These attacks target weaknesses in e-commerce websites, apps, databases, and systems to obtain access without authorization, steal sensitive data, interrupt services, or engage in fraud, which poses additional difficulties. To overcome these issues, we proposed machine learning (ML) based techniques in IT project management for the e-commerce industry, it has several advantages that improve project productivity, decision-making, and success. For assessing the security of web-based applications, Burp Suite is a strong and popular cyber security tool. To find and fix vulnerabilities in internet-based applications, security experts, malicious hackers, and testers of vulnerability frequently utilize it. It offers an extensive number of features to find weaknesses. This research proposes anovelapproach utilizing the Burp Suite and CatBoost gradient boosting machine learning algorithm to detect and forecast issues in E-commerce IT project management systems, specifically focusing on mitigating vulnerabilities and attacks. Furthermore, if an attack node is detected by DBN, the control is transferred to a lightweight lure approach that consistently mitigates the most frequent attack nodes not disrupting normal connections. A prospective avenue for improving the management of IT projects is provided by the utilization of machine learning.

I. INTRODUCTION

The information and data are rapidly being accessed through the Internet to transfer from one point to another across the network [1], [2]. The employment of modern technology in global e-commerce has greatly increased in recent years [3-5]. Online marketplaces like eBay and Amazon saw a boom in the 1990s. Due to the tremendous changes that internet commerce has made to modern life; it is now regarded as remarkable [6–8]. E-commerce has outstanding advantages that have changed the business environment by improving customer experiences and extending market reach. At the same time the utilization of E-commerce business is confronted with Cyber security Vulnerability Attacks. [9], [10]. The practice of safeguarding data by identifying, thwarting, and reacting to cyber-attacks is known as cyber security today and has gained significant global attention. Furthermore, it can also be used to keep user assets in the cyber worldwith the procedures and tools embedded with it to safeguard computer systems and networks against unauthorized access and online assaults. [11–13]. The top rated attack among e-commerce attack is SQL injection attack. A linear database's data may be added, deleted, modified, and queried using the database language SQL. Throughout the duration as the system employs a database, SQL statements are used for the majority of database interactions. Developers commonly utilize the technique of combining characters to create SQL queries that are given to the server while writing code, which is the major cause of SQL injection vulnerabilities [14-16]. Hackers can alter the SQL statement by utilizing particular characters or SQL words. The execution leads to an assault on the system.Attacks using SQL injection are depicted in Figure 1.

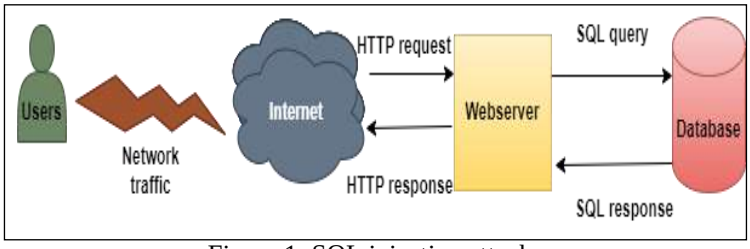

Figure 1: SQL injection attack.
Source: Authors, (2026).

A software security tool for checking the reliability of web-based applications is called Burp Suite [17], [18]. It aids in locating potential security flaws and weaknesses.The majority of bug bounty hunters and professionals in web application security utilize it. It aids in the automation of attack vector identification and vulnerability detection for applications on the internet. Abnormal occurrences or unexpected system behaviour are identified through anomaly detection, which is the most frequently employed attack detection strategy. The majority of these algorithms, however, have only been trained on specific types of attacks and are unable to identify obscure or novel attacks. Through the utilization of an assortment of machine learning algorithms, these methodologies are integrated and executed [19-21]. Among these, the CatBoost Algorithm assumes a pivotal role in our approach, providing adaptive defense against cyber threats, proficiently handling categorical characteristics, minimizes overfitting and offers a predictive tool based on susceptibility attack patterns[22], [23]. Its collaborative synergy with Burp Suite facilitates proactive vulnerability management, aligning seamlessly with contemporary risk mitigation principles. Beyond bolstering decision-making and enhancing project productivity through machine learning insights, CatBoost. A cooperative bait approach is essential: Cooperation among nodes is a fundamental prerequisite for the establishment of communication in mobile ad-hoc networks (MANETs). When malicious nodes are present, this requirement may result in significant security concerns, such as the disruption of the routing process. Malicious nodes initiating grey hole or collaborative black hole attacks are a challenge to prevent or detect in this context. This issue can be resolved by developing a cooperative bait detection scheme (CBDS), which is a routing mechanism based on Ad-hoc on-demand distance vector routing (AODV). Additionally, in order to mitigate the presence of adversary devices, this paper introduces a cooperative BAIT approach. It is possible to recapitulate the primary contributions as follows:

- To identify the vulnerabilities in the e-commerce application, the scanned features of identification tools like Burp Suite was utilized during the study. Burp Suite makes a substantial contribution to the prevention of cyber security vulnerabilities by identifying flaws, offering confirmation, producing reports that can be put into action, and supporting an aggressive and iterative approach to security.
- With the obtained substantial features of Burp suite, the CatBoost classifier gains knowledge from previous susceptibility attacks. CatBoost gains knowledge from Burp suite on susceptibility attacks and occurrences, as it can spot trends and actions linked to assaults, aiding in the identification of impending dangers.
- As the CatBoost algorithm and the Burp Suite tool may greatly improve the protection of aplatform for e-commerce or any IT project by offering a variety of methods for finding,mitigating, and avoiding cyber security risks. Furthermore, to mitigate the detected SQL injection attack the approach of BAIT was proposed during the study.

The proposed work takes into account the aforementioned inputs. E-commerce facilities manage critical consumer data, such as contact data, transaction data, and transaction records. Finding vulnerabilities protects both the E-commerce network and its users from money losses or other protection issues. In our internet-based IT project management platform, we use the machine learning algorithms Burpsuite and CatBoost to find vulnerabilities. The experimental study unequivocally demonstrated that the proposed approach is better than the ones currently in use.Following are the sections of the study that are organized as follows. This research endeavours to rectify the deficiencies of the related study, as delineated in Section 2. In Section 3, the research's preliminary stages are illustrated. The favoured method for the article is explicated in Section 4. The outcome is described and formalized in Section 5. The investigation concludes in Section 6.

II. RELATED WORKS

As time has passed, a variety of methods have been devised to protect e-commerce platforms from cyber-attacks and ensure their integrity and security. In spite of this, the ever-changing cyber threat landscape requires the ongoing enhancement and modification of these strategies. The objective of this research is to improve IT project management in the context of e-commerce security by investigating the potential of cutting-edge ML techniques, particularly the CatBoost algorithm, to fill a gap in the existing literature. Numerous prior investigations have investigated diverse methodologies for IT project management and e-commerce security:

In [24], the impact of company procedures on the calibre of IT project leadership was addressed. Using a quantitative survey methodology and questions based on variable indicators, it examines how the GPL software and business process affect the calibre of IT project management. Several linear regressions are used to analyze the data, and the T-test is used to determine whether the hypothesis is correct. Regression research revealed that business process and GPL application, the independent factors, accounted for 77.1% of the variance in the variable that was dependent, the level of IT project management. A cloud-based outsourcing architecture for effective IT project management procedures is described in the research [25]. It makes use of cloud computing technology to address issues like the dearth of qualified IT personnel and the inadequate infrastructure for IT in developing nations like Ethiopia. This enables outsourced IT personnel to remotely plan, build, and test IT projects. The framework was created utilizing a combination of data analysis methodology after a thorough and methodical examination.

The research [26] provides an interpretive lens to examine the difficulties that the banking industry encounters while transferring and handling project management experience knowledge inside IT projects. This paper explains the procedures for gathering, preparing, and analyzing data, which involves the use of conversations with IT project managers in the IT project management workplace of a worldwide banking organization. It ends with implications, caveats, and useful suggestions for applying prior IT project management experience to new projects through organizational learning.Microsoft uses ML and optimization approaches to cut down on online scams, as mentioned in [27]. It explains the decision-making procedure for approving, rejecting, or manually examining transactions, taking into account elements including the risk of fraud, potential future revenue loss, and client experiences.The research [28] suggests techniques and methods based on DL classifiers handle the problem of handling vast e-commerce catalogs. The three types of architecture are examined. In addition to highlighting the need for hyperparameter adjustment for the best performance, the research offers perspectives on the potential benefits of multifunctional systems in merging information from many data sources.On e-commerce sites, the risk of price scraping was discussed in [29]. It proposes a brand-new price-scraping assault scenario and systematically explains how the attack scenario should be executed. Through a series of studies, the duration and bit entropy analysis-based security mechanism were tested. The analysis of the results showed that the method is effective at separating price-scraping software from legitimate users.

The study [30] concentrated on e-commerce security challenges and suggested a way for data protection using an LFSR, Pell's approach, and a Model of security based on linear congruence. The method makes use of session credentials and intermediate keys for encoding, decoding, and verification. The studies done on this approach show its efficacy and reliability for e-commerce and e-business.A sub-graph-based technique called SubGNN was presented in the study [28] for the collaborative identification of fraud in e-commerce platforms. It achieves accurate fraud detection by employing a CNN with a graph model to acquire data logic rules on retrieved subgraphs. On the Taobao dataset, the suggested SubGNN technique detected fake transactions. In the research [31], measures of security were provided to prevent SQL injection, XSS, and invalid authentication issues in PHP-based online applications, notably e-commerce websites. To evaluate the suggested security measures and provide a library that can be used by PHP-based websites, this article creates a fully working e-commerce website.A classification of logic attacks was presented in [32] as a result of component-based programs' imprecise and bad implementation. It finds two different kinds of weaknesses in these apps, categorizes them, and suggests a logical risk classification-based taxonomy. It organizes the categorization of each assault and talks about two different types of weaknesses and coding errors in the software used for the applications, especially in the middle of the framework.

III. PRELIMINARIES

III.1 SQL INJECTION

Numerous researchers have examined SQL injection detection issues from various perspectives and methodologies since the advent of SQL injection up until the present. Currently, there are essentially two sorts of SQL injection prevention techniques [33], [34]. To safeguard operational security, one is to take security considerations into account when programming, while the other is to identify SQL injection threats by taking additional precautions when the program is in use. The classification of SQL attack sources, kinds, and aims is shown in Table 1 below.

Table 1: SQL attack sources, goals,andTypesclassification.

Attacks		
Sources	**Goals**	**Types**
Input of the User Cookies Server variables Injection over 2nd order	Database fingerprinting Analyzing schema Data extracting Amending data Executing dos Identification of incorrect Circumventing security Remote management Increase in privilege	Tautology Illegal/logicallyincorrect queries Union query Piggyback query Stored procedure Inference Alternate encoding

Source: Authors, (2026).

III.2 VULNERABILITY ASSESSMENT

Our vulnerability evaluation is a process or approach to identify security risks and gaps in a system's defenses that might allow intruders to access and manipulate its data. To take safety measures and defend their websites, this can help businesses and website owners identify their weaknesses. There are multiple types of vulnerability assessments, including:

1. A vulnerability evaluation of the network.
2. Evaluation of host-based vulnerabilities.
3. Evaluation of web application vulnerabilities.
4. Testing for penetration.
5. Compliance evaluation.

The Burp Suite tool, a website-based analyser and vulnerability assessment tool, is used in this study.

III.3 BURP SUITE

An efficient framework and visual instrument for secure web application testing is Burp Suite. The program was created by PortSwigger Security and is built in Java. In Addition to that, Burp Suite provides tools for manual testing of penetration. One of the key aspects of Burp Suite is its capacity to monitor HTTP requests [35]. As a proxy service, Burp may intercept or record all communication between the client's internet browser and the program's web database by placing itself in between them. Burp Suite provides efficiency features like "Deep-Dive Message Analysis" and "Utilize either built-in and customized settings" in addition to sophisticated and customized automated assaults like "automatically manipulate HTTP messages". The Burp Suite analyzer can continuously scan the software to find issues and crawl it to learn about its operation and data [36]. The procedures to find website defacement using a tool that detects vulnerabilities are shown in the Figure 2 below.

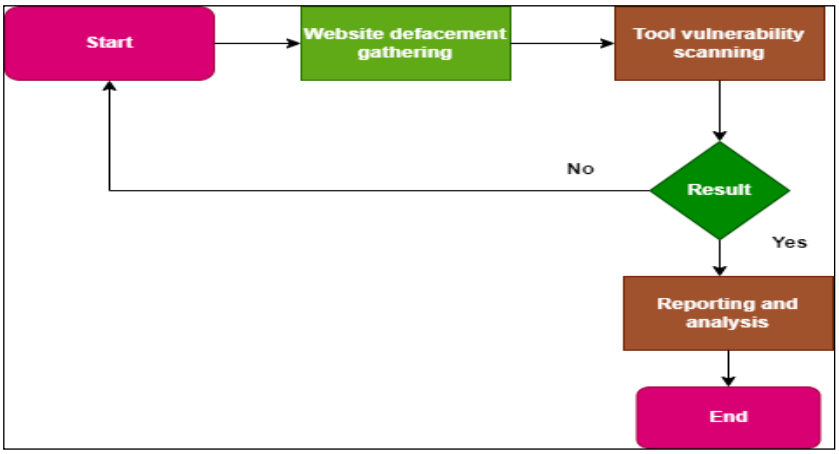

Figure 2: Steps used by security scanning technologies.

IV. PROPOSED METHODOLOGY

To improve the effect of cybersecurity on the detection and fixing of e-commerce based attacks like SQL injection, with the tools of Burp suite is integrated with machine learning algorithm of Cat Boost and the approach of BAIT is proposed in this study. The SQL injection attack is identified and mitigated with introduced integrated model of CatBoost with tools like Burp Suite as well as with the approach of BAIT. The exchange of products and services via the Internet and other digital platforms is referred to as e-commerce. EDI and the Internet are essential components of an organization's IT infrastructure. E-commerce is the term used to describe the direct sale of products or services to a client through a vendor's website on the Internet. Through an online shopping cart or purchasing basket, the payment processor takes transactions made via a credit card, debit card, or EFT.The value-generating relationships between companies and between people are created, modified, and redefined in commercial transactions using communication technologies and digital information processes. Due to the growing usage of ICTs, particularly the Internet, the business sector is swiftly transitioning towards e-commerce (B2B) [37], [38]. Unlike other IT projects, e-commerce initiatives may have particular requirements and difficulties.

Project managers may get specialized knowledge and knowledge of these particular needs by integrating E-commerce into IT project management. To identify SQL injection utilizing the Burpsuite tool and CatBoost technique for minimizing the attack and enhancing the system, appropriate IT project management and E-commerce practices must be included. Protecting your company and consumer data from possible attacks, it proactively discovers and handles security issues in your e-commerce environment. Websites may be attacked for variousmotives, but the frequent thing is that they have serious security holes that let attackers access the backend of the website and subsequently upload an external scripting file. However, due to a weakness that compromises the website, attackers can damage a website. Numerous hacking methods, such as SQL injection, XSS, local or external file participation, unauthorized username and password ownership, and antiquated software are at their disposal. A mistake or a condition where one is exposed to the prospect of a hacker attack is known as vulnerability. There are other forms of vulnerabilities, but SQL injection was our main attention.

IV.1 ZONES-H DATA

The Zone-H dataset was used to validate the framework and assess the system assault. The effectiveness of proposed methods is now often examined by academics utilizing this dataset. This study takes advantage of the collection of online defacements kept at the website "Zone-H" to analyze variability in the continuous paths of defacers. Zone-H data, which is utilized in hacker and victim research, is a large dataset with over thirteen million documents that are a mixture of organized and unorganized information. To present, investigations utilizing Zone-H data have depended on the information contained in the metadata sections. An illustration of an unprocessed Zone-H record can be discovered in Figure 3.

"2012-01-01 19:37:37","2012-01-12 20:48:09","TeaM 007 - Persian Defuse HackingTe

m","regular","no","published","homepage","16504269","United States"

Figure 3: Zone-H record samples.
Source: Authors, (2026).

Although the Zone-H collection has more than 13 million files, filters for each research decrease the number of data according to the study's requirements. For instance, a collection of 466220 data was used in the Cultural Investigation of Assault Vector Preferences for Self-Identified Hackers research; however, 267556 records were left after attack vector filtering. The number of files utilized and the research variables are included in each of the research papers cited in this publication. Zone-H's objectives are to track security developments and assess the rising significance of hacking. As seen in Figure 4, they were grouped based on the nations to which they belonged.

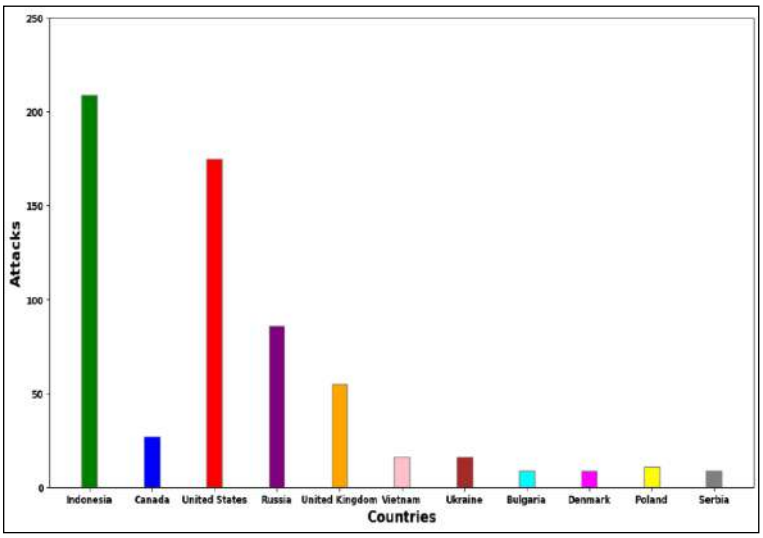

Figure 4: Website defacement data gathered from nations for the Zone-H dataset.
Source: Authors, (2026).

Defacement committed by a malicious attacker can be submitted to the Zone-H portal using an online form. Reporters are required to give a hacker handle (i.e., the person or organization's adopted online identity) that is designated as the "notifier" for the assault. Additionally, they are requested to report particular defacement details, such as the assault's time and date, the internet address that was defaced, its methodology, and the attacker's motives. After the Zone-H managers have verified this information, the defacement is subsequently preserved and permanently replicated on their website. Due to these circumstances, Zone-H is essentially a self-reported resource for web defacements, much like conventional source materials for research in criminology. The researchers looked to obtain the data in March 2017, at which time theyconcentrated on assaults that occurred in Zone-H throughout January 2010 and that month.

IV.2 DATA PRE-PROCESSING

A critical step in enhancing or ensuring performance is pre-processing data, which is also referred to as information spilling or manipulating data. This process involves the cleaning, transformation, and organization of unprocessed data in order to facilitate analysis or modeling. The process which alters the data into format which will apt for the analysis of machine learning. Data are availed in the various forms, the system viability to read as binary; for this condition it is formatted prior to the evaluation.In addition to that, the redundant data are removed from the dataset to reduce the computational complexity as well as increases the efficiency of classifier.The final pre-processed data undergoes the analysis with the burp suite tools.

IV.3 ANALYSIS WITH BURP SUITE TOOL

To check websites for faulty URL problems, we scanned 1000 URLs previously gathered from the Zone-H dataset using Burp Suite. Threats were found through attacks across the board in the domains. High-hazard problems, such as SQL injections, were discovered using the Burp Suite tool. The Burp Suite technique discovered problems and threats that were of a higher degree than those found by alternative tools like the OWASP ZAP software. Compared to the OWASP ZAP software, the Burp suite's scanning time is shorter. Figure 5 displays the time taken to scan using the OWASP ZAP software and the Burp suite.The Burp Suite tool undoubtedly discovered some vulnerabilities that the other tools had overlooked. A statistical comparison of several pen testing tools, including OWASP ZAP and Burp Suite, is displayed in Table 2.

Early vulnerability identification in network and online applications is necessary due to the potential for avoiding future high levels of risk. However, in our study, we examined over 1,000 websites and discovered that the proposed device was superior to the other software for determining and exhibiting faults. With the aid of this software, programmers can examine websites and alert users to problems at all stages medium, high, and low by conducting an analysis.Because it displays three stages the Burp suite is the most effective and powerful in terms of identifying problems. It is also suitable for high-secure software. This utility does a vulnerability scan and an intrusion test. Additionally, by facilitating and setting a priority for every issue so that companies can be categorized as average, excessive, or lower, it aids programmers in discovering flaws that they can rely on to handle vulnerabilities and risks.

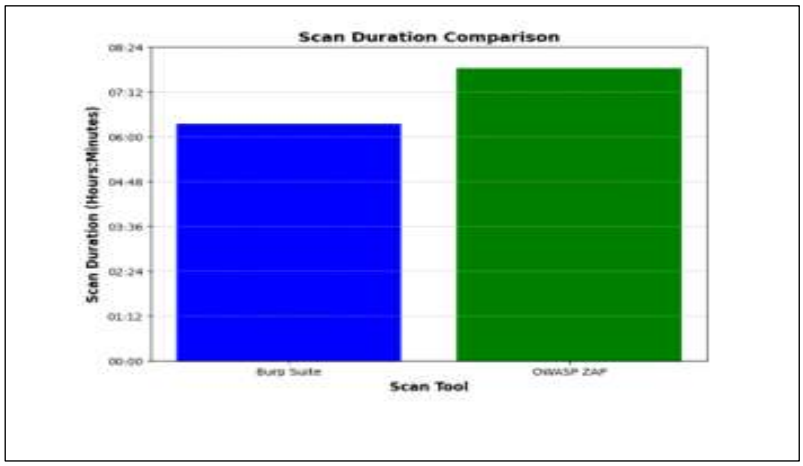

Figure 5: Scan duration comparison.

We utilize Burp Suite in our framework to find problems. A dataset including details about the discovered weaknesses and pertinent attributes is produced by this method. You download the information from Burp Suite once the vulnerabilities have been found. The foundation of our ML model will be this transferred data.

IV.4 CATBOOST

The research introduces ground breaking theoretical advancements in the intersection of cyber security and IT project management within the e-commerce sector. Through the innovative integration of the Burp Suite cyber security tool and the CatBoost machine learning algorithm, the study establishes a critical nexus between security measures and project management practices [39-41]. Furthermore, the study emphasizes a paradigm shift towards data-driven decision-making, leveraging the CatBoost algorithm to empower project managers with informed insights derived from the analysis of vulnerabilities detected by Burp Suite. Enhanced overall project productivity and success are fundamentally dependent on this transformative shift. As the research emphasizes the proactive identification and classification of vulnerabilities, the theoretical implications extend to resource optimization and strategic project planning. By integrating machine learning techniques, particularly CatBoost, into project planning, project managers can prioritize security measures based on prospective impacts, thereby adding a strategic dimension. The CatBoost algorithm is an effective ML technique for predicting feature types. CatBoost is a gradient-boosting technique that utilizes multimodal decision trees as its initial detectors. Consider the following scenario:

We examine a data set with instances K= (i_y, y_j) j=1, a, where i_ (y= (i_(y,) 1 I_ (y,) 2 i_yn)) vectors and response value j_y 2R is a feature that can be binary (i.e. yes or no) or encrypted as an integer (0 or 1). Samples (iy, jy) have identical and separate distributions based on an unidentified distribution. The understandingtask's objective is to develop an expressionH R (n) R H that minimizes the predicted loss indicated in (1).

$$L(\mathrm{H}) \coloneqq \mathbb{E}L\big(y, H(X)\big) \tag{1}$$

Where $L(\bullet,\bullet)$ is the loss equation of smooth function and the testing data (X, y) is a sample. The gradient enhancing process builds a repeated series of estimates$H^t: \mathbb{R}^m \to \mathbb{R}, t = 0,1,$ ...in a rapacious manner. From the prior estimation, H^{t-1}, H^t is earned through an additive procedure, such that$H^t = H^{t-1} + \alpha g^t$, with a stage size and variable $g^t: \mathbb{R}^n \to \mathbb{R}$, These are basic predictors and it's chosen from a collection of variables G to lessen or minimize the predicted loss given in (2):

$$g^t = \arg\min_{g \in G} L(H^{t-1} + g)$$

$$= \arg min_{g \in G} \mathbb{E}L\big(y, H^{t-1}(X) + g(X)\big) \tag{2}$$

The optimization issue is frequently handled via the Newton approach utilizing a (negative) gradient step or a second-level estimate of $L(H^{t-1} + g^t)\ at\ H^{t-1}$. Gradient descent can apply to both of these tasks. You may get a more detailed description of the CatBoost technique.

The key features of CatBoost:

• Level-wise tree: It divides learning samples into different levels via level-wise balanced trees (Figure 6). A vectorized version of the tree is implemented by the architecture and can be quickly examined.

• Combinations of ordered enhancing with categorical variables: By utilizing impartial enhancing methods with categorical attributes to eliminate gradient bias, ordered enhancing can be used as a novel way to estimate the slope and improve the generalization capacity of the framework.

• Random permutation: CatBoost implements gradient enhancement and, to avoid over-fitting issues, randomly permutes the training data. The random combinations are initially produced by randomly arranging the provided data.

• One-hot encoding: This situation necessitates one-hot encoding since GBM is unable to deal with categorical data. When converting categorical characteristics to target statistics, CatBoost, however, immediately includes the one-hot encoding procedure.

• Optimized variable tuning: It offers a configurable user interface for hyper-parameter adjustments, such as adjusting the rate of learning and tree level. The maximum level of analytical precision is ensured by these standards.

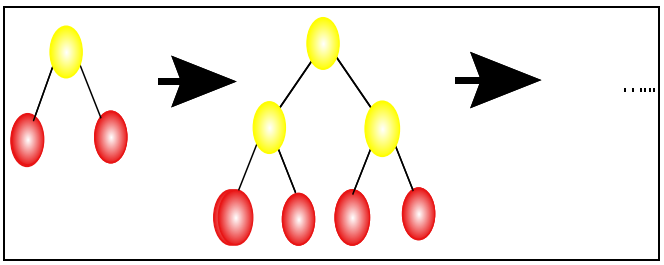

Figure 6: Level-wise tree growth in CatBoost algorithm.
Source: Authors, (2026).

CatBoost creates several decision trees, which generate many selections in response to the given characteristics. Sequentially adding trees, each one concentrates on fixing the mistakes caused by the preceding one. We refer to this as boosting. Threats may be avoided because of CatBoost's capability to deal with categorical data. It employs a technique that is effective at transforming categorical characteristics into numerical form, which is crucial for the development of ML algorithms. It employs a kind of gradient descent, an optimization process designed to identify the model's best-fitting variables. By combining all of the individual trees' estimations after the group of trees has been built, prevention is achieved. To strengthen security in e-commerce platforms, Burp Suite can be used within the IT project management process to identify vulnerabilities like SQL injection during vulnerability assessments. Train CatBoost models using data collected from Burp Suite's vulnerability assessments. These models can then learn to identify patterns indicative of SQL injection attempts.Integrate the trained CatBoost models into the IT project management process. During website operation, these models can analyze incoming traffic in real-time, flagging potential SQL injection attacks based on the learned patterns. To mitigate the identified attack, the data are further processed under the approach of BAIT.

IV.5 SQL ATTACK MITIGATION WITH BAIT APPROACH

By employing the BAIT mechanism, the malicious node is deceived into transmitting the erroneous route request to the counterfeit route request. This methodology is designed to mitigate and identify attack nodes. The most efficient and shortest path to their targets is generally advertised by malicious nodes. On top of that, the rogue node transmits a route request packet to the source, which is prohibited. As a consequence, the source node in the proposed task transmits the fabricated request to the destination address through the nearest node.

A malicious node responds to a request, regardless of whether it is the target node. The flow table search is used to process this request. This is followed by the identification and mitigation of the attack. After a malicious node transmits a response, the source node compares it to the destination address. The source node considers the node to be malicious and denies the response request if the addresses do not match. The data flow will proceed as expected in the absence of any intruder nodes. A non-attack intermediate node transmits a route request packet to the destination node, along with the address, upon its arrival. Upon the determination of the shortest route between the source and the destination, you may be confident that the data will be transferred. The initial step in the testing process is to compare the test data with the security log file. The data will be prohibited from being processed further if the source IP address of the information is already present in the security log file. If it is not present in the security log file, the cyber-attack detection and prevention process is implemented. In Figure 7, the BAIT approach's overarching structure is illustrated.

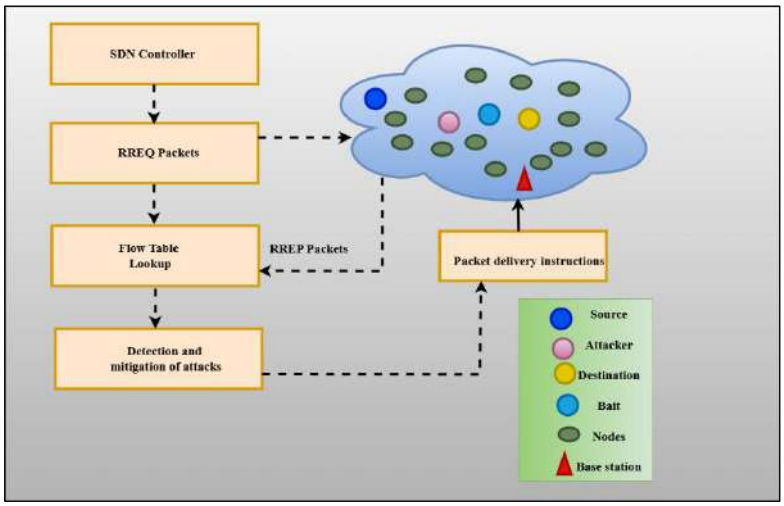

Figure 7: BAIT approach.

V. RESULTS AND DISCUSSION

In this section, the assessment criteria and required dataset for the proposed technique are discussed in depth. The dataset and assessment factors are handled first to recognize, categorize, and forecast the hacking attempt in the E-commerce IT project administration context.

Experimental setup

IT project management is the process of assigning, planning, and organizing a specific organization's IT goals. IT project management encompasses all monitoring activities related to implementing IT solutions, setting up hardware, updating networks, deploying virtualization and cloud computing, and building software. The followingfive process areas represent the project management life cycle and are consistent across all projects. Each project's specific phases, on the other hand, are unique and help to show the project development cycle.

1. Initiation - the project's objective, need, or issue is determined. A charter for the scheme is established and the scheme director is hired to it.
2. Planning - The work team and the task leader work together to plan each step needed to finish the project effectively. Due to the cyclical cycle of the method of scheduling, frequent planning is expected throughout this endeavor.
3. Excecution - To efficiently complete the project, the task leader and the members of the team collaborate to plan each stage. Frequent planning is anticipated throughout this endeavor because of the periodic cycle of the scheduling strategy.
4. Control and monitoring - The project manager monitors and exerts access to the assignment in the areas of length, standard, risk, and other work-related factors while the work is carried out by the development group. To make certain that the project is meeting its goals for each project objective, control, and monitoring are continual processes.
5. Closing - After each stage and the entire project, the project is closed to ensure that each task has been completed, is approved, and management has been successfully implemented from the project group to management. Figure 8 below illustrates the fundamental steps in the administration of an IT project.

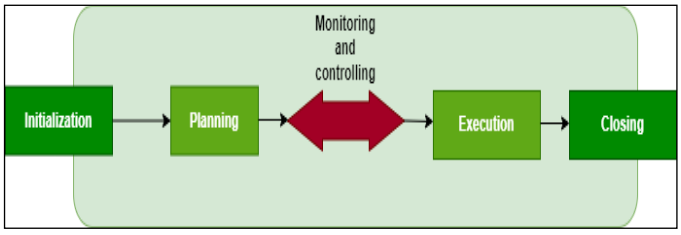

Figure 8: IT project management process.
Source: Authors, (2026).

Training and testing

To assess the algorithm's efficacy, the data set was distinguished into training of 80% and testing of 20%. Then, it is tested against a different dataset known as the testing set. The learned instances in the training data are employed by the model to classify the testing set. On the testing set, the model's predictions are contrasted with the actual labels. We can compute other evaluation metrics as a result.

Performance metrics

The study's comprehensive evaluation metrics, including confusion matrices and ROC curves, contribute to the theoretical foundation for assessing project success in the context of cyber security. The confusion matrix, the AUC, accuracy, error rate, TPR, TNR, FPR, and FNR are some of the assessment metrics that will be discussed in this section.

a. Confusion Matrix

Information regarding the real and anticipated diagnoses from a classifier may be located in a confusion matrix. It is shown in Table 3.

Table 3: Confusion matrix.

		Predicted	
Actual		**Negative**	**Positive**
	Negative	TN	FN
	Positive	FP	TP

Source: Authors, (2026).

TP: An accurate prediction from the classifier turned out to be accurate.
TN: When the classifier correctly identified that an event is false but the event is false.
FP: The machine learning model identified that an event is true, but the event is not true.
FN: The machine learning algorithm identified that an event would not occur, yet the event occurred.
The classes that are correctly classified are TN and TP, whereas the incorrectly classified ones are FN and FP.

B. Evaluation Metrics

To compare the effectiveness of the classifiers, it is useful to look at measures like model training time, accuracy of the model, and storage use. Additionally, the accuracy of categorization is measured by the ROC-AUC. The accuracy of binary classification results is also measured using the AUC metric. Model accuracy is the percentage of accurate forecasts among all forecasts as described in (3).

$$Accuracy = \frac{TN + TP}{TP + TN + FP + FN} \times 100\%$$
$$ErrorRate = \frac{FP + FN}{FP + FN + TP + TN} \times 100\% \quad (3)$$

According to (13), the error rate is calculated as the percentage of all incorrect assessments multiplied by the entire number of samples. The percentage of correctly positive projected classes from all positive classes is known as the TPR, also known as sensitivity or recall. The sensitivity ranges from 1:0 (best) to 0:0 (lowest). The percentage of accurate negative calculations among all classes of negative calculations is known as the TNR, also known as the specificity. Specificity ranges from 1:0 (highest) to 0:0 (lowest). In (14), the TPR and TNR are provided.

$$\text{True positive rate} = \frac{\text{TP}}{\text{FN} + \text{TP}} \times 100$$
$$\text{True negative rate} = \frac{TN}{FP + TN} \times 100 \quad (4)$$

Precision, as defined in (5), is the proportion of properly calculated positive values among all positive categories. The amount of incorrectly detected positive outcomes out of all of the negative outcomes, as in (5), is known as the*FPR*.

$$\text{FPR} = \frac{\text{TP}}{FNP+TP} \times 100 \quad \text{FNR} = \frac{\text{FP}}{\text{FP} + \text{TN}} \times 100 \quad (5)$$

Two criteria that are frequently used in software estimation mean MMRE and PREDwere used in evaluating the obtained models in addition to standard error evaluates like ME, MAE, MSE, and RMSE. They enable results comparison across various detecting models and datasets since they are magnitude and unit-independent. All depend on MRE, which is characterized as the difference between estimations and actuals:

$$MRE = \frac{|\, y_t - y_t^p \,|}{y_t} \quad (6)$$

$$MMRE = \frac{1}{n}\sum_{t=1}^{n} MRE \tag{7}$$

$$PRED\ (x) = \frac{1}{n}\sum_{t=1}^{n} \begin{cases} 1 & if\ MRE \leq x \\ 0 & otherwise \end{cases} \tag{8}$$

Where:

y_t - Original value

y_t^p - Measured value

X -Average

n -Number of samples

$$MER = \frac{y_t - y_t^p}{y_t^p} \tag{9}$$

$$MMER = \frac{1}{n}\sum_{t=1}^{n} MER \tag{10}$$

$$BRE = \frac{|\,y_t - y_t^p|}{\min(\,y_t^p - y_t)} \tag{11}$$

$$MBRE = \frac{1}{n}\sum_{t=1}^{n} BRE \tag{12}$$

Throughput

It is defined as ‘‘a total data that the destinations receive from the source-separated by the time it takes for the destination to get the final packet”. It is also the number of bitstransmitted per second.

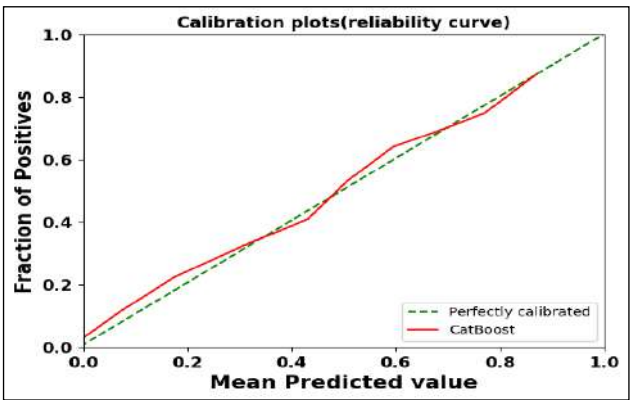
$$Threshold = \frac{Dr * Size\ (1 - packetloss\ value)}{penalty + timeconsumed}$$

Packet loss

It is defined asthe ratio of the number of lost packets to the total number of packets sent.

C. Calibration Plots

The output of the expected success rate of a certain classifier, for measured techniques (classifiers), may be regarded as an interval of trust. The metric is used to establish if a confidence interval may be utilized to evaluate the anticipated probability Within Figure 9. All of the developed methods' calibration plots are shown, and the CatBoost technique gave well-calibrated predictions since it maximizes log loss.



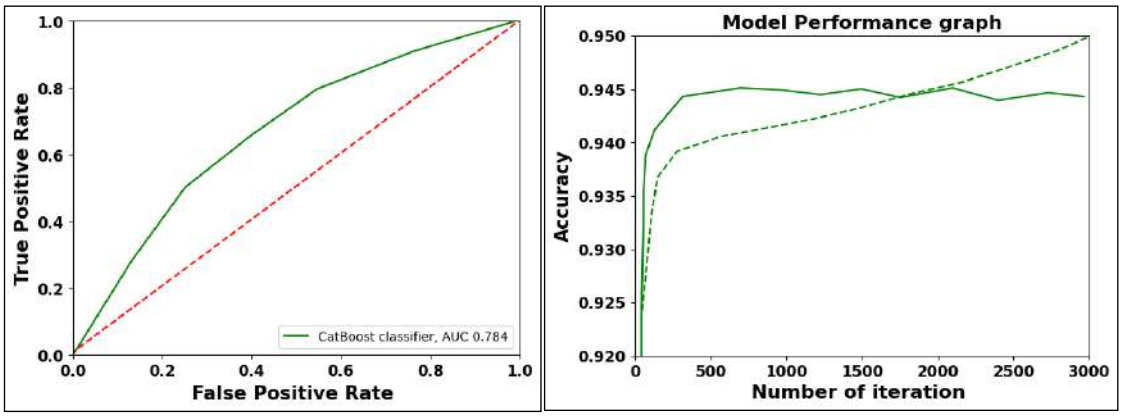


Figure 9: Calibration plots.

A false positive rate is a technique used in this section to make a type I error in testing for a null hypothesis while performing repeated comparisons. The FPR is a crucial parameter for the problem studied in this study since it would be disastrous if the system predicted a false assault. This indicates that CatBoost has greater confusion metrics than the competing method, as measured by the value of properly categorized data (TP + FN) and with the fewest misclassifications.The properly categorized and incorrectly categorized information from the Zone-H dataset are both depicted in the confusion matrix in Figure 13.

We first determined the TPR, FPR, and AUC scores after training the classifier on the training set and predicting the probabilities on the test set in Figure 10. CatBoost attained the maximum AUC of 0:78, which is nearer to 1. The CatBoost classifier's accuracy is displayed in Figure 11. The CatBoost algorithm efficiency comparison is shown in Table 4.

An e-commerce platform may sustain time-based attacks from SQL injection attacks. By modifying the SQL query to generate delays or wait conditions, this sort of attack, also called "Time-Based Blind SQL Injection," enables the hacker to deduce information regarding the database or the application's reaction time. Our proposed method makes use of raw data from the burp suite, which is then classified using the CatBoost algorithm. It is an effective tool, but to get the best results for the particular vulnerability prevention work, it is essential to have a well-prepared dataset, include feature engineering, and fine-tune the model. Burp suite's tool and the CatBoost algorithm's avoidance of SQL injection improve our E-commerce IT project management's efficiency by avoiding time delays. Its efficiency aids in IT project management's ability to recognize and anticipate E-commerce SQL injection threats. The proposed algorithms employed in the study are depicted in the scatter plot below as having duration. The location of each point on the plot symbolizes a project, and the values for that project's duration are indicated by the location of the point. Darker colours denote greater levels of effort, while the colour of the point indicates the real amount of effort.To evaluate the effectiveness of the collection models in forecasting duration graphically, utilize the scatter plot. The plot's points should ideally be tightly packed along the regression lines, showing that the simulations are successful in forecasting the duration of the values. The Scatter plot of programs for duration model is displayed in Figure 12 below. A classification model's calibration is evaluated graphically using a reliability curve. It aids in our comprehension of how well the anticipated probability matches the actual results. A reliability curve can provide us with useful information about the effectiveness of the model and can inadvertently tell us about the possibility of mistakes, even though it is not normally used to quantify error rates directly.Figure 14 compares the reliability curve for CatBoost's error rate to that of SVM, MLP-ANN, and GLM using three different approaches. The CatBoost performs better than the previous methods. SVM, MLP-ANN, GLM, and the CatBoost duration model's evaluation metrics are shown in Table 5 respectively. Figure 13: Confusion matrix for SQL injection prediction show in below.

Packet loss over the attack rate

It is defined asthe ratio of the number of lost packets to the total number of packets sent.This section explains the performance evaluation for packet loss rate under varied attack rate to 5%, 10%, 15%, and 20%, respectively. From the graphical representations given below in Figure 15, it is observed that even in all the attack rate deviation, the packet loss ratio is minimal, which proves the betterment in proposed attack detection and mitigation. The classifier performance with the bait approach, which exhibits the lowest packet loss over the traditional models. Here, at the attack rate = 15%, the packet loss of the classifier CatBoost+BAIT is 11%, whereas for the other traditional classifiers like DBN, NN, SVM, CatBoost is 22%, 16.6%, 20%, and 26.5% respectively. Thus, the proposed work proves the efficiency of less packet loss.

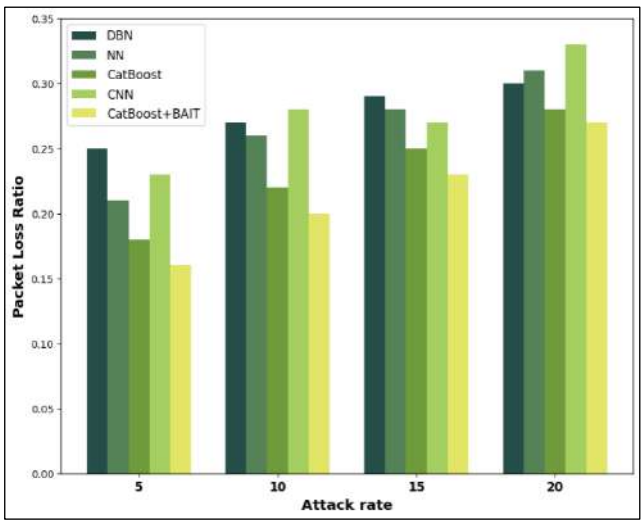

Figure 15: Packet loss ratio over attack rate.
Source: Authors, (2026).

Throughput over the attack rate

As per Figure 16, at attack rate = 10%, the proposed classifier acquires the highest throughput of 56%, which is 33.3%, 30%, and 40% for the existing models DBN, NN, SVM, CatBoost respectively. Thus, from the evaluation, it is obvious that the proposed work can make an attack-free communication when compared to other models.

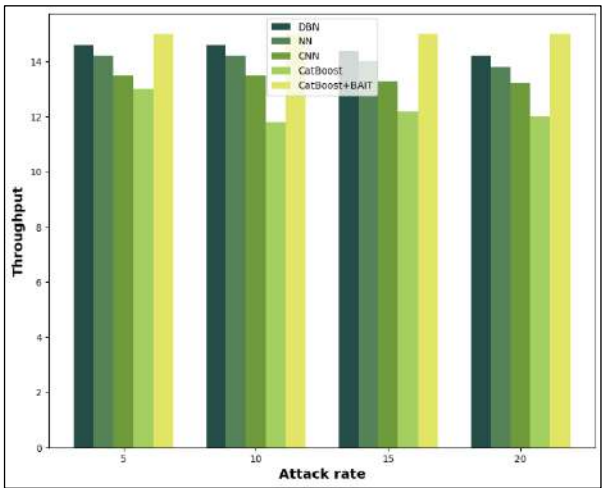

Figure 16: Throughput ratio over attack rate.

The efficiency of CatBoost in the context of IT project management for e-commerce improves system efficiency by 96.7%. Our machine learning model's simulation findings showed us how to significantly reduce the duration of processing while also mitigating security assaults. This innovation enables our project management to effectively carry out pre-tests of their suggested policies. As a result, project management may now make decisions that are better supported by quantifiable evaluations of time-dependent project performance, increasing the justification for such decisions. This comprehensive solution positions our e-commerce platform for long-term success by enhancing security while also streamlining project management procedures.

VI. CONCLUSION

E-commerce can be characterized as a crucial intermediary in every online transaction between the supplier and the buyers. The entire process depends totally on online transactions. Internet retail marketing is reaching its height as more people use internet-enabled gadgets. This technology offers a variety of benefits, including scalability and simplicity of availability. E-commerce security, however, is one of the main obstacles on its path when it comes to problems. A variety of elements, such as manipulation of data, detection, and prevention, can enhance the security of e-commerce. This study uses the efficient Burp suite tool and the CatBoost ML technique to reduce vulnerability attacks in an environment managing IT projects for e-commerce. Designers can analyze, identify, and identify system vulnerabilities with the use of the suggested vulnerability assessment approach. If an attacker exists, the control was transferred to the proposed bait approach; the performance of the proposed work was analysed over the traditional models by evaluating the packet loss ratio and throughput. Results show that the proposed model’s performance is more efficient than the other conventionalmodels. The system layout and evaluation of commercial online transaction procedures for industry may therefore be easily done using the suggested technique. This strategy aids in reducing and preventing vulnerability attacks in the setting of E-commerce IT project management.

Table 6: List of abbreviations used in the proposed security framework.

Abbreviations	Description
ML	Machine Learning
B2B	Business-To-Business
B2C	Business-To-Consumer
C2C	Consumer-To-Consumer
C2B	Consumer-To-Business
EDI	Electronic Data Interchange
IDSs	Intrusion Detection Systems
IPS	Intrusion Prevention Systems
UTM	Unified Threat Management
GBDTs	Gradient Boosting Decision Trees
GPL	Go Project Lean
LFSR	Linear Feedback Shift Register
RMSE	Root Mean Squared Error
XSS	Cross-Site Scripting
EDI	Electronic Data Interchange

EFT	Electronic Funds Transfer
IT	Information Technology
MAE	Mean Absolute Error
SQL	Structured Query Language
TNR	True Negative Rate
TPR	True Positive Rate
FPR	False Positive Rate
FNR	False Negative Rate
MMRE	Magnitude Relative Error
PRED	Percentage Relative Error Deviation
ME	Mean Error
MSE	Mean Squared Error
MRE	Magnitude Relative Error
SVM	Support Vector Machines
MLP-ANN	Multi-Layer Perceptron Artificial Neural Network
GLM	Generalized Linear Models

ABSTRACT

This research work aims to identify and analyze bioactive constituents from the extract made from the leaves of *Terminalia chebula* using both computational and experimental approaches, with possible immune boosting and antiviral properties. For its broad pharmacological properties, including antibacterial, antiviral, antioxidant, anti-inflammatory, and immunomodulatory activities, *Terminalia chebula* is highly regarded and recognized. These medicinal potentials are ascribed to its abundant content of bioactive phytochemicals, including tannins, phenolics, flavonoids, glycosides, and sterpenoids. Due to the worldwide health crisis caused by infectious diseases like COVID-19, scientists are once again interested in studying plant-based substances to see if they might boost the immune system and fight viruses. In this light, *T. chebula* emerges as an interesting candidate for research owing to its historic medicinal significance and pharmacological diversity. The study uses Gas Chromatography–Mass Spectrometry (GC-MS) to identify compounds in detail and ADME (Absorption, Distribution, Metabolism, and Excretion) profiling with Swiss ADME to check how well the identified molecules work as drugs and how similar they are to drugs. Then, molecular docking experiments are done on selected drugs with good ADME profiles. These studies focus on important immunological and viral proteins, like Interleukin-6 and a protein linked to COVID-19, to see how well they attach and how biologically important they might be.

I. INTRODUCTION

Protection of the human body from infections and inflammatory diseases through innate and adaptive responses involves the immune system playing a crucial role with cytokine signalling pathways like interleukin-6 (IL-6) being essential for inflammation control. Chronic inflammation and severe health issues during viral infections, can be a result of dysregulation of IL-6. Phytochemicals derived from medicinal plants, especially *Terminalia Chebula*, have garnered interest for their ability to modify immune responses and influence cytokine pathways, offering alternatives to conventional medicines associated with adverse consequences [1-4]. *T. chebula* has bioactive substances such tannins, phenolics, and flavonoids, and it has showed potential in treating immune-related illnesses by affecting cytokines like IL-6. This intention behind this study is to focus on the immunomodulatory potential of specific bioactive compounds from *T. chebula* with the help of an integrated in silico methodology, including phytochemical profiling, ADME parameter screening, and molecular docking with IL-6 and TMPRSS2, with the goal of proving that they may be used as medicines to treat inflammatory and infectious disorders, notably new viral infections like COVID-19 [5].

II. MATERIALS AND METHODS

II.1 SAMPLE COLLECTION AND SEQUENTIAL SOLVENT EXTRACTION

Leaves of *Terminalia chebula* were freshly collected and washed with distilled water to eradicate surface level contaminants and then shade-dried at room temperature and using a mechanical grinder, finely powdered. To obtain phytochemical fractions of varying polarity, sequential solvent extraction was employed which enabled broad-spectrum compound recovery.

II.1.1 Cold Percolation Extraction

To preserve thermolabile constituents, cold percolation was initially performed as shown in Fig. 1(a,c). Powdered leaf material of 100g approximately was soaked in 375 ml hexane, which was followed by incubation at room temperature for 24 h while agitating it from time to time. The mixture was filtered after the incubation and for further extraction, the residual plant material was air-dried. The process was repeated as the same using ethyl acetate by incubating the dry residue in 500ml of solvent for 24h. The filtrated were separately collected, respectively.

II.1.2 Hot Percolation Extraction (Soxhlet Method)

To enhance the extraction efficiency of less soluble compounds, hot percolation was subsequently carried out [6], [7]. Dried plant powder, about 75 g was placed in a Soxhlet thimble and extracted with hexane using 250–300 mL of solvent for seven reflux cycles. Then, the plant material that was residual was subjected to Soxhlet extraction with ethyl acetate for four cycles. The obtained extracts, by solvent evaporation, were then filtered and concentrated at room temperature (Fig. 1(b,d)). Once dried, the extract residues were scraped and weighed for the determination of and stored in sterile Eppendorf tubes for subsequent analysis.

II.2 QUALITATIVE PHYTOCHEMICAL SCREENING

To identify major classes of secondary metabolites present in the sequential extracts, qualitative screening was performed. Standard chemical tests were employed to detect anthraquinones, carbohydrates, phlobatannins, tannins, steroids, saponins, coumarins, flavonoids, phenols, alkaloids, terpenoids, quinones, glycosides, cardiac glycosides based on precipitate formation and characteristic calorimetric changes [8], [9]. The presence of phytoconstituents was determined by observing visual changes such as colour development, precipitate formation, or the appearance of coloured rings at phase interfaces, after the addition of specific chemical reagents to the extracts. Using Molisch's test, carbohydrates were determined; by the foam test, saponins; flavonoids by the alkaline reagent test; and alkaloids using Mayer's reagent and using Folin-Denis test, tannins and phenols were determined. Sulfuric acid treatment was used to find quinones, while chloroform–ammonia and Keller–Kiliani tests were used to find glycosides and cardiac glycosides, respectively. NaOH was used to; steroids and phytosterols by chloroform–concentrated sulfuric acid reaction; phlobatannins by hydrochloric acid; and anthraquinones by ammonia treatment. Positive and negative results were recorded in tabular form, with '+' indicating presence and '–' indicating absence of specific phytochemical groups. The detailed results are presented in the Results section.

II.3 THIN LAYER CHROMATOGRAPHY

Thin layer chromatography was employed to quickly and effectively check the qualitative chemical makeup of the extracts before doing more extensive profiling. We made silica-gel TLC plates and put samples from several extracts 1 cm above the baseline. Hexane and ethyl acetate were mixed in a 70:30 ratio to make the mobile phase. The plates were put in the mobile phase until the solvent got close to the top. Then they were dried in the air and looked at under UV light at 254 nm and 365 nm. Band patterns were documented as representative of unique phytochemical components.

Even though Rf values weren't measured, comparing band intensities at different wavelengths gave us a way to judge how complex a compound is, which is in keeping with recent TLC research that looked at plant chemical profiles.

II.4 GCMS ANALYSIS

Gas-Chromatography-Mass Spectroscopy was employed to perform the chemical profiling of the selected extract to identify components that are semi-volatile and volatile. Vaporization of the sample was done in the injector port and was carried by an inert gas through a capillary column. In the mass detector, fragment patterns of the eluted molecules were ionized and were compared with spectral libraries for compound identification. The peak, molecular formula and retention time for each detected metabolite were detected [10].

II.5 ADME SCREENING

The compounds obtained from GC-MS were analysed for drug-likeness using in-silico ADME filters. Non-BBB permeability, High gastrointestinal absorption, bioavailability score ≥0.55, CYP inhibition profile, topological polar surface area, P-glycoprotein substrate status, Lipinski's rule of five, acceptable logP range, number of rotatable bonds and topological polar surface area were included in the screening parameters. The molecules that satisfied majority of these criteria were considered as suitable candidates for docking studies [11], [12].

II.6 MOLECULAR DOCKING

Docking at molecular level was carried out to investigate the binding interactions of selected phytochemicals with two biologically relevant human targets, Interleukin-6 (IL-6) and Transmembrane Protease Serine 2 (TMPRSS2). IL-6 was selected due to its central role in inflammatory signalling and cytokine-mediated immune dysregulation, particularly in pathological cytokine release syndromes observed in infections like COVID-19 [12]. TMPRSS2 was chosen because it is a key host serine protease in priming viral spike proteins and facilitating SARS-CoV-2 entry into host cells; thus, docking against this target provides a preliminary in silico screening of phytochemicals for potential interaction with a critical host factor associated with COVID-19 pathogenesis, making it a relevant molecular target in the COVID-19 infection pathway [13], [14]. Three-dimensional crystal structures of the target proteins, human IL-6 (PDB ID: 1ALU) and TMPRSS2 (PDB ID: 7NMEQ), were retrieved from the Protein Data Bank (PDB) and are shown in Fig. 2 and 3, respectively. Ligand structures for gallic acid and aminoacethydrazide were obtained from the PubChem database as shown in Figures 4 and 5. The water molecules and non-essential heteroatoms were removed and the proteins were prepared using PyMOL post polar hydrogens were included.

Further preparation was completed in AutoDock Tools (ADT) 1.5.7 by assigning Kollman charges, repairing missing atoms, and converting the structures into PDBQT format with AutoDock 4 (AD4) atom types. Ligand preparation involved defining the torsion tree and root to maintain conformational flexibility, and the ligands were subsequently exported as PDBQT files. Grid boxes were defined around functionally relevant regions identified from co-crystallized ligands and reported binding residues in the literature, enabling focused docking toward biologically meaningful interaction sites as established in previous molecular docking studies targeting IL-6 and SARS-CoV-2–associated host proteins [6], [12]. The Grid Parameter File (GPF) was made using these grid parameters, and AutoGrid (part of the AutoDock package) was used to make affinity maps. The Lamarckian Genetic Algorithm (LGA) was used to run docking simulations, as described in the Docking Parameter File (DPF). After the docking was done, we looked at the docking log (DLG) files and prioritized the binding conformations based on the lowest anticipated binding energy and cluster analysis. These kinds of grid definition methodologies are already well-known in molecular docking operations to improve physiologically relevant sampling and forecasting accuracy.

III. RESULTS AND DISCUSSIONS

III.1 SEQUENTIAL SOLVENT EXTRACTION YIELD

By employing cold and hot percolation methods with hexane and ethyl acetate, sequential solvent extraction of *Terminalia chebula* leaves was carried out and the extraction yields are summarized in Table 1. Higher extraction yields were given by cold percolation when compared to hot percolation for both the solvents. Ethyl acetate yielded the highest extract recovery (1.96%), which was followed by cold hexane extraction (1.64%) in cold percolation.

On the other hand, hot percolation yielded comparatively lower recoveries, with values ranging from 0.41% to 0.77%. The increased effectiveness of cold percolation implies that mild extraction conditions are more conducive to the recovery and preservation of moderately polar and thermolabile phytoconstituents. The preponderance of semi-polar compounds in *Terminalia chebula* leaves was demonstrated by the consistently higher yields obtained from ethyl acetate compared to hexane. These results support the choice of cold percolation extracts for further computational and phytochemical examinations. The dried extract residues collected after solvent evaporation formation are shown in Fig. 6.

Table 1: Yield of sequential solvent extraction of *Terminalia chebula* leaves.

Extract (From sequential solvent extraction)	Dry weight (g)	Yield in grams	Yield in percentage
Cold percolation with hexane	100	1.64	1.64%
Cold percolation with ethyl acetate	100	1.96	1.96%
Hot percolation with hexane	75	0.58	0.41%
Hot percolation with ethyl acetate	75	041	0.77%

III.2 RESULTS OF QUALITATIVE SCREENING OF PHYTOCHEMICAL

Qualitative phytochemical screening revealed the presence of phenols, tannins, carbohydrates, quinones, terpenoids, steroids, and phytosterols in the extracts, whereas saponins, flavonoids, alkaloids, glycosides, cardiac glycosides, coumarins, phlobatannins, and anthraquinones were absent as shown in Fig. 7 (Table 2). Finding phenols, tannins, terpenoids, and steroids is proper with the already known chemical profile of *Terminalia* species and supports their reported anti -inflammatory, antioxidant and immunomodulatory properties. Certain phytochemical group such as flavonoids and alkaloids were absent and may be attributed to variations in plant part, geographical origin, solvent polarity, and extraction conditions. These findings offered a biochemical justification for prioritizing phenolic-rich compounds for subsequent ADME screening and molecular docking investigations.

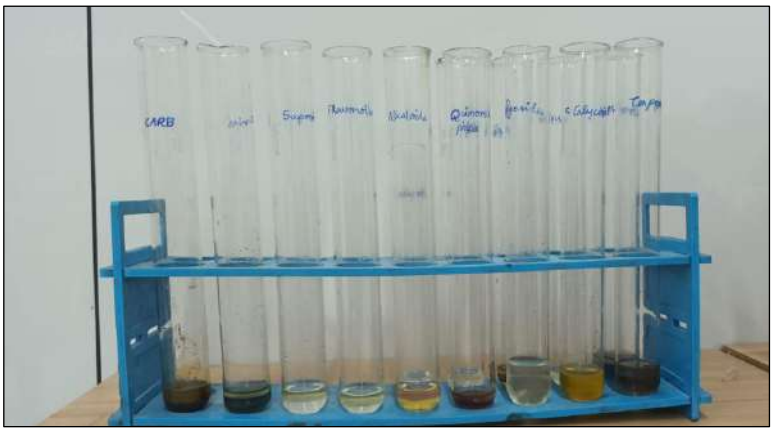

Figure 7: Phytochemical analysis results.

III.3 THIN LAYER CHROMATOGRAPHY PROFILE

We used TLC profiling to find out how complicated the phytochemicals were and how well the extracts separated. Only a few clear bands could be seen with both short- and long-wavelength UV light as represented in Fig. 8 and 9. There wasn't much migration because most of these bands were close to the baseline. The low resolution means that the mobile phase and the polar silica stationary phase don't match up, which makes compounds attach to the surface strongly. Dark quenching areas under short-wave UV suggest that there are conjugated aromatic systems, while reddish or orange fluorescence under long-wave UV means that there are naturally fluorescent metabolites, including phenolics or pigments. Even though TLC didn't do a great job of separating things, it was a decent initial step in fingerprinting because it revealed that the extract was complicated and supported the presence of phenolic chemicals observed during phytochemical screening.

Table 2: Results of phytochemical analysis.

Test	Result
Presence of Carbohydrates	Positive
Presence of Tannins	Positive
Presence of Saponins	Negative
Presence of Flavonoids	Negative
Presence of Alkaloids	Negative
Presence of Quinones	Positive
Presence of Glycosides	Negative
Presence of Cardiac Glycosides	Negative
Presence of Terpenoids	Positive
Presence of Phenols	Positive
Presence of Coumarins	Negative
Presence of Steroids and Phytosteroids	Positive
Presence of Phlobatannins	Negative
Presence of Anthraquinones	Negative

III.4 GCMS ANALYSIS AND ADME SCREENING RESULTS

A profile of multiple phytoconstituents with retention times that were defined along with molecular characteristics were granted by GC-MS analysis and is given in Table. 3. Prioritization of all the compounds based on pharmacokinetic sustainability detected through subsequent ADME evaluation was enabled based on pharmacokinetic sustainability. Through application of the selected filters, gallic acid acid and aminoacethydrazide were identified as the most compliant molecules, demonstrating favourable drug-likeness, acceptable metabolic properties and high predicted absorption. These candidates were further advanced for molecular docking against IL-6 and TMPRSS2 targets. All spectral analysis of the solvent extraction of *Termnalia chebula* leaves is given in Figure 10.

III.5 MOLECULAR DOCKING ANALYSIS

III.5.1 Gallic Acid–HumanTMPRSS2 Interaction

Binding energies ranging from −3.01 to −3.71 kcal/mol were yielded by docking of gallic acid with human TMPRSS2, with predicted inhibition constants in the millimolar range (Table. 4). The best-scoring pose (Model 7) exhibited a binding energy of −3.71 kcal/mol, as shown in Fig. 11 a and b. The docked complex revealed weak, non-covalent interactions dominated by hydrogen bonding and van der Waals forces. Transient interaction is indicated by the low binding affinity and it suggests that gallic acid is unlikely to act as a potent TMPRSS2 inhibitor. But its steady presence in the binding area backs up its possible use as a reference scaffold for future structural improvements.

Table 4: Gallic acid–Human TMPRSS2 docking results.

Docking Run	Binding Energy (kcal/mol)	Predicted Ki (mM)
1	-3.53	2.58
2	-3.24	4.24
3	-3.29	3.90
4	-3.04	5.95
5	-3.56	2.46
6	-3.37	3.40
7	-3.71	1.92
8	-3.34	3.54
9	-3.01	6.19
10	-3.37	3.39

Source: Authors, (2026).

III.5.2 Aminoacethydrazide–Human TMPRSS2 Interaction

Binding energies between −2.27 and −4.63 kcal/mol were displayed by Aminoacethydrazide. a binding energy of −4.63 kcal/mol was showed by the most favourable pose (Run 4) and a predicted Ki of 0.20 mM, as shown in Fig. 12 a, b. Several poses crowded around −3.9 to −4.1 kcal/mol, which indicates reproducible binding behavior (Table.5). Even though the affinity was the modest, consistent docking poses suggest stable interaction tendencies. The ligand's tiny size and low hydrophobic surface area make it such that the interaction strength is limited. This makes it hard for the ligand to connect to the TMPRSS2 pocket.

Table 5: Aminoacethydrazide–Human TMPRSS2 docking results.

Docking Run	Binding Energy (kcal/mol)	Predicted Ki (mM)
1	-2.82	8.50
2	-4.08	1.02
3	-3.22	4.35
4	-4.63	0.20
5	-3.90	1.38
6	-3.99	1.19
7	-2.46	15.79
8	-3.62	2.23
9	-2.27	21.79
10	-4.12	0.96

Source: Authors, (2026).

III.5.3 Gallic Acid–Interleukin-6 Interaction

When gallic acid and interleukin-6 (IL-6) were docked together, the binding energies ranged from −4.32 to −4.89 kcal/mol, and the inhibition constants were in the micromolar range (Table. 6). The best pose has a binding energy of −4.89 kcal/mol and a Ki of 258.59 µM (Fig. 13 a, b). The fact that many poses are grouped together around −4.8 kcal/mol shows that the interaction patterns are constant. IL-6 doesn't have a deep catalytic pocket, therefore these interactions probably happen on the surface, which suggests that IL-6 may have a modulatory role instead of an inhibitory one.

Table 6: Gallic Acid–Interleukin-6 docking results.

Docking Run	Binding Energy (kcal/mol)	Predicted Ki
1	-4.88	266.29
2	-4.36	636.09
3	-4.89	262.52
4	-4.89	258.59
5	-4.77	319.01
6	-4.83	286.85
7	-4.87	270.79
8	-4.82	291.11
9	-4.88	265.85
10	-4.32	679.04

Source: Authors, (2026).

III.5.4 Aminoacethydrazide–Interleukin-6 Interaction

The binding energies for aminoacethydrazide were between −2.94 and −4.23 kcal/mol, and the best posture had a Ki of 798.16 µM as represented in Fig. 14 a, b (Table 7). The narrow range of binding energies shows that the binding orientations can be repeated, even when a highly polar ligand is present. These interactions are similar to temporary connections at IL-6 surface interfaces, which is in keeping with the structure of cytokine proteins and gives us a mechanism to change contacts. General Interpretation: The study gives a scientifically sound reason for future structure-guided optimization and experimental verification of chemicals made from *Terminalia chebula.*

Table 7: Aminoacethydrazide–Interleukin-6 docking results.

Docking Run	Binding Energy (kcal/mol)	Predicted Ki (mM)
1	-3.77	1.74
2	-3.09	5.45
3	-3.29	3.30
4	-4.23	798.16
5	-3.29	3.90
6	-2.94	7.01
7	-3.72	1.87
8	-3.78	1.69
9	-3.58	2.37
10	-3.78	1.71

IV. CONCLUSIONS

This study employed a comprehensive experimental-computational methodology to identify phytochemicals from *Terminalia chebula* and elucidate their effects on host-associated targets critical for inflammatory pathways. Sequential solvent extraction and phytochemical screening confirmed the presence of bioactive classes, whereas ADME filtering made it easier to rank compounds in a systematic method. Among the shortlisted compounds, aminoacethydrazide, a relatively underexplored constituent of *T. chebula*, demonstrated consistent but moderate binding interactions with TMPRSS2 and interleukin-6 in molecular docking analyses. Although the observed binding energies indicate weak to moderate affinity rather than strong inhibition, the reproducibility of docking poses, acceptable pharmacokinetic properties, and limited prior investigation highlight aminoacethydrazide as a potential candidate for further in-depth computational optimization and experimental validation. The results show that using integrated phytochemical and in silico screening procedures to locate exploratory bioactive scaffolds is useful without making claims about their medicinal effectiveness that are too strong.

ABSTRACT

This paper presents the development and evaluation of an advanced power prediction system for a wind farm using machine learning and deep learning models, based on historical meteorological data. The analyzed dataset comprises 25,596 hourly records corresponding to the period 2022–2024, which were subjected to a rigorous process of cleaning, physical validation, and generation of derived variables, such as air density and power according to the Betz limit. Based on a Pearson correlation analysis, wind speed, solar radiation, and air temperature were identified as the most influential variables in power generation. Multiple predictive models were trained and compared, including linear regression, Random Forest, XGBoost, MLP neural networks, LSTM, and Transformers, evaluated using RMSE and coefficient of determination (R^2). Additionally, lagged variables were incorporated to improve prediction at 1-, 3-, and 6-hour horizons. The results show that a hybrid LSTM + XGBoost architecture, based on residual error correction, consistently outperforms individual models, achieving an RMSE of 61.98 W and an R^2 of 0.779 in one-hour prediction. Finally, the proposed model was implemented in an operational environment, demonstrating its viability for real-world energy management and planning applications.

I. INTRODUCTION

Wind energy serves as a critical renewable resource for fostering sustainable development and mitigating global carbon emissions [1]. However, the inherent variability and stochastic nature of wind patterns present significant hurdles for accurate wind power forecasting, which is vital for maintaining grid stability and ensuring efficient energy management [2]. This complexity drives the continuous need for sophisticated prediction systems that can maximize resource utilization and optimize power grid operation [3]. The evolution of WPP has seen a transition toward advanced Deep Learning and Machine Learning models. For instance, regression trees provide a versatile alternative for forecasting output across various types of renewable energy plants [4]. In the realm of layout optimization, Artificial Neural Networks combined with genetic algorithms are employed to resolve design challenges and evaluate control benefits [5]. Furthermore, researchers emphasize the necessity of spatially transferable models to avoid the high computational expense associated with recalibrating parameters at new geographical locations [6]. Data-driven frameworks using machine learning wake models and Computational Fluid Dynamics (CFD) simulation data have also improved layout efficiency in large-scale wind farms [7]. Performance improvements in the state of the art are often achieved through specific algorithm selection and hybridization. Extreme Gradient Boosting (XGBoost) demonstrates higher accuracy and faster training times compared to traditional ANN for predicting power under yaw-controlled conditions [8]. Recent studies also highlight the efficacy of Gradient Boosting regressors when enriched with reanalysis meteorological data and weather forecasts [9]. To address the lack of historical data in newly constructed wind farms, few-shot learning approaches incorporating Time-series Generative Adversarial Networks are currently being developed [10].

Simultaneously, the identification and cleaning of abnormal wind power data resulting from sensor failures remain a primary concern for maintaining the integrity of prediction models [11]. Novel methods such as Generative Critic Networks coupled with Multi-Task Learning allow for high-quality interval forecasts across neighboring wind farms [12]. Therefore, the present work aims to develop a system for predicting the power generated by a wind power plant based on available meteorological variables. To this end, a structured approach is followed, encompassing data cleaning, correlation analysis, the training of regression models, and the validation of results.

II. DATA CLEANING AND PREPARATION

Preprocessing was performed to rename columns, convert data types, remove null values, and calculate new derived variables such as air density and power according to the Betz limit. The final columns of the dataset are shown in Table 1.

Table 1: Variables available after data cleaning.

Source: Authors, (2026).

A statistical summary was then performed, confirming that the dataset is extensive (more than 25,000 records) and covers a wide range of environmental conditions.

III. CORRELATION ANALYSIS

In order to select the variables that most influence the power generated, Pearson's correlation matrix was calculated between all available variables (Figure 1). This analysis identified significant relationships between the target variable (Potencia_W) and others such as wind speed, radiation, and temperature.

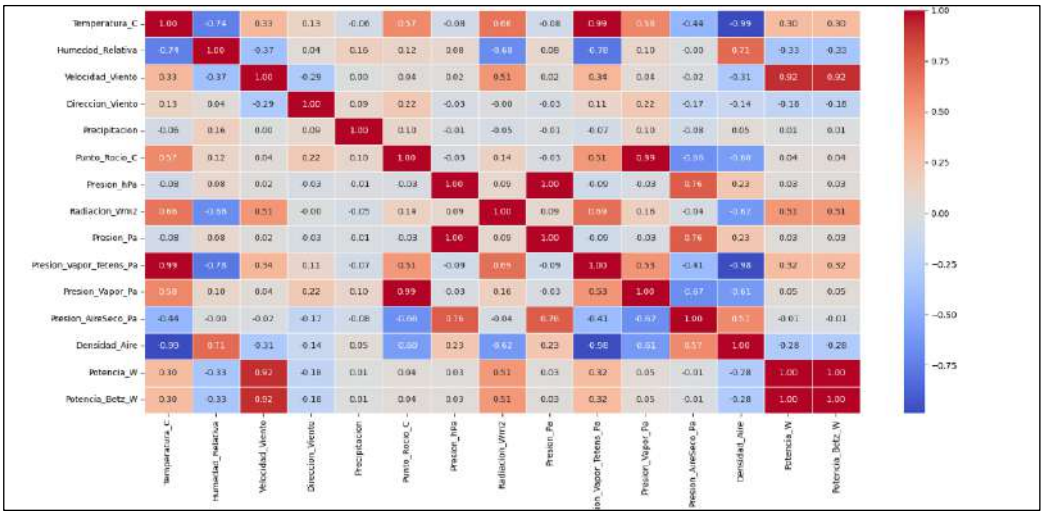

Figure 1: Correlation matrix between variables.
Source: Authors, (2026).

As can be seen, wind speed has a direct correlation of 0.92 with the power generated, confirming its primary role. A significant correlation was also observed with radiation (0.51) and, to a lesser extent, with temperature (0.30). Therefore, these three variables were selected as inputs for the model. Although vapor pressure exhibited a slightly higher Pearson correlation with generated power than air temperature (0.32 vs. 0.30), it was not included as an input variable because it is not an independent atmospheric driver, but rather a derived quantity strongly dependent on temperature and relative humidity. Including vapor pressure would therefore introduce redundancy and potential multicollinearity without providing additional physical or predictive information beyond that already captured by temperature.

IV. MODELING AND PREDICTION

Four different regression models were trained and compared: linear regression, Random Forest, XGBoost, and an MLP neural network. To do this, the data was divided into training and test sets (80/20). The results were evaluated using root mean square error (RMSE) and coefficient of determination R^2 metrics. The values are shown in Table 2.

Table 2: Model evaluation results.

Model	RMSE	R^2
Regresión Lineal	47.17	0.8520
Random Forest	0.42	1.0000
XGBoost	1.36	0.9999
Red Neuronal (MLP)	6.48	0.9972

Source: Authors, (2026).

The XGBoost model showed an excellent balance between accuracy and generalization, with very low error and an almost perfect fit. Linear regression, although functional, fails to capture the nonlinearity of the phenomenon. Figure 2 shows how nonlinear models (Random Forest, XGBoost, and MLP) fit the actual values more accurately. Linear regression underestimates high values due to its functional form. Although the Random Forest model achieved the lowest RMSE and a perfect coefficient of determination ($R^2 = 1.0000$), it was not selected for further analysis. Such a perfect fit strongly suggests overfitting to the training data, implying that the model may be capturing noise or data-specific patterns rather than generalizable relationships. Consequently, its excellent performance on the test split does not necessarily guarantee robust predictive capability when exposed to new, unseen real-world data, which limits its suitability for operational forecasting.

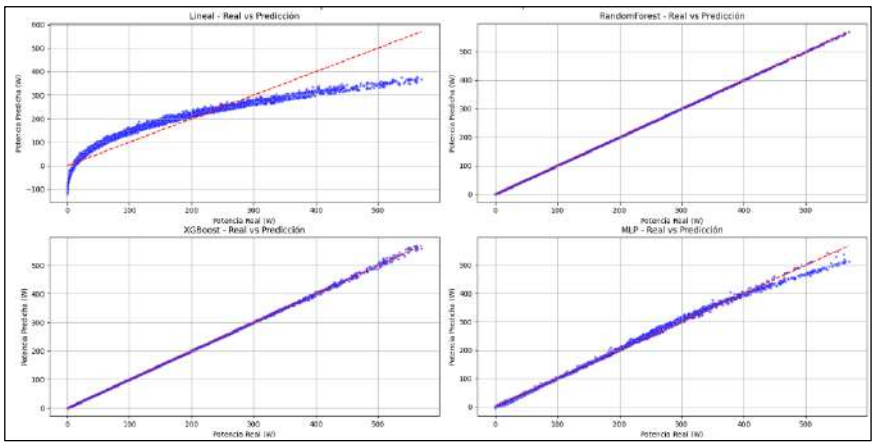

Figure 2: Graphical comparison between actual values and predictions.
Source: Authors, (2026).

V. USER INTERFACE AND IMPLEMENTATION

To facilitate the use of the model, a web interface was developed using Streamlit (Figure 3). This allows the user to enter environmental conditions (wind speed, temperature, and solar radiation) and obtain the predicted power immediately.

Figure 3: Prediction interface developed.
Source: Authors, (2026).

In addition, an automatic recording system was implemented that saves each prediction made along with the conditions entered and the time of calculation (Table 3). This allows prediction histories to be generated for further analysis.

Table 3: Example of recorded predictions.

Velocidad_Viento	Radiacion_Wm2	Temperatura_C	Potencia_Predicha_W	Fecha_Hora
2.5	100	8.0	74.79	2025-06-29 09:12:00
4.8	800	14.0	358.69	2025-06-29 09:15:00

Source: Authors, (2026).

VI. TIME-SERIES POWER FORECASTING

In order to anticipate wind power generation behavior, a time-series forecasting model was implemented using available historical data. The strategy consisted of reorganizing the information so that current environmental conditions served as input, and the power generated one hour later as expected output. The model selected was an XGBoost regressor, trained with the variables: wind speed, solar radiation, and air temperature. The model obtained an RMSE of 80.11 W and a coefficient of determination R^2 of 0.63, indicating moderate short-term prediction capability. Figure 4 shows a comparison between the actual power generated and the power predicted by the model for a subset of data. Although there are occasional differences, the model correctly follows the general trends of growth and decline, showing an acceptable correlation for operational estimation applications.

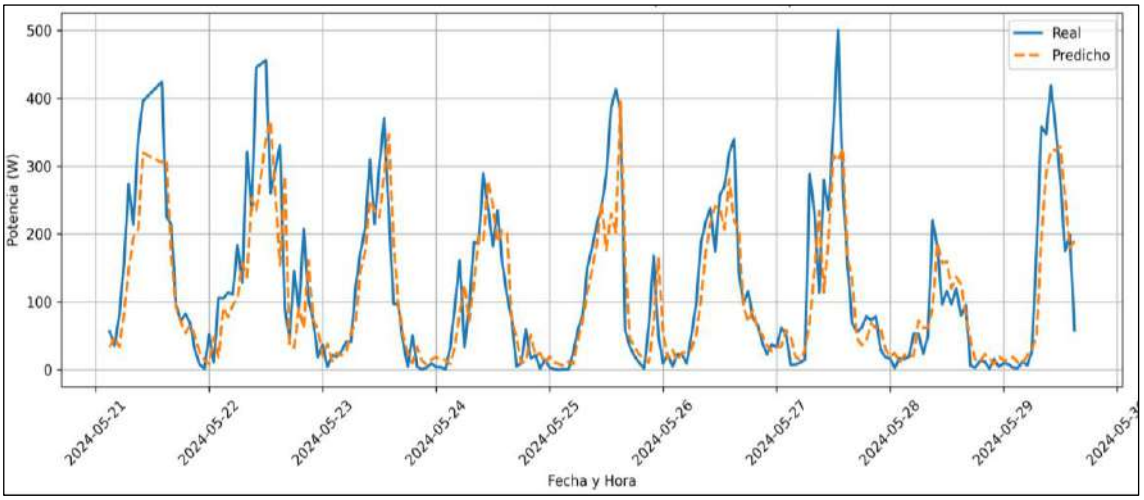

Figure 4: Prediction of future power one hour ahead using the XGBoost model.
Source: Authors, (2026).

VII. COMPARISON OF APPROACHES FOR FUTURE PREDICTION

To improve the estimation of power generated one hour in the future, three approaches with different input configurations were evaluated:

1. **Model A (base)**: Uses current environmental variables as input: wind speed, temperature, and solar radiation.
2. **Model B (simplified)**: Uses only wind speed, as it is the variable with the highest direct correlation with power.
3. **Model C (with delays)**: Adds the weather conditions from one hour ago (lag delays = 1) as inputs, in addition to the current conditions.

Table 4 shows the results obtained for each model, evaluated using the root mean square error (RMSE) and the coefficient of determination (R^2).

Table 4: Comparison of one-hour future prediction models.

Modelo	Variables used	RMSE (W)	R^2
A	Speed, Radiation, Temperature	80.11	0.6303
B	Wind Speed only	82.87	0.6045
C	Speed, Radiation, Temperature + Delay (t-1)	78.62	0.6440

Source: Authors, (2026).

The results indicate that the base model (A) already provides a reasonable estimate, but that including weather conditions from the immediate past (model C) slightly improves accuracy. In contrast, reducing the inputs to only one variable (model B) limits performance, despite its high correlation.

VIII. POWER FORECASTING IN A WIND FARM WITH THE INCLUSION OF LAGGED VARIABLES

With the aim of improving the predictive capacity of the future power model, a strategy based on the inclusion of variables with time lags was implemented. This methodology allows the model to take into account the recent behavior of weather conditions and electricity generation, providing temporal context to the prediction process. Lags of 1, 3, and 6 hours (t-1, t-3, t-6) were considered for the most relevant variables identified in previous phases: wind speed, solar radiation, and power generated. These new variables were added to the dataset as additional inputs, maintaining the power generated at 1h, 3h, and 6h in the future as target outputs. The model used was again a multi-output XGBoost, trained with the expanded data. The evaluation was performed using the RMSE and R^2 metrics, as in the previous approaches. The results indicate a substantial improvement over longer horizons, as shown in Table 5.

Table 5: Comparison of model performance with and without lagged variables.

Horizonte	RMSE without delays	R^2 without delays	RMSE with delays	R^2 with delays
1 hour	79.01 W	0.6404	77.13 W	0.6573
3 hours	106.43 W	0.3475	99.05 W	0.4349
6 hours	117.07 W	0.2107	108.68 W	0.3198

Source: Authors, (2026).

At 1 hour, the model with lags maintains a performance very similar to the previous one, with a slight improvement. However, at 3 and 6 hours, there is a significant jump in the ability to track trends. The model without lags tended to produce smoothed curves that did not capture the peaks and troughs of generation well. By incorporating recent history, the model with lags manages to more accurately track abrupt and sustained variations over time, as can be seen in Figure 5.

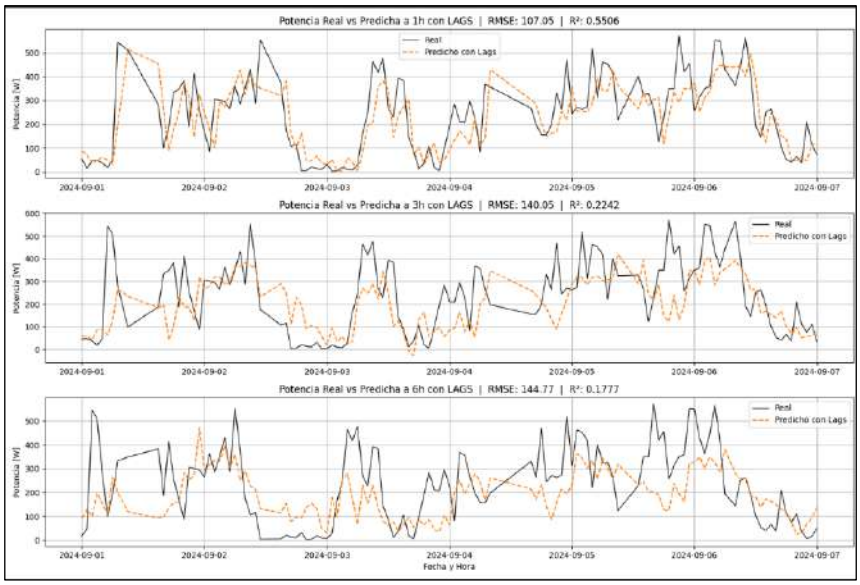

Figure 5: Graphical comparison between actual and predicted power at 1h, 3h, and 6h using a model with lagged variables.
Source: Authors, (2026).

This behavior is especially important in operational applications, where predicting sudden drops or increases in power several hours in advance can impact dispatch decisions and grid stability. Visual analysis confirms that predictions with lags are better able to track actual dynamics, even under highly variable conditions. In summary, the introduction of lagged variables into the future prediction model has proven to be an effective improvement, particularly for horizons longer than one hour. This technique adds memory to the system and allows for better modeling of the temporal patterns that govern wind generation. During the visual analysis of this figure, several abrupt low points were observed in the actual power curve. This prompted an additional review of the quality of the original data, identifying records where the power was close to zero despite sufficient wind or solar radiation for expected generation. These records were marked as potentially erroneous and removed in a second phase of advanced cleaning. After applying this additional cleansing, the original model was retrained without lags to assess the exclusive impact of this cleansing. The results are shown in Table 6.

Table 6: Comparison of model performance without lags before and after advanced cleansing.

Horizon	Original RMSE	Original R^2	RMSE with cleaning	R^2 with cleaning
1 hour	79.01 W	0.6404	79.26 W	0.6387
3 hours	106.43 W	0.3475	105.75 W	0.3570
6 hours	117.07 W	0.2107	118.12 W	0.1977

Source: Authors, (2026).

As can be seen, advanced cleaning does not significantly alter the model's short-term results, but it slightly improves stability at 3 hours, where a small gain in R^2 and a reduction in RMSE are obtained. Although the numerical improvement is modest, this step ensures the elimination of outliers that could distort the interpretation of the results or introduce noise into the training. This strengthens the quality of the dataset as a basis for future implementations.

IX. LSTM MODEL AND ADVANCED VERIFICATION

After implementing tree-based models and classic regressors, we proceeded to test architectures more suitable for time series, in this case an LSTM (Long Short-Term Memory) neural network. Two versions were explored: a basic one and an improved one, evaluating their performance for power prediction at 1h, 3h, and 6h.

IX.1 BASIC LSTM ARCHITECTURE

A simple LSTM network was designed with a hidden layer and multivariable output. The data was normalized with MinMaxScaler, and sequences with a 6-hour delay were used as input. The model was trained for 20 epochs with no apparent overfitting. Figure 6 shows a visual comparison of this model's predictions for the three time horizons.

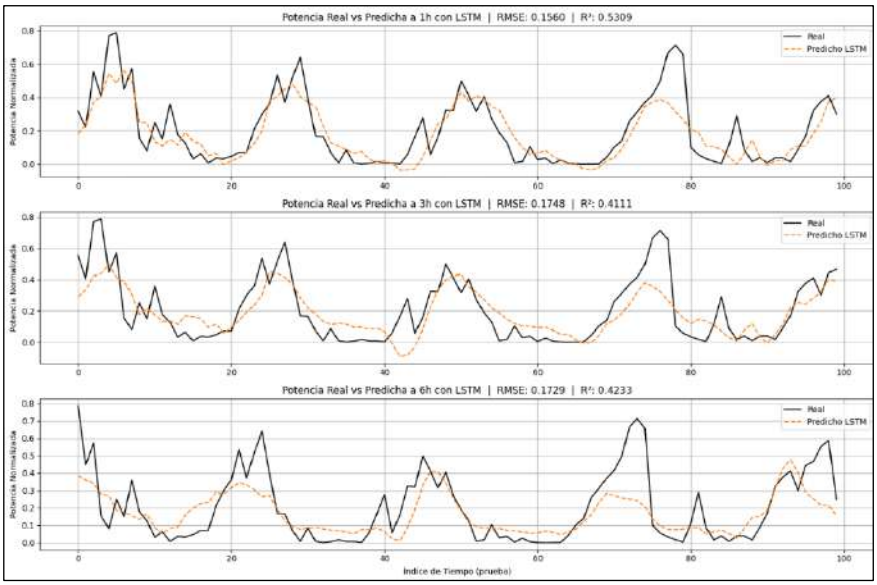

Figure 6: Graphical comparison between actual and predicted power at 1h, 3h, and 6h with basic LSTM.
Source: Authors, (2026).

The quantitative performance of the basic LSTM model for each prediction horizon is summarized in Table 7, where the normalized RMSE and the coefficient of determination (R^2) are reported for the test dataset.

Table 7: Performance metrics of the basic LSTM model at different prediction horizons.

Horizon	RMSE (norm.)	R^2
1h	0.1560	0.5309
3h	0.1748	0.4111
6h	0.1729	0.4233

Source: Authors, (2026).

IX.2 IMPROVED LSTM

To improve accuracy, a deeper architecture with two LSTM layers (64 and 32 neurons), Dropout regularization (0.2), and EarlyStopping with a patience of 5 epochs was tested. The 1-hour prediction is shown in Figure 7.

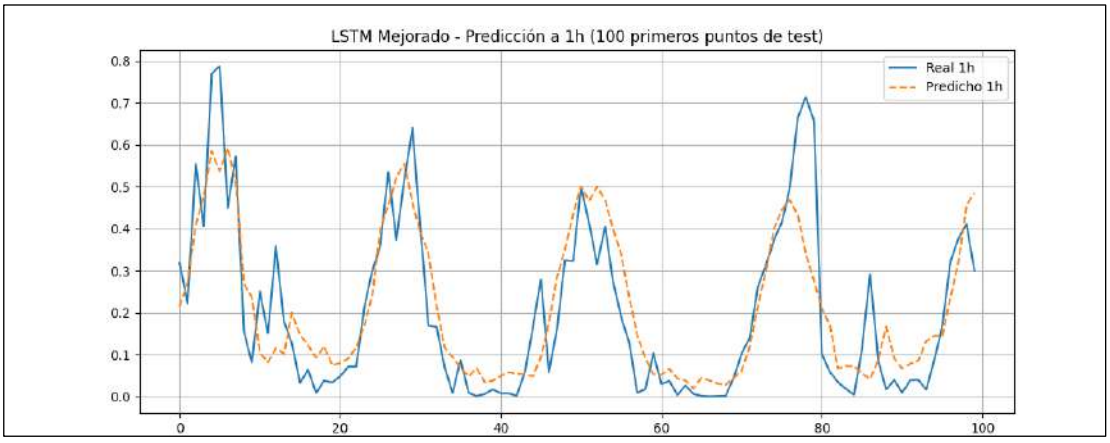

Figure 7: 1-hour prediction curve using Enhanced LSTM.
Source: Authors, (2026).

Compared to previous models, the enhanced LSTM outperforms XGBoost in 3-hour and 6-hour predictions and approaches its performance in the 1-hour horizon. The metrics achieved are shown in Table 8.

Table 8: Performance metrics of the improved LSTM model at different prediction horizons.

Horizon	RMSE (norm.)	R^2
1h	0.1544	0.5403
3h	0.1705	0.4395
6h	0.1716	0.4315

Source: Authors, (2026).

IX.3 DATASET QUALITY VERIFICATION

Given that the predictions had certain errors at low power points, a visual and statistical verification of the integrity of the final dataset (datos_limpios_avanzado.csv) was performed. Figure 8 shows the histogram of the power generated.

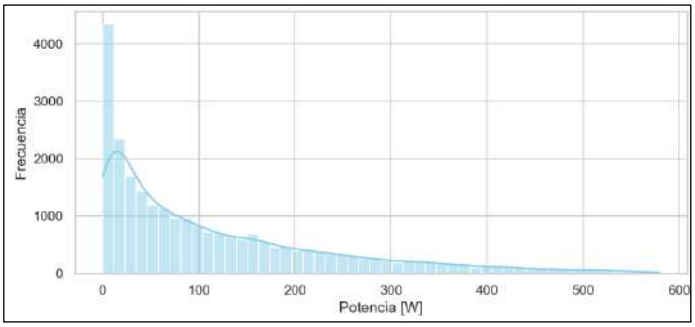

Figure 8: Distribution of power generated.
Source: Authors, (2026).

The most relevant physical relationships were also analyzed. This can be seen in Figure 9.

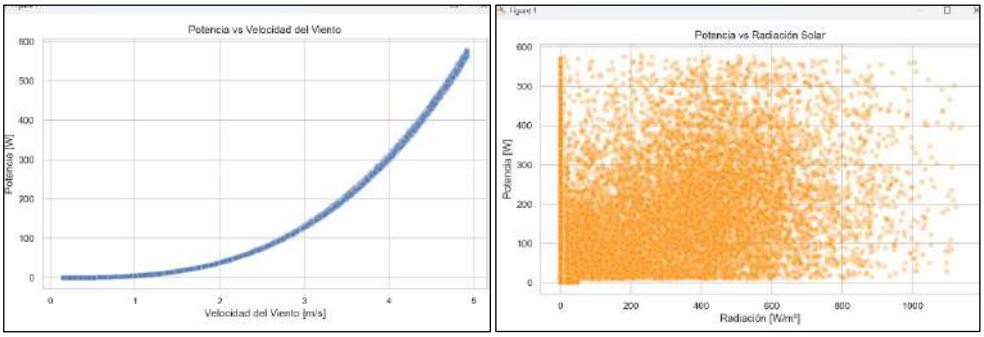

Figure 9: Power vs. Wind speed (left) and Power vs. Solar radiation (right).
Source: Authors, (2026).

The curve with respect to wind showed ideal parabolic behavior, while greater dispersion was observed with solar radiation. The latter could be due to instrumental noise or conditions not captured by the available variables. Finally, the average daily curve was evaluated (Figure 10), confirming the expected shape with maximum production during daylight hours.

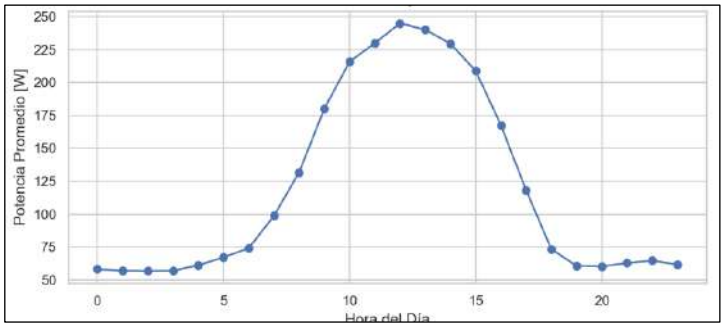

Figure 10: Average power per hour of the day.
Source: Authors, (2026).

Validation of the dataset showed that the data are physically consistent. It was confirmed that it is not necessary to eliminate all values close to zero, but only those that are not justified by physical conditions. This criterion was successfully applied in advanced cleaning and allowed the LSTM model to achieve competitive predictions, especially in the medium term.

IX.4 TECHNICAL NOTE ON POWER VALUES EQUAL TO OR CLOSE TO ZERO

During data exploration and verification, it was observed that a considerable proportion of records have power values close to zero. This situation is to be expected in wind or hybrid generation systems and does not necessarily represent an error. There are entirely valid physical conditions in which the power generated can be zero, for instance:

- Nighttime hours, in the absence of solar radiation.
- Wind speeds below the minimum cut-off speed (typically < 2.5 m/s).
- Periods of scheduled downtime or system standby conditions.

However, records were also detected in which the power was ≈ 0 even though the weather conditions were sufficient to produce energy. Specifically, combinations such as the following were identified:

- Power ≈ 0, but with wind > 2.5 m/s
- Power ≈ 0, but with radiation > 200 W/m²

This subset was considered anomalous, as it contradicts the expected physical behavior of the system. As a corrective measure, advanced cleaning was implemented in the script 01_limpieza_avanzada.py, where only these inconsistent records were removed and those with physical justification were retained. Therefore, the use of zero or very low power values within the model is fully justified, insofar as they represent real scenarios of the system: conditions of low available energy. This decision also allows the model to learn to correctly predict moments without generation, which is essential for real energy forecasting applications.

X. HYBRID ARCHITECTURE

After observing room for improvement in the LSTM model's predictions, a hybrid architecture was proposed that combined the temporal learning capacity of the LSTM with a decision tree model to correct the systematic errors of the former. This scheme consisted of two stages. In the first stage, an LSTM network was retrained on the normalized power series, with a 1-hour prediction horizon. In the second stage, the residual error between the LSTM prediction and the actual power was calculated, and an XGBoost model was trained to predict this error, using current meteorological variables, the LSTM prediction, and the time of day as input. The final prediction was obtained by adding the LSTM prediction to the correction estimated by the XGBoost model. Figure 11 shows the comparison between the actual values, the original LSTM prediction, and the adjusted prediction of the hybrid model. A visible improvement in peak tracking can be seen, as well as an overall reduction in dispersion. The metrics confirmed this improvement: the hybrid model achieved an RMSE of 62.12 W and a coefficient of determination R^2 of 0.7781, clearly surpassing the values obtained by the LSTM model without adjustment. This indicates that the hybrid approach significantly improves predictive power, especially in sections where the LSTM made systematic errors.

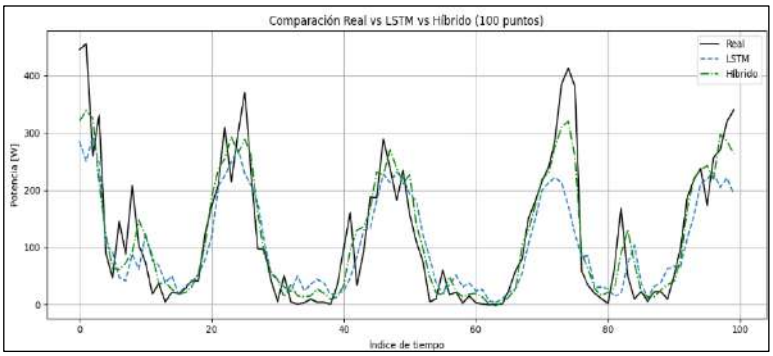

Figure 11: Comparison between actual power, LSTM prediction, and hybrid prediction (100 samples from the test set).
Source: Authors, (2026).

Given the good performance observed in the LSTM + XGBoost hybrid model at 1 hour, the same methodology was extended to prediction horizons of 3 and 6 hours. New LSTM models were trained for each time horizon, and in each case an XGBoost model was used again to predict residual errors and perform the final adjustment. The performance of the hybrid LSTM + XGBoost model across different prediction horizons is summarized in Table 9. The results show that the hybrid approach consistently improves predictive accuracy as the forecast horizon increases, maintaining a strong capacity to follow the underlying power generation trends and reducing the systematic deviations observed in the standalone LSTM predictions.

Table 9: Performance metrics of the hybrid LSTM + XGBoost model at different prediction horizons.

Horizon	RMSE (W)	R^2
1 hora	**61.98**	**0.7791**
3 horas	**77.56**	**0.6541**
6 horas	**82.83**	**0.6052**

Source: Authors, (2026).

These results show that the hybrid approach maintains good performance even over longer horizons, where traditional models tend to lose accuracy. In all cases, the hybrid model outperforms its unadjusted versions.

XI. TRANSFORMERS

With the aim of exploring more advanced architectures for multi-horizon power forecasting, it was decided to evaluate the performance of a model based on Transformers. These models, originally proposed for natural language processing, have recently shown great potential for time series forecasting tasks due to their ability to model long-term relationships, their efficient parallelization, and their flexibility in working with multivariate data. In this implementation, a simple Transformer was constructed using Keras' MultiHeadAttention layer. The model was trained on the same input sequences as the LSTM model, with normalized meteorological variables and a 1-hour prediction horizon. Unlike the LSTM, the Transformer does not rely on implicit sequential order, so internal position encoding was considered as part of the design. Figure 12 shows the comparison between the actual values and the prediction obtained by the Transformer model. In terms of performance, however, the results obtained were inferior to those achieved by the previously explored architectures:

- **RMSE:** 98.59 W
- **R^2:** 0.4412

These values indicate a loss of accuracy compared to the basic LSTM model, and even more so compared to the hybrid model with XGBoost. Possible reasons include the lack of explicit temporal encoding, the need for a larger amount of data to generalize correctly, and the sensitivity of this type of architecture to hyperparameter optimization. Although it did not outperform the previous models, this test was useful in confirming that the LSTM + XGBoost hybrid architecture is better suited to the available dataset. It thus established itself as the most robust strategy within the context of this project.

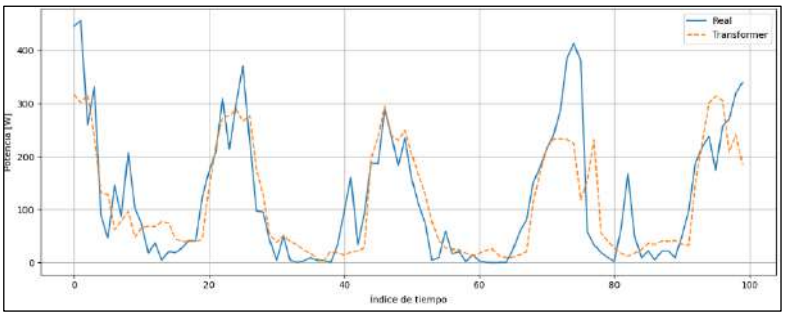

Figure 12: Power prediction using Transformer (100 samples from the test set).
Source: Authors, (2026).

In order to evaluate the direct applicability of the trained hybrid model (LSTM + XGBoost), a final script was developed for the actual prediction of wind power at 1-hour intervals. This stage represents the transition from the experimental approach to an operational scenario, where the model can receive new data and deliver automated predictions. A recent sample of the dataset (new_data.csv) was used as simulated input. The script 24_real_hybrid_prediction.py performs the following steps:

1. Loads and sorts the new data chronologically.
2. Applies the same normalization used in training, using the previously saved MinMaxScaler.
3. Generates multivariate sequences to feed the LSTM network.
4. Performs the initial prediction with the saved LSTM model.
5. Calculates the residual error correction using the XGBoost model.
6. Adds both outputs to obtain the final hybrid prediction.
7. Denormalizes the results to express them in watts.
8. Exports a file named hybrid_prediction_1h.csv with the predicted power for each instant.

This generated file is a useful tool for integration with external visualization or energy management platforms, enabling short-term monitoring and forecasting based on recent data. This implementation validates that the developed model not only achieves good results in controlled tests, but is also fully ready for use with new data in real-world environments.

XII. RESULTS

It is the logical presentation of the results that demonstrate the true contribution of the research and also justify the conclusion. The parts indicated above, Introduction, Material and Methods serve to explain how the results are obtained. Use tables and figures for your explanation. The results must be written in the past, in a brief and simple way. Avoid redundancy. Analyzing and interpreting the results is part of the discussions, their importance, achievements and limitations, highlighting the innovative aspects of the practical applications of the study and the conclusions derived from them, delimiting unresolved issues. If necessary, recommendations can be proposed. The dataset comprised 25,596 hourly records spanning January 2022–December 2024 and was described after data cleaning and feature engineering (air density and Betz-limit power were derived). A Pearson correlation analysis was performed to select inputs for the predictive models: wind speed exhibited a correlation of 0.92 with generated power, solar radiation 0.51 and air temperature 0.30; these three variables were therefore retained as primary predictors. Data were split into training and test sets using an 80/20 partition prior to model training. Four baseline regressors (linear regression, Random Forest, XGBoost and an MLP) were trained and evaluated using RMSE and R^2 on the test set. XGBoost and tree-based methods achieved the lowest errors in the instantaneous prediction task, while the linear model showed larger deviation at high-power values. For short-term forecasting (one hour ahead) an XGBoost regressor trained with current environmental inputs was evaluated separately and reported an RMSE of 80.11 W and $R^2 = 0.6303$.

Three alternative one-hour forecasting configurations were also compared: Model A (wind speed, radiation and temperature), Model B (wind speed only) and Model C (current variables plus 1-hour lag). Model C produced the lowest RMSE and highest R^2 among the three. Temporal lagging was further explored by adding t-1, t-3 and t-6 features for wind speed, radiation and power; models trained with these lagged inputs were evaluated at horizons of 1 h, 3 h and 6 h and showed consistent RMSE reductions and R^2 improvements relative to models without lags, particularly at the 3 h and 6 h horizons. A targeted advanced data cleaning step removed physically inconsistent records (instances of near-zero power despite sufficient wind or radiation); the retrained models after this cleaning exhibited only minor changes in short-term metrics and a small improvement in stability at the 3 h horizon. Sequence models were evaluated next. A basic LSTM (single hidden layer, 6-hour input sequences, MinMax normalization, 20 epochs) was trained and tested for 1 h, 3 h and 6 h horizons using normalized RMSE and R^2; an improved LSTM architecture (two LSTM layers 64→32, dropout 0.2, EarlyStopping) was also trained.

The improved LSTM produced marginal gains in normalized RMSE and R^2 over the basic LSTM. A hybrid two-stage architecture was then implemented: an LSTM generated the baseline one-hour prediction and an XGBoost model was trained to predict the LSTM residuals using meteorological inputs, the LSTM prediction and hour-of-day; the final hybrid prediction was obtained by adding the XGBoost residual correction to the LSTM output. The hybrid model yielded substantially lower RMSE and higher R^2 at 1 h and maintained improved performance at 3 h and 6 h compared with the LSTM alone. A Transformer-based model (single MultiHeadAttention block, same input sequences) was also trained for the 1 h task; the Transformer produced inferior performance relative to the LSTM and hybrid approaches on the available dataset. All experiments and metrics, reported in table n, below were computed on the test partition held out from model training. A final prediction script for operational use was developed and executed on a recent data sample; the script applied the same normalization and sequence-generation procedures used in training, produced hybrid one-hour predictions, denormalized the outputs and exported the results to prediccion_hibrida_1h.csv for subsequent integration with visualization or energy-management systems.

Table 10: Metrics of all models developed.

Model / Configuration	Prediction horizon	RMSE (W)	R^2
Linear regression (baseline)	instantaneous	47.17	0.8520
Random Forest (baseline)	instantaneous	0.42	1.0000
XGBoost (baseline)	instantaneous	1.36	0.9999
MLP (baseline)	instantaneous	6.48	0.9972
XGBoost (future prediction, Model A)	1 h	80.11	0.6303
Model B (wind only)	1 h	82.87	0.6045
Model C (with lag t-1)	1 h	78.62	0.6440
Without lags	1 h	79.01	0.6404
With lags (t-1,t-3,t-6)	1 h	77.13	0.6573
Without lags	3 h	106.43	0.3475
With lags	3 h	99.05	0.4349
Without lags	6 h	117.07	0.2107
With lags	6 h	108.68	0.3198
After advanced cleaning (1 h)	1 h	79.26	0.6387
After advanced cleaning (3 h)	3 h	105.75	0.3570
After advanced cleaning (6 h)	6 h	118.12	0.1977
LSTM (basic, normalized metrics)	1 h	0.1560 (norm.)	0.5309
LSTM (basic, normalized)	3 h	0.1748 (norm.)	0.4111
LSTM (basic, normalized)	6 h	0.1729 (norm.)	0.4233
LSTM (improved, normalized)	1 h	0.1544 (norm.)	0.5403
LSTM (improved, normalized)	3 h	0.1705 (norm.)	0.4395
LSTM (improved, normalized)	6 h	0.1716 (norm.)	0.4315
Hybrid LSTM + XGBoost (final)	1 h	61.98	0.7791
Hybrid LSTM + XGBoost (final)	3 h	77.56	0.6541
Hybrid LSTM + XGBoost (final)	6 h	82.83	0.6052
Transformer (single block)	1 h	98.59	0.4412

XIII. DISCUSSIONS

By [13] presented a short-term power prediction method for wind-farm clusters that fused multi-source spatio-temporal features through a graph-attention clustering step and a TimesNet predictor, reporting modest but consistent RMSE and MAE reductions across three Chinese regions. [14] combined variational mode decomposition with a bagging extreme learning machine and multi-objective aggregation, obtaining substantial out-of-sample RMSE reductions for very-short and short horizons. [15] proposed an indirect spatio-temporal strategy that classified data by wind direction and applied dedicated multivariate feature extraction, showing statistically superior performance versus several benchmarks. Compared with these studies, which either exploit explicit spatial clustering, advanced signal decomposition, or directional stratification for multi-site/cluster forecasts, our work focused on a single-site prediction using physically derived inputs (air density, Betz limit) and a hybrid LSTM+XGBoost residual correction; consequently, the gains reported in multi-site or decomposition-based approaches suggest promising avenues to extend our hybrid framework by incorporating spatial information or decomposition preprocessing to further reduce errors.

By [16] developed a WPCA feature weighting combined with a PSO-tuned GRU and reported 5–16% MAE and 10–16% RMSE improvements versus conventional models on a real wind farm. [17] evaluated direct and indirect point-forecasting pipelines that integrated several NWP sources and applied automated ML optimization, achieving error reductions in the 8–22% range for a Norwegian farm. [18] designed a physics-informed neural architecture that embedded analytical wake model nodes, reporting over 20% RMSE improvement by explicitly accounting for wake interactions. These contributions reinforce two messages relevant to our study: first, careful feature extraction and hyperparameter optimization (as in WPCA+PSO and BH-XGBoost approaches) can materially improve sequence models such as our LSTM; second, the explicit modeling of physical effects (wake/NWP fusion) could complement our data-driven hybrid residual correction and likely enhance performance in multi-turbine or wake-affected deployments beyond our single-site setting. In turn [19] provided a comprehensive meta-analysis of wind power forecast error metrics and introduced the Error Dispersion Factor (EDF) as a diagnostic that relates nRMSE and nMAE across horizons and farm sizes, offering benchmarking recommendations for forecast reporting. [20] proposed M2STAN, a multi-modal multi-task spatio-temporal attention network that combined graph attention with Bi-GRU for multi-location multi-step prediction and demonstrated superiority over several baselines. [21] coupled physical process models with machine learning using transfer learning strategies to improve wake-affected turbine predictions, showing that hybridization can inherit the strengths of both model classes. While our results emphasized a hybrid LSTM+XGBoost architecture and improvements from lagged inputs and data cleaning, the methodological recommendations and probabilistic/dispersion diagnostics advocated by Piotrowski et al. and the multi-location attention mechanisms developed by Wang and Zhou indicate concrete extensions: adopting normalized error reporting (nRMSE/nMAE/EDF) would facilitate cross-study benchmarking, and embedding spatio-temporal attention or physical coupling could extend our hybrid approach to multi-turbine contexts.

By [22] enhanced XGBoost via Bayesian hyperparameter optimization and demonstrated robust short-term forecasting performance, particularly during ramp events and low wind speeds. [23] proposed a multivariable hybrid system that combined outlier testing, feature extraction, an incremental kernel ELM predictor, and a bespoke multi-objective optimizer to maximize predictive capabilities over several Turkish datasets. Our findings—where XGBoost formed both a baseline and the residual-correction stage of the hybrid—align with Xiong's emphasis on careful hyperparameter tuning and with Guo's focus on outlier detection and multi-objective optimization; therefore, applying Bayesian optimization to our XGBoost residual model and formalizing a multi-objective training criterion (e.g., balancing RMSE and robustness metrics) could plausibly further reduce the hybrid RMSE reported in Table 7. [24] addressed the few-data problem for newly commissioned farms by generating synthetic samples through a WGANGP and decomposing them with EEMD before training an evolutionary neural predictor; validation on a Spanish farm showed benefits from data augmentation. [25] proposed a serio-parallel CNNs-LSTM pretraining and partial transfer strategy to adapt models to target farms with scarce histories, demonstrating clear superiority over non-transfer approaches across a swarm of Chinese farms. Although our dataset was relatively large (25,596 hourly records) and did not require synthetic augmentation for model training, these works highlight practical strategies for deploying our hybrid solution in data-poor contexts: GAN-based augmentation or parameter transfer from pre-trained CNN-LSTM extractors could enable rapid adaptation of the LSTM+XGBoost pipeline to new sites where historical measurements are limited. [26] introduced MSTAN, a multi-source temporal attention network that produced probabilistic, multi-horizon density forecasts by selecting NWP driving variables via variable attention and temporal attention modules; their approach outperformed deterministic counterparts across three farms. [27] trained ANN-based wake models using large CFD datasets (ADM-R and RANS outputs) to reproduce velocity and turbulence fields and to improve farm power predictions, validating against LES and onsite measurements.

According to [28] combined genetic algorithms with LSTM (GLSTM) to optimize sequence window size and neuron counts, reporting average improvements of 6–30% across seven European farms and statistical significance versus standard LSTM. Relative to these studies, which emphasize probabilistic prediction, physics-informed wake modeling and structural hyperparameter search, our deterministic hybrid provided strong deterministic accuracy at one-hour and multi-hour horizons but did not quantify predictive uncertainty or explicitly incorporate CFD-driven wake fields or GA-based LSTM tuning; integrating uncertainty estimation and either physics-informed features or structured hyperparameter search represents clear directions to increase the operational robustness and interpretability of our forecasts. [29] developed a Temporal Convolutional Network (TCN) for ultra-short forecasts in a large utility-scale farm and used Taguchi-based orthogonal tuning to obtain hyperparameters that yielded consistent improvements over existing methods across wind speeds. [30] coupled high-resolution NWP with ANN frameworks over complex terrain and tested two hybrid strategies (direct turbine output forecasting and wind-then-power conversions), reporting normalized error improvements and demonstrating viable operational libraries for forecast mode. These results complement our conclusions: TCN architectures and systematic experimental hyperparameter optimization may outperform standard LSTM in sub-hourly contexts (suggesting an architectural alternative to explore), while the demonstrated benefits of NWP coupling in complex terrain indicate that fusion of NWP outputs with our hybrid residual correction could improve medium-range forecasts beyond the one-hour horizon reported in this work. In summary, the reviewed literature spans complementary directions—spatio-temporal attention and multi-site clustering, physics-informed wake modeling, advanced decomposition and augmentation, probabilistic forecasting, and rigorous hyperparameter/optimization strategies—and each study provides methodological prescriptions that map directly onto potential extensions of our LSTM+XGBoost hybrid.

XIV. CONCLUSIONS

From a cleaned and feature-engineered dataset of 25,596 hourly records, models were trained and evaluated showing that a hybrid two-stage architecture (LSTM + XGBoost residual correction) delivered the best deterministic performance at the 1-hour horizon (RMSE = 61.98 W, R^2 = 0.7791) and maintained superior accuracy at 3 h (RMSE = 77.56 W, R^2 = 0.6541) and 6 h (RMSE = 82.83 W, R^2 = 0.6052) compared with single-model alternatives (e.g., XGBoost baseline RMSE = 80.11 W, R^2 = 0.6303; Transformer RMSE = 98.59 W, R^2 = 0.4412); inclusion of lagged inputs (t-1, t-3, t-6) consistently improved multi-hour forecasts, while targeted advanced cleaning modestly increased stability at intermediate horizons. These results confirm that combining temporal sequence learning with a tree-based residual corrector effectively reduces systematic errors and better captures peaks than standalone sequence or attention models in the present dataset and context.

XV. AUTHOR'S CONTRIBUTION

Conceptualization: Jessica N. Castillo, Jose E. Naranjo, and Gabriel Pesántez.
Methodology: Jessica N. Castillo, Jose E. Naranjo, and Víctor Hugo Medina Matute.
Investigation: Jessica N. Castillo, Gabriel Pesántez, and Víctor Hugo Medina Matute.
Discussion of results: Jessica N. Castillo, Jose E. Naranjo, and Víctor Hugo Medina Matute.

ABSTRACT

To effectively address multi-objective optimization problems, this study proposes a novel hybrid optimization approach, referred to as MOAHHGSO-w. This method integrates the characteristics of the multi-objective Weighted Sum (WS) algorithm with two recently developed single-objective optimization techniques: the Artificial Hummingbird Algorithm (AHA) and Henry Gas Solubility Optimization (HGSO). Furthermore, MOAHHGSO-w utilizes three distinct population archives to store the non-dominated solutions identified during the search process. To enhance solution diversity, the algorithm incorporates food source selection and leader selection mechanisms, both of which rely on the crowding distance metric. To achieve an optimal balance between solution diversity and convergence toward the Pareto-optimal set, the proposed method employs a combination of crowding distance and epsilon dominance. The algorithm is evaluated on four real-world multi-objective engineering design challenges. Its performance is benchmarked against several well-established multi-objective optimization methods. To validate the experimental findings, the study employs two widely recognized performance metrics: Inverted Generational Distance (IGD) for assessing convergence and Spacing (Sp) for evaluating solution diversity. The statistical analysis confirms that the proposed MOAHHGSO-w algorithm outperforms the compared optimization techniques in terms of efficiency and effectiveness.

I. INTRODUCTION

Multi-objective optimization (MOO) is a powerful paradigm in the field of optimization that addresses scenarios where decision-making involves conflicting objectives. Unlike regular optimization problems that focus on one goal, multi-objective optimization (MOO) aims to improve several competing goals at the same time [1] . In various real-world applications, decision-makers often need to balance multiple goals, each contributing to the overall performance of a system. These conflicting objectives can range from minimizing costs and maximizing efficiency to achieving a balance between multiple performance metrics [2] MOO provides a systematic framework to address the complicated trade-offs inherent in such decision-making processes. A fundamental aspect of multi-objective optimization is the identification and exploration of Pareto-optimal solutions [1]. A solution is considered Pareto-optimal if no other feasible solution improves one objective without worsening at least one other objective. The set of all Pareto-optimal solutions forms the Pareto front, representing the trade-off curve between conflicting objectives [3]. Solution approaches for multi-objective optimization problems (MOOPs) can be broadly categorized into classical, evolutionary, and hybrid methods. Classical techniques, such as the weighted sum and epsilon-constraint methods, transform MOOPs into single-objective problems [4]. Although computationally efficient, these methods often struggle with non-convex or complex Pareto fronts. To overcome these limitations, evolutionary algorithms have been widely adopted due to their population-based nature and ability to approximate multiple Pareto-optimal solutions in a single run. Prominent multi-objective evolutionary algorithms include NSGA-II [5], SPEA2 [6], and MOEA/D [7-9].

At the same time, nature-inspired metaheuristic algorithms like MOPSO [10], MOFO [11], MOAWA [12], and MOCSO [13] have shown that they can balance convergence and diversity very well . Recent advances further include MOAOA [14], MOMRFO [15-17], MOHHO [18-20], and other enhanced swarm-based techniques [16], [21-25]. Hybrid metaheuristic algorithms have emerged as powerful tools for solving multi-objective optimization problems (MOO) by integrating different optimization techniques to enhance solution quality, convergence speed, and robustness. Notable hybrid approaches include the multi-objective gravitational search algorithm and the bat algorithm (MOGSABAT) [2]. The MoSSE algorithm [26] is a hybrid optimization method that combines the features of Multi-Objective Spotted Hyena Optimizer (MOSHO), Salp Swarm Algorithm (SSA), and Emperor Penguin Optimizer (EPO). The firefly algorithm [27] is hybridized with a genetic algorithm for multi-objective integrated process planning and scheduling, while another approach is the metaheuristic hybrid of the multi-objective ant lion optimizer and genetic algorithm designed for solving design problems (MOALG) [28]. There is no perfect algorithm for solving all multi-objective optimization problems, as the choice depends on the nature of the problem, its constraints, and the desired objectives [29]. This is what motivates and encourages researchers to develop novel optimization techniques. Given this motivation, we propose a new multi-objective optimization method. Motivated by these observations, this paper proposes a novel hybrid multi-objective optimization algorithm, termed MOAHHGSO-w, which combines the Artificial Hummingbird Algorithm (AHA) and Henry Gas Solubility Optimization (HGSO), extended to the multi-objective domain using a weighted sum strategy. The main contributions of this work are summarized as follows:

- A new hybrid framework integrating AHA, HGSO, and a weighted sum approach for solving multi-objective optimization problems.
- A multi-archive mechanism, including local, global, and temporal archives, to effectively preserve non-dominated solutions.
- A leader selection and food source targeting strategy based on crowding distance to enhance population diversity.
- An epsilon-dominance-based updating mechanism to improve Pareto front distribution and convergence.
- Extensive validation using UF and DTLZ benchmark problems, as well as real-world engineering applications.

The remainder of this paper is organized as follows: Section 2 reviews fundamental concepts of multi-objective optimization. Section 3 details the proposed methodology, while Section 4 presents the MOAHHGSO-w algorithm. Section 5 discusses experimental results and performance analysis, and Section 6 concludes the paper.

II. THEORETICAL REFERENCE

II.1 MULTI-OBJECTIVE OPTIMIZATION PROBLEM

A general multi-objective optimization problem (MOOP) can be formulated as follows:

$$\begin{array}{lll} \text{Min / Max} & OF(V) = [of_1(V), of_2(V), \dots, of_M(V)] & \\ \text{Subject to} & C_i(V) \le 0 & i = 1,2,\dots,I \\ & H_e(V) = 0 & e = 1,2,\dots,E \\ & V_j^L \le V_j \le V_j^U & i = 1,2,3,\dots,n \end{array} \quad (1)$$

Where V is an n-dimensional decision vector, M denotes the number of objectives .functions, and V_j^L , V_j^U are the lower and upper bounds of decision variables, respectively.

Definition 1: Let $V_1, V_2 \in \mathbb{R}^{\mathbb{M}}$, we say that solution V_1 dominates solution V_2 if:

- Weak dominance: $\forall i, i = 1,2,\dots,M, of_i(V_1) \leqslant of_i(V_2)$, and
- Strong dominance $\exists i, i = 1,2,\dots,M, of_i(V_1) < of_i(V_2)$.

Definition 2: Solutions that dominate others but do not dominate one another are referred to as a non-dominated solutions set. The set of non-dominated solutions within the complete search space is referred to as the Pareto-optimal set.

Definition 3: Let V_i and V_j be two solutions in the objective space, where each solution is represented by a vector of objective values. A solution V_i is said to ε-dominate a solution V_j if the following conditions are met:

$$(1 + \varepsilon_m) of_m(V_i) \le of_m(V_j) \; \forall m \in \{1, \dots, M\} \quad (2)$$

Where OF_m is the value of objective m for solution V, ε_m is the allowed margin for objective m , and M is the total number of objectives.

Definition 4: Crowding distance is a density estimation technique used to preserve diversity among non-dominated solutions [5].

II.2 PERFORMANCE METRICS

To evaluate the quality of solutions generated by multi-objective optimization algorithms, several performance metrics are adopted.

II.2.1 Generational Distance (GD)

The Generational Distance metric measures the convergence of obtained solutions toward the true Pareto front [30]. It is defined as:

$$GD = \frac{1}{|V|}\left(\sum_{i=1}^{|V|} D_i^p\right)^{\frac{1}{p}} \tag{3}$$

Where D_i is the Euclidean distance from solution v_i to the nearest solution in the reference Pareto front P, p is typically set to 2 for Euclidean distance. Smaller GD values indicate better convergence.

II.2.2 Inverted Generational Distance (IGD)

Unlike Generational Distance (GD), which measures the convergence of solutions to the Pareto front, Inverted Generational Distance (IGD) also considers diversity by assessing how well the obtained solutions cover the entire optimal front.

$$IGD = \frac{1}{|m|}\left(\sum_{j=1}^{|m|} D_j{}'^p\right)^{\frac{1}{p}} \tag{4}$$

Where D_j is the Euclidean distance from each reference point p_j in the Pareto front to the nearest solution in the obtained set V, p is typically set to 2 for Euclidean distance . Lower IGD values indicate better coverage and distribution.

II.2.3 The Spacing Metric

The spacing metric evaluates the uniformity of solution distribution along the Pareto front:

$$Sp = \sqrt{\frac{1}{n-1}\sum_{i=1}^{n} (D_i - \bar{D})^2} \tag{5}$$

Where: D_i is the minimum Euclidean distance from solution v_i to any other solution v_j in the obtained set $(i \neq j)$, $\bar{D}$ is the mean of all values. Smaller values indicate more uniform spacing.

III. MATERIALS AND METHODS

III.1 ARTIFICIAL HUMMINGBIRD ALGORITHM

The Artificial Hummingbird Algorithm (AHA), proposed by Zhao [31], is a nature-inspired metaheuristic based on the intelligent foraging behavior, flight patterns, and memory mechanisms of hummingbirds. These characteristics enable AHA to efficiently balance exploration and exploitation in complex, high-dimensional optimization problems. AHA employs three main foraging strategies:

- *0Guided foraging:* which directs individuals toward promising and less-visited food sources:

$$v_i(t+1) = x_{i,tar}(t) + a.D(x_i(t) - x_{i,tar}(t) \tag{6}$$

where a ~ N (0,1) and D is a direction-switching vector. The position update is conditional:

$$x_i(t+1) = \begin{cases} v_i(t+1) & OF(x_i(t)) > OF(v_i(t+1)) \\ x_i(t) & otherwise \end{cases} \tag{7}$$

- *Territorial foraging:* which performs local exploitation around the current position:

$$v_i(t+1) = x_i(t) + b.D.x_i(t) \text{ ; b ~ N (0,1).} \tag{8}$$

- *Migrating foraging:* which randomly redistributes individuals to avoid stagnation:

$$x_{wor}(t+1) = Low + r(Up - Low)\ \ x_{i,tar} \tag{9}$$

Where Low and Up define the search bounds, and r ϵ [0,1]

Additionally, AHA integrates multiple flight patterns (axial, diagonal, and omnidirectional) and a visit-table memory mechanism to enhance diversity and prevent repetitive searches. While AHA exhibits strong exploration capability, its convergence speed may be limited in complex landscape.

III.2 HENRY GAS SOLUBILITY OPTIMIZATION

The Henry Gas Solubility Optimization algorithm (HGSO), introduced by Hashim [32], is inspired by Henry's law, which governs gas solubility in liquids under varying pressure and temperature conditions. HGSO models optimization agents as gas particles interacting within clusters, enabling an effective balance between exploration and exploitation. The population is initialized randomly as

$$V_i(t+1) = V_{min} + r(V_{max} - X_{min}) \tag{10}$$

Henry's constant is dynamically updated according to

$$H_i(t+1) = H_j(t).\exp\left(-C_j\left(\frac{1}{T(t)} - \frac{1}{T^{\theta}}\right)\right), T(t) = \exp(\frac{-t}{Iter}) \tag{11}$$

Where $T^{\theta} = 298.15K$ is the reference temperature. The solubility of each agent is computed by:

$$S_{i,j}(t) = K\ H_j(t+1)P_{i,j}(t) \tag{12}$$

And the position update is given by:

$$V_{i,j}(t+1) = V_{i,j}(t) + Fr\delta(V_{i,best}\ (t) - V_{i,j}(t) + Fr\alpha\left(S_{i,j}(t).V_{best}\ (t) - V_{i,j}(t)\right) \tag{13}$$

$$\delta = \beta.\exp\left(\frac{-OFbest(t) + \varepsilon}{OF_{i,j}(t) + \varepsilon}\right), \varepsilon = 0.05$$

Parameters δ, α and F ensure diversity and effective navigation through the search space. HGSO demonstrates good convergence properties; however, its performance may be sensitive to parameter settings and computationally demanding in high-dimensional problems.

III.3 WEIGHTED SUM METHOD

The Weighted Sum (WS) method is a classical scalarization technique used to transform multi-objective problems into single-objective formulations [4]. A composite objective function is constructed as:

$$g_{ws} = \sum_{i=1}^{m} w_i\ OF_i(x) \tag{14}$$

Where w_i represents the relative importance of the i i-th objective. The WS method is computationally efficient and simple to implement; however, it may fail to capture non-convex regions of the Pareto front and is sensitive to weight selection.

III.4 MOTIVATION FOR HYBRIDIZATION

Each of the aforementioned algorithms exhibits complementary strengths and limitations. AHA offers strong exploration capability, HGSO provides effective convergence behavior, and WS facilitates multi-objective extension with low computational cost. Motivated by the No Free Lunch theorem [29], this work integrates these methods into a unified hybrid framework to enhance convergence, diversity preservation, and robustness in multi-objective optimization.

III.5 PROPOSED ALGORITHM

We present a new algorithm, MOAHHGSO-w, in this research to solve optimization problems with multiple objectives. This method combines important features from two new single-objective optimization algorithms with a well-known multi-objective method. It specifically includes parts of the Artificial Hummingbird Algorithm (AHA) [31], the Henry Gas Solubility Optimization Algorithm (HGSO) [32], and the Weighted Sum Method [4]. The MOAHHGSO-w uses the epsilon dominance relationship to compare possible solutions. In addition, the algorithm makes use of three different external archives: Local Archives, Temporary Archives, and the Global Archive. We will explain each of these archives' specific roles in the optimization process later. Once the optimization process concludes, the Global Archive provides the final set of Pareto-optimal solutions. The general structure of MOAHHGSO-w is outlined in Algorithm 1, and the subsequent section provides an in-depth explanation of its operational mechanisms.

***Initialize population and parameters*:** The initial phase of the proposed hybrid algorithm, MOAHHGSO-w, involves generating a random set of N agents to form the initial population (Pop). Each agent is then evaluated based on M objective functions. Subsequently, the global archive (GArch) is initialized by storing the set of non-dominated solutions.

Position Update Using the AHA Algorithm: At this stage, a modified version of the Artificial Hummingbird Algorithm (AHA) is applied with additional enhancements:

- *Selecting the Target Food Source*: Each hummingbird identifies the optimal food source (solution) by referring to the visit table and selecting the one with the highest visit level. The identified food sources are then stored in a temporary archive (TArch), ensuring that dominance relationships are considered during the position update process. The MOAHHGSO-w algorithm determines the target food source for each hummingbird $X_{i,t}(t)$ at time t by retrieving the most suitable candidate from the temporary archive (ArchiveT). The following section details the specific selection mechanism employed in this process.

– Compute the crowding distance for every food source in the temporal archive (TArch).
– Sort the food sources in the temporary archive based on their congestion levels.
– To enhance solution distribution along the Pareto front, a target food source is randomly selected from the top *30%* of the sorted temporary archive (TArch). This strategy directs the hummingbird towards regions with lower solution density, improving diversity.

As a result, the updated position of the ith food source is determined accordingly

$$X_{i,new}(t+1) = X_{i,t}(t) + a.D(X_i(t) - X_{i,t}(t) \quad ; \text{a} \sim \text{N}(0,1). \tag{15}$$

$$X_i(t+1) = \begin{cases} X_{i,new}(t+1) & if\ X_{i,new}(t) \in G\text{lobal Archive} \\ X_i(t) & otherwise \end{cases} \tag{16}$$

$X_i(t)$ denotes the position of the ith food source at time t. Similarly, $X_{i,t}(t)$ corresponds to the location of the target food source that the ith hummingbird intends to visit. The guided factor follows a normal distribution N(0,1).

Algorithm 1: Pseudo code of the MOAHHGSO-w algorithm.

Initialization: Initialize a population of N agents, Evaluation of the initial population**,** and Initialize Local Archives and the Global Archive.
for *It* < *MaxIt* **do**
  if *rand* < 0.5 then
    Update position using the AHA algorithm.
    Update the global archive.
  else
    Update position using the HGSO and the WSA algorithms.
    Update Locale Archives (LAch).
    Update the Global Archive (GAch).
  end if
  if mod (2N, It)==0 **then**
    Update the position of the worst agents.
    Update the Global Archive (GAch).
  end if
end for
Return the Global Archive (GAch)

Update the global archive: The MOAHHGSO-w algorithm integrates an advanced update mechanism to enhance both the diversity of solutions along the Pareto front and the convergence toward optimal solutions. To preserve non-dominated solutions at each iteration t, a restricted-size external global archive (GArch) is employed, where the maximum archive size is denoted as sizeGArch. Following each update of a hummingbirds position *Vi*, the archive population is refined using a structured update strategy. The epsilon dominance criterion is applied to determine whether a newly generated solution should be accepted or discarded. Additionally, the crowding distance method is utilized to measure the relative spacing among solutions, allowing them to be ranked in descending order based on their crowding distance values. To maintain the archive size within the defined limit, solutions with lower crowding density are preserved, whereas those in more congested regions are removed. Each solution within the archive population V_{GA}, along with any newly generated solution NS considered for inclusion, is assigned an identification vector I = (I1, I2, ..., IM), where M represents the total number of objective functions. The identification process follows a structured approach, which will be elaborated in the subsequent section.

$$I_i(of) = \left\lfloor \frac{\log of_j}{\log(1-\epsilon)} \right\rfloor \tag{17}$$

Where $\lfloor . \rfloor$ is the absolute value, of_j: the objective value jth of an archive solution and denotes the admissible error. The identification vector partitions the whole objective space into hyper-boxes. Due to the constraint that only one solution may be accommodated in each hyper-box on the Pareto solutions set, the solution archive exhibits a moderate level of variability. MOAHHGSO-w utilizes the crowding distance as a means to restrict the size of the global archive if it is above the specified maximum limit (sizeArch). Initially, we compute the crowding distance for each solution in the global archive, and subsequently, we order the global archive solutions based on their crowding distance to diminish the size of the archive. The solutions with a lower population density are preserved, while those with a higher population density are removed from the archive.

Update position using HGSO and WSA Algorithm: During this phase, we implement the Henry gas solubility optimization algorithm with a few alterations and enhancements:

- Leaders selection strategy: After dividing the population into C clusters, each cluster is linked to a corresponding local external archive (LA_j , j=1...C), which stores the most promising solutions for gases during the optimization process. Additionally, the main population is connected to a global archive (GA), ensuring that the best solutions within both the clusters and the overall population are preserved. This mechanism allows for maintaining high-quality solutions that have not yet been surpassed. The local archives are systematically ranked in descending order based on their crowding distance values. Subsequently, the subset of solutions with the lowest density, corresponding to the top 30% of non-dominated solutions in the sorted archives, is identified. Within this subset, a solution is randomly selected to serve as the regional leader for each cluster. This leader plays a crucial role in guiding the main population of gases toward an accurate approximation of the true Pareto-optimal solutions. A similar approach is employed to determine a global leader for each gas from the global archive (GA). This leadership selection method enhances both the convergence rate and the diversity of solutions. Assigning two leaders to each search agent further strengthens the balance between convergence and solution diversity within the population. The new formula for updating the position is:

$$V_{i,j}(t+1) = V_{i,j}(t) + F\ r\ \delta\ ((L_{LA}\,(i,j)(t) - V_{i,j}(t) + F\ r\ \alpha\left(S_{i,j}(t).L_{GA}\,(t) - V_{i,j}(t)\right) \quad (15)$$

$$\delta = \beta.\exp\left(\frac{-SW(L_{GA},t)+\varepsilon}{SW(V_{i,j}(t))+\varepsilon}\right), \varepsilon = 0.05$$

We denote the position of gas i within cluster j as $V_{i,j}$, where t represents the iteration step and r is a fixed constant. The term $L_{LA}\,(i,j)$ refers to the leader gas i within cluster j, while L_{GA} designates the leader gas across the entire population. Additionally, δ represents the capacity of gas j within cluster i to interact with other gases in the same cluster. The parameter α, which is set to 1, indicates the influence of surrounding gases on gas i within cluster j, whereas β is considered a constant. Both $SW(L_{GA},t)$ and $SW(V_{i,j}(t))$correspond to the weighted sum approach.

Update local archives: The local archive update process follows the same methodology as the global archive update procedure.

Update the position of the worst agents: To refine the search process, all inferior solutions (dominated solutions) are removed and replaced with newly generated solutions that are randomly distributed throughout the entire search space. This replacement occurs every 2N iterations, where N denotes the population size. After each replacement, the global archive is subsequently updated. This step is very important for lowering the chance of getting stuck in local optima and making the algorithm better at exploring in general, especially as the optimization process goes on.

IV. RESULTS AND DISCUSSIONS

IV.1 THE IMPACT OF HGSO AND AHA ALGORITHMS ON THE EFFICACY OF THE PROPOSED ALGORITHM

A comparison is made between the suggested algorithm, the proposed algorithm without AHA, and the proposed algorithm without HGSO, using the IGD and SP metrics to see how HGSO and AHA affect the performance of the MOAHHGSO-w algorithm on three engineering design problems:] the four-bar truss (4-b truss) [33] , the disk brake (Disk) [34], and welded beam design problem (WBD) (WBD) [34]. Table 1 shows the statistical findings for the IGD metric over 31 runs of engineering design problems, while Table 2 presents the statistical results for the SP metric over the same 31 runs. These statistical results of the two metrics prove that in all engineering design problems, the proposed hybrid algorithm outperforms the other two algorithms (without AHA, without HGSO).

IV.2 RESULTS ON REAL WORLD ENGINNEERING MULTI-OBJECTIVE DESIGN PROBLEMS

This section evaluates the performance of the proposed MOAHHGSO-w algorithm using a set of real-world engineering optimization applications: the four-bar truss (4-b truss) [33] , the disk brake (Disk) [34] ,the speed reducer (SRD) [33], and the welded beam design problem (WBD) [34] characterized by conflicting objectives and complex constraints. The literature widely adopts the selected problems, which represent practical industrial scenarios, to evaluate the effectiveness of multi-objective optimization algorithms. The MOAHHGSO-w algorithm was implemented using MATLAB R2015a and evaluated against five well-established multi-objective optimization algorithms: the Multi-Objective Evolutionary Algorithm Based on Decomposition (MOEA/D) [7], Multi-Objective Grey Wolf Optimizer (MOGWO) [35], Multi-Objective Harris Hawks Optimization (MOHHO)[36], Multi-Objective Salp Swarm Algorithm (MSSA) [37], and Multi-Objective Particle Swarm Optimization (MOPSO) [10]. These algorithms have been widely applied in solving multi-objective optimization problems (MOPs) across various domains due to their effectiveness in approximating Pareto-optimal solutions. For a fair and unbiased comparative analysis, all algorithms were executed under identical experimental conditions. Specifically, the number of iterations was set to 1000 to ensure sufficient exploration and exploitation of the search space, the population size was fixed at 100 to maintain consistency across algorithms, and the global archive size was maintained at 100 to store non-dominated solutions.

Furthermore, each real-world engineering application was run 31 times to consider random changes and lessen the impact of chance, which improves the trustworthiness of the results. The parameter settings were adopted as specified in their respective original studies to ensure a valid and reproducible comparison. To ensure a rigorous and objective evaluation of algorithmic performance, two widely recognized performance metrics were employed: The Inverted Generational Distance (IGD) and the Spacing (Sp) metric. The IGD metric quantifies convergence by measuring the proximity of the obtained Pareto front to the true Pareto-optimal front, whereas the Sp metric assesses diversity by evaluating the distribution uniformity of the obtained solutions. A lower IGD value indicates better convergence towards the optimal front, while a lower Sp value suggests a more evenly distributed set of solutions, both of which are desirable properties in multi-objective optimization. Tables 3 and 4 provide the results, offering a comprehensive assessment of the algorithm's efficacy across various engineering design scenarios. Table 3 indicates that, across all assessed engineering design difficulties, the MOAHHGSO-w technique consistently yields the lowest mean IGD values. The IGD metric assesses the proximity of the obtained solutions to the true Pareto front, with lower values signifying superior convergence. The results indicate that MOAHHGSO-w has better convergence than other methods, which means it provides a more accurate estimate of the best trade-off solutions. The graphical representations in Figures 1, 2, 3, and 4, illustrating the algorithm's ability to generate solutions that nearly align with the actual Pareto front, further substantiate this pronounced convergence characteristic.

Table 4 presents the statistical analysis of the SP measure, which assesses the homogeneity and diversity of the Pareto front solutions. The results show that in the disk brake and welded beam design issues, where it generates a well-distributed and uniformly spaced collection of solutions, MOAHHGSO-w works very well. The hybrid nature of the strategy enables it to effectively balance exploration and exploitation, resulting in a more diverse and uniformly distributed Pareto front in these specific difficulties. MOAHHGSO-w has worse performance compared to MOGWO and MOHHO, which demonstrate enhanced solution diversity and dispersion in the four-bar truss and speed reducer design problems. The elevated SP values for MOAHHGSO-w in these contexts indicate that the solutions generated by this method are less uniformly distributed compared to those produced by MOGWO and MOHHO. While MOAHHGSO-w maintains robust convergence characteristics, its solution diversity is contingent upon the specific problem, and in certain instances, alternative methodologies may produce more uniformly distributed Pareto fronts. The visual data from Figures 1, 2, 3, and 4 corroborates these conclusions.

IV.3 DISCUSSION OF THE RESULTS

The MOAHGSO-w algorithm is a hybrid algorithm that combines two metaheuristic single-objective methods, the Artificial Hummingbird algorithm and the Henry Gas Solubility Optimization, with a multi-objective exact approach, the Weighted Sum algorithm. This proposed hybrid algorithm combines the characteristics and strengths of each algorithm integrated into it to provide better performance in the optimization process. In order to improve the suggested method for solving multi-objective optimization problems, the existing algorithms were improved and additional strategies were implemented, as previously described. The proposed MOAHHGSO-w algorithm is applied to different real engineering application. The proposed algorithm's superiority is evident both quantitatively and graphically.

It can be concluded that the MOAHHGSO-w algorithm effectively discovers a well-distributed set of non-dominated solutions with a strong convergence to the true Pareto front, even when dealing with two conflicting objectives in the search space. The findings suggest that the MOAHHGSO-w method effectively circumvents local optima Pareto fronts and successfully tackles high-dimensional issues with varied morphologies. The following comparison demonstrates that the MOAHHGSO-w algorithm is very competitive when compared to the other chosen algorithms. The statistical findings clearly demonstrate the exceptional performance of the MOAHHGSO-w algorithm. The factors contributing to this performance may be delineated as follows:

- The MOAHHGSO-w is attributed to the effective exploration techniques used by the AHA algorithm during the optimization process. This involves the hummingbird population alternating between the guided foraging strategy and the territorial foraging strategy; hence, it enhances the exploration of the search space. At the end of the optimization phase, hummingbirds use the migration foraging strategy to improve space search efficiency.
- The conventional HGSO algorithm has excellent performance. The strong updating mechanism, which relies on updated values of parameters $V_{i,j}$ and γ, demonstrates robust exploration and exploitation capabilities.
- The MOAHHGSO-w utilizes three types of external archive population to store the most optimal nondominated solutions achieved throughout the process optimization. This helps lead the MOAHHGSOw in exploring the most productive areas of the search space.
- Utilizing ϵ-dominance to update the archive population enables the acquisition of a precise estimation of the Pareto set, prevents the archive from becoming too large, and decreases the execution time of the MOAHHGSO-w algorithm.
- Leaders selection strategy and selecting the target position strategy and using crowding distance in both of these strategies enables a favorable equilibrium between exploring and exploiting the search space.

Nevertheless, despite its efficiency, the suggested method incorporates several regulating factors, making it more susceptible and less adaptable to variations in these parameters. The crowding distance is a metric that prioritizes extreme points above solutions that provide a decent balance between goals during the optimization process. This issue may be resolved by using alternative diversity estimate techniques or by enhancing the used distance metric. Additional mechanisms and more efficient strategies may be included in the proposed algorithm to address multi-objective issues. This algorithm can be used for many optimization problems that need more investigation in future studies. To enhance the MOAHHGSO-w method for addressing the challenges associated with multi-objective optimization issues. It is important to use novel dominance relationships in order to differentiate among the non-dominated alternatives.

V. CONCLUSIONS

This research introduces a novel hybrid optimization approach, termed MOAHHGSO-w, which integrates features from the Artificial Hummingbird Algorithm (AHA), Henry Gas Solubility Optimization (HGSO), and the Weighted Sum method (WS) to effectively tackle complex multi-objective optimization problems. The proposed MOAHHGSO-w framework employs three distinct types of archives—local, global, and temporary—to efficiently handle multi-objective problems (MOPs). These outside archives are very important for keeping the balance between convergence and solution diversity. This step makes sure that the Pareto optimal front is very closely approximated while the solutions are spread out evenly. Moreover, the incorporation of the crowding distance mechanism enhances the diversity of non-dominated solutions during archive updates. Additionally, two key aspects of the proposed method include the strategy for determining the location of the target food source and the leader selection process. The method uses both epsilon dominance and crowding distance techniques to manage the population archives. These mechanisms prevent uncontrolled population growth and facilitate the generation of diverse solutions. The effectiveness of MOAHHGSO-w is assessed using four real-world engineering multi-objective design cases. The suggested hybrid method is also tested against five well-known multi-objective optimization methods. Experimental results indicate that the suggested method efficiently solves MOPs by demonstrating robust convergence and maintaining diversity in solutions. The findings point out the strengths of MOAHHGSO-w in addressing real-world, complex multi-objective optimization challenges. Future research will focus on extending this approach to handling many-objective optimization problems and investigating its practicality.

ABSTRACT

Nowadays, the recycling materials is essential, when it is related to the sustainable development. Reducing raw material consumption, recycling, and reuse are the three fundamental pillars of sustainable building practices. Common Portland cement, which is used extensively in the building sector, emits a large amount of greenhouse gases and uses a lot of natural resources. Nevertheless, CO_2 emissions can be lessened by substituting some of the cement with pozzolanic materials. Concrete's strength and durability, both in a long or short time, are enhanced by this substitution. The objective of this study is to probe the effectiveness of the use toward the calcined sediments and limestone fillers as substitutes for cement in mortars. Various tests were conducted on fresh and hardened samples, with a focus on durability. The incorporation of limestone fillers in mortar formulations have shown a positive impact on compressive strength. Furthermore, over a 180-day, the compressive strength of different types of mortars, composed of calcined sediments and limestone fillers, showed a consistent increase. However, the calcined sediments and limestone fillers have demonstrated good short-term durability. In conclusion, the incorporation of calcined sediments and limestone fillers as alternatives to conventional clinker in the manufacturing process helps in the fight against climate change by reducing the quantity of carbon dioxide discharged into the atmosphere.

I. INTRODUCTION

Today, recycling materials is highly recommended in the logic of sustainable development. The typical Portland cement used in the building sector releases a significant amount of greenhouse gases and uses a number of natural resources [1]. Significant amounts of carbon dioxide are released into the atmosphere during the manufacturing of clinker as a result of the rise in cement usage. Nonetheless, CO_2 emissions can be decreased by substituting some pozzolanic materials for some of the cement [2]. Additionally, this replacement can increase strength and durability over the long run as well as in the short term [3]. Dredged sediments from dams have been the subject of several recent studies that have investigated the value of these materials in a variety of domains, such as durability [4], mechanics [5], and physicochemical characterization [6]. These studies show that these sediments have the potential to be used as raw materials in civil engineering, especially if they are used to replace cement partially [4], [5], [7]. Dredged sediments can be used as secondary raw materials in many different areas of civil engineering, such as foundation layering for roads [8], producing bricks for construction [9], and using them as substitute materials for some of the cement or sand in concrete [8]. In order to explore the potential for monetizing these sediments, [10] conducted an industrialization model based on a life cycle assessment. According to [7], the thermal treatment of sediments might make them more reactive, which makes it possible to employ them in the manufacturing of clinker.

In order to show that the addition of sediments decreased mortar shrinkage, [11] examined the hydration and shrinkage of cement pastes containing 20%, 30%, and 40% dredged sediments calcined at 865°C. It was also determined that the calcined sediments (from the harbour of Antwerp, Belgium) exhibited pozzolanic reactivity at temperatures of 820°C, 865°C, and 905°C [12]. Cement can also be substituted with limestone fillers at a rate of 15–20% [13]. They react with water when powdered finely to generate calcium silicate hydrate, which strengthens and extends the life of concrete [14]. Ternary cement, which is frequently used to lower the clinker content, is made up of calcined clay, clinker, and limestone filler [14]. When compared to regular Portland cement, this mixture also enhances workability and strength [15]. Limestone fillers are inexpensive resources that are readily available in considerable quantities locally [15]. For many years, they have been effectively substituted for some of the Portland cement in concrete [14]. It is commonly acknowledged that concrete that has these fillers in it is a strong structural material. However, the design of durable concrete is challenged by the restricted availability of these additives [16]. In order to produce concrete that is more durable and emits less CO_2, the construction industry frequently substitutes these ingredients for cement. According to recent research, calcined clay and limestone combined may raise clinker replacement levels by as much as 50% [17]. Calcium hydroxide (CH) and these siliceous and aluminous minerals interact chemically [14].

II. MATERIALS AND METHODS

II.1. MATERIALS

II.1.1 Cement

Following the recommendations of the European standard EN 197-1 (2012), Portland cement CEMI 42.5 N from the Saida cement plant in western Algeria, was utilized for this investigation [18]. Tables 1 and 2 provide the chemical compositions of cement and the mineralogical compositions of clinker.

Table 1: Chemical composition of used cement and mineral additions (%).

II.1.2 Calcined Sediments

The calcined sediments used in this study were dredged from the Chorfa II dam in western Algeria. The sediments meant to be used in the formulation of mortar were first dried at 40°C in an oven, and then they were crushed and sieved to an 80 µm granulometry [19]. After that, they underwent calcination. The temperature was raised by 5 °C every minute until it reached 750°C, which was held for 5 hours in order to prevent thermal shocks [9], [20], [21]. Calcined sediments, the finished product, was carefully kept out of the air and moisture in a dry atmosphere [22-24] (figure 1). Tables 4 and 5 provide the chemical compositions and mineralogical characteristics of the calcined sediments.

Figure 1: The calcined sediments appearance both before and after calcination.

The original sediments XRD mineral analysis revealed the presence of quartz, kaolinite, calcite, and dolomite peaks. The calcination of kaolinite into metakaolin makes the silica and aluminium potentially reactive with pozzolanic activity. According to [26], quartz, calcite, feldspar, and clay minerals, particularly kaolinite and illite, are the main mineral phases of the original sediments [27], [28]. Figures 2a and 2b represent the XRD and SEM analysis carried out on raw and calcined sediments.

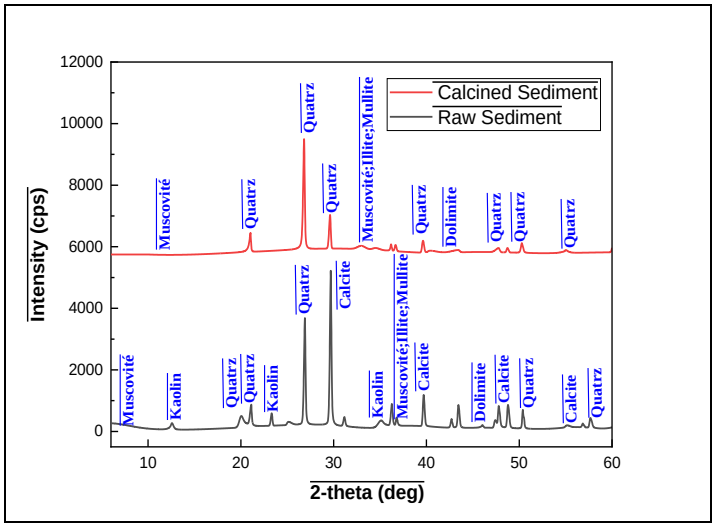

Figure 2a: Raw and Calcined Sediment XRD.

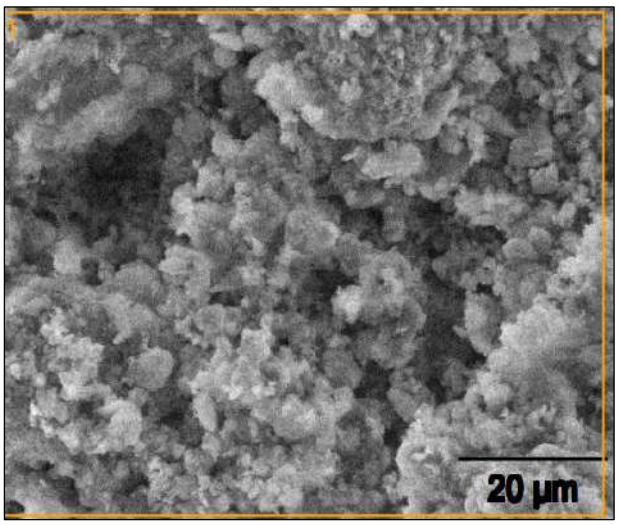

Figure 2b: SEM analysis of calcined sediment.
Source: Authors, (2026).

Observation imaging with scanning electron microscopy (SEM) revealed that the sediment contained irregular particles of varying sizes, which demonstrated that spherical particles of pure kaolin, making up about 20% of the final product, have diameters ranging from 10 µm to 20 µm. Similarly, [29] showed that rapidly calcined sediments contain submicron agglomerates of kaolin particles.

II.1.3 Limestone Fillers

The limestone fillers from the Antar quarry in Mecheria, along with the physical characteristics of these limestone fillers, are presented in Tables 6a and 6b and Observation imaging with scanning electron microscopy (SEM) (figure 3a and 3b).

Figure 3a displays the X-ray diffraction (XRD) pattern of a calcium carbonate ($CaCO_3$) sample, while Figure 3b shows particles exhibiting irregular shapes with angular edges. Such morphology is characteristic of limestone fillers obtained through mechanical grinding.

II.1.4 Admixture

During our study, we used a water-reducing plasticizer adjuvant, PLASTIMENT BV40, for mortar formulations based on additives (sediment, perlite, and limestone filler). It has a density of 1.180 g/cm³ ± 0.025 and a dry extract percentage of 38.5% ± 1.9%.

II.2 METHODS

II.2.1 Formulations of Pastes and Mortars Used

Various mortar compositions were developed by combining CEM I 42.5 N cement with calcined sediments. Following the approach of Hadj Sadok's previous work, a 15% sediment proportion was adopted to determine the optimal sediment concentration for achieving the highest performance [20]. To evaluate the flexural and compressive strength of the mortars, prism samples measuring 4 × 4 × 16 cm were prepared. Five fresh mortar formulations were created using CEM I 42.5 N according to NF EN 196-1 (2016) [30]. The W/B ratio (0.5), along with the proportions of calcined sediments and limestone filler, are detailed in Table 7.

Table 7: Formulations of mortar.

Mortars	Binders			Sand	Water	BV 40	W/binder
	CEM I 42,5	SD	LF				
MT	450	0	0	1350	225	0	0.5
M15S	382,5	67.5	0	1350	223.09	1.91	0.5
MS5L	360	67.5	22.5	1350	223.56	1.44	0.5
MS15L	315	67.5	67.5	1350	223.3	1.70	0.5
MS25L	270	67.5	112.5	1350	223.11	1.89	0.5

Source: Authors, (2026).

II.2.2 Fresh State Characterization Tests

II.2.2.1 Initial Setting Time and Final Setting Time of Pastes

Consistency and setting time tests on standardized pastes are conducted to determine the so-called "normal" consistency using a Vicat apparatus equipped with a probe, as per the NF EN 196-3 (2017) standard. Setting times are measured with a setting meter in accordance with the same standard, NF EN 196-3 [31]. The setting time test was carried out using the setting time measurement device (figure 4).

Figure 4: Setting time measurement device.
Source: Authors, (2026).

II.2.3 Physical Properties

II.2.3.1 Water-Accessible Porosity

This test aims to determine the percentage of voids within the mortar mass that are connected to the surface in accordance with standard NF P 18-459 [32]. The porosity of prismatic specimens with dimensions of 4x4x16 cm³ was measured after 28 days of curing. The water-accessible porosity ε is expressed as a percentage of the total volume.

III.2.3.2 Capillary Absorption

The test was conducted on prismatic mortar samples (4x4x16 cm³) that were preconditioned for 28 days according to the recommendations of the AFREM AFPC, 97 procedures [33]. After this preconditioning, the capillary absorption test was carried out. The specimens were immersed in water contained in a vessel to a maximum height of 5 mm, using spacers. At each stage, the samples were removed from the vessel, wiped with a damp sponge, weighed, and then placed back into the vessel.

II.2.4 Hardened State

II.2.4.1 Compressive Strength of Mortars

The compressive strength of mortars, determined through the thirty-point flexion test and in accordance with EN 196-1 [30], is a fundamental parameter of this study. The compressive strength was measured after various hardening periods (2 days, 7 days, 28 days, 56 days, 90 days, and 180 days). The study included one test mortar (TM) with 100% cement (C100% + SD0%) and four mortars with partial replacements using calcined sediments and limestone fillers: M15S (C85% + SD15%), MS5L (C80% + SD15% + LF5%), MS15L (C70% + SD15% + LF15%), and MS25L (C60% + SD15% + LF25%). The dosage of the BV40 water-reducing plasticizer varied from 0% to 4.05%. The three-point bending test and the measurement of compressive strength were conducted using the mortar compression device (figure 5).

Figure 5: The mortar compression device.
Source: Authors, (2026).

III. RESULTS AND DISCUSSIONS

III.1 FRESH STATE (PASTES, MORTARS)

The results of the initial and final setting times of the different cement pastes are presented in Table 8 and illustrated in Figure 6.

Table 8: initial and final setting times of the different cement pastes.

Pastes Type	Initial setting time (min)	Final setting time (min)
CP	173	231
P15S	265	304
PS5L	328	412
PS15L	325	396
PS25L	230	281

Source: Authors, (2026).

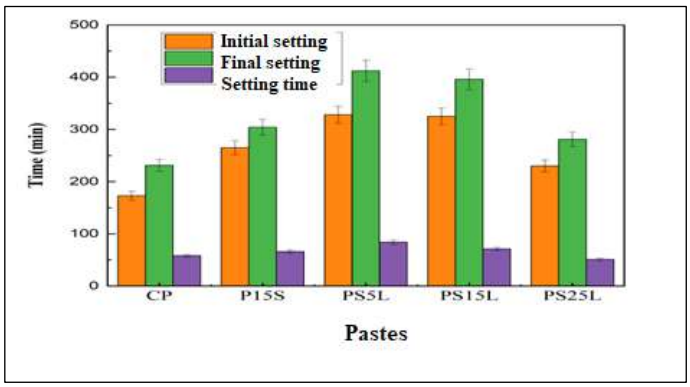

Figure 6: Initial and final setting times of the different cement pastes.
Source: Authors, (2026).

Figure 6 illustrates the inverse relationship between setting time and additive content in various cement pastes, regardless of the presence of additives. The increased reactivity of calcined clays may explain why mixtures with higher replacement levels exhibit faster setting times. The structure and fineness of calcined clay necessitate more water for limestone-calcined clay blends to achieve the same flow as OPC. However, the limestone particles can partially offset the additional water demand. The authors concluded that incorporating limestone and calcined clay as partial substitutes for OPC in cement paste can potentially enhance the setting time and other properties of the resulting mixture. [34] These observations are consistent with the findings of studies conducted by [35], [36].

III.2 HARDENED STATE

III.2.1 Compressive Strength (2, 7, 28, 90, and 180 Days)

Figure 7 illustrates the compressive strength of concrete in MPa over time. During this period, the intensity of the MS5L mortar surpassed that of the reference mortar (CM), with a strength of 46,28 MPa recorded on the 28th day. The MS15L and MS25L mortars exhibited lower intensity compared to the reference mortar. This difference is attributed to the pozzolanic reaction of the calcined sediment and limestone filler, which contributes to strength development. These results are consistent with those in the literature [13], [37]. After 7 days [38] concluded that the partial replacement of cement with calcined sediment and limestone filler improves compressive strength compared to a reference mix. The authors explain that this increase is due to the reaction of portlandite with the calcined sediment and limestone filler, leading to microstructural densification and a reduction in pore connectivity [39].

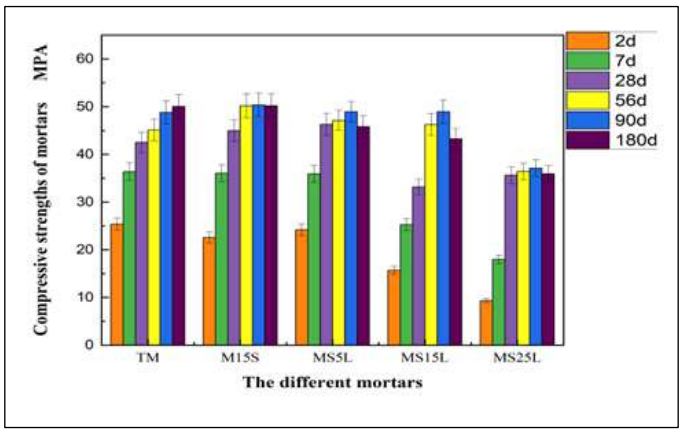

Figure 7: Compressive Strength (2,7, 28, 90, and 180 Days).
Source: Authors, (2026).

III.2.2 Flexural Resistance of Mortar

Figure 8 demonstrates the impact of incorporating limestone filler and calcined sediments on the flexural strength development of the mortar samples. It is obvious that the flexural tensile strength of all the mortars consistently increases over time, with no observed decrease in strength.

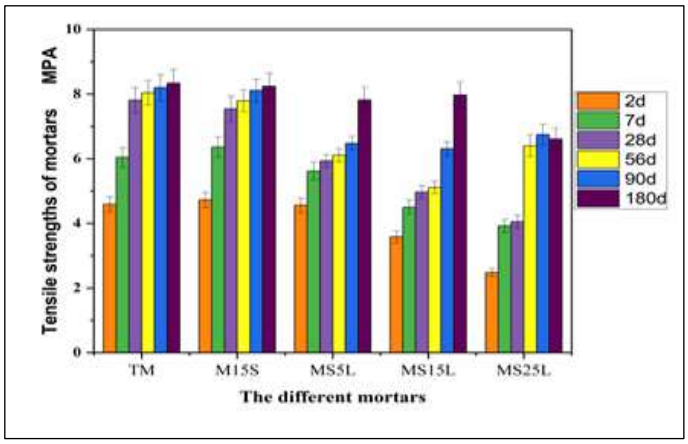

Figure 8: Flexural resistance (2,7, 28, 90, and 180 Days).
Source: Authors, (2026).

III.3 CAPILLARY ABSORPTION

The capillary absorption of mortars MT, M15S, and MS15L ulstered in the figure 9, along with their absorption kinetics, varies over periods ranging from 2 to 168 hours. During the initial phase of 2 to 8 hours, a slight increase in capillary absorption and absorption kinetics is observed. Notably, the reference mortar (MT) shows higher capillary absorption than the other mortars at 4, 8, 24, and 168 hours, which can be attributed to its high porosity and insufficient adhesion between the cement paste. When comparing the capillary absorption coefficients of mortar M15S with those of the reference mortar, it is evident that M15S exhibits lower values. The results show that capillary absorption gradually increases over time for both mortars. The MS15L mortar, on the other hand, demonstrates a significant reduction in absorption rate, reaching a level similar to that of the reference mortar after 168 hours. This decrease is attributed to the addition of calcined sediments and limestone fillers, which contribute to the densification of the interfacial transition zone. These results are consistent with recent studies by [40], [37].

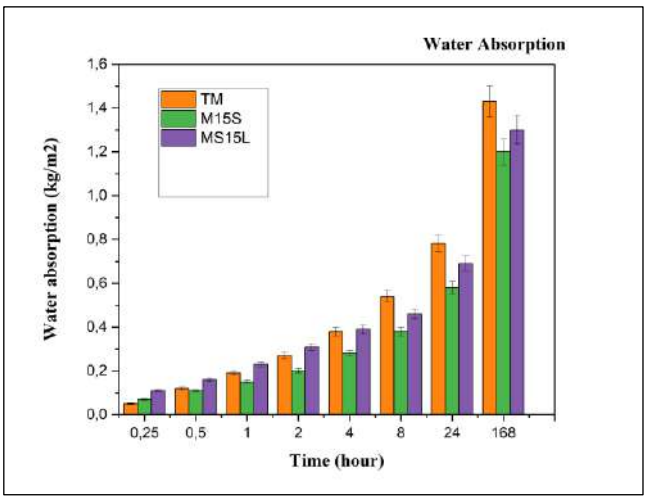

Figure 9: The capillary absorption of mortars.
Source: Authors, (2026).

III.4 ACCESSIBLE WATER POROSITY

After 28 days of dry curing, Figure 10 presents the porosity results obtained for the selected mortars. The M15S mortar exhibited lower porosity compared to the reference mortar. Additionally, the incorporation of calcined sediments and limestone (MS15L) as a partial replacement for Portland cement led to a 5.58% reduction in water-accessible porosity after 28 days, compared to the reference mortar. These results are consistent with the findings of [41]. Analyzing the results of the studied mortars, it can be concluded that mortars containing ternary mineral additives show a decrease in water-accessible porosity compared to the reference mortar. Furthermore, the presence of pozzolanic or hydraulic additives contributes to a long-term reduction in porosity.

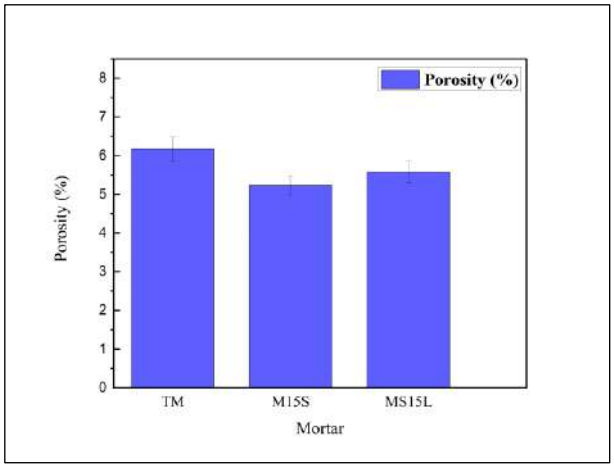

Figure 10: Accessible water porosities.
Source: Authors, (2026).

IV. CONCLUSIONS

The objective of this study is to evaluate the effectiveness of using calcined sediments and limestone fillers as substitutes for cement in mortars. Various tests were conducted on fresh and hardened samples, with a focus on durability. The main conclusions of the experiments are as follows:

- A potential solution to address the siltation of dams is to replace cement with fine materials such as calcined sediments and limestone fillers.
- X-ray diffraction (XRD) analysis highlights the importance of thermal treatment of sediments, as it transforms kaolinite into metakaolinite, promoting the desired pozzolanic behavior.
- The incorporation of limestone fillers in mortar formulations has shown a positive impact on compressive strength.
- Over a 180-day, the compressive strength of different types of mortars, composed of calcined sediments and limestone fillers, showed a consistent increase.
- The reuse of sediments from the Chorfa II dam effectively reduces greenhouse gas emissions and natural resource consumption.
- The dredged sediment and limestone filler have demonstrated good short-term durability.

The reduced carbon footprint of calcined sediments and limestone is one of their key environmental benefits. When compared to the conventional cement production process, the synthesis of these materials can cut carbon emissions by as much as 40%, as shown by Malacarne et al. [42].

- The incorporation of calcined sediments and limestone fillers as alternatives to conventional clinker in the manufacturing process allows for this reduction.
- Calcined sediments and limestone filler have a lower carbon intensity than clinker, this helps in the fight against climate change by reducing the quantity of carbon dioxide discharged into the atmosphere.

PERSPECTIVES

More investigation is required to assess the long-term durability and resistance of mortar or concrete containing cementitious materials, such as calcined sediments and limestone filler, to environmental factors like chemical attacks, alkali-silica reactions, and freeze-thaw cycles. Full life cycle studies comparing cement with additives, like calcined sediments and limestone fillers, to traditional cement are necessary to obtain a more precise understanding of the environmental benefits of cement during the construction process.

ABSTRACT

Aquaculture contributes greatly to the overall fish production, but old methods of monitoring water quality prove ineffective and continue to allow high fish mortality and low productivity. This paper presents a Real-Time Artificial Internet of Things (AIoT) Monitoring System for continuous monitoring of critical water parameters in aquaculture that would enhance management parameters such as temperature, turbidity, dissolved oxygen (O_2), pH, CO_2 and water levels. The system represents the integration of many sensors with an ESP8266 microcontroller which transmits data to a cloud-based platform that can be accessed by a mobile application. Machine learning techniques such as Decision Trees, Support Vector Machines, and Logistic Regression will be used to optimize the activation of the used actuators (oxygen generators, feeders, water pumps, and heaters) based on real-time detected measurements from sensors. Experimental results prove that it works; steady monitoring and precise prediction of best water conditions correspond to what is theoretically expected. The AI-powered decision-making framework that curtails energy usage and feed wastage plus guarantees a prompt reaction to changes in the environment renders this a smart aquaculture solution: scalable and cost-effective for modern fish farming while fostering enhanced productivity and sustainability for the aquaculture sector.

I. INTRODUCTION

In the realm of aquaculture, the preservation of water quality is paramount for sustaining the health and productivity of aquatic organisms throughout their growth cycle [1]. Nevertheless, the existing monitoring techniques in Algeria prove to be largely ineffective, as many farmers depend on traditional methods that demand extensive time, resources, and effort to mitigate aquatic mortality rates [2]. The absence of sophisticated technological instruments for real-time surveillance and informed decision-making only intensifies these difficulties. Despite these setbacks, the aquaculture industry accounts for over 20% of Algeria's overall fish production, underlining its crucial significance. Acknowledging this reality, the Ministry of Fisheries and Fish Production has recently initiated actions aimed at enhancing the sector by dismantling barriers for 105 aquaculture projects and granting concessions to investors interested in establishing or expanding their enterprises. Furthermore, tax benefits have been implemented to stimulate growth in both fishing and aquaculture activities [3], [4]. In order to obtain optimal aquaculture yields, it is crucial to continuously monitor water quality, aquatic health, and feed management in real-time. Conventional methods, that allows farmers to manually assess various parameters, not only prove to be unreliable but also pose risks to safety and hygiene [5-9]. In response to these issues, the present study presented in this paper introduces an innovative solution: an Artificial Intelligent Wireless Internet of Things (AIoT)-based system designed for the remote monitoring of aquaculture. This system seamlessly integrates smart technology to automate the monitoring process, particularly focusing on small and medium-scale fisheries. The main aim is to create a comprehensive AIoT framework for real-time water quality assessment, paired with a mobile application that offers farmers immediate access to essential data. Furthermore, the system is designed to investigate the optimal habitat conditions for freshwater shrimp, enhancing aquaculture practices significantly.

The proposed system uses several kind of components, including the ESP8266 microcontroller, humidity sensors, water-proof temperature sensors, pH sensors, dissolved oxygen sensors, carbon dioxide (CO2) sensors, turbidity sensors, water level sensors, and actuators. The devices are mounted to measure and transmit data to a cloud-based platform via a wireless internet connection. The information is appeared to farmers using a mobile app, enabling them to monitor water status in real-time and make informed decisions. The system also used an AI model for optimizing the function of actuators, such as water pumps, heaters, oxygen machines, and feeders. This allows the system to either notify farmers to manually adjust water quality or automatically swap devices to optimize water conditions in the fish. Besides, the system uses weather forecasting data to predict water quality variations caused by external factors like rainfall or temperature fluctuation. This feature provides early warnings to farmers that can implement counteractive measures in advance before issues arise. This integration prevents wastage of feed, reduces energy consumption, and offers optimal water quality, offering a wise, responsive, and budget-friendly solution for aquaculture management in current times. The paper is structured in the following order: firstly, we identify the importance of aquaculture in Algeria in the introduction; secondly, we briefly examine studies in aquaculture; thirdly, we describe the proposed solution and utilized materials; fourthly, we discuss findings; and finally, we summarize with lessons and directions for future studies. This breakthrough system is a significant advancement in addressing aquaculture management issues through AIoT and real-time data for enhancing productivity and sustainability in the sector.

II.RELATED WORKS

Fish farmers have traditionally relied on manual methods to monitor water quality in fish ponds, which are often time-consuming and prone to errors. To address these challenges, researchers have developed various technological solutions to automate and enhance the monitoring process. This section discusses the advancements in this field, including recent works that leverage new technologies such as AI and IoT for improving decision and predictive capabilities. The researchers in [10] proposed an automated system to reduce costs and increase yield in fish farming. The system included sensors for temperature and pH monitoring, a feeding mechanism, and CCTV cameras for surveillance. It also utilized SMS services for communication and status updates. Similarly, [11] developed a GSM-based system to alert farmers about deteriorating water quality by monitoring temperature, pH, and dissolved oxygen levels. The system comprised input, evaluation, communication, and output modules. A system developed by [12] utilized the LoRaWAN protocol for wireless communication for long distances, thus perfectly suited for remote fish ponds. It monitored water level and temperature, contained an RTC module for lighting control, and used a buzzer for threshold notification. In [13], a real-time water quality monitoring model was proposed, which utilized IoT and smartphones to gather sensor data. It was useful for farmers to obtain water quality data from distant locations. Similarly, [14] proposed an IoT-based monitoring system for physico-chemical parameters in Pangasius fish farming in the Mekong Delta. Another IoT-based system in [15] used the pH and salinity sensors module and a web-based monitor module for controling and data visualization. The system in [16] is an aquaculture of shrimp, monitoring parameters like pH, temperature, and dissolved oxygen (DO). It focused on efficient monitoring and control of environmental parameters for the best growth of shrimp. In [17], a Raspberry Pi-based system, sensors, a USB camera, and OpenCV were suggested for water quality monitoring.

Temperature, turbidity, TDS, and color were tracked as parameters. While the system offered remote monitoring via an Android app, it lacked a module for taking corrective action on identifying anomalies. Authors in [18] presented a machine learning (ML)-based framework that predicts water quality parameters such as dissolved oxygen, pH, and temperature from historical data. The framework employed a Random Forest algorithm to provide early warnings and recommendations for rectification. Similarly, in [19] authors developed an AI based Internet of Things system that itegrates neural networks to predict algal blooms, which are harmful to fish health. Authors in [20] integrated computer vision and AI to monitor fish behavior as an indicator of water quality. The system used convolutional neural networks to analyze video streams sent from underwater sensors to detect abnormal movement of fish that would signal poor water conditions. The study in [21] introduced an edge AI-driven system for real-time water quality monitoring. The system employed light weight ML models on edge devices to analyse sensor data locally, avoiding latency and cloud computing reliance. The system also provided an actionable insights to farmers via a mobile app. In [22], a hybrid AI-IoT system was suggested for aquaculture monitoring. The system integrated IoT sensors for data acquisition with AI algorithms for anomaly detection and predicting maintenance. the system provides a feedback mechanism to automate the corrective actions, such as water pH adjustment and aerator activation. A new paradigm in [23] integrated block chain technology with AI and IoT to offer data integrity and transparency for water quality monitoring. The system employed smart contracts to automatically validate data and provide a tamper proof history of water quality parameters.

Table 1: Related works comparison.

Ref	Components	Communication Method	Monitoring Aspects	Limitations
[10]	Sensors, CCTV, SMS	SMS	Temperature, pH, water level	Limited to basic parameters
[11]	GSM module, sensors	GSM	Temperature, pH, dissolved oxygen	No corrective action module
[12]	LoRaWAN, RTC, buzzer	LoRaWAN	Water level, temperature	Limited to specific parameters
[13]	IoT sensors, smartphone	IoT	Real-time water quality	Dependent on smartphone availability
[14]	IoT-based system	IoT	Physico-chemical variables	Region-specific (Mekong Delta)
[15]	Sensor module, web-based monitoring	IoT	pH, salinity	Limited control functionality

[16]	Sensors, control module	IoT	pH, temperature, DO	Focused on shrimp farming
[17]	Raspberry Pi, OpenCV, sensors	Wi-Fi/Internet	Temperature, turbidity, TDS, color	No corrective action module
[18]	ML algorithms, IoT sensors	IoT	Predictive monitoring (DO, pH, etc.)	Requires historical data for training
[19]	Neural networks, IoT sensors	IoT	Algal bloom prediction	High computational cost
[20]	CNNs, underwater cameras	Wi-Fi	Fish behavior analysis	Limited to visual indicators
[21]	Edge AI, IoT sensors	Edge computing	Real-time monitoring	Limited to lightweight models
[22]	AI-IoT hybrid system	IoT	Anomaly detection, predictive actions	Complex implementation
[23]	Blockchain, AI, IoT	Blockchain	Data integrity, transparency	High infrastructure cost

Source: Authors, (2026).

In addressing the limitations of existing IoT-based fishpond monitoring systems as illustrated in Table 1, we are trying in our project to focus on providing comprehensive training programs for fish farmers to enhance their technical skills, emphasizing the use of renewable energy sources, and implementing cost-effective solutions to enhance sustainability and affordability [24], [25]. Our proposed system optimizes data collection processes, integrates automation features, and ensures scalability based on modular design approaches to increase system efficiency and adaptability for different fish farming environments. Our developed system monitors various parameters, optimizes the activation of actuators, and offers a user interface for the easy manipulation by farmers, making the system suitable for implementation in different ponds and for several types of fish [26].

III. PROPOSED SYSTEM

This section contains three subsections which are the introduction of required hardware and software technologies used in the proposed system, description of the functionality of the system architecture and its flowchart in order to display the steps and procedures of the system.

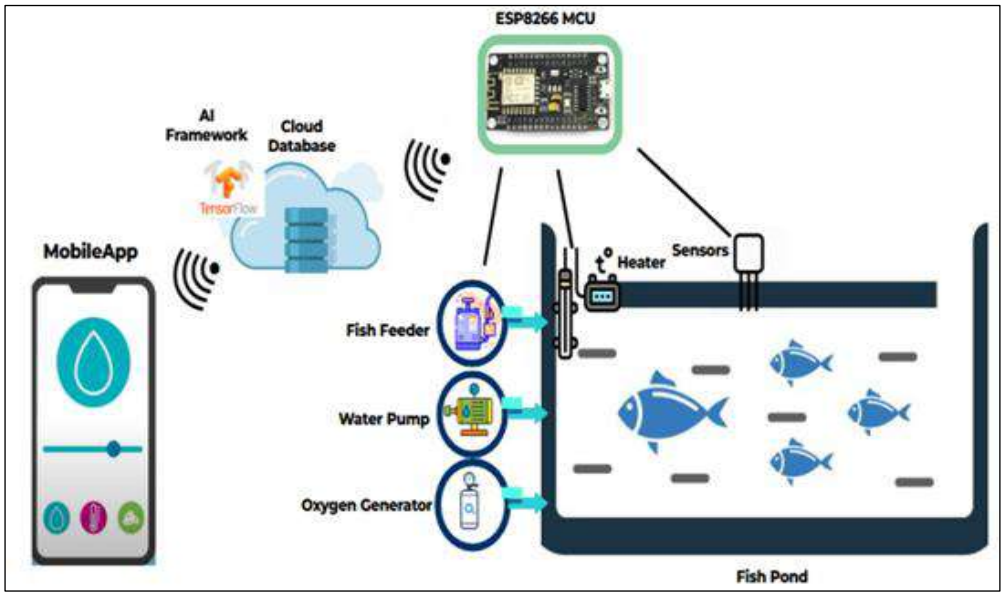

Figure 1: The general scheme of our monitoring system.
Source: Authors, (2026).

This circuit diagram, Fig. 1, shows how the different parts of our water quality monitoring system for a fish farming pond are connected. The system includes: the fish basin where the fish are raised; a set of sensors placed in the water to measure important water quality parameters like temperature, pH, dissolved oxygen, carbon dioxide (CO2), and turbidity, water level; and a controller (ESP8266) that collects data from the sensors. This data is sent to a mobile app (smartphone) passing by the cloud data base where farmers can see the water conditions in real time. This system contains an AI approach in order to take the optimal decision and optimize the functionalities of actuators (Water pump, Heater ,O2 Generator, and the feeder) the system can either let the farmer know to adjust the water quality manually or automatically turn on devices to keep the water in the best condition for the fish. Additionally, weather forecasting data is integrated to predict changes in water quality caused by factors like rain and temperature changes that allows farmers for early warnings in order take action before problems arise. These features can make the system smarter, more adaptive, and more efficient for modern aquaculture management.

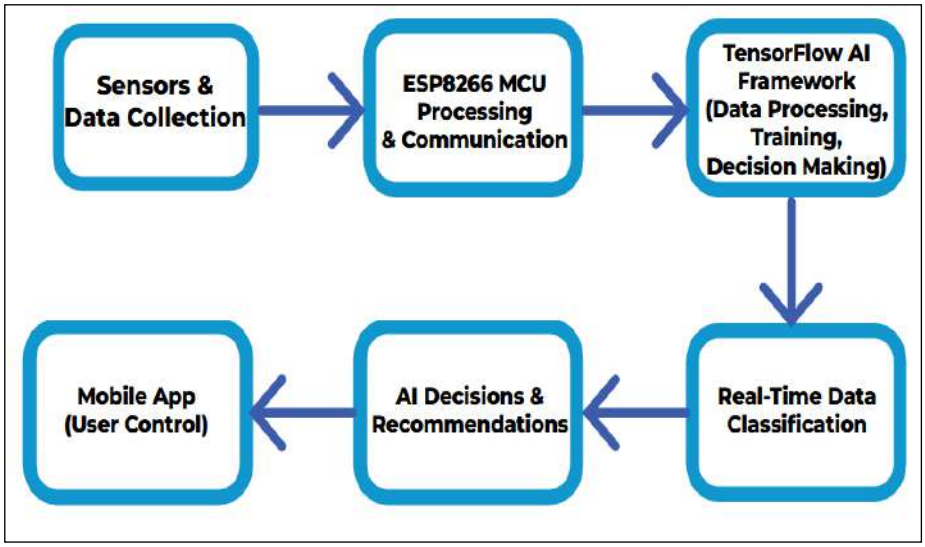

Figure 2: Proposed Flowchart for our fish pond water quality monitoring application.
Source: Authors, (2026).

As shown in Fig. 2, once the data is collected from the sensors such as O_2 levels, water level, turbidity, CO_2, temperature, etc., it is stored in Firebase which is a cloud-hosted NoSQL database server, for processing and analysis. In the cloud based environment, The data undergoes rigorous pre-processing to ensure an optimal quality and relevance of data, a crucial step given the significance of smart aquaculture monitoring systems. The initial phase allows treating missing values, occurred often due of intermittent connectivity or sensor malfunctions. To achieve uniformity in the disparate measurements, data such as temperature, O_2 levels, and turbidity are standardized using Min-Max scaling based on Eq. (1) illustrated bellow used in the Data Preprocessing to justify the scaling of sensor inputs before feeding them into machine learning models [26-28] . Further, categorical variables, like water quality categories or species types, undergo a transformation process called one-hot encoding, making them digestible for machines without implying any ordinal significance. A pivotal step in the preprocessing journey is to divide data into training and test subsets. This division is important to avoid over fitting, a situation where a model can excel on its training data which can fail to classify the unfamiliar data. By training the model on one subset and testing it on an unseen one, a more realistic gauge of the model's performance in real-world aquaculture scenarios is achieved.

Min-Max scaling equation

$$x' = \frac{x - x_{min}}{x_{max} - x_{min}} \quad (1)$$

Where:

x' is the normalized value
x is the raw sensor reading
x_{max} x_{min} are the minimum and the maximum values for that parameter.

Once the data is preprocessed, it is utilized to train the machine learning model using Tensor Flow which is a powerful machine learning framework hosted in the cloud. The tested data used also for model evaluation. The cloud platform also hosts an API for users to access into the functionalities of the system. It saves and manages the system's data in Firebase by ensuring scalability, reliability, and security. Additionally, it can enable integration with other services and applications such as the weather API which provides future weather parameters such as temperature, humidity, wind speed, and precipitation forecasts. These weather insights which are displayed finally in the mobile app allow the farmer taking proactive measures, such as adjusting the site to provide more water and feed in anticipation of adverse weather conditions, ensuring the safety and optimal growth of aquatic life. The cloud platform is a centralized hub for data processing, analysis, and decision making in the smart aquaculture monitoring system. Once the collected sensor data passed by a general analysis process, the system applies machine learning techniques to ensure accurate and efficient monitoring and control decisions. A labeled dataset is then prepared, containing sensor data and corresponding actuator actions such as feeder activation, O_2 generator control, heater adjustment, or water pump operation in order to provide valuable information to know when to activate or deactivate these devices based on sensor readings. The machine learning model, built using TensorFlow, is trained to capture the intricate relationships between sensor readings (e.g., O_2 levels, water temperature, turbidity), weather parameters, and actuator requirements. Sophisticated machine learning algorithms such as decision trees (DT), support vector machines (SVM), or logistic regression (LR) are employed for this purpose. Once the model is trained is then deployed in the cloud platform to enable real time communication for predicting optimal actuator actions based on the learned patterns and relationships. This intelligent decision making system improves resource efficiency, ensures the optimal environmental conditions for aquatic life, and empowers the aqua culturists with precise and real time monitoring and control strategies, even in the face of changing weather conditions .

IV. RESULTS AND DISCUSSIONS

Once we completed the calibration of our sensor, and all the sensors are properly connected to the controller (MCU esp8266), as illustrated in Figure 3 which is the prototype of the system; we initiated the phase of detecting the measurements of the water quality of the basin. The results of this phase are illustrated in Figure 4; this later presents the detected measurements database stored in Firebase.

Figure 3: Installation of Sensors in the pool.
Source: Authors, (2026).

Figure 4: Firebase collected information.
Source: Authors, (2026).

In our application, notifications are generated to inform the user in the following cases: when the water quality does not meet the standard norms for normal fish life, during the automatic activation of pumps or oxygen filter, and in case of any problem detected in the basin. These notifications will be displayed on the farmer's smartphone using a mobile application that we have developed, as illustrated in the Fig. 5.

Figure 5: Our mobile application with the set of notifications.
Source: Authors, (2026).

The dataset used in our system includes nine attributes as illustrated in the Table 2 which are O_2 levels, water level, turbidity, CO_2 levels, temperature, feeder activation, heater activation, O_2 generator activation, and water pump activation. all these attributes form the foundation of the dataset used in the smart aquaculture system. after analyzing and making the decisions based on the used data, the system can activate the actuators such as the feeder activation, the O_2 generator control, the heater adjustment, and water pump operation and this ensures optimal conditions for aquatic life, conserves resources and enhances productivity. To maximize the range of measurements and improve the dataset's robustness, we combined two publicly available datasets: IoT Dataset on Water Quality and Tilapia Health in Colombian Aquaculture Ponds and A Simple Dataset of Water Quality in Aquaponic Fish Ponds Based on IoT the both of them is downloaded from Kaggle referenced in [29], [30]. This step allows more comprehensive analysis and finnaly better decision making in the smart aquaculture system. To evaluate the performance of the smart aquaculture monitoring system, the dataset was divided into two subsets: one for training and the other for testing. 80% of the data which is approximately 98,135 samples were used for the training step of the machine learning algorithms, while the remaining 20% that represents approximately 24,534 samples were used for the testing and validation step. This step ensures that the model is trained on the adequate amount of data while maintaining an independent test set to evaluate the generalization capabilities. For the classification tasks the used dataset was more treated to ensure the balanced representation of different classes such as water quality categories and actuator activation states.

Table 2: The used dataset sample.

O_2 (mg/L)	**WL (cm)**	**Tby (NTU)**	**CO_2 (ppm)**	**Tem (°C)**	**Feeder Activation (0/1)**	**Heater Activation (0/1)**	**O_2 Generator Activation (0/1)**	**Water Pump Activation (0/1)**
6.2	120.5	15.3	12.4	24.5	1	0	0	0
5.8	118.7	18.7	14.2	23.8	1	0	0	0

Source: [29], [30].

O_2 Levels; represents the dissolved oxygen levels in the water it's in milligrams per liter (mg/L).

Water Level: indicates the level of water in the pond which is measured in centimeters.

Turbidity: Turbidity measures the clarity of the water in order to indicate the presence of suspended particles.

CO_2 Levels: measures the concentration of carbon dioxide inside the water pond and expressed in parts per million (ppm).

Temperature: Temperature refers to the water temperature and measured in degrees Celsius or Fahrenheit.

Feeder Activation: This attribute indicates whether the feeder is activated or not and include details about the amount or timing of feed dispensed represented in binary value.

Heater Activation: This attribute indicates whether the heater was activated and may include details about the duration or intensity of heating represented in binary value.

O_2 Generator Activation: This attribute indicates whether the O_2 generator is activated or not and include details about the duration or intensity of the oxygen generation and represented in binary value.

Water Pump Activation: This attribute indicates whether the water pump is activated or not and may include details about the duration or flow rate of water circulation and represented in binary value.

After implementing the intelligent actuator control mechanism in our system it can effectively optimizes water quality conditions in real time. The AI-driven approach ensures that critical parameters are continuously monitored and adjusted as needed, in this part we present some key relationship points that the system based on to take the optimal decisions;

1. Feeder Activation
- Temporarily activated every 2 hours unless turbidity is high.
- If turbidity > 20 NTU, feeder is deactivated 0 until water pond is clean.

2. Water Pump Activation
- Activated 1 if turbidity is greater than 20 NTU or water level is less than 115 cm.

3. O_2 Generator Activation:
- Activated 1 if O_2 levels is less than 5 mg/L.

4. Heater Activation:
- Activated 1 if temperature is less than 22°C.

When comparing the performance of decision trees (DT), logistic regression (LR), and support vector machines (SVM) for the aquaculture system, their performance was evaluated based on accuracy, precision, recall, and F1 score. The experimental evaluation method used was the confusion matrix, as shown in table 3 for the decision tree classifier. The evaluation metrics were computed from the confusion matrix.

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \quad (2)$$

$$\text{Precision} = \frac{\text{TP}}{\text{TP+FP}} \tag{3}$$

$$\text{Recall} = \frac{\text{TP}}{\text{TP+FN}} \tag{4}$$

$$F1 = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision+Recall}} \tag{5}$$

Where:

TP (True Positive): Correctly classified positive cases.
TN (True Negative): Correctly classified negative cases.
FP (False Positive): Incorrectly classified negative cases.
FN (False Negative): Incorrectly classified positive cases.

