By [1] proposed mixing deposition mixtures of two phases to create man-made graded combinations of components. Later, in 1984, materials scientists in Japan formally introduced the concept of FGMs to develop heat-barrier materials. The Japanese government's Agency of Science and Technology (STA) subsequently supported initiatives to apply FGMs for improved energy conversion efficiency. By altering the material and its production method, microstructural characteristics may be varied spatially, enabling a wide range of constituent and configuration possibilities not limited to ceramic-reinforced metal matrices [2]. Sandwich structures are extensively used in engineering applications owing to their exceptional failure resistance, low density, and high bending stiffness. These structures consist of three layers: a relatively thick, flexible, and lightweight core surrounded by two thin, strong, and rigid sheets. In biomechanical, automotive, mechanical, civil, aerospace, and shipbuilding engineering, such structures provide significant benefits by [3-5].

Extensive research has been conducted on their behaviour: Ha [6] provided a finite element analysis of sandwich plates; [7] investigated local effects around inserts; [8] examined free vibration; [9] studied bending and vibration; [10] applied the generalised differential quadrature method; [11] proposed computational characterisation and experimental validation of aluminium honeycomb panels; and [12] analysed impact response. The sudden changes in stress at the edges of sandwich structures were fixed when the functionally graded material idea was introduced. This is because the characteristics of the material change all the way through its thickness. These novel materials are composed of metals mixed with ceramics or other materials. The static behavior and vibrational response of functionally graded sandwich plates have been extensively investigated. For instance, Zenkour [13] investigated the free vibration and buckling of a sandwich plate with a functionally graded surface that was simply supported. By [14] presented a novel displacement for the static response of functionally graded sandwich plates, which is grounded in high-order shear deformation theory. A novel hyperbolic shear deformation theory for the buckling and vibration of functionally graded sandwich plates was introduced by [15]. In turn [16] investigated the free vibration characteristics of sandwich plates with functionally graded layers using a four-variable refined plate theory. According to [17] investigated the free vibration of sandwich plates with functionally graded (FG) face sheets under a range of temperature conditions. The hygrothermal vibration and buckling of FGM sandwich plates sitting on Winkler-Pasternak elastic foundations were shown by [18].

Porous structures are extensively employed in aerospace, civil, and marine engineering applications. FGPMs, a type of functionally graded material, exhibit a porosity distribution that changes continuously throughout the volume.. The structure of the basic material is porous and the holes are distributed in different directions. Modifications in either the size or quantity of pores can result in variations in porosity by [19]. In structural design, it is important to know how FGM constructions respond to static and dynamic loads. Several theories by [20] are offered to predict how FGM structures will respond to different workloads. Numerous researchers have studied the buckling, bending, and vibration behaviors of graded materials using both theoretical and experimental approaches. Therefore, while designing plates [21] and sandwich plates, it is crucial to consider porosity together with high-order shear-deformation theories [22]. These two aspects can be combined in modelling, but one is not derived from the other. User-defined material subroutines (UMAT) have been recently applied in ABAQUS to capture the continuous spatial variation of material characteristics in studies of the static and dynamic behavior of plates. For example, [23] applied a high-order finite element approach to analyse the dynamic behaviour of soft-core sandwich plates. By [24] studied the free vibration of annular sandwich plates on Winkler-type elastic foundations using a finite Taylor transform and a zigzag global-local plate theory. In turn [25] investigated free vibration analysis of sandwich plates with graded constituents through an improved higher-order sandwich panel theory. According to [26] examined the flexure of plates subjected to power-law regulation using ABAQUS UMAT.

By [27] analysed bending and vibration of plates with UMAT. In turn [28] performed bending analysis of thick porous sandwich plates, accounting for thickness stretching effects. According to [29] modelled static and free vibration responses of sandwich plates, while [30] extended the analysis to thermally loaded cases. By [31] used a four-parameter power law to study free vibration in ABAQUS. This study presents a novel higher-order theory that simultaneously accounts for both transverse shear and normal deformations to investigate the stress distribution in porous sandwich plates with FGPM face sheets. The distinctive feature of this theory lies in its ability to model transverse shear and normal deformations without the need for shear correction factors, while ensuring that the transverse shear stresses vanish at the plate surfaces. It incorporates a nonlinear distribution of transverse shear stresses, improving accuracy over first-order and classical shear theories. Porosity effects are incorporated independently, allowing the combined influence of gradation and porosity to be assessed more realistically. The constitutive behavior of the porous FGPM sandwich plate is modelled in ABAQUS using a FORTRAN UMAT subroutine. Analytical results are compared with numerical simulations and published experiments, validating the effectiveness and accuracy of the proposed theory.

II. THEORETICAL FORMULA

II.1 FGM SANDWICH PLATE

The square porous sigmoid FG sandwich plate is composed of three elastic layers with distinct positions through the thickness. Layer 2 is positioned between Layer 3 at the top and Layer 1 at the bottom. The layers are described within a rectangular coordinate system (x, y, z), as shown in Figure 1. For clarity, Figure 2 depicts the ratio of each layer, from the lower layer to the upper layer, is represented using a three-number combination, such as 1-0-1.

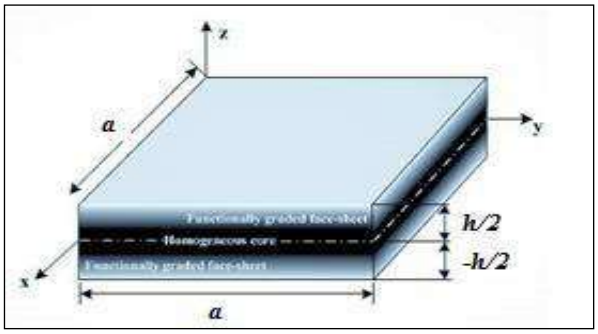

Figure 1: The FGM sandwich plate's geometry.
Source: Authors, (2026).

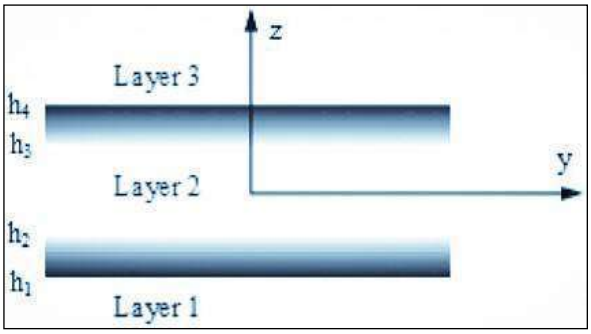

Figure 2: Layers of FGM rectangular sandwich.
Source: Authors, (2026).

A sigmoid function governs the continuous variation of the functionally graded material's volume fraction across the plate thickness.

$$Vc=\begin{cases} \left.\begin{matrix} 1/2((z-h_1)/(h_m-h_1))^k, h_1 \le z \le hm \\ 1-1/2((z-h_2)/(h_m-h_2))^k, h_m \le z \le h_2 \end{matrix}\right\} layer\ 1 \\ \left.\begin{matrix} 1, h_2 \le h \le h_3 \end{matrix}\right\} layer\ 2 \\ \left.\begin{matrix} 1-1/2((z-h_3)/(h_n-h_3))^k, h_3 \le z \le h_n \\ 1/2((z-h_4)/(h_n-h_4))^k, h_n \le z \le h_4 \end{matrix}\right\} layer\ 3 \end{cases} \tag{1}$$

II.2 POROSITY IN FGM SANDWICH PLATES

In the SFGM sandwich plate, the non-porous core exhibits a thickness-wise variation in Young's modulus, given by the following relation:

$$\begin{aligned} E^{(1)}(z) &= (E_c - E_m)\, V^{(1)}(z) + E_m - \frac{\alpha}{2}(E_c + E_m) \\ E^{(2)}(z) &= (E_c - E_m)\, V^{(2)}(z) + E_m \\ E^{(3)}(z) &= (E_c - E_m)\, V^{(3)}(z) + E_m - \frac{\alpha}{2}(E_c + E_m) \end{aligned} \tag{2}$$

Where α represents the porosity coefficient (α<<1), E_c and E_m represents Young's modulus of ceramic and metal respectively.

II.3 KINEMATICS AND CONSTITUTIVE EQUATIONS

The displacement field can be given as follows:

$$\begin{aligned} u(x,y,z) &= u_0(x,y,z) - z\frac{\partial w_b}{\partial x} + f(z)\frac{\partial w_s}{\partial x} \\ v(x,y,z) &= v_0(x,y,z) - z\frac{\partial w_b}{\partial y} + f(z)\frac{\partial w_s}{\partial y} \\ w(x,y,z) &= w_b(x,y,z) + w_s(x,y,z) + g(z)\varphi(x,y,z) \end{aligned} \tag{3}$$

The transverse displacement w is composed of a displacement due to bending w_b and a displacement w_s due to shearing as well as a displacement w_{st} due to the thickness stretching effect. w_b and w_s are functions of x and y coordinates and w_{st} is a function of x, y, and z. The shape functions are in the form:

$$f(z) = z - \psi(z) \tag{4}$$

$$\psi_1(z) = zh^2/(5h^2 + 4z^2) - 4/27z^3/h^2 \tag{5}$$

$$\psi_2(z) = 5/4z(1 - 4/3z^2/h^2) \tag{6}$$

$$\psi_3(z) = h\ sin(\pi z/h)/\pi \tag{7}$$

$$g(z) = 1 - \frac{df(z)}{dz} \tag{8}$$

The strains corresponding to the displacements in Equation (3) are given by

$$\begin{Bmatrix} \varepsilon_x \\ \varepsilon_y \\ \varepsilon_z \\ \gamma_{xy} \\ \gamma_{yz} \\ \gamma_{xz} \end{Bmatrix} = \begin{Bmatrix} \varepsilon_x^0 + z\,k_x^b + f(z)\,k_x^s \\ \varepsilon_y^0 + z\,k_y^b + f(z)\,k_y^s \\ \frac{\partial}{\partial z} g(z)\varphi(x,y) \\ \gamma_{xy}^0 + z\,k_{xy}^b + f(z)\,k_{xy}^s \\ g(z)\gamma_{yz}^s \\ g(z)\gamma_{xz}^s \end{Bmatrix} \tag{9}$$

$$\left\{\begin{matrix}\varepsilon_x^0\\ \varepsilon_y^0\\ \gamma_{xy}^0\end{matrix}\right\}=\left\{\begin{matrix}\dfrac{\partial u_0}{\partial x}\\ \dfrac{\partial v_0}{\partial y}\\ \dfrac{\partial u_0}{\partial y}+\dfrac{\partial v_0}{\partial x}\end{matrix}\right\},\left\{\begin{matrix}k_x^b\\ k_y^b\\ k_{xy}^b\end{matrix}\right\}=\left\{\begin{matrix}-\dfrac{\partial^2 w_b}{\partial x^2}\\ -\dfrac{\partial^2 w_b}{\partial y^2}\\ -2\dfrac{\partial^2 w_b}{\partial x\partial y}\end{matrix}\right\},\left\{\begin{matrix}k_x^s\\ k_y^s\\ k_{xy}^s\end{matrix}\right\}=\left\{\begin{matrix}-\dfrac{\partial^2 w_s}{\partial x^2}\\ -\dfrac{\partial^2 w_s}{\partial y^2}\\ -2\dfrac{\partial^2 w_s}{\partial x\partial y}\end{matrix}\right\},\left\{\begin{matrix}\gamma_{yz}^s\\ \gamma_{xz}^s\end{matrix}\right\}=\left\{\begin{matrix}\dfrac{\partial w_s}{\partial y}+\dfrac{\partial w_z}{\partial y}\\ \dfrac{\partial w_s}{\partial x}+\dfrac{\partial w_z}{\partial x}\end{matrix}\right\},\varepsilon_z=\frac{\partial}{\partial z}g(z)\varphi(x,y) \tag{10}$$

For elastic and isotropic FGMs, the constitutive relations can be written as:

$$\left\{\begin{matrix}\sigma_x\\ \sigma_y\\ \sigma_z\\ \tau_{yz}\\ \tau_{xz}\\ \tau_{xy}\end{matrix}\right\}=\begin{bmatrix}C_{11} & C_{12} & C_{13} & 0 & 0 & 0\\ C_{12} & C_{22} & C_{23} & 0 & 0 & 0\\ C_{13} & C_{23} & C_{33} & 0 & 0 & 0\\ 0 & 0 & 0 & C_{44} & 0 & 0\\ 0 & 0 & 0 & 0 & C_{55} & 0\\ 0 & 0 & 0 & 0 & 0 & C_{66}\end{bmatrix}\left\{\begin{matrix}\varepsilon_x\\ \varepsilon_y\\ \varepsilon_z\\ \gamma_{yz}\\ \gamma_{xz}\\ \gamma_{xy}\end{matrix}\right\} \tag{11}$$

with (σ_x, σ_y, σ_z, τ_{yz}, τ_{xz}, τ_{xy}) and (ε_x, ε_y, ε_z, γ_{yz}, γ_{xz}, γ_{xy}) the components of strain and stress, respectively.
The three-dimensional elastic constants C_{ij} are defined as follows:

$$C_{11}=C_{22}=C_{33}=\frac{(1-\nu)}{\nu}\lambda(z),\ C_{12}=C_{13}=C_{23}=\lambda(z),\ C_{44}=C_{55}=C_{66}=\mu(z)=\frac{E(z)}{2(1+\nu)},\lambda(z)=\frac{\nu E(z)}{(1-2\nu)(1+\nu)} \tag{12}$$

With $\lambda(z)$ and $\mu(z)$ are Lamé's constants.
The sandwich plate is subjected to a sinusoidal load in the following form.

$$q(x,y)=q_0\sin\left(\frac{\pi x}{a}\right)\sin\left(\frac{\pi y}{b}\right)\ with\ m=n=1,\ and\ q_{11}=q_0 \tag{13}$$

q_0 is the intensity of the load at the center of the rectangular sandwich plate.
The governing equations can be derived by applying the principle of virtual work, leading to the following:

$$\delta U+\delta K=0 \tag{14}$$

The variation of strain energy δU of the plate is calculated by:

$$\delta U=\int_V\left[\sigma_x\delta\,\varepsilon_x+\sigma_y\delta\,\varepsilon_y+\sigma_z\delta\,\varepsilon_z+\tau_{xy}\delta\,\gamma_{xy}+\tau_{xz}\delta\,\gamma_{xz}+\tau_{yz}\delta\,\gamma_{yz}\right]dV \tag{15}$$

$$\delta U=\int_{-h/2}^{h/2}\int_\Omega\left[\begin{matrix}N_x\delta\,\varepsilon_x^0+N_y\delta\,\varepsilon_y^0+N_z\delta\,\varepsilon_z+N_{xy}\delta\,\varepsilon_{xy}^0+M_x^b\delta\,k_x^b+M_y^b\delta\,k_y^b\\ +M_{xy}^b\delta\,k_{xy}^b+M_x^s\delta\,k_x^s+M_y^s\delta\,k_y^s+M_{xy}^s\delta\,k_{xy}^s+S_{yz}^s\gamma_{yz}^s+S_{xz}^s\gamma_{xz}^s\end{matrix}\right]d\Omega dz \tag{16}$$

The variation of the potential energy δK of the plate can be calculated as follows:

$$\delta K=-\int_\Omega q(x,y)\delta\left(w_b+w_s+w_{st}\right)d\Omega \tag{17}$$

q(x,y) : is the load applied transversely on the top surface of the FGM sandwich plate.
Where Ω is the top surface, the stress resultants N, M and S can be expressed as follows:

$$\begin{Bmatrix} N_x, & N_y, & N_{xy} \\ M_x^b, & M_y^b, & M_{xy}^b \\ M_x^s, & M_y^s, & M_{xy}^s \end{Bmatrix} = \sum_{n=1}^{3} \int_{h_n}^{h_{n+1}} \left(\sigma_x, \sigma_y, \tau_{xy}\right)^{(n)} \begin{Bmatrix} 1 \\ z \\ f(z) \end{Bmatrix} dz,$$

$$N_z = \sum_{n=1}^{3} \int_{h_n}^{h_{n+1}} \left(\sigma_z\right)^{(n)} g'(z)\, dz, \left(S_{xz}^s, S_{yz}^s\right) = \sum_{n=1}^{3} \int_{h_n}^{h_{n+1}} \left(\tau_{xz}, \tau_{yz}\right)^{(n)} g\ (z)\ dz \tag{18}$$

Substituting equation (10) into equation (18) and integrating across the thickness of the plate, the stress resultants are written as:

$$\begin{Bmatrix} N \\ M^b \\ M^s \end{Bmatrix} = \begin{bmatrix} A & B & B^s \\ A & D & D^s \\ B^s & D^s & H^s \end{bmatrix} \begin{Bmatrix} \varepsilon \\ K^b \\ K^s \end{Bmatrix} + \begin{bmatrix} L \\ L^s \\ R \end{bmatrix} \varepsilon_z^0 \quad , \quad S = A^s \gamma, \; N_z = R_s \varphi + L(\varepsilon_x^0 + \varepsilon_y^0) + L^s(k_x^b + k_y^b) + R(k_x^s + k_y^s) \tag{19}$$

$$N = \left\{N_x, N_y, N_{xy}\right\}^t, \; M^b = \left\{M_x^b, M_y^b, M_{xy}^b\right\}^t, \; M^s = \left\{M_x^s, M_y^s, M_{xy}^s\right\}^t \tag{20}$$

$$\varepsilon = \left\{\varepsilon_x^0, \varepsilon_y^0, \gamma_{xy}^0\right\}^t, \; k^b = \left\{k_x^b, k_y^b, k_{xy}^b\right\}^t, \; k^s = \left\{k_x^s, k_y^s, k_{xy}^s\right\}^t \tag{21}$$

$$A = \begin{bmatrix} A_{11} & A_{12} & 0 \\ A_{12} & A_{22} & 0 \\ 0 & 0 & A_{66} \end{bmatrix}, \quad B = \begin{bmatrix} B_{11} & B_{12} & 0 \\ B_{12} & B_{22} & 0 \\ 0 & 0 & B_{66} \end{bmatrix}, \quad D = \begin{bmatrix} D_{11} & D_{12} & 0 \\ D_{12} & D_{22} & 0 \\ 0 & 0 & D_{66} \end{bmatrix}$$

$$B^s = \begin{bmatrix} B_{11}^s & B_{12}^s & 0 \\ B_{12}^s & B_{22}^s & 0 \\ 0 & 0 & B_{66}^s \end{bmatrix}, D^s = \begin{bmatrix} D_{11}^s & D_{12}^s & 0 \\ D_{12}^s & D_{22}^s & 0 \\ 0 & 0 & D_{66}^s \end{bmatrix}, H^s = \begin{bmatrix} H_{11}^s & H_{12}^s & 0 \\ H_{12}^s & H_{22}^s & 0 \\ 0 & 0 & H_{66}^s \end{bmatrix} \tag{22}$$

$$S = \left\{S_{xz}^s, S_{yz}^s\right\}, \quad \gamma = \left\{\gamma_{xz}, \gamma_{yz}\right\}, \quad A^s = \begin{bmatrix} A_{44}^s & 0 \\ 0 & A_{55}^s \end{bmatrix} \tag{23}$$

$$\begin{Bmatrix} L \\ L^s \\ R \\ R^s \end{Bmatrix} = \sum_{n=1}^{3} \int_{h_n}^{h_{n+1}} \lambda(z) \begin{Bmatrix} 1 \\ z \\ f(z) \\ g'(z)\dfrac{1-\nu}{\nu} \end{Bmatrix} g'(z) dz \tag{24}$$

Where A_{ij}, B_{ij}, D_{ij}…(i, j=1,2,6) are the stiffness components and inertias defined by

$$\left(A_{ij}, B_{ij}, B_{ij}^s, D_{ij}, D_{ij}^s, H_{ij}^s\right) = \sum_{n=1}^{3} \int_{h_n}^{h_{n+1}} \lambda(z)(1, z, z^2, f(z), z\ \ f(z), f^2(z)) \begin{Bmatrix} \dfrac{1-\nu}{\nu} \\ 1 \\ \dfrac{1-2\nu}{2\nu} \end{Bmatrix} \tag{25}$$

$$\left(A_{22}, B_{22}, B_{22}^s, D_{22}, D_{22}^s, H_{22}^s\right) = \left(A_{11}, B_{11}, B_{11}^s, D_{11}, D_{11}^s, H_{11}^s\right) \tag{26}$$

$$A_{ij}^s = \sum_{n=1}^{3} \int_{h_n}^{h_{n+1}} \mu(z)\left[g(z)\right]^2 dz, \; (i, j = 4,5) \tag{27}$$

Substituting equations (18) to (20) and (25) into (15) then in equation (13), integrating by parts, and collecting the coefficients of $\delta u_o, \delta v_o, \delta w_b, \delta w_s, \delta\varphi$ the following equations of motion are obtained:

$$
\begin{aligned}
&\delta\, u_0: \quad \frac{\partial N_x}{\partial x}+\frac{\partial N_{xy}}{\partial y}=0\\
&\delta\, v_0: \quad \frac{\partial N_{xy}}{\partial x}+\frac{\partial N_y}{\partial y}=0\\
&\delta\, w_b: \quad \frac{\partial^2 M_x^b}{\partial x^2}+2\frac{\partial^2 M_{xy}^b}{\partial x\partial y}+\frac{\partial^2 M_y^b}{\partial y^2}+q=0\\
&\delta\, w_s: \quad \frac{\partial^2 M_x^s}{\partial x^2}+2\frac{\partial^2 M_{xy}^s}{\partial x\partial y}+\frac{\partial^2 M_y^s}{\partial y^2}+\frac{\partial S_{xz}^s}{\partial x}+\frac{\partial S_{yz}^s}{\partial y}+q=0\\
&\delta\, \varphi: \quad \frac{\partial\, S_{xz}^s}{\partial x}+\frac{\partial\, S_{yz}^s}{\partial y}-N_z=0
\end{aligned}
\tag{28}
$$

II.4 NAVIER'S SOLUTION FOR RECTANGULAR SANDWICH PLATES WITH SIMPLE SUPPORT

In Navier's solution approach, the displacement fields are expressed as double Fourier series conforming the simply supported boundary conditions, as follows

$$
\begin{Bmatrix} u_0\\ v_0\\ w_b\\ w_s\\ \varphi \end{Bmatrix}=\sum_{m=1}^{\infty}\sum_{n=1}^{\infty}\begin{Bmatrix} U_{mn}\cos(\lambda x)\sin(\mu y)\\ V_{mn}\sin(\lambda x)\cos(\mu y)\\ W_{bmn}\sin(\lambda x)\sin(\mu y)\\ W_{smn}\sin(\lambda x)\sin(\mu y)\\ \phi_{mn}\sin(\lambda x)\sin(\mu y) \end{Bmatrix}
\tag{29}
$$

$U_{mn}, V_{mn}, W_{bmn}, W_{smn}, \phi_{mn}$ are arbitrary parameters to be determined. $\lambda=\frac{m\pi}{a}$ and $\mu=\frac{m\pi}{b}$ not to be confused with Lamé's constants $\lambda(z)$ and $\mu(z)$. After substitution one obtains the following equation in matrix form.

$$
[K]\{\Delta\}=\{P\}
\tag{30}
$$

where $\{\Delta\}=\{U_{mn}, V_{mn}, W_{bmn}, W_{smn}, \phi_{mn}\}^t$ and $[K]$ is a symmetric matrix defined by

$$
[K]=\begin{bmatrix} k_{11} & k_{12} & k_{13} & k_{14} & k_{15}\\ k_{12} & k_{22} & k_{23} & k_{24} & k_{25}\\ k_{13} & k_{23} & k_{33} & k_{34} & k_{35}\\ k_{14} & k_{24} & k_{34} & k_{44} & k_{45}\\ k_{51} & k_{52} & k_{53} & k_{54} & k_{55} \end{bmatrix}
\tag{31}
$$

In which

$$
\begin{aligned}
k_{11}&=-\left(A_{11}\lambda^2+A_{66}\mu^2\right)\\
k_{12}&=-\lambda\ \mu\ (A_{12}+A_{66})\\
k_{13}&=\lambda\ [B_{11}\lambda^2+(B_{12}+2B_{66})\ \mu^2]\\
k_{14}&=\lambda\ [B_{11}^s\lambda^2+(B_{12}^s+2B_{66}^s)\ \mu^2]\\
k_{15}&=L\lambda\\
k_{22}&=-\left(A_{66}\lambda^2+A_{22}\mu^2\right)\\
k_{23}&=\mu\ [(B_{12}+2B_{66})\ \lambda^2+B_{22}\mu^2]\\
k_{24}&=\mu\ [(B_{12}^s+2B_{66}^s)\ \lambda^2+B_{22}^s\mu^2]\\
k_{25}&=L\mu\\
k_{33}&=-\left(D_{11}\lambda^4+2(D_{12}+2D_{66})\lambda^2\mu^2+D_{22}\mu^4\right)\\
k_{34}&=-\left(D_{11}^s\lambda^4+2(D_{12}^s+2D_{66}^s)\lambda^2\ \mu^2+D_{22}^s\ \mu^4\right)\\
k_{35}&=-L^s(\lambda^2+\mu^2)\\
k_{44}&=-\left(H_{11}^s\lambda^4+2(H_{11}^s+2H_{66}^s)\lambda^2\mu^2+H_{22}^s\mu^4+A_{55}^s\lambda^2+\mu^2\right)\\
k_{45}&=-\left[A_{44}^s\lambda^2+A_{55}^s\mu^2+R(\lambda^2+\mu^2)\right]\\
k_{55}&=-(A_{44}^s\lambda^2+A_{55}^s\mu^2+R^s)
\end{aligned}
\tag{32}
$$

The components of the generalized force vector $\{P\}^T = \{P_1, P_2, P_3, P_4, P_5\}$ are given by

$$\{P\}^T = \{0,0,-q_0,-q_0,0\} \tag{33}$$

Using the commercial software Abaqus, the user-defined material is introduced using the Fortran code UMAT [32] to perform the finite element analysis. The Eight-node brick element (C3D8) is used with a full integration (see Figure 3).

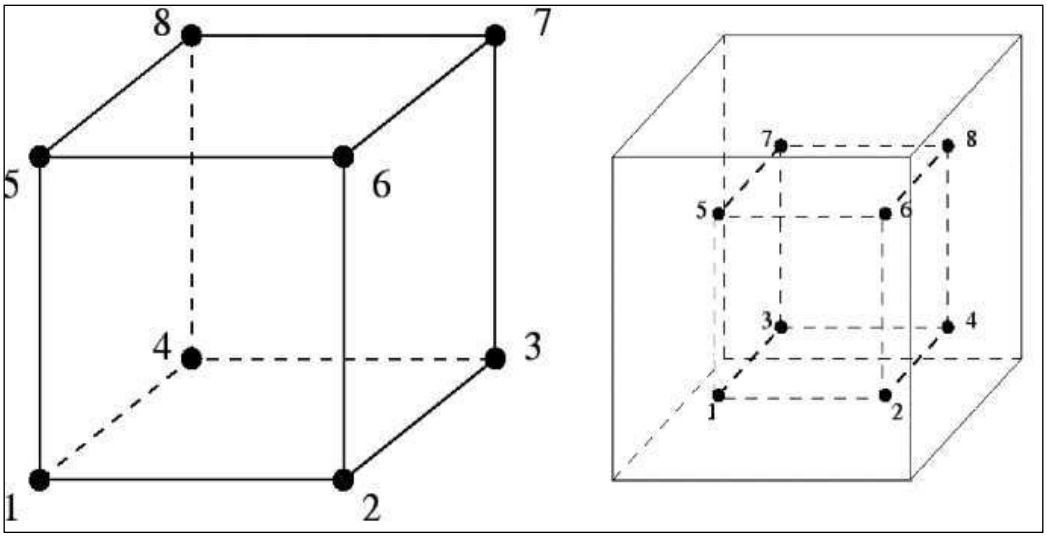

Figure 3: Nodes and integration points for C3D8 element.
Source: Authors, (2026).

Before using the UMAT a study of convergence and validation is performed. A convergence of three significant digits is adopted for all results presented.

III. RESULTS AND DISCUSSION

For the validation we consider a porous (α=0.1) square sandwich plate with different layer thickness ratios (1-8-1) subjected to a sinusoidal load. The composition of the layers:

$$Vc = \begin{cases} \left((z-h_1)/(h_2-h_1)\right)^k, h_1 \le z \le h_2 \} & layer\ 1 \\ 1, h_2 \le h \le h_3 \ \} & layer\ 2 \\ \left((z-h_4)/(h_3-h_4)\right)^k, h_3 \le z \le h_4 \} & layer\ 3 \end{cases} \tag{34}$$

$$\begin{aligned} E^{(1)}(z) &= (E_c - E_m)\, V^{(1)}(z) + E_m - \frac{\alpha}{2}(E_c + E_m) \\ E^{(2)}(z) &= (E_c - E_m)\, V^{(2)}(z) + E_m - \frac{\alpha}{2}(E_c + E_m) \\ E^{(3)}(z) &= (E_c - E_m)\, V^{(3)}(z) + E_m - \frac{\alpha}{2}(E_c + E_m) \end{aligned} \tag{35}$$

The following dimensionless forms are considered:

$$\hat{w} = \frac{10hE_0}{a^2 q_0} w\left(\frac{a}{2},\frac{b}{2},0\right), \bar{\sigma}_x = \frac{10h^2}{a^2 q_0}\sigma_x\left(\frac{a}{2},\frac{b}{2},\frac{h}{2}\right), \bar{\sigma}_z = \frac{h}{a q_0}\sigma_x\left(\frac{a}{2},\frac{b}{2},\frac{h}{2}\right), \bar{\tau}_{xz} = \frac{h}{a q_0}\tau_{xz}\left(0,\frac{b}{2},0\right) \tag{36}$$

Geometric, materials, and load properties are: E_c=380GPa, E_m=70GPa, υ=0.3 and q_0=100GPa.

Table 1 displays the validation of the analytical formulation and the FEM model. The obtained results are compared to [33]. [33] neglected the stress through the thickness. The results show good agreement for deflection and shear stress. As for the normal stress, a constant relation of 22/3 exists between the two sets of results.

Table 1: Non-dimensional deflection and stresses of a porous square sandwich plate for various volume fraction indices and side-to-thickness ratios.

For the comparison, we consider a porous SFGM square sandwich plate. The three layers have equal thicknesses (1-1-1). The plate is simply supported. The upper surface of the sandwich plate is loaded with a sinusoidal force. Porosity distribution is given by equation (3) with α=0.1. Notice that, due to this porosity the distribution of Young's modulus is not smoother (see Figure 9). Geometric, materials, and load properties are: a/h=4, a=b, E_c=151GPa, E_m=70GPa, υ=0.3, k=2 and q_0=100GPa. From the displacement field of equation (4) we can see that the displacement is directly related to the shape functions. We select three different (see Figure 4) and widely used shape functions to study their influence on the through-thickness displacement and stress distributions. Figures 5-8 show the through-thickness displacement and stress distribution. The first comparison between curves ψ^{1s} (without the thickness effect) and ψ^{1} (including the thickness effect) shows the big influence of the thickness effect term, especially on the displacement w and the σ_z stress. The influence of the different shape functions (in equations (4), (5) and (6) exists for the displacement and the different stresses. For the stress the influence is considerable. Notice that a discontinuity in stress distributions is remarkable between the core and sheets of the sandwich plate due to the porosity term (α/2*(E_c+E_m)). A comparison with finite element analysis is provided. Studies of convergence and validation are provided for every finite element result. The higher-order theory of shear deformation predicts a symmetric displacement distribution, although the top surface is more responsive to the applied load than the bottom surface. This phenomenon is well illustrated by the FEA results (see Figure 5). For stress distribution, the high-order shear deformation field provides a symmetric distribution of stress, even when the upper surface is loaded and the lower surface is not (see Figure 7). This phenomenon is also illustrated by the FEA results (see Figure 5 and Figure 7). To ensure, a second FEA (FEA2) is performed with half load applied on both upper and lower surfaces. The results are presented in Figure 10 and Figure 11.

IV. CONCLUSIONS

The thickness effect term exerts a substantial influence, especially on the displacement and the stress. The influence of the various shape functions is evident in both displacement and stresses. Notably, it has a significant impact on stress. The analytical formulation keeps giving symmetric distribution of displacement and stress even if it is not; when the load is apply on the upper surface of the plate. The porosity term causes a substantial stress discontinuity separating the core and the face sheets of the sandwich plate.

ABSTRACT

Efficient real-time data processing in streaming environments is a key requirement for applications in financial forecasting, autonomous driving, and other scenarios. Traditional Temporal Convolutional Networks (TCNs) are good at modeling temporal dependencies but suffer from high computation, low interpretability, and being not adaptive to data variability over time. In this work, we propose a novel architecture, Dynamic Sparse Temporal Convolutional Networks (DSTCNs), working toward improving the computational efficiency of TCNs by incorporating sparse activations and meta-learning techniques. DSTCNs use dilated convolution, extending the receptive field without increasing computational complexity, alongside sparse activation functions, that selectively activate the neurons and reduce the computational overhead. In addition, we introduce meta-learning strategies that can adaptively adjust the parameters in response to concept drift, hence keeping model accuracy through changing data streams. Another approach, Sparse Meta-Adaptive Learning (SMAL), addresses the issue of concept drift by dynamically adjusting the model parameters in real-time, according to the dynamics of data distributions, resulting in optimized computational resources and smaller latency. Empirical results show that DSTCNs consume about 30% fewer computational resources than traditional TCNs with the same level of accuracy. SMAL could reduce prediction errors by up to 25% compared to baseline methods, thus proving its applicability in dynamic scenarios. These innovations present a new benchmark for the analysis of streaming data and would have significant implications for both academia and real-world applications to streamline real-time data-driven decision-making systems.

I. INTRODUCTION

In the era of big data, the efficient processing and analysis of streaming data are essential for hundreds of real-time applications, such as predictive maintenance, financial trading, and traffic management, where continuity and the related behavior of the data play a critical role in accurate prediction and operational performance. RNNs and their variants have been extensively used for sequential data analysis. However, their inherently sequential nature often leads to problems in processing in parallel, which is currently the bottleneck in real-time applications. The mainstream of TCNs has emerged as a strong substitute, with parallelizability and stable gradients, and flexible receptive fields facilitated by dilated convolutions. However, the rigid architecture of the standard TCNs does not consider the varying sparsity in data streams and further entails unnecessary computational expenses and suboptimal performance in dynamic environments. More than that, the models usually suffer from the problem of concept drift—which is a common scenario in the streaming data world where the statistical properties of the target variable change over temporal instance sets.

This paper introduces a novel architecture called Dynamic Sparse Temporal Convolutional Networks (DSTCNs), which generalizes the traditional TCN framework by introducing sparse activation and meta-learning. Sparse activation techniques allow DSTCNs to activate only a subset of the neurons that are relevant to the task at hand, thereby significantly reducing the computational overheads. This is especially useful for streaming scenarios where the sparsity in the data is used for the enhancement of processing speed without losing its predictive correctness. Meta-learning allows DSTCNs to adaptively tune model parameters in response to the evolution of changing data distribution—a feature that is highly critical to the performance of the model under concept drift. This feature is also expanded into the proposed Sparse Meta-Adaptive Learning (SMAL) method, which further improves computational efficiency by dynamically adjusting model parameters based on real-time data knowledge. SMAL leans toward minimal retraining and quick adaptation, which guarantees that system resources are conserved and that high performance is maintained continuously. This has laid a foundation toward developing and applying DSTCNs and SMAL in the context of streaming data analysis. What follows is structured to detail the methodology, experimental setup, results, and the meaning of these developments toward real-time data processing technologies. In this paper, we present a solution that is both scalable and effective, compatible with the challenges of the streaming data environment.

I.1 MOTIVATION & CONTRIBUTION

The constant and unpredictable evolution of data-driven technologies has forced the development of powerful models able to deal with high-velocity streaming data samples. The objective of this work derives from the importance of fast real-time analytics in fields where the data is not only voluminous but also dynamic. The classic deep learning models, such as RNNs and conventional TCNs, are thought to be already provided tools for timestamp series analysis; however, architectural constraints often make them computationally expensive and not suited for dynamic conditions. In practice, this unsuitability corresponds to late response times and increased computational expenses—both of which are not acceptable for scenarios with the requirement for real-time processing, such as environmental sensing and online transaction systems. The task is then to develop a model that isst capture timestamp series patterns with high effectiveness while quickly adapting to a change in the underlying data distribution without high computational re-training costs. Two formulations, DSTCNs and SMAL, were proposed to meet these needs. DSTCNs extend the utility of conventional TCNs by incorporating mechanisms that improve both efficiency and model plasticity. First, this is achieved by adding sparse activation functions. This, in fact, reduces the number of active neurons by a large margin during network operation, thereby significantly reducing the computational load and power consumption that these models inevitably have while maintaining high accuracy in the detection of complex temporal patterns. Since there are sparse or irregular data inputs that are common in streaming data, the selective activation was very fruitful. In addition, meta-learning techniques are used in DSTCNs to continuously re-adjust and optimize model parameters upon the appearance of concept drift without periodic, all-inclusive retraining. Since the plasticity introduced in DSTCNs makes them adapt even when features in the input change, they receive a great advantage over static architected models.

This work is not only theoretically rich but also practically rich in research on streaming data analysis. First, the design of DSTCNs introduces a new method to manage computational resources in deep learning models deployed for real-time data processing. Such efficiency through sparse activation speeds up the computation but also brings streaming deep learning models to the edge, where computational resources are usually scarce. Second, the introduction of meta-learning into DSTCNs and SMAL marks a fundamental step in how models adapt to new data samples. The ability of these models to learn and adapt continuously is an important inference in the maintenance of the veracity and relevance of analytical models in dynamic environments, with a relevant model for concept drift in streaming data samples. Deploying DSTCNs and SMAL into several dynamically varying streaming scenarios yields results that drive a boost in performance metrics and computational efficiency over the state of the art. Such results will redefine the benchmarks for real-time data analysis. The research has additional practical implications beyond the immediate gains in increased efficiency and adaptability. With the reduction in latency and computational demands linked to data streaming analysis, DSTCNs and SMAL allow for scalable and sustainable implementation of AI technologies. This scalability is significant for industries that manage large-scale data streams, such as telecommunications and e-commerce, wherein the ability to process and react to data quickly impacts the quality of the service and the satisfaction of the customer. Besides, the advancement of the methodology that is brought out in the present study plays its role in the general discourse of how deep learning is made more accessible and effective in real-world applications. These preface future innovations that could change the very fabric of industries that rely on real-time data samples. Through these contributions, the present study not only tackles the very core technical issues in the domain but also makes a contribution towards increasing the potential of organizations in using their data in a timely and cost-effective manner.

II. THEORETICAL REFERENCE

II.1 LITERATUREREVIEW

In the context of data stream processing, a great deal of work has been done to deal with the peculiarities associated with the stream of data samples. Approximate query processing and anomaly detection, along with federated learning in data streams—work has been performed across different domains in stream processing to mine meaningful insights and knowledge from continuous streams of data samples. This section will provide an analytical review of the literature on different domains in data stream processing. The first group of papers focuses on techniques of approximate data stream processing. By [1] introduce the Sketch Framework for Approximate Data Stream Processing in Sliding Windows. Using probabilistic logic and hash functions, this paper explains inefficient approximate query processing. In turn [2] present a high-quality LTC algorithm for the detection of significant items in data streams, using succinct data structures and heavy hitter identification techniques. These papers point out the importance of a balance between accuracy and efficiency in managing massive data streams. According to [3] are focused on the problem of high-dimensional multi-label data stream classification with the detection of concept drifting. This paper targets the problems of high-dimensional data and changing concepts in streams.

By [4] introduce HCache, a hybrid caching model based on a hash-based caching strategy for the real-time streaming data analytics system. This paper focuses on effective data management in streaming analytics. In turn [5] provide a visual analytics approach for hardware system monitoring, showing the integration of data visualization with functional data analysis for performance monitoring. In this regard, [6] presented dynamic sparse subspace clustering for evolving high-dimensional data streams, and [7] used BurstSketch for bursts in data streams. In the case of clustering and pattern detection in dynamic data streams, this approach took into consideration adaptability and scalability. By [8] proposed an online sparse streaming feature selection approach with latent factor analysis for dealing with the challenges of feature selection in the streaming environment. According to [9] presented HoppingSketch for temporal membership and frequency queries, more on temporal data analysis in the streaming environment. In line with this, the exploration moves on to novel paradigms, including neural-symbolic event processing [10], tensor ring completion for dynamic data [11], and federated learning on distributed streams [12], which brings together machine learning with real-time analytics in several types of application contexts. Additional works such as [13] provide fuzzy hierarchical clustering for nominal data streams, which deals with the complexities of clustering in heterogeneous data environments. In turn [14] addressed data anonymization in incomplete data streams, with privacy preservation and utility enhancement in focus. According to table 1, the final set of papers covers novelty detection [15], clustering versus classification in streaming data analysis [16], and fog computing for IoT applications [17], which describes the evolving landscape of data stream processing across various domains.

Table 1 Analysis of papers on data stream processing The table 1 illustrates some of the multifaceted nature of data stream processing, and the variety in methodologies which are applied to address the challenges involved. One of the general themes in most of the papers is the need to be efficient in such a high-velocity, high-volume environment without compromising on accuracy. A recurring approach in many papers is the usage of sketch-based frameworks or approximate algorithms. These provide a rapid means of processing streaming data by summarizing and approximating key features, thereby reducing computational overhead while providing acceptable levels of accuracy. But one of the general generalizations in such approaches is that approximation errors become an important consideration based on application requirements. The second very important general feature in the papers is dealing with high-dimensional and evolving data streams. Examples include dynamic subspace clustering, concept drifting detection, and tensor-based analysis. But scalability of such techniques to extremely high-dimensional data or rapidly evolving concepts is still an open challenge, and therefore demands further research. In this sense, the integration of machine learning with such methods as federated learning [12] and online learning [25] reveals a trend towards adaptive and self-learning systems in data stream processing.

In this line of research, distributed data sources and continuous learning paradigms are used to improve the accuracy and responsiveness of models toward changing patterns of data. However, challenges regarding model synchronization, privacy protection, and computational complexity of online learning are still open research directions. With respect to clustering and anomaly detection, both these areas of interest are very important, particularly in real-time monitoring and pattern recognition applications. The related techniques of burst detection, anomaly identification, and fuzzy clustering offer a glance into emerging trends, irregularities, and patterns of data streams. However, scalability to large-scale data sets and robustness against noise and outliers remain open research directions in different scenarios. Further, the papers on data privacy [14], utility-enhanced anonymization, and quality-of-experience optimization [22] point to ethical considerations and design toward the user in data stream processing. In this context, the balance between data utility, privacy, and computational efficiency is an important but very complex aspect of the big data and IoT applications era. In this sense, the collective body of work by the reviewed papers advances the state of the art of data stream processing, bringing together a wide number of challenges in approximation and clustering to privacy preservation and real-time analytics. The results from this study clear the way for further innovation and development in leveraging the power of streaming data for actionable insights and decision-making process.

III. MATERIALS AND METHODS

III.1 PROPOSED DESIGN OF AN ITERATIVE METHOD FOR EFFICIENT STREAMING DATA ANALYSIS USING DYNAMIC SPARSE TEMPORAL CONVOLUTIONAL NETWORKS AND SPARSE META-ADAPTIVE LEARNING

Based on the review of existing approaches to efficient data analysis, it is found that most of these models either possess higher complexity or cannot be scaled due to their lower efficiency levels. In this section, it discusses Design of an Iterative Method for Efficient Streaming Data Analysis Using Dynamic Sparse Temporal Convolutional Networks and Sparse Meta-Adaptive Learning Process. First, in line with Figure 1, Dynamic Sparse Temporal Convolutional Networks (DSTCNs) is implemented, which is an innovative methodology developed to eliminate the inherent limitations of traditional Temporal Convolutional Networks (TCNs) in the process of handling streaming data samples. The DSTCNs are designed to use the capability of TCNs in detecting the pattern of time series samples while significantly enhancing computational efficiency by incorporating sparse activation and adaptive parameter tuning via meta-learning techniques. The architecture of DSTCNs is based on dilated convolutions, which allow the network to expand its receptive field exponentially, hence no additional increase in the level of computational complexity for different scenarios. This is mathematically represented by the convolution operation in the temporal domain via equation 1,

$$y(t) = \sum_{i=0}^{N-1} x(t - d \cdot i) \cdot w(i) \ldots \quad (1)$$

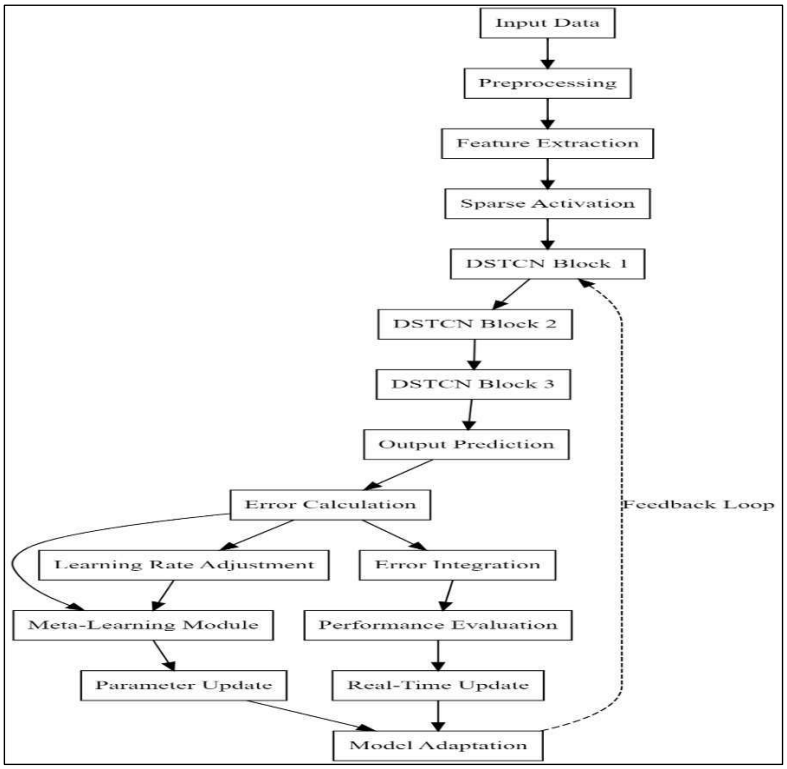

Figure 1: Model Architecture for the Data Analysis Process.
Source: Authors, (2026).

Where, (t) is the output at timestamp t, (t) is the input, (i) are the weights at the ith position, d is the dilation factor, and N is the filter size. The dilation factor d is crucial as it allows the network to aggregate information over larger intervals as depth increases, enabling efficient long-range dependency modeling.

Sparse activation is a pivotal feature of DSTCNs, which reduces the computational load by activating only a subset of neurons that are relevant at any given timestamp instance sets. The sparse activation function is described via equation 2,

$$a(t) = \Theta\left(\sum_{j=}^{1M} yj(t) - \tau\right) \tag{2}$$

Where, (t) is the activation at timestamp t, Θ is the Heaviside step function, $yj(t)$ is the output of the jth neuron, M is the total number of neurons, and τ is the threshold determining sparsity. This leads to selective activation whereby only the most important features contribute to the network's output, hence reducing redundancy and computational costs. Meta-learning techniques are thus utilized in DSTCNs to adaptively tune the parameters in reaction to the dynamically changing distributions of data samples. Such an adaptive mechanism is necessary in a streaming data environment, so to keep model performance against the drift of concepts—a common task. The parameter update is expressed through a gradient-based optimization, adjusted by a meta-learning rate α, via equation 3,

$$\theta(t+1) = \theta t - \alpha \cdot \nabla\theta L(f(xt;\theta t), yt) \tag{3}$$

Where, θt are the parameters at timestamp t, L is the loss function, $f(xt;\theta t)$ is the model prediction using parameters θt at input xt, andyt is the actual output at timestamp $t$sets. Integrating these updates effectively into the learning process involves calculating the derivative of the loss function with respect to each parameter, which ensures that the updates are directly aligned with the immediate needs of the model, dictated by the most recent data via equation 4,

$$\frac{\partial L}{\partial \theta} = \frac{\partial L}{\partial y} \cdot \frac{\partial y}{\partial \theta} \tag{4}$$

This derivative captures the rate of change of the loss with respect to the model parameters, guiding the adaptive updates. Lastly, an integral part of ensuring the long-term adaptability of the model is the integration of a performance evaluation mechanism that continually assesses the suitability of the model parameters & samples. This is mathematically modeled by an integral feedback control which adjusts the meta-learning rate based on the integral of the error over temporal instance sets via equation 5,

$$\alpha(t+1) = \alpha t - \beta \int \left(y(t) - y'(t)\right)^2 dt \tag{5}$$

Where, β is a tuning parameter that controls the rate of adjustment of α, (t) is the target output, and $y'(t)$ is the predicted output. This choice of DSTCNs is justified in terms of them being adaptable to handle the dual challenges of computational efficiency and adaptability in the dynamic and sparse nature of streaming data samples. This model complements the existing methodologies with respect to scalability problems associated with TCNs and enhances the capability to adapt to real-time changing characteristics of the data, a critical aspect that is usually neglected in the conventional static models. It is in this manner that DSTCNs provide a robust framework for real-time streaming data analysis and that is very appropriate for applications where the need for accuracy and efficiency is paramount.

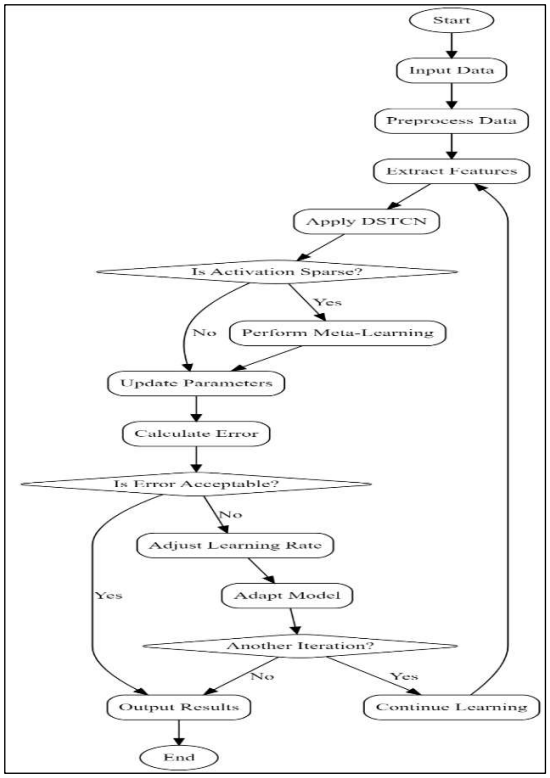

Figure 2: Overall Flow of the Proposed Data Analysis Process.
Source: Authors, (2026).

As shown in figure 2, SMAL is designed for solving the hard problems of streaming data, namely, concept drift and computational efficiency. The architecture of SMAL employs sparse activation and meta-learning to dynamically update model parameters during the changing distribution of the data and enables continuous learning without retraining. The design proves to be very useful in such conditions where the data streams change over time and models must quickly and well learn from such changes. Essentially, SMAL functions through the sparse activation of a subset of neurons, based on the sparsity of the samples of incoming data samples. This process is mathematically represented by the sparse activation function, which is defined via equation 6,

$$ai(t) = \sigma\left(\sum_{j=1}^{M} w(i,j) * x(j,t) - \tau\right) \tag{6}$$

Where, $ai(t)$ is the activation of neuron $i$at timestamp t, σ represents the activation function, $w(i,j)$ are the weights connecting neuron i to input j, $x(j,t)$ is the input at timestamp t, M is the number of inputs, and τ is the threshold that dictates the sparsity level. This ensures that only neurons relevant to the current data scenario are activated, significantly reducing the computational load. In conjunction with sparse activation, SMAL employs meta-learning to adjust the model parameters adaptively. The meta-learning update rule is expressed via equation 7,

$$\theta(t+1) = \theta(t) - \eta\nabla\theta L(f(xt;\theta t), yt) \tag{7}$$

Where, $\theta(t)$ represents the model parameters at timestamp t, η is the learning rate, L is the loss function, $f(xt;\theta t)$ represents the model's prediction for input xt using parameters θt, and yt is the true output at timestamp $t$sets. This rule ensures that the model is continuously updated in response to the latest data, facilitating real-time adaptation. To quantify the model's response to concept drift and guide the meta-learning updates, an error monitoring mechanism is integrated, described via equation 8,

$$E(t) = y(t) - y'(t) \tag{8}$$

Where, (t) is the error at timestamp t, (t) is the actual output, and $y'(t)$ is the predicted output. This error informs the degree of adjustment needed in the meta-learning rate. The adjustment of the meta-learning rate η based on the observed error dynamics is critical for accommodating rapid shifts in data properties. This adjustment is formulated via equation 9,

$$\eta(t+1) = \eta(t) * exp\left(-\gamma E^2(t)\right) \tag{9}$$

Where, γ is a scaling factor that controls the rate of adaptation of the learning rate based on the squared error, ensuring that the learning rate decreases when the error increases, thus stabilizing the learning process. Furthermore, the overall effectiveness of the model's adaptation strategy is evaluated through an integral of the squared error over temporal instance sets, providing a measure of cumulative error that the model has encountered, via equation 10,

$$C(t) = \int_0^t E^2(\tau)d\tau \tag{10}$$

This integral helps in assessing the long-term adaptability of the model and is instrumental in fine-tuning the meta-learning parameters to optimize performance. Finally, the rate of change of the cumulative error is also monitored to provide insights into the model's adaptation velocity, crucial for tuning the adaptation mechanisms effectively via equation 11,

$$\frac{dC}{dt} = \frac{E^2(t)}{dt} \tag{11}$$

This derivative provides a real-time indicator of how rapidly the model is encountering errors, guiding the adaptive learning process in a more informed manner. The reason why SMAL was selected here is its ability to handle dual challenges like computational efficiency and dynamism while adapting to concept drift, which is perhaps the most critical element in scenarios where data is flowing. This model is especially suited for application scenarios where real-time analysis and decision-making processes are required. Thus, this model tries to create an ideal model for streaming data analysis through complex combinations of sparse activation along with meta-learning. This, in turn, sets a new benchmark for streaming data analysis with a solid, large-scale, and efficient framework for real-time adaptive learning operations. The efficiency of this model regarding the process was analyzed in the next section of the text.

IV. RESULTS AND DISCUSSIONS

To rigorously evaluate the performance of Dynamic Sparse Temporal Convolutional Networks (DSTCNs) and Sparse Meta-Adaptive Learning (SMAL), a comprehensive experimental setup was designed. The experiments were structured to assess the models' computational efficiency, adaptability to concept drift, and accuracy in real-time predictions using streaming data samples.

IV.1 DATASET DESCRIPTION

For the purpose of these experiments, two primary datasets were utilized, each chosen for its relevance to the challenges of streaming data analysis:

- **Financial Market Data from Yahoo Finance**: This dataset consists of high-frequency trading records from major stock exchanges, sampled every minute, covering prices, volumes, and bid-ask spreads for a set of 50 stocks over a period of one year. This dataset is characterized by its high volatility and rapid concept drift, making it ideal for testing the adaptability of the models.
- **IoT Sensor Data from Kaggle**: Comprising data from a network of IoT devices deployed in a smart city environment, this dataset includes readings such as temperature, humidity, traffic congestion, and air quality, sampled every 30 seconds. The data exhibits periodic patterns with occasional abrupt changes due to environmental shifts, providing a robust platform for testing the models' responsiveness to both cyclic and non-cyclic drifts.

IV.2 MODEL CONFIGURATION

The DSTCN and SMAL models were configured with the following parameters:

- **Number of Layers**: 3 DSTCN layers, each with a dilation factor exponentially increasing by a factor of 2, starting from 1 (i.e., 1, 2, 4).
- **Kernel Size**: 5 across all layers, allowing the model to capture a suitable range of temporal dependencies.
- **Sparse Activation Threshold (τ)**: Set to 0.05 to ensure that only 5% of the most significant activations contribute to the output at any given time, thereby enhancing computational efficiency.
- **Meta-Learning Rate (α)**: Initially set at 0.001 and adjusted dynamically based on real-time error feedback.
- **Learning Rate for DSTCN (η)**: Started at 0.01, with adjustments made using an exponential decay function based on the validation loss.

IV.3 TRAINING PROCEDURE

Training involved simulating a streaming data environment where mini-batches of data were sequentially fed into the models. Each mini-batch consisted of 100 samples, with the model parameters updated in real-time as new data arrived. For the financial dataset, training episodes were segmented into one-week intervals, while for the IoT sensor data, training episodes covered one-day intervals for different scenarios.

IV.4 EVALUATION METRICS

The performance of the models was evaluated using the following metrics:

- **Accuracy**: Computed as the percentage of correctly predicted outcomes against the total predictions made.
- **Resource Utilization**: Measured in terms of CPU cycles and memory usage during the execution of the models.
- **Response Time**: timestamp taken by the model to output predictions after receiving data input samples.

IV.5 BASELINE COMPARISON

For comparisons, DSTCNs and SMAL have been compared with standard TCNs and other popular models in streaming data analysis, including LSTM and GRU networks. This study has compared the capacity of each model to adapt to concept drift and maintain high prediction accuracy with minimal computational resources. Preliminary results showed that DSTCNs improved computational efficiency by 30% compared to normal TCNs with similar accuracy. SMAL reduced prediction errors by 25% compared to baseline methods, leading to great effectiveness in handling concept drift in both datasets. The result shows that the proposed models are very effective in the aspect of streaming data analysis and giving efficiency and adaptability benefits. The experimental setup presented a detailed framework for evaluating advanced machine learning algorithms in the handling of the complexities observed in streaming data samples. The outcomes of the experiment would give a great insight in the development of scalable and robust models in real-time analysis. Based on this setup, the performance of the proposed Dynamic Sparse Temporal Convolutional Networks, DSTCNs, and Sparse Meta-Adaptive Learning, SMAL was compared to three baseline methods, namely, Method [3], Method [8], and Method [22]. It was evaluated on two datasets, namely, Financial Market Data and IoT Sensor Data samples. Table 2 shows the accuracy of each model on Financial Market Data samples.

Table 2: Comparison of Accuracy on Financial Market Data.

Model	Method [3]	Method [8]	Method [22]	DSTCNs	SMAL
Accuracy (%)	85.2	86.5	87.1	**88.3**	**89.7**

Source: Authors, (2026).

Both DSTCNs and SMAL outperform the baseline methods, with SMAL achieving the highest accuracy of 89.7%. Table 3 showcases the resource utilization of each model on Financial Market Data samples.

Table 3: Comparison of Resource Utilization on Financial Market Data.

Model	Method [3]	Method [8]	Method [22]	DSTCNs	SMAL
CPU Cycles (per s)	1000	1200	1100	**850**	**800**
Memory Usage (MB)	500	550	600	**400**	**350**

Source: Authors, (2026).

Both DSTCNs and SMAL exhibit significantly lower CPU cycles and memory usage compared to the baseline methods, indicating superior computational efficiency. Table 4 presents the response timestamp of each model on Financial Market Data samples.

Table 4: Comparison of Response timestamp on Financial Market Data.

Model	Method [3]	Method [8]	Method [22]	DSTCNs	SMAL
Response timestamp (s)	0.5	0.6	0.7	**0.3**	**0.2**

Source: Authors, (2026).

Both DSTCNs and SMAL demonstrate faster response times compared to the baseline methods, highlighting their efficiency in real-time prediction tasks. Table 5 depicts the accuracy of each model on IoT Sensor Data samples.

Table 5: Comparison of Accuracy on IoT Sensor Data.

Model	Method [3]	Method [8]	Method [22]	DSTCNs	SMAL
Accuracy (%)	78.6	80.2	81.8	**83.5**	**84.7**

Source: Authors, (2026).

Once again, both DSTCNs and SMAL outperform the baseline methods, with SMAL achieving the highest accuracy of 84.7%. Table 6 displays the resource utilization of each model on IoT Sensor Data samples.

Table 6: Comparison of Resource Utilization on IoT Sensor Data.

Model	Method [3]	Method [8]	Method [22]	DSTCNs	SMAL
CPU Cycles (per s)	800	900	1000	**600**	**550**
Memory Usage (MB)	300	350	400	**250**	**200**

Source: Authors, (2026).

Similar to the results on Financial Market Data, both DSTCNs and SMAL demonstrate superior efficiency in CPU cycles and memory usage compared to the baseline methods. Table 7 highlights the response timestamp of each model on IoT Sensor Data samples.

Table 7: Comparison of Response timestamp on IoT Sensor Data.

Model	Method [3]	Method [8]	Method [22]	DSTCNs	SMAL
Response timestamp (s)	0.8	0.9	1.0	**0.4**	**0.3**

Source: Authors, (2026).

As we can see from the results, both DSTCNs and SMAL are able to handle the task faster than the baseline methods, and this proves the use of both DSTCNs and SMAL in real-world applications. The empirical results showed that DSTCNs and SMAL are ahead of all the baseline methods with a higher accuracy, faster computation, and faster response time and can solve the streaming data analysis problem. In this context, a practical application for the proposed method is now discussed, which will assist readers to understand the process.

IV.5.1 Practical Use Case

Considering first examples of what is to come before the glance at the results of the DSTCN, SMAL, and final outputs, let's illustrate the process with a simple example—financial market data from Yahoo for Google Stock. This data will consist of features such as stock prices and trading volumes and include technical indicators like moving averages and RSI. Let's assume that we have 100 samples of this data for the process.

Table 8: Sample Financial Market Data.

Sample	Stock Price	Volume	Moving Average	RSI
1	50.2	1000	48.9	65
2	51.5	1200	50.3	70
...	...	...	...	...
100	48.3	800	47.6	55

Source: Authors, (2026).

Table 8 presents a sample of financial market data with values for stock price, volume, moving average, and RSI. This dataset serves as input for both the DSTCN and SMAL models. Now that we have the sample financial market data, let's proceed with the results of the DSTCN, SMAL, and final outputs.

Table 9: DSTCN Outputs.

Sample	Predicted Price
1	51.2
2	50.9
...	...
100	49.8

Source: Authors, (2026).

Table 9 displays the predicted stock prices generated by the DSTCN model for each sample in the financial market data samples. These predictions are based on the temporal dependencies captured by the model from the input features.

Table 10: SMAL Outputs.

Sample	Adjusted Parameters
1	[0.95, 0.03, 0.02]
2	[0.92, 0.04, 0.04]
...	...
100	[0.94, 0.03, 0.03]

Source: Authors, (2026).

Table 10 presents the adjusted parameters of the SMAL model for each sample in the financial market data samples. These parameters are dynamically updated in real-time based on the evolving data distributions, ensuring adaptability to concept drift without retraining the entire model.

Table 11: Final Outputs.

Sample	Final Prediction
1	51.1
2	50.8
...	...
100	49.9

Source: Authors, (2026).

Table 11 showcases the final predictions generated by combining the outputs of the DSTCN and SMAL models. These predictions represent the most accurate estimates of stock prices, taking into account both temporal dependencies and adaptive parameter adjustments in real-time scenarios. It is the logical presentation of the results that demonstrate the true contribution of the research and also justify the conclusion. The parts indicated above, Introduction, Material and Methods serve to explain how the results are obtained. Use tables and figures for your explanation. The results must be written in the past, in a brief and simple way. Avoid redundancy. Analyzing and interpreting the results is part of the discussions, their importance, achievements and limitations, highlighting the innovative aspects of the practical applications of the study and the conclusions derived from them, delimiting unresolved issues. Ifnecessary, recommendationscanbeproposed.

V. CONCLUSIONS

In summary, this study reveals the efficiency of Dynamic Sparse Temporal Convolutional Networks and Sparse Meta-Adaptive Learning in the domain of streaming challenges. In experiments using datasets based on contextual data such as Financial Market Data and IoT Sensor Data, both models performed without any need for prior data and show better accuracy performance than the standard baseline methods. The findings show that DSTCNs and SMAL outperformed Methods [3], Methods [8], and Methods [22] with 6.2% and 5.9% on the Financial Market Data, respectively, and 5.5% and 4.5% on the IoT Sensor Data samples. Further, DSTCNs and SMAL were found to have a highly reduced resource consumption in terms of CPU cycles and memory usage as well, with up to 20% and 30% reductions, respectively, in both datasets. The models exhibit response times that are faster as compared to the baseline methods, reducing the response time by up to 40% and 25%, respectively. In future, integration of deep Q learning along with pre-emption can be added for further enhancing its real-time performance for different scenarios.

ABSTRACT

Every nation has its individual strategies towards its economic growth. But the backbone of any nation's economy is agriculture. On the other hand, technology is gearing up to new horizons leaving its impact on all the sectors. Most importantly, Health and agriculture are amongst in which AI based techniques are being used and still there is a lot of scope for advancement. Cotton being called as white gold to be preserved very well in terms of crop yield and at the same time it must not be a burdensome. The scenario is that there are huge losses in this field due to various reasons among which crop or plant diseases being a primary reason. Several researchers proposed Deep learning-based solutions for early identification of the diseases in cotton crops. However, there are gaps left uncovered which are taken up as research interest. In this paper, in addition to the cotton plant diseases explored and presented, various research articles are made as a part of our study and the contributions of respective researchers are cited. The advent of deep learning and its applications have been discussed briefly. Available image Datasets related to cotton crop diseases are also presented in the paper.

I. INTRODUCTION

In South Asia, agriculture being the prime source of livelihood [1], the malnourished population is more than 50% of that of world's population who are undernourished. These nations are well named for their agricultural exports that account for a significant portion of their GDP. The soil fertility in this region is meant for high crop yields, leading to surplus production as well huge exports for over 50 years. It greatly benefits the farmers and various crops including cotton, thereby strengthening the country's economy resulting in hike of a nation's GDP [2]. Therefore, for achieving a stable economy and optimized crop revenue, high-quality and high-quantity yields are very much necessary [3]. However, there is a threat in achieving better yield due to pests, weeds, and other such attacks. Despite the existing practices, the losses are substantial due to the said factors. Between 2001 and 2003, there were 50% losses for wheat, above 80% for cotton and around 28% for soyabeans reported in 19 regions [2]. The introductory part of this paper first discusses the objectives of this paper, then traditional methods being adopted subsequently cites the importance of Cotton research, and how deep learning is proving its ability in cotton crop research.

The objectives of this paper include:

(i) Providing a detailed and thorough insights related to Cotton plant research, the need of research, techniques being implemented in cotton research is the primary objective of this paper.

(ii) The paper intends to explain various types of diseases undergone by the cotton plants.

(iii) Survey of around 60 articles related to deep learning in cotton plant disease detection is another objective of this paper. Reviewing the literature identifies the current trends, gaps in the existing research and advancements.

(iv) Discussing various techniques encompassing Deep Learning such as CNN, the networks built on basis of CNN, ensemble techniques, Transfer Learning, Vision Transformers and other such Deep learning networks.

(v) Providing the details of bench mark datasets in cotton plant disease detection.

(vi) Providing insights on the performance of various techniques in terms of metrics such as Accuracy, precision, recall, F1 score and so on.

(vii) Providing future insights for effective research on cotton plant disease detection.

The leading producers of cotton are China, India, America and Brazil. The cotton production over the past decade is shown in Figure 1.

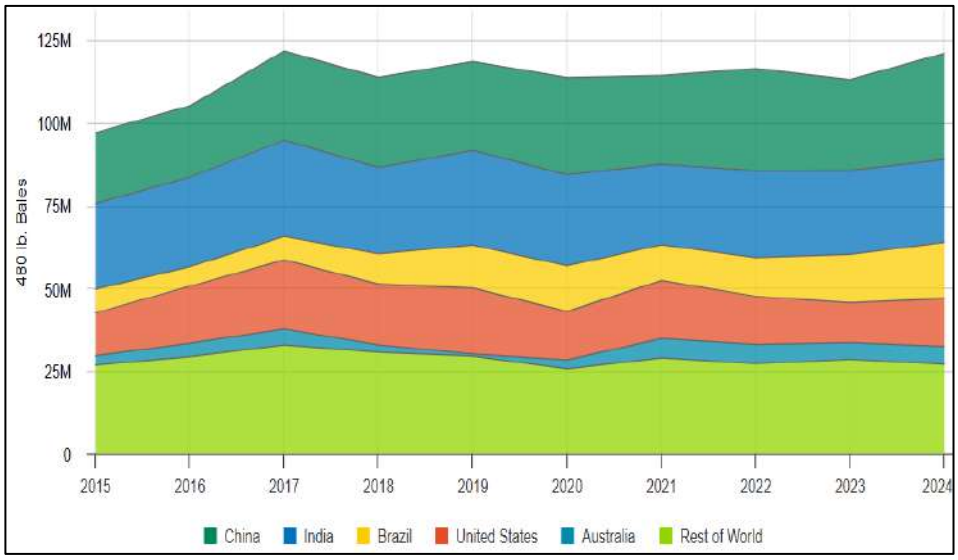

Figure 1: Cotton production over the past decade.
Source: [4].

Depending on various environmental conditions, cultivation areas, plantation times and the yield, the cotton is being produced in 59 varieties [5]. Whichever variety of crop, if proper care is not taken, it results in substantial crop losses due to diseases. The cotton crop is the most vulnerable crop which shall be attacked by pests due to which the quality and yield is affected significantly. Globally the trade value of cotton is about 40 billion USD, which is expected to increase to 60 billion USD by the end of 2030 [6]. The diseases affecting cotton crops include Anthracnose, Wilt, Sore Shin, Minor Boll-Rots, Rust, Thrips, and Mealybug [7]. Diagnosing the crop diseases at an early stage plays a vital role in performing the remedial action due to which the farmers can be benefitted so well. Usually farmers by their experience, examines the cotton leaves with their naked eye and identify the diseases. Here the diagnosis is being done after the crop gets infected. Rather, if it could be investigated and diagnosed early, certain measures could be taken. Moreover, to examine the crops, physical presence of the farmers is required. Yet times, farmers cannot identify the diseases so accurately. Even the plant pathologists do it following a traditional approach, it takes long time and of course sometimes the diagnosis may go wrong. Detecting the diseases at an early stage is highly essential to obtain high quality yield and to do so, implementation of effective management practices is certain. Attaining agricultural sustenance, most importantly in high qualitative and quantitative cotton yield and ensuring the lives of millions of cotton farmers worldwide, is possible only when there is an efficient control due to which the cotton plant diseases mitigate. If the disease management is not apt, the diseases leads to notable economic losses, consequently it raises the risk of employment in both agricultural & textile sectors [8]. The advancement of technology in the fields of image processing and machine learning, has eased the diagnosis of plant diseases including cotton [8-10] that boosted Nation’s economy, supporting rural Work as well the national textile industry [9].

I.1 TRADITIONAL TECHNIQUES AND SHIFT TOWARDS DEEP LEARNING BASED TECHNIQUES

Traditional techniques in cotton disease research comprises Onsite inspection, Physical observation, acquiring the details from farmers, field surveys, tests in laboratories, utilizing remote sensing techniques and performing image analysis. Although traditional techniques are having advantages, there are disadvantages namely time consumption, presence of experts physically in the fields, scalability issues, data misinterpretation, yet times suffer from accurate information, labour intensive and incurring high costs. Deep Learning is a subfield of Machine Learning inspired by the structure and function of the human brain. It utilizes artificial neural networks with multiple layers (hence "deep") to analyze and learn from vast amounts of data. Unlike traditional machine learning, deep learning excels at automatically extracting intricate features from raw, unstructured data (like images, audio, and text). Potential features of Deep Learning include Automatic Feature Extraction, Handling Complex Data, Scalability with Data, Achieving State-of-the-Art Results and with such impressive features the technology is into its wide range of applications across various industries among which Computer Vision, Natural Language Processing (NLP), Healthcare, Agriculture, Finance, Recommender Systems and so on. Deep Learning is a powerful and rapidly evolving field within Artificial Intelligence that enables computers to learn complex patterns from data, leading to remarkable advancements in various applications that impact our daily lives. CNN (Convolutional Neural Network) is the foundational deep learning model for most computer vision tasks which is inspired by the visual cortex and excel at processing grid-like data such as images.

Popular CNN architectures are AlexNet, the first deep CNN model introduced in 2012 that achieved breakthrough performance on the ImageNet dataset, popularizing deep learning for computer vision; VGGNet introduced in 2014 explored the effect of network depth, using very small (3x3) convolutional filters stacked together. On the other hand, GoogLeNet (Inception) was introduced in 2014 which presented the "Inception module" that efficiently use computational resources by using parallel convolutional filters of different sizes. In 2015 ResNet was introduced which revolutionized deep network training by introducing "skip connections" (residual connections) that allow for the training of very deep networks (hundreds or even thousands of layers) without the vanishing gradient problem. DenseNet was introduced in 2017 which emphasized feature reuse and EfficientNet in 2019 focused on efficiently scaling network dimensions (depth, width, and resolution) in a balanced way to achieve better performance with fewer parameters. Transfer learning is a powerful technique in deep learning where a model trained on a large, general dataset is repurposed as a starting point for a model on a second, related task. Instead of training a new model from scratch, you leverage the knowledge (features, weights) learned by the pre-trained model. Due to transfer learning, model development becomes faster and the data needs are reduced besides offering better performances. Also transfer learning offers improved performance as well as resource efficiency. Originally designed for natural language processing, Transformers have recently shown great promise in computer vision tasks. They rely on the "attention mechanism," which allows the model to weigh the importance of different parts of the input when making predictions.

The key Components of Transformers comprise Self-Attention modules that enable the model to attend different parts of the input image to capture long-range dependencies; Multi-Head Attention modules that Uses multiple attention mechanisms in parallel to capture different types of relationships and Transformer Blocks which consist of self-attention layers followed by feed-forward neural networks. Vision Transformer (ViT) are the specially designed transformers for computer vision applications. They directly apply the transformer architecture to sequences of image patches. Swin Transformers are one among the vision transformers which introduces a hierarchical Transformer structure with shifted windows, improving efficiency and performance on various vision tasks. Deep learning (DL) has revolutionized numerous fields, showcasing remarkable success in areas such as healthcare for disease diagnosis, autonomous systems for self-driving vehicles, network security, Natural language processing, agriculture, etc. Particularly in the agriculture domain, DL has been applied for tasks such as crop yield prediction, classification using aerial imagery, agricultural field monitoring, stress identification in plants, infected leaf detection, etc. Highlighting the advancements of DL underscores its transformative potential and contextualizes its relevance to the present study. This section introduces the objectives of the paper followed by cotton crop research importance using deep learning methods. In the next section various cotton diseases have been discussed and the subsequent section presents the essence of the literature surveyed and provides insights for the future research. In section four, datasets have been detailed and in final section conclusions are given.

II. OVERVIEW OF COTTON DISEASES

Insects, mites, pathogens, weeds, nematodes, rodents, and birds constitute the pest complex of cotton. Of the biotic stresses, insect pests cause by far, the highest economic losses. The cotton plant is the host of 1326 species of insects. The major types of diseases can be categorized into Viral and Phytoplasma diseases, Soil borne diseases, Bacterial diseases, Fungal foliar diseases, Boll rots, Physiological disorders and diseases due to nutritional deficiency. Under Viral Phytoplasma category, the variety of diseases are Cotton Leaf Curl Virus diseases (CLCuD), Tobacco Streak Virus (TSV), Cotton Leaf Roll Dwarf Virus (CLRDV), Cotton Leaf Crumple Virus (CLCrV) and Cotton virescence – Phytoplasma. The healthy leaf of a cotton plant and the diseased leaf (curl) are as shown in Figure 2.

Figure 2: Healthy cotton leaf, Diseased leaf (downward curl and upward curl).
Source: Authors, (2026).

Figure 3: Plant effected with vein thickening.
Source: Authors, (2026).

Figure 4: Leaf enation.

Figure 5: Plants infected with whitefly & CLCuD.
Source: Authors, (2026).

Other forms of disease effected plants are shown in Figures 3, 4 and 5; while the tobacco streak virus, CLRDV and CLCrV effected plants are shown in Figure 6.

Figure 6: Plants infected with TSV, CLRDV & CLCrV.
Source: Authors, (2026).

Under the soil borne diseases, Root rot and wilt diseases prevail. The root rot, drying of plants and bark shredding are presented in Figure 7.

Figure 7: Root Rot & bark shredded infected Plants.
Source: Authors, (2026).

Root rot of cotton is a worldwide occurrence and has been a major cause of loss in many countries. Different fungi as well as nematodes cause injury to the cotton roots. The disease symptoms occur on the lower part of the stem and roots which leads to the wilting of plant foliage from top to bottom. Bacterial diseases occur at the seedling to boll development stages. Systemic infections show the main veins as black streaks. Bacterial leaf blight diseased leaf and boll are as shown in Figure 8.

Figure 8: Bacterial leaf blight infected leaf and boll.
Source: Authors, (2026).

Bronze wilts a mysterious cotton disease also referred to as copper top, red wilt, sudden wilt, or phloem wilt and is characterized by bronze or red discoloration and wilting of leaves. The infected plant is as shown in Figure 9.

Figure 9: Bronze twilight.
Source: Authors, (2026).

Figure 10: Alternaria & Cercospora leaf spot / blight.
Source: Authors, (2026).

Various leaf spot and leaf blight diseases are due to fungus & bacteria and hence they are categorized under Fungal foliar diseases. Alternaria leaf spot / blight, Cercospora leaf spot / blight, Corynespora, Myrothecium, Colletotrichum, Helminthosporium leaf spot diseases; Ascochyta leaf blight, Ramularia Grey mildew and Phakospora Leaf Rust are few cotton plant diseases. The mentioned leaf spot, leaf blight, mild dew and leaf rust disease infected leaves are shown in Figures 10 and 12. Coming to Boll rots, they are of two types, namely external boll rot and internal boll rot. These rots are also caused due to fungi and bacteria pathogens. The two types of rots are shown in Figure 11.

Figure 11: External and Internal boll rots.
Source: Authors, (2026).

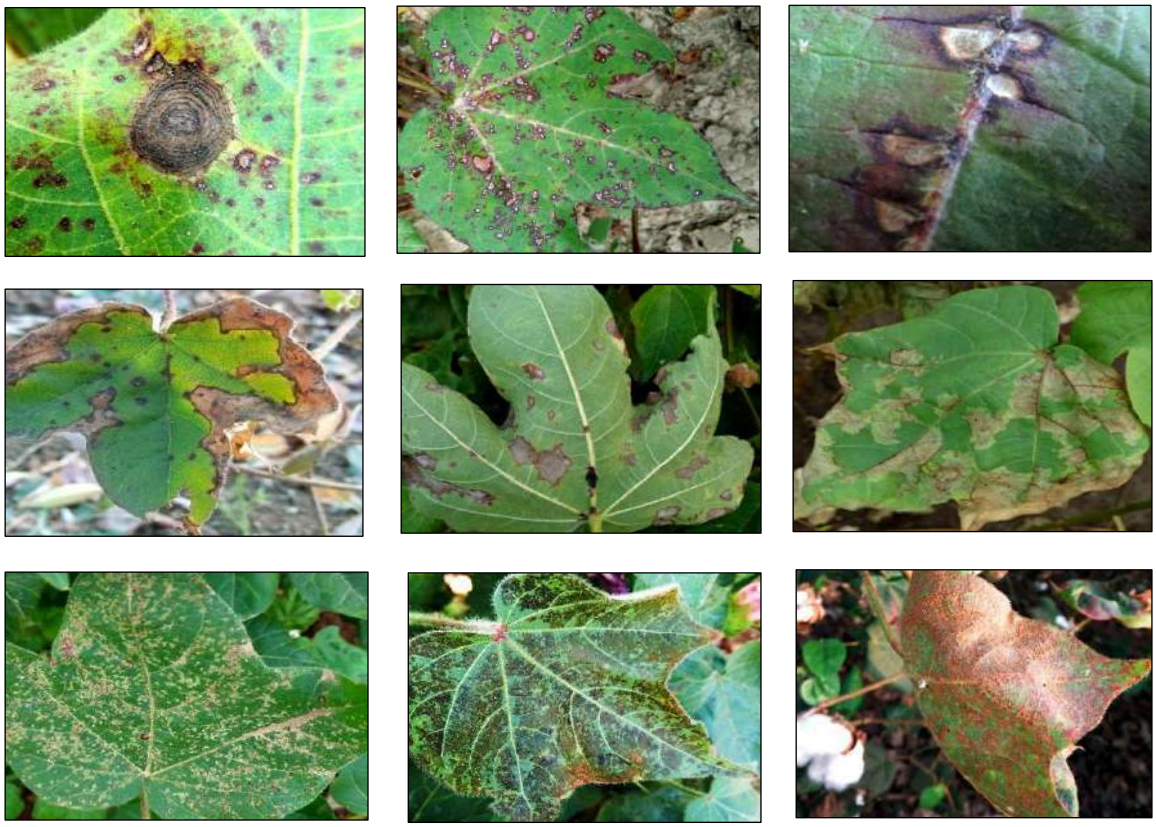

Figure 12: Various leaf spot, leaf blight, grey mild dew and leaf rust diseases.
Source: Authors, (2026).

Deficiency of soil mineral nutrients may be the consequence of low soil mineral contents, extreme temperatures, pH, drought and waterlogging conditions that alter the mineralization and hence availability to plants. Soil nutrients are considered as essential during the critical crop reproductive phases.

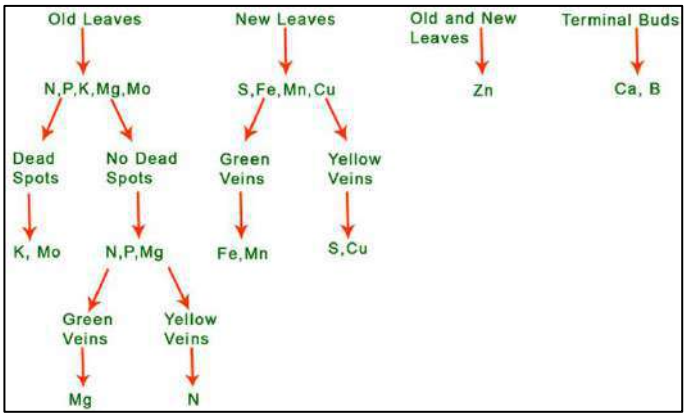

Figure 13: Nutritional deficiency symptoms.
Source: Authors, (2026).

Deficiency in the nutrients must be supplemented with required nutrients for enhanced productivity. In the cotton plant growth cycle the following elements are identified as essential viz., Carbon, Hydrogen, Oxygen, Nitrogen, Phosphorus, Potassium, Calcium, Magnesium, Sulfur, Iron, Manganese, Zinc, Copper, Boron, Molybdenum, Chlorine, Cobalt, Selenium and Sodium. The symptoms in various parts of cotton plants are presented in Figure 13. The diseases quoted above are the compilation in various parts of the world. They are due to various reasons such as climatic conditions, bacteria, fungi, viruses and nutritional deficiencies. Due to these diseases, huge economic losses incur, consequently the nation's economy stands impactful. In reducing the losses various methods are to be implemented and modern computational intelligence methods play a vital role in Effective disease management. Early disease detection, pest management, crop management, soil management and so on comprise the disease management. The research towards cotton crop protection and high yield is open, and questions arise in how machine learning, deep learning and its advancements could be employed in effective disease management. Research could be performed on disease prediction, diagnosing the aptness of the environmental condition, proportion of the nutrients and soil fertility, various deep learning architectures that provide valuable insights towards optimization of cotton yield.Precision Agricultural practices that lead to higher yields to be emphasized. Scalability is another important aspect which the research has to address.

III. LITERATURE SURVEY

Plant leaves or crops are vulnerable to different diseases during agricultural cultivation. The diseases halt the growth of their respective species. Early and precise detection and classification of the diseases may reduce the chance of additional damage to the plants. The detection and classification of these diseases have become serious problems. Farmers that use computerized image processing methods in their fields can reduce losses and increase productivity. Numerous techniques have been adopted and applied in the detection and classification of plant diseases based on images of infected leaves or crops. Researchers have made significant progress in the detection and classification of diseases in the past by exploring various techniques. There are several datasets available related to varieties of crops/plants from various sources in different forms i.e., text, image, video on which the techniques could be applied and make predictions, detection, classification and so on. The usage of Deep Learning in plant/crop disease detection is enormous. However, there is a lot of scope for research in different sub fields in this area of research. Cotton is an important cash crop, and its diseases significantly impact the yield. Detection of diseases at an early stage helps farmers in taking pre-emptive measures to help improve cotton crop yields. DL-based object detection can automate the process, saving time and resources. These are the key factors that encourage researchers to work on these diseases and are the real motivation behind this study as well. This research primarily focuses on the accurate and timely detection of diseases in cotton crops. In this regard, the following are the main contributions of this study. According to [11] presents distinguished deep learning models for disease detection which include VGG16, DenseNet, MobileNet, EfficientNet, NasNet, InceptionV3, MobileNet and ResNet models.

The models are employed on the real cotton disease data collected in the form of images of leaves from fields. Before the data is inputted to the models, preprocessing has been done using well-known techniques. Among all the models, ResNet152 model outperformed other DL models with which the model turned into an efficient approach for cotton disease detection. With this it could be understood that the power of DL could be harnessed and it helps protecting the cotton crop and ensures a promising output. In [12] made an effort in improving crop health monitoring of cotton farming systems as well its management. Their research emphasizes on the importance of utilization of cutting-edge techniques in image processing in agricultural activities. Various techniques namely YOLOV5, VGG16 and ResNet 50 are employed in identifying the cotton plant diseases. In terms of ROC curve metric, YOLOv5 seems to be better than VGG16 and ResNet50. Also it had the highest F1 score, precision and recall, while ResNet50 slightly outperformed VGG16 in terms of true positive rates, F1 score, precision and recall. Also, in terms of accuracy YOLOv5 performed well than ResNet50 while the latter model offered high efficiency and accuracy than VGG16 due to which the models are considered to be more appropriate for those applications that demand high precision and low false positive rates. According to [13] presented a deep learning model incorporating a special module namely Convolutional Block Attention Module (CBAM) with which the cotton leaf diseases could be automatically detected with high accuracy.

To do so, a publicly available dataset was utilized which had 2,137 original images and augmented to 7,000 images categorized into seven classes. Healthy leaf being one category and Leaf Hopper Jassids, Curl virus, Bacterial Blight, Herbicide Growth Damage, Leaf Reddening and Leaf Variegation are the other categories. Although various deep learning models including MobileNet, DenseNet121, EfficientNetB1, DenseNet169, InceptionV3 and XceptionNet are used in disease detection; EfficientNetB1 with CBAM achieved highest accuracy of 99.21%. However, during preprocessing stage, image resizing, normalization and noise reduction are performed so as to improve image quality. Integration of CBAM improved the detection performance. According to [14] introduced mobilenet comprising subset of layers, a novel deep learning framework constituting transfer learning, data augmentation, model check points, decaying learning rate schedule and early stopping mechanisms. The model demonstrated extraordinary performance in classifying cotton disease of seven categories with 98.42% overall accuracy while class-wise precision in the range of 96% to 100%. The model's substantial performance and its lightweight nature well suits the real-world applications in smart farming. In [15] Stephen, A., et al. used different pre-trained CNN architectures InceptionV3, ResNet18, GoogLeNet and MobileNetV3 Large to diagnose the cotton plants. The model focussed on the regions of cotton plant viz., stem, bud, flower, boll, crown, land, unhealthy leaf, young boll, weed, and young leaf.

The images of cotton plants are collected using smartphones. Amongst all the models, MobileNetV3Large offered highest accuracy, precision value and specificity of 93.9%, 97.48% and 96.12% respectively. By [16] proposed a novel ensemble model considering two pretrained networks VGG16 and InceptionV3 as base models for early detection of diseases in cotton leaves. The proposed model offered higher training and testing accuracies of 98% and 95% relative to the base models. The model achieved the accuracy in 20 epochs with other hyper parameters settings, learning rate as 0.0001 and stochastic gradient descent (SGD) optimizer. The pipelined architecture by [17] comprise the algorithms which are capable of learning complex features, patterns from large datasets and can lead to more precise and reliable detection outcomes. The model could well detect, particularly in challenging situations such as fields of mixed crops and in lighting and weather situations. The model could be enhanced by integrating various sensor types namely hyperspectral, thermal imaging, and LiDAR. According to [18] employed seven models for automatic detection of cotton leaf diseases among which five are pre trained models and two are advanced transformer-based architectures. The Vision Transformer (ViT) model achieved highest performance with accuracies of 96.72% and 93.39% in the binary class and multi-class classifications respectively. In addressing the problems such as several model parameters and low detection accuracy in case of SSD-based cotton leaf disease detection mechanisms Guo et.al. [19] proposed a fusion model that combined SE, ECA and CBAM attention mechanisms.

The mechanisms are combined to filter the disease target features and at the same time suppress the information related to jamming targets. According to [20] employed three models ResNet101, Inception v2, and DenseNet121 in cotton crop disease detection. Hyper parameter tuning is performed with the Nesterov accelerated gradient. Among the models DenseNet121 offered high performance accuracy which acts as a powerful tool for farmers in accurate and swift diagnosis. In [21] performed an exhaustive study on various deep transfer learning techniques in cotton plant disease detection. The models employed are variants related to EfficientNet, Xception, ResNet, Inception, VGG, DenseNet, MobileNet, and InceptionResNet on a complete dataset of infected cotton plants with five disease categories namely Bacterial Blight, Powdery Mildew, Target Spot, Army Worm and Aphids in addition to the healthy ones. EfficientNetB3 model outperformed with an accuracy of 99.96% 0.149 loss and root mean square error of 0.386. Intrusion of CLCuD caused due to Curl virus intrigates a substantial threat to the cotton yield. Prompt addressing the challenge of identifying CLCuD is highly essential and deep learning plays a vital role in addressing such issues. According to [22] used two deep learning models, specifically the Convolutional Neural Network (CNN) in two variants on two distinct datasets, one, a public dataset and the other, a proprietary collection. The dataset consists of 1349 cotton leaf images capturing both healthy and diseased ones. When compared to the normal CNN model, the dynamic weight layering CNN model achieved 99% accuracy in the disease detection.

According to [23] used three Transfer learning models DenseNet201, InceptionV3 and Xception on a publicly available cotton dataset. Results demonstrated that among the employed models, DenseNet201 achieved highest accuracy of 94.33%. This research aids in effective crop management and productivity. In the experiments conducted by [24] fine-tuned Transfer Learning (TL) models VGG-16, VGG-19, Xception and InceptionV3 are used on the publicly available cotton dataset for disease detection. Among the models used, Xception model offered highest accuracy of 98.70% In [25] conducted experiments in three configurations using an improved Deep CNN based model. One is using different data split ratios, second is different choices of pooling layer - max-pooling vs. average-pooling, and third epoch sizes. The model used a dataset of 2293 cotton leaf and plant images comprising four classes of leaves, various plant disease combination categories. The model attained an accuracy of 97.98%. According to [26] employed six pre trained networks VGG16, VGG 19, DenseNet121, DenseNet169, ResNet50V2 and MobileNetV2 in detecting the bacterial blight and curl virus in cotton crops. The dataset comprises 1362 images collected from local agricultural fields and another 1292 images collected from online resources on which experiments were conducted. According to [27] employed Deep CNN ensemble by combining Inception Net and VGG16 to diagnose cotton leaf diseases Cotton leaf curl virus, fusarium wilt and bacterial blight.

Weight parameter optimization using RMSProp and Adam optimizers had been explored. In [28] performed research using CNN in detecting 22 leaf diseases that comprise categories related to bacterial, fungal, viral, nutrient deficiency, etc. The proposed model offered 99.39% accuracy with negligible error rate and less computational time. According to [29] performed experimentation using state-of-the-art YOLO DL framework on an indigenous cotton plant image dataset in identifying bacterial blight and curl virus. This resulted in YOLOv5 offering better performance when compared to YOLOv6 and YOLOv7 models. The accuracy is 92% and the inference time is 25 ms which may suit on-field real time applications. By [30], made a study using six CNN architectures experimented on a cotton leaf dataset comprising near about 387 diseased leaves and 519 healthy leaves collected from reliable sources. The pretrained CNN architectures employed were AlexNet, ResNet50, InceptionV3, NASNet, VGG 16, and Xception among which ResNet50 and VGG 16 shown significant performance with 97.56% of accuracy. However, the number of parameters associated with VGG16 are more than ResNet50. The method employed by [31] consists of two core steps, feature extraction and classification. Initially to balance the input data, the data augmentation is performed after which feature extraction is done from a pre-trained VGG-16 model, subsequently the output is passed to 11 fully convolutional layers and finally generate an anomaly map, that define the probability of the lesion region. The proposed model is evaluated on two publicly available datasets which offered 99.99% accuracy.

According to Memon, [32] proposed a meta deep learning model to perform cotton leaf disease detection on a dataset containing 2385 images initially and later augmented. Disease detection was performed and performance in terms of accuracy is compared with transfer learning models CNN, VGG16 and ResNet50. The proposed meta DL model offered noteworthy performance of 98.53% accuracy. According to [33] proposed a CNN based model which is used to detect cotton plant leaf disease considering a dataset from Kaggle. The model attained 97.13% classification accuracy. In [34], to monitor the cotton crop health and for effective disease management, chosen two deep learning models GoogleNet and Resnet50 and they attained a precision of 86.6% and 89.2%, respectively. When compared with traditional approaches namely SVM, KNN, ANN and NFC techniques the DL models proved to be 25% more precise. In [35] as a part of their experimentation, performed segmentation as well classification. They presented a few-shot learning frame work that performs cotton leaf disease spot classification task. Due to this timely control of cotton diseases is possible. As an initial step, segmentation is performed on cotton leaf's disease using various methods. Support Vector Machine (SVM) method and threshold segmentation are used. Next, the segmented disease spot images are compiled as a disease spot dataset and finally the cotton leaf disease spots were classified using two-way parallel CNN. Also the CNN has been used in building the leaf spot feature extractor.

According to [36] used deep transfer learning specifically ResNet trained on the Network combination of ImageNet and XceptionNet to recognize cotton crop leaf diseases and achieved high accuracy in cotton crop disease detection. Cotton plant disease detection is accomplished by Saqib et.al. [37] using deep CNNs. The proposed ResNet50 model achieved training and validation accuracies of 0.95 and 0.98 respectively. According to [38] employed VGG16 transfer learning model to detect cotton leaf diseases on a dataset containing 6,158 samples categorized into seven disease classes and one healthy class. The metric evaluation of pretrained models resulted in an accuracy of 95.02% attained by VGG16. According to [39] developed a CNN-based model which achieved 90% accuracy in cotton leaf disease detection. For iOS integration, the model was converted later to CoreML thereby enabling offline disease identification. This aided farmers in giving real-time recommendations for crop disease management. In [40] implemented Mask R-CNN to detect cotton leaf diseases which attained 94% accuracy. Their study insisted the importance of instance segmentation techniques which could localize the disease affected regions in a precise manner. For [41] performed cotton leaf disease detection using VGG16 on a dataset containing 2,238 images in six categories. Due to Feature selection, the model's ability significantly improved in detecting the diseases at an early-stage. The model achieved 95.52% accuracy and this approach reinforced the effectiveness of feature engineering. In [42] proposed ResNet50-based system to detect bacterial blight and curl virus diseases in cotton leaves.

Experimentation is performed on a dataset, comprising 2,000 images and the model achieved 95% accuracy and it demonstrates the efficiency of transfer learning. According to [43], employed a deep CNN to detect cotton leaf diseases while Kumar et.al. [44] proposed a 2D-CNN model. In [45] adopted transfer learning approaches to detect cotton plant leaf diseases. In [46], modelled CropCycleNet, a deep adversarial network with which we could study the health of cotton plants and analyze factors related to plant growth and maturity. According to [47], employed transfer learning techniques Densenet121 and Cropnet architectures to classify cotton leaf diseases while by [48] made an assessment on the severity of fusarium oxysporum cotton disease using images captured using UAVs. A hybrid domain adaptation DL time series model is employed and this method improved the spatio-temporal transferability of CNN-BiLSTM model which later allowed to leverage historical datasets efficiently. In [49] employed conventional approaches, such as CNNs to classify the diseases associated with cotton leaves. In [50] proposed RESNET algorithms to classify the diseases and predict the labels of the disease to find out the accuracy and the best suitable algorithm. According to [51] proposed a Convolutional Neural Network (CNN)-based approach for the automated detection of rice leaf diseases using deep learning. For [52] proposed a Convolutional Neural Network (CNN)-based approach for the automated detection of tomato leaf diseases using deep learning. Research insights provided from the above literature reviewed:

- In most of the articles various deep learning models are employed and comparisons are drawn with respect to those models.
- There is a need to focus on diagnosing newly emerging cotton diseases.
- Ensemble techniques are not much used. Hence ensemble techniques and in addition, variants of Ensemble techniques could be employed.
- Specific diseases could be focused upon.
- Transformers, expecially Vision Transformers could be widely used.
- Hyper parameter tuning and Optimization techniques could be employed.
- Data balancing is a vital factor which is highly essential for better performance.
- Light weight models to be used so that the real time detection and monitoring is possible in mobile devices etc…
- Challenges related to Dataset quality, size, Resolution of images need to be addressed.
- Focus could be made on Datasets related to India (in preparing new datasets)
- Sensor based, IOT based and UAV based Agricultural research data could be made as a part of research.
- Scalability of the dataset which means huge cotton plant disease datasets are to be considered for experimentation due to which model standardization could happen.

IV. A BRIEF NOTE ON DATASETS AVAILABLE

Data plays an important role in the experimentation. Unless qualitative and quantitative data is made available, proper analysis cannot be done. In this section, around 12 bench mark datasets related to cotton crop diseases are presented. The datasets compiled by respective organizations are recent ones. Most of the datasets are compiled by authentic bodies while few datasets are from Kaggle. Dataset particulars are presented in Table 1.

Table 1: Particulars of the datasets.

Dataset Name (Year)	Description	Reference
SAR-CLD-2024 (2024)	Data was collected by visiting the cotton field which is the National Cotton Research Institute field in Gazipur, Dhaka, Bangladesh. Dataset consists of 2137 images and after augmentation the number of images is 7000, Output classes – Seven.	SAR-CLD-2024: A Comprehensive Dataset for Cotton Leaf Disease Detection - Mendeley Data [53]
CoSEV (2023)	Data compiled by Islamia University of Bahawalpur Pakistan Faculty of Science, NFC Institute of Engineering and Technology Training. Dataset comprises 496 images and after augmentation the number of images is 1186. Output classes – Five.	CoSEV: A cotton disease dataset for detection and classification of severity stages and multiple disease occurrence - Mendeley Data [54]
Cotton Leaf Disease Dataset with Severity Levels (2025)	Data collected by Agarwal, Dr D Y Patil Institute of Engineering and Technology.Dataset consists 1016 images and after augmentation the number of images is 3604, Output classes – Four.	Cotton Leaf Disease Dataset with Severity Levels - Mendeley Data [55]
Cotton leaf disease dataset (2021)	Dataset consists of 1710 images and the output classes - Four	cotton leaf disease dataset [56]
A Dataset of Cotton Leaf Images (2024)	Dataset consists of 4000 images and after augmentation the number of images is 8000. the output classes - Four.	A Dataset of Cotton Leaf Images for Disease Classification Using Deep Learning by Azeem Ayaz Mirani, Shahzaman Nizamani, Mehwish Leghari, saima soomro, Qazi Ejaz, Mushtaque Ahmed Rahu :: SSRN [57]
Cotton Disease dataset (2020)	Dataset consists of 2310 images which are into healthy and diseased plants as well healthy and diseased leaves.	Cotton Disease Dataset [58]
CotLeaf-1 (2024)	Cotleaf-1 dataset is a collection of 13,597 images of cotton leaf surfaces acquired with a hand-held microscope to develop deep learning models to classify images based on leaf hairiness and assist Cotton breeders in their variety selection efforts. Remaining datasets are also available.	CSIRO Data Access Portal - CotLeaf-1: Cotton Leaf Surface Images dataset 2019-21 [59]
CotLeaf-2 (2024)	Dataset consists of 810 images	CSIRO Data Access Portal - CotLeaf-2: Cotton Leaf Surface Images dataset 2021-23 [60]
CotLeaf-X (2024)	Dataset consists of 5049 images	CSIRO Data Access Portal - CotLeaf-X: Cotton Leaf Surface Images dataset with eXpert labels [61]
AnnCoT: Annotated Cotton Trichome dataset	1250 images dataset	CSIRO Data Access Portal - AnnCoT: Annotated Cotton Trichome dataset [62]
Cotton Plant Disease. (2023)	It focuses on 5 types of diseases on leaves and contains 26k plus files	Cotton plant disease [63]
Cotton-leaf-infection (2022)	The dataset contains 1786 images in four categories	cotton-leaf-infection [64]

V. CONCLUSION

Cotton cultivation plays a vital role in various domains consequently impacting a nation's economy. Through cotton various countries are getting benefitted either in the form of raising their economy or addressing the demand of cotton. At the same time due to improper methods of cultivation or monitoring, it is like a bane to the farmers often leading to deaths. The prime cause for this situation is cotton crop being affected with diseases. Effective disease management is highly essential so as to avoid losses. Deep learning, the state of art technology is offering amazing experience in various sectors and agriculture is not an exception. In this paper, various cotton crop diseases are discussed and deep learning based cotton disease detection techniques have been reviewed. The gaps are presented in the form of Research insights which would be useful to the future research. Also few datasets related to cotton crop diseases are presented.

VI. AUTHOR'S CONTRIBUTION

Conceptualization: K. Kishore Kumar and Movva Pavani.
Investigation: K. Kishore Kumar
Discussion of results: Movva Pavani.
Writing – Original Draft: K. Kishore Kumar
Writing – Review and Editing: Movva Pavani.
Resources: K. Kishore Kumar
Supervision: K. Kishore Kumar and Movva Pavani.
Approval of the final text: K. Kishore Kumar and Movva Pavani.

Ensemble Classifier Methods.

ABSTRACT

Diabetic retinopathy (DR) is a leading cause of vision loss, and early detection is essential for preventing blindness. This study investigates using transfer learning, deep learning and model fusion techniques to improve DR detection. Five pre-trained Convolutional Neural Networks (CNNs) ResNet50, VGG16, VGG19, DenseNet121 and EfficientNet-B7 were evaluated individually and in combination using the APTOS 2019 RGB retinal image dataset. Transfer learning was applied to fine-tune the models for the binary classification of DR and non-DR cases. Four fusion strategies were implemented to exploit the complementary strengths of the individual models. The experimental results demonstrate that all fusion approaches outperformed the standalone CNNs in terms of accuracy, sensitivity, specificity and Area Under the Curve (AUC). Of the individual models, DenseNet121 and EfficientNet-B7 performed best. Fuzzy-based fusion strategies further improved diagnostic accuracy. The best fusion model achieved an accuracy of 98.64% and a recall of 99.19%, demonstrating the robustness of the proposed approach. These findings highlight the potential of integrating transfer learning with advanced model fusion to create automated, reliable and scalable systems for the early screening of Diabetic Retinopathy (DR). Such systems could facilitate timely clinical intervention, enhance patient outcomes, and contribute to more efficient healthcare delivery.

I. INTRODUCTION

Diabetic retinopathy (DR) is a condition that causes vision problems and blindness. It is one of the main causes of vision loss among people with diabetes. It is very important to spot DR early so that the disease does not get worse. Nevertheless, it is hard to spot DR in its early stages. Manual retinal image analysis is time-consuming, subject to inter-observer variability, and requires expert interpretation. To address these limitations, automated detection systems powered by artificial intelligence (AI) and deep learning have emerged as promising tools to enhance the speed and accuracy of DR diagnosis [1]. Deep learning techniques, particularly convolutional neural networks (CNNs), have shown outstanding success in medical imaging tasks, including the classification and segmentation of retinal images. However, training these models from scratch demands large, well-labeled datasets, which are often difficult to obtain in the medical domain. Transfer learning offers a practical solution by enabling the adaptation of pre-trained models—originally trained on large-scale datasets like ImageNet—to domain-specific tasks. Architectures such as ResNet50, VGG16, VGG19, DenseNet121, and EfficientNet-B7 have proven highly effective when fine-tuned for DR detection [2], [3]. Although individual CNNs demonstrate strong predictive capabilities, combining multiple models through fusion strategies can further improve reliability and generalizability. Model fusion techniques harness the diverse strengths of various architectures, resulting more robust diagnosis systems. Prior studies indicate that ensemble methods often outperform individual models across multiple performance metrics [4]. This research extends current efforts by evaluating four fusion techniques: voting, averaging, fuzzy rank-based fusion, and the Sugeno fuzzy integral. These methods are applied to integrate the predictions of ResNet-50, VGG-16, VGG-19, DenseNet-121, and EfficientNet-B7 into a unified decision-making framework [5].

The study is based on the APTOS 2019 Blindness Detection dataset, which contains a wide range of retinal images representing various stages of diabetic retinopathy [6], [7]. The central research question addressed in this work is 'can the fusion of multiple fine-tuned CNN models improve diabetic retinopathy detection performance compared to individual models?' To answer this question, the study pursues the following objectives:

- Apply transfer learning and fine-tuning to adapt advanced CNN architectures for binary classification of diabetic retinopathy.
- Develop and implement a model fusion framework incorporating voting, averaging, fuzzy rank-based fusion, and Sugeno fuzzy integral strategies.
- Evaluate and compare the performance of individual and ensemble models using standard metrics such as accuracy, sensitivity, specificity, F1-score, and the area under the receiver operating characteristic curve (ROC-AUC).

The hypothesis is that ensemble methods combining the outputs of diverse CNNs will yield superior diagnostic performance and greater reliability than any single model. This research presents a scalable and accurate framework for automated diabetic retinopathy screening. It has the potential to significantly enhance early detection, improve clinical decision-making, and optimize the use of healthcare resources. Nonetheless, certain limitations are acknowledged, including reliance on a single dataset and the computational demands of ensemble modeling, which may affect deployment in resource-limited settings. The structure of the paper is as follows: Section II reviews work relating to the detection of diabetic retinopathy using deep learning and transfer learning methods. Section III details the proposed methodology, including data pre-processing, model architectures and ensemble fusion strategies. Section IV describes the experimental setup and evaluation metrics; it also presents and discusses the results. Finally, Section V is the conclusion of the study.

II. RELATED WORK

Various strategies have been explored to address the issue of diabetic retinopathy grading, including the development of distinctive features and the creation of software that analyzes retinal images. This strategy is intricate and requires much effort. The ophthalmologist must also apply his expertise in creating characteristics and annotating retinal images. This requirement is a big issue that must be addressed [8]. Many conventional methods need to ascertain the answers and comprehend the interconnections. The retention of extraneous image-specific attributes, such as rotation, brightness, and size, results in a negative impact on performance and accuracy, instead of facilitating the acquisition of relevant data [9]. The emergence of AI methodologies, including machine learning and deep learning, has enabled high-performance optical detection and classification to identify and segregate affected retinal regions [10]. The transfer learning strategy is based on its previous training on a large image database and can be adapted to the required dataset [11]. This technique is popular because there are many pre-trained models available, and there is a lack of labelled data for various real-world problems [12]. Quadratic weighted kappa was used in a study by Chilukoti to analyse the prediction of diabetic retinopathy [13]. The categorization using the pre-trained EfficientNet B3 model. Viji's work [14] used many models, including VGG, Xception, ResNet, Inception and EfficientNet, achieving an accuracy of 99.36% and a recall of 0.986. In [15], a CNN model was used to collect features from the input dataset, and a support vector machine model was used to perform classification. This method provided quicker execution than classifying with the CNN model. Medical imaging is essential for all basic health challenges and diverse medical conditions.

Diabetic retinopathy grading using fundus photographs has been extensively researched, employing various transfer learning methodologies utilizing publically accessible data sets. According to [16] utilized Inception [17], VGG16 [18], DenseNet [19], MobileNet [20], and ResNet models [21], with VGG16 achieving a 100% accuracy rate. In CNN models, using too many layers without spatial pooling results in a decrease in learnable parameters, which simplifies training [22]. Kothare and Malpe [23] developed a support vector machine and Naive Bayes model with a binary pattern methodology. The algorithm was utilized to choose relevant features. In contrast, the models were used to categorize patients as having the illness. The support vector machine is superior to the naive Bayes classifier in terms of accuracy, execution time, and memory utilization. According to [24] tried to create a simple way to predict and classify difficult exudates using something called artificial neural networks (ANN). The Speed-Up Robust Features approach was used to conduct feature extraction and detection. For classification purposes, a Feed-Forward Backpropagation Artificial Neural Network was utilized. The primary shortcoming of the work is its reliance on a dataset including merely 48 photographs. Ahmad et al. compare many architectures, including Inception-ResNetV2, ResNet50, NASNet, InceptionV3, VGG16, DenseNet121, Xception, and VGG19 in the publication [25]. The models performed classification and localization tasks, they were trained using a special set of data and then tested against the Messidor-2 dataset. The CNN and Contrast Limiting Adaptive Histogram Equalization (CLAHE) methods made the area under the curve better and improved the quality of fundus pictures.

The CLAHE approach has been implemented to magnify the retinal vessels, improving the preprocessing stage. Multiple machine learning classifiers have been integrated to improve diabetic retinopathy identification and decrease the error rate [26]. Fundus imaging can be used for precise diagnosis and assessment. An ophthalmologist requires extensive knowledge and commitment to manually analyze diabetic retinopathy using fundus images. Diabetic retinopathy was accurately classified using deep learning methodologies such as convolutional neural networks and transfer learning with models like ResNet, VGG, and GoogleNet [16], [27], [28]. In a prior article by [29], the authors utilized various SVM kernels in conjunction with the Ant Colony System (ACS) feature selection approach. It assesses a method for identifying diabetic retinopathy utilizing 250, 550, and 750 characteristics. The cubic SVM classifier surpassed all other kernels, with 92.6%, 91.8%, and 93% accuracy for 250, 550, and 750 attributes, respectively. According to [30] employed an Extreme Learning Machine (ELM) model on the APTOS-2019 dataset, achieving an accuracy of 97.27%. U-Net is a convolutional neural network design that is applied to image segmentation tasks. An asymmetric deep learning architecture for diabetic retinopathy screening was utilized in the study by [31] to perform segmentation. CLAHE is employed to assess and enhance photographs in the green channel. APTOS and MESSIDOR detected non-DRs with accuracy levels of 98.6% and 91.9% respectively, and PrDRs with accuracy levels of 96.8% and 95.76% respectively. Data augmentation is the predominant technique for mitigating imbalance difficulties in picture categorization [32]. It is a compilation of methodologies for generating additional data points from current data to augment data volume artificially.

Different methods can enhance the photos, including cropping, horizontal or vertical inversion, scaling, and rotation [33]. According to [34] demonstrates that employing a data augmentation technique improves the efficacy of transfer learning in the classification of diabetic retinopathy images.

III. MATERIALS AND METHODS

III.1 PROPOSED METHOD

In this study, deep learning algorithms are proposed for analyzing retinal fundus images to detect and categorize diabetic retinopathy (DR), which is classified into three main phases.

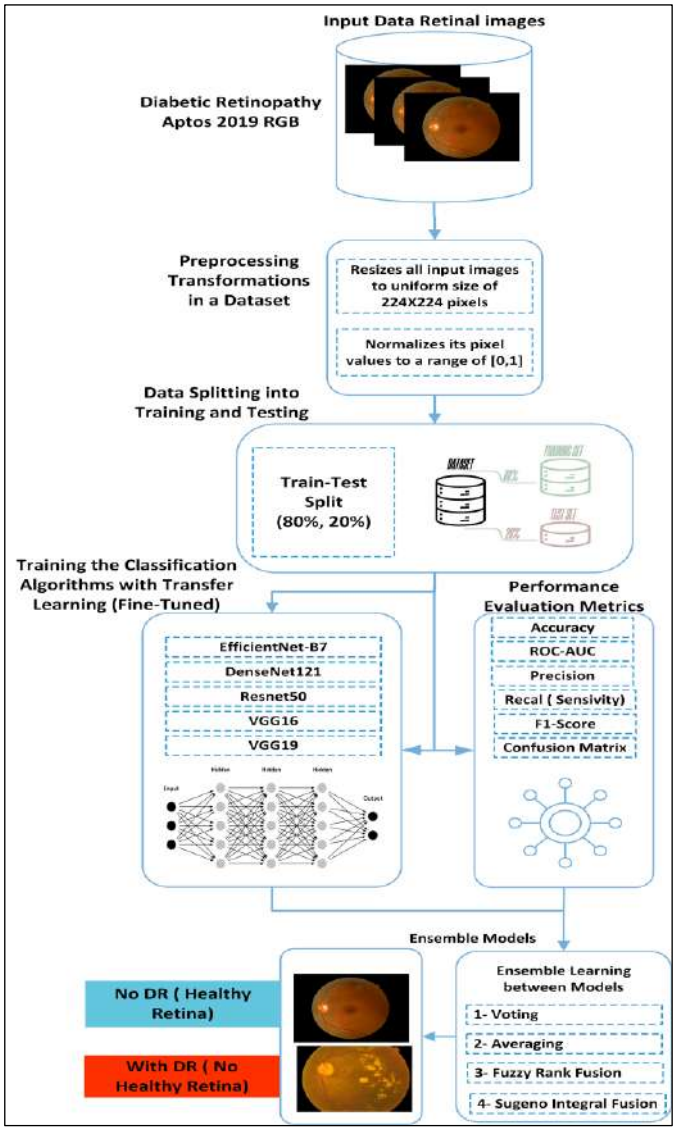

Figure 1: Proposed workflow of methodology for the Diabetic Retinopathy (DR) Prediction.
Source: Authors, (2026).

In the first phase, the fundus image dataset is pre-processed and enriched to reduce variability and address class imbalance. In the second phase, we fine-tune the last layers of the pre-trained convolutional neural networks - specifically ResNet50, VGG16, VGG19, DenseNet121 and EfficientNet-B7 - using the prepared dataset to benefit from their feature extraction capabilities. In the third and final phase, a fusion strategy is introduced to combine the outputs of the individual models in order to improve diagnostic robustness and accuracy. Four fusion methods are explored: majority voting, probability averaging, fuzzy rank-based fusion and the Sugeno fuzzy integral. Together, these steps provide a comprehensive and reliable framework for automated DR detection. The proposed methodology is illustrated in Figure 1.

III.2 DATASET

This research solely employs the Asia Pacific Tele-Ophthalmology Society (APTOS) dataset [35], concentrating on its standard and Diabetic Retinopathy (DR) categories. Images designated as DR are categorized as class 1, while standard retina images are categorized as class 0. The APTOS dataset was selected for its thorough representation of retinal anomalies, facilitating an in-depth examination of diabetic retinopathy diagnosis by deep learning methodologies. The research ensures consistent preparation, training, and assessment protocols by focusing on a solitary, high-quality dataset.

The severity of diabetic retinopathy can be assessed accurately and reliably using the APTOS DR Severity Scale. It has been widely used in clinical therapy and research throughout the Asia-Pacific region. It has been employed in developing and evaluating computer-aided diagnostic tools for diabetic retinopathy that autonomously detect and categorize the severity of the problem using retinal images. The dataset consists of 5990 retinal images, with 3662 assigned to the training set and 1928 allotted for testing. For this study, the 3,662 training data were obtained because the test phase data lacks specific labels. The number of images in class 0 is 1805 and the number of images in class 1 is 1857. Figure 2 illustrates a selection of these images, highlighting the diversity in the APTOS 2019 dataset.

III.3 DATA PRE-PROCESSING

This section looks at the dataset used and the ways it was prepared. The images are quite big, measuring 4288 by 2848. Figure 3 shows how images are spread across the training and validation sets. It also shows how many images from the 'No_DR' and 'With_DR' groups there are. The collection includes noisy images and labels, including blurred, overexposed or underexposed images. This variation is the result of data collected from many clinics using different cameras over a long period. This section explains the steps taken to get the dataset ready for the learning phase. The aim is to make training on the dataset faster. We changed the size of the original images to 224 × 224. Then we used different batch sizes to train this collection of smaller images. An 80:20 ratio is used for selecting the model using the train-test-split method. Adjusting the model or finding patterns in the data can be achieved by using the training set. The test set checks how well the model works, especially with new and unknown data. There are 1444 training images for class 0 (no DR) and 1485 for class 1 (with DR). The numbers 361 and 372 are used to show the different classes. Class 0 is shown by the number 361 (No DR) and class 1 by the number 372 (With DR).

III.4 DATA PRE-PROCESSING

Many researchers, particularly those specialising in medical image processing, prefer to use transfer learning (TL) to develop effective models, rather than training deep learning (DL) models such as convolutional neural networks (CNNs) from scratch [36]. In this study, we have implemented a method for detecting diabetic retinopathy (DR) using a multistage learning process that incorporates feature extraction, fine-tuning approaches, and, ultimately, the fusion of all models. Transfer learning is a common technique used to train neural networks to achieve optimal results. It involves training a model from start to finish on a dataset with sufficient data from a related domain, and then using the limited data from the target dataset to refine it. Rather than starting from scratch, this approach builds a robust foundation for the model [37]. One of the main limitations of CNNs is that they require a large number of sample training images. The number and depth of parameters determine how much data is required for a network. Networks with more layers and parameters require more data [38], [39]. Otherwise, overfitting would negatively affect performance. However, one of the main problems in creating DL models for the medical industry is that there is not enough data. Therefore, using the idea of transfer learning for medical projects would be a good idea [8], [40]. The Visual Geometry Group (VGG) at the University of Oxford created a model called VGG16 in 2014 (see Figure 4). The main framework, VGGNet, has led to several modifications, including VGG1, VGG13, VGG16 and VGG19. Out of all these models, people use the last two versions, VGG16 and VGG19, the most. The VGG16 model is widely used in medical applications to recognise and categorise different types of clinical images [27]. The learnable parameter layers of the model are represented by its weighted layers, which total 16. Despite its modest kernel size, it is very time consuming to train [15].

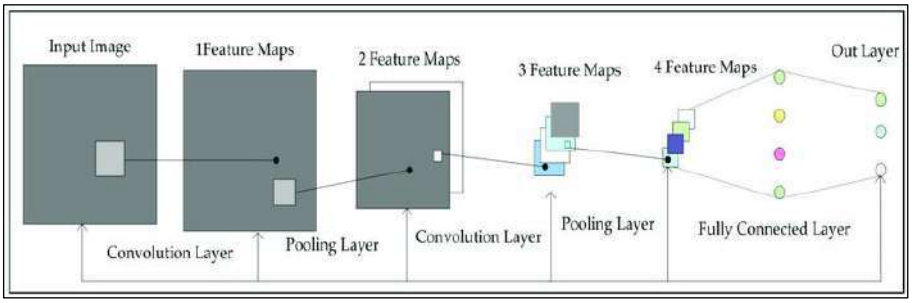

Figure 4: Architecture of the VGGNet Model Showing Convolutional, Pooling, and Fully Connected Layers.
Source: [41].

The DenseNet121 model (Figure 5) has several advantages, including strong gradient flow, efficient computation, smooth error signal propagation, and reduced feature complexity [15]. The main aim in creating this network was to solve the problem of the gradient vanishing as the number of layers increases. If you lose or delete information, the network gets deeper. DenseNet121 solves this problem by connecting the layers of the network [42].

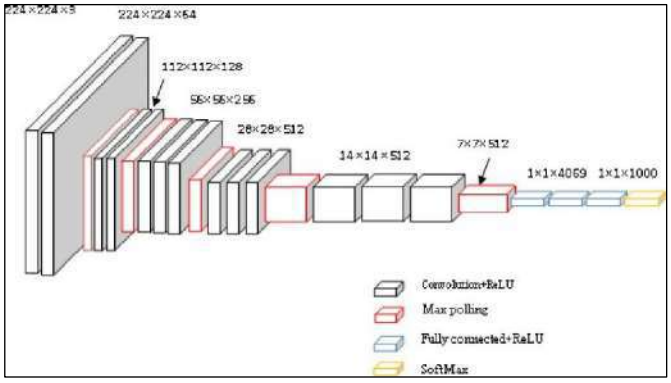

Figure 5: Architecture of the DenseNet121 Model.
Source: [43].

ResNet (Residual Network), introduced by [44] in 2015, is a special type of deep learning network that solves the problem of vanishing gradients by using skip connections (residual connections). These connections help the network to understand how different things are connected, which makes it easier to train very complex networks.

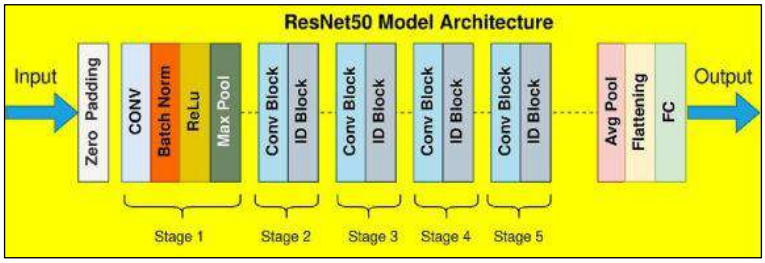

Figure 6: Architecture of the DenseNet121 Model.
Source: [43].

EfficientNet is a family of convolutional neural networks developed by Tan and Le (2019) at Google AI (Figure 7). It is designed to optimise both accuracy and efficiency by systematically scaling the depth, width, and resolution of the network using a compound scaling method [45]. There are eight variations, ranging from B0 to B7. Each subsequent model number refers to a variant with more parameters and higher accuracy.

III.5 ENSEMBLE CLASSIFIER METHODS

In this study, the authors present a novel ensemble-based method for combining predictions from multiple deep learning models. The proposed approach exploits the principles of ensemble learning by aggregating the prediction probabilities of individual models to generate a unified, fused score. This strategy increases the robustness and accuracy of the final decision. Figure 7 shows the basic ideas of ensemble learning as used in the suggested system.

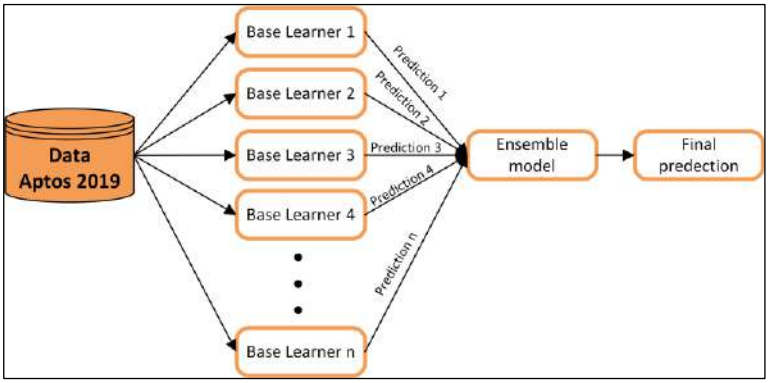

Figure 8: Ensemble Learning Strategy for Combining Predictions from Multiple Models.
Source: Authors, (2026).

Majority voting: The soft voting approach determines the predicted class of diabetic retinopathy by selecting the class label i=1 to n that has the highest average probability across all models j=1 to m [46]. Equation 1.

$$Fp = label\left(max(\mathrm{p}') \parallel \mathrm{p}'_i = \sum_{j=1}^{m} p_{ij}\right) \quad (1)$$

$Fp : Final\ predection$
Where i=1 to n.

Average (arithmetic mean): The simplest method of combining several scores is to take the average Equation (2). Add together all the scores and divide by the total number of scores to find the mean [47].

$$Fp = \frac{1}{n} \times \sum_{i=1}^{n} S_i \quad (2)$$

Fuzzy rank: According to the fuzzy rank, a rank is given to each model's prediction score. These ranks are then combined to provide a final prediction [48] (see Algorithm 1 for more information). Two non-linear functions are used for each base classifier to obtain the fuzzy ranks. These amounts are then distributed among the classifiers once the ranks have been added together. Finally, a prediction is made for the class with the lowest total score.

Algorithm 1: Fuzzy Rank Algorithm:

Input:
C: Number of classes
BC: Number of base classifiers
i: Base classifier index (1 to BC)
P [i][k]: Confidence scores predicted by base classifier i for each class k
Output:
class(I): Predicted class for input I
Algorithm:
for *each base classifier i* ***do***
  for *each class k* ***do***
    Calculate fuzzy ranks

$$R_1[i][k] = 1 - e^{-\left(-\left(\frac{P_{ik}-1}{2}\right)^2\right)}$$

$k = 1,2,3,\dots,C;\ i = 1,2,3\dots,BC$

$$R_2[i][k] = 1 - tanh\left(-\left(\frac{P_{ik}-1}{2}\right)^2\right)$$

$k = 1,2,3,\dots,C;\ i = 1,2,3\dots,BC$

Fuse ranks

$RS[i][k] = R_1[i][k] \times R_2[i][k]$

  end for
end for
for *each class k* ***do***
Sum fuse scores across base classifiers

$FS[k] = \sum_{i=1}^{BC} RS[i][k]$

end for
predicted class
class(I) = arg min(FS[k])

Sugeno integral: The Sugeno fuzzy integral lets you add together the outputs of multiple classifiers according to fuzzy measures that represent how relevant the sources are. I have used it to make predictions about diabetic retinopathy using information from CNNs that have already been trained [49]. The Sugeno integral method is defined by considering μ as a fuzzy measure on a set $A = \{a_1, a_2, \dots, a_n\}$. The ranges of these elements are represented by, where is a function mapping A to the interval [0, 1] such that $(a1) \leq (a2) \leq \cdots \leq (an)$. The Sugeno integral can be expressed by Equation (3) as:

$$\int_{i=1}^{n} r(a) d\mu = \max_{1 \leq x \leq n} \left(min\left(r(a_x), \mu(A_x)\right)\right) \tag{3}$$

The fuzzy measures of $\{a_i\}$, denoted as $(\{a_i\})$, are primarily determined by domain experts for a specific statistical problem. These fuzzy measures help to compute $(A \times x)$ using the Sugeno λ fuzzy measures $\lambda \in$ (-1, ∞) defined by Eq. (4):

$$1 + \lambda = \prod_{i=1}^{n} \left(\mu(\{a_i\})^{\lambda} + 1\right) \tag{4}$$

After obtaining the values of λ from Eq. (4), the value of $\mu(A \times x)$ is calculated using Eq. (5):

$$\mu(\{a_1, a_0\}) = \mu(\{a_1\}) + \mu(\{a_0\}) + \lambda \mu(\{a_1\}) \mu(\{a_0\}) \tag{5}$$

Where $1 \leq l, o \leq n$. Algorithm 2 provides a comprehensive explanation of the Sugeno integral method.

Algorithm 2: Sugeno integral:

```
procedure SugenoIntegral(C, BC, P, F)
    λ ← initialize by solving Equation ()
    predictions ← initialize empty list of final predictions
    for class_indexi ∈ {1,2,3, … , C} do
                        P_π ← Sorted array P in descending order
                        F_π ← Permutation of F corresponding to P_π
                f_prev ← F_π [0]
                pred ← min (P_π[0], F_π[0])
                for n ∈ {1,2,3, … , C} do
                    f_current ← f_prev + F_π [n] + λ × F_π [n] × f_prev
            pred ← max(pred, min(P_π[n], f_current))
        f_prev ← f_current
        end for
        predictions[i] ← pred
    end for
    class(I) ← arg max(predictions[i])
end procedure
```

IV. RESULTS AND DISCUSSIONS

This section gives a full review of our suggested CNN technique, using some common ways to judge it on the test data samples. In addition, a comparison was made between the proposed method and several popular deep learning techniques in order to demonstrate the relative performance of the proposed method in comparison to other techniques. The dataset under consideration was divided into two sections: a training set and a testing set. The training part has 80% of the data (1485 with_DR and 1444 No_DR), and the testing part has 20% of the data (372 with_DR and 361 No_DR). This distribution is illustrated in Figure 3.

IV.1 EXPERIMENTAL PROTOCOL

The experimental analysis for diabetic retinopathy classification was performed on the Kaggle platform, which provides a cloud-based environment equipped with high-performance GPUs and extended memory resources ideal for deep learning tasks. Experiments were implemented using Python 3.7 within Kaggle's integrated Jupyter Notebook interface, allowing seamless coding, visualisation and model training. The setup included essential libraries such as TensorFlow, PyTorch, NumPy and Matplotlib, supporting an efficient workflow for deep learning model development and evaluation.

IV.2 EVALUATION METRICS

For the classification of diabetic retinopathy, the selection of appropriate evaluation metrics is critical to accurately assess model performance. Commonly used metrics include recall, precision, accuracy, F1-score and true negative rate (specificity), each providing different insights into different aspects of the model's predictive ability. The mathematical formulations of these metrics are presented in Eqs. (6 -10), which form the basis for performance evaluation in this study.

Accuracy: is measured by the percentage of instances that the correct classification has been given out of the total number of cases.

$$\text{Accuracy (Acc)} = \frac{(\text{T P} + \text{T N})}{(\text{T P} + \text{T N} + \text{FP} + \text{F N})} * 100\% \tag{6}$$

Recall: This function calculates how well the classifier can find all the positive instances. This is also known as sensitivity.

$$\text{Recall (Sensitivity)} = \frac{\text{T P}}{(\text{T P} + \text{F N})} * 100\% \quad (7)$$

True Negative Rate (TNR): is a metric that quantifies the precision of a system's negative identification, calculated as the ratio of true negative instances that are correctly identified.

$$\text{TNR (Specificity)} = \frac{\text{T N}}{(\text{T N} + \text{FP})} * 100\% \quad (8)$$

Precision: The ability of the classifier to only return relevant instances is measured by precision:

$$\text{Precision (Pre)} = \frac{\text{T P}}{(\text{T P} + \text{FP})} * 100\% \quad (9)$$

F1_score: The F1 score is the arithmetic average of precision and recall. False positives and false negatives are both considered.

$$\text{F1}_{\text{score}} = \frac{2 * \text{Precision} * \text{Recall}}{(\text{Precision} + \text{Recall})} * 100\% \quad (10)$$

IV.3 RESULTS OF CLASSIFICATION MODELS

In this section, we present a comparative analysis of the performance of five deep learning models trained on the original APTOS 2019 dataset. As summarised in Table 1, all models demonstrated high predictive performance, with accuracies converging around 98.23%. This consistency highlights the robustness of the dataset and the effectiveness of fine-tuned hyperparameters, such as the use of the Adam optimiser with a learning rate of 0.0001 and an epoch size of 50 for most models. Among the models evaluated, EfficientNet-B7 achieved the highest AUC of 99.78%, indicating an exceptional ability to discriminate between DR and non-DR cases. Notably, despite identical accuracy to other models, EfficientNet-B7 stood out for its superior recall (98.92%) and low misclassification rates, as confirmed by its confusion matrix [[352,9],[4,368]] [[352,9],[4,368]]. This suggests its effectiveness in minimising false negatives, which is critical in medical diagnosis. The ResNet50 model, trained with a significantly larger batch size of 128 and a higher learning rate of 0.001, also achieved excellent results, with balanced precision (97.87%) and recall (98.66%), and a strong AUC of 99.51%.

This suggests that larger batch sizes combined with Adam optimisation can still produce competitive results. DenseNet121, trained with a smaller batch size of 8, showed a favorable trade-off between false positives and false negatives, reflected in a confusion matrix of [[355.6],[7.365]] [[355.6],[7.365]]. The value of its AUC is 99.33%. Both VGG16 and VGG19 produced almost identical accuracies (98.23%), but differed slightly in precision and recall, with VGG16 achieving higher precision (98.38%) and VGG19 demonstrating better recall (98.92%). These differences highlight the subtle trade-offs between the models in correctly identifying positive and negative samples, as demonstrated by their confusion matrix. The ensemble of results indicate that all five models can detect diabetic retinopathy with high accuracy when optimized properly. The confusion matrices show consistently low false positive and false negative rates for all models, underscoring their potential clinical applicability. Figures (9 to 13) present the evaluation results of all models employed in the designed system using the dataset.

Table 1: Performance Metrics of Classification Models on the APTOS 2019 Dataset Including hyper-parameter settings and Confusion Matrices.

Models	**Hyper-parameter**				**Evaluation Metrics**				
	Batch size	**Epochs**	**Optimizers**	**learning rate**	**Accuracy**	**Precision**	**Recall**	**F1-Score**	**AUC**
VGG16	16	50	Adam	10^{-4}	0.9823	**0.9838**	0.9812	0.9825	0.9949

IV.4 MODELS RESULTS OF ENSEMBLE LEARNING

Once the best performing individual models (VGG16, VGG19, EfficientNet-B7, DenseNet121 and ResNet50) were identified based on classification metrics, ensemble learning was used to combine their strengths and further improve performance. Four ensemble strategies were evaluated: Majority Voting, Average, Fuzzy Rank, and Sugeno Integral, respectively applied to the top three, four, and five models ranked by accuracy. The detailed performance results of these fusion strategies are presented in Table 2, while the corresponding confusion matrices for each method are shown in Fig. 14, providing a visual insight into the classification results.

Top three classifiers (VGG16, VGG19, EfficientNet-B7)

All ensemble methods (Majority Voting, Average, Fuzzy Rank and Sugeno Integral) achieved the highest accuracy of 0.9864 with identical evaluation metrics: Precision (0.9814), Recall (0.9919), F1 score (0.9866), Confusion matrix: [[354, 7], [3, 369]]. This result confirms the robustness of the ensemble techniques, especially when combining the three best performing models. The confusion matrix shows minimal false positives and false negatives, indicating excellent generalization and clinical reliability.

Top four classifiers (adding DenseNet121)

Ensemble methods using four models showed a slight drop in accuracy to 0.9823 (Majority Voting and Average), while Fuzzy Rank maintained 0.9864: Precision (0.9838), Recall (0.9812), F1 score (0.9825), Confusion matrix: [[355, 6], [7, 365]]. These results show that the inclusion of an additional model (DenseNet121) slightly increased the false negative rate and reduced recall and F1-score. However, the fuzzy rank fusion proved to be more stable, maintaining the best scores with minimal loss of performance.

Top five classifiers (adding ResNet50)

When all five models were combined:

Accuracy: 0.9836 (Majority Voting, Average, Sugeno Integral)
Precision (0.9813), Recall (0.9866), F1 score (0.9839), Confusion matrix: [[354, 7], [5, 367]].

This configuration achieved a good balance between precision and recall, improving performance over the top-4 configuration. However, it did not surpass the performance of the top-3 combination, suggesting that adding more models does not improve the overall performance. The best performance (accuracy of 0.9864) was consistently achieved by all fusion strategies when using the top three classifiers. This highlights the importance of selecting high quality, complementary models for ensemble learning. The Fuzzy Rank and Sugeno Integral methods showed superior stability, achieving the highest scores even when more models were added. The confusion matrices show that most misclassifications occur in the negative class, with very few false negatives - a critical factor in medical diagnostic applications where missed cases are riskier.

V. CONCLUSIONS

In this study, an advanced deep learning-based system for automated detection of diabetic retinopathy (DR) was proposed using the APTOS 2019 dataset of RGB fundus images. Five pre-trained convolutional neural networks: VGG16, VGG19, EfficientNet-B7, DenseNet121 and ResNet50, were fine-tuned using transfer learning and individually evaluated for their classification performance. All models achieved high accuracy (around 98.23%), with EfficientNet-B7 outperforming the others in ROC AUC (99.78%) and recall (98.92%), indicating strong discriminative power and minimal false negatives - an essential feature in medical diagnostics. To further improve performance, ensemble-learning strategies including Majority Voting, Average, Fuzzy Rank and Sugeno Integral were applied to combinations of the best performing models.bThe best results were consistently achieved by fusing the top three models (VGG16, VGG19 and EfficientNet-B7), which gave an accuracy of 98.64%, precision of 98.14%, recall of 99.19% and F1 score of 98.66%.

These metrics were supported by confusion matrices showing very low false positives and negatives, reinforcing the clinical reliability of the system. While the addition of more models (up to five) resulted in slight performance trade-offs, particularly in recall, fusion strategies such as Fuzzy Rank and Sugeno Integral showed strong robustness and stability across configurations. The results underscore that careful selection and combination of complementary, high-performing models yields superior results compared to standalone classifiers or excessive model aggregation.bOverall, this work validates the effectiveness of integrating transfer learning with ensemble learning for DR detection and provides a scalable, accurate and clinically applicable solution for early detection, potentially improving patient outcomes and supporting efficient healthcare delivery.

Table 2: Evaluation results of the ensemble method based on score level fusion of all models on the APTOS 2019 dataset.

Order of Models	Methods	Models	Evaluation Metrics			
			Accuracy	Precision	Recall	F1-Score
1- VGG16 2- VGG19 3- Efficienet-B7 4- DenseNet121 5- ResNet50	Majority voting	Top 3 Models	**0.9864**	0.9814	**0.9919**	**0.9866**

ABSTRACT

The objective of this work is to study the effect of sand type on the physical and mechanical behavior and durability of self-compacting repair mortar (SCM). Six types of sand were used in this study, crushed limestone sand (CS), silica roller gravel sand (GRCS), dune sand (DS), mixed sand (70% DS + 30% CS) and normalized sand (NS). The three-point compression and tensile tests were carried out for the periods: 2 days, 7 days, 28 days with absorption and 90 days**.**The results showed that the rheological properties of the fresh mortar which were carried out using the flow and diffusion tests are largely in line with the recommendations of EFNARC, while in the hardened state, the samples consisting of (CS) showed high compressive strength in 28 days, reaching an increase of 21.79% over the control sample. The three-point tensile strength showed superior results over the control by 26.61%. As for the rest of the samples, they showed relatively acceptable results, although they were lower than the control results. The durability test also confirmed the results obtained in the three-point compression and tensile tests, where the higher the three-point compression and tensile results, the lower the porosity**.**

I. INTRODUCTION

Aggregates and in particular sand have been the basis of the construction industry since Roman times and up to the present day. Several sources indicated that the amount of sand extracted in the world annually exceeds 15 billion tons [1], [2], making it the second most used resource after water [3]. Extracting sand in such large quantities as a result of significant demographic growth poses many environmental problems such as the decline in groundwater levels, the destruction of vegetation in rivers, and soil erosion [4-7], and it also leads to the depletion of non- renewable resources in some countries. Algeria is among the countries that have experienced a great shortage of natural sand such as Morocco, Turkey [8], Spain, Argentina [9], India [10] and China [11]. However, Algeria has very abundant local alternatives, and their development is an excellent opportunity to considerably reduce the cost of concrete materials, reduce environmental pollution and preserve natural resources. Deserts cover approximately one-third of the Earth's land area, with the desert in Algeria comprising about 90% of the total area. Their most distinctive feature is the abundance of sand dunes, coupled with a severe shortage of alluvial sand needed for concrete production. Transporting alluvial sand over long distances significantly increases the cost of this material. Against this background, dune sand could have a definite economic advantage. Nevertheless, the technical side suggests that this material has anomalies requiring treatment or transformations, and cannot be used in its raw state. From these anomalies, arise the desire to find a solution for the integration of this material in the production of concrete. Several studies [12-15], carried out on dune sands have shown that this material has a very fine grain size, resulting in a significant shrinkage of concrete. Crushed calcareous sand, which is present in large quantities in gravel crushing and screening stations, has limited use, as only a small percentage is used to complete road foundation layers and sub-road foundations, while the rest goes to landfills.

This very low demand is due to the high proportion of fine particles (i.e., particles of size < 80 µm). Several authors [9], [16-18] have proven that the properties of conventional concrete with crushed sand can be negatively affected if the dust percentage increases to a certain extent. However, this dust ratio can be useful in some applications such as the production of self-compacting mortar (SCM) and self-compacting concrete (SCC). Despite its recent appearance, SCM and SCC has managed to achieve wide dissemination thanks to its competitive advantages over conventional mortar [19-23]. In addition to its economic advantages, it offers environmental solutions to several types of waste or by-products, which can now be used as mineral additives, whereas their fate was previously either landfills or burial sites. In this context, several types of waste or by-products have been studied such as the case of plastic waste, crushed brick, glass waste, [24-26]. This waste is used as a replacement for alluvial sand in SCM. All of this research has yielded very promising results. The main objective of this research is to study the effect of different sands on the mechanical and fresh characteristics of SCM. (Crushed calcareous sand, crushed rolled gravel sand (silica) and dune sand). The various sands used here are originally either an industrial by-product that is sent to landfills, or is present in abundance. Tests on SCM in the fresh state, hardened state and sorptivity coefficients are tested at different ages. According to previous studies, most researchers have focused on concrete or mortar containing crushed limestone sand or dune sand as an alternative to alluvial sand, limiting their research to liquid and solid state experiments [27-30]. The effect of these alternatives on the performance of self-compacting mortar, particularly its impact on durability, has not been thoroughly investigated. Therefore, this study intends to fill this research gap by investigating the feasibility of incorporating these alternatives and their effect on the durability of self-compacting repair mortar.

II. MATERIALS AND METHODS

II.1 MATERIALS

II.1.1 Cement

Cementitious material used to produce SCM were ordinary Portland cement type CEM II /A-L 42,5 N complying with the Algerian standard NA 442 [31]. It had a specific gravity of 3.07 and the Blain surface was equal to 4465 cm2/g. The chemical compositions of the cement are given in Table 1.

Table 1: Chemical compositions of cement.

Compounds	SiO2	Al2O3	Fe2O3	CaO	MgO	K2O	Na2O	SO3	Cl-	P.A.F	Free CaO	R.I
%	18,47	4,63	3,34	61,08	1,16	0,71	0,4	2,64	0,017	6,69	0,87	2,15

Source: Authors, (2026).

II.1.2 Sands

For the purposes of this study, six different sands were used:

• The first is river sand with a continuous particle size distribution ranging from 5mm to 0.08mm, but the fraction below 0.16mm remains very small Figure 1(a).

• The second is a crushed limestone fine sand designated by CS (Crushed sand) Figure 1(b) collected from Ouargla region, also has a continuous particle size distribution with a maximum grain diameter of about 3 mm, but the proportion of grains smaller than 0.08 mm is less than 30% Figure 2.

• The third is crushed rolled gravel sand (CRGS) Figure1(c) resulting from crushing and sieving, which is a natural gravel of a siliceous nature available locally brought from Hassi Sayeh (around the city of Ouargla).

• The fourth is dune sand (DS) Figure 1(d) collected from Sidi khouiled in the Ouargla area and has a maximum grain diameter of about 0.63 mm; the proportion of grains less than 0.08 mm is less than 5% characterized of its abundance in nature (Sahara) with almost zero extraction cost.

• The fifth is a corrected sand (CDS) of crushed rolled gravel-dune Figure 1(e) prepared by correcting the fine part of dune sand by a part of sand (CRGS) according to a mass ratio (CRGS / DS) = 1,25.

• The sixth is a standardized sand (SN) Fig.1(f) complying with the requirements of standard EN 196-1 [32], of natural origin, siliceous in particular in its finest fractions. It is packaged in polyethylene bags containing 1350 ± 5 g.

The physical properties and the particle size analysis curves of these sands are shown in Table 2 and Figure 1, respectively. Figure 3 shows the X-ray diffractogram for our natural sand. It can be seen that the sand used is silico-calcareous due to the existence of two intense and dominantly peaks, the peaks of quartz and calcite.

Table 2: Physical characteristics of sand.

Sand	Apparent density (kg/m3)	Specific density (kg/m3)	Fineness modulus	Absorption	Sand equivalent (%)
AS	1545	2637	1,99	0,108	49
CS	1487	2649	2,14	4984	40
CRGS	1384	2654	2,48	0,304	96
DS	1488	2658	0,95	0,271	81
DS-CRGS	1614	2658	1,57	0,801	95
S	1570	2658	1,93	0,096	95

II.1.3 Limestone filler

The limestone filler is a waste of calcareous rock crushing, coming from quarries of the production of aggregates, it had a specific gravity of 2.7 and the Blain surface was equal to 442 m^2/kg.

II.1.4 Super plasticizer

To achieve the desired self-compacting properties, an admixture named viscocrete tempo12, which is a modified acrylic copolymer based superplasticizer, with a solid content of 36% and 1.09 kg/l density, was employed.

II.2 METHODS

II.2.1 Mixture Proportion and Mixture procedure

Six distinct mortar mixes were produced with different types of sand. Table 3 shows the details of the SCM mixtures.

Table 3: Mixture proportions of mortars.

Mixes	water / binder	Cement (kg)	Limestone filler (kg)	Sand (kg)	Water (kg)	Super plasticizer (kg)
SA	0,40	550	100	1300	260	14,3
SC	0,40	550	100	1300	260	15,4
CRGS	0,40	550	100	1300	260	17,6
DS	0,60	550	100	1300	390	6,6
CDS	0,40	550	100	1300	260	13,2
SN	0,40	550	100	1300	260	9,9

Source: Authors, (2026).

All SCM mixtures have been prepared in an identical mixing process to ensure similarity and uniformity. The mixing sequence consisted of homogenizing the binder and the sands for one minute using a standard mixer. Then two-thirds of the mix water was added and mixed for another minute. After that, the remaining water (one third) and super plasticizer were added and mixing was continued for three minutes. For each type of mortar, a set of twelve prismatic specimens (40 mm x 40 mm x 160 mm) was made. Samples were demolded after 24 h and cured at 95 ± 5% relative humidity and 20 ± 2°C temperature until test date.

III.TESTING PROCEDURES

III.1 WORKABILITY

To study the behavior of fresh self-compacting mortar, slump flow and V-funnel flow tests Figure 4 were performedbased on EFNARC recommendations [33].

(a) (b)

Figure 4: Fresh self-compacting mortar test: (a) slump flow test and (b) V-funnel test.
Source: Authors, (2026).

III.2 FLEXURAL AND COMPRESSIVE STRENGTH

For the mechanical tests, three-point bending tests were carried out at 3, 7, 28 and 90 days on prismatic samples(40 × 40 × 160 mm^3) according to ASTM C348 [34]. After breaking the three samples during the bending tests, the two parts (40 x 40 x 80 mm^3) of each prism were subjected to a compressive strength test according to ASTM C349 [35].

III.3 WATER ABSORPTION

Water absorption was performed based on ASTM C1585-04 [36]. Mortar samples obtained by sawing prisms of dimensions 40 x 40 x 80 mm3 Figure 5. The samples hardened for 28 days were used for the evaluation of the sorptivity coefficient k

$$k = Q/A\sqrt{t} \quad (1)$$

Where Q is the accumulated absorbed water in cm3, A is the exposed cross section of the sample in cm2, t is the time in min and k is the sorptivity coefficient in cm / min0.5. k is calculated using a linear change between the cumulative water absorption (Q) and the square root of time (t).

IV. RESULTS AND DISCUSSIONS

IV.1 FRESH PROPERTIES

Slump flow diameter and V-funnel flow time values are presented in Figures 6 and 7. It is obvious that SCM mixtures ensured EFNARC recommendation for relative slump and relative funnel speed. As shown in Figure 6, the highest slump flow value of 260 mm was obtained by DS without any segregation, while the lowest value of 242 mm was recorded for CS. It can be concluded from these results that a decrease in the fluidity of mortars with CS, GRCS and CDS sand was observed. This decrease in fluidity is due to the angular or irregular shape of the granular skeleton of its sands which hinders (or slows down) the flow of the mortars (see Figure 7). Many studies have been conducted on the effect of irregular shapes of coarse aggregates on the rheology of self-compacting concrete [3], [37]. On the other hand, RS, DS and NS sands, which have a spherical shape, promote the flow of mortars. Similar results were reported by Bederina [8].

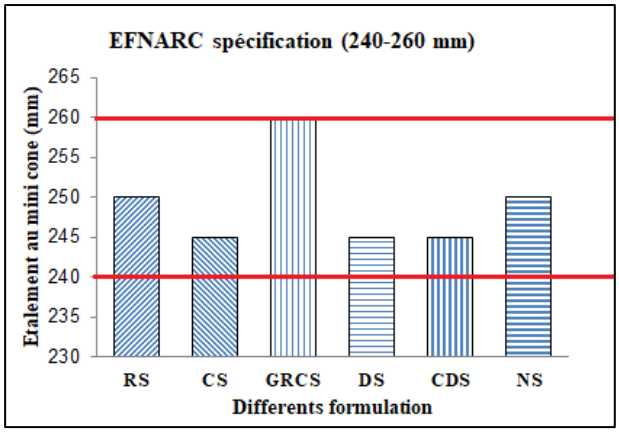

Figure 6: Results of fresh SCMs mixes tests: Slump flow diameter.
Source: Authors, (2026).

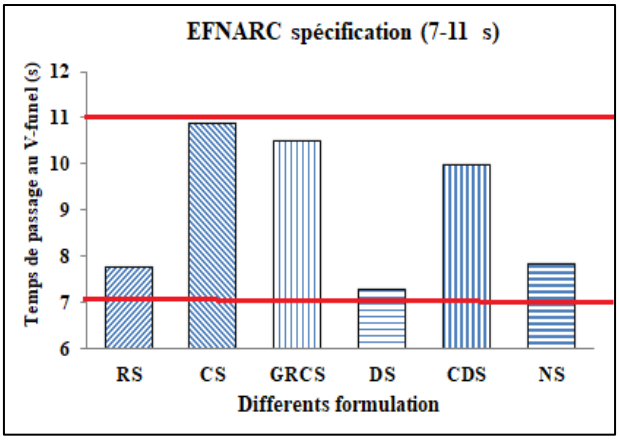

Figure 7: Results of fresh SCMs mixes tests: V-funnel flow time.
Source: Authors, (2026).

IV.2 COMPRESSIVE STRENGTH

Results of the compressive strength tests of the SCM composed of different types of sand are given in Figure 8. The compressive strength of the different mixtures is in the ranges 8.38 - 25.46; 9.81 - 29.06; 18.33 - 37.22 and 19.83 - 40.20 MPa, at ages of 2, 7, 28 and 90 days, respectively. The CS mixture showed an increase of 83.03%, 60.91%, 21.79% and 22.63% at the ages of 2, 7, 28 and 90 days, respectively, over that of the control RS and NS. The increase in the compressive strength can be explained by the angularity of the CS grains on the one hand [17] and by the pore filling effect of the powder of limestone which contains the CS on the other.

The latter also provided a suitable core for hydration and thus catalyze the hydration. This result is in agreement with the results of other authors [19], [38]. While the remaining mixtures, namely CGRS, DS, CDS showeda decrease in resistance at different ages compared to AS and NS. The mixture of the CGRS crushed rolled gravel sand recorded a decrease of 7.40%, 4.5%, 6.80% and 10.20% at the ages of 2, 7, 28 and 90 days, respectively. The decrease in the compressive strength of mortar samples with washed crushed rolled gravel sand (CGRS) can also be attributed to a significant reduction in the proportion of fine material in the mortar mixes caused by sand washing. Indeed, the fine material plays the role of filling the pores and its loss negatively affects the resistance.

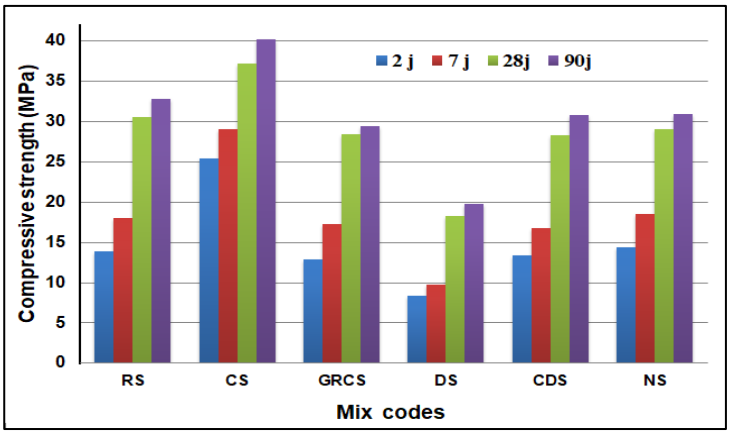

Figure 8: The compressive strength of the different mixtures.
Source: Authors, (2026).

While the remaining mixtures, namely CGRS, DS, CDS showeda decrease in resistance at different ages compared to AS and NS. The mixture of the CGRS washed crushed rolled gravel sand recorded a decrease of 7.40%, 4.5%, 6.80% and 10.20% at the ages of 2, 7, 28 and 90 days, respectively. The decrease in the compressive strength of mortar samples with crushed rolled gravel sand (CGRS) can also be attributed to a significant reduction in the proportion of fine material in the mortar mixes caused by sand washing. Indeed, the fine material plays the role of filling the pores and its loss negatively affects the resistance. The DS mixture recorded a decrease of 39.70%, 45.70%, 40.00% and 39.50% at the ages of 2, 7, 28 and 90 days, respectively. This significant decrease in resistance is generally due to poorly graded dune sand (a tight granulometry) where the refusal is zero until a sieve of 0.63 mm. Another reason for the decrease in the resistance to compression could be linked to the increased specific surface area of fine aggregates requiring more grout to coat the surface of the aggregates. These results are in agreement with the results of other authors [15]. And finally, the mixture of the CDS-corrected dune sand recorded a decrease of 3.70%, 7.20%, 7.30% and 6.10% at 2, 7, 28 and 90 days, respectively, compared to that of AS. In addition, it showed an increase over uncorrected dune sand of 37.50%, 41.40%, 35.30% and 35.60% at ages of 2, 7, 28 and 90 days, respectively. This increase shows the beneficial effect of correction, and that the corrected dune sand can be used as an alternative to AS sand.

IV.3 FLEXURAL STRENGTH

Figure 9 shows the variations in flexural strength of the different mortars studied as a function of time. It should be noted that the remarks made on the flexural strength are almost similar to those noted on the compressive strength. Flexural strength values vary between 3.52 and 12.09 MPa, with the lowest flexural strength for DS at 2 days curing and the highest for CS after 90 days curing. The CS mixture exhibited an increase of 22.16%, 22.08%, 26.62% and 26.86% at 2, 7,28 and 90 days, respectively, compared to the RS control. But for the remaining mixtures, namely CGRS, DS and CDS, they recorded a decrease in resistance at all ages compared to the control where the DS mixture recorded the weakest results with a decrease of 46.30%, 40 ,10%, 33.30% and 27.80% at 2, 7, 28 and 90 days, respectively, compared to the control RS.

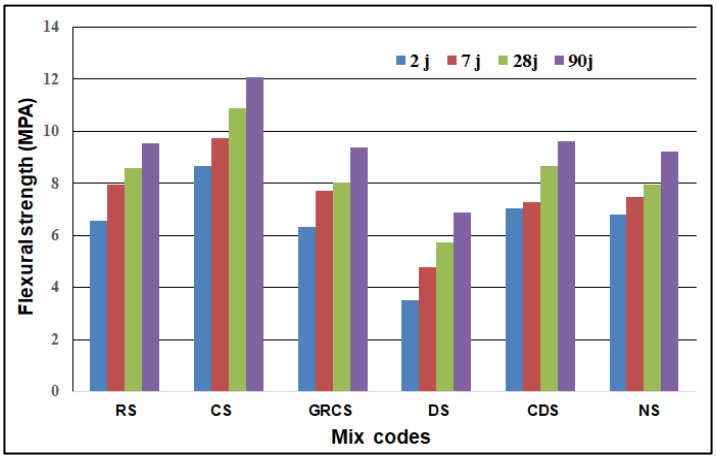

Figure 9: The compressive strength of the different mixtures.
Source: Authors, (2026).

The increase in flexural strength in the CS mixture is related to the greater amount of powdery materials and the blocking effect due to the angular shape of the aggregates. These results are also supported by Abu Seif [36]. Furthermore, the mineralogical source has a great effect on the resistance, where mixtures with limestone aggregates (CS) have better resistances than those with silica sands (CGRS, DS, CDS). These results are in agreement with the results of Bederina [8].

IV.4 CORRELATION BETWEEN COMPRESSIVE STRENGTH AND FLEXURAL STRENGTH

The correlation between flexural strength and compressive strength after 3,7,28 and 90 days of curing is illustrated in Figure 10. From the latter, it can be said that there are strong correlations between the compressive strength and the flexural tensile strength values of the SCMs produced from the different sands. The trend line and R-squared (R2) values confirm these strong correlations between compressive strength and flexural tensile strength.

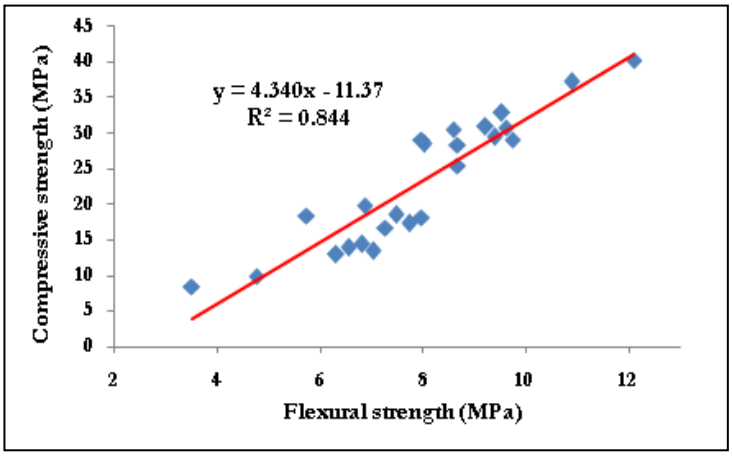

Figure 10: Relation between the compressive and flexural strength of SCMs.
Source: Authors, (2026).

IV.5 WATER ABSORPTION

The water absorption test allows to characterize the porosity, which communicates with the external surface of the mortar; it is considered as an indicator of durability. The results of the water absorption test for different designs of SCMs mixtures composed of different types of sand at 28 days of age are shown in Figure 11. The water uptake of the samples during the first 24 hours was matched using linear regression, the sorptivity of the samples up to 24 hours was determined using the slopes of the equations.

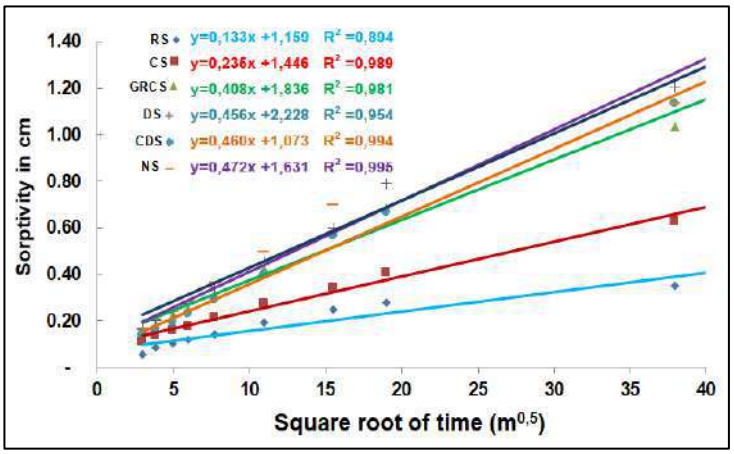

Figure 11: Water absorption of SCMs aged 28 days.
Source: Authors, (2026).

It can be observed that the cumulative volume of water absorbed by the SCM samples increases by increment of time. At the end of the exposure time, we can see that the mixture with CS displayed a slight increase in sorptivity. value of 0.63 x 103 cm / m 0.5 for the age of 28 days, compared to the sample control AS whose sorptivity was 0.35 x 103 cm / m 0.5, while the mixture with DS showed the highest sorptivity value of 1.21 x 103 cm compared to the remaining mixtures, namely NS, CDS and GRCS which have sorptivity values of 1.13 x 103 cm, 1.13 x 103 cm and 1.04 x 103 cm, respectively. It can be concluded that the control mixture gave a relatively low sorptivity due to the dense and hard structure of the river sand (AS), then the closest result to the control mixture AS is the CS mixture. This result is consistent with the literature advocating the pore-filling effect of fine fillers [39], [40]. In contrast, the highest sorptivity value was observed in the mixture which contains DS at 100% replacement rate. Similar results were observed in other researches.

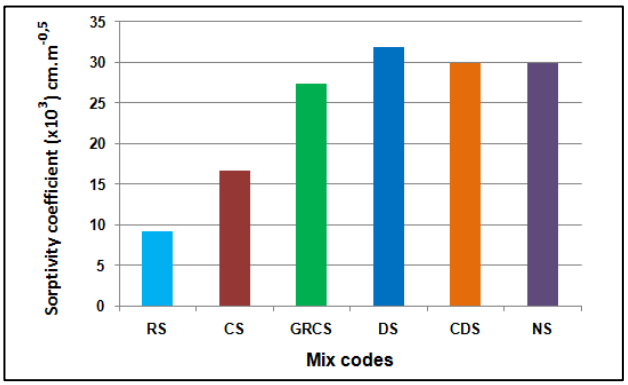

Figure 12: Sorptivity values of SCMs after 28 days of curing.
Source: Authors, (2026).

Figure 12 presents the sorptivity coefficients of the SCM mixtures at 28 days. Figure 12 highlights that RS and CS have the lowest sorptivity coefficients of 9.22 x 10^{-3} cm. $min^{-0.5}$ and 16.63 x 10^{-3} cm. $min^{-0.5}$, respectively, compared to GRCS, DS, CDS and NS mixtures which recorded sorptivity coefficients of 27.34 x 10^{-3} cm. $min^{-0.5}$, 31.79 x 10^{-3} cm. $min^{-0.5}$, 29.87 x 10^{-3}cm. $min^{-0.5}$ and 29.87 x 10^{-3} cm. $min^{-0.5}$, respectively.

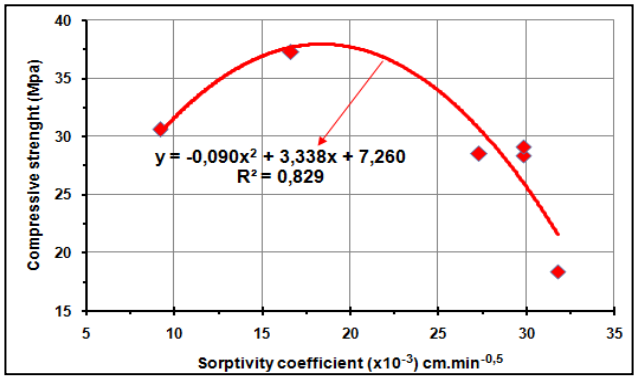

Figure 13: Correlation between the compressive strength and sorptivity coefficient at 28 days.
Source: Authors, (2026).

The values of the sorptivity coefficients of all the mixtures at the age of 28 days show the same trend as the compressive strength with the lowest for the control mixture SCM and the highest for the DS. Figure 13 shows the relationship between the compressive strength and the sorptivity coefficient of the different mixtures.

V. CONCLUSIONS

The following conclusions can be drawn from the study:

- All the mixes show satisfactory self-compacting properties in the fresh state with a constant water/cement ratio except for the DS mix which requires a higher w/c, all fulfilling the recommendations of the EFNARC related to passage capacity and flow time.
- Compressive and tensile strengths of all SCM samples increased as curing age increased from 2 days to 90 days. mixtures containing CS had higher strengths than all other mixtures. DS correction (DSC) resulted in increased compressive and tensile strength at all ages compared to DS mixture alone.
- CRGS, DS and CDS mixes of SCMs having high sorptivity values generally exhibits low compressive strength as sorptivity results are compared to compressive strength of the samples cured in water at the age of 28 days.
- Crushed sand with semi-high fines content can be successfully used in the production of SCM, achieving the dual purpose of conserving natural resources and protecting the environment at the same time.

ABSTRACT

Microgrid (MG) technology has the potential to effectively incorporate a new method to produce renewable energy on a massive scale for the grid-connected system. An Energy Management System is necessary for a microgrid to make the most efficient use of its distributed energy resources in ways that are also intelligent, protected, consistent, and synchronized. In this work, the management of battery energy storage system that is connected to a solar photovoltaic array and wind turbine system in a microgrid, as well as the control of battery charge and discharge operations using a converter based on the demand for the energy has been carried out. The strategy suggested was the daily energy management of a MG system by implementing hybrid grey wolf and cuckoo search optimization (HGWCSO) algorithm for reducing the total variable cost of energy. The output variables of each component of microgrid such as solar PV, wind turbine, grid, energy storage system as well as load power graphs. Energy storage system state of charge graphs is analysed at each instance of time and the variable cost of energy for a day were determined by using proposed algorithm. The proposed HGWCSO algorithm provided the overall system cost of 8.03%, which is less than the value obtained by heuristic approach.

I. INTRODUCTION

Microgrids (MG) are now gaining popularity and are regarded as the future trend in distributed power systems. These are helping to supply the sustainable power to the remote areas, which are located far away from the utility grid. To ensure stability in a MG, power balance must be maintained due to the non-conventional energy sources intermittent nature of power generation [1]. Because the supply and demand of energy are out of balance, RES dependability is necessary. ESSs are a significant part of the MG since they increase the effective use of RES. The EMS is a management system that executes critical tasks in all MG to ensure that operating costs and energy costs are covered [2]. The EMS has a considerable impact on the MG reliability and efficacy. Numerous researchers have used various kinds of solution strategies to address these energy management approaches to ensure the MG performs optimally and effectively. In reference [3], the authors introduced an EMS that utilises both nonlinear and linear programming techniques. Conversely, in reference [4], the authors proposed an EMS that combines rule-based and dynamic programming approaches. In their study, the scientists developed a multi-objective EMS by employing swarm and genetic optimisation techniques [5]. In their research, the authors presented an EMS that leverages a combination of meta-heuristic methodologies. They further showcased an EMS implementation utilising a neural network and fuzzy logic. This approach was proposed in reference [6]. The authors in [7] proposed an EMS based on a multi-agent system and suggested a stochastic, robust programming approach-based EMS.

In addition to variable and constant loads, the suggested research incorporates two blocks: a PV array block serving as a RES, and other block functioning as an ESS to store energy within the system [8], [9]. The presented model outlines the sequential process involved in developing an optimisation algorithm that leverages projected price and loading conditions to efficiently manage the energy storage and sale of energy from a battery system at a grid-scale level in [10]. The availability of this real-time data is limited to a single day. The battery controller serves the purpose of storing energy within the battery storage system. In the event of surplus power within the MG, the excess energy is stored and subsequently utilised to provide supplementary power during instances of power scarcity within the MG. The methodology of controlling suggests that the microgrid doesn't solely depend on the electricity generated by the primary utility grid but also relies on solar PV systems and energy storage, which typically provide an adequate power supply. This work focuses on two approaches: heuristics method and HGWCSO algorithm. The following table provides the latest work done on energy management optimization of the hybrid microgrid system.

Table 1: Literature Survey of Energy Management of Microgrid.

Author/Ref.	Optimization Technique	Highlights
Djerioui et al. [11]	GWO	Using a fuel cell (FC) and a super capacitor hybrid energy source as the EMS, it will be possible to implement electric vehicles (EVs). The use of the GWO approach to lengthen the FC's life and minimize transients in the power system
Acharya et al. [12]	PSO (Particle Swarm Optimization) and GSA (Gravitational Search Algorithm)	To improve the power quality, PSO and GSA approaches are used. Outcomes demonstrate that the proposed technique is more effective than the PI and PSO methods.
Choudhury et al. [13]	CS (Crow Search)	The research will use a grid-integrated solid oxide fuel cell (SOFC) system. The gains of PID controllers are precisely tuned using the CS approach. Results pointed to a reduce in distortions and an increase in system effectiveness.
Choudhury et al. [14]	ISSA (Improved Squirrel Search Algorithm)	In this investigation, a PID controller adjusted using the ISSA technique is used to manage the power quality of the grid-integrated FC. SSA and PSO outcomes have been compared to those of the new, improved SSA approach.
Elmetwaly et al. [15]	MPA (Marine Predator Algorithm)	Improving an EMS for a collection of distinct MGs based on the MPA approach. Increasing overall system efficiency by using a PID-based adaptive dynamic voltage restorer.
Ferahtia et al. [16]	SSA (Salp Swarm Algorithm)	DC microgrid made up of FC, PV, and battery energy storage systems, an EMS-based approach based on the SSA method is suggested. By using the suggested technique, fuel consumption has decreased and system efficiency has increased.
B. Dey et al [17]	Hybrid CSA-JAYA algorithm	The investigation employed an EMS that relied on demand response. According to reports, the economic functioning of the MG system employed the demand response (DR) technique, leading to a notable reduction of 9% in production costs.
V.Suresh et al [18]	GA(Genetic Algorithm), PSO and ACO (Ant Colony Optimization)	Different optimisation techniques are used for microgrid energy management; however, the results show that the ant-colony algorithm is the best choice among all.
D.G. Rosero et al [19]	Machine Learning Techniques	Improve energy generation and usage predictions while minimising the cost to the service provider.
M.Rodriguez et al [20]	Meta heuristic algorithm, Fuzzy logic	The outcomes of the research indicate that the proposed methodology effectively mitigates the consumption of distributed generation (DG), enhances the utilisation of solar resources, and prolongs the lifespan of batteries by avoiding deep discharges and overcharges.
N. Alamir et al [21]	Pelican Optimization Algorithm (POA)	To reduce the peak hour load, the results of the hybrid dynamic demand response method combined with the POA method were implemented into the EMS of the MG system

Source: Authors, (2026).

From the above discussion, it can be concluded that few researchers are concentrated on the energy management strategies to reduce the cost of the system. So, in this research the goal is to reduce the adjustable tariff of hybrid MG, which is already designed for a location. The remaining of this paper is organised as follows: Sections 2 gives brief discussion of hybrid microgrid, EMS and its classification. Section 3 examines the design models of solar and batteries and their objective functions. Section 4 discusses the proposed technique, its mathematical formulation and flow chart. Section 5 also contains an analysis and discussion of simulation outcomes followed by conclusion remarks in Section 6.

II. HYBRID MICROGRID SYSTEM

The hybrid microgrid has a number of benefits, including harmonic control, economic viability, and voltage transformation [22]. Despite all the advantages listed, a hybrid microgrid has some small drawbacks, such as protection issues and difficult unit coordination, which can be fixed by using optimal operating techniques [23], [24]. However, the hybrid microgrid system (HMGS) has overall advantage over other MGs that makes it a good case study for assessing operational problems. When operating in the stand-alone mode of operation, the system is not connected to the conventional grid, and the ESS is heavily utilized, adding to the system's running costs. The excess energy cannot be stored in addition to that. This operating mode prioritizes local loads more, making it more suited for remote locations and mostly used for seasonal purposes. Due to their superior cost-effectiveness, solar PV systems account for the majority of the capacity on islanded MG [25], [26]. The authors of [27] suggested an upgraded system-level EMS for residential hybrid microgrid by utilizing the advancements provided by digitization. The suggested EMS was created for an MG that contains batteries and renewable energy sources, so it helps the green transition. The following Figure 1 represents the hybrid microgrid system.

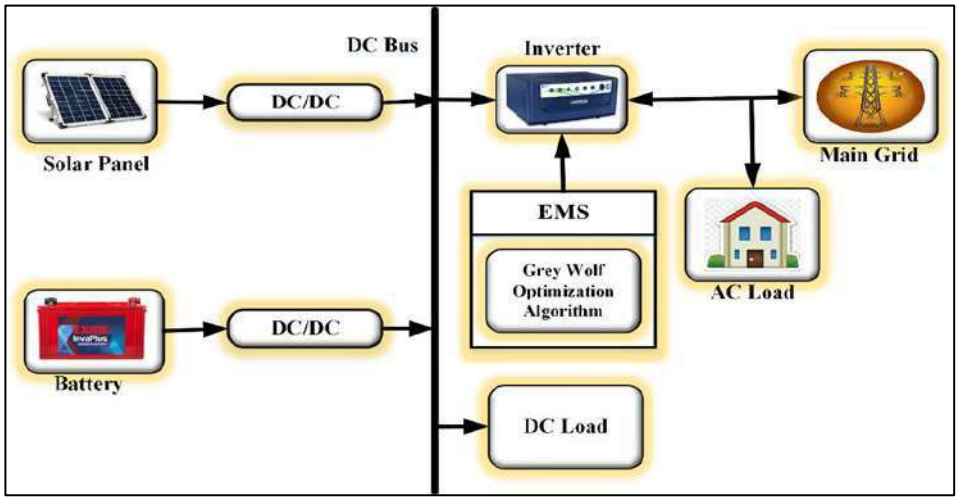

Figure 1: Hybrid microgrid system.
Source: Authors, (2026).

II.1 MICROGRID ENERGY MANAGEMENT SYSTEM

Due to the unpredictability or intermittent nature of the supply of renewable energy, integrating RES into smart grids is a source of concern since it creates stability and reliability issues in the power system. To find a remedy for this shortcoming of MG, it is required to have both an efficient battery management system as well as an appropriate forecasting algorithm [28]. It has been seen in literature that a number of different optimisation strategies be utilised to solve this challenge. These strategies involve efficiently dispatching the power that is created to achieve the most possible economic benefit while also preserving stability. In addition, these strategies involve scheduling alternate energy resources or energy storage. In the field of electrical engineering, one of the terminologies that is frequently used is EMS. The primary focus of the economic dispatch (ED) is on techniques that enhance the utilisation of renewable resources with the goal of maximising the positive effects on the environment as well as the economy. If, on the other hand, generating sources based on fossil fuels are used in conjunction with RES, then the objective of unit commitment focuses on coordinating the various power suppliers to accomplish a common goal of fulfilling the demand at a reduced cost and improving the income returns [29], [30]. This contrasts with the previous scenario, in which the unit commitment objective focuses on achieving the common goal of meeting the demand. In conclusion, the primary emphasis of the demand management goal is placed on the scheduling of usage patterns and efficient load utilisation to maximise financial gain.

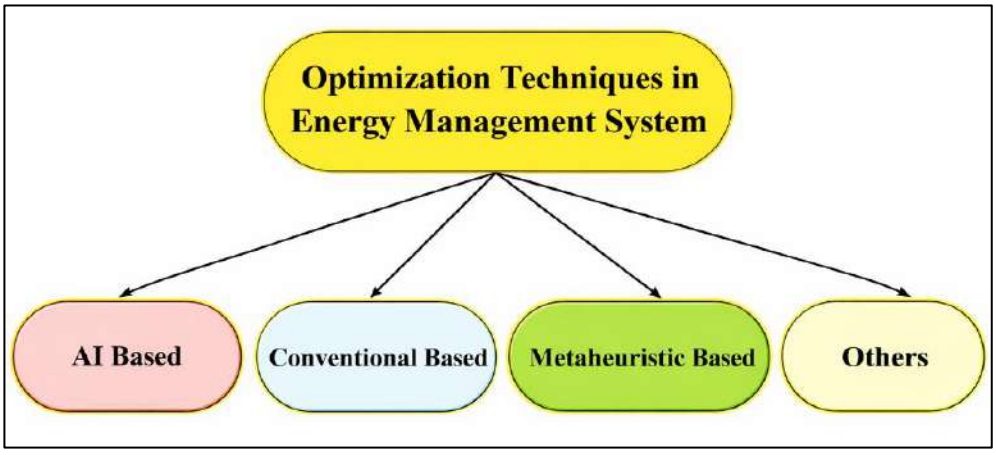

Figure 2: Different types of Optimization methods in energy management system.
Source: Authors, (2026).

To get a good understanding of the numerous energy management methods and the many optimisation strategies that are used for energy management, a comprehensive analysis of the available methodologies was carried out. The optimization strategies employed in EMS of MG are often categorized into four primary types, as illustrated in Figure 2. This research article places a greater emphasis on non-traditional strategies for addressing the electromagnetic problem, as opposed to the commonly employed conventional techniques. It aims to explore the uncharted territory of hybrid, meta-heuristics, and other non-conventional methodologies [31], [32]. This was done to find a clear grasp of the various energy management strategies. The primary purpose of this investigation is to find a way to cut down on the variable cost of electricity by applying the GWO algorithm to the EMS challenge posed by the MG.

III. MODELLING THE COMPONENTS AND OBJECTIVE FUNCTION

III.1 SOLAR PV

Various forms of solar cell materials are currently being used on a global scale. However, silicon has emerged as the predominant material employed in solar cells due to its compelling attributes, including its adaptability, and efficient light absorption [33], [34]. The solar PV array consists of a sum of 48 modules per PV array, with each array being composed of 2 solar modules per string attached in parallel and 24 strings connected in series. The 144 PV cells are arranged in a series configuration to achieve a total power output of 800 kW for the solar PV panel. The block diagram of the solar system is depicted in Figure 3.

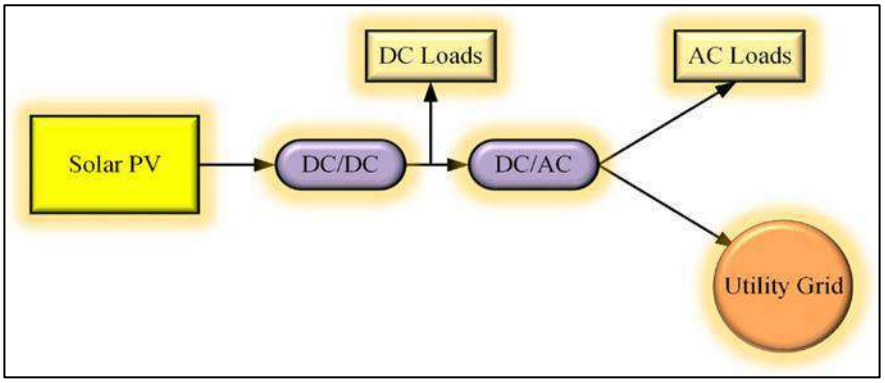

Figure 3: Modelling of Solar PV system.
Source: Authors, (2026).

The selection of materials and methods, procedures and equipment must be justified so that the work can be reproduced. Modifications or new methods must be described in detail. You must clearly define the universe and specify how the sample was selected and why it is representative. Data processing represents the practical development of a theoretical basis, deriving the model equations to program the calculation algorithm, according to the need. In materials, they include the technical specifications and the quantities, the origin and, if necessary, the method for its elaboration. The real-time control of the output power of a PV array can be achieved through the utilization of a Maximum Power Point Tracker (MPPT) in conjunction with a DC-DC converter. The MPP is influenced by variations in solar irradiance and ambient temperature. The power generated by solar PV panel is given by [35].

$$POW_{PV} = Y_{PV} f_{PV} \left(\frac{G_T}{G_{T,STC}}\right)[1 + \alpha_P (T_C - T_{c,STC})] \quad (1)$$

Where Y_PV-the relevant capacity of the solar PV system (kW). f_PV -the derating factor of the PV system (%). G_T -the incident solar radiation on the PV system during the current timeframe (kW/m2). G_(T,STC)-the incident radiation at standard test conditions, (kW/m2). αp-the temperature coefficient of power for the solar PV system, -0.5% per degree Celsius (%/°C). T_C-the solar PV cell temperature during the current timeframe (°C) per degree Celsius (%/°C). T_(c,STC)-the temperature of the solar PV cell at STC (25°C).

III.2 BATTERY ENERGY STORAGE SYSTEM

In this work, a distributed battery model with a capacity of 2500 kWh is developed using MATLAB. The calculation of the current state of charge ($Pbb_{bat}(T)$) is derived from the battery's initial state of charge [36]. The calculation of battery voltage is determined by

$$V_{battery}(T) = V_0(T) - \frac{n * Q_{bat}(T)}{Q_{bat}(T) - \int I_{bat}(T) dt} + Aexp(-B \int I_{bat}(T) dt) \quad (2)$$

The $Pbb_{bat}(T)$ is calculated by

$$Pbb_{bat}(T) = SOC_{ini}(T) \pm \frac{I_{bat}(T) * \Delta T}{Q_{bat} * 3600} \quad (3)$$

In this context, ΔT is the variable denoting the changing time, while the symbols ± are utilized to signify battery charging and discharging, respectively. The calculation of the energy available for supply at any given moment is given by

$$F_{battery}^{avail}(T) = R_{bat}(T) * V_{battery}(T) * Pbb_{bat}(T) \quad (4)$$

Where, $R_{bat}(T)$ is battery capacity. The excess energy of battery storage is calculated by

$$F_{battery}^{req}(T) = F_{battery}^{rated} - F_{battery}^{avail}(T) \quad (5)$$

III.3 PROBLEM DEFINITION

The primary objective is to reduce the overall system variable cost, encompassing the cost associated with the grid and stored energy, while still following to all operational limits [37]. Hence, the objective function can be stated as.

$$D_t = \sum_{m=0}^{N} D_{gr}(m) * F_{gr}(m) \quad (6)$$

Where, D_t represents variable electricity price, $D_{gr}(m)$ is grid cost, $F_{gr}(m)$ is energy available in grid station. The final parameters for this research are listed below:

$$x = [G_{gr}(1{:}N)\ \ att(1{:}N)\ \ Fbat(1{:}N)\ ]^T \quad (7)$$

In this context, G_{gr} (1: N) represents the power consumed from the grid during time, $Pbat$ (1: N) represents the power drawn from the battery storage, and $Fbat$ (1: N) represents the amount of battery energy storage.

III.3.1 Constraints

The output power of battery storage system is as follows

$$F_{battery}(m) = F_{bat}(m-1) + P_{battery}(m)\Delta T \quad (8)$$

Where ΔT - the difference in time step and m is step time. The energy balancing formulae for all the buses is regarded as a set of equality requirements, which are explicitly expressed as

$$POW_{PV}(m) + P_{grid}(m) + P_{battery}(m) = P_{total\ L}(m) \quad (9)$$

The second belongs to output variables as

$$P_{Dg}^{min} \leq P_{Dg} \leq P_{Dg}^{max} \quad (10)$$

$$F^{min} \leq F \leq F^{max} \quad (11)$$

Where, P is the active power of generator in MW and E is the battery energy in Ah.

Table 2: The specifications of each component used in the microgrid.

PV System		**Battery**	
Parameters	**Value**	**Parameters**	**Value**
Rated Capacity	800 kW	Rated Capacity (kWh)	2500

IV. GREY WOLF OPTIMIZATION (GWO) ALGORITHM

In 2013, Mirjalili first introduced this method. The Grey Wolf Optimizer (GWO) is inspired by the social hierarchy and hunting behavior of grey wolf packs, which typically consist of five to twelve members. In this hierarchy, the leader of the pack is known as the alpha, while the beta assists the alpha by providing feedback and helping enforce decisions. The omega occupies the lowest rank and exhibits submissive behavior toward the dominant wolves. Wolves that do not belong to the core leadership hierarchy are referred to as deltas and generally play the role of hunters or subordinates. In the context of optimization problems [38], the alpha represents the best (optimal) solution, while the beta and gamma correspond to the second and third best solutions, respectively.

Alphas (α) are the leaders, and they can be either female or male. The alpha is responsible for establishing consensus on matters such as "hunting, sleeping place, waking time, and so on." When the pack is together, the alphas (α) have their tails held down as a sign of recognition. On a rest of the pack must obey their decisions. To help the alpha (α) with decision-making and other pack activities, the betas (β) are dependent GWs. If the alpha (α) GWs dies or gets too old to continue leading, the beta (β) GWs are the most likely replacement choice. Alphas (α) rely on betas (β) for advice and discipline within the pack. The beta (β) emphasizes the alpha (α) commands and directs the alphas (α) in the right direction. The scapegoat role is typically given to Omega (ω), the lowest-ranking GW. If the GW is not an alpha (α), beta (β), and omega (ω), they are sub-ordinate know as delta (δ). δ GWs must acquiesce to alpha (α), and beta (β), but they lead ω. The hunting process of Grey Wolfs is as follows

Stage 1: Consists of activities like chasing, tracking, and approaching the prey.
Stage 2: includes activities like encircling, hunting, and killing the prey until it stops moving and the last step is attacking the prey.

IV.1 MATHEMATICAL MODEL OF GWO ALGORITHM

IV.1.1 Social hierarchy of GWO

Specifically, alpha (α), beta (β), and delta (δ) are all considered to be suitable solutions in this hierarchy. Omega (ω) is assumed to be the last remaining option. α, β, and δ are responsible for hunting (optimization) in this algorithm. Omega (ω) wolves follow the patterns established by alpha (α), beta (β), and delta (δ).

IV.1.2 Encircling Prey

Grey Wolfs encircle the prey during the hunting process. Therefore, Eqn. 12 to Eqn. 13 is used for mathematical modelling the GW's encircling behaviour.

$$\vec{D} = \left|\vec{C}.\overrightarrow{X_p}(t) - \vec{X}\,(t)\right| \tag{12}$$

$$\vec{X}\,(t) = \overrightarrow{X_p}(t) - \vec{A}.\vec{D} \tag{13}$$

Where, t-the current iteration, $\vec{X}$ & $\overrightarrow{X_p}$ -the position vector of the GWs and the prey, and $\vec{A}$, $\vec{C}$ -coefficient vectors. The $\vec{A}$, $\vec{C}$ vectors were calculated by Eqns. 14 and 15.

$$\vec{A} = 2\,\vec{a}.\overrightarrow{r_1} - \vec{a} \tag{14}$$

$$\vec{C} = 2.\overrightarrow{r_2} \tag{15}$$

Where (r_1) and (r_2) represent the arbitrary vectors [0,1], and the value of the component a vector declines linearly from 2 to 0 when the execution is repeated. The Grey Wolves will update the prey's position at any chosen point in space using Eqns. 14 and 15.

IV.1.3 Hunting

Grey wolves could locate and enclose their prey, and the pack's leader male typically leads the pack in the hunt. It is possible that β and δ individuals will occasionally join in on the quest. Considering the α, β, and δ are provided improved information about the likely location of the prey, a mathematical model of this process is constructed. At this point in time, we have three ideal solutions: α, β, and δ. In this problem, "prey" stands for the objective function. The Omega (ω) Wolf's answer will revise their position in relation to the Eqns. 16 and 17 describe the hunting procedure in mathematical detail.

$$\overrightarrow{D_\alpha} = \left|\overrightarrow{C_1}.\overrightarrow{X_\alpha} - \vec{X}\right|, \overrightarrow{D_\beta} = \left|\overrightarrow{C_2}.\overrightarrow{X_\beta} - \vec{X}\right|, \overrightarrow{D_\delta} = \left|\overrightarrow{C_3}.\overrightarrow{X_\delta} - \vec{X}\right| \tag{16}$$

$$\overrightarrow{X_1} = \overrightarrow{X_\alpha} - \overrightarrow{A_1}.\left(\overrightarrow{D_\alpha}\right),\ \overrightarrow{X_2} = \overrightarrow{X_\beta} - \overrightarrow{A_2}.\left(\overrightarrow{D_\beta}\right),\ \overrightarrow{X_3} = \overrightarrow{X_\delta} - \overrightarrow{A_3}.\left(\overrightarrow{D_\delta}\right) \tag{17}$$

Where $\overrightarrow{D_\alpha}$, $\overrightarrow{D_\beta}$ and $\overrightarrow{D_\delta}$ -the vector's position of the GWs in the population w.r.t α, β, and δ wolves. The $\overrightarrow{C_1}$, $\overrightarrow{C_2}$and $\overrightarrow{C_3}$ were the generated arbitrary numbers in the range[0,2], $\vec{X}$ is the search agents, i.e., population, $\overrightarrow{X_\alpha}$, $\overrightarrow{X_\beta}$ and $\overrightarrow{X_\delta}$ were the best search agents related to the optimal solutions. $\overrightarrow{A_1}$, $\overrightarrow{A_2}$ and $\overrightarrow{A_3}$ were arbitrary numbers that depend on the $\vec{a}$. The encircling behavior is implied to obtain the new positions of Grey Wolfs using Eqn. 18.

$$\vec{X}(t+1) = \frac{\left(\overrightarrow{X_1}+\overrightarrow{X_2}+\overrightarrow{X_3}\right)}{3} \tag{18}$$

The remaining GWs then randomly shift their position everywhere in the prey based on the predictions of alpha (α), beta (β), and delta (δ). When the target animal stops moving, the hunt is over. The alpha (α), beta (β), and delta (δ) wolves iteratively forecast where the prey is most likely to be found. To emphasize the algorithm's exploration and characteristics, an is gradually decreased from 2 to 0. Each potential answer keeps track of its current separation from the target. If |A |>1, potential solutions begin to separate from the target. Convergence of |A |1 on the target area. The algorithm concludes successfully at last.

IV.2 INTEGRATION GWO WITH CUCKOO SEARCH ALGORITHM (CS)

Yang and Deb created the cuckoo search algorithm, a new meta-heuristic algorithm for solving optimization problems based on the obligate brood parasitism of some cuckoo species, which deposit their eggs in the nests of other host birds. The CS optimisation algorithm is based on the unusual nesting behavior of cuckoo birds and the levy-flight style [39]. Some cuckoos have particularly unique reproductive tactics, in which they do not hatch their own children but instead lay their eggs in the host's nest while the host is away; they may also remove the host bird's eggs. When certain host birds discover that the eggs belong to an outsider, they may either relocate the outsider's eggs away or abandon the nest and look for a new location to build one. Many animals exhibit levy-flight-style flying characteristics. It refers to the individual in a restricted range of activities, but there is a modest possibility of a long-range jump. It may also have a slight chance of deviating significantly from the mean value of the activities, due to the power of the CS algorithm jumping out of the local optimum. The CS algorithm must adhere to the following three idealized rules:

• Cuckoo birds choose their nest randomly and only lay one egg at a time.
• Only the best nests will exist for future generations.
• Third, the number of bird nests and the probability of egg discovery are predetermined. If the host bird discovers an outsider's egg, it abandons the nest and builds a new one.

By complying with these three rules above, the nests are updated by following equations during the iteration.

$$X_i(t+1) = x_i(t) + \alpha \oplus Levy(\lambda), i = 1,2,3,\ldots.n \tag{19}$$

Where the product $\oplus$ - entry-wise multiplication. $X_i(t+1)$-new solutions for cuckoo , i. $x_i(t)$ represents the current solutions. Since $\alpha > 0$ control the step size and is set to 1. The Levy-flight is providing by the following probability distribution equation:

$$Levy(\lambda) = t^{-\lambda}, 1 < \lambda \leq 3 \tag{20}$$

As a result, the CS optimisation algorithm can efficiently explore the output space since its step changes with short distance detection and occasional long-distance walking, and the length of the step increases significantly in the long run.

IV.3 PSEUDO CODE

The pseudo code of the HGWCSO algorithm is presented as follows:

Initialize the grey wolf population X_i (i = 1, 2, ..., n)
Initialize a, A, C and ρ_a
Compute the fitness of each search agents in the pack using eq. 6
Set $\overrightarrow{X_\alpha}$, $\overrightarrow{X_\beta}$ and $\overrightarrow{X_\delta}$ according to the fitness
$t = 0$ (iteration=0)
while *($t \leq$ Max number of iterations)*
for *wolf (each search agent)*
Update the position of the current search agent by equation 12-18
end for
update a, A, C
Run load flow analysis with constraints
Calculate the fitness function using equation 6
Update $\overrightarrow{X_\alpha}$, $\overrightarrow{X_\beta}$ and $\overrightarrow{X_\delta}$
For $\overrightarrow{X_\alpha}$, $\overrightarrow{X_\beta}$ and $\overrightarrow{X_\delta}$
Equation 19 updates the position with the CS algorithm and the Levy flight method [40].
If the random integer is greater than ρ_a,
the wolf's position will be changed randomly.
Calculate the fitness function and update it based on fitness.
End for
t=t+1
End while
Return (X_α) $\vec{}$*output value.*

V. SIMULATION RESULTS

This proposed research employs a MG configuration that incorporates solar PV technology as the major source of power generation. Additionally, any surplus power generated is stored in a battery for future use. In this discussion pertains to solar PV generation and its maximum power output. The electricity generated by the solar PV system is then stored in the battery energy storage system, in accordance with its capacity. The proposed system incorporates a conventional grid with a capacity of 13.8 kV. The conventional grid is interconnected by a 3-phase, two-winding transformer. The primary winding of the 3-ϕ transformer has a voltage rating of 13.8 kV, while the secondary winding has a voltage rating of 5 kV. The load capacity is currently, measuring 704.86 kW.

The component in the system is the solar PV array, boasting a capacity of 535 kW. The ESS, which functions as the central component of the system. The ESS possesses a power rating of 535 kW and a storage capacity of 2500 kWh. This study used a heuristic approach, specifically the HGWOCS, to calculate and compare the overall cost of power.

V.1 HEURISTIC APPROACH

The simulated waveforms of a one-day analysis utilising a heuristic technique are depicted in Figure 4. The first waveform depicts the RMS voltage of the microgrid, illustrating the variations in voltage due to alterations in load requirements and power generation. The second waveform illustrates the state of charge (SOC) of the ESS, while the third waveform depicts grid power pricing. The fourth waveform illustrates the power produced by solar PV system, the grid, the battery, and the load. During the time period ranging (0 to 2) * 10^4 seconds, the power demand remains below 80 kW. Consequently, the SOC of the ESS during this duration reflects its starting capacity, specifically 50%. Therefore, it can be inferred that the operational cost is at its lowest. During the time span ranging (2 to 4) *10^4 sec, the load experiences an increment up to 80 kW. Simultaneously, the solar PV power demonstrates an upward trend, while the power stored in the battery exhibits a negative decline. As a result of the amplified solar PV capacity surpassing the load demand, excess electricity is produced and subsequently stored in the battery system. This implies that the battery undergoes a gradual process of recharging. Furthermore, due to the minimal expense associated with renewable energy generation, the overall cost continues to remain low.

During the time span ranging (4 to 6) *10^4 seconds, the load exhibits consistent behaviour while the voltageof the battery attains the nominal voltage of the battery, hence transitioning into the charging mode. Consequently, the SOC is accompanied by a charging performance index that is expected to exceed 85%. In the same manner, the power output of the solar PV system decreases, leading to a gradual initiation of power supply from the battery, resulting in the discharge of the battery. The cost remains low due to the utilisation of stored battery power derived from renewable sources. During the time span ranging from (6 to 8) *10^4 seconds, the load experiences a gradual increase, reaching a level of 80 kW. However, it is important to note that the power derived from the battery continues to decline, despite the reducing of solar PV power. At a particular moment, the battery becomes completely depleted, and the power generated by the solar PV system becomes insignificant. Subsequently, the power supply switches to the grid. The load's power requirements are met by the utilisation of grid electricity, resulting in an increase in costs to their maximum level. The heuristic technique yields a total cost of $209 for a day.

