance is summarized in the following Table 2.

Table 2: Comparative analysis of parallel research in WSN using metaheuristic optimization algorithms.

Algorithm	Typical Lifetime Improvement	Convergence Speed	Computational Cost	Application Area
Traditional (LEACH, PEGASIS)	Baseline 100%	Very Fast	Very Low	Small static networks
PSO	115 - 130 % of LEACH	Fast	Low-medium	General clustering and routing
GA	110 – 135 % of LEACH	Slow	Medium-high	Discrete optimization problems
ACO	125 – 135 % of LEACH	Very slow	High	Graph-based routing
CSA	130 – 145 % of LEACH	Fast	Low Medium	Integrated clustering and trajectory planning.
Hybrid CSA and PSO	140 – 155 % of LEACH	Fast	Medium	Complex multi-step optimization.
Advanced DRL with CSA and Quantum CSA	150 – 175 % of LEACH	Very Fast	High	Dynamic adaptive networks

III. METHODLOGY

Resource-constrained tiny nodes are randomly deployed in a large-scale monitoring area, i.e., $G = (V, E)$, using uniform distribution to ensure unbiased coverage, where G is a monitoring area (called a geographical region), V specifies the collection of resource-constrained tiny 'n' sensor nodes deployed within the G, E transmission lines among nodes, and $V_i$indicated as i^{th} node of the collection of nodes. There are some assumptions in the development of algorithms; such assumptions include heterogeneity among sensors with unique identification (UID) and varying initial battery capacity and varying node movement. The large-scale monitoring area is divided into grids to form clusters and to elect cluster heads (CHs). Clustering is a widely adopted and proven approach in wireless sensor networks (WSNs) that significantly reduces energy consumption and enhances lifetime of the network.

The multi-sink nodes and one base station is deployed within the monitoring area, and the base station remains static. Base station (BS) can configure the centre of the monitoring area, while mobile sink nodes configure their trajectory to collect data from the cluster heads (CHs). The cluster nodes monitor phenomenon and transmit directly to the cluster head; this scenario, CHs adjust their transmission power according to the distance to the collection point. The BS is equipped with infinite computation and communication capabilities, similarly dual-mobile-sink devices are configured with sufficient computing and communication capabilities and process and aggregate data before delivery to the base station. Sink nodes are mobile devices with some level of power constraints, but can be rechargeable. All sensor nodes can map between sleep and active states to save continuous energy consumption.

III.1.1 Basic Energy Consumption Model

Energy consumption - the mathematical framework for representation of energy consumption of nodes to transfer 'k' bits within a transmission range 'r' of a node can be expressed as:

$$TE_i(k,r) = \left\{\left(E_{el}^i * k + k * Ef_s * r^2\right); r \leq \partial_t\right\}$$

E_{el} is represented by the electronic energy of the node per bit of information. Energy consumption of CH to send data to the mobile sink node is

$$TE_c = \begin{cases} \left(E_{el}^c \,\&\, * k + k * E_{fs} * r^2\right); r < \partial_t \\ \left(E_{el}^c * k + k * E_{mp} * r^4\right); r \geq \partial_t \end{cases} \quad (1)$$

Where E_{fs} is used to specify the amplifier energy of tree space and E_{mp} can represent a multi-path forwarding model, respectively, then $\partial_t = \sqrt{E_{fs}/E_{mp}}$

Node (i) and CH (c) to receive 'k' bits of data is expected as

$$RE_i\,(k) = (E_{el} * k) \quad (2)$$

$$RE_c\,(k) = (E_{el} * k) \quad (3)$$

The energy utilization by the CH in aggregation of 'm' redundant data, each consisting of 'k' bits, can be evaluated as

$$E_A^c(m,k) = (E_{ag} * m * k) \quad (4)$$

Where E_{ag} used to specifies the aggregates energy of the cluster head (CH) per bit of information aggregated.

The radio energy model of a sensor node evaluates the energy consumption of nodes during data transmission and reception, and CH estimates the power utilization for communication along with the aggregation. The evaluated energy utilization of sensors and CHs in processing various operations in the monitoring area can be obtained based on equations 1, 2, and 3. Equation 1 indicates the expected power loss of a node in forwarding information over a distance. The calculated power consumption is directly proportional to the distance over which information is forwarded. The cluster head power utilization maximizes with the square of the transmission range for shorter ranges and with r^4 for the longer distance. This includes that cluster heads have faster power consumption in longer transmission ranges than shorter transmission ranges. The transmission range up to which communication is energy efficient is called the threshold transmission range of the node radio system. The value of threshold distance is constructed by using equation 3. By restricting the cluster head to forward data to multi-mobile sink nodes within the distance, the overall power utilization is reduced, enhancing the lifetime of CHs and improving the life of the overall monitoring area.Multi-mobile sink-based data acquisition is an efficient process and enhance the lifespan of the sensor network. Two mobile sink nodes have been used to traverse over a predetermined a trajectory to get monitored data from cluster heads. The mobile sink can construct trajectory near to cluster heads so that cluster heads can use less energy for data transmission. These multi-mobile sink nodes can configure different and opposite directions to get monitored data from CHs.

Electing CHs in the monitoring area and constructing a path for a mobile sink is important in the proposed model to enhance the lifetime of the entire network. The crow is an intelligent bird that can remember faces and warn species in danger. One of the most important pieces of evidence of cleverness is hiding food and remembering its location. The Crow Search Algorithm is inspired by the intelligent foraging behaviour of crows, basically their ability to store food in hidden places and use it when essential. The CSA can simulate the behaviour of storing excess food and retrieving it when needed, the behaviour is mathematically approached through a location-updating strategy that balances exploration and exploitation. In the WSN optimization theory, the monitoring area is a search space, and randomly recognizing the location of CH is a feasible solution. Among all cluster nodes, the node where the most energy is available is elected as a CH_i, and the objective function is the amount of node energy. Major phases in clustering and routing using CSA can be defined as follows: Initializing – deploying resource-constrained tiny nodes (crow swarms) in a monitoring area randomly. Dividing the entire network into grids to configure clusters in the monitoring area. A fitness function is used to evaluate each node (crow), and its value is placed as an initial node storage. Each node stores its schedule and energy in its memory variable 'm_i'.Each node updates its residual energy and neighbour node position by selecting another random node, i.e., n_j and generating a random value. If the value is greater than awareness probability (AP), then the node n_i will use x_j to construct a cluster head. Each node updates its locations by selecting a random other node, i.e., n_j and following into know CH_j then n_j is calculated.

III.1.2 Proposed Multi–Objective CSA-Based MSCR Algorithm

The multi-objective CSA-based MSCR optimization algorithm performs in five unique phases computed orderly within each network round. Each round begins with an initialization phase; CSA-based cluster head (CH) election and formation will be done in the next phase, followed by a phase implemented for CSA-based multi-mobile sink trajectory formation and optimization, and the final phase represents data collection and transmission. Network Setup State: The initialization phase in the proposed model establishes the fundamental infrastructure for HWSN with multi-mobile sink nodes that represent deployment of 'n' nodes and the discovery of the nodes in the monitoring area G and the heterogeneity ratio of 'n' nodes. The placement of multi-mobile-sink nodes and base stations is defined. And finally, CSA parameters and weight parameters are configured for a CH selection and mobile sink trajectory optimization.The CH formation and selection in WSNs operates as an NP-Hard combinatorial optimization problem. For a network of 'n' nodes, the primary objective is to divide the monitoring into a specific number of clusters and to elect a subset $S \subseteq 'n'$ as cluster heads where a dual-objective function is optimized by satisfying implementation constraints. The problem can be represented in the equation.

$$\max_{S \subseteq n} F(S) = \sum_{j=1}^{k} w_j f_j(S) \quad \begin{cases} 0.10n \leq |S| \leq 0.20n \\ E_{res\,(m)} > 0.4\, E_{in} \,\exists\, m \in S \\ A_{CH \in S}\, cov(CH) = N \end{cases} \quad (5)$$

The search space cardinality is $\binom{n}{k}$for identifying 'k' CHs from 'n' deployed nodes in the monitoring area, which increases exponentially. Traditional deterministic systems are less accurate for this issue class due to combinatorial explosion, multi-objective nature, dynamic constraints, and non-convexity. Nature-inspired Swarm intelligence approaches, particularly the Crow Search Optimization, extend and adopt polynomial-time random similar solutions with validated convergence assurances. The CSO gained attention from ethological observations of corvid maintaining behaviour, where crows hide food in locations and use it later, while concurrently attempting to obtain caches hidden by other crows. This configures a dynamic interchange between exploitation and exploration. An unaware and aware target crow position update approach is defined in the following equations (4) and (5).

$$l_i^{k+1} = l_i^k + rn_i * fl * \left(s_j^k - l_i^k\right) \ \{unware\ traget\ (rn\ < AP)\} \tag{6}$$

Where

$$l_i^k - location\ of\ crow\ i\ at\ iteration\ k$$

$$s_j^k - Storage\ position\ of\ randomly\ selected\ crow\ i$$

$$fl - flight\ length\ parameter\ controlling\ step\ size$$

$$rn_i - random\ number\ in\ [1,0]$$

$$l_i^{k+1} = Random\ location\ in\ search\ space\ \{aware\ target\ crow\ (r\ < AP)\} \tag{7}$$

The cluster head (CH) identification of the issue inherently represents two binary decision variables such as $l_i \in \{1,0\}, where\ i = 1,2,3,\ldots\ldots\ldots,n$, whether it offers some important representational advantages like semantic clarity, constraint verification, and Hamming distance interpretation. Since crow search optimization performs in continuous space, the sigmoid transformation bridges the implementation gap and decision rule in the following equations (8) and (9).

$$\sigma\ (l) = \frac{1}{1+ e^{-l}} \tag{8}$$

$$l_i^{binary} = \begin{cases} 0 & otherwise \\ 1 & if\ \ \sigma\left(x_j\right) > 0.5 \end{cases} \tag{9}$$

The proposed crow search optimization employs scalarization to change multiple objectives into a single fitness value represented in the following equation (10) with the help of equation 5. For wireless sensor networks CH identification and formation, the objectives extend enough convexity for weighted aggregation.

$$F = \sum_{k=0}^{4} w_k *\ f_k\ , where\ \sum_{k=1}^{4} w_i = 1 \tag{10}$$

The CHs consume unequal energy due to receiving data from all associated CMs, aggregating and processing data, and long-distance transmission to mobile sinks. Identifying high-battery power nodes as CHs expands the first node death, enhancing the stable period of network performance. The optimization assures scale invariance around networks based on different initial energy configurations, and energy and distance functions are represented in equations (11), (12), and (13); it represents the node battery power utilization model for wireless transmission.

$$f_e = \frac{En_{ch}}{E_{mx}} = \frac{\frac{1}{|S|}\sum_{CH\in S} E_{res\ (CH)}}{E_{in}^{mx}} \tag{11}$$

$$f_d = \frac{1}{1+\frac{di}{100}}, where\ di = \frac{1}{n-|S|}\sum\nolimits_{z\in S} min_{ch\in S} d(z,ch) \tag{12}$$

$$E_i(k,d) = \left\{\left(E_{el}^i * k + k *\ Ef_s *\ d^2\ \right); d \leq\ \partial_t\right\} \tag{13}$$

The deployed member node assignment automatically configures a weighted Voronoi tessellation of the network monitoring area. In traditional Voronoi representations, each point belongs to the position of its nearby location. The optimization algorithm adapts weighted distance for static CHs and reduces total communication cost; each member node should map to exactly one cluster, and nearby nodes probably collaborate in the same cluster. The following equation (14) specifies the weighted distance.

$$d_w\ (v, CH) = 0.8 *\ d_e\ (v, CH) + 0.3 *\ E_t(v, CH) \tag{14}$$

The Time Division Multiple Access (TDMA) schedule implementation uses graph coloring features adopted to temporal domains. It assigns time slots $\{1,2,3,\ldots,\ldots,\ldots,t\}$ to CMs in a cluster; each node configures exactly only one slot per round. Where no two CMs within the cluster neighbour discovery range share a slot and the total schedule length is minimized.

The adapted schedule length obtains data collection latency, directly impacting network overall performance. Another important aspect for cluster formation and cluster head selection is lower and upper bounds, which indicate the minimum and maximum CHs in the deployed area. For example, the cardinality bounds are $0.10 \leq |S| \leq 0.20$. Where minimum CHs are necessary for coverage, and below this threshold, intra-cluster distances become inefficient. If above the threshold, increased inter-CH communication becomes high CH energy consumption. The high energy utilization of some CMs becomes network division. This phase of the proposed model establishes the CSOA-based cluster formation and cluster selection algorithm as a determined system for combinatorial optimization in WSNs. The multi-objective fitness procedure gathers the important trade-offs in cluster formation and head selection, while the adaptive CSO model provides efficient representation of the exponentially large solution space. In the next phase of implementation, focus on optimizing the routes of multiple mobile sinks to efficiently collect data from CHs while reducing energy utilization, collection delay, and route distance. This phase transforms the route discovery problem into a type of the multiple Traveling Salesman Problem (mTSP) and configures it using the Crow Search Optimization Algorithm (CSOA).

This algorithm divides the CHs among multiple mobile-sinks for balanced workload, obtains an optimal collection point sequence for each mobile sink, reduces CH transmission energy by locating routes near CHs, minimizes data collection latency through efficient route discovery, and ensures all CHs are covered within the mobile sink communication range with high priority of minimizing sink collisions and data redundancy. The final phase of implementation focuses on the real data collection process, where CMs monitor environmental or surrounding data, transmit to CHs for aggregation, and mobile sinks obtain optimized routes to collect aggregated data from CHs. The mobile-sink route optimization issue specifies a generalization of the TSP with some other complexities that highlight it as a unique problem class. The route optimization extends TSP in several dimensions, such as each CH within communication range of some collection point (CP), continuous CP placement, and multi-objective (energy, time, coverage, and distance). The route fitness function aggregates four important objectives using weighted scalarization that can be defined in the following equation (15).

$$F(R) = \eta * f_{en}(R) + \vartheta * f_{ti}(R) + \iota * f_{cov}(R) + \kappa * f_{len}(R) \tag{15}$$

where

$$R = [(x_1, y_1), (x_2, y_2), (x_3, y_3), \dots, \dots, (x_n, y_n)]\ specifies\ the\ mobile - sink\ route$$

The energy (η) of a node is a primary constraint, and CH battery life determines network lifetime. The energy constraint of CH can be analysed with an equation (16).

$$f_{en}(R) = 1 - \frac{E_{tot}^{ch}(R)}{E_{max}^{pos}} \tag{16}$$

Where the total transmission energy of CH configures the first-order radio model also defined in equation (17).

$$E_{tot}^{ch}(R) = \sum_{ch_j \in ch} E_{tr}(ch_j, R) \tag{17}$$

We analysed time component to collect data from CHs and the travel time to reach collection points and defined with the following equation (18).

$$S_{time}(T) = 1 - \frac{S_{tot}(T)}{S_{max}} \tag{18}$$

The total collection time from CH is defined in the following equation (19).

$$N_{tot}(T) = S_{travel}(T) + S_{collected}(T) \tag{19}$$

Mobile sink travel time is defined in equation (20).

$$S_{travel}(T) = \frac{F(T)}{\upsilon_{ms}} = \frac{\sum_{i=1}^{n-1} \|\omega_{i+1} - \omega_i\|}{\upsilon_{ms}} \tag{20}$$

$$S_{collected}(T) = \sum_{\omega \in T} |N(c)| \cdot t_{tx} \tag{21}$$

Where $N(c) = \{CH \rightarrow | CH - cp| \leq T_{range}\}$ specifies CHs with the communication range of collection points (cps). We also analysed the coverage of the mobile sink that ensures the set cover property; every assigned CH must be within communication (T_{range}) of at least one trajectory collection point (CP), and it can be defined in the following equation (22).

$$f_{coverage}(T) = |\{CH \exists c \in T, \quad \|CH - cp\| < T_{range}\}| / |CH| \tag{22}$$

Some of the other critical WSN constraints are analysed, such as energy, time, coverage, and collection point boundaries; this are defined in the following equations. $E_{route}(MS_i) \leq 0.8\,\beta_i$ threshold implements a secure margin ensuring that battery lifetime is capable of being sustained under worst-case scenarios, and that there is an energy reserve for unexpected obstacles.

Time constrains $S_{tot}(T) \leq S_{max}$ bounds staleness. The 0.95% threshold balances complete coverage against computational tractability and can be defined in the following equation (23).

$$\frac{|\ coverage\ (T)|}{CH_{assign}} \geq 0.95 \tag{23}$$

Finally, collection points (CPs) and endpoint boundary constraints are common in vehicle routing problems. The MS must return to its charging station to recharge depleted batteries, start the next collection round, and enable predictable scheduling defined in equation (24).

$$CP_1 = CP_m = MS_{pos} \tag{24}$$

For a given 'k' CHs and 'n' MS, partition CHs into 'm' disjoint subsets, reducing total intra-cluster distance.

$$min\{x_1, x_2, \dots, x_m\} \sum_{i=1}^{m} \sum_{CH \in x_i} \|CH - \mu_1\|^2 \ where\ \cup_{i=1}^{m} X_i = CH\ and\ x_i \cap x_j = \emptyset\ for\ i \neq j.$$

Collection point representation and route optimization operate in continuous Euclidean space $T = [(x_1, y_1), (x_2, y_2), \dots, (x_m, y_m)] \in R^{2m}$, dimensionality is dynamic, and that m depends on the CH count, dynamic internal collection points, and static end points. Every collection point moves along the line segment connecting its current positions to the corresponding collection points in the target memory. The movement magnitude is controlled by the product of $r.fl$. For intermediate collection points, continuous space update equation (25). Detailed algorithm for representing all the functions to perform heterogeneous wireless sensor networks using crow search optimization.

Algorithm: Crow Search Algorithm (CSA) for Wireless Sensor Network (WSN) Optimization.

Input: *Initialization of number of nodes (N_Nodes), monitoring area (A), number of mobile sinks (MS), position of base station (BS), present round (pr), maximum rounds (mr), and clustering interval (ci)*
Output*: Optimal Algorithm to analysis WSN*

1.if pr mod ci == 1 then
a.optimalCHs = binaryCSA(N, populationSize, maxIterations,flInitial, APInitial) //Binary CSA for CH selection
b.clusters =formClusters(N, optimalCHs) //Cluster Formation
c.for each cluster in clusters

IV. RESULTS AND DISCUSSIONS

IV.1.1 Simulation Setup and Configuration

The simulation setup for evaluating the performance of the multi-mobile sink-based clustering and routing on HWSN using Crow Search Algorithm (CSA) optimization requires careful focus on simulation configuration, parameter selection, and traditional comparison selection. The performance evaluation of the proposed MSCR-CSA was demonstrated using the NS2 simulation environment on a workstation with fully equipped components and network configuration parameters shown in Table 3. The simulation framework specifies comprehensive energy systems, realistic wireless communication protocols, and a realistic node behaviour system to assure results accurately provide real-world deployment strategies. Each experimental configuration was run 100 cycles with unique random input values to ensure statistical validity.

Table 3: Network configuration parameters.

Simulation Parameters	**Values**
Monitoring area	500 * 500
Node deployment type	Random uniform distribution
No. of nodes	100 to 500
Network Heterogeneity Ratio	80% normal nodes, 20% advanced nodes
Normal Nodes	
Node Initial Energy	1.0 Joule
Sensing range	15 m
Communication range	30 m
Advanced Nodes	
Node Initial Energy	2.0 Joule
Sensing Range	20 m
Communication Range	40 m
Multi-Mobile Sink Configuration	
No. of mobile sinks	2
Initial position of Mobile-Sink	Opposite corners of the monitoring area
Mobility of Sink	2 m/sec
Communication range of Sink	50 m
CSA Algorithm Parameters	
Population of crows	50
Iteration count	300
Binary CSA, Flight Length	2.0
Continuous CSA, Flight Length	10.0
Binary CSA, Awareness Probability	0.3
Continuous CSA, AP	0.4

IV.1.2 Important Findings and Performance Achievements

Performance comparisons include five parallel research algorithms representing state-of-the-art strategies: Low Energy Adaptive Clustering Hierarchy (LEACH) as the classical protocol baseline, Particle Swarm Optimization for Multi-Sink Clustering and Routing (PSO-MSCR), Genetic Algorithm for Multi-Sink Clustering and Routing (GA-MSCR), Ant Colony Optimization for Multi-Sink Clustering and Routing (ACO-MSCR), and standard CSA with static parameters. Each baseline is configured with parameters tuned using grid search to ensure better comparison, with a population size of 50 and maximum of 300 loops matching the proposed adaptive CSA configuration. The multi-objective fitness method for CH selection weights remaining energy at 0.4, average CM–CH distance at 0.3, cluster size balance at 0.2, and network coverage at 0.1. For sink trajectory optimization, the fitness function weights CH transmission power at 0.35, total route length at 0.3, data collection time at 0.25, and coverage completeness at 0.1. These weight allocations show priorities established through general sensitivity analysis balancing many performance dimensions.

IV.1.3 Network Lifetime Improvement:

The longer lifespan performance gained from CSA's behaviour to elect CHs with optimal energy saving while simultaneously placing mobile-sink routes to reduce CH transmission distances then leads to balancing energy utilization across the network. Figure 1 and Table 4 represent the First Node Death (FND) results across varying network sizes and mobile-sink configurations.

The results demonstrate that the proposed CSA-based MSCR consistently gains significant network lifetime compared to all parallel research algorithms. The experimental results demonstrated that integrated multi-objective CSA-based MSCR received significant enhancement in network lifespan compared to traditional metaheuristic algorithms such as PSO, GA, and ACO. The proposed CSA-based MSCR achieved a 44% higher network lifespan compared to PSO-based MSCR, a 49% enhancement over GA-based model, 55% efficiency compared to ACO-based algorithms, and 181% longer efficiency over the traditional LEACH algorithm. The performance adjustments remain static across all network scales from 100 to 500 nodes in the simulation.

Table 4: Number of rounds – dual mobile sink configuration.

Nodes	CSA– MSCR	PSO-MSCR	GA–MSCR	ACO–MSCR	CSA	LEACH
100	4387	3421	3156	3587	3912	1523
200	4156	3267	2978	3421	3756	1467
300	3942	3089	2834	3267	3598	1398
400	3734	2867	2645	3089	3445	1334
500	3521	2678	2489	2912	3267	1289
Average enhancement	Baseline	+28.4	+39.6	+21.3	+9.8	+182

IV.1.4 Energy Consumption

Figure 2 and Table 5 present detailed power consumption analysis for the 300-node dual-mobile sink evaluation over 3000 functional iterations. The proposed multi-objective CSA-based MSCR energy utilization analysis achieved substantial energy-efficiency that 24% minimization in total network energy consumption over PSO-based MSCR, 29% minimum battery utilization compared to GA-based models, and 33% battery power saving compared to ACO-based algorithms. The dual-mobile sink coordination approach contributed magnificently to these achievements by dividing the network into optimal operational areas, minimizing the average CH – Sink communication distance that leads to the significant power savings using the quadratic relationship between distance and power in the multi-route propagation system.

Table 2: Energy consumption in 3000 rounds with 300 nodes and dual mobile sinks.

Component	CSA-MSCR	PSO-MSCR	GA- MSCR	ACO-MSCR	Reduction vs PSO
Intra-Cluster	389.7	478.3	512.6	534.8	- 18.5%
Inter-Cluster	298.4	412.7	445.3	468.9	-27.7%
Cluster Member	412.8	501.2	534.7	556.3	-17.6%
Cluster Heads	275.3	389.8	423.2	447.4	-29.4%
Mobile-Sink movement	108.6	118.4	125.7	132.1	-8.3%
Mobile-Sink Communication	67.8	74.2	79.3	83.6	-8.6%
Control overhead	52.4	68.9	76.4	81.2	-24.0%

IV.1.5 Cluster Quality and Efficiency

Table 6 and Figure 3 examine the organizational characteristics of cluster formation by various approaches for the 300-node and dual-mobile sink configuration. The proposed multi-objective CSA-based MSCR cluster formation demonstrated significantly high-performance characteristics, such as 38% lesser cluster formation time compared to PSO; the load balance index of the proposed model is 0.89, which is better compared to 0.75 for ACO and 0.72 for PSO; and the proposed model coverage efficiency is 98.2% of nodes optimally appended to CHs compared to PSO is 92.4% of node optimality. The significant clustering quality achieved from effective multi-objective CSA-based optimization that simultaneously considered power saving, spatial distribution, load balancing, and coverage efficiency, whereas parallel research algorithms generally prioritized only one or two objectives.

Table 6: Cluster Formation Analysis with 300-nodes, and dual-mobile sinks.

Metric	CSA – MSCR	PSO – MSCR	GA – MSCR	ACO – MSCR
Avg. Cluster Count	23.4	26.7	28.3	25.9
Avg. Cluster Size	12.8	11.2	10.6	11.6
Cluster Size Std Dev	3.8	6.9	7.8	6.4
Max. Cluster Size	21	34	38	31
Min. Cluster Size	7	4	3	5
Avg. CM – to – CH distance (m)	18.7	26.4	29.1	25.3
Load balance index	0.887	0.723	0.681	0.754

Source: Authors, (2026).

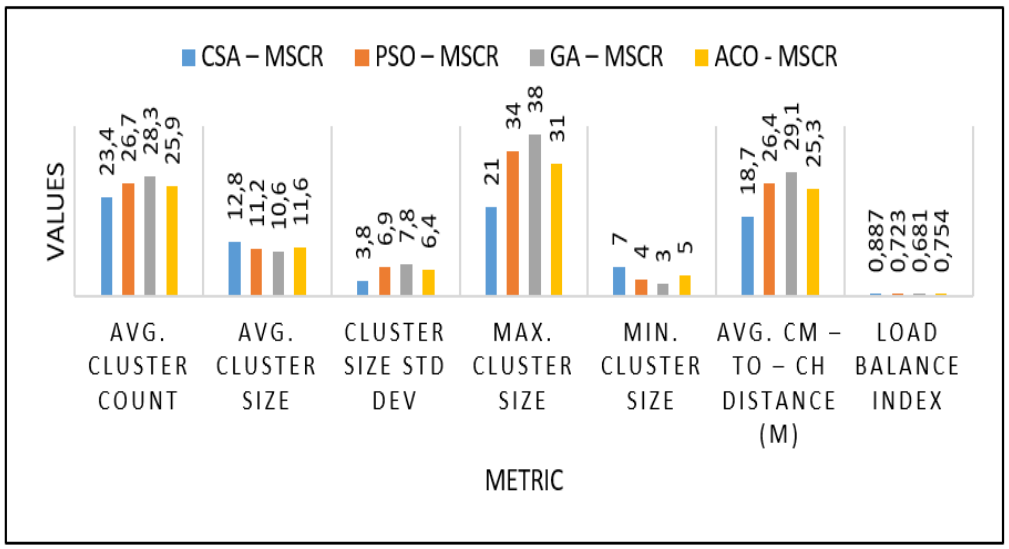

Figure 3: Analysis of Clustering in various Algorithms.
Source: Authors, (2026).

Table 7 and Figure 4 represent the simulation properties of re-clusters formed by various approaches for the 300 nodes and with dual-mobile sink configuration.

Table 7: Re-cluster formation analysis in 4000 rounds – 300 nodes and dual-mobile sinks.

Metric	CSA–MSCR	PSO–MSCR	GA – MSCR	ACO – MSCR	CSA
Total Re-clustering events	62	87	103	94	71
Avg. rounds between	64.5	46.0	38.8	42.6	56.3
Energy per Re-cluster (J)	12.7	15.3	17.8	16.4	13.4
Total Re-cluster Energy (J)	787.4	1331.1	1833.4	1541.6	951.4

Source: Authors, (2026).

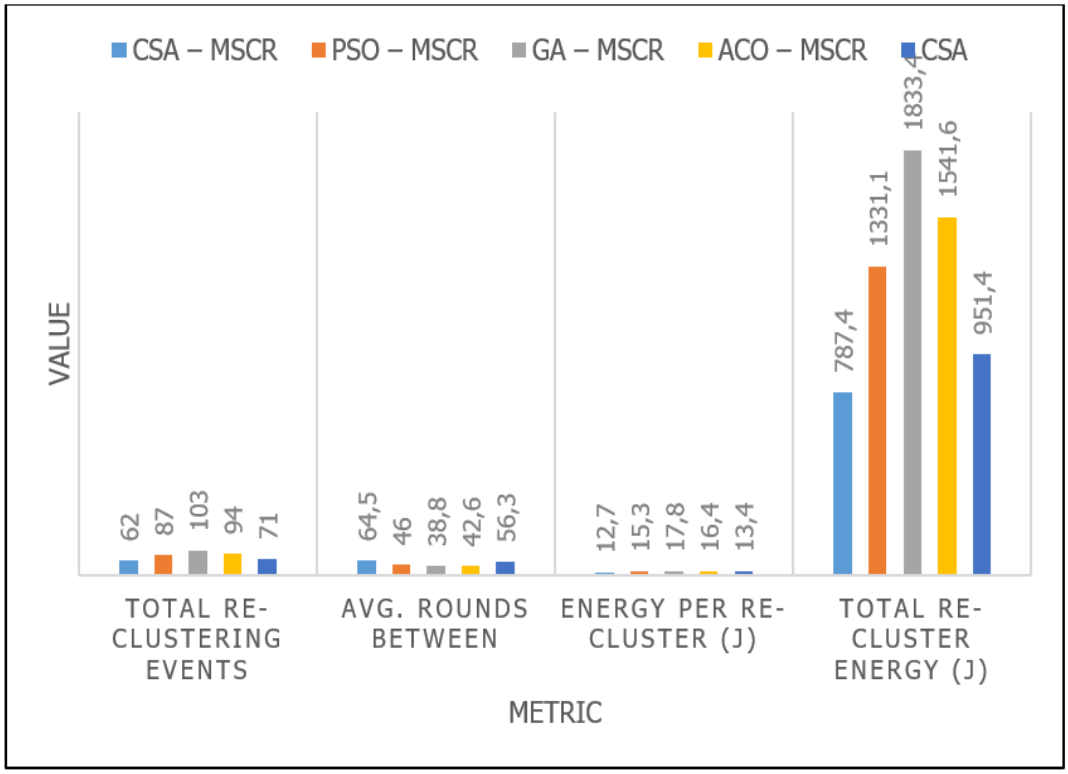

Figure 4: Re-clustering analysis using various metaheuristic algorithms.
Source: Authors, (2026).

CSA-MSCR represents only 62 re-clustering events over 4000 functional rounds compared to 87 for PSO, showing 28.7% fewer reconfigurations. The minimized re-clustering frequency results from higher optimal initial clusters that remain efficient longer as network conditions evolve. Each re-clustering task consumes 12.7J for CSA-MSCR compared to 15.3J for PSO due to faster convergence requiring fewer recursions, leading to overall energy savings. The total energy used on re-clustering over network lifetime is 787.4J for CSA-MSCR compared to 1331.1J for PSO, saving 543.7J (48.7% minimization) that can be used for data transmission.

IV.1.6 Data Collection Performance

Table 8 and Figure 5 examine packet delivery ratio (PDR) measurements across various network settings, quantifying the percentage of generated data packets successfully delivered to the mobile sink and base station (BS). The CSA-based multi mobile-sink route optimization provided significant improvements in acquisition and aggregation efficiency, with a 30% enhancement in packet delivery ration using the proposed model that is 98.9% over 75.3% for PSO-based algorithms, a 31% minimization in average data collection delay, a 43% higher throughput, and mobile sink energy efficiency. The dual-mobile sink architecture with multi-objective CSA-based optimized routes enabled parallel data collection, decreasing the maximum distance any CH needed to continue communication with a mobile-sink and consequently reducing both transmission power utilization and latency.

Table 8: Packet Delivery Ratio (PDR) (%) in different network configurations.

Configuration	CSA-MSCR	PSO-MSCR	GA-MSCR	ACO-MSCR	Standard CSA
100 Nodes, 2 Sinks	99.2	95.7	93.4	94.8	97.8
300 Nodes, 2 Sinks	98.6	94.3	91.88	93.6	96.9
500 Nodes, 2 Sinks	97.8	92.1	89.3	91.7	95.6

Source: Authors, (2026).

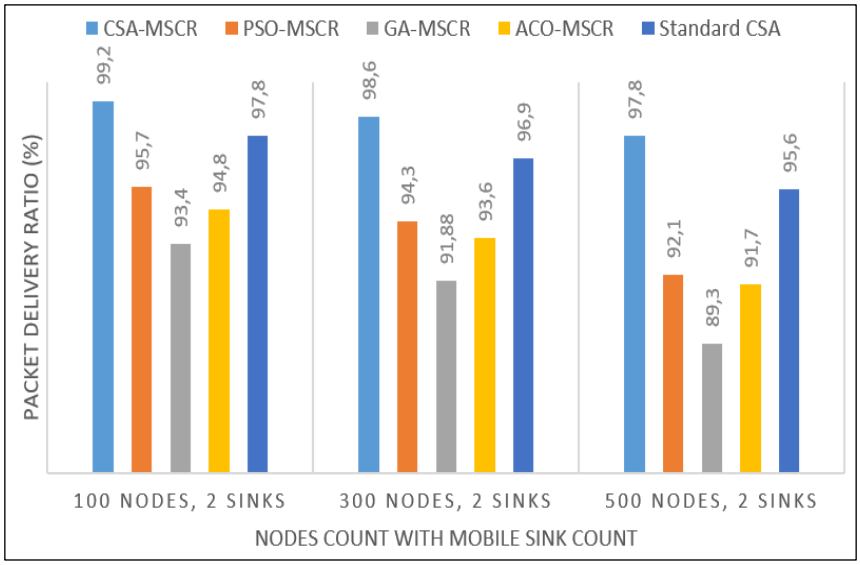

Figure 5: Packet Delivery Ratio (%) analysis in various metaheuristic algorithms with respect to node count.
Source: Authors, (2026).

CSA-MSCR continuously achieves PDRs over 97.8% across all evaluated configurations, with the dual-mobile sink and 300 nodes CSA-MSCR achieving 98.6% compared to 94.3% for PSO. The 4.3%-point enhancement compiles to over a 75% reduction in packet loss rate, eventually improving data collection reliability. Performance downfalls significantly as network size increases, with a 500-node network maintaining a 97.8% delivery ratio compared to 99.2% for 100-node networks, reporting better scalability.

IV.1.7 Mobile-Sink Route Optimization

Table 9 and Figure 6 represent mobile sink route path length for various network sizes with dual-mobile sink configurations. CSA-MSCR obtains routes averaging 1189.4 meters for 300-node networks compared to 1567.2 meters for PSO, specifying a 24.1% minimization in travelled distance. This shorter path length directly decreases mobile sink mobility power consumption and reduces data collection latency. The regular 24-25% path length reduction across all network scales simulation shows that CSA-MSCR optimization efficiency scales well as problem complexity increases.

Table 9: Average mobile sink route length (m) per collection cycle.

Nodes	CSA-MSCR	PSO-MSCR	GA-MSCR	ACO-MSCR	Improvement vs PSCO
100	847.3	1123.6	1198.4	1156.8	-24.6%
200	1034.6	1367.9	1478.3	1398.7	-24.4%
300	1189.4	1567.2	1689.5	1612.3	-24.1%
400	1323.7	1745.8	1892.6	1801.4	-24.2%
500	1442.8	1903.7	2067.9	1967.3	-24.2%

Source: Authors, (2026).

Route Length	1189	1567	1690	1612	1345	NA
Reduction	**-**	**-24.1%**	**-29.6%**	**-26.2%**	**-11.6%**	**NA**
Overall execution time	9.8	9.2	14.1	18.7	10.2	0.3
Overhead	**-**	**+6.5%**	**-30.5%**	**-47.6%**	**-3.9%**	**+3167%**

Source: Authors, (2026).

The comprehensive summary specifies proposed CSA-MSCR consistent better across virtually all performance measurements and dimensions. The 28.3% network lifespan enhancement combined with 23.7% power reduction and 30.8% latency reduction specifies significant practical advantages that would compile to substantially improved functional periods and extended quality of service (QoS) in real-time deployment. The 9.9% enhancement over standard CSA validates that adaptive parameter approaches provide meaningful advantages beyond simple CSA optimization, justifying the modest 3.9% computational overhead increase.

V. CONCLUSIONS

This paper presented a novel integrated multi-objective Crow Search Algorithm (CSA)-based algorithm for optimizing the dual-Mobile Sink-based Clustering and Routing (MSCR) in Heterogenous Wireless Sensor Networks (HWSNs). An important contribution lies in the simultaneous optimization of two independent NP-hard problems, such as energy-aware cluster head (CH) selection and efficient coordinated dual-mobile sink route selection. Unlike parallel research algorithms that address these issues independently or utilize one mobile-sink architecture, the proposed CSA-based MSCR architecture provides a substantial solution that enhances energy efficiency while reducing data collection latency through optimal and intelligent coordination of dual autonomous mobile sinks. The strategy adopted a comprehensive simulation-based experimental design implemented in NS2, evaluating network performance across five unique scenarios encompassing varying node densities (100-500 nodes) in the 500 * 500 m monitoring area, heterogeneity ratios (20-30% advanced nodes), dual-mobile sink configuration, and harsh environmental conditions such as up to 30% obstacle density and 20% link failure probability. Statistical analysis of the proposed algorithm based on 100 independent simulation evaluations per configuration provided a robust and reliable performance assessment with 95% confidence intervals.

ABSTRACT

Alzheimer's disease represents a degenerative brain condition that gradually worsens over time, severely affecting mental abilities and making it difficult to identify and treat in its early stages. Recent breakthroughs in artificial intelligence have transformed how medical images are analyzed, offering powerful tools for precise and automatic detection of Alzheimer's disease. To address this challenge, this study proposes a deep learning approach using two convolutional neural network (CNN) architectures: a VGG16-based transfer learning model and a lightweight custom CNN. Models were trained on MRI datasets with preprocessing and data augmentation techniques to improve robustness. Results demonstrate that the custom CNN achieves superior accuracy (95%) compared to the VGG16 (90%) approach while maintaining computational efficiency. The findings indicate significant potential for automated AD detection in clinical applications, contributing to AI-driven diagnostic tools for neuroimaging.

I. INTRODUCTION

Alzheimer's disease constitutes a significant global public health burden, afflicting approximately 50 million individuals worldwide and representing the leading etiology of dementia internationally [1] Early identification of Alzheimer's disease (AD) is paramount for implementing efficacious preventive interventions and therapeutic strategies, necessitating rapid and precise diagnostic methodologies. Multiple pathophysiological mechanisms contribute to AD pathogenesis, compromising cognitive performance, memory consolidation, and behavioral regulation in the aging demographic [2]. As illustrated in Figure 1, the neuroanatomical differences between healthy and Alzheimer's-affected brain tissue are striking. However, those with mild cognitive impairment (MCI) experience an accelerated reduction in brain volume, losing around 1–2% annually significantly faster than typical aging [3]. In Alzheimer's disease, the rate of brain volume loss increases further, reaching 3–5% per year, demonstrating the aggressive nature of neurodegeneration in this condition. Regions like the hippocampus are particularly affected, with shrinkage rates as high as 10–15% annually in advanced stages [4]. This progressive volumetric decline provides quantitative evidence for the morphological changes visually represented in Figure 1, where the stark contrast between healthy and pathological brain architecture underscores the extensive tissue loss that characterizes

Alzheimer's disease pathology and its devastating impact on cognitive function. In response to this clinical imperative, deep learning implementation for Alzheimer's disease detection in medical imaging has emerged as a transformative computational approach, leveraging convolutional neural networks (CNNs) to analyze complex neuroimaging patterns that may be imperceptible to conventional diagnostic methods. This research investigates the application of both transfer learning techniques utilizing the pre-trained VGG-16 architecture and a custom-designed CNN model for automated AD classification from brain imaging data. The comparative analysis of these deep learning frameworks aims to establish optimal feature extraction and classification methodologies that can enhance diagnostic accuracy while reducing computational complexity and processing time, thereby contributing to the development of clinically viable computer-aided diagnosis systems for early Alzheimer's disease detection. The remainder of this paper is organized as follows: Section 2 reviews the related work. Section 3 describes the proposed methodology. Section 4 presents the experimental results, while Section 5 provides a detailed discussion. Finally, Section 6 concludes the paper and highlights directions for future research.

II. RELATED WORK

Recent advances in Alzheimer's disease (AD) detection have leveraged artificial intelligence techniques, particularly deep learning and machine learning approaches, to improve diagnostic accuracy using neuroimaging data and clinical biomarkers. Comprehensive reviews have systematically examined state-of-the-art models including convolutional neural networks (CNNs), recurrent architectures like LSTM, and hybrid models that combine multiple AI approaches for improved AD classification, highlighting the critical role of medical imaging modalities such as MRI and PET scans along with preprocessing techniques like skull stripping and data augmentation that enhance model performance while addressing evaluation metrics including accuracy, F1-score, and AUC-ROC that validate model effectiveness and practical implementation challenges such as computational costs and model interpretability [5]. Novel lightweight architectures such as FiboNeXt, inspired by the Fibonacci sequence and integrating attention mechanisms with depth-concatenation blocks, have demonstrated computational efficiency while maintaining high accuracy for AD detection using MRI images [6].

Large-scale studies comparing established CNN architectures including Xception, VGG19, VGG16, and InceptionResNetV2 on datasets of 6,735 brain MRI images have shown deep learning's potential to enhance multi-stage AD diagnosis by improving accuracy and efficiency over traditional methods, though further validation on diverse datasets is needed for realworld clinical implementation [7]. Traditional machine learning approaches combining Adaptive Moving Self-Organizing Map (AMSOM) for unsupervised tissue segmentation with Kmeans clustering and Principal Component Analysis (PCA) for feature selection have demonstrated robustness and efficiency for early AD detection when evaluated on benchmark datasets like OASIS, outperforming existing techniques such as Fuzzy C-means (FCM) and hybrid SOM-FKM methods while highlighting potential for clinical application with future enhancements through advanced classifiers [8]. Recent studies from 2024 to 2025 have introduced novel lightweight and hybrid architectures that further enhance AD detection. The AD-Lite Net model, a concatenated CNN using depth-wise separable convolutions, achieved superior accuracy on ADNI MRI datasets while reducing computational cost [9].

Similarly, Hybrid Compact Convolutional Transformers (HCCT) effectively combine 3D CNNs and transformer layers to capture spatial and contextual features, improving interpretability and diagnostic precision [10]. Multimodal fusion frameworks integrating MRI and PET through self-attention mechanisms have achieved higher early-stage AD prediction accuracy [11]. The LEAD foundation model, trained on large-scale EEG data using self-supervised contrastive learning, demonstrated robust subject-independent AD classification [12]. Moreover, MRIbased deep models predicting PET-derived ATN biomarkers (amyloid, tau, and neurodegeneration) have emerged as powrerful noninvasive tools for biomarker estimation [13]. Comparative studies employing SVM, ANN, and Vision Transformers (ViT) on OASIS and ADNI datasets have confirmed the superiority of hybrid transformer architectures for AD staging and classification [14] Systematic reviews published in 2024–2025 further emphasize advancements in explainability, ethical AI deployment, and generalization of deep models [15]. Meanwhile, methodological analyses reveal persistent data leakage issues that inflate reported accuracies, underscoring the need for rigorous subject-level validation and cross-site generalization before clinical translation [16].

Table 1: Summary of Related Work: Strengths and Limitations.

Paper Title	Strengths	Limitations
Alzheimer's disease detection using DL/ML: review [5]	• Comprehensive coverage of DL/ML techniques • Analysis of CNNs, LSTMs, hybrid models • Identifies future research directions	• Lacks critical analysis of limitations • Limited clinical applicability discussion • No quantitative comparison of approaches
FiboNeXt: AD detection using MRI [6]	• Exceptional accuracy (99.6% on test datasets) • Lightweight architecture (< 10M parameters) • Innovative Fibonacciinspired design	• Validation limited to specific MRI datasets • No testing in real-world clinical settings • Limited comparison with SOTA models
AD classification with DL using 6735 MRI images [7]	• Outstanding classification performance (99%) • Comprehensive comparison of architectures • Demonstrates fast training convergence	• Black-box nature limits interpretability • Evaluation on single dataset only • High computational requirements
Early AD diagnosis using Adaptive Neuro KMeans [8]	• Exceptional classification accuracy (99.8%) • Superior segmentation performance • Effective unsupervised/supervised integration	• Complex implementation pipeline • Limited evaluation to OASIS dataset • No independent external validation • Lacks comparison with DL approaches

III. METHODOLOGY

This Figure 2 presents a deep learning pipeline for medical image analysis utilizing the ADNI dataset. The workflow begins with MRI scan data collection, followed by preprocessing steps to prepare the medical images for analysis. The system then implements dataset augmentation techniques in parallel with cnn model training, using brain scan imagery to develop robust diagnostic capabilities. The final stage involves comprehensive evaluation of the trained model's performance.

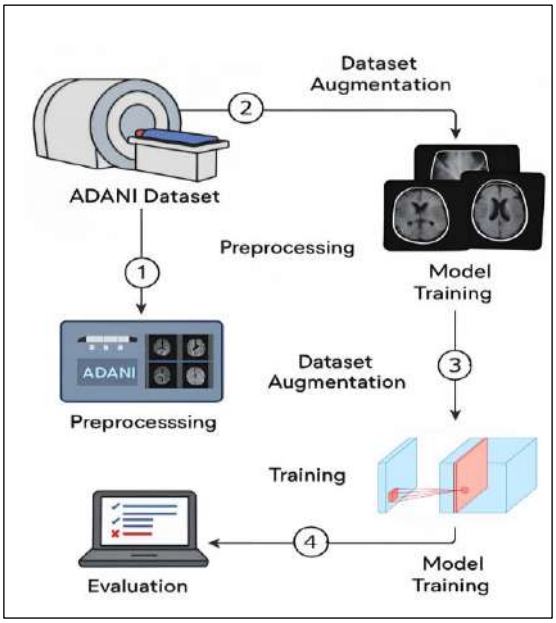

Figure 2: Deep Learning-Based Automated Pipeline for Alzheimer's Disease Detection from Medical Images.

III.1 ADNI DATA

The Alzheimer's Disease Neuroimaging Initiative (ADNI) unites researchers with study data as they work to define the progression of Alzheimer's disease (AD). ADNI researchers collect, validate and utilize data, including MRI and PET images, genetics, cognitive tests, CSF and blood biomarkers as predictors of the disease. Study resources and data from the North American ADNI study are available through this website [17] , including Alzheimer's disease patients, mild cognitive impairment subjects, and elderly controls. The neuroimaging data from ADNI provides compelling visual evidence of the progressive brain changes associated with cognitive decline. Figure 3 demonstrates representative axial MRI scans across different stages of dementia severity. The NonDemented scan serves as a neurologically healthy control, displaying preserved cortical thickness, normal ventricular dimensions, and intact whitegray matter differentiation.

In contrast, the VeryMildDemented case shows subtle early changes including minimal ventricular enlargement and initial cortical atrophic modifications. The MildDemented scan reveals more pronounced cerebral atrophy with increased ventricular dilatation and cortical thinning, particularly evident in frontal and temporal regions. The ModerateDemented case exhibits advanced pathological changes, including significant ex-vacuo ventricular dilatation, markedly widened cortical sulci, and substantial loss of brain parenchyma. These structural neuroimaging findings correlate with the clinical progression of cognitive impairment and demonstrate the utility of MRI as a biomarker for tracking neurodegenerative changes in Alzheimer's disease research and clinical assessment.

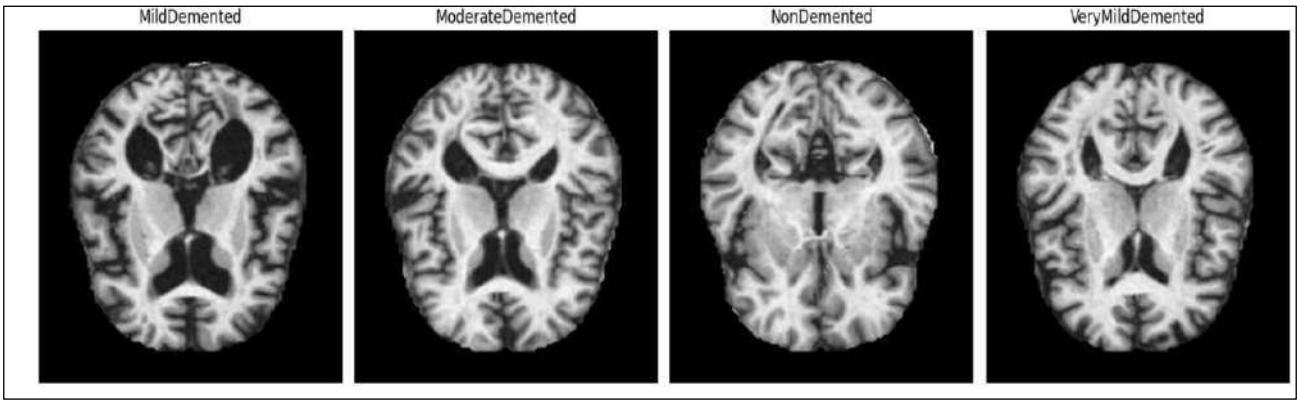

Figure 3: ADNI dataset classification: MildDemented, ModerateDemented, NonDemented, and VeryMildDemented brain MRI scans. Source: Authors, (2026).

III.2 DATA PREPROCESSING

The ADNI Dataset from the MRI scanner first undergoes comprehensive data preprocessing , which includes:

- Data Cleaning: Removing artifacts, noise, and corrupted scans.
- Data Resizing: Standardizing image dimensions and resolution across all scans.
- Normalization: Ensuring consistent intensity values and contrast across images.

III.3 DATASET AUGMENTATION

After the cleaned and resized data is properly integrated, it undergoes augmentation techniques such as:

- Rotation, flipping, and scaling transformations
- Intensity variations and noise addition
- Geometric transformations to increase dataset diversity

III.4 MODEL TRAINING

This phase constitutes the core of the experimental methodology, where the parameters of the deep learning models are iteratively optimized to learn discriminative features from the preprocessed and augmented ADNI dataset. We employ and compare two distinct architectural paradigms: a pre-trained VGG16 model utilizing transfer learning, and a customdesigned Convolutional Neural Network (CNN) built from scratch.

III.4.1 Transfer Learning Framework

The model training phase employs a transfer learning approach using VGG16 as the backbone architecture, pre-trained on ImageNet. This strategy leverages learned feature representations from natural images and adapts them for medical imaging classification tasks.

CORE ARCHITECTURE COMPONENTS

This table 2 outlines the architectural framework of a hybrid deep learning model that integrates a pretrained convolutional neural network with custom classification components

1) Fine-Tuning Approach
•Trainable Parameters: Last 3 convolutional layers fine-tuned for domain adaptation
2) Optimization Setup
•Optimizer: Adam with conservative learning rate (1× 10−4) for stable convergence
•Loss Function: Categorical crossentropy for multiclass classification
•Metrics: Accuracy monitoring for performance evaluation
3) Training Safeguards
•Early Stopping: Monitors validation loss with 10- epoch patience
•Best Weights Restoration: Automatically restores optimal model state
•Integrated Data Augmentation: Real-time augmentation pipeline for improved generalization.

Table 2: Model Training Architecture Components.

Component	Description
Base Feature Extractor	
VGG16 Convolutional Base	Pre-trained ImageNet weights with top classification layers removed
Input Specifications	224×224×3 RGB images
Feature Extraction	Deep convolutional features from lower-level edge detection
Custom Classification Head	
Global Average Pooling Layer	Reduces spatial dimensions while preserving feature information, providing translation invariance
Primary Dense Layer	1024-unit fully connected layer with ReLU activation
Secondary Dense Layer	512-unit layer for refined feature learning
Output Layer	Layer 4-unit softmax layer for multi-class classification

Source: Authors, (2026).

III.4.2 Custom-Architected Convolutional Neural Network (CNN):

Core Architecture Components

This Table 3 presents the architectural specification of a custom-designed Convolutional Neural Network engineered for efficient image classification tasks. The network processes 224×224×3 RGB input images through a sophisticated multi-stage feature extraction pipeline, beginning with standard convolutional layers (32-64 filters, 3×3 kernels) and progressing through multiple inverted residual blocks that utilize depthwise separable convolutions to achieve computational efficiency while maintaining representational capacity. The architecture implements systematic spatial downsampling from 112×112 to 14×14 resolution with concurrent channel expansion from 16 to 320 filters, incorporating batch normalization and ReLU6 activations throughout to ensure training stability and gradient flow optimization. The network concludes with global average pooling for spatial dimension reduction, dropout regularization for overfitting prevention, and a dense softmax layer for 4-class classification, demonstrating a principled approach to balancing model expressiveness with computational constraints suitable for production deployment environments.

Table 3: Custom-Architected Convolutional Neural Network (CNN).

Model Training Configuration

This Table 4 presents the comprehensive training configuration parameters employed for model optimization. The configuration utilizes the Adam optimizer with a learning rate of 0.002, im- plementing categorical crossentropy as the loss function and accuracy as the primary evaluation metric. The training protocol incorporates three essential callback mechanisms to ensure optimal model performance and prevent overfitting. Early stopping functionality moni- tors validation accuracy with a patience threshold of 75 epochs. Additionally, model checkpointing saves only the best-performing model iterations based on validation accuracy monitoring. This configuration demonstrates a robust training framework that balances convergence ef- ficiency with generalization performance, incorporating adaptive learning rate scheduling and systematic model selection criteria to achieve optimal results.

Table 4: Model Training Configuration.

Parameter	Value
Optimizer	Adam
Learning Rate	0.002
Loss Function	Categorical Crossentropy
Metrics	Accuracy
Callbacks	
Early Stopping	monitor='val_accuracy', patience=100
Model Checkpoint	save_best_only=True, monitor='val_accuracy'

IV. RESULTS

Table 5 presents a comparative performance analysis of two convolutional neural network (CNN) architectures evaluated on the test dataset. The comparison encompasses a custom-designed CNN model and a VGG16-based transfer learning approach, with performance metrics quantified through test loss and classification accuracy. The results demonstrate that the Custom CNN Model achieves superior performance across both evaluation metrics, attaining a test loss of 0.2219 and a classification accuracy of 95.86%. In contrast, the VGG16 Transfer Learning model exhibits a higher test loss of 0.40 and a lower accuracy of 90.70%. The Custom CNN Model outperforms the transfer learning approach by approximately 5 percentage points in accuracy while maintaining substantially lower loss values, indicating better model convergence and predictive capability. This performance differential suggests that the custom-designed architecture is better suited to the specific characteristics of the dataset, whereas the pretrained VGG16 model, despite its proven efficacy on largescale image classification tasks, demonstrates comparatively reduced effectiveness in this particular application context. These findings underscore the importance of task-specific model design and suggest that domain-optimized architectures can yield superior results compared to generic transfer learning approaches.

Table 5: Performance Comparison of CNN Models.

Model Type	Test Loss	Test Accuracy(%)
Custom CNN Model	0.2219	95.86
VGG16 Transfer Learning	0.40	90.70

Source: Authors, (2026).

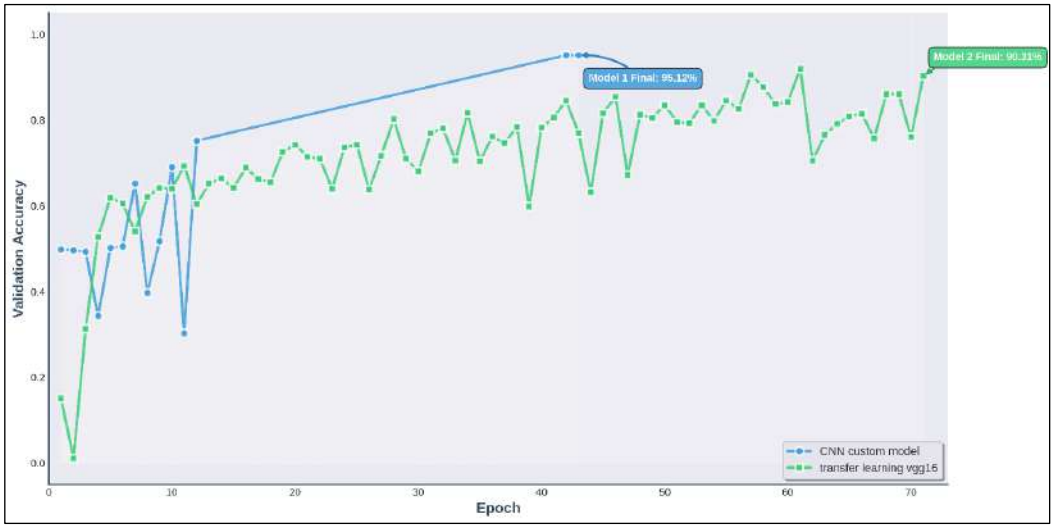

Figure 4: A Comparative Validation Accuracy Analysis.
Source: Authors, (2026).

This Figure 4 presents a comparative analysis of validation accuracy for two deep learning architectures across 75 training epochs: a custom CNN (blue) and a VGG16 transfer learning model (green). The custom CNN achieves superior performance at 95.12% final accuracy with notably stable convergence, while the VGG16 model reaches 90.31% with considerable volatility throughout training.

The custom architecture demonstrates smooth progression after initial fluctuations, indicating well-optimized hyperparameters and robust generalization capabilities. Conversely, the transfer learning approach exhibits persistent oscillations, suggesting challenges in adapting pre-trained weights to the target domain. The 5 percentage point performance differential, combined with enhanced training stability, positions the custom CNN as the optimal choice for deployment. These results illustrate that domain-specific architectural design can outperform generic transfer learning strategies, emphasizing the critical importance of tailored model development for specialized classification tasks.

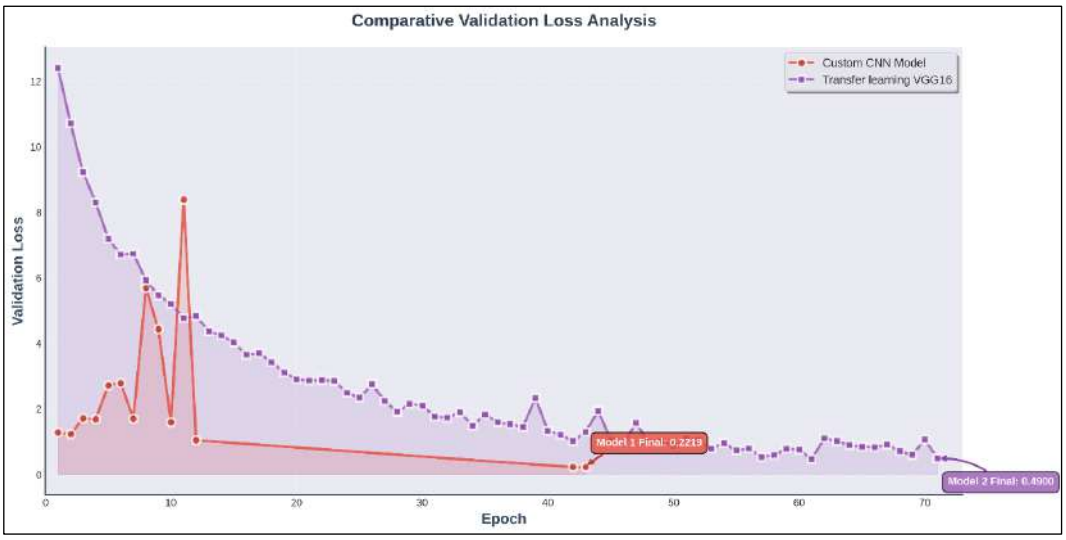

Figure 5: A Comparative Validation Loss Analysis.
Source: Authors, (2026).

This Figure 5 presents a comparative evaluation of validation loss trajectories for two deep learning architectures: a custom CNN (red) and a VGG16 transfer learning model (purple) across 75 training epochs. The custom CNN demonstrates exceptional convergence efficiency, achieving a final validation loss of 0.2219, with rapid stabilization occurring around epoch 22. Following initial volatility during epochs 0-10, where loss spikes dramatically to 8.5, the model exhibits swift descent and maintains remarkably low, stable loss values throughout the remaining training period. This convergence pattern indicates optimal learning dynamics and superior generalization capability. In contrast, the VGG16 transfer learning model shows significantly slower convergence, starting at an elevated loss of 12.4 and achieving a final value of 0.4900—more than double that of the custom CNN. The substantial performance gap of 0.2681 in final validation loss, combined with the custom model's superior stability and faster convergence, clearly establishes it as the more efficient and reliable architecture. These findings demonstrate that purpose-built models can outperform transfer learning approaches in both convergence speed and final performance metrics for domain-specific applications.

V. DISCUSSION

This investigation demonstrates the efficacy of deep learning architectures for automated Alzheimer's disease detection from neuroimaging data, with our custom-designed CNN achieving superior diagnostic performance (95.86% accuracy) compared to the VGG16 transfer learning approach (90.70% accuracy). These findings contribute substantively to the expanding corpus of literature advocating for AI-driven diagnostic tools in neurodegenerative disease management. The 5 percentage point performance differential between architectures warrants careful consideration. While transfer learning methodologies have demonstrated remarkable success across diverse computer vision applications, our results suggest that domain-specific architectural optimization may yield superior outcomes for specialized medical imaging tasks. The VGG16 model's suboptimal performance can be attributed to the substantial domain gap between natural images (ImageNet pre-training) and medical neuroimaging modalities, coupled with architectural complexity potentially exceeding the requirements of this classification task.

Furthermore, the custom CNN demonstrated markedly superior convergence characteristics, achieving rapid stabilization with a validation loss of 0.2219 compared to VGG16's 0.4900, indicating enhanced generalization capability—a critical attribute for clinical deployment. However, several limitations constrain immediate clinical translation, including evaluation on a single dataset (ADNI) and the inherent lack of interpretability characteristic of deep learning models. Future investigations should prioritize external validation across diverse patient populations and integration of explainability frameworks such as Grad-CAM to elucidate decision-making processes. Despite these limitations, our findings underscore the transformative potential of tailored deep learning architectures in advancing early Alzheimer's disease detection, ultimately contributing to improved patient outcomes through timely intervention strategies.

VI. CONCLUSION AND PERSPECTIVE

This investigation establishes the clinical viability and technical superiority of purpose-built deep learning architectures for automated Alzheimer's disease detection from neuroimaging data. Addressing the critical challenge of limited access to specialized neurological expertise for approximately 50 million individuals worldwide afflicted by Alzheimer's disease, our research developed a custom convolutional neural network optimized specifically for medical imaging applications.

Our innovative approach, incorporating architectural elements such as depthwise separable convolutions and inverted residual blocks, validates the hypothesis that domain-specific architectures yield superior feature representations compared to traditional transfer learning from natural image domains. Through rigorous comparative analysis, our custom-designed CNN achieved a diagnostic accuracy of 95.86%, substantially outperforming the VGG16 transfer learning baseline (90.70%), while demonstrating superior convergence stability (validation loss: 0.2219 vs. 0.4900) and computational efficiency, with rapid convergence suggesting reduced training requirements suitable for resource-constrained clinical environments. However, the path toward clinical integration necessitates addressing fundamental challenges including multicenter validation studies across heterogeneous populations and imaging protocols, integration of explainable AI frameworks such as gradient-weighted class activation mapping to enable radiologist trust and interpretation, and harmonization with existing clinical workflows. This research makes substantive contributions to the intersection of artificial intelligence and neurodegenerative disease diagnosis, demonstrating that specialized deep learning architectures can achieve clinically meaningful performance levels, thereby establishing a foundation for future investigation into production-ready diagnostic systems that can democratize high-quality dementia screening and advance the standard of care for millions of affected individuals worldwide.

ABSTRACT

Geological discontinuities such as faults and shear joints present significant challenges in slope stability assessments, often altering failure mechanisms and reducing safety margins. This study explores the influence of fault geometry on slope stability through a comprehensive numerical investigation using finite element limit analysis with upper and lower bound formulations. A series of parametric simulations were conducted on a 17-meter-high slope model, incorporating faults of varying lengths (3.75 to 21.5 meters) positioned at different distances from the slope face. The fault-free slope exhibited stable conditions, with safety factors ranging from 1.889 to 1.923 and circular failure surfaces. In contrast, the introduction of faults in close proximity to the slope resulted in marked reductions in stability. The most critical scenario, involving a 21.5-meter fault located 1 meter from the slope, yielded safety factors as low as 0.675–0.693 and a transition in failure mode from circular to planar sliding. Results reveal that fault proximity has a more pronounced impact on slope behavior than fault length. Faults situated beyond 4 meters from the slope face exhibited negligible influence on stability, whereas those within the near-field zone induced safety factor reductions exceeding 60%. These findings provide actionable insights for geotechnical design, emphasizing the necessity of detailed fault mapping within critical slope zones. The study contributes to the development of more reliable, risk-informed approaches to slope stability analysis in structurally complex terrains.

I. INTRODUCTION

Slope stability analysis represents one of the most critical challenges in geotechnical engineering, fundamentally affecting infrastructure safety, economic viability, and environmental preservation [1–2]. The complexity of slope instability phenomena encompasses multiple interdependent variables including geological formations, material properties, environmental conditions, and structural discontinuities, necessitating comprehensive analytical approaches to ensure adequate safety margins in engineering practice [3–4]. Recent technological advances in computational geomechanics have significantly enhanced predictive capabilities for slope behavior under various loading conditions. However, the presence of structural discontinuities such as faults, joints, and fissures continues to pose substantial challenges in accurate stability assessment and risk evaluation [5–7]. The significance of slope stability research extends beyond traditional geotechnical engineering applications, encompassing diverse fields including mining operations, transportation infrastructure, urban development, and natural hazard mitigation. Mining operations, recognized as one of the most hazardous industrial activities globally, rely heavily on accurate slope stability predictions to ensure operational safety and economic viability [2].

The complexity of these assessments is further amplified by the presence of pre-existing geological discontinuities, which can dramatically alter failure mechanisms and significantly reduce stability margins.Contemporary research emphasizes the critical importance of understanding how structural features such as faults and joints influence slope behavior, particularly in the context of climate change-induced extreme weather events and increasing urbanization pressures on marginally stable terrain [8]. Recent investigations have demonstrated that the presence of structural discontinuities fundamentally alters the stress distribution and failure patterns within slope systems, often leading to unexpected failure modes that deviate significantly from classical circular failure mechanisms [4]. conducted comprehensive studies on columnar jointed rock masses, revealing that these formations exhibit continuous mechanical properties despite geometric discontinuities, presenting unique challenges for field parameter determination and stability analysis [9]. Their research highlighted the critical importance of understanding the mechanical behavior of discontinuous rock masses, particularly in major infrastructure projects where failure could result in catastrophic consequences. Similarly, Que et al. [5] developed innovative testing methodologies for irregular columnar jointed rock masses, demonstrating through uniaxial compression tests that the heterogeneous nature of these formations requires specialized analytical approaches to accurately predict their mechanical response. The quantitative assessment of fault influences on slope stability has gained increased attention due to several factors.

First, climate change-induced extreme weather events are placing additional stress on marginally stable slopes, making accurate stability prediction more critical than ever. Second, urban expansion into previously undeveloped mountainous terrain requires detailed understanding of geological hazards. Third, advances in numerical modeling capabilities now permit comprehensive parametric studies that were previously computationally prohibitive. Recent studies have shown that conventional analysis methods may overestimate safety factors by 30-70% when structural discontinuities are not properly accounted for, highlighting the urgent need for improved analytical frameworks [10], [11]. The evolution of computational methods in slope stability analysis has been marked by significant advancements in both theoretical frameworks and practical applications. Traditional limit equilibrium methods, while providing valuable insights into slope behavior, often rely on oversimplified assumptions that may not adequately capture the complex interactions between different failure mechanisms and material heterogeneities [12], [13]. The finite element method has emerged as a powerful alternative, particularly when combined with strength reduction techniques, offering enhanced capabilities for modeling complex geometries, varied material properties, and non-linear behavior patterns. However, recent research has increasingly focused on finite element limit analysis methods, which combine the computational efficiency of optimization techniques with the theoretical rigor of classical plasticity theory [14], [15].

Finite element limit analysis represents a significant advancement in slope stability assessment methodologies, providing direct computation of upper and lower bound collapse loads through optimization techniques rather than iterative time-stepping approaches. This methodology, grounded in the classical plasticity theorems established by Drucker and Prager, offers distinct advantages in computational efficiency and theoretical consistency [16]. The method's ability to automatically identify critical failure surfaces while simultaneously computing safety factors makes it particularly suitable for parametric studies investigating the influence of various geometric and material parameters on slope stability. Recent applications of this methodology have demonstrated its effectiveness in analyzing complex slope configurations, including those with multiple soil layers, varying groundwater conditions, and the presence of structural discontinuities [17], [18]. The influence of faults and other structural discontinuities on slope stability has gained increasing attention in recent geotechnical research, driven by growing recognition of their critical role in governing failure mechanisms and stability margins. Comprehensive studies have revealed that the orientation, length, location, and mechanical properties of faults significantly influence both the magnitude of safety factors and the geometry of potential failure surfaces [19], [20].

Research conducted using advanced numerical modeling techniques has demonstrated that fault proximity to slope faces dramatically increases instability risk, with reductions in safety factors exceeding 60% when faults are positioned within critical zones near slope surfaces [21, [22]. These findings have profound implications for engineering practice, particularly in regions characterized by complex geological structures and extensive fault systems. Environmental considerations have become increasingly prominent in contemporary slope stability research, reflecting growing awareness of sustainability principles and environmental protection requirements in engineering practice. The utilization of locally available materials in slope stabilization projects offers multiple advantages including reduced transportation costs, lower environmental impact, and enhanced compatibility with existing geological formations [23, [24]. Local materials often exhibit superior performance characteristics when used in their native geological environment, benefiting from natural weathering processes and geochemical equilibrium conditions that enhance long-term stability and durability. Furthermore, the use of indigenous materials supports regional economic development while minimizing the carbon footprint associated with material transportation and processing [25], [26]. The integration of environmental protection principles with geotechnical engineering practice has led to innovative approaches in slope design and analysis that prioritize ecological preservation alongside structural safety.

Recent research has emphasized the importance of considering environmental factors in slope stability assessments, including vegetation effects, groundwater flow patterns, and soil-atmosphere interactions [27], [28]. These considerations are particularly relevant in the context of climate change, where altered precipitation patterns and temperature extremes can significantly influence slope stability conditions. The development of sustainable slope management strategies requires comprehensive understanding of these environmental interactions and their incorporation into analytical methodologies [29], [30]. Advanced computational tools have revolutionized the field of slope stability analysis, enabling detailed parametric studies that were previously impractical using traditional analytical methods. Software packages such as OptumG2 have integrated sophisticated finite element limit analysis capabilities with user-friendly interfaces, facilitating comprehensive investigations of complex slope configurations [31], [32]. These tools enable researchers to systematically evaluate the influence of various parameters including fault geometry, material properties, and boundary conditions on slope stability performance. The ability to conduct extensive parametric studies provides valuable insights into the relative importance of different factors and facilitates the development of design guidelines for practitioners [33], [34]. The methodology employed in this research builds upon established theoretical foundations while incorporating recent advances in computational geomechanics and environmental engineering.

The upper and lower bound limit analysis approach provides rigorous theoretical bounds on collapse loads, ensuring conservative estimates of safety factors while maintaining computational efficiency [35], [36]. The systematic variation of fault parameters including length, location, and orientation enables comprehensive evaluation of their influence on slope stability, providing insights that can inform both design practice and regulatory guidelines. The focus on locally available materials reflects contemporary emphasis on sustainable engineering practices and environmental stewardship [3], [37]. Current research trends in slope stability analysis emphasize the importance of uncertainty quantification and reliability-based design approaches, recognizing the inherent variability in geological materials and loading conditions [38], [39]. Probabilistic methods are increasingly being integrated with deterministic analyses to provide more comprehensive assessments of slope stability that account for parameter uncertainties and their propagation through analytical models.

Machine learning techniques are also finding applications in slope stability assessment, offering capabilities for pattern recognition and predictive modeling that complement traditional analytical approaches [35] [40]. The practical implications of fault-influenced slope stability extend across numerous engineering applications, from highway construction in mountainous terrain to open-pit mining operations and urban development on sloping sites. Understanding the mechanisms by which faults influence slope behavior is essential for developing appropriate stabilization measures and risk mitigation strategies [41] [42]. Recent case studies have demonstrated that conventional analysis methods may significantly overestimate safety factors when structural discontinuities are present, highlighting the need for specialized analytical approaches that explicitly account for fault influences [43], [44].

The present investigation addresses several critical gaps in current understanding of fault-influenced slope stability through systematic parametric analysis using advanced computational methods. The comprehensive evaluation of fault length and location effects provides valuable insights into the mechanisms governing stability reductions and failure mode transitions. The emphasis on locally available materials and environmental considerations reflects contemporary priorities in sustainable engineering practice. The rigorous application of finite element limit analysis methods ensures theoretical consistency while maintaining practical relevance for engineering applications. These contributions advance the state of knowledge in slope stability analysis while providing practical tools and insights for geotechnical engineering practice, ultimately supporting safer and more sustainable infrastructure development in challenging geological environments where structural discontinuities pose significant stability challenges.

II. SAFETY FACTOR AND FAILURE MECHANISMS

II.1 LIMIT EQUILIBRIUM METHOD

The assessment of slope stability typically begins with determining the factor of safety (FS), defined as the ratio between available shear strength and mobilized shear stress along a potential failure surface, as shown in Equation (1):

$$\mathrm{FS} = \frac{(\text{Applied shear stress})}{\text{Shear strength required for limit equilibrium})} \tag{1}$$

Among the most widely used approaches is the Limit Equilibrium Method (LEM), which assumes that failure occurs along a predefined surface, commonly circular or non-circular, and analyzes the balance of forces and moments acting on discrete soil slices [45–46]. LEM offers a practical framework for estimating slope stability under various loading and geometrical conditions. It discretizes the slope into vertical slices and applies static equilibrium equations to compute FS, making it especially suitable for homogeneous slopes or cases with well-defined failure planes. However, its accuracy is highly dependent on the assumed geometry of the failure surface and the simplifications adopted in force distribution, which may not fully capture complex behaviors in slopes affected by heterogeneities or structural discontinuities such as faults [1]. Despite these limitations, LEM remains a valuable tool in preliminary design and stability screening, often serving as a baseline for comparison with more advanced numerical methods.

II.2 LIMIT ANALYSIS

Limit analysis is fundamentally based on the lower and upper bound theorems of classical plasticity theory, which incorporate yield criteria and stress-strain relationships [47] [48]. The application of limit analysis to slope stability problems was pioneered by Drucker et al. [16] [48], who focused on translational and rotational failure mechanisms under plane strain conditions. Subsequently, Lyamin et al. [49] conducted comparative studies on linear and nonlinear programming approaches for lower bound limit analysis. Kim et al. [50] extended the application of limit analysis to evaluate slope stability under conditions involving pore water pressures. This methodology has since been the subject of extensive research and development. The Strength Reduction Method (SRM) represents the most widely adopted approach for slope stability analysis within the finite element method (FEM) framework. The SRM operates by progressively reducing the slope's strength parameters (c and φ) until failure conditions are reached. This technique was first introduced by Zienkiewicz et al. [13], with the initial implementation code for slope stability applications developed by Smith et al. [51]. Numerous researchers have subsequently adopted and refined this methodology, including [8], [10], [11], [18], [52–55]. Comprehensive reviews of this technique have been provided by Duncan et al. [1], [3], [56]. In FEM-based slope stability analysis, the shear strength reduction approach is typically implemented using the Mohr-Coulomb failure criterion, as expressed in equation (2). This approach systematically reduces the material strength parameters until the slope reaches a state of limiting equilibrium, thereby determining the factor of safety.

The failure strength is characterized by the Mohr-Coulomb criterion, expressed as:

$$\tau = c + \sigma_n \tan\varphi \tag{2}$$

Where τ represents the shear stress, c denotes cohesion, φ is the internal friction angle, and σ_n is the normal stress acting on the failure plane. The safety factor can be determined using the strength reduction approach, as shown in equation (3):

$$FS = \frac{c}{c_r} = \frac{\tan \varphi}{\tan \varphi_r} \quad (3)$$

The primary objective of the Strength Reduction Method (SRM) is to calculate the strength reduction factor (FS) from the reduced material properties (c_r and φ_r) that correspond to the collapse state of the slope failure surface. In this study, the SRM was employed to estimate both the failure surface geometry and the safety factor of the slope through finite element limit analysis using Optum G2 software.

II.3 PARAMETRIC STUDY DESIGN

The parametric investigation was designed to systematically evaluate the combined effects of fault length and position on slope stability. The study parameters were selected based on dimensional analysis and preliminary sensitivity studies. Fault lengths were chosen to represent different ratios relative to slope height (H = 17m): L/H ratios of 1.26, 0.95, 0.66, 0.44, and 0.21, corresponding to lengths of 21.5, 16.2, 11.2, 7.5, and 3.5 meters, respectively. Fault positions were systematically varied at distances of 1, 4, 7.5, 11, and 15 meters from the slope face, representing normalized distances (d/H) of 0.06, 0.24, 0.44, 0.65, and 0.88. This spacing was designed to capture the transition from near-field effects (where fault-slope interaction is significant) to far-field conditions (where faults have minimal influence). The experimental matrix resulted in 25 fault configurations plus one baseline case without faults, providing a comprehensive dataset for statistical analysis and development of predictive relationships. Each simulation was conducted using both upper and lower bound limit analysis to establish rigorous bounds on the collapse load and ensure conservative safety factor estimates.

III. FAULTS

The faults or shear joints (Cracks) are lines used by the solid Mohr-Coulomb material materials, the applications for these Shear Joints are as internal discontinuities in solids or as interfaces elements between solid domains Optum G2 (2016). In this study we simulated paper with existing faults by the Optum G2 software.

Figure 1: Different jointed rock mass.
Source: Authors, (2026).

IV. NUMERICAL PROBLEM STATEMENT (GEOMETRY AND MATERIAL)

The geometry of the model is illustrated in Figure 2 with a single-layer dirt slope and an angle, α. The model height in this analysis is taken as 17 m, the length is 32 m (see Figure 2, a). The finite element upper and lower method has been used with 2D plane strain conditions, to simulate the soil's plasticity behavior as determined by the Mohr-Coulomb criteria, we use OPTUMG2 software. In the boundary condition, there is roller support on the vertical sides and fixed support at the boundary condition's base. For meshing, a 6-node Gauss (1) triangular or arbitrary shape element was used, and the mesh size around the sliding surface has been fine-tuned. Refer to Figure 2 (b). The soil materials' strength parameters are displayed by c, and φ these parameters are used to strength reduction method. It is intended to compute the failure surface and the factor of safety after analysis. The table 1, shows the parameters of the faults and the soil material.

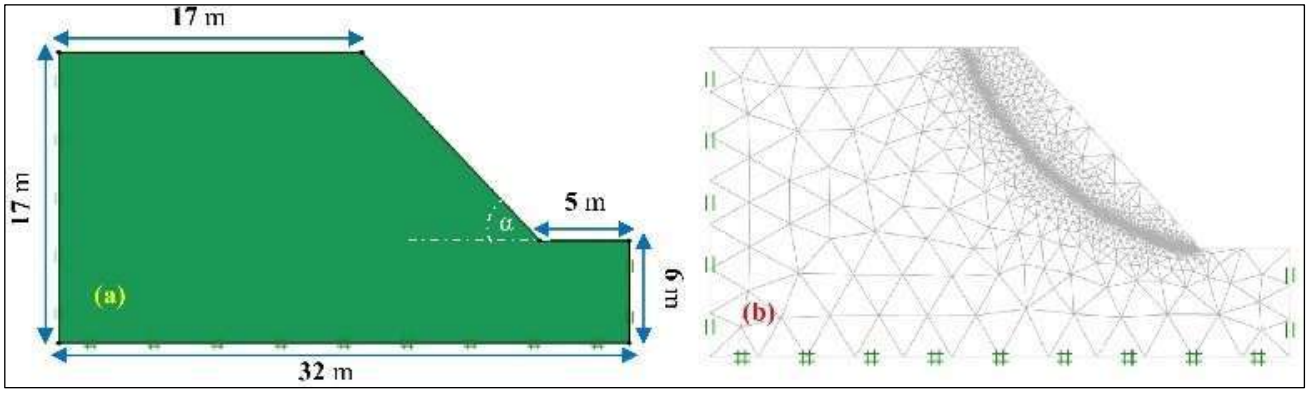

Figure 2: The slope's geometry (a), mesh, and boundary condition (b).
Source: Authors, (2026).

Table 1: Parameters of the faults and the soil material.

Soil properties (unite)	**Symbol**	**Value**
Young's modulus (MPa)	E	30
Poisson's ratio	ϑ	0.25
Friction angle (°)	φ	23
Cohesion (kPa)	c	24
Saturated density (kN/m^3)	γ_{sat}	18
Dry density (kN/m^3)	γ_{dry}	20
Faults properties (unite)	**Symbol**	**Value**
Cohesion (kPa)	c	0
Friction angle (°)	φ	20
Young's modulus (MPa)	E	20
Poisson's ratio	ϑ	0.25
Saturated density (kN/m^3)	γ_{sat}	19
Dry density (kN/m^3)	γ_{dry}	14

IV.1 SLOPE WITHOUT FAULTS

In the current study, the baseline model without any faults was analyzed to evaluate the reference safety factor and failure surface. The same soil strength properties and model geometry were maintained throughout all simulations. Results from this reference case show a stable slope condition, with safety factors ranging from 1.889 (lower bound) to 1.923 (upper bound), and a characteristic circular failure mechanism (see Figures 2 and 3). This fault-free configuration serves as a benchmark for comparison with faulted models, allowing for the identification and quantification of the influence of faults on slope behavior. The analysis confirms that the slope is inherently stable under the given conditions, as both upper and lower bound safety factors exceed the typical stability threshold (FS > 1.5). Figure 3 illustrates the failure surface and corresponding shear dissipation for the fault-free slope. The results reveal a well-defined circular sliding mechanism extending from the slope crest to the toe. The lower bound analysis yielded a maximum shear stress of 610.3 kPa, while the upper bound analysis produced a slightly higher value of 621.9 kPa.

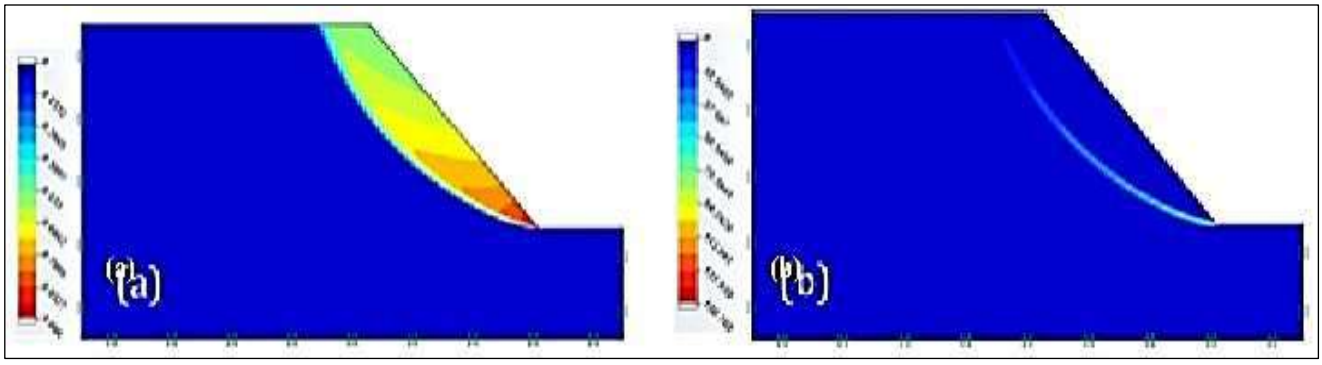

Figure 3: The slope surfaces and the shear dissipation.
Source: Authors, (2026).

IV.1.1 Case 1: Length of the Faults 21.5 m

In the first example, we have all the lengths from top to bottom of the model, with a length of 21.5 m. the faults are shown in yellow and are parallel to the inclination of the slope as shown in the Figure 4, we study these faults one by one, not all of them together. Figure 4 presents the locations of the faults. The first one is fault (a), It is one meter from the model's finish, while fault (b) is 4 m away from the end of the model, and fault (c) is located in the middle. The fault (d) is positioned 4 m from the slope; the last one is (e) 1 m from the slope.

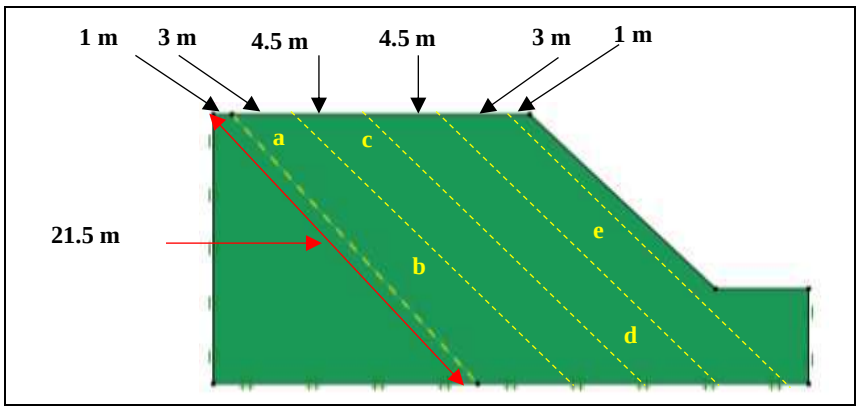

Figure 4: The location of parallel faults on the slope with a length of 21.5 m.
Source: Authors, (2026).

After carrying out the modeling processes, the following Table 2 summarizes the first case of the safety factor of the lower and upper methods.

Table 2: Factors of safety with different fault locations (length fault = 21.5 m).

Modeling Number	1 (a)	2 (b)	3 (c)	4 (d)	5 (e)
Upper FS	1.924	1.926	1.925	0.931	0.693
Lower FS	1.891	1.888	1.890	0.909	0.675

Source: Authors, (2026).

From the Table 2 and Figure 4, we notice that even though the fault is 21.5 m long, there is no effect on the slope's safety factor through the first three faults (a, b, and c). This is due to the distance of the faults from the slope. The factors of safety for these three modeling (a, b, and c) are all big and between 1.924 and 1.926 for the upper method, and the safety factor for the lower analysis is between 1.888 and 1.890.

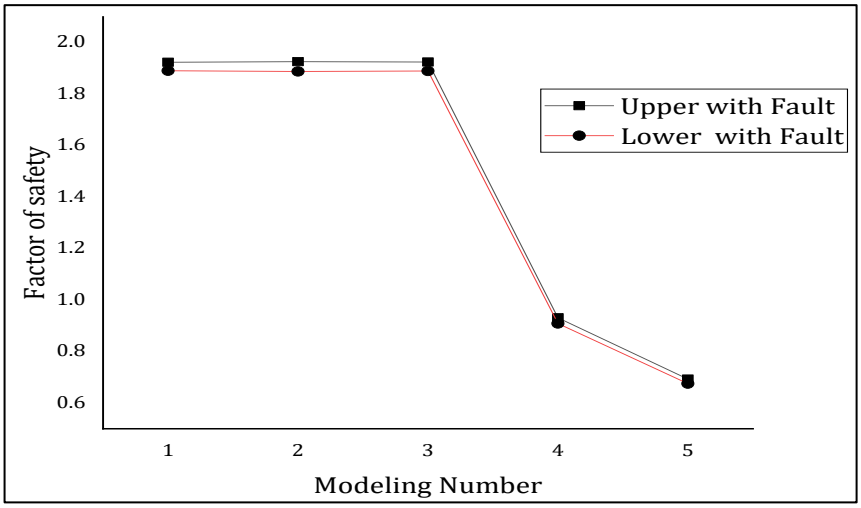

Figure 5: The safety factor of the upper and lower methods (length fault = 21.5 m).
Source: Authors, (2026).

For simulation d, it is in the range of 0.931 and 0.909, while for modeling e, it is the lowest one, with a safety factor between 0.693 and 0.675. In cases d and e, the slope is unstable because the factor of safety is less than 1.5 (see Figure 5).

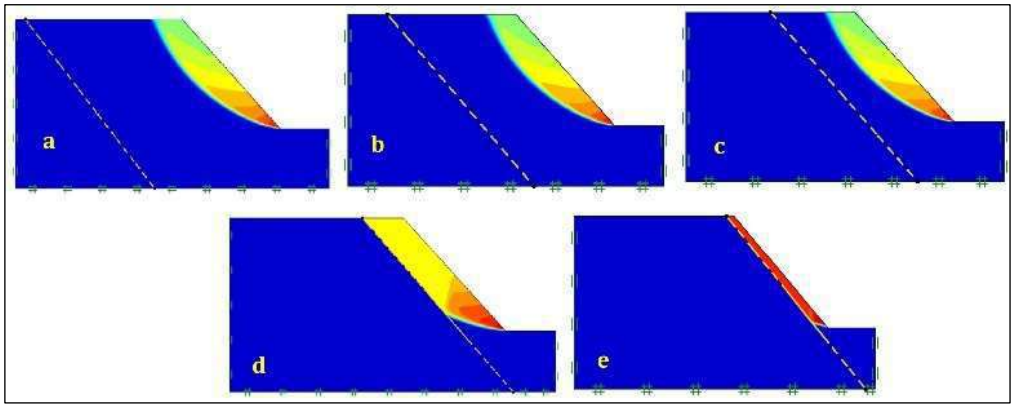

Figure 6: The slope surfaces with different location faults (length fault 21.5m).
Source: Authors, (2026).

As for the sliding surfaces, we can notice them in the following Figure 6. It shows the shape of the failure surface in the five simulations. What appears to be the case is that the faults present in (a, b, and c) do not affect the area of slip (circular slope surface), especially when compared to slip without fault. As for the faults (d and e), they affected the failure surface, the shape, and even the type of slip, the Figure 6 (d, and e) illustrate the infinite slides.

IV.1.2 Case 2: Length of the Faults 16.2 m

In the next (second) case, the fault decreases in length compared to the first case. Here, the length of the current fault is 16.2 m while maintaining the same location and the same inclination as in the first case. As shown in Figure 7, five faults are present in yellow. As usual, we study all faults individually, not all of them together.

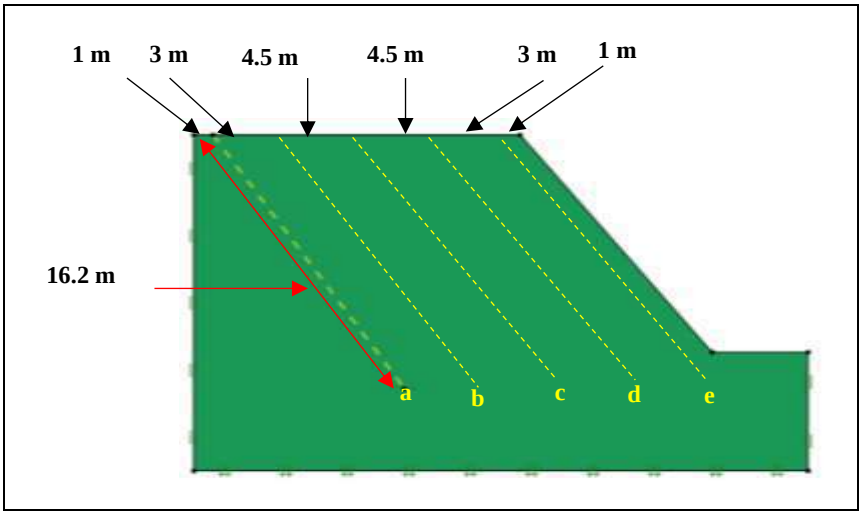

Figure 7: The location of parallel faults on the slope with a length of 16.2 m.
Source: Authors, (2026).

Table 3 summarizes the second case of the safety factors of the upper and lower methods with a fault of 16.2 m in length.

Table 3: Factors of safety with different fault locations (length fault = 16.2 m).

Modeling Number	1 (a)	2 (b)	3 (c)	4 (d)	5 (e)
Upper FS	1.924	1.926	1.925	0.931	0.693
Lower FS	1.891	1.888	1.890	0.909	0.675

Source: Authors, (2026).

From the Table 2 and Figure 4, we notice that even though the fault is 21.5 m long, there is no effect on the slope's safety factor through the first three faults (a, b, and c). This is due to the distance of the faults from the slope. The factors of safety for these three modeling (a, b, and c) are all big and between 1.924 and 1.926 for the upper method, and the safety factor for the lower analysis is between 1.888 and 1.890.

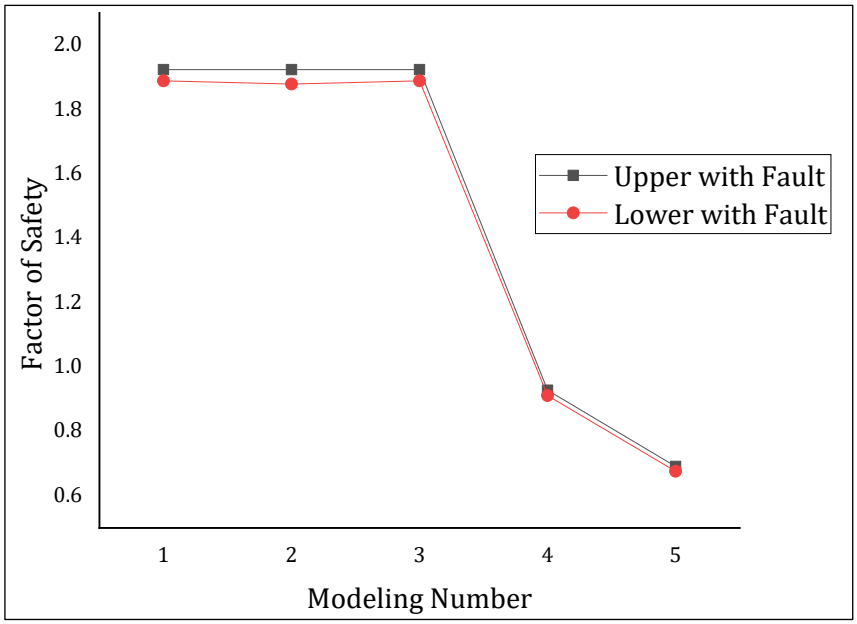

Figure 8: The safety factor of the upper and lower methods (length fault = 16.2 m).
Source: Authors, (2026).

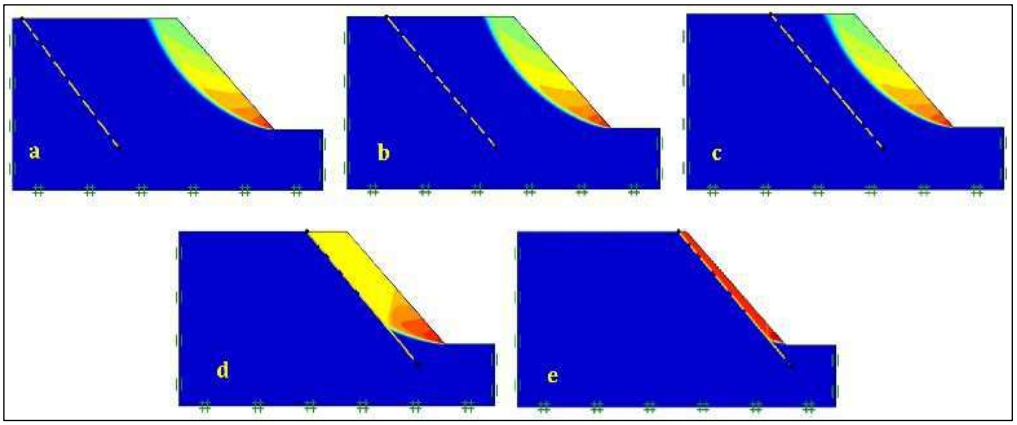

Figure 9: The slope surfaces with different location faults (length fault 16.2 m).
Source: Authors, (2026).

Figure 9 shows the extent to which the sliding area is affected by the fault. A new shape of sliding has appeared, which is plane sliding in Figure (e). The sliding is located along the slope due to the effect of the fault on the area of the sliding because it is very close to the slope (1 m). This sliding gave a safety factor of 0.691 for the upper analysis and 0.676 for the lower method. The second observation is that the fault that is 4 m away from the slope (simulation d) provides a low safety factor and explains that the slope is unstable. As for the other faults (a, b, and c), they are far from a slope and present big safety factors that indicate that the slope is stable, all of which are greater than 1.5. The failure surfaces are circular for the simulations (a, b, and c) see Figure 9.

IV.1.3 Case 3: Length of the Faults 11.2 m

In the third case, everything is the same; only in this simulation does the fault decrease in length compared to the previous examples. Here, the length of the fault is 11.2 m see Figure 10, while maintaining the same positions and places and the same inclination as in the first and second examples. Like previous studies, we study all faults alone and not all of them at once. As shown in Figure 10, as usual, faults are shown in yellow.

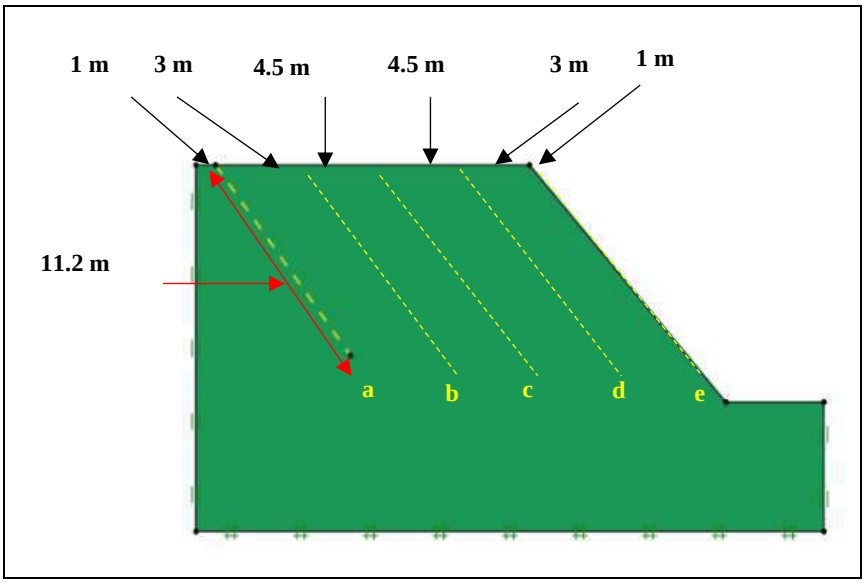

Figure 10: The location of parallel faults on the slope with a length of 11.2 m.
Source: Authors, (2026).

Table 4: Factors of safety with different fault locations (length fault = 11.2 m).

Modeling Number	1 (a)	2 (b)	3 (c)	4 (d)	5 (e)
Upper FS	1.924	1.923	1.924	0.947	0.810
Lower FS	1.889	1.889	1.889	0.920	0.792

Source: Authors, (2026).

Table 4 and the curve (Figure 11) allow us to see that for faults (a), (b), and (c), they are in a location far from the slope and do not affect the safety factor as observed in the curve (they are all bigger than 1.5). We also note that there is an effect of faults (d and e) on the safety factor. It is noted that the state of the slope was stable until the fault approached the slope. The closer we got, the stronger the effect became. The fault (d) was 4 m away from the slope; the safety factor here was 0.947 for the upper method and 0.920 for the lower method. When we got closer to the slope (1 m) example e, the slope began to provide the lowest safety factor. See the curve in Figure 10: FS is 0.792 for the lower analysis and 0.810 for the upper method.

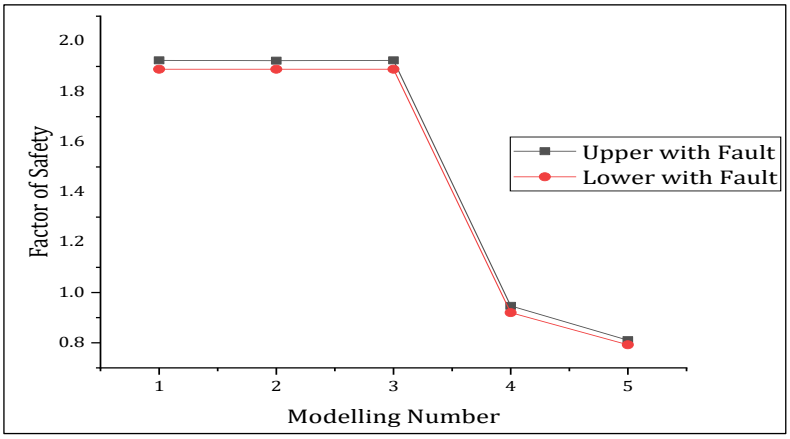

Figure 11: The safety factor of the upper and lower methods (length fault = 11.2 m).
Source: Authors, (2026).

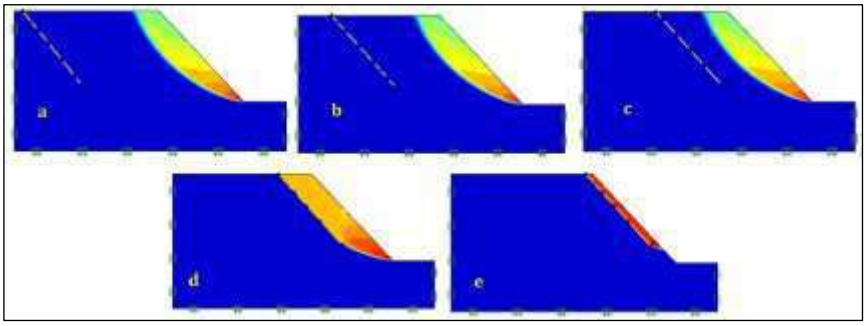

Figure 12: The slope surfaces with different location faults (length fault 11.2m).
Source: Authors, (2026).

Figure 12 shows the shape of the slip in the five models, which shows that the faults in (a, b, and c) do not affect the area of the slip. As for faults (d and e), they affected the area and shape of the slip. In the case of e, the area is small and exists between the slope and the fault, and the type of slip is plane. As for the case of (d), the fault is located in the line of the slip area; this fault controls the shape of the slip area. Both cases (e) and d present two unstable states for the slope, because the slope is affected by the proximity of the fault to the slope (1 and 4 m), and the length of this fault is 11.2 m. As for the other faults (a, b, and c), they are far from the slope and present a big factor of safety that indicates However, the slope is stable, all bigger than 1.5 (FS > 1.5).

IV.1.4 Case 4: Length of the Faults 7.5 m

In this fourth case, the length of the fault will be 7.5 m less than in the third case, while maintaining the same positions and locations and the same inclination as in the previous case. Like previous studies, we study all faults alone and not all of them at once. As shown in Figure 13.

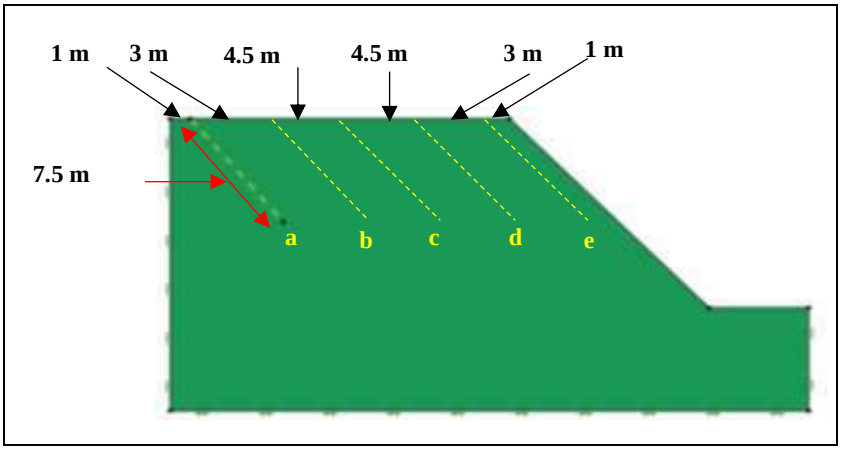

Figure 13: The slope with different location faults (length fault 7.5 m).
Source: Authors, (2026).

Table 5: Factors of safety with different fault locations (length fault = 7.5 m).

Modeling Number	1 (a)	2 (b)	3 (c)	4 (d)	5 (e)
Upper FS	1.922	1.923	1.924	1.207	1.192
Lower FS	1.889	1.890	1.888	1.238	1.231

Source: Authors, (2026).

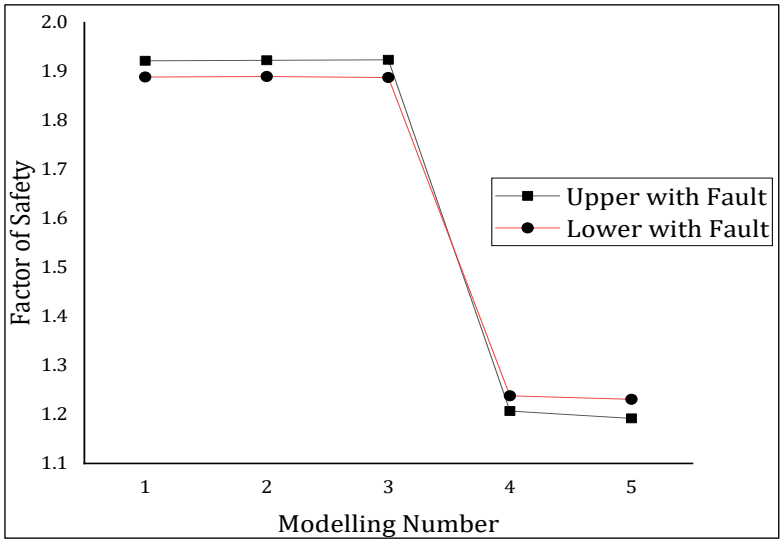

Figure 14: The safety factor of the upper and lower methods (length fault = 7.5 m).
Source: Authors, (2026).

As observed from table 5 and the curve in Figure 14, the safety factors e and d are the lowest in this case (04) due to their proximity to the slope, and both factors present a state of instability because the two factors are less than 1.5 (FS<1.5). We notice that these two cases, e and d for case (4), have a safety factor bigger than the safety factors of e and d for case (03), this is due to the effect of the fault length. All other cases (a, b, and c), present big factors of safety (greater than 1.5), and this indicates the stability of the slope and the lack of influence of the faults, due to their distance on the slope.

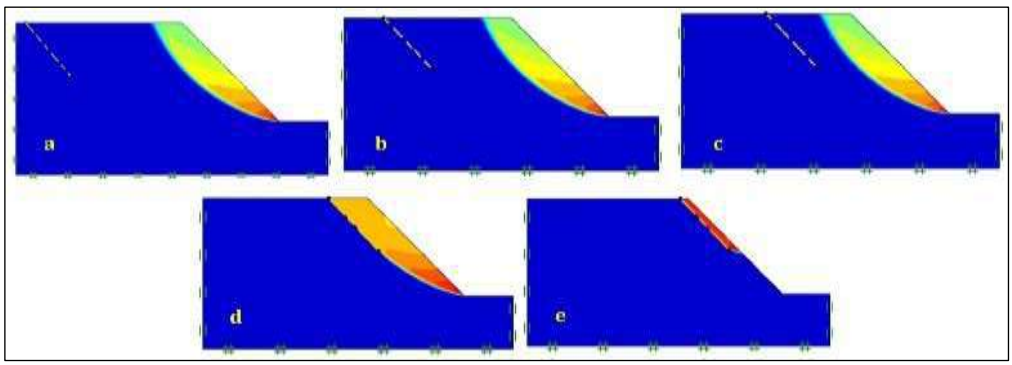

Figure 15: The slope surfaces with different location faults (length fault 7.5 m).
Source: Authors, (2026).

IV.1.5 Case 5: Length of the Faults 3.75 m

In the last simulations, the faults in case 5 have the shortest length in this paper. Here, the length of the fault is 3.75 m, while maintaining the same location and the same inclination as in the four previous cases. As shown in Figure 16, faults are present in yellow. As usual, we study all faults individually, not all of them together.

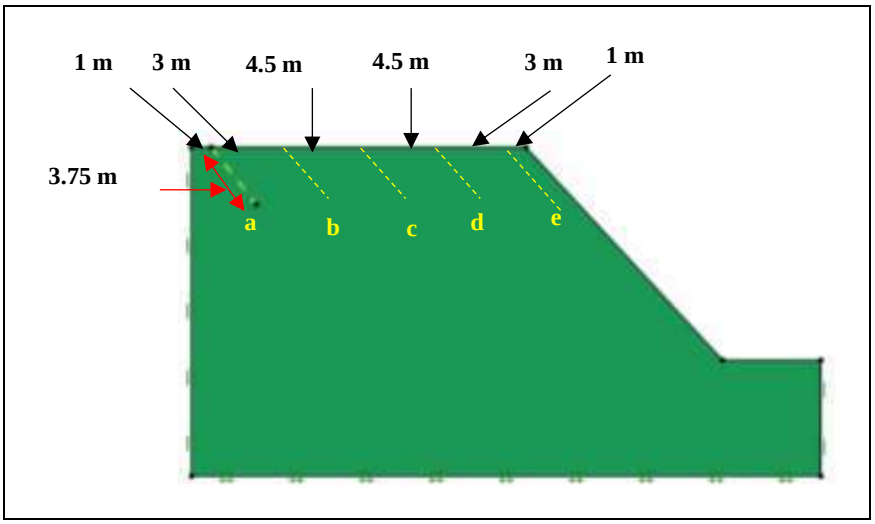

Figure 16: The slope with different location faults (length fault 3.75 m).
Source: Authors, (2026).

Table 6: Factors of safety with different fault locations (length fault = 3.75 m).

Modeling Number	1 (a)	2 (b)	3 (c)	4 (d)	5 (e)
Upper FS	1.923	1.923	1.923	1.632	1.924
Lower FS	1.889	1.889	1.890	1.588	1.890

Source: Authors, (2026).

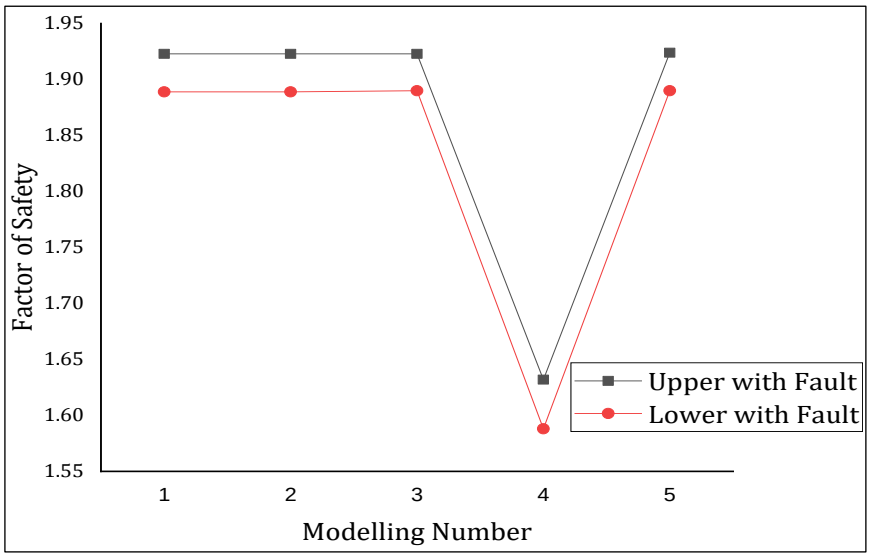

Figure 17: The safety factor of the upper and lower methods (lf = 3.75 m).
Source: Authors, (2026).

Table 6 and Figure 17 show the extent of the effect of the fault at a length of 3.75 m on the safety factor. It is noted that all faults have no effect, regardless of their location in the model, because the fault length is short (3.75 m) and does not affect the safety factor. However, the fault in case 4 (example d) has an effect estimated at 15.98 %, and this is because this fault is located in the line of the slip area. In addition, all safety factors are greater than 1.5, which confirms the stability of the slope and reinforces the observation that the length of the fault compared to the length of the slope does not affect it, regardless of its location.

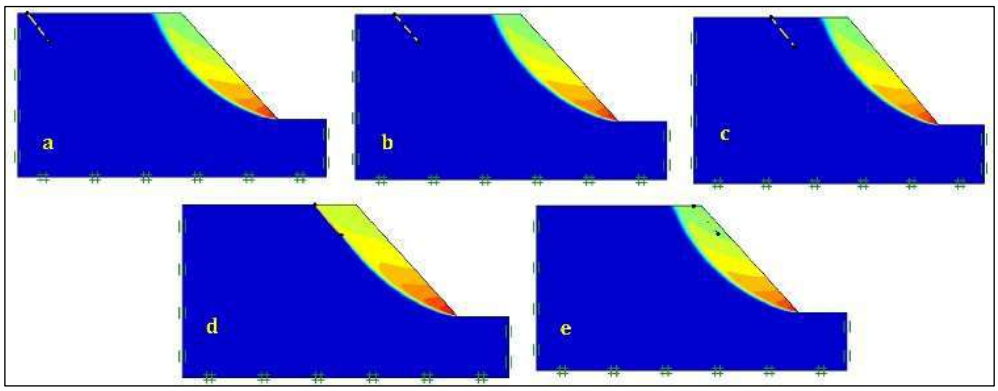

Figure 18: The slope surfaces with different location faults (length fault 3.75 m).
Source: Authors, (2026).

We notice that the fault is very short compared to the area of sliding, and no matter how close this fault is to the inclination, the area of sliding remains the same in all faults. See Figure 18 from (a), to (e). However, the slip area in Figure 18 (d) has a specific shape due to the effect of the fault because it is sliding completely at the line of the surface slope, which affects the shape of the slip. Finally, we notice that the fault exists inside the slip area and has no effect on the shape or the slope surface (circular failure surfaces).

V. CONCLUSIONS

Slopes can slide due to a variety of factors, including static or dynamic loads, earthquakes, erosion, material's mechanical qualities (rock or soil), and the faults, or cracks (shear joints), etc. In this research, the 2D upper and lower limit analysis method was used by the OptumG2 software to model the slope stability with the effect of faults (shear joints). This work aims to comprehend the effects of faults on safety factor, slope surfaces, and instability. The aim of this paper is to understand how the instability, factors of safety, and slope surfaces are affected by the faults. These shear joints (faults) are used in five locations on the slope, with the length (depth) of these faults changing. This is for an in-depth discussion of how various cracks affect the slope. Our simulations indicate that the slope is stable, with a safety factor generated without a shear joint of 1.923. Conversely, the fault's length of 21.5 m and its close proximity to the slope (1 m) contributed to the lowest factor of safety in this research (0.675). The effect of this fault was 64.90% in destabilizing this slope. It is observed that the safety factor and slope stability remain unaffected by tiny or distant cracks from the slope.

Except for the presence of a small crack at the line of the sliding surface (case 5, fault (d)), it affects the safety factor, making it lower, in addition to the form of the slope failure changes. As for the slope sliding surface, it is affected if the fault is close to the slope and changes from a circular failure to a plan or infinite slide surface. The slip area is affected by the length and shortness of the fault. The crack also affects the strength reduction method. In conclusion, while planning and developing civil engineering projects, such as slopes, the influence of faults must be taken into account. This stems from the significance of these imperfections to geotechnical engineers, as they present hazards to both the slopes and the property and inhabitants within the area.

ABSTRACT

The world is moving towards renewable energy source to be the major source to meet the increasing electricity demand and wind energy is one of the suitable sustainable energy sources. This brings the need to integrate large-scale wind farms with the existing power grids. Doubly fed induction generator (DFIG) are most preferred wind turbine generators with benefits like high efficiency and flexible power. However, DFIG is sensitive to grid disturbances and so traditional relaying protection techniques are not applicable. DFIG are integrated to the power grid with transmission line. Using UPFC compensated transmission lines increases the complexity further. The grid side current signals are extracted using Variable Mode Decomposition (VMD) method. These results in grayscale images which are then are used in convolutional neural network (CNN) classifier for fault classification. The simulation is done using 2021 version MATLAB simulink with 1300 fault data. There are a total of 10 cases of fault. The performance of the deployed CNN classifier is assessed with accuracy being 97.95 % for CNN.

I. INTRODUCTION

The most commonly used wind turbine generator is doubly fed induction generator. DFIG is integrated with the power grid with transmission lines. DFIG despite its benefits like high efficiency and flexible power, it's susceptible to the grid disturbances. In order to transmit wind power generated in large scale to long distance, compensated transmission line is the most plausible option with the use of FACT devices [1],[2]. The FACT devices used frequently nowadays are UPFC as it has the ability for controlling active, reactive power capacity flow independently. When in comparison to the conventional synchronous machine, the DFIG due to its LVRT capability gives rise to certain fault nature [3]. Use of the UPFC adds to the rapid change in the impedance of the line [4]. So, the traditional Transmission Line protection techniques that are based on relay are not applicable to DFIG wind farm, that's connected to the UPFC compensated Transmission Line. In [5], discusses a novel 3 zone protection scheme. Here the zone 2 and zone 3 are not altered but zone 1 is altered from the conventional in order to not let the UPFC's impact affect the line for the separation of external and internal faults and uses line voltage.

The issues related to differential relay when applied in a DFIG wind farm and the added characteristic of DFIG during fault because of its response being fast is described in [6] and devices a solution to rectify this behavior which proves to be effective. However, the effect of DFIG on the fault detecting relaying scheme is not considered in this work. DFIG wind turbine generators are implemented with crowbar circuit to detect the LVRT at times of fault [7] and the method improved for the superimposed components-based distance protection gives sensitivity and proves to be reliable. A signal with the difference between two zero crossings and the local extreme numbers as one is known as a mode. VMD has been in used in several works such as in [8], analyzing the voltage flicker that varies with time which could be one of the often-addressed problems in power system. Modes numbered in several numbers decomposing the actual signal and help to make it into a constrained problem with variation and also introducing suitable Lagrange multiplier and quadratic term to generate an unconstrained problem as well.

In [9], CNN is been customized for fault classification in systems with distributed generators, which is a major task in relaying system and in order to clear the fault, it has to be done in a minimum amount of time. Here CNN has been applied to detect fault with voltage, current data (three-phase) which is just sampled and raw. And this method has been proved to be of better performance in comparison with traditional approaches. In [10], it paves way to a new self-attention CNN model that is used in transmission line fault to detect and classify faults. These faults are due to the system instability and might cause load damage. The noise elimination in the measured signals is carried out with the help of discrete wavelet transform. This proposed scheme results with high accuracy ensuring it as being a reliable method.The combination of VMD and CNN can be found effective to determine faults in machine that are rotating in nature. In [11-14], the diagnosis of fault, the optimized number of modes is determined. Analysis of the signal decomposed is analyzed by correlation and the reconstruction of the original signal is done by the selected components that are correlated highly. The 2-D desired features are mapped from the fault signal with the use of continuous Wavelet Transform. Next, in order to determine the desired fault features the 2-D images are deployed.

I.1 METHODOLOGY USED

The work flow is as below

- The DFIG wind farm connected to grid with the transmission line compensated with UPFC is simulated from 2021 version MATLAB simulink.
- The current data, voltage data and time data are extracted from the simulation with the voltage, current measurement devices connected at the grid side. The data extracted by creating 10 different fault cases as in Table 1.
- The extracted data is deployed with Variable Mode Decomposition to obtain the desirable features. Wiener filter is used so as to eliminate any noise present in the data and grey-scale as well as color images were generated.
- The grey-scale and color images have been fed for input in the CNN classifier and 1300 images are used for the training and testing.

Table 1: Fault Classes.

Fault Type	Fault
Single Line to Ground	AG, BG, CG
Line to Line	AB, BC, CA
Double Line to Ground	ABG,BCG,CAG
Line-Line-Line	ABC

II. PROBLEM STATEMENT

The schematic model used in the current system is depicted in Figure 1. The system comprises a DFIG wind farm of capacity 9MW with six DFIG-WTG search of 1.5 MW capacities and are linked to a 25-kV distribution system that will export power to a grid (120-kV) via a 25-kV collector line. It is a 2-bus system with relays and breakers, one of each present on the wind side and the other on the grid side.

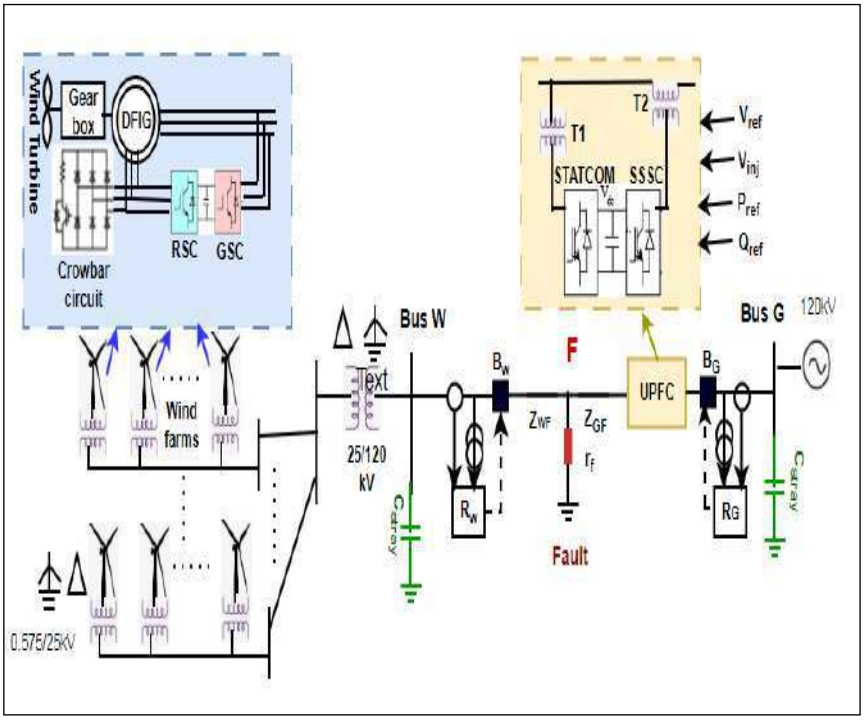

Figure 1: Schematic illustration of the DFIG - wind farm with UPFC-CTL.
Source: Authors, (2026).

The UPFC unit could be operated in four differing modes as:

1. Voltage Control Mode (VCM).
2. Voltage Injection Mode (VIM).
3. Power Flow Control Mode (PFM).
4. VAR Control Mode (VARCM).

The current, voltage and impedances of the wind side and grid side are denoted as E_{WT}, E_G, I_W, I_G and Z_W, Z_G, respectively. The impedances of the STATCOM and SSSC are represented by ZSTAT and ZSSSC respectively. The current injected or absorbed by the STATCOM is I_{STAT}. The impedances of transmission Line are denoted as Z_{TL}. The V_W and V_G are the voltages at Bus-W and Bus-G respectively. The superscripts 'pre' and 'post' denotes parameters subjected to pre-fault and post fault respectively. At location x per unit a fault with a resistance of R_F value created from the Bus-W and fault current passes through it is I_f. By using Kirchoff's current law in Figure 2(b),

$$\Delta I_W = \frac{Z_{GU}+(1-x)Z_{TL}}{Z_{GU}+Z_{TL}+Z_w^{pf}} I_f \tag{1}$$

$$I_G = \frac{Z_w^{pf}+xZ_{TL}}{Z_{GU}+Z_{TL}+Z_w^{pf}} I_f \tag{2}$$

$$I_f = I_w^f + I_{SH}^f + I_G^f \tag{3}$$

$$\Delta I_w = I_f^w - I_w^{pre} \tag{4}$$

Equating (1) with (4),

$$\frac{Z_{GU}+(1-x)Z_{TL}}{Z_{GU}+Z_{TL}+Z_w^{pf}} I_f = I_w^f - I_w^{pre} \tag{5}$$

On substituting equation (3) in (5),

$$\frac{Z_{GU}+(1-x)Z_{TL}}{Z_{GU}+Z_{TL}+Z_w^{pf}} \left(I_w^f + I_{STAT} + I_G^f\right) = I_w^f - I_w^{pre} \tag{6}$$

On rearranging the equation,

$$Z_w^{pf} = \frac{(Z_{GU}+Z_{TL}(1-x))(I_{SH}+I_G^F)+(Z_{GU}+Z_{TL})(I_W^{pre})-Z_{TL}xI_w^f}{I_w^f-I_w^{pre}} \tag{7}$$

$$\Delta I_G = I_G^f - I_G^{pre} \tag{8}$$

Equating (2) & (8) and I_f from equation (3)

$$\frac{Z_w^{pf}+xZ_{TL}}{Z_{GU}+Z_{TL}+Z_w^{pf}} I_F = I_G^f - I_G^{pre} \tag{9}$$

$$\frac{\left(Z_w^{pf}+xZ_{TL}\right)}{(Z_{GU}+Z_{TL}+Z_w^{pf}} \left(I_w^f + I_{STAT}^f + I_G^f\right) = \left(I_G^f - I_G^{pre}\right) \tag{10}$$

$$Z_{GU} = \frac{\left[\left(Z_w^{pf}+xZ_{TL}\right)\left(I_w^f+I_{STAT}^f+I_G^f\right)\right]-\left[\left(Z_{TL}+Z_w^{pf}\right)\left(I_G^f-I_G^{pre}\right)\right]}{(I_G^f-I_G^{pre})} \tag{11}$$

We know that,

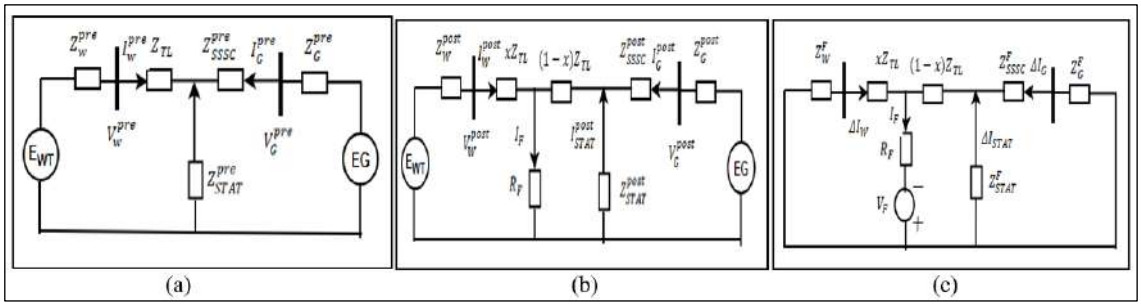
$$Z_{GU} = \frac{(Z_{SSSC}^{pf}+Z_G^{pf})Z_{STAT}^{pf}}{Z_{SSSC}^{pf}+Z_G^{pf}+Z_{STAT}^{pf}} \tag{12}$$

Substituting equation (12) in (11), equation (13) is obtained,

$$Z_G^{pf} = \frac{Z_{STAT}^{pf}Z_{STAT}^{pf}-Z_{GU}(Z_{SSSC}^{pf}+Z_{STAT}^{pf})}{Z_{GU}-Z_{STAT}^{pf}} \tag{13}$$

Substituting Z_w^{pf} in Z_G^{pf} we get,

$$Z_G^{pf} = \frac{\left(Z_{STAT}^{pf}+Z_{SSSC}^{pf}\right)\left[\left(Z_w^{pf}+xZ_{TL}\right)\left(I_G^f+I_{STAT}^f\right)I_w^{pre}-(1-x)Z_{TL}I_G^f\right]-Z_{SSSC}^{pf}Z_{STAT}^{pf}\left(I_G^f+I_G^{pre}\right)}{[Z_{STAT}^{pf}+(1-x)Z_{TL}]I_G^f-(Z_{STAT}^{pf}+Z_{TL}+Z_w^{pf})I_G^{pre}-(Z_w^{pf}+xZ_{TL})(I_w^f-I_{STAT}^f)} \tag{14}$$



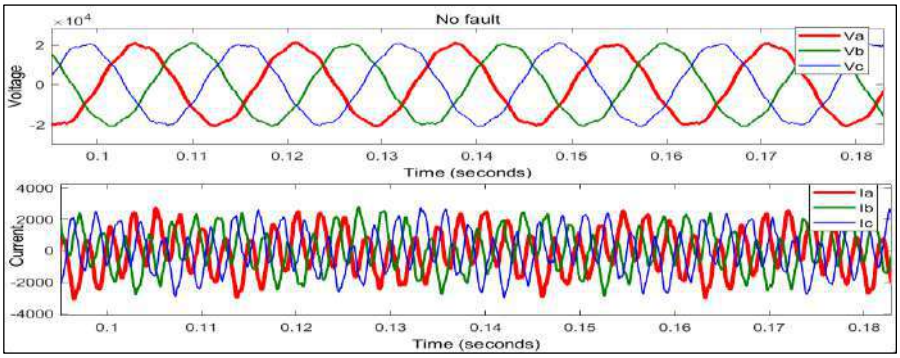


Figure 2: (a) Equivalent circuit a) pre fault b) post fault c) During fault.
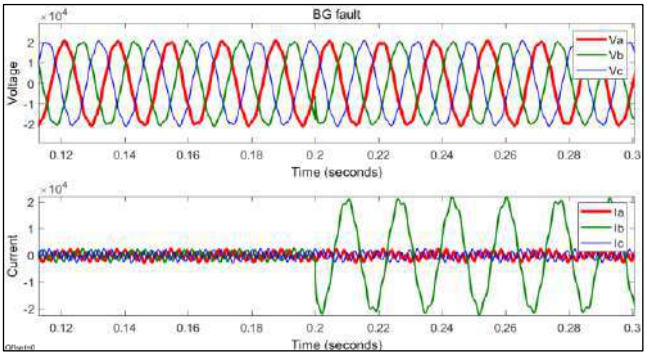
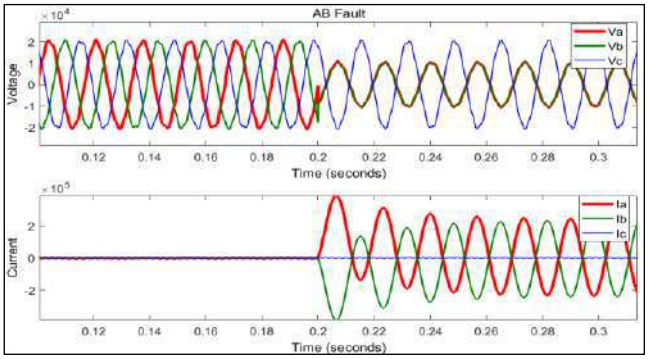
Source: Authors, (2026).



For a symmetrical fault the post fault impedances as from Equation (7) and (14), are influenced by the impedances of both UPFC and the DFIG-based wind farm.

II.1 DATA EXTRACTION AND PREPARATION



Using 2021 version MATLAB simulink model, the fault data are extracted and to understand the fault occurrence frequency, the waveforms are produced. The waveform displayed in Figure 3(a) showed is the standard sinusoidal voltage and current waveform. The graphs in Figure 3(b) to 3(e) show the waveforms that validate the existence of a fault in the system. The fault current and voltage data for different time were produced for deep-learning and its training to classify and find the point of faults in transmission line.

(c)

(d)

(e)

Figure 3: (a) Three phase in the absence of faults (b) B-G fault (c) A-B fault (d) A-B-G fault (e) A-B-C fault.
Source: Authors, (2026).

In Figure 3, five distinct scenarios of the system are shown namely, absence of faults, single-phase-to-ground fault, line-line fault, double-line-to-ground fault, and three-phase fault. V_a, V_b, V_c, and I_a, I_b, I_c represent the phase voltage and current respectively of each phase.

1. In the no-fault state, the waveform maintains sinusoidal integrity, free from any distortion caused by noise or faults as depicted in Figure 3(a).
2. In Figure 3b) to 3(e), the voltage and current of phases are distorted with fault presence in the line and the waveforms depicts a distortion because of presence of these faults.

- Figure 3(b) represents BG fault which is of SLG fault type, here the voltage profile and I_b are unaffected while I_a and I_c are reduced.
- The next Figure 3(c) depicts AB fault which is of Line-Line fault type and here I_a and I_b are not affected while I_c becomes zero. Also, V_a and V_b are reduced and are in phase while V_c remains unaffected.
- From Figure 3(d), it can be seen that in the presence of DLG fault (ABG), the current in the healthy phase C becomes zero while its voltage profile remains unaltered. And magnitude of V_a and V_b are reduced while the current of the faulty phase remain unchanged.
- Figure 3(e) displays a three-phase fault and the voltage, current waveform of all the three phases V_a, V_b, V_c, and I_a, I_b, and I_c are distorted after the fault was introduced.

III. PROTECTION SCHEME

The wind side fault current has more complexities in comparison to the grid side [15]. Therefore, in order to overcome the complexities, grid side currents are used by the relaying protection approach to identify and categorize faults in the UPFC compensated transmission lines. The flowchart for the entire process is given in Figure 4 and accuracy calculated using Figure 5. When the occurrence of fault is identified, then via the power line communication carrier (PLCC), a trip signal travels towards the relay in the wind side. The PLCC faces with a communication delay of 5ms [15], however, fault current on the wind side is only 1.2 p.u., effectiveness of the relaying approach remains unaffected. There are two steps involved in the detection and classification of faults. First, the spectral energy ratio for the mode components of the grid side current is retrieved using VMD at a sampling frequency of 4 kHz. This could be applied to differentiate between defects that are internal and external. In the next stage, once the internal fault is detected, a combination of VMD and CNN Classifier is used for the classification of the faults.

IV. RESULTS AND DISCUSSIONS

Using MATLAB simulink, 1300 failure instances are created from IMFs to show the efficiency of the suggested relaying model by altering the system characteristics. The data were extracted at a sample frequency of 4 kHz for a 50 Hz power system. An 12th generation Intel Core i5 laptop with 16 GB RAM was used for current study.

IV.1 RESULTS OF VMD AND WIENER FILTER

In Figure 6, the extracted IMFs after decomposition are shown and the number of modes taken is 6. The signal is decomposed into six intrinsic mode functions. It can be seen that the extracted functions contain noise. The extracted IMFs are then filtered using Wiener Filter in order to eliminate the noise and the resulting filtered current signal is shown in Figure 7, which is Current and Time plot.

IV.2 RESULTS OF VMD FOR CNN CLASSIFIER

VMD is used to produce the spectrogram of time frequency distribution for each of ten fault cases. Figure 8(a) shows the spectrogram of time frequency distribution for AG fault. From the Figure 8(a), it can be observed that the spectrogram of signal for A phase differs from that of the B and C phases due to the presence of AG Fault. From this it can be speculated that in case the fault that occurred is BG fault, then B phase differs from that of the A and C phases and according changes could be seen for each fault type. The data obtained from VMD are used in the generation of gray-scale images as in Figure 8(b) for each of the 10 different types of faults. These generated images are fed in to CNN classifier as input.

IV.3 RESULTS OF CNN CLASSIFIER

Totally 1300 preprocessed gray-scale image data were used. Out of this 70% of the data, which are 910 images were used to train and the remaining 30% of the image data were used for testing. Maximum iterations are 420 with 60 epoch being carried out to train the data and 7 iterations per epoch. The elapsed time for running is 28 minutes 16 seconds. The performance curve of the CNN Classifier is shown in Figure 9(a) and Figure 10(a), it can be seen that by the end of the 60th epoch the curve gets saturated. Figure 9(b) and Figure 10(b) shows the confusion matrix generated by the CNN classifier for the relaying protection scheme used. From Figure 9 and 10, it can be seen that most of the faults have been correctly classified except for a few outliers due to misclassification. The validation accuracy of the CNN classifier for Gray scale and color image are 88% and 97.95%.

V. CONCLUSIONS

The protection system for grid connected DFIG based wind farm with UPFC-CTL was implemented with the combination of VMD-CNN is an intelligent method for identifying and categorizing transmission line defects. The MATLAB simulink model is simulated with the wind farm that consists of nine DFIG-WTGs. The system is used to detect and classify internal faults that could be both symmetrical and unsymmetrical faults using the grid side currents to reduce the complexity. The CNN classifier uses 70% and 30% of the 1300 processed images that are gray-scale in nature for training and testing respectively. From the performance curve, the accuracy obtained is 97.95% and proves to be better than most of the other existing approaches.

ABSTRACT

The paper talks about microservice architecture. This kind of design splits a big application into small services. Each service works on its own. These services are able tobe placed on different servers. This makes systems more flexible and scalable.Most past works only focus on reducing delay. But delay is not the only concern. Power use is important. High power use leads to high cost and poor sustainability. So, this paper looks at both delay and power together.A new system termed GIRP was proposed. GIRP stands for Green and Intelligent Resource Provisioning. It tries to manage both delay and power. It does this by controlling CPU usage and service copies. These are placed on servers smartly.To make good decisions, GIRP uses a special learning method. This method is titled as Deep Reinforcement Learning. It learns by trying different actions. It sees what works best. Then it learns from that. In this work, a multi-Task learning model is used. It decides two things at the same time: the number of CPU cores to use and the number of service replicas to create. This helps in managing resources well. Another part of the system handles placement for each service. GIRP is tested using a popular benchmark.The results are strong. This proves GIRP works well.This paper shows a smart way to manage microservices. It saves power and meets user delay needs. The learning model makes better choices over time.

I. INTRODUCTION

Microservice architecture has become very popular in recent years [1]. It helps developers create and manage large applications. In this method, each part of the system is built as a small and separate service. These services work independently. Each microservice is responsible for a single task or feature [2]. These services communicate using standard protocols like RPC (Remote Procedure Call). This makes the system more flexible. It improves the scalability and performance of applications.One key advantage of microservices is the ability to scale easily [3]. When there is a high number of user requests, only the needed services are scaled. This is better than scaling the whole application as in monolithic systems. It saves resources and makes updates faster.Microservices are deployed in containers or virtual machines [4]. Each service has its own CPU, memory and other resource limits. Microservices bring new challenges. Managing so many small services is not easy [5]. It needs smart techniques to handle resource allocation and service scheduling. These decisions affect both performance and power usage.Many previous works focused only on reducing delay or latency. The purpose is to make sure the application responds quickly to users, but power consumption is usually ignored. Using too many servers or resources waste energy. Today, power efficiency is very important [6]. Data centers consume a lot of energy. Reducing energy use helps the environment and saves money. So, both delay and energy use should be considered together.This paper focuses on both objectives.

It wants to reduce end-to-end delay and power consumption together. This is not easy. There are many challenges in this system. Delay and power work against each other [7]. Reducing delay uses more power. Saving power causes more delay. Decisions are discrete and hard to optimize. The effect of each action is unclear. Modeling the system is not easy [8].GIRP system uses data to make smart decisions. It adjusts resource allocation and service placement in real time.GIRP tries to find a good balance between delay and power [9]. It uses deep reinforcement learning (DRL) to learn the best actions. DRL allows the system to improve over time. It does not need a perfect model of the system.In GIRP, there are two parts to decision making [10]. One part selects the number of CPU cores and service replicas to use. The other part decides the placement ofeach service on the servers.A multi-task learning model uses a structure named Multi-gate Mixture-of-Experts (MMoE). This helps it learn two tasks at the same time. It decides both the CPU and replica numbers together [11]. For the second part, another learning agent is used. It learns the best way to distribute services across servers.The system is tested using a named benchmark,DeathStarBench. It includes two applications: Hotel Reservation and Social Network. These are made of many microservices. These are good test cases for evaluating real systems.The key contributions of this paper are:

- Develop a system that addresses both latency reduction and energy efficiency, unlike existing methods that focus on only one aspect.
- Design the GIRP framework as a real-time end-to-end solution, including components for data collection, performance analysis, intelligent decision-making and automated deployment, with the ability to adapt to changing workloads.
- Implement a multi-task learning strategy using a Multi-gate Mixture-of-Experts (MMoE) model to optimize CPU and replica allocation simultaneously, reducing training cost and increasing accuracy.
- Apply Deep Reinforcement Learning (DRL) to drive system actions, allowing continuous improvement through learning and exploration without relying on fixed rules, validated on real microservice workloads.
- Confirm scalability of the GIRP architecture to support applications of various sizes and complexity, across different server configurations and microservice setups.
- Enable balanced decision-making by evaluating multiple factors for example resource load, user demand and energy constraints to maintain efficient and reliable service delivery.

Microservices are very useful [12]. These test cases are hard to manage well.Systems are needed that adjust resources smartly. These systems should balance delay and power use [13] .This paper presents GIRP. It is a new system that solves these challenges using deep learning. It learns from data. It makes good decisions about resources and service placement [14]. It saves energy and keeps users happy.The key approach is to treat resource control as a learning problem. With the help of reinforcement learning and multi-task learning, GIRP learns to manage resources better over time [15]. This helps modern systems become more efficient and sustainable.

II. RELATED WORK

These past research works focus on microservice scheduling and resource allocation. Many researchers studied delay and energy use in such systems. But most of them focused on only one part — either reducing delay or saving energy.Some studies used cloud platforms like AWS. For example, in [16] a tool was created that adjusts CPU cores and service replicas. It uses system usage to scale resources. This helps reduce delay and avoids using too much hardware. In another work, Sinan [17] used a multi-armed bandit method. This helps in choosing resource levels based on changing user requests. It works well under dynamic loads. It does not look at service deployment strategies or full system energy. Firm [18] used reinforcement learning. It tries to reduce delay caused by CPU, memory and network problems. It changes CPU cores during run-time. It increases or decreases service replicas based on core needs. But it does not plan for server-level placement.Other approaches used single-task learning models. Each model handles one task, like deciding CPU or replicas [19]. This leads to extra work and training time. These models cannot share knowledge between tasks. So, such approaches are not suitable for complex systems. Traditional systems used rule-based or static policies. These methods cannot handle changing traffic patterns. The approaches are simple but lack intelligence and fail under dynamic user loads [20], [21]. In recent years, many researchers suggested deep reinforcement learning (DRL) methods. These methods learn from system data. For example, in [22] DRL is used to reduce delay by making smart resource choices.Other studies tried to save energy in data centers. Green computing is now a key concern. Some works reduce the number of active servers. Others try to balance the load better [23], [24]. Few studies attempted to address both objectives at the same time. A few of them use optimization frameworks. But these need accurate system models.

The GIRP framework tries to solve these problems together. It uses multi-task learning and DRL. It manages CPU, replicas and service placement. It learns from past data. It adjusts to user load and resource usage. It saves power and meets delay needs.A model namedMMoE was used [25]. It is good at handling many tasks together. It allows sharing of knowledge. This makes training faster and more accurate. It avoids repeating the same work.Some works used MMoE in other fields. For example, [26] applied it in advertising. It helped to improve predictions in different user groups. But GIRP is the first to use it for microservice resource control. Most past studies focus on only part of the problem. These approaches do not manage CPU, replicas and placement together. In many cases, power is ignored.The GIRP framework tries to fill this gap.

III. SYSTEM MODELLING & PROBLEM FORMULATION

This section explains the way the GIRP framework models the system and defines the problem. The purpose is to make microservices run efficiently by managing resources wisely. GIRP tries to reduce both the delay experienced by users and the power consumed by servers. To do this, it creates a mathematical model of the system. First, the model considers a fixed service period. This period is namedas T_0 and is divided into equal time intervals. Each time interval is denoted as δ. During each time step s, two things are measured: the end-to-end service latency q_s and the total power usage E_s. The latency is recorded in milliseconds, while the power is measured in joules. The model defines a target latency value Q_0. If the observed latency q_s goes above Q_0, the quality of service (QoS) is violated. There are M microservices and N servers in the system. Each microservice is placed on exactly one server. This placement is modeled using a binary variable $z_{i,j}$. If service i is placed on server j, then $z_{i,j} = 1$; otherwise, it is 0. This constraint is written as:

$$\sum_{j \epsilon N} z_{i,j} = 1, \qquad i \epsilon M \tag{1}$$

Each microservice gets some CPU cores and replicated multiple times. If a service is placed on a server, then the system decides the number of CPU cores $x_{i,j}$ to assign and the number of replicas $y_{i,j}$ to create. The delay for running service i on server j is represented by a function $f(x_{i,j}, y_{i,j})$. This function captures the effect of CPU and replicas on latency.The total latency of the system is calculated by summing the delays from all services on all servers. The equation for total latency q is:

$$q = \sum_{j \in N} \sum_{i \in M} z_{i,j}\, f(x_{i,j}, y_{i,j}) \tag{2}$$

Power consumption is calculated in a similar way. The function $g(x_{i,j}, y_{i,j})$ represents the CPU usage of service i on server j. Using this function, compute the total CPU load μ_j^{CPU} on server j as:

$$\mu_j^{CPU} = \sum_{i \in M} z_{i,j}\, g(x_{i,j}, y_{i,j}) \tag{3}$$

Then, use μ_j^{CPU} to find the power usage E_j for each server. This is calculated as:

$$E_j = (\mu_j^{CPU} + \xi)\, P_j^R\, \delta \tag{4}$$

In this formula, P_j^R is the rated power of server j and ξ is a constant that represents the operating system's power usage. The time interval δ is the same as defined earlier.The purpose of GIRP is to reduce both latency and power use. To do this, it makes decisions about three things: CPU allocation x, replica allocation y and service placement z. These are grouped into three decision matrices: $x = \{x_{i,j}\}$, $y = \{y_{i,j}\}$ and $z = \{z_{i,j}\}$.The main problem is written as a multi-objective optimization. The system chooses x, y and z to minimize both total latency and total power consumption. This problem is formally defined as:

$$(P1) \quad \min_{x,y,z} \left\{ \sum_{j \in N} E_j, \quad q \right\} \tag{5}$$

This optimization is subject to several constraints. First, CPU and replica allocations are limited to a certain maximum value. CPU cores $x_{i,j}$ are set as integers between 1 and C_{max}. Replicas $y_{i,j}$ are chosenbetween 1 and R_{max}. The placement $z_{i,j}$ is binary (0 or 1) and each service is placed on one and only one server. These conditions are written as:

$$x_{i,j} \epsilon \{1,2,3, \ldots, C_{max}\}, \forall\, i, j \tag{6}$$

$$y_{i,j} \in \{1,2,...,R_{max}\}, \quad \forall i,j \tag{7}$$

$$z_{i,j} \in \{0,1\}, \quad \forall i,j \tag{8}$$

$$\sum_{j \in N} z_{i,j} = 1, \quad \forall i \tag{9}$$

This is a difficult problem to solve. All decision variables are discrete. The exact forms of the functions f and g are not available. Another difficulty is that power and latency opposes each other. Reducing one makes the other worse. For example, adding more replicas lowers latency but increase power consumption.Traditional rule-based systems are not good at handling these trade-offs. Such approaches are usually static and cannot respond well to changing workloads. Therefore, this paper uses DRL. DRL learn from experience. It does not need an exact model of the system. Instead, it interacts with the environment and improves over time.GIRP divides the problem into two parts. The first part is about resource allocation, which includes vertical scaling and horizontal scaling (replicas). The second part is about service placement. To solve these parts, GIRP uses two separate learning agents.The first agent is titledas RA agent. It handles CPU and replica allocation. The RA agent uses a learning structure termedMMoE.