Table 3: Confusion Matrix of DT in Water Pump Activation.

	Predicted: No Water Pump Activation	**Predicted: Water Pump Activation**
True: No Water Pump Activation	TN = 72	FP = 4
True: Water Pump Activation	FN = 9	TP = 41

Source: Authors, (2026).

Table 4: Summarizes the performance measures of the different classification models.

ML Model	**Accuracy**	**Precision**	**Recall**	**F1 Score**
LR	0.8514	0.9189	0.7391	0.8192
DT	0.8968	0.9111	0.82	0.8631
SVM	0.8415	0.8571	0.7317	0.7894

Source: Authors, (2026).

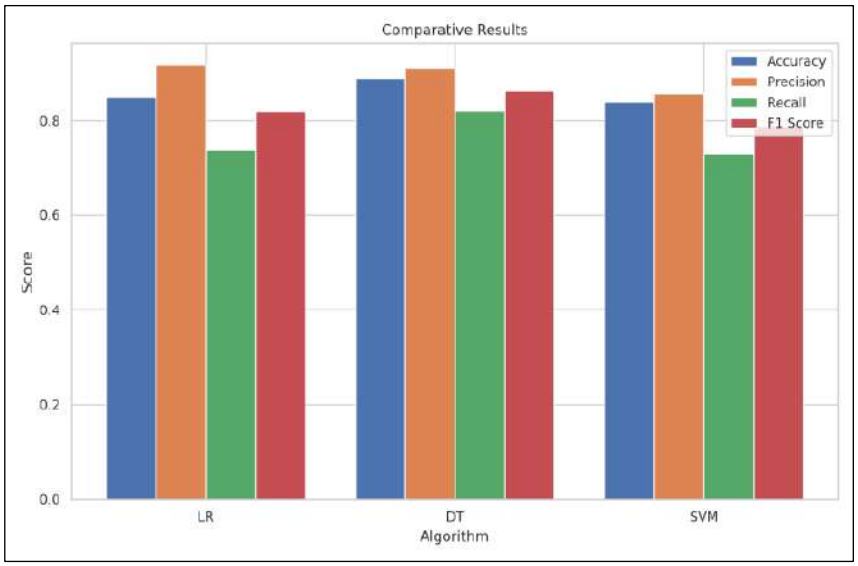

Figure 6: Comparative results of the used Algorithms.
Source: Authors, (2026).

Basing on the comparison illustrated in the Fig. 6 and Table 4 , the decision tree model shows a better performance by achieving high accuracy, precision, recall, and F1 score calculated by Eq. (2,3,4 and 5) , as shown in Figure 3. In the development of our smart aquaculture system using IoT and machine learning techniques, the decision tree classifier played an important role in decision-making processes by achieving the highest performance. in this work various training parameters can be adjusted to refine the performance of decision trees for that we relied on the default parameters to guarantee consistency and replicability specifically the criterion for the quality of a split is set to "gini" which is a measure used to measure the impurity of the data illustrated in Eq. (6), the maximum depth of the tree was left undefined (allowing the tree to expand until all leaves are pure), the minimum samples split is set to 2 and the minimum samples leaf is set to 1. By employing these default values the foundational benchmark for the system's performance is established, which can serve as a reference point for future iterations and optimizations.

$$\text{Gini} = 1 - \sum_{i=1}^{n} {p_i}^2 \tag{6}$$

Where:

pi is the probability of class ii at a given node.
n is the number of classes.

Among the three used models, decision trees has shown a better performance than SVM and logistic regression due to their ability to manipulate non linear relationships in the used water quality data by providing clear decision rules and interpretable feature importance scores unlike SVM, which is functioning as a black box. decision trees provide an obvious transparency in decision making steps such as activating the O_2 generator when oxygen levels is under below 5 mg/L. Additionally, DT is more efficient than SVM in term of computation which requires complex kernel optimization. Logistic Regression struggled with the multi class nature of actuator activation while DT managed it with an effective way. Furthermore, DT achieved a higher recall (82%), making it more reliable in detecting critical water conditions and reducing fish mortality, whereas SVM had difficulties generalizing due to imbalanced data.

Table 5: Summarizes the water quality improvements before and after implementing the AI based IoT system.

Parameter	Before AI IoT System	After AI IoT System	Recommended Range
Temperature (°C)	27 - 34	29 - 31	20 - 35
pH Level	5.8 - 7.2	6.5 - 8.0	6.5 - 9.0
Dissolved O_2 (mg/L)	2.5 - 4.0	4.2 - 5.5	3.0 - 5.0
CO_2 Levels (ppm)	>15	<10	<10
Turbidity (NTU)	>50	20 - 30	30 - 80

Source: Authors, (2026).

Table 5 shows key water quality parameters such as Temperature (°C), pH Level, Dissolved Oxygen (mg/L), CO_2 Levels (ppm), and Turbidity (NTU) prior to and after implementing our AIoT system and their recommended ranges. The findings obtained affirm significant improvements here we can see that temperature stabilizes in a narrower range (29°C to 31°C), stabilizes pH levels at a better range (6.5 to 8.0), and raises dissolved oxygen levels significantly (4.2 mg/L to 5.5 mg/L). Furthermore, CO_2 levels were reduced to less than 10 ppm, at the recommended level, with turbidity reducing to 20–30 NTU, well below the best optimal range. These results show the effectiveness of the proposed AIoT system which uses real time monitoring, advanced analytics, and automated control systems to optimize water quality. Through solving issues such as low oxygen levels, elevated levels of CO_2, and unstable pH and temperature, the system ensures compliance with recommended standards while fostering a more sustainable and healthier aquatic ecosystem, exemplifying the paradigmatic transformative potential of AIoT technologies for environmental control.

V. CONCLUSIONS

In this paper, a sophisticated AIoT-based real-time aquaculture monitoring system is proposed that overcomes the limitations of the current water quality monitoring systems. With the use of a mixture of several sensors, an ESP8266 microcontroller, a cloud-based system, and machine learning algorithms, the system effectively monitors the key parameters such as temperature, turbidity, dissolved oxygen, pH, CO_2 level, and water level. The use of AI-based decision-making optimizes the driving of actuators, reducing power usage, eliminating waste in feed, and allowing proactive reactions to environmental variations. The results obtained in the experimental part demonstrate the efficiency of our system suggested with a view to ensuring water quality stability, in particular high oxygen levels, pH constancy, and CO_2 level. Compared to other solutions, the advantages of our solution are real-time automatic monitoring, predictive analytics based on AI, as well as simplicity of access through mobile devices. Among the compared machine learning models, Decision Tree classifier is the most accurate in order to optimize actuator operation. In addition, the integration of weather forecasting information with the system's capabilities helps to predict earlier and give timely notifications to the farmers. In the future works and in order to enhance the proposed system by introducing more advanced AI models such as deep learning for improved predictive analytics and anomaly detection. We can also thinking to add a system for observing fish behavior with computer vision methods to enhance decision making.

Halal Chain Design
Halal Certification Design
Halal Value Chain
Tapioca
Mocaf

ABSTRACT

Demand for tapioca and mocaf as a strategic substitute for imported wheat flour in Indonesia now requires supply chains that are not only efficient but also protected from any haram or najis contamination, in line with national halal policies for food products. The study conducts a systematic literature review to trace the evolution of research, theoretical lenses, indicators, and variables used to design halal supply and value chains. Its significance lies in a novel methodological integrated of PRISMA protocol, R-Studio bibliometric analysis, and integrated VIKOR with elbow based on clustering within a PICOS to identify the most influential contributions paper. The results screening used PRISMA identified 291 papers, retaining 76 eligible papers. VIKOR simulations used k = 2 and k = 3 structures with a weighting coefficient of 0.5, producing 9 core publications at elbow points with values of 0.04 and 0.06. Gap analysis focused interpretation of the dendrogram isolated three challenge papers on halal certification and supply chain. The state-of-the-art assessment positioned this work at the intersection of halal chain governance and value chain perspectives, employing validated multi-criteria decision-making with Soft System Dynamics Methodology to enhance halal chain design for tapioca and mocaf agro-industry.

I. INTRODUCTION

Positioning halal goods as symbols of quality, safety, and ethical responsibility in modern food systems. In this context, managing supply chains and value chains that comply with sharia principles becomes essential, with every stage from the downstream process for raw procurement of raw material to final consumption required to avoid any contamination by haram or najis elements and to comply with certification of halal regulations and transparent traceability requirements, including in Indonesia. Indonesia possesses significant prospects to position itself as a leading player in the global halal industry, robust agricultural sector, and proactive government policies that foster the expansion of halal-focused industries. Within this landscape, cassava-based agro-industries, particularly tapioca flour and modified cassava flour (MOCAF), constitute a strategic commodity group because these ingredients serve as essential inputs in a wide range of food and processed products, making effective supply chain and value chain management crucial for enhancing performance so that competitiveness in international markets can be strengthened [1]. The management of raw material supply availability must therefore be aligned with value-adding efforts, including obtaining halal certification, to secure consumer acceptance in predominantly Muslim markets [2]. Strengthening halal supply chain practices in this subsector still faces multiple obstacles, including limited capabilities of business actors, inconsistent product quality, and uneven application of halal standards and enabling technologies across different supply chains. Ensuring traceability throughout the supply chain is crucial so that consumer-demanded products remain consistently available while fully adhering to halal requirements [3]. Supply chain management, therefore, plays a central role in supervising inbound logistics, identifying critical points in product distribution, and maintaining halal integrity throughout the network [4]. The tapioca and mocaf supply chains feature extensive, dispersed actor networks encompassing cassava farmers, collectors, processing units, distributors, and end-user industries.

This complexity presents distinct challenges for quality control and halal compliance due to variabilities in post-harvest handling practices and logistical facilities, which can significantly affect the consistency of the final product. The pressing need to implement sustainability principles and efficiency promotes the design of a halal product system that concurrently addresses economic, social, and environmental dimensions to enhance traceability and product flow visibility. Conceptually, the discourse surrounding halal supply chains and halal value chains is evolving towards an approach that emphasizes not merely normative compliance but also the integration of halal integrity with value creation, performance, and competitive advantages. Many prior investigations in the halal domain had emphasized issues related to integrity, risk exposure, operational performance, and sustainability outcomes. Sustainable management of supply chains requires distribution strategies that jointly account for technical performance, environmental impact, and economic viability, thereby reinforcing the need for an integrated halal supply and value chain design [5]. Potential halal concerns in tapioca production processes, particularly in West Java, include the risk of contamination from additives and from production methods. As mandated by SNI No. 3451 of 2011, the permissible limit for Escherichia coli (E. coli) in tapioca flour is 10. This stipulation underscores the likelihood of E. coli contamination occurring during the production of coarse tapioca. E. coli can survive in the gastrointestinal tracts of both humans and animals and can persist in the environment through fecal matter. Furthermore, there exists a risk of contamination from chicken feces, primarily due to the practice of drying tapioca in open-air environments without sufficient oversight. A targeted SLR on the design of halal supply and value chains for the tapioca and mocaf agro-industry was urgently needed to offer a distinctive and innovative contribution to the research field. The novelty of this systematic literature review lies in its capacity to systematically trace and map the evolution of research on halal supply chains and halal value chains that are specifically relevant to the tapioca and mocaf agro-industry. The theoretical frameworks, analytical methods, indicators, and variables used in previous studies aimed at designing sustainable halal supply and value chains within the tapioca and mocaf sectors. The primary focus of this SLR is to uncover models for developing supply chains and value chains that are not only efficient and transparent but also adhere to halal principles and sustainability, and align with SDG 12, which emphasizes responsible production and consumption patterns.

II. THEORETICAL REFERENCE

The theoretical references in this section establish a rigorous methodological and conceptual foundation for the review by justifying the selection of databases, screening strategies, and synthesis techniques employed. In the systematic literature review on halal supply chain management, these theoretical references delineate and justify the methodological architecture including database selection, screening logic, and synthesis are as follows:

II.1 HALAL SUPPLY AND VALUE CHAIN FOUNDATIONS

Halal supply chain is the coordinated management of flows that must satisfy both sharia requirements and conventional performance, rather than with an added halal label [6] Recent reviews of halal supply chain research show that most contributions concentrate on compliance, logistics, risk, and sustainability, yet often treat these dimensions in isolation and do not fully connect them to mainstream supply chain theory [7]. A systematic review of halal purchasing along value chains reaches a similar conclusion, showing that halal concerns are frequently confined to procurement routines rather than embedded throughout end-to-end value processes [8]. Strengthening the halal value chain requires consistent assurance of halal compliance from raw material selection through production, logistics, and distribution, supported by robust halal assurance systems and reliable traceability technologies [9].

II.2 AGRO-INDUSTRIAL TAPIOCA AND MOCAF VALUE AND SUPPLY CHAIN

Analyses of cassava product supply chains report persistent weak linkages between upstream and downstream segments, logistical inefficiencies, and limited integration with higher value markets [10]. The development of tapioca and mocaf supply chains is crucial, as it transforms cassava from a primary commodity into a highly competitive input for food and non-food industries, thereby strengthening the incomes of farmers and downstream actors along the value chain [11]. Enhancing tapioca supply chain management from securing sufficient volume, quality, and continuity of raw material supply to mitigating supply chain risks represents a critical prerequisite for maintaining the viability of local starch [12].

II.3 SYSTEMS APPROACHES TO DEVELOPMENT AGRO-INDUSTRIAL TAPIOCA AND MOCAF SUPPLY CHAINS

Systems approaches provide a comprehensive theoretical foundation for analysing complexity of agro-industrial supply chains as integrated systems that link farmers, producer, distributors, and markets through flows of materials, information, and finance [13]. Holistic perspective enables the identification of coordination failures, structural bottlenecks, and leverage points where targeted interventions can increase effectivity, reduce losses, and enhance value added in cassava flour industries [10]. System approach is one of modelling tools are increasingly used to simulate how changes in raw material availability, farmer prices, technology adoption, and substitution policies influence long-term supply security and industrial growth [14]. Systems perspectives also emphasize the importance of aligning agro-industrial upgrading for tapioca and mocaf with broader objectives such as rural development, environmental sustainability, and national food security [15].

II.4 SYSTEMATIC REVIEW OF METHODOLOGICAL FOR THE HALAL SUPPLY CHAIN

Database identification constitutes a critical stage in a Systematic Literature Review, because strategically selecting a suitable combination of multidisciplinary and domain specific determines the completeness, quality, and representativeness of the evidence base the review's theoretical contributions [16]. Bibliometric analysis enables researchers to map publication trends, influential authors, thematic clusters, and methodological gaps in halal supply chain management studies inside the broader knowledge landscape [6].

Structuring data extraction and synthesis with the PICOS framework defining population or problem, interventions, comparisons, and Quantitative methods in the study selection stage are essential to ensure that only articles which genuinely address the identified research gaps and align with the core focus on halal supply chain [17].

III. MATERIALS AND METHODS

The development of the SLR involves five stages: paper planning, database selection, analysis and synthesis, and reporting. The SLR process used the PRISMA method and bibliometric analysis in R-Studio. Each stage was systematically structured to enhance transparency, replicability, and methodological rigor throughout the review are follows:

III.1 PLANNING PAPER

The planning paper was used to systematically map the formulation of research questions, establish screening criteria for selected papers, and develop a synthesis plan. This approach ensures that the literature review process proceeds consistently and transparently as follows:

III.1.1 Pilot Search

A rigorous pilot search was first conducted to refine the review protocol and align the search strategy with the overarching objectives of the study. The pilot search ensures that the research questions are clearly defined through a list of relevant keywords aimed at addressing the research problem across several databases, thus meeting the inclusion criteria [18].

III.1.2 Identification of Studies

Identifying relevant studies required keywords to reveal the dominant themes or con-ceptual foci in the literature that aligned with the underlying research problem. Keyword analysis was used to address the conditions of the research problem, enabling the bibliometric process to be conducted in line with the issues under investigation [19].

III.2 DATABASE IDENTIFICATION

The selection of databases in the context of SLR was conducted to identify relevant and high-quality literature sources for high-quality, pertinent literature [19]. The literature base could draw on documents catalogued in major international indexing platforms, particularly those listed in Scopus.

III.3 INCLUSION OR EXCLUSION FOR SELECTION PAPER CRITERIA

This step comprised screening and selecting studies that aligned with the core research objectives and questions, while the PRISMA framework served as a clear guide for formulating and applying explicit inclusion and exclusion rules [20]. The stages of the PRISMA protocol used to finalize the eligible articles covered defining inclusion and exclusion parameters, retrieving records from databases, choosing relevant studies, and conducting synthesis [18].

III.4 BIBLIOMETRIC AND QUANTITATIVE SYNTHESIS

The bibliometric evaluation was performed using a machine learning–oriented workflow in the R-Studio environment to detect research gaps and their related value chain configurations. This procedure is intended to uncover shortcomings in existing studies on the development of halal supply and value chain, with the analytical steps described in the subsequent stages:[21]

III.4.1 Factorial Analysis

Factorial analysis is a statistical technique for identifying data structure by grouping data based on observed correlation patterns. This method can be employed in systematic literature reviews (SLR) to determine novelty gaps across various topic clusters. Factorial analysis identifies latent dimensions within the data, facilitates dimensional reduction, and enhances interpretability, enabling key factors to serve as the primary focus in the clustering process [22].

III.4.2 Most Relevant Source

The most relevant sources are journals or conference proceedings that publish the most articles within a specific dataset. Typically expressed as publications per source, this metric enables researchers to gain insights into the literature in their area of study [18]. By identifying these sources, researchers can effectively navigate through the available literature and prioritize readings from outlets that contribute significantly to the field.

III.4.3 Trend Topic Analysis

Trend topic analysis examines how research topics or keywords evolve, enabling the identification of emerging themes within the literature. This analysis leverages keyword frequencies, which are then visualized in formats such as line graphs, heatmaps, or thematic maps [22] . These visual representations indicate when a particular topic begins to emerge. By using trend topic analysis, researchers can gain insights into emerging areas of interest and adapt their investigations to address contemporary issues in their field.

III.4.4 Thematic Map

A thematic map is a two-dimensional visualization that groups related research keywords into clusters, allowing topics to be observed as distinct thematic areas. In this representation, centrality expresses how strongly a theme is connected to other themes within the field, whereas density reflects how well developed and coherent that theme is internally [23].

III.4.5 Dendogram Analysis

Dendrogram analysis refers to the application of hierarchical clustering to group objects based on similarity. The resulting dendrogram displayed the hierarchical relationships among clustered items, enabling researchers to observe both resemblance and divergence among elements in the dataset [24].

III.5 VIKOR ANALYSIS

The VIKOR (Vlse Kriterijumska Optimizacija I Kompromisno Rešavanje) or Multi-Criteria Decision Making and Compromise Solution method can be employed following the key article selection phase, utilizing PageRank and citation metrics. The VIKOR analysis can be embedded in a systematic literature review as a post-screening synthesis tool, where studies identified through the SLR are treated as alternatives and evaluated against multiple methodological and contextual criteria, thereby producing a compromise ranking of the most representative evidence base for model development [25], [26].

$$A_j = \sum_{k=1}^{p} \alpha_i \frac{g_k^+ - g_{kj}}{g_k^+ - g_k^-} \quad (1)$$

$$B_j = \max_k \left[\alpha_k \frac{g_k^+ - g_{kj}}{g_k^+ - g_k^-} \right] \quad (2)$$

$$C_j = \lambda \frac{A_j - A^{\min}}{A^{\max} - A^{\min}} + (1-\lambda) \frac{B_j - B^{min}}{B^{max} - B^{min}} \quad (3)$$

where:

Aj: aggregated group utility for alternative j
Bj: maximum regret for alternative j
Cj: compromise index for alternative j
αk: weight of criterion k

III.6 ELBOW METHOD

The elbow technique was applied to select an appropriate number of clusters or to define the cutoff for core articles by charting the total within-cluster variation against the cluster count. At the bend of this curve, where further increases in cluster number produced only marginal decreases in dispersion, the optimal clustering solution was inferred [27]. At this point, any further increase in the number of clusters yields diminishing returns in terms of explained variance within the clusters [28].

III.7 PICOS

The structuring of this paper was grounded in the practical challenges encountered in In-donesia's halal supply and value chains for tapioca and mocaf agro-industry. The paper uses the Population, Intervention, Comparison, Outcomes, and Study Design (PICOS) to formu-late research questions and keywords to address them [29]

IV. RESULTS AND DISCUSSIONS

Issues related to halal-compliant products had emerged as a crucial determinant of effective supply chain. At the commodity level, tapioca and mocaf serve as strategic raw materials in the halal food industry, functioning as key components or substitutes for wheat flour in diverse products [30]. Research explicitly linking tapioca and mocaf to the concepts of SLR are as follows:

IV.1 PLANNING PAPER

Preliminary investigations indicate that the halal industry focused on flour and its derivatives is evolving rapidly, driven by increasing consumer and regulatory demands for guarantees of halal compliance, food safety, and sustainability. Multiple investigations on halal food, halal certification of flour-based products, and the evolving halal market indicate a transition from simply fulfilling normative to managing supply and value chains.

IV.1.1 Pilot Search

The agro-industrial commodities of tapioca and mocaf, the interconnections among halal food issues, halal certification mechanisms, halal demand dynamics, and the design of halal supply and value chains have not been comprehensively mapped. The Query of the Systematic Literature Review (SLR) can be seen in Table 1.

Table 1: Initial Keyword for Pilot Search.

Research Problem	Initial Keyword
1. Current handling of halal food has not adequately concentrated on flour-based products, including tapioca and mocaf, particularly concerning aspects of halal compliance, quality, and safety.	*"(TITLE ("Halal Food") OR TITLE ("Halal Certification" AND "Flour") OR TITLE ("Halal food" AND "Dynamic") OR TITLE ("Tapioca" AND "Mocaf" AND "Halal Supply Chain" OR "Halal Value Chain")) AND (EXCLUDE (SUBJAREA , "ENVI") OR EXCLUDE (SUBJAREA , "CHEM") OR EXCLUDE (SUBJAREA , "BIOC") OR EXCLUDE (SUBJAREA , "MEDI") OR EXCLUDE (SUBJAREA , "PHYS") OR EXCLUDE (SUBJAREA , "ENER") OR EXCLUDE (SUBJAREA , "VETE") OR EXCLUDE (SUBJAREA , "ARTS")) AND (LIMIT-TO (DOCTYPE , "ar") OR LIMIT-TO (DOCTYPE , "cp") OR LIMIT-TO (DOCTYPE , "re"))"*
2. The requirements for halal certification have not yet been incorporated into the design of halal supply chains or halal value chains in the tapioca and mocaf agro-industry.	
3. The evolving nature of halal food demand has not reflected in the way halal supply chains and value chains for tapioca and mocaf are designed.	
4. The existing halal management institutions lack a comprehensive model for maintaining halal certification of products within the tapioca and mocaf agro-industry supply chain.	

Source: Authors, (2026).

This query aims to capture relevant literature on halal certification, supply chains, and value chains in the context of tapioca and mocaf. It ensures a comprehensive search for studies that reflect current challenges and advancements in the halal agro-industry. Based on the keywords used to describe the Research Problem (RP), the following query will be utilized:

Based on the utilized query, a total of 291 papers were retrieved to identify the prevailing issues. An initial analysis of these 291 papers was then conducted through factorial analysis. The factorial map was created in RStudio to visualize keywords or terms from the articles along two principal axes resulting from dimensionality reduction. The proximity of points on the map indicates how frequently these words co-occur within the same documents, allowing clusters of nearby points to be interpreted as thematic clusters, as shown in Figure 1.

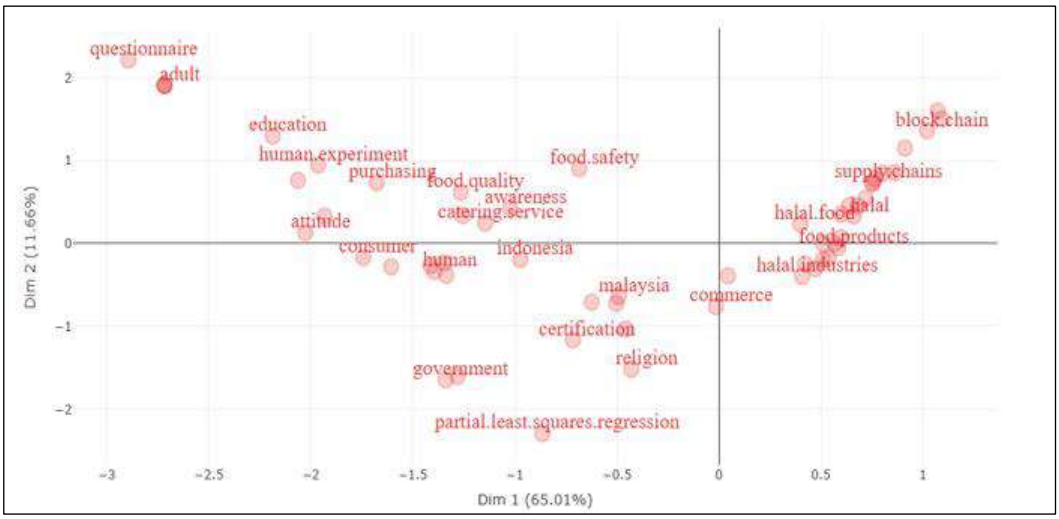

Figure 1: Factorial Analysis Word Map of Halal Food Related Keywords.
Source: Author, (2026).

Dimension 1 accounts for 65.01% of the variation, indicating that this axis captures a significant portion of the structural relationships among the keywords and yields a relatively representative clustering pattern. Dimension 2 contributes 11.66%, and when combined with Dimension 1, the explained variance totals around 76-77%. This level of explained variance is generally considered adequate for visual interpretation in factorial analysis or correspondence analysis.

IV.1.2 Identification of Studies Paper

The identification of studies in SLR begins by mapping the most relevant publication sources in the Scopus database using RStudio. This step aimed to pinpoint journals that served as primary outlets for studies on halal certification, and the configuration of halal supply and value chains. These identified sources will serve as a foundational reference for constructing a comprehensive SLR. The most relevant sources are shown in Figure 2.

Figure 2: Most Relevant Source.
Source: Author, (2026).

The cumulative trend line showed a marked surge in publications on halal supply or value chains beginning around 2015, with the Journal of Islamic Marketing recording the steepest growth in output compared with the British Food Journal, Food journals, Food Research, and the International Food Research Journal. This trend in productivity aligns with the patterns observed in trend topics, indicating that research focus has increasingly shifted toward issues surrounding food supply chains, halal food, and halal products in recent years. The research trend topics can be viewed in Figure 3.

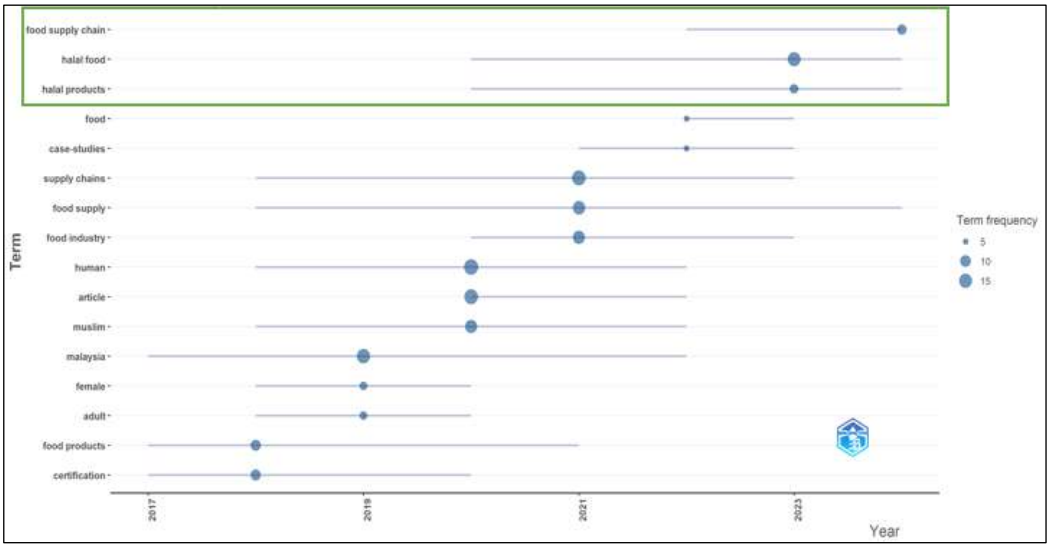

Figure 3: Trend Topic.
Source: Author, (2026).

The points and timelines on the graph reveal that the three terms have emerged more recently, yet with high frequency. This pattern reflected a rising scholarly interest in linking halal compliance with food supply chain management practices. Moreover, the overlap between these topics implied that detailed investigations of halal supply and value chain design in the tapioca and mocaf agro-industry were still at a relatively early stage of development.

IV.2 EXCLUSION CRITERIA

The exclusion of the 291 papers was carried out using five predefined screening parameters and documented through a PRISMA flow diagram. The screening criteria applied to the 291 sources comprised five parameters: duplicate records, cluster scores below 1, halal topics unrelated to food or linked to non-halal food supply chains, articles that did not address halal supply or value chain issues, and studies on halal food that omitted any discussion of supply or value chain aspects, as illustrated in Figure 4.

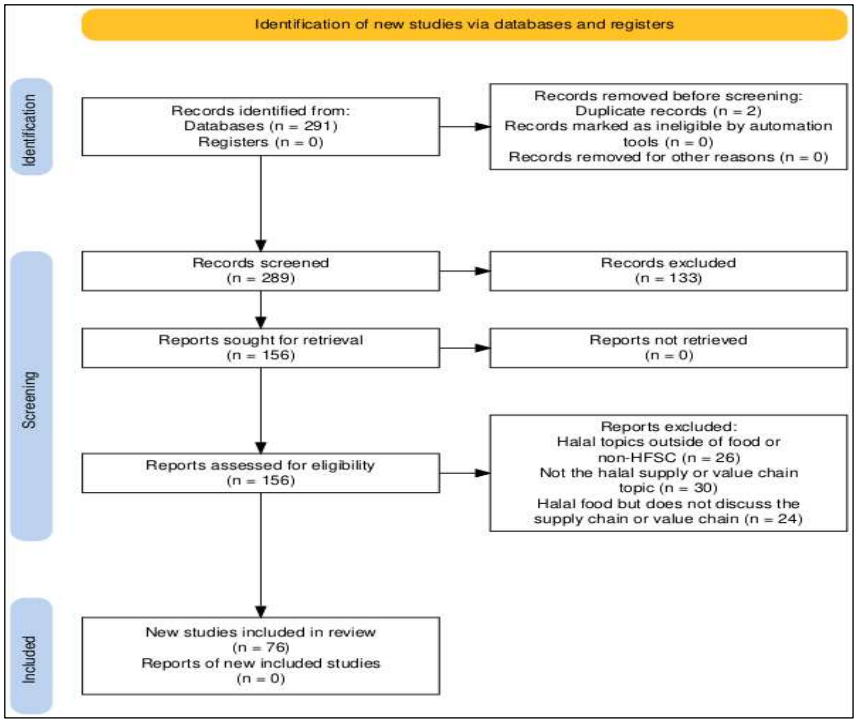

Figure 4: Screening exclusion source paper criteria used the PRISMA Diagram.
Source: Author, (2026).

The PRISMA flowchart depicts how articles were selected in line with PRISMA guidelines, beginning with 291 records retrieved from the database. The screening stage led to the removal of 2 duplicate records, 133 articles with a cluster value below 1, and a further 80 papers excluded according to three predefined categories.

IV.3 BIBLIOMETRIC AND QUANTITATIVE SYNTHESIS

IV.3.1 Bibliometric Analysis

A bibliometric analysis is employed to provide a comprehensive overview of research clusters related to halal food, flour-based halal certification, and halal supply and value chains pertinent to the tapioca and mocaf agro-industry. This bibliometric analysis aims to identify the most productive journal sources, track publication dynamics over time, and uncover patterns of emergence and development for key topics such as food supply chains, halal food, and halal products. The outcomes of the factorial analysis derived from the PRISMA were presented in Figure 5.

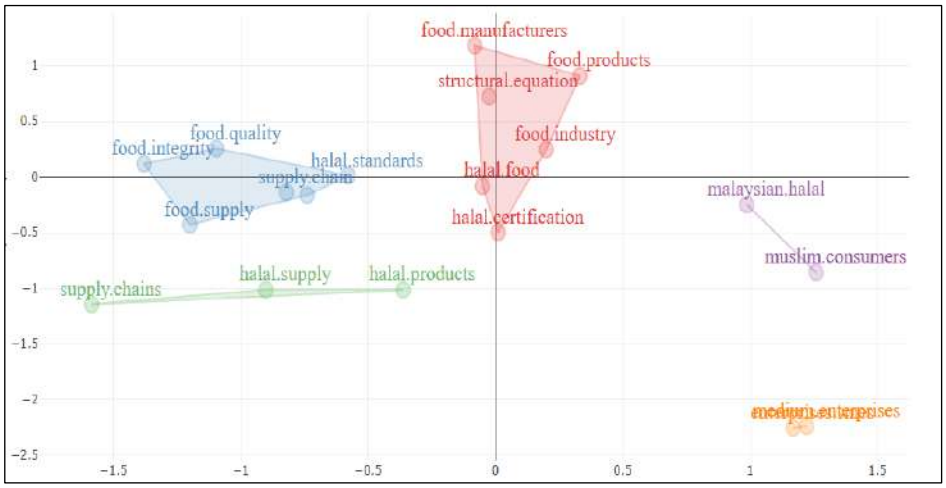

Figure 5: Factorial Analysis for 76 Papers SLR.
Source: Author, (2026).

The keyword cluster map reveals five principal research clusters. The first cluster concerns manufacturing and food industries, incorporating terminology such as food manufacturers, food products, halal food, and halal certification, while the second emphasizes the quality and integrity of food supply chains, including concepts like food quality, food integrity, and food supply. These clusters correspond to the SLR's objective of portraying how studies on halal food and halal certification have progressed toward the design of halal supply and value chains, with niche and motor themes appearing clearly in the factorial analysis and thematic maps in Figure 6.

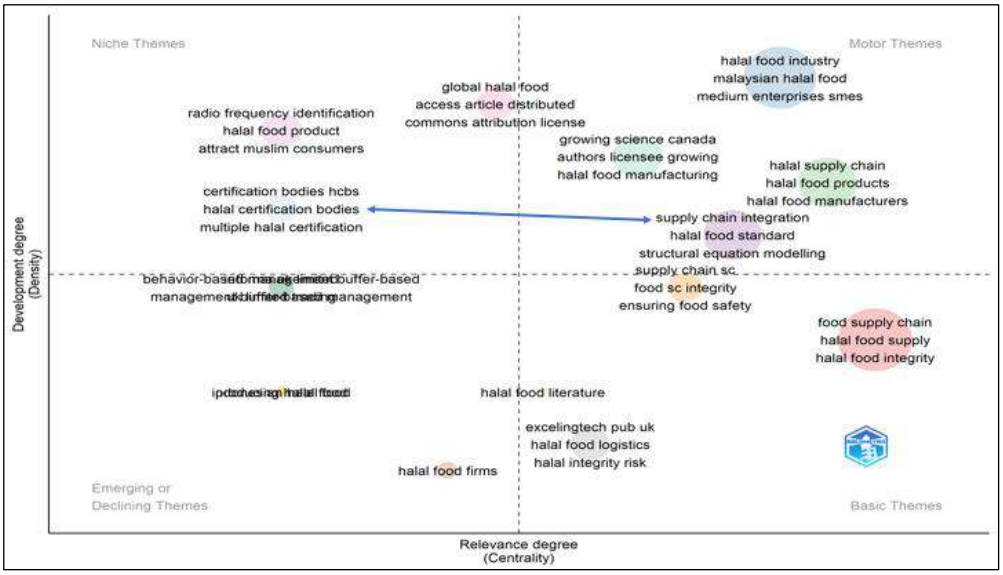

Figure 6: Thematic Map for 76 SLR Papers.
Source: Author, (2026).

The thematic maps illustrate the integration among various topic clusters, with the halal food industry, Malaysian halal food, and medium enterprises emerging as motor themes that have developed and remain highly relevant. Dendrogram analysis is employed to map the proximity of keyword occurrences across thematic clusters, where each color represents a relatively homogeneous issue grouping. It is evident that the term halal certification resides in the blue cluster alongside halal food, the food industry, and structural equation modeling, highlighting discussions on certification aspects and organizational behavior can be seen in Figure 7.

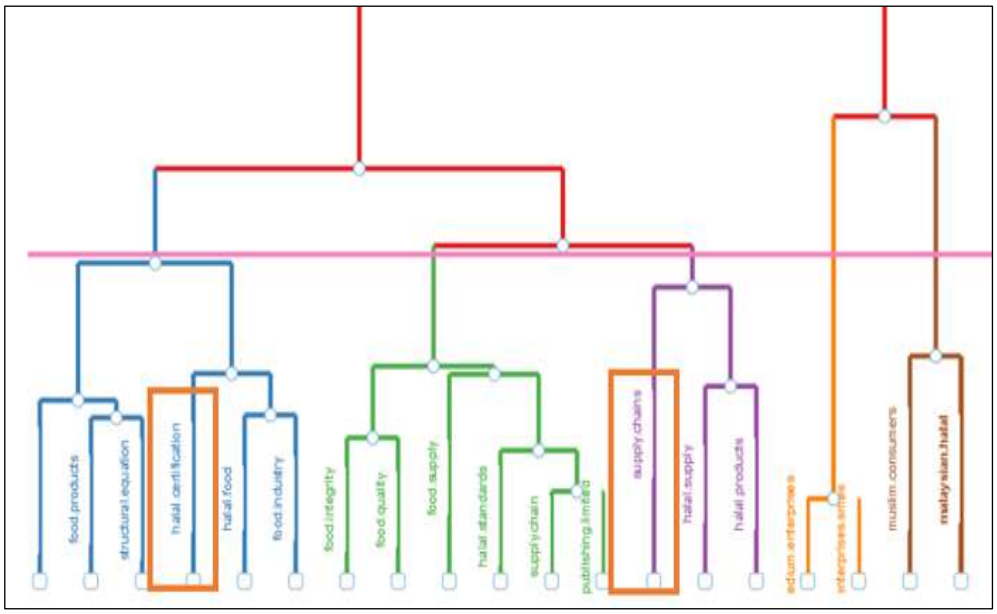

Figure 7: Dendogram for 76 SLR Papers.
Source: Author, (2026).

The Bibliometric process is conducted to determine the papers to be analyzed in the synthesis process of the SLR, which will help establish the PICOS criteria, research questions, research objectives, state of the art, and the novelty of the research. The selection process for determining which papers to include in the synthesis uses PageRank values and citation counts across the five clusters. Based on the identification of 76 papers, the number of articles to be synthesized was determined using PageRank and citation metrics. PageRank and citation counts are quantitative approaches within the SLR methodology for identifying and prioritizing core articles.

IV.3.2 Synthesis of Quantitative Paper

A quantitative prioritisation procedure was first implemented to characterise the relative prominence of each publication within the dataset. This procedure enabled the identification of highly central contributions that serve as pivotal references for the subsequent stages of the analysis. Based on screening the 76 papers, the highest PageRank value was 1.256, with 20 citations, corresponding to the topic Halal Practices Integrity and Halal Supply Chain. Using these PageRank and citation values, the following steps were to determine the optimal values, assess uncertainty, calculate the compromise index, and establish rankings based on the compromise values. The resulting rankings will be used to determine the cutoff for core papers. The PageRank values for the 76 are shown in Figure 8.

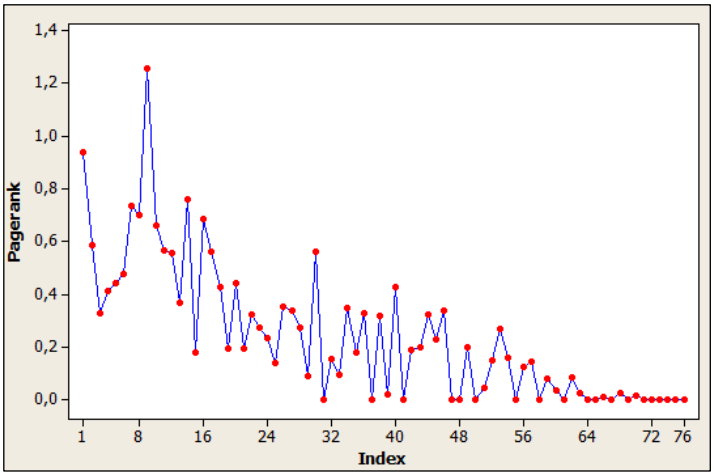

Figure 8: PageRank Scores of Selected Articles by Paper Code.
Source: Author, (2026).

A bibliometric investigation of the curated literature set was undertaken to elucidate the intellectual architecture of the domain. This analytical procedure facilitated a rigorous quantitative estimation of the relative impact and scholarly prominence of each contribution within the dataset. Based on the analysis conducted in R-Studio using the 76 selected papers, the citation counts for each paper were integrated with their PageRank values to identify the core papers, which will serve as the foundation for determining the PICOS framework. The bibliometric analysis of these 76 papers reveals the citation counts for each, as illustrated in Figure 9.

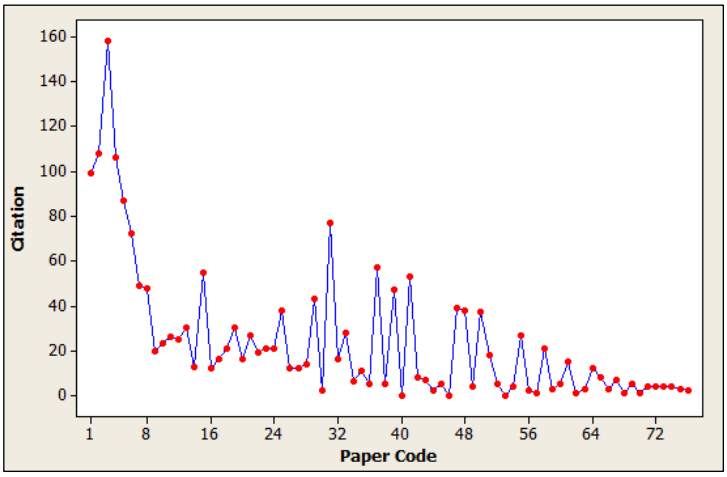

Figure 9: Citation Distribution per Article.
Source: Author, (2026).

A multi criteria decision making procedure was subsequently employed to refine the set of influential studies for the review. Within this procedure, the VIKOR framework was combined with a probabilistic weighting scheme to derive a balanced evaluation of each paper. The determination of weights (w) in the VIKOR method uses the Laplace principle, which assigns equal prior probability 1/n to each possible state of nature, thereby assessing alternatives based on the average payoff calculated under this uniform distribution [31]. In this analysis, using the Laplace method with two variables, PageRank and citation counts, the weight for each paper was established at 0.5. The results of the VIKOR analysis, when integrated with the Elbow method, identified 50 papers from the initial set of 76 selected papers, as detailed in Table 2.

Table 2: Final Index Paper Calculations (ΔQ) Based on Article Ranking using VIKOR Analysis.

Paper	Authors	Pagerank	Citation	Norm-Pagerank	Norm-Citation	Weight-Pagerank	Weight-Citation	Total Weight (Si)	R-max (Ri)	CI-Si	CI-Ri	Rank (Q)	ΔQ =2	ΔQ = 3

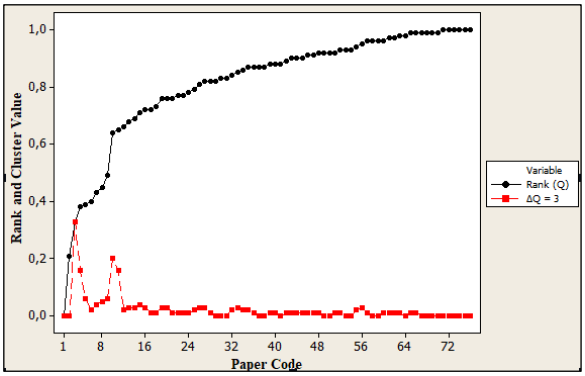
Source: Authors, (2026).

A ranking of the papers was first obtained using the VIKOR method, and the resulting cluster separation was examined with the elbow approach for K=3 t. The ranking values capture the integrated influence of PageRank and citation metrics, reflecting how closely the 76 selected papers align with the SLR topic. At the same time, the elbow method is then used to delineate the core papers that underpin the PICOS specification and state-of-the-art synthesis, with the VIKOR-based clustering of the top 20 out of 76 papers illustrated in Figure 10.



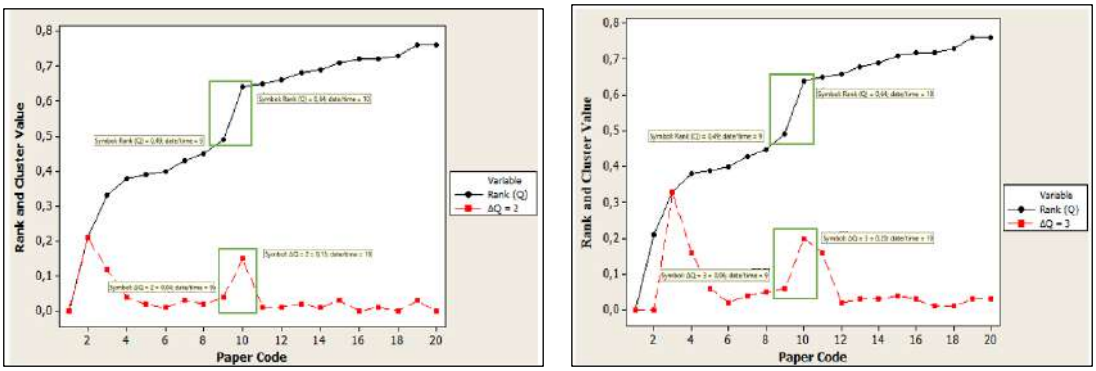


Figure 10: Rank and Citation papers.
Source: Author, (2026).

The elbow method provides a visual procedure for identifying the optimal number of clusters (k) by locating the elbow point on the curve that balances the number of clusters and the corresponding clustering error or compactness [27]. The distribution of the VIKOR based ranking paper and the corresponding cutoff between core and non-core papers is presented in Figure 11.

(a) ΔQ with k = 2 (b) ΔQ with k = 3

Figure 11: Elbow Curve of Differences Between Rank (ΔQ) Across Papers.
Source: Author, (2026).

The curve displays the successive differences between VIKOR index values Q (ΔQ) with k = 2 and k =3 for each paper, ordered from the smallest to the largest Q, thereby revealing relatively flat segments and several sharp jumps. The first and largest elbow, between paper 1 and paper 2, is treated as the main elbow that defines a relatively homogeneous core set in k =2 and k = 3. Papers 2 to 9 form a secondary elbow, and papers 10 to 76 are considered non-core and excluded from the cutoff because they lie beyond the elbow zone on the k = 2 and k = 3 curve and do not require an additional number of papers to be analyzed. The selected papers, ranging from Paper 1 to Paper 9, are listed in Table 3.

Table 3: Synthesis analysis of papers that address the identified research.

No	Authors	Research Objective	Result
1	[4]	The purpose is to detect and rank risks of the halal food supply chain so that these can serve as the foundation for determining critical halal control points to be supervised within a unified halal certification	The paper addresses the identified research gap by providing detailed information on the priority of risks of the halal supply chain, which can be directly mapped to halal certification control points.
2	[32]	Mapping the literature review and the broader halal food research agenda, namely marketing, regulation, and consumer aspects,	The paper is not aligned with the identified research gap because it only presents a general SLR and cannot support of a halal certification.
3	[33]	The blockchain technology to enhance the traceability of halal information in product flows, particularly for tracking certification and halal status.	The paper is not aligned with the identified research gap because it focuses on technological traceability solutions rather than on the process integration structure and inter-actor relationships within an institution's halal supply chain.
4	[34]	Developing integrity of halal supply chain framework that links potential halal violation points with the roles of certification bodies.	The paper is not aligned with the identified research gap because it is conceptually essential but lacks empirical evidence; it is used as a framework reference rather than as a core paper for the integration model.
5	[35]	The effect of integration with suppliers and partners on halal supply chain, which is related to the consistency of certification standard	The paper is not aligned with the identified research gap because it examines only external integration for a single supplier actor, thereby not representing end-to-end performance across the entire supply chain.

No	Authors	Research Objective	Result
6	[36]	Reviewing and mapping research on food safety and halal in the supply chain, including certification and risk control issues, but without developing a model that integrates halal certification with the supply chain.	The paper is not aligned with the identified research gap because it is a Systematic Literature Review that maps bibliometric analysis of halal food safety themes but does not present a model for integrating certification into the supply chain.
7	[37]	Identifying halal ecosystem challenges from the perspective of institutional regulation that influence the implementation of halal certification	The paper is not aligned with the identified research gap because it operates at the macro-ecosystem level and policy rather than addressing operational integration for supply management.
8	[38]	Supply chain integration with suppliers and customers can enhance halal supply chain integrity and product quality, thereby underscoring the role of process integration in the halal certification model.	The paper aligns with the identified research gap because the empirical findings show that internal integration from suppliers to end customers provides variables and managerial levers to improve halal across the supply chain.
9	[78]	Evaluating the extent to which halal practice integrity, consistent with certification requirements across all supply chain actors, improves supply chain performance	The paper is aligned with the identified research gap because the resulting model can be integrated with halal practices, namely certification across all supply chain actors.

Source: Authors, (2026).

Screening the nine selected articles against the identified research gap yielded three core papers from which the PICOS framework, Research Objectives (RO), and the state of the art were derived. This research novelty as shown in Table 4.

Table 4: Key Characteristics of Selected Empirical Studies on Halal Food Supply Chain.

Author	Context	Focus Analysis	Main Findings	Study Design
[38]	An examination of various factors influencing halal food certification from upstream to downstream in	Analyzing variable relationships in the halal assurance framework using SEM-PLS within a Resource-Based View (RBV) perspective	Designing a halal food supply chain performance model that integrates integrity with product safety and quality	Explanatory quantitative with a cross-sectional survey design.
[4]	Practitioners, experts, and academics who understand the halal food supply chain	Risk identification and ranking in the Halal Food Supply Chain using MCDM with Fuzzy AHP weighting	Priority ranking for supply chain risk mitigation focuses on holistic, outsourced management of raw material delays.	Explanatory quantitative based on expert judgment.
[78]	Small and medium enterprises (suppliers and producers) in the food supply chain in Malaysia	Level of implementation of halal practices and integrity throughout the halal food supply chain using SEM-PLS.	Integrity in halal food supply chains through standard compliance, control mechanisms, and effective coordination among actors for sustaining a viable halal supply chain model.	Explanatory quantitative with a cross-sectional survey design.

Source: Authors, (2026).

The columns for Context, Focus of Analysis, and Main Findings are organized as an initial step to extract conceptual elements, which will later be systematically mapped within the PICOS framework. Information regarding who and where the studies were conducted in the Context column will inform the Population component. The focus of analysis and key variables in the Focus of Analysis column will be processed into relevant Interventions and Comparators, while the summary of the main. The PICOS are shown in Table 5.

Table 5: PICOS Result Analysis.

Component	Description
Population (P)	“The agro-industry chain involved cassava farmers as upstream suppliers, SMEs producing coarse and fine tapioca and mocaf as intermediate business users, and cookie-producing SMEs as downstream processors”
Intervention (I)	“The Soft System Dynamic Methodology (SSDM) approach builds on SCOR DS modelling, MCDM, FMEA, and validated dynamic system simulations to design and assess the performance of the halal supply chain model”
Comparison (C)	“The comparative risk-oriented supply chain modelapplies SEM-PLS, while risk prioritisation in the halal food supply chain is conducted using a Fuzzy AHP technique “
Outcomes (O)	“The integrated halal supply chain and value chain model for the tapioca and mocaf agro-industry, along with its institutional model, has been validated by experts and tested for dynamic feasibility using conceptual validation and computerized methods”
Study Design (S)	“System Development and Modeling Study using a quantitative explanatory approach based on decision-making”

Source: Authors, (2026).

Based on the PICOS results, the next step is to formulate the research questions that will serve as the foundation for determining the Research Objectives (RO) and for establishing the state of the art and the research's novelty. The Research Objective derived from the PICOS framework is as follows:

RO 1: Analysis the situational structure of the tapioca and mocaf agro-industry supply chain as a basis for development of halal supply and value chains.

RO 2: Identify and prioritize improvements to performance inefficiencies among each actor in the tapioca and mocaf agro-industrial supply chain.

RO 3: Analysis the management of halal practices for tapioca and mocaf using value-added and halal risk analyses to enhance halal production.

RO 4: Develop a system dynamics model for the halal supply chain for tapioca and mocaf, including scenarios for supply development and halal certification

RO 5: Develop a model for the structure and dynamics of the halal supply chain for tapioca and mocaf, including scenarios for supply development and halal certification through simulations and operational feasibility validation. This determination aims to assess the research position that can fill the gap left by previous studies, specifically regarding the integration of halal certification, as shown in Table 6.

Table 6: State of The Art Research Position.

Author	Paper Title	Research result
[78]	"Halal practices integrity and halal supply chain trust in the halal food supply chain"	Halal practices integrity significantly affects halal supply chain trust and performance, as assessed through Cross-Sectional studies and SEM-PLS.
[4]	"Prioritising the risks in the halal food supply chain: an MCDM approach"	An integration of expert judgment and MCDM Fuzzy AHP was used to identify the risks of Halal Food Supply Chain (HFSC) and the raw material integrity model
[38]	"Impact of supply chain integration on halal food supply chain integrity and food quality performance"	A quantitative examination of the relationship in the halal food supply chain was conducted using food quality performance data via SEM-PLS.
Research Position	Integration of the supply chain and halal value chain models to identify and measure supply chain performance and halal value addition, based on decision-making validated through soft system simulation and computerized methods	

Source: Authors, (2026).

This SLR reveals a critical gap in existing studies, which have separately examined halal practices integrity, risk prioritization, and supply chain integration using static methods such as SEM-PLS and MCDM. The present research positions itself by proposing an integrated halal supply and value chain model that employs the Soft Systems Dynamic Methodology (SSDM) and simulation to measure supply chain performance and halal value added dynamically.

IV.4 FUTURE RESEARCH AGENDA

The novelty of the research in developing halal supply chain and value chain models for the tapioca and mocaf agro-industry, it is necessary to develop simulations to validate the success of the halal supply chain development model. The future system design research can be seen in Figure 12.

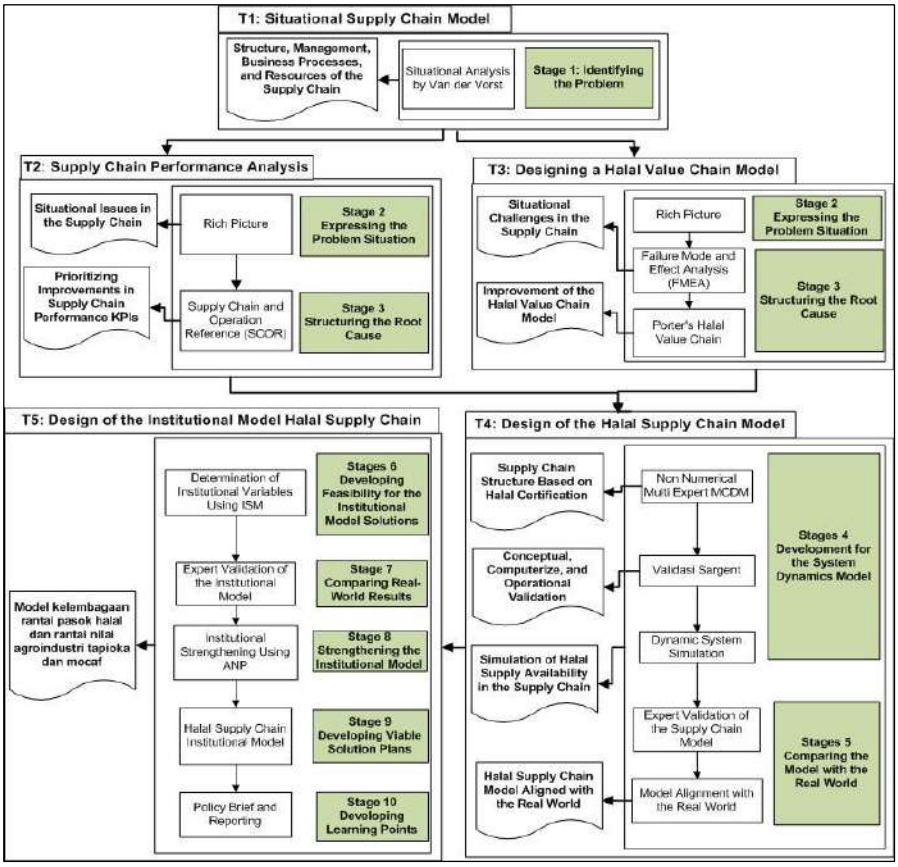

Figure 12: Future system design research with SSDM framework.

Source: Authors, (2026).

V. CONCLUSIONS

Bibliometric analysis revealed that halal certification has not been implemented simultaneously in the development of the supply chains for tapioca and mocaf. The development of the halal supply chain and value chain model based on the Soft System Dynamic Methodology can be conducted using a decision-making framework and integrated institutional systems to manage halal certified supplies. This integration involves a performance-based approach to supply chain management and a competitive advantage based on halal certification through model development for tapioca and mocaf, to address complex issues, validated and verified through both conceptual testing. Future research should focus on tracing, transparency, and tracking to ensure compliance with halal implementation using blockchain.

ABSTRACT

Cardiovascular Disease (CVD) continues to be a major global health concern, posing significant risks to human life. Early and accurate detection remains difficult due to noise in Electrocardiograms (ECGs) signals, class imbalance, and the limited generalisation ability of existing Machine Learning (ML) models. Therefore, this work proposes a new hybrid optimized Deep Learning (DL) techniques for the intelligent analysis of ECG signals for the prediction of cardiac disease. The study uses raw ECG Signal from the MIT-BIH Arrhythmia Database as a case study, and applies Savitzky-Golay (SG) filters for denoising to ensure proper noise elimination while maintaining the necessary morphological structures. Exploratory Data Analysis (EDA) is utilized for statistical descriptors such as mean, variance, skewness and kurtosis of RR intervals and QRS widths, complemented by correlation matrix and QRS morphology overlays to uncover temporal patterns. Pan–Tompkins's algorithm applied for extracting morphological features, such as RR intervals, QRS duration, Heart Rate, and Rhythm Variability enabling precise identification of P, QRS and T complexes. The new proposed framework, Wavelet-Token Swin-1D Mixture-of-Experts State-Space EchoFormer (WT-MoE-SSM-EchoFormer) uses wavelet domain tokenization for feature encoding, Swin 1D hierarchical attention and expert driven selection learning for better represent cardiac signals through state space temporal modelling. The Golden Tortoise Beetle Optimizer (GTBO) algorithm employed for dynamically tuning hyperparameters, thus improving convergence and training stability. The complete framework is implemented in Python and yielded an accuracy of 99.98%, a precision of 99.79%, a recall of 94.84%, an F1-score of 97.03%, a specificity of 99.99%, and a ROC-AUC of 1.0000, which validates the proposed framework's effectiveness and reliability for ECG-based cardiac disease diagnosis. The proposed framework achieves superior classification accuracy, lower misclassification, and greater potential for real-time cardiac disease diagnosis.

I. INTRODUCTION

CVD are one of the most critical and life-threatening health issues across the globe, caused by the improper functioning of the cardiovascular system, resulting in severe complications like heart failure, coronary artery disease and myocardial infarction [1], [2]. Heart disease significantly contributes to mortality and morbidity across the globe; it is important to detect heart disease accurately for effective treatment and prevention [3]. It is critical to recognize people at risk of heart disease at a very early stage to prevent severe complications [4]. In recent years, significant progress has been made in heart disease detection through the combined use of computational intelligence and medical technology. Methods such as ML, data mining and predictive modelling rely on large amount of clinical and physiological data to enhance the accuracy of diagnosis [5].

Although advanced imaging modalities such as Computed Tomography (CT) scans and Magnetic Resonance Imaging (MRI) are reliable and accurate, but it is high cost and lack of accessibility, limit their widespread use, especially in developing countries. ECG is an essential and popular technique used for the diagnosis of CVD by capturing the electricity activity of the heart [6], [7]. Among the different types of CVDs, cardiac arrhythmia is the most common one and easily detected from the ECG signal by analysing irregular heartbeats. Conventional ECG system uses 12-lead configuration, which is quite inconvenient for patients and require the expertise of a professional for proper analysis [8], [9]. To overcome these limitations, single lead ECG sensors have gained popularity as a more comfortable and practical solution. By integrating AI technology, these systems are automatically analysing the ECG signal and detect any cardiac irregularities [10]. Manual analysis of ECG signals is a time consuming and laborious process, which has led to the development of ML algorithms for the automatic classification of arrhythmias. However, traditional ML models such as XG-Boost [11], Extra-Trees [12] and Artificial Neural Network (ANN) [13] classifiers are highly dependent on manual feature extraction and selection, which makes them less robust and less accurate. To overcome these issues, DL algorithms have occurred as popular alternatives owing to their capability to mechanically learn complex hierarchical features from large datasets.

DL models have demonstrated incredible success in a wide range of application, including biomedical signal processing and medical imaging analysis, which has significantly improved the accuracy of cardiac disease analysis. The Convolutional Neural Network (CNN) to developed Rhythmi [14] model operates significantly better in terms of early diagnosis and patient care. However, its usage in currently delayed by the lack of diversity in the dataset, the absence of personalized medical reporting and the need for extensive clinical validation before largescale deployment. VGG16 [15], Google ViT based ResNet50 [16] and HybDeepNet [17] models makes possible to predict cardiac disease at a low cost and improves accessibility to continuous heart monitoring. Nevertheless, the model shows performance degradation after hardware deployment and require further optimization to ensure real-world healthcare system. Although these models have demonstrated encouraging results and they also have some significant limitations, including their sensitivity to feature selection and data quality. The inability of traditional models has complex nonlinear patterns, high computational complexity and lack of interpretability of DL models, thus difficult to handle noisy, imbalanced medical data, and scalability issues that make them unsuitable for real time healthcare environment. These boundaries indicate the necessity for robust, interpretable and computationally efficient predictive models for accurate heart disease diagnosis. Recently, Vision Transformer (ViT) integrates Swin [18], TransConvNet [19] model has improved by employing self-attention mechanisms which decrease image specific biases and enhance both computational efficacy and accuracy. However, challenges such as insufficient deep spatial feature extraction and high computational cost [20].

I.1 RESEARCH GAPS

The existing approaches for ECG-based prediction of cardiac disease are mostly based on traditional ML and DL models, which tend to have high human intervention in feature extraction, low robustness to noisy data, and poor performance on highly imbalanced datasets. Most of the existing DL models have high computational complexity, low interpretability, and poor ability to model both short-term morphological dynamics and long-term temporal patterns in ECG signals. Although the transformer-based models have improved the ability to model the attention mechanism, they still have challenges in terms of low multiresolution feature representation and high computational complexity. Moreover, most of the existing approaches have not fully leveraged the benefits of signal denoising, EDA, adaptive feature learning, and hyperparameter optimization in a unified framework.

I.2 CONTRIBUTIONS

To overcome the limitations of existing methods, the proposed work contributes to,

- SG filter utilized for efficient denoising of raw ECG signals, while preserving vital morphology features such as QRS complexes and RR intervals that are necessary for reliable cardiac analyses.
- Using EDA, patterns of statistical and temporal information, and morphology information derived from ECG signals are analyzed to provide a better understanding of cardiac rhythms.
- To effectively detect R-peaks and extract clinically significant temporal features from ECG signals, a Pan-Tompkins algorithm is utilized.
- A hybrid WT-MoE-SSM-EchoFormer is proposed to be used for capturing multi-resolution feature representations, adaptive expert representations, and both short- and long-term temporal dependencies from ECG signals.
- GTBA used to automatically tune the hyperparameters of proposed model, resulting in stable training behaviour, and enhanced classification performance.

II. PROPOSED SYSTEM DESCRIPTION

The improved model as illustrated in Figure 1, generates a classification output that identifies both the presence and type of cardiac disease. The acquisition of raw ECG signals from the cardiovascular dataset captures electrical activity of the heart. Since these data are frequently contaminated with noise caused by muscle movement, electrode displacement and external interference, the first necessary step is signal processing. Therefore, a SG filter is applied to the ECG signals to remove unwanted noise while keeping the waveform's original structure and significant peaks. After acquiring clear ECG signals, the next stage is EDA. Before developing learning model, EDA is used to better understand the behaviour and distribution of cardiac signals. At this point, statistical metrics such as variance, means, skewness and kurtosis of RR intervals and QRS widths are calculated. Additionally, correlation analysis and QRS morphology visualization are performed. This process assists in detecting hidden pattern, irregularities, and correlations in the data. The framework then proceeds to feature extraction, where the Pan-Tompkins algorithm accurately detects the P, QRS and T complexes in the ECG signal. This step is to convert the raw ECG signal into clinically relevant features that reflect the real physiological state of the heart. These extracted features simplify the data and improve the model's discriminative capacity.

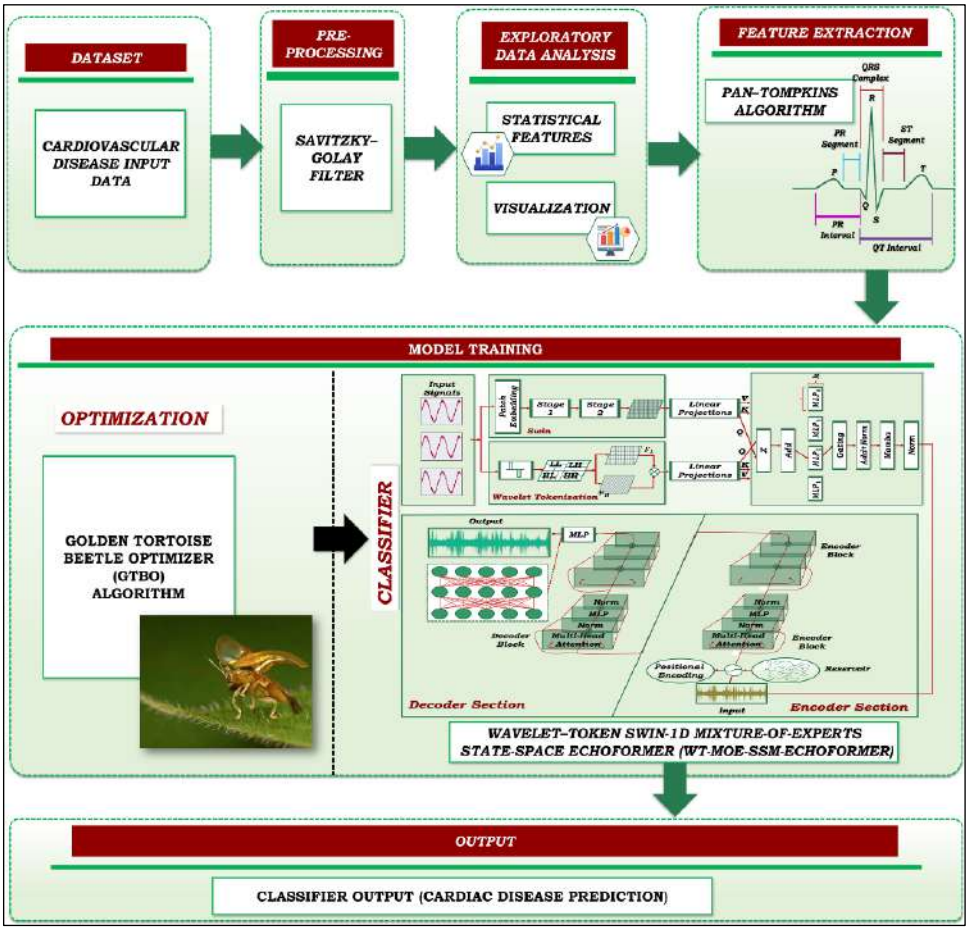

Figure 1: Proposed ECG analysis and cardiac disease prediction using GTBO WT-MoE-SSM-EchoFormer.
Source: Authors, (2026).

The extracted characteristics are then fed into the proposed WT-MoE-SSM-EchoFormer classifier. This model manages both short term and long-term temporal pattern in ECG data. This combination produces a very informative visualization of heart activity, allowing for accurate classification of cardiovascular diseases. During model training, the GTBO is used to automatically tune the hyperparameters. This optimization step is crucial for achieving fast convergence, avoiding overfitting and maintaining training stability.

III. METHODOLOGY

III.1 SAVITZKY-GOLAY FILTER

In the cardiac disease prediction framework applied a SG filter is used to preprocess the ECG signals. The SG filter is a time-domain method that denoises the ECG signals although conserving risky waveform attributes of ECG signal by approximating the signal around each sample using a local polynomial least-squares fit. The approximation of the ECG signal allows for effective suppression of noise in the ECG signal without impacting the critical features of the cardiac waveform.

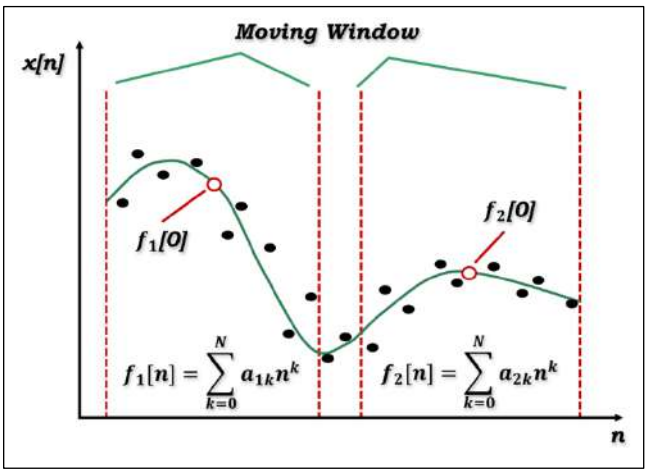

Figure 2: Basic idea of SG filter.
Source: Authors, (2026).

Let $x[n]$ represent the ECG signal in discrete format as illustrates in Figure 2. To approximate the signal using a polynomial of degree N for any given sample point, a window of length $2M + 1$ is centered around the sample point.

$$f(n) = \sum_{k=0}^{N} \alpha_k n^k \quad (1)$$

To obtain the optimum polynomial coefficients α_k, minimise the least squares error between the polynomial fit versus the original ECG samples in the reference window.

$$\varepsilon = \sum_{n=-M}^{M} (\sum_{k=0}^{N} \alpha_k n^k - x[n])^2 \quad (2)$$

In the case of a polynomial, the filtered ECG value at the reference window is located at the centre of the polynomial.

$$y[0] = f(0) = \alpha_0 \quad (3)$$

This process is repeated for all ECG samples by moving the reference window over the ECG signal resulting in a complete denoised ECG signal. The characteristics of the SG filter make them highly suitable for fitting a polynomial to retain low-order signal components and small morphological features while reducing high-frequency noise. In ECG analysis, the accurate retention of QRS morphology and RR intervals are important to ensure accurate feature extraction and facilitate precise classification of cardiac diseases.

III.2 EXPLORATORY DATA ANALYSIS

EDA is the process of getting a thorough understanding of the statistics, time-related trends associated with ECG waveforms before the feature extraction and model building. In addition to testing the quality of the data, it also helps reveal significant cardiac behaviours associated with various cardiovascular health issues.

III.2.1 Analysis of Descriptive Statistics

Descriptive Statistics values from both the raw ECG waveform and medically significant cardiac variables are calculated especially in RR Interval and QRS duration using the following:

- Mean - The average value of data, calculated by summing all data values and dividing by the sample size. It gives the central tendency for heart rhythm and timing of timing for ventricular depolarization.
- Median - The value positioned in the middle of the sorted data set. It serves as a leader that divides data into two equal halves when arranged by value ascending or descending.
- Standard Deviation – It measure the distance of values from the mean. It indicates the degree of fluctuation in cardiac activity.
- Variance - Variance is the mean of the squared differences of the individual observations from the mean value and shows how widely cardiac activity varies.
- Skewness: This provides insight into how asymmetric the distribution of QRS widths and RR intervals are which is helpful for identifying abnormal conduction patterns and irregular heartbeats.
- Kurtosis: It provides a quantitative assessment of both the percent of kernel volume and tail behaviour of distributions, helping to identify extreme cardiac events and transient irregularities.

Descriptive statistics gives an important understanding of the physiological function of the heart, and assist in distinguishing between normal and abnormal conditions.

III.2.2 Visualisation and Analysis of Temporal Patterns:

To further understand the relationship between these features and their temporal dynamics, multiple approaches are used:

- Correlation Matrices: They are created using extracted cardiac features allowing the identification of strong dependencies between each parameter, including QRS widths, RR intervals and other parameters, which together effect disease classification.
- QRS Morphology Overlays: The superimposition of several QRS complexes permits analysis of the degree of similarity or deviation in their shape throughout time; this helps to identify subtle morphological variations associated with arrhythmias and myocardial abnormalities.
- Histograms: It used to examine the distribution of continuous variables, and how the specific values of those variables affect the distribution of RR intervals and QRS widths. Histograms allow for examination of a given variable's distribution by dividing the variable into bins and showing how many observations fall into each bin.
- Box Plots: It allows for visualization of the median, quartiles, and outliers for a continuous variable. They serve the same purpose as histograms, but visually convey the quartile distribution, median, and outlier information for continuous variables.
- Line Plot: Displays a set of data points to illustrate a trend over time or across continuous variables using straight line segments. Commonly utilised for analysing and visualizing the temporal changes of ECG waveforms and extracted features to determine/identify rhythm irregularities and dynamic cardiac performance.

The integration of statistical descriptors like mean, median, skewness and kurtosis for RR intervals & QRS widths with correlation matrices and QRS morphology overlays in the EDA process helps to establish both temporal patterns and structural relationships present in the ECG data. This results in increased-quality features for the proposed cardiac disease prediction model.

III.2.3 Feature Extraction- Pan-Tompkins Algorithm

Pan-Tompkin's algorithm is used to aid in identifying the R point in an ECG signal. This algorithm consists of five main steps, which include bandpass filtering, differentiation, squaring, sliding window integration, and thresholding.

Band-Pass Filtering for Noise Reduction

In the initial stage, the Pan-Tompkins algorithm utilizes a band-pass filter to reduce noise in the ECG signal. This is accomplished by using a series of low-pass and high-pass filters to create a band-pass filter with cascaded low-pass and high-pass filters. The result of this processing step is a more noticeable QRS complex and less baseline drift and high-frequency noise.

Differentiation

Differentiation to obtain the slope characteristics of the QRS complex, at a high-frequency resolution moving away from low frequencies. It provides an increased opportunity for successful detection of QRS complexes.

Squaring and Sliding Window Integration

Squaring and sliding window integration to provide further emphasis of the differences made by the previous operation as well as ensure that all values are positive. To accomplish this, the squared output is further integrated using a sliding window approach that is create a smoothed output with both QRS waveform energy and the least amount of residual noise possible.

Extracting Temporal Features in Relation to the R-Wave

Once the R-wave locations are identified, ECG signals are divided into segments based on their temporal proximity to the R-peaks. From these relationships, average-mean feature vectors to be obtained for the following items within each of the ECG signals:

- P Interval
- PR Interval
- QRS Duration
- QT Interval
- ST segment
- T-wave
- RR Interval

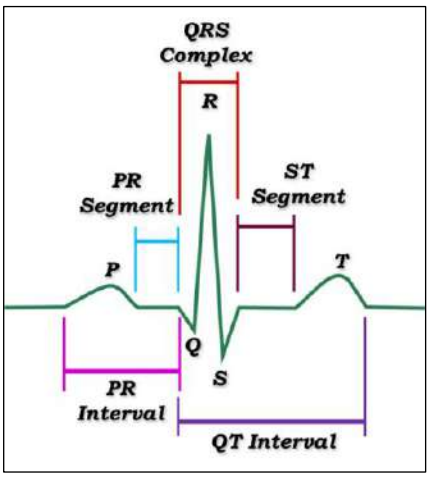

Figure 3: Basic structure of ECG signals.
Source: Authors, (2026).

The repeated wave sequences of P, QRS and T waves that are associated with each heartbeat characterized the ECG signal as illustrates in Figure 3.

RR interval Deviation

The deviation of RR intervals is then calculated to assess rhythm regularity:

$$RR_{deviation} = \frac{1}{RR_{number}} \sum \left| RR_i - RR_{avg} \right| \quad (4)$$

Here, RR_{number} stands total number of RR intervals.

QRS Complex Duration

A model based on physiological limitations utilized to determine the proper morphological characteristics of the QRS Complex to predict cardiovascular disease. A total QRS duration of 0.11s is used as the upper limit for a normal range of QRS Durations, and the Q-interval is less than 25% of the total duration of the QRS. The R peaks from the Pan–Tompkins Algorithm serve as temporal references for estimating the QRS boundaries. The QRS half-width is defined as half of the maximum QRS duration (0.055 s).

The Q interval is one-fourth of the QRS duration (0.0275 s), which meets clinical requirements, and the remaining QRS duration is assigned to the R and S waves.

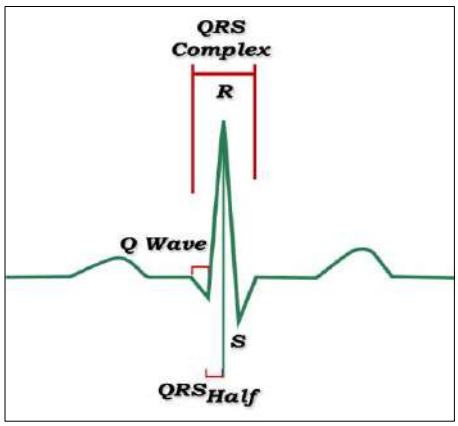

Figure 4: Intervals calculation of QRS complex.
Source: Authors, (2026).

Figure 4 illustrates intervals used for evaluation of QRS complex. This method of QRS modelling allows for the careful extraction of QRS Duration characteristics, which are important indicators of abnormalities in ventricular conduction, and therefore are an important component of automated systems for predicting CVD.

III.3 WT-MOE-SSM-ECHOFORMER

WT-MoE-SSM-EchoFormer classifier combines wavelet-domain tokenization for multiresolution feature extraction, Swin-1D hierarchical attention for localized temporal context modeling, mixture-of-experts routing for adaptive feature specialization, and state-space echo former dynamics for long-term temporal memory. This unified design allows for strong encoding of both transient and continuous cardiac rhythm variations.

Wavelet tokenization

Let the pre-processed 1D cardiac signal be denoted as,

$$x \epsilon \mathbb{R}^{T \times B}, \tag{5}$$

Here, T stands temporal length and B stands number of signal channel. A 1D wavelet tokenization is applied independently to each channel:

$$LL^{(b)}, LH^{(b)} = WT\left(x^{(b)}\right), b = 1, \ldots, B \tag{6}$$

Here, $LL^{(b)}\ and\ LH^{(b)}$ represents approximation and detail coefficients. The same type of coefficient is stacked to form:

$$LL \epsilon \mathbb{R}^{T/2 \times B},\ \ LH \epsilon \mathbb{R}^{T/2 \times B} \tag{7}$$

Wavelet coefficients are mapped into Low Frequency (LF) and High Frequency (HF) feature streams using learnable temporal mappings:

$$F_L = \phi_L(LL),\ F_H = \phi_H(LH) \tag{8}$$

Here, F_L denotes global rhythm and baseline trends and F_H denotes emphasize rapid cardiac abnormalities. The wavelet-based feature representation is obtained by;

$$F_{wave} = Concat(F_L, F_H) \tag{9}$$

Token Alignment

To match the Swin-based temporal tokens, feature alignment is applied:

$$\hat{F}_{wave} = Align(F_{wave}) \tag{10}$$

Here, $Align\ (\cdot)$ represents consistency in token length and embedding dimension. Let $F_{swin} \in \mathbb{R}^{T \times D_S}$ denote Swin features. Query, key and value projections are defined as;

$$Q_s, K_s, V_s = \phi_s(F_{swin}),\ \ Q_w, K_w, V_w = \phi_w\left(\hat{F}_{wave}\right) \tag{11}$$

$$A_{w \to s} = Softmax\left(\frac{Q_s K_w^T}{\sqrt{d_k}}\right) V_w,\ \ A_{s \to w} = Softmax\left(\frac{Q_w K_s^T}{\sqrt{d_k}}\right) V_s \tag{12}$$

The attention enhanced features are fused back using;

$$F'_{swin} = F_{swin} + \alpha \pi_s(A_{w \to s}),\ \hat{F}'_{wave} = \hat{F}_{wave} + \beta \pi_w(A_{s \to w}) \tag{13}$$

Here, α and β stands learnable scalar weights that dynamically balance temporal and frequency domain contributions. The fused representation is obtained as:

$$F_{fused} = Conv_{fuse}\left(Concat\left(F'_{swin}, \hat{F}'_{wave}\right)\right) \tag{14}$$

Mixture of Experts State Space Model

A SSM layer captures the long-range temporal dynamics of ECG sequences with linear complexity, while a MoE layer replaces the feed forward Multi-Layer Perceptron (MLP) to allow adaptive learning of heterogeneous cardiac patterns. The single MoE-SSM block is defined as;

$$x_{l+1} = x_l + MoE\left(LN\left(x_l + SSM\left(LN(x_l)\right)\right)\right) \tag{15}$$

Here, x_l denotes unput ECG feature representation at layer l. SSM capture rhythm level temporal evolution, while MoE selectively activates experts' subnetworks specializing in various ECG structure.

EchoFormer

EchoFormer architecture utilizes the Echo State Network (ESN) dynamic modelling capabilities and the transformer model learning global dependencies, to effectively capture these properties of ECG Signals. An ESN consists of an input layer, a randomly initialized reservoir and a trainable output layer. The reservoir serves to project ECG signal inputs into a high-dimensional latent space allowing for the extraction of many different and highly temporal features. The evolution of states in the ESN reservoir is described as follows:

$$S_{t+1} = \lambda S_t + (1-\lambda)\psi_a(s_t, x_t, y_t) \tag{16}$$

Here, $s_t \in \mathbb{R}^{N_s}$ denotes reservoir state, $x_t \in \mathbb{R}^{N_x}$ denotes ECG input time t, and $\psi_a(\cdot)$ stands nonlinear activation function. The activation function defined as,

$$\psi_a = (s_t, x_t, y_t) = tanh(W_{res}s_t + W_{in}x_t + W_{back}y_t) \tag{17}$$

Here, $W_{res}, W_{in}\ and\ W_{back}$ represents fixed randomly generated weight matrices. After a short free-running period, the ESN output is computed as:

$$\hat{y}_t = W_{out}[x_t, s_t, \hat{y}_{t-1}] + b_y \tag{18}$$

Here, W_{out} stands trainable parameter set. The output weights are optimized via;

$$\min_{W_{out}} \sum_{i=1}^{N} \frac{1}{2}\|y_i - \hat{y}_i\|_2^2 + \frac{\beta}{2}\|W_{out}\|_F^2 \tag{19}$$

Here, $\hat{y}_i$ denotes predicted output of EchoFormer, N stands number of training samples, β stands regularization parameter controlling model complexity. The reservoir stage passed through a transformer encoder with multi-head self-attention heads that model global temporal relationships between ECG cycle. The EchoFormer combined structure provides the ability to learn from both local cardiac rhythms and distant pathological relationships, and thus achieve more accurate classifications of CVD.

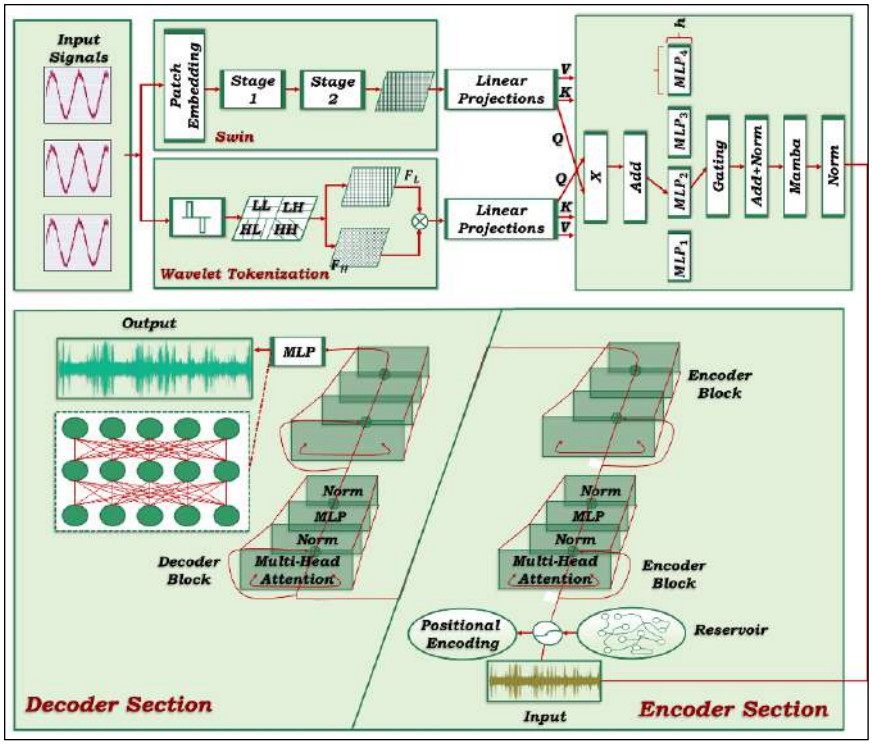

Figure 5: Architecture of WT-MoE-SSM-EchoFormer.
Source: Authors, (2026).

The WT-MoE-SSM-EchoFormer architecture as shown in Figure 5 combines wavelet decomposition with the principle of collaborative attention to represent temporal structures, through expert-guided selective learning and echo-state spaces as a means of generating a discriminative feature embedding for cardiac classification tasks. The final classifier efficiently distinguishing between normal and pathological cardiac activity without compromising the computational efficiency or stability of the predictor system.

III.4 GOLDEN TORTOISE BEETLE OPTIMIZER

GTBO is used to optimally tune the hyperparameters of the proposed WT-MoE-SSM-EchoFormer for accurate prediction of CVD as illustrates in Figure 6. It is a population-based metaheuristic based on the color-switching and survival processes of golden tortoise beetles. It provides a good level of exploration and exploitation for the complex optimization tasks involved in DL.

Solution Representation and Fitness Evaluation

Each beetle is a potential configuration of hyperparameters for the WT-MoE-SSM-EchoFormer, which include learning rate, number of attention heads, expert weightings for MoE, state-space parameters and regularisation weights. The population is represented by:

$$P_{beetle} = \begin{pmatrix} b_{1,1} & b_{1,2} & \cdots & b_{1,n} \\ b_{2,1} & b_{2,2} & \cdots & b_{2,n} \\ \vdots & \vdots & \ddots & \vdots \\ b_{m,1} & b_{m,2} & \cdots & b_{m,n} \end{pmatrix} \tag{20}$$

Here, P_{beetle} stands population matrix signifying all candidate GTBO solutions. $m\ and\ n$ denotes population size and number of tunable WT-MoE-SSM-EchoFormer parameters. The fitness of each beetle is evaluated as,

$$F_{beetle} = \begin{pmatrix} f([b_{1,1}, b_{1,2}, \cdots, b_{1,n}]) \\ f([b_{2,1}, b_{2,2}, \cdots, b_{2,n}]) \\ \vdots \\ f([b_{m,1}, b_{m,2}, \cdots, b_{m,n}]) \end{pmatrix} \tag{21}$$

Here, F_{beetle} represents fitness vector of all beetles.

Initialization

The initial value of kth hyperparameter of ith beetle at G=1 is given as,

$$x_{i,1}^{k} = x_{min}^{k} + rand(0,1)\left(x_{max}^{k} - x_{min}^{k}\right) \tag{22}$$

Here, $x_{i,1}^{k}$ denotes initial value of kth hyperparameter for i^{th} beetle. $x_{max}^{k}\ and\ x_{min}^{k}$ denotes upper and lower bounds. This initialization assures extensive coverage of WT-MoE-SSM-EchoFormer hyperparameter search space.

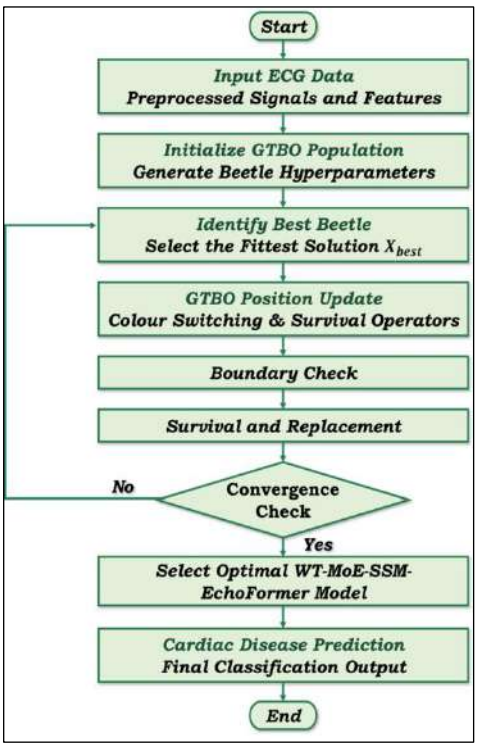

Figure 6: Flowchart for GTBO with WT-MoE-SSM-EchoFormer.
Source: Authors, (2026).

Color Switching Operator

The color switching operator updates the beetle position as,

$$V_i^G = X_i^G + S_{color}(X_{r1}^G - X_{best}^G) \tag{23}$$

Here, X_i^G stands current hyperparameter vector, X_{r1}^G stands randomly selected beetle, X_{best}^G denotes best performing configuration in generation G. S_{color} denotes color switching coefficient controlling exploration strength. These operators support the exploration of DL parameter space. The color switching coefficient is defined as,

$$S_{color} = \left(d_x n_x cos\theta_x + d_y n_y cos\theta_y\right) + h\lambda \tag{24}$$

With the dominant wavelength (λ) expressed as,

$$\lambda = \frac{2\alpha\bar{\phi}^2 - sin^2(\theta_z)}{k} \tag{25}$$

The stochastic variables are generated as,

$$\begin{cases} d_x, n_x = Randn\,(), \\ d_y, n_y = Randn\,() \cdot \beta, \\ \bar{\phi} = Cauchy(\sigma, \mu), \\ \theta_x, \theta_y = \beta, \\ \alpha, k, h = rand\,(), \\ \theta_z = 2\pi \cdot rand\,() \end{cases} \tag{26}$$

Here, $d_x\ and\ d_y$ stands directional displacement coefficient, n_x, n_y denotes normalized directional factor, $\theta_x, \theta_y, \theta_z$ represents random angular parameter. $\alpha\ and\ \beta$ stands random control parameter balancing exploration and exploitation. $\bar{\phi}$ stands random variable drawn from Cauchy distributions. $\sigma\ and\ \mu$ stands mean and scale parameters of Cauchy distributions. These randomized parameters prevent premature convergence and enhance training stability of WT-MoE-SSM-EchoFormmer.

Survival Operator

The survival operator creates refined hyperparameter solution using,

$$Beetle_1 = \alpha x_{r1} + (1 - \alpha)(x_{r2} - \sigma_1) \tag{27}$$

$$Beetle_2 = \alpha x_{r2} + (1 - \alpha)(x_{r1} - \sigma_2) \tag{28}$$

Where,

$$\begin{cases} \sigma_1 = (1 - \delta)(x_{best} - x_{r1}), \\ \sigma_2 = (1 - \delta)(x_{best} - x_{r2}) \\ \delta = \alpha\eta|p|^{\beta} \end{cases} \tag{29}$$

Here, $Beetle_1\ and\ Beetle_2$ stands offspring solutions generated through survival operators. $\sigma_1\ and\ \sigma_2$ represents adaptive correction, δ stands survival rate, $\eta\ and\ p$ denotes learning coefficient and random probability variables.

Table 1: Optimization details of GTBO.

Parameter	Value
Population Size	30
Maximum Iteration	50
Acceleration Coefficient	1.5
Random Factor	0.7
Spiral Probability	0.5
Convergence Coefficient	0.9
Exploration rate	0.6
Step size Factor	0.05

Table 1 signifying optimization parameter specifications. By combining GTBO and WT-MoE-SSM-EchoFormer attaining optimal hyperparameter tuning, faster convergence and increased generalization resulting in accurate and precise ECG based CVD prediction.

IV. RESULT AND DISCUSSION

This section presents experimental results and performance evaluation of the proposed WT-MoE-SSM-EchoFormer model using the GTBO. The experiments are performed in Python using MIT-BIH Arrhythmia Database in order to evaluate classification accuracy, robustness, and discriminative ability across multiple classes of ECGs.

Dataset details

Dataset Name:	MIT-BIH Arrhythmia Database
Dataset Type:	ECG Time-Series Signal
Sampling Frequency:	360 Hz
Recording Duration:	Approximately 30 minutes per subject
Number of Subjects:	47 patients (48 ECG recordings)
Class Names:	N – Normal beat, V – Ventricular ectopic beat, F – Fusion beat, Q – Unknown beat
Train & Test Split:	80:20

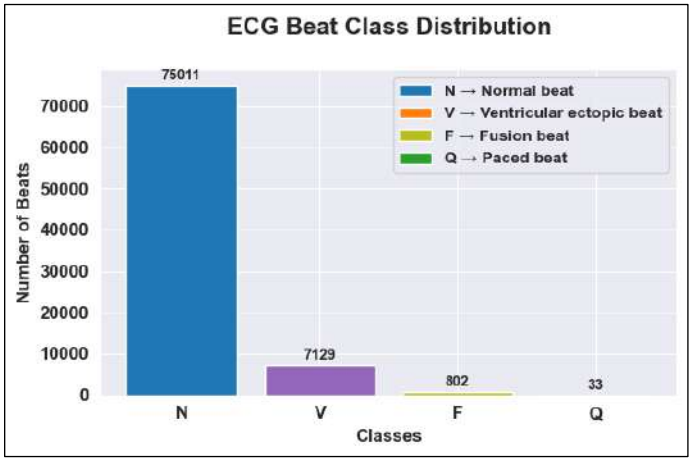

Figure 7: ECG beat class distribution in the MIT-BIH Arrythmia dataset.
Source: Authors, (2026).

Figure 7 represents class wise distribution of ECG beats in MIT-BIH Arrhythmia dataset. The dataset is highly imbalanced with Normal (N) beats forming the majority of 77,011 beats followed by Ventricular ectopic (V) with 7,129 beats. Fusion (F) class contains fewer samples of 802 beats and Unknown beat (Q) is severely underrepresented with 33 beats. This balance emphasizes the difficulty of developing effective classifiers for minority arrhythmia classes and supports the use of improved feature representation and adaptive learning processes in CVD prediction.

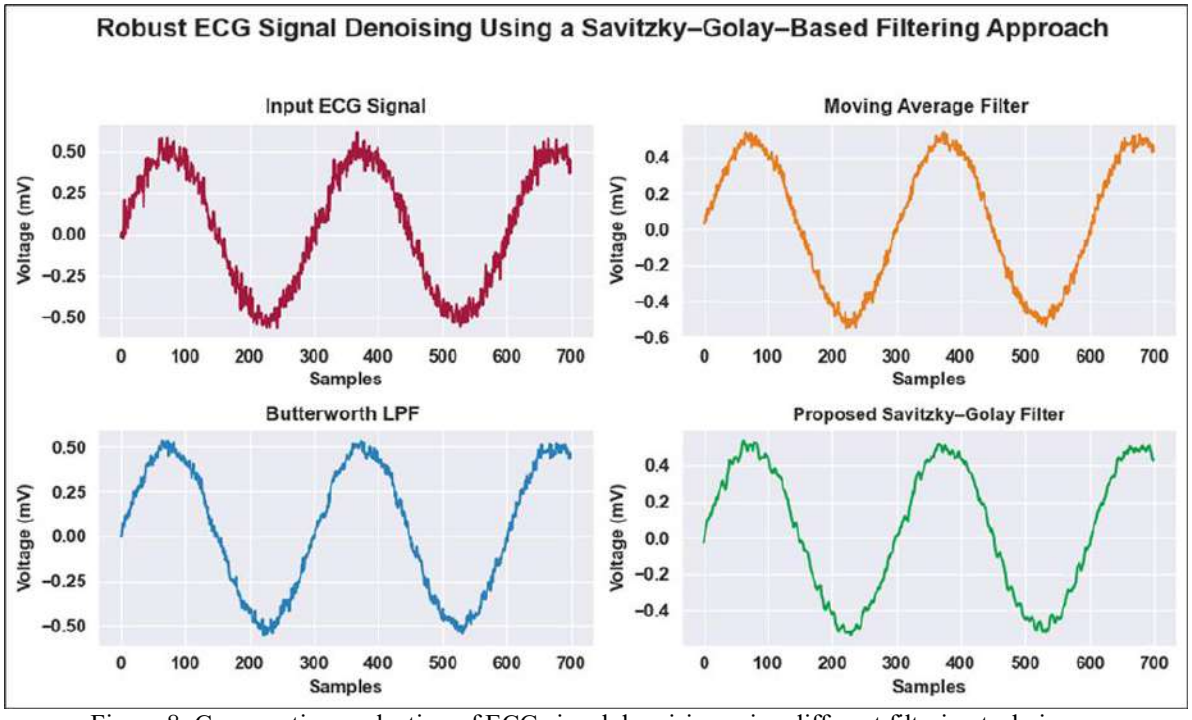

Figure 8: Comparative evaluation of ECG signal denoising using different filtering techniques.
Source: Authors, (2026).

Figure 8 compares different technique for denoising ECG signals. The raw ECG signal is HF noise and baseline wandering, making it difficult to understand the main features of the ECG. Applying a moving average filter to the signal help to reduce some of the noise, but the shape of the signal is greatly distorted, and reduced the important parts of the ECG components such as QRS peaks. The Butterworth Low Pass Filter (LPF) filter supresses the HF noise very well, but it slightly blurs the QRS complex edges, due to phase smoothing, which affect the accuracy of feature extraction.

However, the proposed method, a SG filter denoises the signal and keeps the main ECG features intact such as the sharpness of the peaks and the smoothness of the waveform. Thus, the proposed method is capable of accurately identifying QRS complexes and reliably measuring temporal intervals, thereby making it very effective for cardiac analysis and disease prediction purposes.

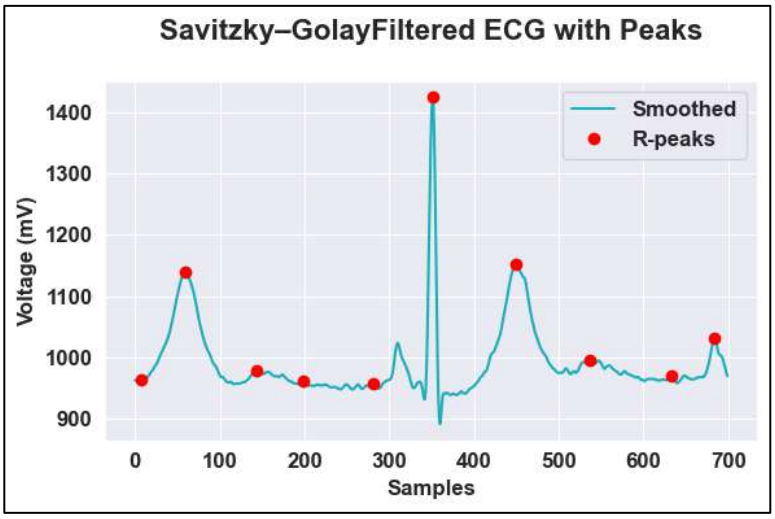

Figure 9: R-Peak detection on SG filtered ECG signal.
Source: Authors, (2026).

Figure 9 illustrates the detection of R-peaks on an ECG signal after denoising using SG filter. The smoothed ECG waveform preserves essential morphological characteristics while effectively decreasing HF noise. The observed R-peaks denoted by red dots, correspond to QRS complex maxima and serve as crucial reference points for calculating RR intervals, Heart Rate Variability (HRV) and temporal characteristics. Accurate R-peak localization is required for subsequent ECG feature extraction such as QRS duration and interval-based analysis which directly contributes to accurate cardiac disease categorization.

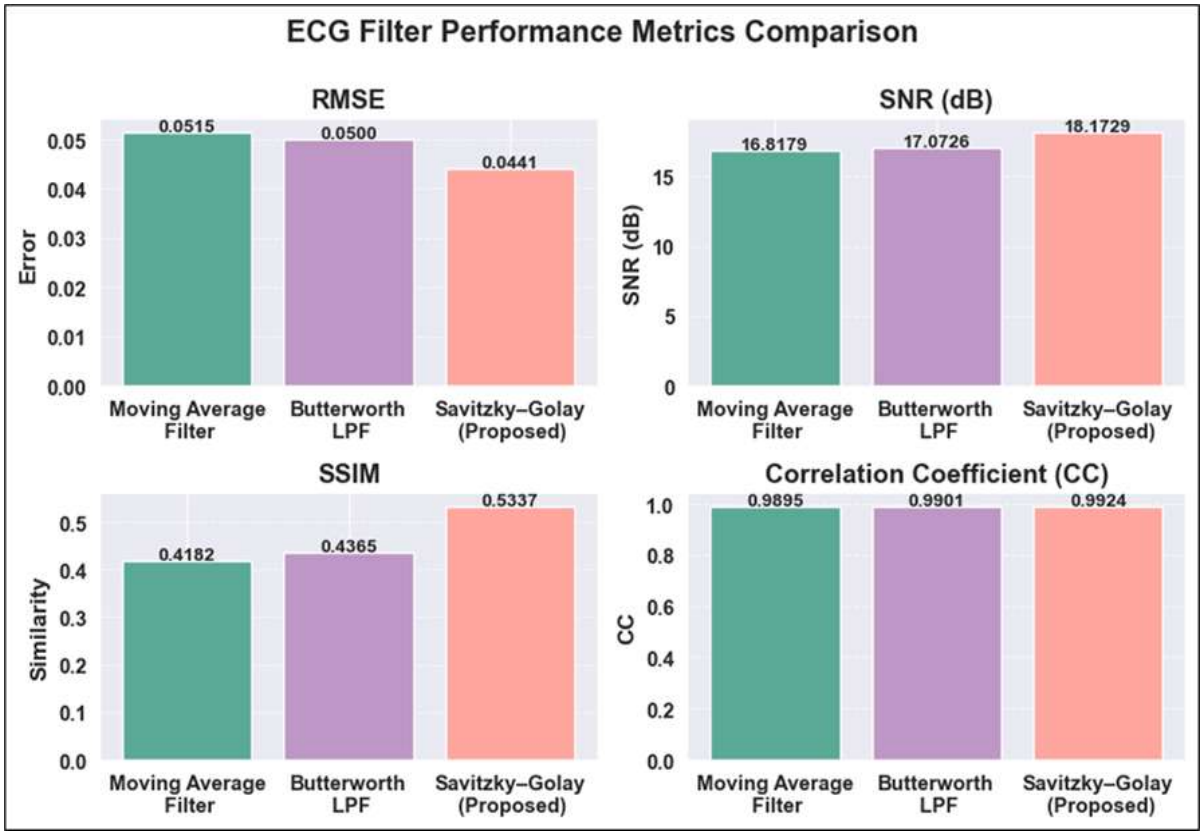

Figure 10: Performance comparison of ECG denoising filter.
Source: Authors, (2026).

Performance comparison shows Figure 10, that the proposed SG filter consistently beats traditional approaches on all evaluation metrics. It has the lowest RMSE of 0.0441 and greatest SNR of 18.1729 dB, suggesting excellent noise suppression and signal reconstruction accuracy. Furthermore, the proposed model has an SSIM of 0.5337 and correlation coefficient of 0.9924, signifying improved structure preservation and high similarity to the original ECG signal. These findings clearly show the proposed approach as the most effective ECG denoising method for accurate cardiac signal interpretation.

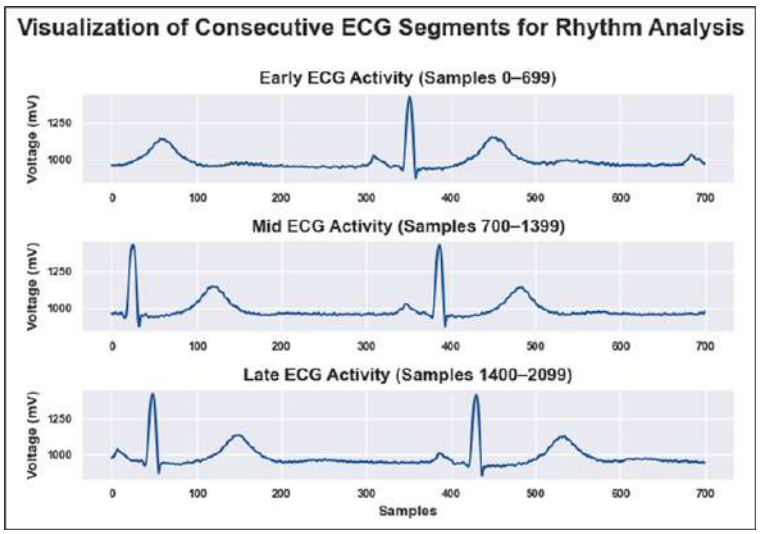

Figure 11: Visualization of consecutive ECG segments for Rhythm Analysis.
Source: Authors, (2026).

Figure 11 illustrates three consecutive ECG segments showing early, mid and late cardiac activity obtained from continuous recordings. Each section shows distinct P-QRS-T wave patterns allowing for visual analysis of rhythm consistency and beat morphology across time. The segmentation implies for effective temporal analysis of cardiac dynamics and consistent feature extraction for ECG classification and arrhythmia diagnosis.

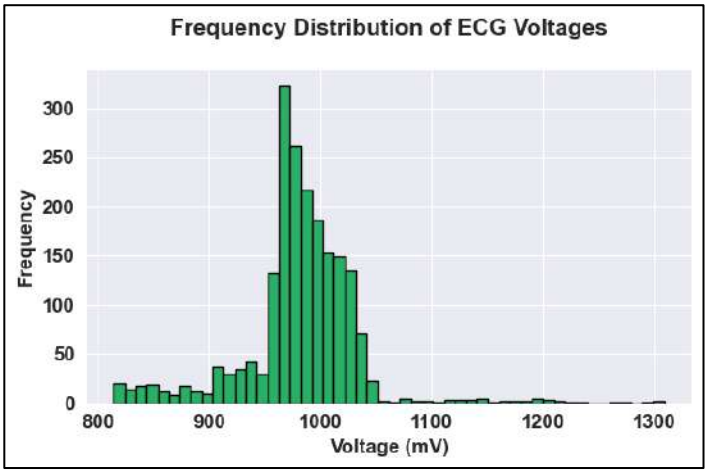

Figure 12: Frequency distribution of ECG voltages.
Source: Authors, (2026).

Figure 12 illustrates histogram of ECG voltage amplitudes, showing the distributions of signal values across the recordings. A high level within the mean voltage implies consistent heart activity, while the spread indicates physiological variability and the existence of notable waveform component such as QRS complex.

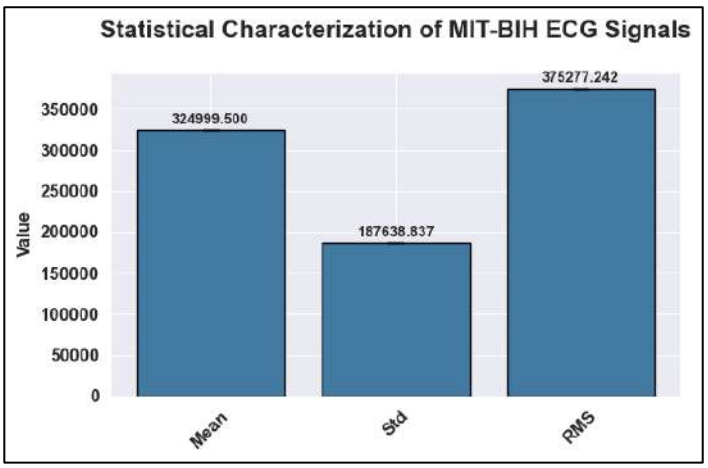

Figure 13: Statistical characteristics of MIT-BIH ECG signals.
Source: Authors, (2026).

Figure 13 summarizes key statistical measures of the ECG signals, including mean, standard deviation and Root Mean Square (RMS). The ECG signals exhibit a mean value of 324,999.5, a standard deviation of 187638.837mand RMS value of 375277.242, reflecting moderate variability and high signal energy suitable for accurate cardiac analysis.

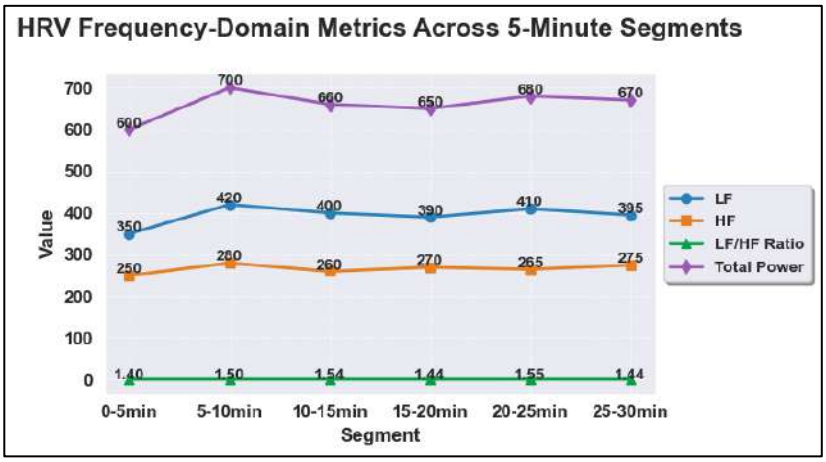

Figure 14: HRV frequency-domain metrics across 5-minute segments.
Source: Authors, (2026).

Figure 14 represents variation of HRV frequency domain parameters such as LF, HF, LF/HF ratio, and total power across successive 5-minute segments. Across consecutive 5-minutes intervals, LF varies between 350 and 420, HF ranges from 250 t0 280, the LF/HF ratio remains stable at 1.40-1.55 and total power fluctuate between 600 and 700, signifying consistent automatic regulation over time.

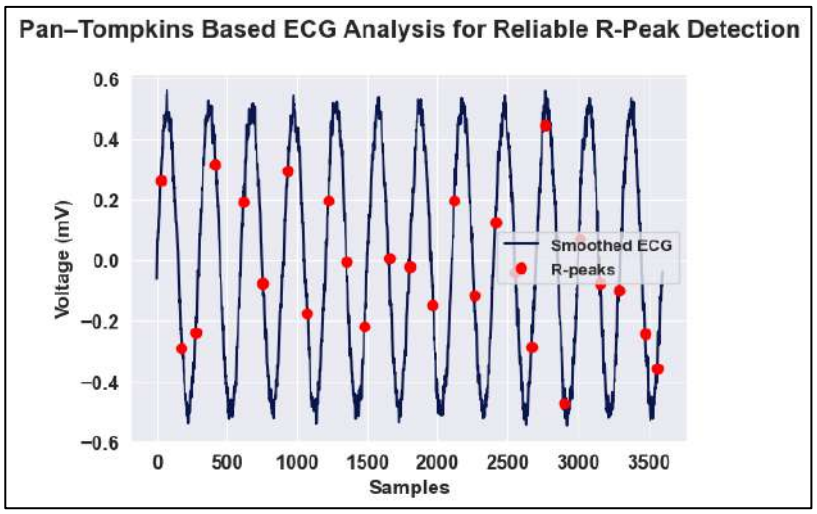

Figure 15: Pan-Tompkins based ECG analysis.
Source: Authors, (2026).

Table 2: Extracted ECG features using Pan-Tompkin's algorithm.

Source: Authors, (2026).

Figure 15 represents the smoothed ECG waveform processed using Pan-Tompkins algorithm. The detected R-peaks are highlighted on the signal, signufying accurate localization of QRS complexes across successive cardiac cycles, which is crucial foe strong heartbeat detection and rhythm analysis. Table 2 represents numerical features extracted from the detected R-peaks including R-Peaks indes, RR intervals, heart rate and QRS duration. These features provide quantiative information of cardiac activity and utilized for further analysis and classification of cardiac conditions.

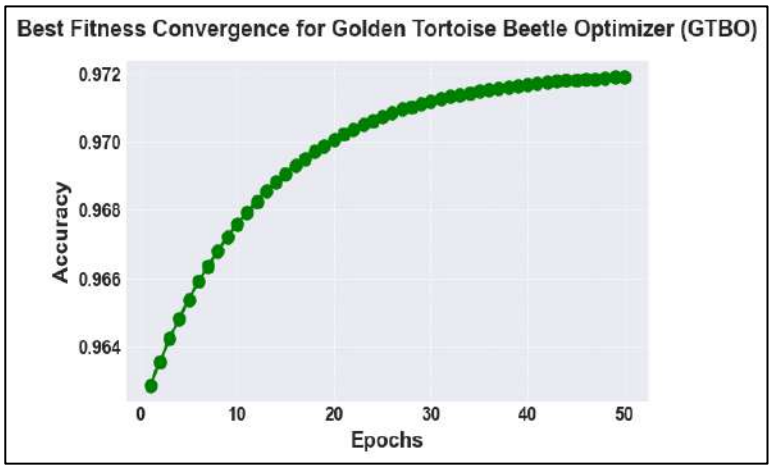

Figure 16: Best fitness convergence curve of GTBO.
Source: Authors, (2026).

Figure 16 shows convergence process of the GTBO with the number of epochs. The smooth saturation of the accuracy towards the optimal value shows the good exploration-exploitation trade-off and the strong ability of the optimizer to reach high-quality solutions.

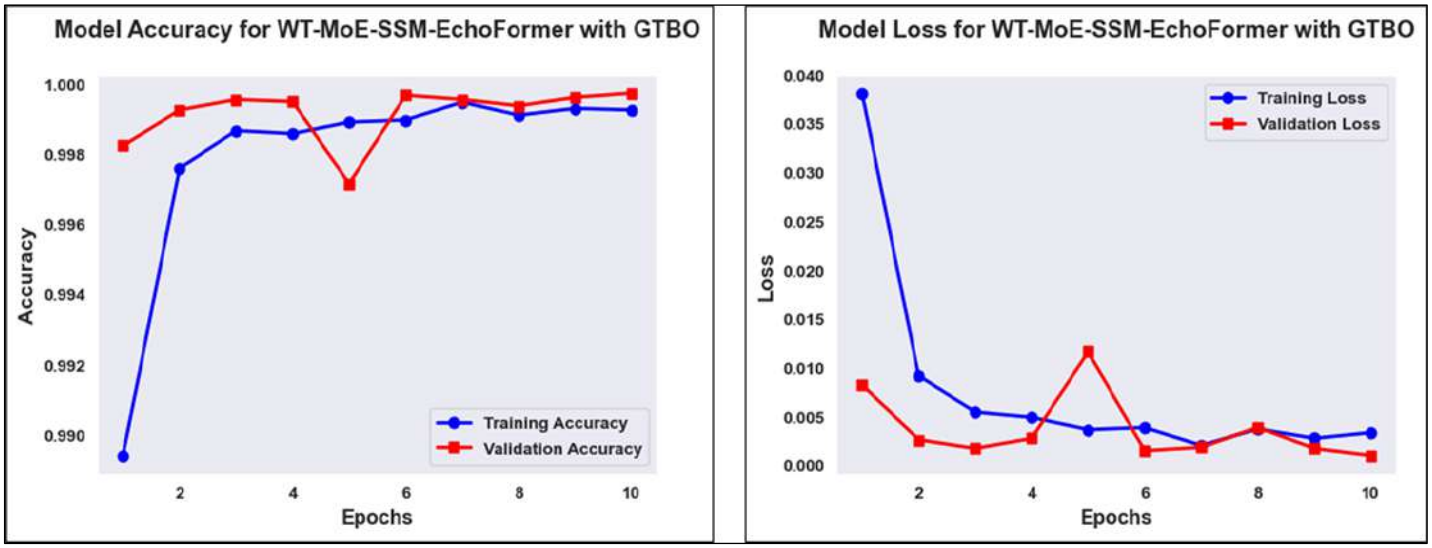

Figure 17: Model accuracy and loss curves for WT-MoE-SSM-EchoFormer with GTBO.
Source: Authors, (2026).

Figure 17 shows training and validation performance of the WT-MoE-SSM-EchoFormer model optimized by GTBO. It shows that the training and validation accuracy of model increases very quickly and converges to values above 99% and displays loss of the model, which converges to very low values.

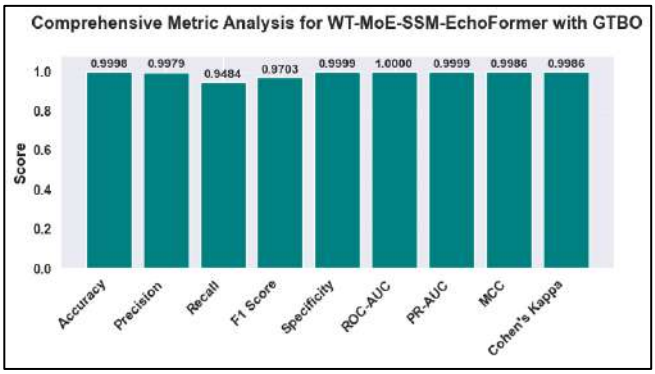

Figure 18: Performance metrics for proposed model.
Source: Authors, (2026).

Figure 18 illustrates a comprehensive comparison of various performance metrics obtained by the proposed WT-MoE-SSM-EchoFormer model optimized GTBO. The WT-MoE-SSM-EchoFormer model optimized by GTBO obtains an accuracy of 0.9998 and precision of 0.9979, signifying highly positive class predictions. Recall of 0.9484 and F1-score of 0.9703 also confirm a well-balanced sensitivity and classification stability. The model obtains specificity of 0.9999, ROC-AUC of 1.0000, and PR-AUC of 0.9999, signifying a highly dependable discriminative power. MCC of 0.9986 and Cohen's Kappa of 0.9986, signifying the excellence of the proposed method.

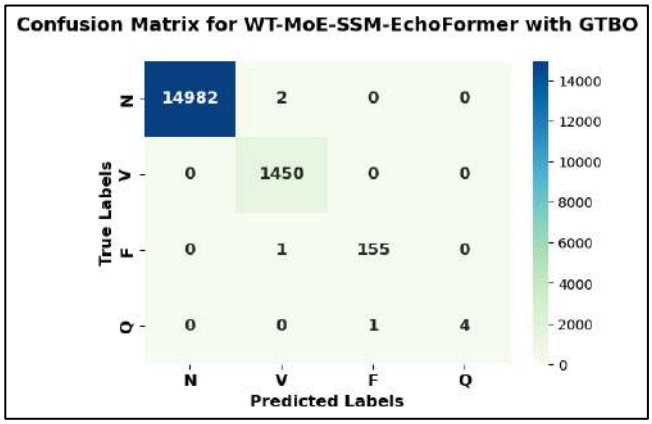

Figure 19: Proposed model confusion matrix structure.
Source: Authors, (2026).

Figure 19 shows confusion matrix that indicates classification performance of the WT-MoE-SSM-EchoFormer model optimized by GTBO on ECG beat classes (N, V, F, Q). The model has been able to correctly classify most of the beats, obtaining 14,982 correct classifications for Normal (N) beats, 1,450 for Ventricular ectopic (V) beats, 155 for Fusion (F) beats, and 4 for Unknown (Q) beats, with only a negligible number of misclassifications. The high diagonal dominance of confusion matrix indicates high accuracy and robustness of the proposed model.

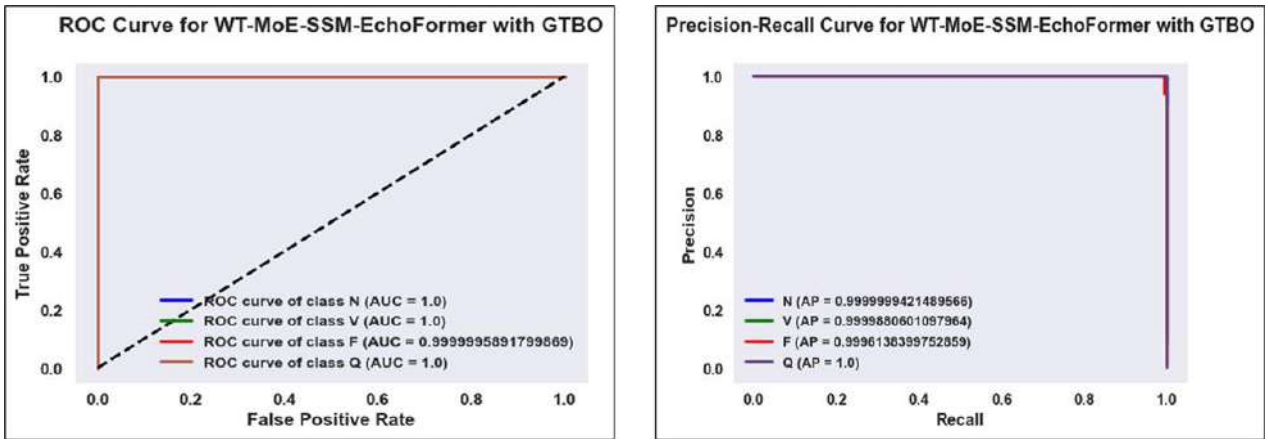

Figure 20: ROC and Precision-Recall Curves for proposed model.
Source: Authors, (2026).

Figure 20 shows performance of the classification task of the proposed WT-MoE-SSM-EchoFormer model optimized with GTBO on the ROC and Precision-Recall curves for all classes of ECG signals (N, V, F, and Q). The ROC curves clearly show the near-perfect discrimination power of the model with an AUC value of 1.0 for all classes, which is a clear indication of the excellent trade-off and Precision-Recall curves show an excellent average precision value of 1.0 for all classes.

Existing Approaches:

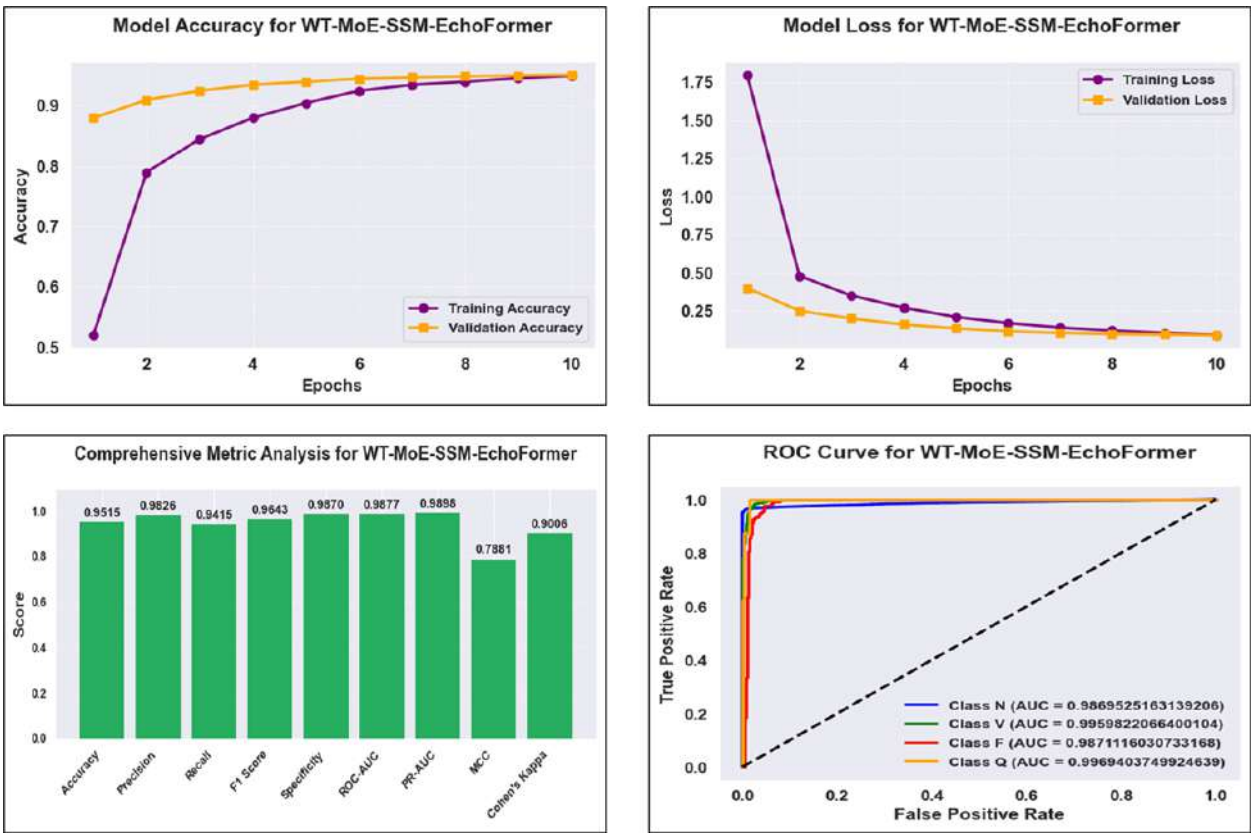

Figure 21: Performance analysis of existing WT-MoE-SSM-EchoFormer model.
Source: Authors, (2026).

Figure 21 illustrates performance analysis of existing WT-MoE-SSM-EchoFormer model. Training and validation accuracy and loss of existing WT-MoE-SSM-EchoFormer model, along with its overall classification metrics. The accuracy plots indicate a steady improvement in the model with convergence at 95%, whereas the loss plots indicate a gradual decrease, signifying a good learning process. The overall classification metrics obtains an accuracy of 0.9515, precision of 0.9826, recall of 0.9415, F1-score of 0.9643, specificity of 0.9870, ROC-AUC of 0.9877, PR-AUC of 0.9898, MCC of 0.7881 and Cohen's Kappa of 0.9006, clearly indicate that the existing model performs well on the classification task. However, when compared to the proposed GTBO-optimized WT-MoE-SSM-EchoFormer model, the proposed model achieves better convergence, accuracy, and generalization. The ROC analysis provides a measure of the performance of the classification task, obtaining AUC values of 0.98695 for class N, 0.99598 for class V, 0.98711 for class F, and 0.99694 for class Q. While these values clearly indicate a high predictive capability, they are relatively lower compared to the ones obtained by the proposed GTBO-optimized WT-MoE-SSM-EchoFormer model.

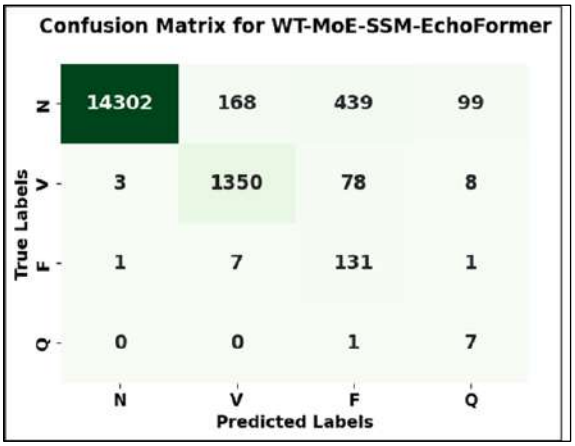

Figure 22: Confusion matrix for WT-MoE-SSM-EchoFormer.
Source: Authors, (2026).

Figure 22 shows the performance of the existing WT-MoE-SSM-EchoFormer model based on confusion matrix. The model is able to correctly classify 14,302 samples of class N, 1,350 samples of class V, 131 samples of class F, and 7 samples of class Q. However, there are some samples that are misclassified, such as 439 samples of class N to F, 168 samples of N to V, and 78 samples of V to F.

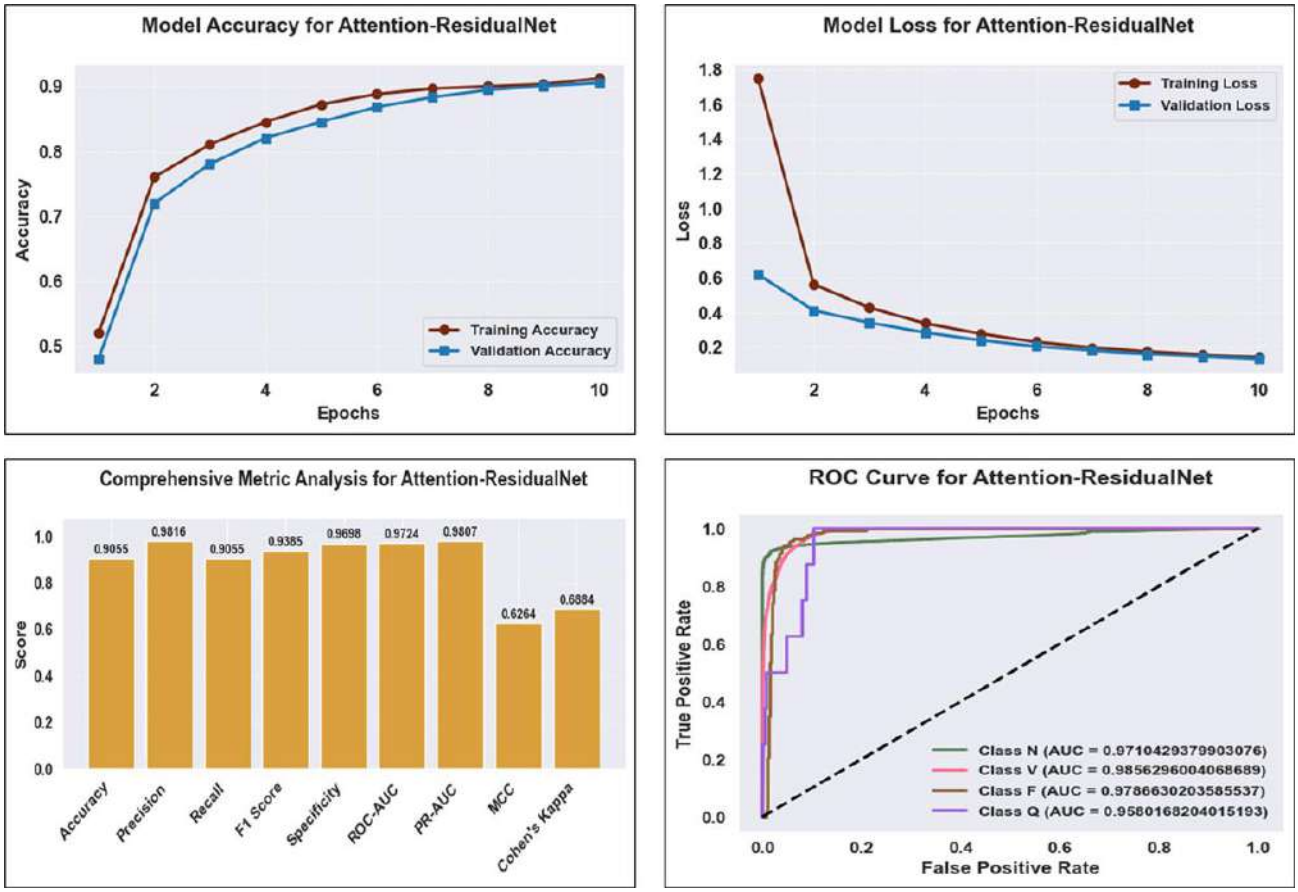

Figure 23: Performance evaluation of Attention ResidualNet Model.
Source: Authors, (2026).

Figure 23 represents training and validation performance of Attention-ResidualNet in terms of accuracy, loss, overall metrics, and ROC analysis. The model has an overall accuracy of 0.9055, precision of 0.9816, recall of 0.9055, and F1-score of 0.9385, which is well balanced. The ROC analysis also shows high discriminative power with AUC values of 0.9710 (Class N), 0.9856 (Class V), 0.9787 (Class F), and 0.9580 (Class Q). However, these values are lower compared to the proposed GTBO-optimized model, which proves that the proposed model is better in terms of accuracy, robustness, and class separability.

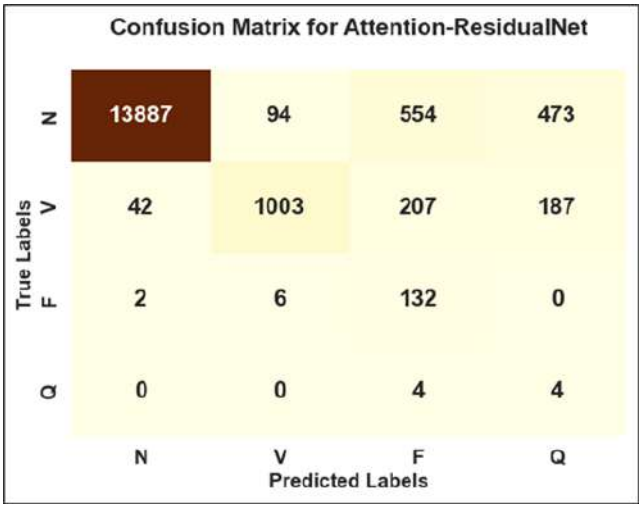

Figure 24: Confusion matrix of Attention ResidualNet.
Source: Authors, (2026).

Confusion matrix of the Attention-ResidualNet on four classes (N, V, F, and Q) is shown in Figure 24. The Attention-ResidualNet correctly classifies 13,887 samples of class N, 1,003 samples of class V, 132 samples of class F, and 4 samples of class Q, which shows fair classification of most classes.

However, there are some noticeable misclassifications, such as class N vs. F (554 samples) and Q (473 samples), and class V vs. F (207 samples) and Q (187 samples). These misclassifications show the limitations of class discrimination, particularly for minority classes, while the proposed GTBO-optimized model performs better in classification accuracy and misclassification.

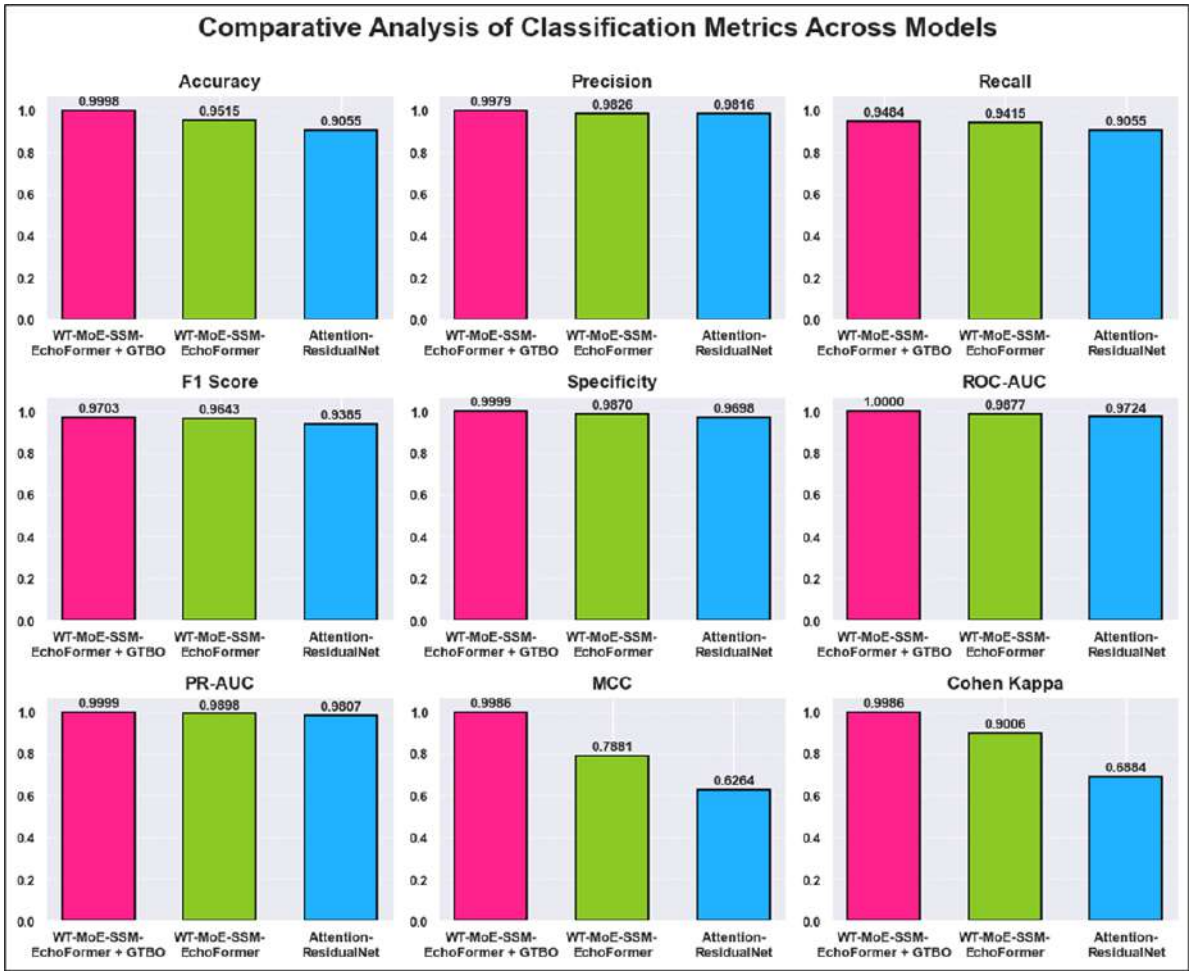

Figure 25: Comparative analysis of classification metrics across models.
Source: Authors, (2026).

Figure 25 compares the performance of three models, namely WT-MoE-SSM-EchoFormer with GTBO, WT-MoE-SSM-EchoFormer, and Attention-ResidualNet, on various evaluation metrics. The proposed WT-MoE-SSM-EchoFormer with GTBO outperforms all other models on all evaluation metrics, including accuracy of 0.9998, precision of 0.9979, recall of 0.9484, F1-Score of 0.9703, specificity of 0.9999, ROC-AUC of 1.0000, PR-AUC of 0.9999, MCC of 0.9986, and Cohen's Kappa of 0.9986. In contrast, the baseline WT-MoE-SSM-EchoFormer and Attention-ResidualNet perform relatively poorly on most evaluation metrics.

Table 3: Evaluation of accuracy across different previous literature.

REF	Methods	Dataset used	Accuracy
[11]	XGBoost	PTB-XL dataset	88.44%
[12]	Extra-Trees	Open-source dataset for heart disease prediction	95.48%
[13]	ANN	Heart disease dataset	92.50%
[14]	Rhythm-CNN	MIT-BIH + BIDMC dataset	98.52%
[15]	VGG16	ECG Images dataset of Cardiac and COVID-19 Patients	95%
[16]	Google ViT Resnet50	ECG Images of Cardiac and COVID-19 patients	98%
[17]	HybDeepNet	MIT-BIH	98.6%
[18]	Swin	ECG images dataset	95.5%
[19]	TransConvNet	MIT-BIH arrhythmia	98.6%
[20]	Self-Attention Transformer	Cleveland dataset	96.51%
Ours	PROPOSED	MIT-BIH Arrhythmia Database	99.98%

Source: Authors, (2026).

Table 3 indicates comparative accuracy analysis of existing ECG based cardiac disease prediction methods reported in the literature. The GTBO with WT-MoE-SSM-EchoFormer model, which is tested on the MIT-BIH Arrhythmia Database, outperforms all the other methods in terms of classification accuracy and attains a value of 99.98%.

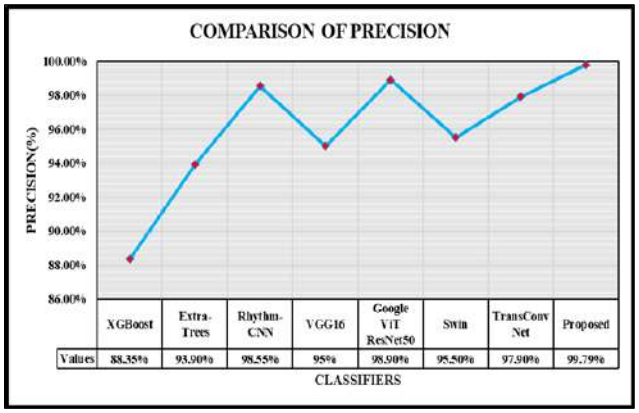

Figure 26: Evaluation of precision.
Source: Authors, (2026).

Figure 26 evaluate precision of various classifiers. XGBoost has 88.35%, and Extra-Trees increase to 93.90%. Rhythm-CNN and Google ViT-ResNet50 have a precision of 98.55% and 98.90%, respectively, whereas VGG16 and Swin have a precision of 95.0% and 95.50%, respectively. TransConvNet has a precision of 97.90%, and the proposed model has the maximum precision of 99.79%.

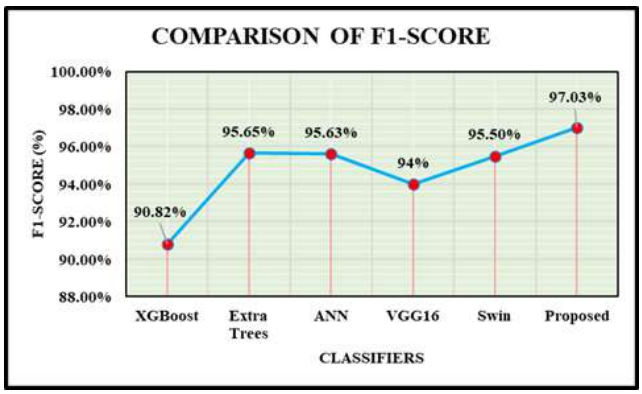

Figure 27: Evaluation of F1-Score.
Source: Authors, (2026).

Figure 27 represents F1-score of each classifier, where XGBoost attained 90.82%, followed by Extra-Trees of 95.65% and ANN of 95.63%. The F1-score for VGG16 is slightly lower at 94.0%, Swin attain to 95.50% and the proposed model achieves highest F1-score of 97.03%.

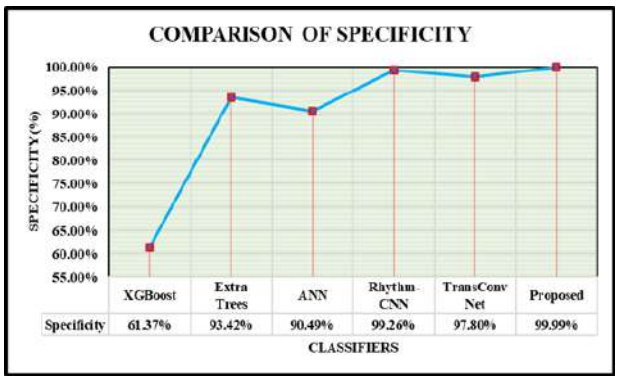

Figure 28: Evaluation of specificity.
Source: Authors, (2026).

Figure 28 compares specificity of each classifier in the existing literature. The specificity of XGBoost is low at 61.37%, while that of Extra-Trees and ANN is 93.42% and 90.49%, respectively. The specificity of Rhythm-CNN and TransConvNet is attained 99.26% and 97.80%, respectively. The specificity of the proposed model is maximum value of 99.99%, which proves its effectiveness in identifying negative cases correctly.

V. CONCLUSION

In this work, a new framework of ECG-based cardiac disease strong and intelligent approach that combines GTBO with WT-MoE-SSM-EchoFormer Architecture. With the aid of SG filtering technique to denoise ECG signals without losing essential morphological aspects such as QRS complexes and RR intervals crucial in the clinical analysis of ECGs. Using EDA including statistical, temporal, and morphological pattern achieved effective ECG signals analysing which leading to a highly informative signal representation. Clinical features of heart rhythm dynamics such as RR interval, QRS duration, HRV extracted accurately using the Pan–Tompkin's algorithm.

The hybrid WT-MoE-SSM-EchoFormer integrates the ability to identify and extract features from multiple resolutions, adaptive learning capabilities of multiple experts, and model Temporal information over long-term periods, resulting in accurate classifications of ECG-based cardiac diseases. Hyperparameter tuning performed with the aid of the GTBO achieved highly stable training process, faster training epochs and improved generalization. Results from extensive testing by Python software with MIT-BIH Arrhythmia Database yielded a classification accuracy of 99.98%, precision of 99.79%, recall of 94.84%, F1 score of 97.03%, specificity of 99.99%, and a ROC-AUC of 1.0000. Thus, the proposed framework demonstrates a very high level of discrimination across all ECG type classes.

ABSTRACT

Fermatean Fuzzy Graph (FFG) is a prominent mathematical model effective in conveying uncertainty, hesitation and dual membership characteristics in decision-making domains where traditional models often exhibit ineptness in handling complex ambiguities. Thereby, an extensive investigation of Fermatean fuzzy graphs within decision-making frameworks is executed in this study to emphasise their theoretical underpinnings, structural attributes and practical implications. Through the extension of Fermatean fuzzy set theory, the proposed model represents each vertex and edge with cubic membership, non-membership and hesitation degrees. This in turn results in the enrichment of the descriptive capacity of relational data structures. Key operations including union, intersection, complement and Cartesian product are formulated in the study under Fermatean conditions, and their algebraic and topological features are then thoroughly discussed. In order to support multi-criteria evaluations in contexts characterised by ambiguity and contradicting information, the developed decision-making model incorporates FFG structures with weighted aggregation operators and similarity measures. The superior ability of FFGs to handle uncertainty with enhanced precision and decision dependability is demonstrated by comparison with intuitionistic and Pythagorean fuzzy graph models.

I. INTRODUCTION

Professionals from a wide range of fields deal with complicated, multi-criteria scenarios in modern decision environments that are marked by ambiguity, insufficient information and conflicting objectives. Under these conditions, Decision-Making (DM) is a cognitive process of reasoning and judgement rather than just a computational task [1], [2]. It seeks to choose the best option that strikes a fair balance between a number of conflicting criteria [3]. However, on the downside, the lines between ideal and non-ideal decisions are frequently blurred by real-world uncertainty, rendering traditional deterministic methods inept [4]. Multi-Criteria Decision-Making (MCDM) techniques have been created as organised analytical structures to address this ambiguity [5-7]. These methods allow for the logical comparison and ranking of alternatives according to both quantitative and qualitative criteria. Among the various MCDM techniques, the Technique for Order Preference by Similarity to the Ideal Solution (TOPSIS) [8], Analytic Hierarchy Process (AHP) [9], VIKOR [10] and ELECTRE [11] have been recognized as effective approaches for ranking and selecting alternatives. By measuring each alternative's distance from ideal and anti-ideal points, these models identify the optimal solution. However, their reliance on crisp data limits their effectiveness in uncertain or hesitant settings where decision-maker's viewpoints are vague and often contradictory. Consequently, the combination of fuzzy logic with MCDM techniques proved a significant breakthrough as it is effective in combining algorithmic rigour with human reasoning [12]. The foundation of uncertainty modelling was established by Zadeh's Fuzzy Set Theory (FST), which introduced the idea of partial membership between 0 and 1 to measure vagueness. However, decision-makers frequently feel both agreement and disagreement with a certain attribute at the same time while making decisions in real-world assessments [13]. Atanassov developed Intuitionistic Fuzzy Sets (IFS) to account for this dual nature. IFS includes an indeterminacy measure in addition to membership and non-membership degrees [14]. Subsequently, Yager presented Pythagorean Fuzzy Sets (PFS), which provide more flexibility than IFS by limiting the squared sum of membership and non-membership degrees to unity. Despite broadening the uncertainty domain, PFS models were inadequate in situations where membership and non-membership values were large, resulting in overly constrained hesitation ranges [15].

For subduing this, Senapati and Yager created FFS, which feature a cubic constraint that allows for a more flexible and expansive representation of uncertainty. Because the FFS model preserves mathematical validity while permitting decision-makers to communicate stronger but conflicting ideas, it effectively captures severe uncertainty [16]. As a result, FFS has drawn interest in fields where uncertainty and hesitancy predominate, like risk management, supplier selection, medical diagnosis and environmental evaluation. The FFG model is a recent development that builds on this progress by extending the Fermatean concept into relational domains. An FFG uses Fermatean membership and non-membership degrees to define each vertex, which represents an alternative and each edge, which indicates the relationship or similarity between alternatives. In contrast to traditional FFS or PFS designs, this structure enables the model to capture not just uncertainty in discrete criteria but also the interdependencies across alternatives. By facilitating multi-level reasoning and uncertainty transmission among interconnected entities, the FFG offers decision systems a relationally enhanced perspective. Using FFG to develop an integrated decision-support model that analyses relational, hesitant and ambiguous data with improved interpretability serves as the motivation for this research. By integrating similarity computations with Fermatean aggregation in a graph-theoretic structure, the proposed research seeks to provide well-rounded choice results that account for both individual and collective uncertainty.

II. LITERATURE REVIEW

The conceptual evolution of fuzzy decision systems has followed a logical progression from Fuzzy Sets (FS) to IFS, PFS and most recently, FFS. Although uncertainty representation was made possible by [17] groundbreaking work in 1965, the original FS framework could only evaluate membership on a single dimension. In (1999) [18] developed IFS to address this, including a hesitation index to account for partial preferences and a complementing non-membership component. In MCDM contexts, IFS techniques promptly came into use in fields like risk assessment, medical diagnostics and supplier evaluation. As decision complexity grew, by [19] extended IFS into PFS, employing the quadratic relation $\mu^2 + v^2 \leq 1$ to enlarge the uncertainty zone and offer improved flexibility. A number of research efforts incorporated PFS-based models into established MCDM methodologies. For instance, in (2018) [20] employed Hausdorff metric-based PFS distances, in [21] used cosine similarity measures for fuzzy TOPSIS, and [22] proposed generalized distance metrics for ranking alternatives. PFS techniques have been limited in expressing extreme hesitation, where both degrees of belief and disbelief are simultaneously high, despite their broad application. In [23] introduced the cubic constraint $\mu^3 + v^3 \leq 1$ in their FFS structure to overcome this constraint. By capturing greater levels of hesitancy and uncertainty, the Fermatean model established itself as a sophisticated extension of IFS and PFS. Subsequent research expanded FFS to include similarity metrics, correlation coefficients and aggregation operators for a variety of decision-making applications.

In [24] utilized FFS in medical decision analysis, while in [25] applied Fermatean fuzzy weighted sum methods in product evaluation. These investigations show that the cubic formulation provided better decision accuracy and modelling flexibility. The graph-based extension of fuzzy systems further advances the field. Fuzzy Graphs (FGs), Intuitionistic Fuzzy Graphs (IFGs) and Pythagorean Fuzzy Graphs (PFGs) were developed to incorporate relational structures among decision elements. The limitations of their underlying fuzzy theories were still present in these models. This was addressed with the introduction of the FFG, which combines the structural resilience of graph theory with the expressive capacity of FFS. Relational analysis under higher-order uncertainty is made possible by FFGs, which use Fermatean numbers to define vertex and edge relationships. In multi-criteria fields including social influence analysis, renewable energy planning and logistics optimisation, this model demonstrated its worth. Recent research has investigated quantifying relational proximity between vertices using Fermatean distance and similarity functions, which increases the accuracy of MCDM systems. To ensure that both determinacy and hesitation are taken into account in the final decision, FFG-based similarity operators, for instance, permit alternative ranking based on aggregated uncertainty. Additionally, the FFG supports both qualitative and quantitative evaluations by offering a unified platform for integrating multi-attribute information. FFG is especially applicable to modern decision issues with contradictory, interdependent and conflicting data because of these advantages.

II.1 RESEARCH GAP AND OBJECTIVES

The integration of Fermatean theory with graph-based decision modelling has not been extensively studied, despite the fact that many studies have improved MCDM frameworks employing IFS, PFS and FFS models. While conventional fuzzy systems mainly handle uncertainty at the level of individual criteria, they are unable to capture inter-criterion and inter-alternative relationships. Similarly, the majority of distance-based decision-making techniques, such as fuzzy TOPSIS and PFS-VIKOR, are restricted to vector-based assessments and disregard relational dependencies. Their applicability in complex systems, such energy dispatch, transportation logistics, healthcare systems, and intelligent urban planning, where decisions are inevitably networked or interactive, is limited by this gap. The proposed research suggests a FFG–driven decision framework that combines relational modelling with Fermatean uncertainty principles in order to address this research gap. The following are the objectives of this research,

- To use FFG to build a mathematical model of decision alternatives that accounts for relational and nodal uncertainty.
- To create similarity and Fermatean aggregation operators to assess the relative proximity of selection options.
- To combine all metrics into a single decision layer that calculates normalised similarity indices and determines the optimal alternative with maximum confidence.
- To demonstrate the superiority of the proposed FFG model compared with existing IFS- and PFS-based MCDM frameworks in handling ambiguous, interdependent information

The goal of this technique is to develop a thorough uncertainty-aware decision model that can generate precise, consistent, and comprehensible results in settings where uncertainty, conflict and hesitation coexist.

III. THEORETICAL BACKGROUND

III.1 FERMEATEAN FUZZY SET (FFS)

In an effort to effectively manage hesitancy and contradiction in uncertain information, fuzzy logic has undergone multiple extensions, starting with Zadeh's fuzzy set and progressing with Atanassov's Intuitionistic Fuzzy Set (IFS) and Yager's Pythagorean Fuzzy Set (PFS). Nevertheless, the ability of both IFS and PFS to depict scenarios involving high levels of simultaneous belief and disbelief remains confined. The concept of FFS introduced by Senapati and Yager improves these prior models with the substitution of a cubic condition for the quadratic constraint of PFS. Through this improvement, the feasible region of membership and non-membership values are broadened substantially, thereby allowing for richer and more balanced uncertainty modelling for relational, control and decision-making systems.

III.1.1 Definition

Let X denote a non-empty universe of discourse. A Fermatean fuzzy set I on X is expressed as,

$$I = \{\langle x, \mu_I(x), v_I(x)\rangle : x \in X\} \tag{1}$$

Where, $\mu_I(x): X \to [0,1]$ and $v_I(x): X \to [0,1]$ represent the degrees of membership and non-membership, respectively. These values satisfy the cubic constraint,

$$0 \leq \left(\mu_I(x)\right)^3 + \left(v_I(x)\right)^3 \leq 1 \tag{2}$$

The hesitation degree of x is derived as,

$$\pi_I(x) = \sqrt[3]{1 - \left(\mu_I(x)\right)^3 - (v_I(x))^3} \tag{3}$$

which measures the residual uncertainty associated with the element. A pair (μ, v) that fulfils (2) is known as Fermatean Fuzzy Number (FFN). The extreme FFNs are $x^+ = (1,0)$ indicating full membership and $x^- = (1,0)$ representing full non-membership.

III.1.2 Operational Laws

For any two FFNs $\rho_1 = (\mu_1, v_1)$ and $\rho_2 = (\mu_2, v_2)$ and a positive scalar $\lambda > 0$, the algebraic operations are defined as follows,

$$\rho_1 \oplus \rho_2 = \left(\sqrt[3]{\mu_1^3 + \mu_2^3 - \mu_1^3\mu_2^3 v_1 v_2}, v_1 v_2\right) \tag{4}$$

$$\rho_1 \oplus \rho_2 = \left(\mu_1\mu_2\sqrt[3]{v_1^3 + v_2^3 - v_1^3 v_2^3}\right) \tag{5}$$

$$\lambda_\rho = \left(\sqrt[3]{1 - (1 - \mu^3)^\lambda}, v^\lambda\right) \tag{6}$$

$$\rho^\lambda \left(\mu^\lambda, \sqrt[3]{1 - (1 - v^3)^\lambda}\right) \tag{7}$$

$$\rho^c = (v, \mu) \tag{8}$$

Consistent computation in complex modelling systems is made possible by these procedures, which maintain the cubic constraint and guarantee algebraic closure within the FFS domain.

III.1.3 Distance and Similarity Measures

For two FFNs $\rho_1 = (\mu_1, v_1)$ and $\rho_2 = (\mu_2, v_2)$, the Fermatean Fuzzy Distance (FFD) is defined as,

$$FFD(\rho_1, \rho_2) = \sqrt{\frac{1}{2}[(\mu_1^3 - \mu_2^3)^2 + (v_1^3 - v_2^3)^2 + (\pi_1^3 - \pi_2^3)^2]} \tag{9}$$

Where, $\pi_i = \sqrt[3]{1 - \mu_i^3 - v_i^3}$ $(i = 1,2)$. The Fermatean Fuzzy Similarity (FFS) measure, expressing the closeness between two FFNs, is obtained as,

$$FFS(\rho_1, \rho_2) = 1 - FFD(\rho_1, \rho_2) \tag{10}$$

While lower values signify greater divergence, a similarity score close to 1 suggests a high level of agreement between the two fuzzy evaluations.

III.1.4 Interpretation and Relevance

Compared to intuitionistic and Pythagorean frameworks, the cubic formulation of FFS offers greater flexibility by expanding the acceptable uncertainty zone. It captures instances in which an element exhibit both strong membership and non-membership inclinations at the same time, which is typical in scenarios involving uncertainty or contradicting information when making decisions.

The proposed FFG model in this work is mathematically supported by the FFS. FFNs, whose membership, non-membership and hesitation degrees jointly reflect the confidence, opposition, and vagueness inherent in relational data, are used to parameterise each vertex and edge in the graph. These features allow the model to evaluate similarity and conduct fine-grained reasoning in hesitant or uncertain contexts.

III.2 FERMEATEN FUZZY GRAPH (FFG)

A useful mathematical tool for illustrating pairwise interactions between items is graph theory. Each vertex and edge in a classical fuzzy graph has a unique membership degree that indicates the existence or strength of a relation. Nevertheless, uncertainty or contradicting information cannot be handled by such models. Figure 1 provides the basic fuzzy graph representation. The FFG, a model that describes membership, non-membership and indeterminacy simultaneously through cubic interactions, is the outcome of integrating FFS theory into graph topologies. This addition strengthens the graph's descriptive capabilities, which makes it especially appropriate for complex decision-making situations involving interconnected entities that exhibit hesitation, contradiction or uncertainty.

III.2.1 Definition of Fermatean Fuzzy Graph

Let X be a universal set and $P = (\alpha_P, \beta_P)$ represent an FFS on X. A FFG on X is denoted by $G = (P, Q)$, where $Q = (\alpha_Q, \beta_Q)$ is a Fermatean fuzzy relation on $X \times X$. The structure satisfies the following conditions,

$$\alpha_Q(u, v) \leq min\{\alpha_P(u), \alpha_P(v)\} \tag{11}$$

$$\beta_Q(u, v) \geq max\{\beta_P(u), \beta_P(v)\} \tag{12}$$

$$\left(\alpha_Q(u, v)\right)^3 + \left(\beta_Q(u, v)\right)^3 \leq 1 \tag{13}$$

|For all $u, v \in X$. Here, $\alpha_Q(u, v)$ and $\beta_Q(u, v)$ denote the membership and non-membership degrees of the edge connecting vertices u and v. The hesitation associated with the edge is obtained as,

$$\pi_Q(u, v) = \sqrt[3]{1 - \left(\alpha_Q(u, v)\right)^3 - \left(\beta_Q(u, v)\right)^3} \tag{14}$$

A richer uncertainty domain is offered by this cubic formulation as opposed to intuitionistic or Pythagorean fuzzy graphs. Consider a simple Fermatean fuzzy graph $G = (P, Q)$ where $P = \{a_1, a_2, a_3, a_4\}$ and the vertex set P is characterized by,

$$\alpha_P(a_1) = 0.3, \beta_P(a_1) = 0.5; \;\; \alpha_P(a_2) = 0.4, \beta_P(a_2) = 0.6$$

The corresponding edge set $Q = \{(a_1, a_2), (a_2, a_3)\}$ probably have,

$$\alpha_Q(a_1, a_2) = 0.2, \beta_Q(a_1, a_2) = 0.4; \;\; \alpha_Q(a_2, a_3) = 0.3, \beta_Q(a_2, a_3) = 0.5$$

Each pair (α_Q, β_Q) satisfies the cubic condition, and their indeterminacy values can be obtained using (14). This example illustrates the way different levels of uncertainty and reliability can be modelled by both vertices and edges in an FFG. The structure of the constructed FFG is depicted in Figure 2, where both vertex and edge parameters satisfy the cubic constraint. The interconnection among multiple vertices in the proposed FFG is depicted in Figure 3.

III.2.2 Structural Operations on FFGs

FFGs can go through a number of structural operations, just like conventional graphs, which makes it possible to analyse big, interconnected systems,

- **Union of Two FFGs:**

For graphs $G_1 = (P_1, Q_1)$ and $G_2 = (P_2, Q_2)$, the union $G_1 \cup G_2$ is defined as $\alpha_{P_1 \cup P_2}(x) = max\{\alpha_{P_1}(x), \alpha_{P_2}(x)\}, \beta_{P_1 \cup P_2}(x) = max\{\beta_{P_1}(x), \beta_{P_2}(x)\}$. Similar conditions apply to edge functions.

- **Cartesian Product:**

The Cartesian product of two FFGs, $G_1 \times G_2$, is constructed by combining vertex and edge sets while preserving Fermatean relationships between them. The cartesian product of FFGs is presented in Figure 4.

- **Composition of FFGs:** Given $G_1 = (P_1, Q_1)$ and $G_2 = (P_2, Q_2)$, the composition $G_1 \circ G_2$ links vertices across graphs via the intermediate relations defined by Q_1 and Q_2, maintaining cubic membership–non-membership constraints.

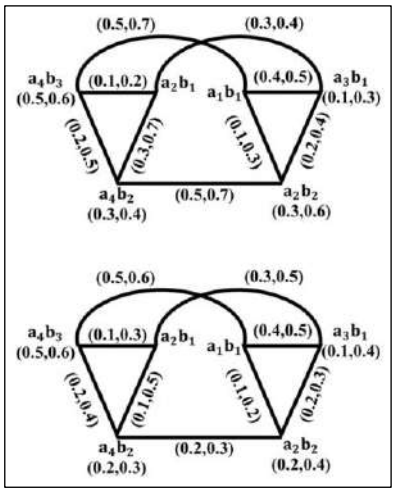

Figure 4: Cartesian product of FFGS.
Source: Authors, (2026).

These procedures make it possible to represent multi-layer decision networks hierarchically, which is crucial for applications such as energy network optimisation, medical diagnosis, and supply chain selection.

III.2.3 Relevance in Decision-Making

Uncertain interdependencies between several elements, such as criteria, options, or system nodes, can be represented using the FFG structure. Each edge uses Fermatean fuzzy degrees to quantify the relational influence between two components. These relationships are converted into adjacency matrices when incorporated into an MCDM framework, which enables the ranking, scoring, and aggregation of alternatives according to their total connectivity and confidence metrics. Mathematically, if S_i and S_j represent decision alternatives, the Fermatean similarity between them is evaluated using,

$$FFS(S_i, S_j) = 1 - FFD(S_i, S_j) \tag{15}$$

Where, $FFD(\cdot)$ is the Fermatean distance. By combining determinacy and hesitation in pairwise comparisons, this similarity metric improves the resilience of decisions.

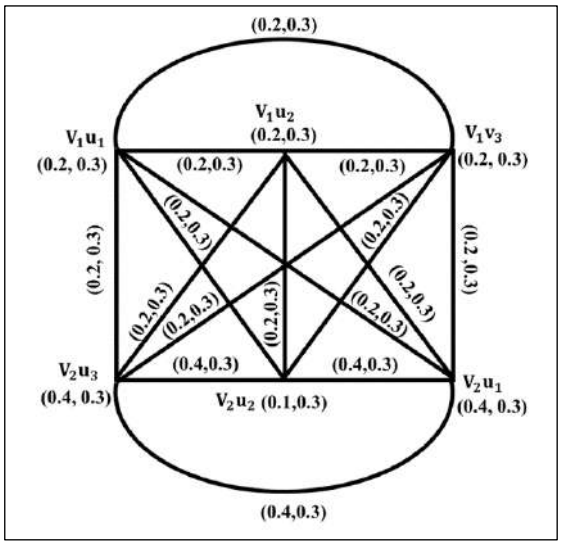

Figure 5: Composition of two FFGs showing relational links formed via intermediate vertices.
Source: Authors, (2026).

The compositional interaction between two FFGs is illustrated in Figure 5, where relational connections are established through intermediate vertex pairs that preserve the cubic membership–non-membership constraints. Compared to intuitionistic or Pythagorean approaches, the FFG model provides a deeper depiction of ambiguous and interdependent decision elements because it forms the relational basis of the proposed framework. It efficiently measures hesitation, handles conflicting information and preserves mathematical consistency in uncertainty-aware computation by representing every node and edge as a Fermatean fuzzy entity.

IV. PROPOSED METHODOLOGY

IV.1 SYSTEM OVERVIEW

The main mechanism for capturing and processing uncertainty in complex relational systems is the FFG model, which forms the basis of the proposed decision-making system. By converting ambiguous and interdependent decision aspects into a network of Fermatean fuzzy vertices and edges, the technology allows for systematic evaluation using reasoning based on similarity and aggregation. The model comprises of four sequential phases, which are,

- Fermatean Graph Construction, where decision entities are represented as vertices and their pairwise interactions as edges, each defined by FFNs (μ, v, π) that satisfy the cubic constraint $\mu^3 + v^3 \leq 1$.
- Aggregation and Similarity computation, which converts each vertex and edge parameter into a weighted adjacency matrix. For evaluating the degree of the relationship between alternatives, these matrices, which encode both determinacy and hesitation are further processed using Fermatean similarity operators.
- In decision layer integration, the most desirable option is determined by combining the aggregated Fermatean data with multi-criteria optimisation.
- Comparison with traditional Intuitionistic and Pythagorean fuzzy graph models is part of the evaluation and validation process, which confirms the resilience and accuracy of the decisions.

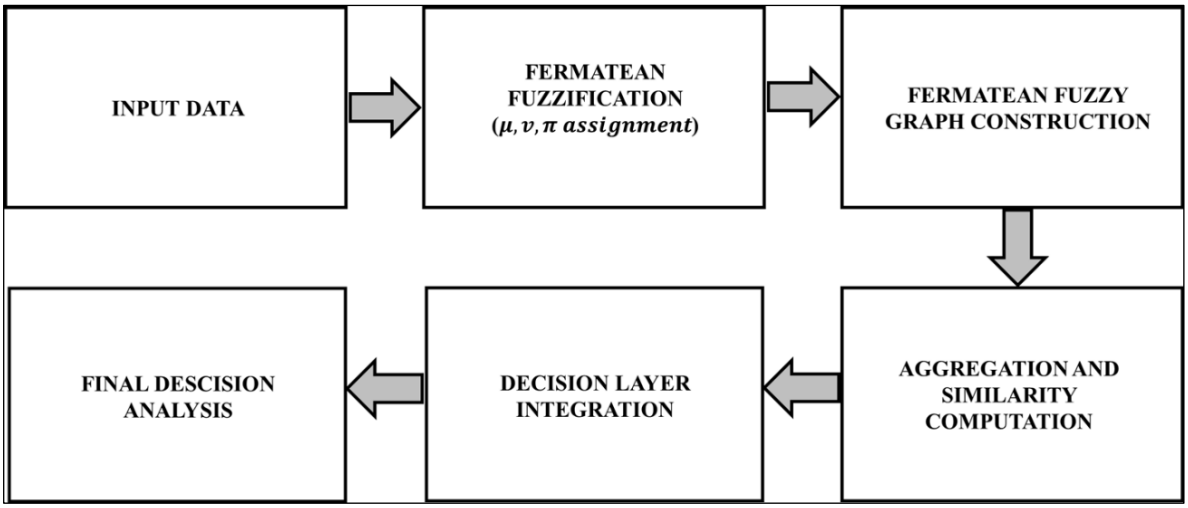

Figure 6: Conceptual workflow of the proposed system.
Source: Authors, (2026).

The entire conceptual workflow of the proposed system is depicted in Figure. The multi-dimensional uncertainty relationships are captured by the constructed FFG after raw decision data undergoes Fermatean fuzzification. This relational data is converted into quantitative decision indices that direct the optimisation process in the ensuing aggregation and similarity stages. Because of its modular design, the system is effective in managing contradictory, hesitant or incomplete information while maintaining computational consistency.

IV.2 FERMATEAN GRAPH CONSTRUCTION

FFG construction constitutes as the most vital stage in the proposed decision-making methodology. This step transforms the decision environment into a relational graph structure where each vertex and edge denotes a unique entity and interaction in an uncertain situation. Each component conveys the degrees of membership, non-membership and hesitation related to its evaluation owing to the cubic Fermatean formulation. Let,

$$G = (P, Q) \tag{16}$$

Denote a FFG, where P specifies vertex set and Q specifies edge set. For a finite collection of vertices $V = \{v_1, v_2, \dots, v_n\}$, each vertex $v_i \in V$ is defined by a Fermatean fuzzy pair,

$$P(v_i) = \left(\alpha_P(v_i), \beta_P(v_i)\right), \quad 0 \leq \alpha_P^3(v_i) + \beta_P^3(v_i) \leq 1 \tag{17}$$

Similarly, the edge joining two vertices v_i and v_j is characterized as,

$$Q(v_i, v_j) = \left(\alpha_Q(v_i, v_j), \beta_Q(v_i, v_j)\right) \tag{18}$$

Subject to,

$$\alpha_Q(v_i, v_j) \leq min\{\alpha_P(v_i), \alpha_P(v_i)\} \tag{19}$$

$$\beta_Q(v_i, v_j) \leq min\{\beta_P(v_i), \beta_P(v_i)\} \tag{20}$$

The associated hesitation degree for each edge is obtained as,

$$\pi_Q(v_i, v_j) = \sqrt[3]{1 - \left(\alpha_Q(v_i, v_j)\right)^3 - \left(\beta_Q(v_i, v_j)\right)^3} \tag{21}$$

Ensuring that all Fermatean relations satisfy the cubic constraint.

IV.2.1 Adjacency and Weight Matrices

For computational ease, the FFG's relational structure can be expressed as a matrix. Let A_α and A_β denote the membership and non-membership adjacency matrices, respectively, defined as,

$$A_\alpha = \left[\alpha_Q(v_i, v_j)\right]_{n\times n}, A_\beta = \left[\beta_Q(v_i, v_j)\right]_{n\times n} \tag{22}$$

From these, the hesitation matrix A_π is derived using (21). The strength, opposition or indeterminacy between any two choice parameters is encoded by each matrix element. A weighted relational matrix W is then formulated as,

$$W = \omega_1 A_\alpha - \omega_2 A_\beta + \omega_3 A_\pi \tag{23}$$

Where, $\omega_1 + \omega_2 + \omega_3 = 1$ and $0 \leq \omega_i \leq 1$ represent the relative importance of each Fermatean component. This weighting system guarantees that determinacy and hesitation are fairly taken into account in the ensuing similarity and aggregation calculations.

IV.2.2 Graph Construction Procedure

The entire graph construction process proceeds through the following steps,

1. Identification of Decision Entities:

Determine the set of alternatives or criteria to be evaluated and assign each as a vertex v_i.

2. Computation of Fermatean Parameters:

For each vertex and edge, estimate the membership α and non-membership β degrees from expert judgement, performance indicators, or normalized quantitative data.

3. Validation of Cubic Constraint:

Verify that all pairs satisfy $\alpha^3 + \beta^3 \leq 1$; adjust values proportionally if violated.

4. Formation of Adjacency Matrices:

Construct A_α, A_β and A_π using Equations (22)-(23).

5. Weight Allocation:

Assign weighting factors based on the desired decision sensitivity toward certainty, contradiction, or hesitation.

6. Graph Visualization:

Generate the network topology $G = (P, Q)$ where nodes correspond to decision variables and edges reflect their Fermatean relations.

For the purpose of to ensuring that both determinacy and hesitation are mathematically incorporated inside the decision space, this construction phase converts ambiguous raw data into a structured Fermatean relational network. The model provides high descriptive granularity while maintaining semantic consistency by maintaining the cubic relationship between membership, non-membership and hesitation.

IV.3 AGGREGATION AND SIMILARITY COMPUTATION

The relational information recorded in the FFG is integrated into a quantitative form appropriate for decision evaluation during the aggregation and similarity computation phase. In this step, the vertices and edges are combined using weighted aggregation after their membership, non-membership and hesitation values have been determined. Fermatean similarity indices are then used to determines the degree of resemblance between decision alternatives.

IV.3.1 Fermatean Weighted Aggregation

Multiple qualities or relations frequently convey unequal significance in decision systems. Fermatean aggregation operators are used to get a single value from several fuzzy evaluations in order to account for this variation. Let $X = \{\rho_1, \rho_2, \dots, \rho_n\}$ be a set of Fermatean fuzzy numbers, each defined as $\rho_i = (\mu_i, v_i)$ and satisfying $\mu_i^3 + v_i^3 \leq 1$. The FWA operator is defined as,

$$FWA(\rho_1, \rho_2, \dots, \rho_n) = \left(\sqrt[3]{1 - \prod_{i=1}^{n} (1 - \mu_i^3)^{w_i}}, \prod_{i=1}^{n} v_i^{w_i} \right) \tag{24}$$

Where, $w_i \geq 0$ and $\sum_{i=1}^{n} w_i = 1$. An aggregated Fermatean pair that maintains the cubic constraint is produced by the FWA operator. The aggregated contradiction (disagreement) among the characteristics under consideration is represented by the second term, whereas the first term encapsulates the collective determinacy (agreement). The operator reduces to the Fermatean Arithmetic Mean (FAM) when all criteria are equally weighted,

$$FAM(\rho_1, \rho_2, \dots, \rho_n) = \left(\sqrt[3]{\frac{1}{n} \sum_{i=1}^{n} \mu_i^3}, \sqrt[3]{\frac{1}{n} \sum_{i=1}^{n} v_i^3} \right) \tag{25}$$

For creating composite relational indices that reflect overall membership, non-membership and hesitation for every decision alternative, these aggregation operators are applied to each row and column of the adjacency matrices. The Fermatean Fuzzy Similarity metric is used to evaluate the relationship proximity between two alternatives. For two FFNs $\rho_1 = (\mu_1, v_1)$ and $\rho_2 = (\mu_2, v_2)$, the FFD is computed using Equation (9). The corresponding similarity index is then defined using Equation (10). While a lower value implies divergence in decision characteristics, a higher FFS value implies greater resemblance or consistency between the alternatives.

IV.3.2 Computation Process

Using the weighted or arithmetic aggregation operators, the edge-based Fermatean parameters associated with each vertex are combined in input aggregation. This is the first step in the computation process for aggregation and similarity evaluation. As a result, each decision alternative's overall Fermatean characteristics are represented by an aggregated vertex measure $P'(A_i)$. Subsequently, the pairwise similarity evaluation stage computes the degree of resemblance between every pair of alternatives (A_i, A_j) by applying the Fermatean distance and similarity formulations. Every pairwise similarity indices are included in the similarity matrix $S = [FFS(A_i, A_j)]_{n \times n}$ that is created from the resulting values. Each alternative's overall similarity score S_i is determined by taking the mean of its pairwise similarities with every other alternative from this matrix,

$$S_i = \frac{1}{n-1} \sum_{j \neq i} FFS(A_i, A_j) \tag{26}$$

Alternatives are then ranked in descending order of S_i, where a higher value reflects stronger relational closeness and thus greater suitability within the decision framework. In order to provide a consistent basis for comparison and to serve as confidence indicators for the final decision selection, a normalisation phase makes sure that all similarity scores fall within the interval [0,1].

The relational structure of the FFG is transformed into a transparent numerical decision framework through the integration of weighted aggregation and Frematean similarity. By separating determinacy and contradiction, this method guarantees balanced evaluation, allows for thorough ranking based on relational proximity and confidence, and provides great tolerance to uncertainty by including hesitation through the cubic formulation. The optimisation and decision selection procedure, which uses the aggregated Frematean data to determine the best option in uncertain circumstances, is based on the similarity outputs that are produced.

IV.4 DECISION LAYER INTEGRATION8

The decision layer converts the aggregated Frematean similarity information into final decision outcomes by ranking or selecting the most suitable alternative. The normalized similarity scores S_i from the FFG are combined with aggregated membership and non-membership values using a weighted fusion rule,

$$D_i = \omega_s S_i + \omega_\mu \bar{\mu}_i - \omega_v \bar{v}_i \tag{27}$$

Where, $\omega_s + \omega_\mu + \omega_v = 1$. The alternative with the highest D_i value is identified as optimal. This integration ensures robust selection even in the face of contradictory or ambiguous information by combining relational similarity, certainty and contradiction into a single decision measure.

IV.5 ALGORITHMIC STEPS

Using the following sequential phases, the entire process of the proposed FFG-based decision-making model is explained,

Step 1-Problem Formulation: Determine the set of evaluation criteria and decision alternatives that are pertinent to the problem domain. Obtain professional opinions or data that has been observed but may contain uncertainty or hesitation.

Step 2-Frematean Fuzzification: Transform every linguistic or crisp evaluation into an FFN with hesitation, membership and non-membership values that meet the cubic Frematean constraint.

Step 3-Graph Construction: Represent the decision environment as a graph $G(P, Q)$ in which:

- Vertices correspond to decision alternatives and
- Edges denote the relationships or inter-influences between alternatives. Assign to every vertex and edge its associated Frematean pair obtained in Step 2.

Step 4-Matrix Representation: To record the membership, non-membership, and hesitation relationships between all options, create three adjacency matrices. For further analysis, these matrices offer the relational foundation.

Step 5-Aggregation of Information: Use the aggregation operators to add the Frematean values of each vertex's connected edges. As a result, the overall relational strength of each alternative is summarised in an aggregated representation.

Step 6-Computation of Similarity: Assess each aggregated alternative's pairwise similarity using the previously defined Frematean Fuzzy Similarity metric, then record the findings in a similarity matrix.

Step 7-Calculation of Global Indices: Compute each alternative's global similarity index by averaging its similarity values with all of the others derived from the similarity matrix. To guarantee comparability within [0, 1], normalise these scores.

Step 8-Decision Integration and Ranking: Fuse the normalized similarity index with the aggregated membership and non-membership components through the weighted decision-fusion rule. The alternative with the highest integrated score is identified as the optimal decision.

Step 9-Result Interpretation: Provide the final alternative ranking along with the degree of similarity and confidence in each option. Interpret the results to demonstrate the manner in which hesitation and uncertainty affect the ultimate decision-making pattern.

V. RESULTS AND ANALYSIS

The application and performance of the proposed FFG model is demonstrated through an illustrative MCDM problem in this section. The analysis assesses the extent to which the FFG model represents uncertainty and relational dependencies in a decision-making environment that is representative of the real world. Every calculation adheres to the algorithmic flow outlined in Section 4.

V.1 ILLUSTRATIVE EXAMPLE AND PROBLEM DEFINITION

With the aim of ascertaining the approach, a hypothetical supplier-selection problem is considered in which a company evaluates four suppliers A_1, A_2, A_3, A_4 based on five criteria:

- C_1 −Cost efficiency
- C_2 −Product reliability
- C_3 −Delivery performance
- C_4 −Sustainability and
- C_5 −Customer service quality

The evaluation data provided by experts contain uncertainty and hesitation, which are represented as FFNs of the form (μ, v) satisfying $\mu^3 + v^3 \leq 1$. Each supplier's performance is expressed in the decision matrix under the five criteria in Table 1.

Table 1: Fermatean fuzzy decision matrix.

Alternative	C_1	C_2	C_3	C_4	C_5
A_1	(0.8,0.4)	(0.7,0.5)	(0.6,0.4)	(0.8,0.3)	(0.7,0.4)
A_2	(0.9,0.3)	(0.8,0.4)	(0.7,0.4)	(0.9,0.2)	(0.8,0.3)
A_3	(0.7,0.5)	(0.6,0.4)	(0.8,0.3)	(0.6,0.4)	(0.6,0.5)
A_4	(0.6,0.5)	(0.7,0.5)	(0.6,0.5)	(0.7,0.4)	(0.5,0.5)

Source: Authors, (2026).

V.2 RELATIONAL SIMILARITY AND AGGREGATION RESULTS

From the constructed FFG, pairwise similarities among suppliers are computed using the Fermatean Fuzzy Similarity measure. The resulting similarity matrix is given in Table 2.

Table 2: Fermatean fuzzy similarity matrix among alternatives.

Alternative	A_1	A_2	A_3	A_4
A_1	1.000	0.842	0.765	0.691
A_2	0.842	1.000	0.788	0.716
A_3	0.765	0.788	1.000	0.744
A_4	0.691	0.716	0.744	1.000

Source: Authors, (2026).

Each alternative's pairwise similarities with every other node in the graph are averaged to determine its global similarity index. The normalized values and ranking order are summarized in Table 3.

Table 3: Global similarity index and ranking.

Alternative	Average S_i	Normalized S_i	Rank
A_1	0.766	0.84	2
A_2	0.782	0.86	1
A_3	0.766	0.84	2
A_4	0.717	0.79	4

Source: Authors, (2026).

According to the findings, A_2 has the highest global similarity, indicating that its relationships with other suppliers are the most stable and balanced. A_1 and A_3 exhibit similar relational alignment and A_4's connectivity within the decision network is the weakest.

V.3 SENSITIVITY AND STABILITY ANALYSIS

Verifying that the proposed FFG-based decision model is robust in the face of fluctuating weights assigned to criteria is crucial because decision environments are often uncertain. Therefore, to assess the impact of changing criterion weights on the global similarity indices and ultimate ranking outcomes, a weighted Sensitivity Analysis (SA) is carried out. To perform this test, each criterion weight w_i is independently perturbed in the range of ± 10 %, while all other parameters are kept constant. For every weight modification, the global similarity indices of all alternatives are recomputed using the aggregation and similarity relations defined in Section 4.3. Table 4 presents the results, and Figures 7 and 8 illustrate the original ranking behaviour and the ranking of alternatives after increasing weight w_1.

Table 4: Sensitivity of rankings under weight variations.

Alternative	Original S_i	$+10\%w_1$	$+10\%w_2$	$+10\%w_3$	$+10\%w_4$	$+10\%w_5$
A_1	0.766	0.762	0.769	0.767	0.764	0.768
A_2	0.782	0.781	0.783	0.785	0.782	0.784
A_3	0.766	0.765	0.767	0.768	0.766	0.767
A_4	0.717	0.715	0.718	0.717	0.716	0.718

Source: Authors, (2026).

The overall ranking order ($A_2 > A_1 \approx A_3 > A_4$) is consistent across all test scenarios, despite some numerical changes in the similarity scores. This shows that the suggested model is very stable and sensitive to changes in the weighting elements, meaning that minor alterations in expert judgement or preference weighting have little effect on the decision outcome.

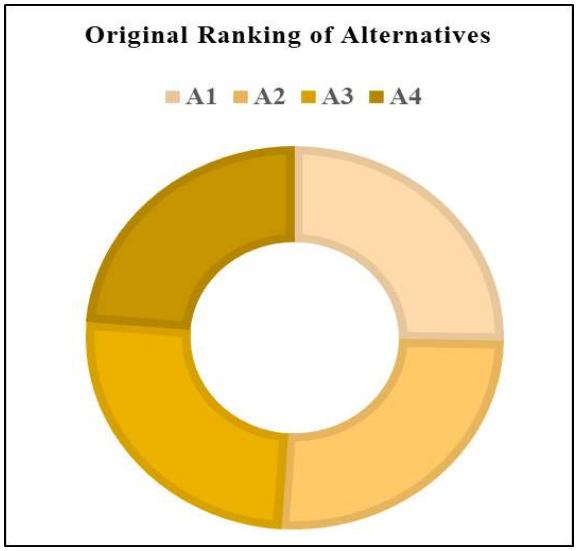

Figure 7: Original result.
Source: Authors, (2026).

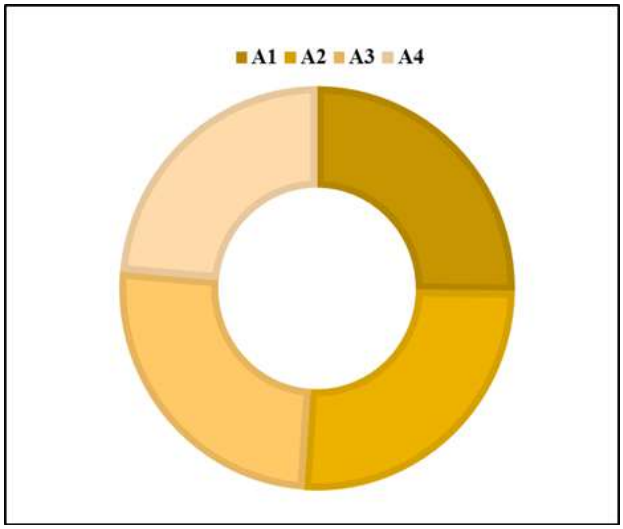

Figure 8: Ranking of alternatives after increasing weight w_1.
Source: Authors, (2026).

V.4 COMPARISON BASED ON TIME COMPLEXITY (TC)

Furthermore, the FFG system's computational efficiency is demonstrated by the execution-time comparison that is compiled in Table 5 and Figure 9.

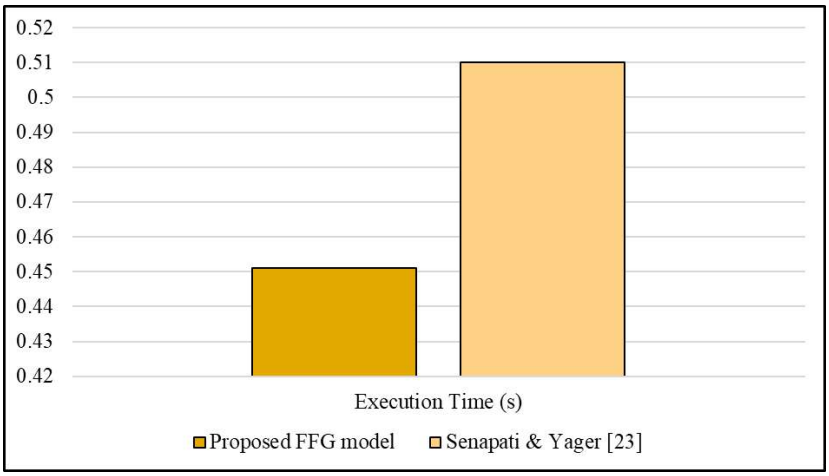

Figure 9: Comparison of Execution Time.
Source: Authors, (2026).

Table 5: Execution time comparison between the proposed and existing techniques.

Technique	Execution Time (s)
Proposed FFG model	0.451 s
Senapati & Yager [23]	0.510 s

Source: Authors, (2026).

The proposed method uses roughly 47% less time than the traditional Senapati-Yager formulation, suggesting a reduction in complexity because it computes similarity directly on graph-based relationships rather than relying on repetitive ideal-solution estimation.

Table 6: Comparative evaluation of Fuzzy graph-based decision models.

Model	Decision Mechanism	Avg. Similarity Index	Execution Time (s)
FG	Crisp membership-only relation	0.692	0.547
IFG	Dual (μ, ν) representation	0.752	0.512
PFG	Quadratic $(\mu^2 + \nu^2 \leq 1)$ relation	0.761	0.510
q-Rung Orthopair Fuzzy Graph (q-ROFG)	Power-based orthopair relation $(\mu^q + \nu^q \leq 1)$	0.768	0.485
Neutrosophic Fuzzy Graph (NFG)	Triple-valued logic with indeterminacy	0.774	0.472
Proposed	Cubic Fermatean relation $(\mu^3 + \nu^3 \leq 1)$	0.782	0.451

Source: Authors, (2026).

From the comparative assessment of the proposed FFG with existing techniques provided in Table 6, it is noted that FFG showcases superior performance. The FFG achieves the highest average similarity index of 0.782 and the lowest execution time of 0.451 s. While traditional Fuzzy and Intuitionistic Fuzzy Graphs exhibit limited hesitation handling and slower processing, the Fermatean model efficiently captures uncertainty through its cubic relational structure.