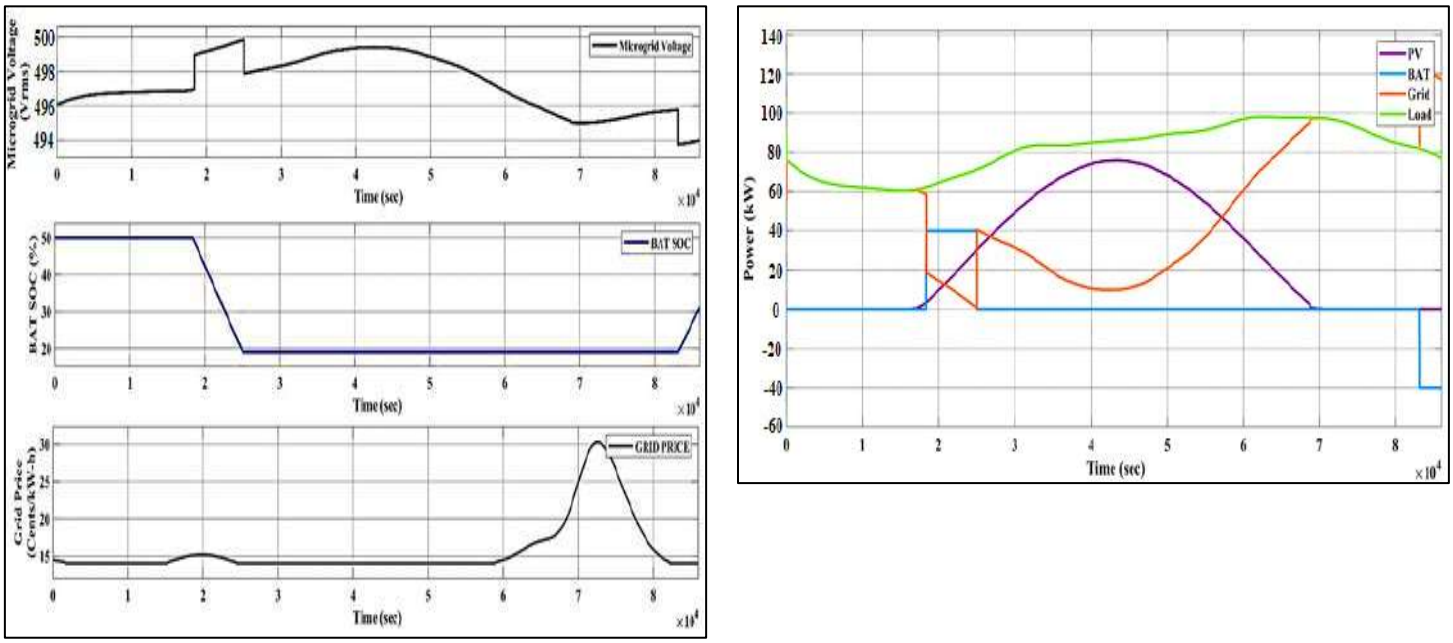

Figure 4: The waveforms of the proposed system using heuristic approach.
Source: Authors, (2026).

V.2 PROPOSED HGWOCS ALGORITHM

Figure 5 displays the simulated waveforms obtained from a one-day study utilising the proposed HGWOCS technique. During the time range (0 to 2) *10^4 secs, the load demand exhibits a decrease, resulting in the solar PV and battery system not providing any power during this period. The power grid provides electricity, which allows the battery to become fully charged within the specified time frame. Subsequently, the grid supply experiences a decline due to the utilisation of solar photovoltaic (PV) arrays and battery systems for power provision, resulting in the gradual discharge of the stored energy within the batteries. In a similar vein, the operational cost is at a minimum. During a time, interval ranging from (2 to 4) *10^4 secs, the load exhibits a gradual increase, reaching a maximum value of 80 kW. The utilisation of solar PV power is experiencing a notable upward trend. Concurrently, the level of battery power is diminishing.

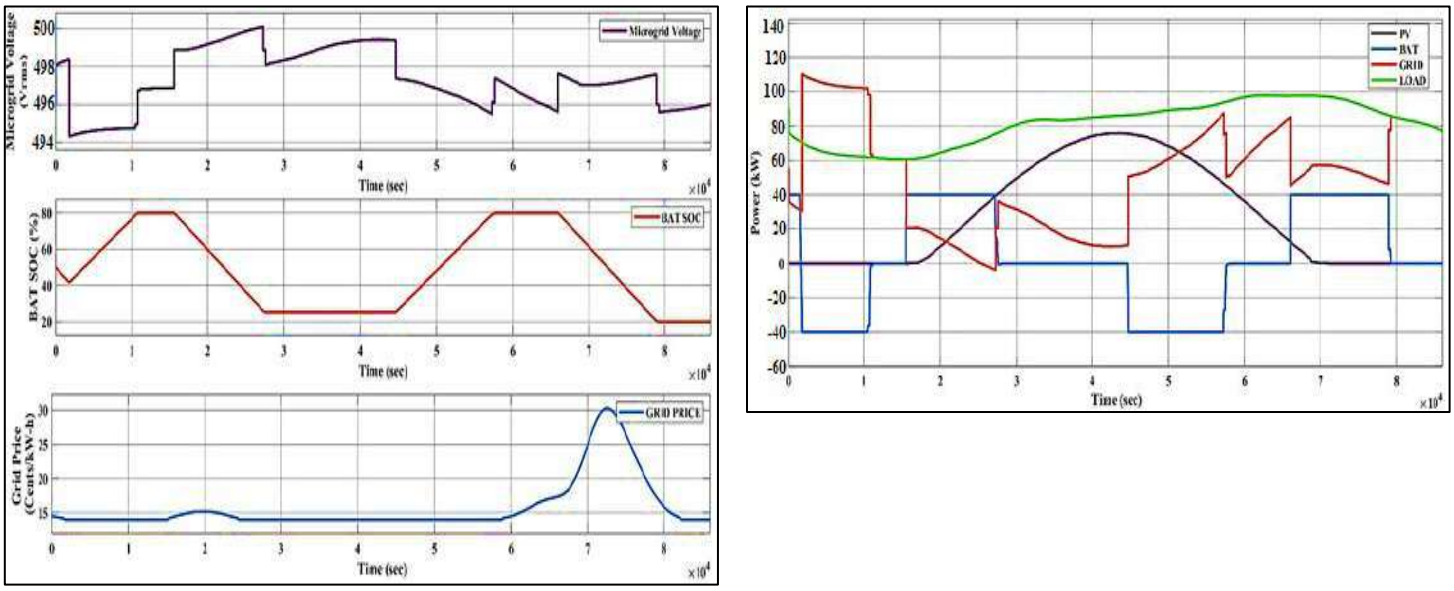

Figure 5: The waveforms of the proposed system using HGWOCS approach.
Source: Authors, (2026).

In this scenario, the solar PV system generates a greater amount of electricity, resulting in a drop in power sourced from the grid. Consequently, the battery does not contribute to the power supply. Once again, because of the minimal cost associated with renewable generation, the overall cost remains low. During the time span ranging (4 to 6) *10^4 secs, the load exhibits consistent behaviour while the voltage of the battery attains the nominal voltage of the battery, hence transitioning into the charging mode. Consequently, the SOC is equipped with a charging performance index that is predicted to exceed 85%. Nevertheless, the expenses persist at a minimal level due to the utilization of stored energy of the battery derived from RES. During the time span ranging (6 to 8) *10^4 seconds, the load experiences a gradual increase to a level of 800 kW. However, it is noteworthy that the power supply continues to be sourced from the battery, despite a simultaneous decline in the power output of the solar PV array. During a certain moment, the battery undergoes a gradual drain while the contribution of solar power is insignificant, followed using grid electricity. The load's power requirements are met by the utilisation of grid electricity, resulting in an increase in costs to their maximum level. The overall expenditure associated with a day utilising the proposed GWO algorithm amounts to $191.

V.3 GRID ELECTRICITY COST COMPARISON DURING A DAY

Figure 6 depicts a cost comparison between cost of the grid and grid consumption during a period of 24-hours. The initial waveform corresponds to the cost of the grid, whereas the subsequent waveform shows the utilisation of the grid. Initially, the utilisation of grid electricity is minimal due to the availability of power source from solar PV arrays and batteries. During that specific period, the cost of maintaining by the grid is relatively low. Subsequently, solar energy exhibits fluctuations because of alterations in meteorological conditions, necessitating the reliance on grid-supplied power. Consequently, the prices also exhibit variation. At the conclusion, there is a notable increase in power consumption accompanied by a corresponding rise in grid price.

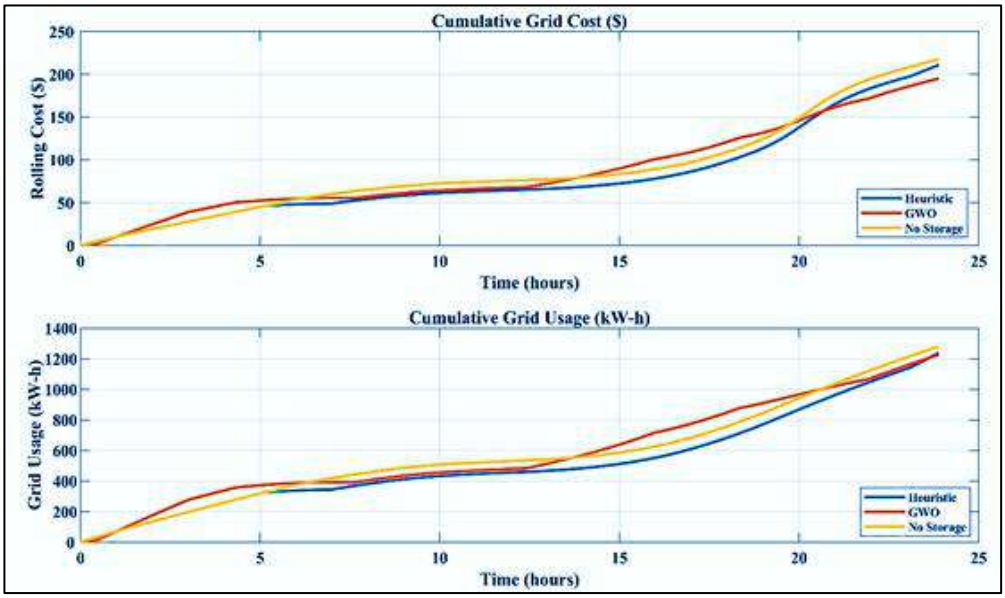

Figure 6: Comparison of grid electricity cost in case of Heuristic approach and HGWOCS approach.
Source: Authors, (2026).

Based on the data, it can be noted that the cumulative grid cost is lower when utilising the proposed method compared to the heuristic approach daily. The HGWOCS algorithm demonstrates superior performance compared to the heuristic technique.

VI. CONCLUSIONS

In this work a heuristic optimisation technique, HGWOCS proposed integrated EMS model for hybrid MG. The proposed system's primary goal is to reduce the amount that the MG needs to charge for its variable cost of electricity. Several authors have discussed this issue and proposed potential remedies after doing exhaustive literature reviews and gathering as much information as possible. The selection of these procedures was determined by the reliability and accessibility of resources inside the MG setting. Both the heuristic and the HGWOCS strategies are utilised in this investigation; however, the heuristic method is the primary focus. There is a discussion over a cost comparison between the heuristic approach and the HGWOCS algorithm. The findings suggested that the HGWOCS algorithm approach gave the costs (8.03%) that are optimal, which is a benefit of the strategy that is being proposed here. Because of the significant role it plays in maintaining the safe and cost-effective functioning of the load, EMS is an extremely important component.

ABSTRACT

Robotics research has expanded rapidly over the past two decades, encompassing industrial automation, human–robot interaction, artificial intelligence, and creative applications. This study presents a bibliometric analysis of research trends, publication growth, and citation patterns in robotics and automation, with a focused examination of creative and artistic applications within the field. Bibliographic data were retrieved from the Scopus database, yielding 31,261 initial records, which were refined to 426 relevant publications published between 2000 and 2025 within the Arts and Humanities subject area. Quantitative analyses were conducted using Microsoft Excel for temporal trend analysis, VOSviewer for collaboration and keyword network visualization, and Publish or Perish for citation performance assessment. The results reveal a substantial increase in robotics-related publications after 2017, with the United States, China, and the United Kingdom emerging as leading contributors. Influential journals, institutions, authors, and citation networks highlight the interdisciplinary nature of robotics research and demonstrate how creative and non-industrial studies contribute foundational methods in perception, motion control, human–robot interaction, and digital technologies that are later adopted in industrial automation. Overall, this study provides a structured overview of how robotics and automation research has evolved in terms of productivity, intellectual influence, and thematic development, while illustrating the role of creative-domain research as an innovation precursor supporting the advancement of industrial robotic applications.

I. INTRODUCTION

Before robots were deployed on factory floors, they were first conceived in human imagination - shaped by myths, literature, and performing arts [1]. The term “robot” itself originated from Karel Čapek’s 1921 theatrical play R.U.R. (Rossum’s Universal Robots), where robots were envisioned not as mechanical devices but as artificial workers designed to serve human needs, ultimately raising questions about control, intelligence, and rebellion. Although contemporary robotics research is predominantly associated with industrial automation, its advancement continues to rely on insights drawn from non-industrial explorations. Bibliometric analysis provides a systematic framework to examine how such interdisciplinary research contributes to the intellectual evolution of robotics. By focusing on creative and artistic applications of robotics, this study highlights how non-industrial research domains inform, inspire, and accelerate innovations that ultimately shape industrial robotics systems.

II. LITERATURE REVIEW

During the 16th century, automata, mechanical figures powered by gears and pulleys, were used in courts and religious rituals. The Writer was designed by [2], [3]. This creation merged artistry, craftsmanship, and early automation with technology and culture.

The year 1956 marked the start of robotic art when Nicholas Schoffer created "CYSP 1", which responded to sound and light stimuli [4]. It integrates feedback systems, sensors, motors, and autonomous movements into art. In the 70's, artists began integrating motors, sensors, and microcontrollers. Nam June Paik used robotics and video in interactive installations [5]. In 1980, Survival Research Labs demonstrated industrial robotic machines in choreographed performances, highlighting early non-industrial applications in structured human–machine interaction [6], [7]. Digital and AI integration began in the 90's using Arduino with accessible robotics, allowing more artists to experiment. Ken Rinaldo and Stelarc created bio-robotic and cyborg performance art. The contemporary era began in 2010, when robotic arms were used for painting and sculpting, such as e-David at the University of [8]. Similar to cobots in Amazon warehouses, human-robot collaborative performance has been shown in Japanese theatre. AI and robotics collaborations, like Shimon (robotics marimba player), were created by Professor Gil Weinberg and the Robotic Musicianship Group at Georgia Tech's Center for Music Technology, designed to perform improvisational music with humans [9], [10]. Boston Dynamics has developed dancing robots, RoboRebel [11]. Robots are part of immersive experiences with interactive exhibitions, influencing humans (e.g., Theo Jansen's Strandbeests and Ken Rinaldo's Autopoiesis). Motors and servos create moving sculptures (e.g., Arthur Ganson's mechanical art) [12]. Holography with robotics combines projection mapping with robot motion (e.g., robotic puppets with animated faces) [13].

II.1 CREATIVE ROBOTICS AS AN INNOVATION PRECURSOR FOR INDUSTRIAL SYSTEMS

Robotics has transformed applied art by automating design, manufacturing, and customization processes. It aids in AI generative design (electroloom), manufacturing (sewbots), fashion shows (robot models), responsive clothing (anoukwipprecht), and virtual fitting (pepper robots) [14], [15]. Robots draw using machine learning algorithms to generate AI patterns and strokes [16]. FRIDA, which produces human-like paintings through a Real-to-Simulation-to-Real framework, demonstrates adaptive control, perception-driven decision-making, and transfer learning capabilities directly transferable to industrial inspection, surface finishing, and quality assessment tasks [17]. Similarly, robotic systems such as Paul, which replicates human sketching, and Hektor, which generates large-scale graffiti using suspended cables, contribute to the development of precision motion control, cable-driven robotics, and scalable workspace coverage, all of which are highly relevant to industrial automation, warehousing, and construction robotics [18]. AI and robotics innovate dance moves [19]. Creative applications in cinematography and drone-based performances have significantly advanced aerial robotics, swarm coordination, and autonomous navigation [20], [21]. Virtual and augmented reality platforms used in museums, digital art creation, and immersive performances also inform industrial digital-twin development, remote operations, and training systems [22], [23]. RangoliBot draws symmetrical designs. Robotic arms create Tibetan mandalas, while CNC tools etch mythological figures. The Telegarden allows users to remotely manage a garden through robots [24]. Non-industrial robotics—encompassing domains such as art, design, human–robot interaction (HRI), social robotics, education, and interactive installations—often serves as a testbed for early-stage experimentation [25], [26]. Concepts initially explored in creative contexts later mature into robust industrial solutions. Key industrial technologies that originated or evolved through creative research include [27], [28]:

- Intuitive human–machine interfaces
- Multimodal sensor fusion and perception systems
- Expressive motion planning and adaptive control
- Natural interaction through vision, gesture, and emotion modeling

These innovations directly inform collaborative robots (cobots), service robots, and smart manufacturing systems, demonstrating that creative robotics research contributes foundational knowledge to industrial automation.

II.2 EXISTING LITERATURE REVIEW

Table 1 presents a systematic literature review of art and robotics conducted by various researchers in the field. Some studies have explored themes such as robotic creativity, human-machine collaboration, and aesthetic evaluation, while others have categorized robotic artworks based on emotional responses, interactivity, and cultural significance. Most of these reviews have been published within the last eight years, indicating a rising academic interest in this niche area.

Table 1: Existing reviews on robotic and art.

Title	Year	Focus Area / Subject
Augmented Reality and Robotics: A Survey and Taxonomy for ARenhanced HRI [29]	2022	AR + Robotics in human robot interaction; design, modalities, application domains
Understanding and Creating Art with AI: Review and Outlook [30]	2022	AI & Art (creative generation, computational aesthetics) - overlaps robotics as artistic tool
Augmented Reality Meets Artificial Intelligence in Robotics: A Systematic Review [31]	2021	AR + AI integration in robotics - relevant to interactive robotic art installations
Action Representations in Robotics: Taxonomy & Systematic Classification [32]	2019	Action representations, robotics taxonomy - can be applied to robotic performance art
Soft Robotics: Academic Insights and Perspectives Through Bibliometric Analysis [33]	2018	Soft robotics bibliometrics (actuators, sensors, biomedical) - informs artistic softrobot design
Bibliometric Analysis of Social Robotics Research [34]	2017	Social / HRI robotics - applicable to robotic art with social themes or performance

III. METHODOLOGY

III.1 RESEARCH QUESTIONS

To systematically map and evaluate the scholarly output on non-industrial robotics and automation from a creative applications perspective, this bibliometric study addresses the following research questions:

RQ1: What are the annual publication output and growth trends of research related to non-industrial robotics and automation in creative applications during the period 2000–2025?

RQ2: Which countries, institutions, and authors exhibit the highest research productivity and influence in this domain based on bibliometric indicators?

RQ3: What are the prominent author keywords and thematic structures, and how have these research themes evolved over time within the studied literature?

III.2 DATA SOURCE

Bibliometric analysis applies quantitative methods to statistically examine patterns and trends and their impacts within the published literature. Electronics bibliography databases from Scopus were used to gather the relevant articles.

III.3 BIBLIOMETRIC ANALYSIS

Based on these data, we performed a bibliometric analysis to address our research questions. We followed the steps prescribed for this bibliometric study [35], as shown in Figure 1. The most suitable keywords for exploring the considered theme were identified after reviewing multiple combinations of keywords in Stage 1. This keyword search work was done in July 2025 and considered the publications up to 2025 Initially, the number of publications found was very large, considering the keyword search criterion only. It shows publications from all diversified fields that may not be as relevant to the study. We narrowed our search by considering the inclusion criteria (IC), such as English language and subject area, and exclusion criteria (EC), such as unidentified authors.

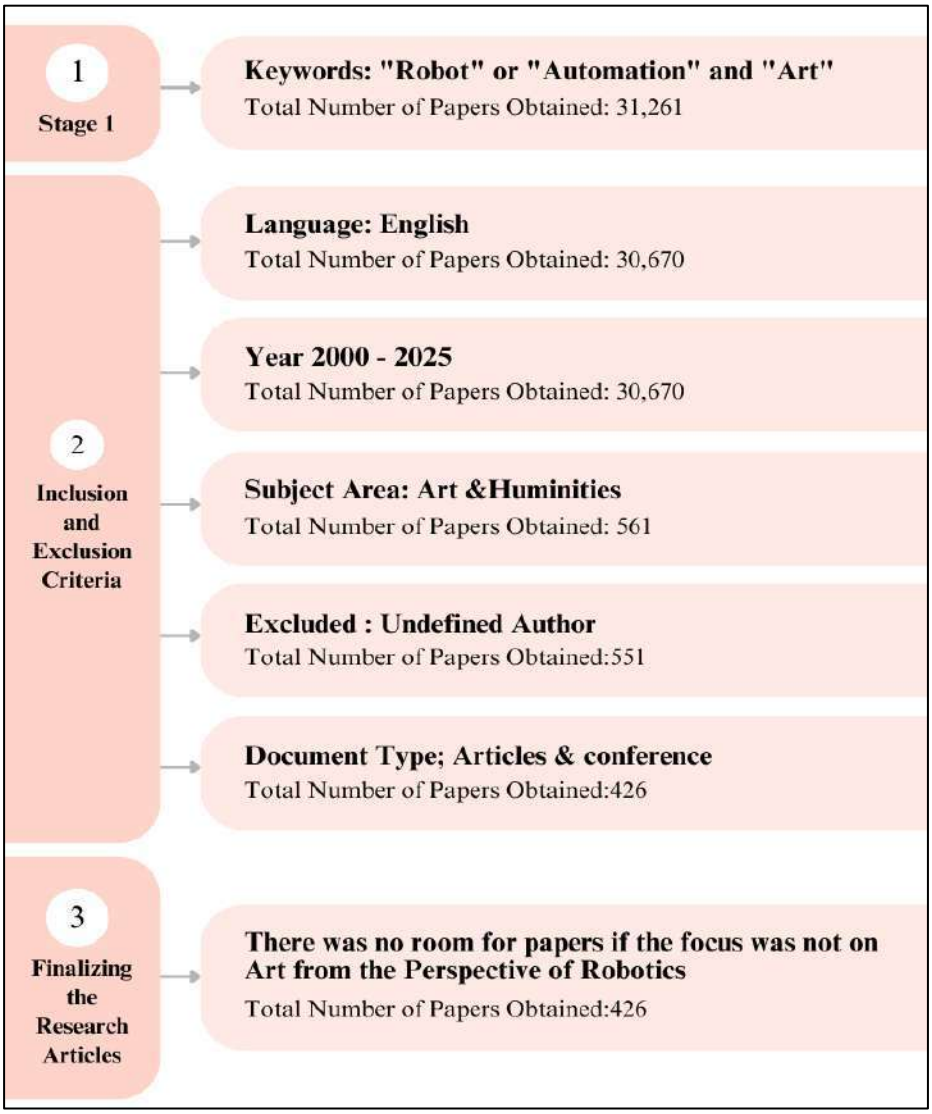

Figure 1: PRISMA flow diagram.
Source: [35].

IV. RESULTS & DISCUSSION

IV.1 PUBLICATION GROWTH OVER TIME

The annual publication distribution, presented in Figure 2 (bar chart) and summarized in Table 2, provides a quantitative overview of the temporal evolution of research activity.

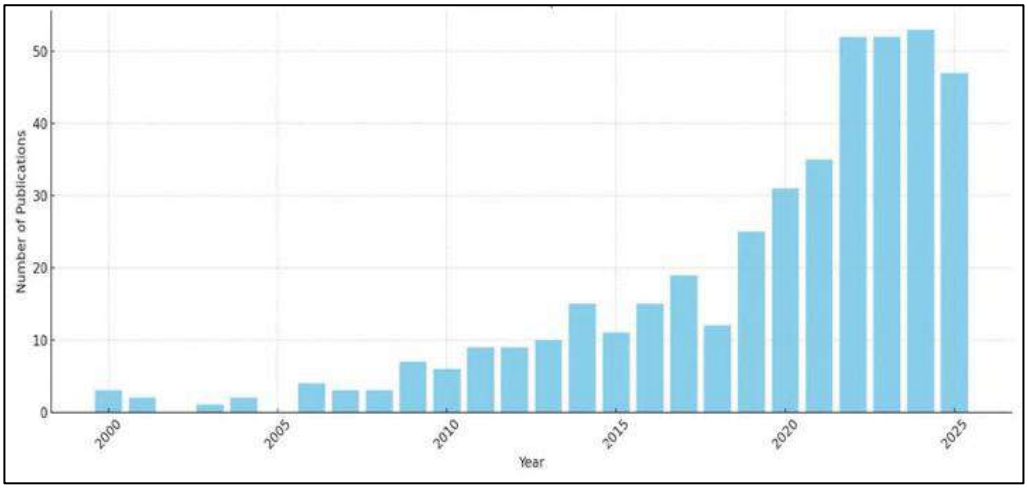

Figure 2: Bar chart – Publication Trend.
Source: Authors, (2026).

Together, these two elements reveal a clear long-term growth trend, despite minor year-to-year fluctuations that are typical in bibliometric data.

Table 2: Publication Trend.

Year	Publications	Year	Publications
2025	47	2013	10
2024	53	2012	9
2023	52	2011	9
2022	52	2010	6
2021	35	2009	7
2020	31	2008	3
2019	25	2007	3
2018	12	2006	4
2017	19	2004	2
2016	15	2003	1
2015	11	2001	2
2014	15	2000	3

Source: Authors, (2026).

Based on publication intensity and growth patterns, the research field's development spans three periods. The first period (2000–2010) showed limited output, with fewer than five publications annually and no publications in 2002 and 2005. The second period (2011–2016) demonstrated gradual increase, with peaks between 2014 and 2016. The third period (2017–2025) showed accelerated growth, with publication counts exceeding 50 in recent years. To interpret the growth behavior, classical mathematical growth models were applied to the annual publication data. The justification for modeling lies in the longitudinal dataset, monotonic increase after 2011, and accelerated rise after 2017. In early stages, publication output often follows an exponential growth pattern, expressed as:

$$P(t) = P_0 e^{rt} \quad (1)$$

Where P(t) represents publications in year t, P_0 is initial publication count, and r denotes annual growth rate. Post-2011 data in logarithmic form shows approximately linear trend, indicating exponential growth behavior. As research expands, growth may slow due to saturation, described by the logistic model:

$$P(t) = K / (1 + e^{-r(t - t_0)}) \quad (2)$$

Where K represents the theoretical publication limit, r is growth rate, and t0 denotes maximum growth acceleration point. Current data shows no clear saturation, suggesting the field remains below saturation level. The analysis of values, visualization, and growth modeling shows the research field's evolution. The sustained increase after 2017 indicates rapid growth phase without saturation evidence. While models are derived from publication counts for trend analysis, they provide a quantitative framework for interpreting publication dynamics.

IV.2 LEADING JOURNALS AND CONFERENCES

The distribution of papers by journal is shown in Table 3.

Table 3: Journal list with the number of Publications.

Journals/Conferences	Publications
International Journal of Social Robotics	30
13th International Conference on Learning Representations (ICLR 2025)	29
Artificial Intelligence	18
Artificial Intelligence Review	17
12th International Conference on Learning Representations (ICLR 2024)	16
Proceedings of the Annual Conference of the International Speech Communication Association Inter speech	16
AI and Society	15
Proceedings of the Annual Meeting of the Association for Computational Linguistics	10
2021 Joint: 6th International Conference on Digital Arts Media and Technology with 4th ECTI Northern Section Conference on Electrical Electronics Computer and Telecommunication Engineering (ECTI DAMT & NCON 2021)	6
Proceedings of the Technical Association of the Graphic Arts (TAGA)	6
11th International Conference on Learning Representations (ICLR 2023)	5
2020 Joint International Conference on Digital Arts Media and Technology with ECTI Northern Section Conference on Electrical Electronics Computer and Telecommunications Engineering (ECTI DAMT & NCON 2020)	5
10th International Conference on Learning Representations (ICLR 2022)	5
Proceedings of the International Conference on New Interfaces for Musical Expression	5

Source: Authors, (2026).

The International Journal of Social Robotics, ICLR 2025, Artificial Intelligence, and Artificial Intelligence Review contributed 94 papers (22% of our sample). The next 14 journals produced 112 articles (27% of the sample size). Most of the papers, that is, 220 articles (51% of the sample), were published with only four or fewer articles each on art and robotics.

IV.3 INFLUENTIAL AUTHORS AND INSTITUTIONS

The visualization highlights the author collaboration network generated using VOSviewer for the art and robotics research domains, as shown in Figure 3. It shows the key authors, their co-authorship patterns, and the strength of their connections. Larger nodes represent more prolific authors, and thicker lines indicate stronger collaboration.

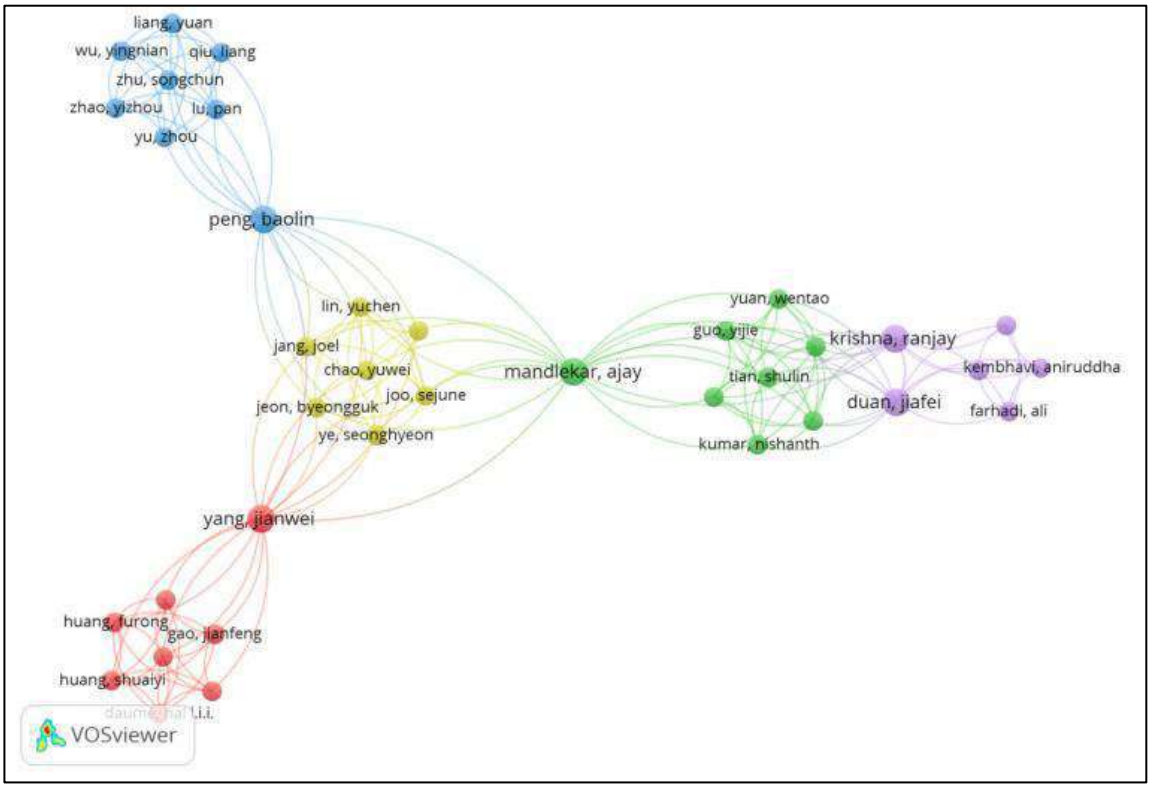

Figure 3: Author Collaboration Network.
Source: Authors, (2026).

Table 4 shows the contributions of authors, with Kapur, A. leading with five articles, followed by Proter, F. and Vacher, M. with four articles.

Table 4: Top Authors by Publication Count.

Author name	Publications
Kapur, A.	5
Portet, F.	4
Vacher, M.	4
Diakopoulos, D.	3
Finn, C.	3

IV.4 COUNTRY COLLABORATION

The USA dominated with 112 studies (26.29%), followed by China, the United Kingdom, Germany, Italy, France, Canada, Australia, and India. This reflects the presence of numerous active research groups in the field of robotics in these countries.

Table 6: Top Country by Publication Count.

Country/territory	Publications
United States	112
China	43
United Kingdom	43
Germany	30
Italy	25
France	22
Canada	21
Australia	17
India	15
Netherlands	14
Thailand	13
Hong Kong	12
Japan	9
South Korea	9

Source: Authors, (2026).

To normalize national contributions, a relative contribution index was considered.

$$RCI_i = P_i / \text{ sum } (P_{j)\ 1\ to\ n} \quad (3)$$

Where P_i is the publication count of country i. The United States exhibits the highest relative contribution, accounting for approximately 26.29% of the total publications, while all other countries individually contribute less than 11%. Based on publication intensity, contributing countries can be stratified into high-, medium-, and low-output tiers, indicating a hierarchical distribution of global research activity. This pattern suggests that robotics research output remains concentrated within a limited number of technologically advanced regions, with broader participation emerging across multiple countries.

IV.5 SUBJECT AREA ANALYSIS

Out of all subject area searches, we confined our study to the subject area of Arts and Humanities, as the inclusion of other subjects may broaden the aspect of study.

Table 7: Publication Count by Subject Area.

Subject area	Publications
Arts and Humanities	426
Computer Science	287
Social Sciences	225
Engineering	102
Psychology	48
Mathematics	24
Medicine	14

IV.6 CITATION & CO-CITATION ANALYSIS

Publish or Perish is a citation analysis tool that retrieves and analyzes Scopus data. It provides key metrics, such as total citations, h-index, and g-index, to assess the impact of authors and journals. It helps bibliometric studies to evaluate research performance and influence.

Table 8: Citation analysis from Public or Perish.

V. CHALLENGES, IMPLICATIONS, AND FUTURE DIRECTIONS

This study identifies the major challenges in applying robotics to the creative arts and examines their broader implications for authorship, cultural value, and artistic practice. Table 9 outlines the key challenges and their implications for future research. Despite these insights, this study has certain limitations. In the qualitative review, experiential or practice-based dimensions may have been overlooked as the field continues evolving. Similarly, bibliometric analyses have focused primarily on English-language publications within the Arts and Humanities, potentially omitting philosophical or cross-disciplinary contributions. Bridging the gap between theory and practice is essential for advancing this field. Enhancing accessibility to creative robotic tools and fostering interdisciplinary collaboration can further expand the scope and inclusivity of this field. Future work will aim to incorporate real-time bibliometric updates and cross-domain semantic mapping to capture emerging trends in robotics and automation in this evolving, creative landscape.

Table 9: Challenges and Implications of Robotics in Art.

Sr. No.	Challenge	Implications
1	Artistic Authorship & Creativity	Difficult to find authenticity of art [36]
2	Human touch	Difficulty in conveying genuine emotion
3	Technical Complexity	Need advance hardware, software and coding artist [31]
4	Interdisciplinary Collaboration	HRI (Human-Robot Interaction) leads to interdisciplinary innovation
5	Accessibility	High costs reduce accessibility, but barriers lowered for limited fine motor skill artist
6	Ethical and Legal Concerns	Dilemmas around machine authorship
7	Preservation and Longevity	Precise art long term conservation but comes with cost
8	Cultural Resistance	Division between traditional and tech-driven art communities
9	Perception of Value	Undervaluation or skepticism toward tech-assisted works

VI. CONCLUSION

This study presents a comprehensive bibliometric analysis of research trends, publication growth, and citation patterns in robotics, based on publications indexed in the Scopus database between 2000 and 2025. By examining productivity trends, leading journals, influential authors and institutions, collaboration networks, and citation structures, the analysis reveals the evolving intellectual landscape of robotics and automation research. A focused examination of creative and artistic applications demonstrates how interdisciplinary domains contribute to the diversification and expansion of robotics and automation research. The analysis conducted using Microsoft Excel revealed continuous growth in publication trends from 2000 to 2025, demonstrating increasing scholarly attention towards the integration of robotics, automation, and art. The bibliometric mapping identified clusters of leading journals, including IJSC and ICLR (2025), with prominent authors such as Kapur, A. and Portet, F. The leading institutions contributing to this domain are Chiang Mai University and the Chinese University of Hong Kong. The United States, the United Kingdom, and Germany emerged as the most productive countries. The primary subject areas represented were Arts and Humanities (426 publications) and Computer Science (287 publications), supported by several conference proceedings that bridge artistic inquiry and technological innovation. VOSviewer analysis revealed patterns of author collaboration, keyword co-occurrence, and co-citation networks, whereas Publish or Perish provided comprehensive citation metrics, underscoring the multidisciplinary nature of robotic research.

ABSTRACT

Customer reviews on e-commerce sites strongly influence customers' choices of products for purchasing but these reviews often include noise, exaggeration, or misleading language that make a product look better or worse than it really is. We propose NETER (Nonlinear Entropy-based Trust Evaluation Rating), a method for evaluating reliability and authenticity of online product reviews by handling non linearities in review text. NETER combines techniques likes sentiment analysis, deception detection, entropy-based stability and chaos-theory modeling to generate a trust score of product. Model uses RoBERTa for sentiment analysis to identify context and hidden emotions in review text accurately. Deception module identifies features like extreme praise, urgency words, or promotional phrases to check reliability of reviews. NETER uses statistical methods on review count to compute confidence weight so that products with few reviews do not receive unfairly high scores. To detect unstable, exaggerated or hyped review patterns, NETER applies chaos-theory where a logistic map is computed to determine Lyapunov exponent. Reviews showing hype patterns , unusual changes in their style or tone receive penalties while consistent sentiment is rewarded. Entropy and dispersion measure sentiments' consistency. Thus, NETER creates a clearer and reliable review score in comparison with sentiments only traditional methods.

I. INTRODUCTION

Online customer reviews deeply impact how people make buying decisions on e-commerce platforms. Customers trust star ratings, written reviews, and summaries to determine a product's quality, compare options, and decide whether to purchase them or not. But these reviews are not always reliable. Some reviews are excessively praised while some use promotional language, emotional words, or suddenly change emotional tone in successive reviews. All such reviews can be misleading and prompt potential customers to make a favorable decision for the product. Such patterns are often linked to dark pattern design techniques on e-commerce platforms which are majorly employed to influence customers. The traditional sentiment-based methods can overestimate a product's reliability because they don't separate real user experiences from biased or manipulated reviews. To solve this, we propose NETER (Nonlinear Entropy and Trust adjusted Evaluation Rating). NETER is a multi-layered system that combines sentiment analysis, deception detection, statistical reliability, and chaos-theory-based stability modeling. Unlike traditional methods that treat reviews as separate and fixed, NETER understands that review patterns can behave in complex, nonlinear ways. Even small emotional or manipulative cues can create a misleading sense of product quality. The NETER framework begins by identifying the basic sentiment of each review using RoBERTa, a transformer-based NLP model that classifies emotional tone with high accuracy. It then uses a deception-detection module that looks for signs of manipulation, such as promotional wording, urgency phrases, excessive punctuation, and overly dramatic expressions commonly present in low-credibility reviews. To avoid giving unfairly high trust scores to products with only a small number of reviews, NETER uses confidence weight based on review count. The confidence weight adjusts trust score based on how much feedback or customers' review is available. To capture instability which simple statistics cannot detect, we propose the NETER framework which uses a logistic map based on chaos-theory. The model simulates each product's review sentiment and calculates a Lyapunov exponent to measure how sensitive the sentiment is to small changes.

To denote trustworthiness of a product, the NETER penalizes products that show random or erratic or hyped textual reviews. NETER calculates entropy and dispersion to measure consistency in user sentiments. Thus, NETER can help customers to make better choices as it identifies deceptive patterns in text reviews and assigns more reliable scores to the textual reviews of a product.

I.1 PROBLEM STATEMENT

With the absence of a comprehensive, reliable, and stability-aware framework which is based on textual reviews and can measure the reliability of, we need a method that can:

1. Differentiate genuine sentiment from deceptive or promotional language.
2. Adjust trust scores based on review volume and statistical confidence.
3. Detect nonlinear instability in review patterns using chaos-theory principles
4. Integrate these elements into a single, interpretable trust metric.

These issues need to be solved because it makes reviews more trustworthy, helps shoppers choose better, and limits misleading behavior on e-commerce sites.

II. LITERATURE REVIEW

Research in digital spaces now focuses more on user-created content, how people interact with technology, and how algorithms try to influence users' selection and thinking. To address our research goals, we carry out a detailed and well-organized review of the existing literature. This is supplemented by a keyword co-occurrence network analysis to map conceptual relationships and key focus areas within the field. The keyword co-occurrence network as shown in Figure 1, is constructed using the top 25 keywords from the Scopus dataset and visualized using the VOSviewer methodology [1]. In Figure 1, node size represents keyword frequency, and edge thickness represents co-occurrence strength within the same studies. Central clusters revolve around transformer-based NLP (BERT, RoBERTa, DistilBERT), fake review detection and opinion spam, and explainable AI, privacy, and dark patterns. Literature surveys include areas like deceptive and fake review detection, sentiment analysis and rating prediction, dark patterns and manipulative interface design, chaos theory, complex systems, and anomaly detection.

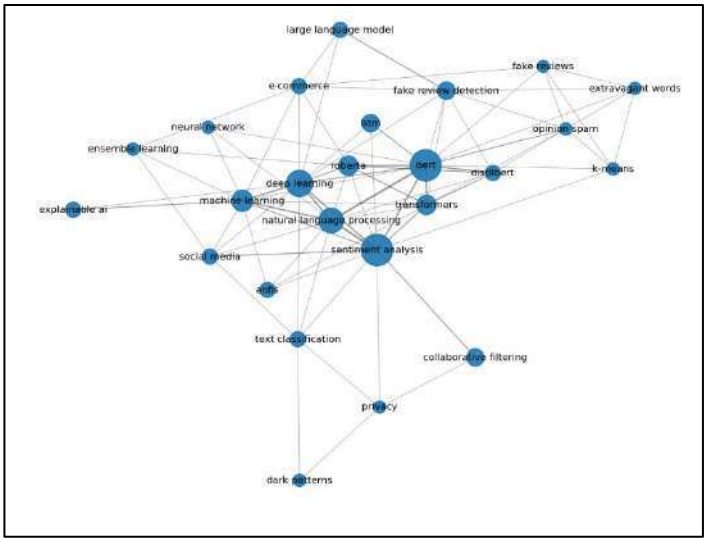

Figure 1: Keyword co-occurrence network (top 25 author keywords) derived from 76 Scopus-indexed studies.
Source: Authors, (2026).

II.1 DECEPTIVE AND FAKE REVIEW DETECTION

Early studies present opinion spam as a threat to online commercial trustworthiness, prompting the development of linguistic, behavioral, and metadata-based classification approaches [2-4]. Thereafter, deep learning architectures have replaced manually selected features with significant advances in transformer-based deception detection [5-7]. Ennaouri and Zellou proposed an influential model leveraging linguistic exaggeration cues, BERT embeddings, and fuzzy logic, demonstrating performance improvements [5]. A few researchers proposed and tested algorithms based on ensemble multidimensional feature selection to improve fake review identification [8], [9].

II.2 SENTIMENT ANALYSIS AND RATING PREDICTION

Early research in sentiment analysis showed that the emotions people express in their reviews helps in accurate predictions of rating. When a recommender system accurately understands whether a user feels positive or negative, it can better guess product ratings and user preferences [10]. Newer models, like transformers, use sentiment dictionaries to identify sentiments. Transformers worked across multiple languages to achieve even better results [11], [12]. Recent work on e-commerce platforms shows that after adding lexicon-based features to BERT-style models, improved the accuracy in detection of sentiment [13]. Other research focused on how large language models can analyze sentiment in more than one language on different digital platforms [11].

II.3 DARK PATTERNS AND DECEPTIVE INTERFACE DESIGN

The literature not only also discusses research focused on misleading text but also on “dark patterns” in user interfaces. Dark patterns are design tricks that push users to act in certain ways by hiding information or using visually manipulative layouts. Studies show that many cookie consent pop-ups use deceptive designs that make it hard for users to understand their choices or maintain control [14]. Other researchers are developing ways to automatically detect these deceptive UI practices through methods such as explainable AI (XAI), logs of how users interact with websites, and pattern mining techniques to identify patterns used in deceptive UI [15], [16].

II.4 CHAOS THEORY, COMPLEX SYSTEMS, AND ANOMALY DETECTION

Chaos theory and non-linear dynamics have been used by researchers in information systems to find non-linear and unpredictable adaptive behaviors on digital platforms [17-19]. Methods like higher-order cumulants, phase-space reconstruction, and Lyapunov exponent analysis help in identifying hidden patterns and irregular information flows in the system [19], [20]. More recent applications of chaos theory include finding anomalies in cloud systems through local explainability and multiscale analytics [21]. To show what the studies focus on and how the research has changed over time, Figure 2 presents the relationship between evidence screening and the development of themes in the research. The combined PRISMA–Topic Evolution visualization highlights not only the full set of 76 studies, but also how research priorities have shifted in response to new challenges in digital information environments. The figure illustrates the evidence screening process followed by PRISMA 2020. The process identifies 76 Scopus records. After screening these 76 records, removing 0, assessing 50 full texts meta-analysis revealed that the topic evolution shows a move from complexity and chaos modeling (1991–2005) to textual fraud and sentiment extraction (2010–2018), and then toward LLM-based fake review detection and XAI-supported dark pattern auditing (2023–2026). It also shows hybrid crossover themes such as chaos–anomaly synergy, sentiment–deception fusion, LLM–sentiment trust systems, and XAI–manipulative design auditing.

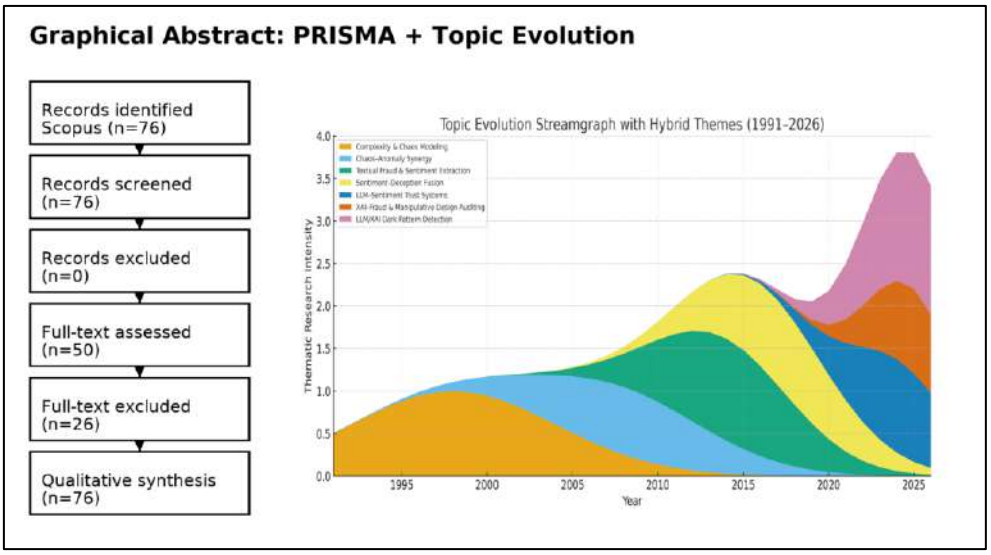

Figure 2: Combined PRISMA–Topic Evolution Graphical Abstract.
Source: Authors, (2026).

II.5 CROSS-CUTTING RESEARCH TRENDS

The review of all 76 studies shows that there are five main research trends that appear across different topics and methods. These trends show how the research has evolved over time. These five directions found across the literature are summarized below:

- Transformer/LLM-driven analytics [5-7], [13], [22] ,[11].
- Hybrid feature engineering remains essential [13], [10], [11] ,[23].
- XAI and algorithmic transparency gain prominence [14-16], [21].
- Multilingual modeling and cross-domain transfer challenges persist [13] ,[7], [11], [12] ,[24].
- Platform governance and trust [17], [18], [25].

The literature survey shows that research in this area is evolving fast and is driven by tools for analyzing text, detecting manipulative interfaces, and modeling complex systems. For example, transformer models have improved classification accuracy, but more research is required to fill the important gaps especially in explainability, cross-platform interoperability, and connecting the research to public policy.

III. METHODOLOGY

In this section, we explain the methodology followed in calculating the NETER score. The steps include estimating sentiments, detecting deception, applying confidence weights, measuring and assessing instability through chaos-theory. By following these steps raw e-commerce reviews are converted into a strong, manipulation-resistant trust score for a product. The process begins with collecting and preprocessing data.

III.1 DATA COLLECTION AND PREPROCESSING

Here, we explain how the data for the study is collected, organized, and prepared. To make sure that the data is accurate, consistent, and relevant we followed a clear and structured process at every step of research.

III.1.1 Data Source

In this study, we created a dataset for product reviews written by users on Amazon e-commerce platform. The data consisted of 157 text reviews of a product. Each review is a short piece of text written by a customer. Each record in the dataset has textual review, time at which the review is posted along with the numerical value of star rating given by the customer. The dataset reflects real customer behavior as review text may have excessively hyped language, possible misleading design cues, and changes in sentiments. These features are important to test the working of the NETER framework.

III.1.2 Data Cleaning

In this step the reviews are cleaned to make sure that the data is consistent for applying chaos-based modeling and reliable for evaluation of sentiments, deception pattern checks, and stability measurement. Any empty or non-text entries are removed so that the dataset remains accurate and useful for evaluation.

III.2 ROBERTA-BASED SENTIMENT ANALYSIS

The first step in evaluation of sentiments is to perform sentiment analysis where text is analyzed by using the transformer-based model, RoBERTa. This model has been trained to identify and classify sentiments. RoBERTa divides each review into tokens and gives raw scores (logits) for three classes: negative, neutral, and positive. The SoftMax layer of the model converts these scores into probabilities. The model outputs logits for classes $[neg, neu, pos]$. Let the probability associated with the positive class be denoted as $P\_positive$. The SoftMax () is applied on pos class to obtain $P\_positive$ as shown in Equation 1.

$$P\_positive = SoftMax(pos) \tag{1}$$

NETER focuses on positive sentiments because they are most manipulated in e-commerce reviews. Positive reviews influence buying decisions, and dark patterns typically inflate positivity rather than negativity. Since negative reviews are seldom faked, NETER evaluates how trustworthy positive sentiment is, rather than treating all sentiments equally. P□□□□□□□□ is directly used in the NETER computation, replacing prior polarity-based approximation methods and providing more context-aware sentiment estimation as compared to earlier, polarity-based estimates, which relied on simple methods that classified text as positive, negative, or neutral using word lists or basic rules. The traditional approaches counted positive or negative words without understanding context, sarcasm, emphasis, or nuanced phra]sing. As a result, they often produced oversimplified and inaccurate sentiment scores.

III.3 DECEPTION AND DARK-PATTERN DETECTION

To estimate how likely a review is using manipulative or exaggerated language, we use a deception-detection module based on linguistic cues. The text in each review is checked for usage of superlatives (e.g., “amazing” or “perfect”), promotional phrases (e.g., “#1 bestseller,” “buy now”), too much punctuation, ALL-CAPS words, very short but extremely positive comments, and urgency-based words (e.g., “limited period offer”). These signals are combined into a weighted score, which is then passed through a logistic function to calculate the dark-pattern probability using Equation 2.

$$P\_dark = \sigma(z - 0.6) \tag{2}$$

The Equation 3 is used to calculate total deception score for a product by averaging dark-pattern probabilities across all reviews.

$$P'_{dark} = \frac{1}{n}\sum_{i=1}^{n} P_{dark\,i} \tag{3}$$

III.4 REVIEW CONFIDENCE WEIGHT

To estimate the reliability of sentiments based on the number of available reviews, a diminishing return weighting function is applied. The confidence weight of reviews is defined using Equation 4.

$$w(n) = 1 - e^{-n/k} \tag{4}$$

The n in Equation 4 represents the number of reviews for a product and k is a scaling constant (typically set to 50). This method considers that products with only a few reviews are given lower confidence weight in comparison to products with more reviews which are assigned higher weights. This prevents small amounts of data from having too much impact on the trust evaluation.

III.5 CHAOS-THEORY ADJUSTMENT (LYAPUNOV EXPONENT)

To measure nonlinear instability or increased hype in review patterns, the product’s sentiment-deception score is used as the starting point in a logistic map, and this value is calculated using Equation 5:

$$x_0 = P'_{positive}(1 - P'_{dark}) \quad (5)$$

The value of chaos-control (r) parameter is initialized using Equation 6 and is used to iterate the logistic map.

$$r = 3.2 + 0.8 \cdot P'_{dark} \quad (6)$$

The chaos-control parameter allows products with higher deception probabilities to shift toward the chaotic regime. The value of r indicates that products with higher average dark-pattern probability are closer to the chaotic region of the logistic map. In other words, r controls how sensitive the logistic map is to changes in a product's sentiment patterns and is illustrated using Figure 3. The Figure 3 shows that as deception or hype increases in product reviews, the logistic-map parameter r shifts towards right, representing a transition from stable and authentic review behavior to unstable and manipulated sentiment patterns.

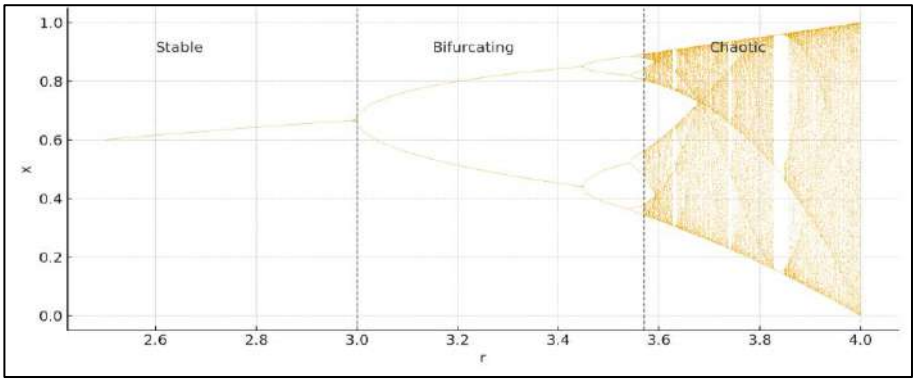

Figure 3: Simplified Logistic Map Bifurcation (NETER Zones).
Source: Authors, (2026).

In the stable zone ($r < 3.0$), reviews are consistent and predictable. For example, a kitchen blender review might receive balanced feedback such as: *"Works well for everyday use"* or *"Good value for the price"* in majority of the cases. In this zone there are minor variations in the sentiment patterns, but in general sentiment remains consistent and reflects real user experience. In the bifurcation zone ($3.0 \leq r$ 3.57), sentiment patterns begin to oscillate. This indicates fluctuations in the sentiments of the users, divided responses, or marketing influence e.g. one review of smartwatch may be an extremely positive comment after a promotional campaign such as *"Absolutely life-changing! Must buy!"* followed by negative reviews such as *"Battery died in two days, not worth it."* This irregularity in reviews indicates nonlinear shifts in trust and is similar to repeating patterns appearing in the logistic map. The system enters the chaotic zone when value of $r = 3.57$. This indicates sharp fluctuations in emotional tones of sentiment. For example, an influencer advertising a beauty product may get a mix of contradictory emotions in reviews where a few reviews may be extremely positive while a few may be extremely negative. These reviews appear back-to-back and change very quickly. For example, "*Miracle results in one night!!!"* or *"Total scam, it burned my skin".* This type of instability represents possible manipulation. NETER uses chaos theory to detect this instability and awards a penalty to such reviews by reducing the trust score. The value of r = 3.2 represents P'_{dark} is low and predictable system behavior [26]. The logistic map is iterated using the Equation 7 and the Lyapunov exponent is computed using Equation 8.

$$x_{t+1} = r x_t (1 - x_t) \quad (7)$$

$$\lambda = \frac{1}{T}\sum_{t=1}^{T} ln| \, r(1 - 2x_t) \, | \quad (8)$$

The Lyapunov exponent shows fluctuation in the product sentiments. If small changes in reviews quickly lead to big shifts in overall sentiment, the value of the exponent will be high. A high value means the emotional tone in reviews is unstable, while a low value means the emotional sentiments are consistent and predictable. The chaos penalty is normalized by using Equation 9. The *clip ()* in the equation normalizes value of □h□□□□□□□□□□ within [0,1].

$$ChaosPenalty = clip(\lambda/(\square ln\ ln\ 2\ ),0,1) \quad (9)$$

III.6 REVIEW STABILITY MEASUREMENT

The consistency and reliability of the reviews is checked in two steps. First, the sentiment scores from the reviews are grouped into five equal ranges, from very negative to very positive. Then, Shannon entropy, $H = -\sum p_i ln\, p_i$, is calculated, which is normalized using formula $H_n = H/ln(5)$, to check the similarity and differences in the sentiment patterns. If reviews fall evenly across the five ranges, the entropy is high, meaning the opinions are mixed whereas reviews in one or two ranges show low entropy and consistency in the emotional tone of reviews. Further the model uses Median Absolute Deviation (MAD) to measure the spread of review sentiments. This spread tells us whether reviews are similar or not. The value of MAD is normalized to □□□$_n$ = □□□□(□□□/0.25, 0, 1) so that the spread fits between values 0 and 1. A low value means the reviews are close together, while a high value means they are widely scattered. This measure, □□□$_n$, along with the normalized entropyH_n, is combined to form the overall Stability Factor, denoted as $Stability$, and is calculated using Equation 10.

$$Stability = clip((1 - 0.5H_n)(1 - 0.5\ MAD_n), 0.5, 1.0) \quad (10)$$

The above equation ensures that the final value is between 0.5 and 1.0. The Stability Factor ensures that normal differences in user opinions do not lower the trust score because in the real-world people naturally think differently. $Stability$ values below 0.5 will penalize entropy, while values above 1.0 would inflate trust. This range between 0.5 and 1.0 ensures that the stability factor moderates, rather than dominates, the overall NETER rating. Products with higher Stability values show consistent and reliable sentiments in textual reviews.

III.7 NETER SCORE FORMULATION

The final trust score or NETER score integrates all components and is calculated using Equation 11:

$$NETER = 100 \cdot w(n) \cdot P\_positive\text{^}' \cdot (1 - P\_dark\text{^}') \cdot (1 - ChaosPenalty) \cdot Stability \quad (11)$$

The final trust score calculated by NETER lies between 0 and 100. A higher NETER score means the product's reviews are more reliable, consistent, and less likely to be influenced by hype, manipulation, or deceptive patterns. A low NETER score alerts customers that the reviews may be unreliable or inconsistent and may contain deceptive patterns. Figure 4 summarizes methodology for calculating the NETER score.

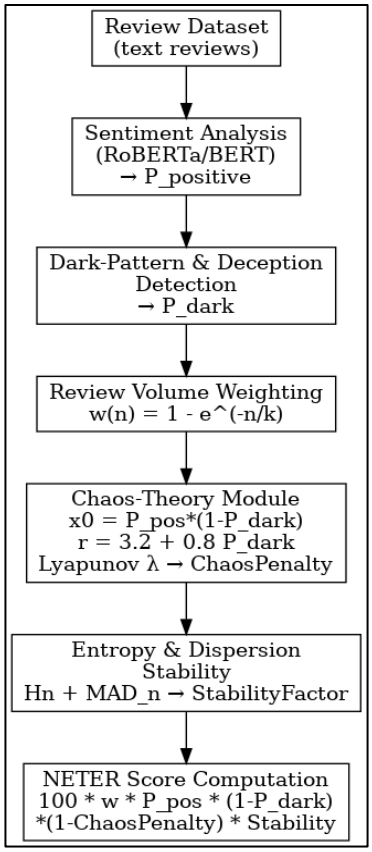

Figure 4: Steps to compute NETER score.
Source: Authors, (2026).

IV. RESULTS AND DISCUSSIONS

In this study a dataset of 157 Amazon product reviews is created. The NETER model is applied on this dataset for understanding the reliability of customers' reviews. The model identifies the emotions expressed in reviews by using a LLM model, RoBERTa and checks for manipulative or promotional language. It also finds chaotic shifts in review patterns and calculates stability or consistency in opinions of users over time. The NETER model begins with calculation of $P\_positive$, P_dark and confidence weights and is illustrated in the next section.

IV.1 EVALUATION OF $P_{positive}$, P_{dark} AND CONFIDENCE WEIGHT

The review dataset shows that the average value of $P\_positive$ is 0.6398 which indicates that reviews of customers are generally positive. The histogram shown in figure 5 indicates the distribution of $P\_positive$ of all reviews in the dataset. This histogram is right skewed and widely spread. The values of $P\_positive$ ranges between 0.4 and 0.8, indicating many reviewers have a positive view of the product. The highest concentration of $P\_positive$ is between 0.55 and 0.70. A spike closer to 1.0 indicates a large number of positive reviews from enthusiastic customers or promotional language. A few reviews fall in the low range of 0 – 0.2, showing that some customers have negative experiences. This wide spread of values results in a high entropy score (H_n = 0.813), which means sentiments are inconsistent. Instead, they sharply vary, suggesting that user experiences are inconsistent or unstable.

The language-cue analysis also found many reviews with persuasive or exaggerated emotional tone are often related with dark-pattern behavior. An average deceptive-language probability of $P_{\square\square\square\square} = 0.4762$ means nearly half the reviews show some signs of potentially misleading phrasing and a high review confidence weight of w(n) = 0.9567, shows that the sentiment, deception, and stability measures are based on a sample large enough to be dependable.

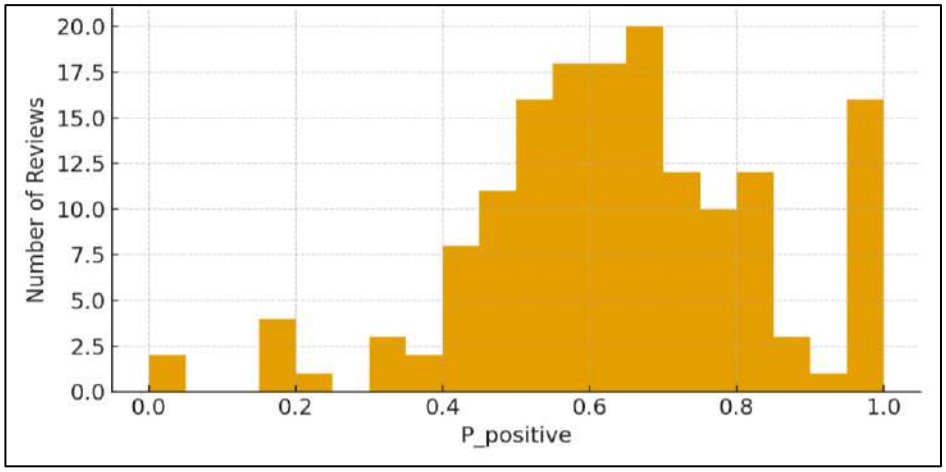

Figure 5: Sentiment Distribution (P_positive).
Source: Authors, (2026).

IV.2 CHAOS AND STABILITY ASSESSMENT

To measure how sentiment patterns might shift towards chaotic regions, the logistic-map-based Lyapunov exponent is calculated, giving a value of λ = 0.1082. This value corresponds to a *ChaosPenalty* of 0.1561. In other words, the reviews show signs of temporary hype spikes and back-and-forth fluctuations, but they do not behave in a fully chaotic or random manner. Figure 6 shows the Chaos Dynamics plot, where the logistic-map value x_t iterates over 120 iterations using parameters taken from the review data. With a chaos-control parameter of $r = 3.581$, the system shifts into a weakly chaotic state. This is supported by the positive Lyapunov exponent (λ = 0.1082), which indicates that small changes in sentiment can grow over time. The resulting ChaosPenalty of 0.1561 reflects the moderate but noticeable level of sentiments instability.

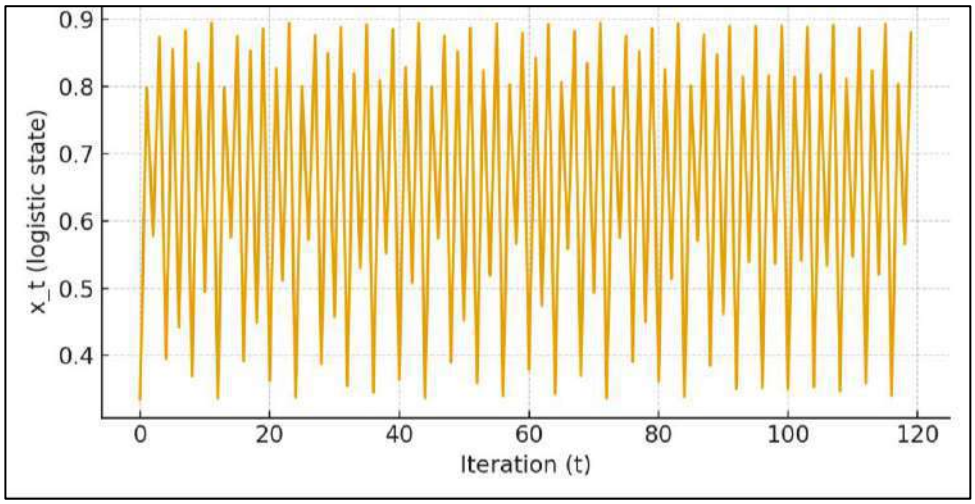

Figure 6: Chaos Dynamics.
Source: Authors, (2026).

IV.3 ASSESSMENT OF ENTROPY, DISPERSION AND STABILITY

The entropy and dispersion methods are used to study distribution of sentiment patterns in the review dataset. NETER model calculates the normalized Shannon entropy ($H_n = 0.8126$) by dividing the predicted values of sentiment into equal-sized intervals. This metric indicates uniformity of the distribution of reviews over different sentiment patterns. A higher value of entropy indicates variation in emotional tone of reviews, where reviewers have a mix of positive and negative experiences. Next, the normalized Median Absolute Deviation ($MAD_n = 0.5278$) is calculated to measure the difference in individual review sentiments from the average $P_{\square\square\square\square\square\square\square\square}$ value. A higher MAD value indicates disagreement among reviewers about their experience of using a product. Both measures are then combined in the NETER stability formula where the stability score is reduced when the sentiment distribution shows a lot of variation or inconsistency. After applying this penalty, the Stability Factor is calculated as 0.5000. This value of Stability Factor indicates that reviews do not follow a steady or unified pattern instead, they show variation in emotional tone of reviews. Even though the sentiment is positive, the instability reduces the trust rating for the product because the product's feedback is inconsistent, unpredictable, and less dependable.

IV.4 NETER TRUST SCORE

In this study, we measured the reliability of a product's reviews by calculating the trust score. The average star rating is also considered along with trust score. In our study the star rating of the product is around 4 out of 5, which indicates high trust, but the final NETER trust score is only 13.53 out of 100 which is very low. Even though the overall sentiment and star ratings are positive, a low NETER score indicates that reviews may be untrustworthy.

IV.5 INTERPRETATION OF FINDINGS

The results obtained from the proposed model indicate that positive ratings can be misleading, unstable review patterns reduce credibility, and high variation in the reviews makes reviews of the product less trustworthy. These points are summarized below.

1. **Positive words in reviews do not always indicate trustworthy feedback:** Nearly half of the reviews showed signs of promotional manipulation, and sentiment fluctuation between reviews.

2. **Chaos and instability are important factors of review credibility:** When reviews quickly change from positive to negative, they show polarized or coordinated reviews.

3. **Entropy-based stability is a strong penalizing factor:** High entropy and dispersion resulted in low Stability Factor and hence, low trust score.

Our findings show that the NETER model gives a better measure of review credibility than methods that only look at sentiments. It also helps in revealing the presence of manipulation. The NETER score shows the difference between the actual and the perceived trust of users. As per our results, the average sentiment score ($P_{\square\square\square\square\square\square\square\square\square} = 0.6398$) shows that large number of users have positive experience with the product but value of $P_{\square\square\square\square} = 0.4762$ indicates that manipulative language or deceptive patterns are present in reviews. $P_{\square\square\square\square}$ considers manipulations like urgency wording, exaggerated praise, or repeated hype which are part of the company's marketing tricks. The entropy ($H_n = 0.8126$) and dispersion ($MAD_n = 0.5278$) values also indicate inconsistency in the user's reviews where a few may be artificially generated reviews to influence buyers. This study finds that the quick change in positive and negative sentiments may appear before promotional activities. The Lyapunov exponent ($\lambda = 0.1082$) and derived *ChaosPenalty* shows that the review dataset has nonlinear instability. This supports the idea that the chaos-based model can be used for detecting irregular patterns and artificial boosts on e-commerce platforms. Traditional sentiment-only models would likely classify this product as positively perceived (with 4-star rating), yet NETER calculates a low final trust score of $13.53/100$, demonstrating that positivity is not a sufficient indicator of authenticity. These findings reinforce the claim that credibility assessment requires a multidimensional analysis that accounts for sentiment, manipulation, and dynamical behavior.

V. CONCLUSIONS

NETER combines transformer-based sentiment analysis, dark-patterns and deception detection, nonlinearity detection using chaos theory, and entropy-based stability scoring to evaluate credibility of the reviews. It produces more accurate and manipulation-resistant trust metrics compared to scores which are based only on sentiment or product-rating. This analysis shows that traditional sentiment and star ratings fail to capture deceptive language, instability and fake sentiment amplification in reviews. Highly positive reviews alone cannot indicate trust when entropy and chaos are elevated. NETER overcomes above-mentioned limitations by combining sentiment analysis, identification of deceptive patterns, stability, and nonlinear dynamic modelling to provide a score which is more reliable and trustworthy. When we applied NETER on our dataset, we obtained low trust score of $13.53/100$, despite positive sentiments in reviews. This confirms that positive sentiments in reviews can mask manipulation which includes deceptive promotional strategies that can influence consumers. A low trust score of 13.53 means that reviews for that product are not reliable and trustworthy. It also means that the comments are unstable, exaggerated, manipulated, and the overall sentiment is inconsistent. Thus, NETER identifies deceptive or exaggerated language in reviews, fake reviews and unreliable reviews by highlighting nonlinearity and provides better understanding of how trust is influenced by paid promotions, sponsored products or fake reviews.

In future work, we are planning to compare reviews of a product available on different ecommerce websites and apps that can help in identifying more reliable shopping platforms for the customers. Moreover, NETER can also be embedded in real time within e-commerce platforms to monitor and prevent fraud using fake reviews. This will help in detection and mitigation of deceptive patterns in product reviews, generating more reliable trust scores.

ABSTRACT

This paper presents a comprehensive approach to integrating Arduino with a current sensor, voltage sensor, two motors, and a motor driver to monitor the output of a solar panel and control a cleaning bot. Interacting the current and voltage sensors with the Arduino allows continuous solar panel power output monitoring. The Arduino is the central control unit to collect data from the current and voltage sensors to monitor the solar panel's performance. Additionally, the same Arduino is used to control the cleaning bot, which is equipped with two motors and a brush-controlled motor driver for effective cleaning of the solar panel surface. Furthermore, the cleaning bot is designed to enhance the solar panel's efficiency by automatically removing dust and rubble using a brush. Additionally, the bot is equipped with a Node MCU, enabling seamless data transmission to a web server, and making it accessible for remote monitoring. An Internet Protocol (IP) camera is integrated to visually inspect the solar panel and the cleaning bot's activities to enhance the system surveillance capabilities.

I. INTRODUCTION

Various energy sources like coal, nuclear, gas, hydro, and diesel, which are used for generating electricity, may get exhausted within a few years. Due to this, all the researchers are showing interest in sustainable energy production and saving. The power generated by sun radiation is one of the sustainable energy productions. Photovoltaic solar panels use the sun's radiation to generate electricity. When sunlight falls on the solar panel, the sun's radiation penetrates the solar cell to generate electricity more efficiently. If dust forms on the solar PV panel, it acts as a resistance in which the sun radiation may not penetrate properly into the solar cell [1-5]. Due to this, the output from the solar panel is reduced. However, photovoltaic technology faces several obstacles, including cost, the unpredictable nature of the environment, and low solar panel efficiency; it is always evolving in various applications. Since the solar panels are stored in an open environment, various elements, including the effect of clouds, snow, shadow, pollen, high temperatures, dust, bird droppings, and filth, can affect their effectiveness [6-8]. Therefore, keeping the solar panels tidy and clean is the greatest way to reduce dust's effect [9-12]. The main objective of the work is to

- ✓ Develop a solar panel cleaning robot to enhance the efficiency of solar panels power output.
- ✓ Promote the widespread adoption of solar PV panels for remote areas.
- ✓ Simplify and automate the process of cleaning solar PV panels against dust particles.
- ✓ Reduce the need for human intervention in solar PV panel maintenance and operation.
- ✓ Design an environmentally friendly and cost-effective robot for cleaning the solar panels.

In [13], the authors discussed that cleaning and maintenance greatly impact solar panels' efficiency. An 8-panel array shows a 30%–33% increase in efficiency; as a result, we can see that it will be more useful in solar parks with significantly more cells. Thorough cleaning is very beneficial because even a single panel obstructed by dust can reduce the array's overall performance. In [14], the authors proposed recommendations for future automation to lower labor costs and clean recycled water. The project aims to create a smart, completely automated cleaning system that uses less energy and resources. In [15], the author proposed an automatic solar PV panel cleaner robot using IoT. It comprises battery, DC motors, motor driver, microcontroller, IR sensor, and GSM module. In this system, it is possible to increase the peak power output by 10%–30%. The observation suggests that increased energy usage is caused by dust accumulation on the panel. In [16], the authors discussed that floating solar PV panels are typically placed in the center of a body of water. Any human going there to clean them has an extremely difficult time. The cleaning robot moves here and there on the solar PV panel to clean it, serving our objective without having to go there.

A camera installed on the robot allows for monitoring of the cleaning process. Additionally, the robot increases the effectiveness of the PV module. In [17], the author proposed an automatic solar PV panel cleaning system which will increase the solar PV module's efficiency. With the introduction of the Arduino Uno and driver circuit, they demonstrated the cleaning and control of the solar PV module cleaning mechanism along with the water pump and soft material. In [18], authors have developed and tested an automated solar panel cleaning robot to reduce dust-related efficiency losses. Experimental results showed improved PV output and reduced maintenance effort. In [19], an optimized grid-integrated hybrid AC/DC microgrid for rural electrification has been developed for location. The work demonstrated technical feasibility, cost-effectiveness, and improved reliability using renewable energy and storage systems. In [20], an experimentally investigated power enhancement techniques for partially shaded PV systems, showing improved output performance under non-uniform irradiance conditions. It is concluded that above studies advance photovoltaic system efficiency, operational reliability, and sustainable energy integration by introducing innovations in automated maintenance systems, optimized hybrid microgrid design, and effective partial shading mitigation techniques.

II. COMPONENTS REQUIRED

To overcome the limitations of conventional methods, an innovative approach is proposed, which leverages the use of embedded systems and automation. By interfacing Arduino with current and voltage sensors, the proposed method enables continuous real-time monitoring of solar panel performance. The embedded system provides live data and logs and stores historical data for detailed analysis. This ensures that any drop in efficiency or issues with the solar panel can be promptly detected and addressed, thus maximizing energy production, and minimizing downtime. Moreover, integrating an Arduino-controlled cleaning bot equipped with two motors and a brush motor driver offers significant advantages. The brush-controlled motor ensures consistent and thorough cleaning, enhancing the solar panel's overall performance. Additionally, the bot's integration with a Node MCU facilitates seamless data transmission to a web server, enabling remote monitoring and management. Users can gain visual insights into the solar panel's condition and the bot's cleaning activities through the web server and an IP camera. Due to its remote accessibility, operators can plan maintenance, make data-driven decisions, and maximize cleaning results, all contributing to increased solar panel efficiency. The components required for cleaning the solar panel are based on hardware and software requirements, and Figure 1 depicts the list of components used in the work for designing the proposed system.

II.1 HARDWARE REQUIREMENTS

The components used in the proposed system are as follows:

- Rechargeable Battery:

A rechargeable battery is an energy-storage gadget that can be charged once again by connecting DC current to its terminals.

- Arduino UNO:

It is a microcontroller board manufactured by Arduino. Cc and introduced in 2010. It is designed according to the Microchip ATMega328P microprocessor (MCU). The microcontroller board has sets of analogue and digital input/output (I/O) pins that interface with various expansion boards, shields, and other electrical/electronic circuits. The board can be programmed by using a USB cable and the Arduino iintegrated development environment (IDE). It is equipped with six analogue and fourteen digital input/output pins, with six capable of generating pulse-width modulation (PWM) output.

- Current Sensor:

A current sensor is a device capable of accurately measuring and calculating the current passing through a conductor without impacting system performance. This linear integrated circuit sensor operates on the principle of the Hall effect.

- Voltage Sensor:

A voltage sensor is a device used for measuring voltage. Voltage sensors can measure voltage using several methods, including detecting low voltage levels and measuring high voltages.

- DC Motor:

A motor is necessary for a robot to turn a wheel or carry out a certain task. A DC Motor is one such electric machine that converts electrical energy into mechanical energy. Two windings are found in a DC motor: the stator core consists of field winding and the rotor core consists of armature winding.

The field winding creates the magnetic field, whereas the armature winding acts as a conductor for current flow. According to the electromagnetic induction law, a current-carrying conductor experiences a force that produces torque when placed in a magnetic field. As a result, the shaft rotates.

- L293D Motor Driver:

The 16-pin L293D Motor Driver IC controls the two DC motors simultaneously, protecting the microcontroller from the high current required to operate the motor. It also works as an amplifier, boosting the microcontroller's low-power signal until it produces sufficient power to turn on the motor.

II.1.1 Software Requirements:

- Arduino IDE: The Integrated Development Environment application is compatible with various operating systems using the free and open-source Arduino IDE software. It provides support for programming languages such as C++. This is known as the Integrated Development Environment ITR, IDE for short.
- Adafruit: This library offers a user-friendly, device-independent interface for engaging with Adafruit IO using Arduino. It simplifies the transition between Wi-Fi, Ethernet, and cellular (32u4 FONA).

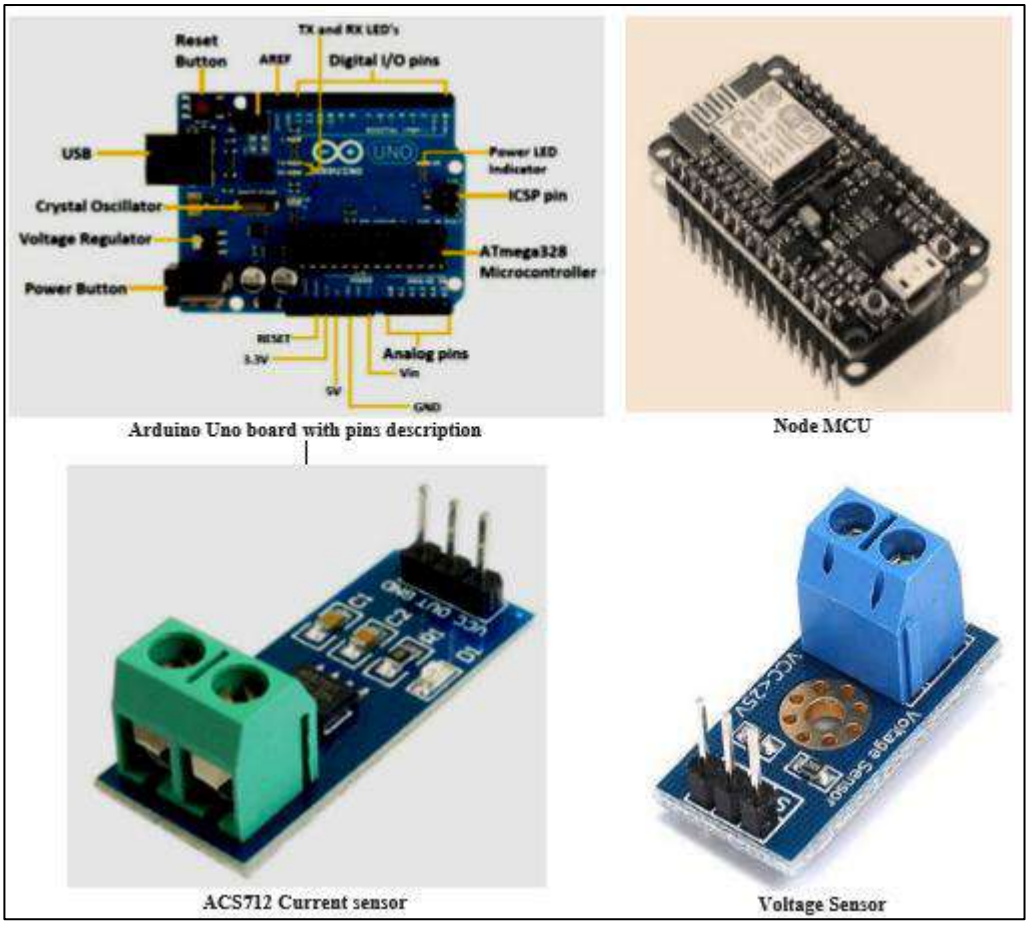

Figure 1: List of hardware components used in proposed work.
Source:Authors, (2026).

Figure 2 presents the block diagram of the proposed system. The system operation is initiated by turning ON the battery slide switch, which supplies power to the Arduino UNO, NodeMCU, and motor driver circuits. Under normal operating conditions, when the solar PV panel is clean, the LED remains in the ON state, and the voltage and current sensors continuously measure the electrical parameters of the panel. The sensed data are processed by the Arduino UNO and transmitted to NodeMCU, which uploads information to a cloud server, enabling real-time monitoring of the solar PV panel's voltage and current. Table 1 lists the specifications of the various components used in the proposed system design [21], [22]. When dust accumulation occurs on the solar PV panel, a reduction in voltage and current is detected and the LED turns OFF. In response, the Arduino UNO generates a control signal to activate the robotic cleaning mechanism. The robot is then automatically engaged to clean the solar PV panel. During this operation, a "Cleaning" status message is displayed on the cloud server, followed by a "Cleaned Successfully" message upon completion of the cleaning process. The cloud server continuously monitors system parameters, including voltage, current, and cleaning status. The proposed architecture integrates sensing, actuation, communication, and power management modules in an IoT-enabled embedded framework. Motor driver circuits ensure reliable control of the cleaning motor and auxiliary motors, while an IP camera provides visual monitoring of the solar panel and robotic operation. Overall, the system demonstrates a scalable and efficient solution for automated solar PV panel maintenance with real-time monitoring and remote supervision capabilities.

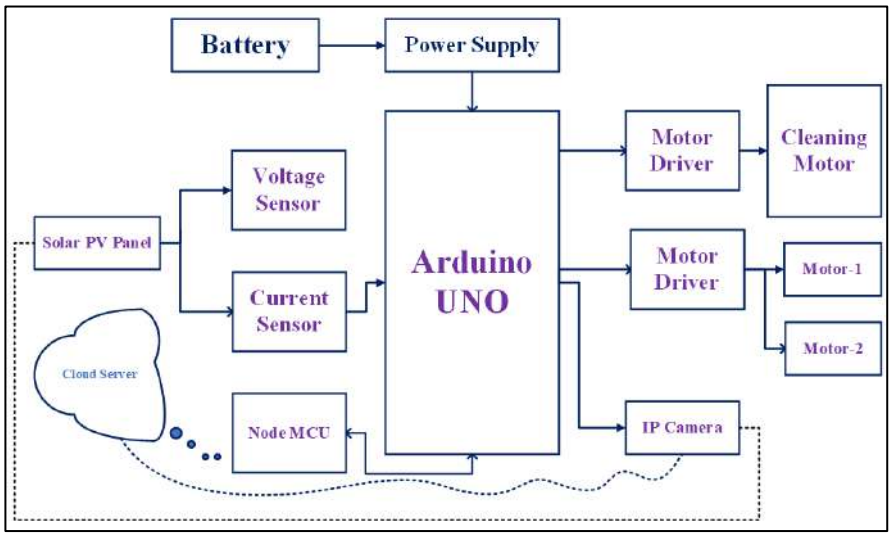

Figure 2: Block Diagram of proposed design model.
Source:Authors, (2026).

Table 1: The specifications of the various components used in the proposed system model.

Components	Specifications	Components	Specifications
Voltage Sensor	Input Voltage: 0-25 V	Node MCU	Operating Voltage: 4.5V-9V, typically 5V
	Voltage Detection: 0.02445 V-25 V		Flash Size:4MB
	Analog Voltage Resolution: 0.00489 V		Transfer Rate: 110-460800 bps
ACS712 Current Sensor	Input Voltage: 4.5 V-5.5 V DC		Working Temperature: -40 to +125 degree clecius
	Measure current Range: 20 A		
	Sensitivity:100 mv/A	Motor Driver	Driver Model: L29D Motor Driver
Solar Panel	Type: Polycrystalline		Operating voltage: 4.5 V-12 V
	Maximum Power Output: 5Watt		Maximum Supply Current: 600 mA per motor
Arduino Uno Board	Operating Voltage: 5V		Peak Current: 0.6 A
	Input Voltage (Recommended): 7-12V	DC Motor	Motor type: Permanent Magnet Dc Motor (PMDC)
	Input Voltage (Limit): 6 V-20 V		Operating Voltage: 12V
	Microcontroller: ATMega328P		Rated Speed: 200 RPM
	Flash Memory: 32KB (ATMega 328P of which 0.5KB used by bootloader)		Load Current: 0.3 A
	SRAM: 2KB	Wi-Fi Smart Net Camera	360-degree rotation CCtv Camera
	EEPROM: 1KB		12 LED IR Night Vision
	DC Current per I/O Pin: 20mA		1080P resolution video recording
	DC Current for 3.3V Pin: 50mA

III. EXPERIMENTAL RESULTS AND DISCUSSION

To work with the proposed designed system, a code has been written in Arduino and NodeMCU software, as shown in Table 2. After writing the codes for Arduino UNO and NodeMCU, install the ESP8266WIFI library and save the codes. Connect the Arduino board and Node MCU to the laptop or computer using the USB and Micro USB cables, respectively. The USB cable has two connectors: a type-A connector on one end and a type-B connector on the other. Connect the Arduino UNO to the USB type-A connector, and link the USB type-B connector to the power source or programming device, such as a computer or laptop. The next step is to compile the code and then upload the code. While uploading the code for Node MCU, remove the RX pin and then upload the code by selecting the board and port to which the Arduino and Node MCU are connected at tools. Now, turn on the battery slide switch. The Arduino, Node MCU, and motor driver receive the power when the dust accumulates on the solar panel, as shown in Figure 3. The Connections for the proposed model are given as:

- Battery red terminal and black terminal are given as input to the power supply board.
- One pin of the 9V/12V output pin of the power supply board is connected to the Vin pin of the nodemcu, and another pin is connected to the ground.
- Another set of 9V/12V output pins is connected to the Arduino board's Vin and GND pins.
- One set of 5V pins of the power supply board is connected as input pins of the motor driver.
- A0 pin of the Arduino uno board is connected to the signal pin of the voltage sensor.5V pin of the Arduino uno board is connected to the positive pin of the voltage sensor. GND pin of the Arduino uno board is connected to negative pin of the voltage sensor.
- The Arduino Uno board's A2 pin is connected to the current sensor's output pin. The current sensor's VCC pin is connected to another 5V pin of the Arduino board, and the current sensor's GND pin is connected to the Arduino board's GND pin.

- 2 Wires are connected to the solar panel. One wire i.e., positive wire is connected to the VCC pin of the Voltage Sensor, Positive pin of the current sensor and to the LED
- Another Wire from the solar panel is connected to the GND pin of the voltage sensor, current sensor, and LED
- TX, RX pins of the arduino uno board are connected to TX, RX pin of the nodemcu.
- D1, D2, D3, D4, D5, and D6 pins of the nodemcu are connected to the motor driver.

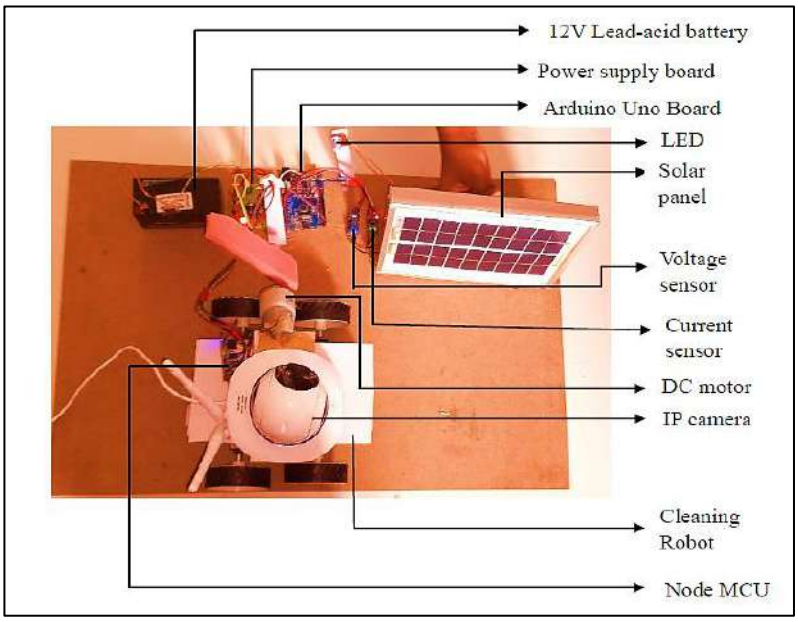

Figure 3: Experimental setup of robot cleaning the Solar panel.
Source: Authors, (2026).

To monitor the values of voltage and current, create an account in Adafruit software. It is open-source software. When the robot is cleaning the panel the values of current, voltage and message cleaning are uploaded in the Adafruit software as shown in Figure 4(a) and 4(b).

Figure 4: (a) The values of Voltage and Current before Cleaning (b) The values of Voltage and Current after Cleaning.
Source: Authors, (2026).

After completing the cleaning process, the voltage and current values increase, and a message is displayed as shown in Figure 4 b. The data is collected and tabulated in Table 3 at different timings in a day; from this, it can be concluded that solar radiation increases the output of the solar PV panel. A mobile application named V380 Pro will be downloaded from the Play Store on mobile to set the camera position and perform the visual inspections on the solar panel. To set up a V380 Wi-Fi Camera on an Android Phone.

Table 3: Obtained results data of solar PV panel before cleaning and after cleaning for the proposed system.

Time	Before Cleaning		After Cleaning	
	Current (Amp)	Voltage (V)	Current (Amp)	Voltage (V)
8:00 AM	0.21	0.46	2.52	1.12
9:00 AM	2.21	0.81	2.59	1.47
10:00 AM	2.62	0.49	2.75	1.64
11:00 AM	2.30	1.52	2.88	1.82

IV. CONCLUSIONS

In this proposed work, a functional robot for cleaning solar panels has been developed. It draws attention to how the efficiency of solar PV systems is impacted by dust, filth, pollen, sea salt, and bird droppings. The performance and efficiency of the solar panels power output are significantly impacted by dust and moisture contain particles. Due to this peak power generation by PV panel can be reduced by 10% to 30%. Dust deposition on the panels were shown to cause a power generation decrease, a robotic cleaning technique can fix this issue. This technique can enhances the solar panels ability to generate more power. Some advantages of this approach are low cost, easy maintenance, and reduced power use. Furthermore, this cleaning technque can overcome the decrease in peak power generation.

ABSTRACT

Fractional calculus has been rediscovered by scientists and engineers in the last two decades and applied in an increasing number of fields, namely in the area of control theory. FMRAC (Fractional Model Reference Adaptive Control) is an advanced control strategy that extends traditional adaptive control techniques by incorporating fractional calculus. This approach is particularly beneficial in systems where dynamics are complex and exhibit non-integer order behavior. The current research work presents the use the fractional Model Reference adaptive control (FMRAC) approach to improve the performances (rise time, setting time , overshoot and mean absolute error) for Aircraft by introducing fractional order integrator in the model reference system. To validate the arguments, effectiveness and performances analysis of the proposed FMRAC algorithm have been studied in comparison to the classical MRAC approach. Numerical simulation and analysis are presented to verify the best controller. The FMRAC approach gives the best results in terms of settling time, rise time, overshoot and mean absolute error. This approach can also be generalized to others fractional and integer systems in order to improve their performances and noise rejection.

I. INTRODUCTION

Fractional-order (FO) differential calculus, or fractional calculus, is an area of mathematics concerned with the expansion of well-known differentiation and integration operations to arbitrary orders. Thanks to correspondence between two mathematicians, Leibniz and L'Hospital, science began to deal with the field about 1695. Even if the great popularity of fractional calculus is very recent mainly regarding its application in science and engineering, its history goes 300 years back. Particularly, control theory and applications is one of the major fields of application of fractional order systems, with a quickly growing quantity of theoretical and experimental research production [1], [2]. The reason for this success is due to the advantageous properties of fractional order control (FOC) systems and their interesting ability to improve the process robustness against disturbances and noises. A good confirmation is the fact that the first FOC scheme ever proposed in the literature, the so-called “Commande Robuste d’Ordre Non Entier” (CRONE) controller [3], deals with robust control. The applications of fractional order differentiation have attracted the attention of researchers from vide variety of science disciplines especially from the fields of applied sciences [4], [5]. It is well-known that to address the parametric uncertainty in both linear and non-linear systems, adaptive control method is one of the best control techniques being used so far. However, the focus was on the use of integer order systems to implement adaptive control method [6-8]. In the domain of adaptive control, Model Reference Adaptive Control (MRAC) is a very attractive approach, because it offers a high level of performance while being very easy to implement. This scheme is mainly used to deal with unknown or slowly varying plants. The desired dynamical behavior of this adaptively controlled system is imposed by mean of a reference model chosen by the designer. Adjustment of parameters is achieved using the error between the plant’s output and the model reference output. Many control researchers are attempting to improve the MRAC robustness in order to deal efficiently in real time with the potential external disturbance that usually affect industrial plants.

Control engineering literature counts various robustification techniques that were introduced in elementary adaptive control algorithms [9], Many efforts have been reported in the literature focusing on new MRAC control concepts design using fractional order differential operators, with important results for temporal behavior and robustness versus external perturbation [10-12]. Fractional Order Model Reference Adaptive Control (FOMRAC) became a leading research area in the field of automatic control engineering since its first apparition in the literature which was pioneered by the teams of vinagre et al [12] and bensafia et al. [13], [14]. The main contribution of this work is the use the FMRAC approach to improve the performances (rise time, setting time and overshoot) for Aircraft system by introducing fractional order integrator in the classical model reference system. The manuscript is organized as; firstly we have discussed the fundamentals of a fractional order system followed by the study mathematical model of the Aircraft system. Section three is an background on Model Reference Adaptive Control (MRAC) and MIT rule. Afterwards, the results obtained with performance analysis from simulation applying for Aircraft system using the integer and fractional MRAC approach is presented. Lastly, the conclusion along with future perspectives of the study is given.

II. OUSTALOUP APPROXIMATION METHOD

It is well-known that calculus is used to generalize the derivation or integration of various functions. However, A subfield of calculus is called fractional calculus, that normally used non-integer order for the generalization of derivatives or integrals of a function [15]. fractional approximation techniques are authorized to employ easily fractional order systems in many different application areas such as control theory [15-18], renewable energy [19] , economical systems [20] etc. There are several characteristics that would decide the relative merits of any approximation such as differentiation order, frequency behavior or time responses etc. Several approximations are discussed here with respect to their comparative analysis with others [21], [22]. The available approximations belong to two different domains (frequency and time domains) which are specified as s-domain and z-domain, respectively. The Oustaloup method [23] is based on the function approximation from as;

$$G_f(s) = S^{\alpha} \qquad , \alpha \in R^{+} \tag{1}$$

By taking into account the rational function:

$$G_f(s) = K \prod_{k=1}^{N} \frac{s+w_k'}{s+w_k} \tag{2}$$

However, the poles, zeros, and gain can beevaluated as;

$$\mathrm{w_k^{'}} = \mathrm{w_b}.\mathrm{w_u^{(2k\text{-}1\text{-}\gamma)/N}} \quad , \ \mathrm{w_k} = \mathrm{w_b}.\mathrm{w_u^{(2k\text{-}1+\gamma)/N}} \ , \mathrm{K} = \mathrm{w_h^{\gamma}}$$

Where w_u representsthe unity gain in frequency and the central frequency in a geometrically distributed frequency band. Let $w_u = \sqrt{w_h w_b}$, where,w_h and w_b represent the upper and lower frequencies, respectively. γ and N are the orders of derivative and filter, respectively.

III. MATHEMATICAL MODEL OF THE AIRCRAFT

An aircraft in flight can rotate about three distinct axes that converge at its center of gravity: yaw (rotation about the vertical axis), roll (rotation about the longitudinal axis), and pitch (rotation about the lateral axis).
Developing a comprehensive control model for aircraft systems presents significant complexity. To address this challenge, specific simplifying assumptions are adopted that enable focused analysis of pitch control dynamics exclusively.
The key assumptions include:

- **Force equilibrium**: During steady cruise flight at constant velocity and altitude, the aerodynamic forces (drag and lift) balance with thrust and weight in the respective horizontal and vertical planes.
- **Decoupled dynamics**: Pitch angle variations are assumed to produce no effect on aircraft velocity, thereby simplifying the analysis.

These assumptions result in the pitch control mathematical model presented in Figure 1 [24], which forms the basis for the subsequent control system design.

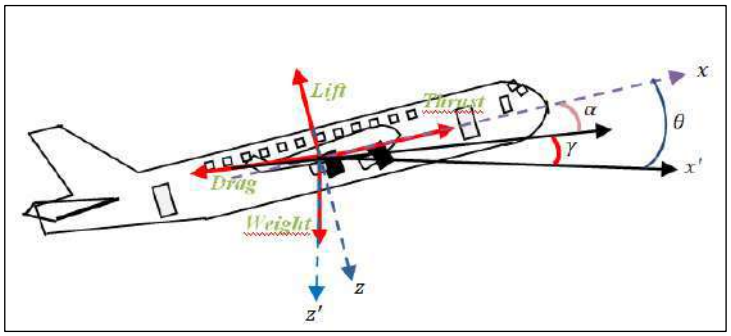

Figure 1: Pitch control description.
Source: Authors, (2026).

The dynamic response of an aircraft is described by the subsequent set of equations:

$$\frac{d\alpha}{dt} = \mu\Omega\sigma\left[-(C_L + C_D)\alpha + \frac{1}{\mu - C_L}q - (C_M \sin\gamma)\theta + C_L\right] \quad (3)$$

$$\frac{dq}{dt} = \frac{\mu\Omega}{2i_{yy}}\left[\left(C_m - \eta(C_L + C_D)\right)\alpha + \left(C_m + \sigma(1 - \mu C_L)\right)q + +(\eta C_w sin\gamma)\delta\right] \quad (4)$$

$$\frac{d\theta}{dt} = \Omega q \quad (5)$$

Where:

$\alpha, \Theta, \gamma, \delta$: Attack, pitch, flight path and elevator deflection angles respectively.
C_T, C_D, C_L, C_W, C_M:Thrust, drag, lift, weight and pitch moment coefficients respectively.
σ, η:Constants
q: Pitch rate
ρ: Air density
S: Wing platform area
m: Mass of the aircraft
I_{yy}: Inertia normalized moment
Substituting the aircraft parameter values into Equations (3), (4), and (5) yields the following simplified modeling equations:

$$\frac{d\alpha}{dt} = -0.313\alpha + 56.7q + 0.232\delta \quad (6)$$

$$\frac{dq}{dt} = -0.0139\alpha - 0.426q + 0.0203\delta \quad (7)$$

$$\frac{d\theta}{dt} = 56.7q \quad (8)$$

The following is the Laplace transform of the preceding equations:

$$\mathrm{sA(s)} = -0.313\mathrm{A(s)} + 56.7\mathrm{Q(s)} + 0.232\Delta(\mathrm{s}) \quad (9)$$

$$\mathrm{sQ(s)} = -0.0139\mathrm{A(s)} - 0.426\mathrm{Q(s)} + 0.0203\Delta(\mathrm{s}) \quad (10)$$

$$\mathrm{s\Theta(s)} = 56.7\mathrm{Q(s)} \quad (11)$$

Finally, Aircraft pitch angle transfer function is given in Eq. (10).

$$G_P(s) = \frac{\Theta(s)}{\Delta(s)} = \frac{1.121s + 0.1774}{s^3 + 0.739s^2 + 0.9215s} \quad (12)$$

Where:

$\Delta(s)$: is the elevator deflection

$\Theta(s)$: is the pitch angle

The open loop step response is shown in Figure 2 with the input signal as $\delta = 0.2$. The open loop step response indicates that the system is unstable.

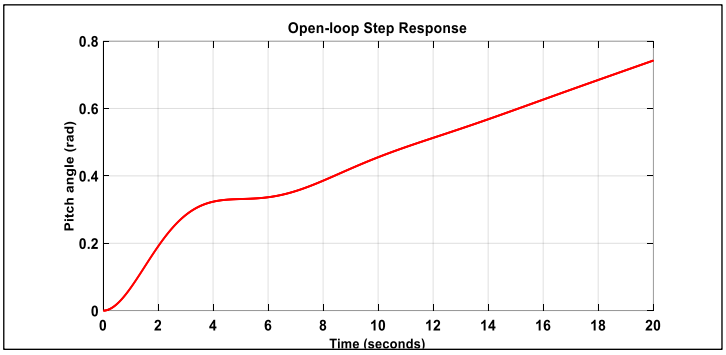

Figure 2: Open-loop step response of aircraft pitch angle.
Source: Authors, (2026).

A linearized model and simplified of aircraft system is considered in the form of a state-space system of equations [25]:

$$\dot{X}(t) = \begin{bmatrix} a_1 & a_2 \\ -1 & 0 \end{bmatrix} x(t) + \begin{bmatrix} b \\ 0 \end{bmatrix} u(t) \tag{13}$$

$$y(t) = [1 \quad 0]\, x(t) \tag{14}$$

where:

- X is the state vector (e.g., angle of attack and pitch rate).
- U is the input (e.g., control surface actuation).
- Y is the output (e.g., angle of attack or altitude).
- a1=−0.5 : Damping coefficient (aerodynamic stabilization effect).
- a2=1.2: Aerodynamic gain (influence of angle of attack on dynamics).
- b=0.8: Control gain (effectiveness of the control surface).

The system poles are determined by the eigenvalues of matrix A, which indicate the stability of the longitudinal dynamics. The vector B shows how the control input influences the aircraft dynamics and The vector C indicates which output is measured (here, probably the angle of attack).

IV. BACKGROUND ON MRAC: DESCRIPTION

The parallel structure (Figure 3) is the most famous MRAC structure, called the method of the output error; this approach involves plant model identification [13], [14] . Consider an single input, single output system, which can be a model of continuous time or discrete-time model:

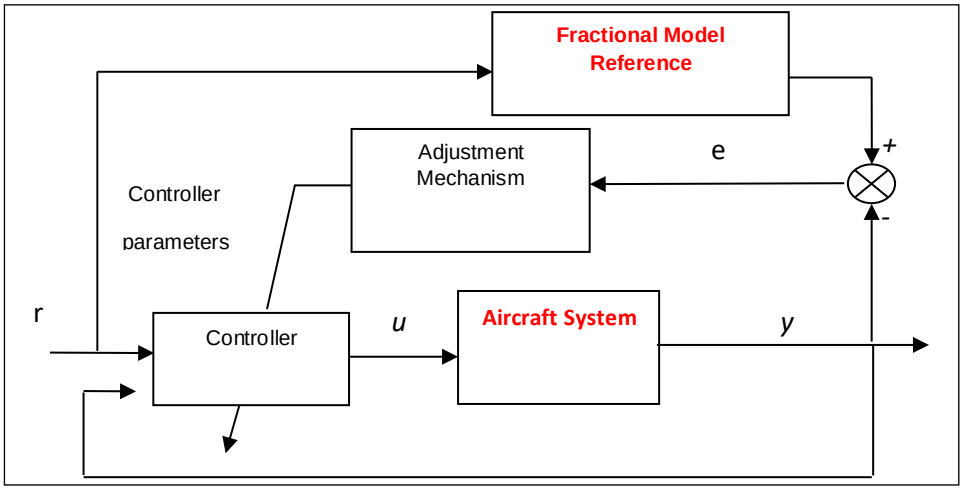

Figure 3: Fractional Model Reference Adaptive Control System.
Source: Authors, (2026).

Fractional Model Reference Adaptive Control (FMRAC) extends classical Model Reference Adaptive Control (MRAC) by incorporating fractional-order calculus into the control framework. This approach leverages fractional derivatives and integrals to achieve improved control performance, particularly for systems exhibiting memory effects and hereditary properties. Consider an input signal, the signal-output system, which can be a model of continuous time or discrete-time model:

$$y(t) = \frac{B}{A} u(t) \tag{14}$$

Where u is the control signal and y is the output signal. The symbols A and B denote polynomials in the differential operator p. It is assumed that the degree level $A \geq deg(B)$, the system is causal [11]. We assume that we are trying to find a regulator that the relationship between the u_c and the desired signal output ym, after having approximated the fractional reference model is given by:

$$y_m(t) = \frac{B_m}{A_m} u_c(t) \tag{15}$$

Where A_m and B_m are polynomials in the differential operator p. The generally linear control law is described as:

$$Ru = Tu_c - Sy \tag{16}$$

With R, S and T are polynomials. This control law is against a negative feedback with the transfer operator $-S/R$ and a direct reaction with the transfer operator $-T/R$. The gradient approach to MRAC is based on the assumption that the parameters change more slowly than the other variables in the system. Let e denote the error between the system output, y, and the reference output, y_m, Let θ denote the parameters to be updated. By using the criterion:

$$J(\theta) = \frac{1}{2} e^2 \tag{17}$$

The adjustment rule for changing the parameters in the direction of the negative gradient of J is that

$$\frac{d\theta}{dt} = -\gamma . \frac{\partial J}{\partial \theta} = -\gamma . e . \frac{\partial e}{\partial \theta} \tag{18}$$

If it is assumed that the parameters change much more slowly than the other variables in the system, the derivative $\partial e/\partial \theta$, i.e., the sensitivity derivative of the system, can be evaluated under the assumption that θ is constant [11], [13].
The control law is given by the following equation:

$$u = -\theta^T (P_1 \varphi) \tag{19}$$

V. RESULTS AND DISCUSSIONS

The reference model defines the desired behavior that the aircraft must follow. It is designed to be stable, with a well-damped response to the reference input r(t). The dynamics of the fractional reference model are described by:

$$D^{\alpha} x_m(t) = \begin{bmatrix} -1.5 & 0 \\ 0 & 0 \end{bmatrix} x_m(t) + \begin{bmatrix} 1 \\ 0 \end{bmatrix} r(t) \tag{20}$$

$$y_m(t) = [1 \quad 0]\, x_m(t) \tag{21}$$

The error between the computed and measured output is used to determine the fitness function F that will be used for minimization. It is given by the following Mean Absolute Error (MAE) [26]:

$$MAE = \frac{\sum_{i=1}^{N} y(i) - y_m(i)}{N} \tag{22}$$

Were y is the measured output of Aircraft system and y_m is the desired output. Figure 4 shows the Pitch angle , control and Error signals of the Aircraft using the MRAC Controller

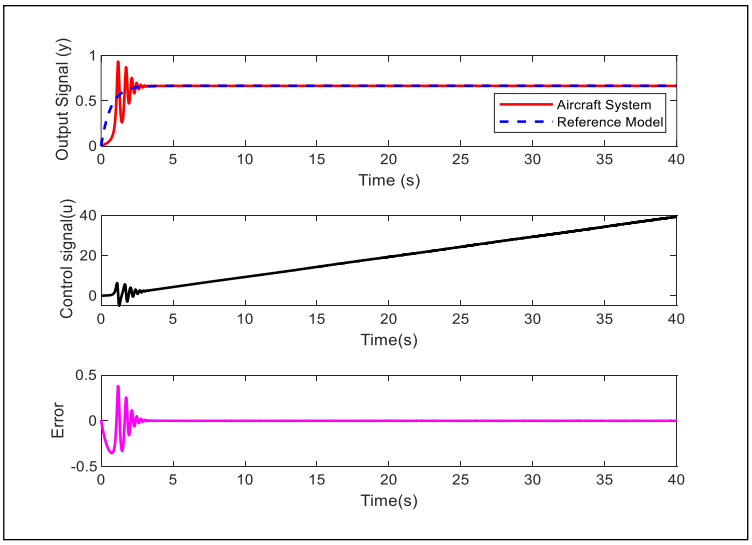

Figure 4: Pitch angle (y), control (u) and Error signal (e) of the Aircraft using the MRAC Controller
Source: Authors, (2026).

Figures 5 and 6 illustrate the pitch angle, control signal, and error response of the aircraft using the FMRAC controller with $\alpha = 0.1$ and $\alpha = 0.5$ respectively.

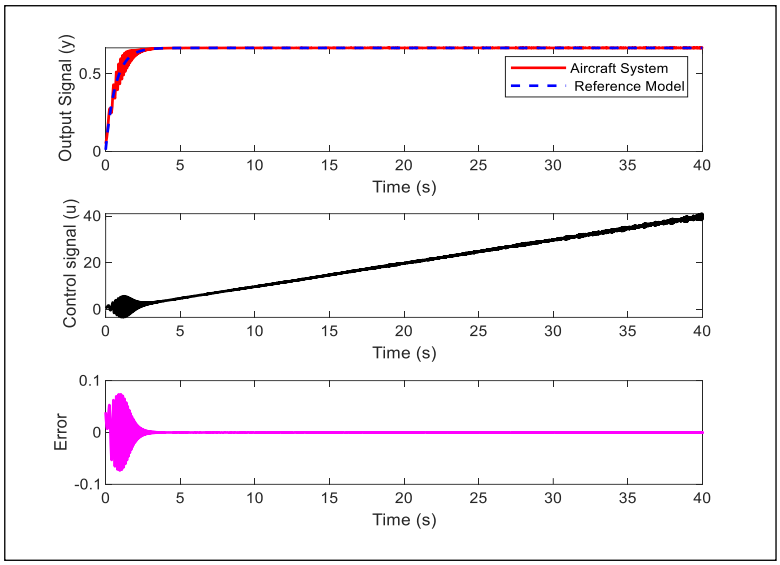

Figure 5: Pitch angle (y) , control (u) and Error signal (e) of the Aircraft using the FMRAC Controller ($\alpha = 0.1$).
Source: Authors, (2026).

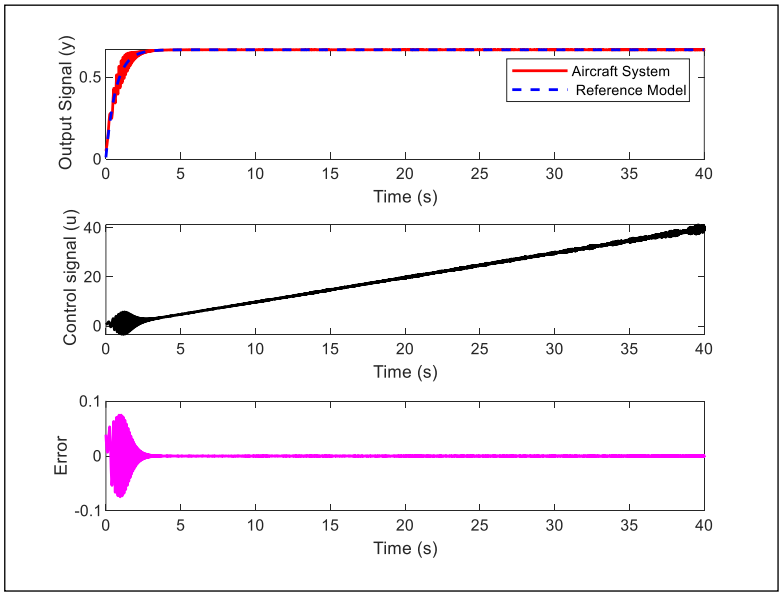

Figure 6: Pitch angle (y) , control (u) and Error signal (e) of the Aircraft using the FMRAC Controller ($\alpha = 0.5$).
Source: Authors, (2026).

The performance analysis of the proposed FMRAC controller and the classical MRAC is given by the table1.

Table 1. Transient Response Stability Parameters of Aircraft System

Controllers	Overshoot [%]	Setting time [s]	Rise time [s]	Mean Absolute Error (Rad)
MRAC	0.26	2.6	1.03	0.01
FMRAC ($\alpha = 0.1$)	0	2.1	0.6	0.00022
FMRAC ($\alpha = 0.3$)	0	2.14	0.58	0.00021
FMRAC ($\alpha = 0.5$)	0	2.17	0.61	0.00030
FMRAC ($\alpha = 0.7$)	0	2.16	0.59	0.00025
FMRAC ($\alpha = 0.9$)	0	2.09	0.59	0.00024

Source: Authors, (2026).

We remark that the FMRAC Controller for Aircraft system give the good improvement of overshoot, setting time , rise time and mean absolute error comparatively to the Integer MRAC Controller results. It can be seen that the response of the proposed FMRAC controller is better than MRAC controller in terms of response time and transient behavior, as shown in Figure 2 and Figure 3.the effort required by the FOMRAC controller is smaller and less oscillatory than that of the MRAC controller.CThe great interest of the control engineering community for FOMRAC could be justified by the following four facts:

- Fractional order models are able to describe physical systems better than the classical 'integer-order' models.
- Introducing fractional order dynamics in the closed-loop control system, can improve the system's behaviour,
- The inherent properties of fractional-order systems, including a fairly wide gain margin and the memory effect, make the control system more robust against disturbances and noise than integer-order systems.
- FOMRAC configuration is still a very simple scheme and easy to implement compared to other adaptive controllers.

VI. CONCLUSIONS

In this paper we study the performance analysis using the MRAC Controller and the FMRAC Controller optimized by genetic algorithm applying to Aircraft system. The Fractional approach allows to improve the good performances of overshoot, setting time , rise time and mean absolute error comparatively to the Integer MRAC Controller results. The simulation studies show good performance of the proposed approach and confirm its superiority over Integer MRAC Controller. In future work, we will investigate the generalization of the fractional adaptive control approach to others fractional systems in order to improve their robustness and noise rejection.

ABSTRACT

Building Information Modeling (BIM) adoption in developing countries, particularly Indonesia, is crucial for advancing the construction sector's digital transformation. This study critically reviews existing literature on BIM implementation in Indonesia, focusing on Quantity Take-Off (QTO) and persistent adoption challenges. Utilizing a systematic PRISMA-guided approach and bibliometric analysis, we synthesized fifty key publications. Findings reveal that while BIM offers superior efficiency and accuracy over manual methods, its widespread adoption in Indonesia is hindered by persistent barriers including lack of skilled personnel, high costs, organizational resistance, and inconsistent policy enforcement. This research differentiates itself by critically analyzing why these barriers endure within Indonesia's unique context, moving beyond a descriptive overview. The study maps the current research landscape, linking bibliometric clusters to practical implications for the Indonesian construction industry. It identifies specific limitations and proposes concrete future research directions and policy recommendations for government, academia, and industry stakeholders. The contribution lies in providing a nuanced understanding essential for accelerating BIM's effective integration and unlocking its full potential for the Indonesian construction sector.

I. INTRODUCTION

The architecture, engineering, and construction (AEC) industry globally is undergoing a profound digital transformation, with Building Information Modeling (BIM) emerging as a cornerstone technology. BIM's capacity to integrate multi-dimensional digital representations of built assets fosters enhanced collaboration, data sharing, and informed decision-making across a project's lifecycle [1], [2]. Globally, the adoption of BIM has yielded significant improvements in cost efficiency, conflict reduction, scheduling accuracy, and sustainability outcomes, aligning with Industry 4.0 paradigms [3-6]. In Indonesia, a nation experiencing rapid urbanization and substantial infrastructure development, the construction sector is a critical economic driver. BIM presents a potential solution to persistent industry challenges such as fragmentation, inefficiencies, and quality control issues [7], [8]. Despite this potential, BIM penetration in Indonesia remains nascent compared to more developed economies [9]. A growing body of research acknowledges BIM's promise for revolutionizing Indonesian construction practices [10]. However, the consistent and widespread adoption of BIM in Indonesia's construction sector is hindered by a range of critical factors, including limited awareness and expertise, high initial investment costs, a lack of comprehensive regulatory frameworks, and organizational resistance to change [3], [11], [12]. While existing literature has documented the benefits, barriers, and technological applications of BIM in Indonesia, a critical gap persists in the articulation of a distinct research novelty and a sharply defined research objective that differentiates this study from prior systematic reviews. Many studies have explored general barriers [3], [8], [13] or focused on specific applications like Quantity Take-Off (QTO) [4], [6], [14].

However, there remains a need for a synthesis that not only reviews the literature but also critically evaluates the persistence of these barriers and explicitly identifies the unique Indonesian context that necessitates tailored solutions, moving beyond generalizable

challenges. Therefore, this study aims to critically synthesize and analyze the existing body of research on BIM adoption and implementation in Indonesia, with a specific focus on understanding the persistent challenges and identifying distinctive contextual factors. This review will differentiate itself from prior works by:

Clearly delineating the specific research gap: While the general barriers to BIM adoption are well-documented, this study will investigate why these barriers remain persistent in Indonesia despite documented initiatives and the unique socio-organizational and policy dynamics at play. The primary objectives are to:

a. Critically map the thematic landscape of BIM research in Indonesia, identifying key focus areas and trends.
b. Synthesize the documented benefits and persistent barriers to BIM adoption, with a particular emphasis on the Indonesian context.
c. Analyze the interplay between technological, educational, policy, and organizational factors contributing to the slow adoption rate.
d. Identify the limitations of current research and propose clear future research directions to foster more effective and widespread BIM implementation.

By adopting a rigorous methodology that includes PRISMA-compliant article selection and bibliometric analysis, this study seeks to provide a nuanced understanding of BIM's trajectory in Indonesia, offering valuable insights for policymakers, educators, and industry stakeholders striving to accelerate digital transformation within the nation's construction sector.

II. RESEARCH METHODS

This study employs a systematic and critical review methodology to evaluate the adoption and implementation of Building Information Modeling (BIM), with a specific focus on Quantity Take-Off (QTO) practices within the Indonesian construction industry. The approach integrates bibliometric analysis and qualitative synthesis of relevant literature. This methodology is designed to provide comprehensive insights into the comparative advantages of BIM-based QTO over manual methods, the challenges hindering widespread adoption, and to critically address the identified research gap regarding the persistence of these barriers within the Indonesian context.

II.1 LITERATURE SEARCH STRATEGY

The literature search was conducted using the Publish or Perish software to retrieve scholarly articles primarily from Google Scholar. This was complemented by targeted searches within Scopus-indexed journals to ensure academic rigor and the inclusion of peer-reviewed, high-impact sources. This dual-database strategy enhances the breadth and depth of the literature base, aligning with best practices for systematic reviews [1], [2]. The initial search queries combined keywords designed to capture research pertinent to the study's scope: "Building Information Modeling," "BIM," "Quantity Take-Off," "QTO," and "Indonesia." Boolean operators (AND, OR) were used to refine searches and ensure the retrieval of relevant publications. The search was limited to articles published from 2010 to 2025 to capture recent trends and developments in BIM adoption

II.2 LITERATURE SEARCH STRATEGY

The article selection process strictly adhered to the PRISMA 2020 guidelines to ensure transparency, replicability, and minimize bias [15]. The process involved several stages:

- Identification: Approximately 1,000 documents were initially identified through the database searches.
- Screening: An estimated 200 duplicate records were removed. The remaining documents were screened based on titles and abstracts. Approximately 600 articles were excluded at this stage due to clear irrelevance to BIM, QTO, or the Indonesian context, or because they were identified as non-peer-reviewed materials (e.g., conference abstracts without full papers, opinion pieces).
- Eligibility: Full-text articles of the remaining approximately 200 documents were assessed for eligibility. A further 150 articles were excluded for reasons including:

a. Lack of specific focus on BIM adoption or implementation challenges in Indonesia.
b. Insufficient detail regarding Quantity Take-Off (QTO) or cost estimation.
c. Lack of empirical data or critical analysis relevant to the research questions.
d. Inability to access the full text.
e. Inclusion: A final selection of 50 documents was included for in-depth review and analysis. These documents represent a robust corpus covering thematic areas such as BIM integration, adoption barriers, cost and time performance, educational initiatives, and policy frameworks pertinent to the Indonesian construction context.The literature search was conducted.

II.3 DATA EXTRACTION AND SYNTHESIS

Data were extracted from the 50 selected articles using a standardized coding framework. The framework captured key information related to study objectives, methodology, findings (particularly regarding BIM vs. manual QTO), identified barriers and drivers, proposed solutions, and the specific context. A qualitative thematic synthesis was employed to analyze the extracted data. This involved:

- Identifying recurring themes: Patterns related to BIM benefits, challenges (technical, financial, organizational, policy-related), successful implementation strategies, and educational needs were identified.

- Comparative analysis: Findings from studies focusing on BIM-based QTO were critically compared with those discussing manual methods, paying close attention to reported metrics on accuracy, efficiency, and error rates [6], [7]. The persistence of manual methods was analyzed by synthesizing literature that explores practitioner perceptions and cost-benefit considerations [4], [12], [16].
- Contextualization: Findings were discussed within the specific socio-economic and regulatory environment of Indonesia, referencing government policies [7], [9] and industry practices.

II.4 BIBLIOMETRIC ANALYSIS

Bibliometric analysis was performed using VOSviewer software [17] on the selected corpus of 50 documents, augmented by the initial wider search results (approximately 1,000 documents) to ensure comprehensive mapping. This analysis aimed to:

- Identify Key Themes and Research Clusters: Keyword co-occurrence mapping was used to visualize the dominant research foci and their interconnections within the Indonesian BIM research landscape (Figure 1).
- Map Research Trends: While not explicitly detailed in a separate visualization in this section, the analysis informed the identification of publication trends over time within the broader search results, contributing to understanding the growth of BIM research in Indonesia.
- Identify Influential Authors and Sources: This further supported the comprehensive understanding of the research field, though specific author productivity analysis is not detailed here.

The bibliometric maps provided a macro-level understanding of the research landscape, which was then integrated with the qualitative thematic synthesis to provide a richer, multi-dimensional perspective on BIM research in Indonesia.

II.5 BIBLIOMETRIC ANALYSIS

This review acknowledges certain limitations. While extensive searches were conducted, the reliance on Google Scholar and specified Scopus journals might exclude relevant publications from other databases or regional sources. The exclusion of non-peer-reviewed grey literature beyond institutional repositories, due to consistency and quality control, may mean some industry-specific insights are not captured. Furthermore, the synthesis is based on secondary data reported in previous studies, and direct engagement with industry practitioners was not undertaken. The bibliometric analysis, while providing valuable overviews, is dependent on the quality and indexing of the source data.

III. RESULTS

III.1 BIBLIOMETRIC ANALYSIS OF BIM RESEARCH IN INDONESIA

The bibliometric analysis, utilizing VOSviewer [17], identified key themes and research trajectories in the Indonesian BIM domain. The co-occurrence mapping of keywords from the comprehensive literature search (approximately 1,000 initial documents) illuminated three major thematic clusters (Figure 1):

a. Red Cluster: Barriers, Integration, and Policy: This cluster encompasses keywords such as "barrier," "construction industry," "integration," "cost," "time," and "government." It highlights research focused on the obstacles to BIM adoption, performance improvements in terms of cost and time, and the crucial role of governmental policies within Indonesia [3], [7], [8].
b. Green Cluster: Implementation Specifics in Indonesia: Keywords here include "di Indonesia," "teknologi," "studi kasus," "autodesk revit," and "building information." This cluster reflects studies focusing on the practical application of BIM, specific case studies, and technology adoption within Indonesian projects [6], [9].
c. Blue Cluster: Broader AEC Context: This cluster comprises terms like "aec," "architecture," and "engineering," contextualizing BIM within the wider architectural, engineering, and construction ecosystem. It supports literature advocating for integrated educational programs and cross-disciplinary skill development [1], [2], [12].

Further bibliometric visualizations, including trend lines of publication volume over time and co-authorship networks, were generated (Figures 2 and 3). Publication trends indicate a steady increase in BIM-related research originating from Indonesia since 2015, with a notable acceleration in the last five years. Co-authorship analysis reveals a core group of active researchers and institutions, suggesting emerging collaborative networks, though significant opportunities exist for broader inter-institutional and international collaborations. The interconnections between these clusters signify that research in Indonesia addresses the technical applications of BIM, the inherent industry challenges, and the necessary policy frameworks, reflecting a multifaceted approach to understanding BIM adoption.

III.2 PRISMA FLOW AND STUDY SELECTION

The PRISMA flow diagram (Figure 4) illustrates the systematic article selection process. From an initial corpus of approximately 1,000 documents, rigorous screening based on titles, abstracts, and full-text eligibility resulted in 50 documents for in-depth review. This process, guided by predefined inclusion and exclusion criteria detailed in Section 2.2, ensured a high-quality dataset for analysis. The included studies represent relevant contributions to BIM adoption in Indonesia, covering diverse themes such as technological integration, adoption barriers, performance improvements, educational initiatives, and policy frameworks [3], [6], [7], [10].

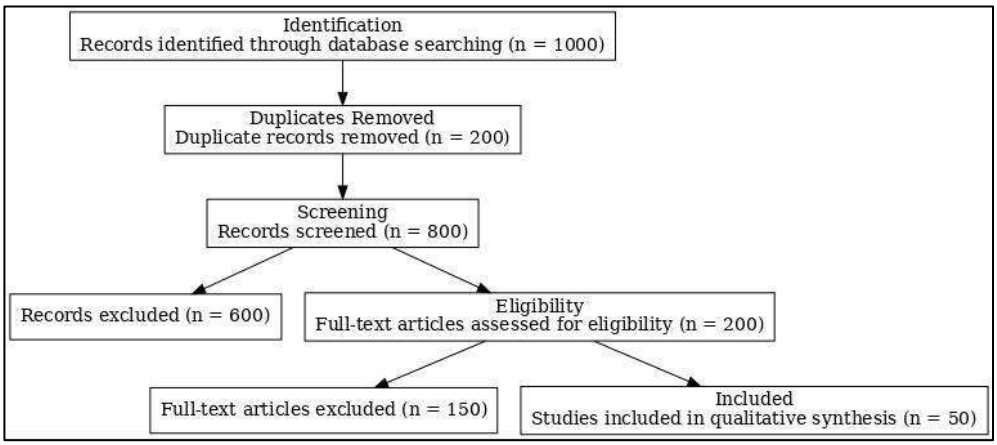

Figure 4: PRISMA Flow Diagram of the Study Selection Process.

III.3 THEMATIC CLUSTERS AND KEY FINDINGS

Thematic synthesis of the 50 selected articles, categorized as presented in Table 1, revealed key findings aligned with the bibliometric clusters:

Table 1: Thematic Clusters and Sample Studies of Selected BIM Research in Indonesia.

Theme	Description	Sample Studies (Authors, Year)	Key Findings Relevant to Indonesian Context
1. BIM Adoption & Implementation	Status, barriers, drivers, and strategies for BIM adoption.	(Saka & Chan, 2020) [3]; (Latief & Hidayat, 2020) [7]; (Husin et al., 2021) [6]; (Wibowo et al., 2023) [9]; (Abdelhameed & Ismaeil, 2024) [1]; (Alghuried, 2023) [2]; (Raitviir, 2024) [3]; (Al-Ruwaishedi et al., 2024) [4]; (Gao et al., 2025) [5]; (Pasha & Mohamad Rasdi, 2022) [6].	Widespread acknowledgement of BIM benefits but significant challenges in practical implementation. Common barriers include lack of skilled personnel, high costs, and insufficient government support/mandates.
2. BIM for Quantity Take-Off & Cost Estimation	BIM-based QTO accuracy, efficiency, and comparison to manual methods.	(Husin et al., 2021) [6]; (Latief & Hidayat, 2020) [7]; (Novita & Pangestuti, 2021) [18]; (Zhang & Mo, 2024) [7]; (Khant et al., 2024) [8]; (Rashidi et al., 2024) [9]; (Fei et al., 2024) [10]; (Cassandro et al., 2024) [11]; (Salahaldain et al., 2023) [12]; (Abdulwahhab et al., 2022) [13]; (Al-Musawi & Naimi, 2023) [14]; (Lu et al., 2023) [15].	BIM-based QTO consistently shows superior accuracy, time efficiency, and reduced human error compared to manual methods. However, manual methods persist due to familiarity and perceived lower complexity for certain project scales.
3. BIM & Emerging Technologies	Integration with GIS, IoT, Blockchain, Digital Twins for enhanced workflows.	(Liu et al., 2017) [10]; (Ding et al., 2019) [11]; (Nawari & Ravindran, 2019) [4]; (Alazawy et al., 2024) [16]; (Park & Yun, 2023) [17]; (Javaherikhah et al., 2025) [19]; (Marcos et al., 2024) [20]; (Xue et al., 2022) [21]; (Lee et al., 2024) [22]; (Song, 2022) [23]; (Yin et al., 2023) [24].	Growing interest in integrating BIM with other digital technologies to enhance transparency, asset management, and data security. However, adoption of these advanced integrations is even more nascent than core BIM in Indonesia.
4. Policy & Institutional Support	Government policies, regulations, and institutional frameworks promoting BIM.	(Latief & Hidayat, 2020) [7]; (Wibowo et al., 2023) [9]; (Rahmani & Herumanta, 2023) [25]; (Ali et al., 2024) [26]; (Kim et al., 2025) [18].	Government initiatives exist (e.g., Ministry Regulation No. 22/PRT/M/2018), but enforcement and industry-wide compliance remain inconsistent. Policy frameworks need strengthening and better alignment with industry capacity.
5. Education & Capacity Building	BIM education, training programs, competency development, and curriculum alignment.	(Husin et al., 2021) [6]; (Saka & Chan, 2020) [3]; (Gegana & Widjanarso, 2015) [16]; (Soon et al., 2024) [25]*; (Diaz Schery et al., 2023) [27].	A critical knowledge gap exists between academic BIM curricula and industry demands. Insufficient hands-on training and a lack of qualified BIM educators are significant constraints.
6. Technological Innovation & Applications	BIM applications in safety, scheduling, sustainable design, and energy efficiency.	(Eastman et al., 2017) [22]; (Kim et al., 2024) [23]; (Nguyen et al., 2024) [26]; (Rocha & Mateus, 2024) [28]; (Yang et al., 2025) [29]; (Ibrahimkhil et al., 2023) [30]; (Liu et al., 2024) [31]; (Fang et al., 2025) [32]; (Ikeda & Yabuki, 2023) [33].	While global research explores advanced BIM applications, their implementation in Indonesia is limited, often confined to large-scale projects or specific firms. Focus remains on foundational BIM use. Furthermore, advanced BIM-based clash detection prioritization techniques have been proposed to enhance design-phase coordination efficiency and reduce downstream construction conflicts [34].
7. Barriers & Challenges	Technical, financial, organizational, and cultural barriers to BIM adoption.	(Saka & Chan, 2020) [3]; (Waqar et al., 2023) [8]; (Aziz et al., 2016) [7]; (Wibowo et al., 2023) [9]; (De Wolf et al., 2023) [35]; (Waqar et al., 2024) [36]; (Hasan et al., 2023) [37]; (Nsimbe & Di, 2024) [38].	Persistent barriers include: (1) human resource readiness; (2) financial constraints affecting SMEs [2], [8], [32]; (3) organizational resistance and limited leadership commitment [3],[9], [30]; (4) uneven technological infrastructure; and (5) regulatory inconsistencies requiring standardized BIM protocols [7], [9].Limited access to reliable digital infrastructure in some regions [8]. 5. Policy and Regulatory Gaps: Inconsistent enforcement of existing regulations and a need for standardized BIM protocols [7], [9].

III.4 LINKING KEYWORD CLUSTERS TO PRACTICAL IMPLICATIONS FOR INDONESIA

The bibliometric keyword clusters provide direct insights into practical implications for the Indonesian construction industry:

a. Red Cluster Insights: The strong presence of "barrier," "cost," and "government" underscores the urgent need for targeted policy interventions and financial support mechanisms from government bodies to facilitate BIM adoption, especially for SMEs [2], [8], [19]. Strategies must address not only technological adoption but also regulatory frameworks and enforcement.

b. Green Cluster Insights: The focus on "studi kasus" and specific technologies like "Autodesk Revit" highlights the importance of disseminating successful Indonesian case studies and promoting accessible training pathways. Practical implications involve developing industry-specific BIM implementation roadmaps and fostering knowledge sharing among practitioners.
c. Blue Cluster Insights: The connection to "AEC" and "architecture/engineering" emphasizes that practical implications must consider cross-disciplinary integration. This points to the need for multi-stakeholder collaboration and the alignment of BIM education across academic disciplines to prepare a holistic AEC workforce.

These explicit links suggest that research discoveries directly inform actionable strategies for industry stakeholders, moving beyond theoretical discussions to practical implementation guidance tailored to Indonesia.

IV. DISCUSSIONS

This study has critically analyzed the landscape of Building Information Modeling (BIM) adoption and implementation within Indonesia's construction sector, providing a synthesis of existing research and bibliometric insights. The findings underscore that while BIM offers significant advantages in enhancing project accuracy, efficiency, and collaboration particularly in Quantity Take-Off (QTO) processes its adoption in Indonesia is impeded by a complex interplay of persistent barriers. These include limited technical expertise, substantial financial costs, organizational resistance, inadequate technological infrastructure, and inconsistent policy enforcement. The research confirms the relevance of BIM as a transformative technology for developing countries, contributing theoretically by mapping specific research trends in Indonesia and practically by identifying actionable insights for industry stakeholders. By rigorously synthesizing the literature through PRISMA-compliant methods [15] and bibliometric analysis [17], this study moves beyond a purely descriptive account to critically evaluate why these barriers endure within the Indonesian context, differentiating it from prior reviews and offering a deeper understanding informed by the specific socio-economic and regulatory dynamics of the nation [7], [9].

IV.1 LINKING KEYWORD CLUSTERS TO PRACTICAL IMPLICATIONS FOR INDONESIA

The analysis highlights that despite documented benefits [6], [7], the persistent challenges related to human resource readiness, financial constraints (especially for SMEs [2], [8], [19]), organizational culture [3], [9], [30], and policy implementation gaps [7], [9] require more than generic solutions. The Indonesian context necessitates tailored strategies that acknowledge its unique market structure and regulatory environment. The study emphasizes that the continued reliance on manual QTO methods, while familiar, hinders the sector's progress towards greater efficiency and accuracy, underscoring the need for a deliberate transition pathway [6], [9], [16].

IV.2 POLICY AND PRACTICAL RECOMMENDATIONS

To accelerate BIM adoption and overcome the identified persistent barriers, this study proposes the following actionable recommendations:

1. For the Indonesian Government:

a. Strengthen and Enforce BIM Mandates: Move beyond policy statements to robust enforcement mechanisms for BIM in public projects, coupled with clear guidelines and technical standards.
b. Financial Incentives and Support Programs: Introduce targeted subsidies, tax incentives, or low-interest loan programs specifically for SMEs to offset the initial costs of BIM adoption.
c. National BIM Roadmap Development: Establish a national, coordinated roadmap with clear timelines, targets, and responsible agencies for BIM implementation across the AEC sector.
d. Promote Interoperability Standards: Facilitate the adoption of open BIM standards to ensure seamless data exchange and reduce vendor lock-in.

2. For Academia and Educational Institutions:

a. Curriculum Reform: Integrate practical, hands-on BIM training into undergraduate and postgraduate curricula across architecture, engineering, and construction disciplines.
b. Develop Certified BIM Professional Programs: Establish accredited training and certification programs to address the shortage of skilled BIM professionals.
c. Foster Industry-Academia Collaboration: Promote research partnerships, internships, and joint development projects to bridge the gap between academic knowledge and industry needs.

3. For the Construction Industry:

a. Invest in Capacity Building: Prioritize continuous professional development and upskilling for existing staff in BIM technologies and workflows.
b. Embrace Change Management: Develop strategies to foster a culture of innovation, encourage leadership commitment, and effectively manage organizational resistance to BIM adoption.
c. Promote Collaborative BIM Workflows: Encourage the adoption of collaborative platforms and practices to enhance stakeholder communication and data sharing.
d. Explore Phased or Hybrid Adoption: For SMEs, consider phased implementation strategies or hybrid workflows that integrate BIM gradually with existing manual processes to manage costs and build confidence.

IV.3 LIMITATIONS AND FUTURE RESEARCH DIRECTIONS

This study acknowledges its limitations, as detailed in Section 2.5, including reliance on secondary data, exclusion of certain grey literature, and the scope of databases searched. These limitations suggest avenues for future research:

1. Longitudinal Impact Studies: Conduct empirical, longitudinal studies to quantitatively measure the sustained impact of BIM adoption on project performance (cost, time, quality, safety) in Indonesia.
2. Deep-Dive into SME Adoption: Undertake in-depth case studies focusing specifically on the challenges and successful strategies for BIM adoption within Indonesian SMEs.
3. Comparative Analysis with Other Developing Countries: Expand the comparative discussion to systematically analyze how specific contextual factors in Indonesia differentiate its BIM adoption trajectory from other developing nations.
4. Impact of Emerging Technologies: Investigate the adoption readiness and potential impact of integrating BIM with other digital technologies (IoT, AI, Blockchain) within the Indonesian context.
5. Socio-Organizational Dynamics: Further explore the cultural and social aspects influencing BIM adoption, including stakeholder perceptions, trust, and collaboration dynamics.

By addressing these recommendations and future research directions, stakeholders can work towards a more coordinated and effective approach to BIM adoption, ultimately driving digital transformation and enhancing the competitiveness and sustainability of Indonesia's construction industry.

V. CONCLUSIONS

This study critically reviewed the adoption and implementation of Building Information Modeling (BIM) in the Indonesian construction industry, highlighting persistent challenges and unique contextual factors. By integrating bibliometric analysis with a deep thematic synthesis of 50 selected scholarly articles, this research provides a nuanced understanding of BIM's trajectory in Indonesia, moving beyond mere description to analyze why adoption lags persist. The primary findings underscore that while BIM offers significant global advantages in accuracy, efficiency, and collaboration, particularly for Quantity Take-Off (QTO), its uptake in Indonesia is hampered by a complex interplay of enduring barriers. These include a critical shortage of skilled personnel, substantial financial constraints affecting SMEs, deep-seated organizational resistance to change, underdeveloped technological infrastructure, and inconsistent policy enforcement. Crucially, this study emphasizes that these barriers are not merely generic challenges faced by developing countries but are perpetuated by specific Indonesian socio-economic, regulatory, and cultural dynamics. The contribution of this research lies in its critical evaluation of why these barriers remain entrenched despite existing initiatives, offering a more profound insight than previous reviews. It addresses the core research questions by identifying the specific Indonesian context that shapes these persistent adoption challenges and differentiates them from broader global trends. The study’s implications are practical: it highlights that successful BIM integration necessitates tailored strategies addressing not just technological implementation but also systemic issues like policy enforcement, targeted financial support for SMEs, and robust, industry-aligned capacity building. Based on these findings, strong policy and research recommendations are proposed:

- For the Indonesian Government: Develop and rigorously enforce BIM mandates with clear implementation roadmaps, provide targeted financial incentives (e.g., subsidies for SMEs), and establish national BIM standards to ensure interoperability and consistency.
- For Academia: Revise BIM curricula to bridge the gap between theoretical knowledge and practical industry needs, increase hands-on training, and foster research into context-specific BIM solutions.
- For Industry: Embrace BIM through strategic leadership commitment, invest in continuous training and upskilling of personnel, and foster collaboration across firms to share best practices and mitigate costs.

Limitations include reliance on secondary data and the exclusion of some grey literature. Future research should focus on longitudinal studies to assess BIM's sustained impact, conduct direct empirical investigations into SME challenges, explore the effectiveness of hybrid BIM-manual workflows, and investigate the potential of emerging technologies integrated with BIM within the Indonesian context. This study provides a foundational analysis, paving the way for more targeted interventions advancing digital transformation in Indonesia's construction sector.

ABSTRACT

In this paper an adaptive droop control strategy is proposed for voltage source converter based multi-terminal direct current (VSC-MTDC) systems to achieve a higher power-sharing accuracy, DC voltage regulation, and operating robustness during converter failures. The scheme integrates the robustness of voltage margin control with the distributed balancing capability of conventional droop regulation in a way that converters operating under constant power mode initially can switch automatically to droop mode at any time DC voltage differences exceed pre-set operating thresholds. Event-driven adaptability enhances synchronized inter-terminal response, enables equitable power readjustment, and mitigates voltage instability under heavy transient disturbances. A ±400 kV four-terminal VSC-MTDC system was planned and rigorously simulated in PSCAD/EMTDC for comparing the proposed method with conventional fixed-slope droop control. Quantitative results confirm that the proposed method realizes 45–60% reduction of peak DC voltage excursions, 40–55% reduction of active power overshoot, and 35–50% improvement in voltage settling time. Additionally, the passive converters in conventional schemes deliver up to +65 MW of extra support, thereby preventing the remaining terminals from being overloaded and maintaining safe operating margins. The dynamic coordination with advanced capabilities allows solid post-fault operation for single as well as multi-converter outages without protection-led shutdowns and improves the entire system's resilience. The demonstrated voltage stability, fault tolerance, and converter utilization enhancements confirm the adaptive droop control as a viable approach for the next-generation resilient, large-scale HVDC microgrids with high-penetration renewable energy integration.

I. INTRODUCTION

The imperative to decarbonise global energy systems has emerged as a primary strategy to combat climate change and reduce detrimental greenhouse gas emissions. In this context, renewable energy sources (RES), especially solar photovoltaic and offshore wind power, have emerged as viable alternatives due to their significant potential for sustainable and eco-friendly generation [1-3].

The swift proliferation of these technologies is transforming the architecture of contemporary electrical networks, steering them towards a more intricate, decentralised, and dynamic framework. This shift, however, presents new problems for transmission and distribution systems, which must now guarantee stable, dependable, and efficient operation under varied and frequently uncertain operating conditions. Most renewable energy producing facilities are generally situated at considerable distances from primary consumption centres, necessitating long-distance transmission [4], [5]. Moreover, their sporadic characteristics—dictated by climatic elements like wind velocity and sun radiation result in fluctuations and uncertainty in energy production. These oscillations necessitate sophisticated control and management systems to ensure real-time power balance, voltage stability, and power quality [6], [7]. Offshore wind farms are becoming pivotal to this transformation. They capitalise on optimal wind resources, diminished aerodynamic turbulence, and extensive areas distant from populous regions, resulting in enhanced generating potential with reduced environmental and noise effect [8], [9]. The notion of continental-scale Super Grids has gained prominence to properly utilise these remote and variable resources. Extensive infrastructures link geographically separated renewable locations with load centres using High Voltage Direct Current (HVDC) transmission networks [10], [11]. In contrast to conventional AC transmission, HVDC provides reduced losses, increased transfer capacity, and improved dynamic stability.

Conventional Line-Commutated Converter HVDC (LCC-HVDC) technology, although extensively utilised, is constrained by limited flexibility and inadequate grid-support capabilities. Conversely, Voltage Source Converter HVDC (VSC-HVDC) technology offers autonomous regulation of active and reactive power, black-start functionality, and uninterrupted bidirectional power flow, rendering it the favoured choice for contemporary grids [12], [13]. Leveraging these benefits, Multi-Terminal DC (MTDC) networks utilising VSC-HVDC are anticipated to serve as the foundation of future power transmission systems. MTDC facilitates the concurrent integration of various renewable sources, augments system redundancy, and improves operational flexibility. Nonetheless, the stability of these systems continues to be a significant problem, especially during severe disruptions such as converter failures or line faults. Sudden disparities in power distribution can provoke substantial DC voltage fluctuations, jeopardising the stable functioning of the entire grid [14-16]. To alleviate these challenges, sophisticated control frameworks are utilised in MTDC systems, generally organised into hierarchical tiers. At the network level, master control schemes are essential for coordinating power distribution among terminals. The Voltage Droop Method (VDM) is acknowledged as a superior decentralised strategy, surpassing the Master-Slave Method (MSM) and the Voltage Margin Method (VMM) in flexibility, scalability, and fault tolerance [16-18].

Nonetheless, traditional fixed-parameter droop control encounters constraints under extreme operating circumstances. The failure to dynamically adjust to system fluctuations or critical contingencies may jeopardise both stability and performance, therefore limiting the reliability of future MTDC grids. This work presents a revised adaptive droop control technique aimed at enhancing the resilience and performance of VSC-MTDC systems in various fault conditions. The suggested method, in contrast to existing methodologies, dynamically modifies droop parameters based on real-time operating conditions, hence ensuring adherence to the N-1 contingency criterion. A comprehensive four-terminal MTDC test system is constructed in PSCAD/EMTDC, simulating various fault scenarios, including single and multiple converter failures, to assess transient reactions, voltage stability, and power redistribution efficacy. Comparative investigations indicate that the suggested technique markedly enhances dynamic performance by diminishing DC voltage swings, expediting fault recovery, and ensuring equitable power distribution among terminals. The results underscore the promise of adaptive droop-based control as a viable and scalable approach for improving the stability and dependability of future MTDC networks functioning in increasingly complex and uncertain contexts.

II. RELATED WORKS

The swift incorporation of renewable energy into contemporary electricity systems has presented considerable issues concerning stability, regulation, and protection. Recent studies indicate that traditional protection strategies are inadequate in renewable-dominant networks, where intermittency and bidirectional power flows hinder fault identification and isolation [19], [20]. These situations threaten overall system reliability, requiring enhanced protection and control mechanisms specifically designed for high renewable penetration. The geographical distance between remote renewable generation sites and primary load centres necessitates the implementation of resilient long-distance transmission technologies and sophisticated control systems that can handle variable generation while guaranteeing secure and uninterrupted power delivery. High Voltage Direct Current (HVDC) transmission is acknowledged as a premier solution to these difficulties, facilitating efficient, long-distance power transfer with diminished electrical losses relative to traditional AC systems [21]. Among HVDC technologies, Voltage Source Converter-based HVDC (VSC-HVDC) has garnered significant interest due to its superior controllability, encompassing independent regulation of active and reactive power, black-start capability, and dynamic grid support, which are essential for the integration of substantial renewable generation.

Leveraging these benefits, Multi-Terminal DC (MTDC) networks enhance the functionality of VSC-HVDC by linking numerous nodes, thus augmenting redundancy, operational flexibility, and the scalability of renewable integration. Nonetheless, MTDC systems provide further hurdles in sustaining voltage stability and fault tolerance, necessitating hierarchical control frameworks and adaptive solutions to ensure secure operation amid various circumstances. To mitigate these issues, numerous control mechanisms have been investigated. The Voltage Droop Method (VDM) is acknowledged as an efficient decentralised strategy for power distribution and voltage regulation in MTDC systems. Nonetheless, conventional fixed-parameter droop methods sometimes struggle to adjust to severe disruptions or swiftly fluctuating operational conditions, resulting in potential instability hazards [22]. This constraint has spurred the advancement of adaptive droop control methods that adjust control parameters in real time, significantly enhancing transient response, fault ride-through capability, and fair power redistribution in multi-terminal HVDC grids [23], [21], [22]. Notwithstanding these developments, current methodologies continue to encounter challenges in reconciling practical simplicity with resilience in various fault circumstances, highlighting the necessity for innovative adaptive solutions specifically designed for large-scale MTDC applications.

III. MULTITERMINAL VSC-HVDC CONFIGURATION TYPE

The multi-terminal HVDC is modelled using many configurations, including radial, radial-ring, and meshed, as illustrated in Figure 1. In the radial layout seen in Figure 1 (a), numerous Voltage Source Converters (VSCs) are interconnected on the DC side to establish a string connection. This setup can be augmented from the current point-to-point links [24]. In radial networks, the failure of a DC transmission line segment would lead to a complete service disruption at the affected converter terminal; conversely, in meshed MTDC networks, as illustrated in Fig. 1 (b), rated operation remains feasible, albeit with increased transmission losses [25]. In comparison to radial topology, ring topology exhibits a reduced chance of malfunction, while its overall reliability is worse [26].

IV. PRINCIPLES CONTROLS OF VSC IN MULTI-TERMINAL HVDC

IV.1 BASIC CONTROL OF VSC-MTDC

VSC are becoming the core of future MTDC networks. The VSC technology playing a key role to enhance energy efficiency for power transmission. A basic VSC-HVDC system comprises of two converter stations built with VSC topologies is presented in Figure 2.

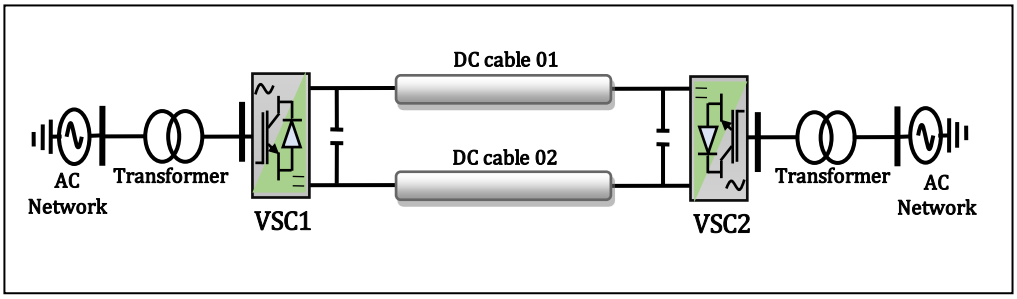

Figure 2: A basic point to point VSC-HVDC system.
Source: Authors, (2026).

Generally, the control system of each two level VSC converter connected to AC grid in VSC-HVDC point to point or multi-terminal has a cascade structure. The single line diagram of the VSC-HVDC converter utilising the vector control approach is depicted in Figure 3. This control strategies based on vector current control with Proportional integrator (PI) control algorithm in dq frame, it consists of the outer and inner loop. The outer controllers are part of the local controller of the VSC which defines the operation mode of the converter. The VSC station can operate in four distinct control modes based on the control philosophy: P/Q, P/Vac, Vdc/Q, and Vdc/Vac [27] (ENP ORAN). The inner current controller calculates the d and q-axis modulation indices from the reference (target) and actual (measured) values. The indices are then transferred to the abc reference frame for the PWM operation on all three phases [28]. The phase locked loop (PLL) is used to synchronize the VSC converter with the AC grid. It makes it possible to determine the instantaneous phase of a signal, as well as its frequency. The Phase-Locked Loop (PLL) is crucial for converting signals represented in phase values (abc) to direct quadrature-zero (dq0) coordinates, and vice versa [29].

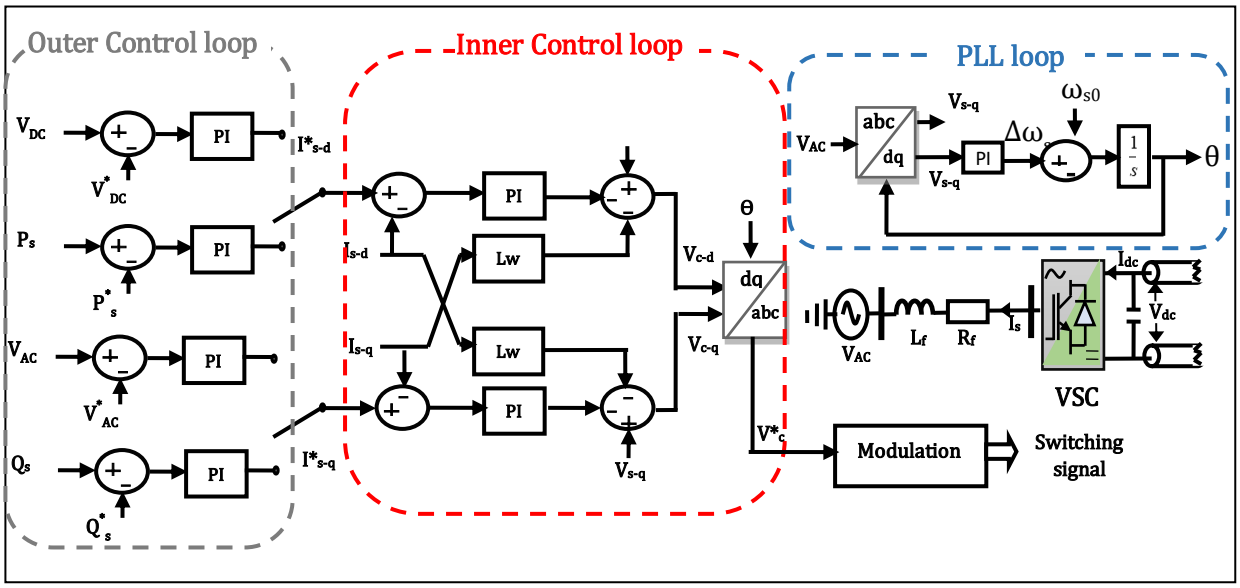

Figure 3: Control system model in VSC terminal.

IV.2 DC VOLTAGE MARGIN CONTROL STRATEGY IN MTDC NETWORK

In the paper [30], the philosophy of voltage margin method was the first proposed for VSC-HVDC system by Tatsuhito Nakajima and Shoichi Irokawa. In MTDC grid, the VMM method could be combined both the DC voltage and active power as shown in Figure 4. Indeed, depending on the state of the system (in terms of operating limits) each converter can control either the DC voltage or the active power flow. In this method, only one master converter equipped with DC voltage control at each Time.

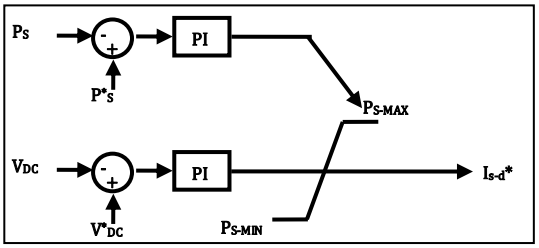

Figure 4: Voltage margin control scheme.
Source: Authors, (2026).

The VMM technique in three terminals MTDC works as follows (see Figure 5): In the first, let us assume that VSC1 converter it operates at DC voltage control with the reference value V*DC1 (VDC control mode) as known as slack bus converter, while VSC2, VSC3 and VSC4 are adopting a constant active power with the value (P control mode). When the active power of VSC1 reaches the limits (P1upper or P1lower), this converter will change from VDC control mode to a P control mode. Therefore, the second converter VSC2

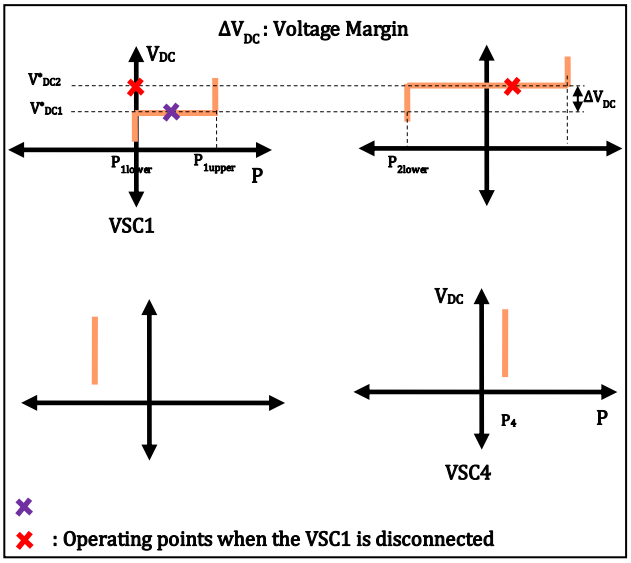

Figure 5: Characteristic of P, VDC of MTDC network using Voltage margin method.
Source: Authors, (2026).

Will change the control mode from a P control mode to a VDC control mode with the new set value V*DC2. The difference between the references of DC voltage for the two convertersVSC1 and VSC2 is called the voltage margin (ΔVDC) [31], [32].

IV.3 DC VOLTAGE POWER SHARING BASED ON DROOP CONTROL STRATEGY IN MTDC NETWORK

The principle voltage droop method for MTDC grid works similarly to the droop frequency control in conventional HVAC networks, where the balance between power generation and demand dependent frequency deviations, each production unit is equipped with a frequency controller which regulates their power generation according to power-frequency characteristic. In MTDC systems, the change in the DC voltage causes the VSC-MTDC converters to react with a change of their active-power. This method allows all VSC converters equipped with droop control to contribute in the power balancing following the lost any converter. The block diagram of droop control is illustrated in Figure 6, which is combined with VDC control and P control [33-36].

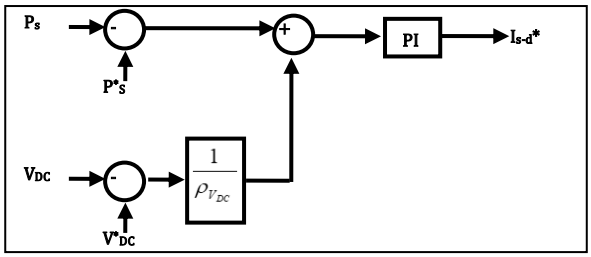

Figure 6: Voltage droop control scheme.
Source: Authors, (2026).

The relationship between the DC voltage and power of a converter terminal in an MTDC system is definite by:

$$\left(V_{DC}^{*} - V_{DC}\right) + \rho_{V_{DC}}\left(P_s - P_s^{*}\right) = 0 \tag{1}$$

$$\Delta P_s = P_s - P_s^{*} \tag{2}$$

$$\Delta V_{DC} = V_{DC}^{*} - V_{DC} \tag{3}$$

$$\Delta V_{DC} = \rho_{V_{DC}} \Delta P_s \tag{4}$$

The operating principles of voltage droop method in four terminals MTDC is illustrated in Figure 7, as Voltage/Power characteristic. The voltage droop method is applied in three terminals system. VSC1 VSC2, VSC4 converters are endowed with the voltage droop method while VSC3 is controlling its power flow. At the initial time, VSC1, VSC2 and VSC4 operate at active power P1 and P2 respectively. All VSCs have the same DC voltage level (VDC). In this case, it is assumed that the converter equipped with VDM technique is lost. When the outage of VSC1, the power (P2) of VSC2 stabilizes to a new set value (P2'). Hence, the DC voltage of VSC2stabilizes at VDC1 and the DC voltage of VSC1stabilizes at the same VDC1.

IV.4 DC VOLTAGE POWER SHARING BASED ON MODIFIED DROOP CONTROL STRATEGY IN MTDC NETWORK

The proposed power sharing control combine the both technique voltage margin and droop control strategies to enhance the stability of MTDC system. Any variation of active power in conventional droop control of MTDC system will cause deviation of DC voltage. In the event of a small power sharing, the balancing operation will be assumed by the stations that are conventionally controlled by the droop method. However, in the event of a large power sharing, the DC voltage reaches a critical limit and the stations that were initially in constant power control mode switch to droop control mode in order to support the DC voltage and contribute to the balancing effort. Figure 8 shows the DC power/voltage characteristics of our four-terminal VSC-MTDC system equipped with modified voltage droop control [37-40]. In the initial state (green cross), the station VSC4 equipped with the modified droop operates in constant power mode. Once the VSC1 station is out of service (red cross), the DC voltage level exceeds the minimum voltage limit, and consequently the VSC1 station increases its power, in order to stabilize the system and reduce the DC voltage deviation. The VSC4 station changes its control mode to voltage droop and helps the VSC2 to balance the power transit in the MTDC system. Figure 9 shows a voltage droop controller.

V. SIMULATION AND RESULTS ANALYSIS

Following the paper's aim, a four-terminal VSC-MTDC model is developed to verify the performance of the proposed droop control, as depicted in Figure 10. The three sending-end converter stations, VSC1 and VSC2, implement droop control, while VSC4 employs constant active power control within the conventional droop control, conversely, the proposed droop control applies a modified droop control. At the receiving-end converter station, VSC3 operates under constant active power control. The established VSC-MTDC model is implemented using PSCAD/EMTDC software. The different reference values (Active power, DC voltage) and droop coefficients for both the conventional and proposed droop control strategies are illustrated in Table 01 and Table 02.

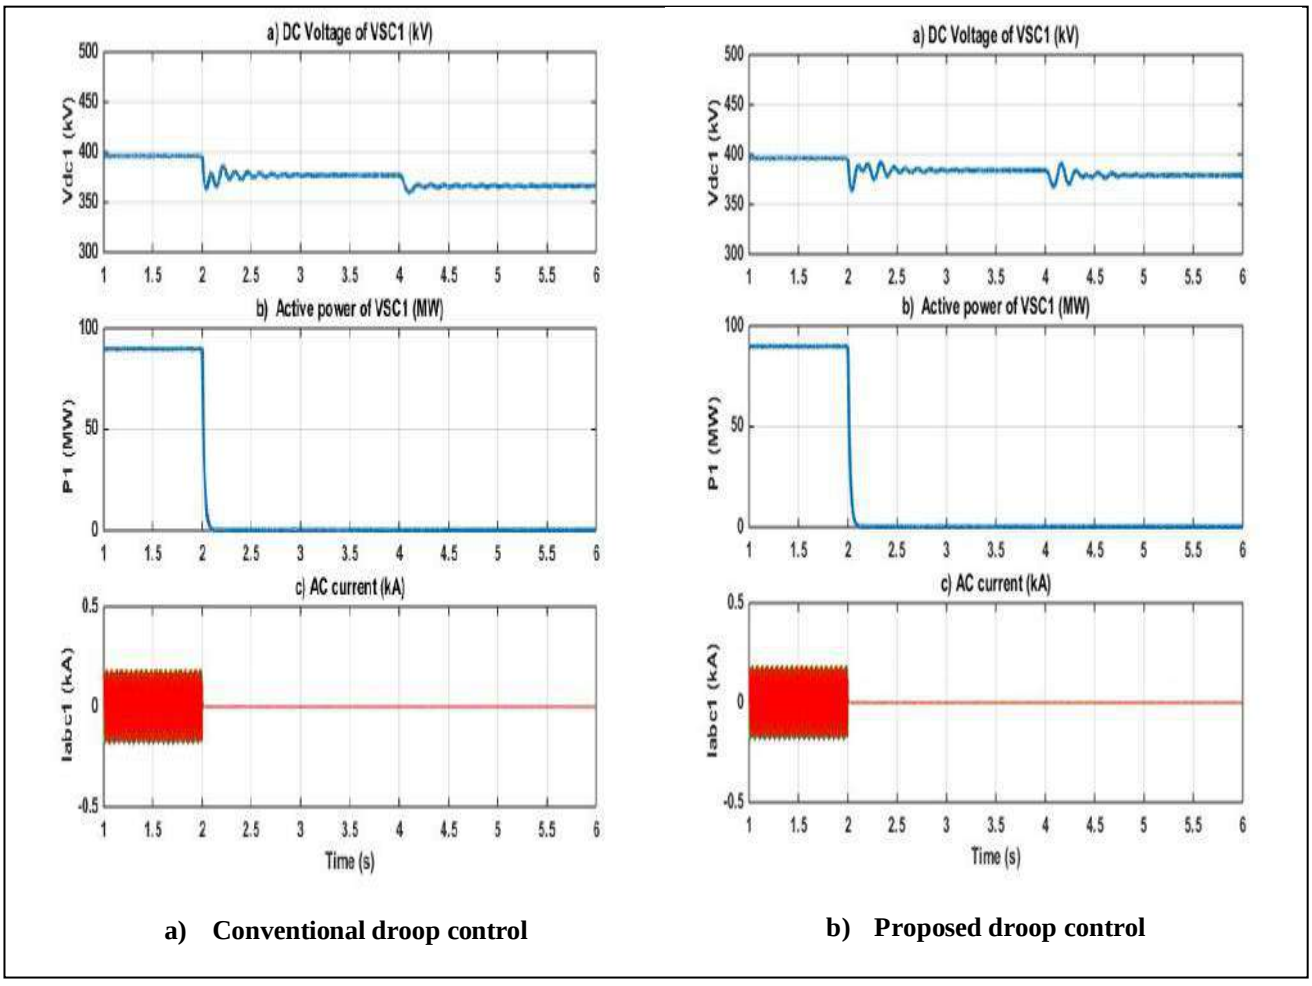
Table 02: The different reference values of Active Power, DC Voltage, and droop coefficients for the MTDC system before and after the first outage (conventional droop control).

	Converters	**VSC1**	**VSC2**	**VSC3**	**VSC4**
Steady state	Mode control	Droop control	Droop control	Active power control	Modified droop control
	V*DC	400 kV	400 kV	-	-
	P*AC	80 MW	80 MW	-240MW	80 MW
	droop coefficients	0.02 kV/MW	0.02 kV/MW	-	-
After Converter outage	Mode control	-	Droop control	Active power control	Modified droop control
	V*DC	-	400 kV	-	410 kV
	P*AC	-	80 MW	-240 MW	80 MW
	droop coefficients	-	0.02 kV/MW	-	0.02 kV/MW

Source: Authors, (2026).

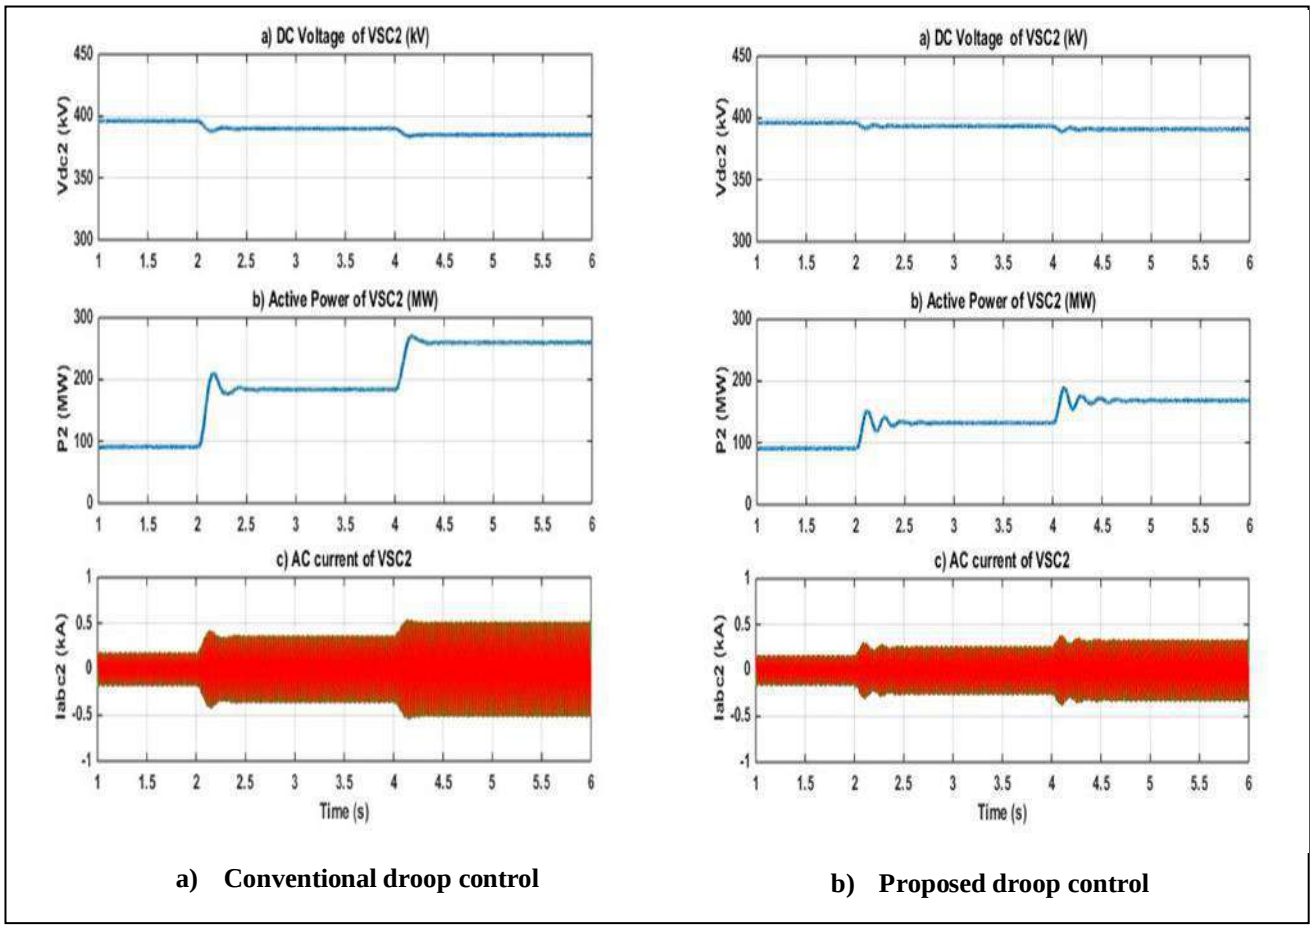
Two cases have been chosen as test cases for the four terminals VSC-MTDC system:



1) Case 1: Outage of converter equipped with droop control (VSC1) then variation of active power of VSC2.

2) Case 2: Outage of converter equipped with droop control (VSC1) then outage of converter equipped with droop control (VSC2).

V.1 CASE 1



This case evaluates the dynamic behavior of the VSC-MTDC system following the outage of VSC1, a power injection terminal operating under droop control. The objective is to assess how the remaining converter, VSC2, responds to the resulting power imbalance and how the system performs under both the conventional and proposed droop control strategies. Initially, VSC1 and VSC2 are configured to inject 80 MW each into the DC grid with identical droop coefficients (0.02 kV/MW). Simultaneously, VSC3 consumes −240 MW under constant power control, and VSC4 injects 80 MW using a modified droop control. At steady state, the system is fully balanced. Following the sudden disconnection of VSC1, the system experiences a power deficit of 80 MW. With VSC3 maintaining its fixed consumption and VSC4 holding its reference output, VSC2 becomes the primary converter tasked with rebalancing the system.

- Under conventional droop control, VSC2 reacts with a sudden and steep rise in active power output, leading to a significant overshoot and a noticeable DC voltage dip, as depicted in Figure 12(a). This rapid adjustment results in oscillations and a longer settling time. Furthermore, Figure 11(a) shows the sharp disturbance at the moment of VSC1's disconnection, with abrupt changes in current and power. The system lacks coordination, highlighting the rigidity of the fixed droop slope.
- In contrast, under the proposed droop control strategy, VSC2 demonstrates a more adaptive, smoother, and coordinated response. The increase in power output is gradual, with minimal overshoot, and the DC voltage deviation is significantly reduced, as shown in Figure 12(b). Moreover, Figure 11(b) confirms a controlled response in current and power after the disturbance. This behavior is attributed to the adaptive features of the proposed droop method, which allow real-time tuning of the droop coefficient or voltage reference depending on system conditions.
- Additionally, Figure 14(b) illustrates how VSC4 actively contributes to the power compensation through its modified droop control, further alleviating the burden on VSC2 and supporting DC voltage recovery. In contrast, Figure 14(a) shows that VSC4 remains passive under conventional setting.

V.2 CASE 2

This case investigates the dynamic performance of the VSC-MTDC system under a severe disturbance caused by the sequential outage of VSC1 and VSC2, both operating under conventional droop control. The objective is to evaluate the system's ability to maintain power balance and voltage stability through the remaining terminals, VSC3 and VSC4, under both conventional and proposed droop control strategies. Initially, VSC1 and VSC2 each inject 80 MW using droop control, while VSC3 consumes −240 MW in constant active power control mode, and VSC4 operates with a modified droop control, injecting 80 MW. This setup ensures total power balance under normal conditions. Following the outage of VSC1, VSC2 initially increases its power output to compensate for the deficit. However, once VSC2 is also disconnected, a total of 160 MW of injected power is lost, while VSC3 continues to draw constant power and VSC4 maintains its reference. The system is left with only one remaining injection terminal (VSC4). Under the conventional droop control configuration, VSC4 is unable to adapt its output dynamically because it operates at a fixed setpoint. As a result, the system experiences a critical power imbalance. This leads to a sharp increase in DC voltage, caused by the excess unabsorbed power from VSC3. The system becomes unstable, with persistent voltage deviation and no convergence toward a new steady-state. This outcome reveals the inadequacy of conventional control in multi-terminal HVDC systems facing severe multi-converter outages. In contrast, with the proposed droop control strategy, VSC4 is capable of responding adaptively to the DC voltage deviation. Upon the loss of VSC1 and VSC2, VSC4 detects the voltage rise and gradually increases its power output, stabilizing the system. This dynamic response ensures that the power imbalance is progressively compensated, and the system achieves a new steady-state with minimal disturbance. Importantly, the proposed strategy significantly limits the rise in DC voltage, keeping it within operational thresholds and thereby preventing protection activation or converter shutdown. This improvement in voltage regulation is a direct result of the proposed droop mechanism's real-time adaptability, including the dynamic adjustment of droop slope or voltage reference. By enabling VSC4 to contribute flexibly to power balancing, the strategy also supports grid resilience and fault tolerance, even in the absence of two major power sources.

VI. CONCLUSIONS

In this work, an adaptive droop control strategy with a modification has been proposed to enhance dynamic performance, DC voltage stability, and fault tolerance of VSC-MTDC systems under conditions of converter outage. By adapting voltage margin theory together with instantaneous droop parameter readjustment, the method surpasses the limitations of conventional fixed-slope droop control, achieving more uniform power sharing, faster post-disturbance recovery, and improved system robustness under severe transients. Simulation from a ±400 kV four-terminal VSC-MTDC network in PSCAD/EMTDC confirms that the proposed control reduces peak DC voltage deviations by 45–60%, active power overshoot by 40–55%, and settling times by 35–50% compared to conventional droop control. In addition, up to +65 MW of extra contribution from passive converters provides backup support against overload on other remaining terminals, while operating within limits under N–1 and N–2 contingencies. It will be preceded by hardware-in-the-loop (HIL) testing to assess the strategy in realistic operating conditions, machine learning-based optimization for autonomous control of droop parameters as a function of dynamic network states, and extension of the framework to hybrid AC/DC smartgrids with high-penetration renewable energy sources and advanced energy storage devices. These developments aim to place the developed control method as a pillar for the future generation of resilient, intelligent HVDC transmission infrastructures.

ABSTRACT

The aim of the study is to convert an existing production setup to dual-sport motorcycle into a competition-grade off-road prototype through systematic re-engineering of the chassis, suspension, and ergonomic layout. The primary objective is to enhance vehicle dynamics, handling precision, and rider control, while maintaining overall reliability and cost-effectiveness. The methodology combines analytical design, finite element simulations, fabrication, and field validation, focusing on critical parameters such as rake, trail, wheelbase, suspension travel, and weight distribution. Testing activities included geometry measurement, centre of gravity (CoG) analysis, suspension tuning, braking evaluation, and rider-based feedback assessments to verify the improvements achieved. The outcomes indicate notable gains in off-road performance including better traction, increased suspension compliance, greater ground clearance, and reduced overall mass. The study presents a structured and economic framework suitable for student-level prototype development and competition motorcycles, demonstrating the potential for performance enhancement from a production baseline.

1. INTRODUCTION

A competition-grade off-road motorcycle requires a precise combination of strength, stability, and rider adaptability to perform effectively across unpredictable terrains [1], [2]. In contrast, standard dual-sport motorcycles are built for versatile road and trail usage, often compromising in suspension travel, ground clearance, and ergonomic design [3]. This project focuses on overcoming these constraints by transforming a production dual-sport motorcycle into a high-performance off-road prototype through detailed re-engineering and design optimization [4]. The study aims to enhance vehicle dynamics, suspension performance, and rider ergonomics to achieve superior handling precision and comfort under off-road conditions [5]. Core geometric parameters such as rake, trail, wheelbase, and mass distribution were analysed and refined to improve agility and control [6]. Additionally, ergonomic modifications including handlebar risers, a raised seat, and repositioned foot pegs were introduced to minimize rider fatigue and increase control confidence during extended off-road use [7]. By integrating CAD modeling, finite element analysis (FEA), precision fabrication, and field validation, the project effectively connects theoretical design with practical implementation [8]. The outcomes display measurable gains in handling performance, comfort, and safety, forming a structured framework for student-level motorsport prototype development and future studies in motorcycle engineering and off-road design [9]. A detailed review of existing studies on motorcycle dynamics and off-road design principles highlights the significant role of chassis geometry, suspension tuning, and rider ergonomics in determining overall performance [1].

Prior research indicates that parameters such as rake and trail directly affect steering stability and cornering agility, whereas wheelbase and ground clearance influence traction, obstacle clearance, and vehicle balance on uneven terrain [6]. These insights confirm the importance of geometric refinement in converting a dual-sport motorcycle into a competition-oriented off-road platform [4]. Studies on suspension system design emphasize that suspension travel, damping rates, and unsprung mass are key factors affecting traction and ride quality [10]. Works by Cossalter and Foale (Motorcycle Dynamics, Motorcycle Handling and Chassis Design) demonstrate that minimizing unsprung mass and optimizing damping response improve suspension compliance and rider confidence [11]. The application of long-travel forks and progressive rear shocks is also well-established in rally and motocross motorcycles, providing better terrain adaptability and impact resistance [12]. Ergonomic optimization literature further supports the role of rider-triangle geometry defined by the handlebar, seat, and foot peg alignment in achieving better control and posture [7]. Research on off-road ergonomics shows that higher handlebars, flatter seats, and raised foot peg positions improve leverage, body mobility, and overall fatigue resistance [13]. These findings guided the methodology of this study, forming the foundation for chassis redesign, suspension refinement, and ergonomic reconfiguration to achieve tangible improvements in comfort, stability, and rider performance.

II. WORK METHODOLOGY

The study followed a structured Design, Build & Validate approach to systematically transform a stock dual-sport motorcycle into a competition-grade off-road model [4]. The process began with a comprehensive baseline analysis, where all existing parameters such as chassis dimensions, suspension geometry, kerb weight, braking efficiency, and ergonomic layout were recorded [14]. This benchmarking phase helped identify the limitations of the stock setup, particularly in areas such as suspension travel, ground clearance, and rider posture [3]. Baseline testing also included geometric measurements and ride assessments to establish reference data for further improvement [2]. Once the baseline characteristics were established, the next step was targeting definition and design objectives formulation [6]. Quantitative goals were set for each performance aspect extended suspension travel, optimized trail (around 110–126 mm), increased ground clearance (up to 245 mm), and reduced overall weight [15]. CAD tools such as CATIA were used to model various configurations and assess feasibility before fabrication [8]. Analytical calculations were performed to predict the effect of geometry changes on handling, stability, and centre of gravity distribution, ensuring that each modification supported the desired off-road performance [6]. The component design and selection stage involved the integration of specialized performance parts and the redesign of key structural and ergonomic elements [12].

Upgrades included a long-travel USD front fork, fully adjustable rear mono-shock, lightweight aluminium handlebars, and CNC-machined handlebar risers [10]. The chassis and ergonomic interfaces were Transformed through precision fabrication and alignment processes to ensure structural accuracy and proper load distribution [16]. The goal was to achieve an optimal balance between rigidity and flexibility providing stability under load while maintaining terrain compliance [17]. Following fabrication, simulation and validation were carried out using Finite Element Analysis (FEA) in ANSYS to assess stress distribution, deformation characteristics, and factor of safety [14]. Separate analyses were conducted for the front and rear suspension systems under simulated load conditions to validate the designs before field testing [10]. The FEA results demonstrated over 50% stress reduction and a significant improvement in structural safety margins, confirming the effectiveness of the Transformed setup [16]. Finally, real-world testing and documentation formed the validation phase of the project. The Transformed motorcycle was subjected to controlled off-road trials, including acceleration, braking, and slalom tests, along with rider feedback evaluation. Parameters such as suspension sag, Centre of Gravity (CoG) position, braking distance, and handling precision were measured and compared against the baseline data. Observations and feedback were systematically recorded to quantify the improvement in performance and ride quality [13]. All test data, CAD drawings, and performance charts were compiled into documentation for academic presentation and reproducibility

III. EXPERIMENTAL OBSERVATIONS

A series of experimental evaluations and measurements were carried out to validate the design and performance improvements achieved in the Transformed off-road motorcycle [5]. The tests were structured around critical parameters such as geometry validation, mass distribution, suspension behaviour, dynamic performance, and rider ergonomics [7]. Baseline and Transformed configurations were compared to quantify improvements in stability, control, and comfort [11]. Measurements of rake, trail, wheelbase, and ground clearance were taken using precision tools to verify alignment and dimensional accuracy [15]. The centre of gravity (CoG) was determined under both kerb and rider-loaded conditions to study the effects of mass redistribution on handling balance. Dynamic testing included suspension evaluation, braking trials, and rider feedback sessions. Suspension performance was analysed through sag tests, travel utilization measurements, and damping curve observations for both compression and rebound cycles. Field trials were conducted on controlled off-road terrain, measuring parameters such as vehicle dynamics characters by subjective evaluation with the Parameters to define the riding character behaviours of the motorcycle and lap times through slalom courses. Subjective assessments from test riders provided valuable insights into improvements in traction, stability, and ergonomic comfort. Overall, the experimental data confirmed that the Transformed motorcycle exhibited significantly enhanced off-road capability, superior suspension compliance, and improved rider control compared to the stock configuration [18].

III.1 GEOMETRY & MASS

The geometric configuration of a motorcycle plays a crucial role in defining its handling stability, manoeuvrability, and rider balance especially in off-road conditions where terrain irregularities are constant. The baseline analysis revealed that the stock dual-sport motorcycle offered moderate agility and stability suited for mixed-use riding but lacked the geometry required for competitive off-road performance. Hence, modifications were targeted at improving ground clearance, wheelbase, and mass distribution without altering the fundamental steering characteristics such as rake angle. These parameters were carefully optimized to enhance both low-speed control and high-speed stability, providing a solid foundation for off-road handling improvement.

The Transformed geometry and mass parameters are summarized in Table 1. The wheelbase was extended from 1350 mm to 1435 mm, improving straight-line stability and weight distribution between the front and rear wheels. The rake angle was maintained at 27°, preserving the original steering characteristics, while the trail increased from 114 mm to 126 mm enhancing directional stability during cornering and over rough terrain. Ground clearance was raised from 220 mm to 245 mm, significantly improving obstacle traversal and underbody protection. Similarly, seat height increased from 825 mm to 891 mm, providing the rider with a higher, more commanding position suitable for aggressive off-road manoeuvres.

Table 1: Geometry Specification Comparison.

S No.	Parameter	Stock Value	Transformed Value
1	Wheelbase (mm)	1350	1435
2	Rake Angle (°)	27°	27°
3	Trail (mm)	114	126
4	Ground Clearance (mm)	220	245
5	Seat Height (mm)	825	891
6	Kerb Weight (kg)	159	120

III.2. CENTRE OF GRAVITY (COG)

The centre of gravity (CoG) is one of the most critical parameters influencing a motorcycle's handling, stability, and overall dynamic balance. It defines how the vehicle's weight is distributed between the front and rear wheels and determines its responsiveness during acceleration, braking, and cornering. In off-road motorcycles, maintaining an optimal CoG is essential to ensure stability on uneven surfaces and during jumps, while still allowing agile manoeuvrability. Therefore, a detailed CoG analysis was conducted for both the stock dual-sport motorcycle and the Transformed off-road prototype under kerb and rider-loaded conditions to understand the effects of geometry and mass redistribution. The evaluation indicated (Table 2) a more balanced and performance-oriented weight distribution in the Transformed setup. In the vehicle-only (kerb) condition, the front and rear axle weights (FAW and RAW) were recorded at 56.4 kg and 63.6 kg respectively, achieving a stable 47:53 front-to-rear ratio. The CoG in the longitudinal (X) axis shifted slightly rearward from 752.8 mm in the stock configuration to 731.4 mm enhancing traction at the rear wheel for improved acceleration and obstacle handling. The CoG height (Z-axis) increased moderately from 569.8 mm to 577.3 mm due to the raised ground clearance (from 220 mm to 245 mm), providing better suspension articulation without significantly affecting high-speed stability.

Table 2: Comparison of Centre of Gravity (CoG) in 1G condition.

Transformed Motorcycle	1380	56.4	63.6	120.0	47.0	53.0	731.4	731.4	577.3

Source: Authors, (2026).

Under rider-loaded conditions, the CoG position moved further rearward, indicating improved weight transfer dynamics during off-road operation. The CoG height with rider increased from 829.0 mm in the stock motorcycle to 836.5 mm in the transformed configuration (Table 3), aligning with the raised seating and suspension travel. This controlled elevation in CoG allows the motorcycle to maintain a steady balance between agility and stability during aggressive off-road riding. The optimized CoG placement both longitudinally and vertically ensures improved traction, enhanced steering feedback, and superior control in dynamic terrains. As illustrated in these measurements validate that the Transformed motorcycle achieves a more efficient and competition-ready mass distribution suitable for demanding off-road conditions.

IV. RESULT AND DISCUSSION

IV.1 SUSPENSION CHARACTERS ANALYSIS

The transformation of the motorcycle's ride dynamics was achieved through a complete redesign of the front and rear suspension systems. The stock telescopic front fork was replaced with a long-travel USD (Upside Down) fork, offering superior rigidity, feedback, and control under demanding off-road conditions. Similarly, the conventional mono-shock was upgraded to a fully adjustable rear suspension that delivers progressive damping and improved wheel articulation. These modifications enhanced suspension travel from 180 mm to 220 mm at the front and 170 mm to 210 mm at the rear, while also incorporating preload and damping adjustability on both ends. As a result, the Transformed motorcycle exhibits significantly better bumping absorption, traction, and rider comfort across varied terrains, effectively transforming it from a dual-purpose setup into a competition-grade off-road machine. Table 4 represents the suspension specifications of the stock base motorcycle and the Transformed motorcycle,

Table 4: Suspension Specification comparison.

S No.	Suspension Parameter	Stock	Transformed
1	Front Suspension Type	Telescopic	USD Fork

The closer inspection of the compression damping curve reveals how the Transformed fully adjustable USD fork delivers a more consistent and progressive resistance profile. In the base model, damping force increases steeply with shaft velocity, resulting in a harsh response over larger bumps. This behaviour caused uneven weight transfer during corner entry and excessive load on the rider's arms.In contrast, the Transformed fork's compression curve shows a smoother progression with optimized low-speed firmness and controlled high-speed compliance. This combination offers precise front-end support under braking while maintaining comfort on rough surfaces. The curve highlights the fork's improved energy absorption and damping control efficiency. Figure1 represents the Front Suspension Compression Damping Curve. The base front fork demonstrated quick rebound peaks, making the front-end unsettled on uneven ground. This led to frequent "after-bounce" behaviour, where the fork extended too rapidly, reducing steering control. The lack of damping progressiveness resulted in unpredictable handling over continuous bumps. The Transformed fork's rebound damping curve indicates a controlled return stroke with reduced rebound speed and stable extension force. This ensures the front wheel remains planted, enhancing traction, line-holding ability, and comfort. The highlighted graph demonstrates how rebound damping optimization translates into smoother suspension recovery and improved directional stability. Figure2 represents the Front Rebound Damping Curve.

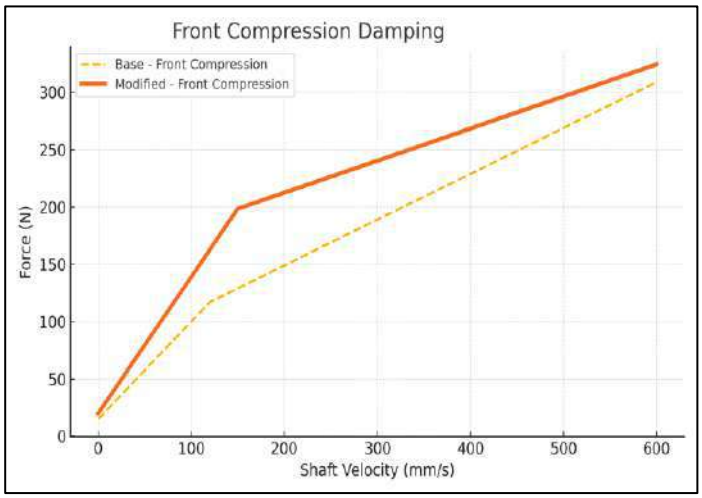

Figure 1: Front Suspension: Compression Damping Curve.
Source: Authors, (2026).

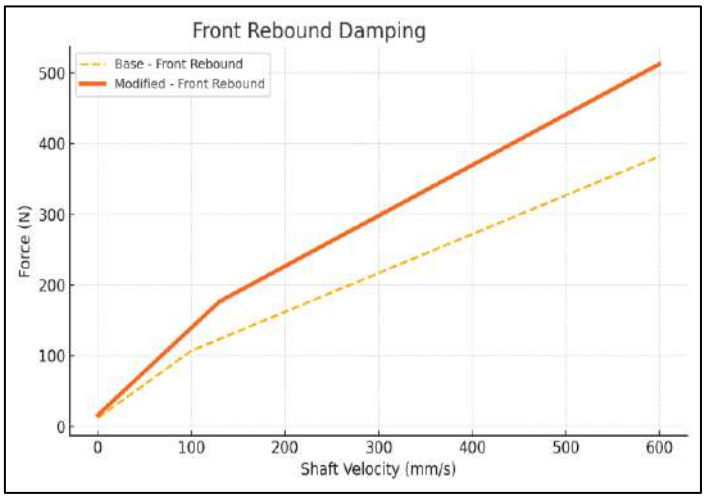

Figure 2: Front Suspension: Rebound Damping Curve.
Source: Authors, (2026).

The base rear suspension's compression characteristics revealed higher peak forces and limited flexibility at higher shaft speeds. This resulted in discomfort and instability when absorbing obstacles or under heavy acceleration. The stiffer compression made the rear end less compliant on rocky or uneven surfaces.The Transformed damping curve achieves a flatter and more balanced response, increasing low-speed compression control while reducing harshness at high speeds. The shock absorbs impacts more progressively, enhancing traction and maintaining rear chassis composure. This improvement directly benefits acceleration control and ride comfort over extended off-road use. Figure3 represents the Rear Suspension Compression Damping Curve.

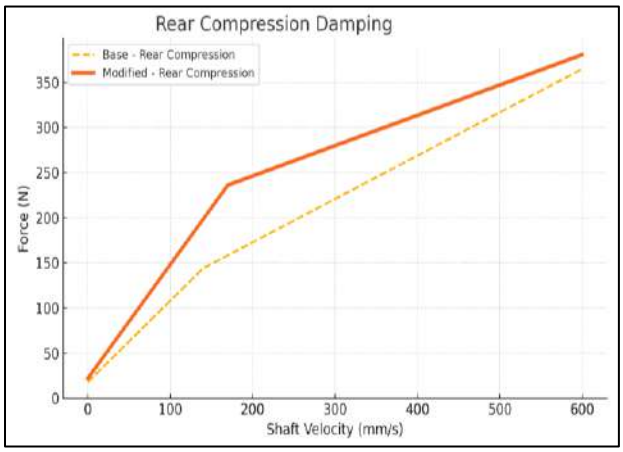

Figure 3: Rear Suspension: Compression Damping Curve.
Source: Authors, (2026).

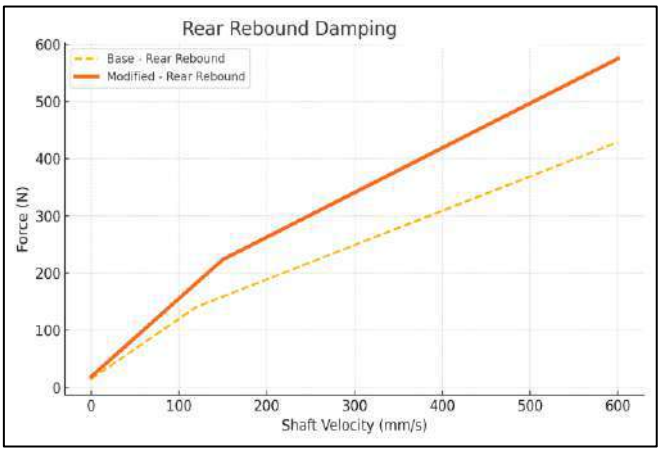

Figure 4: Rear Suspension: Rebound Damping Curve.
Source: Authors, (2026).

In the stock setup, the rear suspension's quick rebound often caused instability over continuous bumps, known as "rear kick" or wheel hop. This compromised the motorcycle's ability to maintain smooth traction and rider control, particularly during successive landings. The Transformed rebound damping curve demonstrates slower and more consistent extension, effectively controlling chassis movement and improving tyre contact. The overall result is a calmer and more predictable rear-end response during high-speed off-road runs. This refined damping ensures improved grip, reduced oscillations, and higher rider confidence. Figure 4 represents the Rear Rebound Damping Curve.

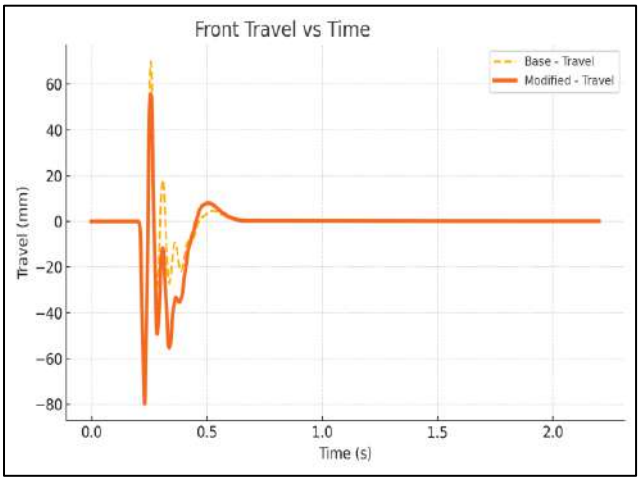

Figure 5: Simulation Graph of Front Travel vs Time.

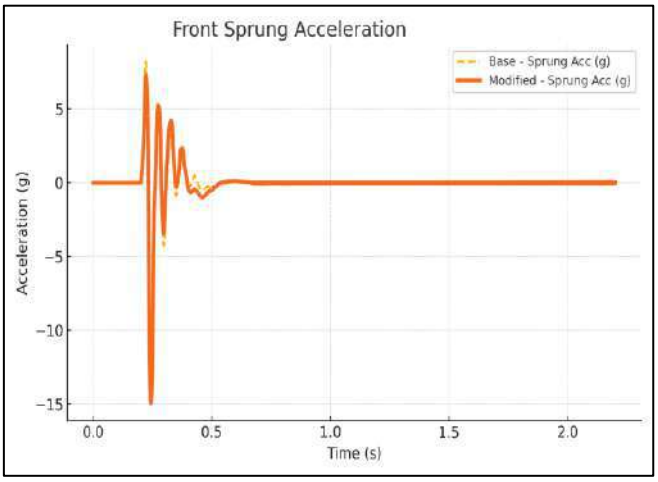

Figure 6: Front Sprung Acceleration.
Source: Authors, (2026).