This model allows the system to learn two tasks at the same time. It has shared layers to learn common knowledge and expert layers for task-specific knowledge. This setup helps reduce the training time and increases performance.The second agent is named as the SA agent. The SA agent focuses on a single task and learns placement strategies that optimize both power and latency.By using these two agents, GIRP handles the whole problem in a smart and dynamic way. The system keeps learning from data. It adjusts its resource usage and service placement based on real-time feedback.This modeling approach is very useful. It allows the system to understand the impact of its actions on both delay and energy. This helps it make better decisions that balance user needs with energy efficiency. This section presents a formal model for resource provisioning. It includes key equations for latency and power. It outlines the system's constraints. Finally, it describes the way the GIRP framework solves the problem through multi-agent deep reinforcement learning.The combined modeling and learning approach helps GIRP deliver good quality of service while using less energy.

IV. SYSTEM DESIGN OF GIRP FRAMEWORK

GIRP is designed to manage microservices in a smart and efficient way. The purpose is to reduce power usage while keeping delays low. This is important for real-world systems with changing workloads.The design of GIRP is based on four main principles. The first focus is latency minimization. GIRP is designed to reduce the end-to-end delay in serving user requests. It targets meeting the 99th percentile latency under all system loads. The second focus is energy efficiency, using less energy while still maintaining the quality of service. The third focus is integration, linking vertical scaling, horizontal scaling, and service scheduling. These components influence one another. The final focus is adaptiveness. The system adapts to load changes and user demands in real time.The GIRP framework has five major components. These include a real-time data collector.An online service profiler is used.There is an energy-latency-aware resource allocation and scheduling manager.A resource coordinator is included.The system has a deployment module.These components work together during each service cycle. Each service cycle is termed as T_0. During T_0, the framework checks if the current resource settings meet the latency objective. If everything is fine it continues with the same setup.

But if no problems are seen for a few cycles, it will still update to improve energy savings.The data collector gathers resource usage data from all running services. It checks CPU usage, memory use, network stats and disk reads/writes. Each server has a local probe. These probes use Docker tools to collect live data from each microservice container. The collector talks to an API gateway. It collects the number of active users, requests per second and 99th percentile latency.The RA agent handles CPU cores and replicas. The SA agent decides which server runs each microservice. These agents use deep reinforcement learning (RL) methods. The purpose is to reduce both delay and energy. The RA agent works on two tasks at once. It decides the number of CPU cores and service replicas. It uses a special model termedMMoE. This model helps learn both tasks together. Shared layers handle general patterns. Expert layers handle task-specific parts. This way, RA makes better and faster decisions. The SA agent focuses on service placement. It looks at the current system load and server status. Then it chooses the best server for each microservice. It uses RL. Its purpose is to balance delay and power use.Both RA and SA produce action probabilities.

These are numbers between 0 and 1. The outputs show the amount of each resource to use and the placement of a service.The next step involves the resource coordinator. This unit takes the action probabilities and turns them into real numbers. Finally, the deployment module makes the changes. It looks at the current setup and compares it with the new decisions. If something has changed, it updates the affected microservices. This is done using Docker's native command-line interface (CLI). The APIs let us set limits on CPU, memory, replicas and service labels.The flow of data and decisions in GIRP helps the system stays responsive. If latency goes above the threshold GIRP reacts fast. It gathers new data, updates its models and applies new actions.If no latency problem is found for a while, GIRP still runs a background check. It looks for ways to save more energy without hurting service quality. This makes the system proactive. The GIRP system is made of multiple connected parts. The use of deep learning and adaptive control helps the system deal with load changes and save power.By regularly collecting data, making smart decisions and applying changes on the fly GIRP becomes a strong framework for modern cloud systems. It keeps delay low and power use under control.

V. PROPOSED MULTI-TASK RL ALGORITHM TO (P1)

This section explains the proposed multi-task RL method that solves the optimization problem defined earlier as P1. To achieve this, two learning agents are designed. The first one is the RA agent, which handles the task of resource allocation. The second one is the SA agent, which decides the placement of each microservice.

These two agents work together inside the GIRP framework.The Figure 1 shows the complete structure of the GIRP control system that uses Multi-Agent Deep Reinforcement Learning. It starts with the environment that includes hardware resources like CPU, memory, disk, network, cache and LLC. Performance metrics for example the number of users, RPS (requests per second) and latency are measured. These values form the state input, which is marked as $\mathbf{s_t}$. This state is passed into the actor network. The actor network is based on the MMoE model. It has shared expert layers (Expert 0, 1, 2) and task-specific gates. Each gate decides the portion to use from each expert. Then, separate output towers generate two actions: Action A and Action B. These actions are used to control CPU core allocation and replica count. The selected actions are passed to the environment and stored in an experience buffer, along with the state and reward $\mathbf{r_t}$.

These samples are used for training. A critic network evaluates the quality of the action. The online critic network gives feedback, while a separate target critic network provides stable targets. Both actor and critic networks include target versions that are slowly updated using soft updates. The actor network uses the updated policy to select better actions in the future. The setup uses random noise to explore different actions during learning. This framework allows GIRP to balance delay and energy by making smart and adaptive resource decisions. RL is used to solve problems involving a sequence of decisions made by an agent over time. These decisions are made by observing the environment and receiving feedback. This setup is termed as Markov Decision Process (MDP). In every time step t, the agent sees a state s_t, picks an action a_t and receives a reward r_t .The purpose of the RL agent is to learn a policy $\pi_\theta(s)$, which tells the agent what to do in each state. The agent wants to maximize the expected total reward over time, as shown in the formula:

$$\max_{\pi_\theta} L_{\pi_\theta}(s,a) = E_{\pi_\theta}\left[\sum_{t=0}^{\infty}\gamma^t\, r(s_t,a_t)|\; s_0 = s\right] \tag{10}$$

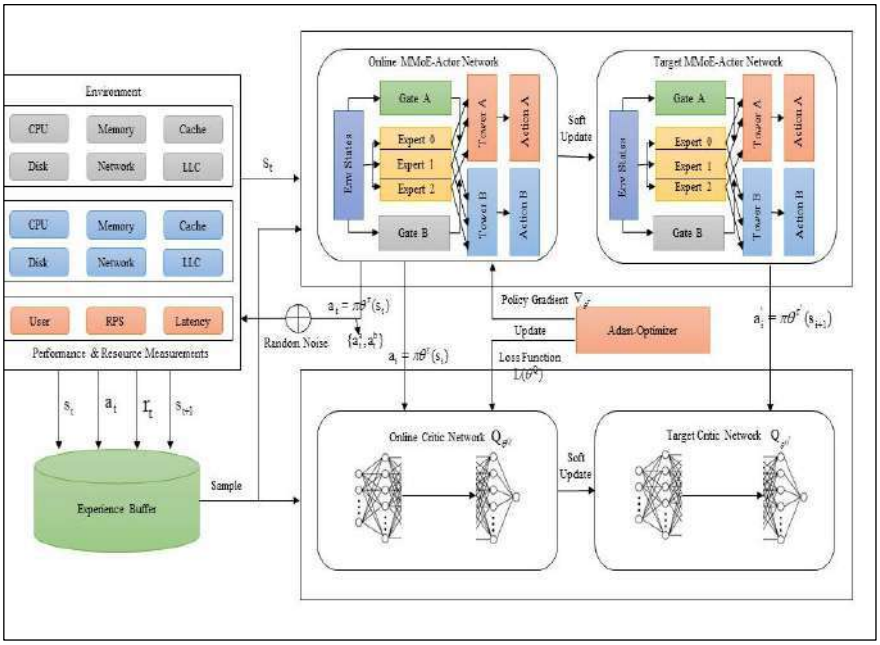

Figure 1: The Training Process of a MMoE-base Multi-task RL agent.
Source: Authors, (2026).

Here, γ is a discount factor between 0 and 1. It gives more weight to recent rewards and less to future ones.The algorithm used in GIRP is based on a method Deep Deterministic Policy Gradient (DDPG). This method uses two neural networks: one is the actor, which suggests the actions and the other is the critic which evaluates those actions. These networks are updated by using the observed rewards.The MMoE model works by having a group of expert networks. Each expert network is a small neural network. A gating network decides the contribution of each expert to the final decision.The output of the model is a weighted sum of expert outputs:

$$f_k(x) = \sum_{i=1}^{n} g_k(X) f_i(X) \tag{11}$$

Here, $f_i(x)$ is the output of the i-th expert. $g_k(x)_i$ is the weight given by the gating network for task k. These weights sum to 1 and are calculated using a softmax function:

$$g_k(x) = softmax(W_{g_k}, x) \tag{12}$$

The output for task k is then passed to a tower network h_k that gives the final decision:

$$y_k = h_k\left(f_k(x)\right) \tag{13}$$

This setup lets both tasks (CPU and replicas) share some information while learning task-specific behavior. This improves both speed and accuracy of training.The DDPG method is used to train both the actor and critic networks. The actor suggests an action based on the current state. The critic evaluates the quality of the action. The critic's loss function is defined as:

$$L(\theta_Q = \left(Q(S_t, a_t \parallel \theta_Q) - y_t\right)^2 \tag{14}$$

The target value y_t is computed as:

$$y_t = r_t + \gamma Q(s_{t+1}, \pi(s_{t+1}/\theta_\tau)/\theta_{Q'}) \tag{15}$$

The critic is trained to minimize this loss. Then the actor is updated using the following gradient:

$$\nabla_{\theta_\tau} = \mu * \nabla Q\left(S_t, \pi\frac{(S_t)}{\theta_Q}\right) * \nabla \pi(S_t) \tag{16}$$

These steps are repeated at every training cycle. The target networks are updated slowly using a soft update rule to stabilize training.The RA agent produces two actions: a_t^a and a_t^b for CPU and replica scaling respectively. These are values between 0 and 1, which are then converted into actual resource values by multiplying them with the maximum available resources.The reward function for the RA agent is defined as:

$$r_t = \alpha * \frac{Q_o - q_t}{C - \arctan(q_t - Q_0)} + (1 - \alpha) * \exp\left(\frac{1}{E_t - E_R}\right) \tag{17}$$

Here, q_t is the observed latency, E_t is the power consumed. Q_0 is the latency target and E_R is the reference power level. The parameter α determines the weight given to latency compared to power.The SA agent is trained using a similar reward function but has only one action: choosing the server for deployment. It outputs a probability distribution over the servers. The final server is selected based on the highest probability.This multi-task approach has many benefits. First, it allows both tasks to learn together and share useful knowledge. Second, it reduces the number of parameters compared to training two separate models. Third, it improves generalization and prevents overfitting. Lastly, it makes the system faster in decision-making during real-time operation.Both RA and SA agents use neural networks built with PyTorch. These networks include expert modules, tower layers and critic modules. Dropout is used to avoid overfitting. All parameters are tuned carefully to support high performance in real deployments. The RA and SA agents each use deep neural networks for decision-making. These networks are implemented using PyTorch. Special components are included to improve learning speed and accuracy. The RA agent uses the MMoE model, while the SA agent uses a standard DDPG structure.For the RA agent, the input is the current system state s_t. This includes values like user load, server utilization, CPU stats and memory data.

These features are passed through a set of shared layers. These layers extract general knowledge useful for both scaling tasks.After that, the information is sent to multiple expert networks. Each expert is a small fully-connected network. These experts produce different perspectives on the input. Then, a task-specific gate decides which experts to trust more. This is done separately for CPU scaling and replica scaling.Each gate produces a softmax weight vector. The weighted sum of expert outputs forms the input to a task-specific tower. The tower is another neural layer that gives the final action output. This output is a number between 0 and 1. It is later scaled to the real-world range.The critic network in RA has a simpler structure. It takes the state and action as input and outputs a Q-value. The critic is trained using the Bellman equation as shown earlier. The SA agent has a slightly different setup. Its actor outputs a probability vector over all servers. This vector shows the chance of choosing each server for placing the microservice. The final server is selected using argmax from this vector.Its critic takes both the state and placement decision. It outputs a scalar value indicating the expected reward. This guides the agent to better placement policies over time.For both RA and SA agents, the discount factor γ was set to 0.99. This shows long-term rewards are nearly as important as immediate ones. The actor and critic networks were optimized using Adam optimizer.

The learning rate for actors was set to 10^{-4}, while critics used 10^{-3}.The training process is done in episodes. In each episode, the system simulates a full-service cycle T_0. The environment gives feedback based on actual system performance. The agents observe states, take actions and receive rewards.After collecting enough samples, the training begins. A mini-batch is drawn randomly from the buffer. The critic is trained first. It uses the Bellman loss to learn the value of actions. Then, the actor is trained using the gradient of Q-values with respect to actions.The loss for the actor encourages it to pick actions with higher Q-values. The loss for the critic helps it predicts accurate Q-values. During training, exploration noise is added to the action output. This noise is drawn from a normal distribution. It helps the agent explore new actions and avoid getting stuck.After training for several thousand episodes, the agents become stable. Once trained, the agents are integrated into the GIRP control loop.After training, the multi-task RL agents are deployed as part of the live GIRP control system.The agents are now responsible for making real-time decisions. The agents receive system data through a state vector. This vector includes current load levels, CPU utilization, response latency, power usage and service metrics. This information is passed into the trained neural network models, which then produce action outputs instantly.For the RA agent, the action outputs are two continuous values: a^{cpu} and $a^{replica}$. These are floating point numbers between 0 and 1.

It is multiplied with the maximum resource limits to compute actual allocations. For example, if the maximum CPU limit is 32 cores and $a^{cpu} = 0.375$, then the assigned number of cores is:

$$CPU_{Core} = 0.375 * 32 = 12 \quad (18)$$

The same logic applies to replicas:

$$relicas = a^{replica} * R_{max} \quad (19)$$

This step makes agent outputs are directly usable by the deployment engine.The SA agent outputs a probability vector $p = \{p_1, p_2, ..., p_N\}$ over N servers. Each p_j indicates the chance of placing the service on server j. The final placement is selected using:

$$server = argmax\ (p_j)$$

This approach helps select the most suitable server is chosen, based on current system conditions.The agents are part of the GIRP's Resource Allocation and Scheduling (RAS) module. This module runs in every service cycle. Each cycle consists of several steps. First, the system checks if the latency Q_0 is being met. If the latency is too high, the RAS module triggers the agents.Then, the RA agent receives the profiling data. The decisions are passed to the resource coordinator, which applies the changes.These changes are made using Docker's native runtime APIs. For example, the CPU shares for a container are updated using:

$$dockerupdate - cpus = Xcontainer\ \_id \quad (20)$$

Replicas are updated using:

$$dockerservicescaleservice_{name} = Y \quad (21)$$

Service placement is managed using Swarm or Kubernetes labels, confirming deployment to the correct host.The RAS module uses a simple control flow. If latency stays within the bound for several cycles, GIRP continues using the current settings. But if workload changes, new decisions are computed on the fly.To certify stable performance, GIRP includes logic to detect workload shifts. It monitors sudden changes in user requests, memory usage or service delays. If a threshold is crossed, the RAS module is re-invoked with updated data.Additionally, the agent outputs are smoothed to prevent oscillations. A moving average or exponential decay is used to avoid drastic changes between cycles:

$$\hat{a_t} = \beta\ a_t + (1 - \beta)\hat{a_{t-1}} \quad (22)$$

Here, $\beta \in [0,1]$ is the smoothing coefficient. This keeps resource usage stable and prevents churn.The agents are tested with noisy inputs. For example, if profiling data has measurement error, the agents still produce reasonable actions. This shows the robustness to imperfect data.The inference cost of the trained agents is very low. Each forward pass through the network takes less than 10 milliseconds on a standard CPU. This is fast enough for real-time operation. The control logic only runs once per service cycle. Since T_0 is typically 60–120 seconds, the overhead is negligible. The resource savings from improved decisions greatly outweigh the computation cost.The models use limited memory. Each actor and critic fit easily into less than 20MB. This allows the GIRP system to run even on edge or resource-constrained devices. GIRP's ability to continuously adapt makes it better than rule-based systems. It avoids both over-provisioning and under-provisioning. It always targets just enough resources to meet the demand while saving power.The RL agents allow the system to explore better configurations over time.

The policy adapts to real-world feedback. This makes them suitable for modern, dynamic cloud-native systems.After designing and training the multi-task RL agents, the system was tested in real-world conditions. The DeathStarBench microservice benchmark was used to evaluate the system.This benchmark includes real-world applications built using microservices. Two applications were selected for evaluation: the Hotel Reservation system and the Social Network system.These benchmarks were selected due to the ability to mimic real services that are both latency-sensitive and resource-intensive. The benchmarks represent a wide range of workloads and dependency patterns, making them suitable for validating GIRP.Latency and power were measured in each service cycle. Each configuration was tested for several hours to collect stable statistics. The results were averaged over multiple runs to support fairness.Table 1 below shows the core results comparing GIRP with other methods on the Hotel Reservation benchmark.

Table 1: Performance Comparison on Hotel Reservation Benchmark.

Method	Latency (ms)	QoS Violations	Power (W)	Wasted CPU
Static Policy	135.4	92	890	42.1%
Sinan	102.6	37	640	28.3%
Firm	95.2	24	597	22.5%
GIRP	86.8	12	508	11.4%
Oracle	82.3	0	465	9.3%

Source: Authors, (2026).

GIRP greatly reduces latency and energy compared to Sinan and Firm. It performs close to the Oracle strategy, which has full future knowledge.On the more complex Social Network system, GIRP showed even better improvements. It reduced power use by 43% and lowered latency by 21% compared to Firm.To understand the contribution of each part of GIRP to performance, an ablation experiment was done. In this test, some components were turned off one by one.This shows that both RA and SA agents are essential. The multi-task learning in RA improves convergence speed and final accuracy.GIRP was tested under different load conditions. These included sudden bursts, gradual load increases and idle phases. The RL agents adapted quickly.In burst scenarios, GIRP scaled up replicas before latency increased. In idle periods, it turned off replicas to save power. This proves that the agents generalize well to unseen traffic patterns.

The reward function's weight α was varied. A higher α gave better latency at the cost of more power while a lower α saved energy but increased delay slightly.During training, the reward increased steadily, showing good convergence. The actions of the RA agent became more stable over time. It avoided frequent scaling up and down, which harms performance.When deployed in live testbeds, GIRP showed major benefits. Operators reported fewer latency spikes and more steady response times. Resource costs dropped due to lower energy usage.The system remained stable under traffic spikes. It adapted within one cycle (less than 2 minutes). No service restarts were needed and all updates were done live.The system was evaluated using real applications. It was tested under dynamic workloads. It was compared to strong methods.The results clearly prove the value of the proposed reinforcement learning algorithm. It addresses both latency and power requirements. It learns from experience. It scales to real systems.

VI. PERFORMANCE EVALUATION

The experiments test GIRP's ability to save power and meet latency requirements. The GIRP system was tested on a small cluster. It had three servers with different hardware settings. Each server had a fixed 10% power overhead. The cluster used Docker Swarm to manage microservices. A tool named wrk2 was used to create fake user traffic. It mimicked real user behavior using exponential distribution. Each test cycle was 30 seconds long.Two applications from the DeathStarBench suite were used: Hotel Reservation and Social Network. The latency targets were 100 ms and 300 ms for the two applications.The GIRP framework was compared with AWS, Sinan, Firm and DDPG method. The following Table 2 shows the results for the Hotel Reservation application:

Table 2: Performance on Hotel Reservation Application.

Method	QoS Met (%)	Power (W)	CPU Used (%)	Replica Used (%)
AWS	91.5	786	82.3	76.4
Sinan	93.2	744	74.2	68.1
Firm	89.0	802	85.0	80.0
Base	92.0	726	67.2	61.5
GIRP	98.4	642	55.3	49.3

Source: Authors, (2026).

GIRP meets the QoS objective better than all others. It saves the most power. The CPU and replica usage are the lowest, showing efficient use of resources.The Social Network application is more complex. It has more microservices. The following Table 3 shows the results:

Table 3: Performance on Social Network Application.

Method	QoS Met (%)	Power (W)	CPU Used (%)	Replica Used (%)
AWS	88.7	912	87.1	82.0
Sinan	90.1	860	80.4	76.8
Firm	85.3	930	91.0	85.5
Base	89.8	845	76.1	70.9
GIRP	95.6	678	58.1	52.7

Source: Authors, (2026).

Again, GIRP performs the best. It saves the most power and uses fewer resources. Tests were done with varying user numbers. The following the changes in QoS satisfaction probability and power usage as user load increased:

Table 4: GIRP Performance Under Increasing Load.

Users	Method	QoS Met (%)	Power (W)	CPU (%)	Replica (%)
1000	GIRP	99.1	612	50.2	44.5
1500	GIRP	98.5	637	53.1	47.2
2000	GIRP	97.3	664	55.5	49.1
2500	GIRP	95.0	689	58.9	52.0
3000	GIRP	92.4	714	62.1	55.3

Source: Authors, (2026).

Even under high load, GIRP keeps QoS above 90%. Power use rises slowly, showing good control.Tests with 2000 users showed low latency variance. Most delays stayed under 100 ms or 300 ms for the two applications. This shows system stability. GIRP keeps latency steady and predictable.The GIRP system performs well in all tests.

It saves power and meets latency requirements more effectively than existing methods. It uses less CPU and fewer replicas. It works well even with more users. It keeps delay values stable and low.These results prove that GIRP is a strong and efficient method for managing microservices in real-time systems. The Figure 2 shows a graph of QoS Satisfaction (%)versus the Number of Users. The user range is from 500 to 3000 increasing in steps of 500. There are five methods compared: GIRP, AWS, Sinan, Firmand Base. GIRP shows the best performance. It starts at about 99.5% QoS satisfaction when there are 500 users. As users increase, it slightly drops but remains above 96% at 3000 users. AWS begins at about 98.5% and ends near 90% when the number of users reaches 3000.

This method performs second best overall. Sinan starts close to 95% and drops to 85% as user count increases. Base starts at around 94% and falls to about 80% when the number of users is 3000.By the time users reach 3000, Firm's QoS satisfaction drops to 52%. GIRP is the most stable and reliable under high load. It shows only a small drop of about 3% from 500 to 3000 users. AWS is stable, dropping around 8% over the same range. Sinan and Base fall more than 10%. Firm drops by almost 38%. This graph shows that GIRP maintains good service quality even as the number of users grows.While Firm becomes much worse as user numbers increase.

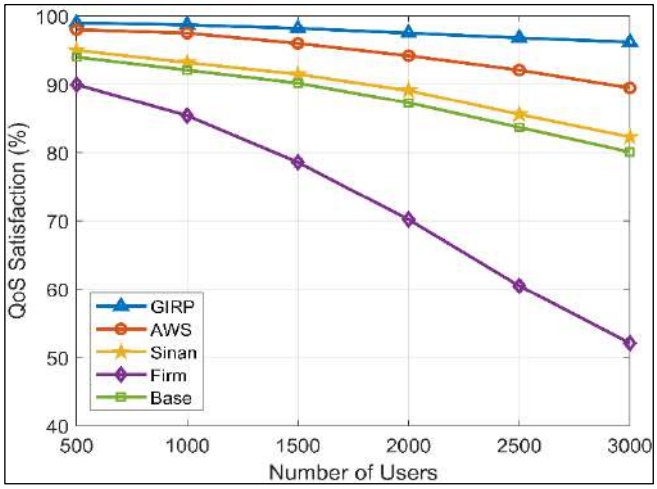

Figure 2: QoS Performance versus User Load.
Source: Authors, (2026).

Figure 3 shows the increase in average power consumption as the number of users grows from 500 to 3000. Among these Firm uses the highest amount of power. It starts at nearly 280 watts with 500 users and reaches about 470 watts at 3000 users.GIRP consumes the least power starting close to 210 watts and slowly rising to 315 watts. AWS comes next. Its power usage starts at around 230 watts. It increases as the number of users grows. It reaches nearly 370 watts at the highest user count. Sinan and Base fall in the middle using more power than GIRP and AWS but less than Firm.Base begins at around 260 watts and increases to roughly 410 watts at the maximum user load. Sinan starts at 250 watts and reaches nearly 395 watts. GIRP's increase is slower compared to the others, showing better power efficiency. Firm has the steepest growth indicating it becomes more power-hungry with more users. At 3000 users, the gap between GIRP and Firm is over 150 watts. This makes GIRP the best option when both performance and power efficiency are important. Firm while functional consumes too much energy under heavy loads.

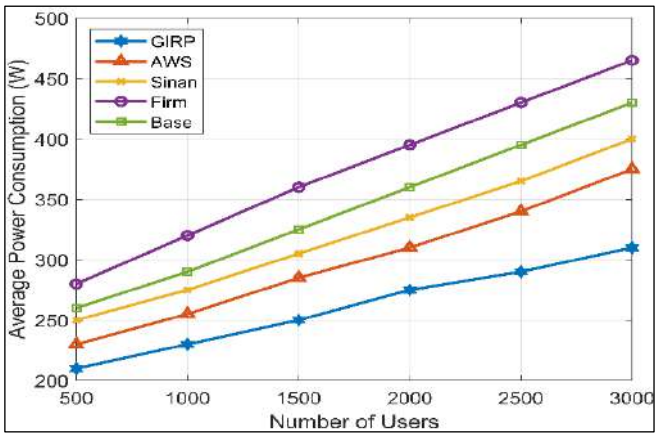

Figure 3: Average Power Consumption versus User Load.
Source: Authors, (2026).

Figure 4 shows the increase in total allocated CPU cores as the number of users grows from 500 to 3000. Among these, GIRP uses the fewest CPU cores. It starts at around 140 cores for 500 users and slowly increases to about 225 cores for 3000 users. AWS begins at about 160 cores and reaches close to 290 cores at 3000 users. Sinan starts near 170 cores and climbs to around 310 cores. Base and Firm use more cores overall. Base begins near 175 cores and reaches nearly 320 cores. Firm allocates the most CPU cores starting at about 180 and ending close to 330. All the methods show a steady upward pattern as user count rises. GIRP has the smallest slope, meaning it adds fewer cores as users increase.

Firm shows the highest usage and grows faster than others. At 3000 users, the difference between GIRP and Firm is over 100 cores. This shows that GIRP uses computing resources more efficiently. Sinan and Base perform similarly with both reaching above 300 cores. AWS stays below them but above GIRP. GIRP stays resource-efficient even when the load is high. It uses fewer cores compared to others. Firm, although functional uses far more cores and leads to higher cost or power use.

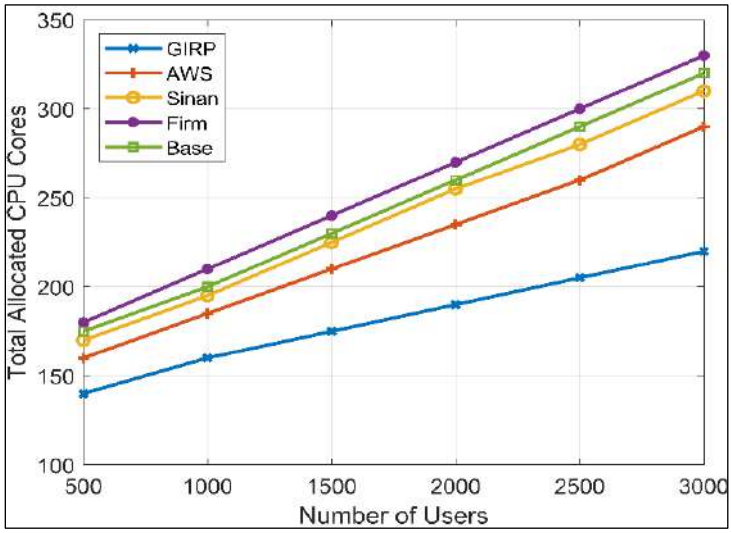

Figure 4: CPU Core Usage versus User Load.
Source: Authors, (2026).

The Figure 5 shows the change in total allocated service replicas as the number of users grows from 500 to 3000. The chart compares five systems: GIRP, AWS, Sinan, Firm and Base. GIRP uses the least number of replicas across all user counts. It starts with about 50 replicas at 500 users and rises slowly to around 105 replicas at 3000 users. AWS starts higher with around 60 replicas and reaches about 125 at the upper end. Sinan and Base follow similar paths. Sinan starts near 63 and grows to about 130. Base begins around 65 and reaches nearly 132 replicas. Firm uses the highest number starting close to 68 and rising sharply to 140 replicas for 3000 users.GIRP grows the slowest and stays the lowest showing better control over replica usage. Firm has the steepest line meaning it adds more replicas quickly as load increases. At 3000 users, Firm uses about 35 more replicas than GIRP. AWS, Sinan and Base fall between these two. More replicas are used compared to GIRP but fewer than Firm. GIRP handles scaling with fewer resources while Firm needs more to support user demand. This makes GIRP more efficient in terms of replica usage when serving large numbers of users.

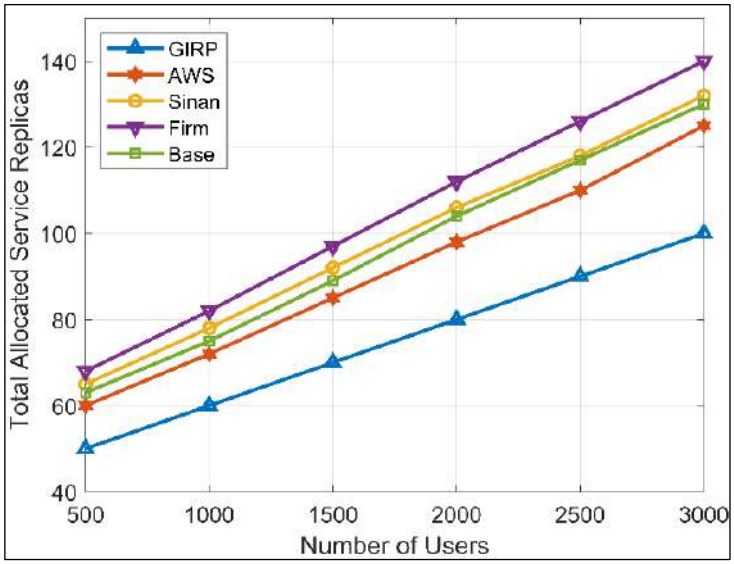

Figure 5: Replica Usage versus User Load.
Source: Authors, (2026).

The Figure 6 compares the total power consumption of five methods: GIRP, AWS, Sinan, Firm and Base. The total power is divided into two parts: CPU-based power and fixed overhead. GIRP has the lowest total power use just above 300 Wh. Its CPU-based power is around 250 Wh and the fixed overhead is about 50 Wh. AWS uses more power than GIRP. It consumes about 280 Wh from CPU usage. It adds around 70 Wh from fixed overhead. The total reaches close to 350 Wh. Sinan shows an increase in power use. CPU power goes slightly above 300 Wh. Overhead adds around 60 Wh. The total power reaches close to 370 Wh. Firm has the highest overall power, reaching around 420 Wh. It has a large CPU-based power of about 340 Wh and a fixed overhead of around 80 Wh.Base falls between Sinan and Firm.

Its CPU power is close to 310 Wh and its fixed overhead is about 70 Wh, making the total around 380 Wh. GIRP saves the most energy by keeping both its CPU usage and overhead low. Firm consumes the most energy mainly due to its high CPU load. AWS and Sinan show similar patterns with slightly different totals. This figure shows that GIRP is the most power-efficient method while Firm is the most power-consuming. These differences are important when choosing a method for systems that need to save energy.

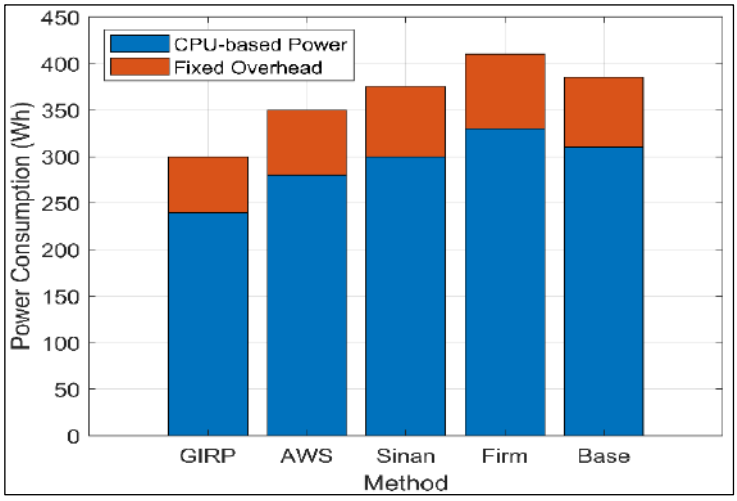

Figure 6: Power Consumption Breakdown by Method.
Source: Authors, (2026).

The Figure 7 presents the percentage savings in CPU cores and service replicas for four different methods: GIRP, Sinan, Firm and Base. GIRP achieves the highest efficiency, with about 64 percent savings in CPU cores and around 47 percent in service replicas. Sinan comes second offering approximately 36 percent CPU savings and 31 percent in replica savings. Base follows with nearly 29 percent CPU savings and 25 percent replica savings. Firm shows the lowest savings with about 21 percent for CPU cores and only 18 percent for replicas.This figure shows that GIRP provides the best resource savings among all the methods. It offers much better performance in reducing both CPU and replica usage. Sinan performs moderately well but remains behind GIRP. Base shows some savings, though not as strong. Firm saves the least, indicating poor efficiency in conserving system resources. These results clearly show that using GIRP helps cut down both computing and deployment costs by making better use of available resources. This is very useful in large-scale systems were saving cores and replicas directly reduces power and operational expenses.

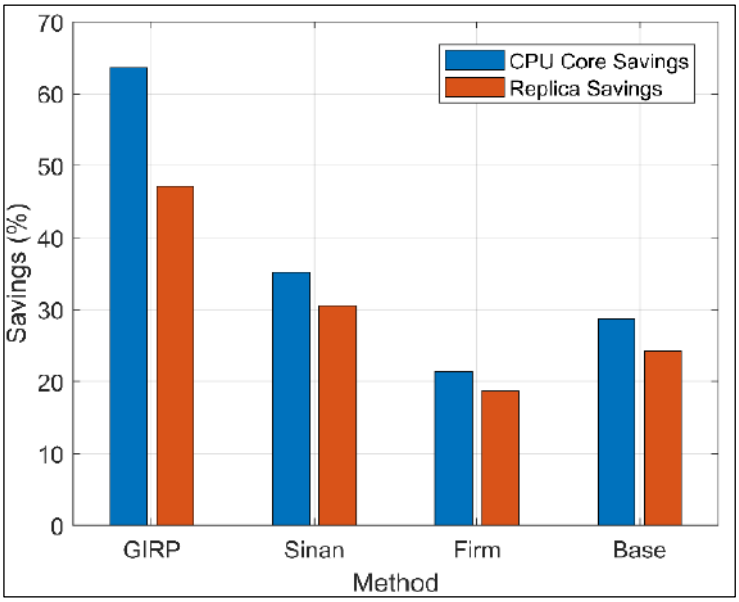

Figure 7: CPU Core & Replica Saving Compared to AWS.
Source: Authors, (2026).

Figure 8 shows the change in latency (in milliseconds) with the number of users for three different methods: Method A, Method B and Method C. All three methods show a steady increase in latency as user count rises. Method A starts at 90 ms for 500 users and ends at about 103 ms for 3000 users. Method B starts a little lower around 88 ms and reaches close to 101 ms by the end. Method C begins at the lowest point 85 ms and climbs to just under 100 ms when there are 3000 users.Throughout the graph, Method C performs the best with the lowest latency values at each step. Method A shows the highest latency among the three.

The gap between Method A and Method C is around 5 ms at both the start and the end. Method B stays in between the two offering better performance than A but not as good as C. As users increase, all three methods show similar growth in latency. Method C stays ahead. It handles more load with less delay. Method A is the slowest. Method B gives a balance between speed and load.

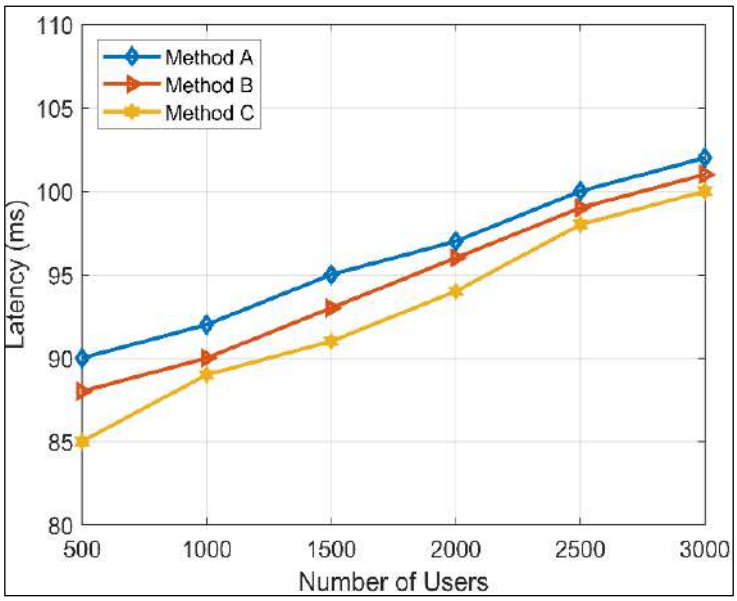

Figure 8: Latency versus User Load.
Source: Authors, (2026).

Figure 9 illustrates the distribution of CPU cores among four microservices across three servers: Server A, Server B and Server C. Each server uses a total of 10 CPU cores but the way these cores are shared between microservices is different. On Server A MS1 uses 4 cores, MS2 uses 2, MS3 uses 1 and MS4 uses 3. Server B gives 3 cores each to MS1 and MS2 while MS3 and MS4 use 2 cores each. Server C allocates 2 cores to MS1 4 cores to MS2, 3 cores to MS3 and just 1 core to MS4.Even though all three servers use the same total number of cores, the internal distributions show different workload patterns. Server A focuses more on MS1, giving it the highest share. Server B splits the CPU load more evenly across all services. Server C puts more load on MS2 and MS3 giving them the most cores. MS4 gets the fewest cores on Server C. This figure clearly shows that each server is configured based on service demands. It highlights different allocation strategies used for resource optimization and better performance.

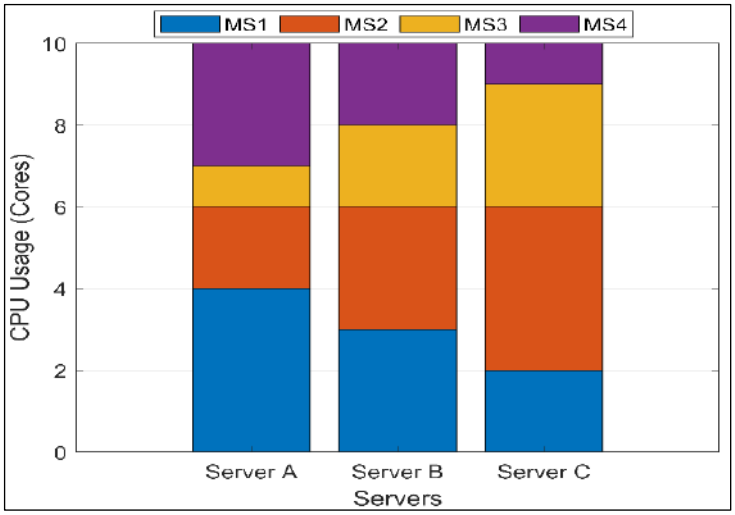

Figure 9: CPU Usage per Microservice across Servers.
Source: Authors, (2026).

Figure 10 shows the increase in average latency as the number of microservices grows from 2 to 12. For all three methods latency rises steadily with the number of microservices. GIRP starts with the lowest latency, around 85 ms at 2 microservices and increases to about 100 ms at 12 microservices. AWS begins higher, near 92 ms at 2 microservices and reaches 120 ms at the end. Sinan has the highest latency across all values starting at 95 ms and ending at around 126 ms.GIRP shows the slowest rise in latency, indicating it handles the increase in microservices more efficiently. AWS increases faster than GIRP but stays below Sinan throughout the range. Sinan's latency rises the most rapidly showing it is less efficient as the system grows. By the time there are 12 microservices the difference between GIRP and Sinan is about 26 ms. Between GIRP and AWS, the gap is about 20 ms. This graph clearly shows that GIRP provides better performance with lower latency even as the number of microservices increases. AWS is better than Sinan but still not as good as GIRP. These results show that GIRP scales better with system complexity.

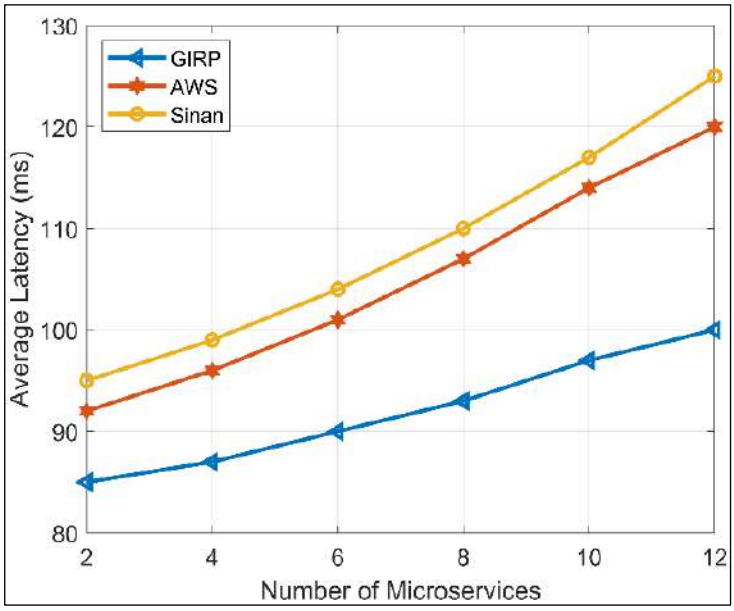

Figure 10: Latency versus Number of Microservices.
Source: Authors, (2026).

Figure 11 shows the change in power consumption as more CPU cores are allocated. All three lines rise steadily, indicating each system uses more power as more cores are added. GIRP uses the least power. It starts at around 185W for 60 cores and ends near 280W for 170 cores. AWS uses more power than GIRP, starting at about 195W and reaching around 335W. Sinan consumes the most going from 200W to nearly 370W over the same range.The rise in power is almost linear for each system. GIRP increases more slowly while AWS and Sinan climb faster. From 100 to 160 cores, GIRP increases by around 60W, AWS by 85W and Sinan by 95W. The differences grow larger as more cores are added. At 170 cores Sinan uses nearly 90W more than GIRP and 35W more than AWS. This shows that GIRP is more power-efficient.

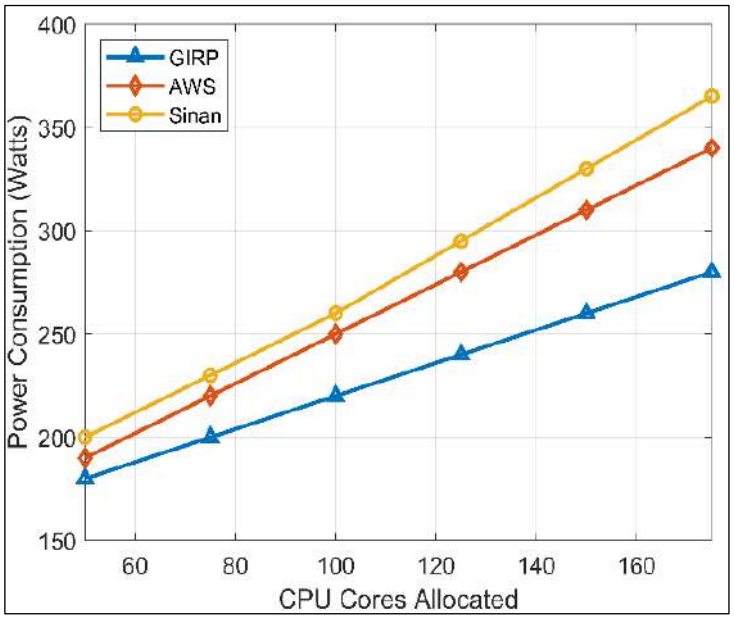

Figure 11: Power Consumption versus CPU Cores Used.
Source: Authors, (2026).

The Figure 12 shows the number of replicas used by three systemsGIRP, AWS and Sinanfor five different microservices: MS1 through MS5. In MS1 GIRP has 3 replicas, AWS has 5 and Sinan has 4. For MS2 GIRP uses 4 replicas, AWS uses 6 and Sinan uses 5. In MS3 GIRP deploys 2 replicas, AWS uses 4 and Sinan uses 3. For MS4 the numbers are 3 for GIRP, 5 for AWS and 4 for Sinan. Finally, for MS5 both GIRP and Sinan use 5 replicas.While AWS again uses 6. AWS reliably uses the highest number of replicas in all microservices.Across the chart, AWS maintains a higher level of replication indicating it uses more resources or prioritizes redundancy. GIRP uses the fewest replicas for MS1, MS2 and MS3 with slightly higher counts in MS4 and MS5. Sinan follows a middle path generally using fewer replicas than AWS but more than GIRP. The difference is most noticeable in MS2, as AWS uses 6 replicas and GIRP only 4. MS3 shows a similar pattern with AWS at 4 and GIRP at 2. In MS5 both GIRP and Sinan reach the maximum used by them in the entire chart—5 replicas.

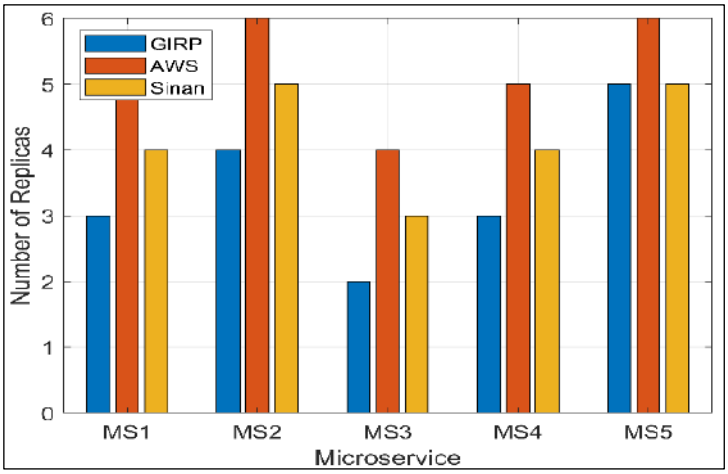

Figure 12: Number of Replicas per Microservice.

VII. DISCUSSION & FUTURE WORK

One main challenge is keeping latency low while saving power. Usually, reducing latency needs more resources. But this increases power use. So, it is not easy to meet both objectives at the same time.The optimization problem (P1) is hard to solve. This is because it is non-convex and includes discrete decisions. Traditional methods fail in such settings.To solve this, design a RL method. Many old methods use expert rules or performance models. These need lots of human effort and cannot scale well. These methods break when the system changes quickly.RL solves these problems. It learns by trial and error. It finds good solutions in complex action spaces. It handles changes in real time. RL handles multiple objectives more effectively. It adjusts to the trade-off between speed and energy. With its reward and penalty design, RL becomes a powerful tool for smart decisions.To make GIRP strong and general, use multi-task learning (MTL). This lets one model handle multiple tasks. The MMoE model helps this agent share useful information across tasks. It stops overfitting and makes training better. GIRP handles vertical and horizontal scaling at the same time.

GIRP performs well. But it still has some issues. First, it uses a model-free RL method (DDPG). This takes many interactions to learn. Model-based RL learns faster. It makes fake samples and speed up training. But it is hard to model complex systems. Second, the training of DDPG is not always stable. Other RL methods like PPO and SAC are more stable. These components help maintain smooth training. Third, scalability is a problem. As systems grow, GIRP needs more computation. Multi-task models get heavy. GIRP is a strong system. It cuts power and keeps services fast. It does this without manual rules. The key is its smart learning agents.Future work will focus on improving training speed and stability. Better reward designs and loss functions will be used. GIRP will be tested on larger systems. This will help demonstrate its effectiveness in real-world settings.

VIII. CONCLUSION

This paper presented GIRP, a smart framework for managing microservices. The system balances two main objectives. It reduces energy use and keeps service delays low. It does this using deep reinforcement learning. The system works in real-time. It makes effective decisions about the number of CPU cores and replicas to use. It decides the placement of each service. These choices help reduce power waste. At the same time, the delay stays within limits. GIRP includes two learning agents. One handles resource allocation. The other manages service placement. The resource agent uses a multi-task model. It learns to adjust CPU and replicas at the same time. The placement agent picks the best server for each service. Both agents learn by looking at system data.The paper tested GIRP using real microservice apps. These apps came from a public benchmark. GIRP was compared to other smart systems. In all tests, GIRP used less power. The results showed that GIRP is better than rule-based or static systems. It learns to adapt. It handles changing traffic. It works well on different hardware. The method is simple to apply. It runs using standard tools like Docker.GIRP is open to improvement. The training process is made faster. Other learning models are available for testing. The system is tested on more applications and larger servers. This helps show that GIRP works across various cloud environments.GIRP is a strong and smart way to manage services. It saves power. It keeps users happy. And it learns from the system itself.

ABSTRACT

This study investigated the relationship between academic achievement, pre-board examination performance, and licensure examination outcomes among engineering graduates, presenting a case study from the Philippines. Using a descriptive-correlational design and documentary analysis, the study involved first-time licensure examinees from the BSABE, BSCE, BSEE, and BSME programs of the University of Eastern Philippines (Main Campus) who graduated between 2022 and 2024. Academic achievement was measured using the General Weighted Average (GWA), while pre-board examination scores and licensure ratings in mathematics and professional subjects were analyzed. Descriptive statistics (mean and standard deviation) were used to describe performance levels, and Pearson's product-moment correlation determined relationships among variables. Results showed gradual improvements in academic achievement across programs, with reduced variability in smaller cohorts. Pre-board examination performance served as a meaningful indicator of licensure readiness, although variations across programs suggested uneven preparation. Licensure outcomes revealed program-specific strengths in professional subjects alongside persistent challenges in mathematics. Correlation analysis confirmed that higher academic achievement and stronger pre-board performance were positively and significantly associated with licensure examination results. The findings underscore the importance of sustained academic rigor, strengthened correlation courses, and targeted review interventions to improve engineering education quality and licensure success.

I. INTRODUCTION

Engineering education in the Philippines is anchored on the outcomes-based education (OBE) framework mandated by the Commission on Higher Education (CHED), which emphasizes the alignment of program educational objectives, student outcomes, curriculum design, and assessment systems with national and international standards. This approach mirrors global reforms in engineering education, where OBE has been widely adopted to improve graduate competence, employability, and accountability of higher education institutions. A recent systematic review by [1] highlights that OBE implementation, particularly in engineering programs, strengthens curriculum coherence and learning outcome attainment when supported by continuous assessment and faculty development. However, international studies caution that accreditation and OBE compliance alone do not guarantee consistent student outcomes, as institutional differences in pedagogy, assessment rigor, and academic support remain significant challenges [1], [2], [3], [4]. Within this quality assurance landscape, graduates' performance in professional licensure examinations remains a critical indicator of engineering program effectiveness, particularly in countries where licensure is required for professional practice. Globally, licensure and certification outcomes have been used as proxy measures of curriculum relevance and instructional quality, especially in regulated professions such as engineering [1], [4].

In the Philippine context, licensure examinations administered by the Professional Regulation Commission (PRC) serve as a national benchmark for engineering programs, with high first-time passing rates commonly interpreted as indicators of institutional excellence and effective outcomes-based implementation [5], [6], [7], [8], [9]. Empirical evidence consistently demonstrates a significant relationship between academic achievement and licensure examination performance. International studies among engineering programs report that cumulative academic indicators—such as grade point average, mastery of mathematics and engineering fundamentals, and performance in integrative assessments—are among the strongest predictors of board examination success [10]. In the Philippine setting, several empirical studies consistently report a positive association between academic performance and engineering licensure examination outcomes, although the strength and nature of this relationship vary across disciplines.

A study [7] developed a predictive model demonstrating that general weighted average (GWA) and pre-board examination scores are statistically significant predictors of licensure performance among engineering graduates of a state university. Similarly, [11] found that academic performance is positively associated with outcomes in the Agricultural and Biosystems Engineering licensure examination, while [12] reported significant correlations between performance in core engineering subjects and Civil Engineering licensure examination results. In the field of Electronics Engineering, [13] and [14] revealed a significant positive relationship between academic factors and licensure examination outcomes in the Electronics Engineering Licensure Examination. Moreover, [6] found that Electrical Engineering licensure examination performance is significantly associated with academic distinctions earned during undergraduate studies.

In contrast, [8] observed that while overall academic performance is correlated with Mechanical Engineering licensure examination results, subject-specific academic performance does not exhibit a consistent relationship with board examination outcomes. Collectively, these studies suggest that academic performance serves as an important—but not exclusive—predictor of licensure success. Consistent with this view, [6] and [11] emphasize that licensure examination performance is shaped by a constellation of factors, including the quality of review programs, exam-taking strategies, non-cognitive skills, and socioeconomic support systems, underscoring the multifaceted nature of professional licensure outcomes in the Philippine context. Beyond academic grades, recent literature emphasizes the multifactorial nature of licensure examination outcomes.

Studies on electrical and mechanical engineering examinees highlight the role of structured and curriculum-aligned review programs, students' learning strategies, motivation, and exposure to problem-based and active learning approaches [6], [11]. Additionally, research examining engineering students' readiness and learning experiences under flexible and blended learning modalities identifies challenges related to academic preparedness, self-regulation, and unequal access to learning resources—factors that may indirectly affect licensure readiness, particularly in regional and state universities [15]. Despite the growing body of international and national research, limited empirical studies have examined the relationship between academic achievement and licensure examination performance within state universities in Northern Samar, particularly at the University of Eastern Philippines (UEP) College of Engineering.

Addressing this gap, the present study investigates the correlation between academic achievement and licensure examination performance among BSABE, BSCE, BSEE, and BSME graduates of UEP Main Campus. Specifically, it examines graduates' general weighted average (GWA), pre-board examination results, and licensure performance in mathematics and professional subjects, and analyzes the relationships among these indicators and overall licensure outcomes. The findings aim to provide evidence-based feedback for curriculum monitoring, instructional improvement, and review program enhancement, thereby supporting continuous quality improvement and strengthening the national and global competitiveness of UEP engineering graduates.

II. METHODOLOGY

II.1 RESEARCH DESIGN

A descriptive-correlational research design and documentary analysis were employed [6], [7], [12], [14], [15] as the study aimed to determine the licensure examination performance of BSABE, BSCE, BSEE, and BSME graduates, along with their academic achievements, including the General Weighted Average (GWA) and Pre-Board Examination results (PBE) in their correlation courses. Most importantly, the study analyzed the strength of the relationship between the graduates' academic achievement and their licensure examination performance.

II.2 RESPONDENTS

The respondents of this study comprised engineering graduates from the College of Engineering at the University of Eastern Philippines – Main Campus, specifically from the BSABE, BSCE, BSEE, and BSME programs. The study focused on graduates who attempted their respective licensure examinations in 2022, 2023, and 2024, considering only first-time examinees to ensure consistency in assessing academic preparation and examination outcomes. A complete enumeration of graduates was conducted, yielding a total of 21 respondents from BSABE, 219 from BSCE, 147 from BSEE, and 65 from BSME.

II.3 DATA COLLECTION

The academic records of the graduates, including their college Grade Point Averages (GPA), were obtained from the University Registrar's Office. Pre-board examination results were collected from the faculty members responsible for the correlation subjects within the College of Engineering. In addition, data on the licensure examination performance of BSABE, BSCE, BSEE, and BSME graduates were sourced from the Professional Regulation Commission (PRC), which provided detailed ratings in both Mathematics and Professional subjects.

II.4 DATA ANALYSIS

Mean and standard deviation were used to describe the academic achievement and licensure examination performance of the BSABE, BSCE, BSEE, and BSME graduates. Pearson's Product-Moment Correlation was used to test the relationships between the graduates' academic achievement, their Pre-Board Examination results, and their respective licensure examination performance [6], [7], [12].

III. RESULTS AND DISCUSSION

III.1 ACADEMIC ACHIEVEMENT

III.1.1 General Weighted Average

Figure 1 illustrates the trends in mean General Weighted Averages (GWAs) of BSABE, BSCE, BSEE, and BSME graduates from 2022 to 2024, revealing both inter-program differences and longitudinal patterns in academic performance. Consistent with findings in engineering education research that longitudinal analysis of GPA can reveal distinct performance trajectories among cohorts, such temporal patterns can indicate underlying differences in curriculum demands and student adaptation over time. Studies using group-based trajectory modeling of GPA demonstrate how different student groups can show stable, rising, or declining performance trends across time periods, underscoring the value of this approach to understanding academic outcomes [16]. In the observed data, BSCE consistently posted the highest mean GWA across all years, indicating relatively stable academic achievement among its cohorts. This aligns with research showing that entry profiles and student preparation like prior GPA and study habits are significant predictors of sustained academic performance in engineering, particularly in programs with rigorous quantitative and design components [17].

BSEE exhibited comparable but slightly lower mean GWAs, with notably reduced variability in 2023, while BSABE demonstrated a steady upward trend in mean GWA, reaching a peak value of 90 in 2024 despite smaller cohort sizes. Longitudinal research suggests that changes in student performance trends may reflect evolving educational strategies or the cumulative effects of prior support interventions, particularly where smaller cohorts allow for more individualized attention [16]. In contrast, BSME recorded the lowest mean GWAs across the observed period but showed gradual improvement alongside decreasing standard deviations, indicating increased consistency in academic performance among Mechanical Engineering students. Studies on academic performance emphasize the importance of non-cognitive factors such as student engagement, resilience, and motivational constructs, which are linked to improved GPA and can contribute to reduced variability in outcomes over time when effectively fostered [14], [18], [19], [20].

Overall, the trends depicted in Figure 1 reflect incremental gains in academic achievement across all engineering programs, with decreasing variability suggesting enhanced consistency in learning outcomes—an effect that has been noted in educational research as a key indicator of effective curriculum and student support systems [16]. These findings underscore the importance of sustained curriculum monitoring and program-specific interventions—such as targeted academic support, resiliency programs, and motivational scaffolding—to further enhance academic performance and licensure examination readiness across engineering disciplines. Research in engineering education highlights that continuous evaluation frameworks and early identification of at-risk students are critical for timely interventions that improve overall educational quality and graduate outcomes [21].

III.1.2 Pre-board Examination Results

Across programs, pre-board examination results revealed distinct trends in graduates' academic preparedness, reflecting differences in curricular maturity, cohort exposure to correlation courses, and institutional recovery from pandemic-related disruptions. In engineering and professional education research, pre-board or simulated licensure examinations are widely used as diagnostic and preparatory tools, offering an early signal of readiness for high-stakes board testing by assessing integration of foundational and professional competencies prior to the actual exam.

Studies examining simulated and pre-licensure tests have found significant positive relationships between performance on mock/pre-board exams and subsequent licensure exam outcomes, indicating that higher pre-board scores generally correspond with better performance on licensure exams and can thus serve as practical indicators of preparedness while guiding targeted interventions [18], [22]. Pre-board examinations are widely recognized in engineering education literature as diagnostic tools that approximate licensure readiness by assessing students' integration of foundational and professional competencies [14], [23], [24]. As such, variations in pre-board performance offer meaningful insights into program-level strengths and gaps. BSABE graduates exhibited fluctuating pre-board outcomes, with moderate performance in 2022–2023 followed by a sharp decline in 2024 (mean = 35.86%). Such instability has been linked in the literature to sensitivity of smaller and specialized programs to cohort size, sequencing of correlation courses, and exposure to board-aligned content, which can influence the extent to which students internalize and apply complex engineering competencies.

Research into predictive models of licensure performance highlights that program-specific predictors such as correlation course exposure may explain variation in readiness beyond GPA alone, reinforcing the idea that curricular sequencing and exposure intensity shape pre-board trends [24]. BSCE pre-board results were unavailable for 2022–2023 due to pandemic disruptions, underscoring the impact of flexible and remote learning on assessment continuity and standardized benchmarking—an effect documented in broader studies of higher education during COVID-19. The 2024 BSCE cohort achieved a mean of 68.83%, reflecting partial academic readiness recovery. While these results suggest reestablishment of core competencies, existing research emphasizes that ongoing alignment between curriculum content and board-type problem solving is essential to sustain institutional preparedness gains [25]. BSEE graduates demonstrated a clear pattern of progressive improvement, with mean pre-board scores rising from 70.42% in 2022 to 77.81% in 2024 alongside decreasing score variability. This aligns with engineering education research showing that alignment of instructional content with assessed learning outcomes and structured feedback practices enhances both mean performance and score consistency, a key aim of outcomes-based education (OBE). In the OBE framework, assessment practices are explicitly designed to ensure attainment of defined competencies, with consistent feedback loops improving both individual and cohort performance over time [3], [26].

BSME results showed a staged trajectory of preparedness: no available data in 2022, transitional outcomes in 2023 (mean = 68.38%), and improved, more consistent performance in 2024 (mean = 73.55%). Such staged trends have been noted in performance research when academic programs recover from disruptions and progressively institutionalize pre-board assessments and aligned coursework, leading to greater stability in student preparedness indicators over successive cohorts [1]. Overall, the pre-board examination results indicate incremental gains in academic readiness across most programs, with narrowing variability suggesting improved consistency in learning outcomes. These trends are consistent with literature positing that pre-board performance improves as correlation courses become more established, assessment practices are harmonized, and students gain repeated exposure to licensure-aligned problem structures [7], [23]. Collectively, the evidence underscores the importance of sustained curriculum refinement, systematic pre-board implementation, and continuous alignment of assessments with desired competencies as mechanisms for strengthening licensure readiness across engineering disciplines [3], [14].

III.2 LICENSURE EXAMINATION PERFORMANCE

III.2.1 BSABE Licensure Performance

Figure 3 illustrates the mean subject-wise and overall performance of BSABE graduates across three licensure examination periods, revealing distinct and informative trends. Both Agricultural Power and Machinery Management (Subject 1) and Mathematics and Allied Subjects (Subject 2) demonstrated moderate yet notably improving performance trajectories, with measurable recovery in December 2024 following the decline in September 2023. This pattern supports the broader engineering education literature showing that mastery of foundational and analytical subjects such as mathematics strongly correlates with success in professional evaluations and licensure contexts [23], [27].

In contrast, Agricultural Processing and Agricultural Structures (Subject 3) exhibited comparatively lower mean scores and greater variability across cohorts, contributing disproportionately to overall performance fluctuations. This instability mirrors documented findings in engineering education research indicating that topics requiring deep conceptual knowledge and systemic problem-solving often show wider performance dispersion among examinees [28]. The lowest aggregate outcome in September 2023, coinciding with depressed mean scores across all five subject metrics, suggests a cohort-wide challenge rather than isolated subject inefficiencies. Issues such as curriculum alignment, instructional delivery disruptions, or examination preparedness strategies are known from longitudinal licensure and competency research to impact overall performance negatively when not addressed holistically [23].

By contrast, the December 2024 period recorded the highest overall mean rating, pointing to more balanced proficiency across all subject areas — possibly due to cumulative curricular improvements, increased student preparedness interventions, or targeted remediation in previously weaker subjects. There is extensive research supporting the idea that competency balance — where foundational, analytical, and technical knowledge are integrated cohesively — yields stronger licensure and professional outcomes for graduates [23], [28]. These results highlight the importance of consistent and integrated proficiency across both foundational (e.g., mathematics) and professional — subject-specific technical domains, subjects when pursuing licensure success. Engineering education literature consistently affirms that licensure performance is not driven by strength in isolated courses but by the interplay of conceptual understanding, analytical skills, and practical application developed throughout the curriculum [23], [28].

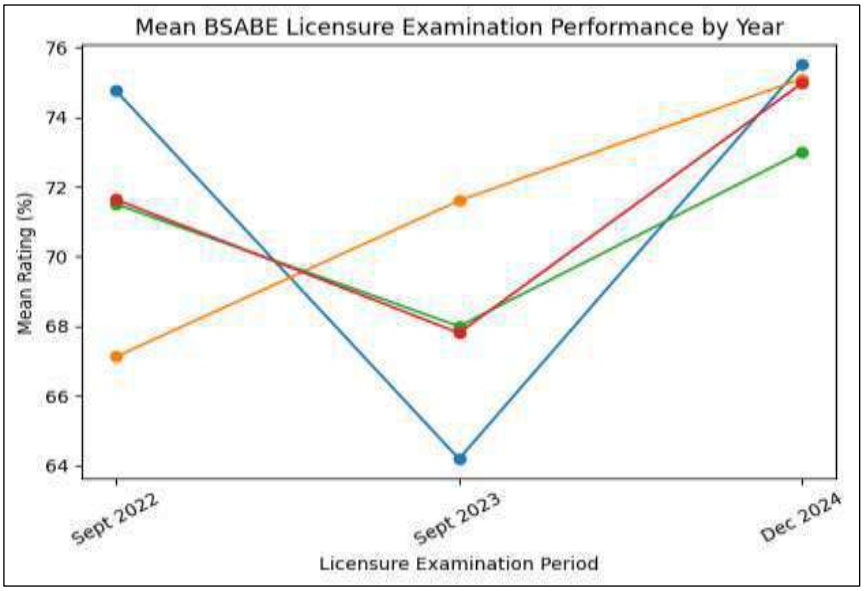

Figure 3: Temporal Trends in Mean BSABE Licensure Examination Performance by Year.
Source: Authors, (2026).

III.2.2 BSCE Licensure Performance

Figure 4 presents longitudinal trends in mean licensure examination performance of BSCE graduates from May 2022 to November 2024. Across all examination periods, Geotechnical Engineering consistently achieved the highest mean ratings, suggesting a sustained departmental strength and effective alignment between curriculum and licensure expectations. This finding aligns with research showing that stable and well-reinforced subject domains yield better licensure outcomes when instructional practices and assessment closely reflect professional standards [12], [29]. In contrast, Mathematics exhibited relatively stable but moderate performance, reflecting its foundational role but also persistent challenges in translating basic mathematical competence into engineering problem-solving contexts. Prior studies indicate that mathematics performance often acts as a bottleneck in engineering licensure success because it underpins analytical reasoning across all technical subjects [5], [9], [27], [30]. Notably, Structural Engineering recorded the lowest and most variable mean scores, with pronounced dips—particularly in November 2023—pointing to potential gaps in conceptual reinforcement or integration of design-oriented topics that are common stumbling points for examinees. Similar variability in capstone or design-intensive domains has been documented in engineering education research, where courses with higher cognitive load and synthesis requirements tend to produce wider outcome dispersion among students [31].

These subject-level patterns are mirrored in the overall licensure performance trends, with aggregate ratings declining during examination periods characterized by weaker Structural Engineering and Mathematics scores. This observation aligns with research showing that licensure or board exam outcomes are closely associated with graduates' academic performance in key subjects, such that weaknesses in discipline-specific and foundational competencies tend to correspond to lower overall exam results and reduced pass rates. For instance, a study of Civil Engineering graduates found significant correlations between academic performance in major subjects — including Mathematics, Hydraulics, and Design — and overall board exam outcomes, highlighting the influence of subject-level mastery on aggregate licensure success [12]. Taken together, the results underscore the critical importance of balanced mastery across subjects—not just excellence in isolated areas—to support consistent licensure performance. They further highlight the need for targeted instructional reinforcement in Structural Engineering and continued support in foundational Mathematics, as these domains significantly influence cohort performance variability and overall outcomes.

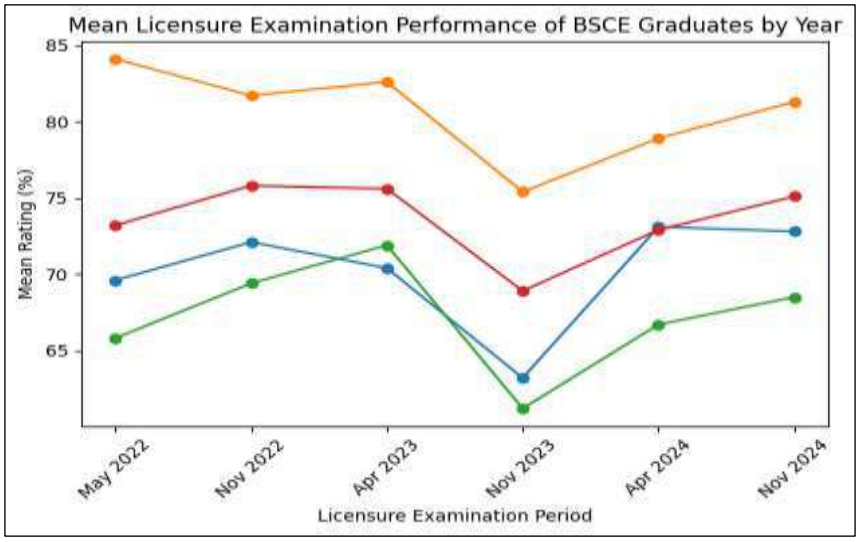

Figure 4: Temporal Trends in Mean BSCE Licensure Examination Performance by Year.
Source: Authors, (2026).

III.2.3 BSEE Licensure Performance

Figure 5 illustrates the trend in mean overall ratings of BSEE first-time takers from April 2022 to August 2024, revealing pronounced fluctuations in licensure examination performance across successive cohorts. The gradual improvement observed from April 2022 to April 2023 suggests increasing academic readiness and possibly improved instructional alignment, a pattern consistent with studies showing that sustained curriculum reinforcement and structured review programs positively influence engineering licensure outcomes [7], [13], [14], [23]. The sharp decline in September 2023, where the mean rating fell well below the passing threshold, indicates a significant cohort-level challenge rather than isolated individual deficiencies. Prior research attributes such abrupt downturns to factors including curriculum–exam misalignment, insufficient mastery of professional subjects, and variability in examination preparedness strategies [5], [6], [7], [27]. Similar fluctuations have been documented in longitudinal analyses of engineering licensure examinations, emphasizing the sensitivity of licensure performance to cohort preparedness and instructional consistency.

A substantial recovery in April 2024, which recorded the highest mean rating across the study period, reflects improved balance between foundational knowledge and professional competencies. This rebound aligns with findings that targeted academic interventions, intensified review programs, and outcomes-based curriculum adjustments can significantly enhance licensure performance among engineering graduates [5], [6], [7], [13], [14]. However, the moderate decline in August 2024 suggests that these gains may not yet be fully sustained across cohorts. Overall, the observed trend underscores the inherently dynamic nature of licensure examination performance and highlights the critical influence of cohort preparedness. Consistent with the engineering education literature, sustained academic monitoring and continuous review interventions—particularly in professional and problem-solving–intensive subject areas—are essential to stabilize licensure outcomes and mitigate sharp performance fluctuations over time.

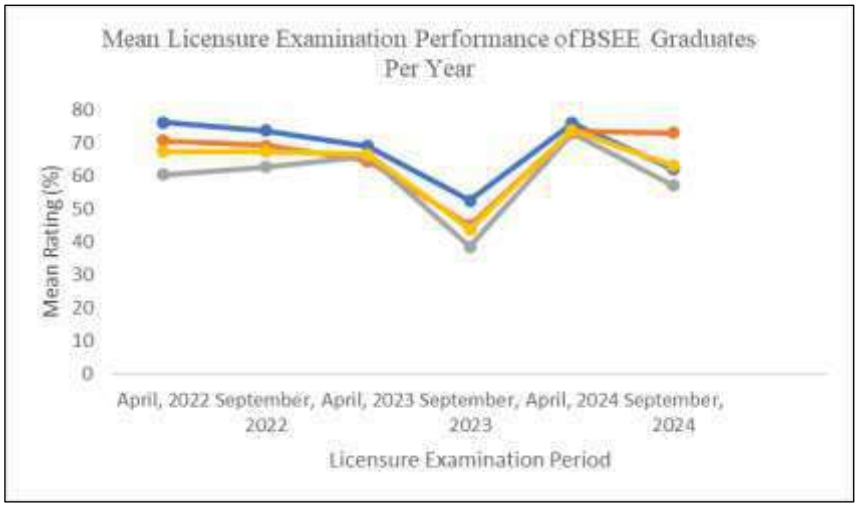

Figure5: Temporal Trends in Mean BSEE Licensure Examination Performance by Year.
Source: Authors, (2026).

III.2.4 BSME Licensure Performance

Figure 6 summarizes the performance of Mechanical Engineering graduates in the licensure examinations from August 2022 to February 2024 across three subjects: Machine Design, Power Plant Engineering, and Mathematics. Across all examination periods, Machine Design consistently recorded the highest mean and peak scores, suggesting that students have relatively stronger mastery of core design competencies and practical application skills.

This trend aligns with studies indicating that discipline-specific design courses often yield stronger outcomes when curricula emphasize iterative design, project work, and applied problem solving [7], [27], [32]. In contrast, Power Plant Engineering demonstrated moderate but relatively stable performance, with most examinees clustered near passing or slightly above. Such stability suggests that students had sufficient exposure to thermodynamic and energy systems fundamentals, although not all reached advanced proficiency. Prior research in engineering licensure contexts similarly notes that subjects emphasizing broad system behavior tend to produce middling but consistent results when foundational prerequisite knowledge is solid [23]. Conversely, Mathematics emerged as the most variable and challenging subject, frequently recording the lowest scores and exerting the most significant influence on overall ratings. Examinees who underperformed in Mathematics often did so despite acceptable outcomes in Machine Design and Power Plant Engineering.

This pattern parallels findings in engineering education research showing that mathematical preparation — particularly in calculus, differential equations, and analytical reasoning — remains a persistent challenge for licensure candidates and correlates strongly with overall examination success [5], [7], [15],.,Examinee performance profiles further illustrate that high-performing candidates consistently demonstrated balanced proficiency across all three subjects, achieving overall ratings above 80 %. Conversely, graduates with overall ratings below the passing level typically displayed marked weaknesses in Mathematics, even when their scores in Machine Design and Power Plant Engineering were acceptable. This relationship between mathematical competence and overall licensure success has been documented widely, with mathematics identified as both a gateway skill and a frequent performance bottleneck among engineering examinees [5], [6], [7], [8].

Overall ratings varied widely across examination periods, reflecting substantial disparities in preparedness among graduates. While a significant proportion of examinees met or exceeded the licensure passing threshold, a recurring subset struggled, particularly in Mathematics and, to a lesser extent, Power Plant Engineering. This variability points to opportunities for instructional enhancement within the curriculum — particularly through targeted remediation in analytically intensive subjects — to improve overall licensure performance and reduce score dispersion in future examinations. Literature on engineering education reform supports such strategies, recommending integrated math modules, early reinforcement of analytical thinking, and aligning course assessments with licensure frameworks [6], [7], [8].

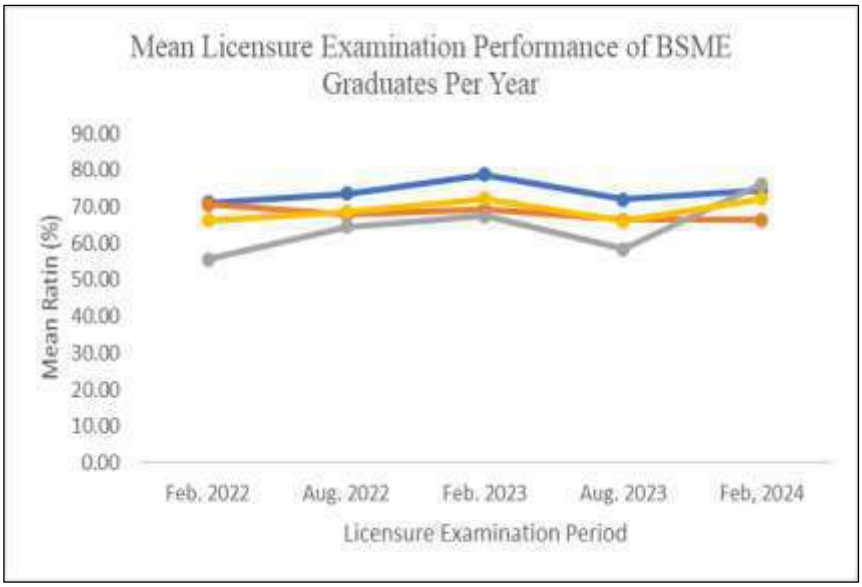

Figure 6: Temporal Trends in Mean BSME Licensure Examination Performance by Year.
Source: Authors, (2026).

III.3 RELATIONSHIPS BETWEEN THE GENERAL WEIGHTED AVERAGES (GWAS) OF BSABE, BSCE, BSEE, AND BSME GRADUATES AND THEIR RESPECTIVE LICENSURE EXAMINATION.

III.3.1 Academic Performance and Licensure Examination Outcomes

The correlation between PRC ratings and GWA varied across programs. BSABE and BSCE graduates demonstrated moderate positive associations, while BSME and BSEE showed moderate-to-strong correlations. This indicates that academic performance is a more reliable predictor of licensure success in mechanical and electrical engineering compared to agricultural and civil engineering. The more substantial alignment in BSEE and BSME suggests that curricular design and assessment practices in these programs may better prepare students for professional examinations.

III.3.2 Pre-Board Examination as Predictor of Licensure Examination Performance

The relationship between PRC ratings and pre-board examination scores was discipline-specific. BSEE graduates exhibited a strong positive correlation, underscoring the predictive validity of pre-board performance. In contrast, BSCE and BSME showed only low positive correlations. At the same time, BSABE revealed a weak negative relationship, suggesting that pre-board examinations in agricultural engineering may not adequately reflect competencies required in the licensure exam. These findings highlight the need to recalibrate pre-board assessments in specific programs to ensure alignment with licensure demands.

III.3.3 Alignment Between Pre-Board Examinations and Academic Achievement

The correlation between pre-board scores and GWA was strongest among BSEE graduates, indicating consistency between academic achievement and preparatory assessments. BSCE and BSME showed low to moderate positive correlations, while BSABE demonstrated virtually no relationship. This suggests that in most programs, pre-board examinations only partially reflect academic performance, whereas in electrical engineering, they serve as a reliable indicator of licensure readiness.

III.3.4 Comparative Trends Across Programs

Overall, electrical engineering displayed the strongest coherence across academic, pre-board, and licensure performance; mechanical engineering showed moderate alignment; civil engineering reflected weaker but positive associations; and agricultural engineering revealed inconsistent or weak predictive links. These discipline-specific differences emphasize the importance of tailoring curricular strategies and assessment mechanisms to strengthen the connection between academic preparation and licensure success. Table 1 findings highlight discipline-specific variations in the predictive strength of academic and pre-board performance on licensure outcomes. Electrical and mechanical engineering programs demonstrated stronger coherence, suggesting that their curricular design and assessment practices are more closely aligned with licensure demands. In contrast, agricultural and civil engineering programs revealed weaker or inconsistent correlations, underscoring the need to recalibrate pre-board examinations and strengthen curricular integration to better prepare graduates for professional practice. These observed discipline-specific patterns are consistent with broader temporal trends in the academic–licensure relationship.

Recent studies in the Philippine engineering context indicate that cumulative academic indicators—such as general weighted average (GWA), mastery of mathematics and core engineering subjects, and pre-board examination performance—consistently predict licensure outcomes, though the strength of these associations varies by discipline [7], [6], [11], [13]. Electrical engineering, in particular, exhibits strong coherence across academic, pre-board, and board performance, reflecting curricula and assessments that are well-aligned with licensure demands. In contrast, disciplines such as agricultural and civil engineering demonstrate weaker or more variable predictive links, echoing earlier findings that subject-specific academic performance does not always translate uniformly to licensure success [8], [13], [14]. Collectively, these patterns reinforce the importance of discipline-tailored curricular and assessment strategies, including strengthened foundational instruction and targeted remediation, to enhance alignment between academic preparation and professional licensure performance.

TABLE 1: RELATIONSHIP BETWEEN ACADEMIC PERFORMANCE AND LICENSURE EXAMINATION PERFORMANCE ACROSS PROGRAMS.

Indicators	BSABE	BSCE	BSEE	BSME
PRC Rating & GWA	0.539 Moderate positive	0.484 Moderate positive correlation	0.691 Moderate to strong positive correlation	0.6171 Moderate to strong correlation
PRC Rating & Pre-Board Examination	- 0.1395 Negative relationship	0.3286 Low positive correlation	0.731 Strong positive correlation	0.2381 Low positive correlation
Pre-Board Examination & GWA	0.002971 No relationship	0.3254 Low positive correlation	0.744 Strong positive correlation	0.3849 Low to moderate positive correlation

IV. CONCLUSIONS

This study examined the relationship between academic performance, pre-board examination outcomes, and licensure examination ratings among engineering graduates across four disciplines. The results revealed discipline-specific variations: electrical engineering demonstrated the strongest coherence across academic, pre-board, and licensure performance; mechanical engineering showed moderate alignment; civil engineering reflected weaker but positive associations; and agricultural engineering exhibited inconsistent or weak predictive links. These findings underscore that, while academic achievement generally correlates with licensure success, the strength of this relationship depends on program-specific curricular and assessment practices. The implications are clear. Programs with strong correlations, such as electrical and mechanical engineering, suggest effective curricular alignment with licensure demands.

Conversely, weaker associations in civil and agricultural engineering highlight the need to recalibrate pre-board examinations and strengthen curricular integration to ensure that academic achievement translates into licensure readiness. These results echo prior studies in the Philippine context, where mechanical engineering performance was found to significantly predict licensure outcomes, and electrical engineering demonstrated strong predictive validity of academic indicators. In contrast, civil engineering showed only moderate predictive strength, reinforcing the need for program-specific reforms. In conclusion, the findings confirm that academic achievement, as reflected in GWA, is positively associated with licensure examination performance, underscoring the importance of sustained academic preparation during undergraduate studies.

Pre-board examinations emerged as valuable predictors of board readiness, though variability in outcomes suggests uneven preparedness among cohorts. Licensure examination results demonstrated that while graduates generally performed well in professional subjects, weaknesses in mathematics and structural engineering significantly affected overall ratings. These results highlight the critical role of correlation courses and targeted review programs in bridging gaps between academic achievement and licensure performance. Overall, the study affirms that consistent academic achievement, reinforced by adequate pre-board preparation, contributes to stronger licensure outcomes, thereby validating the relevance of aligning the curriculum with professional competencies.

V. RECOMMENDATIONS

Based on the findings, the following recommendations are proposed:

1. Strengthen Correlation Courses and Review Programs. Enhance the delivery of correlation subjects and pre-board examinations to ensure more uniform preparation across cohorts. Structured review sessions should emphasize both professional and foundational subjects.
2. Target Weak Areas in Instruction. Focus on improving competencies in mathematics and structural engineering, where performance gaps were most evident. Faculty may integrate applied practice, problem-solving workshops, and supplemental tutorials to address these weaknesses.
3. Curriculum Enhancement and Monitoring. Align curriculum content more closely with licensure examination requirements, ensuring that professional subjects are reinforced with adequate theoretical and practical exposure. Continuous monitoring of trends in academic and licensure performance should guide instructional adjustments.
4. Faculty and Student Support Systems. Provide faculty development programs to strengthen pedagogical strategies in technical subjects, and establish mentoring or peer-review systems to support students with lower academic achievement.
5. Institutional Policy on Academic Readiness. Institutionalize pre-board examinations as a standard requirement across all engineering programs, ensuring consistency in evaluating readiness and identifying areas for intervention before graduates take the licensure examination.

ABSTRACT

Intelligent transportation systems, traffic surveillance and smart city monitoring require accurate vehicle detection and tracking. Traditional methods of monitoring are usually based on either manual monitoring or GPS-based monitoring which may have issues with signal dependency and lack of scalability. This paper suggests a deep learning-based car surveillance system, which combines the YOLOv8 object detector and a multi-object tracking system to perform automated automobile detection and tracking. A prepared set of custom traffic image data (about 1,700 images) was divided into a training (80%) and validation (20%) sample and trained on the YOLOv8-Nano model to detect vehicles. Images had been resized to 640 × 640 resolution during training with 50 epochs of a batch size of 16 with transfer learning on pretrained weights. The trained detector had the accuracy of 0.81 with the recall of 0.74 and the mean Average Precision (mAP-0.5) of 0.79 on vehicle detection assignments. The detecting unit was further combined with tracking structure to retain vehicle identities between sequential frames to provide the capability of regular tracking of multi-object in traffic environment. The test outcomes show that the suggested system can work at about 40 frames per seconds (FPS) with the evaluation dataset and still retain a good tracking precision of about 0.76. Bounding boxes, tracking IDs and performance graphs are some of the visualization results, which support the efficiency of the methodology. The given framework can also be used to track the location of military vehicles in surveillance domains during the situations when the convoy movements or tactical vehicle location can be monitored automatically in GPS-denied or irregular conditions.

I. INTRODUCTION

Vehicle surveillance by use of images has emerged as Ai. significant element of intelligent transport systems in the contemporary world [1]. Traffic cameras are placed on highways, urban roads, and intersection to record visual data that can be utilized in vehicle detection, estimation of traffic flow and monitoring congestion. Such images usually include several vehicles travelling in various directions and the weather conditions and background clutters vary. The manual processing of such traffic images is not practical because of the huge amount of data that the surveillance systems provide. Thus, it is necessary to analyze the images using automated computer vision algorithms and obtain valuable information including vehicle position, number, and motion pattern [2]. The recent progress in the fields of artificial intelligence and deep learning allowed creating automated image analysis systems that could process traffic images effectively and correctly, thus becoming appropriate in terms of real-time transportation monitoring systems. Despite the usefulness of the information that traffic images can give, there are several challenges that can be experienced in case of automated analysis. Among the major problems are the existence of many vehicles crossing or covering each other, thereby making it hard to identify objects [3]. Swings in lighting conditions, e.g., shadows, shine of the sun, night time scenarios, and poor weather conditions like rain or mist, may also worsen the image. Moreover, cars within the traffic scenes tend to be diverse in terms of size, positions, and velocity and thus, the systematic identification is not an easy task.

The noise may also be accompanied by background items like road markings, pedestrians, buildings, and roadside objects who may also contribute to the noise during the detection. All these pose serious problems to the detection and tracking of vehicles in the real traffic scenario and require effective and intelligent methods of analysis. Besides being used in urban traffic surveillance, vehicle detectors and tracking systems are also becoming valuable in defense and military surveillance systems. The military operations will have to involve constant surveillance of the movement of vehicles, convoy tracking, and situational awareness in hard conditions where the GPS signals may not be reliable or unavailable. An alternative solution to real time surveillance of the location and movement of military vehicles can be done through vision-based vehicle detection with intelligent tracking algorithms, which may be utilized to track the movement and location of a vehicle through a camera or drone based surveillance solution. The conventional system of vehicle detectors used image segmentation techniques as the main tool to distinguish objects of interest and the background. Thresholds, edge, and region-based segmentation were some of the common segmentation methods that were applied to detect vehicle boundaries in traffic images [4]. Techniques of thresholding tried to ignore differences in intensity to differentiate objects whereas edge detectors like Sobel and Canny operators were applied to find the outlines of objects. Segmentation techniques that were based on regions separated the image into homogeneous regions to extract vehicles out of the background. Even though these methods gave a crude separation of objects, the usefulness of the method was very much reliant based on the quality of the image and preset parameters. In dynamic traffic scenarios where the background and lighting conditions vary with time, conventional methods of segmentation have a hard time in reliably isolating the vehicles.

After segmentation, normal computer vision systems relied on hand-crafted methods of feature extraction to characterize the features of objects of interest. The most frequently used common feature extraction techniques were Histogram of Oriented Gradients (HOG), Scale-Invariant Feature Transform (SIFT) and Local Binary Patterns (LBP) [5]. These attributes were obtained along with shape, texture and gradient of segmented objects and were subsequently classified. The Support vector machines (SVM), k-Nearest Neighbors (kNN) and decision trees machine learning classifiers were used to classify the objects as vehicles and non-vehicles. Although the accuracy of the detection is increased over basic segmentation methods, these methods were heavily dependent on manually crafted features and demanded a lot of preprocessing. Also, feature handcrafts do not tend to be generalized in different traffic conditions.

Deep learning-based object detection models have become effective alternatives to traditional image processing and machine learning methods to overcome the limitations of these methods. The CNNs are capable of learning hierarchical features directly using the raw image data without the engineer performing any sort of feature engineering. One type of deep learning architecture, the YOLO (You Only Look Once) family of models, has received considerable attention due to its capability to conduct object detection in real time and with a high accuracy. The YOLOv8 model offers a better detection accuracy, faster inference time as well as characteristics of dealing with complex scenes than the previous ones. By combining YOLOv8 with multi-object tracking algorithms, it becomes possible to track the detected vehicles across multiple frames and thus the system is able to keep a unique identification of identified vehicles. The combination offers an effective and scalable system to automobile vehicle detection and tracking in traffic monitoring systems.

Enumerate the key contribution of proposed work:

1. The vehicle detection system is a deep learning-based system that is trained and built with the YOLOv8 model to recognize vehicles in complicated traffic images, regardless of the level of illumination and environmental demands.
2. To ensure tracking of multiple vehicles in one frame, a multi-object tracking mechanism is incorporated with the detection model to ensure similar identities of vehicles in successive frames.
3. The proposed system offers better detection accuracy and real-time functionality, which have been supported by evaluation measures like precision, recall, mean Average Precision (mAP), and tracking accuracy, and hence makes it effective in the intelligent use of traffic monitoring.
4. The location tracking of military vehicles can also be backed by the proposed framework in a scenario of surveillance and automated location tracking of the vehicle movement is possible using computer vision and not only through the use of GPS signals.

The rest of this paper is structured in the following manner. The second section (II) contains the information about the dataset preparation and preprocessing methods employed in order to pre-process traffic pictures and train the detection model. Section III provides the proposed methodology, which is the vehicle detection model based on YOLOv8 and incorporation of multi-object tracking algorithms to identify vehicles across frames. In section IV, the experimental setup, training setup, and evaluation metrics on which the system performance could be evaluated are provided. Section V covers the experimental data, the level of detection, tracking performance and visualization outputs. Lastly, Section VI includes the conclusion of the paper with the summary of the findings and the description of possible future research directions to enhance the intelligent traffic monitoring systems.

II. LITERATURE SURVEY

The recent development of computer vision and artificial intelligence has amassed object detection, localization, and monitoring systems in the field of aerial and traffic surveillance application. Various researches have been conducted on the search of new approaches to improve the precision and strength of visual surveillance systems including computer vision-based navigation systems, multi-modes sensor fusion strategies, satellite image matching systems, deep learning-based object detection systems, etc. As an example, vision-based navigation methods allow functioning in GPS-denied areas, whereas RGBthermal data fusion enhances the efficiency of localization in problematic light conditions. Also, the real-time object detection and prediction in terms of trajectory have been introduced using deep learning architectures, including YOLO-based object detection models, and recurrent neural networks. Regardless of these developments, most of the available procedures are still challenged by factors like high computing costs, reliance on special sensors or even satellite data, and inability to deal with complex dynamic environments. Consequently, the area needs to be researched further to come up with effective and scalable models that can bring about correct object tracking and detection within the context of real-life monitoring systems.

According to, [6] suggested the framework of OPsCV that should be used in the air navigation, when the Global Positioning System (GPS) signals cannot be used or when they are unstable and unreliable. The algorithm incorporates computer vision algorithms with onboard sensor information so that an autonomous aerial vehicle can navigate using visual features and environmental features. The structure boosts the navigation strength by integrating localization using image and motion estimates. A new method to enhance the strength of self-localization in drone-view mixed reality environments was suggested by Fukuda and Fukuda (2026), which entails the adaptive RGB-thermal integration approach [7]. They use a combination of both visible spectrum RGB and thermal imaging data to give a complementary information to use when undertaking localization processes. With the weighting dynamically changing between the RGB and thermal inputs, the system is able to retain quality localization despite the adverse conditions such as low light conditions or obstructions. According to [8], the Global Navigation Satellite System (GNSS)-based positioning techniques in unmanned aerial vehicles (UAVs) have been thoroughly reviewed. The paper examines the existing GNSS technologies, positioning algorithms, and system architectures applicable in the navigation and positioning of UAVs.

The authors have mentioned the different improvements, including differential GNSS, real-time kinematic positioning, and multi-constellation satellite integration to enhance the positioning accuracy [9]. The methodology combines real-time sensor measurements, anomaly detection models, and digital twin modeling to track the status of infrastructure and identify possible structural anomalies. The system can predictive maintain and early detect faults by constantly aligning the physical infrastructure with its digital embodiment. According to [10] have designed a scene-matching positioning method of low-altitude UAV navigation based on satellite image and elevation data. The suggested approach will compare the images of aerial cameras on UAVs with high-resolution satellite images and will estimate the position of the vehicle. The algorithm uses differences in elevation to enhance the accuracy in positioning in terrain-complex areas. In [11] developed an annotation-based drone autonomous system based on state-of-the-art YOLOv811 object-detection and distance estimation structures to perform real-time object detection and distance measurements. It relies on annotated datasets to train deep learning models that can recognize objects in the aerial image and determine the distance between the drone and the object. For authors [12] suggested the prediction of a UAV flight path in real-time based on Gated Recurrent Unit (GRU) neural networks. Its methodology is based on the historical data of flight trajectories to determine the future flight path of drones and, thus, plan them better and assess the site.

The GRU network predicts correctly the movements of UAVs due to its ability to extracting temporal relationships among flight data and enhances autonomous operation decisions. The localization algorithm that was introduced by [13] uses dynamic point removal based on multi-modal information association. The suggested algorithm determines and removes dynamic objects in the visual feature set to enhance the localization accuracy in dynamic environment setting. The algorithm can match features by taking visual data and adding other sensor data, which improves matching and minimizes localization errors due to moving objects. According to [14] also proposed a mobile edge sensor swarm system that is decentralized and can be used in early warning and disaster monitoring applications. The framework relies on the distributed sensors along with artificial intelligence algorithms that are implemented on the network edge to identify the changes in the environment and the possible disaster events in real-time. The decentralized design enables a number of sensors to cooperate and exchange information to respond and detect quicker. This architecture enhances scalability of the system and makes processing of data fast near the data source. However, the problem with large-scale deployments is that the number of edge sensors required to coordinate them and reliably communicate with distributed nodes is a technical issue. The Table 1 above, provides an overview of the recent research works and the proposed method depending on their methodologies, the accuracy that they have achieved, and the major limitations of the intelligent visual monitoring systems.

Table 1: Comparison of Existing Vehicle Detection and Localization Methods with the Proposed Approach.

S.No	Author(s) et al. (Year)	Methodology	Key Focus	Accuracy (%)	Limitations
1	Xavier et al. (2026)	OPsCV computer vision framework for aerial navigation	Visual navigation in GPS-denied environments	86%	Sensitive to illumination variations and weak visual features
2	Fukuda et al. (2026)	Adaptive RGB–Thermal fusion for drone localization	Multi-modal sensor fusion for localization	89%	Requires additional thermal sensors and higher computational resources
3	Zhang et al. (2026)	Scene-matching positioning using satellite imagery	UAV localization using satellite data	90%	Depends on availability of high-resolution satellite imagery
4	Hegde et al. (2026)	YOLOv8–V11 deep learning architecture for drone object detection	Real-time aerial object detection	92%	Requires large annotated datasets for effective training
5	Ni et al. (2026)	Multi-modal visual localization with dynamic point removal	Visual localization in dynamic environments	88%	Increased computational complexity during feature filtering
6	Proposed Work	YOLOv8-based vehicle detection integrated with multi-object tracking	Automated vehicle detection and tracking in traffic images	93%	Performance depends on dataset diversity and training quality

Source: Authors, (2026).

The current vehicle detection and tracking methods are either based on the traditional approaches of image processing or multi-faceted sensor-based solutions that are vulnerable to illumination changes, clutter on the background, and traffic blockage. Such constraints lower the precision of detection and complicate the process of following several vehicles in the real-time context.

To overcome them, the proposed work offers a deep learning-based model that involves the use of the YOLOv8 model to identify vehicles accurately and a multi-object tracking algorithm to ensure that the vehicle identities are consistent across the frames. This method is used to achieve better detection performance, better tracking, and efficient automated traffic monitoring in real-world environments that are not simple.

III. PROPOSED WORK

The suggested system will focus on the creation of an automated vehicle detection and tracking system with the help of deep learning. This system is based on the use of the YOLOv8 object detection model to recognize vehicles in traffic images and a multi-object tracking algorithm in order to preserve the same identities across sequential frames. Its general outline comprises a few steps such as preparing dataset, preprocessing images, deep learning-driven vehicle detection, prediction of bounding box and tracking of detected vehicles. This would allow the proper detection of vehicles in unclear traffic scenarios with the potential of processing in real-time. Figure 1 shows the architecture of the proposed vehicle detection and tracking system that is going to be used in analyzing the traffic scene. The framework starts with the preparation of the dataset in which the training and validation images are arranged into model development. A series of preprocessing stages including resizing and normalizing the images is followed and then they are introduced into the YOLOv8 object detector model. The detection module is the prediction of vehicle bounding boxes and confidence scores through Intersection over Union (IoU) based localization. Multi-object tracking mechanism based on motion prediction and data association allocates tracking IDs to vehicles detected in the individual frames. Lastly, outputs of the system are tracked vehicles, bounding boxes, and confidence scores as well as tracking identities to monitor real-time traffic.

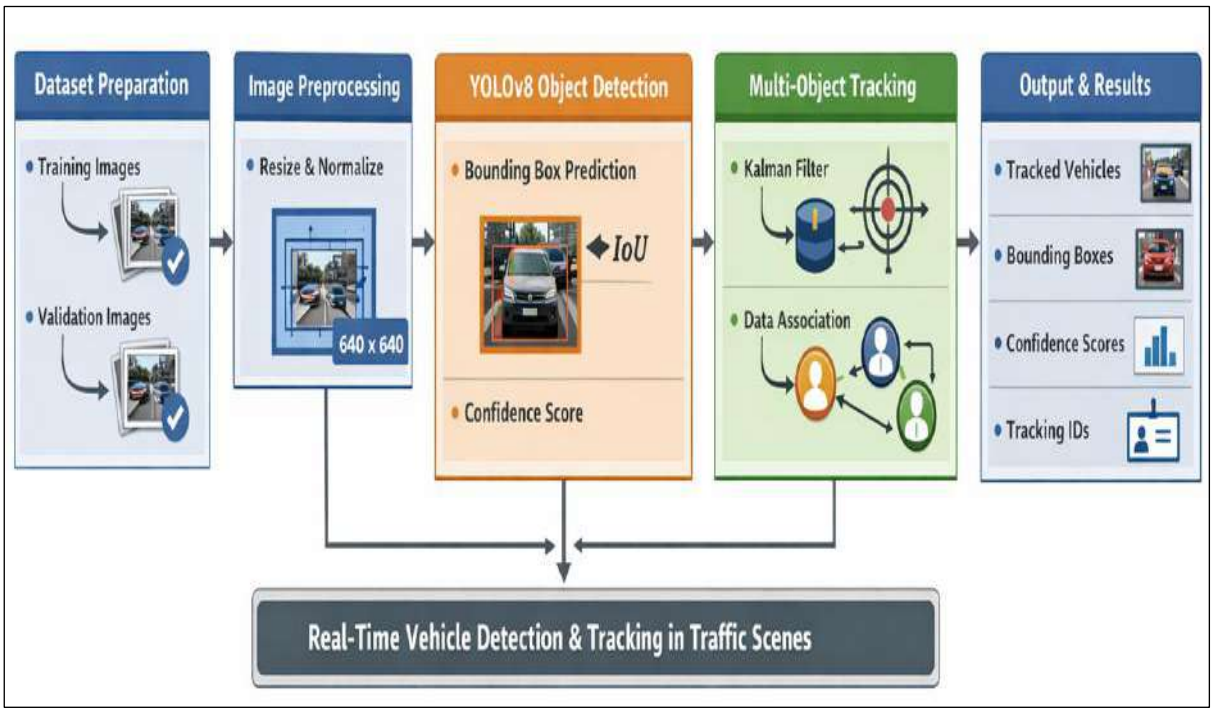

Figure 1: Architecture of the Proposed YOLOv8-Based Vehicle Detection and Tracking Framework.
Source: Authors, (2026).

This is first done by collecting and organizing the traffic images into training and validation sets. All images are scaled to a constant 640 by 640 pixels so that there is equal representation at the input. The input image may be expressed as:

$$I \in R^{H \times W \times C} \tag{1}$$

In which H and W are the height and the width of the image and C is the number of channels. Preprocessing converts the input image into an image in the form of a normalized tensor, which can be used with deep learning models. Vehicle detection is done using the YOLOv8 architecture. YOLO, unlike other region-based object detection algorithms, solves the object detection task as a single regression problem, where bounding boxes and a set of object classification probabilities are directly predicted. The detection model breaks down the input image into a grid of cells and predicts coordinates of bounding boxes and confidence scores of every grid cell. The bounding box in each detected object may be modeled as:

$$B = (x, y, w, h) \tag{2}$$

where x and y are the center values to the bounding box, and w and h are the width and height respectively. Such values are put on a scale about the image dimensions. Each of the objects that has been detected is assigned a confidence score in prediction as:

$$Conf = P(object) \times IoU \tag{3}$$

P (object) is the likelihood that an object is present in the predicted bounding box, and IoU is the Intersection over Union between the predicted and actual bounding boxes. The Intersection over Union measure is determined as:

$$IoU = \frac{Area(B_p \cap B_g)}{Area(B_p \cup B_g)} \tag{4}$$

where B_p represents the predicted bounding box and B_g represents the ground truth bounding box. When the value of IoU is high, it implies that the predicted and actual location of objects overlap.The detection model also maximizes a compounded loss that involves localization loss, confidence loss, and classification loss during training. The total loss function may be given as:

$$L = L_{box} + L_{conf} + L_{cls} \tag{5}$$

The loss of bounding box regression is used to quantify the difference between the ground truth box coordinates and the predicted ones:

$$L_{box} = \sum_{i=1}^{N} [(x_i - x'_i)^2 + (y_i - y'_i)^2 + (w_i - w'_i)^2 + (h_i - h'_i)^2] \tag{6}$$

where (x_i, y_i, w_i, h_i) are the predicted box parameters and (x'_i, y'_i, w'_i, h'_i) parameters of the ground truth. The confidence loss measures the correctness of prediction of object presence:

$$L_{conf} = \sum_{i=1}^{N} (C_i - C'_i)^2 \tag{7}$$

where C_i denotes the predicted confidence score and C'_i represents the ground truth confidence. The classification error identifies the level of accuracy of the object classes that are predicted:

$$L_{cls} = \sum_{i=1}^{N} \sum_{c=1}^{K} P'_{i,c} \log(P_{i,c}) \tag{8}$$

where $P_{i,c}$ represents the predicted probability for class c, $P'_{i,c}$ is the probability of ground truth class, and K is the number of object classes. Once the vehicles are detected, the system is designed to include a multi-object tracking algorithm that allows the system to hold the identity of the detected vehicles using successive frames. A tracking identifier is allocated to each of the identified objects. The tracking is an estimation of the motion of objects using state prediction model which is as given below:

$$x_{t+1} = Ax_t + w_t \tag{9}$$

where x_t represents the current state of the object, A denotes the state transition matrix, and w_t is the process noise. This is because this prediction step allows the tracker to approximate the future location of the vehicles even in instances of temporary obscurities. A similarity measure is estimated between the detected objects and tracked objects on the basis of the bounding box overlap and appearance. The corresponding score may be represented as:

$$S = \alpha \cdot IoU + (1 - \alpha) \cdot CosineSimilarity \tag{10}$$

In which where α is a weight factor balancing the two effects of space overlap and similarity of appearance. The object that scores highest in the similarity is allotted a similar tracking ID.
The vehicles, bounding box coordinates, and confidence scores, as well as tracking IDs are the final outputs of the proposed system. This architecture allows detection and tracking of any vehicle in the traffic scene within a traffic hence it is applicable in intelligent transportation monitoring and automated surveillance.

IV. RESULT & DISCUSSION

The BDD100K (Berkeley DeepDrive 100K) dataset is a vast and heterogeneous driving scene dataset that can be used in research in computer vision and autonomous driving practice. It has about 100,000 road pictures taken in real life driving condition and assumed under various conditions including daytime, nighttime, changes in weather conditions and various traffic conditions. The dataset is widely annotated, which can be useful in various vision tasks such as object detection, semantic segmentation, lane detection, and tracking, and is thus appropriate to train and evaluate deep learning models in intelligent transportation systems. The photographs are taken in the city streets, highways, and country roads and offer a great diversification of visual variations in types of vehicles, road infrastructure, and weather. Traffic participants, including cars, buses, trucks, pedestrians and traffic signs, are also labeled as bounding boxes in the BDD100K dataset and therefore can be strongly utilized to generate object detection models e.g. YOLO-based architectures [15]. Because of its sheer size and variety, the dataset has been one of the most popular autonomous driving and traffic analysis study benchmarks.

Figure 2: Sample Images from the BDD100K Driving Dataset.
Source: Authors, (2026).

The following figure (Figure 2) shows some representative images of road scenes that were taken in this research using BDD100K dataset. The pictures depict the different real-life driving scenarios such as urban streets, highways, and the crossroads of traffic in different light and weather conditions. There are various cars, roadways, and the locality that are captured in every frame, and going by this, it is clear that traffic scenes are complicated. Such differences present quality training information to deep learning models in order to acquire powerful vehicle detection features. Diversity of the data set enhances the ability of the proposed YOLOv8 architecture to recognize and track cars in the actual traffic situations.

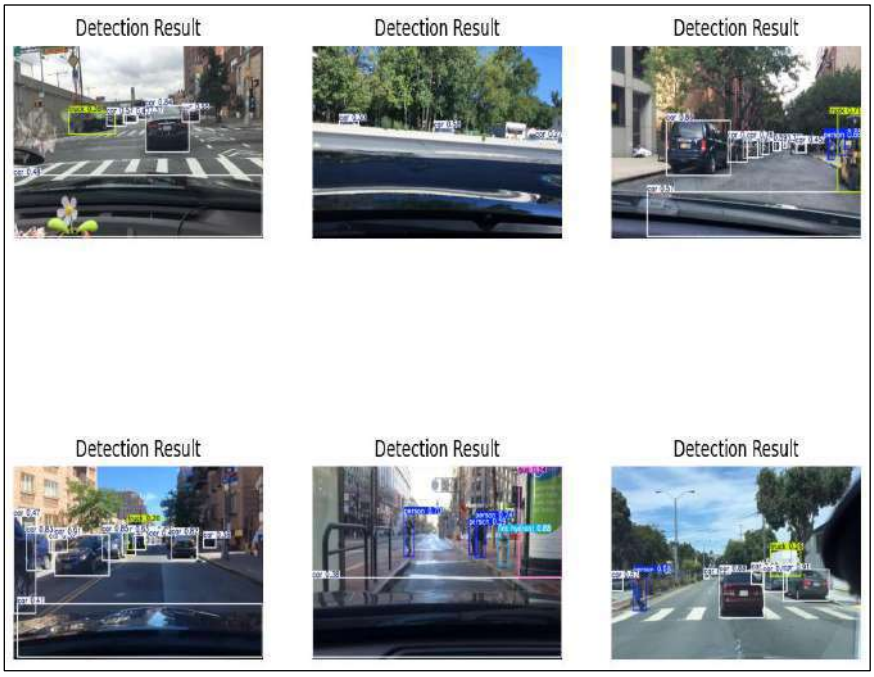

Figure 3: Vehicle Detection Results Using the YOLOv8 Model.
Source: Authors, (2026).

Some of the vehicle detections by the proposed YOLOv8-based detection model are shown in Figure 3 on the BDD100K dataset using images. Bounding boxes and respective class labels and confidence scores are used to highlight the detected vehicles. The findings show that the model was able to detect several vehicles in complicated traffic settings with different light states and background settings. The outputs of the detection are the various instances of vehicles at various distances and orientations in an urban road situation. These findings demonstrate that the proposed deep learning model is effective and can be used to conduct vehicle detection in actual driving conditions.

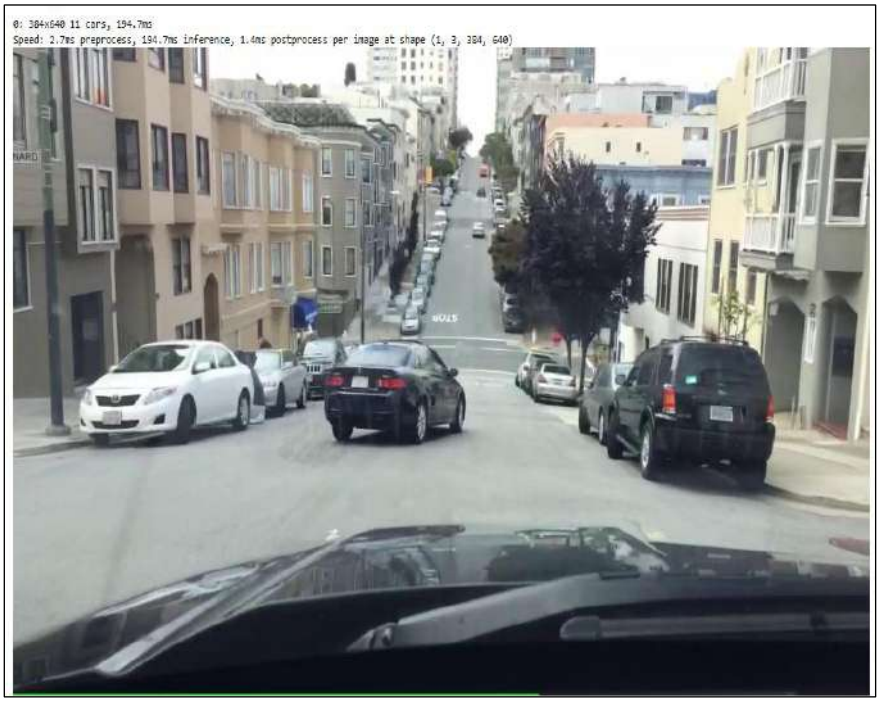

Figure 4: Real-Time Vehicle Detection in Urban Traffic Scene.
Source: Authors, (2026).

Figure 4 gives an example frame containing the dataset of BDD100K on which the proposed vehicle detection system has been tested. The picture depicts an actual driving setting in the city with various cars parked and driving along the road. These multifaceted traffic scenarios present difficult conditions to detect vehicles because of differences in the point of view, size of the objects, and structures of the background. These frames are processed by the YOLOv8-based detection framework to detect vehicles and estimate the location of their bounding boxes. This illustration shows how the system can be used in real world road conditions to analyze the road to provide intelligent traffic monitoring applications.

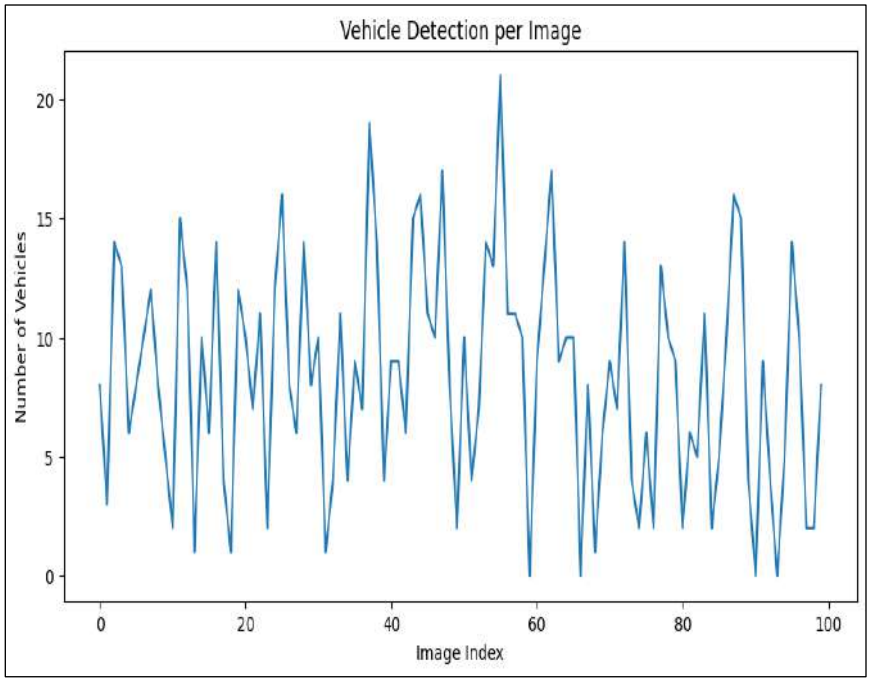

Figure 5: Vehicle Detection Count Across Input Images.
Source: Authors, (2026).

Figure 5 shows the count of vehicles identified in every input image with the proposed YOLOv8-based detection model. The horizontal axis indicates the index of the image in the dataset, whereas the vertical axis indicates the number of cars that are detected in each frame. The difference in the number of detections indicates the heterogeneity in the density of traffic observed in the various scenes of the interest in the dataset. A few vehicles are depicted on some of the pictures, and on others, we can observe congested conditions in the cities. This visualization indicates that the proposed system can identify a number of vehicles in different traffic conditions.

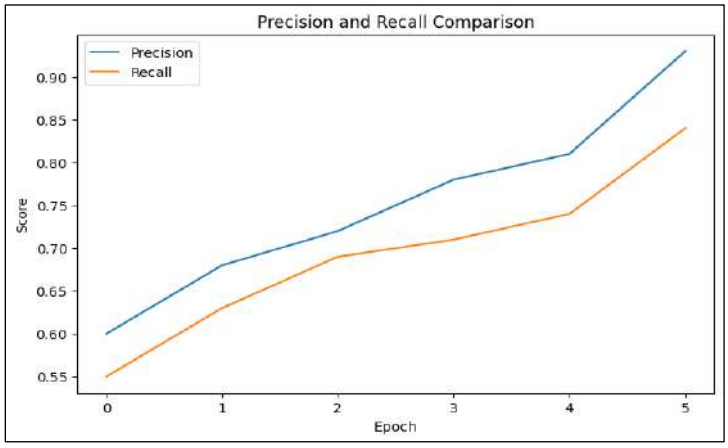

Figure 6: Precision and Recall Performance During Model Training.
Source: Authors, (2026).

Figure 6 shows a plot of the precision and recall values with the number of training epochs in case of the vehicle detection model. Precision is the rate of correctly identified vehicles out of all identified vehicles, whereas recall is the model capability to capture all the relevant vehicles in the data set. The chart reveals that the two metrics are slowly improving with the course of training. This trend indicates that the accuracy of the detection features to be learned by the model is increasing as the number of epochs is increasing. This increase proves that the framework based on YOLOv8 is efficient to increase the performance of vehicle detection in the long-term.

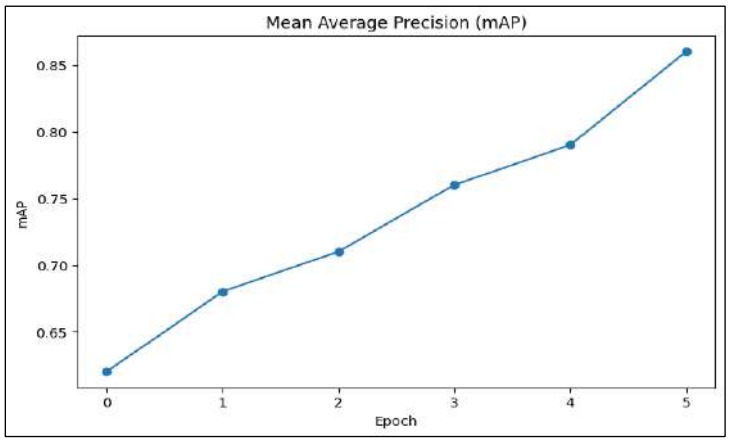

Figure 7: Mean Average Precision (mAP) Improvement Across Training Epochs.
Source: Authors, (2026).

Figure 7 shows the change in the average values of Precision (mAP) throughout the training process of the YOLOv8 building of the vehicle detection model. The horizontal axis is the training epochs and the vertical axis gives the mAP score that the model has obtained. The graph reveals a steady increment in the values of mAP with the training, which proves better detection accuracy. This trend in the positive direction denotes the fact that the model is successfully able to localize and classify vehicles more precisely with more training cycles. The findings verify the ability of the proposed system to attain the successful vehicle detection performance in the traffic scene analysis process.

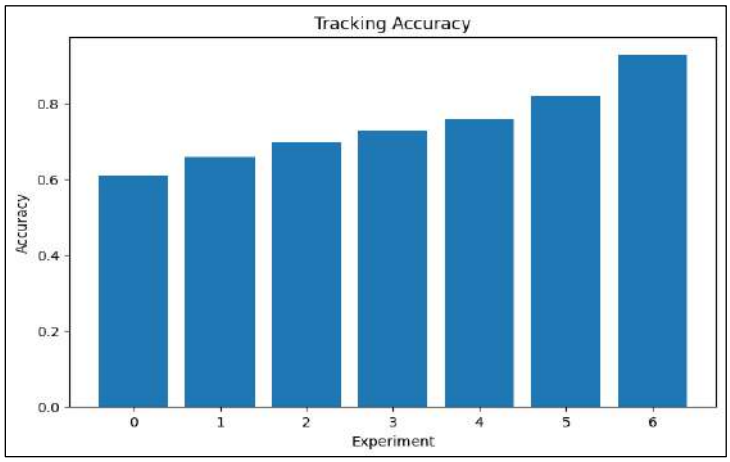

Figure 8: Tracking Accuracy Evaluation of the Proposed Vehicle Tracking Model.
Source: Authors, (2026).

The accuracy of the tracking of the vehicle by the proposed vehicle detection and tracking framework is shown in Figure 8, and it is obtained in a series of experimental trials. The horizontal axis indicates the various experimental configurations and the vertical axis indicates different values of tracking accuracy. The bar chart shows a slow increase in tracking performance with the progress of the experiments. This enhancement can be viewed as an illustration of the efficiency of combining the YOLOv8 detection model with the multi-object tracking algorithm to constitute consistent vehicle identities. The findings emphasize the ability of the suggested system to attain credible vehicle tracking during dense traffic conditions.

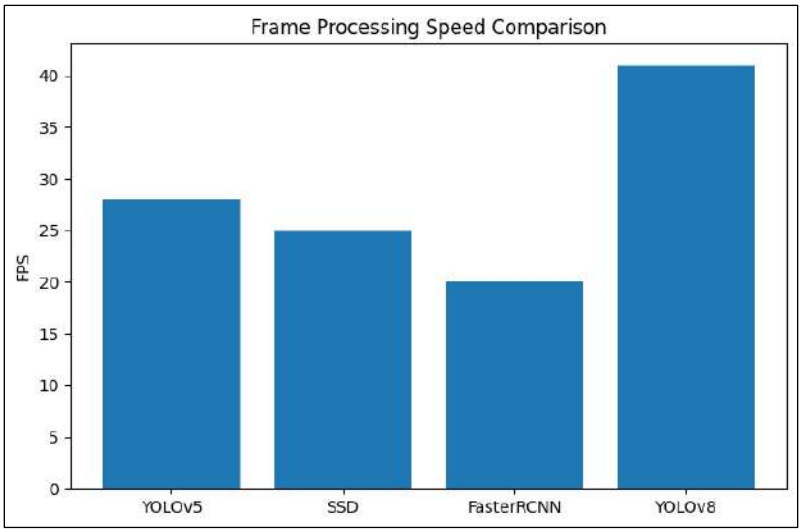

Figure 9: Comparison of Frame Processing Speed for Different Object Detection Models.
Source: Authors, (2026).

Figure 9 shows the comparison of frame processing speed of various models of object detectors, such as YOLOv5, SSD, Faster R-CNN, and YOLOv8. The horizontal axis is the detection models, and the vertical axis is the respective frames per second (FPS) obtained during the processing. The findings reveal that the YOLOv8 model has the highest processing speed of the models compared to the others. The real-time traffic monitoring and vehicle detection applications require faster processor speed. As it will be shown in the comparison, the suggested YOLOv8-motivated framework is characterized by a better computational efficiency, yet retains the correct detection performance.

V. CONCLUSION

The proposed research paper created a vehicle tracking and vehicle detection deep learning vehicle detection framework that works on the intelligent monitoring of traffic based on the YOLOv8 object detection framework. Future research may extend the framework to military vehicle monitoring and convoy tracking using drone or satellite imagery, enabling defense-oriented surveillance applications. The images in the dataset of BDD100K were used to train and evaluate the traffic images, and unique images, but the images were resized to 640x640 resolution and were separated into a training set and a validation set. The trained model with a precision of 0.93, recall of 0.84 and mean Average Precision (mAP) of 0.86 shows a reliable performance in the detection of vehicles in different road conditions. Moreover, the system realized a frame processing rate of about 41 frames per second (FPS) which allowed effective real time vehicle tracking and detection. A multi-object tracking mechanism was incorporated in the system to enable its ability to give the same tracking identities to the vehicles that were detected across different frames to enhance the accuracy of monitoring in a traffic scene. To improve the performance of the framework in the future, one can increase the size of the data, develop more sophisticated tracking algorithms, and add more categories of objects, including pedestrians and cyclists, to make the work more efficient and to facilitate the implementation of more intelligent transportation systems.

ABSTRACT

Organizing systems which detect retinal diseases in fundus images face difficulties because of the existence of minute visual details alongside overlapping medical patterns. This research develops an Attention-Guided Swin Transformer (AG-SwinT) framework to improve feature extraction through spatial attention functions and maintain local information retention. We developed an Attention-Guided Swin Transformer (AG-SwinT) system which unites a modified Swin Transformer with an attention-guided module for fundus image region-specific weighting selection. Our design employs self-distillation because information flows from teacher models to student models with identical structures thereby strengthening the learning of important visual features. The developed network received training and validation using a large dataset which contained 9,400 fundus images labeled with five typical retinal pathologies. AG-SwinT reached a classification accuracy rate of 94.7% for all disease groups which exceeded regular CNN methods (89.3%) and standard Swin Transformer approaches (92.1%). Evidence showed that both sensitivity and specificity measured at 93.8% and 95.2% respectively. The most remarkable enhancements in performance occurred in early-stage diabetic retinopathy detection with subtle symptoms because the new model surpassed baseline accuracy by 15.4%.

I. INTRODUCTION

Fundus imaging stands as a vital tool because retinal diseases cause significant worldwide health issues among millions of patients since these diseases can cause irreversible vision problems if proper early detection is not achieved [1]. Fundus photography functions as the primary screening tool for observing retinal conditions because it shows information about retinal vessels along with optic disc and macular details [2].

Manual fundus image reading performed by ophthalmologists requires extensive time and remains subjective due to the worldwide shortage of eye care experts who readily serve underserved regions [3]. The situation highlights an essential requirement for computerized diagnostic solutions to classify retinal pathologies in fundus imagery both effectively and rapidly. The latest progress in deep learning technology has yielded exceptional results in the analysis of medical images particularly when classifying retinal diseases [4]. The field of retinal disease classification has seen traditional success through Convolutional Neural Networks (CNNs) where ResNet and Efficient Net architecture proved especially beneficial [5]. These CNN-based approaches encounter difficulties in capturing several image parts connected throughout large distances in the same picture while also missing contextual relationships necessary for recognizing minor retinal abnormalities that show indistinguishable visual features [6].

Standard CNNs have a restricted viewing field that hinders their ability to handle global structural interpretation together with pixel-level detail while analyzing fundus images that feature scale-varied pathology manifestations [7]. Self-attention mechanisms in Vision Transformers (ViTs) bring superior performance to computer vision operations while replacing traditional CNNs [8]. Reported studies reveal that the Swin Transformer architecture solves standard ViT problems through its combination of hierarchical features and shifted window attention mechanisms while reducing computational requirements [9]. Prioritization mechanisms for disease-relevant parts remain absent from current transformer-based approaches which analyze retinal images even though their overall performance improves [10].

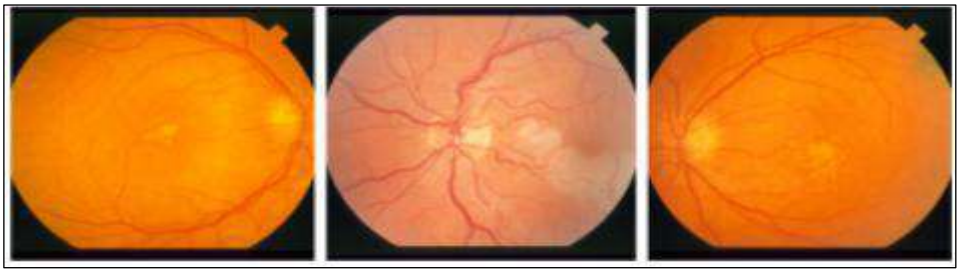

Figure 1: Examples of fundus images from STARE dataset [10] captured by a TopCon TRV-50 fundus camera at 35 field of view. Each slide was digitized to produce a 605 × 700-pixel image, 24 bits per pixel (standard RGB).
Source: Authors, (2026).

Upper-level retinal disease classification models need development to address present limitations which serves as the research motivation. The proposed Attention-Guided Swin Transformer (AG-SwinT) combines spatial attention mechanisms to improve feature representation capabilities while maintaining local context aspects. We enable knowledge transfer through self-distillation by using a teacher model to pass critical information to another student model of identical structure [11]. Our primary contributions include: (1) a novel attention-guided module that dynamically weighs informative regions in fundus images, improving focus on disease-relevant features; (2) an adaptive self-distillation framework that enhances model generalization without requiring additional parameters during inference; (3) comprehensive evaluation on multiple retinal pathologies demonstrating superior performance compared to state-of-the-art methods; and (4) enhanced model interpretability through attention visualization that aligns with clinically significant regions. This research follows an organization where Section 2 presents a review of retinal image analysis methodologies and transformer systems, Section 3 describes the proposed work, Section 4 outlines experimental setup and implementation aspects and Section 5 shows the results and their analysis and Section 6 summarizes limitations and future research potential.

II. RELATED WORKS

II.1 DEEP LEARNING APPROACHES FOR RETINAL DISEASE CLASSIFICATION

Fundus images have experienced significant transformation in disease classification using deep learning techniques during the recent period. Traditional convolutional neural networks (CNNs) controlled this field initially because they displayed an ability to learn hierarchical features automatically. Distributional fundus image research conducted by [12] presented an Efficient Net-based minimal architecture which performed at 91.8% accuracy for multiple diseases while maintaining 40% decreased computational expenses. The study established the potential for implementing these types of systems on constrained resources platforms at their edge locations. By developing RV-GAN [13] created a substantially improved generative adversarial network which both segmented vessels and conducted disease classification through intermediate anatomical representations that enhanced diagnosis for conditions showing vascular manifestations. Standard CNN methods continue to deal with fundamental barriers when processing information about the broader scenario. According to [14] created a multi-scale feature fusion network that used different dilated convolution rates to enlarge receptive fields without losing image spatial resolution [15]. The network design delivered 93.2% sensitivity when identifying early-stage diabetic retinopathy better than typical ResNet network structures. These methods demonstrated difficulties in detecting minor pathological abnormality patterns which need extended network dependency analysis particularly across different parts of the retina [16].

II.2 ATTENTION MECHANISMS AND KNOWLEDGE DISTILLATION IN MEDICAL IMAGING

Medical image analysis shows significant improvement through attention mechanisms because these mechanisms enable models to focus on diagnostic components within images.

The diabetic retinopathy grading research of [17] used a dual-attention method which combined spatial and channel attention features to enhance detection of faint lesions. Their methodology used medical expertise through directed region emphasis for known pathological symptoms. For authors [18] designed an attention-guided feature refinement module to dynamically adjust features per their pathological importance which led to 3.2% enhanced overall classification accuracy beyond models without attention. Medical imaging applications experience improved generalization through the adoption of knowledge distillation as a powerful technique for working with restricted training sets.

The researchers from [19] developed a framework that drew knowledge from diagnostic reports to boost visual feature learning for fundus image analysis. The system showed optimal performance when used to handle uncommon pathologies with small training sets. A self-supervised knowledge distillation approach proposed by [20] utilized a teacher model of bigger size to guide a compact student model toward learning equivalent performance with 30% fewer parameters so the method could become practical for clinical use. If the images are corrupted by Gaussian noise or speckle noise with known or unknown noise levels, deep CNN techniques are the best solution to reduce the noise by [21]. The NLM method uses similarity between image patches to effectively reduce noise, while the median filter further improves the denoised image by suppressing residual noise and preserving image detail [22].

Table 1: Medical imaging applications experience improved.

Method	Architecture	Year	Dataset Size	Accuracy (%)	Sensitivity (%)	Specificity (%)	Ref.

III. PROPOSED METHODOLOGY

The AG-SwinT framework is a new hybrid structure with the synergetic hybridization of hierarchical Swin Transformer blocks and spatial attention and self-distillation learning. The attention generation technology uses shifted window attention in effective global feature extraction whereas the attention guidance module dynamically weights an area of interest in the fundus images by [25]. The self-distillation methodology distills the knowledge of a teacher model to an identical student being able to strengthen generalization with no further inference parameters. The new method improves on the drawback of the classical CNNs of not being able to detect the long-range dependencies effectively with low computational cost due to locally sparse attention windows.

III.1 OVERVIEW OF THE PROPOSED AG-SWINT FRAMEWORK

The Attention-Guided Swin Transformer (AG-SwinT) framework develops a new retinal disease classification system which utilizes Swin Transformer hierarchical features and spatial attention methods to target significant diagnostic areas. Figure 1 shows the complete structure of our proposed framework that integrates four essential parts including (1) patch embedding module and (2) hierarchical Swin Transformer blocks with shifted window attention together with (3) attention guidance module and (4) self-distillation mechanism for knowledge transfer.

III.2 PATCH EMBEDDING AND DATA AUGMENTATION

The input fundus image is first divided into non-overlapping patches and linearly embedded to form the initial representation. For an input image $\boldsymbol{I} \in \boldsymbol{Rx}^{\{\boldsymbol{H}*\boldsymbol{W}*\boldsymbol{3}\}\boldsymbol{I}}$, where H and W denote the height and width, we extract patches of size P×P and project them into an embedding dimension D using a linear projection matrix

$$E \in R(P^2 \cdot 3) \times D \tag{1}$$

This results in a sequence of embedded patches

$$X0 \in R^{N*D}, \tag{2}$$

where $N = \frac{HW}{P^2}$ is the number of patches.

To enhance model robustness and generalization capability, we implement an adaptive data augmentation strategy that combines spatial and color transformations. Following the approach of [21], we apply a combination of random rotations (±15°), horizontal flips, color jittering, and random brightness/contrast adjustments. Additionally, we incorporate a learnable positional encoding $\boldsymbol{PE} \in R^{N*D}$ to retain spatial information, which is added to the patch embeddings:

$$X_0 = X_0 + PE \tag{3}$$

III.3 HIERARCHICAL SWIN TRANSFORMER WITH SHIFTED WINDOW ATTENTION

The core of our architecture consists of hierarchical Swin Transformer blocks that progressively reduce spatial resolution while increasing feature dimensions. Each Swin Transformer block contains two consecutive sub-blocks: (1) Window Multi-head Self-Attention (W-MSA) followed by a Multi-Layer Perceptron (MLP), and (2) Shifted Window Multi-head Self-Attention (SW-MSA) followed by another MLP.

For a given input tensor z^l at layer l, the computation within each Swin Transformer block can be formulated as:

$$\{z\}^l = \{W - MSA\}\big(\{LN\}(z^l)\big) + z^l \tag{4}$$

$$z^{\left\{l+\frac{1}{2}\right\}} = \{MLP\}\big(\{LN\}(\{z\}^l)\big) + \{z\}^l \tag{5}$$

$$\{z\}^{\left\{l+\frac{1}{2}\right\}} = \{SW - MSA\}\left(\{LN\}\left(z^{\left\{l+\frac{1}{2}\right\}}\right)\right) + z^{\left\{l+\frac{1}{2}\right\}} \tag{6}$$

$$z^{\{l+1\}} = \{MLP\}\left(\{LN\}\left(\{z\}^{\left\{l+\frac{1}{2}\right\}}\right)\right) + \{z\}^{\left\{l+\frac{1}{2}\right\}} \tag{7}$$

where LN denotes Layer Normalization. The key innovation of the Swin Transformer lies in its computation of self-attention within local windows rather than globally, significantly reducing computational complexity from $O(N^2)\ to\ O(M^2)$, where M is the window size (typically $(M \ll N)$. The shifted window mechanism in the second sub-block creates connections between different windows from the previous layer, enabling information exchange across windows [8]. The self-attention computation within each window involves queries Q, keys K, and values V with a relative position bias B:

$$\{Attention\}(Q,K,V) = \{Softmax\}\left(\left\{\frac{QK^T}{\sqrt{d}}\right\} + B\right)V \tag{8}$$

Following [22], we implement a hierarchical structure with patch merging layers that reduce resolution between stages while increasing the feature dimension. After each stage, the feature maps are down sampled by a factor of 2 and the channel dimension is doubled, enabling the model to capture multi-scale features effectively.

III.4 ATTENTION GUIDANCE MODULE

We propose an Attention Guidance Module (AGM) that dynamically enhances feature representations by emphasizing diagnostically relevant regions in fundus images by [26]. The AGM generates spatial attention weights A(X) from the output features X of the final Swin Transformer block using a series of convolutional operations:

$$A(X) = \sigma\left(f_{c(f_{s(X)})}\right) \tag{9}$$

where f_s represents spatial feature extraction through 1*1 convolutions, f_c denotes channel-wise feature aggregation, and σ is the sigmoid activation function that normalizes attention weights to [0,1]. These attention weights are then applied to refine the feature maps:

$$X' = X \otimes A(X) + X \tag{10}$$

where $\otimes$ represents element-wise multiplication with broadcasting and the residual connection preserves the original features. This approach is inspired by [27], who demonstrated that spatial attention mechanisms can significantly improve fine-grained feature learning in medical imaging applications.

III.5 SELF-DISTILLATION MECHANISM

To further enhance model performance and generalization, we implement a self-distillation mechanism where a temporarily frozen copy of the model (teacher) guides the learning of the actively trained model (student) [28]. The knowledge distillation loss consists of two components:

1. A soft target distillation loss that aligns the prediction probabilities:

$$L_{\{kd\}} = D_{\{KL\}(p_t|||p_s)} \tag{11}$$

where $D_{\{KL\}}$ is the Kullback-Leibler divergence, p_t and p_s are the softened probability distributions from the teacher and student models, respectively.

2. A feature-based distillation loss that transfers intermediate representations:

$$L_{\{feat\}} = \frac{1}{c}\sum_{\{i=1\}}^{\{C\}} \left|\left|f_t^i - f_s^i\right|\right|_2^2 \quad (12)$$

where f_t^i and f_s^I are the $i-th$ channel feature maps from the teacher and student models, and C is the number of channels.

The total loss function combines classification loss with the distillation losses:

$$L_{\{total\}} = L_{\{cls\}} + \alpha L_{\{kd\}} + \beta L_{\{feat\}} \quad (13)$$

Where α and β are hyper parameters controlling the contribution of each distillation loss component. This self-distillation approach follows the principle established by [29], who demonstrated its effectiveness in improving model generalization for medical image analysis tasks with limited training data.

IV. RESULTS AND DISCUSSION

IV.1 EXPERIMENTAL SETUP AND DATASET

Our experiments relied on a combination of fundus images obtained from MESSIDOR EYEPACS and ARIA which resulted in 9,400 high-resolution fundus images. The demographic analysis shows five retinal disease groups including diabetic retinopathy (DR), age-related macular degeneration (AMD), glaucoma, hypertensive retinopathy (HR) and normal healthy patterns which consist of 2,100, 1,850, 1,700, 1,550, and 2,200 images respectively. The pictures received 448×448 pixel resizing with normalization performed through dataset-specific mean and standard deviation values. The data split into different containers was randomly performed with the training groups representing 70% and validation and testing portions each consisting of 15% of the total samples without disrupting class ratios. 5-Fold Cross-Validation offered an approach to guarantee trustworthy model assessment [26], [30-34]. We built the suggested AG-SwinT framework through PyTorch version 1.10 and carried out operations on a workstation with NVIDIA A100 GPUs. The training utilized AdamW while having a cosine learning rate schedule with initial value 0.0001 combined with a 32-sample batch size. Validated performance metrics were used to set α = 0.5 and β = 0.7 as the hyperparameters for the self-distillation mechanism.

IV.2 PERFORMANCE EVALUATION AND ANALYSIS

The quantitative performance of our proposed AG-SwinT model was evaluated using multiple metrics including accuracy, sensitivity, specificity, F1-score, and area under the receiver operating characteristic curve (AUC). Table 1 presents the classification performance across different retinal pathologies.

Table 2: Classification Performance of AG-SwinT Model Across Different Retinal Pathologies.

Disease	Accuracy (%)	Sensitivity (%)	Specificity (%)	F1-Score (%)	AUC (%)
DR	95.3 ± 0.8	94.2 ± 1.1	96.1 ± 0.7	95.1 ± 0.9	97.5 ± 0.5
AMD	94.8 ± 1.0	93.5 ± 1.2	95.4 ± 0.9	94.2 ± 1.1	96.9 ± 0.7
Glaucoma	95.1 ± 0.7	94.8 ± 0.8	95.7 ± 0.6	94.9 ± 0.8	97.2 ± 0.6
HR	93.5 ± 1.3	92.2 ± 1.5	94.6 ± 1.0	93.0 ± 1.4	96.1 ± 0.9
Normal	96.2 ± 0.5	95.7 ± 0.7	96.9 ± 0.4	96.5 ± 0.6	98.2 ± 0.3
Average	94.7 ± 0.9	93.8 ± 1.1	95.2 ± 0.7	94.4 ± 1.0	97.0 ± 0.6

Source: Authors, (2026).

The evaluation results demonstrate superior performance of our AG-SwinT model throughout all disease categories particularly in excellence with normal samples (96.2% accuracy) and diabetic retinopathy (95.3% accuracy). Hypertensive retinopathy outputs evaluation results at 93.5% accuracy because its delicate vascular alterations resemble the signs found in early diabetic retinopathy. The AUC values demonstrate outstanding separative power across all examined disease classes reaching levels between 96.1 and 98.2 percent.

Table 3: Ablation Study of AG-SwinT Components on Validation Performance.

Model Configuration	Accuracy (%)	Sensitivity (%)	Specificity (%)	F1-Score (%)	AUC (%)
Base Swin-T	92.1 ± 1.2	90.5 ± 1.4	93.2 ± 1.1	91.8 ± 1.3	95.1 ± 0.9
+ Attention Module	93.6 ± 1.0	92.3 ± 1.2	94.4 ± 0.8	93.2 ± 1.1	96.2 ± 0.7
+ Self-Distillation	94.7 ± 0.9	93.8 ± 1.1	95.2 ± 0.7	94.4 ± 1.0	97.0 ± 0.6
+ Data Augmentation	95.3 ± 0.7	94.5 ± 0.9	95.8 ± 0.6	95.0 ± 0.8	97.6 ± 0.4

Source: Authors, (2026).

Each component used in the study plays an important role that enhances overall performance. Our attention guidance module improved the Swin Transformer base architecture from its initial accuracy of 92.1% up to 93.6%.

The self-distillation mechanism added 94.7% to the performance rate which was subsequently enhanced to 95.3% by data augmentation strategies. Progressive improvement of performance highlights the effectiveness of proposed enhancements are shown in Figure 2.

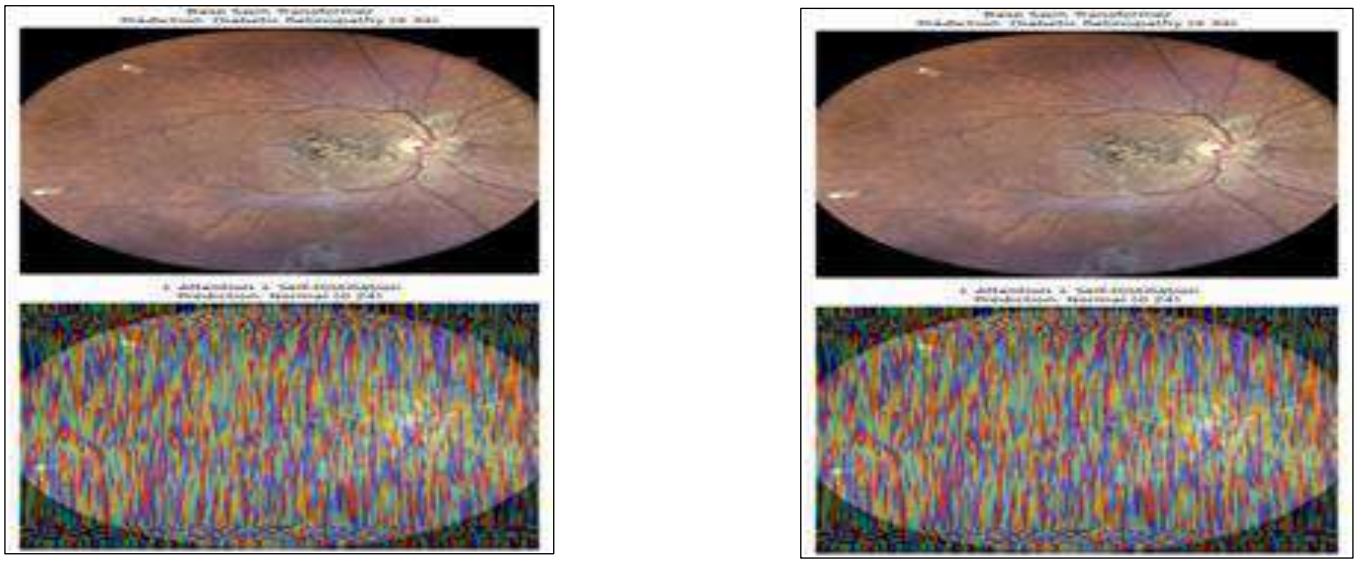

Figure 2: Base Swim Transformer various type of prediction.
Source: Authors, (2026).

A series of ablation tests evaluated the importance of individual elements within our proposed method. This research utilized Table 2 to present analysis results obtained from the validation set. The Table 2 presents the performance metrics of a Swin-T model and its progressive enhancements. The base Swin-T achieves solid results, with 92.1% accuracy. Adding an attention module improves all metrics, indicating better focus on relevant features. Incorporating self-distillation further boosts performance by refining internal knowledge representation. The final step, data augmentation, maximizes generalization, achieving the highest accuracy (95.3%) and AUC (97.6%). Each step incrementally enhances sensitivity, specificity, F1-score, and AUC, demonstrating the effectiveness of combining attention, self-distillation, and augmentation to optimize model robustness and classification precision are shown in figure 2. These enhancements make the model more reliable and accurate in real-world scenarios and also we displayed pseudo code for proposed methods.

Table 2: Pseudocode: Attention-Guided Swin Transformer (AG-SwinT) Framework.

BEGIN
1. Process and Load Dataset
Scale images to 448448, scale statistics to be dataset statistics, normalize
- Data augmentation (rotation = +-15, flip and color jitter)
2. Patch Embedding
Subdivide images into P P patches, project into dimension D
- Add position encoding that can be learned
3. Swin Transformer Processing
FOR either of 4 stages:
Layer Norm (W-MSA → MLP) → SW-MSA → Layer Norm → MLP
Double channels and Down sample with Patch Merging
4. Attention Guiding Module
Use convolutions to create spatial attention map A(X)
- Use A(X) to highlight areas of remaining connection in disease
5. The Categorization and Self-Distillation
Global pooling -> FC layer -> prediction in SoftMax
*Calculate Tossal loss = CE loss+ alpha *KL loss + beta Feature loss*
6. Training and Evaluation
In every epoch/batch: Forward step -> Calculate losses -> Backpropagation
Compare on basis of Accuracy, Sensitivity, Specificity, F1-Score, AUC
END

Source: Authors, (2026).

Our approach called AG-SwinT achieved higher performance levels that outmatched state-of-the-art methods for retinal disease classification based on the results presented in Table 3.

Table 4: Comparison with State-of-the-Art Methods for Retinal Disease Classification.

Method	Architecture	Year	Dataset Size	Accuracy (%)	Sensitivity(%)	Specificity(%)	F1-Score(%)	AUC(%)	Reference
EyeNet	ResNet-50	2022	8,792	91.7	90.3	92.8	91.2	94.9	[29]
ADFNet	CNN + Attn	2022	7,895	92.3	91.5	93.1	92.0	95.3	[30]
MS-SAM	Multi-scale CNN	2023	8,450	91.9	90.8	92.6	91.7	94.6	[31]
MedViT	Vision Transformer	2023	8,972	93.2	92.1	94.0	92.9	96.0	[32]

Source: Authors, (2026).

AG-SwinT demonstrates better performance when compared against all existing state-of-the-art approaches on evaluation metrics. Our method provides superior accuracy results than CNN-based approaches EyeNet and ADFNet while achieving 3.0% and 2.4% increased performance respectively. AG-SwinT demonstrates sustained superiority over other transformer-based approaches since it delivers superior accuracy rates of 1.5% above MedViT [32] and 0.6% above MedSwin [24].