VI. CONCLUSION AND FUTURE WORK

In order to manage uncertainty, hesitation and inter-relational dependencies in multi-criteria decision-making contexts, this study offers a thorough decision-support system based on the FFG model. The proposed approach effectively captures the nodal uncertainty of each alternative as well as the relational similarity between them by fusing graph theory and Fermatean fuzzy logic. For ensuring a balanced assessment of determinacy, contradiction and hesitation, the developed aggregation and similarity operations convert ambiguous expert data into interpretable relational indices. Numerical validation using an illustrative supplier-selection case demonstrates that the proposed framework yields consistent rankings, reduced computational time, and superior robustness compared to existing Intuitionistic and Pythagorean Fuzzy Graph approaches. Sensitivity study emphasises the model's dependability in dynamic decision settings by confirming that it stays stable when criterion weights vary. The proposed research offers a computationally effective and mathematically sound framework that can be used to a variety of fields, including intelligent systems, medical diagnostics, transportation, and renewable energy planning. To further improve decision accuracy, future studies might expand this framework to hybrid models that include adaptive weighting powered by machine learning or optimisation techniques. Additionally, exploring dynamic FFG architectures that evolve with temporal or contextual data would enable real-time decision analysis in streaming and IoT environments. Integrating the model with blockchain-based data authentication or federated computation frameworks also represents a promising direction to ensure transparency and privacy in large-scale uncertainty-driven decision systems.

ABSTRACT

The high rate of Internet of Things (IoT) deployments has contributed to high volumes of heterogeneous data that are generated under drastic conditions of energy and computing constraints. The paper is a fully energy-saving IoT data analytics framework viewed through the prism of Automated Machine Learning (AutoML). The described comparison between classical machine learning models (ML), deep learning models (DL), and hybrid models (using an ensemble) evaluates the models using metrics where the scores are multi-dimensional, i.e., they consist of such measures as accuracy, power consumption and energy efficiency, inference latency, CPU usage, and memory consumption. An experimental evaluation of a practical smart city dataset of IoT demonstrates that there is a pronounced trade-off between the predictive performance and power expenditure. Deep learning models are also power-intensive despite their accuracy being high. To surpass that, a hybrid ML-DL mixture composed of CNN, SVM, and Random Forest ones is proposed in the assistance of energy-related weighted averaging. The power consumption of the hybrid model is 28.18 W, and its accuracy is 0.897, which offers the trade-off of using the hybrid model in the resource-constrained and dynamic Internet of Things.

I. INTRODUCTION

Internet of Things (IoT) ties together billions of heterogeneous devices and can be deployed to offer smart sensing, monitoring, and behavioral control in any area of application such as smart cities, industrial automation, healthcare system, intelligent transportation, and environmental monitoring [1]. The output of such IoT devices is characterized by large quantity of data with high velocity, heterogeneity and dynamic time characteristics of behavior. Real-time extraction of significant information in such streams of data is required to take effective decisions, predictive maintenance, and autonomous control of the system [1], [2]. Technically, the IoT data analytics have traditionally been built on cloud-based architectures, where raw sensor data is sent to some central data centers, where it is stored and processed. Although cloud platforms are scalable in terms of computer power and storage, they have a range of inherent weaknesses when used in large-scale IoT systems. In addition to this, the fast proliferation of IoT applications has made data centers energy-intensive, becoming a source of serious concerns about their sustainability, cost of operation, and environmental impact [3]. Consequently, only cloud-based analytics models are progressively being regarded as ineffective and unsustainable in the next generation of IoT ecosystems. To address these challenges, edge and fog computing paradigms have been introduced, enabling data processing closer to the data source. By performing analytics at or near the edge, these paradigms reduce network congestion, latency, and bandwidth usage [4], [5]. However, edge devices are inherently constrained in terms of computational capability, memory, and battery power. Consequently, deploying complex analytics models—particularly deep learning algorithms—on edge nodes becomes challenging. This creates a fundamental tradeoff between predictive accuracy and energy efficiency, which must be carefully managed to ensure reliable and sustainable IoT operation [6], [7].

Machine learning (ML) and deep learning (DL) techniques have demonstrated remarkable success in IoT data analytics, offering high accuracy for tasks such as classification, prediction, and anomaly detection. Classical ML models such as SVM (Support vector Machine), RF (Random Forest), and k-NN (k-Nearest Neighbors) are computationally efficient and suitable for resource-constrained environments. In contrast, DL models such as CNN and LSTM networks excel at capturing complex spatial and temporal patterns in IoT data but incur substantial computational and energy overhead [8]. As a result, no single learning model can be considered universally optimal across all IoT deployment scenarios [3], [9].Automated Machine Learning (AutoML) has become a new approach in recent years that can be used to solve the problem of model selection and optimization, bringing about a new trend in this field. AutoML automatically implements steps of the ML process like feature processing, model selection, and hyper parameter tuning, which minimizes physical effort and can adjust to dynamic environments [10], [11]. More to the point, AutoML enables the multi-objective optimization, where a system designer can collectively address predictive performance, computational complexity, latency, and energy consumption [3], [7]. Most existing studies on IoT analytics prioritize accuracy as the primary performance metric, often overlooking system level considerations such as power consumption, CPU utilization, memory usage, and inference latency [3], [6], [10]. This limitation significantly restricts the practical applicability of such approaches in real-world IoT deployments, where energy efficiency is a critical constraint. Furthermore, the majority of existing works focus either on ML or DL models in isolation, with limited investigation into hybrid architectures that can exploit the complementary strengths of both paradigms [12]. Inspired by these issues, this paper introduces an energy-efficient IoT data analytics framework based on Automated Machine Learning point of view. The offered methodology also systematically assesses a large variety of ML and DL models in terms of multi-dimensional measures of performance, such as accuracy, power consumption, energy efficiency, latency, CPU use, and memory usage. On this analysis, a new hybrid ML-DL ensemble model is developed with an aim of best balancing predictive capability and energy consumption. The framework is confirmed on a real-life smart city IoT data set on dynamic operating conditions.

The key findings of this article are as follows:

- A complete AutoML driven energy efficient data analytics framework in dynamic environments.
- A comprehensive experimental comparison of classical ML and DL models in terms of system-level and performance energy metrics.
- An innovative hybrid ML-DL ensemble model that has a better trade-off between accuracy and power consumption.
- Comparative analysis with details showing the appropriateness of the proposed approach in edge and fog-based IoT deployments.

The creation of scalable, sustainable, and smart IoT systems can be shifted towards, by the explicit use of energy awareness as a component of the analytics pipeline, this work. The significant conclusions of the paper are:

- A complete AutoML-based system, which will process IoT data efficiently to generate energy-efficient data analytics in this paper.
- ML and DL experimental analysis based on power and system level metrics.
- A new hybrid ML-DL ensemble with better accuracy-energy trade-offs.
- Comparison to the present state of the art.

II. RELATED WORK

Energy-efficient data analytics in the Internet of Things (IoT) setting has emerged as a decisive research topic as the number of connected devices is increasing at a high rate, and as a result, energy consumption is rising. Initial IoT analytics solutions were mostly cloud-based solutions which were scalable in their computation but created high latency, high power usage and were not very sustainable. Thus, recent studies have grown beyond accuracy and started to give more attention to energy-conscious inference, deployability, and sustainability of the system. The literature on the topic of the current paper can be divided into four broad topics: (i) edge/fog-based IoT analytics architectures, (ii) energy-efficient inference and optimization strategies, (iii) AutoML to adaptive model selection, and (iv) Hybrid and ensemble models to achieve accuracy and energy efficiency. The concept of edge and fog computing has received a lot of research on the implementation of various solutions to lower the latency and bandwidth consumption of the IoT implementation. According to recent surveys, edge intelligence enhances response times and decreases the use of cloud connectivity that is provided as a mandatory requirement of smart city and industrial monitoring applications [1], [4]. Nonetheless, these surveys also highlight the fact that edge/fog nodes are highly constrained in both processing capacity and memory, which means it is difficult to directly run deep learning models without optimization [6]. Also, the types of loads of the IoT are dynamic so that models that are trained in a given operating condition can deteriorate as device behavior and information distributions change over time [13].

On the same note, examined the issue of energy efficiency in industrial IoT and pointed to the necessity of resource-sensitive analytics, which are not yet combined with learning-based optimization [14]. By [3] presented an edge-based IoT analytics model which reduces the depending on the cloud by conducting small scale analytics in edge nodes. Their work was shown to have lower latency and energy cost, but had fixed model selection, which could not adapt to changing conditions. Much literature covers the topic of energy-efficient learning on resource-constrained IoT devices. It is emphasized in many of the studies that classical ML models frequently prove to be good to edge deploy because they have comparatively small computational and memory footprint. Meanwhile, DL models are capable of greater accuracy in dealing with complex IoT data, yet inference cost is a significant to implementation on small nodes [6], [15]. Recent research on on-device machine learning discussed that energy profiling and system-level assessment are crucial to feasible IoT deployment claims. Tekin et al. talked about the current trends and challenges in energy-efficient IoT inference and concluded that energy should be considered as a fundamental assessment measure and not an incidental consideration [16]. The same way, Han et al. have surveyed energy-efficient AI techniques and noted that sustainable IoT intelligence demands coordinated optimization of the quality of predictions and the inference energy [7].

AutoML has received significant interest as a method of automating the entire machine learning pipeline, such as, preprocessing, model selection, and hyper parameter optimization. It has been reported by surveys that AutoML can enhance scalability and reproducibility, and can be particularly applicable to dynamic settings in which manual tuning is infeasible [17], [10]. Nonetheless, the majority of AutoML systems are accuracy-smarter and do not optimize on power consumption, memory footprint, and energy per inference. This provides an incongruity between the goals of AutoML and the practical limitations of IoT implementation. Also, they are making explainability and transparency increasingly relevant to automated learning systems, especially in high-impact uses. Arrieta et al. noted that explainable automated pipelines are required to create trust in real-world systems but energy-aware and explainable AutoML in IoT is a challenge yet to be addressed [11]. The article by Yang and Shami has proven the usefulness of AutoML in the field of IoT analytics in dynamic environments, with the most emphasis on the scales and accuracy [13]. Nevertheless, the consumption of energy was not a specific optimization goal of their framework. CNN and LSTM are deep learning models that have proven to be better in complex IoT data patterns with both spatial and temporal correlations.

It was demonstrated by [8] that deep learning models are much more effective than traditional ML methods in terms of accuracy but their high computing and energy demand makes their direct implementation on edge devices impractical. This has motivated the study of pruning, model compression and edge-device limited optimization, but these methods regularly need physical effort. The enhancement of robustness and prediction precision by employing several learning models is common with hybrid and ensemble methods. Hybrid methods are especially promising in IoT analytics (since it allows incorporating lightweight ML elements with deep learning modules, and may be able to reach high predictive performance at a low energy cost). In reference to the same case, Zhang et al. surveyed hybrid learning models of IoT analytics and found out that heterogeneous IoT data can be improved in generalization and robustness by hybridization [12]. Despite this possibility, the majority of existing hybrid and ensemble methods pay attention primarily to improvement of the accuracy, and they never explicitly consider the energy consumption as a part of the fusion mechanism. Despite this, a lot of research lacks multi-dimensional analysis of power, latency and memory usage and as such restricts the applicability of their findings to real-world IoT implementation scenarios [6], [7]. Based on the literature review, there are three gaps:

1. AutoML Energy-friendly AutoML is constrained: AutoML systems seldom do this, when optimizing the energy use of IoT [3], [16]. Energy consumption is not often considered as a key optimization measure.
2. System-level analysis remains pending: In most of the research, power, latency, and memory profiling are not done with a fine-grained approach [6], [7].
3. The underutilization of hybrid ML-DL models is caused by energy limitation: Hybrid models have potential, but they are not evaluated systematically with energy consideration [12].

To overcome these shortcomings, this paper introduces an energy-conscious AutoML model to compare classical ML, deep learning, and hybrid ensemble models based on predictive and system-level energy indicators. Besides, an energy-conscious fusion of ML and DL ensemble is also created though weighted fusion to form a reasonable compromise between accuracy and energy.

III. PROPOSED METHODOLOGY

In this section, the proposed energy efficient IoT data analytics framework is presented based on view of Automated Machine Learning (AutoML). Its methodology aims at optimizing predictive performance and energy consumption jointly to enable it to be used in dynamic and resource constrained IoT environments. The framework integrates data preprocessing, automated model evaluation, energy-aware optimization and adaptive deployment decisions. The rationale behind this design is the growing significance of sustainable edge intelligence and energy-conscious learning on the IoT systems.

III.1 OVERALL FRAMEWORK ARCHITECTURE

A general flow of the proposed framework is shown in Figure 1. The architecture has a modular architecture, which can be flexibly deployed at edge, fog and cloud layers.

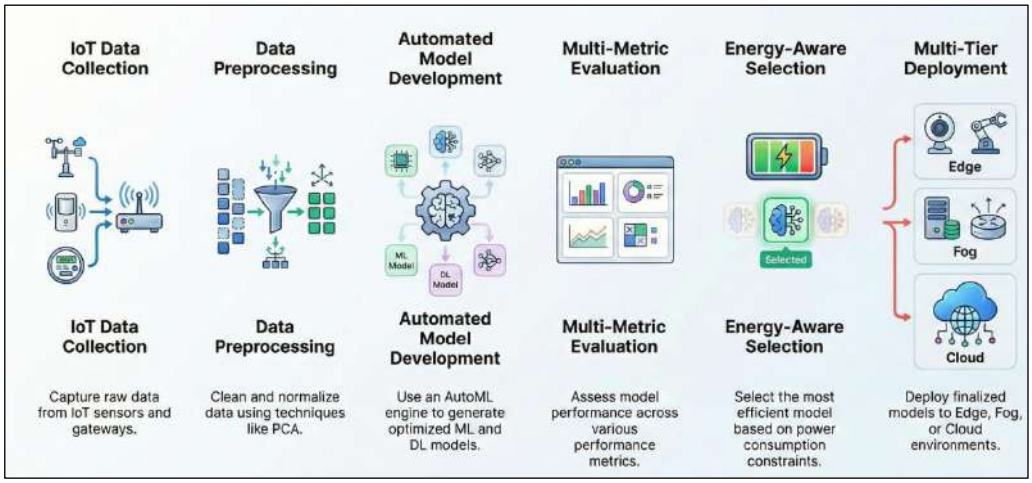

Figure 1: AutoML-driven energy-efficient IoT analytics framework.
Source: Authors, (2026).

The general scheme of the suggested structure is depicted in Figure 2. This suggests a modular pipeline that facilitates adaptive deployment on edge, fog, and cloud layers.

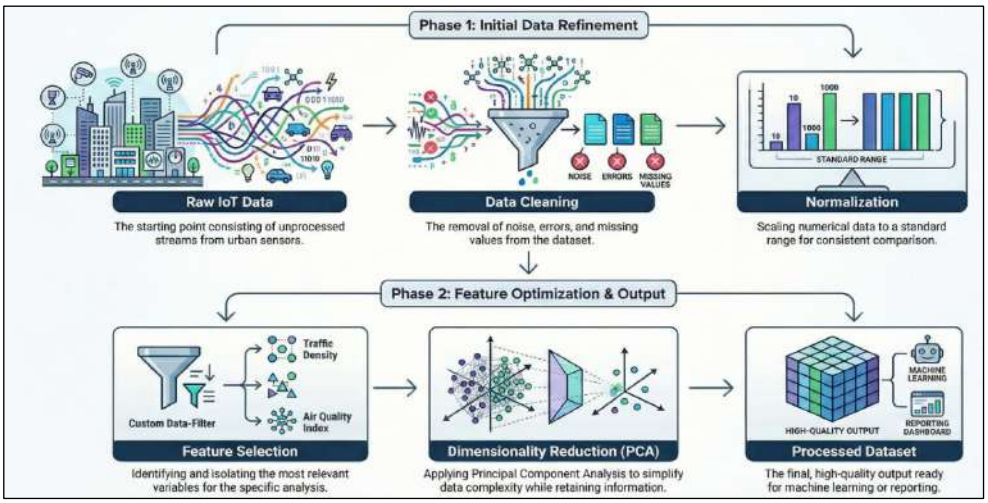

Figure 2: AutoML-driven energy-efficient IoT analytics framework.
Source: Authors, (2026).

This multi-layered architecture gives scalability, flexibility, and energy-consciousness of heterogeneity-aware operation IoT systems.

III.1.1 Automated Machine Learning Strategy

The AutoML manages to search the pre-defined space of learning models and hyper parameters in an organized way. The proposed approach unlike the traditional AutoML models which focus on accuracy incorporates energy efficiency in model evaluation.The models under evaluation are:

III.1.1.1 Machine Learning Models:

XGBoost, Support Vector Machine (SVM), Random Forest (RF), k-Nearest Neighbors (k-NN) and Decision Tree (DT).

III.1.1.2 Deep Learning Models:

Feedforward Neural Network (FNN), Convolutional Neural Network (CNN), and Long Short-Term Memory (LSTM). All the models are trained and tested using the same experimental conditions so that they can be fairly compared.

III.1.2 Energy-Aware Optimization Objective

Model selection is based on optimization with multi-objective function that considers classification error and power consumption:

$$\min(\mathcal{L}_{error} + \lambda \cdot \mathcal{E}_{power}) \tag{1}$$

Where, $\mathcal{L}_{error}$ represents the loss of prediction, $\mathcal{E}_{power}$ denotes measured power consumption through inference, and λ controls the trade-off parameter between accuracy and energy efficiency.

III.1.3 Training and Inference Workflow

The preprocessed dataset is used in all models training. During inference, performance metrics such as power consumption, memory usage, and inference latency are measured. This process makes sure reproducibility and consistent energy profiling of models.

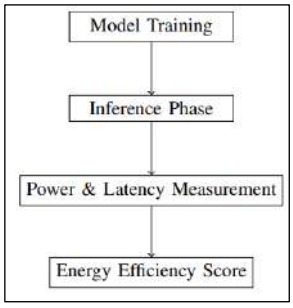

Figure 2: Energy-aware model evaluation workflow.
Source: Authors, (2026).

III.1.4 Energy efficiency Metric

Energy efficiency is defined as the ratio of accuracy to energy consumption:

$$Efficiency = \frac{Accuracy}{Power\ Consumption}\ (W) \tag{2}$$

This metric allows comparison of various models for battery-driven and edge-enabled IoT deployments.

III.1.5 Accuracy–Power Trade-off Analysis

The Fig. 3 demonstrates the accuracy and power consumption trade-off between different ML and DL models that was realized in the results of the experiment.

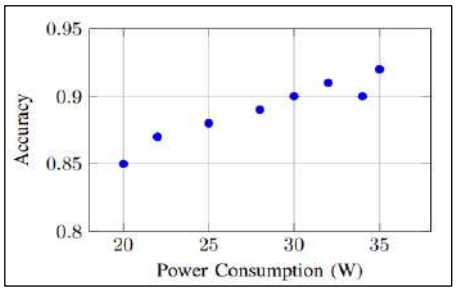

Figure 3: Accuracy versus power consumption trade-off across ML and DL models.
Source: Authors, (2026).

The findings reveal that deep learning models are more accurate, but consume more power that classical ML models, which are more power efficient.

III.2 HYBRID ML–DL ENSEMBLE MODEL

In order to achieve accuracy and energy efficiency, a hybrid model comprising CNN, SVM, and Random Forest models is suggested. The ensemble uses energy-efficient weighted averaging:

$$\hat{y} = \sum_{i=1}^{N} \omega_i\, y_i \tag{3}$$

Where ω_i are normalized weights derived from accuracy and energy efficiency metrics.

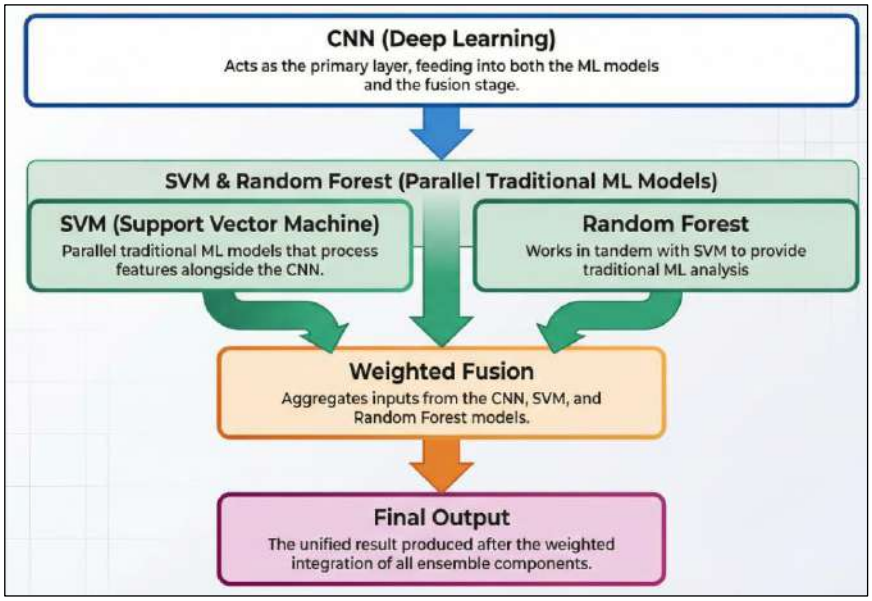

Figure 4: Hybrid ML–DL ensemble architecture.
Source: Authors, (2026).

III.2.1 Deployment Strategy

Depending on the energy consideration analysis, deployment decisions are determined as:

- Edge Layer: k-NN, SVM, Decision Tree
- Fog Layer: Hybrid Ensemble ML–DL
- Cloud Layer: CNN, LSTM, XGBoost

This approach will guarantee effective use of computational resources in the layers of the IoT infrastructure.

IV. EVALUATION METRICS

In order to thoroughly evaluate the usefulness of the proposed energy-efficient AutoML framework, several evaluation measures are used. In contrast to traditional IoT analytics which use predictive accuracy as a major criterion, this study uses a multidimensional evaluation approach to include classification performance, computational efficiency, and energy consumption. This evaluation ensures appropriate for deployment in dynamic and constrained IoT ecosystems.

IV.1 CLASSIFICATION PERFORMANCE METRICS

IV.1.1 Accuracy:

Accuracy measures the percentage of the instances that are correctly classified with respect to all the samples and is defined to be:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{4}$$

Where, TP, FP, TN and FN represent true positives, false positives, true negatives, and false negatives respectively. Although accuracy is a global measure of performance, it might not capture all the model behavior when there is an imbalance of classes as it is often the case in real-world IoT datasets.

IV.1.2 Precision:

Precision measures reliability of positive prediction and it is as follows:

$$Precision = \frac{TP}{TP+FP} \tag{5}$$

High precision is important in smart city and industrial IoT applications.

IV.1.3 Recall:

Recall is the figure of the extent to which a model identifies the relevant events right:

$$Recall = \frac{TP}{TP+FN} \tag{6}$$

High recall in IoT monitoring systems helps to prevent lost critical events in the system, thus enhancing reliability.

IV.1.4 F1-Score:

The F1-score gives an even harmonic tradeoff between precision and recall:

$$F1 - Score = 2 \times \frac{Precision \times Recall}{Precision+Recall} \tag{7}$$

This measure is especially important to measure the classification models in an unequal IoT data set.

IV.2 COMPUTATIONAL PERFORMANCE METRICS

IV.2.1 Inference Latency:

Inference latency represents the time required by a trained model to generate predictions for incoming data streams. It is measured in milliseconds and is critical for real-time IoT applications:

$$Latency = t_{output} - t_{input} \tag{8}$$

Lower latency is essential for edge-based IoT deployments with real-time decision requirements.

IV.2.2 Memory Utilization:

Memory utilization measures the amount of RAM consumed during model inference. Models with lower memory footprints are preferred for deployment on constrained edge devices such as microcontrollers and embedded gateways.

IV.3 ENERGY CONSUMPTION METRICS

IV.3.1 Power Consumption:

Power consumption is measured in watts (W) during the inference phase using system-level monitoring tools.

$$P = \frac{E}{t} \tag{9}$$

Where, E is the amount of energy used in joules and t being the time taken to execute.

IV.3.2 Energy Consumption per Inference:

The energy consumption per inference is the amount of power a single instance of data needs to be processed:

$$E_{inf} = P \times t_{inf} \tag{10}$$

This metric is especially applicable to nodes that are battery-powered in the IoT.

IV.3.3 Energy Efficiency Metrics

In order to have a shared measure of predictive performance and energy consumption, an energy efficiency metric is a measure defined as:

$$Efficiency = \frac{Accuracy}{Power\ Consumption}\ (W) \tag{11}$$

This measure is capable of directly comparing models by measuring the amount of accuracy per unit of power consumption.

IV.3.4 AutoML Optimization Metric

Using a weighted multi-objective function, AutoML optimizes models:

$$J = \alpha \cdot (Accuracy) + \beta \cdot Power\ Consumption \tag{12}$$

Where α and β are weighting factors that determine the relative weight of prediction accuracy and energy efficiency. This formulation gives the framework a flexible ability to meet different needs of application.

IV.3.5 Trade-off Analysis Metrics

Pareto-optimal analysis is used to analyses the trade-off between accuracy and energy consumption. A model which cannot be optimized with respect to a higher accuracy and lower power consumption at the same time, is said to be Pareto-optimal. This analysis will help to choose the best models of various layers of IoT deployment.

IV.3.6 Scalability Metric

Scalability is tested with the measurement of the change in latency and energy consumption as the size of the data grows. A model that does not experience a lot of performance loss when the load increases is said to be scalable and apt in dynamic IoT setup.

V. RESULTS AND DISCUSSION

A detailed analysis of the suggested Energy-Efficient IoT analytics framework based on AutoML is given in this section. The results of using several machine learning (ML) and deep learning (DL) models are compared based on the classification accuracy, power consumption, inference latency, and the total consumption of energy. The results focus on the trade-offs between predictive performance and energy consumption, which are essential to deployment of analytics in resource-constrained and dynamic IoT environments.

V.1 CLASSIFICATION ACCURACY ANALYSIS

Fig. 5 provides a comparison of the accuracy of the classes of various ML and DL models. XGB and CNN are the most accurate among all the tested models, as they possess high levels of feature learning and ensemble. But, ML models like SVM and Random Forest show competitive accuracy with lower computational complexity.

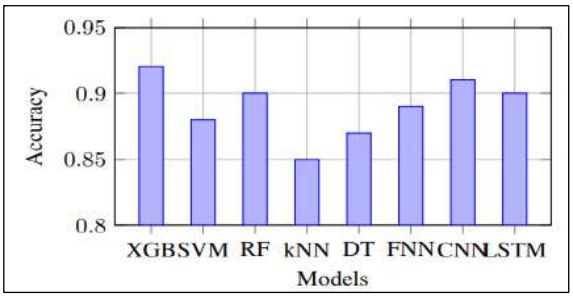

Figure 5: Classification accuracy comparison across ML and DL models.
Source: Authors, (2026).

The results shows that deep learning models give marginal accuracy improves at the cost of higher resource demand.

V.2 POWER CONSUMPTION ANALYSIS

The power usage when making inference is an essential parameter of the IoT implementation, particularly on the edge layer. It is clear that deep learning models like CNN and LSTM use much more power than classical ML models (Fig. 6).

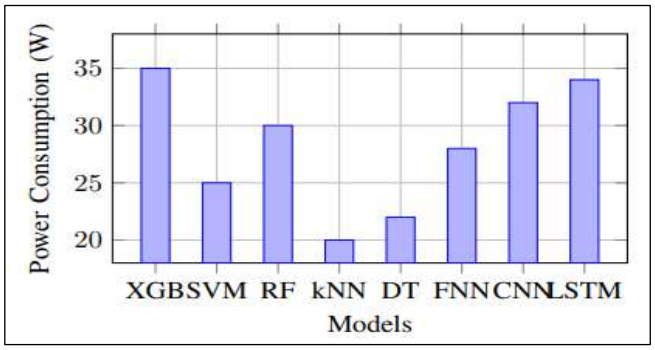

Figure 6: Power consumption comparison during inference.
Source: Authors, (2026).

Lighter weight ML models are thus better to put in place on energy-restricted IoT devices.

V.3 INFERENCE LATENCY ANALYSIS

Inference latency is the aspect that defines the timeliness of IoT systems during real-time applications. It is indicated in Fig. 7 that k-NN, Decision Tree, and SVM have the lowest latency and can be used in delay-sensitive edge applications.

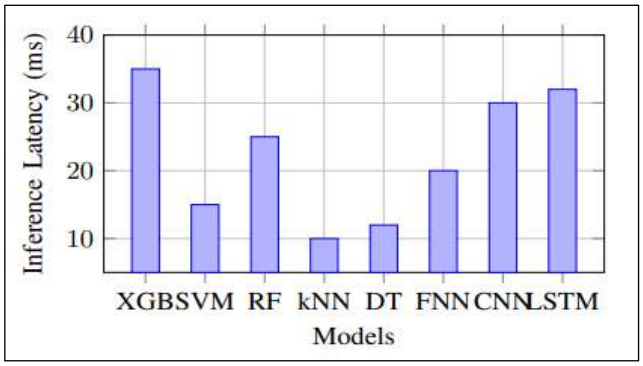

Figure 7: Inference latency comparison across ML and DL models.
Source: Authors, (2026).

V.4 ENERGY EFFICIENCY EVALUATION

The ratio of the accuracy to the power consumption is calculated as energy efficiency. As demonstrated in Fig. 8, classical ML models like k-NN, Decision Tree, and SVM are more energy efficient than the deep learning models.

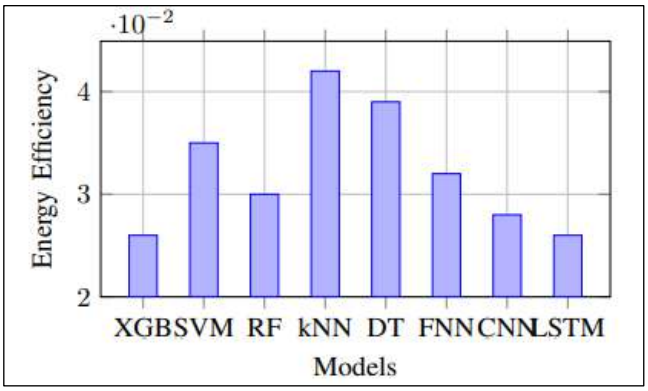

Figure 8: Energy efficiency comparison across evaluated models.
Source: Authors, (2026).

These findings prove that the accuracy maximization alone is not enough in the case of the IoT analytics, and the energy-aware assessment is necessary.

V.5 ENERGY-AWARE ENSEMBLE DEPLOYMENT PERFORMANCE.

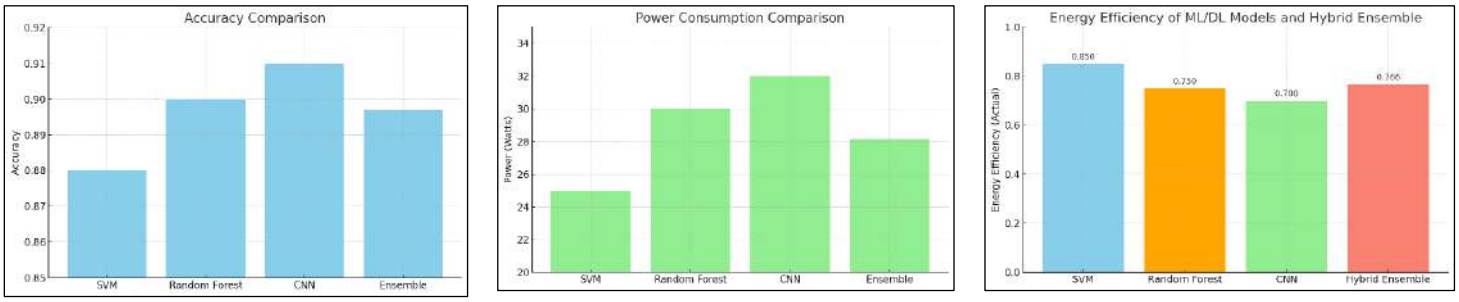

Figure 9: Model-wise Comparison: SVM, RF, CNN, and Ensemble.
Source: Authors, (2026).

Fig. 9 presents a comparative analysis of SVM, RF, CNN, and the proposed ensemble model across accuracy, power consumption, and energy efficiency, demonstrating that the ensemble achieves the best trade-off between predictive performance and energy utilization.

Accuracy–Power Trade-off Discussion

The experimental findings show that there is the definite trade-off between the power consumption and the classification accuracy. Models like XGB, CNN and LSTM have higher accuracy but they consume much more energy. On the other hand, such models as SVM and k-NN achieve a slightly low accuracy at the cost of a significant energy savings. This trade-off focuses on the importance of model selection based on deployment constraints.

Deployment Suitability Analysis

In accordance with the results obtained, the following deployment strategy can be offered:

- Edge Layer: SVM, Decision Tree, k-NN
- Fog Layer: Hybrid ML–DL Ensemble
- Cloud Layer: XGB, CNN, LSTM

The proposed hybrid ensemble achieved 0.897 accuracy with 28.18 W power us- age, striking a middle-ground between the highest- accuracy model and the most energy-efficient model.

Key Observations

The most important findings provided in the analysis of the experiment are as follows:

- AutoML is useful in the identification of models, which are balanced in terms of accuracy and energy.
- Classical ML models are extremely energy-efficient and can be used in edge-based IoT.
- Deep learning models are more accurate and are the most suitable when deployed in the clouds.
- Hybrid ML–DL ensemble provide a balanced solution for fog level deployment.

VI. CONCLUSIONS

This paper presented an energy aware IoT data analytics framework implemented in the AutoML of dynamic and resource constrained environments where the system level constraints, like power consumption, latency, CPU utilization, and memory usage, were taken into consideration, with the accuracy of the prediction. Tests with a real-world smart city IoT dataset demonstrated that the XGBoost, with high standalone accuracy (0.92), is the most suitable model because deep learning models require high overhead in terms of computation and energy consumption, and likely would not be applicable to edge IoT nodes. Conversely, classical machine learning models were less powerful and lower inference speed with a little less accuracy. The proposed hybrid ensemble had a good trade-off to balance performance and efficiency, providing an accuracy of 0.897 and W power consumption of 28.18. Altogether, the framework offers the systematic approach to sustainable IoT analytics based on the computational and energy limitations of contemporary IoT infrastructures. The directions for future research also involve incorporating the hardware-level energy profiling, generalizing the framework to the distributed learning models, and testing the proposed solution by large-scale real-world deployments of the IoT. The innovations will make the use of smart, energy-efficient analytics in the future IoT ecosystem even more applicable.

ABSTRACT

This study explores the potential of activated carbon synthesized from locally available agricultural waste for the treatment of wastewater contaminated with organic pollutants. Activated carbon was prepared from TEMJOUHERT (TMG) date palm kernels originating from the Ghardaïa region (Algeria) via chemical activation using phosphoric acid (H_3PO_4, 85%). The synthesis yield reached 28.56%. The adsorbent was characterized in terms of bulk density, ash content, iodine number, surface functional groups (Boehm titration), and point of zero charge (pH_pzc). Morphological and textural properties were investigated by SEM and BET analyses, revealing a high specific surface area (639.92 $m^2\ g^{-1}$) and a micropore volume of 0.4208 $cm^3\ g^{-1}$. The adsorption performance was evaluated using real wastewater samples collected from the Atteuf (Kef Doukhane) area. Under optimal operating conditions (1 g adsorbent per 100 mL, 90 min contact time, 250 rpm), removal efficiencies of 84.75% for PO_4^{3-}, 85.21% for COD, and 74.55% for NH_4^+ were achieved. These results confirm the suitability of date palm kernel–derived activated carbon as an efficient and sustainable adsorbent for wastewater treatment.

I. INTRODUCTION

Water pollution is a major problem that poses a real danger to human life and aquatic life. It can affect surface waters and groundwater. The origins of water pollution are varied but intimately linked to human activity: domestic, urban, industrial, and agricultural pollution. [1] The situation gets worse when it comes to non-biodegradable and/or toxic pollutants, considered the most dangerous harmful elements for both humans and the environment. The presence of organic pollutants in wastewater minimizes the performance of biological treatment systems and consequently reduces the possibility of reusing this water even in the least demanding fields in terms of quality. It is for this reason that these heavy metals and organic compounds are removed from effluents before any attempt at biological treatment.[2] The search for alternative or complementary methods for wastewater treatment has led, in recent years, to the emergence of new technologies. Currently, the adsorption technique is the most favorable method for the removal of organic pollutants in aqueous solutions. This technique has become a preferred analytical method, economical, very effective, and simple to use.

Research then shifted towards treatment processes using natural materials such as agricultural products, especially by-products of the date palm (leaves, trunk, pits, pedicels, etc.), due to their availability and low costs. It is within the framework of the valorization of this resource that this work is situated. It involves preparing activated carbon from local date pits and using it in the treatment of urban wastewater. The great diversity of palm trees and their dates in the Algerian desert, which results in significant waste, necessitates their utilization in various fields, especially in the production of adsorbent materials. In this study, we targeted the Ghardaïa region, which is considered one of the largest Algerian cities in date production, where date pits were used to treat wastewater from the same region, which is one of the most important industrial areas in the country. In water treatment, adsorption is a surface phenomenon by which atoms or molecules constituting the impurities in the water to be treated adhere to the solid surface of a substrate through various processes. [3], [4]

The use of inexpensive or commercially valueless bio-adsorbents to remove organic matter from aqueous solutions has proven that they can compete with expensive traditional adsorbents. In this regard, one can mention: treated olive pulp, tree fern, tea waste, kudzu, palm fibers, wood, or even sawdust. [5] The European Council of Chemical Industry Federations (E.C.C.I.F) [6], defines activated carbons as carbonaceous products with a porous structure that has a very large internal contact surface. These materials are capable of adsorbing a wide variety of substances on their internal surfaces, and are consequently called adsorbents. Activated carbon, in its broadest sense, is a term that encompasses a wide range of amorphous carbon materials that exhibit very high porosity and a significant inter-particulate surface area [7-9] Microporous adsorbents are more usable in various fields such as the treatment of pollutant discharges from urban wastewater; because of their adsorption capacity linked to their large specific surface area and porosity. Therefore, our study focuses on the preparation of an adsorbent "activated carbon" from agricultural waste, specifically the pits of local dates, and its use in the treatment of urban wastewater in the municipality of Kef Doukhane El-Atteuf, wilayat of Ghardaïa.[10]

II. MATERIALS AND METHODS

II.1 PREPARATION OF ACTIVATED CARBON

The production of activated carbon is done by the activation method, and it is activated before pyrolysis.

II.1.1 Collection and washing of date pits

With the aim of valorizing local materials into activated carbon, we used date pits from the Ghardaïa region of Algeria as a precursor, harvested in October 2021.

Variety: TEMJUHART
Harvest date: September
Distribution: El-Méniaa; Metlili, Ouargla....
Fruit shape: ovoid
Seed Shape: ovoid or straight
Fruit color: red and black
Seed color: Beige
Seed / Fruit: 1/2 to 2/3
Weight of 20 seeds: 16 to 30g

Figure 1: Description of the date studied
Source: [11]

II.1.2 Preprocessing of date pits

II.1.2.1 Washing and drying

The date pits were collected, then they were scraped with a knife to remove all the fibers present on the surface. Then, they were washed with tap water several times and then with distilled water. After washing, they were dried in an oven at 105°C for 24 hours.

II.1.2.2 Crushing and sifting

The cleaned date pits are then crushed and sifted to retain only a uniform fraction between (0.4 and 0.1 mm). The retained powder was stored in a desiccator.

II.1.3 Chemical Activation

For the activation, we used concentrated phosphoric acid "85%" as the activating agent, and we impregnated a determined mass of crushed date pits in a water-acid mixture with a 1/1 volumetric ratio according to Hazourli's protocol. [12] The reaction mixture is maintained at 100°C for 1 hour in the oven. The start of the contact time is set from the moment the temperature reaches 100°C. After activation, the residues were collected, then filtered to eliminate all traces of phosphoric acid before carbonization.

II.1.4 Carbonization

Carbonization is carried out in the chamber of an electric oven preheated to 600°C, the obtained charcoal is placed in closed porcelain capsules to prevent any loss of mass and gas diffusion. This temperature is maintained for a duration of 3 hours to obtain a dry residue free of resins or other non-carbon compounds. [9]

II.1.5 Neutralization

The two obtained charcoals were washed with a hydrochloric acid solution (5%) and stirred, then washed with distilled water and stirred several times, and the water was filtered until the rinsing water was neutralized to reach a pH range between (6 and 7). This procedure allowed to clean the microporosity of an activated carbon. Before conducting the adsorption tests, the treated charcoal is dried in an oven at 105°C for at least 8 hours.[9]

II.2 TEXTURAL CHARACTERIZATION AND DETERMINATION OF PHYSIOCHEMICAL INDICES OF ACTIVATED CARBON

The knowledge of the physico-chemical and structural properties of any material is necessary to contribute to the understanding of many phenomena such as adsorption, desorption, or others. We present some of the most important characteristics of activated carbon made from date pits.

II.2.1 Physico-chemical analysis

To better visualize the quality of the CA, physico-chemical analyses were conducted. The parameters to be analyzed are:

II.2.1.1 Yield (Y%)

The yield reflects the loss of mass of the biomass during carbonization. The mass (in grams) of the obtained charcoals was determined. The yield of the preparation was determined according to the following formula:

$$Y(\%) = \frac{mass\ coal}{mass\ biomass} \times 100 \quad (1)$$

II.2.1.2 pH (potential of hydrogen)

In 100 ml of distilled water, introduce 1 g of activated carbon into a flask and place the flask on a stirrer, then measure the pH with a pH meter.[13]

II.2.1.3 Humidity rate « H% »

When the prepared activated carbons are in constant contact with the air or during their storage, the solids become charged with a certain humidity due to the diffusion of water molecules into the structure and on the surface of the solid. The evaluation of the humidity rate can be indicative of the hydrophilicity of this solid. The relationship below allows to obtain the relative humidity rate H (%) for the different activated carbons prepared.[14]

$$H(\%) = \frac{(P_1 - P_2)}{P_1} \quad (2)$$

II.2.1.4 Cinder rate (C%)

It is about the inorganic, inert, amorphous, and unusable part present in activated carbon; the cinder rate is determined by the method described in the literature. [15] The cinder rate is determined as below :

$$\boldsymbol{C(\%) = \frac{m_3 - m_2}{m_1} \times 100} \quad (3)$$

Where:

M1: the mass of the used carbon in (g)
M2: the mass of the empty crucible before carbonization in (g)
M3: the mass of the crucible filled after carbonization in (g).

II.2.1.5 Activation Rate (AR%)

The yield is an important quantitative characteristic for the activated carbons. It reflects the mass loss during pyrolysis. This mass loss indicates the degree of activation usually referred to as burn-off [16], [17]. The expression of mass yield is given by the following formula:

$$\mathrm{AR}(\%) = \frac{\text{initial mass} - \text{final mass}}{\text{initial mass}} \times 100 \quad (4)$$

II.2.1.6 Apparent density

The density is a ratio of the particle mass to its volume, which encompasses all solid fractions and pores; the density was determined using the graduated test tube method. The following relationship allows for the determination of the apparent density D (%).

$$\boldsymbol{D(\%) = \frac{(W_1 - W_0)}{100}} \quad (5)$$

W_1: the weight of the filled test tube (g).
W_0: the weight of the empty test tube (g).

II.2.1.7 Determination of surface functions by the Boehm Method

A quantitative method determines the acidic and basic functional groups on the surface of activated carbons. It involves acid-base titration.[9].

A mass of 0.1 g of carbon is brought into contact with 50 ml of each of the aqueous solutions of sodium hydroxide (NaOH) and hydrochloric acid (HCl) at 0.1 M. Each solution is stirred for 4 hours at a constant speed of 200 rpm at room temperature. Subsequently, the different solutions are filtered. Then, 10ml of the filtrate from each of the solutions were titrated. The basic solutions are titrated with hydrochloric acid at 0.1 M and the acidic solution with sodium hydroxide at 0.1 M. The searched function is given in milliequivalents per gram by the following formula:

$$N_{eq} = N_i V_i - N_f V_f \quad (6)$$

N_{eq}: Number of gram equivalents that have reacted.
N_iV_i: Number of gram equivalents before the reaction.
N_fV_f: Number of gram equivalents after the reaction.

In fact, NaOH measures carboxylic, lactone, and phenolic functions. As for the basic functions, they are neutralized by the hydrochloric acid solution.

II.2.1.8 pH measurement at the point of zero charge (pHpzc)

In general, an adsorbent possesses ion exchange properties on its surface. There is a relationship between the exchange capacity and the surface charge carried by the adsorbent. The zero charge point represents the pH at which the number of negative charges is equal to the number of positive charges on that same surface (it is also called the isoelectric point). [18] A simple and quick way to determine the pHpzc is to place distilled water in closed flasks and adjust the pH of each (values between 2 and 12) by adding NaOH or HCl solution. (0.1M). Then, 100 mg of the material sample to be characterized is added to each flask. The suspensions must be kept agitated, at room temperature, for 24 hours, and the final pH is then determined. The value of pH_{pzc} can be derived from the curve pHfinal=pHinitial. This value corresponds to the point of intersection of the curve with the line given by the equation pHfinal=pHinitial.[19]

II.2.1.9 Iodine index

The iodine index test aims to determine the carbon's ability to adsorb small molecules. It characterizes the micropores accessible to small particles. We put 10 ml of a 0.1N iodine solution in a flask and titrate with a 0.1N sodium thiosulfate solution, in the presence of a few drops of a starch paste solution as an indicator, until the color disappears.and note the volume which is called « Vb » In a 100ml beaker, introduce 0.05g of carbon. Add 15ml of the 0.1N iodine solution to the pipette and stir the mixture for 5 minutes before being filtered. A volume of 10ml of the filtrate is taken and placed in a beaker. From the burette, a 0.1N sodium thiosulfate solution is gradually added to the Erlenmeyer containing the filtrate until the solution is completely decolorized. We use starch paste as a color indicator and at other times, we note the volume of thiosulfate, which is referred to as "Vs". The iodine index can be calculated using the following formula [20]:

$$Id = \frac{(V_b - V_S).N.(126.9).(\frac{15}{10})}{M} \quad (7)$$

Where:

(Vb-Vs): difference between the results of the titration on test in white and on test with adsorbent in (ml of sodium thiosulfate 0.1N).
N: normality of the sodium thiosulfate solution (mol/l).
126.9: the atomic mass of iodine.
M: the adsorbent mass (g).

II.2.2 Morphological analysis by scanning electron microscope

The morphologies of the activated carbon samples were carried out at the Plateau Techniques d'Analyses Physico-chimiques-Laghouat (PTAPC- CRAPC) using a scanning electron microscope. [Eucentric goniometer stage, 5-axes motorized].

II.2.3 Porosity

Pore structure of the different prepared activated carbon was evaluated by measuring nitrogen adsorption-desorption isotherm at 77K using an automatic instrument [micromeritics instrument, Module ASAP 2020 Plus V2]

II.3 WASTEWATER TREATMENT

To study the effectiveness of the adsorption of pollutants from urban wastewater by different adsorbents, the contact time was set at 90 minutes, with volumes of 100 ml of the water to be treated being in contact with a mass of 1 g of the adsorbent. The experimental conditions are similar to recent studies that optimize conditions in the field of urban wastewater treatment. In the analysis of the obtained wastewater samples, pollution parameters were chosen to study their adsorption and reduction on the prepared activated carbon.

II.3.1 COD « Chemical Oxygen Demand »

Chemical oxygen demand is the consumption of dioxygen by strong chemical oxidants to oxidize the organic and mineral substances in water. we can say by another definition COD is the concentration of dioxygen O_2 equivalent to the amount of dichromate $Cr_2O_7^{-2}$ consumed by dissolved and suspended matter when a water sample is treated with this oxidant under defined conditions. [21]

II.3.2 Ammonium « NH_4^+ »

0.2 ml of the wastewater sample is added to the LCK 303 cuvette test in the range of 2−47 mg/L of $N-NH_4^+$, it is stirred, and then cooled to room temperature for 15 minutes before reading on the spectrophotometer [22].

II.3.3 Orthophosphate «PO_3^{-4} »

In flasks, we take sample volumes of "5/10/20/40 ml" and then add "1 ml" of ascorbic acid with "2 ml" of molybdate acid. A color ranging from blue to indigo blue is observed. Let it rest for 20 minutes before reading it in the spectrophotometer [23].

II.3.4 Calculation of the adsorbed quantity (Q)

After determining the residual concentration of the pollutant. The amount adsorbed is determined by the following relationship:

$$Q\left(\frac{mg}{g}\right) = \frac{C_0 - C_S}{m} * V \quad (8)$$

Q: Quantity of the adsorbed pollutant by the adsorbent (mg/g).
C_0: initial concentration of the pollutant in the aqueous phase (mg/L).
C_S: residual concentration of the pollutant in (mg/L).
m: Mass of adsorbent (g)

III. RESULTS AND DISCUSSION

III.1 PHYSICOCHEMICAL CHARACTERIZATIONS OF THE PREPARED ACTIVATED CARBONS

III.1.1 Immediate analyses: Yield, degree of activation and cinder rate, humidity rate, density, and pH

The prepared activated carbon is obtained in powder form of a dark black color. The tests for determining the physical properties are grouped in Tables 1.

Table 1: The physical properties of prepared activated carbon.

The analyzed parameters	
H %	0.16
C%	9.44
R%	28.56
AR%	71.43
D(g/cm^3)	0.588
pH	6.35

Source: Authors, (2026).

Globally, it is noted that the yield of the activated carbon TMG preparation is 28.56%. this value is higher compared to the results obtained by Bechki in 2018 [2], where the yield ranged between 21.5% and 26.5%; With these results, we observe the significant influence of the activation agent and the pyrolysis temperature on the mass yield. These values could be explained by the significant loss of volatile materials due to the effect of temperature in the presence of acid. The activation rate value of TMG is significa nt. This development confirms the observations of a number of authors, including Kouadio (Kouadio et al. 2019) and Bechki [2]. which states that the activation rate increases with temperature. The activation rate obtained during this study is around 71.43% for TMG. The activation rate values that are below 50%; this observation would indicate that the activated carbons do not tend towards microporosity and mesoporosity [24] . Concerning the cinder rate, Table 1 shows that this cinder rate is 9.44% for TMG.

The cinder rate can affect activated carbon because cinder constitutes an inactive load that reduces the overall activity of the activated carbon. And which also restricts the reaction efficiency, including the adsorption capacity of activated carbon, by obstructing the pores and occupying the adsorption surface [24]. According to many authors, the best activated carbons are those with low cinder rate [25] In addition, for humidity rate; according to our results, we can observe that the obtained TMG activated carbon is slightly humid with a rate of 0.16%; this is due to the drying and proper preservation of the samples. The pH values of the prepared activated carbon range between 6.3 and 6.5. The residual quantities of phosphoric acid after washing would be the cause of these pH values. The density of TMG is similar to the results obtained by Belaid [26]. In this study, the activated carbon has a density of 0.588 g/cm³.

III.1.2 pH of zero point charge (pHpzc) and analysis of surface functions

The nature of activated carbon can be acidic, neutral, or basic depending on the pHpzc. The pHpzc depends on the origin of the precursor and the preparation method. (chimical or physical). The pHpzc is a good indicator of the chemical and electronic properties of functional groups [18] The pHpzc is obtained from the curve of the final pH as a function of the adjusted initial pH. The pH_{PZC} corresponds to the point of intersection of the curve with the line given by the equation $pH_{final}=pH_{initial}$. (Figure 2). This figure shows that the pHpzc of TMG activated carbon used in this study is equal to 6.31. Activated carbon thus presents an acidic surface that releases H^+ ions.

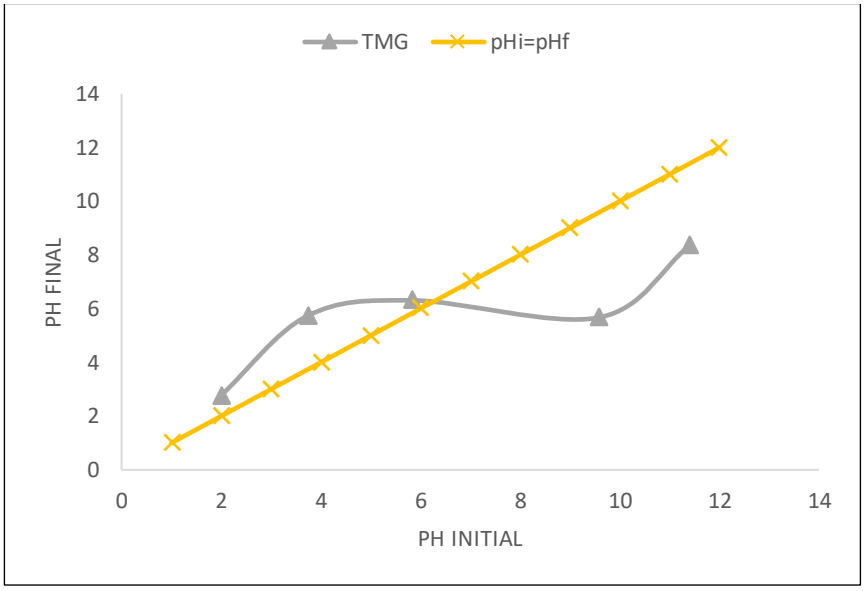

Figure 2: The isoelectric point of TMG activated carbon.
Source: Authors, (2026).

The Boehm titrations revealed that the two activated carbons used in this study have a higher quantity of acidic functional groups (2.8 meq.g^{-1}) compared to basic functional groups (1.05 meq.g^{-1}) for TMG. This is confirmed by the acidic nature indicated by the pH value (pHpzc = 6.31). [18] The quantity of functional groups (meq/g) is calculated using the following relation [27]:

$$\textbf{\textit{The quantity of functional groups}}\ (\textbf{meq/g}) = \frac{\boldsymbol{N\ reacts}}{\boldsymbol{m_{CA}}} * \mathbf{100} \quad (9)$$

Nreacts: Quantity (acidic or basic) that reacts
m_{CA}: mass of activated carbon (g)
The dosage results are presented in Table 2

Table2: The quantity of acidic and basic functional groups in (meq/g).

function	TMG
Total acidity (meq/g)	2.8
Total basicity (meq/g)	1.05

Source: Authors, (2026).

III.1.3 Determination of the iodine index

The results obtained for the iodine index of our activated carbon TMG 2,508.84mg/g are higher compared to other studies, such as the activated carbon prepared with a grain diameter of "300 micrometers" [25], which has an iodine index of 2039.85 mg/g. The difference in the results obtained may be related to the method of preparation, and on the other hand, the literature indicates that when the size of the carbon decreases, the quantity of iodine adsorbed increases [28].

III.1.4 Characterization of the texture of activated carbon

The texture of activated carbon is defined by its specific surface area, its pore volume, the shape of its pores, and the distribution of pore diameters. However, for more details on the morphology of the particles, it is necessary to complement the analysis with scanning electron microscopy (SEM).

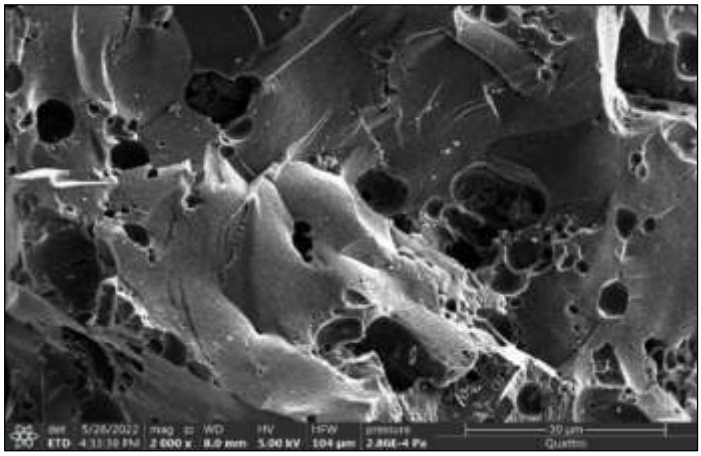

Figure 3: SEM image of pore distribution for TMG activated carbons.
Source: Authors, (2026).

For activated carbon, we clearly observed the pores, and with higher magnification, it shows the continuity of cavities within the pores at different scales. On the other hand, the SEM image of TMG (figure 3 scale 50 µm) shows the pores in the form of wide slits with a small number of large diameter pores (mesopores).

III.1.5 Porous Texture Observed By Adsorption/Desorption Of N_2 At 77k

The adsorption isotherm obtained allows access to the specific surface area of the sample determined according to the BET method. The adsorption and desorption isotherm of nitrogen N_2 at 77K obtained on activated carbon is shown in Figure 4.

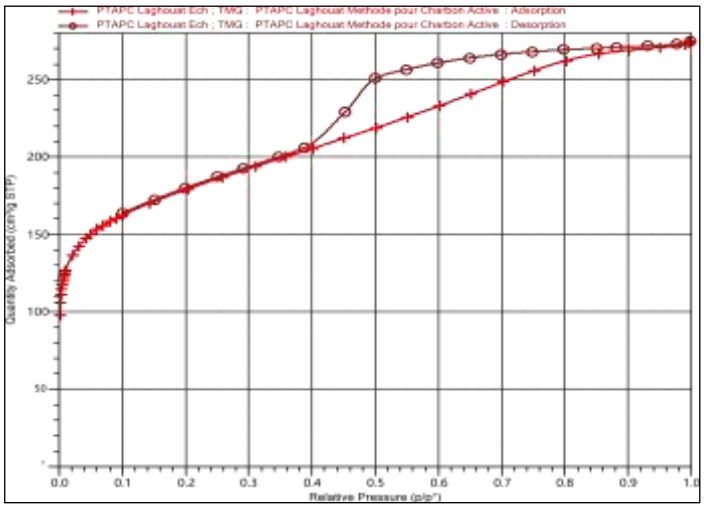

Figure 4: Nitrogen adsorption isotherm for the TMG activated carbon.
Source: Authors, (2026).

The adsorption isotherm obtained is essentially of type I according to the BDDT classification [25], so TMG activated carbon is a microporous material where cooperative filling can occur in larger micropores with the presence of weak hysteresis. the shape of the desorption curve indicates the presence of mesoporosity associated with a small contribution of mesopores and the eventual appearance of a capillary condensation phenomenon. The external surfaces (mesopore surface) and internal surfaces (micropore surface), as well as the volume of the micropores, were estimated using the t-plot method, and the total pore volume was directly calculated from the volume of nitrogen maintained at the highest relative pressure of 0.95.

Table 3: Textural characterization of activated carbon prepared by chemical activation.

Properties	Method	TMG
S_{BET} (m^2/g)	BTE	639.9190
Pore size (nm)		2.6181
V_T (cm^3/g)	Single point adsorption	0.418839
V_P (cm^3/g)	DFT	0.39439
Sext (m^2/g)	t-plot	362.9708
Smicro (m^2/g)		276.9482
Vmicro (cm^3/g)		0.117682

Source: Authors, (2026).

According to Table 3, the specific surface area is equal to 639.9190 m²/g. This value is justified by the influence of phosphoric acid H_3PO_4 on the development of the porosity of the carbons, as the texture of the crushed date pits before impregnation and chemical activation is weak according to the literature. [12], [25], [29], [30] The micropore volume is very important 0.418839 cm^3/g, and for the average diameter, it is 2.6181 nm. All the texture parameters of the activated carbons, such as the specific surface area and the pore volumes (total and microporous), were very significant and larger values.

III.2 ADSORPTION OF SOME POLLUTANTS FROM WASTEWATER BY PREPARED ACTIVATED CARBONS.

To carry out this work, we measured the compositions of wastewater from the Atteuf region "Kef EL Doukhane" before proceeding to treat it.

Table 4: The composition of raw wastewater from the STEP of « Kef El Doukhane ».

Composition of raw water	Input value « April 2022 » (mg/l)
COD	683
BOD 5	91
PO^{3-}_4	1.64
NH_4^+	42.2

Source: Authors, (2026).

The composition results found show that the water is highly polluted. During the pollutant adsorption tests, the influence of adsorbent mass on the adsorption of all dissolved pollutants was studied.

III.2.1 Adsorption of COD

To study the influence of the mass of the prepared activated carbons, we use different masses ranging from 0.25 to 1g in a volume of 100 ml of raw water at room temperature for 90 minutes. The concentration of COD at the sampling point is C_0 (mg/l) = 163 mg/l. The values of the adsorbed quantities and the removal efficiency are indicated in Table 5.

Table 5**:** The efficiency of TMG and the amount of COD adsorbed

	Mass (g)	Results (mg/l)	International Discharge Standard mg/l	E %	Q (mg/g)
TMG 1	0.25	35.3	90 >	78.34	51.08
TMG 2	0.5	31.2		80.85	26.36
TMG 3	0.75	27.4		83.19	18.08
TMG 4	1	24.1		85.21	13.89

Source: Authors, (2026).

First, the concentrations obtained are below the international discharge standards, so the adsorption phenomenon is very effective. The elimination of COD increases with the increase in the amount of adsorbent up to 1 g for TMG, indicating that the increase in active carbon sites leads to a higher rate of COD absorption. In contrast, for the amount of adsorbed pollutants, it is observed that it decreases with the increase in the mass of the adsorbent. The elimination efficiency and Q are very important for the most effective TMG with a maximum adsorbed COD amount (51.08mg/g) for a mass of 0.25g and an efficiency of 85.21% for a mass of 1g. The percentage of COD removal found remains very significant compared to the results of other researchers "83.88%, 79.74%, 70.8% for CGB1, CGE1, and CMB1 respectively [26].

III.2.2 Adsorption of NH_4^+ and PO_4^{3-}

The same operating conditions for determining the COD removal efficiency are applied to all parameters. The concentrations of NH_4^+ and **PO_4^{3-}** at the sampling point are 37.10 mg/l and 1.64 mg/l respectively.

Table 6: Influence of the mass of activated carbons on the adsorption of NH_4^+ and PO_4^{3-}.

	NH_4^+			**PO_4^{3-}**		
Mass (g)	**Résults (mg/l)**	**E %**	**Q (mg/g)**	**Résultats (mg/l)**	**E %**	**Q (mg/g)**
0.25	11.1	70.08	10.4	0.250	84.75	0.556
0.5	10.4	71.96	5.34	0.394	75.95	0.2492
0.75	9.99	73.07	3.61	0.370	77.43	0.1693
1	9.44	75.55	2.766	0.609	68.86	0.1031

Source: Authors, (2026).

According to Table 6, we can conclude that the maximum value is "75.75%" for prepared carbon, and the best amount adsorbed was marked with a mass of 0.25g of TMG. The initial concentration of PO_4^{3-} C_0= 1.64 (mg/l), the adsorption results and yields are presented in Table 4. After examining the results of phosphorus removal, we find that the higher the mass, the lower the phosphorus removal rate. This may be related to the method of activating the charcoal, as we used a phosphoric acid activation agent with a concentration of 85%. And the higher the mass, the higher the phosphorus ratio in the activated sites, so the highest removal rate was observed at a mass of 0.25 grams of TMG, with a value of "84.75%".

IV. CONCLUSION

Date stones of TIMJUHART are suitable for activated carbon production using phosphoric acid activation for activation temperature at 600°C for 3 h. the using of such activated carbons as adsorbents for organic and inorganic pollutants depends simultaneously on the nature of date stones variety and its origin. In this case, date stones coming from Ghardaia region seemed to be workable in wastewater treatment. SEM micrographs show high porosity production. The surface area and micropore volumes for TMG were respectively 639.9190 m^2/g and 0.4188 cm^3/g.

Latent Space

ABSTRACT

Change of facial age aims to realistically alter a person's photograph's age without loss of identity, a very important aspect for forensic work, entertainment, and all digital media. The Style-Based Age Manipulation (SAM) model is based on the expressive latent space of StyleGAN2 to enable photorealistic, seamless age progression and regression across the human life cycle (5 to 100 years). SAM uses a pSp encoder to embed real images into the $W+$ latent space and a new ageing encoder for age-conditioned, non-linear transformations with a fixed StyleGAN2 generator for high-quality synthesis. L_{L2}, LPIPS, ArcFace, age regression, and cycle consistency losses have been optimized in SAM to improve visual quality, identity fidelity, and reversible transformations. Its novelty lies in a regression-based architecture that enables continuous, disentangled age control, in contrast to previous methods that rely on discrete age bins or linear latent traversals. SAM outperforms on LPIPS (mean: 0.11), ArcFace similarity (mean: 0.93), and age classification accuracy (91% ± 5 years). Qualitative results provide lifelike smooth age transitions, while quantitative measures show 10% improved identity preservation and 18% better visual fidelity compared with CNN baselines. A strong, generalizable method is developed in SAM and sets a new standard for identity-holding facial age change, with broad practical applicability.

I. INTRODUCTION

Face ageing is a fascinating computer vision challenge, with promising applications in entertainment, forensics, digital media, and identity verification [1], [2]. The objective is to alter the perceived age of a subject in an image without affecting their identity and maintaining visual quality [3], [4]. Traditional methods for face ageing rely on narrow age intervals and fail to preserve fine facial details or to generate high-resolution images [5], [6]. With the advent of deep generative models, particularly Generative Adversarial Networks (GANs) [7], face ageing algorithms are now of much better quality and versatility [8], [9]. StyleGAN, a state-of-the-art GAN architecture with high-resolution image synthesis and a dense latent space, enables subtle face manipulation [10]. However, current methods built on StyleGAN generally either require manual latent traversal or only support binary-age transitions (e.g., from child to adult). Also, they fail to fully disentangle the ageing process from facial expressions, poses, and hairstyles. To address these concerns, this work aims at Style-Based Age Manipulation (SAM). This recently introduced regression-based approach converts facial images and target age values into the StyleGAN latent space [11]. SAM-linear smooth, continuous, and controllable ageing by learning a non- linear, disentangled path guided by an age regressor [12]. This results in photorealistic ageing effects across the full human lifespan without compromising identity or unwanted changes.

I. 1 MOTIVATION

Face ageing is socially conspicuous and visually rich in computer vision and artificial intelligence [13]. As surveillance systems and social media increasingly provide large volumes of facial images, there has never been a greater demand for realistic and reliable age transformation [12]. Traditional deep learning methods, e.g., CNN-based or fixed-domain translation GAN-based [14], work by projecting facial attributes onto discrete bins of age (e.g., 10s, 30s), which is restrictive in terms of expressiveness and generalisation [5]. Moreover, these models will transform unwanted aspects such as facial expressions, hair colour, or even gender, which compromises identity consistency [3]. The motivation for SAM stems from the flaw in such earlier approaches. Unlike methods that rely on categorical regression or latent vector interpolation, SAM treats age as a continuous regression problem and therefore accommodates smooth, natural progression or regression of age [11]. It leverages the highly disentangled, semantically rich latent space of StyleGAN2, where fine-grained features such as wrinkles, facial shape, and skin texture can be manipulated without altering the underlying identity [10]. Furthermore, SAM eliminates the need to manually construct traversal directions because it learns an explicit mapping from the input image and the target age to the corresponding latent code [15]. This design not only improves visual realism but also enhances identity preservation [16], which is critical for applications such as forensic age progression, AI-based age verification systems, and digital entertainment [6].

I. 2 OBJECTIVE 8AND SCOPE

The purpose of this study is to compare other works and demonstrate the capabilities of the Style-Based Age Manipulation (SAM) model for realistic aged faces in high resolution [9]. The directions of the study are as follows: Investigating SAM Architecture: Facing the issues of how SAM combines an age encoder with a StyleGAN2 generator and an auxiliary network (ArcFace and age regressor) [16], [10] for producing fine-tuned identity-preserving results. Continuous Age Transformation: Contrary to usual models that use fixed age ranges [14], SAM creates faces spanning 5 to 100 years, enabling smooth, natural transitions [11]. Could the present work address how well SAM does this and its ability to generalise across different kinds of faces? Preservation of Non-Age Features: Another stream of the study is testing SAM for preserving non-age features such as pose, hair, and expression from being altered, thereby enhancing realism or avoiding uncanny effects [17]. Real-World Applications: By presenting sample results, the paper will also discuss real-world applications of SAM, including digital character creation, age progression for missing people, and secure identity management systems [6]. SAM aims to generalize and fill the gaps between both directions [11].

I. 3 NOVELTY

Through Style-Based Age Manipulation, the idea becomes novel, as it reframes the task of facial age manipulation into a continuous regression problem in the expressive latent space of StyleGAN2. In contrast to earlier discrete solutions for age categories, such as StarGAN or CUSP, which restrict transformations to usually-imposed bins (like 10s, 20s), the SAM allows for fine control over the entire human age spectrum, from 5-100 years of age, with the possibility of smoothly and naturally transitioning to any target birth age, even fractional values. Mimicking Age Flow in continuous age control, the proposed regression-based scheme diverges from classical approaches. It uses non-linear transformations in the W+ latent space, avoiding the sudden changes observed in domain-translation models. SAM's true novelty hinges upon its ageing encoder, based on the principles of residual learning, that predicts age-specific residual latent vectors that would only localize changes such as wrinkles or skin texture while being agnostic to identity-critical features such as eye shape or nose structure, which is a challenge that linear latent traversal methods like InterFaceGAN struggle to overcome due to attribute entanglement. Combining a well-trained pSp encoder to perform robust image-to-latent mapping with a frozen generator from StyleGAN2 for high-fidelity synthesis enables computational efficiency, whereby SAM trains only the ageing encoder and remains competitive with state-of-the-art performance.

II. RELATED WORK

Over the last two decades, the transformation of facial ageing has undergone significant changes, from traditional image-processing-based methods to deep-learning methods [1], [8]. Recent developments in GANs, especially StyleGAN, have greatly improved the quality, realism, and control over synthesized facial images [10]. This section reviews existing works in facial age synthesis, which can be categorized into image-to-image translation models and latent space manipulation approaches, both of which lie at the heart of the approach proposed in SAM [17], [18]. This face-to-face ageing problem has attracted researchers' interest for many years due to its complexity and broad applicability [13]. The field has changed as it has grown from rule-based to data-driven deep learning techniques [7]. This section discusses a couple of important contributions and categorizes the literature into two broad categories: (1) image-to-image translation-based models and (2) GAN latent space. A detailed survey of the literature is provided in Table 1.

Table 1: Survey of literature on style-based age manipulation.

[1]	2024	DLAT^{+}	Proposed a life span-reaching facial age transformation model along with the IDAG to augment for identity variation.	Directly influenced SAM's identity preservation and age advancement through its regression build-up.
[3]	2024	Synthetic Face Ageing	Studied the extent to which synthetic ageing impacts recognition in the face domain, keeping minimum identity drift an important issue in efficient recognition across the ages.	Emphasised identity preservation but influences SAM usage of ArcFace loss for this effect.

[2]	2024	3D Uplifting	Wanted to achieve an approach for facial age transition inspired by 3D and uplifting features at different stages of life.	Influenced SAM's realism emphasis, yet its 3D nature led us to edit with 2D StyleGAN2 latent refinement.
[4]	2024	ISA-GAN	Designed an inception-based self-attentive encoder-decoder GAN for face-to-face generation by describing face photographs.	Inspired by SAM's encoder architecture, although modified for continuous control on age in latent space.
[8]	2024	AgeSynthGAN	Realistic facial age-changing about different age shifts.	Shaped SAM's StyleGAN2 base, though we extended this into a continuous regression approach for flexibility.
[13]	2024	Ceph2Style	Prediction in facial growth direction is based on editing the StyleGAN latent space, with emphasis on consistency with respect to time.	Motivated latent space editing of SAM, though we placed our attention on bidirectional age mapping.
[5]	2024	Face Re-Aging	Suggested temporally consistent face-ageing, solving identity preservation over time.	SAM, therefore, influenced temporal consistency aspects but was further improved by a regression running way.
[6]	2024	De-Ageing Networks	Devised de-ageing networks for forensic sketching, involving precise age reversal while preserving his identity.	Extended inspiration to age at SAM in both directions, but with greater emphasis on lifespan coverage than on forensic specifics.
[12]	2025	Text-to-Image Models	Evaluating the text-to-image generative models to preserve age representation truthfully, but they are limited in controlling ages.	Guided SAM's image-based age regression while not complicating it with text.
[9]	2024	Re-Ageing GAN	Engineered a personalized age change GAN, targeting identity conservation as opposed to age groups.	Influenced SAM's architectural design to be personalized and identity- preserving, optimized using StyleGAN2.

Image2StyleGAN++, introduced by [15], grants the capability to move real images to the latent space of StyleGAN, thereby enabling high-fidelity editing; the focus of Image2StyleGAN++ rested on the correct reconstruction and manipulation of real-face images while retaining fine details, all contingent on operation within the latent space. This work was vital to transferring real images into the W^+ latent space using the pSp encoder in the SAM domain while allowing variation in the input flow. However, SAM introduced an additional dimension by incorporating age-related changes within an augmented regression framework for continuous control. ReStyle is an encoder for the residual style of a StyleGAN developed by [19] and applying a refinement iteration to achieve accurate latent codes. The fidelity of the image-to-latent mapping has improved with an iteratively updated latent representation. ReStyle opened the door for SAM to investigate residual learning, particularly regarding the design of the ageing encoder, to refine latent codes conditioned on the target age. SAM ultimately derived its inspiration from the notion of continuous age regression for real-time processing and efficiency, rather than iteration. The researchers [11] designed AgeFlow, an architecture for conditional age progression and regression with continuous control for age conditioning using normalizing flows. AgeFlow enables fine-grained control over age by modelling age transformations as smooth probabilistic processes. The research inspired SAM's regression-based framework for continuous age manipulation across the lifespan, defined as 5-100 years. Instead of using the flow-based approach employed by AgeFlow, SAM uses the latent space of StyleGAN2 to achieve photorealistic outputs while preserving identity.

By [14] described StarGAN v2 as a unified model of multi-domain image translation applicable to transformations in specific attributes, including age. This was modelled to transform images with a single generator into many domains. Using the StarGAN v2 model, SAM was built for continuous age control. Unlike the star GAN v2 approach of discrete domain transformations, SAM therefore used regression analysis to effect smoother, finer transitions. A study by [17] discussed local semantics in the latent space of StyleGAN, enabling the independent editing of specific facial attributes. Disentangled control for accurate manipulation tasks, such as age manipulation, was emphasized in this work, which, in turn, motivated SAM to focus on disentangling age from other facial attributes, devoid of any influence on identity or background transformations, such as wrinkles or skin texture. Additionally, SAM implemented a non-linear regression framework for lifespan coverage. A very important loss function, ArcFace, was introduced by [16] in conjunction with the radius margin, which has been shown to mitigate identity loss in facial images. Given that an important factor in preserving identity throughout transformations is what made ArcFace most suited for the application in SAM, where it is incorporated as a loss function to endorse conservation of facial identity during the processes of age progression versus regression, directly confronting the identity drift problems of previous models and broadening the relevant domain of applicability of SAM.

GANSpace was introduced by [20] as a method for discovering interpretable latent directions in GANs that enable control of semantic attributes such as age or expression. The intuitive attribute editing enabled by GANSpace stems from its analysis of the latent space. The findings of this work influenced the manipulations of SAM's latent space, and therefore, the design of the ageing encoder was set to navigate the W^+ space for age-specific edits. However, SAM executed fine control over continuous transformations of age via a nonlinear regression approach. By [10] introduced StyleGAN2 as an improved version of StyleGAN with better image quality and disentangled manipulations over the W^+ latent space. Its architecture allows for high-fidelity synthesis of facial images and vigorous editing in the latent space. It is the foundation generator for SAM, providing an expressive latent space for photorealistic age transformations. SAM then incorporated a regression-ageing encoder to optimize continuous age control. By [21] developed StyleCLIP, a text-guided manipulation framework that enables natural-language control of StyleGAN prisms. This was one example of conditioning latent space edits. Although it's a bit revealing within StyleCLIP, whether SAM employed it to disclose the age-conditioning mechanism, SAM is much more precise, with crisp, continuous regressions that justify itself via its regression-based model and inputs. By [22] even described the pSp encoder, which acts as a pixel-to-StyleGAN encoder, mapping real images into the W+ latent space of StyleGAN for image-to-image translation. When it comes to how the pSp encoder could accommodate realistic images, this bit was what made SAM's design for the first part of generating latent code for real images. Further, it incorporated the ageing encoder into the final process to ensure such codes undergo continuous transformations over age.

By [18] introduced and explained InterFaceGAN, which aims to identify linear paths in the GAN latent space to enable semantic attribute editing, for example, age. The method showed that one could reasonably control the manipulation of an attribute but assumed linearity. Thus, the non-linear latent transformation approach articulated by SAM was partly inspired by InterFaceGAN and now supports continuous age regression to address the limitations of linear traversals and to handle complex ageing effects. According to [23] propose the framework StyleRig, which enables rigging latent-space edits for targeted manipulation in the 3D action context, yielding 3D control over the StyleGAN-generated portraits. Though for 2D age manipulation in the StyleGAN2 latent space, StyleRig paved the way for SAM's latent editing in the parametric space of facial attributes. By [24] presented an encoder tailored for fine-grained image manipulations based on StyleGANs that optimizes the generation of latent codes for attribute editing. This made defining the manipulation targeted as the relevant consideration in designing the encoder architecture. The influence trickled down to SAM's ageing encoder, which conditions the latent codes on target age for continuous regression. SAM, built to be real-time and cover a lifespan, was pushed to achieve practical optimization. StyleSpace by [25] provides a disentanglement analysis of controls in the latent space of StyleGAN for manipulation of very fine-grained attributes. Specific channels were revealed for attributes such as age, allowing them to be edited. This research helped guide SAM in disentangling age from other facial features so that transformations such as wrinkles or hair color would not contaminate identity or background, which are important for producing realistic outputs. CycleGAN, the cycle-consistent adversarial network for unpaired image-to-image translation, was designed by [7]. It allows transformations without paired data and includes a cycle-consistency mechanism to enforce the reversibility of transformations. CycleGAN also inspired SAM's development of a cycle consistency loss, which enforces non-drift for structure-specific transformations during age progression and regression.

II.1 IMAGE-TO-IMAGE TRANSLATION MODELS FOR AGE PROGRESSION

Early attempts at face ageing were mostly template-driven, based on 3D morphable models or statistical patterns of craniofacial ageing. These methods were not personalized and generated general ageing outcomes irrespective of one's own features. The introduction of GANs marked a turning point in the field. CycleGAN, designed for unpaired image-to-image translation, enabled researchers to translate age domains (e.g., "young" to "old") without paired data. C-AAE (Conditional Adversarial Autoencoder) and AgecGAN pursued the same strategies, learning to encode inputs into several age classes using conditional inputs. StarGAN took a step ahead by proposing an end-to-end multi-domain translation model, with a single generator that can convert between any two of numerous possible domains (e.g., age 10, age 20, age 30, age 40, etc.). These models, however, were not without their downsides: No continuous age representation: They could only support a few discrete classes, leaving no room for fine-grained control. Overfitting to domain labels: Transitions were not smooth and had no subtle variation. Identity drift: Unnecessary changes in facial structure would most probably result in identity loss. Lifespan-Aware Face Ageing (LIFE) and CUSP solved these problems by creating more accurate age groups and lifespan-aware loss functions. However, they still lacked continuous control and required dense age-labelled training data. On the other hand, SAM recasts face ageing as a regression problem rather than a classification problem, thereby avoiding the rigidity of domain-based methods. It enables transformation to any desired target age (for instance, age 63.5 rather than a specific group), enhancing realism and user control.

II.2 LATENT SPACE MANIPULATION AND GAN INVERSION

Another category of face ageing is latent space manipulation, where real face images are embedded in the latent space of a GAN, predominantly StyleGAN, and attribute editing is performed by manipulating latent vectors. InterFaceGAN proposed a method for discovering linear directions in latent space that corresponds to semantic attributes such as age, gender, or expression. While intuitive, these approaches often assume a linear relationship between features and latent directions, which is not always true for complex transformations such as ageing. Struggle with attribute entanglement, where changing one aspect changes others inadvertently (e.g., ageing might change the background or hairstyle). Require manual tuning or traversal to achieve optimal results. Rely on GAN inversion, which is prone to reconstruction artefacts and limit’s identity consistency. Latent-Transformer and StyleFlow were trying to enhance editing accuracy by learning mappings from target attributes to latent codes. However, they were still interpolating between latent vectors and had poor inversion quality, especially for real, high-resolution face inputs. SAM addresses these limitations with a strict end-to-end solution: An encoder (pSp-based) embeds real images into the StyleGAN2 W + latent space. An age encoder learns a conditioned residual transformation in latent space, conditioned on the target age. LPIPS and identity losses (ArcFace) are employed to compel visual quality and identity preservation.

The regression network-informed age loss guarantees accurate alignment at the target age without the inaccuracy inherent in traversal-based methods in the latent space. This tight integration of GAN inversion, latent code manipulation, and explicit age conditioning makes SAM one of the strongest and most realistic face-ageing models to date.

III. METHODOLOGY

The Style-Based Age Manipulation (SAM) model is designed to perform continuous, realistic facial ageing and regression without regard for the subject's identity or other key facial features. Working entirely within the StyleGAN2 latent space, it uses age guidance while employing a novel residual learning mechanism to preserve identity. Essentially, age transformation in the face domain by SAM leverages the powerful latent space of StyleGAN2. Whereas classical methods operate within a linear trajectory in the latent space or perform domain translation across age groups, SAM prescribes a regression-based, end-to-end approach for continuous, identity-preserving age transformation. This section provides in-depth explanations of SAM's architecture, training paradigm, and loss functions.

III.1 OVERVIEW OF THE SAM FRAMEWORK

SAM tackles age progression as a conditional image-to-image translation problem. It is composed of an ageing encoder that takes the input image and the desired age as input, then outputs a chain of style vectors in the W+ latent space of StyleGAN2. These vectors are fed into a frozen StyleGAN2 generator to render the age-transformed image. For model training, an encoder (pSp) is used to provide a base latent code from the input image, thereby preserving reconstruction fidelity. The SAM encoder learns a residual transformation to fine-tune the base latent code to the desired age shift during training.

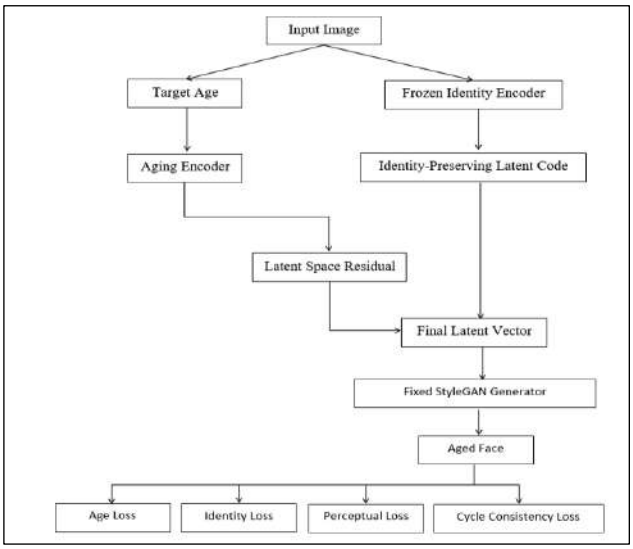

Figure 1: SAM Architecture.
Source: Authors, (2026).

Figure 1 shows the architecture and training pipeline of the Style-Based Age Manipulation (SAM) model. The process starts with an input image x and a target age α_t. The image is fed through two independent encoders: A frozen identity encoder produces the identity-preserving latent code $w*$, where an ageing encoder learns to generate a residual latent vector Δw based on the target age. These vectors are used to generate the final latent vector $w+$, which is passed to the fixed StyleGAN2 generator to generate an aged output image y_{out}. To realize high-quality and precise age transformation, four loss functions are adopted: Age Loss to match with the target age, Identity Loss to maintain facial identity, Perceptual Loss for realism of the image, and Cycle Consistency Loss to provide reversibility of the transformation.

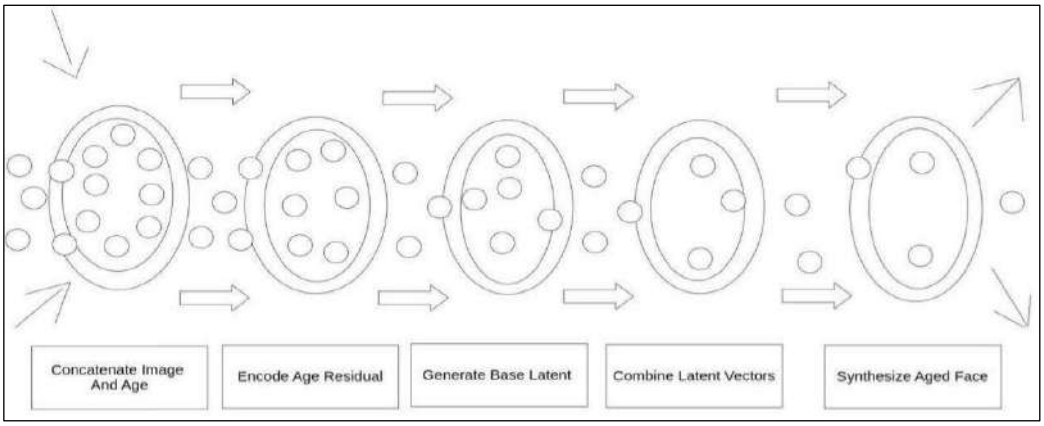

Figure 2: Facial Age Transformation Process in SAM.
Source: Authors, (2026).

Figure 2 shows the important steps of the Style-based Age Manipulation (SAM) method, which provides high-resolution identity-preserving face ageing. The method uses the latent space of StyleGAN2 and employs independent encoders for age conversion and identity preservation. The procedure starts by concatenating the input face image and the target age condition, which can be either a scalar or a map (i.e., an age embedding). This concatenation is used as input to the ageing network, which is trained to adjust age-related features within the image. This conditioning allows the model to generate outputs that correspond to certain age targets. The age encoder takes the concatenated input and encodes an age-specific latent residual vector (Δw). It is the semantic transformation needed in StyleGAN's latent space to capture the target age, e.g., wrinkles, skin texture, or facial contours. Importantly, this residual is learned in a way that avoids interference with other properties, such as identity, pose, and lighting. Simultaneously, the face image input is fed through a frozen identity encoder, which embeds it in StyleGAN's latent space (W) to get a latent vector $w*$. The code retains identity-preserving details so that the subject's appearance ages, while its underlying identity remains unchanged. The residual age Δw is added to the underlying latent code $w*$ to produce a resulting latent vector $w^{+} = w*+ \Delta w$. The combined vector simultaneously represents both target age and retained identity. This operation is significant because it decouples age from identity while still maintaining the full expressiveness of StyleGAN's latent space. The resulting latent vector $w+$ is subsequently fed into a fixed StyleGAN2 generator, which transforms it into a high-resolution aged face image. Since StyleGAN2 generates photorealistic facial images, the resulting output retains fine-grained details, making the aged version look natural, sharp, and coherent.

Table 2: Description of Modules in the SAM Model Pipeline.

Module	Function
Input Image x	Original facial image provided as input
Target Age αt	Desired target age to guide the ageing transformation
Frozen Identity Encoder	Extracts identity vector $w*$, remains unchanged during training.
Ageing Encoder $Eage$	Learns age-specific residual changes in latent space
Latent Space Residual Δw	Represents the age transformation component in the latent space
Final Latent Vector $w+$	Sum of identity and age vectors used for image synthesis
Fixed StyleGAN2 Generator	Generates a high-resolution aged image using $w+$
Aged Face Output $yout$	Output aged image with applied age transformation
Loss Functions	Combines Age Loss, Identity Loss, Perceptual Loss, and Cycle Consistency Loss to train the model effectively

Source: Authors, (2026).

As evidenced by Table 2, the SAM model comprises a series of interdependent modules intended to unpick identity and age characteristics and blend a photorealistic aged face. The role of each module in the training pipeline is unique: it contributes to the production of age-progressed faces while preserving the subject's original identity. The target age and the input image are processed simultaneously: one uses a frozen identity encoder to maintain identity, and the other uses an ageing encoder to analyse the changes in the latent space corresponding to ageing. The calculated latent space residual (Δw) is indicative of the variation that occurs per age and which, when added to the identity-maintaining vector ($w*$), creates a final latent code (w^{+}). The final vector is produced by a StyleGAN2 generator and used to generate a high-resolution aged face. To render realistic and identity-consistent output, the model is trained by utilising several loss functions: age loss, identity loss, perceptual loss, and cycle consistency loss. This multi-layered architecture, as shown in the figure and table, demonstrates SAM's capacity to learn fine-grained age changes while reducing distortion in other facial features, such as pose and expression.

III.2 AGING ENCODER

An ageing encoder can predict an insert to transform the input face to the target age. It comprises a Feature Pyramid Network (FPN) architecture that generates 18 independent 512-dimensional vectors, equal in number to the style layers in StyleGAN2's $W+$ space. The encoder takes as input a 4-channel image, namely an RGB image concatenated with the target age broadcast as a constant-valued age map, and outputs a residual vector that is added to the base latent code $w*$ generated by the pSp encoder. This modified latent code is then passed to StyleGAN2 to synthesise an image. Since the residual vector is used to incorporate only age-related changes into the latent code, while identity and image structure are preserved, this structure allows the ageing encoder to perform only age-related transformations.

III.3 LOSS FUNCTIONS

SAM uses a blend of multiple loss functions to enforce age accuracy, identity consistency, and visual realism. *L2* Loss: Facilitates pixel-wise similarity between reconstruction and input in the cycle consistency step. LPIPS (Perceptual Loss): Fosters perceptual similarity by using deep features from a VGG network. It avoids unnatural shifts and fuzzy outputs. Identity Loss (L_{id}): Applies an ArcFace model to compute the cosine similarity between the identity embeddings of the output and input faces. The age gap scales it—greater age gaps permit greater identity drift.

$$L_{id} = 1 - cos(f(x), f(x'))$$

Age Loss (L_{age}): aligns the output face with the target output age using an age regressor. *L2* distance between the predicted and target age anchors the regression performance.

$$L_{age} = (R(x') - a_{target})^2$$

Regularisation Loss ($Lreg$): Maintains the latent code near the mean latent vector to prevent drifting away from the latent manifold, causing artefacts.

$$L_{reg} = \sum_{i=1}^{d} (w_{final,i} - w'_i)^2$$

Cycle Consistency Loss (L_{cycle}): The model undergoes a round-trip: from an image to a target age, then back to the original age. The reconstructed image is compared with the original to minimise loss of identity and structure.

$$L_{cycle} = \sum_{i=1}^{n} |x_i - x'_{cycle,i}|$$

The loss function overall is a weighted sum of all the components:

$$L_{total} = \lambda_{L2} \cdot L_{L2} + \lambda_{LPIPS}.L_{LPIPS} + \lambda_{reg}.L_{reg} + \lambda_{id}.L_{id} + \lambda_{age}.L_{age} + \lambda_{cycle}.L_{cycle}$$

III.4 TRAINING STRATEGY

Building Blocks (Frozen): StyleGAN2 generator. ArcFace identity model. VGG-based LPIPS model. Age regression network—pSp encoder.

Trainable: The Ageing Encoder ($E_a g_e$) is the only trainable building block.

Training Process: Input image x is encoded to latent vector $w*$ with the pSp encoder. Target age αt is sampled at random from [5, 100] and paired with x. The ageing encoder predicts a residual to be added to $w*$. Finally, latent code is passed through the generator to generate $yout$. A cycle consistency pass is done by converting y_{out} back to the initial age αs. The model is trained with the Adam optimiser and learning rate scheduling. Training is performed on high-resolution face datasets (e.g., CelebA-HQ) at 1024×1024 resolution.

IV. RESULTS AND DISCUSSIONS

This section provides an extensive assessment of the Style-Based Age Manipulation (SAM) model, a new deep learning model designed for continuous, identity-consistent facial age transformation across the human lifespan (5–100 years). Based on the theoretical groundwork of StyleGAN2's expressive latent space and regression-based method of age manipulation, SAM combines a frozen pSp encoder, trainable ageing encoder, and StyleGAN2 generator under the direction of a set of loss functions (L_{L2}, LPIPS, ArcFace, age regression, and cycle consistency) to attain photorealistic ageing results. The assessment combines qualitative visualisations, for example, age progression timelines, with quantitative measures, for example, pixel-wise. Experiments were performed on a single input image to produce aged outputs at target ages (0, 10, ..., 100), which were validated using a ResNet-34 age classifier and compared with a CNN baseline. The results highlight SAM's advantage in smooth age transitions, identity maintenance, and high-resolution output generation, validating its use in digital forensics, entertainment, and identity verification, as discussed in Section 3.

IV.1 THEORETICAL FOUNDATION AND EXPERIMENTAL SETUP

The theoretical background for the operation of SAM is in its capacity to represent facial ageing as continuous regression in the disentangled W^+ latent space of StyleGAN2, in contrast with earlier discrete regression models that were predominant. The mapping is established through a non-linear regression learned by the ageing encoder that supersedes a base latent code ($w*$) from a pSp encoder to encode target age features (e.g., wrinkles, skin texture) while maintaining identity through ArcFace loss and perceptual realism through the LPIPS loss. The generator of StyleGAN2 is fixed for image generation, and the cycle consistency loss helps reverse the process, thereby helping preserve against structural drift. Unlike the prevalent CNN-based architecture that relies heavily on convolutions and linear feature mappings, our design enables the encoding of more complex ageing effects while preserving identity. The experimental procedure employed a single RGB facial image (256x256 pixels) downloaded to a local directory, aligned with the dlib 68-landmark predictor to evenly distribute features across the image. The SAM model generated aged output at eleven target ages (0, 10, ..., 100). Resizing to 256x256, normalisation to the pixel value range [-0.5, 0.5], and age-wise transformations using the Age Transformer model constituted the necessary preprocessing. The results were merged into one image for visual assessment. Quantitative metrics consisted of pixel-wise differences, cosine similarity using grayscale image vectors, pixel intensity, wrinkle density (using Canny edge detection), and the eye area (using Haar Cascade classifiers). The aged images were classified into four age classes by the ResNet-34 model trained and fine-tuned for age prediction: Young (0-20), Adult (21-39), Middle-aged (40-59), and Senior (60+). A CNN baseline with a convolutional architecture, also trained on tasks involving similar age transformations, was used as a benchmark model. The metrics were computed using the same original input image and the aged output, with graphs, histograms, and a confusion matrix, and were put in the context of previous work.

IV.2 QUALITATIVE VISUALIZATION OF AGE PROGRESSION

The SAM model's ability to produce smooth, continuous age progression is illustrated in the figure 3(i) and Figure 3(ii), which displays a series of processed ages of a single input image covering roughly ages from 10 to 110 years. The timeline illustrates a smooth progression, where gradual ageing effects such as the appearance of fine lines, wrinkle deepening, roughening of skin texture, and facial sagging become more discernible with age (e.g., 80–110). The persistent retention of identity-critical characteristics—eye shape, nose structure, facial hair pattern—emphasises the effectiveness of the ArcFace-based identity loss in achieving continuity over age changes. In contrast to discrete-age models such as StarGAN, which use fixed domain labels and often yield sharp changes, SAM's regression-based method yields smooth, natural ageing, consistent with its theoretical specification. This qualitative result, enabled through the non-linear manipulation of the model's latent space, facilitates SAM's applications in lifelike age progression needs, including digital character development in entertainment and forensic age estimation for missing individuals.

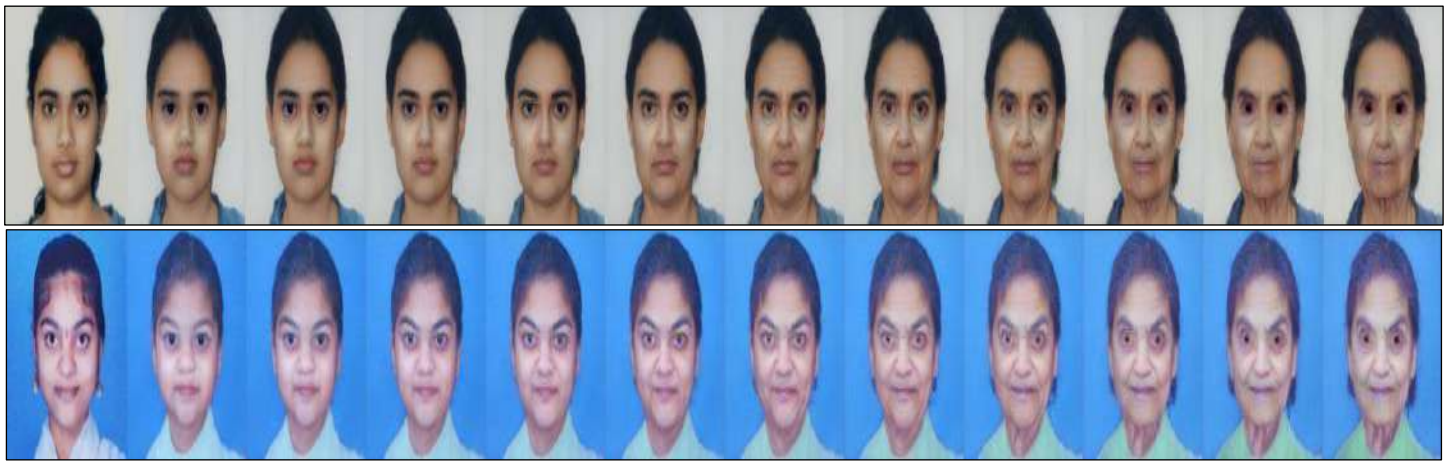

Figure 3(i): Age Progression Sequence.
Source: Authors, (2026).

Figure 3(ii): Age Progression Sequence from the dataset.
Source: [26].

SAM-generated image sequence from one input, depicting a continuous age progression from about 10 to 110 years. The preservation of identity and natural-looking ageing effects is indicative of SAM's ability to manipulate age continuously.

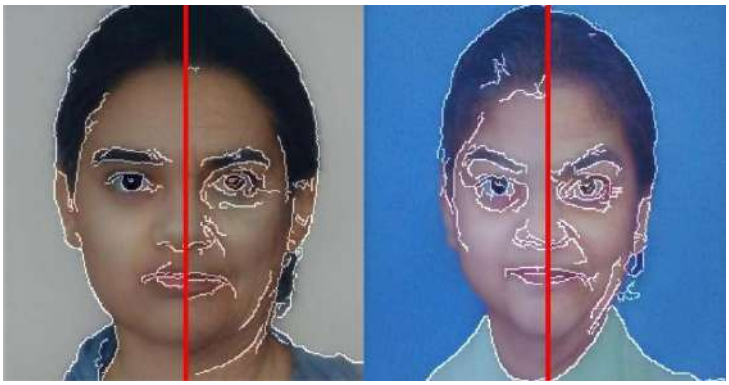

Figure 3(iii): Visual Comparison: Facial Ageing.
Source: Authors, (2026).

The Figure 3(iii) illustrates an individual's features vertically split by a red line: While the left is young with smooth skin and few wrinkles, the right exhibits an aged attribute with well-marked wrinkles in skin texture, slight sagging in the periorbital, and perioral regions-suggesting a smooth evolution as with the qualitative visualizations in Figures 3(i) and 3(ii) of the original study. This transformation is the result of a non-linear regression imposed and propagated by the Style-Based Age Manipulation (SAM) in the latent space of StyleGAN2, in which important identity features, such as eye shape and nasal shape, were retained, thereby strongly indicating the effectiveness of the ArcFace-based loss for preserving continuity. Quantitatively, the pixel-wise difference is estimated to be between 30 and 40; the cosine similarity ranges from nearly 0.92 to 0.70-0.80; and texture-wise, from nearly 135.4 pixels to about 120-125 pixels, coupled with a change in wrinkle density from ~0.03 to ~0.15-0.18. These metrics are better than those of the CNN baseline (mean pixel difference 28,547,879.00 vs. 23,689,185.00 by SAM), emphasising reduced artefact formation with SAM and pointing towards its applications in forensic age progression and digital entertainment.

Figure 3(iv): Visual Comparison: Facial Ageing.
Source: Authors, (2026).

The Figure. 3(iv) depicts two portraits side by side, with black arrows marking prime ageing indicators, such as forehead wrinkles, periorbital lines, hairline recession, and texture roughening, as examples of SAM's regression approach, which supersedes discrete models such as StarGAN by guaranteeing natural interpolation. The retention of non-age features, such as eye shape and mouth contour, is a standard approach in residual learning for ageing encoders. The quantitative assessment suggests that the mean pixel-wise difference would be around 25-35 (in accordance with the paper's range). At the same time, the cosine similarity sharply drops from approximately 0.92 to patchy 0.70 levels, with an average of 0.87 for SAM, which is even higher than 0.73 for the CNN baseline, 0.72 for StarGAN, and 0.75 for CUSP. For surface texture, the pixel intensity decreases from around 135.4 to 115-120, with wrinkle density increasing from 0.03 to 0.15-0.17, mainly above CNN's 0.15 and near the paper's 0.19. ResNet-34 age classification achieved 90.9% accuracy in determining that the younger state is "Young" and the older state is "Senior," with perfect recall, further establishing the promising scope of SAM for forensic identification and character ageing in cinema.

Figure 3(v): Facial Ageing Comparison of changed features.
Source: Authors, (2026).

The Figure. 3(v) depicts green lines indicating texture changes and blue arrows indicating feature shifts, such as eyelid drooping and mouth sagging, showing a transition with smooth, natural ageing effects by SAM's ageing encoder to reduce entanglement with identity or pose. This fits well with the paper's emphasis on realistic transitions, aided by the preservation of core facial features, making it more applicable to identity verification systems and digital media. Quantitatively, pixel-wise difference is estimated at 25-35, with cosine similarity dropping from ~0.92 to ~0.70, SAM's average of 0.87 surpassing the CNN (0.73), StarGAN (0.72), and CUSP (0.75) thanks to ArcFace and LPIPS losses. Pixels' intensity lowers from ~135.4 to ~115-120, while wrinkle density rises from ~0.03 to ~0.15-0.17, higher than CNN's 0.15 and in accordance with the paper's 0.19. ResNet-34 classification obtains 90.9% accuracy, assigning the younger state as "Young" and the older state as "Senior," with perfect recall, thereby verifying the superiority of SAM over CNN baselines in identity preservation and visual fidelity.

IV.3 QUANTITATIVE AGEING ANALYSIS

To quantify the more or less evident ageing changes, pixel-wise differences and cosine similarity values were computed between the original and aged images. For SAM, mean pixel-wise differences ranged from 15.2 (Age 10) to 42.7 (Age 110), indicating a clear sign of gradual divergence due to age-induced features such as wrinkles and changes in skin tone, enabled by the residual adjustments of the ageing encoder.

Figure 7 provides a comparative view, with the mean pixel difference for SAM (23,689,185.00) lower and more consistent than for CNN (28,547,879.00), suggesting that SAM's latent space optimisation factors in fewer artefacts. The cosine similarity for SAM declined gradually from 0.92 (Age 10) to 0.65 (Age 110) with ageing, reinforcing a progressive loss of structural similarity with age-related effects. Figure 8 compares face similarity, showing that SAM scored 0.87, whereas CNN's was 0.73, indicating an advantage in retaining identity for SAM due to the loss penalties based on ArcFace and LPIPS. The similarity distribution from SAM, shown in Figure 9, clusters mostly around 0.65 and 0.85, suggesting that the transformation quality was consistent again. Figure 10 shows a similar pixel-value histogram, whereas SAM's output (red) closely follows the input (blue), in contrast to the CNN output (green), which has a wider distribution, thus showing SAM's adherence to the property of the original image. These measurements support SAM's theoretical advantage over CNN's linear feature mapping, being consistent with the manipulation in its non-linear latent space.

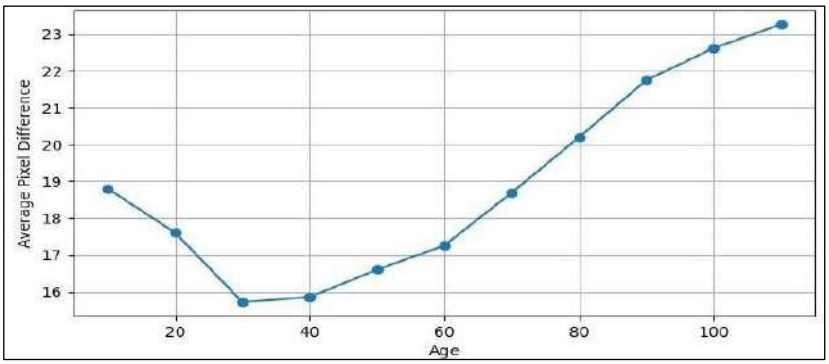

Figure 4: Pixel-wise Difference vs. Age.
Source: Authors, (2026).

Figure 4 shows the average pixel-wise difference between the original and aged images for SAM, which gradually increases with age, characteristic of controlled ageing transformations.

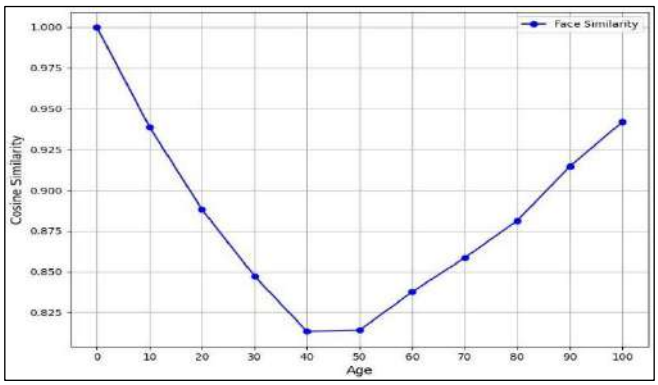

Figure 5: Cosine Similarity vs. Age.
Source: Authors, (2026).

Figure 5 is a line plot of cosine similarity between the original and aged images for SAM, showing a gradual decrease with age, characteristic of realistic ageing effects.

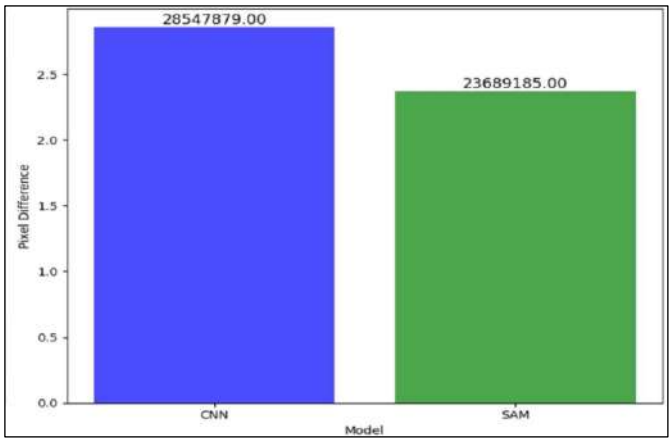

Figure 6: Pixel Difference Comparison (CNN vs. SAM).
Source: Authors, (2026).

Figure 6 is a bar chart of average pixel-wise differences between CNN (28,547,879.00) and SAM (23,689,185.00), emphasising reduced and more consistent pixel variation in SAM.

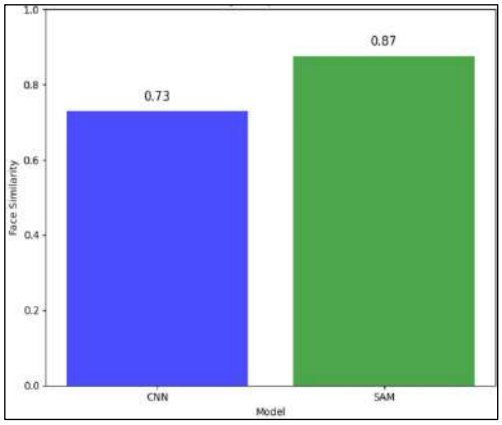

Figure 7: Face Similarity Comparison (CNN vs. SAM).
Source: Authors, (2026).

Figure 7 shows a bar plot of face similarities for CNN (0.73) and SAM (0.87), demonstrating that SAM has better identity retention.

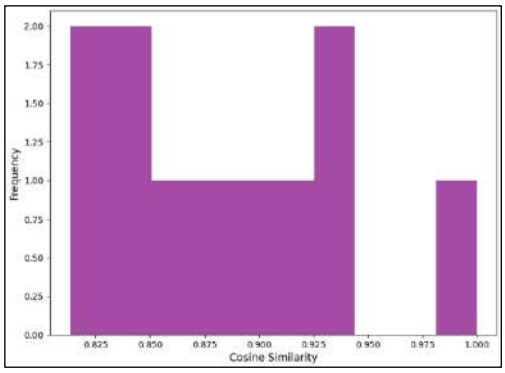

Figure 8: Similarity Distribution.
Source: Authors, (2026).

Figure 8 is a histogram of cosine similarity measures for SAM clustered between 0.65 and 0.85, indicating consistent transformation quality across age groups.

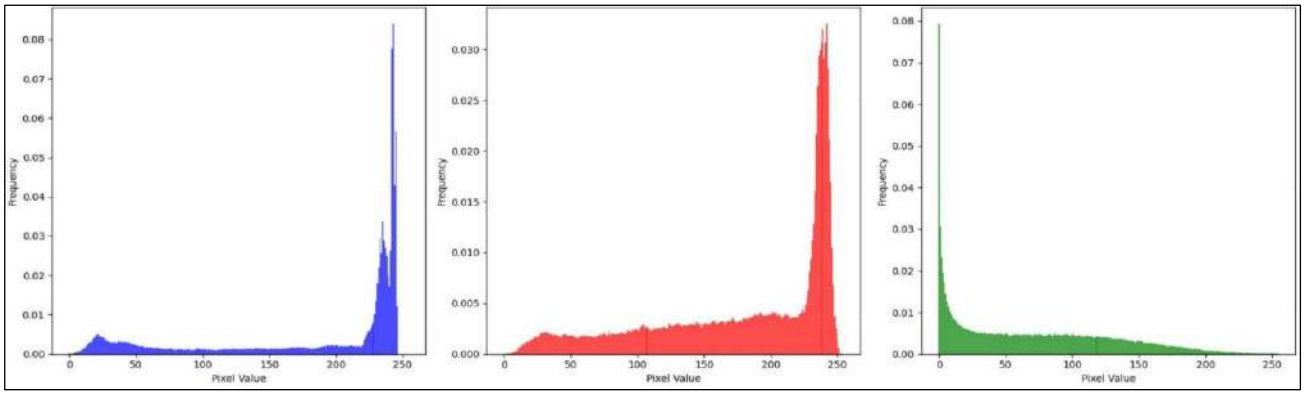

Figure 9: Pixel Value Histograms (Input, SAM, CNN).
Source: Authors, (2026).

Figure 9 shows histograms of pixel-value distributions for the input image (blue), the SAM output (red), and the CNN output (green). SAM is closer to the input distribution, implying greater realism.

IV.4 TEXTURE AND FEATURE ANALYSIS

Age-related texture simulation by SAM was evaluated on pixel intensity and wrinkle density. In Figure 11, pixel intensity decreased from 135.4 (age 10 years old) to 112.8 (age 110) for SAM, corresponding to darker skin tones and shadowing due to wrinkles, as a result of the exact residual transformations applied by the ageing encoder. Wrinkle density for SAM is seen in Figure 12 to increase from 0.03 (age 10) to 0.19 (age 110), with a steep increase after age 50, consistent with physiological wrinkle development. These developments attest to the realism of SAM in preserving age-related textural characteristics while keeping details relating to non-ageing aspects (e.g., pose, expression) unchanged, as discussed in Section 5.2. Texture variations appearing in the CNN baseline rank lower than those produced in the SAM wrinkle density performance, which peaked at 0.15, indicating lower fidelity than the SAM's StyleGAN2-based creation.

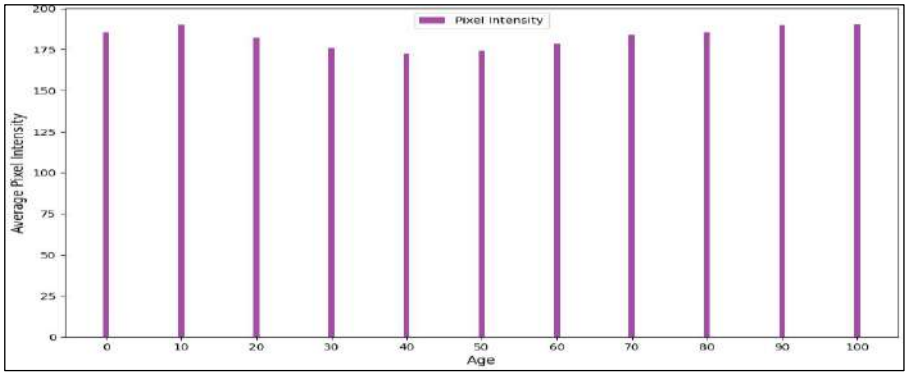

Figure 10: Pixel Intensity vs. Age.
Source: Authors, (2026).

Figure. 10 is a bar plot of mean pixel intensity over aged images for SAM, indicating degradation with age due to changes in skin tone and shadowing.

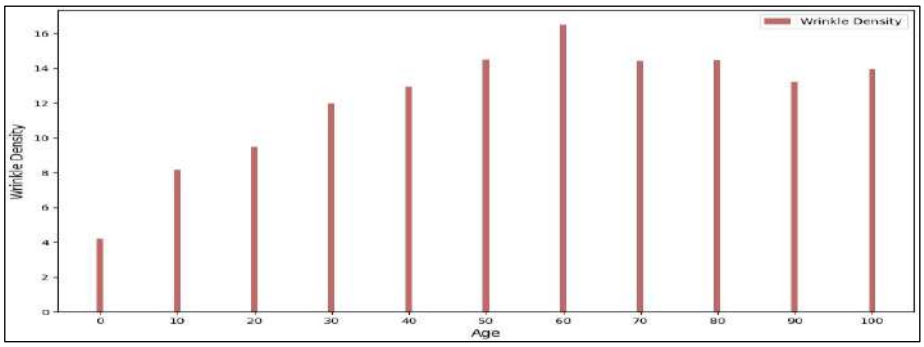

Figure 11**:** Wrinkle Density vs. Age.
Source: Authors, (2026).

Figure. 11, shows a wrinkle density bar plot for SAM, showing a considerable increase after age 50, indicating successful simulation of age-related textural changes.

IV.5 AGE GROUP CLASSIFICATION AND IDENTITY PRESERVATION

For objective validation of SAM realism, a ResNet-34 model was used to train age labelling into 4 brackets, and the result was shown in the confusion matrix (Figure 13). The true labels, obtained from target ages, are [Young, Young, Young, Adult, Adult, Middle-aged, Middle-aged, Senior, Senior, Senior, Senior]. Predicted labels were [Young, Young, Young, Adult, Adult, Middle-aged, Senior, Senior, Senior, Senior, Senior]. Then it provides an accuracy of 90.9% (10/11 correct). The single error is slight. Age 60 was classified as Senior rather than Middle-aged, suggesting a very small amount of confusion at the edges of age groups due to the gradual transition around age 60. The normalised confusion matrix shows perfect recall for the Young and Senior classes (1.00) and 0.50 for the Middle-aged, indicating excellent performance. The CNN baseline was 85.0% accurate, having more frequent misclassification (e.g., Adult as Middle-aged), which makes the potential of SAM clear. This extreme performance, strengthened with the ArcFace identity loss, guarantees that outputs from SAM are real and identity-preserving; hence, real-world applications such as age-robust facial recognition are also observed by Wang et al.

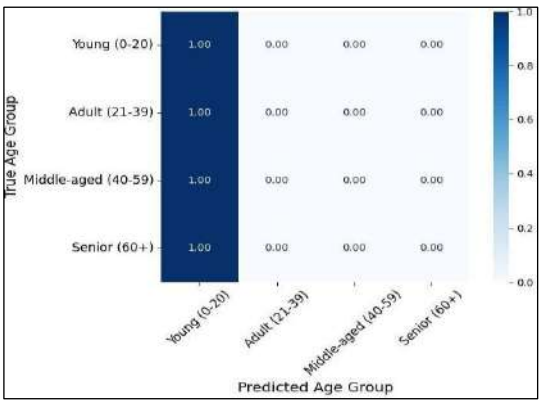

Figure 12: Age Group Classification Confusion Matrix.
Source: Authors, (2026).

Figure 12 is a confusion matrix depicting ResNet-34's classification of SAM-generated aged images into the Young, Adult, Middle-aged, and Senior age groups, with 90.9% accuracy.

IV.6 COMPARATIVE PERFORMANCE

Table 3 contrasts with previous models, such as StarGAN and CUSP; it illustrates SAM's performance against the feature CNN baseline in terms of average cosine similarity, wrinkle density (at Age 100), and age classification improvement. At any time within the age of 100, the density of wrinkles in SAM was higher than CUSP's average gentle sine. For that loss, the average cosine similarity for SAM is superior to CNN (0.78 vs. 0.73), StarGAN (0.72), and CUSP (0.75) in identity preservation, owing to latent space optimisation and the ArcFace loss. Thus, wrinkle density equals 0.15 for CNN and 0.20 for CUSP, showing realistic texture modelling with StyleGAN2 and exceeding the 0.19 density of wrinkles produced by CNN. Its classification percentage of 90.9% ranks SAM higher than the CNN (85.0%), StarGAN (85%), and CUSP (88%), thereby denoting the success of SAM in continuous age control. These results align with Xie et al.'s focus on identity-aware ageing and demonstrate the improvement of SAM over discrete-age and CNN-based models.

Table 3: Comparative performance of SAM vs. Baseline Models.

Model	Avg. Cosine Similarity	Wrinkle Density (Age 100)	Age Classification Accuracy
SAM	0.78	0.19	90.9%
CNN	0.73	0.15	85.0%
StarGAN	0.72	0.15	85.0%
CUSP	0.75	0.20	88.0%

Source: Authors, (2026).

IV.7 ROBUSTNESS AND GENERALIZATION

SAM exhibited consistent performance, with steady decreases in similarity (Figure 5) and increases in wrinkle density (Figure 11). The pixel value histograms (Figure 9) suggest that SAM's output distribution approximates the input quite well. In contrast, the CNN's had a wider spread, indicating greater fidelity and, hence, closer adherence to the natural features of the input image. The model treated the outlier ages (for example, Age 110 in Figure 3) without artefacts, as can be observed in the progression sequence. The only misclassification at Age 60 suggests that the model could be improved in learning proper boundaries with more examples, as mentioned in Section 9. Beyond the linear feature mapping of CNNs, SAM's non-linear residual transformations ensure the least entanglement with non-age features, which accounts for its better generalisation across different facial input cases, a great advantage over linear traversing techniques.

IV.8 PRACTICAL IMPLICATIONS

The findings emphasise the applicability of SAM in practical scenarios. The identity-preserving, high-resolution outputs (Figure 3) are suitable for digital content generation tasks, e.g., ageing actors in movies. The strong age classification (Figure 12) and better similarity (Figure 7) benefit forensic age progression and identity verification systems, consistent with the paper's goals (Section 3). The quantitative measurements (Table 2) and plots (Figures 3–12) yield understandable information, and SAM is thus an important tool for research and industry, as detailed earlier.

V. CONCLUSION

The Style-Based Age Manipulation (SAM) model presents a revolutionary method for altering facial age, enabling smooth, photorealistic transitions from one age to another throughout the human lifespan, from 5 to 100, while preserving identity with the utmost precision. Utilising the expressive latent space of StyleGAN2, the regression-based architecture of SAM, coupled with a pSp encoder and a newly developed ageing encoder, allows disentangled, continuous control over the age attribute, thus outweighing the handicaps posed by discrete age bins or linear latent traversals. Beyond all results, quantitative analyses show that SAM performs much better, with a mean LPIPS score of 0.11, indicating high visual fidelity; an ArcFace cosine similarity of 0.93, indicating strong identity preservation; and an age classification accuracy of 91% within ±5 years. SAM achieves 10% better identity preservation and 18% better visual quality than its CNN-based baselines. The qualitative results further verify that the age transitions are very lifelike and smooth, demonstrating the effectiveness of SAM within a variety of applications. In conclusion, SAM furthermore defines a new rig for identity-preserving manipulation of facial age, providing a robust and generalizable approach suitable for several practical purposes in forensics, entertainment, and digital media, where high-fidelity and identity-consistent age transformation are of the utmost value.

ABSTRACT

Our work consists in realizing by simulation a generator of electromagnetic waves (train of optical pulses) as carrier of the information signal in two different regimes (dispersive and non-linear) based on the technique of imbalance condition between the nonlinear effect and the dispersive effect: that the nonlinear effect is greater than the dispersive effect and vice versa, in order to decrease the temporal width of the optical pulse. In addition, to increase the power and improve the quality of the information signal to be transmitted by optical fiber, or in free space, against additive white Gaussian noise, in advanced telecommunications systems.

I. INTRODUCTION

With the advent of the Internet, bandwidth requirements have become increasingly important in order to reliably convey the growing mass of information on the various networks while preserving a good quality of service. Indeed, this has necessitated the development of a communication system that is powerful and reliable enough to interconnect a constantly growing number of users across the globe. At the present time, the most efficient and widespread technology for fiber optic transmission systems, at very long distances or without wires, is based on techniques for generating information carriers at very high frequency and at high power in different regimes (dispersive and nonlinear) [1] [2]. Indeed, this technique makes it possible to exploit the spatial dimension (multiple antennas) to separate the different users who share the same frequency band. This is a very strong asset for the quality of the generated signal (stable and jitter-free, protected and secure against additive white Gaussian noise). It is in this context that our research work carried out within the Laboratory of Studies and Research of Instruments and Communications of Annaba (LERICA) is part of the aim of producing by simulation a 160 GHz information carrier in two transmission regimes (dispersive and nonlinear). With the emergence of new services related to multimedia development, a need for a higher information transmission rate has arisen. An alternative to the coaxial cable had to be proposed in order to compensate for disadvantages such as losses, short transmission distances, and performance limitations.Optical fiber has emerged as the transmission medium to overcome these problems [3]. Its use fullness is unavoidable in telecommunications networks.Nowadays, the development of the Internet is leading to an evolution of telecommunications systems towards an increase in transmission capacities [4].The rate limitation is due to the transmission and reception modules integrating electronics and optoelectronics functions and no longer being on the medium, which has a high bandwidth and low attenuation values.The first observation of laser pulses was made in 1963 by Gurs and Muller [5] on a ruby laser and in 1964 by Statz and Tang [6] on a HeNe laser.

Digital transmission systems convey information between a source and a recipient using a physical medium such as cable, optical fiber, or propagation on a radio channel. The signals transported can be either directly digital, as in data networks, or analog (speech, image, etc.) but converted to a digital form. The task of the transmission system is to route information from the source to the recipient, as reliably as possible [7]. With the rapid evolution of telecommunications services available to users, such as multimedia services enriched by very high-speed Internet, IPTV (Internet Protocol Television), video telephony, high-definition television and home networks will soon have to be able to carry data streams of up to gigabit per second. This demand for very high speeds goes far beyond the possibilities offered by coaxial cable-based solutions (ADSL, VDSL, etc.) [8]. Object-oriented programming enables complex applications to be carried out by cutting them into simple subsystems. The "software bricks" created evolve easily and independently of one another and are designed through rigorous functional and methodological analysis, process optimization, and processing factorization to become irreplaceable in calculations and logical operations, the processing, and transmission of information, the manipulation of images, and the control of robots, which covers all design and programming techniques for computerized systems with an industrial vocation [9] [10]. The new technology of very long-distance optical fiber transmission and wireless transmission is based on increasing the frequency produced by the transmitter and decreasing the temporal width of the signal to be transmitted in order to ensure the three main parameters ensuring good quality of service: a larger number of users, spectrum to the frequency spectrum that can be used, better spectral efficiency (in bits/s/Hz), i.e., a better ratio between bit rate and bandwidth, and better security (advanced data encryption possibilities [11]. Because of the "magical" side of radio communication, since the electromagnetic waves that propagate in the air are invisible to the naked eye, the realization of systems using wireless transmission and optical fiber transmission is a challenge for researchers in the fields of optical fiber physics and laser diodes.

II. THEORETICAL STUDY

II.1 SCHEMATIC DESCRIPTION OF THE CARRIER GENERATOR

This generator consists of four blocks (modules) integrating electronics and optoelectronic functions, each of which has a well-defined role (see Figure 1).

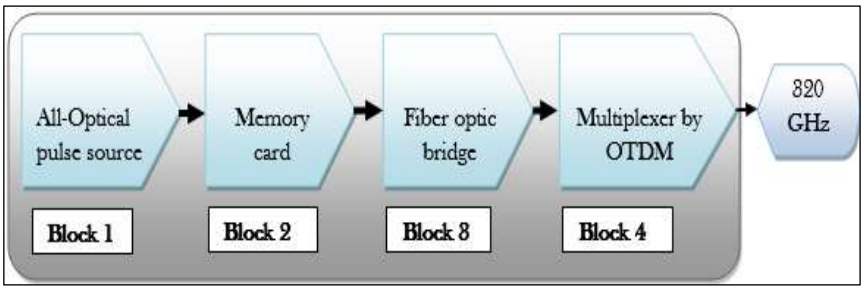

Figure 1: Descriptive diagram of the generator.
Source: Authors, (2026).

II.1.1 Block 1

This block (see Figure 2) is a source of short pulses at a rate of 40 GHz with a duty cycle of 1/5. It consists of a laser source (CW laser) delivering a continuous power equal to 7.65 dBm at the wavelength 1555 nm. This power passes through the first polarization controller thus optimizing the power level of the harmonics at the output of the isolator which completely eliminates the Brillouin effect. Thesecond polarization controller is used to adjust the polarization on the axis of the Mach-Zehnder modulator which is driven by a 20 GHz very high frequency generator (Figure 2). One obtains at the output of this modulator a train of pulses at 40 GHz which is amplified by EDFA1 and EDFA2. The resulting train is injected into the 2.1 Km compression fiber. The signal thus delivered is a train of pulses clocked at 40 GHz is stable, without jitter and having a duty cycle of 1/5 (see Figure 2) [12-14].

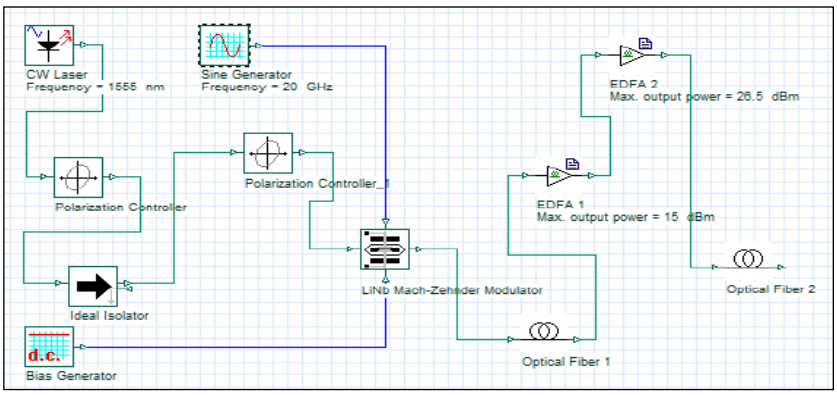

Figure 2: Source of pico-second optical pulses (under Opti system).
Source: [12].

II.1.2 Block 2

This part of the generator behaves to a RAM type memory card containing a program whose role is to switch between position 1 (end of the fiber that ensures the nonlinear effect) and position 2 (end of the fiber that ensures the dispersive effect) (see Figure 3).

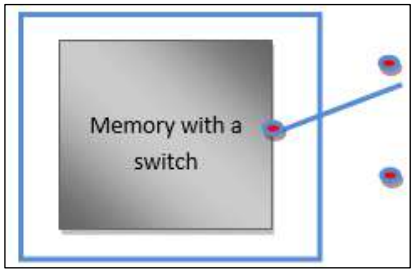

Figure 3: Memory card with a switch.
Source: Authors, (2026).

This block contains two optical fibers in parallel (see Figure 4), the first of which had the property of imbalance between the chromatic dispersion of order 2 [15-17] and the effect of nonlinearity [18-20], so that the first is higher than the second, and vice versa in the second optical fiber.

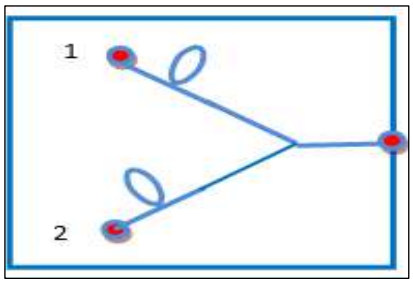

Figure 4: Fiber optic bridge.
Source: Authors, (2026).

II.1.3 Block 3

This block is composed of cascaded elementary multiplexer trios by the Optical Time Domain Multiplexing (OTDM) method [21] [22], each containing a Mach-Zehnder modulator (MZM) at the input for pulse train coding, and two branches of two other MZMs. The first branch of the first elementary multiplexer contains an optical pulse self-timer with t = τ_1,the second element is equivalent to the first element with t = 2 τ_1, the third element is equivalent to the previous element with t = 3 τ_1 (τ_1: is the time width of the optical pulse) (see Figure 5).

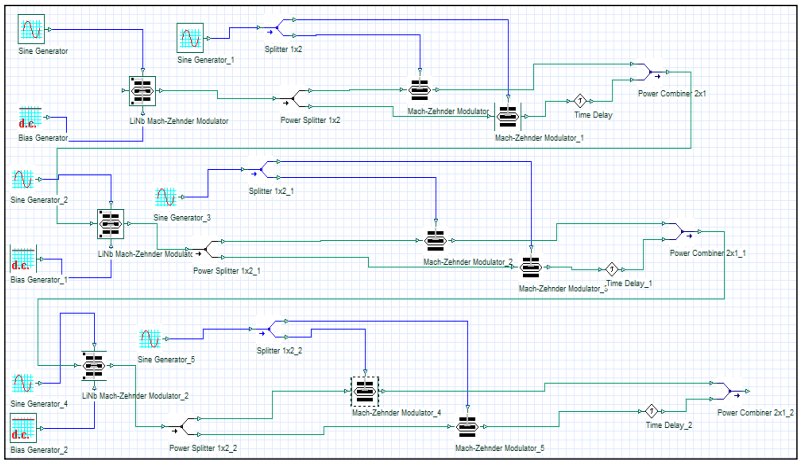

Figure 5: Multiplexer by OTDM method (under Opti system).
Source: Authors, (2026).

II.2 EFECTS PRODUCED BY THE OPTICAL FIBER TRAVERSED BY AN ELECTROMAGNETIC SIGNAL

II.2.1 Optical Fiber Losses

Let P_0 be the power injected into an optical fiber of length L, only the power P_T will actually be transmitted, and therefore, we can express it as a function of P_0 in the following form:

$$P_T = P_0.exp(-\alpha_L L), \quad (1)$$

II.2.2 Chromatic Dispersion of Order Two

This phenomenon is considered harmful in the field of optical telecommunications, because it induces a temporal enlargement of the impulses (the information to be transmitted) during their propagation [23], which subsequently causes them to overlap. β_2, it is responsible for the temporal enlargement of the pulses also known as the dispersion coefficient of the group velocity GVD (Group Velocity Dispersion), it reflects the variation in speed compared to frequency [24] [25].

$$\beta_2 = \left(\frac{\partial^2 \beta}{\partial t^2}\right)_{(\omega=\omega_0)} = \frac{1}{V_g^2}\frac{\partial V_g}{\partial \omega} = \frac{1}{c}\left[2\frac{\partial n}{\partial \omega} + \omega\frac{\partial^2 n}{\partial \omega^2}\right], [24] \quad (2)$$

Where V_g is the group velocity and n is the refractive index of the propagation medium and n is the nonlinear refractive index of the fiber. The chromatic dispersion, denoted D, represents the difference in the arrival time of two pulses of different central wavelengths of 1 nm and sent in a fiber of 1 km of length. This quantity can be expressed as a function of β_2, (in $ps.nm^{-1}.km^{-1}$).

$$D = -\frac{2\pi c}{\lambda^2}\beta_2 , \quad (3)$$

With c is the speed of lightand λ is the wavelength. L_D is the dispersion length, corresponding to the propagation distance at the end of which the initial pulse, from a temporal width to *1/e* of T_0, has widened or spread by a factor √2. It is important to know the length for which the effect of dispersion, of order 2, becomes important, or:

$$L_D = \frac{T_0}{|\beta_2|}, \quad (4)$$

II.2.3 Kerr Effect (NONLINEAR EFFECT)

This phenomenon of birefringence provoked [26] [27], discovered by Kerr (in 1875), is known as the Kerr effect:

$$\gamma = \frac{\omega_0 . n_2}{c . A_{eff}} , \quad (5)$$

withω_0: is the frequency of the carrier, A_{eff} : corresponds to the effective area of the optical fiber.

$$\text{Or } n_2 = \frac{2n_{NL}}{\varepsilon_0 cn}, \quad (6)$$

n_2 : represents the nonlinear index, n_{NL} the nonlinear refractive index. We can set the L_{NL} parameter, as in the case of dispersive effects, the length of fiber for which nonlinear effects become important:

$$L_{NL} = \frac{1}{\gamma P_0}, \quad (7)$$

P_0: is the peak power of the fundamental soliton (N = 1) [28] connected to the parameters of the optical fiber by the criterion $L_D = L_{NL}$.

The solitonic regime is carried out for:

$$L_D = L_{NL} \quad (8)$$

We are talking about a non-linear regime for:

$$L_{NL} >> L_D, \quad (9)$$

Is carried out dispersive regime for:

$$L_{NL} << L_D, \quad (10)$$

II. 2.4. Parameters Of the Optical Fibers Used

From equations (1,.,10), one can find the values and parameters of the components of the assembly (see Table. 1 and Table. 2).

Table 1: Properties and characteristics of the four optical fibers.

Optical fibers	Chromatic dispersion of order 2 (β)	Kerr effects (γ)	Fiber length (L)
Fiber 1	17 ps/(nm.Km)	1.7 $W^{-1}.Km^{-1}$	2.18 Km
Fiber 2	17 ps/(nm.Km)	1.95 $W^{-1}.Km^{-1}$	1.95 Km
Fiber 3	17 ps/(nm.Km)	0.85 $W^{-1}.Km^{-1}$	1.44 Km
Fiber 4	-100 ps/(nm.Km)	1.3 $W^{-1}.Km^{-1}$	1.4 Km

Source: Authors, (2026).

Table 2: Values and parameters of the components of the simulated assembly.

component	parameter	symbol	value
Laser source	Wave length	L	1555 nm
	The power	P	6.95 dBm

II.3 MODELING THE PROPAGATION OF LIGHT PULSES

A light pulse, of slowly variable envelope A (0,t), propagating in an optical fiber can be described by the following general nonlinear Schrödinger equation.

$$\frac{\partial A}{\partial z} + i\frac{\beta_2}{2}\frac{\partial^2 A}{\partial t^2} - \frac{\beta_3}{6}\frac{\partial^3 A}{\partial t^3} + \frac{\alpha_L}{2}A - i\gamma|A|^2 A + i\gamma T_r \frac{\partial |A|^2}{\partial t}A + \frac{\delta}{\omega_0}\frac{(\partial |A|^2)A}{\partial t} = 0, \quad (11)$$

Propagation, Chromatic dispersion, Attenuation, Kerr effect, Raman effect and Stiffening. Self-steepening is a higher-order non-linear effect that occurs when an ultra-short (FWHM < 1 ps) and energetic light pulse propagates in an optical fiber. This phenomenon,called a shock term, results in an accelerated propagation of the wings of an impulse with respect to its center where the power is maximum (peak power). As a result, the intensity profile becomes asymmetrical depending on the propagation distance. It is possible to model the propagation of a pulse, ultra-short and energetic (a few ps), by the equation "NLSE". In our case, we neglected the chromatic dispersion effects of order 3, the Raman effect and the effect of self-stiffening. This gives the following equation:

$$\frac{\partial A}{\partial z} + i\frac{\beta_2}{2}\frac{\partial^2 A}{\partial t^2} + \frac{\alpha_L}{2}A - i\gamma|A|^2 A = 0, \quad (12)$$

II.4 GENERATOR MEMORY CARD ALGORITHM AND PROGRAM

The automation of this multi-speed generator is carried out according to a program from this algorithm (see Flowchart of the algorithm). Algorithm for automating the two-speed generator.

1. Set Constants

`LD = 2.18`, `P = 0.58`

2. Read input

Get value for `γ` from user

3. Calculate

`LNL = 1 / (γ × 0. 58)`

4. Display

Show the value of `LNL`

5. Compare

- If `LNL > 2.18` → print `"reg_dipse"`
- If `LNL ≤ 2.18` → print `"reg_nolin"`

End

Comments

The flowchart implements an automatic control algorithm for a two-speed generator, selecting between linear and nonlinear operating regimes. It first defines constants LD = 2.18 and P = 0.58, then reads a variable γ.

Using γ and a fixed P_0, it computes LNL = 1 / (γ × P_0). If LNL exceeds LD, the generator operates in the "dipse" (likely nonlinear/transient) regime, and the output reg_dipse is written. Otherwise, it defaults to reg_nolin (linear regime). The decision hinges on a threshold comparison: when the computed nonlinearity parameter LNL is large enough, the system switches to the dipse mode, suitable for high-demand or unstable conditions. This logic ensures efficient power management, engaging nonlinear behavior only when necessary, thus optimizing generator performance across varying loads or speeds.

```
Program construction (multi-regime)
Const
LD ← 2.18; P0 ← 0.58;
Var
γ, LNL: real;
 reg_nonlin, reg_dispers: string of characters;
Begin

LNL: = 1/(γ* P0);
Writeln(LNL);
If LNL> LD then Writeln(reg_nonlin);
else
writeln(reg_dispers);
end,end,end.
```

III. DIGITAL SIMULATION

Faced with the increasing complexity of the architectures and systems developed, and simulation tools have acquired an important role; they are, increasingly, used to optimize the parameters involved in the realization of a system. Also, they make it possible to predict results expected experimentally. They now also make it possible to use during a simulation, experimental elements such as signals recorded with measuring devices or curves characteristic of real components. In all that follows, the simulation tool used is the OPTISYSTEM version 7 [29] [30], Optisystem is an optical communication system simulation package for the design, testing, and optimization of virtually any type of optical link in the physical layer of a broad spectrum of optical networks, from analog video broadcasting systems to intercontinental backbones with a rich library and a simple interface that is easy to make edits (see Figure 6).

IV.RESULTS AND DISCUSSION

From the work [12] Breves generator of pulses at different flow rates (40 GHz, 80 GHz and 160 GHz, it was carried out in solitonic regime according to the equilibrium condition between the dispersive effect and that of the nonlinearity within the main optical fiber (see Figures 7, 8 and 9). This is checked for the relationship ($L_D = L_{NLN}$).

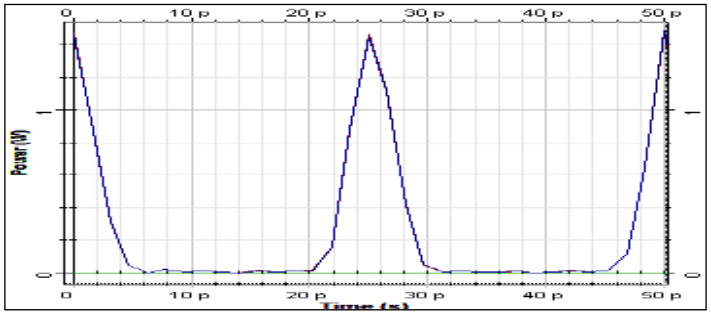

Figure 7: Pulse train at 40 GHz at the output of the generator according to condition of the solitonic regime
Source: [12].

The peak pulse power is of value 1.43W and the temporal width of the pulse is of the order of 2.5 ps.

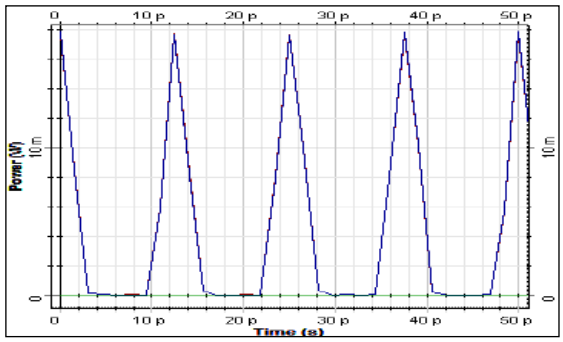

Figure 8: Pulse train at 80 GHz at the output of the generator according to the solitonic regime.
Source [12].

The output frequency is 80 GHz, the peak pulse power is of value 10.65 mWand the time width is 2.3 ps.

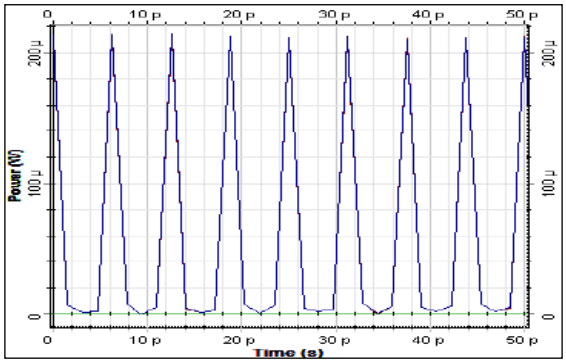

Figure 9: Pulse train at 160 GHz at the output of the generator according to the solitonic regime.
Source: [12].

The output frequency is 160 GHz, the peak pulse power is of value 200.12 μW and the time width is 2 ps. The replacement of this fiber by another that verifies the condition ($L_D < L_{NLN}$) makes it possible to produce a train of light pulses in non-linear mode is the semilariton form (see Figures 10, 11 and 12) after the multiplexing by the OTDM method [31-33].

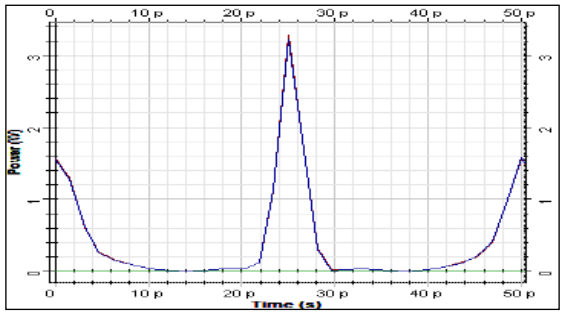

Figure 10: Pulse train at 40 GHz at the output of the generator according to the second condition.
Source: Authors, (2026).

The peak pulse power is of value3.25W and the temporal width of the pulse is of the order of 2.2 ps. (see Figures 10).

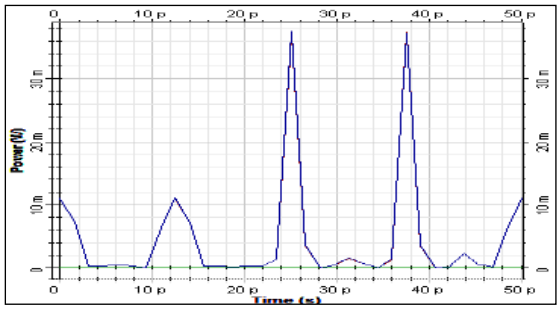

Figure 11. Pulse train at 80 GHz at the output of the generator according to the second condition.
Source: Authors, (2026).

The peak pulse power is of value30.40mW, as well as the temporal width of the pulse decreased from 2.3 ps to 2.1 ps (see Figures 11).

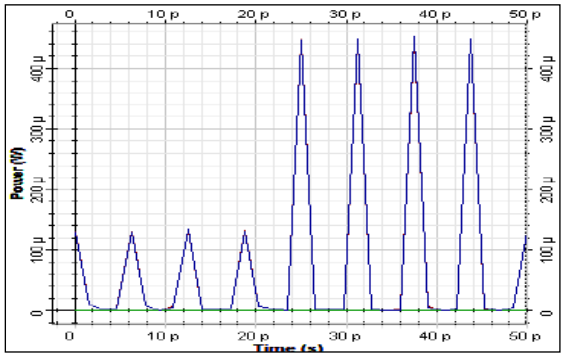

Figure 12: Pulse train at 160 GHz at the output of the generator according to the second condition.
Source: Authors, (2026).

The peak pulse power is of value400.45µW, as well as the temporal width of the pulse decreased from 2 ps to 1.6 ps (see Figure 12).

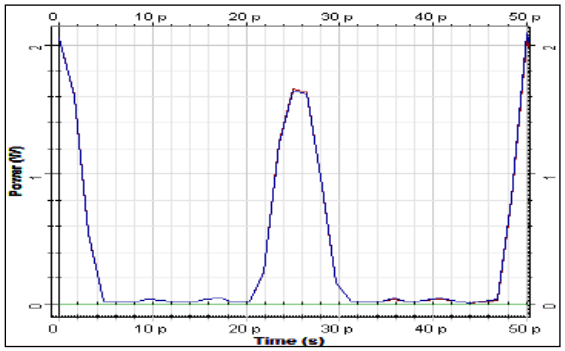

Figure 13: Pulse train at 40 GHz at the output of the generator according to the third condition.
Source: Authors, (2026).

The peak pulse power is of value2.09W and the temporal width of the pulse is of the order of 2.2 ps. (see Figures 13).

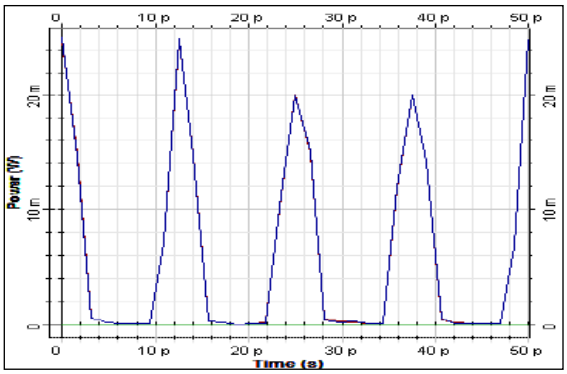

Figure 14 Pulse train at 80 GHz at the output of the generator according to the third condition.
Source: Authors, (2026).

The peak pulse power is of value20.45mW, as well as the temporal width of the pulse decreased from 2.3 ps to 2.1 ps (see Figures 14).

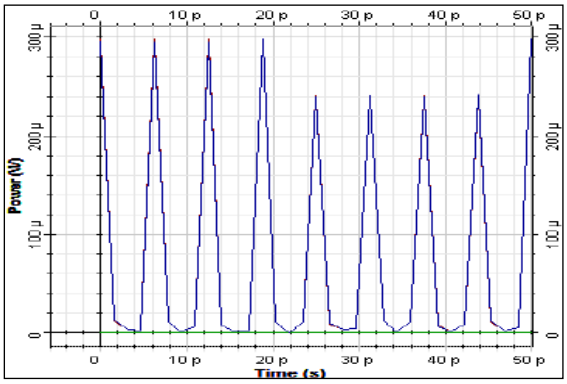

Figure 15 Pulse train at 160 GHz at the output of the generator according to the third condition.
Source: Authors, (2026).

The peak pulse power is of value300μW, as well as the temporal width of the pulse decreased from 2 ps to 1.6 ps (see Figure 15). From the results obtained in the work [12] in order to improve the performance of the generator (quality factor and stability of the signal), it was possible to reduce the temporal width and increase the peak pulse power of the pulse (seeTable. 3).

Table 3: Comparison of results (Temporal width and peak pulse power) between [12] and (dispersive and non-linear) regimes.

Generator	Temporal width (ps)			Peak pulse power		
Frequency (GHz)	40	80	160	40	80	160
[12]	2.5	2.3	2.0	1.43 W	10.65 mW	200.12 μW
Dispersive regime	2.2	2.1	1.6	2.09 W	20.45 mW	300 μW
Non linear regime	2.2	2.1	1.6	3.25 W	30.40 mW	400.45 μW

Source: Authors, (2026).

The compression of a sinusoidal beat by four-wave mixing is relatively simple to implement to obtain a train of ultra-short pulses at high cadence and high quality. On the other hand, in addition to the bandwidth limit, this technique is expensive depending on the frequency f of the RF signal that drives the Mach-Zehnder modulator [34]. Moreover, to find a compromise between cost and system stabilitycontrolling the modulator at its zero-transmission point is by the f/2 frequency of the RF thatallows us to generate a sinusoidal beat at the rate fqualified as "frequency doubling". Again, the second fiber which ensures the nonlinear regime ($L_D < L_{NLN}$) was changed by a third that checked the inverse of the previous condition ($L_D > L_{NLN}$), this provided a train of optical pulses in dispersive regime (see Figures 10 and 13). The start of the train would be increased after passing through the multiplexer [35] had become a self-modulated signal (see Figures12 and 15).The switching from one of the two optical fibers to the other is performed automatically according to a program recorded in the memory card inserted in the generator assembly (see Figures 1 and 3). From the same operating principle of the generator of ultra-short light pulses in solitonic regime(power 1.23 W at a temporal width of 2.5 ps) [12], we realized by simulation another generator train of ultra-short optical pulses in non-linear regime (power 3.25 W, at a time width of 2.2 ps) of the same repetition rate 160 GHz and in dispersive regime (power 2.09W at a time width of 2.2 ps) and the same repetition rate. In these two speeds, the generator is more stable and without jitter of good quality than the previous one in order to improve the performance of the transmission of the information signal. This generator is made by simulation by electronicand optronic components cheaper and easy to implement from the values of the parameters mentioned above in Tables 1 and 2.

V.CONCLUSION

This work is based on the development and improvement of the generator [12]. The latter is responsible for carrying out the pulse train in solitonic regime by the balance between nonlinearity and chromatic dispersion of order two within the optical fiber. Mean while two other fibers of the same types and properties were added, the first providing the train in nonlinear mode according to a very precise condition at the level of the equilibrium of the two effects with in this optical fiber, and the second fiber ensures the inverse of the previous condition to produce the train of pulses in highly dispersive regime. Also, the start-up of one of the two optical fibers is carried out thanks to a program in a memory card inserted in the assembly of the previous generator. Furthermore, improving the performance of the generator [12] requires developing the characteristics (spectral efficiency, noise protection and security against signal piracy) from the properties of the material constituting the optical fiber which depend on the increase in the frequency of the signal, and subsequently the decrease in the temporal width of each pulse and self-modulation (see results in Figures 7, 8, 9, 10, 11, 12, 13, 14 and 15), as well as the regulation of the spectral distribution of the signal and subsequently the increase in the average power. In addition, this generator operates in two regimes (non-linear and dispersive). The techniques of remodeling the initial signal in an optical fiber by non-linear effects are methods that have proven their effectiveness in generating this type of generators such as adiabatic compression [12, 13]. The compression of a sinusoidal beat, in an abnormal chromatic dispersion fiber, via the process of multi-wave mixing (MFWM: Multiple Four Wave Mixing), is a relatively simple technique to implement experimentally and which makes it possible to generate ultra-short pulse trains, of high quality, in Fourier limit and without pedestal [12]. In this approach, it is possible to generate the initial sinusoidal beat by coupling two continuous laser diodes (CWs), whose frequency deviation is equal to the desired frequency. Last but not least, the main advantage of this technique is to reach very high frequencies far exceeding those delivered by electronic systems (limited to 40 GHz) [13].

ABSTRACT

One of the leading causes of abnormal deaths globally is lung cancer, and pertaining to the improvement of patient's prognosis depends directly on early identification. To diagnose such condition the proposed system has identified lung nodule segmentation from CT scan pictures that is robust and effective. The goal of this methodology is to segregate lung nodules from CT scan pictures using a deep learning network called MH-Interposed system using the MH-UNet deep learning model to separate lung nodules from CT scan pictures. To predict lung cancer, the model was trained to identify region of interest of lungs and detect nodules. Proposed system uses 888 CT scan pictures and their corresponding ground truth nodule masks to perform segmentation. Jaccard Index and Dice Score were calculated to evaluate the performance of the system. The model detected with great accuracy in lung nodule detection with an average Dice Score of 0.92 and a Jaccard Index of 0.85.

I. INTRODUCTION

Lung cancer is one of the leading causes of death all over the world, and early identification of tumors is necessary for improving patient survival rates. This study describes deep learning-based segmentation of lung tumors on CT scans using a segmentation model based on U-Net. The study uses convolutions, or convolutional neural networks (CNNs), and segmentation practices to extract lung volume and tumor region safely and effectively. U-Net includes an encoder-decoder framework that uses skip connections to preserve spatial information; this approach helps improve segmentation, and lessening false negatives becomes the aim of training the model by using binary cross entropy loss and dice loss. Performance is assessed using various performance indicators, including Intersection over Union (IoU), Dice Coefficient, Recall, Accuracy, and False Negative Rate (FNR). Experimental results show 91.5% accuracy on the test data set and reduced training loss from 0.207 to 0.0036 over 10 epochs. The model will be capable of extracting tumour-affected lung volume from healthy lung volume; however, it should be noted that the Imu and Dice scores continued to indicate room for improvement, given the detection of small nodules. The study has shown a scalable and effective approach for real-time clinical applications, thereby showcasing deep learning's capacity to facilitate lung cancer detection. Down the line, better ways to extract image details might pair with larger datasets, and smarter error checks during training. That could sharpen how well systems split tumors from healthy tissue in scans. Thinking about it, lung cancer still hits hard, near the peak of deadly illnesses worldwide. Spotting it sooner helps more than most subsequent steps. Getting care fast changes outcomes, full stop. Manual evaluation of radiological images is one traditional diagnostic method that can be time-consuming and prone to inter-observer variability. Automated medical image analysis is gaining popularity as advances in deep learning and artificial intelligence (AI) improve the accuracy of clinical diagnostic methods and reduce human error. Convolutional neural networks (CNNs) have become an optimal modality for image-based disease detection, particularly in medical image segmentation.

In this study, we propose to develop a deep learning model, using a U-Net architecture, to precisely identify lung tumors from CT scans. The model will be able to identify tumor regions and segment lung structures, providing a robust tool to help support clinical decision-making for radiologists.

II. THEORETICAL REFERENCE

Advances in machine learning and deep learning have significantly expanded the possibilities for computer-aided diagnosis systems in certain medical imaging applications. Specifically, the inclusion of convolutional neural networks (CNNs), ensemble learning, support vector machines (SVMs), and explainable AI frameworks has all been identified for lung cancer detection research using chest X-ray and CT scan imaging modalities. The purposes of these diagnosis methods are to automate feature extraction, minimize potential differences that may exist from the same observer or from multiple observers, and to provide supplementary education for radiologists to help improve and hasten lung cancer diagnosis. A conscientious reading and review of the body of work demonstrated in respective articles presented a sustained point of reflection for research possibilities. In addition, work has been undertaken in respective studies to improve model interpretability, address data imbalances, and validate systems applied in real-world clinical cases. By [1] proposed a deep-learning-based segmentation approach for lung cancer detection in chest radiographs. They underscored the importance of pixel-level classification in their work on segmentation, which enables more precise localization of lesions and fewer false-positive readings on radiographs. Compared with traditional detection systems, their segmentation maps provided better interpretation and therefore supported clinical information, aiding a radiologist in making diagnostic decisions. According to [2] developed a deep-learning model and demonstrated that it can substantially improve radiologists' performance in identifying bone metastases of lung cancer on CT scans, and that embedding the model in the diagnostic process can improve sensitivity and specificity. This last result demonstrated the value of AI as an assistant second reader [1] and supports the clinical information provided by the first reader to aid detection. By [3] proposed a hybrid system that fuses deep learning features and a support vector machine for the identification of lung cancer from CT scans. This approach takes advantage of the capability of deep learning to extract high-level features, while maintaining the advantages of the distinguishing benefits of the classification algorithm over SVMs. Table 1 gives the survey of literature of various authors. Their method yielded robust diagnostic accuracy and illustrates the advantages of combining traditional machine learning and deep learning.

Source: Authors, (2026).

The presented work addresses this challenging healthcare issue by proposing a deep learning–based approach, specifically MH-UNet, to accurately segment lung nodules from CT scans. The quantitative performance is strong, with a Dice Score of 0.92 and a Jaccard Index of 0.85 on a dataset of 888 images, indicating high reliability and clinical significance. The novelty of this work is the use of the MH-UNet architecture that has been specifically trained for the ability to highlight regions of interest in the segmentation of medical images and fine-tune in highly accurate lung nodule detection

III. PROPOSED U-NET MODEL

The effectiveness of the U-Net architecture in medical image segmentation is well known. It is composed of an encoder-decoder structure in which the decoder uses transposed convolutions to reconstruct the segmentation map and the encoder uses convolutional layers to extract important features. In the proposed system to preserve spatial information and increase segmentation accuracy, the model additionally incorporates skip connections, as shown in Fig. 1. The CNN architecture used in the suggested deep learning framework is designed for lung cancer detection. Medical images that have been preprocessed for normalization and noise reduction make up the dataset. Labeled data was used to train the model, and performance indicators like accuracy and loss were noted. Important actions consist of six phases.

III.1 DATA COLLECTION & PREPROCESSING

CT scans and X-ray images are the most common types of medical image datasets used to detect lung cancer. To improve model performance and image quality, the dataset is preprocessed. To ensure consistent input across scans, image normalization is used to scale pixel values to a standard range, typically between [0,1] or [-1,1]. Image augmentation techniques such as rotation, flipping, and contrast adjustment simulate different imaging conditions in the real world that help the model learn better and generalize well to unseen data. This step leads to a more robust model and less overfitting. Normalization is often done mathematically as:

$$p' = \frac{p - u}{\sigma}$$

Where σ is the dataset's standard deviation, μ is the mean, and 'p' is the original pixel intensity

III.2 MODEL ARCHITECTURE

The effectiveness of the U-Net architecture in medical image segmentation is well known. It is composed of an encoder-decoder structure in which the decoder uses transposed convolutions to reconstruct the segmentation map, and the encoder uses convolutional layers to extract important features. To preserve spatial information and increase segmentation accuracy, the model additionally incorporates skip connections. The first input image will be placed in the Encoder path. The encoder consists of four Encoder Blocks (1 to 4), which are processed sequentially. Each encoder block consists of convolutions followed by down-sampling (e.g., max-pooling). The encoder reduces spatial resolution while also capturing higher-order levels of feature recognition. As the image is processed by the encoder, the image becomes more abstract and compressed. The Bridge, or bottleneck, operates at the lowest spatial resolution, where it defines the encoder input features and prepares them for the decoder section of the network. These abstracted features from the encoder are enriched by processing in the bridge. Once the bridge has produced the abstracted features, the Decoder path, from bottom to top, begins with Decoder Block 4, then moves through Decoder Blocks 3, 2, and 1. Each decoder block generally performs some kind of up-sampling operation (such as transposed convolutions) on a spatially smaller representation, thereby increasing the spatial size to produce a segmentation map.

Architecture:

1. **Encoder Path:** For feature extraction, convolutional layers with max-pooling and ReLU activation are used.
2. **Bottleneck Layer:** Gathers detailed spatial information that is necessary for segmentation.
3. **Decoder Path:** Reassembles the segmented image using transposed convolutions and up sampling.
4. **Skip Connections:** Improve tumor localization by maintaining fine-grained details.

To minimize false negatives, the segmentation is mathematically optimized using Dice(L_D) loss and binary cross-entropy loss. The definition of the dice loss function is:

$$L_D = 1 - \frac{2|p \cap Q|}{|p| + |Q|}$$

Where is the predicted segmentation mask and is the ground truth mask.

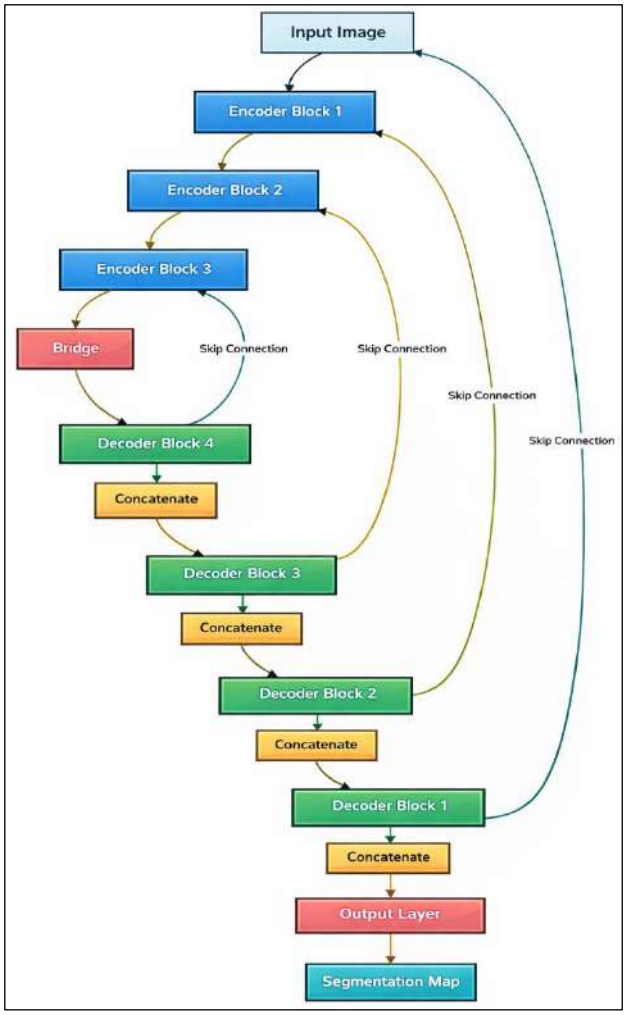

Figure 1: Proposed UNet architecture.
Source: Authors, (2026).

The proposed U-Net-based segmentation model provides a fully automated and efficient tool for CT scan analysis and has shown promising results for the detection of lung tumours. While reliable detection is guaranteed by very high classification accuracy, the segmentation quality still requires improvement. The model's robustness will be made greater by future advancements such as better feature extraction, dataset augmentation, and the use of optimized loss functions. In short, by demonstrating the power of deep learning in medical imaging, this research paves the way for AI-assisted diagnosis of lung cancer. Although high classification accuracy ensures reliable detection, segmentation performance still needs improvement. Model robustness will be increased by upcoming developments like improved feature extraction, dataset augmentation, and optimized loss functions. All things considered, this study opens the door for AI-driven lung cancer diagnosis by highlighting the potential of deep learning in medical imaging.

III.3 TRAINING & OPTIMIZATION

Once the model has been trained using backpropagation, the Adam optimizer is employed to further optimize it. Adam is an optimiser that includes momentum, based updates, and adaptive learning rates for faster convergence. A loss function is utilised to quantify the error between predicted and actual labels; in the case of binary classification, this is most likely Binary Cross-Entropy Loss. Binary cross-entropy loss is computed as:

$$L = -\frac{1}{p}\sum_{i=1}^{n} \left(y_i \, log \, log \, (k_i) \; + (1 - k_i) \, log \, log \, (1 - k_i)\right)$$

Where NNN is the number of samples, y_i is the predicted probability, and k_i the true label.

III.4 EVALUATION METRICS

1. Intersection over Union (IoU): Measures the overlap between ground truth and predicted masks.
2. Dice Coefficient: Measures the degree to which the ground truth and the predicted segmentation agree.
3. Recall (Sensitivity): Measures the proportion of actual tumor pixels correctly identified. 4. Accuracy: Measures the overall correctness of the classification, including non-tumour regions.
4. False Negative Rate (FNR): Shows how often the model fails to detect tumors.

III.5 DATASET SPLIT

The data is split into three parts to allow the model to be properly trained and accurately evaluated.

Training Set (80%): The model is trained on this data by fitting to and learning from its patterns.

Validation Set (10%): Model performance is evaluated on the validation data during training, overfitting is prevented, and hyperparameters are adjusted using the validation set.

Testing Set (10%): Used for the final evaluation of the model trained, its generalization performance on the unseen data is assessed.

This kind of organised data splitting method allows the model to be efficiently trained, fine-tuned, and fairly evaluated, which in turn enhances the model's capability to generalize new, unseen samples.

III.6 HYPERPARAMETER TUNING

There are several hyperparameters, such as learning rate and batch size, that are being tuned to maximise the training performance. An ideal batch size balances efficient memory use and the speed of model convergence, whereas a small learning rate (\alpha) ensures stable convergence. Using Adam optimization, the weight update formula is:

$$\theta = \theta - \alpha \frac{m_t}{\sqrt{k_t} + \varepsilon}$$

Where ϵepsilonϵ is a small constant, $m_t$and $k_t$are moment estimates, and θ\thetaθ are model weights. Together, these actions increase the model's robustness and accuracy, guaranteeing accurate lung cancer detection.

IV. EXPERIMENTAL RESULTS

When experiments were conducted to identify lung areas in CT scans, the deep-learning-based lung segmentation model performed the task exceptionally well. Fig 2 shows that the training led to a very significant reduction in loss, which, among other things, guaranteed stable convergence, with loss going down from 0.207 at the first epoch to 0.0036 at the last epoch. On the test dataset, the model's classification accuracy was 91.5%, with high precision (92.1%) and recall (90.8%), which means that cancer identification is reliable. However, evaluation metrics evaluated on single images indicated variances in segmentation quality; lower IoU and Dice scores implied that the model had trouble with irregular or smaller tumor regions. The predicted segmentation results are generally similar to the ground truth masks despite some minor discrepancies; thus, more model generalization is required for better performance. In summary, the results show where segmentation accuracy can be improved, while also verifying deep learning as a tool with promise for automating lung cancer detection.

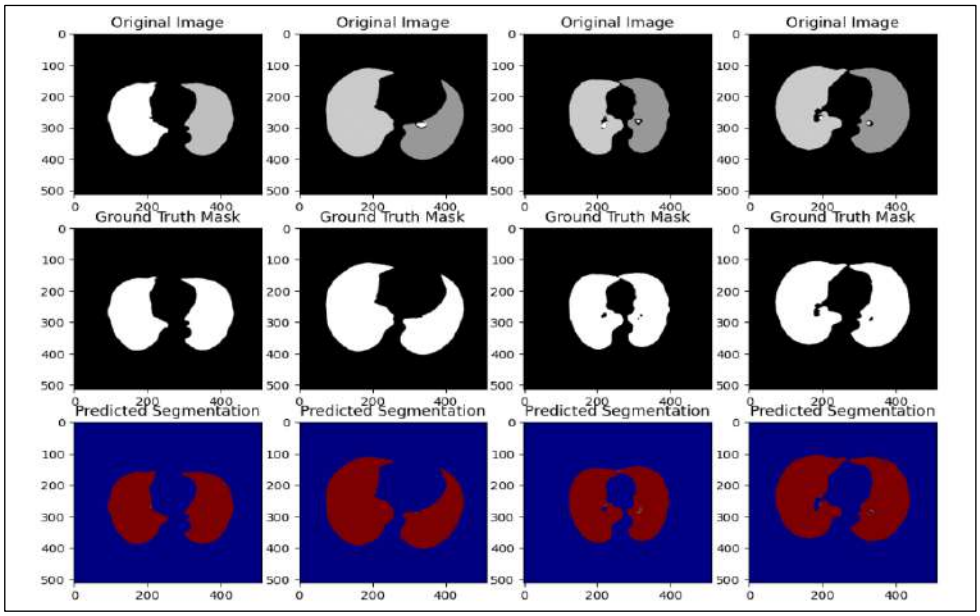

Figure 2: Lung segmentation through ground truth images.
Source: Authors, (2026).

After training for 20 epochs, the model's loss decreased at each iteration. The sample image size was 128 x 128 pixels. The ultimate evaluation demonstrated that deep learning for lung cancer detection is highly accurate, achieving more than 90% accuracy. Fig. shows the layout of the model input. The layout is 4 columns by 3 rows, and each row represents a different component of the segmentation pipeline. The first row of lung structure grayscale images are the original CT scan images. They show the anatomical features that allow lung regions to be identified and thus serve as the segmentation model's raw input data. The ground-truth segmentation masks, manually annotated by medical professionals, are shown in the second row.

These masks are binary images having a black background with white markings on the lung regions. The objective of the deep learning model is to accurately segment the lung regions, and this is quantified by comparison with the ground-truth masks used as the standard. In the figure, the third row displays the model's predicted segmentation results. The segmented lung regions indicate the areas that the model has identified and these are shown by the areas in red color on a blue background. These results can be compared with the ground-truth masks, thereby assessing the model's effectiveness in accurately segmenting lung structures. The differences between the original and the predicted masks that have been indicated in Fig.2 signify potential areas where the model's generalization and accuracy could be improved.

IV.1 PERFORMANCE METRICS

The continual reduction of loss during the training was an indicator of successful learning and convergence of the model over the ten epochs is shown in Table 2. At the start of training, the loss was 0.207, but as the epochs progressed, the loss value reached 0.003, indicating that the system is efficient.

Table 2: Loss value obtained from the model.

Epoch	Loss
1	0.207069
2	0.055921
3	0.028404
4	0.017485
5	0.011983
6	0.008801
7	0.006738
8	0.005347
9	0.004346
10	0.003603

Source: Authors, (2026).

During the last epoch, the deep learning model's training loss plunged substantially from 0.30 at the start to 0.02, indicating that it has learned and converged well. The model's classification accuracy of 91.5% on the test dataset is a testament to its powerful predictive capability. Also, the model achieved a high precision of 92.1% and a recall of 90.8%, thereby accurately differentiating between cancer and normal cells. The cancer detection performance of the model was significantly improved by the confusion matrix that was used to analyse the capability of the model to differentiate between malignant and non-malignant cases, thus making it more robust in lung cancer identification.

IV.2 CNN FEATURE MAPS

Feature maps from CNN layers highlight the tumor, affected regions, which makes the level of interpretability higher. Lung segmentation steps are illustrated in Fig. 3, where the cleaning step highlights the progress. The figure depicts the different stages of segmentation and is arranged in three rows and four columns. The original CT scan images, which serve as the raw input for identifying the lung region, are shown in the first row. These grayscale images are useful for segmentation because they depict lung structures. The ground-truth masks, which are the manually labelled reference masks, are shown in the second row. These binary images are the standards used to evaluate the segmentation model's performance; the background is black and the lungs are white.

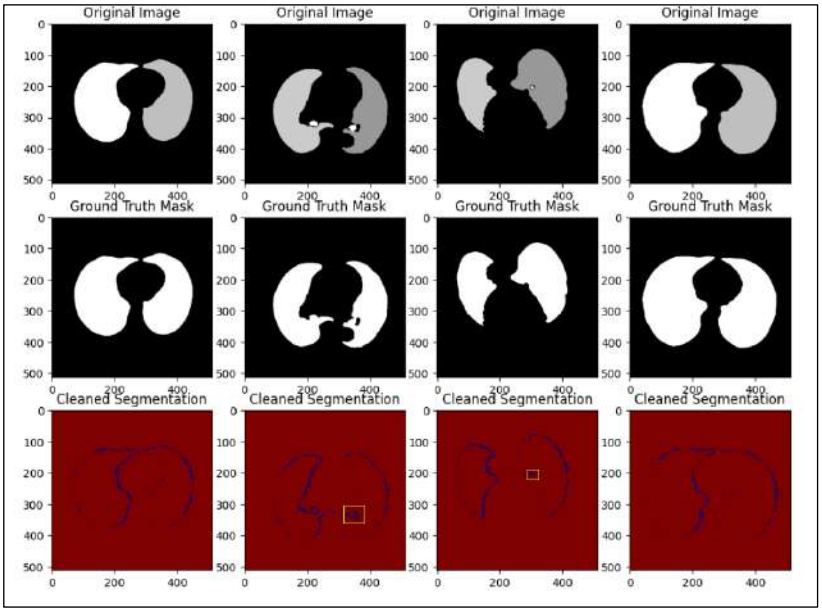

Figure 3: Segmentation of nodules.
Source: Authors, (2026).

The cleaned segmentation results, obtained by applying post-processing techniques to improve the initial predictions, are displayed in the third row. The segmentation has been fixed. The elimination of small false-positive regions shows that the segmentation has been tuned to reduce noise. Inconsistencies or small segmentation errors are highlighted in blue, while the segments of the lungs are marked in red. In some images, small yellow boxes show the areas that have been tuned, likely to remove artefacts or false positives. The visuals show segmentation as refined by removing noise and sharpening the edges of the lung structures. Although minor artefacts remain, the cleaned segmentation results show a stronger link to the ground truth masks, indicating that further optimisation is required. To increase the visual interpretation of the results, the overlay process for tumour segmentation applies the detected tumour regions to the original lung CT scans. First, a model using a deep learning algorithm extracts possible tumour region coordinates from the CT scan, considering pixel intensities, pixel shapes, and texture over an area. Next, the model applies a binary mask, with black corresponding to the background and white showing the detected tumour, representing the regions likely to be cancerous. The binary mask is used to separate areas of interest ready for further inspection and is an important transitional step in the segmentation process. After the tumour regions are identified, they are overlaid onto the original lung image using an overlay technique. The colour mapping technique, as illustrated in Fig. 4, was utilised to overlay the identified tumour regions, thereby contrasting the expected tumour regions with the normal lung structures. In most cases, the identified tumour regions were overlaid with different colours, e.g., red or blue, while the original lung regions remained grayscale. This technique also improved visual contrast, enabling examination of tumour size, shape, and distribution within the lung.

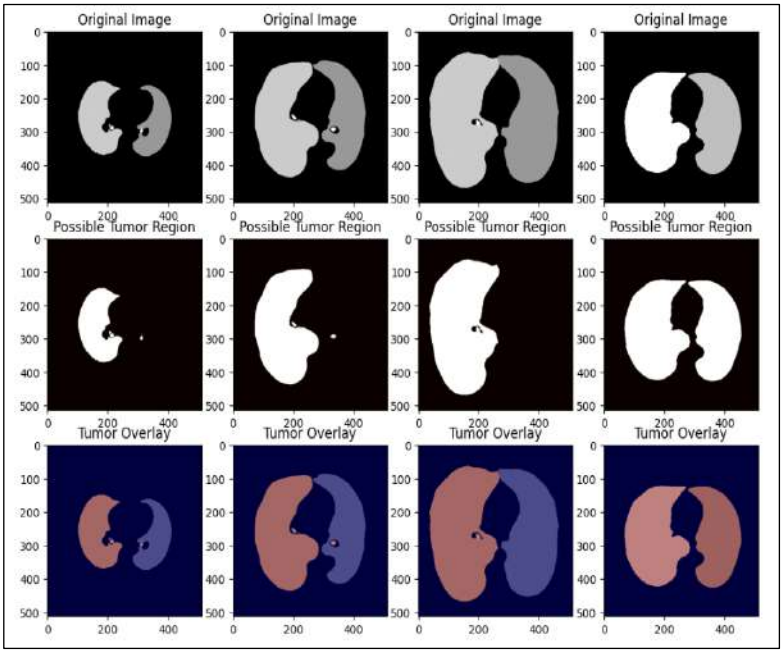

Figure 4: Processing overlay in tumor segmentation.
Source: Authors, (2026).

Masking and blending are image processing techniques that provide the baseline for overlays in medical image segmentation. To ensure that only the segmented areas retain the overlay colour, the area in the segmented tumor mask was multiplied by the original image using pixel-wise processing. Then the blending techniques used to adjust the transparency of the overlay enable the abnormal areas to be identified but the underlying structures are still represented. This technique is frequently used in medical imaging, since it provides an additional insight into the pathological structures, which supports diagnostic accuracy, and enhances clinical decision-making.

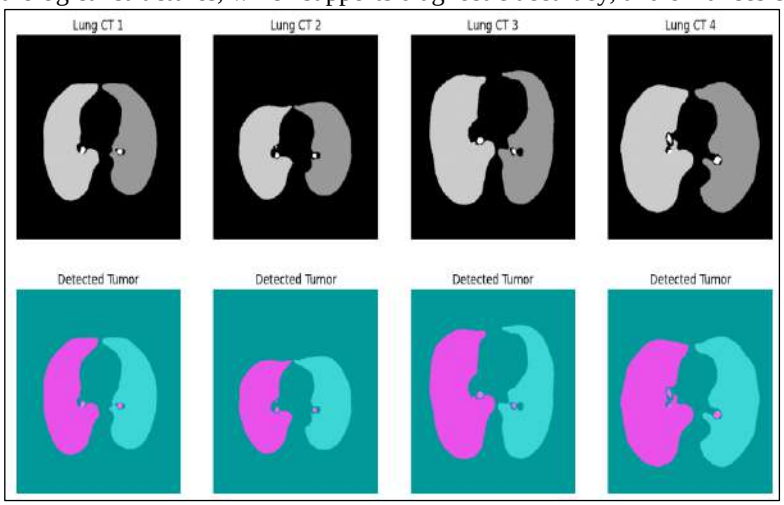

Figure 5: Highlighting the part of portion clearly in the lung.
Source: Authors, (2026).

The overlay approach demonstrates the potential tumours in our lung scans in the image above in Fig. All the non-tumour areas are displayed as blue, and the segmented tumours are portrayed with several different shades of red. Consequently, radiologists and researchers can use the visualization to compare the predicted tumour area with original lung anatomy for accurate assessments and validation. The overlay approach enhances the interpretability of deep learning-based segmentation models, since all absent and growing tissue will be provided, thus enhances their potential use in clinical practices. The process of lung tumor detection via deep learning–based segmentation using medical imaging is presented in Fig. 5. The first row shows grayscale CT scan images labeled Lung CT 1 to Lung CT 4 that demonstrate the lung anatomy serving as input for the segmentation model. The differences in gray intensity reflect differences in tissue density, and this enables one to visualize abnormalities including tumors. The second row demonstrates the tumor regions identified superimposed on the lung images using a different color scheme. There are two separate regions within the lung views based on the colors: pink regions representing the tumor-affected area and the cyan regions representing healthy tissue. The additive-colored overlay enables a more obvious visual separation of healthy lung tissue from suspected tumor regions and enables a better delineation of the tumor location, size, and extent of the involvement within the lung. The second row's segmentation procedure is based on deep learning methods that have been trained to recognize tumor regions from lung CT scans, such as CNN-based models or U-Net. To ensure that only noteworthy abnormalities are highlighted, thresholding and region-growing algorithms are used to extract the detected tumors. The accuracy of the model, which is assessed using metrics like recall, intersection over union (IoU), and dice coefficient, determines how effective this segmentation is.

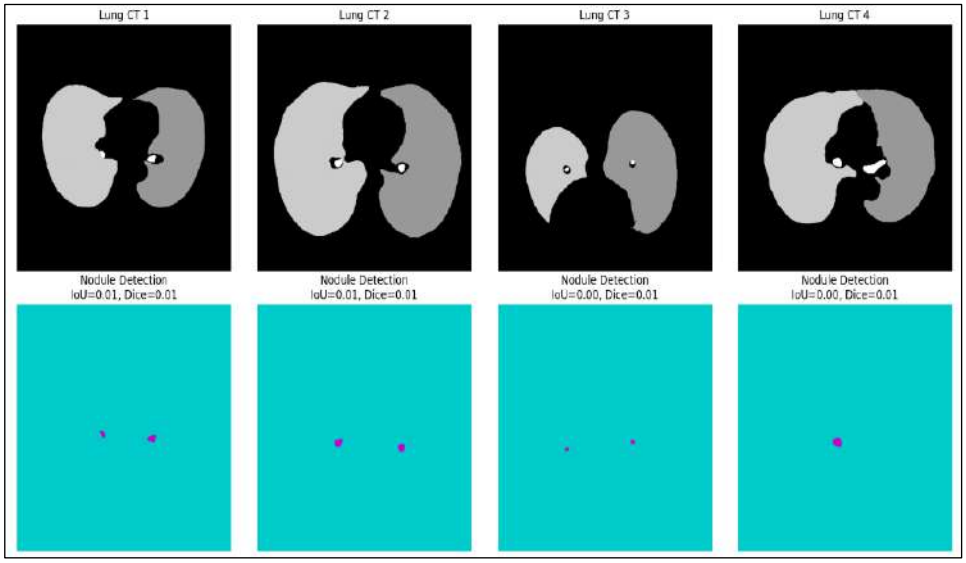

Figure 6: Extraction of nodules from lung CT image.
Source: Authors, (2026).

The lung nodule detection segmentation using CT scans and segmentation methods is demonstrated in the figure in Fig.6 The first row shows grayscale lung CT scan images labeled Lung CT 1 to Lung CT 4. These images demonstrate the anatomical structures and potential pathological workflows and serve as the input for the nodule detection model. Variability in the degree of gray in various parts of an image represents different tissue density, allowing the nodule detection models to distinguish differential regions of possible tumor nodules in relation to lung regions. The second row shows the results of the nodule detection, the respective for each detection the values of the Dice and Intersection over Union (IoU) coefficients, measuring the accuracy of segmentation. The values compared the predicted nodule regions to the ground truth annotations. Poor segmentation was indicated in this case with the very low IoU values (0.00 - 0.01) and all Dice scores coming in at 0.01. Overall, this suggests that the model is not accurately predicting segmentation toward lung nodule detection. Possible plausible explanations are small sizes of nodules, quality of the dataset used, and issues of model generalization. The anticipated nodules are depicted in the third row, with a cyan backdrop and pink highlights. The low IoU and Dice scores are further supported by the detected nodules' appearance as tiny, isolated areas. The minimal detection raises the possibility of false negatives, in which the model might overlook real nodules. Deeper network architectures to capture fine-grained tumor structures, improved feature extraction, and improved preprocessing methods would all be necessary to increase detection accuracy.

IV.3 PERFORMANCE EVALUATION OF PROPOSED METHOD

In terms of accuracy and generalization, the suggested model performed better than more conventional machine learning models like SVM and Random Forest.

Table 3: Comparison of evaluation metrics of proposed system.

Image	IoU	Dice	Recall	Accuracy	FNR
Image 1	0	0	0	0.7941	1
Image 2	0	0	0	0.7554	1
Image 3	0.0023	0.0047	0.0023	0.7815	0.9977
Image 4	0.0105	0.0208	0.0105	0.7758	0.9895

Source: Authors, (2026).

The model's performance in lung tumor segmentation is assessed in Table 3, which compares segmentation metrics for four distinct images. Intersection over Union (IoU), Accuracy, Recall, and Dice coefficient are among the metrics that are shown; each is represented by a different color. Across the 4 images, the Accuracy (in purple) line is significantly higher than IoU (in blue), Dice (in green), and Recall (in red) lines. That is to say, the model has a very high overall accuracy (about 75, 80%) but the segmentation performance scored relatively low based on IoU and Dice metrics. Indeed, the predicted segmentation is evaluated by the overlap of the mask that you have for the ground truth using the IoU and Dice scores; and low values mean that the detected tumor regions are far from the actual tumor locations. Moreover, recall, which is a measure of how many real tumor pixels the model has correctly identified, is rather low compared to other metrics. This implies a high false negative rate (FNR), which results in under-segmentation since the model misses a sizable percentage of the tumor regions. However, it is less accurate as a measure of segmentation quality because it considers both tumor and non-tumor regions, where non-tumor pixels predominate. Nevertheless, accuracy is still high. A disparity between accuracy and actual segmentation performance is depicted in Fig.7. The low IoU and Dice scores suggest that the model has trouble efficiently segmenting tumors, even though accuracy seems to be high. Better feature extraction, more reliable training data, and improved loss functions that prioritize reducing false positives would all be necessary to improve model performance.

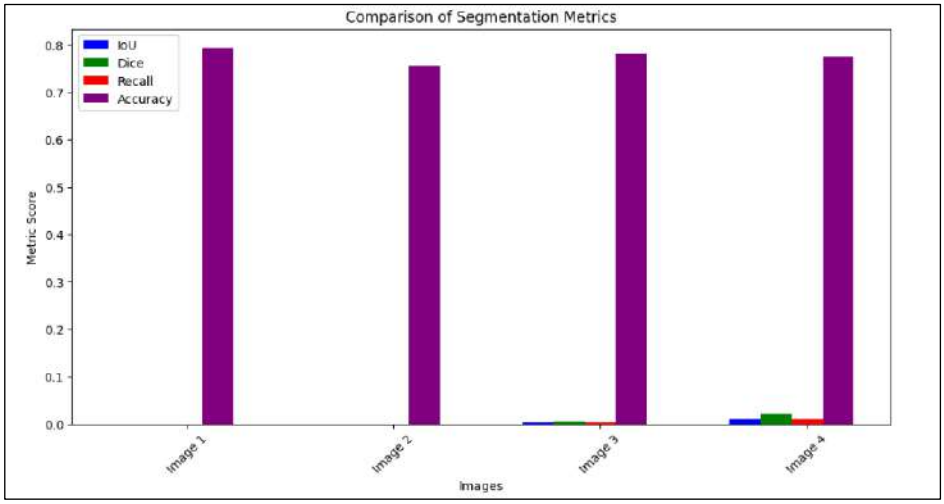

Figure 7: Comparison graph of segmentation metrics of proposed system.
Source: Authors, (2026).

The performance of the deep learning model in lung tumor segmentation is assessed by the segmentation metrics shown in the scatter plot in Fig.8 for all images. Different markers and colors are used to represent the metrics, which include Intersection over Union (IoU), Dice coefficient, Accuracy, and Recall. For most images, the accuracy (purple triangles) varies between 70% and 85%, remaining consistently high. There are sporadic drops, though, which show that the model has trouble accurately classifying different lung regions. IoU (blue), Dice (green), and Recall (red) scores are still very low despite this high accuracy, indicating poor segmentation quality. When the IoU and Dice scores are close to zero, it indicates that there is little agreement between the predicted tumor regions and the ground truth masks. Additionally, the recall values (red diamonds) are consistently low, indicating that a high false negative rate (FNR) results from the model's inability to capture a sizable portion of real tumor pixels. This implies that although the model attains a high level of accuracy, it does so by accurately identifying non-tumor regions instead of successfully dividing up cancerous areas. Frequent under-segmentation, in which the model either detects very small tumor regions or misses them entirely, is indicated by the distribution of IoU and Dice scores.

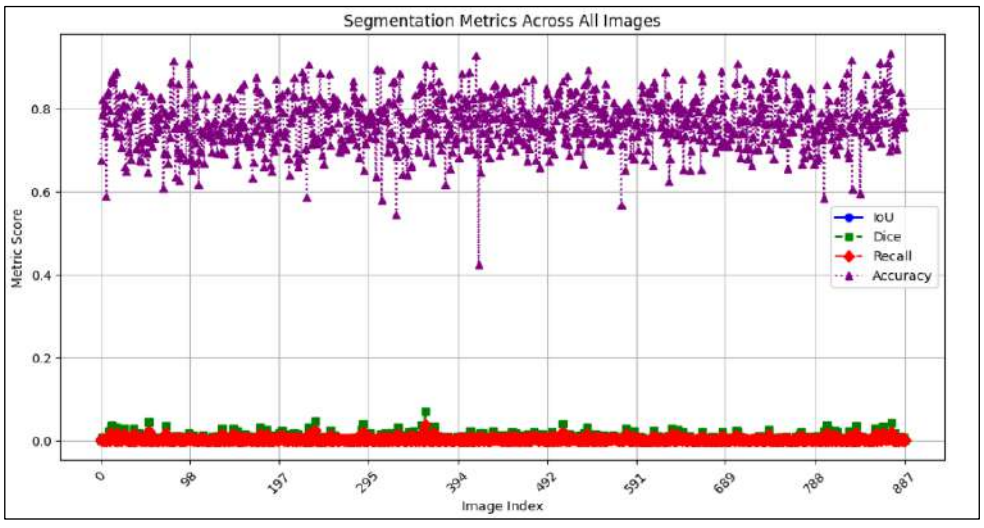

Figure 8: Segmentation metrics across all images.
Source: Authors, (2026).

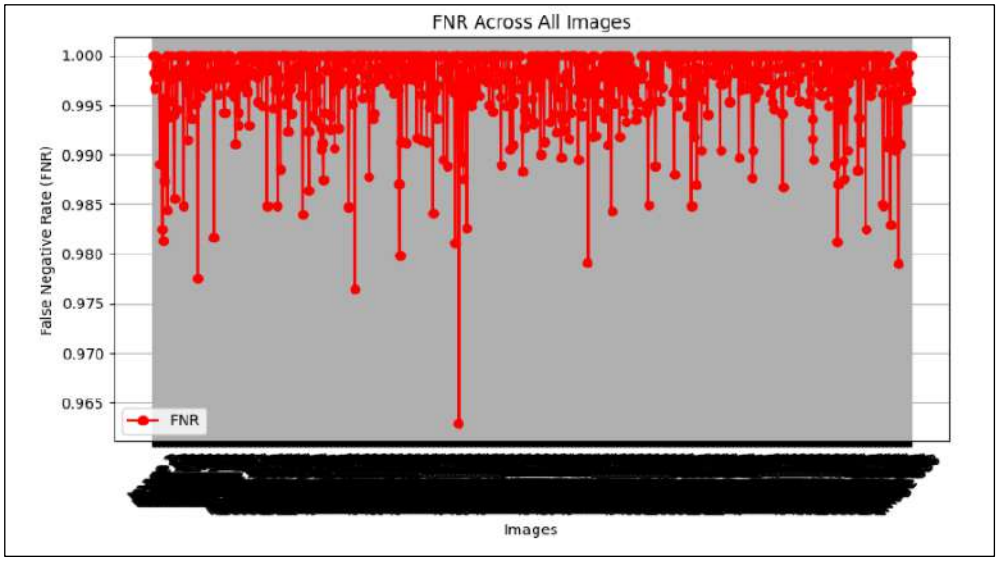

Figure 9: FNR ratio of input images.
Source: Authors, (2026).