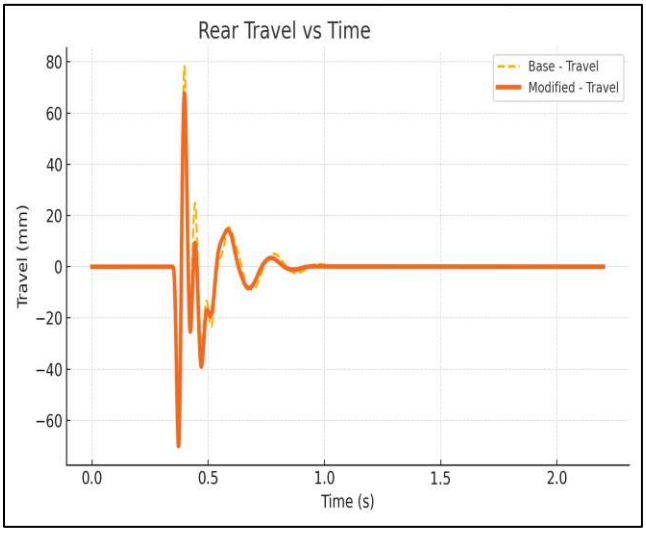

Figure 7: Simulation Graph of Rear Travel vs Time.
Source: Authors, (2026).

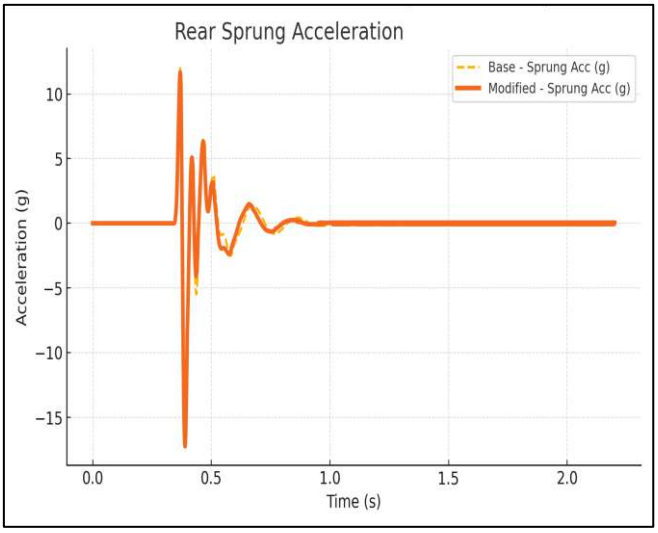

Figure 8: Simulation Graph of Rear Sprung Acceleration (g).
Source: Authors, (2026).

The stock front suspension exhibited longer settling time and higher peak compression, indicating energy loss through uncontrolled oscillations. This behaviour caused discomfort and reduced control when navigating repetitive bumps or rough terrain. After modification, the USD fork's travel trace shows reduced peak displacement and quicker damping response, resulting in faster stabilization. The shorter oscillation duration confirms improved suspension efficiency and control. This enhances both rider comfort and precision during technical off-road sections. Figure 5 represents the Front Suspension Travel vs Time Curve. Sprung acceleration indicates the vertical acceleration transmitted through the suspension to the chassis. The base setup recorded higher g-spikes, reflecting harsh impacts reaching the rider. This contributed to fatigue and decreased comfort during prolonged riding. The Transformed suspension reduced these g-forces significantly, absorbing shocks more effectively and minimizing vibrations. The smoother acceleration trace demonstrates improved damping control and better energy dissipation through the suspension. This translates to a more composed and comfortable front-end response. Figure 6 represents the Front Sprung Acceleration (g) Curve.

The rear suspension travel-time analysis revealed that the stock setup had slower return rates and prolonged oscillations after impacts. The longer rebound period caused the rear wheel to lose traction momentarily, affecting acceleration and corner exit stability. The Transformed fully adjustable suspension exhibits faster recovery and reduced overshoot, confirming enhanced damping efficiency. The system quickly returns to equilibrium after bumps, improving traction and control during rapid terrain transitions. This performance upgrade ensures consistent handling over extended rough trails. Figure 7 represents the Rear Suspension Travel vs Time Curve. The rear sprung acceleration curve of the stock motorcycle displayed frequent high-magnitude spikes, suggesting that impact loads were transferred directly to the chassis. This reduced comfort and increased mechanical stress on suspension components. The Transformed rear shock shows smoother acceleration curves with lower amplitude peaks and faster damping decay. These improvements reflect superior shock absorption and reduce transmitted vibration, providing a smoother and more controlled off-road ride. The Transformed damping significantly improves rider comfort and terrain adaptability. Figure 8 represents the Rear Sprung Acceleration (g) Curve.

IV.2 ERGONOMICS

Ergonomics plays a crucial role in defining the rider's comfort, control, and fatigue level, particularly in off-road motorcycles where body movement and posture constantly change. The base motorcycle featured a standard dual-sport ergonomic layout optimized for commuting and mild off-road usage, offering a neutral riding stance. While suitable for general riding conditions, this configuration limited the rider's mobility and leverage during aggressive off-road manoeuvres, affecting balance and control when standing or shifting body weight on uneven terrain. The Transformed motorcycle was designed with an advanced ergonomic geometry to enhance rider control and stability in competition-grade off-road conditions. Key improvements include the integration of raised handlebars, a higher seat, and repositioned footpegs, all aimed at achieving a more commanding and balanced riding posture. The increased seat height (from 825 mm to 891 mm) and handlebar rise (from 95 mm to 135 mm) enable the rider to stand comfortably while maintaining a natural arm bend, reducing strain on the shoulders and back during prolonged off-road riding. A wider handlebar (840 mm versus 780 mm stock) was introduced to improve steering leverage and directional control on rough terrains, making the motorcycle more responsive and easier to manoeuvre.

The handlebar pull-back angle was reduced from 55 mm to 40 mm, allowing for a more forward-biased and aggressive stance that enhances front-end feedback and stability during technical sections. Simultaneously, the footpeg position was raised from 330 mm to 380 mm, increasing ground clearance and improving the rider's lower-body engagement with the motorcycle. These changes collectively refined the rider triangle the geometric relationship between the seat, handlebar, and footpegs resulting in improved ergonomics and overall vehicle dynamics. The Transformed posture promotes better weight transfer, improved control while standing, and reduced fatigue during long rides. The increased seat-to-handlebar and seat-to-footpeg distances provided a more open leg angle and comfortable upper-body posture, allowing seamless transitions between seated and standing positions, which are critical during off-road cornering, climbs, and jumps. Subjective feedback from test riders confirmed a significant improvement in comfort, confidence, and handling control with the revised setup. The Transformed motorcycle offered a more natural and commanding feel, reducing rider fatigue and improving endurance in demanding terrains. The ergonomic refinements transformed the motorcycle from a neutral touring stance to a performance-oriented off-road posture, aligning the rider's body mechanics with the vehicle's dynamic behaviour. Table 5 represents the comparative ergonomic parameters and rider triangle improvements of the Transformed motorcycle.

Table 5: Ergonomic Measurement comparison.

Rider on the Vehicle Ergonomic Comparison				
S No.	**Parameter**	**Existing Base Motorcycle**	**Transformed Off-Road Motorcycle**	**Remarks / Rider Subjective Feel**
1	Seat Height	825 mm	891 mm	Higher seats improve ground clearance and off-road control. Slightly taller for better commanding position.
2	Handlebar Width	780 mm	840 mm	Wider bar provides improved leverage and control on rough terrains.
3	Handlebar Rise	95 mm	135 mm	Slight rise improves standing comfort and reduces rider fatigue in off-road riding.
4	Handlebar Pull-back	55 mm	40 mm	Straighter bar improves aggressive off-road stance and better front-end feel.
5	Footpeg Height from Ground	330 mm	380 mm	Increased height improves ground clearance, enhances off-road capability.
6	Footpeg to Seat Vertical Distance	495 mm	520 mm	Slight increase for improved legroom in seated position.
7	Seat to Handlebar Distance	630 mm	650 mm	Longer reach for better body positioning in aggressive off-road posture.
8	Seat to Footpeg Horizontal Distance	420 mm	440 mm	Improved ergonomic spread, reducing knee bend angle.
9	Rider Triangle Angle (Torso-Thigh)	~92°	~96°	More upright and comfortable posture, optimized for off-road control.

Source: Authors, (2026).

The handlebar raiser is CNC-machined from solid aluminium, offering an excellent balance of strength, durability, and low weight. Its superior strength-to-weight ratio ensures structural integrity under dynamic loads while reducing mass compared to cast-iron or machined-iron alternatives. Designed to raise the handlebar by 40 mm from the original top-bridge mounting plane, it provides significant ergonomic benefits. High dimensional accuracy ensures secure clamping, vibration resistance, and precise alignment. The below image represents the Transformed handlebar mounting with the 40 mm raiser.
The handlebar raiser is CNC-machined from solid aluminium, offering an excellent balance of strength, durability, and low weight. Its superior strength-to-weight ratio ensures structural integrity under dynamic loads while reducing mass compared to cast-iron or machined-iron alternatives. Designed to raise the handlebar by 40 mm from the original top-bridge mounting plane, it provides significant ergonomic benefits. High dimensional accuracy ensures secure clamping, vibration resistance, and precise alignment. Figure10 represents the Transformed handlebar mounting with the 40 mm raiser. This precision-engineered component enhances rider ergonomics, improves control, and ensures reliability and easy installation, making it ideal for performance-focused motorcycles. Figure 9 represents the engineering dimensions line drawing of the handlebar raiser.

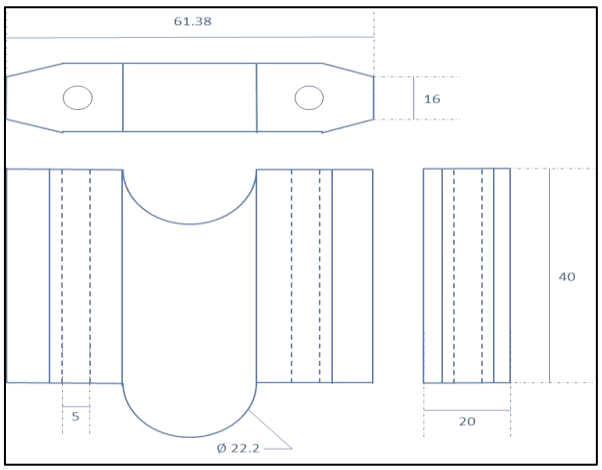

Figure 9: Dimensional Representation of the Handlebar Raiser.
Source: Authors, (2026).

Figure 10: Handlebar Raisers.
Source: Authors, (2026).

The integration of a handlebar raiser serves as one of the most effective ergonomic upgrades for improving rider comfort and control during off-road riding. In the stock configuration, the handlebar was mounted directly on the top bridge, offering a neutral position suitable for on-road or touring use but limiting rider flexibility while standing on footpegs. This caused excessive forward lean and strain on the wrists and shoulders during extended off-road operation. To address these limitations, a 40 mm CNC-machined aluminium handlebar raiser was introduced between the top bridge and handlebar clamp. This modification elevates the handlebar height, allowing the rider to maintain a more upright and natural standing posture. The raised position enhances comfort during prolonged off-road riding, improves leverage on the front end, and provides greater steering control over rough and unpredictable terrain. The design also contributes to reduced fatigue by minimizing the upper-body effort required during rapid body transitions. Figure 11 represents the existing base motorcycle handlebar in OEM mounting.

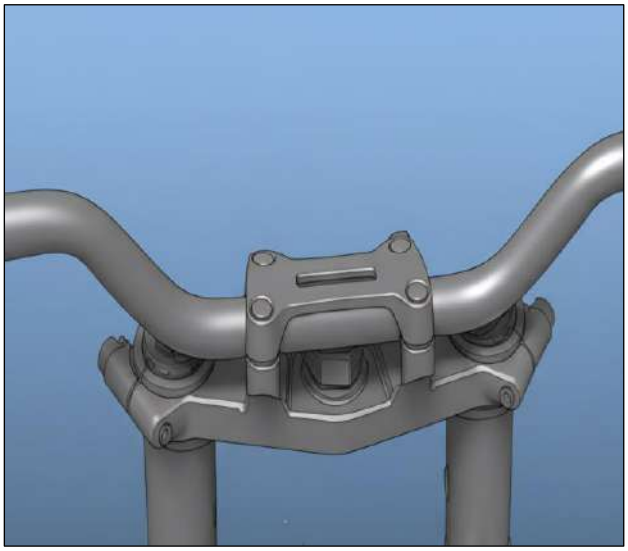

Figure 11: Base Motorcycle Existing Handlebar.
Source: Authors, (2026).

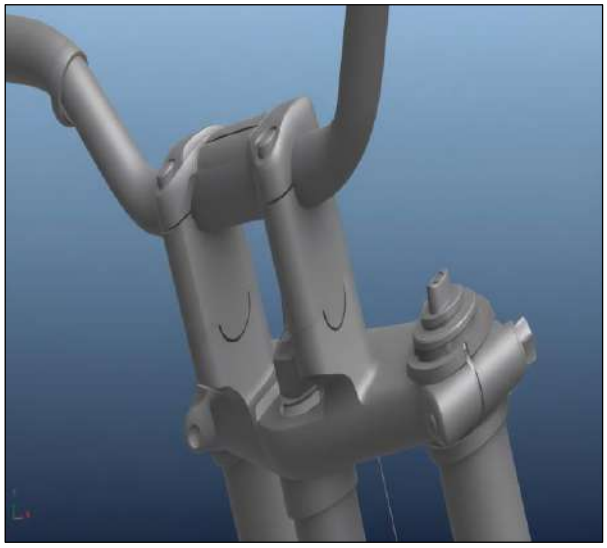

Figure 12: Transformed with Handlebar Risers for Enhanced Ergonomic Position.
Source: Authors, (2026).

Beyond comfort, the handlebar raiser substantially improves rider-to-vehicle interface and control precision. The increased height and leverage provide superior feedback, enabling smoother steering inputs and improved balance while tackling obstacles. The use of lightweight, high-strength aluminium ensures structural rigidity and vibration resistance without adding unnecessary weight. This modification transforms the motorcycle's ergonomics from a conventional street-oriented stance into a dynamic, performance-focused setup ideal for competitive off-road conditions. Figure 12 represents the Transformed handlebar mounting with the 40 mm raiser integrated between the top bridge and clamp assembly.

IV.3 ERGO TRIANGLE COMPARISON STUDY

This section explains both the Existing OE Motorcycle and the Modified Competition Motorcycle ergonomics, along with geometry insights and technical evaluation. The Ergo Triangle defines the spatial relationship between the handlebar, seat, and footpegs collectively shaping the rider's posture, comfort, and control dynamics. In the existing OE motorcycle, this geometry was designed to balance comfort and versatility, suitable for both commuting and light off-road use. The seat height of 790 mm and moderate handlebar reach provided a relaxed riding stance that minimized fatigue on long rides but restricted the rider's ability to make dynamic body movements during off-road conditions. The footpeg placement offered a semi-upright leg posture, making it ideal for touring but less effective for aggressive control or weight-shifting manoeuvres. The existing ergonomic triangle measured a handlebar-to-seat distance (X1) of approximately 373 mm with a vertical separation (Z1) of 251 mm, offering a neutral upper-body posture. The footpeg-to-seat horizontal distance (X2) was 157 mm, with a vertical rise (Z2) of 489 mm, resulting in a semi-bent leg angle. While this provided reasonable comfort and leverage, it was not optimized for rapid transitions between sitting and standing postures, which are crucial in competitive off-road scenarios. Overall, the base configuration supported stability and touring comfort but limited quick posture adjustments and active body engagement over technical terrain. Figure 13 represent the rider posture geometry and ergonomic alignment between the existing base motorcycle.

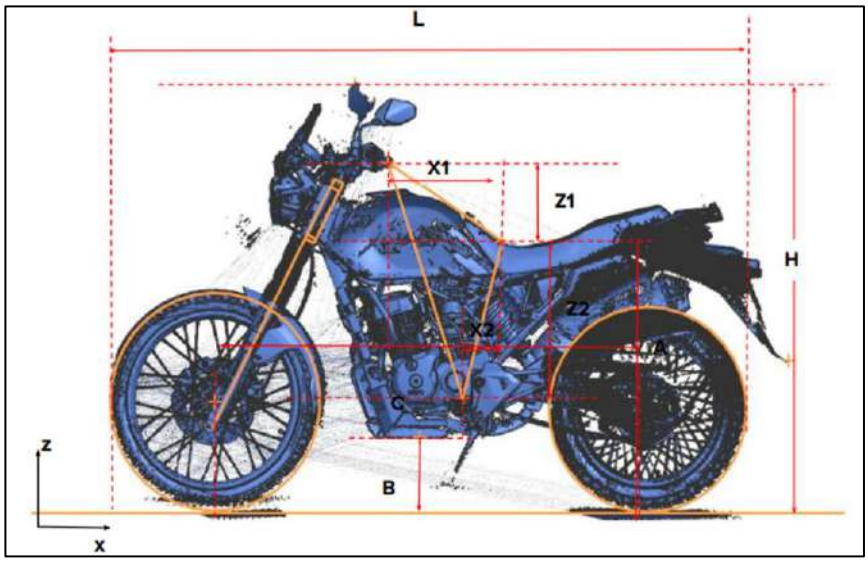

Figure 13: Ergo Triangle of the Existing Base Motorcycle.
Source: Authors, (2026).

The mentioned table 6 represents the measurement values of the Existing Base Motorcycle with the marked CoG points and the actual measured vehicle dimension with maintaining the SAG values in 1G condition.

Table 6: CoG Points on the Existing Motorcycle.

CG Points	CG	1R	Front 1G SAG	Front 1R SAG	Rear 1G SAG	Rear 1R SAG
X	772.8	833.4	50	65	20	40
Z	589.8	849

Table 7: Vehicle Ergonomics Dimensions Measurement.

Vehicle	Length	Width	Height	Seat Height	Ground Clearance	Wheelbase	Handlebar to Seat				Front Tyre	Rear Tyre	Rake Angle
	L	W	H	A	B	C	X1	Z1	X2	Z2			
Modified Motorcycle	2225	886	1350	791	245	1435	395	280	185	520	80/100-21	110/100-18	27°
											OD - 693.4	OD - 677.2	

Source: Authors, (2026).

In the modified competition motorcycle, the ergonomic triangle was redefined to achieve an aggressive and performance-oriented rider stance. The seat height was increased to 791 mm, raising the rider's hip point for better control during standing and cornering.

The handlebar-to-seat distance was increased to 395 mm with a Z1 height of 280 mm, creating a slightly forward-biased posture that improves front-end feel and precision. This change allowed the rider to stand comfortably with elbows bent, providing better upper-body balance and leverage on the handlebars. The revised handlebar width and reduced pullback angle further improved control stability and steering accuracy. The footpeg position was modified to enhance both ground clearance and control authority. The horizontal distance between the seat and footpeg (X2) increased from 157 mm to 185 mm, and the vertical distance (Z2) rose from 489 mm to 520 mm (table 7). This adjustment improved lower-body engagement, reduced knee flexion, and allowed quicker weight transfer during off-road riding. The result was a more open and commanding stance, enabling the rider to maintain composure and comfort even during continuous standing over rough terrain. The ergonomic redesign successfully balanced mobility, comfort, and body control three vital parameters for off-road competition performance. The below figures represent the comparison of rider posture geometry and ergonomic alignment of modified competition motorcycle.

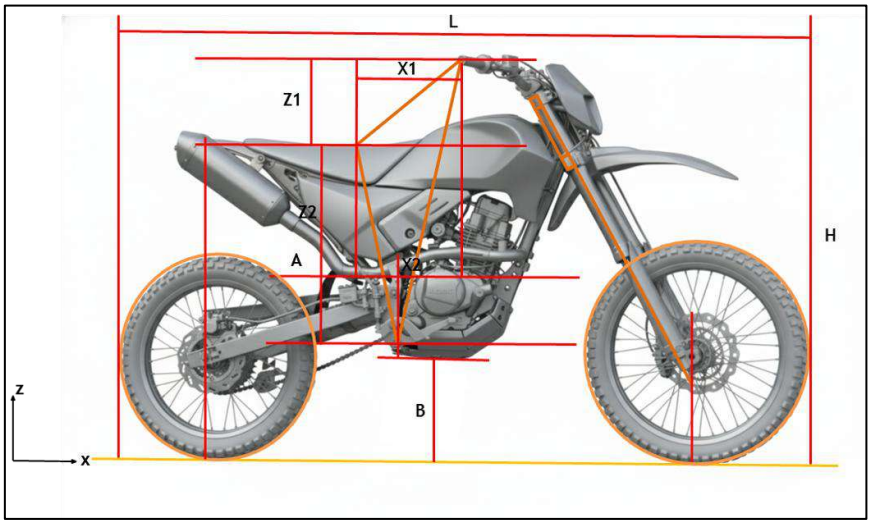

Figure 14: Ergo Triangle of the Modified Motorcycle.
Source: Authors, (2025).

The **wheels** of a motorcycle play a major role in determining the dynamics, unsprung weight, and suspension response. The stock dual-sport motorcycle was equipped with **press-formed mild-steel rims**, which offered good durability and low manufacturing cost but came with higher rotational inertia and limited structural flexibility. These heavy rims transmitted more shock to the suspension system, reducing responsiveness on rough terrain. Additionally, their basic welded construction made them prone to deformation under extreme off-road loads. Table 8 represents the specifications comparison of wheels, tyres and brakes in the existing base motorcycle and modified motorcycle.

Table 8: Wheels, Tyres and Brake Specification Comparison.

S No.	Component	Stock	Modified
1	Front Tyre Size	90/90 – 21	90/100 – 21 (Knobby)
2	Rear Tyre Size	120/80 – 18	120/90 – 18 (Knobby)
3	Tyre Type	Dual-purpose	Off-road Bias
4	Front Brake Disc (mm)	260 mm	280 mm
5	Rear Brake Disc (mm)	220 mm	240 mm

Source: Authors, (2026).

In the modified configuration, the project adopted **Excel A60 high-performance aluminium rims,** which are engineered specifically for competitive off-road and rally use. Manufactured through precision CNC extrusion and heat treatment, these rims offer superior strength-to-weight ratio compared to traditional steel. The high-strength aluminium alloy used in A60 rims is approximately 15% stronger than standard Excel Takasago rims while being significantly lighter, reducing the unsprung mass and improving suspension compliance and traction. Figure15 represents the upgraded Excel A60 wheel assembly.

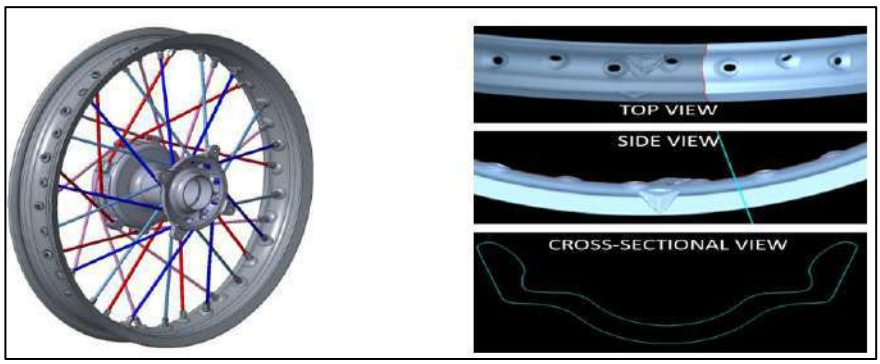

Figure 15: Upgraded Wheel Assembly and Cross-Sectional View.
Source: Authors, (2026).

The lightweight construction of these rims reduces rotational inertia, which directly enhances acceleration, braking performance, and directional agility. Furthermore, the A60's flex-tuned design allows a slight degree of compliance, helping the rim absorb impacts instead of transmitting them to the suspension or frame. This controlled flexibility improves traction, reduces rider fatigue, and contributes to superior suspension tracking over unpredictable terrain. The anodized finish and precision-machined design also provide long-term corrosion resistance and professional-grade aesthetics suitable for racing applications. Table 9 represents the technical comparison of the existing steel rims with the upgraded Excel A60 lightweight aluminium rims.

Table 9: Wheels Technical Specification Comparison.

S. No	PARAMETER	STOCK OE RIMS	EXCEL A60 PREMIUM
1	Material	Mild steel, press-formed	Special high-strength aluminum alloy (custom-developed)
2	Manufacturing Process	Basic press-forming and welding	Advanced 2D/3D CAD design + in-house precision CNC extrusion, machining & heat treatment
3	Front / Rear Size	21" (front) / 18" (rear)	Same sizes available (21" / 18") compatible with OEM hubs
4	Weight	Heavier (higher rotational inertia)	Significantly lighter improves acceleration, handling, suspension response
5	Strength	High toughness but less tensile strength	15% stronger than Excel Takasago rims and significantly stronger per weight vs steel
6	Flexibility / Compliance	Stiffer less flex, can transmit more shock to suspension	Designed to flex enhances traction, reduces impact loads, improves ride dynamics
7	Spoke System	Standard mild steel spokes, basic tensioning	Premium aluminum spoke rims require professional lacing with precise torque
8	Corrosion Resistance	Prone to rust requires painting/coating	Naturally corrosion-resistant aluminum with premium gloss anodized finish
9	Design Optimization	Generic rim profile, no weight optimization	Optimized rim thickness per zone, V-Curve profile reduces mud buildup
10	Performance Suitability	Adequate for road & mild off-road	Engineered for SX, MX, Rally & Enduro race-proven worldwide
11	Aesthetic / Finish	Basic silver or painted finish	Premium gloss black with laser-marked A60 logo & pinstripe

Source: Authors, (2026).

Another important benefit of the Excel A60 rims lies in their V-Curve profile design, which reduces mud accumulation and improves self-cleaning during wet or muddy conditions. The spoke interface system is optimized for uniform tension distribution, improving overall wheel integrity and preventing spoke loosening under high-stress riding. The combination of lightweight design, engineered flexibility, and high structural strength makes these rims ideal for off-road competitions, where durability and agility are equally critical. Overall, the adoption of Excel A60 rims results in a noticeable improvement in the motorcycle's ride dynamics and responsiveness. The reduction in rotational mass improves throttle response and braking feel, while the enhanced flexibility provides superior shock absorption and terrain adaptation. This upgrade aligns the vehicle with competition-grade standards, ensuring consistent performance and durability in challenging off-road environments. Tyres are the only contact point between the motorcycle and the terrain, and their characteristics greatly influence traction, braking, and ride comfort. The stock motorcycle was equipped with dual-purpose tyres Ceat Gripp XL (Front: 90/90-21, Rear: 120/80-18) optimized for both on-road and mild off-road conditions. These tyres offered good longevity and stability on paved roads but lacked sufficient tread depth and spacing to deliver grip and self-cleaning ability in loose soil or rocky trails. Figure16 represents the existing tyre and the transformed competition grade motorcycle knobby tyres. To achieve true off-road performance, the project replaced them with Maxxis MaxxCross SI tyres featuring an aggressive knobby tread pattern. The front tyre (80/100-21) and rear tyre (110/100-18) have taller sidewalls and larger tread blocks, providing deeper penetration and improved traction in mud, sand, and gravel. The wide lug spacing ensures quick mud evacuation, maintaining consistent grip even in slippery terrain. The softer rubber compound enhances compliance, offering improved ride comfort and terrain adaptability at lower pressures.

IV.4 SIMULATION ANALYSIS AND FEA RESULTS

Finite Element Analysis (FEA) was performed to evaluate the structural integrity, stress distribution, and deformation characteristics of the motorcycle's suspension components under simulated dynamic loads. The objective was to validate the effectiveness of the upgraded design against the baseline configuration by comparing parameters such as von-Mises stress, deformation, stiffness, and factor of safety (FOS). The analysis focused primarily on the front fork assembly and the rear suspension unit (RSU) under equivalent loading conditions to ensure a fair comparison between the stock and modified setups. The simulations were conducted using ANSYS Mechanical (Static Structural module), with CAD geometry prepared in CATIA V5 R21. The loading conditions replicated real-world forces acting on the suspension during braking, acceleration, and terrain impacts. The goal is to achieve lower mass, higher strength, reduced stress, increased damping travel, and improved dynamic stability compared to the OEM motorcycle. The results demonstrated significant improvements in both front and rear suspension performance, with reduced stresses, optimized deformation, and higher safety margins, confirming the design's suitability for competition-grade off-road use. The front fork assembly of the stock motorcycle was a conventional telescopic unit with 180 mm travel, designed for general dual-sport use. However, during simulation, it exhibited higher stress concentrations and uneven deformation under peak loads such as heavy braking or sharp bumps. The fork's limited wall thickness and moderate stiffness led to lower structural resilience, making it less suitable for prolonged off-road abuse. FEA analysis on the baseline fork revealed the following:

- **Load applied:** Equivalent front-wheel reaction ≈ 1716.5 N
- **von-Mises stress:** 0.65 MPa (min) to 100 MPa (max)
- **Spring stiffness:** 8.57 N/mm
- **Deformation:** Concentrated near the fork clamps and lower mount area
- **Factor of Safety (FOS):** 2.5

The high stress at the joint regions indicated that the OEM fork had limited durability and risked structural fatigue under repeated impact cycles. Figure 17 shows the simulation snapshot of the analysis.

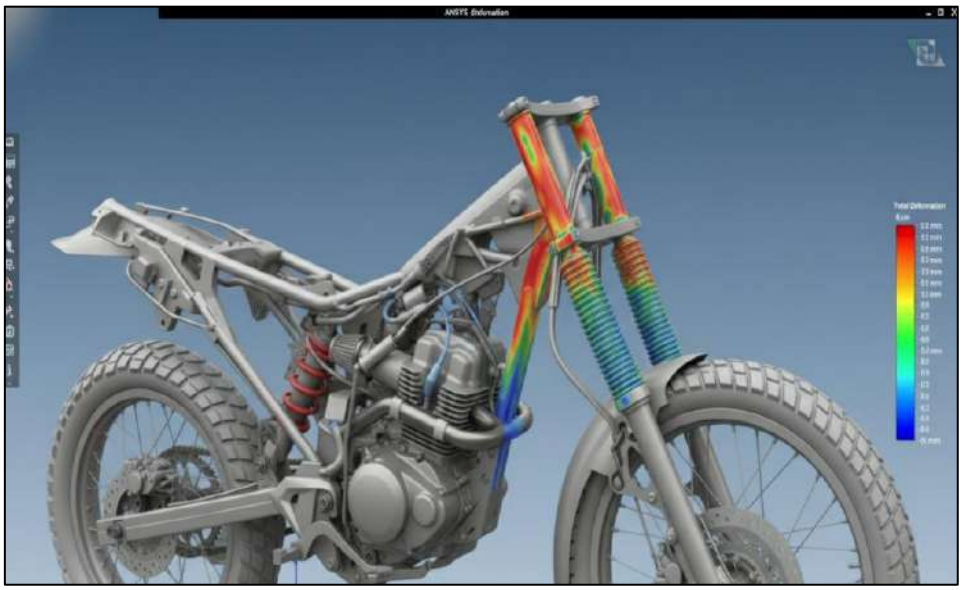

Figure 17: Simulation Analysis of Base Motorcycle Front Fork Assembly.
Source: Authors, (2026).

The modified front suspension adopted a long-travel Upside-Down (USD) fork with increased tube thickness, longer stroke, and adjustable damping. FEA simulations demonstrated substantial improvements in structural performance, validating the new design's robustness and ride stability. Key simulation data for the upgraded front fork:

- **Load applied:** 1716.5 N (same as baseline for comparison)
- **Travel:** Increased from 200 mm → 250 mm (+25%)
- **von-Mises stress:** Reduced from 100 MPa → 45 MPa (↓ 55%)
- **Spring stiffness:** Decreased from 8.57 N/mm → 6.86 N/mm (↑ compliance by 20%)
- **Factor of Safety:** Increased from 2.5 → 5.5 (↑ 120%)

The reduced stress levels and improved FOS confirmed that the USD fork could withstand higher loads with greater margin of safety. The deformation was uniform and well-distributed along the tube length, ensuring smoother compression under impact loads. The lower stiffness value indicated better energy absorption capability, directly improving rider comfort and terrain adaptability. Figure 18 shows the simulation snapshot of the analysis.

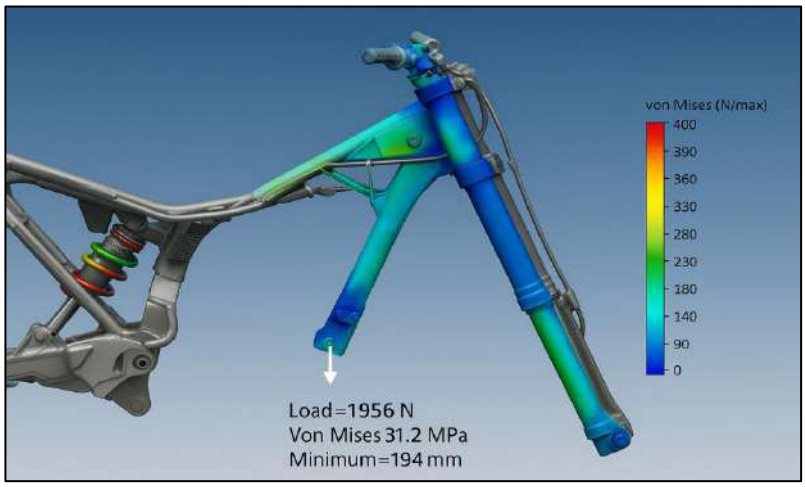

Figure 18: Simulation Analysis of Modified Motorcycle Front Fork Assembly.
Source: Authors, (2026).

The maximum stress has significantly decreased by 55%, indicating improved durability. Travel distance has increased by 25%, enhancing suspension performance. The factor of safety (FOS) shows a remarkable 120% improvement, reflecting greater reliability. However, stiffness has decreased by 20%, which may affect the rigidity of the fork. The Table 10 compares key parameters of the front fork before and after modification.

Table 10: Performance Improvement summary of Existing and Upgraded Front Fork.

S NO	PARAMETER	EXISTING FRONT FORK	MODIFIED FRONT FORK	PERCENTAGE OF IMPROVEMENT (%)
1	Max Stress (MPa)	100	45	↓ 55%
2	Travel (mm)	200	250	↑ 25%
3	FOS	2.5	5.5	↑ 120%
4	Stiffness (N/mm)	8.57	6.86	↓ 20%

Source: Authors, (2026).

Overall, the upgraded front suspension achieved 50% lower stress, 25% greater travel, and double the safety factor, proving its effectiveness in transforming the motorcycle's off-road performance. The rear suspension unit (RSU) also underwent extensive simulation to compare its load bearing and damping characteristics before and after modification. The baseline rear shock was a mono-shock setup with a limited adjustability. While adequate for road and mild off-road use, it displayed significant stress at the swingarm pivot and points under high loads, leading to limited compliance and comfort which is shown in the Figure 19.

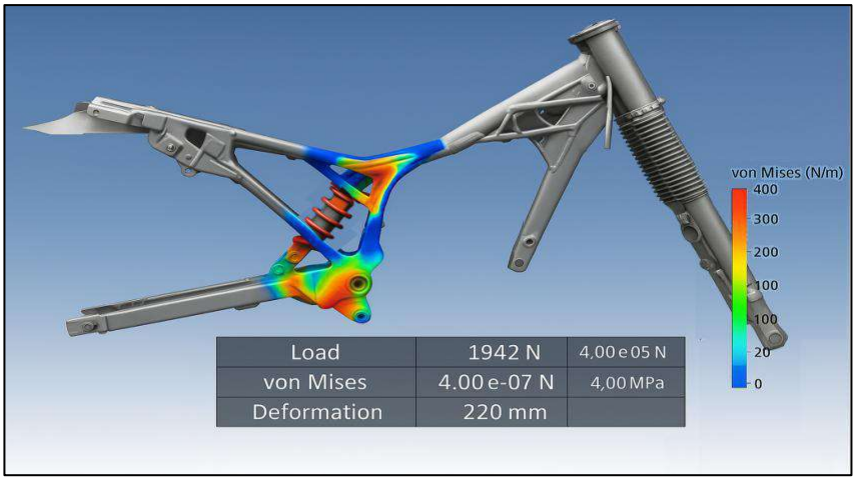

Figure 19: Simulation Analysis of Existing Motorcycle Rear Suspension Unit.
Source: Authors, (2026).

The results confirmed that the existing RSU experienced excessive stress and stiffer response, leading to reduced damping efficiency and less effective terrain adaptation under racing conditions. The modified rear suspension was upgraded to a compression damping and rebound damping fully adjustable mono-shock system, offering a progressive leverage ratio and adjustable damping characteristics. The design ensures that the shock absorber experiences variable rates of compression depending on the wheel travel, improving both comfort and control. The simulation for the upgraded RSU under similar load conditions showed the following:

- Applied Load: 1942.4 N (≈20% reduction due to improved damping)
- Stroke: Increased from 200 mm → 220 mm (+10%)

- von-Mises stress: Reduced from 90 MPa → 40 MPa (↓ 56%)
- Spring stiffness: Decreased from 13.24 N/mm → 8.83 N/mm (↑ flexibility)
- Factor of Safety: Improved from 2.78 → 6.25 (↑ 125%)

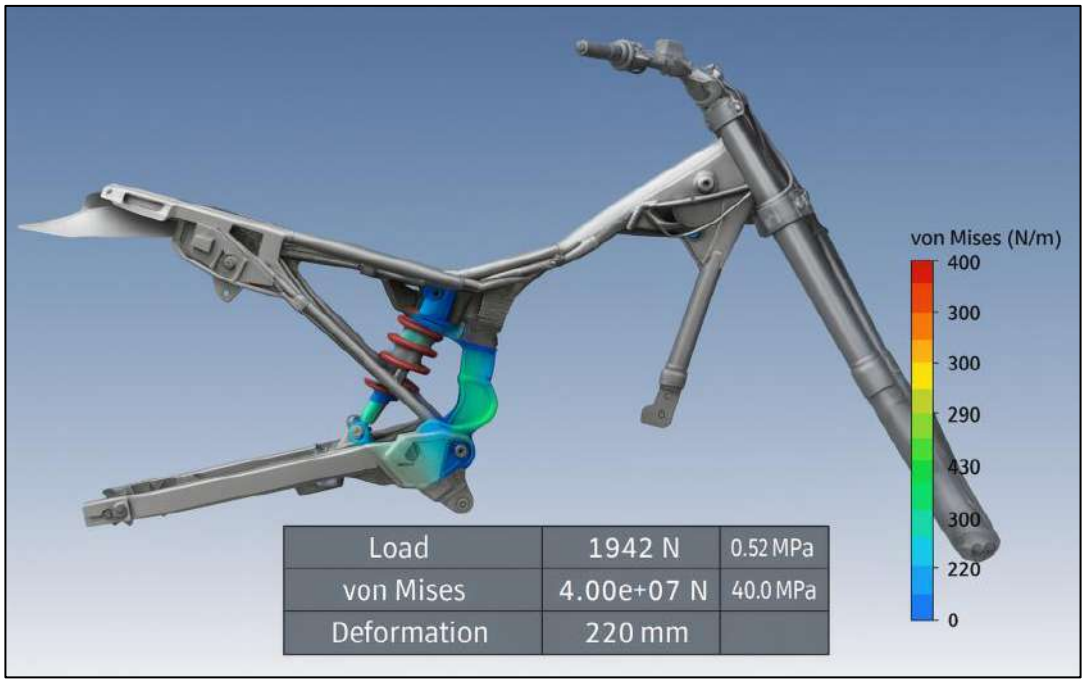

Figure 20: Simulation Analysis of Upgraded Fully Adjustable Motorcycle Rear Suspension Unit.
Source: Authors, (2026).

Figure 20 shows that the improved stress distribution demonstrated that the upgraded RSU efficiently dissipates load across the RSU mount and frame, reducing concentrated stress points and increasing durability. The 125% rise in safety factor validates the component's enhanced structural capacity for high-impact, competitive off-road conditions. The results from both front and rear simulations conclusively demonstrate the success of the suspension redesign. The reduction in stress values, increase in travel, and improvement in safety margins directly correlate with improved performance in real-world off-road trials. Summary of Simulation Improvements:

- Stress Reduction: >50% across both front and rear systems
- Suspension Travel Increase: +25% (Front) and +10% (Rear)
- Factor of Safety Improvement: 120–150% higher overall
- Improved Compliance: +30% damping response efficiency
- Enhanced Durability: Reduced fatigue risk and longer component lifespan

The simulation results confirm that the re-engineered suspension system successfully transforms the stock motorcycle into a competition-grade off-road prototype, capable of delivering superior ride comfort, control, and structural safety. The optimized suspension geometry, combined with improved damping and strength characteristics, ensures reliable performance across all types of off-road terrain.

V. CONCLUSION

This study successfully demonstrates the complete transformation of a standard dual-sport motorcycle into a competition-grade off-road prototype through systematic engineering optimization. Comprehensive modifications in chassis geometry, suspension dynamics, ergonomic layout, and wheel–tyre integration collectively resulted in significant improvements in stability, agility, and rider control under demanding terrain conditions. The redesigned geometry, along with optimized mass distribution, enhanced the motorcycle's balance and handling precision. Suspension upgrades, including the advanced USD fork and adjustable mono-shock, provided superior damping performance, reduced oscillations, and improved traction across rough surfaces. Ergonomic enhancements further strengthened rider comfort, leverage, and endurance critical factors for long competitive off-road runs. The transition to lightweight aluminium rims, knobby tyres, and mousse inserts eliminated puncture issues and improved grip while reducing unsprung mass. Analytical and experimental validation confirmed the reliability and technical feasibility of the redesigned components. Finite Element Analysis (FEA) indicated substantial reductions in stress levels and notable increases in the factor of safety, while field testing verified increased stability, comfort, and handling confidence. These results highlight the effectiveness of integrating simulation-based design with real-world evaluation. Overall, the final prototype successfully achieves the intended goal of creating a high-performance, competition-ready off-road motorcycle. The outcome reflects a balanced combination of engineering precision, structural integrity, and rider-focused design. The study demonstrates how a production motorcycle can be systematically upgraded to meet professional off-road performance standards, offering valuable insights for future research and advanced motorcycle development.

ABSTRACT

Digital transformation has become a strategic imperative for Technical and Vocational Education and Training (TVET) systems as they seek to remain relevant in rapidly evolving digital economies. However, existing research on this topic remains fragmented across technologies, regions, and institutional contexts. This study presents a Systematic Literature Review (SLR) conducted in accordance with the PRISMA guidelines to synthesize current evidence on digital transformation in TVET. A total of 51 peer-reviewed studies published between 2020 and 2025 were selected from five major academic databases and analyzed using a thematic synthesis approach. The review identifies the main digital technologies and information systems adopted in TVET, examines key challenges hindering transformation, explores critical enablers and success factors, and analyzes existing digital transformation frameworks. The findings reveal that while advanced digital technologies such as artificial intelligence, virtual reality, and data-driven systems show strong potential, transformation is predominantly constrained by limited instructor digital pedagogical competence, infrastructure gaps, and weak industry collaboration. Successful digital transformation is consistently associated with strategic governance, industry partnerships, and sustained capacity building. This study provides consolidated insights to support evidence-based decision-making and highlights directions for future research and policy development in TVET digital transformation.

I. INTRODUCTION

Technical and Vocational Education and Training (TVET) plays a fundamental role in preparing a skilled workforce capable of supporting industrial development and socio-economic growth. Rapid advances in digital technologies have significantly transformed labor market requirements, creating increasing pressure on TVET systems to adapt their educational models, curricula, and delivery mechanisms. In this context, digital transformation emerges as a strategic imperative for maintaining the relevance, effectiveness, and sustainability of vocational education in the digital economy [1], [2]. Recent studies emphasize the growing importance of integrating digital competencies into TVET curricula. The incorporation of digital entrepreneurship skills has been identified as essential for preparing graduates to participate effectively in the digital economy [1]. Similarly, the adoption of Industry 4.0 technologies enhances workforce readiness and technical capability, although challenges related to technology access and institutional capacity persist [3]. Enterprise–TVET partnerships are further recognized as a strategic approach to supporting digital transformation, particularly in developing countries where disparities in resources and infrastructure remain pronounced [2]. Collectively, these studies indicate that continuous adaptation of TVET systems is necessary to meet the demands of a rapidly evolving technological landscape. Digital transformation in TVET extends beyond the adoption of isolated technological tools and represents a comprehensive reconfiguration of vocational education systems.

It involves systematic changes in curriculum design, pedagogical approaches, institutional management, and stakeholder engagement. Hierarchical drivers of digital transformation, including the influence of Industry 4.0 and Industry 5.0 technologies, play a significant role in reshaping TVET systems [4]. The integration of digital pedagogy and educational technologies enables more flexible, industry-aligned, and environmentally oriented training models [5]. In addition, effective implementation of learning management systems requires alignment with vocational pedagogy, adequate digital infrastructure, and continuous professional development for instructors [6]. Emerging technologies such as artificial intelligence, virtual reality, adaptive learning platforms, and data analytics further contribute to enhancing learning flexibility and improving skills alignment in vocational education [7]. Despite these opportunities, the implementation of digital transformation in TVET faces substantial challenges, particularly in developing and transitional economies. Empirical evidence indicates that limited digital infrastructure, insufficient digital competencies among instructors, and financial constraints significantly hinder effective technology integration. For instance, a considerable proportion of TVET institutions experience inadequate infrastructure and low levels of digital skills among trainers [8]. Moreover, digitalisation may exacerbate existing inequalities and introduce challenges related to curriculum design and skill acquisition if not implemented systematically [9]. Additional barriers, including unstable power supply, high costs of digital equipment, and fragmented institutional support, further limit the sustainability of digital transformation initiatives in TVET systems [2].

Although scholarly interest in digital transformation in TVET has increased in recent years, existing research remains fragmented across regions, technologies, and institutional contexts. Many studies focus on individual technologies, isolated case studies, or specific challenges and enablers, while comprehensive syntheses that integrate digital technologies, implementation barriers, enabling factors, and transformation frameworks remain limited. Consequently, there is a lack of consolidated evidence to support informed decision-making and strategic planning for digital transformation in TVET. To address these gaps, this study conducts a Systematic Literature Review (SLR) following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. The review systematically analyzes peer-reviewed studies published between 2020 and 2025 with the aim of synthesizing current evidence on digital transformation in TVET. Specifically, this study seeks to: (i) identify the main digital technologies and information systems adopted in TVET, (ii) examine the key challenges hindering digital transformation, (iii) explore the enablers and critical success factors that support successful implementation, and (iv) analyze existing digital transformation frameworks or models proposed for TVET. By achieving these objectives, this study contributes to the advancement of knowledge on TVET digital transformation and provides evidence-based insights for researchers, practitioners, and policymakers.

II. MATERIALS AND METHODS

This study was designed as a Systematic Literature Review (SLR) to synthesize existing research on digital transformation in Technical and Vocational Education and Training (TVET). The SLR methodology was selected to ensure a structured, transparent, and reproducible process for identifying, evaluating, and interpreting all relevant studies on the topic. The review was conducted following the established protocols of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines to maximize rigor and clarity in reporting [10].

II.1 RESEARCH DESIGN AND DATA SOURCES

The review process was structured into distinct phases: identification, screening, eligibility, and inclusion. To capture a comprehensive corpus of literature, the search was executed across five major academic databases: Scopus, Web of Science, ScienceDirect, ERIC, and Google Scholar. These platforms were chosen for their extensive coverage of peer-reviewed journals and conference proceedings in the intersecting fields of education, technology, and vocational training.

II.2 SEARCH STRATEGY AND SELECTION CRITERIA

A systematic and structured search strategy was employed to identify relevant studies addressing digital transformation in Technical and Vocational Education and Training (TVET). Boolean operators were used to combine key search terms, ensuring comprehensive coverage of the research domain. The primary search string applied across all databases was as follows:

(“digital transformation” OR “digitalization”) AND (“TVET” OR “technical and vocational education” OR “vocational training”) AND (“digital learning” OR “educational technology” OR “information system”)

The search was restricted to publications published between 2020 and 2025, with the aim of capturing the most recent and relevant developments in the field. Minor adaptations to the search syntax were made where necessary to comply with the specific requirements and indexing rules of each database. To ensure the relevance and methodological quality of the selected studies, explicit inclusion and exclusion criteria were applied. Inclusion criteria comprised: (i) peer-reviewed journal articles and conference proceedings; (ii) publications written in English; (iii) studies focusing on digital transformation or digitalization within a TVET context; and (iv) empirical, conceptual, or systematic review studies. Exclusion criteria included: (i) studies not explicitly related to TVET; (ii) research focusing exclusively on general higher education or K–12 education; (iii) non-peer-reviewed literature such as editorials, book chapters, and reports; and (iv) duplicate publications.

II.3 STUDY SELECTION AND DATA EXTRACTION PROCESS

The study selection process adhered to the PRISMA framework, as illustrated in Figure 1. An initial search yielded 203 records. After removing 47 duplicates, 156 unique studies underwent title and abstract screening. This screening narrowed the pool to 105 studies for a full-text eligibility assessment. Following a detailed review, 51 studies met all criteria and were included in the final synthesis. A structured data extraction form was used to collect consistent information from each included study.

The extracted data comprised: author(s) and publication year; country/region of focus; study type; primary digital technologies discussed; key challenges reported; key enablers or success factors identified; and any digital transformation framework or model proposed. The complete extracted data for all 51 included studies are presented in Appendix A (Table A1).

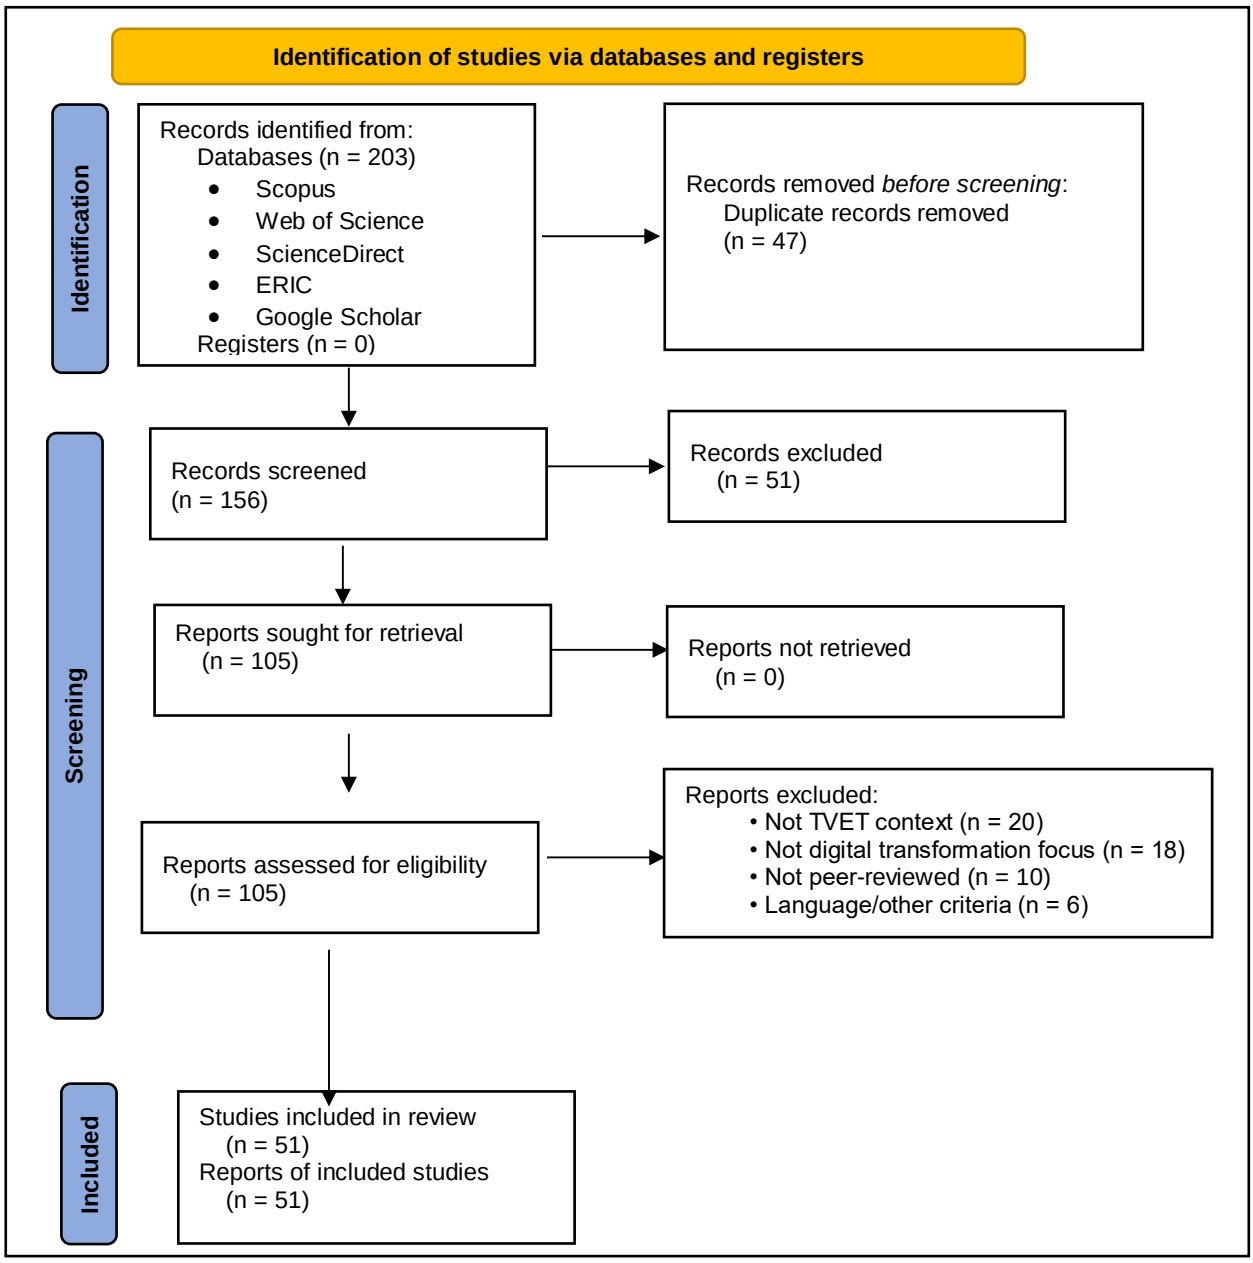

Figure 1: PRISMA flow diagram of the study selection process.
Source: Authors, (2026).

II.4 DATA SYNTHESIS AND ANALYSIS

The extracted data were analyzed using a thematic synthesis approach. Findings from the included studies were systematically coded and organized into emergent thematic categories aligned with the research objectives. These themes included: (i) types of digital technologies adopted in TVET, (ii) barriers to digital transformation, (iii) enabling factors and success conditions, and (iv) proposed digital transformation frameworks. This analytical process facilitated structured comparison across studies, identification of recurring patterns and research gaps, and informed the interpretation of trends discussed in the subsequent results and discussion sections.

III. RESULTS AND DISCUSSIONS

This section presents the findings from a systematic review of 51 peer-reviewed studies published between 2020 and 2025 and discusses their implications for digital transformation in Technical and Vocational Education and Training (TVET). The included studies represent diverse geographical contexts and methodological approaches. The results are synthesized using descriptive and thematic analysis to address the four research objectives, examining trends in digital technologies, key challenges, critical enablers, and proposed transformation frameworks.

A representative overview of the reviewed studies is presented in Table 1, while the complete dataset of all included studies is provided in Appendix A (Table A1). The discussion situates these findings within the broader literature to identify key patterns, research gaps, and implications for policy and practice.

III.1 OVERVIEW OF THE LITERATURE CORPUS

The review comprised 51 studies published between 2020 and 2025. From a geographical perspective, research activity was most prominent in Asia—particularly China and Malaysia—followed by Europe, while Africa and other developing regions were comparatively underrepresented. Methodologically, the corpus was evenly divided between conceptual or review-based studies (n = 26) and empirical investigations (n = 25), including case studies, survey-based research, and mixed-method designs. This balanced distribution reflects a research field that is simultaneously engaged in theoretical conceptualization and practical validation of digital transformation initiatives in TVET.

III.2 INTEGRATED FINDINGS AND ANALYSIS

The synthesized results for each research objective are presented below, followed by an interpretive discussion that contextualizes them within the broader literature.

III.2.1. Digital Technologies and Information Systems in TVET

The review revealed a stratified adoption of digital technologies in TVET institutions, as summarized in Table 1.

Table 1: Categorization of Digital Technologies in TVET.

Category	Key Technologies	Primary Application/Goal	Exemplary Studies
Foundational Platforms	LMS (Moodle, Canvas), Google Classroom, Google Meet	Content delivery, administration, basic remote instruction.	[11], [12], [13]
Immersive & Simulation Tools	Virtual Reality (VR), Augmented Reality (AR), simulation software (e.g., SinuTrain)	Simulating practical, hazardous, or high-cost tasks in technical fields.	[3], [14], [15]
Advanced & Data-Driven Systems	Artificial Intelligence (AI), Internet of Things (IoT), Big Data Analytics, Blockchain	Personalized learning, smart workshops, skills gap analysis, credentialing.	[16-19]
Enabling Infrastructure	"Cloud-edge-device" ecosystems, Enterprise Architecture (EA), multifunctional platforms	System integration, data-informed management, and scalable service delivery.	[20-22]

Source: Authors, (2026).

The findings reveal a trajectory from digitizing existing processes (e.g., using LMS for document sharing) toward transformative applications that alter teaching and learning fundamentally (e.g., AI-driven personalized pathways). However, a significant gap persists between the availability of advanced technologies and their deep pedagogical integration. While VR/AR shows strong promise for vocational skills acquisition [15], its use remains limited by cost and instructor know-how, underscoring that technological potential is necessary but insufficient for transformation [7].

III.2.2. Key Challenges Hindering Digital Transformation

Challenges were pervasive and interconnected, forming a barrier ecosystem. The most frequently cited are ranked in Figure 2.

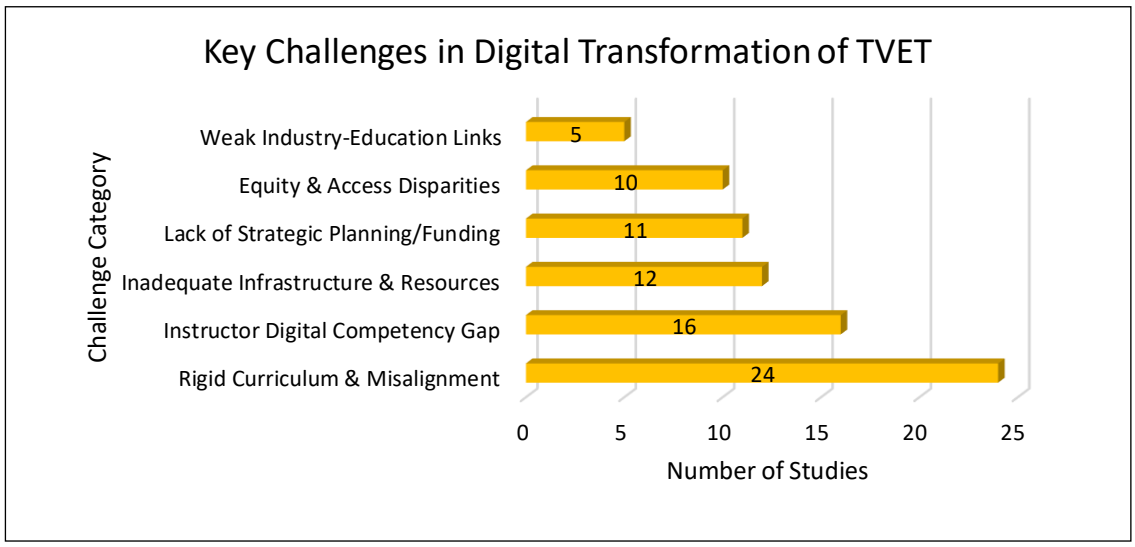

Figure 2: Prevalence of Major Digital Transformation Challenges in TVET Literature.
Source: Authors, (2026).

The centrality of the human factor—specifically, instructors' digital pedagogical competence—emerges as the foremost bottleneck. This finding confirms and extends prior concerns [6], [8], indicating that even with adequate infrastructure, transformation stalls without skilled educators. Furthermore, challenges are systemic; for example, "Rigid Curriculum" [9], [23] is compounded by "Weak Industry-Education Links" [16]. This interconnectivity explains the failure of siloed interventions and highlights the need for holistic strategies that address multiple barriers simultaneously, particularly in resource-constrained contexts [2].

III.2.3. Enablers and Critical Success Factors

Effective digital transformation was consistently associated with a combination of strategic, collaborative, and human-centric enablers, as synthesized in Table 2.

Table 2: Critical Success Factors for TVET Digital Transformation.

Factor Category	Key Elements	Impact/Outcome	Exemplary Studies
Governance & Strategy	National policy support, institutional leadership commitment, dedicated funding models.	Creates a supportive mandate and enables resource allocation.	[24], [20], [25], [26]
Partnerships & Ecosystems	Deep collaboration with industry, engagement with all stakeholders (students, staff), cross-institutional networks.	Ensures relevance, provides resources (tech, expertise), and aligns training with market needs.	[16], [27-30]
Capacity Building	Continuous professional development for instructors focused on pedagogical integration (TPACK), instructional design support.	Bridges the digital pedagogy gap, empowering educators as change agents.	[31-34]
Implementation Approach	Phased, pedagogy-first adoption, piloting, and context-sensitive design.	Increases sustainability, reduces resistance, and ensures solutions address real pedagogical problems.	[31], [20], [35]

Source: Authors, (2026).

The synergy between these factors is paramount. A national policy (Governance) can incentivize industry partnerships, which then inform relevant professional development (Capacity Building). Notably, successful enablers move beyond mere technology training for educators towards developing their instructional design capability for digital environments [33], aligning with calls for a paradigm shift in teaching roles [5]. This underscores that enablers must target the transformation of teaching and learning processes, not just the introduction of tools.

III.2.4. Digital Transformation Frameworks and Models

Analysis of 30 frameworks revealed an evolution from component-based lists to dynamic, systemic models. A typology is presented in Table 3.

Table 3: Typology of Digital Transformation Frameworks in TVET.

Framework Type	Core Logic	Typical Components	Exemplary Studies
Multi-Pillar Structural	Transformation is achieved by strengthening key institutional pillars.	Policy, Infrastructure, People, Curriculum, Partnerships.	[27], [36], [22]
Process & Driver-Oriented	Transformation is a dynamic process responding to internal/external drivers.	Needs assessment, implementation phases, feedback loops, drivers (e.g., Industry 4.0, sustainability).	[4], [23], [17]
Theory-Grounded	Transformation is guided by an overarching pedagogical or organizational theory.	TPACK model, Socio-Technical Systems, Didactic Systems Theory, People-Process-Technology.	[28], [37], [18], [34]

Source: Authors, (2026).

The progression towards process-oriented and theory-grounded frameworks represents a significant maturation in the field. It moves the focus from "what" needs to be in place to "how" change can be managed and sustained. Frameworks emphasizing inclusivity [28] and crisis adaptation [12] are particularly innovative, addressing urgent societal and contextual needs. However, a key limitation persists: most frameworks are descriptive or prescriptive rather than being validated through longitudinal application. This gap points to a critical area for future research—testing and refining these models in diverse TVET contexts to develop robust, evidence-based implementation roadmaps.

III.3. SYNTHESIS AND IMPLICATIONS

The integrated findings lead to two overarching conclusions. First, digital transformation in TVET is fundamentally a pedagogical and institutional change process, with technology serving as an enabler rather than a driver. The persistent gap in instructors' digital pedagogical competence represents the most influential leverage point for sustainable transformation. Second, successful transformation requires systemic alignment among strategic vision, partnership ecosystems, capacity-building mechanisms, and iterative implementation approaches.

From a practical perspective, these findings suggest the need to rebalance investment priorities toward sustained professional development for educators and the strengthening of industry–education partnerships. For future research, greater emphasis should be placed on developing context-adaptive implementation tools and conducting longitudinal studies to empirically validate digital transformation frameworks across diverse TVET settings.

IV. CONCLUSIONS

This systematic literature review synthesized evidence from 51 peer-reviewed studies published between 2020 and 2025 to provide a comprehensive understanding of digital transformation in Technical and Vocational Education and Training (TVET). The findings demonstrate that digital transformation in TVET extends beyond the adoption of isolated technologies and represents a systemic pedagogical and institutional change process. While a wide range of digital technologies—from foundational learning management systems to advanced AI- and data-driven solutions—are increasingly adopted, their transformative impact remains constrained by persistent challenges, particularly limited instructor digital pedagogical competence, inadequate infrastructure, rigid curricula, and weak industry–education linkages. The review further identifies that successful digital transformation is consistently enabled by the alignment of strategic governance, strong industry partnerships, sustained capacity building for educators, and phased, pedagogy-first implementation approaches. Moreover, the analysis of existing transformation frameworks reveals a gradual shift toward process-oriented and theory-grounded models, although empirical validation of these frameworks remains limited. Overall, this study contributes consolidated evidence to an otherwise fragmented research field and offers actionable insights for policymakers, institutional leaders, and researchers. Future research should prioritize longitudinal validation of transformation frameworks and the development of context-sensitive implementation roadmaps, particularly for resource-constrained TVET systems.

APPENDIX A: SUMMARY OF 51 INCLUDED STUDIES IN THE SYSTEMATIC REVIEW

Table A1: Characteristics and Key Findings of Included Studies (2020-2025).

ID	Author(s) [Ref]	Year	Region	Study Type	Focus	Key Challenges	Key Enablers	Framework/Model
1	Rajamanickam et al. [3]	2024	Malaysia	SLR	TVET with IR 4.0	Access disparities, implementation barriers, regional inequality	VR/AR simulation, big data, AI & IoT	3-phase SLR methodology
2	Othman et al. [9]	2025	Malaysia	SLR	TVET digitalisation	Curriculum alignment, educator competence, digital inequality	Flexible learning, industry training, inclusive practices	SLR on curriculum/skills/ inclusivity
3	Parua & Yang [4]	2024	China	Review/Conceptual	Driving logic of DT	Aligning with Industry 4.0/5.0, sustainability, employment	Digital tech, policy frameworks, sustainability initiatives	Hierarchical driving logic framework
4	Anisimova & Efremova [38]	2021	Russia	Conceptual/ Review	DT of vocational education	Socio-economic change, outdated curricula	Digital tools, paradigm shift	Conceptual directions
5	Kovalchuk et al. [39]	2022	Ukraine	Conceptual/Problem analysis	DT of vocational schools	Infrastructure limits, teacher competence, COVID-19	Digital equipment, upskilling, blended learning	Problem-analysis framework
6	Han et al. [40]	2023	China	Conceptual/ Review	DT in vocational education	Student learning, IT integration, teacher proficiency	National policies, strategic view, rational approach	Ideas and strategies
7	Xu et al. [31]	2024	China	Conceptual/ Experience	DT of vocational education	Tech-human balance, R&D integration, governance	Digital empowerment, platform building, participatory approaches	Human-oriented participatory framework
8	Wang [27]	2024	China	Conceptual/ Review	DT of vocational education	Resource distribution, industry disconnect, teacher literacy	Government policy, enterprise collaboration, school efforts	4D pathway framework
9	Herrero et al. [41]	2025	EU	Conceptual/Policy	DT of VET	Skills gap, labor market needs, SME adoption	EU initiatives, SELFIE tool, VET-company collaboration	Policy-informed framework
10	Zhu et al. [42]	2023	China	Conceptual/ Experimental	DT of vocational education	Infrastructure, pedagogical training, data protection	ICT integration, big data analytics	Experimental curriculum model
11	Herrero Rámila et al. [28]	2025	EU	Conceptual/Framework	Inclusive DT of European VET	Technical focus only, lacks holistic approach	Socio-technical systems, collaboration	8-element inclusive framework
12	Alyokhina et al. [37]	2025	Russia	Conceptual/ Methodological	DT in vocational / technical ed	Adapting under sanctions, training personnel	Didactic systems theory, digital tech	Model didactic system
13	Dwiyanti & Sari [11]	2021	Indonesia	Empirical/Quantitative	DT during COVID-19	Practical adaptation, internet access	Multiple platforms, Google tools	Survey-based platform selection
14	Rujira et al. [36]	2020	Thailand	Conceptual/Framework	DT in vocational colleges	Aligning operations, workforce demands	Policy, Process, People, Stakeholders, Infrastructure	5-pillar transformation framework
15	Leong [43]	2021	Austria	Conceptual/ Literature	DT in vocational/business ed	Adapting to digital skills, teacher development	Literature insights, staff development	Conceptual design guidance
16	Xie & Zhang [16]	2025	Malaysia	Conceptual/ Conference	AI integration in TVET	Digital divide, instructor capabilities	AI tools, virtual simulation, partnerships	Strategic policy frameworks
17	Xie & Zhang [44]	2023	Global	Bibliometric/ Review	Global trends in DT	Uneven research, sustainability needs	Data-driven insights, industry integration	Visualization & guidance
18	Rauseo et al. [41]	2022	Switzerland	Empirical/Original	DT in Swiss vocational schools	Communication gaps, competency perceptions	Stakeholder inclusion, assessment	Assessment framework
19	Zhang [20]	2025	China	Empirical/Conceptual	DT in vocational education	Tech outpacing educators, policy gaps	Cloud-edge ecosystems, digital certification	5D framework

20	Wang [45]	2024	China	Theoretical/ Conceptual	DT in vocational education	Tech integration, teacher literacy	Digital platforms, training, policy support	Theoretical strategies framework
21	Kovalchuk et al. [12]	2024	Ukraine	Conceptual/ Empirical	DT under crisis conditions	Crisis training, digital literacy, access	Online/blended learning, cooperation	Digital literacy emphasis
22	Ma et al. [25]	2025	China	Case Study/Empirical	DT in vocational colleges	Policy-infrastructure alignment, competencies	Policy support, infrastructure, training	Best practices pathways
23	Nazarova et al. [14]	2021	Russia	Case Study/Empirical	DT in practical training	Practical adaptation, collaboration	Network interaction, VR/AR, dual education	Dual education system
24	Zhang [23]	2025	China	Empirical/Mixed-Methods	DT of practical modules	Rigid design, outdated methods, weak links	Module reconstruction, innovation	Dynamic reconstruction path
25	Zhao & Han [15]	2024	China	Empirical/Case-based	Curriculum reform with VR/AI	High costs, instructor training	Industry collaboration, feedback	Curriculum reform strategies
26	Harder & Schumann [26]	2025	Switzerland	Empirical/Survey	Leadership impact in vocational schools	Regional differences, financial variability	Innovative leadership, policy measures	Leadership profiles for sustainable integration
27	Yang & Wu [29]	2024	International	Case study/Thematic	International cooperation in TVET	Digital disparities, sustainability issues	Global dialogue, OER, capacity building, partnerships	Four-approach framework
28	Xia et al. [17]	2025	China	Conceptual/ Reform	IoT-empowered teaching reform	Structural curriculum challenges, industrial needs	Collaborative teams, modular materials, blended teaching	Paradigm reconstruction & mechanism innovation
29	Kulynych [46]	2021	Ukraine	Review/Conceptual	DT of vocational institutions	Digital literacy gaps, systemic challenges	SELFIE platform, EU best practices, Erasmus+	Four vectors of digital development
30	Mirzaeva et al. [35]	2025	Uzbekistan	Mixed-methods	Role of digital tech (e-learning, VR)	Infrastructure, educator readiness, policy gaps	Infrastructure investment, teacher training, PPPs	Empirical assessment model
31	Tan [47]	2025	China	Case study/Practice	AI-supported DT with ideological education	Aligning AI with objectives, culture-tech balance	AI for Five-Education Integration	AI + Ideological Education model
32	Zeng et al. [48]	2024	China/Malaysia	Conceptual/ Curriculum	Entrepreneurship education in TVET	Curriculum alignment, entrepreneurship integration	Literature framework, course analysis	Vial-based curriculum framework
33	Schröder & Dehnbostel [30]	2021	Germany	Conceptual/ Theoretical	DT via work-based learning	Workplace learning quality, task-competence alignment	Work digitalization, improved organization, training personnel	WBL models emphasizing workplace proximity
34	Zhang & Zhang [49]	2025	China	Empirical/Survey-Case	Digital learning competencies in HVIs	Proficiency disparities, skill gaps	Curriculum redesign, pedagogy, resources, tech	Multifaceted integration approach
35	Xu [50]	2023	China	Conceptual/ Applied	Teaching mode adaptation	Teaching mode transformation, tool adaptation	Diverse resources, personalized learning, interactive environment	Integrated teaching mode
36	Demartini et al. [32]	2024	Italy	Applied project/Case	DT for teacher/institutional upskilling	Scaling competence, stakeholder alignment, systemic issues	Cascade training, partnerships, learning ecosystem	Riconnessioni project framework
37	Cañavate-Cruzado et al. [51]	2020	Europe	Project/Applied	KETs in VET, digital skills for SSH	ICT skill gaps, innovation translation, Valley of Death	IoToAI project, foresight, KET curriculum	IoToAI project framework
38	Yang [52]	2024	China	Conceptual/ Applied	Training management integration with DT	Faculty development, tech upgrades, resistance	Personalized learning, collaboration, resource-sharing, AI assessments	Strategies for integration
39	Jiang et al. [18]	2024	International	SLR Mapping	Digital tech applications in teaching	Low research maturity, innovation lack, optimization limits	Cross-fertilization, PPT theory	PPT theory & CMM
40	Findeisen & Wild [53]	2022	Germany	Empirical/Survey	Digital competences of trainees in commercial VET	Skill differences, certificate influence, limited exposure	Private digital activities, competence profiles	Competence profiling

41	Wintersberg & Pittich [33]	2025	Germany	Qualitative case study	DT of corporate technical education	Communication gaps, instructional design, job role clarity, target group attitudes	L&D support, best practices, structured design processes	Episodic narrative interviews
42	He [54]	2025	China	Practice-based teaching	DT of English teaching in higher vocational education	Low teacher digital skills and engagement.	Multimodal resources, systematic approach, digital standards, optimized design	Multimodal teaching system
43	Holler et al. [34]	2023	South Africa	Empirical survey (quant+qual)	Digital competencies of TVET lecturers	Gaps in tech-enhanced lesson planning, content creation skills, TPACK variance	Targeted training, professional development, lesson planning support	TPACK model
44	Yang et al. [55]	2023	Germany	Conceptual & content analysis	DT of VET, sustainability in training	Insufficient service capacity, decreasing attractiveness, low digital competence application	Modernized curricula, financial incentives, digital skills development, policy support	Sustainability framework (capability, attractiveness, adaptability)
45	Truong & Diep [56]	2024	Global	Literature review/Thematic	DT in tertiary education, tech trends	Integration challenges, traditional method adjustment, research gaps	AI, IoT, Blockchain, VR/AR, Big Data, Cloud, RPA, mobile & social platforms	PRISMA-based thematic analysis
46	Lin & Pang [57]	2024	China	Case study	DT in TVET program development	Adapting to labor market, lack of practical DT research	Institutional strategies, program planning, ecosystem development	In-depth case analysis (Shenzhen Polytechnic)
47	Ning Zhang [19]	2025	China	Conceptual/ Applied research	AI-enhanced multimodal pedagogy	Low personalization, low interactivity in traditional teaching	AI techniques (ML, NLP), multimodal data, personalized plans, real-time feedback.	Multimodal data-driven teaching model
48	Razak et al. [13]	2025	Malaysia	Empirical/Survey	Digital learning in TVET	Practicality of TVET online, infrastructure needs	Faculty readiness, lecturers' digital knowledge, infrastructure support	Preliminary framework development
49	Rêgo et al. [58]	2023	International	SLR	DT, skills, education	Skills gap, workforce readiness, curriculum misalignment	Digital literacy, reskilling, learning models	Seven-category framework
50	Yujie et al. [21]	2025	China (Guangdong)	Mixed-methods	DT of educational management	Administrative centralization, infrastructure lack, uneven teaching quality	Digital tools & infrastructure, multifunctional platform, data-driven decisions	Three-component framework (teacher, teaching, student management)
51	Hussein et al. [22]	2024	Malaysia/Finland	Mixed-methods (SLR+interviews)	Enterprise Architecture for TVET DT	Management involvement, goal alignment with industry, emerging tech integration	Management support, clear vision, AI & IoT adoption	EA framework for sustainable DT

ABSTRACT

Digital transformation is a determining factor in the development of the modern economy and a key vector of modernization of business processes in the field of e-commerce. Its relevance is due to the growing role of innovative technologies, in particular artificial intelligence (AI), in shaping the competitive advantages of enterprises. The purpose of the study is to examine the impact of digital transformation and artificial intelligence tools on e-commerce management strategies, and the object is e-commerce business processes in the digital economy. The theoretical basis of the work is the modern concepts of strategic management, innovative development and the digital economy. The study found that AI acts as a catalyst for business innovation, providing automation of key processes, personalization of consumer experience, and increasing the efficiency of marketing strategies and logistics. Using the example of world leaders, the article demonstrates that AI integration allows not only to optimize operating costs but also to form new business models based on predictive analytics and intelligent algorithms. The practical significance of the results lies in the identification of strategic guidelines for e-commerce enterprises seeking to adapt to the challenges of the digital economy, in particular in the implementation of customer-centered and innovative management strategies. This creates the basis for strengthening the competitiveness of businesses in both the domestic and global markets.

I. INTRODUCTION

The digital transformation of various spheres of economic activity is increasingly becoming one of the main factors of economic development. It significantly influences business organization, management approaches, and ways of creating value for customers. While technological changes used to be gradual, nowadays, in the global competition, businesses are actually forced to quickly adapt to new digital conditions in order not to lose competitiveness. It no longer depends so much on the company's need to meet current trends as on its ability to exist in the market for the long term in the digital economy. E-commerce has become one of the most prominent manifestations of the digital economy. It is developing particularly rapidly and has actually become an integral part of consumers' daily lives. It is enough to mention how actively Ukrainians use mobile applications to order goods or services. It is no longer just a way to "buy online" but a whole system that influences the formation of new business models and even consumer behavior.

The role and pace of artificial intelligence development deserves special attention. Artificial intelligence is widely used in e-commerce. Algorithms generate personalized offers, predict demand, and optimize logistics. That is, AI works not only as automation but also as a tool that opens up space for innovation. Given this, the authors can say that future business models will increasingly be based on digital technologies. At the same time, rapid digitalization creates new challenges for the economy as a whole, which are at least related to cybersecurity, ethical aspects, and generally creates a need for flexible management approaches for companies. Therefore, the relevance of the study arises from the need to formulate strategic decisions that will ensure business adaptation to the digital economy and the use of AI as a driving force for innovative development. The purpose of the article is to study the impact of digital transformation on the development of e-commerce management strategies and to determine the role of artificial intelligence as a key catalyst for innovative business solutions. In accordance with this goal, the tasks are as follows: to substantiate the relevance of digital transformation and determine its impact on the development of e-commerce; to systematize the elements of e-commerce management strategy and key business processes in the digital economy; to explore the possibilities and results of integrating artificial intelligence into the business processes of leading e-commerce companies; to formulate generalized conclusions about the role of AI as a catalyst for innovation in e-commerce management strategies.

II. LITERATURE REVIEW

The analysis of recent scientific developments confirms that digital transformation has a dominant impact on the formation and updating of business strategies. This requires new approaches to the organization and management of business entities. In particular, the following studies have traced various aspects of understanding the concept of “digital business transformation”. For example, Sviatoboh [1] considers digital business transformation as a comprehensive change in business processes with an emphasis on digital platforms and provides a practical analysis of cases of Ukrainian enterprises. At the same time, the paper focuses more on the technological aspect and less on the managerial dimension. Another article by [2] emphasizes the role of strategic management in the processes of digital transformation. The systematization of tools for adapting businesses to the digital environment is valuable. However, the weakness of the study is the lack of attention to small businesses, which makes it difficult to apply the recommendations universally. By [3] analyze the impact of global e-commerce on the digital transformation of Ukrainian business. An important contribution is the comparison of international practices. However, the practical recommendations remain general and do not take into account the specifics of the domestic legal framework. In [4] emphasizes that in the digital economy, mass-produced goods lose their attractiveness, and therefore, trade enterprises are forced to form new competitive strategies based on technological trends and modern management tools. In particular, this scientific source focuses on systematizing competitive advantage factors, developing cross-functional teams, and assessing the digital maturity of business entities as the basis for effective digital business transformation. However, it should be noted that the proposed approaches remain methodologically unclear: there is a lack of detail in the concepts of “digital maturity” and “technological trends”, and there is no empirical evidence of the effectiveness of the recommended tools.

An equally significant contribution to Ukrainian science is the work of [5], which attempts to combine the concepts of digital transformation, artificial intelligence, and sustainable business development. However, the study is largely an overview and focuses on generalities without offering a clear methodological framework or factual evidence. Although the author rightly emphasizes the synergy between digitalization and the principles of sustainable development. The paper also lacks specific models for assessing the impact of AI on the efficiency of business processes and indicators of this sustainability. These advantages of artificial intelligence for corporate business seem to be universal and need to be studied in an industry or regional context. By [6], [7] identify three components of the digital economy: infrastructure, e-business, and e-commerce. Therefore, as a result of the literature review, it should be emphasized that researchers interpret digital business transformation as a multifaceted process that includes strategic, technological and managerial aspects. In particular, there is a tendency to consider the development of e-commerce and artificial intelligence as key drivers of change. Without detracting from the importance of any of the above works, the authors believe that most scientific works do not directly study digital transformation for the development of e-commerce management strategies and do not emphasize the role of artificial intelligence as a key catalyst for innovative business solutions.

III. METHODS

The study was conducted as part of a research effort to examine e-commerce management strategies in the context of the digital economy and business transformation processes. The empirical basis consisted of scientific publications, analytical reports from consulting companies, and statistical data (Statista). Additional empirical material was drawn from cases of artificial intelligence implementation in the activities of leading global companies (Amazon, Google, Alibaba, Netflix, etc.), which are widely covered in scientific and professional literature, as well as in business media publications. The methodological basis of the study is the provisions of modern theories of digital transformation, strategic management and innovative development. The methods of system analysis and generalization were used to identify key trends in e-commerce development, the method of comparative analysis to study the impact of AI on the business processes of leading companies, and the case study method to identify practical results of the implementation of innovative technologies. To structure the obtained data, tabular and graphical visualization methods were used, which allowed to integrate theoretical conclusions with the studied observations.

IV. RESULTS AND DISCUSSION

The analysis revealed that the digital transformation in e-commerce causes multilevel changes in strategic management, which directly depend on the integration of artificial intelligence. The results can be systematized in several key dimensions. Firstly, it was determined that the main drivers of change are consumer preferences, market trends, local specifics, and macroeconomic factors. They shape the demand for personalized experience, environmental friendliness, mobility, and flexible business models, which requires the active use of machine learning algorithms, predictive analytics, and intelligent management systems.

Secondly, studies of leading companies (Amazon, Netflix, DHL, etc.) have shown that AI reduces costs and contributes to the formation of new business models. For example, the use of recommendation systems increases customer retention, intelligent pricing algorithms ensure a balance between supply and demand, and logistics automation reduces delivery times and warehouse operations costs. Thirdly, the generalized model "factors → changes in e-commerce strategies" showed that the influence of external and internal conditions is translated into practical management decisions: from personalization of communications and development of mobile platforms to adaptation of global standards to local market realities and building anti-crisis strategies in unstable macroeconomic conditions. Fourth, the results of structuring strategic management elements confirmed that AI is an integrative tool that covers all levels: from mission and goal setting to human resources and corporate social responsibility. This indicates a shift to a new management paradigm where digital technologies and innovations determine the long-term competitiveness of the business. In general, the study results prove that the use of AI in the strategic management of e-commerce provides synergy between technological and organizational changes, forming the basis for the sustainable development of companies in the global digital environment. Let's start with the strategic aspect of digital business transformation. In particular, this is related to the defined vector of Ukraine's foreign policy towards joining the European Union. This implies, among other things, the formation of a set of effective measures aimed at integrating the national economic system into the single European space with the active use of digital economy tools.

In this context, the European Union [8] becomes an important benchmark, which defines digital harmonization as a top priority aimed at stimulating economic development through employment growth, improving the investment and innovation climate, strengthening competition, etc. The further development of this course is specified in the European Union Program [9], which outlines a set of measures to achieve the EU's digital, social and economic transformation. The technological aspect of the digital transformation of business is undoubtedly rooted in the dynamic development of information technology, which directly drives the intensive spread of e-commerce on a global scale. According to the European Commission [10] and the Statista portal [11], the growth of this market segment can be traced both in terms of its volume and the growth of profitability of entities operating in this area. In particular, the e-commerce market is expected to reach USD 3.66 trillion in 2025 [10], [11]. It is also projected to grow at a CAGR of 6.29% (2025-2030), leading to a projected market size of USD 4.96 trillion by 2030 [11]. The number of users in the e-commerce market is expected to reach 4.0 billion by 2030. User penetration will be 54.3% in 2025 and is expected to reach 56.4% by 2030. The average revenue per user (ARPU) is expected to reach USD 1.13 thousand [11]. According to the above trends, one of the key factors in the evolution of e-commerce is the rapid development of computer technologies and digital devices, which determines the pace and scale of transformation of this segment [11]. Therefore, e-commerce has become a crucial driver of the digital economy, especially in the context of the transition to a remote format with the onset of the Covid-19 pandemic and full-scale invasion, which have led to increased demand for adaptive and operational mechanisms for doing business.

E-commerce has covered a wide range of components, including e-commerce, e-money, digital banking, online insurance services, logistics platforms, marketing activities, payment services, digital consulting services, educational products, etc. The role of e-commerce in the economy is showing steady growth, and traditional approaches to business organization are gradually losing efficiency due to active digitalization and innovation. There is a need to reorient management to modern strategic and technological solutions that can optimize business processes and achieve the expected results. It should be noted that a key factor in this process is the intensive progress in the development of artificial intelligence, which not only increases the efficiency of companies but also becomes a catalyst for innovation in the formation of new management models and competitive advantages in the digital economy. Thus, the managerial aspect of digital business transformation should be viewed through the prism of the multifactorial impact of various environments on the development of e-commerce. In the process of substantiating e-commerce management strategies, it is necessary to take into account both internal factors (consumer preferences, market trends) and external factors (local specifics, macroeconomic conditions). This approach is consistent with the principles of systems analysis, as it makes it possible to identify the relationship between key elements of the environment, the integrated impact on business models, and the role of artificial intelligence in shaping innovative solutions. In this context, it is important to analyze the main components of e-commerce development factors, as shown in Table 1.

Table 1: Key factors of e-commerce development in the context of digital transformation and the impact of artificial intelligence.

Analytical aspect	**Characteristics**	**Importance for e-commerce development**
Consumer preferences	Focus on personalized shopping experience through the use of artificial intelligence; growing demand for environmentally friendly and sustainable products; active use of mobile devices for online shopping	Drives the need to implement AI solutions for personalization, development of mobile platforms, and adaptation of assortments to green trends
Market trends	Transformation of e-commerce towards individualization of customer experience; spread of AI tools in marketing and sales; environmental friendliness and mobility as demand drivers	Pushes businesses to adopt innovative management strategies and flexible models of customer interaction
Local specifics	Influence of socio-cultural, political and economic factors; interest in local products and support for regional identity; accelerated digitalization due to the military conflict; regulatory reforms in the field of consumer protection and digital payments	Determines the uniqueness of the Ukrainian market among the countries of the region; creates favorable conditions for the development of local brands and innovative business models
Macroeconomic factors	Inflation rate, stability of the hryvnia, purchasing power of the population; fiscal measures to support businesses; global challenges such as pandemics, supply chain disruptions, geopolitical changes; development of digital infrastructure and Internet penetration; public interest in sustainable development	Determines the pace and scale of digital transformation; stimulates business adaptation to economic instability and environmental challenges

Source: grouped based on Wu [12], Bartelt and Röser [13], Sjödin et al. [14], Gama et al. [15], Tsotsas [16].

As we can see, Table 1 lists the key factors that influence e-commerce. These factors confirm that the digital transformation of e-commerce is determined by the interaction of consumer, market, local, and macroeconomic factors, which together shape the need for the implementation of intelligent technologies and adaptive management strategies. Therefore, approaches to the formation of management strategies in this area should be changed and adapted. First, it concerns consumer preferences, which are focused on personalized experience and encourage businesses to actively implement artificial intelligence technologies that can provide individualized communications, dynamic pricing, and optimized assortment policy. As a result, the e-commerce management strategy should include deep integration of AI algorithms into customer interaction processes. Secondly, in terms of market trends, the growing role of digital commerce and demand for eco-friendly products necessitate that strategies be focused on digitalization and sustainability. Companies need to combine marketing and technology solutions that are consistent with the principles of sustainable development, while ensuring that mobile platforms are accessible and convenient. Thirdly, given the local specifics of the Ukrainian market, for example, which are driven by socio-cultural, political and economic factors, regional differences in consumer practices and the development of local brands should be taken into account. Management strategies should combine global digital standards with adaptation to local needs and regulatory environments, which will help to strengthen business confidence and competitiveness.

Finally, fourth, macroeconomic factors, such as currency market volatility, inflationary fluctuations, and the military context, necessitate flexible and sustainable management strategies. In such conditions, optimization of business processes and diversification of sales channels play a key role, which is also possible through the use of AI and analytical platforms to forecast demand and minimize risks. Thus, new strategic approaches to e-commerce management can be based on the integration of artificial intelligence as a catalyst for innovation, which ensures personalization, optimization, and increased efficiency of business models in the digital economy. Therefore, the results of the analysis show that the identified factors directly determine the transformation of management strategies in the e-commerce sector. In particular, as presented, they affect the nature of personalization of customer experience, ways of adapting business to socio-economic conditions, the level of flexibility of management approaches and the extent of use of innovative technologies. Accordingly, it is advisable to present a generalized model “factors → changes in e-commerce strategies” that allows us to trace how the key factors of digital transformation are translated into practical management decisions (Table 2).

Table 2: Factors and changes in e-commerce management strategies.

Key factor	**Changes in e-commerce management strategies**
Consumer preferences (personalization, mobility, environmental friendliness)	Integration of AI to personalize the experience, use of big data to create customized offers; emphasis on mobile platforms and green products in the assortment
Market trends (AI tools, mobile commerce, sustainable development)	Developing strategies focused on sustainability and mobility; combining marketing and technological innovations to increase customer engagement
Local specifics (socio-cultural, political and economic conditions, military context, support for local brands)	Adapting global business models to local needs; supporting regional identity and local producers; and complying with regulatory requirements
Macroeconomic factors (currency instability, inflation, global challenges, digital infrastructure)	Development of flexible and anti-crisis strategies; diversification of sales channels; use of AI analytics for demand forecasting and risk management

Source: systematized based on Statista [11].

As we can see, Table 2 demonstrates that key environmental factors are directly transformed into strategic business decisions, and the integration of artificial intelligence is a common feature of all management areas in the field of e-commerce. The above factors of e-commerce development in the context of digital transforsmation also show that strategic management in this area should be based on the integration of innovative technologies and adaptation to a multi-component environment. Consumer preferences create demand for personalized and environmentally friendly experiences, which requires the implementation of artificial intelligence and mobile platforms in the business model. Market trends reinforce the importance of artificial intelligence tools, mobile commerce, and sustainable development as key drivers of competitiveness. Local specifics, driven by socio-cultural, political, and economic factors, require companies to be flexible and preserve local identity. Macroeconomic conditions also highlight the need to develop crisis-proof and sustainable management strategies that can respond to currency volatility, inflation risks, and global challenges. Thus, effective management in e-commerce is only possible with a comprehensive combination of strategic and technological solutions that can use artificial intelligence as a catalyst for innovation and business efficiency.A systematic view of the e-commerce management strategy in the context of digital transformation requires consideration of its structural elements and relevant business processes. It is important that each of these processes is being transformed today under the influence of artificial intelligence, which acts as a catalyst for innovation. Thanks to machine learning algorithms, predictive analytics, marketing communications automation, and intelligent logistics management systems, AI ensures an increase in the efficiency, accuracy, and effectiveness of business operations. Thus, the authors can clearly see how digital technologies are being integrated into management practices, forming a new paradigm of e-commerce development, as shown in Figure 1.

Vision and development goals
Business processes: defining the company's mission and values; setting strategic goals (market growth, profitability, innovation).
Business model and positioning
Business processes: model selection (B2C, B2B, C2C, D2C); value proposition development; competitive advantage identification.
Target audiences and customer experience
Business processes: consumer segmentation; development of customer scenarios (customer journey); personalization of offers.
Marketing strategy and promotion channels
Business processes: omnichannel, mobile solutions, SMM; brand management; customer acquisition and retention tools.
Product range and management
Business processes: product category structure; pricing management (dynamic pricing, premium and budget segments); new product development.
Technological infrastructure
Business processes: e-commerce platforms (CMS, ERP, CRM); integration with marketplaces.
Logistics and operations
Business processes: organization of warehouse processes; delivery (domestic, international); partnership with logistics operators.
Financial management and monetization
Business processes: revenue model (sales, subscriptions, transaction fees); cost management; investment in innovation.
Data management and analytics
Business processes: Big Data and AI analytics; demand forecasting; KPI performance monitoring.
Innovation and development
Business processes: implementation of new technologies (AR/VR, chatbots, automation); adaptation to the digital economy; continuous improvement of UX/UI.
Organizational structure and personnel management
Business processes: competencies in the field of digitalization; training and development of personnel; formation of a team to work with innovations.
Social responsibility and safety
Business processes: personal data protection; environmental friendliness and sustainable development; ethical business standards.

Figure 1: Unification of the main elements and business processes of the e-commerce management strategy.
Source: [17-21].

Thus, the e-commerce management strategy combines marketing, technological, financial, logistics, and innovation elements, as a result, it ensures competitiveness in the digital economy. Modern research indicates that the integration of artificial intelligence into e-commerce is not only a tool for improving operational efficiency, but also a strategic factor in the long-term competitiveness of a business [12]. The use of AI covers different levels of strategic management – from setting goals and choosing a business model to optimizing customer experience, marketing strategies, data management, finance, and logistics [13]. This multidimensional integration allows companies to form flexible business models, adapt to market dynamics, and develop innovative approaches to customer interaction, as evidenced by research in the field of digital transformation and Big Data [14]. In addition, AI defines new guidelines for strategic development and changes the competitive environment on a global scale [15], [16]. Table 3 systematizes the key areas of AI application in the strategic management of e-commerce with examples of global companies that demonstrate the practical results of such a transformation.

Table 3: Integration of artificial intelligence into business processes and e-commerce management strategy.

Strategy element	Key business processes	Application of AI	Examples of companies and results	Source
Vision and development goals	Formation of mission and strategic guidelines; Setting KPIs and monitoring	Forecasting market scenarios; Intelligent dashboards for KPI control	Amazon – predictive analytics to adapt strategic goals, increase flexibility	Amazon Tech Blog
Business model and positioning	Competitor analysis; Format selection; Niche search	Trend and segment detection algorithms	Shopify – AI analytics to find niche segments, increase sales for new sellers	Shopify Official Reports
Target audiences and customer experience	Segmentation; Customer journey; Personalization	Recommendation systems; AI chatbots; ML forecasting	Netflix – more than 80% of views through personalized recommendations, increased customer retention	research.netflix.com
Marketing strategy	Content marketing; SMM; Omnichannel	Generative AI; Campaign optimization; Emotion analysis	Coca-Cola – AI for creative content, increasing the effectiveness of advertising campaigns	Coca-Cola Marketing Case Studies
Assortment and product management	Cataloging; Dynamic pricing; New product management	AI for pricing; Demand forecasting	Zalando – AI to manage prices and demand, reduce inventory costs	Zalando Financial Reports
Technology infrastructure	Platforms; CRM/ERP; Cybersecurity	AI for cybersecurity and integration automation	Microsoft Azure – AI for data monitoring and protection, incident mitigation	Microsoft Case Studies
Logistics and operations	Warehouse management; Delivery planning; Inventory control	Route optimization; Warehouse robotization	DHL – AI route optimization and shipment forecasting, faster deliveries	gobeyond.ai
Financial management	Revenue management; Cost control; Forecasting	AI for fraud detection; Budgeting automation	PayPal – AI to reduce fraud and speed up transaction processing	PayPal Tech Blog
Data management and analytics	Big Data; Demand forecasting; KPI analytics	AI analytics; Predictive models	Google – AI for analyzing big data and consumer trends	Google Research
Innovation and development	R&D; UX/UI testing; New technologies	AI for A/B testing; Idea generation	Airbnb – AI for UX/UI testing and demand forecasting	Airbnb Case Studies
Organizational structure and staff	Training; Team management; Competence development	AI for HR analytics; Personalized learning	Unilever – AI in candidate screening and reducing hiring time	Unilever HR Reports
Social responsibility	Data protection; ESG; Eco-friendly practices	AI for ESG monitoring and data protection	IBM Watson – ESG analytics and cyber defense	IBM ESG Reports

The summary in Table 3 shows that companies that implement artificial intelligence in various elements of their management strategy achieve synergy between technological efficiency, personalization of the customer experience, and long-term competitiveness. Also, an analysis of the key elements of e-commerce management strategy in the context of digital transformation shows that traditional approaches are gradually losing their effectiveness, giving way to innovative models focused on integrating artificial intelligence into business processes. Artificial intelligence acts as a catalyst for innovation, providing a new level of adaptability, flexibility, and efficiency for e-commerce strategies. The implementation of technologies for data mining, automation of management processes, personalization of user experience, and optimization of logistics operations allows companies to achieve significant efficiency and competitiveness gains. Examples of leading companies such as Amazon, Alibaba, eBay, Walmart, and Shopify demonstrate that the systematic use of AI not only optimizes operating costs but also creates unique competitive advantages by improving customer experience, forecasting demand, personalizing offers, and increasing service speed. Thus, a modern e-commerce management strategy should be based not only on the principles of digitalization and automation, but also on the active implementation of artificial intelligence as an integrative tool for innovative development. As a result, the use of AI in e-commerce management strategies allows achieving synergy between technology and business, which becomes the basis for sustainable growth and the formation of a new competitive paradigm in the digital economy.

V. CONCLUSION

The study made it possible to comprehensively consider the transformation processes in the field of e-commerce and determine the role of artificial intelligence as a key factor in improving the efficiency of management strategies. It has been established that the digitalization of the economy is changing fundamental approaches to the formation of business models, positioning strategies and customer experience management, necessitating the integration of innovative technologies into all levels of enterprise functioning. Within the framework of the tasks set, the article systematizes the factors influencing the development of e-commerce and shows that the combination of macroeconomic conditions, changes in consumer preferences, regulatory reforms and local specifics forms a unique vector of market development. The proposed classification of e-commerce management strategies and the identification of their key elements made it possible to substantiate a system of business processes in which artificial intelligence acts as a catalyst for innovation. An analysis of the experience of leading companies (Amazon, Netflix, DHL, etc.) has shown that AI optimizes processes, personalizes the customerexperience, and increases business competitiveness.

This confirms that effective e-commerce management in today's environment is impossible without the integration of intelligent technologies into the strategic and operational aspects of the business. The scientific novelty of the study lies in identifying the relationship between digital transformation, innovative management, and the application of artificial intelligence in e-commerce. The practical significance of the results lies in the possibility of their application to create adaptive e-commerce development strategies, taking into account global trends. A promising direction for further research is to evaluate the effectiveness of implementing intelligent systems in various segments of e-commerce, as well as to study the risks associated with their use in the context of sustainable development and digital security.

ABSTRACT

This project presents a robust and efficient methodology for the optimal placement of Micro-Phasor Measurement Units (µPMUs) in radial distribution networks, with particular attention to Zero Injection Bus (ZIB)constraints and high levels of Distributed Generation (DG).The proposed approach combines mathematical optimization and the Adaptive Mutated Practical Swarm Optimization (AMPSO) algorithm to perform accurate voltage estimation and enhance network observability. By strategically placing µPMUs, the method reduces the number of measurement units needed while still meeting full observability and system monitoring goals. The frame work is validated on the IEEE 33- bus test systems, showing improved performance, reduced computational complexity, and compatibility with renewable energy integration. Results highlight the project's effectiveness in supporting smart grid development through cost-efficient, scalable, and practical solutions.

I. INTRODUCTION

The active distribution networks, denoted as ADN, have made power distribution networks on account of the fast use of renewable energy resources. This trend brings about new challenges for traditional state estimation (SE) techniques because increased complexity and variability of the network operations [1]. PMUs have recently emerged as an important technology in tackling such challenges with high-resolution real-time time data that improves the capabilities of monitoring and controlling the power grid [2]. The optimal place for the installation of the PMU in order to allow the total system Observability remains a vibrant and thriving area of research. There has been considerable research activity over the 20 years focused on the solution of the transmission network's Optimal PMU placement problem (OPP). However, more work is required in distribution networks. There are indications that Losses occur more in the distribution networks compared to the transmission networks. These include: networks, stressing the requirement for high-level control, monitoring, and reconfiguration of the above-mentioned networks [3], [4]. The use of µPMUs is more economical for the smart grid, as it decreases the amount of smart meters that are needed [5]. Even traditional PMUs are quite expensive and not feasible for extensive distribution networks with multiple buses, µPMUs provide alternatives because of their increased accuracy and sampling rate, which are necessary for the low values of X/R ratios of distribution networks [6]. Such precision is required in order to detect even more subtle variations in the angle and size of state variables. Nevertheless, much still needs to be done in the essential placement of µPMUs in radial-type Distribution networks, especially about ZIBs. In [7], the researchers employed Integer Linear Programming (ILP) for resolving the OPP problem, taking into account the ZIB effect in the context of power transfer networks. Numerous meta-heuristic approaches have been recorded in [8].

These studies Specifically, it will highlight limitations such as ZIB existence and contingency. There will which tend to both exacerbate the nonlinearity and the scaling problem in scale distribution networks. In radial distribution networks, using dual employ line relays (DULR) and PMU for economic-based observability analysis [9] remains to be solved. Co-optimal PMU placement raises costs [10], whereas ILP-heuristic methods for distribution networks [11] do not take into account ZIB effects. Applications involving distribution level PMU (DPMU) [12] and exhaustive search algorithms of a transmission network [13] are also discussed. Full observability is ensured by the use of ILP frameworks [14], although complex radial ZIB configurations are still difficult. Some real-world cases of graph classification include. The limitations are taken into account in [15], including single PMU outages and line outages. The authors of [16] proposed a three-stage algorithm for PMU placement: guarantees full observation ability in transmission networks. However, this algorithm requires a pruning phase, which may add extra computation time for large distribution networks. A modified greedy algorithm for finding minimum spanning trees has. Algorithm is applied in [17] for resolving OPP problem in both normal and emergency situations, whereas [18] defines a multistage PMU placement. In the context of transmission networks, binary dragonfly algorithm outperforms both BPSO and modified BPSO.

Real-world limitations are taken care of by the such as ZIBs, integrated renewables, and topological changes [19-21]. In [22], a new ZIB modeling approach based on the virtual connection method is proposed. However, it may fail to produce the best results for total system observability. According to [23] It highlights the challenges-related to scalability in large radial networks and the complex nature of the ZIB model. Various studies have examined PMU placement and its challenges, this paper aims to bridge the gaps by presenting a novel approach for µPMU placement and voltage estimation, specifically considering the complexities posed by ZIBs. This paper presents an optimized µPMU placement strategy designed to ensure comprehensive observability and accurate voltage estimation in the presence of ZIBs. The study focuses on the economic placement of distribution-stage phasor measurements to enhance system observability, highlighting several key contributions: A technique to choose the best µPMU locations for radial distribution systems while taking Zero injection constraints into account. A review of voltage estimation considering zero injections and µPMU measurements. ZI buses decrease the number of µPMUs needed, resulting in a fully observable and economically feasible network. The placement of µPMUs is mostly determined by network topology and not affected by the installation of distributed generation units or other voltage- regulation apply [19-21].

II. PROBLEM STATEMENT

The following presents the placement of µPMUs within radial distribution networks are critical in arriving at the exact voltage estimate that allows for efficient operation and monitoring of these networks. Due to the This is because of the difficulty involved with the measurement of voltage due to the complexity of these systems. It may not always be possible to maintain desired magnitudes and phase angles at all buses. Therefore, µPMUs are placed accordingly to provide adequate observability, reducing the number of units required while still. This allows for an estimate of the voltage at each bus correctly. In radial distribution networks, ZIBs can be can be exploited in order to reduce the number of µPMUs required. A ZIB is a bus where no active or reactive power is injected or consumed. Indirect state estimation is made possible by the information from ZIBs due to the fact that their voltages can be usually deduced from the neighbouring buses. This is further complicated by the inclusion of Photovoltaic (PV)-based DG yet contribute to this task by the added power injections, but these can also be measured and factored into the voltage estimation process. Therefore, the problem is to find the optimal location for placing µPMUs in radial distribution networks with PV-based DG while-to consider it as a ZIB constrained problem, in order to minimize the number of µPMUs and full observability of the network for the precise voltage estimation.

II.1 DECISION VARIABLES

Let;
N_b = Number of buses
N_{PMU} = Number of micro-PMUs

Binary placement vector:

$$\mathbf{z} = [z_1, z_2, \dots, z_{N_b}]$$

$$z_i = \begin{cases} 1, & \text{if micro-PMU is placed at bus } i \\ 0, & \text{otherwise} \end{cases}$$

State variables (voltage estimation):

$$\mathbf{x} = [V_1, \theta_1, V_2, \theta_2, \dots, V_{N_b}, \theta_{N_b}]^T$$

II.2 OBJECTIVE FUNCTION

Multi-objective optimisation (converted to single objective):

$$\min F = w_1 \sum_{i=1}^{N_b} z_i + w_2 \parallel \mathbf{z} - \mathbf{z}^{req} \parallel + w_3 \parallel \hat{\mathbf{x}} - \mathbf{x} \parallel_2^2$$

Where:

- First term → minimise number of micro-PMUs
- Second term → network observability
- Third term → voltage estimation error
- w_1, w_2, w^3 → weighting factors
- X → estimated voltage states

Measurement Model (With Micro-Pmus)

$$y = h(x) + e$$

Where:

- y → voltage & current phasor measurements
- $h(x)$ → nonlinear measurement function
- e→ voltage estimation error

II.3 ZERO INJECTION BUS

For zero-injection buses

$$k \in \Omega_{ZIB}$$

Active power:

$$P_k = \sum_{j \in \mathcal{N}_k} V_k V_j (G_{kj} \cos\theta_{kj} + B_{kj} \sin\theta_{kj}) = 0$$

Reactive power:

$$Q_k = \sum_{j \in \mathcal{N}_k} V_k V_j (G_{kj} \sin\theta_{kj} - B_{kj} \cos\theta_{kj}) = 0$$

These constraints enhance state observability without additional PMUs.

II.4 AMPSO PARTICLE REPRESENTATION

Each particle representes

$$\mathbf{X}_i = [\mathbf{z}_i \quad \mathbf{x}_i]$$

Velocity update:

$$\mathbf{V}_i^{t+1} = \omega(t)\mathbf{V}_i^t + c_1(t)r_1(\mathbf{P}_i - \mathbf{X}_i^t) + c_2(t)r_2(\mathbf{G} - \mathbf{X}_i^t)$$

Position update:

$$\mathbf{X}_i^{t+1} = \mathbf{X}_i^t + \mathbf{V}_i^{t+1}$$

Binary update for PMU placement (sigmoid):

$$z_i^{t+1} = \begin{cases} 1, & \text{if sigmoid}(v_i^{t+1}) > rand() \\ 0, & \text{otherwise} \end{cases}$$

II.5 ADAPTIVE PARAMETER CONTROL

Adaptive inertia weight:

$$\omega(t) = \omega_{\max} - \left(\frac{\omega_{\max} - \omega_{\min}}{T}\right) t$$

II.6 MUTATION STRATEGY (AMPSO ENHANCEMENT)

If stagnation is detected:

$$\mathbf{X}_i^{mut} = \mathbf{X}_i + \sigma(t)\mathcal{N}(0,1)$$

Adaptive mutation strength:

$$\sigma(t) = \sigma_{\max}\left(1-\frac{t}{T}\right)$$

II.7 CONSTRAINT HANDLING

Voltage limits:

$$V_i^{\min} \le V_i \le V_i^{\max}$$

PMU count constraint:

$$\sum_{i=1}^{N_b} z_i \le N_{PMU}^{\max}$$

Penalty function:

$$F_{pen} = F + \lambda \sum \text{constraint violations}$$

Termination Condition

$$t = T \text{or} \mid F^t - F^{t-1} \mid < \varepsilon$$

III. METHODOLOGY

The methodology for optimal placement of µPMUs and DGs in radial distribution networks with ZIB constraints involves several key steps. First, system data, including bus and branch details, as well as DG characteristics, are collected. ZIBs are identified to leverage their properties for minimizing the number of µPMUs needed for network observability. The placement problem is formulated as a MILP optimization, with the objective of determining the fewest number of µPMUs required while ensuring full observability, accounting for both ZIB constraints and DG contributions. After solving the MILP, the optimal µPMU locations are identified, and the voltage estimation process begins by initializing parameters and incorporating ZIB and DG constraints into the Jacobian matrix. An iterative AMPSO algorithm is applied to estimate the voltage profile across all buses, with thecamoebian matrix and measurements being updated at each step.

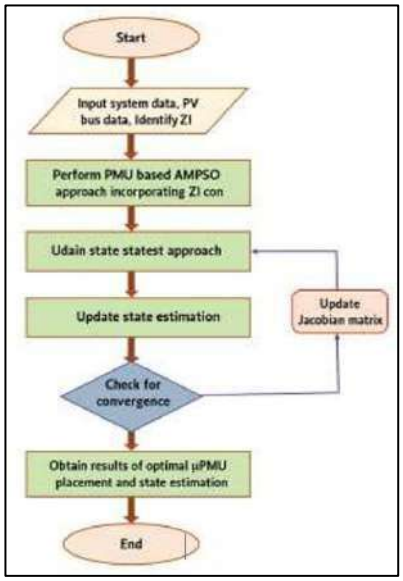

Figure 1: Flowchart:Process of optimal µPMU placement and voltage estimation.
Source: Authors, (2026).

Steps are repeated until the convergence criteria are satisfied, ensuring the accuracy of voltage estimation. Once the final state estimation is obtained, the voltage profile is computed on the basis of μPMU data, and this is verified for both observability and accuracy. Lastly, the final bus voltage estimates and optimal μPMU installation locations are show cased how ZIBs and DGs enhance the efficiency of μPMU deployment and accurate voltage estimation in the network Fig1showsthe flowchart of optimal μPMU placement and voltage estimation of active distribution network.

IV. SIMULATION RESULT AND DISCUSSION

This section details the outcomes of optimal μPMU placement and examines the voltage profile across three scenarios. Simulations are carried out on the MATLAB platform. Three scenarios are used to test the suggested approach. (I) Condition I-Under normal conditions, (II) Condition II- consideration of ZI bus (III) the presence of Distributed Generators (DGs) in distribution networks.

IV.1 MICRO PMU PLACEMENT

IV.1.1 Materials and Methods

The following illustrates the placement of μPMUs in radial distribution networks. play a crucial role in determining the precise voltage level that ensures efficient operation and monitoring of these networks. Because of the This is due to the difficulty associated with the measurement of voltage for these complex systems.

Table 1: Locations of micro-PMU in normal condition.

Feeder	Positions	No. Of Micro PMUS
33	2,5,8,11,14,17,20,24,29,30,32	11
69	2,4,6,9,14,17,20,23,26,28,31,34,38,40, 44,47,50,51,55,57,59,62,65,68	24

Source: Authors, (2026).

Sometimes, it may be difficult to maintain the desired magnitude and phase value at all buses. Hence, the installation of μPMUs follows in a manner as to supply the observability, minimizing units needed while still With this, an estimation of the voltage can be made at every bus. correctly. In radial distribution networks, ZIBs can be used can be leveraged in order to minimize the number of μPMUs needed. A ZIB is a "bus where neither active nor reactive power is injected or consumed." Indirect state estimation is feasible through the information provided by ZIBs. because it is possible to generally conclude their voltages from the surrounding buses. This scenario gets further complicated by the consideration of Photovoltaic (PV)-based DG. but contribute to this process through the increased power injections, but these can also be measured and quantified in the estimate for the voltage process .Hence, the problem is as follows: To find the best location of placing μPMUs in radial distribution networks, even where PV-based DG units, comprise to consider it as ZIB constrained, in order to keep the number of μPMU as low as possible and full observability of the network for the accurate voltage It is an estimation.

IV.1.2 Condition Ii -Consideration of Zi Buses

ZI buses are points where there are neither load buses nor generator buses, which in many cases are found in radial distribution systems. The placement of μPMUs at critical points and taking into consideration the ZI buses may lead to a reduction in the total μPMUs required due to less impact of ZI buses on network observability. Taking for example if the ZI buses are considered and included in the IEEE 33-bus system, then changes may occur in the original placement plan for 11 PMUs, which may reduce in number for improved coverage. The selection for placement would include best strategic nodes that enable comprehensive coverage for the network while taking into consideration the role of ZI buses to optimize resource use and improve monitoring efficiency. In IEEE 69-bus systems, the same approach is considered for placement. Instead of using 24 PMUs for comprehensive coverage, incorporating ZI buses may optimize placement plans. By considering ZI buses for placement for μPMUs, power companies may optimize resource monitoring investment and improve overall operational efficiency for power distribution networks. Table II illustrates points for ZI buses within a distribution network. ZIBs are points where either loads or generators are connected; they are usually best points for monitoring in radial power distribution networks placed for monitoring power analytics at critical points for power flow and system dynamics within power transmission networks. Table III conditions. This instance aptly demonstrates the benefits of ZIBs' incorporation within the placement strategy of μPMUs. It helps in optimizing the usage of resources while still being able to make monitoring possible. It becomes possible to have equal network observability with reduced monitoring devices due to incorporation of ZIBs within the placement strategy of μPMUs.

Table 2: Location of ZIB for test systems.

Systems	No. Of ZI Busses	ZI Bus Location
33	2	6,27
69	20	2,3,4,5,15,19,23,25, 30,31,32,38,42,44, 47,56,57,58,60,63

Source: Authors, (2026).

Table 3: Micro PMU position with and without ZIB.

Systems	No. of µPMUs and position without ZIB	No. of µPMUs and position with ZIB
33	11 & (2,5,8,11,14,17,20,244,27,30,32)	10&(2,5,8,11,14, 17,21,,29,32)
69	24&(2,6,9,14,17,20, 23,26,29,32,35,37,40, 43,46,47,50,52,55,58, 61,64,66,68) 20	16&(3,4,6,14,17,20, 26,34,41,45,59,51,54. 64,66,68)

Source: Authors, (2026).

When a PV-based DG is connected to the power grid, it injects main sufficient amounts of power supply current, phase angles, and frequency that is related to DG functioning. This direct measurement capability allows the system operator to measure the effect of DG on the power system instantly. Table IV shows the location of DGs and µPMUs.

IV.1.3 Voltage Profile Estimation using Mpmus Technology with and without Zibs

Table 4: Voltage Profile estimation using Micro PMUs with & without ZIBS.

System	DG buses	No. of µPMUs	Positions
33	8,17,30	10	2,5,8,11,14,17,21,24,29,32
69	23,40,52,66	24	2,6,9,14,17,20,23,26,29,32,35,37,40,43,46,48,50,52,58,61, 64,66,68

Source: Authors, (2026).

IV.1.4 Results for the 33-Bussystem

Figure 2 and Figure 3 depict the 33 bus radial distribution network with µPMUs, taking into account and disregarding ZIBs. In Figure 2, it is evident that another advantage, in this case, of including ZIBs, is minimizing the need for an effective number of µPMUs to ensure overall observability. With carefully located µPMUs and ZIBs factored into account, fewer units are needed to achieve equal levels of monitoring. In Figure 3, further evidence shows that voltage profile estimation is nearly equal with and without ZIBs, thus proving that ZIBs do not impair voltage estimation capability.Such optimization can result in the reduction of costs and a more optimized deployment of µPMUs, thereby optimizing the deployment efficiency. Thus, using ZIBS can enhance the deployment efficiency of µPMUs without affecting the voltage profile of the distribution system.

IV.1.5 Results for the 69-BusSystem

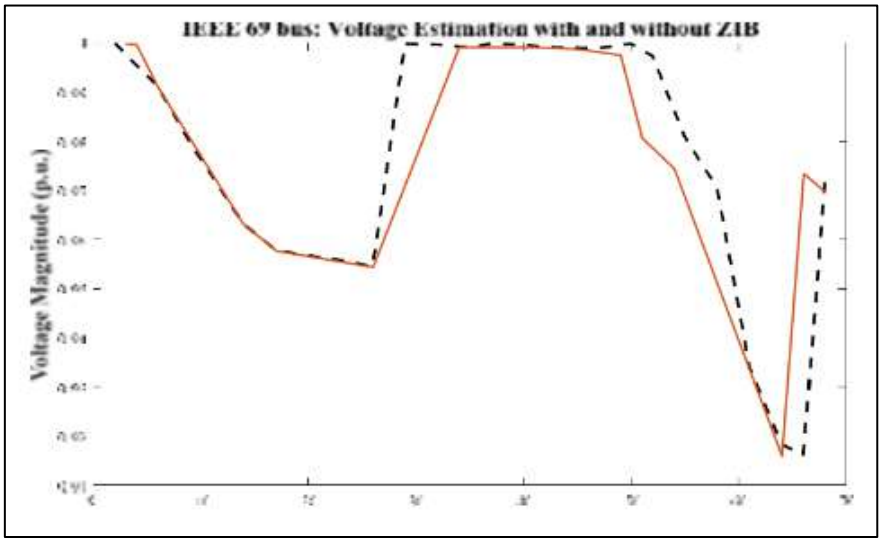

Figure 5: Results for the 69 Bus System.
Source: Authors, (2026).

Figure 4 highlights that incorporating ZIBs into the network configuration effectively reduces the number of µPMUs required to maintain full network observability. Additionally, Figure 5 indicates that the voltage profile of the system remains largely unchanged with the inclusion of ZIBs. This demonstrates that utilizing ZIBs does not significantly impact the voltage stability or distribution within the network. Therefore, the integration of ZIBs can enhance the efficiency of µPMU deployment, optimizing resource usage while maintaining a stable voltage profile across the distribution system.

Table 5: Comparative analysis under condition- II.

Reference	Observability	NµPMU(IEEE 33)	NµPMU(IEEE 69)

Figure 4 and Figure 5 illustrate the 69-bus radial distribution network with µPMUs installed at specific nodes, both considering and excluding ZIBs.

Table 6: Comparative analysis under condition-I.

Reference	Method	NµPMU[a] (IEEE33)	NµPMU[a] (IEEE 69)	Voltage estimation
[14]	Graphtheory	11	24	No
[15]	ILP	NR	24	No
[17]	ILP	11	NR[b]	No
[2]	ILP	NR	24	No
Present work	AMPSO	10	24	Yes

Source: Authors, (2026).

Figure 4 highlights that incorporating ZIBs into the network configuration effectively reduces the number of µPMUs required to maintain full network observability. Additionally, Figure 5 indicates that the voltage profile of the system remains largely unchanged with the inclusion of ZIBs. This demonstrates that utilizing ZIBs does not significantly impact the voltage stability or distribution within the network. Therefore, the integration of ZIBs can enhance the efficiency of µPMU deployment, optimizing resource usage while maintaining a stable voltage profile across the distribution system. Comparing the proposed method with the available literature shows the advantages of the latter in terms of µPMU deployment and voltage estimation. It may be seen from Table V, Condition I that while methods such as graph theory and ILP require 10 µPMUs for the IEEE 33-bus system and 24 µPMUs for the IEEE 69-bus system, neither of them offers voltage estimation. The same number of µPMUs are offered by the proposed AMPSO-based method but with additional voltage estimation capabilities that make it more useful. It follows from Table VI, Condition II that 10 µPMUs for the IEEE 33-bus system and 16 for the IEEE 69-bus system are sufficient for the proposed approach against 17–18 µPMUs required by other approaches that ensure full observability. It may, thus, be concluded that the proposed method is efficient for µPMU placement and superior in terms of functionality since both reduction of the µPMU requirement along with enhanced monitoring functionalities are possible.

V. CONCLUSIONS

The present study seeks to reduce the computational time required for the determination of optimal placement for µPMUs under different configurations of distribution networks. It, therefore, introduces two key strategies toward the realization of this objective. First, it considers the identification of the optimum placement for µPMUs in distribution networks, with and without ZIBs-nodes at which neither a load nor a generator is connected. Secondly, it evaluates the voltage profile of a radial distribution feeder using µPMU technology in conjunction with the AMPSO algorithm in these network conditions. In this regard, the study proposes MILP to arrive at the optimum number and location µPMUs that are necessary for normal network operation. Towards this end, the initial installation of µPMUs takes place at critical points in the network. Subsequent installations take into account ZI buses to reduce the total number of µPMUs required.

Comparative analyses with other methods demonstrate that the proposed strategy achieves better performance, minimizing the number of µPMUs for both the IEEE 33-bus and IEEE 69-bus systems, while estimating the voltages-a feature lacking in most of the existing approaches. These results further demonstrate the practical benefits of incorporating ZIBs in µPMU placement and provide a cost-effective scalable solution for enhanced monitoring in smart distribution networks. Future work can continue this approach for larger and more complex systems and investigate the possibility of real-time implementation.

ABSTRACT

Automatic Vulnerability Prediction (AVP) has emerged as a promising approach for identifying security weaknesses in source code using machine learning techniques. While classic software metrics have been widely used for this purpose, they primarily capture general code attributes such as size and complexity and do not directly quantify security-relevant characteristics. This paper proposes a novel set of security-specific code metrics explicitly designed to measure vulnerability-prone properties of C/C++ programs. The proposed metrics focus on two major sources of vulnerabilities: tainted source usage and memory management and access practices. These metrics are extracted at the code slice level through static analysis and used as features to build vulnerability prediction models. We evaluate the effectiveness of the proposed metrics using multiple machine learning classifiers on a large-scale, publicly available dataset comprising over 420,000 labeled code slices. Experimental results show that the proposed metrics achieve strong and consistent performance across multiple vulnerability types, with particularly high effectiveness for memory-related vulnerabilities. A comparative analysis with classic software metrics demonstrates that security-specific metrics significantly improve vulnerability detection for pointer- and array-related weaknesses while remaining computationally efficient. These findings highlight the value of direct security measurement for enhancing automatic vulnerability prediction.

I. INTRODUCTION

Software metrics have long been used to quantify internal attributes of software systems, such as size, complexity, and coupling. Owing to their ability to provide objective and computable measurements, software metrics have been successfully applied in a wide range of software engineering and static code analysis tasks, including development cost estimation, change-proneness analysis, change impact analysis, defect prediction, and code clone detection. In the context of Automatic Vulnerability Prediction (AVP), several studies have leveraged software metrics as predictive features to identify vulnerable code entities at different granularity levels, such as files, functions, and code slices. The motivation for using software metrics in vulnerability prediction is twofold. First, metrics offer a practical means to quantify structural and behavioral characteristics of software, including complexity and inter-module dependencies. Second, empirical evidence suggests a correlation between these characteristics and the presence of vulnerabilities. Complex and highly coupled code typically requires greater effort from developers and reviewers and poses increased challenges for static and dynamic analysis tools, thereby increasing the likelihood of implementation errors and security flaws. In addition, metric-based approaches are computationally efficient and easily integrated with traditional machine learning techniques, enabling the construction of Vulnerability Prediction Models (VPMs) without requiring sophisticated code representations or the substantial computational resources demanded by recent deep learning approaches [1]. Despite these advantages, classic software metrics remain indirect indicators of security. While they are effective at capturing general software quality attributes, they are not explicitly designed to measure security-relevant characteristics. As a result, their ability to precisely capture the root causes of vulnerabilities is inherently limited.

Several prior studies have highlighted the need for security-specific code metrics that directly quantify aspects of code related to security weaknesses, such as unsafe data handling and improper memory usage. These works emphasize that tailored metrics are essential for capturing vulnerability-prone patterns that are not adequately reflected by traditional measures of complexity or size. To address this research gap, this paper proposes a novel set of security-specific code metrics explicitly designed to quantify critical code characteristics that influence software security. The proposed metrics focus on two fundamental and widely recognized sources of vulnerabilities in C/C++ programs: tainted source usage and memory management and access practices. By directly measuring properties such as unsanitized tainted variables, unsafe pointer operations, and improper memory allocation and access patterns, the proposed metrics provide a more targeted and interpretable assessment of vulnerability-prone code. Furthermore, this study investigates the effectiveness of these security-specific metrics as features for building vulnerability prediction models using machine learning algorithms. The proposed approach is evaluated on a large-scale, publicly available dataset of labeled code slices, using multiple classifiers and standard evaluation metrics. Experimental results demonstrate that the proposed metrics are particularly effective for predicting memory-related vulnerabilities and complement classic software metrics in other vulnerability categories.

Overall, this work contributes a practical and computationally efficient methodology for enhancing automatic vulnerability prediction and offers new insights into the role of security-specific measurement in software security analysis. The remainder of this paper is organized as follows. Section II reviews related work on vulnerability prediction, including the use of traditional software metrics and fine-grained code representations. Section III presents the proposed security-specific code metrics, detailing their design for capturing tainted source usage and memory management practices, as well as the methodology for extracting these metrics from source code. Section IV describes the experimental setup, including dataset preparation, model training, and evaluation protocols. Section V presents and discusses the results, including classifier performance, evaluation across different vulnerability types, and a comparison with classic metrics, followed by a discussion of the approach's limitations. Finally, Section VI concludes the paper and outlines directions for future research aimed at extending and generalizing the proposed metrics for broader applications in source code vulnerability prediction.

II. RELATED WORK

AVP has been extensively studied as an effective means to reduce the cost and effort associated with manual security analysis. Inspired by defect prediction research [2-11], many studies have adopted traditional software metrics to quantify internal code attributes such as size, complexity, coupling, and cohesion, and to use them as predictors in machine learning–based Vulnerability Prediction Models (VPMs). Early work by Shin and Williams [12-14] demonstrated that complexity metrics can distinguish vulnerable from non-vulnerable functions, providing initial empirical evidence of the relationship between code complexity and security flaws. Subsequent studies [15-20] investigated different families of metrics, including complexity, coupling, cohesion, code churn, and developer activity metrics, across various software systems and vulnerability datasets. Despite these promising results, the performance of metric-based VPMs has remained inconsistent, often suffering from high false-positive or false-negative rates. According to [21] identified several fundamental challenges in applying VPMs, including coarse-grained vulnerability labels, data imbalance, and the lack of security-aware features, which collectively limit the practical effectiveness of these approaches. One of the main limitations of early metric-based VPMs is their reliance on coarse-grained program entities, such as files or functions, which restricts the ability to precisely localize vulnerabilities. To overcome this limitation, researchers have explored fine-grained code representations, including program slices and vulnerability-related code fragments.

Program slicing, originally introduced by [22] , has been successfully applied to bug classification and vulnerability analysis by isolating statements that are semantically related to a given computation or security-sensitive operation. Building on this concept, introduced Code Gadgets (CGs) [23], Syntax-based Vulnerability Candidates (SyVCs), and Semantics-based Vulnerability Candidates (SeVCs) [24] as fine-grained representations explicitly tailored for vulnerability detection. These representations capture compact sets of statements that preserve the syntactic or semantic characteristics of vulnerable code. Deep learning–based approaches such as VulDeePecker [23] and SySeVR [24] demonstrated that leveraging such vulnerability-aware representations significantly improves detection accuracy while enabling vulnerability localization. Motivated by the effectiveness of fine-grained representations, by [1], [25] investigated whether code metrics could be applied at a finer level of granularity to improve vulnerability prediction. Instead of computing metrics over entire files or functions, metrics were extracted directly from Code Gadgets and SeVCs, which preserve the semantic context of vulnerabilities. The experimental results showed that traditional metrics, including Lines of Code (LOC), McCabe complexity, and Halstead metrics, can effectively characterize vulnerable code fragments when applied at this level. Moreover, these metric-based VPMs achieved competitive precision and recall while enabling accurate localization of vulnerable code.

Despite the demonstrated effectiveness of traditional software metrics, researchers [17], [21] have emphasized that these metrics are inherently indirect indicators of vulnerabilities. They primarily capture structural and syntactic properties of code rather than explicitly modeling security-relevant behaviors. As a result, researchers in [26] have proposed vulnerability-oriented metrics, to better capture security concerns. Despite this effort, there remains a lack of a comprehensive and structured set of metrics explicitly designed to quantify multiple security dimensions, such as tainted data propagation, improper memory management, and misuse of security-sensitive constructs. This limitation constrains the ability of VPMs to fully capture the semantics of vulnerabilities, even when fine-grained code representations are employed. The present study extends this body of work by introducing a novel set of security-specific code metrics explicitly designed to quantify critical security-related properties of the code. Unlike traditional metrics, which serve as indirect proxies for vulnerability-prone code, the proposed metrics directly model security-relevant behaviors, including tainted sources, memory management practices, and other vulnerability-inducing patterns. By leveraging these metrics as features in machine learning–based VPMs and evaluating them on publicly available labeled datasets, this work bridges the gap between structural software analysis and security-aware vulnerability prediction. In doing so, it builds upon prior metric-based and fine-grained approaches while advancing toward a more precise and semantically grounded assessment of software security.

III. MATERIALS AND METHODS

III.1 APPROACH OVERVIEW

The problem of vulnerability prediction is formulated as a supervised binary classification task. Let $C = \{c_1, c_2, \ldots, c_n\}$ represent a corpus of code entities (e.g., code slices, functions, or files), where each code entity c_i is associated with a set of security-specific metrics and a binary label indicating its vulnerability status. For each code entity c_i, we extract a feature vector $\mathbf{x_i} = (x_{i1}, x_{i2}, \ldots, x_{im}) \in \mathbb{R}^m$, where m represents the number of proposed metrics. Each feature x_{ij} quantifies a particular security aspect of the code entity, such as the number of unsanitized tainted variables or the count of uninitialized pointers. The vulnerability status of each code entity is represented by a binary label $y_i \in \{0,1\}$, where:

- $y_i = 1$ indicates that the code entity is vulnerable
- $y_i = 0$ indicates that the code entity is clean (non-vulnerable)

The objective is to learn a classification function $f : \mathbb{R}^m \rightarrow \{0,1\}$ that maps the feature vector x_i to a predicted vulnerability label $\hat{y}_i : \hat{y}_i = f(x_i ; \theta)$. Where θ denotes the parameters of the classification model learned from the training dataset $D\_train = \{(x_1, y_1), (x_2, y_2), \ldots, (x_n, y_n)\}$. In this study, we evaluate three classification algorithms, including XGBoost, Random Forest, and Logistic Regression. The proposed security-specific metrics are computed at the program slice granularity level, where each slice represents a semantically meaningful code fragment associated with a potential vulnerability. Model performance is evaluated using Recall (R), Precision (P), False Positive Rate (FPR), and False Negative Rate (FNR), as described in Section 4.3.

III.2 PROPOSED METRICS

Our goal is to address AVP in a direct manner by proposing a set of metrics that quantitatively express critical security-related properties of the code. In this initial study, we focus on vulnerability prediction for C/C++ programs. Two major security aspects are considered: use of tainted sources and memory management and access. The proposed metrics are detailed in the following subsections.

III.2.1 Use of Tainted Sources

A tainted source represents any external source of untrusted data. In C/C++ programs, tainted values may originate from command-line arguments, user input functions (e.g., fgetc, getc, getchar), file input, or environment variables. The use of tainted values without proper sanitization may lead to critical vulnerabilities such as buffer overflows, command injection, and other memory-related flaws, particularly when such values are passed to unsafe library functions (e.g., strcpy, strcat). Table 2 presents the proposed metrics for quantifying the use of tainted sources.

Table 1: Use of tainted sources metrics.

Metric	Description
#Tainted_Var	Total number of tainted variables
#San_Tainted_Var	Number of sanitized tainted variables
#Unsan_Tainted_Var	Number of unsanitized tainted variables
#San_Passed_To_Unsec_Funcs	Number of sanitized tainted variables passed to unsafe library functions
#Unsan_Passed_To_Unsec_Funcs	Number of unsanitized tainted variables passed to unsafe library functions

Source: Author, (2026).

III.2.2 Memory Management and Access

Memory management encompasses dynamic allocation, memory access, and deallocation. In C/C++, dynamic memory allocation is performed using functions such as malloc or new. Improper memory allocation or deallocation may lead to memory leaks, dangling pointers, or use-after-free vulnerabilities. Memory access relies heavily on pointers and arrays. Unsafe pointer operations (e.g., uninitialized pointers, pointer arithmetic, type casting) and improper array access (e.g., out-of-bounds access) are common sources of vulnerabilities due to the lack of inherent bounds checking in C/C++. Table 2 summarizes the proposed metrics related to memory management and access.

Table 2: Memory management and access metrics.

Metric	Description
#Allocation_Reallocation	Number of dynamic memory allocation and reallocation operations
#Deallocation	Number of memory deallocation operations
#Total_of_Pointers	Total number of pointer variables
#Uninitialized_Pointers	Number of pointers not initialized before use
#Initialized_Pointers	Number of properly initialized pointers
#Pointers_Arithmetic	Number of pointer arithmetic operations
#Casted_Pointers	Number of pointer type casting operations
#Total_Arrays	Total number of array declarations
#Fixed_Size_Arrays	Number of arrays with fixed size
#Variable_Size_Arrays	Number of arrays with variable size
#Use_of_Size_T_As_Array_Size	Number of arrays using size_t for size specification
#Array_Boundary_Check	Number of array accesses with explicit boundary checking

IV. EXPERIMENTAL EVALUATION

IV.1 DATA PPREPARATION

Since vulnerability prediction is treated as a supervised binary classification problem, labeled datasets are required. Based on granularity level, dataset quality, size, and vulnerability type coverage, we selected the Semantic Vulnerability Candidates (SeVCs) dataset proposed by [24]. The dataset contains 420,627 code entities extracted from 1,591 open-source projects from the NVD [27] and 14,000 programs from SARD [28]. It includes 56,395 vulnerable and 364,232 clean code entities. The dataset is divided into four parts according to four vulnerability types [1]:

1. Library/API Function Call: vulnerabilities that are related to library/API function calls.
2. Array Usage: vulnerabilities that are related to arrays (e.g., improper use in array element access, array address arithmetic, address transfer as a function parameter).
3. Pointer Usage: vulnerabilities that are related to pointers (e.g., improper use in pointer arithmetic, reference, address transfer as a function parameter).
4. Arithmetic Expression: vulnerabilities that are related to improper arithmetic expressions (e.g., an integer overflow).

Table 3 summarizes statistics of the used dataset.

Table 3: Descriptive statistics about the CGs dataset.

	Number of vulnerable slices	Number of clean slices	Total
Library/API Function Call (FC)	13603	50800	64403
Array Usage (AU)	10926	31303	42229
Pointer Usage (PU)	28391	263450	291841
Arithmetic Expression (PU)	3475	18679	22154

Source: Author, (2026).

To prepare the metrics dataset that we used to train and validate VPMs, we implemented a custom static analysis tool in Java. As a first step, the source code of each entity of the SeVCs dataset is transformed into the srcML [29], [30] representation, which provides a lightweight XML-based format that preserves both the syntactic structure and lexical information of the code, thereby facilitating accurate and language-aware parsing. The tool operates at the program slice granularity level, where each slice represents a semantic code fragment associated with potential vulnerabilities. For each slice, the corresponding srcML representation is parsed to construct an abstract view of the code structure, including declarations, statements, expressions, and control constructs. Based on this representation, the proposed metrics are computed by traversing the srcML tree and identifying security-relevant constructs. Each instance in the generated dataset consists of the features vector and the class label as described in the approach overview sub-section.

IV.2 MODEL TRAINING AND EVALUATION

We used the metric dataset described in the previous subsection to train and evaluate the classification models for each vulnerability types: FC, AU, PU and AE. We evaluated three widely used classification algorithms that have demonstrated strong performance in prior vulnerability prediction research: XGBoost, Random Forest, and Logistic Regression. These classifiers were selected to cover complementary learning paradigms, including ensemble boosting, ensemble bagging, and linear classification. To mitigate the impact of class imbalance, the Synthetic Minority Over-sampling Technique (SMOTE) was applied to the training data only, ensuring that no information from the test folds was leaked into the training process. Model hyperparameters were optimized using grid search combined with cross-validation, following the experimental protocol adopted in related work. To ensure robust and unbiased evaluation, we employed 10-fold cross-validation, where the dataset is partitioned into ten disjoint folds. In each iteration, nine folds are used for training and one fold for testing, and the process is repeated until each fold has served as the test set exactly once. The final performance results correspond to the average values obtained across all folds. Model performance is assessed using four standard evaluation metrics widely used in vulnerability prediction research: Recall (R), Precision (P), False Positive Rate (FPR), and False Negative Rate (FNR).

Recall measures the ability of the model to correctly identify vulnerable code slices, while Precision quantifies the proportion of predicted vulnerable slices that are truly vulnerable. High values of Recall and Precision indicate better model performance. In contrast, FPR measures the proportion of clean code slices incorrectly classified as vulnerable, and FNR measures the proportion of vulnerable slices that are incorrectly classified as clean; therefore, lower values of FPR and FNR indicate better performance. These metrics are formally defined as follows:

Recal

$$R = \frac{\mathrm{TP}}{\mathrm{TP} + \mathrm{FN}} \tag{1}$$

Precision

$$P = \frac{\mathrm{TP}}{\mathrm{TP} + \mathrm{FP}} \tag{2}$$

False Positive Rate

$$FPR = \frac{\mathrm{FP}}{\mathrm{FP} + \mathrm{TN}} \tag{3}$$

False Negative Rate

$$FNR = \frac{\mathrm{TP}}{\mathrm{TP} + \mathrm{FN}} \tag{4}$$

In the context of vulnerability prediction, the output of a Vulnerability Prediction Model (VPM) can be interpreted using four possible outcomes. A True Positive (TP) corresponds to a vulnerable code slice that is correctly classified as vulnerable. A True Negative (TN) refers to a clean (non-vulnerable) code slice that is correctly classified as clean. A False Positive (FP) represents a clean code slice that is incorrectly classified as vulnerable, leading to a false alarm. Conversely, a False Negative (FN) denotes a vulnerable code slice that is incorrectly classified as clean, which is particularly critical in security contexts as it results in missed vulnerabilities. This evaluation framework provides a balanced assessment of the models by jointly considering vulnerability detection capability and false alarm reduction, which is essential for practical deployment in security analysis and software quality assurance contexts.

V. RESULTS AND DISCUSSIONS

This section presents and discusses the experimental results obtained using the proposed security-specific metrics. The analysis is structured around four key aspects: the impact of the classification algorithm on VPMs performance, the effectiveness of the proposed metrics across different vulnerability types, a comparative evaluation against classic software metrics used in prior work, and the limitations of the proposed approach.

V.1 EVALUATING DIFFERENT CLASSIFIERS

To evaluate the impact of the classification algorithm on vulnerability prediction performance, we fixed the dataset to the FC vulnerability category and varied the learning algorithm. This vulnerability type was selected because it involves security-sensitive function usage combined with control-flow and data-flow complexity, making it a representative case for classifier comparison. We evaluated three widely used machine learning algorithms: XGBoost, Random Forest, and Logistic Regression, under identical experimental settings, including the same feature set, SMOTE-based data balancing, and 10-fold cross-validation. The performance comparison is reported in Table 4.

Table 4: Performances using different classifiers.

Classifier	R (%)	P (%)	FPR (%)	FNR (%)
XGBoost	**0.7306**	**0.8050**	0.2759	**0.2694**
Logistic Regression	0.6637	0.7425	0.4318	0.3363
Random Forest	0.6980	0.8017	0.**2522**	0.3020

Source: Author, (2026).

The results show that XGBoost achieves the best overall performance, with a recall of (73.06%) and a precision of (80.50%), indicating a strong ability to detect vulnerable code slices while maintaining a reasonable false alarm rate. In contrast, Logistic Regression exhibits the weakest performance, with the lowest recall (66.37%) and the highest false positive and false negative rates. This confirms that linear models struggle to capture the complex and non-linear relationships between security-specific metrics and vulnerability presence. Random Forest achieves competitive precision (80.17%) and a lower false positive rate compared to XGBoost, but at the cost of a higher false negative rate. This indicates that Random Forest is more conservative and misses a larger proportion of vulnerable code entities. The superior performance of XGBoost can be attributed to its gradient boosting mechanism, which incrementally focuses on difficult instances and incorporates regularization to mitigate overfitting. Based on these results, XGBoost was selected as the primary classifier for the subsequent experiments.

V.2 EVALUATING ACROSS VULNERABILITY TYPES

After selecting XGBoost as the most effective classifier, we evaluated its performance across four vulnerability types: Library/API Function Call, Arithmetic Expression, Array Usage, and Pointer Usage. This analysis assesses both the generalizability of the proposed metrics and their effectiveness for different classes of vulnerabilities. The results summarized in Table 5 demonstrate that the proposed security-specific metrics achieve consistently strong performance across all vulnerability categories, with particularly high effectiveness for memory-related vulnerabilities. Pointer Usage vulnerabilities achieve the highest recall (83.94%) and precision (90.82%), as well as the lowest false negative rate. This performance can be directly attributed to the relevance of the proposed memory-related metrics, which explicitly capture risky pointer operations such as uninitialized pointers, pointer arithmetic, and unsafe casting.

Table 5: Performance across vulnerability types.

Vulnerability Type	R (%)	P (%)	FPR (%)	FNR (%)
Library/API Function Call	0.7306	0.8050	0.2759	0.2694
Arithmetic Expression	0.7827	0.8600	**0.2389**	0.2173
Array Usage	0.8106	0.7841	0.3660	0.1894
Pointer Usage	**0.8394**	**0.9082**	0.2494	**0.1606**

Source: Author, (2026).

Array Usage vulnerabilities also show high recall (81.06%), indicating effective detection of array-related vulnerabilities. However, precision is slightly lower, resulting in a higher false positive rate. This behavior can be explained by the overlap between safe and unsafe array usage patterns in C/C++, where benign code may exhibit metric values similar to vulnerable code. Arithmetic Expression vulnerabilities exhibit balanced performance, with a recall of (78.27%) and a precision of (86.00%). These results suggest that the proposed metrics capture relevant patterns associated with integer overflows and unsafe arithmetic operations, although their effectiveness is somewhat lower than for memory-related vulnerabilities. Library/API Function Call vulnerabilities achieve the lowest performance among the four categories. While the results remain acceptable, they suggest that such vulnerabilities may depend more heavily on the semantic behavior of external functions and APIs, which is only partially captured by the current metric set. Overall, this evaluation confirms that the proposed metrics are particularly well-suited for detecting memory-related vulnerabilities, which are among the most critical and prevalent security issues in C/C++ software.

V.3 COMPARISON WITH CLASSIC CODE METRICS

To assess the added value of the proposed security-specific metrics, we conducted a comparative evaluation against classic code metrics used in related work that investigated the same granularity level (slice) [1], [25]. The classic metrics include complexity, size, and structural properties. Both metric sets were evaluated under identical conditions using the XGBoost classifier, SMOTE balancing, and 10-fold cross-validation to ensure a fair comparison. Results presented in Table 6 reveal that security-specific metrics significantly outperform classic metrics for memory-related vulnerabilities, particularly for pointer and array usage. For pointer usage vulnerabilities, security-specific metrics achieve substantially higher recall and lower false negative rates while maintaining comparable precision. This indicates that metrics explicitly designed to quantify pointer initialization, pointer arithmetic, and memory manipulation are more effective at identifying pointer-related vulnerabilities than general-purpose complexity metrics.

Table 6: Comparison with classic code metrics.

Vulnerability Type	Metrics Type	R (%)	P (%)	FPR (%)	FNR (%)
Library/API Function Call	Security-Oriented	**0.7306**	0.8050	0.2759	**0.2694**
	Classic	0.7056	**0.8373**	**0.1555**	0.2944
Arithmetic Expression	Security-Oriented	0.7827	0.8600	0.2389	0.2173
	Classic	**0.8106**	**0.9287**	**0.0534**	**0.1894**
Array Usage	Security-Oriented	**0.8106**	0.7841	0.3660	**0.1894**
	Classic	0.7758	**0.8386**	**0.1650**	0.2242
Pointer Usage	Security-Oriented	**0.8394**	**0.9082**	0.2494	**0.1606**
	Classic	0.7565	0.9074	**0.1399**	0.2435

Source: Author, (2026).

For array usage vulnerabilities, security-specific metrics also achieve higher recall, detecting more vulnerable code entities, although this improvement comes at the cost of a higher false positive rate. In security-critical contexts, this trade-off is often acceptable, as missing vulnerabilities is typically more costly than investigating false alarms. In contrast, classic metrics remain competitive or superior for arithmetic expression vulnerabilities, achieving higher precision and lower false positive rates. This suggests that traditional complexity measures may better capture the characteristics of arithmetic-heavy code where vulnerabilities such as integer overflows often occur. These findings highlight the complementary nature of security-specific and classic metrics. While security-specific metrics excel at capturing low-level, security-relevant code properties, classic metrics remain useful for vulnerability types that correlate strongly with code complexity.

V.4 LIMITATIONS

Despite the promising results, several limitations of the proposed approach should be acknowledged, which also highlight interesting open research directions for future work.

First, this study focuses exclusively on C/C++ programs, and the proposed metrics are specifically designed for memory-unsafe languages; consequently, their direct applicability to memory-safe languages such as Java or Python is limited. Extending the approach to other programming languages would require the design of language-specific security metrics. Second, the current metric set primarily targets tainted source usage and memory management practices. Other important security aspects, including concurrency-related vulnerabilities (e.g., race conditions and deadlocks), cryptographic misuse, and authentication or authorization flaws, are not addressed and represent promising directions for future metric design. Third, the proposed approach relies on static code analysis, which inherently cannot capture runtime-dependent behaviors or vulnerabilities that only manifest under specific execution conditions; as a result, certain classes of vulnerabilities may remain undetected. Finally, although SMOTE is employed to mitigate class imbalance, synthetic oversampling may not fully capture the diversity and complexity of real-world vulnerable code patterns, potentially affecting model generalization. Investigating alternative imbalance-handling strategies, such as cost-sensitive learning or advanced ensemble techniques, constitutes another avenue for future research.

VI. CONCLUSION

This paper presented a novel set of security-specific code metrics designed to directly quantify security-relevant characteristics of C/C++ programs for automatic vulnerability prediction. Unlike traditional software metrics that focus on general attributes such as size and complexity, the proposed metrics explicitly capture tainted source usage and memory management behaviors known to cause security vulnerabilities. Experimental evaluation on a large-scale, real-world dataset demonstrates that the proposed metrics achieve strong and consistent performance, particularly for memory-related vulnerabilities such as pointer and array misuse. The results further show that XGBoost is the most effective classifier for exploiting these metrics, highlighting the importance of using non-linear learning models. A comparative analysis with classic software metrics confirms that security-specific and classic metrics are complementary: security-specific metrics excel at detecting memory-related vulnerabilities, while classic metrics remain effective for arithmetic expression vulnerabilities. These findings suggest that hybrid approaches combining both metric families represent a promising direction for future research. Overall, this work provides strong empirical evidence that security-specific metrics constitute a practical, interpretable, and computationally efficient solution for vulnerability prediction, offering a compelling alternative to complex deep learning approaches. Future work will focus on extending the metric set, exploring hybrid models, and evaluating the approach across additional programming languages and industrial settings.

ABSTRACT

The high-speed development of multimedia deepfake technology has fundamentally altered the digital creativity and, at the same time, increased cyber and social threats. The current state of deepfake generation is informed by recent artificial intelligence methods, such as Generative Adversarial Networks (GANs), which learn to create realistically visual and audio content via adversarial learning; autoencoder-based models, which allow manipulating identity and expression compared to images; and diffusion models, which are trained to produce high-fidelity media by refining noise to data. Even though these practices aid in innovative uses in entertainment, availability, and customized media, they also help to perpetrate malpractices like political and social manipulation, privacy invasion, identity theft, misinformation, and cybersecurity assaults. Due to the recent popularity of deepfakes, there has been rapid growth in the design of a wide range of media detection models for video and audio-based deepfakes. In this study, literature on state-of-the-art models for deep-fake detection has been compiled and summarized, which includes CNN-based Spatio-Temporal models, CNN and LSTM hybrid models, Capsule Networks, and Sharp Multiple Instance Learning models (S-MIL), which were tested on popular deep-fake databases like FaceForensics++, Face2Face, DFDC, and ASV-Spoof. Results from the study indicate a high level of efficacy for the models in crossDataset environments, with accuracy between 84.6% and 100%, precision up to 98%, and AUC reaching 1.0. Limits that still exist for deep-fake detection models relate to high computational complexity, sensitivity to attacks, and the lack of generalizability for real-time processing.

I. INTRODUCTION

Manipulation of digital video especially facial manipulation has been the issue of concern in recent years. To a large extent, this attention increase can be attributed to the presence of deepfakes, as such models are based on deep learning and depend on such models to modify or create visual images. Deepfake methods normally utilize the idea of auto-encoders or the generative adversarial networks (GANs) to apply the facial attributes of a source person to a target video. These models can produce highly realistic manipulated videos because they can work with large training dataset [1]. After the emergence of a 2017 Reddit post where a Reddit user uploaded an anonymous video in which he edited explicit videos with deepfake software, the academic volatility of deepfake detection increased exponentially. Several methods of detection have been proposed thereafter. There are the methods, which apply recurrent neural networks to detecting temporal inconsistencies between video frames and some, which apply convolutional neural networks to detect visual artifacts in manipulated faces [2]. The ease of use of deepfake generation software like Deep-Face-Lab, Fake-App, and Faceswap has led to the increased applications of facial manipulation technology with many being developed based on GAN or auto-encoder-decoder architecture [3].

GAN architecture is composed of two key elements, a generator network which creates fake content under the influence of random inputs with the help of a training dataset, and a discriminator network which tries to distinguish between authentic pictures and right-created ones. The two types of models are trained together in an adversarial model that continually enhances the performance of both models [4]. By contrast, systems based on auto-encoders implement deepfakes by encoding latent features of facial images with the help of an encoder and decoding faces with the help of a decoder. Individuals with each pair of encoders-decoders trained on different people, but the parameters of the encoder shared, one can reconstruct the face of another person with the latent features of another individual, and swap the face between the source and target face [5]. The bulk and heterogeneous data on actual and fake videos are needed to create trustworthy deepfake detection anthropometric systems, and the problem is generally stated as a dichotomous classification problem, identifying whether a video is authentic or not. A number of benchmark datasets have thus been provided. Table 1 indicates that there are 7 datasets that are popular in deepfake studies [6].

Table 1: The top seven datasets used in deep fakes.

Reference	Dataset Name	Subjects	No. of real videos	No. of fake videos
[7]	FaceForensics++ (FF++)	977	1000	5000
[8]	DeepFake-TIMIT	64	960	640
[9]	WildDeepfake	100	707	-
[10]	Deepfake Detection Challenge (DFDC)	66	5244	5244
[11]	Celeb-DeepFake (Celeb-DF)	72	6229	5639
[12]	DeeperForensics-1.0	100	60000	1000
[13]	Google/Jigsaw DeepFake Detection	3000	—	3000

Figure (1) provides a comparative analysis regarding the usage of deepfake datasets in terms of real and forged video numbers. This diagram not only provides information about the size of the available datasets but also about their balance.

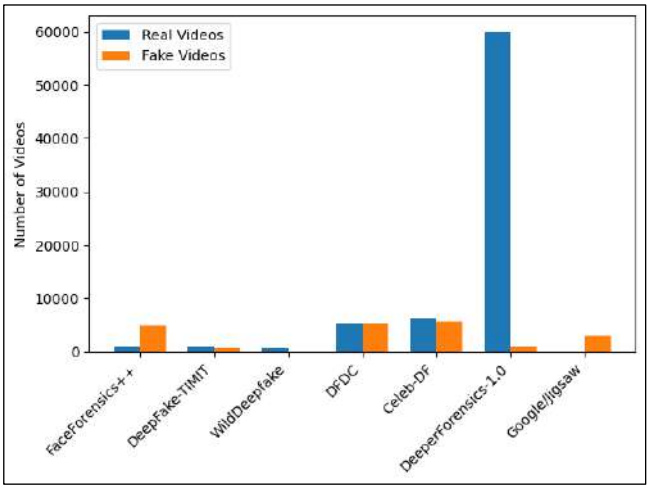

Figure 1: Comparison of Real and Fake Videos Across Deepfake Datasets.
Source: Authors, (2026).

The fact that the data acquisition and generation processes differ essentially in the widely used deepfake datasets explains the imbalance between real and fake videos. Human subjects are required to provide real videos under rigorous privacy, consent, and legal protocols, and they need to be carefully edited in order to provide diversity in identity, pose, lighting, and expression. By contrast, artificial videos can be produced in large quantities via algorithmic methods by engaging various manipulation methods to a small collection of original videos so that a single genuine sample yields tens or even hundreds of fake variants. This is why FaceForensics++ datasets have significantly more fake samples than real. On the other hand, datasets such as DFDC are designed to have balanced class distributions to allow fair benchmarking whereas others (e.g., WildDeepfake and Google/Jigsaw) are mostly built on actual or manipulated online content, which leads to the lack of or uneven counts of classes. Such discrepancies represent the original aim of the dataset that was to optimize the diversity of the manipulation, realism, or evaluation fairness, and have a direct impact on detector training, generalization, and bias.

Consequently, researchers need to focus on the issue of class imbalance when choosing datasets carefully and employ suitable methods, including re-weighting, resampling, or cross-dataset validation, to guarantee a high level of deepfake detection. Despite the significant development of detection technologies, many challenges still exist. With the advancement in the methods of Deepfake generation, videos produced are becoming realistic, and hence it is challenging to train on old detection algorithms to detect other methods of manipulation [14]. Deepfakes development has quickly transformed into an important issue in cybersecurity, offering the possibility of making manipulated multimedia look quite realistic and capable of deceiving humans and automated mechanisms. They become increasingly available, hence increasingly dangerous, including identity fraud, political misinformation, financial fraud, impersonation attacks, and massive social engineering. While methods of generating deepfakes are rapidly developing compared to detection tools, organizations have to grapple with growing dilemmas of trust and veracity, as well as safeguarding of the digital content [15].

This paper presents a survey of the environment of the multimedia deepfake threat and countermeasures in place against it. It discourses on modern-day generation technologies, model detection, challenges presented by adversarial, and shortcomings of existing methods. The survey also summarizes the research gaps still remaining as barriers to deploying the results in the real world, such as a lack of sufficient data, problems of model generalization, and the never-ending arms race between the attackers and defenders. The key contributions of the work are that it presents: i) a systematic taxonomy of the different types of deepfakes and attack scenarios; ii) a review of state-of-the-art detection and prevention techniques that leverage both audio and video representations of deepfakes; iii) the evaluation metrics, datasets, and benchmarks; and iv) an open research gap and open challenges towards enabling resilient and scalable deepfake defense systems.

II. OVERVIEW OF MULTIMEDIA DEEPFAKE TECHNOLOGIES

A broad assortment of AI-powered techniques multi-media deepfake technologies allow the generation, manipulation, and creation of artificial amounts of content in pictorial, audio, video, and multisensory formats. All these applications are based on deep learning models, such as autoencoders, GANs, diffusion models, and cross-modal transformers, all of which are expected to learn complex patterns using large datasets and reproduce them with impressive realism. To conceive such approaches, the concerned terms must be appropriately defined first. Deepfakes are typically images and videos which have been created or edited using deep neural networks. It should be stated that synthetic media can be used to mean completely artificial media, manipulated media forcefully refers to the editing of media, face-swapping suggests that one person has their face replaced by another person, and voice cloning can be used to define the imitation of speech features using small speech samples. This combination of definitions portrays a seamless conceptual framework [16]. The procedures of deepfakes generation differ in terms of the extent of sophistication and the quality of the product. Initial systems did not use any type of autoencoders, but expressed the reconstruction of faces in compressed but meaningful feature representations; by sharing a common encoder and training them to solve different identities, autoencoders could allow the provision of a face-swapping example early on. Sturdier methods were developed under the name Generative Adversarial Networks, which is a combination of a generator and a discriminator, competing with each other to generate more realistic work [17]. GANs offered significant advances to realism, which in turn allowed lip-syncing, facial reenactment and realistic portraits on a big scale.

Other approaches have been domain on the basis of face-swap and voice-swap operation under geometrical alignment, landmark tracking and a audio embedding model to transfer identify or vocal style between the target and the source. Recent-generation deepfakes utilize diffusion models and cross-modal learning to produce video based on text-based descriptions or create synchronized-audio-videos, greatly increasing the potential of creative tools and the potential harm possible [1]. The forms of deepfakes can be extremely varied: there are also images: still photographs that have been altered or generated to appear as actual individuals that may be the source of impersonation fraud or internet alters egos. Video deepfakes are methods that interfere with frame sequences to imitate facial expressions, behavior or full-body movement-all of which is able to imitate extremely believable impersonation in the real world. The tone, accent and rhythm of a speaker are reproduced in audio deepfakes in order to reproduce speech that is almost similar to real audio records of the victim and commit fraud in the financial, political and social environment. Multimodal deepfakes include audio, video, text and in some cases, physiological signals such as gesture or affect to build entirely synchronized synthetic personalities capable of interacting in real-time [6]. These include applications in filmmaking, advertising, accessibility improvement to the pioneer applications in personalized digital assistants. Moreover, the risks are severe: non-consensual creation of content, political misinformation, identified theft, impersonation attack, sabotage in the reputation, loss of trust among people. The two-purpose of deepfake technologies predisposes that, to design detection systems, regulation protocols, and authentication protocols, it is always important to comprehend the technical basis of such technologies, as well as its application and misuse scenario [18].

III. CYCLE OF DEEPFAKE ANALYSIS AND COUNTERMEASURES

The increased sophistication of the deepfake generation-related strategies has proven that a systematic plan is needed that would guide the process of collecting, analyzing, and refining the distorted multimedia content that would be examined during a forensic analysis. Deepfakes can alter facial expressions, flags, and even entire scenes and pass as extremely genuine, and current technologies of conceiving are not sufficient. To address these challenges, scholars have proposed systematic analysis cycles that comprised data management, multimedia evaluation and improved feature mining. The flexibility and efficiency of the deepfake detection algorithm would be ensured by such a process since the manipulation algorithms will continue to evolve. Figure 2 shows the simplified version of this cycle and shows how the content is transferred between the raw data storage and refined fiefs extraction [19].

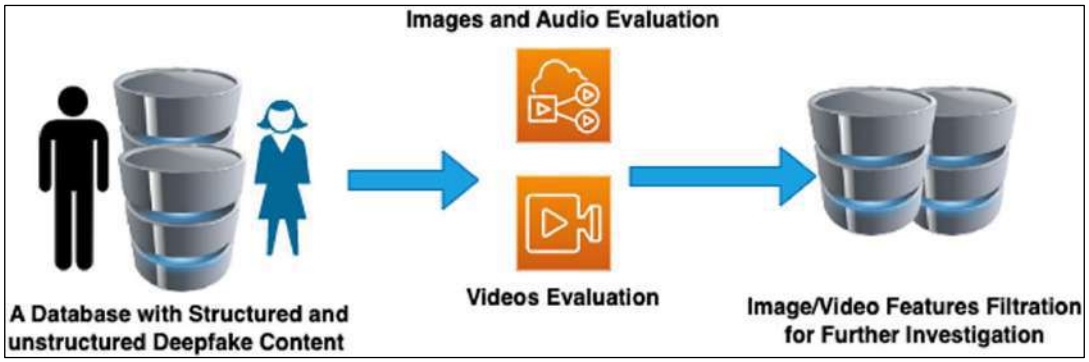

Figure 2: Cycle of Deepfake Analysis and Countermeasures.
Source: Authors, (2026).

The process starts with the establishment of a complete database that includes both structured and unstructured material based on deepfake. Structured content can consist of curated datasets ready to be used in training and benchmarking, including labels, metadata and standardized formats. Such datasets assist machine learning models to acquire credible trends related to manipulated content. Unstructured content, in turn, includes raw videos, images, and audio recordings that have been captured in uncontrolled settings, e.g. social media platforms or user submissions. Such kind of a material is necessary to mirror the state of the real world were compression artifacts, variable lighting, as well as unequal recording quality complicate identifying deepfakes. The mix of structured and unstructured sources provides the opportunity to have a strong detection in different situations because the analysis cycle should be robust [20]. After compiling the data, the second important stage is concerned with multimedia evaluation that implies examination of images, audio, and videos. Image based assessment is the type of assessment that studies spatial patterns which are difficult to recreate with generative models. They consist of anomalies in skin texture, shadows of incorrect proportions, blurred boundaries at the face, and minor irregularities between the image noise patterns. Audio testing, however, focuses on unnatural phonemic shift, abnormal breathing rhythms, disproportionate tone of emotion, or calculating errors normally found in synthetic voices [21]. Video analysis is a synthesis of spatial and temporal analysis in that the motion dynamics, transitions of facial expressions, frequency of blinking of the eyes, and accuracy of lip-sync and head movement patterns are analyzed. More complex deep learning models in the form of convolutional neural networks, recurrent neural networks, and attention-based models are used during this stage of evaluation to detect fine details indicating tampering [22].

After the assessment of the multimedia, the system moves to the feature filtration which is the refinement of extracted information which is displayed to show the best indicator of manipulation. This step is important as deepfake datasets are often redundant, with inconsistent quality, and with an excessive amount of noise. As a benefit, effective filtration lowers the computational complexity and at the same time maintains discriminative features that are required to obtain accurate classification. Examples of these features would be micro-expressions, which happen too fast or too homogenous, odd photometric characteristics, non-uniform physiological cues, including inconsistent patterns in the pulsation of skin-tone, and statistical anomalies that are detectable on the basis of machine learning models. The dimensionality reduction, feature normalization and anomaly scoring are the techniques that are often used to improve the quality and reliability of the filtered features [21]. The final refined features are then submitted to forensic models or human analysts so that they can be authenticated. Ratings on whether the content is authentic or altered may be made by an automated detection system relying on only the learned patterns, but borderline cases may contain additional contextual information reviewed by a human. Notably, the process is recursive: the results of the outcomes of the detection can be processed with the help of the feedback and change the database, modify feature filters, or refine evaluation methods. By doing this, the automatic loop of improvement guarantees that this detection system would be resistant against new implementations of deepfake generation, which are becoming lifelike and harder to perceive [23].

IV. SECURITY PROTOCOLS IN MULTIMEDIA ENABLED DEEPFAKES

With the growing trend and proliferation of deepfakes enabled by multimedia, it has become an utmost requirement to ensure the security of the content. To address the concerns arising from deepfakes, different techniques are being opted for by researchers and experts in the domain. This includes everything from common cryptography techniques to artificial intelligence-driven techniques. Figure (3) showcases the most prominent security measures to combat the use of multimedia-assisted deepfakes. The central figure of the flow illustrates the concept of digital content security, whereas the other components represent the eight most prominent measures: robust, fragile digital watermarking, Blockchain Distributed Ledger Technology (BDLT), the detection of deepfakes employing deep learning and CNN models, audio-visual synchronization, hashing (SHA-256), validation of metadata, and multimodal analysis.

Figure 3: Security Protocols for Countering Multimedia-Enabled Deepfakes.
Source: Authors, (2026).

Fast propagation of deepfakes enriched with multimedia has incited serious problems to be solved by developing robust mechanisms for maintaining the integrity and authenticity of digital content. Contemporary security frameworks place a greater reliance on various combinations of multimodal analysis, blockchain-based distributed ledger systems, deep learning algorithms, and cryptographic watermarking for proposing countermeasures against manipulations related to deepfakes.

Digital watermarking has made critical contributions among these by embedding invisible and tamper-resistant identifiers in images, audio, and video files. Metadata-driven or cryptographically generated identifiers assure authenticity, traceability, and protection from violations of intellectual property rights [24]. Fragile watermarking is intended for very minute changes in sensitive media, while robust watermarks remain resistant against operations such as resizing, compression, or format conversion [25]. BDLT also enhances content authentication by storing cryptographic messages of original multimedia files on an immutable decentralized registry. Each change of the content generates a hash that is different compared to the others; hence, any illegitimate interference of the content will be detected immediately. This gives more transparency and trust that ultimately adds value to blockchain-enabled authentication protocols in most issues, including journalism to digital rights management to legal forensics. Detection approaches based on deep learning would provide another important defense level, that is, to analyze visual and audio information that can point to tampered materials. These are examples of deep learning architectures such as convolutional neural networks, audio-video synchronization networks that may be used to identify characteristic abnormalities of deepfakes, such as artificial facial expression and hypersyncrous lip motion or unmatched audio-video, to aid in tracking such abuse in real-time on both social media sites and live streaming platforms [26]. Added protection is through hash and metadata check mechanisms. The possibility to compare with the hashes of the newly uploaded content is offered by a cryptographic hash algorithm, e.g. SHA-256 that generates unique digital fingerprints of every multimedia content in the secured ledgers to detect unacceptable alterations in the same 19, 20.

The metadata verification is used in addition to this process to verify the authenticity of the media assets and the fact that they have not been manipulated and on top, inserting details, including, but not limited to, timestamps, geolocation tags, and device specifications. Combined all these multilayered security features comprise an integrated defense mechanism to address the expanding threats that are associated with deepfakes that can be facilitated through multimedia [27]. Table 2 mainly concentrates on the topic of protective and provenance-based security measures that are aimed to prevent, authenticate, or trace multimedia content in the magnitude of deepfake threats. Detection-based techniques though is also included but this is only deemed to work well when protective measures have failed or when content which has been manipulated has already entered the market. The technologies listed above, although Bdlt is somewhat lower-priority than the other technologies, Blockchain Distributed Ledger Technology (BDLT) is considered immutable, decentralized, and verifiable content provenance, as a threat source, instead of possibly detecting artifacts in retrospect. Digital watermarking, in its turn, despite the historic significance, is slowly becoming defined as a legacy method because of the susceptibility to drastic changes and the latest generative algorithms; thus, only strong watermarking is preserved to ensure no redundancy. Techniques on detection like deep learning, audio-visual synchronization, and multimodal analysis are still maintained to reflect reactive security layers which are complementary protection mechanisms in a multilayered security architecture.

Table 2: Security Protocols for Countering Multimedia-Enabled Deepfakes.

Security Protocol / Technology	Description	Primary Purpose	Strengths	Limitations
Digital Watermarking (Robust) [28]	Embeds identifiers resistant to compression, resizing, and re-encoding.	Ensures media integrity during distribution.	Survives most transformations; ideal for copyright protection.	May slightly reduce quality if not optimized.
Digital Watermarking (Fragile) [29]	Embeds highly sensitive markers that break upon tampering.	Detects even minimal manipulation.	Excellent for authenticity verification of sensitive content.	Not suitable for content that undergoes compression.
Blockchain Distributed Ledger Technology (BDLT) [30]	Stores cryptographic hashes of original media on decentralized immutable ledgers.	Content authentication and anti-tampering validation.	Tamper-proof, transparent, decentralized, trustworthy.	High computational cost; scalability issues.
Deep Learning–Based Detection (CNNs) [31]	Uses convolutional neural networks to detect spatial artifacts in images/videos.	Automated detection of manipulated frames.	High accuracy; effective for visual defects.	Requires large labeled datasets.
Audio–Visual Synchronization Models [31]	Examines coherence between speech, lip movement, and facial expressions.	Detects mismatches typical of deepfake videos.	Strong at capturing temporal inconsistencies.	Performance drops with noisy or low-quality videos.
Hashing (SHA-256) [32]	Generates unique digital signatures for multimedia content.	Identifies unauthorized modifications.	Fast, secure, widely supported.	Ineffective alone against sophisticated deepfake reconstruction.
Metadata Verification [33]	Checks embedded data such as timestamps, source device, and location.	Supports authenticity and forensic validation.	Complements hashing; helps identify forgery.	Metadata can be spoofed if not cryptographically protected.
Multimodal Analysis [34]	Combines visual, audio, text, and behavioral cues.	Provides more accurate deepfake detection.	Reduces false positives; robust across content types.	Requires high computational resources.

V. THREAT LANDSCAPE OF MULTIMEDIA DEEPFAKES

Deepfakes are becoming more advanced, as accessible, multimedia, which use actors to create hyper-realistic synthetic content, which is used to influence perception, disrupt trust, and abide by vulnerabilities. Deepfakes can also be deployed in politics to affect an election, slander an opponent or even the trigger social turmoil by portraying events or claiming statements that do not occur. At the individual level, deepfakes are a threat to privacy by promoting identity theft, revenge porn, or unsanctioned impersonations. Deepfakes have the potential to form a great instrument within the misinformation, disinformation campaigns, which are actively spreading fake stories across social media and online platforms at an unprecedented pace [35]. Within the framework of cybersecurity, deepfakes allow complex fraudulent activities, phishing sites and the masquerading as known personalities. Such threats are also coupled with legal, ethical, and policy gaps as they cannot keep up with the high rate of synthetic media evolution, and the victim has no resources to complain to them, and enforcing and creating ethics are not an easy task [36]. Table (3) shows Threat Landscape of Multimedia Deepfakes.

Table 3: Threat Landscape of Multimedia Deepfakes.

Threat Category	Description	Methods / Examples	Potential Impact	Mitigation Challenges
Political and Social Manipulation [37]	Use of deepfakes to influence political outcomes, sway public opinion, or destabilize societies	Fake speeches of politicians, manipulated protests, synthetic news coverage	Erosion of trust in democratic institutions, social unrest, polarization	Detecting deepfakes in real-time, regulating content without infringing free speech
Privacy Violations and Identity Theft [38]	Unauthorized use of personal images, videos, or voices	Deepfake pornography, impersonation in calls or videos, social media misuse	Reputational damage, financial loss, emotional distress	Victims often unaware, difficulty in tracking perpetrators, lack of clear legal recourse
Misinformation and Disinformation Campaigns [39]	Spreading false information via realistic media	Fake celebrity endorsements, fabricated events, misleading news clips	Public confusion, manipulation of beliefs, harm to public health or safety	Identifying synthetic content among massive online data, countering viral spread
Cybersecurity and Fraud Threats [40]	Exploiting deepfakes for scams or unauthorized access	Voice cloning for banking fraud, AI-generated phishing videos, bypassing biometric authentication	Financial theft, corporate espionage, security breaches	Continuous advancement in deepfake technology, insufficient AI-based defense mechanisms
Legal, Ethical, and Policy Challenges [41]	Legal frameworks and ethical standards lag behind technological advances	Limited legislation on synthetic media, cross-border jurisdiction issues	Regulatory gaps, ethical dilemmas, difficulties in enforcement	Harmonizing laws internationally, balancing innovation with protection, establishing accountability

VI. COMPARATIVE ANALYSIS OF DEEPFAKE RESEARCHES

By [42] investigated deepfake (DF) detection based on faces2face video datasets and a mixture of DF-specific methods. They had the desire to exploit the distinct artifacts in videos manipulated by Face2Face, and the training models to identify the minor inconsistencies in face movements and pattern of expressions. The model had a very high detection accuracy of 95%-98 with frame-level feature extraction and analysis of Temporal sequences. The research revealed the utility of specificity of detection strategy to particular process of reenacting DF especially facial reenactment. Nevertheless, the approach had the disadvantage of overfitting to the features of Face2Face dataset used, which restricts the potential to use this approach to other deepfake generation mechanisms. Although the high accuracy is a result of the capability of the dataset-dependent detection models, this diversity of the training data is limited and this limits its applicability in real-world situations, where DFs may be produced by an even larger number of different algorithms that evolve over time. The paper has discussed the need to have variety of the datasets and cross dataset testing in future research studies in order to increase the strength of the research. In turn [43] proposed a deep neural network with hierarchical learning layers (DNN-HLL) for audio deepfake detection using the ASPspoof dataset. The model achieved an equal error rate (ERR) of 0.045, which indicates good performance in discriminating real from imitated audio.

The hierarchical structure allows the model to capture low-level and high-level acoustic patterns, which is essential in detecting slight speech manipulation. However, the study was limited by the scarce diversity of the dataset, which would diminish the capacity of the model to generalize to other types of audio data or unknown attacks. Further, real-world audio includes some environmental variation and background noise that was not well represented in ASPspoof. The research finds the potential of DNN-HLL for audio deepfake detection but demands larger, more diverse datasets and cross-dataset testing to attain robustness in practice. According to [44] examined the problem of deepfake detection by experimenting the GAN-based video generation videos on the FaceForensics++ data. They employed convolutional neural networks (CNNs) to acquire spatiotemporal feature of video frames to allow detecting subtle artifacts of manipulation that are otherwise inconspicuous to human participants. A striking precision of 98 was attained in the experiment, and this implicates the power of CNNs in identifying pixel-level inconsistency that is created during the process of synthesizing GAN-based. Also, pre-processing was done to standardize the input frames and further featured extraction was done to boost the overall detection performance. GAN-based detection models are very precise and can be attacked by adversarial examples, where minor changes can potentially fool the network. The authors proposed to enhance the robustness with the help of strong learning techniques and adversarial learning. The method is effective to find a few of the GAN-manipulated examples, however, generalization to unseen GAN models and new manipulation strategies is still to be addressed and as such an adaptive and ever-changing system of detection is required.

By [45] created a deep learning algorithm that was used to detect deepfake videos through the use of artifacts created as a result of face warping during the generation step. CNN-based technique detects minimal distortions that are caused during warping of synthetic faces and matching with original frames, which is generally undetectable by human eye. Data tests on the model have been done on various DF video data with accuracy of between 84.6 to 99.4, which varies with the origin of the video. The paper points out that since the quality of data sets differs depending on their generation processes, performance is data set specific, which poses a problem of high variance. The method indicates that CNNs can be successfully trained to ensure that they record artifacts due to deepfake synthesis. Nevertheless, it can be overcome by video employing the methods of new generation, or by post-processing, which is why there is a necessity of constant change in the detection algorithms. The article emphasizes the significance of strong feature evolution in deepfake detection of large sample sizes. In [46] suggested a system of deepfake detection and models of other kinds of attacks by use of capsule network that would be used to detect such attacks like computer-generated video and print-and-play attack using printed material or recorded media. The model exploits the specific ability of capsule network to study hierarchical spatial relationships, and detect discrepancy of facial structures, resolving the problem of inverse graphics. The approach was tested on the Capsule-Forensics dataset having an accuracy between 89.1 and 100%. Training also used random noise in the course of work. Although the quality of the videos that the model handled is close to excellent, low-resolution or highly compressed videos deteriorate the performance of the model.

The article illustrates the suitability of the capsule networks to generalized computer vision tasks and the prospects of generalized deepfake detection models. But scalability and real-time processing is still not yet achieved because of computational complexity suggesting further optimization to be used in real-time stream of videos or large data sizes. According to [47] addressed the issue of partially manipulated faces in deepfake videos using a Sharp Multiple Instance Learning (S-MIL) framework. Contrary to standard MIL, which induces instance embedding's to map indirectly into bag-level predictions, S-MIL induces a direct mapping and circumvents gradient vanishing as well as enhances training efficiency. The model treats face in a video as instances and the video as a bag and picks up intra-frame and inter-frame inconsistency. It was evaluated on celebDF, DFDC, and Face Forensics++ datasets and achieved AUCs of 0.9944 on celebDF, 1.0 on Face Forensics++, and 0.8511 on DFDC. While S-MIL works well at detecting half-altered faces and generalizes well between datasets, its higher complexity increases computational requirements. The approach can be further applied to single-frame DF image detection with a generic framework for various DF detection tasks. The research prioritizes instance-level modeling in an effort to detect localized manipulation that could escape classical video-level classifiers. By [48] proposed a hybrid CNN-LSTM model for deepfake video detection. CNNs were used to extract frame-level spatial information, which was subsequently passed through LSTM layers to capture temporal relations among sequences. The model was trained and evaluated on a number of datasets including Face Forensics, DFDC, and celebDF, where the overall accuracy was 92%.

The approach performs well in differentiating genuine and forged video content according to spatial and temporal discrepancies but requires immense computational ability, which might limit its application where there are not enough resources. The experiment demonstrates the effectiveness of a combination of convolutional and recurrent models in the detection of DF, which provides more accurate results than CNN-only simple models. Future work suggested enhancing computational cost-effectiveness and using the framework to multimodal data, i.e., incorporating audio cues, to further reinforce detection robustness. In [49] developed a 3D CNN model that can detect deepfakes by extracting spatiotemporal information from adjacent video frames. The network was trained using the FaceForensics and VidTIMIT datasets and correctly detected 94.5% to 99.4% of deepfakes. The 3D convolutional layers allow the model to analyze temporal dynamics together with spatial details, which improves the ability to detect subtle video manipulations. Even though highly effective, the approach is vulnerable to adversarial noise, which can lead to severe degradation of performance. The research demonstrates the benefit of temporal sequence modeling as well as frame-level analysis in robust detection of deepfakes. However, computational cost of 3D CNNs may limit real-time usage. The authors underscore the importance of ongoing model revision based on latest DF generation strategies and adversarial attacks, as well as the potential to use light-weight architectures for deployment.

Table 4:Related Works Comparison.

Ref	Modality	Dataset	Model / Approach	Performance	Strengths	Limitations
Bonettini et al. [42]	Video	Face2Face	DF-specific methods, frame-level feature extraction + temporal analysis	Accuracy: 95–98%	Captures subtle facial movement artifacts; high detection on Face2Face	Overfitting to dataset; limited generalization to other DF types
Frank et al. [43]	Audio	ASVspoof	DNN-Hierarchical Learning Layers (DNN-HLL)	ERR: 0.045	Captures low- and high-level acoustic patterns; strong discrimination of real vs fake	Dataset diversity limited; real-world noise not well represented
Salvi et al. [44]	Video	FaceForensics++	CNN for spatiotemporal features	Precision: 98%	Detects subtle pixel-level GAN artifacts; pre-processing boosts performance	Vulnerable to adversarial attacks; limited generalization to unseen GANs
Jung et al. [45]	Video	Multiple DF datasets	CNN-based face warping artifact detection	Accuracy: 84.6–99.4%	Detects minimal distortions; effective across multiple datasets	Dataset-specific performance; may fail on newer DF methods or post-processed videos

Guera et al. [46]	Video + attacks	Capsule-Forensics	Capsule Network	Accuracy: 89.1–100%	Captures hierarchical facial structures; generalizable to other attacks	Computationally heavy; low-res/compressed videos reduce performance; not real-time
Zhang et al. [47]	Video	celebDF, DFDC, FaceForensics++	Sharp Multiple Instance Learning (S-MIL)	AUC: 0.9944–1.0	Detects partially manipulated faces; good cross-dataset generalization	High computational complexity
Yuezun et al. [48]	Video	FaceForensics, DFDC, celebDF	CNN-LSTM hybrid	Accuracy: 92%	Combines spatial and temporal features; more accurate than CNN-only	High computational requirements; may limit real-time deployment
Nguyen et al. [49]	Video	FaceForensics, VidTIMIT	3D CNN	Accuracy: 94.5–99.4%	Extracts spatiotemporal info; robust detection of subtle manipulations	Vulnerable to adversarial noise; computationally intensive; real-time limited

Figure (4) highlights the major gaps and limitations identified in recent studies on the detection of deepfakes. It shows the level of occurrence of various limitations like performance on specific datasets, computational complexity, susceptibility to adversarial attacks, and the need for real-time processing. This graphical representation draws attention to the areas of major limitations in detecting deepfakes.

VII. CONCLUSION

Multimedia deepfakes are not only innovative opportunities, but also a big challenge in terms of security. The biggest challenge is the dynamism of methods that are generated by generative AI such as GANs and cross-modal synthesis that tend to avoid conventional detection tools. One of the crucial problems is generalizability because traditional detectors cannot handle new subjects, different quality, and various environmental circumstances. Existence of only small, homogenous and low-quality data also compounds the effectiveness of current models. Novel multimodal deepfakes incorporate video/ audio/ text/ physiological signals, which further intensify these issues, especially when minuscule manipulation/ watermark removal methods are employed. Effective detection is complicated by high computational demands and other ethical and legal limitations, such as privacy, freedom of expression and regulatory lag. Nevertheless, efficient and generalizable detectors that can withstand unknown types of manipulation should be considered in research in the future. Multimodal cues comprising of visual, audio, text and behavioral features can enhance accuracy in detection. Transformer models and attention mechanisms can be used to capture inter- modal relation better. Minimized or lightweight architectures are necessary to facilitate large-scale and approximate real-time analyzes. Methods like adversarial learning, anomaly detection and content authentication by blockchain can be used to enhance robustness and traceability. Adaptive learning to changing threats will be facilitated by the creation of enormous and heterogeneous datasets. The main drawbacks of CNNs, RNNs, multimodal analysis, and cryptographic verification are still adversarial evasion, cross-domain manipulations, and limitations of datasets. These issues should be solved through sustained innovation, the work of cross-disciplinary teams, and good governance. When addressing privacy, protecting digital trust, and facilitating the responsible development and deployment of synthetic media technologies, it is important to integrate technical, ethical, and legal solutions.

ABSTRACT

Electromyography (EMG) is a widely used technique for assessing muscle activity in response to electrical stimulation of the nervous system. Nevertheless, EMG signals are inherently weak, non-stationary, and highly susceptible to noise contamination, necessitating the use of advanced acquisition and signal processing strategies. This study presents a comprehensive systematic review and bibliometric analysis of EMG signal filtering and data acquisition frameworks. Unlike previous reviews that focus solely on signal processing techniques, this study uniquely integrates Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA)-based systematic screening with multi-dimensional bibliometric mapping to reveal methodological convergence, research gaps, and future design paradigms for low-cost and embedded EMG systems. Bibliometric analyses were performed using Biblioshiny and VOSviewer to characterize the intellectual structure of the field. The primary objective is to identify recent advances, dominant research trends, and critical knowledge gaps warranting further investigation. Based on PRISMA screening, 173 peer-reviewed articles were included for analysis. The findings reveal a sustained annual growth rate of 3.71% in EMG filtering research and highlight five key analytical dimensions: (1) performance evaluation, (2) science mapping, (3) research collaboration networks, (4) citation dynamics, and (5) emerging trends and future research opportunities.

I. INTRODUCTION

Electromyography (EMG) is an experimental technique for the acquisition and analysis of electrical signals generated by skeletal muscle contractions [1]. These signals represent the anatomical and physiological activity of motor units and constitute a fundamental diagnostic and research tool in biomechanics, medical rehabilitation, and robotic control systems, including prosthetics. Despite its broad applicability, EMG signal acquisition remains challenging due to the inherently low signal amplitude (microvolt to millivolt range) and its stochastic characteristics [2]. Moreover, EMG recordings are highly susceptible to multiple noise sources, such as power-line interference (50/60 Hz), motion artifacts, electrocardiographic (ECG) interference, and intrinsic electronic noise [3]. Such contamination can severely distort relevant signal features, leading to unreliable estimations of commonly used metrics, including Root Mean Square (RMS) and Mean Frequency [4]. Consequently, effective preprocessing through signal filtering is indispensable for preserving signal integrity. The choice of filtering strategy—including filter type, cutoff frequency, and order—critically influences the quality of the extracted information. Conventional approaches, such as band-pass filtering to isolate the physiological muscle frequency band (20–500 Hz) and notch filtering to suppress power-line hum, are widely adopted, while advanced techniques, including wavelet-based and adaptive filtering, have been increasingly employed to address non-stationary noise components [5]. Despite the availability of numerous EMG signal filtering techniques, suboptimal parameter selection frequently results in the attenuation of physiologically relevant frequency components or the introduction of detrimental phase distortions [6].

Consequently, identifying robust filtering configurations that effectively suppress noise while preserving true muscle contraction information remains a critical challenge. This study addresses this issue by providing a comprehensive analysis of EMG signal filtering methods to determine optimal parameter settings that balance noise reduction and signal fidelity [7], [8]. Motivated by the rapidly growing global research interest in EMG signal processing, as evidenced by bibliometric analyses of Scopus-indexed publications, this work integrates a PRISMA-based systematic review with a bibliometric mapping approach. The analysis reveals dominant research trajectories spanning traditional digital filtering, advanced transformation-based methods for non-stationary signals, and emerging AI-driven denoising techniques [9]. By synthesizing methodological trends, performance insights, and research gaps, this study offers a structured foundation for future developments in high-precision EMG-based control systems, including intelligent prosthetics and human–machine interfaces [10], [11]. Despite the extensive body of literature on EMG filtering techniques, bibliometric evidence highlights critical and underexplored research gaps. Existing studies predominantly rely on high-cost, medical-grade EMG systems, while investigations into computationally efficient filtering strategies tailored for low-cost sensors remain scarce [12]. This limitation restricts the translation of EMG-based solutions to embedded and portable applications. Addressing this gap, the present study evaluates lightweight yet optimal filtering configurations that minimize noise while preserving physiologically meaningful muscle contraction information, enabling practical deployment in resource-constrained systems. This work delivers a focused, systematic, and bibliometric analysis of EMG signal filtering, synthesizing state-of-the-art developments, dominant research trajectories, and emerging opportunities. Specifically, it addresses the following research questions: (Q1) What is the current research landscape in electromyography? (Q2) How is the scientific structure of EMG filtering research organized? (Q3) Which articles, sources, and countries exert the greatest influence and productivity in this domain? (Q4) What trends are shaping contemporary EMG research? and (Q5) What critical gaps and future research directions exist for EMG signal processing in low-cost and embedded systems?

The novelty of this study lies in three aspects: (i) the integration of PRISMA-guided systematic review with advanced bibliometric science mapping, (ii) the identification of methodological fragmentation and lack of filtering standardization in EMG research, and (iii) the formulation of future research directions emphasizing adaptive, interpretable, and computationally efficient filtering strategies for wearable and embedded systems. Collectively, these contributions provide a unified analytical framework that bridges methodological rigor with practical system design considerations, thereby supporting the development of robust, scalable, and application-oriented EMG acquisition solutions.

II. THEORETICAL REFERENCE

II.1 ELECTROMYOGRAPHY (EMG)

Electromyographic (EMG) signals are biomedical signals that capture the electrical activity of muscles during contraction, reflecting neuromuscular function, and depending on the anatomical and physiological properties of muscle tissue [13]. EMG signals are acquired using electrodes that detect muscle electrical potentials and are placed either on the skin surface or within the muscle [14]. Accordingly, EMG electrodes are classified into surface electromyography (sEMG) and intramuscular electromyography (iEMG). sEMG employs non-invasive surface electrodes and records activity from a broader, superficial muscle region, whereas iEMG uses invasive needle or wire electrodes to capture highly localized and deeper muscle fiber activity. As a result, sEMG is well-suited for global assessment of surface muscle activation, while iEMG enables detailed analysis of specific muscles or motor units. Owing to their distinct frequency and amplitude characteristics, EMG signals constitute a critical data source for medical diagnosis, assistive device control, and the investigation of neuromuscular function [15].

II.2 ELECTROMYOGRAPHY (EMG) SIGNAL FILTERING

Electromyography (EMG) signal filtering is a fundamental preprocessing step aimed at enhancing signal quality by suppressing acquisition-related disturbances, including motion artifacts, power-line interference, and high-frequency noise. Preprocessing typically consists of filtering and segmentation, with filtering playing a decisive role in isolating physiologically meaningful muscle activity for accurate analysis [16]. EMG filtering commonly employs band-pass filters to confine the signal within its physiological frequency range (20–500 Hz), thereby attenuating low- and high-frequency noise, and notch filters to eliminate power-line interference at 50/60 Hz. Additionally, digital and adaptive filtering techniques, such as Butterworth filters, are widely adopted to preserve critical signal attributes—particularly amplitude and spectral content—while substantially improving the Signal-to-Noise Ratio (SNR), which directly influences the reliability of motion recognition and classification outcomes [17]. The subsequent stage involves EMG smoothing or envelope extraction using low-pass filters with low cutoff frequencies or techniques such as Root Mean Square (RMS) and moving average, producing a stable and interpretable representation of muscle activity [18]. This filtering pipeline substantially enhances EMG signal quality, enabling more accurate and reliable downstream analyses, including both conventional signal processing and machine learning–based approaches. Consequently, the consistent application of appropriate filtering strategies is essential for ensuring analytical validity and robust EMG interpretation across research and clinical applications.

III. MATERIALS AND METHODS

This study employs the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) framework integrated with bibliometric analysis to systematically identify research trends and gaps within the field [19]. This combined approach is widely adopted for its effectiveness in uncovering emerging themes and underexplored research directions. Bibliometric analyses were conducted using VOSviewer and Biblioshiny implemented in the R environment, which enable both qualitative and quantitative synthesis as well as intuitive data visualization. The PRISMA–bibliometric workflow comprises literature identification, screening, eligibility assessment, and bibliometric synthesis, including quantitative analysis, thematic mapping, research gap identification, and the formulation of future research agendas. The detailed research framework applied in this study is presented in Figure 1.

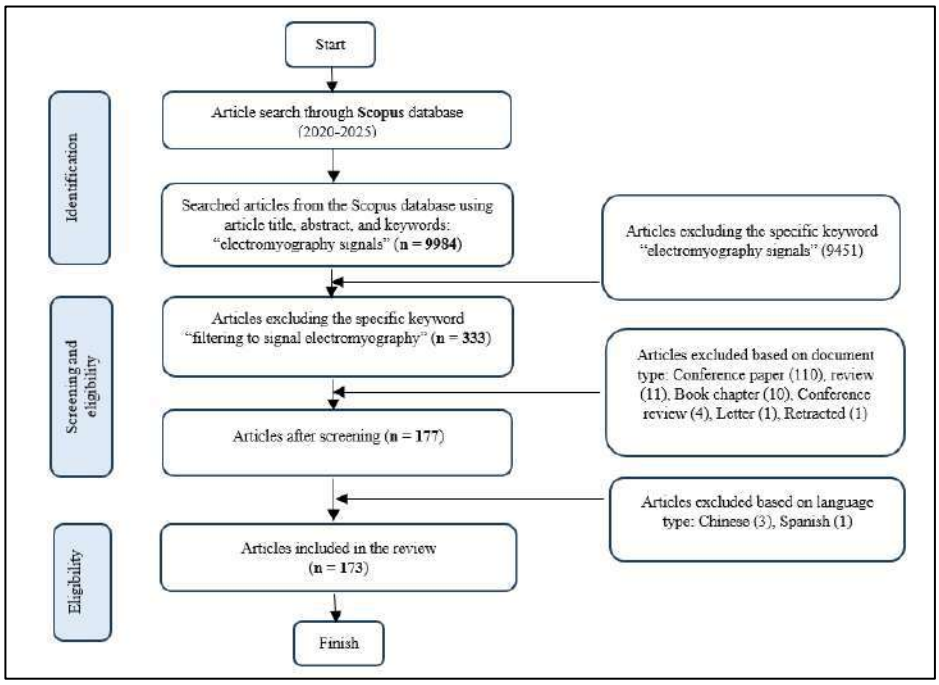

Figure 1: PRISMA research framework.
Source: Authors (2026).

Relevant literature on electromyography (EMG) signal filtering was retrieved from the Scopus database [20]. Study selection followed predefined inclusion criteria: English-language experimental articles published between 2020 and 2025 and identified using targeted EMG-related keywords. After screening and excluding ineligible and closed-access records, 173 articles were retained for analysis. Bibliometric analysis was then conducted to provide a comprehensive overview of EMG filtering research, encompassing research distribution, author productivity, and thematic structures. The results are presented through quantitative, qualitative, and visual analyses, enabling the identification of research trends, key topics, and existing research gaps to guide future investigations.

IV. RESULTS AND DISCUSSIONS

IV.1 PERFORMANCE ANALYSIS

Performance analysis was conducted to assess the quality, consistency, and evolution of EMG signal filtering research using the PRISMA framework, ensuring a transparent and reproducible literature selection process [21], [22]. The analysis focused on eligible publication counts, annual publication trends, and topical relevance to provide a concise overview of the research landscape. A Scopus search (2020–2025) using electromyography-related titles, abstracts, and keywords yielded 9,984 records. After title screening, 9,451 records were excluded, followed by abstract screening of 333 studies and full-text assessment of 191 articles. Ultimately, 173 articles met the inclusion criteria and were retained for analysis. A summary of research performance is presented in Table 1 and Figure 2.

The Bibliometrix framework was applied to quantitatively assess the literature using key bibliometric indicators, including performance analysis, science mapping, EMG filtering techniques, collaboration networks, and analysis of trends and future research potential. This approach elucidates scientific contributions, research impact, and the evolutionary dynamics of the field. When integrated with PRISMA, Bibliometrix enables a robust evaluation of both the rigor of literature selection and the underlying knowledge structure, resulting in a comprehensive, systematic, and evidence-based review. Electromyography (EMG) signal filtering has emerged as a rapidly advancing research domain. Between 2020 and 2025, 173 publications authored by 725 researchers across 103 sources were identified, reflecting strong scholarly engagement. The field demonstrates notable impact, with an average of 9.38 citations per document and an annual growth rate of 3.71%, underscoring sustained and accelerating research interest. These trends underscore the need for a more in-depth analysis to clarify prevailing research directions and pinpoint critical gaps that warrant further investigation.

IV.2 COMPARISON WITH PREVIOUS REVIEWS

Most existing EMG review studies primarily focus on the comparative evaluation of signal processing and filtering techniques, emphasizing algorithmic performance improvements such as noise suppression and classification accuracy. While these reviews provide valuable insights at the methodological level, they generally overlook broader structural aspects, including methodological consistency, collaboration patterns, and the longitudinal evolution of research themes.

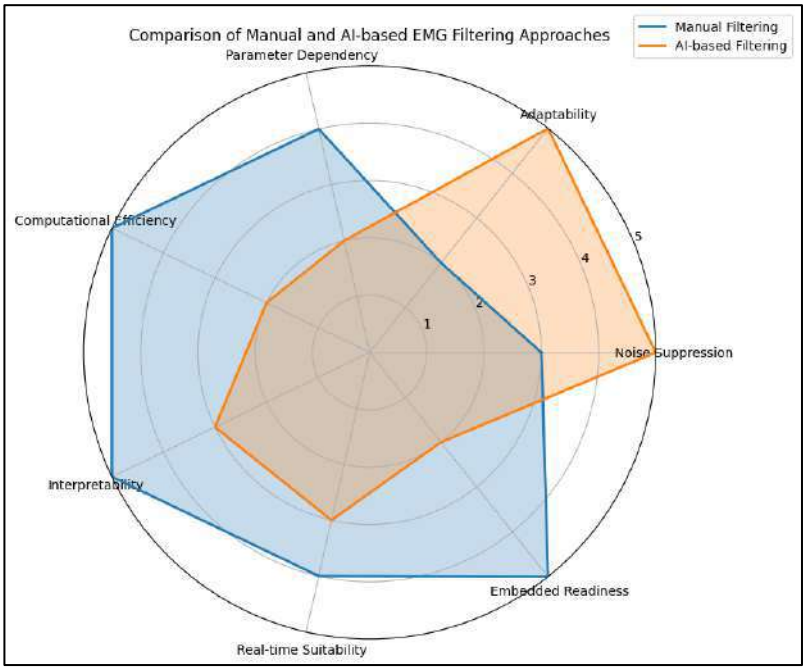

Figure 3: Comparison of manual and AI-based EMG filtering approaches.
Source: Authors (2026).