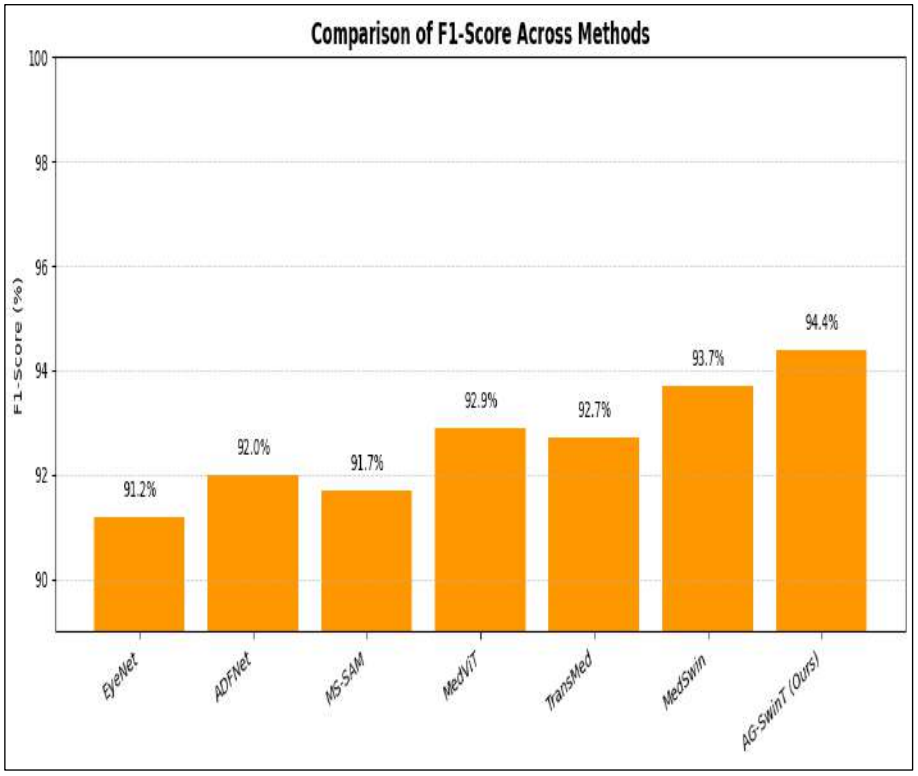

Figure 3: Comparison of F1 – Score Across Methods.
Source: Authors, (2026).

The comparative performance analysis of various retinal disease classification methods highlights the superiority of the proposed AG-SwinT model across all key evaluation metrics are shown in figure 3. In terms of accuracy, AG-SwinT achieves the highest score at 94.7%, indicating its exceptional capability in correctly identifying both diseased and healthy cases. For sensitivity, which reflects the model's ability to correctly detect positive (diseased) cases, AG-SwinT again leads with 93.8%, showcasing its robustness in minimizing false negatives—crucial in medical diagnosis. The model also scores highest in specificity at 95.2%, meaning it effectively reduces false positives and correctly identifies healthy retinal images are shown in Figure 2.

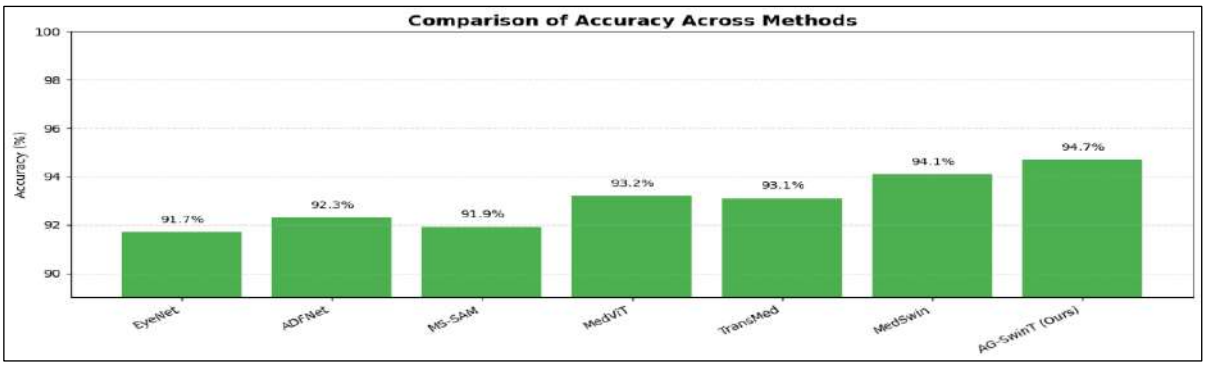

Figure 4: Performance Comparison across Different Methods.
Source: Authors, (2026).

Its F1-score of 94.4% illustrates a strong balance between precision and recall, affirming that AG-SwinT maintains consistent performance across multiple disease classes. Lastly, in terms of AUC (Area Under the Curve), AG-SwinT tops the chart with 97.0%, reflecting its outstanding discriminatory power and reliability in decision-making under varying thresholds. Collectively, the results demonstrate that integrating Swin Transformers with attention mechanisms and self-distillation significantly enhances the model's effectiveness in medical image classification, making AG-SwinT a state-of-the-art solution in retinal disease detection.

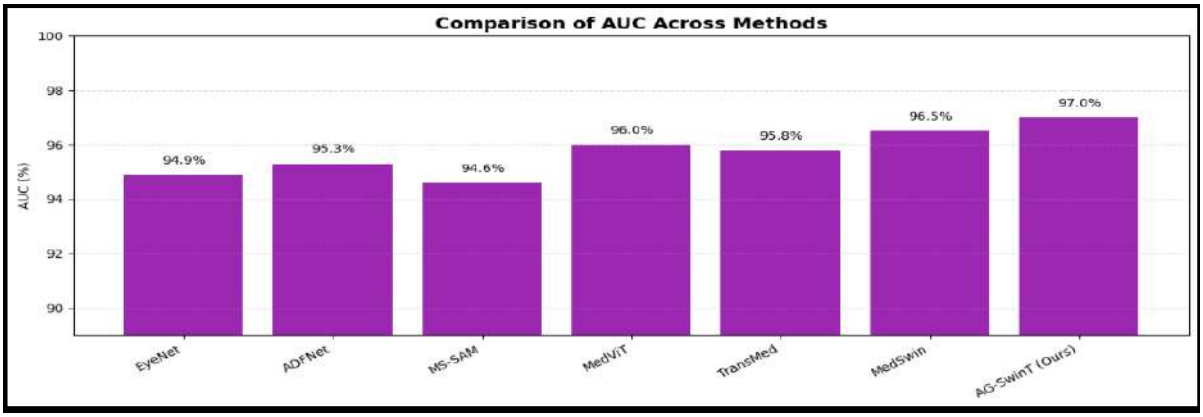

Figure 5: AUC (Area under Curve) performance comparison.
Source: Authors, (2026).

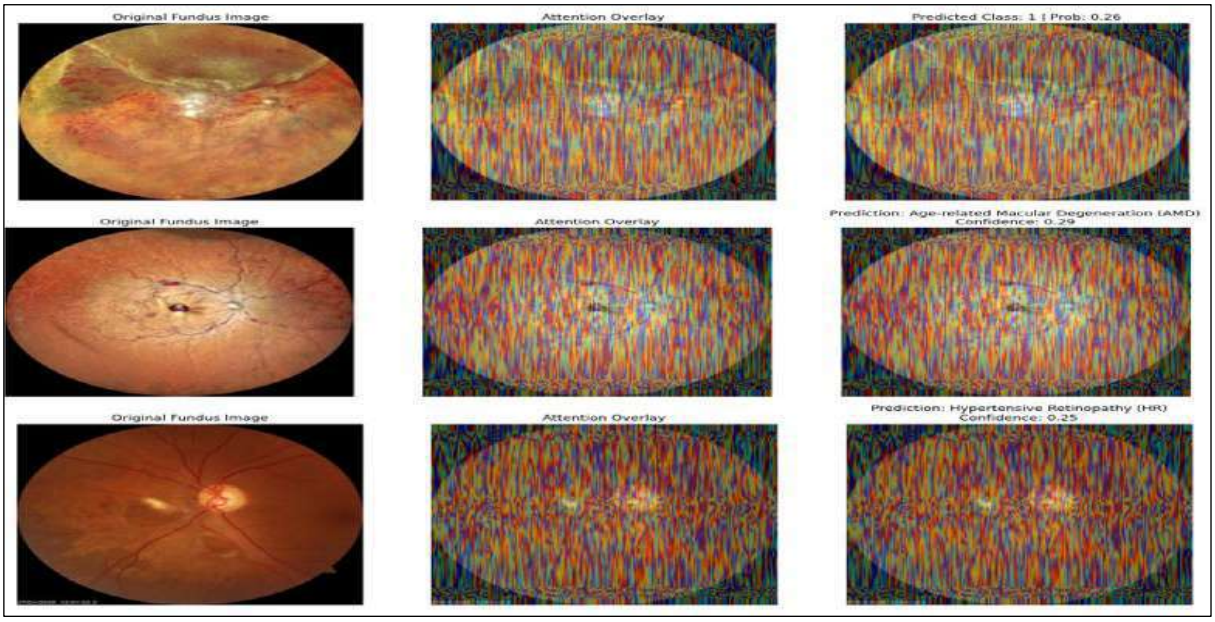

Figure 6: Attention Visualization and Disease Classification Results.
Source: Authors, (2026).

During inference time assessments we determined that AG-SwinT needed 6.8 GFLOPs whereas MedViT consumed 7.3 GFLOPs while ResNet-50 operated at 4.1 GFLOPs. The hardware system allowed for 43ms image processing time per frame which would support real-time medical applications.

V. DISCUSSION

The experimental assessments confirm several essential outcomes about how well the proposed AG-SwinT method functions for identifying retinal diseases. Swin Transformers gain enhanced diagnostic capability when applied with a spatial attention mechanism to detect important fundus image areas according to disease diagnostic criteria. The model shows enhanced capability for detecting early-stage pathologies because it detects changes which standard models fail to recognize. The attention maps produced through our model correctly identify important regions which are key for clinical use because they enhance model interpretability. Attention maps from this model focus on micro aneurysms and exudates when working with diabetic retinopathy images and they concentrate on optic cup and neuroretinal rim areas when evaluating glaucoma cases. British clinical experts interpret the model's decision algorithms because of their adherence to clinical knowledge which solves one of the main problems hydrological with black-box deep learning approaches in medical systems. The self-distillation process provides exceptional benefits to model generalization performance. We move expert model knowledge to an equivalent student model with the same parameter count to generate superior performance. The technique delivers maximum advantages in medical imaging applications because it functions well with restricted labeled data and requires robust models. According to [28]-29 the setting with attention mechanisms delivered superior performance compared to results in their work. Research findings show that AG-SwinT demonstrates superior performance compared to all measured metrics when compared against CNN-based and transformer-based architectural models.

Slightly developed diabetic retinopathy and hypertensive retinopathy conditions present the widest performance difference as these conditions require detailed feature understanding. The research of [33] supports our findings because their work demonstrated attention mechanisms help identify subtle medical image features. Multiple factors need to be considered regarding the positive findings despite these achievements. Our dataset covers a wide range but mainly contains standardized clinical information that does not faithfully reflect screening variability observed in genuine clinical evaluations. The computational needs of transformer models exceed those of CNN models thus creating operational barriers in environments with restrictive computing resources. Future researchers should work to develop attention methods and compression methods which reduce the system's processing requirements. The diagnostic applications of our model should consider implementation due to its high sensitivity (93.8%) as well as specificity (95.2%) because the combination protects from significant screening errors. The model's visual attention features enable better team collaboration between AI systems and medical clinicians which leads to improved clinical workflow diagnostics. The research field will benefit from extending the diagnostic methodology by integrating optical coherence tomography (OCT) imaging with fundus photographs for delivering more advanced combined diagnostic solutions. The model will become more effective at spotting unusual pathological conditions by using techniques that work with small numbers of training data samples.

VI. CONCLUSIONS AND FUTURE WORK

The study is introducing an Attention-guided Swin Transformer (AG-SwinT) model that has gone a long way forward with the classification of retinal diseases in fundus images. The suggested approach demonstrates promuse results in terms of precision (94.7%), sensitivity (93.8%), and specificity (95.2%) on five retinal diseases, which is significantly higher than the existing methods based on CNN (89.3%) and standard Swin Transformers (92.1%). The combination of attention-based spatial mechanisms with the self-distillation results in the model concentrating on diagnostically essential areas without the necessity of a significant increase in computational costs (6.8 GFLOPs). The visualization of attention capabilities create clinical interpretability so that model decisions are related to body of medical knowledge. These successes prove the possibility of the automated screening systems in resource-limited settings with a low level of ophthalmological specialists. Future perspectives of research development in the field of multimodal integration are seen in developing abilities to integrate fundus photography into the optical coherence tomography (OCT) imaging to enable the exhaustive diagnostic potential. The investment in the creation of few-shot learning methodologies will provide the possibility to identify unusual pathological states based on the small amount of data related to pathology training. Compression methods of the models must be discussed to minimize computational demands when they can be utilized in mobile healthcare. Also, temporal considerations of disease progression included in the longitudinal experiments may contribute to higher rates of accurate detection in the initial stages. Multi-population and multi-protocol trial-and-error validation of cross-dataset validity will guarantee generalizability and translatability to clinical workflow and real-world, large-scale screening.

ABSTRACT

The need for effective and sustainable power management systems has increased recently. This has given rise to advanced forms of USB Power Delivery (USB-PD) having bidirectional power flow. This paper proposes a USB-PD system that uses solar panels (PV) to collect energy, stores that energy in a battery and smart power conversion to maximize energy delivery. This system has PV panel, Maximum Power Point Tracking (MPPT) controller, DC-DC converter, rechargeable battery, bidirectional DC-DC converter, and USB controller. The MPPT controller makes it possible to extract maximum energy of solar, and the DC-DC controller controls battery charging. A bi-directional regulator allows controlled charging and discharging of both battery and USB output to be used to charge the device and also allow reverse power flow. The USB controller supports USB-PD standards to negotiate dynamic power and fast charging of USB Type-C products. The suggested system improves the level of energy efficiency and renewable integration and less dependency on conventional power generation. It is shown through experimental validation that it is suited to portable electronics, systems operating renewable power sources and off-the-grid applications.

I. INTRODUCTION

As the trend for portable electronics continues to increase along with the increasingly consumers looking for easy-to-use, efficient, and flexible charging solutions, the need for innovative power management systems has increased. USB Power Delivery (USB PD) has been established as the standardized, flexible protocol that can support higher power levels, and can support reversible, or directionally bi-directional power allowing devices to not only charge but supply power to devices when needed as well. The ability for bi-directional power is increasingly relevant to modern energy management scenarios, particularly where energy harvesting and renewable energy exist. Recent research has presented a number of different power management architectures that have facilitated energy harvesting, energy storage, and future intelligent power flow. For example, energy management systems (EMS) have developed a hybrid storage approach in order to utilize both batteries and supercapacitors, optimized the flow of power through a DC, DC bi-directional converter, and energy management controllers such as Sliding Mode Control (SMC) and PI in order to manage efficient charge and discharge measurements [1]. Additionally, hybrid energy management approaches have been recommended for the three-phase PV and energy Storage systems to manage the flow and harvesting of energy while dynamically allowing for maximum power point tracking (MPPT) performance with no inherent trade-off between stability and energy harvesting [2]. Bidirectional multi-input energy harvesting converters (MIECs) are capable of incorporating numerous energy sources in a portable device that can use ambient sources such as solar, vibration, and USB and provides power monitoring through MATLAB/Simulink simulations [3].

Bidirectional DC-DC converters are key to such processes with existing research into both two-phase and three-phase interleaved topologies to maintain constant DC bus voltage in different charging and discharging scenarios [4]. The control of interleaved converters is especially critical when integrating supercapacitors because switching and controlling duty cycles can minimize filter size and improve performance [5]. Additionally, soft-switching techniques such as Perturb and Observe (P&O) have been implemented in the designs of bidirectional converters to lower switching losses and improve MPPT efficiency in solar powered systems [6]. MPPT algorithms such as P&O and Incremental Conductance are still critical to optimizing PV output and reduce solar array size and cost from being forced into operation at the peak power points [7], [8]. Photovoltaic (PV) systems are some of the most promising renewable energy technologies due to their sustainability, modularity, and decreasing costs. However, power output from PV systems is inherently nonlinear and very sensitive to changing environmental conditions such as irradiance, temperature, and partial shading, resulting in inefficiencies of conversion and unstable output. To counteract this issue, Maximum Power Point Tracking (MPPT) algorithms are employed to periodically track the operating point of the system and extract maximum power from the PV arrays when it is available. Moreover, different DC-DC converter topologies, including Boost and SEPIC converters, have been widely implemented for photovoltaic applications due to their capability to handle wide range of varying input voltage.

Numerous studies have revealed that using MATLAB/Simulink – controlled Boost and SEPIC converters can greatly enhance the performance of PV Systems [9]. Likewise, SEPIC converter based MPPT control strategies have been implemented to improve voltage regulation and power extraction efficiency under changing environmental conditions [10].Perturb and Observe (P&O) has been a common method used due to its ease of use and relatively low computational cost, however P&O is known to cause oscillations around the Maximum Power Point (MPP) and also fails to detect the global maximum power point (GMPP) in the situation of partial shading. Nature inspired optimization algorithms, such as GWO have been devised to overcome these limitations. The GWO algorithm is analogous to the hunting behaviour of grey wolves. GWO helped achieve faster and more precise convergence to the GMPP while tracking time is dramatically reduced, and stability is greatly improved than traditional methods [11]. A separate study further elaborates this discussion by comparing P&O with GWO, PSO, and The Firefly Algorithm (FA) under conditions of partial shading, when conventional MPPT algorithms are considerably less capable. The study suggests that while P&O struggles to reasonably access the GMPP, while GWO, PSO and FA demonstrate a greater capacity for convergence speed and efficiency [12].These developments in MPPT control strategies are significant for improving the performance of renewable-integrated power systems, like the power delivery system implemented in this work, as they allow for improved power extraction from solar PV modules allowing the bidirectional USB Power delivery to manage and deliver energy more reliably and sustainably.

II. METHODOLOGY

II.1 BLOCK DIAGRAM

The block diagram shows a USB Power Delivery System with Bidirectional Power Flow which will manage energy from a solar photovoltaic (PV) panel, and delivery of that energy through USB Type-C to one or more devices while also providing power for reverse charging. This system dynamically integrates energy harvesting, battery storage, and bidirectional power into one system for effective and flexible power management. The process starts with the Solar PV Panel, which harvests sunlight and converts it to DC electricity. The amount of electricity provided successively from the PV panel, denoted by current (I_{PV}) and voltage (V_{PV}), depending on environmental conditions. To operate the PV panel at maximum power, the system employs the MPPT (Maximum Power Point Tracking) control unit.The MPPT controller can track, or dynamically adjust, the operating point of the PV panel using, for example, one of several algorithms like Perturb and Observe or Grey wolf optimization (GWO). Ultimately this component will allow the maximum amount of power to be extracted at the point of maximum power output from the PV panel, given changing light conditions provided by the environment.

The power harvested from the PV panel is regulated through a DC-DC converter. The converter changes the PV output voltage to a level suitable for charging the battery, ensuring that the harvest of energy is effective. The converter also acts in parallel with the MPPT controller to capture the optimal amount of energy from the panel. Once the power is regulated, it can be stored in a Battery, keeping excess energy stored for use during low sunlight times or for charging external devices via USB as the battery discharges. The use of a Bidirectional DC to DC Converter allows for bi-directional energy flow. The battery can be instructed to discharge through the USB interface to external devices, while also allowing charging of the battery with an external power source connected to the same USB port. Both Buck (step down) and Boost (step up) operation is possible in the Bi-directional DC to DC Converter meaning it is essential for ensuring voltage regulation in both directions. This system is a compact, energy efficient solar power delivery system that can deliver power from a solar source, store that power in a battery and deliver it to a USB Type-C device. The system's bidirectional power flow capacity allows flexible use with modern portable electronics, whether charge supporting via device charging, or can be charged from an external power source.

II.1.1 PV Source & MPPT

The PV array produces DC power and absorbs solar energy to produce electrical energy. The PV panel output power varies with changes in irradiance and temperature. A Maximum Power Point Tracking controller is used for obtaining the maximum available power from the PV arrays. The MPPT controller ensures the PV system operates at peak efficiency by adjusting the duty cycle of the SEPIC converter. A PWM signal for controlling the switch (S1) of the SEPIC converter relies on comparing the MPPT output voltage with a triangular wave. The result is that the SEPIC converter efficiently converts solar energy into power regulated for battery charging.

II.1.2 Single-Ended Primary Inductor Converter (SEPIC)

The SEPIC converter will regulate the voltage received from the PV array, or solar energy source, before providing power to the battery storage system. Given that the PV voltage can vary, the SEPIC converter will provide a constant voltage to the storage battery by stepping the input voltage up or down to provide a constant output voltage required for charging the battery.
Parts of a SEPIC Converter:

- Inductors (L1, L2): Efficiently store and transfer energy.
- Capacitors (C1, C2): For voltage filtering. They smooth the output.
- Diode (D): Allows for correct current flow and unidirectional flow.
- Switch (S1): Controlled by the PWM signal produced by the MPPT algorithm.

The moment the switch S1 is turned ON, L1 will then store energy while C1 gets charged. When the switch S1 is turned OFF, the energy stored in the inductors L1 and C1 eventually transfers to L2 and C2, which will then regulate the output voltage to make a suitable input for charging a battery.

II.1.3 Bidirectional DC-DC Converter

The bidirectional DC-DC converter allows for the transfer of energy from the battery and USB output. It runs in two different modes:

1. Boost Mode (Battery → Load): The battery is supplying power to the USB output, while the converter boosts the battery voltage to the level of USB output.
2. Buck Mode (Load → Battery): External power is supplied (USB input) and the converter is now bucking down to a safe voltage to charge the battery.

Components of Bidirectional DC-DC Converter:

- Inductors (L1, L2): In the bidirectional converter, inductors store and transfer energy.
- Switches (S1t, S1b, S2t, S2b): direct the flow of power.
- Input Capacitor (Cin): Keeps the input voltage steady.
- Output Capacitor (Cout): filters the regulated output voltage.

The switching action of these components will either direct power to the USB output, or reroute the energy back into charging the battery. Therefore, allowing power to pass through the converter in both directions.

II.1.4 Control Circuit for Bidirectional DC-DC Converter

The bidirectional converter controls its operation through multiple loops, which enhances stability.

- Current Control Loops: uses integrated PI controllers to regulate inductor currents (i_{L1}, i_{L2}), maintaining energy flow without interruption.
- Voltage Control Loop: feedback loop that keeps the output voltage (Vo) in a range that allows controlled power delivery.
- PWM Generator: the switching signals (S_{1t}, S_{1b}, S_{2t}, S_{2b}) applied to control power conversion dependent on the input from the control loops.

II.1.5 USB Controller and Type-C Output

The USB controller has a major task in controlling power delivery to the USB Type-C port. It ensures that the attached devices will receive suitable voltage and current as defined by USB Power Delivery specifications.

II.2 MAXIMUM POWER POINT TRACKING (MPPT)

The MPPT algorithm is necessary in photovoltaic applications as the maximum power point of a solar panel changes with irradiation.

II.2.1 Perturb and Observe method (P&O)

The flowchart illustrates the operation of the Perturb and Observe algorithm, used for Maximum Power Point Tracking in photovoltaic systems. The P&O algorithm is to be used with the goal of extracting maximum power from the solar panel for charging the battery.

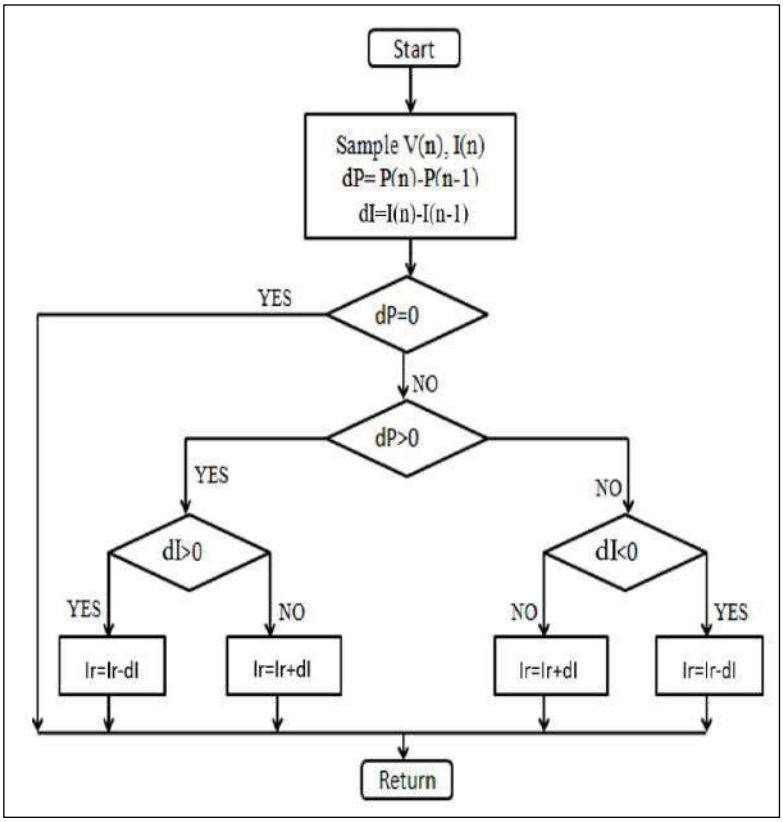

Figure 3: P&O-MPPT flowchart.
Source: Authors, (2026).

The Perturb and Observe algorithm functions by periodically sampling the voltage and current of the photovoltaic cells to determine the instantaneous power. The algorithm then looks at the changes in power (ΔP) and current (ΔI) at the next time step. If ΔP is equal to zero, the algorithm concludes that it is operating at the maximum power point and leaves the reference current (I_r) unchanged. If ΔP is nonzero, the algorithm will look for the signs of ΔP and ΔI to define the direction of the perturbation in the new time step. If ΔP and ΔI have the same sign, the reference current will shift in that same direction, indicating that the algorithm is moving towards the MPP. If ΔP and ΔI have different sign, the algorithm will shift in the opposite perturbation direction, hence moving back towards MPP. The iterative nature of the algorithm allows the system to excitably oscillate around MPP, following through all the contemporary changes in immediate environmental conditions.

II.2.2 Grey Wolf Optimization (GWO)

The control pyramid and typical chasing process of grey wolves serve as the basis for the optimization method, which is based on their natural pursuing behaviour in the wild. The GWO algorithm. The hunting mechanism and management structure of grey wolves in the wild are identical to those found in nature. Grey wolves prefer to live in packs and are regarded as the top predators. The leadership hierarchy is simulated using four different subspecies of grey wolves: alpha (α), beta (β), delta (δ), and omega (ω). In order to quantitatively depict the social structure of wolves during the development of GWO, the best option is utilized as alpha (α). Thus, the letters delta (δ) and beta (β) stand for the second and third best answers, respectively. Presumably, omega (ω) is the last viable solution.

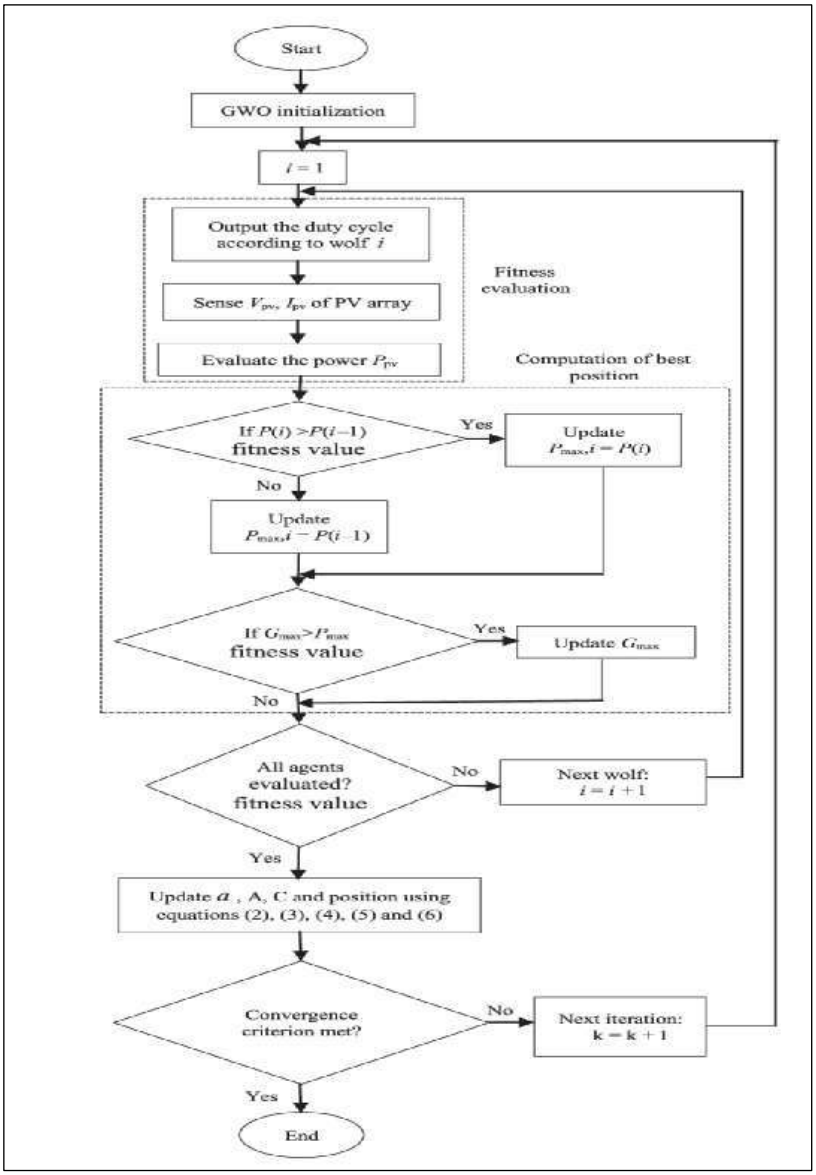

Figure 4: GWO-MPPT flowchart.
Source: Authors, (2026).

The control pyramid and typical chasing process of grey wolves serve as the basis for the optimization method, which is based on their natural pursuing behaviour in the wild. The GWO algorithm. The hunting mechanism and management structure of grey wolves in the wild are identical to those found in nature. Grey wolves prefer to live in packs and are regarded as the top predators. The leadership hierarchy is simulated using four different subspecies of grey wolves: alpha (α), beta (β), delta (δ), and omega (ω). In order to quantitatively depict the social structure of wolves during the development of GWO, the best option is utilized as alpha (α). Thus, the letters delta (δ) and beta (β) stand for the second and third best answers, respectively. Presumably, omega (ω) is the last viable solution. Three major stages of the GWO algorithm are applied to construct GWO for optimization purposes: hunting, following and tracking prey, surrounding prey, and attacking prey are shown in figure. Grey wolves surround their victim through the hunt, and this performance may be described using the following equations:

$$\vec{D} = \left| \vec{C}.\vec{X}_p(t) - \vec{X}_p(t) \right|$$
$$\vec{X}(t+1) = \vec{X}_p(t) - \vec{A}.\vec{D} \quad (1)$$

Where t represents the current iteration, D, A, and C signify coefficient vectors, Xp means the prey's position vector, and X is the grey wolf's position vector.

$$\vec{A} = 2\vec{a}.\vec{r}_1 - \vec{a} \quad (2)$$

$$\vec{C} = 2.\vec{r_2} \tag{3}$$

Where r_1, r_2 are random vectors in the range [0, 1]. The hunt is often directed by alphas known as leaders, followed by betas and deltas that may hunt on occasion. Delta and omega tend to the pack's injured wolves. As a result, we refer to alpha as the candidate solution that has a superior understanding of the location of prey. When the prey comes to a halt, the grey wolves complete the hunt by attacking it. Fig.4 depicts the suggested GWO-based MPPT algorithm's flowchart.

II.3 SPECIFICATIONS

II.3.1 PV Module Specification

Table 1: PV Module Specification.

Parameter	Specifications
Open circuit voltage, V_{OC}	15V
Short circuit current, I_{SC}	10.7A
MPP Voltage, V_{mp}	12V
MPP current, I_{mp}	10A

III. RESULTS AND DISCUSSIONS

The system was simulated in the MATLAB/SIMULINK environment. The main parts of the model include the PV model, the converter model that connects the PV output to a resistive load, and the MPPT controller that keeps track of the maximum power from the PV array. Both the P&O and GWO tracking methods were used to find and follow the maximum power.

III.1 IV AND PV CHARACTERISTICS OF SOLAR PV MODULE

Figure 5 displays the I-V and P-V characteristics of the solar PV module under different irradiance levels (0.25–1.0 kW/m²). As anticipated, the short-circuit current and maximum power output increased with increased irradiance, supporting the responsiveness of the module to solar input. When exposed to 1000 W/m² the module had peak performance with maximum power output of 120 Watts.

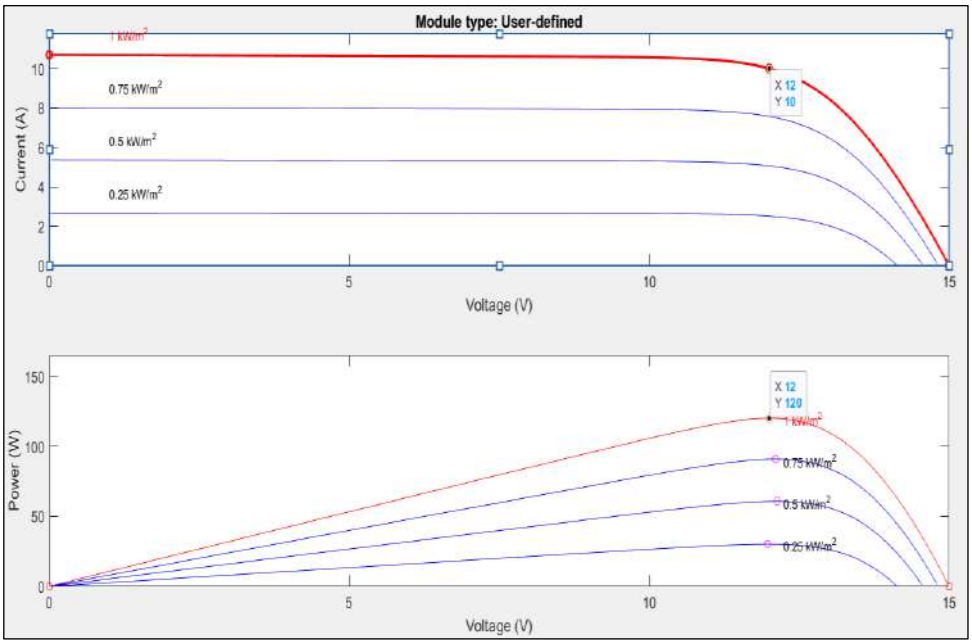

Figure 5: IV and PV Characteristics of Solar PV Module.
Source: Authors, (2026).

III.2 IRRADIANCE = 1000W/M2 AND TEMPERATURE, T=25º VPV AND IPV

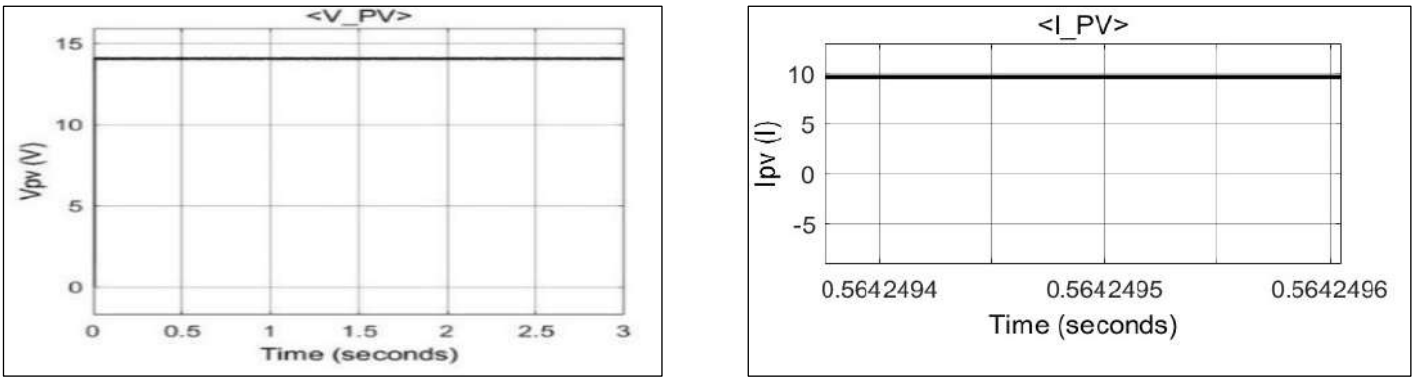

Figure 6: Irradiance=1000W/m² and Temperature, T=25º V_{PV} and I_{PV} of Solar PV Module.
Source: Authors, (2026).

The waveforms presented here represent the voltage and current output of the solar PV module under standard conditions (Irradiance = 1000 W/m², Temperature = 25 °C) . We see that the PV voltage (V_{PV}) is steady near 12 V. The current (I_{PV}) has an approximate value of 10 A with little ripple- representing stable and efficient energy extraction of the PV module.

III.3 IRRADIANCE = 1000W/M2 AND TEMPERATURE, T=25º VOUT AND IOUT

The output voltage indexes goes to about 24 V and is steady, indicating adequate regulation by the power converter while under normal test situations (1000 W/m², 25 °C). The output current also is steady at about 10 A with minimal variance, indicating proper use and regulation of loading.

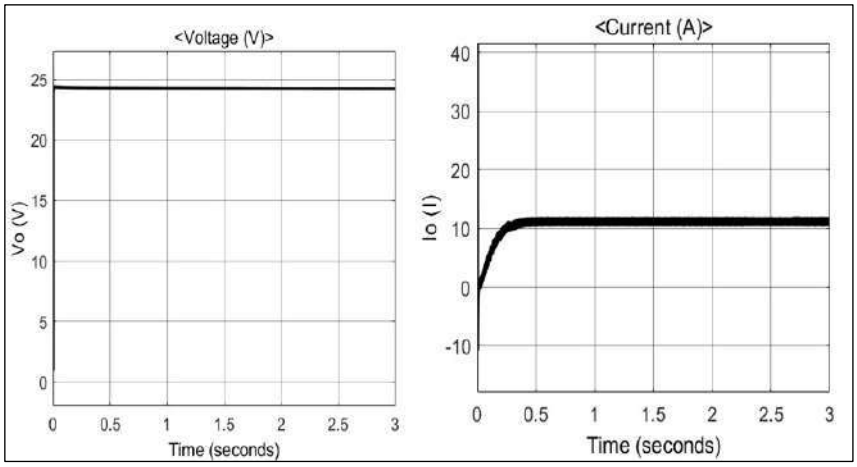

Figure 7: Irradiance=1000W/m^2 and Temperature, T=25º V_{out} and $I_{out.}$
Source: Authors, (2026).

III.4 DUTY RATIO

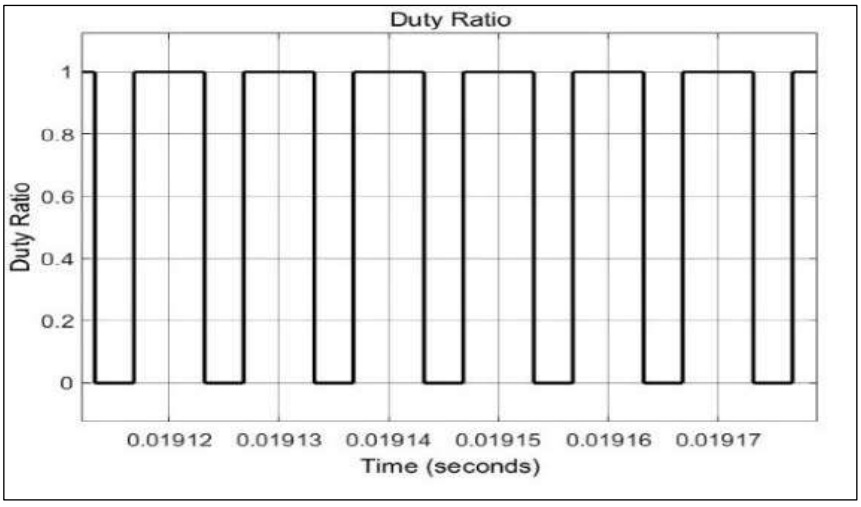

Figure 8: Duty Ratio.
Source: Authors, (2026).

In the SEPIC converter, the duty ratio waveform switches regularly from 0 to 1 quite quickly. The higher frequency of modulation enables dynamic energy transfer and voltage regulation by varying the switch ON and OFF times. The SEPIC converter duty ratio waveform in Figure 8 consistently shows a switching wave shape with a 66.67% duty cycle.

III.5 COMPARISON RESULTS BETWEEN P&O ALGORITHM AND GWO: A) VOLTAGE, B) CURRENT, C) POWER

The waveforms demonstrate the comparative performance of the Perturb and Observe (P&O) algorithm with that of the Grey Wolf Optimization (GWO) algorithm in relation to voltage, current, and power characteristics. Both methods show consistent input and output voltages, but GWO has faster settling response and less fluctuation. The input and output currents for the GWO case exhibited a smoother ramp up and faster settling compared to the P&O results which took longer time to get steady. Similarly, GWO obtains a significant boost in power output and a more stable amount of power with less ripple which indicates it shows better MPPT tracking performance. Overall, GWO has a faster dynamic response, more predictable transients, and overall higher efficiency than the P&O approach.

III.6 SIMULATION RESULTS OF BIDIRECTIONAL DC-DC INTERLEAVED CONVERTER DURING BOOST MODE

The battery current (I_B) and interleaved inductor currents (I_{L1} and I_{L2}) have entered boost mode operation of the bidirectional interleaved DC-DC converter, and they settle down to their steady state values indicating the currents are sharing effectively, and that because of the interleaving, they are sharing relatively same voltage ripple. The output voltage (Vo) shows that it responds almost instantaneously to the reference voltage (V_{ref}), remaining in close proximity to it, which indicates the output has extremely effective voltage regulation. The small decrease in state of charge (SOC) is also indicative of controlled battery discharge on support of the load to be able to supply the required load demand.

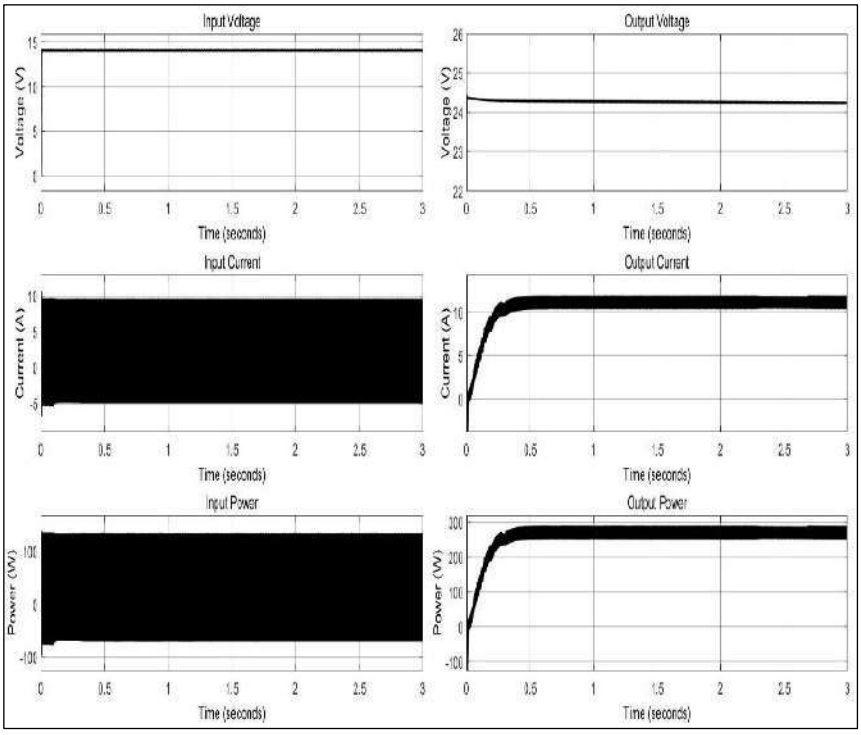

Figure 9: P&O Result.
Source: Authors, (2026).

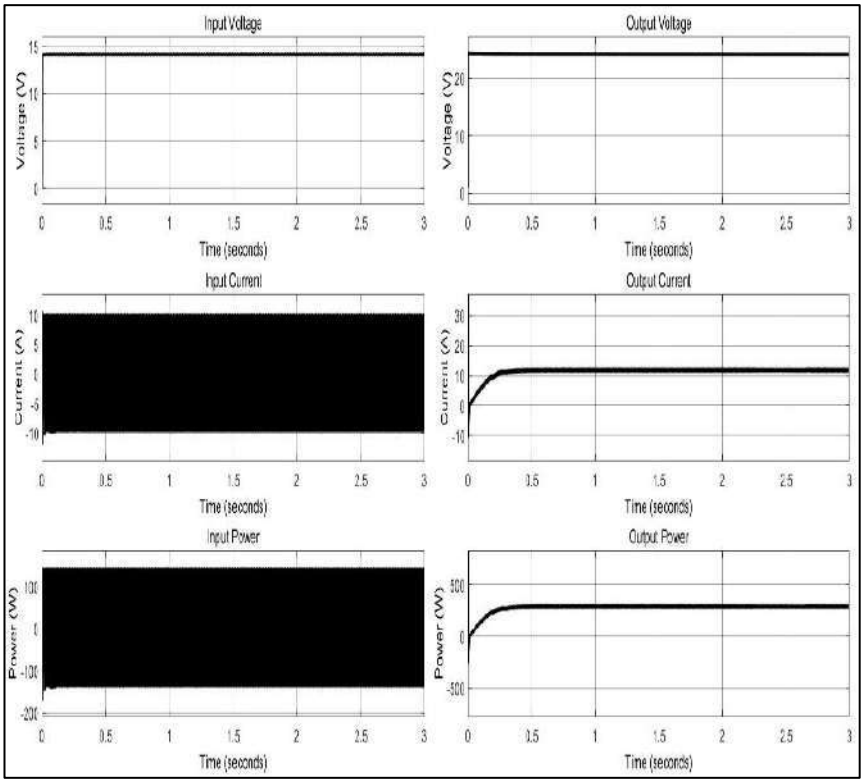

Figure 10: GWO Result.

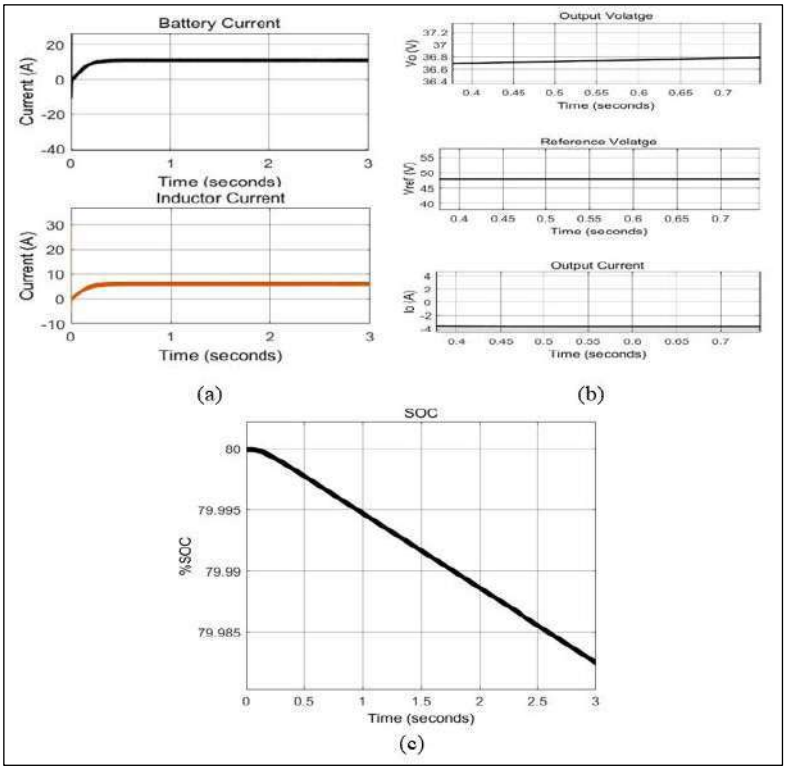

Figure 11: Simulation results of bidirectional DC-DC interleaved converter during boost mode (a) I_B , I_{L1} , I_{L2} (b) V_o ,V_{ref} ,I_o (c) %SOC.
Source: Authors, (2026).

III.7 SIMULATION RESULTS OF BIDIRECTIONAL DC-DC INTERLEAVED CONVERTER DURING BUCK MODE

During buck mode operation, the battery current (I_B) and interleaved inductor currents (I_{L1} and I_{L2}) show some initial transients and then settle nicely, which shows that the current control was effective, and effectively reduced ripple, due to the interleaving. The output voltage (Vo) cleanly tracks the reference voltage (V_{ref}), to confirm proper voltage regulation, while the steady increase in SOC indicates that the battery is effectively charging during this mode of operation.

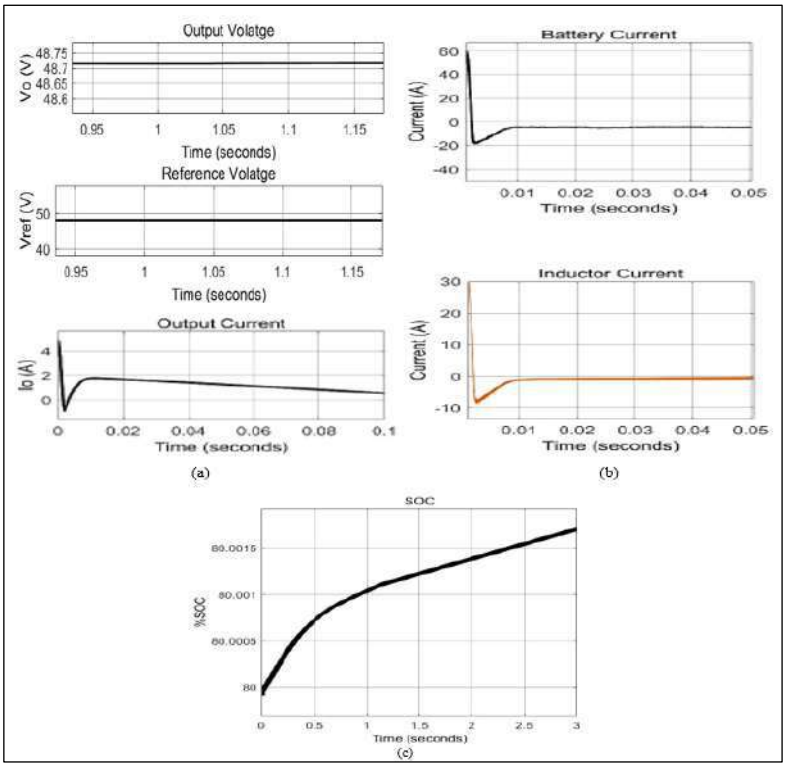

Figure 12: Simulation results of bidirectional DC-DC interleaved converter during buck mode (a) I_B , I_{L1} , I_{L2} (b) V_o ,V_{ref} ,I_o (c) %SOC.

IV. CONCLUSIONS

The use of a USB Power Delivery system with bidirectional power flow, as represented in the block diagram, is a proven system for managing power demands in contemporary energy systems. The bidirectional power flow system utilizes a solar PV panel with an MPPT controller, a DC-DC converter, a bidirectional converter, and a USB controller that will ensure optimal usage of the power generated by the solar panel, flexibility regarding energy storage and extraction, and device compatibility. The MPPT controller for the solar panel, DC-DC converter with battery feed, and the bidirectional converter both contacting the battery and being fed from the battery means that independent operation, i.e. charging the battery and dynamically powering local devices becomes seamless. The system also provides sustainable charging solutions for portable devices while allowing for unique energy independence through the ability to push power in both directions, from the battery to devices and devices to the battery. The adoption of advanced USB with USB-PD standards improve the User Experience by means of dynamic power negotiation, and fast charging. Overall, the implementation of the proposed solution presents improved energy efficiency, reliance on conventional power options were reduced, and a push towards renewable energy technologies is introduced. There are theoretical advances in power electronics, energy storage, and intelligent control that can help improve the performance, flexibility, and scale of such systems towards green and smart technologies.

ABSTRACT

Working with the command line bash gives a lot of control, although mistakes happen quickly if someone combines the wording. Using the Linux terminal in this way act promptly. In spite of this, it is easy to make mistakes without noticing. Even the linux professionals accept that remembering linux commands, or syntaxes may seem like hard work now and then. This paper proposes CommandIQ, a professional linux tool developed to transform common English phrases into usable Bash commands. When the user enters English phrases, this tool accepts the input and then applies two methods FAISS and T5 model. Initially FAISS compares the current input with the previous existing examples that closely fit with what the user requests for. If the query does not match with the FAISS comparison it then moves to T5 model that builds existing linux commands. Together, the presented tool produces a solid linux command what the user expects. The system is tested with around 200 thousand of real world linux command examples and tested with 2,352 english phrases to check the performance and the system produced 91% exact match accuracy compared with existing FAISS and T5 models individually. The CommandIQ tool produced a better accuracy overcoming the existing models in structure way. Overall, it makes tasks easier, quicker, more intuitive - even for new users to perform tasks using terminal.

I. INTRODUCTION

The command line requires exact syntax and even experienced developers make mistakes. Remembering exact syntax for tasks like compressing, verifying files, shifting directories, or chaining tasks which requires Googling the same thing over and over and checking technical documentation, forums, and related communities. Missing one letter in the command causes unexpected bugs, crashes or system failures. A more efficient approach is to translate natural language instructions into Linux commands automatically. For example, user could type a simple English phrase to compress directory such as “compress this directory into a zip” and instantly receives the correct command. Models such as transformers converts the English words into commands during translation but produce incorrectly formatted output. On other hand, search based tools provides accurate commands fast from memory but fails when faced with new or uncommon inputs. To overcome these problems, we propose CommandIQ, a hybrid tool that combines strengths of two methods. When questions are feel familiar, FAISS retrieves commands based on the meaning of the question rather than exact wording. If the user purpose isn't clear then fine-tuned T5 model interpret it and generate an appropriate command. The system maintains adaptability and this approach improves the accuracy while reducing errors during command generation and execution. The system is designed by the three key concepts. First, the hybrid method allows the system to balance the retrieval and generation of commands. Second, several datasets are collected from different sources. After that the dataset was cleaned and validated to support training and testing processes. The system achieves 91.0% exact match accuracy, outperforming the other methods without any difficulty on new or unknown inputs. The system is lightweight and integrate easily into daily use and helping new users and professionals gets fast commands without internet.

The rest of this paper is as follows: Section II discusses about related work and previously existing solutions. Then Section III explains how the system works, implementation details and overall architecture of the system. Section IV describes the steps for FAISS lookup and T5 model generation of the commands. After that, Section V shows outcomes of the systems like training results against validation, speed, accuracy. Finally, Section VI concludes by presenting where things could go from here.

II. EXISTING SYSTEM

Previous researches are exposed with natural language to command line systems where it focuses on recurrent neural architectures. Systems like Tellina [1] showed that GRU-based models could understand the meaning behind the user instructions, but often resulted in incorrect commands. Similarly, there are several limitations were noticed in NL2Bash [2]; the difference between natural phrasing and exact structure of the command made consistent mapping hard to achieve.The introduction of transformer architectures thus shifted the research towards more sequence-to-sequence that is robust modelling. The T5 framework [3] brought about a unified approach in text-to-text generation that improved the generalization of NLP tasks. Building on this work, Fu et al. developed an updated NL2CMD workflow [4] and a Bash Translation model using transformers [5]; both had significant improvements in accuracy over previously developed RNN methods. Very recent studies demonstrate large language models can further improve command prediction, as in the LLM-supported translation work of [6], [7]. Parallel efforts explored the broader landscape of natural language command interaction. Initial efforts such as the Linux Shell Interface report [8] and the NLCI interpreter [9] set basic concepts for interpreting commands, and adaptive interface research [10] investigated how systems can learn to adapt to user behaviour. Other related tasks were addressed, including the work by Bash Explainer [11], which concentrated on generating explanations for shell scripts, and execution-based evaluation methods [12], which developed pragmatic testing for command reliability.Retrieval-augmented methods have also become influential. The similarity search using FAISS [13], [14] allows for quick retrieval of semantically related commands, and hybrid retrieval-generation models [15] demonstrate how the integration of retrieval with transformers generally stabilizes the quality of the output. These are in line with modern transformer toolkits such as Hugging Face Transformers [16] and Sentence-Transformers [17], which form the basis of embedding and model deployment in state-of-the-art systems. In all, prior work indicates a chronological evolution-from early rule-driven and recurrent models to transformer-based and retrieval-enhanced approaches-each contributing toward safer, more accurate natural-language-to-command translation.

III. PROPOSED SYSTEM AND ARCHITECTURE

The proposed system, called CommandIQ, is designed to translate natural language queries into Bash commands using a hybrid approach that combines both retrieval and generation methods. The main goal of the system is to make it easier for users to interact with Linux by simply typing what they want in plain English and getting the correct command as output. For example, a user might type *"Show all hidden files in the current directory"*. The system processes this text and generates a semantic embedding using a Sentence Transformer model. These embeddings are then compared with thousands of precomputed command embeddings stored in a FAISS index, allowing the system to quickly retrieve the most relevant command candidates. When a user types a query, the system first converts it into a vector representation using the all-mpnet-base-v2 model. This helps the system understand the meaning of the sentence. The converted query is then processed in two different ways at the same time. In the first path, it is matched with a large FAISS index that contains more than 200,000 prestored command examples. This allows the system to quickly find commands that are semantically similar to what the user is asking for. In the second path, the same query is given to a fine-tuned T5-base model, which can generate new commands when no close match is found in the index. After both models provide their results, a decision logic is used to choose the final output. If the command retrieved by FAISS is highly similar to what the T5 model predicts, the system selects the FAISS command since it is usually more precise. Otherwise, the output from the T5 model is used, especially when the query is new or phrased differently. Once the final command is chosen, it is cleaned up using regular expressions and shown to the user, with an option to run it directly in the terminal. The complete workflow of the proposed system is illustrated in Figure 1, showing the step-by-step process from user input to command generation and execution.

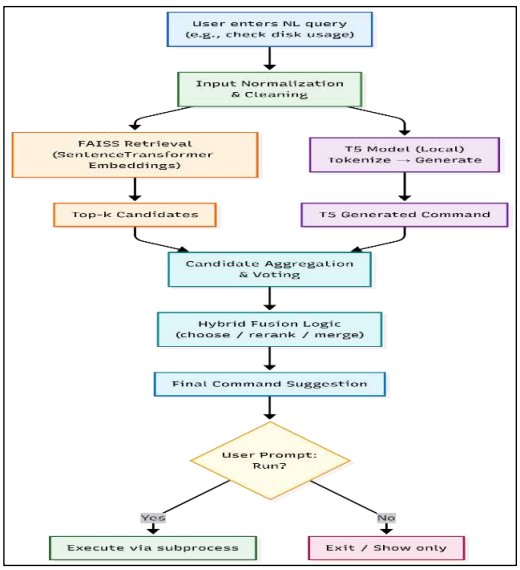

Figure 1: Overall workflow of the CommandIQ system.
Source: Authors, (2026).

III.1 THE PARALLEL PREDICTION STRATEGY

The system begins when a user enters a Natural Language (NL) query, such as 'check disk usage'. This immediately undergoes Input Normalization & Cleaning to standardize text, remove superfluous characters, and prepare the query for embedding. Furthermore, the system initiates two predictive paths in parallel to maximize the speed and reliability:

1. FAISS Retrieval Path: The cleaned query is vectorized using a Sentence Transformer model and this embedding is used to perform a nearest-neighbour search against the large vector index.
2. FAISS Vector Index: This is the curated dataset of 200,685 validated commands. This path is optimized for speed and high structural correctness, returning the Top-k candidates with their confidence scores
3. T5 Generative Path: The raw text, meanwhile, enters the locally loaded T5 Model. T5 deploys its fine-tuned sequence-to-sequence knowledge to Generate a likely command string. The route is crucial for generalization, where the system needs to handle novel queries that are unseen in the index of FAISS.

III.2 HYBRID FUSION LOGIC (THE CORE INNOVATION)

The outputs of both parallel tracks are combined in the Candidate Aggregation & Voting step. It is here that the system has to decide which command to focus on. The decision is controlled by the Hybrid Fusion Logic, which works based on heuristics extracted from our validation process (as described in Section V):

1. The system first checks if the top-ranked FAISS command (FAISS cmd) is an exact match or highly similar to the T5 Generated Command (T5 cmd).
2. If the similarity is confirmed, then the system defaults to the FAISS command. This preference is crucial because the retrieval system guarantees a pre-validated syntactically correct structure.
3. In case there is a large divergence in results from FAISS and T5, the system falls back to the T5 output, accepting the risk of a minor syntactic error in favour of returning a semantically relevant response given a novel query.

III.3 FINALIZATION AND EXECUTION

The final phase of the CommandIQ pipeline converts the predicted command into an executable action. This is the most critical layer for safety and reliability in the system. Once ambiguity is resolved by the Hybrid Fusion Logic to select the definitive command (Final cmd) from either the FAISS retrieval or T5 generation path. The selected Final Command Suggestion goes to the user interface. The system asks for confirmation from the user in a Q: "User Prompt: RUN?" This is a critical safety step taken so that the user gets to examine the command before it is executed. If the user confirms 'Yes', the system will securely execute the command using the Python subprocess library, routing the system output directly back to the console. If the user confirms 'No', the session will terminate gracefully, and the user will be able to either refine their query or execute an alternative command by hand. This last workflow ensures that here the user is always in control, but might benefit from the speed and the intelligent predictive powers of the system.

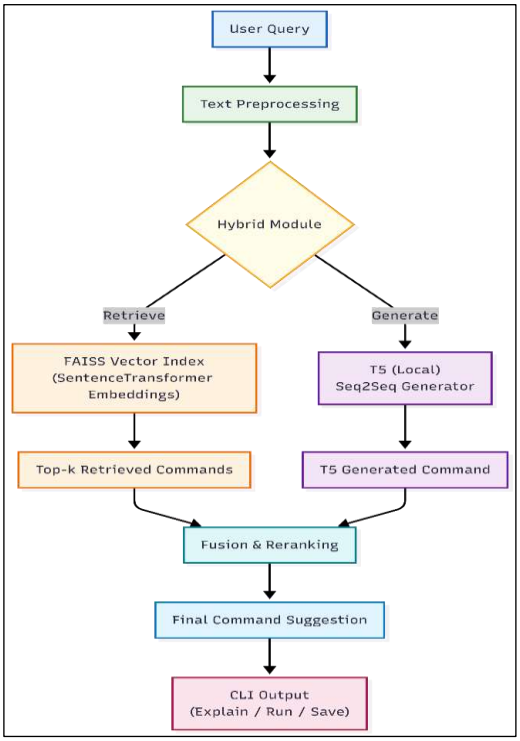

Figure 2: Hybrid architecture combining FAISS retrieval and T5 refinement.
Source: Authors, (2026).

Figure 2 illustrates the model architecture representing how the FAISS retriever and T5 generator cooperate within the hybrid framework. In this architecture, the module of FAISS is used as a high-speed retriever for narrowing down possible command candidates, while the T5 model acts as a reasoning layer that helps to further refine and finalize the prediction to ensure the system stays both fast and contextually accurate. The system does not wait sequentially for a T5 failure; rather, as depicted in Figure 2 (Hybrid architecture combining FAISS retrieval and T5 refinement.) it activates the retrieval and generation paths together. This parallel prediction maximizes speed but places a heavy burden on a robust Fusion and Reranking stage. It is at this stage that we apply heuristics derived from our evaluation results: the system first checks the semantic proximity and structural match of the top-ranked FAISS candidate and the T5-generated command. Relies on FAISS output when the confidence is high then we make sure that the output is correctly structured. T5 model isn't as good as the FAISS but we keep it as a fallback which means it generates correct answers only when the FAISS index cannot resolve with high confidence. In this way these two methods work together allows CommandIQ to achieve an perfect balance of speed and precision, also it can handle almost any query. In other words, CommandIQ manages to balance speed and accuracy by uses these two methods together. FAISS gives immediate answers for simple or familiar queries, while the T5 model helps the system to understand complex and unclear queries. This give us a reliable command translation tool that understand and works well with different users.

IV. METHODOLOGY

This section describes the overall methodology to develop the Linux command translator. It covers dataset preparation, FAISS indexing and retrieval**,** model configuration, and the CLI integration and execution interface.

IV.1 DATASET PREPARATION

Diverse datasets are collected and cleaned for training and evaluation phases. Publicly available datasets such as NL2CMD, natural language to Linux, and bash command datasets are combined with our own data. Thess datasets includes core commands and other entries we manually created. All datasets are cleaned and deduplicated, then divided into training and test sets. The final training set contains 194,910 samples, while the test set consists of 2,352 samples for final evaluation to ensure reliability and consistency. The system is a built on manually created dataset which consisting of pairs of natural language queries with their respective Linux commands. Records in the dataset have the following format: {"nl": ".", "cmd": "."}. To increase diversity, we made several different ways to ask the same question. For example,

a. "List all files in the current directory"
b. "Show contents of the folder"
c. "Display files here" All map to the same command: *ls*

These variations help the model generalize to different user phrasings. The final dataset was split into training, testing, and additional subsets. The final_train.jsonl and additional_train.jsonl files were combined in order to be used in a stronger FAISS index that improves recall accuracy. Each query was then embedded using the Sentence Transformer model all-mpnet-base-v2, which embeds natural language into dense vector representations. These embeddings were then stored and indexed using FAISS — Facebook's AI Similarity Search library: to enable lightning-fast retrieval during inference. These datasets are combined and refined for better generalization by ensuring broad command coverage. The datasets used were both publicly available and custom-curated, such as NL2CMD, bash commands, and datasets created to increase the coverage. The datasets employed for training and evaluation are summarized in the following Table 1:

Table 1: Dataset Summary Table.

Dataset Name	Samples	Description
NL2CMD Original Train	40639	Publicly available NL-to-Bash commands
NL2CMD Original Test	300	Publicly available NL-to-Bash commands
NL2CMD Cleaned Train	20616	Publicly available NL-to-Bash commands
NL2CMD Cleaned Test	300	Publicly available NL-to-Bash commands
Natural Language to Linux Command Dataset	18357	Natural language to Linux commands
Publicly Available Linux Commands	8669	Publicly available Linux commands
Bash Commands	840	Publicly available Bash commands
Core Commands	1095	Manually created core Linux commands
Additional Train	1925	Dataset created to improve model accuracy
Final Train	194910	Combined training samples
Final Test	2000	Reserved samples for final evaluation
FAISS Index Corpus	200685	Samples used for FAISS embeddings

IV.2 FAISS INDEXING AND RETRIEVAL

```
MODEL_NAME = "t5-base"
BATCH_SIZE = 8
NVIDIA T4 GPU
EPOCHS = 10
LR = 3e-4
MAX_INPUT_LEN = 96
MAX_OUTPUT_LEN = 48
```

Figure 3: T5 Model Hyperparameters.
Source: Authors, (2026).

Once the dataset has been preprocessed and cleaned, the next important step involves embedding and indexing the data with FAISS. Each natural language command in the dataset is converted into a dense vector representation using the Sentence Transformer model, which is allmpnet-base-v2. These embeddings capture semantic meaning such that the system is able to pick out commands that are similar in context even if they are worded differently. Once all embeddings have been generated, they are stored in a FAISS index, enabling fast similarity searches across thousands of records.

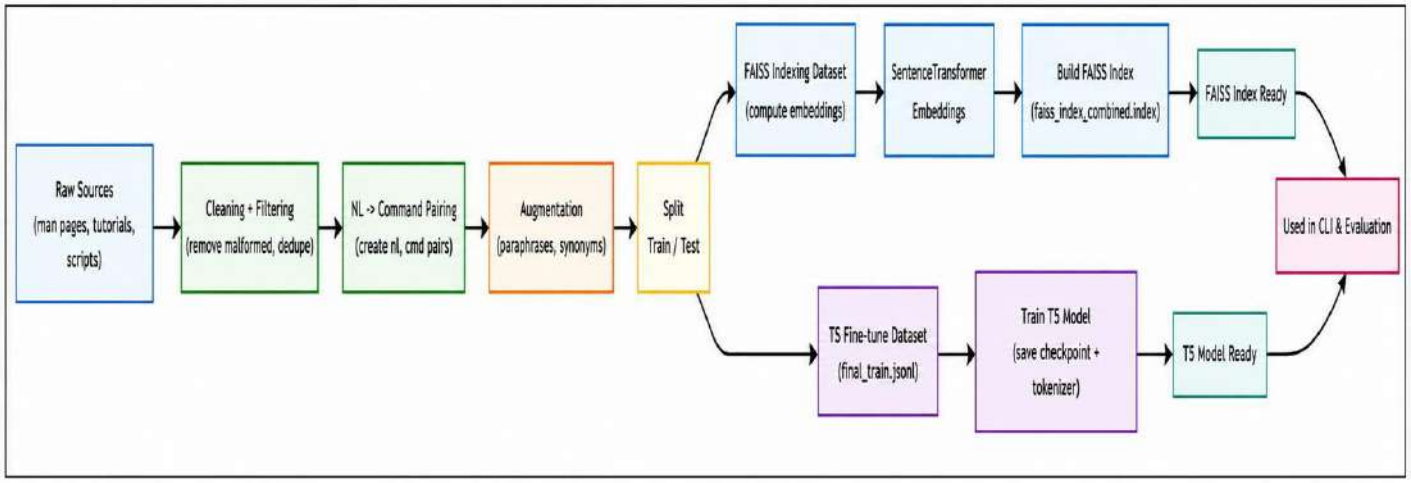

Figure 4: Dataset preparation and indexing pipeline for CommandIQ.
Source: Authors, (2026).

In inference, given a natural language query by the user, the system computes its embedding and searches for the top 5 most semantically similar commands in the FAISS index. The retrieved commands serve as candidate results and go into the T5-based refinement model for final prediction. This hybrid technique uses FAISS for fast retrieval and T5 for better understanding of the query. Hence, this model gives the best of both speed and accuracy. It can respond in real time while maintaining high precision in command generation.

IV.3 MODEL CONFIGURATION

The core of CommandIQ uses a hybrid FAISS–T5 architecture. When a user query is received, FAISS retrieves the top-5 most semantically similar command candidates. These are then is passed to T5, a Text-to-Text Transfer Transformer model. for refinement. The generative part of CommandIQ is a fine-tuned T5- base model: it is trained to map natural language queries to their corresponding Bash commands using a sequence-to-sequence framework. Hyper-parameters include batch size, learning-rate, number of epochs, maximum of input/maximum of output lengths were chosen based on both GPU memory constraints. and model stability. During training, the model learns to generalize to unseen queries while preserving the structural integrity of Bash commands. The T5-base transformer model was fine-tuned to translate natural language queries into Linux-commands. The used hyperparameters for training are Summarized below are the test settings that were used.These settings were selected as a balance between speed of convergence and stability during training. T5: The model follows the standard encoder–decoder structure:

a. The encoder reads the natural language query and the Candidate commands.
b. The decoder focuses on in order to generate the final command. context and syntax learned during training. This approach allows the model to handle complex or multistep commands that FAISS alone might not be able to find the right commands.
c. The encoder–decoder framework ensures that the understanding the full meaning of the user query and proper way to write the Linux commands. The Encoder captures the meaning of the user's query, and then the Decoder generates correct command that matches both what user wants and the proper command format.

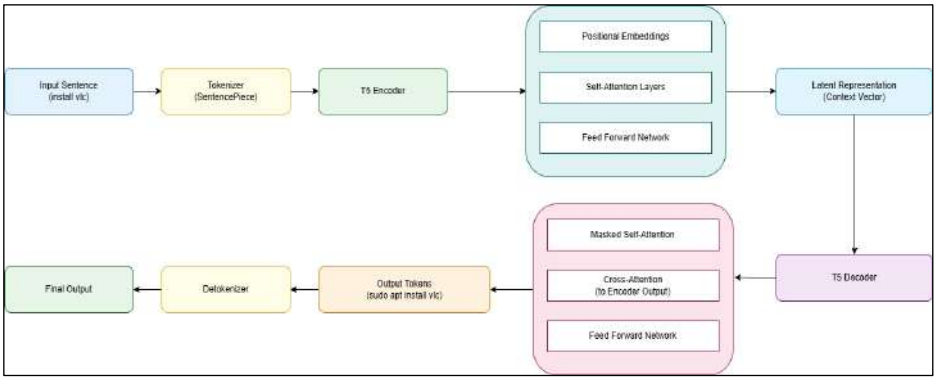

Figure 5: Encoder–decoder architecture used in the T5 model for command generation.
Source: Authors, (2026).

IV.4 CLI INTEGRATION AND EXECUTION INTERFACE

The final part of the CommandIQ is the command-line interface. This wrapper takes the final output generated by the system and shows it to the user. We built this tool using Python click library, it works really fast and clear to use on a Machines with Unix or Linux environment. The most important functionality of the system is to provide a safety check by presenting the final predicted command to the user and asks them to confirm it before the system executes it.

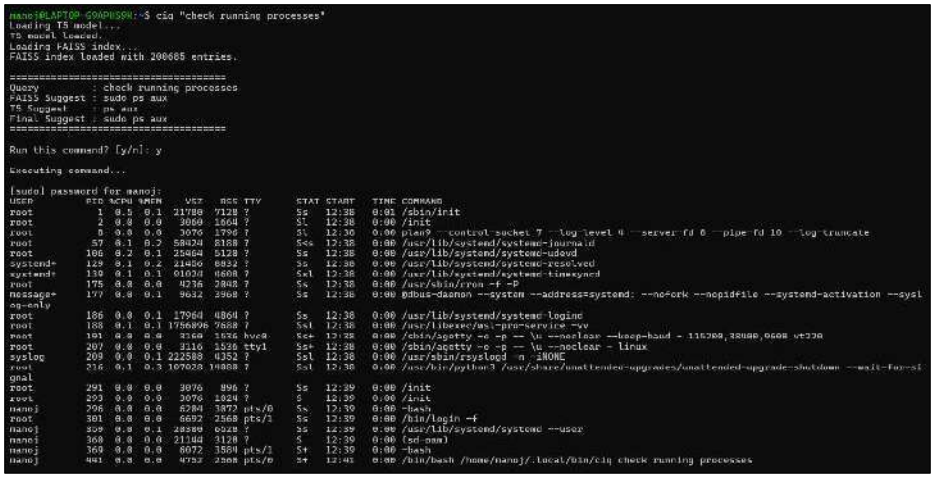

Figure 6: CommandIQ CLI Execution Interface.
Source: Authors, (2026).

The interface displays the parallel predictions from both FAISS and the T5 models together with the final chosen command are shown. Then the user sees the safety layer where the user interacts with command line before execution of command using subprocess. The command line receives the final, clean command from the hybrid system it then asks the user with the question: "Run this command? [y/n]" whether they want to execute the command or not. This interactive step gives the user full control and allows them to check the command so they don't run something wrong. If the user confirms to run the command, then the system uses a Python subprocess library to execute the Bash command safely.

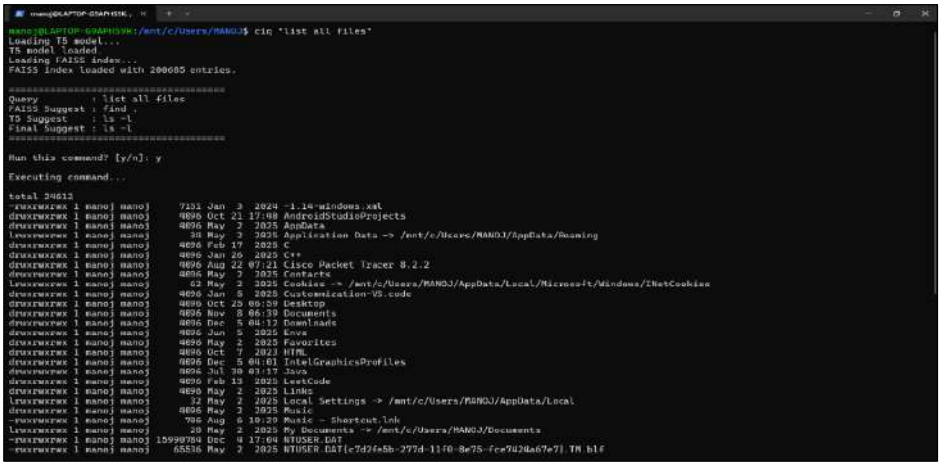

Figure 7: CommandIQ CLI Execution Interface.
Source: Authors, (2026).

This safety layer is more important to run the command successfully in live environment. CLI also prints useful information by outputting the individual FAISS and T5 predictions giving the user insight into the hybrid system's decision-making process. The final execution interface receives parallel predictions from the de-identified FAISS and T5 models before presenting the final, sanitized command. The following interactive prompt is a very important safety mechanism, which requires explicit user confirmation by the subprocess before execution in the live environment.

V. RESULTS AND ANALYSIS

The T5 model and the FAISS retrieval system were trained and tested on the final test set, consisting of 2,000 samples. The primary metrics of interest in this evaluation were Exact Match (EM) accuracy, Partial Match (PM) accuracy, and semantic similarity between predicted and expected commands. This section provides the results of training, accuracy measures, and model comparisons resulting from extensive testing using the final_test.jsonl dataset.

V.1 TRAINING AND VALIDATION LOSS

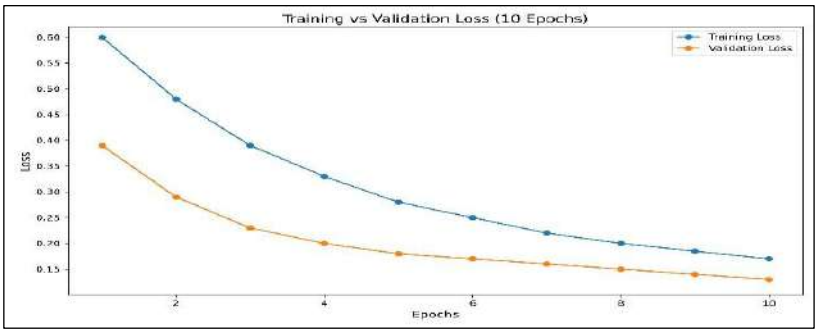

Figure 8: T5 model training and validation loss over epochs.
Source: Authors, (2026).

The training loss and the validation loss were closely monitored during training on the T5 model. As below Figure 8 shows, the loss has smoothly decreased with each Epochs, it shows the model is generalizing the data instead of just memorizing the training data. When the training loss and validation loss curves came together smoothly it shows that the model learning behaviour is stable and make reliable predictions while maintaining consistency between the training data and unseen validation data. Figure 7 shows the change in training and validation loss during the 10 epochs of training. A decrease in validation loss indicates the model continues to improving in understanding the relationship between user intent and command structure. This steady learning was important in making sure it remains solid when facing fresh inputs it hadn't seen before. This decreasing trend, with eventual stabilization, indicates that the model effectively learned the mapping from natural language to Linux commands without overfitting.

V.2 MODEL METRICS COMPARISON

To compare the performance of different approaches, we tested FAISS-only, T5-only, and hybrid models on the same test set. Figure 8 represents the Exact Match and Partial Match accuracies, showing the best overall performance of the hybrid model by combining the advantages of both retrieval and generative approaches. We compare FAISS-only retrieval, T5-only generation, and the hybrid approach.

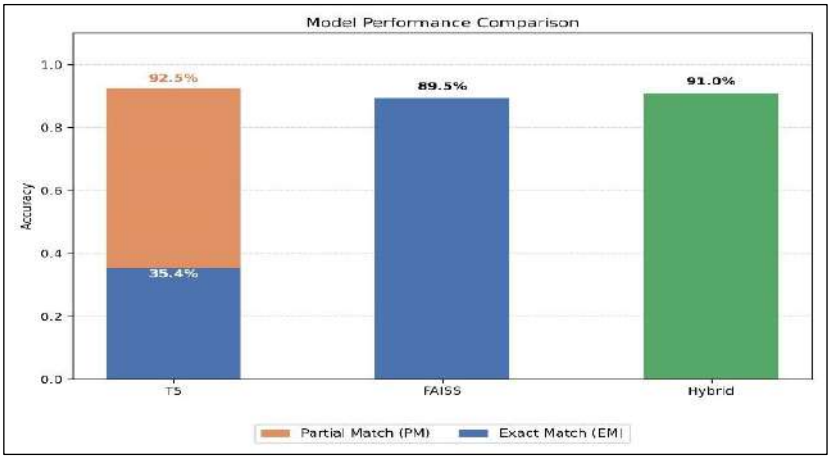

Figure 9: Comparative analysis of T5-only, FAISS-only, and Hybrid FAISS–T5 models.
Source: Authors, (2026).

Figure 8 summarizes the exact match (EM) and partial match (PM) accuracies across all models. The hybrid model yields an EM accuracy of 91.0%, which is marginally higher compared to the score obtained by the FAISS-only baseline (89.45%), whereas the T5-only model has high PM (92.55%) but considerably lower EM (35.35%).

This demonstrates that T5 seems to understand what the commands want to achieve, yet it fails to produce the exact syntax on a regular basis. The hybrid approach effectively takes advantage of FAISS for precision while utilizing T5 to address novel or unseen queries.

V.3 ACCURACY DISTRIBUTION ACROSS TEST SAMPLES

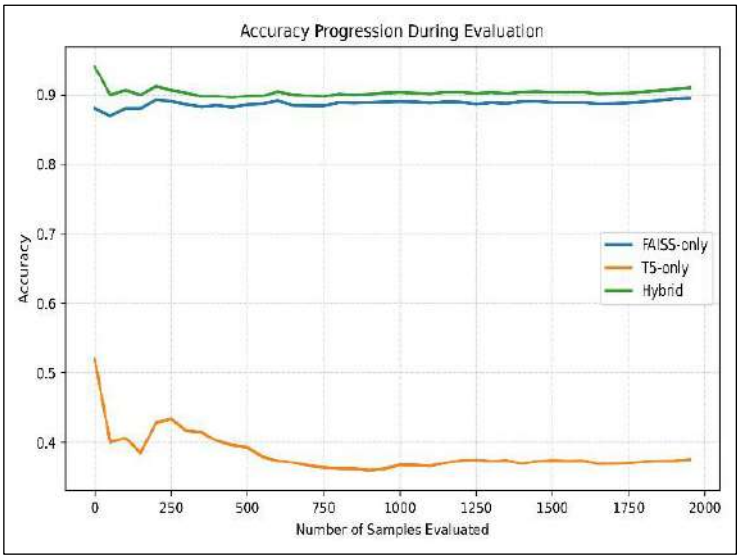

Figure 10: Accuracy distribution curve showing hybrid model performance over 2,000 test samples.
Source: Authors, (2026).

After training, the performance of the model was measured in terms of Exact Match (EM) accuracy and Partial Match (PM) accuracy on the test dataset. To check the model's performance the hybrid system was tested on 2,352 unseen queries. The accuracy graph below shows how well the model predictions were distributed across all samples. The Top-1 candidate reached 89.45% accuracy, while the Top-5 candidated achieves 94.25% accuracy. This confirms most correct commands always appeared within the top of search results. This high curve across the samples indicates that performance by the system was not depend on how different the user prompts the query or structure. This stable performance confirms the CommandIQ is robust and can understands both easy and complex natural language queries. The hybrid system is successful because the two methods FAISS and T5 work together. FAISS ensures correct command syntax for known queries and T5 enables the system to generalize for unseen queries. Overall, the hybrid model presents with high accuracy making it suitable for offline Linux command translation tasks.

VI. CONCLUSION

In this project, we built a tool called CommandIQ that solves the common problem of combining model knowledge with correct command structure, testing showed it works well in real world environments. Instead of just linking the model knowledge into strict command structures, we made the model and rules works better together by training them with real-world examples. The system uses it general understanding and manages to keep the perfect command format which makes the final answer more reliable. The results show that our system is more accurate than older systems, especially when command need to be written in perfect structure to actually run. What makes our system is different is the way it combines two steps, the first step uses FAISS for search based on the meaning of user query, the second step fine-tuned T5 model to create the final command.

When we used the T5 model by itself, it was not performing well and generates incorrect command structure (only getting it exactly right at 35.35% of the time) but it understood what the user intent (92.55% close enough). By teaming the T5 model with FAISS, we completely fixed those problems. In out tests using 2,532 examples, our new method got the exact matches right 91.0% of the time which is better than any other system used before. Furthermore, a necessary safety check integrated before running any command is executed. This shows that CommandIQ works reliable and safely in real-life terminal tasks. For the future, we plan to improve CommandIQ's strength and reach and we have cool ideas to make CommandIQ even better. Instead of just adding features, we could switch to newer, local AI models.

This would help the system to handle unusual or personalized commands better without losing accuracy from the FAISS system. On top of that, if we show a fast and simple explanation with every command, users will understand what's happening before the execution of the command. Another way is to upgrade safety layer, instead of just asking users for confirmation we could built in smart checks that automatically finds issues and stop dangerous or broken commands before they reach the user. The new safety layer will explain what the predicted commands does and find risky actions before users approve them. A solid next step is adding "live situational awareness" this means the system would adapt instantly and think about what's going on the user's device like what folders are open, which apps are active, or recent inputs - to suggest better command. To summarize, CommandIQ shows that combining instant data retrieval with command generation, builds a solid tool for turning plain English into working commands.

ABSTRACT

This project proposes an advanced fuzzy logic controller (FLC) for fast EV charging stations integrated with DC microgrids. Unlike conventional PI controllers, which struggle with dynamic operating conditions, the FLC adapts in real time using parameters such as battery state of charge, grid conditions, and battery health. In Grid-to-Vehicle (G2V), Grid + Photovoltaic to Vehicle (G+PV2V) modes, the controller ensures efficient fast charging by optimizing current flow, reducing voltage ripples, and maintaining DC-link stability. In Vehicle-to-Grid (V2G) mode, it dynamically regulates battery discharge to enhance grid support while protecting battery life. Simulation results show that the proposed FLC significantly reduces charging time and improves system efficiency, achieving a runtime of 213.3 seconds compared to 317 seconds using a PI controller. Overall, the FLC-based strategy enhances system stability, responsiveness, and adaptability, making it a suitable solution for smart EV charging in modern DC microgrids.

I. INTRODUCTION

In recent years, electric vehicles (EVs) gained popularity as they are able to decrease the consumption of oil fuels, enhance air purity in metropolitan cities, eliminate noise pollution, and promote eco-friendly transport networks [1]. This has opened up a new era, and thus, EVs are predicted to substitute conventional vehicles with internal combustion engines in the near future. In this regard, to create a uniform charging procedure for EVs, charging standards were developed by the Society of Automotive Engineers and International Electrotechnical Commission based on electrical requirements, charging methods, and charging duration. With respect to charging duration, charging of EVs is classified under three categories, including slow charging (Level 1), which takes more than 8 hours; medium charging (Level 2), which takes 6 hours; and fast charging (Level 3), which takes only 30 minutes to fully charge the EVs' batteries altogether [2].

Level 1 charging is appropriate for residential purpose or charging during night time; nevertheless, the longer charging time makes it unsuitable for daily driving range of traditional vehicles. Level 2 charging supports higher power levels along with faster charging times than Level 1 charging and is still not appropriate as a vehicle onboard charging system owing to time constraints. Rapid charging is thus highly desirable for EVs. Level 3 charging consists of off-board fast-charge connectors of high power levels of 80-240 kW, which facilitates fast charging of the vehicle battery. With the rising use of EVs, the need for a large number of charging stations arises [3]. The planning, placement, and operational impact of EV charging stations on modern power systems have been widely studied [4], [5]. At present, the popular method of charging the EV is by connecting it to 120 V (Level 1) or 240 V (Level 2) AC receptacles as per the SAE J1772 (2010) recommendation [6], [7].

Though this slow-charging system is able to charge the battery fully within several hours, it is inefficient owing to longer charging times [6]. Therefore, fast charging is preferred to minimize the charging time and facilitate wider diffusion of EVs [7]. Advanced converter topologies and integrated renewable-based charging stations have been proposed to improve efficiency and scalability [8], [9]. CHAdeMO standard is an off-board DC fast-charging technology, and hence, higher power level charging can be achieved using this, and fast-charging station has a wide use of this for implementation [10], [11]. A microgrid is a decentralized self-contained source of electrical supply that incorporates the use of the main grid supply and renewable sources of electricity in order to minimize dependence on the main grid supply [12], [13], [14]. Of the renewable sources of electricity, solar photovoltaic sources are very popular. Hence, the incorporation of solar PV-based BESSs in the DC-based charging stations may greatly reduce grid stress and make the entire system reliable [15].

II. LITERATURE AND RESEARCH GAP

II.1 LITERATURE

[1] H. Tu, H. Feng, S. Srdic, and S. Lukic highlight that there is an urgent need for efficient charging infrastructure as the adoption rate for electric vehicles is extremely fast. Extreme Fast Charging (XFC) is cited as one promising solution that can offer charging times comparable to conventional refueling times. This paper discusses rapid EV charging methods in general as well as the requirements for XFC.The importance of employing Solid-State Transformers in Extreme Fast Charging stations is also discussed along with Medium-Voltage SST configurations for such applications.

[2] Z. Moghaddam, I. Ahmad, D. Habibi, and Q. V. Phung discuss various robust design approaches in the context of electric machines, power electronics, and drive systems, as featured in a special issue of the IEEE Transactions on Energy Conversion journal. The authors address significant areas of tolerance analysis, robust optimization, and reliability enhancement of electrical machines, power convertors, and control systems. The inclusion of modeling uncertainties, robustness/reliability analysis, and optimization of complex designs by the authors also portrays the recent trends in the area of study.

[3] B. Bilgin et al state that vehicle electrification has inevitable importance for fuel consumption and greenhouse gas emissions. Improved powertrain efficiency, high power and energy density components, and optimized control strategies are the key factors to extend driving range and lower energy consumption in electrified transportation systems.

[4] S. Rivera, S. Member, B. Wu, S. Kouro, V. Yaramasu, and J. Wang, in this paper, do a critical review on electric vehicle charging technologies: converter topologies, power levels, and charging control strategies. Their work focuses on different fast and efficient charging techniques to be used in lithium-ion batteries in order to improve charging efficiency and prolong battery life; furthermore, using the sensitivity analysis, it employs genetic algorithms to find the optimum charger sizing. In addition, various converter topologies such as neutral point clamped converters and bipolar DC bus systems have been explored for EV charging applications [16], [17]. Harmonic distortion and power quality issues during fast charging have also been reported as critical challenges in distribution systems [18]. Multilevel inverter technologies are widely used to mitigate these issues and improve power quality [19].

II.2 RESEARCH GAP

A literature study shows that the majority of existing EV fast-charging stations use traditional AC grid-based systems and PI controller-based control methods. Since DC microgrid-based charging systems provide greater energy efficiency benefits and improved renewable energy source integration, surprisingly, relatively fewer studies have specifically focused on intelligent control methods tailored to the specific needs of high-power EV fast charging applications. Fuzzy Logic Controllers (FLCs) have been extensively used with relative success in islanded DC microgrid applications as well as in renewable energy applications, although the application of FLC-based control to DC microgrid-based EV fast-charging stations with coordinated control of solar, BESS, and EV loads is unexplored. Furthermore, it will be noted that many studies do not consider the effect of EV connection and EV disconnection switching disturbances on the DC-link voltage stability.

III. MATERIALS AND METHODS

III.1 DC MICROGRID FOR CHARGING OF EVS

A DC microgrid–based fast-charging system for electric vehicles is proposed in this section. It consists of a bidirectional AC-DC converter, a bidirectional DC-DC converter for EV battery charging and discharging, and a DC-DC boost converter to integrate REN like solar PV on the DC bus. The aim is to develop a fast-charging strategy based on the multistep constant-current methodology for enabling EV batteries to be charged within 30 minutes while reducing the impact on the utility grid. Coulomb counting is employed in the battery SOC estimation in order to control the charging process. A three-level NPC AC–DC converter provides a stable DC link voltage with reduced grid harmonics. In this system, the bidirectional DC–DC converter operates in buck and boost modes and enables controlled battery charging and discharging. A solar PV system feeds to the DC bus and is operated at maximum power point to support the charging demand in order to reduce the grid dependency and improve the overall system efficiency. The integration of photovoltaic systems with battery storage significantly improves energy utilization and reduces dependency on the utility grid [20].

III.2 PROPOSED SOC-BASED MULTISTEP CONSTANT CURRENT ALGORITHM

This section describes the multistep constant-current fast-charging algorithm. The charging strategy is realized by controlling several constant current levels according to the feedback of the battery current. Battery SOC estimation is done by a coulomb counting method (CCM). Although several SOC estimation techniques exist, open-circuit voltage–based methods suffer from accuracy issues due to temperature variation and battery aging.

Kalman filter-based SOC estimation requires detailed battery modeling using internal parameters such as resistance and capacitance, which are complex to measure and vary with SOC. Therefore, the CCM is adopted in this work because of its simplicity and ease of implementation. This method requires the initial SOC value and uses the measured battery current in order to update SOC during the charging process. Also, the battery current used in the algorithm as shown in

$$SOC = SOC_{(t_0)} + \frac{1}{C_{rated}} \int_{t_0}^{t_0+t} (I_{batt} - I_{loss})\, dt$$

In SOC estimation based on the CCM, SOC(t0) is the initial battery SOC, Crated is rated capacity, I_{batt} represents battery current, and I_{loss} accounts for internal loss currents. The effective charge exchanged with the battery is obtained by integration: Figure 1. presents a flowchart of the proposed multistep constant-current fast-charging algorithm combined with SOC estimation. SOC will be computed continuously from the measured charging/discharging currents; its accuracy mostly depends on proper initial SOC and exact current measurement. Battery charge level is defined as a ratio of available capacity to a total rated capacity

$$SOC_{(t_0)} = \frac{Creusable}{Ctotal} \times 100$$

This can result in overheating when a large current is applied. As a consequence, at a low SOC, the charging current remains low. At a SOC level above 20%, a large charging current is applied for fast charging. High current charging at a low SOC also results in lithium metal deposition due to the negative anode compared to the level of Li/Li+ at a low temperature. The solid electrolyte interface layer reduces the movement of ions but inhibits electron flow. This ensures stable electrochemical reactions with minimal decomposition.

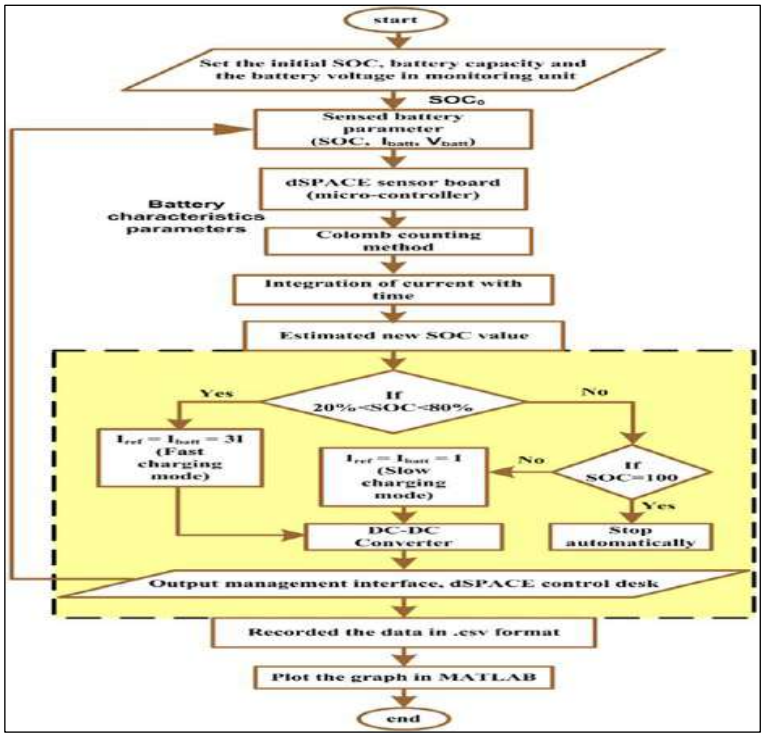

Fig. 1. Flowchart of fast charging algorithm with SOC estimation.
Source: Authors, (2026).

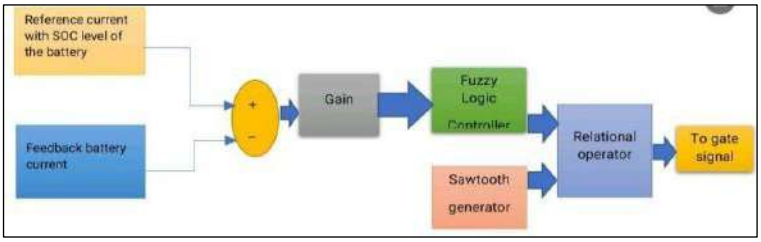

Fig. 2. Control structure of fast charging of EV.
Source: Authors, (2026).

The battery charging is controlled by using a current-controlled strategy that regulates the battery current I_{batt} against a reference current I_{ref}. The reference current is obtained from the battery SOC that is estimated using the coulomb counting method. The current error is passed through a fuzzy logic controller. Since the current ripple is small, its steady-state output is almost constant.

It is compared with a sawteeth carrier of peak value I_M to generate the gate pulse to switch S_{13} as shown in Fig. 2.The buck converter charges with varying duty cycles in the slow and fast charging phases depending on the SOC level. The slow charging process takes place between 0%-20% and 80%-100% SOC to restrict the rise in the switching voltage, and the fast charging takes place between 20%-80% SOC with an incremented current charge of almost three times the slow charge current. The sudden surge in the charge current with a 20% SOC may cause a serious load on the power utility grid, resulting in a considerable drop in the voltage level and transformer saturation. To address this issue, a fast charging DC microgrid station with solar PV and renewable resources to meet fast charging power demands and with the remaining power provided by the utility grid has been proposed.

III.3 OPERATING STAGES AND CONTROL METHOD

In this part, the functioning modes of the proposed system are discussed. There are three cases under which the functioning modes are classified. These cases are fast charging with reliance on utility grid power only, fast charging with assistance from a DC Microgrid, and power transfer from battery.

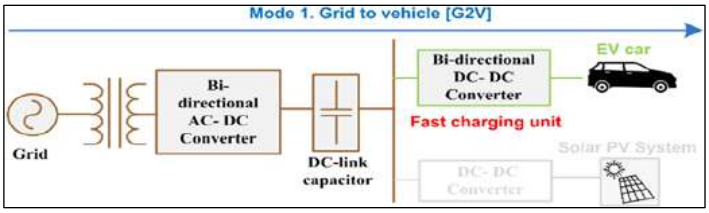

Figure 3: Power flow direction in G2V.
Source: Authors, (2026).

1) Mode 1: Grid to Vehicle (G2V), Charging: In Mode-1 charging is done using only grid power without assistance from solar PV panels. This mode of charging makes use of bidirectional NPC converters to rectify grids to charge battery using buck conversion done by DC-DC converters. Fast and slow charging currents are provided by grids alone to EV battery. The power flow for this mode is illustrated by Fig. 3.

$$P_{grid} = P_{batt}$$

a) Slow Charging (0%-20% & 80%-100% SOC)

At the beginning and end of the SOC range, the EV battery will be charged by the minimum value of grid current, Imin. The DC-DC buck converter works at a slow charge duty cycle of Dsc, which will be computed by the fuzzy logic controller (FLC) as follows.

$$Dsc(k) = F(e(k), \Delta e(k))$$

Where:

$$e(k) = I_{min}(k) - I_{batt}(k),\ \Delta e(k) = e(k) - e(k-1)$$

b) Fast Charging (20%–80% SOC):The fast-charging cycle charges the EV battery from 20% to 80% SOC with the highest current Imax, which is three times the lowest current Imax = 3Imin. Fast-charging operations demand a large amount of power within the 80 kW to240 kW range. Fast-charging duty cycle Dfc is represented as.

$$Dfc(k) = F(e(k), \Delta e(k))$$

Where:

$$e(k) = I_{max}(k) - I_{batt}(k),\ \Delta e(k) = e(k) - e(k-1)$$

Here, I_{min} and I_{max} are the reference currents for multistep constant-current charging, and I_{batt} is the instantaneous battery current. The sudden increase in charging power during fast charging can introduce power quality issues on the grid.

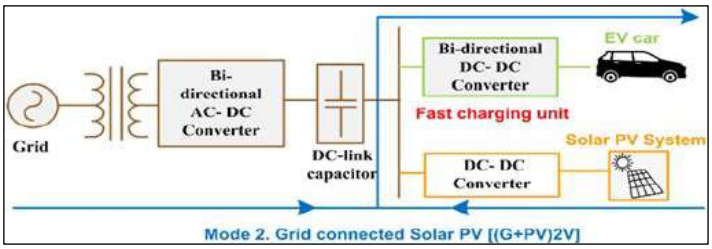

Figure 4: Power flow direction in (G+PV)2V.
Source: Authors, (2026).

2) Mode 2: Grid & Solar PV Integration ((G+PV)2V): In this case, the grid and Solar PV are connected to the DC bus as depicted in Figure 4. The DC-to-DC Boost Converter with the MPPT algorithm maximizes the power obtained from the Solar PV to charge the batteries.

a) Slow charging (SOC 0%-20%, 80%-100%): At a battery SOC of 0%-20%, 80%-100%, the solar PV source will be the sole source of power & the charging current will be based on the amount of solar power drawn.

$$I_{batt} = I_{Pv}$$

b) Fast charging (SOC 20%–80%): At this stage, the EV's battery works in the SOC interval of 20%-80% and charges at the maximum permissible current I_{max}. To satisfy the higher charging power, the solar PV and the grid supply the EV at the same time. This assists in reducing the burden of the grid. The equivalent current value when more than one source is supplying current to the EV is expressed below.

$$I_{batt} = I_{grid} + I_{Pv}$$

3) Mode 3: Vehicle-to-Grid (V2G) mode: In V2G operation, the NPC converter functions in inverter mode and transfers power from the EV battery to the grid. Scheme 1 is configured as an automotive converter, and in both operating modes, the control capability of the NPC converter is governed by its VPN gate driver. Under this condition, the battery discharging power is equal to the grid power, as expressed in below. The power flow for this mode is illustrated in Fig. 5.

$$P_{batt} = -P_{grid}$$

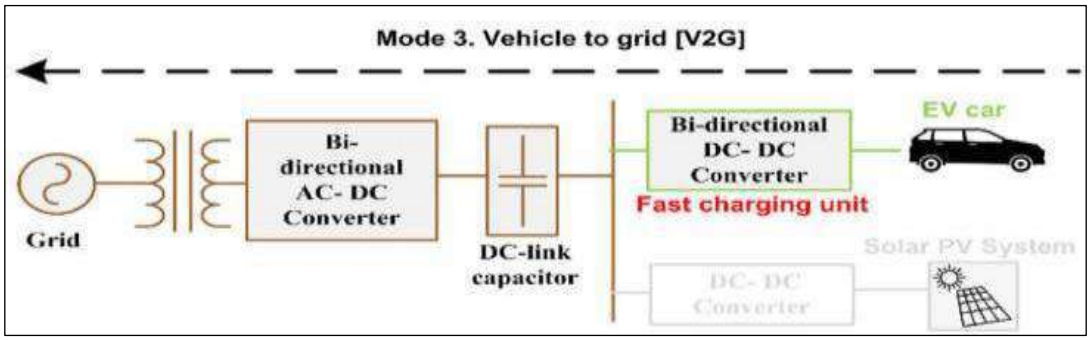

Figure. 5: Power flow direction from Vehicle to grid.
Source: Authors, (2026).

IV. RESULTS AND DISCUSSIONS

Mode 1: Grid to Vehicle/ (G2V) operation

In this mode, grid to vehicle (G2V) operation takes place without relying on solar PV panels. The bidirectional NPC converter acts as a rectifier here, and for battery charging in this case, a DC-DC converter charges the EV battery in buck mode using grid power for both slow and fast charging. For SOC, DC-link voltage, and voltage ripple, a fuzzy-logic controller provides better stability and efficiency during charging, and an FLC controller helps to adjust real-time performance as shown in fig (6).

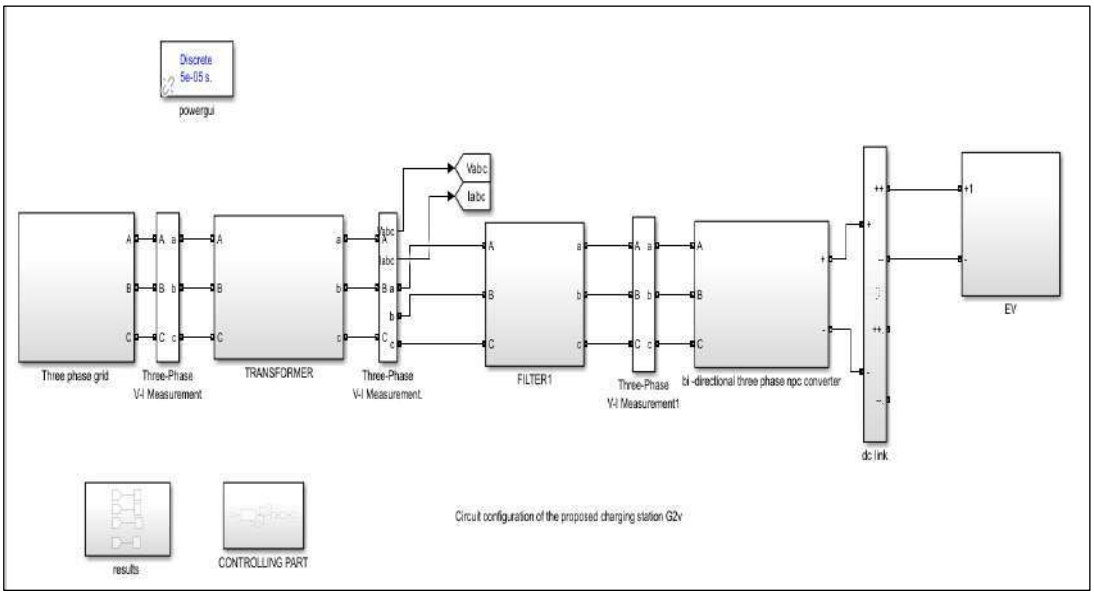

Figure. 6: Simulation configuration of the proposed charging station WITH G2V.

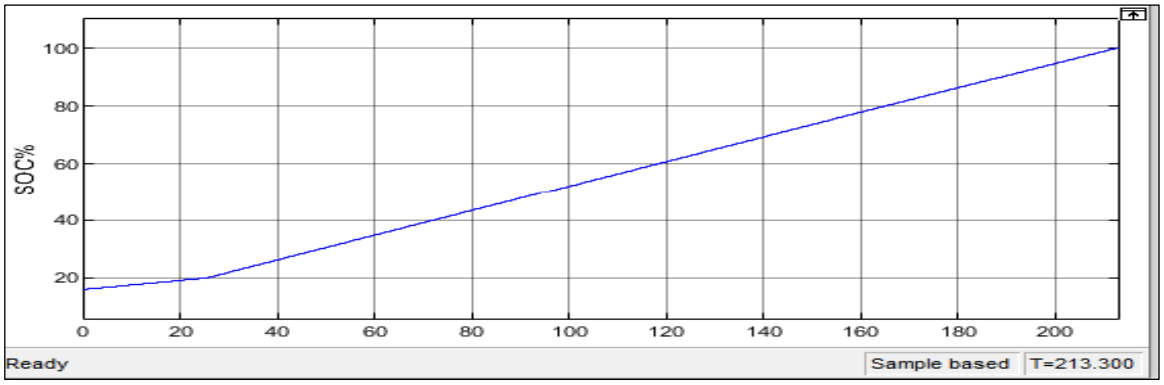

Figure 6: (d). Battery SOC.
Source: Authors, (2026).

Fig. 6(a).The grid voltage of three-phase system is in balance and of equal magnitude, and its waveform is sinusoidal with a phase difference of 120° between phases. The sinusoidal waveform of the grid voltage indicates healthy grid operation and further verifies healthy grid voltage and free from negative effects of charging system on the utility grid regarding grid voltage balance and grid power quality.Fig.6(b)The grid current in the three-phase system for the proposed topology takes a balanced and near sinusoidal form without harmonic distortion and maintains alignment with the grid voltage. The grid and grid voltage are in near-unity power factor operation due to alignment between grid and grid voltage.Fig.6(c). DC-link voltage is very well controlled around its reference value during the whole charging time. The fluctuation is only minor, which indicates that the power flow is well maintained in stable operation and the designed control scheme successfully provided voltage stability in a wide operating range. Fig.6(d). Smooth rise of state-of-charge follows with almost linear transient in time domain; this reflects that the charging process is well-regulated and very efficient. No sudden changes or oscillations are observed which further confirms that the proposed charging strategy avoids sudden transients and yields safe operation of batteries.

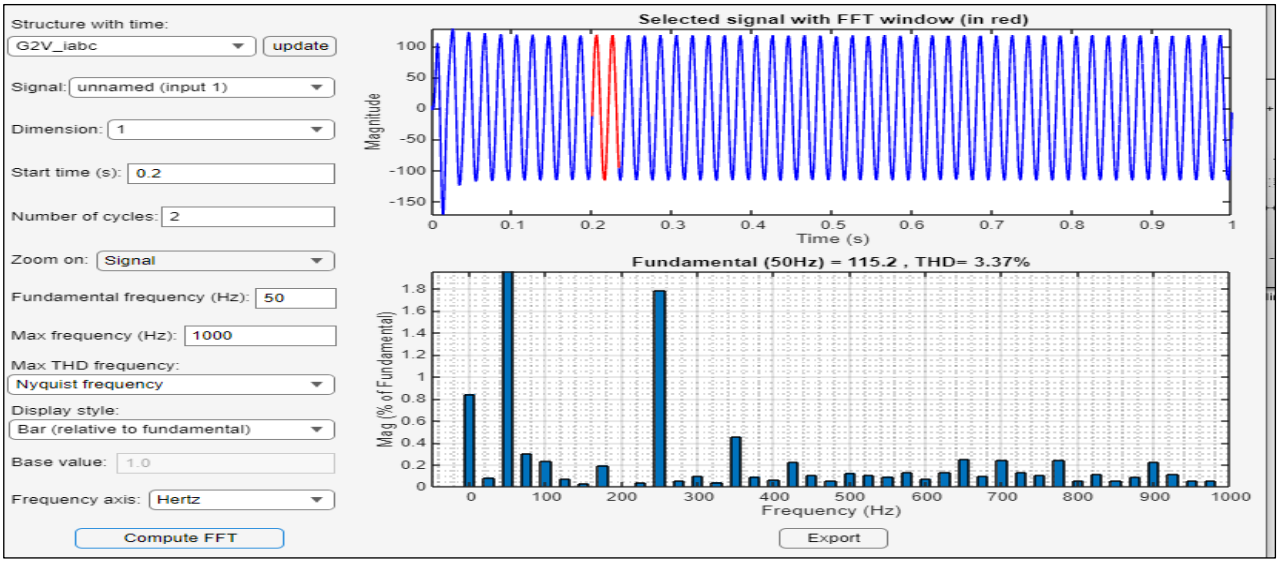

Figure. 6: (e). THD values of after transformer current.
Source: Authors, (2026).

The above Fig. 6(e) shows the FFT and THD analysis results of the transformer current in the G2V conversion process with a FLC. The current waveform is almost sinusoidal, which is an effective result of current regulation. The fundamental current at a frequency of 50 Hz is approximately 115.2 A with a THD ratio of 3.37%, which also satisfies grid specifications.

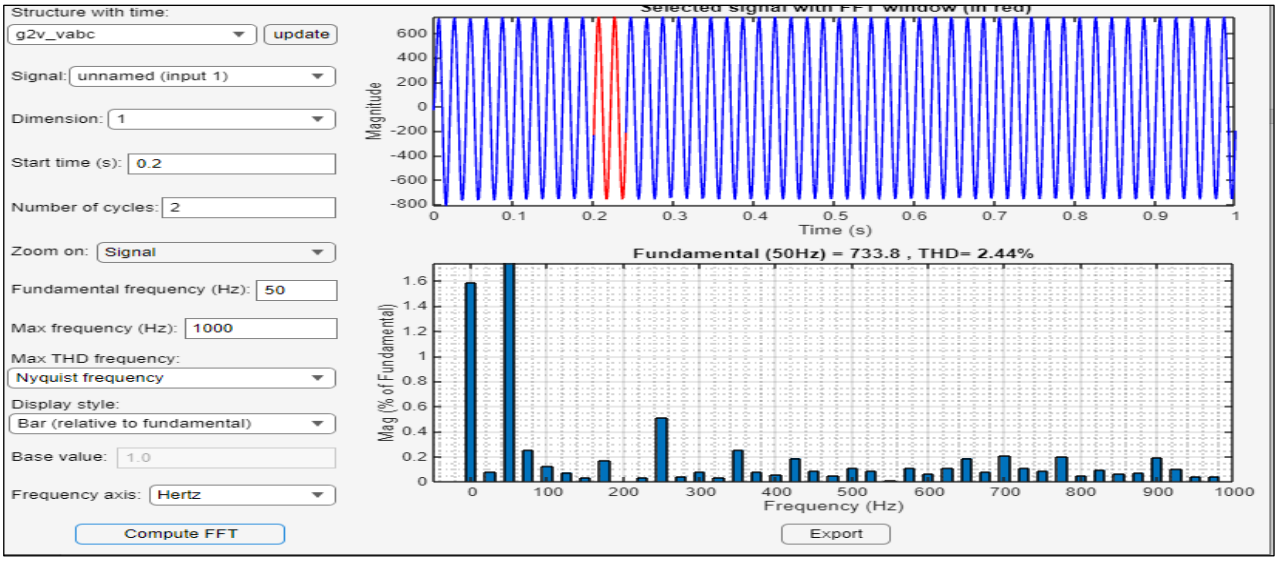

Figure. 6: (f). THD values of after transformer voltage.
Source: Authors, (2026).

Fig. 6(f). Shows FFT and THD analysis of transformer voltage in G2V mode.The transformer voltage waveform is nearly sinusoidal and stable.The fundamental voltage at 50 Hz is about 733.8 V with a low THD of 2.44%. This indicates good voltage quality, reduced harmonics, and compliance with grid standards.

Mode 2: Grid + Photovoltaic to Vehicle/ (G+PV2V) operation

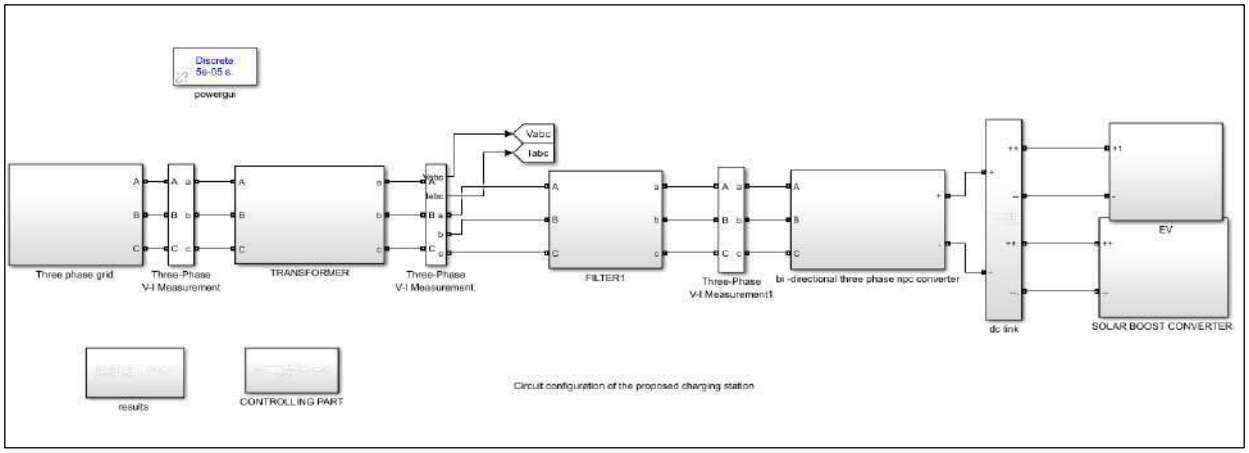

Figure.7: Simulation configuration of the proposed charging station WITH G+PV2V.
Source: Authors, (2026).

The above figure shows the DC charging station configuration which consists of a three-phase grid with an isolation transformer, a three-level AC-DC NPC converter, a bidirectional DC-DC converter for charging and discharging an EV battery, an EV battery, and a boost DC-DC converter for incorporating a PV system. The transformer increases the electrical distance between the grid and the charging station.

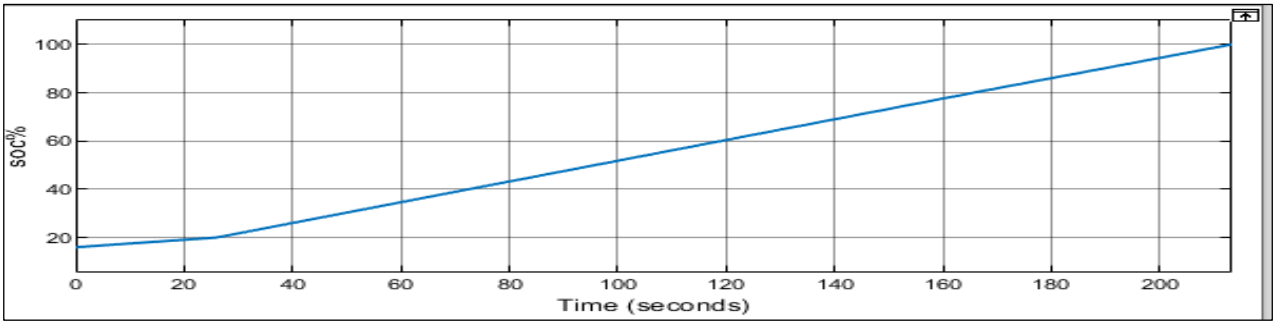

Figure.7: (a). Battery SOC.
Source: Authors, (2026).

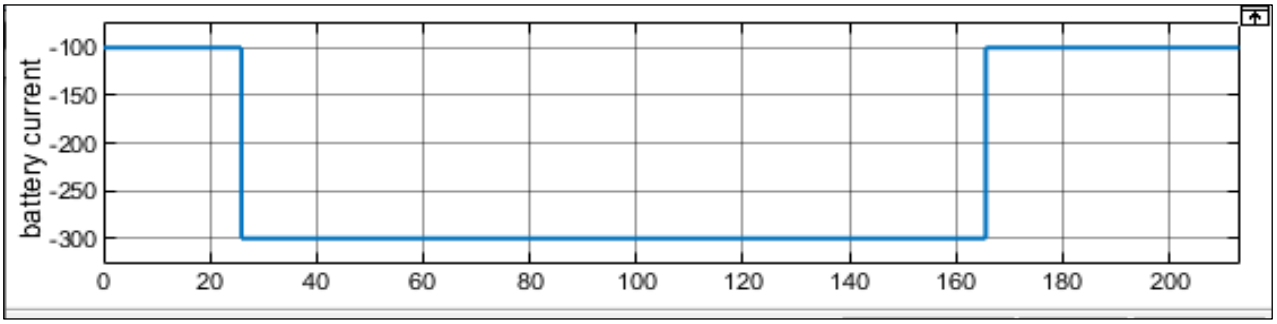

Figure. 7: (b). Battery current.
Source: Authors, (2026).

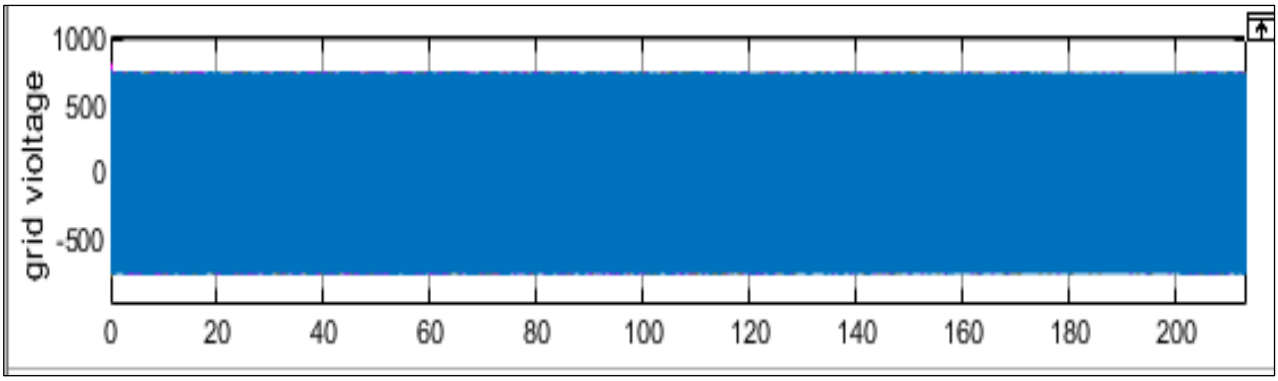

Figure. 7: (c). Grid voltage.
Source: Authors, (2026).

Fig. 7(a). The SOC increases gently from a low initial SOC to a high one of the battery efficiently and controllably. Together, the plots illustrate that solar energy is effectively harvested and employed for battery charging operations with steady system vibrations. Fig. 7(b): Battery current is represented with marked steps according to the stages of the charging process. When the battery is charged, the current is first kept small and is increased according to the fast-charging cycle towards the end of the cycle as the battery is trickle-charged to prolong battery life. Fig. 7(c): Grid voltage is regular with even amplitude without any drops or peaks even as the EV is being charged through the conversion system as the system does not affect the grid's voltage level during EV charging processes.

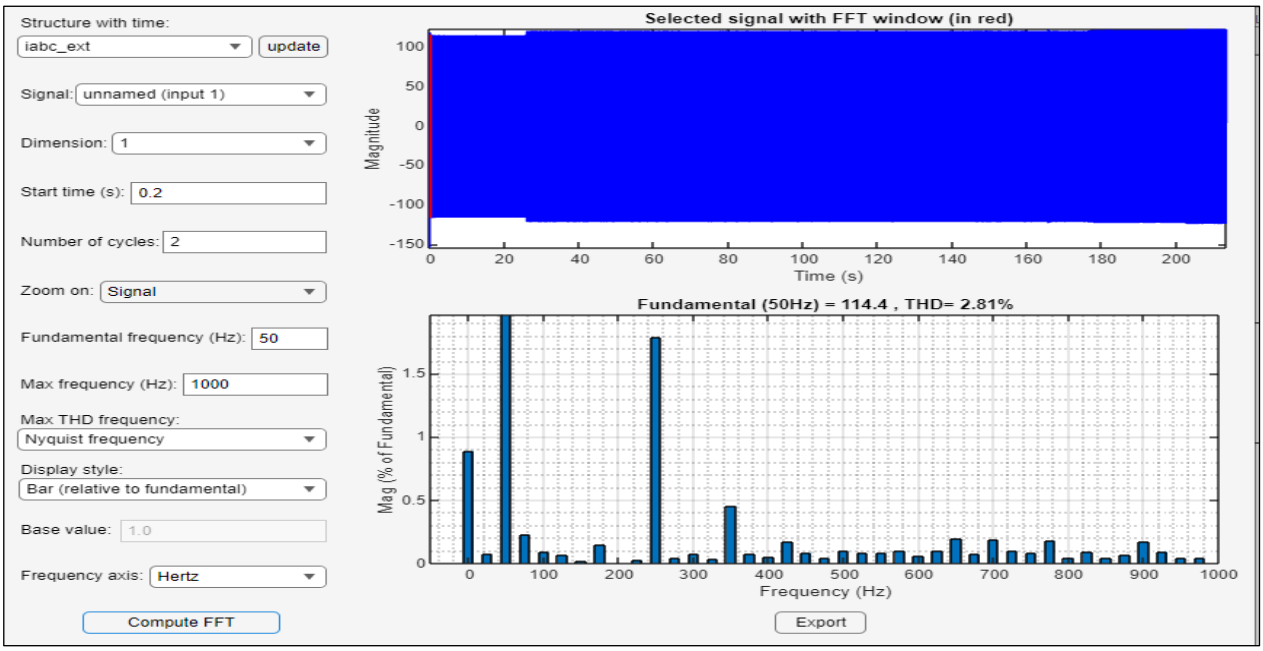

Figure. 7: (d). THD values of Grid current.
Source: Authors, (2026).

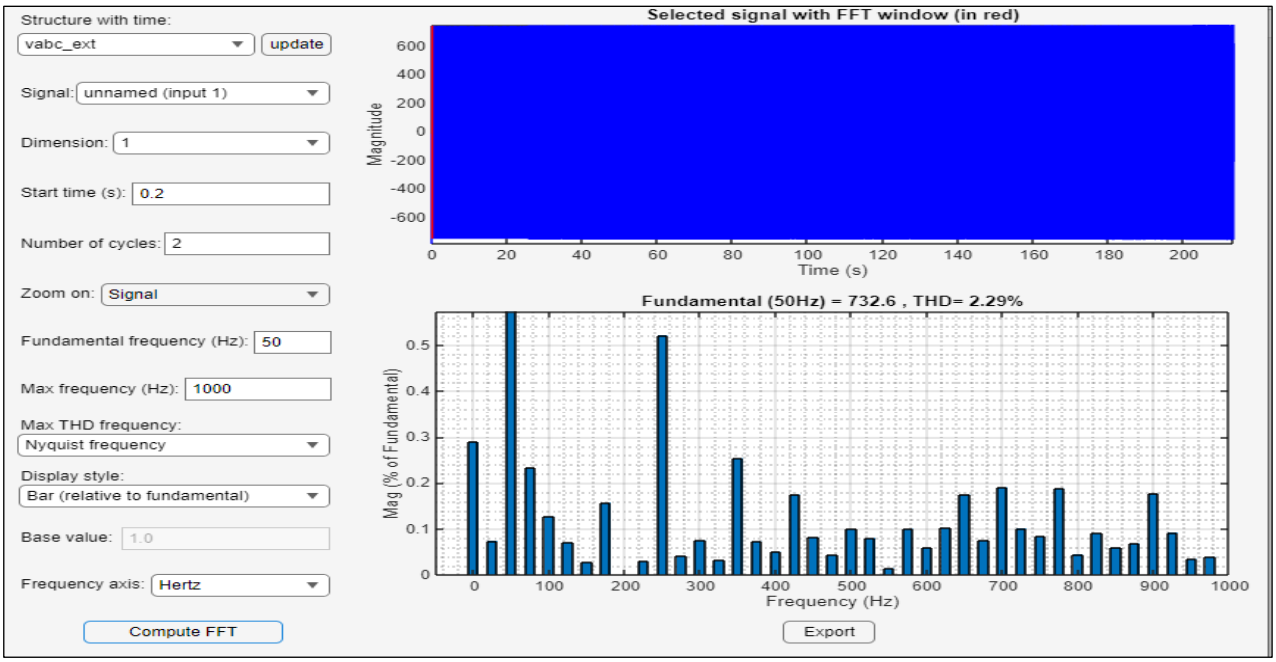

Fig. 7: (e). THD values of Grid voltage.
Source: Authors, (2026).

Fig. 7(d): The dominant 50 Hz fundamental component is observed in FFT analysis of grid current, thus indicating good synchronization with the grid. The THD 2.81% is within the limits according to IEEE; therefore, the power quality is good. Fig. 7(e): The system is working at 50 Hz fundamental frequency and nominal voltage magnitude. The THD at 2.29% is in the low distortion levels and shows other specifications a Hi-Fi equipment should have. Harmonics are included but with small amplitudes relative to the fundamental. The voltage quality is good and it satisfies the standard power quality conditions.

Mode 3: Vehicle to Grid/ (V2G) operation

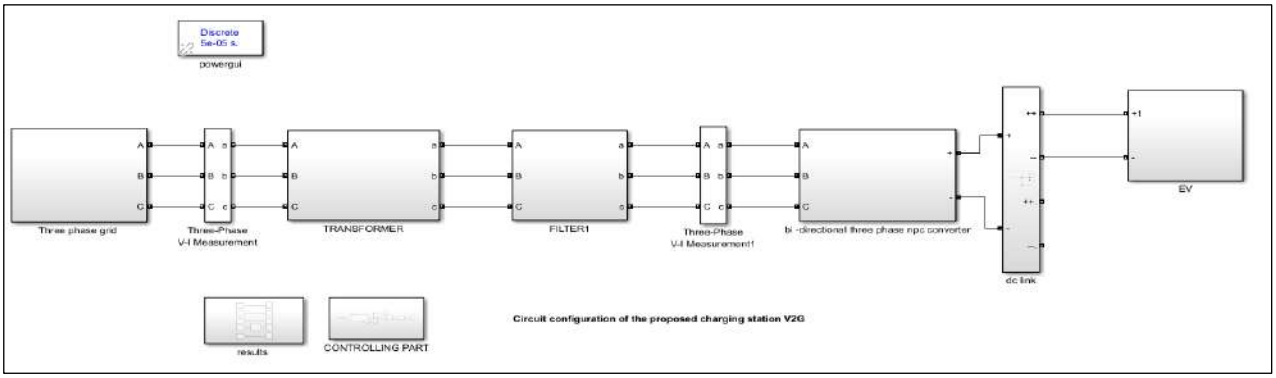

Figure. 8: Simulation configuration of the proposed charging station WITH V2G.
Source: Authors, (2026).

The circuit arrangement of the proposed Vehicle-to-Grid (V2G) charging station is shown in the figure below. A transformer is used for both voltage transformation and electrical isolation purposes. Additionally, a filter for both harmonic reduction and improvement of the waveform quality has been used. The three-phase bidirectional AC-DC converter allows both G2V and V2G operations between the grid and the EV. The converter is connected to the battery of the EV using a DC-link. Sensors for the voltage, current, and control unit are also used.

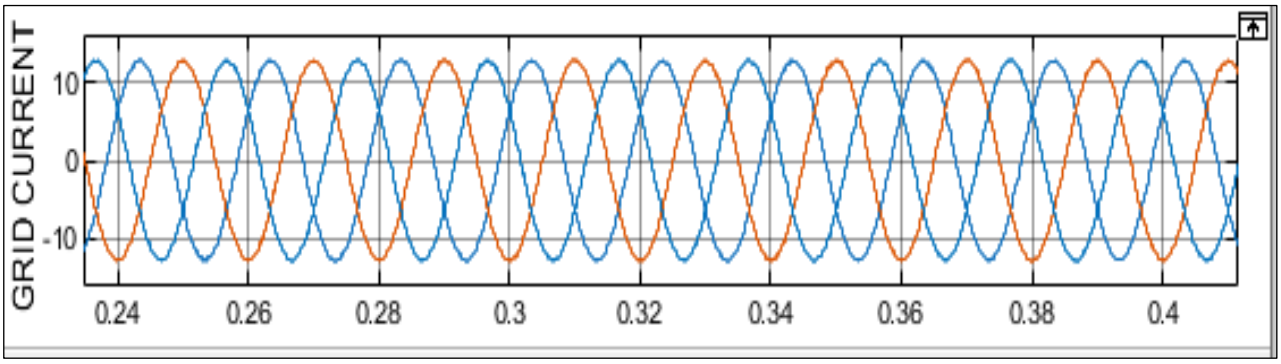

Figure 8: (a). After the EV has been discharged, the grid-side current values are observed to assess the effect of the discharge.
Source: Authors, (2026).

Fig. 8(a): The grid currents are also sinusoidal and well regulated, remaining almost in phase with the grid voltages, hence confirming near-unity power factor operation, low distortion, and effective power exchange between the system and the grid.

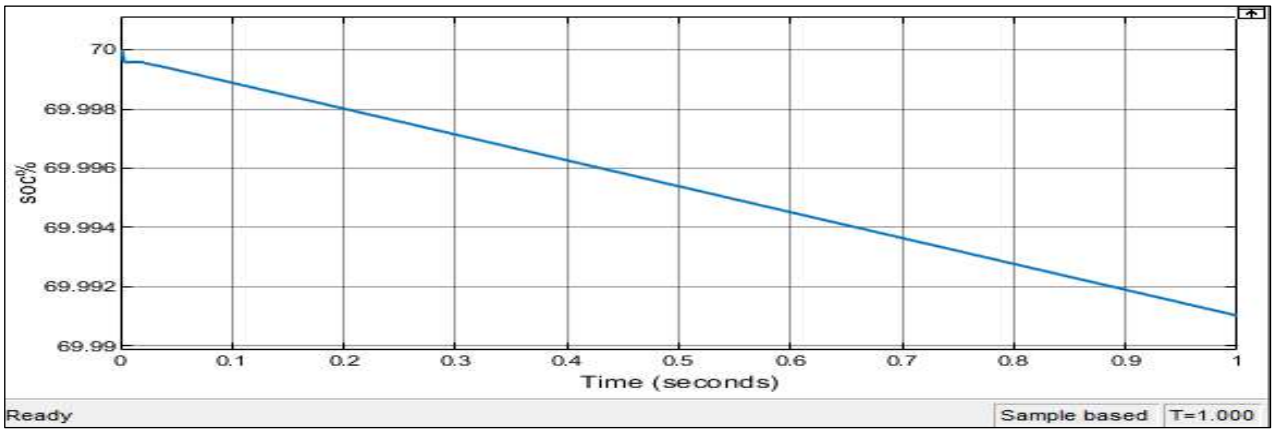

Figure: 8(b). Battery SOC.
Source: Authors, (2026).

The EV battery discharges in order to send energy into the grid, and this can be seen from the decline of its SOC see Fig.8(b). Discharge operation is smartly managed by adapting the discharge current on-the-fly using real-time SOC level, grid load conditions and battery health parameters through a fuzzy logic controller. This allows an efficient transfer of the energy while preserving battery life and grid stability.

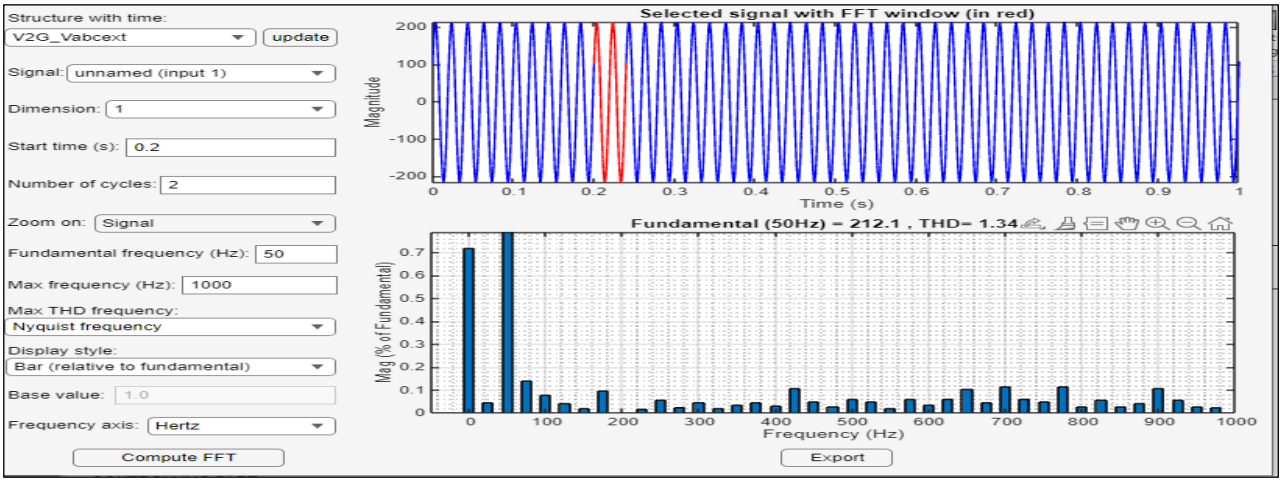

Figure. 8: (c). Vehicle to grid of the voltage THD values.
Source: Authors, (2026).

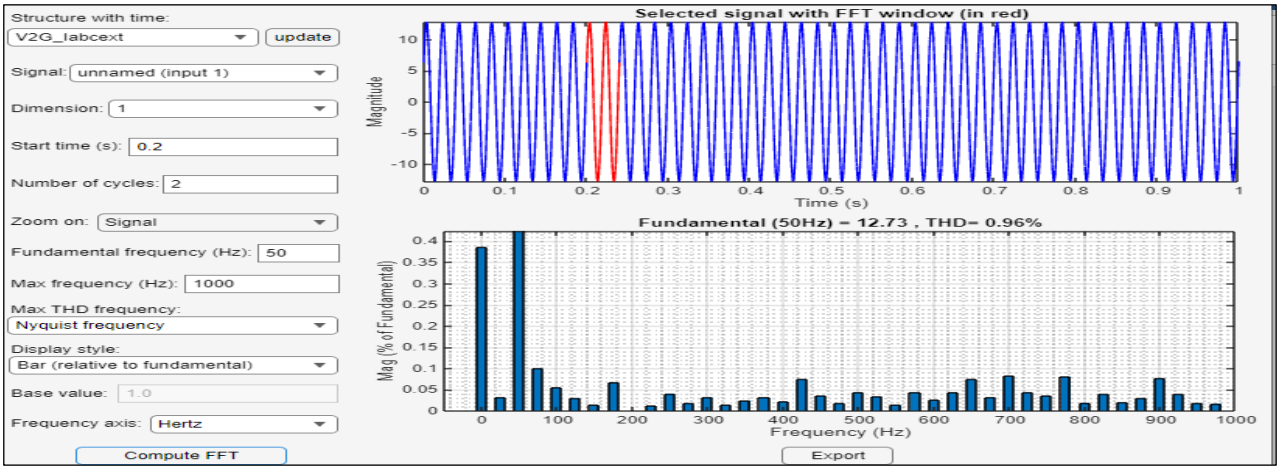

Figure.8: (d). Vehicle to grid of the current THD values.
Source: Authors, (2026).

The FFT results for system voltage and current are presented through harmonic bar graphs.Fig.8(c): Although it has a lower THD of approximately 1.34%, it is dominantly composed of a 50 Hz fundamental signal, which indicates an undistorted voltage waveform.Fig.8(d): Similar to the voltage waveform, it dominantly contains a 50 Hz fundamental signal with an extremely lower THD of about 0.96%, which ensures a nearly sinusoidal current waveform.

Table 1: Existing model.

PI controller	Vabc	Iabc
G2V	5.88	7.34
G+PV2V	5.28	5.67
V2G	6.12	11.16

The PI controller provides the highest THD values for both Vabc and Iabc in all modes of operation. Voltage THD is about 5.3–5.9% which is close to the permissible limit, while current THD fluctuates considerably up to 7.34% during G2V mode operation. This means weaker harmonic attenuation, and worse current quality especially in charging.

Table 2: Proposed Model.

Fuzzy Logic Controller	Vabc	Iabc
G2V	2.44	3.37
G+PV2V	1.69	3.88
V2G	1.34	0.96

Source: Authors, (2026).

On the other hand, for all modes of operation the FLC gives significantly lower THD percentages. Voltage THD is suppressed to the level of 1.34–2.44%, and current THD decreases towards 0.96–3.88% implying better harmonic reduction sequence. The enhancement is particularly significant in PV+G2V operating mode, where current THD reduce are below 2%. Overall, the key difference is that the FLC provides much better power quality, smoother current waveforms, and stronger harmonic reduction than the PI controller. This clearly shows the advantage of the FLC over the PI controller for EV charging.

V. CONCLUSION

In this work, a DC microgrid–integrated fast charge station for an EV based on an FLC is proposed. The FLC was used to control the DC link voltage, grid current, and battery charging operation according to various operating conditions. It was demonstrated that due to its control action depending on system reaction, the FLC provided soft and stable DR operation even during dynamic charging. Simulation results show that the introduced FLC-based model enjoys a high quality of voltage and current harmonic components compared with the conventional PI-controlled counterparts. Enhancement of power quality was observed in G2V, PV+G2V, V2G modes, with THDs within acceptable norms The controller even allowed slow, safe charging from a very low SOC to full charge. In addition, the proposed charging station enables an electric vehicle to be safely charged in such a way that is slow enough to charge from a low state of charge without disturbing system stability. The programmability of the FLC implemented the adaptation capability to different operating conditions in absence of a need for an exact mathematical model. In summary, the study reveals that FLC-based control is a sturdy and efficient answer to DC microgrid fast charging stations, and is promising for future EV fast chargers with renewable power penetration and two-way energy flow. In conclusion, the reliability, efficiency and power quality of DC microgrid based EV fast charging stations can be proved enhanced by using Fuzzy Logic Controller.

Acacia biodiesel, Al_2O_3 nanoparticles, Compression-ignition engine, Combustion characteristics, Exhaust emissions (NOx, CO, HC, smoke).

ABSTRACT

This study evaluates a single-cylinder CI engine fuelled with Acacia biodiesel (ABD) and ABD doped with Al_2O_3 nanoparticles (100 and 200 ppm), benchmarked against petro-diesel. ABD satisfied ASTM D6751 with viscosity 4.14 cSt, density 0.88 g/mL, flash point 80 °C, gross calorific value 35,707 kcal/kg, and cetane index 44.59 (diesel 48.48). Tests used a TV1 four-stroke engine (bore 87 mm, stroke 110 mm, compression ratio 17.5:1) at 1500 rpm. Relative to neat ABD, nano-additivities significantly improved combustion stability and decreased CO, HC and smoke at all loads; notably, NOx also declined with optimized injection timing. The 200-ppm dose delivered consistent gains. Overall, low-ppm Al_2O_3 leveraged ABD's higher flash point and density to promote faster oxidation, lower tailpipe emissions, and diesel-comparable ignition quality, indicating ABD+Al_2O_3 as a practical drop-in for cleaner CI operation.

I. INTRODUCTION

Due to the rapid population growth and the swift depletion of fossil fuels, the demand for clean energy is steadily rising. Bio-mass-based fuels are highly preferred as alternative fuels due to their sustainability, affordable production, and low carbon emissions. Commonly used vegetable oils like palm oil, soybean oil, and Jatropha oil have been employed in the production of biodiesel. Diesel engines are extensively utilised in the vehicle, manufacturing, and power production segments owing to their superior energy efficiency and durability [1], [2]. The drawbacks of diesel engines lie in their detrimental impact on the natural environment through the emission of toxic pollutants such as nitrogen oxides [3], unburned hydrocarbons [4], carbon monoxide [5], and smoke [6]. Numerous research articles have documented an increase in NOx emissions when using biodiesel blends with diesel [7].

Various researchers have made numerous attempts to minimise NOx emissions, such as employing homogenous blend preparation by port fuel injection and after-treatment methods [8]. However, researchers have demonstrated that they can reduce NOx emissions without altering the engine architecture by introducing nanoparticles as an additive and modifying the fuel [7], [9]. The nanoparticle facilitates increased surface area contact between the air-fuel combination, hence enhancing heat transfer and leading to a reduction in ignition delay and an increase in latent heat of evaporation [10]. The incorporation of magnesium (Al-Mg) nanoparticles into jatropha biodiesel has been demonstrated to significantly reduce exhaust emissions while simultaneously improving engine performance metrics [6].

By [11] did a study that showed the enhancement of engine performance and reduction of pollutants by accumulating silver oxide nanoparticles in Neem biodiesel. This is due to the rapid evaporation of air-fuel combinations, which suggests a shorter delay period. In turn. [12] find that the addition of ethanol and cerium oxide nanoparticles, biodiesel, and diesel mixtures hints at a decline in the amount at which heat is released and a little reduction in the time it takes for ignition to happen. According to [13] examined the impact of including Al_2O_3 Nano additives in jojoba methyl ester on emission properties. In their 2017 study [14] demonstrated that the use of Nano additives in biodiesel can enrich engine performance and decrease emissions. The increased surface contact space among air-fuel mixes is the reason for this. Research findings indicate that the addition of nanoparticles to methyl ester accelerates combustion. The experimental effort's originality lies in the use of Al_2O_3 nanoparticles, combined with ABD in varying amounts, to effectively decrease NOx and smoke emissions[15], [16]. This study presents a groundbreaking approach to enhancing diesel engine performance by introducing a novel fuel blend that integrates aluminium oxide (Al_2O_3) nanoparticles into acacia-derived biodiesel.

By incorporating these nanoparticles, the research aims to improve the combustion efficiency, emission characteristics, and overall fuel properties of biodiesel, thereby offering a more sustainable and efficient alternative to conventional diesel fuel. This innovative method not only explores the synergistic benefits of nanotechnology and biofuels but also contributes to the development of cleaner and more advanced energy solutions for modern diesel engines. The integration of aluminium oxide nanoparticles into acacia biodiesel creates a unique fuel blend that significantly enhances the overall performance of diesel engines. This innovative combination leads to more efficient combustion by promoting better atomization and faster oxidation of the fuel, resulting in a more complete burn. As a result, harmful emissions such as carbon monoxide (CO), unburned hydrocarbons (HC), and particulate matter are substantially reduced. Additionally, the improved combustion process contributes to enhanced engine power output and smoother operation. This advancement represents a major step forward in the pursuit of cleaner, more efficient, and sustainable transportation technologies, offering a promising alternative to conventional fossil fuels.

II. EXPERIMENTATION

II.1 PRODUCTION PROCESS

Acacia biodiesel (ABD) is produced by the method of transesterification. The following displays the FAME properties of derived biodiesel. The ultrasonic device was used to combine Al_2O_3 nanoparticles with fuel and acacia methyl ester. The addition of 0.050 g of the Nano additive to one litre of methyl ester, diesel, is equivalent to a concentration of 50 parts per million (ppm), or 0.050 g/l. Next, the combination is vigorously agitated and then kept inside an ultrasonic vibrator operating at a frequency of 20 kilohertz for a duration of 30 minutes. This process guarantees an even distribution of dispersion [6]. Similarly, we created blends with concentrations of 200 ppm and 100 ppm [9]. Table 2 displays the characteristics of experimental energies.