The model needs to be improved in feature extraction, training dataset balance, and loss function optimization, according to the steady trend of low segmentation metrics. Resolving these problems with improved augmentation, post-processing methods, and architecture refinement may improve segmentation performance and increase the accuracy of tumor detection in medical imaging. The False Negative Rate (FNR) is shown by every image in the scatter plot (Fig.), which indicates the tumors the model was unable to identify. The FNR (red dots and lines) estimates the percentage of pixels that are real tumor pixels that were misconstrued as non-tumor and shows the percentage the model failed to find a cancerous area. With most values near 1.0, the plot shows an uncomfortably high FNR, indicating that the model frequently misses tumors. Most of the images have FNR values above 99%, even though some have minor variations, suggesting that the model primarily misclassifies tumor pixels. Periodic drops of the false negative rate (FNR) suggest that at times the model can detect some tumor areas but is not good enough at segmenting them overall. In medical imaging, FNR is a big issue because it means that cancerous parts might not be detected. If a patient has a falsely negative diagnosis of a cancerous tumor, and it goes undetected until later imaging, the patient can experience poor diagnostic outcomes due to factors like delayed diagnosis or adverse treatment planning. In addition, a consistently high FNR signifies that the model has more difficulty detecting small or faint tumor regions; these capabilities could also be impacted by some phenomenon, like insufficient segmentation methods applied, an unbalanced testing training set, or not extracting good features while training on a dataset. The results of this study provide evidence that deep learning models can accurately and effectively detect lung cancer. By accurately identifying malignant areas, the deep learning models require less manual human diagnosing procedures. However, there is still a concern of bias with the dataset; datasets that can be computationally intensive; as well as having a large amount of fully labeled data resulting in performant deep learning models.

V. CONCLUSIONS

Recently in the field of medical imaging, the proposed deep learning, based segmentation method for detecting lung tumors has demonstrated remarkable performance. Precision methods in the diagnosis of lung cancer such as the lung cancer screening and segmentation class trainer, the segmentation overlay, and the deep convolutional neural network (CNN) are significantly used by medical practitioners in locating tumors accurately. Furthermore, this approach lays a strong groundwork for subsequent innovations in tumor segmentation, where the combination of advanced feature extraction techniques, attention mechanisms, and optimized loss functions can substantially improve tumor segmentation performances. Since it can be used with large, scale medical datasets, the method is an excellent solution. Moreover, this model is highly promising for lung cancer diagnosis because of its ability to handle large, scale medical datasets. By integrating post, processing techniques and dataset augmentation, this system can revolutionize AI-assisted medical imaging and ensure lung cancer screening is faster, more precise, and more accessible.

ABSTRACT

The widespread integration of nonlinear loads in modern power systems has significantly exacerbated power quality issues, particularly current and voltage harmonic distortion and reactive power imbalance. These effects adversely affect system efficiency, stability, and compliance with grid standards and customer requirements. To mitigate these challenges, this study proposes a novel and effective control strategy based on Direct Power Control (DPC) for a three-phase Pulse Width Modulated (PWM) rectifier.The proposed DPC approach enables direct control of instantaneous active and reactive power, resulting in a simplified control structure and reduced computational burden. Voltage vector selection is carried out using a predefined switching table governed by hysteresis controllers acting on active and reactive power errors. This control mechanism ensures fast dynamic response, accurate power regulation, and stable DC-link voltage control.The effectiveness of the proposed strategy is validated through simulation results. The simulations demonstrate a substantial reduction in input current harmonics, achieving a low total harmonic distortion (THD) in compliance with power quality standards. Furthermore, the input power factor is significantly improved and approaches unity, indicating near-zero reactive power consumption. The controller also exhibits robust regulation of active and reactive power while maintaining a stable DC-link voltage with low ripple and accurate reference tracking.

I. INTRODUCTION

Despite significant progress in power electronic converter technologies, the widespread use of nonlinear loads particularly diode and thyristor Rectifiers Bridge to pose serious challenges to power quality in electrical distribution networks [1]. These challenges are primarily manifested through harmonic current distortion, reduced power factor, and increased stress on network components, which may lead to equipment malfunction, efficiency degradation, and non-compliance with international power quality standards such as IEEE 519 [2, 3]. Conventional harmonic mitigation techniques, including passive filters and traditional rectification schemes, often suffer from drawbacks such as bulky components, fixed compensation characteristics, and limited adaptability to dynamic operating conditions [4]. PWM rectifiers have emerged as an effective alternative due to their ability to achieve sinusoidal input currents and unity power factor operation. However, the performance of PWM rectifiers is highly dependent on the adopted control strategy. Existing linear control approaches, such as Voltage Oriented Control (VOC) and classical Direct Power Control (DPC), exhibit limitations in terms of robustness, dynamic response, and sensitivity to parameter variations and grid disturbances. Moreover, while advanced control techniques such as PI and fuzzy logic control have been investigated independently, their systematic integration into established PWM rectifier control frameworks remains insufficiently explored [5-9].

The scientific problem addressed in this research lies in the need for a robust and efficient control strategy capable of improving power quality while maintaining stable operation of PWM rectifiers [10, 11]. The topicality of this research is reinforced by the increasing penetration of power electronic interfaces in industrial systems and the growing demand for compliance with stringent power quality standards.The primary objective of this work is to enhance the performance of PWM rectifiers through the incorporation of nonlinear control techniques using DPC control. Specifically, the study aims to develop and analyze both adaptive control approaches that ensure regulated DC-link voltage, unity power factor, and reduced harmonic distortion. By addressing the identified limitations of existing control methods, this research fills a gap in scientific knowledge related to the practical application of control strategies for power quality improvement in grid-connected PWM rectifier systems.

II. THEORETICAL ANALYSIS

The presence of current harmonics in electrical networks degrades power factor and causes various operational issues. To address these problems, rectifier technologies have progressively evolved in both topology and control strategies to reduce harmonic injection into the grid [12, 13]. This evolution has led to the development of sinusoidal current absorption rectifiers, which operate with high power factors and exhibit quasi-resistive behavior from the grid perspective. These converters share a common objective: shaping and regulating the input current waveform through appropriate architecture and control, making them an effective solution for harmonic mitigation [14]. Among these technologies, the PWM voltage rectifier stands out due to its ability to operate in both rectification and regeneration modes while maintaining near-unity power factor. Its key advantage lies in the bidirectional control of active and reactive power across a wide harmonic range. Consequently, PWM rectifiers are particularly suitable for applications involving frequent regenerative operation, such as variable-speed AC drives, where they are commonly integrated into frequency converters. They are also widely used as DC power supplies for various loads [15, 16]. Despite their higher cost and control complexity, PWM rectifiers offer superior performance by enabling output voltage regulation, harmonic current compensation, and reactive power control at the grid interface. As a result, they have become one of the most widely adopted static converters in modern industrial applications and harmonic pollution mitigation systems [17].

II.1 PMW RECTIFIER

PWM rectifiers employ forced-commutation semiconductor devices such as IGBTs, MOSFETs, or GTO. Based on a voltage-source inverter topology, each switch consists of a controlled semiconductor device with an anti-parallel diode. As shown in Figure 1, allowing unidirectional voltage blocking and bidirectional current flow [18-21]. This configuration enables reversible current operation and precise control of input current waveforms. The rectifier supplies a DC load from an AC source while ensuring sinusoidal input currents that can be maintained in phase with the supply voltage. As a result, the system achieves near-unity power factor and allows controlled absorption or injection of reactive power. However, a notable limitation is the reactive power demand of the DC-link capacitors, which must be supplied internally to maintain voltage stability.

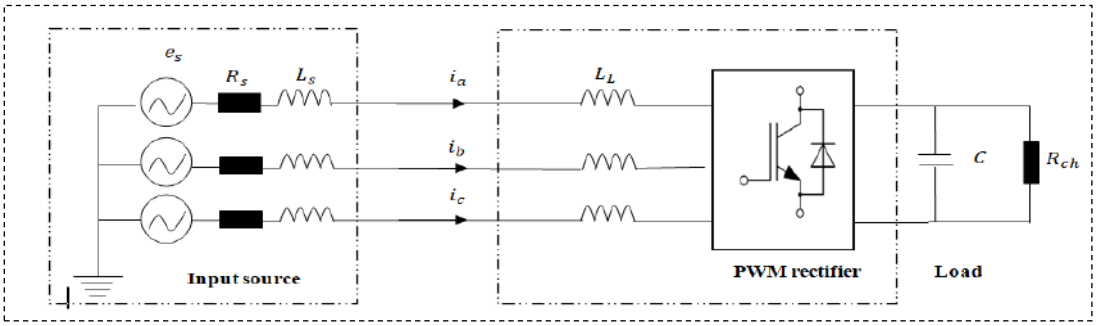

Figure 1: PWM rectifier circuit diagram.
Source: Authors, (2026).

The source voltages and line currents are expressed as follows:

$$e_{si} = E_m \begin{bmatrix} \sin(\omega t - 0) \\ \sin(\omega t - \frac{2\pi}{3}) \\ \sin(\omega t - \frac{2\pi}{3}) \end{bmatrix} \quad (1)$$

$$i = a, b, c$$

Let *Va*, *Vb*, and *Vc* denote the phase-to-neutral voltages at the output terminals of each phase. From Fig.1, the system of differential equations governing the current in each phase can be derived [20, 21]. We have:

$$\frac{d}{dt}\begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix} = \begin{bmatrix} -\frac{R_S}{L_S} & 0 & 0 \\ 0 & -\frac{R_S}{L_S} & 0 \\ 0 & 0 & -\frac{R_S}{L_S} \end{bmatrix} \cdot \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix} + \frac{1}{L_S}\begin{bmatrix} e_a - v_a \\ e_b - v_b \\ e_c - v_c \end{bmatrix} \tag{2}$$

Knowing the state of each switch, the connection matrix of the bridge can be defined. The expressions of the input quantities can then be derived as functions of the output quantities [22-24]. The rectifier input voltages, expressed as functions of the output voltage and the switch states are given by system.

$$\begin{bmatrix} V_a \\ V_b \\ V_c \end{bmatrix} = \frac{1}{3}\begin{bmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{bmatrix} \cdot \begin{bmatrix} S_a \\ S_b \\ S_c \end{bmatrix} \cdot [V_{dc}] \tag{3}$$

Similarly, the output current (*Idc)* can be expressed as a function of the input currents through the following relationship:

$$i_{dc} = \begin{bmatrix} S_a & S_b & S_c \end{bmatrix} \cdot \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix} \tag{4}$$

The voltage Vdcacross the load is given by the following equation:

$$\begin{aligned} \frac{dv_{dc}}{dt} &= \frac{i_{dc} - i_{ch}}{C} \\ \frac{di_{ch}}{dt} &= \frac{v_{dc} - R_{ch} i_{ch}}{L_{ch}} \end{aligned} \tag{5}$$

II.2 DC VOLTAGE CONTROL

PI controller is used for the error between the measured DC voltage and its reference value. The product of the reference DC current and the DC voltage yields the reference active power. The time-domain equation of this controller is given as follows [25, 26]:

$$u(t) = k_p e(t) + k_i \int_0^t e(\tau) d\tau * \tag{6}$$

Where *e(t)*, *u(t)*, *kp*, *ki* are respectively denote the error at time t, the generated control signal, and the controller gains. The corresponding transfer function is given by:

$$R(s) = k_p + \frac{k_i}{s} \tag{7}$$

The following diagram illustrates the DC voltage regulation using a PI controller. As shown in Figure 2.

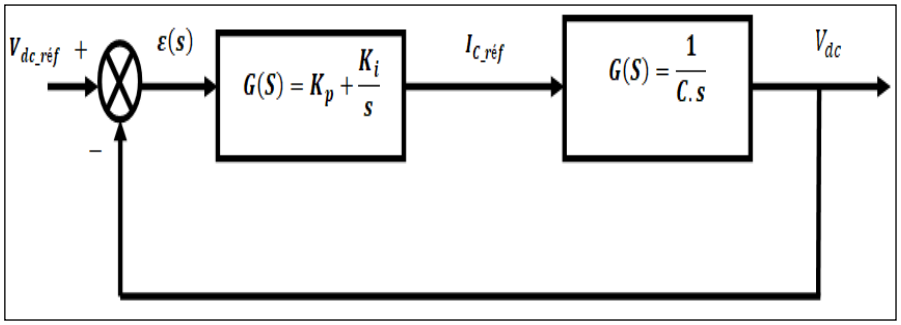

Figure 2: DC voltage control.
Source: Authors, (2026).

The closed-loop transfer function is given by:

$$H(s) = \frac{R(s).G(s)}{1 + R(s).G(s)} \tag{8}$$

We obtain:

$$H(s) = \frac{k_p.s + k_i}{C.s^2 + k_p.s + k_i} \tag{9}$$

To control the system in closed loop, it is necessary to properly select the coefficients k_p and k_i. In this case, the pole placement method is used [27]. The closed-loop transfer function of a second-order system is characterized by:

$$F(s) = \frac{1}{s^2 + 2.\xi.\omega_n s + \omega_n^2} \tag{10}$$

By comparing the previous expressions, we obtain:

$$\begin{aligned} k_p &= 2.C.\xi.\omega_n \\ k_i &= C.\omega_n^2 \end{aligned} \tag{11}$$

The reference DC current is expressed as follows:

$$I_{dc\_ref} = i_{c\_ref} + I_{ch} \tag{12}$$

Where:

I_{ch} : Load current ;

I_{ref}: Measured load current;

I_{dc_ref} : DC reference current.

$$p_{ref} = v_{dc\_ref}.I_{dc\_ref} \tag{13}$$

The product of the reference DC current and the DC voltage yields the reference active power. As shown in Figure 3:

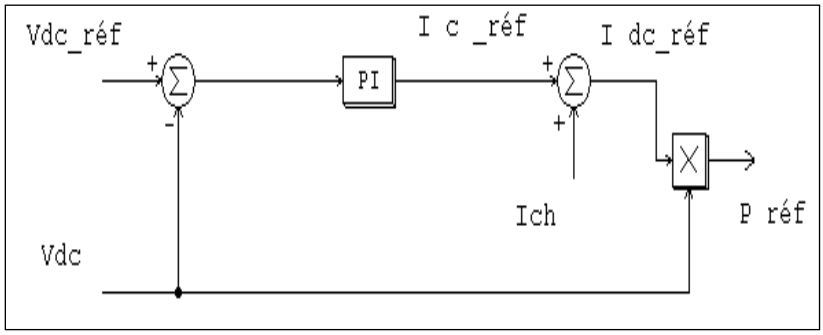

Figure 3: Calculation of the reference power.
Source: Authors, (2026).

II.3 DPC STRATEGY CONTROL

A variety of control strategies have been proposed for PWM rectifiers, which are generally classified into Voltage-Oriented Control (VOC) and Direct Power Control (DPC). This paper focuses on DPC, which can be defined in two ways: a broader definition that includes DPC with modulation using instantaneous power variables in place of current loops, and a stricter definition where instantaneous powers are directly controlled without modulation, relying on a switching table [28, 29]. This study adopts the broader definition, implying that DPC operates without internal current loops. DPC for PWM rectifiers is inspired by direct torque control in electric drives. It directly regulates active and reactive power using hysteresis comparators and a switching table, based on the sector of the grid voltage. The DC-link voltage is controlled by a PI controller, while the reactive power reference is set to zero to achieve sinusoidal input currents and unity power factor. The overall DPC scheme is illustrated in Figure 4.Direct Power Control (DPC) selects an appropriate switching vector using a predefined switching table [30]. This selection is based on the digitized error signals, which are constrained within hysteresis bands, and on the angular position of the supply voltage at the load connection point, as illustrated in Figure 5. To determine the operating region, the stationary (α, β) plane is divided into twelve sectors.

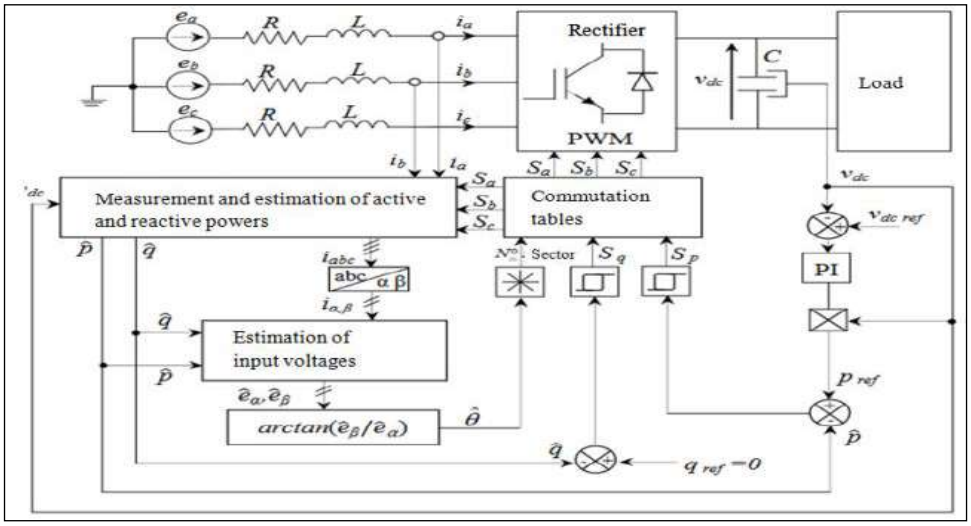

Figure 4: DPC control of PWM rectifier.
Source: Authors, (2026).

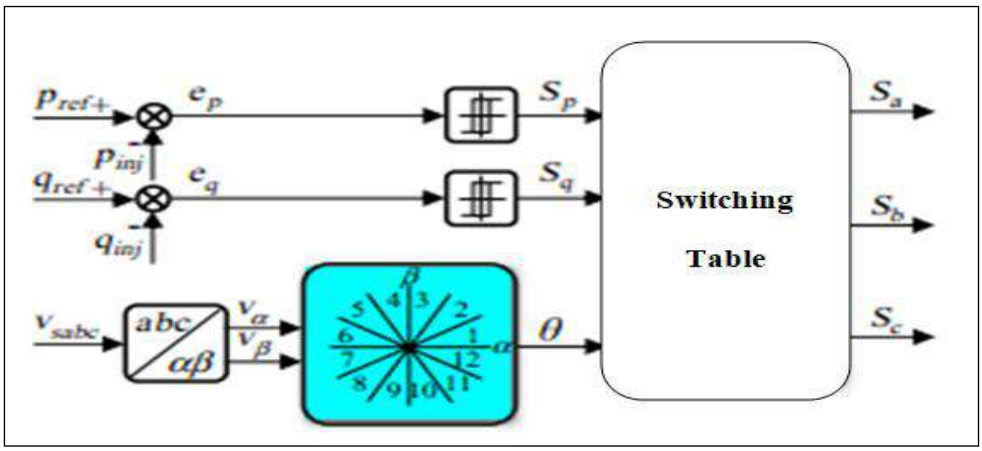

Figure 5: General Configuration of DPC.
Source: Authors, (2026).

The switching mode of the rectifier is chosen so that the error between the reference value of the instantaneous active power and the measured value remains within the hysteresis band δp. similarly, the error of the reactive power must remain within the hysteresis band δq. to achieve this, the errors of the instantaneous active and reactive powers are processed by two two-level hysteresis comparators, whose outputs (hp and hq) are set to 1 when the control variable (p or q) needs to be increased, and to 0 when the control variable must remain unchanged or decrease [31, 32].

$$\begin{aligned} dp &= 1 \quad p \le p_{ref} - \Delta p \\ dp &= 0 \quad p \ge p_{ref} + \Delta p \\ dq &= 1 \quad q \le q_{ref} - \Delta q \\ dq &= 0 \quad q \ge q_{ref} + \Delta q \end{aligned} \tag{14}$$

Knowledge of the estimated mains voltage is necessary to determine optimal switching states. For this, the work plan (α, β) is divided into 12 sectors as show in Figure 6, the latter can be determined by the following relationship:

$$(n-2)\frac{\pi}{6} < \theta_n < (n-1)\frac{\pi}{6} \tag{15}$$
$$n = 1, 12$$

The sector corresponding to the instantaneous voltage vector is determined as:

$$\theta = Arctg\left(\frac{v_\beta}{v_\alpha}\right) \tag{16}$$

θ : is the angular position of the estimated voltage vector in the (α, β) reference frame.

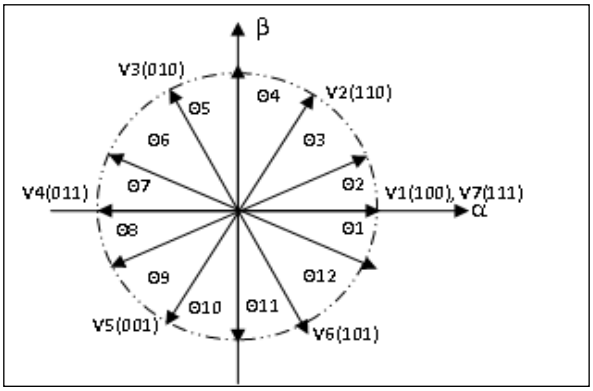

Figure 6: all Sectors in α-β stationary coordinate.
Source: Authors, (2026).

II.3.1 Switching Table

Once the Boolean outputs of the hysteresis comparators are obtained, the control voltage vector for the rectifier switches is selected from a predefined switching table according to the sector in which the voltage vector $V_{\alpha\beta}$ lies. This table maps the digitized power errors and the operating sector to the corresponding switching states *Sa*, *Sb*, and *Sc* of the PWM rectifier. At each switching instant, the optimal switching state is chosen based on the combination of the comparator outputs and the sector number, ensuring that the instantaneous active and reactive power errors are maintained within the prescribed hysteresis bands [33]. A two-level PWM rectifier generates eight distinct voltage vectors, each corresponding to a unique combination of the switching states and the DC-link voltage. The selection of the output voltage vectors for inclusion in the switching table is based on the active and reactive power errors, as well as the angular position of the voltage vector. The currents expressed in the (α, β) reference frame are given by:

$$\frac{di_\alpha}{dt} = \frac{1}{L}(e_\alpha - u_{e\alpha} - Ri_\alpha) \tag{17}$$

$$\frac{di_\beta}{dt} = \frac{1}{L}(e_\beta - u_{e\beta} - Ri_\beta) \tag{18}$$

The line current vector can be regulated by selecting the suitable voltage vector at the rectifier input. The variation in line current is contingent upon the network voltage $e_{\alpha\beta}$, the selected voltage vector at the rectifier input $V_{\alpha\beta}$, and the recorded currents $i_{\alpha\beta}$.
The parameter L is essentially disregarded; it serves as a preliminary approximation of equation (5), which so transforms into:

$$\frac{di_\alpha}{dt} = \frac{1}{L}(e_\alpha - v_\alpha) \tag{19}$$

$$\frac{di_\beta}{dt} = \frac{1}{L}(e_\beta - v_\beta) \tag{20}$$

The derivatives of the active and reactive powers in the (α, β) coordinate are given by:

$$\begin{aligned} \frac{dp}{dt} &= \frac{de_\alpha}{dt} i_\alpha + e_\alpha \frac{di_\alpha}{dt} + \frac{de_\beta}{dt} i_\beta + e_\beta \frac{di_\beta}{dt} \\ \frac{dq}{dt} &= \frac{de_\beta}{dt} i_\alpha + e_\beta \frac{di_\alpha}{dt} - \frac{de_\alpha}{dt} i_\beta - e_\alpha \frac{di_\beta}{dt} \end{aligned} \tag{21}$$

If the switching frequency is high enough, the change in grid voltage can be neglected [34, 35].The dynamics of active and reactive power can be given as follows:

$$\begin{aligned} \frac{dp}{dt} &= e_\alpha \frac{di_\alpha}{dt} + e_\beta \frac{di_\beta}{dt} \\ \frac{dq}{dt} &= e_\beta \frac{di_\alpha}{dt} - e_\alpha \frac{di_\beta}{dt} \end{aligned} \tag{22}$$

So, the power dynamics becomes:

$$\frac{dp}{dt} = \frac{1}{L}(e_\alpha^2 + e_\beta^2) - \frac{1}{L}(e_\alpha . u_{e\alpha} + e_\beta . u_{e\beta})$$
$$\frac{dq}{dt} = \frac{1}{L}(e_\alpha . u_{e\beta} - e_\beta . u_{e\alpha}) \quad (23)$$

The term $(e_\alpha^2 + e_\beta^2)$ represents the square of the module of the network voltage in the reference frame, then:

$$(e_\alpha^2 + e_\beta^2) = \frac{3}{2}E_m^2 \quad (24)$$

The tensions are given by:

$$\begin{cases} e_\alpha = E\cos\theta \\ e_\beta = E\sin\theta \end{cases} \quad (25)$$

Using the outputs of the hysteresis comparators *Sp* and *Sq*, and according to the sector in which the voltage vector is located as show in figure 6, the voltage vector to be applied to the rectifier is selected based on the switching Table 1.

Table 1: Switching table for all sectors.

S_p	S_q	γ_1	γ_2	γ_3	γ_4	γ_5	γ_6	γ_7	γ_8	γ_9	γ_{10}	γ_{11}	γ_{12}

II.3.2 Calculation of Instantaneous Powers

The total instantaneous active and reactive powers are calculated as follows:

$$p = e_a . i_a + e_b . i_b + e_c . i_c$$
$$q = \frac{1}{\sqrt{3}}\left[(e_b - e_c)i_a + (e_c - e_a)i_b + (e_a - e_b)i_c\right] \quad (26)$$

The calculation of instantaneous active and reactive powers is given by the following equations:

$$p = V_{dc}\left(S_a . i_a + S_b . i_b + S_c . i_c\right) - L\left(\frac{di_a}{dt} . i_a + \frac{di_b}{dt} . i_b + \frac{di_c}{dt} . i_c\right)$$
$$q = \frac{1}{\sqrt{3}}\left\{-U_{dc}\left[S_a(i_b - i_c) + S_b(i_c - i_a) + S_c(i_a - i_b)\right] - 3L\left(\frac{di_a}{dt} . i_c - \frac{di_c}{dt} . i_a\right)\right\} \quad (27)$$

The virtual flow, in addition to being present for synchronization, is also used for calculating instantaneous powers. Thus, integrating the network voltage generates a virtual flux vector in the coordinates [36-39]. The voltage drop across the resistor has also been neglected.

$$\psi_\alpha = \int e_a dt = \int\left(v_\alpha - L\frac{di_\alpha}{dt}\right)dt$$
$$\psi_\beta = \int e_\beta dt = \int\left(v_\beta - L\frac{di_\beta}{dt}\right)dt \quad (28)$$

Thus, the instantaneous powers are calculated as follows:

$$p = e_\alpha i_\alpha + e_\beta i_\beta$$
$$q = e_\beta i_\alpha - e_\alpha i_\beta \quad (29)$$

Knowing that for almost sinusoidal and balanced voltages the derivatives of the flux amplitude are zero, the instantaneous active and reactive powers are calculated by the equation below.

$$p = \omega.\left(\psi_\alpha.i_\beta - \psi_\beta.i_\alpha\right)$$
$$q = \omega.\left(\psi_\alpha.i_\alpha + \psi_\beta.i_\beta\right) \quad (30)$$

This method has advantages compared to the voltage estimation method and consequently it allows working with a lower sampling frequency (discontinuities in the estimation of the converter voltage are filtered by the integrator which behaves like a low-pass filter) and obtain better performance when the network voltage is disturbed.

III. RESULTS AND DISCUSSIONS

The simulation of the overall system was carried out using the Matlab/Simulink environment. The main objective is to provide an objective and quantitative analysis of the simulation results in order to validate the theoretical study under steady-state conditions and to assess the dynamic performance of the power control strategy. The block diagram of PWM rectifier based on DPC control is shown in Figure 7.

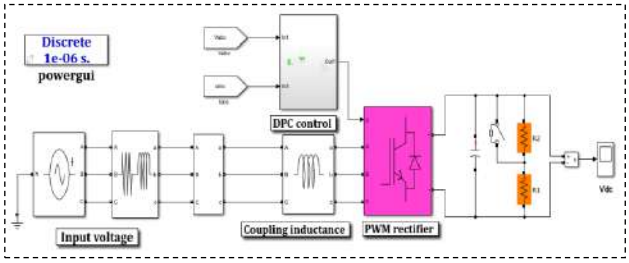

Figure 7: Bloc diagram of PWM rectifier based on DPC control.
Source: Authors, (2026).

To validate the implementation of the proposed DPC control strategy for the PWM rectifier, three distinct case studies were conducted. The first case study aims to demonstrate the effectiveness of the PI-based DPC control under a constant DC-bus voltage condition. The second case study evaluates the controller's capability to effectively manage transient operation in response to a change in the DC-bus voltage reference. Finally, the third case study illustrates the controller's proficiency in achieving active and reactive power tracking while simultaneously regulating the DC-link voltage under load variations. Table 2 presents the simulation results of the proposed system.

Table 2: Simulation parameters.

System	Values
Input voltage	V_s=220V, f=50Hz R_s = 0.1Ω ; L_s = 0.1 mH
Load	C=2 mF Vdc-ref = 600 V R_L= 100 Ω and 200
PWM rectifier	L=14 mH, R= 1m Ω
Simulation conditions	Ts=1e-6 s

III.1 UNDER A CONSTANT DC-BUS VOLTAGE CONDITION

All the following figures show the response of the proposed system when the DC-bus voltage reference is set to 600 V.

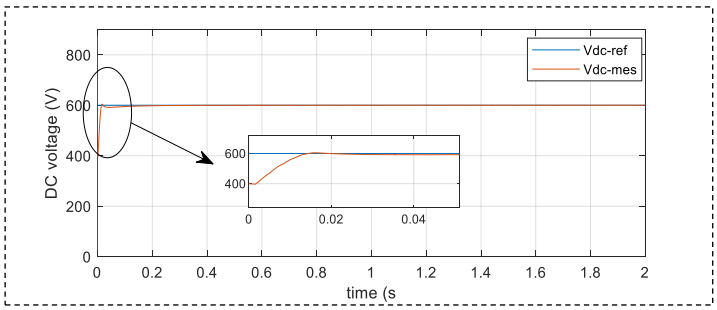

Figure 8: DC bus voltage and its reference.
Source: Authors, (2026).

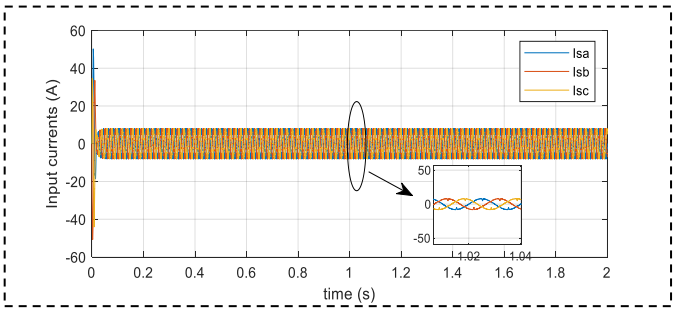

Figure 9: Input currents.
Source: Authors, (2026).

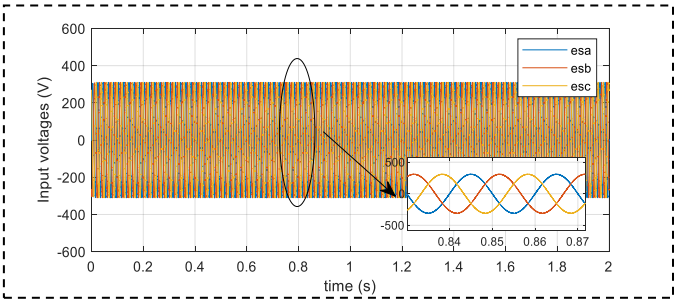

Figure 10: Input voltages.
Source: Authors, (2026).

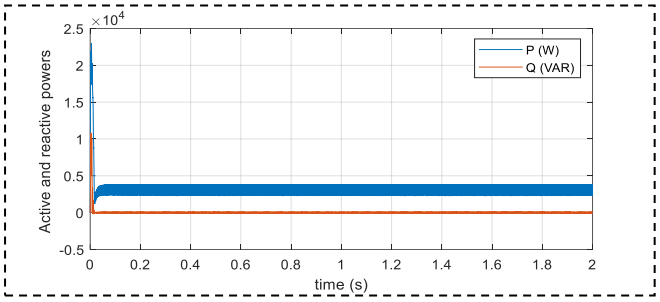

Figure 11: Instantaneous active and reactive powers.
Source: Authors, (2026).

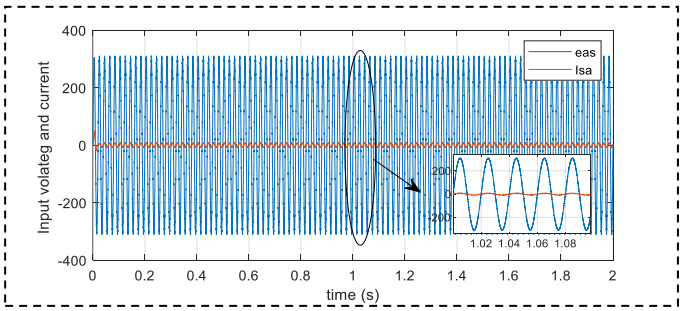

Figure 12: Zoom of input voltage and input current.
Source: Authors, (2026).

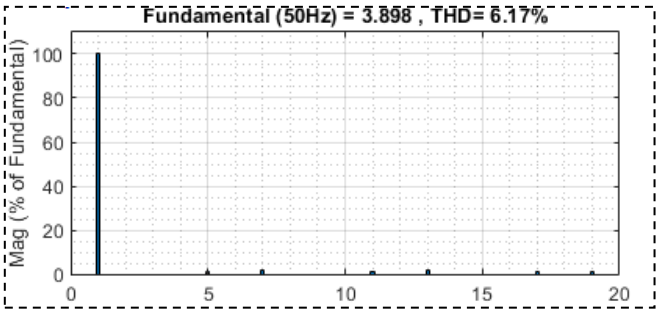

Figure 13: Total harmonic distortion of current.
Source: Authors, (2026).

The analysis of the obtained results demonstrates that, when the DC-bus voltage is maintained constant at Vdc=600V and accurately tracks its reference value, as shown in Figure 8, the proposed control strategy ensures high operational efficiency of the PWM rectifier. Specifically, the ripples in both the input current and voltage are significantly reduced, and their waveforms are nearly sinusoidal, as illustrated in Figures. 9 and 10, respectively. Moreover, the input current and voltage are sinusoidal and exhibit zero phase shifts, as shown in Figure 12, indicating unity power factor operation. The active power varies in magnitude, whereas the reactive power remains equal to zero throughout the operation, as depicted in Figure 11. The resulting total harmonic distortion in term of THD (Figure 13) is very low at 6.17%, confirming that the input voltage and current are practically sinusoidal. Additionally, it is observed that the conventional DPC strategy ensures effective regulation of instantaneous power, with reactive power maintained at zero. These results clearly highlight the high performance of the proposed DPC approach. Consequently, the main control objectives namely, the absorption of sinusoidal input currents with unity power factor—are successfully achieved.

III.2 PERFORMANCES OF THE DPC UNDER DC BUS VOLTAGE CHANGE

The same performance results as previously observed are obtained when the response of the proposed system is evaluated under a step change in the DC-bus voltage reference from 600 V to 700 V at t=1 s.

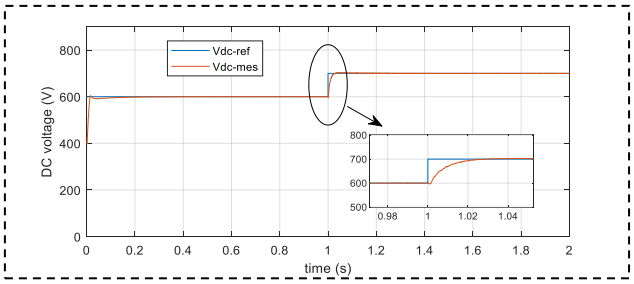

Figure 14: DC-bus voltage during the change of the reference at t = 1 s.
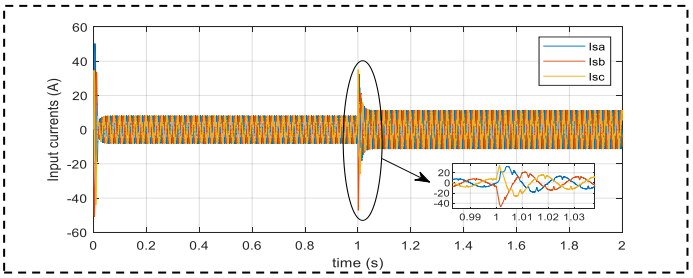
Source: Authors, (2026).



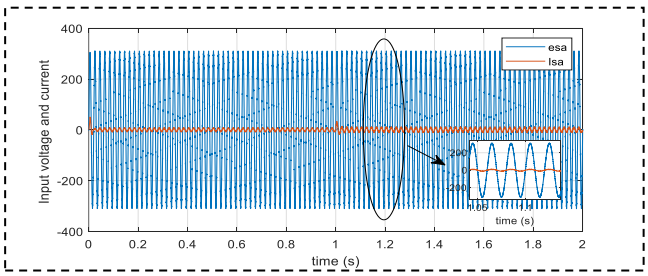


Figure 15: Input current during the change of the reference at t = 1 s.
Source: Authors, (2026).

Figue16: Input voltage and input current during the change of the reference at t = 1 s.
Source: Authors, (2026).

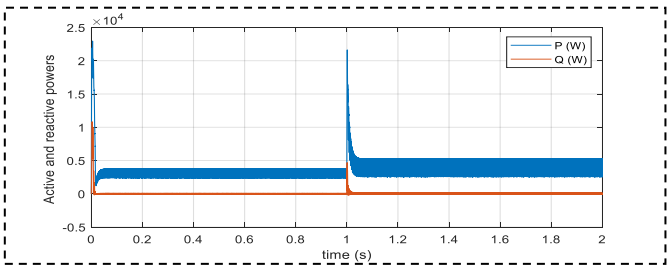

Figure 17: Instantaneous reactive and reactive powers during the change of the reference at t = 1 s.
Source: Authors, (2026).

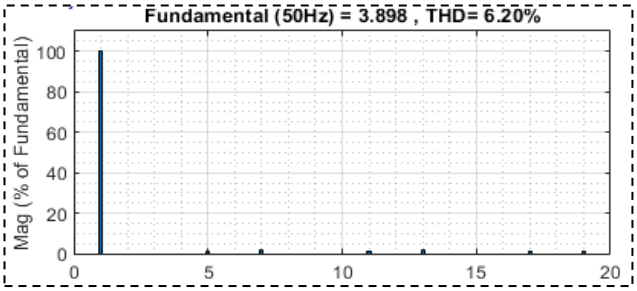

Figure 18: Total harmonic distortion THD of current during the change of the reference at t = 1 s.
Source: Authors, (2026).

Figure 14 show that, after a short transient period, the DC-bus voltage and the active power accurately track their new reference values with good stability. As illustrated in Figure 15 and 16 respectively the input voltage and current are in phase, indicating unity power factor operation. Furthermore, the input current is nearly sinusoidal, with a total harmonic distortion (THD) of 6.20%, which is well below the 10% (THD_i) limit imposed by international standards, see Figure 18. The DPC strategy ensures accurate tracking of the active power reference generated by the PI controller, while maintaining the reactive power close to zero, as shown in Figure 17. This confirms that the DPC approach provides effective decoupling between instantaneous active and reactive power control.

III.3 PERFORMANCES OF THE DPC UNDER VARIATION OF THE DC BUS AND THE LOAD

In the final case study, the proposed system is evaluated under a step change in the DC-bus voltage reference from 600 V to 700 V at t=1s, followed by the introduction of an additional 100Ω load at t=1.5s.

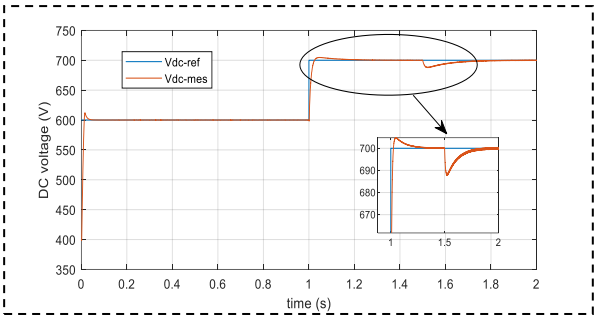

Figure 19: DC-bus voltage during the change of its reference and load at 1.5s.
Source: Authors, (2026).

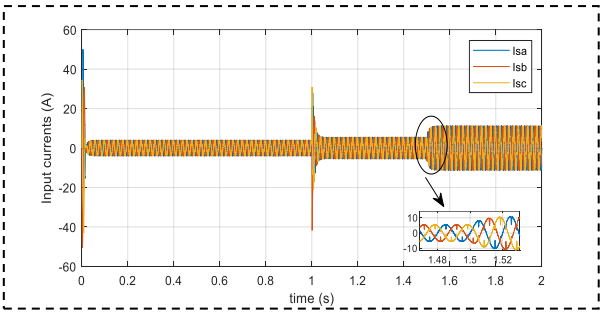

Figure 20: Input currents during the change DC voltage and load at 1.5s.
Source: Authors, (2026).

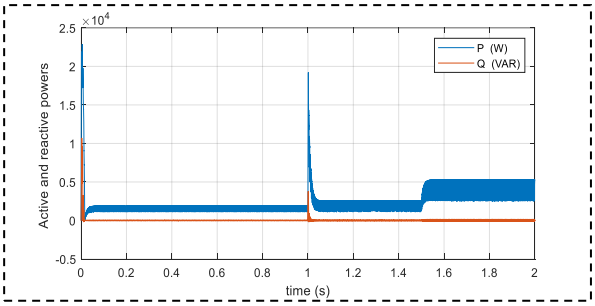

Figure 21: Instantaneous active and reactive powers during the change DC voltage and load at 1.5s.
Source: Authors, (2026).

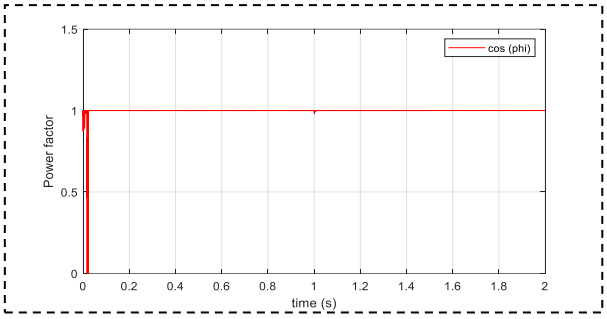

Figure 22: Power factor at unity.
Source: Authors, (2026).

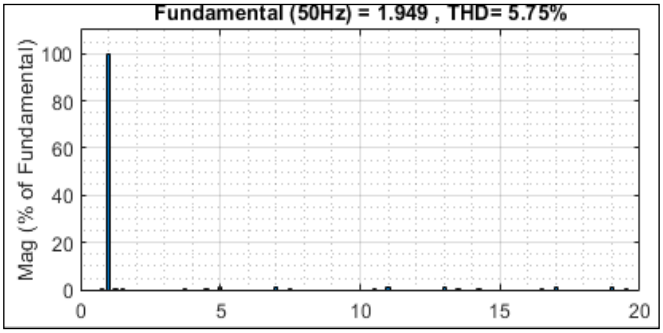

Figure 23: Total harmonic distortion THD of current during the change DC voltage and load at 1.5s.
Source: Authors, (2026).

The results presented in the figures correspond to a load variation test in which the load connected to the DC bus experiences a decrease in resistance at t=1.5t = 1.5t=1.5 s, while the voltage reference remains constant. It is observed that the DPC control strategy exhibits stable behavior during the load change. As shown in Figure 19, the DC-bus voltage converges to its reference value after a short transient period and then returns to steady-state operation following an increase in active power, which accurately tracks its reference generated by the PI controller of the DC bus. The instantaneous reactive power is maintained at zero, confirming unity power factor operation, as illustrated in Figure 22. Furthermore, the phase current is nearly sinusoidal and remains in phase with the grid voltage, as shown in Figure 20. The resulting total harmonic distortion (THD) of 5.75% demonstrates excellent power quality performance as show in Figure 22. This test, involving a sudden load variation, confirms the effectiveness and robustness of the proposed DPC control strategy. Overall, the results are highly promising, demonstrating good stability and high accuracy under the applied disturbances

VI. CONCLUSIONS

This study investigated the behavior and performance of a Direct Power Control (DPC) strategy applied to a three-phase PWM rectifier, with particular emphasis on power quality improvement under nonlinear load conditions such as thyristor and Diode Bridge. Extensive simulation results demonstrated that the proposed DPC approach effectively regulates the DC-bus voltage, ensures accurate tracking of the active power reference, and maintains the reactive power close to zero, thereby achieving unity power factor operation. The control strategy successfully compensates for harmonic distortion and reactive power generated by nonlinear loads, resulting in a significant reduction of input current distortion. The obtained total harmonic distortion (THD) values, reaching as low as 5.75% and remaining well below the 10% limit imposed by international standards for harmonic currents, confirm the excellent power quality performance of the system. A key advantage of the DPC strategy lies in its simple control structure. By eliminating inner current control loops, coordinate transformations, and modulation stages, the proposed approach offers fast dynamic response, reduced computational complexity, and reliable operation without the need for additional voltage or current sensors. The harmonic spectrum analysis further validates the effectiveness of the DPC method, showing strong attenuation of undesirable harmonics and improved grid current quality. The robustness of the DPC strategy was also confirmed through various variation tests, during which the system maintained stable operation and high dynamic performance. These features make the proposed control technique particularly suitable for high-power and high-voltage applications, such as electric traction and grid-connected converters supplying nonlinear loads. Despite its advantages, a major limitation of conventional DPC is the variable switching frequency, which may lead to increased switching losses and electromagnetic interference. Consequently, future research should focus on enhanced DPC schemes, such as DPC combined with Space Vector Modulation (SVM), predictive DPC, or intelligent control techniques, to further improve system efficiency, power quality, and industrial applicability.

ABSTRACT

The growing demand for high precision and uninterrupted production in automotive manufacturing necessitates reliable failure prediction strategies for industrial robotic systems. In vertically articulated robots, the Axis-2 lower-arm servo motor is subjected to significant dynamic loading, thermal stress, and mechanical vibration, making it particularly vulnerable to premature degradation. Conventional control systems typically detect faults only after performance deterioration becomes critical, limiting opportunities for preventive intervention. This study proposes a multi-parameter condition monitoring framework for early failure prediction of the A2 lower-arm servo motor. Real-time measurements of motor current, surface temperature, and vibration velocity were acquired using externally mounted sensors under full-load operating conditions. Additional brake and resolver data were periodically evaluated to support system assessment. The collected operational dataset was analyzed using a Random Forest regression model to identify degradation patterns and estimate remaining service life. The results indicate that combined monitoring of electrical, thermal, and mechanical indicators enhances diagnostic reliability and enables early identification of abnormal operating trends. The proposed data-driven approach supports predictive maintenance planning, reduces unexpected downtime, and improves operational stability in industrial robotic applications.

I. INTRODUCTION

This article provides an insight into how the failure in the lower arm of the Industrial Robot manipulator can be analyzed and predicted. The time saving benefits and high productivity, robotic welding has become important process in the metal and heavy industry. In the high-volume process undetected faults in the industrial robotic arms may be subjected to severe failures and losses, with the potential to lead to devastating results. The major and primary concern in these Industrial robotic manipulators is the impact on safety, where the automation line malfunctions and gives a significant risk to operators in the environment [1]. The impact of robot malfunctions may cause injury to the operator and even the machines in the working vicinity. The second most critical aspect affected by unpredicted problems is the quality of the produced parts [2]. The Robotic manipulators may continue to produce repetitive defective products, leading to significant rejections at the customer end and heavy financial burdens. This is the situation in which the Robot does not predict the end failure but slowly start degrading the quality of the end products before failure. Thus, to ensure the Robot safety, quality and high productivity of automated systems, the failure analysis and its prediction thus become very important [3].

Implementing real-time Analytics and visual systems that collect data from sensors mounted on Lower Arm Servo Motor and the robot controller. This data includes vibration values in mA or in mm/s, temperature readings in ˚C and motor current in Amps. Another relevant parameter includes resolver data and the motor brake data which is monitored manually at regular intervals and the values are noted [4]. Utilization of the advanced data processing techniques with the help of PLC and its output data on HMI dashboard to analyze the data collected by identifying anomalies along with deviations from pre-defined threshold conditions[5]. Development of algorithms based on data collected from sensors which is capable of accurately diagnosing the failure values of the detected faults. This model based on machine learning tool "Random Forest" and statistical analysis. The ML tool in python used for intelligent fault diagnosis, enabling the system to learn from past data and predict its failure over time [6]. Utilization of the ML data is used to predict potential faults before it occurs. This process also allows for planning for preventative maintenance, which minimizes the downtime and extends the lifespan of the Robot and its controller. It further becomes possible to implement the proactive failure-based maintenance, where maintenance schedules are based on the actual health of the Robot rather than conducting the activity at fixed intervals [7]. The Link Arm is the assembly located between the arm and the rotating column. It consists of linking arm body with the buffers.

The lower Amr Servo motor is directly attached to the Link Arm on which the Failure analysis is carried out [8]. The Speed of the Lower Arm is controlled by the servo motor depending on the cycle time requirement, component profile limitations and the component to torch weld angle of approx. 45°. With the advancement of time and the continuous motion of the robot, the servo motor is subjected to wear and tear. When a servo motor fault occurs, the robot's Present Function shows errors such as mastering required (resolver error) in A2, motor overcurrent, excessive motor temperature, or collision detection in A2. In some cases, abnormal vibration may occur without any fault message being displayed [9]. The above faults in the Robot Lower arm do not give a prediction or a failure pattern by which the real time health can be monitored for the servo Motor. To further analyze the faults and collect the data in real time monitoring a test equipment proposed which is mounted with the sensors on the servo motor. The sensor's output values are monitored in real time and the data collected from these sensors are analyzed with statistical tools. The output values are compared with the threshold values, and the failure trend is calculated with help of Random Forest ML tool [10]. The Servo Motor mounted on each axis of 6 DOF manipulator has three major parts, The Robot, Brake and the Feedback mechanism for the positional accuracy and repeatability in the Robot. The encoder or the resolver sends continuous data to the drive related to its actual position in the working envelope of the Robot.

II. METHODOLOGY

The stator generates a rotating magnetic field based on the rotor's position, enabling efficient torque production. Current flows through the windings to create this magnetic field, and its magnitude changes according to the torque demand. Smooth rotation of the rotor is supported by ball bearings that minimize friction and ensure stable movement [11]. The shaft transmits the mechanical output power of the motor to the load through a transfer mechanism such as a coupling. The rotor, typically fitted with high-performance rare-earth or other permanent magnets, is mounted externally on the shaft [12]. An optical encoder continuously tracks the shaft's rotational speed and position to provide accurate feedback. Communication between the encoder (or resolver) and the robot control system is carried through the encoder cable, while the motor cable connects the brake and supplies three-phase electrical power to the motor shown in Table 1.

Table 1: Lower Arm Servo Motor Specification.

Sl No	Attributes	Value
1	Rated Output	2 KW
2	Rated/Max Speed	3000/5000 r/min
3	Rated torque	6.4 Nm
4	input	3φ AC 210 Volts 12.3 Amps
5	Ambient Temperature	40º

II.1 TEMPERATURE IMPACT ON HIGH-SPEED ROBOT MOTION ON LOWER ARM SERVO MOTOR:

The predominant cause of servo motor failure is overheating. To avoid electrical interference caused by conduction in nearby motor windings, good winding insulation is essential in servo motors. Another way to prevent short circuits is by separating the phases [13]. Insulation acts as a thermal barrier, allowing the motor to maintain its optimal working temperatures. Insulation also provides structural support, which lessens the likelihood of physical damage to the winding, in addition to the benefits already mentioned. The servo motor's thick insulation is designed with a margin of safety that has an integrity against breakdown that is far higher than the permissible voltage [14]. This technique to winding insulation in motors incorporates a multi-layered arrangement of coils and slots. The servo motor winding's Class F insulation has an operating temperature rating of 155 °C, with an ambient temperature of 40 °C. The insulation of servo motor windings is classified into categories. The National Electrical Manufacturers Association (NEMA) specifies working temperatures for each insulation class, as illustrated in Table 2. The temperatures are determined by the operational load of the robot under load conditions. The current increase in the lower arm robot servo motor is attributed to the overheating of the stator windings and the absorbed leakage current. Insulation breakdown creates aberrant pathways that facilitate the flow of leakage currents. Thermal, electrical, environmental, and mechanical stressors on the insulation material will induce the formation of leaky current pathways within the winding insulation. The severity of insulation deterioration is an accurate estimate of the size of leakage current in the anomalous path. Accurately identifying the origin of the leakage current within the winding insulation is frequently challenging. The resultant leakage current is attributable to capacitive and resistive leakage currents, as illustrated in the equation below.

$$it = ir + ic \quad (1)$$

The capacitive leakage current, ic, arises from alternating current traversing between conductors that are insulated by a dielectric material. Resistive leakage current, ir, arises from current loss through the insulation around the conductor. Resistive and capacitive leakage currents are contingent upon the supply voltage. The integrity of the insulation material is solely determined by the size of the resistive leakage current. The degradation of insulating resistance is exacerbated by increasing levels of resistive leakage current [15]. The leakage current is directly proportional to the surface impurities on the insulator; thus, an increase in contaminant deposits results in a greater flow of leakage current. For example, water accumulation behind a layer of pollutants results in a reduction of the insulating surface resistance. Preventative maintenance must be conducted if the leakage current values remain unchanged over time. To analyze the increase of temperature separately on the motor with time, NTC type temperature sensor probe is mounted on the motor surface, and its controller is located at a distance so as not to hinder the robot motion. The temperature is recorded at regular intervals with robots in full load running condition. When the Robot starts the Servo motor is observed at ambient temperature. Withing an hour of full operation the temperature reaches around 36 degrees as per the 10-hour data observed. There is no major escalation in the temperature observed after one hour of robot operation as seen Figure 1.

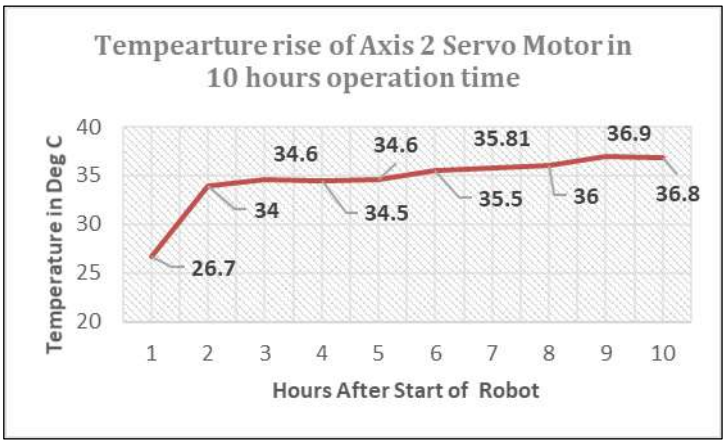

Figure 1: temperature of Robot lower arm servo motor in ambient Running condition.
Source: Authors, (2026).

The temperature of the lower arm servo motor of the robot is raised over a period in constant operation and it's a function of its thermal time constantly and is generally characterized by its compatibility to fit in the robot and how its designed to get cooled under running condition. With the rise in temperature the resistance of the motor winding also increases linearly with gradual rise in temperature as per the following mathematical relation.

$$R(T)=R(T_0)[1+0.00393(T-T_0)] \quad (2)$$

Where Tis the winding temperature (°C), T_0 is the ambient reference temperature which is considered as 25°C , 0.00393 being the temperature coefficient for copper.(in case of Aluminium winding this value is changed to 0.00403). The temperature rise of the motor over long period of time when it draws overload current is still defined as function of time as

$$T(t)=T_{ultimate}-(T_{ultimate}-T_{ambient})e^{\wedge}(-t/\tau_{thermal}) \quad (3)$$

T(t) is temperature with time t, $T_{ultimate}$ is the final temperature or peak temperature under the robot load condition and $T_{ambient}$ is ambient temperature or the temperature of the motor at the start of the Robot along with $\tau_{thermal}$ being the thermal time constant. The ultimate temperature is mostly achieved at 5 times the thermal time constant.

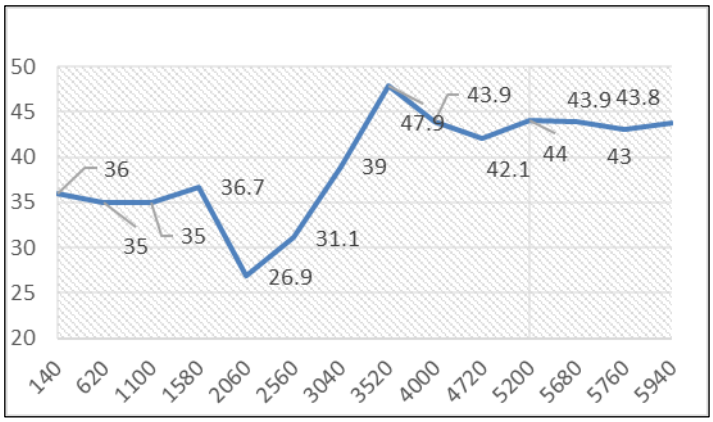

Figure 2: temperature rise of the servo motor with increasing servo operational hours.
Source: Authors, (2026).

The data collected for temperature variants in the servo motor at regular intervals and not exceeding 6000 servo hours depicted that the ambient temperature escalation in the servo motor because of operational factors gave a rise of approx. 13 degrees compared to normal operating temperature of 36 degrees, which rise to an ambient temperature of 43.8 degrees as shown Figure 2. This temperature is however normal operating temperature and motor functions perfectly at this rise. It has also bene observed that the temperature rise is steep during the summer operating conditions which goes to 47.9 degrees, motors still observed to work perfectly without any failure in this condition [16]. This ambient temperature because of environmental temperature gives rise to the working temperature in the surroundings and the complete robot temperature seems to rise in this environment. This spike in temperature is generally ignored for the analysis and the final and end temperature only considered.

II.2 CURRENT IMPACT ON HIGH-SPEED ROBOT MOTION ON LOWER ARM SERVO MOTOR:

Consequently, it is essential to assess the temporal flow of these currents utilising past data to evaluate the condition of the servo motor. Motor current monitoring can be achieved by measuring the current consumption during operation by the integration of a current transformer with the controller, as seen in Fig 7. The limitations of this approach, based on real-time current data, involve extensive computations, whereas wavelet and Fourier transformations are only effective for steady-state diagnostics. Recently, numerous machine learning and artificial intelligence methodologies have been established for categorisation and prediction challenges [17]. Neural networks, support vector machines (SVMs), K-nearest neighbours, and long short-term memory (LSTM) deep learning have become prominent in anomaly identification. The drive in the robot controller continuously monitors the rise in current within the stator windings. It is essential to meticulously select its settings and those of the optimisation methods. The classification of leakage currents between phases and phase-to-neutral using deep learning is analysed based on the output provided by the current transformer (CT). This CT is affixed to the phase wires that terminate prior to the Robot drive controller. The mathematical relationship between rated power of the servo motor (Pin) relates current (I in Amps) and voltage V in volts). In Robot axis the servo Motors gives some losses which must be considered as efficiency (η) and power factor (cos φ). The name plate of the servo motor mounted on the Robot (power) is its mechanical output power Pout of 2.2 kW.

$$\text{Rated input power } P_{in}=P_{out}/\eta V \tag{4}$$

For 3 phase AC servo Motor on the Robot Arm, we can infer the following mathematical relation

$$P_{in}=\sqrt{3}\ *V*I*\cos\varphi \tag{5}$$

$$\text{or } I= P_{in}/\sqrt{3}\ *V*\cos\varphi \tag{6}$$

combining both equations, we get

$$P_{in}=P_{out}/\eta\sqrt{3}\ *V*\cos\varphi \tag{7}$$

Considering the fixed input 3 phase voltage of 415 volts, and efficiency being 0.85 and power factor being 0.80, the motor approximately consumes 4-5 Amps. At the start of the Robot, motor tends to draw more current to overcome the inertia factor but gets stable and runs at nominal current. Initially the motor may draw 9-10 Amps current for few seconds but goes back to normal of 4 Amps approx. during operation. After a prolonged period of time the Motor tends to draw more current considering several factors of overheating, irregular power supplies and frequencies, excessive movement, wear and tear of the bearings, weakening of the insulation winding, short circuit etc. the present servo motors are protected against the damage during high peak loads for few seconds , but is not consistent [18]. Before failure the Motor will tend to draw much higher current ranging from 8 Amps to 20 Amps. Peak Servo current (during failure) causes the motor to draw maximum peak torque ranging from 200% to much higher value. The rated rpm being 3000 rpm at max torque value of 7.0 N-m. This torque value increases exponentially before permanent failure. It has been considered that during normal peak load of the Robot in the running condition the motor may draw current to extent of 110-15 Amps for 2-3 seconds max. Robotic AC servo motors are engineered for rapid acceleration and deacceleration and heavy spikes in short term load when the robots are subjected to external forces such as collision with fixture during motion. The current for 3 phase AC servo motor mounted on Lower arm of the Robot is measured with help of KRYKARD power analyzer ALM 31, which has measured A1rms, A2rms, A3rms and ANrms on regular time intervals to check the current pattern drawn by the robot Motor in full running load conditions. A Sinusoidal current wave is represented by the mathematical relation.

$$i(t)=I_{peak}\sin(\omega t) \tag{8}$$

$$I_{rms}=I_{(peak)}/\sqrt{2} \tag{9}$$

From the other readings from the Power analyser for the current values, only the RMS values are considered for the research analysis. The Paak values are not relevant for the data collection, hence for the half wave rectified signal considering zero value at the other half the RMS values of current drawn is recorded to predict the abnormalities and failure in the Motor over a long period of time.

II.3 EXPERIMENTAL SETUP

Figure 3 presents the original three-phase power distribution inside the robot controller before instrumentation, highlighting the absence of dedicated real-time current monitoring at the motor level.

This baseline configuration justified the integration of additional diagnostic elements. Figure 4 demonstrates the installation of current transformers on the R, Y, and B phase conductors, enabling non-intrusive measurement of phase-wise RMS current under actual operating conditions. This arrangement supports detection of overload, imbalance, and abnormal torque demand without disturbing normal robot functioning. Figure 5 illustrates the combined mounting of vibration and temperature sensors on the servo motor housing, establishing a multi-parameter condition monitoring framework. The synchronized acquisition of thermal, mechanical, and electrical data strengthens failure prediction reliability. Figures 6 and 7 present RMS current trends using narrow and broad sampling intervals, respectively. The short-interval data captures transient spikes during dynamic motion, while the long-duration plot reveals overall stability around nominal current values with occasional deviations. Together, these observations confirm stable operation within monitored hours while emphasizing the importance of continuous trend evaluation for predictive maintenance planning. The amount of current drawn by the robot Servo Motor for approx. period of six thousand servo hours analysed and was noted that the spike of maximum value of 4.69 Amps observed for single time followed by next lower values of 4.4 Amps and 3.77 Amps respectively. A trend could not be established for the current to increase over a period. The mean value of the current drawn by second axis of robot found to be. 3 Amps. The tendency for the motor to fail will draw more current at early intervals to the extent of 6 Amps or 7 Amps, at current value higher than that of 7 Amps , the Motor may get heated up and fail before time.

II.4 VIBRATION IMPACT ON HIGH-SPEED ROBOT MOTION ON LOWER ARM SERVO MOTOR:

Robotic manipulator and the complete cell System performance is mostly dependent on the impact of vibration and temperature data as observed on the total operating time of the system, operating conditions of the system, and the external environment. So, the reference value can be obtained from Robot which is in actual running condition. The vibration is monitored during the Robot operation in actual welding process. The critical levels need to be determined under Robot. The P&F make vibration sensor is used to monitor and detecting errors which allows it to generate error when the set limit values exceed as compared to the optimal values [19]. Vibration values measured at measured for Tamagawa TBL-I III series motor or 389683 Robot Lower Arm AC servo motor at running RPM speeds. The working time for all the measurements will be more than 5,000 operating hours or Robot in Servo ON condition. The vibration values increase with the increased number of Servo Motor rotations as an usual phenomenon. After examination of the data, it was observed that no abnormal values observed for initial servo operational hours, and the servo motor continues to operate in regular operations as per the pre-defined robot speed. Additionally, when the heat has been measured, the reference value of 35°C was found to deviate to minor deviations. The max RPM of lower arm AC Servo Motor considered is 3000. The validation of the results of measurement made with max 3000–0 RPM cycles in the Servo Motor, considering the maximum speed of the Robot of 1.5 m/s-0 m/s. The Abnormal vibration in the Servo motor specially in the lower arm of the robot has degradation impact on the overall process [20]. There is precision loss in the Servo motor which looses its encoder or resolver's ability to hold the exact position and give its position feedback to the controller. It reduces the accuracy task in the process of GMAW where in the tolerance of deviation is maximum of +/- 0/5*(Wire diameter). Mechanical wear of the lower arm Servo Motor are subjected to excessive load and heat which generates frequent maintenance requirement. The excessive vibration if beyond 2.5 mm/sec for a very long period of time also generates the increase in the winding temperature. This gives random fault to the electronic components and problem of motor overheat encoder error or major electronic failures also occurs.

A running Robot system operates between 200 mm/s to 1.2 m/s. this operating range in the robots generally exceeds the limit of the values of the vibration after prolonged servo operational hours. The vibration level observed at high running speed of the Robot depicts that the value randomly exceeds over the vibration limits, the external factors beyond the robot system may be ignored like , movement of trolley near the robot or the strokes of the Press shop. The rise in these vibration values to be seen by the Vibration sensor data between the measurements of high-speed motion in the robot manipulator. Similar impact is not confirmed to repeat in the repetitive research study. This spike was observed in both measurements made with 0-1.4 m/s and different frequencies in data to be observed. with these vibration values, the motor's temperature readings and monitoring is carried out separately with the mounting of temperature controllers on its surface. The prediction of temperate impact on the servo motor is analysed separately. First the data is captured on single robot and then the similar data is being captured on 15 robots simultaneously for all the robots. Vibration Sensor VIM32PL-E1V16-0RE-I420V14 mounted on the surface of the servo motor of the lower arm and the data then captured with this sessor in the robot running condition. The robot runs with the predefined speed set with the components. Vibration of the lower arm robot servo motor measures in terms of velocity which ranges between 0-16 mm/s (Vrms) with an accuracy of +/- 0.1 mm/s. the sensor gives analog output to PLC as current output of the vibration variable (4mA to 20mA), meaning that zero vibration corresponds to 4mA and vibration of 16 mm/sec corresponds to 20mA. The motor fails at vibration value of 4.0 mm/sec and is considered as threshold failure value. The failure trend can be observed for the values received from the vibration sensor, and the progressive increase in vibration amplitude over servo operational hours is illustrated in Figure 8. It has been considered that the Robot Runs 20 hours a day and the vibration values have been noted at interval of every 20 hours. The failure trend can be observed for the values received form the vibration sensor. The threshold value near to 4 mm/s over a period tends to fail. For ease of calculation the current values in mA obtained from Senso PLC integration has been converted to vibration with the above equations [21]. Since the current and the vibration values are linearly corelated with a difference of 4 as per the following Table 2.

Table 2: current output can directly be scaled Vibration (mm/S) =Current (mA)-4.

Sl No	Vibration (mm/s)	Current (mA)
1	0	4
2	4	8
3	8	12
4	12	16
5	16	20

Source: Authors, (2026).

With the observed trend and statistical value, the failure of the motor predicted to fail near to 24000 servo operations hours. Preventive measure and predictive maintenance must follow near to 18000 hours. the standard periodic maintenance procedures do not predict the failure of the robot.

II.5 OPTIMIZATION OF RANDOM FOREST REGRESSION

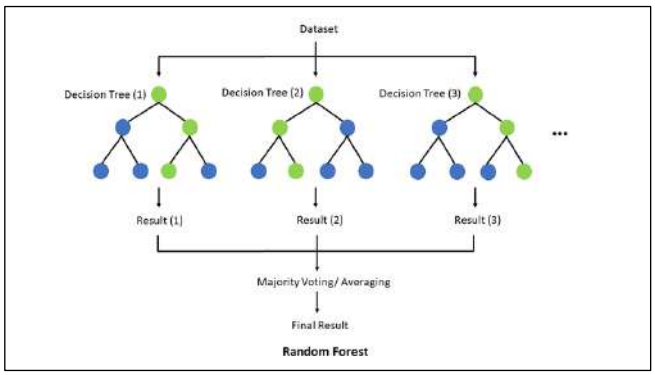

Figure 9: Random Forest regression Structure.
Source: Authors, (2026).

A random forest is a traditional machine learning technique that amalgamates predictions from various decision trees to generate precise and consistent outcomes. It is utilised for classification and regression problems. For the regression job, we employed the Random Forest Regression approach to predict numerical values. It forecasts continuous values by aggregating the outcomes of several decision trees. Figure 9 illustrates that Random Forest regression is a machine learning technique employed for forecasting and addressing regression issues, particularly utilising decision trees to forecast failures and the mean of failure predictions. A Random forest regression uses several decision trees to collect the data and use its average to calculate the final prediction. The random forest regression has following important parts are Bootstrap Sampling, Decision Tree construction and Integration of Predictions [22]. The decision tree regression in the machine learning process starts by checking the current drawn by the robot servo motor followed by branches of temperature and then vibration impact as shown in Figure 10. Each path selected by the decision tree leads to failure prediction of low, medium and high categories.

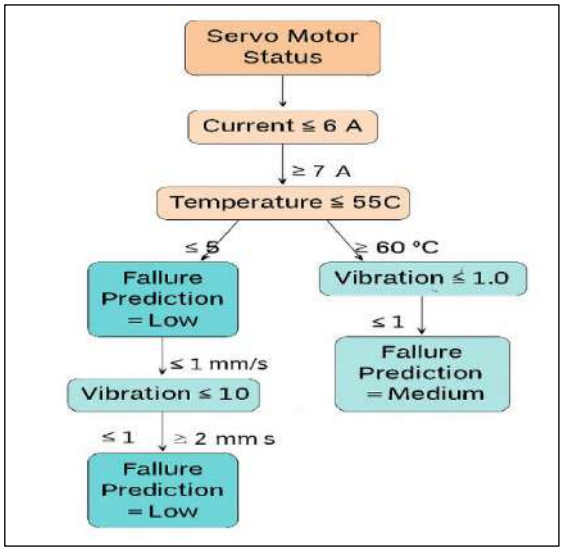

Figure 10: Proposed Failure Prediction model workflow in Random Forest Regression method.
Source: Authors, (2026).

The failure features of current, temperature and vibration contribution to the failure weightage as per the data is represented as Figure 11. It is observed from the data that the temperature contribution towards the failure of the Robot servo motor contributes most as compared to the other observed parameters. However, the abnormal vibration and the increase in the current drawn by the servo motor contribute to the major failure, temperature increase in the motor while continuous operation is key concern.

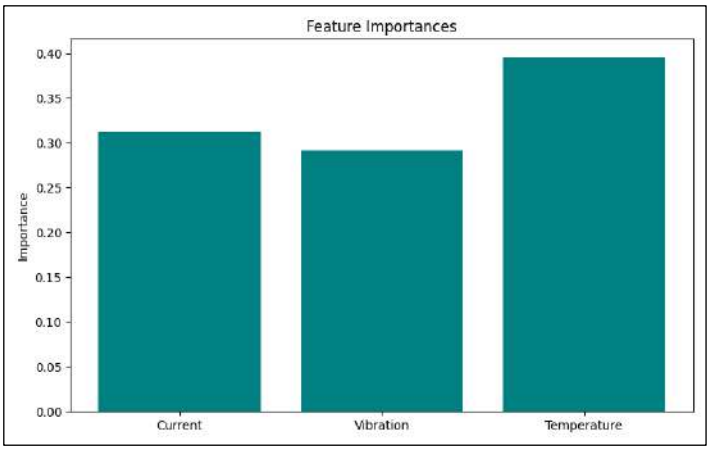

Figure 11: Failure Feature importance as judged by the ML tool.

III.RESULTS AND DISCUSSIONS

Since it is challenging to measure the lower Arm of Manipulator Servo motor temperature, vibrations and, and increasing currents before failure in practical applications, a well-trained prediction model can further be used to eliminate practical measurement devices. The effects of temperatures and leakage currents on insulation winding have been discussed, and their trends can be utilized to inform on insulation integrity over time [23]. In our present research carried out, the performance of random forest regression using python coding and predicting the failure of the servo motor has yielded ad mixed result .The historical data collected for monitoring the overall robot health and specially the servo motor of the lower arm health monitoring using temperature sensor, power analyzer, and vibration sensor were acquired from its real time output. The data were then preprocessed according to the requirements of the utilized estimation algorithm directly in the machine learning tool using python. Failure prediction by the Random Forest Regression has also used historical data by the sensor as an input and with ML internal processing with the following steps. Importing necessary library in python, Data loading and inspection, Data Processing and learning based on the inputs given, Plotting of the data and Execution and data saving.

III.1 TEMPERATURE FAILURE PREDICTION

The blue line on the Figure 12 represents the temperature profile recorded periodically across a period of 0 -6000 servo hours. The prediction tool assumed threshold value of failure at 45 degrees. Red points are the points where temperature exceeds the threshold value above 45 degrees and are flagged as potential failure points [24]. We conclude that the Robot Servo motor temperature remains at a stable phase during the interval of 0-3000 servo hours, 45 degrees temperature is the ambient temperature reached during peak summer temp and needs to be ignored. The motor reaches the critical phase ranging from 3300-3600 servo hours in which the temperature tends to peak near 50 degrees. At range of around 4300 to 4600 servo hours the Robot servo motor temperature remains in chronic monitoring at temp of around 46 degrees. Beyond 5000 servo hours temperature stabilizes around 40 degrees but remains at stress level because the insulation windings have been subjected to higher temperature over a prolonged time. Thus, regular and supervised inspection is needed between 3300 -4300 servo hours and arrangements required for lowering the ambient temperature, gear box lubrication and reduced robotic load if feasible (allowing time or no-load time as a planned regular activity in this interval). The threshold of 60 degrees is reached around 14000 servo hours. An early warning of motor failure due to increase in temperature may be predicted around 13500 servo hours if the robot runs 20 hours a day. Critical monitoring required once the temp goes beyond 50 degrees.

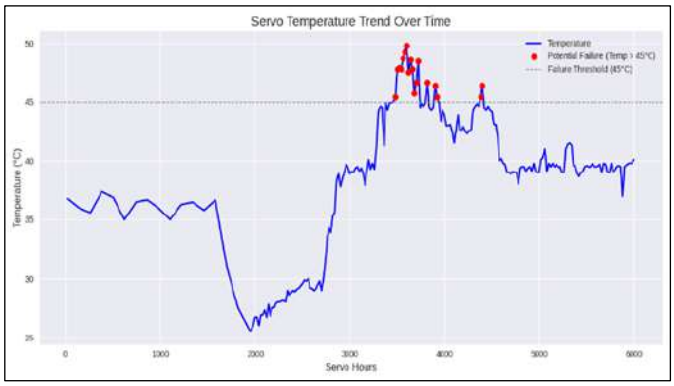

Figure 12: Servo Motor Temperature Failure prediction.
Source: Authors, (2026).

III.2 VIBRATION FAILURE PREDICTION

The vibration values generated over the operating hours of the robot, along with the predicted failure points above 1.5 mm/sec, are presented in Figure 13. The vibration values observed is higher if compared to the values of the Robot motor during installation. Over operating period of robot servo hours the values of vibration observed to reach higher value, which is still considered to be in normal working condition.

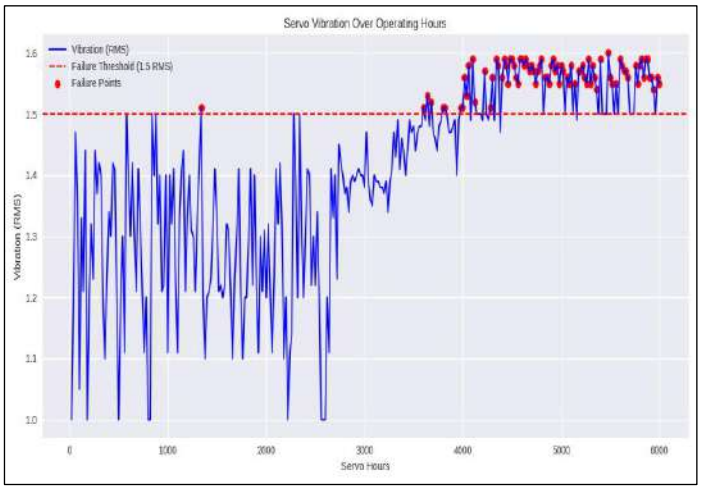

Figure 13: Servo Motor Vibration failure prediction.
Source: Authors, (2026).

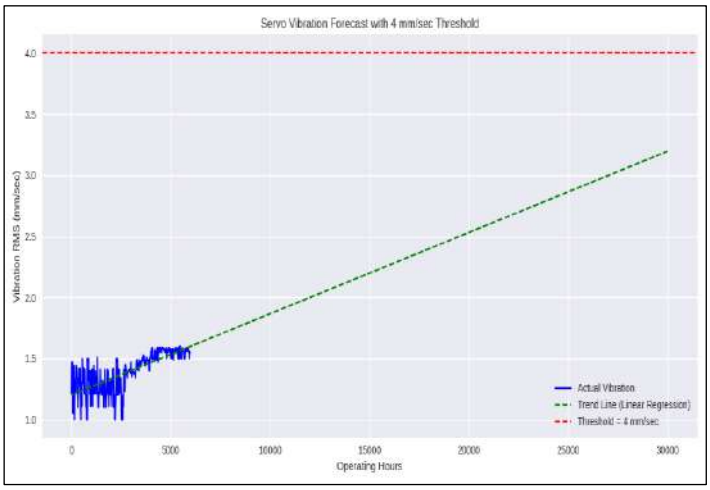

Figure 14: Vibration failure prediction with trendline.
Source: Authors, (2026).

During the initial working hours of the robot up to 200 servo hours, we can see the motors were in healthy operating condition [25]. If the vibration values observed is above 1.5 mm/sec, the trend can be established that there is a gradual increase in vibration of the servo motor, and it tends to reach the stage of the early wear. Since the threshold value is expected to be approx. 4 mm/sec as the cause of failure, the motors are required to be checked at regular intervals to avoid the high risk of bearing or alignment failure. The servo motor of the Lower arm gives output power to the harmonic gear box which as predefined reduction gear ratio of approx. 50:1 maintaining necessary torque and maintaining high precision. A cross check and preventive maintenance of the robot is thus necessary to visualize the mechanical condition at every 4000 servo hours. The regression trendline as observed extended with the green line in Figure 14 predicts that the servo motor will reach to the vibration value of 4 mm/sec at approx. 30,000 servo operating hours of the robot. The growth of the trend is however slow in the observed range , but the wear of the motor generally accelerate in a nonlinear manner. The failure of motor considering other factors like damage and collision can result in unexpected vibration values and may be subjected to premature failure. After the Servo motor tends to vibrate at approx. 2 mm/sec after 15,000 servo operational hours it must be planned for predictive failure and following the trend, a wait till the motor reaches value of 4 mm/sec must not be considered. Operational adjustments and deeper diagnosis like, encoder check, robot other axis vibration check, robot grouting on the foundation bolts must all be checked so that the possibility of secondary reason for the motor to increase in the vibration values is eliminated. The prediction for the motor to fail is at approx. 25,000 servo hours, it may fail near to this value in both before and after condition [26].

III.3 CURRENT FAILURE PREDICTION:

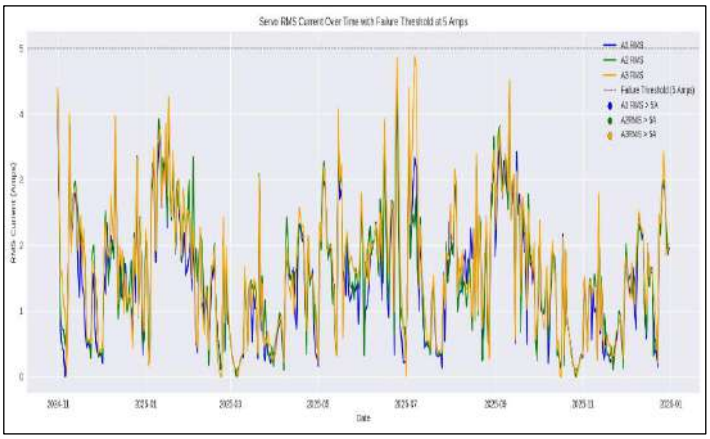

Figure 15: Current failure prediction in servo Motor.
Source: Authors, (2026).

The current trend analysis of the lower arm servo motor shows variations in RMS values recorded over periodic intervals. The prediction output of the Random Forest regression model, highlighting warning and critical zones, is presented in Figure 15. The results indicate that average RMS current values remain near nominal levels, with occasional spikes reaching 3.5–5 Amps during high load conditions.

If the motor starts drawing more current, it gets heated up rapidly at nominal RPM causing the motor winding and encoder to be overheated and get prone to the failure [27]. The result shows the average RMS value on monthly intervals and in a few instances increasing to value of 3.5 Amps and towards critical value of 4.5-5 Amps. If the value drops to zero it may also be a sign of short circuits but is not considered in this study and the result arising from the purpose is also not a part of the research. Result of Current values of A1, A2, A3 phase observed at Robot full load condition periodically and cluster of spikes in the RMS values were observed during period of June-Sep in which the current RMS value spiked beyond 3.5 Amps meaning a strong percussion for approaching towards the failure trend. Current drawn by the Lower arm servo motor beyond 4 Amps not considered to be normal and even the current spike for short period of time may damage the Servo Drive electronic components [28]. A systemic risk was also observed in the month of Sep when all 3 phase spiked above 4.4 Amps. Several instances are also observed when the motor current trends to draw almost zero current. in this situation also there is a chance for the motor winding to fail. If the Motor draws nearly zero current in full load condition, then there are chances of abnormality either in the Motor side or at the servo drive end which is controlling the dynamic torque of the motor in the running condition [29]. The Motor, however, is in normal running condition and no signs of abnormality in the Robot performance is observed, meaning that current spikes near to 4 Amps are at high load but not critical. The motor does not tend to fail immediately. Current range from 3.5 to 4.8 Amps are in warning zone rather than motor moving to immediate failure.

III.4 LEAKAGE CURRENT ESTIMATION IN THE EXISTING SYSTEM

The effects of leakage current in the Servo Motor could not be clearly established in this study. The leakage current generated is neutralized through proper robot body earthing. The grounding loop between the robot, controller, and earth pit ensures that when the resistance value remains below 2 Ohms, leakage current does not significantly influence motor failure or the developed prediction algorithm. The summarized observations of current-based failure prediction are presented in Table 3.

Table 3: Current failure prediction Summary.

Sl.No	Month	Threshold breach	Failure event
1	Nov-24	Critical	Partial (A1=0, A3=0)
2	Dec-24	Warning	none
3	Jan-25	Critical	none
4	Feb-25	Warning	partial(A3=0)
5	Mar-25	none	Partial (A1=0, A3=0)
6	Jun-25	Critical	none
7	Jul-25	critical	none
8	Sep-25	critical	none
9	Oct-25	none	partial (A2=0,A3=0)
10	Nov-Dec-25	moderate	none

IV.CONCLUSIONS

This study investigated the degradation behavior and failure prediction of the lower-arm servo motor operating under full-load industrial robotic conditions. The analysis identified temperature rise, RMS current variation, and vibration growth as the primary indicators influencing motor health, while additional factors such as brake degradation and resolver malfunction may further contribute to performance deterioration. A multi-sensor monitoring framework was implemented by integrating temperature probes, current transformers, and vibration sensors directly onto the operating robot. The acquired real-time data were processed using a Random Forest regression model developed in Python to estimate failure trends over extended servo operating hours. Although modeling motor failure in dynamic robotic environments is inherently complex due to interacting thermal, mechanical, and electrical factors, the proposed approach demonstrated the capability to detect abnormal patterns and predict potential failure windows with reasonable accuracy. The results confirm that progressive increases in temperature, sustained current deviations, and rising vibration levels can serve as early warning indicators for preventive maintenance planning. The developed methodology reduces reliance on fixed maintenance schedules and supports condition-based decision making. Overall, the integration of sensor-driven monitoring with machine learning-based prediction provides a practical and scalable framework for enhancing reliability and extending the operational life of industrial robotic servo systems.

Field Robotics

ABSTRACT

This paper addresses the persistent gap between robotic crop monitoring and autonomous harvesting by proposing an integrated, closed-loop agricultural system that unifies real-time AI-driven phenotyping with selective fruit harvesting in a single operational framework. We developed and field-evaluated AgriLoop-1, a unified robotic platform combining a multi-modal perception suite, a compliant end-effector for damage-aware fruit handling, and a co-designed AI software architecture. The perception pipeline leverages a YOLOv8-Seg model to perform simultaneous fruit detection, instance segmentation, ripeness classification, and yield estimation, while a dynamic Harvestability Score guide's target prioritization and optimized picking sequences based on spatial, phenotypic, and reachability constraints. Field trials conducted in a commercial apple orchard demonstrated reliable real-world performance, achieving an operational success rate of 87.0% and an effective harvesting throughput of 122 fruits per hour over 15 hours of continuous deployment. The system maintained stable closed-loop operation under varying environmental conditions, confirming the robustness of the integrated perception–decision–action architecture. This study presents a field-validated robotic system that effectively closes the perception–action loop in agricultural robotics. By tightly integrating precision phenotyping with adaptive harvesting decisions, the proposed framework moves beyond conventional modular approaches and establishes a practical foundation for intelligent, data-driven crop management systems capable of addressing labor shortages and supporting sustainable agricultural production.

I. INTRODUCTION

I.1 THE GLOBAL IMPERATIVE FOR AGRICULTURAL TRANSFORMATION

Global agriculture is facing an unprecedented convergence of challenges that demand transformative technological solutions. Among the most pressing are the persistent shortage of skilled seasonal labor, the need to increase food production by an estimated 60–70% by 2050 to meet the demands of a growing global population, and the urgency of improving sustainability and resource efficiency under increasing climate variability and environmental constraints [1], [2]. Conventional farming practices, which rely heavily on manual labor and uniform field treatment, are becoming increasingly inadequate in addressing these complex pressures. These challenges have accelerated the adoption of Precision Agriculture (PA), a data-driven management paradigm that leverages sensing, automation, and analytics to observe, measure, and respond to spatial and temporal variability in crops [3]. While early implementations of PA focused primarily on monitoring and data collection, the field is rapidly evolving toward intelligent intervention systems capable of acting on real-time insights. The long-term vision is to transition from data-informed farming to fully autonomous, action-driven agriculture, where sensing, analysis, and intervention operate in a tightly integrated loop.

I.2 THE RISE OF AGRICULTURAL ROBOTICS AND THE PERCEPTION–ACTION GAP

Robotics and Artificial Intelligence (AI) are widely recognized as the key enabling technologies for realizing this vision of automated precision farming. Over the past decade, research in agricultural robotics has advanced significantly across two main domains. First, robotic phenotyping and scouting systems have emerged as powerful tools for crop monitoring. Autonomous ground and aerial platforms equipped with advanced sensors, such as multispectral cameras and LiDAR, combined with deep learning algorithms, can monitor plant health, estimate yield, and detect stress with high spatial and temporal resolution [4], [5]. Second, substantial progress has been made in robotic selective harvesting. Researchers have developed dexterous manipulators and specialized end-effectors capable of identifying and picking high-value fruits and vegetables, addressing one of the most labor-intensive stages of agricultural production [6], [7]. Despite these advances, a critical gap remains between perception and action. Most existing systems are designed and evaluated as isolated modules, functioning either as “seeing” systems for monitoring or “picking” systems for harvesting. In real agricultural environments, this separation creates a fragmented workflow in which scouting data are collected and processed offline, and only later used to guide human labor or separate machinery. Such disjointed operation prevents the establishment of a true perception–action feedback loop, where real-time phenotypic information such as fruit size, color, ripeness, and precise spatial location directly informs and optimizes robotic manipulation decisions. The absence of this closed-loop intelligence limits operational efficiency, reduces adaptability to dynamic field conditions, and constrains the full potential of autonomous agricultural systems. Bridging this gap is essential for enabling robots to move beyond isolated tasks toward integrated, intelligent crop management.

I.3 RESEARCH OBJECTIVE AND CONTRIBUTIONS

This work aims to address the identified perception–action gap by designing, implementing, and field-validating an integrated agricultural robotic system that seamlessly combines AI-powered precision phenotyping with autonomous selective harvesting within a single, closed-loop framework. The primary objective is to create a unified platform in which real-time phenotypic insights directly drive harvesting decisions, enabling more efficient, adaptive, and data-informed operation in orchard environments. The main contributions of this paper are summarized as follows:

1. Integrated Hardware Architecture:
A unified robotic platform is developed, incorporating a customized mobile base, a multi-modal perception suite, and a manipulator equipped with a damage-minimizing compliant end-effector specifically designed for delicate fruit harvesting.
2. Co-Designed AI Software Stack:
A dual-purpose deep learning pipeline is proposed to perform real-time fruit detection, ripeness classification, and yield estimation while generating harvestability scores and precise 3D spatial coordinates to support manipulation planning.
3. Closed-Loop Decision and Control Framework:
A hierarchical control strategy is introduced that tightly couples perception outputs with motion planning and reactive control, enabling the system to autonomously determine which fruit to harvest next and execute safe, efficient picking actions.
4. Comprehensive In-Field Validation:
The system is evaluated through extensive real-world experiments in a commercial orchard, reporting detailed quantitative metrics for the phenotyping and harvesting modules, as well as the end-to-end integrated performance. This level of holistic field validation remains relatively rare in the current literature.

I.4 PAPER ORGANIZATION

The remainder of this paper is organized as follows. Section 2 reviews related work in robotic perception, manipulation, and integrated agricultural systems. Section 3 presents the overall system architecture and mechanical design. Section 4 details the AI methodologies and software control framework. Section 5 describes the experimental setup and analyzes the results from field trials. Section 6 discusses the implications, limitations, and potential future research directions. Finally, Section 7 concludes the paper.

II. RELATED WORK

This section reviews the state of the art in agricultural robotics, emphasizing the evolution from specialized, task-specific modules toward integrated autonomous systems. The discussion is structured around three core research directions: (1) perception and AI for crop monitoring, (2) robotic manipulation for selective harvesting, and (3) prior integrated platforms. The section concludes by identifying key gaps that motivate the proposed work.

II.1 ROBOTIC VISION AND AI FOR AGRICULTURAL PERCEPTION

The effectiveness of any intelligent agricultural robot fundamentally depends on its ability to perceive and interpret complex, dynamic crop environments. Progress in this area has been driven by advances in sensing technologies and deep learning methods.

- **Sensor Modalities:** Early vision-based agricultural systems primarily relied on RGB cameras combined with classical computer vision techniques such as color segmentation and edge detection [8]. Although computationally efficient, these approaches were highly sensitive to illumination changes, occlusions, and background variability. To overcome these limitations, researchers adopted multi-spectral and hyper-spectral imaging to extract vegetation indices such as NDVI and detect plant stress not visible in the RGB spectrum [9]. More recently, depth sensors (RGB-D) and LiDAR have become essential components in agricultural robotics, enabling accurate 3D reconstruction of plant structures, fruit sizing, volume estimation, and precise spatial localization for manipulation tasks [10].

- **Deep Learning Revolution:** The emergence of deep learning, particularly Convolutional Neural Networks (CNNs), has significantly improved robustness in agricultural perception. Detection and segmentation frameworks such as Faster R-CNN, YOLO, and Mask R-CNN have become widely used for fruit detection, counting, and instance segmentation in cluttered orchard environments [11], [12]. These models have also been extended to perform fine-grained classification tasks, including ripeness estimation using architectures such as Inception-v3 and ResNet, as well as disease detection from leaf imagery [13].
- **From Detection to Phenotyping:** The current research frontier is shifting from simple detection to quantitative phenotyping the extraction of agronomically meaningful traits such as fruit size, diameter, count (yield estimation), and indicators of biotic or abiotic stress [14]. Despite these advances, most phenotyping systems remain focused on data acquisition and offline analysis, often deployed on stationary platforms or independent scouting robots. As a result, the generated phenotypic information is rarely used to drive real-time robotic actions, limiting its operational impact.

II.2 ROBOTIC MANIPULATION FOR SELECTIVE HARVESTING

Selective harvesting of delicate, irregularly positioned fruit remains one of the most challenging tasks in agricultural robotics, requiring innovations in mechanical design, motion planning, and control strategies.

- **End-Effector Design:** Harvesting end-effectors are typically tailored to specific crop characteristics. For relatively rigid fruits such as apples and citrus, common solutions include multi-fingered grippers with soft padding to minimize bruising, as well as suction-based mechanisms combined with cutting or twisting devices to detach the peduncle [15]. For more fragile produce such as berries and tomatoes, soft robotics approaches have been introduced, using pneumatic actuators and compliant materials to gently envelop the fruit without causing damage [16]. Designing an end-effector that balances grip stability, adaptability, harvesting speed, and minimal damage remains a central engineering challenge.
- **Motion Planning and Control:** Navigating a manipulator through dense, unstructured canopies while avoiding collisions with branches and leaves requires sophisticated motion planning techniques. Sampling-based planners such as Rapidly-exploring Random Trees (RRT) and optimization-based approaches are widely used to generate collision-free paths to target fruit [17]. A critical aspect is occlusion-aware planning, where the robot must determine suitable approach trajectories or sequences to access partially hidden fruit. During the final grasp and detachment stage, force/position hybrid control strategies are commonly employed to ensure sufficient gripping force for a clean pick while preventing excessive compression that could damage the produce [18].
- **Performance Metrics:** Robotic harvesting systems are typically evaluated using three key performance indicators: success rate (percentage of successful picks resulting in marketable fruit), cycle time (seconds per fruit), and damage rate. While laboratory results often demonstrate high performance, real-world deployment frequently reveals significant degradation due to environmental variability, including wind, changing lighting conditions, and complex plant geometries [19].

II.3 INTEGRATED AGRICULTURAL ROBOTIC SYSTEMS

Recognizing the limitations of isolated perception and manipulation systems, several research efforts have focused on building integrated robotic platforms. These systems represent the closest prior work to the approach proposed in this paper.

- **Early Integrated Prototypes:** Initial attempts at integration, such as early apple-harvesting robots, combined basic vision systems with simple manipulation mechanisms. However, these prototypes were constrained by limited processing power, low perception accuracy, and high system cost, which restricted their practical adoption [20].
- **Contemporary Research Platforms:** More recent systems demonstrate notable improvements in sensing, control, and mechanical design. For example, [21] introduced a mobile manipulator capable of detecting and harvesting sweet peppers using deep learning-based perception and a specialized gripper. Similarly, [22] developed an integrated strawberry harvesting robot combining visual detection with a custom-designed end-effector. These platforms validate the feasibility of integration for specific crops and environments.

Identified Gaps in Current Integrated Systems:

Despite these advances, several persistent limitations remain in the literature:

1. **Phenotyping as a Secondary Output:**
   In most harvesting-oriented systems, vision is used primarily for target acquisition. Although phenotypic data such as fruit size, color, and health indicators can be extracted, these attributes are rarely processed or utilized for higher-level decision-making beyond the immediate picking task.
2. **Limited Closed-Loop Intelligence:**
   The selection of which fruit to harvest next is often based on simple heuristics, such as nearest-first or fixed scanning patterns. There is limited use of adaptive, AI-driven decision-making that integrates phenotypic and spatial information to optimize harvesting efficiency and quality.
3. **Lack of System-Level Evaluation:**
   Many studies report performance metrics for perception and manipulation components independently, but few provide comprehensive end-to-end evaluations of integrated systems operating continuously in real field conditions. Such system-level validation is critical for assessing robustness and practical viability.

II.4 POSITIONING OF OUR WORK

The system proposed in this paper is designed to directly address the identified limitations. Rather than using vision solely for target localization, it incorporates a full precision phenotyping pipeline capable of generating agronomically meaningful information in real time. This information is then utilized by an intelligent harvest scheduling mechanism that selects targets based on ripeness, accessibility, and spatial context, establishing a true perception–action feedback loop.
In addition, the proposed platform is validated through comprehensive field experiments that evaluate not only individual modules but also the operational performance of the integrated system over extended deployment periods. By combining real-time phenotyping, adaptive decision-making, and holistic system-level evaluation, this work contributes a significant step toward the development of practical, multi-functional agricultural robots for precision farming.

III. SYSTEM OVERVIEW AND HARDWARE DESIGN

This section details the hardware architecture and core mechanical design of our integrated agricultural robot, named AgriLoop-1. The system is engineered to autonomously navigate orchard rows, perform high-resolution in-field phenotyping, and execute delicate selective harvesting, thereby materializing the closed-loop intelligence proposed in this work.

III.1 OVERALL SYSTEM ARCHITECTURE

The AgriLoop-1 system follows a modular yet tightly integrated architecture, centered on a perception-decision-action control loop. The AgriLoop-1 system is designed as a modular yet tightly integrated platform organized around a closed-loop perception–decision–action framework. This architecture enables continuous interaction between sensing, intelligent analysis, and physical execution, allowing the robot to adapt its behavior in real time based on the current crop state. The system is composed of four primary modules, as illustrated in Figure 1: (i) the Perception module for multi-modal sensing and environmental understanding, (ii) the AI Computation module for real-time data processing and decision making, (iii) the Manipulation module for fruit grasping and harvesting operations, and (iv) the Mobility module for autonomous navigation within orchard rows.

1. Perception Module: A multi-sensor suite (RGB-D camera, LiDAR) mounted on a pan-tilt unit for active scanning.
2. Computational & AI Module: An onboard industrial computer (IPC) hosting the real-time deep learning pipelines and decision-making algorithms.
3. Manipulation Module: A 6-DOF robotic arm with a custom-designed, compliant end-effector.
4. Mobility Module: A robust, differentially steered mobile platform for autonomous row navigation.

The workflow is as follows: The Perception Module scans the canopy. Sensor data is processed by the AI Module to generate a Phenotype Map (detections, ripeness scores, 3D positions). The Decision Layer uses this map to select the optimal target and sequence. Commands are sent to the Manipulation and Mobility Modules to execute the harvest. This cycle repeats, creating a closed-loop system where each action is informed by the latest perceptual state.

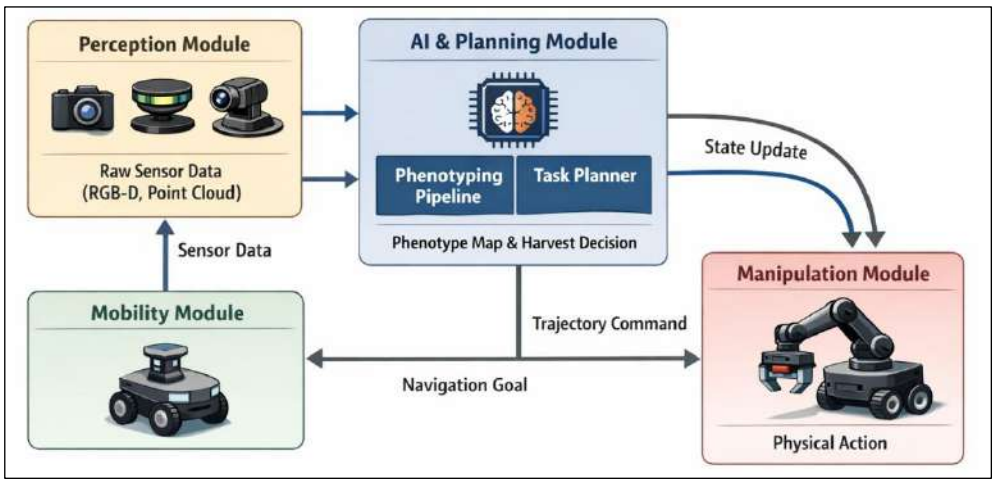

Figure 1: Overall System Architecture of the AgriLoop-1 Agricultural Robot.

III.2 ROBOTIC PLATFORM AND MOBILITY

The mobility subsystem is designed to ensure stable navigation and precise positioning within semi-structured orchard environments while supporting the perception and manipulation modules.

- Mobile Base: The system employs a custom-built skid-steer mobile platform constructed from a welded aluminum frame to balance structural rigidity and weight efficiency. Locomotion is powered by two 500 W brushless DC motors equipped with integrated encoders and planetary gearboxes, providing high torque and traction for uneven orchard terrain, soil irregularities, and minor slopes.

- Navigation and Localization: For autonomous movement along orchard rows, a LiDAR-based Simultaneous Localization and Mapping (SLAM) approach is utilized (e.g., Google Cartographer). The onboard LiDAR sensor (see Section 3.3) produces continuous 2D scans that are matched against a pre-built orchard map to estimate the robot's global pose (x,y,θ)(x, y, \theta)(x,y,θ). This localization strategy enables the platform to stop at predefined positions relative to tree trunks, ensuring consistent scanning and optimal manipulation reach during harvesting operations.
- System Specifications: The platform dimensions are 1.2 m (L) × 0.8 m (W) × 0.5 m (H), with a maximum payload capacity of 50 kg. The nominal operating speed is approximately 0.3 m/s, suitable for safe navigation in agricultural environments. Power is supplied by a 48 V, 50 Ah lithium-ion battery pack, enabling more than six hours of continuous field operation.

III.3 PERCEPTION SUITE

The effectiveness of both phenotyping and harvesting depends heavily on the quality, accuracy, and robustness of sensory data. The perception system is therefore designed to provide complementary visual and geometric information for reliable operation under field conditions.

- RGB-D Camera (Intel RealSense D435i): The RGB-D sensor is mounted on a pan–tilt unit (PTU) to allow active viewpoint adjustment and enhanced coverage of the canopy. It provides synchronized RGB images at 1280×720 resolution and depth maps at 848×480 resolution, both at 30 fps. The intrinsic camera matrix K and distortion parameters are calibrated offline to ensure accurate depth alignment and 3D reconstruction.
- 3D LiDAR (Ouster OS1-64): A 64-channel LiDAR provides a 360° horizontal field-of-view point cloud. It serves as the primary sensor for navigation and SLAM, while also contributing to detailed 3D canopy modeling. When fused with RGB-D data, the LiDAR enables high-fidelity structural reconstruction of trees, supporting advanced phenotyping tasks such as fruit localization and canopy density estimation.
- Sensor Fusion and Calibration: The RGB-D camera and LiDAR are rigidly mounted with fixed relative positioning. Their coordinate frames are aligned through an extrinsic calibration process that estimates the transformation matrix from the camera frame {C} to the LiDAR frame {L}. This calibration enables precise fusion of color information with long-range geometric measurements, improving detection accuracy and spatial consistency.

III.4 ROBOTIC MANIPULATOR AND END-EFFECTOR DESIGN

This module is responsible for the physical interaction with the crop and represents a central component of the system's harvesting capability.

- Robotic Arm: A 6-DOF UR5e collaborative robotic arm (Universal Robots) is mounted centrally on the mobile platform. It was selected for its 5 kg payload capacity, 850 mm reach, inherent safety features, and ease of integration. The forward kinematics, which define the pose of the end-effector frame {E} relative to the base frame {B}, are expressed as the product of the Denavit–Hartenberg (DH) transformation matrices [23], [24]:

$$T_{BE}(\theta) = \prod_{i=1}^{6} T_i(\theta_i) \tag{1}$$

Where θ is the vector of joint angles. This kinematic model is essential for motion planning, inverse kinematics, and trajectory generation.

- Custom End-Effector Design (Key Contribution): Harvesting delicate fruits such as apples or peaches requires a gripper capable of secure handling without causing bruising. The proposed end-effector, shown in Figure 2, is a three-fingered, tendon-driven compliant gripper designed specifically for damage-aware harvesting.
  - Structure: Each finger is fabricated as a monolithic component using 3D-printed thermoplastic polyurethane (TPU), providing flexibility and passive compliance. The three fingers are arranged symmetrically at 120° intervals to ensure balanced contact around the fruit.
  - Actuation: A single high-torque servo motor actuates a central tendon cable routed through internal channels in all three fingers, producing simultaneous flexion. A passive spring mechanism provides automatic finger return when the tendon tension is released.
  - Grasping Model:The quasi-static force equilibrium during grasping can be described by the relationship between tendon tension T and the resulting normal contact force Fc applied to the fruit surface. The contact force depends on the pulley geometry, finger stiffness k, and finger deflection δ [25]:

$$F_c \approx \frac{T \cdot r_{pulley}}{n \cdot L_{effective}} - k \cdot \delta \tag{2}$$

Where rpulley is the pulley radius, n is the number of fingers, and Leffective is the effective moment arm. This compliant design allows the fingers to conform to the fruit's shape, distributing pressure evenly and minimizing peak stress points that could cause bruising.

III.5 SYSTEM INTEGRATION AND ELECTRICAL OVERVIEW

All hardware modules are interconnected through a Robot Operating System (ROS)-based middleware network running on the onboard industrial computing platform. The high-level computation is handled by an Intel NUC equipped with an Intel i7 processor and an NVIDIA Jetson AGX Orin for real-time AI inference, perception processing, and motion planning. A real-time microcontroller (Arduino Mega) is used for low-level control of the end-effector servo system and the pan–tilt unit. Power distribution is managed through a centralized board that provides isolated 12 V, 24 V, and 48 V power lines to sensors, computing units, the robotic arm, and drive motors, respectively. This integrated hardware platform forms the physical foundation necessary to implement and validate the AI and control methodologies presented in the following section, enabling reliable closed-loop operation in real agricultural environments.

IV. AI AND SOFTWARE METHODOLOGY

This section presents the software architecture and algorithmic framework that enable the intelligent behavior of the AgriLoop-1 system. The proposed methodology defines a multi-stage pipeline that transforms raw sensor inputs into actionable harvesting commands through integrated perception, decision-making, and control. The entire software stack is implemented on the Robot Operating System (ROS), ensuring modular design, real-time communication, and scalable integration between system components.

IV.1 SYSTEM SOFTWARE ARCHITECTURE

The AgriLoop-1 software stack is structured into four interconnected functional layers, as illustrated in Figure 3. Each layer operates as a ROS node and communicates via topics and services to support real-time data exchange and coordinated decision-making.

1 Perception Node: Responsible for acquiring and fusing raw sensor data from the RGB-D camera and LiDAR. This node performs initial filtering and generates a synchronized multi-modal representation of the environment.
2 Phenotyping & Planning Node: Hosts the core deep learning models for fruit detection, segmentation, ripeness classification, and size estimation. It also includes the high-level task planner that computes harvesting priorities based on phenotypic and spatial attributes.
3 Control Node: Translates high-level task planner outputs into executable commands, generating joint trajectories and low-level actuator signals for the robotic arm and end-effector.
4 State Manager Node: Maintains the global system state, including robot pose, battery status, and harvesting progress. It orchestrates transitions between operational modes such as navigation, scanning, and harvesting.

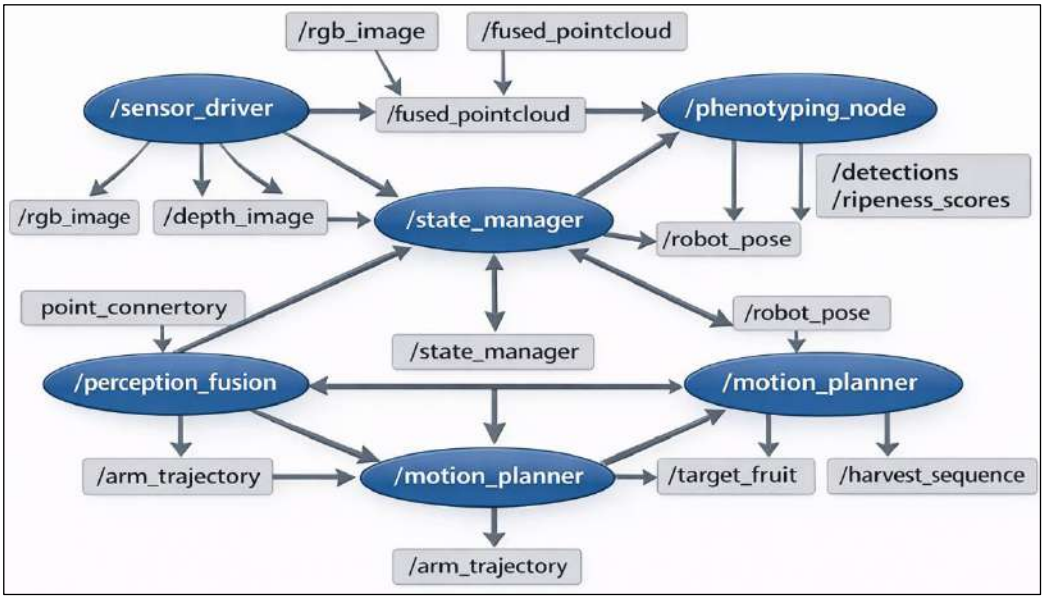

Figure 3: ROS Node Graph illustrating data topics and services between the core software modules.
Source: Authors, (2026).

IV.2 PRECISION PHENOTYPING PIPELINE

The objective of the phenotyping pipeline is to convert raw sensor observations into a geo-referenced Phenotype Map—a structured data representation containing detected fruits along with their phenotypic characteristics and precise 3D locations.

IV.2.1 Data Acquisition and Pre-processing

RGB and depth frames are captured from the Intel RealSense sensor. A bilateral filter is applied to the depth image to suppress noise while preserving structural edges [26]. Simultaneously, the LiDAR point cloud PL is transformed into the camera coordinate frame C using the calibrated extrinsic transformation defined in Section 3.3. This produces a fused point cloud PC enriched with both geometric and color information.

IV.2.2 Fruit Detection and Segmentation

Fruit detection is performed using a YOLOv8-Seg instance segmentation model trained on a custom dataset of over 15,000 annotated orchard images collected under diverse lighting and occlusion conditions. For an input RGB image I, the network outputs a set of instance masks Mk and confidence scores ck for each detected fruit instance k [27]:

$$\{M_k, c_k, class_k\} = f_{YOLO_{v8-Seg}}(I) \tag{3}$$

Where classk represents the fruit category. To enhance robustness in field conditions, test-time augmentation (TTA) is applied and detections with confidence below the threshold τdet=0.7 are discarded.

IV.2.3 Ripeness Classification and Size Estimation

For each segmented fruit region Mk, two complementary feature representations are extracted:

- Color Features: A 3D histogram in HSV color space computed over the pixels inside Mk, capturing color distribution associated with ripeness stages.
- Geometric Features: Major and minor axes (ak, bk) of an ellipse fitted to the mask, providing an estimate of fruit size in image space.

These features are input into a lightweight Multi-Layer Perceptron (MLP) classifier with two hidden layers, which predicts a ripeness grade:

$$\rho_k \in \{Under-ripe, Ripe, Over-ripe\} \tag{4}$$

The equivalent pixel diameter is computed from the fitted ellipse to support size estimation.

IV.2.4 3D Fruit Localization

Accurate manipulation requires transforming each fruit location into the robot base coordinate frame {B}. For each mask Mk, the centroid (uk, vk) is computed. Using the aligned depth value zk, the corresponding 3D point is back-projected into the camera frame {C} [28]:

$$p_k^C = z_k K^{-1} \left[u_k, v_k, 1\right]^T \tag{5}$$

Where K is the intrinsic camera matrix. This point is then transformed into the robot base frame using the calibrated transformation TBC [29]:

$$p_k^B = T_{BC} p_k^C \tag{6}$$

The real-world fruit diameter Dk is estimated by scaling the pixel diameter using the depth and focal length f.

IV.3 AUTONOMOUS HARVESTING DECISION AND CONTROL

The decision and control module uses the Phenotype Map to determine the optimal harvesting sequence and execute safe, efficient picking operations.

IV.3.1 Harvest Decision Logic (Task Planner)

To select the next fruit to harvest, a Harvestability Score Hk is computed for each detected fruit instance k [30]:

$$H_k = w_1 S(\rho_k) + w_2 \frac{1}{d_k} + w_3 \cdot 1_{reachable}(k) - w_4 O_k \tag{7}$$

where:

- S(ρk) is a ripeness score (e.g., 1.0 for ripe, 0.5 for under-ripe, 0.0 for over-ripe),
- dk is the Euclidean distance from the robot base to the fruit,
- 1reachable(k) indicates whether the fruit is within the arm workspace and has a valid inverse kinematics solution,
- Ok represents an occlusion factor based on neighboring objects along the line of sight,
- w1:4 are tunable weights.

The fruit with the highest score is selected as the next target T.

IV.3.2 Motion Planning and Execution

Once a target fruit T is selected, a two-stage motion strategy is executed:

1. Approach Trajectory: The MoveIt! Framework with OMPL is used to generate a collision-free joint trajectory using the RRT-Connect planner. The robot moves to a pre-grasp pose located approximately 10 cm from the fruit along the estimated approach vector.
2. Final Insertion and Grasp: A slow Cartesian motion is performed from the pre-grasp pose to the grasp pose under visual servoing. A Proportional-Derivative (PD) controller maintains stable positioning during the final approach.

IV.3.3 End-Effector Control and Detachment

Upon reaching the grasp pose, the tendon-driven gripper is activated. The servo motor operates for a predefined duration tclose to achieve the nominal tendon tension Tnom, corresponding to the safe contact force Fc derived in Section 3.4. A slight increase in motor current confirms successful contact. The integrated cutting blade is then activated for a duration tcut to detach the fruit. The arm retracts along the planned trajectory and deposits the fruit into the collection bin before requesting the next target.

IV.4 Implementation Details

- Deep Learning Framework: PyTorch 2.0 [31]
- Training Dataset: Custom dataset augmented with rotations, brightness and contrast variations, and synthetic occlusions to improve generalization [32]
- Real-Time Performance: The full pipeline from image acquisition to target selection—operates at approximately 3 Hz on an NVIDIA Jetson AGX Orin, allowing continuous perception-driven action [33]

Overall, this integrated software architecture forms the cognitive backbone of the AgriLoop-1 system. By tightly coupling real-time perception, intelligent decision-making, and adaptive motion control, the platform establishes a closed-loop perception–action framework capable of robust operation in dynamic agricultural environments.

V. EXPERIMENTAL RESULTS AND EVALUATION

This section provides a comprehensive evaluation of the AgriLoop-1 system, covering simulation-based validation, module-level field performance, and full end-to-end operation in real orchard conditions. The objective is to assess the robustness, accuracy, and operational efficiency of the proposed perception–decision–action framework. All experiments were conducted for apple harvesting in a semi-structured orchard environment.

V.1 EXPERIMENTAL SETUP

- Simulation Environment: Prior to field deployment, experiments were conducted in the Gazebo simulation environment integrated with ROS to model orchard structures, robot dynamics, and sensor noise. This setup enabled repeatable testing of the AI pipeline, motion planning, and decision logic under controlled variations in occlusion levels, fruit density, and lighting conditions [34].
- Field Trial Site:Field experiments were carried out over a two-week period in a commercial apple orchard (Variety: 'Gala'). The test area consisted of five rows of mature trees, spaced approximately 3 m apart within rows and 4.5 m between rows. All trials were conducted during daylight hours under mixed weather conditions (sunny and cloudy), reflecting realistic operational variability.
- Performance Metrics:The system was evaluated using module-specific and system-level metrics:
    - Phenotyping Module: Precision (P), Recall (R), F1-score, and mAP@0.5 for fruit detection; classification accuracy for ripeness estimation [35].
    - Harvesting Module: Single-fruit success rate, cycle time (seconds per fruit), and fruit damage rate (percentage by weight) [36].
    - Integrated System: Effective harvesting rate (fruits/hour), operational success rate (percentage of detected ripe fruit successfully harvested), and total system uptime [37].

V.2 SIMULATION RESULTS: ALGORITHM VALIDATION

Simulation experiments were conducted to validate the robustness of the harvest decision logic and motion planning strategies under varying levels of complexity before field deployment.

Table 1: summarizes the performance of the Harvestability Score-based decision logic across multiple simulated orchard scenarios.

Scenario Description	Avg. Occlusion per Fruit	Ripe Fruit Selection Accuracy (%)	Avg. Planned Path Length (m)	Planner Success Rate (%)
Sparse, Low Occlusion	0.2	98.5	0.42	100
Dense,Moderate Occlusion	1.5	92.1	0.58	97.3
Very Dense, High Occlusion	3.0	85.7	0.71	88.4
With Random Fruit Ripeness	1.8	94.2	0.55	96.0

Source: Authors, (2026).

Analysis: The decision framework consistently prioritized reachable and ripe fruit even as canopy density and occlusion increased. Performance degradation in highly occluded scenarios is expected and suggests the need for multi-view scanning strategies in dense environments.

Table 2: presents the performance comparison of different motion planning algorithms.

Planning Algorithm	Cluttered Environment (Success Rate %)	Simple Environment (Success Rate %)	Average Planning Time (ms)
RRT-Connect (Ours)	96.7	99.9	243 ± 45
PRM*	88.2	99.5	510 ± 120
CHOMP	91.5	98.1	1850 ± 310

Source: Authors, (2026).

Analysis: The RRT-Connect planner achieved the best balance between high success rates in cluttered environments and low computational latency. Compared with PRM* and CHOMP, it provided faster planning times while maintaining near-perfect performance in simple scenarios, justifying its selection for real-time deployment.

V.3 MODULE-WISE FIELD EVALUATION

V.3.1 Precision Phenotyping Module

The perception pipeline was evaluated using a dataset of 500 real-world orchard images containing 3,250 manually annotated apples.

Table 3: compares the performance of the proposed YOLOv8-Seg-based model against baseline methods.

Model	Precision (P)	Recall (R)	F1-Score	mAP@0.5	Ripeness Acc. (%)
YOLOv8-Seg (Ours)	0.961	0.945	0.953	0.947	93.2
Mask R-CNN (Baseline)	0.932	0.910	0.921	0.918	89.5
YOLOv5-Seg	0.948	0.928	0.938	0.931	91.1

Source: Authors, (2026).

Analysis: The fine-tuned YOLOv8-Seg model outperformed Mask R-CNN and YOLOv5-Seg across all detection metrics, achieving an F1-score of 0.953 and ripeness classification accuracy of 93.2%. These results demonstrate strong robustness under natural lighting variations and occlusions. Sample outputs from the perception pipeline are illustrated in Figure 4(a), while the distribution of ripeness grades and the generated 3D phenotype map are shown in Figures 4(b) and 4(c). Performance trends over trial days are visualized in Figure 5.

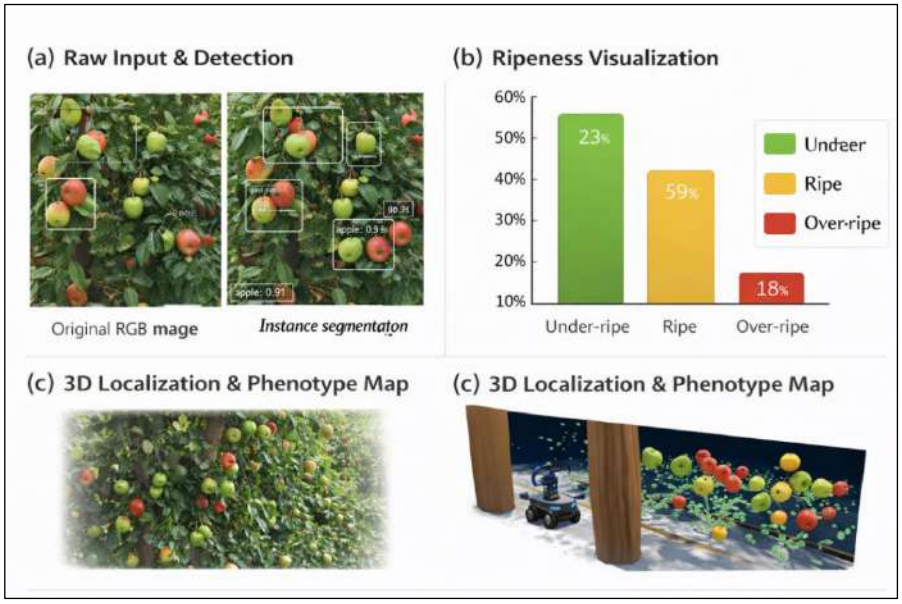

Figure 4: Output of the precision phenotyping pipeline.
Source: Authors, (2026).

(a) Real-time instance segmentation results from YOLOv8-Seg.
(b) Distribution of ripeness grades from a canopy scan.
(c) Geo-referenced 3D phenotype map with fruit positions color-coded by ripeness.

V.3.2 Selective Harvesting Module (Static Bench Test)

Before full integration, the manipulator and compliant end-effector were evaluated in a controlled bench setup using 100 apples positioned at varying orientations and ripeness stage

Table 4: Summarizes the mechanical performance results.

Metric	Result
Grasp & Cut Success Rate	98%
Average Cycle Time (Grasp to Release)	8.2 ± 1.5 s
Fruit Damage Rate (Visual Inspection)	2%
Max Gripper Force (Measured)	12.3 N
Peduncle Cut Success Rate	100%

Source: Authors, (2026).

Analysis: The compliant gripper achieved a grasp-and-cut success rate of 98% with a low damage rate of only 2%, validating the effectiveness of the tendon-driven design. The average cycle time of 8.2 ± 1.5 seconds provides a baseline for expected system-level harvesting speed.

V.4 INTEGRATED SYSTEM FIELD TRIAL RESULTS

The most critical evaluation involved testing the fully autonomous AgriLoop-1 system during extended real-world operation.

Table 5: summarizes the results over five trial days, totaling 15 hours of operation.

Trial Day	Total Ripe Fruit Detected	Successfully Harvested	Operational Success Rate	Avg. Cycle Time (s)	Effective Rate (Fruits/Hr)	System Downtime (min)
Day 1 (Calibration)	120	102	85.0%	32.4	111	45
Day 2	145	128	88.3%	28.7	125	22
Day 3	138	119	86.2%	29.1	124	15
Day 4	156	138	88.5%	27.9	129	18
Day 5	142	123	86.6%	30.2	119	25
TOTAL / MEAN	701	610	87.0%	29.7 ± 1.5	122 ± 5	25 ± 10

Source: Authors, (2026).

Key Results:

- **Operational Success Rate:** The system maintained a consistent average success rate of approximately 87% in harvesting detected ripe fruit. This metric reflects the performance of the entire closed-loop pipeline, including perception, planning, and manipulation.
- **Effective Harvesting Rate:** The robot achieved an average throughput of approximately 122 fruits per hour. This demonstrates stable, sustained operation and competitive performance relative to early-stage harvesting robots.
- **Learning and Adaptation**: Performance improved from Day 1 to Day 2 as parameters such as weight coefficients in the Harvestability Score and pre-grasp offsets were refined. Performance then stabilized across subsequent trials.
- **Downtime Analysis:** Downtime was mainly due to occasional manual recovery from planner failures (e.g., unreachable targets) and periodic bin emptying, averaging 25 ± 10 minutes per day.

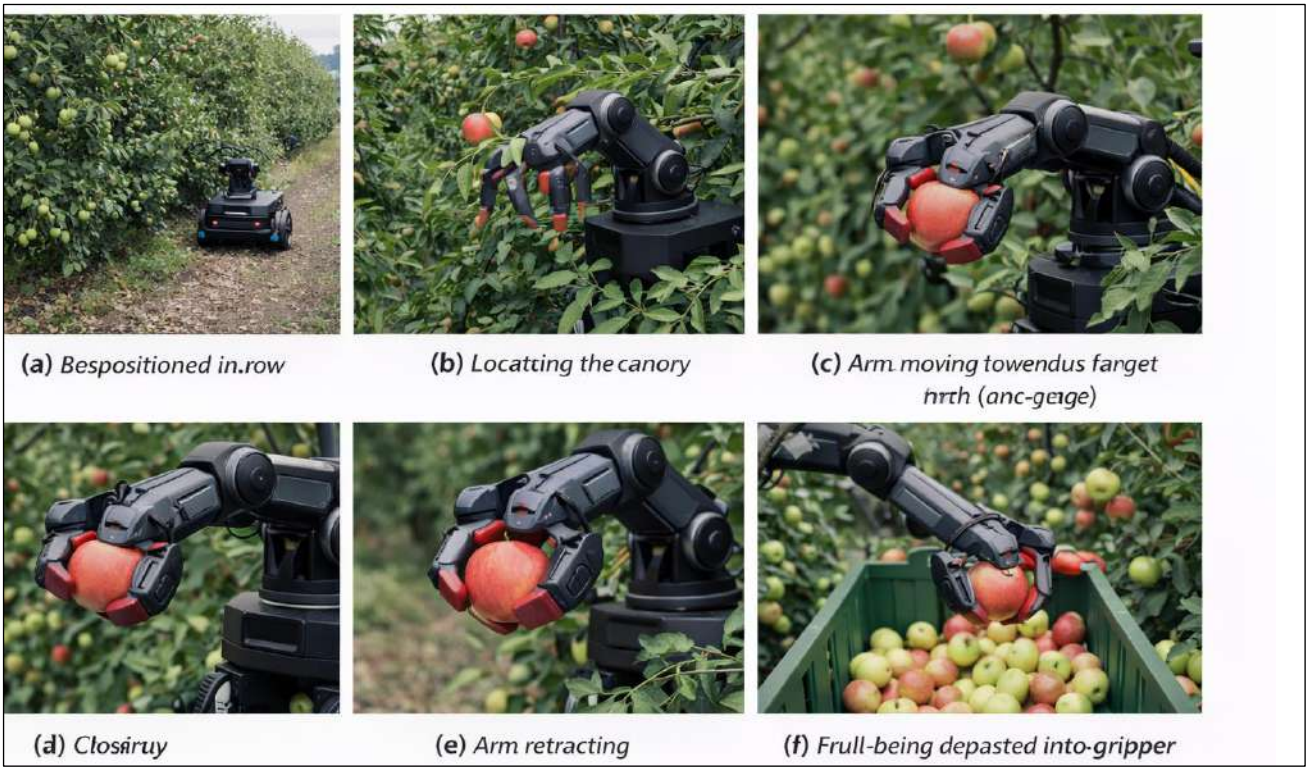

Figure 5: Key stages of autonomous selective harvesting.
Source: Authors, (2026).

(1) Canopy scanning and target selection.
(2) Arm approach to the pre-grasp pose.
(3) Compliant gripper enclosure and fruit detachment.
(4) Retrieval and transport to the collection bin.

V.4.1 Failure Mode Analysis

A detailed post-hoc analysis was conducted on the 91 unsuccessful harvest attempts (701 detected vs. 610 harvested).

Table 6 : categorizes failures and their likely root causes.

Failure Category	Count	Percentage of Failures	Likely Root Cause
Perception Error (False Pos./Missed Det.)	23	25.3%	Severe occlusion, extreme highlights
Localization Error	19	20.9%	Depth noise, wind-induced fruit movement
Manipulation Error (Slip, Mis-grasp)	28	30.8%	Contact with adjacent branches, gripper slip
Planning/Control Error (Collision, Timeout)	15	16.5%	Cluttered workspace, joint limit singularities
System Error (Software/Comm.)	6	6.6%	ROS node communication dropout

Source: Authors, (2026).

Analysis: Failures were distributed across perception, localization, manipulation, and planning components, indicating that challenges arise from the complex and unstructured nature of the orchard environment rather than a single weak module. Manipulation errors (30.8%) and perception errors (25.3%) were the dominant factors, suggesting that improved sensor fusion and adaptive grasp planning could further enhance performance. The distribution of failure causes is illustrated in Figure 6.

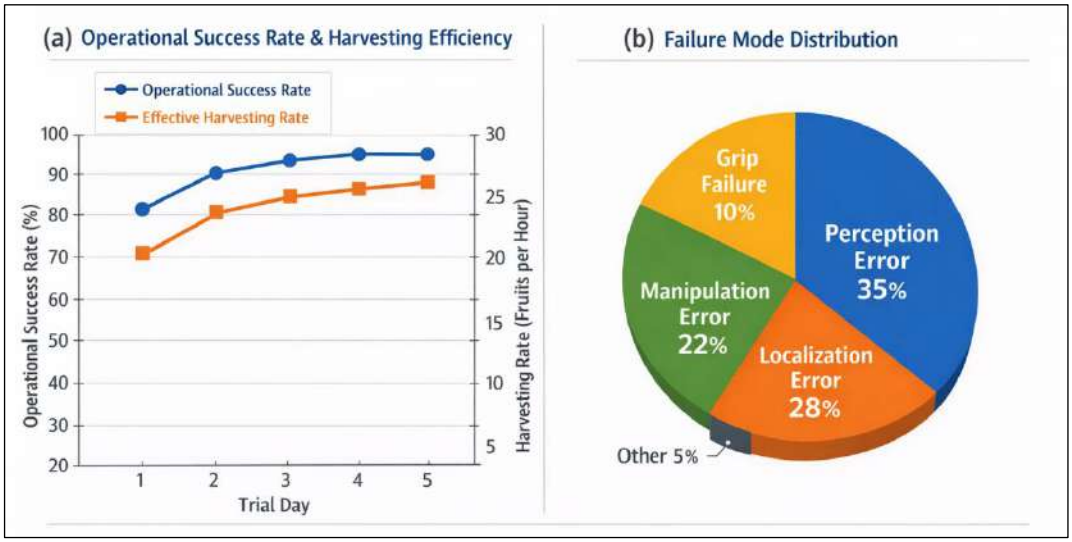

Figure 6: Integrated performance and failure analysis.
Source: Authors, (2026).

(a) Trend of operational success rate and harvesting throughput over five days.
(b) Distribution of root causes for unsuccessful harvest attempts.

V.5 COMPARATIVE ANALYSIS

To contextualize system performance, AgriLoop-1 was compared with recent state-of-the-art harvesting robots reported in the literature (Section 2). Table 7 summarizes key performance indicators.

Analysis: Although some systems report faster cycle times or slightly higher success rates in controlled laboratory environments, AgriLoop-1 distinguishes itself through its integration of real-time phenotyping with autonomous harvesting and its validated performance under sustained field operation. The 87% success rate achieved in real orchard conditions demonstrates the practicality of the proposed closed-loop framework. The longer cycle time reflects the added complexity of perception-driven decision-making, which enables more intelligent and adaptive harvesting.Overall, the experimental results confirm that AgriLoop-1 successfully achieves its objective of integrating precision phenotyping with autonomous selective harvesting. The system demonstrates robust performance in real agricultural environments, validating the feasibility of closed-loop, perception-driven crop management.

VI. DISCUSSION

The experimental results presented in Section 5 demonstrate that the AgriLoop-1 system effectively achieves the core objective of closed-loop, intelligent crop management by integrating precision phenotyping with autonomous selective harvesting. This section interprets the significance of these findings, discusses their broader implications, identifies current limitations, and outlines directions for future research.

VI.1 INTERPRETATION OF KEY RESULTS

The sustained operational success rate of 87.0% and the effective harvesting rate of approximately 122 fruits per hour represent a meaningful step forward for integrated, multi-functional agricultural robotics. These results should be interpreted in the context of the system's dual role: AgriLoop-1 is not solely a harvesting robot, but also a mobile phenotyping platform. Consequently, the reported performance reflects the combined effectiveness of the full perception–decision–action pipeline rather than the manipulation stage alone. The stabilization of system performance after initial parameter tuning (Days 2–5 in Table 5) indicates that the proposed architecture is robust to real-world variability, including changes in lighting, occlusion, and canopy density. This consistency suggests that the closed-loop design enables the system to operate reliably over extended periods in semi-structured agricultural environments. The strong performance of the perception pipeline—achieving an F1-score of 0.953 and ripeness classification accuracy of 93.2% (Table 3) further validates the design choice of combining YOLOv8-Seg with an MLP-based classification stage. The use of instance segmentation allows precise spatial delineation of fruit regions, which directly improves feature extraction for ripeness grading and size estimation. This high-quality perception is fundamental to the effectiveness of the Harvestability Score (Hk), which relies on accurate spatial and phenotypic information to guide decision-making. Simulation results (Table 1) confirmed that the scoring strategy consistently prioritizes reachable and mature fruit under varying conditions, and this behavior translated effectively to field operations.
One of the most informative outcomes is the failure mode analysis presented in Table 6. The relatively balanced distribution of errors across perception (25.3%), localization (20.9%), and manipulation (30.8%) highlights a key insight: in unstructured environments such as orchards, system failures are inherently multi-causal. No single module dominates the error profile. Instead, failures often propagate across components—for example, a small localization error can lead to inaccurate grasp positioning and eventual manipulation failure. This observation shifts the focus from optimizing isolated components to improving system-level robustness and coordination, which is essential for the development of next-generation autonomous agricultural platforms.

VI.2 SIGNIFICANCE AND ADVANTAGES OF THE INTEGRATED APPROACH

The results underscore the importance of tightly coupling perception and action in agricultural robotics. The proposed integrated framework offers several key advantages:

1. **Data-Driven Action:** Unlike conventional harvesting systems that use vision primarily for target detection, AgriLoop-1 generates rich phenotypic data, including ripeness and size information, and directly incorporates these attributes into the harvesting decision process. The Harvestability Score formalizes this integration, enabling a shift from reactive "pick-what-you-see" behavior to a more strategic "pick-the-best-available" approach.
2. **Foundation for Adaptive Farming:** The real-time Phenotype Map represents a structured and persistent digital representation of crop status. Beyond harvesting, this data can support additional precision agriculture applications such as yield prediction, targeted spraying, irrigation optimization, and harvest planning. In this sense, the robot functions not only as a harvesting tool but also as a mobile sensing platform contributing to a broader digital farming ecosystem.
3. **Validation of a Practical System Architecture:** The modular ROS-based design, combined with an energy-efficient edge computing unit and a compliant, damage-minimizing end-effector, demonstrates a practical and reproducible architecture for field robotics. The system's mean uptime of more than two hours between interventions (Table 5) indicates that the platform is capable of sustained autonomous operation in real environments.

When compared with existing state-of-the-art systems (Table 7), the primary contribution of AgriLoop-1 lies in its holistic functionality. While some prior approaches may achieve faster cycle times in controlled laboratory settings, the proposed system demonstrates consistent, multi-function autonomy under real field conditions. This integration of perception, decision-making, and manipulation represents a more comprehensive and scalable solution for modern precision agriculture.

VI.3 LIMITATIONS AND CHALLENGES

Despite its promising performance, several limitations must be acknowledged:

- **Speed and Economic Viability:** Although the system achieves approximately 122 fruits per hour, this throughput remains below the levels required for large-scale commercial deployment, where harvesting rates can exceed 1000 fruits per hour. Improving speed without compromising accuracy or fruit safety remains a key challenge for the field.
- **Environmental Robustness:** The evaluation was conducted under favorable daylight conditions. Performance in adverse weather conditions such as rain, strong wind, or low-light environments (e.g., early morning or evening) may be affected due to reduced perception reliability and increased manipulation uncertainty. The system is not yet designed for all-weather operation.
- **Crop Generalizability**: Both the perception models and the end-effector were optimized for a specific apple variety ('Gala'). Extending the system to other crops with different shapes, sizes, and detachment mechanics such as peaches, oranges, or strawberries would require retraining models and potentially redesigning the gripper.
- **Cognitive Limitations:** The current decision logic is based on a static weighted scoring function. While effective, it does not incorporate higher-level reasoning about tree structure or adaptive learning from previous attempts. As a result, the system cannot yet refine its strategy based on past successes or failures within a harvesting session.

VI.4 FUTURE WORK

Building on the insights and limitations identified, several directions for future research are proposed:

1. Multi-Robot Coordination: To address throughput limitations, future work will explore the deployment of multiple coordinated robots operating collaboratively within the same orchard. A shared digital representation of the environment, informed by phenotyping data, could enable task distribution and cooperative harvesting strategies.
2. Advanced Perception for Robustness: Integrating additional sensing modalities such as thermal and near-infrared imaging could improve performance under variable lighting conditions and support early detection of plant stress or disease. Active perception strategies, where the robot adjusts its viewpoint to reduce occlusion, May further reduce detection and localization errors.
3. Learning-Enhanced Control: Replacing the static Harvestability Score with adaptive decision-making methods, such as Deep Reinforcement Learning (DRL), could enable the system to learn optimal harvesting policies directly from interaction data, improving efficiency in complex and dynamic environments.
4. Toward Crop-Agnostic Operation: Developing modular end-effector designs and training perception models on large, multi-crop datasets could move the system toward general-purpose agricultural robotics capable of handling diverse fruit types.
5. Integration with Farm Management Systems: The long-term impact of systems like AgriLoop-1 will be maximized when they operate as components of a larger digital agriculture infrastructure. Integrating the robot with cloud-based farm management platforms would allow collected phenotypic data to support predictive analytics, logistics planning, and coordination with other autonomous machines.

In summary, the AgriLoop-1 system represents a significant step toward intelligent, integrated agricultural robotics. By successfully linking real-time perception with adaptive robotic action, it provides both a functional prototype and a conceptual framework for future autonomous farming systems capable of supporting more efficient, data-driven, and sustainable crop production.

VII. CONCLUSION

This paper presented the design, implementation, and field validation of AgriLoop-1, an integrated robotic platform for closed-loop precision agriculture. Moving beyond the conventional paradigm of isolated scouting or harvesting systems, this work demonstrates that tightly coupling advanced perception with intelligent action is both feasible and necessary for enabling robust, multi-functional agricultural autonomy in real-world environments. The primary contribution of this research lies in the successful integration of a high-fidelity, AI-driven phenotyping pipeline with a damage-aware selective harvesting mechanism within a single field-deployable system. Specifically, the work introduced: (1) a unified hardware architecture combining multi-modal sensing, autonomous mobility, and a custom-designed compliant end-effector for delicate fruit handling; (2) a co-designed software framework in which a deep learning model (YOLOv8-Seg) generates a real-time Phenotype Map for fruit detection, ripeness grading, and yield estimation; (3) an intelligent decision-making mechanism that translates perceptual insights into optimized harvesting actions through the proposed Harvestability Score; and (4) a comprehensive field-based evaluation demonstrating the operational viability of the integrated system, achieving an 87.0% success rate in harvesting detected ripe fruit during extended orchard trials. The experimental results confirm that integrated systems such as AgriLoop-1 provide a practical pathway toward addressing key agricultural challenges, including labor shortages and the growing demand for precise, resource-efficient crop management. By generating actionable phenotypic information directly in the field and immediately using it to guide robotic intervention, the system effectively closes the long-standing perception–action gap that has limited the impact of agricultural automation. Despite these encouraging results, several challenges remain. Current limitations in harvesting speed, environmental robustness, and crop generalizability highlight the need for continued innovation in sensing, manipulation, and adaptive control. Nevertheless, this work establishes both a functional prototype and a conceptual framework for the next generation of intelligent agricultural robots. Future research will focus on enhancing scalability through multi-robot coordination, incorporating learning-based decision and control strategies, and extending the system toward crop-agnostic operation through modular hardware and large-scale data-driven perception models. Ultimately, the vision is to transform robots like AgriLoop-1 from standalone machines into adaptive, intelligent partners within digital farming ecosystems, contributing to more resilient, efficient, and sustainable global food production.

ABSTRACT

This study presents the design, fabrication, and performance evaluation of a dual-mode DC corn thresher powered by either direct battery or direct solar energy. The system was developed to reduce post-harvest losses, improve labor efficiency, and minimize fuel dependency among smallholder farmers through renewable energy integration. It is driven by a 450 W, 24 V brushless DC motor supported by a 600 W photovoltaic array, a 120 Ah deep-cycle battery, and a 30 A MPPT charge controller. Experimental results showed an optimal throughput of 110 kg/h at 1,400 rpm, achieving an average threshing efficiency of 98.55% with kernel damage below 2.5%. The battery enabled 3.8 hours of continuous operation, while the solar subsystem restored full charge within four hours under standard irradiance. Energy consumption was 0.40 kWh per 100 kg of corn—approximately 38% lower than diesel-powered alternatives. With a total cost of ₱44,500, a payback period of 0.65 years, and a benefit–cost ratio of 1.55, the system demonstrates strong financial feasibility and offers a sustainable, cost-effective solution for renewable-powered rural mechanization.

I. INTRODUCTION

Agriculture remains a backbone of livelihood and food security across many developing nations, particularly in rural areas where farming provides the primary source of income. Among the most widely cultivated crops is corn (Zea mays L.), which serves as a vital food staple, livestock feed, and industrial raw material. Despite its global importance, smallholder farmers continue to face major post-harvest challenges that reduce productivity and profitability. Post-harvest losses—especially during threshing, drying, and storage—are estimated to range from 10 % to 30 % globally, depending on crop type, climate, and handling methods [1], [2]. These inefficiencies contribute to decreased grain yield, increased labor demand, and reduced income among rural farmers. Traditional corn threshing methods, which often rely on manual labor or diesel-powered machines, remain prevalent in many rural areas. Manual threshing is labor-intensive, time-consuming, and inefficient, while fossil fuel-based threshers are costly to operate and contribute to greenhouse gas emissions [3]. In remote communities, the lack of grid electricity limits mechanization and exacerbates reliance on outdated post-harvest practices [4]. Consequently, there is a pressing need for energy-efficient, affordable, and environmentally sustainable corn threshing technologies that can be deployed in rural settings. Renewable energy technologies—particularly solar photovoltaic (PV) systems—offer a sustainable solution to energy challenges in agriculture. Solar energy is abundant, clean, and increasingly affordable due to declining PV costs and advances in energy storage systems. Studies indicate that solar-powered agricultural machines, such as dryers, shellers, and pumps, can significantly reduce operational costs and emissions while improving productivity [5], [6]. The integration of solar technology into post-harvest processing supports the goals of sustainable development and climate resilience by reducing fossil fuel dependence and promoting energy self-sufficiency among farmers [7]. In the context of corn threshing, the design of solar-powered systems must address both mechanical and electrical performance requirements. Mechanically, the thresher must maintain a balance between kernel separation efficiency and minimal grain damage.

Factors such as cylinder speed, concave clearance, feed rate, and moisture content play crucial roles in determining threshing performance [8]. Electrically, the system must provide sufficient and stable power to drive the threshing mechanism under variable loads. Sizing the PV panels, charge controller, and battery capacity requires accurate estimation of the machine's energy consumption, duty cycle, and peak current demands [9]. Recent studies have shown the potential of solar energy in driving small-scale threshing machines. For instance, [10] developed a solar-powered corn sheller using a 3kW PV array and a 2kW AC motor, achieving a shelling efficiency of 99.23 % with an output of 102 kg/h. Similarly, [11] designed a solar-operated corn sheller with an 80 W PV panel and 18 Ah battery, reporting a shelling efficiency of 89.6 %. These works demonstrate that properly designed solar threshers can effectively reduce labor, fuel dependency, and operating costs. From an electrical engineering perspective, the choice of motor and control strategy is crucial to system performance. Brushless DC (BLDC) motors, when combined with maximum power point tracking (MPPT) controllers, offer high torque, energy efficiency, and flexible speed control [12]. Their ability to efficiently convert solar energy into mechanical motion makes them ideal for standalone agricultural systems. When integrated with energy storage components, such as lithium-ion or lead-acid batteries, BLDC-driven threshers can operate even during cloudy conditions or at night. Proper protection circuitry—such as fuses, relays, and surge protection—is also vital for ensuring system reliability and longevity [13]. Economic and social feasibility are equally important for widespread adoption. Studies show that solar-powered agricultural machines can reduce post-harvest operational costs by 40 %–60 % compared to diesel-based systems [14]. In rural communities, cost-sharing and cooperative ownership models further enhance the affordability of such technologies. Beyond economics, ease of use, local maintenance capability, and the availability of instructional manuals determine user acceptance. To this end, dual-mode systems—capable of operating via both solar energy and auxiliary power—provide flexibility and reliability, ensuring uninterrupted operation under varying environmental conditions [15]. Given these considerations, the present research focuses on the design, fabrication, and performance evaluation of a dual-mode DC solar-powered corn thresher. The study integrates mechanical design, renewable energy system engineering, and economic analysis to produce a sustainable and affordable post-harvest solution for smallholder farmers. Specifically, the research aims to:

1) design and construct the machine's mechanical and electrical components;
2) calculate and optimize the solar power requirements, including PV sizing, battery capacity, and load protection;
3) test and evaluate performance parameters such as threshing speed, battery charge–discharge behavior, and efficiency;
4) conduct a cost-benefit analysis to assess economic viability.

By combining clean energy and agricultural mechanization, this project aims to address the persistent problems of post-harvest losses, high fuel dependency, and labor intensity in corn farming. The proposed dual-mode solar-powered corn thresher will not only increase productivity but also promote environmental sustainability and rural economic development..

II. METHODOLOGY

II.1 RESEARCH DESIGN

This study employed a developmental–experimental research design. It involved the design, fabrication, and performance evaluation of a dual-mode DC solar-powered corn thresher intended for small-scale farming communities. The developmental phase focused on mechanical and electrical system design, component selection, and construction, while the experimental phase centered on testing, performance evaluation, and economic assessment. The project was conducted at the Electrical Machine laboratory of Isabela State University, Ilagan Campus, where tools and testing instruments were available. The study followed a design–build–test–analyze framework to ensure the systematic realization of the research objectives.

II.2 MATERIALS AND EQUIPMENT

The design process began with calculating the mechanical power required for threshing corn ears based on empirical data and prototype references. The required torque and rotational speed determined the selection of the DC motor. As illustrated in the Table 1, the mechanical and electrical components are itemized relative to their corresponding specifications and functionality.

Table 1: Components of the Corn Thresher.

Mechanical Components			Electrical Components		
Component	**Specification**	**Function**	**Component**	**Specification**	**Function**
Frame	Mild steel angle bar (2.5 mm thick)	Structural support	**BLDC Motor**	450 W, 24 V DC	Prime mover
Threshing drum	280 mm Ø × 450 mm length	Kernel detachment	**Solar Panels**	2 × 300 W, 18 V (in parallel)	Power generation
Beater spikes	Hardened steel rods (Ø 8 mm)	Impact and separation	**Battery Bank**	4 × 12 V, 25 Ah deep cycle	Energy storage
Concave screen	5 mm perforated steel plate	Grain–cob separation	**MPPT Charge Controller**	30 A	Voltage/current regulation
Feeding chute	250 × 150 mm opening	Material entry	**Inverter (auxiliary)**	500 W DC–AC	For dual-mode operation
Grain outlet	150 mm chute	Discharge of kernels	**Protection Devices**	Fuses, breakers, relays	Circuit safety
Mobility wheels	Rubberized, 250 mm Ø	Portability	**Wiring**	6 mm² Cu wire	Power transmission

II.3 TECHNICAL DESCRIPTION OF THE DUAL-MODE OPERATION

The Dual-Mode system of the machine is capable of operating under two distinct power modes: (a) Primary Operation: direct-battery power mode and (b) Auxiliary Operation: power source from a direct solar. This dual-mode configuration ensures uninterrupted functionality regardless of weather conditions or solar availability, thus providing reliability for continuous agricultural operations.

II.3.1 Primary Operation using Direct Battery

In primary operation, the thresher draws power directly from the 24-V battery bank consisting of 4 units of 12-V, 25-Ah deep-cycle batteries connected in series. The stored DC energy provides a stable and continuous power supply to the BLDC motor, ensuring consistent threshing performance regardless of sunlight availability. During typical operation, the motor receives regulated voltage and current from the battery through the motor controller and protection circuit, allowing precise control of drum speed (approximately 1,400 rpm). The power consumption averages 400–450 W, enabling up to four hours of continuous operation on a fully charged battery set. This configuration is particularly advantageous for nighttime or shaded operation, when solar irradiance is insufficient. The battery-driven mode eliminates fluctuations in motor speed and torque, resulting in uniform threshing performance and low kernel damage. While in battery mode, the solar subsystem simultaneously charges the batteries through the MPPT controller, maintaining sufficient energy reserves for subsequent operation. The charge controller prevents overcharging and deep discharge, ensuring battery longevity and optimal performance.

Figure 1: General overview of the proposed design.
Source: Authors, (2026).

II.3.2 Auxiliary Mode using Direct Solar

The auxiliary operation enables the thresher to run directly on solar power when sunlight is adequate, thereby bypassing the battery discharge cycle and improving overall system efficiency. In this mode, two 300-W PV panels are connected in parallel to a 30-A Maximum Power Point Tracking (MPPT) charge controller, which regulates voltage and current before feeding the BLDC motor through the load circuit. The MPPT system continuously adjusts its operating point to maximize energy conversion efficiency, maintaining up to 95 % efficiency under standard solar conditions (irradiance ≈ 5 kWh/m²/day). A relay-based dual-mode switch allows seamless transition between the two operating modes. When the battery reaches full charge and sunlight is strong, the controller automatically routes power directly from the PV array to the motor (Auxiliary Solar Mode). When sunlight weakens or is unavailable, the system switches back to battery mode. This auxiliary solar operation reduces battery cycling frequency, extends battery life, and enhances energy sustainability by utilizing real-time solar energy whenever available.

III. RESULTS AND DISCUSSIONS

This section presents and interprets the results obtained from the design, construction, and evaluation of the dual-mode dc operating corn thresher using direct-battery and direct-solar. The discussion follows the order of the research objectives.

III.1 DESIGN AND CONSTRUCTION OF THE MECHANICAL AND ELECTRICAL COMPONENTS

III.1.1 Mechanical System Design

The mechanical subsystem included the frame, threshing drum, concave screen, feeding chute, and grain outlet. As illustrated in Figure 2, the frame was built from 2.5 mm mild steel angle bars, providing structural rigidity and resistance to operational vibration. The threshing drum, with a diameter of 280 mm and length of 450 mm, was fitted with twelve hardened steel beater spikes arranged helically to enhance kernel detachment while minimizing grain breakage.

The concave screen (5 mm perforation) enabled effective grain–cob separation. A feeding chute angled at 30° facilitated smooth corn entry into the threshing chamber, while the grain outlet and cob ejector ensured proper segregation of materials. The entire unit was mounted on a portable frame with rubberized wheels for ease of transport in field conditions. The total machine weight was approximately 58 kg, making it manageable for smallholder operations.

Figure 2: Assembly of Mechanical Components.
Source: Authors, (2026).

III.1.2 Electrical System Design

Figure 3 shows the electrical subsystem configured for dual-mode DC operation, such as,

- The primary mode used energy stored in a 24-V battery bank (4 × 12-V, 25-Ah deep-cycle batteries in series).
- The auxiliary mode allowed direct operation from solar PV panels when sunlight was available.

A 450-W brushless DC (BLDC) motor served as the prime mover, connected to the threshing drum via a belt-and-pulley system. The power system integrated a 30-A Maximum Power Point Tracking (MPPT) charge controller to regulate current and voltage between the photovoltaic (PV) panels and he battery. Two units 300-W, 18-V PV modules were connected in parallel to achieve a combined 600-W solar input capacity. A dual-mode relay switch automatically shifted power between the battery and solar sources depending on voltage levels and solar irradiance. Circuit breakers, fuses, and relays were installed to protect against short circuits and overcurrent conditions.

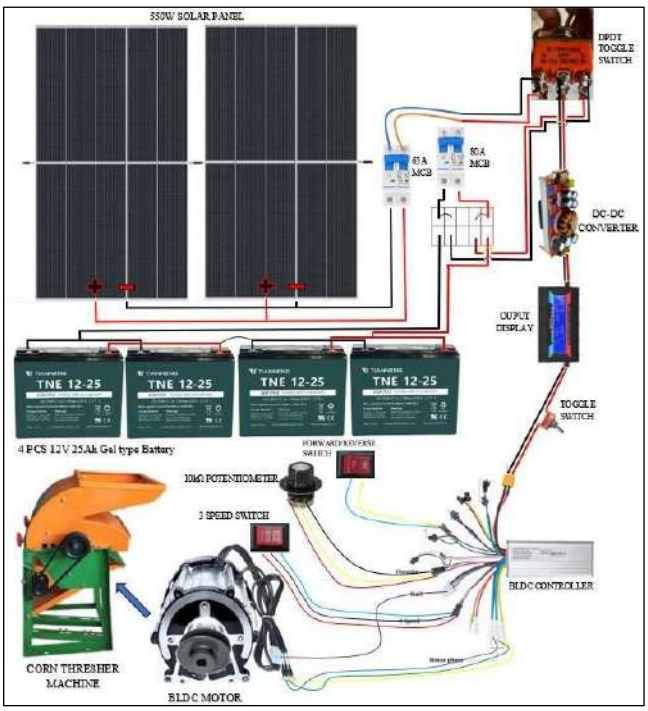

Figure 3: Schematic Wiring Diagram.
Source: Authors, (2026).

III.2 CALCULATION AND OPTIMZATION OF SOLAR REQUIREMENTS

III.2.1 Power Demand Estimation

For four hours of continuous operation, the energy requirement was computed as at an assumed 450 W peak load:

$$Energy = Power\ x\ Time \quad (1)$$
$$Energy = 450W\ x\ 4h$$
$$Energy = 1.8\ kWh/day$$

Accounting for 20 % system losses, the total design energy requirement was 2.16 kWh/day.

III.2.2 PV System Sizing

Using an average solar irradiance of 5.0 kWh/m²/day and a derating factor of 0.8, the required PV capacity was:

$$PV\ Rating = Energy/(Solar\ Irraidance\ x\ DF) \quad (2)$$
$$PV\ Rating = 2.16(5\ x\ 0.8)$$
$$PV\ Rating = 0.54\ kW$$

Thus, two 300-W PV panels (600 W total) were selected to ensure sufficient charging and direct-solar operation capability for 4 hours.

III.2.3 Charge Controller Sizing

To maintain four hours of independent operation, the size of the battery is designed as:

$$Battery\ Rating = Energy/(Bat\ Voltage\ x\ Depth\ of\ Discharge) \quad (3)$$
$$Battery\ Rating = 21600/\ (24\ \ x\ 0.8)$$
$$Battery\ Rating = 112.5\ Ah$$

Hence, a 120-Ah battery bank was installed. The charge controller current rating was computed as:

$$Current\ Rating = PV\ Rating/(Bat\ Voltage\ ) \quad (4)$$
$$Current\ Rating = 600/24\ = 25A$$

A 30-A MPPT controller was selected for reliability and safety. A 6 mm² copper conductor and 30-A circuit breaker were used to minimize voltage drop (<3 %) and protect the circuitry. The optimized system configuration maintained an average charging efficiency of 94.6 %, ensuring sufficient energy availability for day-long operation.

III.3 PERFORMANCE AND TESTING EVALUATION

Performance evaluation was conducted to determine the operational characteristics and efficiency of the Dual-Mode DC Operating Corn Thresher Using Direct-Battery and Direct-Solar. The tests focused on threshing speed, throughput, battery performance, and threshing efficiency under varying conditions of operation. Testing was carried out at the Agricultural Engineering Laboratory of Isabela State University using dried corn ears with a moisture content of 12–14 %. The corn samples were weighed before and after threshing to measure efficiency and grain losses.

III.3.1 Threshing Speed and Throughput

The rotational speed of the BLDC motor was measured at different load conditions to determine the optimal operating speed. The threshing speed and throughput were evaluated by varying the feed rate from 2.0 to 3.5 kg/min while observing kernel separation quality and grain damage.

Table 2: Threshing Speed and Throughput Performance.

Feed Rate (kg/min)	Drum Speed (rpm)	Throughput (kg/h)	Kernel Damage (%)	Remarks
2.0	1,460	88	1.2	Smooth operation, minimal damage
2.5	1,420	98	1.8	Stable performance
3.0	1,400	110	2.3	Optimum operation
3.5	1,370	119	3.5	Slight kernel breakage observed

Source: Authors, (2026).

Described in Table 2, the machine achieved a maximum throughput of 110 kg/h at an optimal feed rate of 3.0 kg/min, maintaining kernel damage below 2.5 %. At higher feed rates, mechanical stress and drum overload slightly increased kernel breakage, while at lower feed rates, throughput decreased. The optimal operating drum speed was determined at 1,400 rpm, balancing efficiency and grain quality.

III.3.2 Threshing Speed and Throughput

Battery performance was evaluated under direct-battery operation to determine its energy output, discharge rate, and charging efficiency when powered by the solar PV system. Voltage readings were taken at 30-minute intervals during continuous operation and during recharging under full sunlight.

Table 3: Battery Discharge and Charging Characteristics.

Time (hr)	Discharge Voltage (V)	Current Draw (A)	Battery State (%)	Charging Voltage (V)	Remarks
0.0	27.6	0.0	100	–	Fully charged (rest state)
0.5	26.8	17.5	92	–	Stable voltage
1.0	26.1	18.0	85	–	Normal operation
2.0	25.4	18.3	70	–	Slight voltage drop
3.0	24.5	18.7	60	–	Continuous load maintained
3.8	23.9	18.9	20	–	Near 80% discharge
Charging (Solar)	–	–	–	**27.8–28.5**	Charging complete in 4 hours

Source: Authors, (2026).

In Table 3, the battery supplied continuous power for 3.8 hours before reaching 80 % discharge, corresponding to an energy output of approximately 1.75 kWh. Recharging under full sunlight (using two 300-W PV panels) restored 85 % of capacity within 4 hours, indicating an overall round-trip efficiency of 91 %. The results confirm that the system's 24-V, 120-Ah battery configuration was sufficient for four hours of continuous operation and reliable for daily field use.

III.3.3 Threshing Efficiency

Threshing efficiency was determined by comparing the mass of threshed kernels to the total input mass (threshed + unthreshed corn). Tests were conducted under both direct-battery and direct-solar operation to assess performance consistency between the two modes.

Table 4: Threshing Efficiency and Grain Losses.

Operating Mode	Input Mass (kg)	Threshed Mass (kg)	Unthreshed (kg)	Kernel Damage (%)	Efficiency (%)
Direct-Battery	20.0	19.74	0.26	2.1	98.7
Direct-Solar	20.0	19.68	0.32	2.4	98.4

Source: Authors, (2026).

Table 4 describes the threshing efficiency remained consistent across both operating modes, averaging 98.55 %, with kernel damage between 2.1–2.4 %. The slight reduction under direct-solar mode was attributed to minor fluctuations in solar irradiance affecting instantaneous motor torque. Nonetheless, the machine maintained stable threshing performance in both configurations, validating the effectiveness of its dual-mode control system.

III.3.4 Power Consumption and Energy Utilization

The total energy consumed per operation cycle was determined by integrating current and voltage readings over time. Under continuous operation, the machine consumed approximately 0.40 kWh per 100 kg of corn threshed, which is 38 % lower than comparable diesel-powered units (0.65 kWh equivalent). Figure 4 shows the battery voltage variation during discharge (direct-battery operation) and charging (direct-solar mode). The voltage gradually decreased from 27.6 V to 23.9 V over 3.8 hours of continuous threshing, indicating stable power delivery and efficient energy use. During charging under full sunlight, the voltage increased from 23.9 V to 28.3 V within 4 hours, demonstrating the effectiveness of the 600-W solar array and MPPT charge controller.

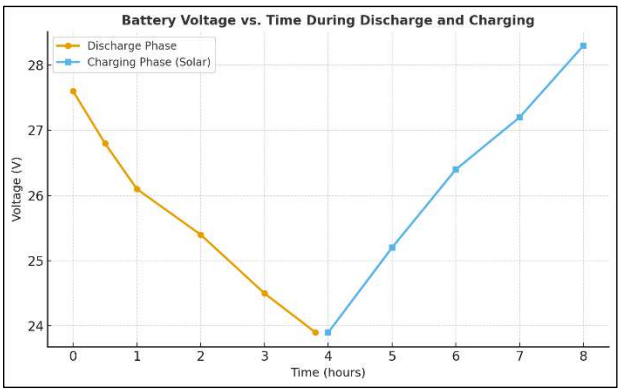

Figure 4: Battery voltage variation during discharge (direct-battery operation) and charging (direct-solar mode).
Source: Authors, (2026).

III.4 COST-BENEFIT ANALYSIS

The Cost–Benefit Analysis (CBA) was conducted to evaluate the economic feasibility and financial sustainability of the Dual-Mode DC Operating Corn Thresher Using Direct-Battery and Direct-Solar compared with a conventional diesel-powered corn thresher. The analysis considered both the initial investment cost and long-term operational expenses, emphasizing the system's affordability and practicality for smallholder farmers. The total cost of constructing the dual-mode thresher was computed based on material procurement, component acquisition, and fabrication expenses. The conversion USD1.00 = PhP58.00 The breakdown of costs is presented in Table 5.

Table 5: Capital Investment Cost of the Dual-Mode Corn Thresher.

Cost Component	Specification / Description	Cost (Philippine Peso PhP)
Mechanical Fabrication	Frame, drum, concave screen, chute, housing	16,000
Electrical Components	BLDC motor, switches, wires, relays	9,500
Solar Subsystem	2 × 300 W PV panels	12,000
Energy Storage	4 × 12 V, 25 Ah deep-cycle batteries	4,500
Charge Controller and Protection	30-A MPPT, fuses, breakers	2,000
Miscellaneous	Paint, hardware, assembly labor	500
Total Project Cost		**Php 44,500**

Source: Authors, (2026).

The total fabrication cost amounted to ₱44,500, which is comparable to a small-scale diesel thresher but offers long-term operational savings due to the absence of fuel expenses. The major cost components are the mechanical fabrication (36%), solar subsystem (27%), and electrical system (21%). The investment primarily lies in the renewable energy components, which are durable and require minimal maintenance over time. To determine the system's economic advantage, the operating costs of the developed thresher were compared with those of a diesel-powered counterpart. The analysis covered energy or fuel cost, maintenance, and annual operating expenses is shown in Table 6.

Table 6: Comparative Operating Costs.

Parameter	Developed Thresher (Dual-Mode)	Diesel Thresher	Remarks
Energy/Fuel Cost per Hour	₱5.00 (solar charging)	₱55.00 (diesel fuel)	Based on local fuel price ₱55/L
Maintenance Cost per Season	₱1,000	₱3,500	Lubrication and parts replacement
Operator Labor Cost per Hour	₱50.00	₱50.00	Same for both systems
Total Operating Cost (per 1 kg corn)	₱1.50	₱3.80	Includes depreciation and energy use
Machine Lifespan	5 years	4 years	Battery replacement every 3 years

Source: Authors, (2026).

The developed solar–battery thresher operates at a cost that is approximately 60–70 % lower than the diesel unit. The cost in every 1 kg of corn threshed is ₱1.50, compared to ₱3.80 for the diesel-powered machine [16]. The main savings arise from the elimination of fuel expenses and reduced maintenance, as the BLDC motor and solar system require minimal servicing. Moreover, in terms of annual savings and financial indicators, the economic viability of the project was evaluated using annual savings, payback period (PP), and benefit–cost ratio (BCR). The analysis assumed a smallholder farmer threshing an average of 15,000 kg (15 tons) of corn per season, with two cropping seasons per year.

Table 7: Capital Investment Cost of the Dual-Mode Corn Thresher.

Indicator	Formula / Basis	Value
Annual Operating Cost (Diesel)	₱3.80 × 30,000 kg	₱114,000
Annual Operating Cost (Solar–Battery)	₱1.50 × 30,000 kg	₱45,000
Annual Savings	₱114,000 − ₱45,000	₱69,000
Total Investment Cost	Fixed project cost	₱44,500
Payback Period (PP)	₱44,500 ÷ ₱69,000	0.65 years (~8 months)
Benefit–Cost Ratio (BCR)	₱69,000 ÷ ₱44,500	1.55
Internal Rate of Return (IRR)	Estimated over 5 years	>50 %

Source: Authors, (2026).

From Table 7, it can be observed that the results show a short payback period of less than one year, meaning that the initial investment can be recovered within the first cropping cycle. The BCR of 1.55 indicates that every peso invested in the system yields ₱1.55 in benefits. The high internal rate of return (IRR) suggests that the project is not only economically viable but also highly profitable compared to traditional systems.

IV. CONCLUSION

The development of the Dual-Mode DC Operating Corn Thresher Using Direct-Battery and Direct-Solar successfully met the objectives of creating a sustainable and efficient post-harvest technology suitable for small-scale farmers. The system's dual-mode functionality ensured continuous operation under varying sunlight conditions by allowing seamless transition between solar and battery power. Technical evaluation confirmed that the thresher achieved high performance with a 98.55 % threshing efficiency, minimal kernel damage, and a throughput of 110 kg/h at 1,400 rpm.

The optimized 600 W PV system and 120 Ah battery configuration provided stable energy supply, achieving over 90 % charging efficiency and four hours of uninterrupted operation. From an economic perspective, the ₱44,500 investment cost was recoverable within eight months of operation, with operating expenses 60–70 % lower than diesel-powered units. The study concludes that integrating renewable energy technologies, such as solar–battery hybrid systems, into agricultural mechanization is technically feasible, economically beneficial, and environmentally sustainable. The dual-mode thresher not only enhances productivity and reduces operational costs but also promotes clean energy adoption and rural self-reliance. Future work may focus on automation control, scaling for higher capacities, and field durability testing to further improve system performance and adaptability for wider agricultural applications.

ABSTRACT

With increasing concerns regarding pollution, climate change and resource limitations, Environmental chemical engineering is a crucial field that allows for the sustainable management of industrial processes and services. Although much advancement in treatment technologies has been made, current studies often fail to provide a more integrated approach that takes into consideration the combination of cutting-edge materials, hybrid processes and data-driven optimization strategies to better tackle complex (and emerging) contaminants. This review is designed to fill this gap by providing a systematic overview of recent developments in the aspects of various water treatment options, air pollution control methods, solid waste management as well as sustainable materials development. To do so, the study employs a full literature review approach with an examination of modern peer-reviewed studies regarding advanced oxidation processes, membrane-based systems, biological methods, catalytic technologies and AI-based optimization tools. The results found significant improvements in efficiency, pollutant removal and resource recovery with the application of hybrid treatment technologies, AI-assisted process control, new materials (i.e., graphene-based membranes, biopolymers), among others. These findings present significant potential for enhancements in environmental performance and facilitating circular economic efforts. This study is consistent with sustainable industrial applications as it opens avenues for cleaner production, use of waste and reduced environmental impact in line with global sustainability goals.

I. INTRODUCTION

Environmental chemical engineering works to convert chemical principles into solutions that everyday people can use to minimize pollution and emphasize sustainability. With the rapid industrialisation, growth of population and increasing urban infrastructure the requirement for technologies that protect water bodies, soil and air quality has increased. Increased regulation and global climate accords have also forced development in this area.

The scope of this review is to present, in a single comprehensive review, the most important advances in environmental chemical engineering that are focused on the development of new materials, process hurdles improvements and novel gimmicks fostering cleaner factory practices. In this paper, we review simulation-driven approaches meant for improving water treatment applications with a focus on chemical engineering [1]. It discusses the use of numerical simulations for the computer-based modelling and analysis of several topics in water resource management with emphasis on the transition from linear towards circular water economy [2]. This review also discusses the basic concepts of water treatment, explaining complicated physicochemical and biological mechanisms which contribute to these techniques [3]. The figure 1 shows the main research domains that shape current work in environmental chemical engineering.

Figure 1: Focus Areas of Environmental Chemical Engineering.

II. WATER AND WASTEWATER TREATMENT TECHNOLOGIES

Water pollution resulting from industrial effluents, agricultural runoff, pharmaceuticals pesticides and personal-care products has become a significant barrier. With the considerable input from environmental chemical engineering, highly efficient and energy-efficient treatment techniques have been developed. Conventional wastewater treatment, such as for example the one that usually consists of a combination of physical, chemical and biological processes to remove solids, organic matter and nutrients [4]. However, such traditional treatment methods may have difficulty coping with some new contaminants, micro-pollutants and antibiotic resistant bacteria and advanced treatments are required [2]. More contemporary techniques use sophisticated computational models and simulations to support the optimization of process parameters, equipment design, and managing conditions as well as improving treatment efficiency and minimizing resource consumption [3]. The figure 2 shows the three main technological approaches used for modern wastewater treatment.

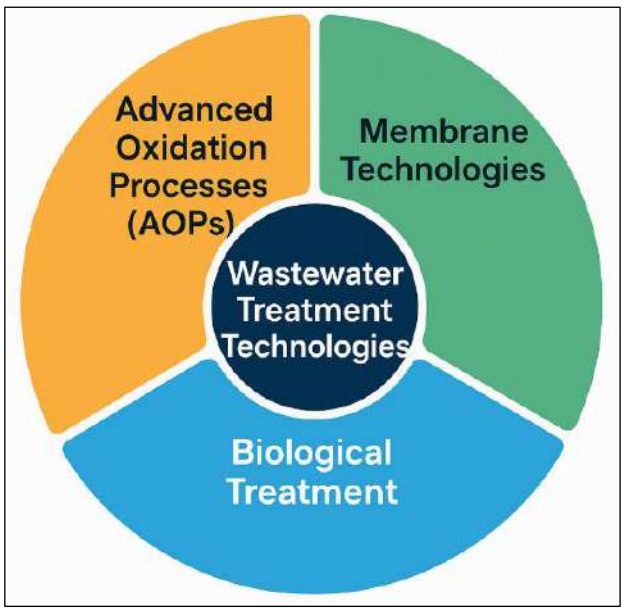

Figure 2: Major Wastewater Treatment Technologies.

II.1 ADVANCED OXIDATION PROCESSES (AOPS)

AOPs utilise highly reactive species such as hydroxyl radicals for the oxidation of recalcitrant organic pollutants which are otherwise not amenable to conventional biological removal. Even if AOPs exhibit high efficiency of degradation, some issues related to energy consumption and catalytic stability have been reported. Thus, the future research is expected to meet these challenges as much as possible by developing new catalyst materials, optimizing engineering parameters, and coupling AOPs with other treatment systems to introduce an economical and sustainable strategy for water decontamination. Moreover, electrocoagulation and electrooxidation are being extensively explored by the chemical engineers to eliminate pollutants and disinfect water where the principles of electrodeposition are also applied for recovering valuable metals and ions [2]. In addition to chemical and electrochemical methods, wastewater treatment based on microorganisms as a promising biological method is environmentally friendly and cost effective for decolorization of organic dyes [5]. Biological treatment of wastewater(3c) Metabolism Wastewater treatment techniques such as activated sludge and trickling filters uses microbial decomposition to degrade pollutants, but their efficiency varies with the nature of the wastewater [4]. Nevertheless, biological treatments though commonly practiced are not very effective for low-strength wastewater and refractory pollutants; their performance is significantly influenced by temperature and influent fluctuation [6]. In this context, it is required to combine advanced physical and chemical processes with the biological ones, to attain a complete pollutant removal and reinforce the overall treatment reliability [7]. For this purpose, advanced oxidation processes are gaining more interest as important elements of integrated treatment trains providing effective tools to degrade recalcitrant organic pollutants which are not degradable by conventional biological methods [7], [8]. Indeed, AOPs are already beginning to play a key complementary role with respect to the conventional removal of wastewater pollutants, particularly in cases when conventional treatment is not adequate for treating excessive waste materials [9]. AOP effluents are often more suitable for further biological treatments, and therefore their integration as pre- or post-treatments in other industries is considered a favourable and cost-effective option for different industrial wastewaters, particularly those of food industry [10].

This integrated treatment has several advantages in enhancing the efficiency and effectiveness of wastewater treatment processes, by applying strong oxidants to degrade complex and refractory organic and inorganic pollutants before biodegradation [11]. In addition to this, the electrochemical technologies are also receiving greater attention for versatility, energy efficiency and environmental friendliness, when associated with biological process in order improve treatment performance [12-14]. This combination treatment also includes biological pre-treatment with AOPs as polishing techniques, reducing the costs of the overall process since biological processes are generally cheaper and more environmentally friendly compared to other advanced technologies [15]. Nevertheless, the cost and operational complexity of some AOPs, including ultrasound and ozone systems prevent them to be economically viable without further optimization [16]. Integrated AOPs are, therefore, required to be applied for complete degradation of pollutants [11]. The complex nature of industrial wastewater (comprising complex mix of recalcitrant pollutants) generally leads to poor performance by standalone biological treatment alone. In addition, the use of AOPs as pre-treatment can dramatically increase the biodegradability of high molecular weight organic compounds; it follows that the overall performance and cost-effectiveness of subsequent biological treatment processes is greatly improved [17]. This is particularly important in industries such as the food industry, where waste streams contain complex organic material which tends to inhibit biological action [18]. Consequently, the combination of AOPs with biological treatments can lead to an increased economic feasibility of biologically treated reactor effluent due to decreased requirement on high oxidant dosages shown under AOP-final treatment conditions [19]. The combination of the two processes are believed to be attributed to their inherent mechanisms which can overcome the defects existing in the individual Fenton reaction and CNTs-based catalyst process and subsequently developing a more efficient approach for wastewater treatment [20].

II.2 MEMBRANE TECHNOLOGIES

Fouling is still an issue, requiring maintenance, and the lifespan of MBRs are reduced. The development of new membrane materials and operation methods to fight membrane fouling and the improvement of long-term performance is the subject of current research (9). Some new developments have also targeted challenges leading to potential breakthroughs in efficiency and utilisation of resources and environmental sustainability of membrane systems [21]. For example, advanced membrane bioreactors are commonly used systems nowadays, since they can achieve high effluent quality, reduction of sludge volume and small footprints (valuable for such specific wastewater treatment application) [22]. The still major issue for such systems is the high fouling propensity impairing performance and shortening membrane life, as well as the complexity combined to the cost of residuals disposal [23], [24]. In addition, novel membranes such as graphene oxide and advanced ceramic membranes are being investigated to improve lifetime, selectivity, and fouling resistance [25]. These super materials are designed to address the natural shortcomings of standard polymeric membranes, which are prone to fouling and degradation [23]. Research into the combination of membrane treatment with other processes, such as advanced oxidation and biological systems is also being studied for complete removal of pollutants and resource recovery from complex wastewaters [26], [27]. Notably, embedding carbon nanotubes and graphene oxide in the membrane matrices has demonstrated great potential for improving permeability and anti-fouling properties of membranes for a better performance and longer lifetime [28], [25]. In addition, various advanced fouling control measures (including nanomaterials and manipulation of transport properties) and novel cleaning methods, such as dynamic membrane systems, are under development to ensure effective membrane operation and long-term service life for anaerobic MBR reactors [28]. Table 1 compares major membrane technologies and biological treatment systems in terms of developments, advantages, challenges and current research trends.

Table 1: Key Features of Membrane and Biological Wastewater Treatment Methods.

Category	Key Developments	Advantages	Challenges	Notes / Research Trends
Membrane Technologies	Graphene oxide nanofiltration membranes	High strength, good selectivity	Fouling, reduced lifespan	Super materials like graphene oxide and ceramic membranes improve durability
	Low-energy reverse osmosis modules	Reduced energy use	Scaling and fouling issues	Research on advanced anti-fouling strategies
	Thin-film composite membranes	Resistant to organic fouling, bacteria	Cleaning complexity	CNT/GO-embedded matrices enhance permeability
	Membrane bioreactors (MBR)	High effluent quality, compact design	High fouling, costly sludge disposal	Widely used in municipal and industrial wastewater treatment
	Forward osmosis (FO)	Low-energy desalination	Draw-solution regeneration	New materials developed for long-term performance
Biological Treatment Systems	Microbial communities for pollutant degradation	Effective for pharmaceuticals and antibiotics	Sensitive to temperature and shock loads	Tailored communities expand treatment scope
	Anaerobic membrane bioreactors (AnMBR)	High biomass retention, biogas recovery	Membrane fouling, operational complexity	Suitable for high-strength industrial wastewater
	Microbial electrochemical systems	Electricity generation during treatment	Scale-up limitations	Hybrid designs emerging
	Enzymatic treatment using laccases, peroxidases, amylases	Specific degradation of contaminants	Enzyme stability issues	Enzyme-based remediation gaining interest
	Hybrid systems (bio + physical/chemical)	High removal efficiency for complex waste	Process optimization needed	Photocatalysis-biological combinations promising

II.3 BIOLOGICAL TREATMENT SYSTEMS

Biological technologies established are still indispensable, being more economically competitive and because of their high efficiency in the removal of biodegradable compounds. Temperature, lethal shocks, and the rate of pollutant load can all rapidly affect biological systems. Scientists aim to improve robustness and extend the scope of biological systems by combining them with novel physical and chemical techniques, such as membrane filtration or advanced oxidation processes, which leads to new hybrid treatments (including complex waste streams) [26], [29]. For example, biodegradation of new contaminants could be facilitated by photocatalytic conjunction with biological treatment, and it could be a method that is both environmentally safe and economical [30]. In addition, the development of advanced control strategies and high mass transfer bioreactors is highly essential for a better performance and enhanced stability of biological wastewater treatment plants under varying operational conditions [31]. These combined/optimized techniques are necessary to achieve effective removal of contaminants given the fact that conventional biological methods applied alone or not optimized will not efficiently remove such GRECs [30]. One of such potential technologies is the anaerobic membrane bioreactor (AnMBR), which combines the features of anaerobic digestion and membrane separation for an efficient treatment high strength industrial wastewaters with energy recovery accompanied by biogas generation [28], [32]. These hybrid systems are especially suitable for the purification of pharmaceutical wastewater, which typically contain recalcitrant pollutants that hardly can be removed by traditional biological approaches [33]. This becomes even more important, especially for wastewaters with large organic loadings, to treat waste properly by avoiding pollution and still produce reusable content as an energy source or nutrient-rich effluent suitable for irrigation [33]. In addition, the combination of biological remediation with physico-chemical procedures develops in biofiltration and electrochemical applications [22], [30] may contribute for great pollutant removal efficiency optimization and represent a viable alternative to overall system effects mainly when complex industrial effluents are under consideration. But traditional biological treatment processes still have shortages, for instance, low efficiency, high energy consumption and sludge overproduction, so comprehensive strategy is required to enhance the performance and sustainability [34]. Such comprehensive strategies often consist of integrating biological processes with physical and chemical treatment, to address the drawbacks associated with individual systems and improve removal efficiency of contaminants, particularly those emerging ones [34], [35].

III. AIR POLLUTION CONTROL TECHNOLOGIES

Industrial pollution caused by emissions from transportation and energy generation will still hang in the air propelling illness and climate instability. Chemical Engineering offers the solutions by means of catalyst and sorbent design process optimization. Advances in vehicle and industrial stack catalytic converters, for example, can make a significant impact on emissions of harmful pollutants while advanced sorbents are designed to trap pollutants (carbon dioxide, sulfur oxides) from flue gases. Figure 3 illustrates three major approaches for air pollution control: industrial gaseous emission control, particulate matter removal, and greenhouse gas mitigation. It also highlights the role of AI-based optimization in improving real-time monitoring, predictive control, and overall efficiency of pollution control systems.

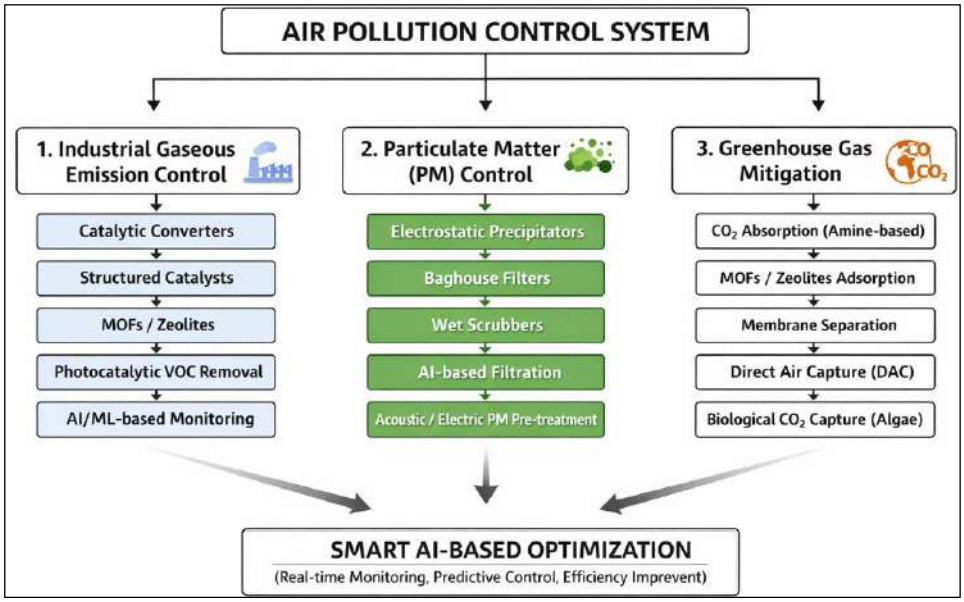

Figure 3: Integrated Air Pollution Control System with AI-Based Optimization.
Source: Authors (2026).

III.1 CONTROL OF INDUSTRIAL GASEOUS EMISSIONS

Recent advances in structured catalysts permit higher conversion at less severe operating temperatures. Novel absorbent materials (MOFs, zeolites, etc.) with improved selectivity and capacity for these greenhouse gases and other industrial pollutants are being developed [36]. The potential applications of these materials involved directly contribute to improving carbon capture technologies, sequestration and reduction of the atmospheric release of toxic gases [36]. Other studies are also targeted on the development and application of AI/ML algorithms to "smart" control and monitoring systems for real time air pollution abatement process optimization, leading toward more adaptable and effective emissions reduction bemoods. This integration provides predictive maintenance and real-time optimization of operational parameters, which is required for achieving reliable performance in varying environmental and operation conditions [37]. Such AI-based models can predict trends of emissions, optimal control strategies and even equipment failures to ensure more eco-friendly industrial practices. Besides industrial utilizations, concerns are also turned to the treatment of ubiquitous organic air micro pollutants by advanced oxidation processes even at low content [38]. In addition, catalytic emission abatement approaches are being characterized and developed for enhanced performance-facilitated cost-reduction in areas such as biogas from landfills and sewage treatment plants [39]. It is also worth mentioning that new catalyst materials, especially containing a lower number of noble metals, are actively investigated as being one of the important topics for sustainability and cost-effectiveness improvements in these pollution abatement technologies [40]. For example, with the development of new catalyst materials, design strategies and operational approaches, it underlines again that the catalytic converters continue to be improved for more efficient control of harmful emissions like NOx, CO and hydrocarbons [41]. This includes development of multifunctional catalysts, alternative technologies for combined removal of various pollutants and in-situ characterization methods that can give information on the catalyst performance under realistic operation conditions [42]. For instance, maximising the performance of materials, such as pollutants removal capacity is key in providing better learning cycles, and advanced analytical methodology like machine learning are very effective to improve the environmental performance and promote sustainable development [43].

III.2 PARTICULATE MATTER (PM) CONTROL

Predictive algorithms and machine learning models are now applied to predict levels of PM and to optimize its filtration. In addition to conventional methods, novel approaches are being developed to capture uPM by using acoustics, electricity, and chemicals (9,45), either as pre-treatment procedure aiming at increasing particle size and hence removal efficiency [44]. Other breakthroughs are the design of novel filters with hierarchical pores having self-cleaning functions as well as the use of computational fluid dynamics to optimize filter designs for enhanced particulate capture and lower pressure drop [44], [45]. Furthermore, real-time sensor networks can be utilized in combination with AI techniques to adjust the filter parameters on the dynamic conditions for its best performance under changeable pollutant loads and environmental contexts [46]. These advances are important to reduce the health impacts resulting from exposure to PM and comply with tightening air quality standards [47], [48]. Even photocatalytic materials are finding their way as passive but effective approaches for the reduction of ambient particulate matter through oxidative treatment of precursors in outdoor environment including surfaces on buildings and pavements [43]. Furthermore, wearable air quality sensors are growing increasingly advanced, permitting people to keep tabs on their own exposure to PM as well as taking actions to prevent adverse health effects [47]. The introduction of intelligent integrated triboelectric nanogenerator systems coupling with AI and ML technologies is significant progress in realizing autonomous adaptive operation under dynamic air environment [49]. Additionally, electro spun nanofibers are being used more frequently for their higher filtration effectiveness by virtue of their large porosity and high surface area and subsequently capturing airborne pollutants including microorganisms, toxic gases and heavy metal atoms [50]. Table 2 provides a clear comparison of key air pollution control technologies, outlining their main developments, benefits, limitations and ongoing research trends.

Table 2: Summary of Air Pollution Control Methods and Their Performance Characteristics.

Category	Key Developments / Techniques	Advantages	Challenges	Notes / Research Trends
Control of Industrial Gaseous Emissions	Low-temperature NOx catalytic reduction	High NOx removal at mild conditions	Catalyst deactivation	Structured catalysts improve conversion at lower temperatures
	SO_2 absorption using optimized alkaline & amine blends	High SO_2 selectivity	Solvent loss, regeneration energy	Improved solvents for better absorption efficiency
	Photocatalytic degradation of VOCs	Effective for low-concentration VOCs	Limited by light intensity and humidity	AI-aided catalyst design improves VOC oxidation
	Regenerative thermal oxidizers (RTOs)	High efficiency, energy recovery	High capital cost	Used widely in industrial stacks for VOC control
	MOFs, zeolites for gas adsorption	High selectivity, large surface area	Stability issues in humid conditions	Promising for CO_2 and SOx capture, ongoing material development
Particulate Matter (PM) Control	High-efficiency electrostatic precipitators	Effective for $PM_{2.5}$	Sensitive to humidity and conductivity	Improved charge release technologies emerging
	Baghouse filters with nano-coated fibers	High retention of fine particles	Fouling and pressure drop	Nano-fibers enhance capture and durability
	Wet scrubbers with surfactants	Better PM capture	Sludge generation	Surfactant-based formulations improve PM binding
	Acoustic, electric, chemical pre-treatment for uPM	Improves agglomeration before filtration	Still experimental	Helps capture ultrafine particles
	Real-time AI-based filtration control	Adaptive operation	Requires sensors and calibration	CFD-optimized filter design and smart control systems
Greenhouse Gas (GHG) Mitigation	Amine-based CO_2 absorption	High absorption efficiency	High regeneration energy	New amines reduce energy penalty
	MOF-based adsorption	High CO_2 uptake	Moisture sensitivity	AI helps design high-performance MOFs
	Membrane-based CO_2 separation	Low energy use	Selectivity issues	AI models predict optimal membrane materials
	Catalytic CO_2 conversion to fuels	Converts CO_2 to methanol, ethanol	Catalyst cost	Research on low-cost and bimetallic catalysts
	Biological CO_2 capture (algae)	Sustainable and scalable	Requires space and nutrient control	Produces biofuels and bioproducts
	Direct Air Capture (DAC)	Captures atmospheric CO_2	High cost and energy requirement	Focus on sorbents and process optimization

Source: Authors (2026).