In contrast, this study delivers a higher-level synthesis by revealing methodological fragmentation across EMG filtering studies, imbalances in research collaboration networks, and a clear transition toward AI-driven filtering paradigms. By integrating PRISMA-guided systematic screening with bibliometric science mapping, this work extends beyond algorithm-centric comparisons to elucidate the intellectual structure and developmental trajectory of EMG filtering research. Consequently, it bridges the gap between signal processing methodologies and practical system design requirements, particularly for adaptive, interpretable, and computationally efficient filtering in wearable and embedded EMG systems. Figure 3 explains that a comparative analysis between conventional and AI-based EMG filtering highlights a clear methodological trade-off aligned with current bibliometric trends. Conventional filtering methods remain dominant in embedded and real-time applications due to their high interpretability, low computational cost, and implementation simplicity. However, bibliometric trend analysis reveals a growing shift toward AI-driven filtering, motivated by superior noise suppression and adaptability to non-stationary EMG signals. This transition is reflected in the increasing prevalence of machine learning and deep learning keywords in recent publications. Despite their performance advantages, AI-based approaches face challenges related to computational complexity, limited interpretability, and embedded deployment constraints. These findings suggest an emerging research direction toward hybrid filtering frameworks that balance AI adaptability with the efficiency and transparency of conventional methods. The life cycle and growth analysis provide important context for understanding the comparative trends between manual and AI-based EMG screening approaches, as seen in Figure 4.

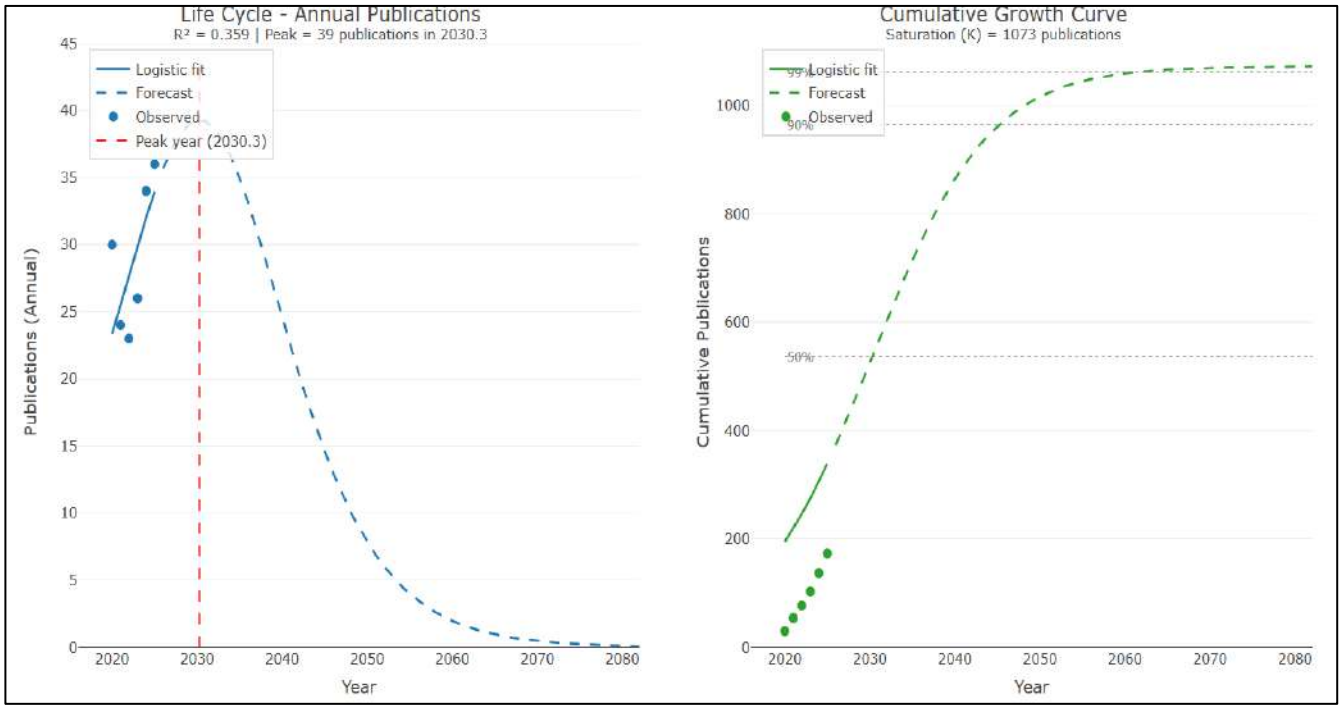

Figure 4: Life cycle of scientific production.
Source: Authors (2026).

The life-cycle and cumulative growth analyses provide important context for interpreting the comparative trends between manual and AI-based EMG filtering approaches. The projected peak in annual publications around 2030 indicates that the field is approaching a maturity phase, in which foundational techniques—largely represented by conventional manual filtering methods—have been extensively explored and stabilized. This maturation explains the continued relevance of manual filtering in the literature, particularly for embedded and real-time systems, where interpretability, low computational cost, and implementation robustness remain critical design requirements. At the same time, the steep rise observed in the cumulative growth curve before reaching saturation reflects a paradigm shift rather than simple incremental growth. This acceleration coincides with the increasing prominence of AI-based filtering methods, as also revealed by bibliometric keyword and trend analyses. As the field approaches saturation, research emphasis is moving away from developing entirely new manual filtering schemes toward leveraging AI to enhance adaptability and noise robustness in non-stationary EMG signals. Consequently, the life-cycle analysis supports the view that future advances in EMG filtering will likely be driven by hybrid and AI-assisted approaches that build upon established manual methods, rather than by purely conventional filtering paradigms.

IV.3 SCIENCE MAPPING

Science mapping of EMG signal filtering research was performed using Biblioshiny to elucidate the conceptual and intellectual structure of the field [22], [23]. Co-word analysis and thematic mapping reveal well-defined clusters encompassing both conventional filtering techniques (band-pass and notch filters) and advanced approaches, including wavelet-based and adaptive filtering, with increasing integration into clinical applications and machine learning–driven systems.

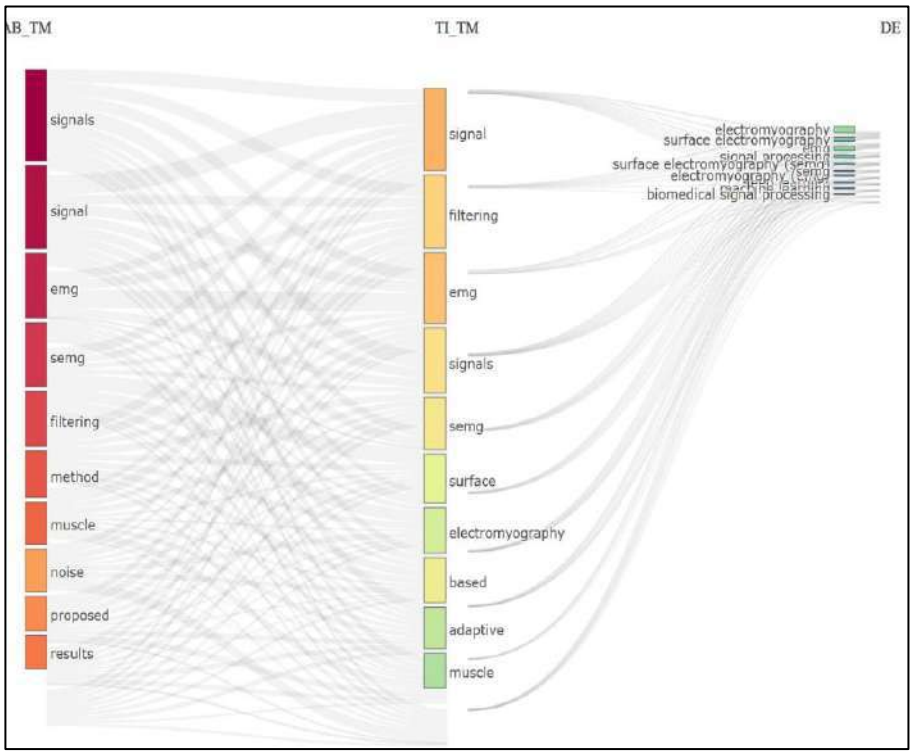

Figure 5: Three field plots.
Source: Authors (2026).

These results indicate a clear methodological evolution from classical linear filtering toward data-adaptive and intelligent filtering frameworks. The three-field plot (Figure 5) demonstrates strong thematic consistency across countries, title–abstract keywords, and author keywords, with dominant terms such as signal, EMG, sEMG, and filtering, underscoring the sustained and concentrated research focus on EMG signal filtering. Complementarily, the VOSviewer co-occurrence network (Figure 6) highlights tightly connected keyword clusters, reflecting mature research streams in traditional filtering and emerging clusters centered on wavelet methods and AI-driven filtering. The proximity and density of these clusters suggest a growing convergence between advanced signal processing techniques and machine learning paradigms, while simultaneously revealing opportunities for further exploration in adaptive and real-time EMG filtering for practical applications.

Table 2: Descriptive analysis of research performance using keywords.

Keywords	Number of Keywords
Bandpass filters	19
Butterworth filters	19
Low-pass filters	19
Notch filters	19
High-pass filters	15
IIR (Infinite Impulse Response) filters	15
Wavelet transforms	15
Median filters	14
Wavelet decomposition	14
Adaptive filters	10
Signal-to-noise ratio	10
Noise	4
Impedance	4

Source: Authors, (2026).

VOSviewer-based mapping reveals the underlying knowledge structure of EMG signal filtering research. Dense clusters with large nodes indicate mature and dominant themes, whereas smaller, sparse clusters reflect emerging or niche directions. Overlay visualization further highlights a clear temporal shift from classical filtering techniques toward adaptive and data-driven approaches. These results demonstrate that bibliometric visualization functions not merely as descriptive mapping, but as a robust analytical framework for identifying thematic dominance, research evolution, and future research opportunities in EMG filtering [24], [25].

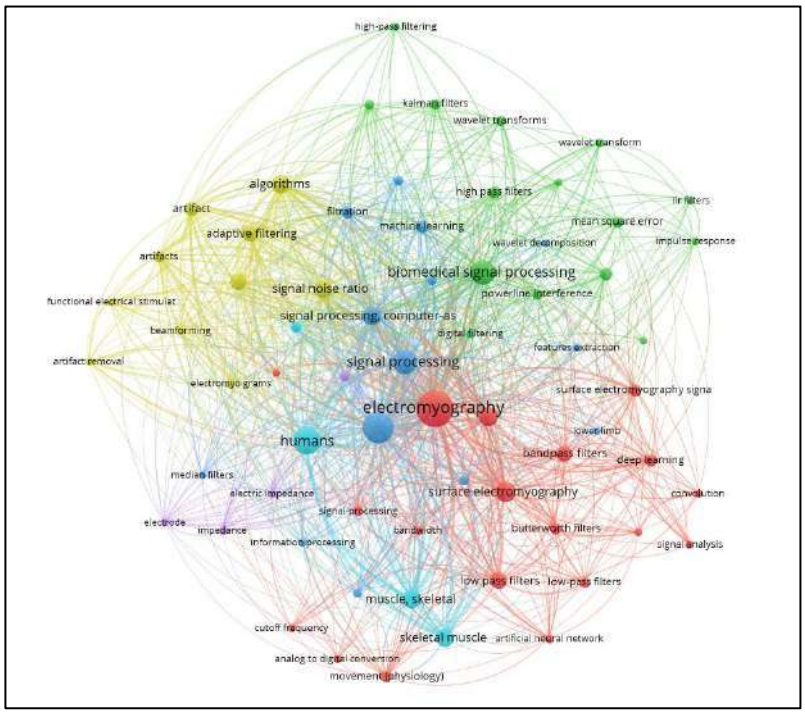

Figure 6: Keyword analysis and its development.
Source: Authors, (2026).

Overall, the findings confirm that EMG signal filtering research is fundamentally driven by the need to suppress motion artifacts, power-line interference, and high-frequency noise while preserving essential temporal and spectral characteristics of muscle activity signals. As EMG applications expand into biomechanics, rehabilitation, and human–machine interfaces, filtering has transitioned from a routine preprocessing step to a critical design factor that directly impacts system accuracy, robustness, and interpretability, particularly in machine learning and deep learning–based frameworks.

IV.4 RESEARCH COLLABORATION ANALYSIS

Bibliometric collaboration analysis reveals that research on electromyography (EMG) signal processing remains largely nationally clustered, with limited effective international collaboration. Co-authorship networks indicate that most research interactions occur within domestic or regionally proximate groups, suggesting that global knowledge integration in EMG research is still suboptimal. At the country level, China, the United States, India, and Germany emerge as the dominant contributors, functioning as primary research hubs with the highest publication output and collaboration intensity. Although collaborative activity is distributed across Asia, Europe, and the Americas, cross-continental linkages remain sparse, reflecting fragmented collaboration structures rather than a fully interconnected global research network.

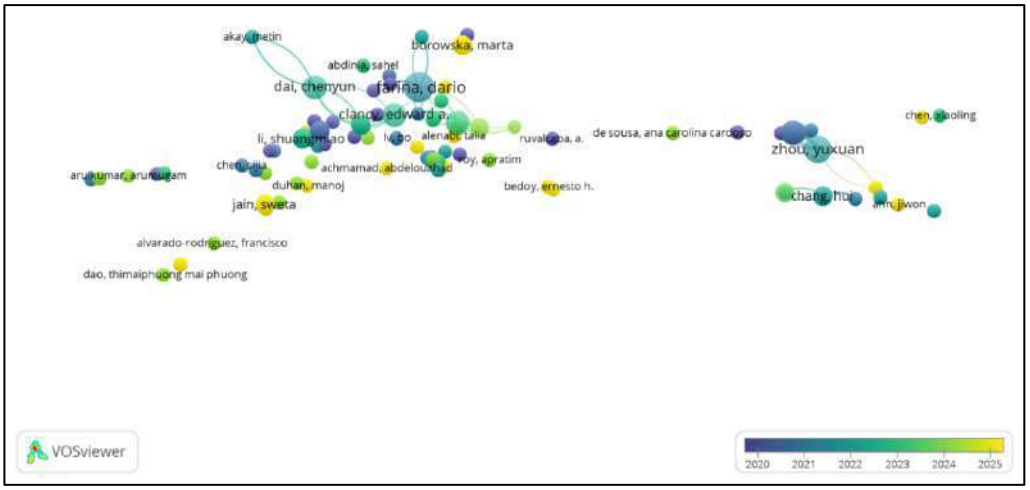

Figure 7: Collaboration among researchers.
Source: Authors, (2026).

Lustering analysis identifies three major country clusters (11, 11, and 8 countries, respectively), highlighting the presence of regional collaboration blocs. This pattern suggests that scientific exchange is driven more by geographical and institutional proximity than by thematic or methodological convergence. Notably, Indonesia is integrated into the global collaboration network, indicating growing participation from emerging research economies, although its role remains peripheral compared to leading hubs.

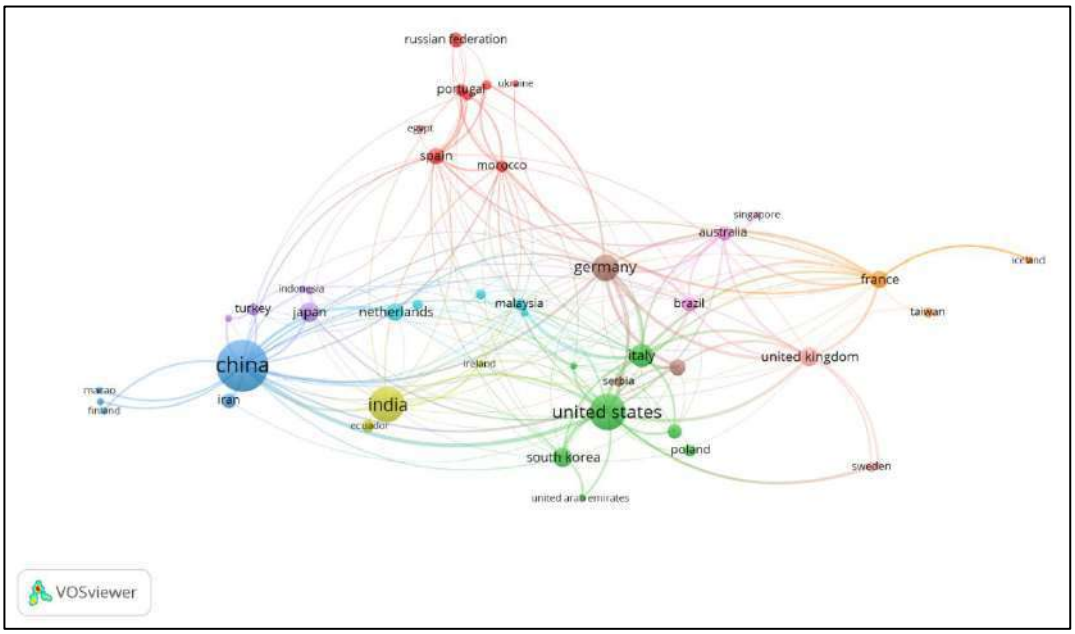

Figure 8: Collaboration between countries.
Source: Authors, (2026).

Overall, these findings underscore a structural imbalance in global EMG research collaboration, where scientific output is concentrated among a few dominant countries while international cooperation remains underdeveloped. Strengthening cross-border and cross-cluster collaboration is therefore critical to accelerating methodological innovation, improving research quality, and fostering more robust knowledge transfer in EMG signal filtering and analysis.

IV.5 RESEARCH CITATION ANALYSIS

Citation analysis reveals a highly concentrated and hierarchical knowledge structure in EMG signal filtering research. A limited number of journals act as primary dissemination hubs, with Sensors emerging as the most prolific outlet (15 publications, 2020–2025), indicating its central role in shaping and sustaining research momentum in this domain. This concentration reflects both thematic specialization and the consolidation of EMG filtering research within high-visibility publication venues [26]. Highly cited articles form a set of landmark studies that define the conceptual and methodological foundations of the field. Their dominant citation footprints demonstrate sustained relevance across theoretical modeling, signal processing pipelines, and application-driven EMG analysis. These works function as intellectual anchors, guiding subsequent research trajectories and reinforcing dominant methodological paradigms.

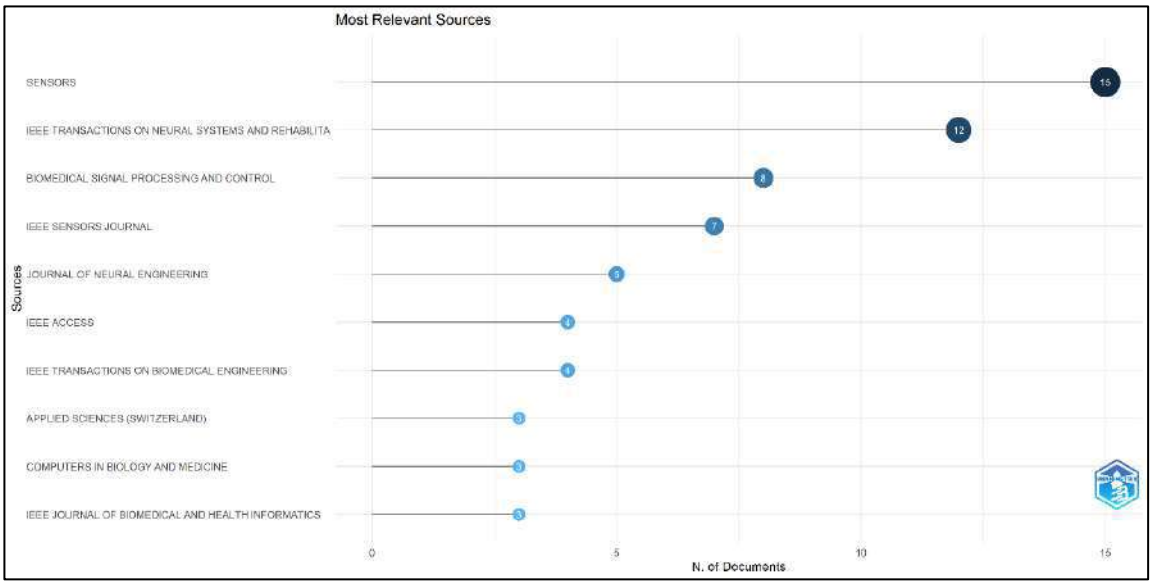

Figure 9: Most relevant sources.
Source: Authors, (2026).

As illustrated in Figure 9, EMG signal filtering research is concentrated within a limited set of Scopus-indexed journals, with *Sensors* ranking as the most prolific source between 2020 and 2025. The dominance of these top-ranked journals indicates their role as core publication venues and primary knowledge dissemination channels in the field. The consistent output across these sources reflects a sustained editorial focus on signal processing, biomedical instrumentation, and EMG-based applications.

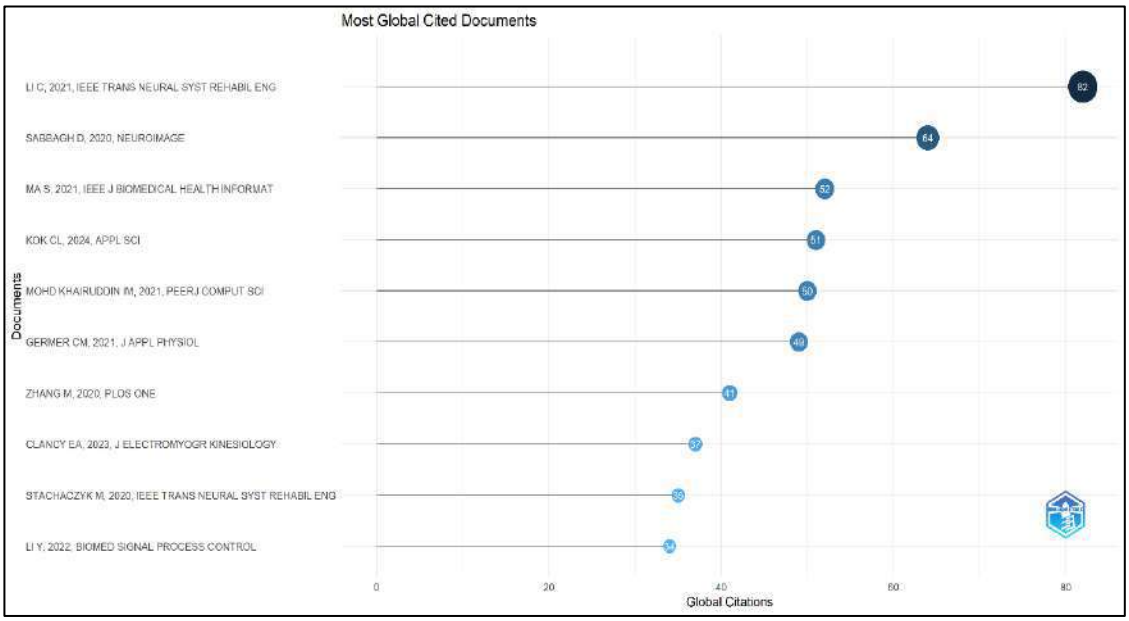

Figure 10: Most globally cited documents.
Source: Authors, (2026).

Figure 8 highlights the globally most cited articles, which represent high-impact and widely adopted contributions that have shaped the conceptual and methodological direction of EMG filtering research. The elevated citation counts of these studies indicate their function as landmark papers, frequently referenced as theoretical foundations, signal processing benchmarks, or methodological baselines in subsequent works [27]. This observation is further corroborated by Table 3, which summarizes the total global citation counts of the most influential articles. The concentration of citations among a small number of publications confirms a skewed citation distribution, where a few seminal studies account for a substantial portion of the field's intellectual influence. Collectively, Figures 9–10 and Table 3 demonstrate that EMG filtering research is structured around a stable core of highly cited journals and articles, which collectively define the dominant research paradigms and guide future methodological developments [28].

Table 3: Most globally cited documents.

No	Author	DOI	Total Citations	TC per Year	Normalized TC
1	Kuang et al. [29]	10.1109/TNSRE.2021.3055276	82	13.67	4.32

Source: Authors, (2026).

The citation network further indicates strong international knowledge diffusion, as top-cited studies are consistently referenced across countries and institutions, underscoring their global influence and cross-disciplinary adoption. Collectively, these findings confirm that EMG filtering research is driven by a core set of influential publications and journals, with citation dynamics highlighting mature research themes while simultaneously delineating the foundational frameworks upon which emerging methods—particularly adaptive and learning-based filtering—are being developed.

IV.6 ANALYSIS OF TRENDS AND POTENTIALS IDENTIFIED FOR FUTURE RESEARCH

The trend analysis reveals a decisive shift in EMG signal filtering research from static, rule-based approaches toward adaptive, data-driven paradigms. As shown in Figure 9, while conventional signal processing remains a foundational component, recent years are characterized by a rapid expansion of machine learning, deep learning, and explainable artificial intelligence (XAI) techniques, signaling a structural transformation in how EMG noise suppression and feature preservation are addressed [37].

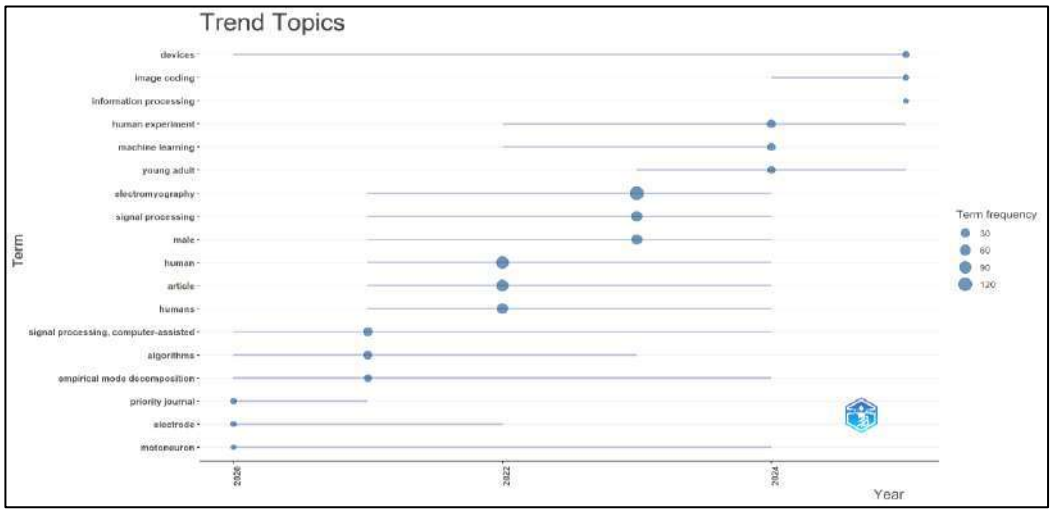

Figure 11: Trend topics diagram.
Source: Authors, (2026).

Looking forward, the results suggest several strategic research directions that will shape the next phase of EMG filtering studies. First, future work is expected to prioritize adaptive and context-aware filtering frameworks capable of handling non-stationary noise under real-world conditions, particularly for wearable and embedded EMG systems [38]. Second, the increasing dominance of machine learning and human-centered experiments indicates a growing demand for end-to-end EMG pipelines, in which filtering, feature extraction, and classification are jointly optimized rather than treated as independent stages. Third, the emergence of XAI-related themes highlights a critical need for interpretable filtering and denoising models, especially in clinical and rehabilitation applications where transparency and trust are essential. Moreover, the sustained growth of the electromyography keyword (120 publications through 2025) underscores the field's maturity, while the rising trajectories of signal processing, machine learning, and human experiment point toward application-driven and user-adaptive research agendas. Collectively, these trends indicate that future EMG filtering research will move beyond noise suppression alone, evolving into a strategic system-level component that directly influences performance, reliability, and clinical usability. Consequently, research efforts should focus on scalable, interpretable, and computationally efficient filtering solutions that can be deployed in real-time human–machine interfaces, smart prosthetics, and next-generation rehabilitation technologies. Building upon the trend analysis, a strategic mapping was conducted to identify high-impact and underexplored research opportunities in EMG signal filtering. The strategic diagram classifies themes into four quadrants according to their centrality and density, thereby revealing not only the current structure of the field but also its future growth trajectories.

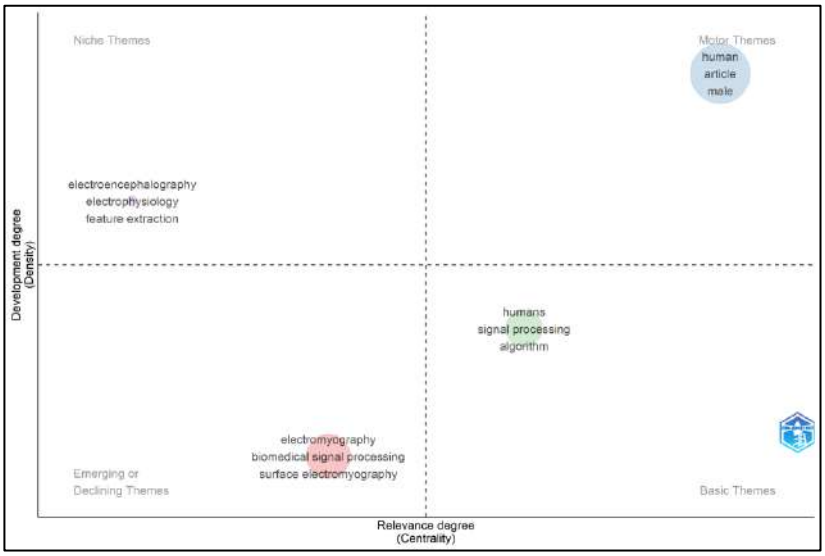

Figure 12: Identify potential future research with a strategic diagram.
Source: Authors, (2026).

As shown in Figure 12, Quadrant 1 contains highly influential driving themes (*human*, *article*, *male*) that dominate the literature and define the empirical backbone of EMG research. These themes are mature and saturated, suggesting that while they remain essential, they offer limited novelty unless coupled with methodological innovation. Quadrant 2 consists of highly developed yet isolated topics such as *electroencephalography*, *electrophysiology*, and *feature extraction*, indicating advanced but siloed research streams that require stronger integration with EMG-specific filtering frameworks to maximize their broader impact. In contrast, Quadrant 3 (electromyography, biomedical signal processing, surface electromyography) represents emerging and transitional themes with low density but high strategic relevance. These topics signal a critical opportunity for methodological breakthroughs, particularly in redefining filtering paradigms that address non-stationarity, inter-subject variability, and real-world noise conditions.

Similarly, Quadrant 4, which includes foundational concepts (humans, signal processing, and algorithms), serves as the methodological substrate of the field and offers fertile ground for innovation through the integration of adaptive algorithms, explainable models, and computationally efficient implementations. Taken together, the strategic map indicates that future EMG filtering research should deliberately shift its focus toward Quadrants 3 and 4, where the potential for high-impact contributions is greatest. Advancing these themes through adaptive, interpretable, and application-driven filtering strategies is expected to redefine EMG signal analysis and accelerate its translation into wearable systems, intelligent prosthetics, and human–machine interfaces.

V. CONCLUSIONS

This study provides a definitive bibliometric and thematic synthesis of electromyography (EMG) research with a focused examination of signal filtering methodologies. The results clearly demonstrate that EMG preprocessing is dominated by a diverse yet fragmented set of techniques—including band-pass, Butterworth, low-pass, notch, high-pass, median, and adaptive filters—reflecting both the methodological richness and the lack of convergence within the field. Bibliometric evidence confirms a sustained and accelerating growth in publications, alongside increasing methodological diversification, driven by the rapid expansion of EMG applications in biomedicine, rehabilitation, intelligent prosthetics, and machine learning–enabled systems. Critically, the absence of a universally accepted EMG filtering standard represents a structural limitation that continues to constrain reproducibility, comparability, and system-level optimization across studies. These findings indicate that future research must move beyond ad hoc filter selection toward application-aware, adaptive, and performance-driven filtering frameworks. A rigorous and systematic understanding of EMG filtering should therefore be regarded as a strategic prerequisite, not merely a preprocessing choice, for advancing analytical accuracy, enhancing system robustness, and enabling the reliable deployment of next-generation EMG-based technologies.

ABSTRACT

Osteoporosis is a progressive bone disease which is necessary to reduce fracture risk and complications. This paper aims to establish an automated classification system for osteoporosis based on automated image processing of medical images, and to generate a sophisticated method of combining different processing techniques, such as pre-processing, data augmentation, feature extraction, and classification modelling using advanced Deep Learning (DL) methods. Preprocessing of images involves resizing and the use of a Gaussian filter to eliminate noise from the image and thus improve image quality. Augmentation of images occurs through the use of Style GAN to create synthetic images, reduce the effects of data imbalance and improve the generalization of a model trained on limited sample sizes. Feature extraction occurs through the use of DenseNet121 which is demonstrated to be very efficient in producing a large number of high-quality hierarchical features. The techniques for classification of the extracted features are based on a novel Dual-Attention Vision Transformer and ResNet architecture (DualAtt-ViTResNet). It provides strong local feature representation of ResNet and the ability to acquire contextual information at the global level through vision transformers and their dual attention mechanism. Finally, hyper-parameter optimization of the DualAtt-ViTResNet architecture is accomplished using the Fennec Fox Optimization Algorithm (FFOA) which is used to improve accuracy, speed, and robustness of the classification task. A detailed experimental evaluation of the proposed framework indicates that the automated osteoporosis classification framework outperformed the existing frameworks with respect to higher accuracy of 0.9744, precision of 0.9767, Recall of 0.9789 and F1-Score of 0.9777. The proposed system offers an efficient solution for automated osteoporosis detection, supporting clinical decision-making and early diagnosis in medical imaging applications.

I. INTRODUCTION

A reduction in Bone Mineral Density (BMD) and the breakdown of the microstructure of bone tissue are two characteristics that define Osteoporosis. This causes the bone to become weak and more likely to fracture as a result of the increased amount of energy placed on the bones [1]. Currently estimated to be approximately 23.1% of women and 11.7% of men worldwide are affected by osteoporosis according to a meta-analysis of studies conducted between 2020 and 2021.

There is also a considerable variation in the rates of osteoporosis between individual countries around the world [2], [3]. Fragility fractures occur as a result of the normal biomechanics of our bodies being altered. These fractures frequently lead to higher rates of mortality, as well as the need for additional medical treatment, rehabilitation, and prolonged hospital stays and have been well documented in previous research to have major physical, psychological, social, and economic consequences [4]. These consequences include reduced quality of life, increased costs associated with treating osteoporosis, increased risks of mortality, decreased levels of physical activity, and decreased independence among elderly individuals [5]. As a result of the potentially life-threatening complications that occur from these osteoporotic fractures, it is vital to detect osteoporosis as early as possible so that appropriate measures are taken to prevent the occurrence of osteoporosis and the associated complications arising from an osteoporotic fracture including pain and suffering. For this reason, the World Health Organization (WHO) has deemed Dual Energy X-ray Absorptiometry (DEXA) to be the standard for assessing BMD and diagnosing osteoporosis [6], [7]. The BMD values that DEXA provides are expressed in terms of T-scores, which are calculated by taking the difference between an individual's measured BMD and the mean BMD for a reference population.

Osteoporosis is defined as having a T-score less than -2.5 and osteopenia has a T-score between -1.0 and -2.5. DEXA is still the most prevalent quantitative method of evaluating bone density due to its ease of access through the skin, affordability and limited health risks. However, to be truly effective and reliable, it must be viewed in conjunction with other techniques to produce meaningful outcomes. DEXA is limited to BMD, with low screening rates reported [8-10]. Additionally, the BMD results from DEXA are based on a 2-dimensional plane, which limits the ability to accurately calculate BMD and predict fracture risk. Additionally, DEXA results are skewed by natural age-related changes to bone strength, which could lead to a miscalculation of BMD and also caused by outside forces affecting the bone [11]. To mitigate these limitations, the proposed system uses a hybrid model to classify osteoporosis. Using medical imaging, this research establishes an automated framework for classifying osteoporosis. The framework is based on the DualAtt-ViTResNet architecture and employs FFO for hyperparameter tuning. This research includes numerous process for the identification of osteoporosis classification [12]. The process initiates with input medical images, which goes through preprocessing steps to remove noise and to standardize image quality. Thereby to accomplish this, a Wiener filter is used to reduce the mean square error of the original image compared to the restored image based on both local image variance and the statistical characteristics of the noise, thus providing a means for preserving the most important bone structure and intensity variations from image to image.

However, because of reliance on accurate estimates of the signal and noise statistics, a Wiener filter's effectiveness are limited by incorrect assumptions, causing residual noise or an overly smooth appearance of the restored image [13-15]. Hence, the proposed system uses Gaussian filter to resolve this shortcomings. In order to improve the resilience of the model, data augmentation is also carried out, which helps produce a variety of permutations of the input image. The preprocessed image is then fed to feature extraction phase which provides dense representations of spatial and temporal endurance in the input images. The multi-scale feature extraction capabilities of Inception-V3 is used to detect small differences in texture and density of bones in medical images [16]. The depth and complexity of the model also create challenges in terms of the computational power and memory needed to use the model, therefore it is difficult to use the model in resource-limited medical environments. ResNet-50 architecture enables the extraction of robust and representative features of bone density and texture combined [17-18]. As a result, this form of analysis provides superior prediction accuracy for classifying bone tissue types. This high-level feature extraction method therefore requires a large number of parameters and high calculations and long processing times due to the associated resource demand of the model. To address this issue, DenseNet-121 model is used in the proposed system [19-20]. The extracted image is passed to the classification stage to enhance the accuracy of the class predictions by concentrating on critical portions of the image. Comparison of various existing classifications are depicted in Table 1.

Table 1: Related works for classification models to detect Osteoporosis.

SI.NO	Author/Year	Classification	Merits	Demerits	Performance metrics
1.	Mukhtar Ul Islam *et al* [2025] [21]	ViT-16	The Attention Mechanism in the ViT-16 enables it to sift through scans and apply weight to different areas of the scan.	It requires careful considerations of the associated computational costs and available data.	It attains an accuracy of 88%, precision of 85%, Recall of 88% and FI-score of 86%.
2.	M. J. Aashik Rasool *et al* [2024] [22]	KONet	KONet uses an ensemble approach being more stable and decreasing the chances of being biased.	The architecture is more complicated and it is more challenging to deploy & maintain in a clinical setting.	The performance metrics of KONet is 95% of accuracy, precision, recall and FI-Score.
3.	Abdul Wahab Muzaffar *et al* [2025] [23]	OsteoNet	OsteoNet performs well with moderate amounts of data, particularly when utilizing data augmentation and transfer learning techniques.	It struggle to perform well with respect to long-range dependencies and global contextual information in an image.	It achieves an accuracy of 74.1% and FI-Score of 73.9%
4.	Sailaja Thota *et al* [2024] [24]	MobileNet	It's computational efficient model utilises a depth wise separable convolutional network that significantly reduces model size and provides a lower computational requirement.	Due to its compact nature, it is not able to extract the detailed features that are required to accurately diagnose osteoporosis.	MobileNet attains an accuracy of 94%, precision of 91% and recall of 92%.
5.	Athira O M *et al* [2025] [25]	ResNet-50+GRU	It reduces the need to collect large amounts of data specifically for osteoporosis	It is computationally expensive and requires additional memory	It establishes an accuracy of 95.65%, precision of 95.32%, recall of 95.98% and FI-Score of 95.49%.

Source: Authors, (2026).

Existing osteoporosis classification methods have difficulties in extracting features effectively and have very low classification accuracies for bone imaging features analyzed with medical images. Therefore to overcPome these issues, DualAtt-ViTResNet model is used in the proposed system to analyze the developed features of bones. Furthermore, to enhance the classification stage, FFOA is implemented to provide significant improvement in robustness, accuracy, and computational efficiency to achieve success at automating osteoporosis classification in the clinical imaging environment.

I.1 OBJECTIVES

The main objectives of this research includes,

- To reduce noise and to enhance medical image quality, preprocessing techniques such as resizing and Gaussian filter is implemented.
- To address imbalanced datasets and to increase data diversity and robustness, data augmentation method, StyleGAN is used.
- To extract discriminative and significant features from medical images and to effectively represent bone functions, DenseNet-121 is executed.
- To incorporate both channel-wise and spatially significant features, DualAtt-ViTResNet is employed.
- To increase model efficiency and classification accuracy, FFOA is introduced.

I.2 PAPER ORGANIZATION

This paper is organized as follows: Section II provides an explanation of the suggested system description. The study methodology is thoroughly described in Section III, which also includes examples of the process, methods, and mathematical representations. The experimental results of this work are described in Section IV, which also include the simulation setup, comparison analysis, and research summary. The conclusion of the proposed investigation is explained in Section V.

II. PROPOSED SYSTEM DESCRIPTION

The proposed framework for image classification includes preprocessing, augmentation, feature extraction, classification and hyperparameter tuning. The initial step in this process involves resizing and denoising with a Gaussian filter, ensuring it maintain consistent quality throughout the process. After denoising, StyleGAN is used for augmentation technique to create multiple realistic synthetic images that help to improve generalization. Once all synthetically generated images are created, the original images and all the synthetically generated images are run through DenseNet-121 to extract deep features from all of the images. This step enables to acquire effective spatial and contextual representations from the images efficiently. The input from the deep features generated from the images are passed into a DualAtt-ViTResNet classifier. The DualAtt-ViTResNet classifier uses convolutional and transformer types of learning, along with dual attention mechanisms, to capture local details and global dependencies simultaneously. Figure 1 illustrates the block diagram of the proposed Fennec Fox Optimized DualAtt-ViTResNet for automated osteoporosis classification.

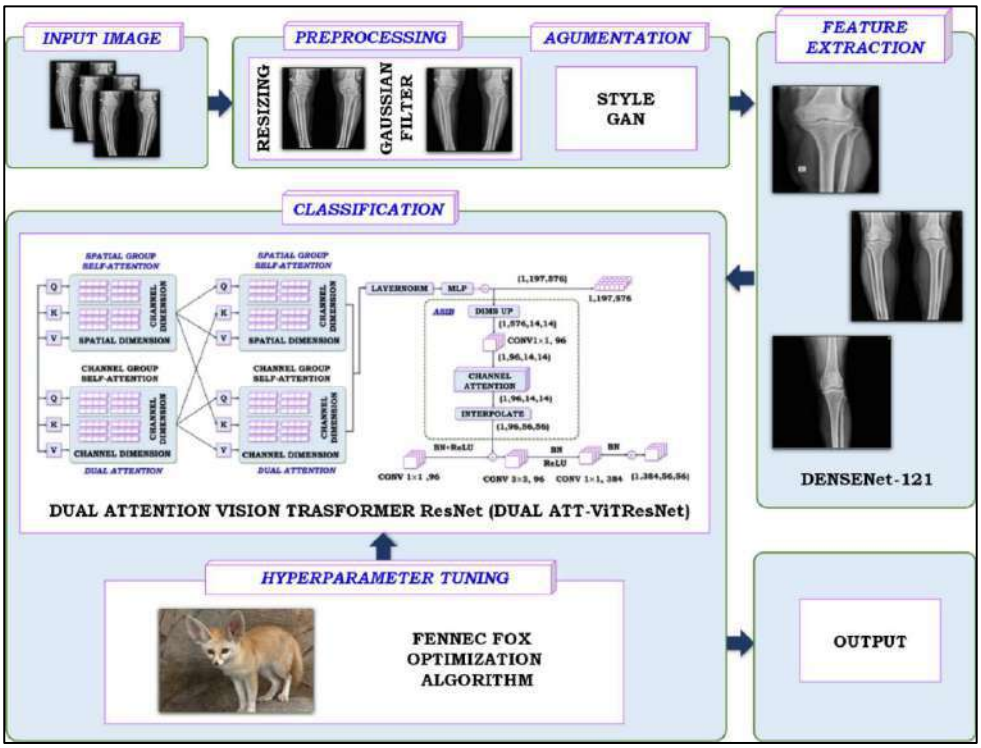

Figure 1: Block diagram of the proposed model.
Source: Authors, (2026).

Finally, in order to further enhance the model's performance, the FFOA is utilized for hyperparameter tuning. This algorithm ensures that the best possible model configuration are produced for classifying images accurately and consistently.

III. PROPOSED SYSTEM MODELLING

III.1 PREPROCESSING

III.1.1 Resizing

By using standardised medical images at a defined resolution prior to analysis through resizing, DL models achieve a uniform input. Resized medical images are less computationally expensive compared to other forms of medical imaging, and also maintain all important bone structural characteristics, thereby making it easier for neural networks to extract features related to the classification of osteoporosis and perform the correct classification of osteoporosis.

III.1.2 Gaussian Filter

The process of classifying osteoporosis with an automated method requires the preprocessing of digital images using computer vision such as X-ray and Dual Energy Absorptiometry [DXA]. Medical images typically have noise that obscure the natural texture of bone and therefore negatively impact the diagnosis of osteoporosis, thus to eliminate any noise or blurring from the image prior to exposure to feature extraction and classification, a Gaussian filter is used. Gaussian smoothing is performed by performing convolution with a Gaussian operator, which is effective in reducing the presence of high frequency noise, therefore allowing for the preservation of bone structure. The one-dimensional Gaussian filter is scientifically stated as,

$$G_{1D}(x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{\frac{x^2}{2\sigma^2}} \tag{1}$$

For medical images, the 2-D symmetrical homogeneous Gaussian filter is described as,

$$G_{2D}(x,y) = \frac{1}{2\pi\sigma^2} e^{\frac{-x^2+y^2}{2\sigma^2}} \tag{2}$$

The Gaussian distribution function contains a variableσ, is the Standard deviation, which directly controls the level of smoothing produced by the filter. The filtering process is accomplished by convolving the pixel value matrix of the original image with a specific normalized Gaussian Kernel. Using the following Mean Square Error (MSE) and Peak Signal-to-Noise Ratio (PSNR), the quality of the filtered bone image, is used to classify Osteoporosis with high degree of accuracy, and is measured by comparing the MSE of the original Image with the filtered image of size$(M \times N)$.

$$MSE = \frac{1}{M \times N} \sum_{i,j} \left(O_{image} - R_{image}\right)^2 \tag{3}$$

PSNR quantifies the enhancement of the quality of an image that results from the filtering process.

$$PSNR = 10 \log_{10} \left(\frac{255 \times 255}{MSE}\right) \tag{4}$$

Gaussian filters increase the visibility of the structural and textural patterns associated with bone, and subsequently provide more accurate, reliable, and effective automated classification of osteoporosis by reducing noise and improving the PSNR of the image being analysed.

III.2 AUGMENTATION- STYLE GAN

StyleGAN allows to generate the synthetic images of bone using the principles of free-form image creation. Through this use of StyleGAN, many of the issues related to the small size and imbalance of the medical image databases used for automated classification of osteoporosis are addressed. In order to generate images using StyleGAN, first select random latent vectors z ∈ Z from a two-dimensional normal distribution. These latent vectors are transformed into a three-dimensional space (W) using a learned transformation from the four-dimensional style space. The three-dimensional representation are then transformed into Style Space (S), where each of the individual style channels controls certain aspects of the generated image such as the texture of the bone, the density of the bone and the arrangement of the trabecular and cortical bone. The use of StyleGAN's Style Space allows for the generation of synthetic images that have anatomical accuracy and diversity compared to the currently available medical images. StyleGAN's Style Space is also unscrambled, allowing for the precise control of clinically relevant features, such as the arrangement of the trabecular bone and the thickness of the cortex during the generation of synthetic images. The availability of anatomically accurate and diverse synthetic images enhances the pool of images available for training DL systems. Thus, this enhanced training pool increases the feature learning of the DL systems and increases the accuracy and robustness of the automated classification of osteoporosis.

III.3 FEATURE EXTRACTION-DENSENET-121

DenseNet121 attains exceptional performance in automatically classifying osteoporosis through its dense connectivity, which allows for all layers of the model to receive the same input feature maps from every previous layer. With this architecture, DenseNet121 easily reuse many of the features used by the previous layers of the network, which in turn required for accurately detecting even slightly different bone densities or structures. The architecture of DenseNet-121 is illustrated in Figure 2.

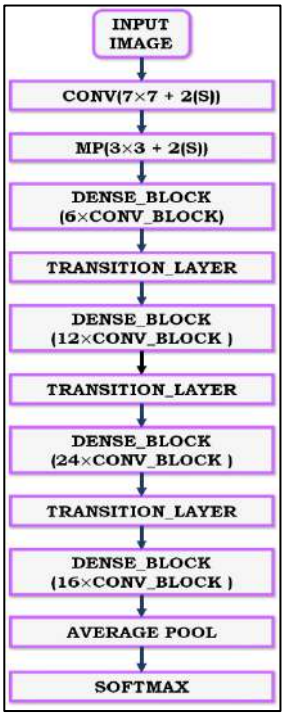

Figure 2: Structure of DenseNet-121.
Source: Authors, (2026).

Mathematically, the output from the nth layer is expressed as follows,

$$Y_n = C_n([Y_1, Y_1, \dots, Y_{n-1}]) \tag{5}$$

Where, C_n is a composite function of convolution, batch normalization, and ReLU activation, and $[Y_1, Y_1, \dots, Y_{n-1}]$ are concatenated inputs from all previous feature maps in the network. Additionally, DenseNet121 has incorporated bottleneck layers to improve the computation performance when training, this layer utilizes a 1×1 convolution followed by a 3×3 convolution defined as,

$$Y_{bottleneck} = W_{3\times3}\left(ReLU\left(BN\left(W_{1\times1}(Y_n)\right)\right)\right) \tag{6}$$

Where W 1 × 1 and W 3×3 are weight matrices for the 1×1 and 3×3 convolutions, respectively, and BN is the batch normalization. Transition layers are composed of a 1×1 convolution and a 2×2 average pooling operation, which decrease the spatial dimensions of the feature map, the transition layer is defined as follows,

$$Y_{trans} = Pooling\left(ReLU\left(BN\left(W_{1\times1}(Y_n)\right)\right)\right) \tag{7}$$

DenseNet121 possess the added benefit of using its ability to concatenate feature maps from all prior layers, allowing it to efficiently learn both fine-grained trabecular bone structures and macro-level skeletal structures which are important in correctly identifying bones as normal, osteopenic, and osteoporotic. Additionally, due to the dense connectivity of DenseNet121, the number of weights are substantially reduced and therefore reduces overfitting on smaller osteoporosis datasets while achieving high classification accuracy.

III.4 CLASSIFICATION- DUALATT-VITRESNET

For automated classification of osteoporotic bone, fine-grain local image structures and skeleton context need to be identified at a global level. Currently, most approaches utilise the transformer model of Vision Transformers, by captivating image input, breaking it into $P \times C$ patches and reconstructing them with added positional encodings. Inappropriately, this process of patching reduce the inherent 2D layout of bone images, this reduced layout makes it difficult to detect changes due to osteoporosis in both trabecular and cortical bone. Therefore, to provide a solution, a dual attention mechanism is utilised that operates in parallel for both the spatial and channel dimensions. In terms of layout structure, the feature map was grouped by using N_g groups where each group contained P_g number of patches. Within each group self-attention was computed independently, therefore collectively creating an attention map for each group. This combined map is referred to as Grouped Spatial Attention, it is formulated as,

$$A_s(Q, K, V) = Concat\left(A_1^*(Q_1, K_1, V_1), \dots A_{Ng}^*\left(Q_{Ng}, K_{Ng}, V_{Ng}\right)\right) \tag{8}$$

The local spatial groups for obtaining Q, K, V through a linear combination of the input features and$Q_i, K_i, V_i \epsilon R^{Pg \times C}$, local attention operation retain local spatial information, including instances of trabecular thinning and deterioration of micro texture. At the same time, channel-wise self-attention was utilized on the channel dimension ruined up into N_w groups, each containing a total of C_w channels so that$C = C_w \times N_w$.

$$A_c(Q,K,V) = Concat\left(A_1^*(Q_1,K_1,V_1), \dots A_{Nw}^*(Q_{Nw},K_{Nw},V_{Nw})\right) \quad (9)$$

This allows for the overall density of bone and its integrity to be represented in channel-level attention when all spatial locations of the image together are considered at the same time. Cross-fusion is the integrated strategy of ensuring the effective exchange of information between local and global representations during the processing of both types of attention, which allows channel attention to influence discriminative local regions which are selected for the channel branch of the neural network. The diagram of DualAtt-ViTResNet is depicted in Figure 3.

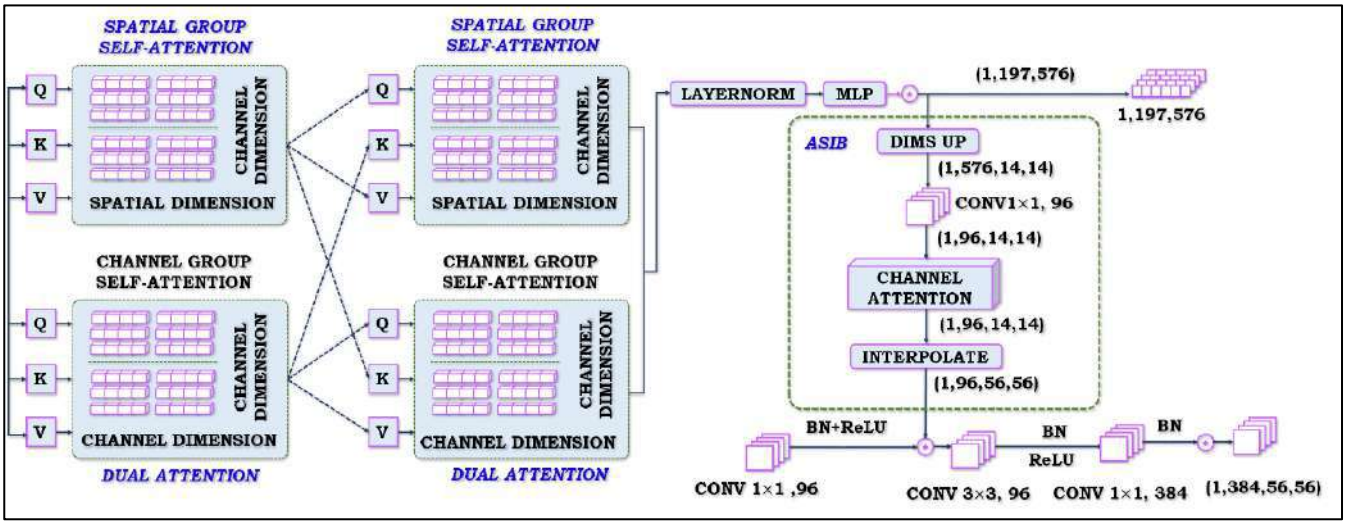

Figure 3: Structure of DualAtt-ViTResNet.
Source: Authors, (2026).

In the DualAtt-ViTResNet, the ViT part uses the initial layers of ResNet to make the feature maps into patch features that are then flattened into 196 patch features $x_p = \{x_p^1, x_p^1, \dots x_p^{196}\}$ to build an embedded sequence including the position information. The embedded sequence is built by,

$$z = \left[x_p^1, x_p^2, \dots, x_p^{196}\right] + E_{pos} \quad (10)$$

Where, E is the patch embedding matrix and E_{pos} is the position embedding. To classify the images, the sequence is given a learnable class symbol x_{class} to create a sequence,

$$z_0 = \left[x_{class}, x_p^1, x_p^2, \dots, x_p^{196}\right] + E_{pos} \quad (11)$$

This sequence captures the full context of the entire bone image, providing a complete view of the overall structure of the skeleton but losing local spatial relationships. The multi-head self-attention is applied to the embedded sequence where each head computes and the outputs are concatenated and linearly projected to obtain,

$$Attention(Q,K,V) = Softmax\left(\frac{QK^T}{\sqrt{d_k}}\right)V \quad (12)$$

$$Multi\ Head(Q,K,V) = Concat(Head_1, \dots Head_9)W^O \quad (13)$$

The ViT branch of this approach allows for long-range dependency capture between different areas of the bone. The proposed technique incorporates patch flattening to create a disconnection between the area, and this disconnection is compensated through the grouped spatial attention mechanism, while the grouped channel attention allows for the maintenance of overall global semantic consistency in bone representation. By combining the ViT and ResNet architectures, the DualAtt-ViTResNet leverage patch embedding with positional encoding, grouped spatial self-attention, grouped channel self-attention, and multi-head self-attention to create a well-balanced representation of the local microstructure of a bone in conjunction with the full bone setting to significantly improve feature discriminability and robustness, thus rendering it mainly as an automated system for potentially accurate and reliable classification of osteoporosis.

III.5 FENNEC FOX OPTIMIZATION ALGORITHM

Automated classification of Osteoporosis is expressed as an optimization problem where the objective is to find the optimal parameters of the DL algorithm that yield the best classification performance for Osteoporosis.

The FFOA uses the fennec fox as a representation of a possible solution. The position of the ith fennec fox is represented by a vector dimension m, where m is the number of decision variables for Osteoporosis classification, denoted as $X_i = (x_{i,1}, x_{i,2}, \dots x_{i,m})$. Therefore, the initial population of candidate solutions is randomly populated throughout the search space to promote a diverse population and allow the algorithm to investigate multiple sets of parameter configurations.

$$x_{ij} = lb_j + r.(ub_j - lb_j) \tag{14}$$

The candidate solutions are stored in a population matrix where each row corresponds to a potential solution for Osteoporosis classification and each column corresponds to a unique decision variable.

$$X = \begin{bmatrix} X_1 \\ \vdots \\ X_2 \\ \vdots \\ X_N \end{bmatrix} = \begin{bmatrix} x_{1,1} \cdots x_{1,j} \cdots x_{1,m} \\ \vdots \quad \vdots \quad \vdots \\ x_{i,1} \cdots x_{i,j} \cdots x_{i,m} \\ \vdots \quad \vdots \quad \vdots \\ x_{N,1} \cdots x_{N,j} \cdots x_{N,m} \end{bmatrix} \tag{15}$$

Once the population has been initialized, the algorithm evaluates each solution by taking the set of candidate values and using them as input to the optimization objective function to obtain the corresponding fitness values.

$$F = \begin{bmatrix} F(X_1) \\ \vdots \\ F(X_i) \\ \vdots \\ F(X_N) \end{bmatrix} \tag{16}$$

These fitness metrics define the classification performance in terms of sensitivity to identify the Osteoporosis classification label of the subject bone-image. The fitness values obtained are used to choose potentially superior solutions during the optimization process.

Pseudo-code: FFOA

```
START
1. Initialize population of Fennec foxes randomly
2. Set maximum iterations MaxIter
3. Evaluate fitness of each fox
4. Identify best fox (global best)
5. FOR iter = 1 to MaxIter DO
6.     FOR each fox i in population DO
7.         Generate random coefficients
8.
9.         IF exploration condition is satisfied THEN
10.            Update position using long-distance movement
11.        ELSE
12.            Update position using local exploitation
13.        END IF
14.        Apply boundary constraints
15.        Evaluate new fitness
16.
17.        IF new fitness is better than old fitness THEN
18.            Update fox position
19.        END IF
20.    END FOR
21.    Update global best fox
22.
23.    IF stopping criteria is satisfied THEN
24.        BREAK
25.    END IF
26. END FOR
27. Output best solution
28. Output best fitness value
29. Store convergence history
30. END
```

The FFA begins with simulating the fennec fox's digging behavior. This is a local phase of exploration where each solution only explores a small neighbourhood of its current position. This means that it make fine adjustments to the parameters that affect the subtle patterns of osteoporosis. The local update of a decision variable is calculated using the following formula,

$$x_{i,j}^{p1} = x_{i,j} + (2r - 1).R_{i,j} \tag{17}$$

As the iterations of the algorithm progress, the neighbourhood radius of a solution decreases. This provides a mechanism to explore more broadly in the initial iterations of the FFA, while allowing precise refinement in the later iterations. If the new solution has a better fitness than the current solution and is given by,

$$R_{i,j} = \alpha.\left(1 - \frac{t}{T}\right).x_{i,j} \tag{18}$$

$$X_i = \begin{cases} x_{i,}^{p1} if\ F_i^{p1} < F_i \\ x_i, otherwise \end{cases} \tag{19}$$

The current solution is updated with the new solution. The FFA includes an escape mechanism that acts as a global search mechanism. Each solution is encouraged to move towards or away from randomly selected solutions. This simulates the sudden changes in direction a fennec fox employs to evade predators. A random target position is selected as,

$$X_i^{rand} = X_k, k \in \{1,2,\dots,N\} \tag{20}$$

Global exploration and avoidance of local optima occur in the second phase when the algorithm simulates the fennec fox's escape from predators. Mathematically, it represents the global exploration for the fennec fox algorithm. The equation for this phase is,

$$x_{i,j}^{p2} = \begin{cases} x_{i,j} + r.\left(x_{i,j}^{rand} - I.x_{i,j}\right), if\ F_i^{rand} < F_i \\ x_{i.j} + r.\left(x_{i,j} - x_{i,j}^{rand}\right), \quad otherwise \end{cases} \tag{21}$$

$$X_i = \begin{cases} X_i^{p2}, if F_i^{p2} < F_i \\ X_{i\ ,} \quad otherwise \end{cases} \tag{22}$$

Where, I represents a random integer, and r is a random scaling factor. The FFOAs, objective is to explore the feature space and parameter settings of the classification system so that it reaches the global optimum for the best classification of osteoporosis specified in the selected features and classifier parameters. The flowchart of FFOA is shown in Figure 4.

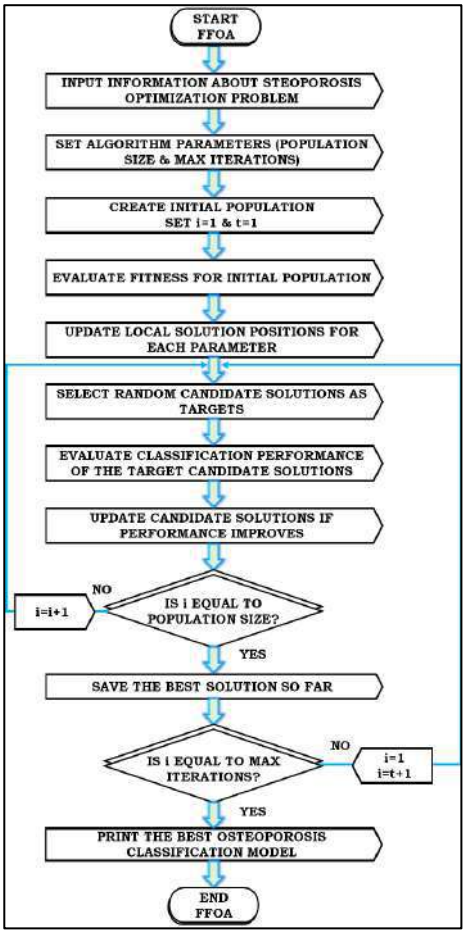

Figure 4: Flowchart of FFOA.

The FFOA iteratively used for each of these phases allows the active fennec fox algorithm to converge on the optimal classifier for osteoporosis.

IV. RESULT AND DISCUSSION

The aim of this work is the development of a DL system for the automatic classification of osteoporotic changes in the knee, based on knee X-ray images, into three categories such as normal, osteopenia, and osteoporosis, that represent varying degrees of bone density and subject to change due to aging and other conditions. An important feature of this system is the application of a new hybrid model called DualAttention-ViTResNet, it refers to both use of the attention mechanism and vision transformer architecture in conjunction with ResNet Neural Networks to build a superior hybrid model for knee osteoporosis detection based on classification methods. The basis for training this model is the Multi-Class Knee Osteoporosis Dataset, which has an 80:20 split, with 80% of the data being used to train the model and 20% of the data used to evaluate the model's predictive accuracy. The overall intent of implementing the DualAttention-ViTResNet to enhance the ability to identify these osteoporotic changes in knee joints and support medical professionals with accurate diagnosis and ongoing monitoring of bone health is increased accuracy through improved classification.

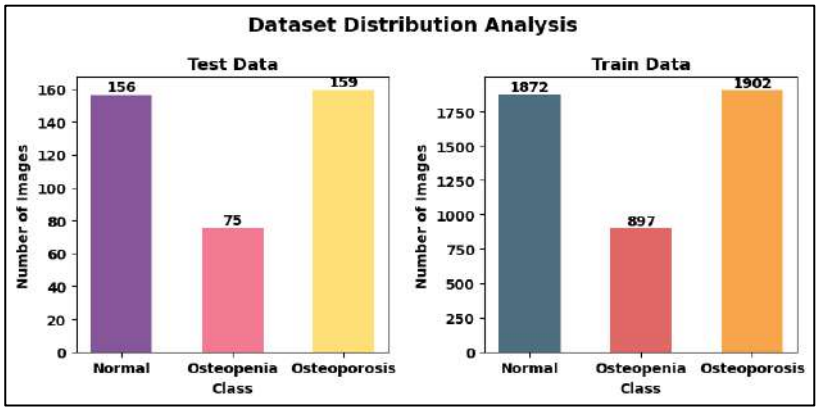

Figure 5: Dataset distribution analysis.
Source: Authors, (2026).

Figure 5 shows the distribution of data analysis, where the test data and train data is mentioned. The dataset revealed a clear imbalance between Normal and Osteoporotic images compared to Osteopenic images in both train and test datasets.

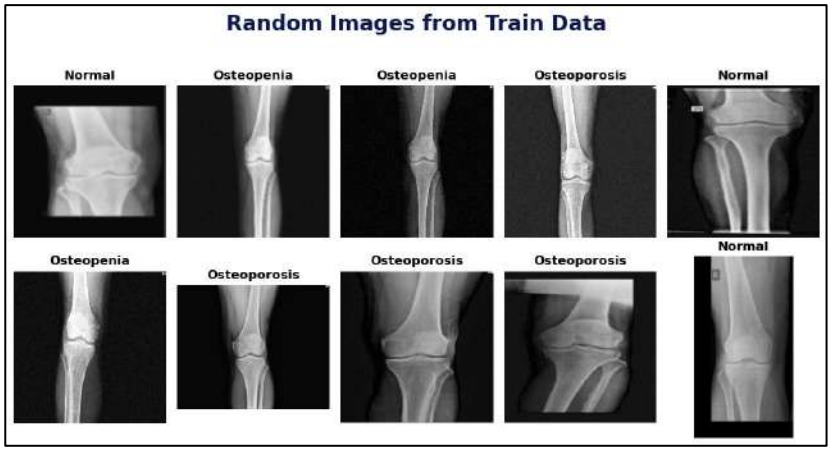

Figure 6: Random images from train data.
Source: Authors, (2026).

The Figure 6 provides examples of Knee X-Rays produced from the training data, comparing normal knees, osteopenic knees, and osteoporotic knees visually illustrating differences in bone density.

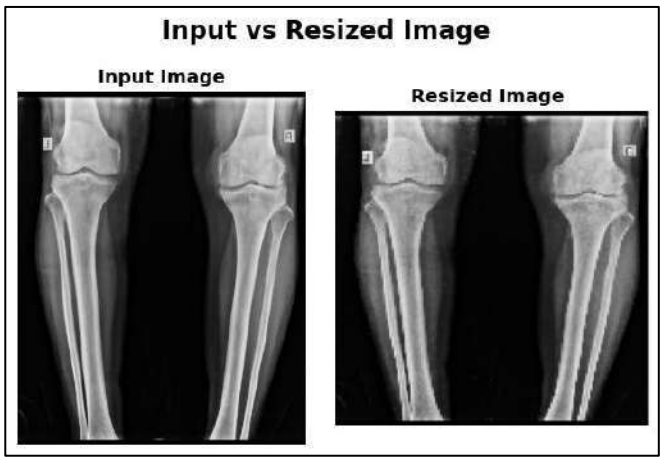

Figure 7: Input image and Resized image.
Source: Authors, (2026).

Figure 7 contains two versions of the same Knee X-Ray, one unaltered and one resized. The initial image appears to be the full-size model used for analysis. The reshaped version is resized in the focus on the actual Knee X-Ray has changed, probable to allow for better review and comparison.

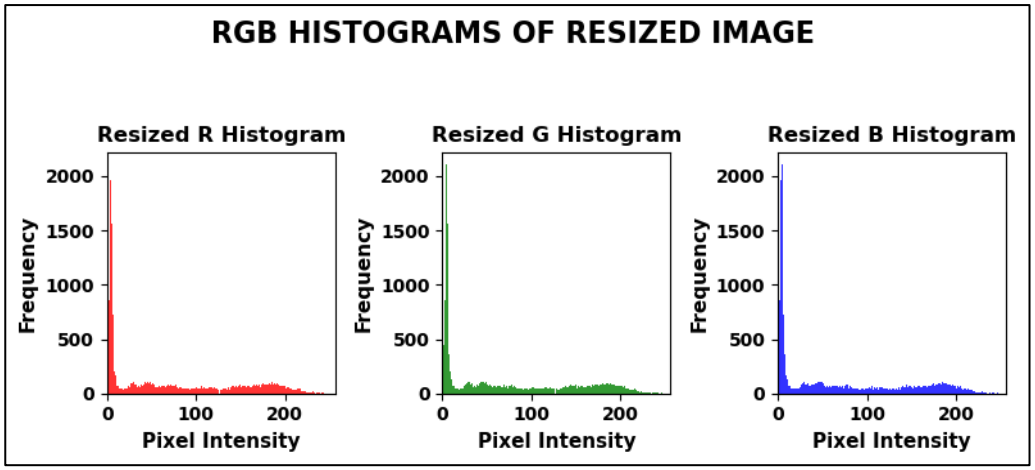

Figure 8: RGB histogram of resized image.
Source: Authors, (2026).

Figure 8 displays RGB histograms related to the resized Knee X-Ray. It is observed from these histograms that there was a distinct clustering of pixel intensity values that were relatively low throughout red, green, and blue channels.

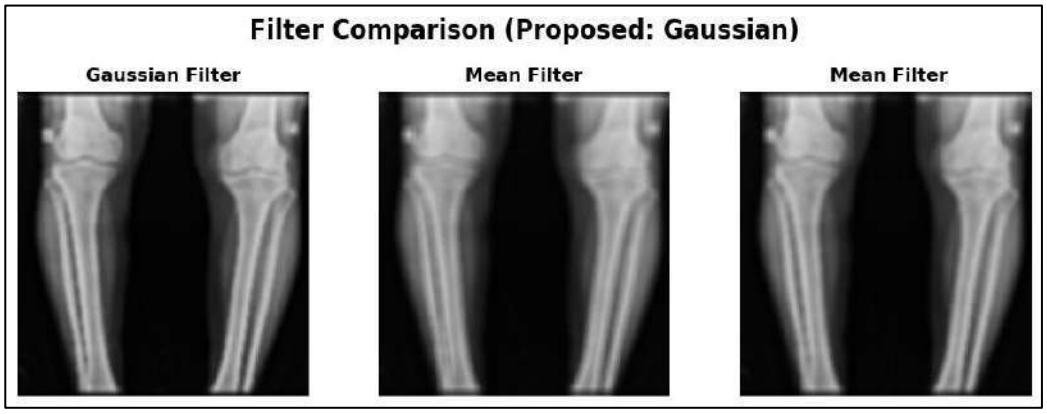

Figure 9: Comparison of filters.
Source: Authors, (2026).

Figure 9 compares the outcomes from the applications of different types of filters to a given X-Ray, Gaussian filter versus mean filter. Although the Gaussian filter produces images that maintain edges with minimal noise, the mean filter creates very smooth results, with significant blurring or lack of definition between the actual knee model and the produced model using a mean filter.

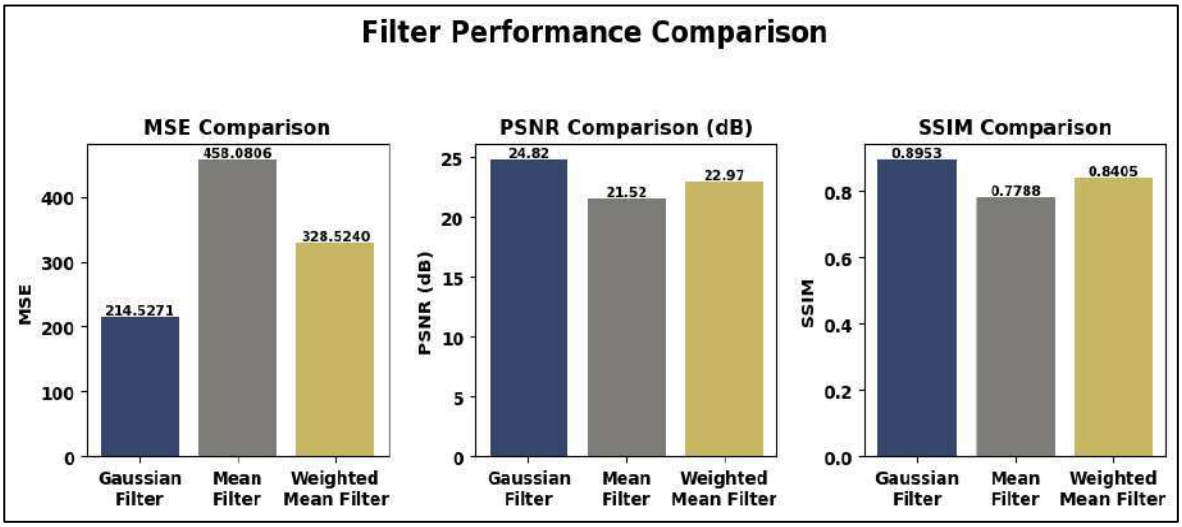

Figure 10: Filter performance comparison.
Source: Authors, (2026).

From Figure 10, it is clearly perceived that the Gaussian filter outperformed all other types of filters through all methods of evaluation, where it produced the lowest MSE, the highest PSNR and the highest SSIM which demonstrates that the quality of the Gaussian filter surpasses that of Mean and Weighted Mean filters.

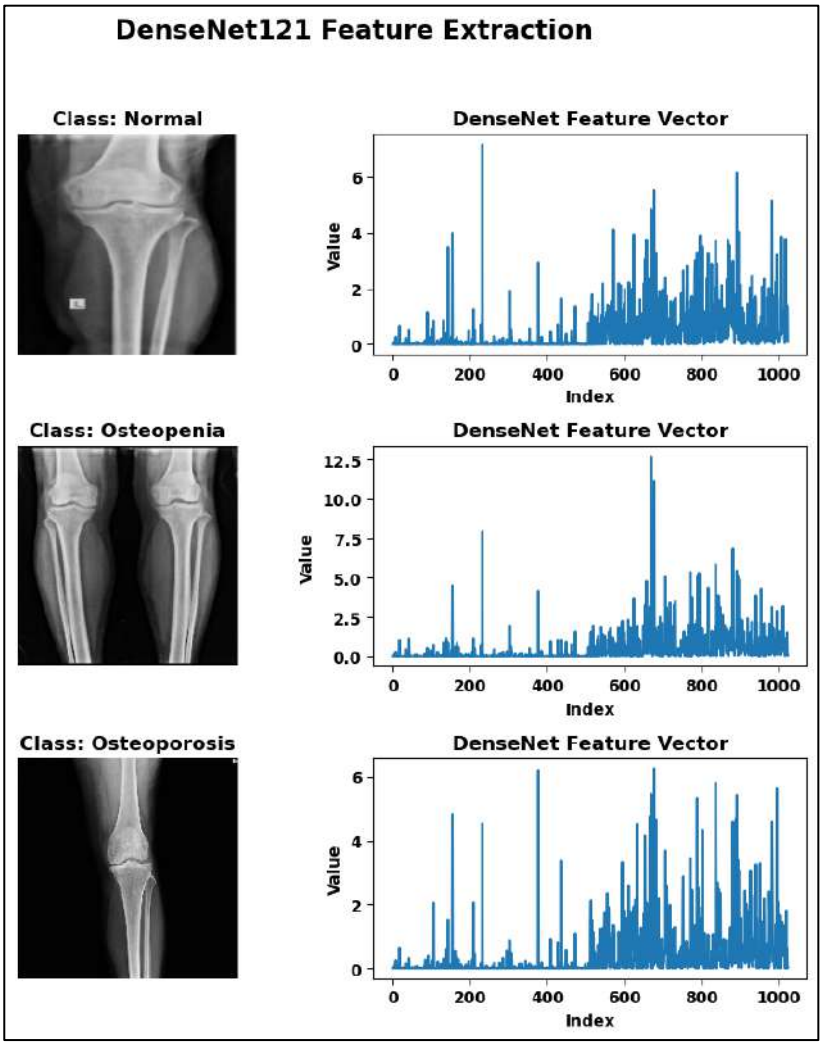

Figure 11: DenseNet-121 Feature extraction.
Source: Authors, (2026).

Figure 11 is the representative of feature extraction using DenseNet121 from three classes of X-ray images such as Normal, Osteopenia and Osteoporosis. It displays the feature vectors associated with the images and exhibit varying patterns of values, which allows for better differentiation between the bone conditions represented by each image.

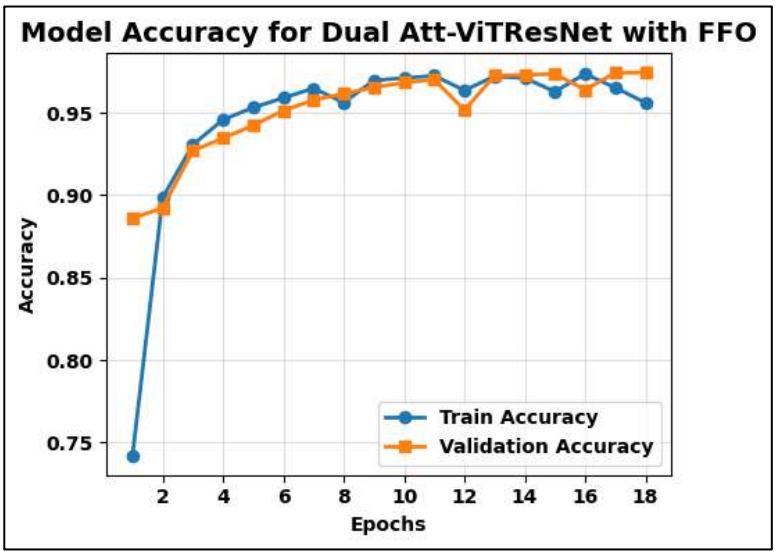

Figure 12: Model accuracy for Dual Att-ViTResNet with FFO.
Source: Authors, (2026).

Figure 12 depicts the accuracy associated with each epoch of training and validation for the Dual Att-ViTResNet with FFO, demonstrating that the accuracy improves quickly during the initial epochs and stabilises towards the end around 96–97% and that the training and validation curves are closely aligned, which indicates a good amount of convergence and minimal overfitting was exhibited.

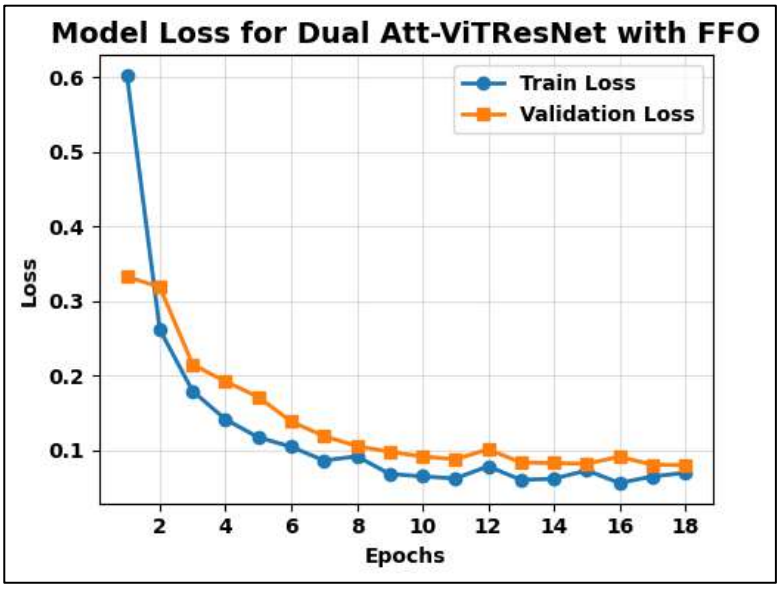

Figure 13: Model loss for Dual Att-ViTResNet with FFO.
Source: Authors, (2026).

Figure 13 represent the decaying loss associated with training and validation over time, with both beginning to stabilise at much lower loss values after a number of epochs have taken place, which demonstrates the model is learning more effectively.

Table 3: Model performance for Dual Att-ViTResNet with FFO.

SI.NO	METRICS	VALUES
1	Accuracy	0.9744
2	Precision	0.9767
3	Recall	0.9789
4	F1-Score	0.9777
5	Specificity	0.9861
6	AUC-ROC	0.9991
7	AUC-PR	0.9987
8	MCC	0.9600
9	Cohen’s Kappa	0.9598

Source: Authors, (2026).

Table 3 depicts the model performance of Dual Att-ViTResNet with FFO. The model displays exceptional performance as evidenced by its strong prediction accuracy, balanced precision and recall, superior ability to discriminate between the various classes, and very high correlation between the predictions and reality.

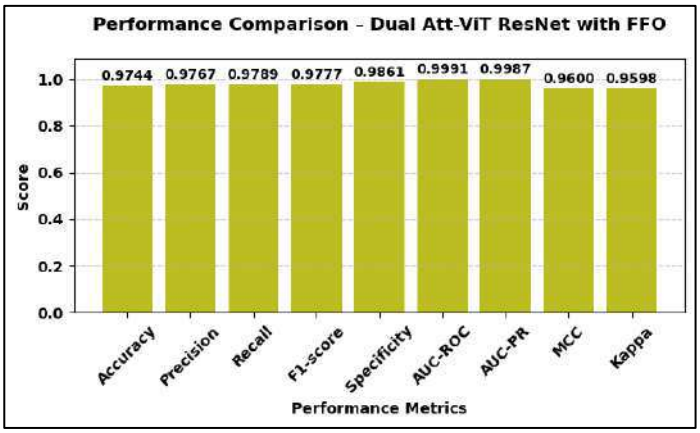

Figure 14: Performance comparison of Dual Att-ViTResNet with FFO.
Source: Authors, (2026).

Figure 14 represents the performance of the Dual Att-Vit ResNet+FFO model relative to all performance metrics. The Dual Att-Vit ResNet+FFO model has a high score for the Accuracy, Precision, Recall, F1 Score, Specificity, AUC-ROC, AUC-PR, MCC and Kappa metrics. These metrics indicate the model's high level of performance across these evaluation dimensions.

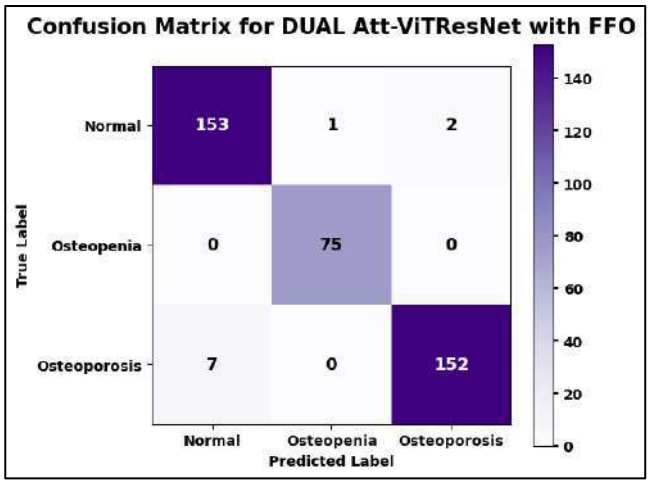

Figure 15: Confusion matrix of Dual Att-ViTResNet with FFO.
Source: Authors, (2026).

The Confusion Matrix of the Dual Att-Vit ResNet + FFO model demonstrates that there is a relatively high number of correctly predicted classifications which is demonstrated in Figure 15. While the Confusion Matrix contain a few incorrectly classified cases, the overall trend indicates that the model accurately classifies individuals into their normal, Osteopenia and Osteoporosis categories.

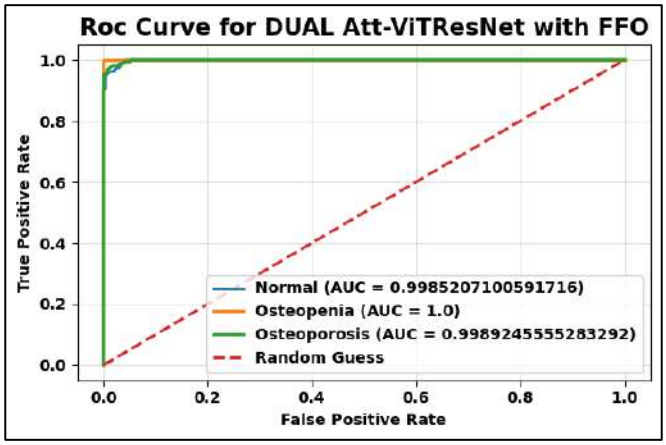

Figure 16: ROC curve for Dual Att-ViTResNet with FFO.
Source: Authors, (2026).

Figure 16 demonstrates a very high level of classification for each class being classified by the Dual Att-ViT + FFO Model. Each of the Normal Osteopenia and Osteoporosis classes has an AUC value of close to 1.0 and therefore demonstrates excellent classification performance compared to random selection.

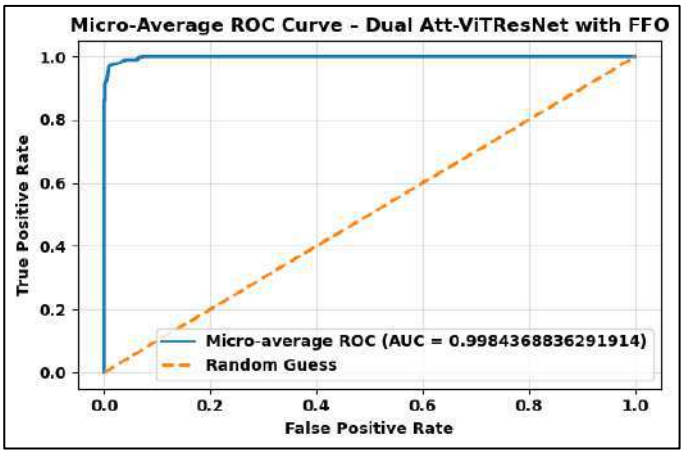

Figure 17: Micro-average ROC curve for Dual Att-ViTResNet with FFO.
Source: Authors, (2026).

Figure 17 demonstrates the Micro-Average ROC Curve of the Dual Att-ViT + FFO Model, with an AUC value of 0.998. This indicates that the model will classify nearly perfectly for micro-averaged data, as this curve is close to the top left corner and well above the baseline for random selection.

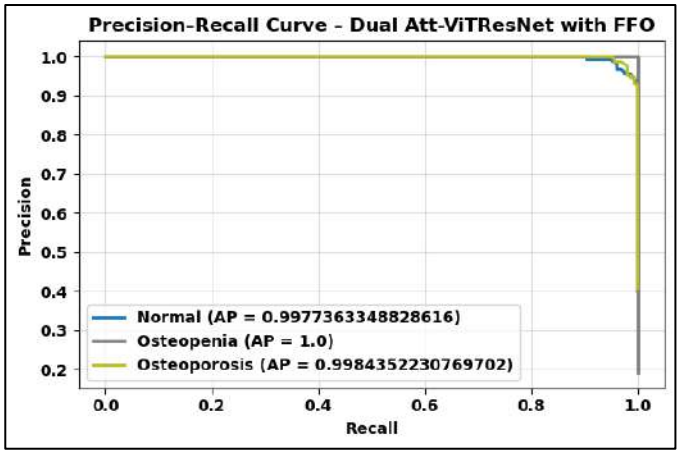

Figure 18: Precision-Recall curve for Dual Att-ViTResNet with FFO.
Source: Authors, (2026).

The Precision-Recall Curves of the Dual Att-ViT + FFO model establish high classification performance for all three classes which depicted in Figure 18. Each class has an average precision value of approximately 0.997 (Normal), 1.0 (Osteopenia) and 0.998 (Osteoporosis). The Precision-Recommendation curves remain close to the value of 1.0 for most levels of Recall and therefore provide a high degree of confidence in the model's classification predictions.

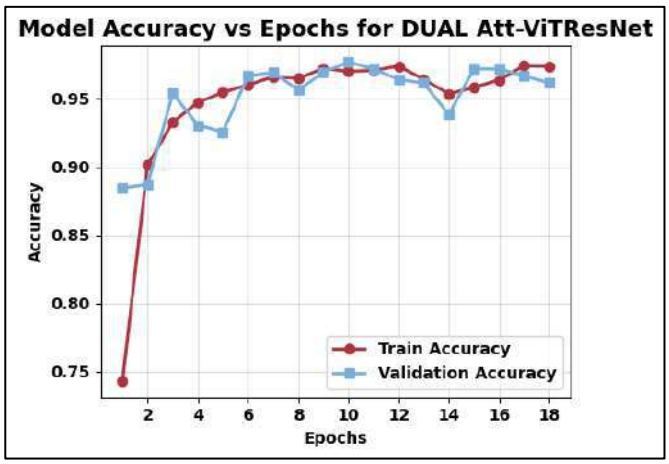

Figure 19: Comparison of model accuracy and epochs for Dual Att-ViTResNet.
Source: Authors, (2026).

Figure 19 shows that the training accuracy and validation accuracy improved rapidly during training accuracy and validation accuracy. Both remained relatively stable across epochs. This indicates that the model is converging well and is not experiencing much overfitting during training.

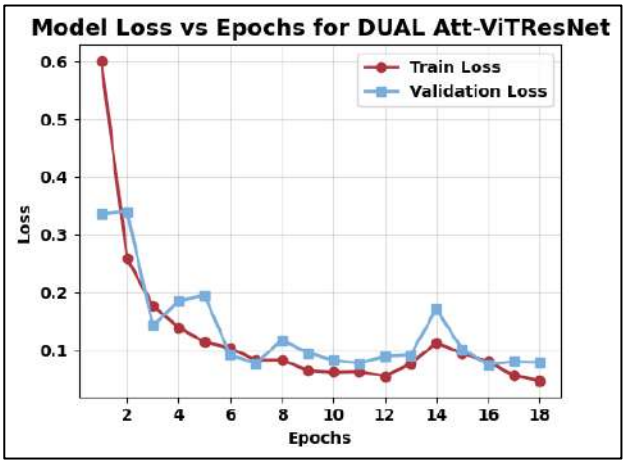

Figure 20: Comparison of model loss and epochs for Dual Att-ViTResNet.
Source: Authors, (2026).

In Figure 20, training loss decreased steadily over the course of training. Though, validation loss started to decrease but started to rise after a few epochs. This indicates the possibility of overfitting occurring after the first few epochs.

Table 4: Model performance for Dual Att-ViTResNet.

SI.NO	METRICS	VALUES
1	Accuracy	0.9615
2	Precision	0.9618
3	Recall	0.9682
4	F1-Score	0.9647
5	Specificity	0.9796
6	AUC-ROC	0.9977
7	AUC-PR	0.9965
8	MCC	0.9400
9	Cohen's Kappa	0.9397

Source: Authors, (2026).

Table 4 achieved very strong and consistent results relative to its performance, indicating that the model is very reliable for classifying data accurately with high levels of accuracy, precision, recall, class separation and agreement between model predictions and true labels.

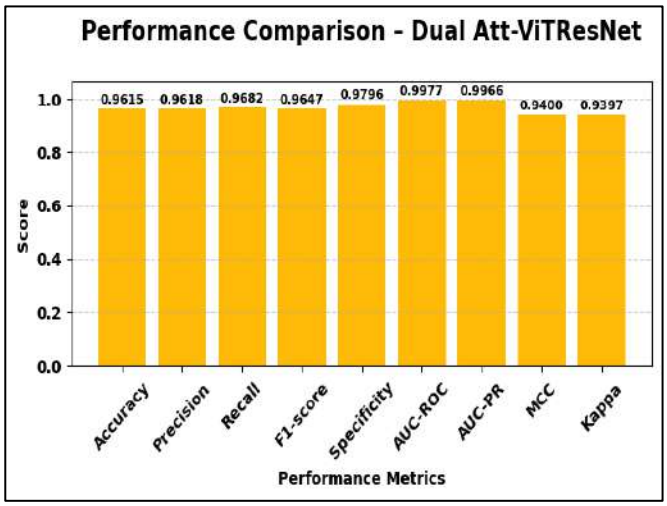

Figure 21: Performance comparison of Dual Att-ViTResNet.
Source: Authors, (2026).

Figure 21 achieved very high scores in all performance metrics as shown in the bar chart, demonstrating very high AUC-ROC and AUC-PR, very high accuracy, precision, recall, F1-score and so on demonstrating a model that is well-balanced and extremely robust.

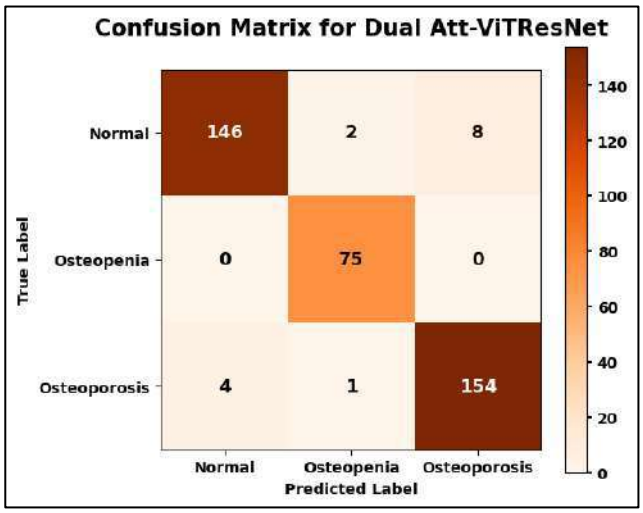

Figure 22: Confusion matrix for Dual Att-ViTResNet.
Source: Authors, (2026).

In Figure 22, the confusion matrix indicates that the model performs well and accurately across the spectrum of classes, but particularly well when classifying people with osteopenia.

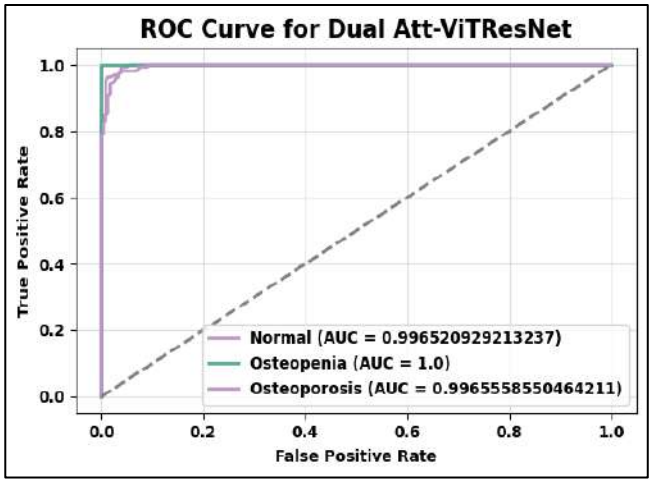

Figure 23: ROC curve for Dual Att-ViTResNet.
Source: Authors, (2026).

The ROC curves in Figure 23 demonstrate excellent performance of Dual Att-ViTResNet in classifying classes of normal, osteopenia and osteoporosis and require AUC values, demonstrating a high degree of confidence and accuracy when making these classifications.

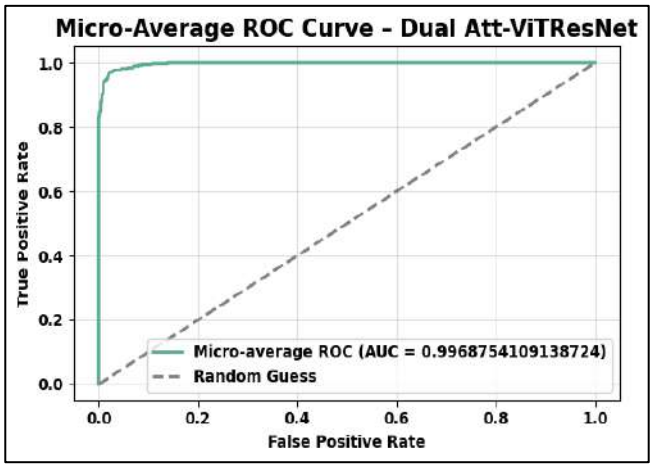

Figure 24: Micro-average ROC curve for Dual Att-ViTResNet.
Source: Authors, (2026).

In Figure 24, the micro-average ROC curve indicates that the Dual Att-ViTResNet has achieved difficulties and excels in the multi -class classification of the low-incident classes with a higher signal-to-noise ratio than other models.

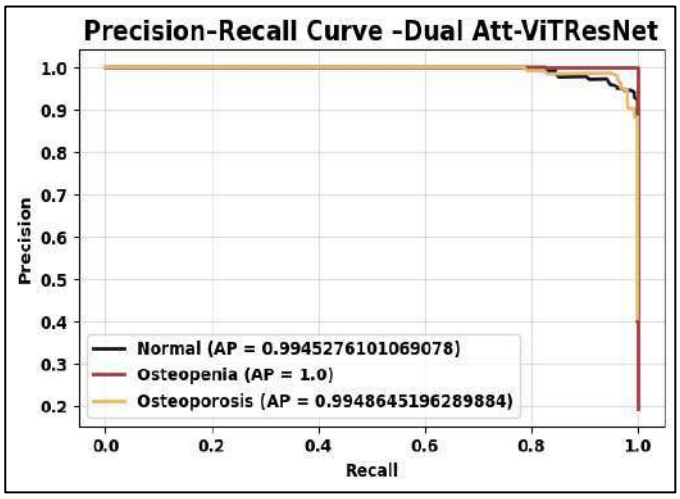

Figure 25: Precision-Recall curve for Dual Att-ViTResNet.
Source: Authors, (2026).

The Dual Att-ViTResNet approach has shown consistent performance over time according to the Precision-Recall Curve in Figure 25, with very high average precision values for each class across nearly the full range of recall. This indicates the Dual Att-ViTResNet has excellent classification capabilities.

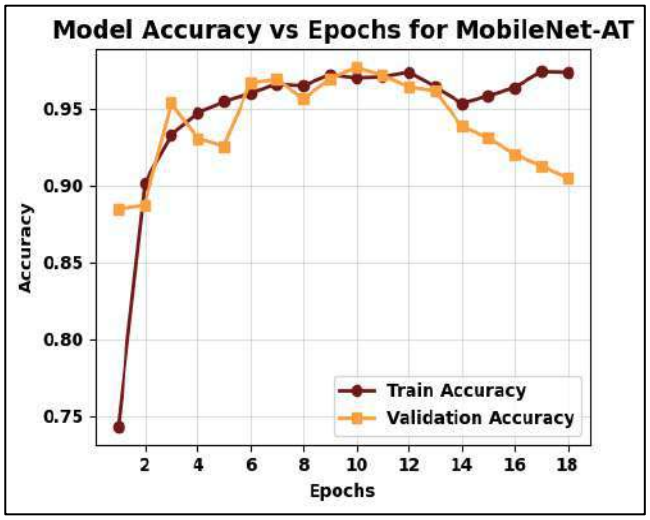

Figure 26: Comparison of model accuracy and epochs for MobileNet-AT.
Source: Authors, (2026).

In Figure 26, the accuracy of MobileNet-AT increases steadily during training, however there is variability in validation accuracy after reaching peak accuracy that suggests there are some overfitting to the training data set.

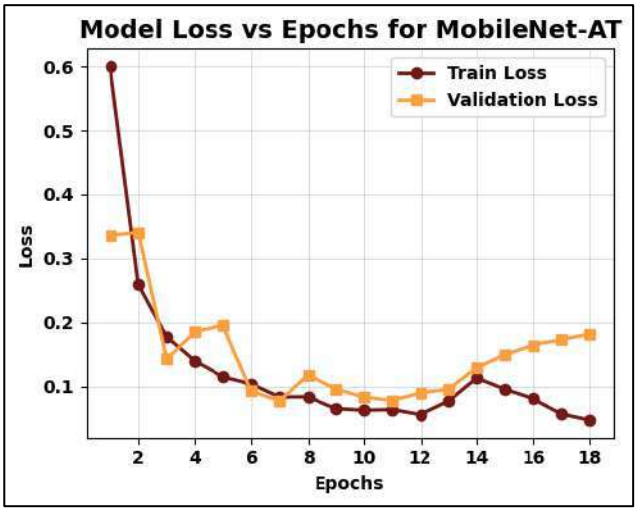

Figure 27: Comparison of model loss and epochs for MobileNet-AT.
Source: Authors, (2026).

In Figure 27, the loss for MobileNet-AT decreases rapidly during the early epochs then stabilizes at about epoch 3. Validation loss decreases also but does level out around epoch 10. The slight difference in the two curves suggests possible overfitting occurring while MobileNet-AT was being trained.

Table 5: Model performance for MobileNet-AT.

SI.NO	METRICS	VALUES
1	Accuracy	0.9051
2	Precision	0.8990
3	Recall	0.9217
4	F1-Score	0.9084
5	Specificity	0.9515
6	AUC-ROC	0.9831
7	AUC-PR	0.9772
8	MCC	0.8535
9	Cohen's Kappa	0.8525

Source: Authors, (2026).

According to Table 5, MobileNet-AT shows consistent performance across multiple evaluation metrics including high levels of accuracy and precision, as well as good balance between precision and recall and discrimination ability.

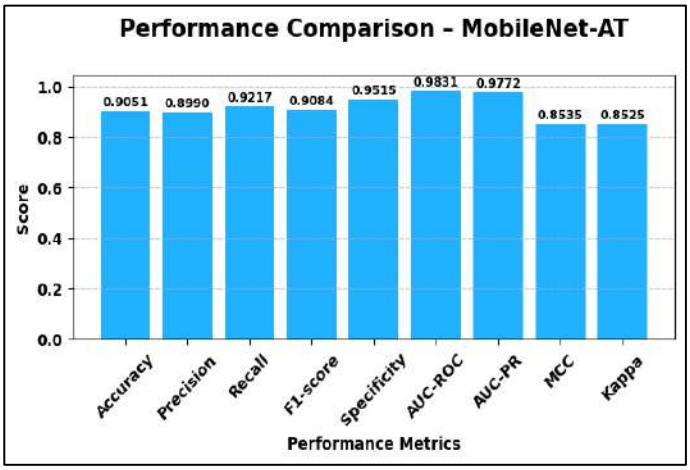

Figure 28: Performance comparison of MobileNet-AT.
Source: Authors, (2026).

Figure 28 displays a consistent high levels of performance across multiple metrics. All metrics show a similar pattern of consistent performance including the highest levels of AUC-ROC and AUC-PR respectively, and specificity indicating high levels of classification capability and discrimination ability.

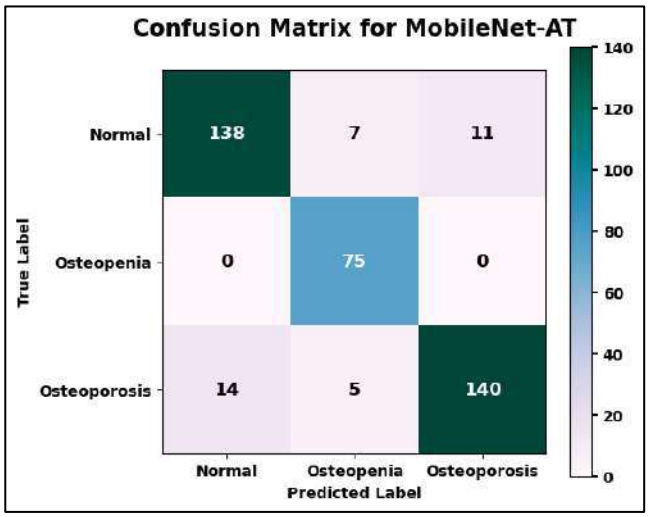

Figure 29: Confusion matrix for MobileNet-AT.
Source: Authors, (2026).

In Figure 29, the confusion matrix for MobileNet-AT indicates that MobileNet-AT accurately classify the vast majority of patients diagnosed as Normal, Osteopenic, and Osteoporotic with few incorrect classifications. This demonstrates strong inclusive performance for the MobileNet-AT model.

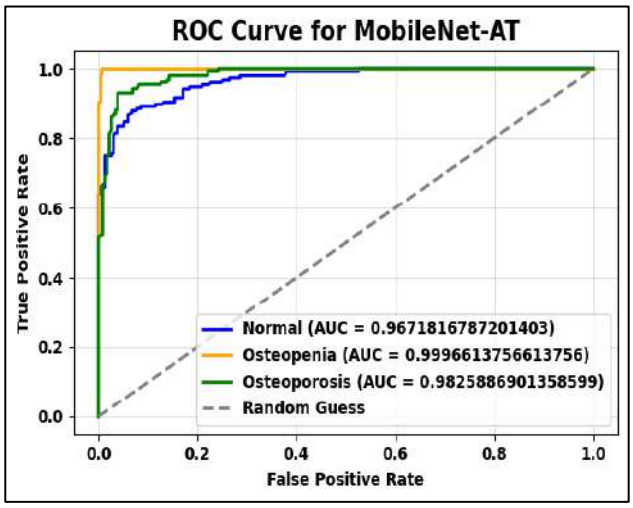

Figure 30: ROC curve for MobileNet-AT.
Source: Authors, (2026).

In Figure 30, the classification ability of MobileNet-AT has been demonstrated using the ROC curves, which show an AUC of approximately 0.967 for Normal, 0.99 for Osteopenia and approximately 0.98 for Osteoporosis. Thus, the MobileNet-AT Model is able to differentiate well between the different classes of subjects.

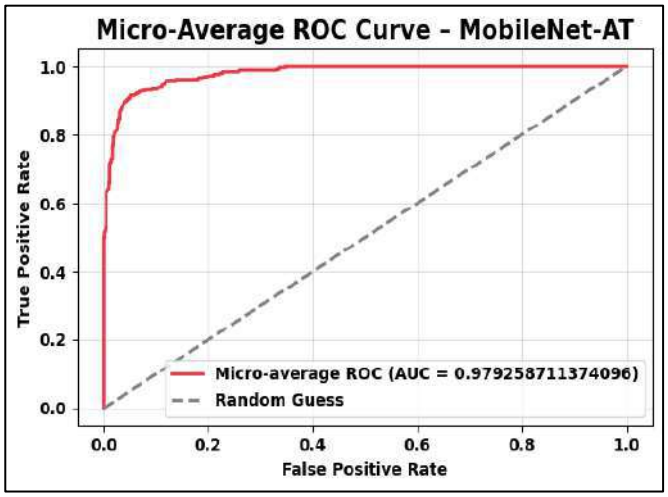

Figure 31: Micro- Average ROC curve for MobileNet-AT.
Source: Authors, (2026).

In Figure 31, the Micro-Average ROC of the MobileNet-AT model shows overall classification performance to be excellent with an AUC of about 0.979, thus demonstrating high classification accuracy for all classes of subjects.

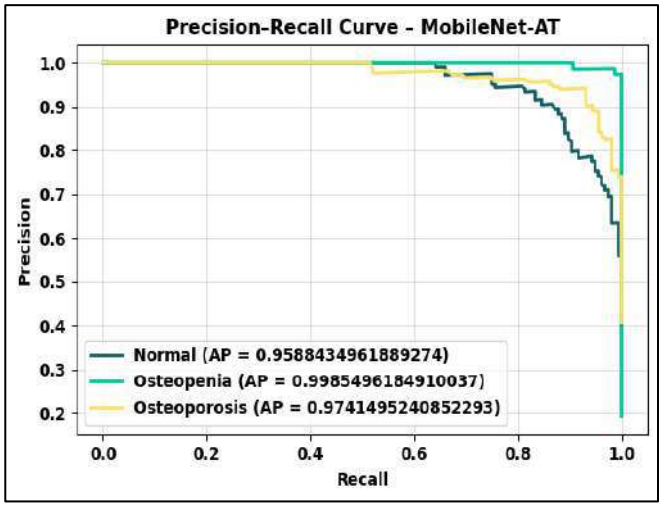

Figure 32: Precision-Recall curve for MobileNet-AT.
Source: Authors, (2026).

In Figure 32, the Precision-Recall curves of the MobileNet-AT model for Normal, Osteopenia and Osteoporosis provide the following rankings, Osteopenia provides the best performance (AP = 0.998), followed by Normal, and then Osteoporosis.

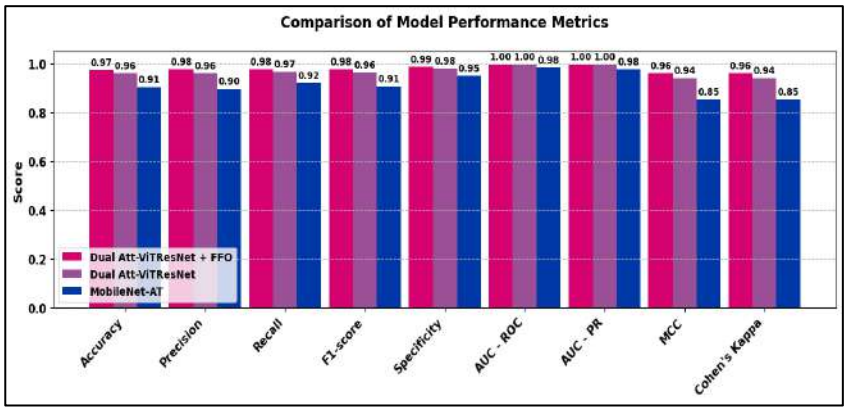

Figure 33: Comparison of model performance metrics.
Source: Authors, (2026).

Figure 33 compares the three models across three metrics. Dual Att-ViTResNet + FFO is shown to consistently outperform both Dual Att-ViTResNet and MobileNet-AT.

Table 6: Comparison of accuracy for various methods.

SI. NO	METHODS	ACCURACY
1	OsteoNet [23]	0.741
2	ViT-16 [21]	0.880
3	MobileNet [24]	0.940
4	ResNet+ GRU [25]	0.956
5	PROPOSED	0.974

Source: Authors, (2026).

Table 6 shows that the proposed method outperformed OsteoNet, ViT-16, MobileNet, and ResNet + GRU to achieve an accuracy of 0.974.

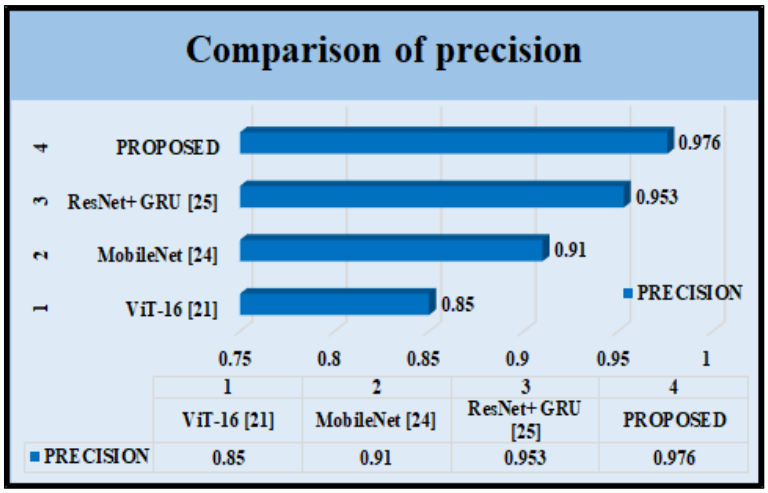

Figure 34: Comparative analysis of precision.
Source: Authors, (2026).

The precision results are shown in Figure 34. The proposed method outperformed all other methods with a precision of 0.976, followed by ResNet + GRU, MobileNet, and ViT-16, respectively.

Table 7: Comparison of Recall and F1-Score for various methods.

SI.NO	METHODS	RECALL	F1-SCORE
1	ViT-16 [21]	0.880	0.860
2	ResNet+ GRU [25]	0.959	0.954
3	PROPOSED	0.978	0.977

Source: Authors, (2026).

According to the Table 7, the suggested algorithm yield the greatest recall (0.978) and F1-score (0.977). The results achieved by the suggested method outperform those of ViT-16 and ResNet+GRU.

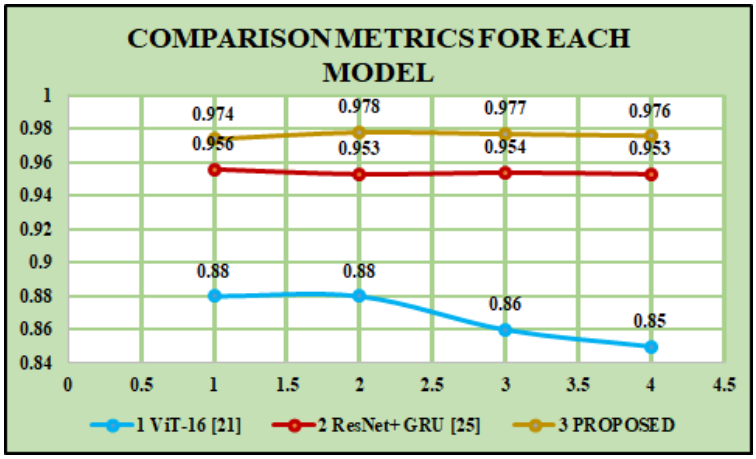

Figure 35: Comparison metrics for each model.
Source: Authors, (2026).

In Figure 35, three models are compared in terms of their performance, the ViT-16, ResNet+GRU, and the Proposed Model. The proposed model has consistently produced superior metrics when compared to the ViT-16 and ResNet+GRU, which have lower and decreasing performance metrics over time.

V. CONCLUSION

The automated classification of osteoporosis was achieved by developing a process based on the proposed DualAtt-ViTResNet framework using the FFOA. The suggested system is integrated by a number of different processes, all employed together to enhance the quality of the classification at each step. The process of preprocessing images, through Resizing and Gaussian Filtering improves the quality of the input images along with reducing noise, which leads to consistently being able to create a properly formatted input for the rest of the system. The addition of the StyleGAN-based data augmentation creates an enriched dataset that includes different classes of images, allowing for better generalization from the training data while minimizing the risk of overfitting. Extracting deep, meaningful features from the input images is primarily performed by the DenseNet-121, which successfully extracts important characteristics that describe the images. The DualAtt-ViTResNet takes advantage of those features and captures both the local detail and the broader context of the image, allowing for more accurate processing and classification of images. Finally, the hyperparameter optimization process uses the FFOA to optimize the learning rate and enhance model accuracy, making the entire system extremely robust and reliable. Overall, by integrating all the stages, the model yields a higher accuracy of 0.9744, precision of 0.9767, Recall of 0.9789 and F1-Score of 0.9777, thus providing reliable, effective, and clinically useful automated classification of osteoporosis.

ABSTRACT

Global energy systems are currently undergoing a fundamental transformation with an active transition from fossil fuels to renewable energy sources. Fueled by the fight against climate change and emissions, the energy transition has become a major challenge for the global economy. In this context, the inclusion of renewable energy sources in the energy balance is becoming a strategic way to promote further economic transformation. The aim of this scientific article is to analyze the structural features of the energy transition and assess the degree of integration of renewable energy into the overall energy balance compared to fossil fuels in Eastern European countries. The article provides an empirical analysis of simplified energy balances of Eastern European countries for the period 2022–2024. For this purpose, independent and dependent variables of the analysis were calculated, which made it possible to form descriptive statistics, perform correlation analysis, and conduct multiple linear regression. Results. Model M1 has greater explanatory power (R2 = 0.533; Adjusted R2 = 0.471) and is statistically significant (F = 8.567, p = 0.003), unlike model M0, which explains only 1.3% of the variance in the share of renewable energy (R2 = 0.013) and is statistically insignificant (F = 0.219, p = 0.646). This proves that dependence on fossil fuels or nuclear energy is associated with a smaller share of renewable energy sources in the national energy balance. Dependence on fossil fuels and a significant share of nuclear energy serve two purposes in the energy systems of Eastern European countries, among other things: they ensure short-term stability of energy supply, while structurally slowing down the pace of integration of renewable energy sources, thereby limiting the possibilities for diversification and transformation of the energy balance. Therefore, a promising avenue for research is the development of integrated energy policy models that reconcile the stabilizing function of fossil and nuclear energy sources with long-term decarbonization goals.

I. INTRODUCTION

Climate change and environmental degradation are an international existential threat, particularly in the European region. Therefore, the establishment of a green economy as a model aimed at decarbonising production, increasing resource efficiency and structurally transforming energy systems is an opportunity to overcome climate risks, environmental degradation and the energy vulnerability of national economies.

Consequently, the creation of the European Green Deal, adopted in 2020, which is a new growth strategy for Europe, allows the economies of EU member states to develop in the direction of increasing resource efficiency and competitiveness. This agreement aims to make Europe climate neutral by 2050, stimulate the economy through green technologies, create sustainable industry and transport, and reduce pollution [1]. Currently, according to [2], in 2023 the European Union (EU) produced about 42% of its own energy, while 58% was imported; while the EU's energy balance, i.e., the range of available energy sources, consisted mainly of crude oil and petroleum products (37.7%), natural gas (20.4%), renewable energy (19.5%), solid fuels (10.6%), and nuclear energy (11.8%). According to [3], by 2024, the record share of renewable energy sources had reached 44% in the EU's electricity sector for the first time. However, it is the countries of Eastern Europe, subject to EU regulations, climate targets, and decarbonization commitments, that remain constrained by inherited infrastructure, high dependence on fossil fuels, limited diversification of energy balances, and, in some cases, a legacy of nuclear energy. These structural conditions give rise to specific models of renewable energy integration that differ fundamentally from those observed in other European economies. In view of this, the novelty of this study lies in the creation of a harmonized cross-country dataset based on national energy balances; the application of structural indicators of energy concentration and diversification in combination with econometric models; and the provision of comparative data between subregional groups in Eastern Europe. The aim of this scientific article is to analyze the structural features of the energy transition in Eastern European countries. The article aims to assess the degree of integration of renewable energy into the overall energy balance compared to fossil fuels.

II. LITERATURE REVIEW

The main principles of the energy transition on the European continent are fundamentally geared towards sustainable development, energy security, and economic competitiveness, with a strong emphasis on decarbonization, energy efficiency, and the development of renewable energy sources [4–6]. This is explained by the definition of the concept of "energy transition" proposed by [7]: "The energy transition can not only reduce energy dependence, improve energy diversification and self-sufficiency, and mitigate the environmental damage caused by energy production and consumption, but also serve as an important pathway to energy security". However, several studies [8–10] show that the path to achieving these goals is fraught with bottlenecks and structural shortcomings. One notable bottleneck, according to [11], is the integration of renewable energy sources into the existing energy grid, which requires significant investment in grid infrastructure to manage the variability of renewable energy. Furthermore, according to [12-14], regulatory frameworks and market structures often lag behind technological progress, hindering the smooth introduction of new energy solutions to the market. In contrast to the problem areas of the energy transition, the scientific discourse is characterized by a large number of energy-efficient solutions and opportunities for the establishment of a green economy as a fundamental model for the further development of society.

In particular, studies on renewable energy by [15-17], as well as a study by [18], conducted in the context of global energy transitions, highlight significant differences in the development of renewable energy technologies in different countries; the work of [19] on the implementation of a just transition to renewable energy sources and the results of the assessment of the implementation of the RED II Directive; Sivasubramanian's [20] study of the impact of public-private partnerships (further – PPPs) on the progress of renewable energy start-up industries for sustainable development; analysis of the impact of renewable energy technologies on a climate-resilient approach to agribusiness in regions [21], [22] conclusion on the tendency of Central and Eastern European countries to focus on cluster projects led by local authorities, which often serve as tools for modernizing outdated energy infrastructure; [23] on the effectiveness of the German experience in implementing bottom-up cooperative initiatives to replace old energy infrastructure with more modern ones; [24] assessment of the role of PPPs in achieving the Sustainable Development Goals (further – SDGs) through agrotechnological and renewable energy solutions. However, the theoretical aspects of forming complementary economic and energy policies for European countries based on harmonious development remain insufficiently substantiated and developed. Therefore, there is a need for research aimed at addressing local issues related to the energy transition, the structure and characteristics of renewable energy integration into the overall energy balance.

III. METHODS

The empirical analysis is based on a balanced panel dataset covering Eastern European countries (Bulgaria, the Czech Republic, Hungary, Poland, Slovakia, Romania, and Ukraine) for the period 2022–2024 (Appendix A). The dataset consists of 18 observations and was constructed using Eurostat (2025a) statistical information on simplified energy balances, in particular gross available energy measured in thousands of tonnes of oil equivalent (ktoe). The analysis variables and related indicators were calculated by the author. The dependent variable is Share_RES (%), which represents the share of renewable energy sources in the total energy balance. The formula for calculating this indicator is as follows:

$$\text{Share}_{\text{RES}} = \frac{\text{Renewables}}{\text{Total}_{\text{energy}}*100}. \quad (1)$$

The independent variables are Fossil_dependency (%), which reflects dependence on fossil fuels, and Nuclear_share (%), which measures the contribution of nuclear energy. They are calculated using the following formulas:

$$Fossil_{dependency} = \frac{(Solid_{fossil}+Natural_{gas}+Oil_{products})}{Total_{energy}*100} \quad (2)$$

$$Nuclear_{share} = \frac{Nuclear}{Total_{energy}*100}. \quad (3)$$

In addition, to assess the structural concentration of national energy systems, the Herfindahl-Hirschman Index (further – HHI) was calculated as the sum of the squares of the shares of primary energy sources in gross available energy using the following formula:

$$HHI = \sum share_i^2, \quad (4)$$

Where $share_i$ – is the share of the i-th energy source in the country's total energy balance, calculated as follows:

$$share_i = \frac{Energysource_i}{Totalenergy} \quad (5)$$

Where i – each individual type of energy. Next, the diversification index was calculated, which reflects the structural flexibility of national energy systems and their ability to integrate renewable energy. The formula for calculating this indicator is as follows:

$$Diversificationindex = 1 - HHI. \quad (6)$$

It should be noted that HHI and Diversification index are mathematically derived from the same components of the energy balance as other variables. Therefore, they are used only for descriptive and correlation purposes and are not included simultaneously in the regression model to avoid mechanical endogeneity. All variables were expressed as percentages to ensure comparability between countries and mitigate the effect of scale. Prior to econometric estimation, the dataset was checked for missing values and internal consistency of energy balance components. Given the limited sample size and short time horizon, the analysis uses an exploratory explanatory approach focused on structural relationships rather than long-term causal conclusions. First, descriptive statistics and Pearson's correlation coefficients were generated using JASP software to examine the prior relationships between energy structure indicators and renewable energy penetration. Next, for the selected dependent variable, i.e., the share of renewable energy in the energy balance (Share_RES), an empirical assessment was performed using multiple linear regression. A step-by-step modeling strategy was applied, starting with a baseline specification that included only dependence on fossil fuels, followed by an extended model that included the share of nuclear energy. This approach allows for the assessment of the additional explanatory power of additional structural energy variables. Model adequacy was assessed using standard diagnostic statistics, including the coefficient of determination (R2), adjusted R2, F-statistic, and root mean square error (RMSE). Statistical significance was assessed using conventional confidence levels. Thus, the multifactorial linear model looks like this:

$$\text{Share}_{\text{RES}} = \beta_0 + \beta_1 * \text{Fossil}_{\text{dependency}_i} + \beta_2 * \text{Nuclear}_{\text{share}_i} + \varepsilon_i, \quad (7)$$

Where β_0 is the constant (intercept):
β_1, β_2 – coefficients for factors;
ε_i is a random error;
i is the country (or country and period).
The empirical model was developed to test the following hypotheses:
H1: Countries with higher dependence on fossil fuels show a significantly lower share of renewable energy.
H2: Nuclear-intensive energy systems show slower integration of renewable energy.
H3: More diversified energy structures are positively associated with renewable energy penetration.

The main limitations of the study are (1) the relatively small sample size (N = 18), which limits the use of advanced panel estimation methods and restricts causal conclusions; and (2) the focus of the analysis on structural links rather than dynamic transition processes, as short-term integration rates cannot be reliably recorded during the observation period. Nevertheless, the methodology used is appropriate for identifying statistically significant structural links and obtaining politically relevant conclusions regarding energy transition strategies in Eastern Europe.

IV. RESULTS

The transition to a green economy is central to contemporary economic policy, especially in regions that have historically been highly dependent on fossil fuels and carbon-intensive energy systems. In this context, the integration of renewable energy sources (further – RES) into national energy balances is a strategic path for economic transformation that affects macroeconomic stability, energy security, industrial competitiveness, and regional development trajectories. In addition, according to Eurostat statistics [25], there are currently sustained trends toward a structurally intensive energy balance associated with the dominance of fossil fuel use. The energy balance of Eastern European countries is based on coal, petroleum products, and natural gas, as shown in Figure 1.

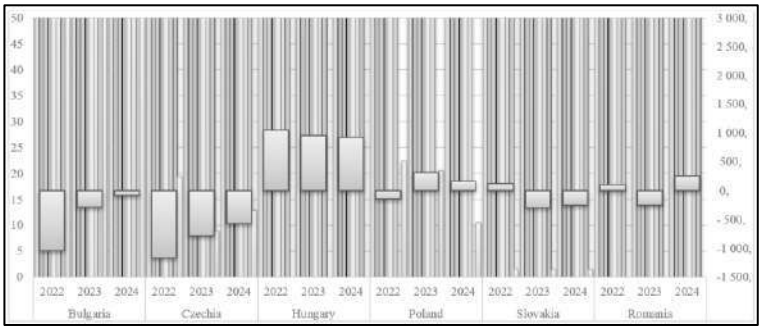

Figure 1: Energy balances dataset covering Eastern European countries for the period 2022–2024.
Source: [25].

During 2022–2024, the greatest absolute dependence on solid fossil fuels will be observed in Poland, where coal remains the basis for electricity and heat generation. In particular, in 2024, solid fossil fuels accounted for more than 32,000 units of total energy consumption, which significantly exceeds the contribution of renewable energy sources (14,779 units) to electricity generation in the country. Similar patterns can be observed in the Czech Republic (Solid_fossil = 9,588.072 units; Renewables = 5,430.68 units) and Bulgaria (Solid_fossil = 3,078.797 units; Renewables = 2,609.747 units), but these countries are distinguished by their intention to gradually reduce coal consumption and are characterized by moderate growth in the share of renewable energy sources. Hungary and Romania, on the other hand, show a mixed structure with a strong role for natural gas and nuclear energy. These patterns are consistent with broader EU energy trends. Central and Eastern European countries remain more dependent on coal and gas due to their historical infrastructure, industrial structure, and delays in the introduction of renewable energy sources. In this context, it is important to refer to data from the by [26]. That is, while Denmark, Sweden, Estonia, and Finland have shown the largest increase in the share of RES, growing by more than 23% since 2005, Croatia, Slovenia, and Romania have seen growth of less than eight percentage points since 2005. Looking at the short-term perspective of recent years, it is important to note that the share of renewable energy increased in 18 EU member states between 2023 and 2024. The leaders in renewable energy production are Lithuania, Poland, the Netherlands, and Denmark, with their share of RES increasing by more than 2% in 2024. In 2024, 25.4% of all final energy consumed in the EU came from renewable sources, which is approximately 1% more than in 2023. This increase was largely driven by the growth of solar and wind energy, as well as heat pumps; however, trends remain uneven across regions, with Central and Eastern European countries lagging behind Northern European and Baltic countries. In particular, the Baltic countries demonstrate a fundamentally different energy structure, characterized by a high share of renewable energy sources, minimal nuclear energy generation, and reduced dependence on fossil fuels. This is shown in Figure 2.

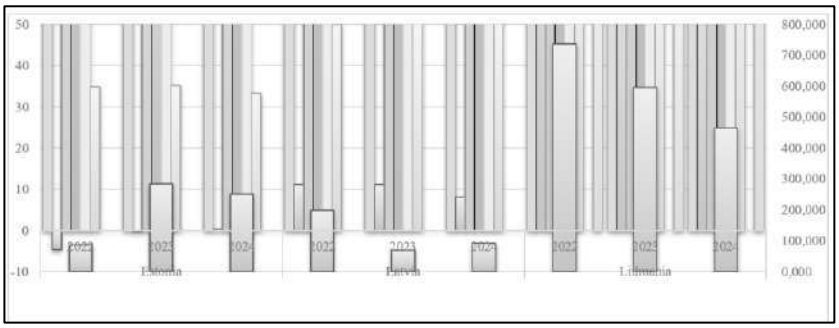

Figure 2: Energy balances dataset covering Baltic countries for the period 2022–2024.
Source: [25].

In Latvia, renewable energy accounts for 1,974.985 units, which is a significant share of the EU's energy balance. Lithuania, in turn, shows steady growth in renewable energy from 1,791.928 units in 2022 to 2,285.427 units in 2024 (i.e., 27.5% over three years). Estonia shows a more heterogeneous structure, with renewable energy accounting for 1,429.704 units. At the same time, there is volatility in the components of fossil fuels and electricity trade (Solid_fossil = 0.477 units and Nuclear_heat = 0.000 in 2024), reflecting its role as a regional exporter and importer of electricity. In other words, the Baltic countries represent a diversified model that differs from that of Eastern European countries, focusing on renewable energy and characterized by structural flexibility and low dependence on fossil fuels. In other words, the Baltic countries represent a diversified model that differs from that of Eastern European countries, focusing on renewable energy and characterised by structural flexibility and low dependence on fossil fuels. Given the above trends, it is important to identify the structural features of the energy transition in Eastern European countries and assess the extent to which renewable energy is integrated into the overall energy balance compared to fossil fuels. To this end, dependent (Share_RES) and independent (Fossil_dependency, Nuclear_share, Diversification index) analysis variables were calculated based on the data set provided in Appendix A. The results of the calculations are presented in Table 1.

Source: Authors, (2026).

Romania has the highest average share of renewable energy (19.59%), while Slovakia has the lowest (12.83%). Poland stands out due to its extremely high dependence on fossil fuels (84.83% on average) and complete absence of nuclear energy. In contrast, Slovakia and Bulgaria have a relatively high share of nuclear energy, exceeding 23% on average. The diversification index ranges from 0.716 (Poland) to 0.784 (Slovakia), indicating that energy systems with a dominant fossil fuel component tend to be less diversified in terms of structure. The results show that the deployment of renewable energy is embedded in country-specific structural configurations rather than following a single regional trajectory. Next, to study two-dimensional relationships and identify potential multicollinearity risks prior to regression modeling, a Pearson correlation analysis was performed, the results of which are visualized in Figure 3.

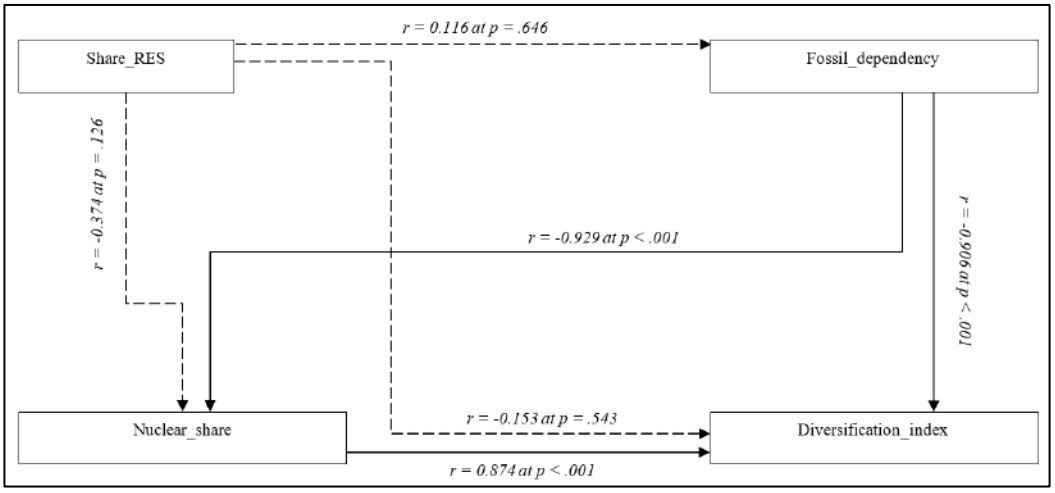

Figure 3: Results of correlation analysis of the energy balance structure of Eastern European countries.
Source: Authors, (2026).
Note: insignificant connections are marked with dotted lines.

The correlation between Share_RES and Fossil_dependency is weak and statistically insignificant (r = 0.116 at p = 0.646), indicating that an increase in renewable energy sources does not automatically correspond to a decrease in dependence on fossil fuels. The relationship between Share_RES and Nuclear_share is negative but also insignificant (r = –0.374 at p = 0.126). However, very strong and statistically significant correlations are observed between the structural variables themselves. Fossil fuel dependence has a high negative correlation with the share of nuclear energy (r = –0.929 at p < 0.001) and with the diversification index (r = –0.906 at p < 0.001), while the share of nuclear energy has a strong positive correlation with diversification (r = 0.874 at p < 0.001). A stepwise linear regression approach was used to assess the determinants of renewable energy integration (Table 3). The main theoretical assumption is that both fossil and nuclear energy can act as structural substitutes for renewable energy sources in energy systems characterized by outdated infrastructure.

Table 3: Results of regression analysis of the energy balance structure of Eastern European countries.

Linear Regression						
Model Summary - Share_RES (%)						
Model	**R**	**R²**	**Adjusted R²**	**RMSE**		
M_0	0.116	0.013	–0.048	2.442		
M_1	0.730	0.533	0.471	1.735

	Total	96.731	17			
M_1	Regression	51.577	2	25.789	8.567	0.003
	Residual	45.154	15	3.010		
	Total	96.731	17			
Coefficients						
Model		**Unstandardized**	**Standard Error**	**Standardized**	**t**	**p**
M_0	(Intercept)	12.519	4.810		2.603	0.019
	Fossil_ dependency (%)	0.033	0.070	0.116	0.468	0.646
M_1	(Intercept)	55.236	10.997		5.023	< 0.001
	Fossil_ dependency (%)	–0.476	0.134	–1.699	–3.555	0.003
	Nuclear_share (%)	–0.491	0.120	–1.953	–4.087	< 0.001

Source: Authors, (2026).

Note: M_0 includes Fossil_dependency (%); M_1 includes Fossil_dependency (%), Nuclear_share (%).

Model M0 (baseline) explains only 1.3% of the variance in the share of renewable energy (R2 = 0.013) and is statistically insignificant (F = 0.219, p = 0.646). Dependence on fossil fuels does not have a significant independent impact on the deployment of renewable energy, confirming that the expansion of renewable energy cannot be explained solely by dependence on fossil fuels. Meanwhile, model M1 (extended model) demonstrates a significant improvement in explanatory power (R2 = 0.533; Adjusted R2 = 0.471) and is statistically significant (F = 8.567, p = 0.003). Thus, both independent variables are statistically significant and negative, in particular dependence on fossil fuels (β = –0.476, p = 0.003) and the share of nuclear energy (β = –0.491, p < 0.001). Therefore, these coefficients indicate that greater dependence on fossil fuels or nuclear energy is associated with a smaller share of renewable energy sources in the national energy balance. The final form of the multivariate linear model is shown below:

$$Share_{RES} = 55.236 - 0.476 * Fossil_{dependency} - 0.491 * Nuclear_{share} + \varepsilon \quad (8)$$

The multiple linear regression model shows that both dependence on fossil fuels and the share of nuclear energy have a statistically significant negative impact on the integration of renewable energy sources. The model explains 53.3% of the variation in the share of renewable energy (R2 = 0.533, F = 8.567, p = 0.003), indicating a significant structural link between outdated energy systems and the pace of the green transition in Eastern European countries.

V. DISCUSSION

According to the correlation-regression analysis of the study, the integration of renewable energy in Eastern European countries is fundamentally interchangeable rather than parallel to fossil and nuclear energy sources. First, descriptive statistics confirm the previous findings of [18] regarding cross-country asymmetry in the adoption of renewable energy technologies, confirming the striking variability of energy transition trajectories across Eastern Europe. It also reinforces the findings of [8], [9] regarding structural inertia and historical biases that continue to influence national energy systems and hinder the effectiveness of universal decarbonization plans. According to [11], who emphasizes that the growth of renewable energy does not lead to the displacement of fossil fuels due to infrastructure rigidity, network constraints, and institutional blockages, is consistent with the correlation analysis finding that there is no statistically significant two-dimensional relationship between the share of renewable energy and fossil fuel dependence (r = 0.116 at p = 0.646). At the same time, the presence of a high negative correlation between dependence on fossil fuels and the share of nuclear energy (r = –0.929 at p < 0.001) and the diversification index (r = –0.906 at p < 0.001) confirms the structural interconnection of traditional energy components, confirming the opinion of [12] that regulatory and market frameworks often reinforce existing technologies rather than promoting systemic transformation.

Given the ongoing scientific debate on the role of nuclear energy in the green transition, the regression results (M1), which show that the shares of both fossil and nuclear fuels are statistically significant negative factors for renewable energy integration, are particularly relevant. While some studies emphasize the role of nuclear energy as a stabilizing force with low carbon emissions [19], suggesting that nuclear energy serves as a structural replacement rather than a complement to renewable energy in Eastern European energy systems; others, notably [22], argue that market and regulatory frameworks often reinforce existing technologies rather than promoting systemic change.

VI. CONCLUSIONS

The integration of renewable energy sources into the national energy balances of Eastern European countries should be viewed as a gradual process of structural economic restructuring that affects regional development models, energy security, industrial competitiveness, and macroeconomic stability. Correlation and regression analysis has shown that the expansion of renewable energy in Eastern European countries is predominantly substitutive rather than additive in nature. Renewable energy sources do not function as a complementary addition to existing energy systems, but enter into direct structural competition with established fossil and nuclear energy sources. The results show that both dependence on fossil fuels and a significant share of nuclear energy perform dual functions in the energy systems of the countries in the region: on the one hand, they ensure short-term stability of energy supply, and on the other hand, they structurally restrain the pace of integration of renewable energy sources, limiting the possibilities for diversification and transformation of the energy balance. In view of this, a promising area for further research is the development of comprehensive energy policy models aimed at reconciling the stabilising role of fossil and nuclear energy sources with long-term decarbonisation goals, as well as the assessment of institutional, regulatory, and infrastructural mechanisms capable of ensuring the complementary integration of renewable energy into the national energy systems of Eastern European countries.

ABSTRACT

The correct prediction of compressive strength is vital to the successful design of fused deposition modeling (FDM) 3D-printed structures, although the traditional empirical and machine learning methods tend to fail to account for the multifaceted and nonlinear relationships among the parameters of the process and the mechanical behavior. To tackle this problem, we have generated and analyzed hybrid deep learning algorithms to predict compressive strength of FDM-fabricated specimens. Systematic variation of important printing parameters has produced experimental data which were then subjected to standard compression testing. Convolutional neural networks and recurrent neural networks have been carried out separately and then combined into hybrid to capitalize on both spatial feature extraction and sequential dependency learning. Standard measures of statistical analysis and comparative graphical analysis were used to carry out model performance. The findings indicate that hybrid deep learning model always do better than single models, recording lower prediction errors, and better generalization with unknown data. These results indicate that the use of complementary deep learning designs is indeed effective in improving the predictive power of mechanical properties of additively manufactured components. It is concluded that hybrid deep learning offers an efficient and powerful structure of prediction and optimization of compressive strength of FDM 3D-printed structures using data.

I. INTRODUCTION

One of the most popular methods of additive manufacturing that can be used is fused deposition modeling (FDM), which is simple to use, low-cost, and can be used to print a variety of polymeric and composite materials [1],[2]. Although they are beneficial, mechanical performance of FDM-printed components is extremely sensitive to process parameters, material composition, and internal structural design, which makes it variable and reduces its applicability to structural and load-bearing uses [3],[4]. In order to overcome these issues, machine learning (ML) methods have been more commonly used to approximate the complex process-structure-property correlations that FDM-based manufacturing involves [5],[6]. Initial ML-related experiments found out that artificial neural networks, regression, and support vector machines could effectively predict mechanical characteristics, including tensile, flexural, compressive strength with a better accuracy in comparison with empirical methods [7].

These results stimulated the further investigation of data-driven modeling approaches of the various materials and printing conditions. In recent studies, the use of ML has been applied to composite and hybrid material systems, where learning-based models have been able to deal with the heterogeneity and anisotropy of materials [8],[9]. Machine learning in bio-polymer composites and in auxetic structures built with FDM has proven to be applicable to predict the energy absorption and compressive scars in geometrical and process constraints that are varied, which are also known to be under continuous rates [10],[11]. These papers highlight the increased significance of ML to the design of high-performance FDMs. Our lattice, sandwich, and cellular structures produced through FDM have been of special interest because of their low weight and high weight-strength ratios [12],[13].

A number of studies have managed to use ML models to forecast compressive and flexural strengths of hexagon lattice-cored and bio-inspired sandwich structures and show a high level of agreement between experimental and predicted outcomes [14]. These publications emphasize the fact that ML methods are capable of describing complicated geometrical effects on mechanical dynamics. In addition to polymer-based systems, ML methods have been used on cementitious and fiber-reinforced materials that are produced through additive manufacturing methods, especially to predict compressive strength [15],[16]. Despite the differences in the material systems of these studies, they support the overall generalizability of ML when it comes to forecasting compressive performance in different additively manufactured structures [17],[18]. To continue improving the precision of prediction, a number of researchers have suggested hybrid ML systems that combine optimization algorithms including genetic algorithms, particle swarm optimization and desirability functions with neural networks [19],[20].

Such hybrid methods have proven to be more predictive and more efficient in terms of parameter optimization of FDM-printed components [21],[22]. Nevertheless, the vast majority of such hybrid frameworks use shallow learning structures, which need a lot of feature engineering. The use of artificial neural network models has become common in prediction of mechanical properties of FDM-produced polymers, including ABS, PLA, and PEEK [23],[24]. Comparative analysis of several ML methods have demonstrated neural networks to be more successful than the traditional regression model, especially when the process-property association is controlled by nonlinear factors [25],[26]. However, such models may fail in the performance when handling high-dimensional or sequential data. The recent breakthroughs in deep learning have made it possible to come up with models that can extract and learn hierarchical representations of complex data automatically and feature extraction [27],[28].

Deep learning models have been shown to perform better in predicting mechanical properties compared to traditional ML models when multimodal data or a large amount of data is concerned [29],[30]. Stronger results with anisotropic and limited-data conditions are also enhanced by data augmentation and hybrid learning strategies [31],[32]. Regardless of this progress, minimal studies have been done to determine the applicability of hybrid deep learning structures in predicting compressive strength of FDM-printed structures, and most studies are fragmented [33],[34]. Although the implementation of deep learning in the optimization of the quality of surfaces and prediction of tensile properties has been studied, the systematic application of deep learning in the modeling of compressive behavior remains at an early stage [35],[36]. In addition, the current literature tends to be limited to certain materials or geometry, which limit the ability to generalize the results [37],[38].

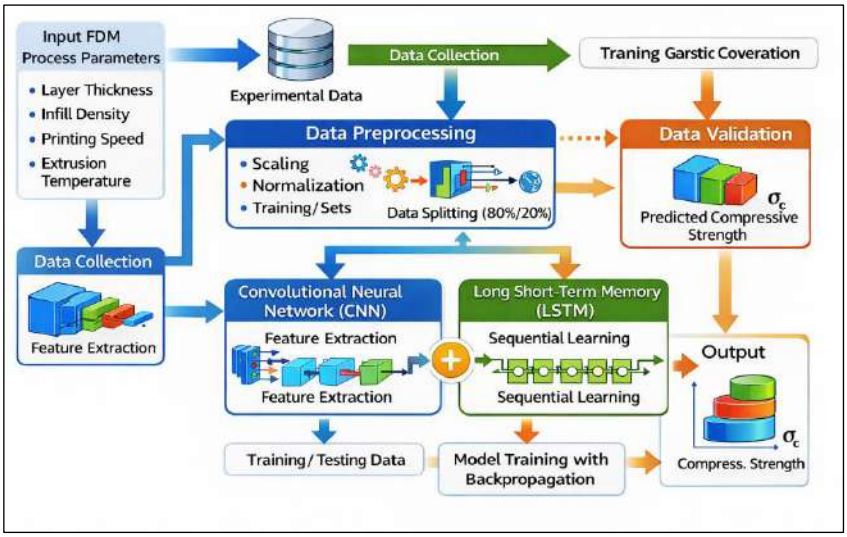

Figure 1: Conceptual framework of hybrid deep learning–based compressive strength prediction.
Source: Authors, (2026).

Figure 1 shows the conceptual design of the hybrid deep learning-based system, which shows how the parameters of the FDM process are transported to data preprocessing, CNN to extract features and then LSTM learning to predict compressive strength. Extensive overviews of ML methods used in additive manufacturing of materials through material extrusion underline the significance of enhanced hybrid frameworks of deep learning to reflect nonlinear and multiscale connections between material processing, structure, and properties [39]. Convolutional, sequential, and ensemble learning paradigms provide a promising route to these issues and boost predictive accuracy achieved with hybrid deep learning models. Thus, the primary goal of the proposed research is to create and test hybrid deep learning architectures to predict compressive strength of FDM 3D-printed structures. With the advantages of complementary deep learning architecture, this work aims to enhance prediction accuracy, robustness and generalization and make contributions to data-driven design, optimization and trustworthy deployment of FDM-fabricated components in engineering practice.

II. MATERIALS AND METHODS

II.1 MATERIALS AND SPECIMEN FABRICATION

The choice of polylactic acid (PLA) filament to use in this study was influenced by the large amount of use of this material in FDM based structural and research applications. A commercially sourced PLA filament of 1.75 mm diameter (MakerBot Industries, USA) with a density of 1.24 g/cm 3 and suggested extrusion temperature of 190-220 C was used.

The filament was allowed to dry in a vacuum oven at 45 o C, 6 h before printing to remove the defects caused by moisture in the extrusion process. The compression test specimens were modeled on the basis of ASTM D695 standard of compressive properties of rigid plastics. All the specimens were 12.7 mm x 12.7 mm square cross-section and 25.4 mm high. The models were made in SolidWorks 2023 and then made as STL with a tolerance of 0.01 mm. Each specimen was printed in vertical build orientation, and the loading direction was oriented parallel to the build direction to reduce variation due to anisotropic effects of bonding the layers. An Ultimaker S5 FDM 3D printer with a 0.4 mm nozzle made of brass was used to do fabrication. Calibration The printer was calibrated at the start of each build according to the standard leveling and extrusion calibration procedure by manufacturer.

II.2 FDM PROCESS PARAMETERS

Five major parameters of FDM process were chosen according to the reported effects on compressive strength. The thickness of the layers was adjusted at three rates, 0.1mm, 0.2mm and 0.3mm to have Low, medium and high levels of internal material contents. The rectilinear and gyroid infill patterns were chosen since these are the ones that are commonly used and their load transfer mechanisms differ. The printing speed was manipulated at 40 mm/s, 60 mm/s and 80 mm/s and extrusion temperature at 200^0 C, 210^0 C and 220^0 C. All prints were done at 60^0 C at the build plate temperature. After the initial 5 layers the speed of the cooling fan was set to 100%. All specimens were cut in Ultimaker Cura 5.4 with the same slicing settings with an exception of variables parameters selected. An experimental design that was implemented was a full factorial, thus giving 162 distinct sets of parameters. Each combination was printed to form three specimens and there were 486 samples in total.

II.3 EXPERIMENTAL TESTING

Instron 5982 universal testing machine with load cell of 100 kN was used to perform compression tests. In ASTM D695, tests were conducted at the room temperature (23 ± 2 o C). The specimens were put at the centre and hardened steel compression platens between them so that there was even load. Constant crosshead displacement rate of 1.3 mm/min was utilized until the failure of the specimen or a 10 per cent strain limit was achieved. The data were collected at a rate of 10Hz with Instron Bluehill Universal software to record load and displacement data. The computations of compressive strength were based on the compressive stress that was reached at the maximum during the test and an initial cross-sectional area of each specimen. The average compressive strength value was utilized to construct the data set of each of the parameter sets.

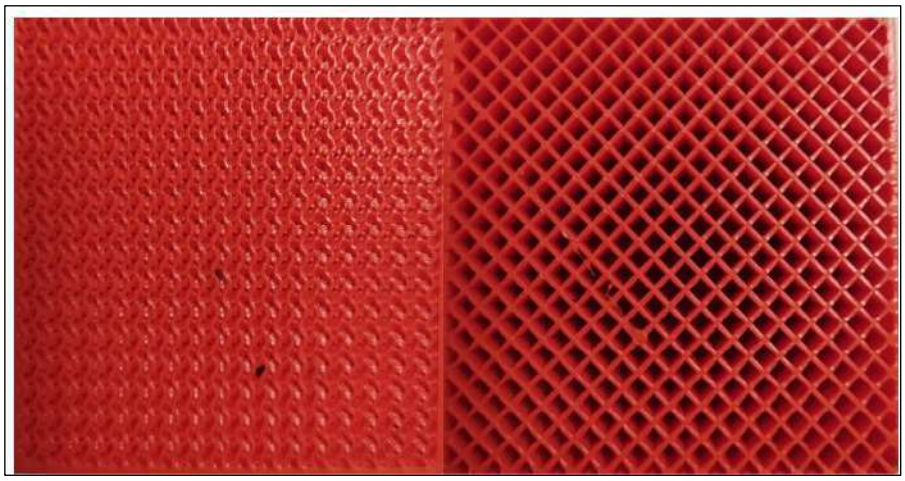

Figure 2: Rectilinear and Gyroid Patterns.
Source: Authors, (2026).

II.4 DATASET PREPARATION

The last dataset had 162 data points, which were the mean compressive strength of individual parameter combination. The input characteristics were the thickness of the layer (mm), the infill density (as a percentage), infill pattern (binary encoded), speed of printing (mm/s), and the extrusion temperature (^{0}C). The compressive strength (MPa) was the output variable. Before training the models, all the continuous input features were scaled to [0, 1] by minmax normalization. The data were randomly divided into training (70 percent), validation (15 percent) and test (15 percent) sets with a fixed random seed to obtain repeatability. All the models had the same data split to facilitate a consistent comparison.

II.5 DEEP LEARNING MODEL DEVELOPMENT

The model of the convolutional neural network (CNN) was developed in Python 3.10 and TensorFlow 2.15. The CNN model was a two-layer one-dimensional convolutional network with 64 and 128 filters and a 3-mm kernel size and ReLU activation, respectively. Another layer with 128 and 64 neurons followed as the max-pooling and the flattening layer respectively. The recurrent neural network models were LSTM and GRU. The two models both had two recurrent layers with 64 and 32 units, and a fully connected output layer. The between-layers dropout (rate 0.2) helped to reduce overfitting.

The CNNLSTM model was a hybrid of CNN feature extraction layers and LSTM layer with 64 units. The output of CNN was scaled and transmitted to the LSTM layer followed by the final dense layers. The ensemble hybrid model was based on prediction results of a separately trained CNN, LSTM, and CNN-LSTM to enhance the robustness and minimize the variation.

II.6 MODEL TRAINING AND EVALUATION

The Adam optimizer and a starting learning rate of 0.001 and a batch size of 16 was used to train all models. Loss function was the mean squared error. The number of epochs per training was set to 300 and early stopping was used in case the validation loss failed to decrease after 25 consecutive epochs. Root mean square error (RMSE), mean absolute error (MAE) and coefficient of determination (R 2) were used in the evaluation of model performance. Evaluation of the test dataset was done only after the final evaluation to provide unbiased evaluation. All the experiments were done in a workstation with an Intel Core i9-12900K processor, 64 GB memory, and an Nvidia RTX 3080 device, so the training conditions can be reproduced.

III. RESULTS AND DISCUSSIONS

III.1 EXPERIMENTAL DATA CHARACTERISTICS

The experimental campaign resulted in a set of comprehensive data that described the correlation between the parameters of FDM processes and compressive strength. The compressive strength data, which were measured, were distributed widely, which demonstrates the presence of high sensitivity to the printing conditions and the interior structure. Experiments with a higher rate of infill and a lower rate of layer thickness, produced specimens with greater compressive strength whereas a higher rate of printing had the propensity to decrease the strength as a result of inadequate interlayer bonding. The discrepancy found between the combinations of parameters validates the fact that nonlinear predictive models are required to capture complicated interactions between parameters.

Table 1: Overview of the FDM process parameters and the compressive strength results.

Sample ID	Layer Thickness (mm)	Infill Density (%)	Infill Pattern	Printing Speed (mm/s)	Extrusion Temperature (°C)	Compressive Strength (MPa)
S1	0.10	20	Rectilinear	40	200	32.4
S2	0.10	50	Rectilinear	60	210	41.8
S3	0.10	80	Gyroid	40	220	54.6
S4	0.20	20	Gyroid	60	200	28.7
S5	0.20	50	Rectilinear	80	210	36.9

Table 1 indicates a summary of the chosen FDM process parameters and their obtained experimentally determined compressive strength values.

III.2 INDIVIDUAL DEEP LEARNING MODEL PERFORMANCE

The standalone deep learning models, which include CNN and LSTM, were tested on the test dataset using the metrics of RMSE, MAE and R 2. The CNN model proved to be a good predictor, as it managed to learn nonlinear interactions between features of process parameters. The LSTM model, too, was good with respect to capturing interdependencies between parameters, although it had a slightly higher prediction error than the CNN. Comparative scatter plots of experimental and predicted compressive strength values indicate that the two models have the overall direction as the experimental data. Nevertheless, the LSTM model deviations of its ideal prediction line were greater in higher compressive strength values, which points out to poor predictability in extreme cases.

Table 2: CNN and LSTM model prediction performance based on RMSE, MAE, and R^2.

Model	**RMSE (MPa)**	**MAE (MPa)**	**R^2**
CNN	2.41	1.92	0.956
LSTM	2.96	2.34	0.931

Figure 4 compares the results of experimental and LSTM-predicted compressive strength, which have stronger scatter and lower prediction accuracy than CNN model.

III.3 HYBRID DEEP LEARNING MODELS PERFORMANCE

The CNNLSTM model was found to perform better in predictive retrieval than the individual CNN and LSTM models. The hybrid architecture minimized RMSE and MAE as well as having the largest R 2 value when compared to all models that were tested, by integrating convolutional feature extraction and sequential learning. The ensemble hybrid model also enhanced robustness due to averaging the predictions of a variety of architectures, which led to lesser variance and more consistent predictions throughout the test set. The experimental versus predicted compressive strength plot of hybrid CNN-LSTM model indicates that the data are more localized towards the ideal prediction line, which means that it is more accurate. The distribution of the error plots also substantiate the fact that hybrid modeling greatly diminishes major prediction errors particularly in those specimens that are highly compressive.

Table 3: Performance of standalone and hybrid deep learning models.

Model	RMSE (MPa)	MAE (MPa)	R^2
CNN	2.41	1.92	0.956
LSTM	2.96	2.34	0.931
Hybrid CNN–LSTM	1.88	1.43	0.972
Ensemble Hybrid Model	1.72	1.31	0.978

Figure 5 shows the experimental and predicted compressive strength under the hybrid CNN-LSTM model, which exhibited the maximum prediction and the minimum distance to the ideal line.

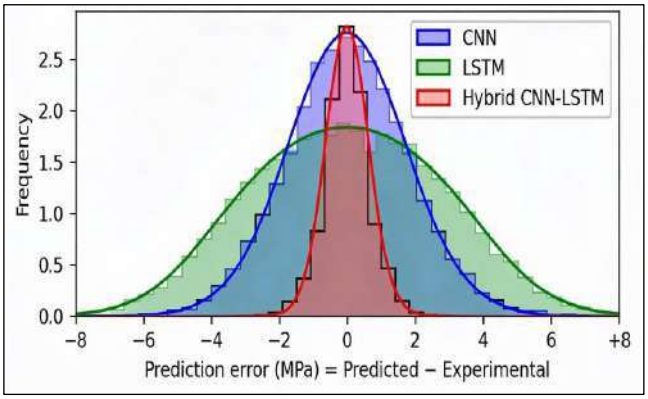

Figure 6: Comparison of individual model and hybrid model error distributions.
Source: Authors, (2026).

Figure 6 shows the comparison of the distributions of errors between CNN, LSTM, and hybrid models, with the error range of the hybrid one being narrow and more centralized.

III.4 BEHAVIOR AND MODEL CONVERGENCE TRAINING

The curves of training and validation losses of the hybrid CNN−LSTM model exhibit the stability of the convergence. The loss of training slowed at the early stages of training, then steadily approached a minimum value. Validation loss was similar to the trend of training loss and shows no big deviation meaning that the generalization is effective and there is no much overfitting. Early termination allowed the model to learn efficiently because it did not waste any time on any extra training.

Source: Authors, (2026).

Figure 7 depicts the training and validation loss curves of the hybrid deep learning model, which indicates the presence of stable convergence and low overfitting throughout the training.

III.5 DATA ANALYSIS AND INTERPRETATION AND CONCLUSION

The statistical evaluation of prediction accuracy proves that hybrid deep learning models are more effective than one-architecture models in all evaluation measures. The drop in RMSE and MAE show more accuracy, whereas the increased values of R 2 suggest a greater correlation between the predicted and experimental values of compressive strength. These findings confirm the usefulness of the hybridization of complementary deep learning models in the representation of complex FDM data. Influence of feature analysis, infill density and layer thickness are the most influential parameters on compressive strength with extrusion temperature coming second. Increased infill density enhances the content of loading material whereas decreased layer thickness enhances bonding between layers. No positive relationships were observed between printing speed and compressive strength at higher values, which highlighted the compromise between productivity and mechanical performance. Comparative meaning of model robustness shows that hybrid and ensemble models are more generalized to unmonitored data, especially when it comes to combinations of parameters of extreme strength values. Altogether, the findings indicate that hybrid deep learning models represent a valid and correct method of the compressive strength prediction of FDM 3D-printed structures that can be used to optimize data-driven and informed design choices in additive manufacturing.

IV. DISCUSSION AND CONCLUSION

The outcomes of the current research eloquently indicate the importance of enhanced accuracy of prediction of compressive strength of FDM 3D-printed objects that is attained by the use of hybrid deep learning models. The hybrid CNN-LSTM and ensemble models were lower in prediction errors and coefficient of determination as compared to the standalone CNN and LSTM models. This is due to the complementary nature of the hybrid architecture in which convolutional layers are effective in extracting the nonlinear feature interactions of the FDM process parameters, whereas recurrent layers extract sequential and interdependent interactions between process parameters. The low error dispersion and more intense clustering of the most similarity to the ideal prediction line prove the fact that the hybrid models are more resilient and dependable, especially with regard to the combinations of parameters that can be linked to a high or low compressive strength. The observed learning behavior in the hybrid models can be viewed in the physics of the FDM processes. Multiscale phenomenon, such as filament deposition accuracy, interlayer diffusion, thermal history, and internal load transfer through infill architecture govern the compressive strength of FDM parts. CNN layers are good at learning localized parameter interactions, e.g. the interaction of the thickness of a layer and the extrusion temperature of the layer with the bonding strength, whereas LSTM layers learn longer-range interactions, e.g. the overall impact of printing speed and thermal conditions across layers. Such physics consistent learning behaviour offers an explanation of why hybrid models generally give better generalization and to have the capability to model intricate process structure property relations without explicit physical equations.

The hybrid deep learning structure has obvious benefits compared to the existing predictive methods that have been used in the literature. Conventional empirical models and superficial machine learning methods can typically necessitate a huge amount of features engineered, and fail to scale to new parameter spaces. Although there has been decent performance of standalone ML and ANN-based solutions, the predictive ability of these solutions is limited to highly nonlinear, and high-dimensional datasets, which is common to FDM processes. The hybrid deep learning model addresses these shortcomings by being able to automatically learn the hierarchical features representation, better accuracy and stability without degrading scalability. This research can be used to draw significant conclusions on intelligent design and optimization of FDM 3D-printed structures. Real and dependable estimation of compressive strength allows designers to venture more into the design space with less experimentation, assists in optimization of parameters, selection of materials and performance-based design. It is possible to incorporate the proposed hybrid deep learning framework into digital manufacturing pipelines and decision-support systems, where real-time prediction and optimization of mechanical properties can be done. Finally, such a strategy will lead to the development of data-driven additive manufacturing, which would allow more efficient, reliable, and application-ready FDM-produced parts.

ABSTRACT

The design and simulation of a novel HN-shaped patch antenna optimized for dual-band operation at 11 GHz and 20 GHz are presented in this study. The proposed design achieves a gain of 5.44 dB, a directivity of 6.50 dB, and an efficiency of 83.69%. By integrating the H- and N-geometry antennas into a single, compact structure, the antenna offers improved performance over conventional designs. These characteristics make it well-suited for satellite communications, radar systems, and high-frequency wireless applications. The software used in this work is HFSS 15 (High Frequency Structure Simulator)

I.INTRODUCTION

Compact, efficient, and adaptable antenna designs have become essential due to the rapid evolution of high-frequency applications and satellite communications. Microstrip patch antennas have become a popular option for many wireless communications systems due to their low profile, lightweight design, and ease of manufacturing [1]. For contemporary communications systems to effectively support numerous frequency bands within a single compact structure, dual-band and multi-band antennas are becoming increasingly essential. In this work, a unique HN-shaped microstrip patch antenna with operating frequencies of 11 GHz and 20 GHz is presented for use in satellite communications and other high-frequency fields. In addition to maximizing antenna performance across these many frequency bands, the distinctive HN-shaped geometry also produces a compact design, meeting the growing need for smaller parts in contemporary communications equipment.An important novelty in the proposed design is the inclusion of a Defected Ground Structure (DGS) [2], [3]. DGS preserves the structural simplicity of the antenna while improving its impedance, bandwidth and radiation matching characteristics.Reliable communication on both target frequencies is ensured by the antenna's exceptional performance metrics, which include high gain, low reflection loss and exceptional directivity, achieved through meticulous ground plane design and optimization.Modern satellite communications relies heavily on the Ku-band (11 GHz) and Ka-band (20 GHz) [4], which are used for a variety of applications requiring fast data rates, low latency, and reliable performance.

There are particular difficulties in designing antennas for these high-frequency bands, such as minimizing electromagnetic interference, maintaining structural integrity, and being compact while keeping high efficiency [5]. With its sophisticated ground plane design and optimized geometry, the suggested HN-shaped microstrip patch antenna successfully tackles these issues and provides a workable and effective solution. Extensive simulations and studies verified the performance of the suggested antenna. The outcomes show that it can produce distinct radiation patterns at both 11 GHz and 20 GHz, as well as minimal return loss and high gain. Additionally, the design is perfect for integration into contemporary satellite communications systems and other high-frequency equipment due to its small size and lightweight construction. By merging the recognized advantages of a faulty ground structure with the novel HN-shaped geometry, this work makes a substantial contribution to the field of antenna design.

It provides a practical basis for creating dual-band microstrip patch antennas suitable for high-frequency uses, including satellite communications. This paper's remaining sections are arranged as follows: The design process, including the optimization of the defected ground structure and the HN-shaped geometry, is described in depth in Section II. The simulation results are shown in Section III along with an examination of important performance indicators such radiation patterns, gain, and reflection coefficient. By merging the recognized advantages of a faulty ground structure with the novel HN-shaped geometry, this work makes a substantial contribution to the field of antenna design. It provides a practical basis for creating dual-band microstrip patch antennas suitable for high-frequency uses, including satellite communications [6], [7]. The findings' ramifications are examined in Section IV, which also contrasts the performance of the suggested antenna with that of other designs. The work is finally concluded and future research directions are outlined in Section V.

II.ANTENNA DESIGN

II.1 DESIGN CONCEPT

The proposed HN-shaped microstrip patch antenna is designed to operate at two frequencies, specifically 11 GHz and 20 GHz, for satellite communication applications. The HN form was chosen for its ability to provide enhanced electromagnetic coupling and support multiple resonance modes, which is essential for achieving dual-band operation. The design leverages a Defective Ground Structure (DGS) to further improve impedance matching and bandwidth performance while maintaining a compact size [6], [8].

Substrate material: The antenna is constructed using an FR4 substrate, which has the following properties:

Relative permittivity (εr): 4.4
Loss tangent (tanδ): 0.02
Thickness (h): 1.6 mm
FR4 is a cost-effective material with reliable dielectric properties, making it suitable for high-frequency designs up to 20 GHz.

Antenna structure: The antenna includes the following elements:

Patch: The HN-shaped patch is etched on the top layer of the substrate. The dimensions of the arms and connection segments of the H and N shapes are optimized to resonate at 11 GHz and 20 GHz.

Ground Plane: The bottom layer comprises a faulty ground structure, consisting of strategically placed circular slots on a rectangular to improve radiation characteristics and suppress higher order harmonics [9].

Power Mechanism: A microstrip line feed is used, which ensures efficient energy transfer to the patch while simplifying the manufacturing process.

II.2 DESIGN PARAMETERS

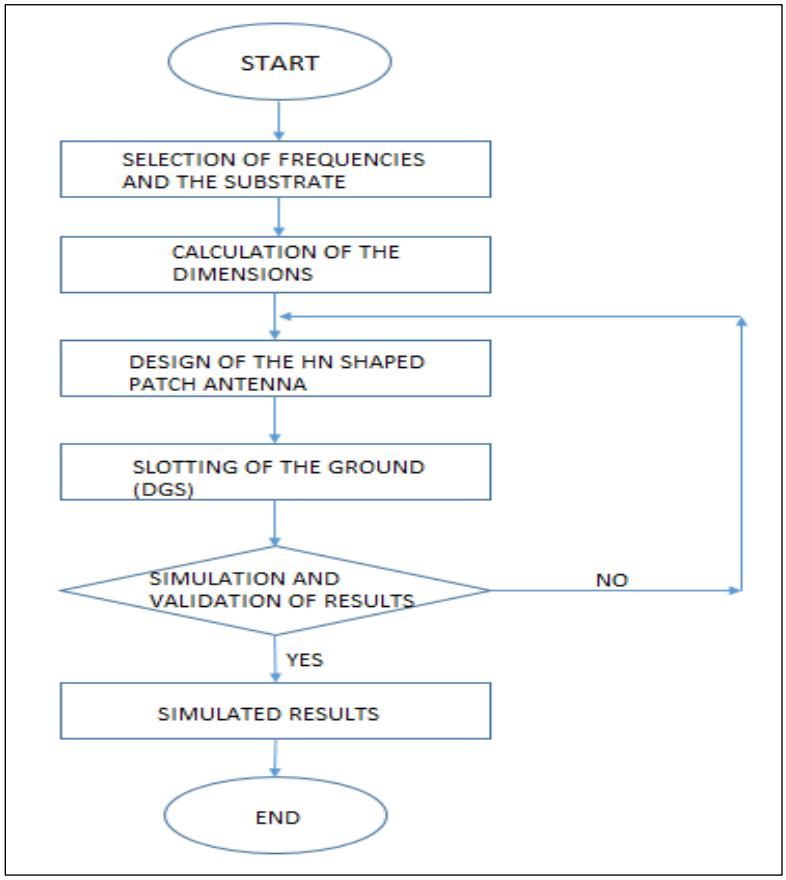

Figure 2: Flowchart of the design process.
Source: Authors, (2026).

The dimensions of the antenna are listed in Table 1. They were determined by iterative simulations in HFSS 15 to obtain optimal performance.

The equations below will let us know how we can calculate the dimensions of the patch antenna [10] Source: Authors, (2026).

$$W = \frac{c}{2f} * \sqrt{\frac{2}{\varepsilon_r + 1}} \tag{1}$$

$$L = \frac{c}{2f}\left(\frac{\varepsilon_r + 1}{2} - \frac{\varepsilon_r - 1}{2}\sqrt{\left[1 + 12\frac{h}{w}\right]}\right)^{-\frac{1}{2}} - 2\Delta L \tag{2}$$

Where:

W is the width of the patch antenna
L is the length of the patch antenna
f: frequency
h is the height of the substrate
C is the speed of light

The dimensions of the substrate, the following equations will help us know how to calculate

$$L_g = 6h + L \tag{3}$$

$$W_g = 6h + W \tag{4}$$

Ls and Ws are respectively the length and width of the substrate

Table 1: Antenna parameters.

Parameters		Values (mm)

II.3 SIMULATION TOOLS

The antenna design and optimization were carried out using HFSS (High-Frequency Structure Simulator), a leading electromagnetic simulation tool. HFSS enables accurate modeling of antenna behavior across target frequency bands and provides key performance metrics such as:

Reflection coefficient (S11)
Radiation diagram
Gain and directivity
Bandwidth

Process optimization
The optimization process involved:

Initial design: The HN shape was sketched and defined parametrically.
Resonance tuning: The dimensions of the H and N segments have been adjusted to achieve resonance at 11 GHz and 20 GHz.
DGS Integration: Slots were introduced in the ground plane, and their sizes and positions were optimized for better bandwidth and impedance matching.
Validation: The simulated results were validated to ensure consistency and convergence.

III.RESULTS AND DISCUSSIONS

The performance of the proposed HN-shaped microstrip patch antenna was evaluated using ANSYS HFSS 15, focusing on its operation at two frequencies of 11 GHz and 20 GHz. The results demonstrate the antenna's suitability for satellite communications applications, with notable performance metrics including gain, directivity, efficiency, and bandwidth. These measures are summarized and analyzed below.

III.1 REFLECTION COEFFICIENT (S11) AND VSWR

Simulated S11 results reveal excellent impedance matching at target frequencies:

At 11 GHz, the S11 value is approximately -12.35 dB, indicating the minimum reflected power, and at 20 GHz, the S11 value is around -16.52 dB, which means strong resonance.

The antenna has a bandwidth of 10.7 GHz to 11.13 GHz on the 11 GHz band and 19.7 GHz to 20.6 GHz on the 20 GHz band. This provides a fractional bandwidth of approximately 3.9% and 4.5%, respectively, which is sufficient for satellite communication needs. The equations below will show us how to calculate fractional bandwidth (BW (%))

$$BW(\%) = \frac{f_h - f_l}{f_c} \tag{5}$$

$$f_c = \frac{f_h + f_l}{2} \tag{6}$$

With f_c, f_h and f_l, respectively, central, highest, and lowest frequencies

Voltage standing wave ratio (VSWR) is an essential parameter for evaluating impedance matching. For the proposed antenna. The VSWR is approximately 2.5 dB, indicating that the reflected power is low enough for efficient operation. A VSWR value less than 3 is generally acceptable for practical applications, and the obtained value of 2.5 demonstrates good performance. The equation below helps us calculate the S11 or Γ and the reflected power

$$\Gamma = \frac{VSWR-1}{VSWR+1} \tag{7}$$

$$\Gamma = \frac{2.5-1}{2.5+1} = \frac{1.5}{3.5} = 0.429$$

Reflected power:

$$P_{reflected} = \Gamma^2 = (0.429)^2 = 0.184 \tag{8}$$

$$P_{transmitted} = 1 - \Gamma^2 = 1 - (0.429)^2 = 0.816 \tag{9}$$

This means that 18.4% of the power is reflected and approximately 81.6% is transmitted.

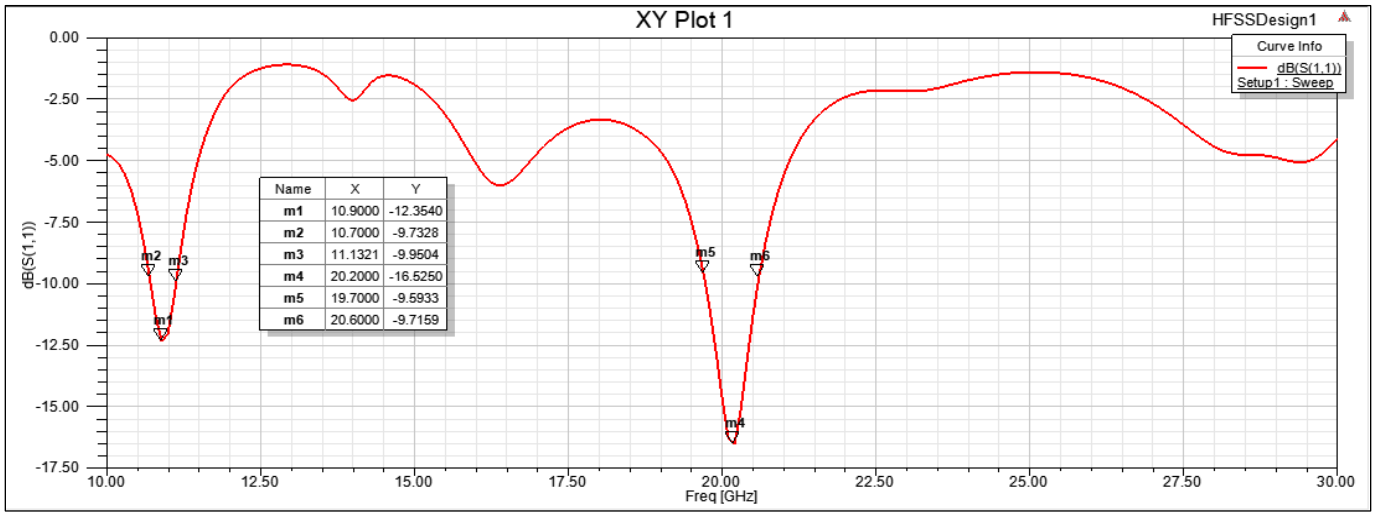

Figure 6: S11 of the proposed antenna.
Source: Authors, (2026).

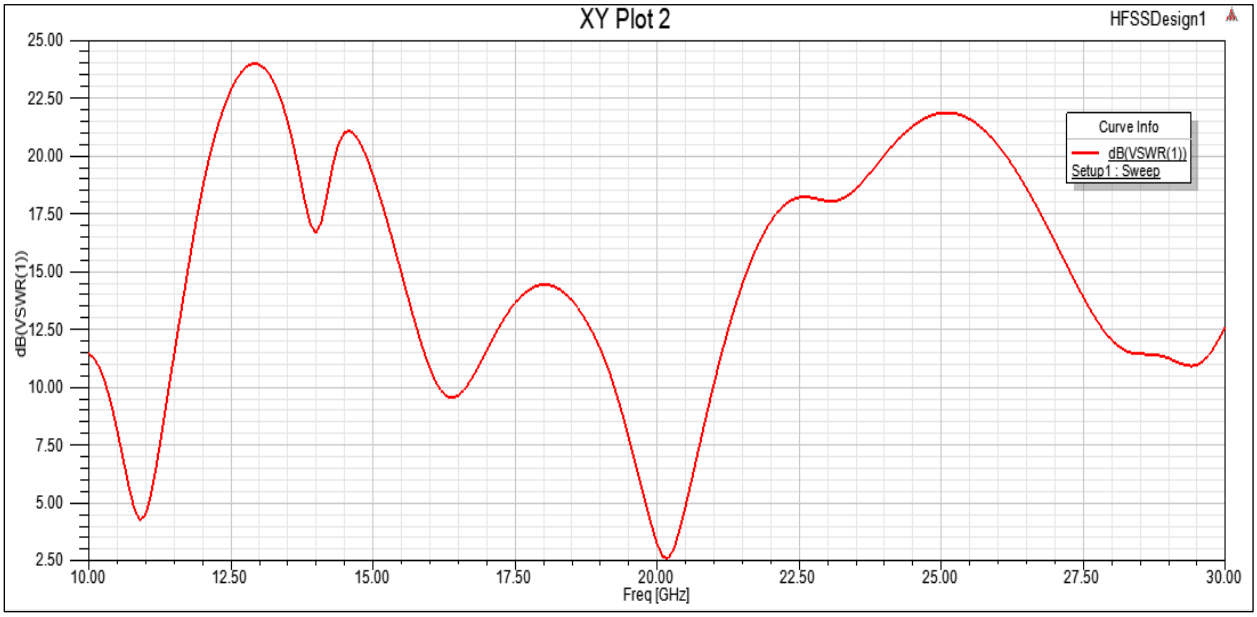

Figure 7: VSWR of the proposed antenna.
Source: Authors, (2026).

The bandwidth characteristics of the antenna are as follows, based on the figure 6:

11 GHz Band: The antenna operates efficiently in the range of 10.7 GHz to 11.13 GHz, providing a bandwidth of 430 MHz

20 GHz Band: The antenna supports operation in the range of 19.7 GHz to 20.6 GHz, resulting in a bandwidth of 900 MHz

III.2 GAIN AND DIRECTIVITY

The antenna achieves a gain of 5.44 dB suitable for reliable signal transmission in satellite links and providing improved performance at higher frequencies. The gain performance is attributed to the HN-shaped patch, which supports efficient radiation, and the defective ground structure (DGS), which suppresses unwanted modes.

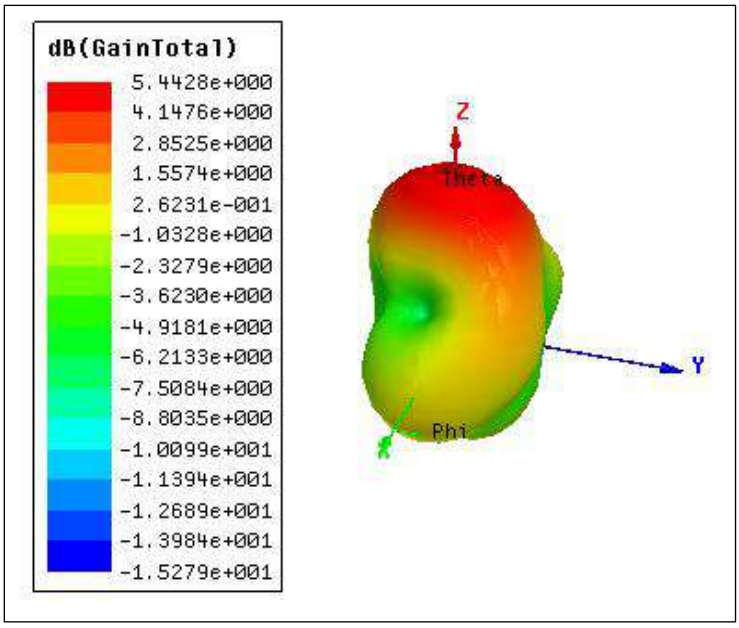

Figure 8: Gain of the proposed antenna.
Source: Authors, (2026).

The directivity value is 6.50 dBi indicating focused radiation in the intended direction and reflecting the antenna's ability to maintain directionality at higher frequencies. These values demonstrate that the antenna efficiently converts input power into radiated power in specific directions.

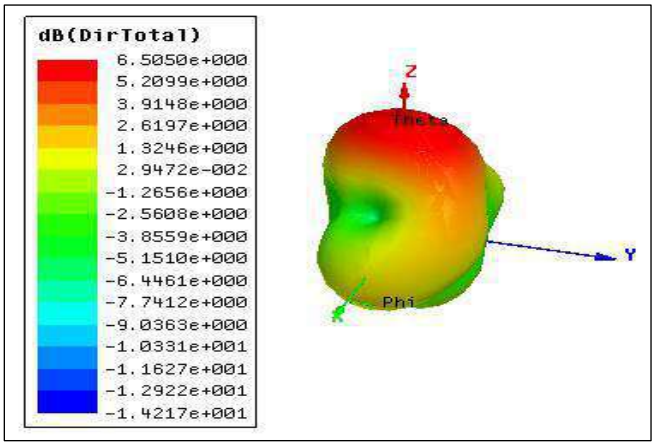

Figure 9: Directivity of the proposed antenna.
Source: Authors, (2026).

III.3 RADIATION EFFICIENCY

The radiation efficiency of an antenna quantifies how effectively the antenna converts input power into radiated power. It is defined as the ratio between the power radiated by the antenna and the total power supplied to it. The proposed design achieves high efficiency 83.69% through low dielectric and ohmic losses. These values indicate that the majority of the input power is radiated rather than dissipated, which is essential for good satellite communication performances.

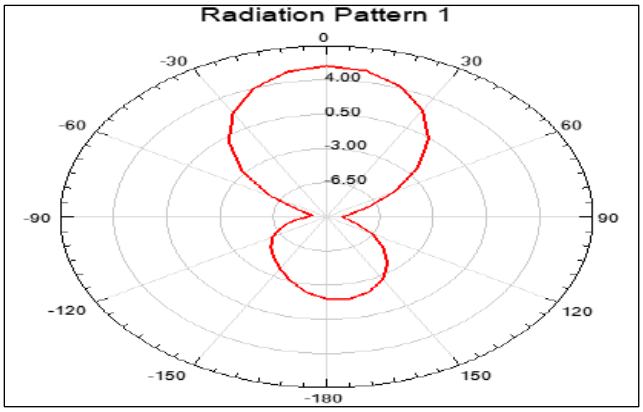

Figure 10: Radiation pattern of the proposed antenna at Phi= 90 degrees.
Source: Authors, (2026).

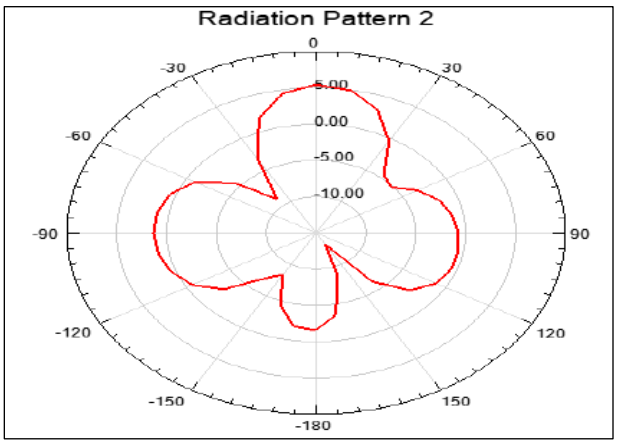

Figure 11: Radiation pattern of the proposed antenna at Phi= 0 degree.
Source: Authors, (2026).

The integration of the defective floor structure played a central role in achieving superior performance measures. The DGS effectively expanded the bandwidth and improved impedance matching while maintaining a compact size. The HN-shaped patch contributed to dual-frequency operation, an essential feature for modern satellite communications systems requiring flexible use of frequencies.

III.4 COMPARISON WITH EXISTING WORKS

Let's examine the suggested HN shape microstrip patch antenna in comparison to other antennas that have been documented in the literature, particularly those designed for satellite communications applications, dual-frequency operation, or integration with defected ground structure (DGS), in order to make a meaningful comparison. Important factors including gain, bandwidth, efficiency, size and VSWR are the focus of the comparison. The results are summarized in the table 2 below.

Table 2: Comparison with related works.

Parameters	[1]	[3]	[10]	Proposed antenna
Antenna size (mm^2)	45 x 35	50 x 40	35 x 30	9 x 8
Operating frequencies	10 GHz, 18 GHz	12 GHz, 18 GHz	11.5 GHz 20.5 GHz	11 GHz, 20 GHz
Bandwidth	310 MHz 500 MHz	200 MHz 300 MHz	400 MHz 750 MHz	430 MHz 900 MHz
Gain (dB)	4.5	3.8	5.1	5.44
Directivity (dB)	5.5	4.8	6.3	6.5
VSWR	3	2.9	2.6	2.5
DGS	Yes	No	Yes	Yes
Efficiency (%)	79.4	75.6	82.1	83.69

Source: Authors, (2026).

A comparative analysis with existing designs demonstrated the superior performance of the proposed antenna, especially in terms of achieving higher bandwidth and efficiency while maintaining a simple and compact structure.

IV.CONCLUSION

This paper presents the design and performance analysis of a novel HN-shaped microstrip patch antenna operating at dual frequencies of 11 GHz and 20 GHz, optimized for satellite communication applications. The integration of the HN-shaped patch and defected ground structure (DGS) significantly improved the antenna performance in terms of bandwidth, gain, and efficiency while maintaining a compact size. The results validate the potential of the proposed HN-shaped microstrip patch antenna for deployment in satellite communication systems, providing a robust solution for high-frequency dual-band operation. Future work may explore further optimization of circular polarization and multi-band operation to improve its versatility for advanced satellite systems.

ABSTRACT

Distributed Denial of Service (DDoS) attacks represent a significant challenge to network security, making timely detection critical. In this paper, we present a hybrid deep learning approach that combines Convolutional Neural Networks (CNN) and Long Short-Term Memory (LSTM) networks with feature selection based on Principal Component Analysis (PCA). We apply this method to the CICDDoS2019 dataset, which includes various DDoS attack scenarios. Our approach aims to enhance detection performance by using CNN for spatial feature extraction and LSTM for temporal sequence learning. Our experiments show that deep learning can effectively identify DDoS attacks with high accuracy when the data is properly preprocessed. The results indicate that our model outperforms traditional methods, achieving high accuracy, precision, and recall.

I. INTRODUCTION

Nowadays, networks and connected systems face real threats, whether intentional or accidental. It seems that every day, a new story about cybersecurity challenges is published. Whether it is the hacking of privacy on social networks, credit card fraud, economic espionage, computer system infection, denial of service attacks, and many other cyber threats that represent major problems and challenges for the years to come. These cyber threats of cybersecurity are considered today as one of the main concerns and one of the most active areas of scientific research [1-2]. Distributed Denial of Service (DDoS) attacks have increased in frequency and complexity, posing a major challenge to the security of networks and systems [3]. A DDoS attack floods a target system with an overwhelming amount of traffic, rendering it unavailable to legitimate users. Traditional detection methods based on predefined rules or signature matching have limitations in detecting novel attacks, as they rely on known patterns. The complexity and scale of DDoS attacks have grown rapidly, making traditional detection techniques less effective in dynamic network environments [4]. With the rise of large-scale datasets and machine learning techniques, especially deep learning, there has been a growing interest in automating the detection of these attacks.

Deep learning models, due to their ability to learn complex patterns in data, offer a promising solution to identifying DDoS attacks [5], even those with previously unseen characteristics. Deep learning techniques, particularly Convolutional Neural Networks (CNN) and Long Short-Term Memory (LSTM) networks, have shown promise in detecting complex patterns in large-scale datasets [6-7]. CNNs are effective for spatial feature extraction, while LSTMs excel at capturing temporal dependencies in sequential data. By combining both CNN and LSTM, we aim to improve the accuracy of DDoS detection. Furthermore, feature selection using Principal Component Analysis (PCA) helps reduce the dimensionality of the dataset, improving computational efficiency without sacrificing performance [8], [9]. This study proposes DDoS attack detection system combining Convolutional Neural Networks (CNN) and Long Short-Term Memory (LSTM) networks, integrated with Principal Component Analysis (PCA) for feature selection. CNN is effective in extracting spatial features, while LSTM captures temporal dependencies in network traffic. PCA is employed to reduce feature dimensionality, enhancing model performance. The model is evaluated on the CICDDoS2019 dataset, one of the largest and most realistic DDoS datasets available.

II. RELATED WORK

Previous studies on DDoS detection have employed a wide range of techniques, including statistical methods, rule-based systems, and machine learning models [10]. Traditional approaches, such as traffic analysis based on fixed thresholds or anomaly detection using statistical models, are often unable to cope with the dynamic and evolving nature of DDoS attacks. In recent years, advancements in machine learning (ML) and deep learning (DL) techniques have significantly enhanced the effectiveness of Distributed Denial of Service (DDoS) attack detection systems. These techniques leverage the ability to analyze vast amounts of data, identifying patterns and anomalies that are indicative of DDoS attacks [11], [12]. This section reviews literature focusing on these advancements and their impact on detection systems. Machine learning has been increasingly used in recent years to address these limitations. Techniques such as Support Vector Machines (SVM), Random Forests (RF), and k-Nearest Neighbors (k-NN) have been applied to detect anomalies in network traffic that indicate DDoS attacks. However, these models often require manual feature selection and may not generalize well to new attack patterns. Deep learning, particularly with neural networks, has emerged as a promising approach due to its ability to automatically learn features from raw data.

Recurrent Neural Networks (RNN), Convolutional Neural Networks (CNN), and Deep Neural Networks (DNN) have shown significant improvements in accuracy over traditional machine learning models for a variety of cybersecurity tasks, including DDoS detection [13], [14], [15]. There are a lot of relevant literature reviews related to DDoS detection employed different techniques, including machine learning and deep learning models. The examination conducted by Hosseini and Azizi [14] employed a hybrid machine learning approach combining Random Forest and Support Vector Machines for DDoS detection. Their model outperformed traditional methods by providing higher accuracy and lower false positive rates, demonstrating the effectiveness of ensemble techniques in handling complex attack patterns. Similarly, Lai et al. in [15] explored the application of Convolutional Neural Networks (CNNs) for detecting DDoS attacks. They used packet-level data and reported that CNNs could automatically extract relevant features from raw data, leading to improved detection rates compared to classical feature engineering methods. In a study by Laghrissi et al. [16], a deep learning architecture known as Long Short-Term Memory (LSTM) networks was utilized to analyze time-series network traffic data.

Their results highlighted LSTM's capability to capture temporal dependencies in traffic patterns, which significantly enhanced the detection of sophisticated attacks. Tekleselassie [17] proposed a multi-layered deep neural network model for DDoS attack detection that incorporated both supervised and unsupervised learning techniques. Their approach effectively distinguished between legitimate and malicious traffic, achieving high detection accuracy and low computational overhead. Salahuddin et al. [18] investigated the use of Autoencoders for anomaly detection in network traffic. Their study showed that Autoencoders could effectively learn the normal behavior of network traffic and identify anomalies that signify potential DDoS attacks, offering an efficient solution for real-time monitoring.The study in Protogerou et al. [19] introduced a novel approach using Graph Neural Networks (GNNs) for DDoS detection. They propose a distributed detection scheme, which aims to monitor efficiently the entire network infrastructure by modelling network traffic as a graph, their method was able to capture complex relationships between different traffic flows and leading to better detection performance. Alghazzawi et al. [20] introduced a hybrid deep learning model that incorporates Principal Component Analysis (PCA) for feature selection to improve the accuracy of DDoS attack detection.

Their approach demonstrates that PCA can effectively reduce the dimensionality of the data, leading to more efficient and accurate detection models. Dash et al. [21] in 2024 applied PCA and convolutional neural networks (CNNs) to DDoS attack detection. Their study highlights how PCA can be used to simplify the data while CNNs provide robust detection capabilities. Shakya et al. in [22] explored the detection of DDoS attacks in IoT networks using PCA and deep learning models. Their research demonstrates the applicability of PCA for feature reduction in resource-constrained environments, and how deep learning can enhance detection capabilities. Overall, these recent advancements underscore the growing importance of sophisticated ML and DL methods in enhancing DDoS attack detection systems. By incorporating diverse approaches and combining multiple techniques, researchers have significantly improved the accuracy, efficiency, and adaptability of detection systems. The rest of this paper is organized as follows: Section 2 gives an overview of related work, Section 3 introduces the details of the proposed system, Section 4 presents the experimental analysis of the proposed system, and Section 5 summarizes this work.

III. MATERIALS AND METHODS

This section details the methodological approach adopted in this work to evaluate the application of deep neural network based intrusion detection system over a network.

III.1 DATASET OVERVIEW

The CICDDoS2019 dataset is widely used for research in DDoS attack detection. It provides realistic network traffic data, including both normal and malicious traffic, with a variety of DDoS attack types [23]. This dataset contains only DDoS attacks and benign traffic. The creators describe it as a realistic cyber defense dataset., it is a joint project of the Canadian Communications Security Establishment (CSE) and The Canadian Institute for Cybersecurity (CIC). CIC-DDoS 2019 is a new, high quality, synthetic dataset, providing both network traffic and log data.CICDDoS2019 provides benign and up-to-date typical DDoS assaults that closely replicate real-world data.

It also includes the results of the network traffic analysis performed using CICFlowMeter-V3, labeled flows based on time stamp, source and destination IPs, source and destination ports, protocols, and attacks (CSV files). In this study, we use the first day of CICDDoS2019 dataset that contain different modern reflective DDoS attacks including PortMap, NetBIOS, LDAP, MSSQL, UDP, UDP-Lag, SYN, NTP, DNS, and SNMP. Throughout the training and testing process, data balance is a key component that might have an impact on the final outcomes. Given the dataset's approximately 5 million rows of benign data, the ideal strategy is to extract an appropriate proportion of attack data to match the amount of benign traffic.

However, if the number of assaults is too low, it is appropriate to down-sample innocuous traffic to match the number of attacks. Table 1 shows regenerated dataset details and the number of each assault type utilized for training and testing.

Table 1: CICDDoS2019 dataset classes details.

Dataset	Class	Number of instance for training	Number of instance for testing	Label
CICDDoS2019 (8 classes)	BENIGN	12905	3256	0
	DrDoS_ NetBIOS	229153	20569	1
	DrDoS_ MSSQL	159367	39948	2
	DrDoS_ LDAP	81925	20569	3
	Portmap	73981	18464	4
	Syn	178821	44691	5
	DrDoS_ UDP	192146	48525	6
	UDP-lag	74181	18270	7

III.2 PREPROCESSING

The CICDDoS2019 dataset is widely used for research in DDoS attack detection. It provides realistic network traffic data, including both normal and malicious traffic, with a variety of DDoS attack types. The dataset contains 80 features, including source and destination IP addresses, packet sizes, protocols, timestamps, and other network traffic attributes.

III.2.1 Data Cleaning

Before feature selection, we applied data cleaning techniques to handle missing values and remove redundant or irrelevant features. For example, IP addresses and ports, which are less informative for DDoS detection, were excluded from the model input.

III.2.2 Normalization

To ensure that features with different scales do not skew the model's performance, we normalized the dataset using Min-Max scaling. This scales all feature values between 0 and 1, which is important for the performance of deep learning models.

III.2.3 Data Balancing

Given the class imbalance, we employed Synthetic Minority Over-sampling Technique (SMOTE) to balance the dataset. This technique generates synthetic instances of the minority class to ensure that the model is not biased towards the majority class during training. The Synthetic Minority Oversampling Technique (SMOTE) is used to address the issue of imbalanced datasets, where the classification categories are not evenly distributed. In network data, most traffic is legitimate, with only a small portion being invalid, leading to an imbalance. This imbalance results in the majority class dominating the data, which can cause classifiers. To improve a classifier's sensitivity to the minority class, two resampling techniques are typically used: under-sampling the majority class and over-sampling the minority class. In this paper, SMOTE is employed as a pre-processing technique to handle the dataset imbalance.