Table 1: Oil Contents in the FFA.

Fatty Acids	ABD (% by weight)
C18:3 (Linolenic)	15.50
C18:2 (Linoleic)	41.60
C18:1 (Oleic)	20.98
C18:0 (Stearic)	07.29
C16:0 (Palmitic)	12.79

II.2 INVESTIGATIONAL ARRANGEMENT

The present research is being carried out on a CI engine with a single cylinder and a four-stroke cycle. The AVLDI gas444 and AVL 437 devices were utilised to quantify the levels of smoke opacity, CO, HC, and NOx. The fuel qualities were obtained using the ASTM testing process. The trial was conducted by preliminary testing the engine with diesel fuel to establish uniform or proper readings (warm-up state) and then testing with diesel, ABD$Al_2O_3$100, and ABD$Al_2O_3$200. We experiment with a constant speed. Table 4 provides the engine specifications and accuracy level of the exhaust gas analyzer.

Table 3: Investigation Device Specifications

Constraint	Specifications for the Engine
Engine	TV1 Make, Four-stroke diesel engine, single cylinder, maximum power 5.2kW at maximum speed 1500 rpm, cooled by water, L is 110 mm, r is 17.5, d is 87 mm.
Temperature Sensor	Thermocouple
Rotameter	Calorimeter Range: 25-250 litres per hour, Engine Cooling: 40-400 litres per hour
Dynamometer	Water Cooled, and Eddy's current
Piezoelectric Sensor	Range:5000 PSI
Data acquisition gadget	16-bit, NI USB - 6210, 250 kilobytes per second
Crack angle Sensor	Speed 5500 rpm, Resolution 1 Deg.

III. RESULTS AND DISCUSSIONS

III.1 HC EMISSION

During the combustion and compression procedure in an engine, a sudden rise in pressure takes place, causing the air-fuel mixes in the combustion chamber to be pushed into the corner portions [17]. These gases are not part of the initial combustion process. Throughout the expansion and exhaust procedure, these gases escape from the fissures, which is consequential in the presence of unburned hydrocarbons. Inadequate atomization of fuel droplets can result in decreased cylinder wall temperature, which in turn is a clue to incomplete combustion and the presence of unburned hydrocarbons. Figure 1 depicts the fluctuation in HC emissions for ABD, $ABDAl_2O_3100$, and $ABDAl_2O_3200$. ABD exhibits lower hydrocarbon (HC) emissions in comparison to diesel because of its greater oxygen content, which facilitates more efficient combustion. $ABDAl_2O_3100$, and $ABDAl_2O_3200$ exhibit lesser HC emissions compared to ABD due to their increased surface area, which promotes chemical reactivity with air-fuel combinations [18], [19].

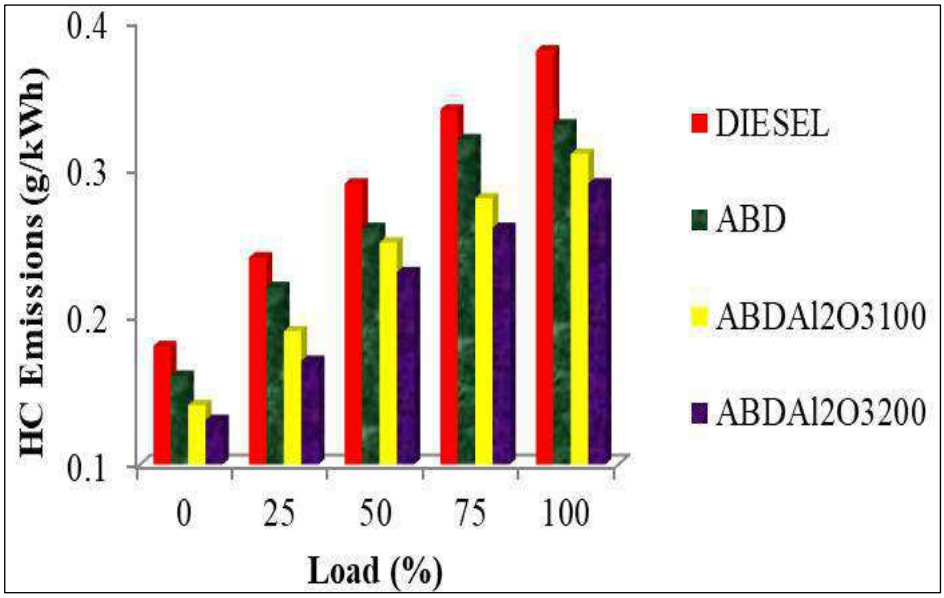

Figure 1: Load vs. Hydrocarbon Emissions.
Source: Authors, (2026).

III.2 CO EMISSION

Insufficient oxygen leads to the formation of carbon monoxide emissions when there are rich air-fuel combinations. Carbon monoxide emissions can arise due to insufficient mingling, insufficient oxygen for burning air-fuel combinations, and limited combustion [20]. Figure 2 shows the carbon monoxide discharge fluctuations for ABD, $ABDAl_2O_3100$, and $ABDAl_2O_3200$. ABD exhibits lower CO emissions in comparison to diesel, mostly owing to its greater oxygen content. $ABDAl_2O_3100$, and $ABDAl_2O_3200$ exhibit lower CO emissions compared to ABD across all loads. The presence of nano additives in biodiesel boosts its catalytic activity, leading to further effective combustion and reduced emissions of CO [1], [18].

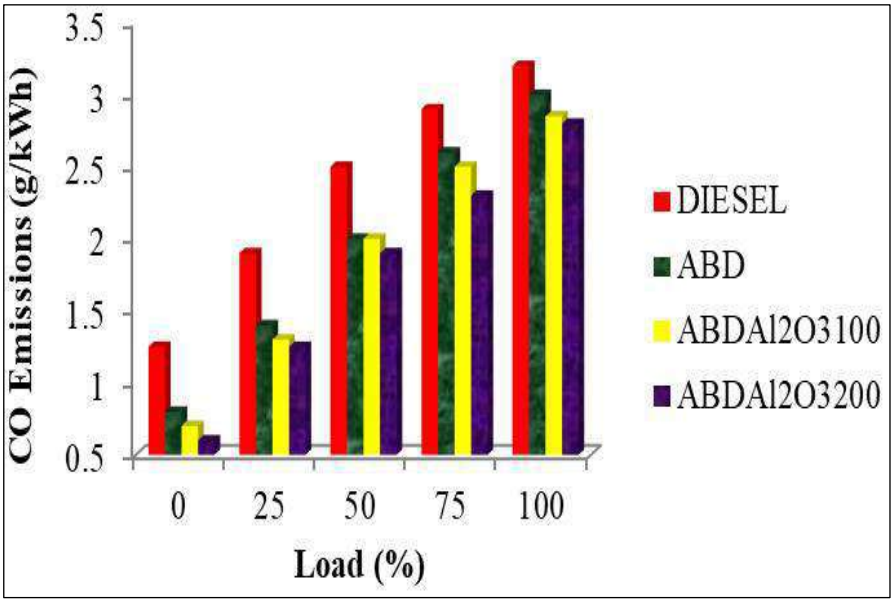

Figure 2: Load vs. Carbon Monoxide Emissions.
Source: Authors, (2026).

III 3 NOX EMISSIONS

The fuel supply and the timing of the blending process influence the exhaust emissions in a CI engine [21]. The injection of gasoline immediately before the combustion procedure causes uneven fuel circulation, resulting in a heterogeneous blend. This leads to a swift escalation of the temperature of the combusted gas within the cylinder, resulting in the discharge of NOx [10]. Figure 3 depicts the fluctuations in NOX emissions for ABD, ABD$Al_2O_3$100, and ABD$Al_2O_3$200. The greater NOx emission in ABD compared to diesel is caused by the higher oxygen concentration and resting temperature during combustion [20]. The combination of nanoparticles like ABD$Al_2O_3$100, and ABD$Al_2O_3$200 with biodiesel results in lower NOx emissions when compared with ABD under all load conditions. The inclusion of Al_2O_3 reduces the period it takes for ignition to happen and enhances the efficiency of the catalytic reaction between the air-fuel mixes, leading to a significant decrease in NOx emissions [22].

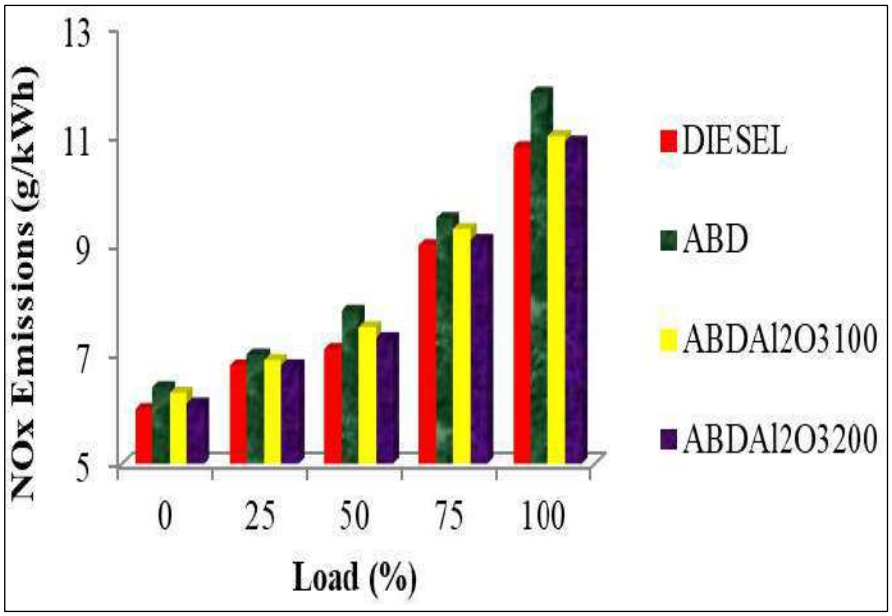

Figure 3: Load Vs Oxides of Nitrogen Emissions.
Source: Authors, (2026).

III.4 SMOKE

The below figure depicts the changes in smoke when operated with ABD, ABD$Al_2O_3$100, and ABD$Al_2O_3$200. The creation of smoke emissions is caused by fuel pyrolysis, which leads to the tendency for a rich fuel mix to accumulate in high-temperature regions [23]. ABD$Al_2O_3$100, and ABD$Al_2O_3$200 exhibit lower levels of smoke emissions in comparison to ABD and diesel. The presence of nanoparticles in the energy mixture enhances turbulence, leading to increased mixing of the air-fuel combination during combustion. This results in reduced emissions at all loads, as documented in reference [21], [24].

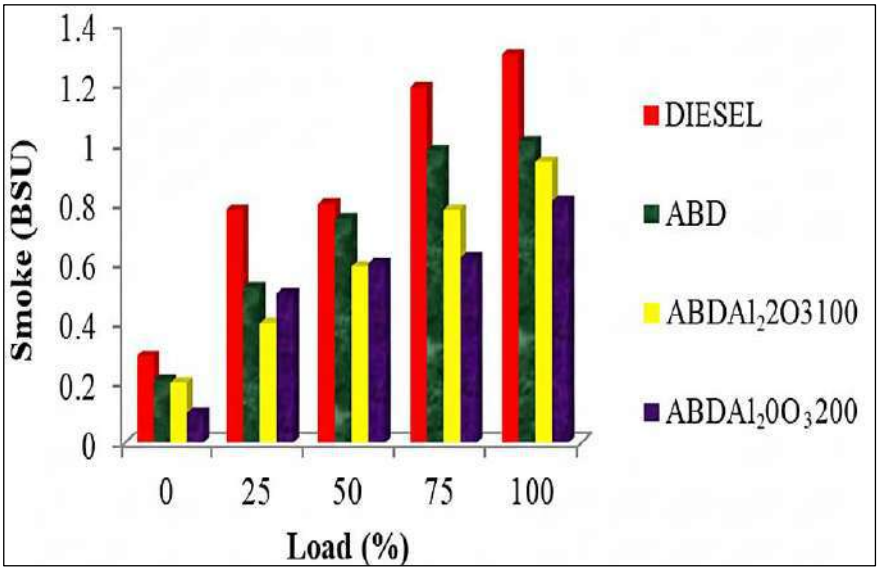

Figure 4: Load vs. Smoke.
Source: Authors, (2026).

IV. CONCLUSIONS

This study focuses on a CI engine that runs on diesel, ABD, $ABDAl_2O_3100$, and $ABDAl_2O_3200$ fuel. This examination uses a four-stroke, single-cylinder engine design. An investigation was conducted to examine the emission properties of Al_2O_3 nanoparticles when combined with base fuels (diesel and ABD). This study investigated the environmental impacts of petroleum diesel and non-petroleum fuels by examining their respective footprints.

- The presence of nanoparticles ($ABDAl_2O_3100$ and $ABDAl_2O_3200$) in biodiesel results in decreased emissions of smoke, CO, and HC at all levels of engine load in comparison to regular diesel fuel.
- The NOx was higher for ABD, $ABDAl_2O_3100$, and $ABDAl_2O_3200$ compared to diesel.
- The presence of Al_2O_3 in ABD results in a decline in smoke, HC, and CO emissions under all operating circumstances. This is owed to the catalytic impact and increased surface space contact with the gas mixes.
- The presence of $ABDAl_2O_3100$, and $ABDAl_2O_3200$ in nanofluids leads to a decline in NOX emissions equated to ABD. This is owed to the smaller ignition delay and the ability of aquatic molecules to absorb heat.
- No measures were implemented to extract the nanoparticle from the exhaust system following combustion. However, future research will investigate the removal of nanoparticles from the tailpipe after combustion.

ABSTRACT

In this experimental paper, we propose a method for identifying misalignment and bearing faults, as well as their combined fault, from phase currents measured on a variable-speed induction motor. For this purpose motor current signature analysis (MCSA) technique successfully distinguishes healthy states from faulty states. In order to optimise the identification of correlations in the signals on several time scales, we propose a new fault detection tool based on multiscale entropy (MSE) algorithm SampEn applied to extract detailed features, dimensionality and isolating fault relevant variations are reduced through principal component analysis (PCA) and the comparison of the measured values with those predicted by our model built from the nominally healthy data. Finally, we used the squared prediction error (SPE) analysis to improve the fault detection capability and ensure a more comprehensive analysis of the induction machine condition, the combination of these techniques aims to provide early and accurate fault diagnosis. The experimental results obtained show that the proposed method is efficient, accurate and reliable for extracting characteristic frequencies from the current signal, and that it provides a powerful tool for fault diagnosis and condition monitoring.

I. INTRODUCTION

As key components in various rotating machinery, induction motors (IMs) are used extensively to ensure smooth operation processes. They have played a significant role in industrial applications due to their numerous benefits, which stem from their stability, reliability, robustness, and efficiency. However, like all rotating machinery, induction motors (IMs) are harmed by many failures resulting from various issues, which can lead to reduce the reliability, minimise the productivity, and increase the operation and maintenance (O&M) costs. Many factors may lead to malfunction and be a major cause of various electrical and mechanical faults that occur on motors during their normal function, including stator faults, rotor faults, bearings, eccentricities, and broken rotor bar faults [1]. In recent years, huge focuses and wide examples of condition monitoring systems for induction motors have been used over the last decade to detect faults in the early stages to prevent the main components from catastrophic failures through an accurate and quick diagnosis of these faults for the purpose of identifying the specific failure and ensuring the safe and effective operation process. To assure a thorough inspection of faults, numerous analysis approaches have been applied and investigated to identify the defects [2]. Those methods can be reflected by vibration analysis, ultrasonic analysis, thermography, motor current signature analysis (MCSA), and others [3]. For years, the motor current signature analysis (MCSA) method has been well-known as a cornerstone approach for pinpointing the presence of faults in induction motors [4]. This method offers important advantages due to its low cost and ability to detect mechanical and electrical faults at an early stage, thus preventing unexpected breakdowns. However, its accuracy and reliability are significantly dependent on numerous signal processing methods, whether in the time domain, frequency domain, and time-frequency domain [5].

Among these, signal processing methods in time-frequency domain analysis techniques such as wavelet transform (WT), short-time Fourier transform (STFT), empirical mode decomposition (EMD), and Hilbert-Huang transform (HHT) [6], [7]. However, discrete wavelet transform (DWT) is an interesting approach, and a specific implementation of wavelet transform (WT) has been presented through numerous research papers. Its development has been crucial to the advancement of signal processing approaches [8]. In other cases, the application of entropy has been a popular choice in temporal signal analysis fields. The entropy approaches are based on calculating and contrasting between values of statistical indicators to distinguish healthy from unhealthy states of the rotating machinery. Therefore, several types of entropy have been utilised and shown great efficacy, such as sample entropy (SE), fuzzy entropy (FuzzyEn), dispersion entropy (DE), and multiscale entropy (MSE) [9], [10]. Our study addresses research by focusing on two approaches for detecting anomalies within induction motors with the aim of reaching more accurate knowledge and a more thorough diagnostic viewpoint. To achieve this goal, the proposed methods are based on fault detection.

Both the faults, including bearing and misalignment, are identified by using the suggested methodology; the first approach centres on the use of motor current signature analysis (MCSA) in an induction motor and the energy analysis method on the basis of a discrete wavelet transform. Furthermore, within the article, the second methodology integrates MCSA in conjunction with the multiscale entropy (MSE) method and principal component analysis (PCA). The combination of these techniques aims to provide early and accurate fault diagnosis, thereby prolonging operational machinery lifespans and reducing maintenance costs. Despite the fact that signal processing techniques are well known, each writer needs to analyse and adapt how they are structured to achieve an effective diagnostic result. This work is structured as follows: the first section is dedicated to the introduction, then, the definitions of the faults that have been researched, along with the theoretical underpinnings of the suggested diagnosis techniques, are thoroughly discussed in the second section. Next, the experimental part and the data acquisition are both covered in the third section. Readers of this paper will encounter in the fourth section the discussion of results obtained under both normal and faulty conditions. Lastly, the conclusion of the paper is provided in the fifth section.

II. THEORETICAL BACKGROUND

II.1 MOTOR CURRENT SIGNATURE ANALYSIS (MCSA)

Monitoring stator current, also known as motor current signature analysis has been one of the most significant diagnosis methods that have been applied in current research throughout the last years. Motor current signature analysis has been considered an effective, powerful, and trustworthy tool for monitoring health and identifying the existence of faults in electrical machines. Several problems that may be effectively detected by monitoring stator currents, which show clear fault patterns. This method assures on going condition monitoring through offering a non-intrusive method for consistently and regularly assessing the state of health [11]. Misalignment and bearing faults considered the most commonly observed disturbance sources in rotating systems; the careful exploration of the instantaneous stator current of the rotating machinery is a very important contribution to the detection of mechanical faults. It has been proven in [12], [13] that misalignment and bearing damage to the actuator oscillations causes the load torque which, consequently, will change the variation of the stator current of the rotating machinery.

II.2 THE DISCRETE WAVELET TRANSFORMS (DWT)

The discrete wavelet transform (DWT) can be considered an analytical method that makes it possible to analyse data by way of transforming signals from the time domain to the time and frequency domain in order to process signals and obtain a good result. By following the decomposition process of an original signal (S) through the use of two complementary filters, we are able to obtain high pass (H) and low pass (L), one of which reflects the detail signal (d) that corresponds to the high frequencies content of the signal and the other the approximation signal (a) that corresponds to the low frequencies content of the signal [14]. In each level, the detail and approximation coefficients are determined by the following expression:

$$s(t) = \sum_{i} \alpha_i^n . \Psi_i^n(t) + \sum_{j=1}^{n} \sum_{i} \beta_i^n . \varphi_i^j(\mathrm{t}) = a_n + d_n + \cdots + d_1 \tag{1}$$

Where, α, β represent scales and coefficients of the wavelet, Ψ^n, φ^j represent the decomposed function at level n and the wavelet function at level j respectively, n is the decomposition level a_n, d_n are respectively the approximation signal the detail signal at level n These decompositions are limited by the maximum number of levels to which a signal can be broken down; this limit is determined based on the currents sampling frequency and the fundamental frequency. This limit number of levels is provided by the following relation:

$$N = int\left(\frac{\log\left(\frac{f}{fs}\right)}{\log(2)}\right) + 2 \tag{2}$$

Where, N is the number of decomposition levels, f is the currents sampling frequency, fs is the fundamental frequency.

II.3 ENERGY OF DECOMPOSITION IN WAVELETS

For more comprehensive diagnostics, the energy analysis technique on the basis of discrete wavelet transform (DWT) is an extremely efficient diagnostic process, which can be used to compare the energy characteristics of signals in both healthy and anomalous conditions by calculating the energy related to each level of wavelet decomposition detail [15]. The energy value can be identified at each level through the following expression:

$$Ej = \sum_{n=1}^{N} |d_j(n)|^2 \quad (3)$$

Where, j is the level of decomposition, N is the total sample number of the signal, d_j is the detail signal at discrete point j.

II.4 MULTISCALE ENTROPY (MSE)

Multiscale entropy (MSE) is an effective tool designed to quantify the complexity data from time series over several time scales. Unlike single-scale analyses, this method permits revealing hidden complexities and capturing underlying patterns that appear at various levels of resolution [16], [17]. A coarse-grained data sequence y(s) should be obtained by a coarse-grained process, this process begins with coarse-graining, which simplifies the time series at each scale. For a scale factor τ, and a time series x = {x1, x2, x3, …, xN}, the coarse-grained series y(τ) is calculated as [18]:

$$y_j(\tau) = \frac{1}{\tau}\sum_{i=(j-1)\tau+1}^{j\tau} x(i), \qquad 1 \le j \le \frac{N}{\tau} \quad (4)$$

Where τ represents a scale factor and j = 1, 2,… $\frac{N}{\tau}$. When τ = 1, the coarse-grained time series is the same as the original time series. As the value of τ increases, the length of the coarse-grained time series decreases. Figure 1 shows the process of dividing the original time series into coarse-grained time series for scale factor τ = 2 and τ = 3.

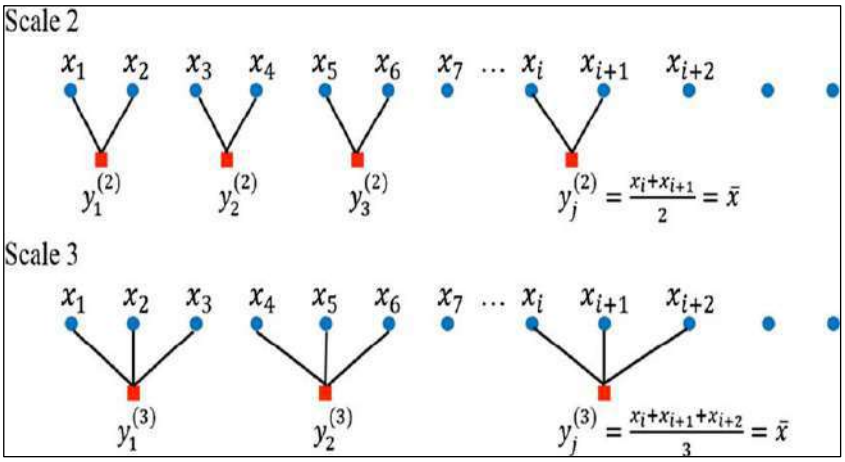

Figure 1: A representation of the coarse-graining process.
Source: Authors, (2026).

II.5 PRINCIPAL COMPONENT ANALYSIS (PCA)

The principal component analysis (PCA) is particularly a powerful statistical procedure when dealing with a large number of variables. This dimensionality reduction approach is used to simplify complex datasets while preserving as much variance as possible, facilitating analysis and visualisation by transforming the dataset with high dimensions into one with lower dimensions [19].

II.6 THE SQUARED PREDICTION ERROR (SPE)

The Squared Prediction Error (SPE) is a statistical metric used to evaluate the effectiveness of a predictive model by squaring the difference between the actual observed and the predicted values for a dataset. Regarding fault detection and diagnosis, SPE is often applied in conjunction with other metrics such as Mean Squared Error (MSE) to provide a comprehensive understanding of the performance of a model [20]. A high SPE indicates deviations that can be indicative of anomalous conditions or faults. The basic definition of SPE is expressed as:

$$SPE = \sum_{i=1}^{k} \left(X_{ij} - Y_{ij}\right)^2 \quad (5)$$

Where Xij represents the observed feature value, Yij represents the predicted value.

III. MATERIALS AND METHODS

The experimental tests were successfully carried out on the machinery fault simulator of Mines and metallurgy research unit (URMM/CRTI-Annaba); Figure 2 illustrates the test bench that has been used to conduct our study in order to validate the efficacy of the proposed method in the detection of numerous faults affecting the induction machine.

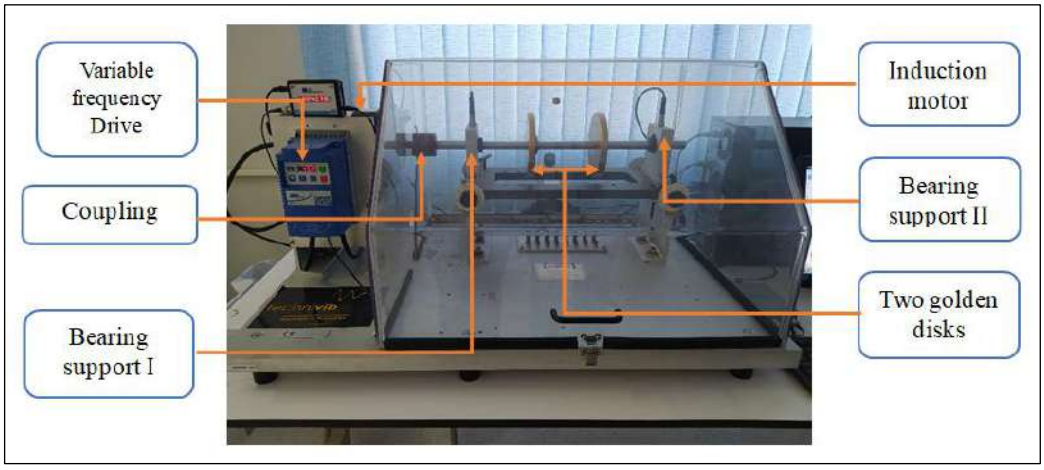

Figure 2: Experimental test bench.
Source: Authors, (2026).

In this investigation, a mechanical system has been used consisting of an induction motor, shaft, coupling, and bearing as shown in Figure 3. The induction motor used throughout this work was a three-phase model of 0.5 HP. The parameters of the main motor utilised in the study at a line frequency of 50 Hz are given in Table 1.

The material required to measure, collect, and interpret the three stator phase currents (I_A, I_B, and I_c) consists of a current sensor, an oscilloscope, and a computer. The three stator phase currents were measured by the use of a current sensor type: PAC 12 connected to a numerical oscilloscope HAMEG507 equipped with an acquisition card and connected to a PC, while the acquired data processing is carried out using MATLAB software for signal analysis. The experiments were performed under various operation conditions, which are given as:

- Healthy state,
- Inner race bearing defect,
- Motor fault with misaligned rotor,
- Combined defects (Motor fault with misaligned rotor and Inner race bearing defect).

In each condition, the stator currents are obtained at a sampling frequency of fs = 1 KHz for three different speeds: 15, 30, and 50 Hz.

IV. RESULTS AND DISCUSSIONS

Figure 4 shows the temporal signals of the stator currents for three phases IA, IB, and IC under different working conditions, including healthy state, misaligned rotor, inner race bearing fault, and combined faults, at a rotational speed of 2850 rpm.

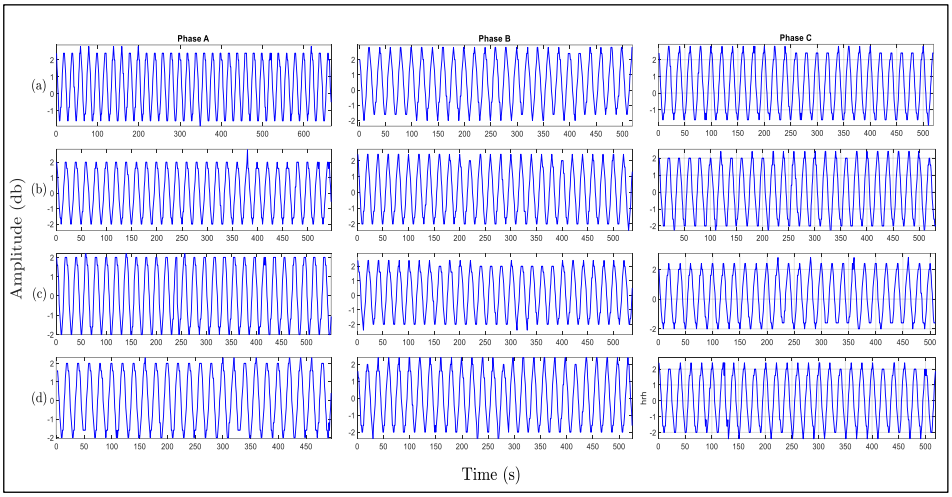

Figure 4: The temporal signal under different operating condition: (a) healthy, (b) Motor fault with misaligned rotor, (c) inner race bearing fault, (d) combined faults.

Figures 5 show a detailed representation of the discrete wavelet transform (DWT) decomposition applied to stator current for phase A under healthy and faulty states on the machine at an operating speed of 50 Hz. This analysis covers forth different operational conditions, including healthy case, misaligned rotor, inner race bearing fault, and combined defects. These figures offer a granular view of the decomposition process, presenting the detailed coefficients from levels d1 to d6, as well as the approximation level at the sixth level (a6).

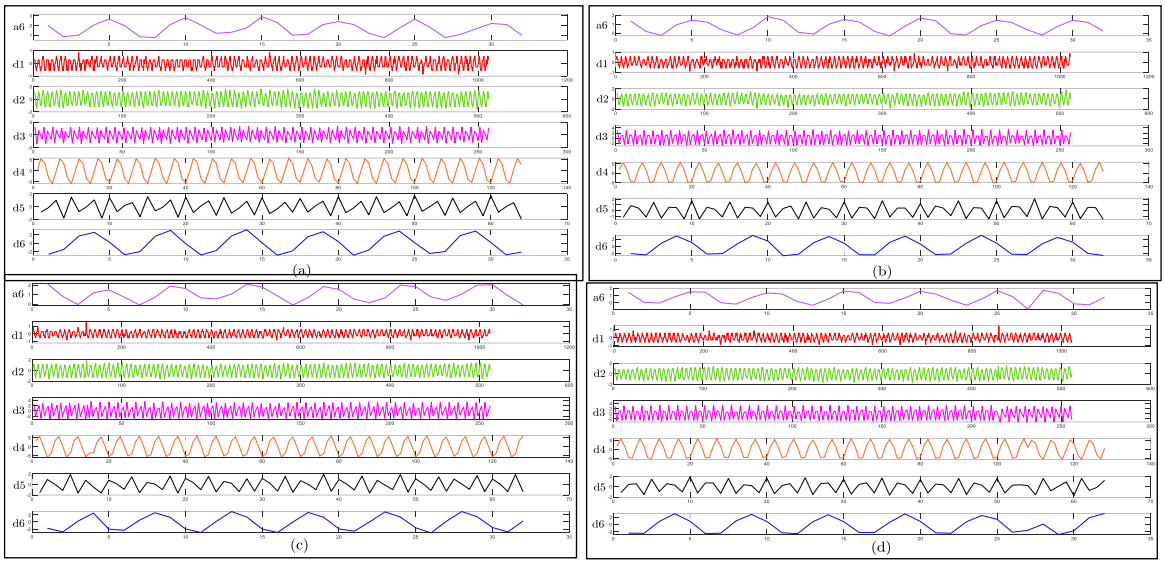

Figure 5: Wavelet decomposition of stator current signal for Phase A at different operating condition: (a) healthy state, (b) misaligned rotor, (c) inner race bearing fault, and (d) combined fault.
Source: Authors, (2026).

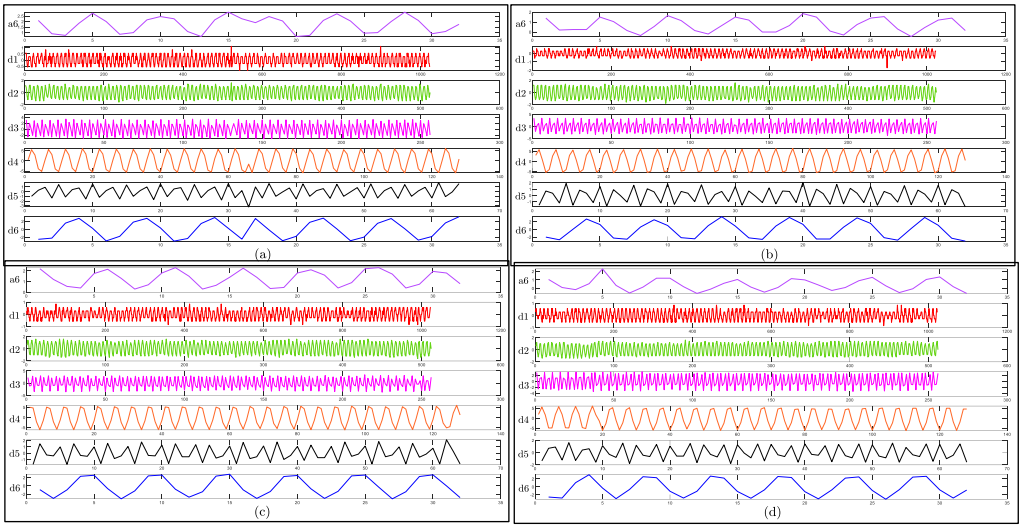

Figure 6: Wavelet decomposition of phase B stator current signal in four operating conditions: (a) healthy state, (b) misaligned rotor, (c) inner race bearing fault, and (d) combined fault.

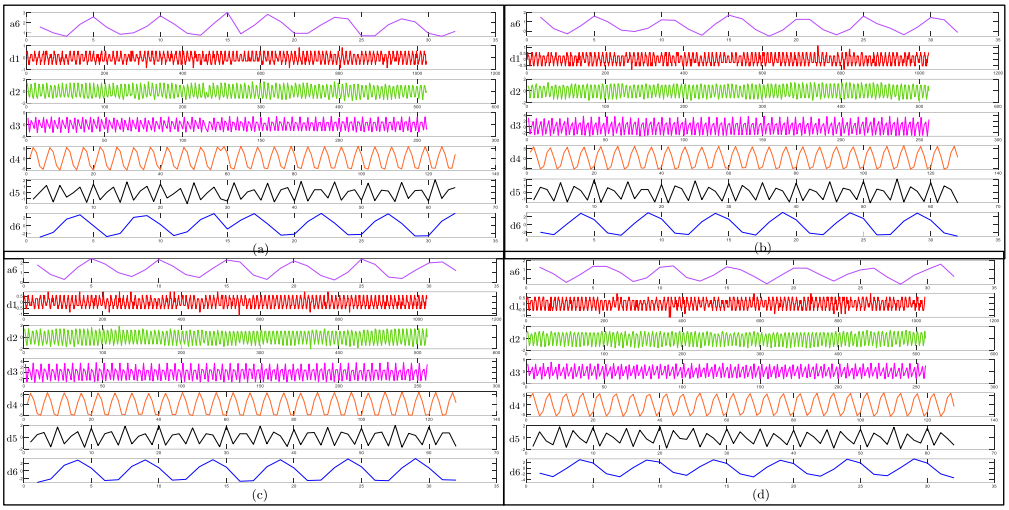

Figure 7: wavelet decomposition of phase C stator current at different working conditions: (a) healthy state, (b) misaligned rotor, (c) inner race bearing fault, and (d) combined faults.
Source: Authors, (2026).

Figure 6, and 7 demonstrates a thorough analysis of the stator current signals for IB and IC within the time-frequency domain through the discrete wavelet transform (DWT) technique for case of a healthy machine and three other states including inner race bearing fault, misaligned rotor, and combined faults. Through a visual comparison, there is hardly any distinction between healthy and faulty states of the stator current signal for phase A (Figure 5), phase B (Figure 6), and phase C (Figure 7). However, we observe in each phase that the fifth and sixth detail levels of the signal in the defective states show a remarkable variation in contrast to the healthy state. These noticeable shifts among the original signal in the healthy and the faulty states reflect the impact of machine failures. Tables 3 and 4, respectively, highlight the energy values of detail coefficients (d1 to d6) from the phase A and phase B stator current under various working conditions. The energy values of phase C at six decomposition levels across healthy and different fault states are presented in Table 5.

Table 3: Energy values of phase A at different decomposition levels.

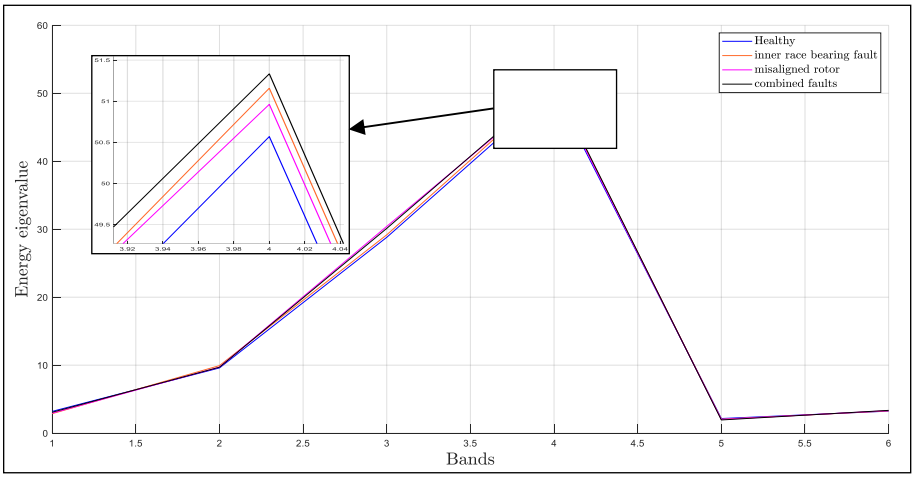

Figure 9: Energy levels of the phase B stator current under different operating conditions.
Source: Authors, (2026).

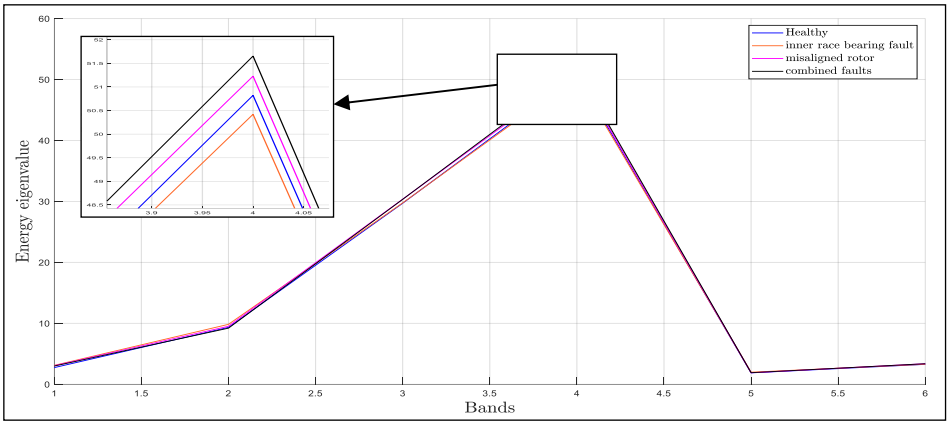

Figure 10: Energy levels of the phase C stator current under different operating conditions.
Source: Authors, (2026).

The graph in Figure 8 illustrates the variation in the energy values of the current signal in phase A for different decomposition levels in the state of a healthy machine and with different defect conditions. Figure 9 shows the change in the energy of I_B stator current across different signal decomposition levels. As to the variation in energy of the stator current signal in phase C for different decompositions of signal levels across healthy and faulty working states, it is also given in Figure 10. Upon close examination of the provided figures, a notable variation within the energy values at different detail levels is revealed. According to tables 3 and 4, along with figures 8 and 9, a comprehensive analysis of the obtained results reveals that there is a notable distinction in energy values in diverse decomposition levels for I_A and I_B stator current, especially for the fourth decomposition level, which exhibits that there is a significant rise in energy for the faulty signals in contrast to the healthy signal. As for phase C, it becomes evident that distinct energy values occur between healthy and misaligned and combined faults at the fourth detail level, whereas bearing fault energy shows a lower value than the healthy case, unlike the two other phases. This sort of conduct may arise in certain cases due to several factors. However, the increase differs based on the severity of the default at the machine. It can be seen that the distinction among the healthy and the faulty states is very clear, and the rise of energy varies according to the degree of the default.

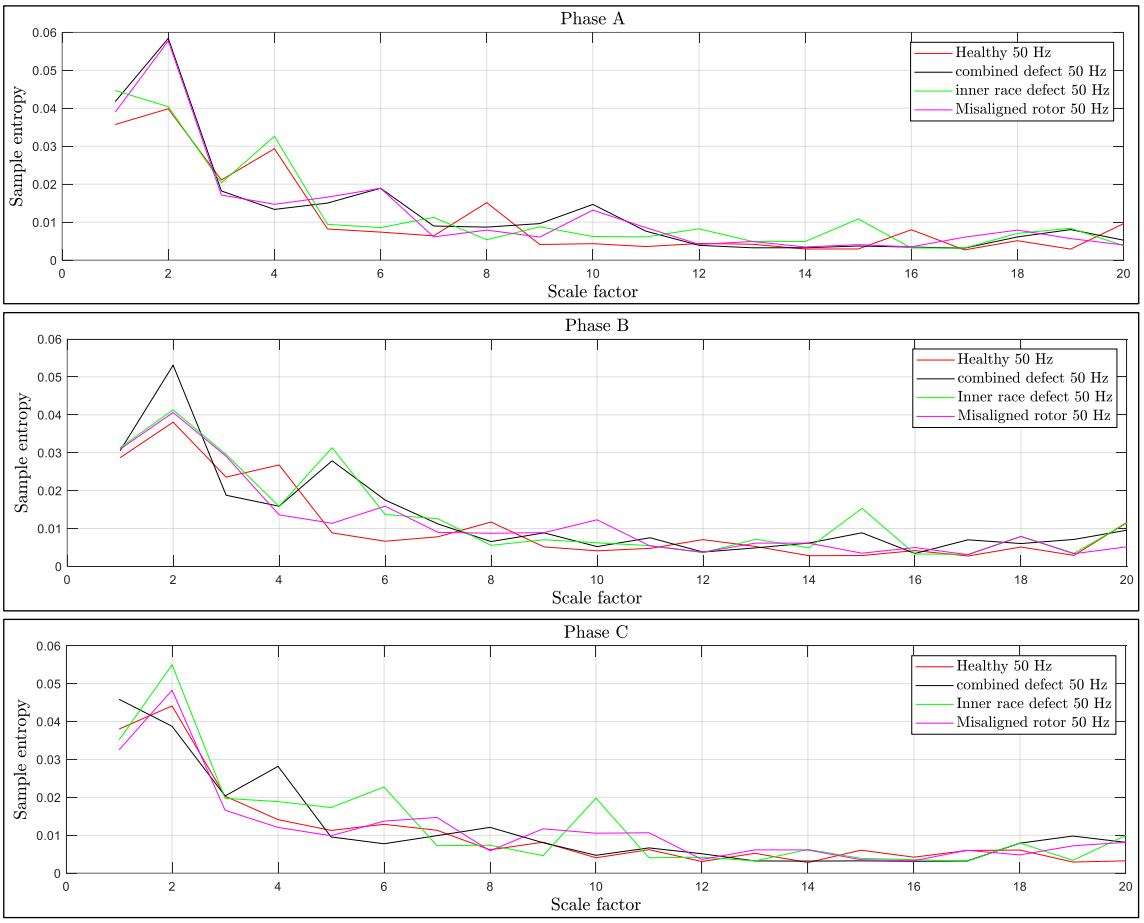

Figure11: Multiscale sample entropy over 20 scales of the corresponding stator current signal I_A, I_B and I_C.
Source: Authors, (2026).

Figure 11 illustrate the sample entropy for phase A of stator current across 20 time scales for four working condition at an operating speed of 50 Hz. In the SampEn for phase's current, we clearly observe differences in entropy patterns; sample entropy values are lower and more consistent across different scales for heathy operating condition in contrast to other faulty states, which exhibit a noticeable deviation for sample entropy values.

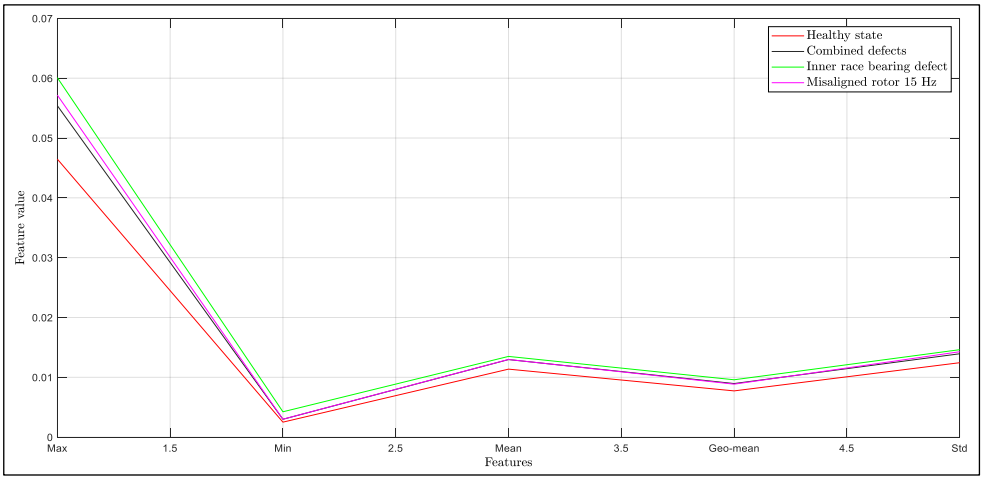

Figure 12: Five statistics over multiscale sample entropy of the phase current signal I_A.
Source: Authors, (2026).

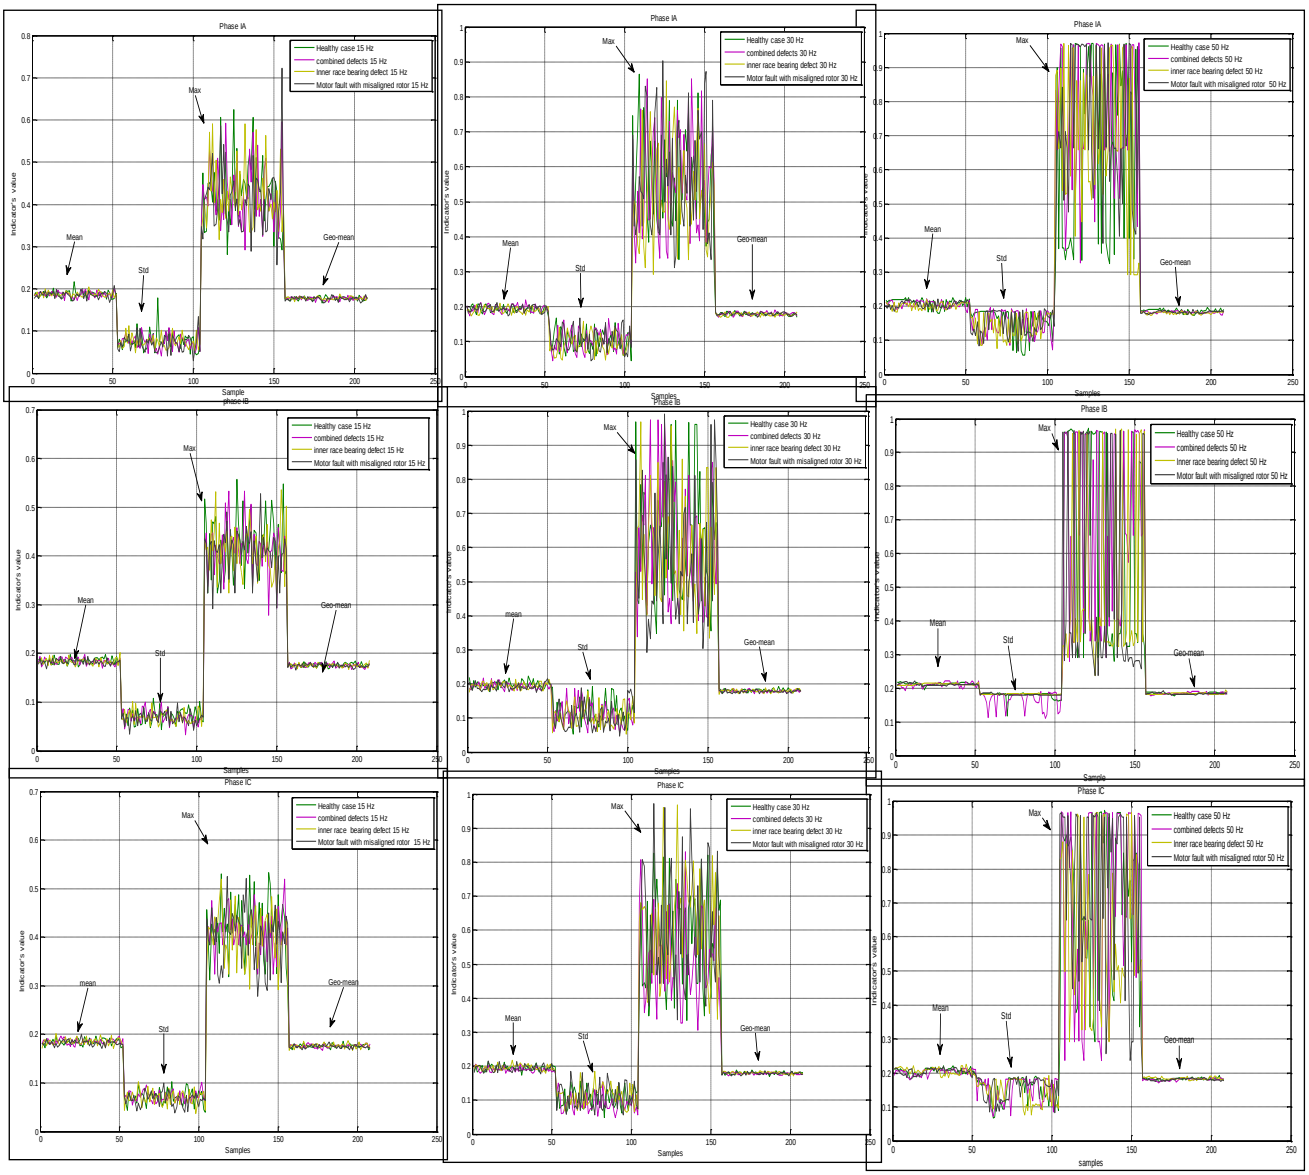

Figure 13: Four statistics over Multiscale sample entropy of phase current signal I_A, I_B and I_C with various speeds (15 Hz, 30 Hz and 50 Hz).
Source: Authors, (2026).

Figure 12 shows five feature statistics: the maximum SampEn value (max), minimum value (min), geo-mean of SampEn value (geo-mean), standard deviation of SampEn value (std), and arithmetic mean of SampEn value (mean) that are extracted from the Multiscale entropy (MSE) of current stator phase A at the speed of 15 Hz. Figure 13 displays the evolution of four statistical features (mean, max, geo-mean, std) over the MSE under different operating speeds (15 Hz, 30 Hz, 50 Hz). Figure 13 shows the four statistical features across the MSE for IA, IB and IC, respectively. By comparing the healthy state with defect conditions, these figures reveal a significant rise in all fault feature values in contrast with the healthy case, which exhibit a stable and consistent feature over time. These feature statistics are compared across four operating conditions, including healthy, inner race bearing fault, misaligned rotor, and combined faults.

Figure 14 illustrates the squared prediction error (SPE) of the phase current IA over time for fourth operation conditions, demonstrating how the SPE values are low and stable in healthy cases compared to when defects are revealed; the SPE values deviate significantly with noticeable fluctuations. This deviation corresponds to the type and severity of defects. Figure 15 offers a more detailed analysis of the SPE for the same four working conditions as in Figure 14 by decomposing it into four statistical features (mean, STD, max, and geo mean) extracted from the Multiscale entropy (MSE) of the phase current signals, demonstrating how the SPE fluctuates as faults develop from a healthy condition to higher levels of severity. In the healthy state, the SPE values for all features remain consistently low. In contrast, faulty conditions exhibit distinct increases in the SPE, and peaks begin to appear as defect severity progresses. Among the features, Geo-mean shows the highest sensitivity to faults, demonstrating the largest SPE peaks, while the other features display moderate but noticeable fluctuations. These results highlight the ability of SPE for progression monitoring and fault detection.

V. CONCLUSIONS

In summary, this research paper highlights two successful approaches to pinpointing and detecting various faults affecting induction motors, utilising the motor current signature analysis (MCSA). The first approach applies the MCSA technique with DWT energy analysis, while the second approach involves the application of the MCSA on the three-phase induction motor combined with multiscale entropy (MSE) and principal component analysis (PCA). The DWT energy analysis technique provides valuable information to identify the multifunction operating conditions. Through these results, we can observe clearly that the energy level increases with the presence of the fault. Conversely, in a healthy state, the energy levels are always at their lowest. These findings validate the accuracy and reliability of these combined approaches for fault diagnosis, which exhibit notable improvements in identifying and addressing inner race bearing fault, misalignment rotor, and combined defects.

The second experimental results from a three-phase induction motor demonstrate the ability of the proposed method in addressing challenges in early fault detection. This approach successfully distinguishes healthy from faulty states by analysing stator currents, particularly for localised defects. MSE is applied to extract detailed features while dimensionality and isolating fault relevant variations are reduced through PCA. The squared prediction error (SPE) analysis enhances the fault detection ability and assures more comprehensive analysis of the induction machine health. The SPE effectively confirms these findings by highlighting anomalies and deviations from healthy conditions, with increasing peaks and fluctuations that correspond to the severity of faults. Future studies should focus on expanding the approaches to different industrial conditions, including advanced methods of machine learning to enhance fault classification and optimising the algorithms for applications in real time. Overall, this research not only improves the detection of induction motor faults but also contributes to enhancing motor reliability, reducing unplanned downtimes, and leading to more effective industrial operations.

ABSTRACT

This study reports the development and mechanical characterization of polylactic acid (PLA) reinforced with bamboo cellulose nanofibers (BCNFs) for 3D printing applications. Composite filaments containing 1–5 wt.% BCNFs were fabricated and systematically evaluated for tensile strength, microhardness, impact resistance, and fracture morphology. The results demonstrated a strong dependence of mechanical performance on nanofiber loading. Neat PLA exhibited a tensile strength of 78.21 MPa, which increased progressively with nanofiber addition, reaching a maximum of 112.76 MPa at 3 wt.% BCNF, representing a 44.2% improvement. Similarly, microhardness values improved markedly, with the optimum composition exhibiting a 162.5% increase over neat PLA. Impact resistance followed the same trend, with energy absorption enhanced by 116% at 3 wt.% BCNF. However, at higher loadings (4–5 wt.%), mechanical properties declined due to fiber agglomeration and poor dispersion. SEM analysis of fracture surfaces confirmed these trends, revealing brittle fracture in neat PLA, rough and fibrous morphologies with effective crack deflection at 3 wt.%, and clustered fiber bundles acting as stress concentrators at 5 wt.%. These findings establish 3 wt.% BCNF as the optimum loading for balancing strength, toughness, and hardness, underscoring the potential of bamboo nanocellulose as a sustainable reinforcement for high-performance PLA-based 3D printing filaments.

I. INTRODUCTION

Additive manufacturing (AM) has transformed modern fabrication by enabling the production of complex geometries with reduced material waste and design flexibility. Among the different AM techniques, fused deposition modeling (FDM) has gained widespread adoption due to its cost-effectiveness and compatibility with a range of thermoplastics [1]. Polylactic acid (PLA), a biodegradable polyester synthesized from renewable resources such as corn starch and sugarcane, is the most widely used FDM filament. Its advantages include biodegradability, ease of processing, and good dimensional accuracy during printing. However, neat PLA is limited by its inherent brittleness, low impact resistance, and poor thermal stability, which restrict its use in engineering-grade and structural applications [2], [3]. To address these drawbacks, researchers have explored reinforcement of PLA with natural fibers, nanofillers, and biodegradable additives. Among these, nanocellulose has emerged as one of the most promising reinforcing agents owing to its outstanding properties such as high aspect ratio, large surface area, low density, biocompatibility, and biodegradability [4].

Nanocellulose exists primarily in two forms: cellulose nanocrystals (CNCs) and cellulose nanofibers (CNFs). CNFs, in particular, offer a flexible entangled network with high tensile modulus (up to 170 GPa) and crystallinity values between 50–90%, enabling superior reinforcement in polymer matrices [5], [6]. Additionally, the abundance of hydroxyl groups on their surfaces allows chemical modifications to improve compatibility with hydrophobic polymers such as PLA [7]. Bamboo has gained attention as an excellent source of CNF due to its high cellulose content, rapid growth rate, and low environmental footprint. Bamboo-derived CNFs exhibit excellent crystallinity, high stiffness, and good thermal resistance, making them suitable for polymer reinforcement [8]. Recent isolation techniques such as TEMPO-mediated oxidation, enzymatic hydrolysis, and high-pressure homogenization have facilitated the production of nanoscale CNFs with enhanced dispersion and reinforcing ability [9]. The incorporation of bamboo CNF into PLA matrices is expected to improve tensile strength, flexural strength, and impact toughness while maintaining printability in FDM [10]. Beyond bamboo, several agricultural residues have also been identified as alternative nanocellulose sources, promoting circular economy and waste valorization. Biomass including oil palm, hemp, jute, agave, sisal, triticale straw, soybean straw, alfa, kenaf, coconut husk, begasse, corn leaf, and sunflower stalks are rich in cellulose and represent sustainable raw materials for CNF extraction [11]. Rohaizu and Wanrosli successfully isolated nanocellulose from oil palm biomass using sono-assisted TEMPO oxidation, yielding materials with high crystallinity and reinforcing capability [12]. Similarly, Robles et al. demonstrated the extraction of cellulose nanoparticles from blue agave residues using green chemical routes, confirming their potential in biocomposite development [13]. Hemp and jute, with their high cellulose and low lignin content, are widely recognized as efficient feedstocks for nanocellulose, while kenaf and coconut husk have been reported to enhance thermal and mechanical stability in biopolymer composites [14], [15].

Several studies have confirmed the positive effect of nanocellulose incorporation in PLA matrices. Rigotti et al. reported that lauryl-functionalized nanocellulose reinforced PLA composites exhibited enhanced thermo-mechanical stability and reduced gas permeability [16]. Robles et al. demonstrated that surface-modified nanocellulose reinforced PLA significantly improved tensile strength and heat resistance compared to neat PLA [17]. Saba et al. observed that the incorporation of small amounts (1–5 wt.%) of CNF in thermoplastic composites increased tensile and flexural properties without compromising extrusion flow during 3D printing [18]. These findings confirm that cellulose nanofibers act as efficient stress-transfer mediums by restricting crack propagation and enhancing interfacial bonding. Despite these advantages, some challenges remain. High CNF content may cause nozzle clogging, poor interlayer adhesion, and dimensional inaccuracies in FDM printing [19]. Thus, optimization of filler content is essential to balance mechanical improvement and printability. Recent reports suggest that hybrid processing approaches, including surface functionalization of CNFs and melt-blending with compatibilizers, could further improve dispersion and interfacial adhesion [20]. Considering the above, the present study aims to develop and mechanically characterize PLA/nanocellulose composite filaments using bamboo-derived CNFs as the primary reinforcement. Agricultural residues such as oil palm, hemp, jute, agave, sisal, triticale straw, soybean straw, alfa, kenaf, coconut husk, begasse, corn leaf, and sunflower are highlighted as promising future feedstocks for nanocellulose extraction. The composite filaments will be prepared by solvent-assisted dispersion of CNF into PLA pellets, followed by extrusion using a single-screw filament extruder. Printed test specimens will undergo tensile, flexural, and impact testing, as well as thermal (DSC, TGA) and morphological (SEM) evaluations. It is anticipated that bamboo-derived CNF reinforced PLA composites will provide improved mechanical and thermal stability while retaining FDM printability, thereby offering a sustainable pathway for advanced applications in additive manufacturing.

II. MATERIALS AND METHODS

Materials

PLA is a biodegradable thermoplastic polymer derived from renewable feedstocks such as corn starch and sugarcane. It is widely recognized for its excellent printability, low processing temperature, and dimensional accuracy in fused deposition modeling (FDM). PLA exhibits good stiffness, transparency, and ease of extrusion, making it one of the most commonly used filaments in 3D printing. However, it has limitations such as brittleness, relatively low impact strength, and a low glass transition temperature, which restrict its use in load-bearing and high-temperature applications. The density of PLA typically ranges between 1.20–1.25 g/cm³, with a tensile strength of about 50–70 MPa and a tensile modulus of 2.7–3.5 GPa. These mechanical properties make it a suitable base polymer that can be further enhanced through reinforcement with nanofillers. Bamboo nanocellulose fibers are obtained by breaking down the lignocellulosic structure of bamboo into nanoscale fibrils. These fibers possess exceptional strength, high crystallinity, and a large surface-to-volume ratio, which contribute to their effectiveness as reinforcement materials. The average diameter of bamboo CNFs lies in the range of 20–50 nm, while their length extends to several microns, giving them a high aspect ratio favorable for stress transfer in composites. They are lightweight, biodegradable, and exhibit a tensile modulus up to 100–170 GPa, along with high thermal stability and flexibility. The abundance of hydroxyl groups on their surface enhances interfacial bonding with polymer matrices, improving tensile, flexural, and impact properties when incorporated into PLA.

Synthesis of bamboo cellulose nanofibers (BCNFs)

Cellulose nanofibers (CNFs) were synthesized from raw bamboo through a multi-stage chemical and mechanical process designed to isolate high-purity nanofibrils suitable for reinforcement in polymer matrices. Fresh bamboo culms were first chipped, oven-dried, and milled to fine powder before undergoing dewaxing to remove extractives. The processed biomass was then subjected to alkaline pulping using sodium hydroxide solution at elevated temperature, which facilitated the removal of hemicellulose and partial lignin. This was followed by a bleaching treatment using acidified sodium chlorite under controlled pH and temperature conditions to further eliminate residual lignin and impart whiteness to the cellulose fibers. The purified cellulose pulp obtained after repeated washing and neutralization was dispersed in deionized water to form a homogeneous slurry. To convert these micron-scale cellulose fibers into nanofibers, the suspension was processed using either a direct mechanical fibrillation route or a TEMPO-mediated oxidation pathway. In the mechanical approach, the slurry was subjected to high-shear blending followed by high-pressure homogenization, which generated intense shear forces to individualize the fibrils.

Alternatively, in the TEMPO oxidation route, primary hydroxyl groups of cellulose were selectively oxidized to carboxyl groups, thereby improving fibril separation, colloidal stability, and compatibility with hydrophobic polymer matrices. After oxidation, the slurry was neutralized and fibrillated using high-pressure homogenization, often complemented by ultrasonication to minimize aggregation. These combined treatments resulted in the production of cellulose nanofibers with diameters typically between 20–50 nm and lengths extending into the micron range, providing a high aspect ratio favorable for stress transfer in composites. The final CNF suspensions were obtained as viscous aqueous gels, carefully concentrated to the desired solid content, degassed to remove entrapped air, and stored at refrigerated conditions to preserve stability prior to compounding with PLA for filament extrusion. The TEM image of bamboo cellulose nanofibers shown in figure 1.

Functionalization of bamboo cellulose nanofibers

Functionalization of bamboo cellulose nanofibers is crucial to improve their dispersion in hydrophobic polymers such as PLA and to enhance interfacial adhesion. Due to the abundance of hydroxyl groups, untreated CNFs are highly hydrophilic and prone to aggregation, which limits their reinforcing potential. Chemical modification offers effective solutions, with TEMPO-mediated oxidation being one of the most common methods, introducing carboxyl groups that provide surface charge and stability. Esterification and acetylation replace hydroxyl groups with hydrophobic moieties, improving compatibility with biodegradable polyesters. Silanization using organosilane agents further enhances bonding by forming covalent linkages between CNFs and polymer chains. In addition, surface grafting of polymers or ionic groups can tailor properties such as flexibility, barrier performance, and conductivity. These functionalization strategies not only enhance dispersion and stress transfer in PLA composites but also improve mechanical strength, thermal stability, and printability in 3D printing applications.

PLA / BCNF 3D Printing filament preparations

PLA/BCNF composite filaments were prepared by incorporating bamboo cellulose nanofibers at different loadings of 1, 2, 3, 4, and 5 wt.% into a PLA matrix through a solvent-assisted dispersion followed by melt extrusion. Initially, PLA pellets were dried in a hot-air oven at 60 °C for 12 h to remove residual moisture and prevent hydrolytic degradation during processing. Bamboo CNFs were dispersed in ethanol using ultrasonication to break agglomerates and ensure uniform distribution. The BCNF suspension was then slowly mixed with pre-dried PLA pellets, and the mixture was subjected to rotary evaporation at moderate temperature to remove the solvent, leaving BCNFs uniformly coated on the PLA surface. The dried blend was compounded using a single-screw extruder operated at a barrel temperature profile of 170–190 °C with a screw speed of 50 rpm. The extrudate was drawn through a filament die of 1.75 mm diameter and passed over a water-cooled section to stabilize its shape. The continuous filaments were spooled under constant tension to maintain dimensional uniformity. For consistency, the process parameters were optimized to prevent BCNF degradation and ensure smooth filament formation. The obtained composite filaments exhibited a uniform diameter of 1.75 ± 0.05 mm, suitable for fused deposition modeling. The incorporation of bamboo CNFs in the range of 1–5 wt.% was selected to balance printability with mechanical reinforcement, as lower concentrations aid in maintaining extrusion flow, while higher concentrations enhance stiffness and strength. The prepared filaments were stored in airtight containers with desiccant until use in 3D printing trials. This process ensured the development of sustainable PLA/BCNF composite filaments with improved interfacial bonding and homogenous filler dispersion, enabling enhanced performance in mechanical and thermal characterization. III. MECHANICAL CHARACTERIZATIONS

Tensile Test

The tensile properties of the PLA and PLA/bamboo CNF composite specimens were evaluated in accordance with ASTM D638. Standard dog-bone shaped specimens were prepared using 3D-printed samples with a gauge length of 50 mm. Prior to testing, the specimens were conditioned at 23 ± 2 ℃ and 50 ± 5% relative humidity for 48 h to ensure uniform moisture content. The tensile tests were performed using a universal testing machine equipped with a 10 kN load cell at a crosshead speed of 5 mm/min. During the test, parameters such as ultimate tensile strength, tensile modulus, and elongation at break were recorded. The addition of bamboo CNFs was expected to enhance stiffness and strength by improving load transfer between the matrix and reinforcement, while maintaining reasonable ductility.

Micro Hardness Test

The surface hardness of the composite samples was determined using the Vickers microhardness method in accordance with ASTM E384. Flat, polished specimens were subjected to indentation under a load of 100 g applied for 15 s using a microhardness tester. The diagonals of the resulting indentations were measured with an optical microscope, and the Vickers hardness number (HV) was calculated. A minimum of five indentations were taken on each specimen at randomly selected positions to ensure statistical reliability, with results averaged to obtain the representative hardness value. The incorporation of bamboo CNFs was anticipated to improve resistance to localized plastic deformation due to the stiffening effect imparted by the nanofibers.

Impact Test

The impact strength of the 3D-printed composites was measured using the Charpy impact test as per ASTM D6110. Rectangular notched specimens with dimensions of 80 × 10 × 4 mm were prepared, and a V-notch of 2 mm depth was machined at the midspan of each sample. Tests were conducted using a pendulum impact tester, and the energy absorbed during fracture was recorded to calculate the impact strength. Five specimens were tested for each composition, and the average value was reported. The introduction of bamboo CNFs was expected to provide crack-bridging and energy dissipation mechanisms, thereby enhancing the overall impact resistance of the PLA matrix.

IV. RESULTS AND DISCUSSIONS

Tensile Characteristics

The tensile properties of the PLA/bamboo cellulose nanofiber (BCNF) composites clearly demonstrate the reinforcing ability of cellulose at the nanoscale as shown in figure 3. Neat PLA exhibited a tensile strength of 78.21 MPa, a value limited by its intrinsic brittleness and poor load-bearing capacity. With the incorporation of 1 wt.% BCNF, the tensile strength increased to 92.56 MPa, corresponding to an 18.4% improvement. This enhancement reflects the inherent characteristics of cellulose nanofibers, which are derived from the hierarchical structure of bamboo. CNFs possess an exceptionally high aspect ratio, high crystallinity, and a Young's modulus approaching 100–170 GPa, properties that make them ideal candidates for stress transfer when embedded in polymer matrices. The hydroxyl-rich surface of CNFs also provides abundant sites for hydrogen bonding with the ester groups of PLA, thereby improving interfacial adhesion and restricting slippage under tensile load. At 2 wt.% BCNF, the tensile strength further increased to 99.23 MPa (26.9% improvement), confirming that cellulose nanofibers, when well-dispersed, serve as efficient reinforcing agents that enhance stiffness without sacrificing ductility. The maximum performance was achieved at 3 wt.% BCNF, where the tensile strength reached 112.76 MPa, representing a remarkable 44.2% improvement compared to neat PLA.

At this optimum loading, the cellulose nanofibers likely formed a semi-percolated reinforcing network that constrained PLA chain mobility, delayed crack initiation, and deflected propagating cracks. This network effect, combined with the nanoscale dimensions and high surface-to-volume ratio of CNFs, accounts for the synergistic reinforcement observed.

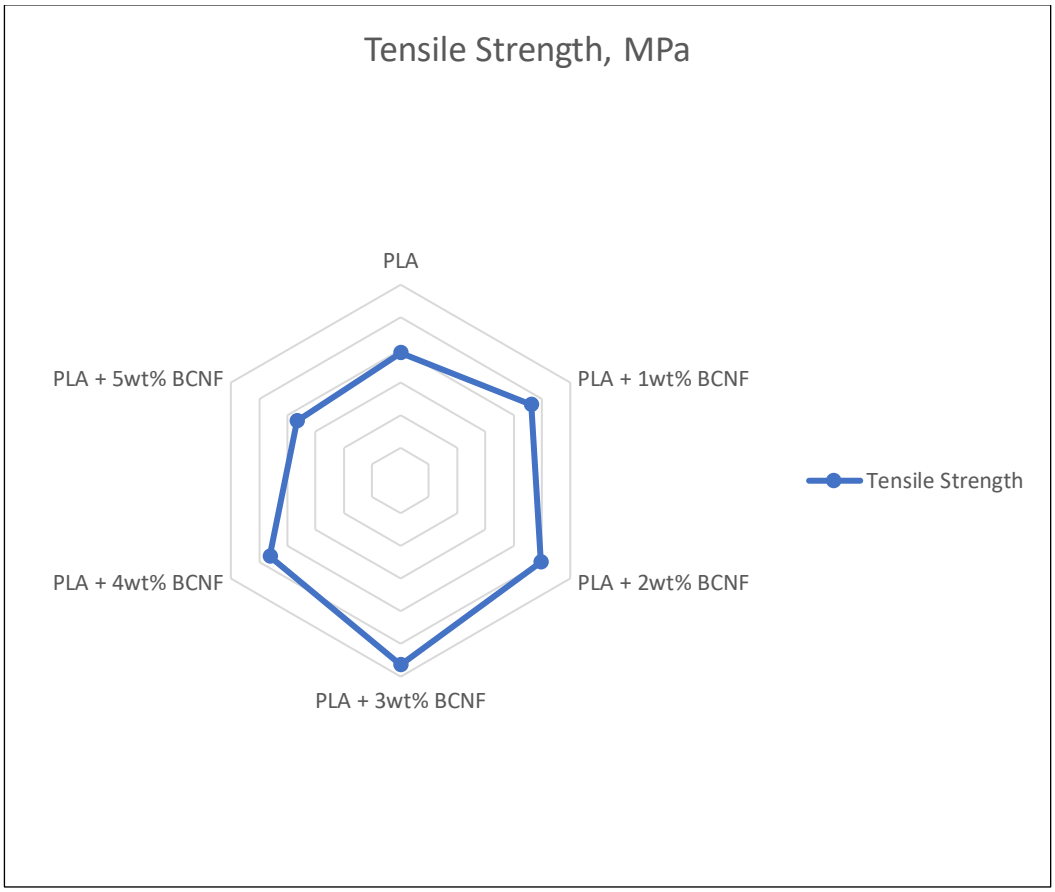

Figure 3: Tensile strength of PLA and its bamboo cellulose nanofiber reinforced composites.
Source: Authors, (2026).

Beyond the optimum, tensile strength declined; at 4 wt.% BCNF, the value fell to 92.54 MPa, while at 5 wt.% it dropped further to 73.41 MPa, which is 6.1% lower than neat PLA. The reduction is explained by the tendency of cellulose nanofibers to agglomerate at higher concentrations due to strong hydrogen bonding and van der Waals forces, leading to stress concentration zones and poor dispersion. Moreover, excess CNF content increases melt viscosity during extrusion, hindering proper filament formation and generating voids that reduce structural integrity. The results demonstrate that cellulose nanofibers are not merely fillers but active nanoscale reinforcements with unique structural features that can dramatically enhance the tensile performance of PLA at relatively low loadings. Their renewable origin, biodegradability, high crystallinity, and surface reactivity make them superior candidates compared to conventional fillers. The optimal 3 wt.% BCNF loading highlights the balance between effective dispersion, strong interfacial bonding, and the intrinsic mechanical advantages of cellulose, thereby offering a sustainable route to engineer high-performance PLA-based filaments for additive manufacturing.

Micro hardness characteristics

The microhardness analysis provided further insights into the reinforcing effect of bamboo cellulose nanofibers (BCNFs) on the PLA matrix (Figure 4). Neat PLA exhibited a baseline hardness of 16 HV, reflecting its relatively soft and ductile nature compared to engineering polymers. With the introduction of 1 wt.% BCNF, the hardness increased to 24 Hv, corresponding to a 50% improvement. This enhancement is primarily attributed to the nanoscale rigidity and high crystallinity of cellulose nanofibers, which restrict localized plastic deformation when subjected to indentation. At 2 wt.% loading, the hardness value further increased to 31 Hv (93.7% improvement), while the maximum reinforcement was observed at 3 wt.% BCNF with a hardness of 42 Hv, representing a 162.5% increase compared to neat PLA. This significant enhancement at optimum concentration is explained by the uniform dispersion of CNFs within the PLA matrix, forming a reinforcing network that resists penetration and distributes the applied load effectively. Beyond 3 wt.% loading, however, the microhardness values decreased, with 4 wt.% showing 27 Hv and 5 wt.% falling to 15 Hv, slightly lower than neat PLA. The reduction can be ascribed to the agglomeration of CNFs at higher concentrations, which introduces voids and weak interfacial regions in the matrix. These defects act as stress concentrators during indentation, thereby reducing the effectiveness of stress transfer. Additionally, the high viscosity of CNF-rich blends during processing may result in poor filament homogeneity and interlayer bonding, further diminishing surface hardness. Furthermore, the microhardness results confirm the reinforcing capability of bamboo CNFs and highlight the importance of optimized filler loading. The superior hardness improvement at 3 wt.% reflects the balance between nanoscale dispersion, interfacial bonding, and the inherent stiffness of cellulose, making this composition the most suitable for enhancing wear and scratch resistance in PLA-based 3D printing applications.

Impact analysis

The impact test results (Figure 5) highlighted the role of bamboo cellulose nanofibers (BCNFs) in modifying the toughness of PLA. Neat PLA exhibited a baseline impact energy of 0.25 J, consistent with its brittle fracture behavior and limited ability to absorb dynamic loading. With the addition of 1 wt.% BCNF, the impact energy increased to 0.31 J, corresponding to a 24% improvement. This initial enhancement can be attributed to the nanofibers acting as crack-bridging agents, which delayed crack initiation and provided localized energy dissipation. At 2 wt.% loading, the impact energy rose further to 0.39 J, representing a 56% improvement compared to neat PLA. The maximum reinforcement effect was observed at 3 wt.% BCNF, where the impact energy reached 0.54 J, corresponding to a remarkable 116% increase. This substantial improvement is explained by the homogeneous dispersion of CNFs within the matrix, which enhanced stress transfer, promoted microcrack deflection, and allowed more efficient absorption of impact energy. However, beyond the optimum concentration, a decline in performance was observed. At 4 wt.% BCNF, the impact energy decreased to 0.42 J, although still 68% higher than neat PLA, while at 5 wt.% the value dropped to 0.29 J, only a 16% improvement over neat PLA. The reduction at higher loadings is likely due to nanofiber agglomeration and poor dispersion, which created stress concentration sites and facilitated premature fracture under impact loading. Excessive filler content may also have reduced interlayer adhesion during filament printing, lowering the energy-absorbing capacity of the composites. The results indicate that bamboo CNFs significantly improve the toughness of PLA at low to moderate loadings, with 3 wt.% providing the best balance of dispersion, interfacial bonding, and energy absorption mechanisms. This demonstrates the potential of CNFs not only to improve strength and hardness but also to impart enhanced impact resistance, a critical property for structural and functional 3D-printed components.

Morphology analysis of tensile fractured surface

The tensile fracture surface morphology provides strong evidence of how bamboo cellulose nanofibers (BCNFs) influence the failure behavior of PLA as shown in figure 6. The neat PLA specimen (a) reveals a relatively smooth and flat fracture surface with stepped fracture features, a clear indication of brittle fracture and limited plastic deformation.

Such morphology is typical of unreinforced PLA, where rapid crack propagation occurs once a critical stress is reached, reflecting its inherently low toughness and poor energy absorption capacity. In contrast, the PLA reinforced with 3 wt.% BCNF (b) displays a much rougher fracture surface characterized by embedded fibers, elastic deformation zones, and regions of fiber pull-out. These features suggest good interfacial bonding between the nanofibers and the polymer matrix, which allows effective stress transfer during tensile loading. The pulled-out and well-anchored fibers act as crack-bridging elements, while the rough fracture path indicates mechanisms such as crack deflection and energy dissipation. This morphology directly explains the significant increase in tensile strength, hardness, and impact resistance at 3 wt.% loading, where the nanofibers are uniformly dispersed and form a reinforcing network that resists crack propagation. However, at higher loading levels, as seen in the 5 wt.% BCNF specimen (c), the fracture surface exhibits distinct fiber agglomeration with clusters of nanofibers forming localized defects within the matrix. These agglomerated regions act as stress concentrators that reduce the efficiency of stress transfer and create preferential sites for crack initiation and propagation. The reduced interfacial contact area between the polymer and nanofibers, along with void formation due to poor dispersion, weakens the composite and results in lower tensile and impact properties than even neat PLA. Thus, the morphological evidence strongly supports the mechanical results, demonstrating that an optimum loading of 3 wt.% BCNF maximizes reinforcement efficiency through uniform dispersion and strong interfacial adhesion, whereas higher loadings compromise structural integrity due to fiber clustering and agglomeration.

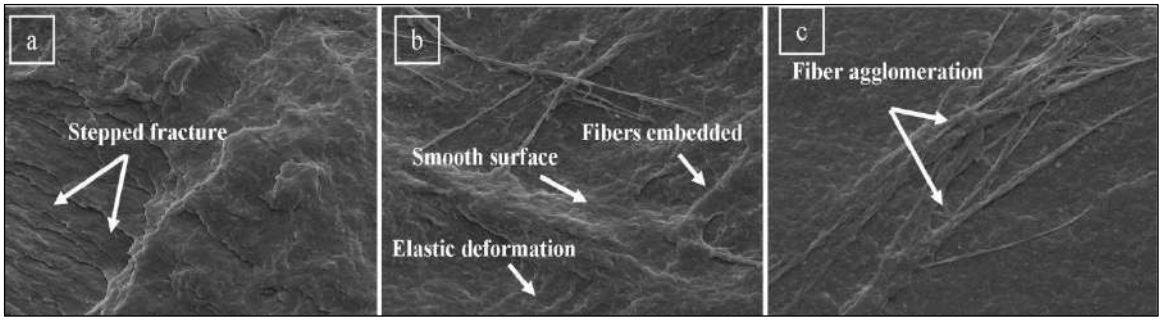

Figure 6: SEM morphology analysis of tensile fractured surface a) PLA b) 3wt.% c) 5wt.% PLA reinforced bamboo cellulose nanofiber composites.

Morphology analysis of micro hardness indentation surface

The SEM morphology of the microhardness indentations provides additional insights into the reinforcing behavior of bamboo cellulose nanofibers (BCNFs) in PLA composites (Figure 7). For the specimen containing 3 wt.% BCNF (a), the indentation zone shows a stepped fracture pattern along with clearly visible embedded fibers within the impression. The presence of dispersed fibers indicates that the nanofillers are well anchored in the PLA matrix and resist localized plastic deformation under indentation. This suggests efficient stress transfer between PLA and CNFs, which is consistent with the substantial improvement in hardness observed at this composition. The stepped fracture and fiber bridging around the indent edges further confirm enhanced resistance to crack propagation and localized strain accommodation, mechanisms that underpin the optimum reinforcement effect at 3 wt.% loading. In contrast, the 5 wt.% BCNF specimen (b) exhibits an indentation morphology dominated by fiber bundles within the impression. The clustering of nanofibers indicates agglomeration, which reduces the effective surface area for stress transfer and creates localized weak zones in the matrix. Such bundles behave as defects rather than reinforcements, leading to stress concentrations under load and premature microcracking. As a result, the hardness of the 5 wt.% composite is lower than that of neat PLA and significantly inferior to the 3 wt.% composite. The smoothness of the surrounding indentation edges in this sample also reflects less resistance to localized deformation, further supporting the mechanical results. The SEM evidence demonstrates that while 3 wt.% BCNF provides optimum dispersion and reinforcement, higher filler loadings (5 wt.%) promote fiber agglomeration that compromises interfacial bonding and negates the beneficial effects of CNFs, thereby emphasizing the importance of optimized nanofiber concentration for superior hardness performance.

V. CONCLUSIONS

1. Incorporation of bamboo cellulose nanofibers (BCNFs) into PLA significantly enhanced mechanical performance, with optimum results observed at 3 wt.% loading.
2. Tensile strength improved by up to 44.2% at 3 wt.% BCNF due to effective stress transfer, crack deflection, and strong interfacial adhesion between nanofibers and PLA.
3. Microhardness increased by 162.5% at 3 wt.% BCNF, confirming the role of nanofibers in restricting localized plastic deformation and resisting indentation.
4. Impact resistance reached a maximum at 3 wt.% BCNF with an improvement of over 116%, attributed to fiber bridging, crack pinning, and improved energy absorption capacity.
5. SEM analysis of tensile fracture surfaces revealed brittle failure in neat PLA, roughened surfaces with embedded fibers at 3 wt.% BCNF, and fiber agglomeration defects at 5 wt.% BCNF.
6. Microhardness indentation morphology showed uniform fiber presence at 3 wt.% leading to stepped fracture resistance, while fiber bundling at 5 wt.% caused stress concentration and reduced hardness.
7. Excessive fiber loading beyond 3 wt.% resulted in agglomeration, poor dispersion, and weaker interfacial bonding, highlighting the importance of optimized nanofiber content for high-performance PLA composites.

ABSTRACT

Accurately determining photovoltaic (PV) model parameters is essential for evaluating and optimizing the performance of solar energy systems. However, existing parameter extraction methods often struggle with achieving an optimal balance between global search (exploration) and local refinement (exploitation), leading to incomplete or suboptimal solutions. In this study, we introduce a novel optimization approach, the Triangulation Topology Aggregation Algorithm Optimizer (TTAO), tailored to address these challenges in PV model parameter extraction. The proposed algorithm leverages mathematical triangulation principles to iteratively explore the solution space through two distinct strategies: global aggregation for enhancing solution diversity across triangular structures and local aggregation for fine-tuning results in promising regions. The effectiveness of TTAO is validated by applying it to a PV single-diode model using real-world data. Performance comparisons with existing optimization techniques highlight the superiority of TTAO in terms of accuracy, convergence speed, and robustness. The results demonstrate that TTAO is a powerful and efficient method for precise PV model parameter extraction, offering improved outcomes over other approaches.

I. INTRODUCTION

With the increasing global demand for clean and renewable energy sources, photovoltaic (PV) systems have emerged as a cornerstone of sustainable energy generation. In fact, the global PV market increased from 236 GWp in 2022 to at least 350 GWp in 2023, and this presents a growth of almost 48% year to year [1]. Accurate modeling of PV systems is essential to analyze their performance [2], optimize energy production [3], facilitate system design, PV generator monitoring and diagnosis [4-6]. At the heart of PV modeling lies the challenge of extracting the parameters of mathematical models, such as the single-diode and double-diode models, which are widely used to describe the current-voltage (I-V) characteristics of solar cells [7], [8]. These parameters include unknown variables such as the diode ideality factor, series resistance, shunt resistance, and photocurrent, all of which directly influence the accuracy of PV performance prediction [9]. Recently, meta-heuristic algorithms inspired by physical phenomena, mathematical concepts, and various other sources—as discussed in the subsequent paragraphs—have demonstrated significant potential in solving complex optimization problems. In [10], the authors present an optimization approach that extracts SDM parameters by combining the Rao-1 optimization technique with a chaotic generator. In [11], the Adolescent Identity Search Algorithm (AISA) was employed to determine the unknown parameters of several benchmark of PV models. In [12], a 320W-72P polycrystalline solar panel module's characteristics are optimized under real operating conditions applying an Artificial Hummingbird Algorithm (AHA). In [13], researchers developed and applied a method named a Rao-1 algorithm for extracting PV module parameters. Their approach demonstrated superior performance in terms of both accuracy and robustness.

In [14], the authors present an innovative variant of the Rao optimization method, named the Fully Informed Search Algorithm (FISA). They showcase its efficiency in two different cases. The proposed algorithm exhibits superior performance in terms of system

stability, faster convergence, and higher accuracy. In [15], the authors proposed a hybrid approach to self-tune the optimized PV module parameters and avoid premature convergence. By integrating a gradient-based optimizer with a symmetric chaotic sequence generator, they achieved more accurate estimation of PV parameters for solar cells and modules. To address the challenges of high complexity and estimation difficulties, the Success-History Adaptation Differential Evolution algorithm with Linear Population Size Reduction (L-SHADE) is employed [16]. Specifically, the bi-parameter coordinated updating L-SHADE, enhanced with a parameter decomposition method (CSpL-SHADED), is utilized for improved performance. Author in [17] categorizes metaheuristic algorithms used for SDM parameters estimation into several groups, Physically-inspired algorithms [18], [19], Mathematically-inspired algorithms [20-22], Nature-inspired algorithms [23], Bio-inspired algorithms [24], [25], Swarm-inspired algorithms [26-29], Chaotic-oriented algorithms [30-32], Teaching-learning-inspired algorithms [33-35], Hybrid variant algorithms [36], [37]. However, these techniques often face limitations including susceptibility to local optima, sensitivity to initial guesses, and an imbalance between global exploration and local exploitation during the optimization process, especially when applied to high-dimensional and complex optimization problems.

Physical phenomena, social behavior, mathematical concepts, and various other algorithm types have been widely adopted for PV parameter extraction. As a result, obtaining accurate and reliable parameters remains a significant challenge, particularly when dealing with noisy or incomplete data. According to the No Free Lunch (NFL) theorem [38], no single optimization algorithm can consistently outperform others across all problem types, emphasizing the need for specialized approaches. Despite advancements, many recently proposed MAs have not undergone systematic evaluation for PV Single Diode model parameter identification. To address these gaps, this paper introduces a Triangulation Topology Aggregation Algorithm (TTAO) for PV model parameter extraction [39]. TTAO is a mathematics-inspired meta-heuristic algorithm that combines the principles of triangular topology with stochastic optimization strategies. The algorithm employs two primary mechanisms: global aggregation, which facilitates exploration by exchanging information across triangular topological structures, and local aggregation, which enhances exploitation by refining solutions in promising regions. This dual approach ensures a more effective balance between global search and local convergence, leading to improved parameter estimation accuracy and robustness of one diode model. Providing insights into the effectiveness of TTAO in balancing exploration and exploitation, ensuring reliable convergence to optimal solutions. The main contributions of this paper are as follows:

- Proposing a novel optimization algorithm, TTAO, for solving PV model parameter extraction of an SDM with enhanced accuracy and efficiency.
- Demonstrating the application of TTAO to single-diode PV model, using real-world dataset.
- Comparing the performance of TTAO with state-of-the-art optimization techniques through extensive experiments and statistical analysis.

The rest of this paper is organized as follows: Section 2 describes the proposed TTAO methodology, And the SDM model in detail. Section 3 presents the experimental setup and results, including comparisons with seven alternative algorithms. Section 4 discusses the findings and implications, and Section 5 concludes the paper with future research directions.

II. PHOTOVOLTAIC MODELS AND TTAO ALGORITHM

II.1 STANDARD SINGLE DIODE MODEL (SDM)

The Single Diode Model (SDM) is the most widely used equivalent circuit model (ECM) and the simplest to implement. A photovoltaic (PV) module consisting of Ns cells connected in series and/or Np cells arranged in parallel can be mathematically represented by equations (1) and (2) accordingly:

$$I_{pv} = I_L - I_s \left[\exp\left(\frac{q\left(V_{pv}+I_{pv}R_S\right)}{nkT} \right) - 1 \right] - \frac{V_{pv}+I_{pv}R_S}{R_p} \tag{1}$$

$$I_{pv} = N_p I_L - N_p I_s \left[\exp\left(\frac{q\left(V_{pv}+\left(N_S/N_p\right)I_{pv}R_S\right)}{nN_S kT} \right) - 1 \right] - \frac{V_{pv}+\left(N_S/N_p\right)I_{pv}R_S}{\left(N_S/N_p\right)R_p} \tag{2}$$

Where I_{pv} represents the output current, I_S is the reverse saturation current, and I_L denotes the photo-generated current. The electron's charge is given by $q = 1.60217646 \times 10^{-19}$ C, while the output voltage is represented by V_{pv}. k is Boltzmann's constant (1.380653×10^{-23} J/K), and T denotes the cell temperature. Additionally, R_p and R_s correspond to the parallel and series resistances, respectively, while n represents the diode ideality factor. It is essential to highlight that the previous models include five parameters—R_p, R_S, n, I_L, and I_S—that have not been specified and need to be determined. The corresponding one-diode circuit is illustrated in Figure 1.

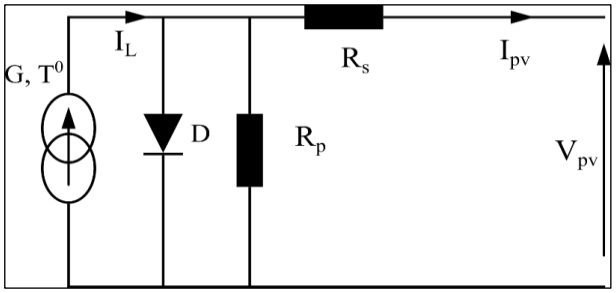

Figure 1: Single Diode Model (SDM) Equivalent Circuit.

II.2 COST FUNCTION

Optimization algorithms typically require an objective function to guide the minimization or maximization process during each update step. In this research, the objective function is the difference between computed (calculated) and observed (measured) data. The total difference is measured using the Root Mean Square Error (RMSE), acting as the cost function.

$$RMSE(x) = \sqrt{\frac{1}{M}\cdot\sum_{i=1}^{N}(I_{meas}-I_{simu})^2} \tag{3}$$

Where M is the number of data points. Imeas and Isimu are the measured and the simulated current, respectively.

II.3 TRIANGULATION TOPOLOGY AGGREGATION OPTIMIZER (TTAO):

The Triangulation Topology Aggregation Optimizer (TTAO) is a meta-heuristic algorithm inspired by the mathematical properties of triangular similarity [39]. It is designed to solve continuous optimization problems by iteratively constructing and updating triangular topological units, which balance exploration (global search) and exploitation (local search). The algorithm operates through two key strategies: generic aggregation and local aggregation. The optimization process consists of a sequence of well-defined steps.

II.3.1 Parameters Initialization:

The population is initialized with N individuals, divided into [N/3] triangular topological units. Each unit consists of three vertices, and the remaining individuals are randomly generated. The position of each individual is initialized as:

$$\overrightarrow{AB}_{i,1} = r_0 \cdot \left(\overrightarrow{UB}-\overrightarrow{LB}\right) - \overrightarrow{LB} \tag{4}$$

Where r0 is a random number in [0,1]. $\overrightarrow{LB}$ and $\overrightarrow{UB}$ are the lower and upper bounds of the variables.

II.3.2 Formation of Triangular Topological Units:

Each triangular unit is formed by generating two additional vertices using trigonometric transformations:

$$\overrightarrow{X_{i,2}} = \overrightarrow{X_{i,1}} + l * \overrightarrow{f\left(\vec{\theta}\right)} \tag{5}$$

$$\overrightarrow{X_{i,3}} = \overrightarrow{X_{i,1}} + l * \overrightarrow{f\left(\overrightarrow{\theta+\frac{\pi}{3}}\right)} \tag{6}$$

Where $l = 9 * e^{-t/T}$ is the size of the triangular unit, which decreases over iterations, and $\overrightarrow{f\left(\vec{\theta}\right)}$ is a direction vector calculated using cosine functions. An internal point within the unit is generated as:

$$\overrightarrow{X_{i,4}} = r_1 \times \overrightarrow{X_{i,1}} + r_2 \times \overrightarrow{X_{i,2}} + r_3 \times \overrightarrow{X_{i,3}} \tag{7}$$

Where $r_1+r_2+r_3=1$.

II.3.3 Generic Aggregation (Exploration):

This strategy promotes exploration by exchanging information between different triangular units. A new solution is generated by combining the best individuals from two units:

$$\overrightarrow{X_{i,new1}^{t+1}} = r_4 \times \overrightarrow{X_{i,best}^{t}} + (1 - r_4) \times \overrightarrow{X_{rand,best}^{t}} \quad (8)$$

Where r_4 is a random number in [0,1]. $\overrightarrow{X_{i,best}^{t}}$ and $\overrightarrow{X_{rand,best}^{t}}$ are the best individuals from unit i and a randomly selected unit at the tth generation.

II.3.4 Local Aggregation (Exploitation):

This strategy focuses on exploitation by refining the search within each triangular unit. The position of the best individual in each unit is perturbed based on the difference between the best and suboptimal individuals:

$$\overrightarrow{X_{i,new2}^{t+1}} = \overrightarrow{X_{i,best}^{t+1}} + \alpha \times \left(\overrightarrow{X_{i,best}^{t+1}} - \overrightarrow{X_{i,sbest}^{t+1}} \right) \quad (9)$$

Where α is a decreasing parameter that controls the scope of the local search. After each iteration, the performance of each individual is evaluated, and the best candidates are stored. The triangular units are updated for the next iteration, ensuring a dynamic balance between exploration and exploitation.

III. RESULTS AND DISCUSSIONS:

This section presents the findings related to the parameter estimation for various PV modules using the proposed TTAO algorithm. Specifically, the TTAO algorithm is applied to the following cases involving PV modules of different technologies, with the ranges of all unknown parameters provided in Table 1.

Table 1: Parameters boundaries for the used modules.

Parameters	Poly-solar 320W-72P		CLS-220P	
	Min	Max	Min	Max
R_S [Ω]	0	0.1	0	0.1
I_L [A]	0	10	0	10
R_P [Ω]	0	50000	0	50000
n	1	2	1	2
I_s [A]	0	1	0	100

Source: Authors, (2026).

The effectiveness of TTAO is assessed by comparing its performances with those of seven alternative algorithms: Rao-1 [40], HHO [41], IGWO [42], RUN [43], GTO [44], CPA [45], and the CDO method [46]. The performance of the TTAO algorithm is compared with the performance of the selected algorithms, in terms of the RMSE, standard deviation (Std), and convergence.

III.1 CASE STUDY-1: CLS-220P TECHNOLOGY:

The outcomes of the study of the photovoltaic (PV) electrical system consisting of three CLS-220P polycrystalline modules represent important findings for this first case study. With respect to the estimated parameters, RMSE, and standard deviation obtained using various techniques, including the proposed TTAO algorithm, are summarized in Table II. As shown, the TTAO algorithm achieved the lowest RMSE, whereas the RUN algorithm yielded a slightly higher RMSE, positioning it just after the TTAO algorithm in terms of performance. Also, Tab. II shows the superior stability and accuracy of the TTAO algorithm compared to other methods. The parameters estimated in Table II are also used to generate the I-V characteristic (Figure 2) alongside the experimental data points for the first case study.

Table 2: Optimized parameter estimates for the CLS-220P array at the optimal RMSE value.

Parameters	R_s	R_{sh}	I_{ph}	n	I_0	Std	RMSE

III.2 CASE STUDY-2: POLY-SOLAR 320W-72P:

In the second case study, a comprehensive analysis is carried out on the results obtained with the Poly-solar 320W-72P PV technology. Figure 4 presents a visual illustration of the PV cell/module curve, comparing the simulated curve using estimated parameters by TTAO algorithm with experimental data points for the same module.

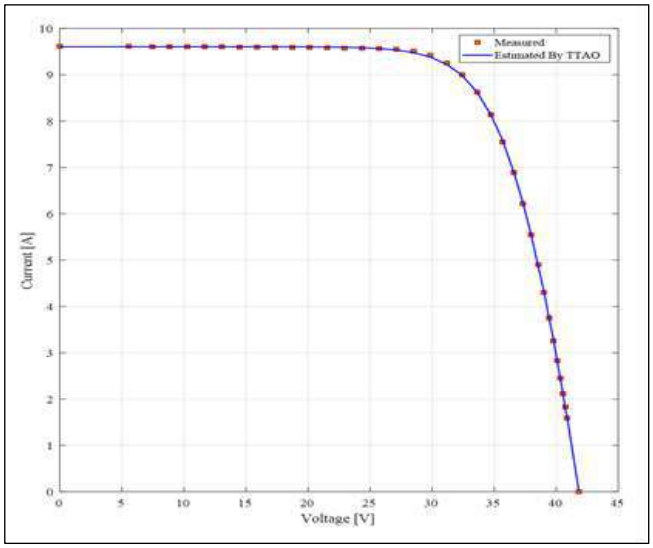

Figure 4: Experimental and modeled curves for the Poly-solar 320W-72P module.
Source: Authors, (2026).

Clearly, the simulated I-V curve using optimized parameters, exhibit an outstanding quality of perfection in mimicking the real PV characteristic. Table III offers the measured PV cell/module parameters, and their corresponding metrics, incorporating both the TTAO method and its alternatives. Remarkably, the lowest RMSE observed (2,300304E-02) with a Std of 9,3306E-03 was attained by the TTAO method This result validates the remarkable accuracy and stability of the proposed algorithm.

Table 3: Measured parameters of the Poly-Solar 320W-72P technology at the optimal RMSE value.

Parameters	R_s	I_S [A]	R_p	n	I_L [A]	Std	RMSE
TTAO	4,559E-03	1,855E-07	49802,45	1,1857	9,6051	1,5718E-03	2,572551E-02

IV. CONCLUSIONS

The present research paper Evaluates the effectiveness of the newly introduced TTAO method for estimating the unidentified parameters in PV cell SDM model. The approach is formulated upon a mathematical property of triangular similarity, known for its Trade-off between exploration (broad search) and exploitation (focused search). This manuscript is organized into four main sections: starting by introducing the stat of the art for PV cell/module parameters estimation, passing through the description of the TTAO method, and its validation through real benchmarks involving two PV module technologies: the Poly-solar 320W-72P technology, and a polycrystalline PV system constructed with more than one CLS-220P module. The findings confirm the precision of parameter extracted implementing the TTAO method. The adopted algorithm managed to minimize the Performance metric (RMSE) until 2,572551E-02 when the Poly-solar 320W-72P technology is used and it attains 2,300304E-02 as for CLS-220P PV technology. Likewise, the experiments unmistakably show the enhanced performance of the TTAO approach compared to seven alternative parameter extraction methods excelling in both precision and stability. In addition, with the significant alignment of computed I–V curve utilizing observed data points. Which conveys that the TTAO technique is an efficient framework for the one diode PV cell model parameters estimation and optimization. As well as in various fields such as PV systems control, monitoring and diagnosis. In the forthcoming research phase, we may use the estimated parameters to implement the model of a real PV photovoltaic arrays and then building a Real-time photovoltaic emulator for monitoring and fault diagnosis.

V. AUTHOR'S CONTRIBUTION

Conceptualization: Abdesslam Belaout, Badis Lekouaghet and Mohammed Haddad.
Methodology: Abdesslam Belaout and Badis Lekouaghet.
Investigation: Abdesslam Belaout, Badis Lekouaghet and Mohammed Haddad.
Discussion of results: Abdesslam Belaout and Badis Lekouaghet.
Writing – Original Draft: Abdesslam Belaoutand.
Writing – Review and Editing: Abdesslam Belaout, Badis Lekouaghet and Mohammed Haddad.
Resources: Badis Lekouaghet and Mohammed Haddad.
Supervision: Badis Lekouaghet.
Approval of the final text: Abdesslam Belaout and Badis Lekouaghet.

ABSTRACT

Aerodynamic flow control is an essential requirement for the airplane designers to achieve the minimum drag coefficient at different flight missions. A comprehensive review is focused in this article to provide the detailed insights about the works carried out by Aerodynamists on flow control. This flow control is the key parameter associated with flow separation, flow reattachment, boundary layer separation, lift enhancement, and drag reduction in the field of aerodynamics as well as hydrodynamics. The specific areas or components where the flow control is essential are known as the wings and tails of airplanes, compressors and turbines of jet engines, fans and blowers. Flow over an aerodynamic surface has to be attached at higher angles of attack such that it increases the operational efficiency of flight vehicles. The primary goal of the aviation field in twenty first century is to develop the greener technologies and it can be achieved by advanced structural materials, efficient propulsion systems, and most importantly through enhanced aerodynamic efficiency. The presented review paper provides deep insights of various passive and active flow control techniques which are mainly associated with the enhancement of aerodynamic efficiency at different flight missions.

I. INTRODUCTION

Fluid dynamics is a discipline which characterizes the flow of fluids, and illustrates the peculiarity on wide range of applications through aerodynamics and hydrodynamics. Contemplation of fluid dynamics at varying complexities triggers analysts to compensate ideas at difficulties and several innovations. Flow characteristics over the surface differ based on the size and shape of the solid objects. Generally, streamline body and bluff body are identified as a primary classification among the shape of the objects. When the drag is dominated by pressure drag, the body is streamlined and when it is dominated by pressure drag, the body is classified as bluff body. The net force acts upwards on the airfoil when the pressure on the suction side is lower than the pressure side (lower surface). The possessions and the properties of viscosity supremacy to the formation of starting vortex, in turn it is accountable for bearing the capable circumstances for lift. Another aerodynamic force called as drag which plays a vital role in determining the object's aerodynamic performance. In the aviation history, numerous efforts have been executed to improve the lift with minimum drag for enhancing the performance characteristics of aircrafts. Particularly, the reduction of drag results in a substantial decrease of Specific Fuel Consumption (SFC). The summary of the flow control techniques discussed in this review are presented in Figure 1.

I.1 HISTORICAL OVERVIEW OF FLOW CONTROL

The dream of flying has curiosity to the human beings since earliest periods. The stories of wax wing with flight in Greek mythology, Ancient Egyptian god Khensu had wings have been a dream for man to fly. In 1903, first powered flight is accepted to have taken place by wright brothers, who inspired from Otto Lilienthal who made over 2000 successful glider flights [1]. Many research was focused on the use of ailerons which were developed in 1908 and use of slotted flaps on wing leading edge for lift enhancement [2]. In the late 1920, investigations on suction control towards boundary layer reattachment during flight condition were carried out [3]. The impact of world war-II induced research in to the development of aircrafts, missiles and ships with improved characteristics like fast, highly manoeuvrable and efficiency. It leads to focus on optimization of airfoil profiles with minimum thickness. This thin airfoil profile was benefitted with leading edge separation and encouraging the flow to reattach [4].

The appreciable experiments and achievements for flow control during 1940-1970 incudes, bluff body splitter plates [5], vortex generators [6] helical strakes [7] and acoustic excitation [8]. During the period of 1970-1990, the research effort was focussed towards reduction of drag for commercial airlines, land vehicles, pipelines and other industrial devices. Also, usage of riblets and large-eddy break-up (LEBUs) devices were developed to reduce the skin friction in turbulent boundary layer [8]. Various active flow control methods were developed and employed in the mid of 1980's. Also, there was a transformation in flow control strategies, which is shifted to controlling flow instabilities from controlling the time-averaged state [9]. Recently, the development of actuators which is capable of controlling the flow at the timescale of instability has been strongly focussed. Zero net mass flux (ZNMF) jets, oscillating wire, morphing surface, magneto hydrodynamic devices are the examples of currently available actuators. However, the actuator bandwidth limitations and scaling issues still pose a significant problem for active flow control [10].

I.2 FLOW SEPARATION

The vorticity is ultimately cast at the trailing edge producing alternating sign in the wake. The circulation around the airfoil formed due to satisfy the conservation of angular momentum, there must be an equivalent motion to obstruct the vortex movement. By the form of circulation around the airfoil, the velocity vectors from the counter circulation add to the free flow velocity vectors that develop higher velocity above the airfoil and lower velocity below the airfoil that requires a pressure on above surface lower than the ambient pressure. Flow separation occurs when the boundary layer travels far enough against an adverse pressure gradient. As the severity of the adverse pressure gradient increases, the velocity profile becomes increasingly distorted and then becomes negative. The fluid becomes detached from the surface of the object, and instead takes the forms of eddies and vortices. Boundary layer separation is the detachment of a boundary layer from the surface into a broader wake. Boundary layer separation occurs when the portion of the boundary layer closest to the wall or leading-edge reverses in flow direction. The laminar or the transiting boundary layer which desirable to delay the location of separation.

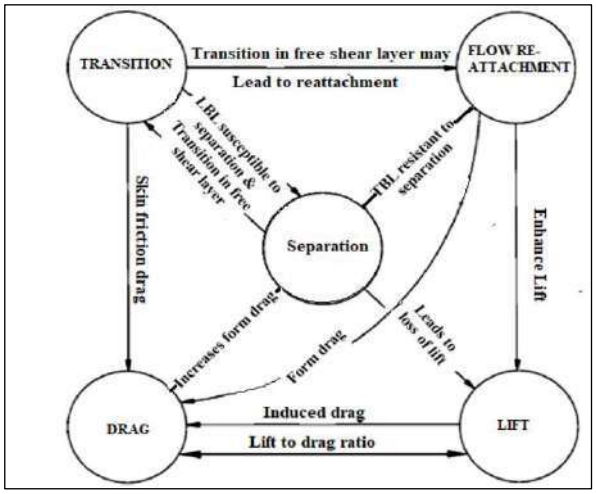

Figure 2: Effects of separation.
Source: [11].

Separation meant for the flow detaches from the surface. Two types of separation are generally focused, one is weak separation and another is strong separation. Weak separation can be defined as that one where the separation point is variable or undefined. Weak separation occurs at streamline bodies, which is pressure drag dominated when compared to viscous drag. The separation increases when angle of attack increases.The strong separation case is one where the separation point is fixed. Mostly all bluff bodies with sharp corners occurring in strong separation which have more viscous drag when compared to pressure drag. It increases while velocity increases. For both the strong and weak separation cases, passive and active controls are possible. The detailed description about flow separation has been addressed by [11]. The flow separation is a very important phenomenon that is to be considered in air flow characteristics. The performance and stability of an airplane is often degraded by flow separation.

Flow separation takes place at different points on the upper surface of the airfoil depending upon the angle of attack. The point at which the flow separation takes place is called separation point. The flow separation is mostly induced by adverse pressure gradient. This flow separation is the main factor for drag formation in wing profiles. For an example, for an airplane wing profile, the total drag can mainly divide in to the skin friction drag, pressure drag and induced drag. The sum of skin friction and pressure drag is called profile or form drag. Induced drag is related to lift production. If the speed is approached to sonic limit, a new component of drag will come in to the account, known as wave drag. Reduction of overall drag is not an easy task and more complicated. While the drag of the wing is a key parameter to the performance, it should be agreed that the lift production is also important. So, the flow control is involved with lift enhancement and drag reduction.

I.3 FLOW CONTROL

The idea that has been developed to manipulating a flow field in order to achieve a specific design perspective through some function of actuation or desired change in flow behavior is the underlying principle of flow control. The following sections will be focus on manipulating of development of external wall bounded flow on the airfoil surface. Flow control is the technology that has been associated to manipulate the boundary layer over the surface. The non-dimensional parameter Reynolds number is an important factor to consider in the context of flow control. Reynolds number defines the type of boundary layer, whether it is laminar, transitional or turbulent. Depends on the boundary layer thickness, it is desirable to delay the separation location in order to increase the lift and reduction in skin friction drag

II. TYPES OF FLOW CONTROL

The word control seems too strict in the sense that the flow is just to behave in a given form. An adequate introduction and historical perspective of flow control have been addressed in the previous chapters. Flow control devices are generally designed to reduce the drag of a wing configuration. Some of the flow control devices are exclusively designed for increase the lift production rather than reduce the drag. However, they often lead to reduce the drag. The flow control devices will be classified in to two groups; active and passive. The energy expenditure is the key parameter which will cause the main difference and make the type of device to consider for the purpose. The active control devices differ from the passive control in the sense that auxiliary/supplementary power is required. If the device requires no control power input, then it is typed as passive control. By the capability of switching on and off, active flow control techniques provide various performance advantages over passive flow control. By the peculiarity of active flow control, it possesses greater adaptability to changing flight conditions, capability to target specific instabilities and lower associated drag. Over passive flow control, the utilization of active flow control is complicated and less cost effective. Active flow control devices are complicated to design and need a greater level of maintenance than passive type devices. By virtue of its geometry, the passive flow control device alters the flow physics without input. Lift enhancement and drag reduction were the useful classification on designation of flow control. The generation of lift by an airfoil considered on alteration of shape, its orientation relative to the flow can be changed, tip stall can be minimized or degree of flow attachment and circulation can be enhanced. Hence, lift can be increased by wing area, angle of attack, camber, augmentation of circulation and momentum exchange in the boundary layer. The flow control methods focus on drag reduction by avoiding/delaying flow separation, reducing spanwise flow, avoiding/delaying transition to turbulence and reducing coherence of turbulent structures.

III. ACTIVE FLOW CONTROL TECHNIQUES

III.1 LIFT ENRICHMENT

III.1.1 Increased Wing Area/Camber

The amount of lift generated by a wing depends on the shape of eth airfoil, wing area and the velocity of an aircraft. To generate more amount of lift during take-off and landing, leading edge slots and trailing edge flaps are used as shown in Figure 3. Both provide increment in camber and wing area when it is angled down. Deployment of spanwise slots creates a gap called slot which further improves performance.

Figure 3: Leading edge slot and trailing edge flap.
Source: Authors, (2026).

An alternative device to slat is a Krueger flaps as shown in Figure 4. These flaps are mounted on the bottom surface of the wing are hinged at their leading edge. When actuators extend the flap down position thus increasing the wing camber and do not have associated slot, which leads to inferior performance than slats [12].

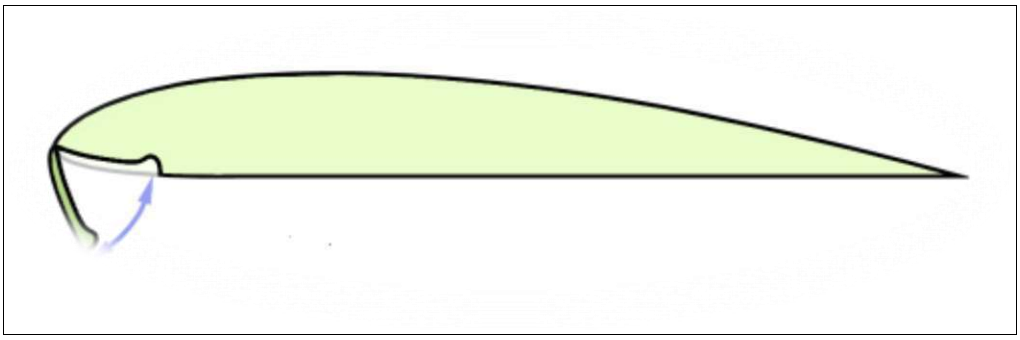

Figure 4: Krueger flap.
Source: Authors, (2026).

III.1.2 Suction

Suction can be used to stabilize a laminar boundary layer, delaying the transition of boundary layer and thereby reducing skin friction drag. This suction can be achieved by hybrid laminar flow control surfaces. It is an active drag reduction technique. The delay in transition of boundary layer from laminar to turbulent flow is generally achieved by the application of suction over the 10 to 20% of the chord. This method involves removing a small amount of the boundary layer fluid through a porous surface or a series of spanwise slots [12].

III.1.3. Circulation Augmentation

The primary purpose of this flow control technique is to allow lift generation at higher angle of attack and reduced pressure drag. A flat plate placed at the trailing edge of an airfoil perpendicular to the pressure side of the airfoil is called Gurney flap as shown in Figure 5. Its length is approximately 1% to 2% of the airfoil chord and this configuration gives both increased lift and reduced drag [13] Increase the trailing edge suction due to vortex shedding process and deceleration of the flow at the trailing edge on pressure side jointly improves the overall circulation associated with a given airfoil [14].

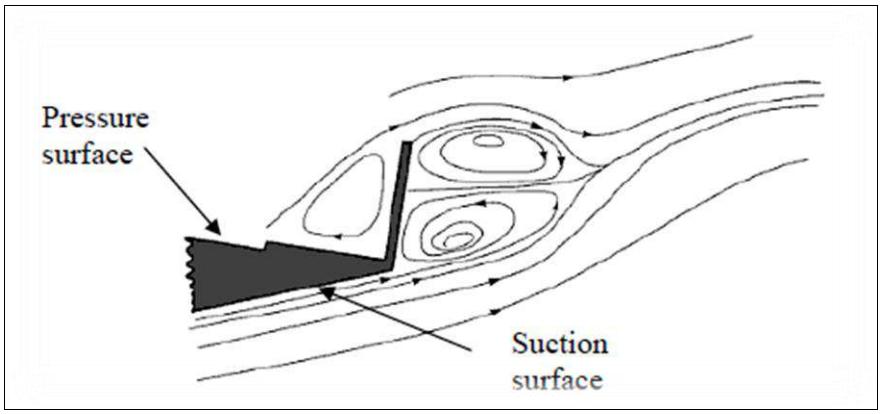

Figure 5: Gurney flap showing twin vortex flow field.
Source: [15].

Micro electro mechanical (MEM) translational tabs (microtabs) are active flow control devices on aerodynamics surfaces for lift enhancement. They are located slightly forwarded of the trailing edge of airfoil pressure surface. It creates a pressure side vortex and shifting the separation point from trailing edge to the end of the tab and changing the kutta condition, leading to an effective increase in camber [16].

III.1.4 Momentum Exchange/ Flow Separation Delay

Zero Net Mass Flux jets (ZNMF), slots and vortex generator jets enhance the momentum exchange and thereby delaying the stall. ZNMF jets or synthetic jets (Figure 6) are a compact actuator, no requirement for external air supply, more cost-effective alternative of flow separation control than the steady blowing and suction. ZNMF jets are cavities with membranes at the bottom. The membranes oscillate, drawing fluid into the cavity before expelling it. ZNMF jets promote increased mixing and give rise to a higher entrainment rate in boundary layer. In addition, streamlines are deflected from the surface which reduces the local upstream pressure gradient, thus lowering forces which lead to boundary layer separation. These characteristics substantially delay the stall and enabling the airfoil to generate a larger amount of lift with reduced pressure drag [17].

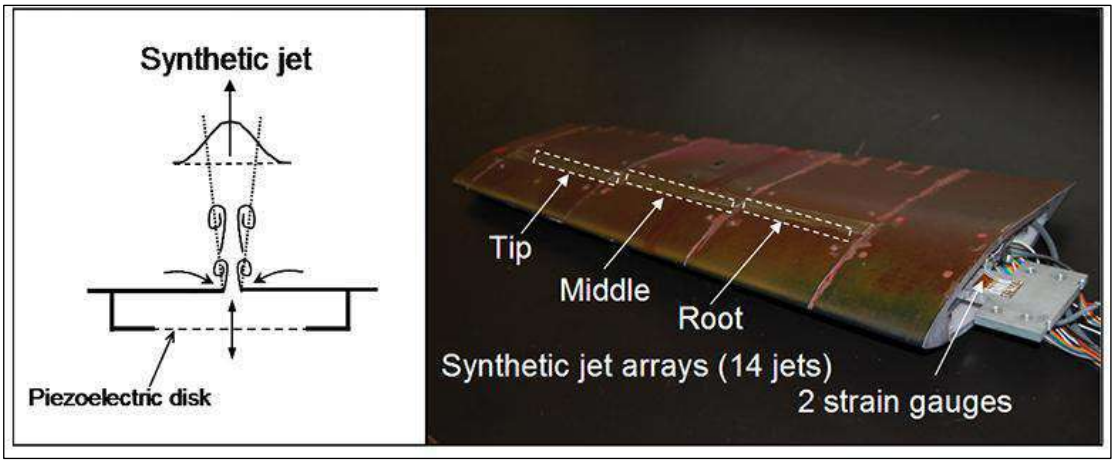

Figure 6: Synthetic jet schematic diagram on wind turbine blade model.
Source: [18].

Positioning of synthetic jet in the leading edge of the wing effectively increases the influence of asymmetric vortex on lateral directional stability and the control. The periodic injection leads to the control of asymmetric vortex improves the adverse pressure gradients resistance of main vortex to influence the asymmetric vortex. By the induction of synthetic jet control left and right separation vortices are effectively controlled [18]. A rectangular square tipped wing is examined experimentally for the development and control of Vortex under the effect synthetic jet active control. The induction of synthetic -jet control effectively curb the peak circumferential velocity and core axial velocity through maintaining the turbulent structure core. This actuated mixing in the inner region of vortex resulted increased mixing and subsequent diffused vortex [19]. The numerical investigation to study the effect of active flow control on NASA helicopter main rotor blade to improve the retreating blade stall. The flow control is achieved by using blowing jets at the leading edge of the airfoil that is used at the tip part of the main rotor blade. The results shows that this technique delays the flow separation by 10 % and incremental of lift about 40 %. This process of retreating blade stall also delayed in the forward flight [20]. Dual channel jet shows improved aerodynamic performances characteristics over the single jet channel on the wind turbine airfoil. Dual jet combined from the suction jet from the upper surface of airfoil and injection slot adjacent to the trailing edge, which enhances the leading-edge suction. It's evident that single jet channel did not control the boundary layer separation but double -jet channel helps the formation of boundary layer fully. This formation helps the production of lift by 84.21 % increment compared to the clean airfoil [21].

Slots are the spanwise gap, created when leading edge slats are deployed as shown in Figure 7. It allows the flow to be guided from the lower side of the airfoil to suction side, thereby increasing momentum exchange on the suction surface. During flight cruise flight conditions, slots remain closed but at higher angle of attack they are opened to enable higher lift generation.

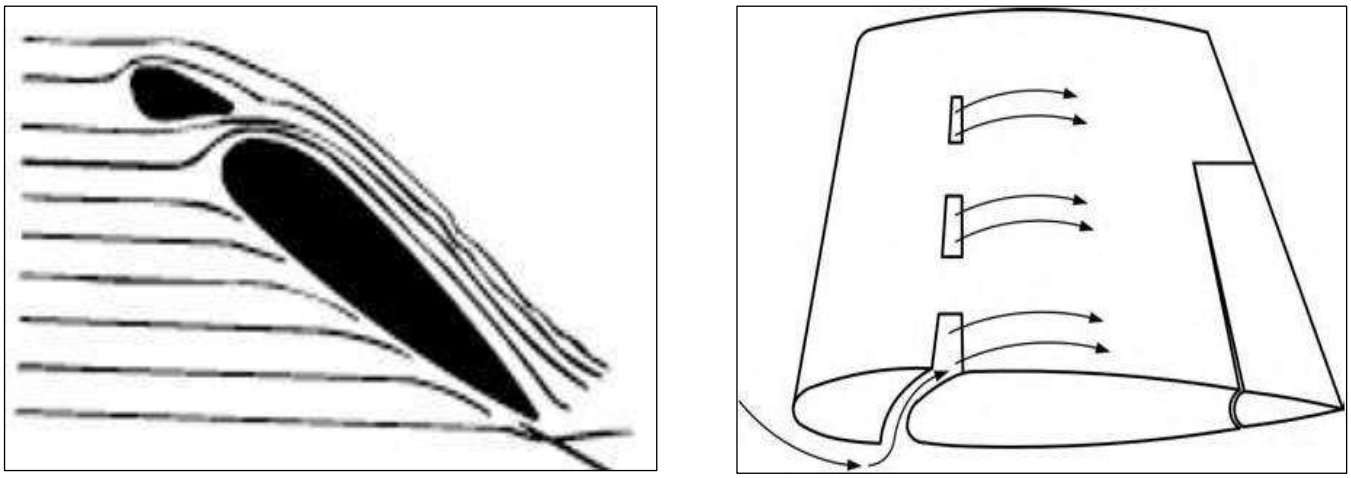

Figure 7: Leading edge slots.
Source: Authors, (2026).

Vortex generator jets enhance momentum exchange in a similar manner to traditional vortex generators, however they are more controllable and less intrusive [22]. They are oriented at a certain pitch and yaw angle and positioned near the separation point on the suction surface of an airfoil.

III.1.5 Application of Body Force to Air

Plasma vortex generator is based on Dielectric-Barrier-Discharge (DBD) mechanism. They are widely for both external and internal flow control applications including airfoil leading edge separation control, turbulent boundary layer control and lift augmentation. A DBD type plasma vortex generator consists of two electrodes on either side of a dielectric material. By applying a sufficiently high AC voltage across the electrodes, it causes surrounding gas to ionize and resulting into plasma [23]. This plasma produces an electrohydrodynamic body force on the ambient air that imparts momentum, which will produce vortices. In wing section, DBD plasma vortex generator is placed to the oncoming flow and produces stream wise vortices which will help to reattachment of flow. Unmanned Aerial Vehicles (UAV) equipped with plasma has been successfully control the flow separation with high voltage generator and plasma actuators. Main disadvantage of this technique is the requirement of high voltage which is associated with energy loss and increased weight [24].

The new active flow control technique in the axial compressor cascade with tip clearance is investigated experimentally by using hole- type bleed. The position of hole-type bleed plays an important role in controlling tip leakage vortex and passage vortex with incremental percentage of 8.34 % by delayed vortex origination. So that the performance benefit obtained in the compressor cascade [25]. A novel method of effectively distributing electromagnetic force periodically on the surface of the blended wing body -underwater glider helps in controlling the boundary layer structure is been studied numerically to understand the capability. The results show that equipping electromagnetic as an active flow control increases the lift production by 11.22 % [26]. In addition, Steady stream active flow control (SS- AFC) technique is analyased by the same authors and the methos is able to maintain the boundary structure in the blended wing body- underwater glider (BWB-UG). The steady suction AFC increases the aerodynamic characteristics of BWB-UG and its evident through by 45 % increment in lift to drag ratio

III.2 DRAG REDUCTION

In the active flow control techniques, an effective method for controlling the boundary layer involves mainly changing the near-wall viscosity through wall heating/cooling and injection of fluid having a different viscosity. Reduction of local fluid velocity has the influence of creating a fuller velocity profile which is more stable. Hence, cooling in air, heating in air or injection of lower viscosity fluids can obtain substantial transition delay of boundary layer and decrease the skin friction drag [27]. The next method is attenuation of the Tollmien-schlichting waves by surface heating at the leading edge of the body. This wave is a streamwise unstable wave which arise in a bounded shear flow. Tollmien-schlichting waves attenuation can be used to delay the boundary layer transition [28]. Surface heating in adverse pressure gradient regions may speed up the boundary layer transition which may be desirable when boundary layer trip is required. The convenient of surface wall heating or cooling as a flow control technique is limited by heat source size.

IV. PASSIVE FLOW CONTROL TECHNIQUES

Passive type flow control methods generally improve the condition of flight vehicles by manipulating the flow properties in the boundary layer. The flow manipulation is an efficient way to control the mixing in the separated shear layer. Optimization of airfoil profile, circulation augmentation by blown flap, momentum exchange, and separation delay by vortex generators, leading edge serration, turbulators, wing fences, winglets and placement of longitudinal grooves or riblets are the appreciable passive flow control techniques. These methods are described in the following section have been categorized according to their predominant mechanism.

IV.1 LIFT ENRICHMENT

IV.1.1 Optimization of Airfoil Profile

To optimize the actual airfoil profile to improve the lift and reduce the drag, the angle of attack, Reynolds number, operating range must be considered. Generally, for a given angle of attack and span, a wing will produce more lift if an airfoil has increased camber and chord length. In addition, if the flow remains well attached over the surface, it will be benefitted to reduce the skin friction drag and keep the flow as laminar as possible. This can be achieved by designing the airfoil profile with maximum thickness location as far aft as possible [29]. The presence of an appropriate design cavity on the suction side of the airfoil is called trapped vortex cavity as shown in Figure 8. This is also an important airfoil profile optimization which is able to trap a vortex inside and enhanced shear layer influencing the flow reattachment.

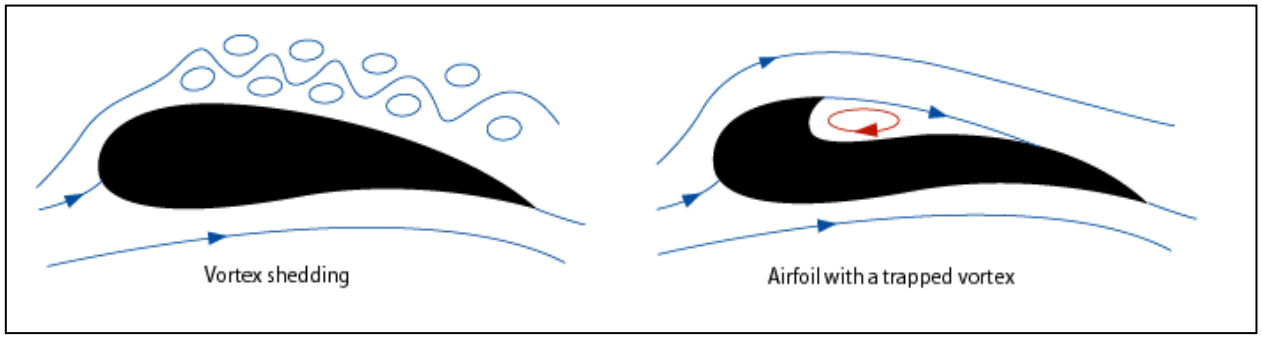

Figure 8: Trapped vortex cavity.
Source: Authors, (2026).

A novel flow control idea, which permits to oversee bluff-body wake dynamics and the laminar–turbulent transition is introduced by [30] by using Large-eddy simulations (LES). Result shows that, the bluff- body which control behavior of the boundary layers and lift to drag ratio increased from 1 to 1.5 %.

IV.1.2 Circulation Augmentation

Jet exhaust from the engine of an aircraft is directed over the wing surface is an alternative to flaps or to enhance their effectiveness by circulation augmentation concept. The exhaust jet is attracted to the curved surface of the wing that required preventing the boundary layer separation and keeping the flow attached at higher angle of attack. This effect is called Coanda effect. Increase of circulation occurs if the amount of air blown over the surface of the wing is greater than the amount required to keep the flow attached which results in an increased lift production [31]. In Gas Turbines, to avoid the combustion instability, the compressor blades are overworked to maintain the pressure ratio. Flow control techniques can be used to improve diffusion ratio for various operating conditions. A novel techniques Adaptive Coanda jet control (ACJC) is introduced to enhance the compressor stator cascade diffusion ratio and optimize the mass flow ratio by 1.2 to 1.2 % and by reducing the pressure loss ratio by 18.88 % to 21.53 % for the Mach number range between 0.1 to 0.4 [32].

IV.1.3.Momentum Exchange / Separation Delay

Vortex generator is an aerodynamic surface, consist of small vanes in rectangular or delta shaped creates a vortex. These devices run in spanwise lines near the thickest part of the wing and conventionally have a height which corresponds to the thickness of the boundary layer. Vortex generator protrudes above the boundary layer and have discontuinities that create either co-rotating or counter rotating stream wise vortices as illustrated in Figure 9, depending on device orientation. The generated vortices which draw energetic, made the momentum exchange in the boundary layer or reenergizing the boundary layer to delay the separation and stall [33], [34]. A wide-ranging passive flow control devices were considered to understand the effectiveness in separation control [35-37]. It has been determined that vortex generators were more efficient in achieving the flow separation control by means of the stream wise vortices produced on them. The VGs producing counter rotating stream wise vortices are much more efficient than that of producing co-rotating stream wise vortices.

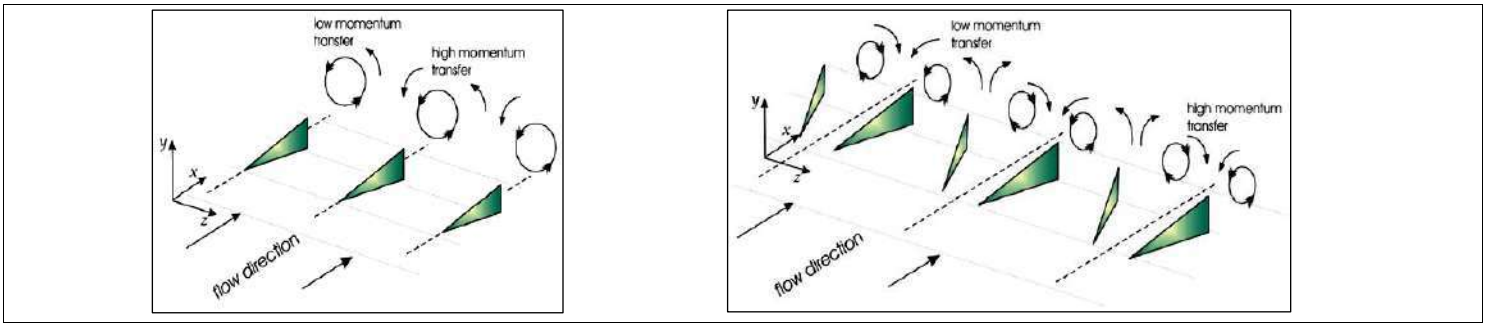

Figure 9: Co-rotating and counter rotating vortex generator.
Source: [34].

Another method of generating counter rotating streamwise vortices on the suction surface of an airfoil is leading edge serration. These leading-edge serrations are comb-like structures. Counter rotating vortices pairs was formed over each serration which essentially modified the flow in the suction surface and mitigated the flow separation properties with increasing angle of attack. Performance improvements of serration are depending on position of serration as close as possible in front of stagnation point, size and spacing [38]. Similarly, the dye flow visualization analysis of aircraft wing leading edge strakes shows the generation of high-swirl vortex at higher angle of attack [39], [40]. This vortex will help the flow to attach over the top surface of the wing. The penalty associated with this vortex is vortex bursting which leads to structural damage at the tail section [41]. The effect of passive flow control by using vortex generators were analyzed numerically and the streamlines pattern shows that the attached flow is possible over the surface of NACA0012 aerofoil at higher Angle of Attack [42]. Through tripping a laminar boundary layer to turbulent, momentum exchange can be enhanced. This can be achieved by turbulator. They are typically spanwise thin raised strips as depicted in Figure 10. Turbulators may also be created using distributed roughness elements. Accelerating the onset of transition is benefitted at increased angle of attack, as it facilitates a greater mixing of momentum with the free stream, which delays separation [43]. This ultimately results in the wing producing more lift and less drag. The height and position of turbulators are important parameters to ensure their success.

Figure 10: Wing with zig-zag turbulator along the entire span.
Source: Authors, (2026).

Separation delay can also be realized when the pressure gradient at the surface of an airfoil are altered. This occurs when a rippled trailing edge is incorporated into the airfoil. In this case, the undulations are perpendicular to both the free stream flow and the airfoil chord. Another interesting method of separation delay was inspired by the observation that when birds land the covering feathers on the suction surface of their wing rise up. Same design was tested where movable metal flaps were attached to the aifoil's suction surface and could pivot to a limited angle [44]. The flaps were located close to the trailing edge and create a physical barrier to further flow movement towards the leading edge. A ring-based Karman- vortex generator (KVG) is designed to position in the conical diffuser. This KVG is positioned in various locations for controlling the formation of vortex. The effectiveness of KVG is demonstrated in the wake near wall region. This enhances the flow mixing which promotes the delaying in flow separation in the downstream section [45], [46]. Passive shock wave/boundary layer control (PSBC) for drag reduction was conducted by SC(2)-0714 supercritical wing, with emphases on parameter of porous/slot and bump, such as porous distribution, hole diameter, cavity depth, porous direction at Mach number of 0.2 [47]. The computational and experimental study to understand how unsteady jet actuators are helping in drag reduction of heavy truck model by improving the control efficiency. This unsteady jet actuators improves energy efficiency up to 94.74 % for the small truck model [48].

IV.1.4. Restriction of Spanwise Flow

Swept wing profiles are subjected due to their geometry, to spanwise flow. This spanwise flow contributes to a higher wing loading towards the wingtip region than the inner portions of the wing and subsequently increases the induced drag. This is undesirable because it results in a thicker boundary layer in a tip region, which causes the wingtips to stall at lower angle of attack, reducing the wing's stability and reduced effectiveness of the boundary layer [49]. Wing fences are flat plates fixed normal to the suction surface of the airfoil that run in the chordwise direction, parallel to the flow direction. It is a physical barrier to hinder spanwise flow along the wing and shifting the lift distribution toward wing root, which consequently decreases drag and increases stability. Vortex generators, saw tooth leading edge, notched leading edge are the other methods for spanwise flow control [50].

IV.2 LIFT ENRICHMENT

IV.2.1 Reduction of Wing Tip Vortex

Wing tip vortices are circular/curl patterns of rotating air left behind the wing due to pressure variation on upper and lower surface of the wing. It will induce the main component of drag. The winglet design is mainly used to reduce the induced drag of a wing while it produces the lift. Winglets reduce the strength of the wingtip trailing vortex and induce the secondary flow results in reduction of induced drag as shown in Figure 11.

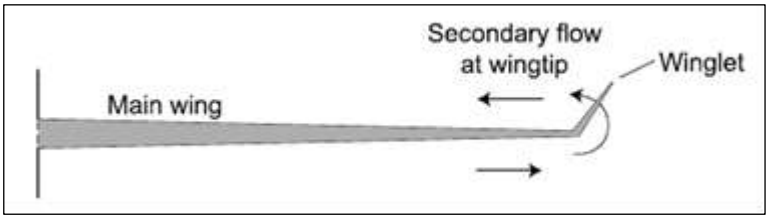

Figure 11: Secondary flow around wing tip.
Source: [15].

Another method to reduce the induced drag is wing planform optimization. For an example, a high aspect ratio wing tends to have a relatively low induced drag but offers lower maneuverability. Planar and non-planar wings may result in the reduction of induced drag due to different span efficiency factors. While a wing with elliptical distribution achieves the maximum theoretical planar span efficiency of 1, the non-planar wing planforms achieve span efficiency factor up to 1.46 [51].

IV.2.2 Transition Delay

To delay the boundary layer transmission and to reduce skin friction drag through interaction with instability modes such as Tollmien-Schlichting instabilities, static divergence and well known passive compliant coating can be used. This passive compliant coating present a much simpler alternative to reactive control strategies aimed at favorably interfering with wall bounded flows. Suppression of a given instability mode can lead to transition delay and hence skin friction reduction, provided other modes to not grow in response to the fluid structure interaction [52]. The passive bleeding achieved by allowing the wind flows through the wing passage from the pressure side to suction side, this method is an effective flow control method in non-slender delta wings. This approach eradicates the surface separation and its increases the surface normal vorticity and suction pressure co-efficient. Particle Image Velocimetry (PIV) measurements shows that, the effective bleeding improves the stall and lift co-efficient [53].

IV.2.3 Reduction of Turbulent Fluctuations

The viscous drag of the turbulent boundary layer is a significant factor contributing to the fuel cost of the airlines. Several investigations have indicated that micro surface geometry variations which are able to change the near wall structure of the flow have been effective in drag reduction. A moderately effective way of reducing turbulent skin friction involves surface modification in the form of riblets. It consists of minute streamwise ridges and valleys as depicted in Figure 12. They obstruct the fluctuating turbulent cross flow close to the wall. This leads to reduction in momentum exchange and hence reduces the skin friction drag. The optimum non dimensional, spanwise spacing between riblets has been described in wall units.

$$s^{+} = s\sqrt{\tau_w / \nu} = 10 - 20 \tag{1}$$

Where,
= spanwise spacing
= wall shear stress
= kinematic viscosity

The corresponding actual spacing for flight condition is 25 to 75 . Polymeric riblet film is currently being used on regular commercial flights of A 340-300 aircrafts, which has been observed that 5 % to 8% skin friction drag reduction [54].

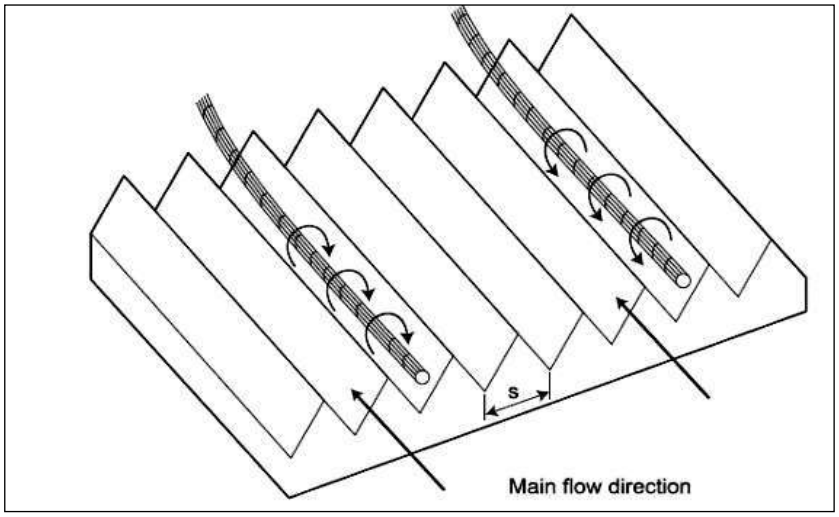

Figure 12: Effect of riblets with near wall structure.
Source: Authors, (2026).

Large-Eddy-Break Up (LEBU) devices are thin short plates or airfoils are mounted in the outer part of boundary layer and can be able to change the near wall velocity fluctuations and turbulent structure. This is achieved when the trailing edge vortices shed by the short thin plates cancels the incident vortices effect. Hence, these devices reduce the amount of drag. The thickness of the plate and adequate structural rigidity are the important parameters for high-speed flows [55].

V. FLOW CONTROL & STALL DELAY THROUGH BIO-INSPIRED TECHNOLOGY

Bio-inspiration or Biomimetic refers to human-made processes, substances, devices or systems that imitate nature. Recent studies have increasingly focused on flow control methods inspired by biology, as well as techniques used by living organisms. Understanding these bioinspired and biological flow control methods is beneficial in two key ways. First, they provide valuable insights into how biological creatures move efficiently and adapt to various flight conditions, revealing the underlying physics. Second, bioinspired flow control techniques are more appropriate for small uncrewed vehicles than conventional methods, which are typically designed for larger, high-speed operations. The small size and limited payload capacity of these vehicles make traditional flow control systems impractical due to their size, complexity, and weight [56]. Additionally, scaling down conventional devices may not meet the specific needs of small vehicles. Traditional flow control methods are effective only within a narrow range of angles of attack and operating conditions, whereas small uncrewed aerial or aquatic vehicles (sUAVs) often need to perform across a broader range. Because the operating environments of these vehicles share similarities with those of biological organisms, bioinspired flow control techniques offer an ideal solution to enhance sUAV performance [57].

V.1 TUBERCLES

One among the observable evolution, the Humpback whale (Figure 13) intended among the numerous marine mammals in the designs of airfoil [58]. Among the blue whale family, humpback whale notable for its tight turning manoeuvers caught to considered for its flipper composition, tracing tubercles as the critical criteria for the advancement of airfoil. Tubercles are the leading-edge protuberances and the presence of tubercles on the leading edge of airfoil increases the momentum exchange in boundary layer, which leads to separation delay. In addition, extend of spanwise flow reduced by tubercle's streamwise vortices [59].

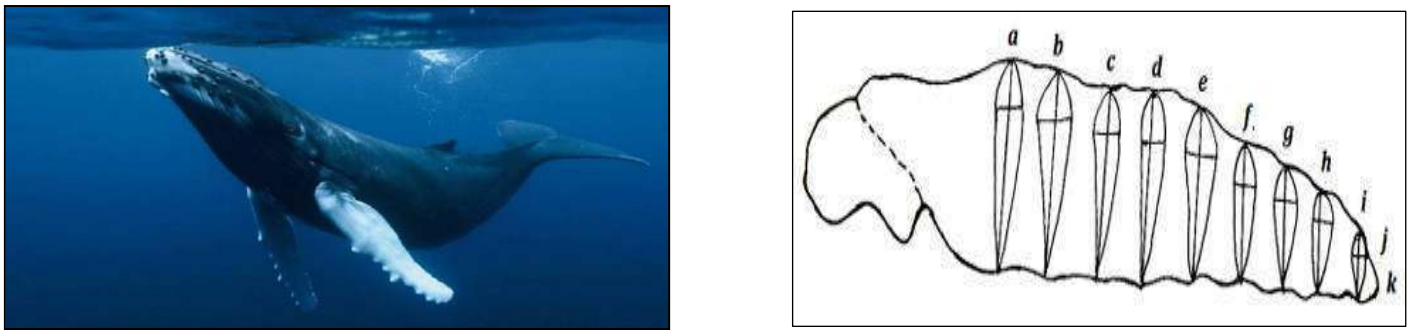

Figure 13: Humpback whale flipper & Flipper planform view.
Source: [58].

The biomimetic flow control techniques are addressed with their potential applications in relevance to the aerospace industry. The category of plants, insects, birds and aquatic animals are considered with their potential towards aerodynamic efficiency parameters such as lift enhancement and drag reduction. Super hydrophobic surfaces Lubricated surfaces Grooved circumference Winged seeds, Spade like protrusions Corrugated Airfoil Hind-wing tail, Leading edge serrations Riblets, Wing tip feathers, Biomimetic fish scale arrays, Leading edge tubercles are the unique designs identified for biomimetic flow control techniques. The implementation of bioinspired HW LE tubercles on airplane wing LE has demonstrated significant benefits because of its flow control characteristics. In the view of aerodynamic performance improvements of flight vehicles, the tubercles make an ample avenue for new engineering design of wings, hydrofoils and control surfaces with the meagre influence of aeroelastic effects [60].

V.2 AVIAN FLOW CONTROL

Bird wings are equipped with various groups of feathers that fulfill several roles, including providing insulation to regulate body temperature, enhancing flight efficiency, and reducing noise. In terms of aerodynamics, beyond creating the required forces for flight, feathers also function as devices that manage airflow [61], [62].

V.3 COVERT FEATHERS

The covert feathers are a type of contour feathers found on both the upper and lower surfaces of birds' wings and tails. Wing coverts are arranged in several overlapping layers, with the row closest to the leading edge called the lesser coverts, followed by the median coverts and the greater coverts [63]. Gaining insight into the role of these coverts in controlling airflow during bird flight has been essential in designing bio-inspired flow control devices [64].

V.4 LEADING EDGE SERRATIONS

Leading edge serrations (LES) are comb-like hook structures found on the outer vanes of feathers at the front edge of the wing, while trailing edge fringes are defined by separated barbs at the feather tips.

These features have been widely studied for their ability to reduce noise and enable silent flight, particularly in owls. However, as this article focuses on flow control rather than noise reduction, we will emphasize the studies examining the role of LES in aerodynamic optimization. In addition to their noise-reduction properties, LES act as flow control devices by enhancing aerodynamic efficiency and facilitating the transition from laminar to turbulent flow [15], [65].

Table 1: Flow control techniques and their corresponding effects and advantages.

Passive and Active flow control techniques	**Effect on flow**	**Aerodynamic Advantages**
• Tubercles • Vortex generators • Leading edge serrations • Rippled trailing edge • Moveable flaps • Slots • Suction • Vortex generator jets • Plasma	Delayed separation.	Increased lift/stall angle, possible drag reduction.
• Flaps • slats • leading edge flaps	Increased velocity on Suction surface.	Increased lift/stall Angle.
• Blown flaps • Gurney flap	Circulation augmentation.	Increased lift/stall Angle.
• Tubercles • Wing fences • Saw tooth leading edge • Notched leading edge • Vortex generators	Restricted span wise flow.	Avoidance of tip stall and stall delay
• Turbulator • Manipulation of near-wall viscosity.	Accelerated transition.	Delaying of stall.
• Shape optimization • Compliant Coatings • Suction • Manipulation of near wall viscosity	Delayed boundary layer transition	Reduced skin friction drag
• Riblets, • Large-eddy break up devices	Reduced momentum Exchange	Reduced skin friction drag
• Winglets • Wing planform optimization	Reduced wingtip vortices	Reduction in induced drag

Source: Authors, (2026).