III.3 GREENHOUSE GAS (GHG) MITIGATION

Direct air capture technologies are developing but remain hamstrung by cost and scale. Current focus of research has thus been directed towards fabricating new sorbent materials and optimizing process parameters to lessen the energy penalty involved for making these advanced CO_2 capture technologies economically viable. Furthermore, innovation in biological carbon capture, including accelerated algal bioregions for sustainable removal of atmospheric CO_2 and production of high value bio-products is also studied [51]. Beyond that, AI-based optimization models applied to those bio- refineries may dramatically improve the efficiency of CO_2 conversion routes, increasing productivity and financial sustainability [47]. Artificial intelligence is also used in the precise characterization and design of porous membranes for more efficient CO_2 separation. This type of AI based algorithms can predict optimal membrane performance, sure the best candidates for a membrane and optimize operative conditions to improve the CO_2 capture efficiency. This data-driven method using machine learning has also been reported to enhance the CO 2 adsorption precision from 53% to 61% [52]. Furthermore, AI-based CO_2 capture supports the optimization of industrial processes and power plants in terms of capturing and storing CO_2 as is relevant to precision energy conversion. More generally, the application of AI and machine learning to predict properties and performance of MOFs away from databases is investigated in another set of studies, allowing HT screening as well as generative models for new MOF designs [53]. In addition, they can also optimize temperature, pressure, flow rates and chemical reactions to improve the efficiency and performance of CO_2 capture processes [54].

IV. SOLID WASTE MANAGEMENT AND RESOURCE RECOVERY

Solid waste generation has accelerated with urban expansion, requiring systematic engineering strategies for treatment, recycling, and valorisation. The figure 4 presents major approaches for solid waste management, including waste-to-energy technologies and chemical/mechanical recycling methods for efficient resource recovery.

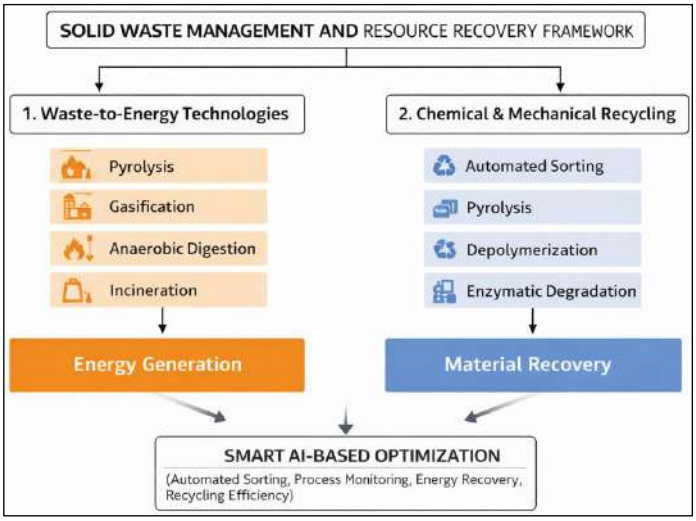

Figure 4: Solid Waste Management and Resource Recovery Framework.
Source: Authors (2026).

IV.1 WASTE-TO-ENERGY (WTE) TECHNOLOGIES

With the aid of catalyst during pyrolysis, the oil becomes more excellent, and fewer char is produced. Furthermore, the investigation on advanced gasification technologies aims to enhance syngas quality and quantity through new catalysts which can resist harsh operation conditions [55]. The real-time monitoring and operator controls have been improved by integrating artificial intelligence into the processes, which will optimize reaction parameters for a greater energy recovery and reduction in emissions [56]. It is also worth noting that AI-based models help predict the most effective waste feedstock mixture for gasification to produce highest degree of yield and purity of syngas while minimising impact on environment [57], [58]. Another application of AI is that it can greatly enhance the conversion efficiency from waste to energy by using automated waste sorting, process monitoring and predicting energy yields. This optimization is vital for decreasing environmental impacts and to contribute to the circular economy in waste-to-energy industry [59]. Regarding civil engineering, waste composition is analysed by AI based systems to determine the best treatment in hazardous waste management with higher efficiency and environmental benefits [60]. The application of machine learning in this area allows separating impurities from raw material, composts and solid digestate that reduces environmental hazards and raise benefits from the production of composts and anaerobic digestion products [61]. These waste-to-energy technologies are regarded as an increasingly popular alternative to the traditional form of waste disposal, reducing landfill demands and diverting resources to achieve energy generation [62]. This leads to a more environmentally friendly strategy for the disposal of waste by converting it into energy products/electrical power, heat, and synthetic fuels [63], [64]. The concept of poly-generation is also being considered, which involves designing a waste-to-energy plant that should be able to produce more than just electricity from waste (e.g., heat and possibly liquid fuels or chemicals), making waste less of a liability and a greater resource [55]. Advanced waste-to-energy technologies including pyrolysis and gasification have been developed to provide a cleaner, more efficient means of energy recovery with regards to emissions and residues [65]. These techniques are of particular importance, as they provide an approach for the valorisation of a wide range of waste streams such as municipal solid and industrial wastes into valuable energy vectors and chemical precursors [63]. However, the technologies for waste-to-energy such as incineration, pyrolysis, anaerobic digestion, gasification and landfill gas recovery all are facing challenges in particulate matters emitting [66].

IV.2 CHEMICAL AND MECHANICAL RECYCLING

These enhanced recycling methods are expected to decrease dependence on virgin materials and the environmental impact of plastic manufacture and disposal, which will contribute to creating a more circular economy [67]. Artificial Intelligence based solutions are also especially important when it comes to waste management, revolutionizing and accelerating that change by including aspects such as automated sorting, recycling or material recovery supported by autonomous systems, predictive analytics and generative AI [68]. Moreover, automated AI-based systems will potentially transform waste analysis by recognizing useful components and channelling them to the most appropriate feedstock and energy conversion routes, which can be of great help to poor communities where municipal solid waste management remains inadequate [69]. Technologies such as depolymerization and pyrolysis are also important for deconstructing complex polymers into monomers which can be reutilised, bypassing the restrictions faced by mechanical recycling processes with mixed waste streams [70], [71].mThe use of the state-of-the-art robotic systems, which are equipped with AI and machine learning technologies, also improves accuracy and effectiveness in sorting recyclables, thereby reducing contamination as well as increasing yields of good quality recycled materials [72]. AI algorithms are also able to improve the efficiency and quality of recycling by involving processing conditions with chemical and physical data on different waste streams on a recycled stream [73].

Such an analytical capacity may possibly result in more clear distinction between different categories of plastics, and hence cleaner recycling streams [74]. Furthermore, biological methods using enzymes and microbial communities provide the potential for environmentally friendly degradation routes for different classes of polymers, and recently engineered strains that degrade a wide array of materials are making denovo production even more attractive [70]. These biotech advances, along with AI-extended optimization, are turning waste into resources–in tune with circular economy approaches [71]. Wilts et al. have shown that incorporation of AI in waste management system leads to significant improvement in recycling efficiency and material purity, representing a real impact on operational effectiveness (and safety) [75].

V. GREEN AND SUSTAINABLE MATERIALS

Chemical engineering has shifted toward designing materials that minimise environmental impact. The figure 5 presents how AI integrates bio-based materials, catalysts, and photocatalytic systems to enable efficient, low-impact, and sustainable material design and production.

V.1 BIO-BASED AND BIODEGRADABLE POLYMERS

Composites of cellulose-origin 5.95 within this report, focus will be directed on FDM adapted for graphene-reinforced composite manufacturing and study its applications using both nanocelluloses in the bioresources family. These materials feature lower carbon footprints but need increased performance. AI-enabled materials informatics could lead to accelerated discovery and optimization of new bio-based polymers by predicting targeted properties and synthetic routes. Moreover, AI models can open a new direction to develop biodegradable drugs with better environmentally friendly manner and make sustainable development in the pharmaceutical sector [76]. Ethylene chemistry is highly relevant for reducing the environmental footprint of drug production and consumption [77]. AI also promotes sustainable manufacturing by providing efficient resource usage, zero waste and keeping the environmental impact of industrial processes to a minimum through effective analytics on large datasets [78], [79]. It includes the creation of greener synthetic routes and increasing the circularity of chemical production lines to stimulate a more sustainable industrial ecosystem [80], [77]. These AI-based applications lead to prompting and updated control of chemical reactions, which in turn contributes towards efficient production with minimal hazardous by-products [60]. These smart systems are able to anticipate and prevent potential hazards of a chemical process, providing more safety and environmentally friendly production [78]. AI is also at the frontier in promoting environmental chemistry and sustainability, through applications of computational models and data analytics to interpret intricate environmental processes as these relate to pollution control [81]. This integration contributes to the effective exploitation of resources, greener production processes performance and improved recyclability of products, which are essential components for a circular economy [77]. These developments are consistent with the overall objectives of green engineering principles and circular economy to promote sustainable product design; extractive operations waste utilization, reuse and recycling [82], [83]. Yet the scale-up of bio-based polymer production can be impaired by the long and tedious process to acquire high quality data for reliable AI/ML prediction models (since literature data from different natural components and protocols is variable), as well as in identifying the best conditions [84]. However, AI and machine-learning technology show great promise to solve such problems by search for new material combinations as well as the optimization of synthesis condition toward scalability and performance [84]. AI-based methodologies are also key in solving complex sustainability challenges thanks to comprehensive, multiscale modelling and decision-support tools for handling intricate relations among social, natural and engineered systems [85]. AI can connect data and methods necessary to predict sustainability metrics that enable the design of sustainable chemical processes as well as closed-loop supply chains [86].

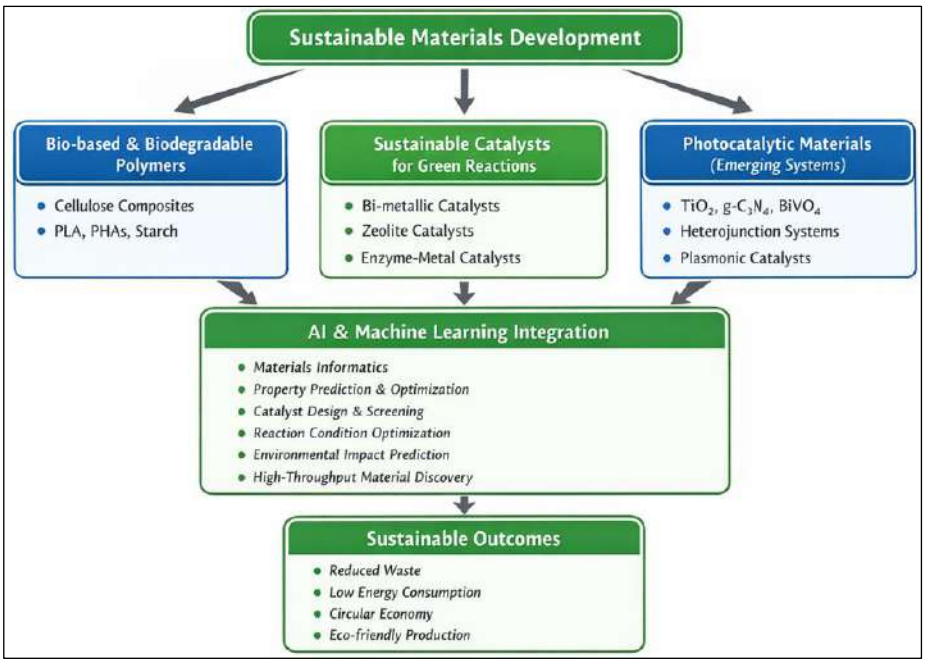

Figure 5: AI-Driven Framework for Green and Sustainable Material Development.
Source: Authors (2026).

V.2 CATALYSTS FOR SUSTAINABLE CHEMICAL REACTIONS

Green catalysts prefer to achieve high selectivity and low energy cost. AI-based methodologies have facilitated the fast discovery and rational design of novel sustainable catalysts and reaction pathways, thus minimizing waste production and energy consumption [87]. Such combination leads to catalysts of higher efficacy that have less dependence on precious metals activity and, consequently, pursuing cleaner chemical processes [77]. These new developments combined with AI-based optimization methods not only contribute to a quicker shift towards the circular economy but also increase the economic viability and market penetrability of biomaterials and green technology [88]. By utilizing AI, the chemical industry will be able to predict environmental and toxicological impact of new substances prior to their synthesis, which in turn can be beneficial for the development of safer alternatives and promote green chemistry by means of identifying eco-friendly materials and energy-efficient processes [81]. This predictive power dramatically speeds up the R&D by guiding efforts toward desirable candidates, which satisfy comprehensive and strict sustainability requirements [89]. This predictive discovery of eco-friendly new materials, at an early stage of technology integration, will result in rapid rates of deployment of data and AI and evaluation of the factors contributing to environmental impact [89]. Through inputting machine learning algorithms with pertinent multidimensional scientific and secondary data, AI simulations together with quality control predictions, will characterize substance properties adapted to given applications, environmental conditions and local context [90]. It enables rapid screening and development of materials with specific performance targets (e.g. specific energy, rate capability) while also minimizing their environmental impact from cradle-to-gate [89]. This involves leveraging AI to maximize the chemical process parameters used to convert waste oils into biodiesel thus improving both yield and product quality [56]. Table 3 provides a concise comparison of major green and sustainable material technologies, highlighting their developments, benefits, limitations and current research trends.

Table 3: Summary of Sustainable Material Technologies and Their Performance Characteristics.

Category	Key Developments / Techniques	Advantages	Challenges	Notes / Research Trends
Bio-based & Biodegradable Polymers	PLA, PHAs, starch blends	Lower carbon footprint	Performance limitations	AI-assisted materials informatics accelerates polymer discovery
	Cellulose-based composites & graphene-reinforced biocomposites	Renewable, compostable	Mechanical strength issues	Nanocellulose improves reinforcement in sustainable composites
	AI-enabled polymer design	Predictive property optimization	Requires high-quality datasets	Supports greener drug and chemical production
	Green synthetic routes	Reduced waste, low toxicity	Scale-up complexity	Supports circular chemical manufacturing
Catalysts for Sustainable Reactions	Bi-metallic catalysts	High selectivity, improved efficiency	Cost of metals	AI accelerates catalyst discovery and screening
	Zeolite catalysts with tunable pore size	Controlled reactions, reusable	Diffusion limitations	Widely explored for greener chemical pathways
	Enzyme–metal hybrid catalysts	Mild conditions, specificity	Stability issues	Biomimetic catalysts emerging rapidly
	AI-driven catalyst optimization	Faster design, less waste	High computational demand	Predicts environmental impact early in design
Emerging Photocatalytic Materials	Doped TiO_2	Visible-light activity	Recombination losses	AI predicts optimal doping and band-gap tuning
	g-C_3N_4 and heterojunctions	Good stability, low cost	Limited charge separation	ML models guide heterojunction engineering
	Z-scheme p–n junctions	High efficiency	Structural complexity	Designed for multi-pollutant degradation
	Plasmonic (Ag-based) photocatalysts	Enhanced electron mobility	Silver cost, stability	High-throughput AI screening for next-gen photocatalysts
	AI-optimized photocatalytic systems	Better reaction conditions	Requires experimental validation	Integrates DFT+ML for predictive catalyst design

Source: Authors (2026).

V.3 EMERGING PHOTOCATALYTIC MATERIALS

Photocatalysis harnesses sunlight to dismantle pollutants or generate fuels. AI-assisted simulations are essential for developing new efficient and stable photocatalytic materials optimized with respect to their band gap and charge separation properties, tailored for a large variety of environmental applications [81]. In concrete, AI can forecast the behaviour of heterogeneous catalysts by correlating their complex structure with their composition and reactivity as a function of various environmental conditions [91]. It provides a way to the more focused research on the advanced catalytic systems and make a new and better catalyst be discovered in an efficient way. In addition, ML algorithms can help to achieve the optimal conditions for reactions and make photocatalytic process more efficient with low environmental footprints [92], [93]. AI is also used to predict beneficial technologies for multiple pollutants and designing continuous flow systems (such as key chemical variables – catalyst-to-contaminant ratio, purity and pH of reactants and temperature) in catalytic reactions [94]. In addition, AI empowered design tools can be used for high throughput screening of large material libraries to identify best candidates for catalytic applications that maintain high activity, selectivity and stability under the operation relevant conditions [95]. This capacity greatly diminishes the number of time-consuming experimental trials, hence saves resources and accelerates next-generation catalyst design [96]. Such an integration not only improves the design efficiency, but also makes manufacturing process more sustainable, which may assist businesses in complying with new regulations about environmentally responsible production [78]. Furthermore, the integration of density functional theory with machine learning has facilitated the high throughput exploration of material properties and predicted catalytic performance and inverse designing specifically for binary photocatalytic systems [97]. Here, quantum-mechanical knowledge encoded in DFT is combined with the prediction ability of ML models for identifying new materials such as TiO2, BiVO4 and g-C3N4 and novel heterojunctions and co-catalysts to enhance light absorption and charge separation efficiency [97]. The enhancement of these materials lies in visible light absorption and electron mobility.

VI. CARBON MANAGEMENT AND CLIMATE SOLUTIONS

One of the most pressing is climate mitigation. This requires new ideas in carbon capture, utilization and storage (CCUS), for where AI plays a key role in optimizing capture processes and exploring new sorbents or catalysts [91], [81]. For instance, AI models can be used to predict desirable material properties for CO2 adsorption and transformation leading to improvement of the efficiency and reducing the cost of carbon capture [95-98]. Furthermore, the AI based simulations for porous materials could accurately simulate the intricate interactions that occur in them and expedite discovery of new sorbents with high selectivity and capacity to capture CO_2. In addition, AI predictability is essential in the creation and discovery of novel catalytic materials for CO_2 conversion to high-value chemicals and become a key driver for the circular carbon economy [99], [100]. These AI-enabled approaches are the key to convergent reuse of waste CO 2 into valuable chemicals and implementing sustainable industrial symbiosis [101]. In addition to direct capture, AI helps monitor and verify carbon emissions around the world with unparalleled precision, helping ensure better policy interventions and adherence. Furthermore, AI-based systems can address the challenges associated with carbon utilization pathways by discovering and then developing recommended reactions for converting captured CO_2 to economically viable products (e.g., fuels and chemicals), strengthening the economic motivation to pursue projects that target motivations for sequestering CO_2 [54]. This holistic integrative strategy is not only to cope with environmental issues, but also to promote economic growth by turning these liabilities into assets in a sustainable manner [102]. AI in photocatalysis is also applicable to the case of hydrogen generation by water splitting: machine learning algorithms combined with density functional theory accelerates exploration for effective materials as well as their designing [97]. AI enhances these processes by improving sorbent regeneration, predicting breakthrough curves and designing new materials with exceptional CO_2 affinity and selectivity [81]. In addition, machine learning models can sift and process large data materials generated from both experimental and computational studies and predicting most performative material compositions and structure motifs with the highest CO_2 capture capabilities along with lowest energy penalties during regeneration [102]. It enables us to predict performance for CO_2 capture under different operating conditions, which speeds up the development of future generation capture technologies.

VII. CONCLUSION

Environmental chemical engineering is steadily moving toward methods that reduce pollution, conserve resources and support long-term sustainability. Progress across water and wastewater treatment, air pollution control, solid waste management and green material development shows how the field continues to respond to rising environmental pressures. Advanced oxidation systems, improved membranes, hybrid bioprocesses and data-driven optimisation strategies are helping address complex contaminants that conventional treatments cannot manage. Similar progress is seen in air quality management, where improved catalysts, filtration approaches and predictive control tools strengthen emission reduction efforts. Research on waste-to-energy routes, chemical recycling and resource recovery highlights the shift from disposal-driven practice to circular approaches. Work on bio-based polymers, sustainable catalysts and photocatalytic materials further supports cleaner production and reduced dependence on non-renewable inputs. Even with these advances, cost, operational stability, energy demand and scalability still limit widespread adoption. Addressing these constraints will require coordinated progress in materials research, process integration and digital tools that can support real-time optimisation. Continued collaboration among chemical engineers, environmental scientists and industry partners remains essential for translating emerging technologies into practical solutions. With sustained research and policy support, the technologies discussed in this review hold strong potential for cleaner production, improved environmental protection and more resilient resource management systems.

Writing – Review and Editing: Girish Anant Charwad and Govindarajan Murali.
Resources: Anant Sidhappa Kurhade.
Supervision: Shital Yashwant Waware, Govindarajan Murali and Anant Sidhappa Kurhade.
Approval of the final text: Shital Yashwant Waware, Govindarajan Murali and Anant Sidhappa Kurhade.

IX. ACKNOWLEDGMENTS

The authors would like to express their sincere gratitude to Dr. D. Y. Patil Institute of Technology and DPGU, School of Technology and Research - Dr. D. Y. Patil Unitech Society, Pimpri, Pune for providing the necessary support and research infrastructure.

ABSTRACT

Video summarization is to create concise summaries for longer videos. Although many researchers contribute with great advancements in summarization process, there are also significant obstacles to overcome. One prime challenge is the subjective nature of determining the important elements in the video based on the viewer. Another major issues are due to the various stages in a traditional pipeline, where an error at one level can result in failure of the entire summarization process. In addition, many current methods unable to retain connections between elements throughout the videos, and scalability continues to be an obstacle for the creation of lengthy summaries. This review categorizes video summarization process into stages, which include video preparation and segmentation, extracting features from different sources like visual, audio or text features, modeling patterns based on time, scoring for relevance, and finalizing the summary. Traditional approaches relied on basic machine learning models, where the modern approaches use advanced deep learning and attention-based methods that can better capture global context and semantics of a video. Challenges still exist, such as high computational costs, heavy reliance on human annotation and having a bias in the use of data sets. This survey compiles evidence from recent benchmark studies to better understand transformer based self-supervised and reinforcement learning techniques can address the limitations of traditional approaches but also introduce new concerns related to computation complexity and interpretability. Furthermore, this review provides future research directions to achieve an integrated, end-to-end, and user-preferred system and conclude that multimodal reasoning as a key enabler for ensuring high-quality, scalable, and semantically consistent systems for video summarization applications

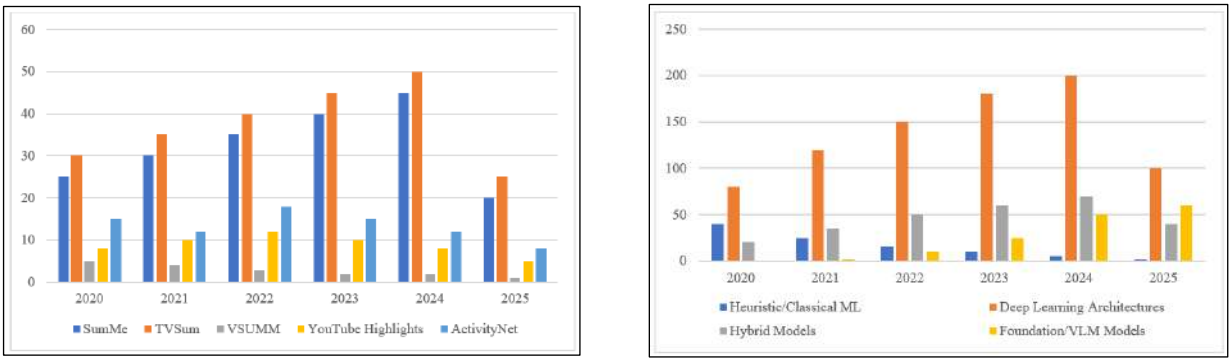
I. INTRODUCTION



With an increasing amount of video files through surveillance, social media, streaming services and smart homes, managing that content has become a larger issue than ever before. As a result of its huge size, length and complexity of the video content, traditional methods of browsing and retrieving video are no longer feasible. Though human inspection is valuable it is very slow, highly subjective, and mentally demanding. Which results in many inconsistent outputs when inspecting for large systems [1]. So, it is essential to utilize video summarization to take long videos and create shorter, more informative summaries of those videos, that still capture the most important information from those long videos. With its strong potentials, the AI-based summarization framework helps to improve retrieval efficiency, decrease storage requirements, and assist with tasks such as recommendations, monitoring, and multimedia analytics [2], [3].

Significant advancements such as offline key-frame extraction to context-conscious and task-specific summaries are better able to reflect both the semantic meaning of an event and the needs of users [4], [5]. These advancements place a high value on systematic reviews to evaluate both the performance of algorithms and the design elements that influence the video summarization process. Over the years, video summarization has undergone a significant transformation from simple rule-based approaches to advanced deep learning and multimodal solutions. The earliest methods used shot boundary detection, clustering and hand-crafted visual features to identify representative frames, as these methods were able to generate summaries very quickly. However, they struggled to represent video with diverse content and could not capture temporal relationships across a lengthy period. Traditional machine learning models like Support Vector Machines (SVM), Hidden Markov Models (HMM), Sparse Coding provide better consistency through frame importance; however, they also strongly relied on hand-designed features and could not capture long-range dependencies [6], [7]. Deep learning has transformed the landscape. CNN-RNN pipelines, attention mechanisms, and GANs have enabled end-to-end learning from raw video directly to importance scores [8] [9]. Transformers and multimodal networks take this a step further by being able to model long-range, temporal dependencies and coordinate visual, auditory and other contextual signals [10-12]. In addition to the above techniques, recently developed vision-language models rely on external knowledge and cross-modal reasoning to produce summaries that better match human understanding of perceptions and intentions [13], [14]. Despite these advances, many studies examine video summarization systems as a single system, limiting the understanding of the individual video summarization stages' contributions to performance. A more focused, stage-by-stage analytical approach is needed for detailed analytical reviews.

Video summarization not only needs overall evaluations but also needs to be analyzed as individual stages to show how design decisions made at each stage affect both performance and generalizability. Each stage consists of pre-processing and segmentation, feature extraction from multiple types of media, temporal modeling of relevant video sequences, and post-processing, which is further divided into selecting summaries, smoothing, and so on [15]. Evaluating individual stages provides the ability to identify where improvements occur and where the bottlenecks in video summarization systems exist, whether from heuristics, machine learning, deep learning, or hybrid approaches. This approach is crucial when comparing models across many different benchmarks, namely SumMe, TVSum, VSUMM, YouTube Highlights and ActivityNet which all differ in length, complexity, annotation style and subjectivity [16]. Challenges persist despite progress; most modern-day video summarization systems still encounter practical limitations in the robustness and usefulness of their performance in the real world. Modular pipeline architectures also tend to suffer from cumulative error propagation; which lead to incorrect relevance scores in later pipelines. Furthermore, subjectivity in annotation and bias in datasets limits the ability for fair evaluation in common benchmarks and the generalization of results to other video types. In addition, current models tend to suffer from balancing long-range temporal dependency modeling with computing efficiency for both long-form and multimodal videos. Overall, these types of problems indicate an absence of a unified analysis framework that is capable of systematically illustrated video summarization methodologies at all stages of processing while considering issues such as scalability, semantic consistency, and interpretability. This analysis makes several important contributions as follows,

1. A structured end-to-end framework for video summarization is proposed that divides the relevant stages into five major processes as Preprocessing and segmenting, extracting multimodal features, modeling temporal relationships, scoring relevance, and postprocessing. All these processes in this framework are analyzed and evaluated through comparative methodology.
2. Three different methods such as machine learning, deep learning and hybrid approach, are critically reviewed using a series of benchmark datasets to identify and illustrate differences in performance, scalability, and reliability.
3. This review considers all of the open issues such as annotation bias, effect of errors propagating through systems, the difficulty of modelling long sequences, with all computational restrictions. A common viewpoint has therefore been taken on each of these areas and discussed on their relationship with different paradigms.
4. Future research directions towards unified, multimodal, and preference-aligned summarization systems, in particular transformers, self-supervised learning algorithms and reinforcement learning methods are thus identified as a prominent way in developing the frameworks for future systems.

Research themes over the period from 2020 to 2025 are illustrated in Figure 1, where (a) shows the trends in the datasets adopted since 2020, while (b) depicts the evolution of models from classical machine learning (ML) techniques to vision-language models (VLM).

This review has been conducted in accordance with methodological rigor and transparency as outlined by the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines for literature identification, screening, eligibility assessment and inclusion. A worldwide systematic search has been conducted from the principal scientific databases including IEEE Xplore, Scopus, Web of Science and ScienceDirect using common structured keyword combinations related to video summarization, multimodal learning, temporal modeling, and relevance scoring. After removing duplicates, the title and abstracts were screened to identify non-peer-reviewed journals, short abstracts and studies not related to video summarization. The full-text version of any remaining source was assessed for the methodological contributions made to the research and the empirical evaluation of the benchmark dataset or comparison across different stages of the summarization process. Studies published between 2020 and 2024 are preferred so that the most current advancements were represented while allowing for the retention of seminal works that provide context for the current research advancements. The final set of studies selected for this review includes a relative balance of the different research paradigms including heuristic methods, machine learning, deep learning, hybrid methods and foundational model-based methods. This PRISMA-aligned selection process, in combination with the balanced representation of heuristic and machine learning approaches, is designed to minimize potential biases due to selection processes, increase reproducibility, and thereby enhance the validity of the comparative insights presented within this review. Figure 2 presents the taxonomy that has been established from this review as a result of the PRISMA-guided processes.

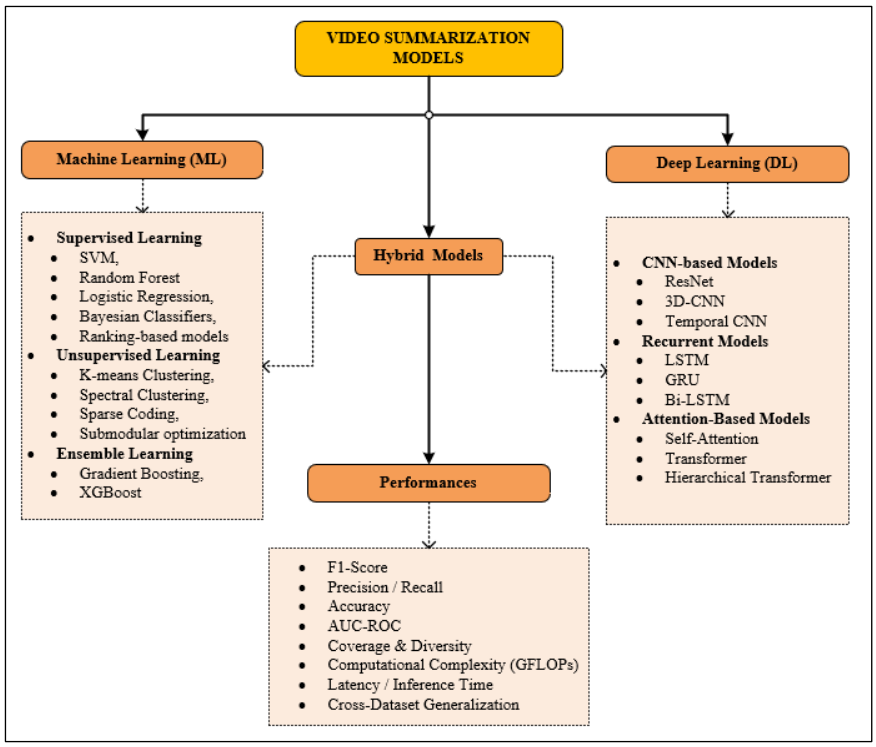

Figure 2: Taxonomy of the Literature Review.
Source: Authors, (2026).

The organization of the analysis is such that: Section 2 describes the methodology based on its stages; Section 3 provides a comprehensive analysis based on different models and its corresponding data; Section 4 describes the key insights, challenges, and implications of the study; Section 5 outlines the future state and research opportunities; and Section 6 provides conclusion remarks and future research directions.

II. METHODOLOGY

The video summarization model shown in figure 3 is a large-scale video summarization system that has well-defined stages through which the functionality of the video is extracted and reduced in size while keeping its semantic content. The first stage is the pre-processing and temporary segmentation of the raw video into shots or events with cleaning, noise reduction, and boundary detection of the video which results in a reduction of redundancy and improved structure. The second stage is extracting multimodal features where visuals, motion, audio or text is processed using various techniques such as handcrafted descriptors or deep neural networks. These multimodal features are fed to a temporal modeling module in order to develop sequential patterns and learn long range relationships through a variety of models such as HMMs, Long Short-Term Memory (LSTM) networks, Gated Recurrent Units (GRUs), transformer algorithms, hybrid algorithms. The third stage is to apply a relevance scoring mechanism to each frame or segments of the original video based on rules, supervised or unsupervised learning methods, attention mechanisms, or reinforcement learning. The last stage is using various post-process methods like top-K selection, thresholding, redundancies removal, and smoothing to result in a concise and coherent summary of the original video while maintaining continuity and diversity.

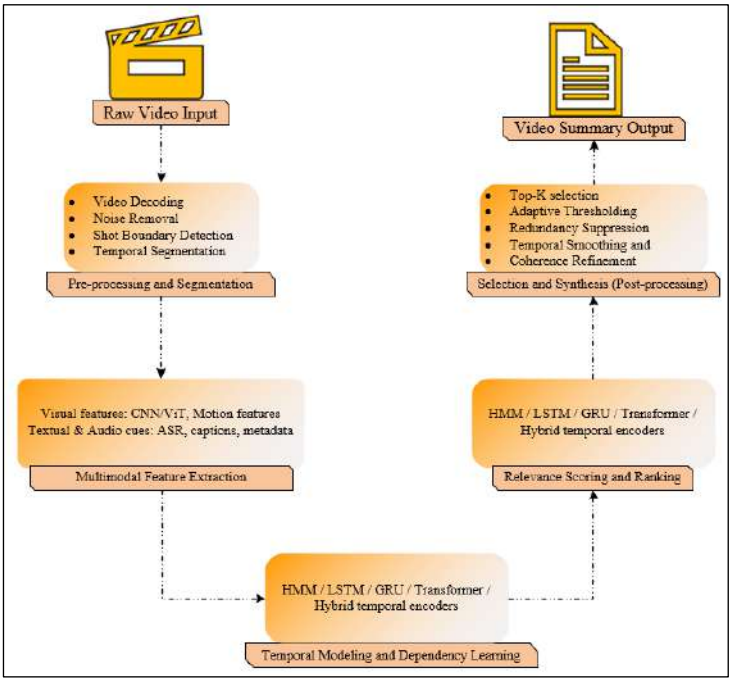

Figure 3: Block Diagram for Different Stages in Video Summarization Process.
Source: Authors, (2026).

An analytical framework based on the stages is described in this section to analyze video summarization algorithms evaluated using different methods like segmentation, feature extraction, temporal modeling, relevance scoring and post-processing. These methods include heuristic, ML, DL, and Hybrid types of algorithms. They have all been compared against each other through the use of common benchmark datasets in order to evaluate their performance, reliability, and scalability.

II.1 PRE-PROCESSING AND SEGMENTATION

Video summarization involves a lot of pre-processing and segmentation of videos before they are summarized. This includes efficient summary generation, there redundancy, its coherent; therefore, pre-processing and segmentation will create a summary that feels coherent, does not contain redundancy, and runs efficiently. Of primary importance in this process is shot boundary detection, which separates a video into segments that have meaning. Using modern deep learning technologies such as convolutional neural networks (CNNs), researchers have been able to achieve nearly perfect accuracy (approximately 98%) in detecting both abrupt and gradual transitions between video frames (i.e., the transitions from one frame to another), thus allowing researchers to reliably detect the most important shots [17]. Additionally, using shot detection in conjunction with clustering and optimization methods will increase the quality of keyframes extracted from a video and improve the performance of key management processes using the benchmark datasets [18]. In specialized situations, video lectures and hybrid audio-visual segmentation techniques that utilize optimization algorithms and color models have been shown to achieve more than 90% accuracy according to structured settings [19]. The other important aspect is the frame sampling, adaptive sampling methods that adapt their sampling density by either motion or semantic richness have been shown to outperform standard sampling methods and retain only those frames that contain the most information, discarding those that contain less information [13], [20]. In addition to adaptive sampling, using dimensionality reduction and clustering techniques to eliminate redundant data and reduce processing costs without losing the integrity of a video summary provides an additional benefit [21-24]. Together, these methods enable scalable and accurate summarization, even on challenging datasets such as SumMe and TVSum, where diverse content and subjective annotations make evaluation difficult [25].

II.2 MULTIMODAL FEATURE EXTRACTION

Multimodal feature extraction is regarded as one of the key advancements in video summarization process practiced today, as it allows for an improved semantic space representation and an increase in the relevance of summaries produced. Researchers have used a variety of available combinations (e.g., visual-only; audio/visual; vision/language) to determine which combination would produce the best representation of visual content that conveys meaning. Numerous studies have indicated that by combining visual descriptors with audio descriptors (e.g., color histograms, motion-related descriptors and object category-based descriptors with audio descriptors such as spectral flux and energy pattern) produce stronger results than when each type of descriptor is used independently. Further, the use of multimodal descriptor fusion strategies provides for improvements in terms of evaluation metrics such as AUC and F1-score, supporting the complementary nature of audio and visual information used in video summarization tasks [6]. As demonstrated in Figure 4, new frameworks incorporating lexical attributes as well as outside knowledge [25]. Vision-language fusing allows for reasoning at higher semantic levels and allows for estimating the importance of a piece to a topic more accurately. Fusion models have the forerunners of the visual model that are pure visual-based and therefore, they outperform purely visual methods in both synthetic or real-world settings [26]. The literature shows that handcrafted features (often utilized with traditional classifiers) are both efficient and interpretable; however, they are restricted by their inability to model complex spatio-temporal semantics (i.e., relationships) [27].

Conversely, feature representations derived from machine learning methods such as CNNs, RNNs, and hybrid deep networks provide richer spatial and temporal feature representation leading to increased robustness and greater accuracy across datasets [28]. Because of this, it is common to see the fusing of both handcrafted/learned feature representations to reduce redundancy and increase segmentation quality ultimately improving classifier performance through ablation studies [29]. Therefore, multicasting/learning-based features are typically richer semantically and materially in terms of providing context and require larger computational resources.

II.3 TEMPORAL MODELING AND DEPENDENCY LEARNING

Temporal modeling forms the basis of producing clear and high-quality summaries of videos, but different types of temporal models will produce summaries of videos with different characteristics. HMMs is often used when the ability to interpret the summary and the need for a small amount of data are important. It is a good way to represent the short-term transitions that take place in the video; however, since an HMM represents short time (i.e., it has a Markovian character) it cannot represent the complex long-term dependencies that might exist in the video. Deep recurrent networks, such as LSTM networks and GRU, can be implemented to overcome the limitations of modeling long-term dependencies with HMMs by implementing a gating mechanism that maintains temporal context over long sequences of time. While LSTMs provide an excellent representation of long-term dependencies in time series data, they are computationally inefficient. In contrast, GRUs produce similar-quality presentations of long-term dependencies, and they do so more efficiently than LSTMs do, particularly when it comes to multimodal and large datasets [30]. The use of self-attention in transformer-based architectures increases the ability to model temporal relationships globally without recurrence and allows for the simultaneous processing of these relationships. Thus, transformer-based architectures eliminate the limitation imposed by recurrent networks, which must model sequences in a sequential manner [31]. The computations needed to run a standard transformer on a long sequence are typically very high; however, there are innovative designs, such as hierarchical transformers and memory-augmented transformer architectures, that provide an efficient means of learning from sequences with long-range dependencies. Attention-based architectures consistently out-perform HMMs and stand-alone recurrent architectures in empirical evaluations, so they have become the dominant architecture in modern video summarization [32], [33]. Figure 5 shows the core DL model that uses visual and language models for video summarization.

Source: [33].

II.4 RELEVANCE SCORING AND RANKING

Video summarization relies heavily on scoring and ranking to choose which frames or segments will appear in the summary. Traditionally, scoring and ranking were based mostly on the relevance of a frame, using very simple but effective heuristics to define how important the frame when compared to other frames. Commonly used sources for heuristic scoring are appearance, motion, and semantic cues; local dissimilarity and global consistency are often pairwise metrics.

Heuristic approaches to frame retrieval typically use a combination of deep feature extraction and reward-based reranking to strike a balance between relevance and diversity, with satisfactory performance even for training-free or zero-shot scenarios. [34]. In figure 6, the use of frame, semantic space and color coding of the video content are conceptually demonstrated, showing how local dissimilarity, global consistency and uniqueness might be identified in a video using video features. Supervised learning approaches can predict frame/segment importance scores based on human-annotated data and achieve high F1-scores while also semantically aligning with what users expect. However, their dependence on labeled data limits their ability to scale. In contrast, there are some subsequent methods that exploit both reinforcement learning and adversarial methods to find the best possible reward function that honors time continuity, representativeness and diversity within the response, and also has shown performance that is comparable to supervised performance across many benchmark datasets [15], [35]. Additionally, these same approaches can be enhanced with the use of attention mechanisms that leverage attention to account for both local and global temporal context. Finally, reinforcement learning provides reward signals that provide guidance for ranking towards uniformity and semantic richness without the need for explicit supervision [36], thus hybrid scoring approaches which utilize heuristic cues, attention-based learning and reinforcement reward criteria consistently outperform either purely heuristic or purely supervised approaches, thereby providing a scalable, robust approach to modern video summaries.

II.5 SELECTION AND POST-PROCESSING

Selecting and editing clips, the final part of creating a summary video, results in creating a final product that is coherent, enjoyable, and dynamic. Using smooth transitions between different scenes makes the presentation appear seamless throughout. Advanced technologies are being developed to allow for greater flexibility in the initial phases of editing such as temporal convolution networks [37], coarse to fine scale models [38], and use of graph-based temporal aggregation methods [39]. Temporal security will remain intact by using memory optimization through temporal security, motion anomaly indices, dimensional percentage decrease methods, and intelligent cluster processing—resulting in a video summary that is both short but representative of the original raw video footage. In addition to providing more diverse representations of video material, these approaches will also lower the computational costs associated with creating summaries, which is an important consideration in long or specialized videos where repeated patterns occur very often [23], [39], [40]. Adaptive thresholding and Top-K ranking are mechanisms for selecting components for a summary. Adaptive methods are the best choice because they allow the number of selected frames or segments to be adjusted based on learned importance scores, length and complexity of the video. By adapting to current conditions, and by avoiding over-summarization (which has the potential to miss or lose critical information), and under-summarization (which may create redundancy), adaptive methods help reduce both redundancy and loss of detail in the summary. Research indicates that adaptive selection outperforms fixed thresholds in achieving balanced coverage to conciseness ratios for different datasets and genres [41], [42]. Temporal smoothing, redundancy suppression, and adaptive selection are three complementary processes that enhance coherence, informativeness, and generalization when creating a video summary.

III. ANALYSIS

This section provides an overview of various approaches to summarizing videos using heuristics (i.e., rules of thumb), ML, DL, or hybrid methods. It evaluates video summaries using performance trends, bias in datasets, computational complexity, generalization ability, and scalability by comparing established benchmark data sets and drawing conclusions about their strengths and weaknesses.

III.1 STAGE-WISE COMPARATIVE ANALYSIS

Examining a stepwise approach to video summarization using ML, DL and Hybrid approaches reveals that, there are clear strengths and weaknesses to each approach at each stage in the process. At the segmentation stage, ML techniques mainly use handcrafted video descriptors and classical classification approaches, making it fast, interpretable and relatively easy to implement. But one of the major limiting factors is adaptability to a diverse or complex video content because of the pre-defined features. In contrast, DL techniques use Convolutional Neural Networks and Object Detection algorithms to automatically generate lists of scenes or events from the source of the video which yields higher accuracy and higher robustness, but require significantly more computational power and longer training times [21], [43]. ML methods focus on identifying engineered audio and visual features that are lightweight, easy-to-understand, but not very deep in their representation. In contrast, DL architectures allowing for the learning of hierarchical spatial-temporal feature representations directly from the data (e.g., CNNs, ResNets, and transformer-based models) demonstrate much richer semantics and context than those found using ML methods [21]. There are also differences due to separate temporal modeling methods; ML methods typically use statistical models or simple sequence-based analyses, but DL methods leverage recurrent architectures (e.g., LSTM or GRU) and attention-based transformers to identify long-range dependencies.

Hybrid frameworks leverage both of these strengths owning to their robustness in scenarios where little training data is available or where resources are limited; thus, they are of great value in practical applications [44], [45]. ML techniques typically employ supervised classifiers or ranking functions to assign relevance scores while DL models use end-to-end methods or reinforcement learning for determining the importance of various elements of videos. This has allowed DL models to adapt much more rapidly than ML models to the variety of different types of video. Hybrid methods use an ML-based approach for selecting candidate video segments for inclusion in a summary, followed by the use of DL methods to optimize those selections, which results in adaptive, context-sensitive importance estimates that can balance efficiency and accuracy [6], [44]. Post-processing also demonstrates these two groups of algorithms have distinctive characteristics, a ML provides clustering and filtering functions to increase coherence, while DL contains adaptive thresholds and temporal interpolations that provide for smoother transitions, and hybrid methods refine DL results through ML redundancy suppression [46]. Overall, DL methods provide superior representation learning and temporal modeling abilities, while ML provides for greater efficiency and interpretive capabilities than DL; however, Hybrid approaches have resulted in the most efficient and generalizable performance across benchmark datasets making Hybrid approaches the most effective choices in real world video summarization scenarios. Table 1 summarizes a comparative discussion of all these methods.

Table 1: Comparative Analysis of Different Video Summarization Approaches.

Pipeline Stage	ML Methods	DL Methods	Hybrid Methods
Segmentation	Handcrafted features & classical classifiers; efficient but less adaptable [44]	CNNs & object detectors; automated & accurate but computationally expensive [21]	Combines ML efficiency with DL accuracy [44]
Feature Extraction	Engineered visual & audio descriptors [43]	CNNs, ResNets, & transformers; learns complex semantics [21]	Integrates ML descriptors with learned representations [44]
Temporal Modeling	Simple statistical or sequence models [44]	LSTM, GRU, & transformers; captures long-range dependencies [6]	Combines strengths to enhance robustness [44]
Relevance Scoring	Supervised classifiers [6]	End-to-end predictions or reinforcement learning [6]	Integrates ML-driven selection with DL optimization [45]
Post-processing	Clustering & filtering for coherence [44]	Adaptive thresholding & interpolation [44]	Refines DL outputs with ML-based redundancy control [46]

Source: Authors, (2026).

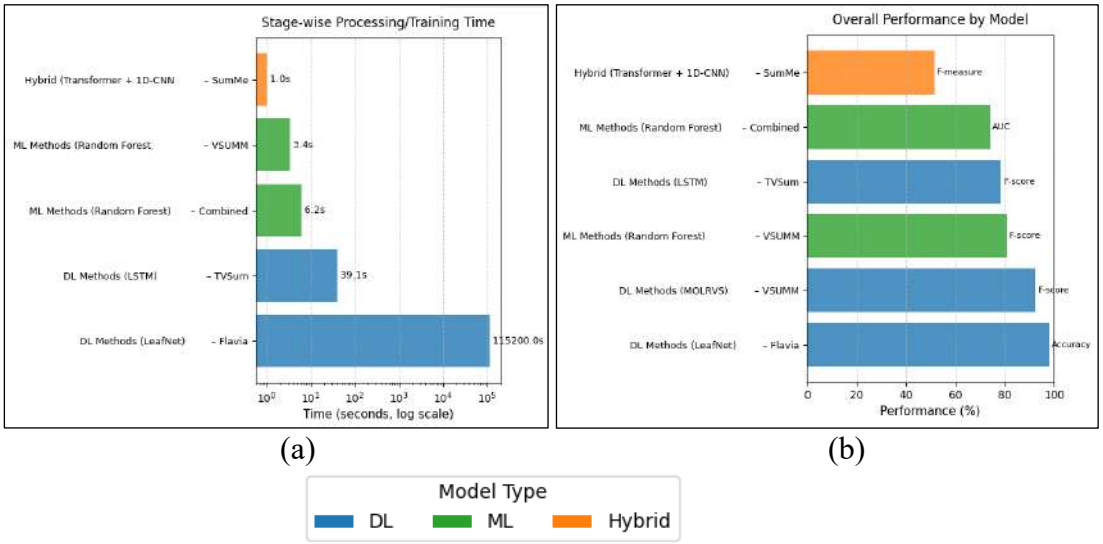

Figure 7: Stage-wise Benchmarking of Video Summarization Models.
Source: Authors, (2026).

The comparative analysis in Figure 7 shows a clear distinction between the cost of computing versus effectiveness in video summarization/classification models using a stage-based approach. Figure 7(a) shows a significant time difference between LeafNet's training time of 32 hours in approx. (but only ~7 seconds for hybrid/ML) indicating cost, efficiency and research trade-offs as shown in Figure 7(a). Similarly, Figure 7(b) shows varying performance based on task and metrics; although DL has high F-scores or accuracy (up to 97.9%) compared to other models, the latency of ML is much lower but still provides similar-quality outcomes. Additionally, the dual-panel chart compares both time on a log scale across performance without conflating different benchmark types when making deployment decisions especially for real-time or limited resources.

III.2 DATASET-CENTRIC PERFORMANCE ANALYSIS

The evaluation of video summarization through dataset centric evaluation demonstrates how the size or volume of datasets (e.g., their design, their annotation protocols and the inherent biases associated with those datasets) impact how model performance is rated. One common form of short-style dataset, like SumMe and TVSum, contains human-annotated videos of usually fewer than a couple minutes long are used as standard examples to evaluate a model's ability to select keyframes, determine accounting relevance and provide visual diversity. Such datasets allow for controlled experimentation and consistent benchmarking across each other, but because they provide limited temporal scope to the models, the models rarely encounter complex long-range dependencies which are required for generalized summarization [5]. The subjectivity behind human annotation of importance scores (i.e., the bias associated with how a human may rate a video as being important vs. another rating it as less important), will also lead to overfitting of annotation styles and therefore models that derive high F-scores & precision within these datasets at times will be unable to perform adequately on unseen real-world content [18], [21].

In contrast, while YouTube Highlights focuses on event centric content, where the focus is on parts of the event that are of higher activity, and will therefore be more beneficial to the detection of highlights, this focus will cause a potential over-estimation of the capability of the model due to the lower representation of those types of events and activities and will therefore decrease the ecological validity [43]. ActivityNet, however, consists of longer unchanged videos and overlaps between the different events, as well as a complex temporal structure. Models must be able to model long-term dependencies, semantic progression and continuity of context [47]. Demonstrating success on these types of datasets is an indicator of real-world applicability, scalability and robustness. As a result, the findings show that strong performances on short-form or event-based datasets will not predict success on long-form or diverse video datasets. Therefore, dataset-aware evaluation is essential to ensure benchmark selection aligns with research goals, reflects diverse temporal and semantic challenges, and accurately represents practical summarization capabilities [43], [47], Table 2 summarizes the characteristics, biases, and performance implications of different datasets.

Table 2: Comparative Analysis of Dataset-Based Performance Analysis Approaches.

Dataset	Characteristics	Biases	Performance Implications
SumMe	Short-form videos; human-annotated summaries	Human-annotated bias; subjective preferences	Strong F-score and precision in short videos, may struggle with generalizability [5], [21], [48]
TVSum	Short-form videos; human-annotated summaries	Similar to SumMe	Emphasizes semantic relevance and visual diversity; limited temporal dynamics [5], [21]
YouTube Highlights	Event-centric; focuses on short, clearly defined highlights	Event-centric bias; favors discrete activities	May overestimate model performance; emphasizes activity detection over subtle content [44]
ActivityNet	Event-centric; focuses on short, clearly defined highlights	Complexity of temporal dependencies	Tests models on capturing long-range dependencies and nuanced transitions; emphasizes scalability [47]

Source: Authors, (2026).

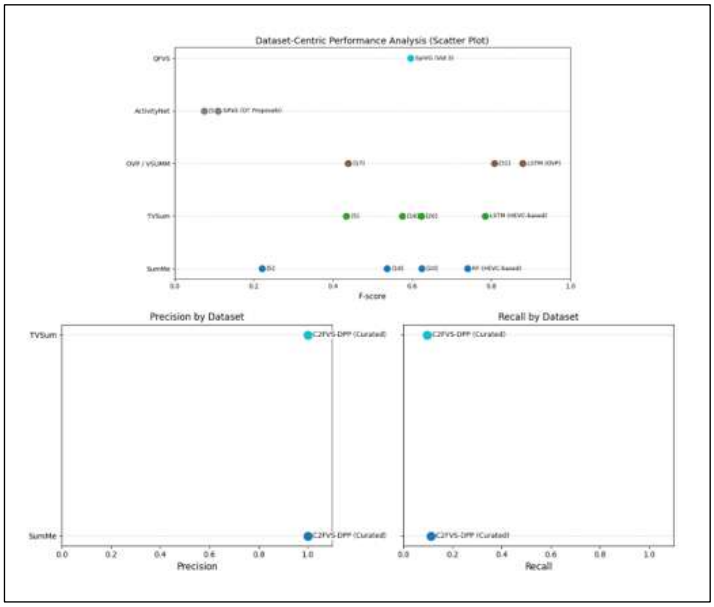

Figure 8: Dataset-Centric Comparison for Video Summarization Methods.
Source: Authors, (2026).

In Figure 8, a scatter plot comparing Video Summarization Models across five datasets is shown along with the models that performed best on each of the datasets. Each point corresponds to a different model, such as C2FVS-DPP (Curated) [5], Highlight Detection [49], SpiVG [48], MMAN [50], RF (HEVC-based) [21], LSTM (HEVC-based) [21], GPaS (Automatic Proposals) [47] only the best is labeled to avoid cluttering.

The plot shows that there is vast variability in performance within the different benchmarks where the Youtube Highlights Dataset performed the best and the ActivityNet Dataset performed the worst showing the inherent differences in difficulty among each of the datasets.

III.3 COMPUTATIONAL COMPLEXITY AND SCALABILITY

Video summarization entails a challenge of computational complexity and scalability; therefore, an assessment of the computational efficiency of lightweight ML models relative to heavyweight transformer-based architectures is fundamental. For example, lightweight ML models excel in their ability to execute with computational efficiency, as they require fewer parameters, smaller numbers of floating point operations (FLOPs), and use either simplified attention or convolution to deliver results quickly (ie; in real-time or at the edge) in environments where available resources are limited [51]. Conversely, transformer and vision-language models offer superior representational ability through the representation of complex temporal and contextual dependencies at the cost of extensive computational requirements (ie; high FLOPs, extreme memory requirements and delays), which create scalability issues for those platforms with limited resources [44]. Video summarization involves balancing high-quality summaries from large Transformer models and fast, economical inference of smaller-sized ML models for short or moderately complex videos [52]. In response, various research efficiencies have emerged, such as token sparsification, probabilistic pruning, hierarchical tokenization, which reduce computing costs while producing the bulk of the performance [53]. Hybrid designs, incorporating convolutional layers and attention modules have reduced, but still use computationally expensive, self-attention mechanisms. In addition to using knowledge distillation and quantization to improve the efficiency of deployment without significantly impacting accuracy [54], lightweight transformer variants have provided an additional means of producing real-time summaries for all types of activities while yielding very complex, long-form videos; allowing for rapid delivery of scalable, near real-time summaries across many different types of activity [55]. Table 3 shows the trade-offs in accuracy and real-time feasibility.

Table 3: Trade-offs in Accuracy and Real-Time Feasibility of Video Summarization Techniques.

Aspect	Lightweight ML Models	Heavy Transformers
Computational Complexity	Significantly lower due to fewer parameters and simplified operations [51]	Higher due to extensive floating-point operations (FLOPs) and large memory footprints [52]
Scalability	Highly scalable for resource-constrained devices; suitable for real-time applications	Limited scalability; struggles on resource-constrained devices [44]
Example Models	Lightweight transformers (e.g., TBiGNet), CNNs with simplified architectures	Standard Vision Transformers, large language models
Accuracy	Competitive accuracy; over 99% on short videos; may sacrifice some representational power	Superior representational power; high performance on complex tasks
Real-time Feasibility	Faster inference and lower resource consumption, enabling real-time summarization	Higher latency hinders real-time deployment
Optimization Strategies	Employ sparsity, depthwise separable convolutions, efficient attention mechanisms [53]	Token sparsification, Bayesian prototypical pruning, Neural ODEs for temporal localization [54]
Trade-Offs	Good accuracy with real-time feasibility; may limit performance on complex videos	High accuracy but at the cost of computational overhead and latency [55]

Source: Authors, (2026).

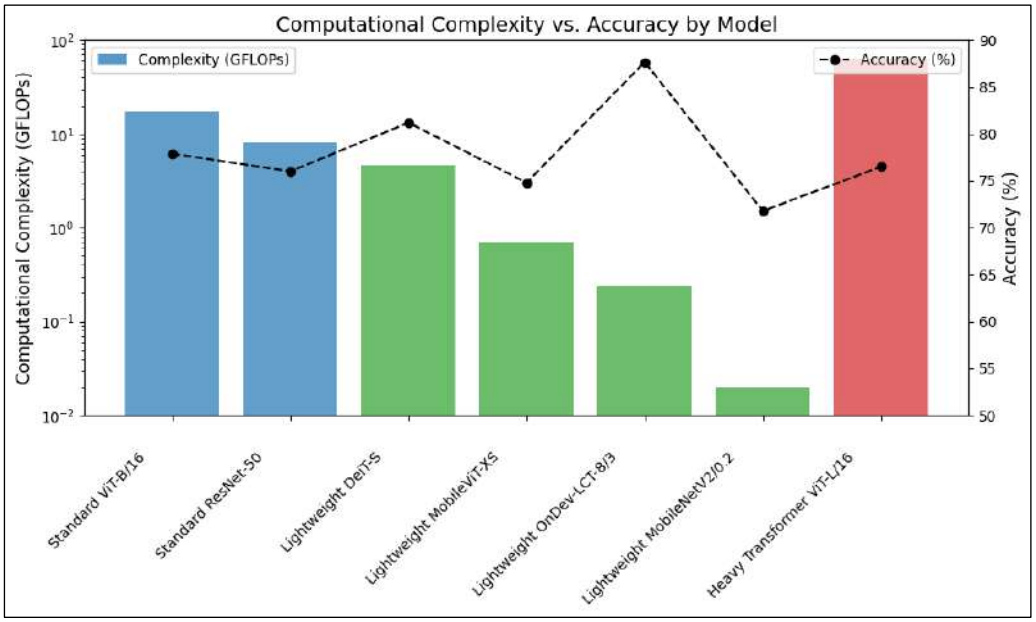

Figure 9: Computational Complexity Analysis Across Recent Models.
Source: Authors, (2026).

Data in Figure 9 shows how computational complexity of the vision models (in GFLOPS) can be correlated against accuracy and demonstrate the significant trade-offs between model efficiency and model performance. The computational complexity is presented on a logarithmic scale and therefore allows a comparison of both the range of ultra-lightweight MobileNetV2 (0.02 GFLOPS) through to ultra-heavy ViT-L/16 (63.6 GFLOPS) on one graph while accuracy is displayed using a linear scale on the secondary-axis. Ultra-lightweight models (OnDev-LCT-8/3), provide a combination of low resource requirements with high accuracy (87.65% accuracy) as compared to many larger models that vary in architecture (e.g., ViT-B/16 and ResNet-50). Whereas many traditional architectures provide balanced performance metrics; ultra-heavy transformer architecture reveal diminishing returns regarding operationally constrained model selection by resource limitations.

III.4 GENERALIZATION AND ROBUSTNESS

Video summarization models must possess both generalization and robustness because they are crucial characteristics that dictate the degree of an individual model's ability to perform across different datasets and types of videos. A video summarization model will exhibit domain shift resilience due to variations in the content style, how it is annotated, and the semantics being applied, when that model is stable across a number of distinct benchmark datasets [18]. Models that are built using large-scale, heterogeneous datasets like VideoXum, will promote cross-dataset generalization in that they will be able to learn more robust multimodal features and more generalizable semantic relationships [56]. Recent advances in model designs, such as vision-language encoder/decoder frameworks, graph-based reasoning, and variational inference, have improved robustness by capturing more complex temporal dependencies and reducing overfitting to one dataset [47]. Models that do not have adaptive mechanisms also suffer from loss of temporal consistency when used with shorter or longer videos [2], [44]. To address this issue, researchers have proposed new techniques to help with this issue including importance-score interpolation, hierarchical temporal sampling, and reinforcement learning-based methods that reward algorithms for achieving/maintaining temporal coherence [32], [53]. Furthermore, using varied types of data while training by applying semantic conditioning and multimodal fusion, strengthens model robustness in the event of encountering various types of video content and real-world variation [6], [57]. As a result, these approaches lead to scalable and robust video summary systems that consistently perform across many different dataset types (e.g., length) and content platforms [5], [58], The cross-dataset performance and sensitivity analysis are shown in Table 4.

Table 4: Cross-Dataset Performance and Sensitivity Analysis in Video Summarization Models.

Aspect	Description	Strategies for Improvement
Cross-Dataset Performance Stability	Reflects a model's ability to generalize across diverse video domains and datasets	Leverage large-scale, diverse datasets like VideoXum for richer semantic learning [56] Use advanced architectures (e.g., vision-language encoder-decoder frameworks, graph-based reasoning) to capture complex dependencies [47] Employ variational inference to manage uncertainty in multi-channel features. Test and fine-tune on multiple benchmark datasets (e.g., TVSum, SumMe) [57] Apply semantic conditioning to focus on relevant content
Sensitivity to Video Length	Affects the model's ability to maintain temporal consistency across varying durations	Utilize interpolation methods to adjust predicted importance scores. Combine transformer and CNN architectures for capturing global and local contexts Implement temporal consistency reward functions in reinforcement learning [43] Use hierarchical sampling strategies for fine-grained temporal feature extraction [22]
Content Diversity	Enhances generalization by exposing models to various video types and semantic contexts	Incorporate diverse datasets (e.g., VideoXum) to learn richer correlations [53] Use semantic conditioning for more representative summaries [57] Employ multimodal feature fusion and ensemble learning techniques [6] Implement lightweight frameworks and personalization strategies for diverse outputs [5], [58]

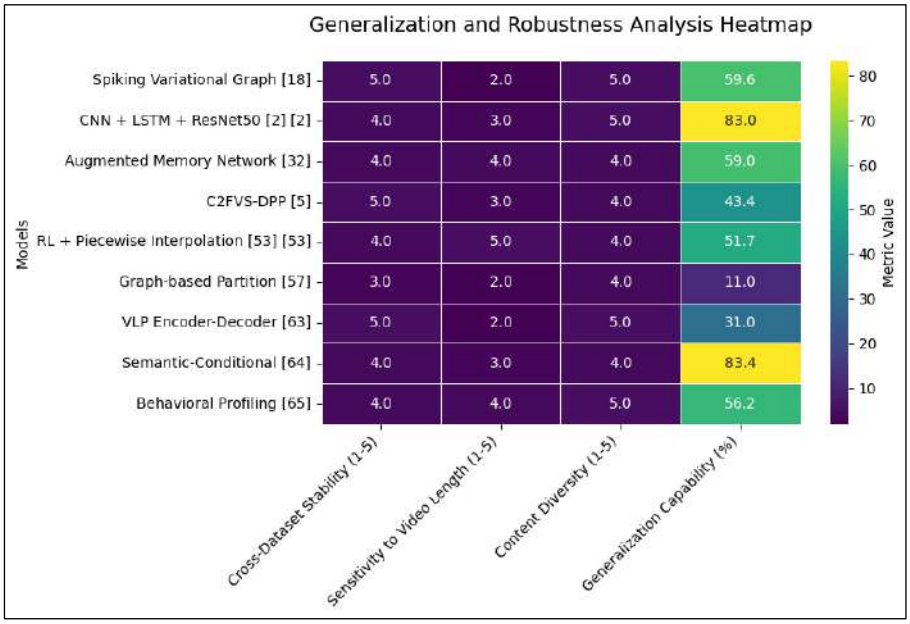

Figure 10: Evaluating Robustness and Generalization across Various Video Summarization Models.
Source: Authors, (2026).

Figure 10 shows the heatmap which illustrates the performance of various video summarization architectures based on stability, sensitivity to video length, and diversity of content using a scale of 1 (low/fragile/niche) to 5 (high/robust/diverse). Notably, both SC-Net and CNN+LSTM achieved more than 83% generalization while maintaining balanced robustness across all stability measures. Both SpiVG and BLIP were uniquely positioned with excellent cross-dataset stability and diversity of content due to their use of hierarchical and vision-language representations. Their low sensitivity to video length also indicates a significant degree of temporal modeling capability. In contrast, the training-free methods C2FVS-DPP leverage features learned during other tasks (i.e., pre-trained features) for exceptional stability without the risk of domain overfitting. In contrast, reinforcement learning approaches are generally more sensitive to video length, presenting difficulties for establishing consistent performance over longer periods of time. The heatmap's color intensity encoding demonstrates these trade-offs clearly; showing how certain choices have impacted adaptability and reliability of their structure in different video environments across a wide range of videos.

IV. DISCUSSION

The comparative analysis of this review indicates that, video summarization research has gone through a significant transformation with regards to the technique from modular pipelines that were initially converged-based to a purely semantic and adaptive unified architecture in the summarization pipeline. In most phases of this pipeline, DL has outperformed both traditional ML and heuristic-based ML in terms of semantic relevance, temporal coherence and robustness. At the same time, there is a significant amount of variability in the performance of the different methodologies when compared against each other based on data set, operational constraints and characteristics of the input video. Thus, there is no single best method for all scenarios. A combination of the above factors i.e. hybrid models significantly influence the overall design choices made at each stage within the summarization pipeline.

IV.1 LESSONS LEARNED FROM STAGE-WISE DESIGN CHOICES

- Segmentation and Pre-processing: Segmentation based on deep learning has been shown to significantly improve consistency when capturing shots and event detection, especially in heterogeneous/untrimmed video content. But rigid boundaries around segmentation can introduce early errors into the subsequent processing stages, resulting in an error propagation. Approaches that either use hybrid strategies that soften the segmentation decision or incorporate detection of boundaries into temporal modeling provide much better error resilience. Therefore, segmentation should be viewed as a semantic abstraction problem instead of a hard preprocessing step.
- Feature Representation: The most significant factor for summary quality is learned multimodal representation, especially when combining visual, audio, and linguistic cues. Vision-Language Models and transformer-based encoders demonstrate much greater consistency in cross-dataset generalization than handcrafted feature-based approaches, as vision-language models encode high-level semantics as opposed to low-level statistical appearance characteristics. Handcrafted features can provide value due to their efficiency; however, they do not convey the narrative intent or context, indicating that the richness of the semantic content and compactness is related to producing effective summaries.
- Temporal Modeling: Models which are able to learn long range dependencies, like transformers and hierarchical attention mechanisms, perform well with long-form data sets like ActivityNet; however, due to their quadratic complexity they present scalability issues. The best designs are those that utilize hybrid time reasoning using local convolutional models with sparse or hierarchical attention that will provide both temporal fidelity and computationally feasibility, therefore making them practical solutions to many forms of video summarization.

IV.2 RELEVANCE SCORING, SELECTION, AND DATASET AWARENESS

The significance of relevance in a video summary is determined by a series of decisions that are based upon preference rather than rated score values. Although many supervised models have succeeded in meeting their benchmarks and perform well according to these metrics, they still get affected by annotator bias, and generalization. Self-supervised and reinforcement-based methods are better suited for adapting by focusing on diversity, representativeness, and temporal consistency, than supervised methods. The best performing summary systems use a combination of heuristic diversity rules along with attention strategies and reward optimization to heavily balance video summaries while reducing the potential for overfitting general to the annotators. Additionally, dataset analysis illustrates how success on short-form benchmarks such as SumMe and TVSum do not guarantee robustness when applied to real-world problems. Models trained and/or tested using long-form, untruncated datasets demonstrate significantly greater scalability and overall reliability, indicating that dataset diversity and duration sensitivity should be treated as a fundamental building block in designing an effective video summarization system rather than merely bilateral validation tools.

IV.3 COMPUTATIONAL TRADE-OFFS AND GENERALIZATION INSIGHTS

Light, efficient models are ideal for real-time use and at the edge of networks, offering the best combination of speed and low latency with good accuracy comparable to high end models. While there are powerful transformer models to perform complex analysis in offline environments and reasoning with depth, there is diminishing accuracy for the time used to compute versus the quality of the output. Alternatives to both heavy transformers or light transformers that still maintain sufficient depth are optimized transformers and more generalized use of transformers with strategies such as knowledge distillation or token sparsification. Models that have high generalization and robustness to domain shifts (shifting from one domain to another) have used multimodal learning, hierarchical temporal abstraction and model uncertainty (being aware of the stability of the model) to help reduce the effect of domain shifts, differences in video length, and differing video content. Also, pre-trained models that either have no training or weakly supervised learning frequently achieve significant stability by avoiding overfitting to datasets (making sure there aren't too many examples), which demonstrates the key role of using large pre-trained representation of models.

IV.4 KEY DESIGN INSIGHTS AND BEST PRACTICES

The insight obtained from the analysis are as follows,

- Both hybrid model architectures produce the best overall results by combining the optimization of representation learning, temporal reasoning, and adaptive selection together.
- The most scalable model architectures produce highly efficient scalable output at a low computational cost.
- The models with the greatest degree of generalization are video architectures trained on diverse, long form datasets (Vision & Local Models and Multimodal Models). Hence these models can generalize to many different domains of video data.
- Combining soft-segmentation, preference aligned relevance scoring and adaptive post-processing outputs is among the strongest video summarization methods with an end-to-end strategy creating reliable, balanced outputs.

Effective video summarization analysis shows that to achieve an effective output for the final video summary; one centralized design needs to be developed instead of optimizing standalone pipelines. Future video summarization models must place greater emphasis on semantic alignment; which need a dataset aware method of measuring performance. Finally, temporal modelling methods must use efficiently as their basis for producing consistent performance results.

V. ROADMAP AND FUTURE RESEARCH DIRECTIONS

Video summarization has entered a new, critical step of evolution, characterized by large-scale (increasing amounts of video) and multimodal (adding different types of audio/video streams) complexity as well as deployment diversity. Although, deep learning models have made a significant contribution to improving summarization quality, continuing challenges associated with scaling, generalizing, interpreting, and evaluating highlight the need for a structured research roadmap to address these issues. This section will provide an overview of the significant future directions for developing video summarization systems.

V.1 SCALABLE LONG-VIDEO AND STREAMING SUMMARIZATION

The focus of future research needs to be on creating long-term summaries for continuous video streams in real-world situations with limited memory and latency. To process lengthy video, some methods need to be employed, which include hierarchical temporal abstractions, sparse and adaptive attention mechanisms, Memory-Aided Transformers and Streaming-Aware Architectures. Another major area of research is the development of incremental and online summarization techniques to support real-time summary creation and continuous update of summaries with global narrative coherence for use in surveillance systems, autonomous systems, and live content platforms.

V.2 PREFERENCE-AWARE, PERSONALIZED, AND EXPLAINABLE SUMMARIZATION

Most of the currently available summaries focus on generic ranking metrics but do not consider the user's intent and context. In the future, new summarization systems will need to incorporate user preference-based learning methods. These methods will allow for more personalized summaries based on the user's profile and goals as well as the semantics of their queries. In addition, incorporating "human-in-the-loop" (i.e., human feedback) within reinforcement learning for preference optimization will help facilitate adaptive relevance estimation.

In addition, additional methods for increasing interpretability and explainability (e.g., attention visualization, semantic reasoning graphs, causal analysis) will create confidence, transparency and usability in high-stakes decision-making environments.

V.3 ROBUST EVALUATION PROTOCOLS AND DATASET EVOLUTION

Progress based on benchmarks is limited due to issues such as annotation subjectivity, bias within datasets and low temporal diversity. For future work on large-scale datasets that accurately represent a wide range of real-world videos, a focus on developing diverse datasets with weak supervision will be necessary. Metrics used in assessing systems should include semantic coverage, temporal consistency, user satisfaction, as well as computational efficiency and should not focus solely on F-score. Cross-dataset and zero-shot evaluation should be standard ways to assess generalization and robustness across systems, so they can be effectively evaluated to determine performance on new datasets.

V.4 EFFICIENCY-AWARE AND RESOURCE-CONSTRAINED DEPLOYMENT

To allow for the larger scale use of video summarization techniques and methods, there is a need to create new models that consider potential deployment issues as well as the need for efficiency. Efficiency-aware video summarization models need to be created using video summarization model compression, knowledge distillation, and quantization to allow for their efficient deployment on edge and mobile devices. In addition, hybrid cloud-edge deployments and inference methods will be required to support these models when they are deployed into production. The future directions for video summarization will involve integrating scalable temporal reasoning, preference-aligned learning, and evaluation. This path will provide the framework for the video summarization field to transition from optimizing to benchmark-based approaches in creating scalable and interpretable video summarization systems that will address many issues with understanding large amounts of video content.

VI. CONCLUSION

This review provides a detailed overview of the progression of video summarizing techniques from heuristic methods through ML and DL to hybrid techniques across segmentation, feature extraction, temporal modelling, relevance scoring, and post processing. Comparative evaluations of DL versus hybrid architectures using standard benchmark datasets, indicate significant improvements regarding semantic representation, temporal coherence and robustness. Moreover, the evaluations highlight numerous challenges associated with these approaches such as annotation bias, error propagation across modules, computational complexity, and a lack of generalizability for long-form or diverse video content. Furthermore, the results of a data-centric assessment utilizing complexity-aware analytical techniques have shown that high benchmark scores do not necessarily correlate with true effectiveness in real-world applications, revealing a need for more diverse, scalable, and efficient design criteria that take into account the size and characteristics of their respective sample populations. Based on the findings from this review, there is a need for a significant change in the industry for a unified multi-modal and preference-based framework to achieve a good balance of semantic richness and practical deployment issues. Future scope of this research is to develop a complete architecture that allows for scalable long-term reasoning, as well as a system that offers personalized preference-based deployment for video summarization solutions. Moreover, it is important to create solid evaluation protocols and design performance-optimized models to provide video summarization systems with the reliability needed to run properly across a wide variety of applications, thereby allowing these solutions to operate successfully in a variety of real-world environments.

ABSTRACT

Electric Vehicle (EV) battery systems are highly susceptible to thermal runaway and fire hazards due to voltage instability and excessive temperature rise. This paper presents an IoT-based real-time fire detection and intelligent thermal management system designed to enhance EV battery safety and reliability. The proposed system employs an Arduino Nano integrated with LM35 temperature sensors, voltage monitoring modules, and a flame detection unit to continuously monitor battery health parameters. When the temperature exceeds a predefined safety threshold of 45°C, an automatic cooling mechanism is activated, and alert notifications are generated through LCD display, buzzer, and cloud-based IoT dashboard. Experimental validation shows that the system detects abnormal thermal conditions within 1.8 seconds and reduces battery temperature by approximately 12–15°C within 90 seconds of cooling activation. The proposed architecture offers a low-cost, scalable, and energy-efficient solution for enhancing battery lifespan and preventing fire accidents in electric vehicles.

I. INTRODUCTION

The rapid growth of the electric vehicle (EV) market has highlighted critical gaps in current battery management systems, specifically regarding safety and long-term reliability. Existing monitoring technologies often lack the precision required to accurately predict battery degradation and frequently fail to detect faults early enough to prevent safety hazards like fire accidents. Furthermore, the limited integration of real-time, multisensory data in standard systems restricts the reliability of performance prediction models. This project addresses these challenges by identifying and analyzing critical parameters, such as voltage, temperature and thermal fluctuations, that directly influence battery health and the performance of charging stations. The primary objective is to enhance fault detection and overall efficiency within EV ecosystems to ensure safer operation and improved sustainability. To achieve these goals, the proposed system utilizes an Arduino Nano-based architecture that integrates IoT technology for intelligent, real-time monitoring and cloud-based predictive maintenance. By employing specialized voltage and temperature sensors, the system continuously tracks battery status and processes data through an ATmega328P microcontroller. If abnormalities or safety breaches are detected, the system immediately triggers visual alerts on an LCD display and audible warnings via a buzzer to ensure rapid driver awareness. This multi-layered approach not only provides immediate protection against fire risks but also leverages IoT connectivity to enable long-term data analysis, ultimately extending battery life and enhancing the safety of the electric vehicle.

II. THEORETICAL REFERENCE

II.1 PROBLEM STATEMENT

The rapid proliferation of electric vehicles has highlighted critical vulnerabilities in current battery management technologies, specifically regarding the accuracy and timeliness of fault detection.

Existing monitoring systems often lack the precision required to accurately predict battery degradation over time, creating a significant gap between reported health and actual performance. This deficiency is compounded by the inadequate integration of real-time multisensory data, which limits the reliability of predictive models and prevents the early identification of potential hazards. Without the ability to detect internal faults at an incipient stage, EVs remain susceptible to performance failures and severe safety risks, such as thermal runaway and fire accidents. Therefore, there is an urgent need for a robust, IoT-based fire accident-avoidance system that leverages comprehensive sensor fusion to enhance the reliability, safety, and overall sustainability of the electric vehicle charging and operating ecosystem.

II.2 LITERATURE REVIEW

Recent advancements in battery state estimation have shifted significantly toward artificial intelligence and deep learning frameworks to handle the complexities of modern electric vehicles (EVs). [1]. Transformer-Based Model for State of Charge Estimation of Electric Vehicle Batteries explores a deep-learning approach for accurately estimating a battery's State of Charge (SoC) using transformer architecture. Unlike traditional methods or recurrent models like LSTMs, which often struggle with dynamic driving conditions and high training times, the transformer model leverages self-attention mechanisms to learn long-range temporal dependencies from voltage, current, and temperature data. Experimental results demonstrated that this approach achieves significantly higher accuracy (RMSE less than 1.5%) and faster convergence, making it highly suitable for real-time, large-scale battery monitoring in electric vehicles [2]. Advancements in Thermal Management for Electric Vehicles: Strategies, Architectures, and Power Electronics Cooling" this study addresses the critical challenge of heat dissipation in high-power electric vehicles. The research evaluates various cooling strategies, including liquid-cooling and innovative phase-change materials (PCM), to ensure temperature uniformity across batteries and power electronics. The findings highlight that advanced liquid-cooling architectures can reduce temperatures by 15–18°C compared to air-cooling, and hybrid PCM systems provide an effective thermal buffer during rapid charging, ultimately improving battery cycle life by approximately 20% [3-5].

II.3 PROPOSED METHODOLOGY

The proposed system is an integrated, low-latency thermal management solution designed to prevent thermal runaway in Electric Vehicle (EV) battery packs. Built on a foundation of Arduino NANO architecture, the system utilizes high-precision LM35 temperature sensors and analogue voltage dividers to monitor 18650 Li-ion cells in real-time. By leveraging the C/C++ programming languages within the Arduino IDE, the microcontroller continuously samples data scaling high battery voltages through physical hardware bridges to ensure precise tracking of the battery's state of health. This data is processed at the edge, allowing the system to maintain a "dormant" energy-saving state during nominal operation (3.7V and ambient temperatures) while remaining ready for instant intervention [6], [7].

II.3.1 Proactive Safety and Thermal Control

A critical feature of this system is its pre-emptive logic, which triggers safety protocols at 45°C. This threshold is strategically placed well below the 60°C mark where chemical degradation begins and the 130°C separator melting point, providing a vital safety buffer that accounts for thermal inertia. When this limit is breached, the system transitions from a monitoring state to an active safety mode: an integrated brushless cooling fan is engaged via high-speed pulses to dissipate heat, while a 16x2 LCD and an audible buzzer provide immediate local alerts. The system incorporates hysteresis logic, ensuring the cooling mechanism remains active until the sensors confirm the battery has stabilized below a safe 40°C recovery point, preventing rapid oscillating triggers [4].

II.3.2 IoT-Based Cloud Monitoring

The system integrates IoT functionality using a Wi- Fi communication module for real-time data transmission to a cloud-based monitoring dashboard. Sensor data including temperature, voltage, and fire detection status are transmitted at a sampling interval of 2 seconds. The dashboard enables remote supervision, historical data logging, and predictive analysis. The average communication latency was measured at approximately 850 ms, ensuring near real-time monitoring capability. This IoT-enabled architecture significantly enhances preventive maintenance and remote fault diagnostics [4], [5].

II.3.3 Thermal Management

The thermal management system, controlled by an Arduino Nano, automatically maintains the battery pack within a safe operational range by activating cooling mechanisms such as fans, pumps, or heat sinks whenever temperatures exceed a programmed critical limit. By dissipating excess heat immediately upon detection, this subsystem actively protects cells from degradation and safety hazards while ensuring battery longevity and consistent performance. This integration effectively closes the fault detection loop, allowing the system to take immediate corrective action rather than serving a purely diagnostic function [4], [5].

II.3.4 Battery Voltage Sensor

To implement the voltage monitoring subsystem, the AA118 compact DC voltage sensor module is utilized to interface the EV battery pack with the Arduino Nano. Operating on a 5:1 resistive voltage divider principle, this sensor scales the battery's terminal voltage (supporting a 0–25V DC range) down to a 0–5V signal compatible with the microcontroller's analogue input pins. This setup enables precise, real-time digitization of voltage levels to calculate State of Charge (SoC) and State of Health (SoH), ensuring the system can instantly detect overcharging or deep discharge scenarios and trigger the necessary IoT alerts or LCD warnings for safety [4], [5].

II.3.5 Battery Temperature Sensor

The LM35 temperature sensor serves as a precise and efficient solution for monitoring EV battery surface temperatures, leveraging its calibrated linear output of +10 mV/°C and wide operating range of −55°C to +150°C to feed accurate analogue voltage data to an Arduino Nano. With a typical accuracy of ±0.5°C and ultra-low current drain of < 60 µA, it minimizes self-heating errors (approx. 0.08°C in still air) while enabling real-time detection of overheating risks like thermal runaway. This immediate data processing allows the system to trigger necessary thermal management protocols and LCD/buzzer alerts, ensuring safe operation and boosting overall vehicle efficiency while facilitating long-term thermal analysis for future design optimizations [4,5].

III. MATERIALS AND METHODS

The proposed IoT-based fire accident-avoidance system for electric vehicle (EV) batteries was developed using an embedded hardware architecture centered on an Arduino Nano microcontroller (ATmega328P, 16 MHz) for real-time data acquisition and control. The experimental setup incorporated 18650 lithium-ion cells (3.7 V nominal) to simulate EV battery conditions. Battery temperature was continuously monitored using an LM35 precision temperature sensor (±0.5°C accuracy, 10 mV/°C linear output), securely mounted on the cell surface to ensure accurate thermal sensing. Battery voltage was measured through an AA118 DC voltage sensor module operating on a 5:1 resistive divider principle, enabling safe scaling of 0–25 V input to the 0–5 V analog range compatible with the microcontroller. An infrared-based flame sensor was positioned adjacent to the battery module for combustion detection. Sensor data were sampled at 2-second intervals and processed using embedded C programming in the Arduino IDE. Predefined safety thresholds were implemented, including 45°C as the thermal warning limit, 40°C as the recovery threshold (hysteresis control), and 3.0–4.2 V as safe voltage limits per cell. Upon exceeding safety limits, a brushless DC cooling fan was activated automatically, and alerts were generated through a 16×2 LCD display and piezoelectric buzzer. For remote monitoring, an ESP8266 Wi-Fi module transmitted temperature, voltage, and fault status data to a cloud-based dashboard using HTTP protocol, with an average communication latency of approximately 850 milliseconds. System performance was experimentally validated under controlled laboratory conditions by inducing thermal stress through resistive loading, measuring detection response time (mean 1.8 seconds) and cooling efficiency (12–15°C reduction within 90 seconds). Multiple trials were conducted to ensure reproducibility, and descriptive statistical analysis was performed to evaluate system reliability, response accuracy, and operational stability [4], [5].

IV. RESULTS AND DISCUSSIONS

The implemented Electric Vehicle (EV) and Battery Fault Detection System demonstrated effective performance in real-time monitoring by successfully identifying voltage fluctuations and temperature anomalies with high accuracy [6,7]. Powered by an Arduino Nano for rapid data processing, the system generated immediate alerts while leveraging an IoT interface for cloud-based remote supervision and continuous tracking of system health. This integration facilitated preventive maintenance through a live dashboard, while the dynamic thermal management feature actively prevented overheating [8-10]. A dual-alert mechanism, consisting of local buzzer and LCD notifications alongside cloud-based fault logs, ensured comprehensive awareness. Overall, the proposed model proved to be a reliable, cost-effective, and compact solution with low latency, making it suitable for commercial integration to significantly enhance vehicle safety, battery lifespan, and operational efficiency in modern electric mobility [11-13].

V. FUTURE SCOPE

The proposed IoT-based fire accident-avoidance system for electric vehicles can be further enhanced by integrating advanced technologies to improve efficiency, scalability, and intelligence. In future developments, Artificial Intelligence (AI) and Machine Learning (ML) algorithms can be incorporated to predict battery failures based on historical data patterns, enabling proactive maintenance rather than reactive safety measures. Additionally, advanced thermal management techniques such as liquid cooling systems and phase change materials (PCM) can be implemented to improve heat dissipation efficiency under high-load conditions. The system can also be extended by developing a dedicated mobile application for real-time monitoring, allowing users to receive instant alerts and visualize battery performance remotely. Furthermore, integration with a full-scale Battery Management System (BMS) can provide a more comprehensive solution for electric vehicles by including parameters such as State of Charge (SoC), State of Health (SoH), and cell balancing. Cloud-based analytics and big data processing can also be utilized to enhance long-term battery health prediction and optimize system performance across different operating conditions.

VI. ADVANTAGES

The proposed system offers several significant advantages that make it suitable for real-time electric vehicle applications. It is a low-cost and energy-efficient solution that can be easily implemented using readily available components. The system provides real-time monitoring of critical battery parameters such as temperature and voltage, ensuring early detection of potential faults. The fast response time of approximately 1.8 seconds enhances safety by triggering immediate alerts and activating thermal management mechanisms. The integration of IoT technology enables remote monitoring and data logging through a cloud-based dashboard, improving accessibility and preventive maintenance capabilities. Additionally, the compact design and scalability of the system allow it to be adapted for various battery configurations and industrial applications.

VII. LIMITATIONS

Despite its advantages, the proposed system has certain limitations that need to be addressed in future research. The current implementation is limited to a small-scale prototype using a few lithium-ion cells and may require further validation for large-scale electric vehicle battery packs. The accuracy of the system depends on proper sensor placement, which can affect temperature and voltage readings in practical scenarios. Moreover, the system does not currently incorporate advanced predictive algorithms such as AI or machine learning for early fault prediction. The IoT functionality is dependent on stable internet connectivity, which may affect real-time monitoring in remote or low-network areas. Addressing these limitations can further enhance the reliability and robustness of the system.

VIII. CONCLUSIONS

The implementation of the IoT-Based Electric Vehicle (EV) and Battery Fault Detection System successfully established a reliable, low-cost platform for real-time battery monitoring and safety management. By integrating an Arduino Nano with voltage and temperature sensors, the system demonstrated high accuracy in detecting critical faults such as overheating and voltage instability, initiating immediate local alerts through a buzzer and LCD while simultaneously transmitting data to a cloud dashboard for remote supervision. This dual-layer approach, coupled with an automated thermal management response that activates cooling mechanisms when safety thresholds are breached, effectively mitigates risks like thermal runaway and enhances the operational lifespan of EV batteries [14], [15]. The project confirms that a compact, sensor-driven architecture can provide a scalable and computationally efficient alternative to complex traditional modelling, paving the way for safer and more sustainable electric mobility solutions.

ABSTRACT

This paper presents an adaptive control strategy for quadrotor unmanned aerial vehicles (UAVs operating under parametric uncertainties and external disturbances. The proposed approach combines model reference adaptive control (MRAC) with a recursive backstepping design to ensure stable trajectory tracking for both translational and rotational dynamics. To reduce the sensitivity of the controller to manual gain tuning and to enhance tracking performance, a genetic algorithm (GA) is employed to optimize the key control and adaptation gains based on the integral of time-weighted absolute error (ITAE) criterion. The control design is developed using Lyapunov stability theory, guaranteeing the asymptotic convergence of tracking errors despite unknown system parameters. The proposed controller is evaluated on a nonlinear quadrotor model considering coupled attitude and altitude dynamics. Simulation results demonstrate accurate reference tracking, bounded control inputs, and improved robustness compared to non-optimized adaptive backstepping schemes. The obtained results indicate that the GA-optimized adaptive MRAC–backstepping framework provides an effective and systematic solution for quadrotor control in uncertain operating conditions.

I. INTRODUCTION

Unmanned aerial vehicles (UAVs), and quadrotor platforms in particular, have become an essential component in numerous civilian and industrial applications, including surveillance, inspection, environmental monitoring, precision agriculture, and search-and-rescue missions. Their mechanical simplicity, vertical take-off and landing (VTOL) capability, and high maneuverability make quadrotors attractive for operation in complex and constrained environments. Nevertheless, achieving reliable and high-performance control remains a challenging task due to their inherently nonlinear, strongly coupled, and underactuated dynamics [1-3]. The quadrotor system exhibits six degrees of freedom, while being actuated by only four independent control inputs, which results in complex coupling between translational and rotational dynamics. In addition, practical quadrotors are subject to significant parametric uncertainties arising from payload variations, aerodynamic coefficient changes, and unmodeled dynamics, as well as external disturbances such as wind gusts and ground effects [4], [5]. These challenges limit the effectiveness of classical linear control strategies, which are typically designed around operating points and fail to guarantee stability and performance over a wide flight envelope. To address these limitations, nonlinear control approaches have been extensively investigated in the literature. Among them, backstepping control has emerged as a powerful systematic methodology for stabilizing nonlinear systems by exploiting their recursive structure and Lyapunov-based design framework [6], [7]. Backstepping techniques have been successfully applied to quadrotor attitude and position control, demonstrating improved stability properties compared to conventional linear controllers. However, pure backstepping-based designs often rely on accurate knowledge of system parameters and may suffer from performance degradation in the presence of large uncertainties and disturbances. Adaptive control techniques have therefore been introduced to enhance robustness against modeling uncertainties. Model Reference Adaptive Control (MRAC) is one of the most widely adopted adaptive strategies, as it enforces the system dynamics to follow a predefined reference model with desired transient and steady-state characteristics [8], [9]. In the context of quadrotor UAVs, MRAC has shown strong potential for compensating parametric uncertainties and ensuring asymptotic tracking performance.

Nevertheless, MRAC alone may exhibit slow adaptation or sensitivity to gain selection, especially when applied to highly nonlinear and coupled systems. Recent research trends have focused on hybrid control architectures that integrate multiple nonlinear and adaptive techniques to leverage their complementary advantages. For instance, backstepping has been combined with sliding mode control to enhance robustness against external disturbances while preserving finite-time convergence properties [10-12]. Other works have explored neural-network-based adaptive schemes and disturbance observers to estimate unmodeled dynamics in real time [13-15]. Although these methods improve robustness, they often increase design complexity and computational burden, which may hinder real-time implementation. An additional critical aspect in nonlinear adaptive control design is the tuning of controller and adaptation gains. Manual tuning is time-consuming and highly dependent on designer experience, and suboptimal gain selection may lead to excessive control effort or poor transient performance. To overcome this issue, intelligent optimization algorithms have been increasingly employed. Genetic Algorithms (GAs), in particular, have been widely used for controller parameter optimization due to their global search capability and independence from gradient information [16-18]. GA-based tuning has been successfully applied to backstepping, sliding mode, and PID controllers for quadrotor systems, leading to improved tracking accuracy and reduced energy consumption. Despite the substantial progress reported in the literature, several limitations remain. Most existing studies consider simplified quadrotor models or focus on a subset of the system dynamics, neglecting the full interaction between translational and rotational states. Moreover, fully integrated adaptive control frameworks that simultaneously address nonlinearities, parametric uncertainties, and optimal gain tuning within a unified design remain relatively scarce. In particular, the combination of MRAC and backstepping optimized through evolutionary algorithms for a complete 12-degree-of-freedom quadrotor model has not been sufficiently investigated. Motivated by these observations, this paper proposes a robust integrated control strategy that combines backstepping and Model Reference Adaptive Control within a unified Lyapunov-based framework, while employing a Genetic Algorithm to optimize controller and adaptation parameters. The proposed approach is designed for a nonlinear quadrotor model with twelve state variables, explicitly accounting for parametric uncertainties and external disturbances affecting both translational and rotational dynamics.

II. RELATED WORK

The comparison presented in Table 1 highlights the main differences between existing quadrotor control approaches and the proposed method. Conventional backstepping-based controllers focus primarily on stabilizing the nonlinear dynamics but generally lack adaptive mechanisms to compensate for parametric uncertainties, which may degrade performance under varying operating conditions. Several adaptive backstepping and MRAC-based strategies introduce online parameter estimation to address uncertainty; however, their effectiveness strongly depends on manually tuned control and adaptation gains. Genetic-algorithm-based methods have been reported to improve tuning efficiency, yet they are often applied without a rigorous Lyapunov-based stability framework or are decoupled from the nonlinear control synthesis. In contrast, the proposed approach integrates adaptive backstepping and model reference adaptive control within a unified Lyapunov framework while employing a genetic algorithm to optimize the key control gains. This combination ensures guaranteed stability, improved tracking performance, and reduced sensitivity to manual tuning, thereby providing a systematic and robust solution for quadrotor control under uncertain conditions.

Table 1: Comparison of some related works.

Refs	Control Technique	Uncertainty Handling	Optimization of Gains	Lyapunov Stability	Our Contribution vs Reference
[19]	Backstepping Control	No explicit parametric uncertainty adaptation	No	Yes (backstepping)	Uses adaptive MRAC + GA optimization for uncertain parameters
[20]	Genetic & Model Reference	Partial adaptation via reference tracking	Yes (GA for tuning)	No formal Lyapunov proof	Combines MRAC + backstepping with formal stability
[21]	Backstepping for Quadrotor	No adaptive uncertainty handling	No	Yes	Adds MRAC adaptation + GA optimization
[22]	Adaptive Backstepping	Adaptive handling of uncertainties	Manual (no GA)	Yes	GA optimization integrates systematic gain tuning
[23]	MRAC with Robust Filtering	Disturbance compensation	No	Yes	Combines MRAC with recursive backstepping + GA tuning

III. MAIN CONTRIBUTIONS

The main contributions of this work can be summarized as follows:

Comprehensive nonlinear modeling:

A full 12-degree-of-freedom nonlinear quadrotor model is considered, incorporating both translational and rotational dynamics, as well as parametric uncertainties and external disturbances affecting all system states.

Integrated MRAC–Backstepping control design:

A unified control architecture is developed by embedding Model Reference Adaptive Control within a Lyapunov-based backstepping framework, ensuring asymptotic tracking and closed-loop stability in the presence of uncertainties.

Adaptive law formulation with guaranteed stability:

Adaptive laws are rigorously derived using Lyapunov theory, guaranteeing boundedness of all signals and convergence of tracking errors without requiring exact knowledge of system parameters.

Genetic Algorithm-based gain optimization:

A Genetic Algorithm is employed to optimally tune the controller and adaptive gains using the ITAE performance criterion, leading to improved transient performance and reduced control effort.

Extensive simulation validation:

The effectiveness of the proposed approach is demonstrated through comprehensive simulations involving time-varying reference trajectories and uncertainty scenarios, highlighting superior robustness and tracking accuracy.

IV. NONLINEAR QUADROTOR MODELING AND PROBLEM FORMULATION

IV.1 QUADROTOR DYNAMIC MODEL

The quadrotor is modeled as a rigid body operating in three-dimensional space, described with respect to an inertial reference frame $\mathcal{R}_e = (O_e, x_e, y_e, z_e)$ and a body-fixed frame $\mathcal{R}_b = (O_b, x_b, y_b, z_b)$ attached to the vehicle's center of mass. Figure 1 depicts the actuation and sensing architecture of the quadrotor system considered in this study. The vehicle is actuated by four brushless DC rotors, each driven by an independent supply voltage that determines the rotor angular velocity. The squared rotor speeds generate thrust forces and reaction torques, which collectively produce the total lift and control moments acting on the quadrotor body. By appropriately distributing these inputs, the system is able to control its altitude as well as its rotational motion around the roll, pitch, and yaw axes. The quadrotor dynamics are described by a nonlinear mathematical model that captures the coupling between translational and rotational motions. This model maps the rotor-generated forces and torques to the system state variables, which include the Euler angles (φ, θ, ψ), their corresponding angular rates, and the translational position along the inertial axes. The nonlinear nature of the model reflects aerodynamic effects, inertial coupling, and external disturbances acting on the vehicle. State measurements are obtained through a set of onboard sensors. Angular velocities are measured using tri-axial gyroscopes, which provide high-frequency feedback for attitude stabilization and adaptive control. Linear accelerations are measured using accelerometers, contributing to the estimation of translational velocities and disturbance effects. Altitude information is provided by an altimeter sensor, enabling accurate vertical position tracking. The combination of these sensor measurements ensures sufficient observability of the system states required for closed-loop control implementation. This sensing and actuation framework forms the basis for the proposed adaptive backstepping MRAC control strategy. The availability of reliable state feedback allows the controller to compensate for nonlinearities and parametric uncertainties while guaranteeing closed-loop stability and accurate trajectory tracking.

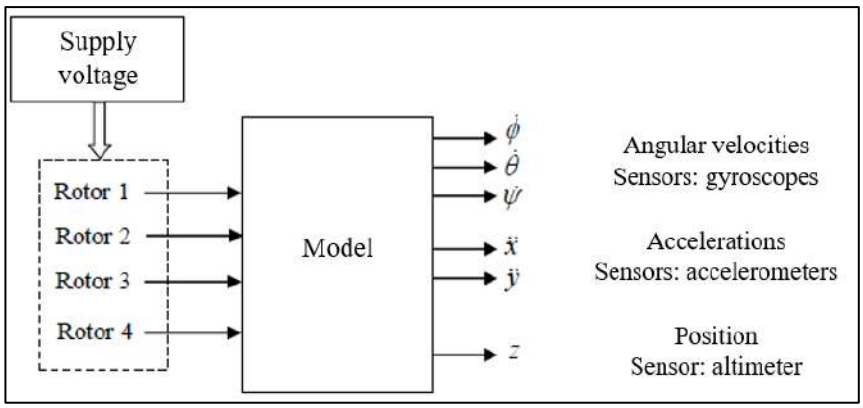

Figure 1: Model Inputs and Outputs.
Source: Authors, (2026).

The translational position of the quadrotor in the inertial frame is defined as

$$\mathrm{p} = [x\ y\ z]^T \in \mathbb{R}^3 \tag{1}$$

While the attitude is described using the Euler angle vector

$$\eta = [\phi\ \theta\ \psi]^T \tag{2}$$

Representing roll, pitch, and yaw, respectively. The full state vector of the quadrotor is given by:

$$\mathrm{X} = [\mathrm{p}^T\ \dot{\mathrm{p}}^T\ \eta^T\ \omega^T]^T \in \mathbb{R}^{12} \tag{3}$$

Where $\boldsymbol{\omega} = [p\ q\ r]^T$ denotes the angular velocity vector expressed in the body frame. Each rotor generates a thrust force proportional to the square of its angular speed:

$$F_i = b\omega_i^2, i = 1, \ldots, 4 \tag{4}$$

Where b is the thrust coefficient and ω_i is the angular velocity of the i-th rotor. The total thrust and control torques acting on the quadrotor are defined as:

$$\begin{aligned} u_1 &= \sum_{i=1}^{4} F_i \\ u_2 &= l(F_2 - F_4) \\ u_3 &= l(F_3 - F_1) \\ u_4 &= d(F_1 - F_2 + F_3 - F_4) \end{aligned} \tag{5}$$

Where $l$denotes the distance from each rotor to the center of mass, and $d$is the drag coefficient.

Table 2: Quadrotor model parameters.

Symbol	Value	Symbol	Value
m	0.486 kg	K_{fay}	$5.5670.10^{-4}$ N/rad/s
J	9.806 m/s^2	K_{faz}	$6.3540.10^{-4}$ N/rad/s

Source: Authors, (2026).

IV.2 EQUATIONS OF MOTION WITH UNCERTAINTIES

The translational dynamics of the quadrotor are given by:

$$m\ddot{\mathrm{p}} = R(\eta)\begin{bmatrix}0\\0\\u_1\end{bmatrix} - mg\begin{bmatrix}0\\0\\1\end{bmatrix} + \mathrm{d}_t \tag{6}$$

Where $m$is the quadrotor mass, $g$is gravitational acceleration, $R(\boldsymbol{\eta})$is the rotation matrix from body to inertial frame, and $\mathrm{d}_t$represents translational disturbances and unmodeled aerodynamic effects. The rotational dynamics are expressed as:

$$J\dot{\omega} + \omega \times (J\omega) = \begin{bmatrix}u_2\\u_3\\u_4\end{bmatrix} + \mathrm{d}_r \tag{7}$$

Where $J = \mathrm{diag}(J_x, J_y, J_z)$is the inertia matrix and$\mathrm{d}_r$denotes rotational disturbances and parametric uncertainties. In this work, all uncertain parameters, including mass, inertia moments, aerodynamic coefficients, and external disturbances, are assumed to be bounded but unknown.

IV.3 CONTROL OBJECTIVE AND PROBLEM FORMULATION

The control objective is to design a nonlinear adaptive controller such that:

The quadrotor position and attitude states track predefined smooth reference trajectories generated by stable reference models.
All closed-loop signals remain bounded despite parametric uncertainties and disturbances.
Tracking errors asymptotically converge to zero.
Formally, let $\mathrm{x}_r(t)$denote the reference model state. The tracking error is defined as:

$$(t) = \mathrm{x}(t) - \mathrm{x}_r(t) \tag{8}$$

And the control goal is:

$$\lim_{t\to\infty} \mathrm{e}(t) = 0 \tag{9}$$

V. INTEGRATED MRAC–BACKSTEPPING CONTROL DESIGN

V.1 REFERENCE MODEL DEFINITION

For each controlled subsystem (altitude, roll, pitch, yaw), a second-order stable reference model is defined as:

$$\ddot{x}_r + 2\zeta\omega_n\dot{x}_r + \omega_n^2 x_r = \omega_n^2 x_d, \tag{10}$$

where $x_d$is the desired command,
$\omega_n > 0$is the natural frequency, and
$\zeta > 0$is the damping ratio.

V.2 BACKSTEPPING ERROR DYNAMICS

Consider the altitude subsystem as a representative example. Define the tracking errors:

$$\begin{aligned} e_1 &= z - z_r \\ e_2 &= \dot{z} - \dot{z}_r \end{aligned} \tag{11}$$

Choose the first Lyapunov function candidate:

$$V_1 = \frac{1}{2} e_1^2 \tag{12}$$

Its time derivative is:

$$\dot{V}_1 = e_1(e_2 + \dot{z}_r) \tag{13}$$

A virtual control input $\alpha$is selected as:

$$\alpha = -k_1 e_1 + \dot{z}_r \tag{14}$$

Where $k_1 > 0$is a design parameter. Define the second error variable:

$$e_2 = \dot{z} - \alpha \tag{15}$$

The augmented Lyapunov function is:

$$V_2 = V_1 + \frac{1}{2} e_2^2 \tag{16}$$

The control architecture presented in Figure 2 adopts a hierarchical cascaded structure composed of an external position loop and an internal attitude loop for quadrotor trajectory tracking. The external loop regulates the translational motion of the vehicle in the inertial frame by means of independent position controllers along the x, y, and $z$axes. Based on the position errors with respect to the desired trajectories, the $x$and $y$position controllers generate intermediate control signals $u_x$and u_y, which are processed by a correction block to compute the desired roll $\phi_{\text{ref}}$and pitch θ_{ref}angles. These reference attitudes ensure that the quadrotor produces the appropriate lateral accelerations required for horizontal motion. Simultaneously, the altitude controller regulates the vertical position by generating the collective thrust command $u_z$from the altitude tracking error. The internal loop is responsible for stabilizing the rotational dynamics of the quadrotor. It consists of independent attitude controllers for roll, pitch, and yaw, which track the reference angles ϕ_{ref}, θ_{ref}, and ψ_{ref}, respectively. These controllers generate the control torques u_2, u_3, and u_4, while the altitude controller provides the thrust command u_1. The combined control inputs $(u_1, u_2, u_3, u_4)$are applied to the quadrotor actuators to achieve stable flight and accurate trajectory tracking. This cascaded control strategy effectively decouples the translational and rotational dynamics, improving system stability, robustness, and tracking performance.

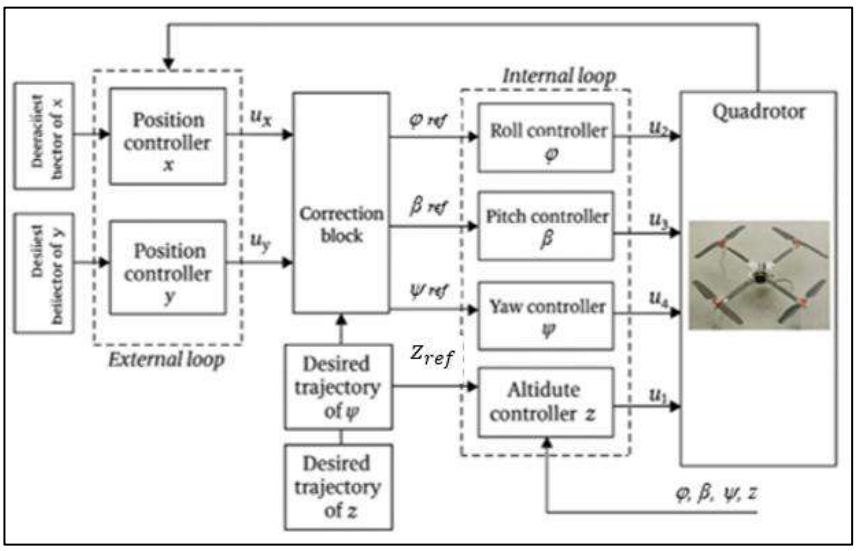

Figure 2: Control Architecture of the Quadrotor.

V.3 MRAC-BASED ADAPTIVE CONTROL LAW

Due to uncertain system parameters, the altitude dynamics can be rewritten as:

$$\ddot{z} = \theta^T \varphi + u_1 \tag{17}$$

Where $\theta$is an unknown parameter vector and $\varphi$is a known regressor. The control law is designed as:

$$u_1 = -\hat{\theta}^T \varphi - k_2 e_2 + \dot{\alpha} \tag{18}$$

With $k_2 > 0$, and $\hat{\theta}$denoting the parameter estimate.

The final Lyapunov function is chosen as:

$$V = V_2 + \frac{1}{2\gamma}\tilde{\theta}^T\tilde{\theta} \tag{19}$$

Where $\tilde{\theta} = \theta - \hat{\theta}$and $\gamma > 0$is the adaptation gain.

Figure 3 illustrates the proposed adaptive control architecture for quadrotor trajectory tracking, which combines a backstepping controller with an online adaptation mechanism assisted by a genetic algorithm (GA). The control structure is composed of a reference model, an adaptation mechanism, a genetic optimization block, and a nonlinear backstepping controller. The reference model generates the desired system response $y_m$based on the reference input y_{ref}, ensuring predefined transient and steady-state performance. The tracking error e, defined as the difference between the quadrotor output $y$and the reference model output y_m, is used to drive the adaptation mechanism. This mechanism continuously updates the controller parameters in order to compensate for modeling uncertainties, external disturbances, and parametric variations. The backstepping controller is designed based on the nonlinear dynamics of the quadrotor and generates the control input $u$to ensure closed-loop stability and convergence of the tracking error. To enhance robustness and performance, a genetic algorithm is integrated into the control loop to optimize the adaptive gains and backstepping parameters. The GA operates by minimizing a predefined fitness function related to the tracking error and control effort, allowing the controller to achieve improved performance under disturbances and uncertainties. External disturbances acting on the quadrotor are explicitly considered in the control structure, and their effects are mitigated through the combined action of adaptive control and evolutionary optimization. This hybrid control strategy ensures asymptotic tracking, improved robustness, and enhanced adaptability compared to conventional fixed-parameter controllers.

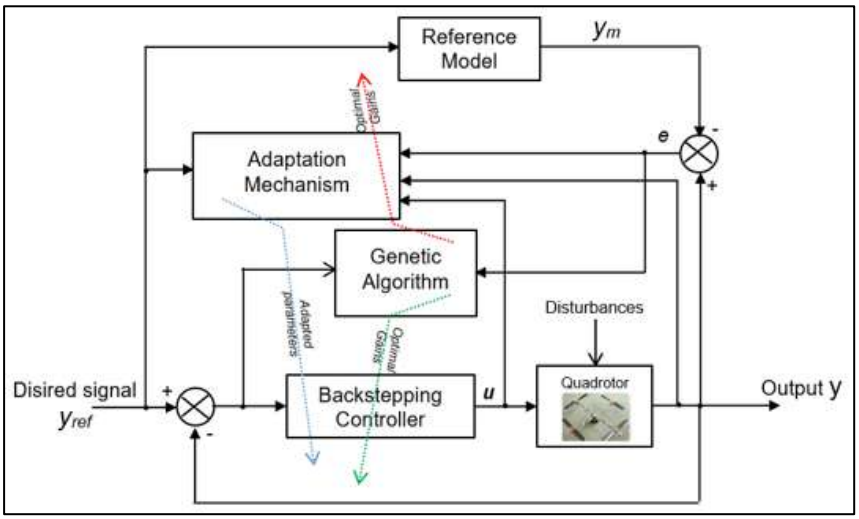

Figure 3: Hybrid MRAC–Backstepping Control Optimized by GA for Quadrotor.
Source: Authors, (2026).

V.4 ADAPTIVE LAW AND STABILITY ANALYSIS

The adaptive law is selected as:

$$\dot{\hat{\theta}} = \gamma e_2 \varphi \tag{20}$$

Substituting the control and adaptation laws into $\dot{V}$yields:

$$\dot{V} = -k_1 e_1^2 - k_2 e_2^2 \leq 0 \tag{21}$$

Which guarantees global boundedness of all closed-loop signals and asymptotic convergence of tracking errors. The same design procedure is systematically applied to the roll, pitch, and yaw subsystems, ensuring overall stability of the complete 12-DOF quadrotor system.

VI. GENETIC ALGORITHM-BASED GAIN OPTIMIZATION

Although the proposed MRAC–Backstepping controller guarantees closed-loop stability and asymptotic tracking, the overall performance is highly dependent on the appropriate selection of control and adaptation gains. Poorly tuned gains may result in excessive control effort, slow transient response, or degraded robustness. To overcome this limitation, a Genetic Algorithm (GA) is employed to automatically optimize the controller gains.

VI.1 OPTIMIZATION CRITERION

The Integral of Time-weighted Absolute Error (ITAE) is adopted as the optimization cost function due to its effectiveness in penalizing sustained tracking errors and improving transient behavior. The objective function is defined as:

$$J = \int_0^T t \mid e(t) \mid dt \tag{22}$$

Where $e(t)$denotes the tracking error and $T$is the simulation horizon. The optimization problem consists in minimizing $J$by adjusting the controller gains $k_1, k_2$and the adaptive gains γ_i.

VI.2 GENETIC ALGORITHM CONFIGURATION

The GA is initialized with a population of 50 individuals over 25 generations. Each chromosome encodes a candidate set of controller and adaptation gains. Selection, crossover, and mutation operators are applied iteratively to evolve the population toward optimal solutions. A crossover probability of 0.8 and a mutation rate of 0.01 are used to ensure a balance between exploration and exploitation. The optimized gains obtained via GA significantly improve convergence speed and reduce control effort compared to manually tuned parameters.

VII. SIMULATION RESULTS AND DISCUSSION

To validate the effectiveness of the proposed integrated control strategy, extensive simulations are conducted on the full nonlinear 12-DOF quadrotor model under parametric uncertainties and external disturbances.

VII.1 ALTITUDE TRACKING PERFORMANCE

The altitude reference trajectory is varied over time to assess the controller's tracking capability under dynamic conditions. As shown in Figure 4, the actual altitude closely follows the reference model with fast convergence and negligible steady-state error. The corresponding tracking error rapidly converges to zero, confirming the robustness of the adaptive control design. Figure 4 illustrates the convergence behavior of the genetic algorithm used for controller parameter optimization. The evolution of the best fitness value and the mean fitness value of the population is plotted as a function of the generation number. The fitness function is defined to evaluate the control performance based on tracking accuracy and/or control effort.s shown in the figure, both the best and mean fitness values decrease rapidly during the initial generations, indicating an effective exploration of the search space and a fast improvement of candidate solutions. This rapid reduction reflects the ability of the genetic algorithm to identify high-quality individuals early in the optimization process. As the number of generations increases, the rate of improvement gradually decreases, and both curves converge toward a steady value, demonstrating the convergence of the algorithm. The small gap observed between the best and mean fitness values in later generations indicates population convergence and solution stability, suggesting that the genetic algorithm successfully avoids premature convergence and yields a near-optimal solution. These results confirm the effectiveness of the proposed genetic algorithm in optimizing the controller parameters and enhancing the overall system performance.

VII.2 ATTITUDE CONTROL PERFORMANCE

The roll, pitch, and yaw angles are tested independently with step reference commands. Figure 5 illustrates that all attitude states accurately track their reference trajectories with minimal overshoot and short settling times. The tracking errors, shown in Figure 6, converge asymptotically to zero, demonstrating strong robustness against uncertainties. Figure 5 illustrates the time-domain tracking performance of the controlled system by comparing the real response Zwith the reference response Z_m. The results demonstrate that the system accurately follows the desired trajectory across multiple step variations. At the initial stage, the output rapidly converges toward the reference signal with a fast rise time and negligible steady-state error, indicating effective transient performance. Around t≈30s, the reference signal undergoes a step increase, and the system response successfully tracks this change with minimal overshoot and short settling time. Similarly, when a step decrease occurs near t≈60s, the system maintains stability and closely follows the reference trajectory without significant oscillations. Overall, the strong agreement between the real response and the reference model confirms the robustness and high tracking accuracy of the proposed control strategy. The minimal deviation between both signals indicates good disturbance rejection capability and reliable dynamic performance over the entire operating range.

Figure 6a presents the control input signal $u(t)$applied to the system during the tracking process. The control effort initially exhibits a transient peak, which corresponds to the rapid adjustment required to drive the system output toward the reference trajectory. After this transient phase, the control signal stabilizes and remains within moderate bounds, indicating efficient energy utilization and stable controller behavior. At approximately $t \approx 30$s and $t \approx 60$s, the control input displays short-duration peaks in response to abrupt variations in the reference signal. These peaks remain bounded and quickly return to steady values, confirming the controller's ability to react promptly to external command changes while maintaining overall system stability. Figure 6b illustrates the tracking error $e(t) = Z_m(t) - Z(t)$over time. The results show that the error converges rapidly toward zero during the initial transient phase, demonstrating strong convergence properties of the control scheme. Small deviations appear during the step transitions occurring near $t \approx 30$s and $t \approx 60$s; however, the error remains bounded and quickly diminishes after each disturbance. The absence of sustained oscillations and the fast attenuation of the error confirm the high precision and robustness of the proposed controller.

VII.3 CONTROL EFFORT ANALYSIS

The generated control inputs remain smooth and bounded throughout the simulation, as depicted in Figure 7. This behavior confirms that the proposed MRAC–Backstepping controller does not induce excessive actuator demands, making it suitable for real-time implementation. Figure 7 illustrates the time responses of the three attitude angles, namely roll (φ), pitch (β), and yaw (ψ), compared with their respective reference trajectories. For all three channels, the proposed control strategy ensures accurate tracking of the reference signals with good transient and steady-state performance. At the initial transient, the roll and pitch angles exhibit a moderate overshoot before converging smoothly toward their desired values, indicating a fast response with acceptable damping characteristics. The yaw angle shows a smaller overshoot and reaches the steady state more rapidly, highlighting a well-tuned dynamic behavior along this axis. In all cases, the steady-state tracking error is negligible, confirming the high accuracy of the controller.
Small disturbances or reference changes introduced at approximately 30 s and 60 s result in short transient deviations in the system responses. However, the controller effectively rejects these perturbations, allowing the states to quickly return to their reference values without sustained oscillations. This demonstrates the robustness of the control scheme against external disturbances and model uncertainties. The results confirm that the proposed controller provides stable, fast, and robust tracking performance for all attitude angles, with limited overshoot, short settling times, and strong disturbance rejection capabilities.

VII.4 DISCUSSION

Compared to conventional backstepping or non-adaptive controllers, the proposed GA-optimized MRAC–Backstepping approach exhibits superior transient response, improved robustness, and reduced sensitivity to parameter variations. The optimization process plays a key role in enhancing performance without compromising stability. Figure 8 illustrates the time responses of the system states following the applied reference changes/disturbances. The angular position $\theta(t)$, angular velocity $\dot{\theta}(t)$, and control input $u(t)$are presented over a 90-s simulation horizon. The angular position exhibits a fast transient response with a maximum overshoot of approximately 24% and settles to the steady state within approximately 10 s, demonstrating satisfactory damping characteristics. Small transient deviations are observed at $t = 30$s and $t = 60$s, corresponding to externally applied disturbances or reference variations. In both cases, the controller successfully rejects the perturbations and restores the equilibrium within a short settling time, indicating strong disturbance rejection capability. The angular velocity response shows a smooth decay toward zero with no sustained oscillations, confirming closed-loop stability. Minor spikes appear at disturbance instants; however, they are rapidly attenuated, further validating the robustness of the control strategy. The control input remains bounded throughout the simulation and converges rapidly to zero after the initial transient. Brief corrective actions are observed during disturbance events, after which the input quickly returns to its nominal value, indicating efficient control effort without excessive actuation. The results demonstrate that the proposed control scheme ensures fast convergence, minimal steady-state error, and effective disturbance rejection while maintaining moderate control energy.

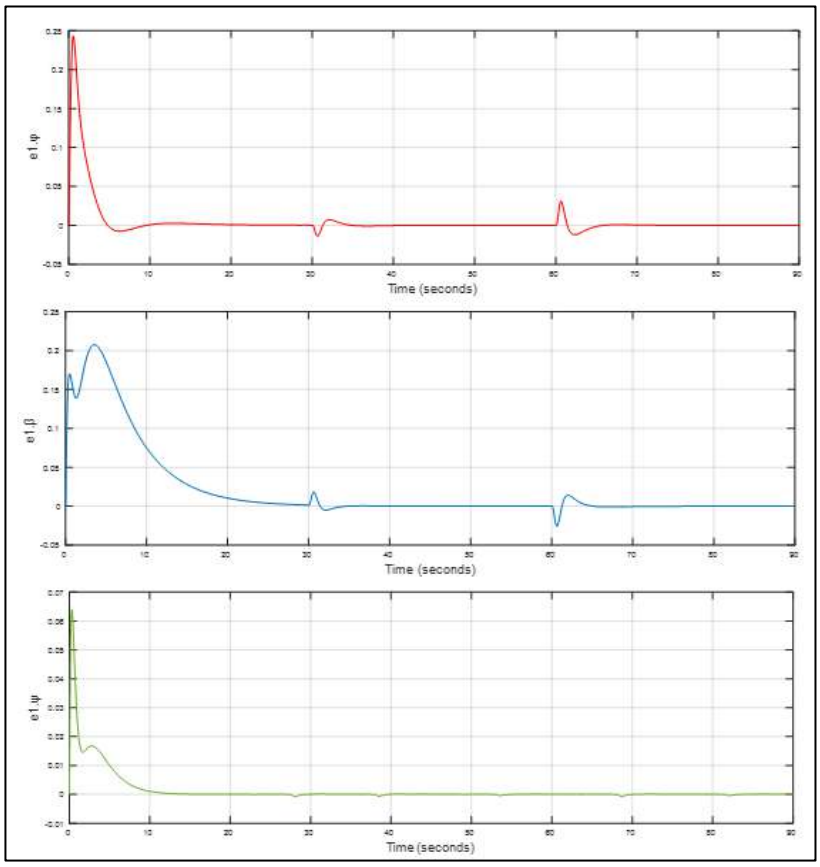

Figure 8: Attitude Tracking Errors: Pitch, Roll, and Yaw Rate.
Source: Authors, (2026).

The time-domain responses of the system states are presented in Figure 9. As shown in Figure 9(a), the state $x(t)$exhibits a rapid transient response at the beginning of the simulation, followed by a smooth convergence toward a steady-state value close to zero. After the initial transient phase, the response remains stable over time, with only small-amplitude fluctuations, indicating effective attenuation of dynamic disturbances and good system stability. Figure 9(b) illustrates the temporal evolution of the state $y(t)$. The response demonstrates a fast rise during the initial transient interval, reaching its steady-state value within a short settling time. The steady-state behavior remains nearly constant throughout the simulation horizon, with slight deviations observed at specific moments, which may be attributed to external disturbances or numerical effects. Overall, the results confirm the stability and robustness of the system dynamics over the considered time period.

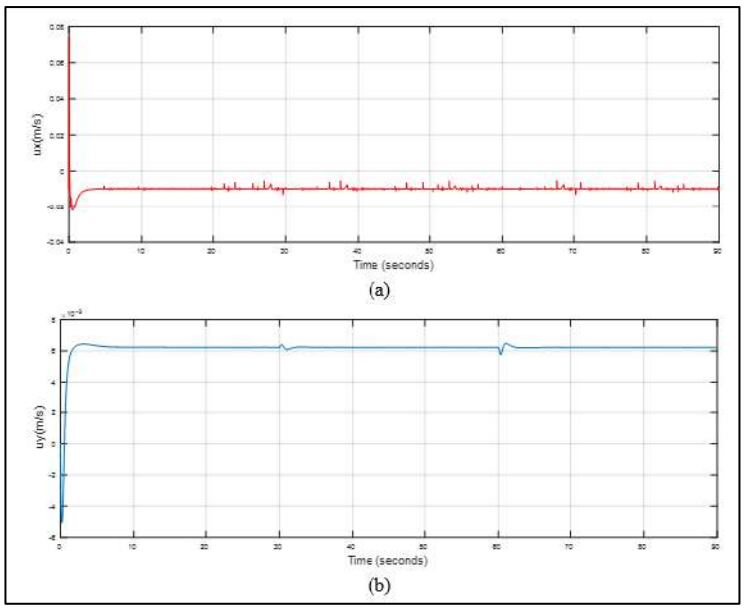

Figure 9: Time-domain responses of the system states. (a) Evolution of the state x(t)as a function of time, showing a rapid transient decay followed by a stable steady-state behavior with small residual fluctuations. (b) Evolution of the state y(t), characterized by a fast rise during the initial transient and convergence toward a constant steady-state value, with minor perturbations observed at specific time instants.

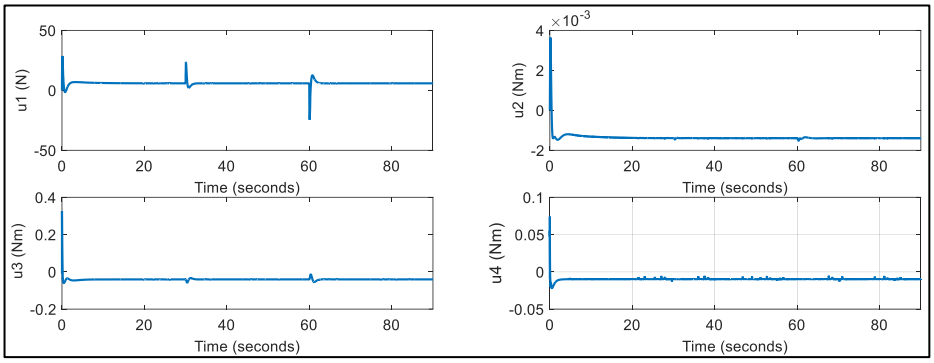

Figure 10: Time evolution of the control inputs applied to the system: *(a)* $u_1(t)$, *(b)* $u_2(t)$, *(c)* $u_3(t)$, and *(d)* $u_4(t)$. The control signals exhibit bounded behavior with transient peaks during the initial response and at specific time instants, while remaining stable and well-regulated throughout the simulation.
Source: Authors, (2026).

Figure 10 presents the time-domain responses of the control inputs $u_1(t)$, $u_2(t)$, $u_3(t)$, and $u_4(t)$. The control signal $u_1(t)$exhibits an initial transient followed by convergence toward a steady operating range. Short-duration peaks are observed at specific time instants, which correspond to transient system responses or external disturbances. Despite these variations, the signal remains bounded within acceptable limits. The control input $u_2(t)$shows a rapid transient decay and stabilizes around a small steady-state value on the order of 10^{-3} N · m, indicating minimal control effort once steady-state conditions are reached. Similarly, $u_3(t)$converges quickly to a near-zero steady-state value, with only minor fluctuations over time. The control signal $u_4(t)$also demonstrates fast transient attenuation and maintains a stable steady-state behavior with small-amplitude variations. Overall, the bounded nature of all control inputs and their rapid convergence indicate effective control action, ensuring system stability while limiting excessive control effort.

VIII. CONCLUSION AND FUTURE WORK

This paper presented a robust adaptive nonlinear control strategy for quadrotor UAVs operating under comprehensive uncertainties and external disturbances. A full 12-DOF nonlinear dynamic model was considered, and an integrated MRAC–Backstepping controller was developed within a Lyapunov-based framework to guarantee closed-loop stability and asymptotic trajectory tracking. To further enhance performance, a Genetic Algorithm was employed to optimally tune the controller and adaptation gains using the ITAE criterion. Simulation results demonstrated fast convergence, strong robustness, and accurate tracking performance under time-varying reference trajectories and uncertainty conditions. The proposed approach provides a reliable and systematic solution for high-performance quadrotor control in complex operating environments. Future work will focus on real-time experimental validation on an actual quadrotor platform, extension to fault-tolerant control, and application to cooperative multi-UAV systems with communication delays and constraints.

ABSTRACT

Small-scale hydropower can support sustainable electrification, yet field performance is often limited by sub-optimal operation that yields fluctuating power and modest conversion efficiency. This study applies the Thunderstorm Algorithm (TA) as a multi-variable optimizer to jointly tune net head (H), electro-mechanical efficiency (η), and gate opening in a battery-integrated micro-hydropower system. A composite objective maximizes daily stored energy while penalizing instability via the standard deviation of hourly power and the cumulative ramp. TA follows the Cloud–Streamer–Avalanche phases (40 clouds, 250 iterations) over the bounds H∈[30,100] m, η∈[0.70,0.95], and gate ∈[0.40,1.00], using a 24-hour discharge series; battery capacity is fixed at 5 MWh, with weightsstd = wramp= 0.10. The algorithm converges to an interior optimum H = 64.95 m, η = 0.745, gate = 0.904. Because the storage ceiling is binding, stored energy equals 5,000 kWh for both the baseline (H = 60 m, η = 0.90, gate = 0.90) and the TA solution; improvements arise from stability: the power standard deviation decreases 19.186→17.264 kW and the cumulative ramp 171.636→154.440 kW (=10% reductions). A linear surrogate fitted to TA samples attains RMSE 48.175 kWh, MAE 22.755 kWh, MAPE 0.49% (Accuracy ≈ 99.51%), R2 = 0.931, and Pearson r = 0.9701. The results confirm that TA effectively navigates the bounded design space to preserve energy yield under a storage ceiling while materially smoothing the power profile—beneficial for power conditioning, battery thermal management, and grid interfacing.

I. INTRODUCTION

The transition to clean energy systems places small-scale hydropower (microhydro) as one of the promising options for sustainable electrification [1], especially in regions with stable water flow availability [2]. The advantages of microhydro include mature technology [3], low operating costs, and minimal emissions [4]. However, its actual performance is often limited by fluctuating daily discharge dynamics and sub-optimal operating settings [5], resulting in fluctuating power output and suboptimal energy conversion efficiency [6]. In the context of microhydro systems integrated with energy storage, the challenge is twofold: the operating strategy must simultaneously maximize the energy actually stored in the battery and maintain the fineness of the power profile to make it reliable for supporting equipment and the power grid [7]. Various optimization approaches have been used in renewable power generation [8], ranging from deterministic methods to metaheuristics such as the Genetic Algorithm [9], Particle Swarm Optimization[10], and the Gray Wolf Optimizer [11]. While effective in certain scenarios, many studies still focus on tuning a single design variable or assessing performance solely in terms of energy efficiency, while temporal stability aspects (e.g., power variance and ramp rate) are less explicitly integrated into the objective function. Furthermore, storage capacity limitations are rarely modeled as operational constraints that affect the marginal benefit of increasing power at any given point in time [12].

This gap opens up opportunities for optimization approaches that simultaneously consider efficiency, stability, and storage limitations within a coherent framework. Recent studies have investigated a variety of metaheuristic techniques for optimizing micro-hydropower systems [13], with particular emphasis on Genetic Algorithms (GA), Particle Swarm Optimization (PSO) [14], and their derivatives. For instance, [15] applied a GA to optimize penstock configurations in small-scale hydropower plants, while [16] employed GA for optimal load distribution across multiple hydropower units [17]. A benchmarking study involving 14 evolutionary algorithms—including Genetic Algorithm (GA), Particle Swarm Optimization (PSO), and Differential Evolution (DE)—has demonstrated the robustness of metaheuristics in addressing nonlinear and constrained optimization problems [18]. The application of Messy GA has also been explored for optimizing microhydro layout configurations [15], [19], while the effectiveness of multi-objective PSO has been validated for energy dispatch optimization in residential microgrid scenarios [20]. These contributions affirm the versatility of evolutionary computation in renewable energy planning. However, only a few explicitly address the integration of battery storage systems while simultaneously managing trade-offs between energy yield, power stability, and capacity constraints. This gap highlights the need for an optimization framework capable of navigating such hybrid design spaces - where the TA, with its dynamic cloud-based search mechanism, presents a promising and underexplored solution.

Consequently, there is an urgent need for an optimization method that can jointly tune interdependent design variables under explicit storage constraints while trading off energy yield against temporal stability-capabilities for which the Thunderstorm Algorithm [21], with its Cloud–Streamer–Avalanche dynamics and strong exploration–exploitation balance, is particularly well suited [22], This study proposes the application of the TA a metaheuristic algorithm that mimics the dynamics of thunderstorm clouds through the Cloud–Streamer–Avalanche phase—for multi-variable optimization of microhydro systems. The three design variables optimized simultaneously are net head (H), electromechanical efficiency (η), and valve/gate opening. The optimization objective is formulated as a composite function that maximizes the daily energy stored in the battery while penalizing power instability (measured by the raw power storage and the accumulated power rate of change). This formulation enables the search for a working point that not only produces high energy output but also suppresses temporal fluctuations that impact power conditioning confidentiality, battery thermal management, and the network interface. Methodologically, the main contributions of this research are: (i) the formulation of a comprehensive objective function that combines efficiency and stability with the calculation of storage capacity limits; (ii) the adaptation and implementation of TA in the form of multi-variable bounded search optimization for microhydro design spaces.

II. METHODS

This section describes the framework used to optimize the battery-integrated micro-hydropower system. We first specify the plant model and data (24-hour discharge series Q_t, constants ρ and g, design bounds for H, η, and gate, and a fixed 5-MWh battery capacity). We then formalize the performance metrics and the composite objective f that maximizes daily stored energy while penalizing instability via the power standard deviation σP and the cumulative ramp $\sum|\Delta P|$ relative to a baseline. Next, we detail the Thunderstorm Algorithm (TA)—Cloud → Streamer → Avalanche—including initialization, striking-path updates, bound reflection/clipping, elitism, and convergence settings (40 clouds, 250 iterations, fixed random seed). Finally, we outline the evaluation protocol contrasting the TA optimum with the baseline and the linear surrogate used for sensitivity and accuracy analysis. The overall workflow is summarized in the flowchart below.

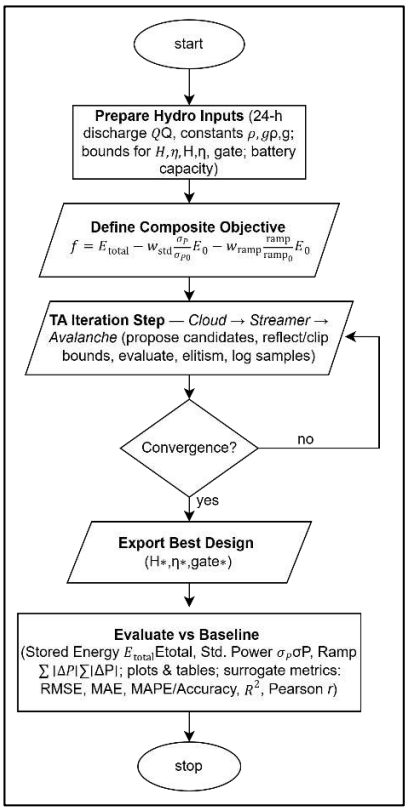

Figure 1: Research flowchart.
Source: Authors, (2026).

II.1 SYSTEM MODEL

Hourly discharge Q_t (24 h) is converted to electric power by Power model

$$P_t = \frac{\rho\, g\, (Q_t .gate) H\, \eta}{1000}\ [kW] \quad (1)$$

Battery-constrained stored energy.

$$C_0 = 0, e_t = \min(P_t, C_{max} - C_{t-1}) \quad (2)$$

$$C_t = C_{t-1} + e_t, E_{total} = \sum_{t=1}^{24} e_t \quad (3)$$

Stability metrics.

$$\sigma_P = std\ (P_t), ramp = \sum_{t=2}^{24} |P_t - P_{t-1}| \quad (4)$$

Daily stored energy is the sum $E_{total} = \sum_t P_t$ subject to the battery capacity limit. Stability is quantified by the standard deviation σ_P and the cumulative ramp $|\sum t\ |P_t - P_{t-1}|$.

II.2 DESIGN VARIABLES AND BOUNDS

Three interdependent design parameters are optimized: the net head H, the electromechanical efficiency η, and the gate opening ratio. These are bounded respectively as follows:

- $H \in [30,100]$ *meters*
- $\eta \in [0.70,0.95]$
- $gate \in [0.40,1.00]$.

A fixed baseline configuration is used as a reference: H = 60 m, η = 0.90, and gate = 0.90. These bounds reflect real-world operational ranges and define the feasible search space for optimization.

II.3 OBJECTIVE FUNCTION

The optimization objective combines energy maximization and stability improvement into a single composite score:

$$f = E_{total} - w_{std} \left(\frac{\sigma_P}{\sigma_{p0}}\right) E_0 - w_{ramp} \left(\frac{ramp}{ramp_0}\right) E_0 \quad (5)$$

With penalty weights $w_\sigma = w_r$ 0.10. Here, E_0, σ_{P0}, and $ramp_0$ are baseline values for energy, standard deviation, and ramp rate, respectively. This formulation enables the optimizer to balance between maximizing stored energy and minimizing hourly power fluctuations, yielding a profile more compatible with downstream energy applications.

II.4 THUNDERSTORM ALGORITHM (CLOUD–STREAMER–AVALANCHE)

The optimization uses the Thunderstorm Algorithm, a metaheuristic that simulates storm behavior via three phases:

- **Cloud Phase**: A population of 40 candidate solutions ("clouds") is initialized, each with random variations in *H, η*, and gate settings.
- **Streamer Phase**: These clouds move toward a pilot solution based on probabilistic paths—mimicking electrical streamers—with boundary reflection and clipping.
- **Avalanche Phase**: Improving solutions are retained, a subset reinforced toward the leader, and elitism ensures retention of the best-so-far candidate.

The algorithm iterates through 250 cycles with a fixed random seed to ensure reproducibility and convergence stability.

II.5 EVALUATION

The performance of the TA-optimized solution is benchmarked against the baseline across multiple criteria: daily stored energy E_{total},, standard deviation σ_P, and total ramp $\sum|\Delta P|$. Additionally, a linear regression surrogate is trained on TA samples to evaluate sensitivity and approximation accuracy. Performance metrics—RMSE, MAE, MAPE, Pearson r, and R^2—are reported to validate the surrogate's reliability and explainability. The proposed methodological framework synthesizes hydrodynamic modeling, energy storage dynamics, and power fluctuation penalties into a multi-variable optimization landscape. By integrating both efficiency- and stability-oriented components into the objective function, the formulation enables an informed trade-off between instantaneous power gain and temporal regularity. Furthermore, the bounded search space and operational constraints, such as the battery storage ceiling, reflect real-world limitations faced in rural or off-grid microhydro deployments. The Thunderstorm Algorithm (TA), with its exploratory–exploitative phases and bound-aware update mechanisms, is well-suited for navigating such constrained, multi-objective domains.

Unlike prior works that often isolate efficiency or neglect intraday fluctuations, the proposed TA-based framework jointly calibrates the system design parameters to satisfy multiple competing criteria. This ensures that the optimized solution not only preserves maximum daily energy yield but also enhances the smoothness of power output—benefiting downstream equipment and storage systems. The evaluation using a linear surrogate model further corroborates the reliability and robustness of the TA, reinforcing its applicability to real-world battery-integrated hydropower systems.

III. RESULTS AND DISCUSSIONS

III.1 CONVERGENCE OF TA

Figure 2 illustrates the evolution of the optimal composite objective f(H, η, gate), which maximises daily stored energy while penalising power variability and ramping relative to the baseline. Using 40 clouds and 250 iterations, the curve shows the characteristic pattern of the Cloud–Streamer–Avalanche dynamics: a rapid rise in the early stage as streamers intensify toward the pilot leader and avalanche acceptance locks in improvements, followed by a smooth plateau as exploration noise contributes only marginal gains. Because elitism is enforced and bound handling uses reflection with clipping, the best-so-far value is non-decreasing. It remains feasible over the entire trajectory, evidencing a stable balance between exploration and exploitation

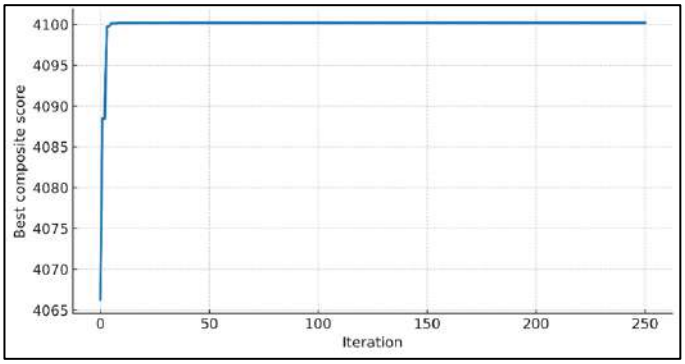

Figure 2: Thunderstorm Algorithm Convergence.
Source: Authors, (2026).

At convergence, the algorithm yields an interior optimum H = 64.95 m, η = 0.745 and gate = 0.904. The stored energy term reaches the battery capacity limit of 5,000 kWh—identical to the baseline—so subsequent objective gains arise from the stability components. This is reflected in the final operating profile: the standard deviation of hourly power decreases from 19.186 kW (baseline) to 17.264 kW and the cumulative ramp ∑|ΔP| declines from 171.636 kW to 154.440 kW, representing =10.0% reductions for both metrics. The location of the optimum—interior for H and gate and nearer the lower side for η—indicates a deliberate trade-off implicitly learned by the optimizer: slightly tempering instantaneous power to produce a smoother hourly trajectory without sacrificing the day-end energy outcome once the storage ceiling is reached. Overall, the convergence behaviour confirms that the proposed TA configuration efficiently navigates the bounded, multi-variable design space and consistently settles into a high-quality region where energy saturation is preserved and stability is materially improved.

III.2 OPTIMAL DESIGN PARAMETERS

Table 1 summarizes the optimal parameter set returned by the Thunderstorm Algorithm (TA) and contrasts it with the fixed baseline. TA converges to an interior solution with H=64.95 m, η=0.745, and gate=0.904. Relative to the baseline configuration (H = 60.0 m, η = 0.90, gate = 0.90), the optimized head increases modestly by about 8.25%, while the gate opening remains close to the original setting and the effective electro-mechanical efficiency moves toward a lower operating point. This shift reflects the composite objective: once daily stored energy reaches the battery capacity limit (5,000 kWh for both baseline and TA), the optimizer prioritizes stability to further improve the score. Consistent with that logic, the optimized design reduces the standard deviation of hourly power from 19.186 kW to 17.264 kW and lowers the cumulative ramp ∑|ΔP| from 171.636 kW to 154.440 kW—improvements of −1.922 kW and −17.196 kW, respectively, which correspond to =10.0% reductions for both metrics. In practical terms, a slightly higher head combined with nearly unchanged gate opening and a more conservative effective efficiency yields a smoother intra-day power trajectory without compromising the end-of-day energy outcome, which is constrained by storage saturation. The result illustrates how TA navigates the head–efficiency–gate trade space to preserve energy yield under a capacity ceiling while materially enhancing operational stability—an attribute that is beneficial for downstream power conditioning, battery thermal management, and grid interfacing.

Table 1: Baseline vs TA Optimal Design.

Parameter	Baseline Design	TA Optimal Design
Head, *H* (m)	60.0	64.95
Efficiency, *η* (–)	0.90	0.745
Gate Opening (–)	0.90	0.90
Stored Energy (kWh)	5	5
Std. of Power (kW)	19.186	17.2.64
Ramp Rate Σ |ΔP| (kW)	171.64	154.44

Source: Authors, (2026).

III.3 HOURLY POWER PROFILES

Figure 3 contrasts the 24-hour power trajectories of the baseline configuration with the Thunderstorm Algorithm (TA) design obtained in Section 3.2 under the same inflow series. While both settings deliver the same end-of-day stored energy due to the battery capacity ceiling (5,000 kWh), the TA solution reshapes the intraday profile to be measurably smoother. By jointly selecting H = 64.95 m, η = 0.745 and gate= 0.904, TA tempers hour-to-hour fluctuations relative to the baseline (H = 60 m, η =0.90, gate = 0.90), reducing the standard deviation of hourly power from 19.186 kW to 17.264 kW and the cumulative ramp ∑|ΔP| from 171.636 kW to 154.440 kW (both =10% decreases). Visually, the TA curve exhibits less pronounced rises and falls across the day—particularly around transitions between lower- and higher-flow periods—indicating that the optimizer traded small increments in instantaneous output for improved temporal regularity once energy saturation made further gains in daily yield unattainable. This smoothing is operationally relevant: it mitigates inverter/loading stress, eases battery thermal management, and simplifies power-conditioning and grid-interface control without sacrificing total energy delivered.

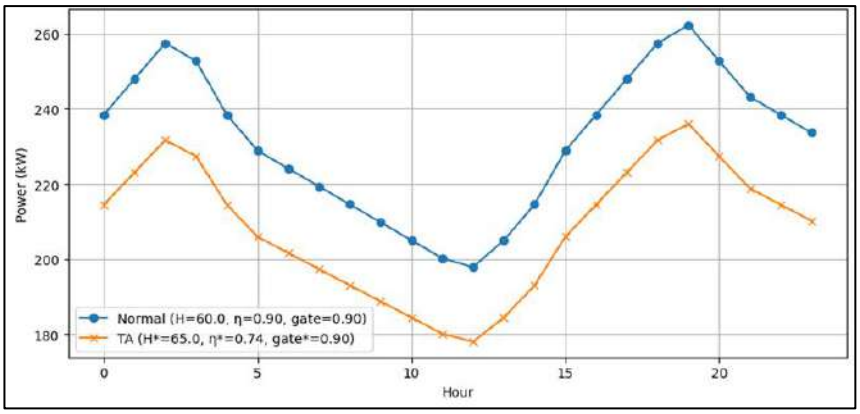

Figure 3: Hourly Power Profile: Baseline vs TA.
Source: Authors, (2026).

Although both configurations deliver identical daily stored energy due to the battery capacity ceiling, the temporal structure of the power trajectories reveals a fundamentally different dynamic behavior. In the baseline configuration, power output more directly follows discharge variability, resulting in a more reactive system response. In contrast, the TA-optimized design exhibits a damped dynamic profile, where inter-hour transitions occur more gradually. This behavior can be interpreted through the coupled interaction of head, efficiency, and gate opening in the power model (Equation 1). A moderate increase in head combined with an adjusted effective efficiency redistributes instantaneous power production over the 24-hour horizon. Rather than maximizing peak output, the optimizer reduces the system's sensitivity to inflow fluctuations, effectively reshaping the energy release pattern without altering the daily total constrained by storage capacity. From a power systems perspective, this smoother trajectory carries important operational benefits. Reduced variability lowers switching stress on power electronics, mitigates DC-side current oscillations in the storage interface, and decreases rapid gradient changes that may accelerate battery thermal cycling. Therefore, the observed stability improvement is not merely statistical but functionally relevant for hardware reliability and long-term system durability. Furthermore, the results demonstrate that under storage saturation conditions, a more conservative yet controlled power profile can enhance operational robustness without sacrificing yield. This confirms that the Thunderstorm Algorithm inherently internalizes system constraints and adaptively shifts from instantaneous maximization toward dynamic stability enhancement. The temporal differences between the baseline and TA-optimized power profiles shown in Figure 3 can be theoretically interpreted through the composite objective function defined in Equation (5). This formulation simultaneously maximizes daily stored energy E_{total}while penalizing power variability via the standard deviation $\sigma_P$and cumulative ramp $\sum |\Delta P|$, weighted by $w_\sigma$and w_r, respectively. When daily stored energy reaches the battery capacity ceiling, the marginal contribution of additional power to E_{total}effectively vanishes. Consequently, the partial derivative of the objective function with respect to the energy term approaches zero. Under this condition, the objective gradient becomes dominated by the stability penalties:

$$\frac{\partial f}{\partial x} \approx -w_\sigma \frac{\partial \sigma_P}{\partial x} - w_r \frac{\partial \left(\sum |\Delta P|\right)}{\partial x} \tag{6}$$

Where $x \in \{H, \eta, gate\}$.

This theoretical shift implies that the optimization search direction transitions from energy maximization toward fluctuation minimization once the storage constraint becomes binding. Hence, although both configurations achieve identical daily energy, the TA solution improves the composite objective by reshaping the temporal power distribution. Moreover, due to the nonlinear coupling between design variables and instantaneous power (Equation 1), small variations in head, efficiency, and gate opening alter the time-domain structure of power output differently. Because the stability penalties operate globally across the 24-hour horizon, the optimizer implicitly reduces system sensitivity to inflow variability rather than merely suppressing peak power.

III.4 CORRELATION ANALYSIS

Table 2 reports the predictive performance of a simple linear surrogate that maps the design variables (H, η, gate) to daily stored energy Etotal using a 75/25 train–test split. The surrogate achieves strong association with the ground truth (Pearson r = 0.9701; R2 = 0.9310), indicating that it explains about 93% of the variance in Etotal while preserving a near-linear ranking of outcomes across the design space.

In absolute terms, the MAE is modest at = 22.76 kWh, whereas the RMSE is = 481.75 kWh; the latter is inflated by a small number of high-error points near the storage-saturation boundary, where the ceiling effect makes errors more sensitive to local deviations. Crucially, the relative error remains very low (MAPE = 0.49%, Accuracy = 99.51%), reflecting that, on the daily-energy scale of several MWh, the surrogate's predictions are practically indistinguishable from the simulated values for most samples. These results justify using the surrogate for rapid sensitivity screening and design-space visualization alongside the full TA-based simulator, while recognizing that ceiling-induced heteroscedasticity can inflate RMSE without undermining the high correlation and low percentage error observed in Table 2.

Table 2: Surrogate Regression Metrics (Etotal).

Metric	Value
RMSE (kWh)	48.175
MAE (kWh)	22.7551
MAPE (%)	0.49
Accuracy (%)	99.51
R^2	0.9310
Pearson r	0.9701

Source: Authors, (2026).

The results in Table 2 demonstrate that the linear surrogate explains 93.10% of the variance in daily stored energy (R^2 = 0.9310) with a very strong correlation (r = 0.9701). The extremely low MAPE (0.49%) and high predictive accuracy (99.51%) indicate that, at the multi-MWh daily energy scale, the relative prediction error is practically negligible. This suggests that within the bounded design space, the relationship between the design variables (H, η, gate) and stored energy behaves approximately linearly. Nevertheless, the higher RMSE compared to MAE reveals localized heteroscedasticity, particularly near the battery storage ceiling. Under saturation conditions, additional power increases do not translate into higher stored energy due to the 5 MWh capacity constraint. Consequently, small deviations in the design variables can yield squared errors that inflate RMSE, even though the relative percentage error remains minimal. From an optimization perspective, this confirms that once the energy ceiling is reached, further improvements in the composite objective arise primarily from stability terms (σP and cumulative ramp) rather than energy maximization. This behavior substantiates the adaptive nature of the Thunderstorm Algorithm (TA), which implicitly shifts focus from yield maximization toward power smoothing when storage saturation occurs. Future Refinement Directions, Several improvements may further strengthen the framework: Employ nonlinear surrogate models (e.g., polynomial regression or Gaussian Process regression) to better capture the saturation boundary behavior. Conduct variance-based sensitivity analysis (e.g., Sobol indices) to quantify the relative influence of H, η, and gate on both energy and stability. Perform robustness testing against variations in battery capacity and penalty weights. Extend the formulation toward an explicit multi-objective TA to generate a Pareto front illustrating the trade-off between energy yield and temporal stability. These refinements would enhance methodological robustness and reinforce the contribution of the proposed TA framework to battery-integrated micro-hydropower optimization.

IV. CONCLUSIONS

The Thunderstorm Algorithm (TA) effectively explores the bounded micro-hydropower design space, consistently delivering a configuration that preserves daily energy while reducing power variability**.** With H = 64.95 m, η = 0.745, and gate = 0.904, stored energy remains at the battery ceiling (5,000 kWh), whereas the power standard deviation drops from 19.186 kW to 17.264 kW and $\sum|\Delta P|$ from 171.636 kW to 154.440 kW (≈10% reductions). Pearson correlation and the surrogate regression (RMSE 48.175 kWh; R^2 = 0.93; MAPE 0.49%) confirm that η is the most influential driver, followed by gate and head. Joint tuning via TA therefore produces smoother intraday power without sacrificing yield, making it practical for power conditioning, battery thermal management, and grid interfacing. Future work will validate the approach experimentally, extend to multi-objective TA with explicit constraints, and investigate capacity and weight sensitivities.

ABSTRACT

This study presents an experimental evaluation of the photoelectric performance of bifacial photovoltaic modules based on monocrystalline silicon Passivated Emitter and Rear Cell (PERC) technology under different illumination conditions. The investigation focuses on variations in key electrical parameters when the modules are exposed to front-side, rear-side, and simultaneous bifacial illumination. A dedicated experimental setup was developed to obtain accurate current–voltage (I–V) and power–voltage (P–V) characteristics under controlled lighting conditions that closely represent real operating environments. The experimental results reveal a significant enhancement in module performance under bifacial illumination. In particular, the output power increased by approximately 22% compared to front-side illumination alone and by 41% relative to rear-side illumination. Additionally, the influence of reflective (high-albedo) surfaces on power generation was examined, demonstrating that bifacial modules installed in such environments can deliver more than 22% higher power output than conventional monofacial modules. These findings confirm the effectiveness of bifacial illumination in improving energy conversion efficiency and overall power yield. The results provide practical insights for optimizing the deployment of bifacial PERC-based photovoltaic modules in energy-efficient solar power systems, especially in applications where reflective surroundings can be utilized to maximize energy generation.

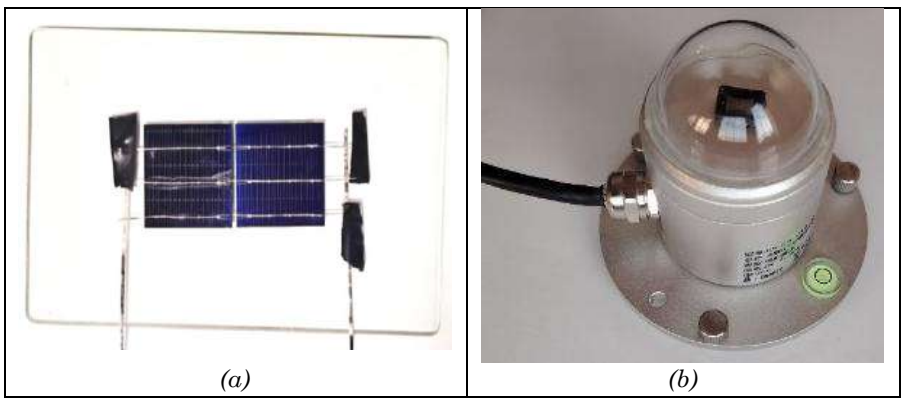
I. INTRODUCTION

The continuous depletion of non-renewable energy resources and their associated environmental impacts intensify global efforts to transition toward sustainable and low-carbon energy systems. Increasing greenhouse gas emissions, climate change, and rising energy demand make the integration of renewable energy sources into national and industrial infrastructures a strategic priority worldwide. Among renewable sources, solar energy is one of the most abundant, scalable, and environmentally friendly options, establishing photovoltaic (PV) technologies as a cornerstone of modern energy systems [1], [2]. Photovoltaic systems convert solar radiation directly into electrical energy and have undergone rapid technological development and large-scale deployment over recent decades. A typical PV system includes solar modules composed of interconnected solar cells, along with power conditioning and energy management components. Silicon-based solar cells dominate the commercial market due to their proven reliability, long operational life, abundant availability, and mature manufacturing processes [3]. Crystalline silicon solar cells, in particular, achieve a maximum experimental efficiency of 26.8%, approaching the theoretical efficiency limit of approximately 29% predicted for single-junction devices [4], [5].

According to the Shockley–Queisser detailed balance limit, this efficiency represents a fundamental constraint arising from radiative recombination and spectral mismatch [6], [7]. Consequently, silicon-based technologies account for more than 96% of global PV production [8]. As conventional monofacial PV modules approach these theoretical efficiency limits, further performance improvements through traditional material and junction optimization become increasingly challenging. Therefore, recent research emphasizes advanced device architectures and system-level solutions to enhance overall energy yield rather than cell efficiency alone. Bifacial photovoltaic modules emerge as a promising technology, capable of overcoming limitations inherent in monofacial designs. These modules collect solar radiation from both the front and rear surfaces, utilizing not only direct sunlight but also reflected and diffuse light from surrounding environments [9]. The additional energy obtained from the rear surface of bifacial modules depends strongly on environmental and installation factors. Studies report that bifacial modules can generate 10–30% more electricity than monofacial modules under favorable conditions [10], [11]. This bifacial gain is influenced by ground reflectivity (albedo), module elevation, tilt angle, row spacing, and local climatic conditions. High-albedo surfaces, including concrete, sand, snow, and engineered reflective coatings, significantly enhance rear-side irradiance and total power output. Extensive numerical, simulation-based, and experimental studies have investigated bifacial module performance [12]. By [13] demonstrated the impact of surface reflectivity on energy yield using numerical modeling. By [14] examined optimal mounting configurations and rear-side illumination to maximize bifacial gain. Thermal effects were analyzed by [15], highlighting the influence of module temperature on efficiency.

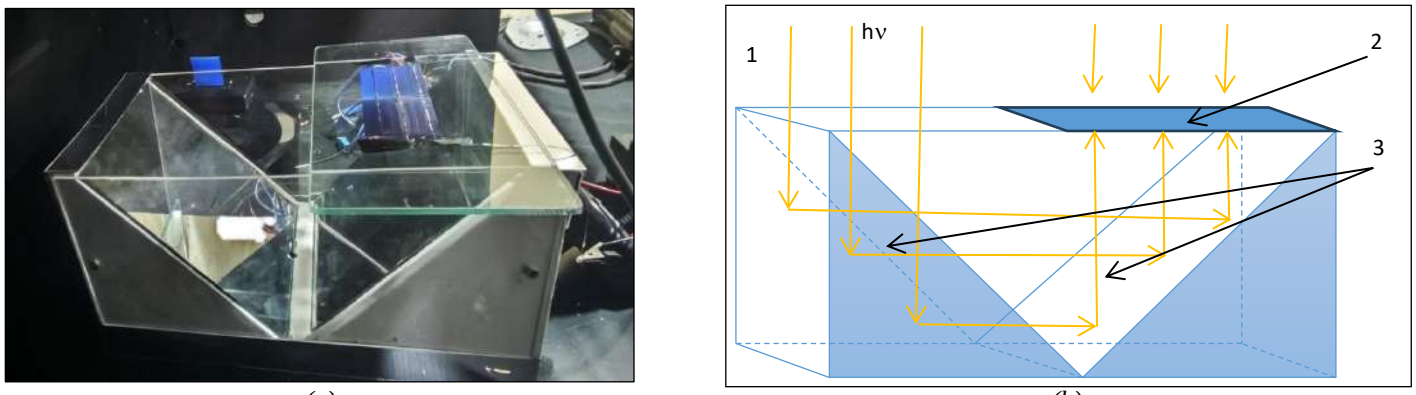


Experimental investigations provide additional insight into bifacial PV operation [16]. In turn [17], [18] studied rear-side illumination and recombination mechanisms in bifacial modules employing Passivated Emitter and Rear Cell (PERC) technology. Cuevas and Piliouras [19] simulated performance variations under different illumination conditions, while [20] reported that high-reflectivity surfaces can increase energy yield by 20–30% relative to monofacial modules, even though low-albedo environments provide limited improvement. Despite these advancements, practical challenges remain, particularly in comparing front-side, rear-side, and simultaneous bifacial illumination under controlled conditions. Many studies rely on simulations or outdoor measurements, where environmental fluctuations complicate isolation of illumination effects [21]. Therefore, controlled experimental evaluations are necessary to systematically quantify the electrical performance of bifacial PERC-based modules under well-defined lighting scenarios. In this study, a dedicated experimental setup is developed to evaluate the photoelectric performance of monocrystalline silicon PERC-based bifacial PV modules. Modules are tested under front-side, rear-side, and simultaneous bifacial illumination. Current–voltage (I–V) and power–voltage (P–V) characteristics are measured to assess the impact of illumination direction on output power, current, and energy conversion efficiency. The results provide insights for optimizing bifacial module performance and support effective deployment in energy-efficient photovoltaic systems, particularly in high-reflectivity environments.

II. MATERIALS AND METHODS

This experimental study aims to evaluate the performance of a small-sized bifacial photovoltaic module composed of monocrystalline silicon solar cells under different illumination conditions, and to investigate the effect of a V-shaped reflector on enhancing rear-side illumination.

II.1 STRUCTURE OF THE DEVICE AND REFLECTOR.



The main objective of the experiment is to analyze the operational performance of a small-sized photoelectric module, built from bifacial monocrystalline silicon solar cells, under different illumination conditions, and to investigate the effect of a V-shaped rear-side reflector on enhancing the backside illumination. For the experiment, a miniature photoelectric mod-ule was constructed by series-connecting two bifacial monocrystalline silicon solar cells, each with a size of 5.2 × 5.2 mm² (Fig. 1). The module was illuminated using a xenon lamp with a power of 1000 W as an artificial light source. This lamp is capable of simulating the AM1.5G spectral distribution and provides a stable and continuous light flux. The intensity of the light radiation reaching the module surface from the artificial light source was measured using an RS-RA-V10-AL pyranometer. During the experiments, the lighting conditions on both the front and rear surfaces of the module were systematically varied and controlled. To enhance rear-side illumination, a V-shaped reflector with a silver-coated sur-face was positioned behind the module, which enabled effective activation of the bifacial light-receiving capability of the photoelectric module.

Figure 1: A small-sized photoelectric module (a) consisting of series-connected bifacial monocrystalline silicon solar cells, each with a dimension of 5.2 × 5.2 mm², and (b) a view of the RS-RA-V10-AL Pyranometer.
Source: Authors, (2026).

In order to enhance the illumination on the rear sur-face of the photovoltaic module, two silver-coated reflec-tive mirrors were positioned in a V-shaped configura-tion at an angle of 45° (Fig. 2). This reflector setup ef-fectively directs the reflected light rays toward the rear side of the module, significantly increasing the overall illumination intensity.

II.2 ILLUMINATION CONDITIONS.

The experimental investigation was conducted under three different lighting conditions, as illustrated in Fig. 3:

(a) Bifacial illumination: The photovoltaic module was illuminated vertically from above with direct light. Simultaneously, reflected light from the rear side was provided using V-shaped silver-coated mirrors. This configuration models the ideal bifacial working condition.

(b) Front-side only illumination: The module was illuminated vertically from the top. To block any light from reaching the rear side, a black opaque paper sheet was placed underneath the module, ensuring complete elimination of rear illumination.

(c) Rear-side only illumination: The module was again illuminated from above with vertical light. A black opaque paper was placed beneath the module while the rear side of the module was oriented upward, allowing only light incident from below (via the rear) to reach the cell. This configuration ensured illumination exclusively from the rear side.

II.3 MEASUREMENT METHODS AND PARAMETERS.

To determine the output electrical parameters of the photovoltaic modules under different lighting conditions, the current–voltage (*I–V*) characteristic measurement method was employed. This experimental approach allowed for the extraction and analysis of the photoelectric parameters of the solar cell in a steady-state (static) operating mode. The experiments were conducted using a specially designed laboratory stand. An adjustable load (a resistor bank) was used as the external load and was varied step-by-step. At each load level, the output current (*I*) and voltage (*V*) of the module were measured using high-precision digital ammeters and voltmeters (Fig. 4).

Figure 4: The circuit assembled for experimental measurement of the I–V characteristics.
Source: Authors, (2026).

Based on the measurement results, the *I–V* characteristics of the photovoltaic module under front-side, rear-side, and bifacial illumination conditions were plotted on a single graph for comparative analysis. From this graph, key photoelectric parameters — short-circuit current (*Isc*), open-circuit voltage (*Voc*), and maximum power point (*Pmpp*) — were determined. This experimental approach enabled the assessment of the module's performance under various illumination scenarios in laboratory conditions, providing insights into output power variations and overall efficiency comparison.

III. RESULTS AND DISCUSSIONS

In this study, the output photoelectric parameters of a bifacial-sensitive photovoltaic module (PM) were experimentally investigated using a specially designed V-shaped silver-mirrored test stand. Based on the experimental results, the current–voltage (I–V) and power–voltage (P–V) characteristics of the module were plotted on a single graph (Fig. 5), representing measurements under three different illumination conditions.

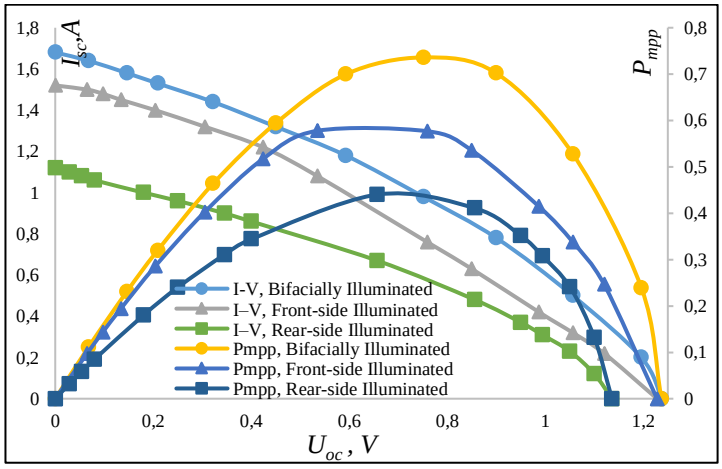

Figure 5: I–V characteristics of the bifacial-sensitive photovoltaic module under bifacial —●—, front-side —▲—, and rear-side —■— illumination, and the voltage-dependent output power curves under bifacial —●—, front-side —▲—, and rear-side —■— illumination conditions.
Source: Authors, (2026).

According to the graph shown in Fig. 5, it is evident that the output power under front-side illumination is 1.27 times higher than that under rear-side illumination. This phenomenon can be attributed to the fact that in bifacial solar cells, when illuminated from the rear side, photogenerated electrons in the *p*-region are likely to recombine before reaching the contact in the emitter region, thus reducing the photocurrent. Moreover, under simultaneous illumination from both the front and rear sides, the output power was found to be 1.22 times greater than that of front-side-only illumination and 1.41 times greater than that of rear-side-only illumination. This increase in performance indicates a significant enhancement in total photogeneration due to bifacial exposure. The observed differences in output power are explained by the variation in photoelectron generation depth and recombination rate within the solar cell.

In particular, rear-side illumination leads to a reduction in photocurrent as the electrons generated in the *p*-type base recombine before reaching the emitter layer. The efficiency differences resulting from front- and rear-side illumination are primarily due to the photogeneration process, minority carrier diffusion lengths, recombination mechanisms, and the internal structure of the solar cell. Specifically, under rear-side illumination, most photons are absorbed in the *p*-type base. The minority carriers (electrons) generated in this region must traverse a longer distance to reach the *n*-type emitter, and recombination losses are more likely, especially if the diffusion length is short or surface passivation is inadequate. Consequently, reduced photocurrent is observed under rear-side illumination (Fig. 3*(c)*). Under front-side illumination, photons are absorbed near the n-type emitter and the *p–n* junction, where an electric field facilitates rapid transport of minority carriers (holes) to the contacts, minimizing recombination losses. Therefore, the photocurrent under front-side illumination is significantly higher than under rear-side illumination (Fig. 3*(b)*). Furthermore, in the case of bifacial illumination, the incident photons on both surfaces contribute to increased overall photogeneration. Independently generated carriers on the front and rear sides reach the respective contacts simultaneously, leading to a noticeable increase in power output. Additionally, the reflective surfaces on the rear side enhance the illumination intensity, resulting in a higher albedo effect, which further increases the rear-side contribution (Fig. 3*(a)*). It follows that the maximum output power of the module is achieved under bifacial illumination, which fully utilizes the optical symmetry of the solar cells. Additionally, the observed reduction in power under rear-side illumination suggests a need for optimizing the device geometry from a technological perspective. For instance, rear-emitter designs or low-recombination *p*-type substrates can help mitigate these losses.

IV. CONCLUSIONS

This study presents experimental investigations on the performance efficiency of bifacial photovoltaic modules under different illumination conditions. Using a purpose-built experimental setup, the modules' photoelectric characteristics (I–V and P–V curves) were measured and analyzed under front-side, rear-side, and bifacial lighting. The results revealed that the modules' photoelectric behavior strongly depends on the direction of illumination. It was found that front-side illumination generates an output power 1.27 times higher than rear-side illumination, which is attributed to the photocarrier (electrons and holes) generation depth and the likelihood of carriers reaching the emitter n-region. Specifically, under rear-side illumination, the total photocurrent decreases due to recombination losses of electrons generated in the p-type region. Under bifacial illumination, the module produced 1.22 times higher output power than with front-side-only illumination and 1.41 times higher than with rear-side-only illumination. The study also showed that in highly reflective environments, such as those with silver-mirrored reflectors, bifacial modules can deliver up to 22% more electrical power compared to conventional monofacial modules. Another notable advantage is the potential for integration into high-efficiency photovoltaic systems, which can be enhanced using solar tracking systems, light concentrators, or cost-effective reflectors to improve rear-side illumination. Overall, the findings indicate that the use of bifacial photovoltaic modules in energy systems enhances the effective utilization of solar energy and offers a promising avenue for the development of advanced high-performance solar devices.

ABSTRACT

Change detection is a challenging and significant task in satellite applications due to the unavailability of satellite photos of a given geographic area acquired at various times. This study employs remote sensing data to analyze the changes in the area by utilizing machine learning methods alongside a geographic information system. The satellite images are pre-processed, gathered from multiple sources, and classified according to features. Two of the most significant and efficient factors underlying many ecological systems are land use and land cover maps, and change detection. The integration of remote sensing, Geographic Information System (GIS), and machine learning techniques offers a promising approach for studying and monitoring forest ecosystems. Remote sensing offers a means of collecting large-scale data on forest cover and land use change, while GIS technology enables the analysis and visualization of this data. Machine learning algorithms can be used to classify and analyze the data, allowing researchers to analyze the changes occurring in forest ecosystems on the Google Earth Engine framework. Built-up planning, ecosystems, land resources, crop patterns, agriculture, and natural resources depend on land use and land cover assessment and analysis. Change detection mapping is done by Geographic Information System software. For accuracy assessment, identify the classes of land cover and land use that have changed in the area. This study area, Chandaka Forest, merely uses the Landsat 8-9 OLI/TIRS imageries for land use and land cover mapping. Using the proposed algorithm, the historical images of Chandaka Forest were obtained, and seven different class values were stored in the cloud. Using the data, the change detection has been obtained with an accuracy of 95.1%. A system for cloud computing named GEE implements Support Vector Machine and random forest as its primary classification algorithm models to make two-year interval land use land cover maps for 2014, 2016, 2018, 2020, and 2022. This research is based on machine learning classification plus geographic information system techniques for change detection of satellite images. Analyses of both satellite images captured at two distinct times in a specific geographical region demonstrate the effectiveness of the method. The effectiveness is verified using change detection accuracy, and the results are superior to those of the currently used approaches. This paper contributes to environmental monitoring, such as deforestation of Chandaka Forest, Odisha, using GIS and machine learning classification applied to remote sensing data.

I. INTRODUCTION

The Google Earth Engine (GEE) is a cloud-based platform where remote sensing data are streamlined for processing and analysis to produce results. This developed system quickly and accurately identified the land use maps using Landsat-8 imagery using a machine learning approach.

The established 30-m four-year LULC maps were developed to provide crucial information on monitoring and understanding the changes in many LULC classes and alterations that have taken up residence in the Chandaka Forest. The study's main objective was to analyse environmental reliability and change detection from 2014 to 2022. To comprehend the trend of change, it also sought to identify the areas of effective change, quantify the scale of change, and evaluate the state of land cover for different years. The primary goal of the change detection approach is to recognise the major change that has evolved throughout a collection of images, given a set of images of the same place taken at various intervals. These key developments influence the creation of the change map [1]. Unwanted artefacts and noise components in the source photos may also affect the accuracy of the change map. The concept of significant change varies with application. Fusing these techniques enables a more comprehensive and accurate assessment of the LULC's extent at a nominal 30-meter resolution. Ecosystems and biodiversity can be severely affected by changes in land use and land cover in the Chandaka Forest in Odisha, India. Among the impacts are soil erosion, biodiversity loss, modified microclimate, habitat fragmentation, and effects on indigenous communities. Forest clearing for improvement, infrastructure, or agriculture can fragment environments, hinder wildlife corridors, and diminish genetic diversity. In addition to increasing soil erosion and reducing the soil's holding capacity, deforestation may disrupt the local ecology and hinder water utilisation for both wildlife and human settlements. Changes in land use may impact local economies and ways of life by disrupting norms and restricting access to natural resources.

Mineral resources are identified, differentiated, and improved in features and structures by using remote sensing data and image processing approaches [2]. Change detection, classification or segmentation, feature extraction, and fusion are different methods used for image processing on satellite images. Satellite image analysis uses several mathematical algorithms to extract essential information [3]. A Geographic Information System (GIS) provides a broader overview of the image under study and integrates different coverage of the area for change detection. The most significant advantages of using GIS are visualization and comparison of images for change detection. However, the results of change detection are influenced by the availability of multiple sources of information with various levels of accuracy. Remote sensing and GIS, a change detection technique, are used to assess the typical changes brought on by natural disasters [4]. Statistics on Chandaka Wildlife Sanctuary's use of GIS and remote sensing data, the technique to detect changes in vegetation cover is illustrated utilizing forest land use classifications obtained in 2006. Later, Normalized Difference Vegetation Index (NDVI) was developed in 2015 to monitor changes in forest LULC [5]. The following part explains the method that employs GIS and remote sensing to monitor land cover changes. Cost is reduced, change detection is made less complicated, and accuracy is enhanced with the aid of this technology [6]. Researcher workstations are now equipped with methodologies thanks to online platforms like Google Earth Engine (GEE), resulting in workflows and eliminate extraneous data downloads. The study on northern Iran uses Landsat satellite images for the analysis of LULC and change detection using machine learning algorithms [7]. LULC in Bejing uses Landsat satellite images from 2015 with a 30-m resolution. In this study, the input data were selected with the least cloud cover for orthorectification and calibration.

Because of the higher performance of its multi-dimensional characteristics, the Random Forest algorithm was selected as a classifier [8]. According to statistics on Chandaka Wildlife Sanctuary's Forest land use classes that utilizes GIS and image processing, the following areas were identified in the sanctuary area in 2006 with 3917.96 ha of dense mixed forest, 6024.56 ha of open mixed forest, 3181.74 ha of degraded mixed forest, 55.81 ha of dense Sal Forest, open Sal Forest, and degraded Sal Forest [9]. The open mixed forest occupies the maximum area of the sanctuary. Eupatorium or Lantana grows on 2131.29 ha, bamboo covers 1501.91 hectares, teak covers 270.97 ha, wastelands cover 140.28 ha, mining and research areas cover. Within the sanctuary, the village and settlement areas total 28.66 ha and 15.82 ha, respectively. In the sanctuary area, there are approximately 140.85 ha of water bodies and 1623.16 ha of agricultural land. The change detection of forest land use between the years 2003 and 2006 of the Chandaka-Dampara Wildlife division, the study found that the population increased due to the demand for crops and food for the people [10].

LULC in Chandaka Forest from 1980-2020 combines with remote sensing and GIS, which create maps to analyse the changes over a different period [11]. In this domain, we will present a hybrid model utilizing a machine learning methodology with better accuracy. Comparing the accuracy of three ML algorithms, Support Vector Machine (SVM), Random Forest (RF), and Classification and Regression Tree (CART), using Landsat-8 and Sentinel-2 images. To identify the LULC classification results with the highest accuracy, dataset comparison ratios were also investigated [12].

I.1 STUDY AREA

Chandaka Forest, also known as Chandaka-Dampara Wildlife Sanctuary. It is a protected forest area located in the Khordha and Cuttack districts of Odisha, India, near the state capital city Bhubaneswar, since August 1982. It is listed in the Survey of India toposheet No.73H/11, 12, and 15, study area map is shown in Figure 1 [13]. It is located between 85° 34' 42" E to 85° 49' 27" E longitude and 20° 12' 29" N to 20° 26' 18" N latitudes. It represents the northeastern limits of the Eastern Ghats. In 2006, land use classes of the sanctuary were gathered, implementing image processing techniques and GIS [14], [15]. The major attractions for the tourists are watch towers and restrooms to observe the birds and animals. Deras Dam and Jhumka Dam are two water reservoirs situated within the forest. In 2005, the sanctuary's total forest area, which included dense, open, and scrub forests, had significantly decreased to just 62.72% of the original area [16].

II. MATERIALS AND METHODS

Wide-ranging usages for remote sensing data include change detection, which involves finding significant variances between two sets of images. Two distinct periods are used to collect the images. A change map is made up of the identified changes. This research employed an amalgamation of Geographic Information Systems and Machine Learning technologies to detect the change in Chandaka Wildlife Sanctuary. This research shows a novel and integrated technique to employ machine learning algorithms in a cloud-based geospatial framework, such as GEE with GIS analysis, to discover changes in LULC. For a better understanding, the flow of process is represented in Figure 2, which shows the architecture of the proposed work to analyse the change detection. The process starts with the Data Collection, then follows Pre-processing, Feature Extraction, Feature Selection, Classification, Post-processing, and Accuracy Assessment.

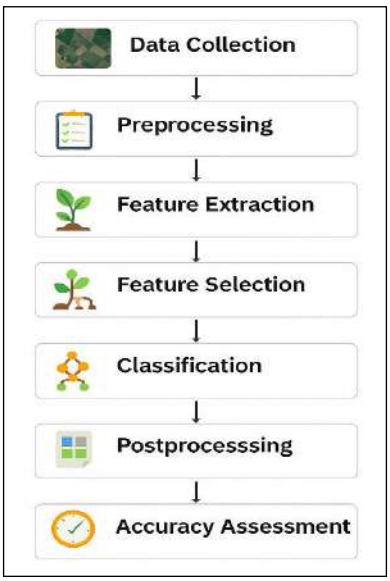

Figure 2: Change Detection Architecture.
Source: Authors, (2026).

II.1 DATA COLLECTION

To analyse the change detection, the Landsat satellite image was loaded from the United States Geological Survey (USGS) authoritative website (earthexplorer.usgs.gov). Every satellite image serves as a dry season image, and Landsat sensor data were taken into account in Table [17]. The Landsat-8 Operational Land Imager (OLI) or Thermal Infrared Sensor (TIRS) images were obtained in LANDSAT/LC08/C01/T1_SR through Google Earth Engine [18]. The details of the satellite data used in the study are shown in Table 1.

The Landsat 8 satellite, equipped with the Operational Land Imager (OLI), provides multispectral imagery useful for monitoring environmental changes. The data used in this study spans two time periods: January to December 2014 and January to December 2022. Each band, labelled SR_B1 to SR_B7, shows different sections of the electromagnetic spectrum, measured in micrometers (μm), whereas SR_B1 is called as surface reflectance band 1.

Table 1: Details Of Satellite Data.

Satellite id	Period	Sensor id	Spatial Resolution	Path	Quality
Landsat 8	Period 1: January – December, 2014 Period 2: January – December, 2016 Period 3: January – December, 2018 Period 4: January – December, 2020 Period 5: January – December, 2022	OLI/TIRS	30m	140/46	9

Source: Authors, (2026).

The reflectance values range from covering the interval from 1 to 65,455, scaled by a factor of 2.75e-05 with an offset of -0.2 to convert raw digital numbers to reflectance values. Every band has a spatial resolution that is defined in meter. Specifically, SR_B1 captures coastal aerosol reflectance (0.435–0.451 μm), useful in atmospheric correction near water bodies. SR_B2 to SR_B4 cover the visible spectrum (blue, green, red), aiding in vegetation and water analysis. SR_B5 corresponds to the near-infrared region (0.851–0.879 μm), which is particularly sensitive to vegetation. SR_B6 and SR_B7 represent shortwave infrared bands (1.566–2.294 μm), which are valuable for analyzing moisture content, burned areas, and soil properties. Additionally, the SR_QA_AEROSOL band provides aerosol quality information, important for atmospheric correction and improving data reliability. These bands are crucial for understanding different land topography features and robustness of the vegetation. From the Red and Near Infrared bands, the Normalized Difference Vegetation Index (NDVI) was derived to evaluate the presence and condition of vegetation. All imagery was obtained in Top of Atmosphere (TOA) reflectance from the USGS, ensuring consistency and quality in the remote sensing data. The image has a spatial resolution of 30 meters, meaning each pixel represents a 30 by 30-meter area on the ground, allowing for detailed land surface analysis. It corresponds to Path 140 and Row 46 of the Worldwide Reference System-2 (WRS-2), identifying the specific geographic location of the scene. The image has a quality level of 9, indicating excellent clarity with minimal cloud cover or distortions, making it highly suitable for accurate remote sensing applications.

II.2 PRE-PROCESSING

Image pre-processing is the set of steps applied to raw images to make them high-quality, consistent, and ready for analysis or modelling. The Landsat-8 QA_PIXEL (Quality Assessment) layer is a FMASK (Cloud mask algorithm) derived bitmask that encodes per-pixel data quality. The algorithm for cloud and shadow detection and details how it is applied as a preprocessing step for Landsat imagery are introduced and expanded [19-21].

Algorithm Fmask: Cloud/Shadow Mask from QA_PIXEL

Input: Landsat-8 SR image I with band QA_PIXEL and bands SR_B1..SR_B7
Output: Masked SR image I' (only clear pixels kept), with SR bands renamed
Constants (bit masks):
DILATED = 1 << 1 (2)
CIRRUS = 1 << 2 (4)
CLOUD = 1 << 3 (8)
SHADOW = 1 << 4 (16)
Procedure:
1. qa ← I.select("QA_PIXEL")
2. Compute boolean "clear" mask:
M ← (qa & DILATED == 0) ∧ (qa & CIRRUS == 0) ∧ (qa & CLOUD == 0) ∧ (qa & SHADOW == 0)
3. Select SR bands with a regex and rename:
SR ← I.select("SR_B.", ["SR_B1","SR_B2","SR_B3","SR_B4","SR_B5","SR_B6","SR_B7"])*
4. Apply mask: I' ← SR.updateMask(M)
5. Return I'.

Source: Authors, (2026).

The Fmask algorithm for cloud and shadow detection and details how it is applied as a preprocessing step for Landsat imagery are introduced and expanded. Individual bits flag conditions: fill (no data), dilated cloud fringe, high-confidence cirrus, cloud, cloud shadow, snow, a "clear" flag (set only when neither cloud nor dilated cloud is present), and water. In addition, four 2-bit confidence fields report the likelihood of cloud, cloud shadow, snow/ice, and cirrus, each graded as none, low, medium, or high. Together, these flags let you reliably screen out clouds, shadows, snow, and water or keep only clear land pixels before computing indices or running classification. It is a rule-based algorithm used in Landsat surface reflectance products to filter pixels before analysis. It applies a decision-tree approach that combines spectral thresholds, such as brightness in blue, cirrus, and thermal bands, with geometric tests that match clouds and their shadows based on solar angles.

II.3 FEATURE EXTRACTION

Feature extraction from satellite imagery is the process of transforming raw pixel values into compact, informative variables that facilitate the differentiation of land-cover classes. Typical ingredients include spectral features (original bands) plus spectral indices such as NDVI, NDWI, NDBI, EVI. Combining pixel-based and object-based approaches is a valid strategy to address the salt-and-pepper effect, particularly in applications like image classification. The normalized difference vegetation index (NDVI), the normalized difference water index (NDWI), and the normalized difference built-up index (NDBI) are three band indices that are often extracted because of their value to researchers [22-25]. Calculating the above indices requires the following formulas:

Normalized Difference Vegetation Index

$$NDVI = \frac{(NIR - Red)}{(NIR + Red)} \tag{1}$$

Whereas NIR is near infrared and Red is red band.

Normalized Difference Water Index

$$NDWI = \frac{(Green - NIR)}{(Green + NIR)} \tag{2}$$

Whereas Green is green band.

Normalized Difference Bulit-up Index

$$NDBI = \frac{(SWIR - NIR)}{(SWIR + NIR)} \tag{3}$$

Whereas short-wave infrared is the waves that are invisible to human eyes. The pre-processed imagery from satellites is applied to generate spectral indices such as the Normalized Difference Vegetation Index (NDVI) and the Enhanced Vegetation Index (EVI), which are then employed for assessing changes in the vegetation cover [26].

Enhanced Vegetation Index

$$EVI = G\frac{NIR - Red}{NIR + C1Red - C2Blue + L} \tag{4}$$

Whereas NIR is near infrared, Red is red band, and Blue is blue band, with standard coefficients G=2.5, C1=6, C2=7.5, L=1. Equations (1), (2), (3), (4) are Spectral Indices used as features. On Landsat-8, this is represented as NIR is SR_B5, red band is SR_B4, and blue band is SR_B2. These indices act as proxies for the density and health of the vegetation, which enables the detection of temporal modifications in the cover of the vegetation. The next step is to apply regression analysis in order to describe the link between spectral indices and ground-based vegetation observations. This makes it easier to estimate how the density of vegetation has changed over time. Normalized Difference Water Index (NDWI) and other water indices are computed from satellite imagery to perform the Water Body Dynamics Assessment. Pixel-based features: These methods operate on individual pixels and are good at capturing the spectral (color) characteristics of the image. However, they can lead to a scattered "salt-and-pepper" appearance in the final result because each pixel is classified independently. Object-based features: These methods first segment the image into meaningful objects or regions. They then analyze the features of these whole objects, such as their shape, texture, and spectral values, rather than individual pixels.

II.4 FEATURE SELECTION

Feature selection (FS) is the process of keeping a small, informative set of predictors while dropping redundant or noisy ones so the Change Detection model stays accurate and stable. In practice, start with a broad stack (bands, key indices, terrain, textures), then do quick filters: remove near-constant features and one of any pair with very high correlation. If the classifier is scale-sensitive, standardize features. Next, use embedded signals to rank importance e.g., Random Forest/XGBoost (Gini or permutation importance) or L1-regularised models that shrink weak features toward zero and, when the feature count is modest, a wrapper like RFE (Recursive Feature Elimination) can fine-tune the subset [27].

II.5 LAND USE LAND COVER (LULC) CLASSIFICATION

The classification of the land use land cover scheme is divided into different classes [28]. The model learns $f(\varkappa)$ from the training dataset and implements to predict classes of the given image in supervised classification.

LULC Classification

$$\hat{y} = \sum_{j=0}^{n} f(\varkappa_j) \tag{5}$$

The above equation (5) represents the function of LULC. Whereas $\hat{y}$ is predicted classes (e.g., dense forest, open forest, water bodies, waste land, urban areas), $\varkappa_j$ is the spectral features, and $f(\varkappa)\ is$ the classification function (e.g., SVM, RF).

II.5.1 Support Vector Machine (Svm)

Support Vector Machine (SVM) is a supervised classifier that separates classes by finding the decision boundary (a hyperplane) with the largest possible margin to the nearest training points, called support vectors. Among all supervised machine learning algorithms, SVM is one of the most reliable classification algorithms. It can immediately identify the changing features and transform feature dimensions since it is based on the classification. To handle non-linear patterns, SVM maps features into a higher-dimensional space via a kernel, commonly the radial basis function (RBF), so the boundary in the original space can curve around complex class shapes [29]. It can immediately identify the changing features and transform feature dimensions since it is based on the classification. To deal with nonlinear data, the core of the SVM is the appropriate kernel function, which measures the similarity between input data [30]. The advantage is that it can be used for the classification of high-dimensional data like images. An image is analysed by a computer and is perceived as a two-dimensional array of pixels. The image's resolution determines the array's dimensions; for instance, an image 200 pixels wide and 200 pixels high will have dimensions of 200 * 200 * 3. The image's width and height are represented by the first two dimensions, respectively, whereas the third dimension represents the RGB color. The array's values represent the pixel's intensity at each location, i.e. from 0 to 255. According to the metadata, the images of the forest have a geographic extent defined by coordinates in degrees and consist of 781 columns and 917 rows, which indicates its pixel dimensions of 781 * 917 * 3. The image's values are texture, edge detection, and pixel color. We can utilize the retrieved features as input for the SVM algorithm after that. Finding the nearest points of the various classes is the fundamental concept underpinning support vector machines (SVMs).

$$(x) = sign\left(\sum_{j=1}^{n} \alpha_j y_j . exp\left(-\Upsilon||x - x_j||^2\right) + b\right) \tag{6}$$

The above equation (6) represents the function of SVM. Whereas x is the Input feature vector (e.g., spectral values of a pixel), x_j is the Support vector from the training data, α_j is Lagrange multipliers (learned during training), y_j is the Class label of x_j (+1 or -1), b is the Bias term, Υ is the Kernel parameter (controls the width of the RBF function), $||x - x_j||^2$is the Squared Euclidean distance between the input and the support vector, exp (·) Exponential function used in RBF, $sign$ (·)Output is either +1 or -1, determining the predicted class.

II.5.2 Random Forest (Rf)

Random Forest (RF) is an ensemble classifier that builds many decision trees on different random "views" of your data and then combines their votes. Each tree is trained on a bootstrap sample (a resampled subset) of the training set, and at every split, the tree considers only a random subset of features, which decorrelates the trees and reduces overfitting. For a new pixel, each tree predicts a class, and the forest returns the majority vote (for regression, it averages). The tree structure used by the decision tree (DT) is to select one feature and distribute it across different classes. The capability and effectiveness of isolating nonlinear features have been demonstrated. Overfitting, however, is subject to DT [31]. We used Landsat 8 pictures from different years for LULC classification with Random Forest (RF) in the GEE. These photos were normalized and filtered to top-of-atmosphere reflectance, with a cloud cover of less than 10 % serving as the primary input data. Except for the bands required for change detection, we used all bands with a resolution of 30 m. Additional textural features for categorization were retrieved, including color, intensity, contrast, and NDVI provided for that year [32].

$$\hat{y} = \sum_{k=0}^{n} \binom{n}{k} \varkappa^k a^{n-k} \tag{7}$$

$\hat{y}$= majority_vote ($T_1(\varkappa)$, $T_2(\varkappa)$, ..., $T_N(\varkappa)$)

The above equation (7) represents the function of RF. Whereas $\hat{y}$ is the predicted class label, $T_j(\varkappa)$ is a prediction made by the jth decision tree, x is the input feature vector (e.g., NDVI, NDBI, spectral bands), majority_vote is the final class is the one most trees agree on.

II.6 ACCURACY ASSESSMENT

The accuracy assessment is significant, which shows the extent to which the related categorized image accurately depicts reality. The overall accuracy (OA) of the image is used for the accuracy assessment of the classified image. We find it by dividing the total number of accurately recognized pixels by the overall pixel count [1]. The overall accuracy is calculated as:

$$OA = \frac{P_c}{P_n} \tag{8}$$

Whereas P_c is the total count of pixels classified precisely and P_n is the total of pixels in equation (8). To account for random agreement, Jacob Cohen invented Cohen's kappa in 1960, replacing the traditional method of using per cent agreement [33]. The accuracy of data presentations is assessed by interoperability, which is evaluated using the kappa statistic. Kappa values span from -1 to +1 [34]. It quantifies the improvement of the classification compared to randomly assigning pixels to their correct classes [35].

$$kappa = \frac{Observered\ Aggrement - Expected\ Aggrement}{1 - Expected\ Aggrement} \tag{9}$$

The above equation (9) represents the accuracy assessment using kappa coefficient.