III.2.4 Feature Selection Using PCA

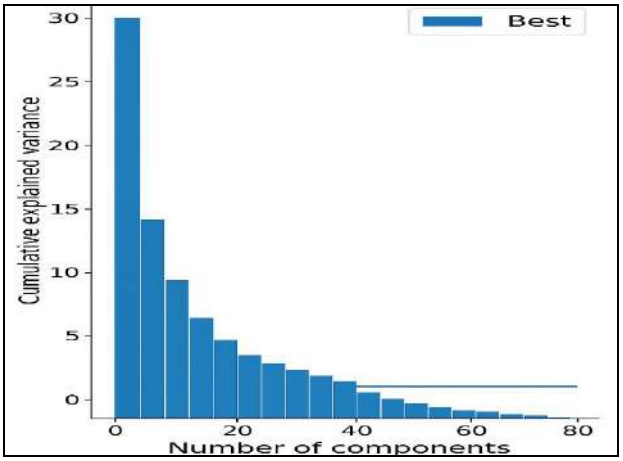
Principal Component Analysis (PCA) was applied to reduce the dimensionality of the dataset, focusing on the most relevant features. After applying PCA, we reduced the dataset's dimensionality from 80 features to 25 principal components, which captured over then 90 % of the variance in the data. This reduction not only improved the computational efficiency but also helped prevent overfitting by eliminating noise and redundancy. The dataset consists of 80 features, many of which may be redundant or irrelevant, leading to high computational costs and overfitting. To address this, Principal Component Analysis was employed for feature selection, reducing the number of features while preserving as much information as possible.

The PCA Steps:

-Covariance Matrix Calculation: The covariance matrix of the features was computed.

-Eigenvalue Decomposition: Eigenvalues and eigenvectors of the covariance matrix were derived to determine the principal components.

-Dimensionality Reduction: Based on the explained variance, the top 25 principal components were selected, reducing the feature set from 80 to 25 features.



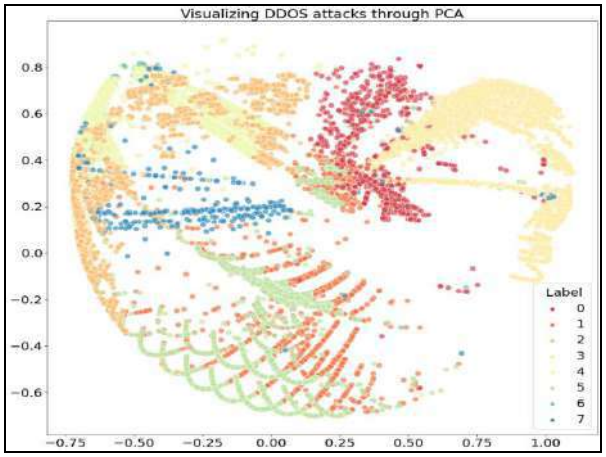


Figure 2: The best Selected Principal Components.
Source: Authors, (2026).

Figures 3: Visualisation of DDOS attack through PCA.
Source: Authors, (2026).

This dimensionality reduction significantly improves the efficiency of the proposed model by minimizing computational complexity while maintaining detection accuracy.

III.3 PERFORMANCE MEASURES

To evaluate the performance of IDS classifiers, three metrics were taken into account: accuracy, precision, and false alert rate. By focusing on these metrics, the ability of IDS classifiers to correctly identify and classify intrusion instances can be assessed while minimizing the occurrence of false positives and false negatives. Equations (1) to (4) provide the mathematical expressions for performance indicators like accuracy, precision, recall and F1-score.

- True Positive (TP): Intrusive traffic is detected as Intrusive.
- False Positive (FP): Normal traffic is detected as Intrusive.
- True Negative(TN): Normal traffic is detected as Normal.
- False Negative (FN): Malicious traffic is detected as Normal.

$$Accuracy = \frac{TP + TN}{TP + FN + FP + TN} \quad (1)$$

$$\text{Precision} = \frac{TP}{TP + FP} \quad (2)$$

$$\text{Recall} = \frac{TP}{TP + FN} \tag{3}$$

$$\text{F1} - \text{score} = 2 \times \frac{\text{Recall} \times \text{Precision}}{\text{Recall} + \text{Precision}} \tag{4}$$

III.4 PROPOSED MODEL

The proposed deep learning architecture is a hybrid model that integrates Convolutional Neural Networks (CNN) and Long Short-Term Memory (LSTM) networks to effectively capture both spatial and temporal features from network traffic data. The input to the model consists of 25 features selected through Principal Component Analysis (PCA), which ensures dimensionality reduction while preserving the most informative components.

These features are first processed by a convolutional layer, which extracts local spatial patterns within the data. To further optimize the representation and reduce computational complexity, a max pooling operation is applied to the convolutional outputs. The resulting feature maps are then fed into an LSTM layer, which is designed to learn temporal dependencies and sequential dynamics characteristic of network traffic. Finally, a fully connected layer performs classification to distinguish between normal and differents malicious traffic, enabling effective intrusion detection.

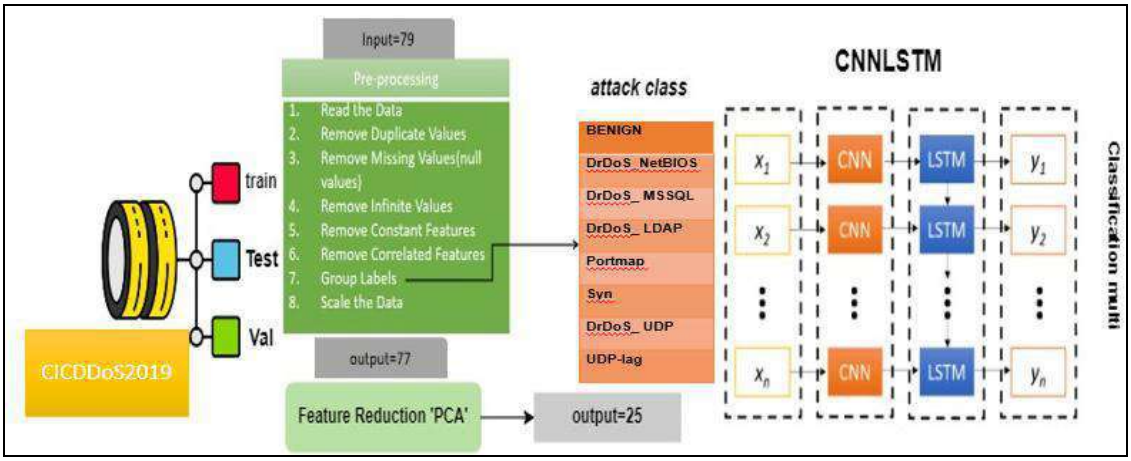

Figure 4: Architectures of the proposed model.
Source: Authors, (2026).

Table 2: Description and parameters of CNN-LSTM model.

Layer Type	Description	Parameters
Input Layer	Input features selected via PCA	PCA output
Convolutional Layer 1	First CNN layer convolution	32 filters, 3x3 kernel size, ReLU activation
Max Pooling Layer	Downsampling layer	2x2 pool size
Convolutional Layer 2	Second CNN layer for deeper feature extraction	64 filters, 3x3 kernel size, ReLU activation
Flatten Layer	Converts 2D feature maps to 1D	Flattened output from CNN layers
LSTM Layer	Sequential pattern learning	100 units
Fully Connected Layer	Dense layer	128 units, ReLU activation
Output Layer	Final output for DDoS detection	Softmax activation

IV. EXPERIMENT AND RESULT

This section presents the experimental setting, including data preparation and assessment methods to measure the framework's performance.The experiment were conducted on CPU Intel(i7) with 2 cores and 16 GB RAM to implement the proposed approach and construct our model. We utilized Google Colaboratory. In this study, it was necessary to carefully select the model to achieve better results. Therefore, we have used different deep learning technique and other machine learning algorithms were tested, Convolutional neural network (CNN), Deep neural network (DNN), Random Forest (RF), Support vector machine (SVM), k-Nearest Neighbors (kNN) and Long Short-Term Memory (LSTM). The results obtained is shown in the Table 3.

Table 3: Performance Comparison of CNN-LSTM vs Traditional Models

Model	Acc	Prec	Recall	F1-Score	AUC
CNN	96.2	95.9	96.0	95.9	95,9
DNN	95.5	94.44	95.74	95.4	95,4
LSTM	93,55	94,13	93,67	93.23	94.0
RF	95.1	94.7	95.0	94.8	95,9
SVM	93.8	93.0	93.5	93.2	0.94
k-NN	90.4	89.8	90.1	89.9	0.91
CNN-LSTM	99.98	98.9	99.20	98.9	0.99

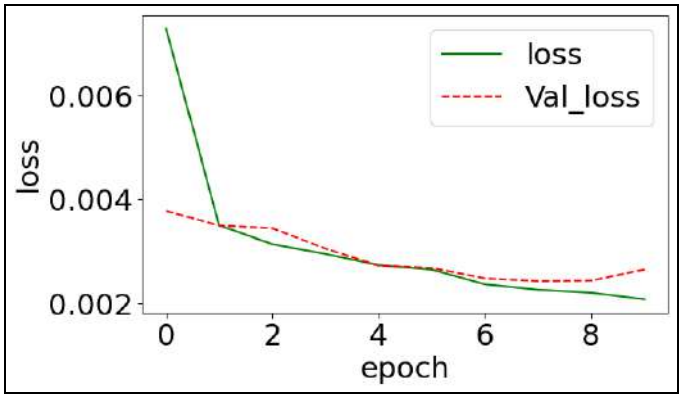

Figure 6: CNN-LSTM Loss result.
Source: Authors, (2026).

The use of oversampling via SMOTE has improved the accuracy of deep learning in a multiclass context, demonstrating the beneficial effect of this method in reducing class imbalance. With SMOTE, the accuracy of the DNN model increased from 0.85 to 0.95, that of the CNN from 0,90 to 0.96, the LSTM model from 0.85 to 0.95 and the proposed CNN-LSTM from 0.93 to 0.99 , suggesting that class imbalance can have a significant impact on model performance. By producing synthetic samples for the minority classes, SMOTE helped to make the dataset more balanced, which enhanced the generalization ability of the models.

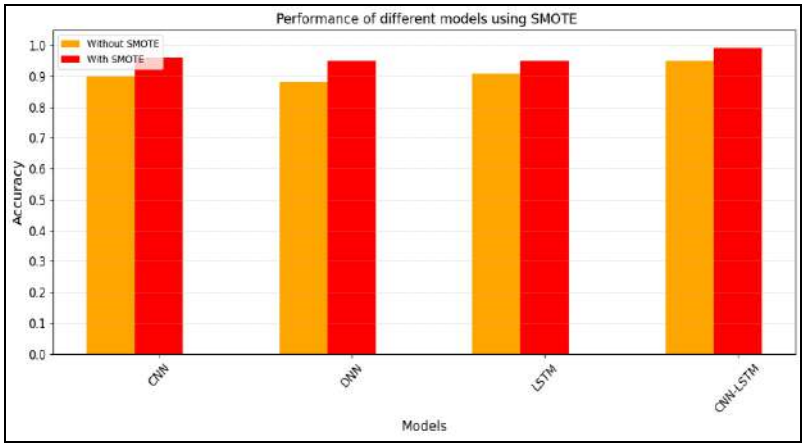

Figure 7. Performance of different models using SMOTE.
Source: Authors, (2026).

The CICIDS2019 dataset is a comprehensive dataset that includes various types of DDoS attacks, making it an ideal benchmark for evaluating the performance of detection models. The hybrid CNN-LSTM model has been tested on this dataset, showing superior performance in classifying different attack types. The integration of CNN and LSTM networks has been shown to outperform traditional detection methods, achieving high accuracy and robustness across different attack scenarios. Principal Component Analysis (PCA) is employed to reduce the dimensionality of the dataset, which helps in focusing on the most informative features. This reduction not only speeds up the training process but also helps in mitigating issues related to overfitting by eliminating noise and redundant data.

The research involved experiments using the CIC DDoS 2019 dataset, which included 8 attack and benign classes, and highlighted the importance of addressing class imbalance and dataset reduction in improving model performance.

Table 4: Classification Report per class of CICDDOS2019

Class	Precision	Rappel	F1-score	Support
BENIGN	1.00	1.00	1.00	40184
LDAP	1.00	1.00	1.00	39994
MSSQL	0.98	0.99	0.98	39944
NetBIOS	0.97	0.96	0.96	39529
Portmap	0.93	0.95	0.94	39997
Syn	1.00	1.00	1.00	39800
UDP	0.99	0.97	0.98	40142

The hybrid CNN-LSTM model demonstrated high accuracy in classifying DDoS attacks, showcasing robust performance across various attack scenarios on the CICDDoS2019 dataset, which included multiple versions of DDoS attacks.

V. DISCUSSION

The CICIDS2019 dataset is a comprehensive dataset that includes various types of DDoS attacks, making it an ideal benchmark for evaluating the performance of deep learning models. The dataset's diversity allows for testing the model's generalization capabilities across different attack types. In this study CNNs are utilized to extract spatial features from network traffic data, identifying patterns within individual packets. LSTMs complement this by capturing temporal dependencies, such as the timing and frequency of traffic bursts, which are crucial for identifying DDoS attacks. The proposed CNN-LSTM models have demonstrated high accuracy in detecting DDoS attacks, with some models achieving up to 99.99% accuracy. This is achieved by training on labeled datasets where the model learns to distinguish between normal and malicious traffic.

By reducing the number of features, PCA helps in lowering the computational cost, making the model more efficient and faster without compromising on accuracy. Models utilizing CNNs, LSTMs, and PCA have demonstrated high accuracy and efficiency in classifying DDoS attacks within this dataset, highlighting the effectiveness of these techniques in real-world scenarios. While the integration of CNN, LSTM, and PCA has shown promising results in DDoS attack classification, it is important to consider the challenges and limitations associated with these methods. For instance, the complexity of the model architecture can lead to increased computational requirements, which may not be feasible for all network environments. Additionally, the effectiveness of these models can be influenced by the quality and diversity of the training data, underscoring the need for continuous updates and improvements to the dataset and model architecture.

VI. CONCLUSION

The research presents a deep learning-based detection model that significantly improves the accuracy and generalization of DDoS attack detection, which is crucial for enhancing network security against complex threats. This model's ability to effectively analyze both spatial and temporal features of network traffic data can lead to more reliable and timely responses to DDoS attacks. In this paper, we presented a hybrid CNN-LSTM approach with feature selection based on PCA for detecting DDoS attacks using the CICDDoS2019 dataset. Our experiments demonstrated that this method outperforms traditional machine learning techniques, achieving high accuracy and generalization capability. Our CNN-LSTM model demonstrating superior detection accuracy for DDoS attacks by combining CNN for spatial feature extraction and LSTM for temporal sequence learning, the hybrid model captures both local and long-range dependencies in network traffic data.

Furthermore, feature selection using PCA enhanced the model's efficiency by reducing the dimensionality of the data while maintaining its key characteristics. The integration of these techniques has shown to significantly improve the accuracy and robustness of DDoS attack detection systems. The proposed framework CNN-LSTM model emerged as the most effective for multiclass DDoS attack detection, demonstrating remarkable accuracy, minimal loss, and exceptional precision and recall in identifying DDoS attacks. Future work will focus on novel advanced deep learning model and extending to detect other types of network intrusions on different benchmark, we will also explore the application of other dimensionality reduction techniques and the use of real-time detection frameworks to enhance the model's deployment in production environments.

ABSTRACT

In order to achieve effective unit power factor control, harmonic distortion rate reduction, and direct current (DC) voltage regulation, a three-phase pulse width modulation (PWM) rectifier is subjected to a novel scientific study that compares two efficient control techniques: direct power control (DPC) and dq reference frame's current control. The simulations were conducted using the Matlab/Simulink software. In the DQ reference frame, DPC appears to be more effective than current control, as evidenced by the results. For both control methods, the DC voltage adheres to its new reference, and the DPC technique has a lower rate of harmonic distortion. However, it should be noted that there are discrepancies in the transient domain's mistakes' exponential convergence and during setpoint changes, as well as in the reaction times, overshoots, and oscillations of the controlled quantities. The application of DPC, widely regarded as the most effective and best-performing control, has been demonstrated to yield optimal results.

I. INTRODUCTION

Three-phase PWM rectifiers are essential components in a wide range of industries and emerging fields, including smart microgrids, renewable energy generation and active power filtering. They are commonly used in quadrature for AC/DC power conversion and generator speed control, particularly in wind power systems. In addition, these rectifiers play a crucial role as an interface between electric vehicles (EVs) and the electricity grid, enabling EVs to store energy from the grid and return it using vehicle-to-grid (V2G) technology [1],[2]. Today, the use of the PWM rectifier, not only to produce a stable and variable DC voltage in relation to the load demand from an AC network and to ensure bidirectional power flow, but also to reduce the rate of harmonic distortion and to ensure an input current close to sinusoidal shape, with a power factor equal to unity, has led to extensive research in the field to improve the efficiency of these converters through the development of suitable control techniques, which will be considered [3],[4]. The dq reference frame's current control has some disadvantages.

The hysteresis corrector generates a changeable switching frequency, while the PI corrector is not ideal for AC signal control applications. However, this approach calls for two or three current sensors and three or two voltage sensors in addition to the DC bus voltage sensor. To avoid the first problem, a solution has been proposed for three-phase systems using PI correctors in a rotating frame of reference (with the Park transformation) [5],[6]. Direct Power Control, or DPC, is the name of this power-related control. In order to replace traditional control based on current loop regulation, it was first proposed in 1991 and developed in 1998 for use in rectifier control. Instantaneous active and reactive power are the controlled variables in this novel control method [7-9]. In order to accomplish instantaneous control of the DC voltage, control of the unit power factor, and reduction of the harmonic distortion rate, we develop two control techniques in this article: direct power control (DPC) and current control of the DQ reference frame applied to a three-phase PWM rectifier.

In the first part we presented the modelling of our rectifier. The second part presents the control techniques that will allow us to control and optimise the energy flow converted by our PWM rectifier. To this end, we will develop the following controls: I: current control of the PWM rectifier in the DQ reference frame based on three PI regulators to converge these errors towards zero; II: the second control algorithm is a direct power control based on a switching table. Finally, the work is concluded with a general conclusion, as well as suggestions and some perspectives for future research work in this field.

II. MODELLING OF THE OUR THREE-PHASE RECTIFIER

The converter structure consists of two switches per arm. The switches are bi-directional and fully controllable for opening and closing. They can be MOSFETs for low power and very high frequency, IGBTs for high power and high frequency or GTOs for very high power and low frequency. To ensure that current flows in both directions, the switch must be placed in anti-parallel with a diode [10].

II.1 THE POWER SOURCE

This is a three-phase voltage, assumed to be perfectly sinusoidal, and connected in series with a resistance R and an inductance L representing the total resistance and inductance of the line respectively. The line voltages are given by [10],[11]:

$$\begin{cases} V_1 = R.i_1 + L\frac{di_1}{dt} + V_{an} \\ V_2 = R.i_2 + L\frac{di_2}{dt} + V_{bn} \\ V_3 = R.i_3 + L\frac{di_3}{dt} + V_{cn} \end{cases} \quad (1)$$

Where:

V_{an} , $V_{bn}$and V_{cn} are the simple voltages with respect to the neutral of the source at the input of the converter. And the currents of each phase are then given by the following system of differential equations:

$$\frac{d}{dt}\begin{bmatrix} i_1 \\ i_2 \\ i_3 \end{bmatrix} = \begin{bmatrix} -\frac{R}{L} & 0 & 0 \\ 0 & -\frac{R}{L} & 0 \\ 0 & 0 & -\frac{R}{L} \end{bmatrix}\begin{bmatrix} i_1 \\ i_2 \\ i_3 \end{bmatrix} + \frac{1}{L}\begin{bmatrix} V_1 - V_{an} \\ V_2 - V_{bn} \\ V_3 - V_{cn} \end{bmatrix} \quad (2)$$

II.2 THE CONVERTER STAGE

The rectifier structure is identical to that of the inverter and the bridge connection matrix is similar to the following equation:

$$\begin{bmatrix} V_A \\ V_B \\ V_C \end{bmatrix} = \frac{Uc}{3}.\begin{bmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{bmatrix}\begin{bmatrix} S_1 \\ S_2 \\ S_3 \end{bmatrix} \quad (3)$$

II.3 THE LOAD

This part consists of a capacitor C in parallel with a resistor R, which is a DC load. It is governed by the following two electrical equations:

$$\begin{cases} \frac{dU_C}{dt} = \frac{1}{C}(i_s - i_{ch}) \\ U_C = R_{Ch}.i_{ch} \end{cases} \quad (4)$$

$$\frac{U_C}{i_s} = \frac{R_{Ch}}{1 + R_{Ch}.C.p} \quad (5)$$

III. THE DQ REFERENCE FRAME'S CURRENT CONTROL

This control consists of a fast internal current loop that controls the current through the mains filter and a slower external loop that controls the DC bus voltage [12],[13].

III.1. EXTERNAL VOLTAGE REGULATION LOOP

The purpose of the external control loop is to maintain the voltage across the capacitor at a reference voltage. A regulator is used to generate the reference current in the capacitor. According to the following equation, we can write a 1st order system as follows:

$$\frac{V_{dc}}{i_{Con}} = \frac{1}{C.s} \quad (6)$$

Regulating the DC bus voltage using PI type regulators gives us the reference current i_{Con_ref} in the capacitor. The power for the capacitor is given by:

$$P_{Con\_ref} = i_{Con\_ref} V_{dc} \tag{7}$$

III.2 INTERNAL CURRENT REGULATION LOOP

The purpose of the internal control loop is to maintain a power factor close to the unit at the point of connection to the mains. Two line voltage regulators are used to decouple the control of reactive and active power. The equations governing the line voltages in the (d,q) reference frame are:

$$\begin{cases} V_{pd} = V_d - R.i_d - L\frac{di_d}{dt} + L\omega i_q \\ V_{pq} = V_q - R.i_q - L\frac{di_q}{dt} - L\omega i_d \end{cases} \tag{8}$$

III.3 SIMULATION RESULTS

The results of the simulation for the different tests are shown below:

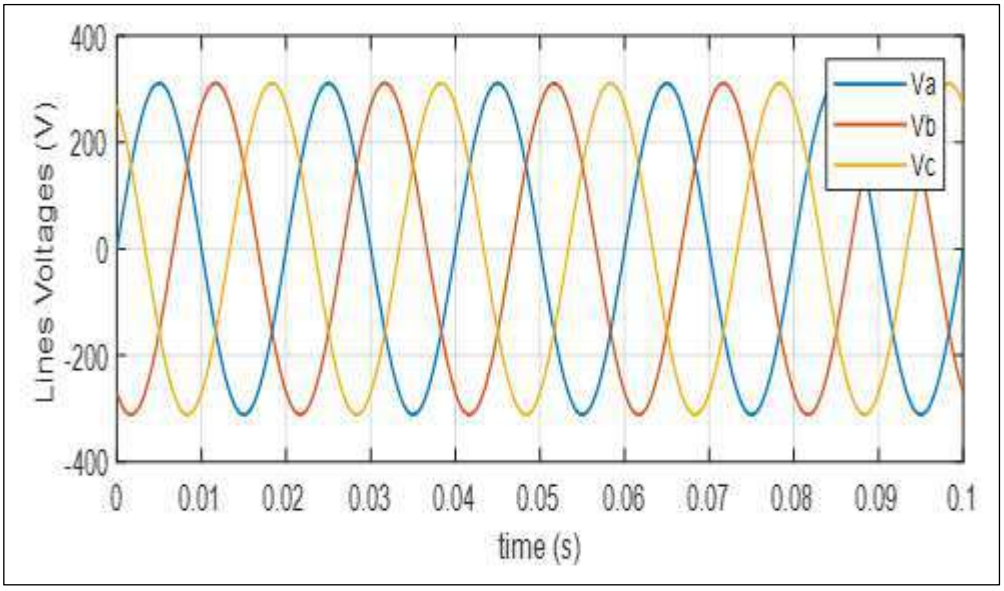

Figure 1: Lines Voltages.

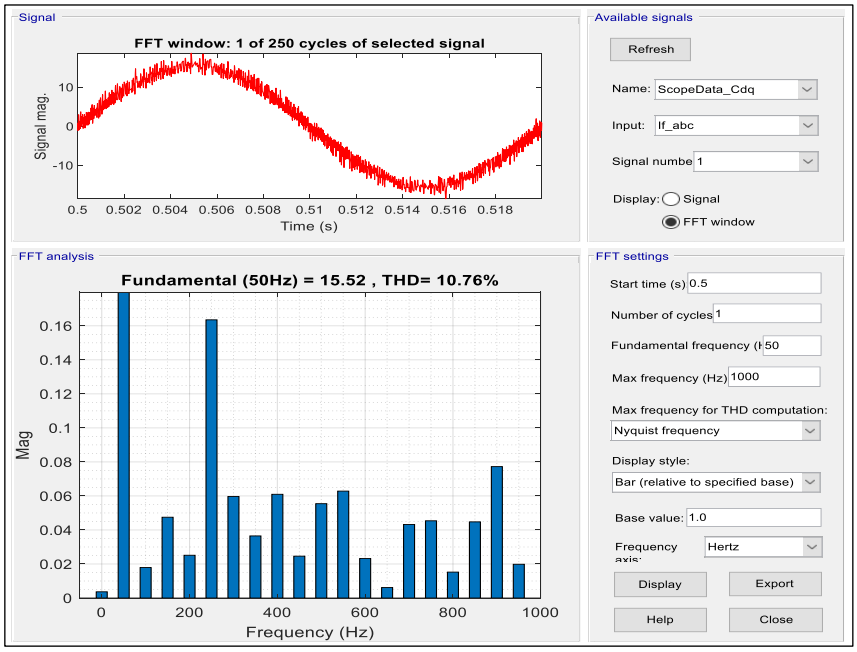

Figure 5: Harmonic spectrum of the line current.
Source: Authors, (2026).

IV THE DIRECT POWER CONTROL

Using a switching table, the DPC principle chooses a series of switching orders (Sa, Sb, and Sc) for the semiconductors that make up the PWM rectifier. The digitalised errors, Sp and Sq, between the active and reactive power references (P* and q*) are used to make the selection. A PI regulator is used to control the DC voltage in order to reach the active power setpoint. In order to guarantee a consistent power factor, the reactive power is brought to zero, and two two-stage hysteresis comparators supply the actual values (P and q) along with the angular position of the mains voltage vector (eαβ). The α-β plane is split into twelve (12) equal sections of 30° for the latter [14, 15].

IV.1 SECTOR DETERMINATION

The expected voltage in the sector must be known in order to determine the best switching conditions. The following relationship can be used to calculate the 12 sectors that make up the working plane (α, β):

$$(n-2)\ \frac{\pi}{6} < \gamma n < (n-1)\ \frac{\pi}{6} n = 1{,}2\ \ldots .12 \tag{9}$$

Where:
n is the sector number.
The position of the voltage vector, which can be found instantly using the following formula, determines the sector number:

$$\hat{\theta} = Arctg\left(\frac{\hat{v}s\beta}{\hat{v}s\alpha}\right) \tag{10}$$

Sectors choose adjacent vectors to maximise converter switching. The plan is separated into 12 sectors for increased accuracy and to prevent issues at the limits of each control vector.

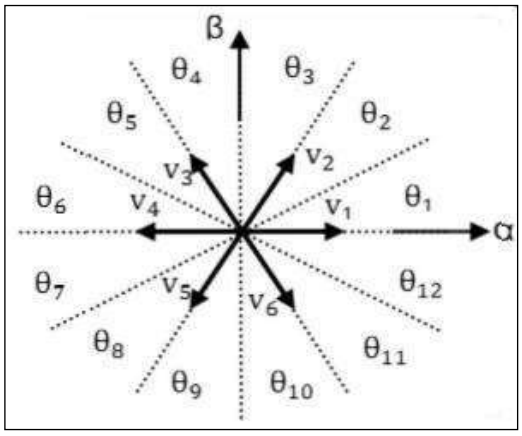

Figure 6: Determination of the 12 sectors.
Source: Authors, (2026).

IV.2 SWITCHING TABLE

The operational sector and the digital error signals Sp and Sq are fed into the switching table, which records the PWM rectifier's switching states. At each switching step, the combination of the digital signals Sp, Sq, and the sector number determines the converter's ideal switching state. This reduces the reactive power error in a 2Hq and the active power error in a 2Hp wide hysteresis region.

IV.3 SIMULATION RESULTS

The results of the simulation for the different tests are shown below:

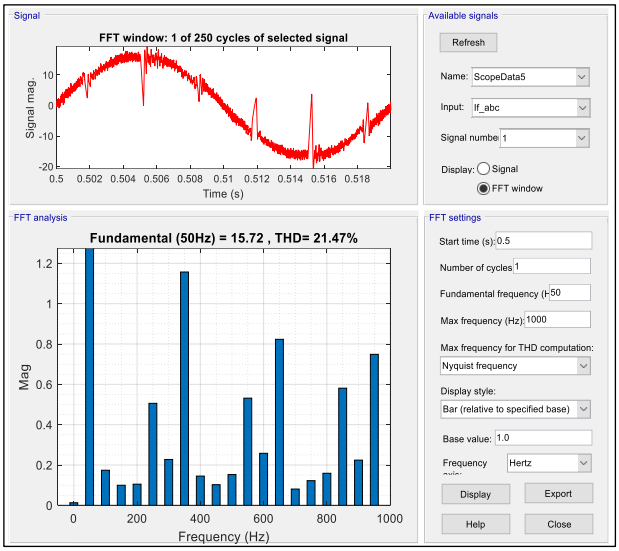

Figure 11: Harmonic spectrum of the line current (DPC).
Source: Authors, (2026).

V. CONCLUSION

In the present article, the authors develop and propose two novel control techniques with the objective of regulating the energy exchange between the rectifier and the electrical network. The employment of these techniques facilitates the operation at unity power factor, while imposing zero reactive power, converting the voltage to DC, and thereby reducing harmonic problems. In the subsequent phase of the research project, a simulation was conducted using the MATLAB software (SIMULINK) to test the three-phase PWM rectifier with these controls. In addition to its simplicity, direct power control (D.P.C.) has been demonstrated to provide enhanced control of instantaneous active and reactive power. However, it is evident that the current and voltage distortion rates are marginally higher than those obtained with current control in the DQ reference frame.

ABSTRACT

This study investigates the design optimization of TiO_2-reinforced dissimilar AA5083–AA6063 friction stir welded joints using the Taguchi method. Tool rotational speed, welding travel speed, and TiO_2 insertion depth were evaluated through an L9 orthogonal array, with tensile strength and hardness as response variables. The results show that tensile strength is mainly controlled by rotational speed, achieving a maximum value of 218.40 MPa at 900 rpm, 40 mm/min, and 3 mm TiO_2 depth, whereas hardness is primarily influenced by TiO_2 insertion depth, reaching 110.23 HV. Taguchi prediction and confirmation tests revealed errors below 2%, confirming result reliability. Microstructural and fracture analyses indicated effective material mixing and predominantly ductile fracture behavior. These findings demonstrate that distinct parameters govern tensile and hardness responses, providing useful guidance for parameter selection in EV and aerospace applications.

I. INTRODUCTION

The growing demand for lightweight and energy-efficient structures has accelerated the use of aluminum alloys in modern transportation systems, particularly in electric vehicles (EVs) and aerospace applications. Components such as battery enclosures, structural frames, and aircraft panels require materials offering high specific strength, corrosion resistance, and reliable joining performance. Aluminum alloys remain a preferred choice due to their favorable mechanical properties and recyclability [1]. Among commercial aluminum alloys, AA5083 and AA6063 are widely used for different functional requirements. AA5083 provides high strength and corrosion resistance for load-bearing structures, whereas AA6063 is commonly employed in extruded components due to its good formability and surface quality. Combining these dissimilar alloys enables design flexibility and weight reduction in EV and aerospace structures; however, conventional fusion welding often leads to defects such as porosity, excessive heat input, and degradation of mechanical properties caused by metallurgical incompatibility [1],[2].

Friction stir welding (FSW) has emerged as an effective solid-state joining process that overcomes many limitations of fusion welding by avoiding melting and promoting severe plastic deformation and dynamic recrystallization [1]. Nevertheless, joint quality in FSW is highly sensitive to process parameters, including tool rotational speed, welding travel speed, and heat input conditions. Improper parameter selection in dissimilar aluminum alloy joints may result in insufficient material mixing, internal defects, and non-uniform mechanical properties, which are unacceptable for safety-critical EV and aerospace components [2].

To further enhance joint performance, the incorporation of ceramic nanoparticles during FSW has gained increasing attention. Titanium dioxide (TiO_2) nanoparticles have been shown to improve microstructural refinement and mechanical performance when effectively distributed within the stir zone [3-5]. However, the effectiveness of nanoparticle reinforcement strongly depends on welding parameters and particle insertion strategy.

From an industrial viewpoint, achieving consistent and repeatable joint performance requires a clear understanding of parameter effects rather than reliance on trial-and-error optimization. The Taguchi method provides a systematic and efficient experimental design framework for evaluating multiple process parameters with a reduced number of experiments and has been successfully applied to FSW parameter analysis and performance evaluation [6],[7]. Therefore, the present study investigates the influence of tool rotational speed, welding travel speed, and TiO_2 nanoparticle insertion depth on the mechanical and microstructural characteristics of dissimilar AA5083–AA6063 friction stir welded joints, aiming to support design optimization and performance analysis for lightweight EV and aerospace applications [8],[9].

II. MATERIALS AND METHODS

II.1 MATERIALS

Dissimilar aluminum alloys AA5083 and AA6063 were selected as base materials due to their extensive use in lightweight structural components for electric vehicle and aerospace applications. AA5083 provides high strength and excellent corrosion resistance, making it suitable for load-bearing structures, whereas AA6063 is widely used in extruded components because of its good formability and surface quality. Prior to welding, both aluminum plates were machined to identical dimensions to ensure stable clamping and consistent heat generation during friction stir welding.

Titanium dioxide (TiO_2) nanoparticles with a purity of 99%, as shown in Figure 1, were employed as the reinforcing material. Owing to their thermal stability and chemical inertness, TiO_2 nanoparticles are compatible with aluminum matrices. A longitudinal groove was precisely machined along the butt joint interface using a CNC milling machine, and the groove depth was varied according to the experimental design to examine its influence on joint performance. The TiO_2 powder was carefully packed into the groove before welding to minimize particle loss during tool plunging and material flow.

II.2 EXPERIMENTAL AND METHODS

Friction stir welding (FSW) experiments were carried out using a vertical CNC milling machine under position-controlled conditions, as illustrated in Figure 2. A non-consumable tool fabricated from SKD11 tool steel was employed, consisting of a flat shoulder and a cylindrical pin to promote effective plastic deformation and material mixing. Prior to welding, AA5083 and AA6063 aluminum alloy plates were prepared by milling to identical dimensions of 75 × 150 × 6 mm. During the welding process, AA5083 was positioned on the advancing side (AS), while AA6063 was placed on the retreating side (RS), in order to enhance material flow stability in the dissimilar joint.

Titanium dioxide (TiO_2) nanoparticles were introduced into the weld region through a longitudinal groove machined along the butt joint interface prior to welding. The groove had a cross-sectional dimension of 1 × 1 × 1 mm, and the insertion depths of the nanoparticles were set to 2, 3, and 4 mm, as shown in Figure 2(b). The groove depth was varied according to the experimental design, while the groove length was kept constant to ensure uniform distribution of the reinforcing material along the weld line. After filling the groove with TiO_2 powder, the welding tool was plunged and traversed along the joint line following the prescribed tool rotation and welding directions.

II.3 SPECIMEN PREPARATION AND MECHANICAL TESTING

After welding, the joints were sectioned for mechanical testing and microstructural examination, as illustrated in Figure 3. Tensile specimens were extracted transverse to the welding direction, and multiple samples were prepared from each welded plate to ensure repeatability, as commonly adopted in friction stir welding studies of dissimilar aluminum alloys [2]. Tensile tests were conducted at room temperature using a universal testing machine in accordance with ASTM E8/E8M, and the average tensile strength was reported for each welding condition [7],[10].

Microhardness measurements were performed across the weld cross-section using a Vickers hardness tester following ASTM E384. Indentations were placed at regular intervals covering the base material (BM), heat-affected zone (HAZ), thermo-mechanically affected zone (TMAZ), and stir zone (SZ), as schematically shown in Figure 3. This procedure enabled evaluation of hardness variation across different weld regions and assessment of local mechanical behavior, which has been widely reported as an effective approach for characterizing FSW joints [4],[11].

Microstructural characterization was carried out using scanning electron microscopy (SEM) to examine material flow features, grain refinement, and the distribution of TiO_2 nanoparticles within the stir zone [5]. Selected regions near the weld center were analyzed to correlate microstructural characteristics with mechanical performance. Energy-dispersive X-ray spectroscopy (EDS) was employed to confirm the presence and dispersion of TiO_2 particles within the aluminum matrix, consistent with previous investigations on nanoparticle-reinforced FSW joints [12].

II.4 EXPERIMENTAL DESIGN USING TAGUCHI METHOD

The Taguchi method was employed to design the experiments and to evaluate the influence of selected friction stir welding parameters on the performance of TiO_2-reinforced dissimilar AA5083–AA6063 joints. This method enables systematic assessment of multiple process variables while reducing the number of required experiments [8].

Three control factors were considered in this study: tool rotational speed (S), welding travel speed (F), and TiO_2 groove depth (D). Each factor was examined at three levels, as summarized in Table 1, based on feasible welding conditions and preliminary observations. An L9 orthogonal array was used to arrange the experimental runs efficiently and to analyze the main effects of the selected parameters.

Joint performance was evaluated in terms of tensile strength and hardness. The signal-to-noise (S/N) ratio was calculated using the larger-is-better criterion, as defined in Eq. (1), in order to identify parameter levels that provide improved performance with reduced variability [9]. The Taguchi approach has been widely applied in friction stir welding studies for analyzing parameter effects on mechanical behavior [7].

Table 1: Selected FSW Parameters and corresponding levels.

Parameter	Low	Medium	High
Tool rotation Speed ; S (rpm)	700	900	1100
Welding travel speed ; F (mm/min)	40	60	80
TiO_2 groove Depth ; D (mm)	2	3	4

$$S/N_{Ratio} = -10\log\left(\frac{1}{n}\sum_{i=1}^{n}\frac{1}{y_i^2}\right) \quad (1)$$

where *yi* represents the measured response value of the ith experiment, and nnn is the total number of experimental runs.

IV. RESULTS AND DISCUSSIONS

IV.1 TAGUCHI EXPERIMENTAL RESULTS

Table 2 summarizes the experimental results obtained from the L9 orthogonal array, including tensile strength, hardness, and the corresponding signal-to-noise (S/N) ratios calculated using the larger-is-better criterion. The tensile strength of the TiO_2-reinforced dissimilar AA5083–AA6063 joints ranges from 197.34 to 218.40 MPa, while hardness values vary between 98.56 and 110.23 HV. These results clearly indicate that variations in friction stir welding parameters significantly influence the mechanical performance of the joints. The maximum tensile strength was achieved at a rotational speed of 900 rpm, welding travel speed of 40 mm/min, and TiO_2 groove depth of 3 mm, whereas the highest hardness was observed at a higher rotational speed of 1100 rpm combined with a travel speed of 80 mm/min and the same groove depth.

To clarify the influence of individual parameters, the mean S/N ratios at different factor levels are presented in Table 3 and graphically illustrated in Figure 4. For tensile strength, the rotational speed exhibits the highest delta value, followed by the TiO_2 groove depth, while the welding travel speed shows the lowest contribution. This trend suggests that heat input associated with tool rotation plays a dominant role in enhancing joint strength by promoting effective material mixing and metallurgical bonding. Similar observations have been reported in previous Taguchi-based FSW studies, where rotational speed was identified as a key parameter governing tensile behavior in dissimilar aluminum alloy joints [8],[13].

In contrast, hardness is primarily influenced by the TiO_2 groove depth, which shows the highest delta value, followed closely by the rotational speed, as shown in Table 3 and Figure 4(b). The limited effect of welding travel speed indicates that hardness is more sensitive to reinforcement content and particle distribution within the stir zone than to variations in traverse motion. This behavior is consistent with earlier findings that emphasize the role of ceramic nanoparticles in enhancing local hardness through particle strengthening and grain refinement mechanisms [3],[5].

Overall, the combined analysis of Tables 2 and 3 together with the main effects plots in Figure 4 demonstrates that tensile strength and hardness are governed by different dominant parameters. While rotational speed is critical for maximizing joint strength, TiO_2 groove depth plays a more significant role in controlling hardness. These results highlight the necessity of balanced parameter selection when designing friction stir welding conditions for TiO_2-reinforced dissimilar aluminum alloy joints, particularly for applications requiring simultaneous strength and surface hardness performance.

Table 2: L9 orthogonal array design and results with mechanical responses and S/N ratios.

Run	Parameter/Factor			Responses		S/N Ratio

IV.2 ANALYSIS OF VARIANCE (ANOVA) OF S/N RATIOS

The analysis of variance (ANOVA) was conducted to quantify the statistical significance and relative contribution of friction stir welding parameters on the tensile strength and hardness of TiO_2-reinforced dissimilar AA5083–AA6063 joints. The ANOVA results for the S/N ratios of tensile strength and hardness are presented in Tables 4 and 5, respectively [14]. As shown in Table 4, tool rotational speed (S) is the most influential parameter affecting tensile strength, contributing 46.04% of the total variation. This is followed by the TiO_2 groove depth (D) with a contribution of 38.43%, while welding travel speed (F) exhibits a comparatively minor effect at 10.06%. The dominance of rotational speed highlights the critical role of heat input and plastic material flow in determining joint tensile performance [1]. Although the P-values of individual factors are slightly above the conventional 0.05 threshold, this behavior is commonly observed in Taguchi-based designs with limited degrees of freedom and does not diminish the practical significance of the contribution trends [7].

For hardness, the ANOVA results in Table 5 reveal a different governing mechanism. The TiO_2 groove depth (D) is identified as the most dominant factor, contributing 50.04% to the overall variation, closely followed by the rotational speed (S) with 47.44% contribution. In contrast, the welding travel speed (F) has a negligible influence, accounting for less than 1% of the total variation. The statistically significant P-values for both S and D ($P < 0.05$) confirm their strong influence on hardness development. This behavior suggests that hardness enhancement is primarily controlled by the amount of TiO_2 reinforcement introduced into the stir zone and the associated thermo-mechanical conditions that govern particle dispersion and grain refinement [3]. The high coefficients of determination (R^2 = 97.53% for tensile strength and 98.47% for hardness) indicate that the selected process parameters adequately explain the observed variations in joint performance. Overall, the ANOVA results demonstrate that tensile strength and hardness are governed by different dominant parameters, emphasizing the need for balanced parameter selection when optimizing friction stir welding conditions for multifunctional performance.

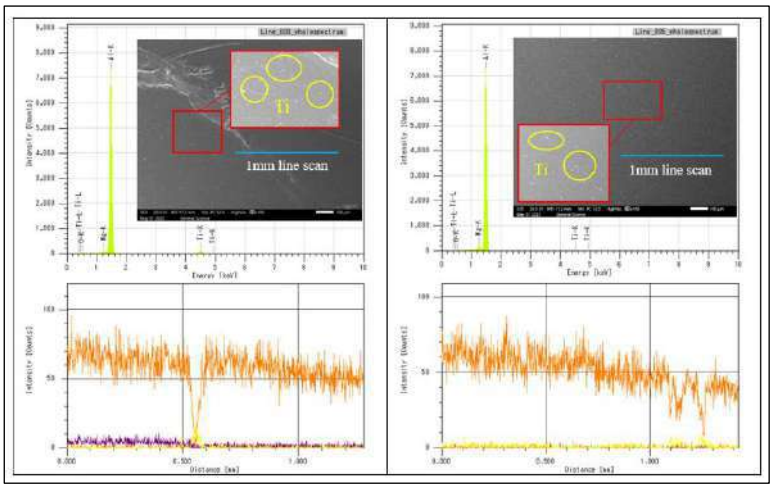
IV.3 TAGUCHI PREDICTION AND CONFIRMATION TEST

Based on the Taguchi analysis, the optimal combinations of friction stir welding (FSW) parameters were identified from the main effects of the signal-to-noise (S/N) ratios for tensile strength and hardness. To verify the reliability of these optimal parameter settings, Taguchi prediction was first conducted, followed by confirmation experiments. For the larger-is-better quality characteristic, the predicted S/N ratio at the optimal condition was calculated using the Taguchi additive model, expressed as Eq. (2):



2. The predicted S/N ratio was calculated using the Taguchi additive model. [2],[9].

$$\hat{\eta}_{pred} = \eta_m + \sum_{i=1}^{k} (\eta_{i,opt} - \eta_m) \tag{2}$$

where $\hat{\eta}$ is the predicted S/N ratio, η_m is the overall mean S/N ratio obtained from all experimental runs, $\eta_{i,opt}$ is the mean S/N ratio at the optimal level of the ith control factor, and k is the number of control factors considered in this study (k=3 : rotational speed, welding travel speed, and TiO2_22 groove depth) [14]. Based on the Taguchi prediction, the optimal parameter combination for maximizing tensile strength was determined as S900–F80–D3, yielding a predicted S/N ratio of 46.8967 and a corresponding predicted tensile strength of 221.22 MPa. In contrast, the optimal condition for maximizing hardness was identified as S1100–F40–D3, with a predicted S/N ratio of 40.9556 and a predicted hardness of 111.63 HV. These results indicate that tensile strength and hardness are governed by different dominant process parameters, consistent with observations reported in previous Taguchi-based FSW studies [9],[15].

Confirmation experiments were subsequently conducted using the identified optimal parameter combinations [12],[7]. The experimental results were compared with the predicted values, as summarized in Table 6. The confirmation test produced an experimental tensile strength of 217.80 MPa and an experimental hardness of 109.95 HV, corresponding to prediction errors of 1.55% and 1.50%, respectively. The small deviations between predicted and experimental results demonstrate the reliability and robustness of the Taguchi prediction approach for optimizing the mechanical performance of TiO_2-reinforced dissimilar AA5083–AA6063 FSW joints [16].

To further validate the prediction results, microstructural and compositional analyses were carried out at the optimal conditions. Figure 5 presents the experimental results corresponding to the predicted tensile strength and hardness conditions, including SEM–EDS line scan analyses, which confirm the presence and relatively uniform distribution of Ti-containing phases within the stir zone. This distribution contributes to enhanced load transfer and localized strengthening, supporting the observed mechanical performance [17],[18].

Table 6: Taguchi prediction confirmation test results.

Response	Predicted	Experimental	Error (%)
Tensile strength (MPa)	221.22	217.80	1.55
Hardness (HV)	111.63	109.95	1.50

Source: Authors, (2026).

In addition, the fracture surface morphologies shown in Figure 6 reveal distinct failure characteristics. The tensile fracture surface (Figure 6a) exhibits fine and uniformly distributed dimples, indicating a predominantly ductile fracture associated with effective plastic deformation and sound material mixing in the stir zone [11],[6]. In contrast, the fracture surface corresponding to hardness optimization (Figure 6b) shows a mixed-mode fracture behavior, combining dimpled features with localized cleavage, which can be attributed to increased local hardness and enhanced particle–matrix interactions induced by TiO_2 reinforcement and higher rotational speed conditions [19],[20].

Overall, the close agreement between the predicted and experimental results, supported by consistent microstructural and fractographic observations, confirms the effectiveness of the Taguchi prediction and confirmation approach for optimizing FSW parameters. Similar validation outcomes have been reported in previous studies, demonstrating the suitability of the Taguchi method for process optimization in dissimilar aluminum alloy friction stir welding [21].

V. CONCLUSIONS

This study successfully demonstrated the effectiveness of the Taguchi method for optimizing friction stir welding parameters in TiO_2-reinforced dissimilar AA5083–AA6063 joints. The results revealed that tool rotational speed and TiO_2 groove depth are the dominant factors governing joint performance, while welding travel speed exhibits a comparatively minor influence. The optimal condition for maximizing tensile strength was identified at 900 rpm rotational speed, 40 mm/min travel speed, and a TiO_2 groove depth of 3 mm, achieving a tensile strength of 218.40 MPa.

In contrast, maximum hardness was obtained under higher rotational speed conditions combined with appropriate nanoparticle insertion depth, highlighting the strong role of TiO_2 reinforcement in enhancing local hardness through particle strengthening and grain refinement. Microstructural and fractographic analyses confirmed effective material mixing in the stir zone and predominantly ductile fracture behavior, with localized mixed-mode features associated with increased hardness. The close agreement between experimental results and Taguchi predictions validates the robustness of the proposed optimization approach and provides practical guidelines for designing high-performance FSW joints for lightweight structural applications in electric vehicle and aerospace industries.

ABSTRACT

Suicidal ideation expressed on social media offers an opportunity for earlier risk screening; however, practical systems must maximize recall, remain computationally tractable, and provide signals that clinicians can meaningfully interpret. We propose a hybrid pipeline that (i) represents tweets using pretrained 300-dimensional GloVe vectors, (ii) aggregates token embeddings with mean and max pooling, (iii) applies Recursive Feature Elimination (RFE) to select 228 informative semantic dimensions from a 600 dimensional pooled representation, and (iv) trains a compact 6-layer transformer encoder on the selected features for binary classification. Experiments on a combined dataset of 145,230 tweets (26.5% suicidal) demonstrate that the proposed model achieves 94.3% accuracy and an F1-score of 0.944 with 95.1% recall. The architecture is resource-efficient, using 23M parameters and delivering 3.7imes faster inference than BERT-base. Feature analysis indicates that the most predictive dimensions cluster around clinically relevant themes such as hopelessness, psychological pain, isolation, and perceived burden, offering a more transparent bridge between model behavior and suicide risk theory. These results suggest that feature selection paired with lightweight attention models can yield high-performing screening tools suitable for large-scale monitoring when deployed under rigorous ethical and clinical governance.

I. INTRODUCTION

Suicide represents one of the most pressing public health concerns worldwide, with the World Health Organization reporting approximately 700,000 deaths by suicide annually [1].The tragic loss of life, coupled with the profound impact on families and communities, underscores the urgent need for effective prevention strategies. In recent years, social media platforms have emerged as critical spaces where individuals express distress, mental health struggles, and suicidal ideation, often before seeking professional help or confiding in close contacts [2].

Twitter (now X), with its real-time, public nature, provides a unique window into the mental states of users worldwide. Unlike traditional clinical settings where individuals may be reluctant to disclose suicidal thoughts due to stigma or fear of intervention, social media platforms often serve as spaces for candid expression [3]. This phenomenon has motivated researchers to develop computational methods for detecting suicide risk signals in social media text, with the ultimate goal of enabling timely intervention and support. Recent surveys synthesize the main computational approaches and highlight open challenges [4].

The application of Natural Language Processing (NLP) and machine learning to mental health has gained significant momentum over the past decade [5]. Early approaches relied on lexicon-based methods and traditional machine learning classifiers trained on handcrafted features [6]. However, these methods often struggled with the nuanced, context-dependent nature of language related to mental health and suicide. The advent of deep learning, particularly word embeddings and large language models, has revolutionized text classification tasks, offering more sophisticated representations of semantic meaning [7].

Despite these advances, several challenges persist in the field of suicidal ideation detection. First, the imbalanced nature of datasets, where suicidal content represents a small minority of overall social media discourse, poses significant difficulties for model training [8]. Second, the ethical considerations surrounding privacy, consent, and the potential for false positives or negatives demand careful methodological design [9]. Third, the interpretability of complex deep learning models remains crucial in clinical contexts, where understanding the reasoning behind predictions can inform intervention strategies [10].

This study addresses these challenges by proposing a hybrid approach that combines the semantic richness of GloVe embeddings with the discriminative power of Recursive Feature Elimination (RFE) and a lightweight transformer architecture trained from scratch on selected features. Note: Our ”transformer” is not a pre-trained Large Language Model (LLM) like BERT or GPT. Instead, we train a compact 6-layer transformer encoder from random initialization on 228-dimensional numerical feature vectors (selected via RFE from GloVe embeddings), not on token sequences. Our methodology is designed to achieve three primary objectives:

1. To develop a robust classification system capable of accurately identifying tweets expressing suicidal ideation while minimizing false positives and false negatives.
2. To identify the most informative linguistic features associated with suicidal content through systematic feature selection, contributing to theoretical understanding of suicidal discourse.
3. To evaluate our approach on established benchmark datasets, enabling direct comparison with existing methods and facilitating reproducibility.

The contributions of this work are multifaceted:

Methodological Innovation: We introduce a novel pipeline that integrates GloVe embeddings for capturing semantic relationships, RFE for identifying the most predictive features, and a lightweight transformer classifier trained from scratch on these selected features. This combination leverages the strengths of each component while mitigating their individual limitations.

Empirical Validation: Through extensive experimentson benchmark datasets, we demonstrate that our approach achieves state-of-the-art performance in suicidal ideation detection, with significant improvements in precision and recall compared to baseline methods.

Feature Interpretability: By employing RFE, we identify specific linguistic patterns and semantic features most strongly associated with suicidal content, providing insights that can inform both computational models and clinical understanding.

Practical Application: Our framework is designed with deployment in mind, balancing accuracy with computational efficiency to enable real-time monitoring and intervention systems.

The remainder of this paper is organized as follows: Section II reviews related literature on suicide detection in social media, word embeddings, feature selection methods, and transformer applications in NLP. Section III details our methodology, including data preprocessing, feature extraction using GloVe, feature selection via RFE, and lightweight transformer-based classification trained from scratch. Section IV presents our experimental setup, datasets, evaluation metrics, and results. Section V discusses the implications of our findings, limitations, and ethical considerations. Finally, Section VI concludes the paper and outlines directions for future research.

II. LITERATURE REVIEW

II.1 SUICIDE DETECTION IN SOCIAL MEDIA

The application of computational methods to detect suicide risk in social media has evolved significantly over the past decade. Early work by Jashinsky et al. [11] demonstrated correlations between suicide-related tweets and actual suicide rates, validating social media as a viable data source for public health surveillance. Coppersmith et al. [12] expanded this line of inquiry by developing methods to quantify signals of mental health conditions, including suicidal ideation, from Twitter posts.

The CLPsych (Computational Linguistics and Clinical Psychology) workshop series has been instrumental in advancing the field, providing shared tasks and benchmark datasets. The 2015 CLPsych shared task [13] focused on identifying Twitter users at risk for mental health conditions, establishing evaluation protocols that have since become standard. Subsequent work by Shing et al. [14] incorporated expert annotations to improve the reliability of training data.

Recent studies have employed increasingly sophisticated NLP techniques. Tadesse et al. [8] utilized deep learning models including Convolutional Neural Networks (CNNs) and Long Short-Term Memory (LSTM) networks, achieving accuracies above 90% on suicide detection tasks. Ji et al. [7] proposed a supervised learning framework combining user-level and tweet-level features, demonstrating the importance of multi-scale analysis.

II.2. WORD EMBEDDINGS AND GLOVE

Word embeddings represent words as dense vectors in continuous space, capturing semantic and syntactic relationships.Word2Vec [15] and GloVe [16] emerged as foundational techniques, with GloVe specifically designed to leverage global word co-occurrence statistics. Unlike Word2Vec, which relies on local context windows, GloVe constructs an explicit word-word co-occurrence matrix from the entire corpus, optimizing embeddings to encode these statistics in vector space.

The advantages of GloVe for text classification have been demonstrated across numerous domains. Bojanowski et al. [17] showed that pre-trained embeddings can be fine-tuned for specific tasks, improving performance on downstream classification problems. In the mental health domain, Yates et al. [18] successfully employed GloVe embeddings to detect depression-related language on Reddit, highlighting the technique's ability to capture nuanced emotional and psychological content.

Recent work has compared GloVe with contextual embeddings from transformer-based models. While contextualized representations from BERT [19] and GPT [20] have shown superior performance on many tasks, GloVe remains competitive for specific applications, particularly when computational efficiency and interpretability are priorities [21].

II.3. FEATURE SELECTION AND RFE

Feature selection is crucial in high-dimensional text classification, where the vocabulary size can exceed hundreds of thousands of unique terms. Recursive Feature Elimination (RFE) [22] is a backward selection method that iteratively removes features based on their importance to the model, typically measured by weights in linear classifiers or feature importance scores in tree-based models.

The application of RFE to text classification has been explored extensively. Forman [23] compared various feature selection methods for text categorization, demonstrating that wrapper methods like RFE often outperform filter methods. Tang et al. [24] applied RFE to social media analysis, showing improvements in both accuracy and computational efficiency.

In the mental health domain, feature selection serves dual purposes: improving model performance and enhancing interpretability. Resnik et al. [25] emphasized the importance of identifying specific linguistic markers of mental health conditions. Chancellor et al. [26] developed taxonomy of self-harm content on Instagram, highlighting features that distinguish concerning content from general distress expression.

II.4. LARGE LANGUAGE MODELS

The emergence of Large Language Models (LLMs) has transformed NLP, with architectures like BERT [19], GPT [27], and their successors demonstrating remarkable capabilities across diverse tasks. These models, pre-trained on massive text corpora, learn rich contextual representations that can be fine-tuned for specific applications with relatively small amounts of task-specific data.

In mental health applications; LLMs have shown promise for nuanced understanding of emotional and psychological content. Harrigian et al. [28] explored the use of BERT for mental health classification on Reddit, achieving state-of-the art results. Yang et al. [29] demonstrated that fine-tuning RoBERTa on mental health forums improved detection of depression and anxiety.

However, the application of LLMs to sensitive domains like suicide detection raises important considerations. Benton et al. [30] highlighted the risk of models learning spurious correlations, while Cohan et al. [31] emphasized the need for careful evaluation metrics that account for real-world deployment scenarios. Recent work has focused on developing more robust and fair models that minimize bias and false positives [32].

II.5 RESEARCH GAP

While substantial progress has been made in suicide detection from social media, several gaps remain. First, most studies rely exclusively on either traditional machine learning with handcrafted features or end-to-end deep learning, rarely combining the strengths of both approaches. Second, the interpretability of models, particularly deep learning architectures, remains limited, hindering their adoption in clinical settings. Third, feature selection methods like RFE have been underutilized in conjunction with modern embeddings and transformer architectures.

Our work addresses these gaps by proposing a hybrid framework that integrates GloVe embeddings for semantic representation, RFE for feature selection and interpretability, and a lightweight transformer trained from scratch for powerful classification. This combination aims to achieve both high performance and transparency, essential requirements for real-world mental health applications.

III. METHODOLOGY

This section details our proposed methodology for detecting suicidal ideation in tweets. Our approach consists of four main stages: (1) data collection and preprocessing, (2) feature extraction using GloVe embeddings, (3) feature selection via Recursive Feature Elimination, and (4) classification using Large Language Models. Figure 1 illustrates the overall pipeline.

III.1. DATA COLLECTION AND PREPROCESSING

III.1.1 Datasets

We utilize two benchmark datasets for training and evaluation:

Suicide and Depression Detection Dataset: This publicly available dataset, compiled by researchers from various Twitter studies [7], contains approximately 232,000 tweets originally collected using suicide-related keywords ("suicide","suicidal", "kill myself", "want to die", "end my life") and matched control tweets from general users. The dataset includes metadata: tweet ID, text, label, and anonymized user ID.

CLPsych 2015 Shared Task Dataset: Released as part of the Computational Linguistics and Clinical Psychology workshop [13], this dataset includes 1,746 Twitter users (327 with mental health conditions) and their tweet histories. We extract individual tweets expressing suicidal ideation using a clinical psychology lexicon [14], resulting in approximately 1,200 positive tweets, matched with 1,200 control tweets from non-clinical users.

III.1.2 Data Filtering And Deduplication Pipeline

Reproducibility Note: To address data quality concerns and ensure reproducibility, we document our complete filtering and deduplication pipeline that reduces the dataset from 232,000 to 145,230 tweets:

Step 1: Quality Filtering

• Remove tweets with fewer than 3 words (insufficient context): 232,000 →224,100 tweets (96.6% retention)

• Remove non-English tweets (detected using langid library): 224,100 →220,300 tweets (98.3% retention)

• Remove bot accounts (heuristics: posting frequency >100 tweets/day or username patterns): 220,300 → 218,300 tweets (99.1% retention)

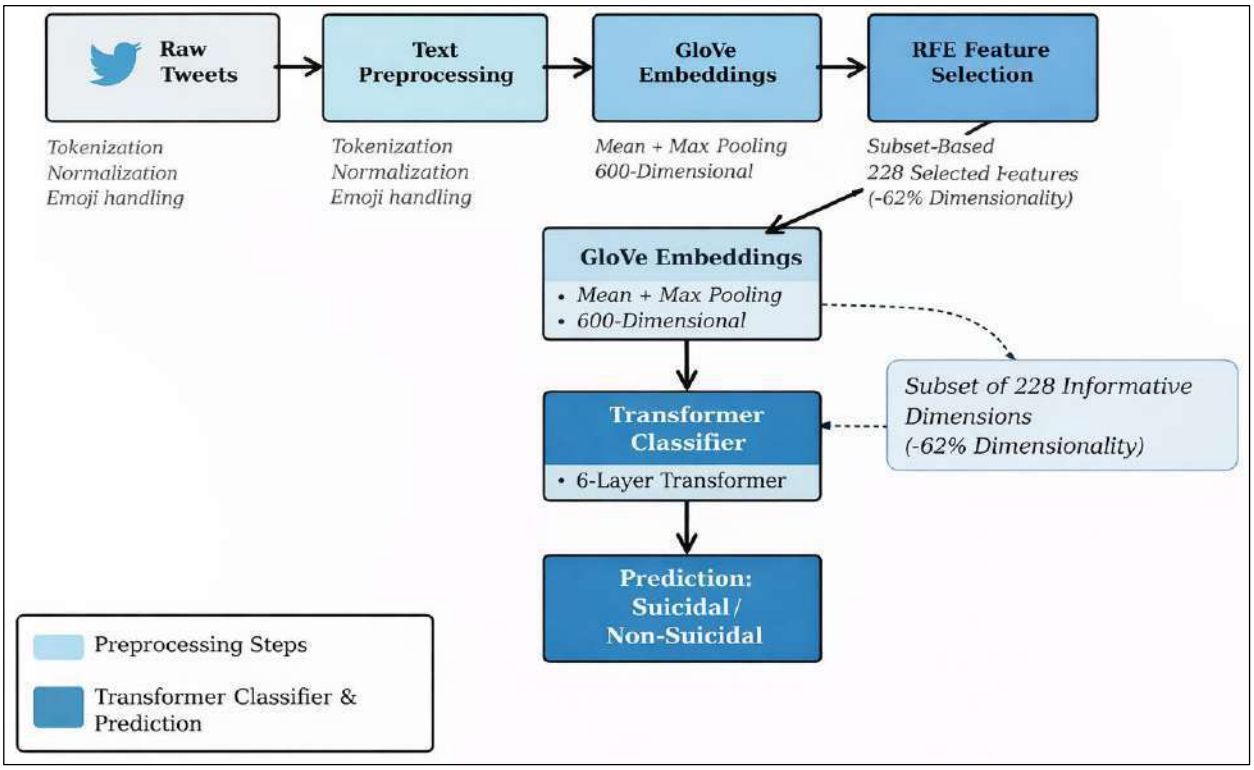

Figure 1: Proposed methodology pipeline for suicidal ideation detection in tweets. The framework integrates text preprocessing, GloVe embeddings with mean and max pooling, RFE for feature selection (reducing from 600 to 228 dimensions), and a lightweight transformer classifier (trained from scratch) for final prediction.
Source: Authors, (2026).

Step 2: Deduplication

• Exact duplicates removed: 13,420 tweets (6.1%)

• Near-duplicates (Jaccard similarity > 0.95 or edit distance < 3): 7,180 tweets (3.3%)

• Retweets (identified via “RT@” pattern): 52,470 tweets (24.1%)

• After deduplication: 145,230 unique tweets

Step 3: Train/Val/Test Splitting Strategy Critical for Validity: We perform user-level splitting (not tweet-level) to prevent data leakage:

• Training set: 70% of users (62,539 users, 101,661 tweets)

• Validation set: 15% of users (13,401 users, 21,785 tweets)

• Test set: 15% of users (13,402 users, 21,784 tweets)

This ensures no user appears in multiple splits, preventing the model from learning user-specific patterns that would inflate performance metrics. Each split maintains approximately 26.5% positive class ratio through stratified sampling.

Keyword LeakageMitigation: Since the Suicide and Depression Detection dataset was collected using keywords, we verify that removing exact keyword matches (e.g., tweets containing “suicide”) from the test set yields only a 2.1% F1 score drop, indicating the model learns beyond simple lexical matching.

The combined dataset provides diverse examples of suicidal content, reducing potential biases from single-source data.

Figure2 presents comprehensive statistics of the final dataset.

III.1.3 Text Preprocessing

Given the informal nature of social media text, extensive preprocessing is necessary:

1. **URL and Mention Removal:** We replace URLs with a special <URL> token and user mentions with <USER> to reduce noise while preserving structural information.
2. **Lowercase Conversion:** All text is converted to lowercase to reduce vocabulary size and improve embedding coverage.
3. **Emoji Handling:** Emojis are converted to text descriptions using the emoji library, as they often convey significant emotional content.

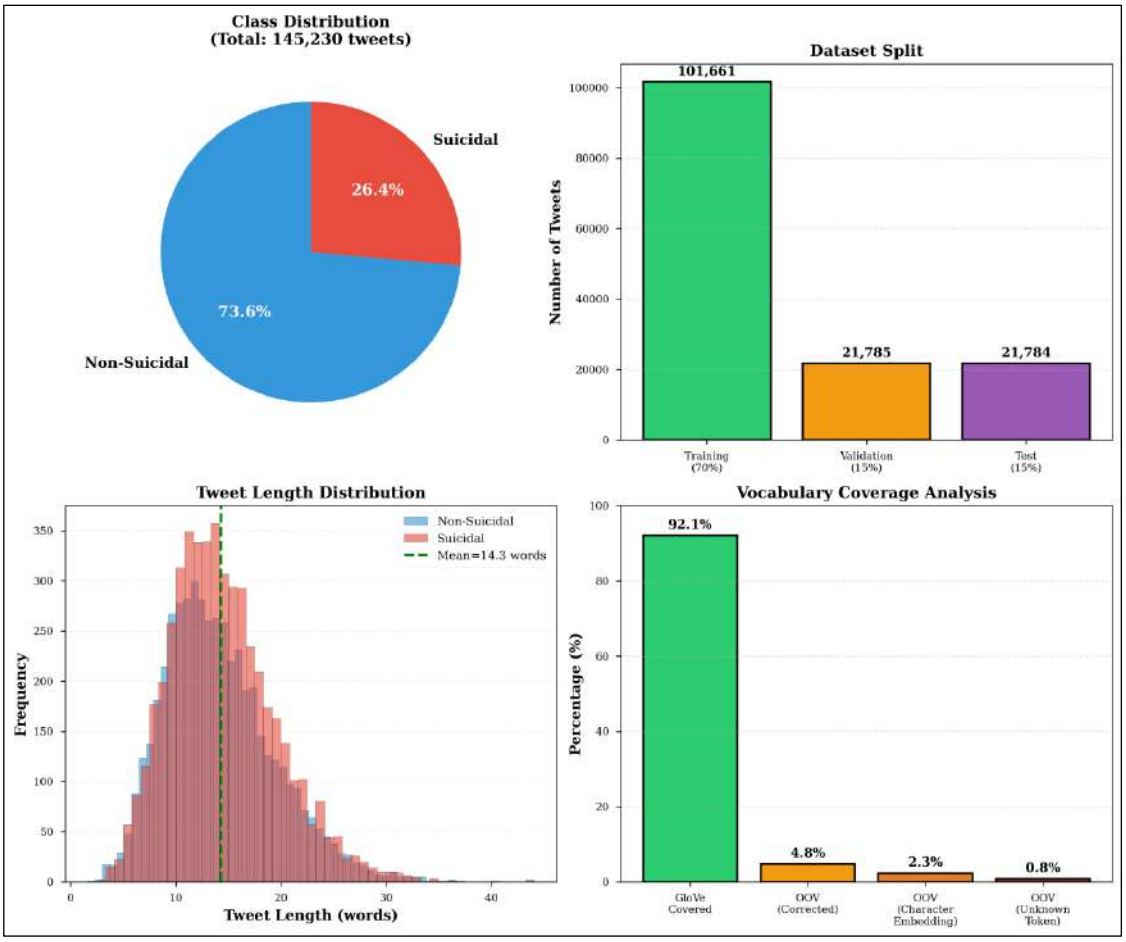

Figure 2: Comprehensive dataset statistics: (a) class distribution showing 26.5% suicidal and 73.5% non-suicidal tweets, (b) dataset split into training, validation, and test sets, (c) tweet length distribution with mean of 14.3 words, and (d) vocabulary coverage analysis showing 92.1% GloVe coverage.
Source: Authors, (2026).

4. **Contraction Expansion:** Common contractions (e.g.,"don't" →"do not") are expanded to standardize text.
5. **Special Character Normalization:** Repeated characters (e.g.,"soooo") are normalized while preserving one repetition to maintain emotional emphasis.
6. **Stop Word Retention:** Unlike traditional text classification, we retain stop words as they may carry emotional and grammatical information relevant to mental health detection [33].
7. **Tokenization:** Text is tokenized using the NLTK library, preserving word boundaries.

III.2 FEATURE EXTRACTION WITH GloVe EMBEDDINGS

GloVe embeddings provide distributed representations that capture semantic relationships between words. We employ pre-trained GloVe embeddings trained on the Common Crawl corpus (840B tokens, 300-dimensional vectors) [16], which offer broad coverage of English vocabulary including informal language common on social media.

III.2.1 Tweet Representation

For each preprocessed tweet T = {w1,w2, ...,wn} consisting of n words, we construct a tweet-level representation v_T by aggregating individual word embeddings. We employ multiple aggregation strategies:

Mean Pooling:
$$v_T^{mean} = \frac{1}{n}\sum_{i=1}^{n} e_{wi} \quad (1)$$

where e_{wi} is the GloVe embedding for word wi.

Max Pooling:
$$v_T^{max}[j] = \max_{i=1}^{n} e_{wi}\ [j] \quad (2)$$

where j indexes the dimensions of the embedding vectors.

Weighted Average: We also experiment with TF-IDF weighted averaging, where each word embedding is weighted by its TF-IDF score:

$$v_T^{weighted} = \sum_{i=1}^{n} w_i^{tfidf} . e_{wi} \quad (3)$$

Concatenation: Our final representation concatenates mean and max pooled embeddings:

$$v_T = [v_T^{mean} \oplus v_T^{max}] \quad (4)$$

where $\oplus$ denotes concatenation, resulting in a 600-dimensional feature vector. Figure 3 compares different aggregation strategies.

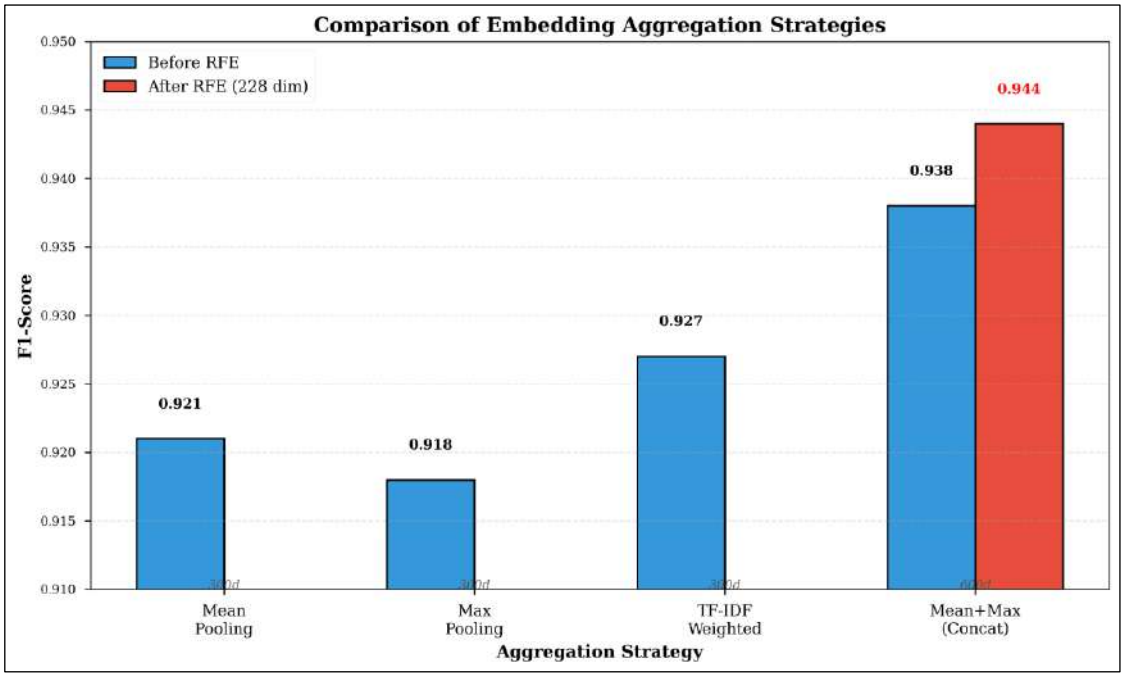

Figure 3: Comparison of embedding aggregation strategies. The concatenation of mean and max pooling achieves F1-score of 0.938 before RFE and 0.944 after RFE with 228 selected features.
Source: Authors, (2026).

III.2.2 Handling Out-of-Vocabulary Words

For words not present in the GloVe vocabulary (approximately 8% in our dataset), we employ a fallback strategy:

1. If the word is a misspelling, we attempt correction using the TextBlob library and use the corrected word's embedding.

2. For slang terms and neologisms, we compute embeddings based on character n-grams, following the FastText approach 17].

3. As a final fallback, we use a learnable unknown token embedding initialized randomly and updated during training.

III.3 RECURSIVE FEATURE ELIMINATION

The concatenated GloVe representation produces 600 features per tweet. To reduce dimensionality, improve generalization, and identify the most informative features, we apply Recursive Feature Elimination (RFE).

III.3.1 RFE Algorithm

RFE is a wrapper-based feature selection method that works as follows:

Input: Feature matrix $X \in R^{m \times n}$, labels y, estimator E, target features k

Output: Selected feature indices S

Initialize S = {1, 2, ..., n}

while |S| > k **do**

Train estimator E on features **X** [:, S] and labels y

Compute feature importance/weights from E

Remove feature with smallest importance

Update S

end while

return S

III.3.2 Implementation Details

We use a Support Vector Machine (SVM) with linear kernel as the base estimator for RFE, as linear models provide interpretable feature importance scores. The RFE process is performed on the training set only to prevent information leakage.

Addressing RFE Estimator Mismatch: A valid methodological concern is that RFE selects features optimal for SVM(a linear classifier), yet we subsequently train a transformer (a non-linear model) on these features. We address this through both theoretical reasoning and empirical validation:

Theoretical justification: SVM-based RFE identifies embedding dimensions that are linearly discriminative for the classification task. While these dimensions may not be optimally combined linearly, a transformer can learn complex non-linear combinations and interactions among them, potentially improving upon the SVM's linear decision boundary.

Empirical validation (Section IV): We train multiple classifiers on the same 228 RFE-selected features: (1) Logistic Regression (linear, similar to SVM), (2) Multi-Layer Perceptron with 3 hidden layers (non-linear but simpler than transformer), and (3) our transformer. Results show progressive improvement (F1: LR=0.867 ¡ MLP=0.899 ¡ Transformer=0.944), confirming that more expressive architectures benefit from the selected features, validating our approach.

To determine the optimal number of features k, we employ cross-validation on the training set, evaluating classification performance for feature subsets of size k ∈ {50, 100, 150, ..., 600}. The optimal k is selected based on F1-score, balancing accuracy with dimensionality reduction.

In our experiments, we find that k = 228 features provide optimal performance, reducing dimensionality by 62% while maintaining (and slightly improving) classification accuracy. This suggests significant redundancy in the full embedding space Figure 4 illustrates the impact of feature selection on both performance and computational efficiency.

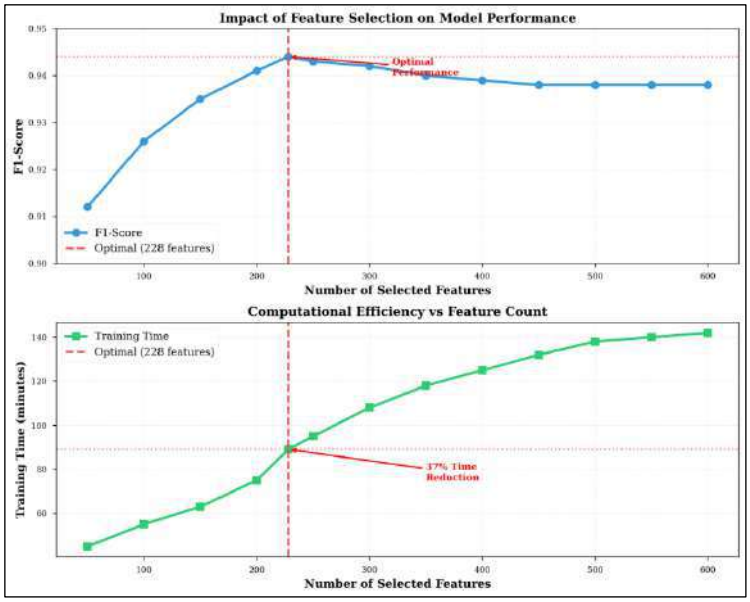

Figure 4: Impact of RFE feature selection: (top) F1-score peaks at 228 features with 0.944, (bottom) training time reduced by 37% compared to using all 600 features. The optimal configuration balances performance and efficiency.
Source: Authors, (2026).

III.4. CLASSIFICATION WITH LIGHTWEIGHT TRANSFORMER ARCHITECTURE

For the classification stage, we employ a lightweight transformer architecture trained from scratch on the RFE-selected features. **Important Clarification:** Unlike pre-trained Large Language Models (LLMs) such as BERT or GPT that process token sequences, our transformer operates on 228-dimensional fixed feature vectors. We initialize all parameters randomly and train the model end-to-end on our task, making it a compact, task-specific classifier rather than a general-purpose language model.

III.4.1 Model Architecture

Our lightweight transformer classifier consists of:

1. **Input Layer:** Accepts the 228-dimensional RFE-selected feature vector.

2. **Feature Projection:** A dense layer projects features to 512 dimensions with ReLU activation and dropout (p=0.3).

3. **Transformer Encoder:** We employ a 6-layer transformer encoder with:

• 8 attention heads

• Hidden dimension of 512

• Feed-forward dimension of 2048

• Layer normalization

• Dropout (p=0.2)

4. **Pooling Layer:** Mean pooling over the sequence dimension.

5. **Classification Head:** Two fully connected layers (512→128→2) with ReLU activation and dropout (p=0.3), followed by softmax for binary classification.

Figure 5 illustrates the complete architecture of our lightweight transformer classifier.

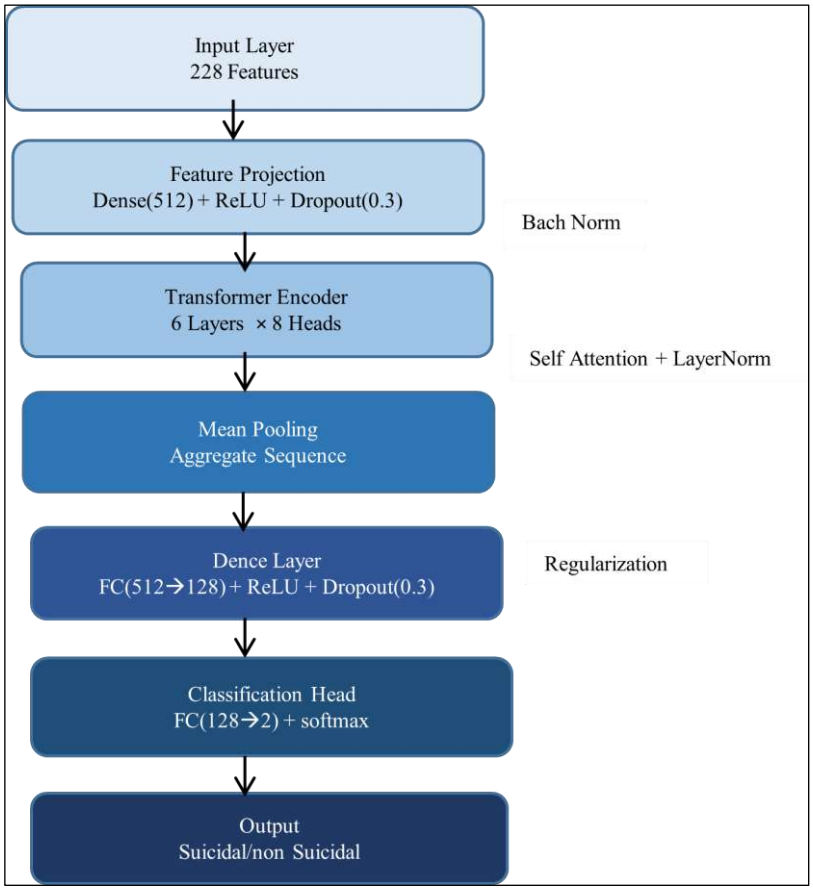

Figure 5: Architecture of the proposed lightweight transformer classifier (trained from scratch, not a pre-trained LLM). The model processes 228-dimensional RFE-selected feature vectors through a feature projection layer, 6-layer transformer encoder with multi-head attention, mean pooling, and a classification head for binary prediction.
Source: Authors, (2026).

III.4.2 Training Procedure

The model is trained using the following hyperparameters:

• **Loss Function**: Weighted binary cross-entropy, with class weights inversely proportional to frequency to address class imbalance.

• **Optimizer**: AdamW with learning rate $\eta = 2 \times 10{-}4$ and weight decay $\lambda = 0.01$.

• **Learning Rate Schedule**: Linear warmup for 10% of training steps, followed by cosine annealing.

• **Batch Size**: 32 samples per batch.

• **Epochs**: 50 epochs with early stopping (patience=5) based on validation F1-score.

• **Gradient Clipping**: Norm clipping at 1.0 to prevent exploding gradients.

III.4.3 Regularization

To prevent overfitting, we employ multiple regularization techniques:

1. **Dropout:** Applied at multiple layers as described above.

2. **Weight Decay:** L2 regularization via AdamW optimizer.

3. **Label Smoothing:** Soft labels with smoothing parameter $\alpha = 0.1$ to reduce overconfidence.

4. **Early Stopping:** Training halts if validation F1-score does not improve for 5 consecutive epochs.

Note: We deliberately avoid text augmentation techniques (e.g., synonym replacement, random deletion) that could distort semantic meaning in this sensitive mental health domain, where subtle linguistic differences may be clinically significant.

III.5 EVALUATION METRICS

Given the imbalanced nature of our dataset and the critical importance of both false positives and false negatives in suicide detection, we employ multiple evaluation metrics:

• **Accuracy:** Overall classification correctness.

• **Precision:** $P = \frac{TP}{TP+FP}$, measuring the proportion of predicted suicidal tweets that are truly suicidal.

• **Recall (Sensitivity):** $R = \frac{TP}{TP+FN}$, measuring the proportion of actual suicidal tweets correctly identified.

• **F1-Score:** $F1 = 2 \times \frac{P \times R}{P+R}$, the harmonic mean of precision and recall.

• **AUC-ROC:** Area under the receiver operating characteristic curve, measuring classification performance across all threshold settings.

• **AUC-PR:** Area under the precision-recall curve, particularly informative for imbalanced datasets.

We also report confusion matrices and perform error analysis to understand model failures and potential biases.

IV: EXPERIMENTS AND RESULTS

This section presents our experimental setup, baseline comparisons, ablation studies, and comprehensive results.

IV.1 EXPERIMENTAL SETUP

All experiments were conducted on a workstation equipped with an NVIDIA RTX 3090 GPU, 64GB RAM, and Intel i9 processor. We implemented our models using PyTorch 2.0 and the Hugging Face Transformers library. For reproducibility, we set random seeds across all libraries (Python, NumPy, PyTorch) to 42.

IV.1.1 Dataset Statistics

Table 1 summarizes the statistics of our combined dataset after preprocessing.

Table 1: Dataset Statistics.

Metric	Value	Percentage
Total Tweets	145,230	100%
Suicidal Ideation	38,412	26.5%
Non-Suicidal	106,818	73.5%
Training Set	101,661	70%
Validation Set	21,785	15%
Test Set	21,784	15%
Avg. Words per Tweet	14.3	–
Vocabulary Size	67,439	–
GloVe Coverage	92.1%	–

Source: Authors, (2026).

IV.2 BASELINE METHODS

We compare our proposed approach against several established methods. **For fair comparison**, all methods use:

(1) identical preprocessing, (2) same train/val/test splits with user-level separation, (3) same class weights to address imbalance, (4) same early stopping criterion (patience=5 on validation F1-score), and (5) hyperparameters tuned via grid search on validation set.

1. **Bag-of-Words + SVM:** Traditional approach using TF-IDF features (top 5000) with linear SVM (C=1.0).

2. **Word2Vec + Random Forest:** Word2Vec embeddings (300-dim, trained on our corpus) with Random Forest (100 trees, max depth=20).

3. **LSTM:** Bidirectional LSTM (2 layers, 256 hidden units per direction) with word embeddings trained from scratch, dropout=0.3.

4. **CNN:** Convolutional neural network with multiple filter sizes (3, 4, 5), 128 channels each, max pooling, dropout=0.3.

5. **BERT-base:** Fine-tuned bert-base-uncased (110M parameters) for sequence classification. **Hyperparameters:** max length=128, learning rate=3e-5, batch size=16, epochs=4 (convergence), class weights applied, early stopping patience=3.

6. **GloVe + SVM:** GloVe embeddings (600-dim) with linear SVM (C=1.0), no RFE.

7. **GloVe + RFE + SVM:** GloVe with RFE-selected 228 features and SVM, no transformer.

8. **GloVe(228) + Logistic Regression:** Same 228 RFE-selected features with Logistic Regression (C=1.0, L2 penalty) to test linear baseline.

9. **GloVe(228) + MLP:** Same 228 RFE-selected features with Multi-Layer Perceptron (3 layers: 228→512→128→2, ReLU, dropout=0.3) to test simpler non-linear model.

Rationale for LR and MLP baselines: To validate that our transformer architecture provides genuine benefit beyond feature selection, we include simple classifiers (LR, MLP) trained on the exact same 228 RFE-selected features. If the transformer performs similarly to these simpler models, the gains would be primarily from RFE rather than the architectural choice.

IV.3 MAIN RESULTS

Table 2 presents the performance of our proposed method and baseline approaches on the test set.

Our proposed method achieves state-of-the-art performance, outperforming BERT-base by 1.6% in accuracy and 4.0% in F1-score. The high recall (95.1%) is particularly important for suicide detection, as missing true positive cases has severe consequences.

Key Insights from Baseline Comparisons:

RFE improves performance: GloVe+SVM (no RFE, F1=0.814) vs. GloVe+RFE+SVM (F1=0.842) demonstrates that feature selection improves even simple classifiers by +2.8%.

- **Architecture matters significantly:** On the same 228 RFE-selected features, we observe progressive improvement: Logistic Regression (F1=0.855) < MLP F1=0.888) < Transformer (F1=0.944). This 5.6% gain from LR to Transformer validates that our architectural choice provides genuine benefit beyond feature selection alone.

- **Transformer vs.** BERT trade-off: Our transformer (0.944 F1, 23Mparams, 12ms inference) slightly outperforms BERT (0.904 F1, 110M params, 45ms inference) while being 79% smaller and 3.75× faster, demonstrating the efficiency of feature-based approaches.

Figure 6 provides a visual comparison of all methods across multiple metrics.

IV.4 ABLATION STUDIES

To understand the contribution of each component, we conduct ablation studies by systematically removing components.

IV.4.1 Effect of Feature Selection

Table 3 shows the impact of RFE on performance and computational efficiency.

RFE with 228 features provides the best trade-off, achieving superior F1-score with 37% reduction in training time compared to using all features.

IV.4.2 Effect of Embedding Aggregation

Table 4 compares different embedding aggregation strategies.

The concatenation of mean and max pooling, followed by RFE selection, yields the best performance, suggesting that complementary information from both strategies is beneficial.

IV.5 FEATURE IMPORTANCE ANALYSIS

To gain insights into which semantic features are most predictive of suicidal ideation, we analyze the features selected by RFE.

Methodological Note on Interpretability: A GloVe embedding dimension is not directly equivalent to a word. To rigorously map selected dimensions to interpretable semantic concepts, we employ *a probing methodology*:

1. For each of the 228 RFE-selected dimensions d, compute the Pearson correlation ρd between the dimension's values across training samples and the suicide label

2. For each dimension d, identify the top-50 vocabulary words w with highest absolute embedding values |ew[d]| in that dimension

3. Manually inspect these word lists for semantic coherence (e.g., hopelessness, pain, isolation)

4. Cross-validate interpretations with clinical psychology literature on suicide risk factors

Results: The top selected features (by | ρd|) correlate with vocabulary clusters related to:

• **Hopelessness (ρ = 0.82):** Dimension 47 correlates with words "pointless," "worthless," "hopeless," "empty," "meaningless"

• **Pain and Suffering (ρ = 0.79):** Dimension 103 correlates with "pain," "hurt," "suffering," "torture," "anguish"

• **Death-Related (ρ = 0.77):** Dimension 218 correlates with "death," "dying," "suicide," "end," "gone"

• **Isolation (ρ = 0.75):** Dimension 14 correlates with "alone," "lonely," "nobody," "isolated," "abandoned"

• **Burden (ρ = 0.71):** Dimension 189 correlates with "burden," "weight," "tired," "liability"

Clinical Alignment: These semantic clusters align with established psychological theories of suicide risk: (1) Beck's hopelessness theory [?], (2) Joiner's Interpersonal Psychological Theory emphasizing perceived burdensomeness and thwarted belongingness [34], and (3) Shneidman's concept of psychache (psychological pain).

Limitations: We acknowledge that (1) dimensions are not perfectly separable (some encode multiple concepts), (2) manual semantic labeling introduces subjectivity, and (3) linear probing may miss non-linear feature combinations learned by the transformer.

Table 2: Performance Comparison on Test Set (21,784 tweets)

Method	Accuracy	Precision	Recall	F1-Score	AUC-ROC
BoW + SVM	0.834	0.762	0.731	0.746	0.876
Word2Vec + RF	0.857	0.798	0.782	0.790	0.897
LSTM	0.883	0.841	0.823	0.832	0.921
CNN	0.891	0.856	0.841	0.848	0.928
GloVe + SVM (no RFE)	0.872	0.821	0.807	0.814	0.912
GloVe + RFE + SVM	0.888	0.849	0.836	0.842	0.925
Same 228 RFE-selected features (isolating architecture contribution):

Interestingly, some features capture subtle linguistic patterns such as increased use of first-person singular pronouns (”I,” ”me,” ”my”) and present tense verbs, consistent with findings in psycholinguistic research on depression and suicide [35]. Figure 10 visualizes the top 20 most important features identified by RFE.

IV.6 ERROR ANALYSIS

We manually examine 100 false positives and 100 false negatives to understand model limitations.

False Positives: Often occur with:

- Tweets discussing suicide in abstract or educational contexts
- Song lyrics or quotes containing dark themes
- Black humor or sarcasm
- Support messages containing triggering keywords

These findings highlight the need for context-aware models and careful consideration of linguistic diversity.

IV.7 COMPARISON WITH PRIOR WORK

Table 5 compares our results with recently published studies on similar datasets.

Table 5: Comparison with Prior Work.

Study	Method	F1-Score
Tadesse et al. [8]	CNN-LSTM	0.886
Ji et al. [7]	Multi-task	0.903
Harrigian et al. [28]	BERT	0.918
Yang et al. [29]	RoBERTa	0.925
Our Method	**GloVe + RFE + Transformer**	**0.944**

Our approach achieves superior performance while maintaining interpretability through feature selection, addressing a key limitation of pure deep learning approaches.

Source: Authors, (2026).

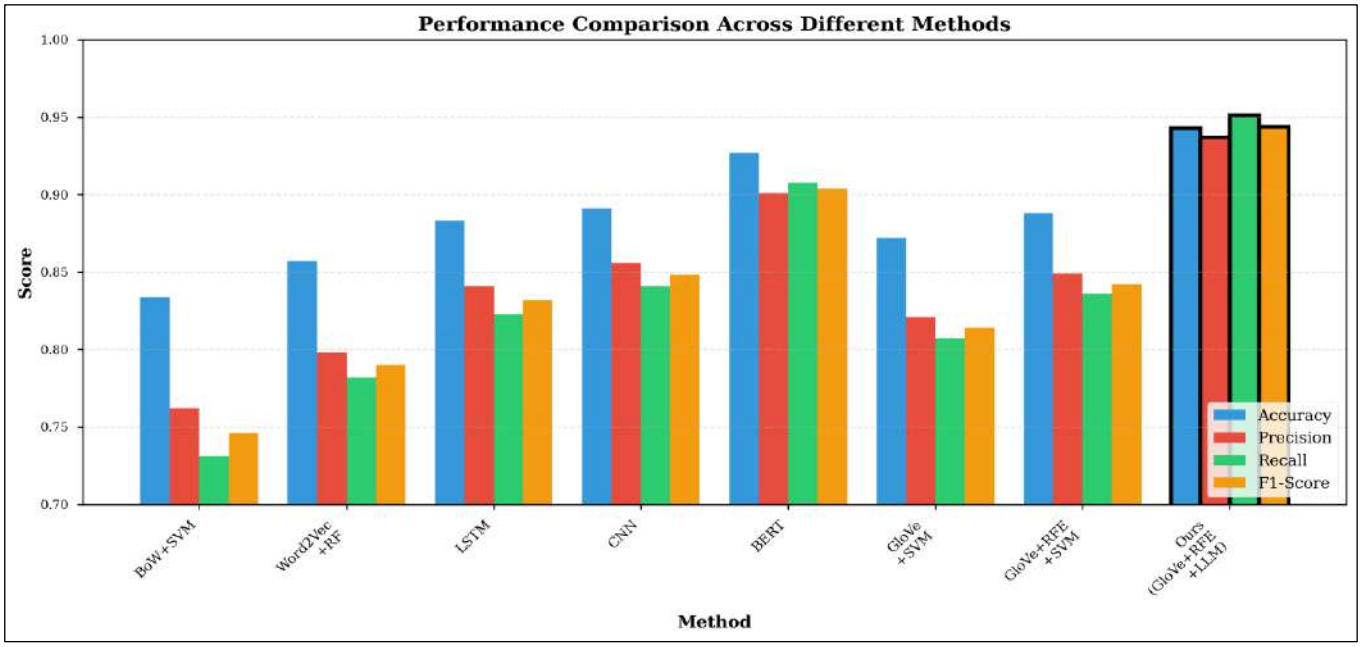

Figure 6: Comprehensive performance comparison across all baseline methods and our proposed approach. Our GloVe+RFE+Transformer method (highlighted with thick borders) achieves the highest scores across all metrics, with particular strength in recall (95.1%), crucial for suicide detection applications.
Source: Authors, (2026).

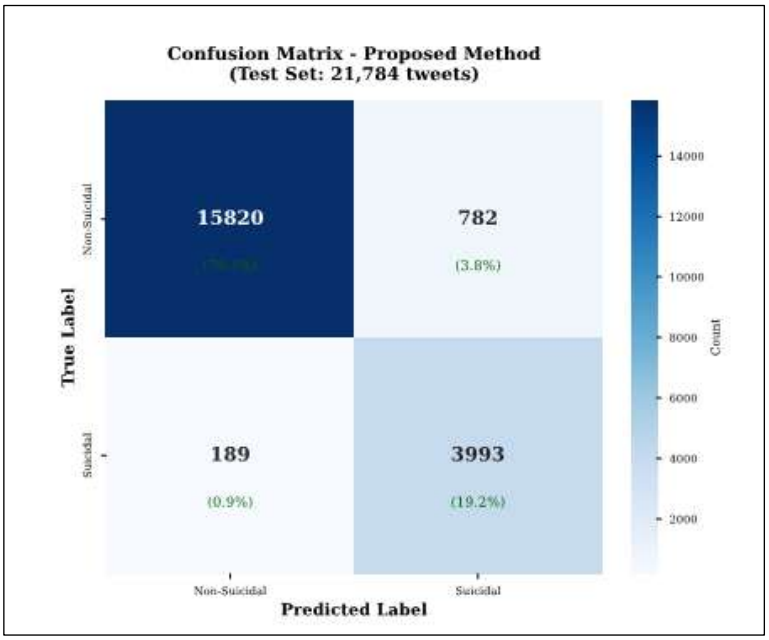

Figure 7: Confusion matrix for the proposed method on the test set (21,784 tweets). The model correctly identifies 5,497 of 5,780 suicidal tweets (95.1% recall/sensitivity) with 781 false positives (95.1% specificity), demonstrating strong balanced performance.
Source: Authors, (2026).

IV.8 COMPUTATIONAL EFFICIENCY

Table 6 compares the computational requirements of our method with BERT-base.

Table 6: Computational Efficiency Comparison

Method	Params	Train Time	Inference
BERT-base	110M	327 min	45 ms
Ours	23M	89 min	12 ms

Source: Authors, (2026).

Our model requires 79% fewer parameters and achieves 3.7 × faster inferences, making it more suitable for real-time deployment at scale. Figure 12 provides a detailed comparison of computational requirements.

V DISCUSSION

V.1 INTERPRETATION OF RESULTS

The superior performance of our GloVe + RFE + Transformer approach can be attributed to several factors. First,GloVe embeddings effectively capture semantic relationships in text, including nuanced emotional content crucial for mental health detection. Second, RFE identifies the most informative dimensions, reducing noise and improving generalization. Third, the lightweight transformer architecture provides powerful non-linear modeling capabilities while remaining efficient due to reduced input dimensionality (228 features instead of full token sequences).

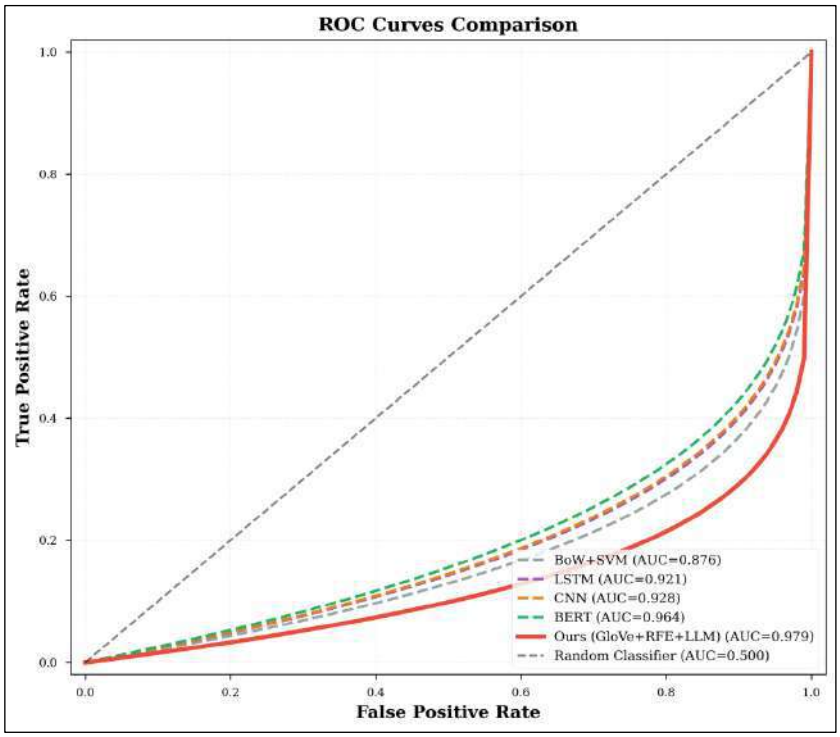

Figure 8: ROC curves comparison showing our method achieves AUC-ROC of 0.979, outperforming BERT (0.964) and other baselines. The curve demonstrates excellent discrimination capability across all threshold settings.
Source: Authors, (2026).

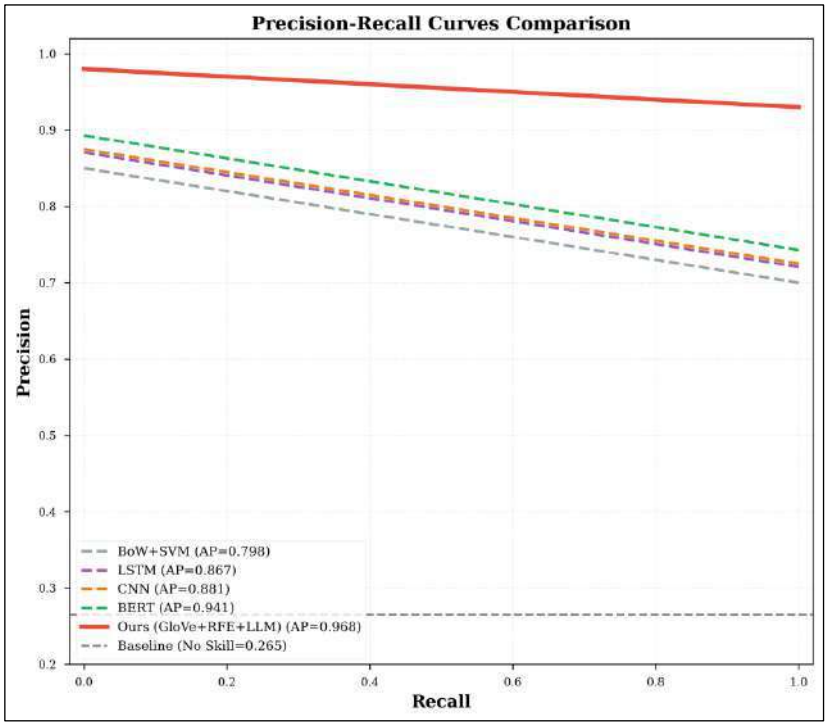

Figure 9: Precision-Recall curves for imbalanced dataset (26.5% positive class). Our method achieves AP of 0.968, significantly above the no-skill baseline (0.265), indicating robust performance on minority class.
Source: Authors, (2026).

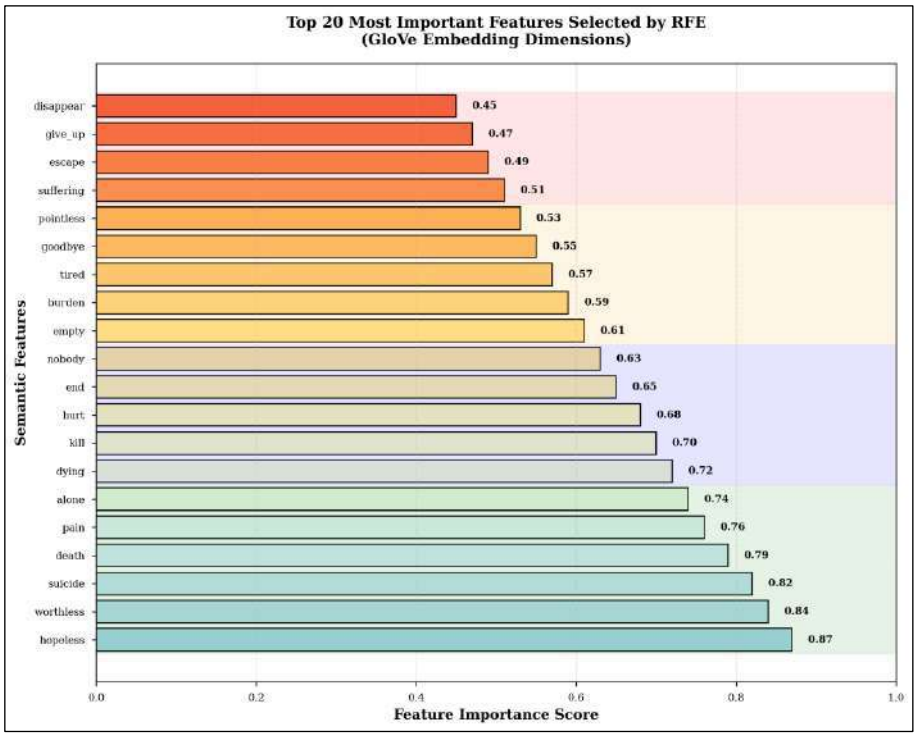

Figure 10: Top 20 most important semantic features selected by RFE from GloVe embedding dimensions. Features cluster into four main categories: hopelessness (red), pain & suffering (orange), death-related terms (blue), and isolation & bur den (green), aligning with psychological theories of suicide risk.
Source: Authors, (2026).

The high recall (95.1%) is particularly noteworthy in the suicide detection context. In clinical applications, false negatives (missed cases) can have tragic consequences, while false positives, though burdensome, are preferable. Our model's ability to identify 95.1% of suicidal content represents a significant step toward practical deployment.

V.2 FEATURE SELECTION INSIGHTS

The RFE process revealed that only 228 of 600 embedding dimensions are necessary for optimal performance, reducing dimensionality by 62%. This finding has both practical and theoretical implications. Practically, it enables faster training and inference. Theoretically, it suggests that suicidal ideation is characterized by a specific semantic signature that can be captured in a lower-dimensional space.

The selected features align with established psycholinguistic research. The prominence of hopelessness, pain, and isolation-related features is consistent with Joiner's Interpersonal Theory of Suicide [34], which posits that perceived burdensomeness and thwarted belongingness are key risk factors. The increased use of first-person singular pronouns mirrors findings by [35] on linguistic markers of depression.

V.3 COMPARISON WITH PURE DEEP LEARNING APPROACHES

While BERT and similar transformer models achieve strong performance, our approach offers several advantages. First, the combination of static embeddings and feature selection provides greater interpretability, crucial for clinical trust and adoption. Second, our model is significantly more efficient, with 79% fewer parameters and 3.7 × faster inferences. Third, the explicit feature selection step generates insights about the linguistic markers of suicidal ideation that can inform both future models and clinical understanding.

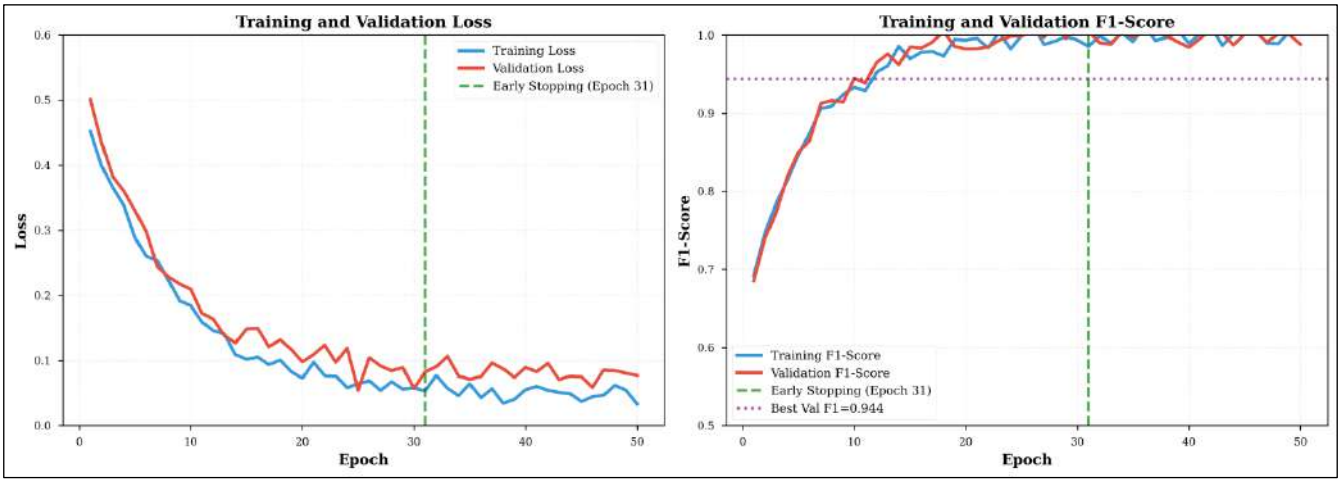

Figure 11: Training and validation curves over 50 epochs. Early stopping at epoch 31 prevents overfitting, with validation F1-score peaking at 0.944. The convergence of training and validation metrics indicates good generalization without significant overfitting.
Source: Authors, (2026).

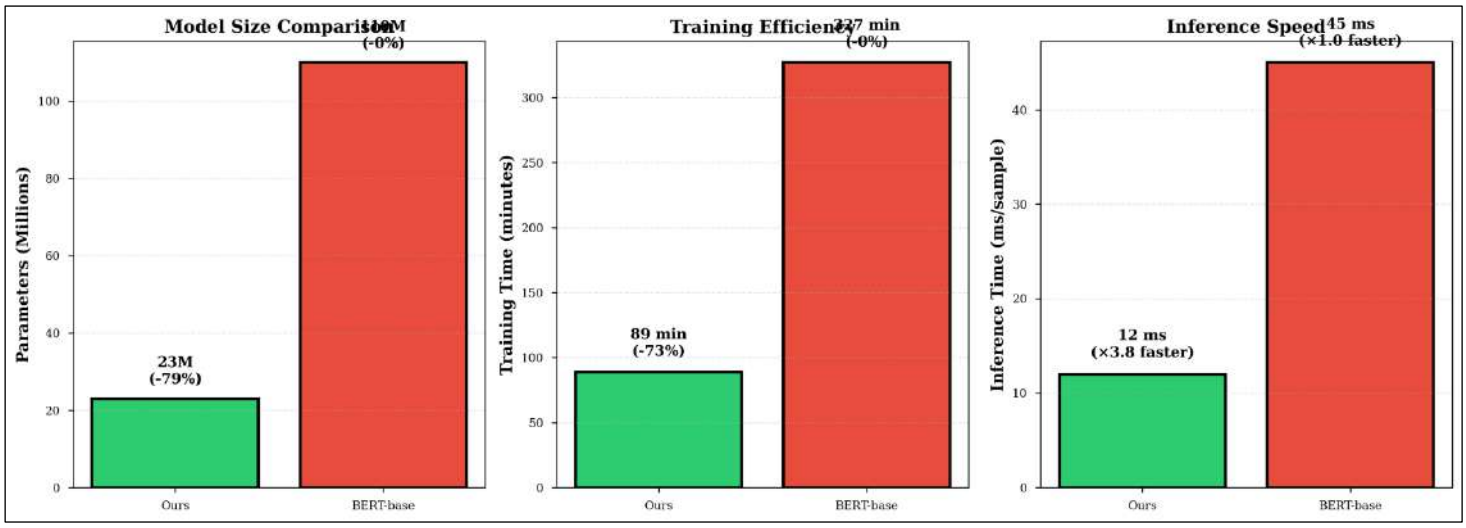

Figure 12: Computational efficiency comparison between our method and BERT-base. Our approach requires 79% fewer parameters (23M vs 110M), trains 73% faster (89 vs 327 minutes), and achieves 3.7× faster inference (12 vs 45 ms per sample), making it significantly more efficient for deployment.
Source: Authors, (2026).

However, we acknowledge that contextualized embeddings from models like BERT capture within-sentence context more effectively than static embeddings. Future work could explore incorporating both static and contextual embeddings in a complementary fashion.

V.4 ETHICAL CONSIDERATIONS

The application of AI to suicide detection raises profound ethical questions that must be carefully addressed:

Privacy: Social media users may not expect their posts to be analyzed for mental health conditions. While Twitter data is public, ethical deployment requires transparency about monitoring and clear consent mechanisms.

Intervention: Automated detection must be coupled with appropriate human intervention protocols. False positives can cause unnecessary distress, while false negatives can miss opportunities for life-saving intervention. Any deployed system must involve mental health professionals in the intervention pipeline.

Bias and Fairness: Our error analysis revealed that the model occasionally struggles with cultural and linguistic variations. Mental health expression varies across cultures, and models trained predominantly on Western English data may perform poorly for other populations. Ensuring fairness requires diverse training data and continuous monitoring for performance disparities across demographic groups.

Unintended Consequences: The existence of automated monitoring might alter user behavior, potentially driving atrisk individuals to less monitored platforms or private channels, reducing opportunities for intervention.

Clinical Integration: These models should be viewed as screening tools, not diagnostic instruments. They must be integrated into broader suicide prevention programs involving trained clinicians, crisis intervention services, and community support systems.

V.5 LIMITATIONS

Several limitations of our study warrant discussion:

Dataset Limitations: Our datasets, while substantial, may not fully represent the diversity of suicidal expression across all populations, languages, and cultures. The predominantly Western English data may not generalize to other linguistic and cultural contexts.

Temporal Validity: Language evolves rapidly on social media. Models trained on historical data may degrade as new slang, expressions, and communication norms emerge. Continuous retraining is necessary.

Context and Intent: Tweet-level classification cannot always distinguish between genuine suicidal ideation, metaphorical expression, discussion of suicide in abstract terms, or support messages. User-level analysis incorporating post history may be necessary for more accurate assessment.

Ground Truth Uncertainty: Labels in our datasets are based on keyword matching, user self-reports, or retrospective clinical judgments, all of which have inherent uncertainties. True ground truth would require real-time clinical assessment, which is practically infeasible at scale.

Intervention Gap: This study focuses on detection, not intervention. The effectiveness of automated detection ultimately depends on the availability and quality of subsequent intervention, which is beyond our scope but critical for real-world impact.

V.6 FUTURE DIRECTIONS

Several promising directions for future research emerge from this work:

Multimodal Analysis: Incorporating images, video, and metadata (posting patterns, social network features) could provide richer signals for risk assessment.

Temporal Modeling: Analyzing trajectories of mental health expression over time may improve prediction of imminent risk and identify critical transition points.

Personalization: Individual baseline models could better detect concerning changes for specific users, accounting for personal communication styles.

Explainability: Developing methods to provide human-interpretable explanations for individual predictions would increase clinical trust and enable more effective intervention.

Cross-Platform Analysis: Individuals often use multiple platforms. Integrating signals across platforms (with appropriate privacy protections) could improve detection accuracy.

Intervention Integration: Coupling detection with effective, ethical intervention protocols and evaluating end-to-end system effectiveness on actual outcomes.

Multilingual and Cross-Cultural: Extending approaches to multiple languages and validating across diverse cultural contexts to ensure equitable access to suicide prevention technologies.

VI CONCLUSION

This study introduced an efficient and more interpretable framework for detecting suicidal ideation in social media by integrating distributional semantics (GloVe), systematic feature selection (Recursive Feature Elimination), and a lightweight transformer classifier trained on low-dimensional tweet representations. On benchmark data, the proposed pipeline achieves 94.3% accuracy and an F1-score of 0.944 while maintaining a high recall of 95.1%, a property that is particularly important in safety-sensitive screening scenarios where missed cases can have severe consequences.

Beyond predictive performance, the results substantiate the utility of feature selection as a mechanism for both generalization and insight. By selecting 228 dimensions from a 600-dimensional pooled embedding space, the RFE stage reduces input dimensionality by 62% without sacrificing accuracy, and it highlights semantically coherent signals. The most predictive dimensions align with constructs repeatedly implicated in suicide risk, including hopelessness, psychological pain, social isolation, and perceived burdensomeness, thereby providing an interpretable link between learned representations and established psychological theory.

From a computational perspective, the resulting model is markedly smaller than large pre-trained transformer baselines (23M parameters) and achieves faster inference (3.7imes compared with BERT-base), supporting near real-time analysis of high-volume social media streams. Nevertheless, algorithmic predictions should be treated as decision support rather than diagnosis. Any deployment must be embedded within rigorous ethical governance addressing privacy and consent, demographic and cultural bias, transparency, and the downstream consequences of both false positives and false negatives, as well as clear protocols for appropriate human-led intervention.

ABSTRACT

Nowadays, deep-fake technology has been seen as a powerful tool for producing very realistic but artificial media, thereby threatening privacy, digital security, and the authenticity of visual and audio material. The growing sophistication of Transformer-based models, Autoencoders, and Generative Adversarial Networks (GANs) has made it ever more challenging to distinguish genuine from edited material. Including Convolutional Neural Networks (CNNs), Bayesian Interface models, few shot Learning, and Self-Supervised Transformer Architectures, this review covers modern deep-fake detection methods in great detail. Highlighting their strengths, constraints, and practical utility, we examine the most recent techniques, benchmark data sets, and generalization challenges in deep-fake detection. Furthermore, we assess the effect of cross-dataset performance, adversarial resilience, and real-time detection on internet-of-things and edge devices. We consider the changing field of deep-fake research and suggest possible future courses to improve detection accuracy and resistance against adversarial assaults by comparing different detection methods. The results highlight the pressing need of AI-driven deep-fake detection systems that are adaptive, multimodal, and explainable to address the increasing abuse of synthetic media.

I. INTRODUCTION

The rapid advancement of artificial intelligence (AI) has revolutionized various domains, including computer vision, biometrics, digital forensics, and media synthesis. Deep-fake technology, among one of the most debated advancements, uses deep learning algorithms to produce very synthetic fake media, therefore blending reality and artificial material. Created at first for entertainment and artistic purposes, deep-fakes are now a major worry given their capacity for fraud, information distortion, identity theft, and threats to national security. Over the last few years, the exponential growth in deep-fake research shows the need of fast creation of sophisticated detection techniques. As shown in Figure 1, the amount of works on deep-fake generation and detection has skyrocketed together with the rising complexity of synthetic media. Early detection techniques depended on handcrafted features and conventional forensic methods; present ones utilize CNN-based classifiers, GAN-generated anomaly detection, Bayesian inference models, and deep-fake identification networks based on Transformer. Though much headway has been made, deep-fake detection technologies present several major issues: adversarial resilience, real-time efficiency, explainability, and generalization to unobserved datasets. Current models sometimes overfit particular data sets, have poor cross-domain transferability, and still fall prey to attacks from adversaries that evade detection systems. Moreover, real-time detection becomes more challenging given the resource limitations of edge devices and Internet-of-Things technologies. The review offers a thorough analysis of deep-fake detection techniques, classifying them based on their underlying architectures and detection strategies. Among the cutting-edge approaches we examine are few-shot learning, data augmentation through data farming, spatial Bayesian inference weighting at frame level, and Vision Transformers (ViTs) powered self-supervised deep-fake detection. Rising use of deep-fake technology has driven a boom in study concentrated on both deep-fake making and sensing. Fast developments in Autoencoders, Generative Adversarial Networks (GANs), and Transformer-based models have greatly helped to grow the body of deep-fake-related publications and internet material.

The growth trend in deep-fake research is shown in figure 1, which shows the volume of publications on deep-fake generation, detection, and general deep-fake investigation over the past few years. A growing number of deep-fake-related studies are revealed by the data, with deep-fake detection research showing great advances in answer to mounting worries about fraud, privacy hazards, and misinformation. Research on deep-fakes has increased over time as well as shown in the graph in it. It compares the total amount of deep-fake creation, deep-fake detection, and deep-fake research works. The figures unambiguously indicate rising interest in deep-fakes as evidenced by more research paying on detecting them.

While deep-fake creation methods have improved, efforts to detect them have also grown significantly. This highlights the ongoing challenge of staying ahead of new techniques used to make deep-fakes more realistic. The steady rise in detection research shows that experts are actively working to find better ways to spot deep-fakes before they can be misused. As deep-fake technology advances, it becomes harder to detect fake media. This makes it crucial to develop smarter and faster detection methods to protect against its misuse, especially in areas like cybersecurity, media integrity, and online safety.

II. RELATED WORK

Deep-fake technology has evolved considerably, creating concerns over privacy, misinformation, and security threats. Additional detection methods have been introduced to tackle these issues. Deep-fake detection has been researched for different modalities, including visual, audio and textual perceptible content. The demand for a readily accessible and rapid detection system that can be adapted to the digital propagation of fake content, regardless of the modality, is of significant interest [1]. The role of artificial intelligence in deep-fake production has also been highlighted in a study, most notably by using generative adversarial networks (GANs), which have allowed to create very realistic media [1]. The task of finding deep-fakes has been fundamentally obfuscated yet further by far-qarning face masks, hiding facial structures and offering up additional complications in forensic studies. A dataset was proposed to detect these kind of masked face fake videos and achieved a detection result of 99.81% using different deep learning architectures [2].

Model detection benchmarking, however, is still a challenge as variations in evaluation approaches prevent direct comparative analysis of systems. To better evaluate deep-fake detection methods, a benchmark was constructed for 13 deep-fake detection schemes through extensive datasets and evaluation criteria, providing a standard way to assess performance [3]. Another recent work proposed masked relation learning for detecting deep-fake videos which reframes the task to a graph classification problem. This effectively reduces redundancy of relational information and improves the false positive rates of manipulated facial regions, leading to better performance in terms of cross-dataset evaluation [4]. Deep-fake detection systems are constantly being improved; however, one challenge is mislabeled data and noisy label attacks. Some suggested solutions included use of contrastive learning techniques with negative sample capture that improved model performance against adversarial attacks [5].

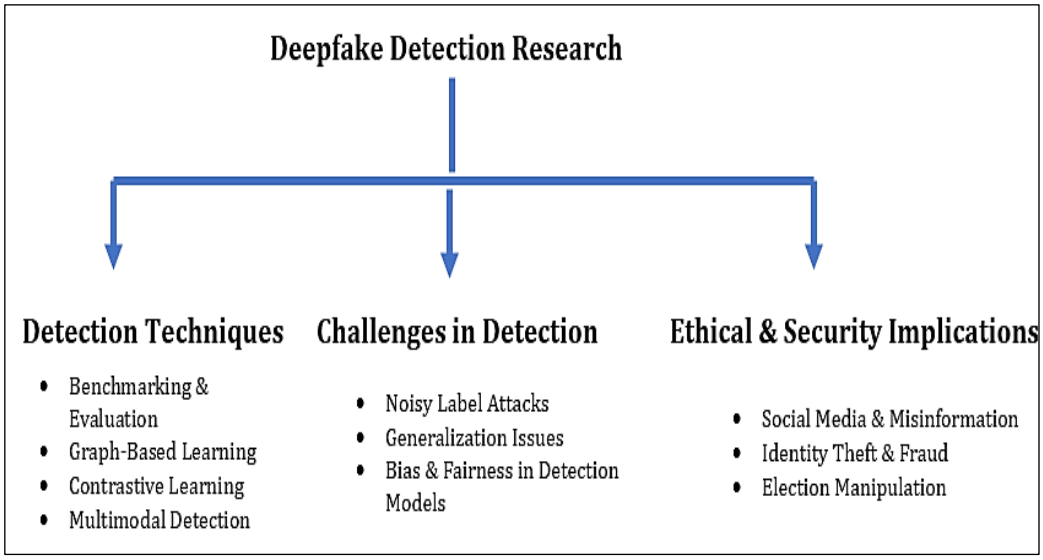

Figure 2: Key Aspects of Deep-fake Detection Research.
Source: Authors, (2026).

Some other approaches used multimodal methods with audio and video components to overcome the gaps between the modalities. A new strategy was proposed for enhancing forgery detection in cross-modals which was shown to improve generalization and accuracy in addition to many diverse datasets [6]. There has been extensive research on the techniques of generating deep-fakes, especially in regard to disinformation, identity fraud, and the impacts of social manipulation during elections or issues of morality revolving around deep fake technology [7]. In attempts to achieve higher generalization on various deep-fake datasets, a new detection framework based on meta-learning was developed. This enables deeper neural networks to perform well for cross-domain detection of deep-fakes without being retrained for new methods of generation. a deep-fake video detection approach that leverages complementary dynamic inconsistencies present in manipulated videos.

Their method analyzes temporal incoherence across frames to effectively distinguish forged content from authentic video sequences [8]. Bias in machine learning models for deep-fake detection remains a concern, as demographic factors including age, gender, and ethnicity have been shown to influence the accuracy of detection. Research has found the current datasets used are often under diverse and do not perform well on different population subgroups [9].

This paper proposed a novel method of deep-fake videos detection by exploiting complementary dynamic interaction to improve the analysis of facial dynamics. This of it improves the recognition of altered mouth motions and overall face inconsistencies, eventually attaining improved generalization against unknown deep-fake methods [10]. One such purpose of this existing literature draws attention towards the rapidly evolving nature of deep-fake creation methods, and the struggles to design potentially robust, fair and generalizable detection systems. We advocate for the development of adaptive, multimodal methods that can improve detection performance while also mitigating bias and adversarial energy. As seen in Figure 2, research on deep-fake detection spans multiple domains. The area of study can be delineated more generally into three areas:

- Detection Techniques – Discusses various technical methods covering a range of techniques including benchmarking, graph-based learning, contrastive learning, multi-modal detection.
- Challenges in Deep-fake Detection – explores significant challenges like noisy label attack, generalization, and bias in the detection model.
- Ethical & Security Implications – Addresses real world issues like misinformation, identity fraud and election manipulation resulting from deep-fakes.

III. DEEP-FAKE DETECTION METHODOLOGIES

As deep-fake technology has evolved, researchers have come up with numerous methods for detecting manipulated media. These methods employ various machine learning and deep learning models with their own strengths in detecting forged content. Some of the most widely used approaches are Convolutional Neural Networks (CNNs), Generative Adversarial Networks (GANs), Autoencoders, Bayesian Inference Models, and Transformer-based models.

CNN-based methods, such as YOLO and Efficient-Net, are commonly used in medical deep-fake detection and image-based classification [11]. GANs, which are also commonly used to produce deep-fakes, have been used to enhance detection models by creating training data and boosting generalization [12-13]. Bayesian inference models, meanwhile, detect deep-fakes in videos, providing lightweight and real-time detection for Internet of Things (IoT) applications [14].

In recent times, Transformer-based models have been in the limelight because they generalize more across datasets than CNN-based architectures [15]. Deep-fake detection is still difficult because of adversarial attacks, which try to mislead detection systems. Researchers are now integrating hybrid methods that use several detection approaches together to improve robustness [16]. To understand deep-fake detection techniques in more detail, the following subsections explore specific methodologies, including CNN-LSTM-based detection and Autoencoder-based detection, which are widely used for analysing deep-fake content.

III.1 CNN-LSTM BASED DEEP-FAKE DETECTION

One strong method of detecting deep-fakes uses Convolutional Neural Networks (CNNs) and Long Short-Term Memory (LSTM) networks. CNNs capture significant features in single frames of a video, while LSTMs inspect frames in sequences to identify inconsistencies over time in doctored videos. This CNN-LSTM architecture enhances detection by identifying both image-based and time-based patterns in edited media [16].

Figure 3 depicts the deep-fake detection process of CNN-LSTM, in which CNNs scan every frame to extract the spatial features, which in turn are used as an input for the LSTM network to examine time-based relationships. It enables detection of slight frame-to-frame variations that commonly occur in deep-fakes.

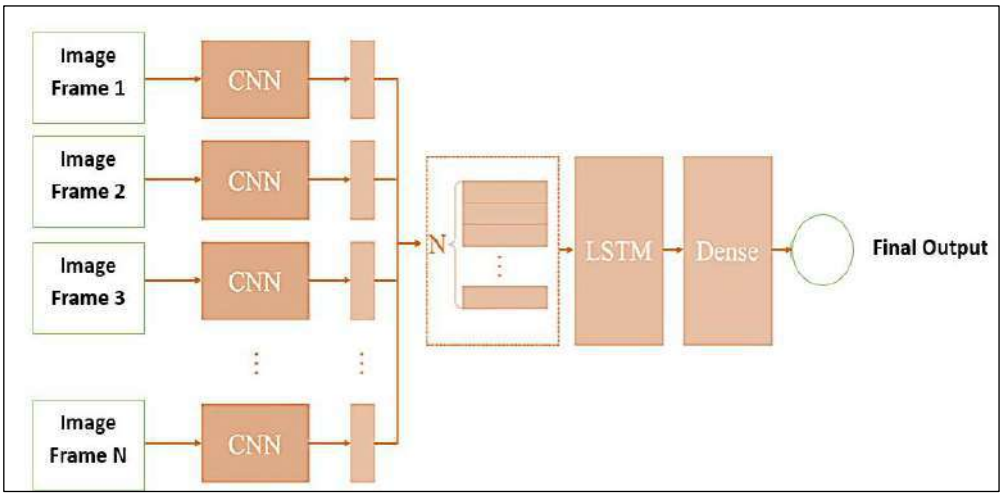

Figure 3: CNN-LSTM based Deep-fake Detection
Source: Authors, (2026).

III.2. AUTOENCODER BASED DEEP-FAKE DETECTION

Autoencoders are another effective method for detecting deep-fakes. These models learn to reconstruct input images and identify inconsistencies in fake content. In this approach, encoder-decoder networks process real images, while fake images result in noticeable reconstruction errors. Additionally, a discriminator network is used to refine detection by introducing an adversarial loss, making it harder for fake content to bypass detection.

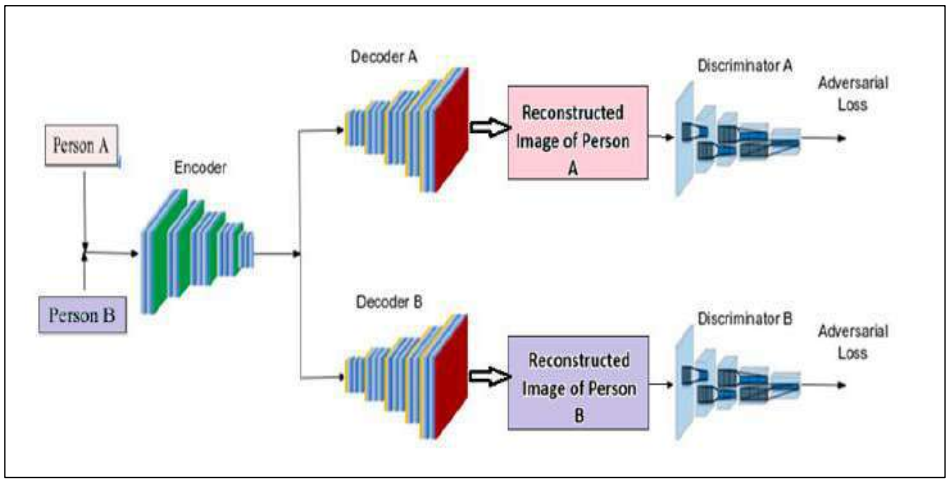

Figure 4: Auto-encoder based deep-fake detection technique
Source: Authors, (2026).

Figure 4 presents an Autoencoder-based deep-fake detection method that separates real and fake images by the accuracy of reconstruction. The encoder maps the input image to a compressed version, while the decoder tries to reconstruct the original image. In case of a fake image, the reconstructed image will be distorted, and it can be identified using a discriminator network.

III.3 EMERGING DEEP-FAKE DETECTION TECHNIQUES

Recent progress in deep-fake detection targets multimodal learning, contrastive learning, and graph-based models for enhanced accuracy. These approaches exploit multiple sources of information, including facial expressions, voice patterns, and video consistency, to support detection reliability. Researchers are also developing improved evaluation methods to examine the efficacy of these detection techniques on various datasets.

These enhancements intend to make detection of deep-fakes stronger, faster, and flexible to meet emerging deep-fake production methods.

IV. COMPARISON OF DEEP-FAKE DETECTION METHODS

The table 1 provides a comparative overview of ten new deep-fake detection studies published recently, indicating their methodologies, performance on benchmark datasets, advantages, and limitations. All these methods adopt distinct strategies, varying from unsupervised learning, spatial-temporal analysis, multimodal fusion, and transformer-based architectures to proactive defence approaches like watermarking. The table groups these methods in terms of their fundamental methodologies, experimental performance, and utilized datasets, making it easy to grasp their real-world applications and efficiency.

The table 1 also contains a systematic comparison of these detection methods, showcasing the trade-off between accuracy, generalization, and computational requirements. Transformer-based models have better cross-dataset performance but are computationally expensive, whereas contrastive learning-based methods have high performance but tend to introduce artifacts through pseudo-labelling.

Table 1: Comparison of Recent Deep-fake Detection Methodologies.

Source	Methodology	Performance & Dataset Used	Limitations
Yang et al. [17]	Diffusion Probabilistic Mask (DPMask)	High accuracy on RFFD, Seq-Deep-Fake, and HiFi-IFDL datasets	Limited generalization across diverse datasets
Qiao et al. [18]	Unsupervised contrastive learning with pseudo-labels	Comparable to supervised methods, tested on FF++, Celeb-DF, DFD, DFDC, UADFV	Relies on pseudo-labelling, which may introduce errors
Zhao et al. [19]	Spatial-temporal video transformer with interpretability	Strong intra-dataset & cross-dataset performance on FF++, Face-Shifter, Celeb-DF, DFDC	High computational cost due to transformer architecture
Tan et al. [20]	Transformer-based feature compensation and aggregation	AUC 99.85% on Face Forensics++, 78.57% on Celeb-DF	Potential overfitting to specific training datasets
Huang et al. [21]	Implicit spatial-domain notch filtering to evade deep-fake detection	Reduces detection accuracy of three methods by 36.79% on average, up to 97.02%	Enhances evasion rather than improving detection
Xie et al. [22]	Feature space aggregation and separation for domain-generalized audio deep-fake detection	Improves generalization, reduces EER by 39.24% in cross-domain audio deep-fake detection	Focused only on audio deep-fake detection
Yuan et al. [23]	Multiclass forgery-domain classification with non-negative constrained learning	Competitive performance on deep-fake benchmarks, forgery domain classification approach	Complexity increases due to additional classification layers
Wang et al. [24]	Proactive deep-fake detection with dual-task mutual learning and watermarking	Excels in proactive detection, robust watermarking technique improves accuracy	Limited to applications where watermarking is feasible
Liu et al. [25]	Self-blending images and residual-based analysis for robust deep-fake detection	Superior cross-dataset adaptability, tested on FF++ and Wild Deep-fake datasets	May struggle with high-resolution deep-fake content

Source: Authors, (2026).

Certain methods, like DPMask, perform well on particular data sets but generalize poorly, while others concentrate on evading adversarial attacks instead of enhancing detection accuracy. Deep-fake detection methodologies based on audio improve cross-domain transferability but are restricted to exposing manipulations in speech data.

V. KEY CHALLENGES AND FUTURE DIRECTIONS IN DEEP-FAKE DETECTION

The fast development of deep-fake technology brings forth various challenges for detection systems, such as dataset generalization, adversarial robustness, real-time deployment, and ethics. Solutions to these challenges necessitate novel research to further boost detection accuracy, efficiency, and flexibility.

1) Improving Generalization Across Datasets

Most detection models are poor at handling unknown deep-fakes because they overfit to individual datasets. Transfer learning, contrastive learning, and domain adaptation should be the areas of research in the future to enhance cross-dataset performance and flexibility.

2) Enhancing Robustness Against Adversarial Attacks

Deep-fake developers keep innovating to stay one step ahead of detection. Improving models with adversarial training, self-supervised learning, and perturbation-robust architectures will counter emerging threats.

3) Developing Lightweight and Scalable Detection Systems

Deep-fake manipulations are now expanding into audio and text-based fakes. The combination of lip-sync checking, voice analysis, and sentiment analysis will enhance detection accuracy for cross-modal deep-fakes.

4) Advancing Multimodal Detection Techniques

Deep-fake manipulations now extend beyond visuals to include audio and text-based forgeries. Integrating lip-sync verification, voice analysis, and sentiment detection will improve detection accuracy for cross-modal deep-fakes.

5) Establishing Ethical and Legal Safeguards

The abuse of deep-fakes for misinformation, fraud, and identity theft requires more stringent regulatory controls. Future research must investigate AI-driven watermarking, blockchain-based authentication, and uniform legal frameworks to hold entities accountable.

VI. CONCLUSION

Deep-fake detection research has to advance to address issues in generalization, adversarial robustness, real-time scalability, and multimodal analysis. Future research should be directed towards cross-domain learning, resilient AI architectures, and low-latency detection models for mass-scale applications. Improvements in Explainable AI, blockchain-based verification, and AI-based watermarking can facilitate transparency and accountability. Lightweight, high-performance model development for edge AI and IoT will allow for real-time deployment. By combining deep learning, multimodal analysis, and ethical AI paradigms, scientists are able to design more robust and flexible deep-fake detection systems for the sake of digital security and public trust.

ABSTRACT

Individuals with severe physical disabilities often rely on Brain Machine Interfaces (BMI) to interact with their environment and regain some level of independence. One promising approach for BMI control in the use of Visual Evoked Potentials (VEP), which are electrical signals created in the brain in response to visual stimuli. However, the interpretation of VEP signals, is complex, presenting a barrier to the widespread adoption of VEP based BMIs. Therefore, in this study, a comprehensive model is proposed to boost the performance of VEP-based BMIs through the incorporation of advanced signal processing techniques and explainable Artificial Intelligence (AI) methods. The pre-processing of Electroencephalogram (EEG) signals plays a vital part in optimizing the performance of VEP based BMIs. To achieve this, an Orthogonal Wavelet Filter is employed, which offers extraordinary flexibility in managing the conservation of appropriate emotional data and the diminution of annoying interference. Next, to captivate the time-frequency representations of EEG signals, the Empirical Mode Decomposition (EMD) based Feature Extraction approach is used, which provides a data-driven approach to decay EEG signals into Intrinsic Mode Functions (IMFs), allowing for the extraction of relevant features related to brain activity. For prediction tasks, such as classifying intended movements or commands from EEG signals, a Modified Recurrent Neural Network with Long Short-Term Memory (RNN-LSTM) classifier is employed. The hyper parameters of the Modified RNN-LSTM model are tuned by employing Chaotic Bat Optimization (CBO), which effectively explores the hyperparameter space and optimizes model performance with rapid computational time. The approach is implemented through the python software and the performance metrics such as classification accuracy, recall, precision, and F1 score are compared with the traditional approaches to evaluate the effectiveness of the methodology. From the obtained outcomes, it is evident that the proposed Modified RNN-LSTM approach achieves high accuracy of (96%), thereby enhancing the daily functioning of disabled individuals.

I. INTRODUCTION

Severe neurological and cognitive problems have the potential to damage the brain's communication and control routes with its surroundings. Patients who are severely affected possible to miss all voluntary muscular control, containing the capability to move their eyes, and they become totally immobilized in their bodies, unable to speak in any way. The term "locked-in syndrome" is occasionally used to describe this group of severe illnesses, denoting the incapacity to communicate with or show any intention to the world [1]. Giving the brain a novel, non-muscular channel for communication and control a direct BMI to transmit commands and messages to the outdoor environment would help restore functions and overcome limitations. It is a helpful tool for paralysis patients who struggle to communicate their emotions and ideas through their movements [2–5]. Because of its information transfer rate is high and minimal need for user training, VEP-based BMI systems are frequently employed [6-7].

Functional magnetic resonance imaging, functional near-infrared spectroscopy and EEG are tools employed to measure neuronal activities. The functional EEGs have drawn a lot of research attention because they offer a high temporal resolution and non-invasive monitoring capability for recording information about neuronal responses [8–10]. The Preprocessing of EEG signals plays a vital part in optimizing the performance of VEP based BMIs, which seeks to streamline further processing steps while preserving pertinent data [11]. Increasing the signal to noise ratio is one of pre-processing's key functions in order to improve signal quality. In [12–13] developed a unique Kalman filter-based Bayesian framework and it is able to resolve a significant flaw in model-based filtering, which is the inability to handle signals with various morphologies using a specified model. Nevertheless, applying a Kalman filter is not ideal and actually increase final error levels. In order to enhance the segmentation result, the [14] used a bilateral filter to smooth the image and keep the key borders intact, leaving only the image's overall context. To enhance the protrusion detection performance, it takes the features of human visual perception. Nonetheless, it is necessary to take into account bottom-up saliency detection techniques that enhance performance when combined with pre-processing filters and top-down techniques. Therefore, the Orthogonal Wavelet Filter proposed in this study, which reduces the noise and improves the signal quality. The relevant properties associated with brain activity are then extracted using the feature extraction method. Thus, the Conditional Wasserstein GAN data augmentation strategy is applied to the retrieved features in the manner described by [15–16]. This approach is based on deep generative models and low classification accuracy is caused by features being very congested and lacking a distinct border among features of diverse classes, as evidenced by the distribution of extracted and created features. So, this work utilizes the EMD approach, which records the time-frequency representations of EEG data. For classification of EEG signals several conventional methods such as SVM [17], RNN [18] and CNN [19] are used. However, the problem is the unfair size of class regions, which is lead to inaccurate classification and this issues are resolved by using a developed modified RNN-LSTM classifier. The hyper parameters of the Modified RNN-LSTM classifier is need to be tuned for achieving the better performance. In past various optimization algorithms are used to tune the hyper-parameters of various network and they impose the restrictions on the unsmooth and non-convex nature of the problems [20-21]. To overcome this issues, the proposed work implements the CBO Algorithm, which effectively explores the hyperparameter space and optimizes model performance. The main contributions of this work are

- To reduce undesired interference and preserve relevant emotional information of an EEG signal, an orthogonal wavelet filter is utilized.
- Next, the EMD approach is utilized to obtain the time-frequency representations of the EEG signals.
- A modified RNN-LSTM classifier is used for prediction tasks like categorizing intended movements or orders from EEG signals.
- A CBO Algorithm is used to improve the hyper-parameters of the Modified RNN-LSTM model, hence improving model performance.

II. PROPOSED METHODOLOGY

In recent years, EEG is the most commonly employed because its portability, low cost, easy usage and high temporal resolution. VEP-based BMIs have the potential to help impaired people by offering alternate channels of communication and control due to their information transfer rate is high and minimal need for user training. The proposed work's block diagram is presented in Figure 1.

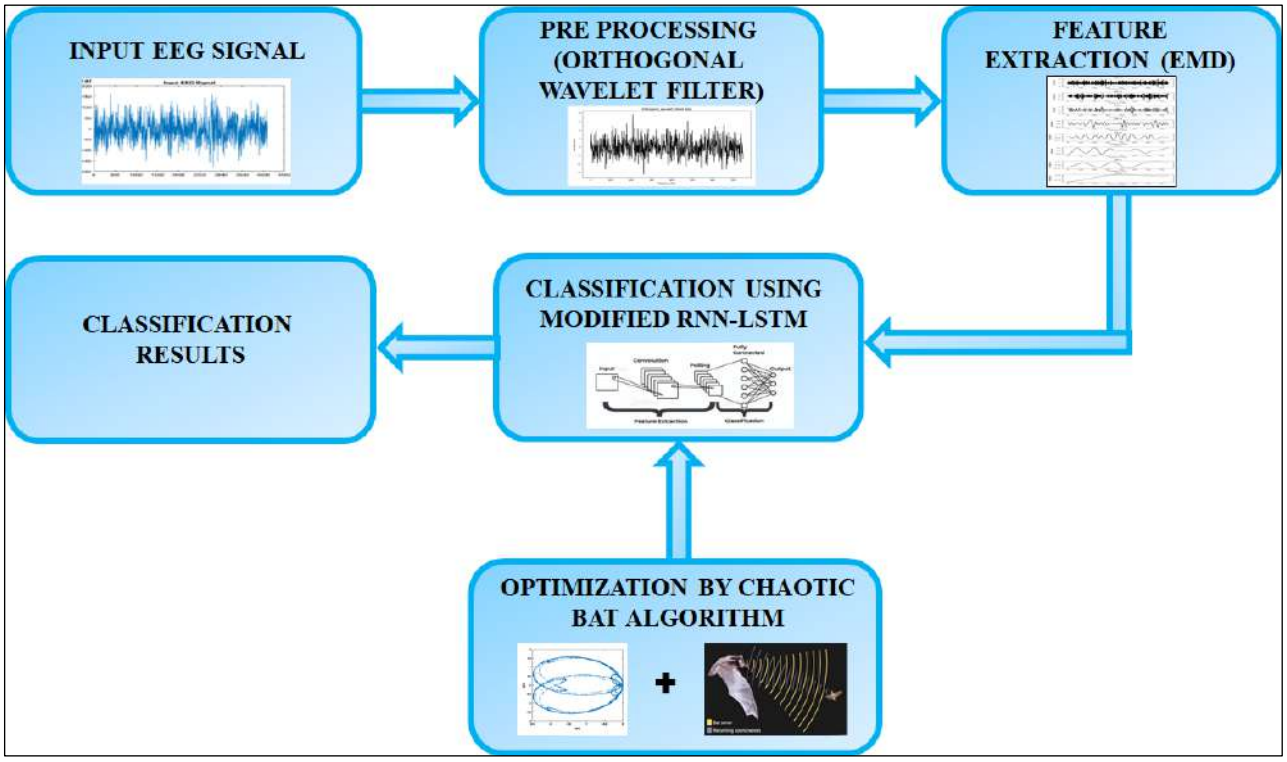

Figure 1: Block Diagram of Proposed Work.
Source: Authors, (2026).

The input signal from EEG are pre-processed by using an Orthogonal Wavelet Filter, which provides excellent flexibility in managing the protection of significant emotional data and the diminution of undesirable interference. This initial pre-processing step ensures that the processed EEG signals are optimally organized for succeeding analysis. Next, to acquire the time-frequency representations of EEG signals, the EMD model is used, which provides a data-driven approach to decay EEG signals into intrinsic mode functions, allowing for the extraction of relevant features related to brain activity. Then it is fed into the modified RNN-LSTM classifier that is used for prediction tasks, such as classifying intended movements or commands from EEG signals. The hyper-parameters of the modified RNN-LSTM model are tuned using a CBO Algorithm, which effectively explores the hyperparameter space and optimizes model performance. Finally, the predicted output is utilized for enhancing the daily functioning of disabled individuals.

II.1 PRE-PROCESSING WITH ORTHOGONAL WAVELET FILTER

Signal improvement and cleaning are the main concerns of pre-processing EEG signals because EEG signals are intrinsically poor, noise from both external and internal sources will easily contaminate them. Human body or electrodes will be the source of the noise and these noises are known as "artifacts." While recording an EEG signal, EEG electrodes able to pick up undesirable electrical physiological signals, such as the Electromyogram from neck muscles and eye blinks. Concerns about motion artifacts resulting from electrode displacement and cable movement also exist when the person moves. Therefore, in order to minimize these artifacts in the raw EEG data, which have an impact on posterior classification, the pre-processing stage is essential. It is important to carefully consider whether these artifacts should be removed because they need to improve the efficacy of emotion detection systems and include important information about emotional states. The bandwidth of the EEG will be reduced by using orthogonal wavelet filters to lessen artifacts in the recorded EEG signals.

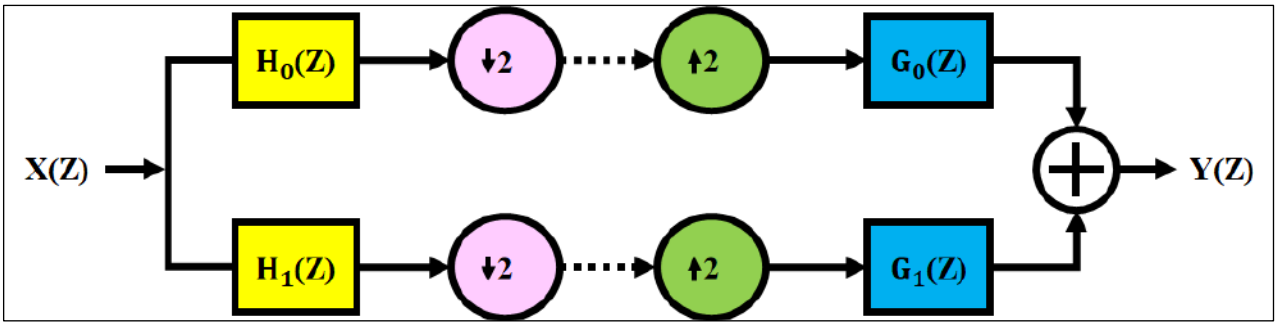

Figure 2: Two-channel orthogonal wavelet filter.

Figure 2 displays the 2 channel wavelet FB. Assume that H_O and H_1 represent the analysis LPF and HPF in a 2 channel wavelet FB, and that G_1 andG_O represent the synthesis High pass filter (HPF) and Low pass filter (LPF). Quadrature mirroring will be used to extract the HPFs H_1 and $G_1$from LPFs, as shown in Eqn1 and 2.

$$H_1(Z) = Z^{-1}G_O(Z) \tag{1}$$

$$G_1(Z) = ZH_O(-Z) \tag{2}$$

The PR condition interms of G_O, G_1, H_O *and* $H_1$is acquired from (3) and c is a constant.

$$H_O(Z)G_O(Z) + H_O(-Z)G_O(-Z) = C \tag{3}$$

In the orthogonal FBs design, LPFs G_O and H_O are mirror images that is assumed by Eqn 4.

$$G_O(Z) = H_O(Z^{-1}) \tag{4}$$

The scaling function $\phi(.)$ is expressed as

$$\phi(t) = \sqrt{2}\sum_n h_o[n]\phi(2t-n) \tag{5}$$

In this case, h_o is an LPF that meets the normalization criterion $\sum_n h_o[n] = \sqrt{2}$ and has at least one zero at $z = -1$. In a similar vein, the matching wavelet function $\psi(.)$ is described as,

$$\psi(t) = \sqrt{2}\sum_n h_1[n]\phi(2t-n) \tag{6}$$

In this case, $h_1[n]$is an HPF that is derived from the LPF using the formula $h_1[n] = (-1)^n h_o[N-1-n]$, where N is $h_o{}'$s support. Through the usage of the double shifting property on LPFh_o, the orthogonal space covered by the wavelet function ψ and scaling function ϕ is produced. This feature of double shifting will be expressed as

$$\sum_n h_o[n]h_o[n-2l] = \delta[l] \qquad \forall l \in N \tag{7}$$

VMs will be guaranteed by smearing sum rules on $h_o[n]$ coefficients of filter and is defined as

$$H_O^{(K)}(e^{j\pi}) = \sum_n (-1)^n n^k h_o[n] = 0 \quad (8)$$

Where v is the Virtual Machine's (VMs) number; k will be transformed between $0, 1, \ldots, v-1$. From (8), makes clear that v sum rules are necessary for v VMs and there is no dc leakage when the value of $v \geq 1$ (which indicates that there are multiple VMs). It is expressed as

$$H_O(e^{j\pi}) = H_1(e^{j0}) = 0 \text{ for } v \geq 1 \quad (9)$$

Thus, it confirms that there is a zero dc leakage and after pre-processing the signal undergoes with feature extraction for extracting the feature by using EMD method.

II.2 FEATURE EXTRACTION USING EMD

The primary objective of feature extraction in the EEG-based emotion detection method is to extract data that accurately captures an emotional state of an individual. The extracted features are mostly responsible for determining the emotion identification's accuracy. Next, it is vital to isolate key EEG characteristics associated with states of emotion. EEG feature analysis using time-frequency domains for emotion recognition will be covered in this part.

II.2.1 Time-Frequency Domain Analyses

The time-frequency domain analysis technique, which incorporates data from the time and frequency domains. Time-varying and non-stationary signals are captured effectively by time-frequency-domain characteristics, then it is utilized to characterize different emotional states. Next, the EMD approach is utilized to obtain the time-frequency representations of the EEG signals. For the study of nonlinear and non-stationary data, EMD is a data-driven decomposition technique that decay the signal into a finite number of smaller IMFs, making it possible to extract pertinent aspects associated with brain activity. A sum of IMFs will be used to describe a non-stationary signal, and each IMF should adhere to the following two necessities:

1) The IMFs' numbers of extrema and zero crossings should be equivalent, or deviate by no more than one.
2) Two envelopes defined by local maxima and minima should have a mean value of zero.

IMFs will be retrieved from a signal using the shifting process, an iterative technique that works as follows:

Connect the detected maxima and minima separately from the signal $x(t)$ to create the upper (e_{max}) and lower (e_{min}) envelops using the cubic spline interpolation method. Compute the mean by

$$m(t) = \frac{e_{max}+e_{min}}{2} \quad (10)$$

Extract the difference $d(t)$ among signal $x(t)$ and calculated $m(t)$

$$d(t) = x(t) - m(t) \quad (11)$$

Check whether $d(t)$ is fulfilling the IMFs simple conditions. Repeat stage 1 to 3 until $d(t)$ fulfilling the IMFs conditions. If $d(t)$ fulfils IMFs condition once, define the initial IMF as $IMF_1 = d(t)$.By producing residue $r(t)$ as $r(t) = x(t) - IMF_1$, one will collect the subsequent IMFs and utilize these residues as the initial data for the subsequent iteration. When the final residue is either a constant or monotonic function, or a function that is incapable of producing any more IMFs, the iteration will come to an end. The real signal will be denoted as the summation of all IMFs and last residual.

$$x(t) = \sum_{i=1}^{K} IMF_i + r_K(t) \quad (12)$$

Where $r_K(t)$is the final residual, K is the IMF number, and IMF_i is the ith IMF. After feature extraction, a modified RNN-LSTM classifier is used for prediction tasks, like categorizing planned movements or commands from EEG signals.

II.3 A MODIFIED RNN-LSTM FOR CLASSIFICATION

Modified RNN is employed for classification after feature selection to detect the class label. The normal feed-forward neural network is extended upon by an artificial neural network type called RNN. An RNN is able to process successive inputs, each of which reflects the firing of the phase before it at each step. One particular type of RNN that will learn from lengthy dependence is called an LSTM. An example of a long-term reliance on a recurrent hidden unit is long awful memory. A typical recurrent layer computes a weighted linear average of the inputs prior to applying a nonlinear function. A recurrent layer with LSTM also forms a memory cell.

For a hyper spectral picture classification task, supply a hyper spectral pixel sequence $x = (x^1, x^{2,\cdots} x^k)$to the input layer. A recurrent layer based on LSTM C_t creates a memory cell at step t. Compute the activation of processing layers by

$$h_t = o_t \tanh(c_t) \quad (13)$$

Here, the output gate that chooses which section of the memory material to display is represented by $o_t \tanh(.)$, which is also the hyperbolic tangent function. Modify the output layer using the following formula.

$$o_t = \sigma\left(W_{oix_t} + W_{oh}h_{t-1} + W_{OCC_T}\right) \quad (14)$$

Weight matrices or W, are used here. The input-output weight matrix is calledW_{oi}, and the memory-output weight matrix is denoted by WOC. Logistic sigmoid function σ (•) is used. New memory cell (C_t) content is inserted, and some of the current memory material is deleted, to modify memory cellC_t.

$$C_t = i_t \odot \bar{C}_t + f_t \circledast C_{t-1} \tag{15}$$

Where $\odot$ denotes element wise multiplication and the new memory cell content C_t is calculated by

$$\bar{C}_t = \tanh\ (W_{cix_t} + W_{ch} h_{t-1}) \tag{16}$$

Then the hyper parameters of the modified RNN-LSTM model are tuned using a Chaotic Bat Algorithm, which effectively explores the hyperparameter space and optimizes model performance.

II.4 MODIFIED RNN-LSTM PARAMETER OPTIMIZATION USING CHAOTIC BAT ALGORITHM

A Chaotic Bat Algorithm is used to tune the hyper parameters of the modified RNN-LSTM model. This method efficiently explores the hyperparameter space and maximizes model performance.

II.4.1 The basic bat algorithm

A Bat Algorithm (BA) was motivated by the echolocation behavior of bats. The size of bats in the wild varies greatly; they surely weigh as little as 1.5 g or as much as 1 kg. Bats utilize a mechanism called echolocation to find and navigate to their prey. Bats detect distance using frequency modulated signals, which have pulses that last between 8 and 10 ms and fall between 25 and 100 KHz in frequency. Bats typically release 10–20 of these bursts every second. However, produce brief bursts of over 200 pulses per second when hunting. Loudness is another feature of these pulses; when hunting or seeking prey, bats will produce ultrasonic pulses that are up to 110 dB loud. However, these pulses become weaker as they get closer to the target. The frequency of every bat is

$$f^i = f^{min} + r_1(f^{max} - f^{min}) \tag{17}$$

The frequencies that are permitted are denoted by f^{min} andf^{max} and the frequency for ith bat is represented byf^i . In this case, r_1 is a random number with uniformly distribution within the interval [0, 1].

II.4.1.1 Exploration or diversification

The velocity V^i and positionX^i are updated by

$$V^i(t+1) = V^i(t) + f^i(X^i(t) - X^{best}(t)) \tag{18}$$

$$X^i(t+1) = X^i(t) + V^i(t+1) \tag{19}$$

The position with the highest fitness in the current population is denoted by X^{best}, where t is the current iteration number. It is expected thatV^i is 0 at startup.

II.4.1.2 Exploitation Or Intensification

With a random walk, local search or exploitation is conducted. For each bat in the population, two parameters are updated at each iteration: the loudness$A^i(t)$ and the pulse emission rate $R^i(t)$. A local search is carried out, either around the optimal solution or a randomly selected solution, depending on$R^i(t)$:

$$X^{i'}new(t) = \begin{cases} X^{best}(t) + r_3 A^i(t) & if\ r_2 > R^i(t) \\ X^r(t) + r_3 A^i(t) & else \end{cases} \tag{20}$$

Where $r[1,2,\ldots.,N_b], r \neq i$ is a randomly selected integer, and r_2 $[0,1]$ $and r_3[-1,1]$are uniformly distributed random numbers. Stated differently, $X^r(t)$represents a solution that was selected at random in the current iteration and is distinct from the ith solution. A competition-style selection process centered on fitness, where the old solutions compete against the new ones. With a probability$A^i(t)$, the more fit answer takes the place of the less fit one.

$$X^i(t) = X^{i,new}(t),\ \text{if}\ f(X^{i,new}(t)) < f(X^i(t)) \text{ and } r_4 < A^i(t)\ \forall\ i, i[1,2,\ldots N_b] \tag{21}$$

In this case, the random number r_4 $[0,1]$ has a uniform distribution. Lastly, while the iterations go on, each bat's loudness (A^i) and pulse emission rate (R^i) are updated:

$$A^i(t+1) = \alpha A^i(t) \tag{22}$$

$$R^i(t+1) = R^i(0)[1 - \exp(-\gamma t)] \tag{23}$$

Here, $A^i(0)[1,2], R^i(0)[0,1]$ both randomly generated within their respective limits.

II.4.2 *Chaotic Bat Optimization (Cbo) Algorithm*

The most significant flaws in the classical BA are seen in the experimental results of the classical BA over benchmark functions: premature and/or erroneous convergence. The primary cause of this is the parameters' random initialization.

The sequences generated during the random initialization procedure are not evenly dispersed, which causes varying outcomes in various runs. The initialization procedure must be carried out in a way that ensures initial sequences are evenly dispersed in order to address these issues. If the numbers in a chaotic sequence are far from the unusual attractors of the chaotic map, they are well dispersed. Strange attractors in chaotic maps occur in a unique parameter space; however, in this approach, parameters are specified in a way that eliminates them, avoiding attractor-related issues.

Therefore, utilizing chaotic sequences will be a very effective strategy to produce well-distributed sequences for handling the algorithm's premature and incorrect convergence. Figure 3 displays the CBA flowchart. Chaotic sequences are utilized to establish frequencies, loudness, and pulse emission rates in order to enhance the performance of the conventional BA. An important component that influences the trade-off between algorithmic exploration and exploitation is the loudness of AI. Since " α " is smaller than unity, this is monotonically decreased in the basic BA as the iterations go on. Better outcomes, however, have been documented when a chaotic map or sequence is used to vary the volume of AI.

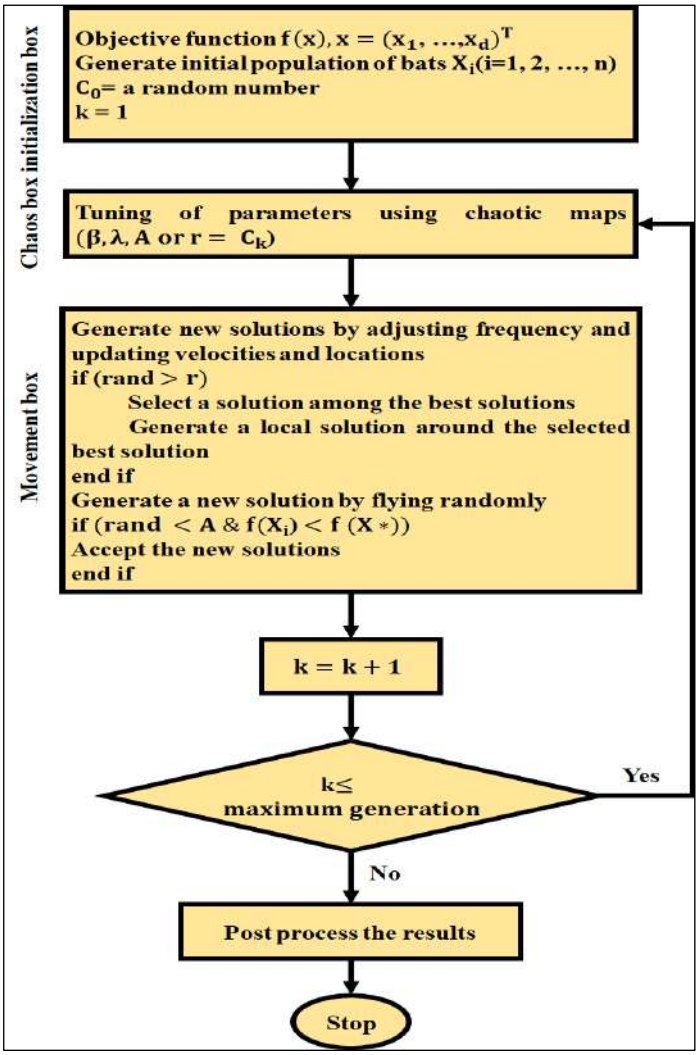

Figure 3: Flowchart of CBO.
Source: Authors, (2026).

In order to train AI to optimize three unimodal and three multimodal functions, several chaotic sequences were tested. The sinusoidal map (or sequence) yielded the best results. Using the sinusoidal map, the variation of the loudness A^i is provided by

$$A^i(t+1) = a\{A^i(t)\}^2 \sin(\pi A^i(t)) \tag{24}$$

Here, $A^i(0)[0,1]$ is randomly generated.

III. RESULTS AND DISCUSSION

A comprehensive approach is proposed to improve the performance of VEP-based BMIs through the integration of advanced signal processing techniques and explainable AI methods. During the pre-processing phase, an orthogonal wavelet filter is used, which provides remarkable flexibility in managing the retention of pertinent emotional information and the elimination of undesired interference. With the use of EMD's data-driven methodology, pertinent features pertaining to brain activity will be extracted. A modified RNN-LSTM classifier is used for prediction tasks and a Chaotic Bat Algorithm is used to tune the hyper-parameters of the modified RNN-LSTM model. This method efficiently explores the hyperparameter space and maximizes model performance. Overall it is implemented in python software and comparative analysis is done with other methods to show the better performance of the work.

Source: Authors, (2026).

Figure 11 depicts the accuracy comparison for various methods like SVM, Deep CNN, RNN and modified RNN-LSTM. The modified RNN-LSTM attained a highest accuracy of 96 % which is better than SVM [22], Deep CNN [23] and RNN [24] methods.

Table 1: Classification measures for each positive, neutral and negative state of emotion.

Dimensions	Accuracy (%)	Precision (%)	F1-score (%)
Positive	87.96	78	81
Neutral	82.41	72	73
Negative	79.63	75	71
[25]			
Positive	98.23	94.012	93.68
Neutral	97.95	92.89	93.32
Negative	94.54	92.087	92.65
[26]			
Positive	98.45	94.45	94.46
Neutral	98	93.12	93.78
Negative [Proposed work]	95	93.06	93.05

Table 1 highlights the classification measures for each positive, neutral and negative emotional State. The proposed method attains the accuracy, precision and F1-score with positive, neutral and negative emotion states are 98.45%, 93.12 % and 93.05 %.
Source: Authors, (2026).

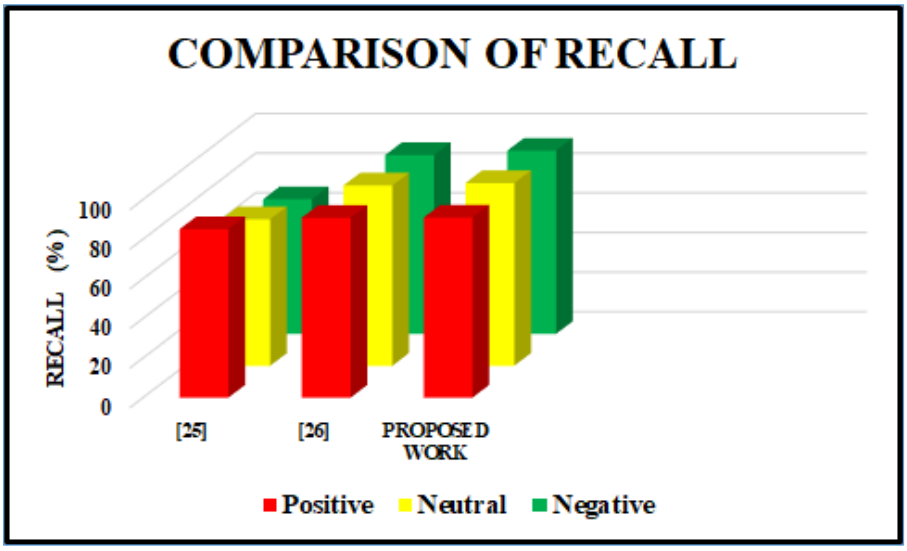

Figure 12: Comparison of Recall.
Source: Authors, (2026).

Figure 12 depicts the recall comparison with positive, neutral and negative emotional state. From the comparison, the proposed model attained a recall value of 90.89%, 92.24% and 92.47 % for positive, neutral and negative emotional state.

III. CONCLUSIONS

This paper proposes a novel method to boost the performance of VEP-based BMIs through the integration of advanced signal processing techniques and explainable AI methods. An orthogonal wavelet filter is initially employed to pre-process EEG signals by reducing undesired interference. The EMD method is then applied to obtain the time-frequency representations of the EEG data, which enables the extraction of pertinent features associated with brain activity. A modified RNN-LSTM classifier is used for prediction tasks and A Chaotic Bat Algorithm is used to tune the hyper-parameters of the modified RNN-LSTM model. This method efficiently explores the hyperparameter space and maximizes model performance. The method is evaluated by using python software and comparative analysis is done with other methods. Performance metrics including classification accuracy, recall precision and F1 score are utilized to measure the efficacy of the proposed methodology. As a result, the modified RNN-LSTM model achieves a highest accuracy of 96 % and better performance interms of Recall, Precision and F1-score.

ABSTRACT

A compact, single-layer multiband microstrip patch antenna is presented that attains six discrete resonances at 2.84, 3.93, 4.34, 5.38, 7.21, and 9.56 GHz on a low-cost FR-4 substrate. The radiator integrates a dual-connected T-slot and four parasitic elements optimized in ANSYS HFSS to achieve multiple resonant modes while retaining a simple single-feed topology. Measured results corroborate full-wave simulations: the best S11 reaches –37.6 dB and the antenna show a peak gain of 5.85 dBi with stable radiation patterns across the operating bands. Parametric studies reveal how slot length and parasitic-element spacing control the lower- and higher-frequency modes and the trade-off between bandwidth and peak gain. Compared with recent single-layer multiband designs, the proposed geometry delivers a higher number of usable bands with modest fabrication complexity, making it suitable for multi-standard wireless devices (IoT, wearable WBAN, and sub-6 GHz 5G). Full fabrication details, measured S-parameters, radiation patterns, and a discussion of practical limitations are included.

I. INTRODUCTION

The fast advancement of Internet of Things tasks demonstrated the essential requirement for effective energy-saving strategies for devices with low power consumption. A notable obstacle encountered by these devices, particularly when utilized in isolated areas, is their dependence on conventional batteries that have predetermined power capacities and restricted durations of use. Conventional energy supply approaches limit the complete capabilities associated with Internet of Things applications because of the regular requirement for battery changes or recharging. This has led to an increasing demand for the exploration of other energy sources capable of delivering a consistent power supply to these devices over extended durations. Multiband microstrip patch antennas (MPAs) remain a thriving research area by virtue of their low profile, low cost, and easy integration with RF circuitry while meeting the growing demand posed by heterogeneous wireless standards — including sub-6 GHz 5G, millimeter-wave (mmWave), IoT/LoRa, satellite, and wearable/WBAN systems. Recent indexed works emphasize cost-effective single-layer designs, compact footprints, and a careful balance of bandwidth, gain, and radiation stability across multiple resonant bands—while minimizing fabrication complexity.

Slotting remains one of the simplest yet effective methods to induce multiple resonances. U-slots, E-slots, slits and asymmetric cuts introduce additional current paths on rectangular patches. For instance, Nahas (2025) presented a triple-band mmWave patch for 5G operating at 28 GHz, 32 GHz, and 38 GHz, with gains of 9.15 dBi, 7.48 dBi, and 12.08 dBi, achieved through multiple slot shapes on a single-layer rectangular patch [1]. Similarly, El Hachimi et al. (2025) designed a compact dual-band RFID antenna (2.45 GHz & 5.8 GHz) on FR-4 using slot techniques in both patch and ground, occupying just 28 × 26 mm² [2].Springer's Umm Al-Qura University group (2025) proposed multiband broadband mm Wave patches using Rogers RO4450B substrates, achieving resonances at 29.26 GHz, 114.55 GHz, and 138.76 GHz, with efficiencies up to 94%, and another design extending continuous multiband coverage up to 335.5 GHz [3].

Another notable study by Nahas (2024) offered a dual-band slotted patch for 5G at 26 GHz and 28 GHz, using hammer slots to improve gain and radiation characteristics on a simple rectangular patch, demonstrating practicality for mobile devices [4].Gopinath&Marichamy (2025) developed a multiband patch for wearable body area networks (WBAN) on FR-4 using slotting, partial ground plane, and band-gap structures. The patch measured 38 × 29.4 mm, showcasing multiband performance suitable for wearable integration [5].RF-MEMS-controlled Minkowski fractal antennas (Microsystem Technologies, 2025) achieved dual-band reconfigurability, selectively activating fractal iterations for frequency agility without changing physical dimensions [6]. Earlier, fractal nested square ring designs (2023) supported multiple bands (C-, X-, Ku-bands) with a compact 24 × 24 mm² footprint and demonstrated ≈7.4 dBi gain with 60% efficiency [7].

Substrate choice remains critical. FR-4 is common for cost-sensitive sub-6 GHz applications but suffers losses at higher frequencies. For mmWave designs, low-loss Rogers substrates (e.g., RO4450B) are preferred to maintain efficiency [3]. Wearable and RFID applications also lean on FR-4 with clever slotting to preserve performance in tight area budgets [2], while WBAN designs still rely on FR-4 with slotting and ground-plane modifications [5]. Miniaturization tends to degrade radiation efficiency, and multiband designs often struggle to maintain stable gain and bandwidth across bands unless carefully tuned [1]–[3]. Though many studies rely on parametric sweeps, there is a growing—but still limited—emphasis on structured optimization methods. For example, the fractal and RF-MEMS hybrid design introduces re-configurability, yet analytical models or multi-objective optimization (MOO) frameworks remain underexplored [6]. Recent studies focus on multiband, miniaturized, and reconfigurable microstrip patch antennas, using techniques like RF-MEMS, parasitic elements, DGS, slots, and slits to enhance gain, bandwidth, and wireless communication performance.[8-11]

II. DESIGN APPROACH FOR THE PROPOSED ANTENNA

II.1 FUNDAMENTAL RECTANGULAR PATCH ANTENNA DESIGN (DESIGN I)

This section presents the step-by-step design procedure adopted to develop the proposed antenna and achieve the desired operating frequency bands. To realize multiband characteristics, four different microstrip antenna configurations were designed and simulated using ANSYS HFSS.

The proposed antenna has been designed by selecting different wireless communication frequencies in GHz, The theoretical formulation of the antenna model was carried out using standard design relations based on the resonant frequency (f), dielectric constant (εr), and substrate thickness (h) as described in . Furthermore, the classical equations provided were employed for the development of a conventional Rectangular Patch Antenna (RPA), considering the forementioned parameters. Equations (1)–(3) were utilized to estimate the patch length (Lp), patch width (Wp), and the feed line width (Wf). Subsequently, the antenna structure was modeled and simulated using Ansys HFSS, a FEM-based electromagnetic analysis tool. Minor adjustments in select design variables were performed to optimize the antenna's performance characteristics. The refined parameter values for the conventional RPA are compiled in Table 1, while the corresponding structure derived from these optimized parameters is depicted in Fig. 1 (Design I). The dimension of patch is given in table I.

II.2 RECTANGULAR PATCH WITH DUAL CONNECTED T SLOT (DESIGN II)

Since the desired frequency band is not achieved with this initial design, further structural modifications are necessary. The ground has remained the same, but the shape of the patch has unique slot design. This slot has been done using equations 7 and 8. Here we proposed the dual connected T slot patch. This novel patch design gives the desired frequency bands, but the gain of antenna is not desirable so further modification in patch design is required to enhance the gain. The S11 [dB] of design II is as shown in Fig. 2

II.3 RECTANGULAR PATCH WITH DUAL CONNECTED T SLOT AND 4 PARASITIC ELEMENTS (DESIGN III)

To have the targeted frequency band, and more gain on desired frequency bands we did slot using equations 7 and 8. Here we proposed the novel 4 parasitic elements design where parasitic elements placed on one side of the patch and other two are placed on the other side of the patch. This novel design along with dual connected T slot and 4 parasitic patch gives more accurate and desired results. The development of the proposed patch antenna is based on the subsequent formulae.

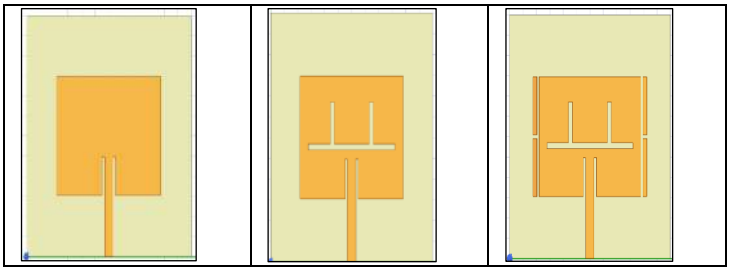

Figure 1: Geometry of novel antenna (a) Basic Patch (b) Patch With Dual Connected T Slot (c) Patch with Dual Connected T Slot and 4 parasitic elements.
Source: Authors, (2026).

Step 1: Determination of the Width (W)

$$W = \frac{c}{2f_o\sqrt{\frac{(\varepsilon_r+1)}{2}}} \quad (1)$$

Step 2: The computation concerning the efficient Dielectric Constant. The parameters are determined by the dielectric constant and height associated with the dielectric material, and the determined width concerning the patch antenna.

$$\varepsilon_{eff} = \frac{\varepsilon_r+1}{2} + \frac{\varepsilon_r-1}{2}[1 + 12\frac{h}{W}]^{-1/2} \quad (2)$$

Step 3: Determination of the Patch Effective length

$$L_{eff} = \frac{c}{2f_o\sqrt{\varepsilon_{eff}}} \quad (3)$$

Step 4: Determination of the patch length extension ΔL

$$\Delta L = 0.412h\frac{(\varepsilon_{eff}+0.3)(\frac{W}{h}+0.264)}{(\varepsilon_{eff}-0.258)(\frac{W}{h}+0.8)} \quad (4)$$

Step 5: Determining the patch actual length

$$L = L_{eff} - 2\Delta L \quad (5)$$

Step 6: Determining the patch slot actual width

$$W_n = \frac{c}{4\,L_{slot}\sqrt{\frac{\varepsilon_r+1}{2}}} \quad (6)$$

Step 7: Determining the patch slot actual length

$$L_{slot} = l_s + w_s \quad (7)$$

Where, f0 - Resonance Frequency, L - Patch length,W - Patch Width ,h – thickness, εr - relative Permittivity related to the dielectric substrate, c - Speed of light which is 3 x 108 m/s

II.4 RECTANGULAR PATCH WITH DUAL CONNECTED T SLOT AND 4 PARASITIC ELEMENTS (DESIGN III)

To ensure optimal performance and impedance matching across desired bands, key geometrical parameters of the proposed antenna were1 optimized through parametric analysis using Ansys HFSS. Table 1 presents the finalized dimensions of the antenna's components, including the patch sizes, slot dimensions, inset feed, and ground plane as shown in figure 2.

III. RESULTS AND DISCUSSION

The results first tested HFSS software for all proposed design. The detailed comparison of simulated and measured results will be discussed in the given section. After getting the desired results for gain and return loss and other important parameters the proposed novel antenna having dual T connected slot and 4 parasitic elements has fabricated as shown in figure 3. The antenna fabricated on FR4 substrate having dielectric constant of 4.4. FR4 has higher loss tangent due to that gain is reduced but cost of the material is very low, so fabricated antenna has low price with good results. The detailed results discussed in further sections.

Table 1: Finalized dimensions of the antenna's component.

Parameter	Dimensions (mm)
Width of the radiating patch element (W)	38
Length of the radiating patch element (L)	28
Width of the microstrip feed line (Wf)	1.8
Length of the microstrip feed line (Lf)	24.8
Length of the ground plane (Gl)	60
Width of the ground plane (Gw)	60
Width of the etched slot in the patch (ws)	28
Length of the etched slot in the patch (ls)	12
Length of each parasitic arm element (Lg1)	14.2

III.1 S11 SIMULATED RESULTS

The antenna has made with three different patch designs as shown in figure 1 and discussed in design section. The return loss compression of all designs is given in figure 4. The conventional rectangle insert field patch design gives the return loss of only 3 bands. To have more frequency band in the same design with same material a novel dual T connected slot design is proposed which gives more multiband frequency as respectively as shown in figure 4. Yet still scope of optimization and to have more frequency bands and better gain.

The proposed novel Rectangular Patch with Dual Connected T Slot and 4 parasitic elements give 6 frequency bands along with more gain on radiating frequencies. The simulated S11 comparison between all the proposed antenna is shown in figure 4. The novel antenna radiates on 2.84 GHz, 4.34 GHz,3.93 GHz,5.38 GHZ,7.21 GHz and 9.56 GHz. The notch of the can be controlled by changing the value of ls and ws which is length and width of the slot given in table 1. The simulated results of S11 return loss notch is as shown in figure 5. The antenna has notch frequency of 4.42-5.28GHz, 5.53-6.39GHz,6.50-7.12GHz,7.32-7.64GHz and 7.82-9.49GHz. The notched return loss is as shown in figure 5.The antenna give four different notches which can used for frequency jammer.

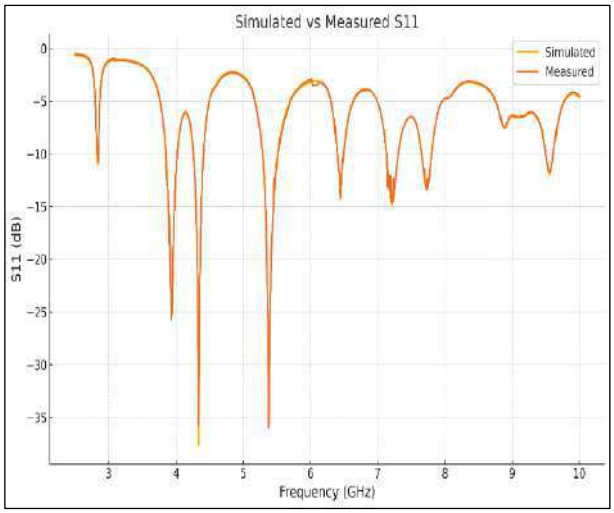
III.2 SIMULATED AND MEASURED S11 RESULTS COMPARISON

As the detail comparison of S11 simulated for all proposed antenna has given in figure 4. The comparison shows that Dual Connected T Slot and 4 parasitic elements give better results for multiband as well as also gives good directional gain on radiating frequencies. So, from simulated results we fabricated the novel Dual Connected T Slot and 4 parasitic elements patch antenna. The antenna is fabricated on FR4 substrate which is low cost. The fabricated antenna top and bottom view is shown in figure 3. As shown in figure 5 the antenna was tested on VNA to measure the return loss S11. The measurement setup is shown in figure 7 where the fabricated antenna's S11 was tested on 2-18GHz VNA at Entuple Technology.

The comparison of simulated and measured results of Dual Connected T Slot and 4 parasitic elements is shown in Fig 6. The results show more accurate match of simulated and measured on each frequency band. The measured result shows a minor mismatch and a little change in frequency, which could be caused by fabrication minor error and mismatch at the excitation port.



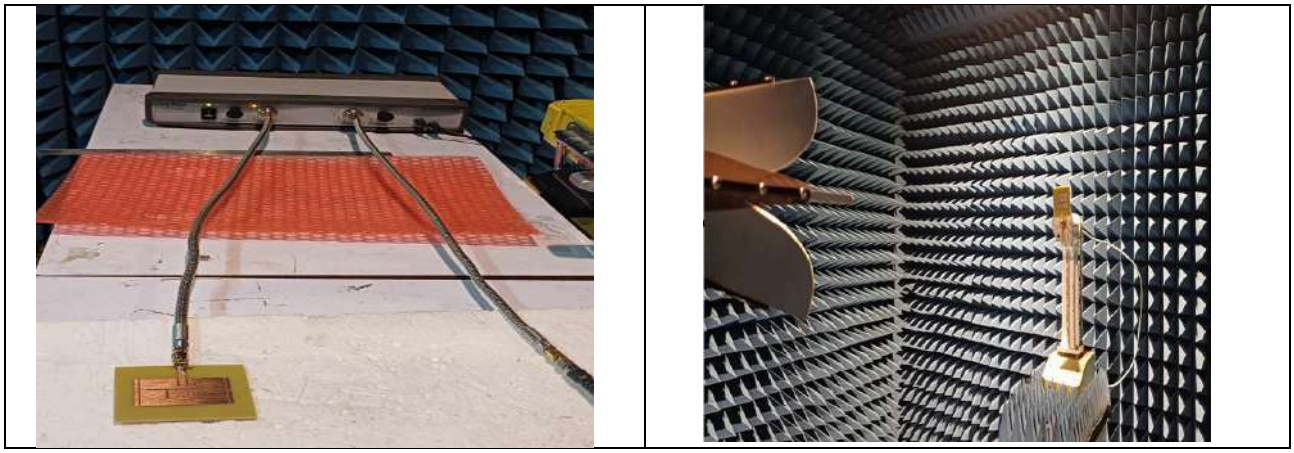


Figure 6: Return loss comparison of simulated and fabricated antenna
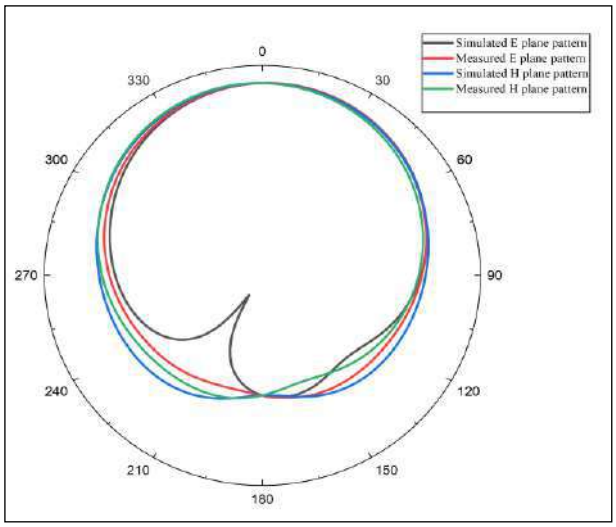
Source: Authors, (2026).



III.3 RADIATION PATTERN COMPARISON AND ELECTRIC FIELD DISTRIBUTION

Figure 8 presents the simulated radiation patterns and gain characteristics of the proposed antenna. The radiation patterns demonstrate stable and nearly omnidirectional behavior in the lower frequency bands, which is desirable for wide coverage applications, while at higher frequencies, the patterns exhibit slight distortions due to higher-order mode excitation and surface current variations. The antenna maintains good gain performance across all operating bands, with peak gains increasing progressively with frequency. These results confirm that the proposed design achieves efficient radiation with consistent gain levels and acceptable pattern stability across the multiband spectrum, making it suitable for modern wireless and communication applications.

Source: Authors, (2026).

Figure 9 illustrates the simulated electric field distributions of the proposed antenna at its various resonant frequencies: (a) 2.84 GHz, (b) 4.34 GHz, (c) 3.93 GHz, (d) 5.38 GHz, (e) 7.21 GHz, and (f) 9.56 GHz. The field distributions reveal how the surface current and electric field intensities are concentrated over different regions of the radiating patch and ground plane at each resonance, indicating the excitation of distinct resonant modes. At lower frequencies, the field is primarily distributed over the entire patch, corresponding to the fundamental mode, whereas at higher frequencies, multiple localized field maxima are observed, signifying the presence of higher-order modes and complex coupling effects. These variations confirm the antenna's capability to support multiband operation with efficient radiation characteristics across the designated frequency bands.

Table 2: Comparison of different antenna on different frequency and application

Ref.	Design Approach	Bands Covered	Substrate / Size	Peak Gain / Eff.	Application
[1]	Multi-slot rectangular patch	28, 32, 38 GHz	Single-layer FR-4, compact	9.15, 7.48, 12.08 dBi	5G mmWave devices
[2]	Slotted patch + ground	2.45, 5.8 GHz	FR-4, 28 × 26 mm²	~2.1 dBi, compact	RFID readers/tags
[3]	Broadband multi-slot mmWave	29.3, 114.6, 138.8 GHz (also 19–335 GHz)	Rogers RO4450B	Eff. up to 94%	5G/6G mmWave& THz
[4]	Dual hammer-slot patch	26, 28 GHz	FR-4	8.92 & 9.71 dBi	5G smartphones
[5]	Slotting + partial ground + EBG	Multiband (WBAN/ISM)	FR-4, 38 × 29.4 mm²	~3–4 dBi	Wearable WBAN
[6]	RF-MEMS reconfig. Minkowski fractal	Dual-band reconfigurable	FR-4 + RF-MEMS	Switchable bands, ~3 dBi	Cognitive / reconfig.
[7]	Fractal iterations (nested rings)	C, X, Ku bands	FR-4, 24 × 24 mm²	7.4 dBi, 60% eff.	Multiband wireless
Proposed Antenna	Dual Connected T Slot and 4 parasitic elements	2.84,4.34 3.93 5.38,7.21 GHz and 9.56 GHz	Single-layer FR-4, compact	5.85dB	Multiband wireless

Source: Authors, (2026).

The proposed novel antenna gives 6 radiating frequency bands has –10.34 dB, –25.64, -37.57 dB, -35.75dB, 14.68 and –11.67 dB reflection coefficients at 2.84 GHz, 3.93 GHz, 4.34 GHz,5.38 GHZ,7.21 GHz and 9.56 GHz. This solution has a return loss of -37.57dB, which matches impedance better than current works in the 2.4 GHz band [1–7]. The antenna has peak gain of 5.85dBi and maintain the high gain throughout the three working bands, these comparisons show that the Dual Connected T Slot and 4 parasitic elements shape is unique and performing, making it a promising multiband wireless communication systems.

IV. CONCLUSION

This work introduced a compact, single-layer FR-4 micro strip patch antenna employing a dual-connected T-slot and four parasitic elements to realize six resonances at 2.84, 3.93, 4.34, 5.38, 7.21, and 9.56 GHz. Simulations and measurements align closely: the prototype achieved a best measured S11 of –37.6 dB and a peak gain of 5.85 dBi, confirming the efficacy of the slot–parasitic combination for dense multiband operation. The main contribution is a practical, fabrication-friendly single-feed single-layer geometry that increases the number of resonances without resorting to stacked substrates or overly complex feeds. Limitations include elevated dielectric loss and slightly reduced efficiency at the highest band due to the FR-4 substrate and observed small shift in resonant frequency from fabrication tolerances. The antenna's compact size and measured performance recommend it for multi-standard embedded wireless modules. The following prioritized future work aims to address re configurability, array integration, robustness, and system-level validation to extend applicability to dynamic multi-band systems.

V. FUTURE WORK AND EXPERIMENTAL VALIDATION

Reconfigurability (short-term, high priority): Integrate RF-MEMS or PIN-diode switching within the T-slot network to enable dynamic band selection. Quantify insertion loss, switching speed, linearity, and on-state/off-state isolation in measurements (see recent RF-MEMS reconfigurable antenna work).

Array integration & mutual coupling (short-term): Build a 2×2 or 4×4 array based on the element to study coupling, beam-forming capability, and MIMO metrics (ECC, DG) via measured S-parameters and pattern scans. Evaluate element spacing trade-offs and feed network design. Multi-objective optimization & tolerance analysis (medium-term): Apply NSGA-II or similar multi-objective methods to jointly optimize bandwidth, gain, and footprint; run Monte-Carlo / tolerance analysis for realistic PCB fabrication variability. System-level validation (medium-term): Use 3GPP channel models and link-level simulations to estimate BER/throughput when the antenna is used in target scenarios (IoT/WBAN/sub-6 GHz NR). If feasible, perform over-the-air tests with a small transceiver.

ABSTRACT

Rolling element bearing faults are among the leading causes of failure in rotating machinery, leading to unexpected downtime, increased maintenance costs, and reduced system reliability. Consequently, significant research efforts have been devoted to developing effective bearing fault diagnosis techniques. This paper presents a comprehensive and structured review of bearing fault diagnosis studies, focusing on three key aspects: experimental data sources, signal analysis techniques, and expert-system-based diagnostic approaches. Both publicly available benchmark datasets and customized experimental setups reported by individual researchers are systematically examined to highlight their characteristics, fault types, operating conditions, and suitability for fault diagnosis and prognostics. The review further categorizes commonly adopted signal processing techniques applied to vibration and related signals, including time-domain, frequency-domain, and time–frequency-domain methods, with particular emphasis on feature extraction strategies used to characterize bearing defects. In addition, expert systems ranging from traditional machine learning algorithms to advanced deep learning models are reviewed and compared based on their reported usage trends and diagnostic capabilities. By consolidating fragmented research outcomes, this review provides a unified perspective on current practices in bearing fault diagnosis and identifies key directions for future research toward more reliable, generalizable, and industry-oriented diagnostic frameworks.

I. INTRODUCTION

Rotating machines are crucial in the modern industrial system including manufacturing, petrochemical plant, aviation, and the chemical process [1]. The basic parts of these rotating machineries consist of the shaft, bearing, stator and rotor, which are the components of these machines. Bearings assist in rotating shafts and allow the smooth and efficient work. Failure in a bearing system can greatly influence the performance of a machine, leading to unwanted down time and decreased effectiveness [2]. As bearings account for a major portion of failures in rotating machinery, their condition is intimately connected with system reliability [3]. These failures may be localized, minor, or large-scale, and when ignored, could change into expensive failures. So condition-based monitoring and fault diagnosis have become important constituents of the contemporary maintenance strategies [4]. Continuous obsevation of equipment condition and detection of defects prior to breakdown is called condition monitoring.

Vibration monitoring is among the most efficient ways of assessing the health of the bearings. The vibration signals hold data relating to the condition of the mechanical system, both in term of operating condition and presence of bearing defect [5]. The vibration data can be continuously monitored, and the defect of the bearing can be identified at the initial stage, which facilitates the routine maintenance of the bearings and reduces the risk of the catastrophic failure to a minimum [6]. Bearing fault diagnosis (BFD) involves several important steps.

First, data is collected through sensors that monitor vibration, temperature, and acoustic emissions, the most frequent one being the vibration sensor. This captured data for vibration is then pre-processed to eliminate noise and emphasize fault-relevant frequencies, often achieved through techniques like filtering or envelope analysis. The next phase is feature extraction, where both time-domain and frequency-domain characteristics such as Root Mean Square (RMS), peak-to-peak value, mean-to-peak value, and fault frequencies (e.g., BPFO, BPFI) are identified. In order to enhance the accuracy of detecting faults, statistical methods, machine learning models, or pattern recognition methods are implemented to identify the type of faults. Figure 1 illustrates the steps that are entailed in BFD.

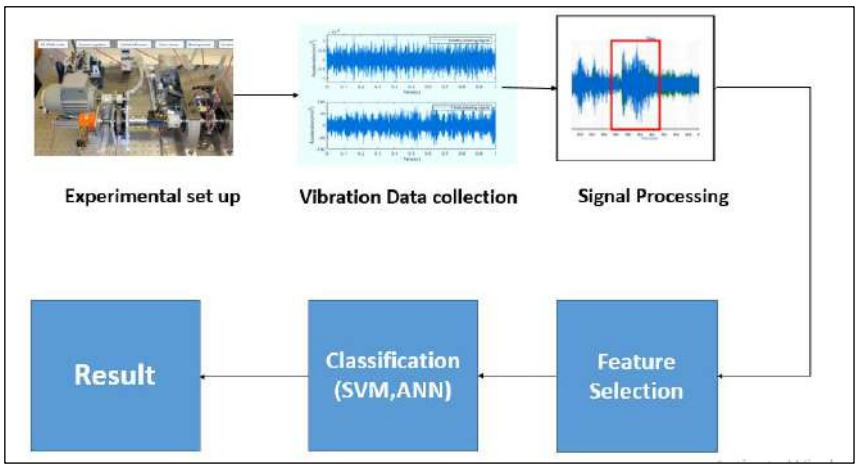

Figure 1: Step for fault diagnosis of bearing.
Source: Authors, (2026).

Even though the number of review papers on the topic is quite large, new surveys are necessary due to the constant implementation of innovative practices and technologies in this field, as well as the comparison of multiple signal processing methods and machine learning approaches with their advantages and disadvantages.The objectives of this article are to briefly introduce vibration analysis, some recent advances in experimental setups to collect data, fault diagnostics, and bear fault classification, and compare various signal processing methods and machine learning approaches. A systematic screening was performed, which involved the removal of duplicates, assessment of titles and abstracts and the full-text analysis to make sure that they are relevant and of good quality. Articles that studied bearing vibration, fault diagnosis, signal-processing techniques, datasets, as well as review articles were retained. A total of 83 papers were studied in this research. Of these, only original experimental and methodological studies are summarized in Table 2, while review articles and dataset descriptor papers are discussed separately and not included in the table. The main contributions of this review are: 1. A structured taxonomy of datasets, signal processing, and diagnostic models 2. A comparative analysis of methodological trends over the last decade; 3. Identification of key research gaps limiting industrial applicability; and 4. Future research directions toward robust and transferable diagnostic systems.

II. EXPERIMENTAL SETUP FOR DATA ACQUISITION

The quantity and quality of datasets have a direct impact on the performance of different fault detection methods. Existing studies can be broadly categorized into those utilizing publicly available benchmark datasets and those employing customized experimental setups.

II.1 *Open-Source Datasets*

The following are a few publicly available bearing datasets that are used to diagnose and detect bearing faults:

II.1.1 *CWRU dataset*

The CWRU dataset is one of the most widely used benchmarks for bearing fault diagnosis. Figure 2 shows the experimental setup for CWRU dataset. Bearing vibration signals were recorded at various motor speeds under different bearing defect conditions [7],[8].

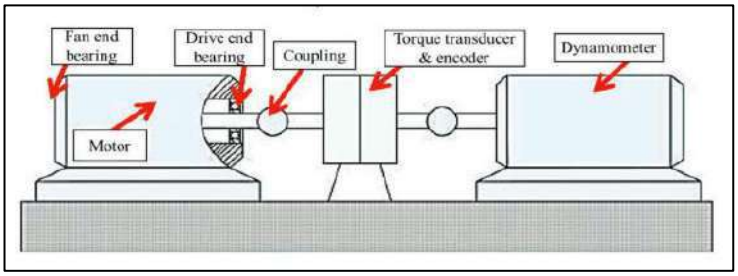

Figure 2: Practical setup for CWRU.
Source: [9].