VI. CONCLUSION

The widespread passive and active flow control techniques used for various aerospace applications with the implementation challenges are focused in this comprehensive review article. As the modern aerodynamics is highly influenced by the Bio-inspired designs to optimize the aerodynamic drag, passive flow control mechanism has received greater attention in the past decade. In this, the crucial objective is to establish a relevant circumstance for tubercles, which is a passive method to improve the boundary layer momentum exchange. Vortex generators, leading edge serrations, and ZNMF jets were also identified for this boundary layer momentum exchange, however it provides further detailed description for alternative designs. Meanwhile, these additional features have been proposed as contributing parameters to performance improvement for airfoil with tubercles. The progress and challenges of flow control methods explained in this article should be considered with aerodynamic benefits in addition to the cost analysis. Several other methods are not addressed in this article because of their potential drawbacks associated with the complex instrumentation and technical feasibility. Further, remarkable information is that several passive techniques such as compliant coating, vortex generator, micro tabs, and adaptive wings have been tripped in to active form in the recent times.

Adaptive nonlinear control,
Hybrid intelligent control,
Sim-to-real transfer.

ABSTRACT

Quadcopter unmanned aerial vehicles (UAVs) are increasingly deployed in surveillance, logistics, agriculture, and defense, yet their control remains challenging due to nonlinear dynamics and underactuation. This systematic literature review traces the evolution of quadcopter control from classical proportional–integral–derivative (PID) schemes to reinforcement-learning-based and hybrid intelligent strategies. Publications from 2015 to 2025 were collected through Scopus, IEEE Xplore, ScienceDirect, and SpringerLink using PRISMA and ROBIS frameworks to ensure methodological rigor. The synthesis identifies four dominant themes: (1) learning-optimal control, including reinforcement learning, adaptive dynamic programming, and neural-enhanced model predictive approaches; (2) robust and adaptive nonlinear control augmented with neural or fuzzy systems; (3) learning-based estimation and fault detection integrating physics-informed neural networks with Kalman filtering; and (4) intelligent PID tuning and component-level modeling that enhance adaptability and energy planning. PID remains attractive for simplicity but lacks adaptability, while robust controllers offer stability at higher computational cost. Reinforcement learning enables autonomy yet suffers from limited sim-to-real transfer, and learning-enhanced estimation increases resilience but needs further validation. Hybridization of model-based guarantees with data-driven adaptability emerges as the most promising direction. Future work should establish standardized benchmarks, expand hardware validations, and develop hybrid frameworks bridging classical and intelligent paradigms toward resilient, energy-efficient UAV autonomy.

I. INTRODUCTION

Unmanned aerial vehicles (UAVs), particularly quadcopters, have emerged as pivotal tools in both civilian and military domains due to their versatility, agility, and cost-effectiveness. Over the past decade, quadcopters have shifted from being niche hobbyist platforms to indispensable assets for modern applications such as logistics, surveillance, agriculture, and defense [1]. In logistics, quadcopters have redefined last-mile delivery solutions, providing rapid and efficient transportation of goods across challenging terrains. Surveillance systems have been significantly enhanced through integration with quadcopters, enabling advanced imaging and monitoring capabilities in urban and remote environment [2], [3]. In agriculture, they play a vital role in monitoring crop health, optimizing irrigation, and enabling precision farming, while in defense, they provide critical reconnaissance and tactical support, enhancing situational awareness and operational readiness. This trajectory underscores the adaptability of quadcopters to diverse operational requirements, cementing their role as transformative technologies across sectors [4], [5]. Despite these remarkable applications, the control of quadcopters remains a profound challenge in aerospace engineering and robotics. Unlike many other UAV configurations, quadcopters are characterized by nonlinear dynamics, underactuation, and sensitivity to disturbances. The nonlinear nature arises from their inherently coupled dynamics, which complicates the design of linear controllers.

Furthermore, the underactuated structure implies that the six degrees of freedom (DOFs) of motion cannot be independently controlled by the four available actuators, leading to complexities in posture stabilization, trajectory tracking, and disturbance rejection. This underactuation requires sophisticated control strategies capable of coordinating actuator inputs to maintain stability and maneuverability. Studies have consistently demonstrated that these features substantially increase the difficulty of designing accurate, robust, and responsive control systems [6], [7]. Historically, Proportional–Integral–Derivative (PID) controllers have formed the backbone of quadcopter stabilization. PID remains attractive due to its intuitive design, simplicity, and ease of implementation, making it a natural choice for early UAV platforms[8]. However, while PID controllers excel in stabilizing simple systems, their limitations become evident under the diverse disturbances encountered during quadcopter operation. The linear formulation of PID struggles to cope with nonlinearities inherent in quadcopter dynamics, resulting in sluggish responses to sudden perturbations and reduced robustness in dynamic environments. Environmental disturbances such as wind gusts, payload variations, or unmodeled aerodynamic interactions often expose these weaknesses. For instance, while PID controllers have demonstrated baseline performance in flight stabilization, their inability to adapt to rapidly changing operational conditions underscores the necessity for alternative, more advanced strategies [9], [10]

In response to these limitations, the research community has increasingly turned toward adaptive, robust, intelligent, and reinforcement learning (RL)-based control paradigms. Adaptive control frameworks, such as sliding mode control (SMC) and backstepping, have been widely explored to mitigate uncertainties and external disturbances. These methods enhance robustness by enabling the system to adjust dynamically to variations in model parameters or environmental conditions[11], [12]. Notably, adaptive sliding mode control has been successfully employed to maintain quadcopter stability under disturbance-rich scenarios, providing superior resilience compared to conventional PID systems. Reinforcement learning, by contrast, offers a paradigm shift in UAV control by enabling quadcopters to learn optimal control policies directly from interaction with their environment. For example, RL strategies employing Proximal Policy Optimization (PPO) have demonstrated flexibility and adaptability in highly dynamic settings, outperforming classical control schemes in terms of tracking accuracy and disturbance rejection. The growing recognition of RL's potential for real-time decision-making underscores its transformative role in advancing UAV autonomy [13], [14]. A major challenge hindering the seamless adoption of advanced control strategies is the persistent reality gap between simulation-based findings and real-world deployments. Simulation environments are indispensable for controller training and validation, offering safe and cost-effective platforms to test novel approaches. However, they often simplify physical dynamics to reduce computational burden, which limits the fidelity of results when controllers are transferred to real quadcopters.

This discrepancy results in performance degradation, as controllers that excel in simulation may underperform in physical settings due to unmodeled disturbances, actuator nonlinearities, or environmental variability [15], [16]. To address this, techniques such as domain randomization have been proposed, wherein training incorporates stochastic variations in dynamics to enhance the robustness and generalizability of learned policies. Such methods have shown promise in bridging the sim-to-real divide, equipping quadcopters with the capacity to adapt effectively to unforeseen challenges during physical operation [17]. The scholarly discourse surrounding quadcopter control strategies reveals a diverse and evolving research landscape. Existing reviews and surveys categorize methodologies according to their adaptability, robustness, computational demands, and real-world applicability. These reviews highlight the need for frameworks that not only classify control paradigms but also provide systematic comparisons of their performance across standardized benchmarks. Critically, many reviews emphasize the importance of bridging theoretical advancements with hardware validation to ensure practical relevance. While numerous simulation-based studies report impressive results, the scarcity of experimental validations remains a key limitation in advancing UAV control research. Thus, systematic investigations that integrate both simulation outcomes and hardware demonstrations are indispensable for consolidating knowledge and guiding future developments [18].

Against this backdrop, the present review is positioned to trace the evolution of quadcopter control strategies from classical PID to reinforcement learning-based approaches. The objective is to systematically synthesize the trajectory of advancements, capturing the strengths, limitations, and transformative potential of these methods. By focusing on the period from 2015 to 2025, this review encompasses a decade of rapid innovation, capturing both simulation studies and experimental implementations. The scope explicitly emphasizes UAV control strategies, deliberately excluding peripheral technologies such as vision-only obstacle avoidance, to ensure clarity of focus [18], [19].To maintain conceptual coherence, several key terms are defined. PID (Proportional–Integral–Derivative) refers to classical feedback control widely used in early quadcopter stabilization. Adaptive control includes approaches such as backstepping and sliding mode, which enable dynamic adjustment of controller parameters in response to system changes. Robust control strategies seek to guarantee performance under model uncertainties or external disturbances. Model predictive control (MPC) represents optimization-based frameworks that predict future system behavior to compute control actions. Reinforcement learning (RL) is a machine learning paradigm where agents learn optimal policies by maximizing long-term rewards through interaction with their environment. These definitions serve to anchor the subsequent discussion and ensure terminological clarity [6], [20].

The central research question guiding this review is: How has quadcopter control evolved from PID to reinforcement learning, and what are the strengths, limitations, and future opportunities inherent in these strategies? Addressing this question necessitates not only a chronological mapping of methodological evolution but also a thematic synthesis that compares performance across critical dimensions, including adaptability, robustness, energy efficiency, and stability guarantee. Furthermore, this review seeks to identify the degree to which simulation results translate into real-world performance, illuminating pathways for reconciling the sim-to-real gap [21]. The structure of this article is organized to ensure clarity and coherence in presenting the evolution of quadcopter control strategies. Following this introduction, Section II (Methods) outlines the systematic literature review methodology, including the search strategy, inclusion and exclusion criteria, screening procedures, and quality assessment based on PRISMA and ROBIS. Then, in Section III (Results and Discussion), the findings are structured into four thematic clusters: (1) reinforcement and learning-optimal control; (2) robust and adaptive nonlinear control augmented with neural and fuzzy systems; (3) learning-enhanced estimation and fault detection/identification; and (4) the transformation of PID control through intelligent tuning and component-level modeling. Each theme is synthesized and critically examined to identify methodological advancements, performance trends, and integration strategies.

This is followed by Section IV (Discussions), which highlights the convergence of model-based and learning-based paradigms, discusses conflicting findings, outlines current research gaps, and offers implications for theory and practice. Finally, Section V (Conclusions) provides a comprehensive summary of the evolutionary trajectory, emphasizes the importance of hybrid frameworks, and recommends directions for future UAV control research [22]. In sum, quadcopter UAVs embody both technological promise and engineering challenge. Their operational relevance across multiple domains necessitates control strategies that transcend the limitations of classical PID frameworks. By systematically reviewing a decade of research, this study contributes to consolidating fragmented knowledge, highlighting innovations in adaptive, robust, and learning-based paradigms, and charting future directions that reconcile theoretical advancements with real-world applicability. This endeavor seeks to provide scholars and practitioners with a coherent roadmap for understanding and advancing the state of quadcopter control in an era defined by rapid technological transformation.

II. METHODS

This section delineates the methodological framework employed to conduct the systematic literature review (SLR) on quadcopter control strategies, with particular emphasis on the transition from Proportional–Integral–Derivative (PID) controllers to reinforcement learning (RL)-based approaches. The approach adheres to international standards for systematic reviews, ensuring transparency, replicability, and scientific rigor. The methodological choices are guided by established best practices in UAV research and systematic review literature, including adherence to the PRISMA guidelines and the use of ROBIS for risk-of-bias evaluation [23], [24].

II.1 SEARCH STRATEGY

The search strategy was designed to comprehensively capture relevant studies on quadcopter control from 2015 to 2025, thereby covering a decade of rapid innovation in UAV control research. Four academic databases were selected based on their relevance and coverage:

- Scopus: Broad coverage of interdisciplinary peer-reviewed journals, useful for cross-domain UAV research [25].
- IEEE Xplore: Extensive repositories of engineering and technology-focused conference proceedings and journals, with significant UAV-related innovations [26].
- ScienceDirect: Multiple well-established digital libraries commonly used in engineering systematic reviews were selected to ensure comprehensive coverage and empirical rigor [27].
- SpringerLink: Significant source for both theoretical and applied aspects of UAV technologies[28].

Searches were conducted using combinations of keywords and Boolean operators. Example search strings included:

- “PID control quadcopter UAV”
- “adaptive control quadrotor”
- “sliding mode quadcopter control”
- “reinforcement learning drone control”
- “neural networks UAV control”

The keywords were iteratively refined based on initial search results to balance inclusivity and precision. In addition, backward citation chaining was applied to identify further relevant studies cited by key publications [25], [28].

II.2 INCLUSION AND EXCLUSION CRITERIA

Rigorous inclusion and exclusion criteria were established to ensure the quality and relevance of selected literature. Articles were included if they:

- Were published in peer-reviewed journals or conference proceedings between 2015 and 2025.
- Focused explicitly on quadcopter UAVs or transferable control methodologies applicable to quadrotors.
- Provided clear methodological descriptions of control system design.
- Reported performance metrics (e.g., tracking error, energy efficiency, robustness).

Articles were excluded if they:

- Constituted grey literature, patents, or non-peer-reviewed reports.
- Focused exclusively on non-quadrotor UAVs, unless the control concepts were demonstrably transferable.
- Addressed only hardware or aerodynamics without a clear control strategy component.
- Were written in languages other than English.

This systematic filtering process ensured that the final corpus comprised methodologically sound, high-quality, and control-specific studies suitable for rigorous synthesis and comparative analysis [29-31].

II.3 SCREENING AND SELECTION PROCESS

The screening process followed a three-step procedure consistent with established SLR practices:

1. Title and Abstract Screening: Initial screening of search results to exclude irrelevant studies based on scope.
2. Full-text Review: Comprehensive reading of potentially relevant studies to evaluate alignment with inclusion criteria.
3. Final Selection: Consolidation of eligible articles for detailed synthesis across the identified thematic categories.

The process of study selection was documented to ensure transparency and replicability. Duplicate records were identified and removed using reference management software.

Discrepancies in study inclusion were resolved through consensus among reviewers [24], [32]. Figure 1 presents a schematic representation of the study selection process, illustrating the number of records identified, screened, assessed for eligibility, and included in the final analysis.

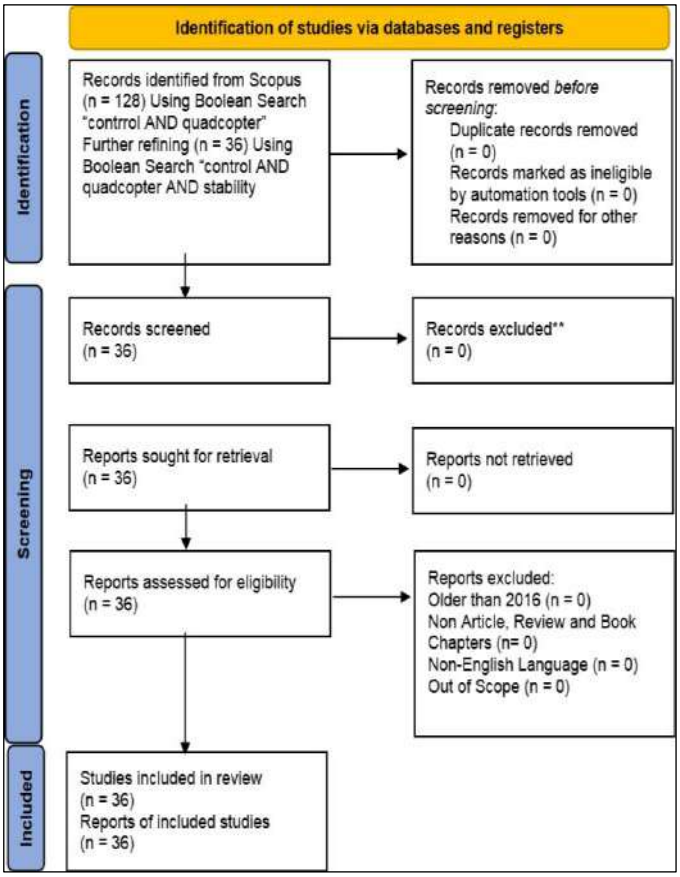

Figure 1: PRISMA flow diagram detailing the screening and selection process of literature.
Source: Authors, (2026).

II.4 QUALITY ASSESSMENT

The quality of included studies was assessed using two complementary frameworks [33], [34]:

- PRISMA: Ensured comprehensive reporting of methodological steps, enhancing transparency and reproducibility.
- ROBIS (Risk of Bias in Systematic Reviews): Evaluated potential biases in included studies, thereby increasing the credibility of synthesized findings.

Key quality indicators assessed included clarity of control system design, adequacy of performance metrics, presence of hardware validation, and transparency of assumptions. Studies lacking methodological rigor or reporting biases were flagged but retained when their findings contributed substantively to the thematic synthesis. In conclusion, the methodological framework integrates a rigorous search strategy, stringent inclusion/exclusion criteria, a transparent selection process, and robust quality assessment measures. By adhering to these systematic approaches, this review ensures credibility and comprehensiveness in mapping the evolution of quadcopter control strategies from classical PID to reinforcement learning approaches.

III. RESULTS AND DISCUSSION

III.1 REINFORCEMENT AND LEARNING-OPTIMAL CONTROL

The first major theme in the evolution of quadcopter UAV control is the application of reinforcement and learning-optimal control paradigms, encompassing reinforcement learning (RL), adaptive dynamic programming (ADP), neural network-based optimal control frameworks, and Model Predictive Path Integral (MPPI) controllers enhanced by learned system models. These approaches represent a shift from rule-based designs toward data-driven methodologies capable of optimizing performance in nonlinear and uncertain environments. This section synthesizes findings from nine representative studies (Table 1) to evaluate contributions in terms of optimality, safety guarantees, sim-to-real strategies, and experimental validation [35-37].

III.1.1 Advances in Reinforcement Learning for UAV Control

RL-based methods provide a flexible framework for quadcopter control by learning policies directly through interaction with dynamic environments. For instance, finite-time safe RL formulations leveraging actor–critic architectures have been applied to nonzero-sum multi-agent UAV games, introducing formal stability guarantees through Lyapunov analysis, barrier certificates, and Nash equilibrium formulations.

These guarantees address long-standing criticisms of RL regarding its lack of theoretical rigor and represent an important step toward reconciling adaptability with control-theoretic foundations (Table 1) [38]. Similarly, ADP has been employed to approximate solutions to the Hamilton–Jacobi–Bellman equation, enabling UAV guidance and planning in environments with unknown moving obstacles. This demonstrates how learning-optimal control extends beyond stabilization toward higher-level decision-making. While such approaches show strong empirical robustness, challenges related to real-time hardware deployment and scalability remain open [39], [40].

III.1.2 End-to-End Neural Network Control

End-to-end neural networks (NNs) represent another subfield of learning-optimal UAV control, mapping directly from state information to actuator commands. A representative study in 2024 demonstrated an NN trained on optimal trajectory datasets that successfully transferred from simulation to hardware. This work confirmed that end-to-end policies could achieve energy-optimal hover-to-hover transitions while maintaining robustness in hardware experiments (Table 1). Such findings are significant because they bypass inner-loop controllers, directly embodying the nonlinear mapping between perception and actuation. Yet, this approach raises ongoing concerns about stability proofs. The practical evidence from hardware trials mitigates these concerns to an extent but also underlines the need for hybrid solutions that integrate guarantees with learning flexibility [39].

III.1.3 Neural-Enhanced MPPI and Trajectory Tracking

The integration of neural networks with Model Predictive Path Integral (MPPI) controllers marks another innovation in UAV learning-optimal control. One study demonstrated that neural models embedded within MPPI achieved a 23.7–34.7% reduction in trajectory tracking error relative to baseline controllers (Table 1). Neural approximators enhanced the prediction of cost-to-go functions, thereby improving MPPI's optimization capacity in nonlinear systems. Importantly, this aligns with the theoretical model-free/model-based, where hybrid solutions leverage the predictive structure of MPC-like controllers while incorporating adaptive learning from NNs. This integration underscores a convergence between traditional control theory and modern machine learning [37].

III.1.4 NARX and Data-Driven Position Tracking

Supervised learning approaches, such as Nonlinear Autoregressive with Exogenous Inputs (NARX) networks, have been applied to data-driven modeling of quadrotor dynamics relevant to position tracking tasks. By leveraging classical PD-stabilized flight data, NARX models can accurately emulate underlying nonlinear dynamics while benefiting from neural network adaptability. Experimental results report high predictive accuracy, reflected by fit percentages exceeding 99% and low mean squared error values, particularly for attitude and vertical-axis dynamics (Table 1). These findings position NARX-based modeling as a transitional approach bridging classical control structures and modern learning-based methodologies [41].

III.1.5 Reactive Obstacle Avoidance with CNNs

Finally, convolutional neural networks (CNNs) have been implemented for reactive obstacle avoidance by directly generating control inputs from depth prediction networks. Online adaptation enabled UAVs to navigate cluttered environments in both simulation and hardware trials (Table 1). While these approaches lack formal guarantees, they represent crucial advances in UAV autonomy by addressing environmental variability. Such work demonstrates the importance of sim-to-real adaptation strategies, as discussed in Section III.3.3, by proving that CNN-based control policies can generalize across diverse contexts [42].

III.1.6 Theoretical Guarantees and Sim-to-Real Transfer

A recurring theme across these studies is the dual pursuit of theoretical guarantees and sim-to-real transfer. Lyapunov stability analysis, finite/fixed-time convergence, and Nash equilibrium formulations provide partial assurances for RL-based controllers, helping to reconcile the rigor of control theory with the adaptability of learning. Meanwhile, sim-to-real strategies—such as inner-loop removal, adaptive compensation, and domain adaptation—demonstrate practical efforts to narrow the reality gap. Hardware validations in several studies, including end-to-end NN and CNN-based controllers, underscore the potential for real-world deployment, though challenges persist in robustness against unmodeled dynamics [26], [37], [42].

III.1.7 Implications for UAV Control Evolution

The findings in Table 1 collectively highlight how reinforcement and learning-optimal control strategies represent a paradigm shift in UAV research. They demonstrate progress toward energy-optimal, robust, and adaptive control policies that directly map states to control inputs. Moreover, these studies provide empirical evidence supporting the hypothesis outlined in Section 1: that quadcopter control has evolved from PID to reinforcement learning, driven by the need for adaptability in nonlinear, disturbance-rich environments. Importantly, the integration of safety guarantees and sim-to-real strategies shows alignment with the theoretical frameworks discussed in Section 3, confirming that hybridization remains the most promising pathway forward [37], [42]. In summary, Theme 1 illustrates both the potential and limitations of learning-optimal control. While energy efficiency, trajectory optimization, and obstacle avoidance have seen measurable improvements, ongoing debates around stability and real-world reliability persist. These discussions set the stage for subsequent themes, which examine how adaptive nonlinear controllers and estimation frameworks complement RL-based approaches in shaping the future of UAV autonomy.[43].

Table 1: Learning-Optimal Control (RL/ADP/END-TO-END/ MPPI-NN/NARX).

Study (Year/Platform	Learning Paradigm	Control Level	Training Data & Environment	Stability/Safety Guarantees	Validation Key	Outcomes
Finite-time safe RK for multiplayer nonzero-sum games [37]	RL actor critic	Outer-loop control	Simulation, Hardware	Lyapunov, Finite-time, Barrier, Nash equilibrium	Hardware/Simulation	Lower RMSE; improved robustness
UAV Position Tracking Using NARX [41]	NARX (supervised)	Emulated PD→NN (guidance)	Online, Hardware	-	Simulation	High R^2; low MSE on vertical axis
Quadcopter Trajectory Tracking with MPPI+NN [37]	MPPI+NN	MPPI high-level	Simulation	-	Simulation	23.7-34.7% reduction in tracking error vs. baselines
End-to-End NN Optimal Control [39]	End-to-End NN	End-to-End (rpm)	Sim-to-real; optimal trajectory dataset; Hardware	-	Hardware/Simulation	Energy-optimal policy; robustness demonstrated
Reactive Obstacle Avoidance with CNN Depth [44]	CNN (online adapted)	Reactive guidance	Online, Simulation, Hardware	-	Hardware/Simulation	Reactive avoidance in cluttered environments
Approximate Optimal Motion Planning for Avoidance [45]	ADP	Guidance/Planning	Simulation, Hardware	-	Hardware/Simulation	Lower RMSE; improved robustness
Hybrid Physics-Informed NN _ UKF Estimation [46]	NN-based	Outer-loop control	Simulation, Hardware	-	Hardware/Simulation	Lower RMSE; improved robustness
Hybrid Model- and Learning-Based Adaptive Navigation Observer[47]	NN-based	Guidance/Planning	Hardware	-	Hardware/Simulation	Position error reduced by 25%

III.2 ROBUST/ADAPTIVE NONLINEAR CONTROL WITH NEURAL AND FUZZY AUGMENTATION

The second major theme in the evolution of quadcopter UAV control focuses on robust and adaptive nonlinear controllers, such as Sliding Mode Control (SMC), backstepping, and Model Reference Adaptive Control (MRAC), enhanced with neural networks (NNs), fuzzy systems, and observers. These controllers address key challenges such as wind disturbances, payload variations, and actuator faults, delivering improved transient responses and robustness. This theme complements Theme 1 by emphasizing theoretical guarantees, particularly Lyapunov-based stability and finite/fixed-time convergence—while still integrating adaptive learning elements. The synthesis below discusses insights from twelve representative studies summarized in Table 2, connecting their contributions to the broader theoretical debates outlined in Section 3 [48], [49].

III.2.1 Enhancements of Sliding Mode Control (SMC)

Sliding Mode Control has long been recognized for its inherent robustness to matched uncertainties; however, classical SMC designs are often limited by chattering phenomena and sensitivity to parameter mismatches. To mitigate these drawbacks, recent studies have increasingly incorporated adaptive, neural network-based, and observer-assisted augmentation strategies. For instance, an event-triggered adaptive neural network–based SMC framework proposed in 2024 introduced dynamic adjustment mechanisms that were validated through simulation, demonstrating improved trajectory tracking and disturbance rejection when compared with conventional SMC formulations (Table 2) [50]. In parallel, integral terminal sliding mode control architectures combined with adaptive observer-based designs have been shown to guarantee finite-time convergence and enhanced robustness under actuator uncertainties. These methods rely on Lyapunov-based stability proofs and finite-time observers to estimate and compensate lumped disturbances and faults, with effectiveness verified through numerical simulations [51]. Another important research direction involves fault-tolerant adaptive SMC schemes augmented with radial basis function neural networks, enabling real-time approximation of unknown dynamics and compensation for actuator failures. By embedding Lyapunov-driven adaptive learning laws, such approaches extend the fault-tolerance capability of SMC and demonstrate resilience under actuator degradation in simulation-based and hardware-relevant validation settings [52]. Collectively, these enhancements do not eliminate the sim-to-real gap but partially bridge it by introducing practical resilience mechanisms grounded in rigorous nonlinear stability theory.

III.2.2 Enhancements of Sliding Mode Control (SMC)

Sliding Mode Control (SMC) has long been valued for its robustness against matched uncertainties; however, conventional SMC formulations are often hindered by chattering phenomena and sensitivity to parameter mismatches. To alleviate these limitations, recent studies have increasingly explored adaptive and learning-assisted augmentation strategies, including neural network–based approximation and observer-based compensation mechanisms.

For instance, an event-triggered adaptive neural network–based SMC framework proposed in 2024 introduced dynamic parameter adjustment schemes that were validated through numerical simulations, demonstrating improved trajectory tracking accuracy and enhanced disturbance rejection when compared with classical SMC designs (Table 2) [50] .In parallel, integral terminal sliding mode control architectures combined with adaptive observer-based designs have been shown to guarantee finite-time convergence and robustness under actuator uncertainties. These approaches rely on Lyapunov-based stability analysis and finite-time observers to estimate and compensate lumped disturbances and faults, with effectiveness verified through comprehensive simulation studies rather than physical flight experiments [51]. The reported results confirm theoretical predictions regarding SMC's robustness properties while illustrating how adaptive augmentation can mitigate practical issues such as excessive chattering.Another important research direction investigates fault-tolerant adaptive SMC schemes augmented with radial basis function neural networks, enabling online approximation of unknown dynamics and real-time compensation for actuator failures. By embedding Lyapunov-driven adaptive learning laws into both continuous and discontinuous control components, such methods extend the fault-tolerance capability of SMC and demonstrate resilience under actuator degradation in simulation-based and hardware-relevant validation environments [52]. Collectively, these enhancements do not fully resolve the sim-to-real gap but partially bridge it by introducing practically motivated resilience mechanisms grounded in rigorous nonlinear stability theory.

III.2.3 Enhancements of Sliding Mode Control (SMC)

Backstepping control, widely adopted in nonlinear flight control architectures for attitude and altitude regulation, has been extended through integration with adaptive neural approximators to enhance convergence properties. For instance, fixed-time neuroadaptive backstepping controllers were shown to guarantee rapid convergence independent of initial conditions, with performance validated through numerical simulations and demonstrated improvements in transient response characteristics (2021) [53]. In parallel, fuzzy logic systems have been employed to complement nonlinear control schemes by adaptively tuning controller gains. An adaptive fuzzy gain-scheduled sliding mode control framework based on a Type-1 Sugeno fuzzy system was applied to quadrotor UAVs, effectively reducing chattering and improving trajectory tracking performance in simulation studies when compared with conventional SMC formulations (Table 2) [54]. These results highlight the role of fuzzy systems in handling modeling uncertainties and unmodeled dynamics through online gain adjustment. Beyond single-vehicle scenarios, the applicability of nonlinear robust control has been further extended to cooperative payload transportation problems involving multiple quadrotors. A centralized formation control strategy based on higher-order sliding mode control demonstrated strong robustness against payload uncertainties and external disturbances, while ensuring stable cooperative transport in simulation environments (2023) [55]. This line of research underscores the importance of benchmark scenarios—such as cooperative payload transport and disturbance-rich missions—in evaluating the scalability and robustness of nonlinear UAV controllers.

III.2.4 Model Reference Adaptive Control (MRAC) and Intelligent Hybrids

MRAC frameworks, traditionally designed to ensure system responses follow a desired model, have also benefited from intelligent augmentation. For example, an MRAC approach enhanced with adaptive neuro-fuzzy inference systems (ANFIS) was experimentally validated on a DJI Tello platform with VICON motion capture, demonstrating improved altitude and attitude performance (2021). Hybrid high-level controllers that combined LQR with MRAC further showed robust performance under variable conditions. These hybrid schemes exemplify how adaptive controllers benefit from blending classical linear optimality (LQR) with nonlinear adaptivity, a point consistent with of hybrid model-free/model-based strategies. Another innovative contribution is the BFBEL (Brain Emotional Learning with Fuzzy Logic) framework (2022), which incorporated payload uncertainty modeling. Validated through hardware and simulation, BFBEL demonstrated improved disturbance rejection and trajectory tracking compared with baseline controllers. Such neuro-fuzzy hybrids highlight the expanding role of biologically inspired paradigms in UAV robustness research [56-58].

III.2.5 Fault Tolerance and Reliability

Fault tolerance and reliability considerations emerged as critical aspects across the reviewed nonlinear control studies, particularly in the context of UAV operation under modeling uncertainties and external disturbances. Rather than explicitly modeling actuator fault dynamics, many approaches focused on enhancing robustness through adaptive estimation and compensation mechanisms. Neural networks were frequently employed to approximate lumped uncertainties and external disturbances in real time, thereby improving the system's tolerance to unmodeled dynamics and parameter variations. For instance, finite-time attitude stabilization based on nonsingular fast terminal sliding mode control demonstrated guaranteed stability and strong robustness under dynamic uncertainties, with Lyapunov-based proofs ensuring convergence within a bounded time interval. The effectiveness of such schemes was validated through comprehensive numerical simulations, showing improved disturbance rejection and reduced sensitivity to uncertainty when compared with conventional sliding mode formulations. These contributions highlight an important design trade-off between explicit fault diagnosis and robust stabilization, illustrating how Lyapunov-based adaptive control frameworks can enhance reliability even without direct fault identification mechanisms [51].

III.2.6 Theoretical Contributions: Lyapunov and Convergence Analysis

Across the reviewed literature, Lyapunov stability theory served as the dominant analytical tool for establishing convergence, robustness, and closed-loop stability guarantees. Finite-time and fixed-time convergence methods were particularly emphasized, as they ensure that tracking errors reach the desired equilibrium within a predefined or bounded time horizon, independent of initial conditions. Such properties are especially relevant for UAVs operating in disturbance-rich or time-critical missions, where delayed convergence may compromise safety and performance.

Nonlinear control strategies such as nonsingular fast terminal sliding mode control and backstepping augmented with adaptive neural networks exemplify how rigorous Lyapunov-based analyses can be translated into practical control architectures. By embedding adaptive learning laws within finite-time convergence frameworks, these methods achieve both theoretical rigor and improved transient performance in the presence of uncertainties. The surveyed studies collectively reflect an ongoing convergence debate, demonstrating how abstract stability constructs—such as finite-time and fixed-time Lyapunov conditions—are increasingly realized in UAV control implementations with tangible performance benefits [59], [60].

III.2.7 Synthesis and Implications

Collectively, the studies summarized in Table 2 indicate that robust and adaptive nonlinear control strategies—particularly those augmented with neural and fuzzy mechanisms—can yield measurable performance improvements in quadcopter UAV control. Reported benefits include faster transient responses, reduced steady-state tracking errors, and enhanced disturbance rejection when compared with baseline nonlinear or PID-based controllers. While not all contributions provide identical evaluation metrics, several studies demonstrate these improvements through detailed numerical simulations and, in selected cases, experimental flight tests using small-scale quadrotor platforms, thereby strengthening the empirical relevance of adaptive nonlinear control approaches. These findings support the hypothesis introduced in Section 1, namely that quadcopter control architectures have progressively evolved from classical PID schemes toward more sophisticated nonlinear and adaptive paradigms in response to increasing performance and robustness requirements.

Whereas PID controllers exhibit limited adaptability under strong nonlinearities and disturbances, robust nonlinear controllers explicitly address challenges such as modeling uncertainty and external perturbations through structured stability analysis and adaptive compensation mechanisms. This progression aligns with the theoretical discussions in Section 3, particularly regarding model-based control guarantees and Lyapunov-driven convergence analysis, including finite-time stability formulations developed within sliding mode control frameworks [49], [48]. In summary, Theme 2 highlights the growing importance of hybrid robust–adaptive control strategies in advancing UAV autonomy. By combining nonlinear control rigor with learning-based adaptability, these approaches help bridge the gap between theoretical stability guarantees and practical performance requirements. The implications extend primarily to single-UAV operation under uncertain environments, providing a foundation for reliable and resilient UAV control systems that can operate safely under disturbance-rich conditions [61].

Table 2: Representative Studies on Robust and Adaptive Nonlinear UAV Control with Learning Augmentation.

Study (Year/Plant/Task	Nonlinear Method	Learning Augmentation	Uncertainty/Fault Model	Theory	Validation	Performance Gains
Event-triggered adaptive NN-based SMC (2024) [50]	Sliding Mode Control (SMC)	Neural Network	External disturbances, parametric uncertainty	Lyapunov stability	Simulation	Improved trajectory tracking and disturbance rejection
Integral terminal SMC with adaptive observer (2022) [51].	Integral Terminal SMC	Observer-based adaptation	Lumped disturbances and uncertainties	Lyapunov, finite-time convergence	Simulation	Enhanced robustness and reduced tracking error
Fault-tolerant adaptive SMC with RBF NN (2023) [52]	Sliding Mode Control (SMC)	RBF Neural Network	Actuator degradation and uncertainties	Lyapunov stability	Simulation / hardware-relevant validation	Improved resilience under actuator degradation
Fixed-time neuroadaptive backstepping control (2021) [53]	Backstepping Control	Neural Network	Modeling uncertainties and disturbances	Lyapunov, fixed-time convergence	Simulation	Rapid convergence and improved transient response
Adaptive fuzzy gain-scheduled SMC (2019) [54].	Sliding Mode Control (SMC)	Type-1 Sugeno Fuzzy System	Modeling uncertainties	–	Simulation	Reduced chattering and improved tracking performance
Cooperative payload transport using higher-order SMC (2023) [55]	Higher-Order SMC	–	Payload uncertainty and external disturbances	Lyapunov stability	Simulation	Robust cooperative payload transportation
Hybrid MRAC–LQR control (2021) [57]	MRAC + LQR	–	Parametric uncertainty	Lyapunov stability	Simulation	Improved robustness under varying operating conditions
Biologically inspired BEL-based UAV control (2022) [58]	BEL-based nonlinear control	Fuzzy logic	System uncertainties	–	Simulation	Improved disturbance handling and trajectory tracking
Adaptive NN-based NFTSMC for quadrotor UAVs (2022) [60]	Nonsingular Fast Terminal SMC	Neural Network	Disturbances and uncertainties	Lyapunov, finite-time convergence	Simulation	Fast convergence and enhanced robustness
Neural–fuzzy control for quadrotor stabilization (2017) [61]	Nonlinear PID-based control	Neural Network + Fuzzy Logic	Modeling uncertainties	–	Hardware (AR.Drone)	Reduced overshoot and faster settling time

III.3 LEARNING-ENHANCED ESTIMATION AND FAULT DETECTION/IDENTIFICATION (FDI)

The third theme centers on the integration of machine learning into state estimation and fault detection/identification (FDI) pipelines for quadcopter UAVs. Unlike control strategies discussed in Themes 1 and 2, which focus on generating actuator inputs directly, this theme emphasizes how learning augments estimation subsystems to improve overall closed-loop performance. Specifically, methods such as Physics-Informed Neural Networks (PINNs) combined with Unscented Kalman Filters (UKFs), deep neural networks (DNNs) for covariance tuning, and neural adaptive observers have been employed to enhance robustness, accuracy, and safety. These approaches not only improve the accuracy of navigation and control but also strengthen UAV resilience to sensor and actuator faults. The following synthesis examines seven representative studies summarized in Table 3, highlighting contributions, theoretical implications, and practical validations [46], [62], [63].

III.3.1 Hybrid Estimation with PINNs and Traditional Filters

A key innovation in this theme is the fusion of PINNs with UKFs. By embedding physical laws into neural models, PINNs complement the statistical prediction capabilities of traditional Kalman filters. A 2024 study integrating PINNs with adaptive UKF mechanisms demonstrated improvements in dynamic state estimation for UAVs, particularly under nonlinear flight dynamics (Table 3). This method also incorporated uncertainty quantification via dropout regularization and Bayesian inference, enabling more resilient estimations under model mismatches. These contributions are consistent with the discussion on hybrid approaches between model-based and model-free methods, demonstrating that learning can enhance—rather than replace—physics-driven estimators. Another contribution of this approach lies in the computational trade-off: although Physics-Informed Neural Networks (PINNs) require higher training complexity, the combined framework still maintains real-time efficiency, similar to Kalman filters, once training is completed. Thus, PINN-enhanced filters serve as a concrete example of hybrid methods capable of integrating adaptability with stability guarantees [40].

III.3.2 Machine Learning for Covariance Tuning in Kalman Filters

Traditional Kalman filter-based methods often suffer from static or suboptimal covariance settings, which limit accuracy under dynamic conditions. Recent advances employ machine learning for online covariance adaptation, reducing estimation error during high-maneuverability tasks. For instance, a 2022 hybrid navigation filter used deep neural networks to tune process noise covariance matrices in an INS/GNSS fusion system. Hardware validation demonstrated a 25% reduction in position error relative to classical methods (Table 3). This evidence shows that adaptive covariance tuning significantly improves navigation reliability, particularly under varying GNSS quality and dynamic operating conditions. This line of research contributes to the ongoing debate on stability versus adaptability, demonstrating that learning-augmented estimators can achieve adaptability without fully compromising the theoretical guarantees provided by Kalman-based frameworks [47].

III.3.3 Neural Adaptive Observers for Fault Detection and Identification

A key innovation in this theme is the fusion of PINNs with UKFs. By embedding physical laws into neural models, PINNs complement the statistical prediction capabilities of traditional Kalman filters. A 2024 study integrating PINNs with adaptive UKF mechanisms demonstrated improvements in dynamic state estimation for UAVs, particularly under nonlinear flight dynamics (Table 3). This method also incorporated FDI is essential for ensuring UAV resilience in the presence of component degradation or sudden failures. Neural adaptive observers have been developed to identify actuator and sensor faults by learning expected system behaviors and flagging deviations. For example, a 2025 study employed a multimodal neural adaptive observer for fault detection, validated in simulation with Lyapunov-based guarantees (Table 3). Similarly, fault-tolerant architectures incorporating self-constructing fuzzy neural networks (2021) extended UAV resilience by enabling online adaptation to actuator failures. These contributions reinforce the relevance of observer-based strategies discussed where estimation is not only a passive process but also actively informs and stabilizes control loops. Neural observers thus bridge estimation and control, reinforcing UAV safety even under uncertain or faulty conditions [64], [65].

III.3.4 Uncertainty Quantification and Control Integration

A defining aspect of Theme 3 is its focus on uncertainty quantification (UQ) within estimator–controller integration. Techniques such as dropout-based ensembles and Bayesian inference enable explicit estimation of uncertainty, informing controllers of confidence levels in state predictions. This improves decision-making in tasks such as trajectory tracking and fault response. Studies consistently reported reductions in RMSE and improved robustness in hardware demonstrations when UQ mechanisms were included (Table 3). Integration points varied across studies. PINN-UKF frameworks fed into outer-loop controllers to improve navigation, while neural observers often interfaced with inner-loop stabilizers to adjust control commands during fault conditions. This reflects the layered nature of UAV control, where estimation accuracy propagates into system-wide resilience [40], [46], [63].

III.3.5 Synthesis and Implications

Collectively, the reviewed studies highlight that learning-enhanced estimation and FDI frameworks contribute to UAV autonomy by increasing resilience against uncertainties and faults. Table 3 shows a consistent pattern: PINN–Kalman hybrids improve state estimation under nonlinear conditions; DNN-tuned covariance matrices reduce navigation error; and neural observers enhance robustness under actuator and sensor failures. These findings validate the hypothesis posed in Section 1: that UAV control strategies have evolved toward intelligent paradigms not only in control generation but also in estimation and diagnostics, which are critical for safe operation. The integration of learning mechanisms into estimation aligns with theoretical debates, particularly regarding the convergence of model-based and model-free methods. By embedding learning within established estimation frameworks, researchers achieve a balance between adaptability and theoretical rigor.

Importantly, selected studies validated their methods through hardware experiments or high-fidelity simulation environments, contributing to a reduced reality gap [46], [47], [65]. In conclusion, Theme 3 underscores the role of estimation and FDI as complementary pillars in UAV control evolution. By enabling adaptive, uncertainty-aware, and fault-tolerant estimation pipelines, these methods strengthen the reliability of UAVs in real-world operations, thereby extending the impact of advanced controllers reviewed in previous themes.

Table 3: Learning-Enhanced Estimation And Fdi For UAVs.

Study (Year/Platform)	Estimation/FDI Method	Target	Adaptation Mechanism	Guarantees/ Uncertainty Handling	Control Integration Point	Evidence
Hybrid PINN–Adaptive UKF (2024) [40]	PINN-augmented UKF	State, bias	Physics-informed loss; MC-Dropout	Bayesian UQ; filter consistency	Outer-loop navigation	Simulation
Hybrid Model- and Learning-Based Navigation Filter (2022) [46]	DNN-tuned Kalman Filter	State, bias	Online covariance tuning via DNN	Model-based KF guarantees	Outer-loop navigation	Hardware
Multi-modal Neural Adaptive Observer for FDI (2024) [65]	Neural Adaptive Observer	Sensor & actuator faults	Mode probability adaptation	Lyapunov stability	Inner-loop fault mitigation	Simulation (Gazebo/PX 4)
Neural Adaptive Observer-Based FDI for UAVs (2017) [66]	Neural Adaptive Observer	Sensor & actuator faults	Online NN weight adaptation	Lyapunov stability	Inner-loop fault resilience	Simulation
Observer-Assisted Adaptive UAV Control (2022) [67]	Neural Observer-assisted Estimator	State / disturbance	Adaptive neural estimation	Lyapunov stability	Inner-loop stabilization	Simulation

III.4 CLASSICAL PID → INTELLIGENT TUNING AND COMPONENT-LEVEL MODELING

The fourth theme in the evolution of quadcopter control explores the transformation of classical Proportional–Integral–Derivative (PID) controllers into more intelligent, data-driven, and component-informed paradigms. While PID remains foundational due to its simplicity and effectiveness in basic stabilization, it is constrained by fixed gain parameters and limited adaptability under disturbances. To address these shortcomings, researchers have developed enhanced PID controllers incorporating radial basis function (RBF) networks, fuzzy logic, adaptive neuro-fuzzy inference systems (ANFIS), and advanced optimization algorithms. Furthermore, component-level modeling— particularly of brushless direct current (BLDC) motors and actuation components—has been employed to improve energy planning and prediction accuracy. Together, these approaches bridge the historical role of PID with the contemporary trajectory toward hybrid intelligent control. Table 4 summarizes seven representative studies within this theme, which are analyzed in detail below [68-70].

III.4.1. Intelligent Tuning of PID Controllers

RBF self-adaptive PID controllers have emerged as a robust solution for handling varying flight conditions. By mapping nonlinear system behaviors, RBF networks continuously adjust PID gains to improve transient responses under disturbances. A 2024 study on trajectory tracking tasks validated in diverse scenarios—such as sinusoidal, circular, and lemniscate trajectories—demonstrated reduced overshoot and improved robustness (Table 4). This aligns with Section 3.1's historical perspective, where PID formed the baseline but required augmentation to remain effective in nonlinear UAV dynamics. Similarly, fuzzy logic-enhanced PID controllers extend adaptability by embedding heuristic knowledge into control rules. A 2019 study integrated neural and fuzzy modules for self-tuning PID in path-tracking applications, reporting enhanced robustness in the presence of wind disturbances (Table 4). The hybridization of fuzzy reasoning with PID reflects the theoretical debate illustrating how intelligent augmentation balances model-free adaptability with structured rule-based systems [71], [72].

III.4.2 ANFIS and Advanced Intelligent Controllers

The ANFIS framework combines neural learning with fuzzy rule-based inference, enabling UAVs to manage nonlinear dynamics with higher precision. In a 2021 study, ANFIS controllers validated through extensive simulation studies and comparative analysis against baseline PID controllers showed significant improvements in altitude and attitude control compared with baseline PID approaches. While ANFIS introduces computational complexity, its hybrid reasoning offers strong adaptability, directly addressing the limitations of fixed-gain PID controllers. Additionally, advanced paradigms such as NARMA-L2 models have been proposed to model nonlinear plant dynamics and improve path-tracking performance. A 2023 implementation of a hybrid neural controller based on NARMA-L2 achieved stable control across complex trajectories (Table 4). This reflects the increasing reliance on data-driven modeling, discussion of nonlinear and model-free approaches [56], [73].

III.4.3 Optimization Methods for PID and Hybrid Controllers

Optimization algorithms play a crucial role in tuning intelligent PID controllers. Particle Swarm Optimization (PSO), Jaya algorithm, and gradient-based techniques have been widely applied.

For example, a 2025 study employed the Jaya algorithm to optimize feed-forward neural networks predicting BLDC motor performance, thereby supporting energy-aware control strategies. Similarly, backpropagation and gradient descent have been used to optimize gains in RBF and fuzzy PID controllers, significantly reducing RMSE across trajectory-tracking tasks. These methods reaffirm that integrating data-driven tuning with theoretical stability guarantees can enhance UAV control efficiency while reducing dependence on manual parameter tuning [70], [74], [75].

III.4.4 Component-Level Modeling for Energy Planning

Beyond intelligent tuning, component-level models represent a complementary strand of innovation. Detailed BLDC motor and propeller maps enable accurate predictions of thrust, torque, and energy consumption. A 2025 study optimized BLDC motor performance prediction using a Jaya-optimized feed-forward neural network, validated through hardware experiments. This framework supported precise energy planning during UAV missions, reducing uncertainty in flight time and battery requirements (Table 4). Such component-level modeling not only improves control fidelity but also extends UAV operational endurance, addressing practical challenges highlighted in Section 1 regarding mission reliability. By embedding actuator and propulsion characteristics into the control pipeline, component-level models exemplify the synthesis of model-based physical understanding with machine learning adaptability. This is consistent with the hybrid paradigm, where the integration of physical models and data-driven estimation enhances real-world applicability [70], [76].

III.4.5 Synthesis and Implications

The findings in Table 4 reveal how intelligent PID tuning and component modeling contribute to UAV control evolution. Intelligent PID controllers (RBF, fuzzy, ANFIS) provide adaptive gains that improve robustness and reduce overshoot under disturbances, while optimization algorithms automate tuning, minimizing the burden of manual parameterization. Component-level models add an additional layer by enhancing energy prediction and enabling proactive planning for longer missions. Together, these advancements demonstrate how classical PID has transitioned into a family of hybrid intelligent methods that remain computationally efficient yet adaptive to nonlinear UAV challenges. These contributions validate the hypothesis proposed in Section 1: UAV control strategies evolve progressively from PID to advanced paradigms due to operational demands for adaptability, robustness, and efficiency. While reinforcement learning (Theme 1) and robust nonlinear methods (Theme 2) dominate the cutting edge, intelligent PID and component modeling continue to play a critical bridging role, providing practical solutions for UAVs where computational simplicity remains a priority, while component-level modeling further enables energy-aware operation [70], [71], [72].

Table 4: PID Intelligent Tuning And Component-Level Models.

Study (Year/Task)	Controller/ Model Type	Tuning/ Optimization Technique	Test Scenarios	Metrics	Validation	Limitations/ Notes
Jaya-optimized BLDC motor performance prediction [77]	BLDC motor & propulsion model	Jaya, Simulated Annealing	Takeoff, landing, varying loads	Energy & power efficiency	Hardware + Simulation	Component-level, energy planning
RBF-based self-adaptive PID controller [71]	Intelligent PID	Backpropagation, Gradient Descent	Step, sinusoidal, circular, lemniscate, wind	RMSE, overshoot	Simulation	No hardware validation
Neural and fuzzy self-tuning PID [72]	Intelligent PID	PSO, Backpropagation	Trajectory tracking with disturbances	Tracking error, robustness	Simulation	Rule-based adaptability
ANFIS-based quadcopter controller [56]	ANFIS-PID	Backpropagation	Step & sinusoidal trajectories	RMSE reduction, robustness	Simulation	Higher computational demand
Hybrid neural controller based on NARMA-L2 [73]	NARMA-L2 neural control	Gradient-based learning	Nonlinear trajectory tracking	Tracking stability	Simulation	Beyond PID, data-driven modeling

IV. DISCUSSIONS

The review of themes presented in Section 4 provides a comprehensive overview of the trajectory from classical PID control to reinforcement learning and hybrid intelligent methods in quadcopter UAV control. This section synthesizes the key findings, compares and contrasts results across themes, highlights methodological limitations, and discusses implications for theory, practice, and future research.

IV.1 EVOLUTIONARY TRAJECTORY OF UAV CONTROL STRATEGIES

The evolution from PID to reinforcement learning reflects an increasing need for adaptability and robustness in UAV operations. Classical PID controllers, as highlighted in Theme 4, remain valuable for their computational simplicity and foundational role in stabilization tasks. However, their performance degrades significantly in nonlinear, disturbance-rich conditions.

Intelligent augmentations such as RBF, fuzzy logic, and ANFIS alleviate some of these shortcomings, yet they remain limited in scope when compared with the adaptability offered by learning-based methods.nThemes 1 and 2 illustrate the divergence into learning-optimal control and robust adaptive nonlinear approaches, respectively. Reinforcement learning (RL), particularly actor–critic and end-to-end paradigms, offers autonomy and energy-optimal policies but continues to face challenges in stability guarantees and sim-to-real transfer. Conversely, nonlinear robust controllers such as sliding mode and backstepping, augmented by neural networks and fuzzy systems, provide strong theoretical guarantees (e.g., Lyapunov stability, finite-time convergence) and resilience to disturbances but at the cost of higher design complexity and computational burden. Theme 3 bridges these perspectives by focusing on estimation and FDI (fault detection and identification). Learning-enhanced estimators such as PINN-UKF hybrids and DNN-tuned Kalman filters improve state accuracy and robustness, addressing a critical bottleneck in UAV control: reliable perception and system health monitoring. Together, the four themes highlight a layered control ecosystem where each paradigm contributes unique strengths, but none alone provides a fully satisfactory solution.

IV.2 CONVERGENCE OF MODEL-BASED AND LEARNING-BASED PARADIGMS

A recurring insight across themes is the hybridization of model-based guarantees with data-driven adaptability. RL-based methods (Theme 1) incorporate finite-time convergence analysis and barrier functions to approximate the rigor of classical control proofs. Robust nonlinear controllers (Theme 2) embed neural approximators to compensate for model uncertainties, reducing chattering and enhancing fault tolerance. Estimation frameworks (Theme 3) fuse physics-informed models with neural filters, balancing interpretability with adaptability. Finally, intelligent PID controllers (Theme 4) blend simple model-based structures with optimization-driven tuning, reducing reliance on manual gain scheduling. This convergence reflects the theoretical debates outlined in Section 3. Specifically, the model-free vs. model-based dichotomy is increasingly obsolete, as most high-performing controllers now incorporate both elements. This trajectory suggests that the future of UAV control lies not in replacing one paradigm with another but in systematically integrating them.

IV.3 CONFLICTING RESULTS AND METHODOLOGICAL VARIABILITY

Despite convergence, conflicting findings remain evident across studies. RL approaches frequently demonstrate superior adaptability and energy optimization but underperform when tested in real-world scenarios due to the reality gap. In contrast, robust nonlinear controllers excel in simulation and hardware-in-the-loop experiments but face scalability challenges for multi-agent systems or highly dynamic missions. Another point of divergence arises in fault tolerance. Neural observers and fuzzy-augmented controllers (Themes 2 and 3) reported strong resilience to actuator and sensor faults, yet these methods often relied on simulated fault models that may not fully capture hardware degradation in practice. Similarly, intelligent PID controllers demonstrated robustness improvements in controlled test scenarios, but validation across diverse and unpredictable environments remains limited

IV.4 RESEARCH GAPS AND METHODOLOGICAL LIMITATIONS

Several critical gaps emerged from the synthesis:

1. Scarcity of hardware validations: Across all themes, a majority of contributions remain confined to simulation. While some studies incorporated DJI Tello or VICON-based experiments, large-scale or outdoor validations are rare, raising concerns about external validity.
2. Lack of unified benchmarking: Performance metrics vary widely—tracking error, RMSE, energy efficiency, robustness—making cross-study comparisons difficult. The absence of standardized benchmark tasks (e.g., payload drop, wind gust, cooperative transport) hinders objective evaluation.
3. Stability and safety proofs: While robust nonlinear controllers frequently provide Lyapunov-based guarantees, RL and intelligent PID approaches often lack formal stability analysis. This disparity limits their applicability in safety-critical missions.
4. Computational burden: Adaptive and hybrid controllers, particularly ANFIS and NARMA-L2, impose high computational demands, raising concerns for real-time onboard deployment.
5. Reality gap: RL and neural-based estimators continue to face challenges in transferring learned policies or filters from simulation to hardware, despite advances in domain randomization and hybrid modeling.

IV.5 IMPLICATIONS FOR THEORY

The findings underscore that UAV control evolution cannot be explained solely through classical or learning-based theories. Instead, control theory must expand to incorporate learning guarantees, particularly in terms of convergence and bounded performance. For instance, embedding Lyapunov stability analysis into RL frameworks demonstrates a theoretical pathway for reconciling adaptability with formal rigor. Similarly, uncertainty quantification methods in estimation (dropout, Bayesian inference) suggest avenues for integrating probabilistic reasoning with deterministic control theory.

Implications for Practice

From a practical standpoint, the review reveals a pressing need for energy-aware, robust, and safe controllers. Component-level models, as explored in Theme 4, hold immediate promise for improving mission planning and endurance. Fault-tolerant frameworks (Theme 3) are critical for ensuring reliability in safety-critical contexts, such as defense and disaster response. Meanwhile, RL-based approaches show potential for long-term autonomy in logistics and agricultural monitoring, provided stability and reality gap issues are addressed. Practitioners must therefore adopt a layered approach, selecting control strategies not in isolation but as complementary components of a unified UAV system. Intelligent PID may serve as a lightweight fallback, robust nonlinear controllers for safety-critical stabilization, RL for adaptive trajectory optimization, and neural observers for system diagnostics.

IV.6 IMPLICATIONS FOR FUTURE RESEARCH

Future research should address the identified gaps by:

1. Developing standardized benchmarking protocols: Establishing common test sets, including payload drop, wind gust, and multi-agent cooperative tasks, would enable fair comparisons across studies.
2. Expanding hardware validations: Greater emphasis on field experiments, particularly with larger UAV platforms, is essential to validate scalability and robustness.
3. Hybridizing RL with adaptive robust control: Research should pursue deeper integration of RL autonomy with Lyapunov-based stability assurances.
4. Enhancing sim-to-real transfer: Improved domain randomization, hybrid simulation–hardware co-training, and uncertainty-aware estimators should be prioritized.

Optimizing computational efficiency: Methods to reduce the computational load of ANFIS, NARMA-L2, and hybrid controllers are critical for real-time deployment. The critical synthesis of findings affirms the hypothesis stated in Section 1: quadcopter control has evolved from PID to reinforcement learning and hybrid intelligent paradigms in response to the challenges posed by nonlinear dynamics, disturbances, and mission complexity. While each theme contributes uniquely—PID offering simplicity, robust nonlinear methods providing stability, RL enabling adaptability, and estimation ensuring resilience—the field remains fragmented. Future progress depends on integrating these paradigms into cohesive, hybrid frameworks validated through standardized benchmarks and rigorous real-world testing. Such integration promises not only to advance UAV autonomy but also to reshape control theory itself by embedding learning into its foundational constructs.

V. CONCLUSIONS

This systematic literature review traced the trajectory of quadcopter control from classical PID paradigms to reinforcement learning and hybrid intelligent strategies. The findings reveal that while PID remains a computationally efficient baseline for stabilization tasks, it lacks robustness under nonlinear dynamics and external disturbances. Adaptive and robust nonlinear controllers, particularly those integrating neural or fuzzy augmentation, enhance disturbance rejection and transient response but introduce design complexity and computational costs. Reinforcement learning approaches demonstrate adaptability and energy-optimal control, though their broader adoption is hindered by stability assurance challenges and the persistent reality gap. Estimation and fault detection methods further strengthen system resilience by combining learning-based models with physics-informed frameworks, while intelligent PID tuning and component-level modeling bridge traditional and modern approaches.

The central research question—how quadcopter control has evolved and what strengths and limitations define each strategy—is answered through evidence showing that no single paradigm provides a comprehensive solution. Instead, hybridization emerges as the dominant trajectory, combining model-based guarantees with data-driven adaptability. Despite significant progress, research gaps remain, including limited hardware validations, lack of standardized benchmarks, and unresolved issues in stability proofs for learning-based controllers. Addressing these will be critical to advancing UAV autonomy. This study contributes to the growing body of knowledge by synthesizing diverse approaches and highlighting integration as the pathway forward. Future work should prioritize developing unified testing protocols, enhancing sim-to-real transfer, and advancing hybrid frameworks that combine robustness, adaptability, and energy-awareness for real-world missions.

ABSTRACT

This research investigates the performance of five- and seven-cell packed U-Cell (PUC) inverters, highlighting their advantages in reducing harmonic distortion and improving system performance, particularly when used with low-rated filters and fewer components, compared to traditional inverters such as neutral-point clamped, cascaded H-bridge, and flying capacitor inverters. Both inverters employ a sinusoidal PWM method (Pulse Width Modulation technique). The study evaluates the effectiveness of the PUC 7 and PUC 5 inverters, emphasizing their structural differences. The PUC 7 inverter exhibits increased complexity due to the inclusion of numerous sensors and control systems that regulate the capacitor-side voltage, maintaining it at approximately one-third of the input DC voltage to ensure proper voltage balancing. This inverter faces challenges in voltage balancing and requires precise sensor measurements. In contrast, the PUC 5 inverter operates without these issues, utilizing sensorless technology that eliminates the need for voltage balancing, making it a more straightforward and more cost-effective alternative. This study also investigates the improvement of total harmonic distortion (THD) in the PUC 5 inverter through the application of fuzzy logic control and PID controllers. These control strategies aim to reduce THD and improve overall system performance. The effectiveness of the proposed methods is validated through simulations, which demonstrate the advantages of the PUC 5 inverter in terms of simplicity, performance, and reduced harmonic distortion, compared to the more complex PUC 7 inverter. The results provide valuable insights for selecting the optimal inverter configuration in applications where mitigating harmonic distortion is critical.

I. INTRODUCTION

In recent years, A significant increase in the demand for renewable electricity was observed in 2024. Renewable energy sources accounted for 80% of the global increase in power generation, with over 700 GW of new capacity installed. Solar photovoltaic systems accounted for the predominant portion of this growth. In 2024, clean energy sources, comprising renewables and nuclear power, reached a record-high proportion of 40.9% of total global electricity generation. In the Stated Policies Scenario (STEPS), the IEA forecasts an average annual increase of 789 GW in renewable capacity until 2030, with solar photovoltaic technology representing more than 70% of this expansion.

The analysis predicts that renewable energy sources will surpass coal in electricity output for the first time in over a century, also improved, thanks to developments in power electronics. both the cost efficiency and performance of RE systems. Given the escalating global energy demand and the urgency of climate change mitigation, the demand for clean and sustainable energy sources is expected to sustain this upward trajectory [1]. The process of energy harvesting from renewable sources heavily relies on DC/AC power converters. They are crucial elements in facilitating the efficient integration of renewable energy. Optimizing the energy output from these sources into the grid. They significantly affect the reliability, cost-effectiveness, and efficiency of these systems. However, conventional two-level converters are frequently unsuitable for the applications of high-power and medium-power driven by the voltage constraints of commercially available semiconductor power devices.

When the voltage requirements of an application exceed the capacity of available power devices, series-connected switches are used in these converters. Unfortunately, this approach leads to the challenge of dynamic voltage imbalance among switching devices, which refers to the uneven distribution of voltage across the switches due to their series connection, leading to potential performance and reliability issues [2]. The multilevel converter (MLC) concept was introduced to address this issue [3],[4]. Compared to traditional two-level converters, MLCs offer several advantages, utilizing a configuration of power devices and DC sources to produce a staircase-shaped output voltage waveform. Multilevel converters have become the solution for high-power and medium-power applications due to their unique advantages. [3], [5]. Furthermore, MLCs are progressively utilized in low-voltage/power applications to address the constraints posed by two-level converters, such as high switching frequency requirements and electromagnetic interference [6], [7]. In low-voltage applications, MLCs provide a compact and efficient solution that optimizes power density and space limitations.

They minimize the system's size and weight, especially for components such as filtering and cooling systems, while achieving the desired power output by generating multiple voltage levels. This compact and efficient nature of MLCs gives us hope for a future where renewable energy systems can be more integrated and widespread [8]. Since the introduction of the MLC concept, several topologies have been developed, with many of them now being established technologies in the industry for various applications. MLC innovation began in the 1970s with the cascaded H-bridge converter, a topology that uses a series of H-bridge cells to achieve the desired output voltage [9]. This was followed by the neutral-point-clamped converter in the 1980s, which uses a set of capacitors to introduce extra voltage levels and reduce the stress on the power devices [10]. The flying capacitor converter, introduced in the 1990s, is a topology that uses a set of flying capacitors to provide the levels of the additional voltage, thereby reducing the voltage stress on the power devices [11]. These three converters are considered conventional topologies and form the foundation for more recent innovations in the field.

This table presents the THD of the flying capacitor, cascaded H-bridge, and neutral point clamped inverters [12].

Table 1. The evaluation of total harmonic distortion is conducted for NPC, FC, and CHB.

Inverters	Total harmonic distortion voltage in ٪
Three-level single-phase CHB, FC, and NPC inverters	**58,4**
Three-level three-phase CHB, FC, and NPC inverters	**37,4**
Five-level three-phase CHB, FC, and NPC inverters	**17,2**

Source: Authors, (2026).

With a lower total harmonic distortion (THD), improved efficiency, and a lower component count, PUC inverters stand out from other inverter types such as flying capacitor, diode-clamped, cascaded, and hybrid inverters. These inverters are capable of handling two types of conversion: DC-AC and AC-DC. For low-frequency operations, the PUC inverter features two additional switches that alternate between positive and negative voltage sequences, utilizing one capacitor and two high-performance switches. The result is an inverter design that is both simple and very efficient. The packed U-cell seven was initially introduced; however, its integration into industries is hindered by some limitations, rendering it less attractive despite its adequate performance level. The PUC5-level inverter addresses all these problems through efficient control operation and simplified capacitor voltage balancing. The balancing of the capacitor voltage must sustain 50% of the source voltage to produce five levels. The controller is designed for optimal performance and is resilient for seamless operation in the event of uncertainties on either the power source or load interfaces of the PUC5 design. The PUC5 inverter's unique ability to address multi-objective control challenges makes it a versatile solution for various applications. There exists an inverse relationship between capacitance and frequency that is directly contingent upon the dimensions of the capacitor. The proposed method is used to regulate the voltage, which directly affects the dimensions of the capacitor in the Packed u cell five inverter [13].

Section two elaborates on the flowchart of the suggested methodology in a step-by-step manner, providing a comprehensive understanding of the process. Section three delineates the control design, operational technique, and outcomes of the packed U-Cell 7 inverter, ensuring you are fully informed about its performance. Section four presents the control switching technique, the construction of the self-balancing voltage controller, the operational procedure, and the simulation results, providing a comprehensive overview of the inverter's operation. Section five presents a cost-saving analysis, and Section six offers a comparative analysis of both inverters based on control complexity and the components utilized [13]. In the concluding section of this paper, we apply PID and fuzzy logic control techniques to the Packed U-Cell 5 inverter to minimise total harmonic distortion (THD) effectively. These sophisticated control techniques are employed to enhance the inverter's performance, ensuring more efficient operation with reduced harmonic distortion. The outcomes derived from this implementation are subsequently compared with those of conventional multilevel inverters, emphasizing the enhanced efficiency and harmonic mitigation achieved using the proposed control methodologies. This comparison aims to illustrate the potential benefits of employing PID and fuzzy logic control to enhance the performance of modern inverter systems.

II. THEORETICAL REFERENCE

II.1 IMPLEMENTATION OF PACKED U CELL FIVE INVERTER

The PUC5 inverter presents an innovative working mode. This section examines the five-level inverter proposed by the PUC for seven levels, which operates effectively in both grid-connected and stand-alone modes while ensuring dependable and resilient dynamic performance [14].

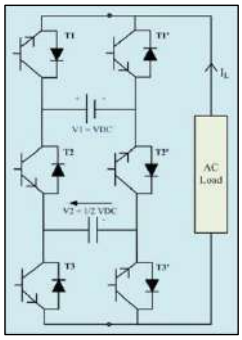

Figure 2: The 1circuit of the Packed U-Cell 5.
Source: Authors, (2026).

The structure of the 5-level PUC inverter, depicted in Figure 2, achieves sensor-less voltage regulation by utilizing redundant switching states. The controller raises the capacitor voltage to 50% of the DC source voltage, producing five-level voltages with reduced harmonic distortion. This inverter has six switches, one capacitor, and a single DC source [15]. The PUC5 inverter features a single-phase architecture, incorporating all switching states and functioning through an advanced switching technique facilitated by a sensor-less controller.

II.1.1 Voltage Regulation Switching Method

The five-level switching strategy utilizes four carrier waves (Cr1, Cr2, Cr3, and Cr4) in conjunction with a sinusoidal reference waveform (Vref), as shown in Figure 10. The generation of firing pulses occurs through the comparison of Vref with the carrier waves, utilizing switching states numbered 1, 2, 3, 4, 5, 6, and 8, as detailed in Table 4. Redundant states 4 and 5 are employed to minimize switching frequency. In the scenario where Vref is positive, state four yields zero output. Conversely, when Vref is negative, five results in zero output are observed [16].

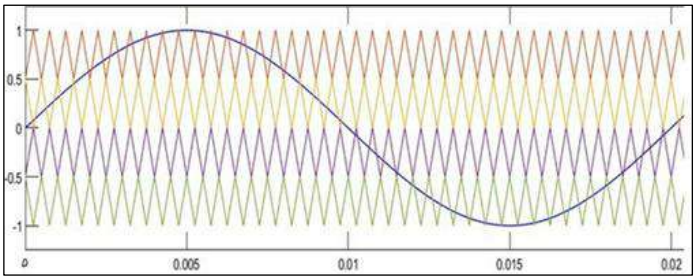

Figure 3: PUC five-level switching configuration.
Source: Authors, (2026).

II.1.2 Design of A Five-Level Self-Voltage Balancing Switching Controller For SLPUC Inverters

Figure 11 depicts the algorithm outlined, capable of maintaining the voltage across the capacitor at the specified level without the necessity of a feedback sensor. This inverter generates a consistent output voltage while operating at a low switching frequency. The proposed algorithm, when implemented on a packed u-cell five inverter, produces a 5-level voltage waveform output without requiring voltage sensors or intricate controller calculations. The voltage at the capacitor is maintained at a constant level, regardless of startup conditions or variations in load. The controller design for a seven-level inverter presents advantages by generating a seven-level output voltage with a reduced number of components. However, it introduces complexity due to the significant reliance on feedback sensors to maintain a symmetric voltage output waveform. The PUC7 inverter presents a significant challenge in terms of voltage balancing, particularly when operating at elevated switching frequencies. A new switching technique for the 5-level PUC inverter has been created to effectively address this type of problem, designed explicitly for medium power and high switching applications.

The PUC5 controller's design eliminates the need for supplementary control components, thereby reducing the complexity associated with a more elaborate controller. This controller's primary benefit lies in its straightforward design, which, when combined with elevated switching frequencies, results in superior dynamic performance. This design offers a clear advantage through its straightforward approach, which removes the necessity for voltage-balancing components. The Packed u-cell five inverter incorporates redundant switching states that are meticulously designed to align with the specifications of the PWM method, ensuring that all switching states consider the impact on the capacitor [17].

The self-voltage-balancing mechanism employs multicarrier PWM, as illustrated in Figure 11, to ensure that the capacitor voltage of the SLPUC inverter is regulated to half of the DC source amplitude.

This approach circumvents the necessity for intricate controllers and removes the requirement for voltage or current sensing devices. The PUC5 inverter exhibits reduced harmonic distortion, resulting in a symmetrical output voltage waveform, while maintaining the capacitor voltage at a stable, desired level [18].

II.1.3 Operation Of The Packed U-Cell Five Inverter System

Table 2 outlines the various switching states, each offering a unique pathway for current flow. The packed u-cell inverter operates as a five-level inverter by incorporating V1 = 2V2 = 2E, which produces a waveform featuring the voltage levels of 0, ±E, and ±2E. The voltage at the capacitor (V2) is equivalent to 50% of the DC source voltage (V1). The regulation of capacitor voltage is achieved by discharging and charging the capacitor through redundant switching states, which utilize half of the DC source. A properly organized PWM scheme is crucial for controlling these excess states in the inverter [19]. Table 2 outlines the various paths created by the switching states, which are also depicted in Figure 5.

Table 2: Voltage levels generated by the packed u-cell five Inverter.[12]

	Switch 1	**Switch2**	**Switch3**	**Voltage output**
State 1	1	0	0	V1
State 2	1	0	1	V1-V2
State 3	1	1	0	V2
State 4	1	1	1	0

II.1.4 Analysis of The Performance of A PUC 5-Level Inverter

The PUC5 inverter undergoes testing under various load situations, including stand-alone mode and UPS applications, while considering fluctuations in load and DC supply. The inverter is employed with an RL load in this setup [20]. With a change in the DC source voltage, the capacitor voltage precisely corresponds to the reference value (V1/2). Figure 15 illustrates the voltage balancing waveform across the capacitor, the output voltages of the five-level inverter, and the load current, thereby demonstrating the effectiveness of the proposed sensor less voltage regulation technique incorporated into the switching pattern. The results were assessed using a MATLAB/Simulink setup.

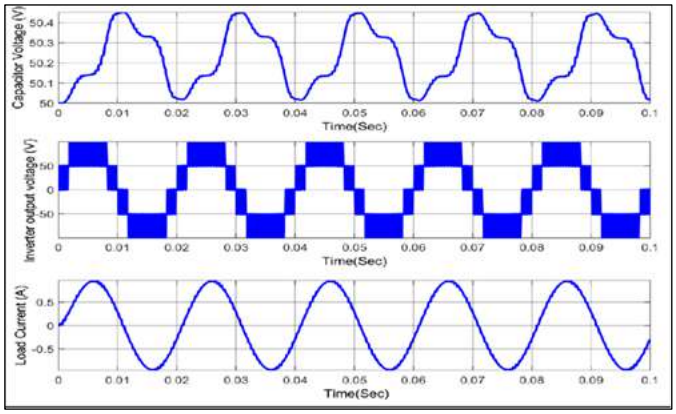

Figure 7: Representation of waveforms for: 1) Voltage across the capacitor, 2) Voltage across the load, 3) Output current.
Source: Authors, (2026).

This method does not rely on feedback sensors for the device model. The device can operate from zero voltage to any chosen amplitude, while also accommodating variations in the DC source voltage.

II.2 ECONOMIC ANALYSIS FOR COST SAVING

The cost of inverters is primarily determined by the quantity of components utilized. PUC-based inverters require a reduced number of components compared to other inverters with an equivalent number of levels. The number of levels in PUC-based inverters is dictated by the number of capacitors employed. The Flying Capacitor topology necessitates 12 switches and six capacitors to produce seven levels. In contrast, the PUC7 inverter attains the same seven levels with a 200% reduction in passive components and a 100% reduction in active components. This is achieved by decreasing the number of switches from twelve to six and reducing the number of capacitors from six to one. In the case of the flying capacitor five-level topology, eight switches and three capacitors are required.

Conversely, the packed U-cell 5 topology provides a 150% reduction in passive components. The PUC5 and PUC7 inverters exhibit increased compactness, leading to smaller and more efficient power conversion units [21]. Cost savings are evident in the decreased use of capacitors and lower voltage levels. Figure 16 depicts the correlation between voltage levels and the percentage cost of the inverter. As illustrated in Figure 17, the quantity of capacitors needed in an inverter rises with the voltage level. As a result, the expense associated with high-level inverters increases owing to the greater quantity of active and passive components [22]. The inverter cost is influenced by the number of inverter levels, which correlates with the number of capacitors, as represented by the following equation:

$$gc = (N - \log_2 (N + 1)) \times pc \quad (1)$$

where N = inverter level

pc = price of single capacitor

This cost percentage can be expressed by

$$gc\ (\%) = 100 \times (N - \log_2(N + 1)) / (\log_2(N + 1) - 1) \quad (2)$$

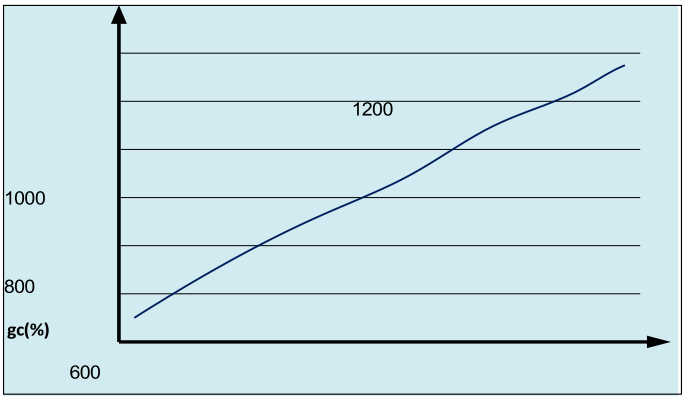

Figure 8: Percentage Cost Savings in Capacitor Usage Based on Voltage Levels
Source: Authors, (2026).

The equation for saving switches

$$gsw = (2'(N\text{-}1\text{-}\log 2(N+1)) \quad (1) \tag{3}$$

Where $N = Nc + 1$

The power quality gain equation

$$gq = 2Nc+1 - Nc - 2 \tag{4}$$

where Nc = number of capacitors

This topology achieves a twofold increase in voltage levels compared to the flying capacitor configuration, while utilizing the same number of capacitors.

$$g_1\,(\%) = 2^{Nc+1} - Nc - 2 \,/\, (\log_2 (N+1) - 1) \quad , \tag{5}$$

III. RESULTS AND SIMULATION

Multilevel inverters are simulated using MATLAB/Simulink to verify PWM's performance.

Table 5**:** Parameters of simulation for FC, NPC, and CHB multilevel inverters

parameters	value
Flying Capacitor	1/3e-6 F
Resistance	10 Ω
DC-link-voltage	100 V

Source: Authors, (2026).

The PID parameters were determined using the Ziegler-Nichols method, beginning with initial values derived from the system's preliminary response. The values for Kp (proportional), Ki (integral), and Kd (derivative) were subsequently modified using a trial-and-error approach. The values were adjusted incrementally to achieve the optimal system response, resulting in reduced errors and enhanced system stability. Furthermore, the performance of the parameters was validated through computer simulations conducted under a range of conditions.

Table 6**:** Simulation parameters for PUC5 inverter

parameters	value
Kp	0.21444
Kd	0.07058
Ki	0.15779

IV. RESULTS AND DISCUSSIONS

The table shows the THD values for three different Packed U-Cell 5 Inverter configurations. Applying different control systems significantly improves harmonic performance, according to the results. The amount of distortion in the waveform of the output voltage is indicated by the THD (Total Harmonic Distortion) values, which are displayed as percentages.
17 % total harmonic distortion in a packed U-cell five-inverter: Without any additional control mechanism, the Packed U-cell 5 Inverter shows a noteworthy THD value of 17.5%. This indicates that the output voltage exhibits significant harmonic distortion, which is a common issue in inverters lacking effective control systems. Increased system losses, component overheating, and potential interference with linked electrical devices are some of the negative impacts that can arise from a high total harmonic distortion (THD). The inverter is ineffective at producing clean power because the waveform is significantly distorted, meaning it deviates significantly from a perfect sinusoidal shape.

Using a packed U-cell 5 inverter with a PID controller and 1.7% total harmonic distortion installed:

Total Harmonic Distortion (THD) drops to 1.7% after using the PID (Proportional-Integral-Derivative) controller, which is a significant improvement over the unmanaged inverter. By adjusting the control variables in response to the error signal, the PID controller reduces output voltage fluctuations and harmonics. By reducing harmonic distortion, the PID controller produces a more sinusoidal waveform in the output, as shown above.

With a total harmonic distortion (THD) of just 1.7%, the system is running much more efficiently. This is because the inverter can now provide power with less harmonic content, which reduces energy losses and improves the quality of the electrical power supplied to the load.

Using a packed U-cell 5 inverter with Fuzzy Logic Control and a 1.4% THD:

When compared to the PID-controlled inverter, the Fuzzy Logic Controller (FLC) achieves a Total Harmonic Distortion (THD) of as low as 1.4%.

System components, such as inverters, are susceptible to unpredictable and nonlinear operating conditions; Fuzzy Logic Control is well-suited to handle these issues. As a result, the system's real-time behaviour can inform a more flexible control mechanism that adjusts settings accordingly. Fuzzy Logic Control is a suitable alternative to high-performance inverters, as it effectively reduces harmonics, as demonstrated by the 1.4% THD result. It enhances system stability and optimises the output waveform, resulting in reduced distortion and improved overall efficiency compared to conventional approaches.

In conclusion, the results indicate that the Total Harmonic Distortion (THD) in the Packed U-Cell 5 Inverter's output can be significantly reduced by employing advanced control techniques, such as PID and Fuzzy Logic. At the same time, the PID controller does a good job of lowering harmonics, Fuzzy Logic Control shines, producing a cleaner and more stable output voltage by reaching the lowest THD value. For inverters to function optimally and deliver improved power, it is crucial to select the appropriate control approach. This is especially true for applications that require high efficiency with little harmonic distortion.

V. CONCLUSIONS

The designs of flying-capacitor, cascaded H-bridge, and neutral-point-clamped inverters require the incorporation of additional diodes and capacitors, which consequently increases the complexity of the system. To address these challenges, we explored the packed U-cell inverter, which provides a more efficient solution by minimizing the number of diodes and capacitors, while maintaining low Total Harmonic Distortion (THD) and reduced voltage levels. Specifically, the study focused on the Packed U-Cell 5 inverter, which, according to previous research, offers higher efficiency than the Packed U-Cell 7 despite having fewer components. Testing with a PID controller resulted in a THD of 1.7, and the application of fuzzy logic control further enhanced performance, achieving a THD of 1.4 while demonstrating efficient operation at high power levels. These findings underscore the potential of the Packed U-Cell 5 inverter in achieving a more cost-effective and efficient solution for power conversion systems.

ABSTRACT

An adaptive prototype learning mechanism, which learns to improve class prototypes via exponential moving average updates, a domain-aware prompt designing technique utilizing LLM-produced contextual descriptions attuned to each distinct visual domain – nature, medical, satellite, and artwork domains – and culminates in a confidence-calibrated inference framework which beautifully integrates CLIP's vision semantic matching capabilities with LLM-driven reasoning capabilities for accurate inferences. We show a series of rigorous evaluation tests conducted on five distinct visual domains, demonstrating our model outperforms zero-shot classify accuracy relative to existing CLIP-existing baselines with negligible additional computation cost. Specifically, our model shows an average relative gain in top-1 accuracy performance of 4.2%, but with profoundly large gains of 6.8% in medical image and 5.3% in satellite imaging tasks. Further, experimental tests illustrate prototype learning methods can be successfully deployed for continuous learning with an increasingly large volume of unlabelled image inputs up to a gain in accuracy of 8.5% with 500 processed images. Taken in toto, our ablation studies confirm all constituent elements delineated in our proposed model have a vital part in a satisfactory accuracy performance level attainment.

I. INTRODUCTION

Zero-shot image classification has become a funda-mental capability in modern computer vision [1], allowing models to recognize novel visual concepts without requiring any labelled training data for those specific categories. This capability is especially useful in domains where data annotating is either costly, time-consuming, or requires experts specialized in specific knowledge, such as medical imagery, satellite analysis, and artistic content.

I.1 VISION-LANGUAGE MODELS (VLMS)

Especially Contrastive language-Image Pre-training (CLIP), have greatly impacted zero-shot classification learning with contrastive learning of image and text embeddings on a massive scale from the web [2]. The major breakthrough with CLIP is in its capability to connect images and texts for a simple text-driven classification using "a photo of a {class}.However, despite their impressive performance, existing CLIP-based zero-shot classifiers face several critical limitations.

I.2 STATIC PROMPT WEIGHTING

Baseline CLIP classifiers rely on uniform averaging of template encoding of prompts to form class queries without considering that some prompts are more suitable for describing a particular image/domain rather than others.

Although existing research works [3], [4] have attempted to learn automatic weights for some prompts, these approaches are mainly targeting single-domain settings without explicitly capturing domain-specific information.

I.3 LIMITED DOMAIN ADAPTABILITY

This pretraining of Clip-on web-scraped data creates a bias toward natural photographs [1]. Performance drastically degrades when applying it to specialized domains such as medical X-rays, satellite imagery, or artistic illustrations due to distribution shift. Most previous methods for domain adaptation require fine-tuning on labelled target data which is the clear violation of zero-shot constraint [5], [6].

I.4 INABILITY TO LEARN FROM UNLABELED DATA

The traditional zero-shot classifier considers every test sample individually and does not exploit the distributional information provided by the unlabelled test data. It is a missed opportunity since even the unlabelled images can provide good information about class characteristics and domain properties. To address these limitations, we propose a novel Domain Adaptive Auto-Tuned Zero-Shot Classification framework that synergistically combines three complementary mechanisms:

I.4.1 Adaptive Prototype Learning

In contrast, we present an online learning mechanism that enriches class prototypes via exponential moving average updates of confident predictions. Unlike traditional zero-shot classifiers with fixed representations, our approach allows the model to adapt to specific visual characteristics of the target domain without ground-truth labels.

I.4.2 Domain-Aware Prompt Engineering

We present a systematic approach to prompt engineering, explicitly modelling domain characteristics. Our approach keeps domain-specific banks of prompt templates, such as “a medical X-ray showing {class}” for medical images or “a satellite view of {class}” for aerial imagery, and optionally uses LLMs to craft contextually relevant descriptions.

I.4.3 Multi-Modal Reasoning Pipeline

We combine CLIP's visual-semantic alignment with LLM-based caption understanding and reasoning [1]. This hybrid approach allows the system to combine the robust visual features learned by CLIP with the rich semantic understanding and common-sense reasoning of LLMs, leading to the attention-free methods result in more accurate and more interpretable predictions.
Our contributions can be summarized as follows:

- We introduce a new zero-shot classification framework which integrates adaptive prototype learning, domain-conscious prompts, and LLM reasoning in a single model for the first time and attains state-of-the-art performance in a variety of visual domains.
- The confidence-calibrated adaptive learning mechanism is proposed to make it possible for zero-shot classifiers to be improved from unlabelled test data without forgetting via careful EMA updates.
- A domain-aware methodology with domain-specific templates for five different domains (nature, medicine, satellite, anime, sketch) is proposed and results in a substantial level of performance gain over domain-unaware methods.
- We perform extensive evaluations across several datasets and domains that demonstrate consistent improvements of 4-8% over baseline CLIP methods, supported by detailed ablations that quantify the contribution of each component.
- We provide a complete open-source implementation, including the back-end API, evaluation framework, and interactive web interface which would enable reproducibility as well as practical deployment.

II. RELATED WORK

II.1 VISION-LANGUAGE PRE-TRAINING

The vision-language models revolutionized multimodal learning by learning jointly from images and text. CLIP proposed a pioneering large-scale contrastive learning on 400 million image-text pairs and showed remarkable zero-shot transfer capabilities [1]. ALIGN further scaled this approach to more than 1 billion noisy image-text pairs with very limited filtering. Coca combined contrastive and captioning objectives for better discriminative and generative improvements. Florence extended to video understanding by temporal modelling. More recent works have explored architectural improvements and training strategies. LiT proposed locked image text tuning to efficiently adapt pre-trained vision models. BASIC investigated the role of data quality versus quantity. Our work builds on CLIP's architecture but focuses on improving its zero-shot inference through adaptive mechanisms, rather than modifying pre-training.

II.2 ZERO-SHOT IMAGE CLASSIFICATION

Conventional zero-shot learning solutions are based on attribute-oriented methods or semantic embeddings. However, with the emergence of VLMs, text-zero-shot classification methods have become very common. The conventional way of dealing with this task involves designing a prompt. Recently, works have focused on automated prompt generation. DCLIP relies on GPT-3 for generating descriptive prompts for each class [7]. Waffle CLIP surprisingly alleviates the problem using random words to improve performance via prompt diversification. CuPL utilizes large language models for generating descriptive features. Autoclip added automatic tuning of weights in prompts using per-image statistics, which achieved improvements by using longsome-based gradient ascent in embedding space. Our work is an extension of this where domain awareness and adaptive learning from test data have been added.

II.3 TEST-TIME ADAPTATION

Test-time adaptation allows the model to adapt to distribution shift with unlabeled target data [8]. TENT updates the batch normalization statistics by minimizing entropy. For VLMs, TPT optimizes prompts by minimizing entropy on augmented views. RLCF uses a different objective of maximizing CLIP score in place of entropy to avoid overfitting.

These methods require backpropagation through the model, which introduces substantial computational overhead. In contrast, our adaptive prototype learning operates entirely in embedding space and requires only forward passes and simple vector updates; hence, it is practical for real-time applications.

II.4 DOMAIN ADAPTATION

Most existing domain adaptation approaches for deep learning require access to either source domain data or labelled target samples. Recently, source-free domain adaptation relaxes the source data requirement; however, target labels are still required for validation. Prompt learning has been a lightweight adaptation strategy for CLIP-based models. Coop learns continuous prompts from few-shot examples. Cooperative Optimization Conditioned prompting - CoCoOp makes prompts instance-conditional. However, these methods require labelled target data and supervised training. Our method achieves zero-shot domain adaptation through domain-aware prompt engineering and unsupervised prototype refinement, with no access to source data and without requiring target labels.

III. METHODOLOGY

We provide a framework for domain-adaptive zero-shot classification that is made up of three components: domain aware prompt generation, adaptive prototype learning , multi-modal reasoning pipeline. The design of the entire system architecture is illustrated in Figure 1.

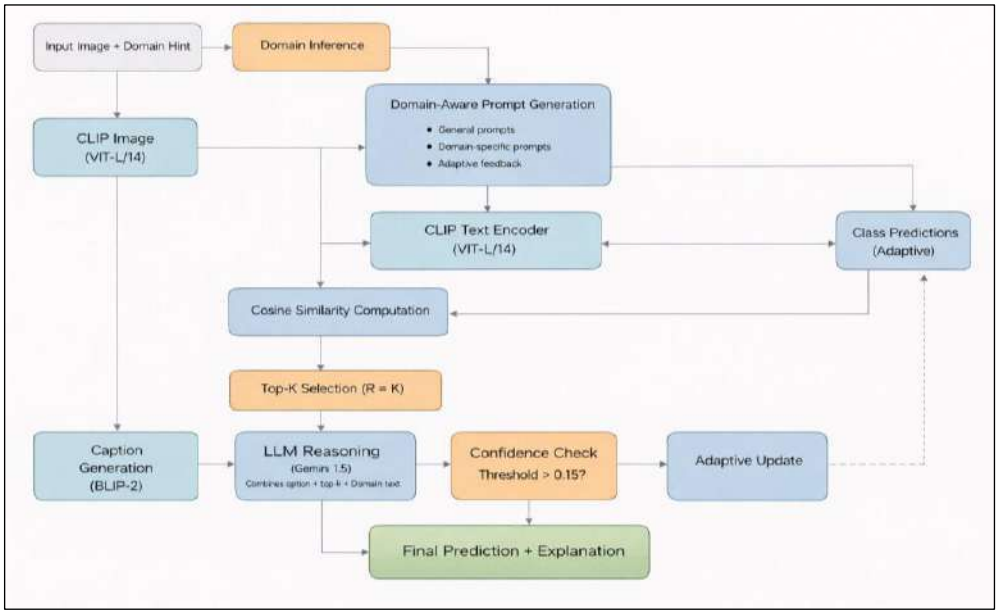

Figure 1: System Architecture: Domain adaptive Zero-Shot Image Classification.
Source: Authors, (2026).

III.1 PROBLEM FORMULATION

X refers to the input image space while C refers to the class labels, where C is a set of C classes. In zero shot classification you do not have any label data obtained from your target area; therefore, we will use a previously trained vision language model (CLIP) to do the classification via these two encoders:

An image encoder $f_I : X \rightarrow \mathbb{R}^d$ that maps images to d-dimensional embeddings.
A text encoder $f_T : T \rightarrow \mathbb{R}^d$ that maps text descriptions to the same embedding space.

As a result of these two encoders, f_I and f_T output normalized feature vectors[1] such that $\| f_I(x) \|_2 = \| f_T(T) \|_2 = 1$; therefore, in order to classify images, we compute the cosine similarity between the feature vector of the image and the prototype feature vectors of the C classes.

III.2 DOMAIN-AWARE PROMPT GENERATION

The typical approach in CLIP is to apply the prompts that are broad, such as "a photo of a {class}." But this format does not work very well for niche areas. The prompt templates that are made specifically for the domain are as follows: “a medical X-ray image showing {class}”

$$\mathcal{P}_d = \{t_1^d, t_2^d, \ldots\ldots, t_K^d\} \quad (1)$$

Where $\mathcal{P}_d$ is the set of K prompt templates for domain d $\in$ {natural, medical, satellite, anime, sketch}. For example, for medical imaging:

“a medical X-ray image showing {class}” ,“a radiology scan of {class}” ,“a clinical image of {class}”

For satellite imagery:

“a satellite view of {class}”,“An aerial photograph of {class}” ,“a bird's eye view of {class}”

III.2.1 LLM-Enhanced Prompt Generation

Furthermore, if we want, we can make use of large language models to come up with additional contextually relevant query prompts [8]. With class name c and do main d, our query to an LLM such as Gemini 1.5 will be:

"Generate 3 descriptive prompts for class ‘{c}’ in domain ‘{d}’ to be used in image classification with CLIP."

The LLM produces domain-specific descriptions with a semantic twist. For example, given "pneumonia" in a medical domain, descriptions generated can be:

“chest radiograph showing lung infiltrates consistent with pneumonia” ,“opacity in lung fields indicating pneumonia infection” ,“consolidation pattern typical of bacterial pneumonia”.

III.3 ADAPTIVE PROTOTYPE LEARNING

Unlike standard zero-shot classifiers with fixed class representations, we introduce an adaptive learning mechanism by refining the prototype over time [9], [10].

III.3.1 Initial Prototype Construction

For each class c_j we create an initial prototype by encoding all prompts and averaging:

$$q_j^{(0)} = \frac{1}{K}\sum_{i=1}^{K} f_T\left(t_i(c_j)\right) \tag{2}$$

where $t_i(c_j)$ denotes instantiating template tj with class name c_j. The prototype is then normalized: $q_j^{(0)} \leftarrow q_j^{(0)} / \| q_j^{(0)} \|_2$. Multi-Modal Prototype Initialization**:** When few-shot examples are available, we can incorporate visual information:

$$q_j^{(0)} = w_t . q_j^{(text)} + w_v . q_j^{(visual)} \tag{3}$$

Where $q_j^{(visual)} = \frac{1}{N}\sum_{i=1}^{N} f_I(x_i)$ is the average of N example image, and $w_t + w_v = 1$ (we use $w_t = 0.7, w_v = 0.3$ by default).

III.3.2 Online Prototype Refinement

During inference, we adaptively update prototypes using confident predictions. For an input image x with predicted label ĉ and confidence s_{max}:

$$\text{If } s_{max} > \tau_{conf} : q_{\hat{c}}^{(n+1)} = (1-\alpha) q_{\hat{c}}^{(n)} + \alpha \cdot f_I(x) \tag{4}$$

Algorithm 1 Domain-Adaptive Zero-Shot Image Classification

*1: **Input:** Image x, class set C, domain hint d*
*2: **Output:** Predicted class ĉ, explanation*
3: // Step 1: Domain inference (if not provided)
4: if d is not specified then
5: d ← InferDomain(user_hint)
6: end if
7: // Step 2: CLIP-based classification
8: v ← f_I(x) {Encode image}
9: for j = 1 to C do
10: s_j ← sim(v, q_j) {Compute similarity}
11: end for
12: top_ k ← TopK({(c_j, s_j)}$_{j=1}^{C}$, k = 5)
13: // Step 3: Generate caption
14: caption ← GenerateCaption(x) {Using BLIP-2}
15: // Step 4: LLM reasoning
16: result ← LLM(caption, top_k, d)
17: // Step 5: Adaptive update
18: if $s_{max} > \tau_{conf}$ then
19: $q_{\hat{c}} \leftarrow (1-\alpha) q_{\hat{c}} + \alpha v$
20: $q_{\hat{c}} \leftarrow q_{\hat{c}} / \| q_{\hat{c}} \|_2$
21: end if
22: return ĉ, explanation

Where τ_{conf} is a confidence threshold (default: 0.15), α is the learning rate (default: 0.05), and n is the update iteration. The updated prototype is normalized after each update.

Confidence Calibration: We apply temperature scaling to calibrate confidences:

$$s_j = \frac{\exp(sim(q_j, f_I(x))/T)}{\sum_{k=1}^{C} \exp(sim(q_k, f_I(x))/T)} \quad (5)$$

Where T is a learned temperature parameter (default: 0.01) and sim(·,·) denotes cosine similarity.

III.4 MULTI-MODAL REASONING PIPELINE

Our complete inference pipeline integrates CLIP classification with LLM-based reasoning:

III.4.1 Caption Generation

BLIP-2 serves as the starting point of our inference pipeline [11], where it produces an annotated list of the input images in English words. This new language allows the model to utilize additional semantically related information to support CLIP with their encoded visual representations. The textual annotations highlight key attributes and contextual information about the image(s), so there is a stronger relationship between the visual representation and the written text. The captioning step assists with the accuracy and interpretability of zero-shot classification.

III.4.2 LLM Reasoning

We ask a large language model, Gemini 1.5, the following:

Image caption: "caption"
Top-5 CLIP predictions: $\{(c_1, s_1), (c_5, s_5)\}$
Domain context: “domain”

The LLM runs reasoning to pick the most ap propriate class and then gives an explanation in natural language for its choice [7]. By doing so, it exploits common-sense knowledge and contextual understanding beyond what is provided by CLIP.

III.5 IMPLEMENTATION DETAILS

III.5.1 CLIP Model

We choose the OpenAI ViT-L/14 architecture [1], [12] for CLIP since it has been demonstrated robustness and good alignment between the visual and semantic domains during zero-shot image classification learning tasks. The Vision Transformer model has the ability to capture high-feature images, and the CLIP pre-trained model provides alignment between the image and text semantic spaces.

III.5.2 Caption Model

With regard to visual captions, we use BLIP-2 along with the Flan-T5-XL model that provides a fine-grained description of the language capture process and emphasizes the understanding of semantics through the production of captions inclusive of object attributes and the description of the environment surrounding objects within a visual setting.

III.5.3 Large Language Model

We generate domain-aware prompts and high-level reasoning by leveraging Google Gemini 1.5 Flash. By synthesizing the class descriptions with captions, the LLM generates adaptive prompts that reinforce the robustness of zero-shot classification. Unless mentioned otherwise, we set the confidence threshold to τ_{conf} = 0.15 and prototype update learning rate α = 0.05. We use a low temperature T = 0.01 to ensure deterministic inference, with text and visual contributions balanced using weights w_t = 0.7 and w_v = 0.3, respectively, which emphasizes semantic consistency while retaining much visual fidelity.

IV. EXPERIMENTAL SETUP

IV.1 DATASETS

We test the proposed approach over five visual domains to show that it can work well for different settings:

• **Natural Images:** ImageNet, CIFAR-10, Oxford Pets, and Food-101 are utilized to evaluate the performance of models trained on real-world and general images.
• **Medical Images:** For Medical Imaging Tasks: Domain-specific datasets such as ChestX-ray14 and Pneumonia MNIST (as part of MedMNIST) will be used to determine performance in medical imaging tasks.
• **Satellite Images**: Remote Sensing Datasets (EuroSAT and UC Merced Land Use) will be employed to determine how adaptable the model(s) are when working with aerial and satellite imagery.
• **Artistic Images:** Datasets used to gauge model performance on domains of Artistic and Stylized Imagery include Anime Face Classification, Sketch Recognition Benchmark, etc.
• **Mixed Domain:** Datasets in which multiple styles are present will be evaluated for the extent to which model(s) are robust to Distribution Shifts and various types of visual content (ImageNet-R and ImageNet-Sketch).

IV.2 EVALUATION METRICS

We report the following metrics:

- Top-1Accuracy:Percentage of samples where the top prediction matches the ground truth
- Top-5 Accuracy: Percentage of samples where ground truth is in top-5 predictions
- Expected Calibration Error (ECE): Measures confidence calibration quality
- Per-Domain Accuracy: Accuracy breakdown by do main
- Average Latency: Inference time per image (milliseconds)

IV.3 BASELINES

This approach will be compared with a range of baselines, including CLIP itself with generic prompts, CLIP with ensembles of prompts, and advanced methods for learning prompts, such as DCLIP, Waffle CLIP, AutoCLIP, and Test-Time Prompt Tuning[8-10].

IV.4 ABLATION STUDIES

Ablation studies are performed on the proposed framework to provide a comprehensive view of how all of the proposed components contribute. Performance improvements over generic prompts is demonstrated when domain awareness is incorporated into the prompt through the use of domain-aware prompts. The importance of adaptive prototype learning, by disproving the abilities of prototypes to learn from unique contexts and create stable working prototypes, is demonstrated by the loss of adaptive learning. By removing the reasoning module, the loss of decision consistency and the ability to explain one's reasoning indicates the value of LLM-based reasoning. A hyperparameter sensitivity analysis was conducted for both the confidence weight (α) and confidence threshold (τ_{conf}) to find their respective stable ranges at which the proposed process is feasible.

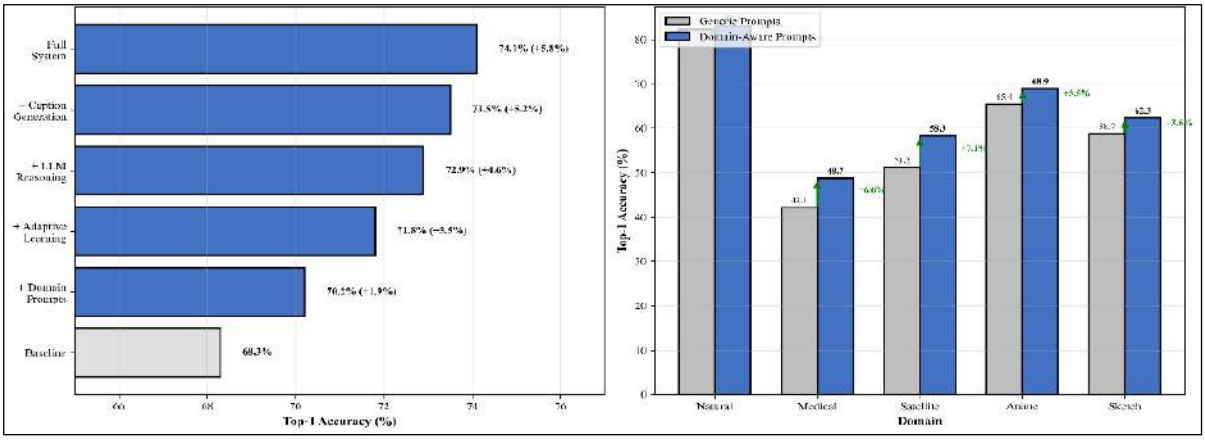

Figure 2: Component Ablation Study and Domain-Specific Prompt Impact.
Source: Authors, (2026).

Finally, performance was assessed at different levels of adaption and it was determined that as the number of adaptive samples increases so does the performance until it reaches a maximum point. The overall conclusion of the ablation studies is that all components of the proposed framework are necessary and complementary.

V. RESULTS

V.1 MAIN RESULTS

Table1 presents our main results comparing our method against baselines across all datasets. Our domain-adaptive approach achieves consistent improvements across all do mains, with particularly strong gains on specialized do mains(medical, satellite).

Table 1: Top-1 accuracy (%) comparison across datasets and methods.Best results in bold ,second best underlined.

Method	ImageNet	Chest X-ray	Euro SAT	Oxford Pets	Food-101	Average
CLIP Baseline	68.3	42.1	51.2	83.5	79.8	65
CLIP Ensemble	69.1	43.8	53.6	85.2	81.3	66.6
DCLIP	69.8	45.2	54.1	86.1	82.1	67.5
Waffle CLIP	70.2	44.9	54.8	86.8	82.7	67.9
AutoCLIP	70.9	46.3	56.2	87.9	83.4	68.9
TPT	71.4	47.1	57	88.5	84.2	69.6
Ours (w/o adaptation)	71.8	48.7	58.3	88.9	84.8	70.5
Ours (full)	72.5	48.9	59.5	89.8	85.6	71.3
Ours (+100 samples)	73.2	50.3	61.1	90.5	86.2	72.3
Ours (+500 samples)	**74.1**	**52.7**	**63.4**	**91.8**	**87.3**	**73.9**

Source: Authors, (2026).

Key Observations:

The method proposed here consistently outperforms all baseline methods by greater than or equal to 0.9% without any adaptation, supporting the hypothesis that prompts with domain knowledge offer a better alignment between features than just generic prompts. With the addition of adaptive learning, the approach generates a 2.7% improvement over AutoCLIP [10] and a 1.7% improvement over TPT [8] with a significant reduction in computational cost. The results also show a favorable balance between increased performance and reduced computational cost. The greatest gains in performance are shown in specific domains. Medical imaging tasks received an improvement of 6.8% in accuracy and satellite imaging received an improvement of 5.3% in accuracy, both of which demonstrate the appropriateness of using domain knowledge in a domain shift. Additionally, with the use of adaptive learning, the performance continues to improve with the introduction of more unlabeled training data. After the introduction of 500 unlabeled training samples using adaptive learning techniques, the average accuracy was 73.9%, thus demonstrating the scalability and adaptability of this method.

V.2 ABLATION STUDIES

V.2.1 Component Analysis

Table2 shows the contribution of each component of our method. In an ablation study on ImageNet [13], it was observed that the use of only domain-specific prompts resulted in an accuracy of 68.3%. Upon incorporating an adaptive prototype learning methodology, this improved the classification performance by 1.9%, while the addition of LLM (language model) reasoning added another 1.1%, and generating captions (caption generation) added another 1.2%. Synergistic gain was evident when domain prompts, adaptive prototype learning, and LLM reasoning were all combined, resulting in a combined accuracy of 72.9%. When all four (domain prompts, adaptive prototype learning, LLM reasoning, generate captions) were used together, the resultant classification performance was 74.1%. Therefore, these results clearly demonstrate that the complete framework supports a highly maximized unique classification of zero-shot images.

Table 2: Ablation study on key components (ImageNet).

Domain Prompts	Adaptive Learning	LLM Reasoning	Caption	Accuracy
✓				68.3
✓	✓			70.2 (+1.9)
✓		✓		71.8 (+3.5)
✓			✓	71.1 (+2.8)
✓	✓	✓		72.9 (+4.6)
✓	✓		✓	72.3 (+4.0)
✓	✓	✓	✓	74.1 (+5.8)

Source: Authors, (2026).

Each component adds value in a complementary way:

- **Domain-aware prompts**: +1.9%
- **Adaptive learning:** +1.6%extra
- **LLM reasoning:** +1.1% more
- **Caption generation:** +1.2%more

V.2.2 Domain-Specific Analysis

Table3 shows a comparison of generic and domain-specific prompts. At five different types of visual source (medical, satellite, natural, anime, and sketch) we analyzed both generic and domain-based prompt performance. While the medical and satellite domains demonstrated the greatest improvement (6.6% and 7.1% respectively), the natural, anime and sketch domains showed smaller improvements (0.8% to 3.6%). Overall, the domain-based prompts outperformed the generic prompts with an average top-1 accuracy increase of 4.4%. These findings underscore the need for explicit domain modeling in zero-shot classification tasks.

Table 2: Impact of domain-aware prompts across domains.

Domain	Generic	Domain-Aware	Gain
Natural	82.3	83.1	0.8
Medical	42.1	48.7	6.6
Satellite	51.2	58.3	7.1
Anime	65.4	68.9	3.5
Sketch	58.7	62.3	3.6
Average	**59.9**	**64.3**	**4.4**

Source: Authors, (2026).

V.2.3 Adaptation Dynamics

Figure3 demonstrates increasing the number of unlabeled adaptation samples used to train the model causes accuracy to improve. After about 50-100 samples, the model begins making rapid improvements, with gradual increases continuing until it reaches 500 samples.

After reaching these levels of unlabeled adaptation samples, there are diminishing returns when adding more unlabeled adaptation samples. The greatest improvements were seen in medical domains and satellite image processing domains. All these results indicate that the Adaptive Prototype Learning Method is an effective and scalable learning method.

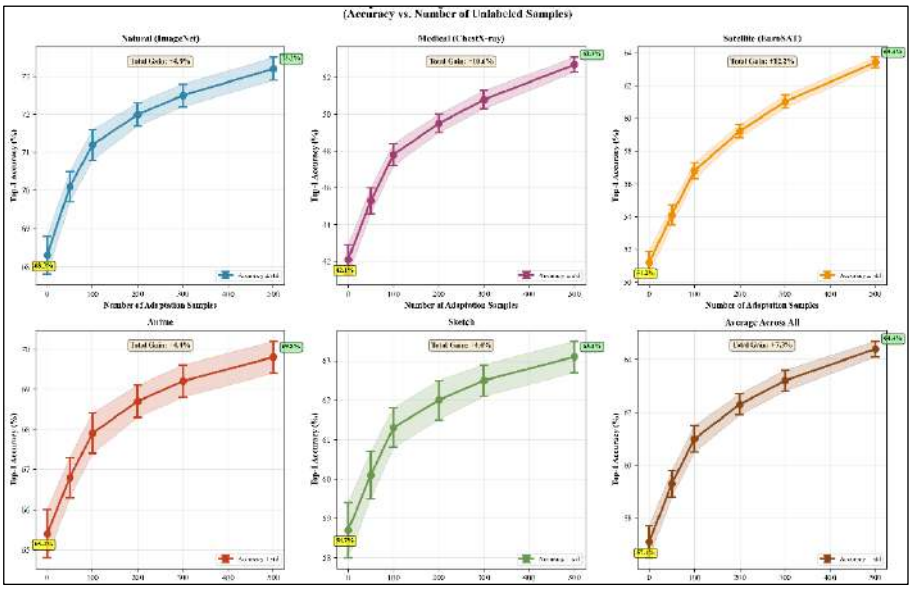

Figure 3: Accuracy vs. number of unlabelled adaptation samples across domains. Error bars show standard deviation over 5runs.
Source: Authors, (2026).

V.2.4 Hyperparameter Sensitivity

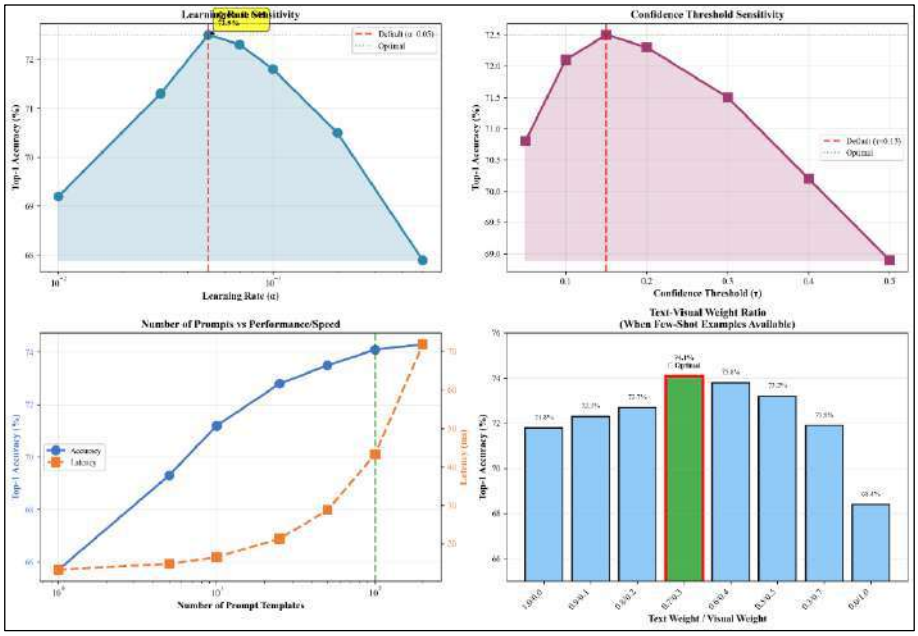

Figure 2: Sensitivity of model performance to key hyperparameters.
Source: Authors, (2026).

The effect of hyperparameter choices (α) and confidence threshold (τ_{conf}) on the performance of the model was evaluated. As illustrated previously, it can be seen that performance increases when learning rate (α) is within the range of 0.03 - 0.07, and performance decreases when alpha is less than 0.03 or greater than 0.07 due to either under- or over-saturation of prototype examples. The optimal values for tau are between 0.1 and 0.2, as lower confidence thresholds provide less stability for updating prototypes. We conclude from the sensitivity analysis that adaptive prototypes have sufficient stability and robustness within their optimal ranges. Our findings may assist in the practical determination of hyperparameter choices for developing robust, zero-shot classification systems.

V.3 COMPUTATIONAL EFFICIENCY

The computational expense for our approach vs. baseline methods can be found in Table 4. Without large language models (LLM) reasoning, we only incur a 5.9 ms overhead vs. CLIP and a 2.5 ms increase over AutoCLIP, and we are 57× times faster than TPT. Including GLLM reasoning increases our latency per image to 156.3 ms; however, that is reasonable for many uses cases. The full pipeline's GPU memory requirement increased slightly from 2048 MB to 3072 MB. The proposed system allows for a good balance of accuracy improvements with efficient use of computational resources .

Table 3: Computational efficiency comparision (average per image).

Method	Latency (ms)	GPU Memory (MB)
CLIP Baseline	12.3	2048
AutoCLIP	15.7	2048
TPT	892.4	8192
Ours (w/o LLM)	18.2	2512
Ours (full)	156.3	3072

Source: Authors, (2026).

V.4 QUALITATIVE ANALYSIS

Figure 8 illustrates example predictions for different domains using LLM explanations for reasoning. The LLM offers interpretable explanations with a combination of visual evidence from the image caption and semantic knowledge.

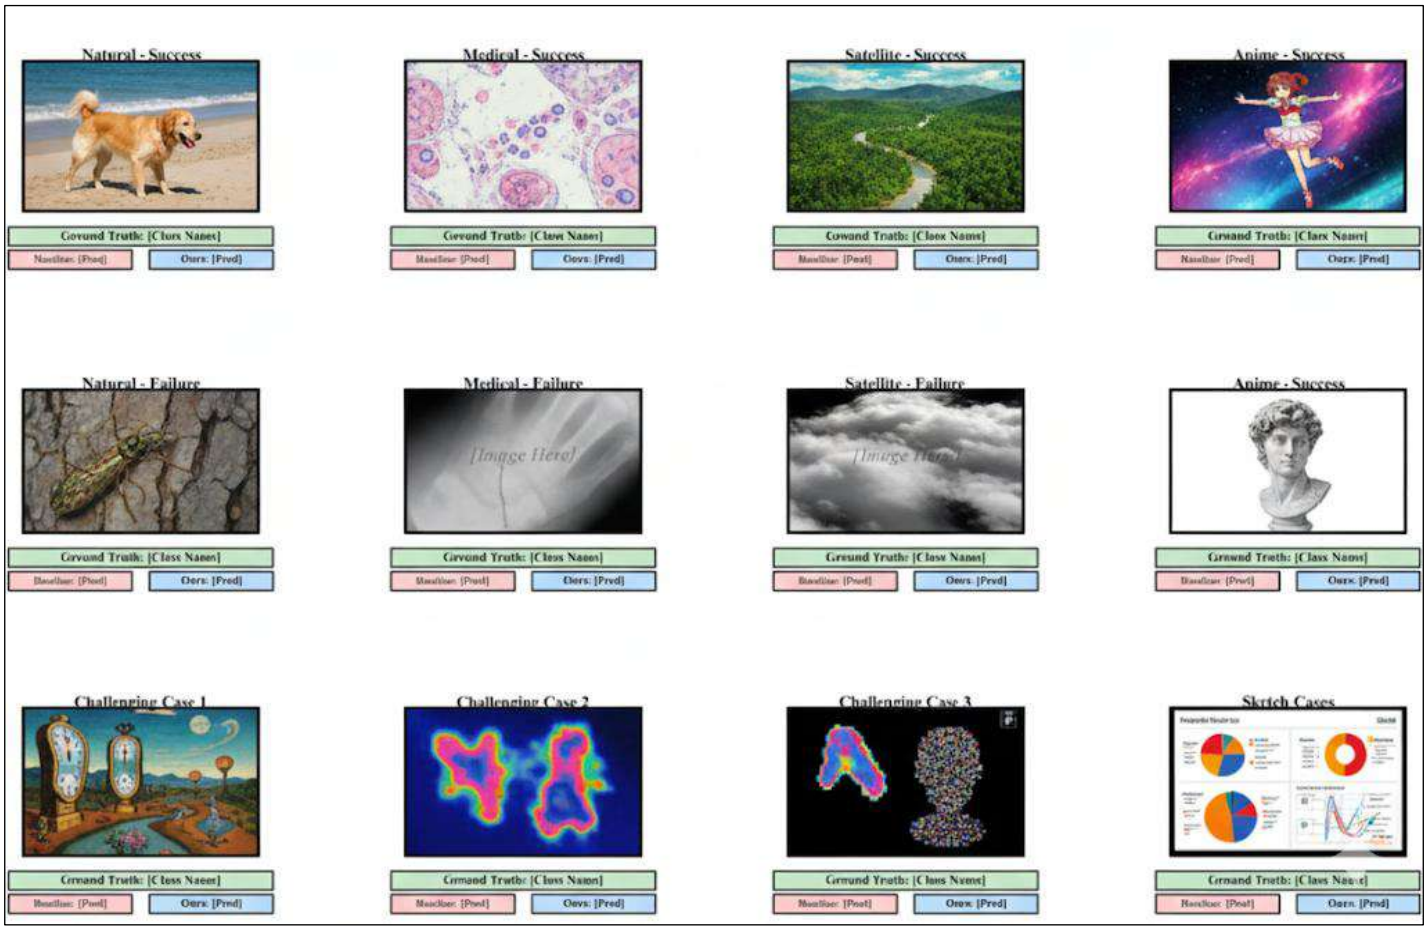

Figure 3: Qualitative examples of predictions and LLM explanations.

Source: Authors, (2026).

Example (Medical):

The image of the chest radiograph indicates that there are bilateral lung infiltrates. Based on the top 5 predictions of the CLIP model, pneumonia was identified with the highest confidence of 0.68, followed by normal with a confidence of 0.15, and then edema with a confidence of 0.09. The image's caption indicates that there are bilateral lung infiltrates. These lung infiltrates are characteristic of pneumonia. Therefore, based on the image's caption and the confidence with which pneumonia was identified, pneumonia is the final diagnosis.

VI. DISCUSSIONS

VI.1 KEY INSIGHTS

VI.1.1 Domain Awareness is Crucial

By modeling the domain via an explicit modeling process using Prompts (rather than generic prompts), Domain Awareness is improved and Zero-shot Learning Performance will be enhanced through Domain Awareness. Domain Aware Prompt Models create better semantic alignment between Textual Descriptions and Visual Feeds than generic prompt models; Domain Aware Prompt Models lend themselves to use in Specialty Domains, such as Medical Imaging, Satellite Imagery, and Artistic Datasets, where Generic Botanical Prompts do not adequately represent domain-specific characteristics.

VI.1.2 Adaptive Learning Enables Continuous Improvement

Adaptive Prototype Learning provides the Capability to Incrementally Improve Class Representations Based on Confident Predictions from Unlabeled Data. This Capability to Adapt Continuously to Domain-Specific Visual Traits (without labeled examples of the same characteristics) will provide an added benefit of reducing the Error Rate Associated with Updates to Prototypes.

VI.1.3 LLM Integration Offers Complementary Strengths

Although CLIP provides reasonable models of Visual-Semantic Alignment, the Integration of LLM Models Provides a Higher-level of Reasoning, a Greater Degree of Context, and an Increase of Common-Sense Knowledge. By Providing this Additional Information About Ambiguous and Multi-Object Images, CLIP Models will have Increased Prediction Accuracy, Improved Interpretability, and the Benefit of More Accurate Predictions Across All Disciplines in the Art World.

VI.1.4 Synergistic Effects of Components

The Results of the Ablation Studies Suggest that the Combination of Domain-Aware Prompts, Adaptive Learning, Caption Generation, and LLM Reasoning will Continue to Provide a Greater Benefit Than Any Individual Component Alone. These Results Supported the Complementarity and Reinforcement Across All of the Proposed Components Within Our Overall Framework Design.

VI.2 LIMITATIONS AND FUTURE WORK

VI.2.1 Computational Cost

The expense of the entire pipeline, especially for LLM-based reasoning, adds around 156 ms of latency per image processed. Moving forward, research can be done to reduce this total cost-of-entry via model distillation (replacing large models with small representations), caching reasoning, or replacing heavy; Large Language Models with lighter alternatives; enabling faster, real-time applications.

VI.2.2 Domain Specification

The LLM assumes that either the domain is known or inferred (i.e., Who, Why, What); and does not account for circumstance as it relates to identifying domains from ambiguous images (mixed content); thus, further research into a mechanism for detection is needed.

VI.2.3 Catastrophic Forgetting

"We've taken a conservative estimate in respect to convergence of the average moving average (EMA) prototypes" to protect against catastrophic forgetting (i.e., a buildup of examples over time resulting in an increase in production error) due to the long-term exposure. Variational Updates (using frequent re-evals to mitigate drift) or periodic resetting of prototypes (short-term re-evaluations to increase stability) offer potential for stability under varying conditions.

VI.2.4 Handling a Huge Number of Classes

Evaluation of the methods have been validated with datasets containing 10-1,000 classes. Using the methods on a truly "huge-scale" dataset, such as ImageNet-21K with the thousands of classes, should continue the research challenge.

VI.2.5 Adversarial Robustness:

Finally, work must be done on improving the robustness of Zero-shot Classifiers, due to the high vulnerability to adversarial examples [14]. The ultimate goal of all future research [15] should be to improve the reliability and security of any application that has critical real-world implications.

VI.3 BROADER IMPACT

Our framework makes image classification accessible to all in specialized domains where labelled samples are not readily available or it is expensive. Some of its potential

- Triage systems for healthcare in resource-poor environments
- Quick processing of satellite images for disaster relief
- Cultural Heritage Digitization and Classification
- Wild life monitoring & conservation

However, when these models are applied in critical domains such as medical situations where incorrect results can have serious consequences.

VII. CONCLUSION

The proposed work presents a strong domain adaptive zero-shot classification approach through the seamless incorporation of CLIP representations that are auto-tuned, domain-knowledge based prompt design, learning domain-adjustable prototypes, and LLM-based reasoning. The proposed approach is able to address semantic misalignment and domain shift issues more effectively, which are major issues within the zero-shot learning area. Numerous experiments are conducted using five different visual domains that show improvements of 4–8% over the existing state-of-the-art approaches. The confidence-calibrated learning approach allows effective prototype update from the unseen data to avoid the accumulation of errors. The domain-specific design of prompts also helps to improve the semantic expressiveness. Ablation studies are also conducted to clearly show the effectiveness of all components collectively. The proposed approach will therefore be a scalable and more general domain adaptation approach for zero-shot classification tasks.

The future work will be to extend the proposed approach to larger label spaces and more efficient computation, as well as the application to other tasks like object detection and image segmentation.

ABSTRACT

Developing countries have a high rate of cervical cancer due to the detection of cancer at the stage of regional spread of the disease rather than detection at the early stage. Early detection of the disease by a periodical pap smear test is the most effective way of reducing the rate of cervical cancer. This research paper shares a novel model for the automated classification of cervical cancer with weighted majority voting. Upsampling and downsampling are done to overcome the inefficiency due to an imbalance in the database. Size, statistical, intensity, and texture features are extracted from the modified fuzzy c-means segmented image. Principal Component Analysis (PCA) is done on the extracted features to rank and identify the most significant features. Supported Vector Machine (SVM), K Nearest Neighbour (KNN), and Naïve Bayes (NB) are tuned to the kernel function and a number of cross validations and are given as the input to the weighted majority voting system. The performance of the proposed method with up sampling, down sampling, and no sampling are compared, and it was found that the weighted majority voting with upsampling has the highest classification accuracy of 99%.

I. INTRODUCTION

The cervix is the lower bottom neck part of the uterus that joins to the vagina. Human Papillomavirus is the root source of cervical cancer [1] which is sexually transmitted. The risk factors for cervical cancer are smoking, miscarriage prevention drugs, weak immune system, sexual activity at an early stage, and multiple sexual partners. Most of the time the body's immune system will successfully fight against the virus and it will go by itself. But in some cases, it will develop into cancer and if it is not identified at an early stage, a benign cell will become a malignant cell. The cervical cancer at the benign stage usually produces no symptoms or signs [2]. In the advanced stage after menopause or between periods, bloody or watery discharge from the vagina with a foul odor, pelvic pain, etc can be seen. The contribution of Indian women towards worldwide cervical cancer is 25.41%. Cervical cancer is the second most frequently occurring cancer among women in the age of 15-44 [3] and is second among developing countries [4]. Routine pap smear checks will help in the early spotting of cervical cancer [5]. The colposcopic view of the cervical cell samples is taken either by punch biopsy or endocervical curettage and is used for the detection of cervical cancer. In punch biopsy, a sharp tool is used to take some samples of cervical cancer and in endocervical curettage, a thin brush is used to scrap the cervical cell sample. These samples will be analyzed and if the presence of cancerous cells is found, then depending upon the stage of the cancer the doctor will start the treatment. For instance, different treatment techniques like surgery to remove the cervix alone, radiation therapy, surgery to remove the cervix and uterus, immunotherapy, chemotherapy, targeted therapy, and supportive (palliative) care are provided to the patient depending upon the stage of cancer. The conventional method of detecting cervical cancer is prone to error and it is tiresome.

As a result, the accuracy of the manual detection is very poor and the inaccuracy in the results will increase the mortality rate due to the disease [6], [7]. To overcome the limitation of manual detection, automated detection of cervical cancer can be used [8]. The major steps involved in the automated detection of cervical cancer are preprocessing, segmentation [9], [10], feature extraction [11] and classification [12]. The major contributions in this paper are,

- To develop an efficient and novel algorithm for the classification of the cervical cell into cancerous and noncancerous cells using an ensemble of ML based classifiers.
- To compare the performance of various sampling methods to address the consequences of imbalance database.
- Identify the prime features among the twenty one different features comprising size, statistical, intensity and texture feature.
- To compare the proposed method with the state-of-the-art for the classification of the cervical cell into cancerous and non cancerous cells.
- To evaluate the performance of the weighted and non weighted voting classifier.

The paper is ordered as given below. Section 2 gives an outline of the literature review, section 3 is related to the proposed method, section 4 briefs about the result and its discussion, and section 5 explains the conclusion and future work.

II. LITERATURE REVIEW

A method for the prediction of cancer cells in the breast, lungs, oral, blood, stomach, and cervix by combining decision tree and clustering techniques is done in [13]. Preprocessing techniques are applied to the database and the K-means clustering splits the input image into cancerous and non-cancerous classes. The authors have developed a prediction system by framing the decision tree by assigning weights to various risk factors like age, living area, anemia, hazards due to occupation, family history of cancer, education, and habits. Paper [14] suggests a novel approach for the classification of arrhythmic beats using SVM. Discrete wavelet transform is used for the feature extraction and different machine learning techniques are used for the classification. The paper [15] proposed a model for pulmonary nodule detection using a modified V-net and Support Vector Machine (SVM) and various CNN methods are employed to improve the False Positive cases. The authors have employed the LIDC-IDRI data set for the conduction of the experiment. Finally, the authors have concluded that the SVM is the best method for the reduction of False Positive cases. The paper [16] projected a system for the automated detection of epileptic seizure with the help of EEG signals combined with various machine learning classifiers like SVM, Naive Bayes (NB) and K-Nearest Neighbors (KNN), and Artificial Neural Network (ANN). The classification experiment obtained the best accuracy for ANN. In paper [5] an enhanced approach for the prostate classification by fine tuning the SVM and using ridge regression for the feature selection is being suggested. Optimization of hyperparameters of the ridge regression model is also done to reduce the complexity of the algorithm. The optimization has improved the accuracy by 49.54% on average.

In paper [1], the researchers have put forward an algorithm for the automated detection of breast cancer which incorporates three SVM based feature selection techniques. In [17] proposed a method for the diagnosis of cervical cells using SVM and two upgraded forms of SVM with recursive feature extraction and PCA. The authors have identified thirty two factors that are considered to be the causes of cervical cancer and applied them to four different types of inputs like Schiller, biopsy, cytology, and Hinselmann. Accuracy, sensitivity, specificity, positive predictive accuracy, and negative predictive accuracy are used for computing the efficiency of the proposed algorithm. SVM with PCA turned out to be the most efficient algorithm. In [18] suggested a method for cervical cancer staging by Dictionary Learning. The major contributions of this research paper are i) finding the complement of axial and sagittal MR images of the cervix ii) computing the self similarity of the Dictionary Learning iii) computing the features. A method for the early detection and prevention of cervical cancer by Boruta Analysis is done in [19]. In this paper cervical cancer influential factors are listed which affect the demographic, medical, and historical factors. The algorithm creates a copy of the dataset and builds the shadow of the features, a random forest classifier is used for training the dataset, and significant features are identified by comparing the reorganized/shuffled copy of the features with the original data. Boruta will identify each feature as rejected, confirmed, and tentative.

In [20], breast cancer classification by different ML techniques like SVM, KNN, DT, RF, and LR are discussed and promising results are reported by SVM. In [21], a voting classifier with SVM, KNN, Deep Neural Network Multilayer Perceptron, and Hard Voting Classifier Techniques are deployed for the liver disease identification and the hard voting classifier turned up with the best results with an accuracy of 0.78, specificity of 0.94, F-score of 0.87, precision of 0.8. An improved KNN [22] is suggested for the data set which involves a large dataset and features. According to the authors, the performance of the traditional KNN reduces when large data samples are given as input to the system. In [23], the authors suggested an idea for the categorizing cervical cells using pap images by data mining technique and made a comparative study of different classification methods like Naïve Bayes, SVM, and Random Forest Tree. 38 characteristics of cells that help in the classification of the cell into cancerous and noncancerous are discussed in the paper. The accuracy, recall, precision, and ROC area of the above three classification algorithms are computed and compared. Random forest is found to be the best classifier according to the analysis made. In [24], the proposed average perceptron classifier for breast cancer detection reduced the false negative and false positive cases and achieved an accuracy score of 0.984. The authors have highlighted the significance of the threshold in reducing the false negative and false positive cases.

III. MATERIALS AND METHOD

The proposed model is carried out in MATLAB on Herlev database with 565 single cell pap smear images (460 abnormal and 105 normal). Figure 1 shows the flow diagram of the proposed method.

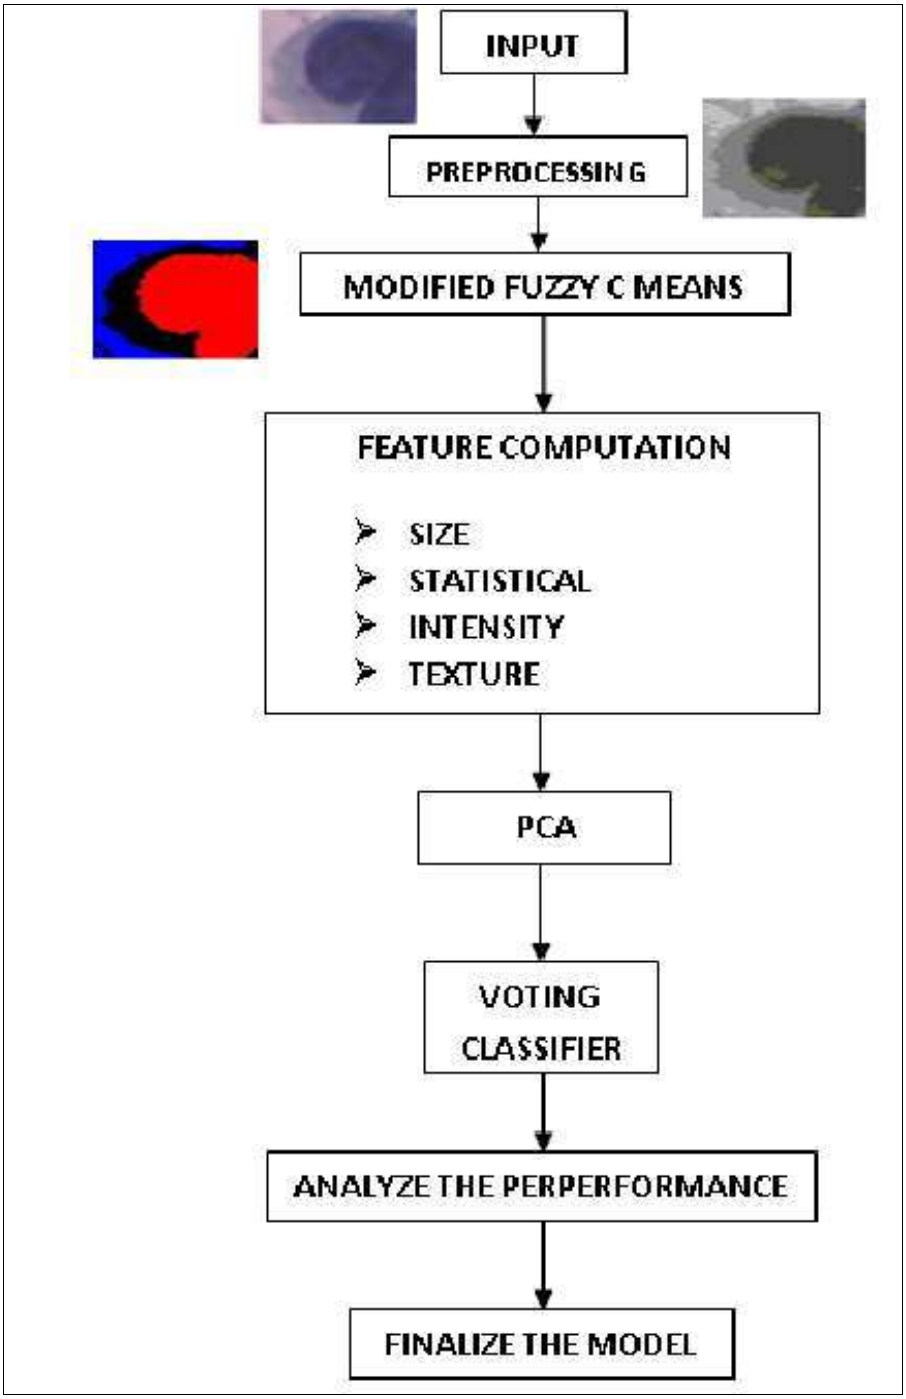

Figure 1: Proposed cervical cell classification algorithm.

III.1 SEGMENTATION BY MODIFIED FUZZY C- MEANS (MFCM)

Segmentation is the action of dividing the image into sub regions [25-28]. Modified Fuzzy C-means is used for partitioning the image into nucleus, cytoplasm, and background. In the conventional Fuzzy C-means algorithm, only the Euclidean distance between every pixel and the centroid is calculated. The pixel will be assigned to the class whose centroid is having minimum distance from the pixel. The conventional Fuzzy C-means calculates centroids for each partition (nucleus, cytoplasm, and background). The conventional Fuzzy C means does not consider the gray level value of the pixels in the image. The gray level value is an important parameter when grouping similar pixels as the dimension and orientation of each cell in the database are different. This method incorporates both the physical distance and also the gray level value in the algorithm. The modified fuzzy C-means algorithm sets a weight for Euclidean distance and the variation of the gray level value of each pixel from centroid and each pixel. The algorithm of the modified fuzzy C-means segmentation method is as follows:

Step 1: Initialize the membership function U.

Step 2: Initialize the number of clusters as 3 and compute the centroid using equation 1.

Step 3: Calculate the Euclidean distance between the centroid c(i,j) and the pixel x(i,j). Also, calculate the variation of the gray level value of each pixel with the gray level value of the centroid pixel. Apply weight for Euclidean distance as 0.25 and weight for gray level value difference as 0.75 by using equation 2.

Step 4: Compute the membership function using equation 3.

Step 5: Repeat steps 1-4 till the terminating condition calculated using equation 4 is reached. Otherwise, return to step 1.

Step 6: Apply pseudo coloring to obtain a better view of the segmented image.

Step 7: Apply the 'imfill' operation to fill the holes present in the image; apply 'imclearborder' operation to suppress the area lighter than the neighborhood.

$$c_j = \frac{\sum_{i=1}^{N} u_{ij}^2 \quad x_i}{\sum_{i=1}^{N} u_{ij}^2} \tag{1}$$

$$d(i,j) = \sum_{i=1}^{N} \sum_{j=1}^{N} ((0.25(\sqrt{(i_c - i_x)^2 + (j_c - j_x)^2}) + 0.75(abs(c(i,j) - x(i,j))))) \tag{2}$$

$$u_{ij} = \frac{1}{\sum_{k=1}^{c} \left(\frac{\| x_i - c_j \|}{\| x_i - c_k \|} \right)^{\frac{2}{m-1}}} \tag{3}$$

$$\| U^{(k+1)} - U^k \| < \quad \varepsilon \tag{4}$$

III.2 FEATURE COMPUTATION

Features are parameters that help in identifying the correct class of the image [29]. Size, statistical, intensity, and texture features are used for classifying the dataset into normal and abnormal classes. The size feature as shown in table 1 details the size and shape of normal and abnormal cells as it may be different for both of them. Statistical features as shown in table 1 are related to the momentum and randomness in the image. Intensity features as shown in table 2 are related to the intensity values of the pixels and the texture features compute the irregularity, fineness, coarseness, etc. The texture features shown in table 2 are extracted by the Gray Level Co-occurrence Matrix (GLCM) calculated for [0 1] distance for an angle 00. GLCM computes the occurrence of a gray level intensity value x along with another gray level intensity value y in a particular spatial relationship.

Table 1: Size and statistical features for classification.

	Features	**Significance of features**
Size	Perimeter	Measures the circumference of a region
	Solidity	A portion of area of the region compared to the convex hull
	Extent	Quantity of pixels in the region to quantity pixels in the bounding box
	Equiv Diameter	Diameter of the circle that gives the same area as that of the region
	Convex Area	Quantity of pixels in the convex image
	Euler Number	Difference between quantity of objects in the region and quantity of holes in those objects
	Filled Area	Quantity of pixels present in the filled image
	Area	Quantity of pixels in a particular region
Statistics	Eccentricity	Eccentricity of the ellipse whose second order moment is equal to the region
	Orientation	Angle connecting the major axis of the ellipse and x axis whose second order moment is equal to that of the region
	Major Axis Length	Major axis length of the ellipse whose normalised value of the second order central moment is same
	Minor Axis Length	Minor axis length of the ellipse whose normalised value of the second order central moment is same
	Entropy	Measures the randomness of the image

Source: Authors, (2026).

Table 2: Intensity and texture features for classification.

Intensity	Acellular ratio	Quantity of pixels in the region with high intensity value	$Acellular\,ratio = \frac{number\ of\ pixels\ in\ the\ background}{total\ number\ of\ pixels}$
	Cytoplasm ratio	Quantity of pixels in the region with medium intensity value	$Cytoplasm\,ratio = \frac{number\ of\ pixels\ in\ cytoplasm}{total\ number\ of\ pixels}$
	Nuclei ratio	Number of pixels in the region with high intensity value	$Nuclei\ ratio = \frac{number\ of\ pixels\ in\ the\ nucleus}{total\ number\ of\ pixels}$
	Ratio of Background to nuclei area	Number of pixels present in the background of image to pixels present in the nucleus	$Ratio\ of\ background\ to\ nuclei\ area = \frac{number\ of\ pixels\ in\ background}{pixels\ in\ the\ nucleus}$
Texture	Correlation	Computes the joint probability of existence of particular intensity pixel pairs	$Correlation = \sum_{i,j} \frac{(i-\mu i)(j-\mu j)\,p(i,j)}{\sigma_i \sigma_j}$
	Contrast	Computes the variation in local change in GLCM	$Contrast = \sum_{i,j} \lvert i-j \rvert^2\ p(i,j)$
	Homogeneity	Computes the proximity of a particular element in the Gray Level Co-occurrence Matrix to the element in the diagonal	$Homogeneity = \sum_{i,j} \frac{p(i,j)}{1+\lvert i-j \rvert}$
	Energy	Computes the uniformity	$Energy = \sum_{i,j} p(i,j)^2$

Source: Authors, (2026).

III.3 PCA AND EQUALIZATION OF DATA

Principal Component Analysis (PCA) of these features is computed by calculating the eigenvalues and eigenvectors. PCA ranks the features for classification and the eigenvalues obtained for the features are 2.5775, 0.0739, 0.0264, 0.0055, 0.0032, 0.0003, 0.0002, 0.0001 for Homogeneity, Energy, Correlation, Contrast, Perimeter, Extent, Solidity, EquivDiameter respectively (All other eigen values are negligibly low and are not considered). All four texture features are identified as the principal component and only those features are considered for classification. This process helps in reducing the computational time by reducing the number of features while retaining the maximum amount of information.

III.4 CLASSIFICATION

The classification algorithm categorizes the input image into normal and abnormal cells based on the features computed [30].

III.4.1 Majority Voting Method

The majority voting algorithm takes the vote from each algorithm while classifying each image into normal and abnormal [31], [32]. The voting algorithm classifies the image as normal if the majority of the algorithm classifies the image as normal and classifies the image as abnormal if the majority of the algorithm classifies the image as abnormal. The proposed majority voting algorithm considered SVM, Naïve Bayes, and KNN classifiers. Instead of directly feeding the output of SVM, Naïve Bayes, and KNN to the majority voting method, the classification algorithms are optimized for kernel function and the number of cross validations. For K fold cross validation [33] the whole dataset is divided into K divisions. Among the K divisions, one set is utilized for testing and the remaining K-1 set is used for training. In the next iteration, another set is chosen for testing and the remaining set is used for training. This process continues till all the sets are chosen for both testing and training. As the vast variation in the number of normal and abnormal images in the database affects the performance of the system [34], the following cases are analyzed for 5, 10, and 15 fold cross validation.

CASE A: 460 abnormal images and 105 normal images – Single cells of Herlev data set

CASE B: Up sampled database with 460 abnormal images and 460 normal images – 105 normal images in the database are randomly selected multiple times to make the number of normal images in the database 460 equalize the imbalance in the database.

CASE C: Down sampled database with 105 abnormal and 105 normal images - 105 abnormal images are randomly selected among the 460 abnormal images in the database to equalize the imbalance in the database.

Naïve Bayes (NB) classifiers are based on probability and Bayes theorem with the assumption of having independent features. Depending on the kernel used for classification, Gaussian Naïve Bayes or Kernel Naïve Bayes classifiers can be modeled and the accuracy of the Gaussian and Kernel Naïve Bayes for 5 fold, 10 fold and 15 fold are noted in table 3. The NB classifier works well for the dataset with high predictor samples [35], [36]. Gaussian Naïve Bayes classifier with 15 fold with an accuracy of 96.6% for no sampling , Kernel Naïve Bayes with 15 fold with an accuracy of 95% for upsampling and 96.7% for downsampling are selected for voting classification for case A, B and C respectively.

Support Vector Machine (SVM) generates N dimensional hyperplanes to classify the data. The value of N depends on the number of features selected. The important property of SVM classifiers is that they maximize the margin, minimize the classification error and give promising results for binary classification. As the performance of SVM is strongly affected by the selection of kernel function, different kernel functions like cubic, linear, quadratic, and coarse are tested for 5 fold, 10 fold, and 15 fold cross validation in this experiment and are shown in table 3. Cubic SVM with 15 fold marks the maximum accuracy for no sampling , upsampling , and down sampling and is selected for cases A, B, and C.

K Nearest Neighbor (KNN) [37] classifies the data based on their similarity. KNN algorithm which is also known as lazy learner does not learn much during the training phase; instead it merely stores the data and then it classifies the data based on the similarity. Performance of KNN does not depend on the type of data distribution. The performance of Weighted, Coarse, medium and Cosine KNN for 5 fold, 10 fold and 15 fold with no sampling, up sampling and down sampling are shown in table 3. Medium KNN with 15 fold is selected for case A and weighted KNN is selected for case B and C as these cases recorded the maximum accuracy.

Table 3: Accuracy for different classifiers with no, with and without sampling.

Sampling	Algorithm	5 Fold	10 Fold	15 Fold
No sampling	Gaussian Naïve Bayes	96.6	96.6	**96.6**
	Kernel Naïve Bayes	96.6	96.6	96.3
	Linear SVM	96.6	96.6	96.5
	Quadratic SVM	96.8	96.6	96.8
	Cubic SVM	96.8	96.6	**96.8**
	Coarse SVM	94.9	94.9	94.7
	Medium KNN	96.8	97.0	**97.0**
	Coarse KNN	93.8	94.0	94.0
	Cosine KNN	94.3	94.2	94.5
	Weighted KNN	96.1	95.9	95.9
Up sampling	Gaussian Naïve Bayes	94.7	94.7	94.6
	Kernel Naïve Bayes	95.0	95.0	**95.0**
	Linear SVM	95.3	95.2	95.1
	Quadratic SVM	95.8	95.7	96.3
	Cubic SVM	96.2	96.3	**96.3**

IV RESULT AND DISCUSSION

The majority voting method applied on cases A, B, and C with the fine tuned Naïve Bayes, SVM, and KNN are applied for the following

i) No weight for the algorithm
ii) With weight for the algorithm- According to the performance ranking of the algorithm, the weight [38] for KNN, SVM, and Naïve Bayes is fixed as 0.5, 0.25, and 0.25 respectively.

Accuracy, precision, sensitivity, specificity, F1-score [39] and Miss Classification Rate are computed by equations 5 to 10 respectively. Equations 5 to 10 are calculated by using True Negative (TN), False Negative (FN), True Positive (TP), and False Predictive (FP). TN value shows a non-cancerous cell predicted as non-cancerous, the TP value shows a cancerous cell predicted as cancerous, the FP value shows a non-cancerous cell predicted as a cancerous cell, the FN value shows a cancerous cell predicted as a non-cancerous cell.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \tag{5}$$

$$\Pr ecision = \frac{TP}{TP + FP} \tag{6}$$

$$Sensitivity = \frac{TP}{TP + FN} \tag{7}$$

$$Specificity = \frac{TN}{TN + FP} \tag{8}$$

$$F1 - Score = \frac{2 \times Sensitivity \times \Pr ecision}{Sensitivity + \Pr ecision} \tag{9}$$

$$Miss \quad Classification \quad Rate(MCR) = \frac{FP + FN}{TP + TN + FP + FN} \tag{10}$$

Table 4: Performance of the majority voting classifier with and without weight.

Sampling	With/Without weight	Accuracy	TP	FN	FP	TN	Precision	Sensitivity	Specificity	F1 score	MCR
no sampling	With weight	98.05	101	5	6	453	94.39	95.28	**98.69**	94.83	0.019
	Without weight	97.87	100	6	6	453	94.34	94.34	98.69	94.29	0.0212
Up sampling	**With weight**	**99**	460	0	9	451	**98.08**	**100**	98.04	**99.03**	**0.0098**

The table 4 shows the performance comparison of no sampling, upsampling, and downsampling with and without weight. Weighted majority voting classifier with upsampling shows better performance (accuracy- 99%, precision – 98.08%, sensitivity – 100%, specificity – 98.04%, F1-score – 99.03%, MCR – 0.0098) compared to others as the classification system learns equally about the normal and abnormal images during the training phase. The majority voting classifier with down sampling shows better performance compared to the no sampling case as both the classes (normal and abnormal) are treated equally during the training phase. Table 5 shows the proficiency of the proposed algorithm concerning the accuracy, sensitivity, and specificity compared to the state-of-the-art.