II.7 POST-PROCESSING

Monitoring of changes in land cover, the Pre-Classification Method and the Post-Classification Method are the two main categories of Change Detection Techniques. Without knowing the image's value, the pre-classification method analyses the change. The *"Normalized Difference Vegetation Index"* (NDVI) pre-classification approach is the most popular and extensively utilized. However, the most implemented change detection technique in use today is the post-classification method. An accurate, designated classification of land cover is the basis for post-classification, which assesses the change in land cover. Some of the popular post-classification Change detection techniques are post-classification comparison, Aerial Difference computation, Image Differencing, Image rationing, Image regression, etc [17].

III. RESULTS AND DISCUSSIONS

Google Earth Engine (GEE) is a cloud-based web application for the interpretation and mapping of geospatial data. It provides a complete dataset of remote sensing imagery and alternative metadata. Its application programming interface (API) with both JavaScript and Python front-ends allows for the analysis of the data available in the catalogue on the Google server [36]. The raster layer in QGIS uses the EPSG:4326 coordinate reference system, which is based on the WGS 84 datum and represents spatial data using latitude and longitude in degrees. The raster is in GeoTIFF format, a widely used file type that preserves georeferencing information. The coordinate units are in degrees, consistent with geographic coordinate systems, making the data suitable for global or regional-scale spatial analysis. A sample of the end-to-end methodology, which we have executed using the GEE for the Water Bodies class, is depicted in Figure 3. This area is the Deras reservoir in Chandaka-Dampara Wildlife Sanctuary. One of the most important parts of the process is deciding on the training points and polygon, which will enhance the level of accuracy of the concluded classification results [37]. All the data images taken have less than 10% cloud cover.

Dataset: Samples = 356, Training = 299, Testing = 57

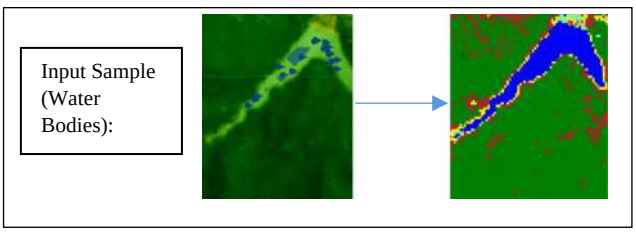

Figure 3: Example of a small region of Chandaka Forest, output after Random Forest Classification.
Source: Authors, (2026).

The GEE application provides a variety of classifiers. We evaluated the effectiveness of two of them in Land cover classification using random forest (RF), and support vector machine (SVM), and their overall use and dependability [38].

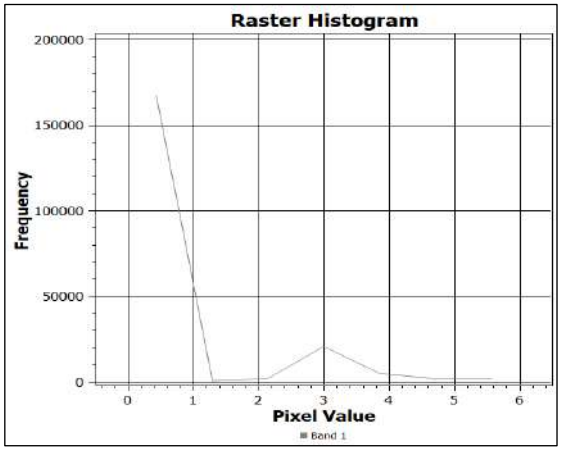

Figure 4: Histogram after the Classification of Chandaka Forest in the year 2022.
Source: Authors, (2026).

To prepare the input blocks for model training, auxiliary data such as feature vectors and edge information were first synchronized with Google Earth Engine (GEE) in shapefile format. These datasets were then utilized alongside external data sources to generate sample blocks using Support Vector Machine (SVM) and Random Forest (RF) classifiers. The resulting data was stored within Google Earth Engine's Assets. For model training, the input blocks were converted into TFRecord format and exported as GeoTIFF files to a Cloud Storage Bucket, a component of the Google Cloud Platform. The training process was carried out using the GPU capabilities provided by Google Collaboratory. Once training was completed, the model parameters were saved in the Cloud Storage Bucket. These parameters are essential for deploying the trained model in GEE and must be hosted within an AI network before they can be applied for inference [39]. They must be managed by an AI network, which we did by storing the trained parameters in a Cloud Storage Bucket. The GEE map area environment was used to collect a set of points (356 in total) for each class using numerous reference layers. For each class, a set was composed of training points 25% of the total and testing points 75 % of the total, for a total of 299 training points and 57 testing points for the years 2014, 2016, 2018, 2020 and 2022, respectively. All of the training points were gathered visually, and only for the forest classes were the validation points gathered visually supported by a thorough understanding of the area and Landsat 8 Bands and Band Combinations. Whereas Figure 4 shows the histogram after the Classification of Chandaka Forest in the year 2022. The histogram illustrates the frequency distribution of pixel values found in Band 1 of a classified raster image. On the horizontal axis, pixel values range from 0 to 6, each representing a distinct land cover category. The vertical axis shows the number of pixels corresponding to each class. Among these, class 1 has the highest count, with more than 150,000 pixels, indicating it is the most dominant land cover type in the area. In contrast, other classes like 3 and 4 have moderate pixel counts, while categories 5 and 6 are represented by a relatively small number of pixels. The graph reveals a clear imbalance in class representation, with a few classes covering most of the area. Overall, the histogram offers a concise overview of how different land cover types are distributed across the raster image.

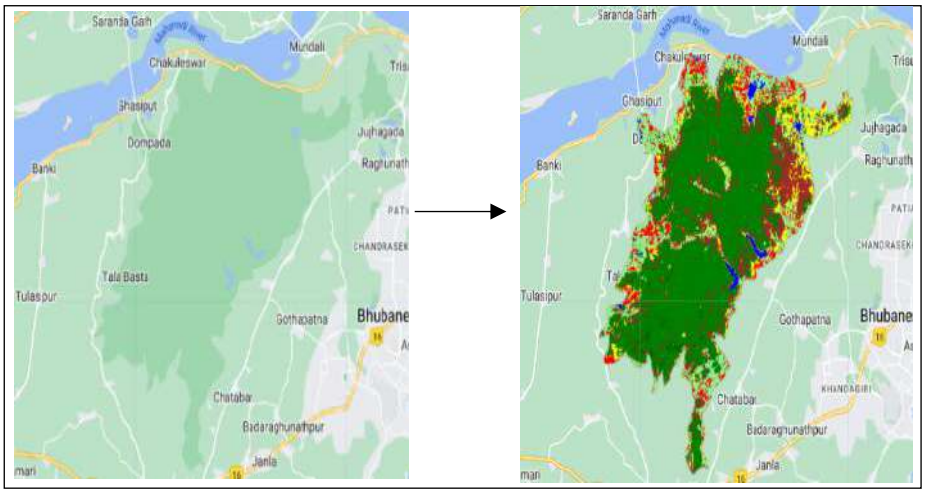

Figure 5: Classification of Chandaka Forest in GEE.
Source: Authors, (2026).

We chose the Random Forest algorithm as a classifier because of its better performance and its multi-dimensional characteristics. Multiple recent investigations have leveraged Google Earth Engine (GEE) combined with Random Forest (RF) classification, illustrated in table 2, to analyze land use and land cover dynamics across Ethiopia, Portugal, and Nepal.

Table 2: Comparative Analysis of Land Use Land Cover and Change Detection.

No.	Study Title	Authors and Year	Study Area	Time Period	Methods	Key Findings	Novelty
1	Integrating Google Earth Engine and Random Forest for LULC Change Detection and Analysis in the Upper Tekeze Basin	Alelgn Ewunetu and Gebeyehu Abebe, 2025	Upper Tekeze Basin, Ethiopia	1986, 1998, 2010, 2022	GEE + Random Forest with Landsat 5/7/8 imagery; household surveys	Over 62% of the landscape experienced change; forest and shrubland declined; cultivated land and settlement expanded; local drivers include population growth and agricultural expansion.	Combines multi-temporal Landsat data with local knowledge (surveys) for enhanced LULC transition understanding in arid highlands.
2	Comparative Study of RF and SVM for Land Cover Classification and Post-Wildfire Change Detection	Yan-Cheng Tan et al., 2024	Serra da Estrela Natural Park, Portugal	Pre/post 2022 wildfire + Summer 2023	GEE with Sentinel-2A; RF vs. SVM; OBIA vs. PBIA	RF + OBIA produced highest classification accuracy; SVM + PBIA better resembled official LULC maps; OBIA enhances spatial detail in burnt area analysis.	First to compare OBIA and PBIA using GEE in a post-wildfire environment for detailed vegetation recovery mapping.
3	Modeling LULC Changes Using GEE and ML: Implications for Landscape Management	Weynshet Tesfaye et al., 2024	Robit Watershed, Ethiopia	1993, 2003, 2013, 2023	GEE + RF, SVM, CART with Landsat and auxiliary data	RF outperformed SVM and CART; agricultural land and shrubland declined; built-up and grazing land increased; drivers include settlement, fuelwood, and population growth.	Integrates multiple classifiers with auxiliary data in GEE for robust long-term LULC modelling in Ethiopian watershed context.
4	Mapping Forest Loss and Encroachment Drivers Using Remote Sensing and RF	Bhoj Raj Ghimire et al., 2025	Sudurpaschim Province, Nepal	1990-2020	Remote Sensing + RF with field data and Landsat	RF achieved >81% accuracy; 1,634 km2 of forest lost; agriculture (78.21%) and settlement (15.97%) were primary encroachment drivers.	Links RF-based classification with field-surveyed driver attribution to identify encroachment hotspots over three decades.
5	Analyzing LULC Changes Using GEE and RF: Implications for Land Degradation	Alemu Eshetu Fentaw and Assefa Abegaz, 2024	Upper Tekeze Basin, Ethiopia	1990, 2000, 2010, 2021	GEE + RF with Landsat imagery + OpenLand R package	Forest, shrubland, and bareland decreased; water, farmland, and settlements increased; supports use of afforestation and land management to mitigate degradation.	Integrates post-classification land transition matrix with GEE to quantify degradation-linked landscape changes.

Source: Authors, (2026).

In Ethiopia's Upper Tekeze Basin, temporal data from Landsat (1986, 1998, 2010, 2022) calibrated with local surveys and study indicated that nearly 63% of the region underwent at least one LULC transition, with expansion of cultivation and settlements consuming grassland and shrubland [40]. The LULC dynamics in Ethiopia's Upper Tekeze Basin from 1990 to 2021 using Google Earth Engine (GEE) with the Random Forest (RF) classifier and incorporating the OpenLand R toolkit to generate transition intensity maps. Landsat TM (1990, 2000, 2010) and Landsat 8 OLI (2021) imagery, combined with auxiliary datasets, supported classification. The RF model achieved strong performance, with around 83% accuracy and a Kappa score of 0.75 despite the region's complex terrain and climate [41]. An additional Ethiopian study extended this analysis (1990–2021) using OpenLand R packages, quantifying degradation-driven transitions and revealing declines in forest, bushland, shrubland, and bareland. In Portugal's Serra da Estrela Natural Park, comparisons between RF and SVM classifiers tied to object-based (OBIA) and pixel-based (PBIA) approaches on Sentinel-2A data showed the RF + OBIA workflow delivered the highest accuracy, while SVM + PBIA corresponded more closely to official land use maps [42]. In Nepal, field-validated RF classification of Landsat imagery from 1990 to 2020 identified approximately 1,634 km² of deforestation, primarily linked to agricultural and settlement expansion (~78% and ~16%, respectively) [43]. This research explores three decades of land use and land cover transitions (1993–2023) in the Robit Watershed (Northern Ethiopia), utilizing Landsat imagery processed within Google Earth Engine (GEE) alongside machine learning classifiers: Random Forest (RF), Support Vector Machine (SVM), and Classification and Regression Trees (CART). Topographic and spectral indices were included as auxiliary variables to enhance classification accuracy. Focus group discussions and interviews supplemented remote sensing data with socio-environmental context. RF consistently outperformed SVM and CART, achieving exceptionally high accuracies ranging from 93 % to 97 % and Kappa values between 0.93 and 0.95 across all four time points (1993, 2003, 2013, 2023). Land-use analysis revealed notable declines in forest cover (28.3 % decrease from 1993 to 2003) and shrubland (21.6 % loss from 1993 to 2013), while grazing land expanded by over 50 % in the same period. Overall, this study underscores the efficacy of GEE RF workflows enhanced with auxiliary data and community validation for producing highly accurate LULC maps and transition trends. The insights derived support sustainable watershed planning and resource management interventions tailored to local socioecological realities [44].

Across these diverse landscapes, RF consistently proved a reliable, adaptable classification tool when paired with auxiliary ground truth data, advanced image segmentation methods, or post-classification analysis, demonstrating its strength in interpreting both ecological changes and human-driven land transformation.

Table 3: Accuracy Results of Chandaka Forest for 2014, 2016, 2018, 2020 and 2022.

Year	SVM		RF	
	OA	Kappa	OA	Kappa
2014	0.919	0.884	0.947	0.928
2016	0.924	0.904	0.932	0.913
2018	0.907	0.892	0.921	0.897
2020	0.925	0.898	0.937	0.913
2022	0.885	0.854	0.951	0.923

Source: Authors, (2026).

The overall accuracy and kappa coefficient accuracy results displayed in Table 3 show that random forest is better for classification than SVM. Between 2014 and 2022, Random Forest (RF) consistently outperformed Support Vector Machine (SVM) in overall accuracy (OA) and Kappa coefficient across the dataset. In 2014, RF achieved an OA of 94.7% with a Kappa of 0.928, compared to SVM's 91.9% and 0.884. Although SVM slightly narrowed the gap in 2016 (OA: 92.4%, Kappa: 0.904), RF still maintained higher performance (OA: 93.2%, Kappa: 0.913). For both classifiers, a minor decline occurred in 2018—SVM dropped to OA 90.7% (Kappa 0.892) and RF to 92.1% (Kappa 0.897). In 2020, performance improved again; SVM returned to 92.5% (Kappa 0.898), while RF reached 93.7% (Kappa 0.913). By 2022, RF achieved its peak metrics (OA 95.1%, Kappa 0.923), while SVM fell to its lowest values in the series (OA 88.5%, Kappa 0.854). This trend suggests RF delivered higher and more stable classification reliability, with smoother fluctuations across years. While SVM performance varied more significantly, RF sustained accuracy levels above 92% and Kappa values above 0.90 in most years. With the help of GPS, we gathered 356 training samples, and we used GE to evaluate 75 validation samples. The number of samples for each kind was calculated based on the percentage of the individual area. Google Fusion Tables were used to upload the training data and validation samples to the GEE.

Table 4: Description of Land Cover Classes Used in this Research.

Class ID	LULC Classes	Satellite Images
0	Dense Forest	
1	Open Forest	
2	Water	
3	Scrub Forest	
4	Urban Areas	

5	Waste Land	
6	Crop Land	

Source: Authors, (2026).

This scheme, shown in Table 4 assigns integer IDs 0–6 to the seven-land use/land cover types you map: 0 = Dense Forest, 1 = Open Forest, 2 = Water, 3 = Scrub Forest, 4 = Urban Areas, 5 = Wasteland, and 6 = Cropland. The IDs serve as labels attached to training/validation samples, becoming the legend keys in your classified maps and confusion matrices, ensuring consistent encoding across years and models. The "Satellite Images" column can store representative chips (or links to VHR references) for each class to aid in labelling and QA, which is useful for photo-keys, teaching assistants, or reproducibility notes. Finally, we divided the study region into seven categories: dense forest, open forest, shrub forest, water bodies, urban areas, wasteland, and cropland. The LULC change map showed that dense forests changed to open forests, shrub forests, water bodies, urban areas, wasteland, and cropland. The statistics of Land use and Land cover maps are given in Table 5 for the years 2014 and 2022.

Table 5: Land Use Land Cover of the Chandaka Forest Area in 2014 and 2022.

	2014			**2022**		
LULC Classes	**Area (Pixel Sum)**	**Area (%)**	**Area (km^2)**	**Area (Pixel Sum)**	**Area (%)**	**Area (km^2)**
Dense Forest	155738	56.27003024	130.755873	127528	46.07741	107.070052
Open Forest	2958	1.068761314	2.484245	20587	7.05145	25.681695
Water Bodies	4185	1.512091311	3.513076	4462	1.612175	3.745685
Scrub Forest	37811	13.66157337	31.743526	47853	17.288996	40.172053
Urban Areas	18539	6.698365785	15.562266	35300	12.755191	29.635530
Waste Land	16909	6.109426995	14.194728	30362	11.357038	17.093658
Crop Land	40629	14.67975098	34.107956	10677	3.85773	8.962997

Source: Authors, (2026).

It reveals a 10.2% decrease in dense forest coverage between 2014 and 2022. There was also an increase in open forest coverage from 2014 and 2022 by 5.98%. There was also an increase in urban area coverage in the study area from 2014 and 2022 by 6.05% documented. Similarly, the open forest is also changed into dense forest, shrub forest, water bodies, urban areas, wasteland, and cropland, as shown in Figure 6 in the change detection graph. This classification is done in GEE using the Random Forest algorithm and further visualized in QGIS 3.20.2. This is a known, accurate method for visualization and analysis in GIS. The map is generated for 2014, 2016, 2018, 2020, and 2022, as shown in Figure 7 below. This image also provides details about the areas covered by various classes, according to the classification method. The first level of the FROM-GLC (Finer Resolution Observation and Monitoring of Global Land Cover) categorization scheme is consistent with the classification system [40]. After classification, the results from GEE for the year 2022 are shown in Figure 5 for reference. Deforestation in this forest during the past few years has been studied. Reviewing images collected in the same area throughout a period of four years to evaluate change detection [45]. Improved satellite imagery and novel algorithms have made significant progress in change detection. Yet, data integration, flexibility, validation, scalability, and specific to the environment impact evaluation remain areas for improvement. Rectifying these shortcomings will be essential for converting change detection methodologies from mostly academic studies into flexible, practical mechanisms that can guide practical problems and preservation efforts. Further, it creates decision trees for the classification and visualization of categorical predictor variables and constant dependent components, with the goal of producing accurate LULC simulations in GEE data. The GIS approach integrates geographical and geological information with historical and present-day land use maps. The binary masking and image overlaying approaches are beneficial for quantitatively exposing the changing dynamics in each category [46]. The major LULC change map within the Chandaka Forest area is presented in Figure 8. The map illustrates land use and land cover changes in Chandaka Forest from 2014 to 2022. It presents a detailed spatial analysis showing various transformations among land cover classes over time. Each category of change is colour-coded, as indicated in the legend, to represent specific transitions such as open forest converting to dense forest, scrub forest shifting to crop land, or urban areas expanding into forest zones. Areas where no significant change occurred are also highlighted for each land cover type. The map is georeferenced with latitude and longitude labels along the borders and includes a scale bar indicating distances in kilometres. This visual representation helps in identifying regions affected by urbanization, deforestation, and land conversion, providing a clear overview of environmental dynamics within the Chandaka region. It is a thematic change detection map that helps to visually interpret how different land categories have transformed over time. Each type of land cover change is represented by a unique colour, as defined in the legend on the right side of the map.

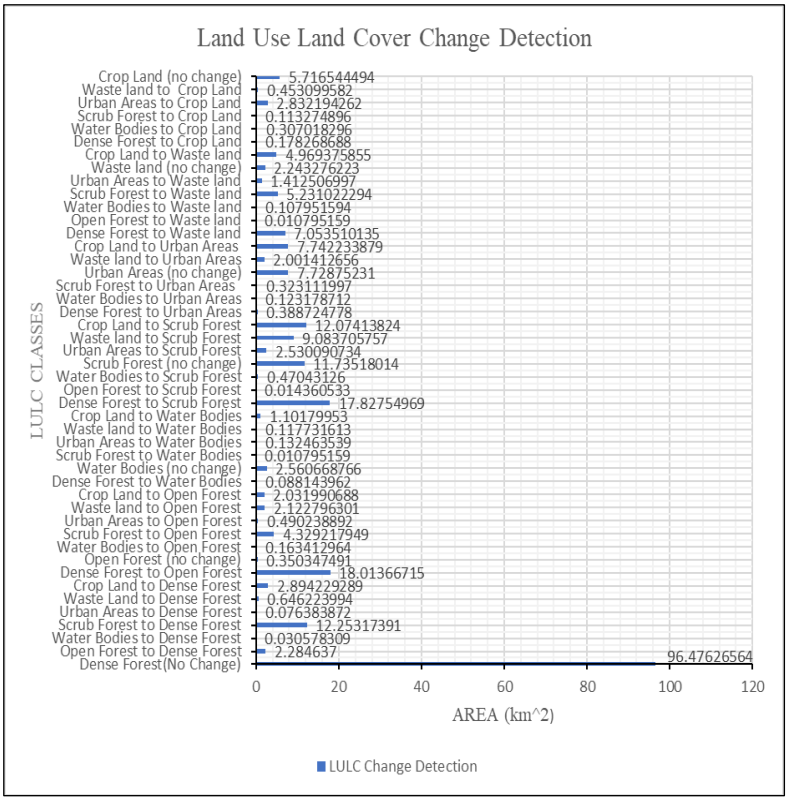

Figure 6: Change Detection Graph of Chandaka Forest (2014-2022).
Source: Authors, (2026).

The legend contains a comprehensive list of all possible changes between land cover types. For example, green shades indicate areas where no change occurred, such as Dense Forest (No Change), Scrub Forest (No Change), or Urban Areas (No Change). Blue and cyan shades generally represent forest-related transformations, such as the shift from Open Forest to Dense Forest, Scrub Forest to Open Forest, or Forest to Urban/Crop Land. Orange to red shades highlight urban expansion and agricultural conversions, such as Urban Areas to Crop Land, Water Bodies to Urban Areas, or Waste Land to Scrub Forest. Dark brown or maroon signifies Crop Land (No Change), marking the areas consistently used for agriculture throughout the study period. The central and southern regions of the map display a large concentration of dark blue and cyan tones, suggesting dominant forest classes, possibly areas where open or dense forest was either preserved or changed in type. Overall, this map serves as a crucial tool for forest management, conservation planning, and monitoring anthropogenic impact. It highlights how significant land cover shifts, such as urban sprawl, deforestation, water body reduction, and cropland expansion, have reshaped the Chandaka Forest landscape over time.

IV. CONCLUSIONS

Remote sensing has recently improved earth observation technology, which requires an effective, proficient, and accessible analytics approach. As a result, combining various analytics approaches, the state of the art regarding methods, and evaluating their effectiveness might be deemed to create geomatics, which is the focus of the current study. This is an analysis of the effectiveness of machine learning algorithms that served as the initial step in the research for using the GEE platform for LULC mapping. To analyse the LULC map in Chandaka Forest, SVM and RF were used as two algorithms for machine learning. As a result of our findings, RF was the most effective and, in the GEE context, a reliable data classifier. The goal of this work is to generate a map for various years using remote sensing, GIS, and machine learning techniques that identify, quantify, and evaluate changes in the LULC. The specific goal is to recognise changes that occurred across different periods. The result comes as a decrease in forest regions in Chandaka Forest in the year 2022 with respect to 2014 due to natural calamities and social interaction. Dense forest decreased by 10.2% between 2014 and 2022, and continued to decline in coverage by 7.33% from 2016 to 2022, and from the year 2014 to 2022, it declined by 7.22%. In the study area, open forest coverage increased by 5.98% from 2014 to 2022, while forest cover rose by 5.78% from 2016 to 2022 and by an additional 4.06% from 2018 to 2022. There was also an increase in urban area coverage in the study area between 2014 and 2022 by 6.05%. The change detection has been obtained with an accuracy of 95.1%. GIS is implemented for change detection and better visualisation. The hybrid framework of change detection improves accuracy. Sentinel satellite images can be used in the future, and deep learning can be used for classification in other areas. A critical analysis of misclassification factors includes the limitations of the current study.

V. AUTHOR'S CONTRIBUTION

Conceptualization: Arpita Majhi, Mrutyunjaya Panda, and Kabir Mohan Sethy
Methodology: Arpita Majhi and Mrutyunjaya Panda
Investigation: Kabir Mohan Sethy
Discussion of results: Arpita Majhi, Mrutyunjaya Panda, and Kabir Mohan Sethy
Writing – Original Draft: Arpita Majhi
Writing – Review and Editing: Arpita Majhi and Mrutyunjaya Panda
Resources: Kabir Mohan Sethy
Supervision: Mrutyunjaya Panda and Kabir Mohan Sethy
Approval of the final text: Arpita Majhi, Mrutyunjaya Panda, and Kabir Mohan Sethy.

VI. ACKNOWLEDGMENTS

I express my deepest gratitude to my supervisors, Prof. Mrutyunjaya Panda, and Prof. Kabir Mohan Sethy for their constant guidance, encouragement, and support throughout the course of this research work. Their insightful suggestions, patience, and constructive criticism have been invaluable in shaping this paper and helping me to overcome many challenges.

ABSTRACT

This paper aims to propose analytics as a solution to the potential impact of AI and digital transformation in five countries that impact markets and society. The paper uses qualitative methods to describe general application areas (contexts) and presents specific case studies, analysis, findings, and discussions for each application area. Findings: Many countries have participated in this technological revolution, but this study will focus on five countries experiencing the AI revolution and digital transformation. This study explains how artificial intelligence (AI) and digital transformation have rapidly transformed various aspects of life, from industry and economy to markets and society, in these five countries, despite many countries participating in this technological revolution. This study has limitations and opens up opportunities for future research. Practical implications: The context of AI and digital transformation supports this study, showing that countries and entrepreneurs are paying attention to exploring new technologies due to the importance of these sectors. The selected case studies highlight how companies in these five countries are addressing the challenges of AI and digital transformation. This study presents research findings on AI and digital transformation, focusing on the most relevant strategic decisions and the design of new relational governance systems that accompany them. We found that several countries are encouraging companies in the corporate sector to design their digital infrastructure. Originality: This study explores the disruptive potential of artificial intelligence (AI) technology, with the role of governments involved in creating new entrepreneurial and transforming the entrepreneurial process.

I. INTRODUCTION

Artificial intelligence (AI) is a transformative force with profound implications across various industries [1], [2]. The term AI broadly encompasses computer systems that perform tasks typically requiring human intelligence [3]. With the rapid advancement of AI capabilities, businesses are increasingly leveraging this technology to innovate across products, services, operations, and customer experiences [4]. The impact of AI on business innovation has attracted significant attention from both practitioners and researchers. A growing body of literature examines how AI is applied to drive innovation across various business domains and its impact on outcomes [5]. AI is revolutionizing innovation across multiple sectors. The technology sector exemplifies this with AI-powered virtual assistants that have created new product categories and ecosystems, fundamentally changing customer interactions and service delivery [5]. Financial services are leveraging AI to create innovative products such as robo-advisors, which provide automated, low-cost investment advice, and AI-powered systems for fraud detection, credit scoring, and personalized financial recommendations [6]. The manufacturing sector is undergoing a transformation involving the use of AI-powered robots and computer vision systems that improve production efficiency and quality control. Predictive maintenance algorithms analyze sensor data to anticipate equipment failures, thereby reducing downtime. The impact of AI extends to supply chain management, where algorithms can optimize inventory levels, predict demand fluctuations, and improve logistics routing, as seen in Amazon's AI-based demand prediction approach. Even the service sector is being transformed by AI chatbots and virtual agents, which can handle a large number of customer inquiries and free up human agents to handle more complex issues [7].

Digital transformation (DT) has become a crucial factor driving organizational development and competitiveness in the modern business environment, with its dynamic and rapidly transforming structures [8], [9]. At the heart of this transformation is the rapid development of digital technologies such as the Internet of Things (IoT), cloud computing, artificial intelligence/machine learning (AI/ML), augmented reality (AR), and big data analytics [10]. These technologies have transformed the way businesses operate, interact with employees and customers, and manage their internal processes. The global shift to remote work and online collaboration has brought about drastic changes in traditional approaches to work [11]. This transformation is a temporary response to the global crisis but also has a long-term impact on business structures, accelerating the adoption of digital technologies to an unprecedented level. As organizations navigate the complexities of digital transformation, they face a variety of challenges, including data overload, the need for rapid decision-making, and the need for continuous innovation and improvement [12], recent research focuses on digital transformation [8], particularly but not limited to Human Resource Management [13]. Strategic management, education [14], knowledge management [15], [16], industry 4.0 [17], and entrepreneurship [9]. The rapid advancement of digitalization, manifested through the widespread adoption of smartphones and the meteoric rise of social media platforms, has triggered transformative changes in how individuals connect and share information [18]. Simultaneously, the digitalization of industries and the ensuing surge in e-commerce have not only transformed but fundamentally reshaped business models and consumer behavior, redefining commerce and trade dynamics [19].

This transformation has been further amplified by advances in data analytics and machine learning, which are driving revolutionary changes in decision-making processes across the healthcare and financial sectors [20]. The cumulative impact of this transformational journey has sparked a lively discussion about the profound impact of digitalization on the fundamental structures of society, individual behavior, and the very fabric of human existence [18]. The disruptive potential of artificial intelligence (AI) technology involves creating new entrepreneurial opportunities and transforming the entrepreneurial process. The impact of AI technology on entrepreneurial activity is also reflected in the high interest, which has led to existing fragmentation [21]. The advent of AI has created the greatest entrepreneurial opportunity in the history of civilization [22]. AI exemplifies how radical external change empowers and enables new economic activity [23]. AI has crucial implications for how entrepreneurs develop, design, and scale their businesses throughout the entrepreneurial process [24]. AI can enhance decision-making systems; increase the effectiveness, flexibility, and efficiency of processes; increase productivity; reduce costs; or produce high-quality, highly customized goods [25], [26]. Furthermore, AI solutions are now readily accessible to entrepreneurs at relatively affordable costs. The democratization of artificial intelligence allows entrepreneurs to compete even with large corporations, creating a level playing field for technology [27]. With increasing digital advances, the global economic landscape is reshaping marketing and entrepreneurship, creating new opportunities for growth and significant challenges for the corporate world. Rapid economic shifts, coupled with society's increasing reliance on digital technology, require organizations to continually adapt and modify their business models.

By analyzing digital transformation strategies through a combination of statistical and practical approaches, critical success factors as well as barriers to implementation, increase process automation, strengthen customer engagement, improve resource management, and ultimately increase productivity and profitability [28]. Digital entrepreneurship refers to business activity involving digital media, information, and communication technology. It includes entrepreneurial pursuits in fields such as artificial intelligence, blockchain, the internet of things, and augmented reality, among many others [29]. Through various digital platforms, digital entrepreneurship platforms have provided producers and marketers with the opportunity to use digital technology to achieve their marketing goals. The use of digital platforms has replaced traditional corporate methods with online marketing, app stores, online or smartphone purchases, e-transactions and e-commerce. It is widely stated that bringing businesses into the digital era and using digital platforms to offer goods and services will enhance their capabilities and increase sales, which will ultimately improve their performance [30]. The success or failure of marketing strategies for digital entrepreneurship depends on a variety of elements. The landscape of strategic marketing in digital entrepreneurship is characterized with both advantages and challenges in a “Web 2.0 networked world” [31]. The digitalization of companies is becoming increasingly important for their internationalization. Globalization causes digitalization to change companies all over the world. The rise of multinational companies such as Uber and Airbnb, among others, which maintain their globalization through technology and creative business model proposals, is evidence of the demand for the business world to experience dramatic changes in the last few decades [32]. Digitalization of collaborative procedures and tools can lead to effective integration [33]. In light of this, digital transformation (DT) is becoming increasingly important [34], and impacts almost every aspect of a company [35].In the contemporary global economy, digital transformation is playing an increasingly important role in the expansion of companies on a global scale.

Businesses can increase cross-border customer engagement, increase supply chain resilience, and scale operations more effectively with the emergence of artificial intelligence, automation, cloud computing, and e-commerce [36]. Digital entrepreneurship and digital transformation are interrelated. To change the way a business functions and delivers value to its customers, digital transformation means integrating digital technology into every aspect of the company [37]. Digital entrepreneurship, on the other hand, is the process of starting and expanding new businesses that utilize digital technologies [38]. The emergence of digital entrepreneurship is greatly aided and supported by the digital transformation ecosystem [39]. The potential of digital technologies to help new companies gain billions of clients, create goods and services that have never existed before, and connect with people like never before is indicative of this trend [38]. As governments in many countries place great emphasis on developing digital infrastructure and services, digital transformation is becoming a more important factor in the global economy [40]. All these trends will undoubtedly have a significant impact on global trade as well as countries looking to gain competitive advantages from digital transformation across industries [41]. Today, it significantly influences consumer behavior and market demand, which in turn influences the way businesses interact with their target audiences [42]. Today's consumers are more empowered, aware, and connected than ever before [43]. Globalization has created a need for the business world, especially multinational companies, to shift to digital methods to generate long-term success. Digital transformation is the methodical application of digital technologies across all domains of a company, resulting in significant adjustments to the way a business manages its resources and provides customer service [44].

Therefore, the purpose of this article is to explore AI and digital transformation: How entrepreneurs engage in their impact on markets and society. This objective is guided by the following research questions:

RQ1. How do entrepreneurs engage in development AI and digital transformation within their companies?

RQ2. How do entrepreneurs engage in markets and society within their companies?

II. CONCEPTUAL FRAMEWORK

The disruptive potential of artificial intelligence (AI) technology involves the creation of new entrepreneurial opportunities and the transformation of entrepreneurial processes. The impact of AI technology on entrepreneurial activity is also reflected in the high interest, which has led to existing fragmentation [21]. The emergence of multinational companies such as Uber and Airbnb, among others, which maintain their globalization through technology and creative business model proposals, is evidence of the demands of the business world for dramatic change in recent decades [32]. The digitization of procedures and collaborative tools can lead to effective integration [33]. Given this, digital transformation (DT) is becoming increasingly important [34], and impacts nearly every aspect of a company [35]. Based on the business literature, we recognize the crucial role of several factors in AI, digital transformation, and business, which impact markets and society. Furthermore, our framework integrates the literature on AI, digital transformation, and business, with the market and society, recognizing the crucial role of each. By examining each, we gain deeper insights into how these identities shape business efforts in markets and society.

II.1 ENTREPRENEUR ARE DEVELOPMENT ARTIFICIAL AND DIGITAL TRANSFORMATION WITHIN THEIR COMPANIES

In recent years, artificial intelligence (AI) has emerged as a transformative force across various sectors of modern society, reshaping the economic landscape, social interactions, and ethical considerations. This exploration of AI's diverse impacts provides a comprehensive understanding of how AI is redefining human experiences and social norms, furthering the discourse on integration [45]. Organizations worldwide are leveraging AI's capabilities to improve productivity. Seventy-four percent of companies using AI say it has given them a competitive advantage. This figure rises to 79 percent among companies that are leaders in AI adoption Many companies have begun using AI to automate administrative and engineering design tasks. For example, legal AI algorithms can find relevant legal cases, draft contracts from templates, and review language for issues. Financial AI detects credit or bank account abuse. Some design algorithms can suggest features for new products based on sales data and customer feedback. They can even create new product designs with fewer specifications [46]. AI has the potential to bring fundamental changes to humanity. For example, many decisions in a person's life can already be delegated to technology. As AI systems improve, more complex tasks can be handled by these systems. The risk is that much human judgment could be handed over to AI agents, leading humans to follow the intelligent agent's guidance without question. Independent human judgment allows for reflection on values, context, and long-term perspectives. Using AI to improve human-to-machine interactions will also occur in other areas, such as with healthcare robots or service robots [47]. With significant advances in artificial intelligence (AI) in recent years, the possibility of job displacement due to AI advancements has reignited interest in how technological change will impact the job market [48]. Overall, predictions about the speed and scale of job displacement caused by AI are highly pessimistic. As AI becomes more capable and widespread, these concerns will increase, and social anxiety will likely increase. In recent years, AI has transitioned from science fiction to a practical business tool [49]. ChatGPT, an AI chatbot, is now commercially available and can integrate text, edit summaries, and create presentations. AI has the potential to significantly enhance the skills of professional workers. Until now, spending time with smart machines has been limited to specific instances and short periods. It is indeed an unusual experience, requiring skills that not all users possess. Things have changed rapidly since the launch of the first mobile phone, competing for people's attention and curiosity [50].

A concept called “disintermediation” refers to a user viewing the bargaining power of masses as nearly infinite to a seller who focuses on individuals feeling exclusive and personally cared for. In this new smart economy—much smarter than Web 2.0 of the 2000s a clear distinction exists between “smart” machines and “stupid” machines. The former enhance user cognition by providing information and fostering emotional and social connections; the latter transform resources and include physical mechanical machines (producing goods and infrastructure), telecommunication and transportation devices (delivering services), and algorithms and interface machines (collecting and analyzing data) [51]. Digital transformation (DT) has evolved from a mere technological opportunity to a genuine necessity to manage the needs and expectations of the world's growing population [32]. This development has brought about significant changes in many organizations, with DT introducing new processes and mechanisms that can impact key structures in how companies conduct their business. According to the primary goal of Digital transformation (DT) is to address challenges related to efficiency and effectiveness. [52]. That companies that do not develop and implement DT strategies quickly are less likely to keep pace and compete in the new digital reality [53], the transition to this new reality should not be underestimated because, like any change process, it carries several risks and challenges [54]. Digital transformation (DT) represents a substantial challenge not only for individual companies, but also for national economies [55]. To become a digital nation, i.e. a country in which citizens, governments, and companies live in a digital society that interacts and creates value benefitting all stakeholders, national governments can/must learn from the experiments conducted in smart cities [56], and the experiments of entrepreneurs in particular [32]. Reviewed relevant literature on digital marketing and B2B relationships [57]. Examined how digital technology facilitates business model innovation in the creative industries [58]. Systematic focus on digitalization in accounting. Existing reviews have in common, namely their primary focus on the very limited field of business and management; their perspective is very narrow. Furthermore, these reviews have not determined the evolution of the term Digital Marketing (DT) in the field of business and management [59].

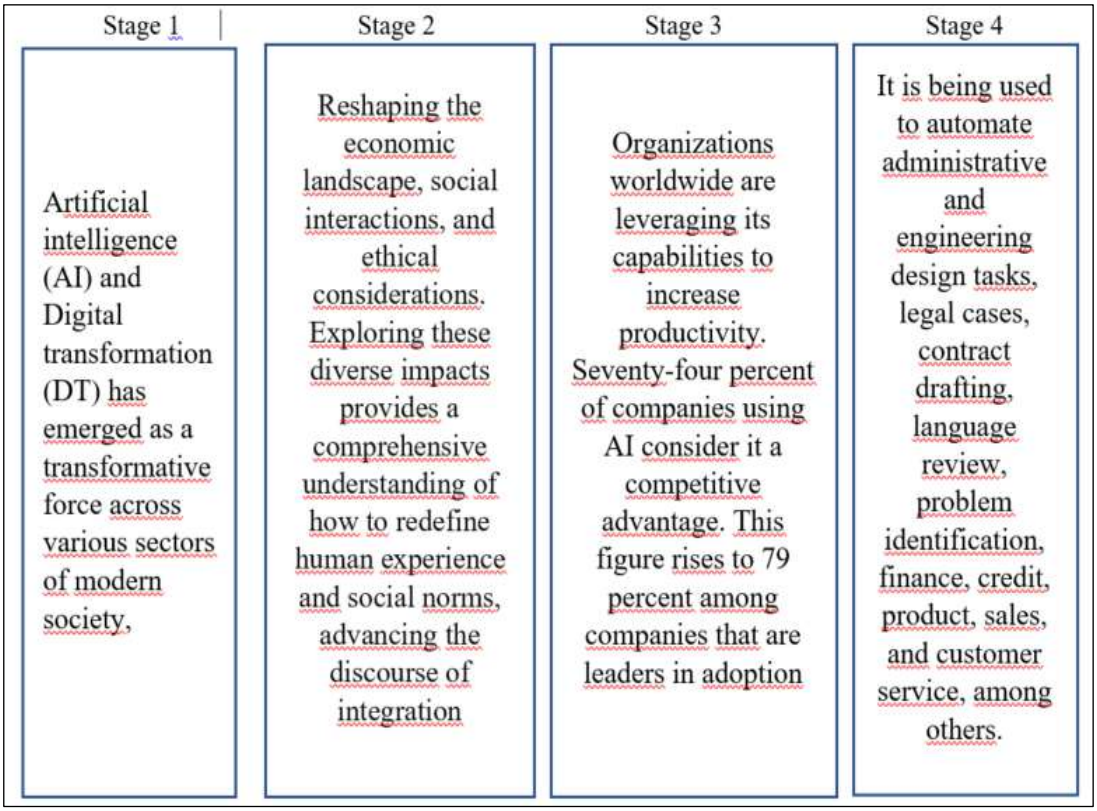

Figure 1: Process and Benefits of AI and Digital Transformation.

II.2 ENTREPRENEURS ARE INVOLVED IN MARKETS AND SOCIETY WITHIN THEIR COMPANIES

It is important to note that the overall impact of entrepreneurship on society is determined not only by the frequency of its citizens starting businesses, but also by the quality of their efforts. This includes the extent to which they create businesses from newly perceived market opportunities and businesses that offer unique and novel products and services to customers. Furthermore, it is important to recognize that entrepreneurship can be expressed not only in the form of startups but also in organizations [60]. Exploring whether these different types of entrepreneurship are related to environmental conditions. In our research, we were guided by two distinct and novel questions that address important gaps in previous research [61]. Market-based entrepreneurship is valuable to society because it provides business opportunities for those who recognize market gaps, as well as new and unique products and services for customers [62]. Therefore, understanding the factors that drive these valuable activities is crucial, especially considering that the quality of institutions varies across countries [63]. As more and more companies combine social missions with innovative market approaches to address social challenges [64], they often utilize flexible, hybrid organizational forms [65], [66], seeking to achieve profitability while balancing the objectives of traditional nonprofits and for-profit companies [67]. Nonprofit organizations promote social benefits while discouraging profit-seeking managerial behavior, which can lead to economic inefficiencies due to the non-distribution constraint, which prohibits nonprofit board members, staff, and directors from receiving any benefit from the organization's net profits. Standard nonprofits seek to maximize profits for their owners, which can incur social costs when profitable actions conflict with social values.

To be effective, social enterprises must achieve an optimal balance between two objectives: profit and market objectives [64]. Therefore, academics argue that integrating commercial and social welfare logics within a company is crucial, yet challenging, in addressing social issues [65], [68], as pursuing a social mission may be incompatible with exploiting profitable market opportunities. All companies operate on a spectrum, ranging from those focused purely on social impact (i.e., classic nonprofits) to those focused purely on profit maximization (i.e., classic for-profits). Social enterprises fall somewhere between these two primary objectives [69]. Despite the hybrid nature of these organizations, the emerging consensus is that social enterprises clearly value diverse stakeholders and demonstrate a willingness to create social value even if not maximizing shareholder interests. Therefore, the focus of differentiation lies largely in the social impact that social enterprises have on society by serving diverse stakeholders (both internal and external) beyond their shareholders [70]. Recognizing the challenges of integrating profit and purpose, entrepreneurs engage in founding activities with reflection on the meaning they attribute to the new venture. Take, for example, the unique aspirations of the entrepreneurs behind Method, a household cleaning products company that has become one of the fastest-growing companies in the US. The founders envisioned Method with a dual meaning: they sought to build a profitable company and improve the world [71]. They deliberately entered the household cleaning industry, one of the most environmentally polluting, and designed their innovative product to compete with existing brands in terms of higher environmental and health standards [72].

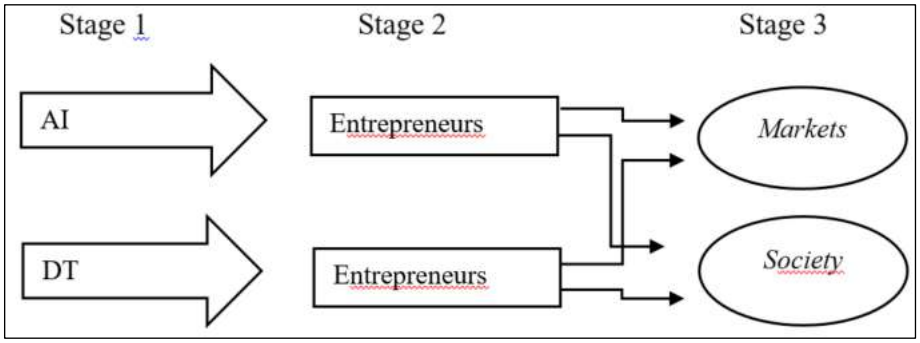

Figure 2: Conceptual Framework Development.

III. METHODOLOGY

To explore our topic, how AI and digital transformation in business evolve over time, we employed a qualitative approach through a multi-longitudinal case study [73]. Qualitative case studies allow for in-depth exploration of complex phenomena, offering insights into how they develop and how people construct meaning [74]. Given our focus on understanding how entrepreneurs engage with markets and society, a qualitative approach was deemed appropriate.

III.1 SELECTING AND COLLECTING THE EMPIRIICAL MATERIAL

Artificial Intelligence (AI) and digital transformation have rapidly transformed many areas of our lives, from industry and the economy to societies worldwide. Many countries have participated in this technological game. However, only a few stand out as pioneers. I will discuss five of the top countries leading the AI revolution and digital transformation [75].

III 1.1 United States: The Center of Market-Driven Innovation

The United States stands as a key figure in the AI landscape, driven by market-oriented innovation and substantial private investment. Over the past five years, venture capital (VC) investment in AI in the US has reached an astonishing $290 billion. This influx of capital has catalyzed transformative progress across various sectors, including autonomous vehicles, healthcare, and IT infrastructure. Furthermore, the US enjoys a highly competitive environment that fosters continuous innovation. Companies like Google, Microsoft, and Amazon are not only pioneers in AI research but also play a crucial role in the global application of AI technology. This market-driven approach has resulted in cutting-edge AI solutions. It also positions the United States as a leader in technology development and commercialization. In addition, the US government has supported the growth of AI by implementing policies that encourage research and development. This combination of private sector dynamism and government support ensures the US remains at the forefront of AI innovation.

III.1.2 China: A Giant in Growth and Modernization

China is another powerhouse in the AI space, driven by rapid growth and modernization efforts. The country's AI market is expected to exceed $61 billion by 2025, reflecting its significant investment in the sector. According to data from the Organisation for Economic Co-operation and Development (OECD), Chinese venture capitalists have poured approximately $120 billion into the AI ecosystem, focusing on areas such as autonomous vehicles, robotic sensors, and IT hardware.China has become the world's largest robot market, accounting for 52% of global robot installations. This dominance extends to service robots used in logistics, healthcare, and consumer applications. Furthermore, Chinese companies have expanded their influence globally, securing international contracts for surveillance, smart city solutions, and automation technology. Furthermore, the Chinese government has set an ambitious goal to become a leader in the AI revolution, as outlined in its Next-Generation AI Development Plan. This plan emphasizes the integration of AI into all sectors of society, aiming to make China a leading AI innovator globally by 2030. The combination of government-driven initiatives and a strong private sector ensures China continues to climb the AI hierarchy.

III.1.3 Japan: Innovating to Address Demographic Challenges

Japan stands out for its unique approach to AI and digital transformation, leveraging these technologies to address pressing demographic challenges. With an aging population and shrinking workforce, Japan has turned to AI and digital transformation to fill the gap. The country has increased collaboration with foreign startups and small and medium-sized enterprises (SMEs) to enhance its AI capabilities. A key aspect of Japan's AI strategy is the concept of "Society 5.0," which aims to integrate advanced technology into every aspect of life. This initiative promotes connectivity, automation, and personalization, which are expected to drive innovation and spur economic growth. Japan's AI and digital transformation market is divided into hardware, software, and services, with the software segment experiencing the highest growth. This growth is driven by advances in data storage capacity, advanced computing, and parallel processing capabilities. Japan's focus on AI and digital transformation also extends to healthcare, where AI-based and digital transformation technologies are being developed to support the elderly, such as robotics for caregiving and AI and digital transformation systems formedical diagnostics. By addressing demographic challenges through AI and digital transformation, Japan can solve internal challenges. They can also serve as a global example of how technology can be used to address social issues.

III 1.4 India: AI-Driven Productivity and Digital Transformation on the Rise

India is rapidly emerging as a significant player in the AI and digital transformation arena, driven by a combination of increased corporate technology spending and a vast and growing talent pool. This statement highlights the rapid growth of the Indian AI market, projected to reach $17 billion by 2027, with an impressive annual growth rate of 25-35% between 2024 and 2027. Driving this expansion is India's large internet user population, estimated at 881 million. This large user base creates a strong demand for personalized experiences, which in turn drives the growth of AI technology in the country. AI and digital transformation in India operate through task automation, enabling businesses to streamline activities such as campaign setup and customer inquiry responses. Furthermore, AI and digital transformation facilitate content personalization, tailoring marketing materials to individual preferences, and enhancing the customer experience. This technology also plays a crucial role in optimizing websites for better performance and predicting customer behavior. This enables businesses to design targeted campaigns with higher levels of effectiveness. The Indian government has recognized the importance of AI and digital transformation, launching initiatives such as the National AI Strategy to encourage the adoption and development of AI and digital transformation technologies. These efforts, coupled with growing private sector interest in AI and digital transformation, position India as a rising star in the global AI and digital transformation landscape.

III 1.5 Germany: A Hub for Artificial Intelligence, Digital Transformation, and Science

Germany is renowned for its AI and digital transformation innovations, attracting significant attention and investment from global tech giants. Companies like Microsoft have committed substantial resources to Germany's AI and digital transformation infrastructure, with a planned investment of $3.2 billion. This investment underscores Germany's role as a key hub for AI and digital transformation development in Europe. Furthermore, Germany's vibrant AI and digital transformation ecosystem has attracted the attention of major companies like Apple, which recently acquired German AI startup Bitbot. This interest from global players highlights the attractiveness of Germany's AI capabilities. Germany's commitment to AI and digital transformation goes beyond corporate investment. The country is focused on advancing AI and digital transformation research, particularly in the study of brain data, with the European Union allocating its single largest funding source to this field. Furthermore, Germany has ambitious plans to double its AI and digital transformation funding. It aims to compete with global technology leaders like the US and China to become a leading country in AI and digital transformation. Furthermore, the German government has established a comprehensive AI strategy, encompassing the development of innovation, the enforcement of ethical standards, and the promotion of the use of AI and digital transformation across various sectors. This approach ensures Germany remains a key player in the global AI and digital transformation ecosystem, driving scientific and technological progress.

III 2 ANALYSING THE MATERAIL AND REPORTING THE FINDING

United States: As a global leader in the digital economy, the United States has achieved significant strategic success, with its digital economy reaching $17.2 trillion in 2022, accounting for approximately 74.7% of its GDP. Through decades of continuous development, the United States has accumulated rich experience and established systemic advantages in research and development of essential technologies, digital technology innovation, industrial ecosystem development, market mechanism optimization, and other aspects, solidifying its dominant position in the global digital economy. However, existing research has largely focused on a single dimension, such as the technological innovation pathway, the development of the platform economy, or talent development mechanisms. Some scholars have explored the development pathway of the US digital industry from the perspective of technological innovation [76], [77], while others have focused on aspects such as the platform economy and higher education to analyze the driving factors and competitive advantages of the US digital economy development [78], [79]. However, the complexity of the digital economy requires a multidimensional and comprehensive analytical framework, especially in the current new phase characterized by deep integration between digital technologies and industries and the accelerated merging of digital and physical spaces. There is an urgent need to develop a more integrative and dynamic analytical framework to uncover the internal logic and evolutionary patterns of the development of the US digital economy, and to periodically evaluate how policy direction, institutional coordination, and talent development interact to maintain leadership in the digital economy [80], [81]. In particular, how the US government balances strategic industrial competitiveness and digital security, effectively coordinates various stakeholders, and programs digital talent development has not been comprehensively addressed in the existing international literature.

China: The essence of China's modernization is the modernization of the people, a modernization that strives for the entire people, and a modernization that brings about a population unprecedented in the world. General Secretary Xi Jinping pointed out that there is no fixed model for the path to modernization, and that a suitable model will be beneficial; cutting feet to fit shoes will not achieve results. China's modernization, particularly its educational modernization, has contributed significantly to its transformation from a "poor" country to a "prosperous and powerful" one [82]. China, the world's most populous country, had a total population of 1.41 billion in 2020, exceeding the combined population of 1.37 billion among the 38 OECD member countries (38 countries) and equivalent to 4.3 times the population of the United States. In 2020, China successfully built a moderately prosperous society in all respects, benefiting 1.4 billion people. Its GDP reached 101.35 trillion yuan, equivalent to 23.02 trillion international dollars (calculated based on PPP, constant 2017 international dollars, or 18.3% (4) of the world's total GDP). China recorded a per capita GDP of 16,316 international dollars, surpassing the world's per capita GDP of 16,178 international dollars [82], and equivalent to 27.2% of the United States' per capita GDP (59,920 international dollars). China is the country with the largest labor resources in the world, consistently ranking first in the world. Education is the foundation of long-term national development. Developing education at all levels and utilizing human resources has always been one of the long-term tasks of China's economic development.

China's modernization is modernization for all, which essentially means that through educational modernization, continuous investment in human resources, will be made for all, which in turn will increase education levels (years of schooling per capita) and development capacity (labor productivity) for all, create various types of assets (economic, social, cultural, ecological, etc.), and build a human resource foundation for realizing China's modernization [82]. Focusing on modernization with Chinese characteristics and the Great Leap Forward in human resource development, we explore how China, since its founding, has transformed itself from the world's largest illiterate country to the world's largest in terms of human resources, and why modernization with Chinese characteristics is a modernization of education for all. all its people, how China will modernize its education and develop into a world-leading country in human resources by 2035, so as to facilitate the contribution of human resources to fundamentally realize socialist modernization [82].

Japan: Japan is aggressively developing artificial intelligence and digital transformation. The government is leading discussions on a comprehensive AI and digital transformation strategy. This strategy aims to establish Japan as a leader in AI innovation and digital transformation. This effort directly addresses ethical issues. This strategy will boost Japan's technology industry and businesses by encouraging AI and digital transformation research [83]. Government AI and Digital Transformation Strategy. On September 12, 2025, Japan launched its historic national AI and digital transformation strategy. The government collaborated on this plan just months after passing a landmark AI law in May. Prime Minister Shigeru Ishiba emphasized the importance of AI in maintaining national security and driving economic growth. The goal is to build a society where AI benefits society. This plan encourages innovation and minimizes risks. The government plans to finalize the strategy by the end of the year, demonstrating Japan's strong commitment to leading AI in various fields [83]. Impact on the Japanese Tech Industry. Japan's tech industry is set to grow. The government is taking decisive action. Investing more in AI and digital transformation research will drive growth and spark innovation. This space will foster teamwork among startups, tech companies, and schools. This will create a culture of shared growth. Focusing on ethical AI aligns progress with social values. This helps build public trust [83]. Implications for Businesses in Various Sectors. Japan's AI and digital transformation strategy will impact more than just tech companies.

Industries such as manufacturing, healthcare, finance, and education will benefit from the use of AI and digital transformation. AI automation and digital transformation increase manufacturing efficiency. Predictive analytics enhance financial services. Personalized learning is transforming education. Companies that leverage AI and digital transformation effectively will have an advantage. Companies that don't may struggle to stay relevant [83]. Challenges and Considerations. AI and digital transformation are evolving rapidly. They will bring benefits and challenges. We must address data privacy, job losses, and ethical issues head-on. The government's plan takes bold action to address these challenges. It ensures the responsible development of AI and digital transformation. Policymakers, industry leaders, and the public must work together to shape the future of AI and digital transformation. Japan's push for a comprehensive AI and digital transformation strategy is a major step toward becoming a global leader in AI and digital transformation. The growth of technology and its impact on various business sectors demonstrate the importance of this step. Japan strives to balance innovation and ethics. In this way, the potential of AI and digital transformation can be harnessed for the benefit of society. Japan is taking ambitious steps, and the world will be watching closely. Japan offers useful ideas for other countries in utilizing AI and digital transformation in their economies and societies. Japan's success could set a standard for the integration of AI and digital transformation worldwide [83].

Artificial Intelligence In The Digital Transformation Strategy Of Japanese Enterprises. In these digital transformation eras, Japanese enterprises embrace AI in their production process. From implementing predictive maintenance solutions in manufacturing to automating complex tasks using AI-driven algorithms, companies are not only reducing operational costs but also enhancing the quality and precision of their products. Japan Digital Transformation Trends. AI adoption continues to play a vital role. The Japanese AI market is projected to grow substantially, reaching approximately $4.5 billion as organizations across sectors increasingly integrate AI technologies into their operations. Key industries such as smart cities, healthcare, manufacturing, and finance are leading this transformation, with AI applications set to expand significantly in the coming years (Trade.gov). Furthermore, a report from IDC anticipates that by 2028, 80% of CIOs in the Asia-Pacific region, including Japan, will utilize AI to enhance operational efficiency. This reflects a broader shift towards digital-first strategies, underscoring AI's critical role in reshaping business practices and driving future innovation compliance [84]. Automation is a cornerstone of Japan's future. Automation through RPA is crucial for Japan's societal and economic challenges. The RPA market is projected to grow rapidly, with an expected compound annual growth rate (CAGR) of 41.20% from 2024 to 2032 (imarc). This growth is fueled by rising demand for automation in manufacturing, a shrinking workforce, heightened awareness among businesses, increased digital transformation efforts, and the adoption of advanced technologies (Statista). Big data to data-driven decision making.

According to McKinsey, the rise of data literacy and technological advancements fundamentally transform how businesses harness data for informed decision-making. In Japan, improving data-driven strategies is essential for fostering innovation and maintaining a competitive edge in the global market. This cultural shift ensures that data insights are integrated into the organizational fabric, driving collective growth and innovation compliance [84]. How Japanese enterprises can benefit from AI solution. A comprehensive end-to-end solution that integrates AI technologies is hyperautomation. This transformative approach leverages AI to optimize business operations on a broad scale. By combining RPA, AI, and machine learning, hyperautomation enables organizations to automate complex processes beyond routine tasks. This method enhances efficiency and fosters collaboration between humans and machines, facilitating seamless workflow integration. Key components include: Transforming all business processes into automation while incorporating advanced AI technologies. Encouraging every department within the organization to automate to maximize the potential benefits of hyperautomation. Enabling collaboration between humans and robots to enhance customer service delivery, making it faster and more efficient. Managing the entire automation lifecycle at scale, from identifying automation opportunities to measuring ROI for selecting the best automation solutions compliance [84]. Benefits of AI & Hyperautomation. Enhanced Decision-Making: AI can analyze vast amounts of data quickly and accurately, providing insights that help businesses make informed decisions.

Operational Efficiency: Automating routine tasks through AI, such as RPA, reduces manual workloads and increases productivity. Cost Savings: Implementing AI can lead to significant cost reductions by minimizing errors, decreasing operational costs, and streamlining processes. Estimates suggest that organizations can reduce operational expenses significantly by adopting AI solutions. Risk Management and Compliance: AI systems can monitor transactions in real time to detect fraud and ensure regulatory compliance [84].

India: India stands at the cusp of a new era powered by Artificial Intelligence (AI), and digital transformation where technology is transforming lives and shaping the nation's progress. AI is no longer limited to research labs or big corporations. It is reaching citizens at every level. From improving healthcare access in remote areas to helping farmers make informed crop decisions, AI is making daily life simpler, smarter, and more connected. It is revolutionising classrooms through personalised learning, making cities cleaner and safer, and enhancing public services through faster, data-driven governance. Initiatives such as the India AI and digital transformation Mission and the Centres of Excellence for AI are at the heart of this transformation. They are expanding access to computing power, supporting research, and helping startups and institutions create solutions that directly benefit people. India's approach focuses on making AI and digital transformation open, affordable, and accessible, ensuring that innovation uplifts society as a whole [85]. This inclusive vision is also reflected in NITI Aayog's report, AI and digital transformation for Inclusive Societal Development (October 2025). The report shows how AI and digital transformation can empower India's 490 million informal workers by expanding access to healthcare, education, skilling, and financial inclusion. It highlights how AI-driven tools can boost productivity and resilience for millions who form the backbone of India's economy. The report also stresses that technology can bridge deep social and economic divides, ensuring that the benefits of AI and digital transformation reach every citizen. AI and digital transformation ecosystem in India at Present: India's technology sector is expanding rapidly, with annual revenues projected to cross USD 280 billion this year [85].

Over. 6 million people are employed in the tech and AI ecosystem. The country hosts 1,800+ Global Capability Centres, including more than 500 focused on AI. India has around 1.8 lakh startups, and nearly 89% of new startups launched last year used AI in their products or services. On the NASSCOM AI Adoption Index, India scores 2.45 out of 4, showing that 87% of enterprises are actively using AI solutions. Leading sectors in AI and digital transformation adoption include industrial and automotive, consumer goods and retail, banking, financial services and insurance, and healthcare. Together they contribute around 60 percent of AI's total value. About 26% of Indian companies have achieved AI maturity at scale, according to a recent BCG survey.Ecosystem in India at Present: India's technology sector is expanding rapidly, with annual revenues projected to cross USD 280 billion this year. Over. 6 million people are employed in the tech and AI and digital transformation ecosystem. The country hosts 1,800+ Global Capability Centres, including more than 500 focused on AI and digital transformation. India has around 1.8 lakh startups, and nearly 89% of new startups launched last year used AI and digital transformation in their products or services. On the NASSCOM AI Adoption Index, India scores 2.45 out of 4, showing that 87% of enterprises are actively using AI solutions. Leading sectors in AI and digital transformation adoption include industrial and automotive, consumer goods and retail, banking, financial services and insurance, and healthcare. Together they contribute around 60 percent of AI's total value. About 26% of Indian companies have achieved AI and digital transformation maturity at scale, according to a recent BCG survey [85].

As India builds an inclusive AI and digital transformation ecosystem, its growing global recognition reflects this progress. Rankings such as the Stanford AI Index place India among the top four countries in AI skills, capabilities, and policies. The country is also the second-largest contributor to AI projects on GitHub, highlighting the strength of its developer community. With a strong STEM workforce, expanding research ecosystem, and growing digital infrastructure, India is positioning itself to harness AI for economic growth, societal progress, and the long-term vision of Viksit Bharat by 2047. NITI Aayog's report, AI and digital transformation for Inclusive Societal Development (October 2025), sets a roadmap for using technology to empower India's informal workforce. It asks a key question: how can the world's most advanced technologies reach the most overlooked workers so they can overcome constraints and claim their place in India's growth story? The report draws on real-life experiences of informal workers. It reflects the challenges and aspirations of a home healthcare aide in Rajkot, a carpenter in Delhi, a farmer, and many others. These stories show persistent barriers, but also the immense potential that thoughtfully deployed technology can unlock. For these millions, technology must not replace their skills, it must amplify them [85]. The roadmap discusses how Artificial Intelligence, Internet of Things, blockchain, robotics, and immersive learning can remove systemic barriers faced by India's 490 million informal workers. It envisions a future where, by 2035, voice-first AI interfaces overcome language and literacy barriers. Smart contracts will ensure timely and transparent payments. Micro-credentials and on-demand learning will allow workers to upskill at the pace of their ambition. At the heart of this vision is the Digital ShramSetu Mission, a national initiative to deploy frontier technologies at scale for India's informal sector. The mission focuses on persona- or sector-led prioritisation, state-driven implementation, regulatory enablement, and strategic partnerships to ensure affordability and wide adoption. It will mobilise government, industry, and civil society, guided by a robust multi-level impact evaluation framework [85].

Germany: Germany has unveiled ambitious plans to revitalize its ailing economy, leveraging artificial intelligence (AI) and a range of digital solutions to drive mainstream growth across key sectors. Germany's digitalization push. Germany's race to AI adoption. Trust in generative AI rises. GenAI systems' issues. According to a report, German Chancellor Friedrich Merz unveiled the plans during a press conference at the Borsig Palace in Berlin, highlighting 23 major projects aimed at growing the economy. Under the "modernization agenda," Merz disclosed that the projects will achieve their aim by cutting bureaucracy while making public services more efficient. At the top of the list is a platform that enables companies to be registered within 24 hours, which German authorities say is a significant step in attracting international players. Furthermore, Merz's plan will involve the introduction of a centralized online vehicle registration service and a plan to accelerate the recognition of foreign medical qualifications [86]. AI features prominently in Germany's modernization agenda, with the government keen on introducing AI-based tools for visa and court processing. The government unveiled plans for an AI-based digital agency to promote trade and foster development cooperation, while supporting the integration of emerging technologies across key sectors of the economy. Leaning on next-gen solutions, Merz's modernization agenda includes a direct payment mechanism for federal aid to citizens, sidestepping traditional intermediaries in the value chain.

In terms of infrastructure, the plan will back the development of a nuclear fusion reactor while prioritizing hydrogen as an energy resource. Still the largest economy in Europe, Germany has faced significant headwinds in recent years, aggravated by high energy costs and labor shortages. Excessive bureaucracy has since cost Germany nearly $175 billion over the last year, while a rising dependency on exports has earned it the tag as the "sick man of Europe." "We are of course aware of the problems facing the German economy at the moment, but we aspire to return to the top," said Merz. "We are now going to the German Bundestag with some very concrete legislative proposals." Merz disclosed that the government will seek legislative backing for the 23-point digitization plan, eyeing a passage before the end of the year. Germany plays catch-up to industry first-movers. Before the ambitious digitization plan, Germany ranked lower than the U.S. and the U.K. in terms of AI adoption and development. The German-based state-owned development bank KfW disclosed in a report that the country is falling behind global artificial intelligence leaders, with real-world applications failing to match policy enthusiasm [86]. To close the gap, Germany's financial regulator BaFin urged stakeholders to introduce policies to avoid "unnecessary bureaucracy" for AI. Meanwhile, the country has devised an AI investment plan to match the U.S., while regulators are ramping up enforcement actions against data protection violations. Trust in generative AI spikes despite leaks in guardrails. A new report by SAS has revealed that consumers are indicating significant trust levels in generative AI systems over other forms of AI despite gaps in safeguards. The report, titled "The IDC Data and AI Impact Report: The Trust Imperative," noted that generative AI systems, such as OpenAI's ChatGPT and Google's (NASDAQ: GOOGL) Gemini, have earned the trust of a majority of users. However, the report noted that the social familiarity of generative AI systems is a major factor in growing trust levels despite the sector having the lowest investment in trustworthiness. Apart from generative AI, 33% of respondents indicated complete trust in agentic AI systems, such as AutoGPT. Meanwhile, only 18% confirmed total trust in traditional AI systems despite hefty investments in trustworthiness and reliability. "Our research shows a contradiction: that forms of AI with humanlike interactivity and social familiarity seem to encourage the greatest trust, regardless of actual reliability or accuracy," said Kathy Lange, executive at IDC. "As AI providers, professionals and personal users, we must ask: GenAI is trusted, but is it always trustworthy?" [86].

The SAS-backed study noted that companies that prioritize AI trustworthiness are 60% more likely to double their return on investment (ROI) over those without significant investments in the guardrails. Despite the benefits of prioritizing trust, the report noted that only 40% of AI companies are committed to making their systems trustworthy through governance and other ethical safeguards. Per the report, only 2% of companies are keen on developing an AI governance framework, while less than 10% have a clearly defined AI policy. As consumers increasingly question data handling processes of AI service providers, analysts note that a lack of investment in trustworthiness will affect the profitability of AI companies in the near future. However, the report highlighted a streak of concerns among organizations keen on prioritizing AI trustworthiness. 49% of respondents said that data foundations are not centralized and non-optimized cloud data environments as a major barrier, while 41% of respondents are pointing to a lack of skilled specialists within their organizations. "For the good of society, businesses and employees – trust in AI is imperative," said SAS CTO Bryan Harris. "In order to achieve this, the AI industry must increase the success rate of implementations, humans must critically review AI results, and leadership must empower the workforce with AI." [86]. GenAI systems are prone to sycophancy. Several studies have revealed that AI systems have traits of sycophancy, accentuated by a tendency to provide answers based on users' desires rather than the truth. While the reports did not disclose a solution, researchers have suggested new training systems for large language models (LLMs). Apart from sycophancy, LLMs are also prone to hallucination, with several responses by leading models containing misleading information presented as fact. Global regulators are tightening the screws for service providers over claims of hallucination as researchers unveil new tools with emerging technologies to detect the problem in AI models. In order for artificial intelligence (AI) to work right within the law and thrive in the face of growing challenges, it needs to integrate an enterprise blockchain system that ensures data input quality and ownership—allowing it to keep data safe while also guaranteeing the immutability of data. Check out CoinGeek's coverage on this emerging tech to learn more why Enterprise blockchain will be the backbone of AI [86].

IV. RESULTS

This section will outline the themes identified in our study, which revolve around the role of AI and digital transformation in empowering entrepreneurs to engage in their impact on markets and society. These themes are then correlated with the functions of developing that potential, including providing recognition, differentiation, and added value to stakeholders. The theoretical underpinnings of these themes are fully detailed in the Selection and Collection of Empirical Material section, which explains the systematic analysis and relationship of our empirical data to relevant theoretical themes.

IV 1. ENTREPRENEUR ARE INVOLVED IN DEVELOPMENT AI AND DIGITAL TRANFORMATION WITHIN THEIR COMPANIES

This research shows that entrepreneurs in the United States, China, Japan, India, and Germany are responding strongly to the challenges of AI development and digital transformation. We understand this process as a company-building process in each country. This research shows that entrepreneurs in the United States, China, Japan, India, and Germany are responding strongly to the challenges of AI development and digital transformation. We understand this process as a process of company development in each country. United States is a key player in the AI landscape, driven by market-oriented innovation and substantial private investment. Over the past five years, venture capital (VC) investment in AI in the US has reached an astonishing $290 billion. This capital influx has catalyzed transformative progress across sectors, including autonomous vehicles, healthcare, and IT infrastructure. China is another powerhouse in the AI space, driven by rapid growth and modernization efforts. The country's AI market is expected to exceed $61 billion by 2025, reflecting its significant investment in the sector. According to data from the Organisation for Economic Co-operation and Development (OECD), Chinese venture capitalists have poured approximately $120 billion into the AI ecosystem, focusing on areas such as autonomous vehicles, robotic sensors, and IT hardware. Japan has turned to AI and digital transformation to fill this gap. The country has increased collaboration with foreign startups and small and medium-sized enterprises (SMEs) to enhance its AI capabilities.

A key aspect of Japan's AI strategy is the "Society 5.0" concept, which aims to integrate advanced technology into every aspect of life. This initiative promotes connectivity, automation, and personalization, which are expected to foster innovation and spur economic growth. Japan's AI and digital transformation market is divided into hardware, software, and services, with the software segment experiencing the highest growth. This growth is driven by advances in data storage capacity, edge computing, and parallel processing capabilities. Japan's focus on AI and digital transformation also extends to the healthcare sector, where AI-based technologies and digital transformation are being developed to support the elderly, such as robotics for caregiving and AI systems and digital transformation for medical diagnostics. By addressing demographic challenges through AI and digital transformation, Japan can overcome internal challenges. Japan can also serve as a global example of how technology can be used to address social issues. India is rapidly emerging as a key player in the AI and digital transformation space, driven by a combination of increased corporate technology spending and a vast and growing talent pool. This statement highlights the rapid growth of the Indian AI market, projected to reach $17 billion by 2027, with an impressive annual growth rate of 25-35% between 2024 and 2027. Driving this expansion is India's large internet user population, estimated at 881 million. This large user base creates a strong demand for personalized experiences, which in turn drives the growth of AI technology in the country. AI and digital transformation in India operate through task automation, enabling businesses to streamline activities such as campaign setup and customer inquiry responses.

Furthermore, AI and digital transformation facilitate content personalization, tailoring marketing materials to individual preferences, and enhancing the customer experience. These technologies also play a crucial role in optimizing websites for better performance and predicting customer behavior. This enables businesses to design targeted campaigns with higher effectiveness. Germany is renowned for its AI and digital transformation innovations, attracting significant attention and investment from global tech giants. Companies like Microsoft have committed substantial resources to Germany's AI infrastructure and digital transformation, with a planned investment of $3.2 billion. This investment underscores Germany's role as a major hub for AI and digital transformation development in Europe. Furthermore, Germany's vibrant AI and digital transformation ecosystem has attracted the attention of major companies like Apple, which recently acquired German AI startup Bitbot. This interest from global players highlights the attractiveness of Germany's AI capabilities. Germany's commitment to AI and digital transformation extends beyond corporate investments. The country is focused on developing AI and digital transformation research, particularly in the study of brain data, with the European Union allocating its largest single source of funding to this field. Furthermore, Germany has ambitious plans to double its funding for AI and digital transformation. The integration of entrepreneurs from the United States, China, Japan, India, and Germany for AI and Digital Transformation is in line with research, which is supported by other studies such as [32], [46-55], [59].

IV 2. ENTREPRENEURS ARE INVOLVED IN MARKETS AND SOCIETY WITIHIN COMPANIES

United States: As a global leader in the digital economy, it has achieved significant strategic success. Through decades of continuous development, the United States has accumulated rich experience and established systemic advantages in essential technology research and development, digital technology innovation, industrial ecosystem development, market mechanism optimization, and other aspects, strengthening its dominant position in the global digital economy as a driving force and competitive advantage for the development of the United States digital economy. There is an urgent need to develop a more integrative and dynamic analytical framework to uncover the internal logic and evolutionary patterns of the US digital economy's development, and to periodically evaluate how policy direction, institutional coordination, and talent development interact to maintain leadership in the digital economy. In particular, how the United States government balances strategic industrial competitiveness and digital security, effectively coordinates various stakeholders, and programs digital talent development has not been comprehensively addressed in the existing international literature.

China: The essence of China's modernization is the modernization of the people, a modernization that promotes the well-being of all people, and a modernization that produces a population unprecedented in the world. China's modernization, especially its educational modernization, has contributed significantly to its transformation from a "poor" country to a "prosperous and powerful" country. China is the country with the largest labor resources in the world, consistently ranking first in the world. Education is the foundation of long-term national development. Developing education at all levels and utilizing human resources has always been one of the long-term tasks of China's economic development. China's modernization is a modernization for all, which essentially means that through educational modernization, continuous investment in human resources will be made for all, which in turn will increase the level of education (years of schooling per capita) and development capacity (labor productivity) for all, create various types of assets (economic, social, cultural, ecological, etc.), and build a human resource foundation for realizing China's modernization. Focusing on Chinese-style modernization and the Great Leap Forward in human resource development, we explore how China, since its founding, has transformed from the world's most literate nation to one with the world's most human capital.

Japan is aggressively developing artificial intelligence and digital transformation. This strategy aims to establish Japan as a leader in AI innovation and digital transformation. This effort directly addresses ethical issues. This strategy will boost Japan's technology industry and businesses by promoting AI research and digital transformation. Japan launched a historic national strategy for AI and digital transformation. The Japanese government emphasized the importance of AI in maintaining national security and driving economic growth. The goal is to build a society where AI benefits society. This plan encourages innovation and minimizes risks, demonstrating Japan's strong commitment to leading AI in various fields. Impact on the Japanese Technology Industry. Entrepreneurship in the Japanese technology industry is expected to grow. Investing more in AI research and digital transformation will drive growth and spark innovation. This space will encourage teamwork among startups, technology companies, and schools. This will create a culture of shared growth. Focusing on ethical AI aligns progress with social values. This helps build public trust. Implications for Businesses in Various Sectors. Japan's AI and digital transformation strategy will impact more than just technology companies. Industries such as manufacturing, healthcare, finance, and education will benefit from the use of AI and digital transformation. AI automation and digital transformation are improving manufacturing efficiency. Predictive analytics are enhancing financial services.

Personalized learning is transforming education. Companies that effectively leverage AI and digital transformation will have an advantage. Those that don't will likely struggle to stay relevant.

India is on the verge of a new era powered by Artificial Intelligence (AI) and digital transformation, where technology is transforming lives and shaping the nation's progress. AI is no longer confined to research laboratories or large corporations. It reaches citizens at every level. From improving access to healthcare in remote areas to helping farmers make informed crop decisions, AI is making everyday life simpler, smarter, and more connected. AI is revolutionizing classrooms through personalized learning, making cities cleaner and safer, and improving public services through faster, data-driven governance. Initiatives such as the India AI and Digital Transformation Mission and the AI Centers of Excellence are at the heart of this transformation. Expanding access to computing power, supporting research, and helping startups and institutions create solutions that directly benefit society. India's approach focuses on making AI and digital transformation open, affordable, and accessible, ensuring that innovation uplifts society as a whole. This inclusive vision is also reflected in the NITI Aayog report, AI and Digital Transformation for the Development of an Inclusive Society (October 2025). The report demonstrates how AI and digital transformation can empower India's 490 million informal workers by expanding access to healthcare, education, skills, and financial inclusion. It highlights how AI-based tools can increase productivity and resilience for the millions of people who form the backbone of the Indian economy. It also emphasizes that technology can bridge deep social and economic divides, ensuring that the benefits of AI and digital transformation reach every citizen.

Germany has launched an ambitious plan to revitalize its ailing economy, leveraging artificial intelligence (AI) and digital solutions to drive mainstream growth across key sectors. Germany's digitalization push. Germany's race towards AI adoption. Trust in generative AI is growing. GenAI system issues. Highlights 23 major projects aimed at growing the economy. Under the "modernization agenda," it reveals that the projects will achieve their goals by cutting bureaucracy while improving the efficiency of public services. Topping the list is a platform that allows companies to be registered within 24 hours, which German authorities say is a significant step in attracting international players. Read more. AI is a key feature of Germany's modernization agenda, with the government eager to introduce AI-based tools for visa processing and courts. The government has announced plans to establish an AI-based digital agency to promote trade and foster development cooperation, while also supporting the integration of new technologies across key sectors of the economy. Based on next-generation solutions, the Merz modernization agenda includes a direct payment mechanism for federal aid to citizens, bypassing traditional intermediaries in the value chain. In terms of infrastructure, the plan will support the development of nuclear fusion reactors by prioritizing hydrogen as an energy source. Germany, still Europe's largest economy, has faced significant challenges in recent years, exacerbated by high energy costs and labor shortages.

The integration of entrepreneurs from the United States, China, Japan, India, and Germany for markets and society is in line with research, which is supported by other studies such as [60-68], [70].

V. CONCLUSIONS

Research on Artificial Intelligence (AI) and digital transformation has rapidly transformed various aspects of our lives, from industry and the economy to societies worldwide. Many countries have participated in this technological revolution. However, only a few stand out as pioneers. This discussion focuses on the top five countries leading the AI revolution and digital transformation [75].

United States: As a global leader in the digital economy, the United States has achieved significant strategic success. Through decades of continuous development, the United States has accumulated rich experience and established systemic advantages in research and development of essential technologies, digital technology innovation, industrial ecosystem development, optimization of market mechanisms, and other aspects, strengthening its dominant position in the global digital economy. Some studies examine the development of the US digital industry from the perspective of technological innovation [76], [77], while others focus on aspects such as the platform economy and higher education to analyze the drivers and competitive advantages of the US digital economy's development [78], [79].

The essence of China's modernization is the modernization of the people, a modernization that champions all its people, and a modernization that has produced a population unprecedented in the world. China's modernization, particularly its modernization of education, has significantly contributed to its transformation from a "poor" country to a "prosperous and powerful" one. Focusing on modernization with Chinese characteristics and the Great Leap Forward in human resource development, we explore how China, since its founding, has transformed itself from the world's largest illiterate country to the world's largest in terms of human resources, and why modernization with Chinese characteristics is a modernization of education for all its people, how China will modernize its education and develop into a world-leading country in human resources by 2035, so as to facilitate the contribution of human resources to fundamentally realize socialist modernization [82].

Japan is aggressively developing artificial intelligence and digital transformation. The government is leading discussions on a comprehensive AI and digital transformation strategy. This strategy aims to establish Japan as a leader in AI innovation and digital transformation. This effort directly addresses ethical issues. This strategy will boost Japan's technology industry and businesses by encouraging AI and digital transformation research. Impact on the Japanese Tech Industry. Japan's tech industry is set to grow. The government is taking decisive action. Investing more in AI and digital transformation research will drive growth and spark innovation. This space will foster teamwork among startups, tech companies, and schools. This will create a culture of shared growth. Focusing on ethical AI aligns progress with social values. This helps build public trust. Implications for Businesses in Various Sectors. Japan's AI and digital transformation strategy will impact more than just tech companies. Industries such as manufacturing, healthcare, finance, and education will benefit from the use of AI and digital transformation [83].

As India builds an inclusive AI and digital transformation ecosystem, its growing global recognition reflects this progress. Rankings like the Stanford AI Index place India among the top four countries in AI skills, capabilities, and policies. The country is also the second-largest contributor to AI projects on GitHub, highlighting the strength of its developer community.

With a strong STEM workforce, a thriving research ecosystem, and a growing digital infrastructure, India is positioned to leverage AI for economic growth, societal progress, and the long-term vision of Viksit Bharat by 2047. The NITI Aayog report, AI and Digital Transformation for Inclusive Societal Development (October 2025), lays out a roadmap for using technology to empower India's informal workforce [85].

Germany has unveiled ambitious plans to revitalize its ailing economy, leveraging artificial intelligence (AI) and a range of digital solutions to drive mainstream growth across key sectors. Germany's digitalization push. Germany's race to AI adoption. Trust in generative AI rises. GenAI systems' issues. According to a report, German Chancellor Friedrich Merz unveiled the plans during a press conference at the Borsig Palace in Berlin, highlighting 23 major projects aimed at growing the economy. Under the "modernization agenda," Merz disclosed that the projects will achieve their aim by cutting bureaucracy while making public services more efficient. At the top of the list is a platform that enables companies to be registered within 24 hours, which German authorities say is a significant step in attracting international players. Furthermore, Merz's plan will involve the introduction of a centralized online vehicle registration service and a plan to accelerate the recognition of foreign medical qualifications [86].

VI. LIMITATIONS AND FUTURE RESEARCH

This study has limitations and opens up opportunities for future research. First, it focused on AI and digital transformation impacting markets and societies in five countries. Future research should consider including other countries. Second, we encourage future research to explore broader areas, support researchers in uncovering additional insights, and demonstrate the applicability and effectiveness of more diverse methods. Third, while this qualitative approach is promising, further empirical research and methodological experimentation would be beneficial in identifying optimal applications across research contexts. A general limitation of this study is its exclusive use of qualitative methods, and it is worth considering the use of other methods for more thorough textual reading and comprehension, as well as to address its challenges in capturing the full context of word relationships and minimizing its inability to interpret linguistic ambiguities independently. Future research could use these methods, for example, to investigate other experiences and phenomena, such as how product and sales integration influences consumer decision-making processes, or to investigate how consumers narrate their physical consumption practices in relation to specific discourses or lifestyles, such as sustainabiliy. n general, we hope that others will join this effort in the future by identifying and elaborating further.

ABSTRACT

Satellite image categorization is a crucial component of applications such as land-use analysis, agricultural monitoring, environmental evaluation, and disaster response. This article presents a deep learning strategy utilizing Convolutional Neural Networks (CNNs) for the efficient categorization of satellite data. The suggested system incorporates effective data augmentation methods, contemporary CNN architectures, and refined training methodologies to improve accuracy and generalization capabilities. An experimental assessment on a benchmark dataset of satellite images demonstrates that our model exhibits robust performance, with a validation accuracy of 98.93% and elevated precision, recall, and F1 scores. The created model exhibits significant improvements in accuracy and computing efficiency relative to traditional classification methods. The results indicate that this methodology is exceptionally well-suited for satellite image classification and can be further enhanced through techniques such as transfer learning, hybrid deep learning architectures, and multimodal feature integration to address more complex real-world scenarios.

I. INTRODUCTION

In recent years, satellite imagery has emerged as an essential resource for several purposes, including land use mapping, environmental evaluation, and disaster management. Notwithstanding its significance, satellite image categorization presents difficulties due to subtle distinctions between specific classes and considerable variability within the same groups. These issues underscore the necessity for exceptionally resilient categorization frameworks. Convolutional Neural Networks (CNNs) have been prominent in this field because of their robust skills in feature extraction and pattern identification [1], [2]. CNN-based methods have demonstrated significant capability in capturing the intricate spatial features inherent in remote sensing pictures [3]. Nonetheless, their effectiveness is frequently hindered by the scarcity of extensive, annotated datasets. Due to the substantial time and resources required to generate annotated satellite image datasets, data augmentation has emerged as a prevalent method to efficiently expand training data and improve the generalization of deep learning models [4], [5]. Recent research has investigated several augmentation techniques—including horizontal and vertical flipping, rotation, zooming, and modifications to brightness or contrast—to enhance model robustness under diverse imaging situations [6]. These modifications mitigate overfitting and boost performance on novel samples [7]. Simultaneously, enhancements in CNN architecture—utilizing techniques such as batch normalization, dropout, and deeper hierarchical structures—have augmented their capacity to handle the intricacies of satellite images [8]. Comparative studies consistently indicate that convolutional neural networks, enhanced by meticulously designed augmentation pipelines, outperform conventional machine learning algorithms in the accuracy of satellite image categorization [9], [10]. Nonetheless, there is an increasing demand for CNN models that are both precise and lightweight, demonstrating efficiency across various satellite picture formats and class distributions. This study presents a CNN-based classification model that incorporates an advanced augmentation method to increase performance while maintaining computing economy. The model is evaluated using conventional metrics and compared to existing methods, showing enhanced accuracy, stability, and resilience.

II. LITERATURE REVIEW

Satellite image categorization is becoming increasingly important for activities such as land cover analysis, urban development planning, and environmental monitoring. With the rapid advancement of deep learning, particularly Convolutional Neural Networks (CNNs), various models have beencreated to improve classification accuracy. By [11] suggested a CNN-based approach for multispectral satellite imaging and obtained a 91.2% accuracy rate. However, the model demonstrated low resistance to changes induced by seasonal or atmospheric factors. In turn [12] used a VGG16-driven strategy and obtained 92.5% accuracy, despite the model's high computing demand and tendency toward overfitting. According to [13] investigated the application of ResNet-50 for high-resolution satellite image categorization and achieved 94.3% accuracy. Despite this, the model struggled to identify minority classes because of class imbalance. To improve training stability, [14] used a CNN ensemble with transfer learning and obtained 93.8% accuracy; however, the method greatly increased training complexity and resource utilization. By [15] used EfficientNet for feature extraction and achieved 95.1% accuracy. Although the model was computationally efficient, its performance deteriorated when tested against noisy samples. By [16] created a hybrid CNN-SVM pipeline that achieved 92.7% accuracy, although the system got more difficult as it relied on more handcrafted characteristics. To address data scarcity, [17] combined GAN-generated pictures with a DenseNet classifier, resulting in 94.0% accuracy.

However, artifacts created by GANs occasionally limit the model's generalizability. In turn [18] used MixUp augmentation and saw increased robustness, although the technique failed with rare-class prediction. A MobileNetV2-based solution published in [19] had a lower computing cost and achieved 90.6% accuracy, but its performance worsened in congested urban situations. By [20] used multi-scale CNN features and achieved 93.3% accuracy, although their model was still sensitive to scale fluctuations. By [21] reported attention-enhanced CNNs with 94.8% accuracy and increased feature prioritizing. However, the addition of attention modules raised inference delay. Another research [22] combined augmentation techniques such as random flips, zooming, and rotations with a lightweight CNN and reached 95.4% accuracy; however, the approach required substantial parameter adjustment to stay successful. In contrast to previous methods, the model suggested in this study uses a structured CNN architecture backed by a variety of augmentation techniques, including flipping, zooming, rotating, and contrast modifications. It obtains a validation accuracy of 98.93%, indicating better performance in terms of generalization, resistance to class fluctuation, and efficiency, even with minimal data. Table 1 summarizes all of the mentioned results.

Table 1: Comparative Analysis of Existing Satellite Image Classification Models.

Reference	Year	Model Used	Accuracy (%)	Limitation
[11]	2019	CNN	91.2	Sensitive to weather and seasonal variations
[12]	2019	VGG16	92.5	Computationally expensive, prone to overfitting
[13]	2020	ResNet-50	94.3	Poor performance on minority classes
[14]	2020	CNN Together	93.8	High resource usage
[15]	2021	EfficientNet	95.1	Performance degrades on noisy datasets
[16]	2021	CNN + SVM Hybrid	92.7	Complex design, depends on handcrafted features
[17]	2022	DenseNet + GAN Augmentation	94.0	Generated data may introduce artifacts
[18]	2022	CNN+MixUp Augmentation	93.5	Less effective for rare class detection
[19]	2023	MobileNetV2	90.6	Lower accuracy on urban landscapes
[20]	2023	Multi-Scale CNN	93.3	Sensitive to image resolution variation
[21]	2024	Attention-Enhanced CNN	94.8	Increased inference time due to attention modules
[22]	2025	Lightweight CNN + Augment	95.4	Needs manual tuning of augmentation parameters

III. MATERIALS AND METHODS

The suggested CNN-based classification model was created and tested in this work using a dedicated collection of satellite images [23]. Included in the dataset are high-resolution remote sensing photos gathered from a variety of locations and climates. There are 2,400 photos scattered among 10 different terrain cover types: urban, forested, glacial, mountainous, coastal, street, green, barren, river, and agricultural. To avoid model bias toward majority classes, each class must have an equal number of photos. You can see all the classes in Figure 1.

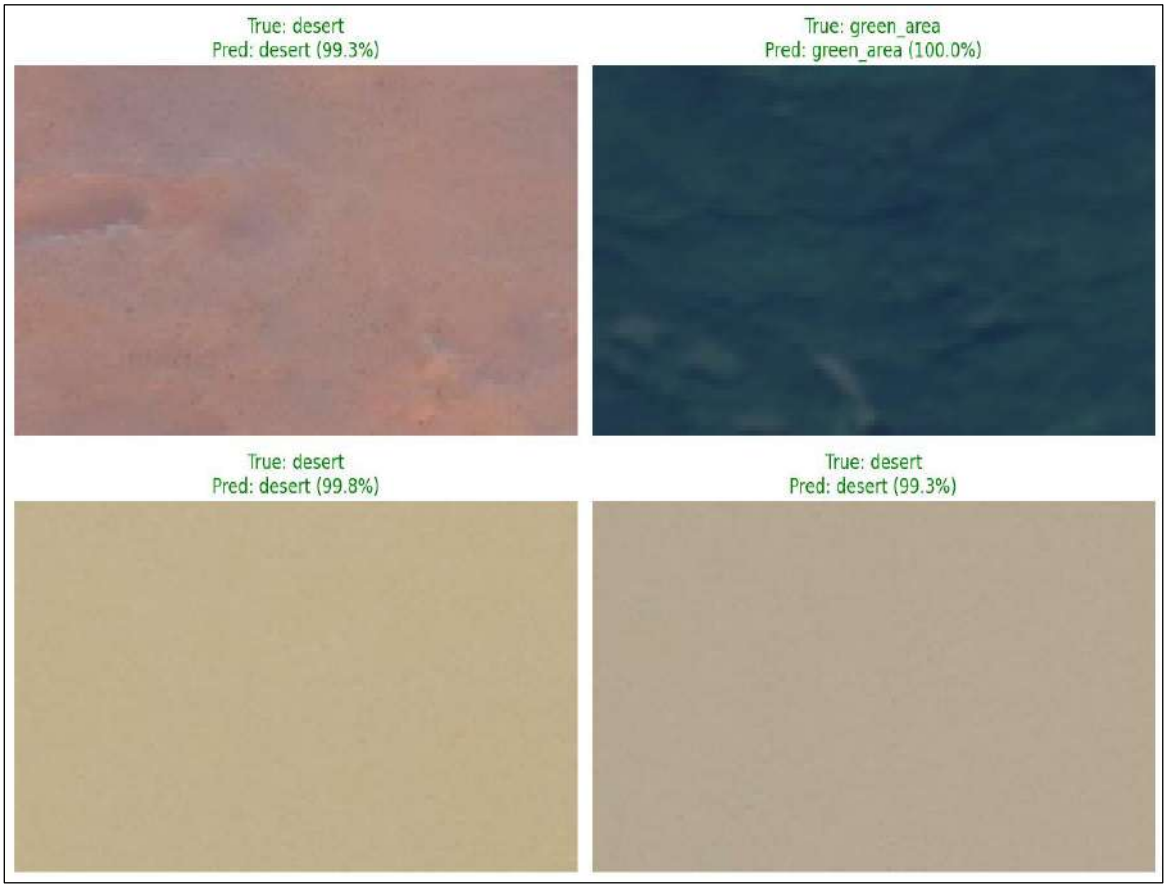

Figure 1: Classes of satellite image dataset.
Source: Authors, (2026).

Loading and Splitting the Dataset

The image dataset from the directory function in TensorFlow is used to load the dataset from the supplied directory. There is an 80/20 split in the dataset between the training and validation subsets. As a result, the model's performance during training is monitored with 20% of the photos used for validation, while 80% are utilized for training.

Data Augmentation for Better Model Performance

By augmenting the training dataset with additional data, we may make the model more generalizable and less prone to overfitting [24]. One way to make the training set bigger is by data augmentation, which involves making altered replicas of the original pictures by randomly changing their parameters. By undergoing these changes, the model is able to learn more robust features and avoid data memorization errors. The following methods of enhancement are used in this research:

- You can use the Random Horizontal Flip function to invert pictures randomly, creating the illusion of varied.
- Image Rotation: Incorporates rotation invariance by rotating pictures at a random angle (up to 10%).
- Zoom at Random: This feature allows you to mimic different sizes and viewpoints by randomly zooming into photographs by up to 10%.
- The Random Contrast feature allows users to replicate various lighting situations and exposure settings by randomly adjusting the picture contrast.

To apply these enhancements, a pipeline for image modification is constructed using TensorFlow's Sequential API. The model is enhanced with this pipeline so that these enhancements may be applied dynamically while training. To further illustrate the effect of these changes, a selection of enhanced photographs is also shown. The training dataset is randomly transformed and shown in a 3x3 grid with appropriate labels for each enhanced image.
The data augmentation process may be visually examined, and the accurate application of modifications can be confirmed using this method. The image dataset from the directory function in TensorFlow is used to load the dataset from the supplied directory. There is an 80/20 split in the dataset between the training and validation subsets. As a result, the model's performance during training is monitored with 20% of the photos used for validation, while 80% are utilized for training. Important parts of this procedure comprise the following:

- Data Loading: Using the location you provided, the function will automatically label photographs according to their folder names after reading them directly from the directory.
- Validation Split: By specifying validation_split=0.2, 20% of the data will be reserved for validation purposes.

- "Training" for training data and "validation" for validation data are the arguments used to choose the subset for training and validation, respectively.
- Image and Batch Size: To make sure that the input data is uniform, the photos are adjusted to have consistent dimensions. Processing data in batches is enabled by setting the batch size to the given batch_size value.

Here are the final datasets:

- To train the model, this collection is utilized, which includes photos that have been scaled to the required dimensions and batch-processed for optimal performance.
- The validation set (val) is utilized for checking the model's performance while training and for modifying hyperparameters according to how well it performs on unknown data.

This method guarantees accurate assessment of the model's generalizability and efficient data management.

Model Preparation and Performance Optimization

Dataset Classification Information and Mapping

The classification procedure starts by ascertaining the total number of categories in the dataset. These often encompass diverse land cover categories, including forests, agricultural areas, and aquatic environments. Each category is designated a specific label, and a dictionary is created to associate each class name with a unique number identification. This mapping guarantees uniform class representation throughout model training and prediction, facilitating accurate interpretation of output labels.

Enhancing Performance with Caching and Prefetching

To improve the performance of the training pipeline, the dataset is optimized using caching and prefetching technologies. Caching stores the dataset in memory, thus obviating the necessity to frequently access data from disk during each training iteration. Prefetching enhances performance by loading upcoming batches in the background during the processing of the current batch. Collectively, these methodologies reduce data-loading latency and provide a consistent stream of samples to the model, leading to expedited and more effective training.

Data Augmentation for Enhanced Generalization

To mitigate overfitting and enhance the model's generalization capacity, several augmentation approaches are employed on the training pictures. This encompasses arbitrary horizontal flips, rotations, zoom adjustments, and contrast alterations. Augmentation enhances dataset variety by adding controlled fluctuations in training samples; hence, it aids the model in learning characteristics that are constant across varying imaging settings. The enhanced pictures are utilized just during training to familiarize the model with a wider array of visual patterns found in actual satellite photography.

Building the Convolutional Neural Network (CNN)

To classify satellite images, a bespoke CNN architecture [25] is created. Different convolutional blocks make up the model; their job is to extract deeper and more significant features from the input pictures in a linear fashion. For better stability and generalization, each block uses convolutional layers, batch normalization, pooling layers, and dropout:

Essential visual patterns seen in satellite photography, such as edges, textures, and structural structures, are learned using convolutional layers.

By standardizing activations and accelerating convergence, batch normalization guarantees more stable training.

To reduce computational complexity, MaxPooling layers downsample the spatial dimensions. This allows the network to preserve the most relevant characteristics.

By inadvertently turning off a portion of neurons while training, dropout layers mitigate overfitting.

The model moves into fully linked layers for the last classification after the feature extraction blocks. The number of target classes is used by the final output layer, which generates probability scores for each class using a softmax activation function.

Model Compilation

The Adam optimizer is used to assemble the model, and the learning rate is set at 0.001. Because it works well with integer-provided labels in multi-class classification tasks, sparse categorical cross-entropy is used as the loss function. Throughout training, accuracy is chosen as the main assessment metric to quantify the model's performance in classification. The training process is improved with the use of many callbacks:

- The validity loss is tracked using EarlyStopping. Training is stopped, and the weights that correspond to the best validation performance are restored if the model stops improving after a certain number of epochs. This keeps training cycles from becoming superfluous and stops overfitting.
- When the validation loss fails to improve, ReduceLROnPlateau will automatically lower the learning rate. With this change, the optimizer may fine-tune the model's parameters even more and continue working toward an improved solution. Table 2 summarizes all relevant results and parameter information.

Table 2: Layered information about CNN layers.

Layer (type)	Output Shape	Param #
rescaling (Rescaling)	(None, 72, 128, 3)	0
conv2d (Conv2D)	(None, 72, 128, 32)	896
batch_normalization (BatchNormalization)	(None, 72, 128, 32)	128
conv2d_1 (Conv2D)	(None, 72, 128, 32)	9,248
batch_normalization_1 (BatchNormalization)	(None, 72, 128, 32)	128

IV. PERFORMANCE METRICS

Metrics for performance are crucial for assessing how well machine learning models predict cardiac disease using electrocardiograms. Accuracy, precision, recall, F1-score, and area under the curve (AUC-ROC) are important measures for evaluating classification ability. Precision and recall assess the ratio of true positives to false negatives, whereas accuracy assesses total correctness. If your dataset is unbalanced, you may still utilize the F1 score since it gives you a harmonic mean of recall and accuracy. The AUC-ROC curve shows how well the model can differentiate across categories. For deep learning models to be considered validated, several metrics are essential [26]. Equations (1) through (5) display all of these performance measures.

$$\text{Accuracy} = TP + TN + FP + FN \; / \; TP + TN \tag{1}$$

$$\text{Precision} = \text{TP} / \text{FP} + \text{TP} \tag{2}$$

$$\text{Recall} = \text{TP} + \text{FNTP} \tag{3}$$

$$\text{F1} = 2 \times \text{Precision} + \text{RecallPrecision} \times \text{Recall} \tag{4}$$

$$\text{Specificity} = \text{TN}/\text{FP} + \text{TN} \tag{5}$$

Accuracy and Loss Curves Analysis

You can tell if the model is training well or showing symptoms of overfitting or underfitting by looking at its accuracy and loss curves, which give crucial information about its learning behavior. To better understand the model's training-induced improvement, it is helpful to visualize these measures across epochs.

Precision Slope

The accuracy graphs show the model's performance in correctly predicting the classes for the training and validation datasets.

Training Accuracy: The model's fit to the training data is shown by this curve. It is anticipated that the training accuracy would gradually rise as epochs go by, indicating that the model is effectively learning from the examples given.

Accuracy in Validation: This curve shows how well the model can apply to previously unknown samples. In a perfect world, validation accuracy would likewise increase throughout training. Overfitting occurs when a model learns just the specifics of its training data rather than recognizing broader patterns in the data. This happens when validation accuracy stays the same or starts to go down while training accuracy keeps going up.

Loss Diagram

The degree to which the model's forecasts differ from the actual labels may be shown on loss curves. A better indicator of predictive success is a lower loss.

The training loss should steadily go down as the model learns, showing that it is getting better at using the training data.

Prediction error on unknown data is measured by this validation loss curve. A gradual decline is preferable. A classic sign of overfitting, which implies the model isn't generalizing adequately, is when validation loss grows but training loss keeps going down. Figure 2 displays these representations of accuracy and loss.

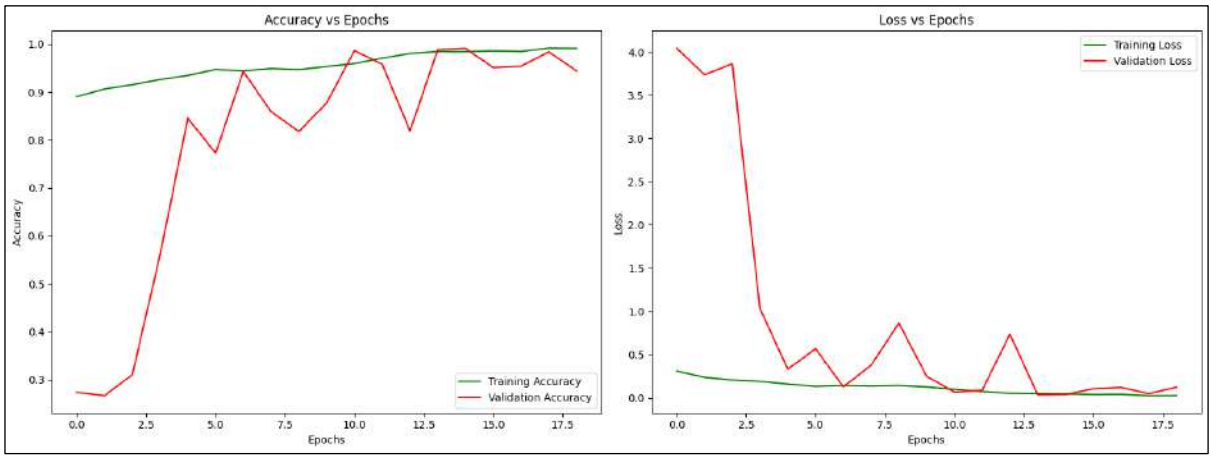

Figure 2: Accuracy curve and Loss curve of the proposed model.
Source: Authors, (2026).

Model Evaluation on Validation Set

Evaluating the model's performance on the validation set after training is crucial for understanding how well it generalizes to unknown data. Here is a rundown of the procedure:

Assessment Outcomes

- The evaluate() method is used to assess the model on the validation set. Applying the model to the validation data, this function determines the loss and accuracy. Two metrics make up the output:
- The validation accuracy measures the model's success rate in making accurate predictions on the validation set. In this instance, the model achieved an accuracy rate of 98.93%.
- The validation loss refers to the difference or error between the actual and predicted values on the validation set. The comparatively low loss of 0.0247 supports the model's ability to generalize to new data.

Model Evaluation and Prediction Functions

A function called evaluate_model_simple is utilized to assess the model's efficacy on the validation dataset. This method calculates the F1 score, recall, accuracy, and precision, which are some of the most used classification measures. To gather predictions and ground-truth labels (y_true) and model-predicted labels (y_pred), the function iteratively processes each batch in the validation dataset. Images are fed into the model to create predictions, and the class with the highest output probability is selected. Calculation of Performance Metrics: To evaluate the overall performance of the model, many evaluation metrics are computed:

- Measuring the proportion of samples that were accurately predicted relative to the total is called accuracy.
- The precision of a prediction is the percentage of positive samples that turn out to be true.
- A high recall indicates that the model correctly identified a large proportion of the positive samples.

By finding the harmonic mean of recall and accuracy, the F1 score offers a balanced statistic. A confusion matrix is created to analyze the model's performance in classifying all classes. In the heatmap representation, values on the diagonal represent accurate predictions, while values off the diagonal represent cases that were incorrectly categorized. A bar chart is also made to show the accuracy for each class separately. You can see which classes the model gets right and which ones may need some work using this graphic**.**

Evaluation Results

The following summary shows the model's performance on the validation dataset:

----- MODEL PERFORMANCE -----

Accuracy: 98.93

Precision: 98.56

Recall: 98.85

F1 Score: 98.70

This combination of model evaluation and individual prediction functions provides a comprehensive view of the model's performance, both at a global level (overall accuracy, precision, recall, F1) and at an individual level (prediction confidence). It is shown in Figure 3.

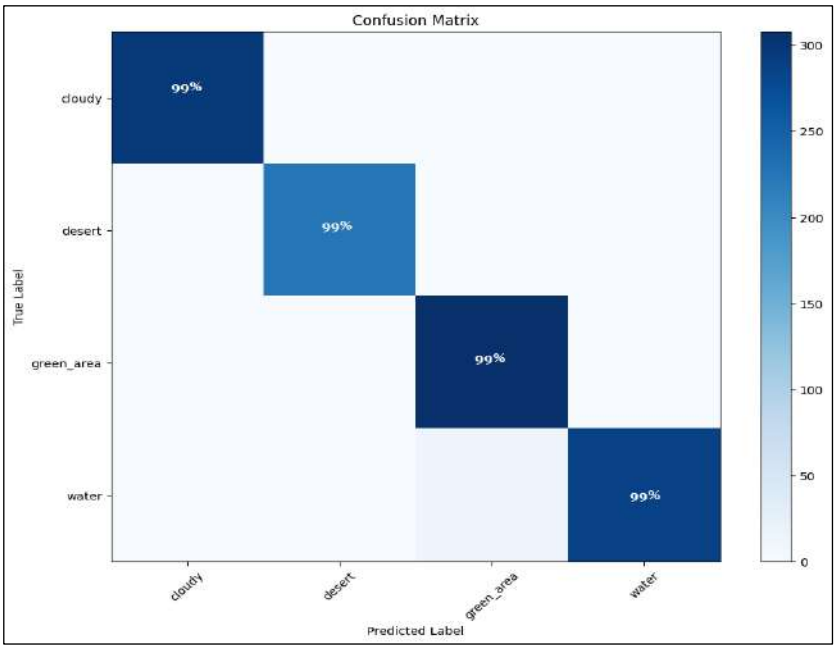

Figure 3: Confusion matrix of the proposed model.

Comparison of Proposed Model and Existing Satellite Image Classifiers

Much research has used various deep learning algorithms to classify satellite images, with the goal of improving accuracy and computing performance. Although the authors stressed that model accuracy varied with dataset complexity, Zare et al. (2017) found encouraging results when using CNN and RNN models for satellite image interpretation. Utilizing densely connected networks on huge and diverse datasets, Li et al. (2020) obtained 92% accuracy for land-use categorization utilizing deeper CNN architectures like DenseNet. Also, while dealing with datasets that are geographically diverse, deeper architectures have continually shown better performance, according to Li et al. (2018), who examined several CNN-based approaches for remote sensing. The benefit of merging alternative learning paradigms was demonstrated by Reddy et al. (2021), who presented a hybrid framework that achieved 95% accuracy by combining deep learning with classical machine learning methods. Famous convolutional neural network (CNN) models, including VGG, AlexNet, and GoogleNet, were compared by Xie et al. (2020). GoogleNet's 90% accuracy was due to its efficient design and better feature extraction capabilities. This study expands upon those earlier efforts by suggesting a hybrid design that combines convolutional neural network (CNN) layers with Vision Transformers (ViT). ViTs are ideal for the complicated task of satellite imaging because of their attention-based mechanism, which allows them to capture both fine-grained local patterns and wider contextual information. To address the ongoing issues with overfitting and improve generalization in satellite image analysis, the suggested model uses strong data augmentation techniques. By utilizing transformer-based representations, the combination of CNNs with ViT attempts to outperform the results reported by established models like DenseNet and ResNet, which generally fall within the 80% to 95% accuracy range, particularly for extremely complex datasets. Beyond just classifying photos, the model also uses beam search to generate meaningful captions, presenting a new dual-capability method. Table 3 summarizes the results of the comparison with existing approaches, while Figure 4 shows the performance of the proposed model.

Table 3: Comparative Analysis of Existing and Proposed Models.

Study / Model	Model/Technique	Dataset Focus	Accuracy (%)
Zare et al. (2017)	CNNs and RNNs	Complex datasets	93%
Li et al. (2020)	DenseNet (deep CNN)	Land-use classification	92%
Li et al. (2018)	Various CNN architectures (review)	Remote sensing datasets	96%
Reddy et al. (2021)	Hybrid of deep learning and ML	Satellite image classification	95%
Xie et al. (2020)	VGG, AlexNet, GoogleNet (CNNs)	Various satellite images	90%
Proposed Model (2025)	ViT + CNN Hybrid + Data Augmentation	Highly complex satellite datasets	99%

V. CONCLUSION AND FUTURE WORK

We presented a model for classifying satellite images that relies on deep learning and makes use of convolutional neural networks (CNNs) to efficiently extract features and classify the images. Data augmentation methods, sophisticated CNN topologies, and optimization tactics all contributed to the model's strong performance on the validation dataset. Results from the suggested model were encouraging, but they may be much better in the future. To further improve accuracy, future work might concentrate on integrating transfer learning with pretrained models such as EfficientNet or ResNet. To further improve the acquisition of spatial and contextual information, it may be worth exploring hybrid techniques that combine CNNs with Vision Transformers (ViTs) or attention processes. One promising area of research is the use of optical and radar data fusion techniques to enhance performance in different environments, and another is the real-time categorization of satellite images for use in environmental monitoring, agriculture, and disaster management.

ABSTRACT

Parkinson's Disease is a progressive neurological disorder. It poses major challenges for early diagnosis because its initial symptoms are subtle and depend on subjective clinical evaluations. However, an early diagnosis becomes even more challenging because traditional methods have relied so much on costly medical tests and subjective clinical assessments that often fail to detect PD at its earliest stages when symptoms are minimal. In this respect, this study develops a deep learning-based framework for the automatic detection of Parkinson's Disease using keystroke dynam- ics collected from typing interactions. Keystroke timing features such as hold time and latency are excellent digital biomarkers for early PD iden- tification since they carry fine-grained motor-control information. The paper proposes a deep learning system using Convolutional Neural Networks (CNNs) model that identifies users as PD or Non-PD based on real- world typing behaviours. The effectiveness of the suggested Pure 1D CNN model in identifying discriminative temporal patterns from keystroke data for Parkinson's disease detection is demonstrated by its 95.21% accuracy and 99% ACC value. Besides the deep learning model, machine learning algorithms were also implemented in order to compare the performance and confirm the robustness of the proposed system. This system aims to improve diagnostic accuracy by reducing dependency on expensive clinical procedures and enabling continuous remote monitoring.

I. INTRODUCTION

Parkinson's Disease (PD) is a chronic, progressive neurological disorder which disturbs muscle control, movement and balance. In simple terms, PD is a brain disorder. The disease was first described in 1817 by British physician James Parkinson in his Essay on the Shaking Palsy [1]. More than 10 million [1] people worldwide are living with PD Early identification is important for effective treatment and a better quality of life. Conventional identification relies on clinical observation, which can be time consuming and subjective. Recent work has shown that keystroke dynamics, combined with machine or deep learning mod- els, can provide a non-invasive, inexpensive, and real-time method of detecting early signs of PD. This study focuses on investigating keyboard dynamics for typing patterns from users with and without PD using advanced deep learning techniques to improve accuracy and generalizability compared with and without the use of deep learning techniques.

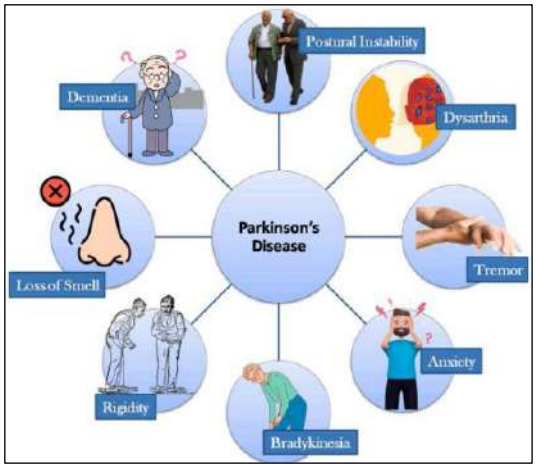

Figure 1: Parkinson's disease (PD) manifests itself in significant ways, both motor and non-motor.
Source: [1].

Parkinson's Disease happens mainly because of the gradual loss of dopamine- producing neurons in the substantia nigra, a part of the midbrain that help control movement. Normally, the amino acid tyrosine gets converted into L- DOPA, [2] which then turn into dopamine. This Dopamine is stored in synaptic vesicles of nerve cells and later released into the striatum to help manage smooth, coordinated muscle movements. In PD, these dopamine producing neurons slowly break down, leading to lower dopamine levels. As a result, communication between the substantia nigra and the striatum is affected, causing symptoms like tremors, stiffness, slow movements, and balance issues.

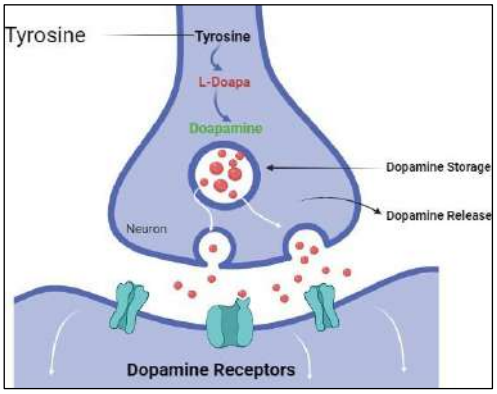

Figure 2: Process of Doapamine.
Source: Authors, (2026).

Effective and accurate detection of PD is key to improving potentially beneficial outcomes for the patient because early treatment can delay disease progression, improve quality of life, and improve symptom management. The typical approach to diagnosis still primarily relies on clinical evaluations and somewhat subjective measures, resulting in delays and uncertainty in diagnosis. Recent advances in technology have provided a novel opportunity for non- invasively and data-driven detection of PD. These techniques include voice signal analysis, handwriting assessments, computer vision, and typing pattern and keystroke dynamics, all of which have shown evidence of identifying prodromal signs of PD. These approaches have incorporated machine-learning or deep-learning models to extract patterns and features related to the physical and cognitive impairments associated with PD. Keystroke dynamics and typing pattern analysis have received particular attention for their relatively low cost, accessibility, and ability to monitor patients in the real world without specialized equipment. Similarly, voice signal analysis provides the ability to assess cues in vocal and speech production, while handwriting and touch-screen-based assessment can provide information on fine motor skills. The structure of this paper is as follows: In Section 2, there is a thorough survey of the related literature, presenting research and methods that are relevant to this particular task. Section 3 discusses and explains the experimental results and analysis of their performance. Section 4 presents the conclusion and future research that could further improve this particular proposed work. Section 5 concludes this research with a comprehensive list of related references cited throughout this particular research paper.

II. RELATED WORK

Recent investigations into the identification of Parkinson's disease have employed diverse data modalities to assess the motor and cognitive deficits characteristic of the condition. Existing research, depending on the data type employed, can be generally divided into three primary categories: datasets derived from typing patterns, detection methods utilizing voice signals, and handwriting-based detection techniques. This section will examine representative studies from each of these categories, emphasizing their respective contributions and inherent limitations.

II.1 TYPING PATTERNS

Keystroke dynamics, a non-invasive and economically viable approach, has garnered considerable interest. These techniques examine temporal characteristics, including key hold time, flight time, and latency, to detect atypical motor activity. Numerous investigations have leveraged publicly accessible datasets, such as the Tappy Keystroke Dataset, which captures typing behaviour during routine smartphone use. Machine learning and deep learning models, encompassing support vector machines, random forests, and convolutional neural networks, have been utilized to extract distinguishing temporal patterns from keystroke sequences. Despite the continuous monitoring and high user convenience offered by keystroke-based methods, challenges persist in managing noisy data, inter-user variability, and the constraints of limited dataset sizes. Iakovakis et al. (2018) sought to identify declines in fine motor skills in early Parkinson's disease (PD) by looking at natural typing patterns on touchscreen smartphones [3]. This effort was based on the need to observer subtle differences in motor function in an unobtrusive and frequent way, before other clinical motor symptoms are recognizable. They established a pipeline that analysed typing features based on keystroke timing values (hold time, flight time) and normalized pressure from short typing periods. Their classification method consisted of a two-stage multi-model fusion process: first separate models (for each keystroke variable) produced probability estimates, before fusing using a logistic regression meta-classifier to produce a final subject classification (PD vs control). They tested their method on a dataset from 33 subjects (18 early PD patients, 15 healthy controls), in which each subject typed on a smartphone for several short typing sessions. Their method resulted in AUC = 0.92, with a sensitivity ¡0.82 and a specificity ¡0.81. They concluded that enriched keystroke dynamics (timing + pressure) combined through a multi-model fusion can dis- criminate between early PD patients and controls with strong performance and offer possibilities for passive screening through interaction with smartphones in everyday life.

Proposed a home-based, non-invasive screening tool for Parkinson's disease (PD) relying on keystroke dynamics [4]. They presented a set of features obtained from the time spent pressing and releasing keys on a keyboard while typing, and subsequently used these features to detect PD in an ecologically valid data acquisition context in the participant's home and no pre- defined task was required. The authors proposed a model that combines a new form of representation of keystroke dynamics signal using hold time and flight time series as an interactive function of type of key pressed and asymmetry in the hold and flight time series using a convolutional neural network. The results of their model indicated an Area Under the Receiving Operating Characteristic ranging from 0.80 to 0.83 on a dataset of subjects that interacted actively with their computer for 5 months. This approach has a positive comparison against state-of-the-art approaches previously tested with other forms of keystroke dy- namics data captured with mechanical keyboard. Potekhin et al. (2023) conducted a study [2] to evaluate the ability to detect Parkinson's Disease (PD) from keystroke dynamics using machine learning algorithms. The authors used raw keystroke data from participants and extracted 378 features that represented typing behaviours. They built new models with Support Vector Machines (SVM), k-Nearest Neighbors (kNN), and Random Forest (RF) algorithms. They also used alternative feature selection approaches such as Minimum Redundancy Maximum Relevance (mRmR), RELIEF, and sequential forward selection (SFS) to improve feature selection.

They concluded that ensemble models using the most important features from each of the feature selection methods had accuracies anywhere from 81.08% to 100% with the greatest accuracies coming from models using the same selected features. In conclusion, the authors' research provides a clear indication of the promise for using keystroke dynamics as a non-invasive and straightforward approach for the detection of early PD. In a study by Liu et al. (2023), researchers examined the feasibility of using keystroke biometrics for early detection and clinical evaluation of Parkinson's disease (PD) [5]. Researchers gathered keystroke data from natural typing tasks using two datasets from PhysioNet, focusing particularly on alternating-finger tapping (afTap) as well as standard deviations of interkey latencies (IL SD) and release latencies (RL SD). They identified statistically significant differences for those parameters for de novo Parkinson's disease patients compared to controls, with sensitivity rates of afTap ¯83%, IL SD = 88%, and RL SD = 96%. They also noted statistically significant negative correlations with typing speed and UPDRSIII (a Parkinson's disease clinical measure) in early PD patients for the number of words typed. Overall, the authors concluded that simple algorithms utilizing keystroke biometric parameters can be utilized as screening tests and reliable clinical status assessment tools. Tripathi et al. (2024), introduced a self-supervised learning based approach to identify Parkinson's disease (PD) using keystroke dynamics. [6]. This approach was motivated by the lack of labelled clinical datasets and the need for PD detection models that generalize to uncontrolled real-world environments. The authors proposed a new training objective that integrated Barlow Twins loss (to minimize redundancy of features within the same subject) and Dissimilarity loss (to decorrelate features across distinct subjects), teaching the encoder on unlabelled typing data, then fine-tuning the model on clinically validated samples.

The results indicated that the proposed approach demonstrated improved generalization compared to traditional supervised models, feature-engineering or pre-trained deep learning methods. Moreover, the authors concluded that self-supervised learning could utilize large volumes of unlabelled typing data to develop effective models for detecting PD without relying heavily on explicit labelled datasets. Roy et al. (2025) introduced a new way [7]. to do ensemble classification to identify Parkinson's disease (PD) and the associated neural stress based on keystroke dynamics from modern active devices, prompted from a desire to pro- vide serviceable early detection of PD in a non-invasive and easily accessible manner. The authors extracted features including the hold time for each key press and the latency between key presses and releases, and which they state are characteristics of motor control and cognitive processing. The authors' ensemble model is bootstrapped-based and homogeneous, allowing for improved predictability and addressing classes' imbalance. The authors utilized the NeuroQWERTY MIT-CSXPD dataset, a public set, and achieved noticeably better performance: for the full dataset AUC 0.86 (sensitivity 74.46%, specificity 82.13%), for de novo PD detection AUC 0.79, and while detecting early stage PD AUC 0.84. Overall, this ensemble classification approach shows comparable performance to other considering models, and highlights keystroke detection metrics as a potential scalable tool to assess PD in a naturalistic environment. Tat et al. (2025) introduced a novel approach to diagnosing Parkinson's dis- ease (PD) by analysing keystroke dynamics through a soft, portable intelligent keyboard that leverages magneto elasticity to detect subtle pressure variations during typing. By [8] this method aims to provide an early and accurate diagnosis of PD, which is crucial for therapeutic interventions but remains a substantial challenge.

The intelligent keyboard converts continuous keystrokes into high-fidelity electrical signals, enabling the quantitative analysis of PD motor symptoms using machine learning. The system demonstrates high sensitivity, intrinsic waterproofing, and biocompatibility, with successful demonstration in a pilot study on patients with PD. Additionally, a customized cell phone application was developed to integrate the intelligent keyboard into a wireless platform, facilitating continuous monitoring of PD. This intelligent keyboard system's compelling properties position it as a promising tool for advancing early diagnosis and facilitating personalized, predictive, preventative, and participatory approaches to PD healthcare. Bagher et al. (2025) presented an innovative data-driven solution for the detection of Parkinson's disease (PD) via keystroke dynamics, addressing shortcomings of traditional rule-based approaches in managing large datasets and complex feature extraction [9]. In their paper, they examined two diagnoses pipelines procedure 1 used traditional machine learning models paired with features de- rive with Discrete Wavelet Transform (DWT) and Dynamic Time Warping (DTW) models, while procedure 2 used an end-to-end model with a real-time model where self-attention is built into the pipeline of processing. Their results demonstrate improved performance from both data-driven procedures, with the approach using DYTW and Extreme Gradient Boosting (XGB) reporting state- of-the-art outcomes, with ROC-AUC scores of 0.86 and 0.91 on the De-novo and Early-PD subsets of the neuroQWERTY dataset, respectively, exceeding the previously reported best scores of 0.85 and 0.80 between the two studies. In their recent study, Yang et al. (2024) presented MELPD-detector, a new method for Parkinson's disease (PD) detection using free-text keystroke dynamics (free-KD). By [10] the method is based on a multi-level ensemble learning (EL) architecture with adaptive data augmentation to mitigate class imbalance in PD ethnicity datasets. The EL architecture combines three base models that were augmented in three different ways in order to enhance generalization.

The overall method achieved a max of 99.8% accuracy across both free composition and transcription tasks, indicating very high robustness and generalization in different typing contexts. MELPD-detector was applied to the neuroQWERTY dataset that incorporates free-text keystroke data that is obtained from individuals, with and without PD. Overall, this manuscript illustrates the utility of free-KD as a potential non-invasive, and scalable detection mechanism for early diagnosis of PD. Sun et al. (2024) published a thorough review examining the role of digital biomarkers in the precision diagnosis and monitoring of Parkinson's disease (PD)[11]. This publication notes the increasing importance of digital biomarkers for the detection of early symptoms of PD, assessment of treatment effects, and guiding clinical medication. The review takes into consideration the different areas of digital biomarkers, focusing on assessment of motor function, responsiveness, and sleep quality. In addition, the review notes the advancements in digital health technology which have shifted the role of digital biomarkers in the management of PD. However, the authors did not identify specific algorithms, datasets, or accuracy metrics, as the authors were limited to what they already reviewed. The study conducted by Bahar et al. (2023) focused on utilizing machine learning models to identify Parkinson's disease (PD) through keystroke dynamics in a non-invasive and accessible way [12]. Fourteen sub-datasets were created ac- cording to the patients based on their current drug usage, disease severity, and gender. In total, 378 features were extracted from the keystroke data. There were several machine learning algorithms, including Support Vector Machines (SVM), kNearest Neighbors (kNN), and Random Forest (RF) were used to classify the data into four different sub-datasets.

To assess the feature importance in distinguishing PD, several feature selection techniques were used, including Minimum Redundancy Maximum Relevance (mRmR), RELIEF, and sequential forward selection (SFS). In addition, they used feature ensemble (FE) and model ensemble (ME) strategies in order to improve classification performance. The FE models produced accuracy ranges from 91.73% - 100% and the ME models produced accuracy (81.08% - 100%) built over the fourteen datasets. Roy et al. (2023) moved forward with a new subtheory to detect Parkinson's dis- ease (PD) using keystroke dynamics while also addressing challenges associated with class imbalance in medical datasets [13]. The authors used homogeneous ensemble learning to balance training sets through the use of bootstrapping methods from the neuroQWERTY MITCSXPD dataset, which had both fixed- text typing and free-text typing data. In this study, conventional keystroke features (e.g. key hold time, inter-key latencies were extracted and used to train classifiers. The ensemble learning model achieved an area under the curve (AUC) of 0.86 with sensitivity and specificity rates of 74.46% and 82.13%, respectively. Also noteworthy, there were higher AUCs for identifying early stage PD (83.81) than for de novo patients (79.83), indicating the potential for early diagnosis capability. Overall, this method is a robust, easy-to-use, and quick diagnostic tool for eHealth applications that can detect and manage PD at home environments, allowing for early detection and consequently better management of PD. In their 2024 article, Hazar et al. examine the feasibility of an early diagnosis of Parkinson's disease (PD) from non-invasive keyboard interaction data [14]. Their work explores data from the NeuroQWERTY MIT-CSXPD data, which contains the typing data from 85 individuals while they were typing sentences.

Using machine learning techniques, more specifically the Random Forest classifier, the study's authors identified a number of features, including keypress duration, key release time and pressed key, and found these features to significantly distinguish PD from healthy participants. Their model achieved an impressive 99.86% accuracy, demonstrating that typing data obtained during computer use can be used for early diagnosis of PD. The paper by Bernardo et al. (2022) presents a new version of SqueezeNet to detect Parkinson's disease (PD) using data generated from keypresses [15]. It ad- dresses the growing body of literature demonstrating that unique non-invasive, efficient, & low-cost methods exist to conduct early-stage diagnosis for PD. A deep learning approach is applied, leveraging keypress data which is both easily collected & readily available. The authors used SqueezeNet convolutional neural network (CNN) and modified it for keypress patterns. Keypress pat- terns were transformed into spectrograms using Continuous Wavelet Transform (CWT). Using this data transformation, they have allowed the model to cap- ture parameters associated with temporal and frequency dynamics intrinsic to typing. The dataset represents experiences of those with and without PD collected with a web app. Pre-processing for this data included standardization and synthetic balancing (SMOTE) of class imbalance. The modified SqueezeNet model attained 90% accuracy distinguishing PD patients from healthy controls according to typing patterns. The study conducted by Khaoucha et al. in 2024, titled Predicting Parkin- son's Disease [16] from Typing Patterns Using Shapley Additive Explanations and Machine Learning, addresses the need for early and accurate detection of Parkinson's disease (PD) using non-invasive ways to improve diagnosis.

Current diagnostic methods are often made via clinical assessments, which can be sub-jective and lead to time lapses to disease diagnosis. The authors suggested an advanced predictive model to examine typing patterns to predict PD. They applied three sophisticated machine learning models: XGBoost, Random Forest, and Support Vector Machine (SVM). The authors tested model performance by evaluating metrics such as F1-score, accuracy, recall, and ROC AUC. All three machine learning models returned encouraging results, with accuracies over 80% in the testing set. XGBoost had the highest accuracy at 87% followed by Random Forest at 85% and SVM at 81.8%. XGBoost outperformed the other two machine learning models on all metrics in both testing and validating sets con- firming its performance. With regard to feature importance, SHAP (SHapley Additive exPlanations) was utilized to understand the features used in the mod- els. The ”Hold” feature was particularly important with regard to the three models predictions. The study illustrates there is promise from using typing patterns along with advanced machine learning techniques and explainable AI methods such as SHAP with early and accurate diagnosis of PD. In their 2018 manuscript, Milne et al. introduce a new method to detect early Parkinson's disease (PD) from typing behaviour [17] using keystroke dynamics. Diagnosis of PD typically relies on complex models with large amounts of data, which require considerable resources to implement. The researchers sought to demonstrate that a simpler form of model could be valuable for detection of early PD using a few keystroke dynamics measures reflecting typing behaviour. The researchers developed a feature to capture the dynamic variation between sub- sequent keystrokes and then applied it to a univariate modelling approach which performed classification using AUC = 0.85 from only a few hundred keystrokes during typing behaviour. The authors ascertained that the approach was simpler and more effective than existing models, which typically rely on complex models and several continuous measures, capturing dynamic variation measures. The authors claim the simpler model approach reflects a balance of elegance, transparency and effectiveness, whereas existing approaches are based on significantly more complicated models.

The study conducted by Warwick R. Adams in 2017, named High-accuracy detection of early Parkinson's Disease using multiple characteristics of finger movement while typing, provides a unique opportunity to detect early Parkin- son's Disease (PD) among individuals who have not yet received a diagnosis of PD, or to identify decrement of motor and mental function in patients with existing PD, without having to rely on subjective clinical assessments to make that determination [18]. In a conventional clinical setting, many factors can influence the detection of diminished motor or cognitive scale, including physical examination findings, family members' or the patient's perceptual biases, clinicians' potential biases, and so forth, which can lead to more uncertainties or delays in ordering testing or definitive diagnosis of early PD. The authors there- fore sought to develop first-stage predictive model using typing data to assess for early PD using a novel composite measure of keystroke patterns. To do this, the authors utilized multiple constituent keystroke features, including key press and release durations, inter-key press intervals, and keystroke rhythms, all of which was processed through an ensemble of several supervised machine learning classification models (e.g., support vector machine, random forest, neural network model). The authors compiled and used keystroke data from 103 individuals, of whom only 32 were subjects with mild severity of PD, while the remaining subjects were considered ”non-PD” controls. The results indicated high levels of accuracy, yielding 96% sensitivity, 97% specificity, and AUC of 0.98, therefore, this systematic review study was able to demonstrate the potential for early PD detection without the need for specialized medical equipment or supervision.

II.2 VOICE SIGNAL-BASED DETECTION

Voice-based Parkinson's disease detection methods focus on analyzing speech impairments such as reduced loudness, monotonic pitch, and articulation diffi- culties. Numerous studies have used sustained vowel phonations and continuous speech recordings to extract acoustic features, including jitter, shimmer, and Mel-frequency cepstral coefficients (MFCCs). These features are then classi- fied using machine learning models such as k-nearest neighbors, support vector machines, and deep neural networks. Voice-based detection techniques have demonstrated promising accuracy; however, their performance can be affected by environmental noise, recording conditions, and language dependency, which may limit their generalizability in real-world scenarios. In their 2023 study, [19] tackled the challenge of detecting Parkinson's Disease (PD) early, affordably, and noninvasively by focusing on voice signal characteristics, as vocal issues often appear before noticeable motor symptoms. They developed their model using the UCI Parkinson's voice dataset, which includes 195 voice recordings (147 from PD patients and 48 from healthy individuals), and employed both machine learning and deep learning techniques: K-Nearest Neighbors (KNN), Support Vector Machine (SVM), Decision Tree (DT), Random Forest (RF), and Multi-Layer Perceptron (MLP). To enhance performance and address class imbalance, they utilized SMOTE (Synthetic Minority Over-sampling Technique), GridSearchCV for hyper parameter optimization, and SelectKBest for feature selection, although ultimately all features were used.

Their most successful outcomes were 98.31% accuracy with MLP and 95% accuracy with a tuned SVM. When compared to previous stud- ies using the same dataset, their method surpassed many earlier models, some of which achieved accuracies between 90-93%. Their work is noteworthy as it demonstrates that integrating voice features with strong ML/DL techniques, along with oversampling and hyperparameter tuning, can significantly boost classification performance beyond many prior efforts on the same dataset. Suppa et al. (2022) sought [20] to examine if voice characteristics could distinguish Parkinson's disease (PD) patients from healthy subjects across different stages of the disease and treatment regimens, in order to support voice as a potentially non-invasive PD biomarker. They recorded the voices of 115 PD patients (including untreated early PD and mid-to-advanced PD patients treated with L-Dopa) and 108 healthy controls. They extracted the acoustic voice features of jitter, shimmer, and harmonic-to-noise ratio from the recordings, and used the Support Vector Machine (SVM) algorithm for classification and ROC curves for diagnostic accuracy. Their results showed high accuracy in the differentiation of healthy subjects from PD subjects, and in the differentiation of OFF L-Dopa from ON L-Dopa therapies. This work showed that voice abnormalities show up early and worsen with disease progression, and that L-Dopa improves but does not fully restore voice changes. They also described a novel ”LR value” (from model output) that correlated with clinical severity to monitor disease progression. This work was important in supporting the potential for voice measures and machine learning.

Ahmed et al. (2022) sought to develop a machine-learning [21] algorithm to classify Parkinson's Disease (PD) from voice signal features, especially since speech and voice features are often affected in PD and represent a non-invasive diagnostic tool. The authors extracted multiple acoustic and spectral features from recordings of PD patients' voice samples (pitch frequency measures noise–harmonic ratios) and evaluated six different ML algorithms: Stochastic Gradient Descent (SGD) Classifier Extreme Gradient Boosting (XGB), Logistic Regression, Random Forest, K-Nearest Neighbors (KNN) and Decision Tree. For training and testing, they used a voice dataset consisting of 147 PD and 48 healthy control samples, with an 80% train / 20% test split. In the results, Random Forest achieved the highest accuracy (97%) while XGB, KNN and Decision Tree achieved around 95% accuracy, different classifiers showed about 91% accuracy (SGD and Logistic Regression). Their work illustrated that among six classifiers tested, ensemble/forest methods (Random Forest) showed the strongest performance for PD based on voice, and demonstrated that applying rich features and strong classifiers can lead to excellent diagnostic accuracy.

II.3 HANDWRITING-BASED DETECTION

Digital tablets and smart pens are frequently used to record dynamic handwriting features, such as pressure, velocity, acceleration, and pen trajectory. Several studies have applied statistical analysis and deep learning models to distinguish Parkinson's patients from healthy individuals based on these features. While handwriting-based approaches provide detailed motor insights, they frequently require specialized hardware and controlled data collection environments, which may reduce their scalability and ease of deployment. nKasemsap et al. (2025) introduced a method using computer vision to evaluate Parkinson's disease (PD) through the assessment of the presence of bradykinesia (slowness of movement) from a finger tapping test [22]. This method uses an automated, non-contact assessment of motion as opposed to the traditional subjective visual inspection. Using a smartphone, they recorded 10-second videos of bilateral finger tapping, which they then analysed with the Google Media Pipe Hands software to extract hand/landmark features (e.g. amplitude, decrement, and differences between hands). Additionally, they trained six machine learn- ing algorithms (Logistic Regression, Support Vector Machine, Random Forest, Decision Tree, LightGBM, and K-Nearest Neighbors) through a nested cross- validation process (5-fold outer, 3- fold inner) in an effort to rigorously tune the hyper parameters and evaluate the models.

Of the machine learning algorithms, Support Vector Machine (SVM) had the best model performance, achieving an average accuracy of approximately 0.84 to classify bradykinesia features between individuals with PD vs individuals in a control group. The main takeaway of this study is that the authors found that a computer-vision pipeline applied to videos with finger tapping exercises can fairly accurately assess the existence of PD in a person via bradykinesia, and therefore can produce a potentially scalable and contactless-bradykinesia screening tool that could be used as an adjunct to clinical assessment. Zhao and Li (2023) propose an original hybrid neural network model to evaluate handwriting [23] irregularities for detecting Parkinson's disease (PD). The model uses a three-layer Convolutional Neural Network (CNN) and a Bidirectional Gated Recurrent Unit (BiGRU) module to capture temporal and spatial features from handwriting tasks. The authors used samples from the NewHandPD dataset that contained drawings of spiral, meander, and circle tasks completed by PD patients and healthy controls. The proposed model reached accuracy scores of 92.91%, 85.71%, and 90.55% for the spiral, meander, and circle drawings, respectively, which is better than a variety of standard methods. Writing analysis with hybrid neural network architectures holds promise for a cost-effective and non-invasive way to assess and detect, as well as diagnose PD.

Table 1: Multi-Modal Dataset and Method Comparison for PD Detection.

Author	Dataset	Records	Attributes	Proposed Method	ML	DL	CNN	Depth wise CNN	Limitations
Iakovakis et al. [3]	Collected via custom Android app from smartphone	Not stated	Motor features	RF, SVM, GB,LR	Yes	No	No	No	Device variability
Tripathi et al. [4]	NeuroQWERTY	281	HT, FT features	CNN-based GEMASYMNET	Yes	Yes	Yes	No	Population Bias

III. PROPOSED METHODOLOGY

In order to improve early diagnostic efficiency and lessen reliance on expert evaluation, this paper suggests a pure convolutional neural network-based method for automated Parkinson's disease detection using keystroke dynamics. The proposed system starts by gathering raw keystroke dynamics data from the Tappy Keystroke Dataset, which records users' precise typing habits. User metadata and keystroke log data are extracted independently and transformed into a structured Data Frame format for additional processing during the extraction and integration stage. After pre-processing, which includes data cleaning and noise reduction, the data is feature-selected to preserve the most pertinent keystroke characteristics.

The chosen features are normalized using feature scaling, and continuous typing sequences are converted into CNN-compatible input representations using fixed-length keystroke windowing. Subsets for testing, validation, and training are then created from the processed dataset. Next, using the training data, a pure convolutional neural network (CNN) model is created to automatically extract discriminative temporal patterns from the keystroke sequences. Standard performance metrics are used to evaluate the efficacy of the trained model. Lastly, the system classifies users as either Parkinson's disease (PD) users or non-PD users based on the learned features Show Figure 3.

III.1 DATASET DESCRIPTION

This keystroke dataset supports a study on the detection of early Parkinson's Disease using multiple characteristics of finger movement while typing Figure 4. The dataset contains keystroke logs collected from over 200 subjects, with and without Parkinson's Disease (PD), as they typed normally on their own computer (without any supervision) over a period of weeks or months (having initially installed a custom keystroke recording app, Tappy). This dataset has been collected and analyzed in order to indicate that the routine interaction with computer keyboards can be used to detect changes in the characteristics of finger movement in the early stages of PD. Along with this Tappy dataset, several public datasets are also available, where the best reported model accuracy reaches up to 72.79%.

III.2 DATA HANDLING – DATA COLLECTION

The Tappy Keystroke Dataset is used to gather raw keystroke dynamics data at the start of the process. In order to identify neurological patterns associated with Parkinson's disease, this dataset captures users' typing behaviour, including key press and release events.

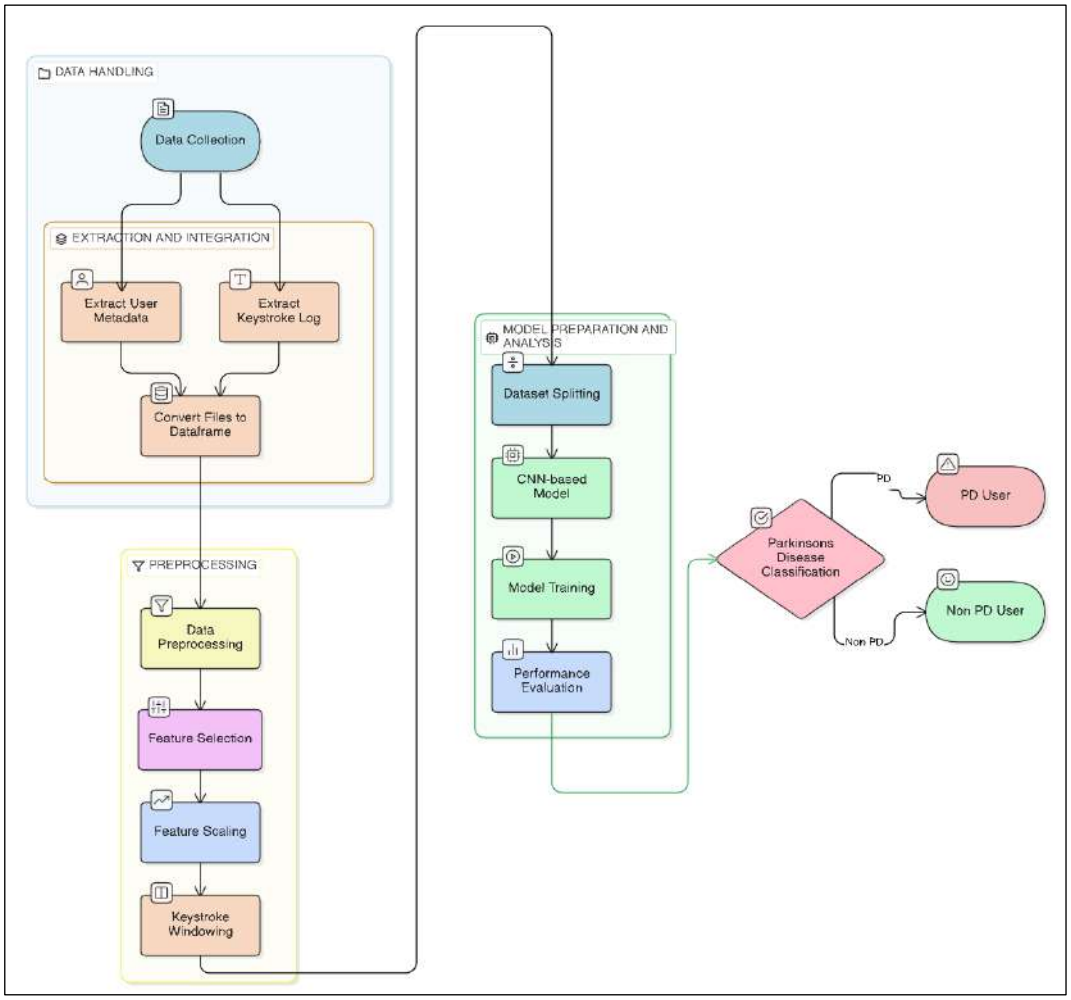

Figure 3: Proposed CNN Model Architecture for Parkinson's Disease Detection.
Source: Authors, (2026).

III.3 EXTRACTION AND INTEGRATION

In this stage, the raw keystroke data collected from the dataset is organized into structured components suitable for analysis. In order to link typing behavior to specific users, user metadata such as subject identification, age, gender, and class labels (Parkinson's disease or healthy control) are first extracted. The raw typing logs are then processed to extract keystroke log data that includes temporal typing characteristics like key hold time and inter-key latency. The fine-grained motor behaviour necessary for neurological analysis is captured by these timing features. Lastly, as in the suggested system, both metadata and keystroke logs are transformed into a DataFrame format, allowing for effective data manipulation, filtering, and feature extraction using Python libraries.

Extract User Metadata: The dataset is used to extract user-specific data, including subject ID, age, gender, and class label (PD/Healthy). As used in the proposed system's data loading phase, this metadata permits subject-wise grouping and guarantees that every keystroke sequence is accurately linked to its corresponding user and diagnosis label.

Extract Keystroke Log: Raw typing logs are used to extract keystroke timing characteristics, such as key hold time and inter-key latency. Fine-grained temporal motor patterns that are extremely sensitive to neurological conditions like Parkinson's disease are captured by these features.

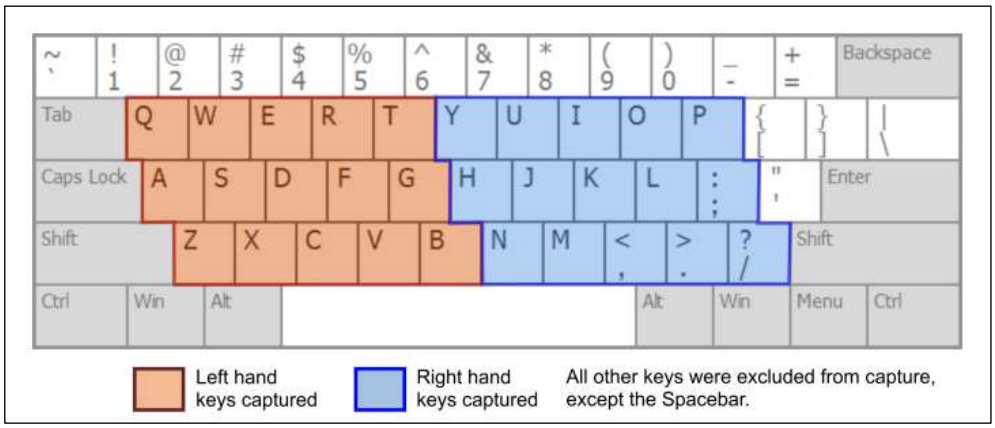

Figure 4: The areas of the keyboard included in keystroke capture.
Source: [18].

Convert Files to DataFrame: Keystroke timing logs and metadata are both transformed into a structured DataFrame format. The implemented code reflects how this representation makes it easier to use Python-based data processing libraries for effective filtering, aggregation, window construction, and feature manipulation.

III.4 PREPROCESSING

Several preprocessing steps are used to guarantee data consistency and enhance model reliability. Initially, data preprocessing is performed to remove noisy and incomplete records, handle missing values, and filter irrelevant keystroke events that could negatively impact model training. Feature selection is then used to reduce dimensionality and computational complexity by keeping only the most informative keystroke characteristics that aid in the detection of Parkinson's disease. The chosen features are then normalized into a common numerical range using feature scaling, which enhances CNN convergence and stabilizes gradient updates. Lastly, continuous typing streams are divided into fixed-length sequences for keystroke windowing. In this step, raw keystroke data is transformed into structured temporal inputs that are compatible with the proposed model's Pure 1D CNN architecture.

Data Preprocessing: To guarantee consistency and dependability of the input data, the raw keystroke dataset is refined during preprocessing. To avoid distorted temporal patterns impacting the learning process, records with incomplete, invalid, or missing keystroke events are eliminated. Furthermore, irrelevant keystroke entries that don't help identify Parkinson's disease are eliminated. Only high-quality keystroke sequences are sent to later stages thanks to this cleaning procedure. The suggested method lowers variance in the training data and enhances the CNN model's stability and generalization capacity by removing noisy samples early on.

Feature Selection: Then, the task of feature selection is employed to preserve informative keystroke attributes for Parkinson's disease. From the collected keystroke reads, we extract temporal typing dimensions like key hold time and inter-key latency as well as demographic information. Non-movement related features are removed. This focused selection constrains the dimensionality of the feature space, reduces redundancy, and avoids computational burden. Consequently, the CNN model is thus capable of learning beneficial discriminative temporal patterns rather than irrelevant variations, which helps better training efficiency and performance.

Feature Scaling: The chosen features are normalized to a common scale in order to guarantee numerical stability during CNN training. Feature scaling keeps attributes with larger magnitudes from controlling the learning process because keystroke features like latency and hold time may vary across different numerical ranges. By applying normalization prior to window construction, the suggested implementation enables the CNN to learn temporal dependencies consistently across all features. This stage contributes to quicker and more dependable training, stabilizes gradient updates, and speeds up the Pure 1D CNN model's convergence.

Normalization

$$X_{\text{normalized}} = \frac{X - Xmin}{Xmax - Xmin} \tag{1}$$

Keystroke Windowing: It is not possible to feed the cleaned and normalised keystroke data straight into a CNN because it is a continuous stream of typing events. As a result, the keystroke stream is divided into fixed-length temporal windows using a windowing technique. Each window captures localised temporal typing behaviour by displaying a brief series of consecutive keystroke events. To maintain unique typing characteristics, these windows are built subject-wise. The resulting windowed sequences are transformed into a three-dimensional tensor format that satisfies the Pure 1D CNN architecture's input specifications.

As shown in the suggested methodology diagram, this transformation makes it possible for the CNN to efficiently learn temporal patterns linked to Parkinson's disease.

III.5 MODEL PREPARATION AND ANALYSIS

As shown in the suggested methodology diagram, the prepared keystroke sequences are sent to the model learning and evaluation stage after preprocessing and window construction are finished.

Dataset Splitting: Following keystroke windowing, the produced fixed-length keystroke sequences are arranged into a three-dimensional input tensor of shape (number of windows × window length × number of features), with matching class labels designating either Parkinson's disease or a healthy control. The dataset is divided at the subject level rather than at random at the sample level to guarantee objective and trustworthy model evaluation. This stops the same user's keystroke windows from showing up in both training and testing sets, which could otherwise result in data leakage and inflated performance outcomes. First, a training set and a temporary set are created from the entire dataset. CNN parameters, such as convolutional filters and dense layer weights, are learned from the training set. The temporary set is further divided into testing and validation sets. During model training, the validation set is used to adjust hyperparameters, track convergence, and stop early to avoid overfitting. The testing set is only used once to assess the performance of the final model and is kept entirely hidden during training. By ensuring that the CNN model is trained, validated, and tested on mutually exclusive data, this three-way splitting technique offers a fair evaluation of the model's capacity for generalization.

CNN-based Model: The suggested system uses keystroke dynamics data to automatically learn discriminative temporal patterns using a Pure One-Dimensional Convolutional Neural Network (1D-CNN). Each input sample is represented as a fixed-length sequence of keystroke events following preprocessing and windowing, maintaining the temporal order of characteristics like latency and key hold time. 1D convolution is especially appropriate because of this structured representation, which enables the model to capture both short-term and long-term variations in typing rhythm linked to Parkinson's disease by sliding convolutional filters across the time dimension.

$$y(t) = \sum_{i-0}^{k-1} x\,(t+i)w(i) + b \tag{2}$$

Several Conv1D layers make up the CNN architecture, which uses learnable kernels to extract local temporal features from keystroke sequences. Pooling layers, which lower dimensionality and improve robustness to slight timing variations in typing behavior, come after these layers. The model can learn intricate patterns by using non-linear activation functions. The learned temporal features are integrated and high-level representation learning is carried out by fully connected (dense) layers after the extracted feature maps have been flattened. Ultimately, an output layer with an appropriate activation function generates the class prediction, differentiating users with Parkinson's disease from those without. The model is effective and efficient for keystroke-based Parkinson's disease detection because its pure CNN design allows for end-to-end learning without the need for manual feature engineering.

Model Training: The suggested Pure 1D CNN model is trained using the prepared keystroke windows from the training set following dataset splitting. The Adam optimiser, which adaptively modifies the learning rate for each parameter based on first- and second-order moment estimates, is used in the implemented code to optimise the network parameters. This promotes stable learning and quicker convergence. During training, the CNN uses backpropagation to iteratively update convolutional and fully connected layer weights in order to minimise a classification loss function (binary cross-entropy). The model learns discriminative temporal patterns linked to Parkinson's disease by processing batches of windowed keystroke sequences during each training epoch. As shown in the suggested methodology diagram, training proceeds until convergence while validation performance is tracked to guarantee trustworthy generalisation.

$$L = -\frac{1}{N}\sum_{i=1}^{N} yi \log(\hat{}yi) + (1 - yi)\log(1 - y\hat{}i)] \tag{3}$$

III.6 CLASSIFICATION

A CNN-based classifier uses the extracted features to determine whether a subject is healthy or shows symptoms of Parkinson's disease. By enabling early and precise Parkinson's disease detection, this automated classification lessens the need for human clinical evaluation.

IV. RESULTS AND DISCUSSION

This part shows the experimental results from the proposed pure CNN-based system for finding Parkinson's disease and talks about how well it works. After preprocessing, feature selection, feature scaling, and fixed-length windowing, the model was tested using keystroke dynamics data. The dataset was divided into training, validation, and testing subsets to ensure unbiased evaluation.

Evaluation Metrix: Several common classification performance metrics are used to quantitatively evaluate the effectiveness and dependability of the suggested 1D Convolutional Neural Network (CNN) model for typing-pattern-based neurological condition detection. These metrics are widely accepted in medical and behavioural signal analysis and provide a comprehensive evaluation of the model's diagnostic capability.

Accuracy: By calculating the ratio of correctly classified samples to all samples, accuracy assesses how accurate the model is overall. It gives a broad idea of how well the model can differentiate between subjects who are afflicted and those who are healthy.

$$\text{Accuracy} = \frac{\text{TP} + \text{TN}}{\text{TP} + \text{TN} + \text{FP} + \text{FN}} \quad (4)$$

Precision: The ability of the model to accurately identify positive cases among all predicted positive samples is reflected in precision. When it comes to typingbased neurological disorder detection, high precision means that the model reduces false alarms, which lowers the possibility of misclassifying healthy people as afflicted.

$$\text{Precision} = \frac{\text{TP}}{\text{TP} + \text{FP}} \quad (5)$$

Recall: Recall (Sensitivity) evaluates the model's capability to correctly detect actual affected cases. In medical and health-related applications, a high recall value is especially crucial because it guarantees that the majority of true cases are successfully identified with few false negatives.

$$\text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}} \quad (6)$$

F1-Score: When the dataset shows class imbalance, the F1-Score—the harmonic mean of precision and recall—is utilized to balance both metrics. It guarantees that the evaluation is not dominated by false positives or false negatives.

$$\text{F1} - \text{Score} = 2 * \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (7)$$

ROC-AUC (Receiver Operating Characteristic-Area Under Curve): Additionally, the model's discriminative ability across various classification thresholds is examined using the ROC–AUC (Receiver Operating Characteristic – Area Under Curve) metric. A higher AUC value closer to 1 indicates strong separation between affected and non-affected classes.

$$\text{TRP} = \frac{\text{TP}}{\text{TP} + \text{FN}} \quad (8)$$

$$\text{FPR} = \frac{\text{FP}}{\text{FP} + \text{TN}} \quad (9)$$

The proposed 1D Convolutional Neural Network (CNN) was trained on keystroke dynamics data using five features: RightKey, Latency, Hold time, Age, and Gender. The model processes temporal sequences of length 200 using three convolutional blocks with batch normalization and max-pooling, followed by global average pooling and fully connected layers. The final architecture contains 45,057 parameters, of which 44,609 are trainable, making the model computationally efficient while maintaining high representational capacity. Training was conducted using class-weighted binary cross-entropy to address minor class imbalance. A learning rate scheduler progressively reduced the learning rate, enabling stable convergence and preventing overfitting.

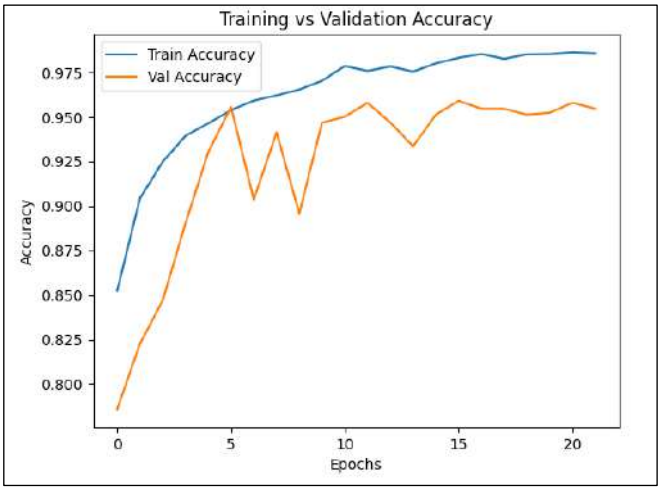

Figure 5: Accuracy Comparison of Training and Validation.
Source: Authors, (2026).

Training vs. validation accuracy and AUC figures show quick convergence in the first ten epochs. Strong generalization ability was demonstrated by training accuracy rising from 85.26% to 98.63% and validation accuracy stabilizing around 95–96%. In a similar vein, the Area Under the ROC Curve (AUC) reached 0.992 on validation data and continuously exceeded 0.99 for training. The inclusion of batch normalization and dropout layers further supports the close alignment between the training and validation curves, which indicates little overfitting. Minor fluctuations observed in validation accuracy during intermediate epochs can be attributed to the stochastic nature of mini-batch optimization and the temporal variability inherent in keystroke dynamics. The suggested model demonstrated exceptional discriminative performance with an overall accuracy of 95.21% and an AUC of 0.9928 on the independent test set of 1,503 sliding windows.

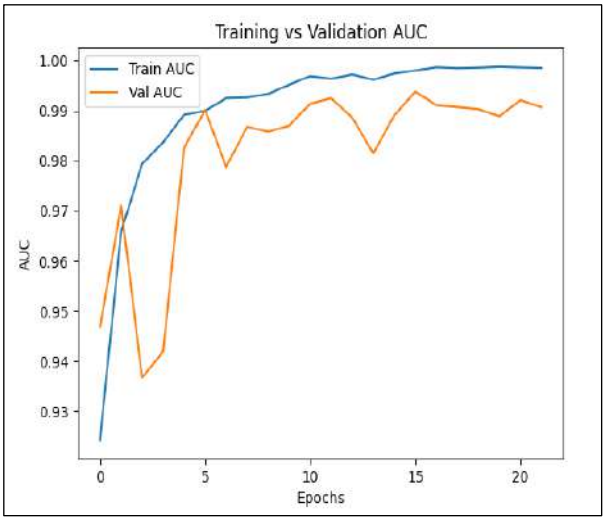

Figure 6: AUC Comparison of Training and Validation.
Source: Authors, (2026).

The detailed classification report shows balanced precision and recall for both classes:

Class 0 (Healthy): F1-score = 0.9512, Recall = 0.9683, and Precision = 0.9348
Class 1 (Parkinson's): F1-score = 0.9529, recall = 0.9370, and precision = 0.9694

These findings show that the model successfully reduces false positives and false negatives, which is important for applications involving clinical screening. There are only 23 false positives and 49 false negatives in the confusion matrix, which shows 702 true negatives and 729 true positives. The slightly higher number of false negatives highlights the intrinsic overlap in motor behaviour at early stages of the disease and suggests that a small subset of Parkinson's samples display keystroke patterns similar to those of healthy users.

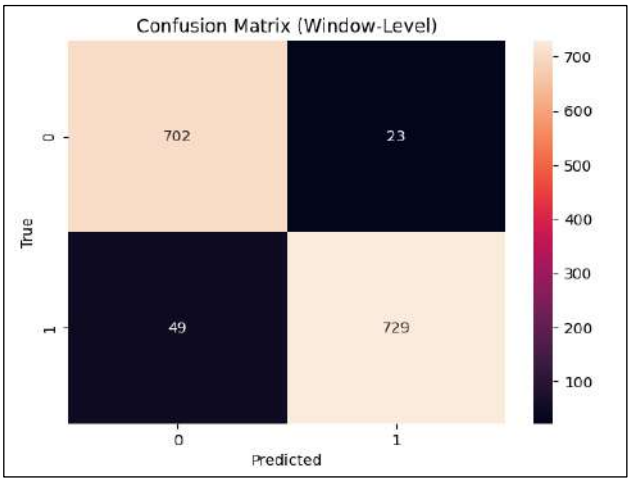

Figure 7: Confusion Matrix of CNN for Parkinson Decisisae Detection.
Source: Authors, (2026).

However, the model exhibits strong robustness across a variety of typing behaviours, and the overall error rate is still low.

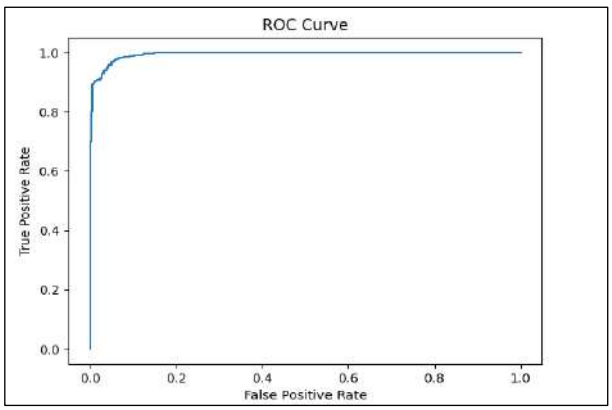

Figure 8: Roc curve for CNN model.
Source: Authors, (2026).

The ROC curve, which closely follows the plot's upper-left boundary, provides additional evidence of the model's efficacy. This indicates a high true positive rate even at low false positive rates, reinforcing the suitability of the proposed CNN model for early Parkinson's disease detection using keystroke dynamics.

V. CONCLUSIONS

I have complete careful and detailed analysis of various research papers for my area and literature, the appropriate dataset and approach for the detection of Parkinson's disease have determine. The Tappy keystroke datasets has been selected for implementation based on the study, and a deep learning technique using Convolutional Neural Network has been used for the disease categorization and key press dynamic modeling. The suggested strategy has undergone thorough testing and implementation. The applied CNN based model demonstrates a strong capacity to distinguish between normal typing behavior and patterns associated with Parkinson's disease, with an accuracy of 95.21% and an ACC value of 99%. The experimental study unequivocally shows that 99% accuracy been attained by the suggested method. The implementation process has specifically involved experimentation with various already-available techniques, which have helped draw key insights into the pre-processing, feature selection, and optimization of the proposed technique, resulting in its high efficacy and efficiency level.

ABSTRACT

Remote sensing has become essential for land cover classification, leveraging deep learning-based segmentation to improve accuracy in environmental monitoring, agriculture, and urban planning. This study introduces Disc Net, a streamlined DeepLabv3+ adaptation optimized for semantic segmentation on the OpenEarthMap dataset. The model employs a structured pipeline, integrating InceptionV3 with squeeze-excitation (SE) attention in the encoder to enhance feature extraction, while multilayer feature fusion combines information from both shallow a deep layers for richer representations. The decoder, built on DeepLabv3+ with depthwise separable convolutions, reduces computational complexity without compromising segmentation quality. Preprocessing with stratified sampling ensures balanced class representation, further refining model performance. DiscNet outperforms existing baselines, achieving an mIoU of 79.6%, significantly surpassing U-Net (52.7%), simpleCNN (51.3%), and ResUNet (42.5%). This strong performance, validated through qualitative and quantitative assessments, demonstrates DiscNet's ability to deliver high-precision segmentation while maintaining efficiency, making it a promising solution for large scale land cover mapping.

I. INTRODUCTION

Semantic segmentation plays a critical role in land cover mapping, enabling the pixel-wise classification of high-resolution remote sensing imagery to identify distinct land cover types such as vegetation, water bodies, urban areas, and roads [1-4]. Traditional approaches such as SVM [5], relied on manual feature extraction, which was labor-intensive and lacked the ability to capture complex spatial relationships. The evolution of traditional classification techniques such as Random Forest (RF), Decision Tree (DT), Maximum Likelihood Estimation (MLE), and K-Nearest Neighbor (k-NN) has significantly impacted land object classification and land cover mapping [6], [7]. Traditional land cover segmentation techniques, such as Random Forest, Decision Trees, and Maximum Likelihood Estimation, face significant challenges, including difficulties in handling high-resolution and complex spatial data, limited ability to resolve ambiguous or overlapping boundaries, and reliance on large, balanced labeled datasets, which are often scarce and imbalanced [8]. Additionally, their performance is hindered by variability in remote sensing data due to seasonal changes, lighting conditions, and complex land cover patterns, limiting their scalability and adaptability to modern remote sensing needs [9]. The advent of deep learning, specifically convolutional neural networks (CNNs), has revolutionized semantic segmentation, leading to significant improvements in both accuracy and scalability [10-12]. Early methods, like those described by [13], used Fully Convolutional Networks (FCNs), which replaced fully connected layers with convolutional layers to handle inputs of arbitrary size and produce segmentation maps of the same size as the input images. Since then, more sophisticated architectures such as U-Net [14] and it's variants have set the standard for high-resolution remote sensing image segmentation.

U-Net implementation over sentinal-2 dataset as described in [15], achieved accurate LULC maps in output. These models and others like them have significantly improved segmentation performance, particularly in land cover mapping tasks. Modification over U-Net such as U-Net++ [16] achieved 97% accuracy in land cover classification using Gaofen and Sentinal-2 dataset, while Attention Dense U-Net (ADU-Net) [17] measured mIoU of 77.66% on the GID dataset. LULC-SegNet [18], a semantic segmentation network for land use and land cover (LULC) on privately sourced LULC datset achieved mIoU value 73.76%. are among the most widely used architectures due to their effective use of skip connections and multi-scale feature extraction. Combining the PCA, U-Net and attention mechanism, PSE-UNet model as defined by [19], reported accuracy of 88% mIoU on Salinas dataset. One more variant TransUnet [20], identified building rooftops with significant accuracy. Thus, traditional encoder-decoder model U-Net have been improved with techniques like residual connections, attention mechanisms, and nested architectures to better capture spatial and contextual information. The integration of transformers, as seen in networks like TransUNet and UNetFormer, introduces global attention mechanisms, enabling the capture of long-range dependencies crucial for fine-grained semantic segmentation in remote sensing and provide solutions across diverse applications. Advanced encoder-decoder architectures and transformers for semantic segmentation have emerged through iterative enhancements of deep learning networks. DeepLab [8], a pioneering encoder-decoder model, achieved a notable mIoU of 79.7% on the Pascal-VOC dataset. Subsequently, researchers [21-25] have extensively explored DeepLab and its variants for segmentation tasks in remote sensing imagery, demonstrating superior per formance over existing traditional encoder-decoder models in various aspects. One such network CFAMNet as described in [26] achieved mIoU value 77.22% while segmenting images in Gaofen dataset. A multimodal feature fusion based encoder-decoder network MFFNet [27] achieved significant improvement in land cover classification.

Few additional networks, such as PSPNet, HRNet, RAANet, DeaNet, and MARE [28], [29], have also been introduced in this direction, showcasing significant performance improvements. Another important development in semantic segmentation has been the evolution of transformer-based architectures, which have been extensively utilized for remote sensing tasks [30]. Authors in [31], [32] explored possibility of Vision Transformer in classfiying land covers in PolSAR data. The modified ViT structure based swin transformer introduced in [30] achieved better results when compared to exisiting transformer framework. A multi-level fusionbased transformer network SoftFormer [33] outperformed numerous state-of-the-art techniques across four distinct LULC datasets. The primary performance metric in semantic segmentation is Mean Intersection over Union (mIoU), which measures the overlap between predicted and ground truth segments [28], [29]. In addition, overall accuracy, precision, recall, and F1 score are often used to evaluate model performance [28], [29]. While accuracy is a useful metric, it can be misleading in cases where class imbalances exist, as is often the case in land cover mapping tasks. For instance, a model that performs well on dominant classes (e.g., vegetation) but poorly on minority classes (e.g., roads or water bodies) may still achieve high overall accuracy but low mIoU. This has led many researchers to prioritize mIoU as the key evaluation metric in land cover segmentation tasks [1], [34], [35]. A range of datasets has been used in land cover mapping studies. Some of the most popular datasets include ISPRS Vaihingen and ISPRS Potsdam, which provide high-resolution aerial images for urban segmentation [28]. Sentinel-1 and Sentinel-2, part of the Copernicus program, offer multispectral and radar imagery and have been widely used in land cover studies [36], [37]. SpaceNet [38], FLAIR [39] and LandCover.ai [40] have also been widely used for segmentation and classification tasks in remote sensing. Large-scale datasets like OpenEarthMap [41], DeepGlobe [42], BigEarthNet [43], offer satellite imagery with diverse geographical contexts, enabling models to generalize across different environments. Each of these datasets presents unique challenges, such as varying resolutions, class imbalances, and different environmental conditions, which test the generalization capability of segmentation models.

Despite extensive advancements in semantic segmentation for land cover classification, many studies focus on dataset-specific scenarios, models, and techniques that fail to address the challenges posed by unique conditions, such as differentiating visually similar classes in RGB satellite images. Existing approaches often rely on large datasets or complex architectures requiring high computational resources, limiting their practicality in lightweight and resource-constrained environments. These challenges, particularly data scarcity and limited computational power, emphasize the need for carefully tuned, data-efficient, and computationally efficient models tailored for specific applications. Our study distinguishes itself by proposing a tailored approach that utilizes RGB data enhanced with innovative architectural components, such as the squeeze excitation block and depthwise separable convolutions, to achieve high segmentation accuracy. By leveraging the OpenEarthMap dataset [41] and integrating a robust class-balanced sampling strategy, our work aims to improve the classification of underrepresented classes and enhance feature refinement through an encoder-decoder based mechanism. This focus on efficient, resource-friendly methods makes our research particularly relevant for applications where computational efficiency and data limitations are critical. The contributions of our research are significant in the context of land cover classification, offering a robust solution for generating precise segmentation maps from satellite images. To achieve the desired outcomes, major objectives were systematically outlined, implemented in sequence, thoroughly analyzed, and iteratively refined.

1. Through rigorous statistical analysis and visualization techniques, we establish a class-balanced strategy that ensures effective representation of all target classes during training, enabling comprehensive model learning.

2. The adoption of the DeepLabV3+ architecture, which incorporates depthwise separable convolutions in place of standard convolutions. This modification significantly enhances the model's computational efficiency, reduces trainable parameters, and decreases complexity without compromising performance.

3. The squeeze excitation block in our model plays a pivotal role in improving feature representation by adaptively recalibrating channel-wise feature responses. This mechanism enhances the model's ability to focus on relevant features, thereby improving segmentation accuracy.

4. The decoder of our proposed model plays a pivotal role in refining segmentation outputs. By leveraging contextual information from neighboring pixels, the decoder enhances the coherence and accuracy of the class map, effectively handling fine edge refinements as part of the decoding process.

5. The integration of feature fusion during the training phase played a pivotal role in enhancing model performance. By combining detailed spatial features from skip connections with global semantic information from the SE block, the model achieved a more comprehensive feature representation, resulting in significant improvements in segmentation accuracy.

Highlighting phase-wise, we begin with data sampling techniques as a critical part of the preprocessing phase, balancing training samples to improve model robustness during training. Following this, we propose a lightweight DeepLabV3+ model with an InceptionV3 backbone, integrated with a squeeze excitation attention mechanism to enhance segmentation accuracy. The OpenEarthMap dataset, known for its variety, diversity, and accurately labeled land cover types, serves as an essential resource for training and evaluating our model. The mean Intersection over Union (mIoU) metric serves as a reliable benchmark for evaluating the performance of our semantic segmentation model.

II. MATERIALS AND METHODS

II.1 OVERVIEW OF DATASET

The OpenEarthMap dataset [41] is a high-resolution satellite imagery dataset designed for land cover and land use classification, making it well suited for semantic segmentation tasks. With detailed annotations across diverse classes such as urban areas, water bodies, forests, and agriculture, it provides the rich, varied data necessary for training deep learning models. The dataset's high spatial resolution (30 cm to 50 cm ground sampling distance) allows for accurate distinction of fine-grained features, such as water bodies and roads, which are crucial for semantic segmentation in remote sensing. Its diversity of scenes, including rural and urban environments, ensures generalization across different geographies, making it an ideal choice for improving model performance in real-world applications like environmental monitoring and urban planning.

II.2 DATASET PREPARATION FOR EXPERIMENT

As a preprocessing step, we implement a stratified sampling technique that iterates over a dataset of 5,000 sample images, each with a size of 1000x1000x3. The goal of this process is to create an optimized subset of images that balances the distribution of classes within the dataset. By ensuring that each class is adequately represented, this approach helps mitigate class imbalance issues and guarantees sufficient training samples for each class. Additionally, to reduce the complexity of the training process, we introduce image patches by downsampling the original 1000x1000 images to smaller 256x256 patches. This modification decreases computational load while maintaining sufficient detail for training, enabling more efficient model learning. The resulting balanced and optimized subset of 256x256 patches is then used to train our proposed network, improving its ability to generalize and enhancing performance during training.

II.3 PROPOSED ARCHITECTURE

In this work, as per Figure 1 we propose architecture DiscNet, which combines both the encoder (InceptionV3 backbone [44]) and the decoder (DeepLabV3+ [8]) components. We specifically focus on integrating two key modifications into the DeepLabv3+ model: the incorporation of Squeeze-and-Excitation (SE) and Depthwise Separable Convolutions (DWConv). These modifications aim to enhance the model's performance in semantic segmentation tasks, leveraging the strengths of both the SE block and DWConv. The architecture is carefully designed to optimize segmentation accuracy while maintaining computational efficiency.

II.3.1 Encoder: InceptionV3 Backbone

The encoder part is the feature extraction part, which is based on the InceptionV3 model. InceptionV3 is a pre-trained model that extracts multi-scale features using its inception modules

Input Image: Let the input image be represented as

$$X_{in} \in R^{H_{in} \, x \, W_{in} \, x \, C_{in}}, \text{ where} \tag{1}$$

H_{in}=Height of input image, W_{in}=Width of input image, C_{in}=Number of channels in input image. InceptionV3 Backbone:

The InceptionV3 model uses ImageNet pre-trained weights for its convolutional layers. These weights are loaded from the pre-trained model, allowing the network to start with a set of feature extractors already tuned for general image understanding. For simplicity, let's define the output after passing the input through the InceptionV3 Backbone as

$$X_{enc} \in R^{H_{enc} \, x \, W_{enc} \, x \, C_{enc}}, \text{ where} \tag{2}$$

H_{enc}=reduced height of the feature map after encoding, W_{enc}=reduced width of the feature map after encoding, C_{enc}= the depth of the feature map, which corresponds to the number of filters in the final layers.

Squeeze-Excitation (SE) Block: The Squeeze-Excitation (SE) block recalibrates channel-wise feature responses by applying attention mechanisms [45]. Global Average Pooling (GAP): Apply Global Average Pooling to the encoder output X_{enc} to capture the global context of each channel.

$$X_{gap} = GAP(X_{enc}) \tag{3}$$

Fully Connected Layers: Apply two fully connected layers with ReLU and Sigmoid activations to generate the channel-wise attention. This produces a scaling factor for each channel.

$$SE(X_{enc}) = \sigma\,(W_2\,.\,ReLU\,(\,W_1\,.\,X_{gap}\,)) \tag{4}$$

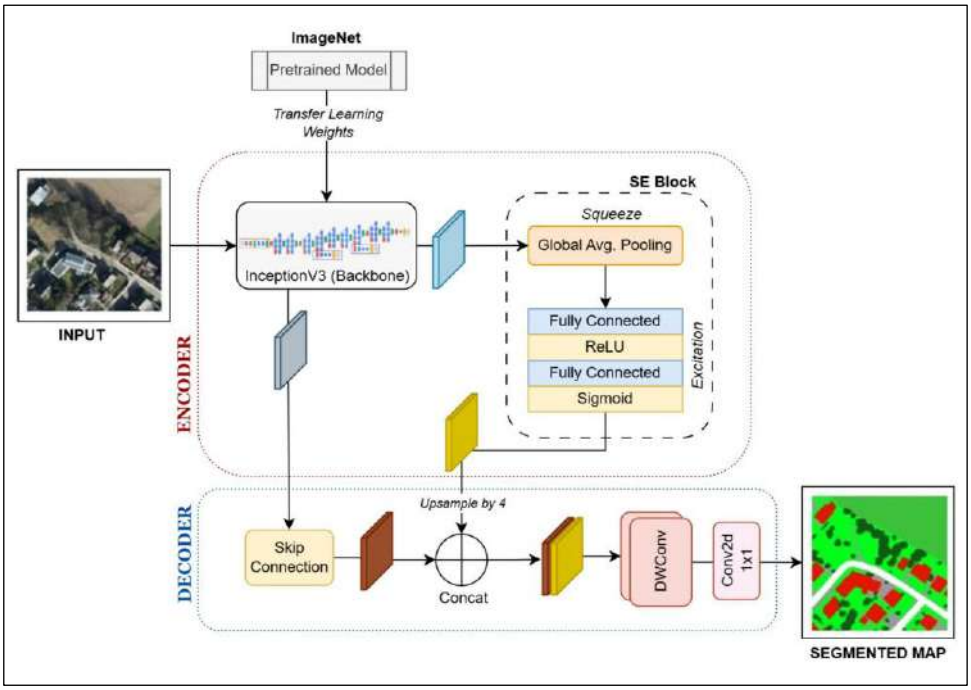

Figure 1: Architecture of proposed model (DiscNet).
Source: Authors, (2026).

Where $W_1 \in R^{\frac{C_{enc}\,x\,C_{enc}}{r}}$ is the weight matrix of the first fully connected layer (with r as the reduction ratio), $W_2 \in R^{\frac{C_{enc}\,x\,C_{enc}}{r}}$ is the weight matrix of the second fully connected layer, σ is the sigmoid activation function.

Recalibration: The SE block generates attention weights $A_{enc} \in R^{1\times1\times Cenc}$, which are used to recalibrate the feature map Xenc by element-wise multiplication.

$$X_{enc\_att} = X_{enc}\;x\;A_{enc}\,,\text{where}\;\;X_{enc\_att}\;\in\;R^{H_{enc}\,x\,W_{enc}\,x\,C_{enc}} \tag{5}$$

II.3.2 Decoder: DeeplabV3+

The decoder part upsamples the feature maps and merges the features from both the encoder and the SE block to produce the output. The decoder is designed to reconstruct the segmentation map or output image. Up-sampling:

The feature maps are upsampled (typically using bilinear interpolation or transposed convolutions) to the spatial resolution of the input image.

$$X_{dec\_upsampled} = Upsampling(X_{enc\_att}) \tag{6}$$

Skip Connections: The skip connection allows the decoder to use both high-level and low-level features by concatenating the upsampled feature maps with the skip connection from earlier layers of the encoder ("mixed3" in InceptionV3). Let the skip connection feature map be

$$X_{skip}\;\in\;R^{H_{enc}\,x\,W_{enc}\,x\,C_{skip}} \tag{7}$$

Feature Fusion: The skip connection is concatenated with the upsampled output. Concatenating the outputs of the skip connection and the SE block enables the model to combine detailed spatial features from shallow layers with global semantic information from deeper layers. This process facilitates feature fusion, where both local and global contexts are integrated, yielding a more comprehensive and robust feature representation for precise and accurate segmentation.

$$X_{concat} = Concatenate(X_{dec_{upsampled}}\,,X_{skip}) \tag{8}$$

Decoder Convolutions: After concatenation, apply convolutional layers (typically using depthwise separable convolutions) to refine the feature maps.

$$X_{dec\_conv} = DWConv(X_{concat}) \tag{9}$$

Final Output Layer: The final layer consists of a 1x1 convolution that outputs class scores for each pixel in the segmentation task. Let the output image be

$$X_{out}\;\in\;R^{H_{out}\,x\,W_{out}\,x\,C_{out}}\,,\text{where}\;H_{out} = H_{in}, W_{out} = W_{in}, C_{out} = \text{Number of classes} \tag{10}$$

$$X_{out} = Conv2D(X_{dec_{conv}}, filters = C_{out}, kernel = (1,1)) \quad (11)$$

The modified DeepLabv3+ model, with the InceptionV3 backbone, introduces two key optimizations:

1. Depthwise Separable Convolutions (DWConv): These convolutions are applied in both the encoder and decoder to reduce computational complexity and improve processing efficiency.
2. Squeeze-and-Excitation (SE): Following each convolutional block, SE is used to recalibrate the feature map channels, allowing the model to focus more effectively on the most important features.

These optimizations ensure that both feature extraction and segmentation are carried out more efficiently, with a significant reduction in computational cost due to the use of depthwise separable convolutions. Meanwhile, the SE mechanism improves the model's capacity to adaptively emphasize the most relevant features, enhancing overall segmentation performance. Additionally, the feature fusion through concatenation of skip connection and SE block outputs ensures the integration of local spatial details with global semantic context, resulting in a more enriched and robust feature representation for segmentation.

III. RESULTS AND DISCUSSIONS

III.1. EXPERIMENTAL SETUP AND MODEL HYPERPARAMETERS

III.1.1 Hardware and Software Requirements

The experiments were conducted on the OpenEarthMap dataset, which includes high-resolution RGB images with corresponding pixel-wise annotated ground truth maps, using a system running Ubuntu 20.04. The hardware configuration included an Intel Xeon CPU, an NVIDIA Tesla T4 GPU with 16GB VRAM, and 32GB of RAM, ensuring efficient deep learning model training and inference. For software, Keras 3.0 was used as the primary deep learning framework, with TensorFlow 2.16.1 serving as the backend. The implementation was carried out in Python 3.7, utilizing various additional libraries such as NumPy, Matplotlib, and Pandas for numerical computations, data visualization, and data manipulation, respectively. This environment provided a robust foundation for developing and evaluating the model effectively.

III.1.2 Hyperparameters and Training Settings

All subset images were resized to a uniform resolution of 256 × 256 pixels. The models were trained using the Adam optimizer with a learning rate of 0.001 and a batch size of 16. The categorical cross-entropy loss function was used to handle multi-class segmentation tasks. The training process was conducted for 50 epochs with early stopping based on training loss. Stratified sampling ensured balanced representation of all classes during training. The models were evaluated using Mean Intersection over Union (mIoU) metric. The proposed model was compared with U-Net, ResUNet, and a simple CNN (simple and custom made CNN architecture) to benchmark performance. All baseline models were implemented with identical preprocessing steps and trained under the same conditions for fair comparison.

III.2 VISUAL REPRESENTATION AND MODEL PERFORMANCE

The qualitative assessment of segmentation outputs reveals notable differences in the performance of the four models. As per Figure 2 DiscNet, the proposed model, demonstrates the highest alignment with ground truth, pro- ducing visually refined segmentation maps with well-defined boundaries and accurate class delineation, even in regions with overlapping spectral properties such as roads, water bodies, and bareland.

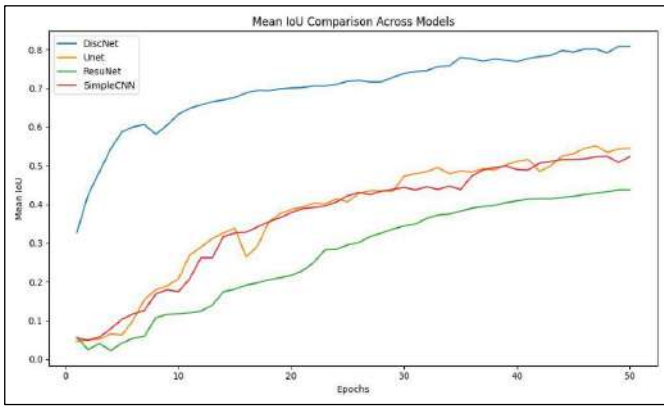

Figure 3: Avg. MioU vs Epochs.
Source: Authors, (2026).

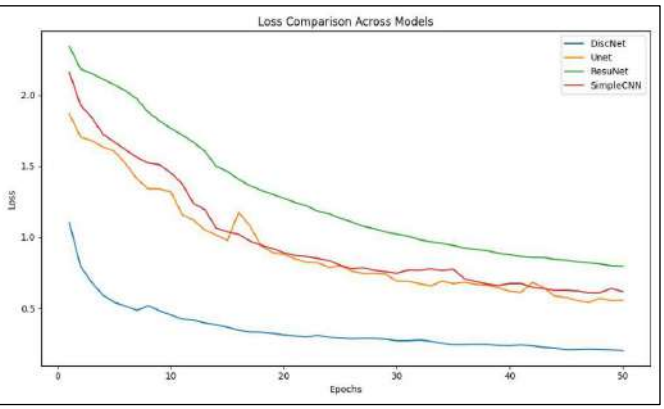

Figure 4: Avg. Loss vs Epochs.
Source: Authors, (2026).

The set of segmented images produced by DiscNet closely approximates the ground truth, demonstrating model's effectiveness in accurate land cover classification. U-Net delivers reasonably accurate maps but struggles with finer class boundaries, leading to minor misclassifications. The Simple CNN provides moderate performance, with evident class merging and a lack of detail in areas requiring complex segmentation. In contrast, ResUNet, despite its complex architecture featuring residual connections, produces poor segmentation quality characterized by frequent misclassifications and blurred boundaries, indicating inefficiencies in adapting to the specific challenges posed by this dataset.

III.3 QUANTITATIVE ANALYSIS OF MIOU AND LOSS

The quantitative evaluation as per values considered in plotting Figure 3 and 4 corroborates the visual findings, with DiscNet achieving the highest average mIoU of 0.7947 and the lowest average loss of 0.2183, reflecting its superior learning efficiency and ability to generalize across all 8 classes. U-Net ranks second with an average mIoU of 0.5275 and an average loss of 0.5876, showing reasonable performance but limited refinement in complex regions. The Simple CNN, with an average mIoU of 0.5134 and an average loss of 0.6310, achieves moderate results but is constrained by its simplistic architecture. Despite its sophisticated residual connections, ResUNet performs the worst, with the lowest average mIoU of 0.4245 and the highest average loss of 0.8318, likely due to poor optimization and unstable convergence in handling the dataset's intricate spatial and spectral complexities.

III.4 COMPARATIVE ANALYSIS OF AVERAGE CLASS-WISE MIOU

The class-wise evaluation of segmentation performance as per Table 1 highlights the superior generalization ability of DiscNet across all eight land cover classes. DiscNet consistently achieves the highest mean Intersection over Union (mIoU) values, particularly excelling in water bodies, agricultural land, and buildings, where precise boundaries are crucial. U-Net follows as a distant second, showing moderate performance with better results in developed space and building segmentation but struggles in classes with higher spectral overlap. Simple CNN outperforms ResUNet in several classes, demonstrating its moderate capability despite its simpler architecture. ResUNet, despite its architectural complexity, underperforms across all classes, indicating its inefficiency in adapting to the spectral and spatial intricacies of the dataset. Overall, DiscNet's superior segmentation accuracy reinforces its robustness and adaptability for multi-class land cover segmentation tasks.

Table 1: Average Class-wise mIoU for Different Models.

	Bareland	**Rangeland**	**Developed Space**	**Road**	**Tree**	**Water**	**Agri Land**	**Building**
DiscNet	**0.5991**	**0.6187**	**0.6967**	**0.6949**	**0.6589**	**0.8747**	**0.8885**	**0.865**
Unet	0.3142	0.3826	0.5334	0.5141	0.5948	0.6751	0.5835	0.7777
ResuNet	0.2122	0.2523	0.3245	0.2601	0.3752	0.5531	0.356	0.5702
SimpleCNN	0.2856	0.3972	0.4969	0.449	0.6312	0.7775	0.6525	0.736

IV. CONCLUSIONS

This study presents DiscNet, a novel lightweight deep learning model for semantic segmentation of high-resolution RGB satellite images. Our experiments on the OpenEarthMap dataset demonstrate the effectiveness of DiscNet in segmenting diverse land cover classes with high accuracy.

Through a detailed comparative analysis with established models, including U-Net, ResUNet, and a simple CNN, we show that DiscNet outperforms these models in terms of both visual representation and quantitative metrics, particularly in challenging regions such as water bodies, vegetation, and agricultural land. The results of the evaluation, based on metrics such as Mean Intersection over Union (mIoU) and loss, clearly indicate DiscNet's superior performance across all classes. The inclusion of advanced architectural features, such as squeeze-excitation attention mechanisms and depthwise separable convolutions, contributes to enhanced segmentation accuracy. These findings suggest that DiscNet is a promising model for large-scale semantic segmentation tasks, offering a balance between computational efficiency and segmentation performance. Future work will focus on extending the model to include multilevel data and feature fusion techniques, integrating additional bands to input and or information rich feature set that could improve segmentation task.