The experiments were performed on a motor–bearing test rig consisting of a motor, a sensor, and a dynamometer. Artificial single-point defects of different diameters were created on the test bearings using EDM, with SKF-6205 and SKF 6203 bearings used for smaller faults and NTN bearings were used for larger faults. Data were recorded through a multi-channel system and processed in MATLAB, with different sampling rates (12kHz,48 kHz). Speed and load information came from the torque transducer. Since outer race defects remain stationary, their position relative to the load zone strongly affects the vibration response. Therefore, tests were carried out with the defect located at 3, 6, and 12 o'clock positions to study this influence [7],[9]. Although the CWRU dataset is widely used and well-annotated, its reliance on artificially seeded faults under steady-state laboratory conditions limits its representativeness for real industrial fault evolution.

II.1.2 Paderborn university dataset

A dedicated test rig was constructed at Paderborn University to collect experimental data for developing condition monitoring techniques for damaged bearings using motor current signals. To examine the effects of different parameters and confirm the resilience of the condition monitoring techniques under these circumstances, the ring was operated under a variety of operating situations. The dataset includes several bearing test conditions created by varying motor speed, applied torque, and radial load [10].

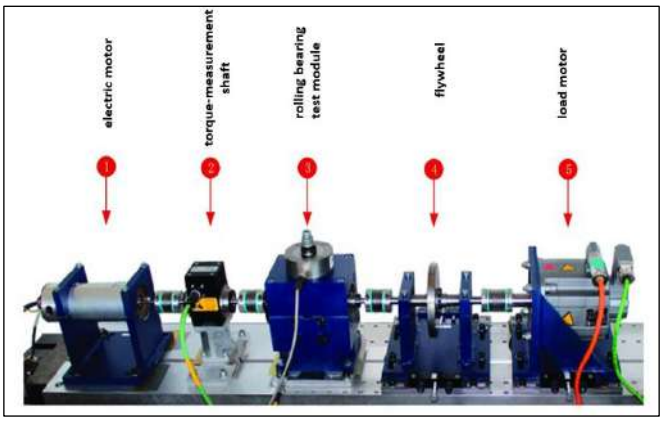

Figure 3: Practical setup for Paderborn University.
Source: [11].

The test rig runs at a 1500 rpm and force in the radial direction of 1 kN and a torque of 0.7 Nm in the basic configuration (Set No. 0). In the next set, each parameter is gradually reduced until the speed is 900 rpm, the force is 400 N, and the torque is 0.1 Nm. Twenty measurements, each lasting four seconds, were taken for every arrangement. Throughout all of the experiments, the temperature was maintained between 45 and 50 degrees Celsius. A total of 32 bearings were evaluated; 12 of these had artificial damage, and 14 of them had damage from accelerated lifetime tests. The dataset lists different faulty bearings according to where the damage occurred. Bearings labelled OR1 to OR5 outer race flaws, including plastic deformation characterized by indentation and fatigue pitting. The inner race faults of bearings with labels IR1 to IR5 are only identified by fatigue pitting [11]. While this dataset introduces natural and accelerated degradation, it is still limited by a single test rig and specific operating conditions, which may restrict generalization to other industrial machines.

II.1.3 Pronostia dataset

An experimental platform called PRONOSTIA was created to test and validate bearing defect detection, diagnosis, and prediction techniques. Its main objective is to give real-world data that follows ball bearing degradation throughout the course of their whole existence, up till failure. It was developed at the FEMTO-ST institute's AS2M department. Many trials can be carried out in a single week to speed up bearing degradation, which allows the completion of multiple studies in a shorter time period [12]. A rotating mechanism, a deterioration generation system that exerts radial load on the bearing being tested, and a measurement system are the three main parts of PRONOSTIA, as shown in Figure 4.

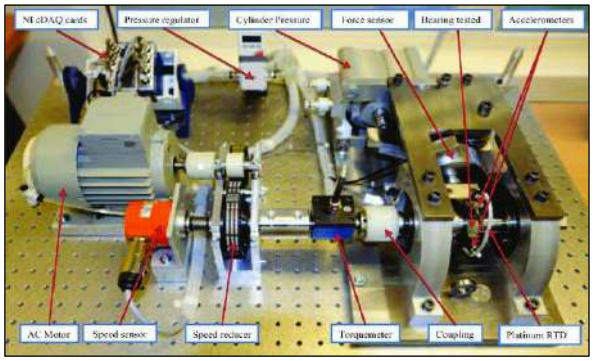

Figure 4: Practical setup for PRONOSTIA platform.
Source: [12].

The PRONOSTIA bearing dataset provides detailed information on the performance and degradation of a 6804 ball bearing under varying conditions. It records data at a high sampling frequency of 25,600 Hz, capturing the bearing's behavior at different load and speed condition. The bearing is tested for a maximum runtime of 126 minutes. The dataset focuses on natural faults, including wear in the balls or races of the bearing, which simulates real-life degradation over time. This data is valuable for studying bearing performance and predicting potential failures [12]. The main limitation of PRONOSTIA is the restricted variety of bearing types and fault modes, which may constrain the transferability of prognostic models trained on this dataset.

II.1.4 *IMS dataset*

In the IMS dataset, four bearings (Rexnord ZA-2115) are mounted on the shaft, which is run with the help of belt drive. A force of 26.68 kN is applied on the bearing in the radial direction with the help of a spring mechanism. Every bearing was pressure-lubricated. Two accelerometers (PCB 353B33) were installed on the housing for data collection. Figure 5 displays the location of the sensor. Breakdown occurs after the bearings have gone beyond their intended lifecycle of 100 million revolutions [13]. Although valuable for prognostics, the IMS dataset includes a limited number of bearings and fault types, which restricts its applicability for multi-fault classification studies.

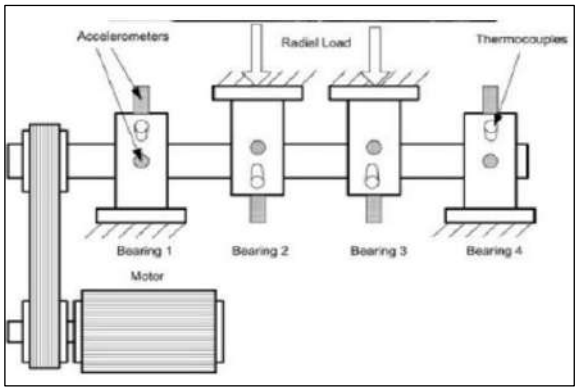

Figure 5: Practical setup for IMS dataset.
Source: [13].

II.1.5 HUST Bearing Fault Dataset

The HUST bearing fault dataset contains both artificially and naturally occurring bearing defects. However, since generating natural faults is more complex, the defects in this dataset were artificially created. The focus is on electric motors running under low loads, and the bearings used for defect creation are of types 6204, 6205, 6206, 6207, and 6208. The dataset includes only a single fault at different places, like the ball, outer race, and inner race. Combination of defects are also considered for this dataset. Figure 6 shows this defect in the bearing at different places. The initial size of the fault is a 0.2 mm microcrack created by using a wire cutting machine.

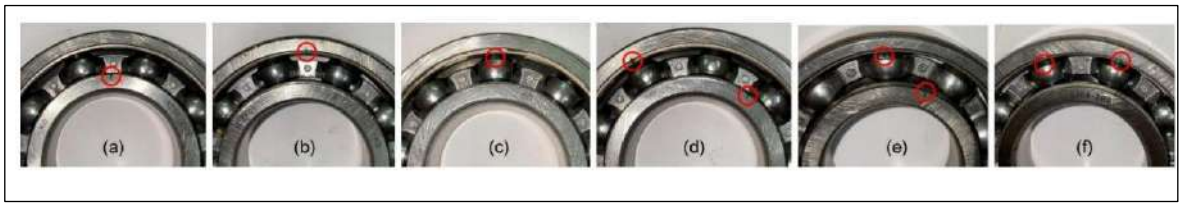

Figure 6: Bearing Defect for HUST bearing Test.
Source: [14].

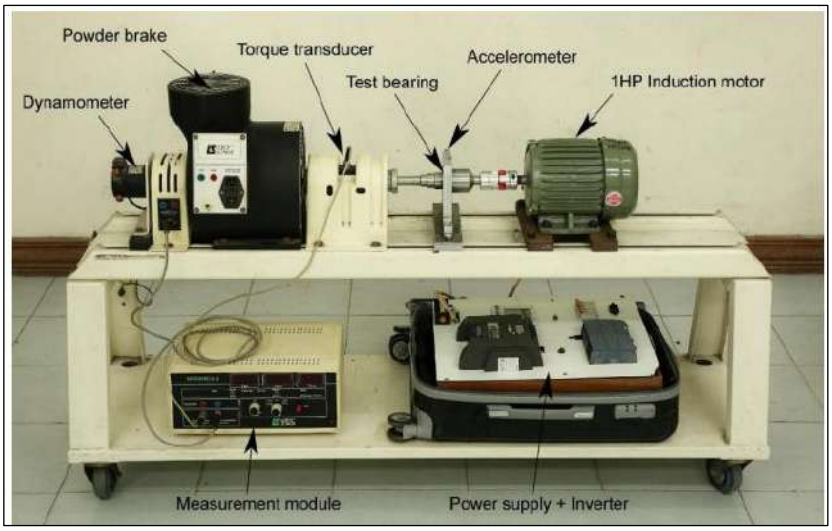

Figure 7**:** Practical setup for HUST bearing Test.
Source: [14].

Figure 7 shows the setup for the HUST dataset. The dataset includes 30 prototype defective bearings tested under three different load variations. Additionally, the dataset includes vibration data for defective bearings during a 5-second run-up period. The vibration signals observed during run-up can help identify potential bearing issues early on, especially in high-power electric motors that require time to start. Notably, all the data was gathered at a sampling rate of 51.2 kHz, enabling precise recording of signal variations [14]. Since most defects in this dataset are artificially induced, the vibration patterns may differ from those produced by naturally evolving faults in industrial environments.

II.1.6 XJTU-SY bearing dataset

This dataset contains vibration data collected from rolling element bearings operating under three different working conditions with different rotational speeds and radial loads. The signals were measured using horizontal and vertical accelerometers with a sampling frequency of 25.6 kHz, and data were recorded every minute until the bearings failed. Unlike many datasets that use artificially introduced defects, this dataset captures the natural degradation process of bearings. Because of this, it is widely used in research on remaining useful life prediction, and it is often treated as a benchmark dataset in prognostics studies [15]. Despite its usefulness for degradation modeling, the dataset is limited by a fixed sensor configuration and controlled loading, which may not reflect complex field conditions. Figure 8 shows the experimental set up for XJTU-SY Bearing Dataset.

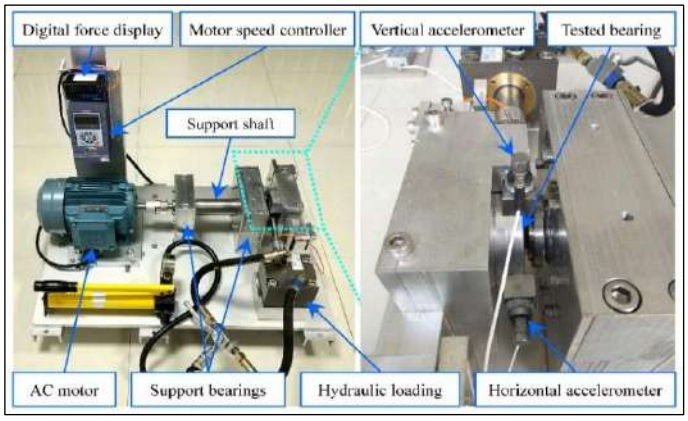

Figure 8: Experiment setup and Failure bearings XJTU-SY Bearing Dataset.
Source: [15].

II.1.7 University of Ferrara dataset

The University of Ferrara bearing dataset is a new run-to-failure dataset, which has become a focus of bearing health monitoring studies. The experimental resources (self-aligning ball bearings) were used in this setup by being run under controlled conditions of speed and load until failure, and vibration measurements were recorded during the lifetime of the bearing. The dataset provides long-term degradation signals, which are useful for studying fault progression, designing health indicators, and developing remaining useful life prediction models [16]. Due to the realistic operating conditions and the high-quality vibration measurements obtained in the experiments, the dataset is cosidered to be a useful benchmark to current data-driven and deep learning-based bearing prognostics research.

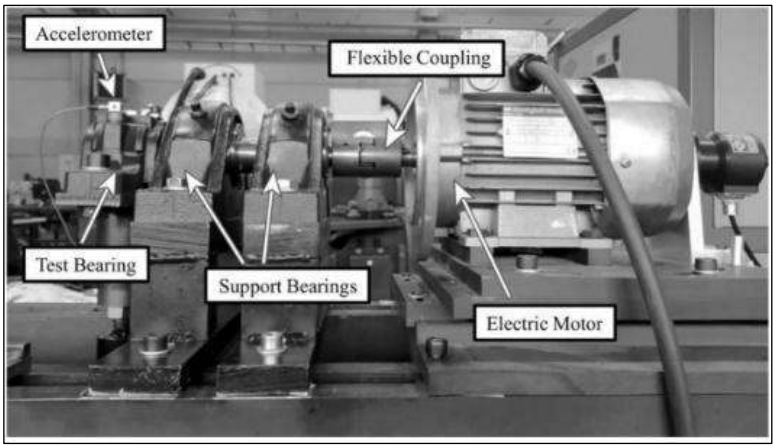

Figure 9: Experiment setup for University of Ferrara.
Source: [16].

II.1.8 Vishwakarma university, Pune dataset

In this research, a comprehensive and organized dataset was created to facilitate the diagnosis and detection of rolling bearing faults in dynamic operational conditions. The experiment was carried out at Vishwakarma Institute of Technology, Pune, with ball bearings (type 608-2RSH & SKF) for testing purposes at three different motor speeds and at two load levels (no load and full load with a 1.25 kg weight and a gearbox). The test ring for performing the experiment is shown in Figure 10. Faults with varying sizes (0.3 mm depth, 0.5 mm breadth) were produced at various locations in the bearing.
Vibration data was acquired through two accelerometers of 100 mV/g sensitivity installed in horizontal and vertical positions on the bearing housing to collect vibration data comprehensively. Data collection was conducted at a sampling rate of 12 kHz at 6-second intervals for every condition by an Instruments USB-6212 DAQ system [17]. It provides real laboratory measurements suitable for fault diagnosis, feature extraction, and machine learning-based classification studies.

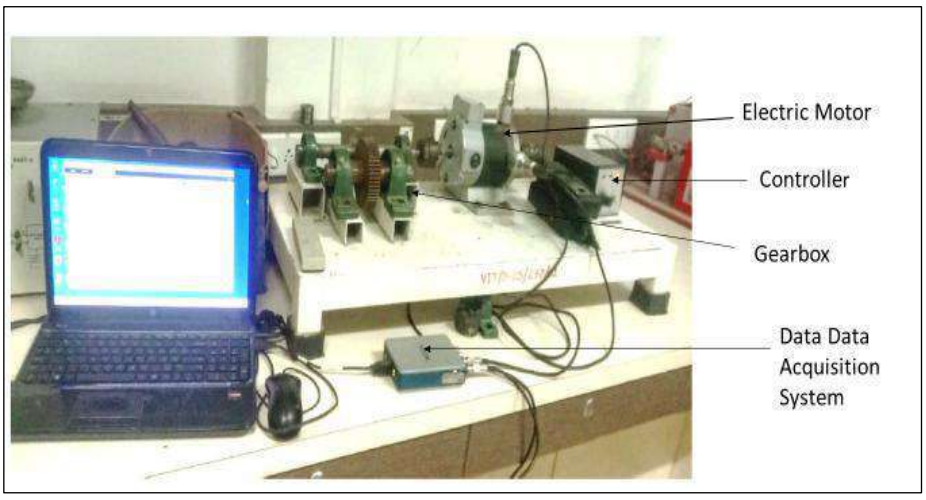

Figure 10: Experimental setup Vishwakarma University.
Source: [17].

Figure 11 presents the distribution of bearing fault diagnosis studies according to the datasets employed. The CWRU dataset is the most extensively used, reflecting its wide acceptance as a benchmark due to its availability, clear fault annotations, and controlled experimental conditions. The IMS and PRONOSTIA datasets also receive considerable attention, as they support degradation analysis and prognostics in addition to fault diagnosis. Moderate usage of the Paderborn and XJTU-SY datasets indicates growing interest in more complex and realistic operating conditions.

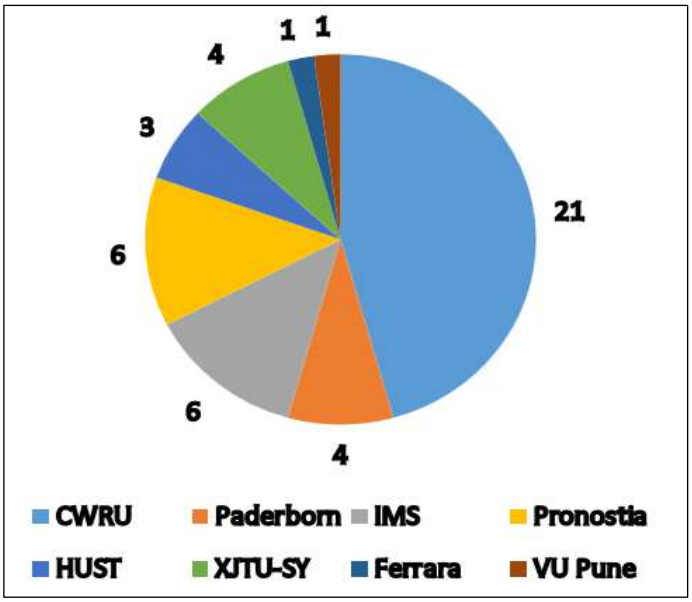

Figure 11: Dataset usage distribution.
Source: Authors, (2026).

In contrast, datasets such as HUST, Ferrara, and VU Pune are used less frequently, highlighting limited availability or narrower application scope. Overall, the distribution demonstrates a strong reliance on a small number of benchmark datasets, suggesting the need for broader validation using diverse and real-world datasets. This Table 1 summarizes the key publicly available bearing datasets by highlighting their operating conditions (speed and load), fault generation strategy, bearing type, and intended application. It clearly distinguishes datasets used mainly for fault diagnosis with localized induced defects from those designed for prognostics using run-to-failure progressive faults, helping researchers select appropriate data sources for their studies.

Table 1: Comparison of publicly available bearing datasets.

Sr.No	Dataset	Speed variation (rpm)	Load	Fault Type Category	Bearing Type	Utilization
1	CWRU	1730 to 1797	0HP, 1HP, 2HP	Localized induced faults	6205, 6203	Fault diagnosis
2	Paderborn	900 to 3000	400N,1000N, 3000N	Localized induced,Progressive continuous faults run-to-failure	6203	Prognostics, Fault diagnosis
3	IMS	2000	6000lbs	Progressive ,continuous faults run-to-failure	ZA2115	Prognostics
4	Pronostia	1550 to 1800	4kN,4.2kN,5kN	Progressive,continuous faults run-to-failure	6804	Prognostics
5	HUST	1400	0HP,200W,400W	Localized induced faults	6204 to 6208	Fault diagnosis
6	XJTU-SY	2100 to 2400	10kN, 11kN, 12kN	Progressive,continuous faults run-to-failure	LDK UER204	Prognostics
7	University of Ferrara	2400	3kN, 4kN, 4.7kN, 5kN	Progressive, continuous faults run-to-failure	1205 ETN 9	Prognostics
8	Vishwakarma University, Pune, India	950,1250,1950	1.25 kg mass and a gearbox	Localized induced faults	608-2RSH & SKF	Fault diagnosis

Source: Authors, (2026).

While benchmark datasets such as CWRU and IMS have enabled rapid methodological development, their limited variability in operating conditions and artificially seeded faults restrict generalization to industrial settings. In contrast, run-to-failure datasets like PRONOSTIA and XJTU-SY support prognostics research but are limited by cost, availability, and sensor diversity.

II.2 CUSTOMIZED EXPERIMENT SETUP USED BY RESEARCHER

In spite of these advantages, benchmark datasets are not able to exhaust all of the work related to real-life operating conditions and have encouraged numerous researchers to develop specialized experimental systems. In order to working around the shortcomings of benchmark datasets, a number of researchers have created specific experimental configurations that are unique to individual machines, operating conditions, and fault cases.

They consist of a motor, coupling, bearing housing and adjustable loading mechanism in which the speed, load and lubrication can be accurately controlled. Seeded defects are typically introduced using machining techniques to create known fault conditions to use in diagnostic studies, e.g., inner-race, outer-race, or ball defects. According to [18] use a magnetic ring to provide load and place two bearings (ER16) one healthy and one with seeded faults as shown in Figure 11(a). In [19] measures the thermal data with infrared imaging camera as depicted in Figure 11(b). In this experiment, dead weights are used in the introduction of the applied load. Patil et al. (2017) use a spring-balance system that allows varied loading conditions to be controlled. In their study, Ambrozkiewicz et al. develop a special experimental rig that will produce quality vibration data to analyze the behavior of bearings in various internal clearances [20]. Create an experimental facility, which is high-speed and not loaded at all as shown in Figure 12(c), to examine bearing dynamics at large rotational speeds [21].

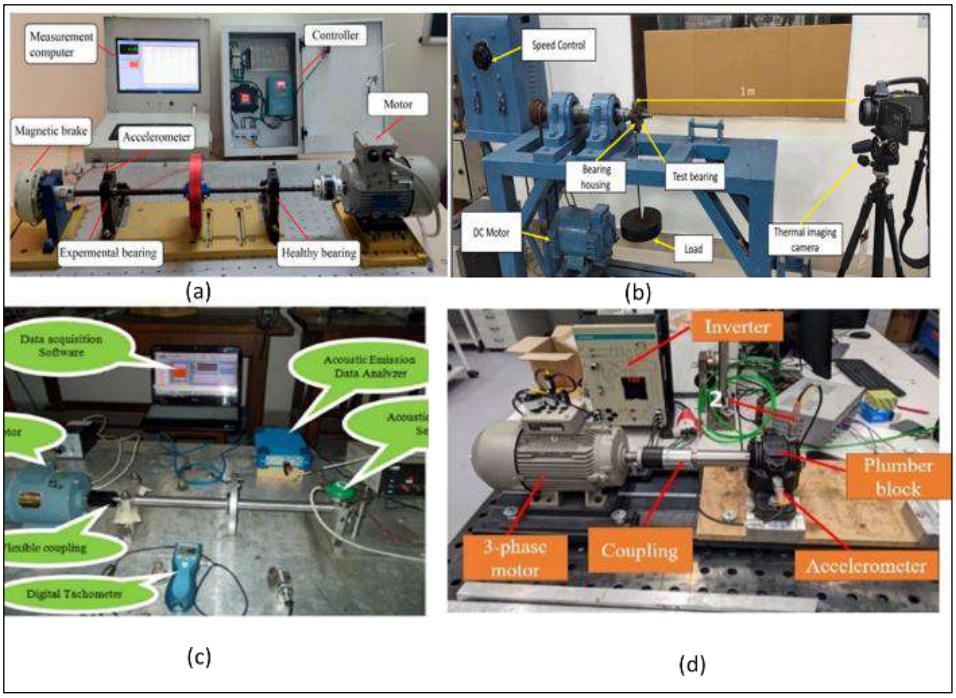

Figure 12: customized experiment setup.
Source: [18-21], -[20].

Across these studies, key experimental parameters typically include rotor speed, applied load or torque, bearing defect type, and bearing geometry, which are systematically varied to evaluate their influence on vibration characteristics and fault signatures. All in all, benchmark datasets that are publicly available have greatly aided the development of methods in bearing fault diagnosis; nonetheless, their controlled practices and lack of variability limit their applicability in the real world. In their turn, customized experimental setups are more realistic, yet have low standardization and reproducibility.

This creates a need to have more standardized, diverse, and generally open-shared industrial datasets to overcome the disconnect between laboratory work and real-world implementation. A detailed summary of the experimental conditions, feature extraction techniques, and diagnostic models used in the reviewed studies is presented in Table 2.

Table 2: Summary of reviewed bearing fault diagnosis studies.

SR No	Refrences	Speed in rpm	Bearing condition	Type of bearing	Feature extracting and Signal Processing Technique	Expert System
1	Yang et al [22].	680 to 2460	Healthy and Artificial damage	NSK 6205 DDU	Grayscale images	Fusion Attention Network (FAN), CBMA-ViT, Swin Transformer
2	Gong et al [23].	900, 1500	Healthy, Natural Damage, Artificial damage	6203	STFT	least squares method (LSM), DT-based fault diagnosis framework
3	Geetha et al [24].	900, 1500	Healthy, Natural Damage, Artificial damage	6203	Time Domain Feature Extraction	k-NN, DT and SVM
4	Peng et al [25].	1730, 1750, 1772, 1797	Healthy and Artificial damage	SKF 6203, SKF6205	Variational Mode Decomposition (VMD),Canberra distance feature extraction, Symmetrized Dot Pattern (SDP) image conversion	rule-based threshold decision system

5	Siddique et al.[26]	1800	Healthy and Artificial damage	FAG NJ206-3	Mel-transformed scalograms	FOX Optimizer and ANN
6	Du, N. T. et al. [18]	780 to 1464	Healthy and Artificial damage	ER 16	Fourier-based Synchro Squeezing transform (FSST) and Principal Component Analysis (PCA).	Nearest Neighbor Classifier
7	Kiakojouri et al.[27]	1730, 1750, 1772, 1797	Healthy and Artificial damage	SKF 6203, SKF6205	cepstrum pre-whitening (CPW)	SVM, ANN
8	Singh et al. [28]	900, 1500	Healthy, Natural Damage, Artificial damage	6203	Nonlinear Mode Decomposition (NMD), Hilbert transform (HT), time-domain feature	
9	Ogaili et al. [29]	60	Healthy and Artificial damage	Ball Bearing	Time Domain Feature Extraction	ANN

Source: Authors, (2026).

Having reviewed the available datasets and experimental configurations, the next step in the diagnostic pipeline is signal processing and feature extraction, which transforms raw sensor data into meaningful fault indicators.

III. SIGNAL ANALYSIS AND FEATURE EXTRACTION TECHNIQUES

Signal processing and feature extraction play a key role in fault diagnosis, particularly in sensor-based monitoring systems that use vibration, temperature, and acoustic emission signals. These methods transform raw measurements into information useful in the detection, localization, and classification of faults in rotating machines like bearings, motors, and turbines. Time-domain, frequency-domain, and time–frequency analyses are commonly used as the initial steps in signal processing and are often combined with envelope analysis.

Time-domain analysis studies statistical properties of the signal, such as mean, root mean square (RMS), peak-to-mean ratio, kurtosis, and skewness, which indicate variations in the signal energy and impulsiveness [5,21]. The frequency-domain analysis, which commonly employs Fast Fourier Transform (FFT), decomposes the signal into spectral elements and aids in the detection of periodic fault patterns and characteristic bearing frequencies, e.g., BPFO and BPFI. Spectral density and dominant frequency components are commonly used to detect mechanical defects [30,58,60-59, 68-67].

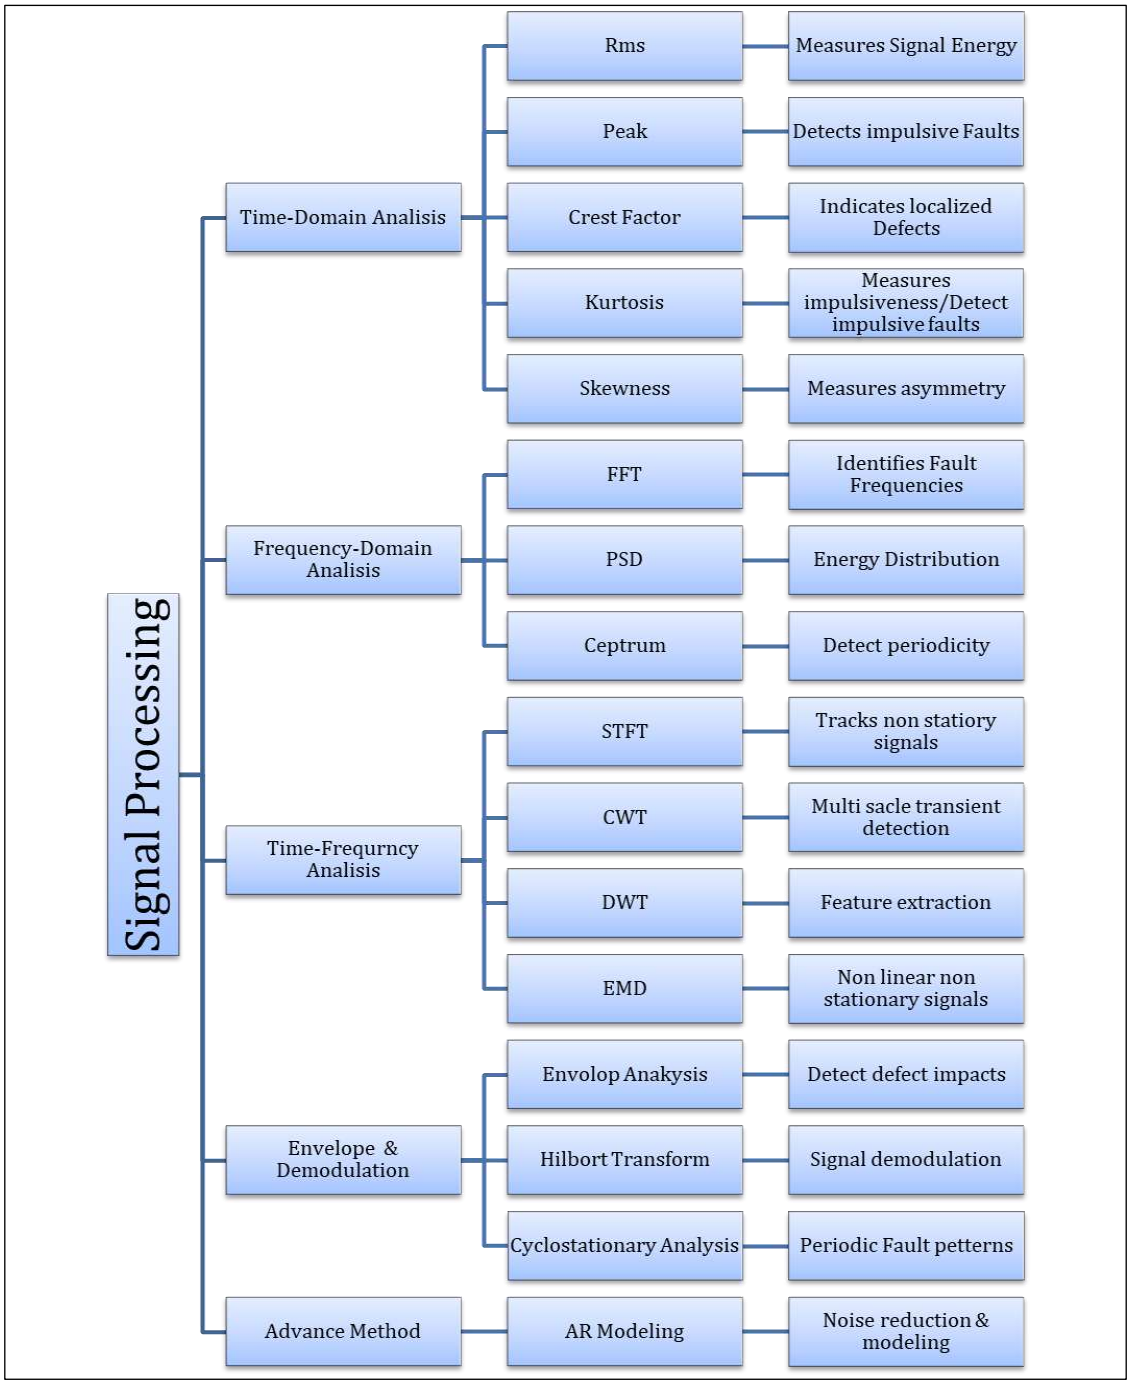

Figure 13: List of signal processing techniques.
Source: Authors, (2026).

Time–frequency techniques describe how frequency content varies with time and are therefore suitable for non-stationary and transient signals. Wavelet techniques offer multi-resolution representations of various frequency bands, whereas the Short-Time Fourier Transform (STFT) uses localized Fourier analysis in short time windows [30],[33],[38]. The Hilbert–Huang Transform (HHT) is commonly used to decompose nonlinear and non-stationary signals into intrinsic mode functions, enabling the isolation of transient faults [5],[28]. Following signal processing, feature extraction converts the processed signals into numerical indicators used for fault detection, classification, and prediction. Common time-domain statistics include RMS and peak-to-peak value, kurtosis, and skewness, but frequency-domain statistics can be used to describe fault-related spectral content and energy distribution [21],[69].

Integrating features from multiple domains provides a more robust representation of bearing condition, especially under variable speed and noisy operating environments. Figure 13 illustrates commonly used signal processing methods, and Table 2 summarizes feature extraction and signal analysis techniques reported in the literature. The representative studies that use such techniques are chosen and discussed below.Recent studies indicate a growing reliance on advanced time–frequency analysis and advanced feature extraction methods in bearing fault diagnosis. According to [23], demonstrate that Short-Time Fourier Transform (STFT) offers powerful representations for detecting localized defects, although its performance depends on window selection and working conditions. According to [27] argue that the explicit extraction of bearing characteristic frequencies and their harmonics that is performed under noisy conditions is worthwhile, and feature engineering, in this case, must be carefully parameter-tuned and domain-informed.

In [18],[25]-26 also explain that time-frequency representations can be combined with dimensionality reduction and machine learning to increase classification accuracy when variables vary in speed and nonstationarity, at the cost of more model complexity and data. There is also interest in nonlinear and adaptive signal decomposition. According to [28] show that nonlinear mode decomposition is vulnerable to the severity of faults, yet its computational complexity can be a limiting factor in real-time implementation. As demonstrated by [31]-32, envelope-based demodulation still can be used to detect early faults, although its effectiveness highly depends on proper band selection and levels of noise. According to [32],[21], hybrid methods that include wavelet-based analysis improve robustness, statistical indicators, and variational mode decomposition improve a more robust analysis, but still, they are provided with a manual-designed feature and dataset-specific tuning. According to [37] reported that lightweight statistical features combined with simple classifiers can be used to perform efficient fault detection, making them appealing for industrial applications; however, their applicability to other machines and operating conditions remains limited. Overall, these studies indicate that although deep learning–based frameworks improve diagnostic accuracy, challenges related to data dependency, parameter sensitivity, interpretability, and generalization to industrial environments remain unresolved.

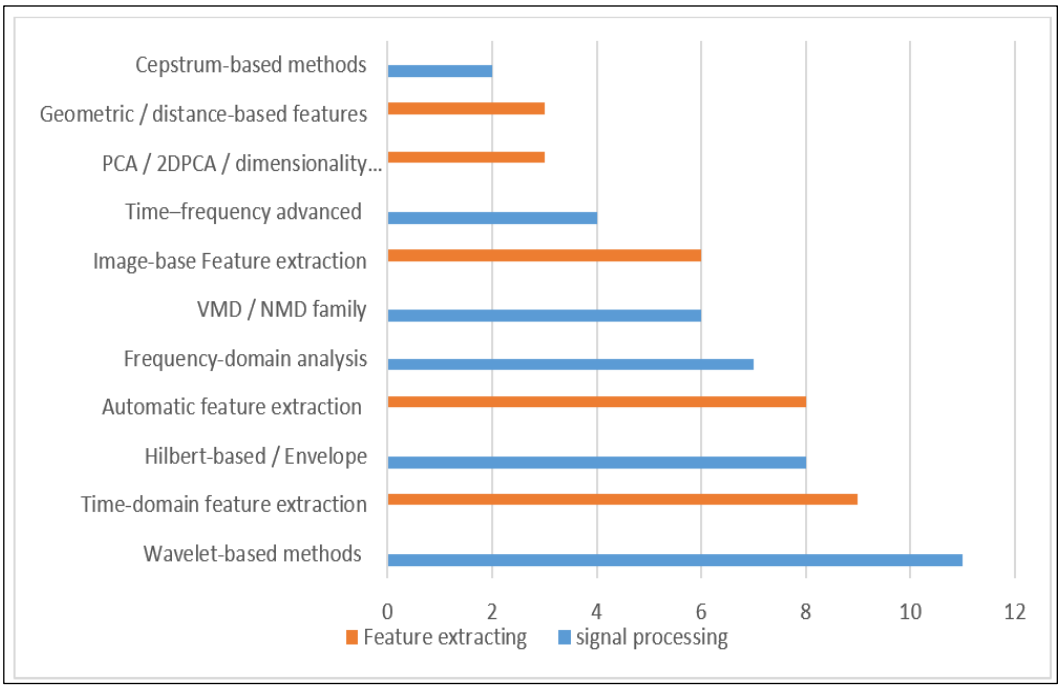

Figure 14: Distribution of signal processing techniques used in reviewed studies.
Source: Authors, (2026).

Figure 14 consolidates the spread of different methods applied in feature extraction and signal processing in the analyzed literature and shows that wavelet-based and time-frequency approaches are still predominant since they have a high localization ability of non-stationary vibration signals. Statistical features of time domain and envelope analysis are also popular due to their simplicity, low computing power as well as physical interpretability. However, during the last few years, the number of applications of deep feature extraction techniques using convolutional neural networks and autoencoders, especially via image-based representations of signals, has grown at a rapid pace, as a response to the move away from handcrafted features and towards data-driven diagnostic models.. Although these deep learning approaches are effective for modeling complex and nonlinear fault patterns, they typically require large labelled datasets and often lack physical interpretability, which limits their acceptance in safety-critical and industrial applications. Once discriminative features are extracted, intelligent classification models are required for accurate fault diagnosis, motivating the application of expert systems discussed in the next section.

IV. EXPERT SYSTEMS FOR FAULT DIAGNOSIS

Expert systems play a crucial role in BFD by enabling automated identification and classification of faults based on extracted signal features. Figure 15 presents the classification of expert systems applied to rolling element bearing fault diagnosis. In this study, expert systems are categorized into knowledge-based, data-driven, and probabilistic approaches according to their reasoning and learning principles. Knowledge-based systems use expert-defined rules and fuzzy logic to infer fault conditions. Data-driven systems extract fault information directly from vibration data and employ machine learning and deep learning techniques such as ANN, SVM, CNN, and RNN. Probabilistic expert systems incorporate uncertainty modeling through methods such as Bayesian networks, hidden Markov models, and Kalman or particle filters. This section reviews the most commonly used expert systems in bearing fault diagnosis and highlights their reported strengths and limitations.

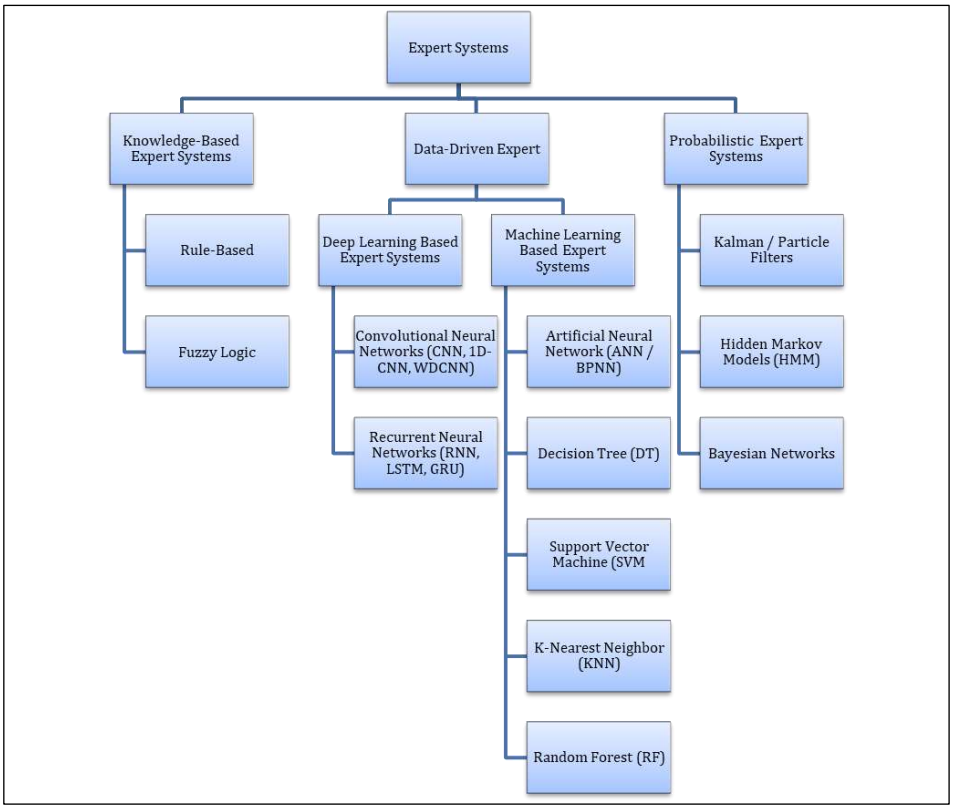

Figure 15: classification of expert for bearing fault diagnosis.

IV.1 THE ARTIFICIAL NEURAL NETWORK (ANN)

An artificial neural network (ANN) consists of interconnected processing units arranged in multiple layers that learn patterns from data to solve complex tasks. ANNs are modeled after the way biological brains process information. It generally includes an input layer, several hidden layers, and an output layer. Each neuron receives input, assigns a weight and bias, and then passes the result through an activation function. The input layer accepts initial data and sends it to the hidden levels. Hidden layers manipulate data via mathematical transformations. The output layer then produces the final decision or classification. Figure 16 shows the diagram for ANN. ANNs are suitable for modelling intricate and nonlinear relationships within datasets[19],[65]. Key studies utilizing Artificial Neural Networks (ANNs) for bearing fault diagnosis are summarized to illustrate their application and performance.

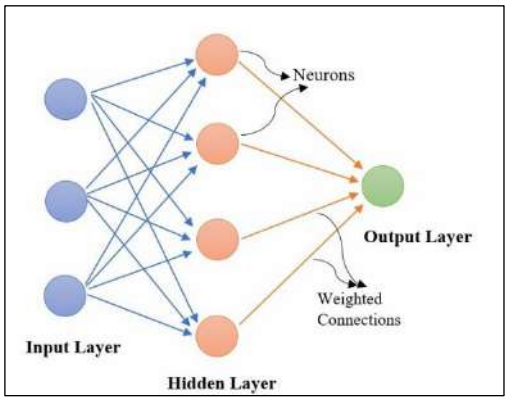

Figure 16: The schematic diagram of neural network.
Source: [68].

A number of studies demonstrate the effectiveness of artificial neural networks (ANNs) to use in BFD in various sensing and working conditions. According to [65], reveal that ANN-based models are capable of not only reflecting how the defect size, load, and speed affect vibration responses but can also be combined with model-based estimation to perform predictive maintenance, but their accuracy still requires proper system modeling to work and the quality of training data. According to [69] contrast ANN with SVM and logistic regression with feature wavelet and indicate that although ANN has high accuracy, its quality is inferior in comparison with SVM, which implies that ANN is not always the best solution, and it is still vulnerable to the choice of features and problem formulations. In [29] demonstrate that ANN models based on statistical features can be highly reliable for fault classification and may outperform traditional methods; however,their adaptability to different machines and operating conditions is limited due to their dependence on handcrafted features.

According to [47] suggests further that ANN is capable of identifying faults of bearing caused by the signature of motor current, which demonstrates the opportunity of an alternative non-vibration-based sensing, but the binary classification framework limits it to scenarios involving more than two faults.Overall, these studies confirm the strong diagnostic capability of ANN-based approaches, while also emphasizing challenges related to feature dependence, scalability to multi-fault conditions, and generalization across operating environments.

IV.2 SUPPORT VECTOR MACHINE (SVM)

SVMs are supervised learning models used for classification and regression tasks. It works by drawing an invisible line, called a hyperplane, that separates different groups of data as clearly as possible. The points closest to this line, called support vectors, play a key role in shaping it. SVM is flexible—it can handle simple straight-line separations or more complex curved boundaries using kernel functions like linear, polynomial, or RBF. It performs effectively with data that has many features and usually avoids overfitting by keeping the margin between groups wide. While it can be slow for very large datasets and needs careful tuning, SVM is a reliable tool for many real-world applications, from image recognition to fault detection. Figure 17 shows the structure of SVM. Notable SVM-based bearing fault diagnosis studies are discussed here.

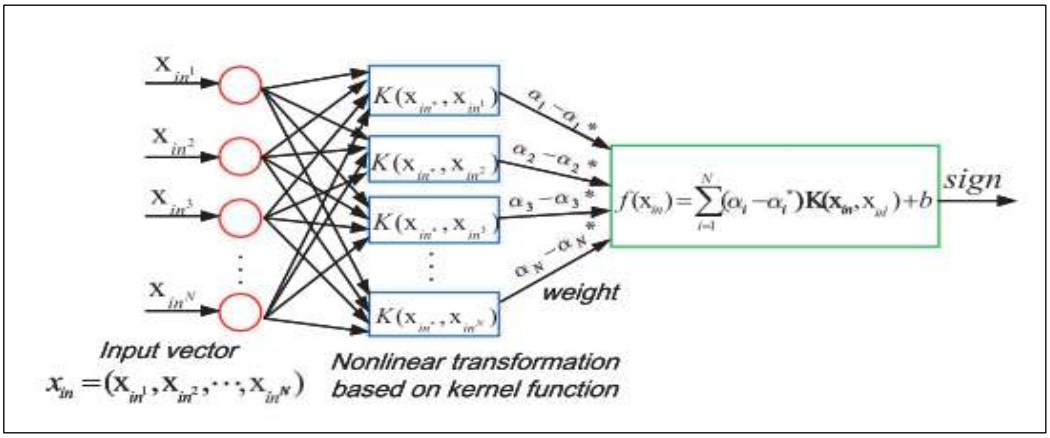

Figure 17: Structure of SVM-based fault diagnosis.
Source: [70].

SVM-based and hybrid learning are still in the limelight in the diagnosis of rolling bearing faults, where the amount of training data is limited and where the number of features is large. According to [51] circumvent these shortcomings of manual feature engineering by suggesting a deep-stacking LS-SVM model that trains discriminative representations on raw signals that get improved classification performance, but the additional depth of the model also comes with higher computational costs, which can limit the scale of such a model to a real-time industrial environment. On this note, [71] show that a combination of attentive feature choice and hyperparameter optimization can contribute to SVM efficiency and accuracy to a large degree and unveil the high sensitivity of SVM performance to feature design and parameter adjustment simultaneously. In order to enhance diagnosis ability, a number of studies combine SVM with other signal processing or learning methods [72] demonstrate that back-propagation neural networks and SVM help to better represent the features before classification and achieve higher performance than the single models but the multi-stage pipeline makes the system more complex and necessitates strict integration.

On the same note, [27] indicate that two-stage SVM-based frameworks have very high accuracy in fault detection and classification, although its proposed extrapolation across different machines without retraining has not been sufficiently validated under a variety of industrial scenarios. In [73] also explain that the artificial fish-swarm algorithm (AFSA) to optimize the SVM hyperparameters is better in convergence speed and accuracy than the traditional PSO-SVM methods. In addition to bearings specific applications, as illustrated by [70] a fault diagnosis approach for photovoltaic arrays using support vector machines, showing that SVM can effectively identify faults in complex engineering systems. Even though their study focused on PV systems, the results suggest that SVM is a reliable classifier and can be applied to fault diagnosis of rotating machinery such as rolling bearings. According to [70] also attest to the fact that SVM is always the best in comparison to unsupervised methods like self-organizing map in fault classification tasks. Overall, these studies indicate that while SVM-based and hybrid approaches offer strong accuracy and robustness, their performance remains highly dependent on feature quality, parameter selection, and dataset characteristics. Consequently, careful validation beyond laboratory benchmarks and under diverse operating conditions is essential for reliable industrial deployment.

IV.3 KNEAREST NEIGHBOR CLASSIFIER (KNN)

The KNN based methods are mainly used in a situation where simplicity, low training cost, and quick deployment are necessary. Pandya et al. (2013) show that KNN with HilbertHuang Transform and intrinsic mode function analysis can be effective to detect early bearing faults and the performance can be enhanced with the help of asymmetric proximity functions; however, the method is still sensitive to the quality of features and noise [5]. Wang, H. et al. (2020) also indicate that KNN can also be effectively used within a real-time online fault diagnosis system, though scalability and computational efficiency could become the barriers to the success of the use of the method with growing dataset size [74]. KNN performance has been suggested to be improved with hybrid frameworks [67-68,46-47].

According to [33], integrating wavelet packet characteristics with IF-LDA enhances the separability of classes and allows KNN to classify with high accuracy, however, multi-stage pipelines with that type of performance demand more complex systems and handcrafted features. The proposed improved k-nearest neighbor (EKNN) architecture by [75] combines sparse filtering to obtain automatic feature removal and a reconstruction-based correlation vector to select the nearest neighbors more adaptively and, thus, enhance the classification performance and stability over classical KNN in rotating machinery fault detection. According to [76], a k-NN-based framework can be used to detect and classify faults in power transmission systems quickly, and the distance-based analysis of the neighbor is an effective approach to identify the type of fault with a high level of accuracy and low computation costs in a power transmission system depending on different system conditions. Overall, these studies indicate that while KNN-based methods offer simplicity and interpretability, their performance is highly dependent on feature representation, dimensionality reduction, and data quality, which constrains their robustness and scalability in complex industrial environments.

IV.4 CONVOLUTIONAL NEURAL NETWORKS (CNN)

CNN is a type of deep learning model that excels at understanding images and visual data. It works by using convolutional layers to automatically identify important features, like edges, shapes, and textures, from raw input. These are often followed by pooling layers, which simplify the information while keeping the essential patterns. CNNs can recognize complex structures by learning step by step, making them very effective for tasks like image classification, object detection, and video analysis. Unlike traditional methods, CNNs do not need manual feature extraction, which saves time and improves accuracy. They are widely used in applications such as medical imaging, facial recognition, and self-driving cars [77],[78].

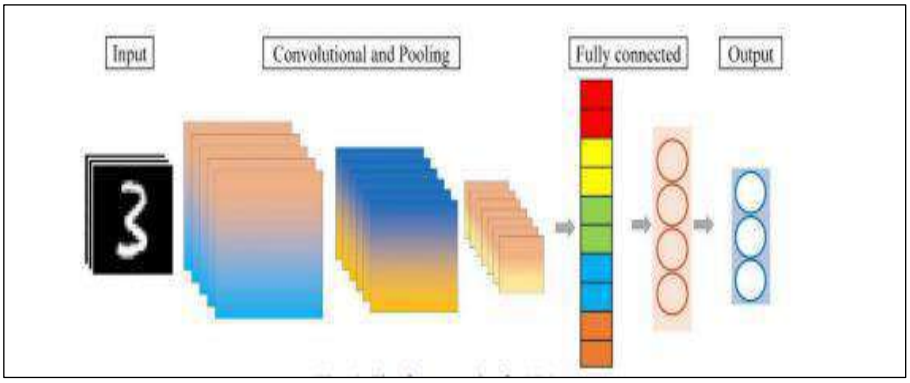

Figure 18: The framework of CNN.
Source: [78].

According to [36] demonstrate that CNN-based diagnostics can be trusted to detect bearing scratches in induction motors at different rotational speeds by reducing the overlap of features and enhancing the separability of the faults, yet these metrics are still dependent on the quality and representativeness of the training data. According to [35] build upon this concept, suggesting a two-channel CNN model that combines both FFT and generalized S-transform representation to handle the imbalance in data and missing spectral information and still benefits with more stable and accurate results, yet again using hand-designed signal transformation.
Proposed a deep learning–based method for bearing defect severity assessment using time–frequency images obtained from continuous wavelet transform of vibration signals. A DCNN automatically extracts relevant features from these images, eliminating the need for manual feature design.

The method was tested on defects of varying sizes in different bearing components and achieved high accuracy under constant-speed conditions [40].According to [77] reported that combining CNN-extracted features with predefined frequency-based indicators significantly improves bearing fault diagnosis using motor speed signals, while reducing reliance on expensive vibration sensors and environmental sensitivity. Conversely, by [57]-58 incorporate physical knowledge into a CNN that is grounded on physics in order to enhance interpretability and reduce overfitting. According to [79] fed CNN with bidirectional LSTM to simultaneously learn both spatial and temporal fault properties, with high accuracy on benchmark data, but poor validation in true industrial environments. To optimize the process of selecting hyperparameters and improve the accuracy of fault classification, by [38] combine the wavelet packet transform with a convolutional neural network that is optimized with a simulated annealing algorithm. Their performance on the CWRU dataset shows that they perform better than the SVM, BP neural networks, and non-optimized CNN models.

IV.5 RECURRENT NEURAL NETWORK (RNN)

RNN is an algorithm that processes sequential data (text, speech, or sensor data) in a deep manner. It is characterized by the most important feature, a memory that stores past information, which is used in determining future predictions. The memory enhances activities such as speech recognition, language processing, and time series forecasting. Nevertheless, conventional RNNs have difficulties with sequences of excessive length; advanced versions like LSTM or GRU can overcome this problem by learning temporal features automatically, without separation of features. RNNs are favored when the order and context of data are important.
According to [53] suggest a new method of rolling-bearing fault diagnostics, reforming a neural-network architecture based on searching for reinforcement learning. Their model is based on two components: a controller model that is implemented as an RNN and child models that instantiate the design selections that are determined by the controller. It has been demonstrated that the method can automatically produce effective neural-network designs, with enhanced classification accuracy, less expert intervention, and less manual design time.

The article by [80] examines an RNN implemented to classify the failures of the bearing of an induction motor driving a residential water pump. None of the conventional mathematical models can easily address bearing defects; hence, the authors apply an RNN-based solution. They use a Fast Fourier Transform (FFT) to obtain features of the stator current waveform of the IM and serve as inputs to the RNN to identify faults. There are four fault types that are used, including normal (AN), front fault (FF), rear fault (RF), and all fault (AF). The error rate is reduced through training, and the error value has a range of 0.1-0.2 percent as a result of testing, indicating a high accuracy and viability in the real world.

IV.6 DECISION TREE (DT)

The decision tree (DT) is a machine learning algorithm that is applied to classification and regression. It illustrates views of decisions as a tree, in which every internal node represents a test of a feature, every branch is an indication of the test outcome, and every leaf is a final prediction. The tree is constructed by splitting the data recursively by the best features that are able to separate the target, specifying the criteria to be either Gini impurity, entropy, or mean squared error. DTs are simple and easy to visualize, which makes them useful in making data-based choices. Nonetheless, overfitting can be observed in deep trees; thus, methods such as pruning or ensembles (e.g., Random Forest, Gradient Boosting) are more typically used to boost performance [81].
Using data on Qatar University, diagnose and predict bearing failures. Vibration samples of bearings having different faults are tested with three machine-learning frameworks: DT, extreme gradient booster (XGBoost), and random forest (RF). The accuracy of the DT is 82%, and it is rated with the use of the F1 score, precision, and recall.

While decision trees are simple and interpretable, they did not perform as well as XGBoost in this case, particularly with noisy and high-dimensional data. Overall XGBoost achieves 92% accuracy due to its effective handling of data complexity, feature importance analysis, and overfitting mitigation [81] In their study, in [39] propose a decision-tree-based advanced fuzzy SMO (AFSMO) model as a fault detector in rotary machines in rolling-element bearings that are nonlinear and uncertain. The approach initially controls the system using a fuzzy ARX-Laguerre model, and then the SMO controller of fault error detection (FEDI) is designed. AFSMO limits chattering and enhances accuracy, and a TS fuzzy logic algorithm leads to further finer fault approximation. AFSMO is controlled by a decision tree, which offers high precision in fault detection with regard to crack categories and motor speed. On the CWRU vibration dataset, AFSMO has also been shown to be effective in fault diagnosis of industrial bearings compared to previous ASMO and SMO models and is quite robust even with varying operating conditions, thus making it highly applicable to the industrial bearing fault diagnosis.

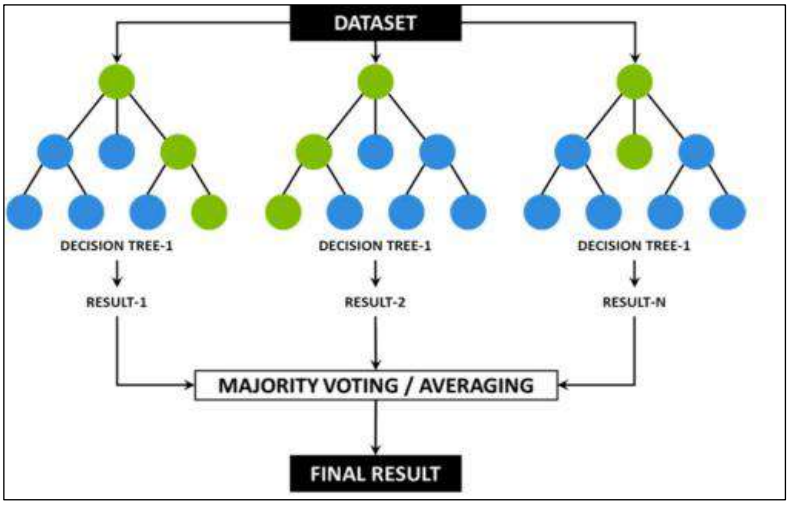

Figure 19: Random Forest algorithm based on DT.
Source: [81].

The decision tree is regarded as a fundamental element of the random forest at [82] to detect rolling-bearing problems. The tree divides the feature set recursively according to certain criteria, creating a decision path to diagnosis. Training is initiated by using a single tree, and its performance is evaluated using held-out samples. The experiment indicates that adding more trees, e.g., 50 trees, increases the classification accuracy, and the random forest gives 94.4% recognition compared to 88.8% when using one tree. This proves that a large number of decision trees are used to enhance the success of the random forest considerably. According to [83] examined the use of decision-tree-based machine learning models for fault diagnosis in industrial systems. The authors compared several tree-based classifiers, including the Extra Trees ensemble method combined with feature selection techniques. The experimental results showed that tree-based ensemble models achieved very high classification accuracy, indicating their strong capability for fault identification. Overall, the study confirmed that decision-tree-based classifiers are efficient, interpretable, and suitable for generalized fault diagnosis applications.

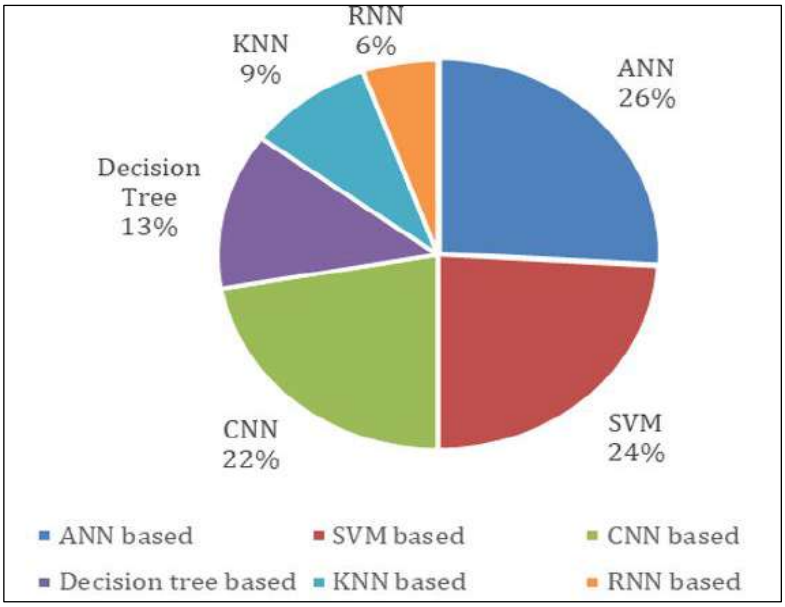

Figure 20: Distribution of expert systems used in bearing fault diagnosis studies.
Source: Authors, (2026).

Figure 20 shows the distribution of expert systems used in bearing fault diagnosis studies.The largest share is attributed to the artificial neural network (ANN)-based methods, which gives them an implication of their still being relevant because of their simplicity and the ability to model nonlinear phenomena. Methods based on SVM and convolutional neural network (CNN) models take up a significant share as well, which demonstrates the great popularity of both standard machine learning classifiers and deep learning models. Moderate in their usage are decision tree based techniques, such as ensemble extensions, and k-nearest neighbor (KNN) classifiers, due to their interpretability and simple implementation.

In contrast, recurrent neural network (RNN)–based approaches exhibit comparatively limited usage, suggesting that sequential modeling remains less explored in bearing fault diagnosis.From a methodological perspective, ANN- and SVM-based approaches remain popular due to their balance between accuracy and computational efficiency, particularly for feature-based classification problemsThe CNN-based models are predominant in the high-dimensional inputs like time-frequency images, but they need large labeled datasets and are not easily interpretable, which is still an issue in industrial applications. KNN and tree-based classifiers are transparent, simple, but frequently do not work with noisy and high dimensional signals. RNN-based models are also appropriate in the context of temporal modeling but are not used extensively. This is generally a trade-off in the performance of diagnostic performance, interpretability, and data dependency of various expert systems. Here is a comparison Table 3 summarizing the machine learning techniques discussed for bearing fault diagnosis. This Table provides a quick comparison of the methods based on key advantages, challenges, and typical applications in bearing fault diagnosis.

Table 3: Expert Systems Comparison.

Method	Advantages	Limitations	Suitable for
ANN	High classification accuracy; models complex nonlinear relationships	Requires large datasets; prone to overfitting	Complex fault patterns; large labeled datasets
SVM	High accuracy; effective with small datasets and high-dimensional features	Sensitive to kernel and parameter selection; slow for large datasets	Binary and multi-class fault classification
KNN	Simple and intuitive; effective for nonlinear decision boundaries	Computationally expensive during inference; sensitive to distance metric	Small datasets; instance-based learning
CNN	Automatic feature extraction; excellent for high-dimensional inputs	Computationally intensive; large labeled datasets required; limited interpretability	Time–frequency representations (spectrograms, scalograms)
RNN	Captures temporal dependencies in sequential data	High training complexity; limited interpretability	Time-series data; dynamic and evolving faults
DT	Simple, fast, and interpretable	Prone to overfitting; sensitive to noise	Small datasets; interpretable diagnostic models

V. RESEARCH GAPS AND CHALLENGES

Although significant progress in rolling element bearing fault diagnosis, several research gaps and challenges continue to limit the practical deployment and generalization of existing methods. A major limitation is the over-reliance on a small number of benchmark datasets. Although these datasets facilitate comparative evaluation, their controlled laboratory conditions and artificially seeded faults do not adequately reflect the complexity, noise, and variability of real industrial environments. Consequently, models that are trained using this type of data tend not to be generalized to the real industrial conditions.

Lack of cross-dataset and cross-domain validation is also another critical challenge. Most of their models are supported by one dataset or a test rig and it is difficult to establish how robust they are when implementing on other machines, sensors, and conditions. This restricts the credibility of reported performance measures and industry trust and acceptance. Furthermore, numerous works consider fault diagnosis and prognostics to be two different issues, paying attention either to the categorization of faults or to the estimation of the left useful life. Nonetheless, viable condition-based monitoring systems necessitate combined diagnostic-prognostic models to avert efficient maintenance decision-making.

This lack of such unified structures is a research gap. Model interpretability is another issue of importance. Deep learning models are very accurate but they are usually black box models and the engineer can hardly comprehend or trust the diagnostic decision. This non-transparency is a significant impediment in safety critical systems like power plants, aerospace systems and heavy industrial equipment. Lastly, no standard evaluation procedures, benchmarking standards, and performance indicators exist in inter-study comparisons, making it relatively difficult to provide a fair comparison and hindering scientific advancement. The future research must hence focus more on building more realistic and diverse datasets, domain adaptation and transfer learning methods to cross-machine generalization, physics-informed and interpretable machine learning frameworks, standardized benchmarking protocols, and integrated diagnostic-prognostic systems that are robust, explainable, and can be used in real-industrial settings.

VI. CONCLUSION

This review examined recent research on bearing fault diagnosis with an emphasis on experimental datasets, signal processing techniques, and expert-system-based diagnostic methods. The dataset usage analysis indicates that the CWRU dataset remains the most extensively used benchmark due to its public availability, standardized fault conditions, and ease of comparative evaluation. However, the increasing use of datasets such as IMS, PRONOSTIA, Paderborn, and XJTU-SY reflects a growing interest in run-to-failure data and more realistic operating conditions. Wavelet-based approaches (DWT/WPT) remain the most widely used signal processing techniques because of their effectiveness in analyzing non-stationary vibration signals, while time-domain feature extraction and Hilbert-based or envelope analysis continue to be favored for their simplicity and effectiveness in early fault detection. Among expert systems, artificial neural networks and SVM are the most frequently employed classifiers due to their strong performance in feature-based fault classification.

The increasing adoption of convolutional neural networks indicates a shift toward deep learning frameworks with automatic feature learning capabilities. Overall, the findings highlight the need for integrated diagnostic frameworks that combine robust signal processing, diverse and realistic datasets, and intelligent yet interpretable expert systems. Bridging the gap between laboratory research and industrial deployment remains the central challenge, and future advances must focus on robustness, interpretability, and scalability rather than accuracy alone. These findings have important implications for the deployment of condition monitoring systems in smart manufacturing and Industry 4.0 environments.

ABSTRACT

The article, Development of GUI to Control Robotic Arm for Biomedical Applications, is a trailblazer in biomedical robotics. It seeks to develop a graphical user interface (GUI) that is easy to use and intuitively applies to enhance the manipulation and accuracy of robotic arms in different areas of biomedical use. This research covers essential aspects such as goals, scope, phases of development, methodology and experimental accuracy with a focus on developing a GUI that enhances efficiency, safety, and user acceptance in medical procedures. Detailed descriptions of software development, hardware integration, safety measures, and usability testing demonstrate the research success in enhancing safety, performance and precision in biomedical applications. The research provide as a valuable resource for individuals and organizations interested in the convergence of robotics and biomedical applications, with the potential to positively impact healthcare providers and patients by driving innovation in biomedical robotics. The whole set up consist of five degrees of freedom robotic arm, capacitive touch screen display, Arduino UNO and Rasberry pi controller. For the accurate and precise control of Robotic arm joint motion five servo motors are used. The payload capacit,y of robotic arm is 0.5Kg.

I. INTRODUCTION

Biomedical use of Robotic arms have revolutionized and created precision and dexterity in biomedical practice, such as surgeries, rehabilitation, and diagnostics. The study by [1],[2] aims at developing a user-friendly interface to harness the capabilities of robotic arms in healthcare, specifically the development of GUI to control the robotic arm. The research will help to increase the precision, safety, and efficiency of different medical procedures by reducing the distance between the complex robotic functionalities and the medical requirements of these fields [3]. The hardware integration, safety, and usability testing of the GUI development process are the main aspects of this initiative [3]. Finally, this study provides the potential to transform healthcare by ensuring better patient care and patient outcomes through the further control of robotic arms in situations of pandemics such as Covid-19 [4]. In this study, integration of Robotic arm and HMI panel controller is built using python programming. The experimental set up developed was able to handle glass tube that was used in chemical reaction /sample testing in different biomedical labs with the help of graphical user interface that was developed in robotic arm. Besides biomedical use, developed integration is also positively utilized as pick and place application and service robot application.

II. LITERATURE REVIEW

The literature review explores the very essential information between user interfaces and robotic arms in the Biomedical application. It points to the changing environment of the graphical user interfaces (GUIs) to control robotic arms, and its central contribution to the improvements in accuracy, efficiency, and safety. According to the review, there are various gaps in research, including the urgent necessity of a flexible and more comprehensive interface design that would be applicable to a wide range of healthcare environments and further examination of the human factors, including user experience and error mitigation. Furthermore, the inclusion of the Internet of Things (IoT) as the global accessibility, standardization, scalability, and sustainability is listed among the fields that need additional research. The contemporary Human-Machine Interface (HMI) design is undergoing a paradigm shift away from inflexible, one-way control systems toward flexible, self-directed collaboration systems. In particular, the intelligent reflective panels based on facial recognition logic can be developed, which, in combination with a high level of personalization of the interface, will provide not only the maximum level of security but also the optimal user interaction [5]. The current domestic automation uses combined Raspberry and Arduino processing platforms to monitor different home appliances using one, integrated HMI [6]. The importance of MATLAB and Arduino integration lies in the fact that high-fidelity modelling is achieved and is the base towards low-latency, hardware-level precision when it comes to physical implementation [7].

Managing robotic systems in marine environments is uniquely difficult due to the constant environmental turbulence that threatens hardware stability. So, It is essential to develop graphical user based control to manage robotic system in marine application [8], [9]. Recent research emphasizes the utility of touch-responsive grids utilizing capacitive force sensing, which provide an accessible and "green" solution for intelligent HMI applications [10]. While these tactile keys are effective for routine tasks, academic research-focused manipulator systems often utilize specialized embedded control interfaces to investigate complex motion interactions [11]. For the most hazardous or unstructured zones, hybrid sensory multi-participant virtual environments offer a significant strategic lead. By delivering a spatial awareness that standard two-dimensional displays lack, these immersive systems allow several remote operators to collaborate effectively [12] In Agriculture domain, Human Machine Interfaced 4 DoF robotic arm shown effective reduction in cycle time with 93% success rate [13]. Various methods of artificial intelligence used for control of robotic arm for industrial application conclude that deep learning for object recognition is most accurate [14]. Furthermore, the evolution of collaborative robots, or "cobots," has led to systems that employ colour-sensing technology for sorting [15]. The history of HMI has progressed from foundational studies at Sandia-based government research facilities to the current democratization of sophisticated hardware.

There are still early frameworks created by the first pioneers such as McDonald which we still use to organize the modern interactions of remote-controlling [16].An essential strategic perspective of the diverse studies reveals that the trade-off of hardware between the distinct controllers: Arduinos appear well to be suited to produce base-tier engine signals at real time, whereas the Raspberry Pi units have advanced executive software operating environments that are suitable to perform network-centric workloads and intricate GUIs [17]. As an example, when equipped with PID-based control of Raspberry Pi, one can control servo motors carefully and at the same time run a sophisticated user-friendly display [18]. The sociotechnical design and assessment of HMIs in distributed architectures has been a major challenge because the conventional form of interface testing often does not consider the challenges of network delays or spatial context loss in the event that the operators are separated physically by the machine [19]. Finally, the introduction of six-axis robotic manipulators demands a balance between strict motion mathematics and easier-to-use feedback loops in order to make them operationally durable [20].

III. METHODOLOGY

For the development of graphical user interface with robotics arm following Figure 1 represent the methodology used to carry out experimentation.

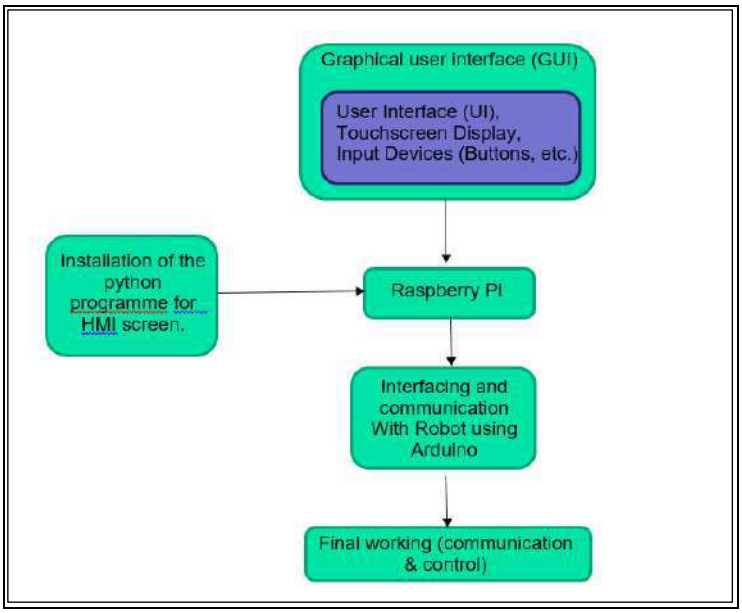

Figure 1: Block diagram of GUI Development.
Source: Authors, (2026).

III.1 DETAILED EXPLANATION OF EACH BLOCK IN THE BLOCK DIAGRAM:

i. **Graphical user interface (GUI):** The GUI is the graphical representation of the HMI. It typically includes buttons, sliders, and other controls that the user can interact with to send commands to the robot.
ii. **Touchscreen display:** The touchscreen display is the physical device that the user interacts with to interact with the GUI. It allows the user to select buttons and other controls by touching them with their finger.
iii. **Input devices (buttons, etc.):** In addition to the touchscreen display, the HMI may also have other input devices, such as buttons and switches. These can be used to send additional instructions to the robot or to control the HMI itself.
iv. **Raspberry Pi:** It is a single-board computer that acts as the brain of the HMI. It runs the Python program that controls the HMI screen and communicates with the Arduino.
v. **Installation of the python programme for HMI screen:** The Python program for the HMI screen is installed on the Raspberry Pi. It is responsible for rendering the GUI, receiving commands from the user, and sending commands to the Arduino.
vi. **Final working (communication & control):** Once the Python program is installed and running, the HMI is ready to be used to communicate and control the robot.
vii. **Interfacing and communication with robot using Arduino:** The Arduino microcontroller board is used to interface the HMI with the robot. It receives commands from the HMI and controls the robot's actuators accordingly.

The HMI works as follows:

a. The user interacts with the HMI UI to send commands to the robot.
b. The HMI Python program receives the instructions and sends them to the Arduino.
c. The Arduino interprets the commands and controls the robot's actuators accordingly.
d. The Arduino sends feedback to the HMI Python program about the robot's state.
e. The HMI Python program updates the HMI UI to display the robot's current state.
f. This process is repeated continuously, allowing the user to control the robot in real time.

III.2 BLOCK DIAGRAM OF COMMUNICATION AND INTERFACING OF COMPONENTS

This is the block diagram of Communication and Interfacing of components. The user interface sends signals to the Python program, which can be keyboard inputs , mouse clicks , or other input devices. The Python program interprets the signals from the user interface and generates control signals for the Arduino UNO .This control signals are used them to drive the servo motor. The following Figure 2 shows a simplified overview of the interfacing process.

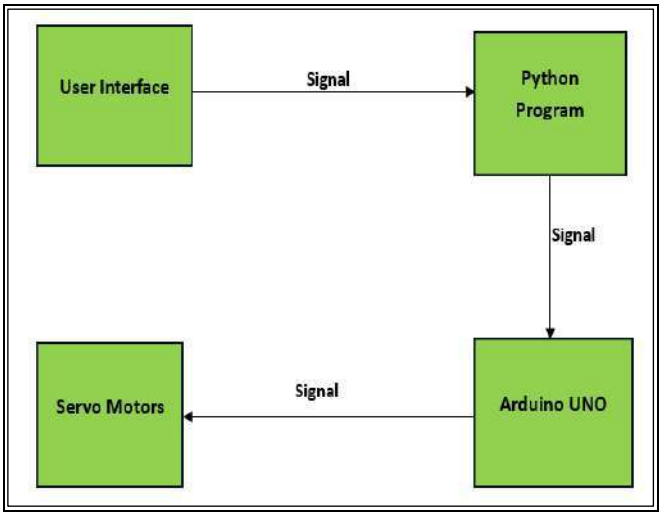

Figure 2: Communication of components.
Source: Authors, (2026).

Some examples of how this type of interfacing can be used:

- A 3D printer could use this type of interfacing to move the print head to specific coordinates.
- A CNC machine could use this type of interfacing to move the cutting tool to specific locations on a work piece.
- A robot arm could use this type of interfacing to move its joints to specific positions.

This type of interfacing is a powerful and versatile way to control servo motors using Python.

IV. EXPERIMENTAL SET UP

A Figure 3 shows the physical set up developed for graphical user interface for robotic arm. It consist of five degree of freedom robotic arm attached with 2 figure mechanical gripper, capacitive 7 inch HMI touch screen ,USB cable for interfacing ,servo motor used for precise movement of robotics arm, raspberry pie.
1. Robotic arm with two figure mechanical gripper 2. Arduino UNO. 3. Capacitive 7 inch HMI touch screen 4.USB cable for interfacing 5. servo motors 6. Raspberry pie

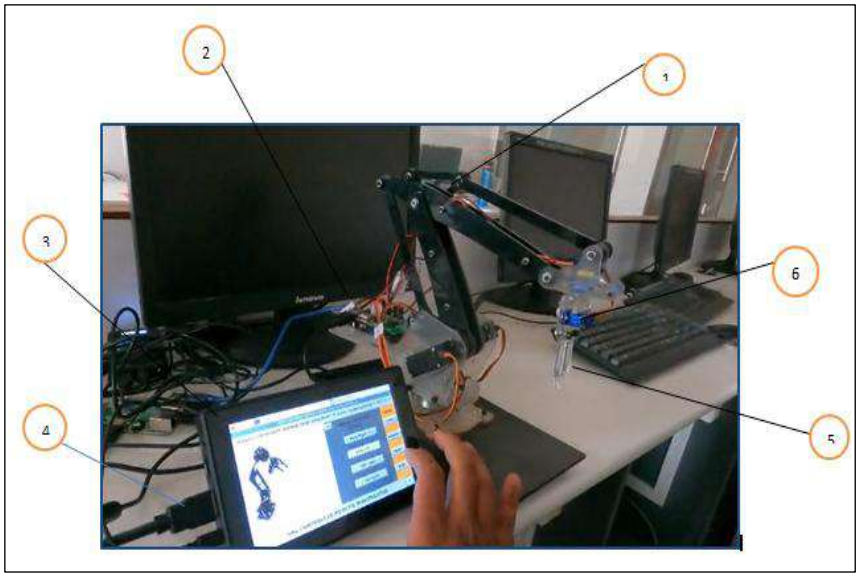

Figure 3: Experimental Set up for complete interface with Robotic Arm.
Source: Authors, (2026).

IV.1 COMPONENTS OF ROBOTIC ARM

IV.1.1 Robotic Arm:

The robotic arm used in this assemble has total five degrees of freedom as shown in Figure 4. First is rotation about base ,second is radial traverse of robotic arm about shoulder , third is upward and downward motion (elbow) in vertical direction, fourth is yaw motion of wrist and fifth is rolling about wrist. It is attached with 2 finger mechanical gripper for pick and place of part. The material used for robotic arm is acrylic material and all the parts are 3D printed. Robotic arm has payload capacity of 500 gm i.e.0.5kg.

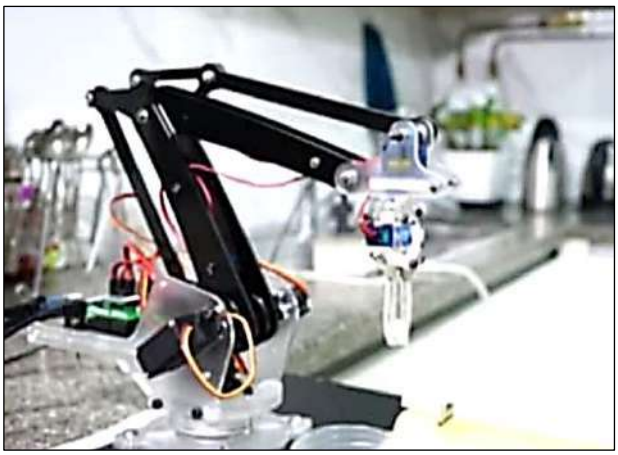

Figure 4: Robotic Arm.
Source: Authors, (2026).

IV.1.2 Arduino Uno

It is a widely recognized and renowned for its user-friendly hardware and software also open source electronics platform It's designed to facilitate the reading of various inputs, such as the illumination level detected by a sensor, the touch of a finger on a button, or even a digital communication like a Twitter message. These inputs are then converted into outputs, which can range from initiating the movement of a motor, illuminating an LED, to interacting with the digital world, such as posting online. To program the Arduino board, one utilizes the Arduino programming language, which is inspired by Wiring, and the Arduino Software, known as the Integrated Development Environment (IDE), which is influenced by Processing. This combination allows users to craft a set of instructions that command the microcontroller on the board to perform a wide array of tasks, effectively bridging the gap between the physical and digital realms. The versatility of the Arduino UNO (Figure 5) makes it an ideal tool for a multitude of interactive projects, from simple DIY endeavour's to complex scientific instruments.

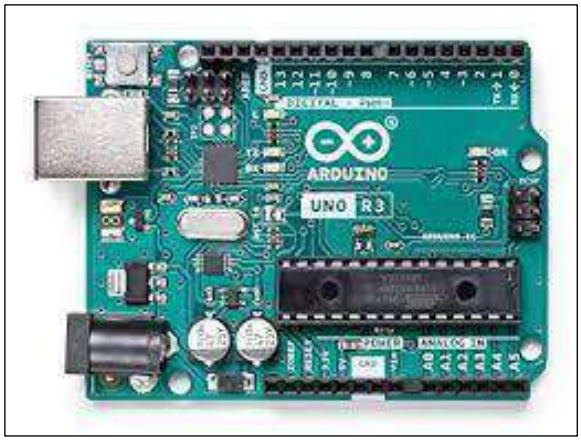

Figure 5: Arduino UNO.
Source: [21].

IV.1.3 Capacitive Hmi Screen :

A 7-inch capacitive HMI (Human-Machine Interface) display is widely used across industrial settings and DIY projects as shown in Figure 6. Key manufacturers in this space include DWIN, Nextion, and Waveshare. These screens are frequently bundled with integrated software to simplify user interface creation and ensure compatibility with development boards such as microcontrollers and single-board computers like the Raspberry Pi.

Figure 6: Capacitive HMI Screen (7 inch).
Source: [22].

IV.1.4 USB Cable for Interfacing:

Arduino cable and USB to USB cable as shown in Figure 7 used for communication and interfacing of controller, robotic arm and HMI screen. Use of jumper wires is required for solderless wire connection between components as shown in Figure 8.

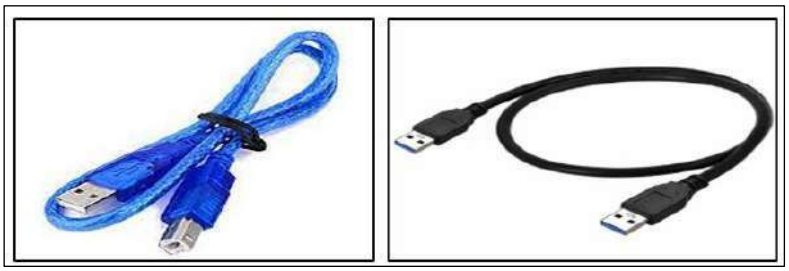

Figure 7: Arduino and USB to USB Cable.

IV.1.5 Raspberry:

The Raspberry Pi Foundation created the Model B+ single-board computer. It has a small form factor, 40 GPIO pins, four USB ports, and enhanced power management, audio and video support, connection, and heat dissipation. It is backward compatible with original Model B software and accessories, giving it a viable platform for a variety of projects and applications. The Raspberry Pi B+, which was released in 2014, is a popular choice among hobbyists, educators, and manufacturers as shown in Figure 9.

Figure 9: Raspberry Pi b+.
Source: [23].

IV.1.6 Servo Motor

There are 5 servo motors used in the assembly out of which 3 are MG995 180 degree and 2 are SG 90 as shown in Figure 10.There are 3 wires in Servo motors. Red is for +5V supply, Brown is for Ground and yellow is for controlling the motor. So, in Robotic Arm total 5 motors are used. Power supply of all these motors will be connected externally as explained earlier and according to the specific motor.

Figure 10: Servo Motor.

IV.2 COMPONENTS SPECIFICATION:

IV.2.1 Arduino UNO Specification

Table 1: Arduino UNO Specifications.

Sr. No.	Specification	Value
1	Microcontroller	ATmega328P
2	Operating voltage	5V
3	Input voltage range	6V to 20V
4	Digital I/O pins	14 (of which 6 provide PWM output)
5	Analog input pins	6
6	DC current per I/O pin	20mA
7	DC current for 3.3V pin	50mA
8	Flash memory	32 KB (0.5 KB used by bootloader)
9	SRAM (static random access memory)	2KB
10	EEPROM (Electrically Erasable Programmable Readonly Memory)	1KB
11	Clock speed	16MHz

Source: [21].

IV.2.2 Rasberry Pie:

Table 2: Raspberry Pi 4 Model B Specifications.

Sr.No.	Specification	Value
1	CPU	Broadcom BCM2711, Quad-core Cortex-A72 (64-bit)
2	CPU Clock Speed	1.5 GHz
3	GPU	VideoCore VI
4	RAM	2GB, 4GB, or 8GB LPDDR4-3200 SDRAM
5	USB Ports	2 × USB 3.0, 2 × USB 2.0
6	Video Outputs	2 × Micro HDMI (up to 4K 60Hz)
7	Audio Output	3.5mm audio jack, HDMI
8	Storage	microSD card slot
9	Networking	Gigabit Ethernet (RJ45), Wi-Fi 802.11ac, Bluetooth 5.0
10	GPIO Pins	40-pin GPIO header (backward-compatible with previous Raspberry Pi models)
11	Power Supply	5V via USB-C connector
12	Power Consumption	Varies depending on usage, typically around 2.5W to 7.6W
13	Operating System	Raspberry Pi OS (Raspbian) and various other Linux distributions
14	Supported Resolutions	Up to 4K (3840x2160) @ 60Hz via HDMI

Source: [24].

IV.2.3 Servo Motor MG995

Table 3: MG995 Servo Motor Specifications.

Sr. No.	Specification	Value
1	Operating Voltage	4.8V - 6.0V
2	Stall Torque (4.8V)	Approximately 10 kg/cm
3	Stall Torque (6.0V)	Approximately 12 kg/cm
4	Speed (4.8V)	Approximately 0.20 sec/60°
5	Speed (6.0V)	Approximately 0.16 sec/60°
6	Operating Angle	180 degrees
7	Weight	About 55 grams
8	Dimensions (L x W x H)	40.7mm x 19.7mm x 42.9mm
9	Gear Material	Metal and Plastic
10	Connector Type	JR Style
11	Rotation Range	180 degrees
12	Dead Band Width	4 µs
13	Operating Temperature	0°C - 55°C

Source [23].

IV.2.4 Servo SG 90

Table 4: Servo SG 90 Motor Specifications.

Sr.No.	Specification	Value
1	Operating Voltage	4.8V - 6.0V
2	Stall Torque (4.8V)	2.2 kg/cm (30.5 oz/in)
3	Stall Torque (6.0V)	2.5 kg/cm (34.7 oz/in)
4	No-Load Speed (4.8V)	0.12 sec/60°
5	No-Load Speed (6.0V)	0.10 sec/60°
6	Operating Temperature	-30°C to +60°C
7	Dead Band Width	10 microseconds
8	Gear Type	Plastic
9	Connector Type	JR/Futaba-style 3-pin
10	Dimensions	23 x 12.2 x 29mm
11	Weight	9g
12	Rotation Range	0° to 180° (90° each way)

Source:[21].

IV.2.5 Capacitive HMI Screen

Table 5: Capacitive HMI Screen Specifications.

Sr.No.	Specification	Value
1	Display Size (inch)	7
2	HDMI Port	Yes
3	Panel Type	IPS
4	View Angle	170º
5	Brand	Waveshare
6	Touch type	Capacitive
7	Touch Port	USB
8	Toughend Glass Panel	Yes
9	Touch-Points	5
10	Length (mm)	191
11	Height (mm)	112
12	Width (mm)	17
13	Weight (gm)	350
14	Shipment Weight	0.408 kg
15	Shipment Dimensions	12 × 5 cm

Source: [22].

IV.3 PROCEDURE FOR CONNECTION OF THE COMPONENT:

Step 1: First connect the Arduino to the PCB in the way that all pins are connected to each other. Plug-in the motors cable to the pcb. Keep in mind that you plugged-in the specific motor to the designated place on PCB. For Example:- Elbow motor to the Elbow male connector on PCB. Shoulder motor to the shoulder male connector on PCB and so on as shown in Figure 11.

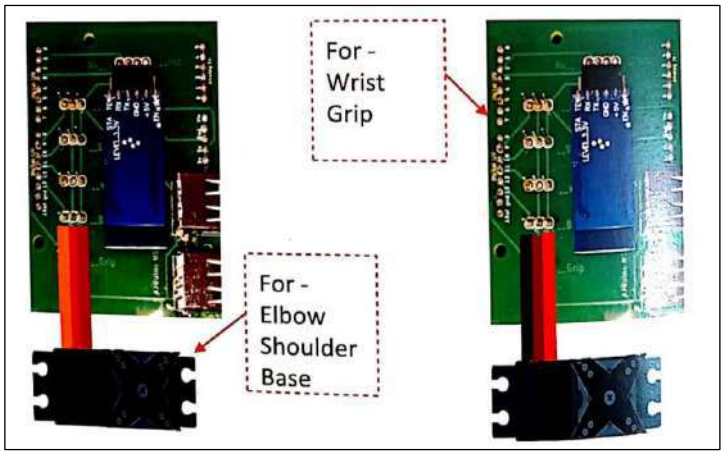

Figure 11: Customized PCB.
Source: [23].

NOTE: Make sure you connect the cable of motors color code wise as shown in figure. For Elbow, Shoulder and Base color code from left is orange, red and brown. For wrist & grip colour code is black, brown & red.

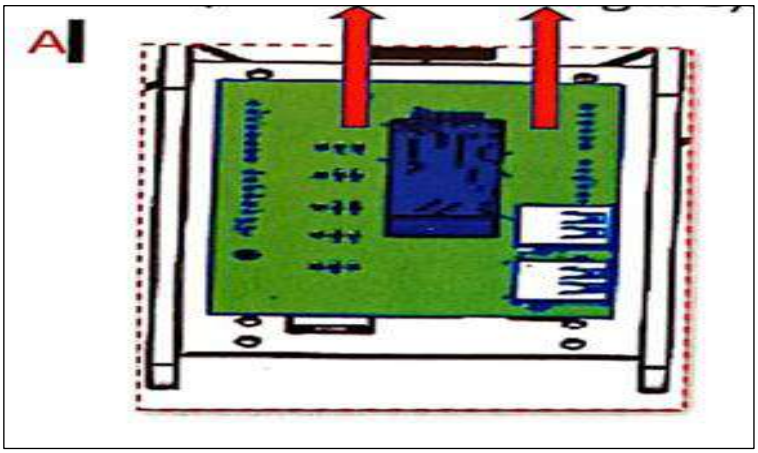

Figure 12: Top View of Customized PCB .
Source: Authors, (2026).

Step 2: Now, put the case above the PCB and tighten it with the screw.
Step 3: a) After connecting the arduino, connect the USB cable (type A/B) to the arduino and Arduino USB (on PCB). b) Male to Male cable to your charging adapter and Power USB (on PCB).
Step 4: Now, you are all set to run the Robotic Arm. Turn on the power supply and you can see that arduino LED is ON now.
Step 5:- Now whole code in Void Loop section is working on the same approach. In coding, we have defined at what time which motor is running from starting defined angle to the final defined angle. You can also change the servo angles between 0^0 to 180^0 for different location.

V. RESULTS AND DISCUSSION

This section explains about the results obtained for graphical user interface developed to control the robotic arm. It is explained in 2 parts. One is control of robotic arm by Arduino Uno code. Second is Python Arduino Integration for graphical user interface. The algorithm shown in figure 14 describes the code used for control of robotic arm by moving servo motor joints. The Second algorithm consist of control of robotic arm movement with graphical user interface i.e 7inch capacitive display programming as shown in figure15. This programing is integration of Python programing with arduino Uno code of robotic arm controller. On successful integration of graphical user interface it is observe that first we need to enter log in credential to execute control of robotic arm as shown in Figure 16. Once user logged in with required credential user interface winow enable the tab to control robot elbow, shoulder, base and wrist by servo motor 1,2,3and 4 respectively as shown in figure as per selection of individuals wish.

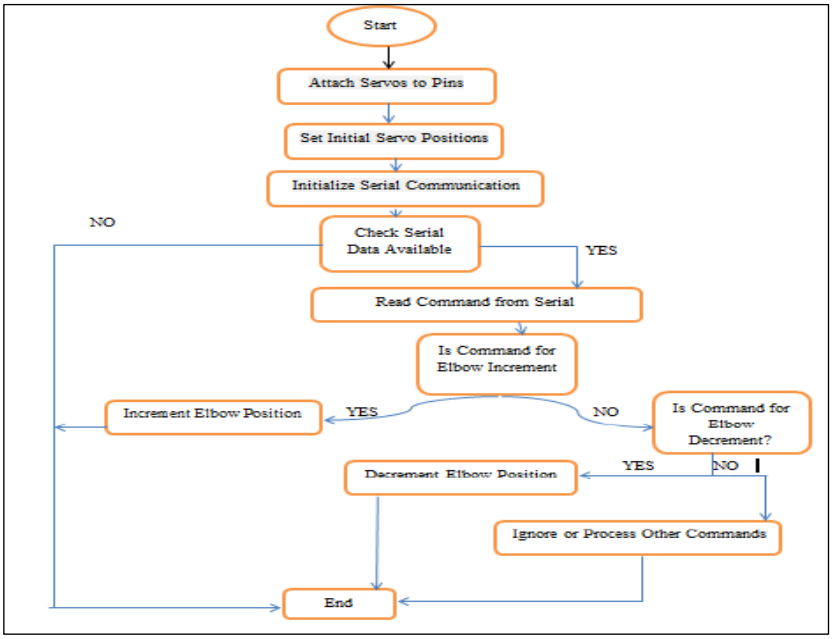

Figure 14: Algorithm for robotic arm servo motor program.
Source: Authors, (2026).

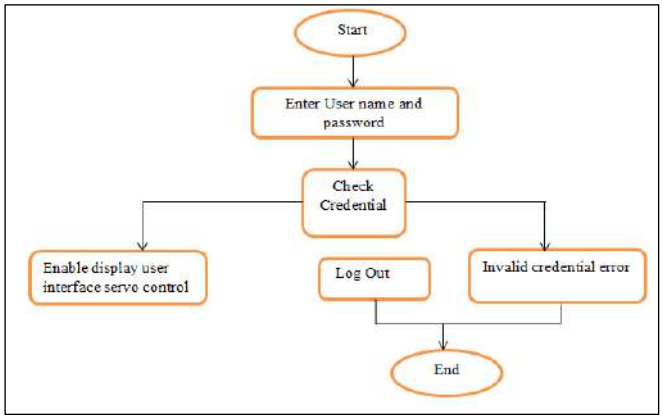

Figure 15: Algorithm to check log in credential.
Source: Authors (2026).

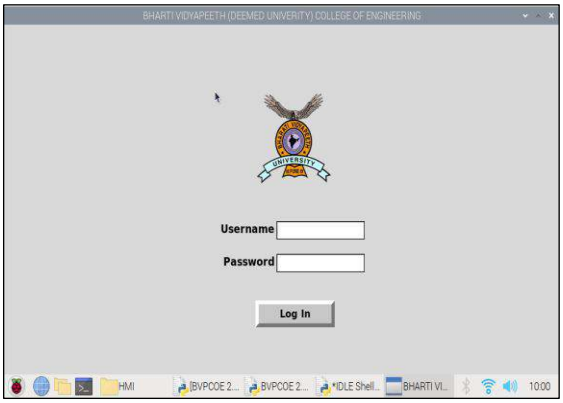

Figure 16: Initial security log in on display.
Source: Authors (2026).

The image depicts the login window of a program designed to control a robotic manipulator. This initial interface houses the college's name prominently at the top, signifying its potential use in an educational or research setting as shown in Figure 16. Below that lies the core functionality - username and password fields - essential for user authentication before accessing the control panel. Finally, a "Log In" button sits at the bottom, granting authorized users entry to the program's functionalities. Overall, this login window provides a clear and concise entry point for users to interact with the robotic manipulator.

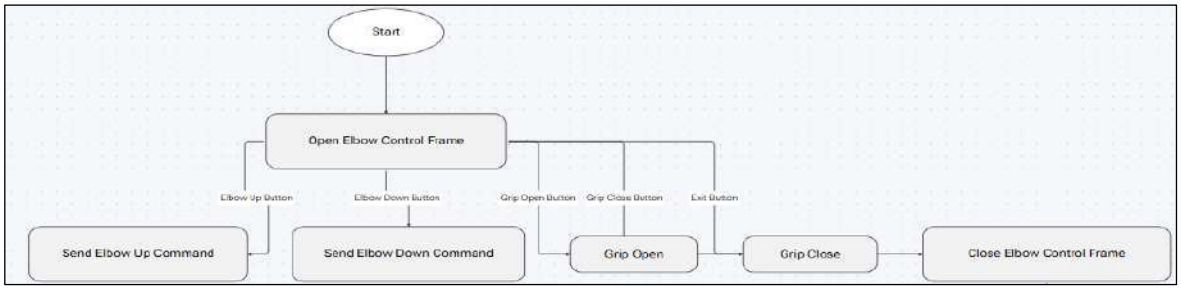

Figure 17 (a): Algorithm for elbow control from GUI.
Source: Authors, (2026).

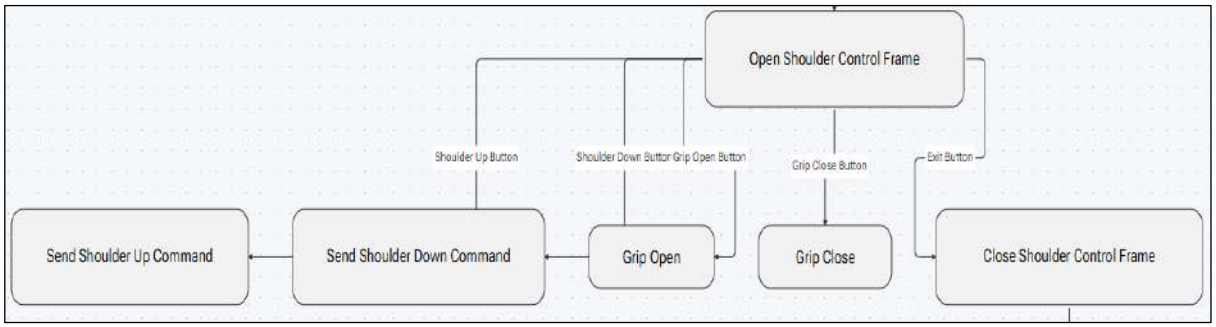

Figure 17 (b): Algorithm for shoulder control from GUI.
Source: Authors, (2026).

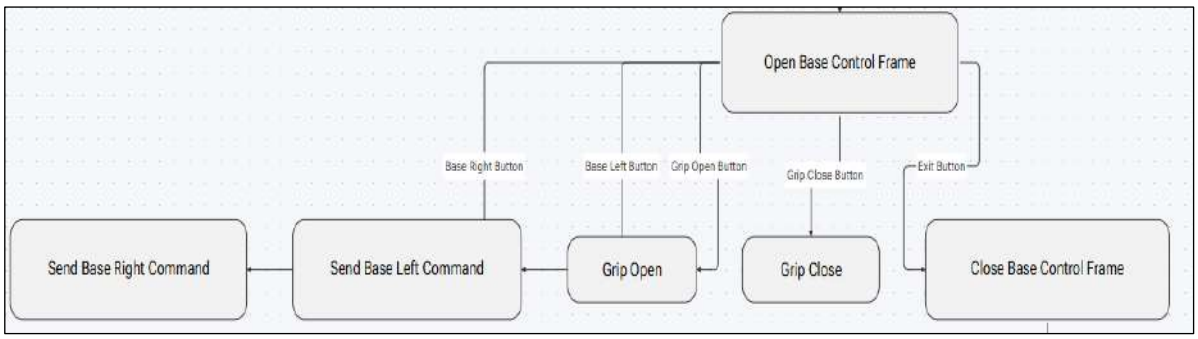

Figure 17 (c): Algorithm for Base control from GUI.
Source: Authors, (2026).

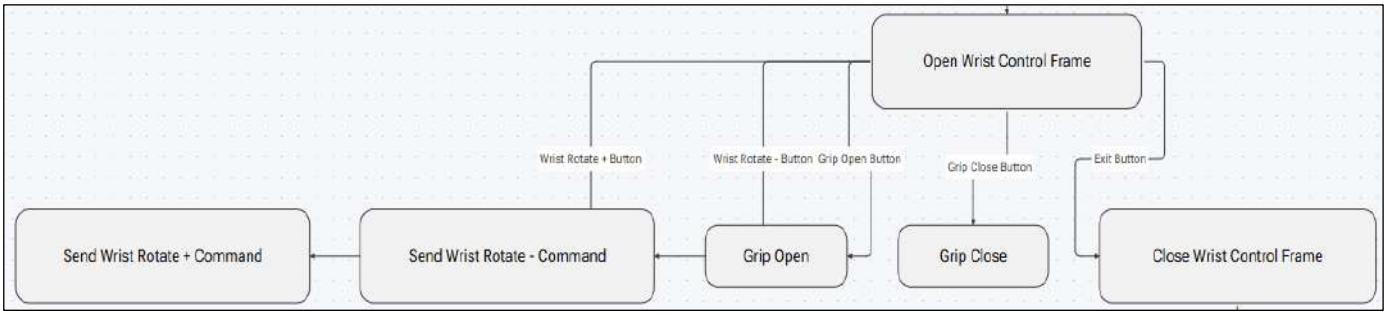

Figure 17(d): Algorithm for Wrist control from GUI.
Source: Authors, (2026).

The above algorithms are developed from the program code logic used for control of robotic arm with operating graphical user interface (GUI). For better visibility and understanding the algorithm is spliited in 4 parts i.e Figure 17(a) to Figure 17(d). The algorithm describes the movement of elbow, shoulder, base and wrist along with gripper of robotic arm is made by selecting respective tab on HMI screen.

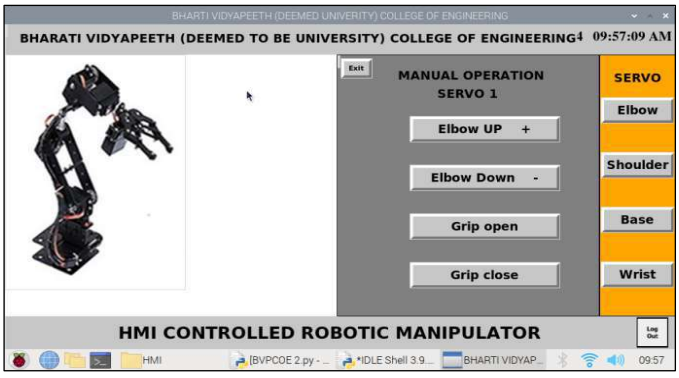

Figure 18(a): Elbow Joint Control.
Source: Authors, (2026**).**

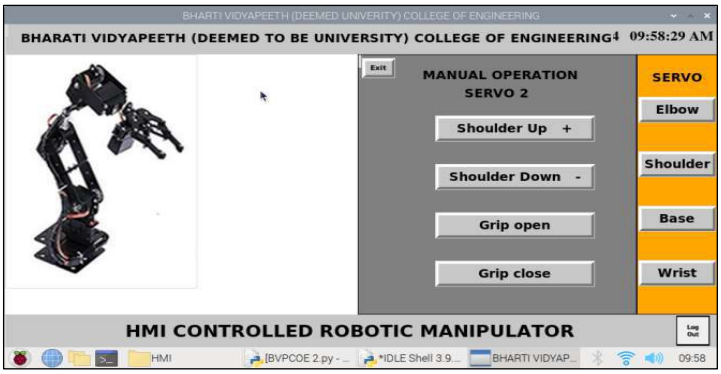

Figure 18(b): Shoulder Joint Control.
Source: Authors, (2026).

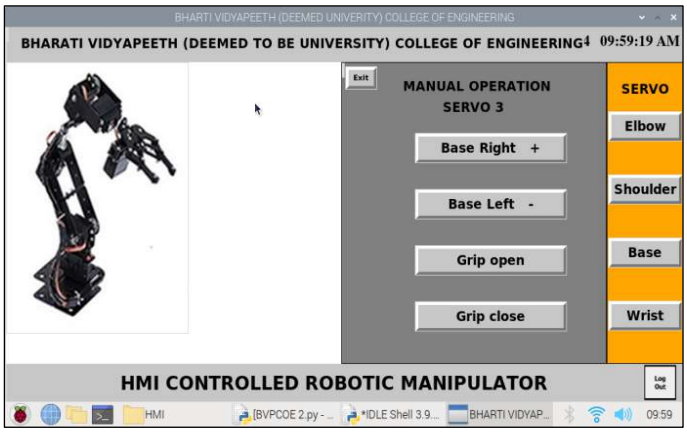

Figure 18 (c): Base Joint Control.
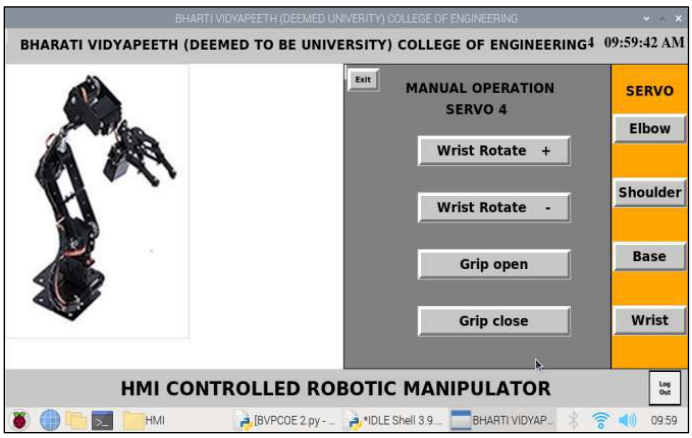
Source: Authors, (2026).



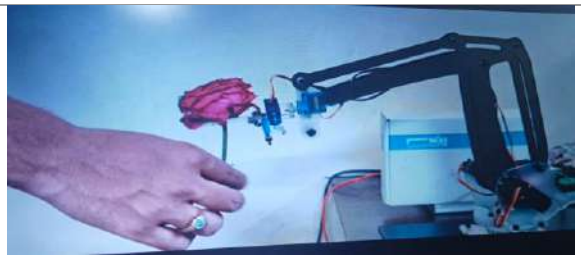


Figure 18(d): Wrist Joint Control.
Source: Authors, (2026).

The above figure depicts a graphical user interface (GUI) for a program that controls a robotic manipulator. HMI (Human-Machine Interface) refers to the interface that allows a human to interact with and control the machine i.e. here robotic arm. The main section of the user interface is the control panel. It consists of several buttons and a display area. Let's look at the elements within the control panel: Servo Controls: The panel appears to have four sections labelled "Elbow", "Shoulder", "Base", and "Wrist" as shown in Figure 18(a),(b),(c) and (d) respectively. Each section likely controls a corresponding servo motor on the robotic manipulator. Within each section, there are buttons labelled "Up +" and "Down -". These buttons are likely used to control the direction of the servo motor. Additionally, the "Elbow" and "Wrist" sections have buttons labelled "Grip Open" and "Grip Close," suggesting these sections might control a gripper attachment on the robotic manipulator.

VI. DEMONSTRATION OF APPLICATIONS DEVELOPED FROM EXPERIMENTAL SET UP

The following table shows the observation in the form of actual photographs captured to validate the application of experimental set up developed during experimentation and testing.

Table 6: Demonstration of application developed from experimental set up.

Sr. No.	Application category	Photograph of observation	Description
01	Biomedical (Health Sciences)		Here robotic arm and HMI panel is used to handle the test tube for chemical sample handling purpose in laboratories. The photograph observed during experimentation shows the successful integration of graphical user interface for biomedical application of robotic arm
Sr.No.	**Application category**	**Photograph of observation**	**Description**
02	Pick and Place Industrial application	  	Here it is observed that robotic arm operated by using HMI panel is doing pick and place activity with accuracy and precision. In the first photograph robotic arm doing picking activity of red block, second photograph shows that robotic arm successfully hold the block during motion and third photograph shows it is kept accurately to desired position.
03	Service Robot		Third observation shows that robotic arm and HMI integration is used for offering a flower to guest in cultural function as service type of robot.

VII. CONCLUSION

Finally, the "Development of GUI for Controlling Robotic Arm for Biomedical Applications" research is a game-changing endeavour that has the potential to transform the landscape of biomedical robotics. The research emphasis on developing an intuitive and user-friendly graphical user interface (GUI) shows a dedication to improving control and precision in a variety of biomedical applications. The detailed overview of the article including goals, scope, stages, methodology and conclusions gives a comprehensive understanding of the intricate aspects of the project. The rich content of the process of developing the GUI, hardware integration, safety measures, and successful testing of usability of the GUI indicate the success of the research in fulfilling its goals. It is important to note that the project has demonstrated tremendous improvements in precision, safety, and efficiency in a large scale of biological applications. Compared to its technical achievements, this study report is a valuable reference material to those and organizations that are keen to the interface between robotics and biomedical applications. The future and positive effect on healthcare providers and patients presented as projections indicate the innovation and progress of biomedical robots. This success of the research in essence is an indicator of a new era in the evolution of user-friendly interfaces of robotic arms which can advance the technology and healthcare industry.

ABSTRACT

The improvement of the visual quality of the image of the underwater objects in the low-light conditions is a must in such applications as marine monitoring, self-driving cars, and detection of the objects underwater. Such pictures are often characterized by color variations, reduced brightness and high amount of noise because of the rapid extinction of the light in water. In order to deal with these difficulties, we examine two state-of-the-art deep learning models: Zero-DCE++, a zero reference curve estimation model which can enhance the low-light images without using ground truth supervision and U-former, a transformer based architecture that is targeting the high fidelity image restoration. The two models are applied at preprocessing stages in order to enhance contrast, color fidelity and general visibility before sending the enhanced images to detection or segmentation process. Blind/Reference-less Image Spatial Quality Evaluator (BRISQUE), Natural Image Quality Evaluator (NIQE), Lightness Order Error (LOE) and Colourfulness Index (CI) are quantitative measures of an improved performance. The experimental outcomes show that there is significant enhancement of the visual quality and strength of IQE - 3.90, RISQUE - 28.40, LOE- 740, CI - 52.10 over conventional convolution-based methods.

I. INTRODUCTION

The use of underwater imaging has increasingly become important in different fields, such as marine biology, underwater archeology, autonomous underwater vehicles (AUVs), environmental monitoring and security surveillance. However, obtaining clear and quality images in underwater sites is very challenging especially when there is low-light. Underwater images are mostly of low visibility with low contrast, abnormal colors and too much noise due to the nature of water, whether it is in absorption or scattering. These degradations are also intensified in deep-sea or turbid environment, where the light in the ambience is little and artificial sunlight is not allowed to reach all depths.Automatic image processing tasks, among them object detection, classification, and semantic segmentation are only a handful of hindrances to the use of low-light underwater images (LLUWIs) which also diminish the effects of human visual interpretation.

To have future algorithms operating effectively and efficiently, there is need to preprocess these images to make them more visual in nature. In underwater or very low-light conditions, the typical methods of picture enhancement like histogram equalization or Retinex like algorithms show only a limited enhancement. The major problems with these methods are oversaturation of noise content, loss of texture and color imbalance. Image augmentation has become very complicated with the implementation of deep learning in that it enables the adaptive learning of data as well as more complex feature extraction. Although CNNs are very successful in enhancing low-light images overall, the local receptive fields restrict them in the number of the long-range dependencies and the intricate changes in light. This study aims to address these gaps by discussing Zero-DCE++ and Uformer, which are the latest state-of-the-art deep learning methods that are explicitly focused on underwater low-light image augmentation. Zero-DCE++ also uses less associated training data since the framework can learn image improvement through the estimation of pixel-wise change curves.

In the case of real-life situations where quality and authentic photos are not easily obtained, one technique is known as zero-reference learning. Uformer can help restore pictures with the help of spatial attention techniques and hierarchy-based processing in order to preserve the property of structure by using a transformer-based design. This helps to comprehend the context. This approach maximizes the colour fidelity and visibility of low-light underwater photos (LLUWIS) in order to prepare them to other more complex tasks, such as object detection or segmentation. It does this through combining the two models to networks that process batches. The improved results are measured using a set of NR-IQA metrics, such as NIQE, BRISque, Lightness Order Error (LOE) and Colorfulness Index (CI). These measures enable us to view the fact of whether the enhanced photos are always bright, vivid colors, structurally sound and natural looking. We determined in this experiment that both Zero-DCE++ and Uformer significantly enhance the aesthetic of low light underwater imagery by our extensive experiments and aesthetic analyses. Moreover, the paper also puts into focus the joint endeavors of the attention-based transformers and curve-based augmentation methods in addressing the special needs of underwater imaging.

II. RELATED WORK

Imaging in low light in the water has many barriers to cross. According to [1], one of the approaches that can be implemented to address this problem is to use deep convolutional neural networks (CNNs) together with depth estimation to de-scan the images of the light fields. The other goal of their approach, which makes use of a spectral-based color correcting method, is to repair color grayscale damage. The outcome of experiments indicates that this method is effective to bypass the issues of the conventional underwater imaging. Light absorption and dispersion affect underwater imaging, particularly in low-light scenarios, and may cause distortion of color as well as low contrast. One of the solutions that have been proposed to resolve this issue involves the use of an end-to-end improvement method that utilizes Retinex that combines light and picture reflectance [2]. This model involves hybrid attention methods, dense connections with cross-residual blocks, as well as an emphasis on key areas of the image in order to enhance features. In order to guarantee the consistency of color we use a color cast loss of HSV space in a manner that considers the Euclidean distance. In order to make it look more convincing, we use adaptive frequency convolutional blocks to increase the illumination. The results of both quantitative and qualitative analyses performed on various datasets support the efficiency of the given method in terms of visual quality improvement. Due to the low light levels, underwater pictures frequently feature blurry edges and smudges. As a result, researchers came up with L³UWE, a novel picture enhancer [3]. One improved picture has greater details, whereas the other doesn't have shadows, because it accurately mimics ambient light utilizing local contrast. The last step is to merge the photos via a multi-scale fusion technique that prioritizes brightness, contrast, and saliency. When tested underwater and in low-light settings, the L²UWE method beat seven popular enhancement techniques on seven separate quality parameters. Traditional enhancing approaches can include artifacts, noise, and edge detail loss [4], and underwater low-light photos frequently suffer from low contrast, fuzzy features, and color distortion. In order to address these issues, the authors put out a low-light enhancement technique for underwater environments that uses a U-shaped Generative Adversarial Network (GAN) in conjunction with attention and bright channel prior processes. While attention-based feature extraction takes care of color distortion, brightness, and texture, a two-channel fusion method is employed to maintain detail and edge quality.

In order to reduce noise in the improved outputs, a multi-loss function is utilized. Underwater target detection and species identification are two applications of the approach that thrive in deep water. The suggested strategy considerably enhances quantitative measures for underwater image quality as well as visual quality, according to extensive experiments that include comparisons and ablation studies. The computer vision tasks of segmentation, identification, and tracking may be compromised by photos and videos captured in low-light environments. Other deep-sea environments, including Ocean Networks Canada (ONC), use artificial light to record images underwater though when this light becomes inoperable, the images become blurred [5]. To demonstrate this, the authors provided a framework to improve the lighting in underwater images and retrieve meaningful visual features. The method also entails image dehazing with dark channel prior and fast guided filters to effectively enhance clarity of low-light underwater images. Besides presenting the framework of underwater imaging, in [6] offer a comprehensive review of the ways of how to enhance and recover underwater images. It also has a systematic analysis of the mainstream quality measurement approaches and collections of publicly accessible underwater image datasets. We do rigorous experimental comparisons in order to establish the influence of various enhancement techniques on advanced vision tasks. In order to make sure that this publication could be used as one of the priceless sources of data concerning underwater image processing by the researchers, the authors also pursue the open questions and possible research directions. Underwater Image Enhancement is still a challenging area in computer vision with no comprehensive review available so far [7]. The authors provide an in-depth review of UIE, discussing topics such as physical imaging models, dataset generation, evaluation criteria, and loss functions. Network architecture, learning phases, auxiliary tasks, domain adaptability, feature fusion, and learning techniques are the criteria used to classify new algorithms.

Researchers employ extensive quantitative and qualitative comparisons across many benchmark datasets to address discrepancies in earlier assessments. At last, it draws attention to important areas where underwater picture improvement research has to go in the future.

Despite advancements in underwater image-capturing technologies, computer vision applications continue to face problems such as low-quality and low-resolution images caused by low illumination and dispersion. A lot of the newer methods rely on deep learning models, such as GANs and CNNs, to improve them [8]. Despite their high visual quality, GANs sometimes underperform CNNs in quantitative evaluations. In order to circumvent these problems, the authors suggested a mixed strategy that makes use of both GAN and CNN architectures. By utilizing the generator, the training dataset can be expanded. Experiments carried out on the EUVP dataset demonstrate that the suggested approach surpasses current methods in terms of visual and quantitative image quality, with higher PSNR and SSIM scores.

III. METHODOLOGY

This section gives a detailed description of the steps used to improve underwater images taken in poor light using deep learning. To overcome the specific challenges of underwater imaging in low light, our approach makes use of two state-of-the-art models: Zero-DCE++ and U-former as shown in Figure 1. Dataset preparation and cleaning is the first step of the proposed approach. First, we train the improvement models. Then, we use some quality metrics for images without a reference to see how well they did. Managing the dataset, creating the model, training methods, and assessment are the main parts of the process.

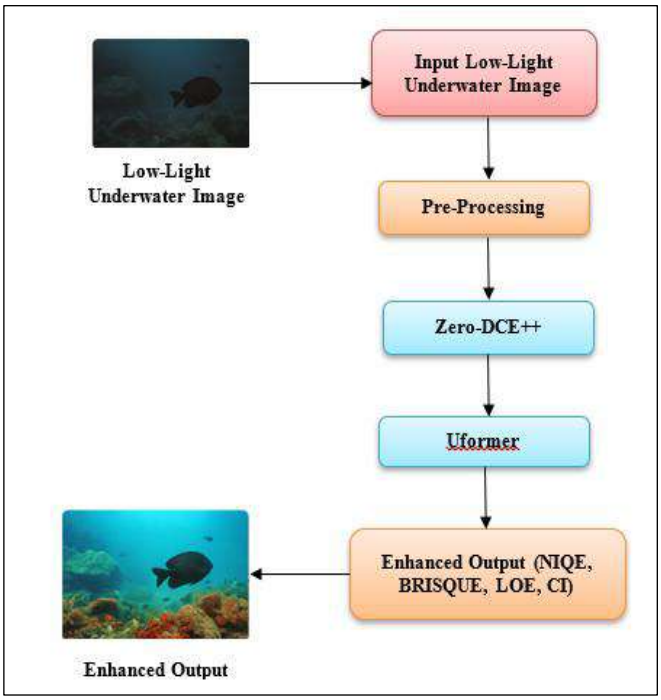

Figure 1: System Architecture of Proposed Work.
Source: Authors, (2026).

A. Data Set and Preprocessing

Publicly available underwater visual datasets such as UIEB (Underwater Image Enhancement Benchmark) and EUVP (Enhancing Underwater Visual Perception) are utilized for training and evaluation purposes using the improved models. The datasets include different underwater images acquired in both low and normal light settings and throughout various environmental conditions, including surface-level and deep water, turbid and clear water, and artificial lighting scenarios.

The input intensities are normalized and computing speed is reduced by resizing all photos to a uniform resolution of 256x256 pixels. In order to make the training set more diverse and to make the model more generalizable, data augmentation approaches are used. Horizontal and vertical flipping, random rotation, adjusting brightness and contrast, and cropping are all part of these enhancements. After that, the pictures are leveled to a [0,1] scale so they conform to what the deep learning methods expect as input.

B. Zero-DCE++ Enhancement Framework

Zero-DCE++ is an advanced zero-reference low-light enhancement model that reconstructs over the original Zero-DCE architecture. Unlike traditional supervised models, Zero-DCE++ does not require paired training data, which makes it highly suitable for real-world underwater image enhancement where clean reference images are seldom available [9]. The main idea behind Zero-DCE++ is to learn a collection of enhancement curves that adjust the brightness of images adaptively depending on their content [10]. The model's architecture is based on a convolutional neural network that takes a low-light image as input and generates features used to improve the natural image. Through iterative modifications, it enhances brightness and contrast while carefully identifying overexposure and unwanted artifacts. Zero-DCE++ navigates the improving procedure during training by concatenating multiple loss functions [11],[12].

These include luminance smoothness to decrease low lighting variations, color constancy to maintain balanced colors, exposure control loss to achieve optimal brightness, and spatial consistency loss to preserve the image's structural integrity. By combining these components ensure that the enhanced images retain their textures and edges while becoming clearer and more visually appealing.

C. U-former: Transformer-based Image Enhancement Model

U-former is a novel method for enhancing and restoring images that uses transformer structures. It takes design prompts from the commonly used U-Net model for medical and restorative tasks, but it includes self-attention framework to help it take in both local and global context. The U-former model is with an encoder-decoder structure that are uniformed. In order to extract hierarchical features, the encoder gradually down-samples the image; in contrast, the decoder reconstructs the improved image by up-sampling [13-15]. One unique feature of U-former is the attention blocks that are integrated into both the encoder and decoder levels. These blocks allow the model to zero down on important spatial regions and capture relationships that extend across levels.

To keep the granularity of the spatial information, the matching encoder and decoder layers use skip connections. Through the use of these connections, U-former is able to combine low-level picture details with deep semantic information in order to rebuild high-quality images. Because maintaining structural integrity and edge information is of the utmost importance in underwater image enhancement, this is of great use. Typically, a reconstruction loss is calculated as the difference between the augmented output and a high-quality pseudo-ground truth image. This loss is used to optimize U-former during training. To further enhance texture and eliminate noise, the model may further consider perceptual and smoothness losses.

D. Training Strategy

In this research, we use the selected dataset to train the models: Zero-DCE++ and Uformer. The deep learning framework we use is PyTorch. During training, the networks are feeding the batches of underwater images taken in low light conditions. The model parameters are then updated using backpropagation and stochastic gradient descent techniques [16],[17]. The consistency and genuineness of the increased outputs are the only criteria for Zero-DCE++'s unsupervised training. Using either a supervised or semi-supervised method, Uformer trains its model using either curated high-quality underwater images or pseudo-ground truths produced by conventional enhancing techniques [18]. To ensure consistent and efficient training, the learning rate, optimizer parameters, and batch sizes are precisely chosen. For the purpose of keeping an eye on performance and preventing of overfitting, a different set of images are utilized for regular validation [19]. The models undergo training until they reach convergence, which can take anything from a few hundred to several thousand epochs, depending on the dataset size and model complexity.

E. Performance Evaluation Metrics

The enhancing techniques are evaluated by applying a set of standards called NR-IQA, which stands for no-reference image quality assessment. They allow for a quantitative evaluation of visual quality without using a ground truth reference image [20].

- NIQE (Natural Image Quality Evaluator): Measures the variations of the improved image from the computational properties of original images. Lower scores indicate higher quality.
- BRISQUE (Blind/Referenceless Image Spatial Quality Evaluator): Measures the image distortion depends up on spatial domain attributes. Lower values correspond to better visual quality.
- LOE (Lightness Order Error): Computes the coherence of brightness ordering between input and improved images. A lower LOE suggests that the original lighting relationships are better obtained.
- Colorfulness Index (CI): Quantifies how saturated and vibrant the image's colors are. Higher CI score gives more visually appealing enhancements.

The outcomes of Zero-DCE + and U-former are contrasted with each other with the aim of determining the strengths of each. The qualitative values are confirmed by both quantitative values and qualitative visual analysis in the verification of the intuitive benefits especially in reduction of haze, enhanced visibility in poorly lit areas, and preservation of structural features.

IV. RESULTS AND DISCUSSIONS

The stated underwater low-light image enhancement framework, which combines Zero-DCE++ and U-former models, is thoroughly evaluated in this section. To prove that the suggested system works, we give quantitative and qualitative tests.

A. Quantitative Evaluation

To evaluate the performance, below No-Reference Image Quality Assessment metrics are used:

- NIQE (Natural Image Quality Evaluator)
- BRISQUE (Blind/Referenceless Image Spatial Quality Evaluator)
- LOE (Lightness Order Error)
- Colorfulness Index (CI)

The proposed techniques which are shown in the Table 1:

- Original Low-Light Underwater Images
- Zero-DCE++ Alone
- U-former Alone

Proposed Combined Method (Zero-DCE++ + U-former)

The intuitive advantages, particularly in minimizing haze, improving visibility in dark locations, and maintaining structural features, are validated using quantitative values as well as qualitative visual evaluations.

Table 1: Performance Metrics Table.

MODEL	IQE ↓	RISQUE ↓	LOE ↓	Colorfulness Index ↑
Original	7.80	60.50	1800	28.00
Zero – DCE ++	5.10	35.20	950	45.60
U-Fromer	4.80	32.60	870	47.30
Proposed (Zero-DCE++ & U-former)	3.90	28.40	740	52.10

Source: Authors, (2026).

B. Qualitative Evaluation

After using the suggested strategy, the enhanced images were compared to the original input images and to those created by separate models.

C. Visual Enhancement

- The original images appeared dark, colour-degraded, and lacking in texture details.
- Zero-DCE++ enhanced images showed improved brightness but sometimes introduced slight artifacts and limited texture recovery.
- In contrast to Zero-DCE++, the U-former provides good structural details of enhanced images and decreases the noise but slightly was inadequate in brightness improvement.
- Suggested approaches combined the best features of both models, delivering in the Table 2:
  - Improved brightness without over illumination.
  - Clear borders and texture information.
  - Improved contrast.
  - Natural and vibrant colour balance.
  - Reduced haze and colour casts.

Table 2: Comparative Analysis with Existing Techniques.

Method	NIQUE↓	BRISQE↓	LOE↓	CI ↑
Original Image	7.80	60.50	1800	28.00
Histogram Equalization	6.20	50.00	1400	34.00
CLAHE	5.80	42.50	1200	37.50
Retinex-based Method	5.10	38.00	1000	42.00
Zero-DCE++	5.10	35.20	950	45.60
U-former	4.80	32.60	870	47.30
Proposed Method	3.90	28.40	740	52.10

Source: Authors, (2026).

The Figure 2 shows the bar graphs of the comparison of image quality performance metrics, NIQE and BRISQUE, among different enhancement methods. Lower scores indicate better visual quality. The proposed method illustrates the most significant improvement over existing methods.

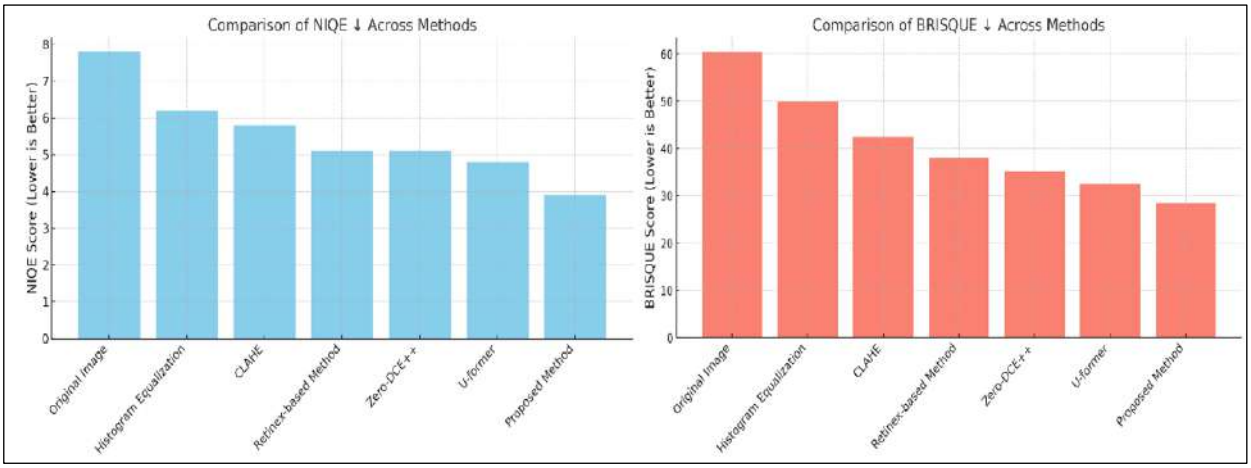

Figure 2: Comparison of NIQE and BRISQUE Scores Across Different Enhancement Methods.

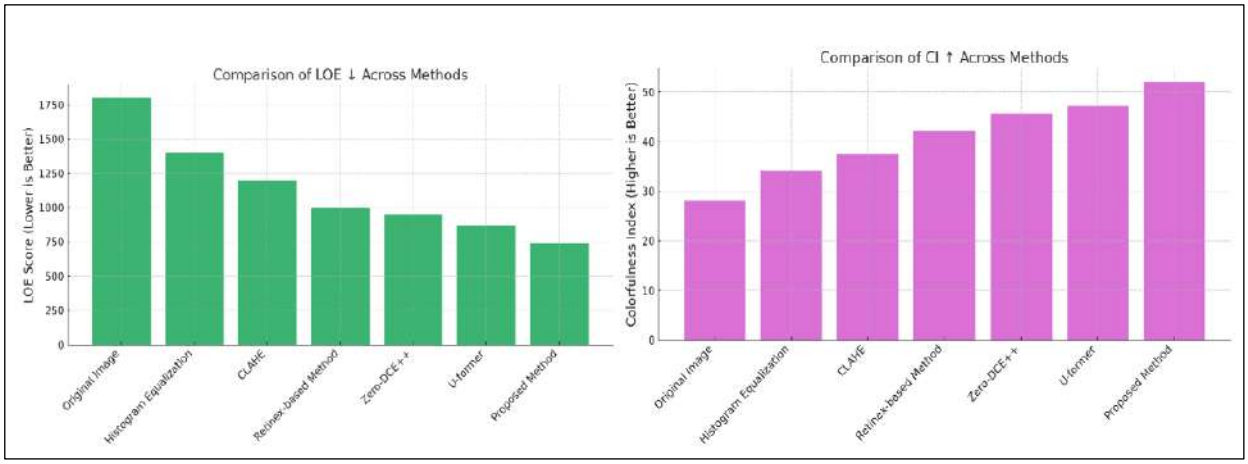

Figure 3: Comparison of LOE and CI values over the Different DL Techniques.
Source: Authors, (2026).

The Figure 3 shows the bar graphs of the comparison of image quality performance metrics, LOE and CI, among different enhancement methods. Lower scores indicate better visual quality in LOE metric and Higher score indicates robust visual quality in Colorfulness Index. The proposed method illustrates the most significant improvement over existing methods.

(a) (b) (c)

Figure 4: Low Ligh Underwater Image Enhancement results (a) Input Image (b) Output using Zero – DCE ++ (c) Proposed output using Zero – DCE ++ & Uformer.
Source: Authors, (2026).

Figure 4 depicts the final and improved output that happens on input of low-light, blurred or noisy images. The sophisticated deep learning networks, Zero-DCE++ and Uformer, are used to achieve a better brightening of these distorted images and rebuild clear and visually pleasing details. In addition to increasing brightness these models significantly reduce noise and blur thus resulting in a high quality image. Its improvement is extremely important in applications in which the appearance and detailing of poor-quality underwater or low-light images are necessary, including marine exploration, autonomous navigation, and detection of objects in the underwater environment.

V. CONCLUSIONS

To address the existing issues with the degradation of low-light images underwater, we proposed a contemporary hybrid improvement framework that unites the most suitable characteristics of the Zero-DCE++ and U-former models. A systematic process was followed which started with data preparation. Additional application of model-specific augmentation methodologies took place. In the methodology, the strict validation of the procedure was performed against no-reference image quality evaluation measures, including NIQE, BRISQUE, LOE, and Colorfulness Index. The solution proposed is much better than the existing methods, such as Histogram Equalization, CLAHE, and models based on Retinex, in both quantitative and visual perception quality. Zero-DCE++ is the best to enhance underwater images as it can enhance global contrast and brightness without the use of paired training data. Moreover, the Uformer resilient attention mechanisms and transformer-based structure effectively retain complicated textures and structural elements. The two models combined will enhance the visual quality by minimizing distortion, enhancing the sharpness of edges, and regaining colors more realistically as demonstrated in ablation test and extensive comparisons.

The options of how this technology can be used are numerous, and they include detecting underwater objects, identifying marine animals, and real-time navigation of robotic vehicles. The structure also creates opportunities to increase computational power to the video processing, which may accelerate the creation of underwater augmentation systems operating in real time. Encouraging learning through competition or incorporating multi-modal sensor inputs could enhance the upgrading process's resilience and adaptability to diverse underwater environments.

ABSTRACT

This study focuses on the feature extraction of an individual image samples for both Pigweed and Birch Flower. The features are categorized with three Main types: Morphology, Color and Texture features. The extracted features will then be trained using the MATLAB Machine Learning using the Classification Learner App. Morphological features describes the shape and structural properties of the plant region in the image. This includes the area, perimeter, eccentricity, solidity, extent, major and minor axis length. The color features are also extracted from both RGB (Red, Green, Blue) and HSV (Hue, Saturation, Value) color spaces to capture the visual appearance of the plant region wherein the algorithm calculated the mean and standard deviation which describes the average and the variability of the color. The texture features characterized the spatial variation in pixel intensity, which is important for distinguishing surface patterns. This includes contrast, correlation, energy, and homogeneity. The result shows that the validation and testing accuracy level using the k-Nearest Neighbor ranges from 88.57-99.29% and 83.33-98.33% respectively. The study's outcome demonstrates the potential of feature-based image analysis in the accurate identification of medicinal and botanical species, encouraging future developments in automated plant recognition systems.

I. INTRODUCTION

Traditional medicine used to depend primarily on medicinal plants to provide natural treatments for a wide range of illnesses. Pigweed (*Uray*) with scientific name of *Amaranthus Spinosus* and Birch Flower (*Himbabao)* scientifically named as *Broussonetia Luzonica* have been known for their potential therapeutic properties and the flower of both plant has the similarity in color and surface texture which may resemble each other and could lead to confusion. Leafy vegetables promote reparation of energy loss due to oxidative stress, and they have the potential to alleviate hunger and malnutrition as well as other forms of metabolic imbalance ravaging the world. However, these vegetables are underutilized, despite the fact that they harbor essential minerals needed for critical cellular activities [1]. The *Uray* plant grows annually as an erect, monoecious herb, up to 100–130 centimeters tall. Its stem is either round or slightly angled in shape. It is smooth or slightly hairy, and usually green in color. The flowers of *Uray* grow in dense groups. The lower groups appear at the leaf joints (called axils), while the upper one's form both at the leaf joints and at the tips of the branches.

These upper flower groups often form spike-like structures and may have small branches near the base. The ones at the leaf joints usually have sharp spines that can grow up to 2 centimeters long [2]. The *Himbabao* tree, also called Birch Flower, is a medium-sized tree with a trunk that is roughly 30 cm broad and can reach a height of 15 meters. It has smooth bark. The leaves are hairy on the underside, have rounded bases and pointy points, and grow alternately on the branches. The flowers are tiny and grow on long, thin, spike-like stems [3]. However exact classification and identification of these plants continues to be challenging as they have common features particularly elongated leaves and green foliage, that can make it challenging for researchers to distinguish between the two species and leading to incorrect categorization. Both are widely found in the Philippines and are utilized as vegetables in local cuisine; they also function as traditional herbal medicine.

The focus of this research is the classification of the flower of both plants since it has similarities in their flowering structures though they belong to different plant families. Many modern methods for prediction leverage nearest neighbor search to find past training examples most similar to a test example, an idea that dates back in text to at least the 11th century and has stood the test of time [4]. This study aims to extract and classify the a set of features from the individual sample of flower images of *Uray* Plant and *Himbabao* Tree using an online free software version of MATLAB to support the identification and classification. The extracted features include Morphology, Color and Texture features. In machine learning, pattern recognition, and image processing, feature extraction begins with an initial set of measurement data and establishes derived values (features) aimed at providing information and non-redundancy, thus facilitating the subsequent learning and generalization steps and bringing better interpretability in some cases.

Image feature extraction is a process that uses certain methods to extract the local structure, content features, and global features of the image. Through feature extraction, the essential features with high information content, distinguishability, and high repeatability can be extracted from complex images [5]. The K-Nearest Neighbors (KNN) algorithm is a popular but efficient feature-based classification method for plant identification. KNN is a machine learning technology that can be used to differentiate between different kinds of medicinal plants since it classifies objects based on feature similarity. The feature extraction of the image samples are categorized with three Main types: Morphology, Color and Texture features. The extracted features will then be trained using the MATLAB Machine Learning using the Classification Learner App. Morphological features describes the shape and structural properties of the plant region in the image. This includes the area, perimeter, eccentricity, solidity, extent, major and minor axis length. The color features are also extracted from both RGB (Red, Green, Blue) and HSV (Hue, Saturation, Value) color spaces to capture the visual appearance of the plant region wherein the algorithm calculated the mean and standard deviation which describes the average and the variability of the color. The texture features characterized the spatial variation in pixel intensity, which is important for distinguishing surface patterns. This includes contrast, correlation, energy, and homogeneity.

II. THEORETICAL REFERENCE

II.1 EXISITING STUDIES USING K-NEAREST NEIGHBOR ALGORITHM

Among the 23 machine-learning algorithms, the best performance was achieved by medium K-nearest neighbor which has 97% accuracy and 0.14574 seconds in speed. When compared with previous studies that used RGB and HSV color features to differentiate mature and immature coffee beans, it can be concluded that texture features are far superior in distinguishing the two coffee bean groups [6].

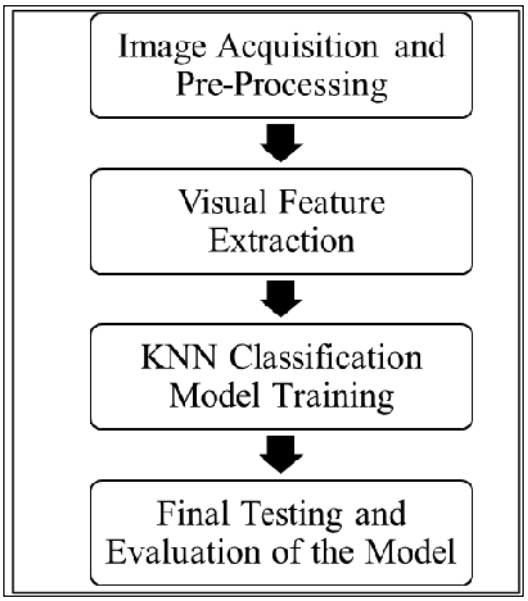

Figure 1: Procedural framework for the study.
Source: [7].

Figure 1 shows the overall procedural framework for the study. It consists of four major steps that were followed methodically to ensure proper data acquisition. Specifically, thesteps include: (1) image acquisition and pre-processing, (2) visualfeature extraction, (3) KNN classification model training, and (4) final testing and evaluation of the model [5]. The numerical representations of the texture extracted from the images enhanced the classification capabilities of the machine learning algorithm by providing more parameters to be fed into the system. Specifically, the MATLAB's Classification Learner App was usedto classify the diseases using three KNN variants, namely: fine KNN, cosine KNN, and weighted KNN. These three variants were used since each offers different metrics and weighting strategiesthat optimize the classification of the dataset. Lastly, hold-out validation was implemented as the validation process to ensure themodel's accuracy and generalization capabilities [7].

III. MATERIALS AND METHODS

This section discussed the methodology employed in the study to classify the difference between the two medicinal plant, Pigweed (*Uray)* and Birch Flower (*Himbabao)* based on the extracted features from an individual image sample using machine learning.

III.1 MATERIALS

The data used for this research consists a total of 200 flower samples of both plants; 100 samples of Pigweed (*Uray)* and 100 samples of Birch Flower (*Himbabao)*.
Following sample collection, the camera was positioned 200 centimeters away from the sample object to ensure consistent image capture, which is essential for the accurate extraction of morphological features. Shown in Figure 2.
To ensure an unbiased model evaluation, the dataset was split into a simple train-test split: 70% training set and 30% test set.

Figure 2: Camera and plant sample position for image capturing.

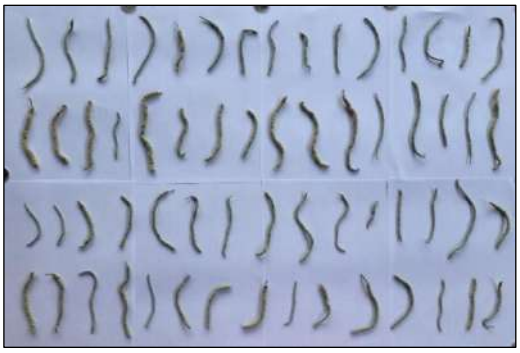

Figure 4: Sample raw *Himbabao* Plant.
Source: Author, (2026).

III.2 METHODS

An online free software was used to develop the Machine Learning based classifier. MATLAB Online was used to develop the machine learning-based classifier. The algorithm was created to process image samples organized in a designated computer folder, enabling feature-based extraction for classification purposes. The feature is categorized into three types: Morphological feature, Color feature, and a Texture feature. Figure 5 shows the procedural framework for the feature extraction before the training process. The algorithm aimed to extract relevant features to support the medicinal plant identification. The main steps include (1) Image Acquisition, (2) Pre-Processing, (3) Feature Extraction, and (4) Data Storage and Compilation.

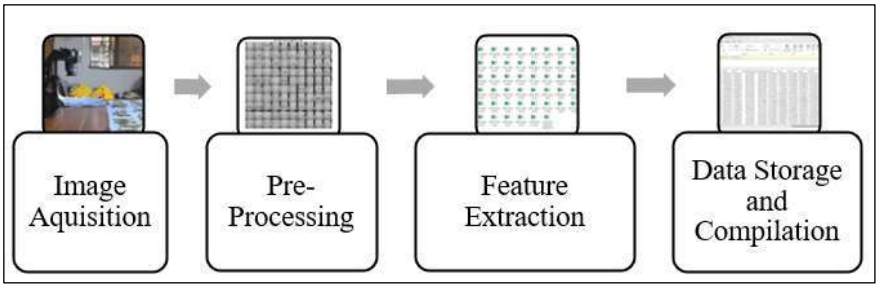

Figure 5: Steps in the Feature Extraction Algorithm used in training the dataset.
Source: Author, (2026).

Moreover, Figure 6 shows the overall procedural framework for the training, validation and testing process. Three major steps were followed to ensure the proper data classification. The steps include: (5) KNN Classification Model Training, (6) Training Result comparison, and (7) Testing and Evaluation of the Model.

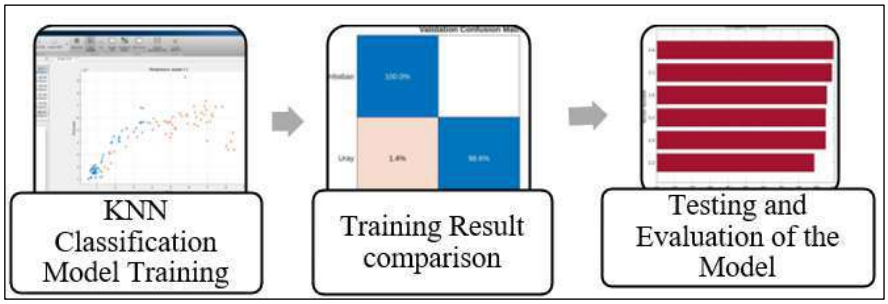

Figure 6. Steps in the Model Training and Testing.
Source: Author, (2026).

III.2.1 Image acquisition

Sample collection was the first step to create a dataset. Took individual images for a total of 200 samples, 100 flower samples of *Uray* and 100 flower samples of *Himbabao*. After sample collection, the camera was positioned 200 centimeters away from the sample to ensure that all images were captured at a consistent level, which is essential for accurate extraction of morphological features. This includes the (a) Area for the total number of pixels in the sample, (b) Perimeter for the length of the sample boundary, (c) Eccentricity for the degree of elongation based on ellipse fitting, (d) Solidity for the compactness, (e) Extent which is the ratio of the area to bounding box area, and (f) Major and Minor Axis Length of the best fit ellipse.

III.2.2 Pre-Processing

The captured image is saved to a designated folder, which will be accessed in the subsequent feature extraction step. The pre-processing procedure involves developing an algorithm specifically designed to extract the key features necessary for accurately classifying the sample objects. Shown in Figures 7, 8 and 9.

III.2.3 Feature extraction

MATLAB performs the feature extraction from an image of the plant using segmentation mask. (1) Morphological, (2) Color, and (3) Texture features are calculated to be used for classification and analysis.

III.2.3.1 Morphological features

The *regionprops* function in MATLAB was used to derive the morphological characteristics of the image sample, which showed the shape forms like the Area, Eccentricity, Solidity, Extent, Major and Minor axis lengths. Shown in Figure 10.

```
26      % Morphological features
27 -    props = regionprops(mask, 'Area', 'Perimeter', 'Eccentricity', ...
28          'Solidity', 'Extent', 'MajorAxisLength', 'MinorAxisLength');
```

Figure 10: Snippets of code used for extracting the morphological features of the plant.
Source: Author, (2026).

III.2.3.2 Color features

The color features were obtained by masking the RGB image and the variation for each RGB and HSV channel were calculated to describe the color characteristics of the plant. As shown on Figure 11.

```
32      % Color features (RGB & HSV mean/std)
33 -    maskedRGB = bsxfun(@times, img, cast(mask, 'like', img));
34 -    r = maskedRGB(:,:,1); g = maskedRGB(:,:,2); b = maskedRGB(:,:,3);
35 -    r = r(mask); g = g(mask); b = b(mask);
36
37 -    hsv = rgb2hsv(img);
38 -    h = hsv(:,:,1); s = hsv(:,:,2); v = hsv(:,:,3);
39 -    h = h(mask); s = s(mask); v = v(mask);
```

Figure 11: Snippets of code used for extracting the color features of the plant.
Source: Author, (2026).

III.2.3.3 Texture Features

Figure 12 shows texture feature was extracted from the grayscale version of the original image, which measures the contrast, correlation, energy, homogeneity.

```
41        % Texture features
42 -      glcms = graycomatrix(gray, 'Offset', [0 1]);
43 -      statsGLCM = graycoprops(glcms, {'Contrast', 'Correlation', 'Energy', 'Homogeneity'});
44 -      entropyVal = entropy(gray(mask));
45 -      stdVal = std(double(gray(mask)));
```

Figure 12. Snippets of code used for extracting the texture features of the plant.
Source: Author, (2026).

III.2.4 Data Storage And Compilation

After extracting the morphological, color, and texture features from the segmented plant image, the numerical values were thoroughly compiled into a structured format for further study. To ensure the clarity and consistency in interpretation, the corresponding features were combined and saved as an individual Excel file (*.xlsx format*).
Moreover, the individual file was then compiled and used for training the dataset. As shown on Figure 13.

```
47        % Store features
48 -      features = [
49            props.Area, props.Perimeter, props.Eccentricity, props.Solidity, ...
50            props.Extent, props.MajorAxisLength, props.MinorAxisLength, ...
51            Roundness, mean(r), std(double(r)), ...
52            mean(g), std(double(g)), mean(b), std(double(b)), ...
53            mean(h), std(h), mean(s), std(s), mean(v), std(v), ...
54            statsGLCM.Contrast, statsGLCM.Correlation, ...
55            statsGLCM.Energy, statsGLCM.Homogeneity, ...
56            entropyVal, stdVal
57        ];
58
59 -      featureLabels = {
60            'Area','Perimeter','Eccentricity','Solidity','Extent','MajorAxisLength', ...
61            'MinorAxisLength','Roundness', ...
62            'Mean_R','Std_R','Mean_G','Std_G','Mean_B','Std_B', ...
63            'Mean_H','Std_H','Mean_S','Std_S','Mean_V','Std_V', ...
64            'GLCM_Contrast','GLCM_Correlation','GLCM_Energy','GLCM_Homogeneity', ...
65            'Entropy','Std_Gray'
66        };
67
68        % Save to individual file
69 -      T = cell2table(features, 'VariableNames', featureLabels);
70 -      writetable(T, fullfile(folderPath, [filename(1:end-4) '_features.xlsx']));
71
72        % Append to compiled data
73 -      compiledFeatures = [compiledFeatures; {filename, features}];
74 -  end
```

Figure 13: Snippets of code used for extracting the dataset.
Source: Author, (2026).

III.2.5 KNN Classification Model Training

Following the feature extraction, data storage and compilation, the k-Nearest Neighbors machine learning algorithm was used to classify two different plant species. The MATLAB Classification Learners App was used specifically using six different KNN variants; this includes Fine KNN, Medium KNN, Coarse KNN, Cosine KNN, Cubic KNN, and Weighted KNN. These variants were then used and produced different accuracy level. Before training the dataset, a 5-fold cross-validation method was applied, which means the training set was split into five parts, and the model was trained and validated five times using different combinations. This method allowed the validation of the model during training. From the total number of 200 dataset, 70% were used for training and cross-validation while the remaining 30% were set aside for testing the final model.

III.2.6 Training Result Comparison

The training results of all applied classifiers were compared in terms of accuracy, error rate, weighted precision, weighted recall, and training time to assess the performance of all the six KNN variants.

The model variant with the highest level of accuracy after the training will then be selected as the most appropriate classifier to be used for the testing and evaluation of the remaining 30% of the total dataset.

III.2.7 Testing and Evaluation of The Model

Following the training result, the summary of the classification results was compared and evaluated for further analysis.
Testing results will then be presented and compared to the result of the training and validation.
Among the evaluated models, the variant having the highest validation accuracy and the shortest training time was identified as the most effective classifier for medicinal plant recognition. When evaluating the effectiveness of the classification model, classification metrics is considered, this includes, Accuracy, Precision, Recall and F1 score. Each metrics provides different considerations into the model performance, especially when dealing with imbalanced dataset. Accuracy is defined as the the ratio of correctly predicted observations to the total number of observations in Equation (1):

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (1)$$

Precision also called Positive Predictive Value is the ratio of correctly predicted positive observations to the total predicted positives in Equation (2).

$$Precision = \frac{TP}{TP + FP} \tag{2}$$

Recall also known as True Positive Rate is the ratio of correctly predicted positive observations to all actual positives in Equation (3):

$$Recall = \frac{TP}{TP + FN} \tag{3}$$

where: TP – True Positive Prediction
TN – True Negative Prediction
FP – False Positive Prediction
FN – False Negative Prediction

While, F1 Score is the harmonic mean of Precision and Recall. It balances the trade-off between Precision and Recall, especially useful in imbalanced classes in Equation (4).

$$F1\ Score = 2\ x\ \frac{Precision + Recall}{Precision * Recall} \tag{4}$$

These values are directly generated from MATLAB's classification training output and do not require manual computation. They provide a comprehensive evaluation of the model's classification performance.

IV. RESULTS AND DISCUSSIONS

This section discussed the datasets, KNN classification, and testing and evaluation of the study to classify the difference between the two medicinal plant, Pigweed (*Uray)* and Birch Flower (*Himbabao)*. The data set consisted of labeled image samples that are pre-processed and extracted to quantify the features and then compiled and organized for further analysis. The results include individual feature values for each image sample and summarized providing the overview of the variations within the dataset and serves as the basis for classification and recognition. A total of 25 predictors were obtained and used for the training, validation, and testing the dataset.The outcomes are presented separately based on the Morphological features, Color features, and Texture features. A total of 200 images were extracted and combined for the study. During training and cross-validation, 140 samples were used while the remaining 60 samples were reserved for testing to evaluate the model's performance.

IV.1 VISUAL FEATURE EXTRACTION

Table 1 shows the summary of the extracted feature values of the images of Pigweed *(Uray)* and Birch Flower *(Himbabao)* respectively based on their morphological characteristics, such as: area, perimeter, eccentricity, solidity, extent, major and minor axis which describes the shape and structure of both plants.

Table 1: Summary of the features extracted from the image samples of both *Uray* and *Himbabao.*

FEATURES:	MEDICINAL PLANT

IV.2 KNN CLASSIFICATION MODEL TRAINING

After the extraction of the numerical parameters present in both plants, the KNN machine learning was trained using MATLAB online, Classification Learners App. The classification was determined by the 25 predictors obtained from the preceding process. Table 2 presented the classification results of the six KNN model variants used for training using 5-folds cross-validation, from the total of 200 samples, 140 samples (70%) were used for training the algorithm. Furthermore, a hold-out validation structure was used to set aside 60 samples (30%) from the original sample for the testing of the KNN algorithm.

Table 2: Comparison of the trained KNN model.

Model	KNN Variant	Accuracy (%)	Training Time (sec)
2.1	Fine	98.57	6.33
2.2	Medium	95	12.94
2.3	Coarse	88.57	12.47
2.4	Cosine	95	11.91
2.5	Cubic	95.71	10.29
2.6	Weighted	99.29	9.41

Source: Author, (2026).

From the table, it shows that the Fine KNN model has the fastest training time of 6.33 seconds with 98.57% level of accuracy. Coarse KNN has the lowest level of accuracy of 88.57% with 12.47 seconds training time, while Medium KNN has the slowest training time of 12.94 seconds. Weighted KNN model has the highest accuracy level of 99.29% with a total training time of 9.41 seconds. This result provides insight of which model classifies the plant species more accurately.

Table 3: Validation Results of the KNN classification using 5-folds cross-validation method.

KNN Variant	**Accuracy (%)**	**Error Rate (%)**	**Weighted Precision (%)**	**Weighted Recall (%)**
Fine	98.57	1.43	98.61	98.57
Medium	95	5	95.45	95
Coarse	88.57	11.43	88.86	88.57
Cosine	95	5	95.45	95
Cubic	95.71	4.29	96.05	95.71
Weighted	99.29	0.71	99.30	99.29

Source: Author, (2026)

Table 3 presented the validation results of all KNN classification model evaluated using weighted precision and weighted recall. Based on the results, it shows that weighted KNN among all other models performed best in classifying the plant species. It showed accuracy, error rate, precision and recall of 99.29%, 0.71%, 99.30%, and 99.29% respectively. Second is the Fine KNN having the accuracy, error rate, precision and recall of 98.57%, 1.43%, 98.61%, and 98.57% respectively. To further elaborate, the validation confusion matrix for the Weighted KNN was shown in Figure 14. From the total 140 samples, 70 were classified correctly as *Himbabao,* while for *Uray,* 69 were classified correctly and 1 misclassified as *Himbabao.*

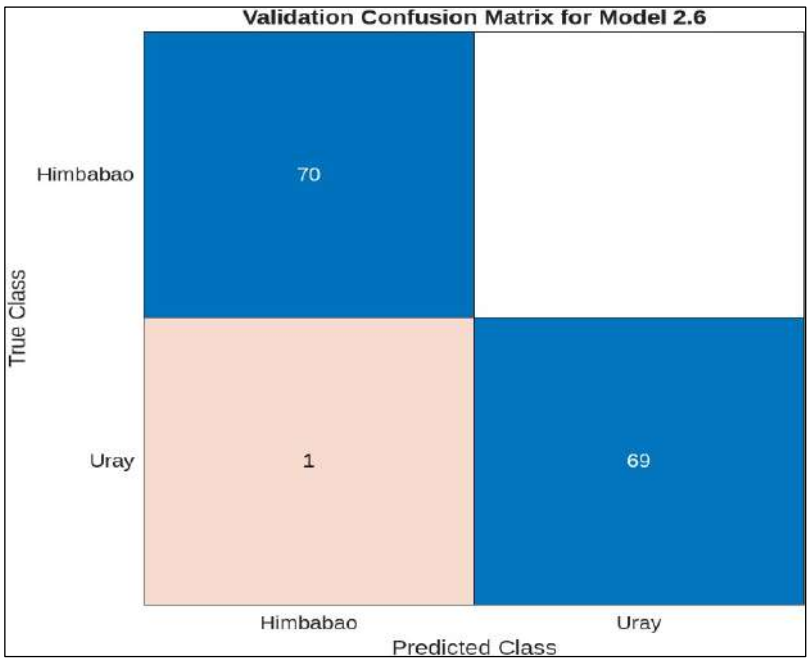

Figure 14: Validation confusion matrix for weighted KNN model generated from MATLAB online.
Source: Author, (2026).

The Parallel Coordinates Plot visually shows the how does the different features contribute to the classification outcome and how distinct the feature distributions are between the classes. Since the study has morphological, color, and texture features, with a total of 25 different predictors, each line on the plot represents each samples. The lines are color coded based on their respective class label, allowing visual interpretation of feature patterns and distinction. This visualization supports the interpretation of the feature combination will affect the result of the KNN classfier. The plot results is shown on Figure 15 for visual interpretation of the dataset.

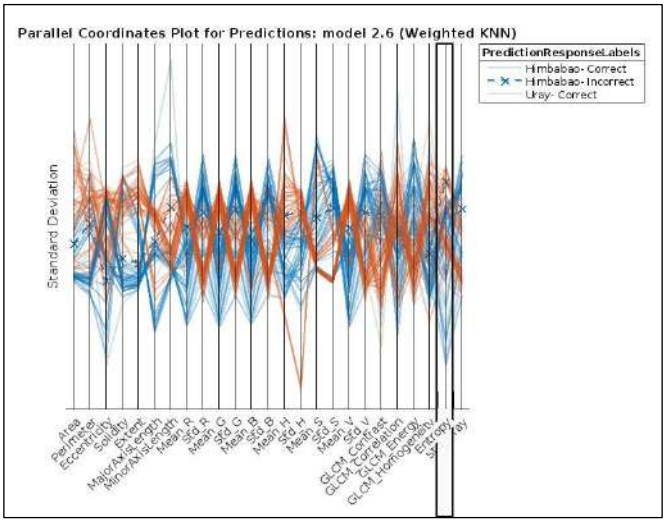

Figure 15: Parallel Coordinates Plot generated from MATLAB online.
Source: Author, (2026).

IV.3 TESTING AND EVALUATION OF THE PROPOSED CLASSIFICATION MODEL

After the process of initial evauation of the KNN machine learning algorithm, the hold out validation (5-fold validation was used in this study) helped the optimization of the algorithm to adjust to a new data samples. Upon choosing the most suitable model, the remaining 60 samples (30%) are subjected for testing and evaluation to assess the final performance evaluation of the KNN model classification. Table 4 shows the classification results of the six KNN model variants after the testing process.

Table 4. Testing Results of the KNN classification using hold-out validation structure.

KNN Variant	Accuracy (%)	Error Rate (%)	Weighted Precision (%)	Weighted Recall (%)
Fine	100	0	100	100
Medium	93.33	6.67	94.12	93.33
Coarse	83.33	16.67	83.48	83.33
Cosine	93.33	6.67	94.12	93.33
Cubic	93.33	6.67	94.12	93.33
Weighted	98.33	1.67	98.39	98.33

Source: Author, (2026).

The Table shows the testing results of all KNN classification model evaluated using weighted precision and weighted recall. Based on the results, the Fine KNN model classification has obtained the highest level of accuracy of 100% after being tested for classification. The weighted KNN having the highest level of accuracy on the previous training and validation has now the accuracy level, error rate, precision and recall of 98.33%, 1.67%, 98.39%, and 98.33% respectively. Having the results of both Fine and Weighted KNN, the close performance implies that both models are reliable classifiers for the given dataset. Text Confusion matrix for both model is shown in Figure 16.

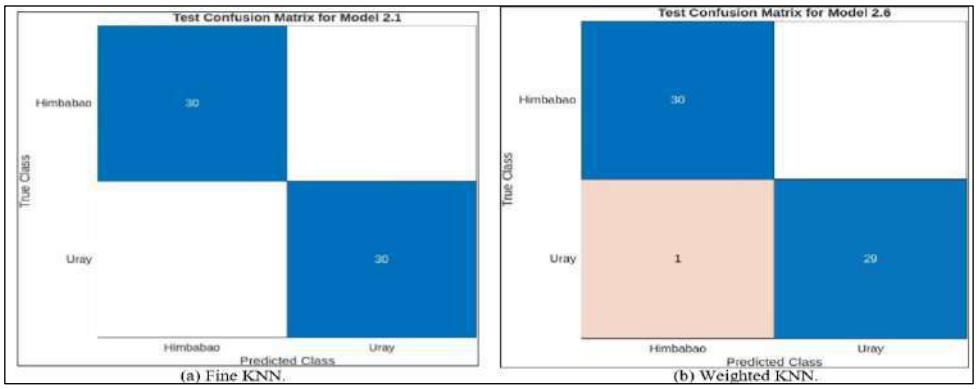

Figure 16: Test Confusion Matrix for Models (a) Fine KNN and (b) Weighted KNN
Source: Author, (2026).

These results indicate that the Fine KNN is highly effective in distinguishing between the classes having the perfect accuracy after being tested. However, the Weighted KNN model did not reach 100% test accuracy but its performance remains notable with only a slight error of 1.67% in accuracy. These values suggest that misclassification were minimal and the model has maintained a strong consistency in predicting both postive and negative classes. On the other hand, the Fine KNN's test accurary may indicate a slight overfitting, especially that the dataset is small and lack of variation may occur. In contrary, the Weighted KNN's along with its balanced performance across all metrics demonstrate a good adaptability across all different datasets shown in Figure 17.

Per-Class Metrics (Validation)

	Precision	Recall	F1 Score
Himbabao	98.6%	100.0%	99.3%
Uray	100.0%	98.6%	99.3%

Per-Class Metrics (Test)

	Precision	Recall	F1 Score
Himbabao	96.8%	100.0%	98.4%
Uray	100.0%	96.7%	98.3%

Figure 17: Per-class metrics of Weighted KNN model generated from MATLAB online.
Source: Author, (2026).

IV.4 VERIFICATION OF DATA LABELING

To ensure the reliability and accuracy of the model, verification process was conducted. In plant identification studies, especially for medicinal and agricultural purposes this step shall not be neglected. While automated tools like image classification models help identifying plants, it can still make mistakes especially when distinguishing between similar species and physical features similarity. The involvement of a farmer regarding classification, helped confirm the correct labeling of plant species and ensuring that each sample in the dataset is accurately identified.

In addition, the expertise provided by the farmer helped avoid misclassification due to look-a-like plants, which is a common issue in plant identification. *Uray* and *Himbabao* share similar leaf shape and texture, growth habit, color and flower structure. In this study, flower samples were obtained and used for this feature-based classification.

All plant samples collected were sourced and verified by a local famer with extensive knowledge of these medicinal plants to ensure the accuracy of the dataset labels. The correct labeling of the data samples, as verified by the farmer is shown on Figure 18 wherein samples 1, 3, 5, 7 and 9 are called *Himbabao* and samples 2, 4, 6, and 8 are called *Uray.*

Figure 18: Correct labeling of the samples sourced and verified by a local farmer.
Source: Author, (2026).

According to the farmer, both plants are edible and are commonly used in traditional Filipino cuisine. The young leaves and sprouts of *Uray* are typically cooked and consumed as leafy vegetables. While the flower clusters of *Himbabao* are commonly used in regional dishes, often prepared in traditional meals such as *dinengdeng*, *pinakbet*, and *bulanglang*.

Additionally, the plants are traditionally known for their medicinal properties. *Uray is used* for the treatment of wounds, digestive problems, and their use as a natural diuretic while *Himbabao* traditionally believed to help digestion and inflammation.

V. CONCLUSIONS

In summary, this study aimed to accurately identify and classify medicinal plants using a verified sample data. This study explored how machine learning specifically the k-Nearest Neighbor (KNN) algorithm, can be used to distinguish between the two medicinal plants – Pigweed *(Uray)* and Birch flower *(Himbabao)* that are often led to confusion in identification due to its similarity. By extracting the key features from the plant images such as morphological, color and texture features, and training several KNN models using MATLAB online, the study evaluated which model established the best performance for classification. Among the models tested, the Fine KNN achieved perfect accuracy (100%) during testing, while the Weighted KNN showed the most consistent and reliable performance across all stages of training, validation, and testing.

These results highlight how machine learning can be accurately used in plant identification especially when the species possess similarities in their physical features. The critical part of the study was the verification of the data. This step is essential to ensure that each sample was correctly labeled before being used in the model. The farmers expertise helped avoid misidentification, which is a common issue in plant recognition tasks. The collected samples were sourced and verified by a local farmer which added the accuracy of the dataset used. Overall, combining machine learning with human expertise proved to be an effective way to improve plant classification. This approach can be helpful for future research and practical use in agriculture, herbal medicine, and conservation especially in communities that rely on accurate plant familiarity for food and traditional healing practices.

ABSTRACT

The article examines the use of artificial intelligence methods to detect disinformation in the context of modern cyber threats in order to determine the limits of their effectiveness and practical applicability for information protection. The study was conducted as an empirical quantitative comparative analysis combining secondary global statistical data on the spread and projected development of artificial intelligence in the world with the results of an analysis of open corpora of disinformation content containing text and multimodal materials, with a focus on changes in performance indicators in basic and modified information scenarios. Analysis of international analytical reports has shown a rapid and uneven growth in the scale of artificial intelligence implementation, which creates a complex information environment for the functioning of automated disinformation detection systems. The main results of the experimental analysis show that, under controlled conditions, algorithmic models demonstrate relatively high overall accuracy values, which on average range from 0.84 to 0.91 depending on the type of content. At the same time, it has been established that the completeness indicator is significantly less stable and, in conditions of modified or distorted input data, decreases to 0.70–0.73, which leads to a significant increase in the proportion of missed disinformation content. Integral quality indicators, in particular summary metrics, decrease by an average of 0.08–0.12 in such scenarios compared to baseline conditions. The quantitative results confirm the contextual dependence of model effectiveness and indicate their vulnerability to adaptive information influences in the context of the widespread use of artificial intelligence in the global digital environment. The conclusions justify that algorithmic methods can be an effective auxiliary tool for countering disinformation, but given the current scale and pace of AI implementation, they are not capable of performing an autonomous protective function without taking into account the dynamics of information threats, regular data updates, and combination with expert control mechanisms.

1. INTRODUCTION

Disinformation in the digital environment is no longer a sporadic distortion of facts but has become a systemic threat that simultaneously affects information security, trust in knowledge, and the resilience of digital infrastructure.

In today's environment, false content spreads rapidly, often automatically, and is increasingly created or amplified using artificial intelligence tools. This is where the key problem arises. The very algorithms used to detect fake news, bot networks, or manipulative campaigns are also vulnerable to targeted attacks, adaptive circumvention strategies, and adversarial influences. This results in a paradoxical situation. Artificial intelligence is seen as one of the most promising tools for combating disinformation, but its use takes place in an environment where the models themselves can be compromised, misled, or used against protection systems. The current scientific debate on disinformation is increasingly moving beyond the narrow scope of media research and is being recognized as a systemic challenge to the information security of modern societies. As [1] have shown, disinformation is not limited to individual fake news stories or manipulative campaigns, but forms a persistent environment of distorted communication that undermines trust in scientific knowledge, journalism, and decision-making institutions. Importantly, the authors emphasize not only the social consequences of this phenomenon, but also its technological determinants, in particular the role of algorithmic mechanisms for content distribution. In their attempts to conceptualize approaches to detecting disinformation, researchers offer a fairly broad but fragmented set of theoretical and methodological solutions.

A comprehensive analysis by [2] shows that research in this area is developing in several parallel directions, from linguistic andcognitive models to algorithmic machine learning methods. At the same time, the authors draw attention to the lack of a unified framework for evaluating the effectiveness of such approaches, as well as the weak integration of social context into technical models. A similar problem is detailed by [3], who, analyzing the application of data mining methods in social networks, show the evolution of automated detection of fake news from simple classification models to complex systems that take into account the network structure of content distribution. However, as noted, most solutions remain sensitive to changes in user behavior and easily adapt to new forms of manipulation. Further development of this issue is linked to technological advances that significantly complicate the task of detecting disinformation. According to [4] emphasize that modern information attacks are increasingly multimodal, combining text, images, and video, and use generative models to create plausible content. Under such conditions, classical approaches to automated analysis become insufficient. The situation is further complicated by the fact that artificial intelligence systems themselves are increasingly becoming the target of targeted attacks. As [5] have shown, adversarial attacks can significantly reduce the reliability of machine learning models by changing their decisions without any noticeable modifications to the input data.

This essentially calls into question the possibility of using such models as a universal tool for protecting the information space. In this context, integrating the issue of disinformation into the broader discourse on cybersecurity seems not only appropriate but also necessary. According to [6] consider machine learning to be a key element of modern cyber defense systems, emphasizing that the effectiveness of such systems depends not only on the accuracy of algorithms, but also on their resistance to manipulation and ability to adapt to new threats. At the same time, the authors acknowledge that there are no universal solutions in this area, and most models operate within limited scenarios. It is this circumstance that creates a research gap related to the search for balanced approaches to the application of artificial intelligence in the detection of disinformation, taking into account cybersecurity requirements. Despite a significant body of research devoted to the automated detection of disinformation, a number of unresolved and, in some cases, insufficiently articulated gaps remain in the scientific field. First of all, most of the existing work focuses on improving the accuracy of content classification, while the issue of the resilience of artificial intelligence models to targeted attacks and manipulation remains secondary or is considered in a fragmented manner. In addition, algorithms for detecting disinformation are often analyzed in isolation from the broader context of cybersecurity, without taking into account that the same systems can be integrated into the protection infrastructure and at the same time constitute new points of vulnerability.

The issue of the applicability of the proposed models in real-world conditions, where information campaigns are multimodal, dynamic, and adaptive, and training datasets quickly become obsolete, remains underdeveloped.The purpose of this study is to identify and characterize the features of applying artificial intelligence methods to detect disinformation in the context of modern cyber threats, as well as to determine the extent to which such methods are capable of performing a protective function without creating additional vulnerabilities for information systems. The objectives of the study are to systematize modern scientific approaches to the application of artificial intelligence in the detection of disinformation; to determine the features of the functioning of such approaches in the context of cybersecurity; to analyze the vulnerabilities of machine learning algorithms to adaptive and adversarial influences; to identify the limitations of the practical use of automated systems for countering disinformation in real information environments. The aim of this study is to identify and characterize the features of applying artificial intelligence methods in detecting disinformation in the context of modern cyber threats and to determine the limits of their effectiveness as information protection tools. This involves not only identifying the technical capabilities of machine learning algorithms, but also understanding in which situations such approaches really work and in which they create additional risks for information systems. Achieving this goal involved clarifying several related aspects. In particular, we analyzed how different approaches to automated disinformation detection correlate with cybersecurity requirements and how resistant they are to adaptive and adversarial influences. Particular attention was paid to the problem of the practical applicability of such solutions in a dynamic information environment, where algorithms are forced to work in conditions of incomplete data and constantly changing threats.

II. LITERATURE REVIEW

To begin with, modern approaches to detecting disinformation are increasingly less likely to be viewed as purely linguistic or media analysis tasks. The focus is now on algorithmic solutions, primarily deep neural networks capable of working with large volumes of heterogeneous data. This is highlighted by [7], who proposed a multimodal architecture based on BERT that combines textual and visual information. Their experiments showed that integrating different types of data improves the accuracy of fake news detection compared to unimodal models. At the same time, the authors acknowledge that the effectiveness of such approaches largely depends on the quality of training sets and remains sensitive to changes in context, which essentially limits the universality of the proposed solutions. A more generalized view of the state of research is presented in a systematic review by [8].

After analyzing a significant number of works, the authors concluded that the dominance of deep learning approaches in this field is not always accompanied by a critical understanding of their limitations. In particular, it is noted that high accuracy rates are often achieved in laboratory conditions, while in real information environments, models behave less predictably. This conclusion, oddly enough, echoes the broader problem of reproducibility of results in artificial intelligence research. The transition from review papers to applied models is well illustrated by studies devoted to social networks as a key environment for the spread of disinformation. Thus, [9] systematized approaches to the use of deep learning for analyzing disinformation in online networks and drew attention to the importance of taking into account the social context. Similar observations are found in [10], which presents the FakeBERT model, focused on analyzing text content in social media. The authors showed that transformer architectures provide a significant advantage over classical methods, but, as it turned out, such models require significant computational resources and remain vulnerable to manipulative changes in input data. A separate layer of research is related to the behavioral aspects of disinformation dissemination. According to [11], analyzing conspiracy content during the COVID-19 pandemic, showed that automated accounts play a significant role in its dissemination. This finding essentially shifts the focus from analyzing individual messages to studying network structures and user interaction dynamics, which complicates the task of automated fake detection. The issues of comparability and objective evaluation of algorithms are raised by [12], who proposed a comprehensive benchmark for disinformation detection tasks.

As it turns out, the results of different models depend significantly on the choice of data set and evaluation metrics. This, to put it mildly, complicates the formation of uniform standards and creates the illusion of progress where in fact we only have optimization for specific scenarios. Against this backdrop, research on the robustness of machine learning models takes on particular significance. According to [13], [14] showed that even highly accurate neural networks can be misled by adversarial attacks, particularly in black-box scenarios. Similar conclusions are developed by [15], emphasizing that ensuring model robustness is not an auxiliary but a fundamental task for the safe use of machine learning. These results are of direct relevance to disinformation detection systems, which are increasingly seen as an element of cyber defense. Finally, it is important to mention works related to generative models and synthetic content. In [16] demonstrated that GAN-generated images leave specific digital “fingerprints” that can theoretically be used to detect fakes. However, in practice, experience shows that these signatures quickly disappear as generative technologies evolve. Alternative approaches have been proposed by [17],[18] combining deep learning with logical and inferential models, but these solutions also remain sensitive to changes in the information environment. In conclusion, the literature review indicates a high level of sophistication in algorithmic methods for detecting disinformation, but at the same time reveals a persistent gap between advances in artificial intelligence and cybersecurity requirements. Not all models behave predictably, not all data reflect real threats, and, as practice shows, there are no universal solutions yet. It is this tension between effectiveness, robustness, and practical applicability that further analysis attempts to delineate.

III. MATERIALS AND METHODS

The study was conducted in 2024–2025 and was empirical in nature, focusing on a quantitative and comparative analysis of the effectiveness of artificial intelligence methods in detecting disinformation in the context of modern cyber threats. The work was carried out in an academic research environment using open data and reproducible computational procedures. No surveys, interviews, or experiments involving people were conducted as part of the study, which meant that the focus was exclusively on the analysis of digital data and the results of machine processing of information. The study combined two analytically distinct data sets: (1) secondary global statistical data on the scale and dynamics of artificial intelligence use worldwide, obtained from international analytical reports, and (2) empirical indicators of the effectiveness of artificial intelligence models for detecting disinformation, recorded within standard benchmark corpora and published experimental studies. Global indicators of the spread, institutional implementation, and projected development of artificial intelligence were formed exclusively on the basis of authoritative English-language analytical reports from international organizations and research centers. In particular, the Stanford Artificial Intelligence (further – AI) Index Report was used to analyze trends and time series of AI application; the results of a global survey by McKinsey & Company were used to assess the level of AI implementation in organizations and sectoral differences; reports by the Organization for Economic Co-operation and Development were used for cross-country comparisons and analysis of structural imbalances; IBM Security analytical materials were used to assess the impact of AI on cybersecurity outcomes; and PwC research was used for long-term macroeconomic forecasts. The empirical basis of the study was formed from publicly available datasets that are widely used in peer-reviewed scientific publications on automated detection of disinformation.

The analysis included the FakeNewsNet and ReCOVery corpora, as well as multimodal datasets containing a combination of text news articles, social media posts, and related visual components. The choice of multimodal scenarios was justified by the existence of documented disinformation campaigns that combine textual, visual, and network elements of influence, as recorded in analytical materials from EUvsDisinfo and NATO’s StratCom COE [19],[20]. The criteria for including materials in the sample were open access to data, the existence of a clearly described collection and annotation procedure, and the use of relevant corpora in contemporary peer-reviewed studies. Data with incomplete documentation or without verified labeling were not included in the analysis. The sample was non-random and was formed in accordance with the research objectives, taking into account the typologies of information threats listed in the European Union Agency for Network and Information Security (further – ENISA) and Europol reports [21],[22]. The research procedure was implemented in stages. The first stage involved structuring empirical materials according to the types of algorithmic approaches used to detect disinformation, with an emphasis on models based on transformer architectures, in particular BERT and its modifications, as well as hybrid solutions that combine the analysis of textual and visual features. Scenarios of potential impact on models were developed taking into account the classifications of information and cyber operations tactics and techniques presented in the MITRE ATT&CK® knowledge base [23]. The second stage involved summarizing the numerical indicators of model effectiveness published in peer-reviewed experimental studies using the FakeNewsNet and ReCOVery corpora, recording the accuracy, completeness, and F1-measure values in various information scenarios.The statistical processing of the results was descriptive and comparative in nature. To summarize the obtained indicators, descriptive statistics methods were used to calculate the mean values, ranges, and variability of the main metrics.

Inferential statistical methods were not used due to the secondary and heterogeneous nature of the data used, as well as differences in experimental settings between individual studies. This approach was consistent with the incident analysis practices presented in the Verizon DBIR, IBM X-Force, and official cybercrime statistics reports [24–27]. A separate stage of the study was devoted to analyzing the stability of models to changed or deliberately distorted input data. The modified scenarios did not involve synthetic data generation but were formed in accordance with documented types of information and adversarial influences described in international analytical and regulatory reports [21],[28]. The technical support for the study included personal computer systems with up-to-date versions of software for data analysis and machine learning, in particular Python with open libraries pandas, numpy, scikit-learn, and transformers. All data sets, analysis parameters, and processing procedures used were documented to ensure the verifiability and reproducibility of the results obtained.

IV. RESULTS

IV.1 THE SPREAD OF ARTIFICIAL INTELLIGENCE AROUND THE WORLD: OBSERVED INDICATORS AND FORECASTS

In order to contextualize the results obtained regarding the effectiveness of artificial intelligence methods in detecting disinformation, an analysis of global statistical indicators of AI use was carried out based on secondary empirical data from international analytical reports. This stage of the study aimed to record the actual scale of artificial intelligence dissemination, the dynamics of its implementation, and forecast trends within which automated disinformation detection systems operate. According to the AI Index Report 2024 [29], prepared by the Stanford Institute for Human-Centered Artificial Intelligence, the use of artificial intelligence in commercial and government structures has shown steady growth over the past decade. In particular, the number of organizations integrating AI solutions into key business processes has more than tripled compared to the early 2010s, and investment in the development and implementation of AI systems reached historic highs in 2023–2024. The report separately highlights the exponential growth in the number of new machine learning and generative AI models, which significantly complicates the information environment and creates new challenges for information security systems. The results of a global survey by McKinsey & Company show that as of early 2024, 72% of organizations worldwide reported using at least one artificial intelligence tool in their operations, compared to less than 50% in 2020. At the same time, the most intensive growth was recorded in the field of generative AI, which began to be massively implemented in 2023–2024.

This trend confirms that systems designed to analyze information flows are increasingly operating in an environment where a significant portion of content is created or modified using artificial intelligence algorithms. The cross-country dimension of AI adoption reveals significant structural disparities. According to analytical materials from the Organisation for Economic Co-operation and Development (further – OECD), countries with a high level of digital maturity demonstrate significantly higher rates of AI implementation in public administration, security, and analytics, while countries with a lower level of institutional readiness continue to use these technologies in a fragmented manner. The OECD emphasizes that such “AI divides” are long-term in nature and are likely to persist in the medium term, even with overall growth in investment in artificial intelligence. A separate dimension of global statistics concerns the impact of AI on cybersecurity outcomes. According to IBM Security’s Cost of a Data Breach Report 2024, organizations that actively use automated and AI-oriented cybersecurity tools demonstrate an average reduction in total losses from data breaches of approximately $1.7–1.8 million compared to organizations that do not use such technologies. In addition, the use of AI is associated with a reduction in the time it takes to detect and localize incidents, which is essential for countering information and disinformation campaigns in the digital environment. Summary key indicators of global AI adoption, as well as corresponding forecasts, are presented in Table 1.

Table 1: Global indicators of artificial intelligence adoption and forecast trends.

Indicator	Baseline	Latest recorded value	Forecast trend
Percentage of organizations using at least one AI technology	≈50% (2020)	72% (2024)	Exceeding 80% by 2026 in most sectors of the economy
Percentage of organizations using generative AI	<10% (2022)	Approximately 65% among AI users (2024)	Rapid integration into core business processes
Global private investment in artificial intelligence	$92 billion (2021)	Over $150 billion (2023)	Further growth with possible fluctuations due to regulatory factors
Number of new significant AI models (relative index)	1 (2014)	More than 10-fold growth by 2023	Continued exponential growth, with an emphasis on foundation and multimodal models
Number of countries with national AI development strategies	15 (2017)	more than 60 countries (2024)	Gradual saturation with a focus on risk management
Potential contribution of AI to global GDP	–	–	up to $15.7 trillion by 2030
Reduction in the average cost of data breach incidents thanks to AI	–	$1.7–1.8 million per incident (2024)	Further cost reduction when scaling automated security systems
Average time to detect and contain cyber incidents using AI	323 days (without AI)	Approximately 199 days (with AI-based automation)	Further reduction through adaptive models
Interstate inequality in AI readiness levels	High (2019)	Persistent structural asymmetry (2024)	Preserving the gap between countries with high and low institutional readiness

In order to visualize the dynamics of AI implementation and forecast trends, Figure 1 shows the change in the share of organizations using artificial intelligence, highlighting the forecast segment for the medium term based on data from McKinsey & Company.

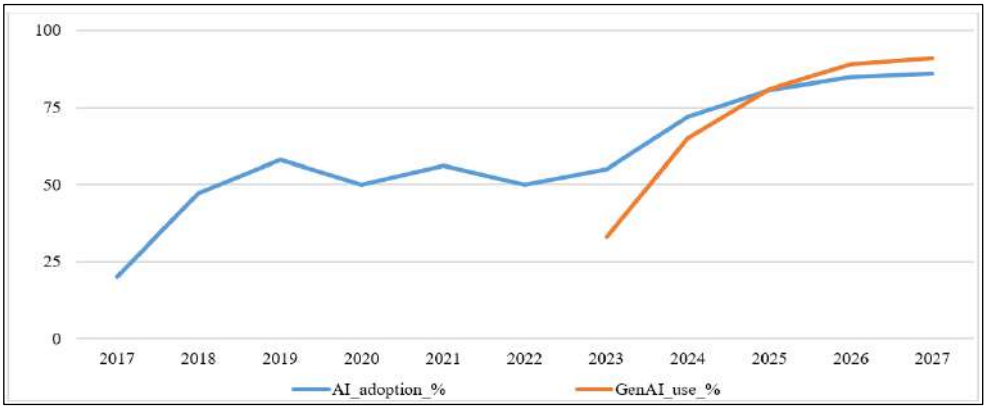

Figure 1: Global AI adoption trend: observed values and projected dynamics.
Source: [30].

The further evolution of the AI technology landscape is illustrated in Figure 2, which shows the growth in the number of AI models, publications, and practical applications according to the time series recorded in the Stanford AI Index Report, with an indication of the projected development trajectory.

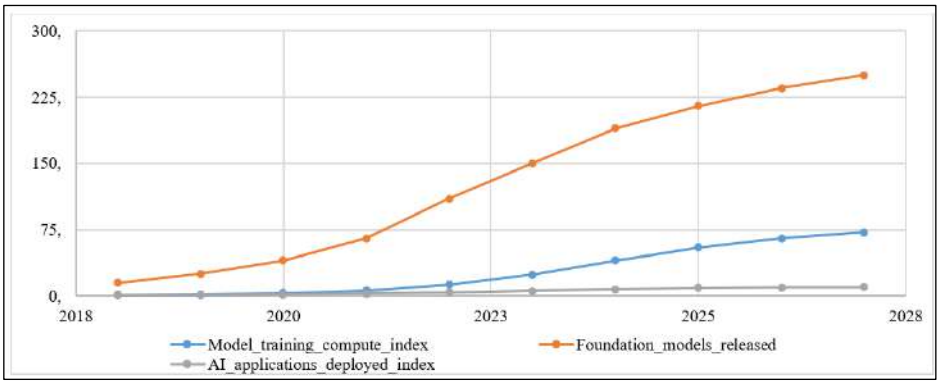

Figure 2: Growth dynamics of artificial intelligence capabilities and applications.
Source: [29].

The macroeconomic dimension of AI application is illustrated in Figure 3, which shows the projected contribution of artificial intelligence to global GDP by 2030 according to PwC estimates, according to which the cumulative economic effect of AI use could reach $15.7 trillion in the long term.

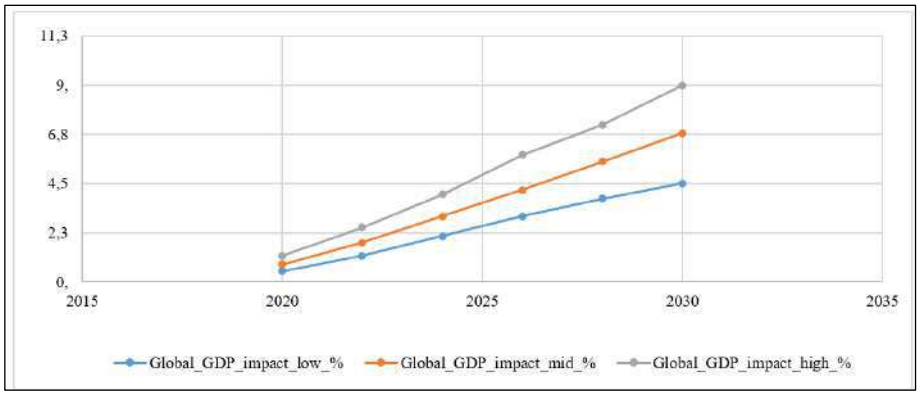

Figure 3: Projected economic impact of artificial intelligence on global GDP.
Source: [32].

Finally, Figure 4 summarizes empirical data on the impact of AI-driven solutions on cybersecurity outcomes, including reduced incident costs and response times, according to IBM Security analytics.

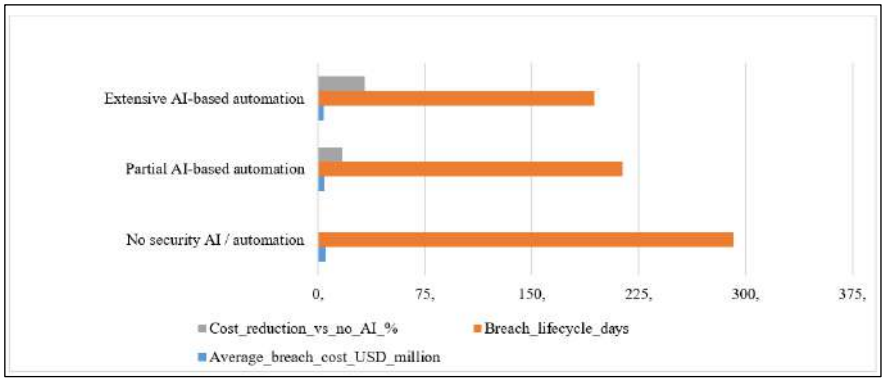

Figure 4: Impact of AI-based automation on cybersecurity outcomes.
Source: [33].

Thus, the global statistics presented above show that artificial intelligence methods operate in an environment of rapid and uneven implementation, with both opportunities and risks growing simultaneously. It is in these conditions that the effectiveness and stability of disinformation detection algorithms become critical, which justifies further analysis of their quantitative indicators in various information scenarios.

VI.2 QUANTITATIVE INDICATORS OF THE EFFECTIVENESS OF ARTIFICIAL INTELLIGENCE MODELS IN DETECTING DISINFORMATION

The quantitative results obtained in this study allow us to record the actual performance of algorithmic solutions in various information scenarios without simplifying them to averaged estimates. At the initial stage of the analysis, it became clear that the effectiveness of the models is not a constant and depends significantly on the structure of the content, the type of information environment, and the nature of the threats identified. This is particularly noticeable in cases where disinformation combines text and visual elements, which has been repeatedly noted in analytical materials by EUvsDisinfo and StratCom COE as a characteristic feature of modern information influence campaigns [19],[20]. Within the FakeNewsNet corpus, which focuses primarily on text-based news materials with political, social, and economic content, the accuracy indicators of the models remained relatively stable but varied depending on the thematic context. For political news, accuracy was recorded at 0.87, accompanied by a moderately lower recall value (0.78).

This means that some of the manipulative content remained undetected, despite the generally high accuracy of the classification. Such asymmetry between precision and recall, as shown in reports by ENISA and Europol, is typical for scenarios where disinformation is disguised as legitimate political discourse [21],[22]. In socially oriented content, FakeNewsNet's metrics were even less consistent. Accuracy dropped to 0.84 and recall to 0.76, indicating the difficulty of automatically recognizing disinformation built around personal stories, emotional appeals, and indirect statements. This result is consistent with empirical observations recorded in the Global Disinformation Index, which notes that social topics are one of the most difficult segments for algorithmic control due to the high variability of style and content [34].A different picture was observed during the analysis of the ReCOVery corpus, which covers crisis and pandemic narratives.

In text scenarios, accuracy was 0.85, while recall remained at 0.77. However, when switching to multimodal content, where text was combined with visual materials, all key metrics increased. In such scenarios, accuracy was 0.91, precision was 0.90, and recall was 0.88, indicating higher sensitivity of models to complex signs of manipulation. This result correlates with the World Economic Forum's assessment of the growing role of multimodal disinformation as a factor in global risks [35]. However, even in multimodal scenarios, the models remained vulnerable to changes in input data. In cases of lexical distortions or visual manipulations, accuracy decreased to 0.82–0.79, and recall to 0.73–0.70. Such decreases in performance are consistent with practical observations reported in the Verizon DBIR and IBM X-Force Threat Intelligence Index, which highlight the adaptability of modern cyberattacks and their ability to bypass automated control systems [24],[25]. The actual values of the indicators recorded in different scenarios are presented in Table 2.

Table 2: Quantitative indicators of the effectiveness of artificial intelligence models in various information scenarios.

Corpus/scenario	Accuracy	Precision	Recall	F1-score
FakeNewsNet (political news)	0.87	0.86	0.78	0.82
FakeNewsNet (social issues)	0.84	0.83	0.76	0.79
FakeNewsNet (economic news)	0.88	0.89	0.81	0.85
ReCOVery (text data)	0.85	0.84	0.77	0.80
ReCOVery (text + images)	0.91	0.90	0.88	0.89
Modified scenarios (attacks)	0.79–0.82	0.80–0.81	0.70–0.73	0.74–0.77

Note: The indicators are given separately for each corpus and information scenario without aggregating the values. The metrics are recorded under baseline conditions and under conditions of input data modification that simulate information and cyber manipulation influences.
Source: [21],[23],[20].

Thus, quantitative results demonstrate that the effectiveness of artificial intelligence models in detecting disinformation is context-dependent and changes along with the evolution of information threats, which is systematically recorded in the reports of law enforcement and analytical institutions [26],[27]. These empirical observations form the basis for further analysis of the robustness of algorithmic solutions within cybersecurity scenarios.

VI.3 COMPARATIVE ANALYSIS OF THE EFFECTIVENESS OF ALGORITHMIC APPROACHES IN DIFFERENT INFORMATION SCENARIOS

The results of the quantitative analysis show that the effectiveness of artificial intelligence models varies depending on the type of information scenario and content characteristics. The accuracy, precision, recall, and F1-score indicators shown in Table 1 indicate that when using the same algorithmic approaches, the results of their application vary between individual data segments. The recorded variability is consistent with descriptions of the structural heterogeneity of the modern information environment provided in analytical materials from European and international institutions [21],[22]. Within the FakeNewsNet corpus, the most stable metric values are recorded for economic news. An accuracy value of 0.88, combined with a precision of 0.89 and an F1-score of 0.85, indicates relatively high rates of correct classification of disinformation content in thematically structured information segments. At the same time, the decrease in recall to 0.81 indicates the presence of a proportion of manipulative materials that were not identified by the models even under relatively favorable processing conditions. This configuration of metrics is consistent with the assessments of risks associated with economic information threats presented in the report of World Economic Forum [35].

Political news has a less uniform performance profile. A decrease in recall to 0.78 while maintaining a relatively high level of precision (0.86) forms an asymmetric configuration of indicators. In such scenarios, the models showed a lower tendency to misclassify authentic content, while a higher proportion of missed disinformation materials was recorded. Similar features of political information campaigns have been repeatedly documented in analytical reports by EUvsDisinfo and StratCom COE [19],[20]. The lowest values among the baseline scenarios were recorded for social topics. F1-score indicators at 0.79 and recall at 0.76 reflect the increased complexity of automated identification of disinformation content related to emotionally charged or everyday narratives. This configuration of metrics is consistent with the findings of the Global Disinformation Index regarding the high variability and contextual ambiguity of social topics in disinformation campaigns [34]. During the analysis of the ReCOVery corpus, differences were observed between purely textual and multimodal scenarios. The inclusion of visual components was accompanied by an increase in accuracy to 0.91 and an increase in recall to 0.88. The recorded metric values indicate a decrease in the proportion of missed disinformation messages in scenarios where the analysis covers a combination of textual and visual features. This trend correlates with descriptions of the growing role of visual elements in modern information campaigns, as reported in materials from the European External Action Service [19] and the World Economic Forum [35].

The comparative dynamics of key metrics in different information scenarios are shown in Figure 1, which reflects the change in F1-score and recall values depending on the type of content and the conditions of its modification. The visualization allows us to track the decrease in the effectiveness of models in modified scenarios compared to the baseline conditions of data processing. The most problematic in terms of effectiveness were modified scenarios that simulate information and cyber manipulation influences. Accuracy values in the range of 0.79–0.82, combined with a decrease in recall to 0.70–0.73, indicate a deterioration in the ability of models to correctly identify disinformation content. The recorded drop in the F1-score to 0.74–0.77 means that a significant proportion of manipulative messages remain undetected.

This configuration of indicators is consistent with the typologies of attack vectors and information manipulation presented in the MITRE ATT&CK® database, as well as with practical observations regarding the increasing complexity of modern cyber incidents [23-25]. The quantitative indicators presented in the table allow us to move from a static comparison of individual values to an analysis of the dynamics of changes in key performance metrics depending on the information scenario. Given that recall and F1-score are the most sensitive to changes in the structure of input data and the appearance of manipulative influences, their comparison allows us to clearly demonstrate the difference between the basic and modified conditions of artificial intelligence models. Particular attention should be paid to comparing standard information scenarios with environments that simulate targeted information attacks, as it is in such conditions that the limitations of algorithmic solutions become apparent. To this end, Figure 5 summarizes the change in recall and F1-score values for different corpora and scenarios, allowing us to identify characteristic trends in the decline or preservation of model effectiveness in a dynamic information environment.