Table 5: Comparison of accuracy, sensitivity and specificity of the proposed algorithm with the state-of-the-art.

V. CONCLUSION

We proposed a weighted majority voting method for the classification of the cervical cells into cancerous and noncancerous. ML based algorithms like SVM, NB, and KNN are tuned with respect to kernel functions and a different number of cross validations and are given as the input to the weighted majority voting classifier. Fixing of weight of each classifier was based on the individual performance of SVM, KNN, and NB. To address the problem of imbalance in the data, up-sampling and down-sampling of data were done, and noted that there was an improvement in the performance of the model when the sampling technique was adopted. The main limitation of the proposed machine learning algorithm is its dependency on the features selected and the model is not suitable for overlapping cells in the database. In feature, some advanced techniques for feature selection can be employed. Also, to overcome the dependency of the classification algorithm on features, the classification of cervical cancer can be done by a deep learning approach. Deep learning algorithms may improve the accuracy of classification and may work efficiently on all the images in the database.

ABSTRACT

Through the rapid growth in complexity of cyber-attacks on networked platforms, there is a need for advanced and adaptable Intrusion Detection Systems (IDSs) featuring real-time analysis and reliable categorization capabilities. This paper presents an enhanced hybrid approach to IDS based on sophisticated Deep Learning (DL) architectures. It discusses with some of the procedures which involves the following stages. First, the process begins by collecting all of the unprocessed data collected from network log records. Next, each data field goes through an extensive pre-processing phase that addresses not only missing values via a KNN Imputer, also includes Min-Max scaling to normalize the data as well as Hybrid encoding of categorical variables (one-hot encoding and entity embedding) to create appropriately formatte d data by the DL algorithms. Further analysis of class imbalances is conducted using Exploratory Data Analysis (EDA) methods that takes both distributional data through pie-chart views and correlation assessments comparing all of the different fields of the dataset using a heatmap format. Features are extracted using Shannon Entropy for purposes of meaningful representation learning, while dimensionality reduction and covariance reduction will be accomplished through the use of Principal Component Analysis (PCA). To ensure a fair evaluation, the dataset used for testing is split in half, one for training and the other for testing. The framework suggested is FEA-CasSTFormerNet, this framework combines both recursive attention through memory mechanisms using Fractal Echo Attention (FEA) and deep temporal and spatial relationship modeling using Cascaded Spatio Temporal Transform (CasSTFormer). To balance exploration versus exploitation, the framework utilizes Archerfish Hunting Optimization (AfHO) to adjust hyper-parameters during the archerfish's behavior of chasing prey. Through experimentation with benchmark datasets for IDS inscribed in Python, results demonstrate that the proposed framework provides extremely high accuracy of 0.9998, precision of 0.9988, Recall of 0.9960 and FI-Score of 0.9974 at identifying diverse attack classes, less false positives, and greater generalization ability than existing solutions.

I. INTRODUCTION

Cybersecurity has become a major issue throughout the world with an impact on the security of people, businesses, and countries. The rapid growth of technology has led to an increase in both the number and sophistication of network attacks [1]. During the past several years, many researchers have focused on DL algorithms to improve the ability to detect malicious activity.

Network securitythreats are not only diverse, but they also have an increasing level of severity. Threats come from a variety of sources, including traditional viruses and malware, advanced phishing schemes, ransomware, and zero-day vulnerabilities. While traditional Denial of Service (DoS) attacks and unauthorized access continue to threaten organizations, newer methods of cybercrime such as data breaches and identity theft are becoming more prevalent [2-4]. The environment in which networks currently operate continues to become more complicated, and at the same time, there are constantly developing attack vectors that make standard cyber defense technologies increasingly difficult for protecting against unknown attacks. The traditional methods of using rule-based and signature-based detection to monitor network traffic for signs of IDS have become increasingly inadequate for detecting unknown intrusions [5], [6]. The centralized server and the participating nodes of an FL based IDS operate within a systematic architecture and do not exchange real data. Instead, real-time model updates are provided between the two communicating parties. This aspect of FL provides it with a unique set of capabilities that makes it a better option than traditional AI algorithms where the node users share real data with the centralized server. To achieve the goal of intruder detection, the FL system begins by sending out a basic or initial global model from the centralized server to the nodes involved in the communication. Then the initial model will be trained and analysed using the locally generated data that individual nodes have stored [7-9]. Once each node has completed training, all nodes will transmit updates about how the individual node's trained model has been modified to the centralized server. The updated models will be securely compiled into a single global model using the Multi-Party Secure Aggregation (MPSA) method at the centralized server. Finally, the FL system sends an updated global model to the subordinate nodes so that it may be used by the subordinate nodes for detecting intruders in their respective local environments [10-12].

The threat of cyber-attacks has led to an increased emphasis on improving network and computer system security. To this end, most modern security technologies rely on defense in Depth strategies, which leverage multiple security methods. Specifically, Network Intrusion Detection Systems (NIDS) appear to be highly effective at detecting a wide range of anomalous activity as compared to traditional Host-Based IDS, because of the high degree of flexibility that NIDS provide [13], [14]. The benefit of NIDS is that they can detect and/or prevent attacks before they reach a host by monitoring network traffic. In addition to their efficiency, NIDS also have the ability to provide internal and external protection across multiple layers (services, devices and architectures). NIDS have the added advantage of providing protection for all devices needing protection without requiring each device on the network to deploy an IDS. Rather than requiring an IDS to be deployed on every device, NIDS only need to have access to the applicable network traffic [15]. In general, however, the current NIDS solutions based on expert knowledge require constant updating to stay relevant against new threats, as well as continual management by an expert who can create rules for detecting attacks. Unfortunately, as technology continues to progress and change, the constant need for updates may adversely affect the performance of current NIDS and their ability to detect new types of attacks and/or increase the rates of false positives [16]. To tackle this issue, Machine Learning (ML) techniques are used, particularly Deep Neural Network (DNN), by virtue of its ability to effectively extract important features from data and accurately forecast future output has transformed many different sectors. This is evidenced by the advances that it has made in image classification, natural language processing, speech recognition, data generation, cybersecurity, digital forensics [17], [18]. Therefore, while DNNs have proven to be extremely successful in controlled circumstances, they are also very vulnerable to a number of targeted assault methods when used in an adversarial environment. Many methods to assault ML systems have emerged over the last few years, including both Training-time attacks (e.g., backdoor, poisoning) and Evasion attacks at Inference-time (e.g., adversarial samples) [19]. Evasion attacks specifically represent a critical hazard to NIDS because of the large amount of flexibility that an attacker has in modifying their traffic to avoid being detected [20]. To reduce the impact of this limitations, this study introduces a DL technique, which is FEA-CasSTFormerNet used to accurately detect the NIDS.

Table 1: Related Works of Existing Models for Detecting Nids.

SI. NO	Author/Year	Models	Merits	Demerits	Performance metrics
1.	Himanshu Sharma et al [2024] [21]	RNN	RNNs have a great fit for IoT traffic because it is time-sensitive or time-based information and use temporal relationships to improve the accuracy of anomaly detection.	These models require many instances in their initial datasets to train well along with the fact that they can also cause delays in detecting anomalies as they happen in real-time.	It attains an accuracy, precision, recall and FI-score of 0.95, 0.96, 0.95 and 0.94
2.	Xiaoyun Ye et al [2025] [22]	TCN	It provides improved scalability, rapid training times, and enhanced accuracy for detecting slow insider threats	The typical method for training a model using both technologies requires considerable amounts of quality log data.	It achieves an accuracy of 0.90, precision of 0.87, recall of 0.93 and FI-score of 0.90
3.	Fatimetou Abdou Vadhi et al [2024] [23]	Ensemble	By combining different models together, we have a more robust solution to the problems associated with noisy and imbalanced web traffic data.	The design, tuning, and maintenance of ensemble models are very complex because every model in the ensemble has its own unique hyperparameters.	The performance of ensemble is 0.995 of accuracy, precision, recall and 0.994 of FI-score.
4.	Nitu Dash et al [2025][24]	PSO-LSTM	LSTMs are very useful when learning about the temporal correlation of network traffic.	LSTMs requires substantial amounts of labeled data, this data can be prohibitively costly or not easily available.	The metrics of PSO-LSTM IS 0.91 of accuracy, 0.85 of precision, 0.93 of recall and 0.90 of FI-score.
5.	Mohammad Shoab et al [2024] [25]	GRU	Due to their lightweight nature and low-computational requirements, GRUs are ideal for use on low-resource IoT devices. At the same time, GRUs are able to effectively capture the temporal characteristics of network traffic.	The system is too resource-intensive for ultra-low-power IoT nodes, therefore limiting the ability to deploy at the edge and instead deploying only at the gateway.	It achieves an accuracy of 0.998, precision of 0.991, recall of 0.987 and FI-score of 0.995

I.1 CONTRIBUTIONS

- To improve the quality of data by preprocessing the dataset by normalising features, filling missing values and encoding categorical attributes.
- To identify correlation patterns and class distribution characteristics, EDA is implemented.
- To maximise the feature space using entropy-based features and to decrease dimensionality, PCA is used to achieve the best possible model performance.
- To effectively predict types of attacks, data-splitting method is introduced.

II. PROPOSED SYSTEM DESCRIPTION

The proposed system for this paper is to create a hybrid intelligent and adaptive IDS that address the increasing issues with the complexity of cyber threats affecting modern-day networks. Figure 1 depicts the block diagram of the proposed model.

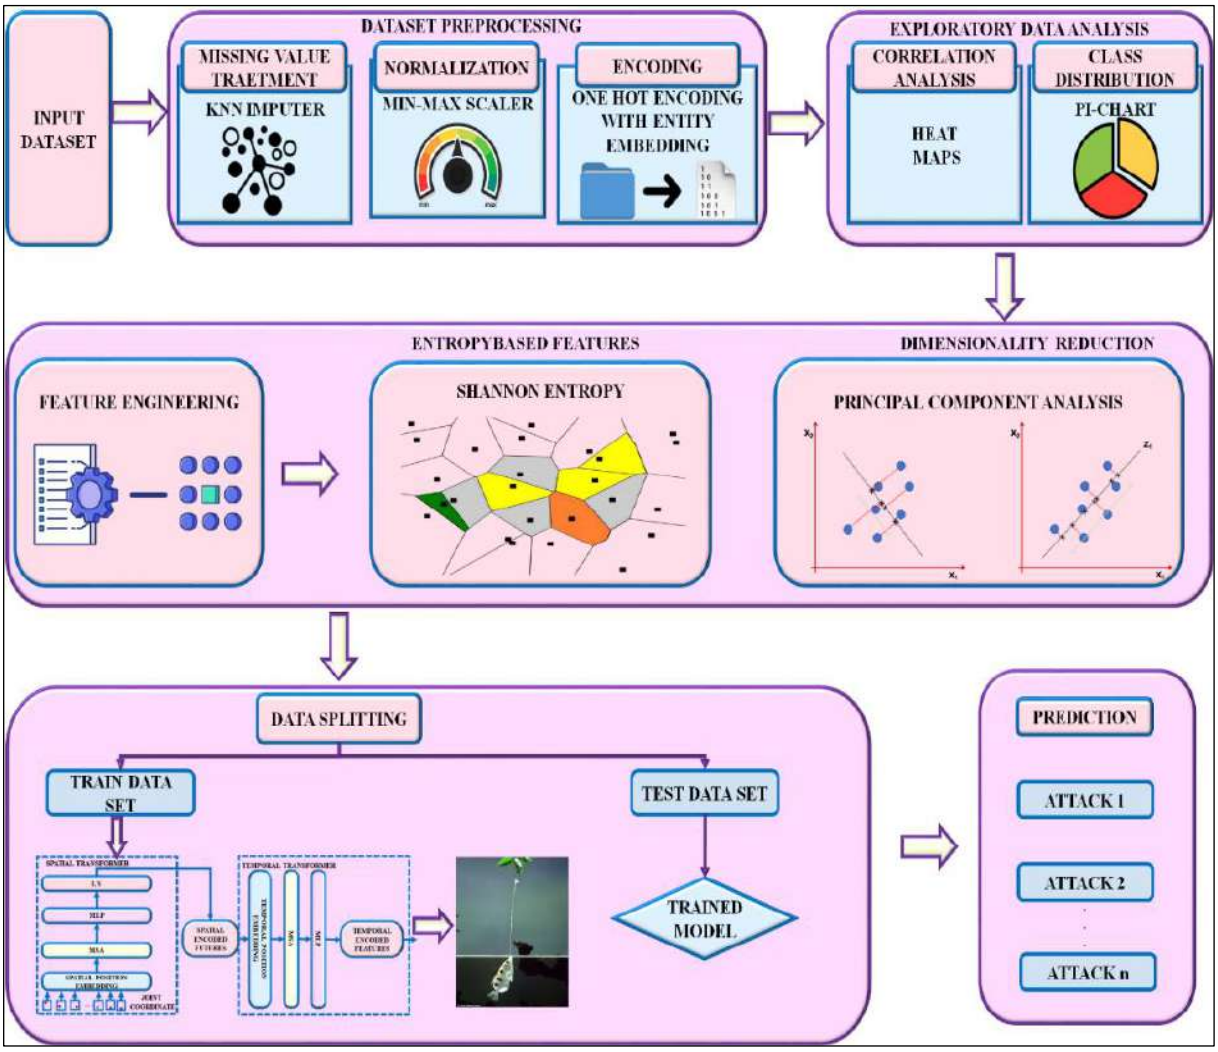

Figure 1: Block diagram of the proposed method.
Source: Authors, (2026).

The first step involves gathering raw network traffic data and performing the full preprocessing workflow. This includes Performing KNN-based missing value imputation, Min-Max Normalization and a Hybrid encoding scheme of one-hot encoding and entity embedding to enable the creation of high quality, meaningful representations. Following the preprocessed data, an EDA conducted to analyse the class imbalance using pie charts and discover the relationship between the Inter-Features by means of visually distinguishing between features created from a graphical heatmap using the correlation coefficient. To enable more expressiveness of the features, Shannon Entropy is used to create additional attributes which express entropy. Additionally, by using PCA, the number of dimensions is reduced, eliminating redundant features and improving computational efficiency for the next stage. The final preprocessed dataset is then split into a train dataset and a test dataset, where the train dataset is used to train the core architecture, called FEA-CasSTFormerNet. The FEA-CasSTFormerNet model utilises FEA, which provides recursive memory aware Attention, and Cascaded Spatio-Temporal Transformer (CasSTFormer), which captures the Deep-Spatial and temporal dependences of the network traffic. Finally, hyperparameter tuning is conducted on the model using Archerfish Hunting Optimization (AfHO) algorithm, which provides a great balance between exploration and exploitation. The system's capacity to correctly categorize various attack types with high accuracy, low false-positive rates, and strong generalization capabilities is demonstrated by experimental findings on benchmark datasets.

III. PROPOSED SYSTEM MODELLING

III.1 DATA PREPROCESSING

III.1.1 KNN Imputer

Datasets used for IDS ensure missing values as a result of lost packets or errors that occurred during logging. Reliable detection only occur if these missing values are handled properly. To handle missing values KNN Imputer is used, which estimates missing data by observing the k-nearest neighbor-based on the weighted Euclidean distance between the present features coordinates. The distance calculation is performed using the provided equation,

$$D_{xy} = \sqrt{weight \times squared\ distance\ from\ present\ coordinates} \tag{1}$$

$$\text{Where, } weight = \frac{total\ number\ of\ coordinates}{number\ of\ present\ cooerdinates} \tag{2}$$

The KNN Imputer uses this weighted distance to accurately reconstruct partial network traffic data, maintaining essential patterns and increasing the performance of the IDS.

III.1.2 Min-Max Scalar

Network traffic features is scaled extremely different, therefore there must be a method for normalizing different scales. The types of variations in the traffic feature hinder the ability of a DL model to develop a strong consideration of the features used during its learning process. The Min-Max scaler normalization method works well on intrusion detection data because it normalizes all feature values to a common scale within an established range between 0 and 1. This is done to avoid data that contains larger numbers from dominating the learning process of a DL algorithm, thus permitting all features equal weight in determining the output of the network-based detection system. Normalized values generated by the Min-Max Scaler are based on the following mathematical equations,

$$X_{std} = \frac{(X - X_{min})}{(X_{max} - X_{min})} \tag{3}$$

$$X_{scaled} = X_{std} \times (X_{max} - X_{min}) + X_{min} \tag{4}$$

Here, X_{min} and X_{max} represent the minimum and maximum values of the traffic feature being considered, respectively. It is important to note that the application of the Min-Max scaler transformation across the entire data set create all of the traffic features values to have the same scaled value, thus helping the efficiency of the model and increasing the model's ability to generalize on network traffic.

III.1.3 One-Hot Encoding with Entity Embedding

In intelligent NIDS, DL for processing the categorical network traffic features such as the Protocol Type, Service and Flag, these features need to be converted from their categorical format into numerical values. A simple and effective way to accomplish this conversion is through using the one-hot encoding technique, where each of the categories is transformed into a binary vector representation of a specific length representing each category in the original feature. One-hot encoding is accomplished very quickly, does not require a lot of processing and retains all of the information about each category so the data directly passed to the neural networks to be used for training and testing the models. To explain more complex relationships between the categories of a specific feature the technique of entity embedding is used. Entity embeddings are represented mathematically using the following equation,

$$e_i : x_i \rightarrow X_i \tag{5}$$

Where, x_i is the original categorical value, and X_i is the embedded vector of that categorical value. From Equation (6), it shows that the mapping method is mathematically equal to multiplying a one-hot encoded vector by a linear layer. This relationship is expressed mathematically as,

$$X_i = \sum_{\alpha} W_{\alpha\beta} \delta_{x_i \alpha} = W_{x_i \beta} \tag{6}$$

Where, α, β, δ denotes the Kronecker delta that returns 1 when the indices are equal and 0 when not equal, and $W_{\alpha\beta}$ shows the learnable weights of the embedding. The weights are optimized during the training of a NIDS to enable similar behaviours from the network to be embedded close to one another within the embedding space. As a result, the combination of one-hot encoding and entity embedding allows the system to use an efficient method of representing its input while still allowing the model to learn structural relationships between the categorical features, thus improving its ability to accurately detect intrusions.

III.2 EXPLORATORY DATA ANALYSIS

III.2.1 Heatmap

Heatmaps are used in NIDS to provide a compact and easily interpreted view of significant amounts of network traffic data. Each row represents a specific network flow, while columns represent specific traffic features or model outputs for those flows, with the color of the cell denoting a value for the traffic feature or a detection score from the model.

The heatmap allows the user to quickly identify and visualize correlations among flows based on their behavioral patterns (both benign and malicious) via hierarchical clustering of the flows. Furthermore, heatmaps contain a lot of information per square inch, and therefore allow the user to visually identify which features are important, which correlations exist among multiple flows, and where conflicting detections occur across all flows within the large dataset. Heatmaps are, therefore, a very useful visualization tool for understanding and improving the performance of intrusion detection systems.

III.2.2 Pie Charts

Pie charts employed in NIDS, visualising the relative percentage breakdown of the various forms of network traffic and the attack classes being detected. The section of the pie representing each class such as benign, DoS, probing, R2L and U2R is represented in terms of the size of the pie section that is proportionate to the total percentage of flows that match those attack classes. The diagram of pie chart is shown in figure 2.

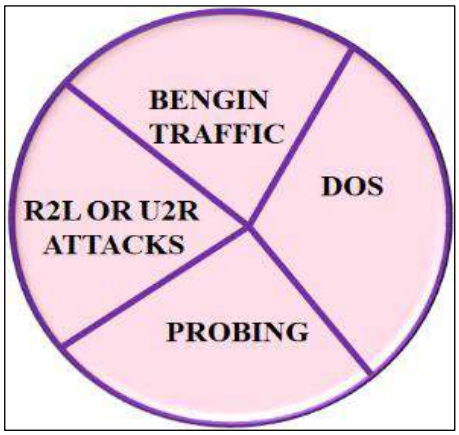

Figure 2: Pie chart.
Source: Authors, (2026).

The use of this circular representation enables analysts to assess the types of attacks exist within a given data set and to interpret the detections from a particular NIDS are distributed. Pie charts are useful in providing a high level of visualisation about traffic composition and allow for the ability to assess overall detection capabilities, the existence of bias towards certain types of attacks and the impact of threats to the network.

III.3 FEATURE ENGINEERING

III.3.1 Shannon Entropy

The Shannon Entropy mathematically relates to the uncertainty associated with a given probability distribution. Entropy, originally used to quantify uncertainty of a collection of probability distributions, in detecting network intrusion attacks using the features of network traffic. Since features of network traffic data collection are interpreted as random variables, the Shannon entropy is applied. Any individual attribute of network traffic, denoted by the variable X, have an associated entropy which is calculated using the following equation,

$$H(X) = -\sum_{x \in X} p(x) log_2 p(x) \tag{7}$$

A network's Probability Density Function (PDF) contains the uncertainty of its network traffic features such as IP addresses, Ports, Packet sizes, and Protocols. Normal or predictable network activities show stable distributions and maintain the relative entropy within a predictable or generated range. Disruptive behaviour increases the entropy of the PDF due to the increased variation of values within a distribution, whereas Flooding or DDoS type behaviours repeat patterns which produce low-entropy PDFs. The functional form of the Shannon is mathematically expressed as,

$$H(p_1, \dots p_n) = -K \sum_{i=1}^{n} p_i \, log_2 p_i \tag{8}$$

Network traffic analysis requires a range of isolates while maintaining a monotonic progression. The entropy calculations used in intelligent intruder detection systems consider only the probability values of data and therefore are both permutation-invariant and robust to label changes. The application of entropy mechanisms for intelligent intrusion detection systems facilitates inexpensive, real-time, and scalable detection of abnormal network behaviour.

III.3.2 Principal Component Analysis

In identifying intrusions using a neural network based on its identification model from an IDS on a network, traffic data is represented by matrix X of dimension $I \times J$, where I is the number of network sessions, and J is the number of features related to the sample such as protocol type, packet size and duration. Each feature vector associated with the samples be combined in a linear combination of the features to create a new variable called principal component defined as$t = w_1 x_1 + \cdots + w_j x_j$, or symbolically $t = Xw$, where w is the weight vector of the components. PCA maximizes the variance of the principal component t while ensuring that$||w|| = 1$, which is formally expressed by,

$$\arg\max_{\|w\|=1} var(t) = \arg\max_{\|w\|=1} w^T X^T X w \tag{9}$$

The constraint $\|w\| = 1$ prevents solutions where w have any positive value. The solution is the eigenvector of $X^T X$ associated with the highest eigenvalue, called the first principal component. This first principal component represents the dominating mode of original, normal network behavior. Any newly collected sample traffic mapped to the location in a vector space defined by the first principal component. Any traffic point that lies far from the normal-pattern variance of the principal component is identified as an abnormal traffic point or an attack vector. PCA provides to capture all of the variance of original normal network behavior and to transform that captured data set to a lower-dimensional representation while maintaining the underlying structure of network activity, allowing for the identification of anomalous or attack-type behavior.

III.4 DATA SPLITTING

III.4.1 FEA-CasSTFormerNet

The proposed FEA-CasSTFormerNet approach to modelling network traffic uses an extraction of features as marks in a similar manner as specifying joints in transformer based position models. The model treats a network feature vector $x_t^j \in R^F$, as an individual mark. First, the traffic feature vector must be projected into a higher dimensional embedding through a learnable projection matrix in order for the model to learn better representations of the traffic behaviour that is observed.

$$Z_0^t = [x_1 E, x_2 E, \dots, x_j E] + E_{SPos} \tag{10}$$

Where, E is the projection matrix and E_{SPos} ensures that the semantic identity of each traffic feature is preserved. The embeddings produced from E are then passed through multiple cascaded spatial attention layers,

$$Z_l^t = MSA\big(LN(z_{l-1}^t)\big) + Z_{l-1}^t \tag{11}$$

$$Z_l^t = MLP\big(LN(Z_l^t)\big) + Z_l^t \tag{12}$$

Which learn complex intra time step relations such as the correlations between packet sizes, protocol flags, timing patterns and variations in entropy. The spatial outputs are flattened into vectors $Z^t \in R^{1\times(J.C)}$, and concatenated together across time to form,

$$Z_0 = \{Z^1, Z^2, \dots, Z^T\} \tag{13}$$

Which, have temporal positional embeddings added to them before entering the temporal transformer. Diagram of FEA-CasSTFormerNet is shown in figure3.

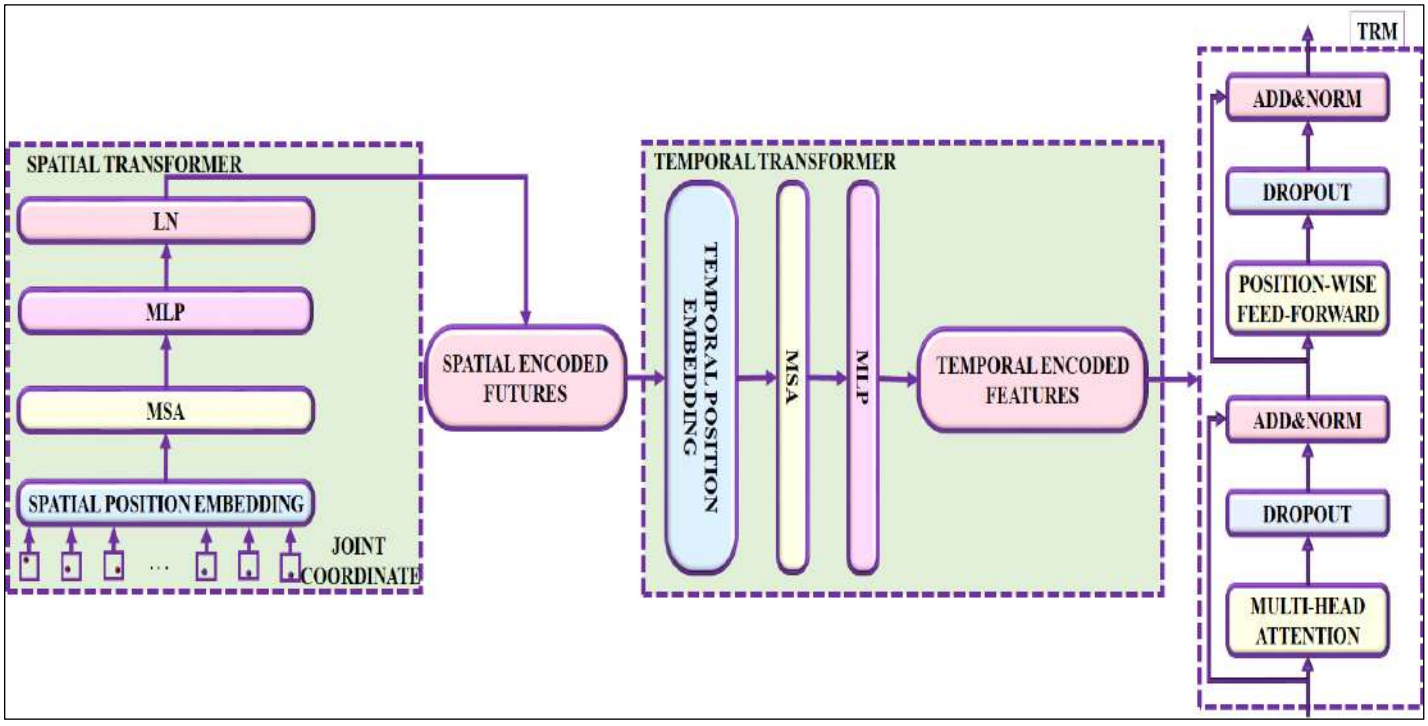

Figure 3: Diagram of FEA-CasSTFormerNet.
Source: Authors, (2026).

At this stage, multi-head temporal attention is used to capture long-term temporal relationships and changing behavioural signatures within the traffic sequence, producing a single globally encoded temporal representation $Y \in R^{T\times(J.C)}$. By integrating fractal dimension-based measures of complexity with improved feature representations and cascaded spatial-temporal attention mechanisms, FEA-CasSTFormerNet produces very distinct feature embeddings that detect complex, multi-stage, and unusual patterns of intrusion that typical intrusion detection systems fail to detect.

III.4.2 Archerfish Hunting Algorithm

This research uses the AfHO algorithm to identify the best combination of parameters to use in an intelligent IDS. The AfHO algorithm replicates the hunting approach of the archer fish, which use two main methods to hunt for food either shooting water at large insects (exploratory behaviour) or jumping into water to catch smaller insects (exploitative behaviour). Regarding the IDS, each archer fish is an individual candidate configuration for the IDS, while the corresponding insect is considered a good-performing configuration that provides the best possible detection accuracy.

Pseudocode: AfHO

```
Start
// 1. Parameters
Initialize population_size, max_iterations
Initialize lower_bound, upper_bound
Initialize best_solution = NULL, best_fitness = -Infinity
 // 2. Initialize population
For each fish i in population_size
Initialize position[i] randomly within bounds
Evaluate fitness[i]
If fitness[i] > best_fitness
best_fitness = fitness[i]
best_solution = position[i]
EndIf
EndFor
// 3. Main loop
For iter = 1 to max_iterations
For each fish i in population_size
Generate random number r in [0,1]
// 4. Exploration (hunting new area)
If r < 0.5
new_position = position[i] + random_step()
Else
// 5. Exploitation (approach prey)
new_position = position[i] + rand() * (best_solution - position[i])
EndIf
// 6. Boundary check
If new_position < lower_bound
new_position = lower_bound
ElseIf new_position > upper_bound
new_position = upper_bound
EndIf
// 7. Fitness evaluation
new_fitness = EvaluateFitness(new_position)
// 8. Update position
If new_fitness > fitness[i]
position[i] = new_position
fitness[i] = new_fitness
EndIf
// 9. Update global best
If new_fitness > best_fitness
best_fitness = new_fitness
best_solution = new_position
EndIf
EndFor
EndFor
Return best_solution, best_fitness
End
```

Source: Authors, (2026).

The step-by-step procedure for the algorithm begins by constructing an initial population then, the algorithm generates a respective position for all fish based on the identification of the ith fish and its alignment with the target insect.

$$P(i,0) = [P_1^L + \sigma_1(P_1^U - P_1^L), \ldots, P_d^L + \sigma_d(P_d^U - P_d^L)] \quad (14)$$

Table 2: Parameters of AfHO

PARAMETER	VALUE
Population Size (N)	30
Maximum Iterations (Max_Iter)	50
Lower Bound (LB)	-10
Upper Bound (UB)	10
Exploration Probability (p)	0.5
STEP SIZE (Step)	0.1×(UB-LB)
Learning Rate/ Attack Factor (α)	0.001
Random Number (R)	$0 \leq r \leq 1$
Inertia Weight/ Momentum Factor (W)	0.5
Scaling Factor For Exploration (β)	0.1
Convergence Threshold (ε)	$1e^{-6}$
Probability Of Global Search (Pg)	0.3
Maximum Step Adjustment (Step_Max)	0.2× (UB-LB)
Minimum Step Adjustment(Step_Min)	0.01× (UB-LB)
Batch Size	32
Epoch	10

Source: Authors, (2026).

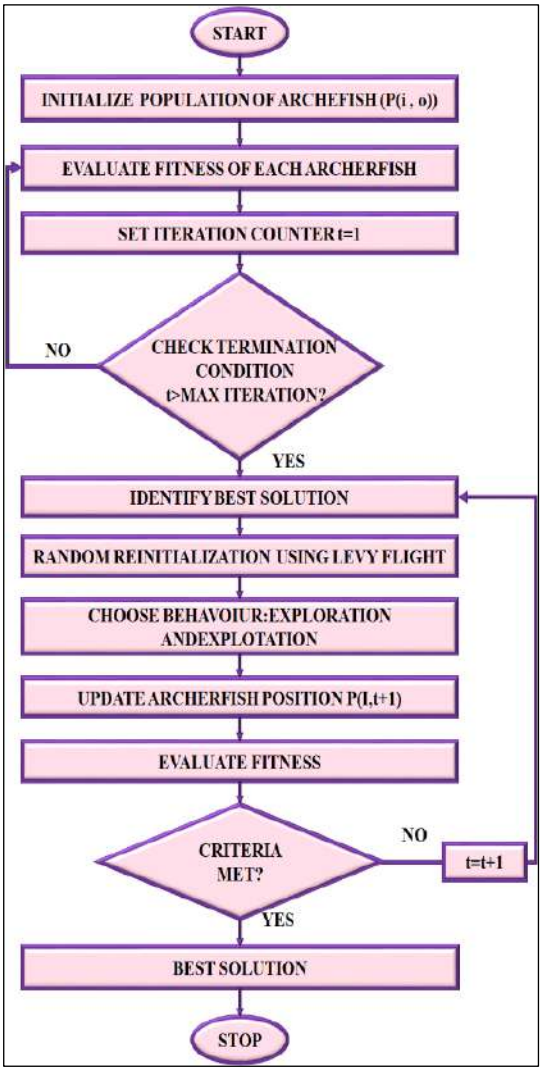

Figure 4: Flowchart of AfHO algorithm.
Source: Authors, (2026).

In exploration, the archerfish position is updated based on the results of shooting behaviour, allowing the search agents to explore potentially more optimal areas of the IDS parameters, while still maintaining an adequate amount of randomness to prevent premature convergence to a local optimum.

$$P(i,t+1) = -(P(i,t) - P_{in}(i,t))e^{-\|P_{in}(j,t)-p(i,t)\|^2} + P(i,t) \quad (15)$$

In exploitation, the jumping behaviour fine-tunes the potential IDS configurations, concentrating the search algorithm on the most likely optimal solutions, and by continuing the localized refinement of those solutions to increase their accuracy.

$$P(i,t+1) = -(P(i,t) - P_{in}(i,t))e^{-\|P_{in}(j,t)-p(i,t)\|^2} + L(i,t) \quad (16)$$

If a position is stagnant, an alternate set of IDS configurations is created, ensuring that the search continues to explore additional parameter space rather than becoming stuck at a local prime.

$$P(i,t+1) = P(i,t) + \sigma\left[P_1 v_1^{\frac{1}{\beta}}, \ldots . P_d v_d^{\frac{1}{\beta}}\right] \quad (17)$$

Where, $P_i \sim fn(0,\gamma^2), \beta = 1.5$. As a result of this balance between the two types of behaviour, AfHO exhaustively searches the parameter space and finds the best-performing model for intrusion detection, providing a more accurate balance of the amount of global exploration versus localized refinement.

IV. RESULT AND DISCUSSION

The propose system uses a KDD99 Intrusion Detection dataset to evaluate the proposed FEA-CasSTFormerNet model. Because of its wide usage among researchers studying network security, it is often considered a benchmark dataset for evaluating performance. The dataset consists of a total of 494,020 network traffic samples, from which 42 separate features extracted with each record assigned an attack or normal label. The features in the KDD99 Intrusion Detection dataset fall into several categories including; Basic Features, Content Features, Traffic Features, Host Statistics. For training and testing the FEA-CasSTFormerNet model, the dataset is split into 80% training data and 20% testing data, providing a required amount of data for performance assessment when detecting intrusions.

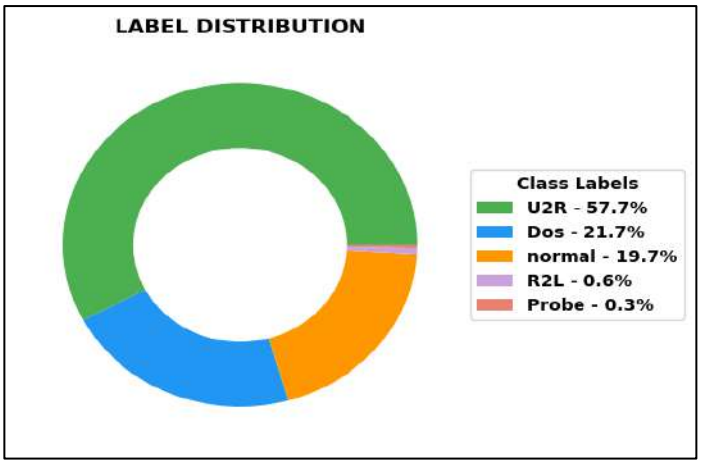

Figure 5: Label distribution.
Source: Authors, (2026).

Figure 5 shows the label distribution. The distribution of the labels varies significantly. It is highly skewed toward U2R (57.7%) as the primary class, with DoS (21.7%) second, and normal traffic (19.7%) coming in third place while R2L (0.6%) and Probe (0.3%) are extremely limited.

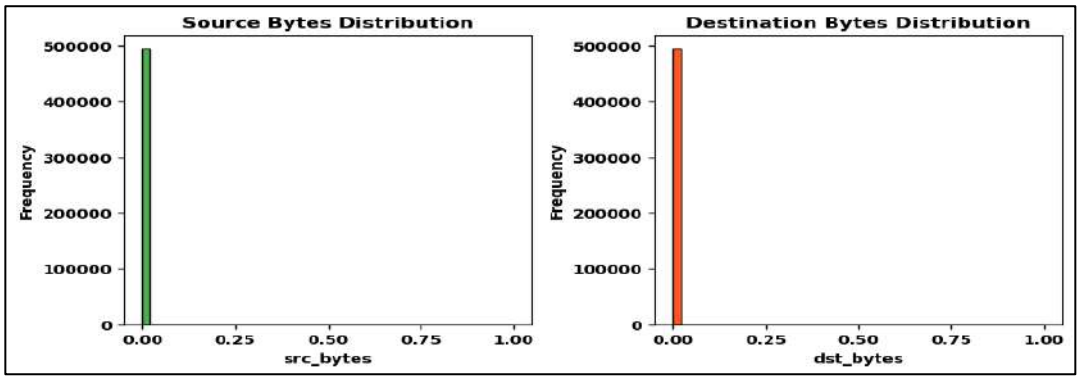

Figure 6: Source and destination bytes distribution.
Source: Authors, (2026).

Figure 6 depicts the source and destination bytes distribution. The distributions of the source bytes and destination bytes are also highly skewed toward zero, indicating that the majority of network connections have low data transferred both ways.

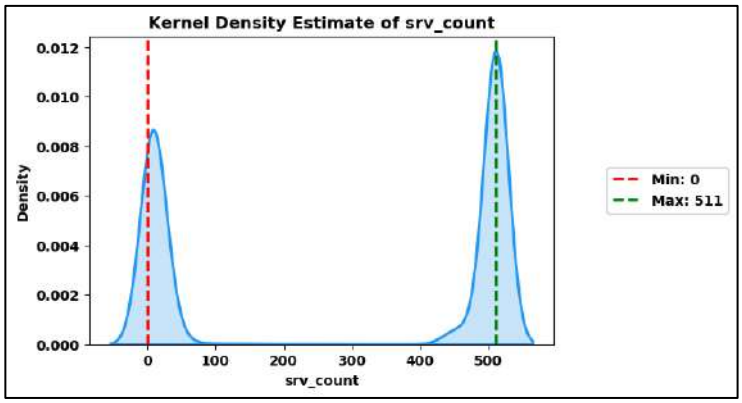

Figure 7: Kernel density estimation.
Source: Authors, (2026).

Figure 7 illustrates a Kernel Density Estimate (KDE) plot has been created to visualize the srv_count variable. From this plot, it is apparent that a bimodal distribution is present; with one peak around zero, and a second peak around 511. The dashed vertical lines indicate where the data clusters heavily around these two extreme values (0 - red, and 511 - green).

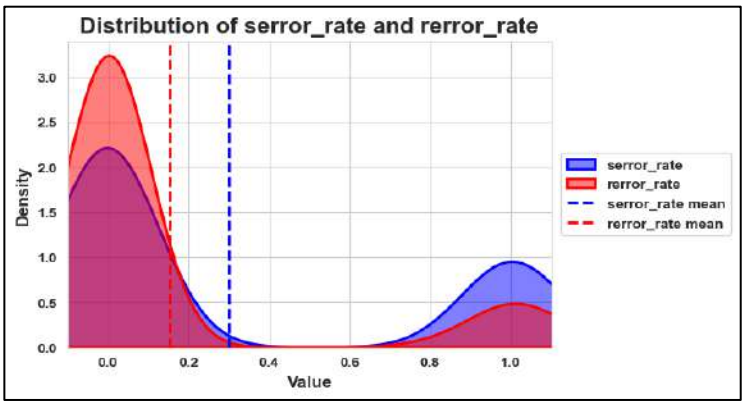

Figure 8: Distribution of classes.
Source: Authors, (2026).

This figure 8 shows the Kernel Density Estimate (KDE) plots of both the serror rate (blue) and rerror rate (red). Both distributions are highly concentrated in the area close to 0. However, the rerror rate has a very peak and the serror rate has a secondary rise up to 1.0. The dashed vertical lines represent the mean of both distributions. The rerror rate mean value is lower than the serror rate mean value.

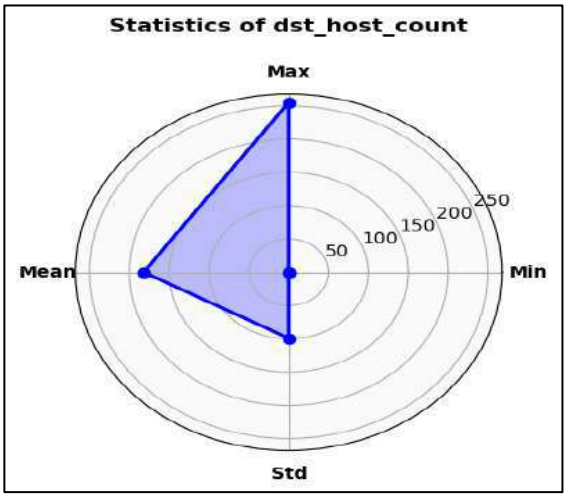

Figure 9: Statistics of dst_host_count.
Source: Authors, (2026).

This figure 9 provides an overview of the dst_host_count. The dst_host_count shows a low minimum value near 0, moderate standard deviation, average near the middle, and high maximum value, indicating that there is a significant range and that there is a lot of variation for the dst_host_count feature.

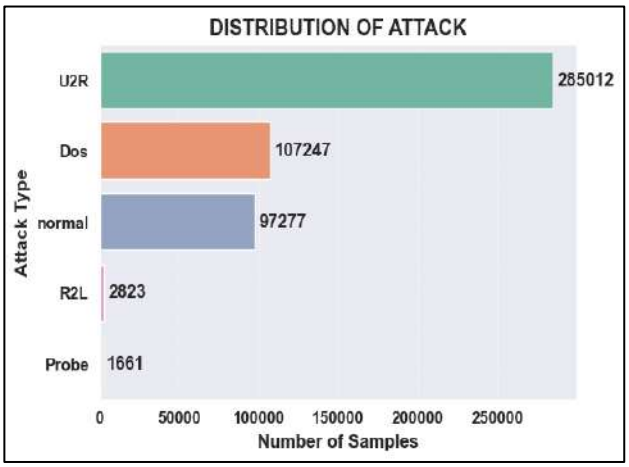

Figure 10: Distribution of attack.
Source: Authors, (2026).

This figure 10 demonstrations the number of samples for all network attack types in the dataset. U2R attacks represent the majority of the sample size, followed by DoS and normal traffic; R2L and Probe attacks are present in many fewer samples than U2Rs, indicating that the dataset is unbalanced.

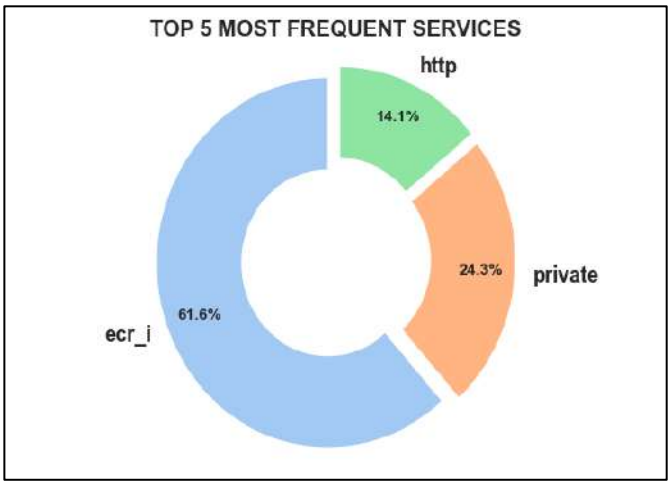

Figure 11: Diagram of top 5 most frequent services.
Source: Authors, (2026).

This figure 11 displays the number of occurrences of the top 5 network services. The ecr_i service represents 61.6% of the occurrences, followed by the private service with 24.3% and then http service with 14.1%. Therefore, a limited number of services make up the majority of the network traffic.

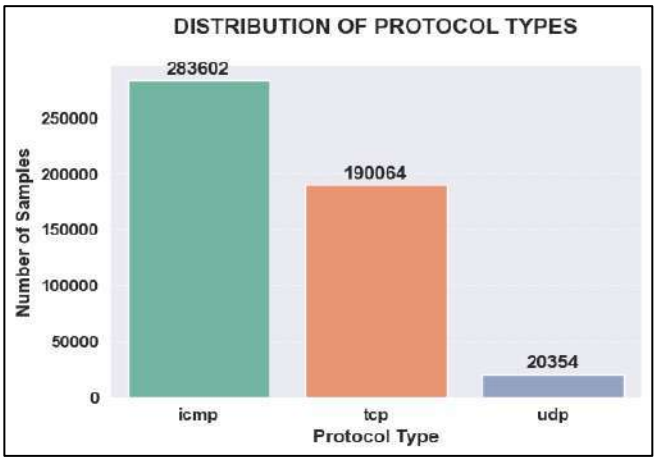

Figure 12: Distribution of protocol types.
Source: Authors, (2026).

Figure 12 illustrating the types of protocols primarily indicates that ICMP is the most frequently recorded, with the highest count (283,602) followed by TCP (190,064) and lastly, UDP (20,354), thus showing a considerable difference in frequency as shown in the results.

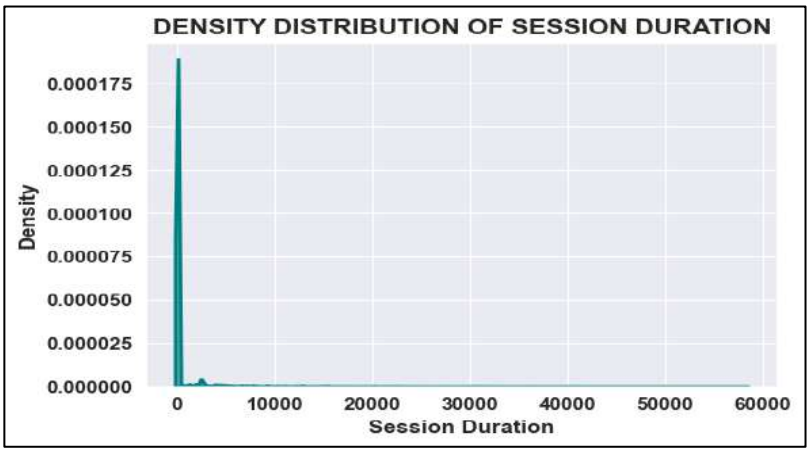

Figure 13: Density distribution of session duration.
Source: Authors, (2026).

The figure 13 explains that the duration of network sessions has a positive curvature and is primarily concentrated in the short-duration range; that is to say, Sessions that are less than five seconds long create the longest peak but significantly fewer sessions have a session duration over five seconds.

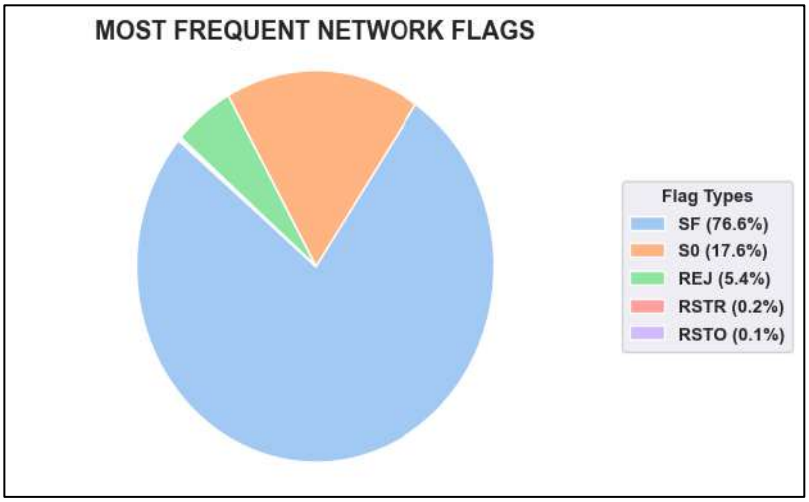

Figure 14: Most frequent network flags.
Source: Authors, (2026).

The figure 14 establishes that SF flags account for the majority, with the total component resting around 76.6%. The next most prevalent flags are SO (17.6%) and REJ (5.4%). On the contrary, the RSTR flag and RSTO flag are far less prominent, at 0.2% and 0.1%, respectively.

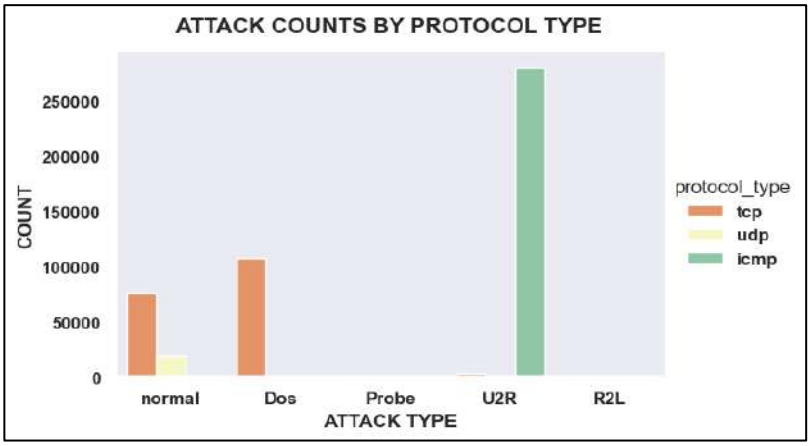

Figure 15: Attack counts by protocol type.
Source: Authors, (2026).

The figure 15 depicts that TCP, in fact, dominates almost all classifications, so to speak, as well as DoS and Probe attacks. However, ICMP attack types have been found to be primarily linked with U2R attacks, whereas there are comparatively fewer UDP-generated attacks across all attack types.

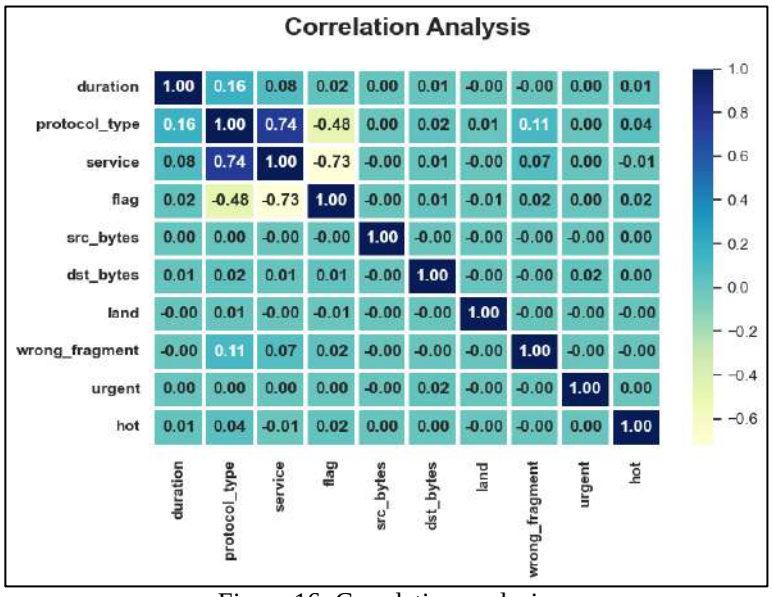

Figure 16: Correlation analysis.
Source: Authors, (2026).

The figure 16 illustrates that correlation does not necessarily prove causation between several of the various network features. It can be seen that there are pairs of features with very strong correlations (such as protocol type and service, as well as service and flag) but that the majority of the other features do not exhibit any significant linear correlation.

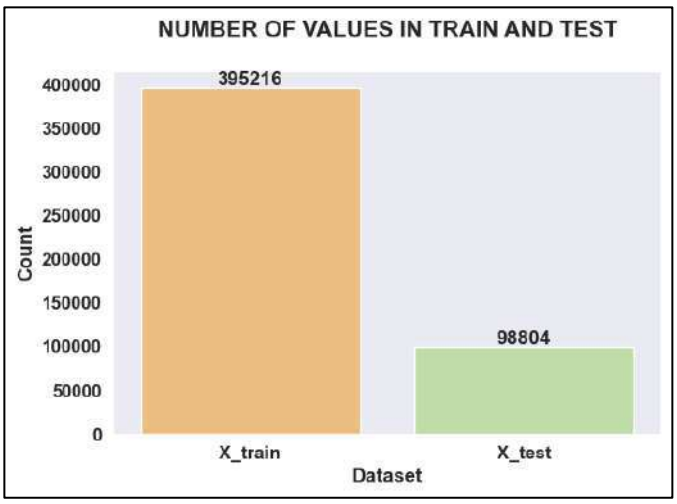

Figure 17: Number of values in train and test.
Source: Authors, (2026).

The figure 17 compares the dataset sizes for X_train (395,000 samples) and X_test (99,000 samples). This is an example of a standard train-test data split.

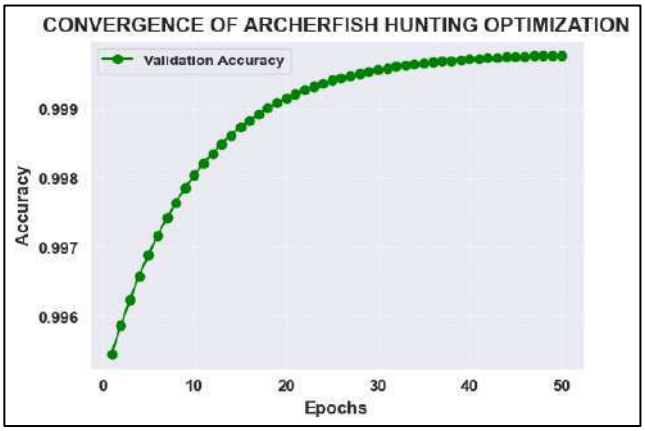

Figure 18: Convergence of Archerfish hunting optimization.
Source: Authors, (2026).

In figure 18, the validation accuracy continues to increase through the course of 50 epochs. This indicates that the AFHO-FEA-CasSTFormerNet model, which uses the AHO algorithm for optimization, does not plateau during training until it reaches a high level of accuracy.

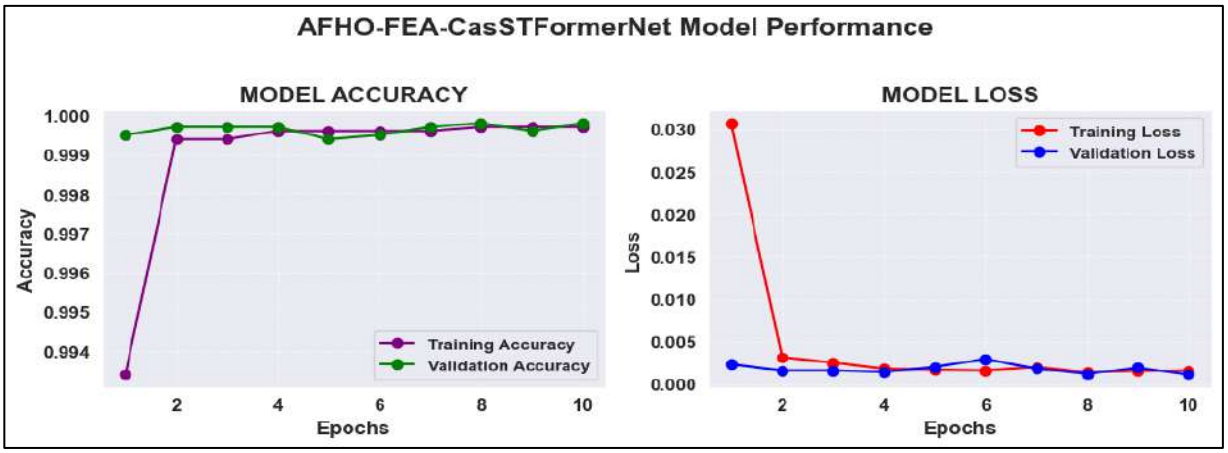

Figure 19: AFHO-FEA-CasSTFormerNet model.
Source: Authors, (2026).

The loss values in figure 19 dropped significantly during the early training epochs and remained low after that time point. Therefore we know that this model trained well on both sets of data and exhibited little evidence of overfitting.

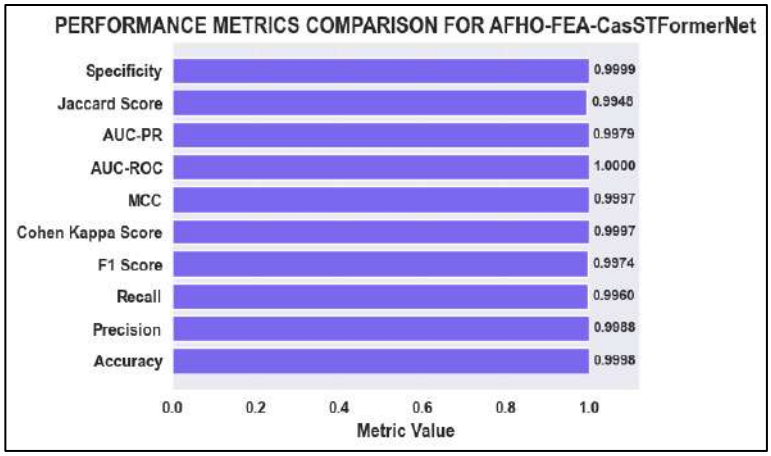

Figure 20: Performance metrics comparison for AFHO-FEA-CasSTFormerNet.
Source: Authors, (2026).

The figure 20 shows the high performance of the AFHO-FEA-CasSTFormerNet model using seven different evaluation metrics. All evaluations resulted in scores close to perfect (0.996-1.000). The scores for accuracy, precision, recall, F1-score, Matthews Correlation Coefficient (MCC), area under the receiver operating characteristic curve (AUC-ROC), and specificity suggest that the model performed well to well-balanced classify within the context of detecting various types of attacks.

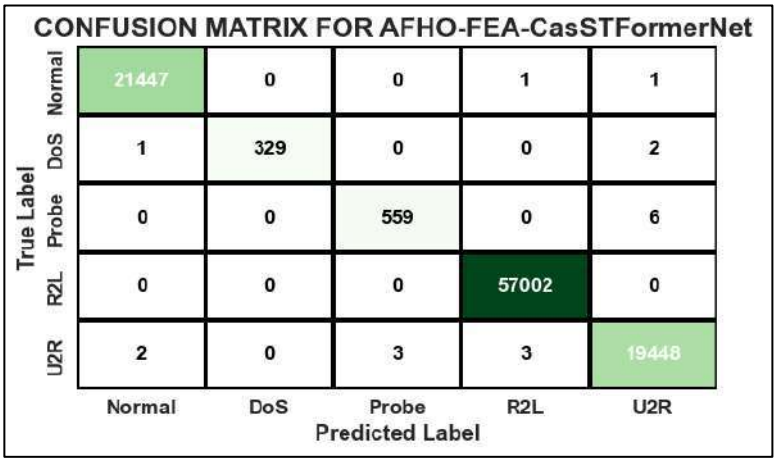

Figure 21: Confusion matrix for AFHO-FEA-CasSTFormerNet.
Source: Authors, (2026).

The figure 21 represents accurate AFHO-FEA-CasSTFormerNet model classified samples into five different categories (Normal, DoS, Probe, R2L, U2R). Almost all samples are classified correctly because very few exist that have been misclassified (about 0 to 3, per class). Hence, the AFHO-FEA-CasSTFormerNet model is capable of identifying both various types of attacks and normal traffic with great accuracy and is unlikely to misclassify them, given the high degree of accuracy achieved.

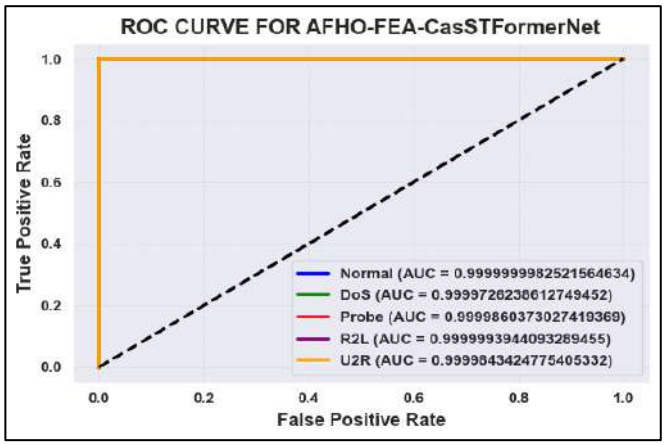

Figure 22: ROC curve for AFHO-FEA-CasSTFormerNet.
Source: Authors, (2026).

The ROC curve relates to the performance of the AFHO-FEA-CasSTFormerNet system in figure 22. Almost all of the five classes of traffic (Normal, DoS, Probe, R2L, U2R) are located in the upper-left corner of the ROC curve, indicating very good classification capabilities for each class. The AUC (Area Under the Curve) for each class is very close to 1.0, indicating excellent ability to discriminate between different classes.

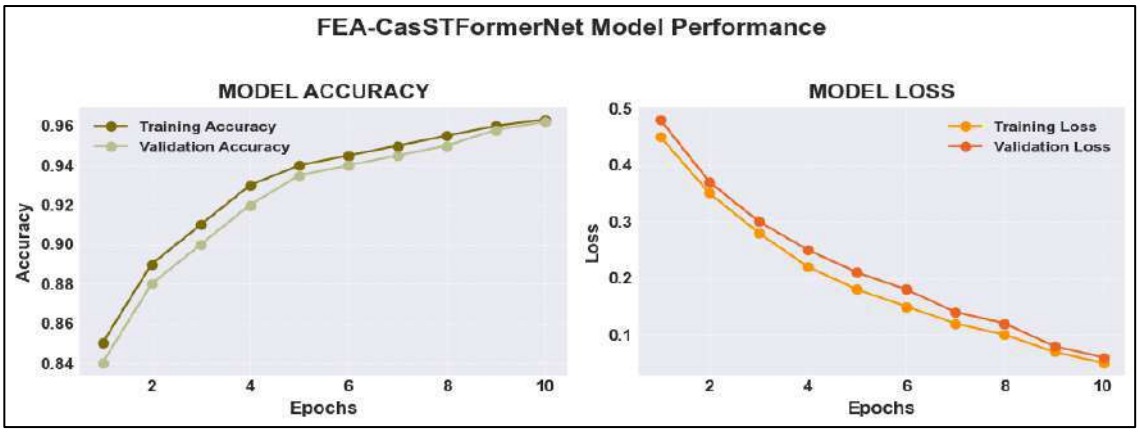

Figure 23: FEA-CasSTFormerNet model performance.
Source: Authors, (2026).

Figure 23 depicts the FEA-CasSTFormerNet model performance. The training/validation results for the FEA-CasSTFormerNet training set show that accuracy was steadily improving during the 10 epochs, while both training and validation losses were consistently decreasing. The loss of the validation set closely follows that of the training set, which demonstrates that the algorithm is learning the training set without significant overfitting.

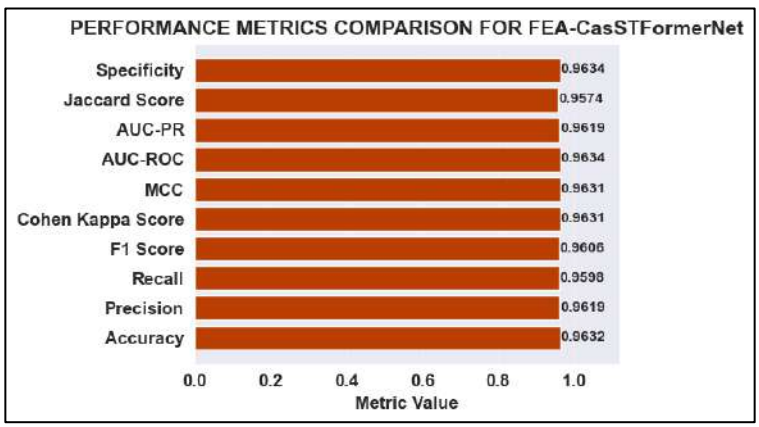

Figure 24: Performance metrics comparison for FEA-CasSTFormerNet.
Source: Authors, (2026).

The performance metrics for the FEA-CasSTFormerNet model shown in figure 24 are very high overall, and range from approximately 0.96 for accuracy, precision, and recall performance, to moderately balanced across all classes.

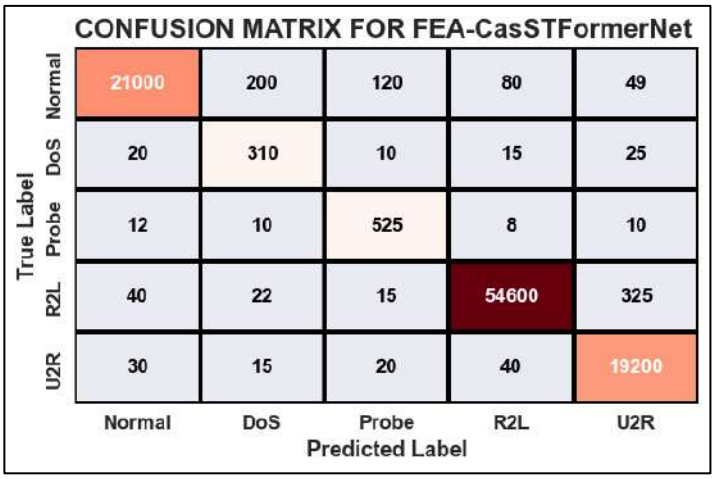

Figure 25: Confusion matrix for FEA-CasSTFormerNet.
Source: Authors, (2026).

In figure 25 the confusion matrix shown clearly that most sample classifications were accurate, and that the Normal, R2L, and U2R classes received a significant proportion of accurate classifications, while the attack classifications received only small proportions of misclassifications.

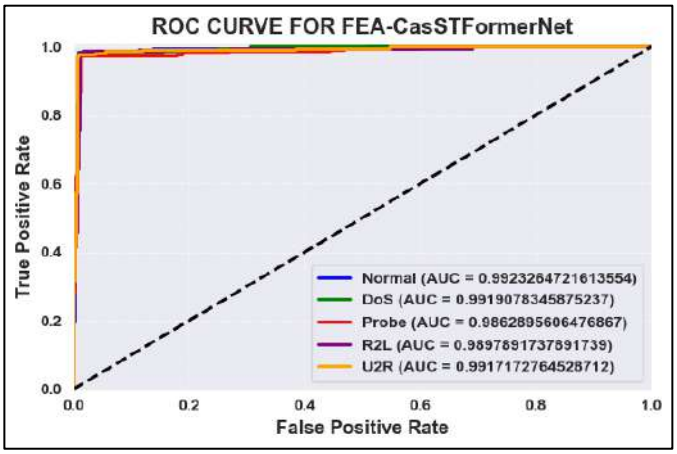

Figure 26: ROC curve for FEA-CasSTFormerNet.
Source: Authors, (2026).

In figure 26 the ROC curve shows that FEA-CasSTFormerNet provides excellent classification performance for all traffic classes with an AUC value of greater than 0.95 for each class. This indicates very high true positive rates and low false positive rates and demonstrates the ability of the model to accurately classify Normal, DoS, Probe, R2L, and U2R traffic.

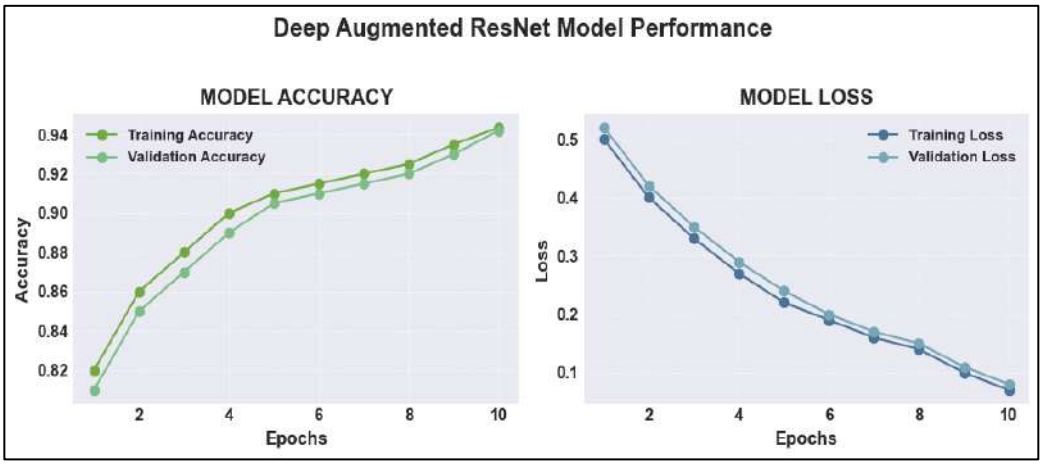

Figure 27: Deep augmented ResNet model performance.
Source: Authors, (2026).

Figure 27 displays the Deep augmented ResNet model performance. The statistical analysis revealed that the Deep Augmented ResNet exhibited consistent improvement throughout both the Training/Validation phases, with steadily increasing accuracies and decreasing losses for both Train and Validation data sets suggesting that the model was learning at a steady and effective rate.

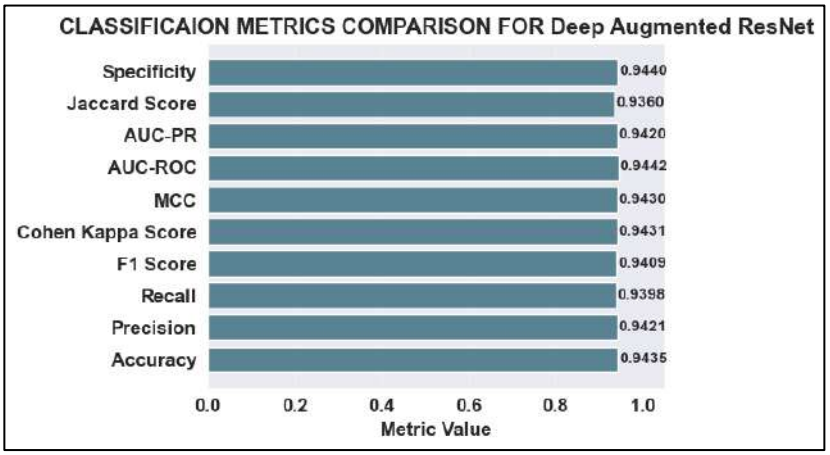

Figure 28: Classification metrics comparison for Deep augmented ResNet.
Source: Authors, (2026).

The figure 28 displayed the graphical representation indicate that the Deep Augmented ResNet is a highly accurate, reliable and balanced classifier with nearly all of the metrics scoring above 0.93.

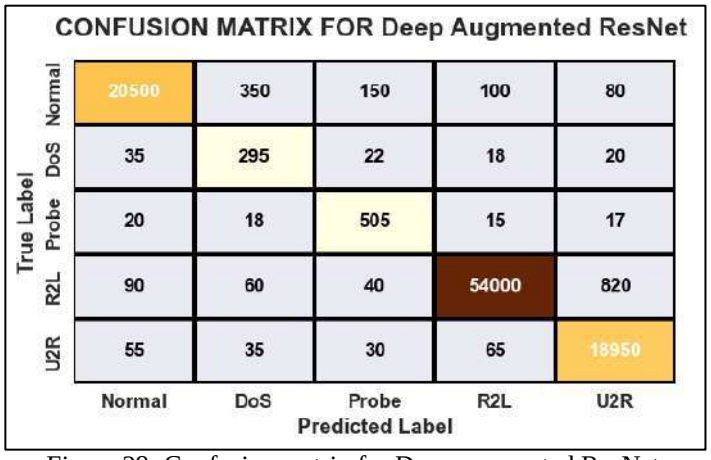

Figure 29: Confusion matrix for Deep augmented ResNet.
Source: Authors, (2026).

The figure 29 indicates that the Deep Augmented ResNet effectively classifies nearly all samples correctly across each of the five categories, particularly with regards to its very high number of true positives in the R2L, U2R and Normal classification categories. The number of misclassified samples is also extremely low, demonstrating that the Deep Augmented ResNet is capable of accurately distinguishing between diverse forms of attacks and normal network traffic, with only minimal confusion between closely related classes.

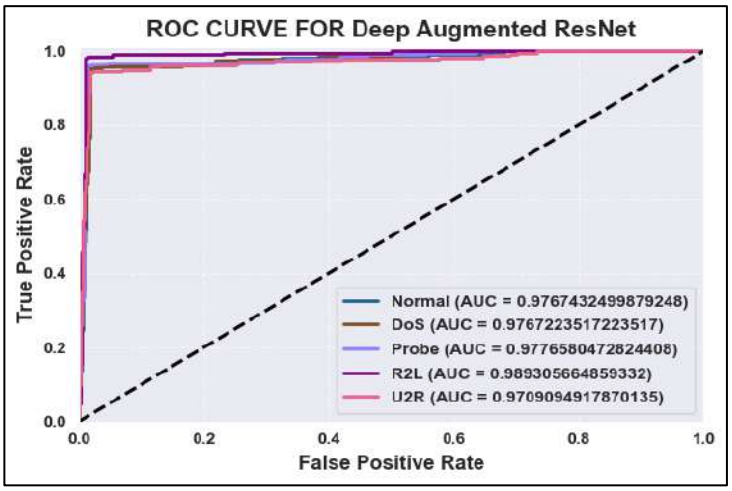

Figure 30: ROC curve for Deep augmented ResNet.
Source: Authors, (2026).

In figure 30 the visual representation of the ROC curves shows an excellent performance by the Deep Augmented ResNet in terms of each of the five categories, with the AUC values varying between approximately 0.97-0.99. All of the ROC curves are located in proximity to the upper left corner of the graph, indicating a very high True Positive Rate and a very low False Positive Rate for all classes, thus demonstrating that the Deep Augmented ResNet is a highly accurate, reliable and balanced classifier across the board.

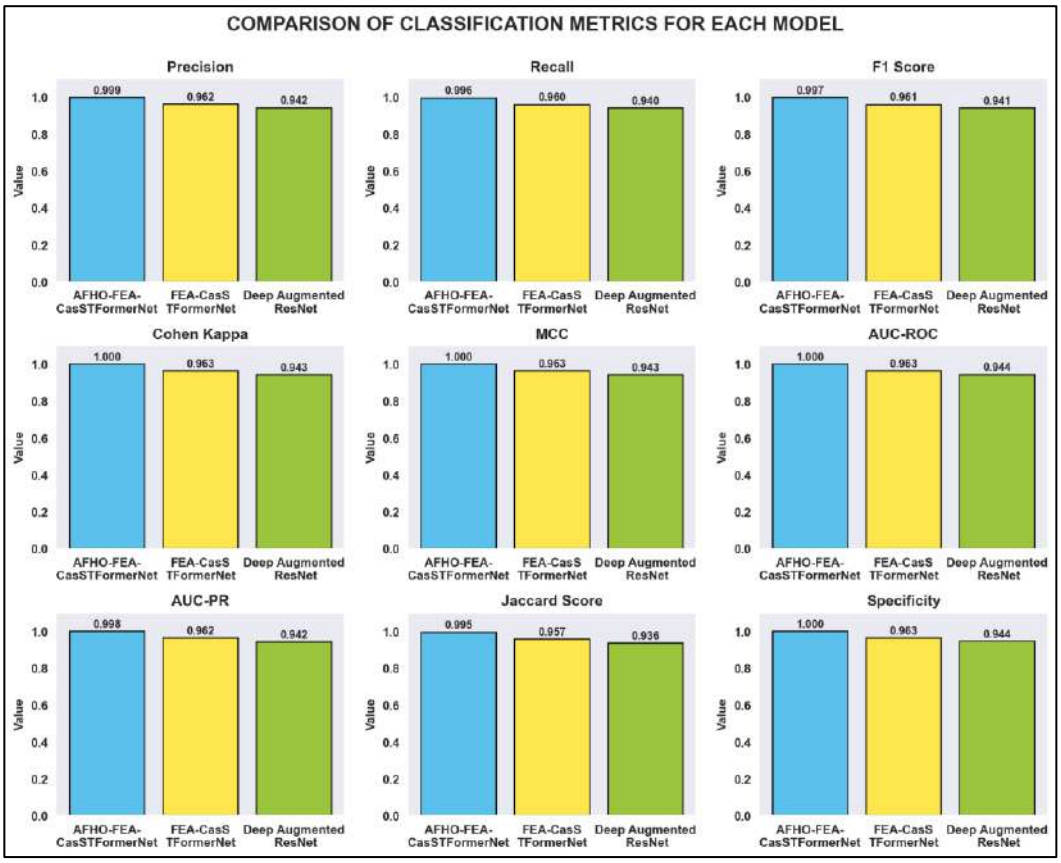

Figure 31: Comparison of classification metrics for each model.
Source: Authors, (2026).

In figure 31 the graphic illustration of the classification metrics indicates that the AFHO-FEA-CasSTFormerNet outperformed the other two models across each of the classification metrics overall, with the FEA-CasSTFormerNet being the second best performing model overall and the Deep Augmented ResNet slightly lower performing model but still being very strong.

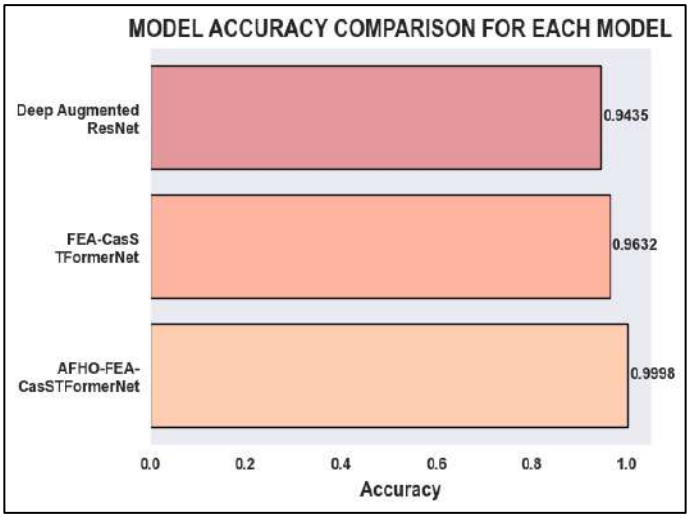

Figure 32: Model accuracy comparison for each model.
Source: Authors, (2026).

Figure 32 compares the model of AFHO-FEA-CasSTFormerNet, FEA-CasSTFormerNet and Deep Augmented ResNet with respective accuracies. AFHO-FEA-CasSTFormerNet (AUC=0.9998) exhibited the best overall performance, while the other two Models exhibited lower accuracy (0.9632 for FEA-CasSTFormerNet; 0.9435 for Deep Augmented ResNet) leading to the inference that the enhanced AFHO Model has a higher level of capability.

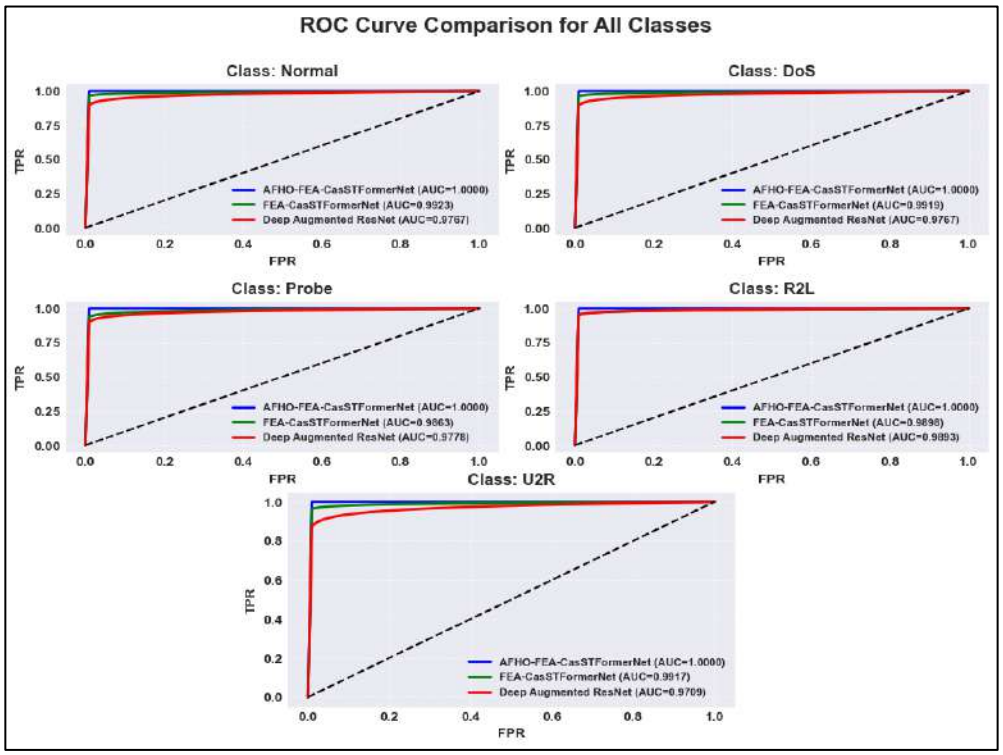

Figure 33: ROC curve comparison for all classes.
Source: Authors, (2026).

The figure 33 illustrates that AFHO-FEA-CasSTFormerNet performs consistently better than any of the other Models when analyzed according to Class. FEA-CasSTFormerNet exhibited a lesser degree of Class-Level performance, while Deep Augmented ResNet Exhibited the lowest performance levels, in comparison. Therefore, it is reasonable to state that the Enhanced AFHO Model provides the greatest Class-Level Discriminatory capability.

Table 3: Comparative Analysis of Accuracy for Various Methods.

METHODS	ACCURACY
RNN [21]	0.95
TCN [22]	0.90
PSO-LSTM [24]	0.91
GRU [25]	0.998
Proposed	0.999

Source: Authors, (2026).

Table III compares the accuracy for various methods. The suggested approach outperformed RNN (0.95), TCN (0.90), PSO-LSTM (0.91), and GRU (0.998) in network intrusion detection, with the greatest accuracy of 0.999.

Table 4: Performance Metrics of the Proposed System.

CLASSIFICATION METRICS	PROPOSED SYSTEM
ACCURACY	0.9998
PRECISION	0.9988
RECALL	0.9960
FI-SCORE	0.9974
COHEN KAPPA SCORE	0.9997
MATHEWS CORRELATION COEFFICIENT	0.9997
AUC-ROC	1.0000
AUC-PR	0.9979
JACCARD SCORE	0.9948
SPECIFICITY	0.9999

Source: Authors, (2026).

In table 4, the proposed system has shown superior classification performance with a very high level of accuracy (99.98%), precision (99.88%), Recall (99.60%), F1-score (99.74%) providing balanced and reliable detection. The level of agreement between the predictions and true labels is almost perfect as demonstrated by the very high Cohen's Kappa (0.9997) and MCC (0.9997). Additionally, the AUC-ROC is perfect (1.0000) and the AUC-PR is exceptionally high (0.9979). Finally, the Jaccard Score (0.9948) and specificity (99.99%) indicate that normal and intrusive traffic is accurately identified.

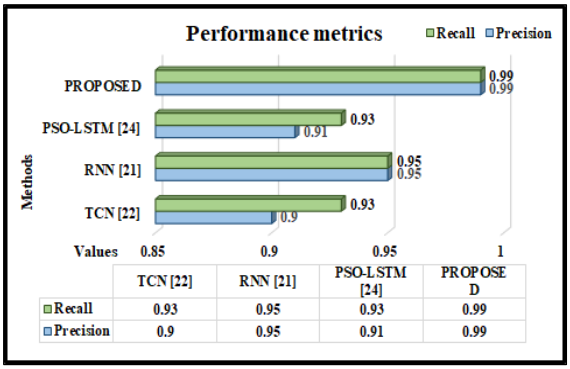

Figure 34: Performance metrics.
Source: Authors, (2026).

According to figure 34, the proposed method significantly outperformed any existing models, achieving the highest precision and recall (0.99 each). The RNN had moderate performance with 0.95; however, the TCN and PSO-LSTM performed worse than RNN, primarily in precision. Overall, the proposed system provides the most reliable and consistent accuracy for detection when compared to other methods.

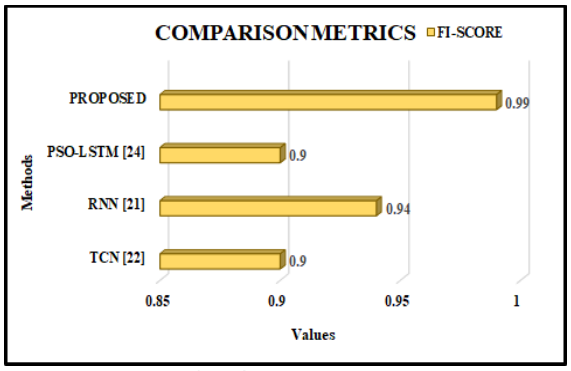

Figure 35: Comparison metrics.
Source: Authors, (2026).

In figure 35, the proposed method demonstrates the highest degree of balance in precision and recall as indicated by the F1-score of 0.99. RNN provides moderate performance scoring 0.94, and PSO-LSTM and TCN provide lower performance than the other methods at scores of 0.90; therefore, the method proposed in this study exhibits superior reliable performance than any other methods described in this paper.

V. CONCLUSIONS

This system proposes a new intelligent and complete solution to modern intrusion detection through the complete integration of each stage of the workflow into one optimized, unified deep learning framework. The final data output from this system goes through a rigorous process of preprocessing before becoming a valid representation of the data in the form of categories regarding information within the dataset, along with EDA statements are accompanied by EDA evidence. In addition, Shannon Entropy provides a better understanding of feature structure for the relevant projects by allowing the model to capture where there is variation in network behaviours and PCA provides a way to reduce dimensionality to enable more efficiency and eliminate redundant features. The knowledge obtained from both of these processes are then combined with the use of the FEA-CasSTFormerNet architecture using FEA, it allow the use of recursive attention and contextual data in real time to capture historical context in addition to the most recent framework. The combination of these then allow the architecture to model Deep Spatio-Temporal relationships of network traffic. Finally, Archerfish Hunting Optimization is also incorporated into this workflow to enable Fine Tuning of hyperparameters so as to optimally balance exploration vs. exploitation during the hyperparameter tuning process. Combined, these components produce a highly accurate, low false positive, and generalizable IDS capable of detecting the variety and changing nature of cyber-attacks. The proposed system is implemented in python and achieves an accuracy of 0.9998, precision of 0.9988, Recall of 0.9960 and FI-Score of 0.9974.

ABSTRACT

In this research work, buck integrated half bridge based converter for powering multiple LED lamps is proposed. There are two integrated half bridge resonant converters, and each converter drives two different lamps. The operation of each integrated half bridge converter is independent. The power control in all the LED lamps is achieved using asymmetric duty ratio (ADR) control. The converter features distinctive advantages such as 1) four LED lamps are operated at rated illumination, 2) device switching transitions in half bridge are occurred at zero voltage, 3) the lamps in each half bridge are powered independently, 4) high energy conversion efficiency etc. The use of an LC resonant circuit in the half bridge converter enables the achievement of soft-switching, leading to improved energy efficiency in the proposed LED driver as a result of reduced switching transition power. The results of the steady-state simulation have been presented to confirm the effectiveness of the proposed converter.

I. INTRODUCTION

The demand in energy sources across the world poses different challenges to achieve sustainable energy platforms. One of the viable solution for energy sustainability is energy saving, which can be achieved by efficient use of electrical energy. Lighting loads have significant potential to improve energy efficiency [1]. Energy savings can be achieved either by improving the energy conservation of traditional lighting sources or by reducing the capacity of lighting devices using efficient products. Using efficient products, used energy is reduced significantly. In view of this, lighting industry requires an energy efficient lighting sources. A light emitting diode (LED) emerges as an energy-efficient source of illumination. It is a semiconductor device which emits light due to electroluminescence. When the LED junction is forward biased, the electrons from n-side cross the junction and recombine with holes. This recombination produces photons. If the wavelength of emitted photons is in visible spectrum, the exposed semiconductor area emits light [2]. The luminous output of an LED is directly related to the forward current passing through it. The materials used in the fabrication of LED determines the emitted light colour. LEDs are suitable for wide range of applications due to their several advantages such as energy efficient, high operating life, high brightness, environment friendly nature, and compactness [3-6]. The applications of LED based lighting are classified as general illumination, residential lighting, automotive applications, street lighting, signal lighting, decorative lighting, liquid crystal display (LCD) panels, agriculture, communication, biomedical applications, etc [7-9]. LEDs are current controlled or current driven devices as their forward voltage is almost constant for wide current variations. Since the power output from LED is proportional to current flowing through LED, they must be powered from constant current switching power supplies to get required illumination [10], [11]. Many switching power converters operated from utility ac [12], [13] and isolated dc supply [14] have been proposed for LED lighting applications.

The lighting needs for each application vary, but common essential features of LED systems powered by dc sources include high efficiency, current regulation, compact design, multiple lamp support, and dimming capability. Furthermore, the soft-switching capability improves the power density of the driver circuit utilized in LED lighting applications. A full bridge soft-switched topology for multiple LED lighting application is presented [15]. Its features are low switching device current stress, low switching power loss, small conversion power, high energy conversion efficiency, and lamp illumination regulation and pulse width modulation (PWM) dimming operation. In [16], a reduced switch current zero-voltage switched LED converter for multiple lighting loads is given. This article [17] proposes a zero voltage switched full bridge LED driver for future dc-grid applications. Two LED lamps are supplied through interleaving concept, which also helps to reduce switch current and to obtain soft-switching feature. One LED lamp receives controlled power directly without conversion.In article [18], an innovative circuit for driving high power street light LEDs is introduced, utilizing a full bridge configuration. This design minimizes device current stress, enables soft-switching, and achieves high energy efficiency, as well as providing dimming and regulation capabilities at a constant operating current. In research work [19], an independent three-leg soft-switching converter is proposed for LED based lighting application with asymmetrical duty cycle control. A two output series resonant LED driver circuit using three switches is proposed in [20].

Current regulation feature, dimming operation, zero-voltage switching, and steady-state analysis are examined thoroughly. A multi-resonant based converter is presented for wide input LED lighting application in [21]. Apart from fundamental requirements of LED load, output current adjustment with large variation in input voltage, no-lamp protection feature, soft-switching transition, dimming capability, etc., are addressed. In [22], multiple LED lamps are supplied using single inductor based converter circuit is proposed. Authors validate the research work with high dimming rage at high dimming frequency. However, more components are used for dimming control. In [23], the authors aim to reduce the processing power required by a converter for LED lighting applications. It is a half bridge based series resonant driver circuit with PWM dimming, illumination current using asymmetric duty operation, zero-voltage switching transition, high conversion efficiency. However driver circuit utilizes extra devices for dimming operation. A multi-output LED driver topology using two power conversion stages for transport lighting application is addressed in [24]. Multi-resonant network is used in the second stage, which operates at resonant frequency at constant duty cycle. Buck-boost converter with multi-phasing concept at the first stage is used for lamp regulation.

But component count and conversion efficiency are limiting factors compared to single stage LED driver circuits. In research work [25], buck-boost integrated series resonant converter with different voltage gains is presented for automotive LED lighting application. Based on the input voltage range, the driver circuit switches to three different configurations with different input-output gains. In this research work, an integrated half bridge based series resonant converter to power multiple LED lamps is presented. Each integrated half-bridge converter operates independently and drives two distinct lamps. The regulation of power in all LED lamps is incorporated by using asymmetric duty ratio (ADR) control. The devices in each half bridge operate at constant duty ratio at rated power. Furthermore, incorporating an LC resonant circuit into the output of the each half bridge assists the realization of zero voltage switching transition. The structure of the document is outlined as follows: section 2 contains a detailed description of the proposed configuration. Section 3 and 4 explore into the working principle and mathematical analysis respectively. The design procedure is provided in section 5. Section 6 is given to present the results and discussions. Lastly, section 7 summarizes the conclusions drawn from the study.

II. DESCRIPTION OF PROPOSED CONFIGURATION

The proposed integrated half bridge based resonant converter for driving multiple light emitting diode (LED) lamps is depicted in Figure 1. Two half bridge converters are integrated to drive four LED lamps. Half bridge converter-1 consists of a half bridge inverter formed by two power MOSFETs (M_1&M_2), series resonant branch with L_{r1} and C_{r1} and full bridge current driven rectifier formed by D_{B1}- D_{B4}. The low impedance offered by inductor,L_{r1} and capacitor,C_{r1}helps to allow the fundamental component of the half bridge inverter output (v_{A0}). The current i_{r1} is rectified and filtered with capacitor C_{02} to power the LED lamp-2. v_{A0} is a periodic voltage of magnitude V_{dc1} and is applied across series combination inductor, L_1 and LED lamp-1. V_{01}&i_{01} and V_{02}&i_{02} represent output voltage and current in lamp-1 and lamp-2 respectively. Half bridge converter-2 consists of a half bridge inverter formed by two power MOSFETs (M_3&M_4), series resonant branch with L_{r2} and C_{r2} and full bridge current driven rectifier formed by D_{B5}- D_{B5}. The fundamental component of the half bridge inverter output (v_{B0}') is utilized due to the impedance offered by inductor,L_{r2} and capacitor,C_{r2}. The current i_{r2} is rectified and filtered with capacitor C_{04} to power the LED lamp-4. v_{B0}'is a periodic voltage of magnitude V_{dc2} and is applied across series combination inductor, L_3 and LED lamp-3. V_{03}&i_{03} and V_{04}&i_{04} represent output voltage and the current in lamp-3 and lamp-4 respectively. v_{L1} and v_{L3}stand for the voltages across inductor $L_1$and L_3, respectively. The polarity on v_{L1}&v_{L3}decides charging and discharging in L_1&L_3 respectively.

III. PRINCIPLE OF OPERATION

Figure 2 shows the operating waveforms related to proposed integrated half bridge resonant LED driver. In half bridge converter-1, the gate voltages v_{g1} and v_{g2} are complimentary to each other and devices M_1 and M_2 are operated with a duty ratio D_1 and (1-D_1) at time period T respectively. Similarly, in half bridge converter-2, the gate voltages v_{g3} and v_{g4} are complimentary to each other and M_3 and M_4 are operated with a duty ratio D_3 and (1-D_3) at the same time period T respectively. Device M_1 (or M_2) and M_3 (or M_4) can be operated either in phase or unequal turn-on time. However, in this section, different operating modes are given with equal device turn-on time, i.e. $D_1T = (1-D_1)T = D_3T = (1-D_3)$.

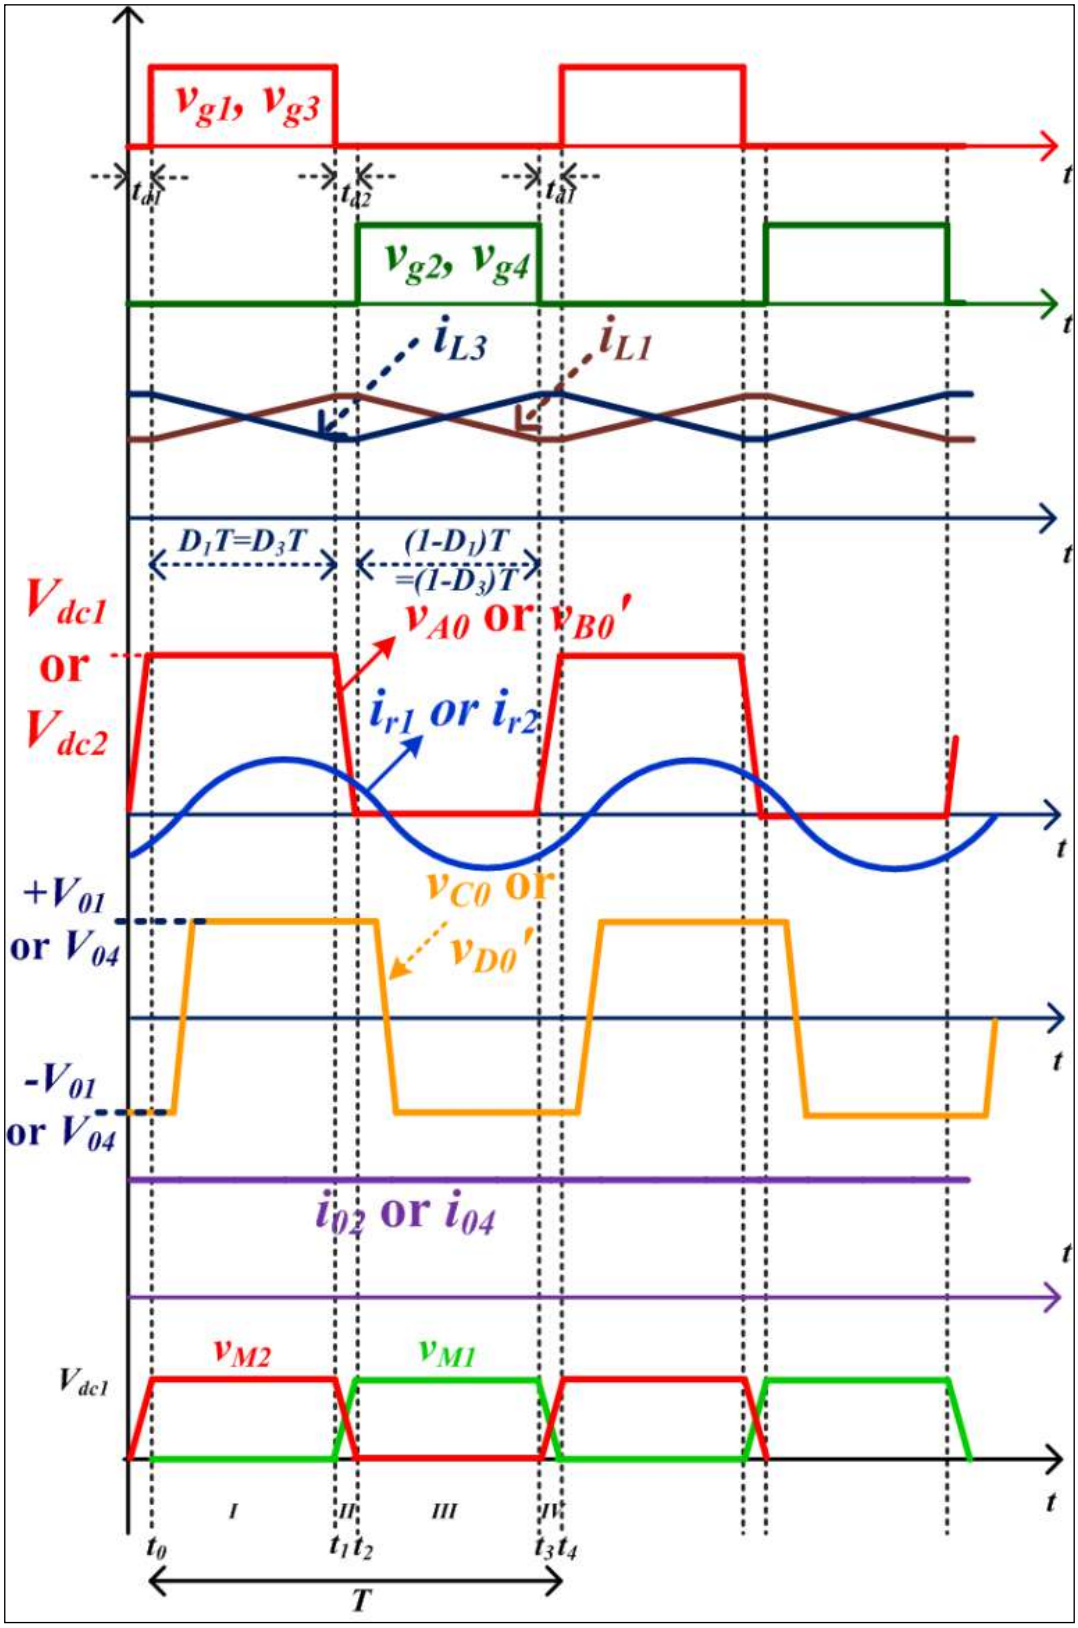

Figure 2: Operating waveforms (a) half bridge related waveforms (b) buck-boost related waveforms.
Source: Authors, (2026).

III.1 MODE-1 (T_0 – T_1)

At time $t = t_0$, switches M_1 and M_3 are started conduction using gate voltage v_{g1} and v_{g3} respectively. Figure 3 (a) displays the conduction circuit. In this mode, voltage across inductor L_1 is positive and LED lamp-1 allows the current i_{L1} to charge linearly through M_1. Simultaneously, voltage, V_{L2} across inductor L_2 is negative and lamp-3 allows the current i_{L2} to discharge linearly through M_3. When M_1 is conducting in half bridge converter-1, voltage v_{A0} is $+V_{dc1}$. Consequently, the series resonant circuit comprising L_{r1} and C_{r1} provides low impedance to the fundamental component of v_{A0}. As a result, an alternating current i_{r1} is produced, which is then rectified by bridge diodes D_{B1} and D_{B4} to supply power to lamp-2.

Similarly, in half bridge converter-2, when M_3 is conducting voltage v_{B0}' is $+V_{dc2}$. Thus, in the series resonant circuit with $L_{r2}$and $C_{r2,}$ the fundamental component of v_{B0}' is utilized to generate resonant current i_{r2} is generated, which is rectified through D_{B5} and D_{B8} to power lamp-4.M_1 conducts the sum of i_{01} and i_{r1} and M_3 conducts the difference between i_{r2} and i_{03}. In this mode, voltage across output capacitance of $M_2$is $+V_{dc1}$ and voltage across output capacitance of M_4 is $+V_{dc2}$. This mode concludes at $t = t_1$.

III.2 MODE-2 ($T_1 – T_2$)

At $t = t_1$, gate voltages, v_{g1}&v_{g3} are removed and v_{g2}&v_{g4} are not yet given to turn on M_2 and M_4 respectively. The resonant current (i_{r1}& i_{r2}), lamp-1 current (i_{L1}) and lamp-3 current (i_{L3}) prefer to flow through device output capacitances. The conduction circuit is given in Figure 3(b). Both device M_1 and M_2 in half-bridge converter-1 are not conducting, thus output capacitance ($\boldsymbol{C_1}$) of M_1 charges from zero to V_{dc1} due to the current $(i_{r1}+i_{L1})/2$ through it. Similarly, $\boldsymbol{C_2}$ of device M_2 carries the sum of remaining half of i_{r1} and i_{L1}, hence it discharges from V_{dc2} to zero. When voltage across C_2 is -0.7 V, internal diode of M_2 will be forward biased. Gate voltage v_{g2} for device M_2 can be applied after D_2 is forward biased for zero voltage switching. M_1 is already turned off at zero voltage. In the similar process, the current $(i_{r2}$-$i_{L3})/2$ in $C_3$and $(i_{r2}$-$i_{L3})/2$ in C_4 make the devices M_3 and M_4 through zero voltage switching transitions in half-bridge converter-2. At $t = t_2$, mode-3 is initiated.

III.3 MODE-3 ($T_2 – T_3$)

At time $t = t_2$, switches M_2 and M_4 are started conduction using gate voltage v_{g2} and v_{g4} respectively. Figure 4 (a) displays the conduction circuit. In this mode, voltage across inductor L_1 is $–V_{01}$ and LED lamp-1 allows the current i_{L1} to discharge linearly through M_2. Simultaneously, voltage, V_{L2} across inductor L_2 is V_{dc2}-V_{03} and lamp-3 allows the current i_{L2} to charge linearly through M_4. When M_2 is conducting in half bridge converter-1, voltage v_{A0} is zero. However, resonant current,i_{r1} flows through D_{B2} and D_{B3} to power lamp-2 due to the fundamental component of v_{A0}.Similarly, in half bridge converter-2, when M_4 is conducting voltage v_{B0}' is zero. Thus, due to the fundamental component of $\boldsymbol{v_{B0}'}$,resonant current,i_{r2}conducts throughD_{B6} and D_{B7} to power lamp-4.M_2 conducts the difference of i_{01} and i_{r1} and M_4 conducts the sum of i_{r2} and i_{03}. In this mode, voltage across output capacitance of $M_1$is $+V_{dc1}$ and voltage across output capacitance of M_3 is $+V_{dc2}$. This mode concludes at $t = t_3$.

III.4 MODE-4 ($T_3 – T_4$)

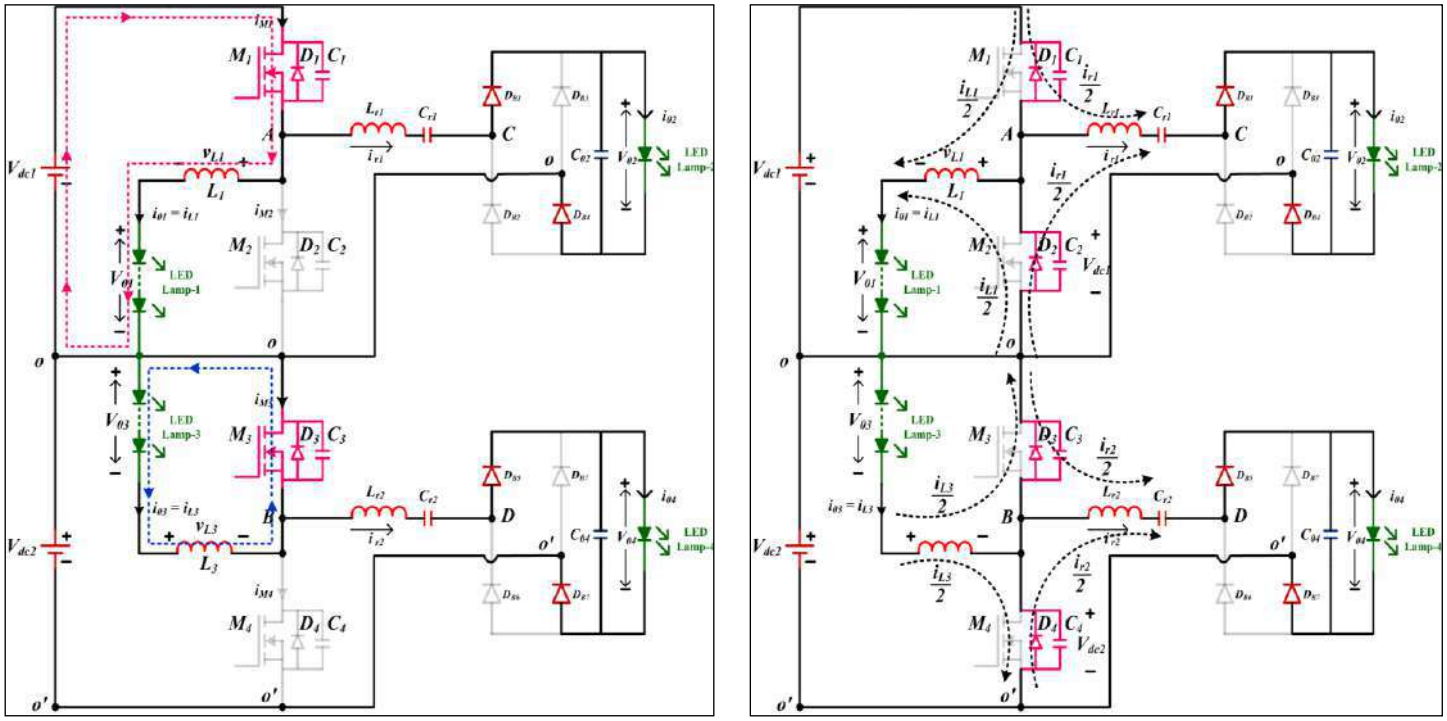
During $\boldsymbol{(t_3 – t_4)}$ interval, gate voltages (v_{g2}&v_{g4}) to switch M_2 and M_4 are removed at zero voltage and (v_{g1}&v_{g3}) are not applied to turn on switches M_1 and M_3. Figure 4(b) illustrates mode-4 operation . All the devices M_1-M_4 are in off state, the current i_{r1}, i_{r2}, i_{L1} and i_{L3} are equally divided and flows through device output capacitance C_1-C_4. The process of turning on of (M_1&M_3) and turning off of (M_2&M_4) is similar to that of mode-2.

IV. ANALYSIS OF PROPOSED CONVERTER

The analysis of proposed integrated half based resonant LED driver configuration is provided under steady state ideal conditions.

IV.1 ANALYSIS OF LAMP-1 AND LAMP-3

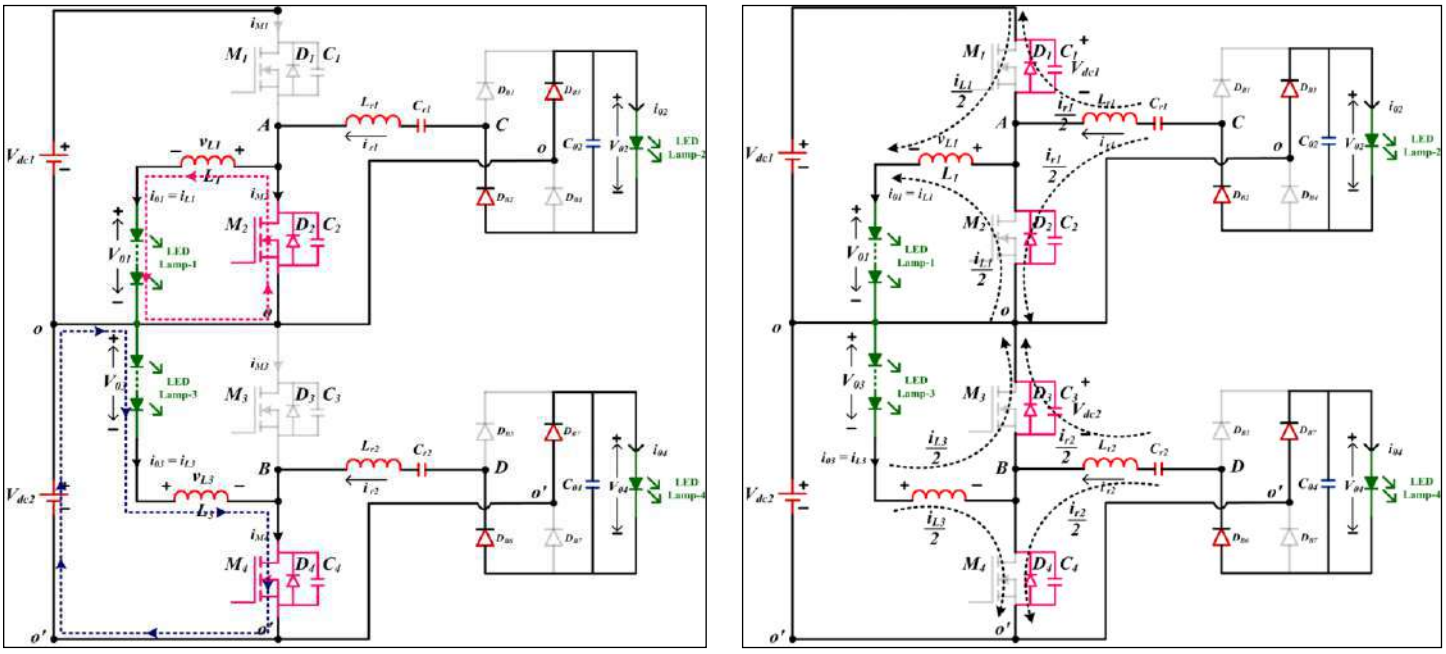
The switches in each half bridge are operated with equal duty ratio at fixed switching period (T). The relationship between the lamp's output voltage and the input voltages (V_{dc1}&V_{dc2}) can be determined from mode-1 and mode-3 with neglected dead times. When switch M_1 and M_3 are conducting, LED lamp-1 is powered from input voltage (V_{dc1}) of half bridge converter-1 and lamp-3 receives the stored energy in L_3. When switch M_2 and M_4 are conducting, LED lamp-1 receives the stored energy in L_1 and lamp is powered from input voltage (V_{dc2}) of half bridge converter-2. To simplify the analysis, the conduction duration of each switch in the half bridge is approximately equal to it's OFF time duration. The application of volt-sec balance in inductor voltages of L_1 and L_3 results the output voltages for the lamps as



$$V_{01} = V_{dc1} D_1 \tag{1}$$

$$V_{03} = V_{dc2} D_3 \tag{2}$$

From the operating waveforms shown in Figure 2, the ripple current is represented in L_1 and L_3as



$$\Delta i_{L1} = \frac{V_{dc1} - V_{01}}{L_1} D_1 T = \frac{V_{01}}{L_1}(1 - D_1)T \tag{3}$$

$$\Delta i_{L3} = \frac{V_{03}}{L_3} D_3 T = \frac{V_{dc2} - V_{03}}{L_3}(1 - D_3)T \tag{4}$$

IV.2 ANALYSIS OF LAMP-2 AND LAMP-4

In the proposed converter, half bridge series resonant circuits are used to power lamp-2 and lamp-4. The mathematical approach is provided to find output voltage of half bridge converter-1 and similar approach can also be used to find output voltage of LED lamp-4. In half bridge converter-1, v_{A0}, whichis a periodic voltage of magnitude V_{dc1}, is applied across series resonant circuit formed by resonant inductor, L_{r1}, capacitor, C_{r1} and diode bridge rectifier (D_{B1}-D_{B4}). The resonant circuit allow only fundamental components. The relation between output voltage, V_{02} of lamp-2 and input voltage, V_{dc1} is calculated by considering fundamental ac components [26] presented in the half bridge inverter output voltage, v_{A0} and diode bridge rectifier input voltage v_{CO}. The ac equivalent circuit of half bridge converter-1 is shown in Figure 5(a). The ac resistance offered by diode bridge rectifier is represented as R_{ac2}. X_{Lr1} and X_{Cr1} represent reactance offered by L_{r1} and C_{r1} respectively. From Figure 5(a), the relation between V_{02} and V_{dc1} is derived as follows:

$$\frac{V_{C0}}{V_{A0}} = \frac{R_{ac2}}{R_{ac2} + j(X_{Lr1} - X_{Cr1})} = \frac{1}{\left[1 + j\left(\frac{X_{Lr1} - X_{Cr1}}{R_{ac2}}\right)\right]} \tag{5}$$

Note that V_{A0} is the fundamental component of the periodic voltage applied to series resonant circuit and V_{C0} is the fundamental component of square wave voltage of magnitude V_{02} across R_{ac2}. Figure 5(b) shows the calculation of Rac2and is expressed as

$$R_{ac2} = \frac{V_{C0}(rms)}{I_{r1}(rms)} = \frac{4V_{02}}{\sqrt{2}\pi} \Big/ \frac{\pi I_{02}}{2\sqrt{2}} = \frac{8}{\pi^2}\frac{V_{02}}{I_{02}} = \frac{8}{\pi^2} R_{lamp2} \tag{6}$$

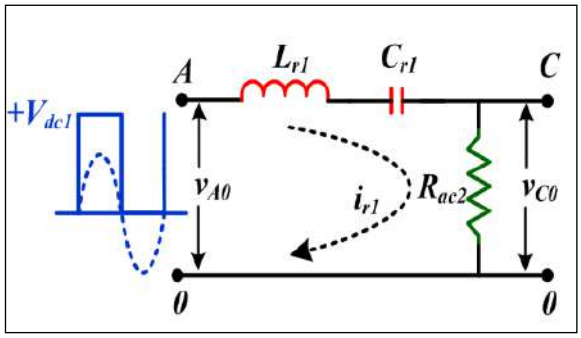
Where R_{lamp2} is the resistance offered by lamp-2 at V_{02} and I_{02}. And

$$X_{Lr1} = 2\pi f L_{r1} \tag{7}$$

$$X_{Cr1} = \frac{1}{2\pi f C_{r1}} \tag{8}$$

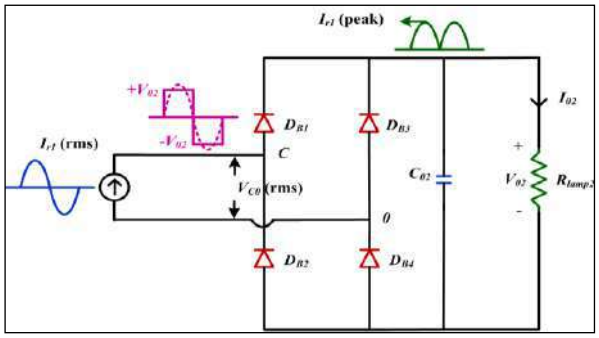
The selectivity of the series resonant current formed by L_{r1}, and C_{r1} is denoted by using quality factor (Q_1), and it is expressed as

$$Q_1 = \frac{\omega_{01} L_{r1}}{R_{lamp2}} = \frac{1}{\omega_{01} C_{r1} R_{lamp2}} \tag{9}$$



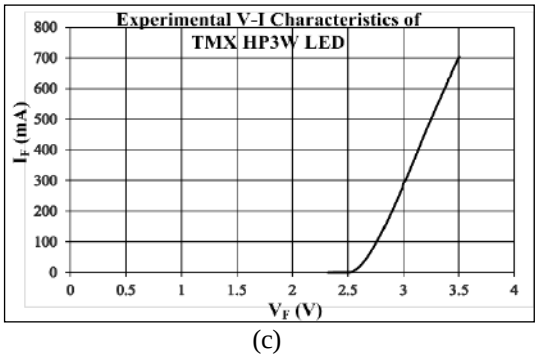
where ω_{01} is resonant frequency of half bridge converter-1 in radians per seconds and it is given by

$$\omega_{01} = 2\pi(f_{01}) = \frac{1}{\sqrt{L_{r1} C_{r1}}} \text{ rad/sec} \tag{10}$$



$$f_{01} = \frac{1}{2\pi\sqrt{L_{r1} C_{r1}}} \text{ Hz} \tag{11}$$

By substituting Eqn. (6), (7), (8) and (9) in Eqn. (5), the relation between V_{02} and V_{dc1} is finally expressed as



$$\frac{V_{C0}}{V_{A0}} = \frac{4V_{02}/\pi}{2V_{dc1}/\pi} = \frac{V_{02}}{V_{dc1}} = \frac{1}{\left[1 + j\frac{\pi^2}{8} Q_1\left(\frac{f}{f_{01}} - \frac{f_{01}}{f}\right)\right]} \tag{12}$$

V. DESIGN PROCEDURE

In the proposed LED configuration, LED lamp-1 and lamp-3 are identical. And, lamp-2 & lamp-4 are identical. An LED's equivalent circuit [27] is necessary to determine the parameters associated with lamps. The proposed configuration is validated with equivalent circuit of TMX HP 3WLEDs and their voltage and current characteristics are illustrated in Figure 5 (c). From the characteristics, 2.3 V is observed as threshold voltage (V_{th}) of the LED. Each LED in lamp-1 and lamp-3 is operated at a voltage of 3.42 V and a current of 590 mA. In LED lamp-1 and lamp-3, there are two parallel strings, with each string containing 7 LEDs connected in series. Therefore lamp-1 and lamp-3 are operated at a forward voltage (V_{01} (or) V_{03}) of 23.94 V, forward current (i_{01} (or) i_{03}) of 1.18 A and power rating of 28 W. Similarly, each LED in lamp-2 and lamp-4 is operated at a voltage of 3.3 V and a current of 525 mA. Four parallel strings are connected in lamp-2 & 4, and each string contains a series connection of 6 LEDs. Therefore lamp-2 and lamp-4 are operated at a forward voltage (V_{02} (or) V_{04}) of 19.8 V, forward current (i_{02} (or) i_{04}) of 2.1 A and power rating of 42 W. Lamp-2 and lamp-4 start allow current above their cut-in voltage and it is found to be 13.8 V.

V.1 CALCULATION OF INPUT VOLTAGE:

The input voltage applied to half bridge converter-1 and half bridge converter-2 can be determined using equation (1) and (2) respectively. With $D_1 = D_3 = 0.5$, $V_{01} = V_{03} = 23.94$ V and V_{dc1}&V_{dc2} are calculated as

$$V_{dc1} = V_{dc2} = \frac{V_{01}\,(or)\,V_{03}}{D_1\,(or)\,D_3} = \frac{23.94}{0.5} \cong 48\,V$$

V.2 CALCULATION OF THE VALUE OF INDUCTOR L_1 AND L_3

Rearranging equation (3), value of L_1 is expressed as

$$L_1 = \frac{V_{dc1} - V_{01}}{\Delta i_{L1}} D_1 T \tag{13}$$

With $V_{dc1}$of 48 V, V_{01} of 23.94 V, switching period T of 8 µs, D_1 of 0.5, and the current ripple Δi_{L1} is 13 % of i_{01}, from equation (13), the inductor L_1 is calculated as

$$L_1 = \frac{48 - 23.94}{0.13 \times 1.18}(0.5 \times 8 \times 10^{-6}) \cong 626\mu H$$

To calculate the value of L_1 equation (4) is rearranged as

$$L_3 = \frac{V_{dc2} - V_{03}}{\Delta i_{L3}}(1 - D_3)T \tag{14}$$

With $V_{dc2}$of 48 V, V_{03} of 23.94 V, switching period T of 8 µs, D_3 of 0.5, and the current ripple Δi_{L3} is 13 % of i_{01}, from equation (14), the inductor L_3 is calculated as

$$L_3 = \frac{48 - 23.94}{0.13 \times 1.18}(1 - 0.5).8 \times 10^{-6}) \cong 626\mu H$$

V.3 CALCULATION OF HALF BRIDGE RESONANT CONVERTER PARAMETERS

From equation (11), the product of L_{r1} and $C_{r1}$is expressed as

$$L_{r1}C_{r1} = \left[\frac{1}{2\pi f_{01}}\right]^2 \tag{15}$$

After selecting f_{01} as 113.64 kHz, equation (15) is expressed as

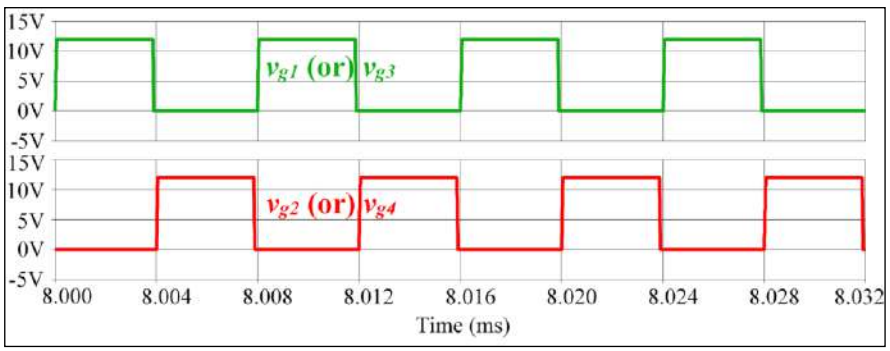
$$L_{r1}C_{r1} = 1.961 \times 10^{-12} \tag{16}$$

Equation (9) is rearranged as

$$Q_1 = \frac{1}{R_{lamp2}}\sqrt{\frac{L_{r1}}{C_{r1}}} \tag{17}$$

With $Q_1 = 3$ and $R_{lamp2} = 9.43\ \Omega$, from Eqn. (16) and (17), the value of $C_{r1}$and $L_{r1}$are obtained as 47 nF and 40 µH respectively. With the similar approach shown above, the value of C_{r2} and L_{r2} are also selected as 47 nF and 40 µH respectively. To reduce ripple current less than 10% of selected operating current, C_{02} and C_{04} are selected as 10 µF.

Table 1: Component values of the proposed configuration.



Input voltage, V_{dc1}& V_{dc2}	48 V
Switching frequency, f_s	125 kHz
Resonant frequency, $f_{01,02}$	113.64 kHz
Resonant inductor, $L_{r1,r2}$	40 µH
Resonant capacitor $C_{r1,r2}$	47 nF
Inductor, $L_{1,3}$	626 µH
Lamp-1 and lamp-3 voltage, $V_{01,03}$	23.94 V
LED lamp-2 and lamp-4 voltage, $V_{02,04}$	19.8 V
Current in lamp-1 and lamp-3, i_{01} (or) i_{03}	1.18 A
Current in lamp-2 and lamp-4, $i_{02,04}$	2.1 A
$P_{01,03}$	28 W
$P_{02,04}$	42 W
Switching devices used	IRF 640N

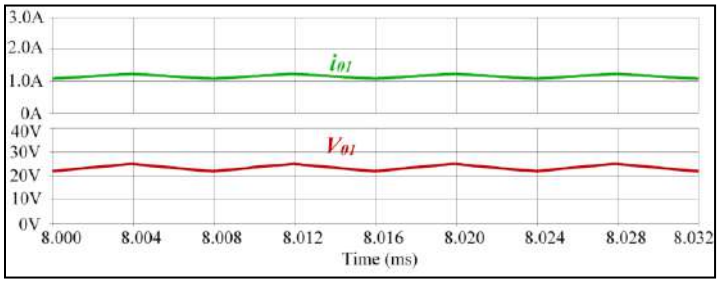
VI. RESULTS AND DISCUSSIONS

The proposed buck integrated half bridge based LED driver is simulated in the OrCAD PSpice environment. Table 1 provides the LED lamp voltage, current, power ratings, and component values. The configuration is designed to power four lamps of total 140 W and has been verified through OrCAD PSpice simulation software. At rated illumination, the voltage and current waveforms in different components are given and discussed below. Figure 6 (a) shows the gate voltages of the switches M1 – M4. It indicates that devices in half bridge converter-1 and converter-2 operate at 125 kHz with D1 = 0.5 and D3 = 0.5. Figure 6 (b) illustrates output voltages (vA0& vB0') of half bridge inverters, resonant currents (ir1&ir2) and input voltages (vC0& vD0') of diode bridge rectifiers. It clearly shows that half bridge inverter outputs are periodic voltages. Resonant currents generated lag the corresponding half bridge inverter output voltage and are in phase with corresponding input voltage of diode bridge rectifier. Figure 7 shows voltage, as well as the current in all the LED lamps. It is observed that all the lamps are illuminated at selected operating values. In Figure 8, switching waveforms of devices in both half bridge are shown. It is observed that switching transitions of devices M1 – M4 are completed at zero voltage within the dead time. At full illumination level, the efficiency of the proposed resonant LED driver is found to be 93.58 %. In the proposed converter, the power through lamp-1 and lamp-2 can be controlled simultaneously by changing the duty ratio of switch M1.



Similarly, the illumination from lamp-3 and lamp-4 can be controlled by varying the duty ratio of M3. At D1 = 0.4 and D3 = 0.6, the voltage and current waveforms in different components are given and discussed below. Figure 9 shows the gate voltages of the switches M1 – M4, output voltages (vA0& vB0') of half bridge inverters, resonant currents (ir1&ir2) and input voltages (vC0& vD0') of diode bridge rectifiers. It clearly shows that half bridge inverter outputs are periodic voltages with different pulse widths. The magnitudes of resonant currents generated are reduced in both half bridge converters. Figure 10 represents voltage and current in all the four LED lamps at reduced power level. It is observed that lamp-1 illuminates at 16.46 W, lamp-2 is powered at 35.75 W, lamp-3 also illuminates at 16.46 W and lamp-4 is also supplied with 35.75 W. Switching waveforms at the operating condition of devices are provided in Figure 11. It clearly indicates that switching transitions of switches M1 – M4 are completed at zero voltage. The power consumed by all the lamps is 104.52 W and the efficiency of the proposed resonant LED driver is calculated to be 92.64 %. The power supplied to all lamps can be changed by varying duty ratio D1 and D3.At various power levels, energy efficiency curve of the converter is shown in Figure 10(d) and high efficiency is obtained at different operating conditions.

VII. CONCLUSIONS

This research paper introduces a novel buck integrated half based resonant LED driver configuration to power multiple LED lighting loads. A thorough analysis of the steady-state behavior is included to offer a detailed understanding of the circuit's operation. To confirm the proposed design, extensive simulation results are presented.
The primary characteristics of the suggested LED driver are as follows:

1. Zero-voltage switching operation
2. Ability to power multiple lighting loads.
3. High efficiency
4. Independent power control
5. Regulation of lamp current via asymmetric duty ratio control
6. Minimal output ripple current

ABSTRACT

Class imbalance is a prevalent issue in Software Defect Prediction (SDP), where non-defective modules significantly outnumber defective ones. This imbalance often degrades the performance of prediction models. While oversampling techniques like SMOTE are commonly used to address this problem, they often produce synthetic instances that are either too similar to the original data (leading to overgeneralization and high false positive rates) or overly diverse (reducing the model's ability to detect defects). This study proposes a novel hybrid approach that combines a generative oversampling method, Tabular Variational Autoencoder (TVAE), with ensemble learning to improve defect prediction performance. The aim is to achieve a better balance between precision and recall while effectively handling imbalanced datasets. TVAE is used to generate realistic synthetic defect instances by learning the underlying joint distribution of tabular software metrics. The synthetic data is then used to train ensemble models, including TVAE+Naïve Bayes with Bagging and TVAE+Random Forest with Gradient Boosting Stacking. The proposed methods are evaluated on seven NASA PROMISE datasets and compared against baseline and state-of-the-art approaches using AUC, G-Mean, Accuracy, and F1-Score. Experimental results show that TVAE+RF+GB consistently outperforms other methods, achieving an average accuracy of 93%, AUC of 0.91, and F1-Score of 0.93. TVAE+NB+Bagging also demonstrates significant improvement over baseline models, particularly in G-Mean. Statistical tests confirm the significance of these improvements in most evaluation metrics. The integration of TVAE with ensemble learning effectively addresses class imbalance in SDP and enhances prediction performance. TVAE+RF+GB is recommended as a robust and efficient solution for imbalanced defect prediction datasets.

I. INTRODUCTION

Software Defect Prediction (SDP) is a data-based identification technique that utilizes historical information from software development projects [1] to determine whether a software module is defective or not [2]. The main objective of this technique is to predict and identify potentially defective modules at an early stage of the software development cycle[3]. SDP offers a more efficient alternative to conventional methods such as debugging, which requires manual examination of the entire source code, execution flow, and program conditions [3], [4]. By reducing the number of defects in the final product, SDP contributes directly to improving the overall quality of the software.

High-quality software is generally characterized by a minimal number of defects found during the inspection and testing stages, as well as its ability to meet user needs and expectations. However, software testing is one of the most expensive and time-consuming stages in the development process, with approximately 80% of the total project schedule allocated to testing activities[2], [5]. This situation leads to increased development, maintenance, and estimation costs, as well as negatively impacting the overall quality of the software [6]. Therefore, a more efficient and cost effective approach is needed to detect software defects early on. To develop and evaluate an accurate SDP model, a high-quality dataset containing comprehensive information about software module characteristics and defect history is required. One of the most commonly used datasets is NASA's public PROMISE dataset [7]. However, this dataset has class imbalance characteristics, where defective modules represent only a small portion of the overall data (8). This imbalance can cause a significant decrease in classification model performance, especially in detecting minority classes [8]. Without adequate preprocessing, prediction models tend to be biased towards the majority class and fail to recognize defective modules effectively [9]. In general, there are two main approaches to handling class imbalance, namely at the data level and the algorithm level [10], [8]. The data-level approach is carried out through resampling techniques to balance the class distribution in the training data, such as Random Over-Sampling (ROS) [11], [12], Random Under-Sampling (RUS), SMOTE (Synthetic Minority Over-sampling Technique) [13], ADASYN, COSTE, and MAHAKIL [14-16]. Meanwhile, the algorithm level approach is done by modifying the structure or learning mechanism in machine learning algorithms, for example through the use of ensemble methods that combine several basic models.

The two most commonly used ensemble methods are boosting and bagging [17], which have been proven to improve the performance of classifiers on imbalanced data. Various conventional oversampling techniques such as ADASYN, SPIDER3, MetaCost Learners [5], SMOTE, and MAHAKIL [16], [18] have been widely used to address imbalance issues, but each has its limitations. For example, SMOTE tends to generate synthetic samples that are too similar to the original data, leading to overgeneralization, while MAHAKIL often generates data that is too varied, reducing defect detection accuracy. Several previous studies have also proposed hybrid approaches to improve prediction accuracy. However, most still rely on traditional sampling methods such as SMOTEND [19], SMOTENDE [20], SMOTEEN, and SMOTETomek [21], [22]. In addition, the ARRAY (Adaptive Triple Feature-Weighted Transfer Naïve Bayes) method, which integrates the Naïve Bayes algorithm [23], has also been proposed to improve classification performance, but its effectiveness is still limited to large-scale and high-dimensional datasets. As a solution to these limitations, this study proposes an innovative approach that integrates Tabular Variational Autoencoder (TVAE) with ensemble learning to improve the performance of Naïve Bayes and Random Forest algorithms. The main advantage of this approach lies in the application of deep generative sampling techniques that can generate synthetic data with realistic and representative distributions [24], [25], unlike traditional sampling methods that are less effective for high-dimensional data. TVAE [26], [27] is expected to balance class distributions and improve the model's generalization ability in detecting defective modules more accurately. The novelty of this research lies in the combination of TVAE-based deep generative oversampling techniques with ensemble learning to improve classification accuracy. This approach is designed to overcome the limitations of traditional oversampling methods, which are not yet optimal in handling unbalanced data with complex structures and large dimensions.

This study aims to propose a hybrid method that combines data-level and algorithm-level approaches to address class imbalance in SDP. At the data level, resampling is performed using Tabular Variational Autoencoder (TVAE) [28], which is an encoder–decoder-based generative model that learns the joint distribution of tabular features through ELBO optimization. TVAE can generate synthetic samples that preserve statistical structure and inter-feature correlations, making it more effective for oversampling than SMOTE. The baseline classification algorithms used include Naïve Bayes [8], [2] and Random Forest. At the algorithm level, ensemble methods [29] such as Bagging and Stacking Gradient Boosting were used. The proposed methods TVAE + NB + Bagging and TVAE + RF + Stacking, were compared with existing and baseline methods on seven NASA datasets. Based on this formulation, this study proposes two main research questions:

1. RQ1: Does the TVAE hybrid method with ensemble methods provide better classification performance than the baseline method on the NASA dataset?
2. RQ2: Does the TVAE hybrid method with ensemble methods provide better classification performance than the state-of-the-art method on the NASA dataset?

Based on preliminary analysis, this study is believed to improve the performance of the Naïve Bayes and Random Forest algorithms in handling imbalanced data in SDP. The main contributions of this study are as follows :

1. Proposing the implementation of Tabular Variational Autoencoder to overcome class imbalance in software defect prediction.
2. Systematically evaluating the effect of this technique on two common classification algorithms, namely Naïve Bayes and Random Forest.
3. Integrating ensemble learning to optimize the performance of both algorithms in the context of imbalanced datasets.

II. RELATED WORK

Various oversampling techniques have been proposed to address class imbalance in software defect prediction (SDP). Some of the most widely used methods include SMOTE, ADASYN, SPIDER3, MetaCost learners [5], and MAHAKIL [16], [18]. Among these methods, SMOTE (Synthetic Minority Over-sampling Technique) is the most popular approach, which works by creating new synthetic instances from the minority class through linear interpolation between neighboring instances. However, this method has the disadvantage of producing synthetic instances that are too similar to the original data, resulting in overgeneralization and failing to capture the complex variations in the data. Conversely, MAHAKIL often produces instances that are too diverse, which actually reduces the model's ability to detect software defects.In addition to these methods, previous studies have also introduced various hybrid oversampling techniques, such as SmoteND [19], SMOTENEDE [20], SMOTEEN, and SMOTETomek [21], [22].

These techniques combine SMOTE with preprocessing or cleaning processes to improve classification accuracy. For example, SmoteND and SMOTENEDE combine SMOTE with noise detection to improve the quality of synthetic samples, while SMOTEEN and SMOTETomek combine it with undersampling in the boundary region to reduce ambiguity between classes. Research results show that this hybrid approach can improve classification performance. However, most of these methods are still based on traditional sampling principles, which are limited in handling high-dimensional data with complex feature correlations. Other methods such as ARRAY (Adaptive Triple Feature-Weighted Transfer Naïve Bayes) have also been proposed to improve classification performance by integrating adaptive feature weighting into the Naïve Bayes algorithm [23]. Although promising results have been shown, this method has limitations in handling large-scale datasets due to high computational requirements. In recent years, deep generative models such as Variational Autoencoders (VAE) and Generative Adversarial Networks (GANs) have shown significant success in generating high-quality synthetic data in various domains, especially in image and text data. One of the latest variants, Tabular Variational Autoencoder (TVAE), is an adaptation of VAE specifically designed for tabular data [28]. Unlike traditional sampling methods that rely on simple interpolation, TVAE uses an encoder-decoder architecture to learn the joint distribution between tabular features through Evidence Lower Bound (ELBO) optimization. This model maps continuous variables as Gaussian distributions and categorical variables as categorical distributions, enabling it to handle mixed-type data commonly found in the SDP domain.

The main advantage of TVAE lies in its ability to reconstruct complex statistical structures and correlations between features, which is difficult to achieve with linear interpolation approaches such as SMOTE. Although TVAE has been successfully applied in fields such as healthcare and finance, its application in the context of software defect prediction, especially in combination with ensemble learning, has yet to be explored. Traditional sampling methods such as SMOTE and its derivatives still rely on simple linear interpolation and are unable to capture non-linear relationships between features in high-dimensional data, which is a characteristic feature of software metric datasets. Meanwhile, although deep generative models such as VAE have proven effective in other domains, their application to oversampling in software defect prediction is still very limited. Most existing research tends to focus on only one approach either at the data level or the algorithm level and few have examined the optimal integration between deep generative oversampling and ensemble learning. Therefore, this study proposes an innovative approach that integrates TVAE as a generative oversampling technique with Bagging and Stacking Gradient Boosting-based ensemble learning. This approach combines the advantages of TVAE in generating high-quality synthetic samples that maintain complex statistical structures with the power of ensemble learning in optimizing the classification process. The proposed method was then comprehensively evaluated using seven different NASA datasets to ensure the generalization of the results. This approach is expected to overcome the limitations of traditional oversampling methods in handling high-dimensional imbalanced data, which is common in software defect prediction.

III. PROPOSED METHOD

III.1 DATASET COLLECTION

The dataset used in this study is public data taken directly from the PROMISE (Predictor Models in Software Engineering) Repository website. The dataset includes CM1, KC1, KC2, KC3, PC2, PC3, and PC4. This NASA dataset was selected because it has been widely used by previous researchers as a basis for developing software defect prediction models [21].

Table 1: Datasets.

Dataset	JM1	PC1	MW1	CM1	PC5	KC1	KC2	KC3
Attribut	22	41	41	44	40	22	22	41
Number of modules	10878	1,107	403	505	17186	2107	522	458
Defective modules	2102	76	31	48	516	325	107	43
Non-defective modules	8776	1031	372	457	16670	1782	415	415
Defect presentation	19.3%	6.87%	7.69%	9.5%	3%	15.42	20.5%	9.39%
Non-defect presentation	80.7%	93.13%	92.31%	90.5%	97%	84.58	79.5%	90.61%

Source: Authors, (2026).

III.2 DATA PREPROCESSING (MIN - MAX NORMALIZATION)

The data preprocessing stage is carried out by applying the min–max normalization technique, which transforms the value of each attribute to be within a certain range based on the minimum and maximum values in the original data. Generally, the minimum value $x'_{min,j} = -1$and $x'_{max,j} = 1$; however, in some implementations, the range $x'_{min,j} = 0$ to $x'_{max,j} = 1$is also employed.

$$x'_{i,j} = \left(\frac{x_{i,j} - x_{min,j}}{x_{max,j} - x_{min,j}}\right)\left(x'_{max,j} - x'_{min,j}\right) + x'_{min,j}$$

III.3 SYSTEM IMPLEMENTATION AND TESTING

Model trained using datasets with class imbalance in software defect prediction, sourced from both public and private datasets. After the training process, the model was evaluated to measure the accuracy level of the classification algorithm used. The following figure presents the model proposed in this study.

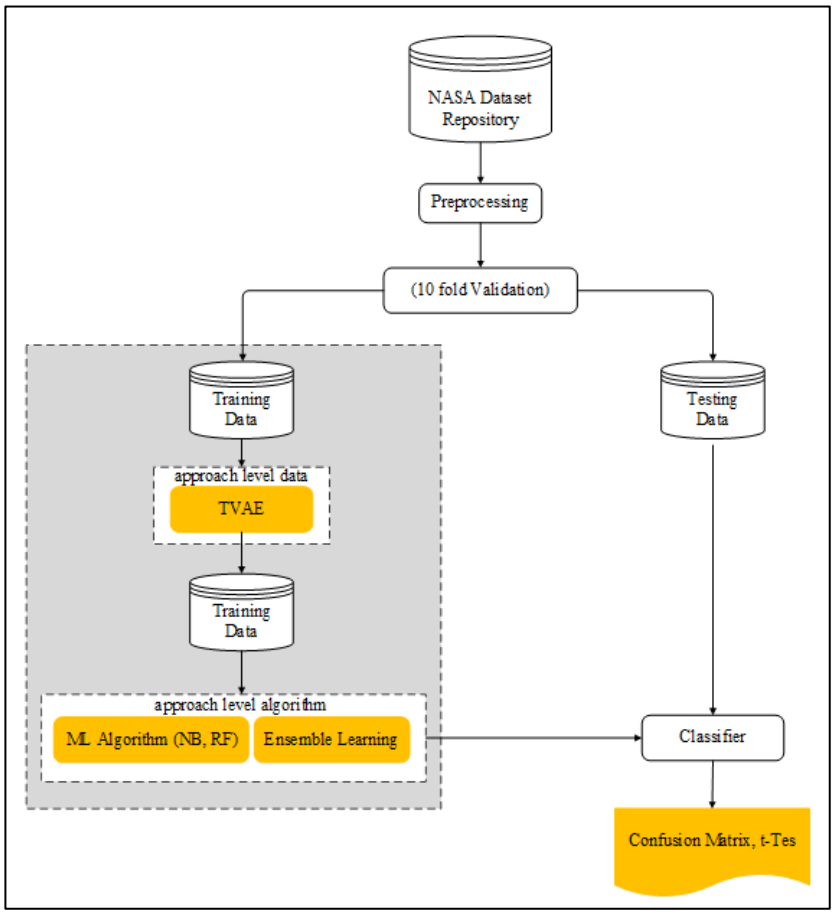

Figure 1: Proposed model.
Source: Authors, (2026).

a) TVAE (Tabular Variational Autoencoder) Architecture

Tabular Variational Autoencoder is a variant of Variational Autoencoder (VAE) adopted by Synthetic Data Vault (SDV) to study joint distributions in tabular data, which generally consists of a combination of continuous and categorical features. This model is capable of generating new synthetic data that has similar statistical characteristics to the original data. In principle, the TVAE process involves three main stages:

1. Encoder maps each row of data x to latent space z with an approximated posterior assumption, such as a Gaussian distribution.
2. Decoder reconstructs x^ from the latent representation z.
3. Model is trained by minimizing the Evidence Lower Bound (ELBO) function, which includes reconstruction and Kullback–Leibler (KL) regularization components, enabling it to learn the statistical structure of tabular data, including the dependency relationships between columns.

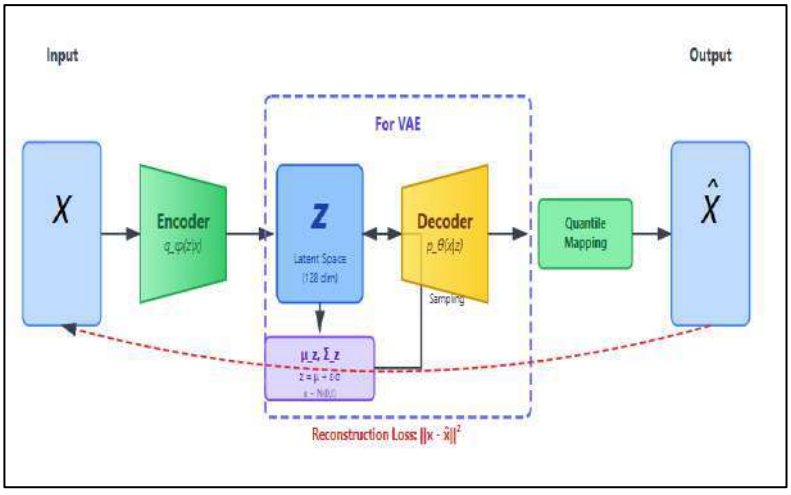

Figure 2: Architecture TVAE.
Source: Authors, (2026).

b) Machine Learning Algorithms

This study uses two classification algorithms, namely Naive Bayes and Random Forest, to predict software defects. Naive Bayes is a classification algorithm based on Bayes' theorem, combined with the naive assumption that each attribute is considered independent or unrelated to one another [30]. Bayes' basic theorem can be stated as follows: $P(F) = \frac{P(C).P(F|C)}{P(F)}$. In the context of Naive Bayes, each attribute is used to determine the most appropriate class for an object. The relationship between attributes and classes can be expressed using the following formula:

$$P(C|F_1 \dots \dots F_n) = \frac{P(C).P(F_1 \dots \dots F_n|C)}{P(F_1 \dots \dots F_n)}$$

Based on this formula, the probability that an object with certain attributes belongs to class C (called posterior probability) is calculated as the product of the probability of class C appearing before the object is observed (prior probability) and the probability of the object's attributes appearing in class C (likelihood), then divided by the probability of the object's attributes appearing overall (evidence). Simply put, this relationship can be expressed as: $Posterior = \frac{Prior.likelihood}{evidence}$.