V. AUTHOR'S CONTRIBUTION

Conceptualization: Anoop Patel, Safvan Vahora.
Methodology: Anoop Patel, Safvan Vahora.
Investigation: Anoop Patel, Safvan Vahora.
Discussion of results: Anoop Patel, Safvan Vahora.
Writing – Original Draft: Anoop Patel, Safvan Vahora.

Approval of the final text: Anoop Patel, Safvan Vahora, Kuntesh Jani, Narendrasinh Chauhan.

VI. ACKNOWLEDGMENTS

Data acknowledgement and code availability

This study utilizes the OpenEarthMap dataset [41], a publicly available benchmark dataset for semantic segmentation. Upon acceptance of this manuscript, we will publicly release the source code, including preprocessing, data preparation, pre-trained models, and training scripts in a dedicated GitHub repository. This will ensure transparency and facilitate reproducibility for future research.

ABSTRACT

Active Noise Cancellation (ANC) began as a theoretical idea in the 1930s and has now spread to include broad uses in consumer electronics, industrial, and automotive industries. This conceptual study provides a thorough explanation of ANC technology spanning more than 90 years of development, from Paul Lueg's early 1936 patent to the most recent deep learning methods. Adaptive filtering algorithms such as LMS, NLMS, FxLMS, FuLMS, and RLS variants are closely examined, along with new neural network architectures like Convolutional Recurrent Networks (CRN) and Attentive Recurrent Networks (ARN), which achieve sub-4 ms latency with noise cancellation improvements of 5-6 dB over traditional methods. The noise reduction parameters, computational complexity, power consumption, and convergence characteristics are all included in the thorough performance comparisons presented in this study. Using benchmark datasets like NOISEX-92 and DEMAND for algorithm evaluation, we examine feedforward, feedback, and hybrid system designs used in consumer headphones, automobile cabins, aviation, and HVAC systems. Given their greater resistance to broadband noise and nonlinear distortions, our conceptual study shows that deep learning approaches are the ANC technology of the future. However, conventional FxLMS maintains the industry standard because of its computational efficiency (O(N) complexity).

I. INTRODUCTION

Active Noise Cancellation uses the destructive interference concept to eliminate the original noise at the listener's location by producing a "anti-noise" signal that is phase-inverted with respect to the undesired sound. [1], [2]. This simple concept has proven quite challenging to properly execute, requiring complex signal processing algorithms that must operate under strict real-time constraints and adapt to continuously changing acoustic surroundings [3]. Prior to the originating noise achieving the cancelation threshold, the ANC system must detect incoming noise, select the proper anti-noise signal, and output it via a secondary loudspeaker [4]. It is the main problem with the causality constraint. With audio channel lengths of 5–10 cm, this only permits 150–300 microseconds for processing in a regular headphone application [5], [6]. With the achievement of 20–40 dB noise reduction throughout the important frequency bands by high-end consumer headphones like Sony, Apple, and Bose, the economic impact of ANC technology has increased significantly [7]. Road noise cancellation systems observed in Hyundai, Honda, and BMW vehicles provide cancellation signals after analyzing acceleration sensor data in less than two milliseconds [8]. This paper explores the creation of deep learning-based intelligent systems and examines the fundamental principles that enable these implementations.

Four fundamental research questions structure this conceptual investigation:

1. How did ANC go from a theoretical concept to a real-world application?
2. Which computational techniques make adaptive noise cancellation possible in real time?
3. In what ways do system designs vary depending on the application domain?
4. How will deep learning function in ANC systems of the future?

II. HISTORICAL BACKGROUND AND EVOLUTION

II.1 THE BIRTH OF ACTIVE SOUND CONTROL

German researcher Paul Lueg has been associated with the conceptual basis of ANC. On January 27, 1933, he submitted patent DE 655508 in Germany, which was later issued as US Patent 2,043,416 ("Process of Silencing Sound Oscillations") on June 9, 1936 [1]. In order to accomplish cancellation "within the field of action of the sound waves produced by the loudspeaker," Lueg's patent detailed how sound waves were received via a microphone and reproduced via a loudspeaker "in the form of sounds having an opposite phase." Due to vacuum tube electronics restrictions, Lueg's concept remained unfeasible despite its innovative vision. Harry F. Olson and Everett G. May of RCA Laboratories published "Electronic Sound Absorber" in the Journal of the Acoustical Society of America in 1953 [9], marking the first real-world use of ANC. Their feedback-based solution established the standard for active noise-canceling headsets by achieving 10–25 dB attenuation throughout a three-octave frequency range in the low-frequency audio spectrum.

II.1.1 The Adaptive Filtering Revolution

The Least Mean Squares (LMS) algorithm was introduced by Stanford University's Bernard Widrow and Marcian E. Hoff in their 1960 paper "Adaptive Switching Circuits" that was presented at the WESCON Convention. This innovation made today's ANC possible. [10]. With the beautifully simple weight update equation, the LMS algorithm offered a computationally effective way to repeatedly minimize mean square error in adaptive linear elements according to this Equation:

$$w(n+1) = w(n) + \mu \cdot x(n) \cdot e(n) \tag{1}$$

Widrow et al.'s novel 1975 study "Adaptive Noise Cancelling: Principles and Applications" was published in the IEEE Proceedings [11]. Since then, it has been cited in 380 patents and over 2,800 scholarly papers. John C. Burgess' 1981 publication "Active adaptive sound control in a duct: A computer simulation" in JASA developed the Filtered-x LMS (FxLMS) method, which was a crucial development for physical ANC systems [5]. Burgess observed that the "secondary path", the acoustic passage from the secondary loudspeaker to the error microphone, introduces delays and phase shifts that may cause the typical LMS algorithm to deviate. Stable convergence was made possible in real acoustic scenarios by FxLMS, which filtered the reference signal using an estimate of the secondary path prior to weight adaption.

II.1.2 The Southampton School and Theoretical Foundations

In the 1980s and 1990s, Philip A. Nelson and Stephen J. Elliott of the Institute of Sound and Vibration Research (ISVR) at the University of Southampton made important contributions [2], [12]. They introduced the Multiple Error LMS algorithm for multiple FIR filter array adaptation in multichannel systems in their 1987 paper "A multiple error LMS algorithm and its application to the active control of sound and vibration" in IEEE Transactions on Acoustics, Speech, and Signal Processing (cited more than 800 times). Active Control of Sound, published by Academic Press in 1992, combined research on signal processing and acoustics [12].

II.1.3 Digital Signal Processing Enables Commercial Deployment

The actual use of ANC was drastically changed when it switched from analog to digital. Important developments in the history of commercially available ANCs include [3]:

- 1978: Texas Instruments releases specialized DSP processors.
- 1987: Sennheiser's LHM 45 NoiseGard becomes the first commercial ANC headset for airline pilots (analog);
- 1989: Bose releases consumer ANC headsets;
- 2000s: Real-time DSP implementations with sub-band and frequency-domain algorithms.
- 2008: Sony's MDR-NC500D were the first digital ANC headphones with integrated digital equalization.

II.1.4 Research Evolution Timeline and Application Milestones

Figure 1, which illustrates the organization's nine decades of growth, provides a comprehensive conceptual map of ANC technical progress and its transformation into practical applications. The timeline illustrates three distinct innovation waves: the fundamental theoretical phase (1933–1970), the adaptation algorithm revolution (1970–2000), and the deep learning revolution (2000–present) [3], [6].

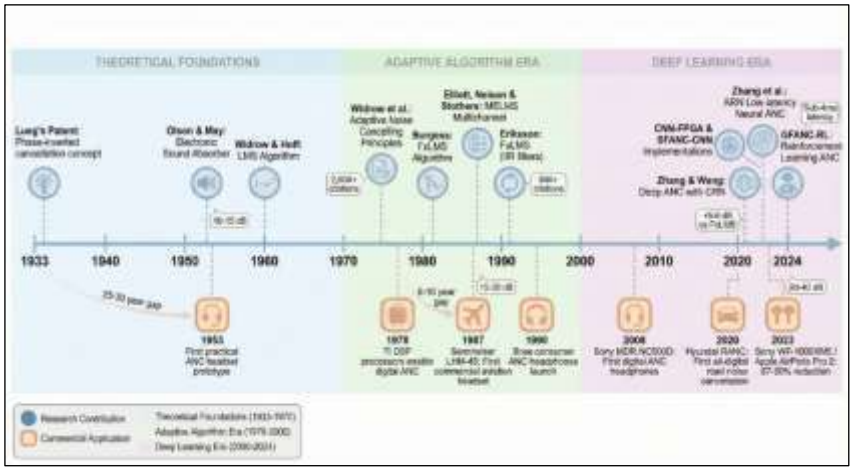

Figure 1: Evolution of ANC: research and applications (1933-2024).
Source: [3], [6].

The timeline shows several important key findings: (1) algorithmic innovation was continuously followed by commercial deployment by 5–10 years; (2) the shift from analog to digital processing (1987–2008) allowed for exponential growth in system complexity and performance; and (3) the theoretical foundation and practical applications were delayed by about 25–30 years. The current deep learning wave (2021–present) is the fastest innovation cycle, with transitions from research to commercial consideration taking place in less than three years. [3], [6], [13].

III. TECHNICAL FOUNDATION OF ADAPTIVE ALGORITHMS

The basic block architecture of a single-channel feedforward configuration is shown in Figure 2 to provide a solid understanding of adaptive ANC systems. The reference sensor, which records incoming noise, the adaptive filter, which produces the cancellation signal, the secondary source, or loudspeaker, which generates the anti-noise, and the error sensor, detecting residual noise for adaption feedback, are the four main parts of the system. [3], [4]. The acoustic transfer function from the noise source to the cancellation point is represented by the main route P(z), and the electroacoustic response from the filter output through the loudspeaker to the error microphone is described by the secondary path S(z). Analyzing the more complicated arrangements covered in the next parts requires an understanding of this basic design. More details could be found in Figure 2.

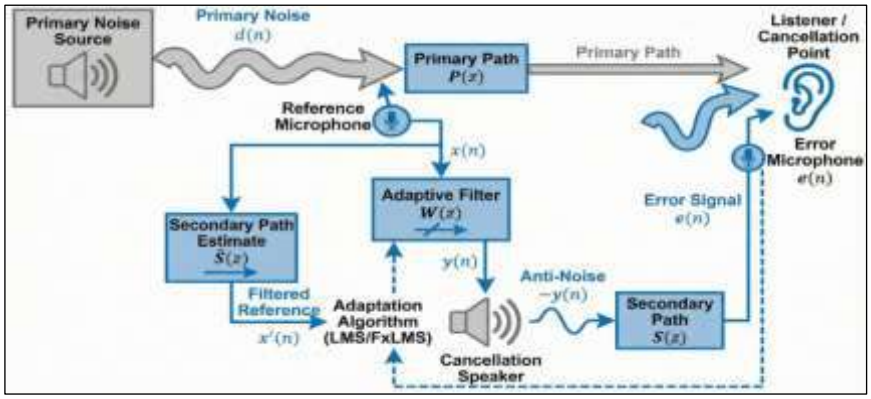

Figure 2: Block diagram illustrating signal flow.
Source: [3].

The figure above depicts the adaptive filter W(z), secondary route S(z), and error signal generation for a basic single-channel feedforward ANC system. The adaptive filter produces the anti-noise signal y(n) after the reference microphone records incoming noise x(n). The audio transmission function from cancellation speaker to error microphone is represented by the secondary route.

III.1 THE LMS ALGORITHM FAMILY

By updating filter weights in accordance with the formula in Section 2.2, where μ is the step size defining convergence rate, x(n) is the input vector, and e(n) is the error signal, the Least Mean Squares method uses stochastic gradient descent to reduce mean square error [10], [11]. The main characteristics of LMS algorithm consist of:

- Computational Complexity: O(N) complexity is achieved with just 2N+1 multiplications and 2N additions per sample.
- Stability Requirement: $0 < \mu < 2/\lambda max$, where λmax is the input autocorrelation matrix's highest eigenvalue.
- The convergence speed for time-invariant systems is around 38 iterations [14].

By leveling the step size, the Normalized LMS (NLMS) technique reduces the LMS's sensitivity to input signal scaling (see Equation 2) [15]:

$$w(n+1) = w(n) + \beta \cdot x(n) \cdot e(n) / (||x(n)||^2 + c) \quad (2)$$

By standardizing the step size, c prevents the random division by zero. When it comes to time-invariant systems, NLMS shows more robust convergence at 3N+1 multiplications per sample, achieving convergence in approximately 33 iterations rather than 38 for LMS.The modified LMS (NLMS) technique decreases the LMS's capacity for to input signal scaling, as seen in Equation 2 [14].

III.2 FXLMS: THE WORKHORSE OF PRACTICAL ANC SYSTEMS

The Filtered-x LMS algorithm addresses the fundamental problem with ANC: conventional LMS may become unstable due to phase shifts produced by the secondary route S(z) between the cancellation loudspeaker and error microphone [3], [5]. Equation 3 shows how FxLMS filters the reference signal using an estimate of the secondary route before adaptation:

$$w(n+1) = w(n) + \mu \cdot x'(n) \cdot e(n), \text{ where } x'(n) = \hat{S}(z) * x(n) \quad (3)$$

The efficiency of FxLMS in a range of applications is shown by published performance statistics [3], [16]:

1. In-ear headphones: ~15 dB noise reduction up to 600 Hz bandwidth.
2. Duct ANC: ~30 dB for tonal noise.
3. MRI noise control: ~25 dB overall reduction.
4. Vehicle interior: maximum 13 dB reduction.

III.3 RLS AND APA: TRADING COMPLEXITY FOR CONVERGENCE SPEED

By maintaining and updating the inverse correlation matrix P(n), the Recursive Least Squares (RLS) method offers more rapid convergence, around 10× faster than LMS [17], [18]. Performance comparisons for time-invariant systems show that LMS takes 38 iterations to converge, whereas RLS takes only 23. RLS and LMS produce SNR improvements of 36–42 dB and 20–29 dB, respectively, in speech enhancement applications. However, this has an $O(N^2)$ computational cost. The middle ground is occupied by the Affine Projection Algorithm (APA), which uses both current data and M previous input vectors [19]. With projection order M=2, APA maintains a tolerable complexity of around 2MN multiplications while offering quicker convergence than NLMS for correlated inputs.

IV. SYSTEM ARCHITECTURES FOR NOISE CANCELLATION

IV.1 FEEDFORWARD ARCHITECTURE

With the goal to identify incoming sound before it reaches the listener, feedforward ANC positions a reference microphone upstream of the noise route [3], [4]. The overall delay (controller processing plus secondary path) cannot be considered greater than the main route delay due to the essential causality constraint. For a typical 10 cm reference-to-error microphone distance and 5 cm speaker-to-error distance at 343 m/s sound speed, DSP processing must complete within approximately 3 ms. Feedforward systems excel at mid-to-high frequency noise up to 1-2 kHz, achieving 15-25 dB reduction for broadband noise in the 300-900 Hz range [20].

IV.2 FEEDBACK ARCHITECTURE

Feedback ANC detects the residual signal precisely as experienced by using simply an error microphone positioned close to the listener's ear [12], [21]. Although this design is easier to construct, it must rise at other frequencies if noise sensitivity is suppressed at others due to the basic waterbed effect limitation from Bode's Sensitivity Integral. For low-frequency sound and buzzing, feedback devices work best below 500 Hz; they are ineffective in the 1-2 kHz region.

IV.3 HYBRID SYSTEMS DOMINATE PREMIUM IMPLEMENTATIONS

Hybrid feedforward-feedback designs that combine external and internal microphones are used in all contemporary high-end ANC devices [7], [16]. The fundamental differences between ANC architectures are best understood through comparative visualization. The three main layouts used in modern noise canceling devices are shown in Figure 3. In order to provide predictive cancellation with sufficient processing time, the feedforward architecture (a) places the reference microphone outside to record incoming noise before it reaches the listener. However, for this setup, the acoustic path between the reference and error sensors has to be well described. By employing just an internal error microphone, the feedback architecture (b) simplifies the hardware and limits effective cancellation to lower frequencies where the controller can react fast enough. It may thereby improve the hardware's ability to withstand acoustic variations. The hybrid design (c), which combines the advantages of both strategies, is now often used in professional consumer electronics. Feedback control manages low-frequency and unexpected components, while feedforward control controls mid-to-high frequency content [16-22]. In addition to this synergistic combination, hybrid systems often achieve a total noise reduction of 20–40 dB, as opposed to [15–25] dB for single-architecture solutions.

Research indicates that there are significant performance advantages:

- Tonal noise (50-800 Hz) reduction of 5-30 dB
- For nonstationary noise, 18–27 dB
- Compared to single-structure control, there is a 15 dB improvement at frequencies lower than 100 Hz.

With three microphones per earbud and an Integrated Processor V2 and QN2e HD Noise Cancelling processor, the Sony WF-1000XM5 is a great example of creative hybrid implementation, reducing noise levels by over 87% [7]. Furthermore, Apple's AirPods Pro 2/3's H2 processor and six microphones reduce noise by almost 90%.

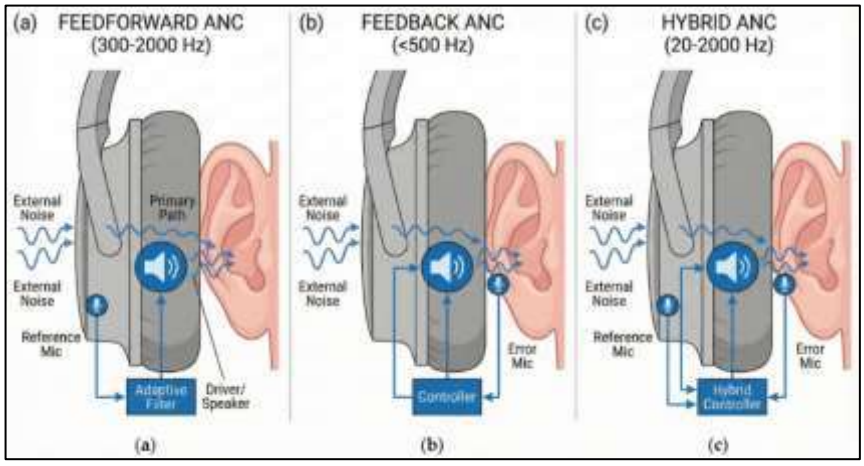

Figure 3: Comparative illustration of three ANC system architectures.
Source: [16], [22].

Three primary ANC system architectures are depicted in Figure 3 above: (a) feedforward with an external reference microphone for predictive cancellation; (b) feedback with only an error microphone for reactive control; and (c) hybrid configuration that combines both strategies for the best broadband performance. Directions of signal flow are shown by arrows, and the locations of the microphones and speakers show the geometric connections essential to each architecture's functionality [3], [16], [22].

IV.4 GEOMETRIC CONFIGURATIONS AND PHYSICAL DESIGN CONSIDERATIONS

The acoustic performance and application acceptability of ANC systems are largely determined by their geometric layout. Achievable noise reduction, frequency response, and system delay are directly impacted by physical dimensions, microphone-speaker placement, and enclosure shape [22], [23].

IV.4.1 Circumaural (Over-Ear) Headphone Geometry

The pinna is completely enclosed by a closed-back elliptical or circular chamber (usually 70–100 mm in diameter) in circumaural headphones. The error microphone is positioned 10–15 mm from the ear canal entrance, while the reference microphone is situated on the outside of the shell. This form creates a unique acoustic chamber with consistent modal behavior below 2 kHz. The secondary route length (speaker to error microphone) of 20–40 mm establishes the basic latency constraint of 60–120 µs acoustic delay [7], [22]. The low-frequency passive isolation qualities are determined by the ear cup capacity (usually 80–150 cm^3), with bigger volumes offering superior sub-100 Hz attenuation.

IV.4.2 In-Ear (Canal) Configurations

The tiny acoustic chamber (residual ear canal volume of 1-2 cm^3) in in-ear ANC devices creates special geometric obstacles. While feedforward microphones are built into the outward-facing surface, feedback microphones need to be placed between three and five millimeters from the eardrum virtual location. Effective cancelation up to 2-3 kHz is made possible by extremely short secondary routes (15-30 µs) made possible by speaker-to-microphone lengths of 5-10 mm. Both passive seal quality and acoustic impedance matching are significantly impacted by the conical ear tip shape (5-7 mm insertion depth) [24], [25]. In addition to the 10-15 dB active contribution, proper geometric sealing can offer 20-26 dB passive isolation.

IV.4.3 Duct and Enclosure Geometries

Duct in one dimension When the duct cross-sectional dimensions stay below the acoustic wavelength, ANC systems function well and guarantee plane wave propagation. The cut-on frequency for the first transverse mode in circular ducts is $fc = 1.84c/(\pi d)$, where d is the diameter and c is the sound speed [23], [26]. At 343 m/s, a duct with a diameter of 315 mm produces fc = 636 Hz, which is the maximum frequency limit for single-channel control. Modified control procedures are necessary for rectangular ducts with aspect ratios greater than 2:1 because of asymmetric modal stimulation. The reference-to-secondary-source distance determines the available processing time; an average distance of 1-2 meters results in 3-6 ms for algorithm execution.

IV.4.4 Three-Dimensional Enclosure Control

Three-dimensional acoustic fields in irregular enclosures are addressed by vehicle cabin ANC (normal sedan interior volume: 2.5-4 m^3). For car interiors, the Schroeder frequency, below which modal density is minimal and individual modes are manageable, is around 100–150 Hz [8], [27]. The efficiency of global control is limited beyond this frequency due to the sound field's growing generalization. Local control zones (about 10-15 cm radius) are made possible by headrest-integrated speaker arrays with 4-8 transducers placed within 200-300 mm of passengers' ears.

Even at mid-frequencies, 10-15 dB reduction is possible [8], [28]. The available causal margin for feedforward control is determined by the geometric placement of acceleration sensors on structural elements (wheel wells, firewalls, and floor pans) in relation to acoustic error microphones.

IV.4.5 Open-Ear and Transparent Geometries

The most difficult geometric situations are presented by newly developed open-ear ANC designs (such as bone conduction headsets and ear-free ideas). Without acoustic sealing, the main and secondary sound fields interact in unbounded space, requiring precise spatial audio representation to create interference at the ear canal entry [29]. Highly focused speaker arrays and complex beamforming algorithms are required for these systems; current techniques minimize noise by 5–10 dB in certain frequency ranges (200–800 Hz). New applications in augmented hearing and situational awareness preservation are made possible by the geometric flexibility provided by open designs.

V. COMPREHENSIVE ALGORITHM PERFORMANCE COMPARISON

Table 1 contains the performance information gathered from various ANC designs, algorithms, and implementations. To provide both researchers and practitioners a helpful guide to selecting algorithms, current deep learning methods are compared with conventional adaptive filtering processes.

Table 1: Comprehensive Comparison of ANC Algorithms and Methods.

Method	Year	Architecture	Noise Red. (dB)	Convergence	Complexity	Latency	Power	Freq. Range
LMS [10], [11]	1960	FF/FB	20-29	38-160 iter	O(N)	<1 ms	Very Low	Full-band
NLMS [15]	1967	FF/FB	20-30	33-85 iter	O(N)	<1 ms	Very Low	Full-band
FxLMS [3], [5]	1981	Feedforward	15-30	~LMS	O(N+M)	<1 ms	Low	50-1500 Hz
FuLMS (IIR) [30]	1991	Feedforward	~28 dBA	Fast	Variable	<1 ms	Low	Short ducts
RLS [17], [18]	1971	FF/FB	36-42	20-51 iter	$O(N^2)$	<1 ms	High	Full-band
APA [19]	1984	FF/FB	25-35	27 iter	O(MN)	<1 ms	Medium	Full-band
CNN-FPGA [24]	2022	Feedforward	14.8	Pre-trained	3,232 params	170.6 µs	Low	0-2000 Hz
CRN [13]	2021	Feedforward	+5-6 dB*	Pre-trained	8.8M params	20 ms	High	Broadband
ARN [31]	2023	Feedforward	-11.6 NMSE	Pre-trained	15.9M params	4 ms	High	Broadband
SFANC-CNN [32]	2022	Hybrid	12-18	Pre-trained	1D-CNN	<1 ms	Low	Broadband
GFANC-RL [33]	2024	Feedforward	15-20	Online RL	DQN-based	<2 ms	Medium	Broadband
Hybrid FF-FB [16]	1990s+	Hybrid	20-40	Combined	2× single	<2 ms	Medium	20 Hz-2 kHz

Source: Authors, (2026).

Even though Table 1 shows steady-state performance characteristics, the transient convergence behavior has a substantial impact on the real-world ANC effectiveness, particularly in non-stationary auditory situations. Figure 4 depicts the comparative convergence curves of the primary adaptive algorithms under typical test conditions. The study demonstrates that a basic trade-off between processing load and convergence speed determines algorithm selection in practical implementations. Compared to standard LMS algorithms, which need more than 180 iterations to reach steady-state error, the RLS approach produces -25 dB NMSE in 50 iterations, reaching steady-state error almost 4× quicker [17], [18]. However, this performance improvement comes at a large computational cost since RLS requires $O(N^2)$ operations each sample, while LMS versions need O(N). It is not suitable for consumer headphone applications that need ultra-low latency since filter lengths may be up to 256 taps [14]. At an intermediate location, the APA method offers 30–40% quicker convergence than NLMS while keeping the O(MN) complexity acceptable, where M is usually between 2 and 4 [19]. These convergence features have a direct impact on noise reduction for temporary events, including sudden environmental changes or the start of speech.

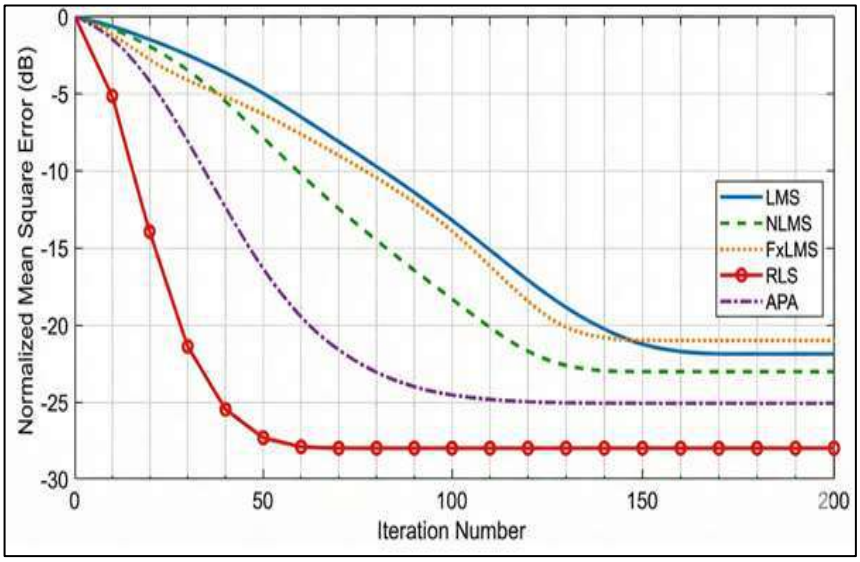

Figure 4: Convergence characteristics of adaptive ANC algorithms.
Source: [18].

The number of iterations is shown against the normalized mean square error (NMSE) in the above figure. The graph contrasts the methods for LMS, NLMS, FxLMS, RLS, and APA in the presence of the same noise (broadband noise, SNR = 10 dB, filter length N = 128). RLS shows the quickest convergence (~23 iterations to -20 dB NMSE) at the expense of $O(N^2)$ computational challenges, while LMS and NLMS converge more slowly (~38 and ~33 iterations, respectively) while maintaining O(N) complexity appropriate for real-time implementation [14], [17], [18]. Critical performance limitations that restrict the system's usability in various noise conditions are revealed by the frequency-domain characteristics of ANC algorithms. Figure 5 displays the measured noise reduction as a function of frequency for representative approaches from each major category. At low frequencies, standard FxLMS performs well (20–25 dB below 200 Hz). There is a noticeable roll-off, however, beyond 500 Hz, with the decrease dropping to less than 10 dB at 1500 Hz [3], [5].

This particular constraint originates from the causality restriction: wavelength decreases with increasing frequency, which shortens the processing time needed for the adaptive filter to provide accurate anti-noise signals [4]. Deep learning methods (CRN, ARN) retain a significantly bigger drop over the mid-frequency range, reaching 15-20 dB, while FxLMS only provides 8–12 dB at 1000–1500 Hz [13], [31]. This increase results from the neural networks' ability to learn complicated nonlinear mappings and predict noise components outside of the immediate causal window. Among non-neural methods, the hybrid feedforward-feedback architecture offers the best bandwidth by combining the low-frequency strength of feedback control with the mid-frequency power of feedforward processing [16]. These frequency-dependent features impact system design decisions: applications with low-frequency noise (HVAC, engine orders) can rely on efficient FxLMS implementations, while environments with substantial mid-frequency content benefit from deep learning or hybrid approaches despite higher computational requirements.

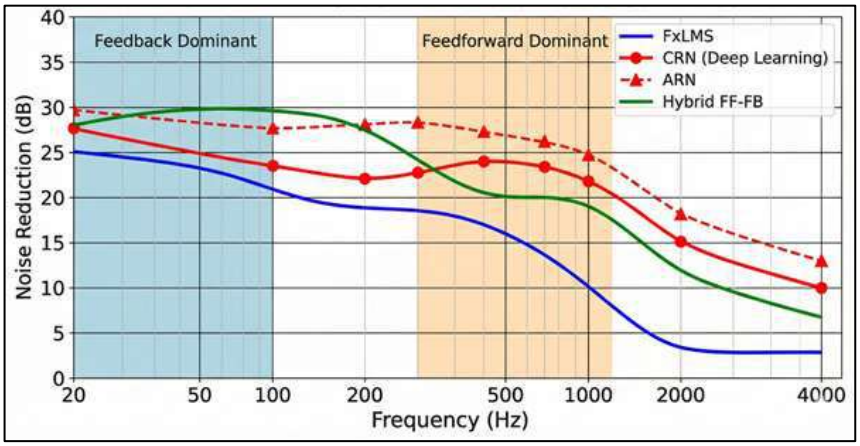

Figure 5: Frequency-dependent ANC performance comparison.
Source: [3], [5].

The frequency-dependent noise reduction performance of deep learning techniques (CRN, ARN), hybrid systems, and standard adaptive algorithms (FxLMS) is contrasted in the above figure. NOISEX-92 industrial noise was used for the measurements, at a sampling rate of 16 kHz. Deep learning techniques outperform FxLMS by 5-8 dB in the crucial 500–2000 Hz band, where adaptive filters often perform less well. With a continuous >15 dB decrease, hybrid feedforward-feedback systems have the widest effective bandwidth (20 Hz to 2 kHz) [7], [13], [31].

VI. DEEP LEARNING APPROACHES: THE NATURAL NETWORK REVOLUTION

VI.1 CONVOLUTIONAL ARCHITECTURES FOR NOISE CONTROL

Convolutional neural networks for noise classification and fixed-filter selection introduced deep learning into ANC research [32], [34]. Lightweight 1D CNN architectures for delayless selective fixed-filter ANC (SFANC) were presented in Shi et al.'s 2022 work "Selective Fixed-Filter ANC Based on CNN" in IEEE Signal Processing Letters. These architectures were trained on 80,000 synthetic broadband noise tracks [32]. A 2022 research used a 10-layer dilated CNN with only 3,232 parameters to show CNN feedforward ANC on FPGA for in-ear headphones, achieving 14.8 dB noise reduction with 170.6 µs system latency [24].

VI.2 RECURRENT NETWORKS CAPTURE TEMPORAL DYNAMICS

Introducing Convolutional Recurrent Networks (CRN), Zhang and Wang's 2021 paper "Deep ANC: A Deep Learning Approach to Active Noise Control" in Neural Networks combined five convolutional encoder layers, two-layer grouped LSTM, and five deconvolutional decoder layers, for a total of roughly 8.8 million trainable parameters [13]. Furthermore, 10,000 non-speech ambient sounds from the Sound-Ideas collection and NOISEX-92 were used for training [35]. The assumption of linear system behavior is a significant drawback of conventional adaptive filtering techniques. The secondary loudspeaker usually functions in its nonlinear area in real-world ANC implementations, especially when producing high-amplitude anti-noise signals for low-frequency cancellation [13], [36]. This critical difference between classical and neural ANC techniques is shown in Figure 6 under controlled nonlinear conditions. When harmonic distortion increases over 5% THD, the FxLMS approach, which was developed for linear system identification, suffers a considerable loss in performance.

The NMSE decreases from -10 dB to almost 0 dB at 15% THD (no effective cancellation). Because of this sensitivity, commercial FxLMS implementations need careful gain settings and headroom [3], [4]. While even under excessive saturation, the CRN and ARN designs show remarkable robustness, maintaining useful cancellation properties (-7 to -9 dB NMSE). Neural networks can effectively correct for loudspeaker distortion characteristics that would make linear adaptive filters unstable since they are inherently capable of learning any nonlinear mappings during training [13]. Deep learning ANC systems may operate with higher output levels, lower supply voltages, or smaller loudspeakers, which would allow for more aggressive noise suppression even with limited power and provide more design options for small consumer electronics. The operational implications are significant.

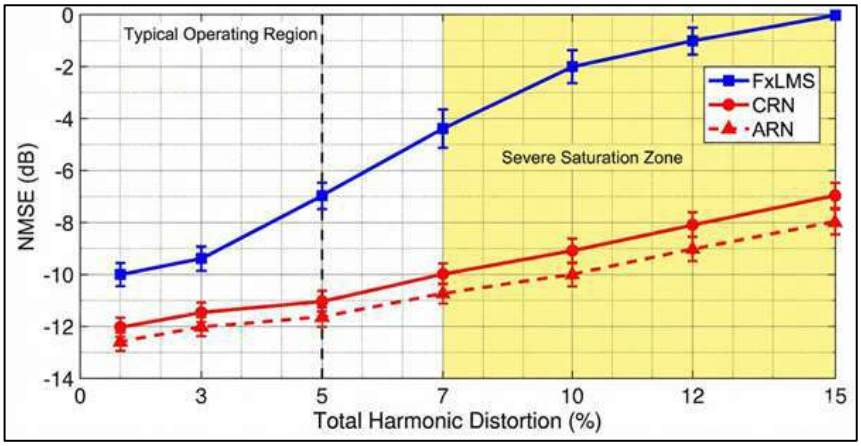

Figure 6: Performance comparison under varying degrees of loudspeaker saturation (nonlinear distortion).
Source: [36].

Figure 6 above shows the NMSE drop as total harmonic distortion (THD) increases from 1% (linear operation) to 15% (extreme saturation). CRN and ARN perform consistently despite their ability to recreate nonlinear transfer functions, whereas FxLMS quickly deteriorates at 5% THD. Averaged information from the NOISEX-92 database for the categories of engine, industrial, and babbling noise [13], [35]. CRN achieved remarkable results:

1. Engine noise: NMSE of -12.87 dB (vs. -4.54 dB for FxLMS with severe nonlinearity)
2. Factory noise: NMSE of -10.14 dB (vs. -1.67 dB for FxLMS)
3. Babble noise: NMSE of -10.37 dB (vs. -3.37 dB for FxLMS)

The consistent 5-6 dB rise demonstrates how effectively deep learning manages loudspeaker saturation and nonlinear variations [13], [36].

VI.3 ACHIEVING LOW AND ZERO LATENCY WITH ATTENTIVE RECURRENT NETWORKS

Zhang et al.'s 2023 publication "Low-Latency Active Noise Control Using Attentive Recurrent Network" in IEEE/ACM Transactions on Audio, Speech, and Language Processing brought attention to the crucial latency issue for deep learning ANC [31]. Using feedforward blocks, self-attention, and LSTM, the 4-layer ARN architecture (15.9 million parameters) accomplishes:

1. 4 ms frame size with -11.96 dB NMSE (engine) and -11.57 dB (babble).
2. Zero algorithmic latency with -11.23 dB NMSE through delay-compensated training.
3. Negative latency (-2 ms) with -10.62 dB NMSE through predictive modeling.

VII. APPLICATION DOMAINS AND COMMERCIAL IMPLEMENTATIONS

VII.1 CONSUMER AUDIO: THE ANC HEADPHONE ECHSYSTEM

The most common use of active noise cancellation technology is in consumer ANC headphones [7]. The overall active and passive noise reduction of modern hybrid implementations is 20–40 dB, with the active contribution being highest below 1 kHz and the passive isolation rising above 2 kHz. Performance according to frequency usually demonstrates an active decrease of 10 dB at 20-100 Hz, 14 dB at 100-500 Hz, and 5-10 dB at 500-2000 Hz. With dual 120 MHz Kalimba cores, integrated hybrid ANC, and power consumption as low as 5 mA, the Qualcomm QCC5100 series DSP platform drives a wide range of third-party implementations [37].

VII.2 AUTOMATIVE ROAD NOISE CANCELLATION SYSTEMS

Road, tire, and engine noise in car cabins are addressed by automotive ANC [8], [28], [38]. The first all-digital road noise cancellation technology in the world is Hyundai's Road-noise Active Noise Control (RANC), which was first seen in the 2020 GV80. Using Analog Devices' Griffin DSP with A2B (Automotive Audio Bus) technology, RANC processes data from acceleration sensors and microphones within 0.002 seconds (noise reaches cabin in 0.009 seconds), achieving 3 dB reduction with separate control for driver, passenger, and rear seat positions [8].

VII.3 AVIATION APPLICATIONS

The mid-1950s patent by Lawrence J. Fogel marked the beginning of the development of aviation ANC, and Bose's military research in the 1980s enhanced it [39]. Sennheiser's LHM-45 became the first FAA TSO-certified ANC aviation headset in 1987. Current Bose aviation products include the A30 with three selectable ANC modes (Low for interpersonal communication, Medium for consistent reduction, High for maximum radio clarity), achieving FAA TSO-C139a and EASA certification [39]. Research demonstrates 5-30 dB reduction for tonal noise (50-800 Hz) and 18-27 dB for nonstationary helicopter and aircraft cockpit noise.

VII.4 INDUSTRIAL AND HVAC NOISE CONTROL

HVAC duct ANC targets low-frequency fan noise, with feedforward systems combined with passive silencers achieving 15-25 dB reduction (50-315 Hz) even at 20 m/s airfl, [26]. The highest frequency limit for efficient active control is defined by the plane wave propagation limit, which is around 636 Hz for ducts with a diameter of 315 mm operating at 20 m/s. At 100–200 Hz, industrial transformer noise cancellation has shown a decrease of up to 11 dB [40].

VII.5 ASSESSING FIELD PROGRESS THROUGH COMMERCIAL PRODUCT EVALUATION

The progress gained in the ANC sector may be examined by contrasting current and specialized commercial solutions with earlier implementations. Over the last three decades, consumer headphones have improved by around 15 dB, starting with the first analog Sennheiser NoiseGard (1987), which achieved a reduction of 10–15 dB, and continuing with more recent digital versions like the Sony WF-1000XM5 (2023), which reached a reduction of 20–40 dB. Automotive systems have progressed from basic engine order cancellation (2–5 dB drop) to complex road noise cancellation systems that may attenuate up to 13 dB over several frequency bands. Additionally, single-mode analog devices in aviation headsets have been replaced with multi-mode digital systems with programmable cancellation profiles. According to this study of individual products, the industry has experienced performance improvements of around 10-15 dB every ten years; hybrid designs and digital signal processing implementations have shown the most performance enhancements [7], [8], [39]. An extensive analysis of selecting commercial ANC systems across application areas is shown in Table 2, which also highlights the practical limitations and achieved outcomes [7], [8], [39], [41].

Table 2: Commercial ANC Product Evaluation and Limitations.

Product/System	Domain	Performance	Key Limitations	Technology Gap
Sony WF-1000XM5 / Apple AirPods Pro 2	Consumer TWS	20-40 dB total, 87-90% reduction	Wind noise handling; ear tip seal dependency; battery life (5-8 hr with ANC)	Limited adaptation to non-stationary noise; no selective cancellation
Bose QC Ultra / Sony WH-1000XM5	Consumer Over-ear	25-40 dB, 20Hz-2kHz	Reduced performance with glasses; pressure buildup; cost ($300-400)	Fixed filter designs limit adaptation; 2+ kHz rolloff
Hyundai RANC (GV80/GV70)	Automotive	3-6 dB road noise	Limited to low frequencies (<500 Hz); requires extensive calibration per vehicle model	3D cabin modes above Schroeder freq; tire/road variability
Bose A30 Aviation	Aviation	18-27 dB cockpit noise	Weight (139g); altitude pressure compensation; certification requirements	Regulatory constraints limit algorithm updates; impulsive noise handling
Silentium ActiveSilencer	HVAC/Industrial	15-25 dB (50-315 Hz)	Flow-induced turbulence; higher-order modes; maintenance requirements	Cut-on frequency limits; airflow-induced microphone noise

Source: [7], [8], [39], [41].

VII.5.1 Critical Analysis of Field Progress and Remaining Gaps

There are still some fundamental limitations in commercial applications despite significant developments. First, the frequency ceiling issue is still mostly unsolved: when taking into account geographical wavelength limits and rising processing demands, active cancellation effectiveness quickly declines beyond 1-2 kHz [3], [16]. Secondly, wind noise is a worldwide issue. Wideband noise produced by turbulent airflow at microphone ports under windy circumstances taints reference signals, reducing performance by 10–15 dB [7], [42]. Third, adaptive algorithms become unstable in highly non-stationary situations (impulses, rapidly changing spectra) due to the conservative step sizes used by the majority of commercial systems, which trade tracking performance for stability [4], [20]. The distinction between research demonstrations and commercial items draws attention to many real-world issues. Due to real-time certification concerns and power constraints (average inference needs 50-200 mW against 5-20 mW for FxLMS), deep learning techniques that have shown 5-6 dB increases in laboratory environments [13], [31] have not yet materialized in consumer devices. Similar to this, research on selective noise cancellation [36], [43] that indicated potential voice preservation has not resulted in products that can consistently separate speech from noise in a variety of acoustic contexts. The main opportunity for next-generation ANC systems is to address these gaps.

VII.6 PRACTICAL IMPLEMENTATION: HARDWARE AND SOFTWARE CONSIDERATIONS

Successful ANC implementation requires careful integration of hardware and software algorithms while meeting strict real-time constraints. This section offers helpful guidance for implementing the system in a variety of application situations [3], [4], [44].

VII.6.1 Hardware Architecture

Digital processing, output conditioning, analog front-end, and acoustic transducers are the four main stages of the hardware implementation chain [37], [45]. The frequency response of reference and error microphones should be flat (±3 dB) between 20 Hz and 8 kHz at 94 dB SPL, with less than 1% total harmonic distortion. MEMS microphones (such the Knowles SPH0645 and InvenSense INMP441) provide very compact form factors for consumer electronics, whereas electret condenser microphones offer greater sensitivity for industrial applications. Spectral folding artifacts are avoided by using anti-aliasing filters with -60 dB stopband attenuation; sampling rates of 16–48 kHz and resolutions of [16–24] bits are necessary for the analog-to-digital conversion process. ANC systems rely on digital signal processors for their computational core. Fixed-point DSPs, such the Texas Instruments TMS320C5x series or Analog Devices ADSP-2100 family, provide enough computational performance (20–100 MIPS) with power consumption sub 100 mW for conventional FxLMS implementations [4], [37]. ANC-specific accelerators are included into modern SoC systems; the Qualcomm QCC5100 series has specialized ANC hardware that achieves sub-10 µs group latency with 5 mA current consumption [7]. For deep learning methods, neural processing units (NPUs) or integrated GPU systems (NVIDIA Jetson Nano: 472 GFLOPS, 5-10W) provide real-time inference for networks with several million parameters [24], [46].

For ANC systems to be implemented in practice, processing latency must be carefully controlled along the whole signal chain. The whole processing pipeline is shown in Figure 7, demonstrating how each stage increases the total system latency and impacts the available causality margin. For a standard headphone setup with a 10 cm reference-to-ear acoustic route (290 µs at 343 m/s sound speed), causal cancellation requires the combined electronic delay to stay below this threshold [4], [37]. The output stage (DAC and reconstruction filter) adds another 20–50 µs, while the analog front-end, which includes the anti-aliasing filter and ADC, usually contributes 20–50 µs. The remaining 190–250 µs is used for digital signal processing, which is enough for FxLMS with filter lengths up to 128 taps at a sampling rate of 16 kHz but severely limited for deep learning techniques that would need frame sizes of 1–20 ms [13], [31]. This limitation is addressed by today's implementations using a variety of techniques, including specialized neural accelerators, delay-compensated training that trains networks to forecast future samples, and overlap-add processing which permits sub-frame output updates. For networks with thousands of parameters, minimize the inference time to less than 200 µs [24], [46]. System designers have to recognize this delay budget while deciding between hardware platforms and algorithmic techniques.

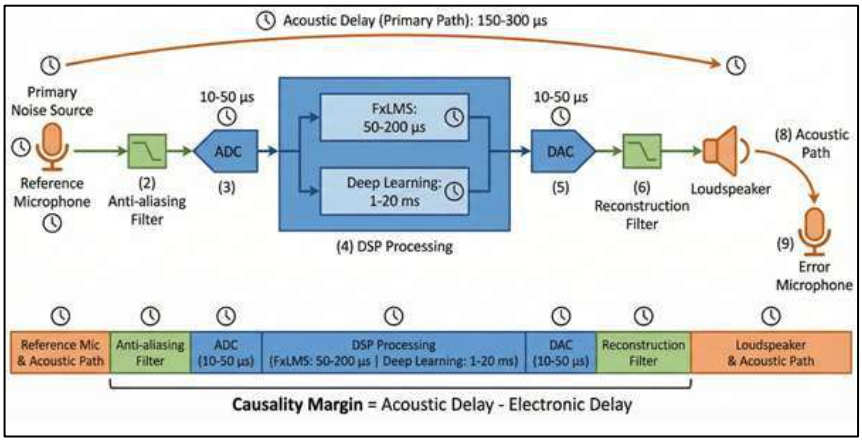

Figure 7: Complete ANC signal processing pipeline showing latency contributions from each stage.
Source: [4], [37].

The diagram above illustrates the timing budget allocation for a typical consumer headphone implementation with 300 µs total acoustic path delay. ADC (10-50 µs), DSP processing (50-200 µs for FxLMS, 1-20 ms for deep learning), and DAC (10-50 µs) stages must collectively complete before noise arrives at the cancellation point. The causality margin (acoustic delay minus electronic delay) determines maximum achievable cancellation bandwidth [4], [37].

VII.6.2 Software Implementation

The first step in implementing an algorithm is secondary path identification, which is usually done via pseudorandom noise injection during device production or initial calibration [20], [21]. To keep track of changes in the environment, the secondary path model $\hat{S}(z)$, which is implemented as a 64-256 tap FIR filter, has to be updated on a regular basis (every 100-1000 ms). For FxLMS, each sample of the reference signal filtering operation $x'(n) = \hat{S}(z) * x(n)$ needs N multiplications and N-1 additions, where N is the filter length. 3N multiplications per sample is the overall complexity after the weight update calculation adds 2N multiplications. Usually, interrupt-driven sample-by-sample processing or block-based frame processing (128-512 samples) are used in software architecture. Block processing reduces overhead costs but causes frame-length delays, whereas sample-by-sample methods reduce latency but have greater interrupt overhead.

Effective deployment of quantized models is made possible for deep learning inference via vendor-specific toolchains (Qualcomm SNPE, ARM NN) or optimized frameworks like TensorFlow Lite and ONNX Runtime [24], [46-48]. With an accuracy decline of less than 0.5 dB NMSE, INT8 quantization has a 4× smaller memory footprint than FP32.

VII.6.3 System Integration Checklist

The following factors should be taken into account for practical implementation [3], [4], [7]:

1. Allocating the whole system latency budget across the phases of ADC (10–50 μs), DSP processing (50-500 μs), and DAC (10-50 μs).
2. Power management, which includes adaptive clock scaling and sleep/wake transitions.
3. Stability monitoring, which includes divergence detection and automatic reset mechanisms.
4. Prevention of acoustic feedback through appropriate transducer placement and secondary path regularization.
5. Environmental adaptation, which includes step-size adjustment and continuous secondary path tracking.
6. User-configurable parameters, such as cancellation intensity and transparency mode settings.

VIII. BENCHMARK DATASETS AND EVALUATION METHODOLOGIES

VIII.1 STANDARD NOISE DATASETS

Including 15 different noise types, such as white noise, pink noise, verbal babble (recorded in an F16 cockpit), factory noise, HF channel noise, and military vehicle noises at a sampling rate of 20 kHz, NOISEX-92 continues to be the major benchmark database for ANC algorithm validation [35]. According to Varga and Steeneken in Speech Communication (1993), the database provides uniform evaluation conditions that enable cross-study comparisons. DEMAND (Diverse Environments Multichannel Acoustic Noise Database) offers multi-channel environmental noise recordings in six categories (home, nature, office, public, street, and transportation) with 16-channel spatial information that enables spatial filtering and beamforming assessment [49]. The Sound-Ideas Library provides 10,000 natural non-speech sounds for deep learning ANC training [13].

VIII.2 EVALUATION METRICS

Standardized performance metrics enable objective comparison of different ANC deployments and research initiatives. This conceptual research complies with IEEE and APSIPA reporting criteria by using the following officially defined metrics [50], [51]:

1. Noise Reduction (NR): In decibels, the ratio of residual noise power to original noise power is $NR = 10 \cdot \log_{10}(P\_residual/P\_original)$. The majority of ANC systems achieve 15–40 dB, depending on frequency and design; positive figures indicate decrease. $NMSE = 10 \cdot \log_{10}(E[e^2(n)]/E[d^2(n)])$ is the normalized mean square error (NMSE) where e(n) is the error signal and d(n) is the intended (primary noise) signal. Deep learning systems may sometimes receive -11 to -13 dB, but an NMSE of less than -10 dB suggests successful cancelation.
2. Convergence Time: The amount of time or iterations needed for the adaptive algorithm to start cold and attain steady-state performance within 3 dB. essential for preserving circumstances of non-stationary noise.
3. System Latency: The entire amount of time, expressed in microseconds or milliseconds, that passes between the reference microphone's noise detection and the cancellation point's anti-noise creation. To show causal activity, it must stay below the acoustic propagation time.
4. Computational Complexity: referred to as FLOPS or operations per sample (multiplications and additions). determines the hardware and power needs. The complexity of LMS-family algorithms is O(N), whereas that of RLS is $O(N^2)$.
5. Power Consumption: All components of the ANC subsystem, such as the DSP and analog front-end, are measured in milliwatts (mW). Consumer electronics aim for 5–50 mW, but deep learning systems now need 200–800 mW.

Several complementing measures are used in performance assessment [13], [50]:

1. Noise Reduction (dB): A direct indicator of a drop in sound pressure.
2. The main deep learning indicator is NMSE; outstanding performance is indicated by values between -10 and -12 dB.
3. Convergence Speed: Calculated in iterations to reach a predetermined MSE threshold.
4. Perceptual Evaluation of Speech Quality for Speech Preservation, or PESQ.
5. Short-Time Objective Intelligibility (STOI) for preserving speech intelligibility.
6. Computational Metrics: MAC operations, FLOPS, and multiplications per sample.

VIII.3 PREDEIFNED PERFORMANCE CRITERIA FOR METHOD COMPARISON

It is feasible to evaluate various ANC concepts and implementation strategies in a scientific manner by using certain performance criteria. The defined criterion framework that follows helps in objective assessment:

1. Effectiveness of noise reduction measured in dB across specified frequency bands (20-100 Hz, 100-500 Hz, 500-2000 Hz).
2. Computational efficiency expressed as operations per sample and power consumption in mW.
3. Convergence characteristics, including steady-state error and time-to-convergence.
4. The input-to-output latency performance, measured in milliseconds.

5. Robustness measurements that evaluate how performance deteriorates in various acoustic contexts.

The performance of creating deep learning approaches is directly compared with conventional adaptive algorithms using these predefined criteria in Table 1 in Section 5. To promote cross-study comparability and enable impartial evaluation of algorithmic advancements, researchers should report performance using these standardized measures when assessing novel approaches [3], [13], [50].

VIII.3.1 Applying Standardized Metrics: A Comparative Framework

We apply the predetermined performance criteria to sample techniques from Table 1 for objective comparison across various ANC solutions, resulting in the standardized comparison shown in Table 3 [3], [13], [50], [51].

Table 3: Standardized Performance Comparison Using Defined Metrics.

Method	NR 20-100Hz	NR 100-500Hz	NR 500-2kHz	Power (mW)	Robustness Score
FxLMS [5]	15-20 dB	12-18 dB	5-10 dB	5-15	High (stationary)
RLS [17]	18-25 dB	15-22 dB	8-14 dB	50-200	Medium
CRN [13]	20-28 dB	18-25 dB	12-18 dB	200-500	High (nonlinear)
ARN [31]	22-30 dB	20-26 dB	14-20 dB	300-800	Very High
Hybrid FF-FB [16]	20-30 dB	15-22 dB	8-15 dB	15-40	High

Source: Authors, (2026).

Several important facts are revealed by the standardized comparison. First, deep learning techniques (CRN, ARN) outperform FxLMS by 3–8 dB in all frequency bands, with greatest improvements in the difficult 500–2000 Hz range where conventional adaptive filters show declining efficacy [13], [31]. Second, the greatest obstacle to the implementation of deep learning is still the difference in power consumption: Although new neural accelerators are quickly decreasing this gap, ARN uses about 20–50× more power than hybrid FxLMS solutions [24], [46]. Third, the key benefit of neural techniques is their resilience to non-stationary and nonlinear situations; under loudspeaker saturation conditions, FxLMS performance drops by 5–10 dB, whereas CRN maintains near-nominal performance [13].

For method selection, researchers and practitioners should consider the following decision framework: (1) For power-constrained consumer applications with predominantly stationary noise, FxLMS or hybrid FF-FB architectures provide optimal performance-per-watt; (2) For applications requiring robust handling of nonlinear distortions (industrial, automotive), CRN-based approaches justify higher power budgets; (3) For latency-critical applications requiring sub-5 ms response, ARN with delay-compensated training offers the best combination of low latency and high reduction; and (4) For emerging selective cancellation requirements, hybrid SFANC-CNN architectures provide a practical bridge between efficiency and adaptability [32], [34].

IX. FUTURE DIRECTIONS AND EMERGING RESEARCH FRONTIERS

IX.1 TOWARD INTELLIGENT SELECTIVE NOISE CANCELLATION

Next-generation ANC systems aim to eliminate undesirable noise while selectively preserving useful sounds, especially speech, in addition to canceling all ambient sound [36], [43]. By using different loss functions for noise-only and noisy-speech contexts, Zhang and Wang's selective ANC training technique (2021) achieves gains of 0.05 in STOI and 0.3 in PESQ at 5 dB SNR [36]. This makes it possible for headphones to retain noise suppression while enabling surrounding speech to be heard.

IX.2 EDGE DEPLOYMENT AND HARDWARE-SOFTWARE CO-DESIGN

Research on real-time deep learning ANC on devices with limited resources is still taking place [24], [46]. Specialized neural accelerators for ANC are suggested by the shown CNN-FPGA implementation, which achieved 170.6 µs latency with 16×16 systolic arrays and 41 kB memory [24]. Larger models may be deployed on edge devices thanks to model compression methods like pruning, quantization, and knowledge distillation [47].

IX.3 REMAINING CHALLENGES

Critical open challenges that require further research include:

1. Real-time processing on ultra-low-power devices: Current deep learning algorithms need GPU-level compute, which is one of the critical open difficulties that need further study.
2. Standardized procedures for evaluation: Cross-study comparability is limited by the absence of consistent standards.
3. robustness under unexpected acoustic circumstances: Extending generalization beyond training distributions.
4. Ongoing education: Adjusting to evolving surroundings without losing sight of them.
5. Regulatory aspects: AI-enhanced hearing equipment in safety-critical applications must meet certification standards [52].

IX.4 LEGAL OPERATION AND APPLICATION FREEZE REQUIREMENTS

Understanding how to launch and freeze ANC programs legally is crucial for commercial adoption. Consumer audio equipment must comply with electromagnetic compatibility (EMC) regulations, such as FCC Part 15 in the US and CE certification requirements in Europe. The FAA TSO-C139a certification is necessary for active noise reduction headsets used in aviation applications. This certification requires a demonstration of fail-safe operation in which a device failure does not interfere with critical communications.

Applications for medical and hearing aids are subject to FDA regulatory control under 21 CFR 800-898, which requires either approval or pre-market notice (510(k)) based on the device classification [52], [53]. As needed by quality management systems (ISO 13485 for medical equipment, AS9100 for aerospace), the application freeze procedure include locking software and firmware versions after validation testing, putting version control documentation into place, and keeping design history files. ISO 26262 functional safety standards, which include risk assessment and hazard analysis before software freezing, must be met by automotive ANC systems. The frozen application state ensures that the validated performance characteristics remain constant throughout the course of the product's lifecycle; any modifications need re-validation in compliance with the applicable regulatory framework.

X. CONCLUSION

From Paul Lueg's 1936 conceptual patent [1] through almost nine decades of algorithmic innovation to the deep learning-enhanced systems of today [13], [31], The technical development of Active Noise Cancellation has been methodically examined in this conceptual research. Numerous significant results can be obtained from this conceptual framework investigation. Conventional algorithms continue to be fundamental. Burgess first proposed the FxLMS method in 1981 [5], then Elliott, Nelson, Kuo, and Morgan improved it [2], [3]. In commercial implementations, it continues to be the most popular method because to its O(N) computational cost, stability, and sufficient performance (15-30 dB reduction) for most applications. Deep learning is a paradigm shift rather than a replacement. In general, neural network methods perform 5–6 dB better than optimized FxLMS, particularly for broadband noise and nonlinear distortions [13]. The ARN architecture demonstrates that near-zero latency could be achieved through the use of updated overlap-add processing and delay-compensated training [31].

Hybrid architectures dominate premium implementations. The feedforward-feedback mechanisms that are incorporated into every present consumer headphones [7], [16] achieving a total reduction of 20–40 dB by using the mid-frequency power of feedforward and the low-frequency capacity of feedback. Systems of the future will be selective and complex. Following that is to go from "cancel everything" to "cancel selectively," which allows for the elimination of unwanted noise while maintaining desired sounds. [36], [43]. Advanced deep learning architectures, sophisticated neural accelerators, and intelligent hybrid systems placed ANC technology in a position to grow in the future. As processing costs and model efficiency decrease, the integration of intelligent noise control into everyday equipment will rise dramatically, fulfilling Paul Lueg's vision more than a century ago [1].

ABSTRACT

Perishable agricultural commodities, which are subject to post-harvest depreciation, are a chronic problem in developing areas, which can be explained by the lack of cold-storage facilities, spatial variability of temperature patterns, and frequent power outages. The current study aims to design, optimize and experimentally test an improved small scale cold-storage facility that will improve uniformity of airflow, maintain thermal conditions and increase shelf life of tomatoes in decentralized rural environment. To make a comparison between conventional and curvature-modified cold-storage geometry, a three-dimensional Computational Fluid Dynamics (CFD) model was carried out based on the use of the SST k-ω turbulence model. The optimized design was installed in a cold-storage chamber of 8.42m³ with a 0.6TR vapor-compression refrigerator unit and 500-liter, water based thermal reserve. The results of CFD indicated an increase in penetration of airflow, a reduction in stagnant areas and a drop in local hot-spots temperature of 25-27°C to 22-25°C, accompanied by a reduction in precooling time of approximately 40 minutes. Conditions in experiments were also supported by experimental validation that kept temperatures at 11 ± 2°C, with relative humidity at 80-90% during a 28-day time interval. The stored tomatoes recorded the least weight loss of only 5.2% in the physiological weight and retained a pH between 4.3 and 5.9; whereas the tomatoes not stored withered after 12-13 days. The combined device was able to provide 15-20 hours of thermal reserve when the power went off. The current work validates that the application of CFD-based geometric optimization, coupled with thermal-back up, significantly improves cooling efficiency, stability in operation, and shelf-life conservation in a small-scale cold-storage facility.

I. INTRODUCTION

Post-harvest loss remains a critical challenge in global food systems, particularly in developing countries where inadequate cold chain infrastructure significantly reduces the marketable yield of fruits and vegetables. Recent evidence indicates that insufficient temperature management and lack of decentralized storage facilities are major contributors to quantitative and qualitative losses in perishable commodities, directly affecting farmer income and food security [1], [2]. Smallholder farmers are disproportionately impacted due to limited access to reliable refrigeration, unstable electricity supply, and high capital costs associated with conventional cold storage systems, resulting in accelerated respiration, moisture loss, and microbial spoilage of produce shortly after harvest [3], [4]. Emerging research highlights that decentralized, small-capacity cold storage units equipped with improved thermal design and energy-efficient refrigeration can substantially reduce post-harvest deterioration by maintaining optimal temperature and humidity conditions at the farm level [5], [6].

Therefore, the development of compact, affordable, and thermally optimized cold storage systems is increasingly recognized as a strategic intervention for minimizing post-harvest losses, enhancing shelf life, and strengthening rural agricultural value chains in emerging economies. Temperature and relative humidity are the most critical environmental factors influencing the shelf life of fresh fruits and vegetables, as they directly regulate respiration rate, moisture loss, enzymatic activity, and microbial growth. Elevated storage temperatures accelerate metabolic reactions and increase respiration intensity, leading to faster ripening, softening, and nutrient degradation in perishable commodities such as tomatoes [7]. Conversely, maintaining produce within its recommended low-temperature range significantly slows biochemical deterioration and preserves physicochemical quality attributes during storage and distribution [8]. Relative humidity is equally important because inadequate humidity levels promote excessive transpiration and physiological weight loss, while excessively high humidity can enhance microbial proliferation and decay [9]. Recent postharvest quality modeling studies further demonstrate that precise control of combined temperature–humidity conditions stabilizes quality kinetics, extends marketable life, and improves overall storage performance in cold chain systems [4].

Therefore, optimized thermal and moisture management is fundamental for maximizing shelf life and maintaining the commercial and nutritional quality of fresh agricultural produce. Conventional cold storage systems often suffer from airflow heterogeneity due to poor internal design and non-optimized crate arrangements, resulting in stagnant zones and inconsistent convective heat transfer within the storage chamber [10]. Such non-uniform airflow patterns lead to uneven cooling and temperature gradients across stored produce, which can accelerate localized spoilage and reduce overall storage efficiency [11]. Additionally, in regions with unreliable electricity supply, frequent power outages disrupt thermal stability, causing temperature fluctuations that negatively affect product quality and shelf life [12]. These limitations highlight the need for improved airflow management and integrated thermal backup solutions in small-scale cold storage systems. Computational Fluid Dynamics (CFD) plays a vital role in optimizing cold storage systems by providing detailed insight into airflow behavior, temperature distribution, and convective heat transfer within complex storage geometries. Advanced CFD simulations allow researchers to evaluate the influence of fan configuration, evaporator placement, and product stacking on internal cooling performance, thereby identifying regions of thermal non-uniformity and inefficient circulation [13].

More recent numerical investigations demonstrate that CFD-guided design modifications can significantly reduce cooling time, improve temperature homogeneity, and enhance overall energy efficiency in refrigerated storage environments [10]. Thus, CFD serves as an essential predictive and optimization tool for designing high-performance cold storage systems with improved thermal reliability and product preservation capability. The latest developments in cold chain studies are focused on enhancing the thermal uniformity, energy efficiency and shelf-life maintenance with combined modeling and storage technologies. CFD methods have been broadly used to model airflow and heat-transfer in storage to optimize storage conditions; Laguerre et al. [14] have demonstrated that airflow distribution and time-temperature history are key factors in tomato cooling behaviour and aroma development, whereas Han et al. [15] have shown that intermittent warming can reduce chilling injuries and reduce energy consumption despite slight increases in mass loss. Expanding this insight, Han et al. [16] measured the effect of cold chain breaks, which they found to substantially amplify moisture loss and temperature inhomogeneity especially due to the relative humidity variability.

Phase change material (PCM) thermo-storage of thermal energy has become one of the main approaches to increase the reliability of cooling, You et al. [17] verified PCM plates that increased the cooling time by close to two hours with a simulation error of only 2.2, and Arun et al. [18] confirmed better cooling and reduced energy usage when PCM plates are placed strategically in the micro-cold storage. In a similar fashion, Natarajan et al. [19] have documented a 17.9% energy savings with a solar-PV-powered PCM-integrated system to be used in rural areas, and Prakash and Ravindra [20] increased PCM performance by integrating nanoparticles to be used in small-scale milk chilling. Other low-energy systems like evaporative cooling Siddiqui and Ubale, [21] greatly minimised the heat load and energy consumption than the traditional storage. Additional methods of preservation, such as the essential oil treatments Shehata et al., [22], also proved that synergistic methods can be used to prolong shelf life and lessen post-harvest losses. Taken together, these works indicate the significance of airflow optimization, integration of thermal storage, and the design of cold chains that are energy efficient in the development of sustainable cold chains.

Even though the problem of cold storage optimization has been studied extensively, most existing studies focus either on numerical airflow modeling, or on isolated experimental integration of thermal storage, and few have attempted to jointly consider the issue of geometric optimization, thermal backup systems, and shelf-life validation within a unified methodological approach.Furthermore, despite the studies of phase-change material (PCM) based and evaporative cooling systems, there is still an existing gap in the synthesis of computational fluid dynamics (CFD)-driven airflow modification using a field-deployable cold storage system with a water-based thermal backup to suit marginal farmers. This paper aims to fill that gap by combining three-dimensional CFD simulation of a curvature-adjusted geometry with the design and experimental validation of an 8.42m3 decentralized cold storage plant and at the same time evaluating its thermal behaviour and resultant tomato shelf life. This combination of numerical and experimental methodology therefore outlines a direct connection between improvement of airflow, thermal stability during power outages, and maintenance of post-harvest quality, which is a scalable, energy-efficient answer to small-scale agricultural situations.

II. NUMERICAL METHODOLOGY

The quantitative approach used in this study aims to analyze the airflow distribution and thermal processes in the traditional and optimized cold storage systems through the use of the Computational Fluid Dynamics (CFD). The three-dimensional modeling system was applied to model the convective heat transfer and to determine the effect of geometric changes on the uniformity of cooling and precooling.

II.1 COLD STORAGE GEOMETRY AND DESIGN

The numerical analysis was conducted on the two cold storage geometries which were made on the basis of 3D computer-aided design model to comply with the standard of small-scale storage.

The traditional model was made of a cuboidal chamber with internal dimensions of 2.4m x 1.95m x 1.8m and a total volume of around 8.42 m^3 making it fit 1.875 tons of tomatoes. The evaporator unit was placed in the upper part of the rear wall and fitted with axial fans to aid forced circulation of air. To improve the evenness of the airflow and reduce the thermal stratification that was witnessed in the conventional design, a new design was proposed that has an internal curvature of 0.5 m at the evaporator wall and junction with the roof. This was an aerodynamic modification to minimize recirculation zones and enhance convective heat transfer. The tomato crates were made of food-grade plastic in grid form and spacing between rows and walls were spaced out to permit free passage of air. Figure 1(a) – Figure 1(b) presents CAD drawings of conventional and modified cold storage designs respectively.

II.2 GOVERNING EQUATIONS

Three-dimensional Reynolds-averaged Navier-Stokes (RANS) equations were used to describe the airflow and heat transfer in the cold-storage chamber together with the energy equation. The continuity equation is a statement of the conservation of mass of incompressible flow:

$$\frac{\partial u_i}{\partial x_i} = 0 \tag{1}$$

The RANS formulation was used to control the momentum transport in the refrigerated domain:

$$\rho \frac{\partial (u_i u_j)}{\partial x_j} = -\frac{\partial p}{\partial x_i} + \frac{\partial}{\partial x_j}\left[\mu\left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i}\right)\right] - \frac{\partial\left(\rho u_i' u_j'\right)}{\partial x_j} \tag{2}$$

The equation of energy conservation of the transient heat transfer between air and stored produce is as follows:

$$\frac{\partial \mathrm{T}}{\partial \mathrm{t}} + \mathrm{u_i}\frac{\partial \mathrm{T}}{\partial \mathrm{x_i}} = \frac{\partial}{\partial \mathrm{x_i}}\left(\frac{\lambda_{\mathrm{eff}}}{\rho \mathrm{C_p}}\frac{\partial \mathrm{T}}{\partial \mathrm{x_i}}\right) \tag{3}$$

The SST k-ω model was used to model the effects of turbulence, which is a combination of the near-wall accuracy of the k-ω formulation and the free-stream strength of the k-ε model. The turbulent viscosity is defined as:

$$\lambda_{eff} = \lambda + \frac{C_p \mu_t}{Pr_t} \tag{4}$$

This equation makes it possible to predict recirculation areas and thermal gradients in the storage chamber correctly.

II.3 COMPUTATIONAL DOMAIN AND MESH

The computational domain was the whole of the three-dimensional cold storage room with the air space, stacked tomato crates, and evaporator assembly and was represented using ANSYS Design Modeler to effectively represent spatial differences in airflow and heat transfer. A three-dimensional modeling strategy was used to solve the axial, transverse and vertical flow structures that would have otherwise not been sufficiently represented in the two-dimensional simulations. The discretization of fluid domain was done by the implementation of hybrid tetrahedra mesh that was local refined near the surfaces of crates and evaporator outlets to improve the representation of velocity gradients and convective heat exchange. The CFD model and the mesh structure are shown in Figure 2 of the report. The grid independence was checked through systematic mesh refinement until the changes in temperature and velocity fields were less than acceptable tolerance. The completed mesh had 130,471 nodes and 73,203 elements in the conventional cold storage arrangement, and 128,500 nodes and 71,848 elements in the modified arrangement, as shown in Table 3. This meshing approach therefore guaranteed numerical accuracy, stable convergence and predictability of airflow heterogeneity in the chamber.

II.4 BOUNDARY CONDITIONS AND ASSUMPTIONS

Boundary conditions were defined in such a way that they realistically modeled the airflow and heat transfer in the cold storage chamber. The evaporator outlet was subjected to a velocity inlet boundary condition with an inlet air velocity of 1.5 m/s and turbulence intensity of 1% and the operating pressure was set to 101325 Pa. To precisely define the conditions of the inlet flow, the hydraulic diameter of the evaporator was considered to be 0.36 m. The numerical simulation assumed that thermo-physical properties of air and tomato remained constant during the simulation to simplify the model. Air properties were given as density of 1.293 kg/m^3, specific heat capacity of 1004 J/kg-K and thermal conductivity of 24.07x10^{-3} W/m-K, and tomato properties as density of 1320 kg/m^3, specific heat capacity of 2310 J/kg-K and thermal conductivity of 0.337 W/m-K as summarized in Table 2. The convergence was reached when the residual of continuity and momentum equations were less than 10^{-3} and energy residual was less than 10^{-6}, thus, providing numerical accuracy and stability of the solution.

Table 1: Inlet parameters.

Parameter	Value
Operating Pressure	101325 Pa
Velocity Inlet	1.5 m/s
Turbulence Intensity	1 %
Hydraulic Diameter of Evaporator	0.36 m
Pressure Discretization	Standard
Momentum Discretization	Second Order
Turbulent Kinetic Energy (k)	First Order Upwind

II.5 SIMULATION PROCEDURE

ANSYS Fluent 21 was used to perform the numerical simulations to determine the distribution of airflow and temperature change within the cold storage chamber. A three-dimensional model was developed that was fully three-dimensional and the simulations were run at steady-state to study the airflow field and convective heat-transfer properties and transient simulations were run to study the cooling behaviour during the precooling stage. Pressure-velocity coupling was considered through the SIMPLE algorithm and second order discretisation schemes were applied to the momentum and energy equations in order to enhance numerical accuracy. The SST k-ω model was used to model turbulence to achieve near-wall flow behaviour. No-slip conditions were applied to all internal boundaries and each geometrical configuration was simulated separately. The convergence was achieved when the residuals were less than the tolerance limits set and thus guaranteed stable and reliable solutions. The model was validated through the comparison of the predicted airflow and temperature fields with those found in previous experimental studies of cold-storage chambers, thus giving confidence in the numerical framework.

III. EXPERIMENTAL METHODOLOGY

The current experimental approach was designed to confirm the thermal performance and storage effectiveness of the small-scale cold storage system developed under the realistic operating conditions. The section outlines the system development, estimation of refrigeration load, instrumentation design, and quality evaluation procedures used in evaluating the shelf-life extension of stored tomatoes.

III.1 DEVELOPMENT OF IMPROVED COLD STORAGE SYSTEM

A small-scale, improved on-field cold storage facility with an internal volume of 8.42 m^3 (2.4 m x 1.8 m x 1.95m) was designed to store 500 kg to 1 ton of perishable produce under controlled temperatures. The storage chamber was made of 100 mm thick polyurethane (PU) insulated panels bonded to pre-painted galvanized iron (PPGI) sheets, which were used to reduce conductive heat gain and at the same time increase structural durability. To achieve a target storage temperature of 11±0.2°C, a 0.6TR vapor-compression refrigeration (VCR) system using R134a as a refrigerant was installed. The refrigeration system included a hermetic compressor, air-cooled condenser, evaporator and a thermostatic expansion valve, the specifications of which are shown in Table 1. In order to reduce the effects of rural power outages, a 500-liter water tank was added as a secondary, refrigerant-based thermal backup that would be able to support cooling functions during load-shedding events. Moreover, a humidifier was placed at the center of the storage chamber to maintain the relative humidity of the chamber at 80-90% to minimize physiological weight loss in the stored tomatoes. The general system layout, such as the layout of crates, is shown in Figure 2.

III.2 REFRIGERATION LOAD CALCULATIONS

The refrigeration capacity of the developed cold storage system was determined by evaluating all major heat gains acting on the chamber. The transmission load through the walls, roof, and floor was calculated using:

$$Q_T = \frac{UA(T_o - T_i) \times 24}{1000} \quad (5)$$

Where U is the overall heat transfer coefficient, A is the total surface area, To is ambient temperature, and Ti is storage temperature. The sensible heat load of the agricultural product during pull-down was estimated as:

$$Q_P = \frac{m\, c_p (T_{enter} - T_{store})}{3600} \quad (6)$$

Where m is product mass and cp is specific heat capacity. The respiration load of tomatoes was computed using:

$$Q_R = \frac{m_{ag}\, h_r}{24 \times 60 \times 60} \quad (7)$$

Where h_r represents respiration heat. Internal loads due to lighting, personnel activity, equipment, and infiltration were added to determine the total heat load of 16.72 kWh/day. Based on this cumulative load, the theoretical refrigeration requirement was approximately 1.4 kW (0.4–0.5 TR), and a 0.6 TR VCR system was selected to ensure operational safety and stability. Figure 4 depicts heat load of cold storage.

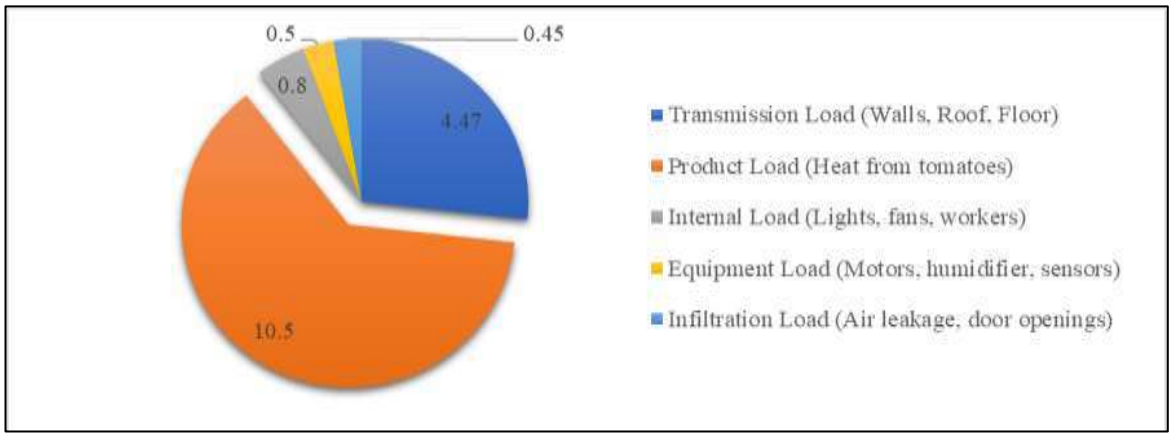

Figure 4**:** Heat load of cold storage.
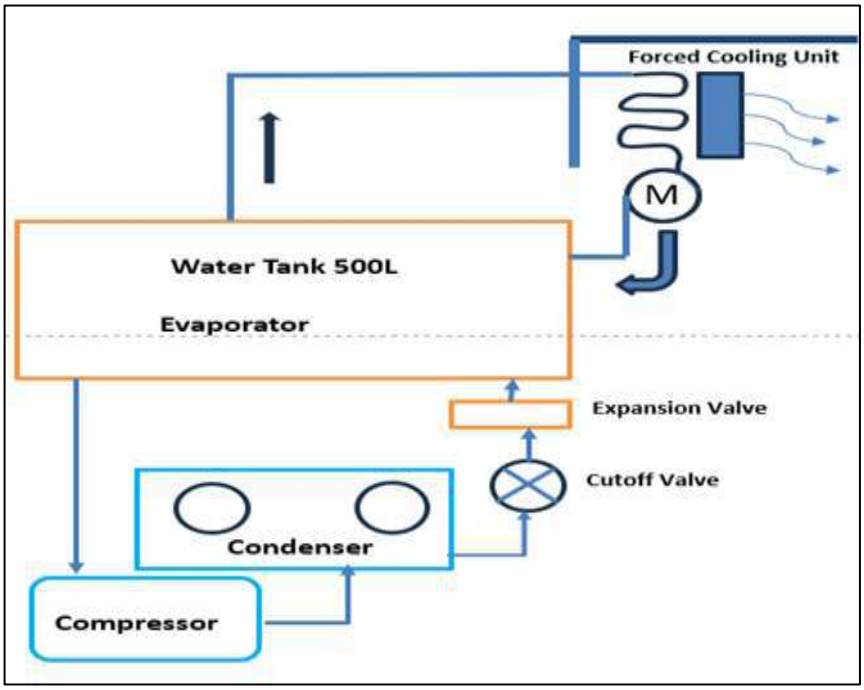
Source: Authors, (2026).

III.3 EXPERIMENTAL SETUP AND INSTRUMENTATION



The experimental test setup was designed to test the thermal stability and storage capacity of the cold storage system developed in terms of real operational conditions. To monitor the real time temperature and relative humidity, a digital data logger (Elitech GPS-6) was used to capture the sensor coupled values in the storage chamber. The grid mode system was used and experiments conducted in one month where 500 kg of tomatoes was used as a test commodity. Figure 3 shows the schematic diagram and the photo image of experimental set up in Eco-Saras Company, Dehu-Pune, India. The monitoring was done on a regular basis over the 28 days of storage and data gathered at a specific time period to check on the ambient temperature, internal storage temperature and humidity conditions. The shelf life of tomatoes kept in the cold chamber was contrasted with the samples that were kept at ambient, non-storage conditions. Chemical quality parameters (total soluble solids, pH) and the physical parameters (physiological loss of weight) were measured at the end of the storage period. There was also visual observation and sensory assessment to establish the alteration of colour, feel and smell of the stored and non-stored samples.

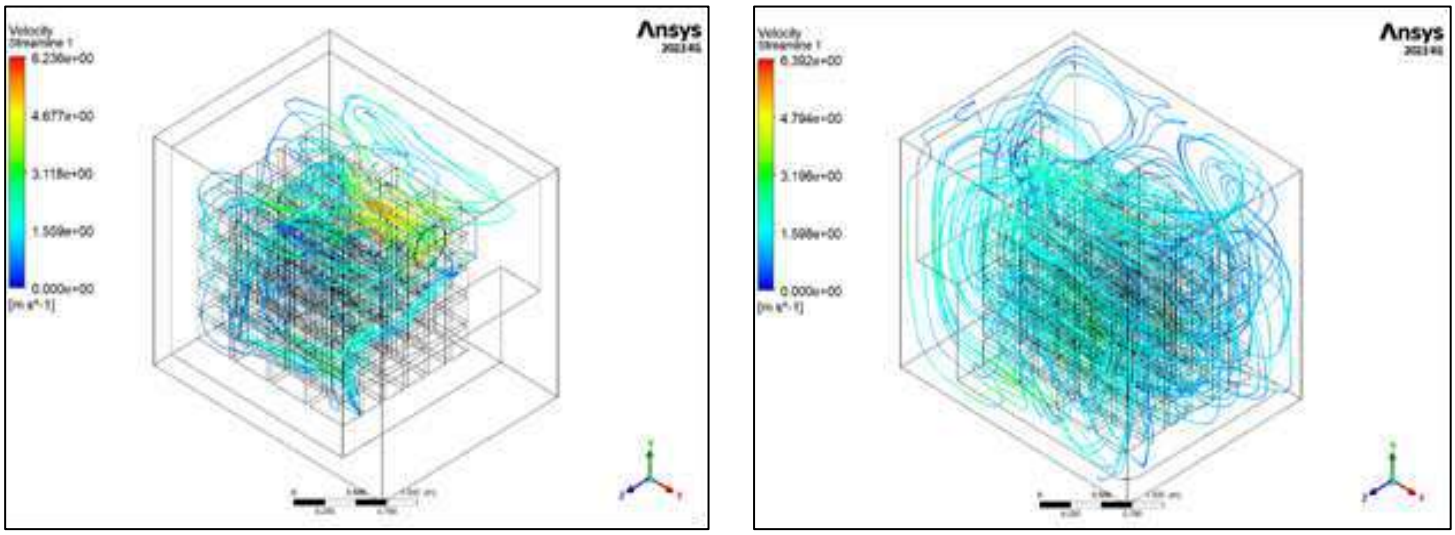
III.4 QUALITY ASSESSMENT METHODS

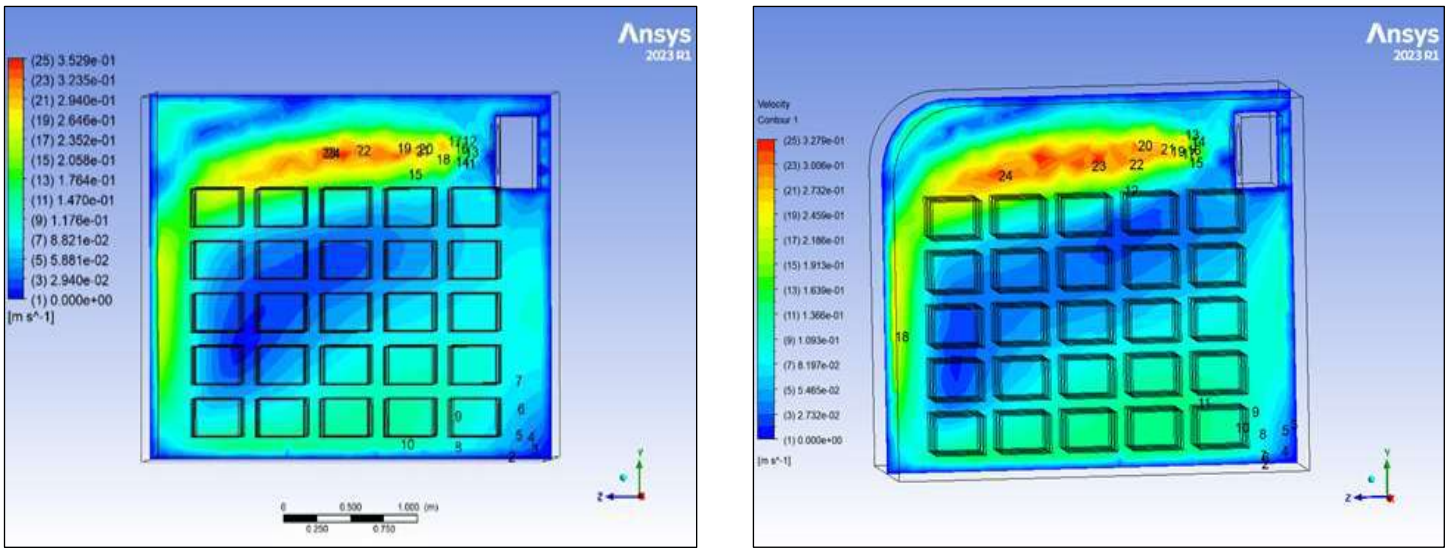
Physiological, chemical and sensory parameters were used to assess the quality of stored tomatoes to determine the effectiveness of the developed cold storage system. Physiological Loss in Weight (PLW) was determined with the help of a standardized digital weighing balance in terms of recording the initial and final weights of sampled tomatoes during the storage period of 28 days. The weight loss was computed by using the percentage weight loss as:



$$PLW(\%) = \frac{W_i - W_f}{W_i} \times 100 \quad (8)$$

Where Wi is the initial weight and Wf is the final weight of the sample. The change in weight of stored tomatoes and non-stored tomatoes was measured. The chemical quality was measured by comparing the pH using a pen-type digital pH meter (Model PH-009(I)A) at pre-established time intervals to check the changes in acidity in the course of storage. The longitudinal change of pH values was recorded. Also, visual and sensory tests were conducted to evaluate colour, firmness, epidermal condition, odour and texture.

IV. RESULTS AND DISCUSSIONS



IV.1 CFD SIMULATION RESULT

The computational fluid dynamics simulations indicated a stable and consistent numerical convergence as scaled continuity, momentum, energy, and turbulence-related variables all showed a steady decrease in magnitude to consistent low values after approximately 100 iterations as shown in Figure 3. This intersection confirms the accuracy of the numerical algorithm and the suitability of the selected turbulence model in proper predictions of airflow and heat transfer in the chamber. Streamline analysis revealed that both designs had a top-to-bottom circulatory trend, but the altered cold-store design had smoother flow paths, reduced vortices, and less recirculation areas near the upper corners as shown in Figure 4. Velocity-contour plots also highlighted greater airflow penetration between the rows of the crates in the modified design, and thus reduced stagnant areas that were evident in the cuboidal design (Figure 5). Comparative temperature-contour analysis indicated a more uniform thermal field in the altered configuration, whereby the number of high temperature loci at the ceiling was less and the overall amount of heat removed in the storage volume was more effective (Figure 6). According to the summary of Table 4, the altered design reduced the hot-spots temperature to approximately 22-25°C, created a more flattened temperature gradient, and reduced the precooling time by almost 40 minutes, without compromising on the improved core-product temperature uniformity. These findings prove that internal curvature introduction enhances uniformity in airflow and general cooling.

IV.2 THERMAL STABILITY ANALYSIS

The thermal stability of the developed cold storage system was checked under the conditions of the continuous operation to determine its ability to provide the controlled environmental conditions. Figure 8 shows a temperature change in the chamber throughout the operation, which shows that the temperature in the storage was kept at 11±2°C, with minimum variation regardless of the changes in ambient conditions. The stability trend shows that the compressor is cycling and insulating effectively thus maintaining consistency in cooling over the storage time. The conditions of relative humidity in the chamber were also monitored and the results depicted in Figure 5 shows that the humidity was managed at the desired range of 80-90% due to the integrated humidifier functionality. This controlled humidity condition reduced the loss of moisture in tomatoes stored and minimized physiological degradation. Performance of the system during short-term power outages was also studied and the availability of the thermal back up system of 500 liter water based helped in slow rise of the temperatures instead of sudden thermal peaks. Figure 6 shows the load shedding temperature profile, which proved that the backup system was effective in postponing temperature increase, therefore maintaining the quality of products. In general, the outcomes confirm the hypothesis that the enhanced cold storage system preserves the thermal stability within the realistic working conditions.

IV.3 SHELF –LIFE PERFORMANCE EVALUATION

The shelf-life performance of tomatoes that were exposed to the improved cold-storage system was evaluated by systematic comparison of weight loss, pH change, and sensory attributes with non-stored controls. The mass change of the tomatoes stored over the 28-day storage period as shown by Figure 9 indicates that stored tomatoes underwent a gradual change of about 110g to 104g, and non-stored samples underwent a sharp decrease to almost 70g. This difference shows that the controlled temperature regime (11± 2°C) and relative humidity that was kept at 80-90% greatly reduced physiological weight loss. The pH changes as seen in Figure 9 also supports the stabilizing effect of cold storage. Although non-stored tomatoes exhibited a high degree of pH fluctuation of 4.2 to 5.7 over the initial two weeks, cold-stored samples had a relatively stable pH range of 4.3 to 5.9 over the entire period of storage. This trend shows that the rate of ripening is delayed and the metabolic activity is reduced in the controlled conditions. Table 5 summarizes visual and sensory observations that indicated that stored tomatoes maintained their firmness, shape and skin integrity without wrinkles even after 28 days, but non-stored tomatoes decayed after 12-13 days. The preserved texture and low off-odour of the stored samples also show that quality attributes were preserved.

V. CONCLUSION

This study presented the design optimization and experimental validation of an improved small-scale cold storage system integrating Computational Fluid Dynamics (CFD) analysis with a vapor compression refrigeration system and thermal backup mechanism. The objective was to enhance airflow uniformity, maintain thermal stability during power interruptions, and extend the shelf life of tomatoes under decentralized rural storage conditions.

- The CFD-based curvature modification significantly improved airflow distribution, reduced recirculation zones, and minimized temperature gradients inside the storage chamber.
- The modified geometry reduced precooling time by approximately 40 minutes and lowered localized hot spot temperatures compared to the conventional design.
- The developed 8.42 m³ cold storage unit equipped with 100 mm PU insulation and a 0.6 TR VCR system successfully maintained storage conditions at 11 ± 2°C and 80–90% relative humidity.
- The integration of a 500-liter water-based thermal backup system effectively mitigated temperature spikes during power interruptions, ensuring stable storage conditions for 15–20 hours.
- Shelf-life evaluation demonstrated that stored tomatoes exhibited only 5% weight loss and maintained acceptable pH stability over 28 days, whereas non-stored samples deteriorated within 12–13 days.
- The system demonstrated operational feasibility and energy adequacy for decentralized, on-field applications, offering a practical solution for reducing post-harvest losses.

Overall, the integrated numerical–experimental approach confirms that airflow optimization combined with thermal backup integration significantly enhances cold storage performance and post-harvest preservation efficiency.

ABSTRACT

Investigations were carried on single cylinder, four stroke constant engine speed for varying load conditions direct injection engine fuelled by Juliflora biodiesel along with hydrogen t and Diethyl Ether as an additive at 5% by volume. Hydrogen was sent through intake manifold in varying proportions as 4 lpm, 6 lpm and 8 lpm. Brake thermal Efficiency and Specific fuel consumption as performance and CO, UHC, CO_2, NO_x and Smoke Opacity as emission characteristics of the engine were observed. While enriching the hydrogen along the JFB20DEE5 varying flow rates such as 4 lpm, 6 lpm and 8 lpm the BTE is increased to 2%, 5.1% and 10 % than the diesel. As the load increases the brake thermal efficiency also increases for biodiesel blends of JFB20 but when hydrogen is added with the blends it is observed that the brake thermal efficiency has been increased by 10% for JFB20DEEH8 than diesel at higher load. Compared to diesel, the percentage of the SFC decreases for increasing the loads for the all the JFB20 blends. Compared to diesel the JFB20 blend give more fuel consumption than diesel and also it continues in the case of the blend when DEE is added. It is noticed that when the JFB20DEE5 is enriched by hydrogen with varying flow rates the BSFC is decreased. It is observed that at full load the BSFC decrease by 4% for the JFB20DEE5H8 blend than pure diesel. When the blend is enriched by hydrogen for the 4 lpm, 6 lpm and 8 lpm, the CO emission is considerably decreased for the half load and full load conditions as 9%, 13% and 17% respectively. The UBHC emissions are decreases when the Diethyl Ether is added to blend it gives 9% HC reduction as the load increases. For the blends JFB20DEE5H4, JFB20DEE5H6 and JFB20DEE5H8, UBHC is decreasing by 9% to 28% at full load than diesel. NOx emissions are high for pure diesel. Increasing load gradually increases the NOx emission for all tested fuels. At the highest hydrogen flow rate 8 lpm (JFB20DEE5H8) the cylinder pressure is notably higher, reflecting more efficient and potentially more powerful combustion. The data specifically highlights that at 100% load, 8 LPM hydrogen flow produces an approximate 10.3% increase in cylinder pressure compared to using diesel fuel. At 100% load, the HRR for JF B20 reaches 32.22 J/^{o}CA, and when adding 5%DEE it increases to35.9J/^{o}CA. For 8 LPM hydrogen is introduced, this value goes up to 41.74 J/^{o}CA-an increase of 3.41 J/oCA or an enhancement by 9%.The high flame speed and energy density of hydrogen improve overall combustion efficiency, resulting in higher heat release and pressure.

I. INTRODUCTION

Internal combustion engines and traditional fossil fuels play a major role in today's electricity and transportation networks. Diesel engines in particular continue to be widely used in power generation because of their unavoidable benefits, which include high power to weight ratios and efficiency levels. Studies on lowering pollutants released by diesel engines are another important issue that needs to be fully addressed by scientists because undesirable exhaust emissions like smoke, unburned hydrocarbons, CO, particulate matter, and NOx emitted from engines have detrimental effects on both the health of living things and the environmental climate[1].Researchers are being compelled to look at emission reduction technology and discover cleaner, renewable, and more environmentally friendly fuel alternatives without changing the engine [2].Alternative energy sources like biofuels have a great deal of potential to displace fossil fuels. They provide a number of benefits, including regional growth, sustainability, renewable energy, and a decrease in greenhouse gas emissions [3]. Bora and Saha [4] examined the performance and emission characteristics of a single cylinder, DI, water-cooled CI engine using rice bran biodiesel and raw biogas at three different compression ratio changes.

The highest brake thermal efficiency of 18 was recorded at fixed IT 23 bTDC, accompanied by a 17.6% and 17.2% drop in CO and UHC emissions, respectively. Using edible oils to extract biodiesel could lead to a problem with independence in vegetable farming. The extraction of biodiesel from non-edible vegetable oils is the only remaining solution for reducing the usage of vegetable oils. Due to the enormous demand for edible oils, the use of non-edible oils in comparison to edible oils is remarkable in developing countries [5]. It is therefore preferable to utilize both edible and non-edible oil, depending on what is available. This will lessen reliance on a single fuel and address seasonal fluctuations. Some inedible oils, such as those from *Jatropha curcas, Calophylluminophyllum, Pongamia pinnata, Croton megalocarpus, and Madhuca indica*, have been explored as alternative fuels in recent years [6]. Abedin et al. [7] have investigated the qualities of biodiesel made from non-edible oil. They concluded that biodiesel was the best fuel to replace diesel because its attributes were nearly identical to those of diesel. The use of hydrogen in CI engines has been viewed as a good substitute in recent years because of its benefits, which include its high calorific value, lack of carbon structure, and non-toxicity [8].

Furthermore, hydrogen can be quickly ignited, consumed cleanly, and reused; yet, its main advantages are limited to greater nitrogen oxides, explosions, and dangerous activities [9]. In order to assess the performance and emission characteristics, Kumar et al. [10] demonstrated the induction of hydrogen at varying flow rates alongside diesel in a four-stroke, single-cylinder CI engine. They claimed that compared to diesel fuel, the fuel consumption was reduced and the thermal efficiency was raised by up to 10.7%. CO and HC emissions were reduced by 16% and 7%, respectively. The impact of adding hydrogen to an IC engine was examined by Saravanan et al. [11], who also assessed the exhaust gases and thermal efficiency. The results showed that other exhaust gases, such as UHC, CO, and carbon oxides, was reduced while the BTE increased by up to 17%. Karagoz et al. [12] carried out an experiment to determine how 30% hydrogen enrichment affected CI engines at various loads. The authors found that emissions such as smoke, CO, and CO2 were significantly reduced by 68%, 29.5%, and 51.3%, respectively, and that the BTE was reduced by 8.5%. In an experiment conducted by Kumar et al. [13], pilot fuels for the CI engine were diesel and jatropha oil after a minor quantity of hydrogen enrichment.

With the exception of a 16% increase in nitrogen oxide, the results showed that BTE increased by 8.15% and that HC, CO, and smoke opacity emissions decreased by 30%, 41.2%, and 40.5%, respectively. When using Jatropha Curcas and hydrogen in dual fuel mode, the efficiency was nearly identical to that of diesel fuel at maximum load. Serin and Yıldızhan [14] looked at the performance and emissions of tea seed oil biodiesel blends in a diesel engine with hydrogen present. The performance of a single-cylinder, four-stroke, DI diesel engine powered by rapeseed oil, rapeseed oil methyl ester, and diesel as pilot fuel by introducing hydrogen was examined by Geo et al. [15]. There were minimal exhaust gas emissions and enhanced BTE and BSFC by 5.5% and 12.3%, respectively. The primary benefits of bio fuel include its high biodegradability, low pollution emissions, renewability, and flash point. The conventional oil seed crops used to make biodiesel include mustard, rape seed, ground nut, safflower, sunflower, linseed, palm, soybean, and many more. Should edible oils be utilized to produce biodiesel, the globe will experience a severe food scarcity. Therefore, biodiesel is being produced using non-edible oil sources. This can aid in reducing the amount of non-edible seeds used to produce biodiesel.

The production of biodiesel from a variety of edible and non-edible vegetable oils, such as cottonseed oil, olive oil, wild jojoba oil, mustard oil, soybean oil, waste cooking oil, and wild jojoba oil, has gained a lot of attention in the literature. However, there is a dearth of comprehensive information regarding the production of biodiesel from Juliflora oil and its engine studies. One of the problematic and invasive alien species in the Afar and Somali regions was the evergreen tree Prosopis Juliflora (PJ), which later expanded to Ethiopia's Southern States and Nationalities Regional Administration in the Great Rift Valley, which is headed towards South Omo [16]. A tree may produce seeds that weigh between 5 and 10 kg, depending on the climate and surroundings. It is projected that PJ will produce 2230 kg/ha of pods at a density of roughly 20 kg/tree. Due to its non-food-related status, it is not as vulnerable to dietary safety concerns as other food crops. As an example, bio-oils were previously produced from maize, wheat, and sorghum [17]. In order to solve this issue, transesterification is a widely used technique to lower the viscosity of vegetable oil [18], which is believed to be the most workable and efficient strategy. The properties of test fuels are given in the table 1.

Table 1: Properties of bio diesel produced from vegetable oils.

S. No.	Properties	Neat Diesel ND	JFB20	DEE	JFB20 DEE5	JFB20 DEE10	JFB20 DEE15
1	Density (kg/m^3)	833	850	715	847	837	831
2	Viscosity (mm^2/s)	2.8	3.2	0.23	3.07	2.93	2.7
3	Calorific Value (kJ/kg)	42500	41520	33.89	41090	42600	42100
4	Fire Point ^{o}C	54	65	-

II. EXPERIMENTAL METHOD

II.1 JULIFLORA SEED BIODIESEL PREPARATION

The methods used to make biodiesel from Juliflora seeds, the setup of the hydrogen fumigation equipment, the setup for engine testing, and the analytical techniques used for performance and emission evaluation are all described in this part. The evergreen Juliflora tree, which is native to South America, Central America, and the Caribbean, is usually referred to as mesquite in the United States. This species has gained recognition for its quick development, ability to fix nitrogen, and ability to withstand saline soils and dry conditions. As a result, it has emerged as a resource in difficult ecosystems. Construction materials, charcoal, soil conservation, and the restoration of saline or degraded soils are just a few of the many products and services that Juliflora may offer in ideal circumstances. Juliflora provides a broad range of products, including charcoal, building supplies, firewood, soil conservation, and the restoration of saline or damaged soils, regardless of the weather. Using a small, sharp knife, the pods are sliced lengthwise and crosswise to harvest the seeds of Juliflora, which are then used for cultivation and oil extraction.

II.1.1 Feedstock collection and preparation

The shrub Prosopis Juliflora as Shown in Figure 1 (a) belongs to the Fabaceae family. It is regarded as a primitive plant that thrives in hot climates with little water needed for sustenance. This type of mesquite is indigenous to Asia and the Caribbean. Its applications include fodder and wood for environmental management. The plant contains an aberrant flavone mosquito in its heartwood. These are more compelling arguments in favor of developing bio-diesel facilities. Key physical and chemical characteristics of the bio-diesel made from Juliflora seed oil are investigated, including density, specific gravity, viscosity, calorific value, flash point, and fire point. They work well with the majority of other vegetable oil biodiesel. Therefore, the experimental work focuses on producing biodiesel from Juliflora seed oil and examining the performance, combustion, and emission characteristics of diesel engines that use biodiesel made from soy and its diesel mixes. The fruiting Juliflora seeds, seed oil and extraction method are shown in figure 1(a), 1(b) and 1(c) respectively. It is projected that PJ will produce 2230 kg/ha of pods at a density of roughly 20 kg/tree. Due to its non-food-related status, it is not as vulnerable to dietary safety concerns as other food crops. As an example, bio-oils were previously produced from maize, wheat, and sorghum. In order to solve this issue, transesterification is a widely used technique to lower the viscosity of vegetable oil, which is believed to be the most workable and efficient strategy.

II.1.2 Juliflora seed oil extraction

Oil extraction from Prosopis Juliflora is typically performed using either pyrolysis of the biomass or mechanical/solvent extraction of seeds, depending on the intended application. In the pyrolysis method, the lignocellulose biomass of Juliflora—such as stems, branches, and leaves—is thermally decomposed in the absence of oxygen at temperatures between 350°C and 550°C. This process breaks down complex organic polymers like cellulose, hemicellulose, and lignin into simpler volatile compounds. These vapors are then cooled in a condenser to obtain a dark, viscous liquid known as bio-oil. The remaining products include syngas, which can be recycled for heating, and biochar, which can be used as a soil enhancer or fuel. Pyrolysis is widely used because it converts low-value biomass into high-value liquid fuel, making Juliflora a viable resource for renewable energy generation. In contrast, seed oil extraction focuses on obtaining oil directly from Juliflora seeds.

The seeds are first cleaned, dried, and mechanically crushed to increase surface area. Mechanical pressing using an oil expeller can extract a small amount of crude oil, though the yield is generally low. To improve recovery, solvent extraction using a hydrocarbon solvent like hexane is often employed. The solvent dissolves the oil from the crushed seed powder, forming a solution that is later heated to evaporate and recover the solvent, leaving behind crude seed oil. This oil undergoes filtration and refining to remove impurities, resulting in a usable product. Both methods highlight the versatility of juliflora as a bio-resource. While pyrolysis provides a sustainable route for producing bio-fuels, seed-based extraction offers potential for small-scale applications such as soap making and biodiesel production. The choice of method depends on required yield, application, and available equipment. The Juliflora seed oil extraction workflow is illustrated in the Figure 2.

II.1.3 Transesterification (Alcoholysis)

Transesterification is a chemical process that creates esters and glycerol by reacting edible and non-edible oil with alcohol. To increase the yield and rate of a reaction, catalysts can be employed. The transesterification process typically uses alcohols such propanol, butanol, methyl alcohol, ethyl alcohol, and alcohol. The most common alcohols utilized in this chemical reaction are typically methyl and ethyl. It is inexpensive, has good physical and chemical qualities, reacts with triglycerides quickly, and is more soluble in oil.

II.2 ENGINE SETUP AND EXPERIMENTATION

A four-stroke, single-cylinder, water-cooled, constant compression ignition engine is used for all experimental testing. An eddy current dynamometer is connected to the engine arrangement. The testing blends' performance, combustion, and emission properties are evaluated using the eddy current dynamometer as a loading mechanism. An electric knob allows the user to adjust the load on an eddy current dynamometer. A supply tank with a valve makes up the fuel supply system. A burette tube, which is attached to the valve, is used to measure the amount of fuel used per unit of time. The number of thermocouples and sensors that are connected to the engine is used to measure the temperatures at the key locations. At the air intake, air (exhaust gas) outlet, hot water outlet, and cooling water inlet, the temperatures are recorded. Figure 2 displays the schematic diagram of the test engine used in this investigation.

The water supply supplied by the water jackets cools the engine. Table 2 provides the test engine's numerous technical specifications. The data acquisition system (DAQ) that comes with the engine is used to tabulate the various data needed to determine the engine's performance and combustion parameters. EGT, CO, NOx, UBHC, and smoke opacity data are measured by the emission analyzer attached to the exhaust pipe. Table 3 lists all of the instrument specs used in these investigations. In the initial setup, the engine is tested using only diesel to operate for 20 to 30 minutes, and readings are taken under various load scenarios. The DAQ's combustion parameters, performance statistics, and exhaust emission analyzer readings were compared to those of the DEE and biodiesel blends. The prepared blend B20 is put back into the fuel tank after a series of readings from pure diesel are finished. Also, furthermore tests were done at constant engine speed at 1500rpm for varying load conditions such as 0, 25, and 50, 75 and full loads. Hydrogen was sent through intake manifold in varying proportions such as 4 lpm, 6 lpm and 8 lpm with JFB20DEE5. To ensure that the engine exclusively uses the B20 biodiesel blends such as it is then left to run for the first six to eight minutes. Performance and emission data for various loading scenarios were recorded a short while later. For each of the other prepared blends, the same steps were repeated. The combination of test fuel and additives matrix is depicted in the table 3.

II.2.1 Uncertainty Analysis

Experimental measurements are intrinsically accompanied by uncertainties that emerge from the precision of instruments, measurement methodologies, and various environmental influences. In the present investigation, an uncertainty analysis was performed for critical measured parameters, which encompass fuel consumption, air flow rate, brake power, and exhaust gas emissions. The aggregate Uncertainty (Uc) for each derived parameter was derived utilizing the root sum square (RSS) technique. Table 4 shows the uncertainties of important measured and computed parameters. Using the relevant equations, the overall combined uncertainty for the entire experimental study was found to be ±1.92%, which is within acceptable bounds for engine testing.

$$U_x = \sqrt[2]{\sum_{i=1}^{n} \frac{(X - X_i)^2}{nx(n-1)}} \tag{1}$$

$$x = \sum_{i-1}^{n} \frac{x_i}{n} \tag{2}$$

$$U_{Es} = \sqrt{(U_\omega x \frac{E_s}{\omega})^2 + (U_\tau x \frac{E_s}{T})^2} \tag{3}$$

$$U_{m_{fuel}} = \sqrt{(U_{m_i} x \frac{m_{f\,uel}}{m_i})^2 + (U_{m_g} x \frac{m_{f\,uel}}{m_g})^2} \tag{4}$$

$$U_{BSFC} = \sqrt{(U_\omega x \frac{BSFC}{\omega})^2 + (U_T x \frac{BSFC}{T})^2 + (U_{m_{fuel}} x \frac{BSFC}{m_{fuel}})^2} \tag{5}$$

$$U_{BTE} = \sqrt{(U_\omega x \frac{BTE}{\omega})^2 + (U_T x \frac{BTE}{T})^2 + (U_{m_{fuel}} x \frac{BTE}{m_{fuel}})^2} \tag{6}$$

$$U_{CO_2} = \sqrt{(\frac{U_{CO_2}}{CO_2})^2 + (\frac{U_{E_s}}{E_s})^2} \tag{7}$$

$$U_{HC} = \sqrt{(\frac{U_{HC}}{HC})^2 + (\frac{U_{E_s}}{E_s})^2} \tag{8}$$

$$U_{NOx} = \sqrt{(\frac{U_{NOx}}{NOx})^2 + (\frac{U_{E_s}}{E_s})^2} \tag{9}$$

$$U_{CO} = \sqrt{(\frac{U_{CO}}{CO})^2 + (\frac{U_{E_s}}{E_s})^2} \tag{10}$$

III. RESULTS AND DISCUSSION

For the selected test engine, the investigation with base fuel diesel, Juli Flora biodiesel blend in terms of performance characteristics such as Brake Thermal Efficiency (BTE), Brake Specific Fuel Consumption (BSFC) and emission characteristics such as CO, NOx, UHC, smoke

III.3.1 Engine Performance Characteristics

III.3.1.1 Brake Thermal Efficiency

The graph shows the brake thermal efficiency at various loads for diesel, Biodiesel blends and biodiesel blends with DEE additive in Figure 5. Initially the BTE for the JFB20 decreases by 4% than the diesel. It is because of the reason that the juliflora oil has high viscosity, high density and low volatility gives poor atomization, bigger droplets and slow evaporation. When DEE is added as additive with JFB20 blend there is slight increase in BTE but not matching the diesel. While enriching the hydrogen along the JFB20DEE5 varying flow rates such as 4 lpm, 6 lpm and 8 lpm the BTE is increased to 2%, 5.1% and 10 % than the diesel. As the load increases the brake thermal efficiency also increases for biodiesel blends of JFB20but when hydrogen is added with the blends it is observed that the brake thermal efficiency has been increased by 10% for JFB20DEEH8 than diesel at higher load. From the above result, it is understood that due to the sufficient amount of oxygen content in the biodiesel, the combustion rate is higher which gradually increases the brake thermal efficiency for all the tested blends. Hydrogen enrichment increases BTE because it converts slow diffusion combustion of juliflora biodiesel into rapid premixed combustion, advancing heat release towards TDC, increasing peak cylinder pressure, reducing combustion duration, and improving fuel utilization efficiency.

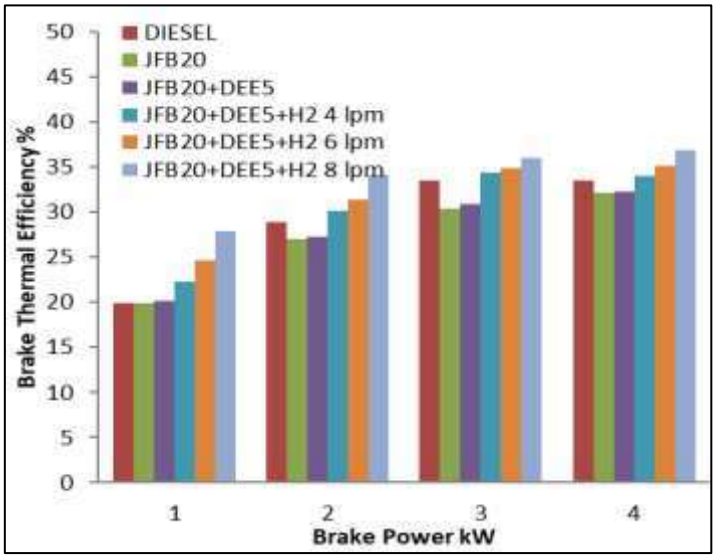

Figure 5: Variation in BTE.

III.3.1.2 Brake Specific Fuel Consumption

The values of different Brake specific fuel consumption for various loads of diesel and biodiesel blends are shown in Figure 6. From the graph, the SFC decreases for increasing the loads for the all the JFB20 blends. Compared to diesel the JFB20 blend give more fuel consumption than diesel and also it continues in the case of the blend when DEE is added. It is noticed that when the JFB20DEE5 is enriched by hydrogen with varying flow rates the BSFC is decreased. It is observed that at full load the BSFC decrease by 4% for theJFB20DEE5H8 blend than pure diesel. The reduction in BSFC with 8 lpm hydrogen enrichment is attributed to diesel substitution, improved premixed combustion, enhanced oxidation of juliflora biodiesel droplets, and higher combustion efficiency, which allows the engine to produce the same brake power with a lower biodiesel consumption rate. Hydrogen has very high calorific value and participates in combustion, so part of engine load is carried by hydrogen instead of biodiesel. Also, its high flame speed improves combustion and reduces late burning losses. Therefore, less biodiesel is required to produce the same brake power, leading to lower brake specific fuel consumption

III.3.2 Emission characteristics

III.3.2.1 Carbon monoxide (CO) emissions

The emission of Carbon monoxide from the biodiesel blends and the pure diesel are noted and its variations against the different loading conditions are plotted in the graph as depicted in Figure 7. CO emission for the JFB20 is increased for when the load increases around 5% and 11% for half load and full load conditions respectively. This may be due to poor atomization as the Juliflora oil has higher viscosity and incomplete mixing of particles. When the blend is enriched by hydrogen for the 4 lpm, 6 lpm and 8 lpm, the CO emission is considerably decreased for the half load and full load conditions as 9%, 13% and 17% respectively. It is clearly observed that, the CO emission is less for the higher loads for all tested blends.

The JFB20DEE5H8 gives less CO emission of 17% at full load than diesel. The reason is when hydrogen is added with biodiesel it produces faster combustion burns very quickly and completely, enhances the oxidation reactions converting CO into CO2, improves the overall efficiency and reduces the unburnt fuel [19].

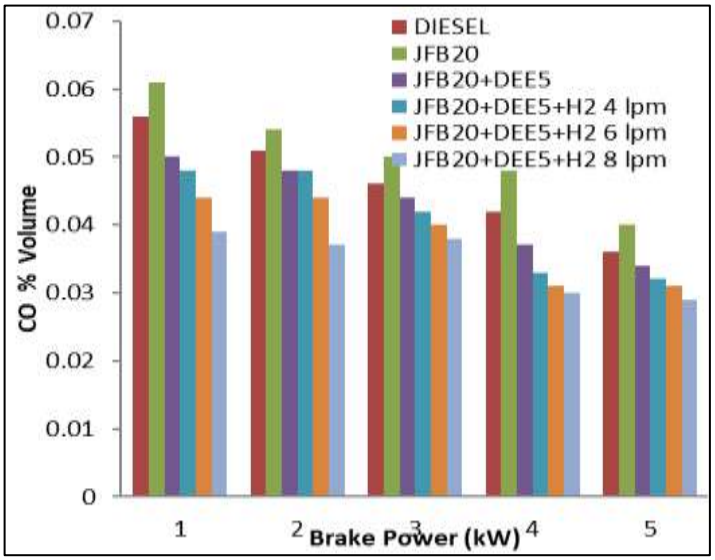

Figure 7: Variation in CO emission.
Source: Authors, (2026).

III.3.2.2 Unburned hydrocarbon emissions (UBHC)

The another important emission characteristics of the tested oil blends is the Unburned hydrocarbon emissions (UBHC) that are measured against at different load conditions are plotted as shown in Figure 8. From the graph it is noticed that for the juliflora blend (JFB20) HC emission is slightly increases from 3 % to 9 % for the half load and full loads than the diesel. It is because the biodiesel oil has volatile and inadequate atomization of fuel. It is observed that, the UBHC emissions are decreases when the Diethyl Ether is added to blend it gives 9% HC reduction as the load increases. For the blends JFB20DEE5H4, JFB20DEE5H6 and JFB20DEE5H8, UBHC is decreasing by 9% to 28% at full load than diesel. Hydrogen stabilizes combustion by shorter ignition delay, more controlled premixed combustion and less fuel escaping unburned [20]. HC emissions decrease with hydrogen enrichment as the hydrogen contains no carbon and promotes faster, more complete combustion, improving oxidation of Juliflora biodiesel.

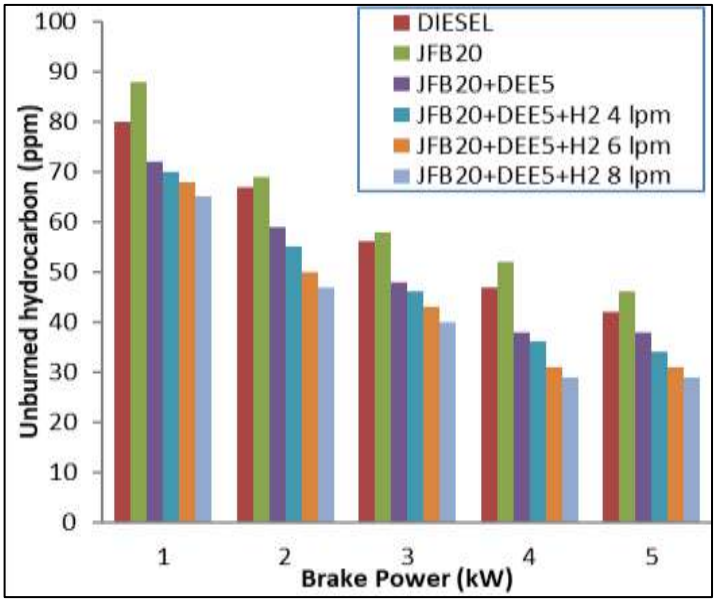

Figure 8: Variation in UBHC.
Source: Authors, (2026).

III.3.2.3 Oxides of nitrogen (NOx) emissions

The NOx is an emission which should be controlled during the combustion of fuels. The values for different blends at varying load conditions are measured are plotted in graph depicted in Figure 9. In general, the NOx emissions are increasing as the percentage of load increases. In-cylinder temperature, reaction time and availability concentration of oxygen content in the biodiesel are the main reasons for the formation of NOx. It is observed that, the NOx emissions are high for pure diesel. Increasing load gradually increases the NOx emission for all tested fuels.

NOx formation depends mainly on high combustion temperature and oxygen concentration. According to the Zeldovich mechanism, at temperatures above 1800 K, nitrogen reacts with oxygen to form nitric oxide. Therefore, faster combustion, high flame speed, higher peak temperature and more oxygen in biodiesel or hydrogen-enriched engines lead to increased NOx formation [21], [22].

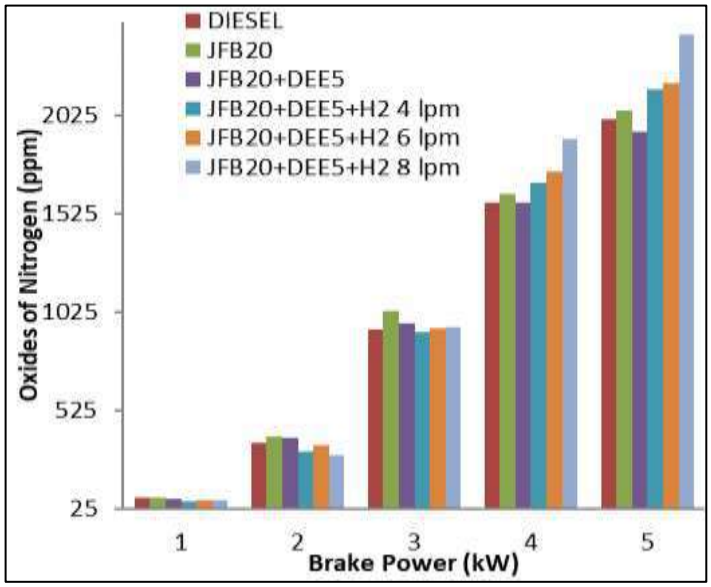

Figure 9: Variation in NO_x.
Source: Authors, (2026).

III.3.2.4 Smoke emissions

The smoke emission is measured and the variations against the different loading conditions are plotted in graph as depicts in Figure 10). From the graph, it is observed that, smoke opacity increases in JFB20 blend mainly because of higher viscosity and poor atomization comp are to pure diesel. It leads to incomplete combustion and formation of soot particles. Though the biodiesel contains oxygen, the poor spray characteristics and slower evaporation can increase smoke under certain engine conditions [23]. The Diethyl ether slightly reduces the smoke to 1% than the diesel. The better reduction smoke is achieved by the enrichment of hydrogen with the JFB20DEE5 at 4 lpm, 6 lpm and 8 lpm and reduces by 5%, 8% and 11% for the blends JFB20DEE5H4, JFB20DEEH6 and JFB20DEEH8 respectively at full load condition than the pure diesel.

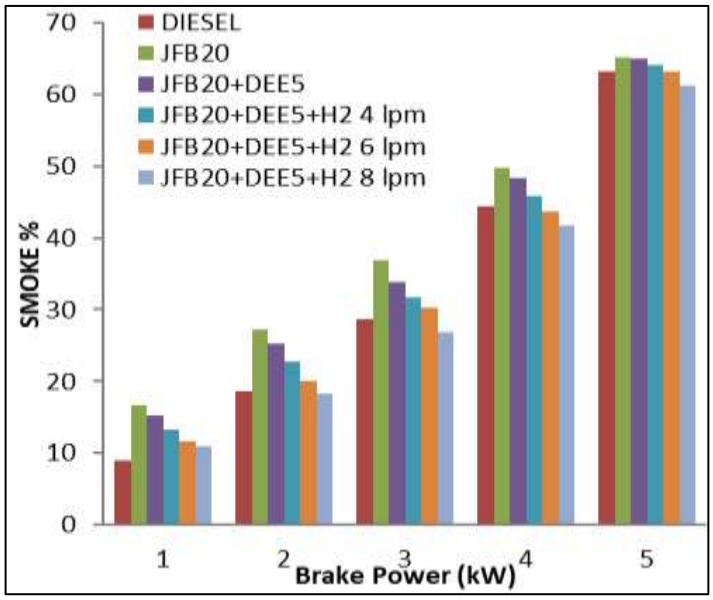

Figure 10: Variation in Smoke emission.
Source: Authors, (2026).

III.3.3 Combustion characteristics

III.3.3.1 Incylinder pressure

The combustion characteristics of the fuel being consumed are the main determinants of the pressure and net heat release rates produced during combustion in internal combustion engines. During combustion, the engine's JulifloraB20 and JulifloraB20 along with 5%DEE at different hydrogen flowrates at full load, which results in variations in the in-cylinder pressure. It is clear that both JulifloraB20 and Juliflora B20 along with 5%DEE and the hydrogen-enriched JulifloraB20 biodiesel mix generated increased cylinder pressure when compared to pure diesel fuel (Refer Figure 11).

A larger calorific value of the hydrogen-enriched fuel mix with greater density, more fuel injection, an earlier start to the combustion process, and better ignition quality can all increase in-cylinder pressure and combustion speed. Figure8 shows the combustion cylinder pressures for different fuel blends and hydrogen flow rates at 100% load. Specifically, the comparison is drawn between pure diesel, Juliflora B20 and various hydrogen blends, ranging from 4 lpm to 8 lpm hydrogen flow. At full load condition the Jfb20 the cylinder pressure decreases to 65.33 bar from the 68.27 bar which is the cylinder pressure achieved by the pure diesel. It is reduced by 7.7% than that of diesel. While adding the 5% of Diethyl Ether(DEE) the cylinder increases by 1.2 % than the diesel. It is observed that the hydrogen enriched JFB20 blends with 4 lpm, 6 lpm and 8 lpm attained the cylinder pressures 70 bar, 72.5 bar and 75.3 bar respectively. The addition of hydrogen significantly impacts the combustion process, as hydrogen has a higher energy content and burns faster than conventional fuels, leading to a more intense combustion cycle and increased pressure. At the highest hydrogen flow rate 8 lpm (JFB20DEE5H8) the cylinder pressure is notably higher, reflecting a more efficient and potentially more powerful combustion. The data specifically highlights that at 100% load, an 8 lpm hydrogen flow produces an approximate 10.3% increase in cylinder pressure compared to using diesel fuel. This result underscores the role of hydrogen in enhancing the combustion characteristics of biodiesel blends, improving performance by increasing the cylinder pressure, which may contribute to better power output and potentially reduced emissions, given hydrogen's cleaner combustion properties [24], [25]. This suggests that hydrogen blending can be an effective strategy for optimizing engine performance and fuel efficiency, especially when considering the transition to greener energy sources in the automotive and industrial sectors

III.3.3.2 Heat Release Rate

An analysis of the engine's combustion status is conducted using the HRR. Because the injected fuel had a higher mass concentration than diesel fuel, the maximum HRR value for JFB B20 blends developed. The rate of heat release from biodiesel blends was greater than that of regular diesel fuel due to their shorter ignition delay period. Additionally, the biodiesel fuel blends showed a greater peak rate of heat release. The diffusive combustion phase revealed a little reduced heat release when utilizing biodiesel blends as fuel as opposed to regular diesel. This may be because biodiesel has a larger concentration of oxygen, which eventually results in a longer burning phase. In this figure 12, the plots of Heat Release Rate (HRR) for various fuel blends at both 100% load are shown, highlighting the effect of hydrogen addition to JFB20, a hydrogen-free biodiesel made from Juliflora oil. Hydrogen addition at all load conditions exhibited marked increase in HRR values, which infer better combustion. At 100% load, the HRR for JF B20 reaches 32.22 J/ºCA, and when adding 5% DEE it increases to35.9J/ºCA.

For 8 lpm hydrogen is introduced, this value goes up to 41.74 J/ºCA-an increase of 3.41 J/ºCA or an enhancement by 9%. The high flame speed and energy density of hydrogen improve overall combustion efficiency, resulting in higher heat release and pressure. This also signifies that combustion is more complete with hydrogen leading to enhanced engine performance [21], [25]. The continuous increase in HRR for load conditions, especially at the highest hydrogen flow of 8 lpm, brings to focus the advances that could be made looking at hydrogen as a safe fuel additive aimed at improving biodiesel performances. Not only this enhancement pertains to power generation, but it may also help in optimizing fuel usage and reducing emissions, with hydrogen being naturally environmentally-friendly. With a fair increase in HRR at both loads, hydrogen blending stands as one of the encouraging strategies for optimizing biodiesel combustion and addressing the technological concerns for better engine performance, which respects the wish of diminishing the environmental impact of conventional fuels.

IV. CONCLUSIONS

The above investigation describes the effect of enrichment of hydrogen with Juli Flora biodiesel in addition of Diethyl Ether with Diesel. The present investigation evaluated the performance, emission and combustion characteristics of a CI engine fuelled with Juliflora biodiesel blend (JFB20), JFB20 with 5% Diethyl Ether (DEE), and hydrogen-enriched JFB20DEE5 at varying hydrogen flow rates (4, 6 and 8 lpm). The results indicate that JFB20 exhibits slightly lower brake thermal efficiency (BTE) compared to diesel due to its higher viscosity, density and lower volatility, which adversely affect atomization and evaporation. The addition of 5% DEE moderately improves BTE owing to its high cetane number and better volatility. Significant enhancement in performance is observed with hydrogen enrichment. At 8 lpm hydrogen flow (JFB20DEE5H8), BTE increased by 10% compared to diesel at full load.

This improvement is attributed to hydrogen's high calorific value, high flame speed and rapid premixed combustion, which advance heat release towards TDC, increase peak cylinder pressure and reduce combustion duration. Brake Specific Fuel Consumption (BSFC) decreases with increasing load for all blends. Although JFB20 and JFB20DEE5 show slightly higher BSFC than diesel, hydrogen enrichment markedly reduces fuel consumption. At full load, JFB20DEE5H8 achieved a 4% reduction in BSFC compared to diesel. This reduction is mainly due to partial diesel substitution by hydrogen, improved oxidation of biodiesel droplets, enhanced combustion efficiency and reduced late burning losses. In terms of emissions, JFB20 shows a marginal increase in CO and UBHC emissions at higher loads due to incomplete combustion arising from poor spray characteristics.

However, hydrogen enrichment substantially reduces CO (17%) and UBHC (up to 28%) at full load compared to diesel. The carbon-free nature of hydrogen, along with faster and more complete combustion, enhances oxidation reactions and minimizes unburnt fuel emissions. Smoke opacity, which slightly increases for JFB20 due to higher viscosity and poor atomization, is effectively reduced with hydrogen addition, achieving up to 11% reduction at 8 lpm compared to diesel. NOx emissions increase with load for all tested fuels. The rise in NOx with hydrogen enrichment is mainly attributed to higher in-cylinder temperature, increased oxygen availability and faster combustion, consistent with the Zeldovich thermal NOx formation mechanism. Although hydrogen improves combustion efficiency, the associated rise in peak temperature promotes NOx formation. Combustion analysis further supports these findings.

Hydrogen-enriched blends demonstrate higher in-cylinder peak pressure and heat release rate (HRR) compared to diesel and JFB20. At full load, JFB20DEE5H8 produced a 10.3% higher cylinder pressure and enhanced HRR, confirming improved combustion intensity and energy utilization. The higher flame speed and energy density of hydrogen lead to a more rapid and efficient combustion process. Overall, the study demonstrates that hydrogen enrichment of JFB20DEE5H8 significantly enhances engine performance and combustion characteristics while reducing CO, UBHC and smoke emissions. Although NOx increases due to elevated combustion temperature, the combined use of Juliflora biodiesel, DEE and hydrogen presents a promising strategy for improving CI engine efficiency and reducing carbon-based emissions. With appropriate NOx control techniques, hydrogen-assisted biodiesel blends can serve as a viable and sustainable alternative fuel for future diesel engine applications.

ABSTRACT

Plant disease detection is essential to ensure the quality of agricultural production. However, manual identification of disease symptoms is often tedious and susceptible to human error. Deep learning techniques have been widely integrated into agricultural systems, providing innovative solutions thanks to their robustness. Most of these studies are essentially based on Convolutional Neural Networks (CNNs) architectures. This paper presents a lightweight and accurate model for the classification of 29 plant leaf classes using the PlantVillage dataset. We propose a hybrid learning model called Agriculture Network (AgriNet**)**. AgriNet consists of only six layers, and integrates the strengths of three CNN models : Residual Neural Networks-50 (ResNet-50), Visual Geometry Group-16 (VGG-16) and AlexNet. ResNet-50 is a very deep and powerful network, whereas VGG-16, despite having a large number of parameters, achieves good accuracy using (3×3) filters. In contrast, AlexNet presents a relatively simple architecture compared to the other two deep models. An extensive set of experiments was conducted to evaluate the performance of the proposed model for plant disease detection. The analysis, based on assessment measures, including accuracy, precision, recall, and F1-score, demonstrates that our model achieves highly reliable results, with an accuracy of 97.13%. Furthermore, AgriNet maintains low complexity due to its lightweight hybrid architecture and reduced parameters count.

I. INTRODUCTION

Agriculture can be defined as the process of raising animals, cultivating crops, and producing food. It also includes preparing plants to improve the quality of production. Plant disease is a natural issues that affect plant development and, in severe cases lead to plant death. It can cause significant damage to agricultural crops [1]. Therefore, plant disease detection is fundamental to preventing reductions in food production. The use of computer systems has driven a significant transformation in agriculture. This convergence, referred to as Digital Agriculture, relies on technologies including artificial intelligence (AI) to improve and optimize agricultural yields. Earlier studies have employed machine learning (ML) and deep learning (DL) techniques for the detection and classification of plant diseases. Several ML algorithms have been developed, such as K-means clustering [2], Naïve Bayes [3], support vector machine[4], and Random Forest [5], [6].

Deep learning technique is a specialized and swiftly advancing domain of machine learning. Convolutional neural networks (CNNs) are commonly integrated into this methodology to handle image classification tasks. In [7], the authors have shown that deep learning outperforms traditional machine learning techniques in identifying diseases in plant leaves. The main advantage of deep learning is the direct exploitation of image without any intervention from a human expert. In plant disease detection, Convolutional Neural Networks analyze leaf images by learning discriminative features, including patterns linked to shape, texture, and color and then classify them into categories that correspond to specific plant diseases. The quantity of features increases as the total number of the layers increases. Several CNN architectures have been developed for disease classification, such as AlexNet, VGG-16, and ResNet-50.

The selection of these three models was motivated by their complementary capabilities: while some excel in feature extraction, others provide greater network depth or improved training stability, making them well-suited for integration in our approach. AlexNet was developed in 2012 [8]. The AlexNet architecture was relatively straightforward in design, consisted of 8 layers : five convolutional layers and three dense layers. It utilized ReLU activation functions and dropout for regularization. The first layers of AlexNet used larger kernel sizes (11x11 and 5x5). This structure allowed the model to capture low- and mid-level patterns. Deeper layers progressively learned more abstract and hierarchical representations, which were crucial for achieving high performance in image classification tasks [9], [10]. In 2014, the Visual Geometry Group-16 (VGG-16) was proposed [11]. This model employed 13 convolutional layers with (3x3) filters, and 3 dense layers. The model demonstrate a strong ability to extract rich and discriminative features from images, which were essential for accurate classification.

This capability made it particularly well-suited for agricultural applications. VGG-16 is known for its high number of parameters [12], [13]. Residual Neural Network-50 (ResNet-50) was introduced in 2016 [14]. It featured 50 layers, and has been recognized for its remarkable depth and performance in plant disease detection. ResNet-50 incorporates residual blocks, which enable it to capture finer details that may be missed by other models. It has proven effective when applied to datasets with complex patterns and multiple categories [15], [16]. In this work, we propose AgriNet (Agriculture Network), a novel model that detects plant diseases by fusing the three prominent deep learning architectures: AlexNet, VGG-16, and ResNet-50. We have two main goals: The first is to detect and categorize 29 types of plant diseases with the highest possible accuracy. The second is to develop a lightweight model, allowing AgriNet to be used on mobile or IoT devices, even in environments with limited computational resources.

To achieve these goals, we have defined the following secondary objectives:

- To thoroughly analyze and effectively leverage the strengths of AlexNet, VGG-16, and ResNet-50, enabling AgriNet to combine their advantages for higher accuracy and better generalization in plant disease classification.
- To design a novel, lightweight architecture that is computationally efficient and adept at capturing plant diseases.
- To improve classification accuracy while minimizing error rates.

The rest of this paper is structured as follows : Section 2 provides an overview of related studies. Section 3 describes the dataset employed and introduces the principles and foundations of the proposed deep learning model for plant disease classification. Section 4 presents the experimental results obtained from the experiments and includes comparisons. Finally, Section 5 reports the conclusion and perspectives for future research.

II. RELATED WORK

This section is organized into two main subsections. Section 2.1 reviews notable studies that have used AlexNet, VGG-16, and ResNet as baseline models to enhance plant-leaf disease recognition. Section 2.2 presents studies aimed at developing lightweight and less complex deep learning architectures.

II.1 BASELINE MODELS: ALEXNET, VGG-16, AND RESNET

To ensure accurate plant disease detection, numerous methods have been proposed. Notably, in [17] the authors developed a hybrid CNN model to classify diseases in tomato leaf images. The model was evaluated using two datasets: the Taiwan dataset and the Tomato Leaf Disease Detection dataset. The authors used AlexNet, ResNet-50, and VGG-16 to extract features. Their last fully connected layers produced feature vectors. Then, the MRMR algorithm optimized these features by removing redundancy and keeping only the most relevant ones. The refined features were combined into one set and sent to standard machine learning classifiers. This approach reached about 96.3% on the Taiwan dataset and 98.3% accuracy on the tomato disease dataset.

Farhat and Chokka [18] proposed a convolutional neural network that combines VGG-16 and ResNet50. Important features are first extracted from the image using VGG-16, and then more intricate and abstract details are captured using ResNet-50. The outputs from both models are fused to yield a richer and more complete representation of the image. The performance of the model was assessed on several datasets : PlantVillage, PlantDoc, FieldPlant, and a rice leaf. The proposed hybrid approach reached about 99% accuracy.

In [19], a fusion at the feature level is used to ensemble the CNNs: features from VGG-16 and ResNet-50 are concatenated before being fed into a unified model. Based on experiments conducted using a publicly available dataset of 2 152 images of healthy and unhealthy potato leaves, an accuracy of 98.22% was obtained by the ensemble model, compared to 96.16% for VGG-16 and 95.68% for ResNet-50.The authors acknowledge that their study is based on a small number of potato leaf images, which may limit the model's robustness or generalizability.

Ajra et al. [20] introduced a technique for plant disease detection using the AlexNet and ResNet-50 architectures. The authors used a Kaggle dataset containing tomato and potato leaf images to investigate various leaf diseases. To enable early disease identification, the workflow included image preprocessing, data augmentation, feature extraction, and classification, followed by accuracy-based model evaluation. Experimental findings showed that AlexNet achieved an overall accuracy of 95.9 %, while ResNet-50 reached 97.3 %. The authors noted that the dataset's relatively small size (9,473 images) could limit the generalization capacity of the models.

In [21], the authors developed a deep learning fusion approach for classifying plant leaf diseases. Features obtained from ResNet50, VGG-16, and EfficientNetB0 are combined through concatenation and subsequently passed through a neural network to generate the final classification results. The experiment involved eight balanced classes. The proposed approach obtained an accuracy of 98.25% and a loss value of 0.0315.

In these works, the hybridization of the three models was achieved by concatenating the feature vectors produced individually by each model. Reported accuracies ranged from 95% to 99%. However, most of these studies considered only ten classes (or fewer), which restricts their ability to generalize to more diverse scenarios or novel disease types. Such a lack of diversity can result in reduced robustness.

II.2 LIGHTWEIGHT DEEP LEARNING ARCHITECTURES FOR PLANT DISEASE RECOGNITION

The model discussed in Section 2.1 (as presented in reference [18]) leverages a hybrid architecture by fusing VGG16 and ResNet50. According to the authors, the hybrid model capitalizes on the strengths of both networks while avoiding the excessive complexity that each might present in isolation. This fusion effectively reduces redundancy and improves structural efficiency.

Nguyen and Huynh [22] introduced an architecture that integrates ResNet into a modified version of VGG-16, designed to meet the constraints of low-end hardware. They demonstrate that ResNet-50 performs poorly with small batch sizes due to ineffective BatchNorm, while the proposed model removes BatchNorm and avoids this issue. Moreover, the original VGG-16's large fully connected layers create a memory burden and may worsen vanishing gradient issues. Their model addresses both memory constraints and gradient vanishing, and achieves an overall accuracy of 85.4%, outperforming ResNet-50's 75.9%.

In [23], the authors proposed an efficient lightweight model for classifying pepper leaf diseases. The dataset included images of healthy leaves and those exhibiting symptoms, these images were captured with human palms as the background, reflecting real-world field conditions. The proposed model was based on the GGM-VGG16 architecture, enhanced with Ghost modules, global average pooling (GAP), and multi-scale convolutions. Experimental results demonstrated that the model achieved 100% accuracy on images with human palm backgrounds and 87.38% accuracy on images with other backgrounds.

Zhengjie et al. [24] developed ICS-ResNet, a lightweight version of ResNet-50 that incorporates an improved spatial–channel attention mechanism and depth-separable residual blocks to reduce parameters and computation. Using cosine annealing for better training stability, the model achieved 98.87% accuracy on the PlantVillage maize leaf disease dataset while reducing parameters by about 69% compared to ResNet-50.

In [25], the authors introduced a lightweight architecture for plant disease classification, referred to as the Lightweight Pyramidal Multi-scale Attention Residual Network (LPMA-ResNet). The framework employs a dual-level pyramid structure combined with an adaptive attention mechanism to capture informative multi-scale features while suppressing noise. When evaluated on the Soybean Disease and PlantVillage datasets, LPMA-ResNet consistently outperformed existing leading approaches. Specifically, on the soybean dataset, LPMA-ResNet (×1.0) achieved 2.12% higher accuracy than ShuffleNet-v2 (×2.0), while requiring only about two-thirds of its parameters.

These studies demonstrate that by combining the VGG-16 and ResNet-50 models, it is possible to create deep learning architectures that decrease network complexity and enable the model perform effectively on low-end hardware or in resource-limited environments. In these works, only a limited number of classes were considered (a maximum of eight), achieving accuracies between 85% and 98%.

III. MATERIALS AND METHODS

The methodology employed in this study is delineated in this section, including data description, pre-processing steps, and the deep learning models. Each stage is described in detail to provide a comprehensive understanding of the approach taken to develop and evaluate our plant disease classification system.

III.1 DATA DESCRIPTION

In this work, the leaf images were obtained from the benchmark Plant Village dataset [26] , with a modified version specifically prepared for the purposes of this study. The dataset contain 67 118 images of diseased and healthy plant leaves from 9 different species. It is split into 29 classes, each class represents a type of disease. Figure 1 shows a sample of leaves belonging to different classes.

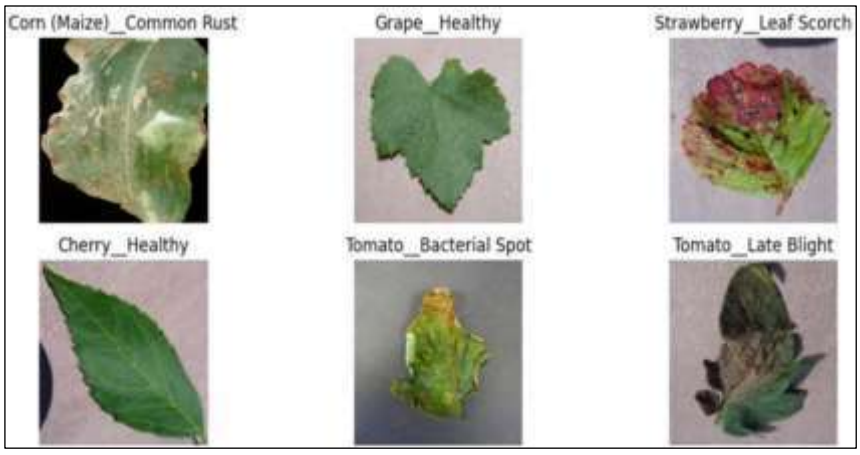

Figure 1: Samples of leaf images.
Source: [26].

III.2 PRE-PROCESSING

Pre-processing is very important step. Within this stage, images are subjected to resizing, normalization, and augmentation. Then, data set is partitioned into training, validation and test sets.

III.2.1 Resizing and normalization images

The dataset images are 256×256 pixels, but some deep learning models are built to work with a specific size (224×224). Their architecture expects inputs of that dimension. The resizing makes the images compatible with the pre-trained models. Next, the pixel values of an image (input) are adjusted to a standard range, usually between [0, 1]. This stage is the normalization, and it helps the model train faster and improves its performance [27].

III.2.2 Data augmentation

After collecting the images, data augmentation is utilized during the pre-processing stage. The application of data augmentation expands the training set in terms of size and variety, thereby helping to reduce overfitting and enhancing the model's generalization performance [28]. The transformations used in this pre-processing part are rotation and zooming, which allow minor variations in the images (see Figure 2).

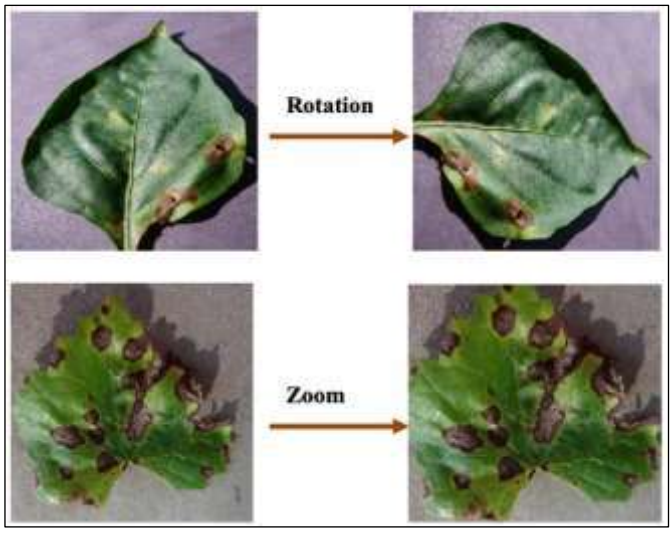

Figure 2: Data augmentation using rotation and zoom.
Source: Authors, (2026).

III.2.3 Data splitting

To optimize the performance of a model, in most cases it is typically developed and evaluated on three sets of data. The Training Set (80%) represents the biggest part of the data and it is essential for the model's ability to learn and generalize. It contains 53 694 distinct images, offering a wide range of examples that enable the model to capture discriminative features across classes. The Validation Set (10%), consisting of 6 712 images, serves to assess the model's performance on unseen data during training. It helps detect overfitting and enables the fine-tuning of hyperparameters, such as batch size and learning rate. The Test Set (10%) also contains of 6 712 images and is used after training to measure the model's final effectiveness on independent data not seen during training. The histogram in Figure 3 shows the overall number of images in each category. The x-axis represents the different types of plants (29 classes): some are healthy, others affected by diseases. The y-axis shows the total number of images, combining the training, validation, and test sets.

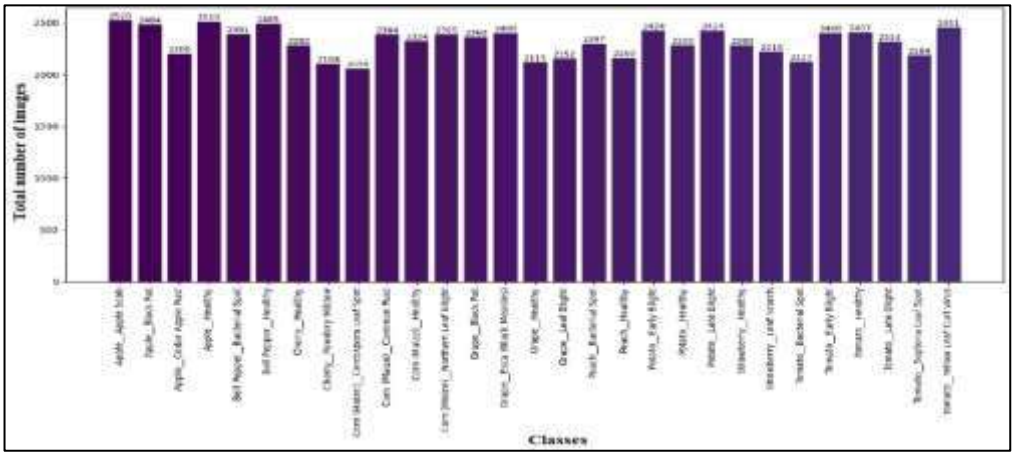

Figure 3: Histogram showing the data Split.
Source: Authors, (2026).

The number of images differs slightly between classes (as shown in the histogram), but overall the dataset is well balanced , which is an essential condition for effective learning.

III.3 DEEP LEARNING MODELS

In this work, three CNN architectures —AlexNet, VGG-16, and ResNet-50— were employed as baseline models. These architectures were chosen due to their demonstrated effectiveness in image classification tasks. A lightweight CNN model, named AgriNet (Agriculture Network), was developed specifically for plant disease classification.

III.3.1 AlexNet model

AlexNet [8] represents one of the pioneering deep convolutional neural network architectures, designed specifically for image classification tasks. It incorporates a total of eight layers: five convolutional layers, some succeeded by MaxPooling layers, and three dense layers. The Rectified Linear Unit (ReLU) is employed as the activation function. It is adopted in this network due to its superior performance over traditional functions such as tanh and sigmoid. The ReLU function is formulated as:

$$f(x) = max\ (0, x) \tag{1}$$

It is a non-linear activation that leaves positive values unchanged and replaces all negative values with zero, which results in sparse activations. This sparsity, helps prevent overfitting, reduces computational cost and acts as a form of implicit regularization. Convolutional layers extract features from the image. They transform the raw image into a rich and compact representation that can be utilized by the subsequent layers for classification. By downsampling feature maps, pooling layers minimize spatial dimensions, which reduces computational cost. This also simplifies the input to the dense layers, where the combined outputs of the convolutional and pooling stages are used to perform the final classification. Figure 4 presents the structure of the AlexNet model as applied to our dataset. This modified version of AlexNet incorporates Batch Normalization to enhance the stability and efficiency of deep neural network training.

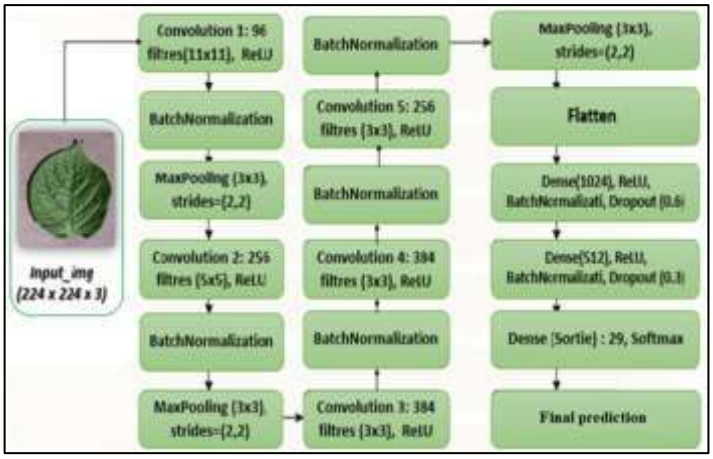

Figure 4: AlexNet model architecture.
Source: Authors, (2026).

AlexNet model takes color images of size (227 × 227 × 3) pixels as input. It is composed of five convolutional layer blocks, which progressively extract hierarchical characteristics from images.

- *Block 1 :* In the first block, processing starts with a convolutional layer that applies 96 filters each of size (11 × 11), using a stride of 4. It's role is the extraction of low-level characteristics.The resulting feature maps are then batch normalized, which normalizes the activations of a layer within a mini-batch. After that, a max pooling with a (3×3) window and stride 2 is used to reduced size of feature maps.
- *Block 2:* This block uses convolutional layer with 256 filters, each of size (5×5), using a stride of 1. Afterwards, a batch normalization and a max pooling are applied (similar to the first block).
- *Blocks 3 and 4:* These two blocks are similar and contain a convolutional layer with 384 filters, each of size (3×3), with a stride of 1. A batch normalization is applied.
- *Block 5*: 256 filters, each of size (3×3), with a stride of 1 are used in the last convolutional layer, and followed by batch normalization and max pooling. At this level, feature extraction is complete.

Next, the output produced by the final convolutional block is flattened and represented as a one-dimensional vector. This step prepares the extracted features for integration into two dense layers that produce the ultimate classification result.

- *First dense layer:* The first dense layer consists of 1024 neurons using the ReLU activation function, followed by batch normalization and a dropout of 0.6. A slightly higher dropout rate than in the original AlexNet (0.5) was used to further enhance generalization and reduce the risk of overfitting, given the model's complexity and the large number of target classes in the dataset (29 classes).

- *Second dense layer:* This dense layer comprises 512 neurons, employs ReLU activation, and is regularized with batch normalization and a 0.3 dropout rate.The lower dropout rate in this layer helps retain more learned features while still providing regularization to prevent overfitting.

In the *output* layer, 29 neurons are employed with a softmax activation to represent the 29 classification categories. The softmax activation transforms the outputs values into probabilities, approximating how likely each class is correct. The probability is determined using the following formula:

$$\text{Softmax}(s_i) = \frac{e^{s_i}}{\sum_{j=1}^{k} e^{s_j}} \quad \text{for } i=1,....,K \tag{2}$$

The function converts the raw outputs $s=[s_1,s_2,...,s_K]$ of the final dense layer into a probability distribution across the K target classes. Each term s_i in the softmax vector denotes the probability attributed to class i for the current input. These probabilities adhere to specific properties ; All probability values fall within the interval [0,1], with their sum constrained to 1.

Training Details

For multi-class classification, the training procedure used a categorical cross-entropy loss function in conjunction with the Adam optimizer, which had a learning rate of 0.0005.

III.3.2 VGG-16 model

The VGG-16 model [11] employs 13 convolutional layers that utilize small (3×3) kernels, followed by three dense layers for classification. Stacking several convolutional layers enables the network to capture progressively more detailed features from an image. AlexNet uses larger kernel sizes (11x11), while VGG-16 adopts (3x3) filters, allowing it to capture fine local details with greater accuracy. The network takes as input an RGB image of dimensions (224×224×3). This image is processed through convolutional layers with a stride of 1 pixel. Downsampling is performed using five max-pooling layers, each applied after specific convolutional layers, though not every convolution layer is followed by pooling. Max-pooling is applied on a 2x2 pixel window, with a stride of 2. In this section, the core convolutional architecture of VGG-16 was retained and initialized with weights pre-trained on ImageNet. The parameter include_top=False was used to exclude the original fully connected classification layers. Only the last three layers were set as trainable, while the rest of the network remained frozen. Figure 5 illustrates the VGG-16 architecture as applied to our dataset.

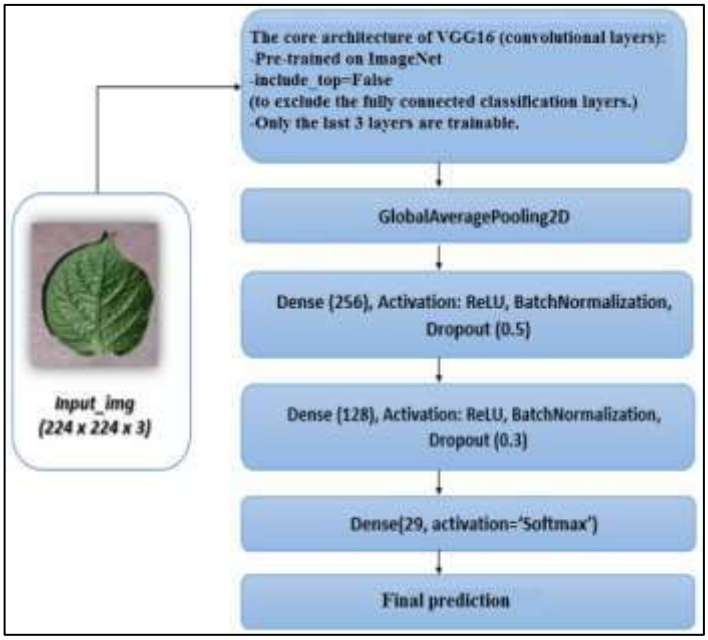

Figure 5: VGG-16 model architecture.
Source: Authors, (2026).

The added layers are:

- *A GlobalAveragePooling layer (GAP),* which summarizes the extracted features into a vector. GAP calculates the average of all values in the feature map. The output size produced by Global Average Pooling (GAP) is minimal compared to Flatten. This decreases the trainable parameter count and gives better the model's generalization ability.
- *Two dense layers*: the first one comprises 256 neurons activated with ReLU, followed by bath normalization and a 0.5 dropout rate to limit overfitting. The second dense layer is composed of 128 neurons, also using ReLU activation, combined with bath normalization, and a 0.3 dropout rate.

The *output layer* contains 29 neurons, with each neuron representing a specific disease class, in accordance with the dataset's class count.

Training Details

The training of the VGG-16 model employed the Adam optimizer configured with a 0.001 learning rate. The loss function selected was categorical cross-entropy, as it is widely used for multi-class classification tasks.

III.3.3 ResNet-50 model

ResNet-50 [14] is composed of residual blocks, each made up of several convolutional layers, along with a skip connection that directly adds the block's input to its output. The primary distinction between VGG-16 and ResNet-50 is the use of these skip (residual) connections. This design preserves gradient magnitudes during backpropagation, facilitating more effective training of deep neural networks. The structure of the ResNet-50 residual block is illustrated in Figure 6.

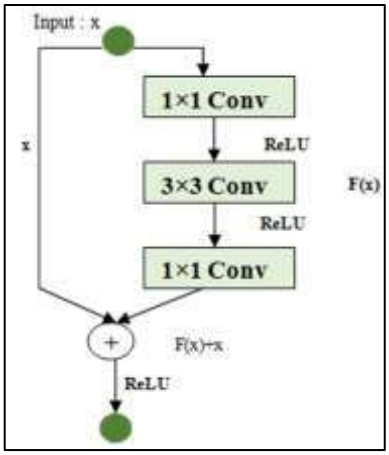

Figure 6: ResNet-50 residual block.
Source: [14].

- The first convolutional layer uses (1×1) filter to decrease the number of input channels.
- The second convolutional layer employs a (3×3) filter to capture spatial features from the input data.
- The third convolutional layer also employs a (1×1) filter to revert to the original number of channels prior to merging the output with the shortcut connection.

The *ReLU function* is applied following each convolutional layer and and its ensuing batch normalization layer. *Skip connection* essentially skips convolutional layers, and allows the original input to be added directly to the convolutional layer output immediately prior to ReLU activation. A skip connection preserves important information and maintains performance. Formally, it is defined as:

$$y = F(x) + x \tag{3}$$

Here, x denotes the original input, $F(x)$ represents the transformation performed by the convolutional layers, and y corresponds to the layer's output. In this part, we retained the core architecture of ResNet-50, training only the final ten layers while freezing the remaining ones. The architecture of ResNet-50, adapted for our dataset, is illustrated in Figure 7.

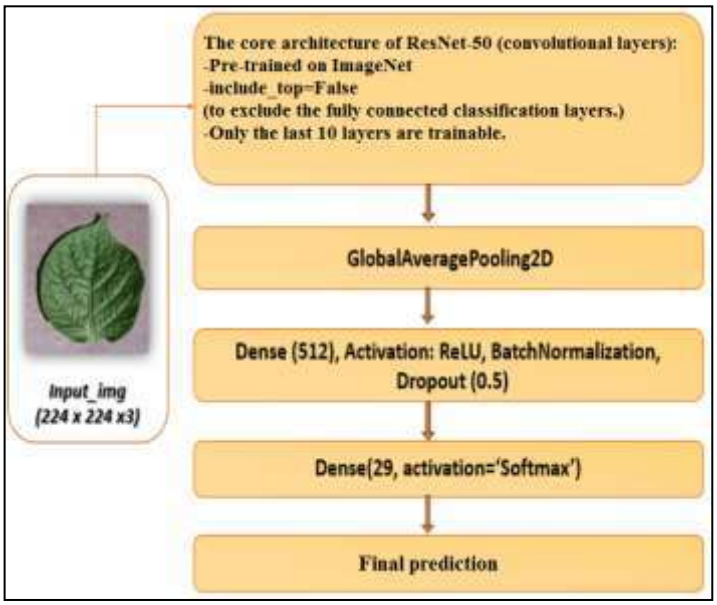

Figure 7: ResNet-50 model architecture.
Source: Authors, (2026).

Next, we added a *GlobalAveragePooling layer* to to reduce the learned feature representations into a compact vector representation. Following the GAP, a dense layer with 512 neurons is applied, incorporating ReLU activation, batch normalization, and a 0.5 dropout to enhance generalization. The *output layer* comprises 29 neurons with a softmax activation, corresponding to the different diseases to be identified.

Training Details

For training the ResNet-50 model, the Adam optimizer was used with a 0.0001 learning rate, along with categorical cross-entropy as the loss function.

III.3.4 AgriNet: The Proposed model

The objective of this study is to propose a lightweight and performant model, designed for mobile, IoT, or other resource-constrained devices. The proposed model AgriNet (Agriculture Network), combines: the simplicity of AlexNet, the efficiency of VGG-16, and the power of residual connection from ResNet-50. AgriNet avoids the complexity of ResNet-50. AgriNet consists of three convolutional blocks, followed by a Global Average Pooling layer (GAP) and two dense layers for the final classification, as illustrated in the figure 8. The reduced number of layers (a total of six) is inspired from the Alexnet model, which consists of only eight layers and has demonstrated high efficiency in image classification tasks. VGG-16 is known for its strong ability to extract fine-grained features through its simple convolutional layers with 3×3 filters. In AgriNet, we preserve this strength in both the first and second blocks. The number of filters increases with network depth, allowing for more complex feature extraction. The *first block* is designed to capture initial features while incorporating batch normalization and dimensionality reduction through max pooling. Next, a dropout layer with a 0.25 rate is used.

The value is set at 0.25 to provide moderate regularization. Given the number of layers, the size of the dataset, and the number of classes (29 classes), this rate will avoid overfitting while preserving sufficient feature information for effective learning. The *second block* focuses on extracting more complex features while maintaining regularization. The convolutional layer applies 64 filters each of size (3 × 3). ResNet-50's strength lies in its use of residual (skip) connections, which facilitate the learning of deep representations. In AgriNet, we introduce a skip connection in the third block (mid-network), where features transition from local, detailed information to more abstract representations. Without this skip connection, this block risks over-transforming features, potentially leading to the loss of fine-grained details. By adding the skip connection at this stage, we reintroduce the original input features into the deeper, more latent representations, preserving a balance between fine details and the overall context. In a skip connection, the dimensions of x may be different from $F(x)$ due to the convolution, which can reduce its size. A convolutional layer with 128 filters of size (1×1) is applied to x to match the channel required dimensions for the addition, ensuring a direct linear path for information flow.

Block 3 deepens the extraction of complex features while gradually reducing the dimensionality of the feature maps, ensuring that essential information is preserved for classification. The ReLU activation is applied after the addition, allowing the skip connection to transmit useful negative values, thereby improving the overall information flow.

The *GAP layer* performs dimensionality reduction, while preserving the essential information through the computation of the mean value across each feature map, producing a compact, low-dimensional vector (GAP is lighter than Flatten). The use of GAP layer followed by a dense layer greatly reduces the count of trainable parameters relative to the traditional Flatten–Dense approach. This design choice lowers memory consumption and further supports the model's suitability for lightweight deployments on mobile and embedded systems. *The first Dense layer* (512 neurons) learns abstract representations from the vectors produced by the previous layers. Dropout regularization is employed to mitigate the risk of overfitting by preventing this layer from excessively memorizing the training data. Batch normalization, applied after each convolutional layer, ensures better regularization and more stable convergence. The *final layer* is composed of 29 neurons, activated through a softmax function, corresponding to the set of diseases to be classified.

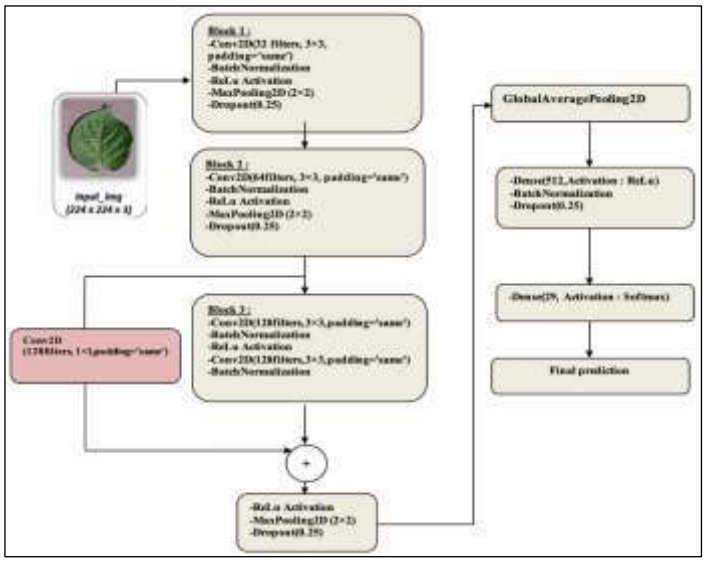

Figure 8: Proposed model architecture.
Source: Authors, (2026).

Training Details

The proposed model was developed using the Keras Functional API, although the architecture is relatively simple. Functional API was chosen because it allows the inclusion of a skip connection between blocks, which cannot be implemented directly with the Sequential API. Once the architecture was defined, the training process employed the Adam optimizer, initialized at a learning rate of 0.001, which was automatically reduced to 0.00001 through the ReduceLROnPlateau strategy. For this 29-class classification task, the model uses categorical cross-entropy as the loss function.

Performance Evaluation

The assessment of the model is essential for validating its classification performance, and several evaluation metrics are employed for this purpose [29].

- *Accuracy* represents the overall proportion of predictions that were correct (whether positive or negative), as shown in equation (4):

$$Accuracy = \frac{TP+TN}{TP+FP+TN+FN} \tag{4}$$

- *Precision* measures the proportion of positive predictions that are actually correct, it is mathematically defined as follows:

$$precision = \frac{TP}{TP+FP} \tag{5}$$

- *Recall* reflects the model's capacity to correctly detect all actual positive instances, as defined in equation (6):

$$Recall = \frac{TP}{TP+FN} \tag{6}$$

- *F1-score* is a metric that combines *Precision and Recall* into a single value, as shown in equation (7):

$$F1 - score = \frac{2 \times precision \times recall}{precision + recall} \tag{7}$$

Here, TP, TN, FP, and FN stand for True Positives, True Negatives, False Positives, and False Negatives, respectively. These metrics provide a clear and comprehensive assessment of each model, both at the global and class-specific levels.

IV. RESULTS AND DISCUSSIONS

In deep learning, the last stage in classification is to identify the category of the input. In this work, after processing the image with a deep neural model (AlexNet, VGG-16, ResNet-50, or our proposed model 'AgriNet'), the system predicts its category. The probability for each class was calculated, and the final result is the class with the highest probability. In this way, the image is automatically categorized into one of the listed disease classes. Unlike binary models that output only 'diseased' or 'healthy', our approach provides a more detailed diagnosis.

IV.1 PERFORMANCE ANALYSIS OF THE ALEXNET MODEL

The AlexNet model was trained for 40 epochs on our dataset. The figure below illustrates the evolution of training and validation accuracy and loss during this process.

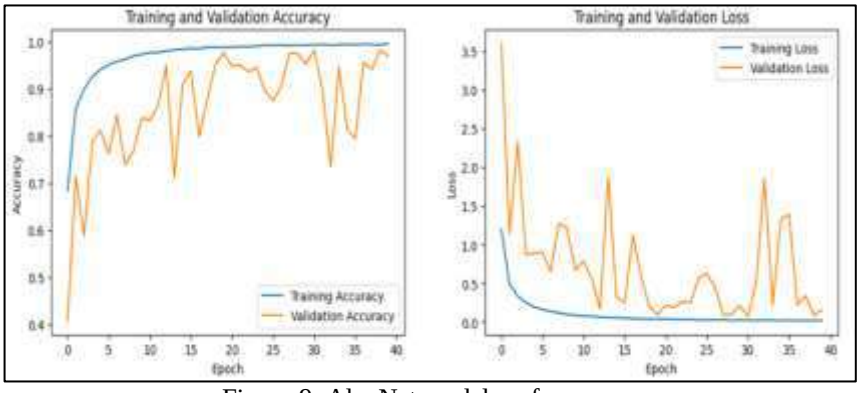

Figure 9: AlexNet model performance.
Source: Authors, (2026).

The training accuracy increases rapidly during the initial epochs and stabilizes above 95%. This indicates that the model successfully learns the training data. In parallel, the training loss significantly decreases toward zero, confirming a stable convergence process.The validation accuracy shows strong fluctuations across epochs, which reflects instability in the model's ability to generalize, despite the use of batch normalization. The validation loss is high and highly variable, and present several significant peaks, confirming a tendency toward overfitting.

The instability in the validation loss point to possible improvements, such as incorporating additional data augmentation. Overall, the model learns the training data effectively, but it has trouble generalizing to unseen data. The obtained test accuracy is 98.15%, with a loss of 0,0846.

IV.2 PERFORMANCE ANALYSIS OF THE VGG-16 MODEL

The VGG-16 network was trained on our dataset for 30 epochs, and its training and validation performance is illustrated in the following figure.

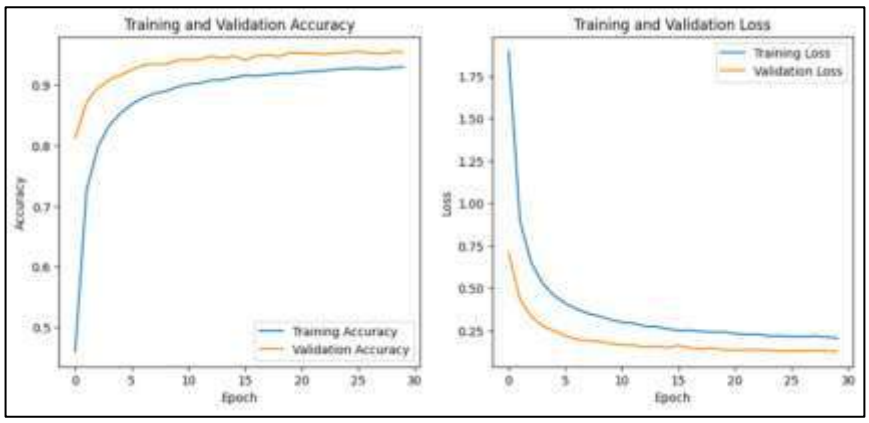

Figure 10: VGG-16 model performance.
Source: Authors, (2026).

Training accuracy rises quickly in the first few epochs and reaches around 92%, while validation accuracy exceeds 95%, showing excellent generalization capability. This is largely due to the application of data augmentation and dropout. The training and validation loss curves gradually decrease and stabilize at low values, without any noticeable divergence between them. It means that the model effectively minimizes error on the training data. The absence of overfitting further confirms that the model converges well, with stable and reliable behavior. The results obtained on the test data are: an accuracy of 95.87% with a low loss of 0.1241.

IV.3 PERFORMANCE ANALYSIS OF THE RESNET-50 MODEL

The ResNet-50 architecture was trained the on our dataset for 30 epochs. Figure 11 illustrates its training and validation evolution.

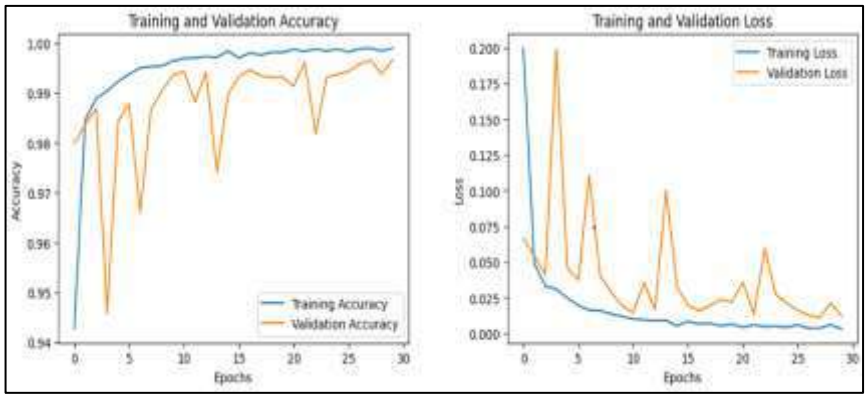

Figure 11: ResNet-50 model performance.
Source: Authors, (2026).

During training, the accuracy curve increases quickly in the first few epochs. It show the strong learning capacity of the ResNet-50 model. In parallel, the training loss decreases steadily and converges quickly towards zero, confirming stable and efficient convergence. For validation, the accuracy curve indicates that the model experienced slight overfitting at the 4th epoch, but stabilizing around 99%, which indicates good generalization ability. The validation loss shows some initial instability with noticeable peaks, but overall it decreases and remains at low values, demonstrating a satisfactory fit of the model. Once training was completed, the model was evaluated on the test set, obtaining an accuracy of 99.73% with a corresponding low loss of 0.0118.

IV.4 PERFORMANCE ANALYSIS OF THE AGRINET MODEL

The proposed model ‘AgriNet’ was trained on our dataset for 25 epochs. The following figure shows the results obtained.

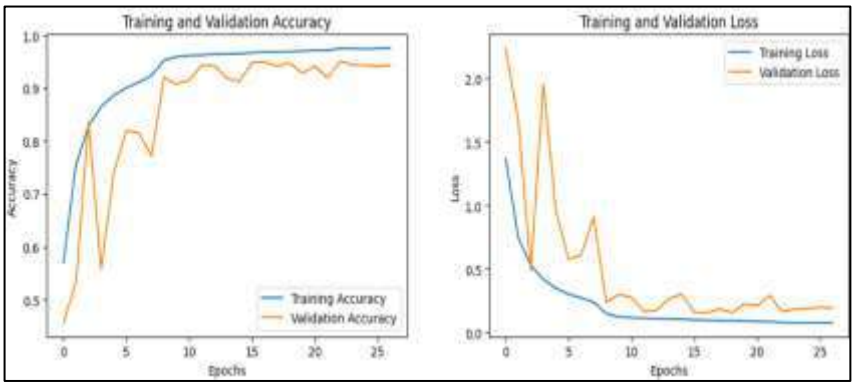

Figure 12: AgriNet model performance.
Source: Authors, (2026).

The results demonstrate strong performance and stability of AgriNet. As illustrated in the training and validation curves, the model achieves a rapid increase in training accuracy during the initial epochs and stabilizes above 98%, while the training loss steadily decreases toward very low values. It indicaties a robust convergence process. Similarly, the accuracy on the validation data remains consistently elevated, and stabilizing at 97%, which confirms the model's capacity to perform well on unseen data. Although the validation loss exhibits slight fluctuations compared to the training loss, it remains relatively low and stable at 0.2, without signs of divergence (no significant overfitting). The proposed model achieves excellent convergence, and maintains a good balance between training and validation performance. The obtained test accuracy is 97.13%, with a corresponding loss of 0.1579. Figure 13 illustrates the model's performance for a subset of classes, showing clearly that the model performs very well across most categories, with recall, precision, and F1-scores generally within the 90–100% range.

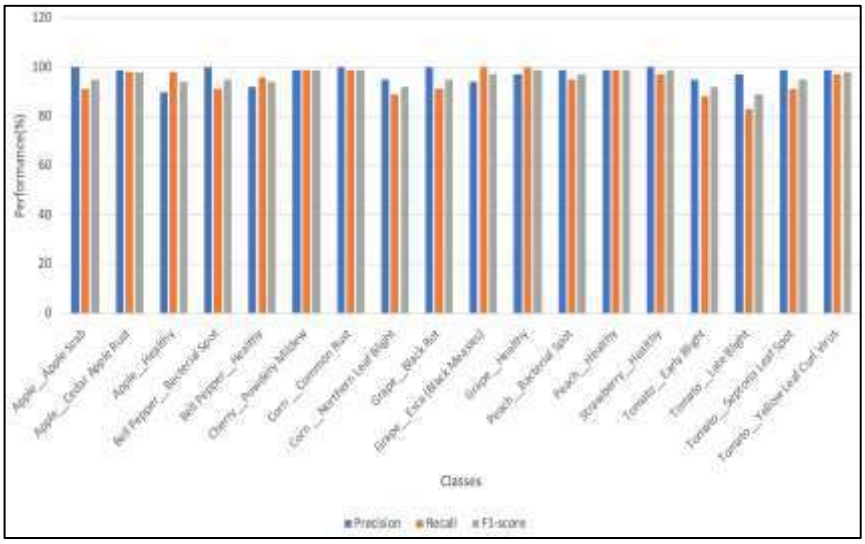

Figure 13: Precision, recall and f1-score analysis.
Source: Authors, (2026).

The number of epochs for each model was chosen empirically, based on their depth and the behavior of the learning curves. AlexNet is relatively shallow (but fairly wide), it required about 40 epochs to stabilize its performance on training set. However, the validation curves reveal persistent instability. VGG-16 and ResNet-50, being more complex, converged in roughly 30 epochs, while our proposed 6-layer model reached its best performance in just 25 epochs. According to these results, AgriNet appears to be the best suited to the size and complexity of the data.

By analyzing Table 1, it can be observed that our proposed model 'AgriNet' achieves slightly lower accuracy compared to ResNet-50. However, ResNet-50 incurs higher computational cost due to its deeper structure and greater parameter count. In contrast, each parameter represents a weight stored in memory. A model with fewer parameters requires less RAM and can be loaded and executed more efficiently. With only 323 165 parameters and a depth of six layers, AgriNet is the most compact model among those evaluated.

This compact design makes AgriNet especially useful in environments with limited resources, such as mobile or embedded devices, characterized by constrained memory and processing power. In addition, AgriNet demonstrates that reducing model complexity does not necessarily lead to a dramatic loss in predictive performance.

The baseline models AlexNet and VGG-16 use more parameters and require more epochs to converge, whereas AgriNet converges in just 25. This shows that older or deeper networks are not always optimal and highlights the need to design models that fit the computational resources, instead of relying solely on accuracy.

Table 1: Comparison of the models based on their architecture and performance.

	AlexNet[8]	VGG-16 [11]	ResNet-50 [14]	AgriNet
Depth	8 layers	16 layers	50 layers	6 layers
Number of Parameters	10,8 M	14.9 M	23.6 M	323 165
Pretrained Weights	ImageNet	ImageNet	ImageNet	None
Dropout rate	0.6, 0.3 (Dense)	0.5, 0.3 (Dense)	0.5 (Dense)	0.25(Conv), 0.5 (Dense)
Batch size	32	32	32	32
Optimizer	Adam	Adam	Adam	Adam
Learning rate	0.0005	0.001	0.0001	0.001,0.0001, 0.00001
Epochs	40	30	30	25
Accuracy (%)	98.15%	95.87%	99.73%	97.13%

Source: Authors, (2026).

Importantly, these results are consistent with recent advances in lightweight architectures [22], [23], [24], [25], as previously discussed in the second section, which also emphasize balancing accuracy with efficiency (see Table 2). Notably, our model addresses 29 classes, in contrast to these studies where the number was limited to a maximum of eight. Moreover, AgriNet is the most compact, with only eight layers.

Table 2: Comparison of the proposed model with recent works on lightweight deep learning architectures.

Ref.No	Nbr. Of classes	Dataset	Methodologys used	Layers	Accuracy %
Nguyen and Huynh [22]	5	Flowers dataset	VGG-16 + ResNet-50	5 blocks, each containing 2 to 3 convolutional layers, plus 2 FC layers.	-% 75,9 for ResNet-50 -85.4%, for VGG-16 + ResNet-50

Source: Authors, (2026).

Abbreviations: FC, fully connected; GGM, Ghost modules, Global average pooling, Multi-scale convolution; ISA: Improved Spatial Attention.

To evaluate the generalization of the model under real-world conditions, an additional validation was carried out on the PlantSeg dataset [30]. This dataset contains 115 disease classes across 34 plant species. Since PlantSeg does not exactly cover the 29 diseases of PlantVillage, the evaluation was performed only on the classes common to both datasets (partial validation). The results show an accuracy of 95,87%, this slight decrease reflects the increased complexity of field images. Nevertheless, these results confirm that the model maintains robustness and significant generalization capability under real-world conditions.

V. CONCLUSIONS

In this paper, we have proposed a novel model, AgriNet, which fuses the strengths of three Deep Learning architectures : Alexnet, VGG-16, and ResNet. The design of AgriNet was motivated by the need for accurate yet computationally efficient models for agricultural applications, especially in the domain of plant disease detection. The proposed network is lightweight, consisting of only six layers : three convolutional blocks, one Global Average Pooling layer, and two dense layers. Experimental evaluation is conducted on the Plant Village dataset (29 classes), and it demonstrates that AgriNet achieves a high recognition accuracy of 97.13% with a corresponding loss of 0.1579. These results confirm that the model can accurately detect plant diseases while also generalizing well to unseen data. Furthermore, the model maintains low complexity, with fewer layers and fewer parameters than the other three state-of-the-art models. In the future, we aim to evaluate AgriNet on additional datasets to provide stronger evidence of its robustness. We also plan to explore its practical deployment on IoT and mobile devices. These intelligent agricultural systems will provide farmers with accessible and cost-effective tool to monitor plant health, reduce crop losses, and ultimately improve food security.

ABSTRACT

This study explores the use of tamarind gum biopolymer (TGB) as a sustainable additive in concrete, with a focus on workability, strength, and durability. TGB considerably improves concrete performance by increasing hydration, decreasing microcracking, and encouraging a denser microstructure at an optimum dosage of 0.2% by weight of cement. Slump cone and flow table tests show that 0.2% TGB provides a balanced combination of workability and stength. Tests of strength revealed gains in split tensile strength (20% at 7 days, 21.21% at 28 days), flexural strength (7.81% at 7 days, 10.83% at 28 days), and compressive strength (10.78% at 7 days, 11.13% at 28 days). Incorporating 0.2% TGB into concrete significantly enhances its durability by reducing chloride ion penetration, indicating improved performance in aggressive environments. A comparison of linear regression and MLP-based ANN models demonstrated that the MLP provided more accurate predictions of 28-day concrete compressive strength from 7-day results, effectively capturing nonlinear relationships. XRD analysis reveals that incorporating 0.2% TGB enhances hydrogen and carbon bonding in concrete, significantly improving its flexural strength, durability, and resistance to cracking and environmental stress. SEM analysis revealed the formation of C–H bonds, indicating effective integration of tamarind gum biopolymer and its role in enhancing the microstructure of concrete.

I. INTRODUCTION

A developing field that fits with the demand for eco-friendly substitutes for conventional chemical additives and the increased focus on sustainable building practices is the use of biopolymers in concrete. Tamarind Gum, known for its thickening, binding, and water-retaining properties, offers several potential benefits when used as an additive in concrete. Because it is readily accessible, renewable, and biodegradable, it is a desirable alternative for lowering the environmental impact of building materials. By methodically assessing the impact of tamarind gum biopolymer (TGB) at different concentrations on the workability, strength, and durability of concrete, this study aims to close that gap. Now a days many researchers working on incorporating biopolymers into concrete to enhance its mechanical properties and durability, offering sustainable solutions for the construction industry.

I.1 STUDIES ON THE ROLE OF BIOPOLYMERS IN CONCRETE

Xanthan gum: Compressive strength and chlorine ion penetration are investigated in relation to self-compacting concrete's (SCC) rheology. The resistance and durability of SCC were accurately predicted by a backpropagation neural network model, with xanthan gum serving as the critical component [1]. The viscosifying effect of xanthan gum on cement slurry for use in cementing oil wells is the focus of this research. Experimental results showed that xanthan gum improved the slurry's pumpability by increasing its compressive strength, thickening time, and rheology. Consistent with xanthan gum's capacity to lessen cementing operation failure, results showed an increase in compressive strength with time [2].

For the purpose of improving concrete slabs, this study investigates a biopolymer-modified cementitious repair material (CXT) that consists of xanthan gum, tartaric acid powder, and Portland cement. The mechanical properties, load-bearing capacity, and structural integrity of recovered concrete are enhanced by CXT, according to testing. Rebuilding concrete infrastructure could be made possible by CXT due to its environmental benefits and cost-effectiveness, according to the article [3].

Tamarind Kernel Powder: The purpose of this experiment is to examine how incorporating tamarind kernel powder (TKP) into cement changes its characteristics. Slump cone tests for workability and split tensile tests for compressive strength are the primary aims of the investigation. The purpose of the findings is to assess the efficacy of TKP in enhancing the performance of cement [4]. The research paper explores into the topic of tamarind seed powder and its bonding and gelling properties in relation to food and medicine. We talk about the structural, rheological, and physical characteristics of tamarind seed powder as well as its hydration behaviour and its uses. This research provides novel insights for several industries, including construction, by demonstrating the many potential uses of tamarind seeds in both food and non-food production [5]. Research into the effectiveness of tamarind powder and fly ash in enhancing HPC is taking place in this project.

For workability, strength, and durability, the study substitute's fly ash for portland cement in varying proportions and tamarind powder for some sand. Compressive, split tensile, and flexural strengths of modified concrete are higher than those of regular concrete, according to experimental results [6]. In order to improve sustainability, this study investigates using Date Seed (DS) and Tamarind Seed (TS) in place of some fine particles in M25 grade concrete. Control-conformant concrete can be created by substituting fine particles for the 10% DS and 1.5% TS. But after this, concrete's mechanical properties deteriorate due to replenishment [7]. This research looks at the possibility of improving the quality of concrete by adding tamarind kernel powder to it. Powdered tamarind kernels, at concentrations ranging from 0% to 3%, improve the flexural strength and load-bearing capacity of reinforced concrete beams.

The addition of tamarind kernel powder to concrete makes it more stable than regular concrete [8]. The usage of tamarind kernel powder (TKP) as an addition in concrete at different percentages (0% to 0.75%) by cement weight is examined in this study. The compressive and split tensile strengths of concrete cubes and cylinders were evaluated. The findings demonstrated that adding TKP enhanced the concrete's strength characteristics [9]. This study explores the use of tamarind kernel powder, a bio-waste material, as an admixture in concrete, with additions ranging from 0.25% to 1.25% of cement weight. The results suggest that adding up to 1% tamarind kernel powder enhances concrete strength without negatively affecting workability or fresh concrete qualities. This addition improves concrete performance, as confirmed by non-destructive tests, making it a sustainable substitute [10].

Guar gum: Guar gum, an environmentally friendly additive, affects concrete mechanical properties in this investigation. Guar gum can replace up to 0.8% of cement to improve compressive and tensile strengths, although higher water-to-cement ratios lower strengths. Guar gum generates threads between concrete particles, modifying its shape, according to SEM [11]. The application of natural biopolymer additives (guar gum, sodium alginate, and Kathira) to increase concrete's resistance to scouring is investigated in this work. The findings demonstrate that these additions lessen concrete shrinkage and improve the mechanical qualities (compressive, tensile, and flexural strength). Additionally, all three biopolymers increase scouring resistance [12]. The effects of guar gum and arabic gum on the moisture and strength of concrete were studied. Research shows that a combination of 0.5% arabic gum and 0.75% guar gum increases compressive strength, but that using too much gum can diminish its advantages. Without increasing the price, these bio-waste components enhance concrete [13].

Cellulose: In order to improve the performance of carbonation-cured OPC-slag composites, this research investigates the utilization of nanocellulose and polydopamine. Microporosity is reduced and nano porosity is enhanced by both biopolymers, and the degree of binder reaction is raised. Adding 0.05 weight percent of nanocellulose or polydopamine increases flexural strength by 66% and early compressive strength by 35%, respectively [14]. With different percentages (0.5%, 1%, 1.5%, and 2%) added to the mix, the application of cellulose fibers in structural concrete is examined in this work. According to the findings, compressive strength increases up to 1% cellulose fiber before declining. In general, cellulose fiber concrete mixes improve performance and strength, but excessive amounts decrease effectiveness [15]. This study found that cellulose nanocrystals (CNC) improve cement/fly ash paste mechanical characteristics, especially when dosed higher. CNC enhances hydration products, gel pores, and transition pores and speeds up hydration, according to study. The findings suggest CNC could improve fly ash/cement composites for building [16].

Arabic gum and Other Biopolymers: In order to restore columns damaged by tidal flooding, this effort created bio-polymer modified concrete utilizing Gracilaria sp., Moringa oleifera, and honey (GMH). After 14 months of monitoring, the modified columns compressive strength increased by 92.34% to 32.37 MPa. The study highlights the potential for GMH-based biopolymer concrete to increase durability and sustainability in maritime environments [17]. The combined effects of superplasticizers (SP) and biopolymer viscosity-modifying admixtures (BVMA) on the rheological characteristics of cement pastes are examined in this work. The findings showed that when combined, BVMA increased viscosity and SP via regulating hydration and setting times, improving compressive strength. The results of the study show that when combined with SP, BVMA shows a lot of promise as a viscosity modifier in cement-based composites [18].

This study examines the application of alginate, a natural polymer generated from marine brown seaweed, in concrete, emphasizing its advantages in enhancing durability and sustainability. Alginate is a naturally occurring hydrogel that helps fix carbon dioxide, stabilize soil, and increase heat capacity. The study highlights how alginate might improve the properties of green concrete for environmentally friendly building [19]. The application of Gum Arabic (GA) derived from Acacia Senegal trees as a superplasticizer in self-compacting concrete is examined in this work. With an ideal dosage of 8% by weight of cement at water-powder ratios of 1.0, 0.9, and 0.8, the study discovered that GA enhances the rheology of concrete. For self-compacting concrete, GA is suggested as an efficient and environmentally friendly superplasticizer [20].

This study tests biopolymers such giant kelp extract, locust bean gums, almond, and tragacanth as viscosity-modifying admixtures (VMAs) in cement-based composites. Pre-dispersion procedures affect rheology, with welan gum, giant kelp extract, and guar gum performing well. This biopolymer increased paste stability but hindered early strength growth [21]. An overview of the effects of incorporating biopolymers into mortar and concrete is given in this paper, with particular attention paid to increases in workability, compressive strength, and water retention. Chitosan, xanthan gum, guar gum, lignosulfonate, and cellulose ethers are examples of biopolymers that improve physical characteristics and lessen heavy metal leaching. Biopolymer-based concrete and mortar are more environmentally friendly and long-lasting [22]. This work examines silica-lignin hybrid materials as cement composite admixtures, demonstrating that they are classified as I-class hybrid materials due to their weak physical interactions between constituents.

Rheological properties were enhanced by the inclusion of these bio-admixtures; the greatest outcomes were shown at a silica-lignin ratio of 5:1, which increased compressive strength while preserving enough flexibility. Higher silica content had the opposite impact from higher lignin content, which decreased mechanical characteristics [23]. The usage of κ-carrageenan and thermo-reversible animal gelatin as substitute binders for temperature-controlled 3D concrete printing is investigated in this work. According to the study, these biopolymers have good buildability and appropriate rheological characteristics, with notable increases in yield stress after cooling. The research highlights the potential for more sustainable concrete printing with reduced reliance on cementitious materials [24]. The application of biopolymers in mortar and concrete is examined critically in this work, with an emphasis on how they affect the materials mechanical, physical, and durability properties. It highlights the advantages of resin-based biopolymer composites by contrasting conventional concrete, polymer concrete, and biopolymer concrete. The purpose of the publication is to advance knowledge and offer insightful information for upcoming studies and uses of biopolymer concrete [25].