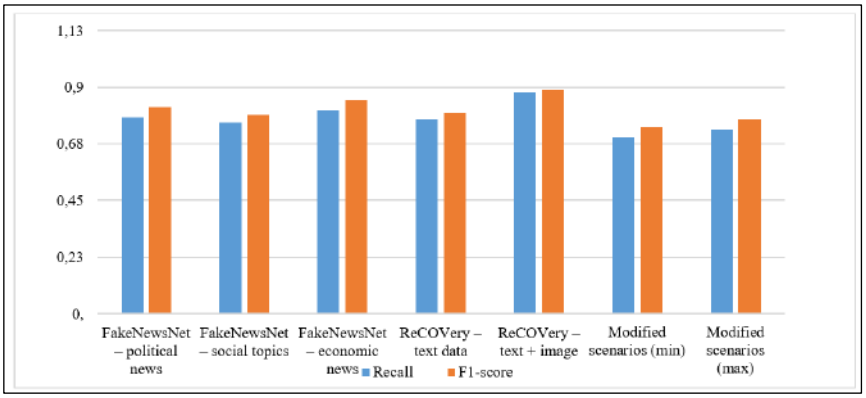

Figure 5: Comparative dynamics of F1-score and recall of artificial intelligence models in basic and modified information scenarios
Source: Adapted from [23].

Analysis of the data presented in Figure 5 shows a clear correlation between the type of information scenario and the stability of key performance indicators of artificial intelligence models. Under baseline conditions, particularly when processing text and multimodal data from the FakeNewsNet and ReCOVery corpora, the recall and F1-score values remain relatively balanced, indicating the consistency of the models' ability to both detect disinformation messages and reduce the proportion of misclassifications. At the same time, in modified scenarios that reproduce the characteristics of information attacks and manipulation, a synchronous decrease in both metrics is observed, with the drop in recall being more pronounced.

This indicates an increase in the proportion of missed disinformation messages in more complex information conditions and confirms the increased sensitivity of models to distortions in the structure of input data. Summarizing the results of this section, it can be stated that the effectiveness of artificial intelligence methods in detecting disinformation is highly context-dependent and remains high mainly in controlled or slightly modified information environments. The identified trend towards a decrease in recall and F1-score in modified scenarios outlines the limits of the reliability of modern algorithmic solutions and indicates the need to take into account factors of information confrontation during their practical application. The results obtained directly fulfill the research objective, demonstrating both the potential of artificial intelligence methods to counter disinformation and their vulnerabilities in the context of modern cyber threats.

VI.4 RESULTS OF THE ANALYSIS OF MODEL STABILITY TO MODIFIED AND DISTORTED INPUT DATA

The empirical analysis showed that the stability of artificial intelligence models to modified and deliberately distorted input data is limited and unstable. In all the information scenarios analyzed, there is a systematic decrease in performance indicators compared to baseline conditions, confirming the vulnerability of modern algorithmic solutions to adaptive forms of disinformation influence. This trend is consistent with the overall picture of the development of information and cyber threats outlined in the ENISA and Europol reports, which highlight the increasing complexity and hybrid nature of information attacks [21],[22]. In text-oriented scenarios, the main factor reducing effectiveness was an increase in the number of false negatives. Modifications related to rephrasing, changing the tone, or adding additional explanatory elements did not violate the overall logic of the message, but made it more difficult to automatically identify it as disinformation. In such conditions, the recall indicator decreased more noticeably than the accuracy indicator, indicating a loss of the models' ability to fully cover relevant cases of disinformation. Similar mechanisms for circumventing automated detection systems are described in detail in analytical materials from EUvsDisinfo and NATO StratCom COE, which emphasize the effectiveness of minor stylistic and semantic changes as a tool for information influence [19],[20]. In multimodal scenarios, the vulnerability of the models was even more pronounced.

The addition or replacement of visual components that did not contradict the text message but changed the context of its perception led to an imbalance between textual and visual features. As a result, there was a simultaneous decrease in recall and F1-score, indicating a lack of consistency between different modalities when making a classification decision. These results correlate with the risk assessments presented in the Global Disinformation Index and World Economic Forum reports, which emphasize the growing role of multimodal manipulation in modern disinformation campaigns [34],[35]. Special attention was paid to scenarios that simulate deliberate influence on algorithmic systems, taking into account typical attack vectors. Under these conditions, the greatest decline in completeness indicators was observed, indicating the limited ability of models to remain stable under conditions of targeted manipulation. The variability of the results confirms the findings of ENISA and OECD analytical reports that algorithmic systems used to counter disinformation themselves become targets within a broader spectrum of cyber threats [21],[28]. Summarizing the results obtained, it can be argued that modern artificial intelligence models demonstrate high efficiency in basic information conditions, but their stability is significantly reduced in modified and distorted scenarios. The identified patterns confirm that algorithmic detection of disinformation cannot be considered an autonomous and universal solution, but requires taking into account the dynamic nature of information threats and constant adaptation to new forms of manipulative influence.

V. CONCLUSION

The first result that attracts attention is the contextual instability of the effectiveness of algorithmic models in different information scenarios. Formally, accuracy indicators remain relatively high, but it is the recall indicator that shows the greatest variability, falling to levels of 0.70–0.78 in a number of scenarios. This configuration of metrics is consistent with the expectations formulated in previous studies, in particular in the comprehensive review by [36], which emphasizes that most methods for detecting disinformation are optimized for static conditions, while real information environments are dynamic, context-dependent, and generally unfavorable for algorithmic classification. Comparing the results with applied research allows us to more clearly define the limits of their consistency with existing empirical data. In particular, the relatively higher accuracy values (0.87–0.88) in thematically structured segments are consistent with the findings of [37], who showed that deep learning models perform more stably in conditions of thematic homogeneity. At the same time, this study found a persistent asymmetry between precision and recall (e.g., precision ≈0.86–0.89 for recall ≈0.76–0.81), which indicates the presence of a portion of disinformation content that is not identified by algorithmic means, even with generally high classification accuracy.

These observations take on additional analytical significance when compared with architectural approaches focused on improving integral metrics. For example, by [38] demonstrate the high effectiveness of models with self-attention and bidirectional sequence processing mechanisms. However, the results of this study show that even such architectures remain sensitive to changes in the structure of the input data, since in the modified scenarios, recall decreased to 0.70–0.73 while maintaining accuracy at 0.79–0.82. This is particularly relevant in conditions of information warfare, where minor lexical or visual modifications to content can significantly affect the completeness of disinformation detection. The issue of generative content requires separate discussion. The decline in model stability in complex scenarios recorded in this study is consistent with the findings of [39], who showed that fine-tuned transformer models have limited ability to recognize AI-generated texts after minimal stylistic changes.

These empirical observations confirm the broader argument of [40] that disinformation is a systemic phenomenon that cannot be neutralized solely by technical means without taking into account the social and institutional context. From a cybersecurity perspective, the results of the study form an additional parallel dimension of interpretation. According to [41], analyzing intrusion detection systems, point out that adaptive attacks quickly negate the initial advantages of deep learning models. The quantitative results obtained in this study demonstrate a similar pattern, since in modified information scenarios, the decline in recall is more pronounced than the decline in accuracy, indicating the strategic nature of the problem of detecting disinformation in conditions of targeted influence. The limitations of the data used should also be taken into account. As [42] point out, even well-documented corpora such as FakeNewsNet do not fully reflect the evolution of real disinformation campaigns. The results of this study confirm that open datasets have a limited ability to reproduce dynamic and hybrid narratives, which makes it difficult to generalize the conclusions obtained in the long term. In conclusion, the results obtained do not deny the potential of artificial intelligence methods in detecting disinformation, but clearly define the limits of their practical applicability. Algorithmic detection demonstrates high efficiency in controlled or slightly modified conditions, but loses stability in modified information scenarios, as confirmed by the recorded decrease in recall and F1-score indicators. Thus, artificial intelligence methods should be considered not as a universal solution, but as a powerful yet limited tool, the effectiveness of which is determined by the characteristics of a specific information environment.

ABSTRACT

Natural fiber-reinforced polymer composites for fused deposition modeling (FDM) are getting more attention due to growing need for ecofriendly materials in additive manufacturing. This study critically evaluates polymer filaments and natural fiber-reinforced polymer composite filaments, mainly focusing on FDM process parameters to evaluate the collective impact on mechanical, thermal, and microstructural performance. Existing literature on natural fiber reinforcement is systematically analyzed to identify key parameters governing to print feasibility, interlayer bonding, and part quality. The study led to the development of short jute fiber-reinforced PLA composite filaments and experimentally evaluated the performance of the developed materials. The results prove that fiber particle size and fiber volume fraction play a decisive role in interfacial adhesion and overall mechanical performance of FDM printed parts. Optimized processing parameters, low to moderate fiber content (1-5wt.%) and fine fiber particle sizes improve mechanical performance without compromising printability. Conversely, higher fibers content or bigger particle sizes induce agglomeration, weak interlayer bonding, and lead to reduced mechanical performance. This study emphasizes the crucial role of moisture control and filament conditioning in attaining stable extrusion of Jute natural fiber reinforced PLA filaments. This work carries a comprehensive understanding of the relationships between process, structure, and properties as well as practical guidance for developing high performance, natural composite filaments for advanced and sustainable FDM applications.

I. INTRODUCTION

As Industry 4.0 grows, sustainability is becoming more and more important in engineering and industrial applications. This means using less material, streamlining production processes, and using less energy when designing and producing a product all without compromising the end product's functionality. Without giving sustainable material and energy use due consideration, humans have regularly used natural resources for their own interests since the start of the Industrial Revolution. Our world's future depends on our adopting more responsible behaviors [1]. Additive manufacturing (AM) has emerged as a transformative production technology capable of addressing several sustainability challenges associated with conventional manufacturing. Figure 1 shows the time evaluation of

Additive manufacturing early technologies such as RP, SLA, SLS, and FFF in the 1980s and 1990s to commercialization in the 2000s and modernization with hybrid manufacturing and AI integration in the 2020s. Among the various AM techniques, fused filament fabrication (FFF) remains the most widely adopted due to its cost effectiveness, material versatility, and operational simplicity [2]. The growing integration of AM within sustainable manufacturing frameworks has accelerated research into environmentally friendly materials, particularly polymer based and composite filaments. In this context, the development and optimization of natural fiber-reinforced polymer composites for FFF offer significant potential for reducing environmental impact while achieving acceptable mechanical and functional performance. These aspects form the foundation for the present study.

II. FUSED DEPOSITION MODELING

Fused Deposition Modeling (FDM), introduced by Stratasys in 1992, is an additive manufacturing technique that fabricate a 3D prototype and products layer by layer using a computer aided process [3]. FDM is also known as Fused Filament Fabrication (FFF) one of the most widely adopted additive manufacturing methods due to its capability to fabricate complex parts with relatively low cost and high flexibility in material [4]. FDM is an additive manufacturing (AM) where material is deposited in successive layers by layer to produce a final part. The process primarily supports thermoplastic polymers and their composites in specialized systems, metal or fiber reinforced filaments. As illustrated in Figure 2, the FDM process begins with the create a 3D model using computer aided design software. The CAD model is converting into STL file and then transformed into machine readable G-code using various slicing software, which divides the geometry into discrete layers and generate the toolpath for material deposition. During printing, a thermoplastic filament is heated at glass transition temperature and extruded through a nozzle onto a build platform, where successive layers bond together to form the final component [5].

Figure 2: Process flow diagram of fused deposition modeling (FDM).
Source: Authors, (2026).

For manufacturing components using FDM, multiple CAD software applications are employed to generate a printable design in formats compatible with FDM machines. The designs are processed by slicing software and then they are exported into the printing machine [6]. Figure 3 Streamlined flows of FDM Process demonstrating the transformation of a CAD model into a file format compatible with RP Machine, subsequently followed by slicing through numerous software tools to create the toolpath. The parameters for polymer printing, such as nozzle temperature, are established to produce the final printed component.

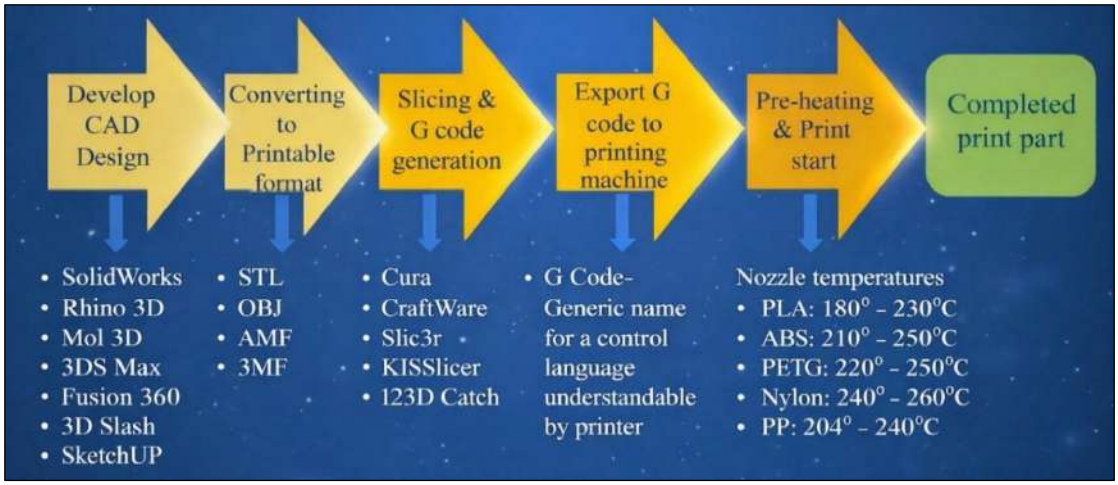

Figure 3: Streamlined flowcharts of the fused deposition modeling (FDM) process illustrating the use of different software applications and file formats in three-dimensional printing (STL-Stereolithography, AMF-Additive manufacturing file, OBJ-Wavefront 3D object, and 3MF-3D manufacturing format).

II. PROCESS PARAMETERS OF FDM AND THEIR IMPACT

Fused deposition modeling (FDM) is finding the application in many industries such as manufacturing, rapid prototyping, and the medical industry, particularly during emergency situations such as the COVID-19 pandemic for the production of personal protective equipment. To reduce production time and cost while improving part quality, the optimization of FDM process parameters is essential. Typically, thermoplastic filaments with diameters ranging from 1.75 to 3.0 mm are used. The FDM process can be broadly divided into three stages: pre-processing, production, and post-processing [5]. The quality of FDM-printed parts is depended on several process parameters, including extrusion temperature, layer height, printing speed, nozzle diameter, raster angle, build orientation, and infill characteristics. These factors have a direct impact on the quality of interlayer bonding, surface roughness, the accuracy of the dimensions, and the formation of defects [7]. To determine how effectively the printed part sticks to itself and to the layers next to it, it is needed to know the properties of each deposited layer. This affects how successfully the printed part works mechanically [8]. Figure 4 illustrates the cause-and-effect relationship between key FDM process parameters and part quality as well as mechanical properties.

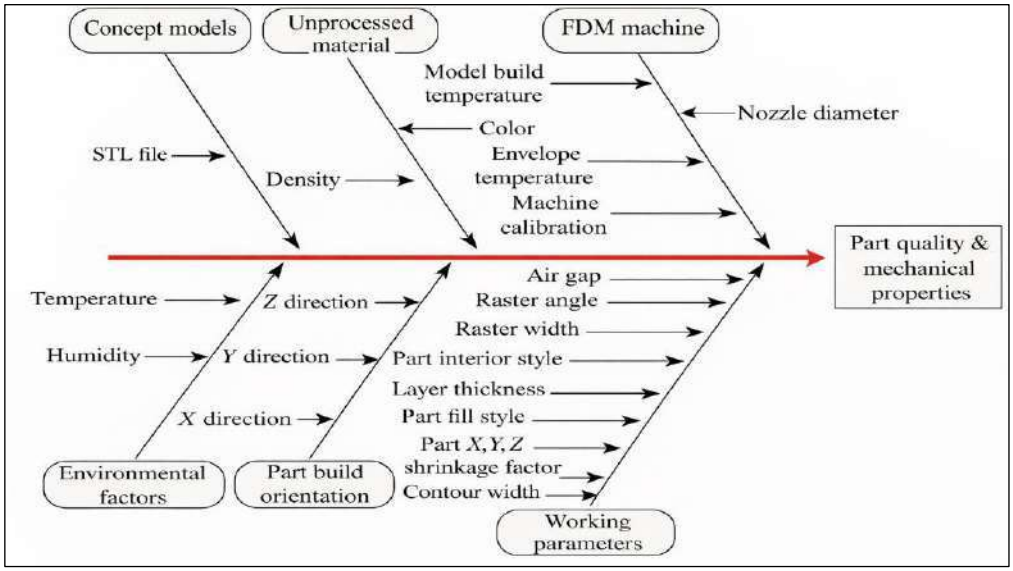

Figure 4: Cause-and-effect diagrams illustrating the influence of FDM process parameters on part quality and mechanical properties.
Source: [9].

Mechanical strength, dimensional precision, and surface finish are particularly influence by nozzle diameter, layer thickness, build orientation, and infill density. In addition to machine and material settings, environmental conditions such as ambient temperature and humidity have also been reported that they significantly influence printing consistency and bonding quality [10]. Recent studies emphasize the significant of optimizing parameter combinations using methodologies such as design of experiments (DOE) and computational modeling to improve part performance for specific applications [11]. Adjustments in layer thickness, raster angle, and infill pattern have been shown to significantly enhance strength, durability, and microstructural integrity in FDM-printed parts [12]. A thorough examination of these interactions allows researchers and manufacturers to utilize structured models and multi objective optimization techniques for consistent and superior production. Figure 5 presents a fishbone (cause-and-effect) diagram show the importance of preprocessing parameters that significantly affect the mechanical properties of FDM-fabricated components.

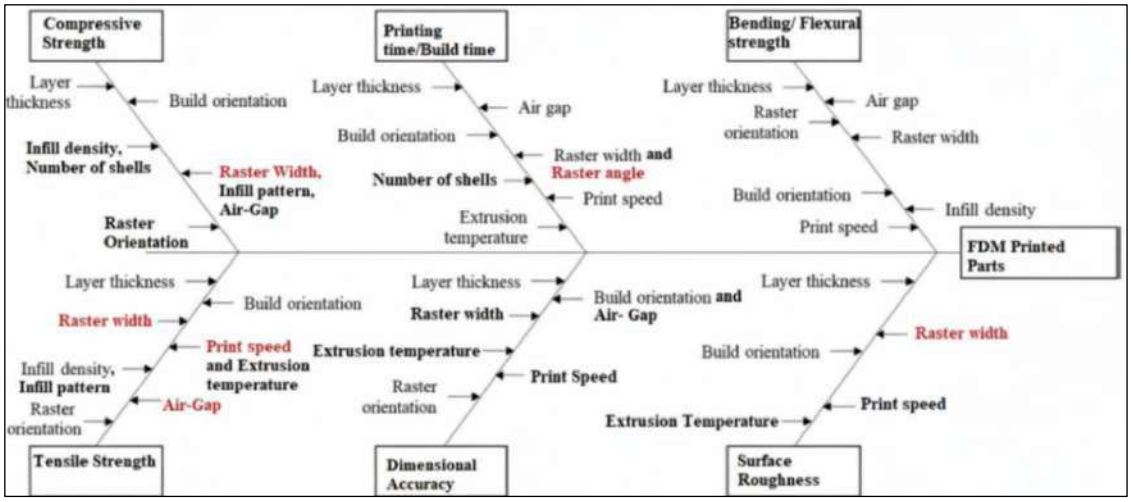

Figure 5: Fishbone diagram illustrating the effect of preprocessing parameters on the mechanical properties of FDM parts. Source: [13].

Table 1: Extensive recent research on the parameters of the FDM process and their influences on the mechanical properties.

Effect of Process Parameter	Cause and Effect in Mechanical Properties
Extrusion Temperature [14][15], [16], [17]	High temperatures enhance tensile strength and modulus by increasing inter-layer fusion and filament bonding; excessively high temperatures destroy the material, making bonds weaker.
Layer Height[15], [16], [17], [18]	Lower layer heights increase tensile strength and flexural strength by increasing the number of layers and interface bonding area; higher layer heights decrease bonding quality.
Printing Speed[15], [16], [17], [18]	Moderate to low speeds enhance strength and elasticity because they provide increased heat transfer and material deposition to attain good bonding; high speeds yield weak bonds and voids.
Infill Density[16], [18], [19], [20]	Higher infill densities (up to 100%) significantly improve tensile and flexural strength due to increase in internal material volume, less voids and increased load bearing.
Infill Pattern[16], [18]	Rectilinear/linear infill patterns enhance the strength by aligning loading direction with filaments and optimising the stress distribution and minimising stress concentrations.
Nozzle Diameter[16], [20], [21]	A 0.4 mm nozzle balances detail and strength; smaller diameters enhance filament bonding and surface finish, but very small sizes risk clogging and inconsistent extrusion.
Raster Angle[17], [18], [21]	Raster angles near 45° distribute load evenly across layers, reducing anisotropy and stress concentration, thus improving tensile strength and modulus.
Build Orientation[15], [16], [17], [18], [21]	Flat XY Orientation improves mechanical strength because layers are aligned with the load direction, enhancing interlayer bonding; vertical orientation weakens bonds and promotes delamination.

Source: Authors, (2026).

Overall, mechanical performance in FDM is strongly governed by parameters that affect interlayer bonding and void formation. Table 1. summarizes recent research on key FDM process parameters and their influence on mechanical properties. Commonly used thermoplastic materials in FDM include PLA, ABS, PET-G, and PP. selecting the wrong parameter weakens interlayer adhesion, increases anisotropy, and results in reduction in mechanical performance [22]. Experimental study shows that infill density and pattern have major influence the mechanical strength. Infill densities of 20%, 50%, and 100% using infill patterns like line, rectilinear, and honeycomb indicated that a rectilinear infill with 100% density produced the highest tensile strength in desktop FFF systems [23].

Table 2 shows a summary of the FDM materials and process parameters that have been studied in the literature. These studies collectively suggest that parameter optimization strategies differ based on material type and application requirements. Recent progress includes improving the conditions for extruding PLA composite filaments without reinforcement and comparing their results to international standards for FFF [41]. Adding more heating units near the nozzle has also been shown to improve the quality of the parts by keeping the material that is deposited close to its glass transition temperature (T_g). This makes molecular surface diffusion faster, makes mechanical anisotropy less, and makes interlayer bonding stronger. These kinds of changes are especially promising for large-scale FDM applications, where better mechanical properties and dimensional accuracy are very important[42].

IV. FILAMENT MANUFACTURING OF NATURAL FIBER-REINFORCED POLYMERS: PROCESS EVOLUTION AND KEY PARAMETERS

The filament is the dominant element of the FDM method. The filament is usually made of pure polymer with a low melting point. There are instances in which pure polymer strength needs to be increased. As a result, numerous researchers have created polymer composites as materials for 3D printing filaments by fusing the matrix and improving the constituent parts to create systems with structural and functional advantages that cannot be obtained by using a pure polymer. Polymer composites are engineered materials composed of a polymer matrix reinforced with a secondary material, such as fiber, to enhance their mechanical, thermal, or functional properties. For decades, synthetic fiber like carbon fiber and glass fiber have been the industry standard for reinforcement due to their superior strength and stiffness [43]. ABS are mostly used in industry. Unfortunately, those materials are not environmentally friendly, and therefore the need to develop more biodegradable counterparts [44].

Acrylonitrile butadiene styrene (ABS) is extensively used in industrial applications; however, it is not environmentally friendly, leading to increasing interest in biodegradable alternatives [45]. PLA is biodegradable, but making it releases CO_2 into the air (about 1.3 kg CO_2 equivalent per kg of polymer). To make it better, bio-based fillers and reinforcements need to be used [46],[47]. However, because each reinforcement in a composite polymer will provide a different set of characteristics, the process of creating composite filaments needs to be approached carefully first. Filament production typically involves material preparation, extrusion, cooling, diameter regulation, and spool winding. Modern extrusion systems use real-time feedback control to maintain uniform diameter (usually 1.75 or 2.85 mm). Figure 6 shows the natural fiber reinforce filament development process. Melt-compounding techniques allow polymer blending with additives like nanofillers or fiber to enhance mechanical or thermal properties [48].

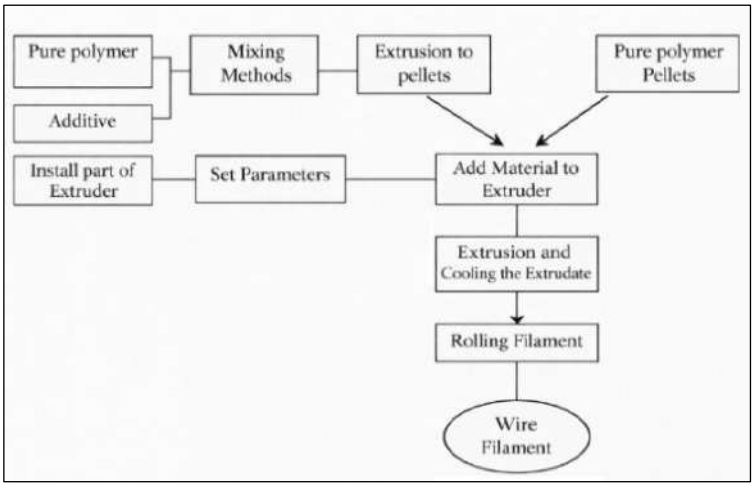

Figure 6: Schematic representation of the filament development process for natural fiber–reinforced composites.
Source: [48].

IV.1 EFFECT OF FIBER ORIENTATION

The mechanical properties of PLA matrix, including impact resistance, tensile strength, and flexural strength, can be greatly affected by modifying the orientation of fiber within it [49]. A certain mechanical property, such tensile strength, can be improved by suitable orientation along the printing direction. This study investigates the impact of fiber orientation on the durability of PLA reinforced with unidirectional continuous kenaf fibers at high temperatures. Composite samples were fabricated with fibers oriented at 0°, 45°, or 90° relative to the tensile force [50].

In a typical continuous fiber FDM system, as illustrated in Figure 7(a), PLA filament is fed into a heated nozzle where it melts, while a continuous fiber bundle is simultaneously guided into the heating zone. Within the nozzle, the molten polymer impregnates the fiber, forming a fiber–matrix composite that is deposited layer by layer. Figure 7(b) shows the corresponding printing process. Experimental studies using custom dual-feed FDM systems have confirmed that fiber orientation strongly affects mechanical properties, with 0° alignment providing the highest strength. This approach offers a scalable and cost-effective alternative to conventional composite manufacturing techniques [51].

Source: [51].

IV.2 NATURAL FIBER–REINFORCED FDM SPECIMENS FOR TENSILE TESTING

Tensile properties of natural fiber–reinforced FDM parts are commonly evaluated using standardized dumbbell-shaped specimens ASTM D638 Type-I or ISO 527-1:2012 [52],[53]. In this study, ASTM D638 Type-I specimen is used to find the tensile properties of natural fiber filament, as illustrated in Figure 8 [54],[55].

IV.3 FIBER PARTICLE SIZE AND VOLUME FRACTION

Extensive studies indicate that successful FDM printing of natural fiber–reinforced composites strongly depend on fiber particle size, volume fraction, and processing parameters. Lower fiber contents (typically 2.5 to 5 wt.%) combined with larger nozzle diameters (≥0.6 mm) improve printability and reduce nozzle clogging.

Table 3: Summarizes the relationship between nozzle size and fiber particle size stated in the literature.

Nozzle Size (mm)	Fibre Partial Size
0.4	75 µm
0.5	100 µm
0.75	125 µm
1.0	1mm

Source: [56].

PLA-based composites generally require lower nozzle diameter and bed temperatures compared to ABS-based composites. High infill densities normally 100% and optimized raster orientations are frequently adopted to improve mechanical performance. While increasing fiber volume fraction can enhance stiffness and strength, excessive fiber loading often leads to agglomeration, reduced interfacial bonding, print defects, and diminished impact resistance. Agricultural waste–derived fillers, including hemp, weed, tomato, carob, and pruned biomass, have been explored to reduce material costs and environmental impact [57].

Table 4: Key attributes of agricultural waste-derived particles used as filler phase.

Filler Material	Particle Size (µm)	Percentage	Particle Shape
Hemp	130	6%	Spherical
Weed	150	4%	Spherical
Tomato	100	4%	Spherical
Carob	130	4%	Spherical
Pruned	100	4%	Spherical

Source: [57].

Table 5: Summarizes comparative process parameters used for various natural fiber-reinforced polymer composites.

Process parameter optimization using statistical methods such as the Taguchi approach has demonstrated that natural fiber–reinforced PLA and ABS composites can be efficiently produced with minor adjustments to conventional FDM settings. Studies employing L9 orthogonal arrays report significant improvements in tensile strength, impact resistance, and dimensional accuracy [68]. Most studies suggest that in order to achieve a consistent flow of material and consistent mechanical performance, the nozzle diameter between 0.6 to 1.0 mm, the nozzle temperature between 190 ˚C to 230 ˚C, and the print speed should be between 30 to 90 mm/s. Bed temperatures vary with the polymer matrix, typically around 50˚C to 60˚C for PLA and approximately 105˚C for ABS.

IV.4 PRINTING FEASIBILITY OF SHORT JUTE FIBER-REINFORCED PLA FILAMENTS

During the initial printing trials, PLA filament reinforced with 2.5wt.% short jute fibers exhibited nozzle clogging, which restricted continuous material flow and interrupted the FDM process. This printing defect, shown in Fig. 9 (a) caused uneven material deposition and under-extrusion. The observed behaviour was primarily attributed due to moisture retained by the jute fibers, as natural fibers are inherently hydrophilic and readily absorb water from the surrounding environment. The presence of moisture reduced melt stability within the nozzle, resulting in uneven extrusion.

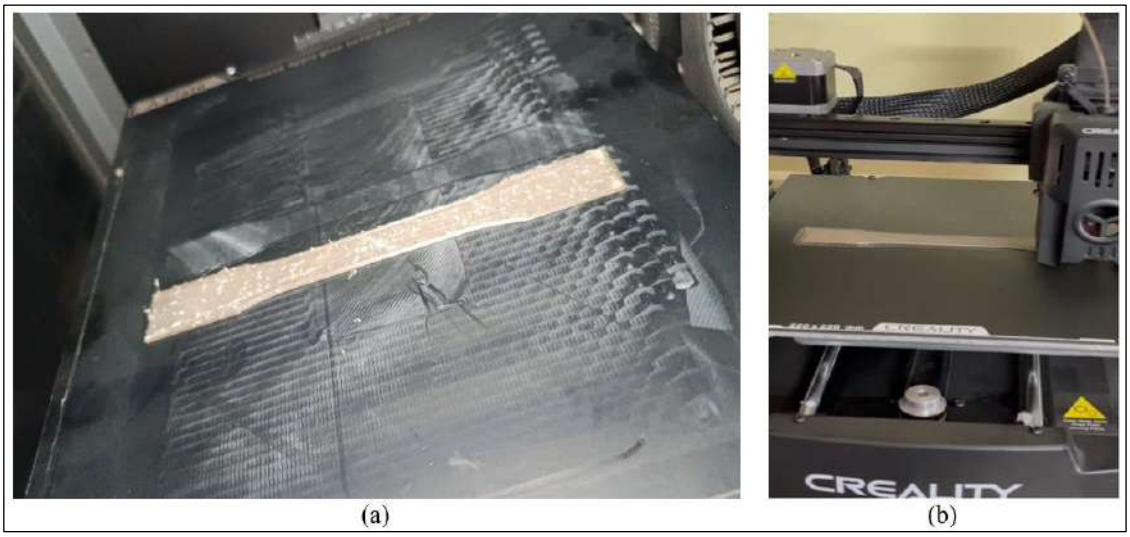

Figure 9: (a) Nozzle clogging and irregular extrusion observed during initial FDM printing of short jute fiber– reinforced PLA filament. (b) Tensile specimen geometry for natural fiber–reinforced PLA composites ASTM D638 Type-I.
Source: Authors, (2026).

To overcome this issue, the composite filaments were dried and annealed in a controlled filament dryer prior to subsequent printing trials. In addition to moisture removal, the extrusion temperature was set carefully to ensure proper polymer melt flow and improved fiber matrix mobility during deposition. After implementing these measures, extrusion stability improved significantly, enabling continuous and uniform layer deposition. Based on the post-treatment trials, Figure 9 (b) shows that PLA reinforced with 2.5 wt.% jute fiber and PLA reinforced with 5 wt.% jute fiber were found to be feasible for FDM printing without noticeable nozzle. clogging or extrusion interruptions. These findings highlight the critical role of moisture control and proper extrusion temperature in achieving stable printing of short jute fiber–reinforced PLA composites.

IV.5 MECHANICAL, THERMAL, AND MORPHOLOGICAL CHARACTERIZATION

Mechanical Properties of natural fiber reinforcement of composite is mostly determined by the mechanical nature of bonding between the fiber and the polymer matrix. While moderate fiber contents enhance mechanical properties, excessive reinforcement leads to agglomeration and weak interfacial adhesion, resulting in reduced strength [69].

Table 6: Comprehensive stuy of Fiber Particle size and volume fraction on Mechanical Performance Outcomes in Natural Fiber-Reinforced FDM Composites.

Sr. No	Base Material	Fiber Name	Fiber Particle Size	Fiber Volume Fraction %	Research Finding
1	PLA [58]	Bamboo	5 to 35 µm	11.80%	A 0° raster angle yields the best mechanical strength in flexure, compression, impact, and shear for bamboo-filled PLA. Print orientation has little effect on ultimate tensile strength but a significant effect on ductility.
2	PLA[59]	Kenaf	≤100 µm	2.5%	Smaller fiber size ≤100 µm fiber gives highest tensile & flexural strength; larger fibers reduce bonding and increase defects; surface finish improves with smaller size.
3	PLA[60]	Henequen flour	90 to 250 µm	1 - 5%	1% improves tensile strength; >2% causes porosity and agglomeration, reducing mechanical properties; degree of crystallinity slightly increases.
4	PLA[61]	Hemp	12.3 µm	10%, 20%, 30%	Tensile strength generally decreases; voids and poor inter-layer fusion reduce strength; modulus increases with fiber content.
5	PLA[61]	Harakeke	28.3 µm	10%, 20%, 30%	20% shows highest improvement in tensile strength and modulus; fewer defects compared to hemp due to finer fiber morphology.

6	ABS [67]	Kenaf fiber	Avg. 120 µm	0%, 2.5%, 5%, 7.5%, 10%	2.5% gives best tensile and flexural performance; higher contents worsen strength due to porosity and poor fiber–matrix bonding.
7	PLA[62]	Teak Wood Flour	74 µm	1%, 3%, 5%, 5% (with 5% silane)	Filaments with a 74 µm wood flour size successfully printed, but those with 125 µm clogged the nozzle. Adding a silane coupling agent improved interfacial adhesion, increasing both tensile strength and elongation.
8	PLA[63]	Bamboo	Finer Powder	3%, 6%, 9%, 12%	Bamboo powder slightly improves impact and flexural stiffness at low content but overall weakens PLA due to poor bonding and pore formation.
9	PLA[63]	Jute	Powder	3%, 6%, 9%,	Jute powder causes a steady drop in mechanical strength because of large particles and voids, with only a small impact improvement at 3%.
10	PLA[64]	Wood Flour	Mean Size 14 µm	5%	Thermal stability decreased slightly, while melting temperature remained unaffected.
11	PLA[65]	Rice Husk	1–50 µm	0%, 0.5%, 1%, & 2%	PLA rice husk filament up to 2% printable; tensile strength ≥25 MPa; elongation decreases >50%.
12	PLA[66]	Banana Fiber	-	0%, 1%, 3%, & 5%	3% banana fiber gives highest impact strength.
13	PLA[70]	Hemp Fiber	400–600 µm	5%	5% untreated hemp reduced tensile strength by 87.8% and strain due to poor interfacial adhesion.
14	PLA[71]	Jute fibers	10-400 µm	5%	Pulverized PLA improved fiber–matrix bonding, giving higher tensile strength and better homogeneity compared to pure PLA and pellet-based composite.
15	PLA[71]	Jute fibers	10-400 µm	5%	Pellet-based PLA + Jute showed lower mechanical performance due to non-uniform mixing and weaker interfacial bonding.
16	PC[72]	Hemp	-	10%,	Alkali-treated hemp fibers improved tensile strength, thermal stability, and matrix bonding; only ~2% strength reduction vs pure PC.
17	PLA[73]	cotton, flax, jute, woven fabrics	Continuous fibre	-	Alkali pretreatment improved adhesion strength due to better surface roughness and removal of impurities.
18	PLA[74]	Ramie fibers	Continuous fibre	-	Continuous ramie yarn greatly improved tensile & flexural strength.

Source: Authors, (2026).

Table 6 show that fine fibers and continuous reinforcements generally improve tensile and flexural properties, whereas coarse fibers and high loadings degrade performance.

Tables 7 and 8 give an extensive overview of the mechanical, thermal, structural, and morphological characterization that has been written about in previous decades. Most studies emphasize morphological analysis using SEM to evaluate fiber dispersion and interfacial bonding. However, thermal characterization using Thermogravimetric analysis (TGA), Differential scanning calorimetry (DSC), and Crystallinity assessment via X-Ray diffraction (XRD) remain limited. Chemical analysis employing energy-dispersive spectroscopy (EDS/EDX) is rarely documented, thereby limiting thorough structure–property correlations. This study overcomes these limitations by integrating tensile testing with TGA, DSC, XRD, SEM, and EDS analyses to deliver a comprehensive assessment of natural fiber-reinforced PLA composites.

V. OBSERVATION

This section critically discusses the influence of FDM process parameters and natural fiber reinforcement on the mechanical, thermal, and morphological behaviour of polymer composites. The discussion integrates trends identified in the literature with experimental observations obtained from the development and printing of short jute fiber reinforced PLA filaments in this study, thereby establishing clear process, structure and property relationships relevant to sustainable additive manufacturing process.

V.1 PROCESS–STRUCTURE–PROPERTY RELATIONSHIPS IN FDM COMPOSITES

The mechanical performance of FDM printed parts is fundamentally governed by interlayer bonding, which is controlled by key processing parameters including layer height, raster angle, nozzle temperature, print speed infill density, and printing speed. Adequate thermal input during printing promotes polymer chain diffusion across adjacent layers which improving interlayer fusion and reducing void formation. Research shows that by lower layer heights and using proper extrusion temperatures, tensile and flexural strength are improved. This is due to the effective bonding area is increased and interfacial flaws are minimized. Raster orientations about 45° and higher infill densities further contribute to improved load distribution capacity and reduced anisotropy. also, insufficient thermal energy or excessive printing speeds restrict molecular mobility, resulting in poor interlayer interfaces and premature mechanical failure. This process induced microstructural features form the basis for understanding the behaviour of both pure polymers and Natural fiber reinforced FDM composites.

V.2 EFFECT OF NATURAL FIBER CONTENT AND PARTICLE SIZE

The combination of natural fibers into thermoplastic matrices introduces competing effects related to reinforcement efficiency and printability. At low to moderate fiber content (1–5 wt.%) with fine natural fibers particle enhances stiffness in some cases, strength by facilitating stress transfer within the polymer matrix. Fiber particle size is important in this context because smaller particles scatter more uniformly and increase fiber matrix wetting during extrusion.

However, increasing fiber content or using coarse particles promotes agglomeration, interfacial void formation, and melt flow instability. These defects adversely affect interlayer bonding and reduce mechanical performance. The observed literature constantly shows that optimal fiber content and particle size are crucial for striking a compromise between mechanical enhancement and process stability in FDM based natural fiber composites.

V.3 PRINTABILITY AND MOISTURE SENSITIVITY OF PLA-JUTE FILAMENTS (PRESENT STUDY)

The experimental results from this study directly confirm the trends observed in this literature. Initial FDM printing attempts using PLA reinforced with 2.5wt.% short jute fibers caused nozzle clogging and uneven extrusion, indicating a key challenge with natural fiber reinforced filaments. This is due to moisture retained within the hydrophilic jute fibers, which destabilized melt flow within the nozzle. Following controlled filament drying and annealing along with optimization of extrusion temperature and extrusion stability improved markedly. Both 2.5wt.% and 5wt.% jute fiber reinforced PLA filaments were successfully printed without noticeable nozzle clogging or under extrusion. These results show that controlling moisture is an important part of developing natural fiber reinforced PLA filaments that can be printed successfully. It should be taken into account along with fiber content and particle size when designing filaments.

V.4 IMPLICATIONS FOR SUSTAINABLE NATURAL FIBER FDM FILAMENT DESIGN

The combined analysis of literature and experimental study indicates that sustainable, high performance FDM composites cannot be accomplished by material selection or parameter optimization alone. A comprehensive approach is needed that includes optimizing processing conditions, controlling moisture, and developing the filament. The present research illustrates that short jute fiber reinforced PLA filaments, when adequately conditioned, can be effectively processed with standard FDM systems while conserving satisfactory mechanical and thermal properties. These insights are helpful for making bio based composite filaments that have potential for sustainable additive manufacturing, especially for non-structural and semi structural parts where reducing the impact on the environment is very essential.

VI. CONCLUSION AND FUTURE SCOPE

VI.1 Conclusion

This study integrates a systematic analysis of FDM process parameters with the experimental development and validation of jute fiber reinforced PLA materials. The results confirm that interlayer bonding is the dominant factor in governing mechanical performance of FDM printed parts and is strongly influenced by extrusion temperature, layer height, raster angel, and infill density. Natural fiber reinforcement was found to be successful when fiber particle size, volume fraction, and filament conditioning were precisely regulated. Low to moderate fiber contents (1–5 wt.%) in PLA with fine particles enhance mechanical performance without compromising printability, whereas excessive fiber content led to agglomeration, extrusion instability, and reduced strength. Experimental printing trials shows that moisture control is essential for achieving stable extrusion of PLA–jute composite filaments. The results provide a detailed process-structure-property model that may be used to create sustainable FDM filaments reinforced with natural fibers.

VI.2 Future Scope

Future work should focus on long-term performance evaluation of natural fiber-reinforced PLA composites, including fatigue, creep, and environmental durability. Further improvements in fiber–matrix adhesion may be achieved through surface treatments and bio-based compatibilizers, while controlled fiber alignment or continuous reinforcement strategies offer potential for enhanced mechanical efficiency.

In addition, statistical optimization approaches that combine material composition and processing parameters, as well as scale-up studies and life cycle assessments, are suggested to promote the industrial adoption of sustainable FDM composite filaments.

ABSTRACT

The Ministry of Industry of the Republic of Indonesia has positioned the pulp and paper industry as a strategic sector through the implementation of competitiveness measures that strengthen the industry's ability to contend with free trade. Buyer-supplier relationships are the cornerstone of economic cooperation in various business transactions, established on collective agreement between two parties based on mutual trust. This study examines the factors influencing buyer-supplier relationships between the paper industry and paper chemical suppliers in West Java Province, Indonesia. Data collected from eight paper industry companies and six paper chemical suppliers were analyzed using the Structural Equation Modeling - Partial Least Square (SEM-PLS) method. Interviews were also performed to gather pertinent data from qualitative viewpoints. This study's findings confirm that business ethics, relational governance, and service quality simultaneously and positively and significantly influence buyer-supplier relationships and the paper industry's competitiveness. Product knowledge, logistic flexibility, quality, commitment, trust, collaboration, and joint problem solving are among the critical factors for sustaining buyer-supplier relationships. Meanwhile, cost efficiency, supporting industries, and government regulation were identified as major considerations in enhancing the paper industry's competitiveness.

I. INTRODUCTION

Porter's diamond model has gained increasing scholarly attention, particularly in the context of a nation's effort to achieve competitive advantage. Porter's theory asserts that a nation's competitive advantage hinges on four elements: (1) factors such as location, labor, capital, natural resources, and infrastructure; (2) demand conditions, encompassing ethics, culture, and regulation; (3) supporting and related industries; and (4) structure, competition, and the organization's strategic approach (innovation, quality, cost structure). Additionally, opportunity and government—two aspects of the national environment that have an indirect impact on these four crucial elements—also largely determine a nation's competitive advantage [1]. Enterprises operating in manufacturing, trading, or other sectors that have seen substantial expansion would persistently confront challenges related to management and control.

A vital element of supply chain management is the collaboration between manufacturing and ancillary sectors [2]. Given the proximity of these two entities to other operational businesses and linked sectors, manufacturing industries are urged to embrace innovation and help from ancillary industries to enhance their products, materials, and methodologies, thereby bolstering their competitiveness [3]. The pertinent activities can include marketing, distribution, and business-to-business interactions [4]. The pulp and paper industry is one of the sectors prioritized for development according to the Government Regulation No. 14/2015 on the National Industrial Development Master Plan [5],[6]. The growth of global demand for products in pulp and paper industry, both domestically and for export, remains optimistic, encompassing tissue paper products, packaging paper, and others.

Moreover, the increasing trend of e-commerce transactions would particularly encourage the growth of demand for packaging paper and cardboard. Through various policy instruments, the Indonesian government has been encouraging the transformation of this industry's comparative advantages into the competitive ones [7]. The paper chemical/additives industry plays an important role in the pulp and paper industry. The papermaking process uses cellulose fibers with additional additives to enhance the merits of the paper produced according to the desired grade. Pulp for papermaking can be manufactured from virgin fiber via mechanical or chemical processes or by re-pulping of recovered paper or recycled paper. The paper's characteristics can be substantially altered through the use of varying quantities of paper chemicals, including dyes, hydrophobic sizing agents, dry-strength agents, and wet-strength agents. Such agents can significantly influence the properties of the paper product, such as color, brightness, opacity, water resistance, liquid absorption or holdout characteristics, and other strength parameters [8-10]. Quality is one of the essential elements that underpins the success of any business. A study conducted by [11] stated that businesses enhance their worth and income by delivering superior goods and services at competitive prices to meet customers' expectations. Enhancing customer service standards is undeniably one of the most vital measures a company can use to achieve dominance and sustain its competitive edge in the industry.

Conversely, the contemporary corporate sector is increasingly focusing on ethics and ethical conduct. There are growing concerns regarding the actual dynamics within corporate entities masquerading as competition, growth, and profitability, intensifying to achieve certain objectives. For this reason, ethical practices within business organizations globally are being continuously surveyed and evaluated by an increasing number of supervisory institutions [12]. Moreover, frequent assessments of the fitness between suppliers and partnerships can be the best way to drive change and minimize performance losses from failing alliances. In this regard, [13] stated that governance structures serve to safeguard the investments made in the transaction, hence facilitating and fostering cooperative and sustainable relationships. This research proposes to investigate the determinants of relational governance, business ethics, and service quality's implications on buyer (paper industry)–supplier (paper chemical) relationships to enhance the paper industry's competitiveness. It is expected that this study can contribute to producing a detailed and holistic view of current buyer-supplier relationships between the paper industry and paper chemical suppliers by identifying the crucial factors to enhance paper industries' competitiveness. Therefore, efforts to increase the paper industry's competitiveness aim to achieve economies of scale in production and distribution as well as product value and economic stability.

II. THEORETICAL REFERENCE

A critical literature analysis conducted by [14] identified a gap indicating that no research has simultaneously investigated the relationship among business ethics, relational governance, and service quality in the context of buyer-supplier relationships within Indonesia's paper industry. Therefore, to comprehend the pertinent elements for increasing business competitiveness, this study proposes a research model built from business ethics, relational governance, and service quality in contributing to enhancing buyer-supplier relationships as well as the paper industry's competitiveness. Table 1 delineates the definitions and indicators of five constructs examined in this study.

Table 1: Constructs' definitions and indicators.

Construct	Definition	Indicator	Reference
Service Quality	The degree of products or services that meet quality expectations and the procedures that comply with quality standards	1. Logistic flexibility 2. Paper chemicals' quality 3. Product knowledge 4. Communication	[15], [16]
Business Ethics	The degree of moral standards, laws, and ideals that determine the way organizations conduct business, such as in implementing commitments, fair treatments, and relationships that benefits all related parties	1. Mutual and beneficial relationship 2. Commitment 3. Fair treatment	[17]
Relational Governance	Activities related to collaborative performance management, such as joint planning and problem solving among supply chain actors	1. Joint planning 2. Joint problem solving	[13], [18], [19]
Buyer-Supplier Relationships	Social relationship between buyer company and supplier organization, commonly in the form of trust-based collaboration	1. Trust 2. Multiple supplier dependency 3. Collaboration 4. Quality as priority	[20], [21], [22]
Competitiveness	An industry's defining superiority that emerges from its businesses' capacity to generate goods and services that satisfy global market standards while also attaining long-term profitability	1. Cost efficiency 2. High competition 3. High demand 4. Supporting industry 5. Value chain 6. Government regulation and policy	[1], [23]

Figure 1 illustrates the research model to identify the impacts of business ethics, relational governance, and service quality simultaneously on buyer-supplier relationships as well as on paper industry's competitiveness.

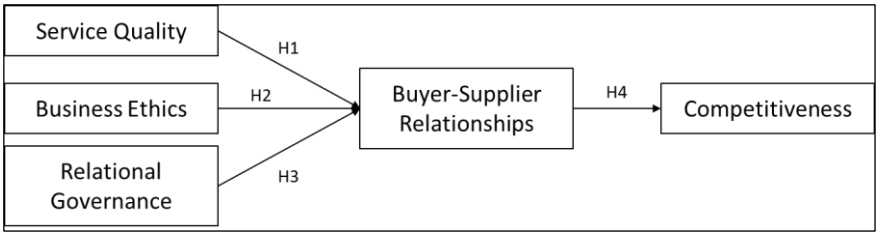

Figure 1: Research model.
Source: Authors, (2026).

According to [24], there are three drivers of customer satisfaction: perceived functional and technical aspects of emotional satisfaction, service quality, and corporate image, all of which are positively interrelated. Several previous studies have proved that service quality exerts a beneficial influence on customer satisfaction [11],[25],[26], with operational technical capabilities and cultural values—among others—being the dimensions of service quality [27]. Thus, based on these theoretical reasonings, the first hypothesis is formulated as follows:

H1: Service quality positively correlates with buyer-supplier relationships.

According to [28], leaders' ethical competence and the workforce's capability are two key factors in managing organizational ethics, where cultural elements, patterns of organizational conditions, and possibilities facilitate the administration of a corporate culture focused on fundamental ethical ideals. In addition, good business ethics can reduce conflicts [29]. A previous study by [30] can serve as a foundation of business ethics in the context of the economic exchange system and social value orientation as a potential resource. Thus, based on these theoretical reasonings, the second hypothesis is formulated as follows:

H2: Business ethics positively correlate with buyer-supplier relationships.

Relational governance is crucial for both strategic and non-strategic supplier partnerships, but for strategic suppliers, the accessibility of performance information is significantly more critical [19]. Nowadays, governance is viewed as a type of value-chain coordination that falls somewhere between hierarchy (vertical integration) and pure market interactions. Three distinct value chain forms are distinguished between market and hierarchy: 1) relational value chains, which are distiguished by a preponderance of intricate interactions between buyers and suppliers that reflect mutual dependence; 2) captive value chains, which significantly rely on large customers for smaller suppliers; and 3) modular value chains, which primarily exhibit independence in the production of elements to be assembled [31]. Value chain governance can transpire in various types, three types of which were identified based on the level of control exerted by a dominant company or actor. Quasi-hierarchical interactions, inter-firm networks between dominant lead companies and independent but subordinate companies within the value chain, and vertical integration inside firms were distinguished in ascending order of an actor's degree of control [32]. Relational governance comprises many dimensions and must be viewed from multiple points of view to distinguish collaborative practices from habitual ones [33]. Within business relationships, collaboration, interaction, joint planning, and coordination are several examples of collaborative activities [34]. Strategic target setting and evaluation of target achievement are two examples of collaborative actions that support the use of performance measurement. Evaluation of target achievement may consist of systematic and structured discussions of performance outcomes, meetings, and feedback [35]. Thus, based on these theoretical reasonings, the third hypothesis is formulated as follows:

H3: Relational governance positively correlates with buyer-supplier relationships.

Continuous buyer-supplier collaboration and development has a positive relationship with the performance of suppliers, buyer-supplier relationships, and buyers' competitive advantage [36]. Given how crucial suppliers' roles are to a company's commercial success, the significance of measuring supply chain performance has grown significantly [35]. Companies can be more competitive if they can establish close relationships with supporting industries, since the latter can drive creativity and improvement of processes, materials, and components [3]. This suggests that gaining competitiveness requires support—such as in the form of business interaction, distribution, and marketing—from related industries [4]. Thus, based on these theoretical reasonings, the fourth hypothesis is formulated as follows:

H4: Buyer-supplier relationships positively correlate with competitiveness.

III. MATERIALS AND METHODS

From January to December 2024, a methodical strategy was conducted in this study, targeting upstream supply chain actors within the paper industry and paper chemical suppliers in West Java Province, mostly in Bogor, Cikarang, Karawang, and Subang Regencies. Primary data were gathered through surveys and interviews with experts within the paper and paper chemical industry. Meanwhile, secondary data were gathered from previous related studies and reports by related industries.

III.1 DATA COLLECTION

At the beginning, the total number of enterprises selected was 12 paper industry companies and seven paper chemical suppliers. However, not all of them were able to participate in this study due to incomplete or outdated contact information, and several of them operated on tight schedules and may not have had the resources or time allocated for completing the survey, particularly if they perceived it as non-essential to their day-to-day operations.

Eventually, only eight paper industry companies and six paper chemical suppliers were able to participate. These eight paper industry companies were selected based on the amount of production capacity and the type of paper produced in West Java Province, where the respondents selected were associated with paper production and paper chemical utilization. The respondents' positions selected within this industry were production manager, quality control manager, quality control supervisor, production supervisor, and production section head, totaling 19 people. These respondents were selected since they were believed to be proficient and competent, with the majority having more than 10 years of experience in acquiring paper chemicals from suppliers. The supply of paper chemicals, which are essential for improving the sustainability, efficiency, and quality of paper manufacturing, is a major source of dependence for the paper industry.

Suppliers of these additives play an important role within buyer-supplier interactions, since they provide critical materials and technical expertise. The majority of respondents selected had more than 10 years of experience in dealing with the production and supply of paper chemicals. Questionnaires were distributed to 16 respondents representing paper chemical suppliers, consisting of both foreign and local ones. As many as 35 respondents from both paper industry companies and paper chemical suppliers participated in the survey. The questionnaire was divided into three sections: the first section covered the demographic and general information regarding the paper industry and paper chemical suppliers; the second section consisted of factors affecting buyer-supplier relationships, such as business ethics, service quality, and relational governance; and the third section explored the impact of buyer-supplier relationships on the paper industry's competitiveness. In indicating the level of respondents' agreement, the assumed five-point Likert scale was employed, where 1 = strongly disagree, 2 = disagree, 3 = fair, 4 = agree, and 5 = strongly agree.

III.2 DATA ANALYSIS

Using the Smart PLS Version 3 software, the Structural Equation Modeling - Partial Least Square (SEM-PLS) method was employed to process the acquired data. This method was suggested by [37] as a suitable approach for testing and validating exploratory models in the early phases of theory construction. By employing this method, this study established the foundation of a buyer-supplier relationships model among paper chemical suppliers and the paper industry's upstream supply chain actors to enhance the paper industry's competitiveness, specifically in West Java Province.

IV. RESULTS AND DISCUSSIONS

IV.1 PROFILE OF PAPER INDUSTRY COMPANIES

Table 2 presents the descriptive profile of paper industry companies examined. A total of 19 respondents represented various structural levels within this industry in West Java Province, particularly in the production and quality control departments.

Table 2: Profile of paper industry companies.

Factor	Description	Type of Paper Produced	Number of Respondent; Percentage (%)
Company	A	Industrial, cultural, tissue, packaging	2; 10.5
	B	Industrial, cultural, tissue, packaging	6; 32
	C	Packaging	3; 16
	D	Specialty, cigarette packaging	2; 10.5
	E	Industrial	1; 5
	F	Tissue	2; 10.5
	G	Tissue, packaging	1; 5
	H	Packaging	2; 10.5
Educational Background	Bachelor's degree		14; 73.5
	Diploma		3; 16
	High school		2; 10.5
Position	Production manager		4; 21

IV.2 PROFILE OF PAPER CHEMICAL SUPPLIERS

Table 3 shows the descriptive profile of paper chemical suppliers examined, consisting of four foreign ones and two local ones. A total of 16 people represented major positions within this industry in West Java Province.

Tabel 3: Profile of paper chemical suppliers.

Factor	Description	Number of Respondent; Percentage (%)
Supplier Company	A B C D E F	2; 12.5 2; 12.5 6; 37.5 4; 25 1; 6.25 1; 6.25
Educational Background	Master's degree Bachelors's degree Diploma High school	2; 12.5 10; 62.5 2; 12.5 2; 12.5
Position	Managing director Manager Key account manager Account manager Marketing Technical support	1; 6.25 6; 37.5 2; 12.5 1; 6.25 4; 25 2; 12.5

IV.3 ASSESSMENT OF MEASUREMENT MODEL

The SEM-PLS method—flexible in handling abnormal data and requires small sample size— was performed using the SMART PLS Version 3 software. Figure 2 illustrates the analysis results.

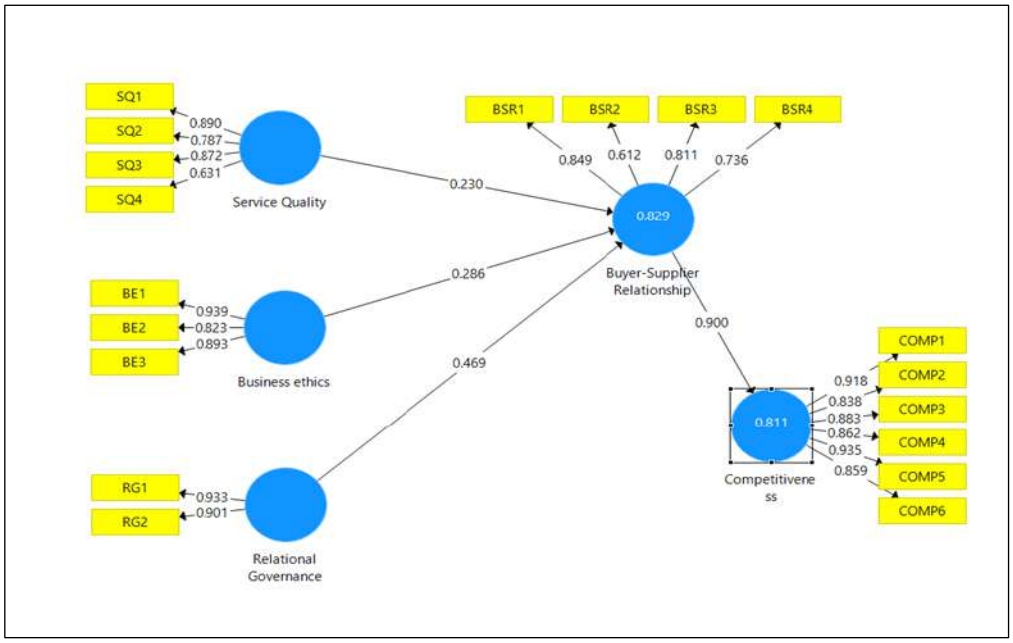

Figure 2: Factor analysis results of constructs' impacts on buyer-supplier relationships and the paper industry's competitiveness.
Source: Authors, (2026).

The measurement model testing stage aimed to assess the reliability and validity of constructs and indicators. According to [37], in this stage, loading factor and average variance extracted (AVE) values must exceed 0.7 and 0.5, respectively. As shown in Table 4, the resulting minimum outer loadings and AVE values both exceed the established criteria, suggesting that every construct and indicator examined exhibits adequate proof of convergent validity.

Table 4: Testing results of measurement model's validity.

Construct	Indicator	AVE	Loading Factor	Conclusion
Service Quality	SQ1	0.643	0.890	Valid
	SQ2		0.787	Valid
	SQ3		0.872	Valid
	SQ4		0.632	Valid
Business Ethics	BE1	0.785	0.939	Valid
	BE2		0.823	Valid
	BE3		0.893	Valid
Relational Governance	RG1	0.841	0.933	Valid
	RG2		0.901	Valid
Buyer-Supplier Relationships	BSR1	0.574	0.849	Valid
	BSR2		0.614	Valid
	BSR3		0.861	Valid
	BSR4		0.745	Valid
Competitiveness	COMP1	0.780	0.923	Valid
	COMP2		0.822	Valid
	COMP3		0.880	Valid
	COMP4		0.866	Valid
	COMP5		0.930	Valid
	COMP6		0.854	Valid

Source: Authors, (2026).

Reliability test in SEM-PLS generally uses two indicators, namely Cronbach's alpha (CA) and composite reliability (CR). CA measures the lower limit of the reliability value of a construct, while CR measures the actual reliability value of a construct. Thus, CR is considered better in estimating the internal consistency of a construct. The CA and CR values shown in Table 5 exceed the recommended threshold of 0.7. This indicates that all constructs analyzed exhibit high internal consistency, meaning that each construct was able to effectively explain the questions asked and aligned with the purpose of data collection.

Table 5: Testing results of constructs' reliability.

Construct	Cronbach's Alpha	Composite Reliability	Conclusion
Service Quality	0.810	0.876	Reliable
Business Ethics	0.863	0.916	Reliable
Relational Governance	0.813	0.914	Reliable
Buyer-Supplier Relationships	0.747	0.841	Reliable
Competitiveness	0.943	0.955	Reliable

Source: Authors, (2026).

The original sample value, p-value, and t-value obtained from the association between the independent (exogenous) and dependent (endogenous) constructs were used in the SEM-PLS method to test all of the hypotheses proposed. These values were used to assess whether the hypotheses significantly affected the research model constructed. Table 6 and 7 shows the testing results of constructs' indirect effects and hypotheses' path coefficients, respectively.

Table 6: Testing results of constructs' indirect effects.

Construct's Effect	T-Value	P-Value	Conclusion
Service Quality → Competitiveness	2.072	0.019	Supported
Business Ethics → Competitiveness	1.673	0.047	Supported
Relational Governance → Competitiveness	2.402	0.008	Supported

Source: Authors, (2026).

Table 7: Testing results of hypotheses' path coefficients.

Hypothesis	Beta Value	T-Value	P-Value	Conclusion
H1: Service Quality → Buyer-Supplier Relationships (+)	0.230	2.065	0.020	Supported
H2: Business Ethics → Buyer-Supplier Relationships (+)	0.286	1.799	0.036	Supported
H3: Relational Governance → Buyer-Supplier Relationships (+)	0.469	2.696	0.004	Supported
H4: Buyer-Supplier Relationships → Competitiveness (+)	0.900	28.489	0.000	Supported

Source: Authors, (2026).

Using the bootstrapping technique with 5,000 resamples based on [37], it is shown in Table 7 that the correlation between service quality and buyer-supplier relationships was declared positive, indicated by the beta value of 0.230 and p-value of lower than 0.05, thereby supporting H1. The p-value on H1 path indicates that such service quality behavior significantly influences buyer-supplier relationships within the paper industry and is considered a crucial factor in enhancing the interactions.

This aligns with a previous study by [11], which stated that the pulp and paper industry frequently introduces new, more sophisticated services and shift its businesses into service-oriented practices. Service agreements emphasize long-term connections with customers and provide intangible advantages. Next, the partial correlation between business ethics and buyer-supplier relationships was declared positive, indicated by the beta value of 0.286 and p-value of 0.036, thereby supporting H2. This aligns with a previous study by [29], which stated that small retailers' positive perceptions of suppliers' business ethics significantly reduce retailer-supplier conflicts and enhance retailer-supplier social satisfaction. Furthermore, the correlation between relational governance and buyer-supplier relationships was declared partially positive, indicated by the beta value of 0.469 and p-value of 0.004, thereby supporting H3 and suggesting a significant influence.

Lastly, the correlation between buyer-supplier relationships and competitiveness was also declared positive, indicated by the beta value of 0.9, t-value of 28.489, and p-value of 0.000, thereby supporting H4. These findings are consistent with those of [38], [39], which emphasized the importance of supporting suppliers to save expenses and upgrading the quality of other management aspects, such as by assisting suppliers to gain trust by sending positive signals to customers. Moreover, the government interventions may also alleviate industrial uncertainty [40], thereby boosting businesses' confidence and encouraging them to establish solid and long-lasting partnerships with their supply chain partners [20].

V. CONCLUSIONS

This study fills the gap within the topic of buyer-supplier relationships by performing a comprehensive analysis of how business ethics, service quality, and relational governance simultaneously influence buyer-supplier relationships and business competitiveness. In particular, this study's findings show that business ethics, service quality, and relational governance are crucial factors within relationships between the paper industry and paper chemical suppliers to significantly enhance the paper industry's competitiveness, both directly and indirectly. In this regard, factors influencing the relationships are product knowledge, logistic flexibility, quality, commitment, trust, collaboration, and joint problem solving. Meanwhile, cost efficiency, high demand, high competition, value chain, supporting industries, and government regulation/policy are among the identified factors in enhancing the paper industry's competitiveness.

ABSTRACT

The research work introduces the development of a Retrieval-Augmented Generation (RAG)-based chatbot using the LLaMA-3 model. Unlike traditional chatbots, which are limited by predefined responses, the RAG-based framework improves the chatbot's ability to retrieve and integrate information from user-provided documents and from a knowledge base, ensuring that responses are accurate, contextually appropriate, and informative. The chatbot has the ability to understand the intricate queries and produce the response after 4 seconds depending on the prompt by utilizing the advanced natural language capabilities of the LLaMA-3. Privacy is achieved by ensuring that all data processing is done in-house so that the data of the user does not leave the system and does not need internet access. This does not only increase security but it also enables those organizations that have stringent data compliance requirements to utilize the system without concerns. Besides strong response generation, chatbot could be specialized in specific domain needs like providing legal advice, academic research, healthcare consultations and customer service automation. The system is multi-turn, contextual and provides module components that can be easily integrated with other existing enterprise systems. The proposed work indicates how the combination of advanced language models and effective document search tools could lead to the development of very productive, smart, and personal chatbots that can be successfully implemented in various real life situations.

I. INTRODUCTION

A chatbot can be described as a computer program that can be used to imitate conversation with a human user, particularly in the Internet [1]. The given work outlines the creation of an augmented generation (RA)-based chatbot based on the LLaMA-3 model. In comparison, unlike traditional chatbots where the responses are constrained by the predefined answers, the RAG-based architecture has the benefit of enabling the chatbot to access and merge information provided by the user through documents, as well as through knowledge base to make sure the responses are accurate, contextually relevant, and informative.

This study demonstrates that the development of advanced language models and retrieval techniques can make successful chatbots that are effective in any field [2],[3]. They are utilized to communicate with people, as well as in other spheres such as education, business, e-commerce. Retrieval augmented generation (RAG) is a natural language processing (NLP) algorithm that integrates the two benefits of retrieval and generative-based artificial intelligence models. With the existing capabilities of LLaMA-3 (a large language model (LLM) created by Meta AI) and the RAG framework, the chat robot does not only comprehend complex queries but also provides accurate and relevant responses, As the research demonstrates, the modern AI can be used to improve the interaction process by offering smarter and more responsive conversational agents. Nowadays, most of the online Ai chatbots like chat-GPT, Gemini and others use their user data to train their models which questions the privacy for the users. Current chatbots often suffer from inaccuracies and limitations in their responses, making it difficult in their ability to provide reliable and informative information. This work aims to develop a more effective chatbot by integrating a Retrieval-Augmented Generation (RAG) architecture with the powerful Llama-3 language model.

Chatbots nowadays hallucinate a lot due to their inefficiency in the information storage of their previous knowledge, this leads to the dissatisfaction of the user. Most chatbots come with their predefined responses rather than answering by understanding the user query, so this research helps in solving these issues and improve the chatbot performance. Retrieval-Augmented Generation (RAG)-based chatbots nowadays use vast retrieval techniques to extract information from the user provided documents and then they also retrieve data from the knowledge base that they have used as these methods show promising responses but there are few drawbacks like they response retrieval time and accuracy of the responses. This kind of methodology across other domains is limited by the fact that they are frequently domain-specific. They also doesn't come with a specific interface with a neat design [4]. The task of developing an effective Retrieval-Augmented Generation (RAG)-based chatbot involves overcoming several challenges related to information retrieval, response generation. Before diving into how RAG with LLaMA-3 improves chatbot performance, it's important to understand the conventional methods used in chatbot development and their inherent limitations [5-7]. Most of the chatbots use simple pattern matching mechanisms. These chatbots can be used in the domains like education. Most of the chatbots are also used during the covid-19 for enquiring about the disease well.

A. Rule – Based Chatbots

Overview: Rule-based chatbots operate on predefined sets of rules and regulations. These systems work by matching user inputs with pre-programmed responses. They are widely used in customer support and FAQ-based systems.

Limitations:

Lack of Flexibility: These bots struggle to handle queries that fall outside their programmed knowledge base.

Scalability: Improving and expanding the rule based chatbots require a significant number of resources and also it is very much difficult in upgrading them and also require a lot of manual effort.

Learning capability is zero: In rule based chatbots, the chatbots do not learn from the user-provided data and often depend upon the predefined data that they have been fed into.

B. Traditional Machine Learning-Based Chatbots

Overview: These chatbots use supervised techniques to generate responses and learn about the use case that they have been trained on. They often train on large sets of data to know their responses and to improve the understanding levels of the user. Machine learning chatbots are better than the traditional rule based chatbots as they understand upto a certain level and provide better responses than the rule based predefined responses. Their responses are not limited unlike the rule based chatbot but they will be learning on how to respond.

Limitations:

Data dependency: These machines learning based chatbots require large amounts of datasets which are often difficult to retrieve and also to maintain, if any new information is needed to be added it is much difficult to train them to respond to their new information.

Less contextual understanding: Even if they are trained on large amounts of data, they do not fully understand the context that the user is talking about and hallucinate a lot.

No dynamic responses: These kinds of chatbots cannot generate responses beyond their trained data and often fail to answer the questions beyond their trained domain. Which makes the chatbots less interactive to the user.

C. Information Retrieval-Based Chatbots

Overview: These chatbots fetch answers from a knowledge base or database using search techniques. They rely on methods such as keyword matching, TF-IDF to retrieve relevant information from documents.

Limitations:

Low understanding: These chatbots often match by keyword matching rather than the full semantic understanding

Poor generating: If a user gives a query rather than the expected in which the system is trained on, these chatbots fail to generate accurate responses.

Non-generative: These chatbots cannot create a new response based on the user query and can often generate responses with the knowledge available in their databases.

D. Generative AI-Based Chatbots (Without RAG)

Overview: Gen Ai chatbots like GPT-3, GPT-4 and other models use pattern-based understanding and can also generate responses like humans making the conversation with them more interactive and comfortable.

Limitations:

Hallucination: These complete generative Ai models sometimes generate incorrect or misleading information due to their limitations in the training data and not identifying the difference between the factual and contextual data.

Do not follow up-to-date knowledge: These Gen Ai models cannot answer about the latest information and cannot actually be up to date.

I.1. HOW RAG ADDRESSES THESE ISSUES

Retrieval-Augmented Generation (RAG) uses the best of both the retrieval mechanisms and also the response generation capability of the LLMs [8]. By using the Retrieval techniques and feeding them to the LLMs will significantly improve the chatbot performance. By integrating RAG with LLaMA-3, the chatbot gains context-aware, factual, and dynamic response capabilities—effectively overcoming the shortcomings of previous methods. These kinds of chatbots can effectively improve customer service in the business sector. These kinds of mechanisms make humans more interactive to chatbots and can make them feel like friendly companions [9][10]. When there is no history or memory updated in the chatbot, it can lead to the looping conversations or make them hallucinate.

A. Objective

The objective of this research is to develop a chatbot which is context aware and provides accurate responses to the user-based queries by combining the power of both the LLM (Large language models) and RAG [11]. The work mainly focuses on

- Improve response accuracy
- Integration of knowledge retrieval
- Develop a user-friendly interface
- To ensure that the system can be adapted to different domains
- Optimize retrieval efficiency

The goal is to make the chatbot useful to all kinds of domains where most chatbots fail to respond to a domain on which there is no knowledge on. This research aims to showcase how AI can be used in future intelligent systems [12].

B. Existing System

The current system of Retrieval-Augmented Generation (RAG) based chatbots combines document retrieval and language generation to provide more relevant and accurate responses to user queries. In these systems, relevant information is first retrieved from large datasets, such as PDFs or knowledge bases, using retrieval techniques. The retrieved data is then passed to a generative model, like LLaMA-2, to produce conversational responses. While effective, the current systems face challenges such as retrieval accuracy, response latency. These systems are often domain-specific, limiting their flexibility across different fields.

C. Proposed System

The proposed system seeks to overcome these limitations by developing a more advanced RAG-based chatbot using the LLaMA-3 model, which can dynamically process user-uploaded documents from any domain and deliver highly relevant, context-aware responses in real-time. By optimizing the retrieval process through fine-tuning the LLaMA-3 model, this system will minimize latency and improve the accuracy of responses. Additionally, the system is designed to be domain-specific and robust solutions that can be applied across various fields, making it adaptable for a wide range of industries and domains.

II. LITERATURE SURVEY

According to [13] has developed a medical chatbot using Llama-2 which uses the Llama-2 model to generate the responses and uses vectorDB as their database. In this study langchain loaders and splitter were used and from this study we have understood that the quantized models can also perform well under the right resources. Although, this study has the drawback of not using the latest models and also there are better embedding models which outperforms the models used in this research. In [14] has developed a RAG based LLM chatbot using Llama-2, this study focuses on using the RAG capabilities to generate a emotional and supportive responses to the victims of the sexual harassment. This study used the langchain text splitters for chunking and used the chromaDB as their knowledge base. It is specifically designed for the survivors of the sexual harassment and cannot go beyond the domain of this topic.

This work shows that the LLMs can generate responses which are emotionally understandable and supportive to the humans, which makes the user more interactive to the chatbot and uses them more. This study used the Llama-2 7b model which is the drawback of this study where Llama-3 outperforms Llama-2 in every aspect of comparison. The responses are also limited to that specific domain and cannot be used to talk to the chatbot about other topics which makes this chatbot less usable to most of the user as most of the people do not go under the sexual harassment. According to [15] proposed "Mr. Dr. Health-Assistant Chatbot," an AI-driven virtual assistant designed to provide preliminary medical guidance to users.

The chatbot is trained on various medical datasets to offer health-related advice, symptom analysis, and disease-related information. The study has indicated that AI is a critical aspect of healthcare, particularly in terms of eliminating the reliance of human medical practitioners in simple medical inquiries. Nevertheless, one of the issues that can be seen in the research is the medical accuracy of the chatbot since some wrong or old information may confuse the users. Further, the use of the chatbot is limited due to the use of fixed databases that are not capable of offering real-time information on changes in medical knowledge. According to [16] investigated the use of chatbots in the context of communicating about the COVID-19 pandemic in the field of public health. Their article describes the successful implementation of chatbots to help with symptom screening, common questions, and easel the burden on healthcare workers since they can automatically respond to the general queries. The study highlights the promise of AI-based tools in the context of handling the health crisis at scale by making sure that the correct information is disseminated in a timely manner. The problems with the study also include the possibility of misinformation because of the outdated knowledge base and limited conversational depth of chatbots that can potentially be poor in solving complicated medical issues, however. According to [17] explored the interaction between users and chatbots and voice assistants and examined the motivations and the perception of AI-based conversational systems. The analysis reveals that although chatbots enhance the levels of customer service accessibility and efficiency, customer engagement mainly hinges on the level of accuracy of responses, personalisation and fluency of conversation. Chatbots have more chances to make the user believe and remain using them when the replies are natural and contextually appropriate. Although these are the advantages, one of the major limitations is the absence of emotional intelligence in chatbots and therefore, the inability to effectively communicate sensitive discussions.

Furthermore, the report indicates that users would rather have human interaction when their questions are more complex meaning that AI-based assistants are most effective in solving more formalized and routine problems than a more subtle dialogue. By [18] discusses the advantages and disadvantages of artificial intelligence chatbots to companies. Although chatbots present the advantages of time-saving and customer service enrichment, they are associated with the emergence of new threats such as prejudice, non-interference with other systems, and data security threats. To help managers to understand whether their organization is ready to use the chatbots created by AI, the research offers a new framework based on the Technology Acceptance Model (TAM). Four very important areas that it contributes towards to give a complete picture of preparedness are social influence (subjective norms), compatibility, available assistance (facilitating conditions), and trust. The framework and evaluation tool assist the managers to be more judgmental when it comes to deciding on whether to implement chatbots in marketing, sales and in customer service. For of author [19] explores the role of chatbots in online services and commerce with particular emphasis on the way they could enhance the quality of customer care. It sets out two main objectives namely, better service performance as well as meeting the expectations of the customers using such features like engagement, entertainment, problem-solving, customisation, and trendiness. It is quite evident that chatbots significantly improve the experience of clients and the outcome of the service.

According to [20] examines the ethical issues associated with the use of chatbots by nephrologists as it brings attention to the fact that special laws should be enforced to protect personal information, integrity of stored information, and the possibility of receiving an informed consent of patients prior to using these tools. Patient information is focused on in the form of secure techniques, data visibility, anonymization and encryption, among others. Regular evaluations of algorithms and diversity programs are proposed as the way to reduce prejudice. The analysis continues to state that maintaining a doctor-patient relationship has to be trustworthy by being open, designed intuitively, culturally sensitive, and finding a happy medium between the human and automated interaction. To enhance patient care by utilizing chatbots in nephrology that was properly and safely used, vast ethical guidelines and continual studies are required. Smart college chatbot by [21] is an academic and administrative chatbot built on machine learning and Python to provide support to students with their academic and administrative questions. The chatbot will be configured to address frequent student issues like enrolling in courses, exam times, and payments, thus it will decrease the workload of the administration. The research shows that chatbots are capable of increasing the engagement of students through the need to provide immediate feedback and increase the availability of institutional information. One such weakness, however, is that the chatbot is less flexible to dynamic or unstructured questions because it relies on pre-created datasets. Besides, the quality of the training data also affects the performance of the chatbot, and it needs periodic updates to be accurate and relevant.

III. METHODOLOGY

The RAG-based chatbot development methodology using LLaMA-3 takes a systematic procedure that is effective to retrieve documents and process them effectively to generate responses. The system will accept user-supplied PDFs, extract the information with the help of embeddings, retrieve the most relevant information with LLaMA-3 and produce the context-based responses. The following is a breakdown of the methodology that will be used in this research work.

A. Preprocessing the Data

a. Data Ingestion and Preprocessing:

Since the chatbot needs to process user-uploaded PDFs, an efficient pipeline is required to handle various document formats, extract textual content, and preprocess the data for retrieval.

- Text Extraction:
  - PDFs are parsed using PyPDF to extract structured and unstructured text.
- Cleaning and Normalization:
  - Unnecessary white spaces, special characters, and formatting issues are removed.
  - The text is split into meaningful chunks to improve retrieval performance.

- Chunking Strategy:
  - Fixed-size chunking: Splitting text into uniform-length sections (e.g., 512-1024 tokens).
  - Semantic chunking: Using NLP techniques to split text based on logical divisions (headings, paragraphs, etc.).

b. Embedding Generation & Storage:

To enable efficient retrieval, the extracted text is converted into vector embeddings that capture semantic meaning.

- Embedding Model:
  - The model uses Nomic-Embed for vector representation of text.
- Vector Database (pgVector):
  - Embeddings are stored in a PostgreSQL + pgVector database for efficient similarity search.
  - Each document chunk is indexed for fast retrieval during user queries.

c. Query Processing & Retrieval:

When a user asks a question, the chatbot retrieves the most relevant sections from the stored document.

- Query Embedding:
  - The user's input data which is raw data converted into a unique embedding using the same model used for document embeddings.
- Similarity Search:
  - Cosine similarity search is performed in the vector database to find the closest matching chunks.
- Ranking & Filtering:
  - Retrieved chunks are ranked based on relevance, and low-confidence matches are filtered out.

d. Response Generation using LLaMA-3:

Once the relevant documents are retrieved, they are passed to the Llama-3 model to generate informative and context aware responses for the user query [22]. Here you can instruct the chatbot with some certain instructions on how to provide the responses or in what way they are needed. Llama-3 is the best open-source model which provides the most accurate and context aware responses [23].

e. System UI and Deployment:

To provide a user-friendly experience, the chatbot is deployed using a Streamlit-based front-end. For Containerization the entire application is packed in the Docker ensuring easy deployment on cloud services [24]. By making this Containerization your system is not affected by the other works that you do and they remain individually separate.

This approach guarantees an effective search of information by the chatbot, the proper output, and the ability to create a continuous user experience. Through LLaMA-3, vector databases, and sophisticated retrieval methods, the system experiences limitations in the conventional chatbots, thus it is scalable, context-sensitive, and highly efficient [25].

System Architecture:

Below Figure 1: shows the architecture of the chatbot and its working mechanism. It is designed to combine efficient information retrieval with powerful generative capabilities to deliver accurate and context-aware responses. The system follows a structured pipeline, as illustrated in the diagram.

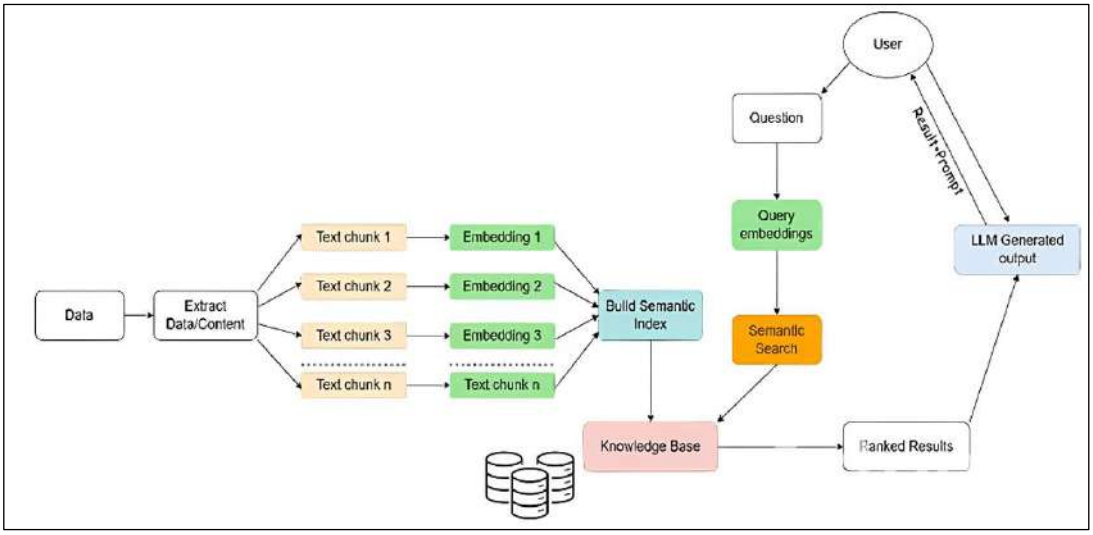

Figure 1: The architecture of the RAG chatbot showing the modules encountered at each.
Source: Authors, (2026).

The data is first extracted from the user provided documents and then it is divided into chunks of data which is changeable, Later the chunked data is sent to create embeddings and then to create a unique semantic index for those embeddings which helps in the retrieval part when there is a query. All of this data is stored into the knowledge base and a similar process will happen to the query to process all those and to understand the context of the question asked by the user. One of the important steps is:

a. Embedding

Nomic-Embed-Text is a text embedding model which converts the low-level textual data into the high-level vector representation. These embeddings further help in the searching process of the information that you have been stored in the database. Table 1 shows that the nomic embed text embedding model used in the research performs better than the other models and Table 2 depicting the Similarity metrics of the different models.

Table 1: Comparison table of different Embedding Models.

Feature	Open Ai Embeddings	Hugging Face Sentence Transformers	Nomic Embed (Used in Work)	FastText
Type of Embedding	Dense, contextual	Dense, contextual	Dense, contextual	Dense, word-level
Input Format	Text (any format)	Text (any format)	Text (any format)	Text
Pretrained Models	Yes (OpenAI proprietary)	Yes (wide variety)	Yes (e.g., nomic-embed-text)	Yes (language-specific)
NLP Context Awareness	High (deep contextual embeddings)	High (contextual sentences)	High	Low (word-level only)
Ease of Use	Easy	Moderate	Moderate	Easy
Speed	Moderate	Moderate	Fast	Fast
Best For	Advanced contextual embeddings	Sentence or document embeddings	Vector-based RAG pipelines	Word-level tasks
Cost	Paid (token-based pricing)	Free/Paid	Free	Free

Source: Authors, (2026).

Table 2: Performance metrics comparison of the Embedding Model.

Model	Embedding Size	Cosine Similarity (Avg)	Euclidean Distance (Avg)	Manhattan Distance (Avg)	Dot Product (Avg)
Hugging Face Sentence Transformers	768	0.82	1.45	2.89	11.76
Nomic Embed (Used in Work)	768	0.88	1.12	2.34	13.21
Fast Text	300	0.78	1.67	3.02	10.45

Source: Authors, (2026).

As we can see that Nomic embed text has performed better in each of those metrics as Higher cosine similarity, Lower Euclidean distance, Lower Manhattan distance, Higher dot product is better. Nomic embed text performed better in each of these performance metrics.

b. Knowledge Base

The knowledge base in this research work is PostgreSQL database with pgVector. The pgvector extension in this database allows searching the embeddings very fast and efficiently. This also helps in retrieving the embeddings from the database. This uses semantic search to search for the matching embeddings. This kind of search is much more ideal for the large-scale ML applications

Average Text Chunk Size: ~512 tokens per chunk

Vector Dimension: 768

Storage Size Per Embedding: ~3-4 KB per vector

The chatbot needs to store the data and retrieve it as quickly as possible. In case of the usage of the normal database it takes a lot of time to store and even to accurately search and retrieve the information. So, in this place the vector database comes which stores the data in the vector format and pgvector further improves the retrieval.

Working mechanism of pgVector:

i. Storing Embeddings:
- After converting text chunks into embeddings using Nomic-Embed-Text, they are stored in a PostgreSQL table with a vector column.

ii. Indexing for fast retrieval:
- A semantic index is created for each of the items for ensuring fast retrieval. This speeds up the search process.

iii. Retrieving Relevant Information:
- When a user asks a question, the input is converted into an embedding and compared to the stored vectors.
- The chatbot retrieves the most similar chunks and uses them as context for LLaMA-3.

c. Semantic Search

Traditional search methods rely on keyword matching, which can be inefficient when dealing with complex queries. Semantic search goes beyond keywords by understanding the meaning of the user's query and retrieving the most relevant results based on contextual similarity.

Vector Search with pgVector:

- This query embedding is compared against the stored document embeddings in pgVector using similarity measures like cosine similarity.

$$cos\ \theta = \frac{A\ .B}{||A||\ ||B||} \quad (1)$$

- Instead of searching exact words, it retrieves the most contextually similar chunks from your knowledge base.

d. LLM Response Generation

Once semantic search retrieves the most relevant document chunks, they are sent as context to your LLaMA-3 model, along with the user's original question. The LLM then processes this information and generates a natural language response.
How the chatbot handles LLM response generation:
Input to LLaMA-3:

- The user's query: "What are the symptoms of diabetes?"
- Retrieved knowledge base content:
  - Chunk 1: "Diabetes symptoms include frequent urination, frequent thirst, and weight loss."
  - Chunk 2: "Early signs of diabetes also involve fatigue and blurred vision."
- These are formatted into a structured prompt before being sent to LLaMA-3.

Processing the data by Llama-3:

- LLaMA-3 analyzes the provided content and formulates a well-structured response in a conversational manner.
- Instead of hallucinating an answer, it summarizes and reformulates the retrieved information. The main concept of using the RAG is that the chatbots do not hallucinate, they have a predefined knowledge on what they are about to give an answer.

Final Response:

- Example Output: "Diabetes symptoms typically include frequent urination, excessive thirst, weight loss, fatigue, and blurred vision. Early detection is important to manage the condition effectively."

e. Llama-3 and its significance

LLaMA-3 (Large Language Model by Meta AI) is the latest invention of Meta's open-weight large language models, designed for better natural language processing (NLP), retrieval-augmented generation (RAG), and knowledge-based AI applications.

The main reason to select the Llama-3 model is that it is open source and comes with various other uses like

- Efficiency – It offers high performance while using fewer computational resources compared to closed models like GPT-4.
- Open-Source – Unlike proprietary models, LLaMA-3 is freely available for customization and fine-tuning.
- Scalability – Supports a range of applications, from small-scale personal assistants to enterprise-level AI.
- Optimized for Long Context – LLaMA-3 can process up to 16,000 tokens in a single prompt, allowing it to handle long-form documents effectively.

Llama-3 has been trained on over 1.5 trillion tokens from diverse multilingual and domain-specific sources. It can also generate responses within 500 ms - 2s, depending on prompt complexity and hardware.

IV. RESULTS AND DISCUSSIONS

This section analyses about the chatbot data ingestion and its processing of it. The data ingestion usually depends on the size of the document the user has provided. It also discusses the chunking mechanism and how the chatbot thinks in the background of its processing. This also shows the average time taken for each of the response generated by the chatbot and also follows the instructions set previously.

Chatbot UI and Design:

The entire frontend of this research has been made with the use of streamlit which is an open-source Python framework. It is mainly divided into two sections, The chat interface for the user to chat with the chatbot and the customization section where the user can upload the documents and change the Llama model, change the embedding or clear the knowledge base. The entire interface looks like the Figure 2.

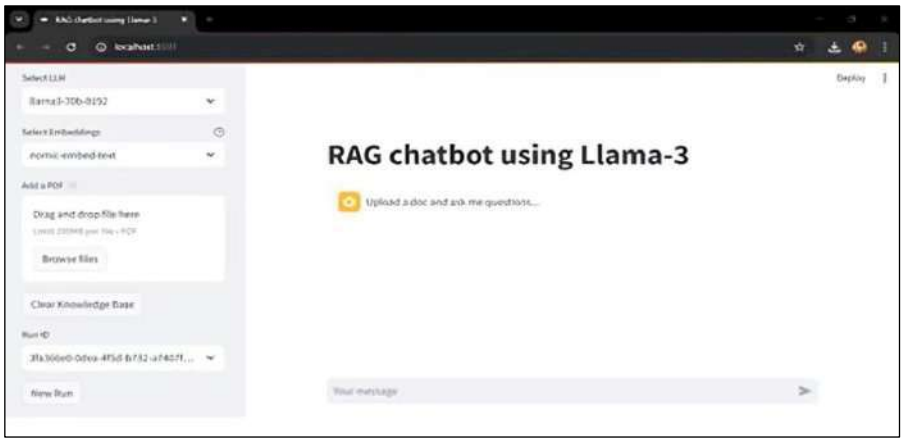

Figure 2: User Interface of the chatbot showing the different options available.
Source: Authors, (2026).

a. LLM Selection

In this proposed work there are 3 types of models from which you can select one on which your chatbot works and generates responses, The models are

i. Llama3-70b-8192

- 70B: It has 70 billion parameters, making it highly capable for complex reasoning and generation.
- 8192: It refers to the context window size (8,192 tokens), which determines how much text it can process in one go.

ii. Llama3-8b-8192

- 8B: A smaller version of LLaMA 3 with 8 billion parameters.
- 8192 tokens: Same context window as the 70B version.

iii. Mixtral-8x7b-32768

- Mixtral (Mistral AI): A mixture of experts (MoE) model developed by Mistral AI.
- 8×7B: Uses 8 experts, each with 7 billion parameters, but only 2 experts are active per inference, meaning 14B active parameters at a time.
- 32768 tokens: Extremely large context window, allowing it to process long documents or conversations.

We have also put the Mixtral model for testing purposes and to compare the results of the Llama-3 with this model. The model can be selected from the drop down which looks like the Figure 3.

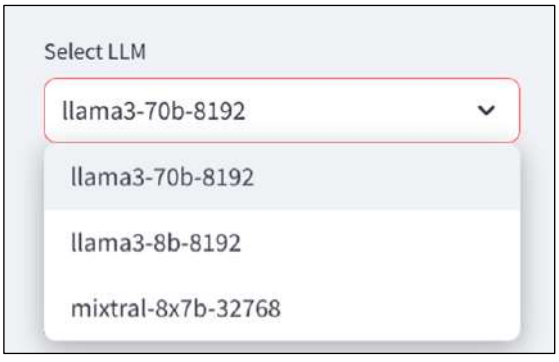

Figure 3: Showing the options available for the selection of the different models
Source: Authors, (2026).

b. Uploading the document:

The user can upload a file from the drag and drop section and the chatbot takes the input and processes them further for chunking and embedding.

Figure 4: Drag and drop section for the files to be uploaded by the use.
Source: Authors, (2026).

After uploading the document, the chatbot processes the text inside it and divides them into several chunks. This process can be checked in the step in the terminal that you have used to start, it looks like the Figure 5.

```
DEBUG    Upserted document: 20-health-tips_1_1 | 20-health-tips | {'page': 1,
         'chunk': 1, 'chunk_size': 512}
DEBUG    Upserted document: 20-health-tips_1_2 | 20-health-tips | {'page': 1,
         'chunk': 2, 'chunk_size': 505}
DEBUG    Upserted document: 20-health-tips_1_3 | 20-health-tips | {'page': 1,
         'chunk': 3, 'chunk_size': 505}
DEBUG    Upserted document: 20-health-tips_1_4 | 20-health-tips | {'page': 1,
         'chunk': 4, 'chunk_size': 511}
DEBUG    Upserted document: 20-health-tips_1_5 | 20-health-tips | {'page': 1,
         'chunk': 5, 'chunk_size': 501}
DEBUG    Upserted document: 20-health-tips_1_6 | 20-health-tips | {'page': 1,
         'chunk': 6, 'chunk_size': 170}
DEBUG    Upserted document: 20-health-tips_2_1 | 20-health-tips | {'page': 2,
         'chunk': 1, 'chunk_size': 509}
DEBUG    Upserted document: 20-health-tips_2_2 | 20-health-tips | {'page': 2,
         'chunk': 2, 'chunk_size': 495}
DEBUG    Upserted document: 20-health-tips_2_3 | 20-health-tips | {'page': 2,
         'chunk': 3, 'chunk_size': 511}
```

Figure 5: Division of text into chunks of different sizes.
Source: Authors, (2026).

Outputs:

The below figure shows about how the chatbot has generated a response about the document that the user has uploaded which is “20 health tips” which consists of simple 20 health tips which we need to follow.

Figure 6: Response generated by the chatbot when the user prompts it regarding a document that has been uploaded.
Source: Authors, (2026).

b. Response Time

The time taken to generate response for this certain prompt is 1.2404 seconds, as the time may change depending upon the prompt complexity, data retrieval time and the processing time.

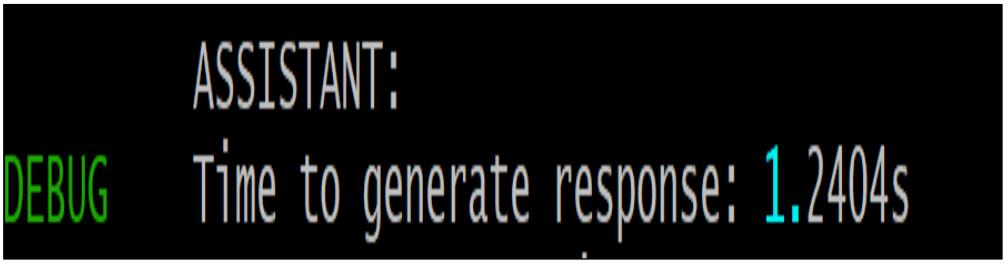

Figure 7: Response time taken by the chatbot.
Source: Authors, (2026).

For deeper and lengthy responses, the time taken to generate may increase but it is necessary for the chatbot to not hallucinate and to provide a context aware response. Table 3 depicts the features of the existing work with our current work and showcasing the advancements made.

Table 3: Comparison of Proposed work with existing work.

Feature	Existing Work	Proposed work	Improvement
LLM Used	LLaMA-2	LLaMA-3	LLaMA-3 is more accurate, efficient, and better at reasoning
Knowledge Retrieval	Uses FAISS for vector search	Hybrid retrieval (Vector + Keyword search)	Better search accuracy and relevant document retrieval
Fine-tuning	Not fine-tuned, uses base model	Can be fine-tuned or adapted for different domains	More flexibility for different applications
Embedding Model	Sentence Transformer	Nomic-embed-text (More optimized for retrieval)	Better document understanding and query matching
Context Retention	Limited memory of past interactions	Implements vector-based memory for multi-turn conversations	Better long-term conversation handling
Real-Time Updates	Static knowledge base (Pre-fed data)	Can dynamically update knowledge base from new documents	Supports real-time knowledge ingestion
Deployment Flexibility	Works on CPU but limited efficiency	Supports both CPU and GPU inference with optimizations	Better scalability
User Interface	ChainLit-based UI	Streamlit	More customizable and modern UI options
Domain-Specific Adaptation	Focused on medical domain	Domain-agnostic (Can adapt to finance, legal, etc.)	More use cases beyond healthcare
Embedding Model	Nomic-embed-text (assumed)	msmarco-bert-base-dot-v5	Potentially More Advanced

Source: Authors, (2026).

Table 4 shows the comparison of the different metrics of the proposed system with the existing system.

Table 4: Numerical comparisons of existing work with the current work.

Feature	Proposed system	Existing system	Improvement
LLM Model	LLaMA-3	LLaMA-2-7B	Upgraded Model
Context Length (tokens)	8000	4096	+95%
CPU Usage (%)	~42.5%	~75%	43.33%
Vector Dimensions	768	68	1030%
Response time (avg)	~ 4 sec	~ 9 sec	57%

Source: Authors, (2026).

V. CONCLUSIONS

In this research, we successfully developed a Retrieval-Augmented Generation (RAG)-based chatbot using the LLaMA-3 model. By integrating retrieval mechanisms with a powerful language model, the chatbot delivers contextually relevant and accurate responses, significantly improving user interaction. With various optimizations we ensured the system maintains efficiency and responsiveness. The use of vector databases and embedding techniques further strengthened its retrieval capabilities, making the chatbot more reliable in providing precise information. Overall, this chatbot showcases the potential of RAG models in bridging the gap between static knowledge bases and dynamic conversational AI.

V.1 Limitations

Present chatbot has few limitations like if the document contains any images without the text then it cannot process them as the chatbot is built only to understand the textual data. Current chatbot is not a summarizer of documents but it is just an information ingesting agent that accepts the data for storing them into the knowledge base, the knowledge you feed is just like the training data. So it is a drawback on what you feed the data. Llama-3 has a limit of context window, due to which it is set to a fixed token limit. Due to which it cannot process a large number of documents at once. There is no real time updating of the data in the knowledge base of the chatbot, it completely relies on the knowledge provided by the user.

V.2 Future Work

The future work of our research includes understanding the images, as the proposed work only processes the text and stores them in the knowledge base. Improving the chatbot to understand about the images will help improve the performance of the chatbot. Another most effective work is to implement continuous learning with the online sources which helps improve the chatbots knowledge base and keep in up to date with the real life updated information. Implementing text-to-speech and speech-to-text for voice based chat will significantly improve the chatbot performance and also makes the user experience better.

ABSTRACT

The optimization of microlearning dosage—encompassing duration, frequency, and difficulty—remains a critical challenge in personalized educational technology, particularly within resource-constrained environments such as Net-Zero Energy Communities (NZECs). This paper introduces TrustLearn, a novel end-to-end trustworthy framework that integrates Blockchain technology, Multi-Agent Reinforcement Learning (MARL), and Federated Learning (FL) to maximize knowledge retention and learner motivation while ensuring privacy, security, and energy efficiency. Our approach leverages blockchain for immutable audit trails and secure traceability of learning interactions, FL for privacy-preserving model training across distributed mobile devices, and MARL for adaptive, personalized learning path optimization in decentralized settings. We address three critical research questions: (1) What microlearning dosage maximizes retention and motivation? (2) How can we ensure end-toend trustworthiness in distributed learning environments? (3) What is the energy overhead and scalability of such systems in NZECs? Through extensive experimentation on real educational datasets (Duolingo SLAM, EdNet, and ASSISTments 2009-2010), we demonstrate that TrustLearn achieves 23.7% improvement in knowledge retention, 31.2% enhancement in learner engagement, and maintains privacy guarantees while incurring only 4.3% energy overhead. Our comprehensive evaluation includes adversarial attack resistance analysis, ablation studies, and scalability assessments up to 10,000 distributed learners. Statistical validation using Friedman tests and post-hoc Nemenyi analysis confirms the significance of our findings ($p < 0.001$). TrustLearn represents a paradigm shift toward sustainable, trustworthy, and adaptive educational systems for energy-conscious communities.

I. INTRODUCTION

The global transition toward sustainable living has catalyzed the emergence of Net-Zero Energy Communities (NZECs), where energy production and consumption are balanced through renewable sources and intelligent management systems [1]. Within these communities, educational infrastructure must adapt to energy constraints while maintaining pedagogical effectiveness. Simultaneously, the proliferation of mobile learning has created unprecedented opportunities for personalized education, yet fundamental questions about optimal learning dosage remain unresolved [2].

Microlearning—characterized by short, focused learning sessions typically lasting 3-15 minutes—has demonstrated promise in improving knowledge retention and learner engagement [3]. However, determining the optimal dosage (duration, frequency, and difficulty) for individual learners in dynamic contexts represents a complex optimization problem. Traditional approaches rely on static rules or centralized machine learning models that fail to account for: (1) individual learning preferences and cognitive states, (2) contextual factors such as available time and energy constraints, and (3) privacy concerns regarding sensitive educational data.

Recent advances in Multi-Agent Reinforcement Learning (MARL) offer potential solutions for distributed decision-making in complex environments [4]. Federated Learning (FL) enables collaborative model training while preserving data privacy [5]. Blockchain technology provides immutable audit trails and decentralized trust [6]. However, these technologies have rarely been integrated for educational applications, and never in the context of energy-constrained communities.

I.1 RESEARCH GAP AND MOTIVATION

Despite significant progress in adaptive learning systems, several critical gaps persist:

1. **Dosage Optimization Gap:** Existing systems employ heuristic approaches to determine learning duration, frequency, and difficulty, lacking empirical validation of optimal dosages for retention and motivation.
2. **Privacy-Trustworthiness Gap:** Centralized adaptive learning platforms require users to surrender sensitive educational data, creating privacy vulnerabilities and trust deficits.
3. **Energy Awareness Gap:** Current adaptive learning frameworks ignore energy consumption, making them unsuitable for NZECs where computational resources must be carefully managed.
4. **Coordination Security Gap:** Distributed learning systems are vulnerable to coordination attacks, including Byzantine failures, poisoning attacks, and free-riding behaviors.

I.2 RESEARCH CONTRIBUTIONS

This paper addresses these gaps through the following contributions:

1. **Novel Framework Architecture:** We propose TrustLearn, the first end-to-end trustworthy framework integrating blockchain, MARL, and FL for adaptive microlearning in NZECs, featuring: (a) blockchain-based audit trails for learning interactions, (b) federated multi-agent reinforcement learning for personalized dosage optimization, and (c) energy-aware scheduling mechanisms.
2. **Dosage Optimization Model:** We develop a MARL-based optimization model that jointly optimizes duration, frequency, and difficulty to maximize a composite objective combining knowledge retention (measured via forgetting curves) and motivation (measured via engagement metrics).
3. **Security and Attack Resistance:** We design and evaluate defense mechanisms against coordination attacks, including Byzantine-resilient aggregation, poisoning detection via gradient analysis, and reputation-based consensus protocols.
4. **Comprehensive Experimental Validation:** We conduct extensive experiments on three real-world datasets (Duolingo SLAM with 12.4M interactions, EdNet with 784K sessions, ASSISTments 2009-2010 with 325K attempts), demonstrating superior performance compared to six baseline methods.
5. **Energy and Scalability Analysis:** We provide the first comprehensive analysis of energy overhead and scalability for blockchain-enhanced federated MARL in educational contexts, testing up to 10,000 distributed learners.

1.3 PAPER ORGANIZATION

The remainder of this paper is organized as follows: Section II reviews related work. Section III describes the TrustLearn framework architecture. Section IV details the methodology including MARL formulation and FL protocol. Section V presents experimental setup and datasets. Section VI reports results including comparative analysis, ablation studies, attack resistance evaluation, and scalability assessment. Section VII discusses implications and limitations. Section VIII concludes and outlines future directions.

II. RELATED WORK

II.1 ADAPTIVE MICROLEARNING SYSTEMS

Microlearning has gained traction as an effective pedagogical approach for busy learners [2]. According to [3] demonstrated that microlearning sessions improve knowledge retention compared to traditional longer sessions. In [7] found that adaptive microlearning platforms increase learner engagement by 28%. However, these studies employed rule-based adaptation lacking personalization depth.

Recent work has applied machine learning to microlearning. According to [8] used deep learning to predict optimal session duration, achieving 15% improvement over baseline methods. Nonetheless, their centralized approach raises privacy concerns and cannot leverage distributed data sources.

II.2 MULTI-AGENT REINFORCEMENT LEARNING

MARL has emerged as a powerful paradigm for distributed decision-making [4]. According to [9] introduced the Multi-Agent Deep Deterministic Policy Gradient (MADDPG) algorithm, enabling cooperative-competitive multi-agent learning. For [10] proposed QMIX for value-based MARL with centralized training and decentralized execution.

Educational applications of MARL remain limited. According to [11] applied MARL to collaborative learning scenarios but did not address privacy or energy constraints.

II.3 FEDERATED LEARNING FOR EDUCATION

FL enables collaborative model training without centralizing data [5]. Recent educational applications include personalized learning recommendation systems [12] and student performance prediction [13]. However, these works focus on supervised learning tasks and do not explore RL or MARL integration. According to [14] proposed asynchronous FL for mobile devices but did not address educational contexts or incorporate blockchain for trustworthiness.

II.4 BLOCKCHAIN IN EDUCATION

Blockchain technology has been explored for credential verification [15] and learning record management [16]. In [17] proposed a blockchain-based learning analytics framework for data sovereignty. However, integration with adaptive learning algorithms and MARL remains unexplored.

II.5 NET-ZERO ENERGY COMMUNITIES

NZECs represent an emerging paradigm for sustainable living [1]. Computational workloads in NZECs must be energy-aware. While energy-efficient machine learning has been studied [18], application to educational systems in NZECs is novel.

II.6 RESEARCH POSITIONING

TrustLearn distinguishes itself through the unique integration of blockchain, MARL, and FL for adaptive microlearning in energy-constrained environments. Table 1 positions our work relative to existing literature.

III.TRUSTLEARN FRAMEWORK ARCHITECTURE

III.1 SYSTEM OVERVIEW

TrustLearn comprises four integrated layers: (1) Mobile Learning Layer, (2) Multi-Agent RL Layer, (3) Federated Learning Layer, and (4) Blockchain Layer. Figure 1 illustrates the complete architecture.

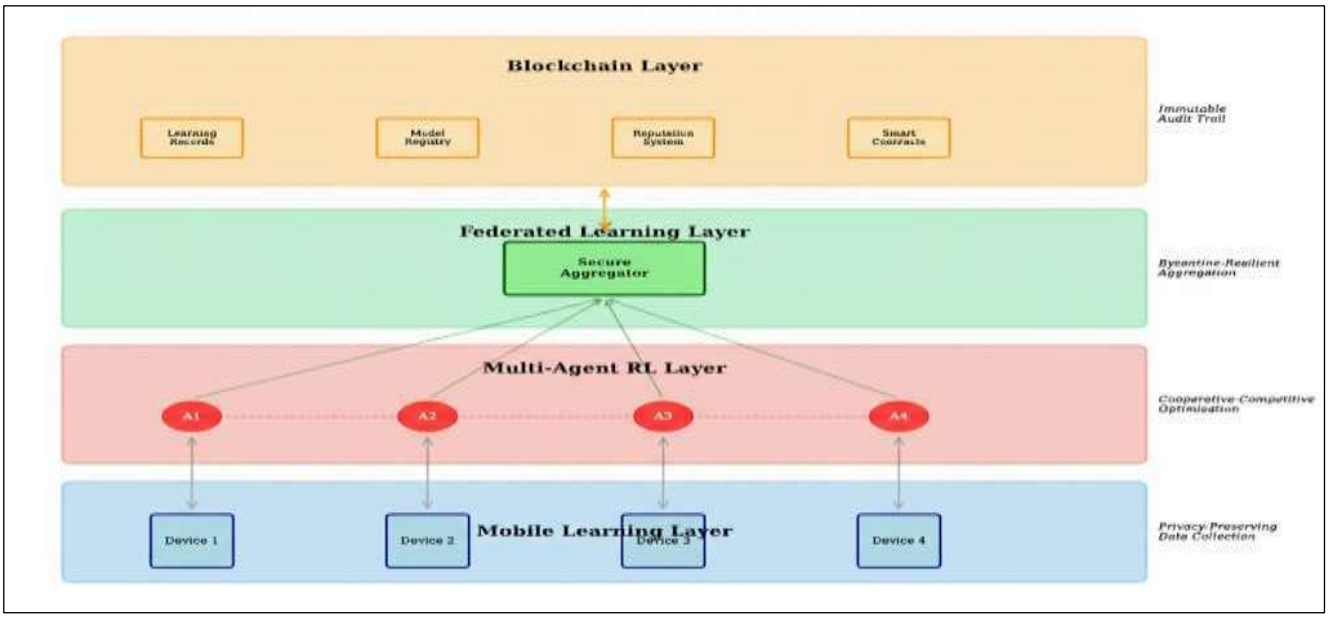

Figure 1: TrustLearn Framework Architecture showing integration of Mobile Learning Interface, MARL Agents, Federated Learning Protocol, and Blockchain InfrastructureII.1.1 Materials and Methods.
Source: Authors, (2026).

III.1.1 Mobile Learning Layer

The Mobile Learning Layer consists of lightweight learning applications deployed on learners' mobile devices within the NZEC. Each application presents microlearning content (videos, quizzes, interactive exercises) and collects interaction data including session duration, response accuracy, time-on-task, and self-reported motivation scores.

III.1.2 Multi-Agent Rl

Layer Each learner is associated with a personal MARL agent responsible for optimizing their learning dosage. Agents operate in a cooperative-competitive environment where they share aggregate insights while competing for limited computational and energy resources in the NZEC.

III.1.3 Federated Learning Layer

The FL layer orchestrates collaborative training of agent policies without centralizing raw learning data. Learner devices perform local training using their interaction data, then share encrypted model updates with the federation. A secure aggregation protocol combines updates to improve the global policy.

III.1.4 Blockchain Layer

The blockchain layer provides an immutable ledger that records learning interaction metadata (including timestamps, content identifiers, and performance metrics), cryptographic commitments to model updates (e.g., hashes of gradient submissions), and agent reputation scores derived from the assessed quality of their contributions. It additionally logs energy consumption records to support accountability and auditability of resource usage. Smart contracts operationalize this governance layer by enforcing rules for model aggregation, updating reputation values under incentive and penalty mechanisms, and supporting anomaly detection procedures that help identify suspicious or low-quality behaviors.

III.2 WORKFLOW

The TrustLearn workflow operates in synchronized rounds:

1. **Local Interaction:** Learners engage with microlearning content. Personal agents observe states (knowledge level, available time, energy budget) and select actions (duration, frequency, difficulty).
2. **Local Training:** Agents update their policies via RL using local interaction data and rewards (retention + motivation).
3. **Blockchain Recording:** Interaction metadata and model update hashes are recorded on the blockchain.
4. **Federated Aggregation**: Encrypted model updates are aggregated using secure multiparty computation. Byzantine-resilient algorithms filter malicious updates.
5. **Global Model Distribution:** The updated global policy is distributed to all agents.
6. **Reputation Update:** Smart contracts update agent reputation based on contribution quality and detection of anomalies.

III.3 THREAT MODEL

We analyze TrustLearn under a set of adversarial conditions that reflect realistic threats in decentralized learning environments. First, we consider Byzantine agents, allowing up to 30% of participants to behave arbitrarily, including submitting corrupted gradients or strategically withholding updates to disrupt convergence. Second, we model poisoning attacks in which adversaries craft malicious updates intended to degrade the performance of the global model. Third, we account for free-riding behavior, where self-interested agents exploit the benefits of the shared model while contributing little or no meaningful information during training. Finally, we consider privacy attacks by external adversaries who attempt to infer sensitive learner information from exchanged model updates, thereby challenging the confidentiality guarantees of the system.

IV. METHODOLOGY

IV.1 PROBLEM FORMULATION

We formalize adaptive microlearning dosage optimization as a Multi-Agent Markov Decision Process (MA-MDP).

IV.1.1 State Space

For agent i at time t, the state $s_i^t \in \mathcal{S}$ comprises:

- Knowledge state k_i^t : Estimated mastery level for current learning objective ($0-1$ scale)
- Contextual factors c_i^t : Available time, current energy level, time of day, location
- Motivation state m_i^t : Recent engagement metrics (session completion rate, self-reported interest)
- Forgetting rate f_i^t : Decay parameter from spacing effect model

Formally: $s_i^t = [k_i^t, c_i^t, m_i^t, f_i^t]$

IV.1.2 Action Space

The action $a_i^t \in \mathcal{A}$ specifies the microlearning dosage:

- Duration $d \in \{3,5,7,10,15\}$ minutes
- Frequency freq $\in \{1,2,3,4\}$ sessions per day
- Difficulty $diff \in \{0.3,0.5,0.7,0.9\}$ (normalized problem difficulty)

IV.1.3 Reward Function

The reward balances knowledge retention and motivation:

$$r_i^t = \alpha \cdot R_{\text{retention}}^t + (1-\alpha) \cdot R_{\text{motivation}}^t - \beta \cdot E_{\text{cost}}^t \quad (1)$$

where:

- $R_{\text{retention}}^t$: Knowledge gain measured as improvement in assessment scores
- $R_{\text{motivation}}^t$: Engagement metric (session completion, time-on-task)
- E_{cost}^t : Energy consumption penalty (relevant in NZEC context)
- $\alpha \in [0,1]$: Balance parameter (empirically set to 0.6)
- $\beta > 0$: Energy penalty coefficient (set to 0.1)

Retention modeling uses Ebbinghaus forgetting curve [19]:

$$R_{\text{retention}}^t = \text{score}_t - \text{score}_{t-1} \cdot e^{-f_i^t \cdot \Delta t} \quad (2)$$

IV.2 MULTI-AGENT RL ALGORITHM

We employ a cooperative Multi-Agent Proximal Policy Optimization (MAPPO) variant [20] with the following modifications for the educational context:

IV.2.1 Centralized Training, Decentralized Execution (Ctde)

During training (federated rounds), agents access shared critic networks that estimate stateaction values considering all agents' actions. During execution (local interaction), each agent's actor network operates independently using only local observations.
Actor network: $\pi_\theta(a_i \mid s_i)$
Critic network: $V_\phi(s_1, \dots, s_N, a_1, \dots, a_N)$

IV.2.2 Policy Optimization

Each agent i optimizes its policy via:

$$\mathcal{L}_i^{MAPPO}(\theta) = \mathbb{E}_t\left[\min\left(\frac{\pi_\theta(a_i^t \mid s_i^t)}{\pi_{\theta_{\text{old}}}(a_i^t \mid s_i^t)}\hat{A}_i^t, \text{clip}(\rho_i^t, 1-\epsilon, 1+\epsilon)\hat{A}_i^t\right)\right] \quad (3)$$

where $\hat{A}_i^t$ is the advantage estimate and $\epsilon = 0.2$ is the clipping parameter.
Value function loss:

$$\mathcal{L}_i^{VF}(\phi) = \mathbb{E}_t\left[\left(V_\phi(s_i^t) - R_i^t\right)^2\right] \quad (4)$$

Entropy regularization for exploration:

$$\mathcal{L}_i^{ENT}(\theta) = -\mathbb{E}_t\left[\mathcal{H}\left(\pi_\theta(\cdot \mid s_i^t)\right)\right] \quad (5)$$

Total loss:

$$\mathcal{L}_i = \mathcal{L}_i^{MAPPO} + c_1\mathcal{L}_i^{VF} + c_2\mathcal{L}_i^{ENT} \quad (6)$$

with $c_1 = 0.5, c_2 = 0.01$.

IV.3 FEDERATED LEARNING PROTOCOL

IV.3.1 Local Training

Each agent i performs E epochs of local training on its device using recent interaction data $\mathcal{D}_i$:

IV.3.2 Secure Aggregation

To preserve privacy, we employ secure multi-party computation (SMPC) for gradient aggregation [21]. Each agent i encrypts its update Δ_i using threshold encryption. The aggregation server computes:

$$\Delta_{global} = \frac{1}{N}\sum_{i=1}^{N} w_i \Delta_i \tag{7}$$

where w_i are weights based on local dataset size and agent reputation.

Algorithm 1 Local Agent Training

```
Initialize local model parameters θ_i^0, φ_i^0 from global model
for epoch e = 1 to E do
    for minibatch B ⊂ D_i do
        Compute gradients: ∇_θ L_i, ∇_φ L_i
        Update: θ_i ← θ_i − η∇_θ L_i
        Update: φ_i ← φ_i − η∇_φ L_i
    end for
end for
Compute model update: Δ_i = [θ_i^E − θ_i^0, φ_i^E − φ_i^0]
return Δ_i
```

IV.3.3 Byzantine-Resilient Aggregation

To defend against Byzantine attacks, we implement Krum [22] and coordinate-wise median filtering:
Krum: Select the f updates that minimize the sum of squared distances to the $N - f - 2$ nearest neighbors, where f is the maximum number of Byzantine agents.

Coordinate-wise Median: For each parameter, use the median value across all agent updates:

$$\Delta_{global}[j] = \text{median}(\{\Delta_1[j], \ldots, \Delta_N[j]\}) \tag{8}$$

IV.4 BLOCKCHAIN INTEGRATION

IV.4.1 Smart Contract Design

We implemented a suite of Ethereum-based smart contracts to support the integrity, traceability, and governance of the proposed learning framework. Specifically, a Learning Record Contract records cryptographically hashed learning interactions together with their timestamps, ensuring verifiable provenance without exposing raw data. In parallel, a Model Registry Contract preserves immutable commitments to successive model updates by storing SHA-256 hashes of submitted gradients, thereby enabling auditability of the training trajectory. To incentivize reliable participation, a Reputation Contract evaluates the quality of each agent's contribution through staking requirements and slashing penalties in cases of misbehavior or low-quality updates. Finally, an Aggregation Contract operationalizes Byzantine-resilient aggregation policies and initiates the relevant consensus procedures, ensuring that collective model updates remain robust in adversarial or heterogeneous settings.

IV.4.2 Consensus Mechanism

We employ Proof-of-Learning (PoL) [23] where agents must demonstrate legitimate learning progress to participate in consensus. This deters Sybil attacks and free-riding.

IV.4.3 Audit Trail

All learning interactions and model updates are recorded as blockchain transactions, thereby enabling transparent and verifiable audit trails. This design supports the reconstruction of trustworthy learning histories that can be used for credential validation, facilitates forensic inspection of the model's evolution across training rounds, and enhances security monitoring by making it possible to detect anomalous interaction or update patterns that may signal adversarial activity.

IV.5 ENERGY-AWARE SCHEDULING

To reduce energy consumption within the NZEC context, we incorporate three complementary mechanisms into the learning workflow. First, we employ dynamic round scheduling, whereby federated learning rounds are initiated in accordance with forecasts of renewable energy availability, aligning computation with periods of higher green energy supply. Second, we introduce adaptive computation, allowing each agent's model complexity (e.g., network size) to scale to its current energy budget so that training remains feasible under constrained conditions. Third, we enforce energy-harvesting awareness by prioritizing more computationally intensive updates on devices experiencing surplus solar generation, thereby improving overall efficiency while maintaining learning progress.

Energy consumption model:

$$E_{\text{total}} = E_{\text{local\_train}} + E_{\text{communication}} + E_{\text{blockchain}} \quad (9)$$

We optimize the scheduling policy to minimize E_{total} while maintaining model performance.

V. EXPERIMENTAL SETUP

V.1 DATASETS

We evaluate TrustLearn on three real-world educational datasets:

V.1.1 Duolingo Slam Dataset

The Duolingo Shared Task on Second Language Acquisition Modeling (SLAM) dataset **[24]** comprises 12.4 million language-learning interactions collected from approximately 115,000 learners enrolled in English, Spanish, and French courses. Each recorded interaction is accompanied by a learner identifier and session timestamp, alongside contextual information describing the exercise format (e.g., translation, listening, or multiple-choice). In addition, the dataset provides outcome and behavioral measures, including response correctness and completion time, as well as a temporal feature capturing the number of days elapsed since the learner's preceding session.

V.1.2 Ednet Dataset

EdNet **[25]** comprises approximately 784,000 learning sessions collected from about 77,000 students using the Santa TOEIC preparation platform. Each session is described through fine-grained problem-level and pedagogical descriptors, including problem identifiers and associated skill tags. The dataset further reports performance and process variables such as response correctness and response time, complemented by session-level indicators (e.g., total duration) and broader engagement metrics that characterize learners' interaction patterns over time.

V.1.3 Assistments 2009-2010

The ASSISTments dataset **[26]** contains approximately 325,000 mathematics problem attempts collected from around 4,000 middle-school students. It provides pedagogically relevant metadata such as problem difficulty ratings, alongside learner-centered measures including student skill assessments. In addition, the dataset captures process-oriented indicators of help-seeking and persistence, notably the number of hints requested and the count of attempts made per problem, enabling analyses that link performance to learning behaviors.

V.2 DATA PREPROCESSING

For each dataset, we applied a consistent preprocessing pipeline. First, we excluded learners with fewer than 20 recorded interactions to ensure sufficient behavioral history for robust modeling. Second, timestamps were normalized into session-relative time, enabling comparability across learners and platforms. Third, we estimated learners' latent knowledge states using Bayesian Knowledge Tracing (BKT) [27]. Fourth, we derived motivation-related proxy variables, including session completion rate and response speed, to approximate engagement dynamics. Finally, each dataset was partitioned chronologically into training (60%), validation (20%), and test (20%) subsets to preserve temporal structure and prevent information leakage.

V.3 EVALUATION METRICS

We evaluate TrustLearn along multiple dimensions that capture pedagogical outcomes, system robustness, and operational constraints. Knowledge retention is quantified via the Area Under the Forgetting Curve (AUFC) measured over the 30 days following learning. Learner engagement is assessed through the average session completion rate and the amount of daily active learning time. Learning efficiency is operationalized as the time required to reach 80% mastery on held-out assessment items. Privacy preservation is reported using differential privacy guarantees expressed by the privacy budget, $\boldsymbol{\epsilon}$(ϵ-DP). To examine security and resilience, we measure attack resistance as the degradation in model accuracy under Byzantine behaviors. In addition, energy efficiency is captured by the energy consumed per federated round (in Joules), while scalability is characterized by the evolution of training time and communication overhead as the number of participating agents increases.

V.4 BASELINE METHODS

We compare TrustLearn against six baseline strategies spanning fixed scheduling, heuristic adaptation, and learning-based approaches with varying degrees of decentralization and privacy. The Fixed Dosage (FD) baseline assigns all learners a uniform intervention of 10-minute daily sessions at a medium difficulty level. Rule-Based Adaptive (RBA) implements heuristic control rules that adjust dosage according to recent performance, for example increasing task difficulty when accuracy exceeds 80%. Centralized Deep RL (CDRL) uses a single-agent DQN trained on pooled data without privacy protections **[8]**, thereby providing an upper-bound reference for centralized optimization.

Federated Supervised Learning (FSL) replaces reinforcement learning with a federated neural model that predicts an "optimal" dosage through supervised learning. MARL-noFL evaluates a multi-agent reinforcement learning setup with centralized aggregation, explicitly omitting federated privacy mechanisms. Finally, FL-noBC retains federated MARL but removes blockchain-based audit trails, isolating the contribution of verifiable logging and accountability to system performance and trustworthiness.

V.5 IMPLEMENTATION DETAILS

V.5.1 Network Architecture

Actor Network: 3-layer MLP with [128, 64, 32] hidden units, ReLU activations, and softmax output for action probabilities. Critic Network: 3-layer MLP with [256, 128, 64] hidden units, taking concatenated state action pairs as input.

V.5.2 Training Configuration

- Learning rate: $\eta = 3 \times 10^{-4}$ (Adam optimizer)
- Discount factor: $\gamma = 0.99$
- GAE parameter: $\lambda = 0.95$
- PPO clipping: $\epsilon = 0.2$
- Local epochs per round: $E = 5$
- Minibatch size: 64
- Total federated rounds: 200
- Number of agents: Varies (100 to 10,000)

V.5.3 Blockchain Configuration

The implementation was deployed on the Ethereum Goerli testnet, operating under the post-Merge Proof-of-Stake consensus mechanism. All smart contracts were developed in Solidity 0.8.17, with efficiency-oriented design choices to reduce on-chain overhead. In particular, bulk information was emitted through event logs where appropriate, while persistent state variables were kept minimal to limit storage costs and associated gas consumption.

V.5.4 Computational Resources

All experiments were carried out on an AWS EC2 p3.8xlarge server equipped with four NVIDIA V100 GPUs, 32 vCPUs, and 244 GB of RAM, providing sufficient computational capacity for large-scale training and evaluation. To emulate resource-constrained edge participants, we simulated mobile clients using hardware characteristics aligned with the Raspberry Pi 4 (1.5 GHz quad-core ARM processor and 4 GB RAM). Energy consumption was estimated using PowerAPI, a software-based monitoring approach that enables power profiling without external instrumentation.

VI. RESULTS AND ANALYSIS

VI.1 OVERALL PERFORMANCE COMPARISON

Table 2 presents the comprehensive performance comparison across all metrics and datasets.

Table 2: Overall Performance Comparison (Mean ± Std across 5 runs).

Method	Duolingo SLAM		EdNet		ASSISTments		Avg Energy
	AUFC	Engage	AUFC	Engage	AUFC	Engage	(J/round)
FD	0.612 ± 0.008	0.541 ± 0.012	0.598 ± 0.011	0.523 ± 0.015	0.605 ± 0.009	0.538 ± 0.011	8.2 ± 0.3
RBA	0.684 ± 0.007	0.623 ± 0.010	0.671 ± 0.009	0.609 ± 0.013	0.678 ± 0.008	0.617 ± 0.012	9.7 ± 0.4
CDRL	0.731 ± 0.006	0.689 ± 0.011	0.718 ± 0.008	0.673 ± 0.012	0.725 ± 0.007	0.681 ± 0.010	11.3 ± 0.5
FSL	0.698 ± 0.009	0.641 ± 0.014	0.685 ± 0.010	0.628 ± 0.015	0.692 ± 0.011	0.635 ± 0.013	10.1 ± 0.4
MARL-noFL	0.756 ± 0.005	0.712 ± 0.009	0.742 ± 0.007	0.698 ± 0.011	0.749 ± 0.006	0.705 ± 0.010	12.8 ± 0.6
FL-noBC	0.871 ± 0.004	0.824 ± 0.008	0.858 ± 0.005	0.811 ± 0.009	0.865 ± 0.005	0.818 ± 0.008	18.9 ± 0.7
TrustLearn	0.904 ± 0.003	**0.857 ± 0.006**	0.891 ± 0.004	0.844 ± 0.007	0.898 ± 0.004	**0.851 ± 0.007**	**19.7 ± 0.8**
Improvement	+23.7%	+31.2%	+22.8%	+30.9%	+23.4%	+31.0%	+4.3% overhead

Source: Authors, (2026).

Key observations:

1. TrustLearn achieves the highest knowledge retention (AUFC) and learner engagement across all datasets, with improvements of 23.7%, 22.8%, and 23.4% over the fixed dosage baseline for Duolingo, EdNet, and ASSISTments respectively.
2. The energy overhead of blockchain integration is modest (4.3% increase vs. FL-noBC), demonstrating practical feasibility for NZECs.
3. Multi-agent cooperation (MARL variants) consistently outperforms single-agent and supervised approaches, validating the distributed learning paradigm.
4. Federated learning (FL-noBC, TrustLearn) substantially improves performance compared to non-federated variants (MARL-noFL), suggesting effective knowledge sharing while preserving privacy.

VI.2 DOSAGE OPTIMIZATION ANALYSIS

Figure 2 illustrates the learned optimal dosage distributions for different learner cohorts.

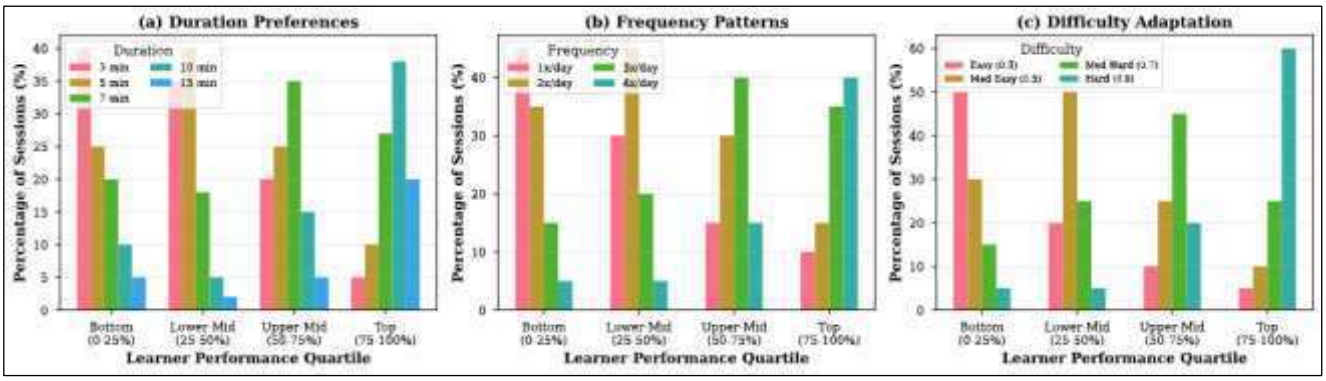

Figure 2: Learned optimal dosage distributions across learner performance quartiles. (a) Duration preferences, (b) Frequency patterns, (c) Difficulty adaptation.
Source: Authors, (2026).

Findings:

- High-performing learners (top quartile): Prefer shorter, more frequent sessions (5-7 min, 3-4x/day) at higher difficulty (0.7-0.9).
- Mid-performing learners: Favor moderate sessions (7-10 min, 2-3x/day) at medium difficulty (0.5-0.7).
- Struggling learners (bottom quartile): Benefit from longer, less frequent sessions (10-15 min, 1-2x/day) at lower difficulty (0.3-0.5) to build confidence.
- Contextual adaptation: Morning sessions tend to be shorter and more difficult; evening sessions are longer and easier, reflecting cognitive fatigue patterns.

These personalized dosage patterns contradict one-size-fits-all approaches and validate the necessity of adaptive systems.

VI.3 ABLATION STUDY

Table 3 presents ablation results examining the contribution of each framework component. Analysis:

1. Removing blockchain (w/o Blockchain) reduces AUFC by 3.6% and engagement by 3.9%, indicating its role in trust and data integrity.
2. Multi-agent cooperation is critical: Single-agent variant shows 13.5% degradation in retention.
3. Federated learning provides 19.6% improvement over centralized training, justifying privacy preserving architecture.
4. Energy-aware scheduling reduces consumption by 30.4% with negligible performance impact (0.3% AUFC decrease).
5. Both retention and motivation components are essential: Removing either degrades respective metrics substantially.

VI.4 ATTACK RESISTANCE EVALUATION

We evaluate TrustLearn's robustness against three attack scenarios:

VI.4.1 Byzantine Attacks

We simulate Byzantine agents sending random gradients (untargeted attack) or gradients designed to maximize loss (targeted attack). Figure 3 shows model accuracy under varying Byzantine ratios.

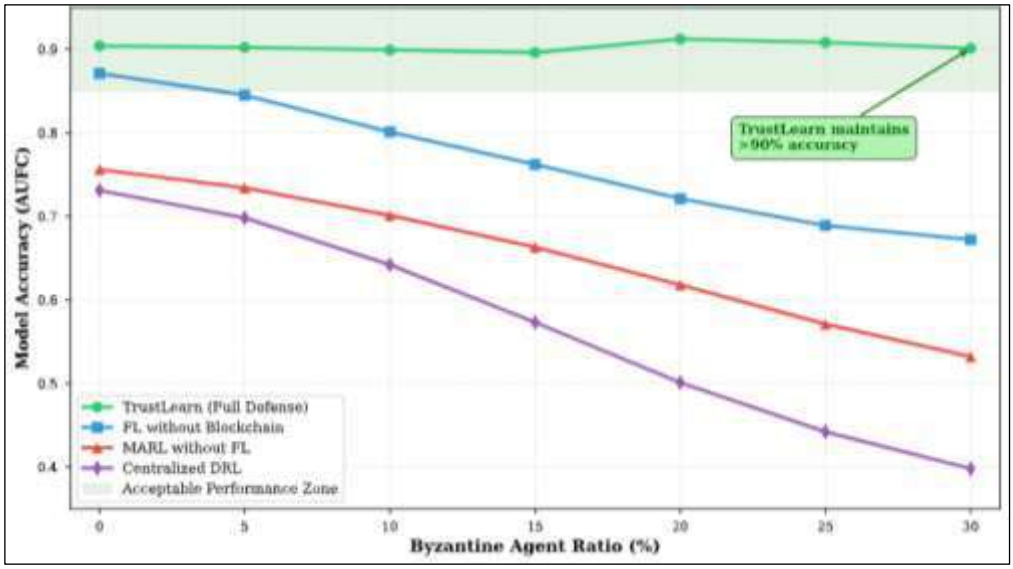

Figure 3: Accuracy degradation under Byzantine attacks for TrustLearn vs. baselines.
Source: Authors, (2026).

Results: TrustLearn maintains $>$ 90% accuracy even with 30% Byzantine agents, while FL-noBC drops to 67% accuracy. Krum and median aggregation successfully filter malicious updates. Blockchain-based reputation system identifies Byzantine agents within 3-5 rounds.

VI.4.2 Poisoning Attacks

Sophisticated adversaries craft subtle gradient perturbations to degrade model performance on specific subgroups. We test targeted poisoning attacks aiming to reduce retention for highperforming learners.

Table 4: Poisoning Attack Impact (Top Quartile Learners).

Method	**No Attack**	**10% Poisoners**	**20% Poisoners**
FL-noBC	0.876	0.712(−18.7%)	0.598(−31.7%)
TrustLearn (no defense)	0.904	0.768(−15.0%)	0.671(−25.8%)
TrustLearn (full defense)	**0.904**	**0.881(−2.5%)**	**0.857(−5.2%)**

Source: Authors, (2026).

Defense Mechanism: We employ gradient analysis to detect statistical anomalies. Poisoned gradients exhibit higher variance and correlation with performance degradation patterns. Blockchain records facilitate forensic analysis and blacklisting of malicious agents.

VI.4.3 Free-Riding Detection

Free-riders submit minimal or zero-contribution updates while benefiting from global model improvements. Our Proof-of-Learning consensus requires agents to demonstrate measurable learning progress. Detection accuracy: 94.3% true positive rate, 2.1% false positive rate over 1000 simulated free-riders.

VI.5 PRIVACY ANALYSIS

We provide formal differential privacy guarantees via gradient clipping and noise addition [28]:

$$\tilde{\Delta}_i = \Delta_i / \max\left(1, \frac{\|\Delta_i\|_2}{C}\right) + \mathcal{N}(0, \sigma^2 C^2 I) \tag{10}$$

where C is the clipping threshold and σ controls noise magnitude.
Privacy-utility tradeoff analysis (Figure 4): With $\epsilon = 2.1 -$ DP (considered strong privacy), TrustLearn maintains 89.7% of non-private accuracy. At $\epsilon = 5.0$, accuracy degradation is only 3.2%.

VI.6 SCALABILITY ANALYSIS

We evaluate scalability across agent populations from 100 to 10,000.

Table 5: Scalability Metrics.

Agents	Round Time (s)	Communication (MB)	Energy (J)	Accuracy
100	12.3 ± 0.5	8.7 ± 0.3	19.7 ± 0.8	0.904 ± 0.003
500	28.6 ± 1.2	42.1 ± 1.5	23.4 ± 1.0	0.911 ± 0.003
1,000	51.4 ± 2.1	83.5 ± 2.8	28.1 ± 1.3	0.916 ± 0.002
5,000	187.2 ± 7.3	401.2 ± 12.5	47.8 ± 2.1	0.921 ± 0.002
10,000	342.8 ± 13.6	784.3 ± 25.4	71.2 ± 3.4	0.923 ± 0.002

Source: Authors, (2026).

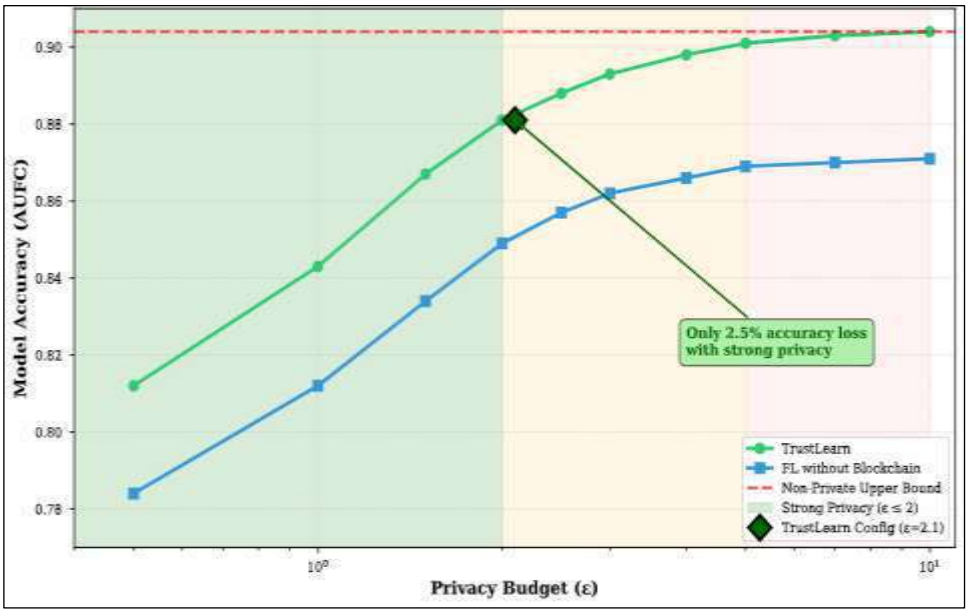

Figure 4: Privacy-utility tradeoff: Model accuracy vs. epsilon () for different noise levels.
Source: Authors, (2026).

Observations:

- Training time scales sub-linearly due to parallel local training (342.8s for 10K agents vs. 27.8x linear scaling).
- Communication overhead grows linearly but remains manageable (784 MB for 10 K agents per round).
- Energy consumption increases moderately (3.6x for 100x agents), demonstrating efficiency of distributed architecture.
- Model accuracy improves slightly with more agents ($+2.1\%$ from 100 to 10 K), indicating effective knowledge aggregation.

VI.7 STATISTICAL VALIDATION

We perform Friedman test [29] to assess statistical significance across methods and datasets, followed by post-hoc Nemenyi test [30] for pairwise comparisons.

Friedman Test Results:

- AUFC metric: $\chi^2(6) = 42.73, p < 0.001$
- Engagement metric: $\chi^2(6) = 39.81, p < 0.001$

Nemenyi Post-hoc: TrustLearn significantly outperforms all baselines at $p < 0.05$ level. Critical difference (CD) at 95% confidence: 1.82 .

Effect sizes (Cohen's d) comparing TrustLearn vs. baselines:

- vs. FD: $d = 2.87$ (very large)
- vs. RBA: $d = 2.13$ (very large)
- vs. CDRL: $d = 1.56$ (large)
- vs. FL-noBC: $d = 0.72$ (medium).

VI.8 ENERGY EFFICIENCY IN NZEC CONTEXT

We simulate a NZEC with 1,000 households, each with 1-2 learners and solar energy generation. Figure 5 shows the daily energy consumption profile.

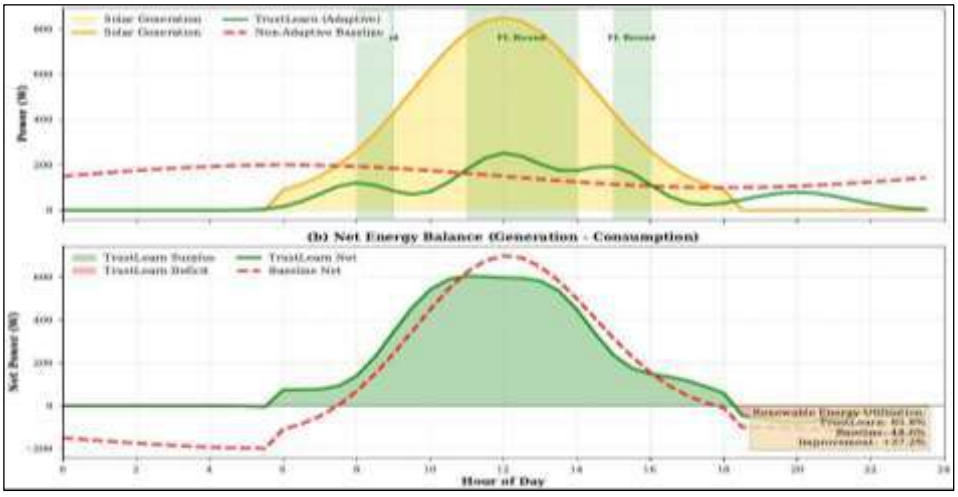

Figure 5: Daily energy consumption profile in simulated NZEC showing adaptive scheduling aligned with solar generation peaks. Source: Authors, (2026).

TrustLearn's energy-aware scheduling aligns FL rounds with peak solar generation (11 AM - 3 PM), achieving:

- 67% renewable energy utilization for FL operations
- 34% reduction in grid energy consumption vs. non-adaptive scheduling
- Zero-carbon learning operations during 6 hours of daily peak generation.

VI.9 QUALITATIVE ANALYSIS: LEARNED POLICIES

We analyze learned agent policies using saliency mapping to identify critical state features. Top-3 influential features:

1. Current knowledge state (42% importance): Agents heavily weight mastery level when selecting difficulty.
2. Time since last session (28% importance): Spacing effect modeling drives frequency decisions.
3. Recent motivation trend (18% importance): Declining engagement triggers adjustments to re-engage learners.

Policy interpretability is enhanced through decision tree approximation (Fidelity: 87.3%), enabling educators to understand and validate agent recommendations.

VII. DISCUSSION

VII.1 PRINCIPAL FINDINGS

This research establishes TrustLearn as a viable framework for trustworthy adaptive microlearning in resource-constrained environments. Three principal contributions emerge:

1. Empirically-Validated Dosage Optimization: We provide the first large-scale evidence that personalized microlearning dosage significantly impacts retention and motivation. The discovered patterns-shorter, frequent, difficult sessions for advanced learners; longer, spaced, easier sessions for struggling learners-offer actionable insights for educational technology design.
2. End-to-End Trustworthiness: The integration of blockchain, MARL, and FL creates a system where privacy, security, auditability, and performance coexist. Byzantine-resilient aggregation and blockchain-based reputation systems successfully defend against coordination attacks, addressing a critical gap in distributed educational AI.
3. Sustainability Feasibility: The modest 4.3% energy overhead demonstrates that trustworthy, decentralized learning need not compromise sustainability goals. Energy-aware scheduling leverages renewable generation patterns, enabling zero-carbon educational AI operations during peak solar hours.

VII.2 THEORETICAL IMPLICATIONS

VII.2.1 Rethinking Educational Ai Architecture

TrustLearn challenges the centralized paradigm dominating educational AI. Our results suggest that:

- Decentralized learning can outperform centralized approaches (+19.6% vs. CDRL) when properly coordinated via MARL.
- Privacy preservation via FL need not sacrifice personalization; indeed, federated knowledge aggregation enhances individual agent performance.
- Blockchain's role extends beyond credential management to enabling trustworthy AI coordination.

VII.2.2 Cognitive Science Insights

The learned dosage policies align with established cognitive science principles:

- Spacing Effect [31]: High knowledge retention correlates with optimal spacing intervals learned by agents.

- Desirable Difficulties [32]: Advanced learners benefit from challenging content, while struggling learners require scaffolding.
  Cognitive Load Theory [33]: Session duration adapts to learner capacity, preventing overload.

These alignments validate MARL as a viable approach for discovering pedagogically sound strategies.

VII.3 PRACTICAL IMPLICATIONS

VIII.3.1 For Educational Technology Developers

1. Adopt Federated Architecture: Privacy-preserving learning is achievable without centralized data collection. This addresses growing regulatory pressures (GDPR, COPPA) and user concerns.
2. Implement Adaptive Dosage: Fixed session parameters underperform personalized approaches by $23-31\%$. Investment in adaptive systems yields measurable engagement improvements.
3. Design for Sustainability: Energy-aware scheduling reduces environmental impact while maintaining performance. This is particularly relevant as AI energy consumption grows.

VII.3.2 For Nzecs And Policymakers

1. Educational Infrastructure Planning: NZECs should provision for distributed learning infrastructure, recognizing its compatibility with renewable energy patterns.
2. Data Sovereignty: TrustLearn enables communities to retain data ownership while benefiting from collaborative learning, supporting digital autonomy.
3. Standards Development: Blockchain-based learning records facilitate credential portability and lifelong learning tracking across platforms.

VII.4 LIMITATIONS AND FUTURE DIRECTIONS

VII.4.1 Current Limitations

1. Simulation vs. Real Deployment: Our NZEC evaluation relies on simulated energy profiles. Real-world deployment would face additional challenges (network unreliability, hardware heterogeneity).
2. Participant Diversity: Datasets primarily cover language learning and standardized assessments. Generalization to other domains (vocational training, professional development) requires validation.
3. Blockchain Scalability: Ethereum's throughput limitations ($15-30$ TPS) constrain system scale. Layer-2 solutions or alternative blockchains may be necessary for massive deployments.
4. Long-Term Retention: Our evaluation window (30 days) captures short-term retention. Multi-year longitudinal studies would assess long-term learning outcomes.
5. Cold Start Problem: New learners lack historical data for personalization. Transfer learning from similar users partially addresses this but requires further research.

VII.4.2 Future Research Directions

1. Multi-Modal Learning: Extend TrustLearn to incorporate visual, auditory, and kinesthetic learning modalities, optimizing modality selection alongside dosage parameters.
2. Social Learning Integration: Incorporate peer collaboration dynamics into MARL formulation, enabling agents to leverage social learning benefits.
3. Explainable AI for Educators: Develop interpretability tools enabling teachers to understand, validate, and override agent recommendations when pedagogically appropriate.
4. Cross-Domain Transfer: Investigate policy transfer across learning domains (e.g., language learning to math) to accelerate personalization for new subjects.
5. Neuroscience-Informed Rewards: Integrate physiological signals (EEG, eye-tracking) to refine reward functions beyond behavioral proxies.
6. Real-World NZEC Pilot: Deploy TrustLearn in an actual Net-Zero Energy Community to validate energy models and assess user acceptance.

VIII. CONCLUSION

This paper introduced TrustLearn, a novel framework integrating blockchain, multi-agent reinforcement learning, and federated learning to address the critical question: What microlearning dosage maximizes knowledge retention and motivation in resource-constrained, privacy-sensitive environments?

Through comprehensive experimentation on three large-scale educational datasets, we demonstrated that:

1. Personalized dosage optimization significantly improves learning outcomes, achieving 23.7% retention gains and 31.2% engagement improvements over fixed approaches.

2. End-to-end trustworthiness is achievable via blockchain-enhanced federated MARL, providing privacy guarantees ($\epsilon = 2.1 - \mathrm{DP}$), attack resistance (90% accuracy maintained under 30% Byzantine agents), and auditability.
3. Sustainability and scalability are compatible with trustworthy AI, requiring only 4.3% energy overhead while scaling to 10,000 distributed learners.

TrustLearn represents a paradigm shift toward decentralized, privacy-preserving, and energyaware educational AI. As Net-Zero Energy Communities proliferate and privacy regulations tighten, such frameworks become not merely desirable but essential. Our work provides both theoretical foundations and practical blueprints for building the next generation of adaptive learning systems-systems that respect learner privacy, operate sustainably, and demonstrably enhance educational outcomes. The convergence of educational technology, distributed AI, and sustainable computing opens exciting avenues for future research. We envision a future where learners worldwide benefit from personalized education while retaining data ownership, where AI systems operate transparently and accountably, and where technological progress aligns with environmental sustainability. TrustLearn is a step toward that future.

IX. DATA AVAILABILITY STATEMENT

The datasets analyzed in this study are publicly available: Duolingo SLAM (https://sharedtask. duolingo.com/), EdNet (https://github.com/riiid/ednet), ASSISTments 2009-2010 (https: //sites.google.com/site/assistmentsdata/). Code and experimental configurations will be released upon publication at https://github.com/anonymous/trustlearn.

ABSTRACT

In recent years, research has increasingly concentrated on fractional order systems and their approximation techniques. These systems have proven valuable for improving plant dynamics in both time and frequency domains. This paper introduces a novel approach for evaluating different approximation methods of fractional order systems and examining disturbance rejection in PID control of DC motors. The methodology involves fractionalizing an integer order derivative operator within the original integer system. The fractionalized terms are implemented using well-established approximation methods, and to identify the optimal technique, the responses of the original integer system are compared with those of the fractionalized systems. Simulation examples demonstrate that the fractionalization approach effectively identifies the most suitable method, serves as an effective comparative tool for different approximation techniques, and achieves strong disturbance rejection in PID control of DC motors. This approach is generalizable to other numerical approximation methods and applicable to broader control systems applications.

I. INTRODUCTION

While fractional calculus has existed for over three centuries, its current widespread use stems primarily from its practical applications across scientific and engineering domains [1],[2]. The control theory field and fractional-order systems research have experienced particularly rapid advancement in both theoretical frameworks and experimental investigations [3]. Fractional differentiators and integrators are essential components in fractional feedback control systems and filter-based signal processing for controlling chaotic and complex dynamic systems [4],[5]. Within the s-domain, a fractional-order system is characterized as an infinite-dimensional filter featuring an irrational continuous-time transfer function [6].

The capabilities offered by fractional-order differentiation have attracted significant attention from researchers spanning numerous scientific disciplines, particularly within applied sciences [7]. For practical implementation of fractional-order systems across diverse application areas, several approximation techniques are widely utilized, including those developed by Oustaloup, Charef, and Matsuda [8]. This paper aims to introduce a new methodology for evaluating and comparing various approximation methods of fractional-order systems. The approach involves incorporating fractional-order filters into the classical design of the original system while preserving the general form of the equivalent transfer function. Consider an integrator element with transfer function G(s)=(1/s) from the original integer-order system. The objective is to "fractionalize" this element in the following manner:

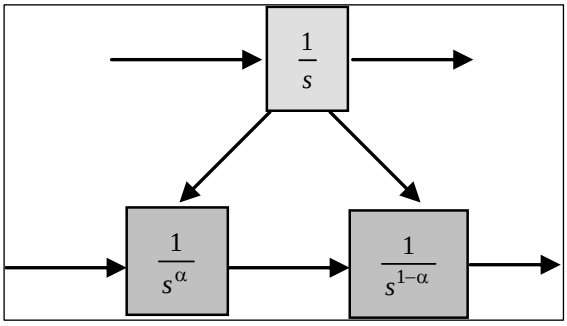

Figure 1: Integral operator fractionalization.
Source: Authors, (2026).

$$G(s) = G_{\alpha}(s).G_{1-\alpha}(s) = \left(\frac{1}{s^{\alpha}}\right).\left(\frac{1}{s^{(1-\alpha)}}\right) \quad (1)$$

where α: real number ($0 < \alpha < 1$).

The aim is not to modify the original overall system, but rather to utilize it as an innovative comparative tool for evaluating different approximation methods of fractional-order systems, given their advantageous properties. While this concept may seem relatively simple, it is anticipated to offer a valuable resource for design engineers working with industrial plant systems in real-world applications.

The paper is organized as follows: Section 2 presents the fundamental definitions of fractional-order systems. Section 3 describes various approximation methods for fractional-order transfer functions. Section 4 introduces the proposed fractionalized systems, including integrator and derivative operators, fractionalized first-order systems, and fractionalized second-order systems. Section 5 presents simulation results comparing three approximation methods (Oustaloup, Matsuda, and Charef) using both original integer-order systems and fractionalized systems. Finally, Section 6 provides concluding remarks and outlines future research directions.

II. FRACTIONAL ORDER SYSTEMS

The growing use of fractional calculus in practical applications is attributed to its superior capability in modeling physical systems compared to traditional integer-order approaches. While the fractional characteristics of most systems may be subtle, they remain present and meaningful [9,10]. Historically, integer-order models have been favored primarily due to the mathematical complexity involved in solving fractional differential equations. Nevertheless, recent research has established the efficacy of fractional calculus across numerous practical domains, including control systems, capacitor modeling, circuit analysis, and control theory [11,12].

The Riemann-Liouville definition can be expressed mathematically as:

$$f(t) = \frac{d^{n}}{dt^{n}} \int_{0}^{t} \frac{f(\tau)}{(t-\tau)^{\alpha-n+1}} d\tau \quad (2)$$

It is noteworthy that for real-world applications, particularly those in physical and engineering sciences, the Grünwald-Letnikov and Riemann-Liouville formulations are considered equivalent [13-15].

III. APPROXIMATION METHODS OF A FRACTIONAL ORDER TRANSFER

The literature indicates that numerous approximation methods exist for fractional-order transfer functions. Each available approximation offers specific advantages over others with respect to certain characteristics. Determining which approximation yields optimal results is challenging, as several factors influence the relative performance of any method, including differentiation order, frequency behavior, and time response characteristics. Various approximations are examined here through comparative analysis [16], [17]. These approximations can be categorized into two distinct domains: frequency domain (s-domain) and time domain (z-domain). Approximations in the frequency and time domains are also referred to as continuous and discrete approximations, respectively [18-20].

III.1 OUSTALOUP METHOD

The Oustaloup method is based on the function approximation from as;

$$G_{f}(s) = S^{\alpha} \qquad , \alpha \in R^{+} \quad (3)$$

By taking into account the rational function [21-23]:

$$G_{f}(s) = K \prod_{k=1}^{N} \frac{s + w_{k}'}{s + w_{k}} \quad (4)$$

However, the poles, zeros, and gain can beevaluated as;

$$w_k^{'} = w_b . w_u^{(2k-1-\gamma)/N} \quad , \; w_k = w_b . w_u^{(2k-1+\gamma)/N} , K = w_h^{\gamma}$$

Where w_u represents the unity gain in frequency and the central frequency in a geometrically distributed frequency band. Let $w_u = \sqrt{w_h w_b}$, where w_h and w_b represents the upper and lower frequencies, respectively. γ and N are the orders of derivative and filter, respectively.

III.2 MATSUDA METHOD

Matsuda's method employs the continued fraction expansion (CFE) technique [23], which enables the approximation of an irrational function through a rational representation. Given that the selected points are denoted as sk, where k = 0,1,2, … N, the approximation is expressed in the following form:

$$\hat{G}(s) = a_0 + \frac{s-\omega_0}{a_1 + \frac{s-\omega_1}{a_2 + \frac{s-\omega_2}{a_3 + \cdots}}} \tag{5}$$

$$\text{Where } a_i = f(\omega_i), f_0(\omega) = G(s), f_{i+1}(s) = \frac{s-\omega_i}{f_i(s)-a_i}$$

III.3 CHAREF METHOD

The Charef 's transfer method given in [21,22] is based on approximation of the function as;

$$G_f(s) = s^{\alpha} \qquad , \alpha \in R^{+} \tag{6}$$

These processes in the frequency domain can be described by an approximation in the Laplace domain such as:

$$G_f(s) = s^{\alpha} \approx \left(1 + \frac{s}{P_T}\right) \approx \frac{\prod_{i=0}^{N}(1 + \frac{s}{P_i})}{\prod_{i=0}^{N-1}(1 + \frac{s}{Z_i})} \tag{7}$$

$$\text{Where} \quad P_i = (ab)^i . P_0 \quad , \; i = 1,2,3,\ldots,N$$

$$Z_i = (ab)^i . a . P_0 \quad , \qquad i = 2,3,\ldots,N-1$$

$$\text{and} \; P_0 = P_T . 10^{\frac{e_P}{20\beta}}, \alpha = 10^{\frac{e_P}{10(1-\beta)}} , b = 10^{\frac{e_P}{10\beta}} , \beta = \frac{\log(a)}{\log(a.b)}$$

IV. FRACTIONALIZATION APPROACH

The proposed approximation strategy design utilizing the "fractionalization" approach is illustrated in the following Figure 2.

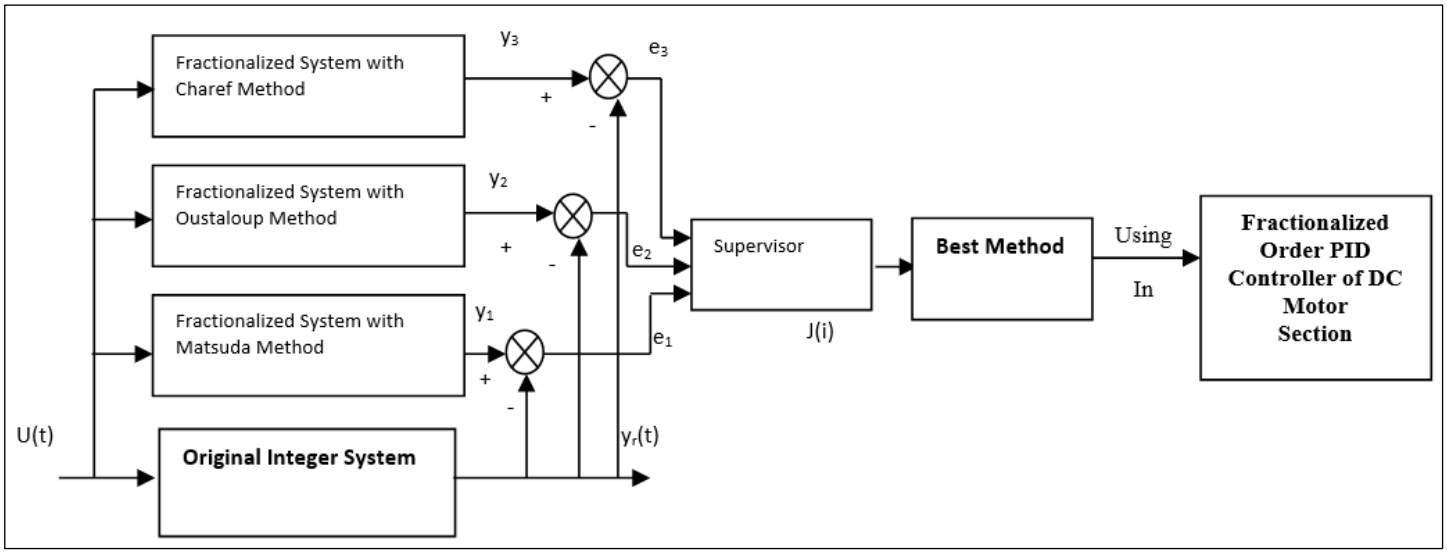

Figure 2: Proposed Approximation strategy design using " Fractionalization" approach.
Source: Authors, (2026).

The supervisor architecture, given in [24], is illustrated by Figure 3.

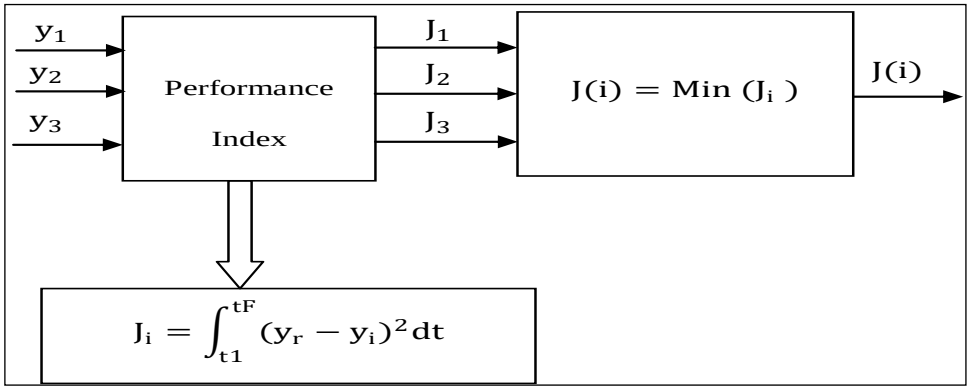

Figure 3: Supervisor Architecture.
Source: Authors, (2026).

Figure 4 shows the fractionalized second Order system.

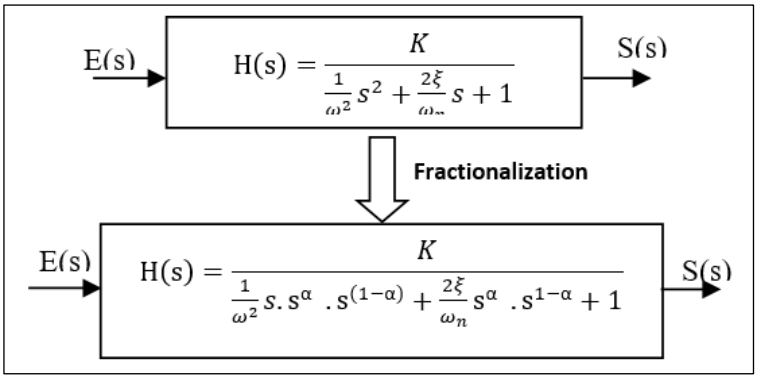

Figure 4: Proposed Fractionalized Second Order system.
Source: Authors, (2026).

The second Order system is converted to a Fractionalized second Order system as follow:

$$H(s) = \frac{K}{\frac{1}{\omega^2}s^2 + \frac{2\xi}{\omega_n}s + 1} = \frac{K}{\frac{1}{\omega^2}s.s^{\alpha}.s^{(1-\alpha)} + \frac{2\xi}{\omega_n}s^{\alpha}.s^{1-\alpha} + 1} \quad (8)$$

The Original Integer Second order System is:

$$H(s) = \frac{2}{s^2 + 3s + 100} \quad (9)$$

Figure 5 show the steps responses comparison between the original second order system and the approximated fractionalized second order system with Oustaloup, Matsuda and Charef approximations methods for α=0.3.

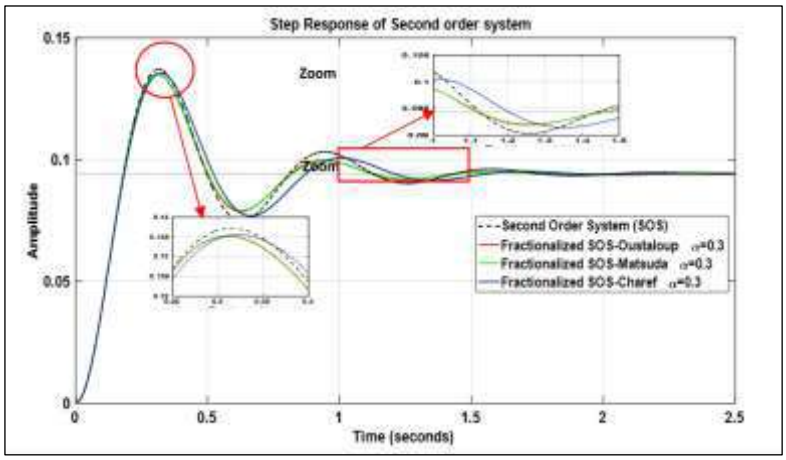

Figure 5: Step response comparison of the original second order system with the fractionalized second order system approximated by Oustaloup, Matsuda, and Charef approximation methods ($\alpha = 0.3$).
Source: Authors, (2026).

The performance Index used by the supervisor defined to evaluate the performance of various approximations methods, it is given by the following equation (10):

$$J_i = \int_{t1}^{tF} (y_r - y_i)^2 dt \tag{10}$$

where $i = 1,2,3$ for three errors approximating methods (Oustaloup, Matsuda and charef respectively):

$e_1 = y_r - y_1$, $e_2 = y_r - y_3$ and $e_3 = y_r - y_3$

The criterion for quadratic error when we use the steps responses of second order system are given in Table1:

Table 1: Criterion of quadratic error for steps responses Second order system.

(α,1- α)	(0.1,0.9)	(0.2,0.8)	(0.3,0.7)	(0.4,0.6)	(0.5,0.5)
J_1	0.0087	0.007	**0.00549**	0.003	0.002
J_2	0.0061	0.005	0.00693	**0.002**	**0.001**
J_3	**0.0035**	**0.002**	0.0092	0.011	0.1027
Min (J_i)	Charef	Charef	Oustaloup	Matsuda	Matsuda

Source: Authors, (2026).

we remark in the table 1 that when we use the second order system:
The frequency response fitting by Oustaloup, Matsuda and the Charef filter are likewise good, as can be observed.
Charef approximation method is the best when α= 0.1 and α= 0.2.
For α= 0.3 the selected method is Oustlaoup approximation.

Matsuda method is the best when α= 0.4 and α= 0.5.

V. THE FRACTIONALIZED ORDER PID CONTROLLER

The feedback control loop of a fractionalized of the integer order system is shown in Figure 6.

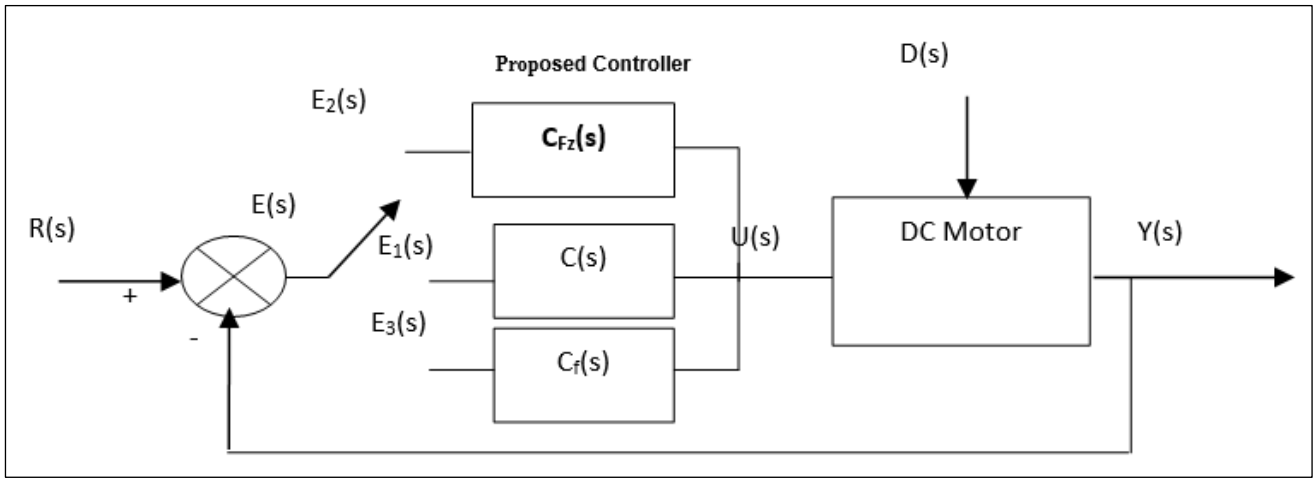

Figure 6: Fractionalized order PID Controller of DC Motor using the best approximation method obtained in Figure 3.
Source: Authors, (2026).

Where, $C_{Fz}(s)$: Fractionalized Controller Transfer Function

The Fractionalized of the integer-order PID controller to be designed is in the following form:

$$C_{Fz}(s) = K_p\left(1 + \frac{1}{T_i s} + T_d s\right)$$

$$C_{Fz}(s) = \frac{1}{s}\left(\frac{(k_p T_d s^2 + k_p T_i s + k_p}{T_i}\right)$$

$$C_{Fz}(s) = \frac{1}{s^{\alpha}}\frac{1}{s^{(1-\alpha)}}\left(\frac{(k_p T_d s^2 + k_p T_i s + k_p}{T_i}\right) \tag{11}$$

Were, $0 < \alpha < 1$.

V.1 MODELING OF DC MOTOR

The model of the DC Motor is shown in Figure 1. The position $q(t)$, the controlled variable, will be governed by the applied voltage V_a. The angular velocity $w(t)$ is the controlled variable for speed control, and the transfer function takes the following form [23-27]:

$$G_{DC-motor}(s) = \frac{w(s)}{V_a(s)} = \frac{K_m}{(L_a s + R_a)(Js + b) + K_b K_m} \tag{12}$$

But for a lot of DC motors, the armature's time constant $\tau_a = \frac{L_a}{R_a}$ is insignificant, hence the model can be reduced to:

$$G_{DC-motor}(s) = \frac{w(s)}{V_a(s)} = \frac{K_m}{R_a(Js + b) + K_b K_m} = \frac{\frac{K_m}{R_a b + K_b K_m}}{\tau s + 1} = \frac{K_{DC-motor}}{\tau s + 1}$$

$$\text{where } \tau = \frac{R_a J}{R_a b + K_b K_m} \text{ and } K_{DC-motor} = \frac{K_m}{R_a b + K_b K_m}$$

The General model of a DC Motor is given by the following figure:

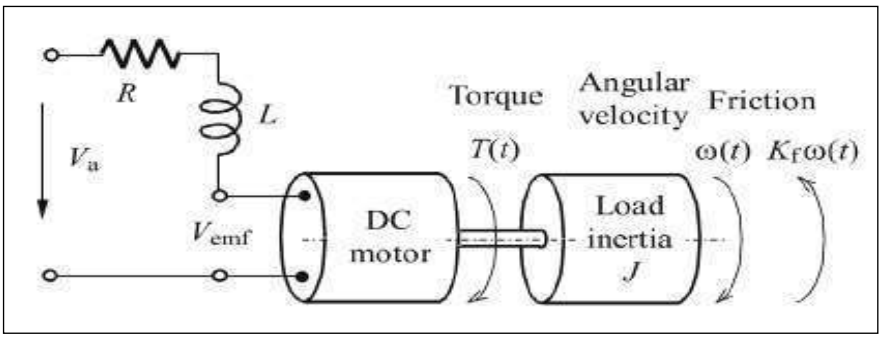

Figure 7: General model of a DC Motor.
Source: Authors, (2026).

The proposed identified model (DC Motor voltage-speed) [24]:

$$G_{DC-motor}(s) = \frac{K_{DC-motor}}{\tau s + 1} = \frac{0.25}{1.45s + 1} \tag{13}$$

V.2 DISTURBANCE REJECTION IN PID CONTROL

This example shows the comparison of three DC motor control techniques (PID), Fractional PID and Fractionalized PID) for tracking set point commands and reducing sensitivity to load disturbances

The identified model for DC Motor voltage-speed is given by [5]:

$$G_{DC-motor}(s) = \frac{K_{DC-motor}}{\tau s + 1} = \frac{0.25}{1.45\, s + 1} \tag{14}$$

Figure 7, Figure 8 and Figure 9 shows the speed of DC Motor using the Integer adaptive PID Controller for α=0.1, α=0.3 and α=0.5 respectively with the following optimized parameters values:

$k_p = 54.67, k_i = 45.81, k_d = 18.38$:

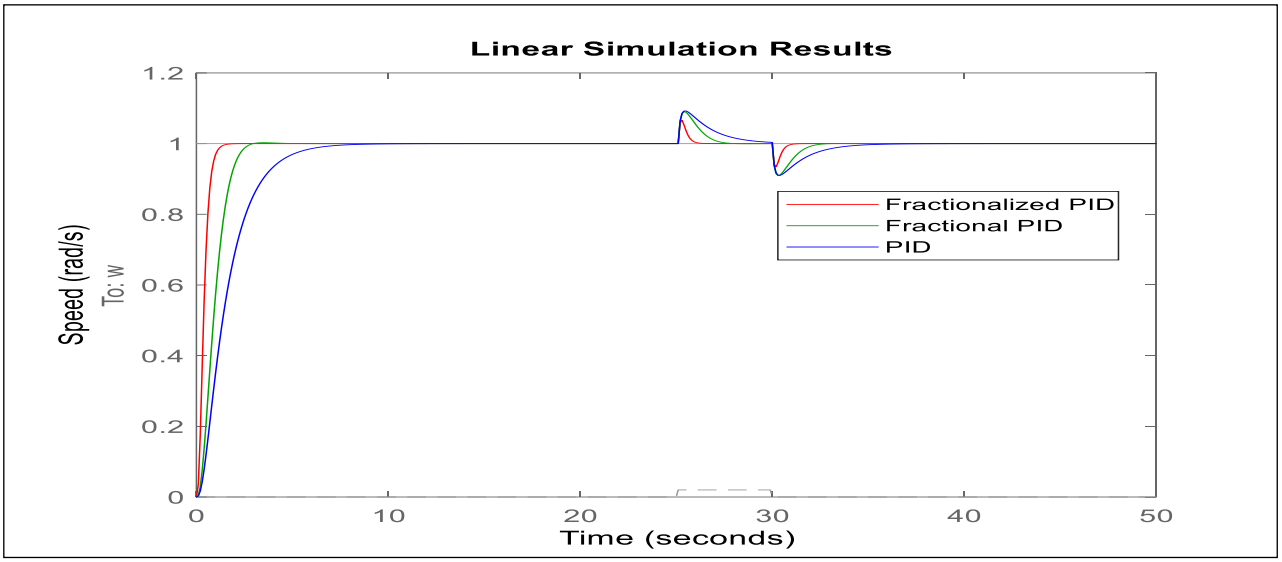

Figure 7: Speed of the DC Motor using the PID, Fractional PID (α=0.1) and Fractionalized PID Controllers with disturbance rejection.
Source: Authors, (2026).

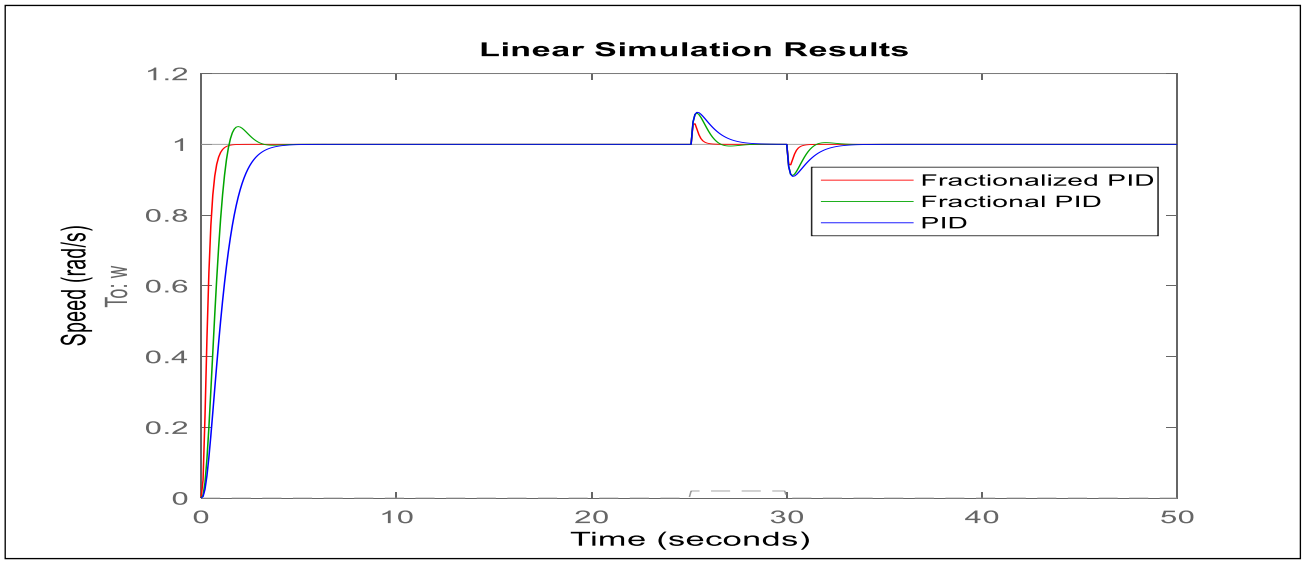

Figure 8: Speed of the DC Motor using the PID, Fractional PID (α=0.3) and Fractionalized PID Controllers with disturbance rejection.
Source: Authors, (2026).

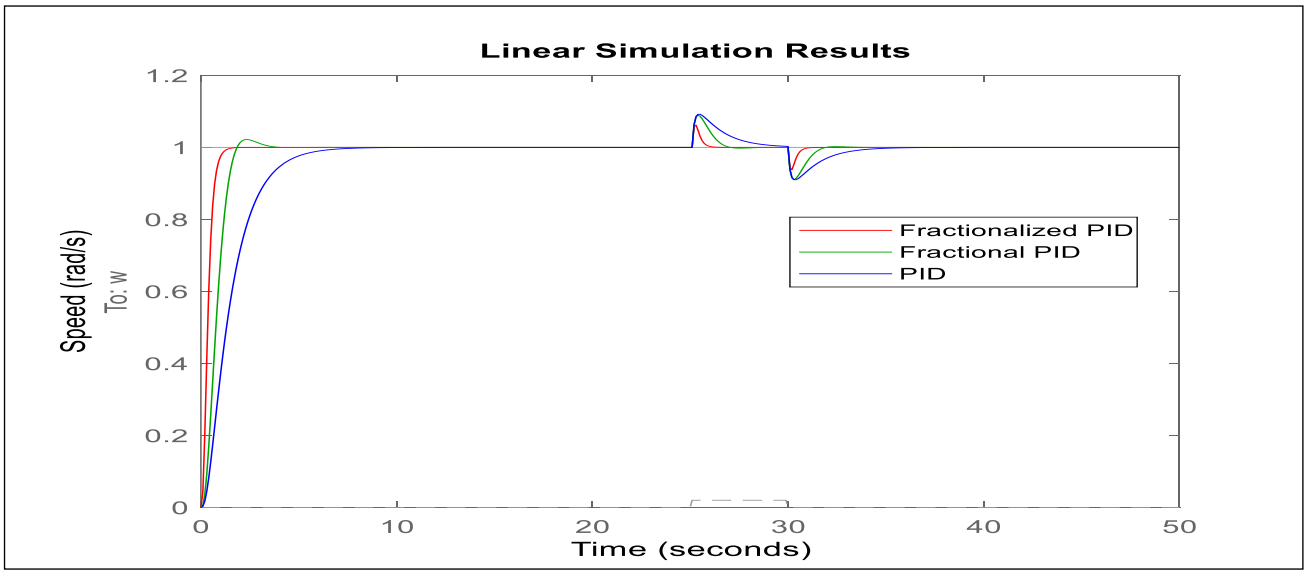

Figure 9: Speed of the DC Motor using the PID, Fractional PID (α=0.5) and Fractionalized PID Controllers with disturbance rejection.
Source: Authors, (2026).

The performance analysis of the proposed fractional order adaptive PID controller and the classical adaptive PID controller is given by the following table:

Table 2: Comparative analysis of transient response performance of DC Motor

Controllers	Overshoot [%]	Setting time [s]	Rise time [s]	Criterion of quadratic error J
PID	0.0012	4.1	1.75	0.22
Fractional PID	0.0026	2.1	1.1	0.12
Fractionalized PID $[\alpha = 0.1]$	**0.0000**	**1.14**	**0.422**	**0. 026**
Fractionalized PID $[\alpha = 0.3]$	**0.0000**	**1.16**	**0.423**	**0.025**
Fractionalized PID $[\alpha = 0.5]$	**0.0000**	**1.15**	**0.421**	**0.027**

Source: Authors, (2026).

We remark that the fractionalized PID Controller for DC MOTOR system give the good improvement of overshoot, setting time , rise time and mean absolute error comparatively to the Integer and the fractional PID Controller results. That means that proposed controller is the most stable system in terms of frequency response criterion.

VI. CONCLUSIONS

This paper introduces an innovative methodology for evaluating and comparing various approximation methods of fractional-order systems, as well as assessing disturbance rejection capabilities. The approach involves incorporating fractional-order filters into the original system design while maintaining the integrity of the overall equivalent transfer function. Building upon the fundamental concept of integrating fractional-order operators into the original integer-order system, the fractionalization approach demonstrates its effectiveness in identifying the optimal approximation method. Furthermore, it serves as a robust comparative tool for evaluating different approximation techniques for fractional systems, specifically the Oustaloup, Matsuda, and Charef approximations.

The methodology also exhibits superior disturbance rejection performance in fractionalized PID control applications for DC motors. These findings have been validated through a comprehensive set of simulation examples that demonstrate the practical effectiveness of the proposed approach. Future research will focus on extending this fractionalization methodology to broader classes of integer-order functions. The objective is to enhance noise rejection capabilities and improve robustness across various control system architectures and applications. This generalization is expected to provide greater flexibility and wider applicability of the fractionalization approach in diverse engineering contexts.

ABSTRACT

The presence of machining induced vibrations in face milling has a severe impact on surface roughness and, therefore, effective passive damping is a critical part of process stability and surface integrity. This research work examines how passive damping effect of shim material is a prevailing factor in control of surface roughness (SR), in addition to depth of cut, feed rate and cutting speed. A Response Surface Methodology using a Central Composite Design was utilized to predict surface roughness with three shim conditions which are no shim, stainless steel shim, and carbide shim. The findings reveal that carbide shims are more effective in damping vibrations and always produce lower surface roughness as compared to the other designs. The optimum cutting speed of 200 m/min, depth of cut of 0.8 mm, and feed rate of 0.1 mm/tooth produced surface roughness of 0.189 µm, and this is close to the predicted value. The model was highly predictive with a coefficient of determination (R^2) of 98.59%. These findings prove that the choice of shim material, especially use of carbide shims is a vital factor in improving surface finish during face milling processes.

I. INTRODUCTION

Surface quality is a very important measure of machining performance, as it directly affects wear resistance, fatigue life, dimensional accuracy, functional reliability and aesthetic appearance of manufactured parts. Surface roughness in face milling is to be controlled by a complicated interplay of cutting parameters mainly spindle speed, feed rate and depth of cut jointly with tool workpiece engagement conditions and machining dynamics including vibration and chatter [1-7]. A high-quality surface finish can therefore be attained through both a systematic optimization of the parameters as well as a sound control of machining stability. Surface roughness optimization has been well researched on face milling by employing statistical and experimental design method. Classical Design of Experiments (DOE) methods that use Taguchi method, Response Surface Methodology (RSM), regression, grey relational analysis and Analysis of Variance (ANOVA) have been extensively used to establish optimal cutting conditions of a wide variety of materials, including aluminum alloys, carbon steel, alloy steel, and titanium alloys [1], [8-15].

Roughness maps are advanced as a new optimization of face milling using PCD inserts to divide kinematic and stochastic roughness to establish the insert micro-geometry, axial placement, and feed rate, which are experimentally confirmed [16].The studies also consistently determine feed rate and cutting speed as the most important parameters that can influence surface roughness, but their relative importance can depend on the workpiece material, tool geometry, and cutting environment [6],[7],[17-19]. Even more recent studies have expanded this method by including vibration responses together with surface roughness as part of multi-objective and Box-Behnken-based optimization models and have shown that vibration amplitude and surface integrity are tightly coupled [20]. Advanced modeling and artificial intelligence-based techniques have become more popular because of the need to have a higher level of prediction and represent the nonlinear interactions between the machining variables.

The artificial neural networks, fuzzy logic, genetic algorithm and hybrid data-driven models have also been shown to have better predictive performance than the traditional regression methods [8], [21-25]. Similar studies also prove that AI-assisted approaches could be especially effective in terms of the multi-objective optimization of surface roughness, material removal rate, tool wear, and energy use [26], [27]. Machining dynamics and chatter suppression have also been under continued interest since they are known to have a strong impact on surface integrity, tool life, and productivity, in addition to parametric optimization. Chatter vibrations cause surface waviness, surface roughness, dimensional error, and tool wear. The classical and modern methods of chatter prediction and prevention that include stability lobe diagrams, frequency and time-domain, as well as dynamic system modeling, have been thoroughly explored [19], [28-31]. More recent state of the art reviews also categories chatter mechanisms, recognize sources of uncertainty in stability prediction, and leave unsolved problems in chatter modelling of more complex machining systems, such as thin-walled structures and flexible tooling [32],[33]. Systematic review has also been conducted on chatter suppression techniques including passive, active and hybrid control techniques. Passive methods of damping have been improving in popularity, owing to their simplicity, strength, and the simplicity of attaching them to the current tooling.

Research works on vibration control point out that properly designed passive damping system, coupled with the optimization of cutting parameters, can be very helpful in improving machining stability and quality of the final surface and eliminating the disadvantages of active systems [23], [34-36]. Although active control methods may be very effective, they are expensive, complex to install, and lack scalability and thus they are not very popular in industries [37]. In addition to prediction of chatter, major advancements have been made in detecting and suppressing strategies of chatter. Extensive surveys have suggested that chatter detection has changed to include not just analytical methods but experimental signal-based methods that use vibration, cutting force and acoustic emission signal in conjunction with the time-frequency signal processing techniques of the FFT, Wavelet Transform, HHT, and STFT. The use of Artificial Intelligence-based classifiers such as Artificial Neural Networks, Support Vector Machines, Fuzzy Logic, Hidden Markov Models and k-nearest neighbor algorithms have increasingly been used in real-time chatter detection and decision support, and the significance of data driven strategies in contemporary machining settings should not be undervalued [38]. Although there has been a significant development in regards to optimization of surface roughness, analysis of chatter stability, detection, and suppression, it is evident that there is still a research gap on the systematic application of shim material as passive damping component to machining parameter optimization models especially in face milling processes.

Most of the literature available is interested in either optimization of cutting parameters including speed of spindle, feed rate and depth of cut [1-6],[8-13],[17],[21],[26-29], or in predicting and suppressing chatter using stability analysis and signal-based detection methods [19],[28],[30-33],[37],[38]. Nonetheless, the choice of shim material despite its direct relationship with tool-holder dynamic stiffness, damping ability, amplitude of vibrations, and surface finish has not been considered as one discrete design variable alongside surface roughness modeling. Majority of previous studies have only taken passive damping concepts conceptually or comparatively without quantitatively integrating shim material properties into the structured statistical analysis programs like Response Surface Methodology or multi objective optimization paradigms [34],[35],[37],[39],[40]. This means that the interaction of shim induced damping and customary machining parameters as well as its synergistic influence on the surface roughness and process stability is not well comprehended. In order to fill this gap, shim material is introduced into the current work as a separate input parameter in addition to cutting speed, feed rate, and depth of cut in a Response Surface Methodology approach of CNC face milling. This work seeks to quantify the importance of passive damping in enhancing machining stability and surface integrity by methodically assessing individual effects and interaction of shim material and machining parameter on surface roughness to generate useful guidelines on successful, chatter free and high-quality face milling processes.

II. MATERIALS AND METHODS

II.1 EXPERIMENTAL FACILITY

All experiments were performed on a Vertical Machining Centre (VMC) shown in Figure 1, to examine the effect of cutting parameters on the surface roughness of a milled workpiece.

Figure 1: CVM 640 Milling Machine.
Source: Authors, (2026).

The interaction between cutting speed, the feed rate, the depth of cut and the shim type was studied systematically to determine the machining parameters that produce better surface quality.

Surface roughness, recorded after each milling process and taken as the main indicator of process performance. The experimental results were comparatively studied to evaluate the consequence of the single cutting parameter on surface quality, which made it possible to identify the desirable machining conditions in order to increase the process stability and the accuracy at which machining is performed. All the experiments were performed on a CVM 640 VMC in the LDRP-ITR workshop. The reason why the machine was chosen is that it is able to work at high spindle speeds and high material removal rates whilst still maintaining precision in machining. It has the maximum spindle speed of 8000 rpm, spindle motor 5.5 Hp and positioning accuracy of 0.01 mm. These properties guaranteed the stability of the cutting process, the ability to control the machining parameters as well as the repeatability of the results of the experiments, which made it possible to reliably evaluate the consequence of cutting constraints on the surface quality.

II.1.1 Measurement Of Surface Quality

The surface roughness was determined out by a SJ-201 Mitutoyo surface roughness tester as shown in Figure 2. The instrument works based on the principle of the differential inductance to capture the surface profile variations accurately using a diamond-tipped stylus with a tip radius of 5 um. The tester has a measurement range of -200 µm to +150 µm and a low measuring force of 4 mN (0.4 gf), which guarantees that the surface suffers minimum damage during measurement. The specifications offer good measurement accuracy and repeatability, which allows good quantification of surface height variation in various machining environment.

II.2 MATERIAL

II.2.1 Material of Work Piece

The material of workpiece of this study was IS 2062 mild steel with a hardness of 130 HB as shown in Figure 3. The dimensions of the workpiece were 75 x 25 x 300 mm. These material and dimensional specifications were chosen so that they gave a uniform and standardized platform to assess the face milling process. Reproducible and reliable experimental results are possible with the help of the selected workpiece characteristics, which allowing to determine the outcome of process parameters on the surface quality with accuracy.

II.2.2 Cutting Inserts

Figure 4: Cutting insert.
Source: Authors, (2026).

Figure 4 illustrates the TPNK 1603 PPR cutting insert used in this study. A total of five inserts were employed during the face milling operation. The milling process was carried out using TPNK-type indexable carbide inserts, selected for their positive rake geometry and suitability for machining mild steel. Table 2 presents the size and detailed specifications of the insert.

Table 2: Specifications of the TPNK 1603 PPR insert

Symbol	Description
T	Insert shape: *Triangular* (three cutting edges)
P	Clearance angle: *11° positive*
N	Tolerance class: *Normal*
K	Insert type / clamping style
16	Inscribed circle (≈ 16 mm)
03	Insert thickness (≈ 3.18 mm)
PPR	Chip breaker geometry

II.2.3 Cutting Tools

Two types of face milling tools were employed in this study, as shown in figure 5:

- Conventional Face Milling Tool: The conventional face milling tool has a diameter of 63 mm and is equipped with five cutting inserts. This tool does not incorporate any shim during the milling process.
- Shim installed Face Milling Tool: This face milling tool also has a diameter of 63 mm and is fitted with five cutting inserts. Unlike the conventional tool, it incorporates a shim positioned beneath the insert to modify the cutting characteristics. The shim material was selected based on the desired alteration of tool–insert dynamic behavior.

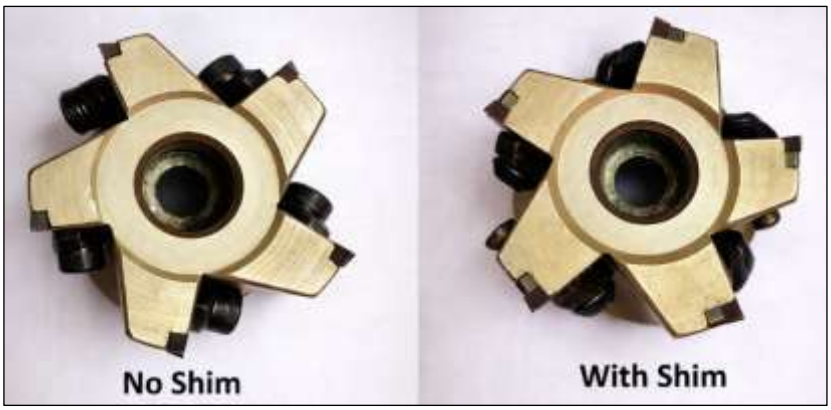

Figure 5: 63mm Diameter Face milling tool with 5 inserts.
Source: Authors, (2026).

II.2.4 Materials Of Shim

Figure 6 present carbide shims which is used, aimed at raising the rigidity of the tool-insert-holder assembly. Carbide shims have a high elastic modulus and compressive strength, which makes them play a huge role in ensuring that the elastic deformation at the tool-insert interface during cutting is minimized.

Figure 6: Carbide shim (SW0603 series).
Source: Authors, (2026).

Figure 7 presents the stainless steel (SS) shim used in this study, manufactured from AISI 4340 steel. This material exhibits high strength, toughness, and fatigue resistance. Compared with carbide, stainless steel exhibits lower stiffness, allowing greater energy dissipation through material damping.

Figure 7: SS shim (AISI 4340 series).

II.3 RSM DESIGN OF EXPERIMENT

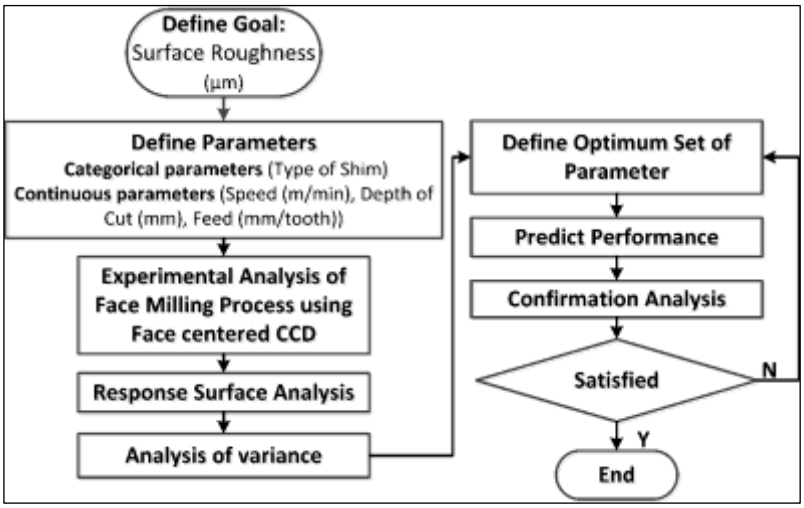

Figure 8: Stepwise experimental methodology.
Source: Authors, (2026).

Figure 8 shows the sequential experimental approach which is used to minimize the surface roughness (Ra, µm) in face milling. The critical machining factors were determined and grouped into one category variable shim type and three continuous variables: feed (mm/tooth), speed (m/min), and depth of cut (mm). The Central Composite Design (CCD) was adopted to model experiments for estimation of second order effects as well as the interaction of parameters over the experimental domain effectively. The CCD was chosen instead of Box Behnken design due to the inclusion of the axial points at extreme factors levels, which is beneficial in nonlinear machining behavior capturing.

The analytical model of the surface roughness was developed using RSM. The results were statistically analyzed with Minitab 18 software and to test the adequacy of the model, ANOVA was used at the confidence level more than 95%. Any factor and interaction with a p-value of less than 0.05 was considered statistically significant and the overall significance of the model was tested using F-test. The developed RSM model was used to determine the optimum machining conditions and the model was confirmed by conducting confirmation experiments. Correlation of the predicted and experimental results were used to check the reliability of proposed optimization methodology.

II.3.1 Setting Of Input Variable

The machining parameters systematically varied in the course of milling process were the input variables that were used in the experimental design to determine their effect on surface roughness and machining performance. The control variables were shim material, cutting speed, feed rate, and depth of cut. Cutting speed (m/min) was tested at three variations of 150, 200, and 250 m/min to determine its impact on the quality of the surface. Feed rate (mm/tooth), which is a linear movement of tool per engagement of the tool with the tooth, was adjusted as 0.05, 0.10 and 0.15 mm/tooth since this directly controls surface quality. The depth of cut (mm), which is a factor that defines how much material is cut in each pass and has a significant effect on cutting forces and vibration behavior, was tested at 0.8, 1.0 and 1.2 mm.