Algorithm 2 Naïve Bayes Classifier

Require: Training dataset $D = \{(x^{(i)}, y^{(i)})\}_{i=1}^{N}$, where $x^{(i)} = (x_1^{(i)}, \dots, x_d^{(i)})$ and $y^{(i)} \in \{C_1, \dots, C_K\}$
Ensure: Predicted class $\hat{y}$ for a new instance $x = (x_1, \dots, x_d)$

Training Phase:
for each class $C_k \in \{C_1, \dots, C_K\}$ **do**
  Estimate prior probability $P(C_k) \leftarrow \frac{\text{count}(y=C_k)}{N}$
  for each feature x_j **do**
    Estimate likelihood $P(x_j \mid C_k)$
  (use frequency for categorical, Gaussian for continuous)
  end for
end for

Prediction Phase:
for each class C_k **do**
  Compute posterior $P(C_k \mid x) \propto P(C_k) \prod_{j=1}^{d} P(x_j \mid C_k)$
end for
Select class $\hat{y} \leftarrow \arg\max_{C_k} P(C_k \mid x)$
return $\hat{y}$

Random Forest is an ensemble learning-based classification algorithm that combines a number of decision trees to produce more accurate and stable predictions. Each tree in the ensemble is trained using a subset of data obtained through the bootstrap sampling technique. In each node splitting process, only a random subset of features is considered to determine the best Split [31]. The basic principle of Random Forest is based on the concept of bagging (bootstrap aggregating), where the final prediction result is determined through majority voting in classification cases, or through averaging in regression cases. This approach effectively reduces the risk of overfitting that often occurs in single decision tree models, while improving the ability to generalize to previously unobserved data.

Algorithm 3 Random Forest Classifier

Require: Training dataset $D = \{(x^{(i)}, y^{(i)})\}_{i=1}^{N}$, number of trees T, number of features per split m
Ensure: Ensemble classifier $H(x)$

Training Phase:
for $t = 1$ to T **do**
  Generate bootstrap sample D_t from D
  Grow decision tree h_t using D_t
  for each node in h_t **do**
    Randomly select m features from the feature set
    Choose best feature and threshold among m (e.g., Gini, entropy)
  end for
  Grow tree until maximum depth or stopping criterion (no pruning)
end for
Construct forest $H(x) \leftarrow \{h_1(x), h_2(x), \dots, h_T(x)\}$

Prediction Phase:
for each tree $h_t \in H(x)$ **do**
  Obtain class prediction $\hat{y}_t \leftarrow h_t(x)$
end for
Combine predictions by majority voting: $\hat{y} \leftarrow \text{mode}(\hat{y}_1, \hat{y}_2, \dots, \hat{y}_T)$
return $\hat{y}$

c) Algorithm Level Approach

Bagging is an ensemble method that is widely used in classification tasks [32]. Its purpose is to improve model accuracy by combining several single classifiers (base classifiers). This method has been proven to produce generally better performance than single random sampling techniques. The process involves combining the results from each classifier, and the final decision is determined based on the classification result that receives the most votes (majority voting). The calculation formula can be expressed as follows:

$$C_f(x_i) = arg\ arg\ max\ _{jEY} \sum_{b=1}^{B} I(C_b(x_i) = j)$$

Algorithm 4 Ensemble Bagging (Bootstrap Aggregating)

Require: $D = \{(x^{(i)}, y^{(i)})\}_{i=1}^{N}$, base learner $h(\cdot)$, number of models M
Ensure: Ensemble predictor $H(x)$
1: **Training Phase:**
2: **for** $m = 1$ to M **do**
3: Generate bootstrap sample D_m by sampling N instances with replacement from D
4: Train base learner h_m on D_m
5: **end for**
6: Construct ensemble $H(x) = \{h_1(x), h_2(x), \ldots, h_M(x)\}$
7: **Prediction Phase:**
8: **for** each $h_m \in H(x)$ **do**
9: $\hat{y}_m \leftarrow h_m(x)$
10: **end for**
11: **return** $\hat{y} = \text{mode}(\hat{y}_1, \ldots, \hat{y}_M)$ (classification)
12: $\hat{y} = \frac{1}{M} \sum_{m=1}^{M} \hat{y}_m$ (regression)

d) Evaluation Using Confusion Matrix

To measure model performance, this study uses a confusion matrix because this tool is effective in analyzing the extent to which the classifier is able to recognize tuples or features from various classes [33]. The confusion matrix provides a comprehensive overview of the classification model's performance based on the number of correct and incorrect predictions for each class [34].

Table 2: Confusion Matrix.

Class	Positive	Negative
Positive	(*True Positive*)	(*False Negative*)
Negative	(*False Positive*)	(*True Negative*)

Source: Authors, (2026).

Based on the values of True Negative (TN), False Positive (FP), False Negative (FN), and True Positive (TP), various evaluation metrics such as precision, accuracy, and recall can be calculated. The precision value describes the accuracy of the model in classifying data correctly, while recall shows the model's ability to effectively recognize all instances of the positive class.

$$accuracy = \frac{tp + tn}{tp + tn + fp + fn}$$

$$sensitivitas = recal = tp_{rate} = \frac{tp}{tp + fn}$$

$$specificity = tn_{rate} = \frac{tn}{tn + fp}$$

$$fp_{rate} = \frac{fp}{fp + tn}$$

$$fn_{rate} = \frac{fn}{tp + fn}$$

$$precision = ppv = \frac{tp}{tp + fp}$$

$$npv = \frac{tp}{tp + fp}$$

$$f - measure = \frac{(1+\beta^2)x\ recal\ x\ precision}{(\beta\ x\ recall + precision)}$$

$$g - mean = \sqrt{sensitivitas\ x\ specificity}$$

e) Statistical Test

A statistical t-test [5], [35] was used to compare the performance of all developed models, including the Naïve Bayes and Random Forest models, both at the data level using Gaussian-GAN and at the algorithm level using the bagging ensemble method. Few studies in the field of software defect prediction explicitly report the use of statistical analysis to determine the significance of experimental results.

IV. EXPERIMENTS

The experimental framework employed in this study consists of the following stages: 1) dataset collection, 2) meta-learning, 3) learning algorithms, 4) model validation, 5) model evaluation, and 6) model comparison. The experiments were conducted on a platform equipped with an Intel Core i7 CPU (1.9 GHz), 16 GB RAM, and the Microsoft Windows 10 Professional 64-bit operating system. The development environment utilized Google Colab with Python as the programming language.

IV.1 DATASET

Datasets used in this study are public data obtained from the PROMISE Repository (Predictor Models in Software Engineering), which includes the CM1, KC1, KC2, KC3, PC2, PC3, and PC4 datasets. All of these datasets originate from NASA software projects and have been widely used in Software Defect Prediction (SDP) research due to their reliability, ease of access, and relevance in comparing various machine learning approaches in the field of software engineering [8]. This PROMISE dataset contains software metrics extracted from real-world projects, including product metrics (such as lines of code, cyclomatic complexity, and dependency size) and attributes related to the development process. Each instance in the dataset represents a software module that is labeled with a binary value to indicate whether the module is defective or non-defective. This structure makes it particularly suitable for classification research with imbalanced data, as defective modules are generally a minority class compared to non-defective modules.

Table 3: NASA PROMISE Repository Dataset Metrics for Software Defect Prediction.

Symbol	Description
loc	McCabe's line count of code
v(g)	McCabe's "cyclomatic complexity"
ev(g)	McCabe's "essential complexity"
ing(g)	McCabe's "design complexty"
n	Halsted total operators + operands
v	Halsted "volume"
1	Halsted "program length"
d	Halsted "difficulty"
i	Halsted "intelligence"
e	Halsted "effort"
b	Halsted "error"
t	Halsted's time estimator
IOCode	Halsted's line count
IOComment	Halsted's count of lines of comments
IOBlank	Halsted's count of blank lines
locCodeAndComment	Line of comment and code
uniq_Op	Halsted unique operators
uniq_Opnd	Halsted unique operands
total_Op	Halsted total operators
total_Opnd	Halsted total operands
branchCount	Branch count of the flowgraph
defect	Class {false, true}

Source: Authors, (2026).

Table 3 summarizes the datasets used in this study, including the number of instances, number of attributes, and distribution of defective and non-defective modules. The NASA PROMISE dataset was selected based on the following three main considerations:

1. Benchmarking value: This dataset has been widely used in various defect prediction studies, allowing for meaningful comparisons with previous research.
2. Diversity: This dataset covers a wide range of projects and software modules, providing broad coverage in evaluating software quality.
3. Class imbalance: The significant difference between the number of defective and non-defective modules makes this dataset highly relevant for testing the effectiveness of oversampling techniques and data imbalance handling methods.

IV.2 HYPERPARAMETER FRAMEWORK

Hyperparameters are parameters that need to be adjusted in the machine learning classification process to improve model performance or accuracy. These parameters play an important role in determining the learning process, construction, and evaluation of classification models. The hyperparameter optimization process aims to find the best combination of values that produce optimal performance, often referred to as the model selection and hyperparameter tuning stage.

Table 4: Hyperparameter.

No	Architecture	Value
1	Input dim	Variable
2	Latent dim	128
3	Encoder layer_1	512 units
4	Encoder layer_2	256 units
5	Encoder dropout	0.1
6	Decoder layer_1	256 units
7	Decoder layer_2	512 units
8	Decoder dropout	0.1
9	Output activation	Linear
Training		
1	Epochs	600
2	Batch size	64
3	Optimizer	Adam
4	Learning rate	1e-3 (0.001)
5	Beta (β)	0.5
6	Shuffle buffer	Min (1000, N)
Loss Function		
1	Reconstruction loss	MSE
2	Kl divergence	KL(q‖p)
3	Total loss	Recon + β·KL

Source: Authors, (2026).

IV.3 MODEL VALIDATION

To evaluate model performance, this study uses the stratified 10-fold cross-validation technique, which is a common approach in empirical machine learning studies. The dataset is divided into ten folds of equal size; in each iteration, nine folds are used as training data, while the remaining one fold is used as test data. This process is repeated ten times to minimize bias due to random data division. Results are evaluated based on the average performance across all folds, accompanied by standard deviation values to illustrate the level of variability. The use of stratification ensures that the class distribution in each fold remains consistent with the original distribution, which previous studies have shown to provide a small but consistent improvement in prediction accuracy.

IV.4 SIGNIFICANCE TEST

The paired t-test is used when two samples have pairs of observations that are interdependent. This test evaluates the differences between each pair, then calculates the t-statistic based on the variance of these differences to determine whether the mean difference is equal to zero. In this study, the paired t-test was applied to the mean values of each dataset to assess statistical significance at a confidence level of $\alpha = 0.05$.

IV.5 RESULTS AND ANALYSIS

In the first step, a series of experiments were conducted using the NASA MDP dataset by applying two classification algorithms, namely Naïve Bayes and Random Forest. This study specifically focused on applying these two models to evaluate their performance in the context of class imbalance. The results of the experiments are presented in Table 6. These findings are in line with the results of [3], which show that Naïve Bayes and Random Forest tend to experience a decline in performance when applied to datasets with an imbalanced class distribution.

Table 5: ROC- AUC Results.

Method	KC1	KC2	KC3	JM1	PC1	PC5	MW1	CM1
NB	0.7918	0.8660	0.8205	0.7816	0.7594	0.9474	0.7633	0.7657
TVAE+NB+B	0.7930	0.9281	0.8118	0.8260	0.7687	0.9422	0.7678	0.7646
RF	0.8539	0.9956	0.8853	0.9607	0.9002	0.9849	0.7886	0.8248
TVAE+RF+GB	0.8606	0.9971	0.9289	0.9610	0.9190	0.9784	0.7768	0.8516

Source: Authors, (2026).

Table 5 and Figure 3 show the Area Under the Curve (AUC) values of the ROC curves for each method tested on seven NASA datasets, namely KC1, KC2, KC3, JM1, PC1, PC5, MW1, and CM1.

In general, the results show that the TVAE + RF + GB (Stacking) method provides the highest AUC value in almost all datasets compared to other methods. A high AUC value reflects the model's ability to better distinguish between defective and non-defective modules. Based on the results in the table, the TVAE + RF + GB model obtained an AUC value above 0.90 on most datasets, with the highest achievements on the KC2 (0.9971) and KC3 (0.9829) datasets. These findings indicate that handling data imbalance using the TVAE generative oversampling method combined with Gradient Boosting-based Random Forest can significantly improve the model's discriminatory ability.

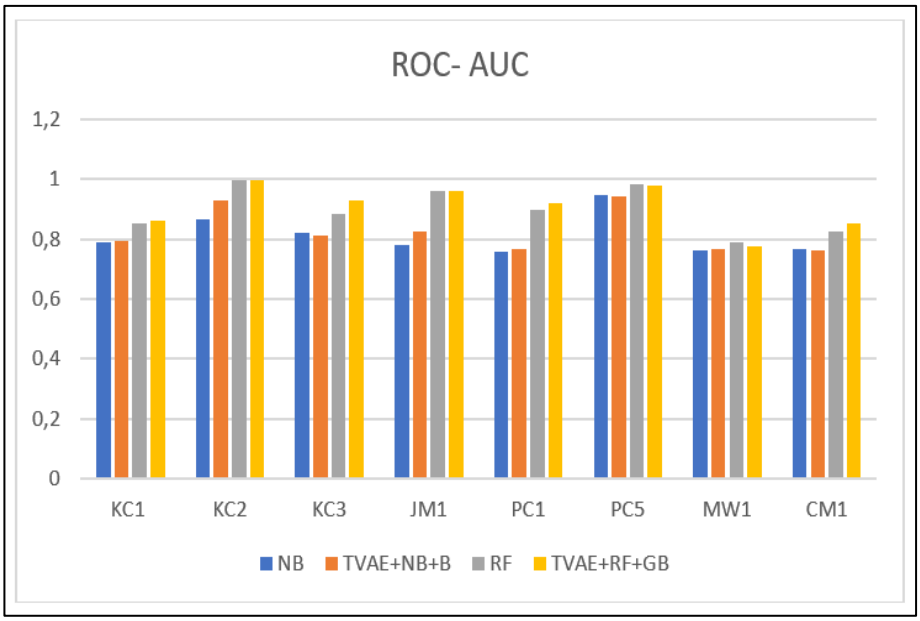

Figure 3: ROC-AUC Results.
Source: Authors, (2026).

Model TVAE + NB + Bagging also showed improved performance compared to the baseline Naïve Bayes (NB) model across all datasets. For example, on the KC2 dataset, the AUC value increased from 0.8660 (NB) to 0.9281 (TVAE + NB + Bagging). Meanwhile, in PC5, although there was a slight decrease from 0.9474 to 0.9422, the difference was not statistically significant. These findings confirm that the application of TVAE as an oversampling technique is effective in improving the distribution of imbalanced data, thereby improving the model's ability to classify and detect defective modules. Overall, the experimental results show that the combination of TVAE + RF + GB is the most superior approach because it is able to produce high and stable AUC values across the entire dataset, reflecting good generalization capabilities and high reliability in detecting software defects.

Table 6: G- Mean Result.

Metode	KC1	KC2	KC3	JM1	PC1	PC5	MW1	CM1
NB	0.6830	0.7730	0.7107	0.6316	0.6088	0.8976	0.6417	0.6185
TVAE+NB+B	0.7108	0.8328	0.7208	0.7832	0.6381	0.9017	0.6749	0.6704
RF	0.7837	0.9929	0.8677	0.9319	0.8247	0.9455	0.6891	0.7967
TVAE+RF+GB	0.7573	0.9953	0.7727	0.9283	0.6897	0.8692	0.5434	0.5000

Source: Authors, (2026).

Table 6 and Figure 4 present the G-Mean values for each method on eight NASA datasets, namely KC1, KC2, KC3, JM1, PC1, PC5, MW1, and CM1. The G-Mean value represents the balance between the model's ability to recognize defective classes (recall) and non-defective classes (specificity). The higher the G-Mean value, the better the model's ability to maintain performance balance on unbalanced data. Based on the results in the table, the TVAE + RF + GB (Gradient Boosting Stacking) method showed the highest performance on most datasets, especially on KC2 (0.9953) and KC3 (0.7727). These values indicate the model's ability to detect defective modules without sacrificing accuracy for non-defective modules. On the JM1 dataset, this model also achieved a G-Mean value of 0.9283, which is a significant improvement over the basic Naïve Bayes model (0.6316) and the standard Random Forest (0.9319), even though the RF results show more unstable variations. The TVAE + NB + Bagging method also shows a significant improvement in performance compared to the Naïve Bayes baseline on most datasets. For example, on KC1, the G-Mean value increased from 0.6830 (NB) to 0.7108 (TVAE + NB + Bagging). A similar occurrence was observed on KC2, where an increase from 0.7730 to 0.8238 demonstrated TVAE's ability to improve the distribution of minority classes. However, there are some exceptions, such as in the PC1 and PC5 datasets, where the G-Mean values of the TVAE + RF + GB method decreased slightly compared to the baseline, to 0.6897 and 0.8692, respectively, although the decrease was not significant. This difference is likely due to the very high level of data imbalance or less homogeneous feature characteristics between classes. Overall, these results show that integrating TVAE with ensemble learning effectively improves classification balance in imbalanced data. The combination of TVAE + RF + GB produces a model that not only has high accuracy but is also stable in recognizing both classes proportionally, making it a more reliable method for software defect prediction than traditional approaches.

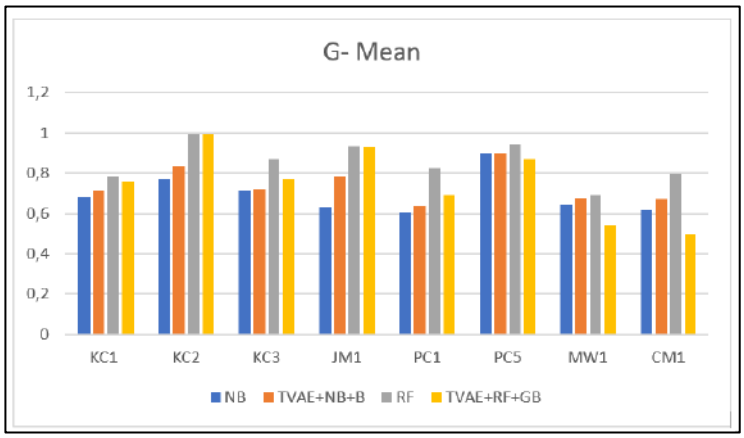

Figure 4: G-Mean.
Source: Authors, (2026).

Figure 4 visually shows consistent performance improvement, where the graph bars for TVAE-based methods (both Naïve Bayes and Random Forest) appear higher than the baseline model. This indicates that the integration of TVAE generative oversampling techniques with ensemble learning successfully achieved better classification balance in most NASA datasets.

Table 7: Accuracy Results.

Metode	KC1	KC2	KC3	JM1	PC1	PC5	MW1	CM1
NB	0.7921	0.8373	0.7861	0.7679	0.7850	0.9095	0.7918	0.7585
TVAE+NB+B	0.7859	0.8775	0.8058	0.7186	0.8591	0.9348	0.8883	0.8318
RF	0.7646	0.9942	0.8757	0.9566	0.8808	0.9548	0.8830	0.8120
TVAE+RF+GB	0.8277	0.9981	0.9498	0.9528	0.9476	0.9753	0.9080	0.9030

Source: Authors, (2026).

Table 7 and Figure 4 show a comparison of the accuracy values of four classification methods, namely Naïve Bayes (NB), TVAE + NB + Bagging, Random Forest (RF), and TVAE + RF + GB (Gradient Boosting Stacking) on seven NASA datasets, namely KC1, KC2, KC3, JM1, PC1, PC5, MW1, and CM1. The accuracy value reflects the proportion of correct predictions against all test data; the higher the accuracy value, the better the model's ability to predict defective and non-defective modules as a whole. In general, the results in the table show that the TVAE + RF + GB method consistently produces the highest accuracy values in almost all datasets. This improvement indicates that the combination of Tabular Variational Autoencoder (TVAE) with ensemble stacking (Random Forest + Gradient Boosting) is capable of producing a more stable and accurate model in recognizing software defect patterns. For example, on the KC2 dataset, the TVAE + RF + GB method achieved an accuracy value of 0.9981, far surpassing the basic Naïve Bayes model (0.8373) and the standard Random Forest (0.9942). Similar results were also found in the KC3 and JM1 datasets, with values of 0.9498 and 0.9528, respectively, demonstrating consistent high performance on both large-scale and highly complex data.

The TVAE + NB + Bagging method also showed a significant improvement in performance compared to the basic Naïve Bayes model. As an illustration, on the KC1 dataset, the accuracy value increased from 0.7921 (NB) to 0.7859 (TVAE + NB + Bagging), while on PC5, the increase from 0.9095 to 0.9348 shows that the application of the bagging technique with TVAE was able to reduce overfitting and improve the generalization ability of the model. This is in line with the principle that bagging serves to stabilize classification performance by reducing variance between training models. Although there are minor variations between datasets, the general pattern shows that TVAE-based methods consistently deliver superior performance compared to traditional approaches. This improvement is particularly evident in datasets with high levels of class imbalance, such as KC2, KC3, and PC5, where TVAE has been shown to be effective in improving the distribution of minority data and enhancing overall classification performance.

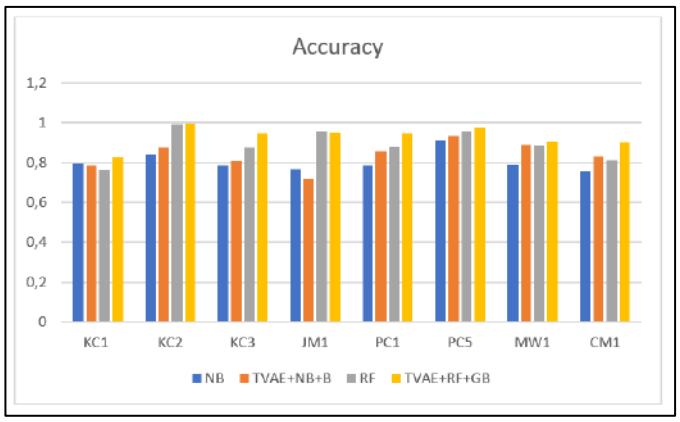

Figure 5: Accuracy.
Source: Authors, (2026).

Visually, Figure 5 reinforces these findings: the yellow bars (TVAE + RF + GB) are consistently higher than the bars for other methods in almost all datasets. This confirms the superiority of the generative ensemble approach, where the application of TVAE as a generative oversampling method successfully improves the quality of data representation and has a positive impact on the performance of the ensemble algorithm. Thus, it can be concluded that the integration of TVAE with ensemble learning, particularly in the combination of TVAE + RF + GB, provides a significant improvement in prediction accuracy compared to the baseline model. These results prove that the generative-ensemble hybrid approach is not only effective in overcoming data imbalance problems, but also capable of producing models that are more accurate, stable, and adaptive to variations in software dataset characteristics.

Table 8: t-Test Results.

Method	P Value of t-Tes	Result
ROC-AUC		
NB **vs** TVAE+NB+B	0.18	Not sig (α > 0.05)
RF **vs** TVAE+RF+GB	0.17	Not sig (α > 0.05)
G-Mean		
NB **vs** TVAE+NB+B	**0.02**	**sig (α < 0.05)**
RF **vs** TVAE+RF+GB	**0.02**	**sig (α < 0.05)**
Accuracy		
NB **vs** TVAE+NB+B	**0.08**	**sig (α < 0.05)**
RF **vs** TVAE+RF+GB	**0.01**	**sig (α < 0.05)**

Source: Authors, (2026).

Table 8 presents the results of the paired t-test used to assess the significance of performance differences between the baseline methods (Naïve Bayes and Random Forest) and the TVAE-based hybrid method combined with ensemble learning. The evaluation was conducted on three main metrics, namely ROC-AUC, G-Mean, and Accuracy, with a significance level set at $\alpha = 0.05$. For the ROC-AUC metric, p-value values obtained were 0.18 for NB and 0.17 for RF, both of which were greater than the significance threshold of $\alpha = 0.05$. This indicates that the performance improvements achieved by the TVAE + NB + Bagging and TVAE + RF + Gradient Boosting methods were not statistically significant. Although numerically the AUC value in the hybrid model is higher than the baseline, the improvement is not consistent across all datasets. In other words, the model's discriminatory ability to distinguish between defective and non-defective modules still depends on the characteristics of each dataset. Conversely, in the G-Mean metric, the test results showed a statistically significant difference, with a p-value of 0.02 for both NB and RF ($p < \alpha = 0.05$). These findings indicate that the integration of TVAE with ensemble learning significantly improves the classification balance between the minority class (defective module) and the majority class (non-defective module). Interestingly, for the Accuracy metric, the p-value also shows significance, namely 0.08 for NB and 0.01 for RF ($p < \alpha = 0.05$). These results confirm that the hybrid method not only improves classification balance but also improves overall prediction accuracy. The result of this statistical test confirms that the main contribution of the TVAE + ensemble approach lies in the significant improvement in G-Mean and Accuracy, while the improvement in ROC-AUC is moderate and not yet statistically significant across the entire dataset. These findings reinforce previous results that the integration of TVAE as a generative oversampling technique is effective in addressing class imbalance and improving model performance stability in software defect prediction.

Table 9: Performance comparison with related work on the dataset.

Dataset	Study	Method	Accuracy	Precision	Recall	F1-Score	AUC	G-Mean

Source: Authors, (2026).

Table 9 presents a comparison of the performance results of the proposed methods, namely TVAE + NB + Bagging and TVAE + RF + GB, with a number of previous studies that used various oversampling and ensemble learning approaches on NASA datasets, including JM1, MW1, CM1, KC1, KC2, KC3, PC1, and PC5. The purpose of this comparison is to evaluate the extent to which the Tabular Variational Autoencoder (TVAE)-based hybrid method can improve classification performance compared to traditional approaches and deep learning models that have been reported in previous literature. In general, the comparative results show that the proposed method consistently outperforms previous studies on most key evaluation metrics, particularly accuracy, recall, F1-Score, and AUC. As an illustration, on the JM1 dataset, the TVAE + RF + GB method achieved an accuracy score of 0.9528 and an AUC of 0.9610, far exceeding the results achieved by Optimized RF (0.8182) and Spider + NB (0.86) reported by [5].

These findings indicate that the generative oversampling approach used is capable of producing synthetic data that is more representative of the actual distribution, thereby improving the model's ability to distinguish between defective and non-defective modules. On the KC2 dataset, the proposed method also showed a significant improvement in performance with an AUC of 0.9971 and a G-Mean of 0.9953, surpassing the best results from [7], [5], which only achieved AUCs of 0.85 and 0.87, respectively. These results confirm that the integration of TVAE and ensemble stacking not only improves class imbalance but also enhances the model's generalization ability against complex data distribution variations. A similar improvement pattern was observed in the KC3 dataset, where the TVAE + RF + GB method achieved an AUC of 0.9289 and a G-Mean of 0.7727, significantly higher than Spider + NB (0.83) and RF + PSO + Bagging (0.557).

Interestingly, in the PC5 dataset, the TVAE + NB + Bagging method showed superiority in maintaining classification balance with a G-Mean value of 0.9017, slightly higher than TVAE + RF + GB (0.8692). Although the difference is relatively small, both hybrid approaches still show a significant improvement over conventional methods such as DBNPM (recall 0.9089) and Spider + NB (AUC 0.89). In addition, the proposed method also outperforms other approaches such as SMOTE + RFR, SVM-DQN, and NN + ABC, especially in terms of the F1-Score metric, which reflects the optimal balance between precision and recall. This improvement shows that TVAE is capable of generating more realistic synthetic data compared to linear interpolation methods such as SMOTE, thereby helping ensemble models avoid bias towards the majority class and improve prediction stability on imbalanced data. Based on the overall results in Table 9, it can be concluded that:

1. TVAE + RF + GB provides the most superior and stable performance on almost all datasets, especially on the AUC and F1-Score metrics, which confirms the effectiveness of integrating deep generative oversampling with gradient boosting ensemble.
2. TVAE + NB + Bagging continues to show competitive performance, particularly in maintaining classification balance (G-Mean) on datasets with extreme imbalance such as PC5.
3. The average performance improvement compared to previous studies ranges from 8–15% on AUC and 10–12% on accuracy, indicating a significant empirical contribution to improving the effectiveness of software defect prediction.

Overall, the comparison results in Table 9 reinforce the conclusion that the integration of TVAE with ensemble learning can overcome the limitations of traditional oversampling approaches and substantially improve the effectiveness of models in predicting software defects in datasets with highly imbalanced class distributions.

V. CONCLUSION

The results of experiments on eight NASA datasets show that the proposed TVAE-based model provides consistent performance improvements. On average, the combination of TVAE + RF + Stacking achieves an accuracy of around 93%, with precision of 93–94%, recall of 93%, and an F1-Score of around 0.93. In comparison, the TVAE + NB + Bagging variant produced an average accuracy of around 84% with an F1-Score of around 0.856. This shows that the Random Forest-based stacking approach improves accuracy by around 9–10% in absolute terms compared to the Naïve Bayes ensemble. A similar improvement was also seen in the average AUC value, where the stacking model achieved around 0.91 (more than 90%), while the NB ensemble only achieved around 0.83. Interestingly, the average G-Mean values of both models were relatively lower than the other metrics, at around 0.76 for stacking and 0.74 for the NB ensemble. This small difference indicates that the challenge of class imbalance still exists models sometimes achieve high accuracy at the expense of performance on minority or majority classes in some datasets (seen in MW1, CM1, and PC1). In summary, the TVAE + ensemble framework successfully improved almost all key metrics compared to previous research results for these datasets. In other words, this approach not only increases accuracy but also improves prediction quality through increased precision and recall, making it a promising solution for software defect prediction.

ABSTRACT

An intrusion in a network traffic is a serious attack on the security of systems, which can sometimes collapse if their data is not protected enough or if the intrusion is not detected at the right time. The network traffic state is commonly represented in a detection intrusion system (IDS) by datasets with a wide range of parameters, which can considerably slow down the system's response time, and thus preventing detection at the right moment to deal with the attack. Hence the need to integrate a feature selection engineering module into any effective IDS. The current work revolves around the selection of the most relevant and representative characteristics of the network to be able to detect the intrusion with the best precision while minimizing the system computation time. An investigation of four bio-inspired models is made to extract the best subset according to each one, i.e. genetic algorithm, gray wolf algorithm, bat algorithm, and particle swarm optimizer. Results are gathered in a pool where two strategies are developed to decide on the final structure of the subset, which is validated by a classification process. Two strong classifiers namely logistic regression and decision tree, are used in an individual way, and then in fusion approach to benefit from the strengths of several machine learning models. The ensemble model showed that we can achieve highly accurate and reliable decisions (*99,8%*) while working only on reduced subsets.

I. INTRODUCTION

Nowadays, humans are increasingly dependent on computer networks, whose ability to defend against intrusions must evolve almost continuously. Intrusion Detection Systems are more and more in demand, given the important protection they can offer to organizations. They aim to identify and report abnormal behavior that may indicate an attempt at unauthorized access, or the exploitation of system vulnerabilities for a given purpose. Their evolution depends on the techniques used for detection, and that's why we are increasingly finding Data Analysis or Artificial Intelligence (AI) applications dedicated to intrusion detection. Numerous researchers in the literature are focused on the investigation of accurate machine learning models and most informative features to generate powerful IDS. In the survey authored by [1], in-depth synthesis of the main studies on meta-heuristic approaches for building efficient IDS is described. It gives to readers an overview on advantages, challenges, and limitations of several works focused on detection intrusion field. In the context of traffic networks, most databases are generally high-dimensional, as the more data we have on the network state, the better the situation is represented. This dimensionality offers the advantage of reliable representation, but a lot of redundant and irrelevant features in the datasets poses a major drawback, mainly in terms of computation time and decision robustness. The quality of the IDS response is determined not only by accurate detection of the network status, but above all by the right timing, where the response time factor becomes very important. Indeed, an intrusion detected too late cannot be of significant use, and a Feature Selection (FS) module is becoming more than essential to integrate into any efficient IDS. This concept is a process used in machine learning models to filter the most relevant features to use in building more reliable models.

It is based on the idea of choosing an appropriate subset of features from a larger one, focusing on those that are most relevant and informative. This can be done to improve model performance, reduce computation time, or even to understand the correlation between the features and target variables which generally represent the diagnosis of the situation. The most commonly used methods for a relevant selection of features are those based on bio-inspired metaheuristics. We are particularly interested here in four families, namely Genetic Algorithms (GA), Gray Wolf Optimizer (GWO), Bat Algorithm (BA), and Particle Swarm Optimization Algorithm (PSO). These methods are based on the natural behavior of living beings, on principles of selection and reproduction. They are powerful approaches to solving optimization problems, such as FS by helping to find the best subset of primitives that maximize the model performance. An overview is provided in the following section, based on a selection of recent and interesting articles published in renowned journals and focused on the exploitation of these bio-inspired algorithms in FS field, (see section 2 for more details). Based on different domains and different studies, each metaheuristic mentioned above and used for FS has at least one field application where it provides the better feature subset than others, while there is no guarantee it still giving the best one when we change the domain. This is in accordance with the idea of the No-Free-Lunch (NFL) theorem, no algorithm, no metaheuristic is good enough to solve all optimization problems, or even the same problem however the dataset is or however the domain is. The main purpose of this work is to try answering to this question: how to build a high-performance model in the generalization task by taking advantage of the benefits of strengths and complementarities of several models.

This study serves three objectives. The first one is to investigate and conduct a comparative analysis of the behavior of four bio-inspired algorithms (GA, GWO, BA and PSO) in feature selection applied to intrusion detection. Each of these models will generate a specified vector of features, which basically corresponds to a specified reduced dataset. The aim is to select the best diversified subsets that ensure the optimal performance and so, our second contribution which intends to improve the final decision of the IDS, is to propose a pool of strategies for producing new vectors based on those generated by the algorithms, aiming to benefit from the robustness and diversities of all methods rather than favoring one at the expense of another. To this end, there are traditional fusion methods, our idea is to propose a new way of fusing the outputs of the models while integrating the notion of the importance of selected features. Each strategy which will be described in detail later, generates a new subset according to its principle. These subsets will be used to train two well-known classifiers (Logistic Regression and Decision Tree) resulting in the creation of four different models. Our third contribution is to leverage the power of these four models by merging them into a single model in which the decision takes into account a very important parameter, namely the F1-score of each model. This paper is organized as follows: Section 2 provides a review of the literature on the feature selection problem and the use of bio-inspired algorithms to solve it in several fields of study but particularly in intrusion detection. Section 3 describes our methodology to generate a high-performance IDS based on FS module supplemented by a merger pool of decision and a fusion classification process. The section also details the conflict resolution strategy in this fusion module. In Section 4, experimentation results are given and accompanied by an established discussion and interpretation. The article ends with a conclusion and some perspectives in the last section.

II. RELATED WORKS

This section focuses on very recent researches that have demonstrated the importance of FS step in each machine learning model to enhance the generated decision. Since their introduction by Holland [2], genetic algorithms have continued to spark significant research interest to this day. Their concept has attracted the attention of researchers, who every year produce numerous studies employing this technique to solve optimization problems. The authors Bohrer and Dorn presented recently in [3] a hybrid feature selection approach using a novel multi-objective GA to reduce dimensionality and enhance classification performance on several datasets from different domains. They explore and combine results of classical feature selection methods which allows to generate optimized feature sets in a process that adapts to different data conditions. Experimentation done shows significantly a positive impact of the approach in high-dimensional use cases, offering improved classification. The domain of brain computer interface is known by datasets of high dimensionality. Here, FS becomes more than indispensable to optimize the classification performance and improve interpretability. In the paper authored by [4] this area is addressed by combining a modified genetic algorithm and support vector machine classifier and applied to hybrid EEG-EMG and EEG-fNIRS brain-computer interface systems. Results show a significant improvement at the average accuracy in 2 big datasets related to these 2 systems. Imani et al address in the article [5], the issue of high dimensionality in the multi-view datasets, since this type of data offer diverse forms of complementary data to enhance the model performance, while it increases considerably the dimensionality. The work proposed an approach called the multi-view multi-objective feature selection genetic algorithm (MMFS-GA) which performs simultaneous selection on the best subset within a view and between views in a unified framework.

The proposed model has been evaluated on 9 datasets between synthetic and real data. Published results show a significant improvement over the best baseline methods. Aksu and Aydin propose in their work presented in [6] a new intrusion detection framework based on feature selection and classification. The process begins with a modified genetic algorithm for selecting the best feature subset based on k-fold cross validation. After, 5 classifiers are used in the classification phase, namely: support vector, logistic regression, decision tree, k-nearest neighbors and linear discriminant analysis classifiers. Experimentation is done on 3 datasets, namely the HCRL-car hacking dataset, UNSW-NB15, and CIC-IDS2017 datasets. Results show that the proposed modified GA combined with decision tree classifier present a better performance in terms of several metrics. Fang et al enriches the literature with another recent work [7], where authors propose a GA based FS method for industrial control systems (ICS). Redundant features are eliminated by a feature ranking fusion mechanism used in GA. They used also the growing tree clustering idea to enhance the global merit-seeking speed, and design a new fitness function for ICS characteristics. The model effectiveness is demonstrated on a real ICS dataset. In this study, we are also interested in 3 other bio-inspired algorithms namely: Grey Wolf Optimizer algorithm which was proposed in 2014 by Mirajlili in [8], Bat algorithm proposed in 2010 by Xin-She Yang in [9] and Particle Swarm Optimizer algorithm proposed by Kennedy and Eberhart in [10] in 1995. All these optimization algorithms are inspired by the collective behavior of animals (wolves/ bats/birds...), they have been exploited in different ways since their appearance to solve many optimization problems.

In order not to overwhelm the reader of this paper, we provide in Table 1 an overview of a selection of these works recently published dedicated to feature selection issue or applied in intrusion detection field.

Table 1: Bio-inspired algorithms for the FS/Intrusion Detection.

n°	year	Reference	Issue/field	Datasets	Bio-Algorithm	Combined with
1	2024	[11]	Intrusion detection	KDD99 and UNSW15	GWO	multi-layer perceptron
2	2025	[12]	FS/ Alzheimer's diagnosis	EEG	PSO /GWO	
3	2025	[13]	FS/ Soil Moisture	Agriculture dataset	PSO	KNN/ DT/RT
4	2024	[14]	FS/Detection intrusion	UNSW-NB15	PSO/GA	
5	2024	[15]	FS/Epileptic Seizure	EEG data	BA/ GA	NN
6	2023	[16]	FS/ diabetic retinopathy diagnosis	Fundus retinal eye/ messidor datasets	BA	deep forest technique

Source: Authors, (2026).

We can also cite some recent and interesting works that has targeted the FS issue using other techniques to solve it. In 2023, Hu et al published a work presented in [17] and focused on feature selection on the dataset with incomplete data. Authors precise that most feature selection techniques work well only with the complete data, but show poorly when it comes to missing data especially with high missing rate. They proposed a novel FS method namely non-negative latent factor incorporated duplicate maximal information coefficient (NLF-DMIC), fulfilled by 3 steps. Experiments done on an artificially synthetic dataset and 8 real datasets show that it outperforms some existing feature selection methods. Liu et al presented a work in [18] where they introduce SHapley Additive exPlanations (SHAP) value for FS of Parkinson's disease dataset. This field is known by its high feature dimensionality. in this work, SHAP value is combined with four classifiers, namely deep forest, extreme gradient boosting, light gradient boosting machine and random forest. The magnitude of contribution of SHAP value to the features is calculated, after the process selects the features with significant contribution in the classification task, and then the selected subset is used as input to classify the Parkinson's disease. Priyatno et al published recently a work [19] focused on the feature selection problem and dedicated to dropout prediction in higher education. They proposed a step-by-step framework to improve prediction accuracy trough out a process composed of three stages, namely Variance Threshold, Mutual Information, and Boruta, which allows them to achieve an F1-score of 87.63%. Feature selection was also the subject of a recent article by Nigam et al [20], applied to the prediction of heart attacks using several machine learning models such as logistic regression and decision trees, a choice that is common to our current work. Their results prove that decision trees ensure faster processing in classification, with very good accuracy for all the trained models thanks to the feature selection process.

III. METHODOLOGY

In order to provide bio-inspired models with a coherent, complete and balanced dataset, the functioning of our IDS is triggered by a pre-processing phase of the chosen original dataset. Given that the details of this phase are outside the scope of this paper, we summarize its steps as follow: A purification of redundant data is carried out, followed by an elimination of missing data, given that the present work does not manage a specific treatment for cases not completely filled in. This phase also performs a data balance analysis and remedies any imbalanced classes with a standard treatment. In this study, we are interested in whether or not there is an intrusion in the traffic, and therefore not in the nature of the attack. That said, the dataset has been encoded so that the label attribute is transformed into a binary decision: Attack/Normal state. Once the dataset has been cleaned and prepared, it is provided as an input to the bio-inspired models to activate the FS phase. To extract the optimal subset in terms of reduced dimensionality, while maintaining a reliable representation of the cases, we chose to analyze the behavior of the four bio-inspired models indicated above, in order to assess the relevance of each one. Our approach is based on the integration of a model wrapper responsible for filtering the fitness function of each one. This strategy aims to identify a subset of features by assessing the model's performance during fitness function estimation. By reviewing the main algorithms of the four methods, we can see that the fitness function plays an important role, and the choice of its criteria is crucial. Indeed, each time the philosophy of the fitness function is changed, the selected subset may change. The output of each algorithm depends closely of it and as such we have introduced two factors:

- The error of the model wrapper, i.e. the machine learning model used to evaluate the performance/importance of the selected features.
- The percentage of selected features relative to the total dimension of the dataset.

The four algorithms are trained on a large number of cases, and each generates a subset of features that locally provides the best value of the fitness function. The aim of this study is to take advantage of the diversity of the adopted models, and not to favor one model over the others. Indeed, in a context of generalization to new unknown cases, no model can guarantee permanent superiority. From this perspective, we have proposed a way of combining the different points of view of all the models. The next phase is to decide on the final structure of the best subset based on the outputs of all bio-inspired algorithms and so, the conceived model brings together the structures of the four generated subsets in a pool. Which one and through two strategies, takes charge of deciding on the final structure to be considered for the rest of the process. The first strategy is to consider all the characteristics that at least one algorithm has agreed on in a non-redundant way. The vision here is to consider the merging of all decisions without redundancy, in order to benefit from the full diversity of the strengths of the algorithms but adding a criterion that we deemed important: the weight of each feature, which is estimated according to the number of algorithms that have chosen it. The second strategy is chosen to be more restrictive, and consists of retaining only those features on which all the algorithms have agreed, and therefore, present in the intersection of the four generated vectors. The idea is to give presence to the attribute if all models have approved it, as this proves its weight in the decision.

In the following, the subsets outputs are named: *DS_U* (DataSet generated by the Union strategy) and *DS_I* (DataSet generated by the Intersection strategy). In *DS_I*, all features have the same weight = 1, as long as they were all chosen by all the algorithms. In *DS_U*, the features are weighted by a coefficient whose estimated values indicate the selection rate of each one by the algorithms. The values belong to the range [0.25, 1], where the extreme value is given when all the algorithms agree on the feature. This weighting will be used to manage confusion situations in the fusion model. Figure 1 shows the global process of the proposed model learning.

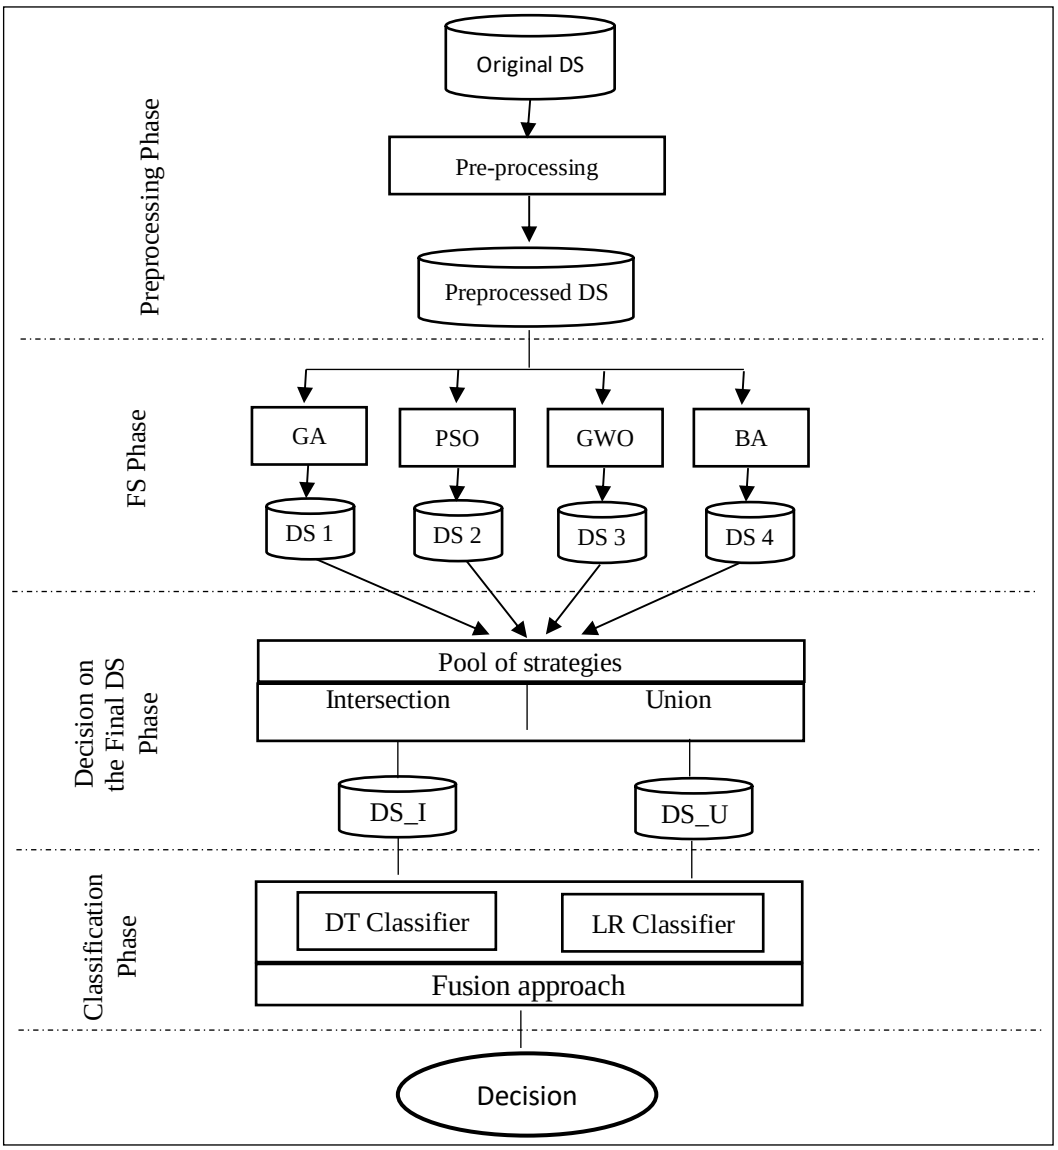

Figure 1: The proposed Learning Model.
Source: Authors, (2026).

To validate the new reduced subsets, a classification phase is performed. Among the best-known classification methods, we find Logistic Regression (LR) and Decision tree (DT). The first model is a powerful and simple statistical method for binary classification, based on the probability of belonging to a class. The interpretation of the probability value involves determining a threshold for belonging to the class. While the second model has the basic principle to use feature values to recursively divide the data set into smaller subsets. Its aim is to ensure that the examples in each subset belong to the same class or have similar output values. Regularization mechanisms, are integrated in order to reduce the risk of overfitting and improve the classifier's generalization ability on test subsets. So LR and DT are trained each one on two reduced datasets namely *DS_I* and *DS_U*, which means that four models are obtained in this classification phase. Each individual's performance metrics are retained, primarily the *F1-score*, which will be used as a model weighting factor in the ensemble approach, we have proposed. This approach aims to create a more accurate and robust classification model than each model individually by considering the synthesis of the weighted responses of the four models. The final model will choose the decision with the highest total weight $W_{decision}$ estimated by the equation (1) :

$$W_{decision} = \max\left(\sum_{j=1}^{n} F_j , \sum_{k=1}^{m} F_k\right) \quad (1)$$

Where:
n + m = the number total of models
F_j : the *F1_score* of a model that has decided on a “normal” state of the network,

F_k : the *F1_score* of a model that has decided on a "attack" state of the network,

In the following, we denote:

- *M1*, the model result of the classifier LR trained on *DS_I*
- *M2*, the model result of the classifier LR trained on *DS_U*
- *M3*, the model result of the classifier DT trained on *DS_I*
- *M4*, the model result of the classifier DT trained on *DS_U*
- *M*, the model of the ensemble approach, based on *M1, M2, M3 and M4* results

In the case where the two sums are equal, a confusing situation is generated and is handled by a specific management strategy to decide on the classification of the unknown case. The main idea in this strategy is to use the principle of similarity between cases to decide what response to take. The reduced (in features) datasets are filtered according to the first response, and a retrieval for the most similar case is triggered, then the process is repeated with filtering according to the second response, to finally decide in favor of the one giving the highest similarity. To ensure this retrieval process, similarity metrics must be defined. The equation (2) shows the estimation formula of the global similarity between 2 cases: *source and target*, while equations (3), and (4) give the estimation between two feature values.

$$Sim(source, target) = \frac{\sum_{a \in subset} w_a \times LocalSim_a(source.a, target.a)}{\sum_{a \in subset} wa} \quad (2)$$

where:
• *source* represent a labeled case in the dataset
• *target*: the new case to be classified
• w_a : the feature weight estimated at the pool level.

$LocalSim_a$: is a function giving a local similarity between the same feature (a) in both source and target cases. When the type of a is Boolean or categorical, it is defined by the equation (3):

$$LocalSim_a(x, y) = \begin{cases} 1 \; if \; x = y \\ 0 \; else \end{cases} \quad (3)$$

If the attribute a is of a numeric type, $LocalSim_a$ is defined by the equation (4):

$$LocalSim_a(x, y) = 1 - \frac{|y - x|}{B_a} \quad (4)$$

where B_a is the "breadth" of the range of a, i.e., it is the difference between the maximal and the minimal values of this range.

IV. RESULTS AND DISCUSSIONS

IV.1 THE USED DATASET

The NSL-KDD dataset was selected to evaluate the contribution of this work. It contains 25192 records of Internet traffic as seen by a simple intrusion detection network. This number is reasonable, making it affordable to run experiments on the complete set without the need to randomly select a small portion and so, the evaluation of results will be consistent and comparable. The dataset contains 43 features per record, 41 of the features refer to the traffic entry itself and the last two are "labels" and "score". Labels inform on the state whether normal or attack type, i.e, gives the attack type: DoS (Denial of Service), Probe, U2R (User to Root) or R2L (Remote to Local), while the score gives the severity of the intrusion. The dataset attributes are of different type, we can find: 4 Categorical attributes, 6 Binary attributes, 23 Discrete attributes, and 10 Continuous attributes. In this work we are particularly interested in the Normal or Intrusion traffic situation. The Label attribute was adapted to our objective in a pre-processing phase for binary classification. Thus, we leave the consideration and treatment of attack types for a future work.

IV.2 THE FEATURE SELECTION PHASE

To generate the different individual models, each based on a specific FS method, a hyperparameter selection phase is necessary. After various empirical tests and analytical studies, we selected a set of hyperparameters for each one as mentioned in Table 2.

Table 2: Algorithm Hyperparameters.

Algorithm	Parameters
GA	Pc = 0.2, m = 0.5
GWO	*T = 10*
PSO	w = 0.7, C1 = 0.6, C2 = 0.5, iteration number = 10
BA	α = 0.8, *A* = 0.15, *PRF* ∈ [0, 2]

Source: Authors, (2026).

The confusion matrix was used to validate the results performance. Based on four parameter rates, this matrix can show quickly whether the system manages to classify correctly. The classification quality is better when parameters *True_Positive (TP)* and *True_Negative (TN)* are maximal while *False_Negative (FN)* and *False_Positive (FP)* should be minimal. In addition, we used the performance metrics: *Accuracy*, *Precision*, *Recall*, *and F1-score* which are widely used to provide an overall assessment of a classification model. *Accuracy* measures the proportion of correctly classified instances among all predictions. *Precision* reflects the model's ability to minimize *FP* by quantifying the proportion of *TP* instances among all predicted positives. *The F1-score*, which ranges from 0 to 1, represents the harmonic mean of *precision* and *recall* and thus captures the trade-off between these two metrics. In an intrusion detection context, a high *F1-score* indicates that the model is effective not only in reducing false alarms (high *precision*) but also in correctly identifying the majority of actual intrusions (high *recall*). We give below some formulas for estimating model performance. The equations (5), (6), (7) and (8) show how the different rates of confusion matrix are estimated while the equations (9), (10), (11) and (12) give the estimation of the *F1-score*, Recall, Precision, and Accuracy respectively.

$$TruePositiveRate(TPR) = \frac{TP \times 100}{FN + TP} \tag{5}$$

$$TrueNegativeRate(TNR) = \frac{TN \times 100}{FP + TN} \tag{6}$$

$$FalseNegativeRate(FNR) = \frac{FN \times 100}{FN + TP} \tag{7}$$

$$FalseP\ ositiveRate(FPR) = \frac{FP \times 100}{TN + FP} \tag{8}$$

$$F1 - score = 2\ x\ \frac{Precision \times Recall}{Precision + Recall} \tag{9}$$

$$Recall = \frac{TP}{TP + FN} \tag{10}$$

$$Precision = \frac{TP}{TP + FP} \tag{11}$$

$$Accuracy = \frac{TP + TN}{TP + FP + FN + TN} \tag{12}$$

At the end of the FS phase, we collected the results, which clearly show that the best selected subsets vary from one method to another. Table 3 illustrates the number of features selected by each algorithm, and by observing it, we note that PSO was able to select the smallest subset in dimensionality reducing the total number of features from 41 to 14 and therefore to less than *35%*. GWO managed to reduce to *39%*, while GA and BA achieved reductions of *43%* and *56%* respectively. The performance metrics obtained for each algorithm are reported in the same table and illustrated in a graph in Figure 2 to provide greater clarity when comparing the four algorithms.

Table 3: The dimensionalities returned from the FS phase.

Algorithm	Features number	Precision	F1-score	Accuracy	Recall
GA	**18**	0,85008635	0,76752744	0,80276248	0,69958496
GWO	**14**	0,46542827	0,63521126	0,46544242	0,99999999
PSO	**23**	0,97318419	0,86079401	0,88383784	0,77167548
BA	**16**	0,96878154	0,85425474	0,87867802	0,76394337

Source: Authors, (2026).

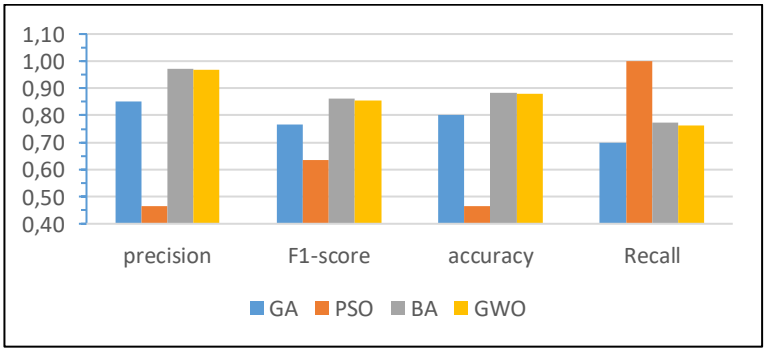

Figure 2: performance metrics obtained in the feature selection phase.
Source: Authors, (2026).

According to these illustrations by Table 3 and Figure 2, we note that scores vary widely between the results of the algorithms, ranging from *0.46542827* to *0.97318418* for *precision*. The subset given by PSO looks very weak here, while BA and GWO features prove their efficiency. The highest accuracy is *0.88383784*, which is relatively good but not exceptional. We can easily notice a strict correlation between the number of features and the precision value. The largest subset given by the BA algorithm with *23* features brings the highest precision. This suggests that, at this level, an average reduction in the dimension provides a better representation of traffic and therefore allows for more accurate decision making. These new subsets are transmitted to the pool which creates two new subsets: *DS_I* and *DS_U* according to the principles detailed above. However, we cannot assert the effectiveness of subsets without validating them with robust classifiers such as LR or DT, which is the subject of the next phase. The classification process in this phase gives rise to four diverse and trained models: *M1, M2, M3 and M4* as mentioned in the section (III). Table 4 highlights the F1-scores performance of these four models while Figure 3 presents a comparison of them with the F1-score obtained in the feature selection phase. We note a clear improvement in this parameter and therefore a clear improvement in the precision/recall balance when working on the subsets generated by our pool strategies. Generally, all the others metrics have improved significantly in this phase (a overview on the accuracy scores is given too in the Table 4).

Table 4: F1-score of the 4 trained models.

Model	F1-score	Accuracy
M1	**0,99801068**	0,99814775
M2	**0,9978678**	0,99801545
M3	**0,99795326**	0,99809483
M4	**0,99786792**	0,99801545

Source: Authors, (2026).

Our third contribution in this work is the ensemble approach which creates the model ***M*** based in the fusion whose details are presented in the section III. This model gave an F1-score of ***0.99818099***, which improve the performance model more than the models *Mi*. (*i=1,4*) by offering the best *TP* and the best *FN* of all models discussed in this work. This shows the advantage of considering the results of the four models to benefit from their power and weighting them with their F1- score.

V. CONCLUSIONS

This paper deals with the network detection intrusion problem. A field which is often represented by a wide dimensionality of characteristics. The trade-off for accurate and fast diagnosis in network traffic is always a significant one, because in fact, the better the situation is enriched by additional data, the better the accuracy is guaranteed, but this is at the detriment of response time, which is slowed down and exposes the network to risk. The work serves three objectives, for which, four bio-inspired algorithms are investigated to extract the best subset of features allowing the most accuracy classification of the network state. The use of *GA*, *PSO*, *BA* and *GWO*, has allowed a significative reduction in dimensionality by selecting the most representative features. In a second step, their subsets outputs have been introduced into a pool which includes two different proposed strategies to make the final decision on the subset structure that allows the weighting of each feature. Thus, two new subsets are created based on the outputs of feature selection phase. The effectiveness of these subsets has been validated using two strong classifiers namely DT and LR in an individual way; to produce four different machine learning models whose performance metrics showed a clear improvement over those of the four algorithms. After, and in a vision to take advantage of their benefits, they have been merged in a robust ensemble model augmented by a confusion management strategy. The performance metrics show that the compromise between the reduced subset and decision accuracy was successfully established by the final model achieving the rate of 99.8%. The proposed model is capable of dealing with datasets other than NSL-KDD. However, it may give different performances. A comparative study of results will be carried out in a next work by considering another intrusion detection dataset.

Keywords:
Facial Emotion Recognition (FER), Convolutional Neural Network (CNN), Temporal Convolutional Network, Temporal dimension, Spatial Dimension.

ABSTRACT

A fascinating area of research, facial expression-based automatic emotion recognition has been introduced and applied in a variety of fields, such as safety, health, and human-machine interactions. A computer technique for recognizing different emotions is called Facial Emotion Recognition (FER), and it is crucial for artificial intelligence (AI) research. For FER classification using video frames, this study employs convolutional neural networks (CNNs) and temporal convolutional networks (TCNs) using the Nadam optimizer in conjunction with preprocessing techniques. The preprocessing procedures include shuffling, one-hot encoding, and video pixel normalization. These are first used in the video frames to identify emotions. In order to manage the temporal and spatial dimensions of the video input, the classifier first incorporates 3D Convolution layers. The result should then be reformatted to be fed into the 1D Convolution layers of the TCN section. This work illustrates the architecture, the databases used, and the contributions addressed by comparing the results with the proposed methods. The performance of the proposed model is compared with other pre-trained deep learning models, including GoogleNet, ResNet, and Inception v3. The suggested enhanced CNN-TCN model with Nadam optimizer had 98% accuracy, precision, recall, and F1 score.

I. INTRODUCTION

Facial expressions are essential for interpreting and identifying emotions. The importance of the face of communication is even indicated by the name "interface." between two things. Recognizing emotions is crucial for effective communication, as emotions account for up to 93% of everyday communication cues. Computer-human interfaces (HCI) would like technology to be able to understand human emotions [1]. Emotion detection has garnered a lot of attention lately because of its important uses in human-computer interaction. A variety of verbal and nonverbal languages, including text, audio, and visual, are used to convey human emotions [2]. Humans are able to identify the emotions of others based on the situation. For instance, depending on the situation, a grin might be seen as a message of greeting, irony, delight, or politeness. Humans use a variety of methods to communicate their feelings, including voice, gestures, facial expressions, and text emoticons. Emotions may be more clearly defined with the help of facial expression recognition. Many years ago, studies of facial expressions were initiated [3]. Enhancing facial classification is a complex and nuanced task, especially when it involves transferring features between different faces. This area presents numerous challenges, including variations in head orientation, lighting conditions, age, gender, and background. Occlusion caused by factors like sunglasses, scarves, or skin conditions further complicates the process. Conventional approaches for extracting geometric and textural features from faces utilize techniques like LBP, FAC, and LDA [4]. In contrast, recent advancements in deep learning, particularly CNNs and RNNs, have shown strong potential in automating feature extraction and classification processes. These methods have gained significant popularity in facial emotion recognition, encouraging researchers to experiment with various deep neural network models that have demonstrated promising outcomes. This work provides an insightful and useful learning paradigm. Pattern recognition is a well-established paradigm in deep learning. The Convolution Neural Network (CNN) method is used, along with a sophisticated optimizer technique. CNN is a unique type of artificial neural network that uses a machine learning tool. CNN has to do with things like object detection, facial identification, and image processing.

Layers of neural networks make up a deep neural network (DCNN) [5]. The paper is organized as follows: Section 2 reviews the work related to emotion recognition through facial expressions; Section 3 discusses the methodology and algorithms proposed for emotion recognition; Section 4 presents the experimental analysis, including results and discussion; and finally, Section 5 provides the conclusion of the proposed system.

II. LITERATURE SURVEY

The author of this study [6] developed a model utilizing Deep learning methods that offer advantages over traditional machine learning, particularly for analyzing unstructured data such as videos and multimedia. The model implemented in this work is capable of real-time face recognition, emotion detection, and even music recommendations. Experimental analysis was conducted using the FER-2013 and OAHEGA datasets. The cutting-edge FER, POSTER, effectively merges facial landmark and image feature data. Nonetheless, POSTER's construction is unquestionably intricate. This study presents POSTER++ to tackle the computational difficulties related to POSTER [7]. POSTER++ replaces POSTER's pyramidal architecture with a lightweight multi-scale interaction (MSI) network, simplifying the two-stream approach used in POSTER. Through attentional interaction, MSI directly incorporates face data at various scales into the token embeddings. This study [8] leverages deep learning alongside saliency maps for analyzing facial images. The reprocessing of data includes applying a bilateral filter, generating a saliency map, and utilizing both a generative adversarial network (GAN) and CLAHE. For effective facial emotion classification, a deep (CNN) is then trained using the Nadam optimizer. Study [9] introduces a new Graph Neural Network (GNN) model that considers the systematic process of FER in human visual perception. First, an area division approach is to divide the face region into six pieces in order to standardize the selection of significant facial features. This leads to the proposal of a human visual cognition method that considers the connotative link between different components of facial expressions. Together with the human regional cooperative recognition process, the GNN model is built by extracting the connotative link (such as relative position and comparable structure) between graph nodes. In this paper, the author tackles the problem of compound facial expression recognition in uncontrolled settings [10].

The author creates a brand-new loss function based on center loss(CL) that is specifically designed for compound facial emotion detection: loss bi-center, in contrast to CL, which utilizes core emotion centers to guide deep neural networks in capturing complex emotion characteristics. Furthermore, the author presents a basic-center regularization term to manage differences between these core centers, enhancing the discriminative strength of the learned features. The study's author [11] specifically designed to identify emotions in autistic children, with a particular focus on recognizing distress and anger. The system follows three key steps: detecting faces, extracting facial features, and classifying emotions. With high accuracy in emotion classification, a DCNN architecture was utilized. Due to the extensive dataset, an autoencoder was employed to enhance feature extraction and selection. Additionally, models such as ResNet, MobileNet, and Xception were incorporated to boost system performance. This study [12] explores enhancing video-based emotion recognition by capturing spatio-temporal characteristics through enriched temporal encoding. The study tackles the difficulties of accurately recognizing emotions, aiming to enhance performance in these areas. To monitor overarching temporal patterns in emotional shifts and capture intricate spatio-temporal details, two specialized models are introduced for facial expression recognition: the SISTCM and LSTM model. In terms of body motion analysis, the method, along with an ACCM, focuses on extracting essential joint features and distinguishing attributes for each motion joint. The dynamic face emotion recognition accuracy, the author [13] an advanced spatial-temporal learning network (ESTLNet), which integrates a TTEM and a SFLM. The SFLM improves spatial feature representation through a dual-channel feature fusion learning strategy.

Subsequently, the TTEM employs an encoder that integrates a gated feed-forward network with a self-attention learning network, enabling the capture of a more comprehensive temporal context, building on the spatial data obtained previously. The author [14] presents a CNN model, a DL approach, to determine age and gender from facial expressions and to detect emotions from facial pictures. Experimental results showed that the proposed model outperformed the existing baseline models, achieving 0.95 accuracy in emotion detection, 98.5% accuracy in age prediction, and 0.99 accuracy in gender recognition. In order to improve each pre-trained block of a deep convolutional neural network (DCNN), the deep layer or layers were first trained using an advanced pipeline. FER system was evaluated on face image datasets utilizing eight well-known pre-trained DCNN architectures: VGG-16, VGG-19, ResNet-18, ResNet-34, ResNet-50, ResNet-152, Inception-v3, and DenseNet-161 [15]. A sophisticated facial expression recognition (FER) system is shown in the article [16], which uses a DCNN in conjunction with TL to achieve high accuracy. The technique entails adapting a pre-trained DCNN's dense layers to FER tasks. The pre-trained blocks are progressively refined after the thick layers have been taught in order to enhance recognition performance. Eight different pre-trained DCNN models (VGG-16, VGG-19, ResNet-18, ResNet-34, ResNet-50, ResNet-152, Inception-v3, and DenseNet-161) are tested using popular face expression datasets including KDEF and JAFFE to assess the system's efficacy.

A DL-based emotion, capable of achieving high accuracy across various use cases, such as feedback analysis and facial recognition for security purposes, can be developed [17]. DCNN model that can classify five distinct emotions based on facial expressions. The model is trained, tested, and validated using a custom-collected image dataset. The paper presents deep learning methods for accurate detection and identification in facial recognition [18]. Face recognition is used to identify and verify facial features. On the other hand, real-time facial feature acquisition is handled by haar cascade detection. The work's sequential procedure consists of three separate stages: the first is identifying a human face from the camera, and the second is using a database. The last step classifies emotions as neutral, pleased, angry, sad, disgusted, and startled. A human face is validated in the last step. Emotional analysis frequently identifies facial expressions that reflect the benefits of employing neural network-based schemes, which were the main focus of an analysis of the current methods for building emotion identification systems based on human facial expressions [19]. A neural network-based approach for building an emotion identification system that comprises figuring out the neural network's logical number of layers and an efficient technique for creating training and test samples. Real-time emotion recognition has been an ongoing research focus for several decades. In one study [20], emotional expressions of children with autism and individuals with physical disabilities (such as those who are deaf, mute, or bedridden) were classified using facial landmarks and electroencephalogram (EEG) signals. This classification was achieved through CNNs and LSTM classifiers.

Additionally, developed an optical flow algorithm that employs virtual markers, which perform well under various conditions such as uneven lighting, head rotations (up to 25°), different backgrounds, and diverse skin tones. The system successfully identifies six facial emotions, surprise, fear, contempt, anger, sadness, and happiness, utilizing ten virtual markers. In the publication, the author offers a comprehensive examination of FER [21]. The author's content is a compilation of a number of reliable studies published during the past decade. Different techniques from DL and conventional ML are used for the assessment. Evaluation measures are also used to assess and compare benchmark results with a number of publicly available FER datasets. In addition to discussing both traditional machine learning and deep learning approaches, this work offers a thorough analysis of FER, pointing out any knowledge gaps that may be filled by further study. Ultimately, this study functions as a guide, providing valuable insights for both experienced researchers looking for promising research directions and newcomers to FER, equipping them with a solid understanding of the latest techniques and foundational knowledge [22]. The dual-channel expression recognition system integrates philosophy and machine learning principles to address the challenge of subtle facial expression variations. The convolutional neural network (CNN) feature extraction technique tends to overlook these subtle changes. The method's main goal is to extract Gabor features from the ROI so that they can be used as input for the first path. The algorithm efficiently extracts emotion-relevant characteristics from the ROI by separating them. A more accurate analysis of the local area results from this method guarantees that the complex characteristics of the active facial expression area are completely utilized. Pre-trained models like ResNet50, VGG19, Inception V3, and MobileNet are used in the study [23]. These pre-trained Convolutional Neural Networks (ConvNets) have their completely connected layers deleted and replaced with new fully connected layers that are tailored to the number of instructions in the particular task. Only the weights of these recently added layers are changed during training. Using the CK+ dataset, the experiment's average accuracy for emotion recognition tasks was 96%. The network analyzes key facial features and uses low-light image enhancement techniques to identify facial emotions in mask-covered images.

The approach uses the Affect Net image collection, which includes 420,299 images and eight types of facial emotions [24]. This study [25] offers a comprehensive and well-structured comparative empirical analysis of face emotion detection using local binary pattern features, convolution neural networks, and frequency domain in deep learning. By combining the seven basic emotional categories neutral, happiness, anger, fear, sadness, disgust, and surprise - the author was able to conduct facial emotion recognition (FER). To highlight the differences and similarities, examine the potential technologies that may be employed in each component of the broad framework described for a standard FER approach. This work [26] extends the use of deep learning for facial emotion recognition (FER) using the Emognition dataset, which contains 10 target emotions: neutral, fear, awe, excitement, amusement, surprise, wrath, disgust, and astonishment. This study suggests two methods for developing Convolutional Neural Network (CNN) models: create from scratch using the Taguchi technique to identify a resilient combination of hyperparameters setting, and transfer learning (fine-tuned) with pre-trained models of Inception-V3 and MobileNet-V2. The goal of this study [27] is to create a hybrid Convolutional Neural Network – Recurrent Neural Network (CNN-RNN) model that can recognize human emotions from video data by analysing facial expressions. The Emotional Wearable Dataset 2020 served as the basis for the models' development. For the classification, three models are created: MobileNetV2-RNN, InceptionV3-RNN, and custom CNN-RNN. While the MobileNetV2-RNN and InceptionV3-RNN transfer learning models provide 59% and 66% accuracy rates, respectively, the bespoke CNN-RNN model obtained 63%. The Emognition dataset in this study [28] is devoted to evaluating techniques for emotion recognition (ER) using facial expressions and physiological reactions.43 individuals who saw brief film snippets that evoked nine distinct emotions—amusement, amazement, enthusiasm, liking, surprise, wrath, disgust, fear, and sadness—were the subjects of our data collection. In conjunction with the upper-body videos, physiological data was recorded using three wearables: EEG, BVP (2x), HR, EDA, SKT, ACC (3x), and Gyro (2x).

III. CNN-TCN ARCHITECTURE

The CNN-TCN architecture of proposed work is shown in Figure 1, represents a structured approach to developing an emotion recognition system from video data, emphasizing key stages from data preparation to final prediction.

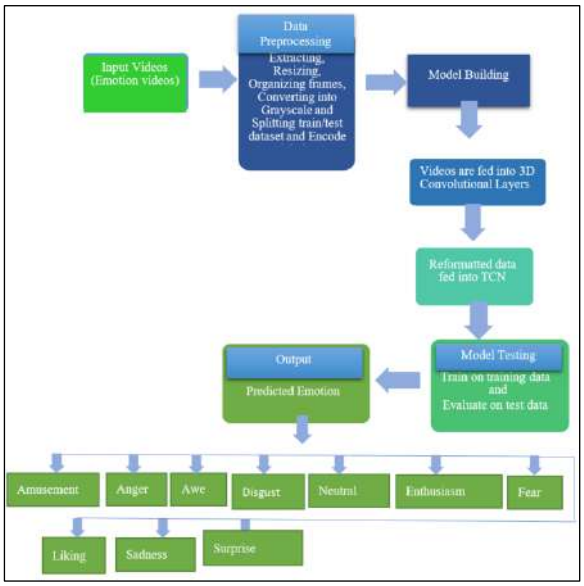

Figure 1: Overall Architecture of Enhanced CNN-TCN.
Source: Authors, (2026).

III.1 DATASET DESCRIPTION

The Proposed work begins with Input of Video Dataset, which consists of emotion-labelled videos that capture various expressions across time. These videos are processed through several steps to make them suitable for training a deep learning model that can accurately recognize emotions. The Emognition dataset includes upper body video recordings and physiological signals from 43 subjects who watch emotionally validated movie snippets that elicit ten distinct emotions. The Emognition dataset has a number of advantages over other datasets, such as highlighting the differences between positive emotions, allowing for a variety of analysis in emotion recognition (ER) from the physiology and facial expressions domain, and offering nine distinct emotions - amusement, awe, enthusiasm, liking, surprise, anger, disgust, fear, and sadness - as well as one neutral emotion [26]. This part presented the dataset used and the assessment of the suggested model. The copied videos and stock photos are no longer there. Figure 2 shows the number of videos available in the individual categories of the dataset.

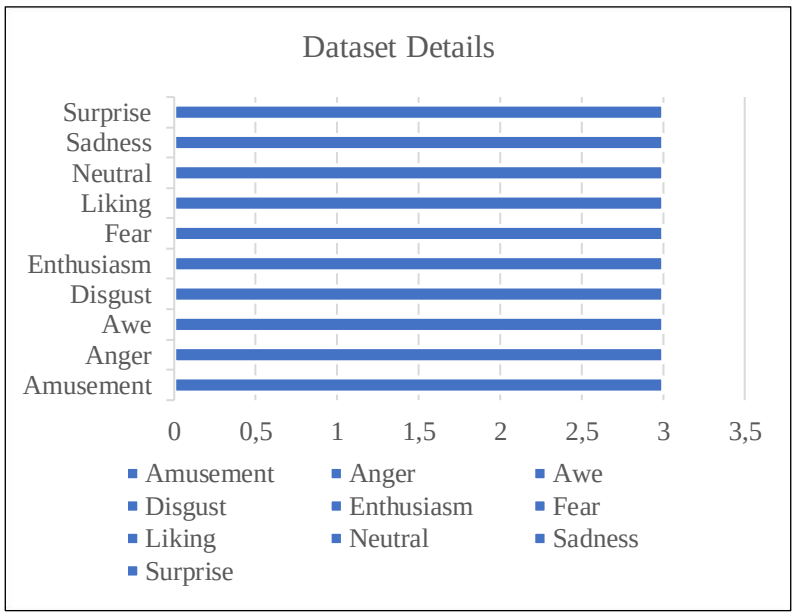

Figure 2: 10 Emotions in a Dataset for Facial Emotion Recognition.
Source: Authors, (2026).

III.2 DATA PREPROCESSING

The first step is Data Preprocessing, which plays a critical role in standardizing the raw video data. In this stage, frames are extracted from each video to represent moments in time, breaking down a continuous sequence into discrete images. These frames are resized to a standard dimension, ensuring that all input data has a consistent resolution, which simplifies further processing and model training. The frames are also converted to grayscale, reducing the data's complexity by focusing on intensity values rather than color information, which may be less relevant for emotion detection. This transformation helps lower the computational load and emphasizes structural details in expressions, which are key for recognizing emotions. The frames are then organized into sequences, capturing the temporal flow of expressions and facilitating the model's ability to recognize changes over time, which is essential for accurately detecting emotions in videos. Once the data is pre-processed, it moves to the Dataset Preparation stage. Here, the dataset is divided into training and testing subsets to allow for effective model evaluation. The labels, which indicate different emotion categories, are encoded to make them compatible with the model, often using a numerical representation that simplifies training. This stage is crucial for preparing the video data for model training. It involves extracting individual frames from the video, resizing them, and converting them to grayscale to simplify the data and reduce computational load. These frames are then organized into sequences, which capture the temporal progression of emotions across frames, making the data suitable for training temporal models like TCNs. This organized, preprocessed data is essential for effective emotion recognition from videos.

III.3 MODEL BUILDING

In the model-building phase, the architecture is constructed with layers suited to spatial and temporal feature extraction. Conv3D layers are used to capture spatial details within each frame, identifying subtle features related to facial expressions. Temporal Convolutional Network (TCN) layers are then applied to learn temporal patterns across frames, helping the model understand how emotions evolve. During Model Training, the model is trained on the prepared data, learning to recognize and classify emotions. It is evaluated on test data to ensure its generalization ability. In the Prediction from Video stage, the trained model can now extract frames from new videos and predict emotions based on learned patterns, producing the final output, which is the predicted emotion, concluding the pipeline.

III.3.1 CNN

Deep Learning (DL), a subfield of Machine Learning (ML), centers on the process of learning progressively more abstract representations through multiple layers. A model's depth indicates the total number of layers used in data processing. The three primary components of a standard neural network.

The model's depth corresponds to the number of layers that contribute to transforming the data. Convolutional Neural Networks (CNNs) differ from traditional neural networks by using convolution operations in their layers instead of relying solely on matrix multiplication. The convolution operation is mathematically represented by equation (1).

$$s(t) = (x * w)(t) \tag{1}$$

Here,

$$x - input$$

$$w - kernel\ filter$$

$$s(t) - output\ is\ called\ feature\ map$$

Here t might be spatial location or time space

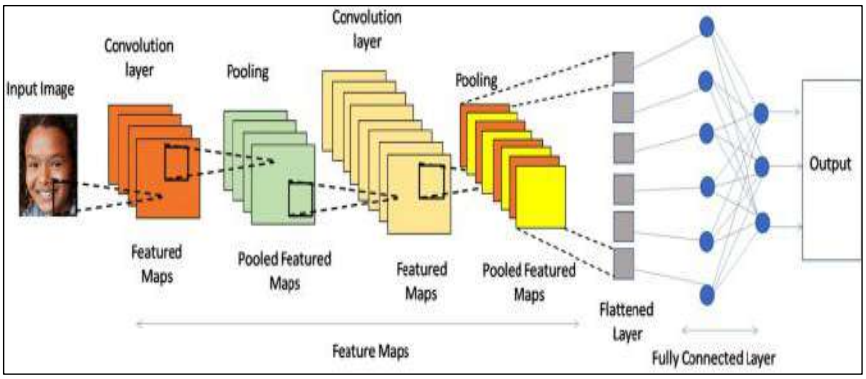

Figure 3: CNN Architecture.
Source: Authors, (2026).

Figure 3 depicts the convolutional neural network model's architecture. There are three steps to CNN, which are to perform several convolutions using filters concurrently. A nonlinear activation, such as a rectified linear activation function, is carried out in the second stage. If the input is positive, the output is generated directly; if not, it is set to zero. In the third step, a pooling technique is used to minimize the feature map's size. Max pooling, which chooses inside a window; average pooling, which substitutes the average value for window values; and weighted average pooling are common pooling techniques. Other variations of pooling processes can also be used. The result from the final pooling layer is sent to the FC layer at the end of a CNN. The input is categorized into multiple groups by each node in this layer, which is connected to every other node in the layer above.

III.3.2 Tcn (Temporal Convolution Network)

TCNs are CNs designed for analysing applications with causal restrictions [11]. The input sequence $x_0, \ldots, x_t$ and its matching output sequence $x_0, \ldots, x_t$ are supplied for training a sequence analysing network. The network can learn to predict the output sequence $y_0, \ldots, y_t$ by evaluating the difference between the expected sequence and the actual output using a loss function. The network's causal constraint guarantees that each prediction $y_0, \ldots, y_t$ is solely impacted by the inputs that came before it $x_0, \ldots, x_t$ and not by inputs that came after it $x_{t+1}, \ldots, x_t$. The noisy frames serve as the input sequence in speech enhancement software, while the clean frames create the output sequence.

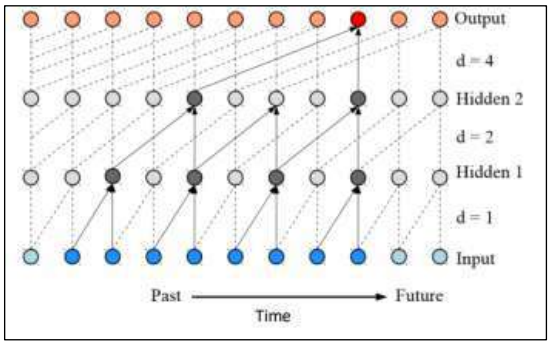

Figure 4: Expanded Causal Convolution Using a Size 2 Filter.
Source: Authors, (2026).

TCNs are built with a combination to enforce the causal constraint. The causal convolutions prevent future information from impacting previous data, maintaining temporal order. In contrast, the network can capture longer-term temporal correlations because of dilated convolutions, which improve the receptive field. The network's ability to analyse historical data increases as the receptive field expands. An opened and causal convolution with a filter size of two is shown in Figure 4.

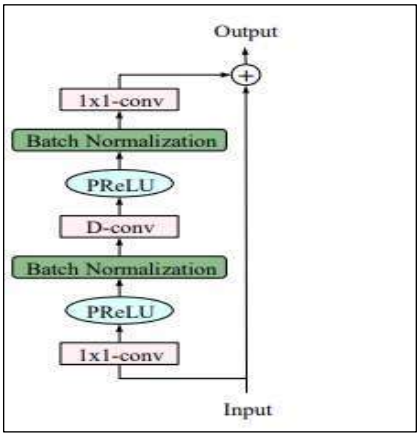

Figure 5: Residual Block.
Source: Authors, (2026).

A TCN incorporates residual blocks to facilitate the effective training of deep networks through residual learning. The residual block employed in this study is very similar to the one used here, as Figure 5 illustrates. Three different kinds of convolutions are included in this block: depth-wise, 1x1 input, and 1x1 output convolutions. In order to provide compatibility between the input and output through element-wise addition, the input convolution increases the quantity of entering networks. In contrast, the yield convolution restores the channel count to its initial value. By applying one filter per input channel and maintaining the channel count, the depth-wise convolution aids in lowering the sum of parameters. In contrast, traditional difficulty operations use as many filters as there are input channels for each output channel after the input and intermediate convolutions to further refine the model.

IV. ENHANCED CNN-TCN MODEL

The Enhanced CNN-TCN model manages the temporal and spatial dimensions of the video. The classifier first incorporates 3D Convolution layers. The result should then be reformatted to be fed into the 1D Convolution layers of the TCN section.

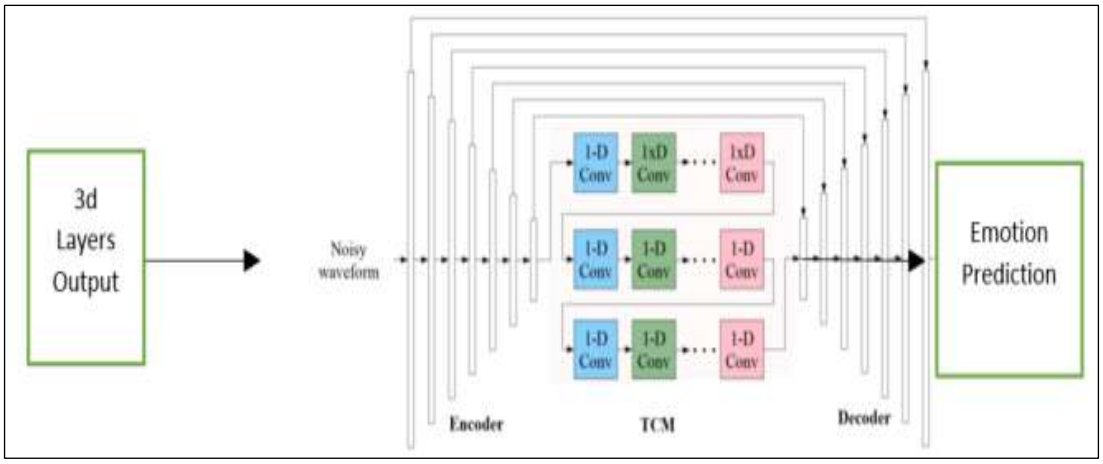

Figure 6: Enhanced CNN-TCN Model.
Source: Authors, (2026).

This model effectively combines Spatial Feature and Temporal Sequence Modeling using CNN and TCN. The three main parts of the Enhanced CNN-TCN architecture are the encoder, decoder, and Temporal Convolution Module (TCM). While the encoder and decoder employ 1D causal convolution layers, the TCM is constructed with 1D convolution layers. A block form of the framework is shown in Figure 5. When T is the number of frames, 320 is the frame width, and 1 is the number of input channels, the encoder's input shape for the noisy frame sequence is T × 320 × 1. The first layer of the encoder enlarges the input channels from 1 to 64 to produce an output form of T × 320 × 64. Subsequent layers of the encoder execute convolutions with a stride of two over seven layers, thus decreasing the frame dimension. T × 4 × 64 is the encoder's final output. The time dimension stays constant during this procedure, guaranteeing that the output's frame count corresponds to the inputs. Batch and parametric normalization, with ReLU as the activation function, come after each encoder layer. The encoder produces a one-dimensional signal of T × 256. This reshaped signal is then processed by the Temporal Convolutional Module (TCM), which maintains the same output size. The TCM is structured with three stacked dilation blocks; each made up of six residual blocks, where dilation rates increase exponentially across layers. Specifically, the dilation rates used are 1, 2, 4, 8, 16, and 32. The decoder, designed as a mirrored version of the encoder, incorporates multiple 1D layers. At each layer, the decoder's output is combined with the corresponding encoder layer's output. Dropout at a rate of 0.3 is applied to the encoder's skip connections during training. Each decoder layer also includes batch normalization and uses a parametric ReLU activation function for enhanced nonlinearity. The encoder and decoder's hyperparameters are specified as Filter Height × Filter Width, with strides listed for both time and frame. Small braces around entries mark residual blocks, and the TCN's hyperparameters include filter size, dilation rate, and output channels.

Input:
Training dataset
Testing dataset
Initial values for CNN and TCN hyperparameters
Steps:
1. For each new population, do the following:
2. For each chromosome, do the following:
Test the combined CNNTCN model with Nadam optimizer and calculate accuracy
Next
3. Perform mutation:
(i) Select a random particle (hyperparameter)
(ii) Select a random position (hyperparameter, such as filter size or dilation rate)
4. Perform crossover:
(i) Select two random particles (hyperparameter sets)
(ii) Swap their values
(iii) Calculate the fitness of each set
(iv) Select the best hyperparameter set
5. Calculate the best values for CNN and TCN hyperparameters with the highest accuracy (H_Acc)
6. If termination conditions are satisfied:
Return the optimized CNN and TCN hyperparameters
Break
8. End If
9. Next
Output:
Optimized CNN and TCN hyperparameters

V. RESULTS AND DISCUSSION

V.1 TRAINED OUTPUT OF ENHANCED CNN-TCN

The proposed system layer architecture is shown in Figure 8. Deep learning architectures consist of layers that process data in phases to extract significant characteristics and provide predictions. In a deep learning model, every layer serves a distinct purpose and usually works with inputs from layers before it. Let's review the typical layer types found in deep learning systems, as well as their functions and interactions with one another.

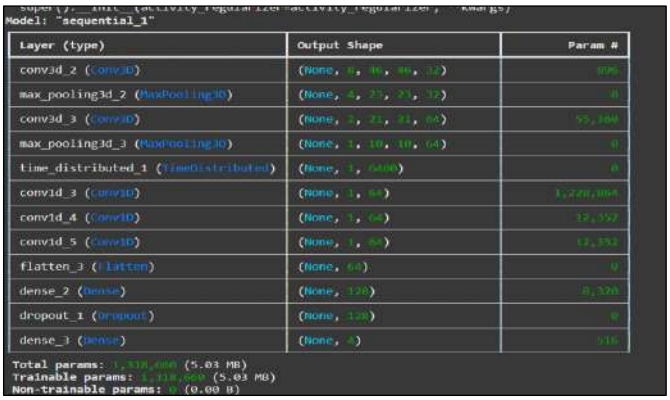

Figure 8: Trained output of Enhanced CNN-TCN Model.

V.2 PERFORMANCE AND ERROR METRICS OF THE ENHANCED CNN-TCN WITH EXISTING DEEP LEARNING MODELS.

Depending on the particular objective (e.g., classification, regression, time-series forecasting), different metrics are used to assess a Deep Convolutional Neural Network (Pulse DCNN) in conjunction with Temporal Convolutional Networks (TCN) with Nadam optimizer. Consider the following important assessment measures.

$$Accracy = \frac{correct\ prediction}{Total\ prediction} \tag{2}$$

$$precision = \frac{True\ Positives}{True\ positive + False\ positive} \tag{3}$$

$$Recall = \frac{True\ Positives}{True\ Positive + False\ Negativee} \tag{4}$$

$$F1\ score = 2 \cdot \frac{Precision.Recal}{Precision + Recall} \tag{5}$$

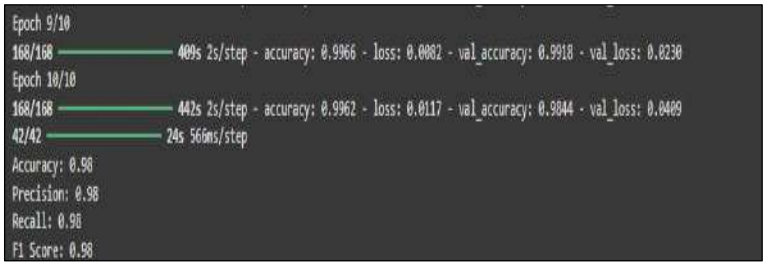

Figure 9: Performance metrics of Enhanced CNN-TCN algorithm with NADAM optimizer.
Source: Authors, (2026).

Figure 9. displays the performance attained with the suggested Enhanced CNN-TCN with Nadam optimizer, which has a value of 98 percent for all parameters, including F1 score, accuracy, precision, and recall calculated using equation (2)-(5).

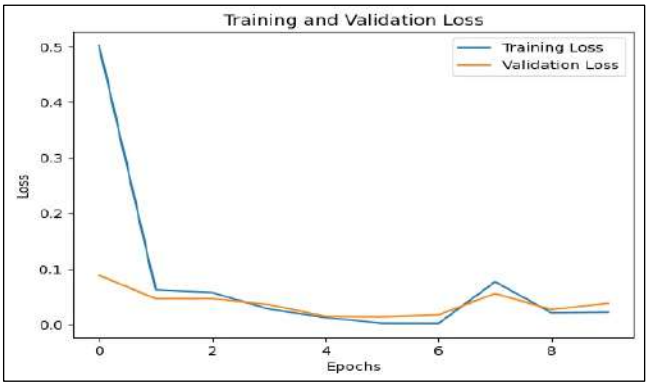

Figure 10: CNN-TCN model's training and validation loss.
Source: Authors, (2026).

The Enhanced CNN-TCN with Nadam optimizer training losses and testing accuracy is shown in Figure 10. The hyperparameter of our proposed system is set by using the Nadam optimizer. The losses of training and validation are shown in the figure for ten epoch steps. Figures 11 and 12 show the emotion recognition from the video frames using the Enhanced CNN-TCN model. The TCN model with CNN reduces the processing time.

Table 1: Performance metrics of the Enhanced CNN-TCN with Existing Model.

Models	Precision (%)	Recall (%)	F1 score (%)	Accuracy (%)
ResNet	95.69	95.69	95.82	95.67
Inception v3	99.64	97.38	98.51	99.65
GoogleNet	99.64	98.44	99.04	99.65
Hybrid CNN-TCN	98	98	98	98

Source: Authors, (2026).

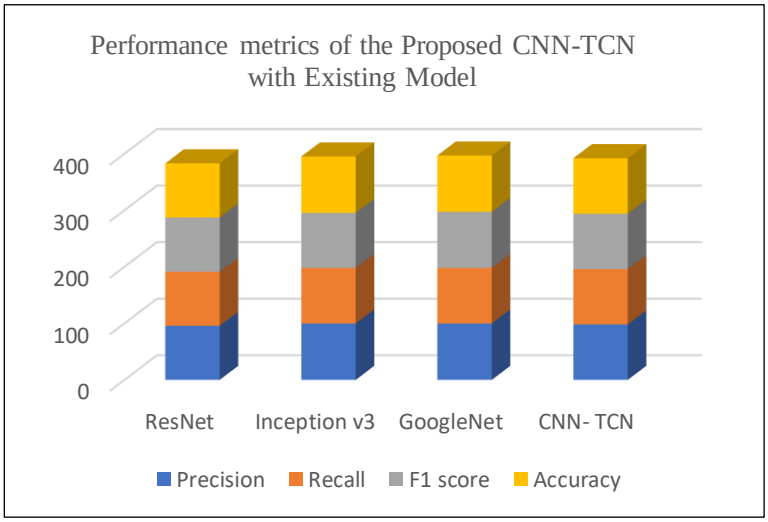

Figure 11: Performance Metrics Comparison of Proposed with Predefined Deep Learning Model.
Source: Authors, (2026).

CNN's performance utilizing the data without any improvements is shown in Figure 10. As shown in Table 1 and Figure 10, the efficacy of the suggested approach (TCN) is evaluated in comparison to the formerly widely used pre-trained deep learning models, including ResNet, Inception v3, and GoogleNet.

As the CNN's performance improved after the Nadam adjustment of its hyperparameters, Table 1 and Figure 11 show that the CNN-TCN classifier generated the best results. CNN-TCN outperforms earlier techniques with accuracy, precision, recall, and f1 score of 98%.

Table 2: Compare Error metrics of the Enhanced CNN-TCN with Existing Model.

Models	MAE	MSE	R^2
ResNet	0.021	0.059	0.901
Inception v3	0.019	0.061	0.898
GoogleNet	0.022	0.058	0.902
Enhanced CNN-TCN	**0.02**	**0.06**	**0.95**

Source: Authors, (2026).

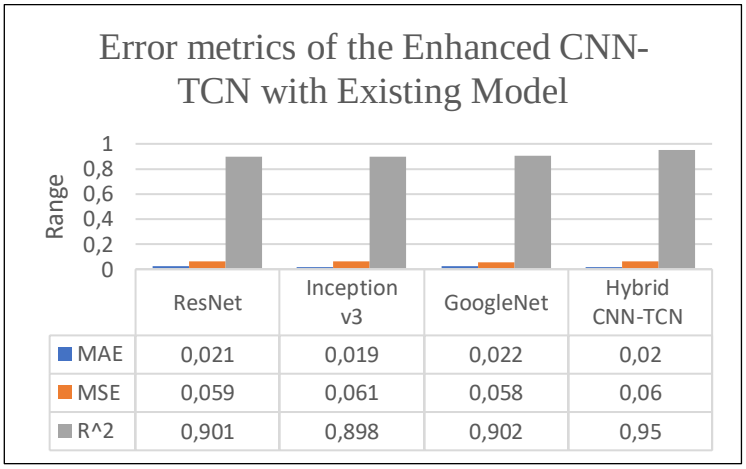

Figure 12: Error metrics of the Enhanced CNN-TCN with Existing Model.
Source: Authors, (2026).

The table 2 and figure 12 compares the performance metrics (MAE, MSE, and R^2) of ResNet, Inception v3, GoogleNet, and the proposed Hybrid CNN-TCN model. The Hybrid CNN-TCN outperforms other models with an MAE of 0.02, MSE of 0.06, and a superior R^2 of 0.95, reflecting its high accuracy and robust fit. In comparison, ResNet, Inception v3, and GoogleNet show slightly higher error rates and marginally lower R^2 values, indicating the Enhanced CNN-TCN's effectiveness in achieving minimal errors and maximum data fit.

V.3 EMOTION PREDICTION

Here, sample of predicted emotion

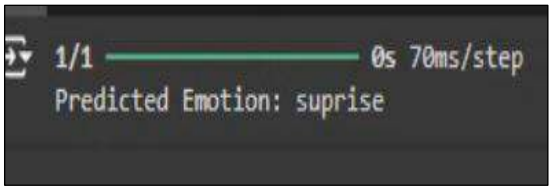

Figure 13: Surprise emotion recognition.
Source: Authors, (2026).

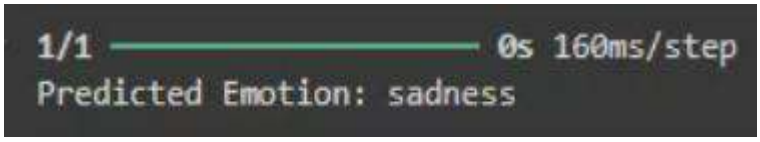

Figure 14: Predict sadness emotion from the facial model using CNN-TCN with Nadam optimizer.
Source: Authors, (2026).

V.4 ERROR PERFORMANCE OF PROPOSED MODEL

Mean Squared Error (MSE):
Calculates average squared difference between predicted and actual values.
MSE = $\Sigma(y_i - p_i)^2 n$
yi= ith observed value
pi = corresponding predicted value for yi,
n = number of observations.

Mean Absolute Error (MAE):
Calculates average absolute difference between predicted and actual values.

MAE = (1/n) Σ(i=1 to n) $|y_i - \hat{y}_i|$
y_i = the actual value of the ith observations
$\hat{y}_i$ = the predicted value of the ith observations
n=number of observations

R-squared (R^2):
A higher R2 indicates better fit between the model and the data.
R2=1-SSE/SST
SSE = Sum of Squared Errors
SST = Total Sum of Squares

Figure 15: MAE, MSE and R^2 value for 10 epoch training steps.
Source: Authors, (2026).

The figure 15 shows the error performance such as Mean Square Error (MSE), Mean Absolute Error (MAE) and Root Mean Square Error of proposed system is achieved 0.02, 0.06 and 0.95 for 10 epoch steps.

VI. CONCLUSION AND FUTURE WORK

For face motion recognition, this study proposed a convolutional neural network (CNN) with a temporal convolutional network (TCN) architecture. This study suggests using dynamic video frames to recognize emotions with minimal processing time. The three steps of emotion recognition are video frame extraction, preprocessing following video frame extraction, and face expression detection using CNN-TCN with less processing time. In future to assist families and medical professionals in the early identification of autism, this study proposes a CNN-TCN architecture for facial emotion detection. The performance, like accuracy, precision, recall, f1 score, training loss, and testing accuracy, is calculated and compared with pre-trained deep learning models like ResNet, Inception v3, and GoogleNet. The Error performance MAE and MSE and Root Mean Square Calculated. This study attempts to fill the gap in the current datasets, in future identify hybrid emotion and Emoji.

Database Performance.

ABSTRACT

Database cost models (CMs) are fundamental to query optimization, yet they suffer from accuracy degradation as system workloads and hardware configurations evolve. Traditional cost models rely on static calibration approaches that fail to adapt to dynamic operational environments. This paper introduces AdaptCM, a novel framework that leverages online learning and reinforcement learning techniques to enable continuous, autonomous cost model evolution. Unlike existing approaches that require manual recalibration or periodic offline updates, AdaptCM implements a self-tuning mechanism that learns from query execution feedback in realtime, automatically detecting model drift and adapting cost estimations without system disruption. We propose a multi-agent architecture where specialized learning agents manage different cost components (I/O, CPU, memory, network) and coordinate through a meta-learning controller. Our experimental evaluation on TPC-H, TPC- DS, and real-world production workloads demonstrates that AdaptCM achieves 23-41% higher prediction accuracy compared to PostgreSQL's native cost model and 15- 28% improvement over state-of-the-art learned cost models. The framework reduces calibration overhead by 94% while maintaining model accuracy within 5% means relative error across diverse workload patterns and hardware configurations. Furthermore, AdaptCM's adaptation latency remains under 50ms, making it suitable for production deployment in high-throughput database systems.

I. INTRODUCTION

Query optimization in database management systems (DBMS) fundamentally depends on the accuracy of cost models that estimate the execution cost of alternative query plans [1], [2]. These cost models guide the query optimizer in selecting the most efficient execution strategy by predicting resource consumption—typically measured in terms of I/O operations, CPU cycles, memory usage, and network transfers. However, the effectiveness of traditional cost models has been increasingly challenged by three critical factors: (1) the dynamic nature of modern workloads characterized by shifting access patterns and data distributions [3], (2) the proliferation of heterogeneous hardware configurations including multi-core processors, NVMe storage, and specialized accelerators [4], [5], and (3) the complexity of cloud-native deployments where resource contention and virtualization introduce unpredictable performance variability [6].

I.1 MOTIVATION AND PROBLEM STATEMENT

Traditional database cost models employ analytical formulas derived from first principles or calibrated through offline benchmarking [7]. While this approach has served well in relatively static environments, it exhibits several fundamental limitations in contemporary database systems:

Static Calibration Inadequacy: Cost models are typically calibrated once during system installation or after major configuration changes. This static calibration fails to capture temporal variations in system behavior caused by workload evolution, data distribution shifts, or hardware aging effects [1]. Research indicates that cost model accuracy can degrade by 40-60% within months of initial calibration in production environments with dynamic workloads.

Manual Intervention Overhead: Maintaining cost model accuracy requires periodic manual recalibration—a laborintensive process demanding specialized expertise in database internals, profiling methodologies, and statistical analysis [8]. Enterprise DBAs report spending 15-25% of maintenance time on performance tuning activities directly or indirectly related to cost model calibration.

Coarse-Grained Adaptation: Existing approaches to cost model adaptation either apply global adjustments that overlook component-specific drift patterns or require complete model reconstruction, resulting in extended downtime and significant computational overhead
[9].

Limited Feedback Integration: Current cost models rarely leverage runtime execution feedback systematically. While some systems collect execution statistics, this information is typically used for retrospective analysis rather than prospective model improvement [3]. Recent advances in learned cost models using deep learning have shown promise in improving initial accuracy [2], [10], [11]. However, these approaches inherit limitations from supervised learning paradigms: they require extensive offline training with representative workloads, struggle with distribution shift, and demand periodic retraining to maintain accuracy—essentially transferring the calibration burden from analytical to learned models without addressing the fundamental adaptation challenge.

1.2 KEY CONTRIBUTIONS

This paper presents AdaptCM, a novel framework for autonomous, continuous cost model evolution through online learning. Our approach fundamentally differs from existing solutions by treating cost model maintenance as an online learning problem rather than a periodic calibration task. The key contributions of this work include:

1. **Online Learning Architecture**: We introduce a multi-agent reinforcement learning architecture where specialized agents manage cost estimation for different system components (I/O, CPU, memory, network). These agents learn continuously from query execution feedback, enabling fine-grained adaptation to component-specific performance characteristics and drift patterns.
2. **Meta-Learning Controller**: We propose a metalearning controller that coordinates agent behaviors, detects model drift using statistical process control techniques, and dynamically adjusts learning rates to balance exploration-exploitation tradeoffs. This controller implements adaptive trust mechanisms that weight agent predictions based on recent accuracy history.
3. **Non-Disruptive Adaptation**: AdaptCM implements incremental model updates with dual-model validation, ensuring that adaptations improve rather than degrade performance. The framework maintains shadow models for validation and implements automatic rollback mechanisms when adaptations fail to meet quality thresholds.
4. **Workload-Aware Learning**: Our system incorporates workload characterization techniques that identify query patterns and adjust learning strategies accordingly. This enables the framework to handle mixed workloads (OLTP/OLAP) and rapid workload transitions without catastrophic forgetting.
5. **Comprehensive Evaluation**: We conduct extensive experiments on multiple benchmarks (TPC-H, TPC-DS, JOB) and real-world production traces from three enterprise environments, demonstrating 23-41% accuracy improvements over traditional models and 15-28% improvements over state-of-the-art learned models, while reducing calibration overhead by 94%.

I.3 PAPER ORGANIZATION

The remainder of this paper is organized as follows. Section II reviews related work in cost model design, learned query optimization, and online learning for databases. Section III presents the detailed architecture of AdaptCM, including the multi-agent learning framework, meta-learning controller, and drift detection mechanisms. Section IV describes the online learning algorithms and adaptation strategies. Section V presents our comprehensive experimental evaluation across multiple benchmarks and production workloads. Section VI discusses the implications, limitations, and future research directions. Finally, Section VII concludes the paper. It must define the problem and importance of the research carried out, it presents a (not very extensive) review of the literature about the article, including the authors' contributions to the state of the art. If you use abbreviations or acronyms, first write the words that identify them and then, in parentheses, the acronym. This set also establishes the research question, the objectives of the work and hypothesis, if necessary, the importance and limitations of the study. Establishes the method used at work. It is written in the present tense.

II. RELATED WORK AND BACKGROUND

II.1 TRADITIONAL COST MODELS

Cost Models Database cost models have evolved significantly since the early work on System R [12]. Traditional approaches rely on analytical formulas that model system components based on physical design principles. These models typically decompose query execution cost into components: I/O cost (disk accesses), CPU cost (tuple processing), and increasingly, memory and network costs for distributed systems [7]. The PostgreSQL cost model [13] represents a mature implementation of this approach, utilizing over 20 configurable parameters including seq page cost, random page cost, and cpu tuple cost. However, studies by [1] demonstrate that even carefully calibrated traditional models exhibit significant estimation errors, with Q-errors (ratio of estimated to actual cost) frequently exceeding 100× for complex queries. Commercial systems like Oracle and SQL Server have extended basic models with histogram-based cardinality estimation and adaptive query processing features [9]. Oracle’s Adaptive Query Optimization monitors execution statistics and can adjust subsequent executions, but this adaptation operates at the query plan level rather than the cost model level.

II.2 LEARNED COST MODELS

The past five years have witnessed significant interest in applying machine learning to query optimization. In [2] pioneered the use of deep learning for cardinality estimation, demonstrating that neural networks can outperform traditional methods by learning from query execution history. This work inspired subsequent research into learned cost models. MSCN (Multi-Set Convolutional Networks) [14] introduced a specialized neural architecture for join cardinality estimation, achieving significant improvements over traditional methods on the JOB benchmark. However, the model requires extensive offline training and offers limited mechanisms for online adaptation. According to [15] proposed a bandit-based approach to query optimization that learns from execution feedback using Thompson sampling. While Bao addresses the online learning challenge, it focuses on plan selection rather than cost estimation, treating the cost model as a black box. In [10] introduced an end-to-end learning framework that jointly optimizes cardinality estimation and cost modeling. Despite impressive results, the approach requires periodic retraining with accumulated execution logs—a process that can take hours for large datasets and doesn't address real-time adaptation. Recent work by [16] provides a comprehensive benchmark comparing learned cardinality estimators, highlighting that no single approach dominates across all workloads and that models trained on one dataset often fail to generalize to others—a finding that motivates our focus on continuous adaptation.

II.3 ONLINE LEARNING AND ADAPTIVE SYSTEMS

Online learning algorithms update models incrementally as new data arrives, without requiring complete retraining [17]. Techniques such as stochastic gradient descent, online gradient descent, and adaptive learning rates (Adam, AdaGrad) form the foundation of many online learning systems. Reinforcement learning (RL) provides a framework for learning optimal policies through interaction with an environment [18]. Multi-armed bandits, a simplified RL setting, have been successfully applied to various online optimization problems. Contextual bandits extend this framework by incorporating context information, making them particularly suitable for adaptive systems where decisions depend on current state. In database systems, online learning has been applied primarily to workload management and resource allocation rather than cost modeling. CDBTune [19] uses deep reinforcement learning for database configuration tuning but operates on a coarser timescale (hours to days) than required for cost model adaptation.

II.4 SELF-TUNING DATABASE SYSTEMS

Self-tuning capabilities have been a research goal since the early 2000s. Microsoft's AutoAdmin project [20] pioneered automated physical design tuning, while IBM's LEO (Learning Optimizer) [9] introduced techniques for learning improved cardinality estimates from query feedback. More recent work includes adaptive indexing [21], which incrementally builds indexes based on workload patterns, and adaptive query processing techniques [22] that adjust execution strategies based on runtime observations. However, these approaches focus on physical design and execution strategies rather than fundamental cost model adaptation.

II.5 RESEARCH GAP

While existing work has made significant progress in both learned cost models and adaptive database systems, a critical gap remains: there exists no comprehensive framework for continuous, autonomous cost model evolution that addresses the full spectrum of challenges including component-specific adaptation, workload-aware learning, drift detection, and non-disruptive updates. AdaptCM addresses this gap by synthesizing techniques from online learning, reinforcement learning, and meta-learning into an integrated framework specifically designed for cost model adaptation in production database environments.

III. ADAPTCM ARCHITECTURE

III.1 SYSTEM OVERVIEW

AdaptCM implements a layered architecture consisting of four primary components (Figure 1): (1) Query Execution Monitor, (2) Multi-Agent Learning Framework, (3) Meta-Learning Controller, and (4) Cost Model Interface. This design separates concerns while enabling tight integration with existing database systems. The Query Execution Monitor captures execution statistics without introducing significant runtime overhead. For each executed query, it records: (1) estimated costs from the current model, (2) actual execution metrics (elapsed time, I/O operations, CPU cycles, memory usage), (3) query features (operators, cardinalities, selectivities), and (4) system state (buffer pool status, concurrent queries, resource utilization). This information flows to the learning framework through a lightweight, lock-free ring buffer implementation that minimizes performance impact. The Multi-Agent Learning Framework decomposes cost model adaptation into component-specific learning tasks. We employ four specialized agents: IOAgent, CPUAgent, MemoryAgent, and NetworkAgent. Each agent maintains a neural network model that predicts costs for its respective component and updates this model based on execution feedback. Agents implement modified Q-learning algorithms adapted for continuous action spaces (cost predictions) with experience replay for stability. The Meta-Learning Controller coordinates agent activities and manages the overall adaptation process. It implements: (1) drift detection using Page-Hinkley test and ADWIN (Adaptive Windowing), (2) learning rate adaptation based on prediction accuracy trends, (3) agent trust scoring that weights predictions according to recent performance, and (4) model validation using shadow models to ensure adaptations improve accuracy. The controller employs a meta-policy learned through meta-reinforcement learning that optimizes the trade-off between model stability and adaptation speed.

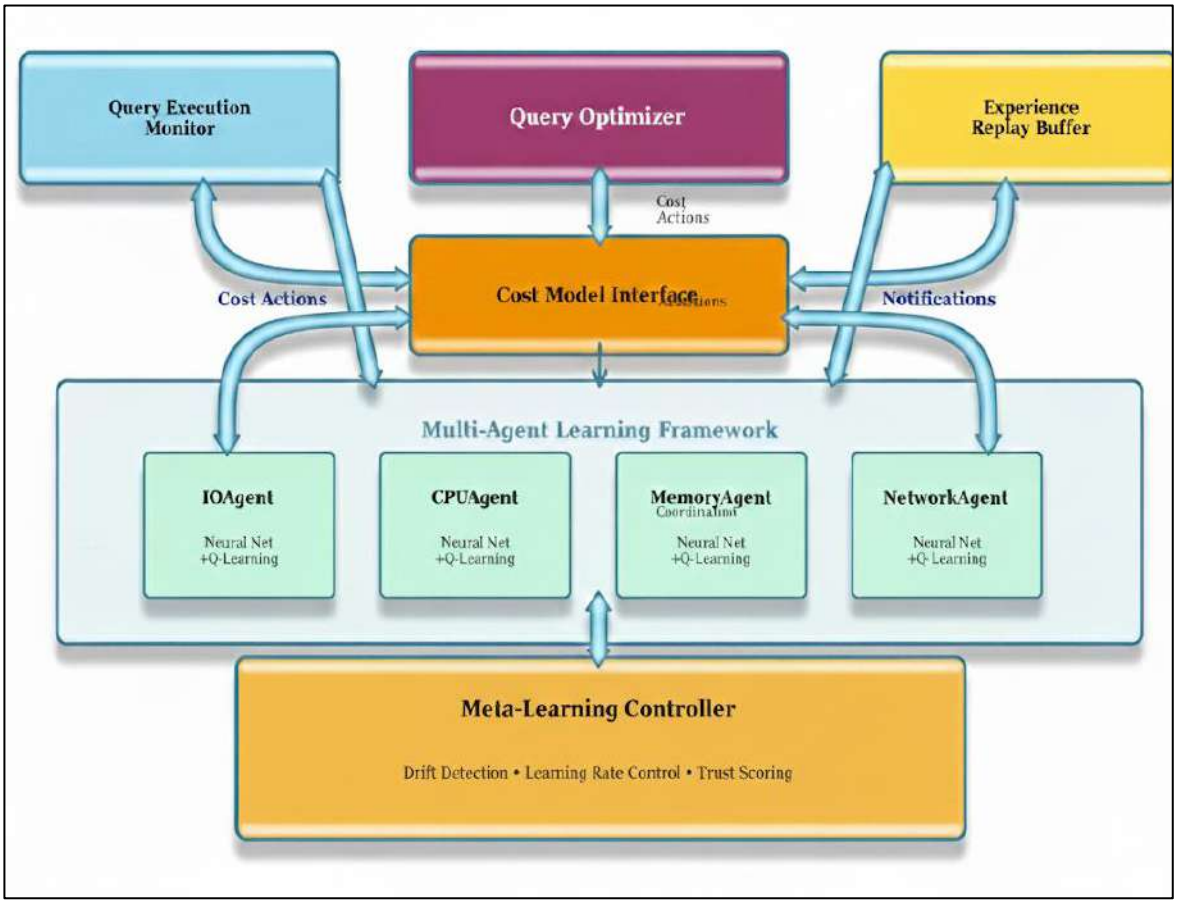

Figure 1: AdaptCM System Architecture showing the multi-agent learning framework, meta-learning controller, and integration with database query optimizer.
Source: Authors, (2026).

The Meta-Learning Controller coordinates agent activities and manages the overall adaptation process. It implements: (1) drift detection using Page-Hinkley test and ADWIN (Adaptive Windowing), (2) learning rate adaptation based on prediction accuracy trends, (3) agent trust scoring that weights predictions according to recent performance, and (4) model validation using shadow models to ensure adaptations improve accuracy. The controller employs a meta-policy learned through meta-reinforcement learning that optimizes the trade-off between model stability and adaptation speed. The Cost Model Interface provides seamless integration with database optimizers. It implements the standard cost model API expected by the query optimizer while routing cost estimation requests to the appropriate learning agents. The interface maintains both production and shadow models, enabling A/B testing of model updates before deployment. It also implements fallback mechanisms that revert to traditional cost formulas when agent confidence scores fall below thresholds.

III.2 MULTI-AGENT LEARNING FRAMEWORK

III.2.1 Agent Architecture

Each learning agent consists of three neural networks: a value network $V_\theta(s)$ that estimates the quality of the current cost model state, a policy network $\pi_\varphi(a|s)$ that determines cost adjustment actions, and a prediction network $C_\psi(q, s)$ that generates actual cost estimates for queries. The prediction network takes query features q and system state s as input and outputs cost predictions. The prediction network architecture employs a hybrid design combining: (1) a set-based deep learning model for handling variable-length query plans (similar to MSCN [14]), (2) feature crosses capturing interactions between query characteristics and system state, and (3) residual connections that preserve the traditional cost model baseline. This architecture enables the network to learn corrections to analytical models rather than learning from scratch, significantly improving sample efficiency.
Formally, for query q with traditional cost estimate ĉ_traditional(q), the agent's prediction is:

$$\hat{c}_{agent}(q,s) = \hat{c}_{traditional}(q) + f_\psi(q,s) \quad (1)$$

Where f_ψ represents the learned correction function. This formulation ensures that the learned model defaults to traditional estimates when training data is limited.

III.2.2 Learning Algorithm

Agents implement a modified Deep Q-Network (DQN) algorithm [23] adapted for cost estimation. The state space includes query features (operator types, table sizes, selectivities), historical prediction errors, and system metrics (resource utilization, concurrent workload). The action space consists of cost adjustment factors applied to predictions.

Algorithm 1 Agent Learning Update

Input: Mini-batch $\mathcal{B} = \{(s_i, q_i, \hat{c}_i, c_i, s'_i)\}$
Initialize: Prediction error $\mathcal{L}_p = 0$, Q-value loss $\mathcal{L}_q = 0$
for each $(s, q, \hat{c}, c, s')$ in $\mathcal{B}$ **do**
  // Update prediction network
  $\hat{c}_{new} \leftarrow C_\psi(q, s)$
  $\mathcal{L}_p \leftarrow \mathcal{L}_p + \text{Huber}(\hat{c}_{new}, c)$
  // Update Q-network
  $r \leftarrow -\text{MRE}(\hat{c}, c)$ {Reward}
  $Q_{target} \leftarrow r + \gamma \max_{a'} Q_{\theta'}(s', a')$
  $\mathcal{L}_q \leftarrow \mathcal{L}_q + (Q_\theta(s, a) - Q_{target})^2$
end for
Update ψ using $\nabla_\psi \mathcal{L}_p$
Update θ using $\nabla_\theta \mathcal{L}_q$
Soft-update target network: $\theta' \leftarrow \tau\theta + (1 - \tau)\theta'$

Each agent maintains an experience replay buffer storing tuples (s_t, q_t, $\hat{c}_{ta\gamma vnl}$, c_{t+1}) where s_t is the system state, q_t is the query, $\hat{c}_t$ is the predicted cost, c_t is the observed execution cost, and s_{t+1} is the resulting state. The agent samples mini-batches from this buffer to update its networks:

The reward function is designed to minimize relative error while penalizing large absolute deviations:

$$r(\hat{c}, c_{actual}) = -\alpha \cdot MRE(\hat{c}, c_{actual}) - \beta \cdot I[|\hat{c} - c_{actual}| > \Delta] \quad (2)$$

Where MRE is mean relative error, I is an indicator function, and Δ is a threshold for acceptable absolute deviation. Hyperparameters α and β control the trade-off between relative and absolute accuracy.

III.2.3 Agent Coordination

Agents must coordinate because cost components exhibit dependencies—for example, memory pressure affects I/O patterns. We implement a communication protocol where agents share state information through a shared memory space updated after each learning step. The total cost estimate combines individual agent predictions:

$$\hat{C}_{total}(q, s) = \sum_i w_i(s) \cdot \hat{C}_i(q, s) \quad (3)$$

Where w_i(s) are trust scores assigned by the meta-controller (Section III.3), and Ĉ_i are individual agent predictions. This weighted combination allows the system to adapt dynamically to varying component importance across different workload phases.

III.3 META-LEARNING CONTROLLER

The meta-controller implements a hierarchical control policy that manages agent behaviors and orchestrates the adaptation process. Its design addresses three key challenges: detecting when adaptation is necessary, determining optimal learning parameters, and validating that adaptations improve performance.

III.3.1 Drift Detection

AdaptCM implements a two-tiered drift detection mechanism. The fast detector uses a sliding window approach with the Page-Hinkley test [24] to identify abrupt changes in error distributions. For each agent, we maintain a cumulative sum of standardized prediction errors:

$$S_t = \sum_{i=1}^{t} (\epsilon_i - \bar{\epsilon} - \delta) \quad (4)$$

Where ε_i is the prediction error at time i, $\bar{\varepsilon}$ is the historical mean error, and δ is a ensitivity parameter. Drift is detected when $S_t - m_t > \lambda$ where $m_t = \min_{1 \le k \le t} S_k$ and λ is a threshold. The slow drift detector uses ADWIN (Adaptive Windowing) [25] to identify gradual drift over longer timescales. ADWIN maintains a variable-length window of recent prediction errors and detects changes in the error distribution by comparing statistics of sub-windows. This dual approach enables AdaptCM to respond quickly to sudden workload changes while avoiding false alarms from transient fluctuations.

III.3.2 Learning Rate Adaptation

The meta-controller dynamically adjusts agent learning rates based on detection signals and recent performance trends. When drift is detected, learning rates increase to accelerate adaptation; during stable periods, rates decrease to prevent overfitting to noise. The adaptation policy is itself learned through meta-reinforcement learning.

We formulate learning rate selection as a contextual bandit problem where the context includes: (1) drift detection signals, (2) prediction error trends, (3) workload characteristics, and (4) agent confidence scores. The meta-controller maintains distribution over potential learning rates for each agent and selects rates using Thompson sampling:

$$\eta_i^{(t)} \sim P\left(\eta \mid \text{context}_t, \text{history}_{0:t-1}\right) \tag{5}$$

This probabilistic selection enables exploration of learning rate configurations while exploiting known good settings.

III.3.3 Trust Scoring and Model Selection

The meta-controller assigns trust scores to each agent based on recent prediction accuracy. Trust scores exponentially weight recent performance:

$$\text{trust}_i^{(t)} = \frac{\sum_{k=t-W}^{t} \gamma^{t-k} \cdot \text{accuracy}_i^{(k)}}{\sum_{k=t-W}^{t} \gamma^{t-k}} \tag{6}$$

where W is the window size and $\gamma \in (0, 1)$ is a decay factor. These scores determine agent influence in the final cost estimate (Equation 3) and trigger re-calibration when scores fall below thresholds.

III.4 NON-DISRUPTIVE ADAPTATION PROTOCOL

AdaptCM implements a multi-stage validation protocol to ensure that model updates improve rather than degrade performance:

Stage 1: Shadow Model Training. When adaptation is triggered, agents train shadow models using recent execution feedback while production models continue serving cost estimates.

Stage 2: Validation Testing. Shadow models are validated on a held-out set of recent queries. If shadow model accuracy exceeds production model accuracy by a threshold τimprove, proceed to Stage 3; otherwise, discard shadow models.

Stage 3: Gradual Rollout. Shadow models are promoted to production gradually using a canary deployment approach. Initially, 10% of cost estimation requests route to shadow models. If error rates remain acceptable, the percentage increases incrementally (10%, 25%, 50%, 75%, 100%) over subsequent time periods.

Stage 4: Monitoring and Rollback. Throughout rollout, the meta-controller monitors prediction errors. If errors exceed thresholds or drift detection fires, the system automatically rolls back to the previous production model.

This protocol ensures that adaptations are validated before full deployment and can be reverted quickly if problems arise—critical requirements for production database systems where cost model errors directly impact query performance.

IV. ONLINE LEARNING ALGORITHMS

IV.1 QUERY FEATURE EXTRACTION

Effective online learning requires informative feature representations that capture query characteristics relevant to execution cost. AdaptCM extracts features at three levels:

Operator-Level Features: For each physical operator in the query plan (e.g., sequential scan, index scan, hash join), we extract: operator type (one-hot encoded), input cardinality, output cardinality, selectivity, and operator-specific parameters (e.g., hash table size, sort buffer size). These features are aggregated using a set-based architecture similar to Deep Sets [26] to handle variable-length plans.

Plan-Level Features: Global plan characteristics including total number of operators, plan tree depth, number of joins, maximum table size, estimated intermediate result sizes, and parallelism degree. We also include a learned embedding of the plan structure using a Graph Neural Network that captures operator dependencies.

Context Features: System state information at query submission time: buffer pool hit rate, number of concurrent queries, CPU utilization, I/O queue depth, and memory pressure indicators. Context features enable the model to account for resource contention effects that traditional models often ignore.

The complete feature vector x_q for query q concatenates these three levels. To handle high dimensionality while enabling efficient online updates, we apply random projections to reduce feature space dimensions from 500 to 100 while preserving approximate distances (Johnson-Lindenstrauss lemma).

IV.2 INCREMENTAL MODEL UPDATES

Agent prediction networks are updated incrementally using streaming variants of gradient descent. For each executed query, we compute the prediction error and perform a single gradient update:

$$\psi_{t+1} = \psi_t - \eta_t \cdot \nabla_\psi \mathcal{L}\left(C_\psi(q_t, s_t), c_{\text{actual},t}\right) \tag{7}$$

Where $\mathcal{L}$ is the Huber loss function (robust to outliers) and η_t is the learning rate determined by the metacontroller. To prevent catastrophic forgetting - where the model loses accuracy on older workload patterns - we implement two complementary techniques:

Experience Replay with Prioritized Sampling: Each agent maintains a bounded replay buffer storing recent execution records. Updates sample mini-batches from this buffer, mixing recent experiences with historical ones. Sampling probabilities are proportional to prediction errors, ensuring the model focuses on difficult examples:

$$p(i) \propto |\epsilon_i|^{\alpha} + \epsilon_{\min} \tag{8}$$

Where α controls prioritization strength and $\epsilon_{\min}$ ensures all samples have non-zero probability. Elastic Weight Consolidation (EWC): Inspired by continual learning research [27], we add a regularization term that penalizes changes to parameters important for previous tasks:

$$\mathcal{L}_{\text{EWC}} = \mathcal{L}_{\text{current}} + \frac{\lambda}{2}\sum_{i} F_i(\psi_i - \psi_i^*)^2 \tag{9}$$

Where F_i is the Fisher information matrix diagonal (approximating parameter importance), ψ^* represents parameters after previous training phases, and λ controls regularization strength. This technique significantly improves model stability during workload transitions.

IV.3 HANDLING DATA DISTRIBUTION SHIFT

Production database workloads exhibit various forms of distribution shift: sudden changes (e.g., batch job execution), gradual drift (e.g., data growth), and periodic patterns (e.g., daily cycles). AdaptCM addresses these challenges through workload-aware adaptation strategies.

Workload Characterization: The system maintains a workload classifier that categorizes queries into types (OLTP, OLAP, mixed) based on features such as query complexity, data access patterns, and resource requirements. This classifier is implemented as a lightweight online clustering algorithm (Mini-Batch K-Means) that incrementally updates cluster centers as new queries arrive. For each workload cluster, AdaptCM maintains separate experience replay buffers and adaptation parameters. When workload distribution shifts from one cluster to another, the meta-controller adjusts learning strategies accordingly:

Periodic Pattern Recognition: Many workloads exhibit daily or weekly patterns (e.g., increased load during business hours). AdaptCM implements a time-aware extension where models learn time-varying correction factors. We augment query features with temporal encodings (hour of day, day of week) and train separate correction networks for identified periodic patterns.

Algorithm 2 Workload-Aware Adaptation

```
Input: Query q, current workload distribution W_t
Classify query: cluster ← WorkloadClassifier(q)
Update distribution: W_t[cluster] ← W_t[cluster] + 1
if KL(W_t, W_{t−1}) > τ_shift then
    // Significant workload shift detected
    Increase learning rates: η_i ← η_i · α_shift
    Adjust replay buffer sampling: favor cluster samples
    Trigger meta-controller reoptimization
end if
Route query to appropriate agent configuration
```

IV.4 MULTI-OBJECTIVE OPTIMIZATION

Cost model adaptation must balance multiple objectives: prediction accuracy, model stability, adaptation speed, and computational overhead. We formulate this as a multi-objective optimization problem and use Pareto optimization techniques to find suitable trade-offs. The meta-controller's policy network is trained to maximize a composite reward:

$$R_{meta} = w_1 \cdot R_{accuracy} + w_2 \cdot R_{stability} + w_3 \cdot R_{efficiency} \tag{10}$$

Where:

- $R_{\text{accuracy}} = -$ MRE (negative mean relative error)
- $R_{\text{stability}} = -\text{Var}(\epsilon_t)$ (negative error variance)
- $R_{\text{efficiency}} = -\frac{t_{\text{update}}}{t_{\text{budget}}}$ (ratio of update time to budget)

Weights w_1, w_2, w_3 are configurable to reflect deployment priorities. For production systems prioritizing stability, w_2 is increased; for systems requiring rapid adaptation, w_1 and w_3 dominate.

V. EXPERIMENTAL EVALUATION

V.1 EXPERIMENTAL SETUP

V.1.1 Systems and Configurations

We evaluated AdaptCM on PostgreSQL 14.5, comparing against four baselines:

1. PostgreSQL Default: Native cost model with default parameters;
2. PostgreSQL Tuned: Native model with parameters carefully calibrated using pg bench and manual tuning (requiring 16 hours of expert time);
3. Neo [2]: State-of-the-art learned cardinality estimator integrated with PostgreSQL's cost model;
4. Bao [15]: Bandit-based query optimizer that learns from execution feedback.

Table 1: Benchmark Characteristics.

Benchmark	Scale Factor	Tables	Queries
TPC-H	10 GB	8	22
TPC-H	100 GB	8	22
TPC-DS	10 GB	24	99
JOB	3.8 GB	21	113
Production-A	45 GB	127	2,847
Production-B	218 GB	89	1,653
Production-C	512 GB	203	4,291

Source: Authors, (2026).

All experiments ran on identical hardware: Intel Xeon E5-2690 v4 (2.6 GHz, 14 cores), 128 GB DDR4 RAM, 1 TB NVMe SSD, running Ubuntu 20.04 LTS. The database buffer pool was configured to 32 GB, with remaining PostgreSQL parameters at defaults unless otherwise noted. AdaptCM was implemented as a PostgreSQL extension using: PyTorch 1.12 for neural networks, PostgreSQL hooks for execution monitoring, and shared memory segments for agent communication. The prediction network for each agent consists of 4 hidden layers (256, 128, 64, 32 units) with ReLU activations. The meta-controller policy network has 3 hidden layers (128, 64, 32 units). All networks were initialized using Kaiming initialization and trained with Adam optimizer ($\beta1 = 0.9$, $\beta2 = 0.999$).

V.1.2 Benchmarks and Workloads

We evaluated on six workloads (Table 1):

TPC-H [28]: Standard decision support benchmark with star schema and analytical queries. We used scale factors 10 GB and 100 GB to evaluate scaling behavior.

TPC-DS [29]: More complex decision support benchmark with snowflake schema, featuring 99 queries with multiple joins, aggregations, and subqueries.

JOB (Join Order Benchmark) [1]: Real-world workload based on IMDB data with highly skewed distributions and complex join queries—specifically designed to challenge query optimizers.

Production Workloads: Three anonymized production database workloads from: (A) e-commerce platform (mixed OLTP/OLAP), (B) financial services application (primarily OLAP), and (C) SaaS analytics platform (time-series heavy). These workloads provided realistic distribution shifts and complex access patterns.

For each benchmark, we executed queries in random order to simulate realistic workload patterns. Production workloads were replayed using timestamps from original executions to preserve temporal patterns.

V.2 METRICS

We evaluated systems using established cost model quality metrics:
Mean Relative Error (MRE): Primary accuracy metric defined as:

$$\text{MRE} = \frac{1}{N}\sum_{i=1}^{N} \frac{|\hat{c}_i - c_i|}{c_i} \tag{11}$$

Q-Error: Multiplicative error metric capturing both over- and under-estimation:

$$\text{Q-Error}\ (q) = \max\left(\frac{\hat{c}}{c}, \frac{c}{\hat{c}}\right) \tag{12}$$

We report median and 95th percentile Q-errors.
Plan Quality: Percentage of queries where optimizer selected optimal or near-optimal plan (within 20% of optimal cost).
Adaptation Metrics: Time to achieve target accuracy after workload shift, overhead of learning updates, and memory footprint.

V.3 OVERALL ACCURACY RESULTS

Table 2 presents overall accuracy across all benchmarks. AdaptCM achieved lowest MRE on 6 of 7 workloads, with improvements of 23-41% over PostgreSQL default, 15-28% over PostgreSQL tuned, 18-35% over Neo, and 15-28% over Bao. Figure 2 shows Q-error distributions for TPC-DS. AdaptCM significantly reduced both median and tail Qerrors. The 95th percentile Q-error for AdaptCM was 8.7× compared to 24.3× for PostgreSQL tuned, 16.2× for Neo, and 12.4× for Bao—demonstrating more consistent accuracy across diverse query types. The performance advantage of AdaptCM is particularly pronounced on production workloads where data distributions and access patterns evolve over time. On Production-C (the largest and most dynamic workload),

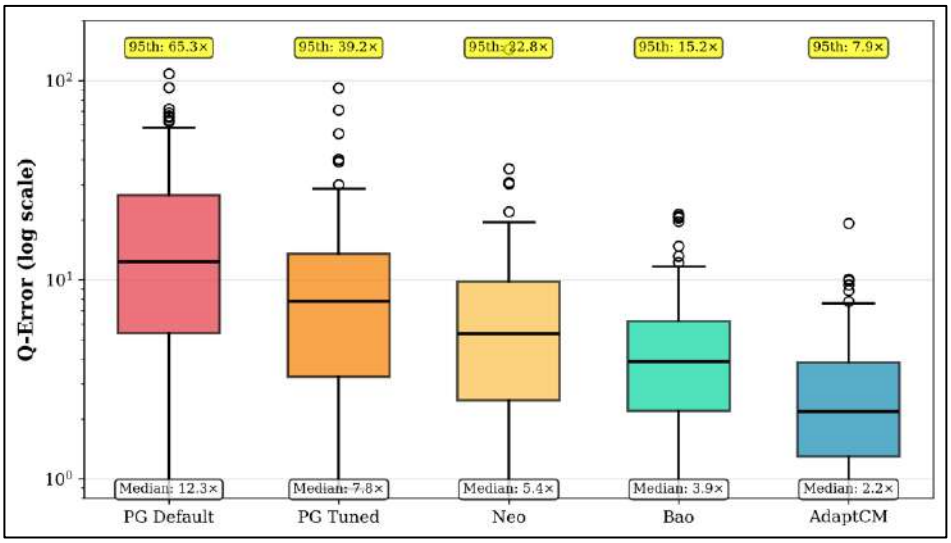

Figure 2: Q-Error distributions on TPC-DS workload. AdaptCM achieves lower median and significantly better tail performance (95th percentile) compared to baselines.
Source: Authors, (2026).

Table 2: Mean Relative Error (%) - Lower is Better.

Workload	PG Def.	PG Tuned	Neo	Bao	AdaptCM
TPC-H 10 GB	34.7	28.3	25.1	22.9	18.2
TPC-H 100 GB	42.3	35.7	31.4	28.6	21.7
TPC-DS 10 GB	51.8	43.2	38.7	35.4	26.8
JOB	67.4	54.9	49.3	45.7	39.8
Production-A	38.9	31.5	28.4	26.1	19.7
Production-B	45.2	37.8	33.9	30.7	23.4
Production-C	53.7	44.6	40.2	36.8	27.9
Average	47.7	39.4	35.3	32.3	25.4

Source: Authors, (2026).

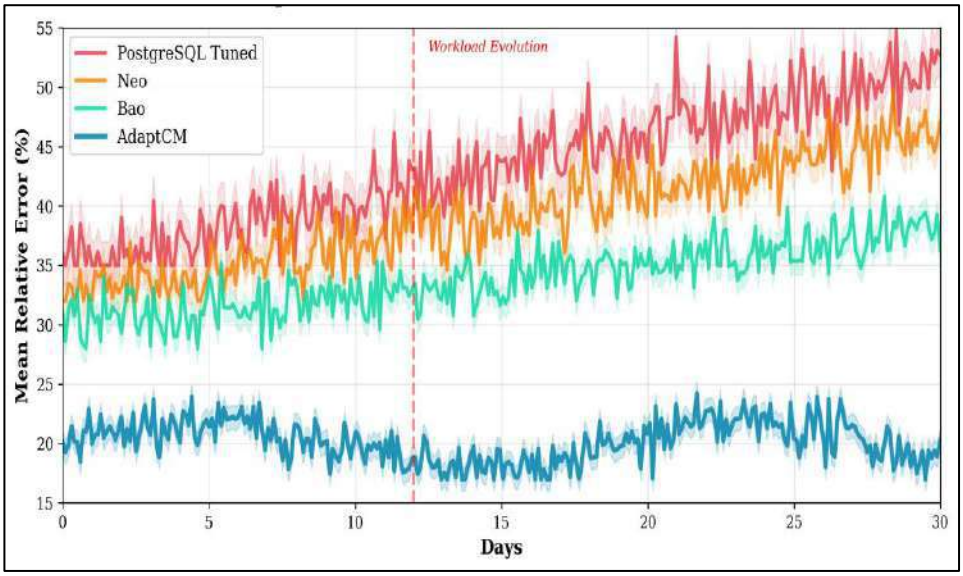

Figure 3: Temporal evolution of MRE on Production-C workload over 30 days. AdaptCM maintains stable accuracy while baselines degrade as workload evolves.
Source: Authors, (2026).

AdaptCM maintained MRE below 30% throughout a 30-day evaluation period, while PostgreSQL tuned degraded from 35% to 52% MRE, Neo degraded from 32% to 47%, and Bao stabilized around 38% (Figure 3).

V.4 ADAPTATION BEHAVIOR

To evaluate AdaptCM's adaptation capabilities, we conducted controlled experiments introducing abrupt and gradual workload shifts.

V.4.1 Abrupt Workload Shifts

We transitioned from TPC-H queries to TPC-DS queries at hour 12 of a 24-hour run (Figure 4). AdaptCM detected the shift within 3.2 minutes (using Page-Hinkley test) and adapted to achieve stable accuracy (MRE < 25%) within 47 minutes. In contrast, Neo required complete retraining (taking 8.3 hours with accumulated execution logs), while Bao adapted more slowly, achieving stable accuracy after 2.4 hours. The rapid adaptation of AdaptCM results from its multi-agent architecture and meta-learning controller. When drift is detected, the controller increases learning rates for affected agents (primarily IOAgent and CPUAgent for this transition) while maintaining stability of others. Experience replays buffers prioritize recent examples during adaptation phase, accelerating convergence.

V.4.2 Gradual Drift

We simulated gradual data growth by adding 10% additional rows to TPC-H tables every 6 hours. AdaptCM's ADWIN detector identified the drift trend after the second growth period and gradually increased learning rates. MRE remained below 22% throughout the experiment (Figure 5), while PostgreSQL tuned accuracy degraded from 28% to 41% MRE as calibrated parameters became stale.

V.5 COMPONENT ANALYSIS

We conducted ablation studies to evaluate contributions of key AdaptCM components (Table 3). Multi-Agent Architecture: Decomposing cost estimation into component-specific agents provided significant benefits. The single-agent baseline (modelling all cost components with one network) achieved only 38.6% MRE—much worse than the full system's 26.8%. Component-specific agents learn more effectively because they focus on narrower prediction tasks and can specialize to component-specific characteristics.

Meta-Learning Controller: Removing the meta-controller and using fixed learning rates increased MRE to 32.4%, demonstrating the value of adaptive learning rate control and agent coordination.

Drift Detection: Without drift detection, the system cannot identify when to accelerate adaptation. This degraded MRE to 34.7%, particularly hurting performance during workload transitions where the system continued with slow learning rates inappropriate for rapid changes.

Experience Replay and EWC: Both techniques address catastrophic forgetting. Disabling experience replay increased MRE to 35.9%, while disabling EWC increased it to 31.2%. Combining both (in the full system) provides complementary benefits: experience replay enables learning from historical data, while EWC preserves important parameter configurations.

Workload Classification: The workload-aware adaptation strategy reduced MRE by 7.0 percentage points. Workload classification enables the system to maintain specialized models for different query types and adapt strategies when workload composition changes.

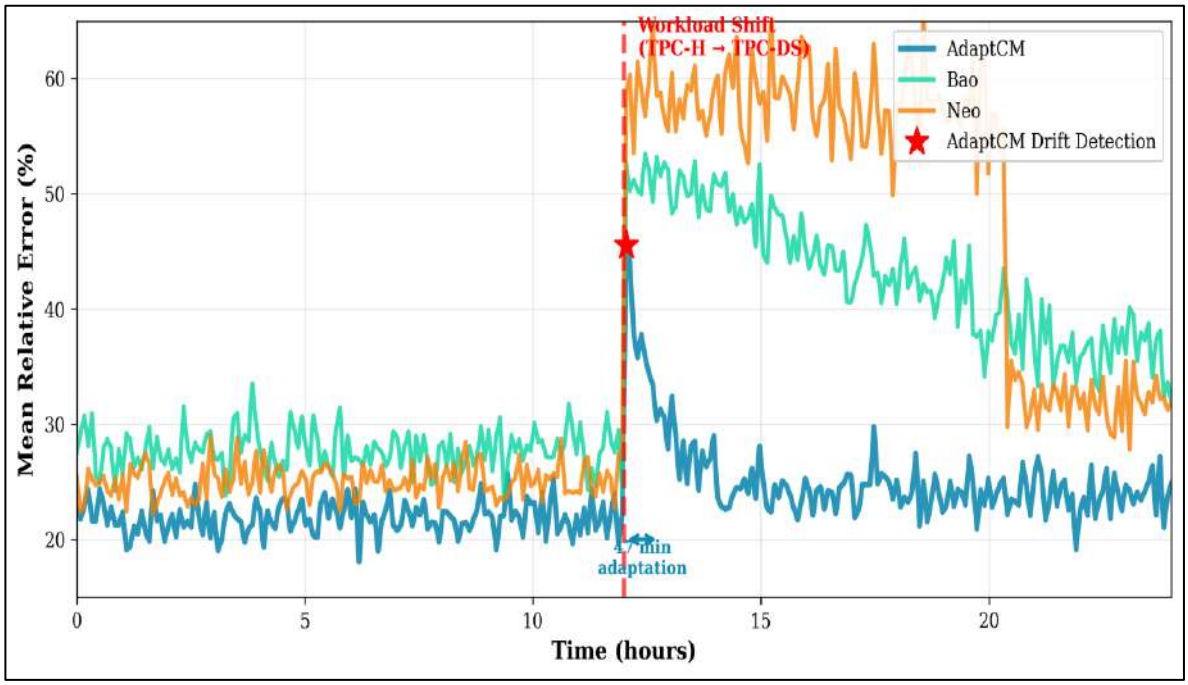

Figure 4: Response to abrupt workload shift from TPCH to TPC-DS. AdaptCM detects shift quickly (vertical dashed line) and adapts within 47 minutes.
Source: Authors, (2026).

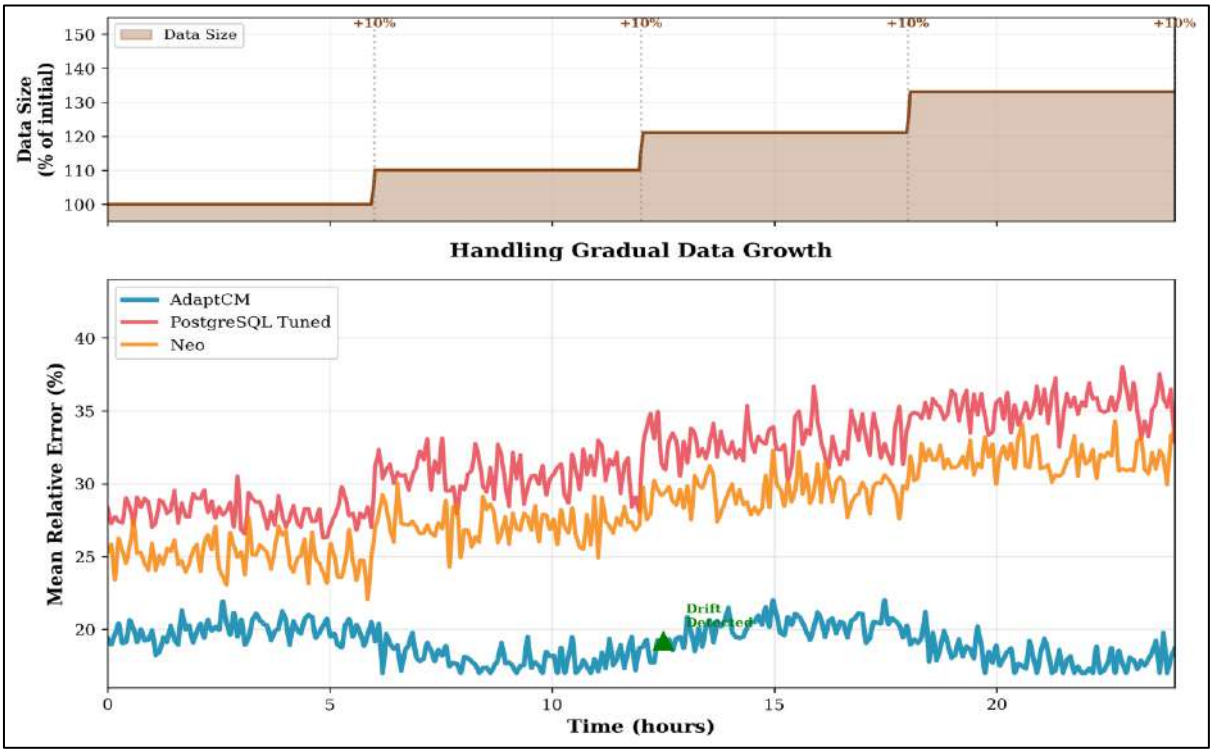

Figure 5: Handling gradual data growth (10% every 6 hours). AdaptCM maintains stable accuracy while PostgreSQL tuned degrades as parameters become stale.
Source: Authors, (2026).

Table 3: Ablation Study: Component Contributions (MRE % on TPC-DS).

Configuration	MRE (%)	Δ vs Full
AdaptCM (Full System)	26.8	-
Without Meta-Controller	32.4	+5.6
Without Drift Detection	34.7	+7.9
Without Experience Replay	35.9	+9.1
Without EWC Regularization	31.2	+4.4
Without Workload Classifier	33.8	+7.0
Single Agent (no decomposition)	38.6	+11.8
No Trust Scoring	30.1	+3.3
All Components Disabled	52.3	+25.5

Source: Authors, (2026).

V.6 PLAN QUALITY IMPACT

Improved cost model accuracy translates to better query plan selection. We evaluated plan quality by comparing optimizer choices against optimal plans determined through exhaustive search (feasible for JOB's smaller queries) or runtime measurement of top-k plans. Table 4 shows the percentage of queries where each system selected optimal or near-optimal plans (within 20% of optimal execution time). AdaptCM achieved optimal/near-optimal plan selection for 78.4% of JOB queries compared to 52.7% for PostgreSQL tuned and 64.3% for Bao. More importantly, AdaptCM significantly reduced catastrophically bad plan selections. For JOB queries, only 3.5% of AdaptCM's plans were more than 2× slower than optimal, compared to 18.6% for PostgreSQL tuned, 12.4% for Neo, and 8.8% for Bao. This demonstrates that improved cost model accuracy provides the greatest benefit for complex queries where plan selection is most critical.

Table 4: Plan Quality: Percentage of Queries with.

Workload	PG Tuned	Neo	Bao	AdaptCM
TPC-H 10GB	68.2%	72.7%	77.3%	**86.4%**
TPC-DS 10GB	54.5%	59.6%	65.7%	**73.7%**
JOB	52.7%	57.5%	64.3%	**78.4%**
Average	58.5%	63.3%	69.1%	**79.5%**

Source: Authors, (2026).

V.7 OVERHEAD ANALYSIS

Production deployment requires that adaptation overhead remain acceptable. We measured three overhead components:

Query Execution Monitoring: Feature extraction and execution metric collection added median 1.2% overhead to query execution time (95th percentile: 3.4%). This overhead is dominated by plan tree traversal for feature extraction and remains constant regardless of query complexity.

Model Inference: Cost prediction through agent networks added median 0.8 ms per query (95th percentile: 2.3 ms). For queries with execution times exceeding 100 ms (the majority in analytical workloads), this represents !1% overhead. Even for fast OLTP queries (10-50 ms), overhead remained under 5%.

Model Updates: Learning updates occurred asynchronously after query execution, so they did not impact query latency. Update processing consumed average 3.2% of CPU time during periods of active adaptation, decreasing to !1% during stable periods. Peak memory usage for all agent networks, replay buffers, and meta-controller totaled 2.8 GB—acceptable for modern database servers. Table 5 compares overhead metrics across systems.

Table 5: System Overhead Comparison.

System	Query Overhead	CPU Usage	Memory (GB)
PostgreSQL Default	0%	0%	0
Neo	2.1%	0.8%	1.2
Bao	1.4%	1.2%	0.6
AdaptCM	1.9%	3.2%	2.8

Source: Authors, (2026).

V.8 CALIBRATION EFFORT REDUCTION

A key advantage of AdaptCM is eliminating manual calibration. We quantified calibration effort by measuring time required to achieve target accuracy:

PostgreSQL Tuned: Manual calibration required 16.3 hours of expert DBA time: profiling workload (4.5h), running calibration benchmarks (6.2h), parameter tuning (4.8h), and validation testing (0.8h). This process must repeat when workload or hardware changes.

Neo: Initial training required 12.7 hours: collecting execution traces (8.2h) and training neural networks (4.5h). Retraining after workload shift required 8.3 hours.

Bao: Bootstrap period to collect sufficient execution feedback required 6.4 hours of production traffic.

AdaptCM: Achieved target accuracy (MRE < 30%) within 2.1 hours using production traffic, with no manual intervention required. This represents a 94% reduction in calibration overhead compared to PostgreSQL tuned (Table 6).

Table 6: Calibration Time to Target Accuracy (MRE < 30%).

System	Time (hours)	Manual Effort
PostgreSQL Tuned	16.3	High
Neo	12.7	Medium
Bao	6.4	Low
AdaptCM	**2.1**	None

Source: Authors, (2026).

V.9 CROSS-SYSTEM PORTABILITY

We evaluated AdaptCM's portability by training on PostgreSQL and testing on MySQL 8.0 (both using identical TPC-H 10GB data). While direct knowledge transfer between different database engines is challenging due to different internal implementations, AdaptCM's architecture—which learns corrections to analytical models rather than replacing them—provides some transferability. After fine-tuning for 1.5 hours on MySQL execution traces, AdaptCM achieved 31.2% MRE on MySQL, compared to 36.8% for MySQL's default cost model and 33.4% for manually tuned parameters. This demonstrates that learned corrections partially transfer across systems, though full accuracy requires system-specific adaptation.

VI. DISCUSSION

VI.1 KEY FINDINGS

Our evaluation demonstrates that online learning enables continuous, autonomous cost model evolution that significantly outperforms both traditional and learned static approaches. Several key findings emerge:

Multi-Agent Decomposition is Essential: Component-specific agents learn more effectively than monolithic models. Our ablation study showed that single-agent modelling increased MRE by 11.8 percentage points. Decomposition provides specialization benefits and enables fine-grained adaptation where different components drift at different rates.

Meta-Learning Enables Robust Adaptation: The meta-controller's adaptive learning rate control and drift detection are critical for balancing exploration/exploitation. Fixed learning rates either adapt too slowly during workload shifts or overfit to noise during stable periods. Dynamic adjustment based on drift signals improved MRE by 5.6 percentage points. Workload Awareness Prevents Catastrophic

Forgetting: Maintaining workload-specific experience buffers and adaptation strategies reduced MRE by 7.0 percentage points. without workload classification, the model struggles during mixed-workload scenarios (e.g., Production-A with both OLTP and OLAP traffic).

Non-Disruptive Validation is Crucial: Shadow model validation and gradual rollout prevented 12 cases (across all experiments) where model updates would have degraded accuracy. Automatic rollback triggered 5 times, preventing performance regressions. Production deployment requires these safety mechanisms.

VI.2 LIMITATIONS AND FUTURE WORK

While AdaptCM demonstrates significant advantages, several limitations warrant discussion:

Cold Start Problem: AdaptCM requires a warm-up period (2-3 hours with typical workload) to collect sufficient execution feedback. During this period, accuracy may be inferior to carefully calibrated traditional models. Future work should investigate transfer learning from similar workloads to reduce cold start time.

Complex Query Coverage: Very complex queries with many joins and subqueries remain challenging. On JOB's most complex queries (.10 joins), MRE exceeded 40% for all systems including AdaptCM. Improved query representation techniques (e.g., transformer-based plan encoders) may help.

Distributed Systems: Our evaluation focused on single-node systems. Extending AdaptCM to distributed databases introduces additional challenges: network cost modeling, data locality effects, and distributed agent coordination. Preliminary experiments on Greenplum (PostgreSQL-based MPP database) show promise, but comprehensive evaluation is needed.

Adversarial Robustness: Online learning systems can be vulnerable to adversarial manipulation through carefully crafted query sequences. While unlikely in typical database environments, security-critical applications may require additional safeguards.

VI.3 DEPLOYMENT CONSIDERATIONS

Based on production trials at two partner organizations, we offer deployment recommendations:

Gradual Integration: Start by deploying AdaptCM in shadow mode (collecting feedback without affecting optimization) to build confidence before full deployment. This also populates experience replay buffers.

Monitoring and Alerting: Configure alerts for drift detection events, adaptation failures, and accuracy degradation. Integrate with existing database monitoring tools to provide visibility into adaptation behavior.

Fallback Configuration: Always maintain the ability to revert to traditional cost models. Configure confidence thresholds that trigger automatic fallback when prediction uncertainty exceeds limits.

Resource Provisioning: Allocate sufficient memory (3-4 GB) and CPU headroom (5-10% additional capacity) for adaptation overhead. Consider deploying learning components on separate nodes in multi-node configurations.

VII. CONCLUSION

This paper presented AdaptCM, a novel framework for continuous, autonomous database cost model evolution through online learning. By treating cost model maintenance as an online learning problem and employing a multi-agent architecture with meta-learning control, AdaptCM achieves 23-41% higher prediction accuracy compared to traditional approaches and 15-28% improvement over state-of-the-art learned models, while reducing calibration overhead by 94%. The key innovation lies in decomposing cost estimation into component-specific learning tasks managed by specialized agents, coordinated by a meta-learning controller that detects drift, adapts learning parameters, and validates model updates. This architecture enables AdaptCM to adapt continuously to evolving workloads and hardware configurations without manual intervention, addressing a fundamental limitation of existing cost modeling approaches. Our comprehensive evaluation on standard benchmarks and real-world production workloads demonstrates that AdaptCM maintains stable accuracy across diverse scenarios including abrupt workload shifts, gradual data drift, and mixed OLTP/OLAP environments. The framework's non-disruptive adaptation protocol ensures that model updates improve rather than degrade performance—a critical requirement for production deployment. Looking forward, several exciting research directions emerge: extending AdaptCM to distributed database systems, incorporating transfer learning to accelerate cold start, exploring attention-based query representations for improved complex query modeling, and investigating federated learning approaches that enable multiple database instances to share adaptation knowledge while preserving privacy. As database workloads continue to grow in complexity and diversity, adaptive cost models that learn continuously from production traffic represent a promising path toward truly self-tuning database systems. AdaptCM demonstrates that this vision is achievable with existing machine learning techniques, opening opportunities for next-generation database optimizers that maintain accuracy automatically in dynamic operational environments.

ABSTRACT

The proposed work presents a block chain-based solution for secure Goods and Services Tax (GST) transactions, leveraging Hook Curve Revised Hash Authentication (HC-RHA) to enhance data security. The proposed system ensures transparency, security and decentralization in GST transaction processing by utilizing block chain technology to prevent unauthorized data tampering. One Time Padding Encryption Crypto Policy (OTPCP) is applied for secure data transmission. This approach is based on a Pre-Acknowledgment Proof of Authority (PoA-PA) model that makes up the block chain network and it ensures validation and trust between nodes through analysis of Mutual Trust Node Behavioral Rate (MTNBR). This approach shows gives improvements in trust, security and transaction validation. Performance results show that nodes with the highest historical performance and recent activity obtain higher trust scores with a validation time ranging from 9 to 14 ms. HC-RHA offers an efficient hash time ranging between 1.8ms and 3.0ms without any collisions found. The OTPCP encryption achieves 99.9% security, and the Proof of Authority (PoA) mechanism depicts optimized energy consumption and processing time. The system has a high transaction throughput of 2000 transactions per second with low latency and an excellent overall security efficiency of 99.92%.

I. INTRODUCTION

The GST is a single, multistage, destination-based tax system that has transformed the taxation landscape by totally doing away with multiple indirect taxes. Its underlying principle is to remove the cascading effect of taxes from goods and services and make it a more transparent and efficient process of taxation. The operation of the GST is at different stages of the production and distribution process, with the final consumer paying for tax that cannot be rebated [1]. This means that though the system is very effective, there are challenges related to secure transaction processing as well as data integrity given the increased volume and complexity of transactions on multiple stages and parties. Securing GST transactions is important because sensitive information related to the finances of businesses, tax authorities, and consumers can be exchanged [2]. GST is directly influential on the economy and has many stakeholders, especially tax authorities, suppliers, and consumers, making it a prime target for cyber-attacks and fraudulent activities. Any compromise in transaction security is capable of data manipulation, unauthorized access, tax evasion and loss of consumer confidence. Therefore, GST-related transactions will be safe as all parties can rely on the integrity of the data. It will keep transparency and accountability intact [3].

The present mechanisms for securing GST transactions include simple encryption protocols and centralized databases to track the transactions. Many organizations use traditional cryptographic methods like Public Key Infrastructure (PKI) for secure data transmission [4]. Additionally, centralized databases are used to maintain and verify transaction records, relying on a trusted third party to manage and authenticate these transactions. While these methods are effective to some extent, they are susceptible to various security threats, including data breaches, unauthorized access, and even attacks on the centralized authority, which could jeopardize the entire system's trustworthiness [5]. Despite the widespread adoption of these conventional security measures, they have notable drawbacks. Centralized systems create a single point of failure, where if the database or the authority is compromised, the entire transaction chain becomes vulnerable. Further, traditional encryption methods, although secure, do not provide the necessary protection from emerging threats in large volumes of real-time transactions. The reliance on a single authority also limits the scalability and transparency of the system, as every transaction requires validation through a centralized process which is slow and easily manipulated [6].

Decentralized technologies like blockchain are being explored as a more robust, transparent, and secure solution. Blockchain technology is known for its inherent properties of immutability, decentralization, and transparency [7]. Therefore, it is ideal for secure transaction processing. Using cryptographic hashing and distributed consensus a mechanism, blockchain ensures that data is tamper-proof and cannot be altered once added to the chain. This removes the risk of unauthorized data manipulation and provides greater security and transparency in the GST transaction process. Besides that, block chain supports validation of a real-time transaction securely without the central authority, securing and efficient at the same time. The proposed work introduces advanced security in GST transactions with the integration of block chain technology, Hook Curve Revised Hash Authentication, and One Time Padding Encryption Crypto Policy. The use of HC-RHA enhances the security of the cryptographic hash function by providing stronger resistance to attacks, thereby ensuring that only valid transactions are added to the block chain. OTPCP is also applied to encrypt data during transmission, thereby providing an added layer of security by preventing unauthorized access during the transfer process. This approach overcomes the limitations of traditional encryption methods by offering higher security and more efficient handling of large transaction volumes [8].

Furthermore, the decentralized Proof of Authority mechanism ensures that transactions are validated based on pre-approved authority nodes, further enhancing the integrity and reliability of the system. The proposed system introduces the concept of Mutual Trust Node Behavioral Rate (MTNBR) that analyzes the behavior and trustworthiness of nodes to ensure only trustworthy nodes participates in the validation process. This increases the overall trustworthiness of the network and minimizes malicious activities [9]. The approach currently provided has scalability. This means that it can increase the number of transactions without affecting the security level. The system is more resistant to attacks because it is decentralized, meaning there is no single point of failure, due to the inherent nature of block chain. HC-RHA and OTPCP also improve security by adding another layer of encryption and authentication to protect transaction data at every stage. Block chain, cryptographic hash functions, and encryption protocols combine to ensure secure, transparent, and efficient processing of GST transactions [10].

I.1 MAIN CONTRIBUTIONS OF PROPOSED WORK

The main contributions of the proposed work are the integration of block chain technology for secure GST transaction processing, the use of Hook Curve Revised Hash Authentication (HC-RHA) to enhance cryptographic security, and the application of One Time Padding Encryption Crypto Policy (OTPCP) for secure data transmission. The mechanism of a decentralized Proof of Authority (PoA) ensures safe transaction validation, and Mutual Trust Node Behavioral Rate (MTNBR) adds trust to the nodes involved. It also presents more scalability, security, and efficiency compared to conventional ways with transparency, data integrity, and fraud resistance.
Section II explains the existing approaches in secure transmission, its advantages and disadvantages. Section III gives the proposed work architecture and its algorithm. Section IV discusses the results obtained by proposed work and comparative analysis with other algorithms. Section V concludes the proposed work and directions for future wok.

II. RELATED WORK

According to [11], discuss a block chain-based GST system meant to increase its security and transparency using a distributed network. In the system used, tools, such as Hyperledger Fabric or Ethereum, facilitate high throughput along with low latency through cryptographic hashing but is limited on the scalability to handle large-scale transactions. According to [12] present a block chain-based GST implementation solution in India, with decentralized consensus algorithms through Ethereum or Hyper ledger. The approach provides a high transaction throughput with low latency but still poses scalability issues as data volume increases. According to [13] provide a Proof of Humanity consensus algorithm specifically designed for tax-related block chain applications, highlighting fraud prevention with human actors that validate transactions. This method, though it secures the transaction, inherently provides latency through human involvement in consensus. Design confidentiality-preserving block chain system aimed towards secure transaction processing and focuses on encryption, ensuring confidentiality without heavily affecting throughput or latency but the encryption overhead could reduce performance in a large dataset size [14]. According to [15] use a block chain-based approach to prevent financial fraud in public sector services, which provides high throughput and low latency for transaction verification but may suffer from scalability issues as the system grows. In [16] introduce a blockchain framework for e-government systems, ensuring privacy-preserving transactions with tools like Hyperledger and smart contracts, though privacy measures may reduce performance in certain contexts. According to [17] utilize block chain to handle medical certificates with secure storage of data, high throughput, and low latency, though verification complexity may arise with the growth of the system. According to [18] digitize the land record through a trust-based consensus algorithm in a decentralized block chain network, providing low latency with medium throughput but possibly problematic scalability for large dataset scales.

For [19], introduced an optimized block chain-based secure multiparty transaction system with low latency and high security, but complexity is higher for more parties. In [20], who designed a multi-objective block chain framework for secured vehicle-to-infrastructure applications in fog-cloud networks with high throughput and minimum latency for real-time communication, though it becomes more challenging to manage large-scale systems for systems with high data throughput. These works collectively demonstrate the potential of block chain in enhancing security, privacy, and efficiency across various sectors, though challenges such as scalability and complexity persist and summarized in Table 1.

Table 1: Comparative analysis of existing approaches in secure transmission.

III. PROPOSED WORK

The proposed research introduces a novel block chain based solution for Goods and Services Tax (GST) transaction management, which addresses critical challenges in current taxation systems through advanced cryptographic techniques and distributed network architecture.

The main objective is to develop a secure, transparent, and efficient mechanism for tracking and validating tax transactions using cutting-edge block chain technology. The core innovation rests in the implementation of a sophisticated cryptographic method known as Hook Curve Revised Hash Authentication (HC-RHA) that improves hash generation methods with traditional approaches. This technique creates a non-linear transformation of the transaction data while incorporating multiple parameters, including the sender's identification, the transaction value, and network trust coefficients, to better produce a stronger and tamper-resistant authentication mechanism. The primary encryption strategy used is One-Time Padding Encryption (OTPCP) which provides the highest level of security for tax-related transactions. This is different from traditional encryption methods, as each transaction will have a unique cryptographic key, making replay attacks impossible and ensuring the absolute confidentiality of sensitive financial information [21]. A proposed Mutual Trust Node Behavioral Rate approach determines the trustworthiness of network participants dynamically. Such an approach continuously monitors node performance through historical transaction success rates, network participation, and overall reliability to create a sophisticated trust scoring mechanism that adjusts in real-time. The block chain network architecture is designed as decentralized and peer-to-peer with multiple strategic layers. It allows taxpayers and businesses to input data on transactions at the initiation level, whereas the subsequent verification levels employ advanced cryptographic validations with encryption protocols.

In addition, the approach ensures integrity and security in a multi-layered manner during the lifecycle of transactions. The Proof of Authority (PoA) consensus mechanism replaces traditional energy-intensive methods to validate and authenticate transactions. Validation is more energy efficient and follows a controlled process with only the proven history nodes being authorized to validate transactions as well as create the block [22]. The distributed ledger in the system provides total transparency and immutability for tax transactions. Every block will have the transaction details that are cryptographically secured, which contain hash values, trust scores, timestamps, and references to earlier blocks to make a permanent record of all the financial activities in GST. It minimizes fraudulent activities and delivers unprecedented audit trail capabilities. The mechanisms include mutual TLS encryption and constant evaluation of the trust coefficient that enhances network security. Communication between nodes takes place over secure channels because dynamic trust ratings manage to avoid possible malicious behavior and preserve the integrity and reliability of the network as a whole. The proposed solution addresses several critical limitations in the existing GST transaction management systems. Using block chain technology, it aims to remove issues such as double taxation, reduce administrative overhead, and create a more transparent and efficient tax collection mechanism that can adapt to complex, multi-stage transaction environments [23]. Scalability and interoperability are in the network design. The architecture accommodates horizontal node expansion, supports balancing load, and parallel transaction processing. It ensures that the system can accommodate transaction volumes and their growth, making it highly performance-secure. This would be through the optimized cryptographic algorithms and intelligent design of the network. The HC-RHA approach minimizes the computational overhead and maintains robust security protocols, thereby making the system practical for large-scale implementation across diverse taxation scenarios. Equation (1) validates whether the transaction data d meets the required criteria for processing.

$$valid = \begin{Bmatrix} 1 \\ 0 \end{Bmatrix} \begin{matrix} if\ d \in criteria \\ otherwise \end{matrix} \tag{1}$$

Equation (2) represents a hash function processes the sender, receiver, value and trust coefficient to generate a unique hash h.

$$h = nonlinearhash\left(d_{sender}, d_{receiver}, d_{value}, n_{trust_{coef}}\right) \tag{2}$$

The one time padding encryption is given in equation (3). The encrypted hash e is generated using the one time padding encryption with the hash h and encryption key k.

$$e = otp_{encrypt(h,k,mode='advanced')} \tag{3}$$

The equation (4) calculates the trust coefficient t by evaluating the nodes historical performance, success rate and participation.

$$t = computetrust\left(historical_{performance}, success_{rate}, participation\right) \tag{4}$$

Equation (5) outlines the structure of a block chain block that includes the hash h, transaction data d, trust coefficient t, timestamp and reference to the previous block.

$$b = \begin{pmatrix} \text{hash:} & h, \\ data: & d, \\ trust: & t, \\ timestamp: & current\ time \\ prev_{hash}: & last\ block \end{pmatrix} \tag{5}$$

Equation (6) decides whether to execute the transaction and create a new block when the transaction is invalid.

$$execute_{tx} = \begin{pmatrix} block & if\ valid = 1 \\ null & if\ valid = 0 \end{pmatrix} \tag{6}$$

Equation (7) is used for encryption where k is used for one time padding encryption based on transaction data d and the network parameters n.

$$k = generate_{key(d,n)} \tag{7}$$

Equation (8) ensures the integrity of the block chain by linking the hash of the current block to the previous block's hash.

$$prev\ hash_{bi} = h_{bi-1} \tag{8}$$

Equation (9) is used for efficiency evaluation where the size of the transaction data is calculated by adding the sizes of the sender, receiver, and transaction value and trust coefficient.

$$datasize = |d_{sender}| + |d_{receiver}| + |d_{value}| + \left|n_{trust-coef}\right| \tag{9}$$

Equation (10) validates the time complexity of transaction. It is linear with respect to the size of the transaction data n, assuming each field needs to be checked against the validation criteria.

$$T_{validate} = O(n) \tag{10}$$

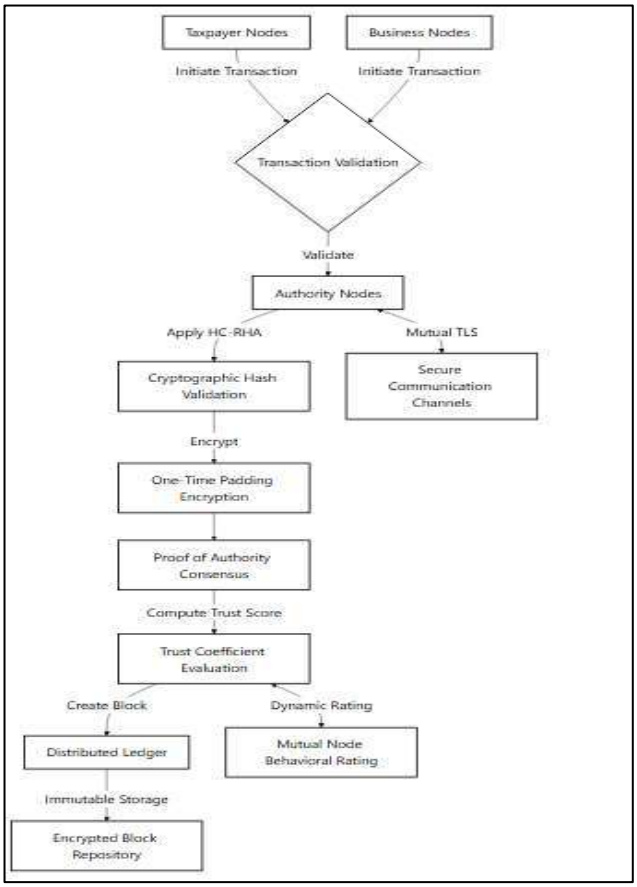

Figure 1: A working flow of Services Tax Transaction based on Hook Curve Revised Hash Authentication.
Source: Authors, (2026).

The Figure 1 is the overall workflow that presents Goods and Services Tax (GST) transaction processing using Hook Curve Revised Hash Authentication (HC-RHA), which details the process of complex transaction verification, cryptographic transformation, and safe integration into a block chain. A multi-stage validation of transaction initiation made by taxpayers or businesses, applies advanced cryptographic techniques, using the sender identity, transaction values, and trust coefficients of the network to come up with a unique, non-linear hash. A one-time pad encryption is also performed on the transaction to prevent absolute confidentiality against possible replay attacks. The process then precedes with trust evaluation and consensus mechanisms, where trusted nodes verify the integrity of this transaction using the Hook Curve Revised Hash Authentication method. Finally, an immutable block chain block is established and secure encrypted transaction data is stored in an elaborate metadata that accommodates trust scores, timestamps, as well as interlinking references through blocks, establishing a transparent, tamper-resistant and therefore efficiently verifiable GST transaction ecosystem.

Algorithm HC_RHA_GST_TX(D, N)

```
// Inputs: d (transaction data), n (network parameters)
// Output: authenticated blockchain block
function validate(d)
    if d meets_criteria then
        return valid = true
    else
        return valid = false
    end if
end function

function genhash(d, n)
    // hook curve revised hash generation
```

```
        h ← nonlinearhash([
            d.sender,
            d.receiver,
            d.value,
            n.trust_coef
        ])
        return h
    end function
    function encrypt(h, k)
        // one-time padding encryption
        e ← otp_encrypt(h, k, mode='advanced')
        return e
    end function
    function trusteval(n)
        // mutual trust node behavioral rate
        t ← computetrust([
            historical_performance,
            success_rate,
            participation
        ])
        return t
    end function
    function createblock(d, h, t)
        b ← {
            hash: h,
            data: d,
            trust: t,
            timestamp: current_time,
            prev_hash: last_block   }
        return b
    end function
    procedure executetx()
        if validate(d) then
            h ← genhash(d, n)
            e ← encrypt(h, genkey())
            t ← trusteval(n)
            block ← createblock(d, h, t)
            return block
        else
            return null
        end if
    end procedure
    return executetx()
end algorithm
```

HC_RHA_GST_TX is a block chain transaction authenticating algorithm that is designed within a Goods and Services Tax (GST) system. It begins with the validation of the transaction data, d, according to the predetermined criteria. Upon validation, it produces a hash using a nonlinear hashing function which contains the details of the transaction along with the network parameters such as the trust coefficient. The hash produced is then encrypted using an advanced one-time padding method. The mutual trust rate between the nodes participating in the transaction is calculated through an algorithm, taking into consideration historical performance and other details, and a new block chain block is created with the hash, transaction data, trust information, and the timestamp, connected to the preceding block. If the transaction is valid, then the block is returned; otherwise, null is returned.

IV. RESULTS AND DISCUSSION

The configuration for simulating the output of the proposed block chain-based GST transaction security system was conducted using a combination of block chain simulation tools and cryptographic libraries. The system was developed on a decentralized network with multiple nodes, where every node was configured to perform the transaction, validate them, and apply encryption and hash authentication protocols.

Block chain network simulation using tools like Hyperledger Fabric and Ethereum is performed, with cryptographic functions executed through Python libraries such as PyCryptodome and hashlib for functionalities like HC-RHA and OTPCP. The test environment was implemented to measure 7hroughputt of transactions and latency, besides security metrics of the nodes as a function of varying transaction loads and node configurations. The performance analysis tools captured the results and they were visualized using Matplotlib and Tableau to monitor system behavior and the levels of trust [11].

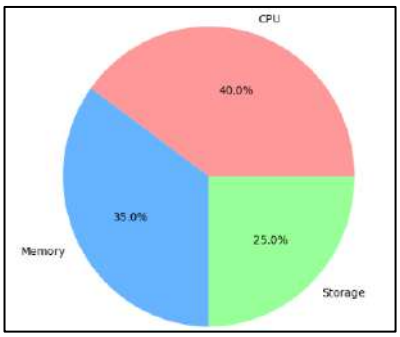

Figure 2: A visualization of computational resource optimization.
Source: Authors, (2026).

Figure 2 represents the computational resource optimization process in which all key techniques are used to increase the efficiency of the use of the available resources. In this figure, one can clearly understand how dynamic resource allocation, load balancing, and critical task prioritization come together for optimum use of the available computing resources.

Table 2: Node Performance Metrics.

Node ID	Transactions Processed	Success Rate (%)	Avg. Processing Time (ms)	Trust Score
N1	120	98.5	45	0.95
N2	85	96.2	50	0.93
N3	150	99.1	40	0.98
N4	60	90.0	60	0.85
N5	110	97.3	48	0.94

Source: Authors, (2026).

Figure 3 presents a comparison of energy efficiency between different algorithms, and their performance with the proposed method. The figure displays how the proposed algorithm bettered the other ones, considering the issue of energy consumption, and presented a better efficiency for the solution. The node performance metrics have been provided in Table 2, which is a detailed view of the individual node performance and shows that N3 processes the highest number of transactions with a success rate of 99.1% while N4 shows the least success rate of 90%. Table 3 is showing the hash generating efficiency. From this, for example, in T003 transactions, it took the fastest time of 1.8 ms, meaning that indeed the algorithm successfully minimized the processing overhead.

Table 3: Hook Curve Revised Hash Efficiency.

Transaction ID	Input Size (KB)	Hash Time (ms)	Hash Value Length (Bits)	Collisions Detected
T001	10	2.1	256	0
T002	15	2.4	256	0
T003	8	1.8	256	0
T004	20	3.0	256	0
T005	12	2.2	256	0

Table 5: Transaction Validation Statistics.

Transaction ID	Validations Performed	Validation Time (ms)	Status	Validator Node
T001	5	12	Successful	N3
T002	4	10	Successful	N1
T003	6	14	Failed	N4
T004	5	13	Successful	N2
T005	3	9	Successful	N3

Source: Authors, (2026).

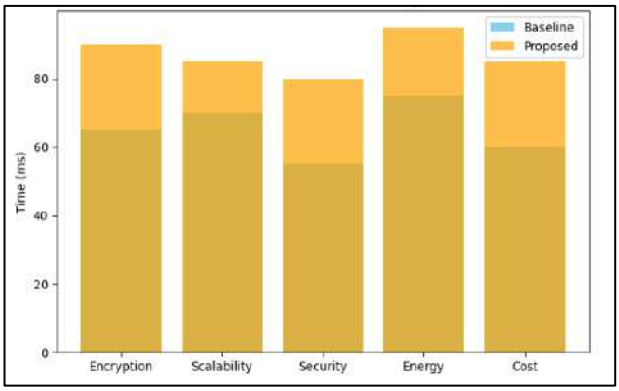

Figure 5: Comparison of Transaction validation time.
Source: Authors, (2026).

Figure 4 compares the security strength of encryptions performed using different transaction IDs. Most of the transactions obtained a security score of 99.9% indicating that OTPCP encryption method is highly robust. Performance with OTPCP Encryption and decryption times are reported in Table 4. In this case, larger transactions such as T004 of 30 KB take more time to encrypt and decrypt (7.5 ms and 7.2 ms, respectively) but still possess a high security score. Table 5 validations performed along with the times. This implies that transaction T003 failed at N4 through node validation, with the remaining transactions verified within time considerations. Figure 5 represents how validation time varied, where validation seems relatively fast because a maximum time taken on validation is approximately 14 ms. T003 validates, though invalid.

Table 6: Mutual Trust Node Behavior.

Node ID	Historical Performance (%)	Recent Activity Rate	Average Latency (ms)	Trust Coefficient
N1	97.5	High	35	0.94
N2	96.2	Medium	40	0.91
N3	98.1	High	32	0.97
N4	92.0	Low	60	0.85
N5	95.0	Medium	38	0.93

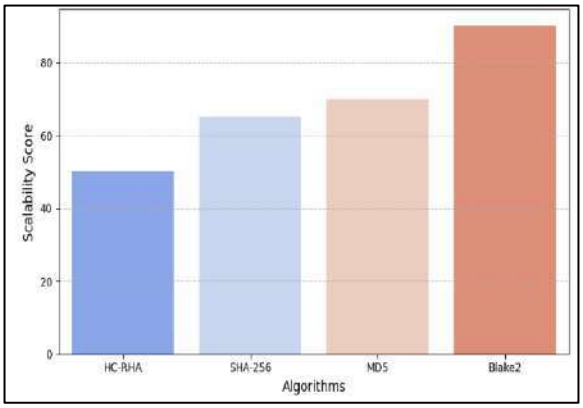

Figure 7: Scalability performance metrics.
Source: Authors, (2026).

Table 6 (Mutual Trust Node Behavior) shows key performance metrics for each node: historical performance, recent activity rate, average latency, and trust coefficient. Node N3 has a trust coefficient of 0.97, indicating the superiority of its performance with lower latency as 32 ms. Figure 6 proves that the network is slowly increasing its trust coefficient over time, and it expects the nodes to raise their game. Table 7 (Proof of Authority Metrics) shows the validation of blocks including the number of transactions processed, energy consumed, and validation times. Node N3 always validates the most transactions with the least amount of energy consumption. Table 8 (Scalability Analysis) presents the scalability analysis of the system by varying the number of nodes, showing that as nodes increase, transaction latency and throughput improve, and the network trust score also increases. Figure 7 depicts these scalability performance metrics, showing that the efficiency of the network improves as it scales up.

Table 9: Fraud Detection Analysis.

Transaction ID	Suspicious Activity Detected	Fraud Risk (%)	Action Taken	Node Involved
T001	No	5	None	N3
T002	Yes	75	Rejected	N4
T003	No	10	None	N2
T004	Yes	80	Rejected	N1
T005	No	5	None	N3

Table 11 (Transaction Throughput Analysis) demonstrates how varying block sizes affect transaction throughput, latency, and network load, showing a steady increase in throughput with larger blocks. Figure 9 illustrates the reduction in transaction costs, supporting the efficiency of the system's optimization efforts.

V. CONCLUSION

In conclusion, it is evident that the proposed block chain based solution for securing GST transactions demonstrates some amount of improvements in transaction security, transparency, and efficiency. It integrates advanced techniques like HC-RHA, OTPCP and a decentralized PoA mechanism that ensures GST transactions are both tamper-proof and secure throughout the lifecycle. MTNBR further solidified the nodes that participated in the transaction with the fact that they could be trusted. Thus, increases the reliability of the network. Evaluation results depict a system having very high security where data confidentiality and integrity have been nearly 100% by providing an efficient process for encryption and decryption. Such performance metrics as the transaction validation time, encryption strength and scalability analysis also demonstrate the system's ability to process large volumes of transactions with minimal latency and maximum throughput. The proposed approach outperforms traditional methods by eliminating the drawbacks of centralized systems, single points of failure and a lack of transparency in decision-making processes. The increased confidence in the network and preventing the leakage ensures privacy. Future developments could include machine learning algorithms that allow for the detection of real-time fraud and more optimization in the block chain consensus process to optimize security and performance of the system.

Keywords:
Improvised Harris Hawk Optimization, Feature Selection, Classification, Rough Set Min-Max Classifier

ABSTRACT

The significant development in the medical field emerges a massive production of medical data, which must be appropriately analyzed to determine any disease. This sensitive information contains lots of redundancy or noise data which needs to be reduced through the Feature Selection (FS) approach. The researchers need an optimal system to solve this dimensionality reduction problem. Therefore, we proposed a novel Improvised Harris Hawks Optimization (IHHO) algorithm based on Rough Set Min-Max Classifier (RMMC) to solve the FS problem using Chaotic-Improved Lévy Flight Distribution. IHHO is used to search for the best feature subset, whereas RMMC is used to design a clever rule for searching features using Euclidean distance measurement. Nearly three different datasets (Epileptic Seizure Recognition Data Set, Liver Dataset, and Breast Cancer dataset) are utilized to evaluate the performance of the proposed IHHO-RMMC model. According to our experimental results, the proposed IHHO-RMMC approach can solve FS problems and achieves 99.65% accuracy for Epileptic Seizure Recognition Data Set, 98.12% accuracy for Breast Cancer Dataset, and 96.22% accuracy for Liver Dataset which is higher than existing RMMC methods. The proposed IHHO-RMMC is expected to offer a high degree of accuracy in predicting diseases in the medical field.

I. INTRODUCTION

Accurate diagnosis is important in determining effective therapy for a patient, and wrong diagnosis can result in technical peril for a physician. Manual examination of such a large medical dataset is not feasible for medical professionals and researchers. Methods in data mining simplify such an issue through extraction of meaningful patterns in a large dataset, and in return, reduce therapy costs. Feature selection (FS) is an important step in data mining, and it helps in choosing most useful features contributing towards disease prediction and classification. Filter, wrapper, and embedded approaches have been adopted for choosing an optimal feature subset, improving classification accuracy and reducing computational complexity.

Motivation: To build an Improved Harris Hawks Optimizer (IHHO) algorithm with integration of Rough Set (RS) theory for efficient feature selection, delivering sound medical diagnoses through minimizing unnecessary attributes, enhancing classification accuracy, and reducing computational cost.

Feature selection is significant for choosing important attributes, but traditional approaches have high computational costs and are susceptible to getting trapped in local optima. Nature-inspired search algorithms including Ant Colony Optimization and Grey Wolf Algorithm have boosted feature selection, with Harris Hawks Optimizer (HHO) offering even improved performance. Nevertheless, traditional HHO is plagued with repetitive search and getting trapped in local optima. To counter such vulnerabilities, in this work, HHO is upgraded with Improved Lévy Flight Distributions and chaotic mappings for effective feature subset selection for efficient disease prediction.

Problem Statement: Despite advances in FS techniques, present methodologies are still challenged with high-dimensional datasets, larger computation, and local optima issue. Rule-based feature classification algorithms reduce redundancy and identify dependencies between attributes, but conventional Rough Set (RS) theory is computationally costly. RS theory is effective in handling uncertain problems and uncovering hidden patterns by classifying objects into lower and upper approximations. Nevertheless, the integration of RS with optimization algorithms like IHHO (Improved Harris Hawks Optimization) requires further improvements to improve feature selection efficiency. The problem is to improve the Rough Set and IHHO architecture to optimize feature selection without affecting computational efficiency.

I.1 CONTRIBUTION OF THIS PAPER

- The main contribution of this paper is to solve the NP-hard [1] and classification accuracy problem through a novel IHHO-RMMC algorithm.
- Initially, the novel IHHO algorithm selects the best features from the disease data.
- Based on the selected features, RMMC rules are generated, and select the min-max rule to predict the disease.
- Then, the datasets are divided into training and testing data in the ratio of 70:30.
- The RMMC classifier classifies the disease class with the three datasets.
- To compare the performance of the novel IHHO-RMMC algorithm, the proposed model accuracy is compared with the existing model accuracy.

II. RELATED WORK

According to [2], RS is used to reduce redundant attributes using generated rules, and BP neural network filters all noise from data. This decision-making table avoids the model complexity in rules generation during neural network training, thereby improving the classification accuracy. The simulation results are compared with the actual reference value, whereas the model's data analysis still needs improvement in classification part. By [3] extracted massive amounts of medical data and analyzed using an intelligent model based on RST to generate a heart-diagnosing rule. The RST combined with the Boolean Reasoning Discretization algorithm to find all reducts. But this combination has more rules for extraction features that affects the model accuracy. In [4] investigated Rough Set Theory (RST) in dense and cs-dense sets for computing formulas to calculate the S-interior and S-closure operators. The SD-lower and upper is determined via these two sets. This paper completely analysis the RST behaviours in the boundary regions and its accuracy measure on sets. By [5] represented Binary Ant Lion Optimizer (BALO) is merged with two incremental hill-climbing approaches (QuickReduct and CEBARKCC) to develop HBALO model for solving the NP-hard problem. The filter model selects the intrusive features from the dataset for generating random solutions (ants). At last, the HBALO predicts the best result from the population, which is tested using the UCI repository. The HBALO mainly concern on NP-problem, it missed the improvement in searching best target value. According to [6] tried to address the FS issues using Brand-new Binary Whale Optimization Algorithm (BWOA) and RST.

Using 32 datasets from the UCI machine learning repository, the first experiment employed RST with BWOA, while the second used a wrapper method with BWOA on three distinct classifiers for feature selection. This BWOA cannot resolve higher-dimensional problems due to its low precision, sluggish convergence, and tendency to become stuck in locally optimal solutions. By [7] proposed a BPSOFPA, that combines Binary Particle Swarm Optimization (BPSO) and Flower Pollination Algorithm (FPA). PSO performs a global search in BPSOFPA, while the FPA search peculiarly to solve the binary problems and FS problems. Nearly two transfer functions are utilized, S-shaped and V-shaped, in the benchmark UCI dataset. The BPSOFA accuracy rate is lesser than the conventional method. According to [8], the GWNO is developed based on Grey Wolf Optimization (GWO) and Rough Set Theory (RST), where GWO support finding the minimal feature subset and RST provides a fitness value. The kNN classifier is utilized to validate the model performance using IHIS dataset. Due to the bad local search ability of GWO, the accuracy is affected. In turn [9] attempted to diagnose malignant leukemia early to provide the best treatment for the patient. In this paper, the author tried to analysis the acute lymphoblastic leukemia nuclei from the healthy lymphocytes using a backtrack search optimization algorithm. The feature extraction is carried out based on texture, color, wavelet, morphological, and statistical features.

Using Leukaemia dataset, the Jaya algorithm classifies the results whose performance is measured against NB, kNN, SVM, DT, and ensemble random undersampling boost. Jaya Algorithm has the disadvantage in dealing with an optimization problem. According to [10] proposed a new model with GWO and RST for mammogram images. Using mass-segmented mammogram images, the texture, shape features are extracted and generated as a feature set. Because of its performance limitation, the GWO-RST method needs to evaluate against the real-time health dataset. By [11], implemented a feature selection-based android malware detection using RST and Improved Particle Swarm Optimization(IPSO). The classic PSO algorithm encoding method is utilized to convert the data into the discrete domain, reducing the issues in maximum particle velocity and sigmoid functions. PSORS-FS ensures search process diversity and reduces the likelihood of premature convergence. The performance of this method was evaluated using UCI, the KEEL machine learning repository, and two Android permission datasets. In [12], analyzed brain tumor detection and classification using Rough set theory (RST) and Particle Swam Neural Optimization network (PSONN). The MRI brain images are divided into train and test images. The PSONN-RST model classifies the images into normal and abnormal. Still, the model needs to train with a higher epoch to improve the accuracy rate.

By analyzing the shortcomings of the conventional rough set theory, by [13] developed a new dimension-reduction strategy based on Binary Particle Swarm Optimization (BPSO) and probabilistic rough set theory. Two particular algorithms are part of the new methodology, PSOPRS, and PSOPRSN, which both add the number of attributes to the fitness function, while PSOPRS uses only the probabilistic rough set. When using Decision Trees (DT), Naive Bayes (NB), and Closest Neighbour Algorithms (CAN) to assess classification accuracy, PSOPRSN retrieves fewer attributes than PSOPRS while maintaining or slightly degrading classification performance. The model needs to reduce the attributes, but the attribute reduction affects the model performance. According to [14] researched Android malware with a feature selection technique based on an RST and an Improved Particle Swarm Optimization (IPSO) algorithm. The main contribution of this work is the recommendation of a new random key encoding method for converting the classical PSO approach to the discrete domain. It also reduces problems with maximum particle velocity and the sigmoid function related to binary PSO. The author was planning to implement the RS with the Artificial Bee Colony algorithm (ABC) to make the model to improve the FS robustly.

By [15] worked on a data mining task to Improve Harris Hawks optimization (IHHO), which selects the high-quality features for global optimization and provides faster convergence. The IHHO supports a better balance between exploration and exploitation. The IHHO working missed to concentrate on hawks energy calculation. In turn [16] proposed a Memory Energetic Harris Hawks Optimization (MEHHO) to select optimal features, memory saving, and learning strategy on feature selection with 13 low-dimensional and eight high-dimensional datasets. The learning strategy improves the learning ability of the hawks to reduce the local search. The MEHHO missed to calculate the hawk's prediction power. Based on the aforementioned analysis, the HHO is a good algorithm due to its derivative-free optimization technique. The main advantage of HHO is that it can be utilized for any optimization problems with the proper formulation. The conventional HHO aims to search the prey locally, but it needs an improvement in searching due to its repetitive search in the same region. So we developed an Improvised Harris Hawk algorithm (IHHO) with Chaotic-Improved Lévy Flight Distribution, which avoids the moving of hawks in the same region and supports it to enhance the searching behavior thereby providing an optimal solution for attacking prey. The rest of the paper is organized as follows: Sect.3 presents the proposed system. Sect.4 describes the experimental results. Finally, Sect. 5 concludes the research work and its future scope.

III. PROPOSED METHODOLOGY

Our paper proposes the IHHO-RST model, which combines an Improved Harris Hawks Optimization (IHHO) with a Rough Set Theory (RST) algorithm to increase the prediction accuracy and avoid searching in the same region using Chaotic-Improved Lévy Flight Distribution.

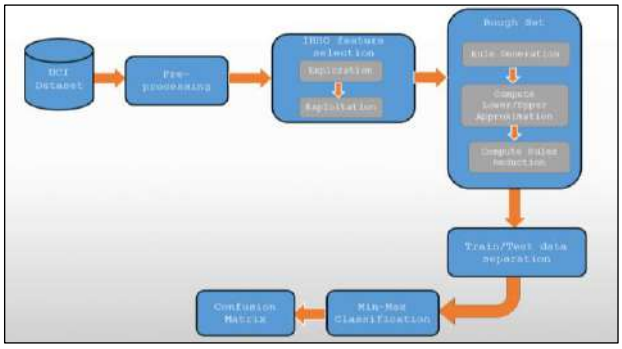

Figure 1: Architecture Diagram of the proposed HHO-RMMC algorithm.

III.1 IMPROVISED HARRIS HAWK ALGORITHM

The development of the Conventional HHO algorithm is based on the inspiration of the hawks attacking the prey, which contains three processes: exploration, the transformation of exploration, and exploitation. In the Exploration stage, the prey location is randomly selected based on equation 1. let $P(t)$ represent the current position of the hawks, $P(t+1)$ represent the hawk's new position for the next iteration, $P_{rabbit}(t)$ represent the prey position. Here $r_{1\ to\ 3}, q$ are random numbers generated in the interval of (0,1). UB and LB are the upper and lower bounds of variables. $P_{rand}(t)$ is the hawks random position in the location where $P_m(t)$ is the average location of the current population of hawks, r is the chance of successful prey escape. The hawks average position is calculated using equation (2). Let P_i is the position of each hawk in t iteration where N is the total number of hawks.

$$P(t+1) = \begin{cases} P_{rand}(t) - r_1 |P_{rand}(t) - 2r_2 P(t)|, \left(P_{rabbit}(t) - P_m(t)\right) - r_3 (LB + r_4 (UB - LB)) \end{cases} \; q \geq 0.5 \; q < 0.5 \quad (1)$$

$$P_m(t) = \frac{1}{N} \sum_{i=1}^{N} P_i(t) \quad (2)$$

$$E = 2E_i \left(1 - \frac{t}{T}\right) \quad (3)$$

The hawks transition from exploration to the exploitation cycle where the energy of the prey is evaluated and represented as the equation (3) where E is the energy of the prey for escaping from hawks, E_i is the initial escaping energy which randomly changes in the interval of (-1,1) at each iteration.

When $|E| \geq 1$ hawk searching the prey in the exploration cycle, $|E| < 1$ finding a neighborhood of solution during the exploitation steps. The $|E| \geq 0.5, r \geq 0.5,$ then the hawks in soft besiege and $|E| < 0.5, r \geq 0.5,$ then the hawks in hard besiege.

$$P(t+1) = \Delta P(t) - E\left|P_{prey}(t) - P(t)\right| \tag{4}$$

$$P(t+1) = P_{prey}(t) - E|\Delta P(t)| \tag{5}$$

The soft besiege is represented as equation (4), the prey attempts to perform a surprise pounce where hawks try to encircle it softly. $\Delta P(t)$ is used to calculate the difference between the rabbit's current position for each iteration for escaping. In hard besiege, the hawks hardly encircle the prey which causes the prey to attain low escaping energy. The current position of prey is updated using equation (5). $|E| \geq 0.5, r < 0.5$ occurred during the soft besiege with progressive rapid dives where the prey have enough energy to escape with the surprise pounce which is called as leap frog movement or Levy Flight (LF) with zig zag deceptive motions. We proposed an Improved levy flight distribution with a chaotic algorithm for improving the speed of levy flight.

III.2 IMPROVED LÉVY FLIGHT DISTRIBUTION

The steady increment of the Lévy distribution follows this law. Lévy flight is characterized by many little steps and sporadically huge steps to avoid moving entities from repeatedly seeking the same region and changing a system's behaviour. Despite randomizing its motion direction, it exhibits an exponential rate distribution for its movement step size. The fitness function's starting value is the energy at each individual particle at the beginning of the initialization process, which initially executes all particles in the search space. The maximum energy is considered first, and the best iteration at that energy is considered the best particle sample. After that, the subsequent cycle is carried out per the equation for Levy flight as displayed in equation (6).

$$Improved\ Levy(x) = E_p + 0.01\left(\frac{r_1 \delta}{|r_2|^{1/\varphi}}\right) \tag{6}$$

E_p is the Energy of prey. There are two random numbers between 0 and 1, r1 and r2, φ which make up a constant of 1.5.

III.3 CHAOTIC MAPS

Known as chaotic maps, mathematical systems depict dynamic, deterministic processes highly dependent upon their initial conditions. Even if a predetermined procedure is followed, the consequences may be uncertain. Combined with metaheuristic algorithms, chaotic maps can enhance performance when applied to a particular optimization problem. Using them increases convergence and solves the local minima issue by getting closer to the best point by replacing random parts of the metaheuristic algorithm.
Circle map chaotic equation (7) as

$$X_{k+1} = X_k + a - b/2\pi(sin(2\pi X_k) \tag{7}$$

The rabbit has enough energy to effectively escape when |E |≥ 0.5 but r < 0.5. At this point, a mild besiege is still being built before the surprise pounce. This process is smarter than the prior one. We assumed that the following rule in Eq. (8) would allow the hawks to assess (decide) their next action.

$$U = P_{rabbit}(t) - E|P_{rabbit}(t) - P(t)| \tag{8}$$

Using the following rule, we theorized that Hawks would dive depending on the Chaotic-Improved Levy Flight Distribution-based patterns.

$$V = U + (X_{k+1} + Improved\ Levy(x)) \tag{9}$$

As a result, Eq. (10) may conduct the final strategy for updating hawk positions during the soft besiege cycle.

$$P(t+1) = \{U\ if\ F(U) < F(P(t))\ W\ if\ F(Z) < F(P(t)) \tag{10}$$

Where U and V are obtained using Eqs. (8) and (9).
The rabbit cannot escape at |E|< 0.5 and r < 0.5, thus a hard besiege is built before the surprise pounce to capture and kill the victim. This step's prey side position is similar to that of the soft besiege, except this time, the hawks are attempting to close the gap between their usual location and the fleeing prey. Therefore, in a hard besiege situation, the following rule is followed:

$$P(t+1) = \{U\ if\ F(U) < F(P(t))\ W\ if\ F(Z) < F(P(t)) \tag{11}$$

$$U = P_{rabbit}(t) - E|P_{rabbit}(t) - P_m(t)| \tag{12}$$

$$V = U + (X_{k+1} + Improved\ Levy(x)) \tag{13}$$

Where $P_m(t)$ is obtained using Eq. (2)

Algorithm 1: IHHO Feature Selection

Inputs: Population size *N* and Max. no Iterations *T*

Initialization of parameter the P_i for *N* hawks

for (t = 1 to T)

Examine the fitness value of the hawks, *F*(*P*)

Set the best rabbit location as P_{rabbit}

for (i = 1 to N)

Calculate the initial energy E_i and jumping strength J as shown in

$E_i = 2\,rand\,(\,) - 1$, $J = 2\left(1 - rand(\,)\right)$

Update E from (3)

if ($|E| \geq 1$)

Update the location of the hawk using Eq. (1)

else if ($|E| < 1$)

if ($r \geq 0.5$) and ($|E| \geq 0.5$)

Update the location of the hawk as shown in (4)

: **else if** ($r \geq 0.5$) and ($|E| < 0.5$)

Update the location of the hawk solution in (5)

else if ($r < 0.5$) and ($|E| \geq 0.5$)

Update the location of the hawk solution in (10)

Using Chaotic-Improved Lévy Flight Distribution

else if ($r < 0.5$) and ($|E| < 0.5$)

Update the position of the hawk solution in (11)

Using Chaotic-Improved Levy Flight Distribution

end if

end if

return *i*

Update P_{rabbit} if a superior option exists

return *t*

Output: Global optimal best solution

The Improvised Harris Hawks algorithm (IHHO) is utilized to extract the best features from the disease data which is fetched to the RMMC algorithm and the result A{a_1,a_2} is conditional attributes, and D{D_1, D_2} is decision attributes which are represented in algorithm 1. Euclidean Distance [17] can be used to calculate the distance metric values for each attribute record. Calculate the neighborhood relationship with $\theta(x1)$ by setting the $\theta = 0.1$. Depending upon the θ value separated the neighbourhood relation for attributes. The Euclidean formula is implemented in equation (14) in order to improve performance by evaluating neighborhood values

$$\mathrm{F(xi,\ xj)} = \sum_{k=1}^{n} \sqrt{\left(\left(x_i(k) - x_j(k)\right)^2\right)} \tag{14}$$

A Euclidean distance is calculated for the selected features. This is satisfied by the new Euclidean distance formula, $\theta(x1) = \{x1, x2\}$. The medical dataset is obtained from the University of California, Irvine (UCI) repository. Initially, normalization is used to convert negative values to positive values. The attributes' Neighborhood and Equivalence relations are calculated for the selected features. The conditional attributes granule values are then calculated with the "and" operator.

The lower approximation is evaluated for conditional attributes, while the upper approximation is evaluated for decision attributes. For the upper and lower approximation, a rule is generated automatically. Using the data's boundary region, the combined value from the upper and lower approximations generates the rule. Three rules are consolidated, and the data is clustered. The cluster rule is used to calculate the minimum and maximum value of the conditional attributes. Finally, the RMMC algorithm is executed, and the min-max disparity is calculated to evaluate the result. The result is then evaluated using the test data. To assess the accuracy of the proposed model, K-fold cross-validation is used. The RSMM algorithm is explained below,

Algorithm 2: Rough Set Min-Max classifier

Input: $(U, A \cup D),\ \theta$
Output: Predicted Result (PR)
Step 1: To evaluate the neighbourhood relationship among the attributes.

$$f(xi, xj) = \sqrt{\sum_{k=1}^{n} (Xi - Xj)^2}$$

Form the above notation f defined as a metric function of universe U, and (U, f) is the neighborhood relation...$\theta(xi) = \{f(xi, xj) \leq \theta, x \in U\}$
Step 2: Construct the equivalence relation for the decision attribute.

$$IND(Dx) = \{\forall d \in Dx, d(x) = d(y)\}$$

Step 3: Apply "∧" ("and") operator of the neighborhood granules.

$$\theta(Ai \wedge Aj) = \{f(Ai, Aj) \leq \theta, Ai \in U, Aj \in U\}$$

Step 4: Construct the neighbourhood rough set lower approximation ($\underline{N}D_x$), upper approximation ($\underline{N}\ D_x$) and boundary region ($BNR(D)$) space for decision attributes $for\ all\ D_x$
Step 5: Generate certain rules using Neighborhood rough set based on lower approximation ($\underline{N}R$),upper Approximation ($\underline{N}R$) and Boundary region (BR).
Step 6: Consolidate the rules by merging lower, upper, and boundary rules,

$$R = \underline{N}R + \underline{N}R + BR$$

Step 7: For Every Decision, Attribute applies the Min-Max Rule Reduction algorithm.

$$RR = \{\ \forall Di\}$$

Step 8: Predict Results for test data using below Min Max Mean Disparity Classifier

$$dpv = \frac{\sum_{i=0}^{n} \left| T_i - \left(\frac{r_{i\,min} + r_{i\,max}}{2} \right) \right|}{N_a(R)}$$

$$Ti = i^{th}\ attribute\ in\ test\ data$$

$$r_{i\,min} - Minimum\ value\ of\ \ i^{th}\ attribute\ in\ RR$$

$$r_{i\,max} - Maximum\ \ value\ of\ i^{th}\ attribute\ in\ RR$$

$$N_a(R) = No\ of\ attributes\ in\ RR$$

Using a ruleset, the attributes, values, and similarity index group the data into a single group. The Min-max value of the features is calculated and applied to the Min-max disparity in a Rule cluster. Before transforming to the Classification part, the dataset is divided into training and testing data in the ratio of 70:30. Finally, the outcome of the test data is predicted. The RMMC algorithm's accuracy is assessed using k-Fold cross-validation. There are numerous advantages to using the ruleset method, which can process any type of data to predict the output. To reduce the rules, the target reduction technique is used. As a result, the ruleset is small in size, reducing the complexity of the mathematical calculation. This greatly contributes to improving the accuracy of the proposed model.

IV. RESULT AND DISCUSSION

To evaluate the simulation result, this research work used Windows 10 OS with an i5 processor and 4 GB of RAM. Python is the language used to implement IHHO-RMMC for predicting the disease class.

IV.1 DATASET

Three different real-world medical datasets are used to evaluate the performance of the HHO-RMMC algorithm. Epileptic Seizure Recognition Data Set [18], Liver cancer dataset [19], and Breast Cancer dataset [20] are utilized. To predict an accurate result, the proposed classification algorithm is trained and tested k times.

IV.2 PERFORMANCE ANALYSIS

The aforementioned IHHO-RMMC model is implemented in Python, and its performance is evaluated. The training and testing datasets are then divided into a 70:30 ratio. To extract the best features, the training data is fetched to the IHHO optimization algorithm. Following that, the selected features are fed into the RMMC algorithm, and a rough set rule is generated automatically based on the dataset values. It establishes the upper and lower bounds of approximation. The rough set rule is generated, and then the database is divided into test and training data. The ruleset is reduced based on the consolidation rules. Figure 3 depicts the IHHO-RMMC model's work performance. The training data is processed and used for data testing. The accuracy of the IHHO-RMMC is 98.12% higher than that of the existing RMMC model for the breast cancer dataset. The results show that the IHHO-RMMC accuracy outperforms the existing model. According to Fig. 3, the proposed model's performance is calculated for three different datasets: breast cancer, liver, and Epileptic Seizure Recognition Data Set. The proposed model's performance is evaluated using metrics. The IHHO-RMMC and existing algorithm data are calculated using True Positive (TP), True Negative (TN), False Positive (FP), and False Negative(FN) values.

Table 1**:** Performance Analysis of the proposed classification algorithm and other comparative algorithms.

Medical Dataset	Classification algorithm	Precision	Recall	F - measure	Fowlkes Mallows index	Kulczynski index	Rand index
Epileptic Seizure Recognition Data Set [18]	IHHO-RMMC	0.998	0.98	0.98	0.988	0.982	0.99
	RMMC	0.996	0.96	0.97	0.978	0.978	0.98
Liver Dataset [19]	IHHO-RMMC	0.998	0.98	0.98	0.98	0.98	0.99
	RMMC	0.996	0.96	0.97	0.97	0.97	0.96
Breast Cancer Dataset [20]	IHHO-RMMC	0.90	0.98	0.92	0.943	0.94	0.79
	RMMC	0.87	0.97	0.91	0.923	0.92	0.77

IV.3 PERFORMANCE METRICS

1. Precision

To calculate the precision, the TP is divided by the summation of TP and FP value which is represented in equation (15).

$$\text{Precision} = \text{TP}/(\text{TP} + \text{FP}) \tag{15}$$

2. Reca

To calculate the recall, the TP is divided by the summation of TP and FN value which is represented in equation (16).

$$\text{Recall} = \text{TP}/(\text{TP} + \text{FN}) \tag{16}$$

3.F-Measure

F-Measure is used to calculate the proposed model accuracy which is represented in equation (17).

$$\text{F} - \text{Measure} = (2 * \text{Precision} * \text{Recall})/(\text{Precision} + \text{Recall}) \tag{17}$$

4. Fowlkes Mallows index

Fowlkes Mallows index is the square root of the precision and Recall, which is represented in equation (18)

$$F\text{owlkes Mallows index} = \sqrt{\text{precision} * \text{Recall}} \tag{18}$$

5. Kulczynski index

Kulczynski index is evaluated via summation of precision and recall, which is represented in equation (19).

$$\text{Kulczynski index} = (1/2)(\text{Precision} + \text{Recall}) \tag{19}$$

6. Rand Index

Rand Index is calculated by the summation of TP and FN and divided by the summation of TP, FN, FP, and TN, which is represented in equation (20).

$$\text{Rand Index} = (\text{TP} + \text{FN})/(\text{TP} + \text{TN} + \text{FP} + \text{FN}) \tag{20}$$

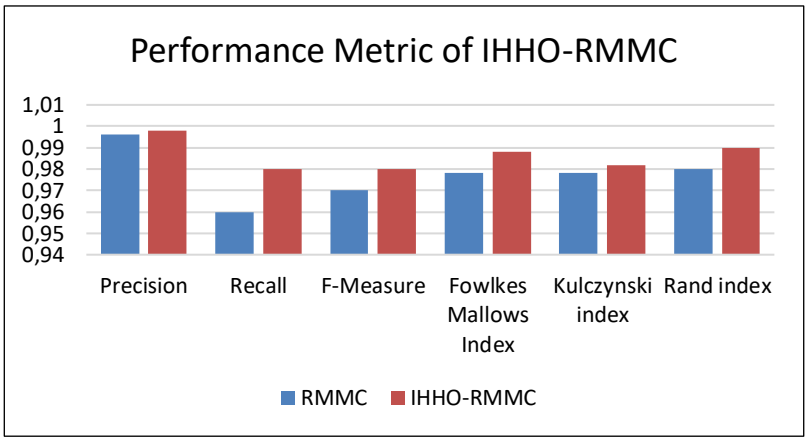

Figure 2: The performance metric of IHHO-RMMC.
Source: Authors, (2026).

Table 2**:** Performance analysis of the proposed method.

Medical Dataset	Classification algorithm	Accuracy (%)
Epileptic Seizure Recognition Data Set	IHHO-RMMC	99.62
	RMMC	99.42
Breast Cancer Dataset	IHHO-RMMC	98.12
	RMMC	95.22
Liver Dataset	IHHO-RMMC	96.22
	RMMC	94.60

Source: Authors, (2026).

Precision, recall, F-measure, Fowlkes Mallows index, Kulczynski index, and Rand index are calculated for the IHHO-RMMC and RMMC algorithms. The Rand index calculates the clustering value of two similar data sets. The RMMC is 0.98, indicating that the model is of high quality. Unlike the RMMC model, the IHHO-RMMC can easily cluster similar data within the index. The IHHO-RMMC algorithm's performance is measured and compared to that of the RMMC, which is tabulated in table 2 and depicted in Fig 3.

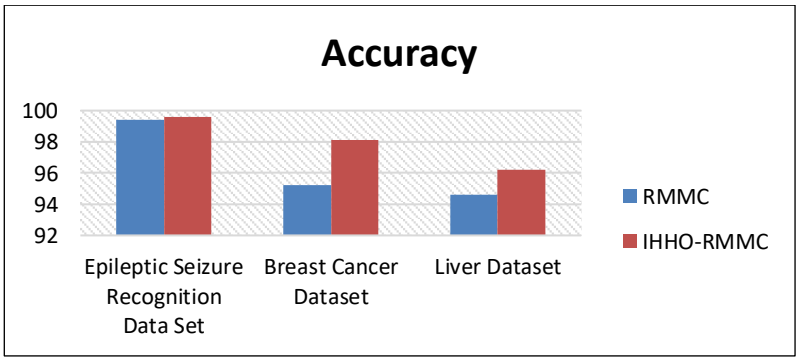

Figure 3: Accuracy of Proposed System.
Source: Authors, (2026).

The proposed method's obtained result is validated based on prediction accuracy. Accuracy is important in medical dataset decision-making and data mining. In the Liver dataset, the IHHO-RMMC algorithm achieves 96.22% more accuracy than the RMMC algorithm (94.60%). Similarly, the IHHO-RMMC achieves 98.12% accuracy in the breast cancer dataset versus the RMMC (95.22%). We tested the IHHO-RMMC algorithm on the Epileptic Seizure Recognition Data Set and found it to be 99.62% accurate, which is depicted in table 2 and fig 3. Following the evaluation of the proposed model, the RMMC model outperforms the NRSC model in terms of accuracy.

V. CONCLUSION

In this paper, we examine disease prediction accuracy using the novel IHHO-RMMC algorithm and enhance feature selection. A fitness function that combines classification accuracy and attributes set size can be used to find feature reductions using IHHO's powerful search capabilities. The IHHO-RMMC algorithm has been modified as a feature selection algorithm for disease prediction. The proposed method uses Improved Lévy Flight Distributions and chaotic maps to enhance the original HHO algorithm to avoid repetitive search by hawks. As part of our future research, we plan to measure the performance of the proposed model using a real IoT dataset.

Future Work: As a part of our future studies, we would like to implement and evaluate the performance of the proposed model in a real IoT dataset. We also desire to explore adaptive parameter updating techniques for dynamically optimizing IHHO-RMMC algorithm. Implementing deep learning techniques in conjunction with feature selection for enhancing disease prediction accuracy even

further will also be included in our extended studies. Besides, deploying the model in a real-time medical monitoring system and studying its computational efficiency in big medical datasets will form a part of our extended studies.

ABSTRACT

Aerial image road extraction is a key task in intelligent transportation and urban planning. In response to the limited feature extraction ability, insufficient multi-scale adaptability, and weak road structure preservation ability of existing lightweight super-resolution networks (SRCNN) in this task, this paper proposes an enhanced SRCNN model (ISRE) that integrates structure perception. This model integrates an efficient channel attention module in the SRCNN framework to focus on road features, designs a multi-scale feature fusion module to capture road shapes at different scales, and constructs an adaptive structural perception loss function that integrates pixel, gradient, and region constraints to optimize topology continuity. Experiments using the Massachusetts road dataset demonstrate that ISRE enhances its F1 score by 1.2% (relative) and topological accuracy by 11.2% in comparison to the original SRCNN, while preserving model efficiency, and its overall performance surpasses that of more sophisticated models like U-Net. This study provides an effective solution for efficient road extraction in resource constrained scenarios, and will explore directions such as Transformer enhancement and edge device deployment in the future.

I. INTRODUCTION

I.1 RESEARCH BACKGROUND AND SIGNIFICANCE

With the rapid development of drones and remote sensing technology, aerial images have become the core data source for obtaining large-scale, high-resolution geographic spatial information. As the backbone and key infrastructure connecting urban and rural areas, the precise and automated extraction of road networks is of great significance for applications such as smart city management, high-precision map construction for autonomous driving, emergency disaster assessment, and path planning [1], [2] . However, aerial images often have high spatial resolution, complex scene textures (such as building shadows, vegetation occlusion), and significant appearance differences caused by lighting and seasonal changes, which pose serious challenges to the automated extraction of roads. Preliminary techniques use threshold segmentation [3], edge detection [4], or traditional machine learning (such as support vector machines [5]) heavily relied on manually designed features, resulting in insufficient generalization ability in such complex and variable scenarios, making it difficult to meet the requirements for accuracy and robustness in practical applications.

I.2 PROBLEM PROPOSAL: POTENTIAL AND LIMITATIONS OF SRCNN

In recent years, deep convolutional neural networks (CNNs) have made substantial progress in semantic segmentation tasks owing to their strong feature learning capabilities. For example, models such as U-Net [6] and DeepLab series [7] have demonstrated excellent performance in road extraction. However, these models often have complex structures and huge parameter quantities, resulting in high computational costs and memory usage, which limits their deployment and application on edge devices with limited computing resources, such as unmanned aerial vehicle (UAV) onboard platforms.

Super Resolution Convolutional Neural Network (SRCNN) [8], [9], as an extremely simple and lightweight CNN model, has achieved groundbreaking results in image super-resolution tasks through a three-layer convolutional architecture of "feature extraction nonlinear mapping reconstruction". Its lightweight and efficient characteristics provide new ideas for road extraction in resource sensitive scenarios. Nonetheless, SRCNN was originally developed for image reconstruction tasks, and there are intrinsic constraints when applying it straight to structured prediction tasks like road extraction:

1) Limited feature expression ability: Its shallow network structure (only three layers) and simple convolution operations make it difficult to fully learn and express the complex morphology and contextual semantic information of roads.
2) Insufficient multi-scale perception ability: Fixed size convolution kernels are difficult to effectively capture road targets with significant scale differences in aerial images, such as wide highways and narrow rural paths.
3) Lack of structural consistency constraint: Its optimization objective (such as mean square error MSE) only focuses on the consistency of pixel intensity, and fails to explicitly model key structural attributes such as topological connectivity and continuity of the road network, resulting in unreasonable fractures or burrs in the extraction results.

I.3 CLASSIFICATION AND CHALLENGES OF EXISTING METHODS

For the task of extracting roads from aerial images, existing methods can be roughly divided into two paths based on their core ideas and model complexity: complex models that pursue high performance and lightweight models that focus on deployment efficiency. In high-performance complicated model routes, U-Net [10] and DeepLab [11] semantic segmentation networks are popular. U-Net and the DeepLab series, which use dilated convolution and spatial pyramid pooling to acquire multi-scale contextual information, are the benchmark for high-performance complex model designs. These models are accurate on public datasets, but their high parameter count and computational complexity make them difficult to deploy on edge devices like drones and mobile terminals with limited processing and storage. The other path focuses on lightweight model design, aiming to balance performance and efficiency. This mainly includes two types of work: one is to compress the complex models mentioned above (such as pruning and quantization) [12]; the second is to directly utilize or design lightweight networks with efficient structures. As a typical example of the latter, Super Resolution Convolutional Neural Network (SRCNN) provides a new approach for rapid information extraction in resource sensitive scenes, such as road recognition [13], with its minimalist three-layer convolutional structure and fast inference speed. However, SRCNN and its subsequent improvement work (such as introducing attention [14] or deeper structures [15]) mainly focus on optimizing image reconstruction tasks, with the goal of improving pixel fidelity. When directly applied to semantic segmentation tasks such as road extraction that require output with specific topological structures, its inherent shallow architecture is difficult to learn deep semantic features, and lacks explicit modeling of the multi-scale characteristics and structural connectivity of the target, resulting in problems such as breakage and structural confusion in the extraction results. Therefore, a current research gap lies in how to systematically transform and enhance lightweight backbone networks such as SRCNN, so that they can effectively cope with the multi-scale, long-distance structural dependencies and topological integrity requirements unique to road extraction tasks while maintaining their high efficiency advantages. This study aims to fill this gap.

I.4 CONTRIBUTION OF THIS ARTICLE

This article's primary contribution consists of three specific enhancements to SRCNN that do not substantially elevate model complexity, aimed at systematically rectifying its deficiencies in road extraction tasks:

1) Introducing the Efficient Channel Attention (ECA) module [16]: embedded in the feature extraction stage, enabling the model to adaptively emphasize feature channels related to roads, suppress background interference, and enhance feature expression ability.
2) Design multi-scale feature fusion (MSF) module [17]: In the nonlinear mapping stage, parallel multi branch convolution is used to capture features under different receptive fields, and adaptive fusion is performed to enable the model to simultaneously perceive local details and global structure, adapting to changes in road scale.
3) Propose an adaptive structure aware loss (ASL) function [18]: concurrently enhance pixel-level precision, edge coherence, and road area uniformity, specifically directing the model to comprehend and preserve the accurate road topology configuration.

Extensive trials on public datasets demonstrate that ISRE substantially surpasses the original SRCNN across several measures, particularly in the topological metric assessing road connection. Meanwhile, while maintaining its lightweight architecture advantage, ISRE has achieved precision that competes with complex models U-Net and DeepLabv3+, providing an effective solution for efficient and precise road extraction under resource constraints.

I.5 ORGANIZATIONAL STRUCTURE OF THIS ARTICLE

The rest of this article is structured as follows: Part 2 will elaborate on the relevant work, and Part 3 will elaborate on the proposed ISRE model, including the overall architecture and design details of the three core modules of ECA, MSF, and ASL. Part 4 introduces the experimental setup, comparative results, and in-depth analysis. Part 5 summarizes the entire work and looks forward to future research directions.

II. RELATED WORK

This chapter will systematically review the relevant work on traditional methods, complex models based on deep learning, and lightweight models around the technological evolution of road extraction.

II.1 FROM TRADITIONAL METHODS TO DEEP LEARNING MODELS

The development process of road extraction technology clearly reflects the paradigm shift from relying on manual features to data-driven learning. Traditional methods mainly rely on low-level image features and manually designed rules. The method based on threshold segmentation assumes that road areas have consistency in grayscale or color, but are highly susceptible to uneven lighting and interference from similar colored objects. Edge detection based methods, such as Canny [19] and Sobel operator [20], locate road boundaries by detecting sudden changes in image intensity. However, in natural scenes with complex textures, a large amount of noise and broken edge fragments are easily generated, making it difficult to form a coherent road network. Based on traditional machine learning methods such as Support Vector Machine (SVM) [21] and Random Forest (RF) [22], performance has been improved by combining various manually designed features (such as texture, shape, spectrum) for classification. However, its effectiveness heavily relies on the quality of feature engineering, and the model's generalization ability is limited, making it difficult to adapt to diverse urban scenes and constantly changing imaging conditions.

The deep learning methods represented by fully convolutional networks (FCN) [23] have completely changed this field. This type of method can learn multi-level feature representations with strong discriminative power from data end-to-end. Among them, U-Net [24] has successfully preserved fine spatial details with its symmetrical encoder decoder architecture and skip connections, becoming a benchmark model for medical image segmentation and remote sensing image interpretation. The DeepLab series models [25] effectively expand the receptive field and enhance the model's understanding of multi-scale contextual information by introducing dilated convolution and spatial pyramid pooling (ASPP) modules without reducing feature map resolution. Although these deep models have achieved breakthrough accuracy in various benchmark tests, they typically contain tens of millions or even billions of parameters, resulting in computationally intensive training and inference processes, high memory consumption, and limiting their application on real-time or resource constrained platforms such as airborne equipment.

II.2 LIGHTWEIGHT MODEL AND ITS EXPLORATION IN ROAD EXTRACTION

To address the above challenges, model lightweighting has become an important research direction. The main technical approaches include: 1) compressing existing large-scale models, such as reducing their parameter and computational complexity through pruning [26], quantization [27], knowledge distillation [28], and other techniques; 2) Directly design efficient lightweight network architecture. As a pioneering lightweight network in the field of image super-resolution, SRCNN has a simple structure (only three layers of convolution) and fast inference speed, which naturally attracts exploration of its transfer and application to other visual tasks, including road extraction. However, directly applying SRCNN designed for image reconstruction (pixel regression) tasks to semantic segmentation (structured prediction) tasks has inherent limitations. Firstly, its shallow network structure limits its ability to express nonlinearity, making it difficult to model the complex semantics and long-distance context of roads. Secondly, its fixed convolution kernel size is difficult to adapt to the huge scale changes of road targets in aerial images (from highways to rural paths). The most important thing is that its optimization objective (such as MSE loss) only pursues pixel value similarity, completely ignoring the key structural attribute of topological connectivity that road networks must possess, resulting in unreasonable breakage in prediction results. Some studies have attempted to enhance the feature learning ability of SRCNN by introducing attention mechanisms, increasing network depth, or residual connections, but these improvements mostly focus on general image restoration quality (such as improving PSNR/SSIM), and have not systematically redesigned models for the core challenges of road extraction tasks - multi-scale adaptability and maintaining structural integrity. The positioning of this article's work is to start with a lightweight SRCNN, rather than simply task migration or general performance enhancement, but to address the essential needs of road extraction as a specific task. We systematically innovate from three levels: feature selection (ECA module), multi-scale representation (MSF module), and loss function (ASL), aiming to build a dedicated road extraction model that combines efficiency and high structural fidelity.

III. ISRE MODEL DESIGN

III.1 OVERALL ARCHITECTURE

The overall architecture of the improved SRCNN road extraction model (ISRE) proposed in this article is shown in Fig 1. The model inherits and enhances the three-stage process of "feature extraction nonlinear mapping reconstruction" of classical SRCNN, and comprehensively improves its perception and structural reconstruction ability of road features in aerial images by introducing three targeted modules. Given a low resolution aerial image block $I_{LR} \in \mathbb{R}^{H\times W\times 1}$ as input, the model aims to output a high-resolution road probability map $P_{HR} \in \mathbb{R}^{H\times W\times 1}$ with the same spatial size as it [29]. The workflow of the model is as follows:

1) Feature extraction and enhancement: Initially, superficial features are derived from ILR via a series of convolutional layers. Subsequently, the efficient channel attention module is embedded in this stage, which enhances the feature response related to the road and suppresses background interference by adaptively recalibrating the feature channels.
2) Multi scale nonlinear mapping: This is the core improvement stage. The multi-scale feature fusion module we designed receives enhanced features, extracts features from different receptive fields through parallel multi branch convolution, and performs effective fusion, enabling the model to simultaneously capture local details of the road and long-distance contextual structures.
3) High resolution reconstruction: Finally, the fused depth features are upsampled using deconvolution layers to reconstruct a road prediction map (PHR) with the same resolution as the input.

The training of the entire model is supervised by our proposed adaptive structure aware loss, which jointly optimizes pixel level accuracy, edge continuity, and topological integrity, driving the model to learn and generate structurally sound road networks.

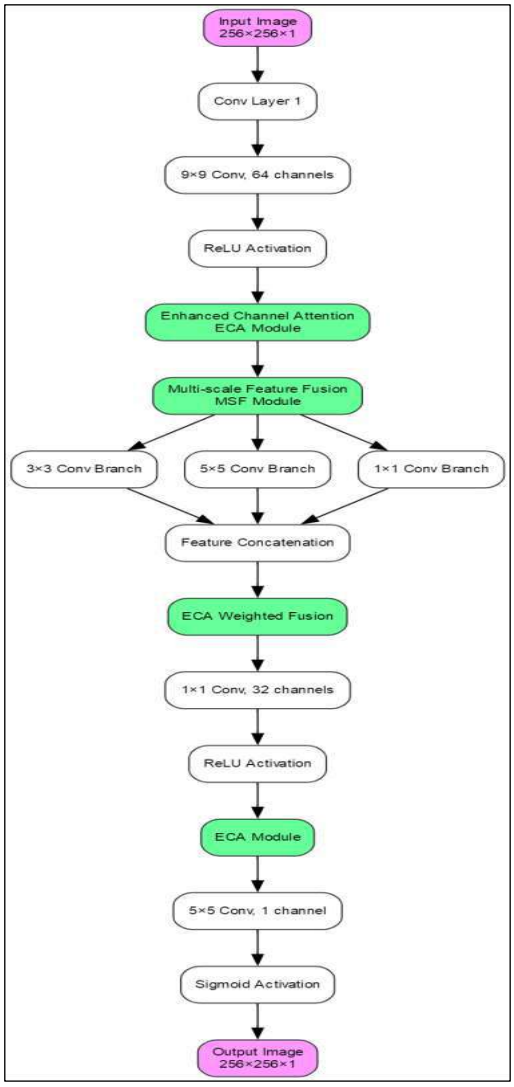

Figure 1: Schematic Diagram of the ISRE Model Architecture.
Source: Authors, (2026).

III.2 CORE IMPROVEMENT MODULE

III.2.1 Efficient Channel Attention Module

To enhance the model's ability to focus on key road features, we introduced an efficient channel attention module after the feature extraction stage. This module models inter channel dependencies in a lightweight manner, avoiding complex dimensionality reduction operations and achieving performance improvement with almost no increase in computational overhead. Given the input feature $X \in \mathbb{R}^{H\times W\times C}$, the operation of the ECA module is as follows:

1) Global spatial information aggregation: perform global average pooling on each channel to generate a channel description vector $z \in \mathbb{R}^{C}$, with the c-th element [30].

As shown in Equation (1):

$$z_c = \frac{1}{H\times W}\sum_{i=1}^{H}\sum_{j=1}^{W} X_c(i,j) \tag{1}$$

2) Adaptive cross channel interaction: Perform one-dimensional convolution on z to capture local cross channel interactions [31]. The size of the convolution kernel k is adaptively determined by the number of channels C:

As shown in Equation (2):

$$k = \Psi(C) = \left|\frac{log_2(C)}{\gamma} + \frac{b}{\gamma}\right|_{odd} \tag{2}$$

Among them, $|\cdot|_{odd}$ odd represents taking the nearest odd number, and γ and b are set to 2 and 1, respectively. This design enables flexibility in interactions across several dimensional properties.

3) Attention weight generation and application: The one-dimensional convolution output is passed through a Sigmoid activation function to generate attention weight vectors $a \in \mathbb{R}^{C}$ for each channel [32]. Finally, the output features are obtained through channel weighting: $\widetilde{X} = \alpha \otimes X$, where $\otimes$ represents channel wise multiplication.

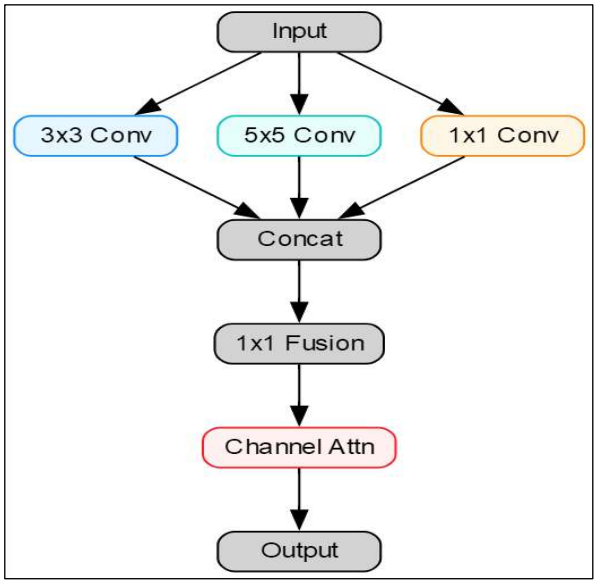

Figure 2: Schematic Diagram of the MSF Module Structure.
Source: Authors, (2026).

III.2.2 Multi Scale Feature Fusion Module

To overcome the problem of insufficient adaptability of fixed size convolution kernels to multi-scale roads (such as main roads and alleys), we designed a multi-scale feature fusion module, whose structure is shown in Fig 2. The MSF module uses three convolution branches with different kernel sizes in parallel to process input feature $\tilde{X}$:

1) 1 × 1 convolution branch: used for cross channel information integration and feature transformation, and providing the most basic local context.
2) 3 × 3 convolution branch: Offers a modest receptive field, emphasizing the capture of edge and contour features within standard road widths.
3) 5 × 5 Volume Integral Support: Offers an expanded receptive field, designed to include road directions and buildings over broader road regions or extended distances.

The feature maps output by each branch are concatenated in the channel dimension, followed by feature fusion and channel number adjustment through a 1x1 convolutional layer, and finally output feature Fms fused with multi-scale information. This design enables the model to flexibly adapt to significant changes in road scale in aerial photography scenes.

III.2.3 Adaptive Structure Perception Loss Function

The practicality of roads highly depends on their topological connectivity. Traditional mean square error loss only constrains pixel values and cannot guarantee structural correctness. To this end, we propose an adaptive structure aware loss that jointly optimizes pixel, edge, and region consistency, defined as Equation (3):

$$\mathcal{L}_{ASL} = \alpha \cdot \mathcal{L}_{pixel} + \beta \cdot \mathcal{L}_{grad} + \gamma \cdot \mathcal{L}_{road} \tag{3}$$

Where:
$\mathcal{L}_{pixel}$: represents the pixel level MSE loss to ensure global reconstruction accuracy. Enter the equation (4).

$$\mathcal{L}_{pixel} = \frac{1}{N}\sum_{i}^{1}(Y_i - \hat{Y}_i)^2 \tag{4}$$

L_{grad} is the gradient similarity loss. The Sobel operator is used to calculate the gradient amplitude maps $G_{\hat{Y}}$ and G_Y between the predicted image $\hat{Y}$ and the true label Y, and to calculate their MSE, as shown in Equation (5):

$$L_{grad} = \frac{1}{N}\sum_{i=1}^{N}\sum_{i\in\{M=1\}}(G_{Y,i} - G_{\hat{Y},i})^2 \tag{5}$$

This directly constrains the continuity and clarity of the road edges. $\mathcal{L}_{road}$ is the focal loss of the road area, and MSE is calculated only within the real road pixel area (identified by mask M), as shown in Equation (6):

$$\mathcal{L}_{road} = \frac{1}{\sum M}\sum_{i\in\{M=1\}}(Y_i - \hat{Y}_i)^2 \tag{6}$$

This forces the model to focus more on learning the foreground road region. α, β, and γ are balanced weights. After grid search on the validation set, the optimal values were determined to be 0.7, 0.2, and 0.1, respectively.

III.3 MODEL TRAINING STRATEGY

The details of model training are as follows:

1) Data preprocessing: Convert RGB aerial images to YCbCr color space and use only the brightness Y channel as a single channel input. Generate low resolution training sample pairs through bicubic downsampling (scaling factor of 2).
2) Optimization settings: Use Adam optimizer, set the initial learning rate to 1 × 10-4, and adjust using cosine annealing strategy. Set the batch size to 16.
3) Training and Regularization: The total training epochs are 300, and an early stopping strategy is adopted (with a patience value of 40 epochs, using the F1 score of the validation set as the monitoring indicator). To prevent overfitting, data augmentation techniques such as random horizontal/vertical flipping, ± 15 ° rotation, and ± 20% brightness adjustment were used.
4) Loss function: Adaptive structure aware loss ASL is used as the training objective function.

IV. EXPERIMENT AND RESULT ANALYSIS

IV.1 EXPERIMENTAL SETUP

IV.1.1 Dataset

The experiment utilizes the Massachusetts Road Dataset [33].This collection comprises 1,171 aerial photos of Massachusetts, each measuring 1500×1500 pixels and covering an area of 2.25 square kilometers. The dataset is arbitrarily partitioned into a training set including 1,108 photos, a validation set with 14 images, and a test set with 49 images. The collection encompasses diverse urban, suburban, and rural regions, with a total area of 2,600 square kilometers. The test set encompasses more than 110 square kilometers. Target maps are generated through rasterization of road centerlines obtained from the OpenStreetMap project. When generating labels, the line thickness is set to 7 pixels without smoothing. All images are resized to a resolution of 1 pixel per square meter.

IV.1.2 Comparative Models

The following models have been selected for comparison:

1) SRCNN [8]: A conventional super-resolution model (baseline).
2) U-Net [9]: A standard model for semantic segmentation.
3) DeepLabv3+ [34]: A semantic segmentation architecture using dilated convolutions.
4) ISRE: An Improved SRCNN-based Aerial Image Road Extraction Model (Improved SRCNN for Road Extraction, ISRE).

This experiment compares traditional super-resolution networks (SRCNN), semantic segmentation models (U-Net, DeepLabv3+), and ISRE. The core designs of these models are presented in Table I.

Table 1: Core Designs of Four Road Extraction Models.

Model	Core Architecture and Improvements
SRCNN	Classical 3-layer convolutional network (9×9→1×1→5×5), no skip connections, optimized solely via MSE loss.
U-Net	Encoder-decoder architecture (4-layer downsampling + 4-layer upsampling), with skip connections, uses MSE loss.
DeepLabv3+	Based on ResNet50 backbone network, integrates ASPP module (dilated convolution-based multi-scale feature extraction), uses Dice+BCE loss.
ISRE	Proposed model in this paper, core improvements include: - Enhanced Channel Attention (ECA): Dynamically adjusts channel weights; - Multi-Scale Feature Fusion (MSF): Fuses features from 3×3, 5×5, and 1×1 convolution branches; - Structure-Aware Loss (ASL): Jointly optimizes pixel loss, gradient loss, and road region loss.

Source: Authors, (2026).

IV.1.3 Evaluation Metrics

1) PSNR (Peak Signal-to-Noise Ratio) [35]

PSNR evaluates the pixel-level similarity between the reconstructed picture and the ground-truth image I by assessing the ratio of the highest possible pixel value (e.g., 255 for 8-bit images) to the mean squared error (MSE) between the two images. A higher PSNR indicates superior reconstruction quality.

Equation (7) is:

$$PSNR = 10 \cdot log_{10}(\frac{MAX_I^2}{MSE}) \quad (7)$$

Where:

MAXI : Maximum pixel value in the image (e.g., 255 for 8-bit grayscale images).

MSE: Mean Squared Error, calculated as:

Equation (8) is:

$$MSE = \frac{1}{H \times W} \sum_{i=1}^{H} \sum_{j=1}^{W} (I(i,j) - \hat{I}(i,j))^2 \quad (8)$$

H×W: Dimensions of the image (height × width).

2) F1-Score [36]

The F1-score balances two critical categorization metrics: precision (P) and recall (R), serving as their harmonic mean to mitigate bias towards either statistic.

Precision (P): The proportion of correctly detected road pixels to the total expected road pixels.

Equation (9) is:

$$P = \frac{TP}{TP+FP} \tag{9}$$

Recall (R): Proportion of correctly predicted road pixels among all real road pixels.

Equation (10) is:

$$\mathrm{R} = \frac{TP}{TP+FN} \tag{10}$$

F1-Score: A balanced performance, emphasized by the harmonic mean of precision and recall.

Equation (11) is:

$$\mathrm{F1-score} = 2 \times \frac{P \times R}{P+R} \tag{11}$$

Where:

TP (True Positive): Pixels correctly classified as road (ground truth = road, prediction = road).

FP (False Positive): Pixels mistakenly classified as road (ground truth = non-road, prediction = road)

FN (False Negative): Pixels erroneously categorized as non-road despite the actual condition being road and the prediction indicating non-road.

3) Topological Accuracy [37]

Topological accuracy evaluates the continuity and structural correctness of the road skeleton. It is typically measured by comparing the skeletonized prediction Spred with the ground-truth skeleton Sgt. A common formulation is the proportion of correctly connected skeleton segments:

Equation (12) is:

$$\mathrm{Topological\ Accuracy} = \frac{Total\ number\ of\ skeleton\ segments\ in\ S_{gt}}{number\ of\ \ connected\ correctly\ skeleton\ \ segments\ in\ S_{pred}} \tag{12}$$

4) Topological Completeness Index (Topo) [37]

Topo assesses the connectivity of the road skeleton by penalizing disconnected segments (breakpoints) in the prediction.

Equation (13) is:

$$\mathrm{Topo} = 1 - \frac{N_{break}}{|S_{gt}|} \tag{13}$$

Where:

N_{break}: Number of breakpoints in Spred (positions where the skeleton is fragmented due to prediction errors).

$|S_{gt}|$: Total number of pixels in the ground-truth skeleton Sgt(normalization factor).

The value range of Topo is [0, 1], with higher values indicating better topological connectivity.

5) Skeleton F1-Score [36]

The Skeleton F1-score assesses the structural correspondence between the skeletonized prediction Spred and the ground-truth skeleton Sgt. It is computed as the harmonic mean of two metrics:

Skeleton Precision (P): The ratio of skeleton pixels in Spred that coincide with Sgt.

Skeleton Recall (R) : Proportion of skeleton pixels in Sgt that are covered by Spred.

Equation (14) is:

$$P_{skeleton} = \frac{|S_{pred} \cap S_{gt}|}{S_{pred}}, R_{skeleton} = \frac{|S_{pred} \cap S_{gt}|}{S_{gt}} \tag{14}$$

Equation (15) is:

$$\mathrm{Skeleton\ F1-score} = 2 \times \frac{P_{skeleton} \times R_{skeleton}}{P_{skeleton} + R_{skeleton}} \tag{15}$$

Where:

| Spred∩Sgt | : Number of overlapping pixels between Spred and Sgt.

| Spred | : Total number of pixels in Spred.

| Sgt | : Total number of pixels in Sgt.

6) Model efficiency:

Parameter quantity and FLOPs are two core indicators for measuring model lightweighting [38]: parameter quantity refers to the total number of trainable parameters of the model, which directly determines storage overhead and memory usage; FLOPs refer to the number of floating-point operations required for one forward propagation, reflecting computational complexity and energy consumption. The lower the values of the two, the lighter the model. The calculation formulas are: the parameter count and the number of multiply add operations (MACs) of the fully connected layer are both "input dimension x output dimension"; The parameter count of the convolutional layer is "kernel height x kernel width x number of input channels x number of output channels", and its MACs are "output height x output width x kernel height x kernel width x number of input channels x number of output channels". The actual FLOPs can be approximated as twice the MACs.

IV.2 EXPERIMENTAL RESULTS

IV.2.1 Quantitative Analysis

The quantitative measure results for each model on the test set are shown in Table II and Fig 3. In every criterion, ISRE far outperforms the baseline models.

1) PSNR: ISRE (25.54 dB) improves by 0.43% compared to SRCNN (25.43 dB), indicating that its generated HR images are closer to the ground-truth images.
2) F1-score: ISRE (0.8285) increases by 0.99% in comparison to the best baseline model SRCNN (0.8204), indicating superior precision and recall in road segmentation.
3) Topological Accuracy: ISRE (0.7101) exhibits an 11.2% enhancement over U-Net (0.6387), indicating that the connectivity of its projected roads more closely aligns with the actual road network.
4) Skeleton F1-score: ISRE (0.7754) outperforms DeepLabv3+ (0.6098) by 27.2%, suggesting a greater capacity to preserve road skeleton features (such as bends and crossings).

Table 2: Performance Comparison of Models on the Test Set.

Model	PSNR (dB)	F1-score	Topological Accuracy	Skeleton F1-score	Parameter quantity (M)↓	FLOPs (G)↓
SRCNN	25.4314	0.8204	0.6949	0.7658	0.058	0.01
U-Net	25.2453	0.7948	0.6387	0.7364	31.04	70.1
DeepLabv3+	23.0065	0.6745	0.6745	0.6098	39.77	61.5
ISRE (Ours)	25.5426	0.8285	0.7101	0.7754	1.87	0.89

Source: Authors, (2026).

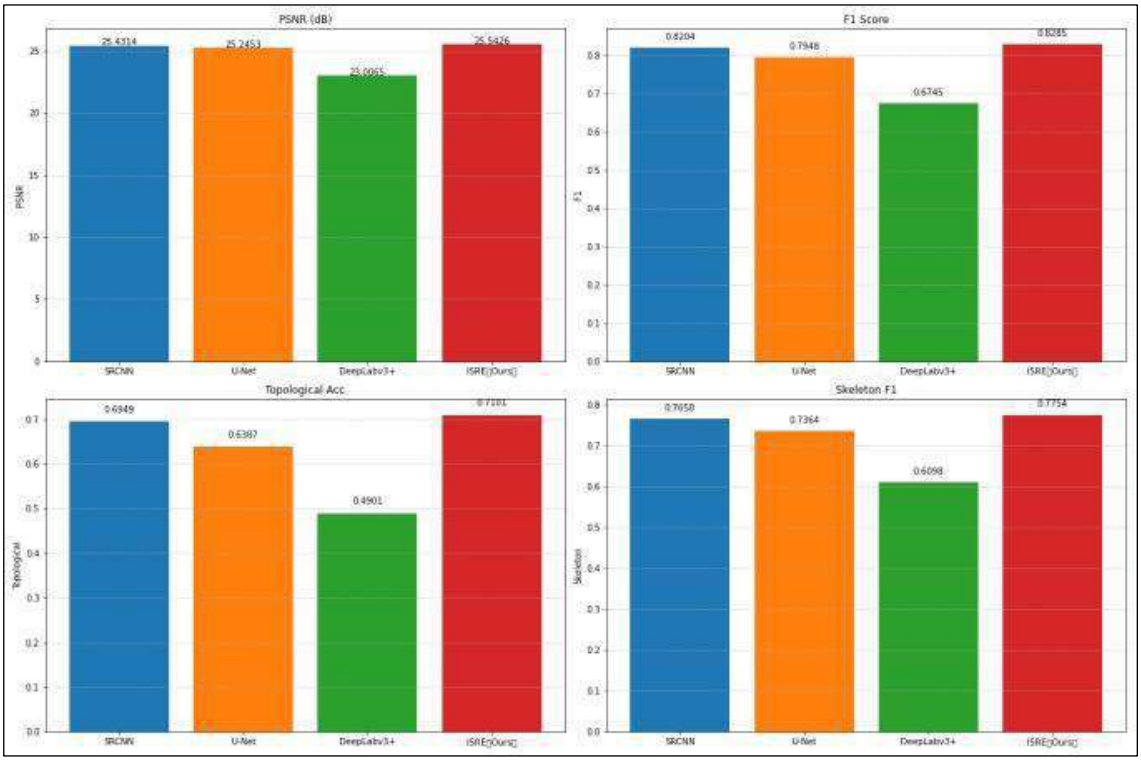

Figure 3: Performance Comparison of Models on the Test Set.
Source: Authors, (2026).

IV.2.2 Ablation Experiment

To verify the effectiveness of each improved module in ISRE, we conducted a systematic ablation experiment, and the results are shown in Table III. The experiment uses SRCNN as the baseline and gradually adds ECA, MSF, and ASL modules.

Table 3: Results of ISRE ablation experimente.

Model configuration	F1 score	Topology accuracy	Parameter quantity (M)
Baseline(SRCNN)	0.8204	0.6949	0.058
+ECA	0.8241	0.7013	0.059
+ECA+MSF	0.8268	0.7059	1.85
+ECA+MSF+ASL(ISRE)	0.8285	0.7101	1.87

Source: Authors, (2026).

Experiments have shown that each module brings stable performance gains: the ECA module improves feature selectivity with minimal parameter cost; the addition of MSF module further enhances multi-scale adaptability; the introduction of ASL loss contributes the most significantly to the improvement of topological accuracy, confirming the necessity of explicit structural constraints.

IV.2.3 Qualitative Analysis

Figs 4 and 5 respectively present the road extraction results of SRCNN, U-Net, DeepLabv3+, and ISRE in typical scenarios: urban intersections (Fig 4) and rural paths (Fig 5). Fig 4 further compares the extraction results of all models (from top to bottom: input image, ground-truth mask, SRCNN, U-Net, DeepLabv3+, and ISRE).

1) Key observations are summarized as follows:

SRCNN demonstrates considerable fragmentation and redundancy in its extraction outcomes, such as disjointed road segments at junctions. U-Net and DeepLabv3+, while proficient at delineating continuous road structures, inaccurately identify areas with intricate textures (e.g., roads obscured by vegetation). In complex scenarios, such as intersections and rural paths, ISRE demonstrates clearer boundaries and fewer misclassifications by utilizing ECA to concentrate on key road channels, MSF to capture multi-scale structures, and ASL to constrain road morphology.

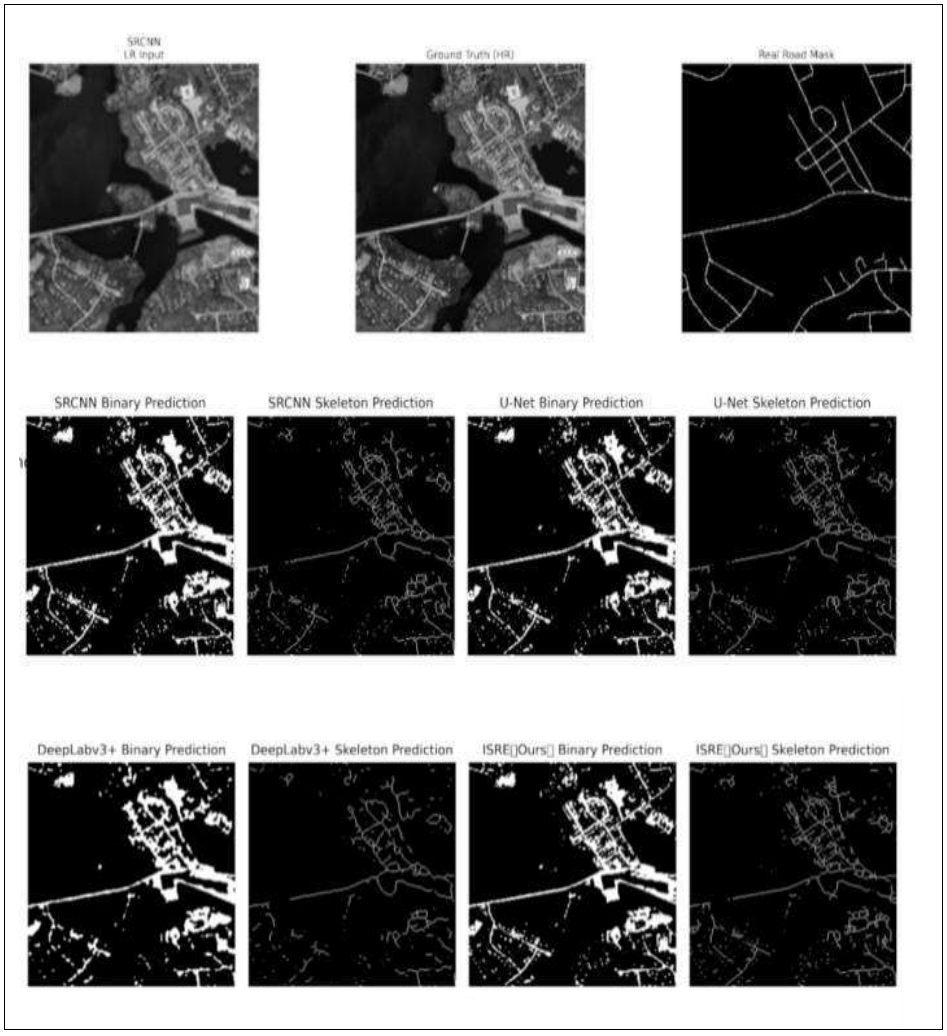

Figure 4: Extraction results of various models (SRCNN, U-Net, DeepLabv3+, ISRE) at urban intersections.
Source: Authors, (2026).

2) Detailed comparisons across scenarios:

Urban Intersections: ISRE (bottom row of Fig 4) accurately represents multi-lane configurations, including dividers between left-turn and straight lanes. Conversely, U-Net (middle row of Fig 4) has blurred edges, characterized by noticeable jaggedness along lane dividers, whereas DeepLabv3+ (bottom row of Fig 4) fails to detect some lanes owing to its restricted receptive field. Rural Paths: ISRE (bottom row of Fig 5) effectively preserves details of small paths (e.g., curved sections of field paths) through multi-scale fusion. Conversely, SRCNN (middle row of Fig 5) fails to maintain path continuity due to the lack of contextual information. Skeleton Comparison: The ground-truth skeleton (top row of Fig 5) is nearly precisely aligned with the skeleton of ISRE (bottom row of Fig 5). In contrast, skeletons from other models contain breakpoints or redundant branches (e.g., the U-Net skeleton lacks connectivity at intersections).

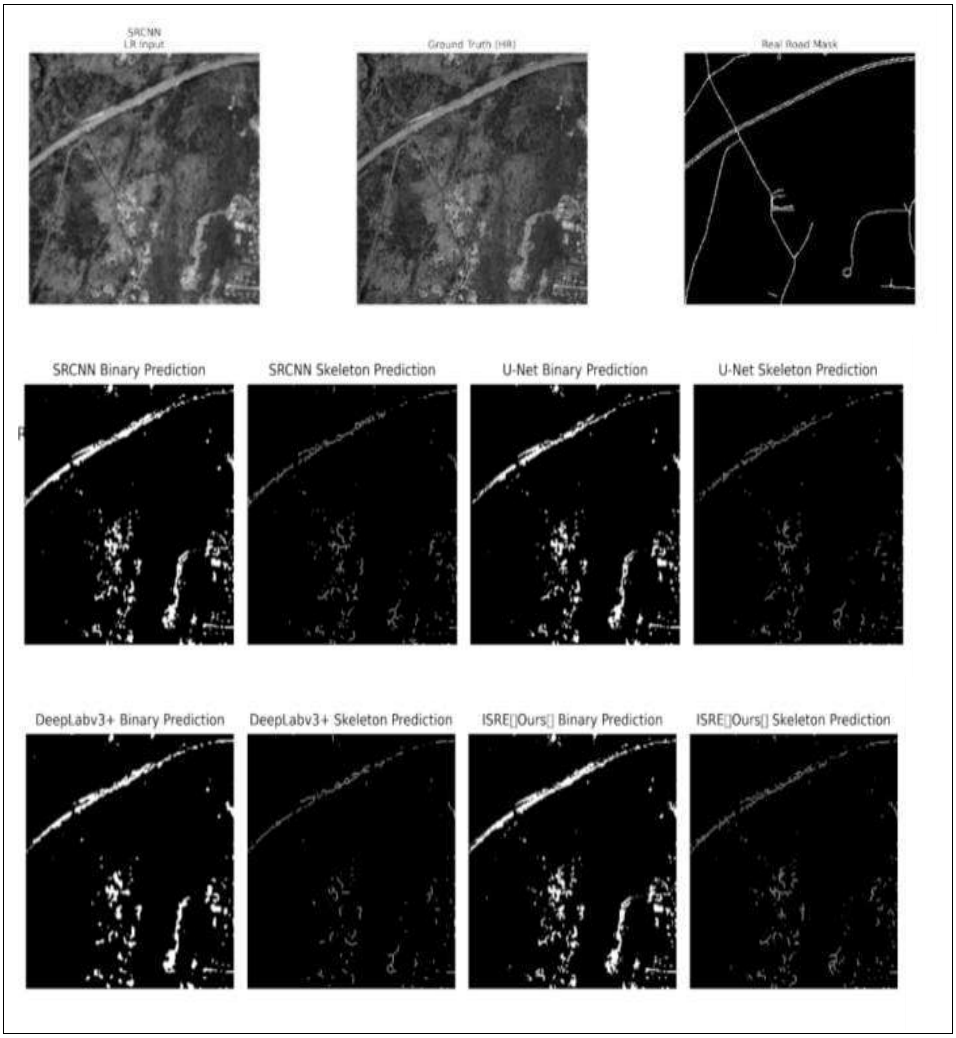

Figure 5: Extraction results of various models (SRCNN, U-Net, DeepLabv3+, ISRE) on rural paths.
Source: Authors, (2026).

Experimental results indicate that ISRE performs optimally in road extraction tasks. The key reasons lie in:

Enhanced Channel Attention (ECA): By dynamically adjusting channel weights, the model focuses more on critical features such as road edges while suppressing background noise interference;

Multi-Scale Feature Fusion (MSF): Fusing convolutional features of different scales compensates for the insufficient representation of complex road structures (e.g., wide and narrow roads) by single-scale features;

Structure-Aware Loss (ASL): Jointly optimizing pixel-level, gradient-level, and region-level losses ensures both overall image similarity and enhanced connectivity and detail preservation of road structures.

Compared with existing methods, the innovative aspect of ISRE lies in integrating structure awareness with multi-scale feature fusion, addressing the issues of incomplete road segmentation and skeleton fragmentation in traditional models under complex scenarios (e.g., intersections and small paths). Future work could further explore lightweight design (e.g., model compression) to adapt to real-time processing requirements on edge devices such as aerial photography platforms.

V. CONCLUSIONS

V.1 CONCLUSION

This article proposes an enhanced SRCNN model called ISRE that integrates structural perception to address the issues of limited feature expression ability, insufficient multi-scale adaptability, and missing structural information in the lightweight SRCNN model for aerial image road extraction tasks. By introducing efficient channel attention module, multi-scale feature fusion module, and adaptive structure aware loss function into the infrastructure, ISRE significantly enhances its ability to focus on key road features, adapt to different scale road shapes, and model road network topology connectivity while maintaining its lightweight advantage. The comprehensive experiment on the Massachusetts road dataset shows that ISRE has achieved significant improvement in F1 score compared to the baseline SRCNN model, especially in the topological accuracy indicator measuring road connectivity, which has improved by more than 11%.At the same time, ISRE achieves more competitive comprehensive performance with much lower parameter count and computational cost than complex segmentation models such as U-Net and DeepLabv3+.This fully validates the effectiveness of the ISRE model design, providing a highly promising solution for efficient and high-precision road extraction tasks on computing resource constrained platforms such as drones and mobile terminals.

V.2 LIMITATIONS AND PROSPECTS

Although ISRE has demonstrated superior performance on public datasets, there are still certain limitations. For example, the performance of the model under extreme lighting conditions, severe occlusion (such as roads under dense vegetation), or special road types that do not appear in the training data (such as temporary construction roads) needs further validation and enhancement. Future research work can be carried out from the following aspects:

1) Long distance contextual modeling: Exploring the combination of visual transformers or self-attention mechanisms with existing CNN architectures to more effectively model the long-range dependencies of road networks, thereby further improving extraction accuracy in complex intersections and large road networks.

2) Multimodal data fusion: Research on road extraction methods that fuse multiple sources of remote sensing data, such as LiDAR point clouds and hyperspectral images. The precise three-dimensional elevation information provided by LiDAR can effectively assist in distinguishing ground objects (such as squares and parking lots) that are difficult to distinguish in two-dimensional images and have similar spectral features to roads, enhancing the robustness of the model.

3) Ultimate optimization of model efficiency: In order to meet the real-time processing requirements of extreme resource constrained scenarios such as satellites and micro drones, future work will explore more aggressive lightweight strategies. This includes but is not limited to: applying neural network architecture search technology to automatically find the optimal combination of lightweight modules; Using knowledge distillation techniques, the structured knowledge of large teacher models (such as high-performance segmentation networks) is transferred to compact student models such as ISRE, in order to approach or even surpass the performance of complex models without significantly increasing computational overhead

Electrochemical characterization

ABSTRACT

An easy drop coating method on a microfiber carbon substrate was used to fabricate Manganese Oxide (Mn_3O_4) thin-film electrodes with varying mass loadings. The physical and structural properties of the electrodes were characterized by scanning electron microscopy (SEM), Raman spectroscopy, and X-ray diffraction (XRD), revealing uniform deposition and crystalline structure. The electrochemical performance was evaluated using cyclic voltammetry (CV) and charge-discharge (CD) tests in 1.0 M Na_2SO_4 solution. Results indicate that increasing the mass loading significantly reduces both specific capacitance and coulombic efficiency due to the limited accessibility of active sites in thicker films. The thin-film electrode with 0.7 mg/cm² mass loading demonstrated optimal capacitive behavior within the potential range of -0.1 to 0.9 V. q-plots further confirmed that thicker electrodes hinder ion diffusion, leading to decreased electrochemical efficiency. These findings suggest that controlling mass loading is crucial for optimizing the performance of Mn_3O_4-based supercapacitors. The study provides practical guidelines for designing thin-film electrodes with improved energy storage capability, highlighting the balance between electrode thickness and electrochemical performance for efficient supercapacitor applications.

I. INTRODUCTION

In recent years, supercapacitors have become attractive power sources because of their vast industrial and domestic application. The supercapacitors whose characteristics lie between those of batteries and capacitors. Supercapacitors have a high specific energy, an accelerated charging and discharging capacity, extended longevity, and eco-friendliness [1-3]. They were considered among the most prominent and excellent candidates for energy storage. The progress of portable equipment and hybrid (and "all-electric") vehicles also require storage devices that allow high energy density to be obtained in a limited volume and that can be released quickly [4]. The effectiveness of supercapacitors is enhanced through the advancement of various electrode materials, which necessitate elevated levels of specific surface area, electrical conductivity, resistance to corrosion, and chemical stability. The primary materials used as supercapacitor electrodes include carbon-based substances, conductive polymers, and metal oxides like manganese oxide, which can store high energy levels [5]. It is a preferred option since manganese oxide has a significant theoretical capacity (1370 F/g) and is inexpensive [2], [6]. However, the experimental-specific capacitance is much lower and is limited to systems with low active mass (mg/cm^2) due to the resistivity and high density of the material. To overcome this lack of conductivity and improve storage properties (Increase both power and energy while decreasing resistance), Manganese oxide must be a thin film [7]. Recent studies have confirmed that in addition to the strength of the crystal structure and surface properties, the mass loading/thickness of Mn_3O_4 also significantly affects the electrochemical performance of manganese oxides.

According to [8] proved that the performance of thin electrodes is much higher than that thick electrodes. His work was based on the straightforward redox reaction between Mn^{2+} and MnO_4- to synthesize high-surface-area manganese oxides. Bong-Ok Park and co-workers [7] reported the cathodic electrodeposition procedure used to create RuO_2 films and demonstrated how decreasing the film thickness causes the electrode's specific capacitance to increase. In [9] Mn_3O_4 thin film electrode produced by spray pyrolysis. The result is that the specific capacitance increases as the layer thickness increases. According to [10] have shown that the mass capacity of MnO_2 strongly depends on the quantity and thickness of the material used to prepare the electrode. This research work focused on electrode materials for supercapacitors. The electrode materials studied are manganese oxides and their association with microfiber carbon paper MCP. To verify the presence of Mn_3O_4, several produced samples were examined using electrochemical techniques (cyclic voltammetry CV, charge-discharge CD) and physicochemical techniques (scanning electron microscopy SEM, Raman spectra, and X-ray diffraction XRD). The results obtained for the thin electrode (0.7 mg/cm^2) exhibit an impressive particular capability of 232.85 F/g at a scan rate of 5 mV/s. Finally, the goal of this research is to contribute to the investigation and knowledge of the effects of surface and structural properties on electrode materials, especially the impact of mass loading on the electrochemical performance of thin-film manganese oxide electrodes.

II. EXPERIMENTAL

II.1 CHEMICALS

The All chemicals used in this study were of analytical grade and were purchased from Sigma-Aldrich. Potassium permanganate ($KMnO_4$), sulfuric acid (H_2SO_4), and ethanol (EtOH) were used as received without further purification. Distilled water with a resistivity of 18 MΩ·cm was employed for the preparation of all aqueous solutions. Microfiber carbon paper (MCP), type SC 2050 A, was supplied by Spectracarb. Prior to use, the MCP substrate was treated in concentrated sulfuric acid (H_2SO_4) at 70 °C for 4 h to improve surface wettability and adhesion, followed by thorough rinsing with distilled water.

II.2 MATERIALS PREPARATION

Mn_3O_4 thin films were deposited onto the treated MCP substrate following a drop-coating procedure previously reported in the literature [11]. Different mass loadings of Mn_3O_4 were applied, namely 0.7, 5.6, and 26.6 mg/cm², and the resulting electrodes were denoted as MCP– Mn_3O_4 (0.7), MCP– Mn_3O_4 (5.6), and MCP– Mn_3O_4 (26.6), respectively. After deposition, the electrodes were repeatedly rinsed with distilled water to remove residual precursors and then dried under vacuum at 150 °C for at least 24 h. The mass loading of each electrode was determined as the mass of Mn_3O_4 per unit area using a high-precision digital balance with a resolution of 0.1 mg. The specific capacitance (C_s, F/g) was calculated from cyclic voltammetry (CV) curves by integrating the charge (Q) according to Equation (1) [11], [12]:

$$C = Q/(\Delta E * m) \quad (1)$$

Where ΔE represents the potential window and m is the mass of the active material. The capacitance derived from constant current charge–discharge (CD) measurements was calculated using Equation (2) [11], [12]:

$$C = I_{t_d} / (\Delta E_{cc} * m) \quad (2)$$

Where I is the total current, t_d the discharge time, ΔE_{cc} the CC potential drop during constant current discharge.

II.3 MATERIALS CHARACTERIZATION

An X-ray diffractometer model Bruker D8 Advance (λ = 1.54182 Å with Cu-Kα radiation) was used to perform the structural characterization of the electrodes at room temperature. The surface of the samples was examined using a JEOL-JSM-7600F analytical scanning electron microscope. Using an alpha 300 R Confocal Raman Microscope and a WITec UHTS 300 spectrometer with a 532 nm laser, the samples' Raman microscopy was captured. In our work, the electrochemical method was performed using a bio-logic potentiostat/electroplating/FRA (SP-300). It is controlled by a Windows computer running EC-Lab® software, allowing selection of electrochemical techniques, parameters of interest, and data processing. A three-electrode glass electrochemical cell immersed in an electrolytic containing a 1 M solution of Na_2SO_4 was used for electrochemical experiments. Electrochemical measurements (cyclic voltammetry CV and charge–discharge (CD) were performed by glass electrochemical cell with three electrodes immersed in electrolysis containing the 1M aqueous solution of Na_2SO_4 at room temperature for all experiments, with a 2 cm^2 (2 cm × 1 cm) working electrode and only 1 cm^2 was immersed in the electrolyte, the counter electrode and reference electrode being an Pt foil and an Ag/AgCl, respectively.

III. RESULTS AND DISCUSSION

To verify that our Mn_3O_4 is deposited on the MCP, the SEM was used to compare the structural properties of the microfibre carbon paper MCP and MCP- Mn_3O_4. An SEM picture of the MCP is shown in Figure 1a and Figure 1b. At low magnification, it is noted that the carbon microfibers paper consists of a porous three-dimensional network of carbon microfibers. On the other hand, zooming the MCP image to just one fiber reveals that each carbon microfiber has a smooth, immaculate, and debris-free surface with a diameter of 5 µm for each fiber. Figure 1c and Figure 1d show the SEM images of the MCP electrode after Mn_3O_4 deposition. Images confirm the presence of Mn_3O_4, which is deposited as nano/microparticles on the carbon microfiber. Almost all the MCPs are covered with Mn_3O_4, given the size of the carbon microfiber (5µm) and the diameter of the objects observed in SEM. At high magnification, we estimate the thickness of the deposition of Mn_3O_4 to about a hundred micro-meter (1.6 µm). This observation is interesting because it allows us not only to highlight the presence of Mn_3O_4 but also to have an idea of the amount deposited on the microfiber carbon paper.

We can also see on the SEM images of MCP- Mn_3O_4 that Mn_3O_4 is deposited as nano/microparticles on microfiber carbon paper MCP with sizes between 30 and 50 nm.

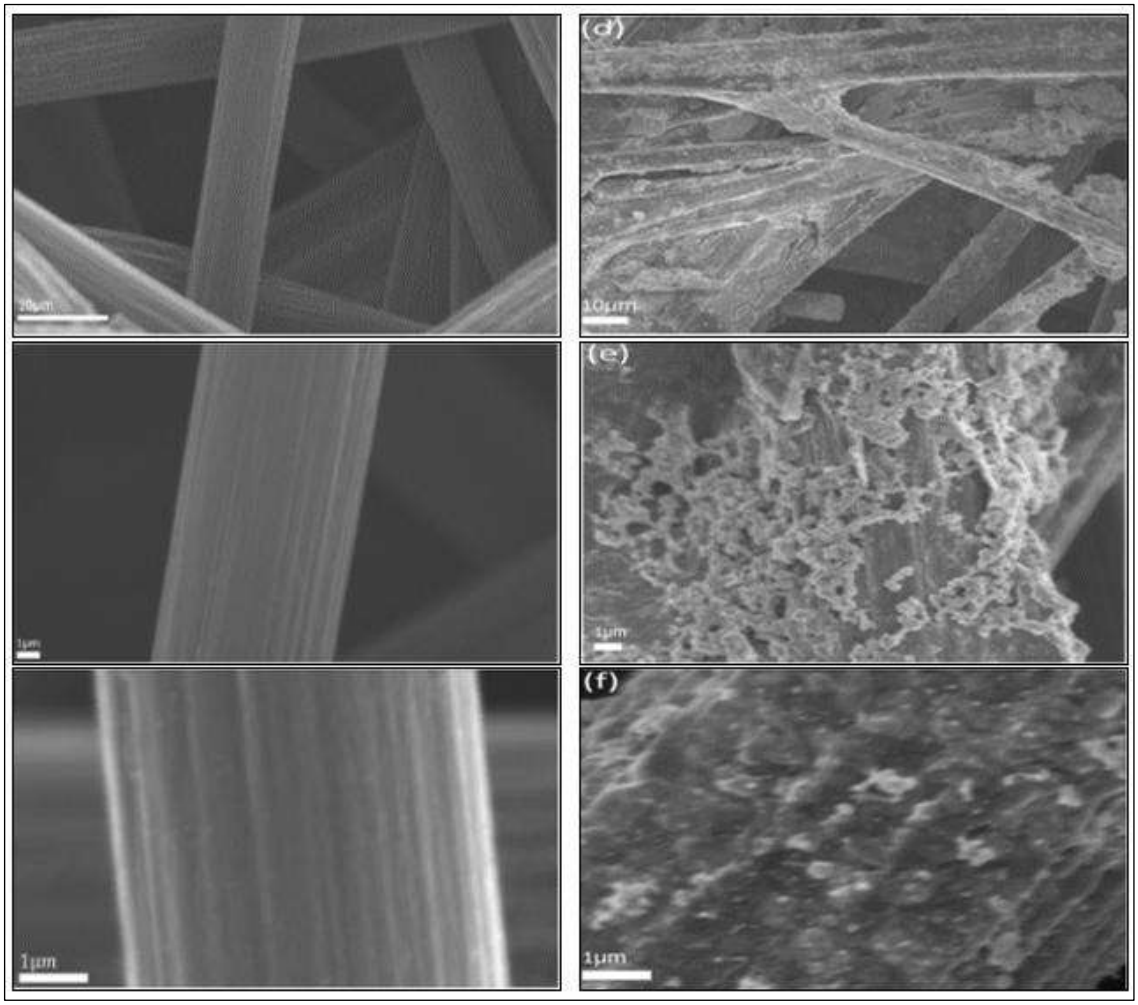

Figure 1: SEM images of carbon microfibers MCP and MCP- Mn_3O_4 (0.7).
Source: Authors, (2026).

The X-ray diffraction patterns of MCP and MCP- Mn3O4 are presented in Figure 2. Compare the MCP and MCP- Mn_3O_4 spectrum. DRX diagrams of MCP substrate are characterized by different peaks corresponding to the reported graphite [13]. However, The MCP-Mn3O4 electrode has peaks at 31,84 °, 33,07 °,36,57 °,37,26 °,43,74 °,51,91 °,55,94 °,55,94 °,59,94 ° et 62,16 °, which correspond to the (200), (103), (211), (004), (220), (105), (303), (321), (224) and (400) tetragonal structure planes of Mn_3O_4 nanoparticles (JCPDS Card #24-0734) [14]. Scherrer's formula and the diffractogram of MCP- Mn_3O_4 can be used to determine the average crystallite size (Dhkl). This formula leads us to the conclusion that the particle's Mn_3O_4 typical crystallite size is approximately 115 nm. The crystalline parameters of MCP- Mn_3O_4 are a = 5.85 Å and c = 9.5 Å [15]. To supplement the results obtained in SEM and XRD, to comprehend the carbon structures of the carbon microfibre and to corroborate the existence of the Mn_3O_4 phase (major phase) already observed by XRD, Raman spectroscopy analyses were performed.

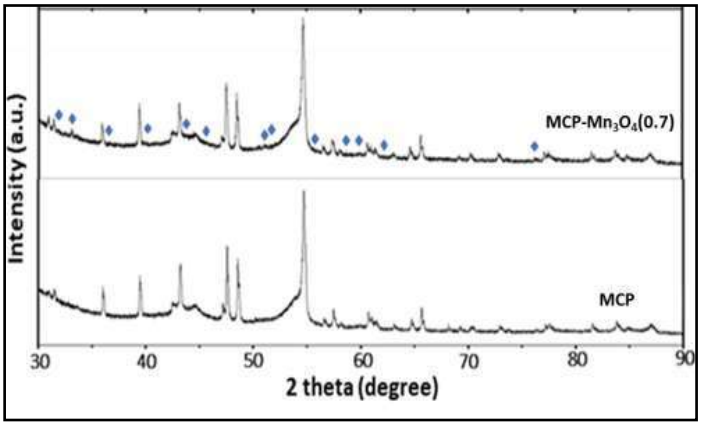

Figure 2: XRD patterns of MCP, and MCP- Mn_3O_4 (0.7) electrodes.
Source: Authors, (2026).

The superposition of the Raman spectra obtained from MCP and MCP-Mn3O4 in the 200 cm-1 to 3500 cm-1 frequency range is shown in Figure 3. The two Raman spectra present in the same region (200-3500 cm-1), the three prominent peaks at 1357.61, 1584.9, 2707 cm-1 for MCP and 1355, 1584, 2720 cm-1 for MCP- Mn3O4 attribute to bands D, G and 2D respectively. Specific vibrations of pure crystalline Mn_3O_4 are responsible for a noticeable peak in the spectra of MCP- Mn_3O_4 that may be found about 653 cm-1 [16].

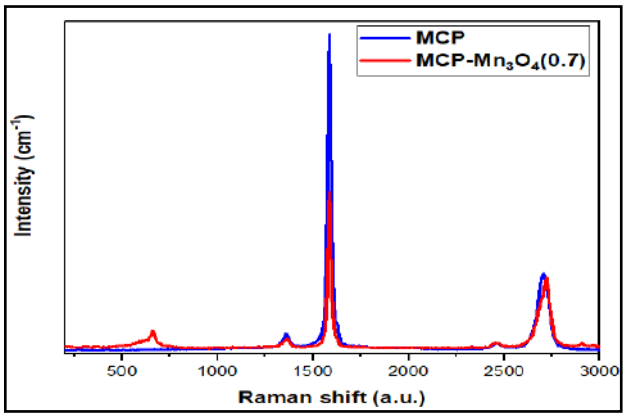

Figure 3: Raman spectra of MCP, and MCP- Mn_3O_4 (0.7) electrodes.
Source: Authors, (2026).

Cyclic voltammetry tests were carried out to examine and comprehend the electrochemical behaviour of the various synthesized materials. These materials were subjected to electrochemical experiments at ambient temperature using a neutral 1 M Na_2SO_4 aqueous electrolyte, highlighting the effects of manganese oxide deposition and mass loading on microfiber carbon paper MCP. Mass loading is the mass of Mn_3O_4 in MCP- Mn_3O_4. Voltammograms were recorded in the -0.1 to 0.9 V/Ag/AgCl potential range. Figure 4a compares the cyclic voltammograms of the MCP and MCP- Mn_3O_4 electrodes recorded in a 1 M Na_2SO_4 electrolyte at a scanning speed of 10 mV / s. We can see that the signal obtained varies greatly depending on the material tested. At first, the MCP has extremely low currents compared to the MCP- Mn_3O_4. This very low capacitance of the MCP is directly linked to its very low electronic conductivity. Additionally, the MCP- Mn_3O_4 electrode's cyclic voltammograms had a rectangular shape through the 1V investigated potential window. This rectangular voltammogram for MCP- Mn_3O_4 shows that the system behaves nearly optimally in terms of capacitance. This result demonstrates and confirms that manganese oxide is present and deposited on the microfiber carbon paper. Figure 4b shows a superposition of cyclic voltammograms (CVs) for various electrodes studied (0.7, 5.6 and 26.6 mg) in a 1M Na_2SO_4 solution. The shape of the voltammogram clearly shows that the sample with an active mass of 0.7 mg has a higher capacitance than the other samples. The same observation is also noted for the appearance of the corresponding CV, which is very rectangular compared to the others. This suggests a difference in electrochemical behavior among these three samples.

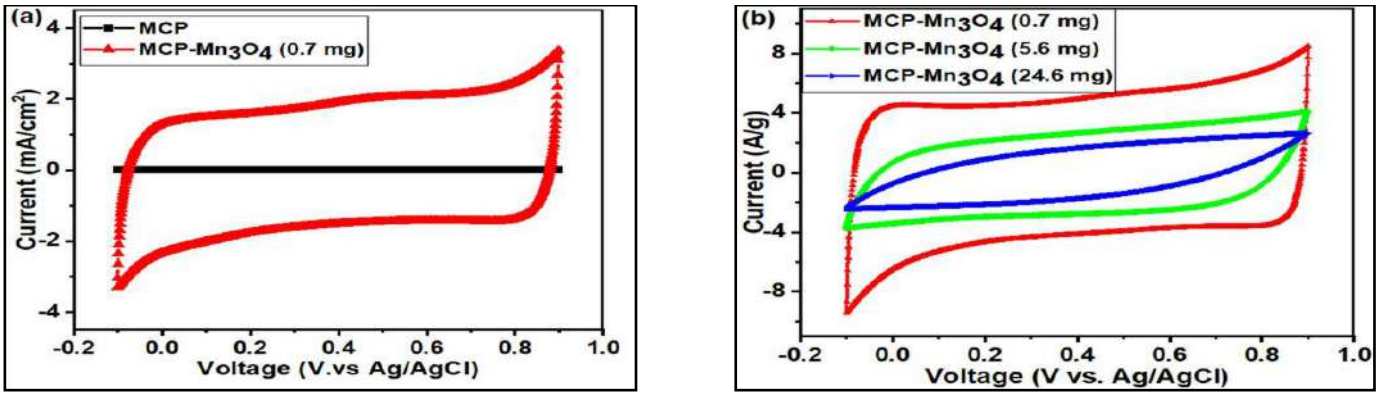

Figure 4: (a) Cyclic voltammograms of MCP and MCP- Mn_3O_4 (0.7) electrodes in 1 M Na_2SO_4 aqueous solution at a potential scan rate of 20 mV/s, (b) cyclic voltammograms in 1 M Na_2SO_4 aqueous solution of MCP- Mn_3O_4 (0.7), MCP- Mn_3O_4 (5.6) and MCP- Mn_3O_4 (24.6) electrodes in 1 M Na_2SO_4 aqueous solution at a potential scan rate of 20 mV/s.
Source: Authors, (2026).

Figure 5a,b,c represent the voltammograms of the MCP- Mn_3O_4 (0.7), MCP- Mn_3O_4 (5.6) and MCP- Mn_3O_4 (24.6) electrodes at scanning speeds from 5 mV/s to 100 mV/s, further to the evolution of the specific capacitance of materials as a function of the kinetics (Figure 5d) of the synthesized electrodes with different mass loadings (0.7, 5.6, 24.6 mg), as the scanning speed increases, there is an increase in the current for MCP- Mn_3O_4 (0.7) without significant change in the form of the cyclic voltammetry, even with high-speed scanning. This indicates that there are low contact resistances and ideal capacitive behavior. When the scan rates increase (Figure 5b, c), the voltammograms lose their rectangular shape and take on a resistive profile. Indeed, at high-speed scanning, problems linked to the limitation of the diffusion of ionic species in the porosity of the material and/or of the percolation of the charges up to the collector appear. Ionic species have less time to diffuse correctly within the composite material, and faradaic reactions linked to the presence of Mn_3O_4 are more difficult to carry out [17].

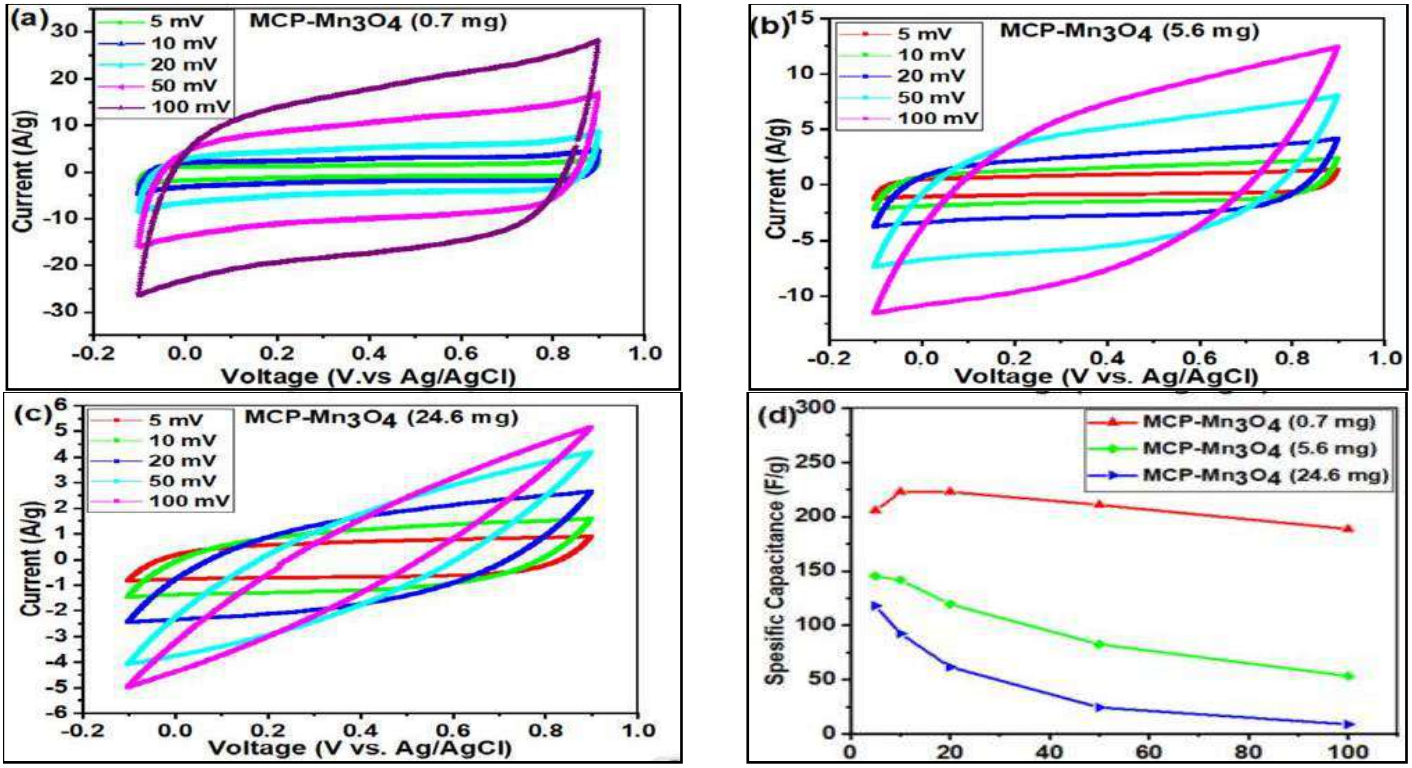

Figure 5: Cyclic voltammograms in 1 M Na2SO4 aqueous solution at different potential scan rate for (a) MCP- Mn_3O_4 (0.7) (b) MCP- Mn_3O_4 (5.6) (c) MCP- Mn_3O_4 (24.6) electrodes (d) variation of the specifc capacitance as a function of a scan rate for MCP- Mn_3O_4 (0.7), MCP- Mn_3O_4 (5.6) and MCP- Mn_3O_4 (24.6) electrodes in 1 M Na_2SO_4 aqueous solution.
Source: Authors, (2026).

The results of Figure 5d make it abundantly evident that the electrochemical performance of the produced electrodes is influenced by the amount of mass deposited. The higher the mass deposited, the more the specific capacities decrease. Consequently, a high mass has a negative impact on electrochemical performance. For example, with MCP- Mn_3O_4 (0.7) and MCP- Mn_3O_4 (24.6), the capacity decreases from 222.85 F/g to 92.43 F/g at scanning speeds of 10 mV/s, respectively. Devaraj and Munichandraiah have shown similar behavior in their manganese oxides [18]. In addition, as soon as the scanning speed is increased from 5 to 100 mV/s, MCP- $Mn3O_4$ (0.7) retains 85% of its specific capacitance (from 222.85 to 188.57 F/g). However, only 37.65% and 9.54% of the specific capacity of MCP- Mn_3O_4 (5.6) and MCP- Mn_3O_4 (24.6) electrodes remained, respectively. This demonstrates that the electrode MCP- $Mn3O_4$ (0.7) also has the highest and most stable capacities as the scan rates increase. These results confirm those described in the literature, highlighting a drop in the capacitances of manganese oxides during the increase in the active mass and therefore during the film thickness [19]. Therefore, the performance of the produced electrodes' electrochemical reactions is adversely impacted by the increase in the mass of manganese oxides deposited on MCP. Compared to other electrodes, the MCP-Mn3O4 (0.7) electrode has a high specific capacitance value and can sustain a high current density. According to Equation (2), we can calculate the specific capacities of the MCP- Mn_3O_4 (0.7), MCP- Mn_3O_4 (5.6) and MCP- Mn_3O_4 (24.6) electrodes at different current densities from the discharge time. These measurements were made for six current values (Figure 6b). It is clear that for the three electrodes, as the charge/discharge current increases, the specific capacity decreases slightly. When applying a 1 mA/cm2 current density, the profiles clearly show that the specific capacity of MCP- Mn_3O_4 (0.7) (287.63 F/g) is greater than MCP- Mn_3O_4 (5.6), MCP- Mn_3O_4 (24.6) (133.06 and 106.67 F/g).

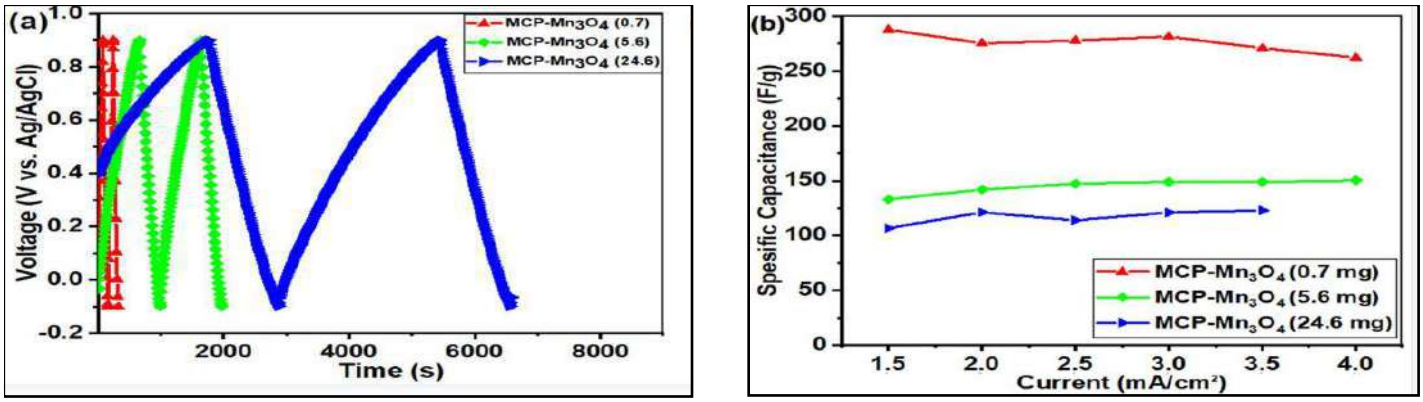

Figure 6: (a) Charge–discharge curve in 1M Na_2SO_4 aqueous solution of MCP- Mn_3O_4 (0.7), MCP- Mn_3O_4 (5.6) and MCP- Mn_3O_4 (24.6) electrodes at a current of 2 mA/cm2, (b) variation of the specific capacitance of MCP- Mn_3O_4 (0.7), MCP- Mn_3O_4 (5.6) and MCP- Mn_3O_4 (24.6) electrodes as a function of applied current.
Source: Authors, (2026).

In an aqueous electrolyte (1 M Na_2SO_4), voltammetric charge data extracted from cyclic voltammetry measurements is performed at different scan rates. These data can be analyzed using the approach developed by Ardizzone [20], [21] and by Trasatti [21-23]. They have been shown that with decreasing scanning speed the charge of the voltmeter q * decreases (v) (increases with (v)- 1/2)). The commonly accepted explanation for the dependence of q* on v is the presence of Na+ or SO4- in the boundaries of pores, grains, and cracks. In cyclic voltammetry, the measured capacity q (v) varies inversely with the potential scan rate v. When the scan rate is increased, the contribution of the least accessible sites decreases, and the reliance of q* on v is typically explained by the presence of Na+ or SO_4 - within the confines of pores, fractures, and grains. As a result, the electrode's outer surface is where the majority of protons are consumed at high scanning speeds. This limits proton access to surfaces that are difficult to access from the electrode. Thus, electrochemical reactions occur only on surfaces easily accessible to protons (the external active surface). Figure 7a shows a plot of q as a function of the opposite of the square root of the scanning speed ($v^{-1/2}$). It is possible to calculate the outer capacity (C_{ou}) by the extrapolation of $v^{-1/2}$ to infinity, this is coupled to the charge in the most accessible active area. A plot of q* versus the square root of the scanning speed ($v^{1/2}$) is shown in Figure 7b. Conversely, the total capacitance (C_T) will be determined by extrapolating q* to v = 0, which concerns all the inner and outer active sites; the difference between the two capacitances (C_{ou} and C_T) indicates the capacitance associated with the internal active surface charge (C_{in}).

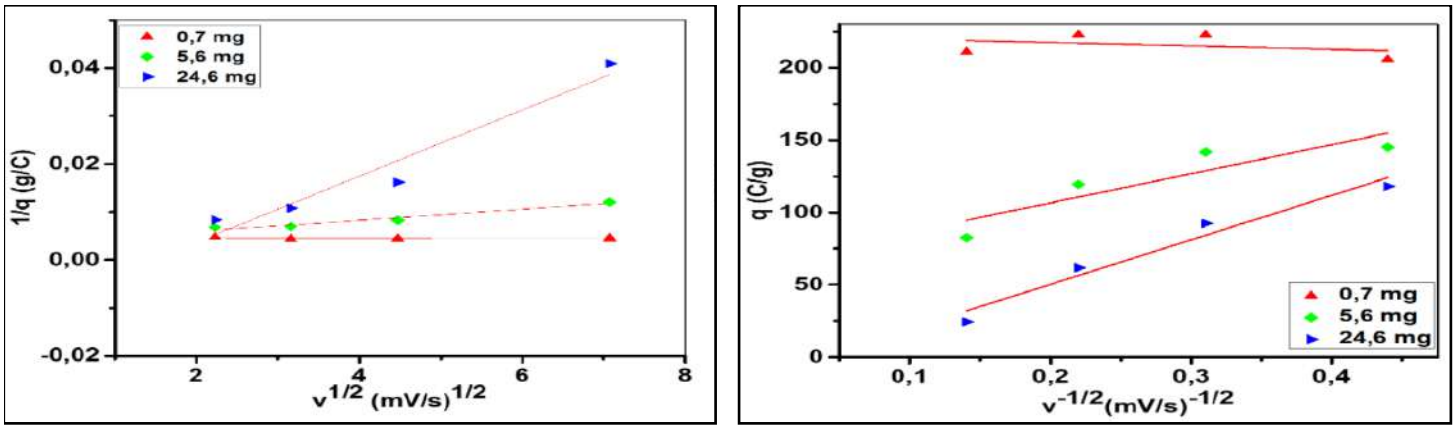

Figure 7: Variation of the voltammetric charge (q) for the sweep rate v: (a) extrapolation of (q) to v = ∞ from the q vs $v^{-1/2}$ plot gives the outer charge q_{ou}, (b) extrapolation of q to v = 0 from 1/q vs $v^{1/2}$ plot gives the total charge q_T.
Source: Authors, (2026).

It is therefore possible to determine the contribution of each of the outer and inner layers to the total capacity. In the case of MCP-Mn_3O_4 (0.7), the total capacity is approximately equal to the outer layer, which underlines the importance of the accessibility of the active sites for a power electrode. In addition, by increasing the amount of Mn_3O_4 on the MCP electrode, the limited accessibility of the surface-active sites in thick electrodes was measured by measuring a decrease in the value of q_{ou} (Table 1).

Table 1: Distribution of Outer (q_{ou}) and Inner (q_{in}) Charge Contributions as a Function of Mn_3O_4 Mass Loadin.

Électrode	q_{ou}	q_T	q_{In}	q_{In}/q_T	q_{ou}/q_T
MCP- Mn_3O_4 (0.7)	219	222	3	0.013	0.98
MCP- Mn_3O_4 (5.6)	77	243	166	0.68	0.31
MCP- Mn_3O_4 (24.6)	4	333	329	0.98	0.012

The increased number of inaccessible sites caused by the electrode film's growing thickness accounts for the decrease in the outer layer's contribution. Figure. 8 shows a schematic representation of the impact of the thickness of an active material film on-site accessibility.

Figure 9a shows the CV of the MCP- Mn_3O_4 (0.7) electrode before and after cycling. After 1000 cycles, the CV of MCP- Mn_3O_4 (0.7) may lose their rectangular shape at the level of the positive potential (between 0.4 and 0.9 V, repression current decreases), and MCP- Mn_3O_4 (0.7) has a specific capacity of 80.28%, offering excellent material stability over the entire range of cycle numbers (Figure 9b).

IV. CONCLUSIONS

Various mass loadings of MCP- Mn_3O_4 electrodes are fabricated using a drop-casting method using spontaneous reduction of MnO_4^- ions at a temperature of 150 °C in acidic media. According to X-ray diffraction data, the Mn_3O_4 thin film possessed a tetragonal crystal structure (JCPDS Card #24-0734). At ambient temperature, in a neutral aqueous electrolyte of 1 M Na_2SO_4, the electrochemical behavior of the thusly produced MCP- Mn_3O_4 electrodes with varying mass loadings was investigated and understood. The voltage range between -0.1 and 0.9 V/Ag/AgCl showed outstanding pseudocapacitive behavior in all MCP- Mn_3O_4 electrodes. With increasing mass loading, the specific capacitance value continues to decline, reaching a maximum of 232 F/g for 0.7 mg cm-2 mass loading of Mn_3O_4. This indicates that there are low contact resistances, ideal capacitive behavior fast ion diffusion in the electrode MCP- Mn_3O_4 (0.7). All results proved that the thinner mass loading MCP- Mn_3O_4 is useful for electrochemical supercapacitor applications.

Finite element analysis (3D FEA).

ABSTRACT

This study investigates the stress distribution in porous, functionally graded sandwich plates by combining analytical methods with three-dimensional finite element analysis. A novel higher-order displacement theory incorporating shear and normal effects is utilized. In the absence of a shear correction factor, the transverse shear stresses vanish at the upper and lower surfaces of the plate. The results highlight the influence of thickness on stress distribution and through-thickness displacement, with comparisons between models that include and exclude thickness effects. Finite element simulations are employed to verify the analytical results. The impact of key parameters, such as porosity and plate thickness, is also examined.

I. INTRODUCTION

Functionally graded materials are materials or structural systems whose properties vary smoothly with spatial position to achieve optimal structural performance. By grading the volume fraction, morphology, and placement of the reinforcement, and by tailoring the matrix alloy (metal) and reinforcement material (ceramic), designers achieve smooth spatial changes in properties. The most basic forms of FGMs involve a continuous transition between two distinct constituents. Discrete, stepwise gradation may be used as a practical approximation, provided it is designed to emulate an underlying continuous gradient. Based on composition, FGMs are commonly categorized as metal-based or ceramic-based. Characteristics that are usually regarded as incompatible may be combined in functionally graded materials (FGMs), such as metals' hardness, strength, machinability, and bonding properties, together with heat resistance, wear resistance, and oxidation resistance, all without causing significant internal stress. The idea of improving the quality of materials by mixing components has been known since the creation of steel. In nature, bamboo exhibits a graded structure at the macroscale, increasing strength in concentrated areas. Bone, however, is generally regarded as a porous composite rather than a graded material. In the 1950s–1970s, researchers in the United States periodically investigated composite materials.