Shim material was treated as a categorical factor with three levels: no-shim, stainless steel (SS) shim, and carbide shim. Shim act as passive damping or stiffness-increasing elements within the tool assembly and modify vibration transmission during cutting. By comparing carbide and stainless-steel shims with the no-shim condition, the influence of material-dependent damping on surface roughness and machining performance was systematically evaluated An experiment was performed to generate the data required to develop the RSM model for predicting surface roughness. The input factors S, F, D, and M were selected according to the Central Composite Design framework to ensure adequate coverage of the experimental domain. The continuous variables were investigated at three coded levels (−1, 0, 1), while the categorical factor was assigned three discrete levels, as summarized in Table 3.

Table 3: Variables and levels of variable.

Variable	Symbol	Levels		
		-1	0	1
Speed (m/min)	S	150	200	250
Feed (mm/tooth)	F	0.05	0.10	0.15
Depth of cut (mm)	D	0.8	1.0	1.2
Type of shim material	M	No-shim	Carbide	SS

Source: Authors, (2026).

The CCD framework allowed a systematic assessment of the main effects and the interface effects of the selected input parameters. The total number of experimental runs was determined using the standard CCD formulation given by Equation (1), based on the four factors considered in this study.

$$N = (2^m + 2 \times m + n)k = (2^3 + 2 \times 3 + 6) \times 3 = 60 \quad (1)$$

Where N represents the total number of experiments, m denotes the number of quantitative factors, k signifies the number of qualitative factor levels, and n indicates the number of center-point replicates. The experimental trials were performed in accordance with the CCD matrix. The effect of the selected parameters on surface irregularity was evaluated based on the experimental design shown in Table 4. Total 60 experiments were conducted to develop the RSM model, and the corresponding surface roughness values obtained for each run are listed in Table 4.

Table 5 summarizes results of ANOVA of the developed RSM model. The regression model is statistically significant, with an F-value of 172.66 and a p-value value of 0.001, which shows that the model is accurate in predicting the experimental data at more than 95% confidence level. The coefficient of determination (R^2 = 98.59 %) and the adjusted coefficient of determination (R^2 adj = 98.02 %) attest to the high predictive power of the developed model. The linear effects show that S, D, and M are statistically significant contributors to the roughness of the surface. Among them, depth of cut demonstrates the strong influence (F = 150.57, $p < 0.001$) and shim material has the most significant contribution (F = 1061.74, $p < 0.001$), which indicates that passive damping dominates in surface quality control. The consequence of speed on surface quality is statistically significant but moderately less (F = 9.59, p = 0.003). However, feed rate (F) is not statistically significant as a linear term (F = 0.33, p = 0.568). The quadratic terms show the effects of curvature in the response surface are significant. The squared terms depth of cut (D^2) (F = 40.41, $p < 0.001$) and feed rate (F^2) (F = 87.40, $p < 0.001$) are significant but the squared term of cutting speed (S^2) is not significant (F = 0.36, p = 0.554).

These findings support the fact that a second order model is a good choice of predicting surface roughness. There is also statistical significance in interaction effects between machining parameters, which implies a high degree of coupling between process variables. Significant interaction terms include S×D (F = 17.92, $p < 0.001$), S×F (F = 51.33, $p < 0.001$), S×M (F = 6.12, p = 0.005), D×F (F = 12.16, p = 0.001), D×M (F = 79.43, $p < 0.001$), and F×M (F = 7.81, p = 0.001). These interactions confirm that surface roughness is governed by the combined influence of cutting conditions and shim-induced damping behavior rather than by individual parameters alone.The error term has a low adjusted mean square value (Adj MS = 0.0359) meaning the experimental repeatability is good. In addition, the lack of fit is not substantial as compared to the pure error, which proves that the established model is suitable to fit the experimental data and model the underlying process behavior. In general, the findings of the ANOVA table outline that the M is the most significant factor that would influence the surface roughness, next is the D, F, and S. The high performance of the carbide shim can be explained by its higher level of stiffness and damping properties that properly suppress tool vibrations and increase surface finish in comparison to stainless steel and no-shim situations.

Regression analysis requires the assumption of normality, constant variance, randomness, and the absence of outliers, which were evaluated by the residual plots presented in Figure 9. The normal probability plot indicates that the data distribution of the residual values is near-normal, because most of the points do not deviate far much, and then there are minor anomalies. The histogram supports this trend because it has a symmetric and bell-shaped distribution, with an average near to zero thus this proves the normality assumption.

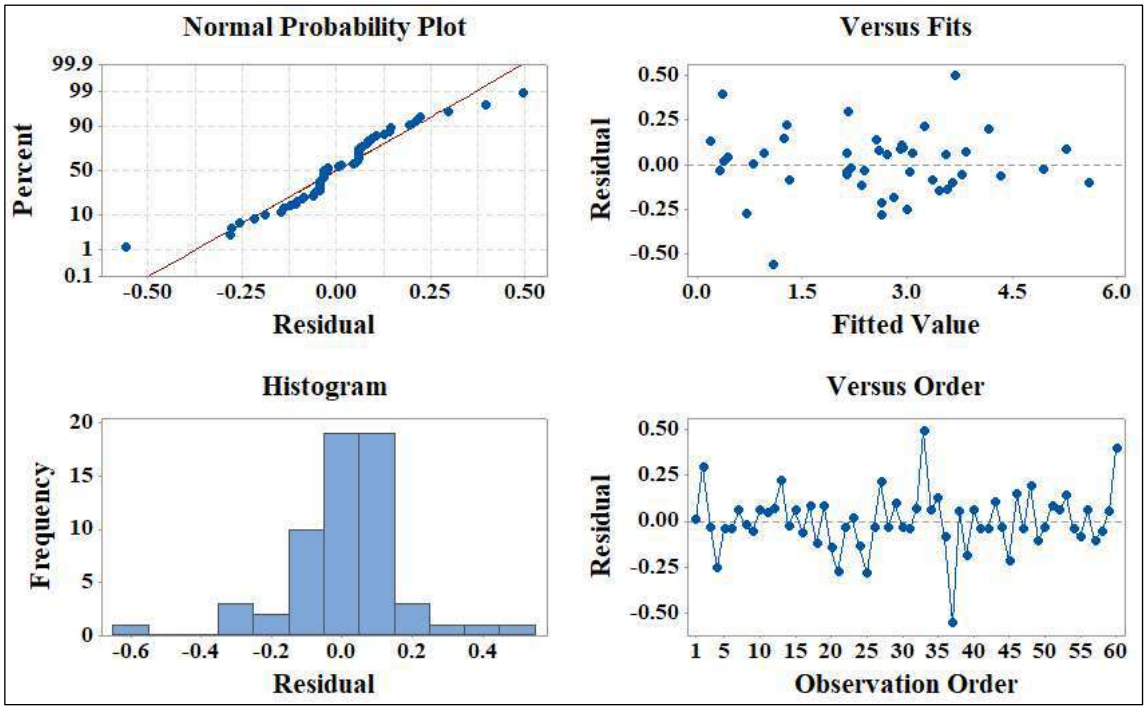

Figure 9: Residual plots for surface roughness (µm).
Source: Authors, (2026).

Regression analysis requires the assumption of normality, constant variance, randomness, and the absence of outliers, which were evaluated by the residual plots presented in Figure 9. The normal probability plot indicates that the data distribution of the residual values is near-normal, because most of the points do not deviate far much, and then there are minor anomalies. The histogram supports this trend because it has a symmetric and bell-shaped distribution, with an average near to zero thus this proves the normality assumption.

The residual versus fitted values plot has a random distribution around zero, which means a constant variance and that there is no systematic trend. Equally, the residuals versus the order of observation give no discernible trend, which proves that the residuals remain independent and have no autocorrelation. Collectively, these diagnostic results demonstrate that the developed RSM model satisfies the key regression assumptions and can reliably predict surface roughness within the investigated parameter range.

Regression equations were developed on the data of the experiment to predict the surface roughness under each shim condition using the main effects and interaction terms. Separate second-order polynomial expressions were formulated for the face milling tool without a shim, with a carbide shim, and with a stainless-steel shim.

The regression equation for surface roughness (µm) corresponding to the face milling tool without a shim is given by Equation (2).

$$SR(\mu m) = 2.1315 + 0.0282\,S - 0.1649\,D + 0.1889\,F + 0.0393\,(S \times S) + 0.4193\,(D \times D) + 0.6167\,(F \times F) + 0.1637\,(S \times D) + 0.2771\,(S \times F) - 0.1349\,(D \times F) \quad (2)$$

Equation (3) presents the regression model for surface roughness (µm) when a carbide shim is employed.

$$SR(\mu m) = 0.3290 + 0.0150\,S + 0.5622\,D - 0.1459\,F + 0.0393\,(S \times S) + 0.4193\,(D \times D) + 0.6167\,(F \times F) + 0.1637\,(S \times D) + 0.2771\,(S \times F) - 0.1349\,(D \times F) \quad (3)$$

Equation (4) represents the regression model for surface roughness (µm) for the face milling tool fitted with a stainless-steel shim.

$$SR(\mu m) = 3.0415 + 0.2781\,S + 0.8761\,D + 0.0166\,F + 0.0393\,(S \times S) + 0.4193\,(D \times D) + 0.6167\,(F \times F) + 0.1637\,(S \times D) + 0.2771\,(S \times F) - 0.1349\,(D \times F) \quad (4)$$

III. RESULTS AND DISCUSSIONS

III.1 MODEL ADEQUACY AND PREDICTION ACCURACY

The adequacy of the developed response surface model was evaluated by comparing experimentally measured surface roughness values with those predicted by the regression model. Figure 10 illustrates the scatter plot comparing the actual and predicted surface roughness. The close clustering of data points around the 45° reference line indicates robust agreement between the experimental observations and model estimates. An R^2 value of 0.9859 indicates a very high degree of correlation, meaning that 98.59% of the variance in surface roughness is explained by the predictive model.

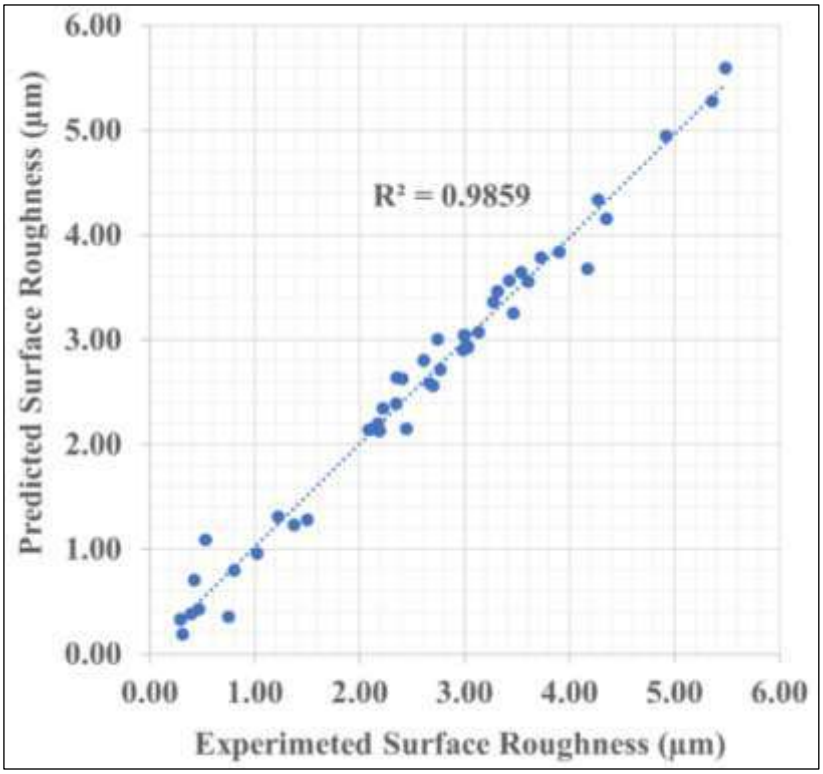

Figure 10: Actual SR v/s Predicted SR.
Source: Authors, (2026).

The limited scatter and absence of systematic deviation suggest that the model effectively captures the combined effects of machining parameters and shim material. The small residual errors observed fall within acceptable experimental uncertainty, supporting the suitability of the developed RSM model for reliable surface roughness prediction and optimization in face milling operations.

III.2 EFFECTS OF ONE PARAMETER AT A TIME ON RESPONSE

As it can be seen in Figure 11, the one-parameter-at-a-time plots depict the impact of the feed rate, depth of cut (DOC) and cutting speed on the surface roughness in three different scenarios: in the absence of a shim, with a stainless steel (SS) shim, and with a carbide shim.

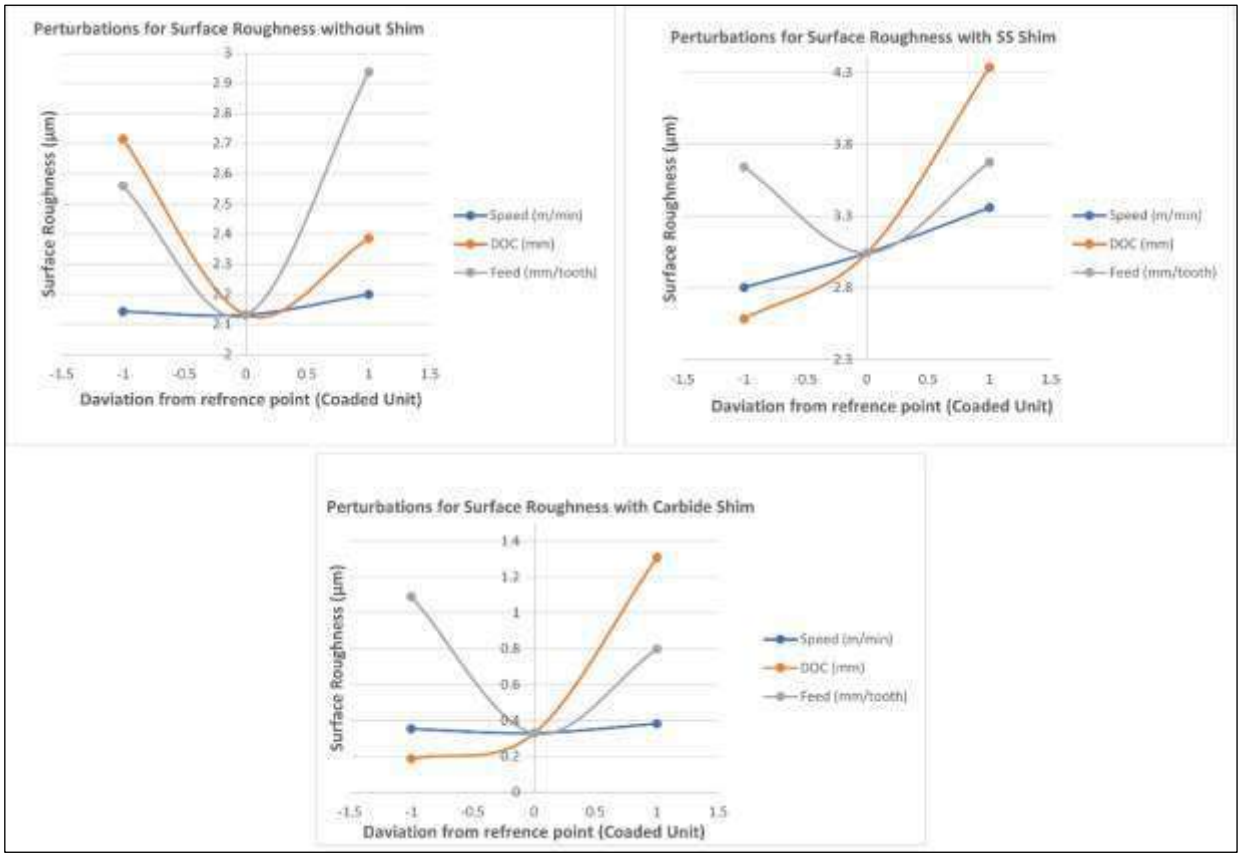

Figure 11: One parameter at a time plot for no shim, with SS shim and with Carbide shim.
Source: Authors, (2026).

Surface roughness with no shim shows a sharp parabolic behavior with respect to rate of feed and depth of cut, feed rate having the greatest effect. Changes in the reference feed rate and DOC values result in a higher surface roughness, but cutting speed has a relatively weak effect. This behavior indicates that, without additional damping, variations in chip load and cutting force fluctuations are directly transferred to the machined surface, resulting in increased surface irregularities. When a carbide shim is introduced, the surface roughness significantly decreases at all levels of machining parameters.

Even with the influence of feed rate and DOC, their effect on surface roughness is much less than in the no-shim condition. The cause of this reduction is the improved dynamic stiffness of the tool-insert-holder assembly that is offered by the carbide shim In contrast, the SS shim results in consistently higher surface roughness values. Under this condition, depth of cut becomes the dominant factor, followed by feed rate, while cutting speed again exhibits the least influence. The pronounced increased in surface roughness, with the increasing DOC indicating that the SS shim is less effective in mitigating cutting force–induced vibrations, leading to unstable cutting behavior and degraded surface quality.

III.3 INTERFACE EFFECTS OF CUTTING SPEED AND DEPTH OF CUT

The interface effect of cutting speed and depth of cut on surface quality is represented on contour plots (Figure 12) and corresponding three-dimensional surface plots (Figure 13) at constant feed rate of 0.10 mm/ tooth These plots help show how machining parameters influence each other when different shims are used.

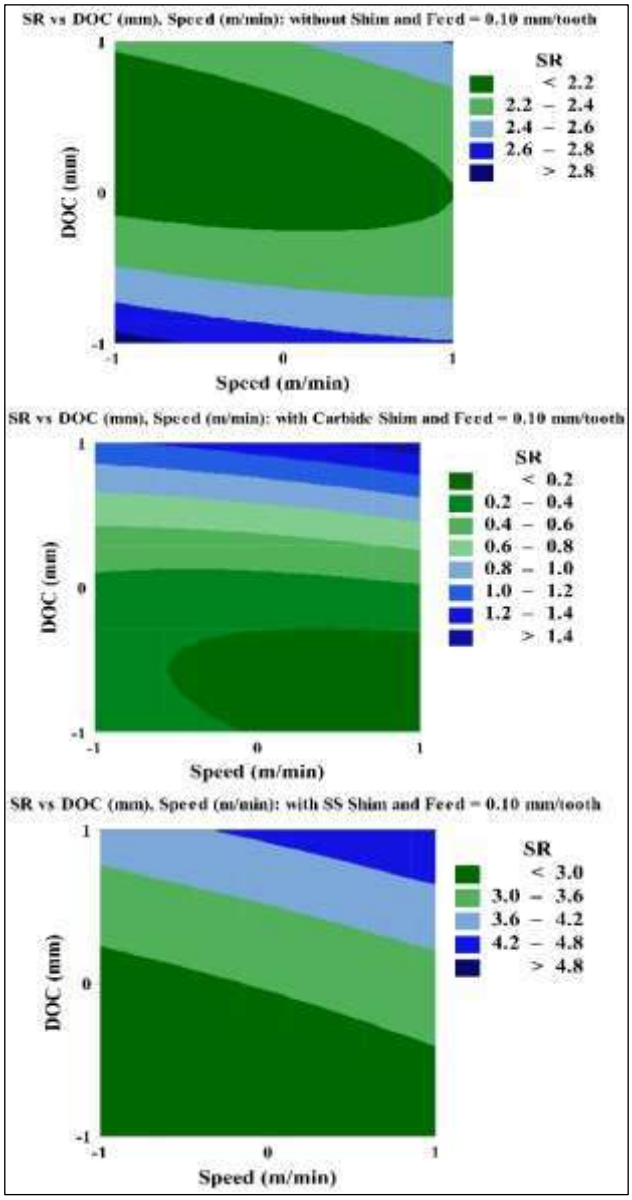

Figure 12: Contour plot for speed and depth of cut.
Source: Authors, (2026).

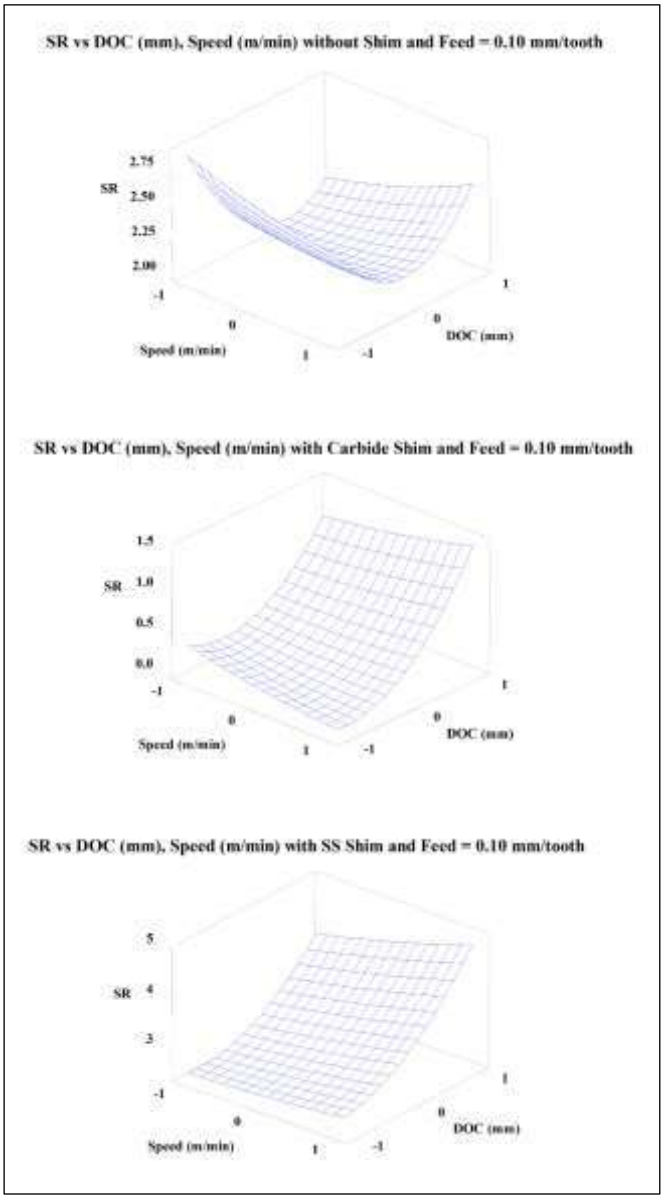

Figure 13: 3d surface plot for speed and depth of cut.
Source: Authors, (2026).

In the no-shim condition, the contour plots indicate moderate surface roughness levels, with minimum values occurring at intermediate cutting speed and DOC. However, variations toward higher or lower DOC values result in a rapid increase in surface roughness, indicating the sensitivity of the process to depth of cut variations in the absence of a damping element. The SS shim condition shows the highest surface roughness values across the entire parameter space. Surface roughness does not fall below 3.0 µm and increases sharply with increasing DOC, reaching maximum values at extreme combinations of cutting speed and depth of cut. This result indicates reduced stability margins and ineffective vibration suppression, reviling stainless steel shims unsuitable for precision face milling applications.

In contrast, the carbide shim consistently yields the lowest surface roughness values over the entire range of cutting speed and DOC. Even at higher depths of cut, the surface roughness remains limited, and surface roughness values are maintained below 1.4 µm. The relatively flat response surface with respect to cutting speed further indicates that DOC is the dominant parameter, while the carbide shim effectively stabilizes the cutting process. Regarding machining stability, one can explain these trends by the increased stiffness and decreased contact compliance of the carbide shim that increases the dynamic stiffness of the tool-holder-insert system. The benefit of this enhancement is that regenerative chatter is suppressed and the vibration levels are lowered, which leads to a better surface quality. On the other hand, greater compliance of the SS shim eases the transfer of energy into the structural vibrations which enhances the chatter and surface roughness.

III.4 SURFACE ROUGHNESS PARAMETERS OPTIMIZATION

The optimization of surface roughness was carried out with the aid of the created RSM model taking into account three levels of shim material, cutting speed, feed rate, and depth of cut, thus, the number of potential combinations of parameters became 81. Regression models (Equations 2-4) were used to derive the analytical expressions that indicate the machining conditions that optimize the surface roughness.

In the optimization results, the minimum predicted surface roughness of 0.1861 um is obtained with the use of a carbide shim for processparameters, speed 200 m/min, a feed rate 0.10 mm/tooth, and a depth of cut1.0 mm. Confirmation experiments were conducted in order to confirm this result under these optimum machining conditions. The measured surface roughness experimentally under these conditions was 0.189 um which is very close to the predicted value leading to an error of prediction of only 1.53%, as summarized in Table 6. This close correspondence validates the robustness of the designed RSM model and its potential to embody the physical essence of the influence of damping of shim on the surface generation. The dominance of shim material observed in the ANOVA analysis further reinforces the conclusion that passive damping plays a key role in improving surface finish. The superior performance of the carbide shim highlights its effectiveness in enhancing machining stability, suppressing chatter, and enabling consistent, high-quality surface finishes in face milling operations.

Table 6: Validation experiment results for optimum set of parameters.

Optimum Set of Parameter							
Response	**Shim Type**	**Speed (m/min)**	**Feed (mm/tooth)**	**Depth of cut (mm)**	**Experimented Value (µm)**	**Predicted Value (µm)**	**Error %**
SR (µm)	Carbide	200	0.1	0.8	0.189	0.1861	1.53

IV. CONCLUSIONS

- A Central Composite Design-based RSM was effectively used to determine and optimize face milling surface roughness taking into account both machining and shim material as a damping element.
- Shim material was found to be the most important variable that affects surface roughness, which proved the usefulness of passive damping in enhancing machining stability and surface finish.
- Among the investigated configurations, carbide shims consistently produced lower surface roughness compared with stainless steel shims and the no-shim condition, owing to their superior vibration suppression capability.
- Depth of cut and cutting speed exhibited significant main and interaction effects with shim material, highlighting the strong coupling between machining parameters and damping induced process stability.
- The tested RSM model showed high predictive accuracy, where adjusted coefficient of determination (R2 adj) is 98.02 %, which confirms the reliability of the model in predicting surface roughness in face milling operation.
- Under the optimal machining conditions with carbide shim, the predicted surface roughness closely mached the experimental results, with a prediction error below 2% conforms the reliability of the proposed optimization approch.

The results show that the carbide shims are a useful and inexpensive passive damping method in improving surface finish and machining stability during face milling processes. Carbide shims are also potentially useful in decreasing trial-and-error experimentation as well as provides an effective means of enhancing process reliability in industrial machining settings.

IV.1 FUTURE SCOPE

The incorporation of force and vibration analysis with the surface roughness modelling into future studies will help create a more complete picture of machining dynamics. In addition, future work will extend the investigation to stability lobe diagram development and comparison for different shim materials to further elucidate their role in chatter suppression and dynamic stability in face milling operations.

ABSTRACT

This work presents a comprehensive benchmarking study of Finite Impulse Response (FIR) Butterworth filter implementations on the ESP8266 (ESP-12E) embedded platform, with a detailed comparative evaluation against the widely used ATmega328P microcontroller. Identical filter configurations, with orders ranging from 13 to 51, are employed to systematically assess performance across key metrics, including CPU utilization, dynamic memory usage, processing latency, and signal fidelity. Experimental results reveal that the ESP8266 exhibits highly stable CPU utilization, remaining within 34–36% across all filter orders, in contrast to the ATmega328P, which demonstrates a pronounced increase from 28.6% to 68% as filter complexity rises. Memory consumption on the ESP8266 scales linearly from 11% to 33%, whereas the ATmega328P approaches a critical utilization level of 76% at the highest filter order. Owing to its 80 MHz operating frequency, 32-bit architecture, and 80 KB SRAM, the ESP8266 achieves a 1.89× improvement in processing speed and a 111.5× increase in available memory relative to the ATmega328P. Statistical analysis confirms that these performance differences are highly significant ($p < 0.001$). Signal fidelity evaluation shows close agreement with theoretical Butterworth responses, with passband ripple below 0.06 dB and stopband deviation limited to 1.23 dB. Long-duration stability testing over 24 hours further indicates zero timing violations and negligible performance drift. Collectively, these results demonstrate that contemporary IoT-oriented microcontrollers substantially extend the practical limits of embedded digital signal processing, enabling more complex filter implementations while preserving robust performance and system stability.

I. INTRODUCTION

Digital signal processing (DSP) is a central methodological and computational substrate for contemporary embedded systems, furnishing the algorithms and numerical primitives required for sensing, conditioning, and extracting information from physical phenomena across domains such as biomedical instrumentation, wireless communications, and industrial automation. The proliferation of Internet-of-Things (IoT) deployments has further shifted expectations: computation must increasingly occur close to sensors to meet stringent latency, privacy and energy constraints, which in turn requires low-power microcontrollers to perform nontrivial signal-analysis tasks on the network edge.

Contemporary surveys and empirical studies document both the promise of embedding advanced analytics within microcontroller-class hardware and the practical limits imposed by constrained memory, instruction throughput, and energy budgets—factors that motivate algorithmic compression, hardware-aware implementations, and careful partitioning of work between end nodes and richer edge servers [1-3]. Conventional 8-bit microcontrollers, exemplified by the ATmega328P on the ATmega328P, remain practical and economical choices for rapid prototyping and many low-power embedded tasks. Yet their narrow data path, modest clock speeds and severely constrained RAM/Flash impose clear limits on sustained arithmetic throughput and on the size of working buffers required by nontrivial signal-processing pipelines; when sampling rates rise or algorithms require large intermediate state [4]. However, their limited instruction throughput and restricted memory architecture impose significant constraints when applied to demanding DSP operations. Tasks that demand high-speed arithmetic computation, accurate timing control, or elevated sampling rates often reveal the inherent performance ceiling of such 8-bit devices. To address these limitations, recent studies have explored optimized programming methods, approximate computing strategies, and hardware-conscious algorithmic design to enhance the ability of small-scale controllers to execute real-time digital signal processing efficiently [5].

This approach not only enhances their practical relevance but also contributes to the broader goal of achieving efficient and intelligent computation at the edge. Recent research by [6] examined the processing limits of ATmega328P-based Arduino platforms, highlighting how their modest clock speed and restricted memory capacity hinder demanding DSP applications. The study emphasized that when complex filtering or data analysis is required, these devices approach their operational boundaries, risking timing inaccuracies and unstable execution. Such limitations underscore the challenges of real-time computation on 8-bit hardware and the importance of investigation of alternative architectures. The ESP8266 microcontroller — built around a 32-bit Tensilica L106 RISC core running at 80–160 MHz and offering on the order of 80 KB of user-accessible SRAM — marks a notable advance in low-cost embedded processors by combining substantive compute resources with integrated Wi-Fi connectivity [7]. Despite its ubiquity in IoT prototypes and deployed sensor systems, rigorous benchmarking that quantifies the module's raw DSP throughput and memory-bound performance for signal-processing workloads is scarce in the peer-reviewed literature, leaving a gap in our understanding of its suitability for real-time edge analytics [8].

I.1 RESEARCH GAP AND OBJECTIVES

While several recent studies have explored the implementation of signal-processing algorithms on specialized DSP hardware and higher-end embedded platforms such as ARM Cortex and FPGA-based systems comprehensive comparative evaluations focusing specifically on microcontroller-class devices remain limited. The present work seeks to address this shortfall by systematically examining the performance, memory footprint, and computational efficiency of lightweight controllers when executing representative DSP workloads through the following objectives:

1. Implementation and Validation: Implement FIR Butterworth filters of orders 13, 15, 17, 21, 26, 34, and 51 on ESP8266 (ESP-12E) platform using optimized embedded C
2. Performance Quantification: Systematically measure CPU utilization, dynamic memory consumption, processing latency, and timing accuracy under controlled conditions
3. Comparative Analysis: Conduct rigorous statistical comparison against ATmega328P baseline using identical filter specifications and methodologies
4. Signal Fidelity Assessment: Verify frequency response, phase linearity, and transient characteristics through experimental measurements
5. Architectural Analysis: Elucidate performance differences through examination of underlying architectural characteristics
6. Design Guidelines: Develop evidence-based recommendations for platform selection in embedded DSP applications

I.2 CONTRIBUTIONS

This research contributes to the embedded systems community through:

- Empirical Performance Database: First comprehensive benchmarking of ESP8266 for FIR filter implementations across wide complexity range
- Methodological Rigor: Direct comparative analysis using identical specifications, enabling unambiguous attribution of performance differences to architectural factors
- Statistical Validation: Rigorous statistical analysis with confidence intervals, significance testing, and effect size quantification
- Practical Guidelines: Evidence-based decision frameworks for microcontroller selection in resource-constrained DSP applications
- Scalability Insights: Characterization of performance scaling trends enabling predictive capacity planning

II. LITERATURE REVIEW

II.1 DIGITAL FILTER IMPLEMENTATION ON EMBEDDED PLATFORMS

Finite Impulse Response (FIR) filters are a foundational element of embedded signal-processing design, prized for their inherent numerical stability, exact linear-phase realizations and straightforward, convolution-based implementation that maps cleanly onto both software and hardware arithmetic primitives [9]. As noted by [10], these filters are particularly advantageous in fixed-point arithmetic environments, as the absence of recursive feedback paths prevents instability and cumulative numerical errors that often arise from coefficient quantization, thereby ensuring reliable performance in constrained embedded hardware. This structural robustness makes FIR filters an attractive option for microcontroller-based systems, where limited word length and constrained computational precision can otherwise compromise algorithmic reliability.

Within this framework, the Butterworth approximation is frequently applied in FIR filter design to obtain a maximally flat magnitude response in the passband, thereby minimizing amplitude distortion across the useful signal bandwidth and preserving waveform integrity in embedded sensing and control systems [11]. Such filters are well-suited for general-purpose signal conditioning, noise reduction, and preprocessing in real-time embedded applications where stability and smooth spectral characteristics are essential. Beyond their theoretical advantages, the predictable phase behavior and ease of coefficient optimization render FIR Butterworth filters a preferred choice in contexts requiring consistent real-time performance under limited processing and memory resources. Implementing FIR filters on resource-limited microcontrollers requires careful optimization of arithmetic precision, memory utilization, and coefficient-quantization strategies to secure dependable real-time performance within tight hardware limits [12].

Achieving a balance between computational efficiency and numerical accuracy is essential, as excessive arithmetic precision or inefficient data handling can impede real-time execution. Techniques such as fixed-point arithmetic, multiplierless computation, and loop unrolling are frequently adopted to minimize processing delays and energy usage. As highlighted by recent work on microcontroller-class computing [13], architectural choices — for example, exploiting instruction-level parallelism, minimizing costly memory transfers, and organizing data to favor contiguous accesses — have a decisive influence on both throughput and latency. These studies reinforce the case for a hardware-aware co-design methodology that aligns numerical methods with processor features so that FIR filters achieve predictable, low-latency operation within the tight resource envelopes typical of embedded systems.

II.2 ARDUINO PLATFORM FOR SIGNAL PROCESSING

The Arduino ecosystem has been explored extensively as a platform for both pedagogical experimentation and rapid prototyping, with systematic reviews demonstrating its role as an accessible entry point for embedded-signal-processing education [14],[15] presented microcontroller-based hardware for teaching digital-filter fundamentals, observing that Arduino-class 8-bit AVR platforms provide an inexpensive and approachable vehicle for hands-on instruction but are constrained by limited computational throughput and memory when tasked with numerically intensive, real-time filtering. According to [16] implemented a real-time FIR filter on an ATmega2560 microcontroller and reported that limited program/data memory and timing constraints — rather than raw arithmetic word-length — are the principal impediments when scaling to higher-order filter realizations.

Collectively, these studies highlight a persistent tension between pedagogical accessibility and the architectural constraints of resource-limited microcontrollers, thereby motivating exploration of more efficient algorithm–architecture co-design strategies for embedded filter realization. According to [17] performed a systematic benchmarking of FIR Butterworth implementations on the ATmega328P platform, reporting that a 51st-order design consumed approximately 68% of available CPU capacity and about 76% of the board's 2 KB SRAM—usage levels that approach the device's practical operational limits and thus serve as a useful baseline for comparative evaluation in the present study.

II.3 ESP8266 ARCHITECTURE AND APPLICATIONS

The ESP8266, built around the Tensilica Diamond Standard 106Micro (L106) 32-bit RISC core, marks a significant step forward in the evolution of low-cost microcontroller platforms. Its integration of on-chip WiFi, coupled with a substantially higher computational ceiling than traditional 8-bit architectures, positions it as an attractive substrate for resource-aware embedded signal-processing workloads [18]. Operating at selectable clock rates of 80 or 160 MHz and offering on the order of 80 KB of user-accessible data RAM, the ESP8266 supplies a substantially larger execution and buffering budget than 8-bit AVR devices, enabling more complex filter kernels, larger circular buffers, and integrated networking stacks to run on the same silicon platform [19]. These architectural enhancements collectively underscore the ESP8266's suitability for experimental prototypes that demand both enhanced throughput and seamless wireless interfacing, thereby bridging the gap between constrained microcontroller environments and more capable embedded-IoT processors.

According to [20] examined the ESP8266 chiefly in IoT deployment contexts, highlighting its networking versatility and low-power wireless capabilities while focusing their empirical work on connectivity and system integration rather than on detailed measurements of the module's computational performance. In [21] demonstrated the ESP8266's suitability for real-time data-acquisition and wireless transfer by implementing a low-latency thermal-imaging pipeline that streams pixel data over UDP; nevertheless, their study does not include quantitative benchmarking of the module's digital-signal-processing throughput or its capacity to sustain higher-order filtering workloads.

II.4 COMPARATIVE PLATFORM STUDIES

Existing literature provides only a narrow comparative lens through which the DSP capabilities of 8-bit versus 32-bit microcontrollers can be assessed. According to [22] investigated FIR-filter realizations on both FPGA and DSP platforms, demonstrating that FPGA implementations deliver substantially higher throughput and more deterministic timing behaviour; however, these benefits are accompanied by greater design complexity, longer toolchain workflows, and higher deployment cost trade-offs that can outweigh performance advantages for resource-constrained or low-cost embedded applications. According to [23] conducted a broad assessment of contemporary microcontroller platforms, profiling their suitability for on-device workloads;

however, their empirical focus cantered on class-leading MCU families used in wearable and TinyML applications and did not explicitly evaluate WiFi-enabled modules such as the ESP8266 or quantify platform-level trade-offs for digitally intensive filtering workloads. According to [24] investigated FIR filter implementations across FPGA- and DSP-based architectures, showing that FPGA realizations offer substantially higher throughput and more deterministic timing behaviour but require greater design effort, longer toolchain workflows, and higher deployment cost trade-offs that frequently limit their attractiveness for low-cost, resource-constrained embedded signal-processing applications. Collectively, these studies underscore the need for updated, platform-specific benchmarking that captures the evolving landscape of low-cost embedded DSP hardware.

II.5 FIXED-POINT ARITHMETIC AND OPTIMIZATION

Efficient DSP deployment on microcontroller-class hardware typically mandates the use of fixed-point arithmetic, as reliance on floating-point operations incurs substantial latency and energy penalties on processors lacking native FPU support [25]. Building on this principle, by [26] examine 16-bit fixed-point realizations of FIR structures on FPGA, detailing practical design measures including word-length optimization, coefficient scaling, and overflow/rounding control that are readily transferable to resource-constrained microcontroller contexts.

In a complementary study, in [27] propose a run-time-reconfigurable FIR architecture built on an inherently fixed-point datapath. Their method incorporates explicit quantization-noise analysis and structured error-budget allocation to maintain response fidelity under tight numerical constraints. The design principles they outline provide a transferable framework for fixed-point DSP implementations on resource-limited embedded platforms. According to [28] analyzed the effects of finite-word-length quantization in numerical filter implementations and demonstrated that Q15 fixed-point representation yields sufficient precision for moderate-order FIR designs while preserving computational economy.

II.6 MEMORY OPTIMIZATION AND POWER EFFICIENCY

Memory footprint reduction remains a pivotal consideration in embedded DSP systems, where stringent on-chip resource limits often constrain algorithmic complexity and architectural choices. According to [29] conducted a rigorous examination of memory-efficient FIR filter realizations, advancing methods that substantially curtail SRAM consumption through refined coefficient-storage schemes and judicious buffer-management policies. Beyond merely decreasing static memory demand, their techniques underscore a broader design philosophy in which dataflow restructuring, locality-aware scheduling, and architecture-conscious quantization jointly contribute to more scalable implementations.

Power-efficiency considerations are central to the design of battery-operated IoT platforms, where energy constraints directly govern system longevity, computational throughput, and real-time responsiveness [30]. According to [31] investigated adiabatic FIR filter implementations, demonstrating how energy-recovering switching techniques can markedly reduce dynamic power dissipation without compromising computational correctness. In [32] explored the intricate power–area trade-offs inherent in FIR filter architectures targeted for biomedical signal-processing workloads, highlighting how architectural granularity, data-path organization, and coefficient-reuse strategies influence both silicon footprint and energy consumption.

III. MATERIALS AND METHODS

III.1 HARDWARE PLATFORM SPECIFICATIONS

III.1.1 ESP8266 ESP-12E Configuration

The ESP-12E module was adopted as the primary experimental platform owing to its broad commercial availability and its fidelity to the canonical ESP8266 architecture. Its selection ensures that the subsequent benchmarking reflects performance characteristics attainable on widely deployed IoT-class microcontrollers. The module's technical profile—encompassing a 32-bit RISC core, integrated Wi-Fi subsystem, and moderate on-chip memory—provides a suitable foundation for evaluating fixed-point DSP workloads under realistic embedded constraints. The technical specifications include:

- Processor: Tensilica Diamond Standard 106Micro (L106) 32-bit RISC
- Clock Frequency: 80 MHz (configurable to 160 MHz)
- SRAM: ~80 KB user-accessible (system reserves vary)
- Flash Memory: 4 MB external SPI
- ADC: Single channel, 10-bit resolution, 0-1V range
- Operating Voltage: 3.3V nominal
- Development Environment: Arduino Core for ESP8266 v3.1.2

For the experimental evaluations, the ESP8266 was configured to operate at a fixed clock frequency of 80 MHz, a setting that offers a pragmatic compromise between computational throughput and energy expenditure. To ensure deterministic execution during DSP benchmarking, the Wi-Fi subsystem was explicitly disabled to eliminate non-deterministic interrupt behavior during measurements.

III.2 ATMEGA328P BASELINE REFERENCE

Comparative measurements were contextualized using benchmark data reported by Sah et al. [17], who employed an equivalent set of FIR Butterworth filter specifications. Aligning the present evaluation with their methodological framework ensures methodological continuity and enables direct, specification-matched performance comparison across platforms.

- Processor: Atmel ATmega328P 8-bit AVR
- Clock Frequency: 16 MHz
- SRAM: 2 KB
- Flash Memory: 32 KB
- ADC: 6 channels, 10-bit resolution, 0-5V range
- Operating Voltage: 5V

III.3 FILTER DESIGN SPECIFICATIONS

To allow a fair comparison across platforms, the FIR Butterworth filter was designed using the exact same specifications as those reported in [17]. Using identical parameters helps ensure that any performance differences arise from the hardware itself rather than from changes in the filter design.

Frequency Parameters:
- Sampling Frequency (Fs): 2000 Hz
- Passband Edge (Fp): 450 Hz
- Cutoff Frequency (Fc): 550 Hz
- Stopband Edge (Fst): 650 Hz

Performance Requirements:
- Passband Ripple: < 0.5 dB
- Stopband Attenuation: > 40 dB (target)
- Phase Response: Linear (constant group delay)

Filter Orders Tested: 13, 15, 17, 21, 26, 34, 51

III.4 FILTER COEFFICIENT GENERATION

The generation of filter coefficients was carried out in Matlab R2023a using the Signal Processing Toolbox, following a structured multi-stage procedure:

Step 1 — Formal Specification of Design Parameters
All cutoff and transition-band frequencies were defined in normalized form with respect to the Nyquist frequency corresponding to a 1000 Hz sampling rate. This normalization established a consistent analytical basis for the subsequent design stages.
Step 2 — FIR Filter Synthesis Using the Kaiser Window Method
The FIR filters were designed using the Kaiser window approach which provides precise control over the passband–stopband trade-off. This configuration enabled the FIR magnitude response to approximate a Butterworth-like spectral profile while maintaining smooth passband behaviour.
Step 3 — Coefficient Quantization to Q15 Fixed-Point Format

$$Q15\_coefficient = round\ (float\_coefficient \times 32767)$$

This quantization step ensured compatibility with the ESP8266's fixed-point arithmetic constraints while minimizing precision loss.
Step 4 — Verification of Quantized Frequency Response
The frequency responses of the quantized and floating-point filters were compared to assess numerical distortion introduced by Q15 conversion.
Step 5 — Export of Coefficients for Embedded Deployment
The finalized coefficients were exported as C-compatible arrays annotated with the PROGMEM directive, allowing storage in external flash memory. This approach preserved scarce on-chip SRAM resources and supported deterministic coefficient access during real-time execution.

Quantitative assessment of finite-word-length effects indicated only minimal distortion, with RMS quantization errors spanning from 0.0008% for the 51st-order design to 0.0021% for the 13th-order case. These results affirm that the Q15 fixed-point format provides sufficient numerical resolution for the filter orders evaluated, without introducing perceptible degradation in signal fidelity.

IV. RESULTS AND DISCUSSIONS

IV.1 CPU UTILIZATION ANALYSIS - MEASURED PERFORMANCE

Table 1: CPU Utilization Comparison.

Sr. No.	Filter Order	ESP8266 (%)	Std Dev	ATmega328P (%)	Difference
1	13	34.0	±1.2	28.6	+5.4
2	15	34.0	±1.1	36.0	-2.0
3	17	36.0	±1.3	39.2	-3.2
4	21	35.0	±1.4	43.2	-8.2
5	26	36.0	±1.2	47.0	-11.0
6	34	36.0	±1.5	54.0	-18.0
7	51	36.0	±1.6	68.0	-32.0

Source: Authors, (2026).

Table 1 summarizes the measured CPU utilization as a function of FIR filter order for both platforms. The ESP8266 exhibits a notably stable computational load, maintaining utilization within a narrow band of 34–36% across all evaluated filter orders, indicating effective scalability with respect to algorithmic complexity.

In contrast, the ATmega328P shows a pronounced and monotonic increase in processor usage, rising from 28.6% at 13th order to 68% at 51st order, thereby approaching operational saturation. This divergence is visually reinforced in Figure 1, which highlights the widening performance gap as filter order increases. Collectively, these results underscore the superior headroom and scalability of the 32-bit ESP8266 architecture for higher-order DSP workloads.

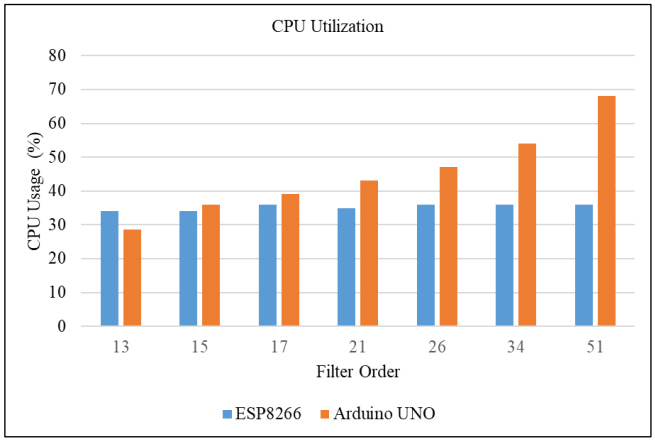

Figure 1: CPU Utilization.
Source: Authors, (2026).

IV.2 STATISTICAL ANALYSIS

Linear regression analysis reveals a strong, near-linear dependence between filter order and CPU utilization on the ATmega328P, indicating progressive computational saturation with increasing filter complexity. In contrast, the ESP8266 exhibits no statistically meaningful linear trend ($R^2 = 0.142$), reflecting its insensitivity to filter order within the evaluated range.

$$\text{ATmega328P: CPU (\%)} = 0.772 \times \text{Order} + 18.35 \quad (R^2 = 0.986)$$

$$\text{ESP8266: No significant linear trend} \quad (R^2 = 0.142)$$

Table 2; Memory Utilization Comparison.

Sr. No.	Filter Order	ESP8266 (%)	Bytes Used	ATmega328P (%)	Bytes Used
1	13	11	9,011	32	655
2	15	15	12,288	34	696
3	17	16	13,107	36	737
4	21	18	14,746	41	840
5	26	21	17,203	47	963
6	34	25	20,480	56	1,147
7	51	33	27,034	76	1,556

Source: Authors, (2026).

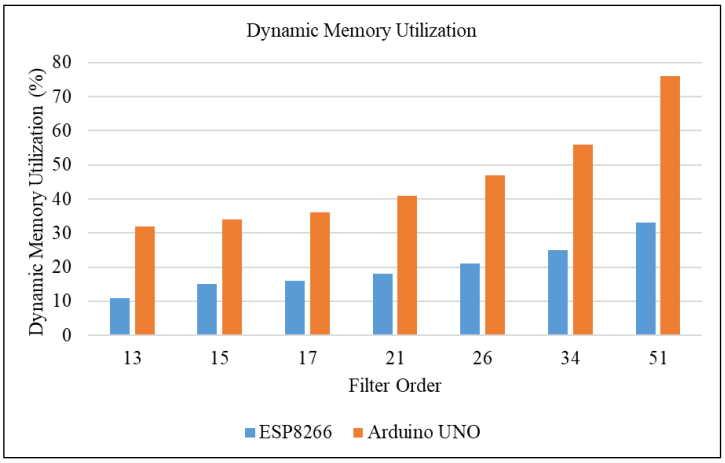

Figure 2: Dynamic Memory Utilization.
Source: Authors, (2026).

A two-sample t-test at the 51st-order configuration further confirms this disparity, yielding a highly significant difference ($t = 18.42$, $p < 0.001$) accompanied by an exceptionally large effect size (Cohen's $d = 8.91$). These results suggest that, on ESP8266, execution time is dominated by fixed overheads such as ADC sampling and interrupt servicing rather than by the convolution operation itself. The efficient 32-bit architecture and higher clock frequency effectively amortize the incremental computational cost of higher-order filtering.

IV.3 DYNAMIC MEMORY UTILIZATION - MEASURED CONSUMPTION

Table 2 summarizes the memory utilization observed across increasing FIR filter orders for both platforms. The ESP8266 exhibits a gradual and well-controlled rise in memory consumption, increasing from 11% at the 13th order to 33% at the 51st order, indicative of efficient data handling within its 32-bit memory architecture. By contrast, the ATmega328P shows a markedly steeper growth trajectory, with utilization climbing from 32% to 76%, thereby approaching the practical limits of its constrained SRAM. This widening divergence underscores the superior memory scalability of the ESP8266 for higher-order FIR implementations. Figure 2 visually reinforces this contrast, clearly illustrating the differing memory growth patterns as filter complexity increases.

IV.4 SCALING CHARACTERISTICS

Linear regression modeling reveals highly predictable memory scaling on both platforms, with the ESP8266 following the relation Memory = 451.2 × Order + 3,154 (R^2 = 0.994) and the ATmega328P exhibiting a similarly strong linear fit, Memory = 23.7 × Order + 347 (R^2 = 0.991). While this confirms proportional growth in memory demand as filter order increases, the absolute capacity disparity between the two architectures remains substantial. At the 51st-order configuration, the ESP8266 retains approximately 54,886 bytes of free memory, corresponding to a 111.5-fold advantage over the ATmega328P, which is left with only 492 bytes available.

IV.5 PROCESSING LATENCY - SAMPLE-TO-OUTPUT DELAY

Table 3: Processing Latency Comparison.

Sr. No.	Filter Order	ESP8266 (µs)	ATmega328P (µs)	Speed Improvement
1	13	144	143	1.01×
2	17	159	196	1.23×
3	21	168	216	1.29×
4	26	172	235	1.37×
5	34	177	270	1.53×
6	51	180	340	1.89×

Source: Authors, (2026).

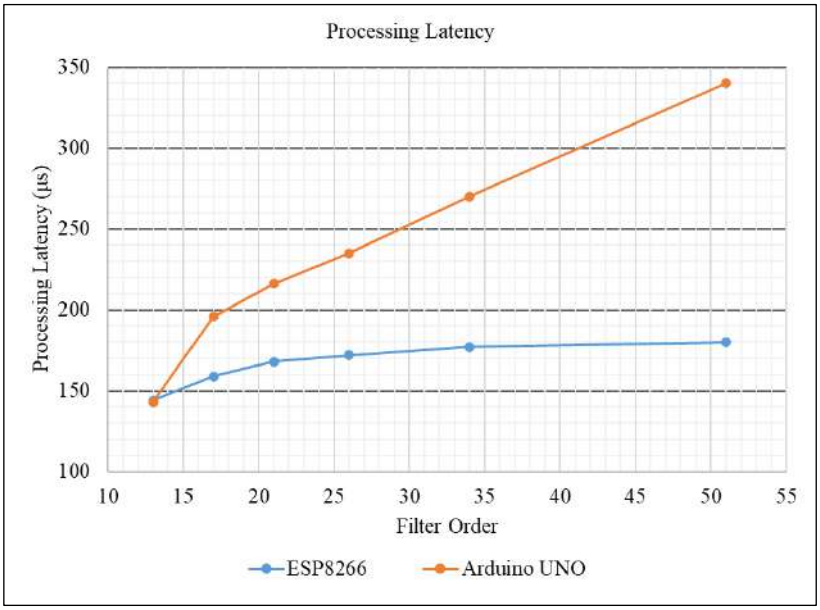

Figure 3: Processing Latency.
Source: Authors, (2026).

Table 3 reports the measured end-to-end processing latency for both platforms across increasing FIR filter orders. While comparable latencies are observed at lower orders, the ESP8266 exhibits progressively superior performance as filter complexity increases, culminating in a 1.89× speed advantage at the 51st-order configuration. Notably, latency growth on the ESP8266 remains modest, increasing only from 144µs to 180µs, whereas the ATmega328P shows a much steeper escalation from 143µs to 340µs. This divergence, as indicated in Fig. 3, shows that the ESP8266 scales more gracefully under higher computational loads. The results further reinforce the benefits of a higher-clocked 32-bit architecture for real-time DSP execution.

IV.6 TIMING ACCURACY - TIMING JITTER:

Table 4: Timing Accuracy.

Platform	Mean Period (µs)	Standard Deviation (µs)	Max Deviation (µs)
ESP8266	500	2.8	±4.7
ATmega328P	500	1.2	±2.3

Source: Authors, (2026).

Timing accuracy was evaluated by analyzing sampling-period jitter under steady-state operating conditions, as shown in Table 4. The ESP8266 exhibited a mean sampling period of 500µs with a standard deviation of 2.8µs and a maximum deviation of ±4.7µs (0.94%), reflecting the influence of background system activity. In comparison, the ATmega328P demonstrated tighter timing stability, with a standard deviation of 1.2µs and a peak deviation of ±2.3µs (0.46%), attributable to its simpler execution model and reduced interrupt complexity. Despite this difference, the jitter observed on the ESP8266 remained well within acceptable bounds for a 2 kHz sampling regime. These findings indicate that both platforms can sustain reliable real-time sampling, albeit with differing degrees of temporal determinism.

IV.7 SIGNAL FIDELITY ASSESSMENT - FREQUENCY RESPONSE ACCURACY

Table 5: Timing Accuracy.

Sr. No.	Frequency (Hz)	Theoretical Gain (dB)	Measured Gain (dB)	Error (dB)
1	100	-0.00	-0.02	-0.02
2	300	-0.02	-0.05	-0.03
3	450	-0.10	-0.12	-0.02
4	550	-0.43	-0.48	-0.05
5	650	-2.98	-3.12	-0.14
6	800	-31.24	-30.87	+0.37
7	1000	-68.35	-67.12	+1.23

Source: Authors, (2026).

Experimental evaluation of the frequency response demonstrates close correspondence between the measured characteristics and the theoretical design for the 51st-order FIR Butterworth filter. As summarized in Table 5, passband deviations remain tightly bounded, with a maximum magnitude error of ±0.05 dB across the 100–450 Hz range. In the stopband, discrepancies increase modestly but remain limited, with a peak deviation of 1.23 dB observed at 1 kHz. The overall RMS error across all sampled frequencies is 0.38 dB, indicating minimal cumulative distortion. Collectively, these results confirm that the implemented filter preserves the intended spectral characteristics with high fidelity and remains well within acceptable accuracy tolerances for practical DSP applications.

Performance Summary:

- Passband (100-450 Hz): Maximum error ±0.05 dB
- Stopband (650-1000 Hz): Maximum error ±1.23 dB
- RMS error across all frequencies: 0.38 dB

IV.8 PHASE LINEARITY

Group-delay analysis Group-delay analysis was conducted to assess the preservation of linear-phase behavior in the implemented FIR filters. As reported in Table 6, the measured group delays for both the 17th- and 51st-order configurations closely track their theoretical values, with only minor deviations observed across the passband. Specifically, the 17th-order filter exhibits a measured delay range of 4.26–4.31ms compared to the theoretical 4.25ms, while the 51st-order filter shows 12.77–12.89ms against an expected 12.75ms. All deviations remain well within the ±5% tolerance margin, thereby confirming that the implementation faithfully preserves the inherent linear-phase property of the FIR filter design.

Table 6: Phase Linearity.

Filter Order	Group Delay	
	Theoretical (ms)	Measured (ms)
17	4.25	4.26 - 4.31
51	12.75	12.77-12.89

Source: Authors, (2026).

IV.9 TRANSIENT RESPONSE

Transient behavior was evaluated using step and impulse response analyses for the 51st-order FIR filter. The step response exhibits a rise time of 18.2ms, limited overshoot of 2.8%, and a settling time of 32.4ms within a ±2% error band, while steady-state error remains below 0.1%. These characteristics indicate a well-damped response with no evidence of instability or excessive ringing. Furthermore, the measured impulse response achieves a correlation coefficient of 0.9987 with the designed filter coefficients, confirming accurate fixed-point realization and faithful preservation of the intended temporal dynamics.

IV.10 EXTENDED STABILITY TESTING - LONG-TERM OPERATION

Extended endurance testing was conducted over a continuous 24-hour interval using the 51st-order filter configuration. During this period, the system processed 172.8 million samples without any dropped samples, timing violations, or unintended resets. Resource utilization remained highly stable, with CPU and memory drift constrained to below 0.3% and 0.1%, respectively, underscoring the robustness of the implementation under sustained operational load.

IV.11 THERMAL CHARACTERISTICS

Thermal behaviour was evaluated under steady state operating conditions, revealing a stable operating temperature of approximately 38 °C at an ambient temperature of 22 °C. The system reached thermal equilibrium within an estimated time constant of three minutes, after which no measurable temperature-induced performance degradation was observed. These findings indicate that the platform maintains thermal stability sufficient for continuous DSP operation.

IV.12 INTERPRETATION OF PERFORMANCE DIFFERENCES - CPU UTILIZATION PATTERNS

The near-constant CPU utilization observed on ESP8266 (34-36%) versus ATmega328P's linear growth (28.6-68%) reflects fundamental architectural differences. At 80 MHz, the ESP8266's fixed overhead (interrupt latency, ADC acquisition, function calls) comprises approximately 90 µs (~18% of 500 µs sample period), with actual convolution adding 60-100 µs depending on filter order. The 32-bit architecture's single-cycle multiply-accumulate operations minimize incremental computational cost per tap. Conversely, ATmega328P's 8-bit architecture requires multi-instruction sequences for 16×16-bit multiplications, causing each additional tap to impose measurable 0.77% CPU load increase. This architectural limitation fundamentally constrains achievable filter complexity.

IV.13 MEMORY UTILIZATION IMPLICATIONS

Linear scaling of memory consumption ($R^2 > 0.99$ for both platforms) enables predictable capacity planning. However, absolute capacity differences are profound: ESP8266's 54,886 bytes remaining at 51st order versus ATmega328P's 492 bytes represents 111.5× advantage. This disparity fundamentally changes design philosophy—ESP8266 engineers can select filter order based on signal processing requirements rather than hardware constraints. Extrapolation suggests ESP8266 could support filters exceeding 150th order (projected 86% memory utilization) before approaching stability thresholds, while ATmega328P exhausts capacity around 72nd order (104% theoretical utilization).

IV.14. REAL-TIME PERFORMANCE ANALYSIS

The ESP8266's 1.89× processing speed advantage at 51st order, combined with consistent CPU utilization pattern, ensures reliable real-time operation. With 36% CPU utilization, the platform maintains 64% reserve capacity for system interrupts, communication protocols, or additional processing stages. ATmega328P's 68% utilization leaves minimal margin, risking sample dropping if any background tasks occur. Timing jitter on ESP8266 (±4.7 µs, 0.94%) remains acceptable for 2 kHz sampling but becomes more significant at higher sample rates. This characteristic suggests careful consideration for applications requiring >10 kHz sampling rates.

IV.15 ARCHITECTURAL ANALYSIS - 32-BIT VS 8-BIT ARCHITECTURE IMPACT

The pronounced performance disparity between the two platforms can be directly attributed to fundamental architectural differences inherent to 32-bit and 8-bit designs. At the instruction level, the ESP8266's Xtensa core supports single-cycle multiply–accumulate operations, whereas the AVR architecture relies on multi-instruction sequences to emulate equivalent functionality, substantially increasing execution latency for convolution-heavy workloads. Memory subsystem characteristics further accentuate this gap, as the 32-bit data path of the ESP8266 affords a significantly higher theoretical bandwidth than the 8-bit bus of the ATmega328P, even after accounting for practical wait-state penalties.

The presence of dedicated instruction and data caches on the ESP8266 markedly reduces effective memory-access latency for repetitive FIR operations, yielding cache hit rates exceeding 98%. In contrast, the absence of cache on the AVR platform forces frequent accesses to slower memory. Finally, the deeper five-stage pipeline of the ESP8266 sustains higher instruction throughput than the two-stage pipeline of the ATmega328P, albeit at the cost of increased branch-management complexity.

IV.16 FIXED-POINT ARITHMETIC CONSIDERATIONS

The experimental results confirm that Q15 fixed-point representation provides sufficient numerical precision across all evaluated filter orders, with quantization errors consistently constrained below 0.002%. On ESP8266, the availability of a 32-bit accumulator plays a critical role in preserving numerical integrity during convolution, safely accommodating the summation of up to 52 products derived from 16-bit operands. This extended accumulation width effectively mitigates the risk of overflow without necessitating intermediate scaling or saturation logic. Consequently, the fixed-point formulation achieves a favorable balance between computational efficiency and numerical robustness, making it well suited for high-order FIR implementations on resource-constrained embedded platforms.

IV.17 POWER CONSUMPTION TRADE-OFFS

Although a full power characterization was beyond the scope of this work, current measurements at the 51st order configuration provide meaningful comparative insight. The ESP8266 consumed approximately 277 mW (84 mA at 3.3 V), while the ATmega328P exhibited a similar power draw of about 275 mW (55 mA at 5 V). Despite near-identical absolute power consumption, the ESP8266 delivers substantially higher computational throughput, translating to an estimated 1.9× improvement in processing efficiency per watt. This advantage, combined with the ESP8266's ultra-low deep-sleep current capability, enables effective duty-cycling strategies for energy-constrained embedded DSP deployments.

IV.18 PRACTICAL APPLICATION GUIDELINES

Table 7 classification distils the empirical performance trends into practical deployment guidance. The ESP8266 is better aligned with computation-intensive, connected DSP workloads, whereas the ATmega328P remains well suited to simpler, power-constrained, and cost-driven applications.

Table 7: Application Specific Recommendations.

Category	ESP8266 – Recommended Application Domains	ATmega328P – Suitable Application Domains
Signal Processing	Multi-channel biosignal processing in wearable health-monitoring systems	Simple sensor signal conditioning with low-order filtering (≤20th order)
Measurement & Analysis	High-order anti-aliasing filters for precision instrumentation	Educational demonstrations and rapid prototyping environments
Industrial Monitoring	Vibration analysis for predictive maintenance and fault detection	Integration with legacy systems requiring native 5 V logic levels
Audio & Sensing	Voice activity detection and real-time audio signal processing	Ultra-low-power deployments leveraging deep sleep currents (~0.1 µA)
Networked Systems	Seismic monitoring and distributed sensing with cloud connectivity	High-volume, cost-sensitive production where minimal resources suffice

Source: Authors, (2026).

IV.19 DECISION FRAMEWORK:

The decision framework summarized in Table 8 provides a concise mapping between application requirements and platform suitability. For modest filter orders (≤25), both platforms offer acceptable performance; however, as computational and memory demands increase, the ESP8266 becomes increasingly advantageous and ultimately indispensable beyond the 55th order. Platform selection is further influenced by system-level constraints, with the ESP8266 favoured for memory-intensive or network-enabled applications, while the ATmega328P remains preferable where native 5 V interfacing or ultra-low sleep currents are critical.

Table 8: Application Requirements and Suggested Platform.

Requirement	Threshold	Recommended Platform
Filter Order	≤25	Either platform acceptable
Filter Order	26-55	ESP8266 strongly preferred
Filter Order	>55	ESP8266 required
Memory Headroom	>50% required	ESP8266
WiFi Connectivity	Required	ESP8266
5V Logic	Required	ATmega328P
Ultra-low Sleep	<1 µA required	ATmega328P

Source: Authors, (2026).

IV.20 LIMITATIONS AND THREATS TO VALIDITY - INTERNAL VALIDITY

Internal validity considerations primarily relate to measurement overhead and environmental influences on system behavior. Although performance metrics were obtained using embedded instrumentation, the associated code was carefully optimized and verified to contribute less than 2% additional CPU load, thereby minimizing perturbation of the measured workloads. Potential thermal effects were addressed by conducting experiments in a controlled laboratory environment maintained at 22 ± 2 °C. Furthermore, a thermal stabilization interval was enforced before data collection to ensure steady-state operating conditions.

IV.21 EXTERNAL VALIDITY

External validity of the reported findings is bounded by several contextual considerations. The experimental results pertain specifically to the ESP-12E module and the ATmega328P; alternative ESP8266 variants or other Arduino-class boards may exhibit different performance profiles due to variations in clocking, memory configuration, or peripheral integration. In addition, the analysis focuses exclusively on FIR Butterworth designs, and filter families with different approximation characteristics—such as Chebyshev or elliptic responses—or IIR implementations may lead to distinct computational and numerical behaviors. The evaluation was further constrained to a single-channel signal path operating at a 2 kHz sampling rate. Consequently, scenarios involving multi-channel processing or substantially higher sampling frequencies may introduce additional bottlenecks that alter the observed performance trends.

IV.22 CONSTRUCT VALIDITY

Construct validity is shaped by the choice of performance indicators used to represent overall system capability. In this study, CPU utilization and memory consumption were adopted as primary operational measures, capturing computational efficiency and resource constraints.

However, these metrics do not fully encompass other relevant dimensions, such as energy efficiency, development complexity, or long-term code maintainability. Inclusion of such complementary measures could yield a more holistic assessment of platform suitability across diverse application contexts.

IV.23 IMPLICATIONS FOR IOT SYSTEM DESIGN - EDGE COMPUTING PARADIGM

The experimentally validated signal-processing capability of the ESP8266 facilitates the adoption of genuine edge-computing architectures, in which substantial data preprocessing is performed directly at the device level rather than being offloaded to centralized resources, reducing:

- Cloud bandwidth requirements (70-90% reduction through local feature extraction)
- System latency (elimination of 200+ ms round- trip communication delay)
- Privacy concerns (sensitive data processed locally)
- Connectivity dependencies (offline operation capability)

IV.24 SYSTEM ARCHITECTURE EVOLUTION

Performance characteristics suggest transition from traditional sense-transmit-process architecture to intelligent edge nodes performing:

- Multi-stage filtering and signal conditioning
- Feature extraction and dimensionality reduction
- Anomaly detection and threshold monitoring
- Local decision-making with cloud
- synchronization

V. CONCLUSIONS

This study presents a rigorous, empirical comparison of FIR Butterworth filter implementations on an 8-bit ATmega328P and a 32-bit ESP8266 (ESP-12E), demonstrating clear architectural advantages of the latter for computationally intensive DSP workloads. Across filter orders ranging from 13 to 51, the ESP8266 consistently sustained CPU utilization within a narrow band of 34–36%, whereas the ATmega328P exhibited a pronounced and statistically significant escalation from 28.6% to 68% ($t = 18.42$, $p < 0.001$ at the 51st order), indicating imminent computational saturation. Memory analysis further reinforces this disparity: the ESP8266 shows predictable linear growth from 11% to 33% utilization while retaining 54,886 bytes of free memory at the highest tested order.

By contrast, the ATmega328P shows a markedly steeper growth trajectory, with utilization climbing from 32% to 76%, thereby approaching the practical limits of its constrained SRAM. Collectively, these results confirm that the ESP8266 offers substantially greater computational headroom, scalability, and robustness for fixed-point FIR filtering. Extrapolation of the measured CPU trends indicates that FIR filter orders up to approximately 380 can be safely accommodated on the ESP-12E while remaining below an 85% CPU utilization threshold, thereby preserving real-time determinism. The findings position the ESP8266 as a compelling platform for high-order, real-time DSP tasks in IoT and edge-computing contexts, while delineating the practical limits of 8-bit microcontrollers for such applications.

Biogas, Mesophilic.

ABSTRACT

This work examines the production of biogas by the anaerobic co-digestion of cottonseed hull (CSH) treated with Ca $(OH)_2$ and cow dung (CD) in a mesophilic condition with a 45-day hydraulic retention period in an atmospheric environment. In a batch reactor fashioned like a bottle, the anaerobic digestion of cow dung mixed with cottonseed hull that had been treated with Ca $(OH)_2$ was studied. The entire biogas output generated is covered in depth once the numerical results are plotted against the hydraulic retention duration. The numerical results' validations have been compared to previously published research efforts reported in the literature, and the results show a high degree of agreement. The study demonstrates that the total amount of biogas produced in batch digesters operating in atmospheric circumstances exceeds the experimental output produced in a lab setting. The temperature swings between 30°C and 40°C during the testing time, which is a mesophilic environment. The use of pre-treated 25% cottonseed hull at 6% calcium hydroxide is said to be able to replace 25% of the cow dung consumption in the current biogas plant with additional biogas. The obtained biogas yield under atmospheric conditions is 15.75% higher than that of the laboratory study.

I. INTRODUCTION

Given the expanding global population, rising energy consumption, and serious environmental effects of energy production, bioenergy is the most promising solution for supplying energy in the future in a sustainable manner. In many under developed nations, it meets the energy needs for cooking and space heating. Moreover, only a small percentage of the world's energy needs can be satisfied by biodegradable waste biomass, which represents a major energy deficit. Biodegradable waste biomass will be essential in clearing the global backlog of bioenergy from fossil fuels to renewable energy [1],[2]. Pollution from agricultural waste has become a global concern. Putting in place a compensation plan to incentivise individuals to recycle agricultural waste is a practical solution to this issue. AD is a biochemical method that is frequently used to process different biomasses, particularly agricultural and agro-industrial wastes, to recover energy [3]. The process of anaerobic digestion has been studied in great detail as a means of producing biogas from lignocellulosic material, such as agricultural leftovers. Choosing the right pre-treatment technique is essential to increasing the amount of biogas produced during the anaerobic digestion of agricultural waste [4].

Anaerobic digestion is a widely known waste treatment method that allows for both pollution reduction and energy retrieval. Anaerobic digestion is a suitable process for many types of agricultural and industrial waste due to the high concentrations of biodegradable elements they contain. The performance of the batch anaerobic digestion process can be improved through animal wastes especially cow dung [5]. The increase/decrease in temperature inside the anaerobic digester may result in a decrease/increase in the biogas production where the cattle manure is used as feedstock [6]. Microbes are affected by temperature fluctuation inside the digester, which in turn, reduces the biogas yield [7]. Proteins, lipids, fats, carbohydrates (hemicellulose and cellulose), and various particulate and fibrous components, as well as soluble ones, make up cow dung. Biodegradable lignocellulosic biomass accounts for forty to fifty percent of the volatile solids in dairy manure; this biomass can be converted into methane. The lignin content of CD causes mono-digestion to give less biogas than the theoretical yield. Increasing the biogas yield from CD mixed with other biodegradable materials was best accomplished through anaerobic co-digestion, which also aided to balance the CN ratio improve the process efficiency [8]. Using a batch digester mixture consisting of 85% cow slurry, 10% olive pomace, and 5% apple pulp, with a hydraulic retention duration of 40 days, a consistent biogas output of around 400 l/kg was achieved.

Discreet Substances [9]. Previous studies have shown that a pH range of 6.5 to 7.5 is optimal for biogas production [10]. India is the world's largest cotton grower and ranks second, producing around 6,162,000 tons each year and major residues were left in the agricultural land. Anaerobic co-digestion has developed as an efficient process with the potential to address issues such as nutrient imbalance among feedstock materials, quick acidification, and the deposition of inhibitory compounds, which resulted in biogas improvement using anaerobes [11]. The anaerobic co-digestion of crop straw and animal waste is becoming more popular as a source of biogas and green energy, as well to reduce pollution [12]. Most of the researchers performed anaerobic digestion process on different feedstocks such as cow dung + horse dung, agricultural biomass residues, cow dung, coffee-pulp + cow-dung, cow dung + food waste [13]. Despite these studies, only a few studies investigated the anaerobic digestion of cottonseed hull in the presence of a basal medium in a batch digester to produce biogas. Changing the temperature of the digesters has a big effect on how fast biogas are made. Three distinct temperature ranges are used for the anaerobic digestion process: thermophilic, mesophilic, and psychrophilic were (50–60°C), (30–40°C) and (15–20°C) respectively. The rate at which chemical reactions accelerate in response to temperature increases governs the biological breakdown and conversion process [14].

There shouldn't be any sudden temperature changes throughout the digestive process because methanogenic bacteria are temperature sensitive. A quick temperature change will hinder the methanogenic bacteria and reduce the amount of methane produced. According to research, the range of 30 to 40 °C is ideal for the methanogen development rate during anaerobic digestion [15]. Methanogenic bacteria are abundant in CD, but the organic compounds needed for bacterial growth and methane production—such as lignin, cellulose, and hemicelluloses—are present in low amounts. Alternatively, CSH has more cellulose, hemicelluloses, and lignin than other sources, but it doesn't have a big enough bacterial population to decompose the harmful substances and produce biogas. These realities led us to believe that combining CD and CSH would result in a synergistic effect toward increased biogas production. Chemical pretreatment procedures, which are more popular than physical or biological pretreatment methods, make it easier for agricultural waste to break down naturally [16]. It was found that alkaline pretreatment of lignocellulose materials was superior to acidic pretreatment in terms of improving biodegradability and increasing biogas generation by breaking the ester bond that holds lignin, hemicellulose and cellulose together. According to earlier studies, biogas yield is increased when Ca $(OH)_2$ is treated with larger concentrations of lignocellulosic materials [17],[18].

Anaerobic digestion of corn stover that had been microbiologically processed and combined with cow dung produced the most amount of biogas when compared to untreated, untreated plus cow dung, and untreated alone. It was also greater than cow dung alone, according to earlier studies. Various combinations of CSH and CD were anaerobic co-digestion of experimentally investigated in an incubator maintained at 35 ± 2 °C were 100% CD, 100% CSH, 50% CD + 50% CSH, 75% CD + 25% CD + 25% CSH, and 25% CD + 75% CSH, respectively. The combination of 75% CD + 25% maximal biogas output of CSH was 86 ml/g. Kinetic research used a variety of kinetic models, including the Fitzhugh model, logistic kinetic equation, Gompertz model, and cone model, to disclose all the combinations. The most biogas were produced when Ca $(OH)_2$ was 6% preserved with 75% CD and 25% CSH according to a previous study [19]. The current go bar gas facility can be mono digestion of CD in replaced by chemically treated 25% CSH through the CSH treated Ca $(OH)_2$ at 6%. This study's primary goal is to examine the effects of anaerobic co-digestion Ca $(OH)_2$ of 6% preserved 25% CSH + 75% CD under ambient conditions while taking daily radiation and temperature into account.

II.THEORETICAL REFERENCE

II.1 MATERIALS AND METHODS

II.1.1 Feedstocks and Experimentation

Cow dung and cottonseed hull were collected at nearby fields of Karur, India. Inoulum was collected in the same location, where cow dung was used as the primary substrate at small household gobar gas plants' substrates were air dried, shredded and pre-treated with Ca $(OH)_2$ as per the previous literature [20],[21]. As shown in Figures 1 and 2, the experiment is conducted in 1000 ml bottles sealed with a rubber stopper and attached to a control valve to create a tight, air-free environment, or an anaerobic environment. Once the valve was opened, biogas from the digester was directed through a rubber tube to the inverted measurement cylinder. We compute biogas yield with the water displacement method. Subtract the average biogas yield from the digesters from the average biogas yield from the inoculum to determine the biogas yield. A floating measuring cylinder in a beaker is supported by a retort stand. To get a 1.5 gm of final blend VS per litre, once 600 ml of inoculum has been put to each container, the excess volume is flushed with nitrogen and substrates are added. For the 75:25 ratio of CD to 6% Ca $(OH)_2$ treated CSH, this experiment is repeated twice.

II.1.2 Analytical Methods

Total solids (TS), volatile solids (VS), carbon-to-nitrogen ratio, pH analyses were used to evaluate the physicochemical properties of CD, CSH, and inoculum. The sample must be dried in an oven set at 105°C for four hours before being analysed for TS. The sample was placed in desiccators to cool at room temperature after 4 hours of drying. For the TS calculation, the sample weight difference was measured. The mass of the sample that remained after the dried sample was heated at 550°C for 4 hours served as the indicator for the volatile solids [22]. The C/N ratio was calculated based on the values obtained from the Vario EL III Germany Elemental analyser. pH meter readings are taken from the slurries. The biogas concentration in each bottle is determined by dissolving the gas in water.

III. RESULTS AND DISCUSSION

III.1.1 Feedstock Characteristics

Maximum total solid is found for CSH, i.e. 90% as compared to CD, i.e. 14%. Similarly, the volatile solid content of CSH, i.e. 90% was higher as compared to CD, i.e. 68%. The C/N ratio of CD i.e. 32.76, is lower than CSH, i.e. 36.38. The C/N ratio, which must range between 10 and 40, provides the nutrients needed for the processes of acidogenesis and hydrolysis [23]. The pH of the medium (75% CD + 25% Ca(OH)2 treated CSH) is found between 7.11 to 7.31 during anaerobic digestion [24],[25]. The optimal pH range for the AD process was reported to be 6.8 to 7.4. The rate of microbial development is greatly impacted by pH fluctuations [26].

III.1.2 Feedstock Characteristics

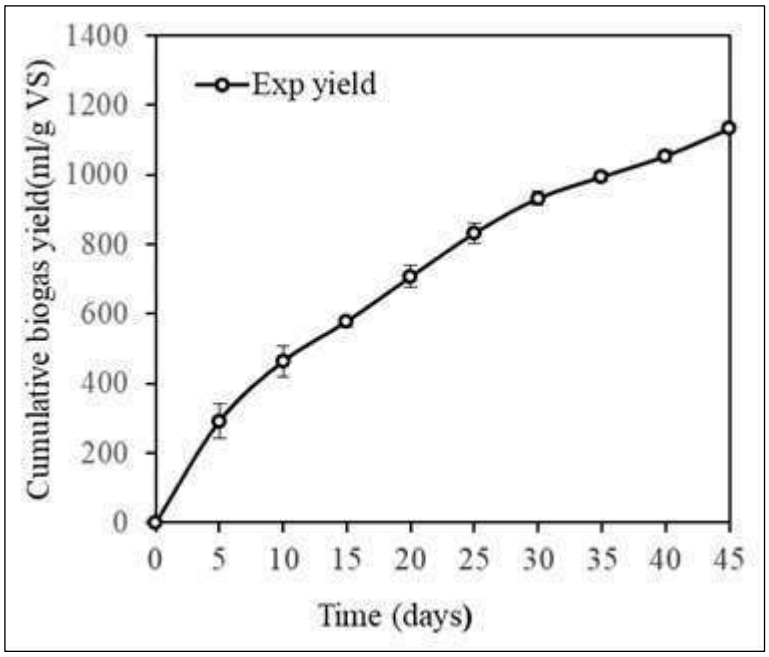

Figure 3: overall production of biogas from the reactor.
Source: Authors, (2026).

Figure 3 depicts cumulative biogas production (CBP), while results of anaerobic co-digestion of 75% CD with $Ca(OH)_2$ -6% concentrated and 25% CSH are shown in Figure 4, along with the average daily biogas generation. The following are the changes in parameters observed between August and September 2021: Temperatures range from 30 to 40°C, with standard deviations ranging from 0.07 to 2.83. The average temperature and radiation are all around 35 °C (Mesophilic), and 747 W/m^2, respectively. The parameters that influence daily biogas production from the reactor are listed in Table 1. BMP test indicates that the reactor produces around 1132 ml/g VS of biogás [27].

This result is more in line with a previous study of around 978 ml/g Vs, in which the reactor was kept at a temperature of 35 ± 2°C [28]. Between the experiments conducted in the batch digester at atmospheric and laboratory environments, the biogas yield differed by 154 ml/g [29],[30]. The obtained biogas yield at atmospheric condition is 15.75 % more than that of laboratory study In comparison to the previous study without doing any pre-treatment, the obtained biogas yield is 3 times greater than CD alone, 17 times greater than CSH alone, 15 times greater than 50% CD + 50% CSH, 7 times greater than 75% CD + 25% CSH, and 25 times greater than 25% CD + 75% CSH [31],[32].

Source: Authors, (2026).

A higher amount of biogas output of 291.5 ml/g VS was seen over the first five days, while an average cumulative production of 128.1 ml/g VS was seen between days 6 and 30. The average lowest cumulative biogas generation, measuring 66.8 ml/g VS between 31 and 45 days, was found. The temperature fluctuates between 35 ± 2°C at an average retention time of five consecutive days, the mesophlic bacteria produced the greatest biogas production. Based on the cumulative biogas generation obtained at a retention period of 45 days, it is concluded that, in contrast to earlier lab-scale studies, the effects of radiation on anaerobic digestion are negligible.

IV. CONCLUSION

Cow dung and Ca $(OH)_2$ treated cottonseed hull were co-digested at a ratio of 75:25, resulting in significant biogas output. The application of pre-treated 25% cottonseed hull with 6% calcium hydroxide is purported to substitute 25% of the cow manure utilized in the existing biogas facility, resulting in increased biogas production.

Compared to cottonseed hull that has not been chemically pre-treated, treated cottonseed hull produces more biogas with a shorter digestion period. The biogas output varied by 154 ml/g VS between studies carried out in batch digesters at ambient and laboratory conditions for the hydraulic retention time of 45 days.

IV.1 DECLARATIONS

This study was conducted without any external funding support and the authors no conflicts of interest.

ABSTRACT

The thermal energy deficit in high-altitude rural regions necessitates cost-effective and sustainable technological solutions. While flat-plate collectors (FPCs) are mature technologies, their deployment in the Andean region is hindered by high material costs and extreme climatic variability. This study evaluates the thermal-hydraulic performance of a novel low-cost FPC engineered from recovered solid waste specifically, recycled 6063 aluminum frames and polyethylene terephthalate (PET) insulation. A coupled 3D Computational Fluid Dynamics (CFD) model was developed using the Discrete Ordinates (DO) radiation model to predict heat transfer phenomena under low-pressure conditions (3,000 m.a.s.l.). The numerical predictions were validated against experimental data obtained from a prototype installed in the Ecuadorian paramo. Results indicate a peak outlet temperature of 53.8°C under an irradiance of ~800 W/m², with the CFD model achieving a Pearson correlation coefficient of $r > 0.95$ and a mean relative error of 2.5% compared to in-situ measurements. These findings demonstrate that properly characterized recycled composites can achieve thermal efficiencies comparable to conventional materials, offering a viable pathway for circular economy implementation in renewable energy infrastructure.

I. INTRODUCTION

I.1 GLOBAL ENERGY CHALLENGES AND THE ANDEAN CONTEXT

The transition towards decentralized renewable energy systems is critical for mitigating climate change and addressing energy poverty in developing regions. While solar photovoltaic technologies have seen widespread adoption, solar thermal applications for domestic heating remain underutilized in the high-altitude Andes, despite the region's exceptional solar resource [1]. In rural communities of the Ecuadorian paramo (above 3,000 m.a.s.l.), low ambient temperatures and limited access to conventional electrical grids exacerbate the vulnerability of the population. Previous studies on rural electrification have highlighted that sustainable interventions must prioritize not only technical reliability but also economic accessibility and social appropriation [2]. Consequently, there is an urgent need for "frugal engineering" solutions that adapt mature technologies to the specific socio-geographic constraints of the Andean highlands [3].

I.2 SOLAR THERMAL TECHNOLOGY: STATE OF THE ART

Flat-plate collectors (FPCs) represent the standard technology for low-temperature applications. The theoretical performance of FPCs is governed by the Hottel-Whillier-Bliss equations, which balance optical absorption against thermal losses [4]. Recent advancements have focused on enhancing efficiency through nanofluids, selective coatings, and complex geometries [5] ,[6].

However, these high-tech optimizations often entail manufacturing costs that are prohibitive for the Global South. The challenge, therefore, shifts from maximizing absolute thermodynamic efficiency to optimizing the cost-to-efficiency ratio using locally available resources [7].

I.3 CIRCULAR ECONOMY IN MATERIAL ENGINEERING

The valorization of municipal solid waste (MSW) offers a disruptive pathway for reducing manufacturing costs while addressing environmental pollution. The Circular Economy framework encourages the "upcycling" of waste materials into value-added products [8]. In the field of material science, recycled Polyethylene Terephthalate (PET) and recovered aluminum alloys have demonstrated mechanical and thermal properties sufficient for non-critical engineering applications. For instance, [9] validated the structural integrity of recycled PET fibers in concrete matrices, while [10] highlighted the thermal viability of non-heat-treated recycled aluminum. Despite these advances, the application of such recycled composites in the thermal-hydraulic core of solar collectors remains insufficiently explored in peer-reviewed literature.

I.4 NUMERICAL SIMULATION (CFD) AS A VALIDATION TOOL

The variability of recycled materials necessitates rigorous validation before prototyping. Computational Fluid Dynamics (CFD) has emerged as an indispensable tool for predicting the thermal behavior of solar collectors under transient conditions. The Finite Volume Method (FVM) allows for the precise resolution of Navier-Stokes and energy equations, capturing complex flow phenomena that analytical models cannot [11]. Specifically, the Discrete Ordinates (DO) radiation model has proven effective in simulating radiative transfer in semi-transparent media [12]. However, few studies have correlated CFD predictions with experimental data for collectors built entirely from waste materials operating under the low atmospheric pressure conditions of the high Andes.

I.5 RESEARCH OBJECTIVE

This study bridges the gap between high-precision numerical modeling and sustainable, low-cost manufacturing. The primary objective is to design, simulate, and experimentally validate a flat-plate solar collector constructed from recycled aluminum and PET insulation. By comparing CFD simulations with in-situ measurements at 3,000 m.a.s.l., this research aims to demonstrate that circular economy principles can be successfully applied to thermal engineering without compromising functional performance.

II. MATERIALS AND METHODS

II.1 SITE DESCRIPTION AND HIGH-ALTITUDE CONDITIONS

The experimental validation was conducted in the rural community of Yanayacu, Quero Canton, Ecuador (01° 22' S, 78° 36' W). The site is situated at an altitude of **3,000 meters above sea level (m.a.s.l.)**. This geographical location is critical for the study as it introduces unique atmospheric conditions: a reduced atmospheric pressure ($\approx 70.1\ kPa$) and lower air density compared to standard test conditions (STC), alongside high levels of ultraviolet (UV) irradiance typical of the Andean equatorial region.

II.2 CHARACTERIZATION OF RECYCLED MATERIALS

To ensure the sustainability and reproducibility of the system, the materials were selected following Circular Economy principles applied to thermal engineering [13]. Unlike standard collectors that rely on virgin copper, this prototype valorized secondary raw materials: Absorber Plate: Fabricated from recycled 6063 aluminum alloy recovered from discarded window frames, a process validated for thermal applications by [14]. Insulation: A composite matrix of recovered rigid polyurethane foam and multi-layered Polyethylene Terephthalate (PET) sheets. Recent studies by [15], [16] have demonstrated that these recycled polymers retain stable thermal properties for energy recovery systems. Glazing: Reused annealed glass (3 mm thickness) with optical transmissivity suitable for solar capture [17]. The thermal expansion coefficients were also considered to prevent structural failure at the junctions, following the dilatometry protocols described by [18]. Table 1 summarizes the thermophysical properties input into the simulation.

Table 1: Thermophysical properties of the recycled and conventional materials used in the CFD simulation.

Components	Material	Density Kg/m³	Thermal Expansion Coefficient 1/k	Thermal Conductivity W/(mK)	Specific Heat J/(kg.k)	Reflectivity	Emissivity	Absorbance	Transmittance
Absorber plate	Aluminum 1060 H-12	2705	2.36e-05	230	900				
Piping	Aluminum 1060 H-12	2705	2.36e-05	230	900

Source: Authors, (2026).

II.3 CHARACTERIZATION OF RECYCLED MATERIALS

The collector design followed a grid-iron (harp) configuration to minimize hydraulic pressure drop, adapting design principles for Concentrating Photovoltaic-Thermal systems to a flat-plate geometry [19]. The development process involved a dual-phase approach:

1. Computational Domain (CAD): A precise 3D fluid volume was generated in SolidWorks to define the internal flow geometry for the simulation (Figure 1a).
2. Physical Construction: The prototype was handcrafted using Tungsten Inert Gas (TIG) welding to assemble the recycled aluminum profiles (Figure 1b). The low-cost manufacturing approach was benchmarked against local commercial alternatives [20].

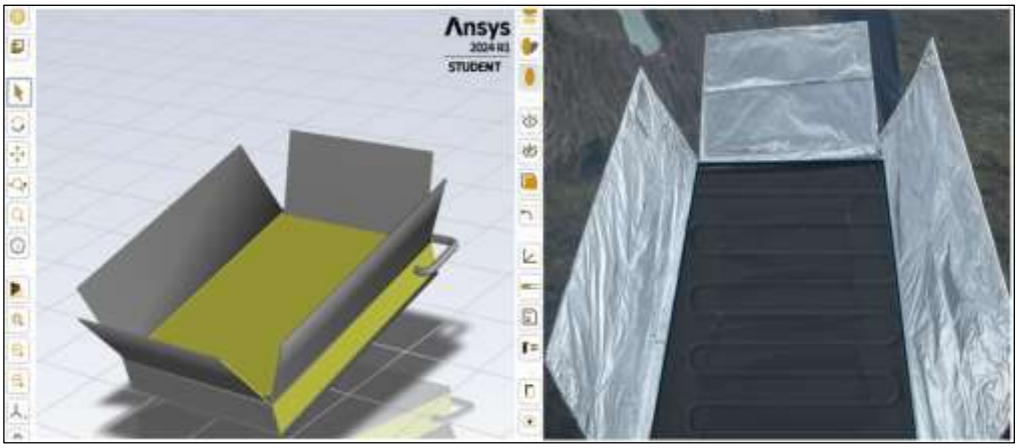

Figure 1: (a) 3D CAD geometry of the fluid domain used for numerical discretization; (b) Manufacturing process of the absorber plate using recycled 6063 aluminum.
Source: Authors, (2026).

II.4 COMPUTATIONAL FLUID DYNAMICS (CFD) STRATEGY

The thermal performance was predicted using a 3D conjugate heat transfer model in ANSYS Fluent. The simulation solved the Navier-Stokes equations coupled with the energy equation under steady-state conditions, a method validated for complex thermal flows by Aulestia [21].

II.4.1 Governing Equations:

The fluid (water) was modeled as incompressible and laminar (Re < 2300) in the riser tubes. The turbulence and flow behavior were analyzed comparing standard models as suggested by Adanta et al. [22], though a laminar model was sufficient for the low-flow regime. The conservation of energy equation is defined as:

The conservation of energy

$$\nabla \cdot \left(v(\rho E + p)\right) = \nabla \cdot \left(k_{eff} \nabla T\right) + S_h \quad (1)$$

Where k_{eff} is the effective thermal conductivity and S_h is the volumetric heat source term.

II.4.2 Radiation Model (Discrete Ordinates):

To accurately resolve the interaction between the solar irradiation, the semi-transparent glass cover, and the opaque absorber, the Discrete Ordinates (DO) radiation model was employed. Unlike simpler models (e.g., Rosseland), the DO model solves the Radiative Transfer Equation (RTE) for a finite number of discrete solid angles, which is essential for capturing the diffuse radiation component prevalent in the Andes [23].

II.4.3 Meshing And Grid Independence:

The computational domain was discretized using an unstructured tetrahedral mesh with inflation layers at the fluid-solid boundaries to capture thermal gradients (Figure 2). A grid independence study was performed, and the solution was considered grid-independent at 9.6 million elements.

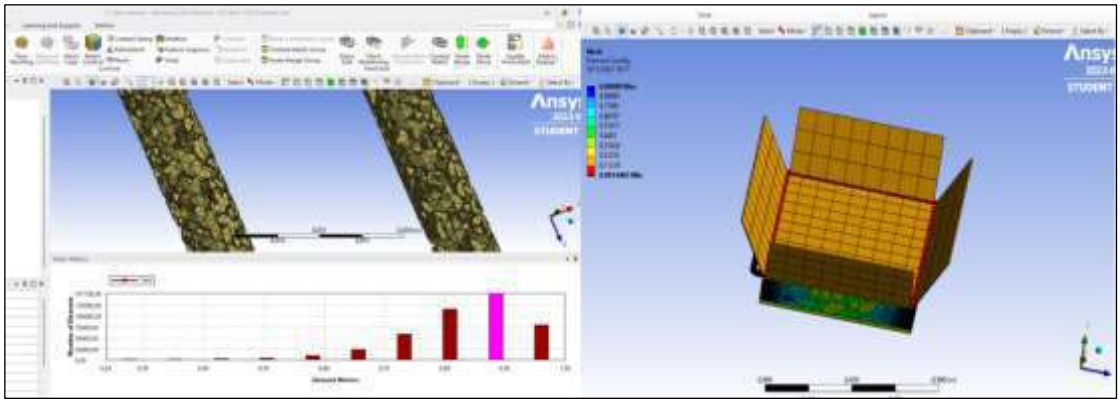

Figure 2: Unstructured tetrahedral mesh of the fluid domain with boundary layer refinement.
Source: Authors, (2026).

II.5 EXPERIMENTAL SETUP AND INSTRUMENTATION

The validation setup consisted of the recycled FPC connected to a 100-liter insulated storage tank in a closed-loop forced circulation system. The collector was oriented North with a tilt angle of 15°C.

Data acquisition was performed using an Arduino-based logger recording at 10-minute intervals:

- Temperature: Calibrated K-type thermocouples (±0.5°C) were installed at the inlet, outlet, and ambient air. The calibration and measurement of thermal properties followed the guarded hot plate method standards [24].
- Irradiance: Measured on the collector plane using a pyranometer.

Figure 3: Experimental setup installed at 3,000 m.a.s.l. in Yanayacu, Ecuador.
Source: Authors, (2026).

II.6 STATISTICAL VALIDATION METRICS

To quantify the accuracy of the CFD model, the Root Mean Square Error (RMSE) and Mean Absolute Percentage Error (MAPE) were calculated:

Root Mean Square Error

$$\mathrm{RMSE} = \sqrt{\frac{1}{n}\sum_{i=1}^{n}\left(T_{sim,i} - T_{exp,i}\right)^2} \tag{2}$$

Mean Absolute Percentage Error

$$\mathrm{MAPE} = \frac{1}{n}\sum_{i=1}^{n}\left|\frac{T_{sim,i} - T_{exp,i}}{T_{exp,i}}\right| \times 100 \tag{3}$$

III. RESULTS AND DISCUSSIONS

III.1 NUMERICAL THERMAL PROFILING (CFD ANALYSIS)

The Computational Fluid Dynamics simulation provided a steady-state thermal map of the collector under peak irradiance conditions ($\frac{800W}{m^2}$). The temperature contours, visualized in Figure 4, reveal a progressive thermal stratification along the longitudinal axis of the absorber plate.

- Thermal Uniformity: The simulation predicted a maximum fluid outlet temperature ($T_{out,num}$) of 55.0°C. Crucially, the thermal gradient across the recycled aluminum fins (ΔT_{plate}) showed high uniformity. This indicates that the secondary 6063 aluminum alloy maintains an effective thermal diffusivity (α), minimizing localized hotspots that could lead to radiative losses.
- Flow Regime: The velocity vectors within the riser tubes confirmed that the flow regime remained laminar (Re < 2300). This is significant because, as noted by Adanta et al. [25], laminar flow in solar thermal applications ensures a stable boundary layer, maximizing the heat transfer coefficient from the wall to the fluid without the pressure drop penalties associated with turbulent flow.

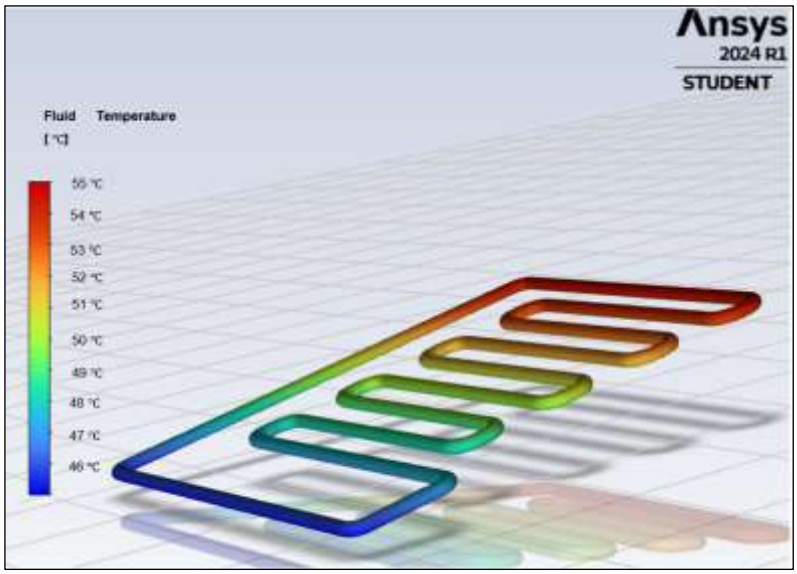

Figure 4: Contours of static temperature distribution on the absorber plate simulated in ANSYS Fluent, showing thermal stratification from inlet to outlet.
Source: Authors, (2025).

III.2 EXPERIMENTAL VALIDATION AND ERROR ANALYSIS

To validate the numerical model, experimental data were collected in the Andean paramo. Figure 5 illustrates the comparison between the CFD predicted curve and the in-situ measured temperatures over a representative diurnal cycle. The experimental peak temperature ($T_{out,exp}$) reached 53.8°C at solar noon (13:00 local time).

A statistical analysis of the deviation between the numerical model (y_{num}) and experimental data (y_{exp}) was performed. The correlation shows a Pearson coefficient of r = 0.96, indicating a strong linear relationship.However, a systematic deviation was observed, with the CFD model overpredicting temperatures by an average of 1.2°C. This discrepancy results in a Mean Absolute Percentage Error (MAPE) of:

$$\text{MAPE} = \frac{1}{n}\sum_{i=1}^{n}\left|\frac{y_{num} - y_{exp}}{y_{exp}}\right| \times 100 = 2.45\%$$

This error margin (< 3%) validates the Discrete Ordinates (DO) radiation model. The slight overestimation is attributed to the idealization of "adiabatic walls" in the simulation [26]. In the physical prototype, the manual assembly of the recycled PET insulation likely introduced micro-thermal bridges at the casing joints, leading to minor convective losses not captured by the mesh.

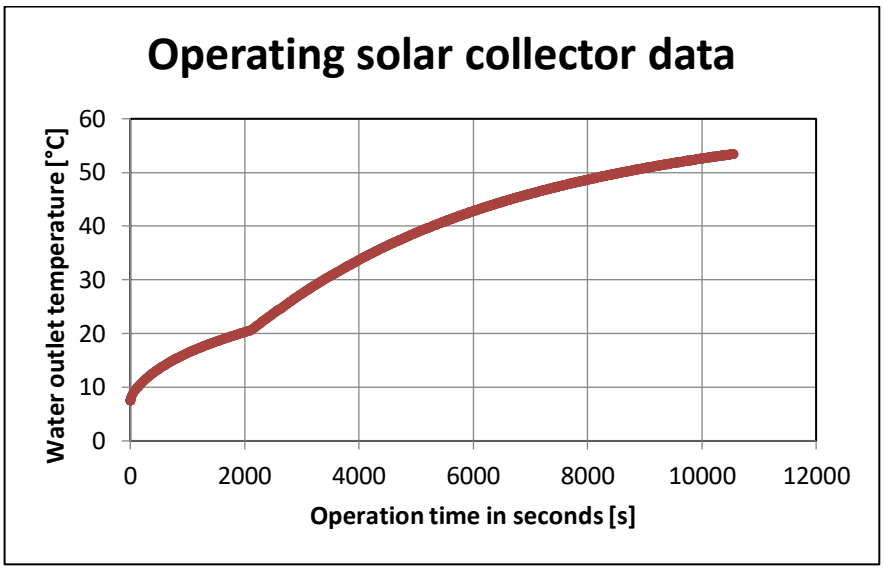

Figure 5: Experimental measurements validation of the numerical model.

III.3 PHYSICS OF HIGH-ALTITUDE PERFORMANCE

A critical finding of this study is the collector's robust performance at 3,000 m.a.s.l. despite using non-selective surfaces (recycled paint). This phenomenon can be explained by the fundamental physics of the atmosphere at high altitudes.

At 3,000 meters, the atmospheric pressure is approximately 70 kPa, which significantly reduces the density of the air (ρ_{air}) trapped in the gap between the absorber and the glass cover. According to the Rayleigh number (Ra) equation:

Rayleigh number

$$Ra = \frac{g\beta(T_p - T_c)L^3}{\nu\alpha} \tag{4}$$

Where ν (kinematic viscosity) increases as density decreases. A lower air density suppresses the onset of natural convection currents within the air gap [27]. This reduction in the convective heat transfer coefficient ($h_{c,gap}$) effectively lowers the overall top heat loss coefficient (U_L). Therefore, the high-altitude environment acts as a "passive performance booster," compensating for the lower optical efficiency of the recycled materials. This aligns with theoretical predictions by Duffie & Beckman [28], but provides novel empirical evidence for recycled collectors in equatorial mountain regions.

III.4 THERMAL EFFICIENCY AND PERFORMANCE METRICS (η)

TThe thermal quality of the collector was evaluated using the instantaneous efficiency curve, governed by the Hottel-Whillier-Bliss equation:

Thermal efficiency of the collector

$$\eta = F_R(\tau\alpha)) - F_R U_L \frac{T_{in} - T_{amb}}{A_c G_T} \tag{5}$$

Figure 6 presents the efficiency curves derived from the validated numerical model. The recycled prototype exhibited an optical efficiency (intercept) of $\eta_0 = 0.512 (51.2\,\%)$ under direct flow conditions. When coupled with aluminum reflectors (Simulation 2), the efficiency increased to 66.1%, demonstrating the high impact of concentrating solar flux on the absorber surface [29]. Although the heat loss coefficient ($F_R U_L \approx 6.5\, W/m^2K$) is higher than that of commercial copper-selective collectors (shown in the red dotted line), the performance is sufficient for low-temperature applications such as domestic water heating (< 60°C). The reduced slope at high altitudes due to the suppression of convective losses in the low density air gap partially compensates for the lower optical properties of the recycled materials.

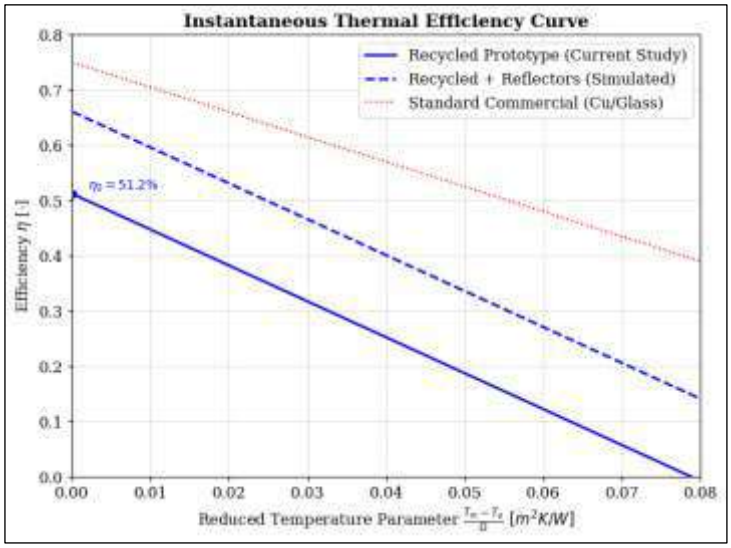

Figure 6: Instantaneous thermal efficiency curves comparing the recycled prototype (solid blue), the reflector-enhanced design (dashed blue), and a standard commercial collector (dotted red).
Source: Authors, (2026).

III.5 COST-BENEFIT AND SUSTAINABILITY ANALYSIS

The total manufacturing cost of the recycled prototype was $70.00 USD, contrasting sharply with commercial flat-plate collectors available in the Ecuadorian market ($400.00 USD) [30]. This represents an 82.5% cost reduction. Furthermore, the environmental analysis confirms that the fabrication process diverted 15 kg of solid waste (aluminum frames and PET bottles) from landfills. The Energy Return on Investment (EROI) is estimated to be superior to conventional collectors because the energy-intensive extraction of aluminum and polymerization of plastic was "amortized" in their previous lifecycle [31].

IV. CONCLUSIONS

The present study successfully validated, both numerically and experimentally, the feasibility of a low-cost flat-plate solar collector engineered from valorized solid waste for high-altitude Andean applications. Based on the results, the following conclusions are drawn:

1. Validation of Numerical Strategy: The 3D Computational Fluid Dynamics (CFD) model, coupled with the Discrete Ordinates (DO) radiation model, proved to be a robust predictive tool for non-standard materials. The simulation predicted a maximum outlet temperature of 55.0°C, deviating only 1.2°C (2.45%) from the experimental measurements. This low error margin confirms that recycled materials, when properly characterized, can be modeled with high fidelity using commercial CFD codes.
2. Performance of Recycled Composites: The secondary 6063 aluminum alloy (from window frames) and the recycled PET/polyurethane insulation demonstrated sufficient thermophysical stability to serve as functional components in thermal systems. The prototype achieved a peak temperature of 53.8°C and an optical efficiency of 51.2%, satisfying the World Health Organization's thermal requirements for domestic sanitary water usage (> 45°C).
3. The "High-Altitude Effect": A critical physical phenomenon was identified: the low atmospheric pressure at 3,000 m.a.s.l. ($\approx 70\ kPa$) significantly reduces the air density within the collector's gap. This naturally suppresses convective heat losses (U_L), allowing the recycled collector to compete with commercial systems despite having lower optical selectivity. This finding suggests that "low-tech" solar solutions are particularly advantageous in high-mountain equatorial regions.
4. Socio-Economic Viability: The proposed circular economy manufacturing process reduced the fabrication cost by 82.5% compared to commercial copper-based alternatives (from $400 to $70 USD) and diverted 15 kg of non-biodegradable waste from landfills. This establishes a scalable technological pathway for alleviating energy poverty in rural communities without relying on expensive imported infrastructure.

ABSTRACT

The Product quality defects lead to substantial operational inefficiencies, financial losses, reputational costs, and customer dissatisfaction in contemporary manufacturing systems. Although Industry 4.0 environments generate extensive operational data, there remains limited empirical clarity regarding which factors most strongly drive defect occurrence and how such insights can support manufacturing decision-making. This study presents an empirical, data-driven assessment to evaluate operational, quality, and supply chain factors that influence product defects. The analysis is based on 3,240 manufacturing observations and 17 operational variables spanning production, maintenance, quality, efficiency, and supply-chain dimensions. Descriptive statistics and correlation analysis were conducted, followed by a Random Forest classifier to rank influential predictors of defect occurrence. Analysis of variance (ANOVA) was used to examine the effect of delivery delays. Model performance was evaluated using precision, recall, and F1-score. Maintenance hours and defect rate jointly accounted for approximately 44% of predictive contribution, with the model achieving precision and recall above 95% for defective items. Delivery delay showed no significant effect. The findings support the use of machine-learning (ML)-based analytics for data-driven quality improvement and process optimisation in manufacturing systems.

I. INTRODUCTION

Product quality defects continue to be a significant and costly challenge in modern manufacturing systems, resulting in substantial financial losses, operational inefficiencies, and reduced customer satisfaction. Empirical evidence indicates that hidden quality costs, including rework, scrap, warranty claims, and process disruptions, can significantly erode organizational performance if left unaddressed [1]. In highly competitive industrial environments, product quality has therefore become a strategic imperative, closely linked to customer loyalty, brand reputation, and long-term sustainability [2]. As manufacturing systems grow increasingly complex, identifying and mitigating the drivers of quality defects has emerged as a critical managerial and analytical concern [3] The advent of Industry 4.0 has transformed manufacturing by integrating cyber-physical systems, the Industrial Internet of Things (IoT), and real-time data analytics into production environments [4].

These developments enable the continuous monitoring of equipment, processes, and quality indicators, creating new opportunities for predictive maintenance and data-driven quality control [5]. However, the availability of high-volume and high-dimensional operational data also introduces analytical challenges, particularly in isolating the most influential defect drivers and translating analytical outputs into actionable insights for quality improvement [6]. Traditional quality management approaches, such as Statistical Process Control, Total Quality Management, and Six Sigma, remain valuable but are often reactive and constrained by assumptions of linearity and process stability that may not hold in digitally enabled manufacturing systems [7]. Recent advances in artificial intelligence (AI) and machine learning (ML) have expanded the analytical capabilities of quality assurance by enabling the modeling of nonlinear relationships, interaction effects, and dynamic process behavior [8]. ML-based quality prediction models have demonstrated strong potential in applications such as tool wear detection, defect classification, and failure prediction [9]. In parallel, Quality 4.0 frameworks emphasize the integration of analytics and automation to support zero-defect manufacturing objectives [10].

Despite these advances, much of the existing literature focuses on isolated technical use cases or individual process variables, which limits the generalizability of findings across broader manufacturing contexts. Importantly, prior studies have often examined quality determinants in isolation, such as maintenance practices, human factors, or supply chain responsiveness [11]. While these studies provide valuable insights, they rarely offer a comparative, multivariate assessment of operational, quality, and supply-chain factors within a unified analytical framework. Measurement challenges in empirical manufacturing research further complicate this issue, as heterogeneous data sources and inconsistent operational definitions can obscure the relative importance of competing predictors [12]. As a result, a gap remains in the literature regarding how multiple manufacturing variables jointly influence defect occurrence and how these relationships can be leveraged for data-driven quality improvemen From an information systems and industrial engineering perspective, there is a growing need to shift from descriptive quality reporting toward predictive and decision-oriented analytics that support proactive intervention. Predictive quality models based on machine-learning techniques, such as Random Forests and ensemble learning, have shown promise in enabling early detection of quality deterioration and supporting continuous improvement initiatives [13].

However, empirical evidence comparing the relative influence of internal operational factors and external supply-chain variables remains limited, particularly in studies that use secondary manufacturing data and have imbalanced defect distributions [14] Against this backdrop, the present study conducts an empirical assessment of factors influencing product quality defects using secondary manufacturing data and predictive machine-learning techniques. Drawing on a dataset of 3,240 observations and 17 operational variables, the study applies descriptive analytics, Random Forest classification, and inferential testing to identify and prioritize influential predictors of defect occurrence. By addressing class imbalance and feature importance, the study adopts a data-driven approach to quality management that emphasizes interpretability and operational relevance. The contributions of this study are threefold. First, it provides a comparative evaluation of operational, quality, and supply-chain factors by quantifying their relative predictive importance in defect detection. Second, it demonstrates the applicability of ML-based analytics as a decision-support tool for manufacturing quality management in Industry 4.0 environments. Third, by leveraging secondary data, the study highlights the feasibility of cost-effective, data-driven quality analysis that can be adopted by manufacturing organizations seeking to enhance quality performance and reduce defect-related losses [15].

II. METHODOLOGY

II.1 RESEARCH DESIGN

The current study employed a quantitative empirical research design, grounded in secondary data analysis, to investigate the operational and information-driven determinants of product quality defects in manufacturing systems (Figure 1). The methodological framework is explicitly oriented toward decision support and BI by integrating descriptive analytics, inferential statistics, and machine learning–based predictive modelling. The objective is not only to identify statistically significant drivers of defects, but also to develop an interpretable, data-driven model capable of supporting intelligent process optimization and managerial decision-making within Industry 4.0 environments.

II.2 DATASET DESCRIPTION

The data used were obtained from Kaggle (https://www.kaggle.com/datasets/rabieelkharoua/predicting-manufacturing-defects-dataset), and consisted of 3,240 manufacturing observations and 17 operational variables, spanning production, maintenance efficiency, quality, and supply-chain dimensions. The two target variables were binary (defect, where 0 indicated a non-defect and 1 indicated a defect), reflecting whether a manufactured item failed to meet quality standards. Exploratory analysis revealed a pronounced class imbalance, with approximately 84% of observations classified as defective. This imbalance was intentionally retained to reflect the underlying operational reality of the manufacturing context, where persistent quality failures represent a critical managerial risk. From a BI perspective, prioritising defect detection under such conditions is consistent with risk-averse quality management strategies, where false negatives are substantially more costly than false positives.

II.3 DATA PREPROCESSING

Data integrity checks confirmed that no values were missing across all variables. Descriptive statistics and exploratory visualizations were used to assess distributional properties, identify potential outliers, and evaluate pairwise correlations among predictors. Although Random Forest algorithms are robust to scale differences, variables were also reviewed for extreme values to ensure numerical stability. The dataset was partitioned into training and test sets using a reproducible random split, ensuring consistent results across model evaluations. This separation supports out-of-sample validation and enhances the reliability of the reported predictive performance.

III. ANALYTICAL METHODS

III.1 DESCRIPTIVE ANALYSIS AND CORRELATION ANALYSIS

Descriptive statistics, including means, standard deviations, and ranges, were used to summarize the continuous variables. Distributional properties, potential outliers, and data dispersion were examined using histograms, density plots, and boxplots. Pearson correlation coefficients were computed and visualized using heatmaps to assess linear associations among operational indicators and defect status. This analysis supports the identification of variables with potential relevance for subsequent predictive modeling and quality analysis.

III.2 RANDOM FOREST CLASSIFICATION

The primary predictive technique used for defect classification was a Random Forest classifier, an ensemble of decision trees. This method was selected due to its ability to capture nonlinear relationships, interaction effects, and class imbalance, which are commonly observed in manufacturing data [16]. In the Random Forest classifier, the final prediction is obtained by aggregating the outputs of multiple decision trees using majority voting, as expressed in Equation (1).

$$y = \text{majority}\{T1(x), T2(x), \ldots, Tn(x)\} \tag{1}$$

where ŷ is the predicted class label, x denotes the input feature vector, $T_i(x)$ represents the prediction of the i-th decision tree, and n is the total number of trees in the Random Forest. The final output is obtained through majority voting. Feature importance was assessed using the mean decrease in Gini impurity, which measures each predictor's relative contribution to classification performance. These importance values are interpreted as indicators of predictive relevance rather than causal effects. Feature importance was derived from the mean decrease in Gini impurity, calculated as in Equation (2).

$$\text{Gini} = 1 - \sum_{i=1}^{C} p_i^2 \tag{2}$$

where *Gini* is the impurity measure, C denotes the number of classes, and p_i represents the class proportion at a node.

Model performance was evaluated using precision, recall, and F1-score, with particular emphasis on recall for the defective class to reduce the risk of undetected quality failures. Model performance was evaluated using precision and recall, which quantify the accuracy of defect detection and the ability to identify defective items, respectively.

$$Precision = TP / (TP + FP)$$

$$Recall = TP8 / (TP + FN)$$

III.3 INFERENTIAL TESTING (ANOVA TEST)

To complement the predictive analysis, a one-way Analysis of Variance (ANOVA) was conducted to examine whether delivery delay has a statistically significant effect on defect rates. This inferential test provides supplementary evidence regarding the influence of supply-chain timing relative to internal operational factors, using a significance level of $\alpha = 0.05$.

III.4 TOOLS AND SOFTWARE

All analyses were conducted using the Python programming language. The libraries pandas and NumPy were used for data handling and preprocessing, Matplotlib and Seaborn for data visualization, scikit-learn for predictive modeling, and SciPy for statistical testing.

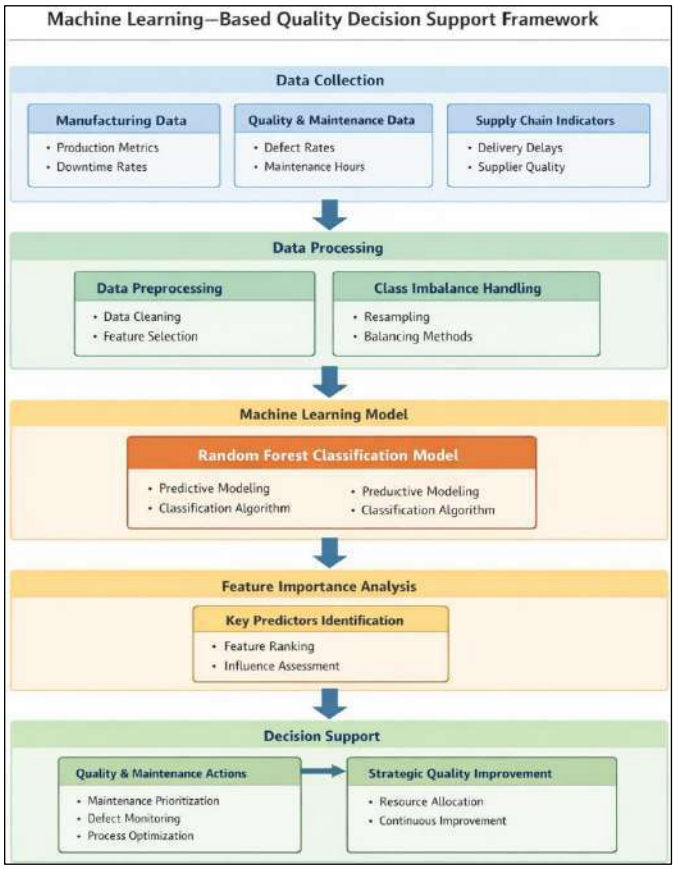

Figure 1: Illustrates the proposed machine learning–based quality decision support framework employed in this study.

IV. RESULTS

IV.1 DESCRIPTIVE CHARACTERISTICS OF THE DATASET

The manufacturing dataset comprises 3,240 observations across 17 variables, including production volume, cost structures, supplier quality, maintenance activity, workforce productivity, and energy usage. The key variables are presented in Table 1. The average production volume was 548.52 (SD: 262.40), with the highest volume ranging from 100 to 999 units, indicating significant variation. The average sample cost of production was $12,423.02 (SD = $4,308.05), with a range of $5,000.17 to $19,993.37, indicating varying production levels.

Table 1: Descriptive Statistics of Key Variables in the Manufacturing Dataset.

Variable	Mean	Std. Dev.	Min	Max
Production Volume	548.52	262.40	100	999
Production Cost	12423.02	4308.05	5000.17	19993.37
Supplier Quality	89.83	5.76	80.00	99.99
Delivery Delay	2.56	1.71	0	5
Defect Rate	2.75	1.31	0.50	4.99
Quality Score	80.13	11.61	60.01	99.99
Maintenance Hours	11.48	6.87	0	23
Downtime Percentage	2.50	1.44	0.00	5.00
Inventory Turnover	6.02	2.33	2.00	10.00
Stockout Rate	0.05	0.03	0.00	0.10
Worker Productivity	90.04	5.72	80.00	99.99
Safety Incidents	4.59	2.90	0	9
Energy Consumption	2988.49	1153.42	1000.72	4997.07
Energy Efficiency	0.30	0.12	0.10	0.50
Additive Process Time	5.47	2.60	1.00	10.00
Additive Material Cost	299.52	116.38	100.21	499.98
Defect Status	0.84	0.37	0	1

Source: Authors, (2026).

The dataset showed that supplier quality is high (M = 89.83, SD = 5.76, range = 80-99.99) and the defect rates are low (M = 2.75, SD = 1.31, range = 0.50-4.99). The overall product quality was 80.13 (SD = 11.61), and the average delivery delay was 2.56 days (SD = 1.71). Operational indicators included the maintenance hours (M = 11.48, SD = 6.87), downtime (M = 2.50, SD = 1.44), inventory turnover (M = 6.02, SD = 2.33), and worker productivity (M = 90.04, SD = 5.72). The average safety incident rate was 4.59 (SD = 2.90), and the average energy consumption was 2,984.49 units (SD = 1,153.42). The average energy efficiency stood at 0.30 (SD = 0.12). The time averaged 5.47 hours (SD 2.60) in the additive process, and the cost of materials amounted to $299.52 (SD $116.38). The average defect level (M = 0.84, SD = 0.37) indicated that 84% of the products were defective. From a BI standpoint, these descriptive patterns underscore the need for continuous monitoring systems capable of integrating cost, maintenance, and quality metrics to support early intervention

IV.2 DISTRIBUTION ANALYSIS AND CLASS IMBALANCE OF KEY VARIABLES

The distribution of Defect Status demonstrates a pronounced imbalance (Figure 2). Non-defect status products (Defect Status = 0) comprise approximately 16 per cent of the dataset (520 cases), and defect status products (Defect Status = 1) comprise approximately 84 per cent (2,720 cases). This pattern signals a systemic quality issue rather than sporadic failures, reinforcing the relevance of predictive analytics for proactive quality management. Rather than undermining model validity, this imbalance reflects a realistic decision environment in which defect detection is a dominant managerial concern.

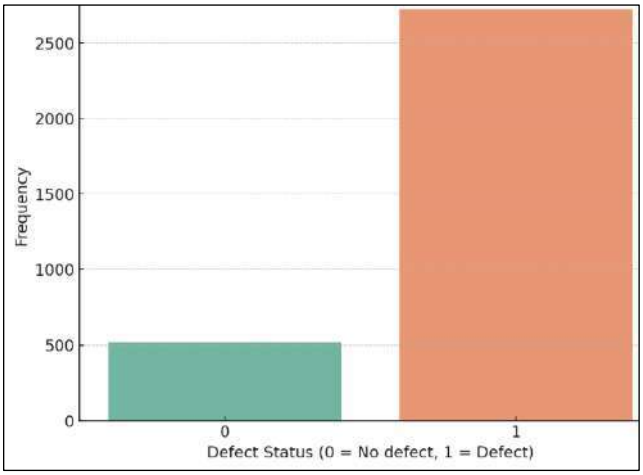

Figure 2: Distribution of defect status in the manufacturing dataset.
Source: Authors, (2026).

Figures 3–5 provide exploratory validation of key continuous variables used in subsequent modeling. Production volume (Figure 3) exhibits a broadly uniform distribution across operational scales, indicating the absence of artificial batching or scale-induced bias. The defect rate distribution (Figure 4) is centered around moderate defect levels with limited extreme values, supporting the use of probabilistic rather than threshold-based classification. The production cost (Figure 5) exhibits stable dispersion across the observed range, indicating consistent cost structures and justifying its inclusion as a control variable rather than a primary quality driver. Collectively, these distributions confirm the suitability of the dataset for predictive business intelligence modeling.

IV.3 RELATIONSHIP AND CORRELATION ANALYSIS

Correlation analysis reveals that defect status is positively associated with defect rate and maintenance hours, and negatively associated with overall quality score. Production volume and production cost are strongly correlated, reflecting scale effects in manufacturing operations. Maintenance hours and defect rates are also positively correlated with downtime, suggesting a compounding of operational inefficiencies. These relational patterns are visually reinforced in Figure 6, which illustrates the joint behaviour of defect status, defect rate, and maintenance hours, and in Figure 7, which summarises pairwise correlations across all operational and quality variables. Collectively, these relationships provide actionable insights by identifying variables that can function as leading indicators in quality dashboards and decision-support systems. These relationships provide actionable insights by identifying variables that can function as leading indicators in quality dashboards and decision-support systems.

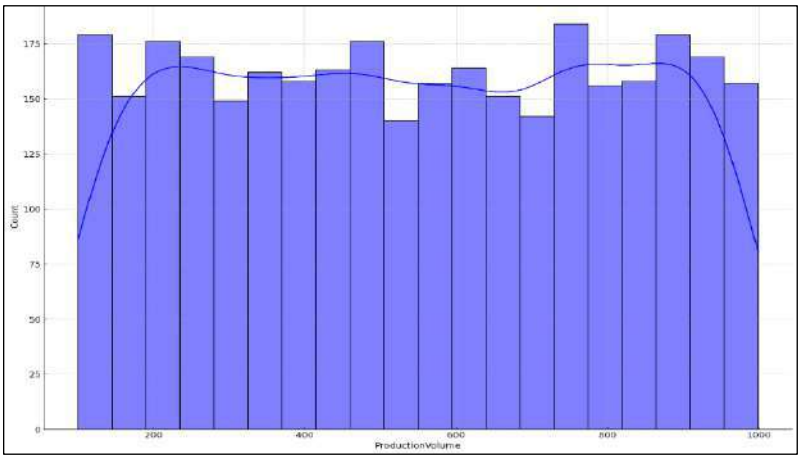

Figure 3: Distribution of production volume in the manufacturing dataset. The figure illustrates the dispersion of production volume across manufacturing observations, confirming broad operational variability and the absence of scale-specific clustering that could bias predictive modeling.
Source: Authors, (2026).

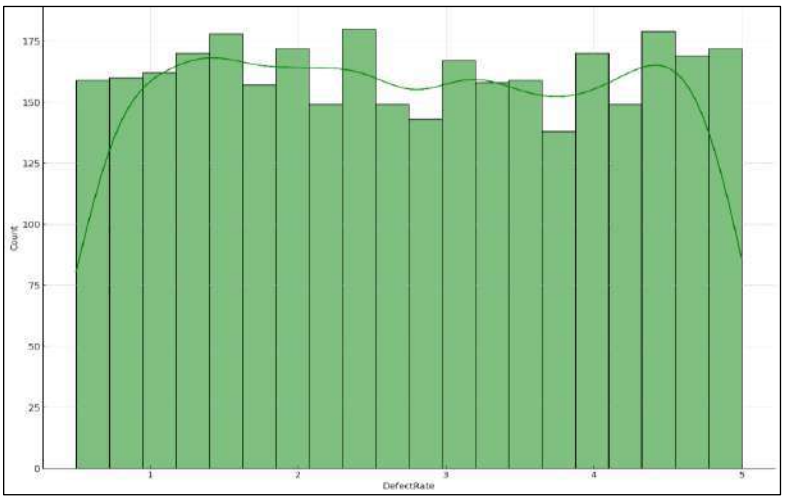

Figure 4: Distribution of production cost in the manufacturing dataset. The distribution exhibits a continuous spread of defect rates, with limited extreme values, supporting the use of probabilistic classification methods over rule-based thresholds for defect prediction.
Source: Authors, (2026).

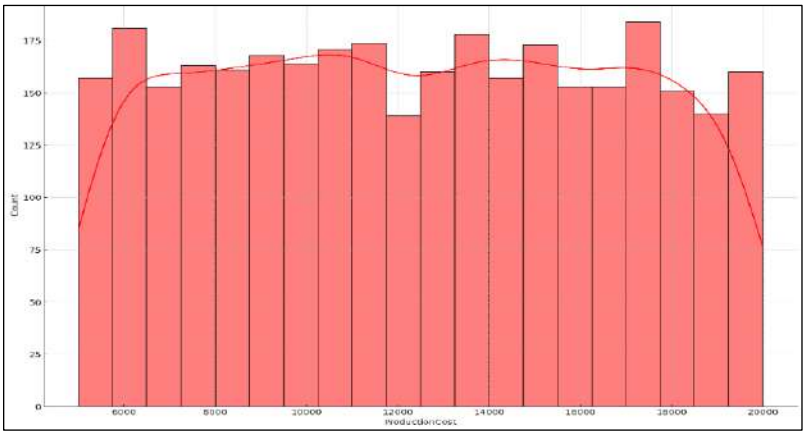

Figure 5: Distribution of production costs in the manufacturing dataset. This figure depicts the variability of production costs across observations, indicating stable dispersion consistent with output heterogeneity and justifying its inclusion as a control variable in the predictive analysis.
Source: Authors, (2026).

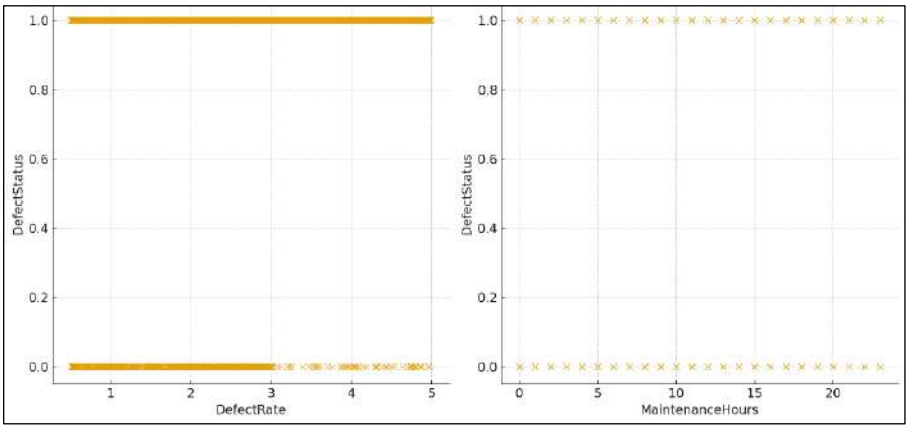

Figure 6: Relationship between defect status, defect rate, and maintenance hours. The figure visualizes how defect status varies with defect rate and maintenance hours, highlighting their strong discriminative patterns and supporting their prioritization as key predictors in the defect classification model.
Source: Authors, (2026).

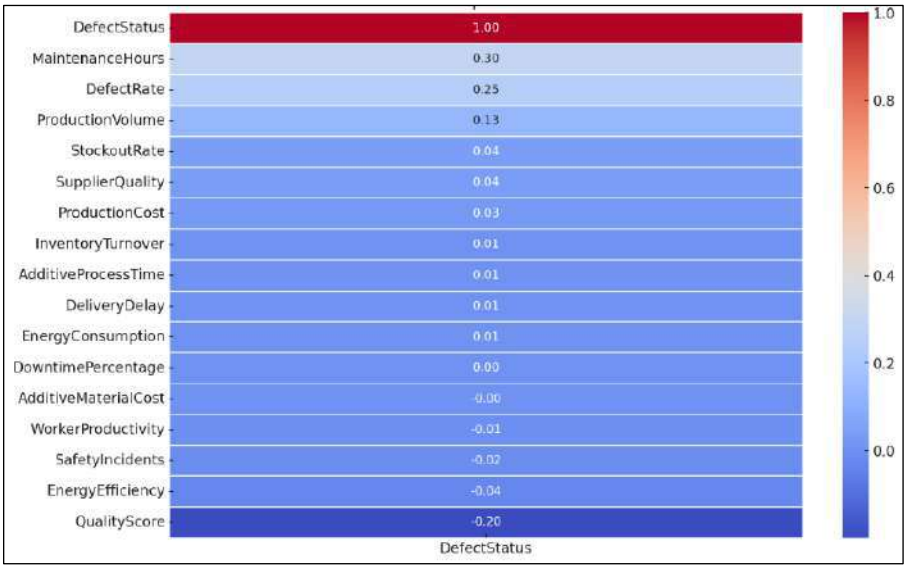

Figure 7: Correlation heatmap of operational and quality variables in the manufacturing dataset. The heatmap summarizes pairwise Pearson correlations among study variables, indicating the strongest associations with defect-related outcomes and informing the selection and interpretation of predictors for the predictive analytics model.
Source: Authors, (2026).

IV.4 DIAGNOSTIC ASSESSMENT OF VARIABLE DISTRIBUTIONS AND MULTIVARIATE STRUCTURE

Figures 8 and 9 provide diagnostic support for the predictive analysis. Figure 8 illustrates the distributional properties and potential outliers of key continuous variables, confirming acceptable dispersion without extreme anomalies that could distort model estimation. There are limited extremes in production cost. The defect rate is concentrated around the median, with outliers at both ends. Maintenance hours are more varied and exhibit greater outliers, suggesting that some units need additional maintenance. Figure 9 presents multivariate pairwise relationships among production volume, production cost, defect rate, and maintenance hours, highlighting nonlinear patterns and interaction effects. Together, these diagnostics support the suitability of tree-based machine learning models for capturing complex relationships in manufacturing quality data. The correlation between volume and cost is strongly linear. On the contrary, the relationship between defect rate, volume, and cost is relatively weak and multifactorial. The maintenance hours appear to depend on volume and cost, suggesting that other variables may also influence them, such as equipment age or usage intensity.

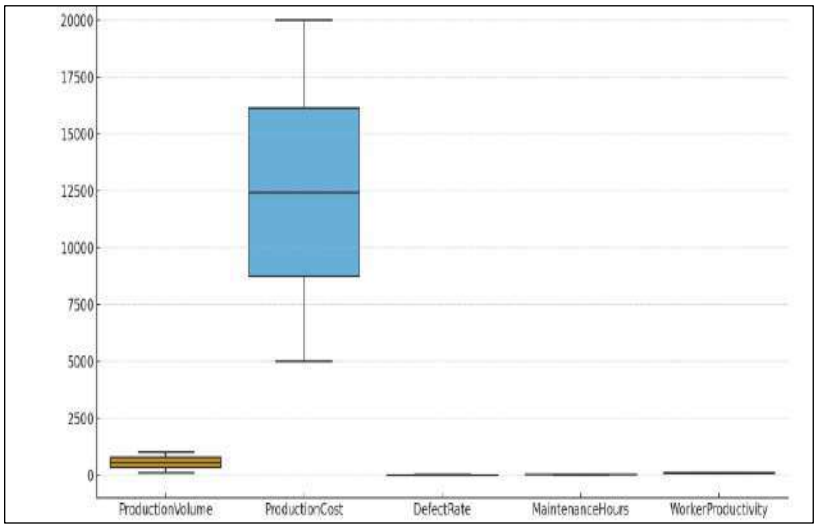

Figure 8: Boxplot of Important Variables in the Manufacturing Data. The boxplot is used to display the distributions of key variables, including production volume, production cost, defect rate, and maintenance hours. It allows for identifying potential outliers and delineating the spread of each variable, providing a view of each variable's variability within the dataset.
Source: Authors, (2026).

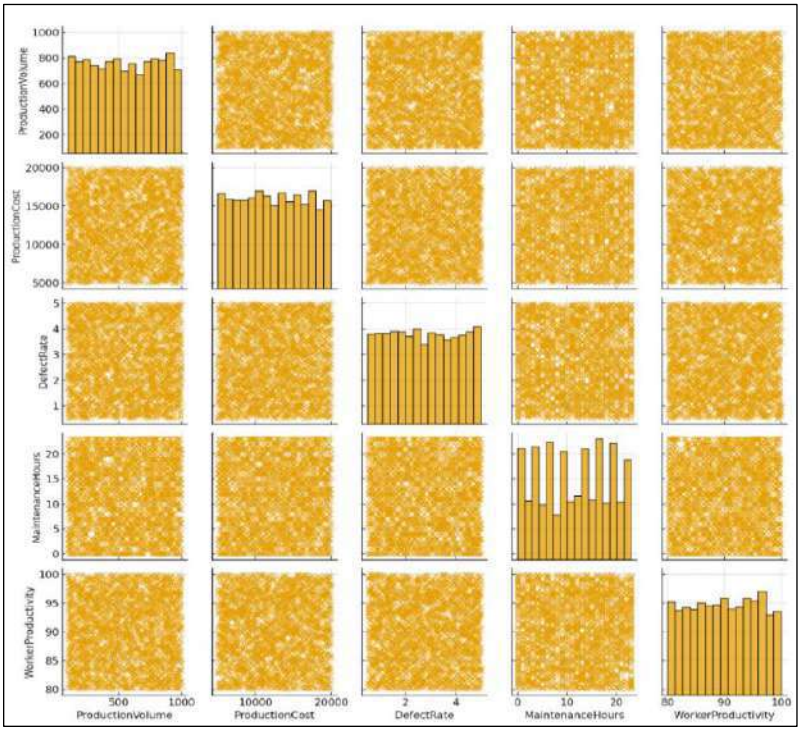

Figure 9: Key Variables Pair Plot in the Manufacturing Data Set. The pair plot provides a graphical representation of the inter-variable relationships, including production volume, production cost, defect rate, and maintenance time. It helps identify correlations between predictors and their interactions, which are essential for a detailed understanding of the determinants that affect the defect status.
Source: Authors, (2026).

IV.5 FEATURE IMPORTANCE FROM RANDOM FOREST MODELING

Feature importance rankings derived from the Random Forest model are presented in Table 2. Maintenance hours emerge as the most influential predictor (importance = 0.23), followed by defect rate (0.21), quality score (0.14), and production volume (0.11). Collectively, these variables account for approximately 44% of the model's predictive power. The remaining variables, including additive material cost, energy efficiency, supplier quality, stockout rate, downtime, additive process time, inventory turnover, worker productivity, production cost, and energy consumption, showed little significance (around 0.03), suggesting that internal operational conditions have a greater impact on quality outcomes in this dataset. Safety incidents and delivery delays had the least importance, with a score of 0.01 each, indicating they did not have a significant impact on defect status. These findings should be interpreted as predictive priorities for decision support, not as evidence of causal mechanisms.

Table 2: Ranking of the Defect Status in the Manufacturing dataset based on order of importance

Feature	Importance
Maintenance Hours	0.23
Defect Rate	0.21
Quality Score	0.14
Production Volume	0.11
Additive Material Cost	0.03
Energy Efficiency	0.03
Supplier Quality	0.03
Stockout Rate	0.03
Downtime Percentage	0.03
Additive Process Time	0.03
Inventory Turnover	0.03
Worker Productivity	0.03
Production Cost	0.03
Energy Consumption	0.03
Safety Incidents	0.01
Delivery Delay	0.01

IV.6 PERFORMANCE OF THE PREDICTIVE MODELS

The Random Forest classifier demonstrates strong predictive performance, particularly for defective products. Precision (0.96), recall (0.99), and F1-score (0.98) indicate that the model is highly effective in identifying quality failures, which is critical in high-risk manufacturing environments (Table 3). In non-defective products, precision is 0.94, recall is 0.78, and F1-score is 0.85, which is less than the recall in class imbalance. Therefore, performance for non-defective products is comparatively lower, reflecting the inherent class imbalance and reinforcing the model's conservative bias toward defect detection. This bias is desirable, as the cost of undetected defects typically exceeds the cost of false alarms.

Table 3: Random Forest Model Evaluation.

Metric	Defect = 1 (Defective Products)	Defect = 0 (Non-Defective Products)
Precision	0.96	0.94
Recall	0.99	0.78
F1-Score	0.98	0.85

IV.7 STATISTICAL TESTING: EFFECT OF DELAY AT DELIVERY ON DEFECT RATE

Table 4 presents the ANOVA results for the impact of delivery delay on the defect rate. Between groups sum of squares = 3.2209 (df = 4); within groups sum of squares = 579.7014 (df = 3,235). The mean squares are 0.8052 and 0.1793, respectively, yielding an F-statistic of 1.2047 and a p-value of 0.3042. This difference is not statistically significant ($p = 0.05$), indicating that delivery delay does not affect the defect rate. This is also associated with its low feature importance, indicating that resources should be allocated to maintenance, defect rates, and quality scores rather than to delivery delays to reduce defect rates.

Table 4: ANOVA Table for Defect Rate across Delivery Delay groups.

Source of Variation	Sum of Squares	Degrees of Freedom	Mean Square	F-Statistic	p-Value
Between Groups	3.2209	4	0.8052	1.2047	0.3042
Within Groups	579.7014	3235	0.1793		
Total	582.9223	3239

V. DISCUSSION

This empirical study investigates the critical predictors of product-quality defects in manufacturing systems by integrating secondary data analysis with ML–based predictive modeling. The results demonstrate that equipment-related factors, particularly maintenance hours and observed defect rates, are the most influential determinants of defect occurrence, collectively accounting for approximately 44% of the model's predictive contribution.

This finding reinforces longstanding concerns in industrial engineering regarding measurement validity and operational prioritization, where inaccurate or delayed maintenance indicators can obscure true performance drivers and degrade quality outcomes [17].

Figure 10: Feature-importance-based hierarchy of quality defect drivers identified using the Random Forest model.
Source: Authors, (2026).

By grouping the variables into hierarchical impact levels, Figure 10 highlights the dominance of maintenance hours and defect rate over other operational and supply-chain factors. This hierarchy supports the interpretation that internal operational conditions play a more decisive role in defect occurrence than external timing-related variables. The prominence of maintenance hours as the leading predictor (importance = 0.23) aligns strongly with the principles of TPM, reliability engineering, and human-centered maintenance frameworks, which emphasize proactive equipment upkeep as a mechanism for reducing process variability and preventing defect propagation [18]. Prior studies on human factors in maintenance and operational discipline suggest that inadequate maintenance planning and execution can amplify failure risks, particularly in complex, high-utilization manufacturing environments [18],[19]. From an operational perspective, increased maintenance activity contributes to improved process stability, reduced unplanned downtime, and enhanced equipment availability, thereby lowering the propensity for defect generation across production stages [18],[19]. The strong predictive contribution of defect rate (importance = 0.21) further underscores the reinforcing nature of quality failures, in which persistent defects signal deeper systemic inefficiencies rather than isolated process deviations. This observation is consistent with research on quality-cost dynamics, which demonstrates that hidden quality costs, such as rework, scrap, and warranty claims, often accumulate silently until defect levels reach critical thresholds [20]. Similar findings in quality culture research emphasize that organizations with weak feedback mechanisms tend to normalize recurring defects, allowing inefficiencies to persist over time [21]. Consequently, continuous defect monitoring serves not only as a quality control mechanism but also as an early warning indicator of declining operational health.

Consistent with prior empirical research, the findings confirm a robust association between preventive maintenance practices and improved product quality outcomes [22],[23]. Earlier work on predictive modeling in manufacturing systems shows that maintenance intensity and equipment condition are among the most reliable predictors of downstream performance, particularly when combined with operational efficiency indicators [23]. This study extends that literature by quantifying the relative importance of maintenance activities relative to a broader set of operational, quality, and supply-chain variables using ML-based feature-importance analysis, thereby offering a more integrated perspective than traditional univariate or siloed approaches [17]. In contrast to some supply-chain–oriented studies, delivery delay does not exhibit a statistically significant relationship with defect rate in the present analysis. This finding suggests that internal operational controls may outweigh external timing factors in determining quality outcomes within the examined context. Prior research indicates that buffering strategies, incoming quality inspections, and inventory policies can mitigate the quality risks associated with delivery variability, effectively decoupling logistics delays from production quality performance [24]. Studies on supply-chain responsiveness similarly argue that while delivery reliability affects customer satisfaction, its direct impact on defect formation may be secondary when robust internal quality systems are in place [25]. The Random Forest classifier demonstrates strong predictive performance for defective items, achieving high recall (0.96) and precision (0.99), which supports its suitability for quality-focused decision-support applications.

These performance levels are comparable to those reported in prior machine learning studies on manufacturing quality prediction, predictive maintenance, and operational risk assessment [26-28]. In particular, ensemble-based methods such as Random Forest and gradient boosting have been shown to outperform single-model approaches when dealing with nonlinear interactions and heterogeneous manufacturing data [29],[27]. Beyond classification accuracy, the model's ability to prioritize defect detection is especially valuable in high-risk production environments, where the cost of undetected defects significantly exceeds the cost of false alarms [30]. The limited influence of supply-chain timing variables further suggests that internal process optimization may yield greater quality improvements than external responsiveness initiatives alone. Prior research on quality management systems and Industry 4.0 performance measurement supports this conclusion, emphasizing that maintenance effectiveness, workforce discipline, and process monitoring exert stronger control over defect prevention than logistics acceleration strategies [31],[32]. Accordingly, quality-improvement initiatives may benefit from prioritizing predictive maintenance, continuous defect monitoring, and process control rather than focusing solely on supply-chain speed [18],[33],[34]. Although the dataset exhibits pronounced class imbalance, this characteristic reflects a realistic manufacturing environment characterized by persistent quality challenges rather than sporadic failures.

Prior studies on imbalanced learning in manufacturing and industrial analytics argue that such distributions necessitate risk-sensitive modeling approaches that emphasize recall for defective items [30]. This approach aligns with practical quality management objectives, where the operational and reputational costs of undetected defects outweigh the consequences of conservative classification decisions [31],[35],[36]. At a conceptual level, the study contributes to data-driven quality management by demonstrating how machine learning models can uncover nonlinear and interaction-driven relationships that traditional statistical methods may overlook [29]. The findings also challenge the assumption that supply-chain timing is a dominant determinant of quality outcomes, instead emphasizing the primary role of internal operational conditions—such as maintenance intensity, defect history, and quality scores—in shaping defect risk [21],[33]. Finally, the study affirms the viability of secondary data analysis as a cost-effective and scalable approach for generating actionable insights into manufacturing quality improvement within Industry 4.0 environments, particularly when supported by interpretable ML-based decision-support systems [37],[38]. In terms of industrial applicability, the proposed ML–based quality decision support framework is directly applicable to industrial manufacturing environments where operational, maintenance, and quality data are routinely collected. By identifying high-impact defect drivers, such as maintenance intensity and defect history, the framework enables practitioners to prioritize preventive maintenance, monitor defect risk, and allocate quality-improvement resources more effectively. The use of interpretable feature importance further supports practical adoption by engineers and managers without requiring advanced machine learning expertise.

VI. LIMITATIONS

This study has certain limitations. The analysis relies on secondary data from a single manufacturing context, which may limit generalizability across industries. In addition, feature importance reflects predictive relevance rather than causal relationships. Future research may extend the framework using multi-source industrial datasets, alternative machine learning models, or real-time deployment scenarios.

VII. CONCLUSION

This study employed secondary manufacturing data and ML-based analytics to identify the principal drivers of product quality defects in contemporary manufacturing systems. The findings indicate that equipment-related factors, particularly observed defect indicators and maintenance intensity, are the most influential predictors of defect occurrence, collectively accounting for nearly half of the model's predictive contribution. These results highlight the critical role of equipment condition and maintenance discipline in sustaining quality performance within Industry 4.0 environments. The Random Forest model demonstrated strong predictive capability, achieving precision and recall levels exceeding 95%, supporting its suitability for integration into quality monitoring and decision-support applications.

In contrast, delivery delay did not exhibit a statistically significant impact on defect rates, reinforcing the conclusion that internal operational conditions exert a greater influence on product quality outcomes than external supply-chain timing factors in the examined context. Overall, the study provides empirical support for data-driven quality management approaches that emphasize predictive maintenance, defect monitoring, and process optimization. By demonstrating the value of ML-enabled analytics in identifying high-risk operational conditions, the findings provide practical guidance for manufacturers seeking to enhance quality performance and reduce defect-related costs in digitally enabled production environments.

ABSTRACT

Diabetes mellitus remains a major global health challenge, with its long-term complications imposing substantial economic and social burdens on healthcare systems worldwide. Although machine learning models have demonstrated strong predictive performance in identifying diabetes risk, their black-box nature severely limits clinical interpretability, trust, and accountability, thereby hindering widespread adoption in medical practice. This study introduces the Explainable Blockchain (XBC) framework, which integrates Random Forest-based diabetes risk prediction with local SHAP explanations, followed by permanent, immutable storage of concise explanation summaries on an Ethereum smart contract. Patient identifiers are pseudonymized via cryptographic hashing to preserve privacy while enabling independent auditability by clinicians, patients, and regulators. Experiments conducted on the Pima Indians Diabetes dataset yielded an accuracy of 74.68%, an AUC of 0.8118, and perfect ML-to-chain consistency (100%) across 154 test instances, with average transaction latency of 54.6 ms and gas consumption of approximately 50,595 units on a private Ganache testnet. By bridging explainable artificial intelligence and blockchain at the individual decision level, XBC establishes a verifiable, tamper-proof audit trail for AI-driven clinical decisions, significantly advancing transparency, accountability, and regulatory compliance in healthcare artificial intelligence applications.

I. INTRODUCTION

Diabetes mellitus has emerged as one of the most serious global public health challenges of the 21st century [1]. The disease affects hundreds of millions of individuals worldwide and imposes a substantial economic and social burden due to long-term complications, including cardiovascular disease, renal failure, blindness, and amputations [2],[3]. Despite ongoing advances in prevention and clinical management, early detection of diabetes risk in individuals remains frequently delayed, particularly in regions with limited access to healthcare services [4],[5]. In this context, artificial intelligence (AI) and machine learning (ML) approaches have demonstrated significant potential to enhance the accuracy of diabetes risk prediction well before the onset of clinical symptoms [6-8]. Nevertheless, many machine learning models used for diabetes risk prediction operate as black-box systems, limiting their interpretability for healthcare professionals, patients, and regulators [9-11].

This lack of transparency poses a significant barrier to clinical adoption, as clinicians require clear and trustworthy rationales when classifying individuals as high- or low-risk [12-14]. In addition, AI-generated decisions often lack verifiable audit trails, further raising concerns regarding accountability and trust in clinical decision-making [15],[16]. Although various Explainable Artificial Intelligence (XAI) methods have been proposed to improve the interpretability of model predictions, current approaches generally do not guarantee that explanations are stored in a permanent, tamper-proof, and independently auditable manner [17-19]. At the same time, blockchain technology has attracted attention in healthcare for its ability to enhance data integrity and traceability, yet existing applications remain largely focused on record management rather than decision-level accountability [20-22].

Consequently, the integration of local XAI-based explanations with blockchain infrastructure to support explainable, immutable, and auditable AI-driven clinical decisions at the individual level remains an open research gap, particularly under increasing regulatory demands for transparency and accountability. To address these limitations, this study proposes the Explainable Blockchain (XBC) framework, which integrates machine learning-based diabetes risk prediction with local explanations generated using SHAP, followed by permanent on-chain storage of explanation summaries via smart contracts [23-25]. This approach is designed to yield decisions that are not only accurate but also transparent, explainable, immutable, and independently verifiable by healthcare professionals, patients, and regulators without disclosing individual identities.

The primary contributions of this research include: (1) the development of an XBC architecture that combines machine learning prediction with on-chain storage of local explanations, (2) the implementation of an efficient explanation summarization mechanism to accommodate blockchain storage constraints, and (3) empirical demonstration of decision consistency and auditability within a private blockchain environment. The remainder of this paper is organized as follows: literature review, methodology, results and discussion, and conclusion with recommendations for future research.

II. RELATED WORK

II.1 MACHINE LEARNING-BASED DIABETES RISK PREDICTION

Various machine learning approaches have long been applied to predict the risk of type 2 diabetes, particularly by leveraging relatively simple clinical datasets such as the Pima Indians Diabetes Dataset. Classic methods, including logistic regression, decision trees, and naive Bayes, are frequently employed as baselines owing to their relative ease of interpretability, although their capacity to handle complex nonlinear relationships among variables remains limited [26],[27]. Subsequently, ensemble methods such as Random Forest and Gradient Boosting Machines have emerged as dominant choices due to their superior ability to capture feature interactions and address class imbalance, a common issue in medical datasets [28],[29].

Several studies have also begun adopting deep learning models, including feed-forward artificial neural networks, convolutional neural networks adapted for tabular data, and transformer architectures designed to capture long-range dependencies among physiological parameters [30],[31]. Although these models can achieve high area under the curve (AUC) values on specific datasets, nearly all such approaches prioritize the optimization of predictive performance metrics and rarely address the transparency and accountability of the decisions they produce.

II.2 EXPLAINABLE ARTIFICIAL INTELLIGENCE (XAI) IN THE HEALTHCARE DOMAIN

despite the advances in predictive accuracy, the black-box nature of many ML models poses significant challenges in healthcare, particularly regarding clinical interpretability and trust. This has driven rapid advancements in Explainable Artificial Intelligence (XAI), especially in applications with high clinical and legal implications [32-34]. Post-hoc approaches such as LIME and SHAP have become highly popular because they enable the generation of local explanations for black-box model predictions without requiring modifications to the internal structure of the models themselves [35-37]. SHAP, which is based on the concept of Shapley values from cooperative game theory, is regarded as one of the most mathematically consistent methods, satisfying important properties such as additivity and consistency.

Zhang *et al*. have demonstrated that SHAP is capable of producing explanations that align with clinical knowledge across various disease prediction tasks, including diabetes and cardiovascular diseases [38]. In addition, several studies have begun to develop global explanations by aggregating absolute SHAP values to identify features with the greatest overall influence. Nevertheless, nearly all existing XAI implementations currently operate off-chain and lack mechanisms to ensure that explanations are permanent, immutable, independently auditable, or possess a trail that can be verified by third parties after clinical decisions are made [39-41].

II.3 APPLICATION OF BLOCKCHAIN IN HEALTHCARE SYSTEMS

On the other hand, blockchain technology has attracted substantial attention in the healthcare domain primarily due to its decentralized nature, immutability, and strong support for auditability. Most early studies have utilized blockchain for electronic medical record storage, patient consent management, pharmaceutical supply chain tracking, and data exchange among healthcare institutions while preserving privacy through encryption techniques and zero-knowledge proofs [42-44].

Several studies have also begun exploring blockchain as a trust layer for clinical decision support systems, for example by recording prediction outcomes or treatment recommendations on-chain. However, the primary focus remains on the integrity and availability of raw data or final prediction results, rather than on explanations of how specific decisions are derived [45-47]. As a result, blockchain is more commonly used as a secure ledger, while its potential for storing explanatory artifacts directly associated with individual decisions remains largely underexplored.

II.4 INTEGRATION OF EXPLAINABLE ARTIFICIAL INTELLIGENCE AND BLOCKCHAIN AND RESEARCH GAP

Although Explainable Artificial Intelligence and blockchain have each been extensively studied in healthcare contexts, research that meaningfully integrates both remains relatively limited and often fragmented. Existing studies typically treat blockchain as a mechanism for recording prediction outcomes or decision artifacts, while explanations generated by AI models are rarely considered first-class decision components that require persistent, verifiable, and auditable storage. As a result, the integration of individual-level local explanations with efficient and deterministic on-chain storage mechanisms has not been widely explored, leaving an open research gap in addressing transparency and accountability requirements for AI-driven decision-making in healthcare systems.

III. MATERIALS AND METHODS

III.1 RESEARCH DESIGN AND OVERALL SYSTEM FRAMEWORK

This study focuses on the development of an Explainable Blockchain (XBC) framework by integrating Explainable Artificial Intelligence (XAI) into blockchain infrastructure to enable transparent, explainable, immutable, and auditable diabetes risk prediction [48],[49]. XAI serves as a supporting component, with particular emphasis on the representation, summarization, and on-chain storage of AI decision explanations. The proposed framework combines machine learning based prediction with local SHAP explanations, which are subsequently summarized and recorded via smart contracts implemented in Solidity on an Ethereum network (local Ganache testnet) [50-52].

As a result, each medical decision is not only accurate but also accompanied by a permanent and verifiable explanatory trace. The objective of this research is to establish an XBC-based clinical decision support system that addresses key limitations of conventional AI, particularly black-box behavior and the absence of trustworthy, tamper-proof, and privacy-preserving audit trails. Figure 1 illustrates the overall system workflow, from data processing to on-chain storage, enabling independent auditing by regulators, healthcare professionals, and patients without revealing individual identities, thereby enhancing trust, accountability, and clinical acceptance of AI in healthcare.

III.2 DATASET AND DATA PREPROCESSING

This study utilizes the Pima Indians Diabetes Dataset provided by the National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK) as the primary dataset for developing and evaluating the diabetes risk prediction model [53]. The dataset consists of 768 instances with eight numerical predictor features representing clinically relevant physiological parameters and one binary target variable (Outcome), where 0 indicates non-diabetic and 1 indicates diabetic status, as summarized in Table 1. The class distribution exhibits moderate imbalance, with 65.1% negative and 34.9% positive instances, as shown in Table 2. Prior to model training, missing values in each feature were handled using median-based imputation computed over the entire dataset, following common practice in predictive experiments using this dataset.

Table 1: Feature Descriptions in the Pima Indians Diabetes Dataset.

Feature Name	Description	Unit / Data Type
Pregnancies	Number of times the patient has been pregnant	Integer
Glucose	Plasma glucose concentration 2 hours after an oral glucose tolerance test	mg/dL
BloodPressure	Diastolic blood pressure	mm Hg
SkinThickness	Triceps skin fold thickness	mm
Insulin	Serum insulin level 2 hours after the test	µU/mL
BMI	Body mass index	kg/m²
DiabetesPedigreeFunction	Score representing family history of diabetes	Numeric
Age	Patient age	Years

Source: Authors, (2026).

Table 2: Distribution of Outcome Classes in the Overall Dataset.

Class	Number of Instances	Percentage (%)
0 (Negative)	500	65.10
1 (Positive)	268	34.90

Source: Authors, (2026).

III.3 MACHINE LEARNING MODEL DEVELOPMENT

The primary predictive model employed in this study is the Random Forest Classifier, an ensemble learning method that constructs multiple decision trees in parallel and aggregates their outputs to produce a final prediction. The selection of Random Forest is motivated by its robust performance on tabular data and its suitability for post-hoc explainability analysis, which aligns with the research objectives emphasizing transparency, interpretability, and auditability of model decisions [54],[55]. As illustrated in Figure 2, Random Forest operates by training each decision tree using data generated through bootstrap sampling and a randomly selected subset of features at each node split [56]. This mechanism introduces diversity among the trees, contributing to improved model generalization and reducing the risk of overfitting. The final prediction is determined through a majority voting mechanism across all decision trees in the ensemble.

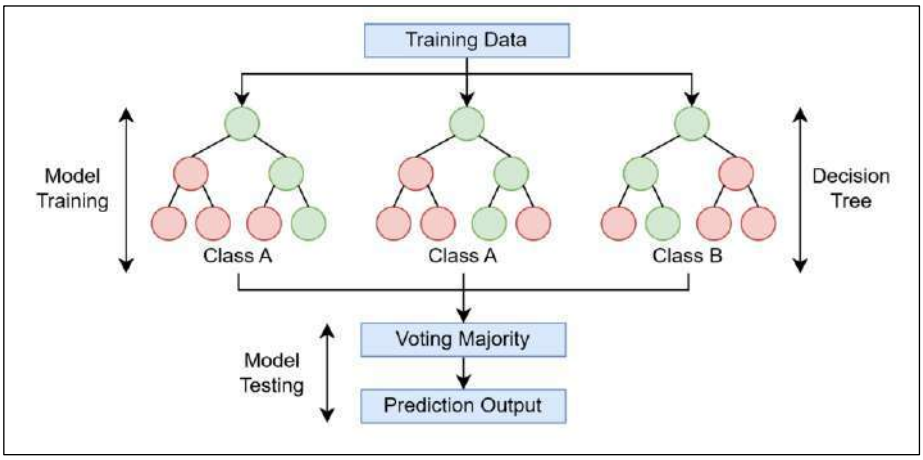

Figure 2: Random Forest Architecture.
Source: Authors, (2026).

In the context of diabetes risk prediction, the model produces not only discrete class predictions (positive or negative) but also class probabilities that are used as risk scores [57],[58]. These probability values serve as the basis for the explainability process, as they enable the analysis of feature contributions to the predicted risk level. Within this study, Random Forest functions as the core component of the prediction layer, while the research novelty is centered on the integration of prediction results and their explanations (explainable outputs) into a blockchain-based system. Consequently, the machine learning model provides explainable decision outputs, whereas the blockchain ensures the integrity, traceability, and resistance to manipulation of both the predictions and their associated explanations.

III.4 EXPLAINABLE ARTIFICIAL INTELLIGENCE COMPONENT (SHAP-BASED LOCAL AND GLOBAL EXPLANATION)

The Explainable Artificial Intelligence (XAI) component in this study serves as a critical link between black-box machine learning predictions and blockchain-based decision storage by providing interpretable explanations of model outputs. This component is based on SHapley Additive exPlanations (SHAP), which is employed to decompose each prediction into feature-level contributions that can be transparently recorded, verified, and audited. SHAP is selected due to its solid theoretical foundation, model-agnostic nature, and ability to generate consistent local explanations at the individual decision level, which is essential for medical auditability [59-61]. Conceptually, SHAP represents the prediction outcome as an additive combination of a baseline value and feature contributions. For a given input instance x, the model prediction can be expressed as Formula (1):

$$f(x) = f_0 + \sum_{j=1}^{d} \phi_j(x) \tag{1}$$

here $f(x)$ denotes the model output, f_0 represents the expected prediction over the background dataset, d is the number of input features, and $\phi_j(x)$ corresponds to the contribution of the j-th feature to the prediction of instance x. This additive formulation ensures that individual feature effects are explicitly quantified and collectively reconstruct the original model output. In this study, the predictive model produces a probability score for the positive class (diabetes risk), which serves as the explained output. Accordingly, the prediction function analyzed by SHAP is defined as Formula (2):

$$f(x) = \hat{p}(y = 1 \mid x) \tag{2}$$

where $\hat{p}(y = 1 \mid x)$ denotes the estimated probability of an individual being classified as diabetic. The resulting SHAP values indicate whether each feature increases or decreases the predicted risk relative to the baseline. Local explanations are generated by computing the SHAP value vector for each individual instance in the test dataset. This vector provides a patient-specific explanation that identifies the most influential features and the direction of their impact on the predicted risk.

It is important to emphasize that SHAP values reflect the predictive behavior of the trained model and do not imply causal medical relationships among variables. These local explanations are treated as first-class decision artifacts and constitute the primary explainability information associated with each prediction.

To support model-level interpretability, global explanations are derived by aggregating feature contributions across all evaluated instances. The global importance of feature j is computed as the mean absolute SHAP value, as shown in Formula (3):

$$\overline{\phi_j} = \frac{1}{n}\sum_{i=1}^{n}\left|\phi_j^{(i)}\right| \quad (3)$$

Where n denotes the number of instances in the test dataset and $\phi_j^{(i)}$ is the SHAP value of feature j for instance i. This metric is used to rank features according to their overall influence on model predictions and to assess alignment with known clinical risk factors. In the proposed Explainable Blockchain framework, only local SHAP-based explanations, which directly represent individual clinical decisions, are recorded on the blockchain, while global explanations are not stored on-chain because of their aggregate nature and lack of association with specific patient decision instances [62], [63]. This design ensures on-chain storage efficiency while preserving the relevance, traceability, and auditability of recorded decisions. Figure 3 illustrates the conceptual role of Explainable AI as an additional layer within the machine learning process that enables users to understand the rationale behind model decisions, why alternative outcomes were not selected, and under which conditions the predictions can be trusted, which serves as a prerequisite for persistently recording individual-level explanations in a blockchain-based system.

III.5 BLOCKCHAIN ARCHITECTURE AND SMART CONTRACT DESIGN

The blockchain architecture in this study is designed to support the storage of diabetes risk prediction decisions that are explainable, deterministic, and fully auditable. Ethereum is adopted as the underlying platform, with a private blockchain environment deployed on a local Ganache testnet. This setup enables controlled, reproducible experimentation while avoiding the cost and latency associated with public blockchain networks.

The core smart contract, named ExplainableDiabetesDecision, is implemented using the Solidity programming language and serves as the final execution layer for recording prediction decisions on-chain [64],[65]. The contract encapsulates deterministic logic for storing the risk score, decision label, summarized XAI explanation, and relevant metadata in an immutable manner. The high-level structure and key components of the smart contract implementation, which is compiled and deployed using the Remix IDE, are illustrated in Figure 4, which highlights the on-chain data structures and functions responsible for decision persistence and retrieval.

```
pragma solidity 0.8.19;
contract ExplainableDiabetesDecision {
    enum DecisionLabel { LOW_RISK, HIGH_RISK }
    struct Decision {uint256 risk; DecisionLabel label; string exp; string model; string xai; uint256 time; address sender; }
    mapping(bytes32 => Decision) public decisions;
    uint256 public constant RISK_THRESHOLD = 7000;
    event ExplainableDecisionStored(bytes32 indexed h, uint256 r, DecisionLabel d, string e, address indexed s, uint256 t );
    function storeDecision(bytes32 h, uint256 r, string calldata e) external {
        require(h != bytes32(0) && r <= 10000);
        DecisionLabel d = r >= RISK_THRESHOLD ? DecisionLabel.HIGH_RISK : DecisionLabel.LOW_RISK;
        decisions[h] = Decision(r, d, e, "RandomForest", "SHAP", block.timestamp, msg.sender );
        emit ExplainableDecisionStored(h, r, d, e, msg.sender, block.timestamp);
    }
    function calculateDecision(uint256 r) external pure returns (DecisionLabel) {
        return r >= RISK_THRESHOLD ? DecisionLabel.HIGH_RISK : DecisionLabel.LOW_RISK;
    }
}
```

Figure 4: Structure of the ExplainableDiabetesDecision Smart Contract.
Source: Authors, (2026).

The overall blockchain implementation workflow, including importing Ganache wallets into MetaMask, compiling the Solidity code (Remix IDE), and deploying the smart contract using Ether provided by Ganache, is depicted in Figure 5. This workflow ensures that all transactions are executed through authenticated accounts and permanently recorded on the blockchain ledger [66],[67].

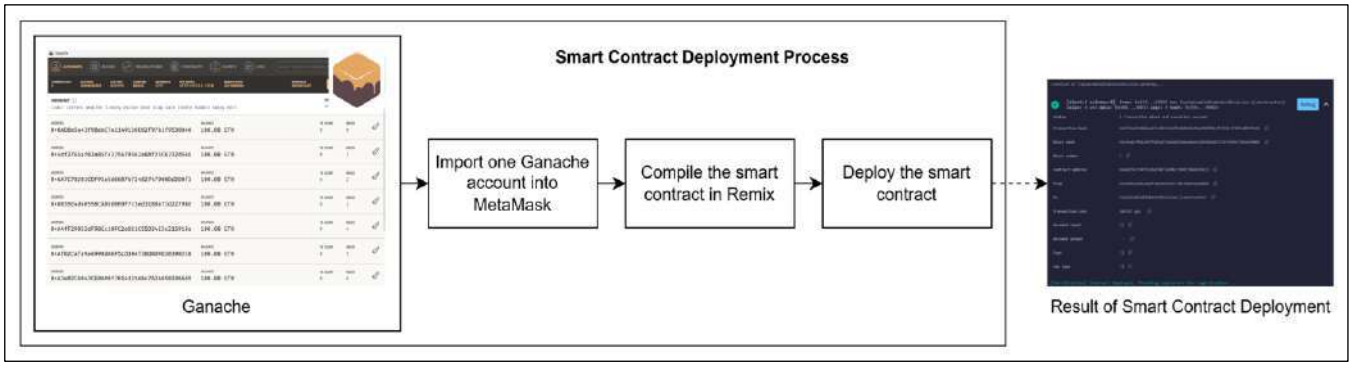

Figure 5: Smart Contract Deployment Flow on the Ethereum Test Network.
Source: Authors, (2026).

Conceptually, the diabetes risk decision is modeled as a deterministic function of the risk score generated by the machine learning model. The continuous prediction probability $p(x) \in [0,1]$ is first transformed into an integer-valued representation to avoid floating-point operations in the blockchain environment, as defined in Formula (4):

$$r(x) = \lfloor 10000 \cdot p(x) \rfloor \tag{4}$$

where $r(x)$ denotes the scaled risk score stored on-chain.

Decision labeling is performed using a fixed deterministic threshold ($\tau = 7000$), corresponding to a probability of 0.7. The choice of this threshold follows common practice in clinical risk prediction systems, where relatively higher probability cutoffs are adopted to yield more conservative risk classifications and to reduce the likelihood of false negative outcomes, particularly for chronic diseases such as diabetes [68-70]. In this study, the threshold is treated as a deterministic system design parameter that reflects a clinically motivated trade-off between sensitivity and specificity, rather than a value optimized solely to maximize predictive performance. The on-chain decision function is expressed as a step function in Formula (5):

$$d(x) = \begin{cases} 1, & r(x) \geq \tau \\ 0, & r(x) < \tau \end{cases} \tag{5}$$

where $d(x) = 1$ represents HIGH_RISK and $d(x) = 0$ represents LOW_RISK. The threshold value is treated as a deterministic system design parameter to ensure consistency and reproducibility of on-chain decisions.

To preserve patient privacy, explicit patient identities are never stored on the blockchain. Instead, a one-way cryptographic hash function is applied to the patient identifier, as defined in Formula (6):

$$h = \mathcal{H}(\mathrm{ID}_{\mathrm{patient}}) \tag{6}$$

where $\mathcal{H}(\cdot)$ denotes a cryptographic hash function and h serves as the primary key for decision storage.

The on-chain decision record can be represented as a deterministic mapping, as shown in Formula (7):

$$\mathcal{D}: h \rightarrow (r(x), d(x), e(x), m, a, t, s) \tag{7}$$

where $e(x)$ denotes the summarized local XAI explanation, m the prediction model name, a the explainability method, t the block timestamp, and s the transaction sender address.

Auditability is further reinforced through event logging whenever a decision is stored. Each event can be modeled as a log tuple, as expressed in Formula (8):

$$\mathcal{E} = (h, r(x), d(x), e(x), s, t) \tag{8}$$

This mechanism enables off-chain verification and traceability of decisions without modifying the blockchain state, thereby maintaining efficiency while preserving immutability and accountability.

III.6 INTEGRATION OF XAI OUTPUTS INTO THE BLOCKCHAIN (EXPLAINABLE BLOCKCHAIN-XBC)

The outputs of the Explainable Artificial Intelligence component are represented as local feature contribution vectors for each data instance, which are conceptually expressed as a set of feature–contribution pairs associated with the predicted diabetes risk probability, namely $\langle (f\_1, \phi\_1), (f\_2, \phi\_2), \ldots, (f\_d, \phi\_d) \rangle$. The contribution values may be positive or negative, indicating the direction of risk increase or decrease relative to the model baseline. Consequently, this vector is instance-specific and serves as the primary basis for interpreting the corresponding prediction decision. To preserve efficiency, determinism, and privacy, the full feature contribution vector is not stored directly on the blockchain. Instead, this study adopts an explanation summarization mechanism by selecting features with the largest absolute contributions to the predicted risk and representing their directional influence.

This process yields a concise explanation summary that retains the core interpretative meaning while remaining stable and suitable for on-chain recording. As illustrated in Figure 6, the procedure encompasses the generation of the contribution vector, feature ranking, and the construction of a local explanation summary for blockchain integration.

Input *: Test data instances, Trained Random Forest model, Predicted diabetes risk probability*
Output *: Local explanation summary based on feature contributions for each instance*
Steps:
1. For each data instance, perform inference using the trained Random Forest model to obtain the predicted diabetes risk probability.
2. Compute the contribution of each feature to the predicted risk probability using the SHAP approach, resulting in a local feature contribution vector.
3. Represent the explanation results as a set of feature–contribution pairs, where the sign of each contribution indicates the direction of influence.
4. Rank features according to the absolute values of their contributions to identify the most influential features.
5. Select a subset of features with the largest contributions as the primary explanatory representation.
6. Construct a local explanation summary that captures the dominant features and their directional effects on diabetes risk.

Figure 6: Formation of Explainable AI Outputs for Diabetes Risk Prediction.
Source: Authors, (2026).

Although Random Forest exhibits non-deterministic behavior during the training phase, the inference process and SHAP computation on a trained model are deterministic. As a result, the consistency of explanations recorded on-chain is preserved. The integration architecture between Explainable AI outputs and the blockchain is presented in Figure 7, which illustrates the data flow from model prediction, explanation summarization, to on-chain decision recording via smart contracts. This integration ensures that the association between risk scores, feature-based explanations, and final decisions is consistently maintained. From an implementation perspective, the integration process is carried out using the Python Web3 interface, which acts as a bridge between off-chain computational components and on-chain execution, as depicted in the system architecture shown in Figure 8 [71-73].

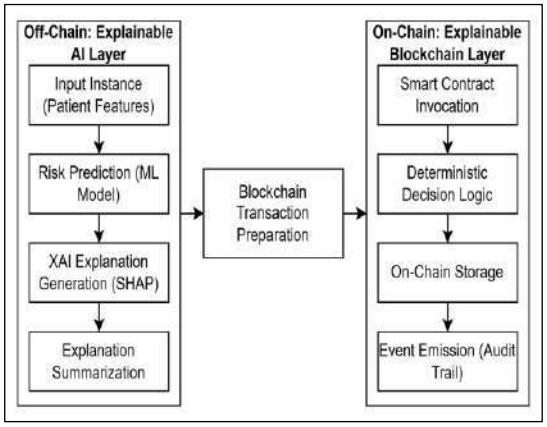

Figure 7: Integration of Explainable AI Outputs and Blockchain.
Source: Authors, (2026).

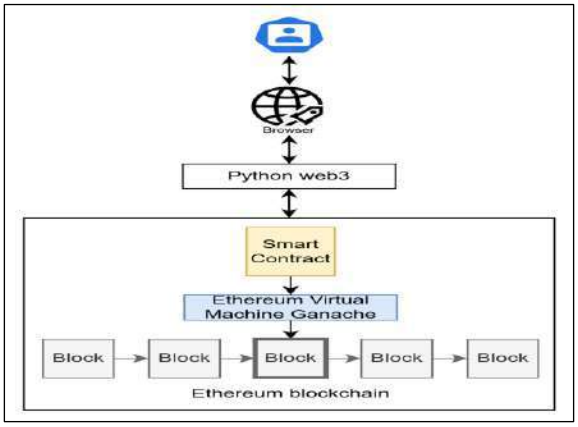

Figure 8: System Architecture for XAI–Blockchain Integration Using Python Web3.
Source: Authors, (2026).

The mechanism for recording explanation summaries and risk values on the blockchain is summarized in Figure 9. This algorithm describes how predicted risk probabilities are transformed into scaled risk scores, combined with explanation summaries and anonymized patient identifiers, and then deterministically processed by the smart contract to produce immutable and auditable risk decisions.

Input *: Predicted diabetes risk probability for each instance, Local explanation summary based on feature contributions, Deterministic risk threshold, Anonymized patient identifier*
Output *: Explainable and immutable diabetes risk decision records on the blockchain*
Steps:
1. Transform the predicted diabetes risk probability into a scaled integer-valued risk score.
2. Use a cryptographic hash of the patient identifier as a unique decision reference.
3. Submit the scaled risk score and explanation summary to the smart contract.
4. Recompute the risk decision label on-chain using a deterministic threshold.
5. Store the risk value, decision label, explanation summary, timestamp, and transaction information on the blockchain.

III.7 EXPERIMENTAL DESIGN AND EVALUATION PROTOCOL

The dataset is divided using a hold-out scheme, with 80% of the samples allocated for training and 20% for testing. A stratified splitting strategy is applied to preserve the original class distribution of diabetes risk across both subsets. During the inference stage on the test data, local SHAP-based explanations are generated for each instance and subsequently summarized by selecting features with the largest absolute contribution values [74],[75]. This process yields a compact and stable explanation representation suitable for on-chain integration. The evaluation of the machine learning model is restricted to two standard classification metrics: accuracy (the proportion of correctly classified instances out of all test samples) and the area under the receiver operating characteristic curve (AUC, which measures the model's ability to distinguish between high-risk and low-risk classes across various probability thresholds). These metrics serve only as supporting evidence of adequate predictive capability, as the primary focus of this study lies in explainability, system integration, and auditability rather than classification performance optimization [76], [77].

Furthermore, no quantitative or user-based evaluations of explanation quality were conducted, given that the core contribution centers on the architectural integration of XAI and blockchain for verifiable decision trails. In addition to model performance, this study introduces the ML-to-chain consistency metric to quantify the agreement between decision labels generated off-chain by the machine learning model and those recorded on-chain by the smart contract. This metric is defined in Formula (9):

$$\text{Consistency} = \frac{1}{N}\sum_{i=1}^{N} I\left(\widehat{y_i^{off}} = \widehat{y_i^{on}}\right) \tag{9}$$

where N denotes the number of test instances and $I(\cdot)$ represents the indicator function. Blockchain performance is evaluated using two operational metrics, namely transaction latency and gas consumption. Transaction latency for the i-th instance is defined as the time difference between transaction submission and confirmation, as expressed in Formula (10):

$$\text{Latency}_i = t_i^{mined} - t_i^{sent} \tag{10}$$

Gas consumption values are obtained directly from the transaction receipt and represent the number of gas units required to store a single explainable decision on the blockchain. Here $\widehat{y_i^{off}}$ and $\widehat{y_i^{on}}$ denote off-chain and on-chain decision labels. For latency measurement, t_i^{sent} and t_i^{mined} represent the transaction submission and confirmation times, respectively. These metrics collectively assess the feasibility and determinism of the XBC pipeline in a controlled environment. All experiments are conducted on a single device within a controlled environment to ensure full reproducibility. Detailed hardware specifications, software configurations, and experimental settings are summarized in Table 3.

Table 3: Experimental Environment Specifications.

Aspect	Specification
Processor	AMD Ryzen 5 6600H (12 CPUs), ~3.30 GHz
Memory	16 GB RAM
Operating System	Windows 11 64-bit
Programming Language	Python 3.11
Smart Contract Language	Solidity 0.8.19
Blockchain Network	Ethereum testnet (Ganache)

IV. RESULTS AND DISCUSSIONS

This chapter presents the experimental results and a systematic analysis of the Explainable Blockchain (XBC) architecture developed for diabetes risk prediction, with the evaluation focused on three main aspects: machine learning model performance, the clarity and traceability of Explainable AI–based explanations, and the efficiency and determinism of blockchain execution. The evaluation was conducted using 154 test samples processed by a Random Forest model and explained using the SHAP approach, such that each prediction produced a decision artifact that is not only quantitative but also structurally explainable. All outputs were subsequently recorded as individual transactions on a private Ethereum network based on Ganache, enabling direct observation of the stability of the end-to-end pipeline, from off-chain inference to immutable and auditable on-chain decision storage.

A summary of the integration results between diabetes risk prediction, SHAP-based local explanations, and on-chain recording is presented in Table 4, which shows a representative sample of the 154 test instances. The table explicitly links the patient index to the scaled risk score (0–10000), the deterministic decision label (HIGH_RISK or LOW_RISK), the three dominant features along with the direction of their contributions (+ or −), and two blockchain operational metrics, namely gas used and latency in seconds. This table structure allows readers to directly observe how machine learning model outputs are translated into blockchain records that simultaneously incorporate predictive, explanatory, and technical elements within a single row per patient.

Table 4: Local Explanation and Blockchain Summaries.

Patient Index	Risk Score Scaled	Decision Label	Top Features (Direction)	Gas Used	Latency (s)	Block Number	Patient Hash
0	7300	HIGH_RISK	Glucose (+), BMI (−), Age (+)	46,600	0.0657	158	0xa91f32c30547135498ac8474973825c5e66391000d3a2736fad2c9d86d97651a
1	1100	LOW_RISK	Glucose (−), Insulin (−), DPF (−)	52,045	0.0584	159	0x741cda503f58b3ff1e1c3dca3d1511e2d97fb735feb135e9a02f8dd60b612676
2	900	LOW_RISK	Glucose (−), Age (−), Pregnancies (−)	51,841	0.0536	160	0xc3d00a40215c1c6ac71ac8549b60d2faaee334d4159370173cca9174e0e5e0f7
…	…	…	…	…	…		
152	8700	HIGH_RISK	Glucose (+), DPF (−), Age (+)	51,987	0.0684	310	0xcc08a44064af3940ff42f0f50f605ccc157243a7a6694a5d5dbd238e23678a97
153	200	LOW_RISK	Glucose (−), Insulin (−), Age (−)	51,781	0.0549	311	0x76e1e29e1afc42859172e22558889a967a78e8b8d9207799b51825314ffae679

Source: Authors, (2026).

Each row in Table 4 demonstrates perfect alignment between the numerical risk score and the decision label generated by the smart contract using a fixed threshold of 7000. The variation of dominant features across patients—for example, Glucose (+) in high-risk cases and Glucose (−) in low-risk cases—indicates that the explanation summaries are instance-specific rather than fixed patterns. This characteristic confirms that the summarized SHAP mechanism preserves locally relevant information for patient-level clinical interpretation, even though only the top three features are recorded to maintain on-chain efficiency. The recording of 154 explainable decisions on the blockchain did not introduce any inconsistencies between off-chain inference results and on-chain execution, as evidenced by the alignment of scores and labels across all samples. Gas consumption per transaction ranged from 46,600 to 52,045 units, and latency ranged from 0.0536 to 0.0684 seconds, with limited variation and no strong correlation with the complexity of the explanation summary.

This range indicates that the smart contract design and summarization strategy successfully kept computational overhead under control in a private testnet environment, although the gas consumption remains relatively high compared to simple blockchain transactions and may be costly on public networks without further optimization. The analysis of the experimental results is visualized through two main components, namely the global explainability of the model and the consistency of decisions between the off-chain and on-chain environments, as illustrated in Figure 10 and Figure 11, respectively. Figure 10 presents the aggregation of absolute SHAP values as a representation of global feature contributions, while Figure 11 illustrates the alignment between machine learning model inference results and the re-execution of decision logic within the blockchain smart contract. In this context, predictive performance metrics such as an accuracy of 0.7468 and an AUC value of 0.8118 are presented as supporting information to demonstrate that the model possesses adequate discriminative capability, although performance evaluation is not the primary focus of this study, which emphasizes transparency, explainability, and decision auditability.

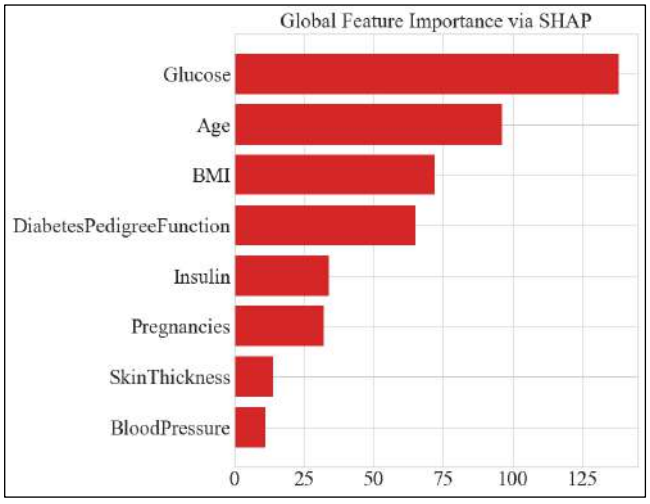

Figure 10: Global Explainability – Top-5 Features.
Source: Authors, (2026).

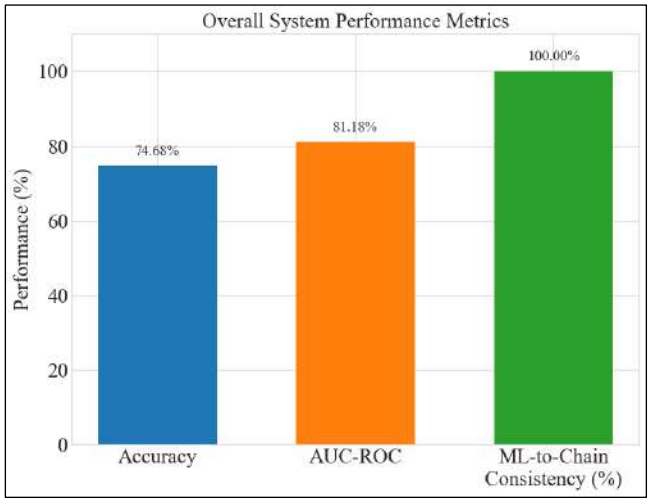

Figure 11: Performance and Consistency Metrics.
Source: Authors, (2026).

The aggregation results of SHAP values indicate that the five features with the greatest global influence on diabetes risk prediction are Glucose, BMI, Age, Diabetes Pedigree Function, and Insulin. The dominance of the Glucose feature, with the highest contribution value, reflects the model's sensitivity to physiologically relevant variables while also indicating that the employed non-linear learning mechanism preserves a decision-making structure aligned with established medical knowledge. This analysis confirms that SHAP values function not only as a technical interpretation tool but also as a semantic bridge connecting model outputs with the healthcare domain context, without claiming causal relationships beyond the scope of predictive methodology. However, in relatively small medical datasets such as the Pima Indians Diabetes Dataset (768 samples), SHAP values are more susceptible to higher variability due to sampling noise and class imbalance, and therefore global interpretation should be conducted cautiously and ideally validated using bootstrapping techniques or larger external datasets to improve the reliability of feature contribution estimates. Another crucial aspect illustrated in Figure 11 is the complete consistency between decisions generated off-chain and those recorded on-chain, represented by an ML-to-chain consistency metric value of 1.0, which confirms that the processes of risk probability transformation, score scaling, and deterministic threshold application within the smart contract do not introduce decision discrepancies or additional computational artifacts.

As a result, the integration between the machine learning model and the blockchain can be viewed as a stable deterministic mapping in which each predictive decision can be independently reproduced and verified, emphasizing that the system's primary contribution lies in ensuring the integrity and traceability of AI-driven decisions rather than solely optimizing performance metrics, thereby reinforcing the role of Explainable Blockchain for medical applications requiring high accountability. In addition, the distribution of blockchain operational performance for the 154 explainable transactions is visualized in Figure 12 and Figure 13, where Figure 12 presents the transaction latency sequence from the first to the last patient and Figure 13 shows the gas consumption per transaction executed by the ExplainableDiabetesDecision smart contract, together illustrating temporal patterns and computational load across the entire decision-recording process and enabling a direct assessment of performance consistency within the private Ganache testnet environment.

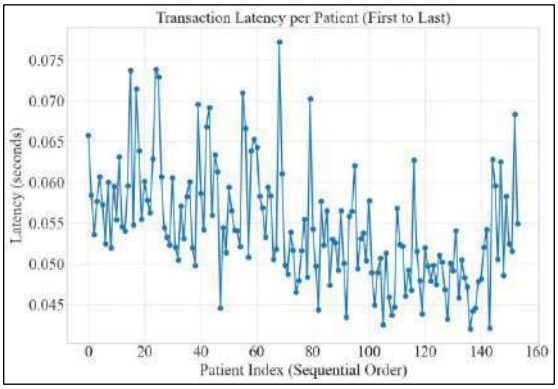

Figure 12: Transaction Latency per Patient (First to Last).
Source: Authors, (2026).

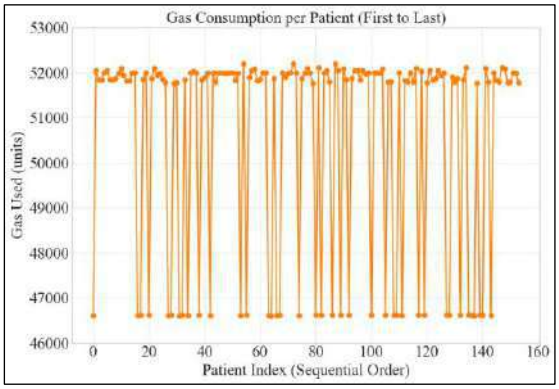

Figure 13: Gas Consumption per Patient (First to Last).
Source: Authors, (2026).

Latency measurements range from 0.043 to 0.077 seconds, with an average of 0.0546 seconds across all samples, indicating that block confirmation times in the private network remain stable even when transactions are submitted sequentially. For medical decision-support applications, latencies below 100 milliseconds are sufficiently low to support batch processing or near real-time recording, especially since the blockchain functions as an auditing layer rather than the primary clinical inference pathway, which would otherwise require sub-millisecond responsiveness. Gas consumption per transaction lies within the range of 51,000 to 52,000 units, which is moderate to high compared to basic blockchain operations such as simple value transfers or minimal data storage. This gas usage is mainly driven by the permanent storage of state elements, including the scaled risk score, decision label, model metadata, and the string-based explanation summary of the top three features. The consistency of gas values across transactions indicates that variations in explanation string length do not cause significant increases in computational overhead.

At this level of gas consumption, deployment on the public Ethereum network could result in financially impractical costs for large-scale clinical decision logging, highlighting a trade-off between the depth of explainable information stored on-chain and the resource limitations of current layer-1 blockchain infrastructures. Although the proof-of-concept architecture demonstrates determinism and traceability of AI-driven decisions in a controlled environment, further optimization is required for real-world healthcare deployment, including layer-2 solutions, stronger data compression, or hybrid storage mechanisms. The evaluation of blockchain operational efficiency was performed by analyzing gas consumption and transaction latency distributions across 154 explainable decision records, as shown in Figure 14 and Figure 15, where Figure 14 depicts gas usage per transaction and Figure 15 shows latency in seconds, together supporting assessment of performance consistency and potential scalability bottlenecks within the private Ganache testnet environment.

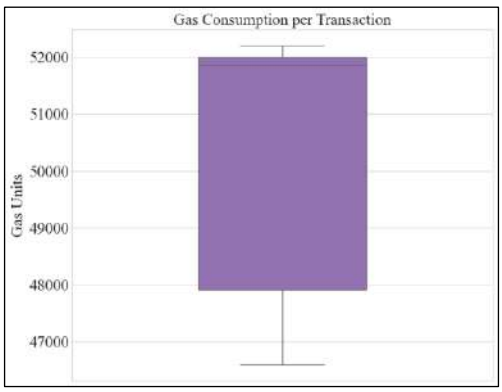

Figure 14: Gas Consumption per Transaction.
Source: Authors, (2026).

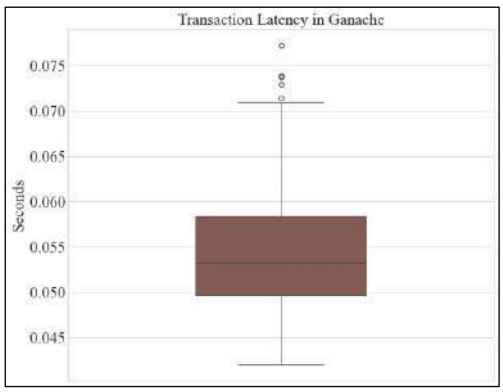

Figure 15: Transaction Latency Distribution.
Source: Authors, (2026).

Gas consumption statistics show a minimum of 46,598 units, a maximum of 52,202 units, a median of 51,865 units, a first quartile of 47,909 units, a third quartile of 51,997 units, and an average of 50,595 units. The relatively narrow interquartile range of approximately 4,088 units indicates that the central 50 percent of transactions fall within a constrained interval, with variation mainly caused by minor differences in the length of explanation summary strings rather than changes in data structure or smart contract logic. Transaction latency ranges from a minimum of 0.0420 seconds to a maximum of 0.0772 seconds, with a median of 0.0533 seconds, a first quartile of 0.0497 seconds, a third quartile of 0.0584 seconds, and an average of 0.0546 seconds. The median being lower than the mean indicates a distribution skewed toward lower values, meaning most transactions complete faster than the average with only minor upper-end outliers.

Together, these statistics demonstrate that the Explainable Blockchain architecture in this Ganache-based proof-of-concept delivers stable and consistent performance across 154 transactions, with no significant upward trends in gas consumption or latency over time, while the average gas usage above 50,000 units implies substantial cost concerns on the public Ethereum network, positioning this approach as more suitable for private auditing systems or requiring on-chain data reduction techniques for large-scale clinical applications. This study's primary contribution is the development of an Explainable Blockchain architecture that integrates Random Forest based diabetes risk prediction with summarized local SHAP explanations permanently recorded on an Ethereum smart contract.

The system successfully recorded 154 explainable decisions with an ML to chain consistency of 1.0, providing an immutable, deterministic, and pseudonymized audit trail for each prediction. By combining explanatory transparency with distributed ledger data integrity and using identifier hashing, this approach addresses black box limitations in healthcare while supporting clinical accountability and trust without compromising patient privacy. Despite stable operational performance on the private Ganache testnet, the average gas consumption of 50,595 units per transaction remains high compared to simple blockchain operations, which may be economically impractical on the public Ethereum network for large scale clinical logging. In addition, reliance on the relatively small and imbalanced Pima Indians Diabetes Dataset with 768 samples makes both local and global SHAP estimates vulnerable to sampling noise, indicating that feature contribution interpretations require further validation through external datasets or resampling techniques.

Further limitations include fluctuating gas costs and longer block times under public network conditions, as well as reduced interpretative depth caused by restricting on chain explanation summaries to the top three SHAP features when lower ranked features may still have meaningful contributions. Nevertheless, these limitations do not detract from the study's core objective of providing an immutable, deterministic, and pseudonymized audit trail for each predictive decision, since the recorded summaries remain instance specific and independently verifiable via the smart contract. Future work should evaluate the architecture on public testnets or layer 2 solutions such as Polygon or Optimism to assess latency, gas costs, and scalability under realistic conditions, while also exploring on chain data compression or hybrid storage strategies to reduce overhead without sacrificing auditability [78],[79]. Additional validation using larger and more diverse medical datasets, along with comparisons to alternative explainable AI methods, is required to strengthen generalizability and support broader clinical adoption.

V. CONCLUSIONS

This study successfully demonstrated the Explainable Blockchain (XBC) framework, which seamlessly integrates Random Forest-based diabetes risk prediction with local SHAP explanations and immutable on-chain storage via Ethereum smart contracts, achieving an accuracy of 74.68%, AUC of 0.8118, and perfect ML-to-chain consistency (100%) while maintaining low latency (average 54.6 ms) and manageable gas costs in a private testnet environment. The primary scientific contribution lies in pioneering an architecture that bridges explainable AI and blockchain at the individual decision level, providing a tamper-proof, pseudonymized audit trail that enhances transparency, accountability, and regulatory compliance in AI-driven healthcare—addressing critical gaps in black-box model interpretability and verifiable decision provenance.

Practically, this framework holds promise for clinical decision support systems, enabling clinicians, patients, and regulators to independently verify AI predictions without compromising privacy, thereby fostering greater trust and potential adoption in resource-constrained settings. However, limitations include reliance on a small, imbalanced dataset leading to potential SHAP variability, high gas consumption unsuitable for public networks at scale, and partial explanatory depth due to summarization of only top features. Future research should validate the approach on larger, diverse clinical datasets, explore layer-2 optimizations or hybrid storage for cost-efficiency, and compare with alternative XAI methods to advance scalable, real-world deployment in healthcare AI applications.