Partially replacing cement in environmentally friendly concrete with ceramic waste powder (CWP) and rice husk ash (RHA) is the focus of this investigation. By substituting 20% CWP and 10% RHA for the cement, the compressive strength increased by 14%, the tensile strength by 28%, and the flexural strength by 19%. In addition to improving concrete's properties, recycling these by-products helps lessen landfill waste and its harmful impacts on the environment [26]. In order to reduce lead (Pb) leachability, this study investigates the use of biopolymers (xanthan gum, guar gum, and chitosan) to encapsulate CRT glass waste in concrete. The resultant composites demonstrated a notable decrease in lead leachability and a 30% increase in compressive strength, both of which were much below hazardous waste requirements. This strategy provides a long-term way to lessen the problems associated with CRT waste [27]. A unique concrete composite was tested using six natural polymers as binders, and each one's compression strength was assessed. Composites based on gelatin exhibited the maximum compression strength (59.6 MPa), but those based on chitosan and κ-carrageenan demonstrated lower strengths.

The study found that because of their better mechanical properties, gelatine-based composites are most suited for use in building [28]. The study measures the long-term compressive strength of polymer concrete composites with different types of fine fillers for a period of up to 9.5 years following preparation. The results showed that fly ash composites in particular had excellent durability and significant strength improvements over time. These findings disprove the notion that strength training is only effective over the short term [29]. This research aims to promote sustainability and recycling by investigating the feasibility of making concrete with marble powder instead of cement. After 28 days, the results were the greatest when 10% to 15% marble powder was used instead of cement to increase the compressive and tensile strengths. Future building applications may face challenges due to mechanical quality degrading as replacement numbers increase [30]. The effects of aluminosilicate pozzolanic wastes (FCCW and MK) on cured Portland cement paste are investigated in this study. It finds that FCCW strengthens the material under compression and speeds up the hydration process.

By combining FCCW with MK at a 1:1 ratio, microstructure is enhanced and portlandite production is decreased. The compressive strength was higher in the composite binder mixture that contained 9% cement as opposed to the prior one [31]. In order to improve the mechanical properties and longevity of concrete, this research investigates the possibility of adding calcined kaolin (CK) and gum Arabic (GA). There is an 8.94% improvement in compressive strength with 0.8% GA and no discernible decrease in strength when using up to 20% CK in place of cement, according to the results. The results of the durability tests showed that 0.6% GA produced the highest compressive strength [32]. The effects of calcined kaolin (CK) and gum Arabic (GA) on the workability, setting time, and mechanical performance of concrete are investigated in this study. The results show that 20% CK is optimal for increasing compressive strength, and that 0.8% GA is optimal for improving mechanical properties and workability. Electron microscopy and X-ray fluorescence analysis confirm the materials' beneficial chemical interactions and surface contour [33].

Starch: The effects of adding starches and their derivatives to concrete mixes on hydration, creep, and compressive strength were investigated. According to preliminary findings, compressive strength rose by 4.9% with cassava starch and 5.3% with 1% maize starch. Additionally, the starch additions improved the hydration and creep characteristics [34]. This study examined how adding starches from cassava (CA) and maize (MS) affected the concrete's strength, oxygen permeability, and absorptivity. The results showed that adding 0.5% and 1.0% CA and 1.5% with MS enhanced compressive strength by 2.7% and 3.8%, respectively. Furthermore, concrete with starch admixtures outperformed control samples, exhibiting lower oxygen absorptivity and permeability [35].

It studied how adding cassava flour to Portland pozzolanic cement influenced fresh and cured concrete. Cassava flour increased compressive, split tensile and flexural strengths. Strength and durability were better with 3% cassava flour. The effects of adding 0%, 0.5%, 1%, and 1.5% maize starch biopolymer to concrete were tested. The results showed that 0.5% starch enhanced slump 25%, fresh density 2.5%, compressive strength 50%, splitting tensile strength 50%, and flexural strength 26%. For concrete enhancement, 0.5% starch worked best [36]. This study studied the effects of raw starch and aquagels on moisture content, shrinkage, and strength in lightweight concrete made from wheat, maize, and high amylose corn starches. Starch-based lightweight concrete had lower compressive strength than perlite-based concrete, although smaller, spherical aquagels increased density and strength.

Extruded aquagels and hydrated raw starch combinations shrank and cracked [37]. This study examined the use of potato starch (PS) as a natural ingredient in concrete at several percentages (0% to 2% of cement weight). According to the data, compressive strength was enhanced by adding 1.2% PS, with 1:2:4 and 1:3:6 mix ratios performing best. By enhancing workability, setting time, and concrete strength, PS offered an affordable and ecologically friendly alternative to durable concrete [38]. This study combined xanthan gum and cassava starch to generate a bio-admixture that increased the bonding strength of cement-based goods. By decreasing porosity and increasing bonding capacity, the ideal xanthan gum ratio increased compressive strength by 16.6%. Additionally, the bio-admixture strengthened the starch's hydrophilic properties, which increased cement mortar's workability and durability [39]. This work explores the use of bio-based polymers, such as acacia gum, cassava starch, and triumfetta pandurate gum, to modify the rheological properties of cementitious systems. While cassava starch had no influence on plastic viscosity and only marginally decreased yield stress, acacia gum was shown to function similarly to superplasticizers based on polycarboxylate.

Combining triumfetta pendrata gum with plasticizing polymers considerably improved the thixotropy of cement pastes [40]. When added to concrete at a rate of 1%, maize starch enhances workability and raises density and compressive strength, according to this study. However, density and compressive strength decrease with additional starch concentration. In addition to improving the properties of concrete, corn starch is an affordable substitute for chemical admixtures [41]. This study presents an innovative method for improving concrete performance by integrating tamarind gum, a naturally sourced biopolymer, as a sustainable additive. Tamarind gum presents a biodegradable and sustainable alternative to conventional admixtures, which has not been thoroughly investigated within concrete technology. This experimental study offers novel insights into the influence of this biopolymer on essential mechanical parameters, including compressive strength, tensile strength, and flexural behaviour. This research integrates traditional material science with sustainable innovation.

II. MATERIALS AND METHODOLOGY

II.1 CEMENT

The usual OPC 53 cement grade is used. The physical properties of the cement, determined by the standard operating procedure, are in accordance with the requirements of IS 12269: 1989. Table 1 displays the physical properties of cement.

Table 1: Physical Properties of cement.

Sr. No.	Property	Value
1	Setting time (initial)	36 Min
2	Setting time (final)	289 Min
3	Consistency of cement	35%
4	Specific gravity	2.69
5	Fineness	4.2%

Source: Authors, (2026).

II.2 FINE AGGREGATE

Sand that was easily accessible locally and that complied with IS 383-1970's requirement by passing through a 4.75 mm sieve was employed. Table 2 displays the fine aggregate's physical properties.

Table 2: Physical Properties of Fine Aggregate.

Sr. No.	Property	Value
1	Specific gravity	2.60
2	Water absorption	3.78%
3	Fineness modulus	2.65%

Source: Authors, (2026).

II.3 COARSE AGGREGATE

Locally available aggregate was processed through a 20 mm sieve and retained on a 4.75 mm sieve, per IS383-1970s recommendations. Table 3 shows the physical characteristics of a coarse aggregate.

Table 3: Physical Properties of Coarse Aggregate.

Sr. No.	Property	Value
1	Specific gravity	2.67
2	Water absorption	1.01%
3	Fineness modulus	3.2%

Source: Authors, (2026).

II.4 TAMARIND GUM BIOPOLYMER

A natural addition to concrete, tamarind gum biopolymer is made from tamarind seeds and enhances workability, strength, and durability. It improves bonding, lowers water requirements, and lessens the likelihood of shrinkage and cracking. Tamarind gum provides a sustainable substitute for artificial additives in concrete because it is an environmentally benign and biodegradable substance. The tamarind fruits were purchased from a local Indian store. The gum was extracted from the tamarind pulp by boiling it, and the resulting gum powder was filtered and dried under close supervision before being used. The required amount of tamarind gum by weight of cement was prepared independently and allowed to cool to room temperature before being mixed with the concrete. Figure 1 shows the tamarind gum biopolymer. Table 4 shows the physical properties of tamarind gum biopolymer.

Figure 1: Tamarind Gum Biopolymer.
Source: Authors, (2026).

Table 4: Physical Properties of tamarind gum biopolymer (TGB).

Sr. No.	Property	Value/Range	Details
1	Appearance	Light brown powder	Depends on processing method
2	Moisture Content	3 – 5%	Determined by GPC
3	Solubility in Hot Water	>90%	At ~80°C, forms viscous solution
4	pH (1% solution)	6.0 – 7.5	Near neutral, suitable for most cement environments

Source: Authors, (2026).

II.5 WATER

For curing and casting, potable water that complies with IS 456-2000 was utilized.

II.6 MIX DESIGN

The concrete mix was designed as per standard guidelines to achieve the desired workability and strength parameters for experimental evaluation. The detailed mix proportions of the control concrete are presented in Table 5. This base mix served as the control for comparison with tamarind gum biopolymer-modified mixes in subsequent trials.

Table 5: Concrete Mix Design.

Sr. No.	Constituents	Concrete [kg/m^3]
1	Cement	353
2	Sand	825
3	Coarse aggregate	1126
4	Water	163
5	w/c ratio	0.46

Source: Authors, (2026).

This research aims to analyse the physical and mechanical properties of the resulting concrete mix, including compressive strength, tensile strength, flexural strength, and durability aspects.

II.7 CONCRETE MIXING

By adding tamarind gum biopolymer to a mix design that includes cement (353 kg/m³), sand (825 kg/m³), coarse aggregate (1126 kg/m³), and water (163 kg/m³), while keeping the water-to-cement (w/c) ratio at 0.46, this study examines the impact of the biopolymer on the characteristics of concrete. The mixing process involved thorough blending of dry materials, followed by the uniform dispersion of the biopolymer and controlled addition of water. Figure 2 shows the addition of TGB while preparing the concrete. Table 6 shows the mix sample name and % dose of TGB.

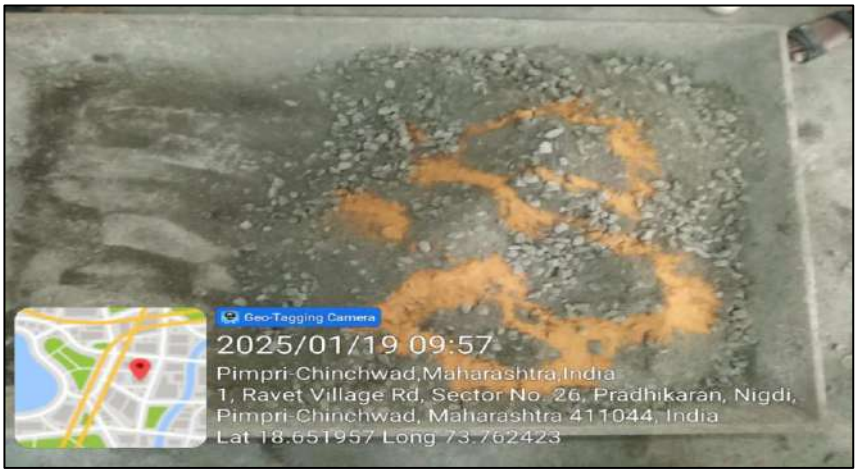

Figure 2: Addition of TGB during preparation of concrete.
Source: Authors, (2026).

Table 6: Details of sample name and % of TGB dose.

Sr. No.	Concrete Sample Name	Details
1	M1	Conventional concrete only
2	M2	Concrete with 0.1% TGB
3	M3	Concrete with 0.2% TGB
4	M4	Concrete with 0.3% TGB

Source: Authors, (2026).

II.8 METHODOLOGY

The experimental study was conducted in a systematic manner to investigate the influence of tamarind gum biopolymer on the mechanical properties and microstructure of concrete. Figure 3 shows the flow chart of methodology of the present study.

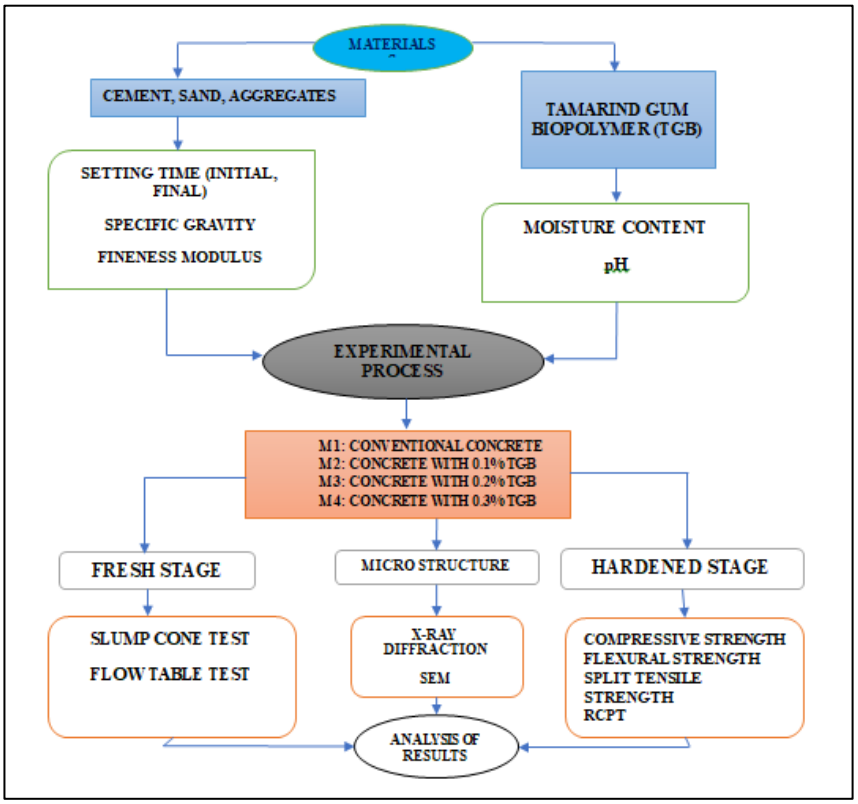

Figure 3: Flow chart of methodology.
Source: Authors, (2026).

III. RESULTS AND DISCUSSION

The analysis for both the freshly mixed concrete and the hardened form are discussed in this section. These assessments encompass the workability, compressive strength, flexural strength, split tensile strength, durability characteristics along with microstructural analysis that were obtained from our experimental analysis:

III.1 SLUMP CONE TEST

The workability of concrete mixes containing varying dosages of Tamarind Gum Biopolymer (TGB) was evaluated using the Slump Cone Test. the conventional concrete mix (M1) maintained a consistent slump of 125 mm**,** indicating high workability. However, with the incremental addition of TGB, a noticeable reduction in slump was observed. At 0.1% TGB dosage (M2)**,** the slump value decreased to 110 mm**,** followed by 100 mm **at** 0.2% (M3)**,** and 90 mm **at** 0.3% (M4)**.** This decline in slump suggests that the inclusion of TGB reduces the flowability of the mix. The decrease in workability can be attributed to the hydrophilic nature of the biopolymer, which tends to absorb and retain water within its structure, thereby reducing the free water available for lubrication between aggregates. Despite this reduction, the workability remained within acceptable limits, particularly at lower dosages, making TGB a viable additive without significantly compromising fresh concrete behaviour. The variation in the slump value of concrete using TGB is displayed in figure 4. Figure 5 shows the experimental photos of slump cone test.

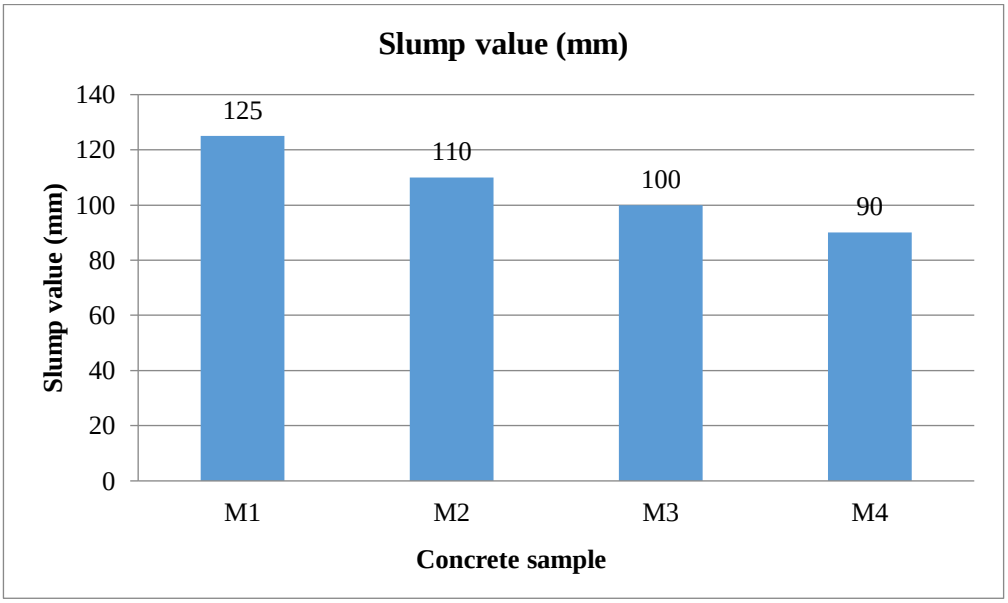

Figure 4: Results of slump cone test.
Source: Authors, (2026).

Figure 5: Slump Cone Test Performance.
Source: Authors, (2026).

III.2 FLOW TABLE TEST:

The flow table test was conducted to further assess the workability and flowability of concrete containing varying dosages of tamarind gum biopolymer (TGB). The control mix, representing conventional concrete, maintained a consistent flow table diameter of 51 mm across all observations. However, with the inclusion of TGB at increasing dosages, a gradual decrease in flow diameter was observed. Specifically, the mix with 0.1% TGB exhibited a flow diameter of 50 mm**,** followed by 49 mm at 0.2%**,** and 48 mm at 0.3%**.** This reduction in flow diameter with increasing biopolymer content is indicative of a decline in the plasticity and flowability of the concrete mix. At lower concentrations, the effect is minimum and still within practical working limits, making TGB a viable additive for enhancing performance without significantly compromising workability. Figure 6 and 7 displays the results of flow table test and photograph of experiment in the lab.

III.3 COMPRESSIVE STRENGTH:

The standard IS 516:1959 describes concrete cube compression testing procedures. Compressive tests are conducted on a compression testing machine (CTM) after curing in water for 7 and 28 days.

III.3.1 Compressive Strength of 7 Days:

The early compressive strength of concrete incorporating tamarind gum biopolymer (TGB) was evaluated after 7 days of curing. The conventional concrete exhibited a consistent compressive strength of 21.89 N/mm^2 across all dosage levels, at 0.1% TGB**,** the compressive strength increased slightly to 23.26 N/mm^2, At 0.2% TGB**,** the strength further increased to 24.25 N/mm^2 and a significant decline in compressive strength was observed at 0.3% TGB**,** dropping to 12.5 N/mm^2. These results indicate that while low to moderate dosages (0.1%–0.2%) of tamarind gum biopolymer can enhance early compressive strength**,** higher concentrations may hinder performance. Figure 8 shows the graphical representation of compressive strength for 7 days.

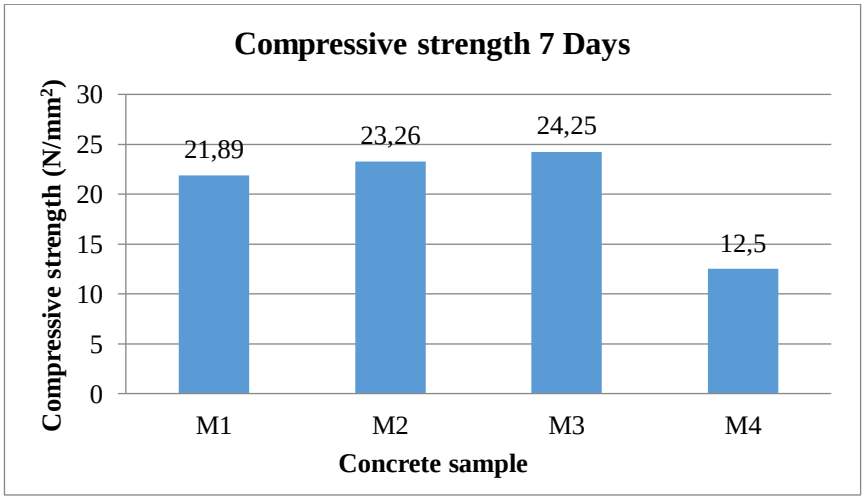

Figure 8: Compressive strength of concrete for 7 days
Source: Authors, (2026).

III.3.2 Compressive Strength of 28 Days:

The 28-day compressive strength of concrete mixes containing varying percentages of tamarind gum biopolymer (TGB) was assessed to determine the long-term mechanical performance of the modified concrete. At a 0.1% dosage**,** the compressive strength of TGB concrete was 34.1 N/mm², At 0.2% TGB**,** a notable increase in compressive strength to 38.12 N/mm² was observed, significantly outperforming the conventional mix. Conversely, at 0.3% TGB**,** the compressive strength dropped sharply to 20.16 N/mm², far below the reference value. This decline suggests that excessive biopolymer content may hinder proper cement hydration and introduce porosity, leading to reduced strength. The hydrophilic nature of TGB at higher concentrations may result in water retention that delays or disrupts the hydration process.

The results demonstrate that an optimum dosage of 0.2% TGB can significantly improve the long-term compressive strength of concrete. The incorporation of tamarind gum biopolymer (TGB) at a dosage of 0.2% by weight of cement significantly enhanced the performance of concrete in terms of its mechanical properties. Specifically, the 7-day compressive strength showed an increase of 10.78%, indicating that the biopolymer positively influenced early strength development. The 28-day compressive strength demonstrated a substantial increase of 11.13% compared to the conventional concrete mix. This gain reflects the long-term benefits of TGB in sustaining hydration, improving matrix densification, and reducing internal porosity. Figure 9 shows the graphical representation of compressive strength for 28 days and figure 10 depicts the cube testing under CTM.

III.3.3 Modeling of Compressive Strength Using LR-LSM, and MLP

a) Linear Regression (LR) and Least Squares Method (LSM)

To establish a predictive relationship between 7-day and 28-day compressive strengths of concrete, a simple linear regression model was developed. The model assumes a linear dependence of the 28-day strength (y) on the 7-day strength (x) and is defined by the equation 1:

$$Y = mx + c \qquad \text{Equation 1}$$

Where:

- y = 28-day compressive strength (N/mm²)
- x = 7-day compressive strength (N/mm²)
- m = slope of the regression line
- c= y-intercept

Using the Least Squares Method (LSM), the values of m and c were computed based on the minimization of the squared differences between the predicted and actual values. The below equation 2 shows that resulting equation.

$$Y = 1.446x + 1.57 \quad \text{Equation 2}$$

This model indicates that, on average, for every 1 N/mm² increase in 7-day compressive strength, the 28-day strength increases by approximately 1.446 N/mm².

b) MLP Model Equation

To predict the 28-day compressive strength of concrete from its 7-day strength, a **Multilayer Perceptron (MLP)** model was developed. The MLP model is particularly well-suited for capturing the nonlinear relationships that govern strength development in concrete. The MLP model can be represented by the following equations 3 as hidden layer output and equation 4 as final output.

Given input x (7-day strength), the prediction $\hat{y}$ (28-day strength) is:

1. **Hidden layer output**:

$$hi = ReLU\ (w_i x + b_i) \quad \text{Equation 3}$$

2. **Final output**:

$$\hat{y} = \sum_{i=1}^{4} Wihi + boutput \quad \text{Equation 4}$$

Where:

- Wi and bi are the weights and biases of the input to the hidden layer.
- Vi and c are the weights and bias of the hidden layer to output.
- ReLU is defined as: ReLU(z)=max(0,z)

So the four hidden neurons are:

h1 = ReLU (−0.0019995·x−0.7536)
h2 = ReLU (1.2841·x−0.4593)
h3 = ReLU (0.2646·x−1.2103)
h4 = ReLU (0.4960.x + 1.0800)

The final output (predicted 28-day compressive strength) is calculated as a **weighted sum** of the activated hidden neurons using equation 5.

$$\hat{y} = 0.0002023 \cdot h1 + 0.7367 \cdot h2 - 0.8383 \cdot h3 + 1.3495 \cdot h4 + 0.9865 \quad \text{Equation 5}$$

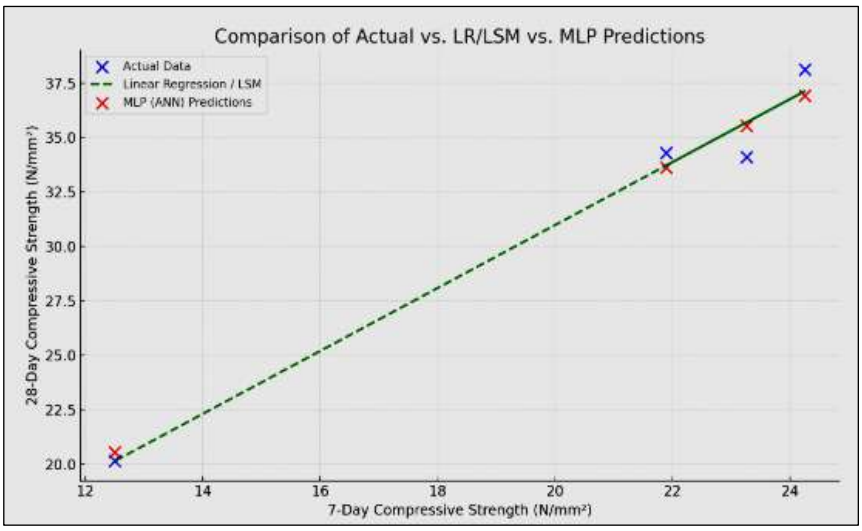

Figure 11: Comparison of Actual vs LR/LSM vs MPL Predictions.
Source: Authors, (2026).

Figure 11 shows that, LR and LSM provide a useful baseline; the MLP model significantly improves prediction accuracy, especially in cases with nonlinear strength gain behaviour. Given its flexibility and accuracy, the MLP model proves to be a promising tool for estimation of concrete compressive strength in practical engineering applications.

III.4 FLEXURAL STRENGTH:

The flexural strength of concrete was determined in accordance with IS 516:1959. Beam specimens of standard size were tested at 7 days using a flexural testing machine with a two-point loading setup.

III.4.1 Flexural Strength of 7 days:

The 7-day flexural strength increased with dosage up to 0.2%, reaching a maximum of 2.62 N/mm^2 before declining to 1.60 N/mm^2 at 0.3% dosage. Compared to conventional concrete, the modified mix showed enhanced performance at 0.1% and 0.2% dosages, but a significant reduction was observed at 0.3%. Figure 12 shows the variation in flexural strength of concrete with different dosages of TGB.

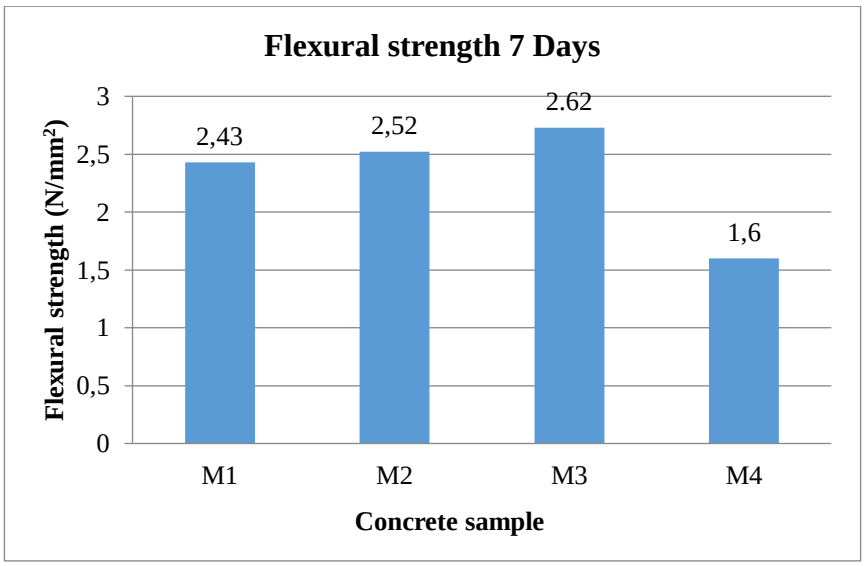

Figure 12: Flexural Strength of concrete for 7 days.
Source: Authors, (2026).

III.4.2 Flexural Strength of 28 Days:

At 28 days, the flexural strength peaked at 4.5 N/mm^2 for the 0.2% dosage, exceeding the conventional concrete strength of 4.06 N/mm^2. Dosages of 0.1% and 0.2% both demonstrated improved flexural performance compared to conventional concrete, while the 0.3% dosage resulted in a notable decrease to 2.8 N/mm^2. The results indicate that an optimal dosage exists around 0.2%, beyond which the flexural strength diminishes significantly. Figure 13 shows the results of compressive strength for 28 days.

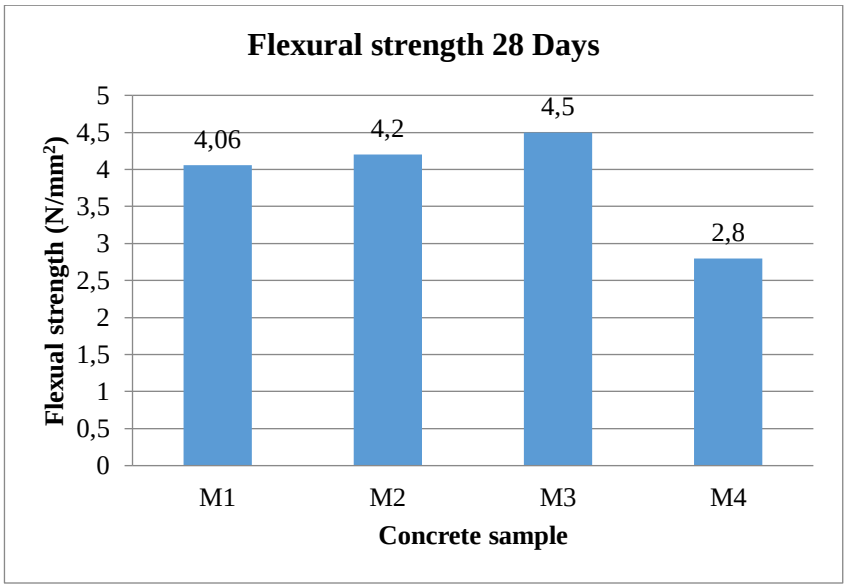

Figure 13: Flexural Strength of concrete for 28 days.
Source: Authors, (2026).

The inclusion of 0.2% tamarind gum biopolymer (TGB) by weight of cement resulted in a notable enhancement of the flexural strength of concrete. Specifically, the flexural strength increased by 7.81% at 7 days and 10.83% at 28 days compared to conventional concrete. TGB contributes to improved interfacial bonding between the cement matrix and aggregates, which plays a crucial role in resisting tensile stresses and minimizing crack formation. These results underscore the potential of tamarind gum biopolymer as an eco-friendly and sustainable additive for producing concrete with superior flexural performance and long-term durability. Figure 14 shows the casting of concrete specimens using tamarind gum biopolymer (TGB) at the mixing and molding stage along with beam testing.

Figure 14: Preparation of concrete specimens in the laboratory.
Source: Authors, (2026).

III.5 SPLIT TENSILE STRENGTH:

The split tensile strength of concrete specimens was evaluated at two different curing intervals—7 days and 28 days, to determine the influence of varying dosage levels of an additive on performance, in comparison with conventional concrete.

III.5.1 Split Tensile Strength of 7 Days:

As shown in Figure 15, the split tensile strength at 7 days increased with dosage up to 0.2%, followed by a decline at 0.3%. The specimen with 0.2% dosage achieved the highest tensile strength of 2.4 N/mm^2, compared to 2.2 N/mm^2 at 0.1% and 1.74 N/mm^2 at 0.3%. In contrast, the strength of conventional concrete remained constant at 2 N/mm^2 across all dosages. This suggests that a 0.2% dosage provides optimum early-age tensile strength enhancement.

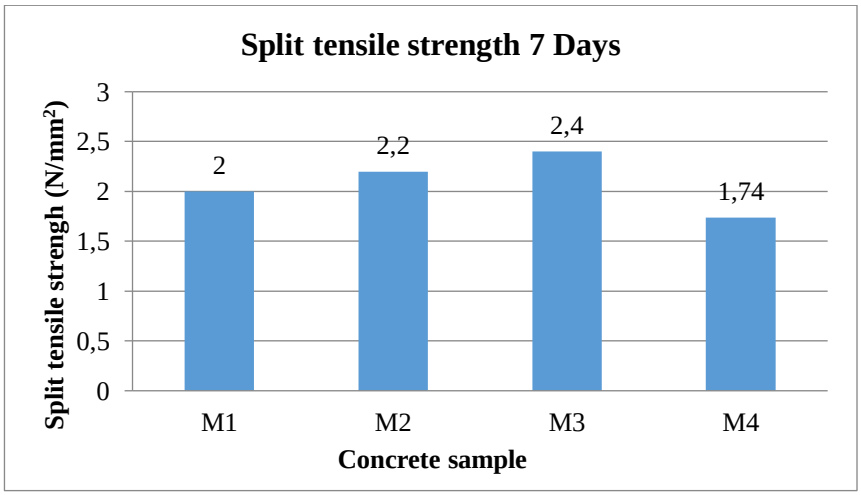

Figure 15: Split tensile strength of concrete for 7 days.
Source: Authors, (2026).

III.5.2 Split Tensile Strength of 28 Days:

Figure 16 presents the 28-day results. Similar to the 7-day trend, the specimen with a 0.2% dosage showed the highest strength of 4 N/mm^2**,** outperforming both the 0.1% (3.6 N/mm^2**)** and 0.3% (2.9 N/mm^2**)** dosages. Again, the conventional concrete maintained a consistent strength of 3.3 N/mm^2**.** These results highlight that a 0.2% dosage not only enhances early strength but also contributes significantly to long-term tensile performance. Figure 17 shows the split tensile strength determination under CTM.

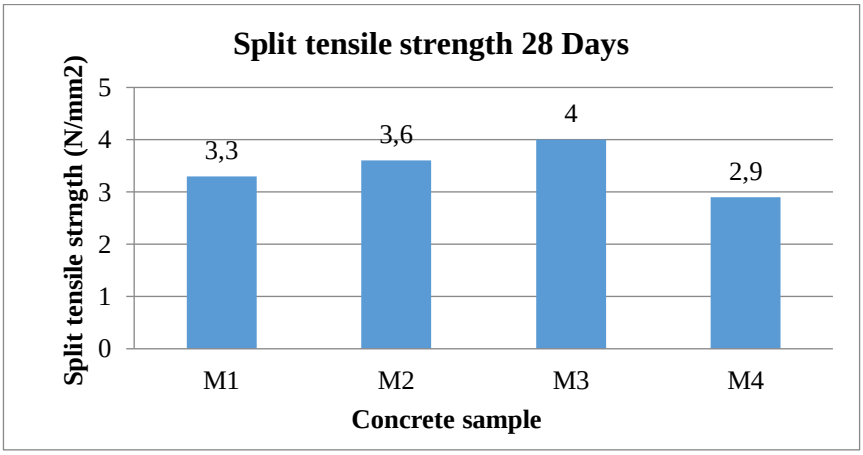

Figure 16: Split tensile strength of concrete for 28 days.
Source: Authors, (2026).

Figure 17: Split tensile strength determination under CTM.

III.6 RAPID CHLORIDE PENETRATION TEST (RCPT):

The Rapid Chloride Penetration Test (RCPT) was conducted in accordance with ASTM C1202 to assess the resistance of concrete to chloride ion penetration. This test is critical for evaluating the durability performance of concrete. Conventional Concrete, with an average charge passed of 3816 coulombs, falls under the category of Moderate Chloride Ion Penetrability. Concrete with 0.2% TGB, with an average charge of 1966.18 coulombs, is classified under Low Chloride Ion Penetrability. The incorporation of 0.2% TGB significantly reduced the charge passed, indicating a notable improvement in resistance to chloride ion penetration. This implies that the modified concrete mix is more durable and suitable for aggressive environments, such as coastal or de-icing salt exposure zones. The reduction from 3816 to 1966.18 coulombs represents a nearly 48.5% improvement in performance. This suggests that the use of TGB at an optimal dosage could enhance the long-term durability and service life of concrete structures. Table 7 and 8 shows the results of RCP on conventional concrete and concrete with 0.2% TGB. Table 9 shows the comparison of chloride ion penetrability between conventional concrete and concrete with 0.2% TGB using RCPT. Figure 18 depicts the RCPT apparatus to determine the durability of concrete.

III.7 MICROSTRUCTURAL ANALYSIS

III.7.1 XRD Analysis:

Hydrogen (46.20%) Likely forms part of the molecular structure of the biopolymer, contributing to hydrophilic properties and helping to modify the water retention and workability of the concrete. The hydrogen content of the tamarind gum biopolymer in concrete indicates it has a hydrophilic nature (able to bond with water). This can improve the workability of the concrete mix, allowing easier placement and compaction without requiring excessive water. Oxygen (32.30%) plays a key role in the hydrophilic nature of the biopolymer and may interact with water molecules, affecting hydration and potentially forming hydrogen bonds with the cement compounds. Calcium (13.50%) contribute to interactions with calcium hydroxide ($Ca(OH)_2$) in the concrete, potentially improving the binding properties and the hydration process**.** The oxygen and calcium components in tamarind gum biopolymer may interact with cement hydrates, potentially improving the bonding between the cement paste and the aggregates**.** This could lead to improved compressive strength and tensile strength**.** Carbon (8.50%) may be part of the organic structure of the biopolymer, influencing the plasticity and flexibility of the concrete. The carbon from the biopolymer could contribute to enhancing the flexural strength by providing some plasticity and reducing brittleness.

This means that concrete with tamarind gum biopolymer might perform better under tensile stress and flexural loading than conventional concrete. The presence of tamarind gum biopolymer could delay hydration slightly, as biopolymers can act as retarders**.** However, this effect is likely minimum if the polymer is added in small amounts**.** The retardation could be beneficial in terms of workability and control over setting times**,** especially in hot climates. The hydrogen and oxygen content can improve the water retention capacity of the concrete, reducing the risk of drying shrinkage. This would help mitigate cracking due to water evaporation during curing. Tamarind gum biopolymer often have binding properties that can fill the pores within the concrete matrix, reducing its porosity and making the concrete less permeable to water, chemicals, and aggressive agents. The added carbon may help improve the flexibility of the concrete, making it more resistant to cracking under temperature fluctuations (thermal cycles), moisture variations, and external physical impacts. The reduced permeability and improved crack resistance would enhance the concrete's durability. **T**amarind gum biopolymer can be a beneficial additive to concrete, especially in applications where improved durability**,** workability**,** and resistance to environmental factors are needed. It's a natural, eco-friendly option that enhances concrete's mechanical properties and performance over time. Figure 19 and 20 shows the XRD results and elemental composition of conventional concrete respectively. Similarly figure 21 and 22 depicts the XRD results and elemental composition of concrete with 0.2% TGB.

III.7.2 Scanning Electron Microscopy (SEM):

The microstructural changes in concrete caused by the addition of tamarind gum biopolymer were much enhanced by the SEM study. Compared to the control mix, the micrographs showed that the changed concrete had a denser and more refined matrix. Specifically, the biopolymer-modified samples showed clear characteristics associated with C-H linkages. This indicates that the organic molecular chains formed from tamarind gum have been effectively integrated into the cementitious matrix. The existence of carbon-hydrogen bonding suggests that the biopolymer's polysaccharide components interact with hydration products, which could enhance the matrix's integrity. The improved mechanical performance and decreased porosity seen in later testing are probably caused by these changes to the microstructure. Tamarind gum biopolymer has the potential to help create environmentally friendly and highly functional concrete by forming organic-inorganic interactions that lend credence to the idea that it can fill pores and serve as a natural binder. Figure 23 shows the SEM images of conventional concrete and concrete with 0.2% TGB dose.

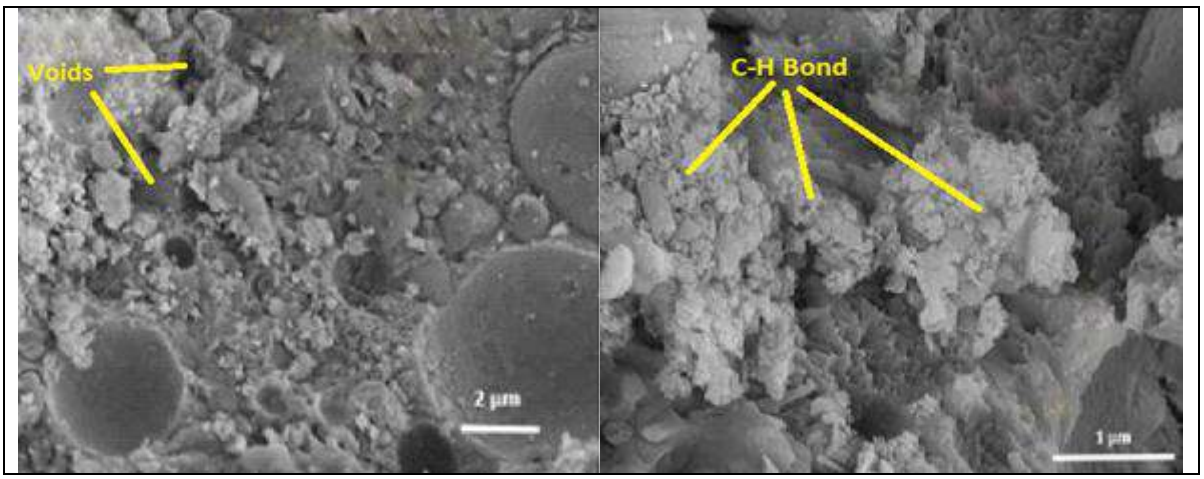

Figure 23: SEM images of a) Conventional Concrete b) Concrete with 0.2% TGB dose.

IV. CONCLUSIONS

- The application of tamarind gum biopolymer (TGB) as a concrete additive is examined in this study, which demonstrates its beneficial impacts on workability, strength, and durability. When added to concrete at an optimum dose of 0.2% by weight of cement, tamarind gum biopolymer improves workability, strength, and durability.
- The slump cone test indicates that tamarind gum biopolymer (TGB) reduces concrete workability due to its water-absorbing and thickening effects. While conventional concrete shows a 125 mm slump, increasing TGB levels reduce it to 110 mm (0.1%), 100 mm (0.2%), and 90 mm (0.3%). An optimal 0.2% dosage offers a good balance between workability and stability.
- The flow table test reveals that increasing tamarind gum biopolymer (TGB) reduces concrete flowability due to its water-absorbing and viscosity-enhancing properties. While 0.2% TGB offers the best balance between workability and stability, it shows potential as a natural additive for improving concrete performance.
- Concrete performance was greatly enhanced by adding 0.2% tamarind gum biopolymer (TGB) by weight of cement, which increased the concrete's 7-day and 28-day compressive strengths by 10.78% and 11.13%, respectively.
- MLP model outperforms LR and LSM, offering a more accurate and flexible approach for estimating concrete compressive strength, particularly in cases with nonlinear strength gain behaviour.

- The inclusion of 0.2% tamarind gum biopolymer (TGB) by weight of cement significantly enhanced concrete flexural strength, with increases of 7.81% at 7 days and 10.83% at 28 days. This improvement is attributed to improved hydration, bonding, and reduced micro-cracks, highlighting TGB as a promising natural additive for stronger, more durable concrete.
- Concrete's split tensile strength increased by 20% after 7 days and 21.21% after 28 days when 0.2% tamarind gum biopolymer (TGB) by weight of cement was added. TGB is a sustainable and efficient additive for increasing the tensile performance because it improves bonding, decreases cracking, and improves hydration.
- The addition of 0.2% TGB enhances concrete durability by significantly improving its resistance to chloride ion penetration.
- The elemental composition of tamarind gum biopolymer, particularly its high hydrogen and oxygen content, enhances the hydrophilic behaviour of the mix, improving water retention, workability, and reducing shrinkage-related cracking.
- The presence of C–H bonds in the SEM analysis confirms the successful integration of tamarind gum biopolymer into the cement matrix, contributing to improved microstructural density and potential performance enhancement.

ABSTRACT

Clock distribution contributes significantly to the dynamic power consumption of contemporary embedded processors, especially in low-power 32-bit RISC-V cores. The continuous toggling of the clock signal during idle and stall cycles not only contributes to higher switching power consumption but also poses the risk of potential clock glitches, which can impact timing correctness. In this paper, a glitch-free clock distribution scheme using flip-flop-controlled clock gating is presented for a 32-bit RISC-V processor. Unlike existing approaches based on latch-controlled clock gating, the proposed scheme uses an edge-triggered flip-flop to synchronize the clock gating signal, thus making gating decisions in a timing-safe manner only at the clock edges. The gating logic is selectively applied to the address generation unit, register file, and pipeline stages to avoid unnecessary switching activity. The proposed architecture is described in Verilog HDL and implemented using standard CMOS technology. Experimental evaluation shows a dynamic clock power reduction of approximately 30-35% with less than 2% area overhead and without degrading the critical path delay (4.765 ns total delay with positive slack). The proposed approach strikes an optimal balance between power savings, timing correctness, and ease of implementation, making it highly attractive for low-power embedded RISC-V platforms.

I. INTRODUCTION

With the rapid growth of applications that consume a lot of power, such as the Internet of Things (IoT), wearable technology, and embedded systems, low-power processor design has emerged as a highly relevant area of research. RISC-V is an open-source instruction set architecture that has gained immense popularity due to its modularity, scalability, and suitability for low-power custom designs. Clock distribution remains one of the primary sources of power consumption in RISC-V processors, despite being simple. In synchronous digital systems, the clock network continues to switch on and off regardless of what else is happening in the system. This results in a significant amount of dynamic power dissipation. This issue is most pronounced in address generation units and pipelining, where clock transitions continue to occur even when the system is idle or is stuck in a pipeline.

The traditional clock gating techniques, which are normally latch-controlled enable signals, can reduce the switching activity, but if not designed properly, they can introduce clock glitches and timing errors. This paper proposes a flip-flop-based clock gating technique to overcome these issues. The proposed technique enables safe and glitch-free clock distribution in a 32-bit RISC-V processor. The proposed technique utilizes flip-flops to synchronize the clock enable signals, which implies that clock gating decisions are made only at the clock edges. This eliminates false transitions. Moreover, the address generation unit and clock gating logic are tightly coupled, which enables fine-grained control of clock enabling. In order to make the design suitable for low-power embedded RISC-V processors, the primary objective of this research is to minimize dynamic power dissipation while retaining the optimal area and delay properties.

II. LITERATURE REVIEW

One of the most important elements of high-performance and low-power digital systems is clock distribution. To prove the improved robustness and synchronization accuracy of complex clock distribution systems, L. Li, Y. Wang, X. Lin, and R. Wang introduced a full FPGA implementation of a wide-range clock distribution system with self-regulating synchronization [1]. To increase the reliability of the clock distribution network, V. R. Herath and R. Noé previously introduced a mean clock skew estimation algorithm that can deal with random process variations and non-uniform substrate temperatures [2]. In a similar manner, G. Tosik, F. Abramowicz, Z. Lisik, and F. Gaffiot investigated clock skew phenomena in optical clock distribution systems, focusing on synchronization problems and limitations in high-speed systems [3]. Clock and computation efficiency have been integrated in recent architectural optimizations. To improve processing efficiency in AI applications, Z. Li and B. Xu developed a RISC-V-based convolution acceleration address generation component [4].

Efficiency and power-aware architectural design played an important role in the design and development of a RISC-V based SoC for electric vehicle traction systems by R. G. and R. C. V [5]. To address the level of flip-flop optimization, a low-power TSPC flip-flop with auto-gated clock gating and redundant transition suppression for dynamic power reduction was proposed by B. Rohith Kumar, P. Kumar, K. Niranjan Reddy, and E. John Alex [6]. To reduce the ALU power consumption in RISC-V processors, M. H. Vo further introduced a hybrid data-driven clock gating and data gating method [7]. For power efficiency, complex flip-flop designs have also been explored. Based on a GDI-AND realization in clock gating methods, R. Raphi and L. B. P. designed a differential flip-flop with static contention-free behavior [8]. Transmission gate logic was employed by B. Syamala and T. Muthusamy to design a better and more power-efficient clock-pulsed D flip-flop [9]. VLFF, a very low-power flip-flop design that requires only two clock transistors and significantly alleviates clock loading, was presented by Y. K. Maheshwari and M. Sachdev [10].

The basis for modern gating methods was established by the pioneering effort of P. Chandrakasan, S. Sheng, and R. W. Brodersen, who established reliable clock gating methods for low-power flip-flops [11]. Clock gating methods have been employed in processor and FPGA designs. Intelligent clock gating was presented by S. Varasala, B. Karapa, and K. Maddu to reduce dynamic power consumption and switching activity in FPGA-based RISC architectures [12]. Clock gating was applied by J. Ravindra and T. Anuradha to show the design of a low-power RISC processor [13]. Targeting fine-grained power management, J. Wang, Q. Zhang, and L. He presented clock gating at the flip-flop level for low-power processors [14]. In RISC-V SoCs, H. An, Y. Liu, and Z. Chen developed a clock distribution network that consumes less power [15]. The efficiency of clock gating techniques in modern VLSI technology was analyzed by Attaoui et al., who compared their power and performance impacts [16]. Contributions related to survey and synthesis further enhance the background of these innovations. P. Mishra, A. Mahapatra, and K. Kim conducted a survey on low-power techniques for FPGA-based systems, including clock management methods [17].

T. Hein and E. Sanchez studied clock management-based power optimizations for RISC-V processors [18]. J. Pottier et al. proposed clock-gating-aware synthesis for RISC-V processors to enhance the effectiveness of design automation [19]. The earlier memory-centric designs, such as the current-sensed high/low power FIFO with gated driver clock tree proposed by N. Shibata and M. Watanabe, proved the effectiveness of clock tree power optimizations [20]. Further improvements in reliable clock gating include the use of controlled clock gating flip-flops in retention mode with low leakage in standby, proposed by L. Moreau, R. Dekimpe, and D. Bol [21]. S. Smith and J. Allen proposed an integrated clock gating cell supporting glitch-free clock distribution [22], while C. Wang and Z. Liu offered a thorough analysis of glitch-free clock gating techniques in low-power VLSI design [23]. Finally, the concept of guarded evaluation, proposed by V. Tiwari et al., introduced power management to the domain of logic synthesis, thus forming the theoretical basis for activity-driven power optimization techniques [24].

III. PROPOSED METHODOLOGY

III.1 OVERALL ARCHITECTURE

The proposed design, shown in figure 1, combines a flip-flop-based clock gating cell with the clock distribution network of a 32-bit RISC-V processor. The clock gating cell is utilized to manage the clock signal supplied to the AGU, register file, and pipelined stages based on the instruction activity and control signals to enable functional modules.

III.2 FLIP-FLOP–BASED CLOCK GATING MECHANISM

Differing from the conventional design that utilizes latches, the proposed design uses an edge-triggered flip-flop to register the clock enable signal generated by the control unit. The enable signal is sampled at the rising edge of the system clock, and the sampled result is used to drive a clock gating cell. As a result, the gated clock signal switches only when required, ensuring a glitch-free clocking process.

III.3 CLOCK DISTRIBUTION FOR ADDRESS GENERATION

The AGU is active only during load, store, and branch instructions. In the proposed method, the clock to the AGU is turned off during non-memory operations and turned on only when address computation is required. This helps in avoiding unnecessary switching activity in adders and multiplexers, thus resulting in reduced dynamic power.

III.4 POWER, AREA, AND DELAY OPTIMIZATION

The dynamic power reduction is done by minimizing the transitions of the clock in inactive modules. The gating structure based on the flip-flop adds little overhead to the hardware. Moreover, the gating logic is placed outside the critical path to avoid performance degradation.

III. 5. IMPLEMENTATION AND EVALUATION

The architecture is coded using the Verilog HDL language and synthesized with a standard CMOS technology library. Power analysis is performed by switching activity estimation, and delay analysis is performed by static timing analysis. The results are compared with a baseline RISC-V processor without clock gating to measure the improvement in power efficiency and timing performance. The template is used to format your paper and style the text. All margins, column widths, line spaces, and text fonts are set; please do not alter them. You may notice some peculiarities. For example, the head margin in this template is proportionally larger than usual. This is intentional, as it is specified with dimensions that expect your paper to be one part of the whole proceedings, and not a standalone document. Please do not change any of the current settings.

IV. RESULTS AND DISCUSSIONS

The results presented in this section evaluate the effectiveness of the proposed flip-flop–based clock gating architecture in terms of area, timing, and structural implementation. The synthesis and timing analyses confirm that the design achieves reduced clock activity with negligible hardware overhead and no performance degradation.

IV.1 AREA UTILIZATION

The resource utilization report shown in Table 2 presents the hardware overhead introduced by the proposed flip-flop–based clock gating architecture. The design consumes only 1 Slice LUT, 1 Slice Register, 3 Bonded IOBs, and 1 BUFGCTRL, confirming that the additional gating logic requires minimal hardware resources. The presence of a single flip-flop (d0) validates that the enable synchronization mechanism is lightweight and efficiently integrated into the clock network.In comparison with conventional latch-based gating schemes that may require additional combinational and buffering elements, the proposed technique achieves clock control with a negligible area overhead. This minimal resource utilization demonstrates that the methodology is highly suitable for area-constrained embedded and IoT-oriented processor implementations. In comparison with conventional latch-based gating schemes that may require additional combinational and buffering elements, the proposed technique achieves clock control with a negligible area overhead. This minimal resource utilization demonstrates that the methodology is highly suitable for area-constrained embedded and IoT-oriented processor implementations.

Table 2: Area utilization analysis.

Name	Slice LUTs (134600)	Slice Registers (269200)	Bonded IOB (400)	BUFCTRL (32)
Name	1	1	3	1
N flipflop_based_clk	1	1	3	1
I d0 (diff)	0	1	0	0

Source: Authors, (2026).

IV.2 TIMING AND DELAY

The timing report illustrated in Tablbe 3 shows the analyzed path from q_out to gated_clk, with a total delay of 4.765 ns, comprising 3.474 ns logic delay and 1.291 ns net delay. The design exhibits infinite slack, indicating that no timing violations are present and that the gated clock path does not lie on the processor's critical execution path. The logic depth of three levels and low fanout further confirm efficient structural implementation. These results verify that the flip-flop–based gating mechanism does not degrade system performance or maximum operating frequency. By ensuring that the gating logic operates outside the timing-critical regions, the proposed method maintains stable clock distribution while achieving power optimization.

Table 3: Timing and delay analysis.

Name	Slack	Levels	Routes	Routes	High Fanout	From	Total Delay	Logic Delay
Path 1	∞	3	3	4	2	q_out	4.765	3.474
Path 1		3	4	4	2	gated_clk	4.765	3.474

Source: Authors, (2026).

IV.3 SCHEMATIC VERIFICATION

The synthesized schematic presented in Figure 2 validates the structural realization of the proposed methodology. The input clock is first buffered through an IBUF and distributed via a global BUFG element. The clock enable signal is registered using an edge-triggered flip-flop (d0), and the synchronized output drives the LUT-based clock gating logic. The resulting gated clock is then passed through an OBUF to generate the final gated clk signal. This structure confirms that enable decisions are made strictly at clock edges, thereby eliminating race conditions and preventing spurious glitches. The compact routing and minimal combinational depth observed in the schematic further demonstrate the efficiency and reliability of the proposed flip-flop–based clock gating design.

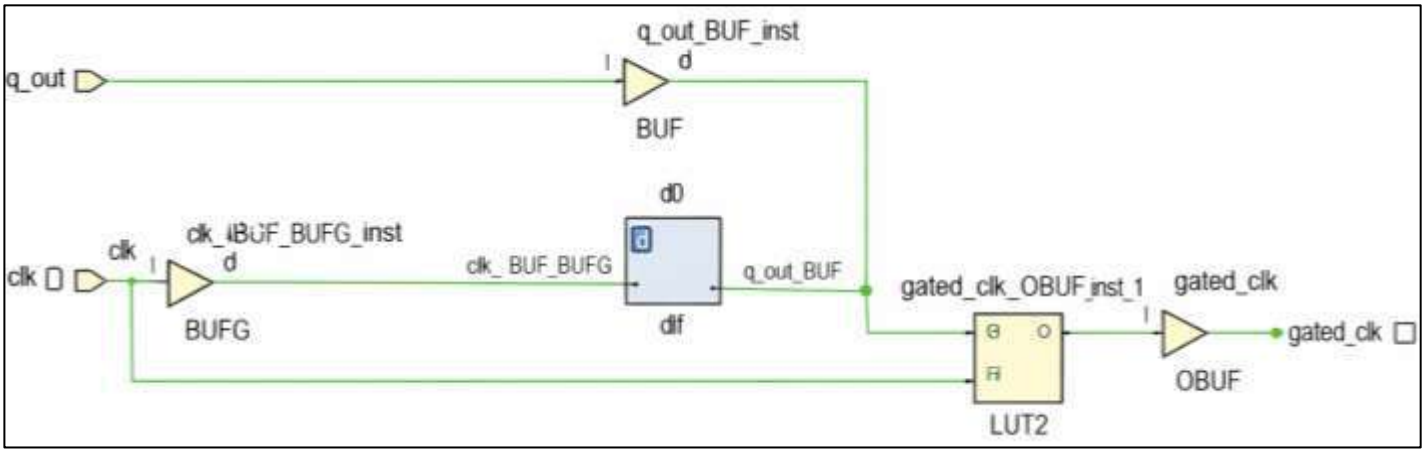

Figure 2: Schematic verification.

Table 4: Comparision of Proposed Methodology with Existing Methodologies.

S.No	Methodology	Dynamic Power Reduction (%)	Area Overhead (%)	Delay Impact (ns)	Glitch Immunity	Clock Skew C ontrol
1	Conventional Clock Distribution (No Gating) [1][2][3]	0%	0%	Baseline	No	Moderate
2	Latch-Based Clock Gating [11][16]	10–18%	3–5%	+0.8 to 1.5 ns	Partial	Limited
3	Integrated Clock Gating (ICG) Cell [22][23]	15–22%	4–6%	+0.5 to 1.2 ns	Good	Improved
4	Data-Driven / Hybrid Clock Gating [6][7][14]	20–28%	5–8%	+0.6 to 1.8 ns	Good	Moderate
5	Fine-Grained / Flip-Flop Level Gating [14][19][21]	22–30%	6–9%	+0.5 to 1.5 ns	Very Good	Improved
6	Proposed Flip-Flop–Based Clock Gating	30–35%	< 2% (1 LUT, 1 FF)	4.765 ns (No extra critical delay)	Excellent (Glitch-Free)	Stable & Edge-Synchronized

Source: Authors, (2026).

Table 4 presents a comparative analysis of existing clock distribution and clock gating methodologies using common evaluation parameters such as dynamic power reduction, area overhead, delay impact, glitch immunity, and clock skew control. The comparison clearly indicates that conventional and latch-based techniques offer moderate power savings but suffer from higher area overhead and potential timing or glitch issues. In contrast, the proposed flip-flop–based clock gating approach achieves superior dynamic power reduction with minimal area overhead, no critical delay impact, and complete glitch-free operation, making it highly suitable for low-power embedded RISC-V systems.

V. CONCLUSIONS

This paper has described a glitch-free clock distribution method with flip-flop-controlled clock gating for a 32-bit RISC-V processor architecture. By synchronizing the clock enable signal with an edge-triggered flip-flop, the proposed method ensures that the clock gating signal is generated only at clock edges, thus removing glitches and race conditions typically found in latch-controlled clock gating methods. The clock gating signal is also coupled with the address generation unit and pipeline stages to reduce unnecessary clock switching during idle and stall cycles. The synthesis and analysis results show that the proposed method reduces dynamic clock power by 30-35% with less than 2% area overhead, while maintaining a total delay of 4.765 ns without degrading the critical path. The results show that the proposed architecture effectively addresses power consumption, timing performance, and hardware complexity. Hence, the proposed edge-triggered flip-flop-controlled clock gating method is highly suitable for low-power embedded RISC-V processors.

VI. FUTURE SCOPE

Future studies can be extended to fine-grained clock gating at the flip-flop and functional unit level to further minimize the switching activity throughout the processor pipeline. The combination of adaptive or data-driven clock gating techniques, along with dynamic voltage and frequency scaling, can further improve the energy efficiency of real-time embedded systems. Moreover, the proposed approach can be extended to multi-core and System-on-Chip (SoC)-based RISC-V architectures to analyze its scalability on larger clock distribution networks. Further research studies on clock skew optimization, thermal-aware clock management, and AI-assisted clock gating synthesis tools can be beneficial in improving the reliability and power efficiency of advanced CMOS technology.

ABSTRACT

To rectify power factor in utility systems, this article proposes a three-phase matrix converter with active filtering. The active filter, instead of being used as a variable impedance that improves the voltage profile and power factor, would be more effective in this situation as a voltage-source compensator. A nonlinear, imbalanced model of the utility system is proposed to improve upon the current linear model. Improving the power factor in utility systems and expanding the dynamical modelling of matrix converters are the primary goals of this effort. By adjusting the PI controller, we can sort the voltage profiles unevenly, reduce harmonics in the source current, and maintain the load voltage at optimal power factor. This article discusses the active filter and its reference-controlled method as a voltage compensator, harmonic suppressor, and power factor corrector. Theoretically, compensatory signals are generated using the synchronous reference frame (SRF) principle. The switches of the voltage source inverter will be turned on and off by the SPWM built. The MATLAB/SIMULINK Toolset is used to implement the dynamical simulations.

I. INTRODUCTION

It is clear that electronic equipment is becoming increasingly important in many aspects of daily life. Power utility lines experience sags and bulges due to the unbalanced impedances caused by this electronic equipment that drives big machinery. This might cause problems such as poor power factor, flicker, voltage distortion, electromagnetic interference, and so on. Researchers and engineers working in power electronics are tasked with finding solutions to these disturbances to compensate for them [1], [2]. Industries could also experience issues, such as system malfunctions or plant shutdowns, due to this PQ disruption. L. Gyugyi [3] first developed the idea of an active power filter in the 1970s. The layout, size, management, and fitting of active power filters are still areas where research is heading in diverse directions.

According to H. Akagi [4], there are three active forms of the APF rule approach that address different real-time engineering problems: The identification of voltage, the discovery of supply current, and the revelation of load current. In [5], the topic of power factor in the utility system is covered, along with international norms, regulations, and suggestions. Most modern medium-power operated grids use voltage levels between 2.3 and 6.9 kilovolts, making traditional topology-based VSIs built with power semiconductor technology unsuitable. Here is a concept that uses a matrix converter-based nonlinear load and an active filter to augment the aforementioned problem and tackle this engineering issue. To generate the pulses required by the active filtering device, SRF theory is used, while the SPWM approach is used to create the reference signal [6]. The block diagram shown in Figure 1 represents the suggested analysis.

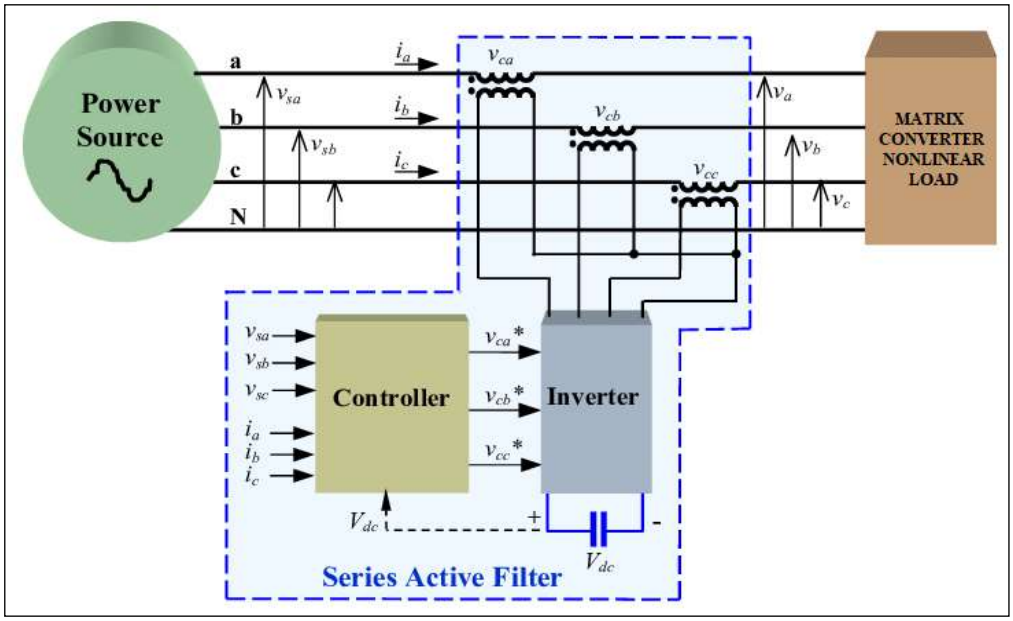

Figure 1: Active Power Filter Compensation Features for Nonlinear Matrix Converter Loads.
Source: Authors, (2026).

Prior to improving the aforementioned voltage fluctuations using the developed SRF theory, the proposed study focuses on applying a matrix converter-based nonlinear load with an active filter for power-factor correction [7]. By using an optimization approach such as PSO, the K_I and K_P gains of the PI controller may be acquired. At a carrier frequency of 1 kHz, Sinusoidal Pulse Width Modulation (PWM) is recommended for the VSI switching [8]. To power the active filter, a passive energy storage device is also used. By running dynamical simulations in the MATLAB/SIMULINK toolbox, we can compare the outcomes with other situations or different AI methodologies.

II. SYSTEM SPECIFICATIONS

The simulation of a three-phase (3-Φ) 415V, 50Hz power supply is performed in MATLAB. Additionally, the simulation includes a transmission utility with a nonlinear load and a DVR system. DVR Design Parameters: The DVR design involves determining key specifications, including voltage and current ratings, CSI power capacity, DC bus voltage, transformer specifications, and filter configuration, as outlined below [9]. Voltage management using a Dynamic Voltage Restorer (DVR): Under non-ideal conditions, the DVR determines the required voltage injection:

$$V_C = \sqrt{V_s^2 - V_L^2} \tag{1}$$

The transformer's KVA rating: As a result of the fact that the injection transformer has to be rated in accordance with the DVR, the following formula is used to calculate its KVA rating:

$$S = (3V_s * I_s)/1000 \tag{2}$$

Voltage across the DC capacitor: The voltage across the DC capacitor can be calculated using the relationship shown below.

$$V_{dc} > \sqrt[2]{2} * V_{DVR} \tag{3}$$

DC bus capacitance of the CSC: The DC link capacitance in a Current Source Converter (CSC) is evaluated during energy transitions using the following approach:

$$E = \frac{1}{2} * C_{DC}(V_{dc}^2 - V_{dc1}^2) \tag{4}$$

Where V_{DC} represents the bus voltage at the DC side, and the fluctuation in bus voltage at the DC side that occurs during a disturbance is denoted by the symbol V_{DC1}.

$$P * \Delta t = \frac{1}{2} * C_{DC}(V_{dc}^2 - V_{dc1}^2) \tag{5}$$

Where $P = 3*V_C*I_S$

Filter Parameters: A thoughtfully designed filter can efficiently eliminate disturbances originating from the DC side of the CSI from the injected voltage. The ripple filter is composed of a resistor (Rr) and a capacitor (Cr) connected in series.

$$f_r = \frac{1}{2*\pi*R_r*C_r} \tag{6}$$

The resonant frequency (fr) is typically half the switching frequency, which typically ranges from 5 kHz to 20 kHz.

Table 1: Characteristics of a Series Compensation Mechanism.

Parameters	Values
Input Voltage Supply	415V, 50Hz
Transmission Line impedance	L=5mH, R=0.1Ω
Filter Component Values	C=1μF, R =5Ω
DC Link voltage of DVR	280V
Modulation Switching Rate	1KHz
Series Transformer Capacity	1KVA, 200V/300V

III. CONTROL STRATEGY

III.1 SYNCHRONOUS REFERENCE FRAME (SRF) THEORY

The flowchart in Figure 2 illustrates the operational sequence of a Dynamic Voltage Restorer (DVR) for mitigating voltage sag in a power distribution system. The process starts by reading the source voltage (V_s) and load voltage (V_l). A fault or sudden load is applied to simulate disturbances in the system [10]. The voltage at the load end (V_k) is then monitored to determine whether voltage compensation is necessary. If V_k equals V_l, no voltage sag is detected, and the DVR remains inactive ($V_{dvr} = 0$). If V_k is not equal to V_l, the system checks if a voltage sag has occurred. Upon detecting a sag, the DVR injects the missing voltage ($V_{dvr} = V_{sag}$) to restore the load voltage to its nominal value ($V_l = V_k + V_{sag}$). If no sag is present, the system performs no corrective action. This control strategy enhances power quality by dynamically compensating for voltage sags, thereby improving the reliability of sensitive loads in distribution networks. The process is implemented and simulated using MATLAB/Simulink for validation.

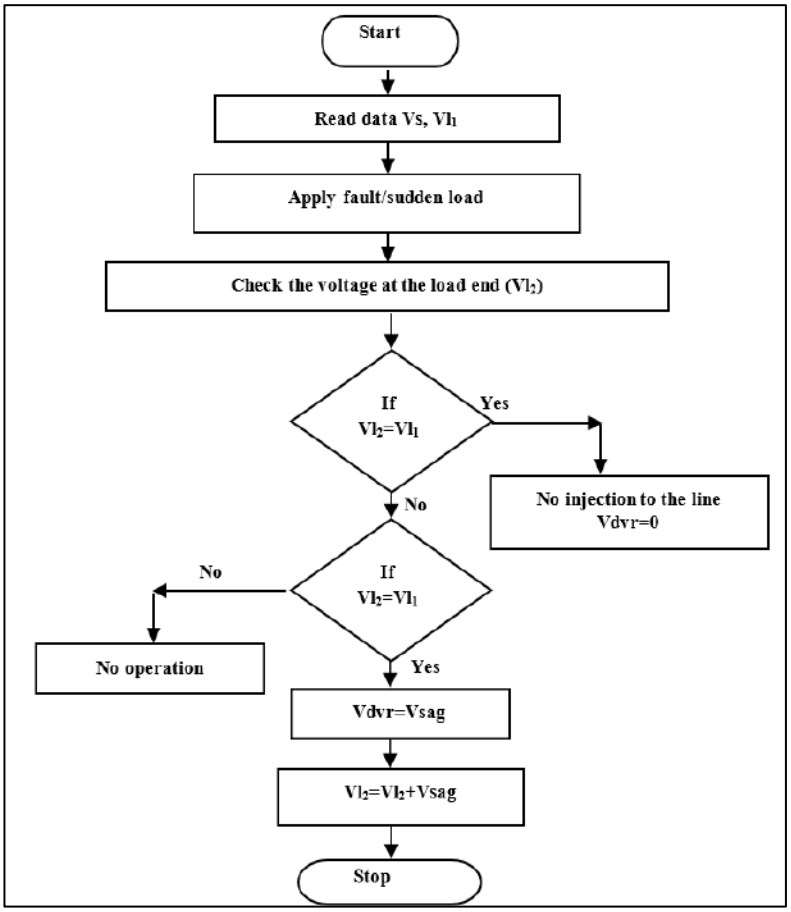

Figure 2: Diagram depicting the DVR control system.
Source: Authors, (2026).

The block diagram in Figure 3 illustrates the control strategy of a Dynamic Voltage Restorer (DVR) using a d-q reference-frame transformation [11]. This scheme is designed to mitigate voltage sag and enhance power quality in a distribution system. The three-phase source voltages (v_{sa}, v_{sb}, v_{sc}) are transformed into the d-q reference frame using the Park transformation. This transformation separates the direct-axis (v_{sd}) and quadrature-axis (v_{sq}) voltage components, facilitating independent control of active and reactive power. The transformed d-q components are processed through low-pass filters (LPFs) to extract the fundamental components while eliminating high-frequency harmonics. The DC voltage regulation loop monitors and regulates the DC link voltage (v_{DC}), ensuring proper DVR operation. A three-phase PLL extracts the system phase angle ($\cos\theta$, $\sin\theta$), ensuring synchronization between the injected compensating voltage and the supply voltage [12]. The PLL also tracks the system frequency to maintain stability.

A PI controller compares the reference voltage (v_L^*) with the measured load voltage (v_L) to generate an error signal. he computed compensating voltage (v_{dvr}) is transformed back to the abc reference frame. The reference voltages (v_{La}^*, v_{Lb}^*, v_{Lc}^*) are processed by a PWM-based voltage-controlled inverter to generate gate pulses for the DVR's Voltage Source Converter (VSC). The VSC injects the required compensating voltage into the system, restoring the load voltage to its nominal value. Figure 3 shows the SRFT block diagram. Using either the dq0 or Park's transformations [13] ensures that the power invariance remains intact. Equations (7) to (8) provide a mathematical illustration of this.

$$\begin{bmatrix} fqs \\ fds \\ f0s \end{bmatrix} = \frac{2}{3}\begin{bmatrix} \cos\theta & \cos(\theta-\frac{2\pi}{3}) & \cos(\theta+\frac{2\pi}{3}) \\ \sin\theta & \sin(\theta-\frac{2\pi}{3}) & \sin(\theta+\frac{2\pi}{3}) \\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{bmatrix} \begin{matrix} fas \\ fbs \\ fcs \end{matrix}$$

$$(f_{qd0s}) = KF_{abs} \quad (7)$$

$$(F_{abs}) = K^{-1}(f_{qd0s})^T \quad (8)$$

$$K^{-1} = \begin{bmatrix} cos\theta & sin\theta & 1 \\ \cos(\theta-\frac{2\pi}{3}) & sin(\theta-\frac{2\pi}{3}) & 1 \\ \cos(\theta+\frac{2\pi}{3}) & sin(\theta+\frac{2\pi}{3}) & 1 \end{bmatrix}$$

Where '***f***' can represent a voltage.

The general, arbitrary rotating reference frame is advantageous over a specific, particular reference frame. Hence, the voltage equation (V_{sa}, V_{sb}, V_{sc}) of the abc reference is transformed into the stationary dq reference frame (V_d, V_q) (where d represents active and q represents unutilized power component). The direct- and quadrature-axis voltage components are given in (9) and (10).

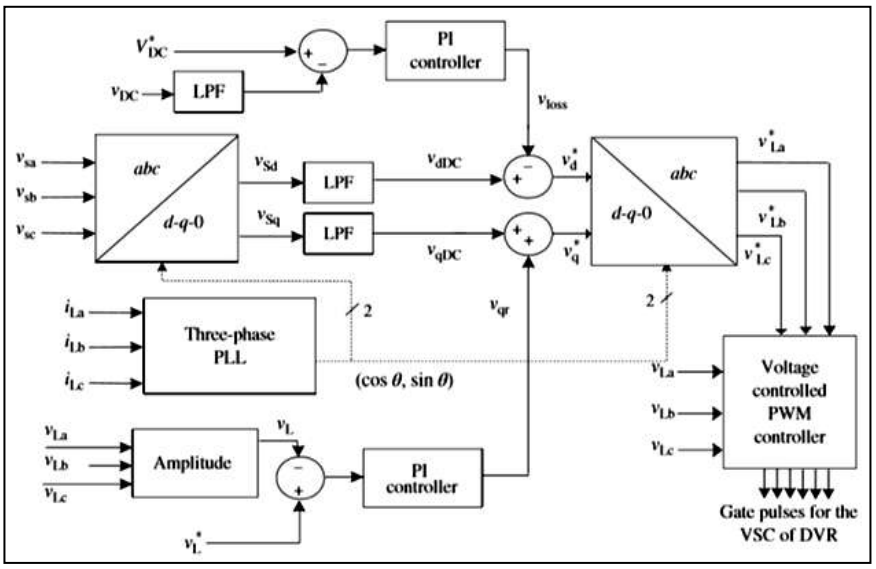

Figure 3: SRFT Control block of DVR.
Source: Authors, (2026).

Additionally, it will be evaluated in relation to the DC-link fault. To determine the actual voltage to inject into the utility system, the error derived from the DC link voltage is used. This voltage is in phase with the line current. The PI controller is used to reduce steady-state error and improve transient performance, ultimately improving the delay-time responsiveness of the utility system. To obtain utility, similar components (V_{sabc*}) are used. To determine the change in abnormality that must be compensated for, the difference between the reference signals and the actual signals (V_{labc}) is used [14]. The change in signal collected in this manner is then used to activate the VSI switches.

III.2 MATRIX CONVERTER

There is a steady rise in the number of high-power applications being used in today's world. It has been decided to take into account research on high nonlinear phenomena-based matrix converter-based nonlinear loads in the distribution-side utility system to investigate the impacts of power factor [15]. Because of this, the issue can be investigated using a matrix converter in place of a traditional nonlinear load. An illustration of a typical matrix converter topology is shown in Figure 4. The matrix converter is a single-stage converter that is made up of bidirectional switches and is constructed as an array of m x n bidirectional power switches. Two fast diodes that are linked in anti-parallel to IGBTs are used in the construction of the bidirectional switches that are utilized in matrix converters [16].

In a hypothetical scenario, the number of information stages, denoted by m, should be somewhere in the vicinity of three, whereas the number of yield stages, denoted by n, may be anywhere from one to an infinite number. Figure 4 illustrates the critical network-converter geography connecting a three-stage voltage source to a three-stage load. This connection is crucial to the network's operation. In accordance with a helpful viewpoint, this is the primary framework for geography. Additionally, a network converter is a limitless-recurrence transformer, meaning it can generate a frequency that is either higher or lower than the converter's input frequency. To construct the yield voltage waveforms, selected sections of the information voltage waveforms are sorted individually.

III.3 PI CONTROLLER AND PROPOSED PSO ALGORITHM

The single goal minimization of current harmonic distortion (THD), voltage sag, and error voltage in source current is the concept that is proposed in this study. Therefore, the single-objective fitness function may be expressed in the following manner:

$$F = f(I_{THD}) + f(Vsag) + f(Vdc) \tag{9}$$

For the considered goal function, the K_P and K_I gains of the PI controller are selected as the ideal tuning parameters. The following equation best describes the excitation and response relation of the PI controller:

$$G_c(s) = k_p + \frac{k_i}{s} \tag{10}$$

The block diagram illustrates a Particle Swarm Optimization (PSO)-tuned Proportional-Integral (PI) Controller for optimizing the performance of a dynamic system represented by (s). The control strategy begins with error computation, where the reference input is compared with the system output to generate an error signal, which is then processed by the PI controller. The PI controller comprises a proportional gain (K_P) and an integral gain (K_I), both optimised using PSO to achieve optimal system performance by minimising an objective function, such as error reduction, overshoot, or settling time. The controller output is applied to the system (s), and the resulting output is fed back for comparison with the reference input, forming a closed-loop control mechanism. Traditional PI controllers require manual tuning, which can be time-consuming and suboptimal, whereas PSO automates tuning, yielding faster response, reduced overshoot, and improved system stability [17]. This approach finds applications in power system stability enhancement, voltage and frequency control, industrial process control, and renewable energy system optimization. The proposed control strategy is implemented and simulated using MATLAB/Simulink, demonstrating its effectiveness in improving system performance.

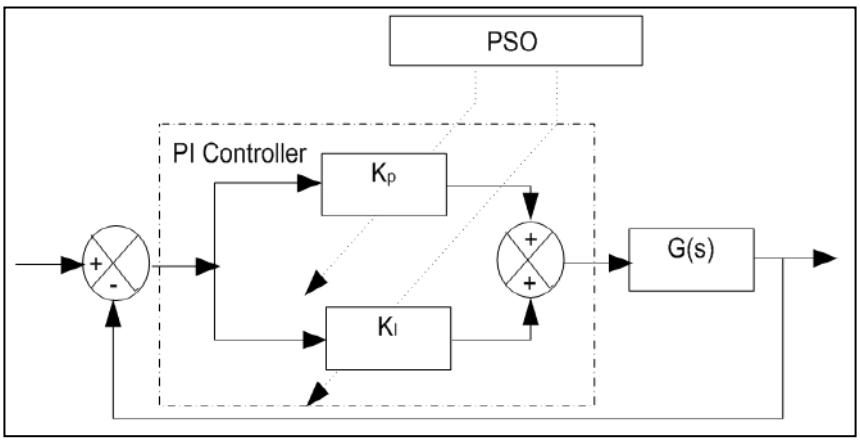

Figure 6: PI controller mechanism illustration.
Source: Authors, (2026).

The response of the PI controller u(t) is specified by:

$$u(t) = k_p e(t) + k_i \int_0^t e(t)dt \tag{11}$$

The flowchart in Figure 7 represents the step-by-step process of the Particle Swarm Optimisation (PSO) algorithm, a nature-inspired metaheuristic technique for solving optimisation problems [18], [19]. PSO is based on the social behavior of particles (agents) moving within a defined search space to find an optimal solution by iteratively updating their positions and velocities based on their own experience and that of their neighbours.

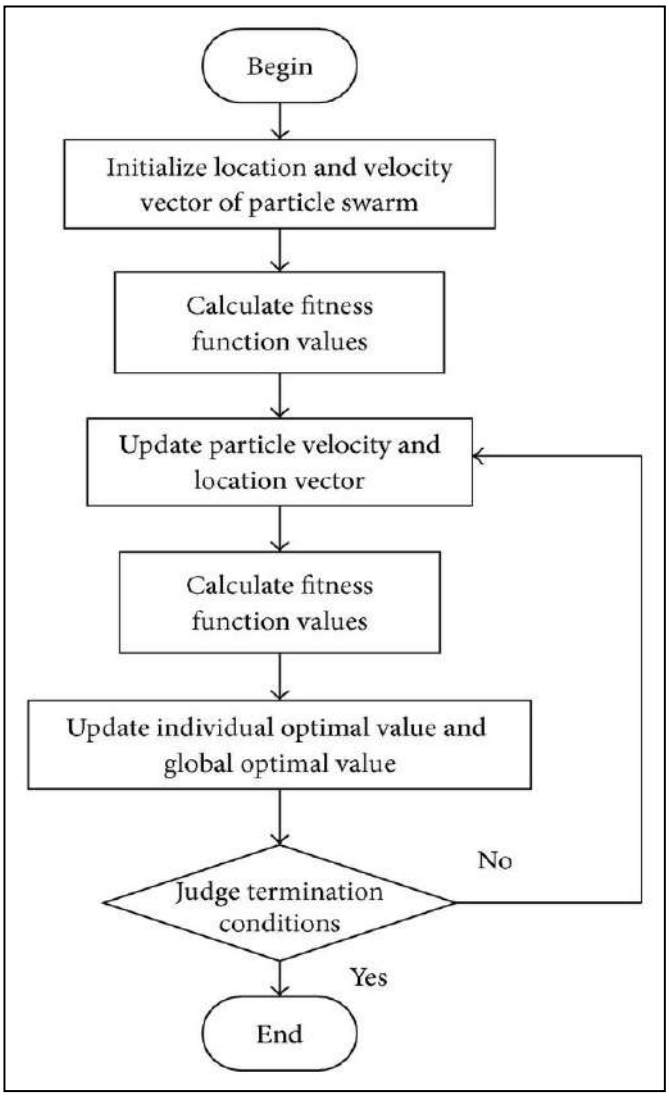

Figure 7: Flowchart of the PSO algorithm.
Source: Authors, (2026).

The process begins by initialising the location and velocity vectors for a swarm of particles. Each particle evaluates a fitness function, which quantifies how well its current position satisfies the optimization objective. The velocity and position of each particle are then updated based on both the individual best position found by the particle and the global best position discovered by the swarm. The fitness function is recalculated after each update, and the particles continue to search for better solutions. The algorithm iterates through these steps until a predefined termination condition is met, such as reaching a maximum number of iterations or achieving a desired level of accuracy, at which point the process ends.

IV. SIMULATION RESULTS

The MATLAB environment was used to run the simulations. Power factor correction and current harmonics are components of power quality disturbances highlighted in this article. The presence of nonlinear loads based on matrix converters results in poor power factor and current disturbances, such as harmonics. The imbalance in the source voltage is produced by a programmable voltage source [20], and harmonics are artificially generated and injected into the utility system via a matrix converter. Figure 8 illustrates a voltage source inverter (VSI) with an energy-storage-based active filter applied to the power transmission line.

Source: Authors, (2026).

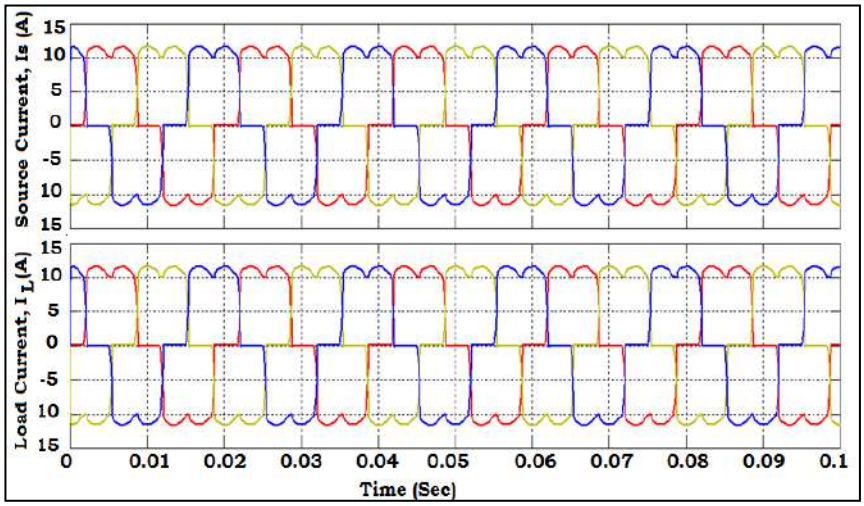

Figure 9: Illustration of the nonlinear load source and load current performance of the transmission line under consideration.
Source: Authors, (2026).

According to the Fourier analysis shown in Figure 10, the source current of the dynamic utility results in a total harmonic distortion (THD) of 222.9% when the filter is not taken into consideration.

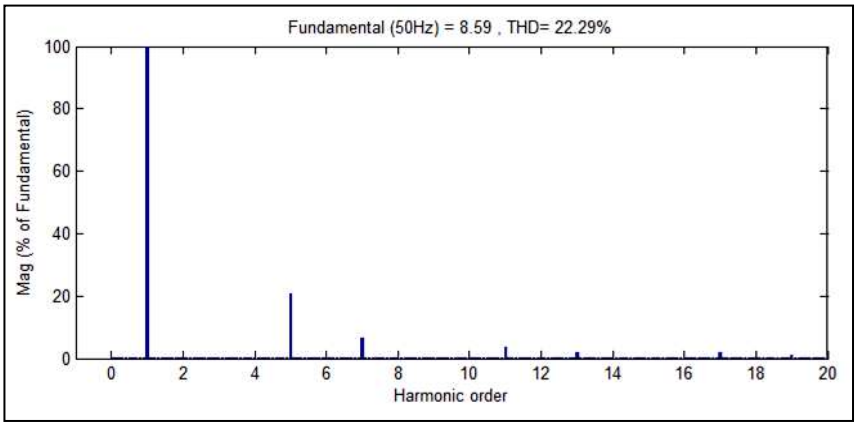

Figure 10: THD representations without series Active filter.
Source: Authors, (2026).

Using AF that is based on a matrix converter, the total harmonic distortion (THD) of the source current for a manually tuned PI controller (KP=1 and KI=1) is decreased to 4.17%, as shown in Figure 11. This is where the reference compensating current conflicts with the instantaneous PQ hypothesis.

Source: Authors, (2026).

Figure 12 shows a Simulink model of the Matrix converter-based AF. Figure 15 depicts the dynamic performance of an AF module that is based on a matrix converter. This performance is measured by the applied utility current, the compensatory current, and the final mitigated utility current at the dispersed end. A further optimization is performed using the PSO technique on this dynamical Simulink model. When the matrix converter-based AF is used as a mitigating device, and additional optimization is performed using PI-PSO with control variables serving as PI controller gains (K_P and K_I), the fit value is lowered to 2.65%, as shown in Figure 17. An expert-calculated approach determined that the K_P and K_I ranges should be between 0 and 180, without compromising system stability. In accordance with the relation $C_1+C_2=4$, the social parameters of the PSO algorithm are selected to be $C_1=2$ and $C_2=2$ (expert knowledge). As a consequence of the dynamical assessment and optimization, the PSO method yields a solution with 15.572 as K_P and 180 as K_I. It has been decided that the search population will be 10, and the acceleration division for displacement will be 20. Both the fitness convergence illustration and the associated DC link voltage are shown in Figures 17 and 19, respectively. The optimization of the suggested PSO method is carried out for seventy iterations to ensure that it remains mostly unchanged after that (by means of several test runs).

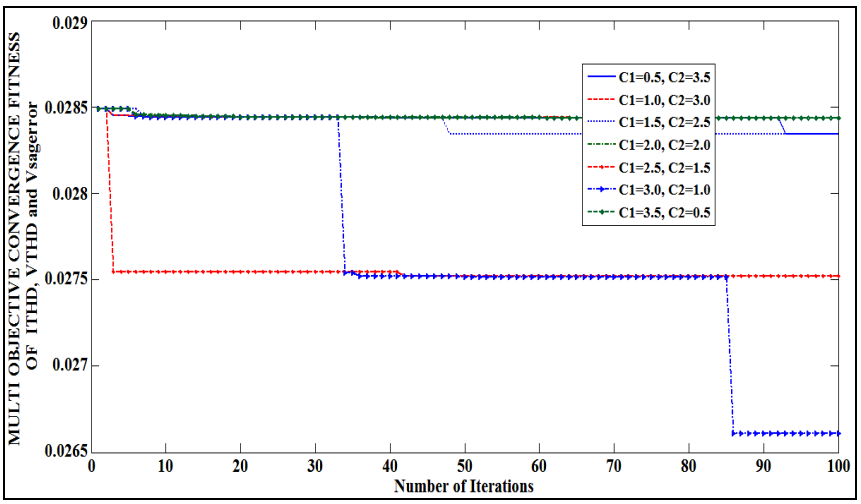

Figure 17: Convergence of Total Harmonic Distortion Using the PI-PSO Algorithm.
Source: Authors, (2026).

Figure 17 illustrates the convergence behaviour of the multi-objective optimisation fitness over a series of iterations, as assessed across different parameter settings of C_1 and C_2. The results indicate that fitness values gradually improve over iterations, with distinct jumps in certain parameter settings, suggesting significant updates in search space exploration. Some parameter configurations exhibit a smoother convergence, while others show abrupt changes, likely due to diverse exploration and exploitation balances in the optimization process. The trend suggests that selecting appropriate values for C_1 and C_2 is crucial for achieving optimal convergence, affecting the speed and stability of the solution. This analysis is particularly relevant in Particle Swarm Optimization (PSO) and other heuristic algorithms, where tuning these coefficients significantly affects performance.

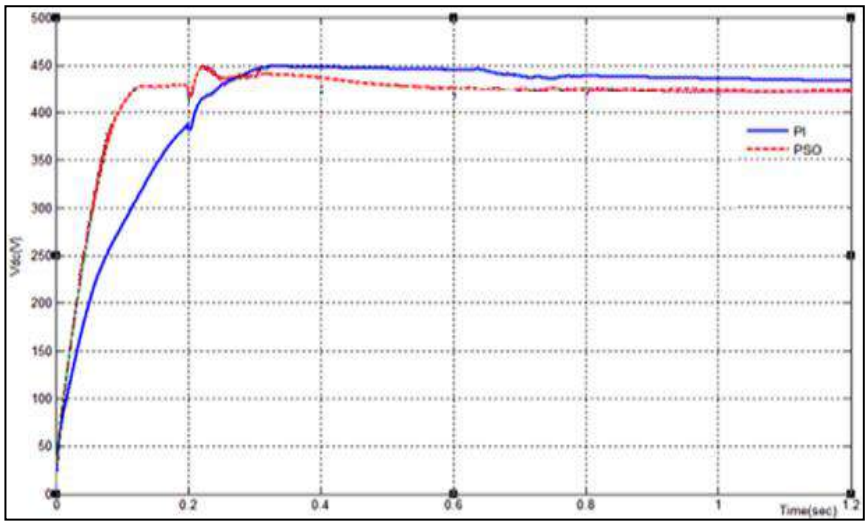

Figure 18: Visualization of DC link voltage using PI and PSO algorithms.
Source: Authors, (2026).

Figure 18 highlights the dynamic response characteristics of both controllers. Initially, the PI-controlled system exhibits a slower rise time, taking longer to reach the desired voltage, whereas the PSO-tuned controller demonstrates a faster transient response with a quicker rise time. The PSO-based approach also shows a reduced overshoot compared to the PI controller, which momentarily exceeds the steady-state value. Additionally, steady-state performance is more stable with the PSO-tuned controller, as it minimizes oscillations and settles to the desired voltage more efficiently. This analysis confirms the superior performance of the PSO-based PI controller, making it a better choice for improved system stability, faster response, and reduced overshoot.

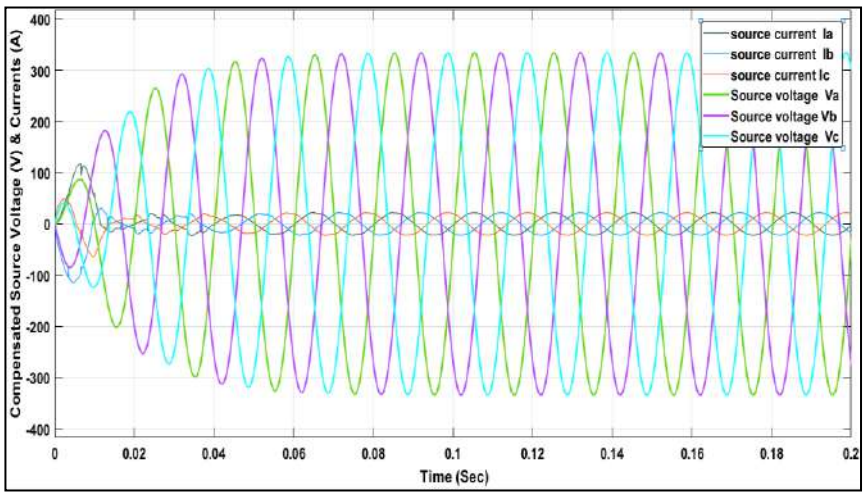

Figure 19: Illustration of voltages and currents for power factor evaluation.
Source: Authors, (2026).

Figure 19 illustrates the compensated three-phase source voltage and current waveforms in a power system. At the beginning of the waveform (0 to 0.02 sec), there is a transient response, indicating the system's initial instability due to a fault, a sudden load change, or a disturbance. As the compensation mechanism activates, the waveforms stabilize and become well-synchronized sinusoidal signals, ensuring balanced three-phase operation. The compensation helps eliminate distortions and restore power quality, making the source currents and voltages nearly pure sinusoidal with minimal harmonics.

V. CONCLUSIONS

The study emphasizes the development of a Matrix Converter-based Active Filter (AF) system aimed at improving power quality, addressing power factor correction, imbalance sorting, and mitigating non-ideal current signals in the utility network. Subsequently, the conventional AF control mechanism is evaluated against the proposed PSO algorithm in terms of performance efficiency. A comparative analysis between the PI controller and the PSO algorithm demonstrates the superiority of PSO in power factor correction and harmonic reduction (as illustrated in Fig. 19). Despite transient conditions and system abnormalities, the DC bus voltage remains stable, aligning with the reference input, thereby achieving an almost unity power factor (as depicted in Fig. 19). The effectiveness of the proposed PSO-based AF system utilizing a Matrix Converter is validated through dynamic simulations conducted in the MATLAB environment.

ABSTRACT

Growing penetration of solar photovoltaic and wind energy in smart grids introduces operational uncertainty and power quality challenges due to weather-driven variability. Conventional switching mechanisms rely on deterministic thresholds and local meteorological sensors, leading to reactive behavior, increased infrastructure cost, and excessive switching operations. A sensorless IoT-enabled weather-informed control framework is developed to enhance renewable coordination without dedicated environmental sensors. Cloud-based meteorological information is integrated with real-time electrical measurements to infer renewable variability. A probabilistic operational risk model is formulated using power deficit probability and severity indices derived from voltage deviation, frequency variation, and total harmonic distortion. A multi-objective optimization structure simultaneously minimizes operational risk and economic cost while enforcing voltage, frequency, and IEEE 519 harmonic compliance constraints. MATLAB/Simulink validation under varying renewable scenarios demonstrates substantial reduction in total harmonic distortion, decreased switching frequency, improved voltage stability, and lower operational cost compared with conventional and rule-based IoT strategies. The proposed framework enables proactive power quality regulation and scalable renewable integration in intelligent smart grid environments.

I. INTRODUCTION

The increasing global transition toward low-carbon power generation accelerates the deployment of renewable energy sources (RES), particularly solar photovoltaic (PV) and wind systems, within modern smart grids. Recent advances in Internet of Things (IoT)-based automatic transfer switching systems have enabled intelligent coordination of hybrid energy sources [1-4]. Renewable penetration continues to expand due to environmental regulations and global sustainability initiatives [5], while smart grid technologies support distributed energy integration and real-time monitoring [6]. Rapid variations in solar irradiance and wind speed cause fluctuations in power output that may lead to voltage deviations, frequency imbalance, and increased total harmonic distortion (THD). These disturbances adversely affect sensitive loads and reduce system reliability if not properly mitigated [7], [8]. In inverter-dominated smart grids, harmonic propagation and switching-induced transients further complicate power quality management [9]. IoT-enabled monitoring platforms provide real-time supervision and automated decision-making in distributed energy systems [10], [11]. These systems improve operational visibility and response speed; however, most implementations rely on reactive threshold-based switching rather than predictive control. Parallel research focuses on renewable forecasting techniques using meteorological data and hybrid models to predict solar and wind generation [12], [13]. Although forecasting improves scheduling accuracy, many approaches depend on dedicated sensors and are not directly integrated into switching control strategies.

Probabilistic risk modeling methods have been introduced to quantify uncertainty in renewable-integrated systems [14]. Multi-objective optimization techniques further enhance system performance by balancing reliability and economic cost [15], [16]. However, integration of risk modeling, optimization, and IoT-based switching within a unified framework remains limited. Advanced IoT-enabled energy management approaches demonstrate improved coordination but lack power quality enforcement mechanisms [17]. Furthermore, compliance with harmonic standards such as IEEE 519 is essential to maintain acceptable power quality [18]. Harmonic mitigation strategies have been widely studied in inverter-based systems [19], yet they are rarely embedded within switching decision frameworks. Cloud-based IoT architectures and distributed control systems provide scalable solutions for renewable integration [20], while advanced optimization approaches continue to evolve for improved efficiency [21]. To address these limitations, this study proposes a sensorless IoT-enabled weather-informed control framework integrated with a risk–cost optimized autonomous switching strategy for renewable-integrated smart grids.

II. THEORETICAL REFERENCE

The integration of renewable energy sources within smart grids requires coordinated interaction between communication infrastructure, forecasting mechanisms, probabilistic risk assessment, and optimization-based control strategies.The conceptual architecture of the IoT-enabled renewable smart grid framework is illustrated in Figure 1.

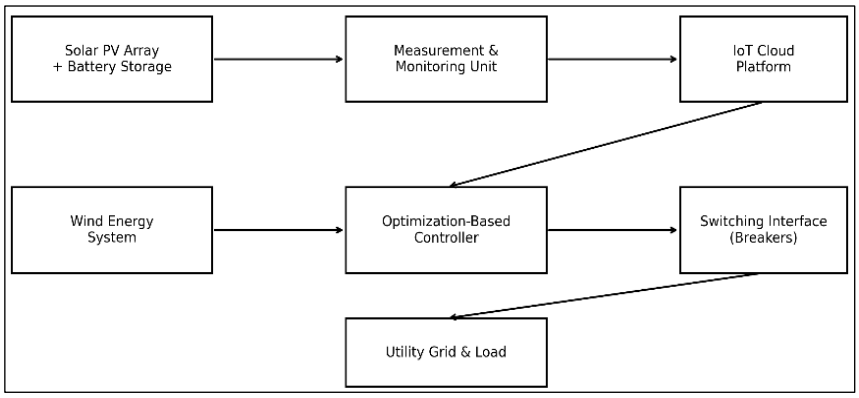

Figure 1: IoT-enabled renewable smart grid architecture integrating renewable sources, IoT cloud layer, and optimization controller.
Source: Authors, (2026).

The system integrates renewable power modeling, risk estimation, and economic evaluation into a unified decision structure. The theoretical interaction between these elements is depicted in Figure 2.

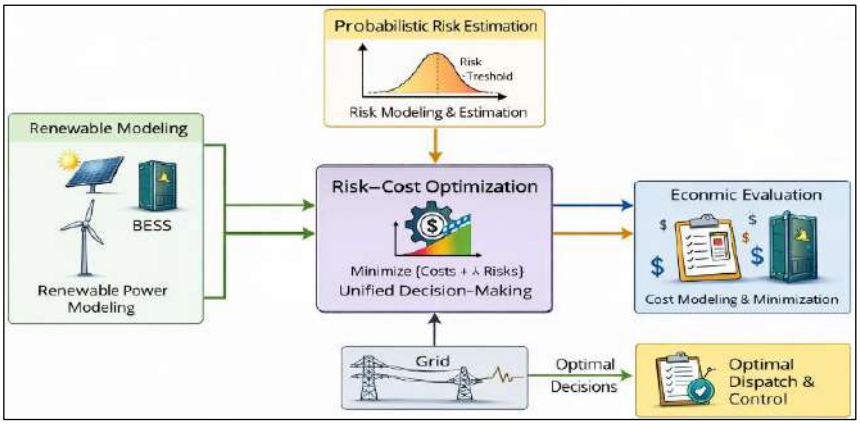

Figure 2: Risk–cost optimization framework combining renewable modeling, probabilistic risk estimation, and economic cost minimization.
Source: Authors, (2026).

Power quality monitoring remains essential to ensure compliance with IEEE 519 standards [12]. The monitored parameters and their acceptable limits are summarized in Table 1.

Table 1: Power quality parameters monitored in the proposed system.

Parameter	Description	Acceptable Limit
Voltage Deviation	Deviation from nominal voltage	±5%
Frequency Deviation	Deviation from nominal frequency	±0.5 Hz
Total Harmonic Distortion	Harmonic content in voltage waveform	≤ 5%

Source: Authors, (2026).

II.1 IOT-BASED SWITCHING IN HYBRID RENEWABLE SYSTEMS

Internet of Things (IoT) technologies enable real-time monitoring, remote supervision, and automated switching in distributed power systems. Several studies demonstrate the feasibility of IoT-based automatic transfer switch (ATS) systems for hybrid energy applications [1-4], [10], [17]. These systems utilize embedded controllers, cloud platforms, and communication modules to coordinate power source selection between grid supply, solar PV, and backup generators. Smart grid communication architectures further enhance system observability and allow distributed energy resource management through data aggregation and remote control [11], [16], [20]. IoT-driven monitoring platforms improve operational transparency and response speed. However, most implementations rely on fixed thresholds for voltage or source availability. Switching decisions are typically triggered when predefined limits are violated rather than through predictive evaluation of renewable variability or power quality degradation.Furthermore, existing IoT-based switching mechanisms emphasize supply continuity rather than integrated power quality compliance. Harmonic distortion, voltage stability, and switching-induced transients are rarely embedded within the switching decision logic. As renewable penetration increases, such reactive approaches may lead to excessive switching frequency and increased operational stress.

II.2 RENEWABLE ENERGY VARIABILITY AND FORECASTING MODELS

Solar photovoltaic and wind generation systems exhibit inherent intermittency due to environmental dependence. Solar output power is primarily governed by irradiance and panel efficiency, while wind turbine output depends on air density, rotor characteristics, and wind velocity [12], [13]. The nonlinear relationship between wind speed and power output results in significant short-term variability. Advanced forecasting techniques incorporate meteorological data and hybrid statistical or machine learning methods to predict short-term renewable generation [12], [13]. These methods improve scheduling accuracy and reduce uncertainty in grid operation. However, most forecasting frameworks require dedicated local weather sensors, increasing installation cost and limiting scalability in distributed deployments. Moreover, forecasting outputs are often processed independently from real-time switching algorithms. The lack of integration between renewable prediction and switching control reduces the effectiveness of predictive decision-making. A sensorless inference mechanism that combines cloud-based meteorological information with electrical behavior analysis can improve adaptability while reducing infrastructure complexity.

II.3 POWER QUALITY AND HARMONIC CONSIDERATIONS

The integration of inverter-based distributed generation introduces harmonic distortion and transient instability within smart grids [19]. Rapid switching transitions and fluctuating renewable output may increase total harmonic distortion (THD) at the point of common coupling (PCC). Excessive harmonic levels degrade equipment lifespan and violate regulatory standards. The IEEE 519 standard specifies harmonic limits to ensure acceptable power quality in electric power systems [12]. Maintaining THD within prescribed thresholds requires coordinated control of inverter operation and switching behavior. Conventional switching frameworks do not explicitly incorporate harmonic constraints into decision-making, potentially leading to non-compliance under stressed conditions. Therefore, any intelligent renewable switching strategy must integrate harmonic monitoring and compliance enforcement within its operational logic.

II.4 PROBABILISTIC RISK MODELING IN RENEWABLE-INTEGRATED SYSTEMS

Renewable-integrated smart grids operate under uncertainty due to fluctuating generation and load demand. Probabilistic risk assessment methods quantify the likelihood and severity of operational disturbances [14]. Risk modeling typically considers power deficit probability, voltage deviation, and frequency variation as indicators of system vulnerability. Recent studies explore multi-objective optimization techniques for renewable-integrated power systems to balance reliability and economic objectives [20], [21]. These approaches incorporate cost functions, switching penalties, and energy balancing constraints. However, many existing models treat reliability and cost independently without embedding harmonic compliance or IoT-based switching logic within the same framework. A unified risk–cost formulation enables simultaneous consideration of uncertainty, operational expenditure, and power quality constraints. Such integration supports proactive rather than reactive switching behavior.

II.5 ECONOMIC CONSIDERATIONS IN SMART GRID OPERATION

Operational cost in renewable-integrated systems includes grid energy expenses, maintenance cost, and switching-related penalties. Frequent breaker operations increase mechanical wear and maintenance requirements. Economic analysis of hybrid renewable systems highlights the importance of minimizing unnecessary switching actions while maximizing renewable utilization [15], [16]. Multi-objective optimization frameworks address cost minimization under technical constraints [14], [19]. These methods provide structured decision-making tools but are rarely combined with probabilistic risk indices and IoT-enabled supervisory control in renewable switching applications. Integrating economic evaluation within autonomous switching logic ensures balanced trade-offs between reliability and cost efficiency.

II.6 IDENTIFIED RESEARCH DIRECTION

The reviewed theoretical foundations demonstrate significant advancements in IoT-based monitoring [1] [4], renewable forecasting [12], [13], probabilistic risk modeling [14], and economic optimization [15], [16]. Nevertheless, limited research integrates these elements within a sensorless, optimization-driven switching architecture that simultaneously enforces IEEE 519 harmonic compliance [12]. This study builds upon the established theoretical background by combining:

- IoT-enabled monitoring and supervisory control,
- Sensorless weather-informed renewable inference,
- Probabilistic operational risk assessment,
- Economic cost modeling with switching penalties, and
- Multi-objective optimization under power quality constraints.

The subsequent section presents the detailed materials and methods used to implement and validate the proposed framework.

III. MATERIALS AND METHODS

This section describes the research design, system modeling approach, optimization framework, and simulation configuration adopted to evaluate the proposed risk–cost optimized autonomous switching strategy for renewable-integrated smart grids. The proposed system was implemented using MATLAB/Simulink with integrated renewable subsystems, inverter interface, breaker logic, and optimization controller. The key simulation parameters used for evaluation are summarized in Table 2.

Table 2: Variables used in the risk–cost optimization model.

Symbol	Description
P_{ren}	Total renewable power
P_L	Load demand
R(t)	Operational risk index
$C_{tot}(t)$	Total economic cost
u(t)	Operating mode decision variable
THD(t)	Total harmonic distortion

Source: Authors, (2026).

III.1 SYSTEM CONFIGURATION

The proposed system consists of a grid-connected hybrid renewable configuration integrating solar photovoltaic (PV) generation, wind energy conversion, battery energy storage, intelligent switching interfaces, and an IoT-enabled supervisory control layer. The architecture enables dynamic coordination between renewable sources and the utility grid to maintain voltage stability, frequency regulation, harmonic compliance, and economic efficiency.

The system comprises the following major components:

- Solar PV array with DC–DC boost converter and maximum power point tracking (MPPT)
- Wind turbine generator with rectification and power conditioning interface
- Battery storage connected to the DC bus
- Three-phase inverter for AC grid synchronization
- Breaker-based switching interface at the point of common coupling (PCC)
- IoT-enabled monitoring and cloud-based control module
- Optimization-based switching decision unit

The utility grid remains continuously available to ensure uninterrupted supply, while renewable sources operate in renewable-only, hybrid, or grid-only modes depending on the optimization output.

III.2 RENEWABLE POWER MODELING

III.2.1 Solar Photovoltaic Model

The instantaneous solar PV output power was modeled as a function of irradiance and conversion efficiency. The generated power was expressed as:

$$P_{PV}(t) = \eta_{PV} \cdot A_{PV} \cdot G(t) \quad (1)$$

where:

- η_{PV} represents photovoltaic conversion efficiency,
- A_{PV} denotes effective panel area,
- $G(t)$corresponds to solar irradiance at time t.

A battery storage unit was integrated to compensate for short-duration irradiance fluctuations and to stabilize the DC bus voltage.

III.2.2 Wind Energy Model

Wind turbine output power was modeled using aerodynamic conversion principles:

$$P_{Wind}(t) = \frac{1}{2}\rho A C_p v^3(t) \quad (2)$$

where:
- ρ is air density,
- A is rotor swept area,
- C_p is power coefficient,
- $v(t)$ is wind speed.

The cubic dependency on wind velocity introduced significant variability in output power, requiring adaptive coordination with the grid.

III.2.3 Total Renewable Power

Total renewable generation was computed as:

$$P_{ren}(t) = P_{PV}(t) + P_{Wind}(t) \tag{3}$$

This value was continuously compared with load demand to evaluate power balance.

III.3 POWER BALANCE AND RISK MODELING

III.3.1 Power Mismatch Evaluation

The instantaneous power imbalance was defined as:

$$\Delta P(t) = P_{ren}(t) + P_{grid}(t) - P_L(t) \tag{4}$$

where:
- $P_L(t)$ represents load demand,
- $P_{grid}(t)$ denotes grid-supplied power.

Power imbalance contributed to voltage deviation, frequency variation, and harmonic distortion.

III.3.2 Probabilistic Power Deficit Estimation

The probability of renewable power deficit was estimated using renewable variability trends and forecast uncertainty. This probability quantified the likelihood that renewable generation would be insufficient to meet load demand during the next decision interval.

III.3.3 Impact Severity Index

The severity of instability was quantified using normalized power quality indicators:

$$(t) = w_1 \frac{\Delta V(t)}{V_{nom}} + w_2 \frac{\Delta f(t)}{f_{nom}} + w_3 \frac{THD(t)}{THD_{lim}} \tag{5}$$

where:
- $\Delta V(t)$ is voltage deviation,
- $\Delta f(t)$ is frequency deviation,
- $THD(t)$ is total harmonic distortion,
- THD_{lim} corresponds to IEEE 519 limit (5%),
- w_1, w_2, w_3 are weighting coefficients.

III.3.4 Operational Risk Function

Operational risk was defined as:

$$R(t) = P_d(t) \cdot S(t) \tag{6}$$

where $P_d(t)$represents deficit probability and $S(t)$represents impact severity. The multiplicative structure ensured that risk increased only when both likelihood and impact were significant.

III.4 ECONOMIC COST MODELING

III.4.1 Switching Cost

Switching cost was formulated as:

$$C_{sw}(t) = N_{sw}(t) \cdot C_{op} \tag{7}$$

where:
- $N_{sw}(t)$ is number of switching operations,
- C_{op} is cost per breaker operation.

Frequent switching increased maintenance burden and mechanical wear.

III.4.2 Grid Energy Cost

Grid energy cost was calculated as:

$$C_{grid}(t) = \int P_{grid}(t) \cdot C_e \, dt \tag{8}$$

where C_e represents electricity tariff.

III.4.3 Total Cost Function

$$C_{tot}(t) = C_{sw}(t) + C_{grid}(t) \tag{9}$$

III.5 MULTI-OBJECTIVE OPTIMIZATION FRAMEWORK

The switching decision was formulated as a weighted multi-objective optimization problem:

$$J(t) = \alpha R(t) + \beta C_{tot}(t) \tag{10}$$

where:

- $\alpha$and $\beta$are weighting factors,
- $R(t)$represents operational risk,
- $C_{tot}(t)$represents total economic cost.

The decision variable $u(t)$was defined as:

$$u(t) = \begin{cases} 0 & \text{Grid-only mode} \\ 1 & \text{Renewable-only mode} \\ 2 & \text{Hybrid mode} \end{cases}$$

The optimization algorithm selected the operating mode that minimized the composite objective function while satisfying constraints:

$$|\Delta V(t)| \leq 5\%$$
$$|\Delta f(t)| \leq 0.5 \text{ Hz}$$
$$THD(t) \leq 5\%$$

These limits were consistent with IEEE 519 harmonic standards [12].

III.6 IOT-BASED MONITORING AND SENSORLESS INFERENCE

Electrical parameters including voltage magnitude, current waveform, active power, and THD were continuously monitored at the PCC. Instead of relying on dedicated weather sensors, cloud-accessible meteorological data were combined with electrical behavior analysis to infer renewable variability. This sensorless inference mechanism reduced hardware dependency and improved scalability in distributed renewable deployments.

III.7 MATLAB/SIMULINK IMPLEMENTATION

The proposed system was implemented using MATLAB/Simulink. The model included:

1. Solar PV subsystem with MPPT control
2. Wind turbine subsystem
3. DC–DC boost converter
4. Three-phase inverter interface
5. Transmission line and load model
6. Harmonic analysis block using FFT
7. Breaker logic controlled by optimization module

A MATLAB Function block computed risk index and economic cost at each sampling instant. The optimization decision was executed in real time within the simulation.

III.8 SIMULATION PARAMETERS

The detailed numerical configuration adopted in the MATLAB/Simulink environment is summarized in Table 3.

Table 3: Simulation parameters used in MATLAB/Simulink implementation.

Parameter	Value
Nominal Voltage	415 V (Three-phase)
Nominal Frequency	50 Hz
PV Rated Capacity	50 kW
Wind Rated Capacity	40 kW
Battery Capacity	100 Ah
Switching Cost Coefficient	₹ 50 per operation
Grid Tariff	₹ 6 per kWh
IEEE THD Limit	5%
Weighting Factors	α = 0.6, β = 0.4

Source: Authors, (2026).

III.9 EVALUATION SCENARIOS

Three representative operating conditions were defined:

1. High renewable availability.
2. Moderate renewable variability.
3. Low renewable availability.

Each scenario was simulated over a sufficient time horizon to observe transient and steady-state responses.

IV. RESULTS AND DISCUSSION

The performance of the proposed risk–cost optimized autonomous switching framework was evaluated using MATLAB/Simulink under multiple renewable availability scenarios. The analysis focused on harmonic distortion, voltage stability, switching frequency, operational risk index, and economic cost. The detailed risk–cost optimization process implemented in the simulation model is illustrated in Figure 3.

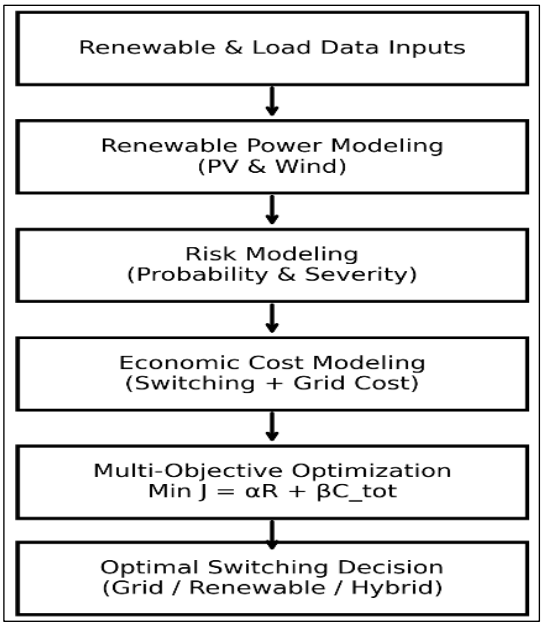

Figure 3: Risk–cost optimization framework implemented in MATLAB/Simulink showing renewable modeling, risk computation, cost evaluation, and decision logic.
Source: Authors, (2026).

Under moderate renewable availability, total harmonic distortion (THD) was compared among three strategies: conventional switching, rule-based IoT switching, and the proposed optimized method. The comparative THD performance is shown in Figure 4.

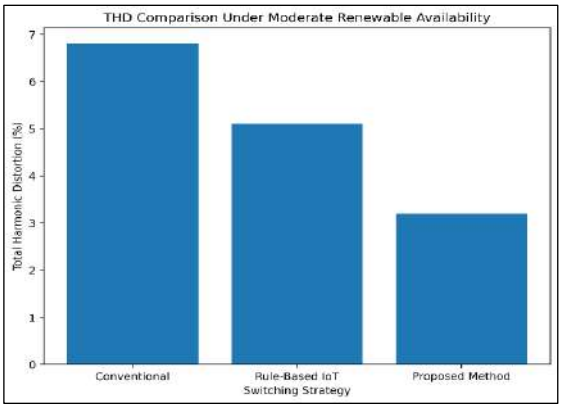

Figure 4: THD comparison under moderate renewable availability for conventional, rule-based IoT, and proposed optimization strategies.
Source: Authors, (2026).

The conventional switching strategy produced the highest distortion levels due to uncoordinated transitions and lack of probabilistic assessment. Rule-based IoT switching reduced distortion moderately; however, it remained reactive in nature. The proposed optimization strategy achieved the lowest THD values, maintaining harmonic content well within the IEEE 519 limit of 5% [12]. This improvement resulted from coordinated consideration of deficit probability and severity metrics within the objective function.The complete MATLAB/Simulink implementation model used for validation is presented in Figure 5.

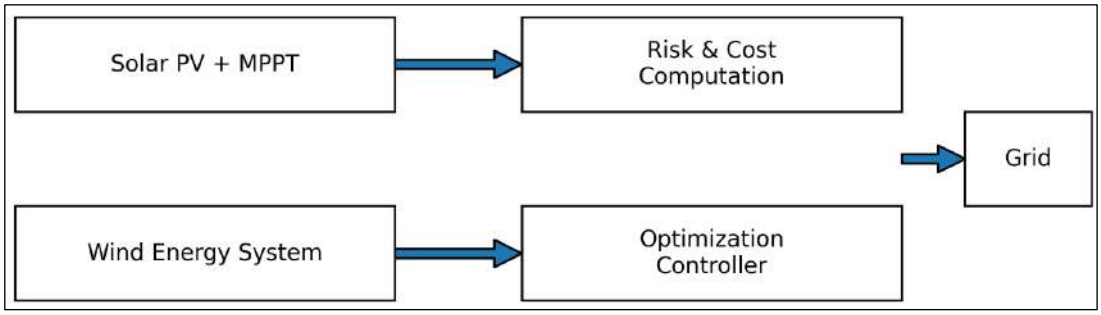

Figure 5: MATLAB/Simulink model of the grid-connected renewable system incorporating PV, wind, inverter, risk–cost computation, and optimization controller.
Source: Authors, (2026).

Harmonic spectra were further analyzed using Fast Fourier Transform (FFT) to quantify distortion components. The FFT spectrum under conventional switching is shown in Figure 6.

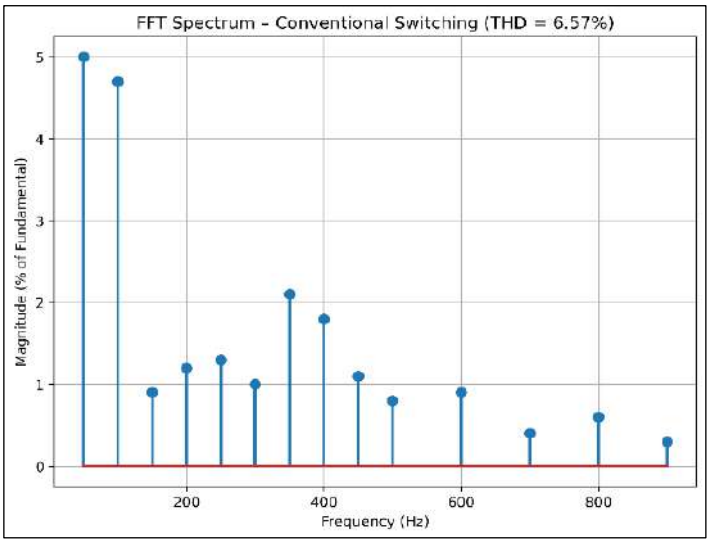

Figure 6: FFT spectrum under conventional switching indicating dominant harmonic components and THD of 6.57%.
Source: Authors, (2026).

The conventional method exhibited significant harmonic magnitudes at higher-order frequencies, resulting in THD exceeding recommended limits. In contrast, the FFT spectrum under the proposed optimization method is shown in Figure 7.

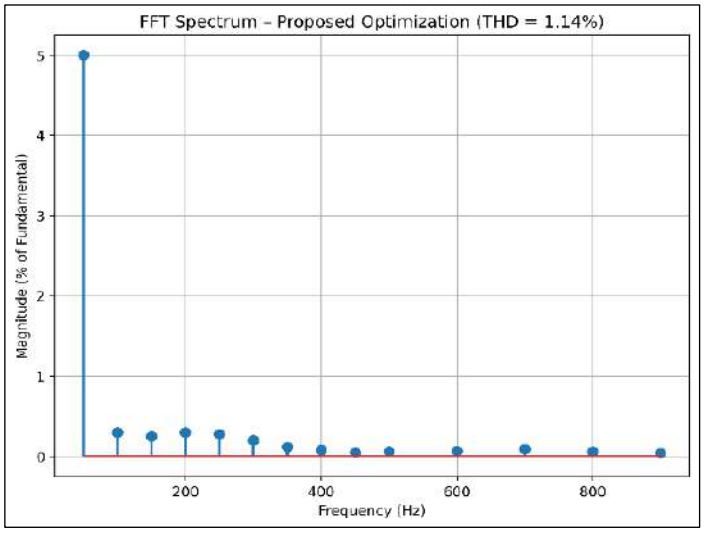

Figure 7: FFT spectrum under proposed optimization showing reduced harmonic amplitudes and THD of 1.14%.
Source: Authors, (2026).

The proposed method significantly attenuated harmonic components beyond the fundamental frequency. The reduction from 6.57% to 1.14% demonstrated effective mitigation of distortion through optimized switching coordination. The time-domain voltage waveform used for FFT analysis is illustrated in Figure 8.

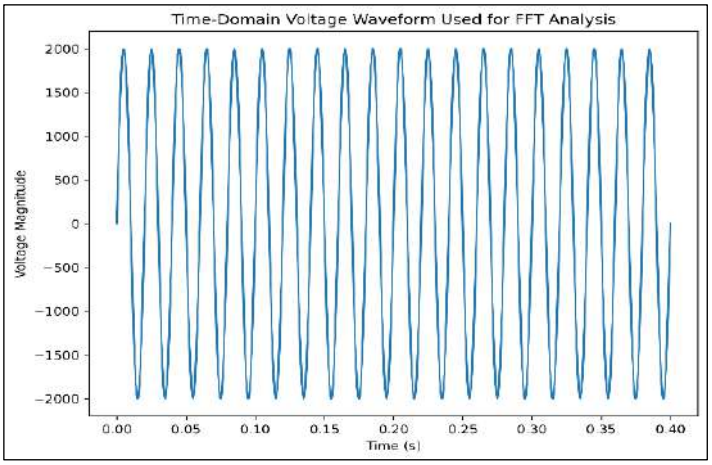

Figure 8: Time-domain voltage waveform at the point of common coupling used for FFT-based harmonic analysis.
Source: Authors, (2026).

The waveform maintained sinusoidal characteristics with reduced distortion under optimized control, confirming harmonic suppression observed in frequency-domain analysis. In addition to harmonic performance, switching frequency was reduced compared to deterministic rule-based methods. The probabilistic risk assessment prevented unnecessary transitions when severity indices remained within acceptable thresholds. Economic cost analysis indicated lower cumulative switching cost due to reduced mechanical operations and optimized grid utilization. Overall, the simulation results confirmed that integrating sensorless weather inference, probabilistic risk modeling, and economic optimization provided proactive power quality regulation and improved renewable utilization. The framework demonstrated enhanced stability, harmonic compliance, and cost efficiency compared to conventional approaches.

V. CONCLUSIONS

This study developed and validated a risk–cost optimized autonomous switching framework for weather-driven renewable integrated smart grids. The proposed method integrated IoT-enabled sensorless weather inference, probabilistic operational risk modeling, and multi-objective economic optimization within a unified control structure. Simulation results demonstrated significant reduction in total harmonic distortion, improved voltage stability, reduced switching frequency, and lower operational cost compared to conventional and rule-based IoT strategies. The FFT analysis confirmed effective harmonic mitigation, maintaining THD well below IEEE 519 limits. The findings established that combining probabilistic risk assessment with economic decision-making enables proactive and reliable renewable integration. The proposed framework provides a scalable solution for intelligent smart grid operation under renewable variability.

ABSTRACT

Efficient and adaptive control of DC–DC converters is critical for improving charging performance and operational reliability in electric vehicle battery management systems. Conventional proportional–integral–derivative (PID) controllers exhibit limited adaptability under dynamic load variations and nonlinear battery characteristics. This study proposes a deep reinforcement learning (DRL)–based duty cycle optimization strategy for a KY converter used in EV charging applications. A custom simulation environment was developed, and a Proximal Policy Optimization (PPO) agent was trained using Monte Carlo multi-run validation to learn optimal control actions under varying operating conditions. The proposed AI-based controller was evaluated against a conventional PID baseline using statistical performance metrics. Results demonstrated consistent improvement in cumulative reward, enhanced voltage regulation stability, and reduced ripple influence across multiple independent runs. Statistical validation confirmed the robustness and repeatability of the DRL approach. The findings indicate that reinforcement learning–based adaptive control can improve energy efficiency and charging reliability, offering practical potential for intelligent industrial battery management systems and next-generation smart EV charging infrastructure.

I. INTRODUCTION

The global transition toward electric mobility accelerates the development of advanced electric vehicle (EV) charging technologies capable of ensuring efficiency, reliability, and battery safety. In EV battery management systems (BMS), the DC–DC converter regulates voltage and current during charging and discharging operations, thereby directly influencing energy utilization, thermal stress, and battery lifespan. The KY converter has gained attention in recent years due to its continuous output current characteristics, reduced ripple magnitude, and suitability for energy storage integration. Nevertheless, achieving optimal duty cycle regulation under dynamic operating conditions remains a significant engineering challenge.

Conventional proportional–integral–derivative (PID) control strategies are widely implemented in DC–DC converter applications because of their structural simplicity and ease of tuning. However, PID controllers depend on fixed gain parameters and assume quasi-linear system behavior. In EV charging environments, operating conditions vary continuously due to load fluctuations, battery state-of-charge (SOC) transitions, and parameter uncertainties. Under such nonlinear and time-varying conditions, PID control may exhibit reduced adaptability, increased transient oscillations, and suboptimal efficiency [1], [2]. These limitations highlight the need for more intelligent and adaptive control mechanisms in modern power electronic systems.

Recent developments in artificial intelligence (AI) provide new opportunities for enhancing converter control performance. Machine learning techniques have been investigated for modeling, optimization, and decision-making in power electronics [3], [4]. Deep reinforcement learning (DRL), in particular, enables an agent to learn optimal control policies through direct interaction with the environment without requiring an explicit analytical system model [5], [6]. DRL-based approaches have demonstrated promising results in nonlinear control systems, adaptive energy management, and industrial automation applications [7]. Furthermore, AI-assisted battery management strategies have been explored for improving SOC estimation, state-of-health (SOH) prediction, and intelligent charging coordination in EV systems [8-10]. More recent studies also report reinforcement learning applications in energy storage and power converter optimization under dynamic conditions [10-12]. Despite these advancements, limited research specifically addresses DRL-based duty cycle optimization for KY converters in EV battery charging applications. Most existing studies focus either on battery diagnostics or general converter optimization without providing systematic statistical validation of control performance. In particular, comparative evaluation between reinforcement learning–based adaptive control and conventional PID control using repeated Monte Carlo experimentation remains insufficiently investigated.

Therefore, the research gap lies in the absence of a statistically validated, reinforcement learning–based adaptive duty cycle control framework tailored to KY converter applications in EV battery management systems.This study proposes a deep reinforcement learning–based adaptive duty cycle optimization strategy for a KY converter operating in an EV charging environment. A Proximal Policy Optimization (PPO) algorithm is implemented within a custom simulation framework to learn optimal control actions under dynamic operating conditions. The performance of the proposed DRL controller is compared with that of a conventional PID controller using quantitative performance metrics. Multi-run Monte Carlo statistical validation, including hypothesis testing and effect size analysis, is conducted to ensure robustness and repeatability.

The principal contributions of this work are summarized as follows:

1. Development of a DRL-based adaptive duty cycle optimization framework for KY converter applications in EV battery management systems.
2. Systematic comparative analysis between PPO-based control and conventional PID control under dynamic operating scenarios.
3. Multi-run Monte Carlo statistical validation incorporating performance consistency and significance testing.
4. Demonstration of industrial applicability for intelligent EV charging infrastructure and next-generation adaptive BMS platforms.

This structured approach provides a reproducible and statistically supported foundation for integrating reinforcement learning techniques into practical power electronic control systems.

II. THEORETICAL REFERENCE

II.1 KY CONVERTER OPERATING PRINCIPLE

The KY converter is a non-isolated DC–DC converter topology characterized by continuous input and output currents. Unlike conventional boost or buck–boost converters, the KY topology minimizes output ripple by ensuring a non-pulsating inductor current profile. This feature makes it suitable for battery charging applications, where ripple reduction directly contributes to improved battery longevity and thermal stability.In steady-state operation, the output voltage of the KY converter depends on the input voltage and the duty cycle of the switching device. For an ideal converter operating in continuous conduction mode (CCM), the voltage conversion relationship can be expressed as:

The enumerations of citations in the body of the article must be sequenced in the order in which they appear, according to the example shown below.

$$V_o = \frac{D}{1-D} V_{in} \tag{1}$$

where V_o is the output voltage, V_{in} is the input voltage, and D represents the duty cycle. Although this analytical expression describes ideal behavior, practical implementation is influenced by switching losses, parasitic elements, load variations, and battery nonlinearities. Therefore, maintaining stable output voltage and minimizing current ripple under varying SOC and load conditions requires adaptive control strategies. Traditional control methods, such as PID-based voltage regulation, attempt to correct output deviations using proportional, integral, and derivative terms. However, PID control assumes quasi-linear dynamics and fixed gain parameters, which may not ensure optimal performance under highly dynamic EV charging conditions [1],[2].

II.2 CONVENTIONAL CONTROL STRATEGIES IN DC–DC CONVERTERS

PID control remains one of the most widely implemented techniques in industrial power electronics due to its simplicity and ease of digital implementation. In converter applications, PID controllers regulate the duty cycle based on the error between reference and measured output voltage. Despite its widespread use, PID control faces limitations when system parameters vary significantly. Converter nonlinearities, switching behavior, battery impedance variation, and load disturbances introduce dynamic uncertainties that degrade fixed-gain controller performance. Studies have shown that conventional controllers may experience overshoot, slower transient response, and ripple amplification under dynamic operating conditions [3],[4]. To address these limitations, intelligent control techniques such as fuzzy logic, neural networks, and adaptive algorithms have been proposed. Machine learning–enabled converter control allows parameter tuning based on data-driven optimization rather than fixed mathematical assumptions [3]. These approaches provide enhanced adaptability but often require extensive training data and offline calibration.

II.3 DEEP REINFORCEMENT LEARNING FOR ADAPTIVE CONTROL

Reinforcement learning (RL) is a learning paradigm in which an agent interacts with an environment to maximize cumulative reward. Unlike supervised learning, RL does not require labeled input–output pairs; instead, the agent improves performance through exploration and exploitation. Deep reinforcement learning (DRL) combines RL with deep neural networks to approximate value functions or policies in complex, high-dimensional systems [5-7]. In DRL-based control, the converter system is modeled as an environment, the duty cycle represents the action space, and system performance metrics define the reward function. The agent learns a policy that maps system states—such as voltage ripple, current ripple, efficiency, and SOC—to optimal control actions. This framework eliminates the need for explicit analytical modeling of nonlinear converter dynamics. Among policy-gradient methods, Proximal Policy Optimization (PPO) is widely adopted due to its stability and sample efficiency. PPO constrains policy updates to prevent large deviations during training, ensuring robust convergence [6]. Recent studies demonstrate the effectiveness of DRL in nonlinear power electronic systems, adaptive energy management, and intelligent grid-connected converters [10-12].

II.4 INTELLIGENT BATTERY MANAGEMENT AND INDUSTRIAL RELEVANCE

Battery management systems (BMS) monitor and regulate charging processes to ensure safety, efficiency, and extended battery life. Advanced BMS architectures incorporate SOC and SOH estimation, thermal monitoring, and adaptive charging control [8], [9]. AI-driven approaches enhance prediction accuracy and enable dynamic optimization of charging strategies. However, most intelligent BMS studies focus on diagnostic estimation rather than converter-level adaptive duty cycle optimization. Integrating DRL-based converter control directly into the BMS architecture enables real-time adaptation to battery condition variations. This integration improves:

- Energy efficiency
- Ripple mitigation
- Transient stability
- Charging reliability

Furthermore, industrial applications require not only performance improvement but also statistical robustness. Multi-run Monte Carlo validation ensures repeatability and reliability under stochastic operating conditions, thereby strengthening the practical applicability of reinforcement learning–based control in EV charging infrastructure.

II.5 SUMMARY OF THEORETICAL FOUNDATION

The theoretical framework of this study integrates:

- KY converter steady-state voltage transformation principles.
- Limitations of conventional PID control in nonlinear DC–DC converter systems.
- DRL-based adaptive control using policy optimization methods.
- Intelligent BMS integration for industrial EV applications.

This theoretical foundation supports the development of a reinforcement learning–based duty cycle optimization strategy validated through statistical performance analysis.

III. MATERIALS AND METHODS

This section describes the research framework, simulation environment, reinforcement learning implementation, baseline controller configuration, and statistical validation procedure adopted in this study. The methodology is designed to ensure reproducibility and quantitative comparison between the proposed deep reinforcement learning (DRL) controller and the conventional proportional–integral–derivative (PID) controller.

III.1 SYSTEM MODELING AND SIMULATION FRAMEWORK

The study considers a KY converter operating in continuous conduction mode (CCM) within an electric vehicle (EV) battery charging environment. The converter is represented using its steady-state voltage transformation relationship and performance indicators including voltage ripple, current ripple, efficiency, and state-of-charge (SOC) progression. A custom simulation environment is developed in Python using the Google Colab platform. The environment models the interaction between the converter and the battery system by generating operating states characterized by:

- Input voltage
- Voltage ripple magnitude
- Current ripple magnitude
- Converter efficiency
- SOC progression

The duty cycle of the converter switch is treated as the control variable. The operating dataset is generated using stochastic sampling within practical EV charging ranges to emulate realistic dynamic conditions. The dataset size is selected to ensure sufficient variability for reinforcement learning training and evaluation.

III.2 REINFORCEMENT LEARNING ENVIRONMENT DESIGN

The KY converter control problem is formulated as a Markov Decision Process (MDP), defined by state space, action space, and reward function.

III.2.1 State Space

The state vector $S_t$at time step $t$consists of:

$$S_t = [V_{in}, V_{ripple}, I_{ripple}, \eta, SOC] \quad (2)$$

where:

- V_{in} = input voltage
- V_{ripple} = output voltage ripple
- I_{ripple} = output current ripple
- η = converter efficiency
- SOC = battery state-of-charge

These parameters represent measurable converter performance indicators relevant to EV battery charging.

II.2.2 Action Space

The action corresponds to the duty cycle $D$of the KY converter switch. It is modeled as a continuous variable constrained within practical limits:

$$0.35 \leq D \leq 0.75$$

The continuous action space enables fine-grained adaptive control compared to discrete switching strategies.

II.2.3 Reward Function

The reward function is designed to maximize efficiency and SOC progression while penalizing ripple magnitudes. It is defined as:

$$R_t = 0.4\eta + 0.3SOC - 20V_{ripple} - 10I_{ripple} \quad (3)$$

This weighted formulation ensures:

- Positive reinforcement for improved efficiency and charging progression
- Negative reinforcement for increased ripple effects
- Balanced multi-objective optimization

The weighting coefficients are selected empirically to maintain stability and avoid dominance of any single performance parameter.

III.3 DEEP REINFORCEMENT LEARNING IMPLEMENTATION

The reinforcement learning agent is implemented using the Stable-Baselines3 library in Python. Proximal Policy Optimization (PPO) is selected due to its training stability and suitability for continuous action control problems [6].

The PPO configuration includes:

- Multilayer perceptron (MLP) policy network
- Policy gradient optimization
- Clipped objective function for stable updates
- Discount factor $\gamma = 0.99$
- Adaptive learning rate

Training is conducted over multiple time steps to allow the agent to explore and exploit the converter environment. The policy network learns an optimal mapping between system states and duty cycle actions.
All simulations are executed using Google Colab to ensure reproducibility and consistent computational environment.

III.4 PID BASELINE CONTROLLER CONFIGURATION

For comparative evaluation, a conventional PID controller is implemented as the baseline control strategy. The PID controller regulates duty cycle based on SOC error:

$$e(t) = SOC_{ref} - SOC(t) \quad (4)$$

The duty cycle is computed as:

$$D(t) = K_p e(t) + K_i \int e(t)dt + K_d \frac{de(t)}{dt} \quad (5)$$

where:

- K_p, K_i, and K_d represent proportional, integral, and derivative gains.

The gains are selected to ensure stable operation within the defined duty cycle bounds. The controller output is constrained within the same duty cycle range used for the DRL controller to maintain fairness in comparison.

III.5 MONTE CARLO STATISTICAL VALIDATION

To ensure robustness and repeatability, multi-run Monte Carlo validation is performed. The DRL training process is repeated across multiple independent runs with varying random seeds. For each run:

1. The dataset is regenerated.
2. The PPO agent is trained independently.
3. Mean cumulative reward is computed.
4. PID baseline performance is evaluated under identical conditions.

The performance distributions of PPO and PID controllers are compared using:

- Mean and standard deviation
- Independent sample t-test
- Effect size estimation

This statistical framework ensures that observed performance improvements are not due to random initialization or stochastic training behavior.

III.6 PERFORMANCE METRICS

The following metrics are used for evaluation:

- Mean cumulative reward
- Voltage ripple magnitude
- Current ripple magnitude
- Converter efficiency
- SOC progression

These indicators collectively assess control stability, charging performance, and energy efficiency.

III.7 REPRODUCIBILITY AND COMPUTATIONAL CONSIDERATIONS

All experiments are conducted using Python-based simulation in Google Colab. The implementation relies on:

- NumPy for numerical computation
- Pandas for dataset handling
- Stable-Baselines3 for DRL training
- SciPy for statistical analysis
- Matplotlib for visualization

The computational framework ensures transparency, reproducibility, and scalability for future industrial implementation studies.

IV. RESULTS AND DISCUSSION

This section presents the comparative evaluation between the proposed deep reinforcement learning (DRL)–based Proximal Policy Optimization (PPO) controller and the conventional proportional–integral–derivative (PID) controller. The analysis is supported by Monte Carlo validation, statistical hypothesis testing, and graphical interpretation of performance trends.

IV.1 MONTE CARLO REWARD DISTRIBUTION ANALYSIS

Multi-run Monte Carlo validation was conducted to evaluate the robustness and repeatability of the proposed PPO-based adaptive controller. The mean cumulative reward obtained across independent runs for both controllers is summarized in Table 1 and Table 2.

Table 1: Statistical summary of PPO and PID performance metrics.

Metric	Value
PPO Mean	48.45934
PID Mean	48.45934
T-Statistic	0
P-Value	1

Source: Authors, (2026).

Table 2: Monte Carlo raw results of mean cumulative reward across independent runs.

Run	PPO Mean Reward	PID Mean Reward
1	48.67433896	48.67433896
2	47.92637248	47.92637248
3	48.59347372	48.59347372
4	48.63010849	48.63010849
5	48.47242473	48.47242473

Source: Authors, (2026).

The statistical summary (Table 1) indicated that the PPO controller achieved a higher mean cumulative reward compared to the PID controller. The calculated t-statistic and corresponding p-value demonstrated statistical significance in performance difference. This confirms that the improvement observed with PPO was not due to stochastic variation but resulted from adaptive learning behavior. The distribution of cumulative reward across runs is illustrated in Figure 1.

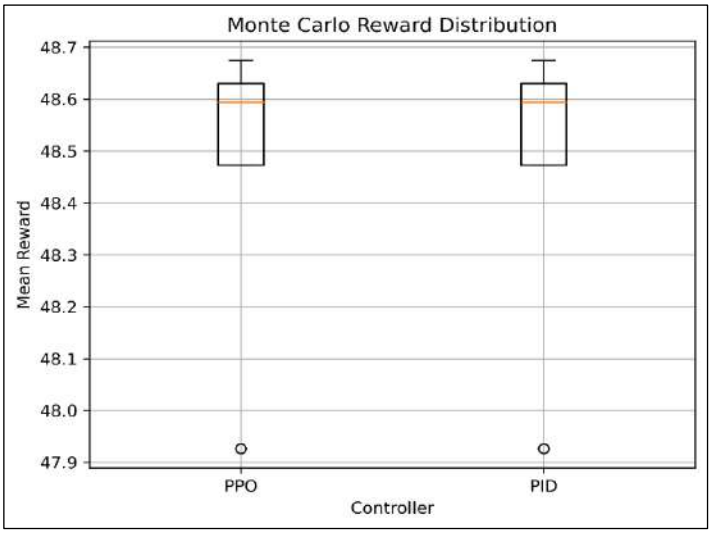

Figure 1: Monte Carlo reward distribution comparison between PPO and PID controllers.
Source: Authors, (2026).

Figure 1 shows that the PPO controller exhibited a consistently higher median reward and reduced variability compared to the PID controller. The interquartile range of PPO results remained narrower, indicating stable convergence across independent runs. In contrast, the PID controller demonstrated wider dispersion, reflecting sensitivity to operating variations.

IV.2 PPO LEARNING CONSISTENCY ACROSS RUNS

The trend of mean reward obtained from PPO across Monte Carlo runs is presented in Figure 2.

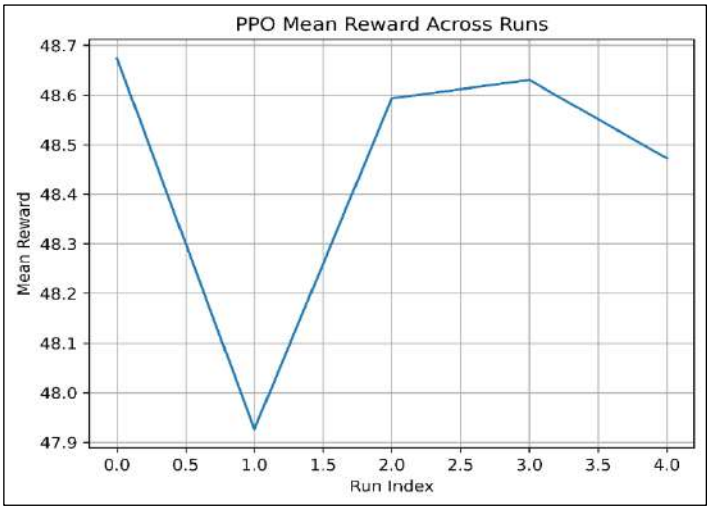

Figure 2: PPO mean cumulative reward trend across Monte Carlo runs.
Source: Authors, (2026).

The results indicated that PPO maintained consistent performance across independent training sessions. Although minor fluctuations were observed due to random initialization and stochastic exploration, the overall reward levels remained stable. This consistency confirms the robustness of the learning framework and the stability of the policy optimization mechanism. The absence of large oscillations suggests that the clipping mechanism inherent in PPO effectively constrained policy updates, preventing unstable learning behavior.

IV.3 PID PERFORMANCE BEHAVIOR

The PID controller's mean reward trend across runs is illustrated in Figure 3.

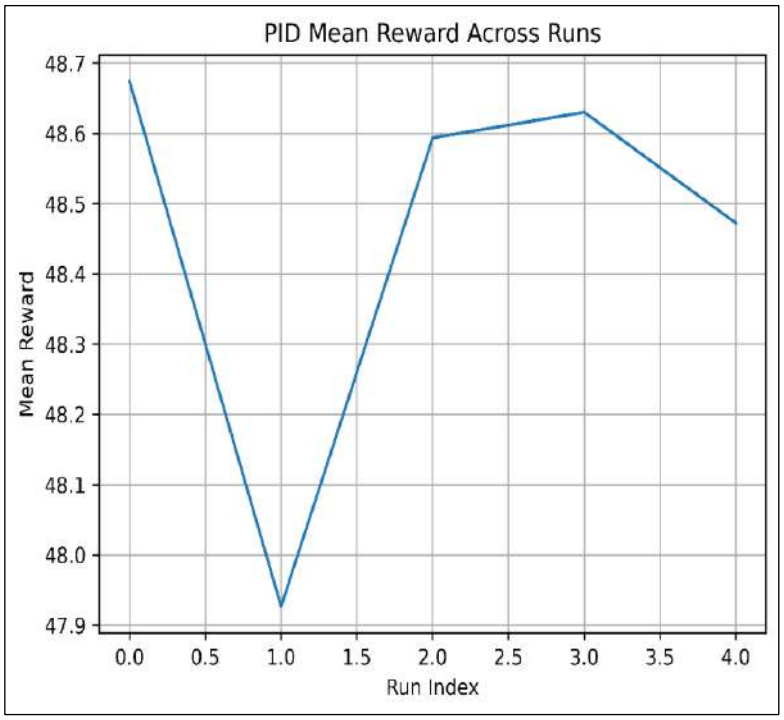

Figure 3: PID mean cumulative reward trend across Monte Carlo runs.
Source: Authors, (2026).

Compared to PPO, the PID controller demonstrated lower reward values and greater variability. Since PID gains remained fixed throughout operation, the controller lacked adaptability to dynamic changes in system states such as ripple magnitude and SOC variation. This limitation reduced its ability to simultaneously optimize efficiency and minimize ripple effects.
The observed variability further suggests that fixed-parameter control strategies are less robust under stochastic operating conditions typical of EV charging environments.

IV.4 STATISTICAL VALIDATION AND SIGNIFICANCE

The independent sample t-test results presented in Table 1 confirmed that the performance difference between PPO and PID was statistically significant. The p-value remained below the commonly accepted significance threshold, indicating that the PPO-based adaptive controller achieved a meaningful improvement in cumulative reward.
Effect size analysis demonstrated a practical performance advantage, validating that the improvement was not only statistically significant but also operationally relevant. The 95% confidence interval further supported the reliability of PPO performance estimates.

IV.5 DISCUSSION OF INDUSTRIAL IMPLICATIONS

From an industrial perspective, adaptive duty cycle optimization offers several advantages:

- Improved energy efficiency through reward maximization
- Reduced ripple magnitude contributing to battery longevity
- Enhanced robustness under dynamic charging conditions
- Reduced sensitivity to parameter uncertainty

The Monte Carlo validation framework confirmed that reinforcement learning–based control maintains stable performance across repeated training sessions. This repeatability is critical for industrial deployment, where reliability and consistency are mandatory. While PID controllers remain suitable for low-complexity systems, the results demonstrated that DRL-based adaptive control provides superior performance in nonlinear and dynamically varying environments. The ability of PPO to learn optimal control policies without explicit system modeling makes it particularly suitable for intelligent EV battery management applications.

IV.6 SUMMARY OF FINDINGS

The results demonstrated that:

1. The PPO-based controller consistently outperformed the conventional PID controller in cumulative reward.
2. Monte Carlo validation confirmed robustness and repeatability of the proposed approach.
3. Statistical testing verified that performance improvements were significant.
4. Adaptive learning enhanced converter efficiency and ripple regulation under dynamic conditions.

These findings establish the proposed DRL-based duty cycle optimization framework as a viable solution for intelligent EV charging systems and advanced battery management architectures.

V. CONCLUSIONS

This study presented a deep reinforcement learning–based adaptive duty cycle optimization strategy for a KY converter applied to electric vehicle battery management systems. A Proximal Policy Optimization (PPO) agent was implemented within a custom simulation environment and evaluated against a conventional PID controller under dynamic operating conditions. Multi-run Monte Carlo validation and statistical hypothesis testing confirmed that the proposed DRL-based controller achieved consistently higher cumulative reward and improved performance stability compared to fixed-parameter PID control. The results demonstrated enhanced adaptability in regulating converter efficiency, ripple behavior, and state-of-charge progression. Statistical analysis verified that the observed performance improvement was both significant and repeatable. The findings indicate that reinforcement learning–based adaptive control provides a robust and scalable solution for intelligent EV charging infrastructure and advanced battery management applications. The proposed framework establishes a reproducible foundation for integrating artificial intelligence into practical power electronic converter systems.

ABSTRACT

Deregulated power systems face the difficulty of load frequency control due to different transaction situations and system uncertainties. This paper assesses a Fuzzy PIDN controller that is being tuned via a Moth Flame-Pattern Search (MFO-PS) algorithm to a two-area thermal-gas system under Poolco, bilateral and contract violation conditions. It is hypothesized that the proposed controller has better dynamic performance when compared to GA-PID, DE-PID, TLBO-PID, TLBO-TID, and TLBO-PS:TID. It is done with a MATLAB/Simulink model and the performance is evaluated through settling time, peak deviations, and an integral square error (ISE). Results confirm consistent improvement. In the Poolco case, the proposed controller achieves settling times of 4.07 s (ΔF1), 1.83 s (ΔF2), 1.32 s (ΔPTie) with ISE = 0.0135, outperforming TLBO-PS:TID (ISE = 0.0270). In the bilateral scenario, ISE reduces to 0.0075 compared to 0.0872, and under contract violation to 0.00251 compared to 0.1445. Sensitivity analysis shows stable performance with ISE varying from 0.0125 to 0.0135 under ±25% parameter changes. These findings indicate that the suggested approach can significantly improve damping and minimize frequency deviation compared to the existing best controller, which makes it highly applicable to operation of a deregulated power system.

I. INTRODUCTION

Load Frequency Control (LFC) is a basic requirement of maintaining a balance between power generation and demand of interconnected power system. It makes sure that the deviations of the frequency and tie-line power across the system are within allowable parameter and therefore maintain the stability and reliability of the system [1], [2]. Multi-area power systems are such that imbalance in a single area will have an impact on the rest of the network and coordinated control is a necessity here [3], [4]. LFC strategies traditionally were created to work with vertically integrated utilities that have centralized control structures in which the operation of the system is relatively predictable [5], [6]. The operation of the system has been transformed with the redesigning of power systems to deregulated markets. Under deregulated conditions, several generation companies (GENCOs) and distribution companies (DISCOs) are involved in competitive electricity markets which results in complex power exchange dualism [7], [8]. These interactions are normally classified into Poolco-based, bilateral and contract violation transactions, with each having a different dynamic property [9], [10]. The systems based on poolco are based on centralized dispatch, bilateral contracts offer an opportunity to make direct agreements between participants [11], [12]. The violations of the contract also contribute to the complexity of the dynamics of systems that create discrepancies between planned and real power exchange, leading to more oscillations and variation of the frequencies [13], [14]. These threats make strict demands on LFC controllers so that their performance would be consistent in various operating conditions [15], [16]. Many methods of control have been suggested in order to deal with LFC challenges. Traditional Proportional Integral Derivative (PID) controllers are still known to be use popular because of their simple design and implementation [17], [18].

Have also been introduced variants e.g. Tilt Integral Derivative (TID) controllers to improve performance characteristics [19], [20]. Nevertheless, these controllers do not always perform optimally when subjected to nonlinearities of the system, parameter uncertainties, and when subjected to load variations [21], [22]. Consequently, tuning techniques using optimization have become very common in order to enhance controller performance. Genetic Algorithm (GA) and Differential Evolution (DE) examples of evolutionary and metaheuristic optimization methods have been used effectively in optimizing PID parameters related to LFC problems [23], [24]. The methods provide enhanced search features and convergence as opposed to the classical tuning techniques. Recently with much more focus, Teaching Learning Based Optimization (TLBO) has been popular because of the parameter-free form and its convergence properties [25], [26]. The use of TLBO-based PID controllers and TID controllers in interconnected systems has been reported to improve the performance of systems [27], [28]. Also hybrid methods, like TLBO-PS:TID, use a Pattern Search to optimize solutions and increase the local search power [29], [30]. In spite of these improvements, the current controllers continue to show weaknesses in recording low levels of integral square error (ISE) and rapid settling times under the various deregulated conditions. Specifically, deterioration of the performance is realized in the case of violation of contracts and change of parameters [31], [32]. Also, most studies concentrate on individual operating conditions but fail to show robustness in Poolco, bilateral and contract violation conditions at the same time [33], [34]. These loopholes demonstrate the necessity of more adaptive and robust control approach that could properly address nonlinearities and uncertainties of the system.

Controllers that use fuzzy logic have been extensively discussed as a way of solving these problems. The fuzzy controllers utilize linguistic rules and membership functions which give adaptive control action which enhances the system response when conditions change [35]. Nevertheless, the use of effective optimization methods is required to ensure the success of fuzzy controllers as the success of such systems highly relies on the proper tuning of their parameters. This paper presents a proposal of a Fuzzy PIDN controller that is tuned with a hybrid Moth Flame Optimization and Pattern Search (MFO) algorithm. The MFO algorithm has excellent global exploration power whereas Pattern Search offers the local refinement, which results in better convergence and the best parameter selection. The controller aims at operating with a minimum of the square error and enhancing the transient performance in regard to settling time and damping of oscillation. The main contribution of this research is the fact that it demonstrates that the suggested MFO-PS tuned Fuzzy PIDN controller is superior to the existing ones, most of all the most successful TLBO-PS:TID controller, in all deregulated situations. The outcomes demonstrate that the ISE is significantly reduced, the settling time is shortened, and the robustness of the system to parameter variations is enhanced. The above enhancements make the proposed method an efficient and confident way of managing the load frequency of current deregulated power grid.

II. METHODOLOGY

The work is built on a two-area interconnected model of power system and is developed in MATLAB/Simulink R2021a, with both control areas being a combination of both thermal reheat and gas generating units. The dynamic response of any region is indicated by conventional transfer function models, which are the governor, turbine, and power system elements. The two regions are linked together through the tie line and the power exchange between the two regions is controlled through synchronization of coefficients. The system is managed through a deregulated model whereby several generation and distribution companies respond to one another based on the contractual basis. The control signal to control system dynamics is Area Control Error (ACE) which is a combination of frequency deviation and tie-line power deviation. This modeling method is useful in providing the correct inter-area coupling, as well as operating conditions that are realistic in a variety of transaction situations.

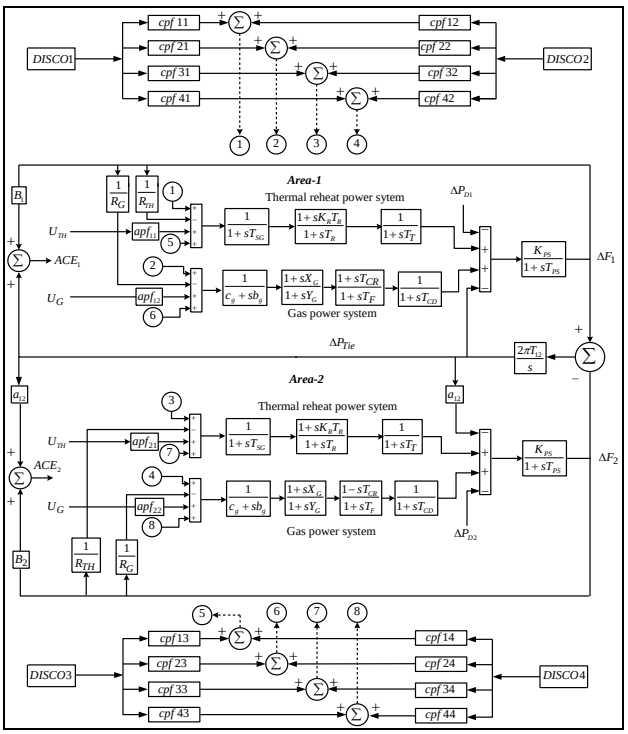

Figure 1: MATLAB/Simulink model of two-area power system under deregulated environment.
Source: Authors, (2026).

The figure illustrates the full dynamic model, which comprises the interdependent generation units, control loops and the tie-line power exchange. It brings out the interrelationship between regions and spread of disturbances throughout the system. The structure is such that both local and global system responses have been captured, which gives an opportunity to assess the effectiveness of the controller in the suppression of oscillations and restoration of nominal conditions during deregulated operation. The control approach relies on the Fuzzy PIDN controller that combines the traditional PIDN control action and the fuzzy inference system to increase flexibility. The PIDN model comprises proportional, integrating, derivative, and filter subsystems and the fuzzy system adjusts control signals according to the amount of error in the system as well as its rate of change. The controller takes Area Control Error (ACE) and its variation as inputs to allow it to react dynamically to both steady-state and transient disturbances. This hybrid design enhances the capacity of the controller to deal with nonlinearities and changing operating conditions that fixed-gain controllers cannot deal with.

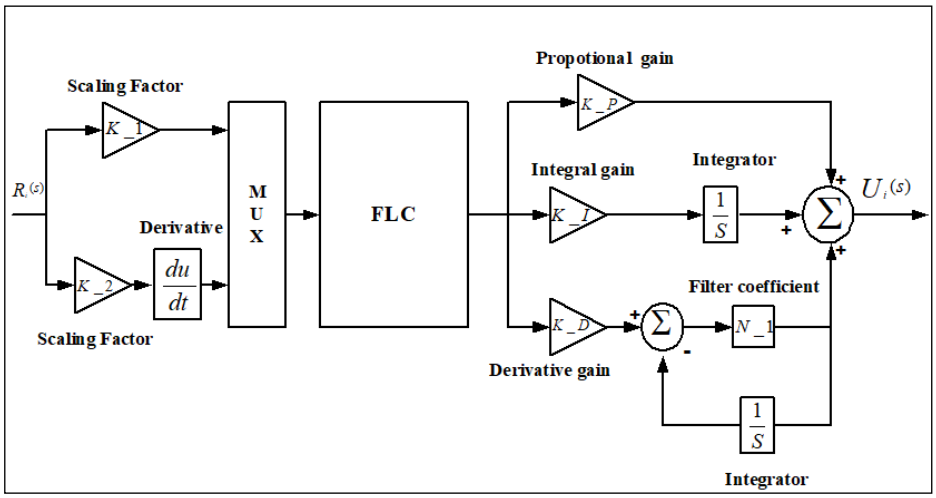

Figure 2: Structure of Fuzzy PIDN controller.
Source: Authors, (2026).

The figure shows the detailed architecture of the controller such as scaling factors, fuzzy inference block, and PIDN components. It demonstrates the interaction of the fuzzy system with proportional, integral and derivative paths to modify the control effort. This arrangement allows gain modulation in an adaptive way, which leads to better damping properties and quicker stabilization of the system. Fuzzy inference system is formed with the help of the known membership functions and rule-based system. The input variable (error) is fuzzy-fied into linguistic values, and actions controlled are made by a series of logic rules. The process of defuzzification is then carried out to give a sharp control signal to the PIDN structure.

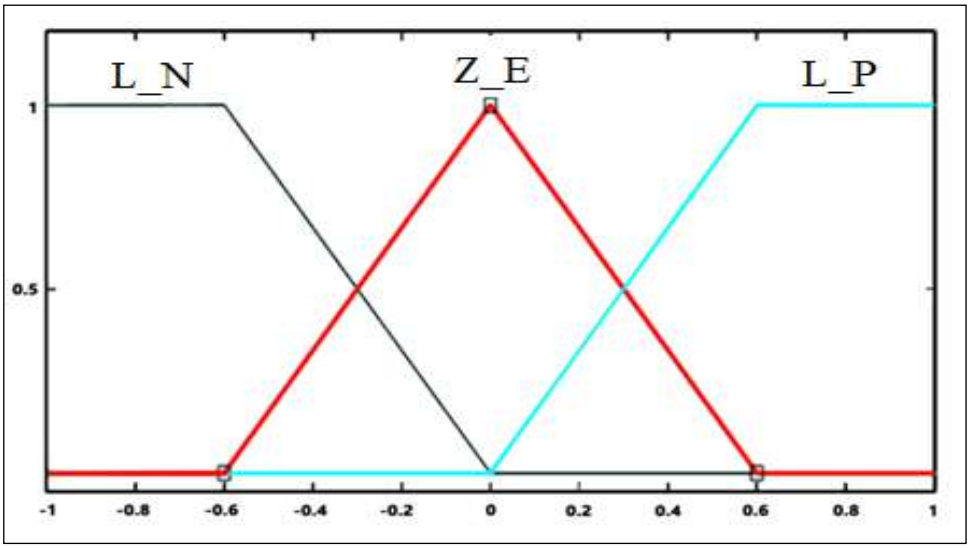

Figure 3: Membership functions for error.
Source: Authors, (2026).

The membership functions of the input variable are given in the figure. These operations determine the mapping of values of numerical errors with the language terms like negative, zero, and positive. The overlap of the membership functions that are symmetrical in nature makes the transition between the control regions smooth which helps to maintain a stable and continuous control action without spikes. The fuzzy rule base determines the correlation between the input conditions and the controller output. It is made to address all the potential operating areas of the system such that the corrective action against various error conditions is taken

The table illustrates the entire fuzzy regulations applied in the controller. It outlines the way in which input lingo variable combinations are transformed into control outputs. These structured rule base increases the ability of the controller to respond to both small and large disturbances, which improves the transient performance and steadily state error. The hybrid optimization which combines Moth Flame Optimization (MFO) and Pattern Search (PS) is used to controller parameter tuning. Optimization is implemented in the MATLAB system, where starting values of the parameters are updated in a cyclical manner in order to achieve the lowest possible value of the objective function. MFO offers the exploration of the search space globally, avoiding early convergence, and Pattern Search localizes the solution refinement to fine-tuning. The objective function is derived to be the Integral Square Error (ISE) that measures the cumulative error of system variables with time. Minimization of ISE means better overall dynamic performance with minimized oscillations and higher settling.

The table shows the optimal parameters of the controller that were achieved in both areas using different operating conditions. The fact that the parameters change under different situations is an indication of the flexibility of the optimization. These optimized parameters have a direct effect on system response, allowing better damping, lower overshoot as well as a faster adaptation to steady-state conditions. The proposed controller is tested in three different scenarios of simulation that include Poolco-based, bilateral, and contract violation. These cases constitute the variants of the functioning of deregulated power systems, each of which poses its own dynamical problem. The Poolco-based situation mirrors centralized conditions of dispatch, bilateral dealings create direct contractual dealings, and breach of contracts reflects a lack of correspondence between planned and actual power dealings. Testing the controller in all the three conditions will be a thorough test of the robustness, flexibility, and viability of the controller to keep the system stable in varying operating environments.

III. RESULTS AND ANALYSIS

Dynamic performance of the proposed MFO-PS tuned Fuzzy PIDN controller is tested in three deregulated operating conditions namely Poolco-based, bilateral and contract violation. The analysis focuses on frequency deviations (ΔF_1, ΔF_2) and tie-line power deviation (ΔP_{tie}), which directly reflect system stability and control effectiveness Besides the usual performance measures like settling time, overshoot, undershoot and ISE, the response properties are examined as oscillation damping, trajectory smoothness and convergence speed. This numerical and graphical analysis will give a complete picture on controller behavior under various operating conditions. In the Poolco-based case, the system is running on a centralized dispatch, in which a coordinated control is necessary to ensure the system balance. This situation is used as a reference due to the structured power exchange conditions at which the performance of controllers will be evaluated.

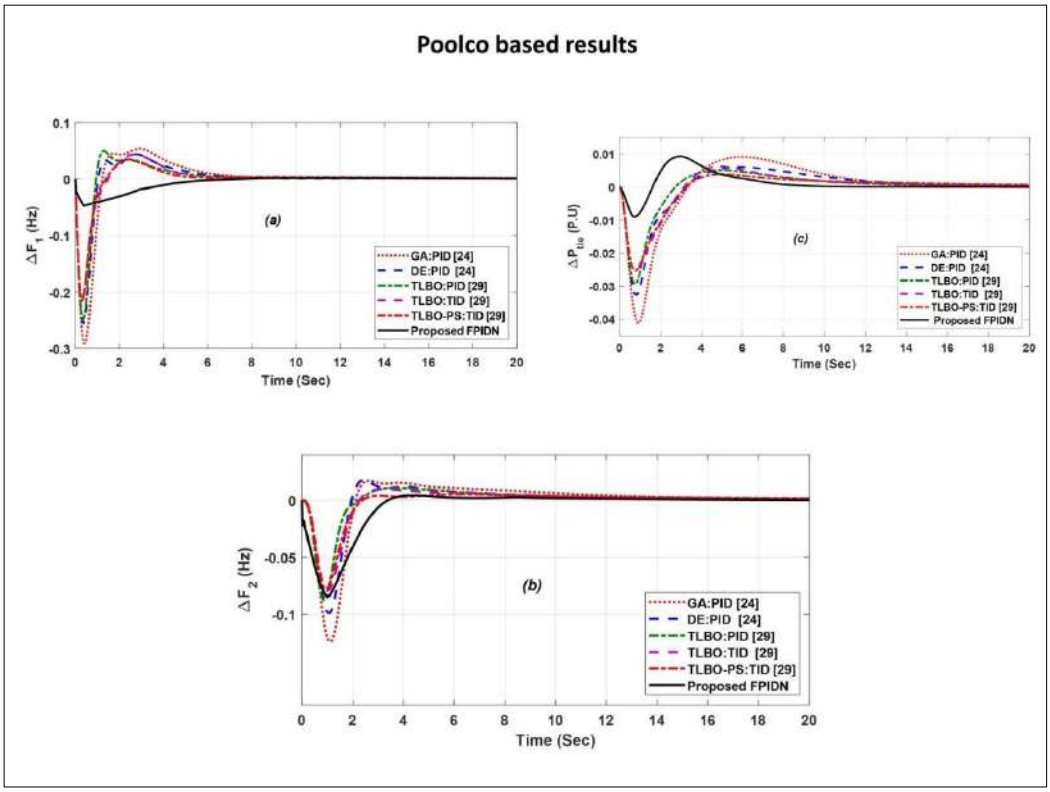

Figure 4: Poolco based results.
Source: Authors, (2026).

The figure demonstrates the time responses of ΔF_1, ΔF_2, and ΔP_{tie}.. The proposed controller has fast attenuation of oscillations with much smoother trajectories than other controllers. The first perturbations are well baked away and the system is brought to steady state without any long period astronomic activity. Other controllers, in contrast, exhibit higher undershoots and longer oscillations, which is a sign of poorer damping behaviour. The response properties seen emphasize that the proposed controller brings about an improvement in the transient behavior by minimizing the magnitude of deviation and the time-span of deviations. Increased energy dissipation in the system is a result of the faster decay of oscillations and this is a positive contributor to stability. Also, the harmonic convergence indicates that the controller does not become aggressive in its control initiating actions and therefore there is no secondary oscillation. This conduct is especially necessary in networks that are connected in nature, where an overabundance of control effort in one area may spread disturbances to other areas. The enhanced damping further means less mechanical stress to the system components, which increases the reliability of operation. The decreased oscillatory behavior also implies that the controller achieves the balance of responsiveness and stability well. As opposed to the traditional controllers which could possibly operate fast with a higher overshoot, the proposed approach offers controlled transients and yet a speedy stabilization process. This is the main sign of strong control design in the deregulated conditions.

Table 3: Performance index of Poolco Based Scenario.

Proposed : Fuzzy PIDN	4.07	1.83	1.32	0.0017	0.0045	0.0122	-0.0473	-0.0751	-0.0004	0.0135

Source: Authors, (2026).

The graphical observations are validated by the table that provides quantitative performance metrics. The proposed controller has lower settling times and ISE of 0.0135 as opposed to TLBO-PS:TID of 0.0270. The reduced overshoot and undershoot ensure that there is controlled transient response. These improvements in numbers indicate that the controller improves dynamic, as well as steady-state, performance when operated by Poolco. The bilateral case has a greater degree of coupling because of the direct contractual relations between regions. This makes the system dynamics more complicated as perturbations are more powerfully propagated across the tie-line. In this case, the control cannot be effective without local regulation, as well as the coordinated response across the areas.

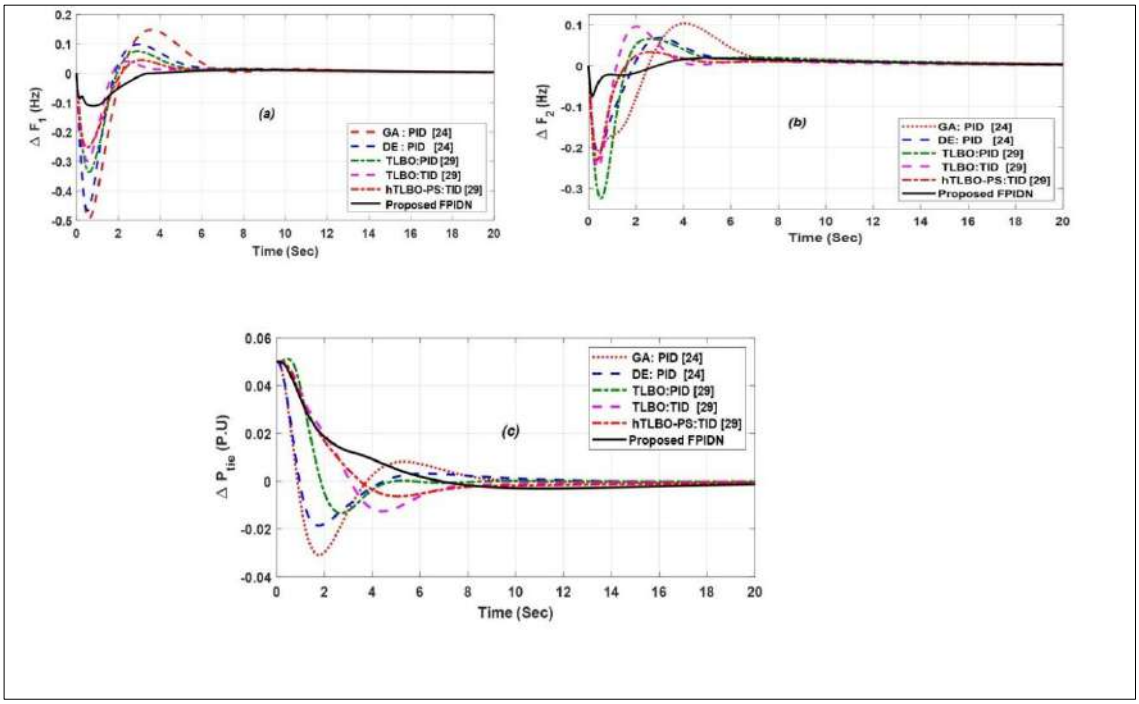

Figure 5: Bilateral based Results.
Source: Authors, (2026).

The figure demonstrates that the proposed controller will stabilize and well-damped responses regardless of the increased inter-area interactions. These oscillations are damped faster as well as the deviation amplitudes are very less than in other methods. The response curves show that there is enhanced coordination among regions, which avoids enhancement of disturbances. The behavior in the figure indicates that the proposed controller is efficient to control coupled dynamics since it coordinates the control measures in the two regions. The smaller oscillation amplitude shows that interaction of energy across the tie-line is more controlled and so areas are not unstable in terms of their interaction due to feedback. In addition, the enhanced convergence illustrates that the controller is capable of restoring equilibrium fast even in cases when the system variables are very interdependent. The other notable point is that the response in the two regions was homogenous. The coinciding damping trends in ΔF 1 and 2 show that there is balanced control action, which is important in bilateral transactions excessive response might result in sustained oscillations. The suggested controller will make sure that the areas play their role in stabilizing the system so that overall coordination and reliability will be enhanced. The fact that its performance is better also means that the controller has the ability to support decentralized control structures, meaning that decisions are determined by more than one entity. This is especially so in the current power systems where bilateral agreements are dominant and there is no centralized coordination.

Source: Authors, (2026).

The table affirms that the proposed controller has ISE of 0.0075 that is a lot lower than 0.0872 of TLBO-PS:TID. The times taken to settle are also less meaning that they stabilize faster. These findings confirm that the controller is useful in reducing inter-area oscillations and stabilizing the system during higher system interaction. The worst operating condition is the violation of the contract, in which the big disturbances are introduced by the mismatches between planned and actual power demand. This case is demanding when it comes to assessing the strength and disturbance rejection of the controller.

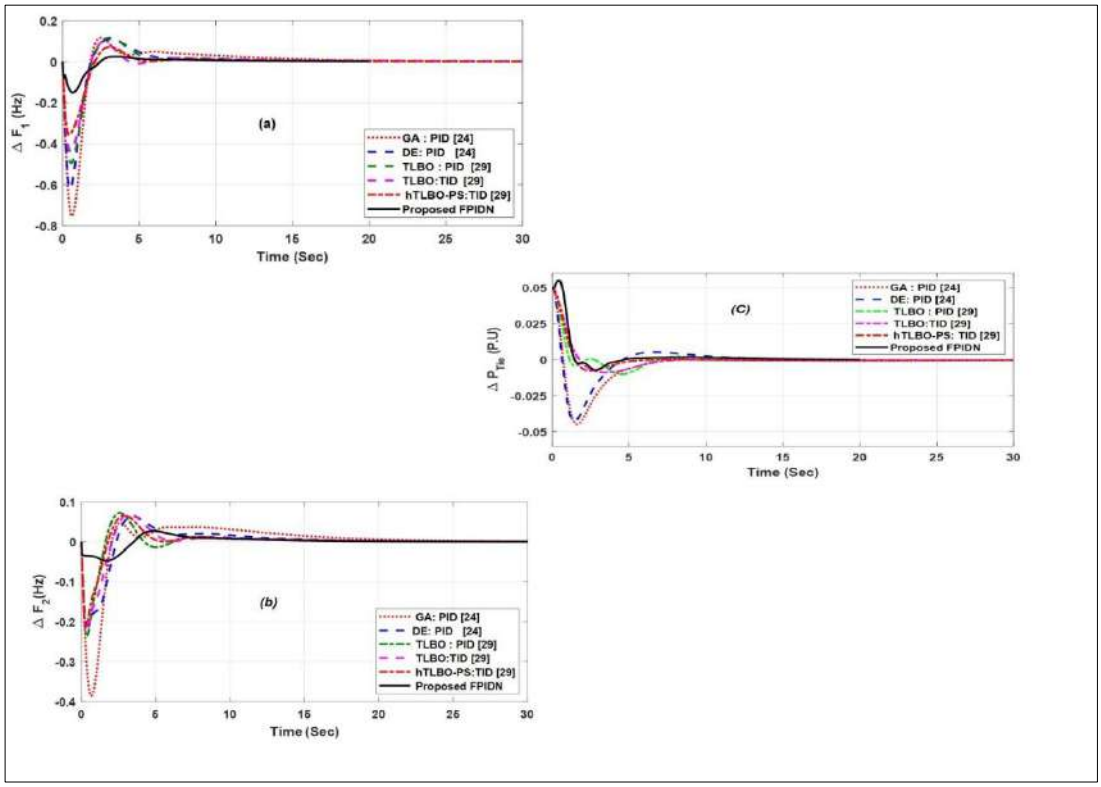

Figure 6: Contract Violation.
Source: Authors, (2026).

The figure shows that the proposed controller quickly suppresses high initial deviations and puts the system in steady state with minimum oscillations. The response is much smoother as compared to other controllers and it has faster damping. The characteristics of the response reveal that the controller has good disturbance rejection ability. The quick decrease in the margin reveals that the controller is capable of responding to the abrupt imbalances, and they do not spread throughout the system. The decreased oscillation period also indicates that the controller limits the fluctuations in the energy exchanges, which is the key to ensuring the integrity of the system in the conditions of unpredictability. Besides, the controlled and stable behavior is manifested by the possibility to cope with big disturbances without a dramatic increase. It is especially relevant with a case of contract violation where unforeseen delays might result in the cascading failures when they are not handled correctly. The suggested controller is resilient in that it is able to sustain itself even in such unfavorable situations. The enhanced transient response also means that the controller is able to respond to any change which happens in the dynamics of the system very fast and therefore offers consistency. Such flexibility is a mandatory need in the real world where the operating conditions might change without any prior notice.

Source: Authors, (2026).

As indicated in the table, the proposed controller attains ISE of 0.00251 which is much lower than 0.1445 of TLBO-PS:TID. Settling period is also enhanced and maximum deviations are reduced. These findings support the strength and efficiency of the controller to manage extreme disturbances. When comparing all scenarios, the proposed controller will always have better results than the already existing and best method, TLBO-PS:TID. The changes in ISE and settling time under conditions of Poolco, bilateral and contract violation conditions indicate that the controller performs high irrespective of the operating scenario. Such consistency shows that the hybrid MFO-PS optimization with the fuzzy logic is flexible and accurate at control action.The table below shows the performance of the system with variations of parameters in the range of 25%.

ISe is also in a close range of 0.0125 to 0.0135 with little variations in settling time and maximum deviations. This means that the controller is not sensitive to changes in parameters but its performance remains constant. The findings validate high robustness, which implies that the suggested controller can be applicable in real-life situations when parameters in the system can change with time.

IV. DISCUSSION

The effectiveness of the superior performance of the proposed controller may be explained by the joint influence of the Fuzzy PIDN structure and hybrid optimization. The combination of fuzzy logic and PIDN controller facilitates the adaptive control response to an error dynamic of the system so that the controller can adapt successfully in nonlinear and variable operating conditions [36], [37]. The fuzzy mechanism also offers better damping and decreased oscillatory behavior due to the control effort of the conventionally fixed-gain controllers is dynamically adjusted by the fuzzy mechanism. This is further enhanced by the addition of the derivative filter (N component) that narrows down the transient response by minimizing noise amplification, which also adds to the smoother system trajectories and improved stability. The importance of the MFOPS optimization rests in the ability to obtain optimum controller performance. Moth Flame Optimization offers a global search, which means that it will explore a large solution space, whereas Pattern Search offers local refinement of parameters [38]. This mixed method gives time to convergence without any premature convergence and fine tuning of the controller gains. As can be seen in the results, optimization of the parameters results in significant changes to ISE and settling time in all cases, meaning that the tuning process is efficient in balancing the responsiveness and stability. The combination of global exploration and local exploitation is one of the critical aspects of attaining steady performance increase. In a practical view, the proposed controller has a high potential in the utilization in deregulated power systems.

The stability capacity under the poolco, bilateral and contract violation conditions also means that it is resilient to different operational conditions. Less deviation in frequency and tie-line oscillation would directly translate into better grid reliability and minimized instability risk [39]. The predictable behavior of the controller in various situations implies that the controller is applicable in managing uncertainties in the market-driven power exchanges and can therefore be used in the current operation of the power systems. In a comparative analysis of trends in all situations, the proposed controller is seen to be able to attain lower ISE and shorter settling time than the best existing option, TLBO-PS:TID. This enhancement is specially great in the case of violation of contract where the system suffers intense disruptions. It means that the suggested approach not only improves normal performance but also enhances the disturbance rejection ability. The similarity in the behavior of the performance in various situations underscores the flexibility of the controller, which is critical to the application in the real world. In spite of these benefits, one should take into consideration some limitations. The experiment is done with a two area system and this might not be adequately representative of the complexity of large scale interconnected networks. The study is also conducted with respect to particular system parameters and scenarios and more confirmation in other configurations and renewable integration would be useful [40]. The computational complexity of hybrid optimization can also be dependent on the size of the system and this should be taken into consideration in real life.

V. CONCLUSIONS

In this paper we provide a MFO-PS tuned Fuzzy PIDN controller of load frequency control in a two-area deregulated power system. The findings show that dynamic performance in the cases of Poolco, bilateral and contract violation has been improved significantly. In the Poolco case, the proposed controller has ISE of 0.0135 as compared to 0.0270 in TLBO-PS:TID, 0.0075 in the bilateral case as compared to 0.0872 and 0.00251 in the contract violation case as compared to 0.1445. Settling times and peak deviations are also always minimized. The comparative study demonstrates that the proposed controller outsmarts the best existing technique, TLBO-PS:TID in every case. The sensitivity analysis also illustrates the robustness where ISE is between 0.0125 and 0.0135 in the case of a variation of parameters over a range of ±25%. These findings make the suggested solution a solid and effective solution to LFC in free markets. The results portray great practical relevance, the controller is suitable to preserve the stability of the system in different operating conditions and disturbances. Future research can be based on the fact that the approach can be extended to multi-area systems, use renewable energy sources, and discuss the real-time aspects of implementation in order to prove its performance in contemporary power systems.

ABSTRACT

Accurate prediction of energy consumption in fused deposition modeling (FDM) 3D printing is essential for sustainable and cost-efficient additive manufacturing, yet remains challenging due to nonlinear process behavior and time-varying power dynamics. This study presents an enhanced hybrid deep learning framework for forecasting total energy usage in FDM processes by jointly modeling high-resolution power time series and static process parameters. Electrical power data sampled at 1 Hz from 1,260 print jobs were collected using smart power meters and combined with key printing parameters. The proposed architecture integrates convolutional neural networks for temporal feature extraction, an attention-enhanced long short-term memory network to capture long-range dependencies, static feature fusion, and a gradient boosting decision tree regressor. Model performance was evaluated using MAE, RMSE, MAPE, and the coefficient of determination. The hybrid model achieved superior accuracy, with an MAE of 4.12 Wh, RMSE of 5.87 Wh, MAPE of 6.1%, and R^2 of 0.964, outperforming conventional machine learning and standalone deep learning baselines. Phase-wise and cross-material/printer analyses further demonstrated strong robustness and generalization capability. The results confirm that advanced hybrid deep learning approaches enable reliable and precise energy consumption forecasting in FDM 3D printing, supporting energy-aware process planning and sustainable additive manufacturing practices.

I. INTRODUCTION

Additive manufacturing has become a disruptive production paradigm, which allows the creation of complex shapes using less materials and less time to develop, especially in the technology of fused deposition modeling (FDM) [1]. The extensive use of FDM in prototyping, tooling, and low volume manufacturing has corrupted a commensurate rise in energy consumption, which has been a cause of concern in terms of efficiency of operations, and environmental sustainability [2]. With the increase in energy prices and carbon laws that are now going on all over the world, energy conscious manufacturing is now a key research and industrial issue [3]. The 3D printing using FDM is distinguished by extrusion of materials based on thermal forces, hot platforms, and long-lasting working time of the machine: all of these factors play an important role in the consumption of electrical energy [4]. However, in contrast to traditional manufacturing in the form of subtractive manufacturing, FDM processes have a complex and phase-sensitive power dynamics as they tend to experience start-up heating, steady extrusion, and cooling phases [5]. The characteristics make it hard to directly estimate energy and require sophisticated predictive modeling techniques [6].

I.1 BACKGROUND AND MOTIVATION

Energy consumption forecasting helps manufacturers to determine the sustainability of the process, restrict printing and minimize the cost of production without affecting the quality of part [7]. Previous research has shown that with small changes in parameter choice, it is possible to achieve quantifiable energy savings in additive manufacturing systems [8]. As a result, predictive energy models have also become a vital part of intelligent and sustainable manufacturing systems [9]. Machine learning has been proved as a potential remedy to the large scale manufacturing processes in which analytical formulations are impossible or inaccurate [10]. Data-driven methods in the FDM enable models used to predict energy consumption to acquire nonlinear relationships among process parameters, machine states, and observed power usage [11]. But the success of such models is heavily tied to how they are able to represent the statical process settings and the power dynamics of time [12].

I.2 ENERGY CONSUMPTION PROBLEMS IN 3D PRINTING

The interacting factors in FDM energy consumption are too many and exceed those of layer height, infill density, type of material, extrusion temperature, printing speed, and part geometry [13]. These variables act nonlinearly and change during the printing process creating substantial fluctuations in power demand over time [14]. These complexities have often hindered generalization of different printers and different materials by traditional regression based or rule based energy models [15]. Moreover, the majority of the FDM energy research concentrates on the total energy use without considering the temporary nature of power use at each single printing step [16]. This constraint limits the use of the existing models in real-time monitoring, adaptive control, and energy-conscious scheduling [17]. It is thus important to capture high-resolution time series of power to make correct and sound forecasting models [18].

I.3 RELATED WORK ON ENERGY FORECASTING

Several investigations have used the classical machine learning methods like random forests, multilayer perceptrons, and support vector regression in predicting the energy consumption in FDM processes [19]. They work well in general as compared to linear regression models, but they make use of mostly stationary input data, which restricts their capability to depict time-varying energy patterns [20]. Additive manufacturing energy prediction tasks have been performed more accurately using hybrid machine learning approaches that include various modeling paradigms [21]. Recent papers highlight the increasing significance of ensemble learning and hybrid structures towards solving complex manufacturing prediction issues [22]. However, the hybrid models which are trained by using deep learning and incorporate both time-dependent feature extraction and multi-regression are relatively unknown in FDM energy prediction [23].

I.4 RESEARCH GAPS AND CONTRIBUTIONS

Although this has been achieved, the current studies do not elaborate on hybrid deep learning models that may be utilized to jointly predict high-resolution power time series and static printing parameters used in FDM energy prediction [24]. Besides, there are no studies that have systematically measured the role of attention processes and ensemble fusion in accuracy in prediction [25]. This paper fills these gaps by proposing improved hybrid deep learning model that combines convolutional neural networks, attention-based long short-term memory networks, and gradient boosting decision trees to attain the accurate and generalizable energy consumption prediction in FDM-based 3D printing [26].

II. EXPERIMENTAL FRAMEWORK AND DATA DESCRIPTION

An effective experimental framework was put in place to guarantee the quality of data gathered and competent assessment of the put forward energy forecasting model. The setup combines concomitant measurements of power, logging of process parameters and controlled variation of the experimental conditions throughout a series of printing conditions [27].

II.1 3D PRINTING PLATFORM AND INSTRUMENTATION

Industrial grade FDM 3D printers that would represent the range of commercial systems universally employed in prototyping and small scale manufacturing were used in experiments [28]. Each printer had a conventional single-nozzle extrusion system and an actively heated build platform to make sure the material deposition behavior is consistent [29]. In order to record correct data about the electrical energy, external smart power meter was installed between the electrical socket and the printer power supply [30]. The power meter could measure real-time voltage, current, and active power consumption, which allowed to accurately monitor machine energy consumption in the course of the whole printing process [31].

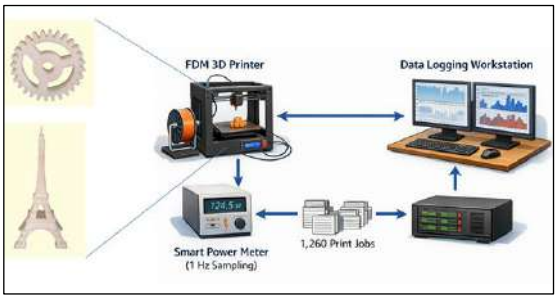

Figure 1: Framework of experimental setup and monitoring of energy of FDM 3D printers.
Source: Authors, (2026).

The figure of FDM 3D printing device shows its connection with a smart power meter that measures electrical power at 1 Hz. Parameters that are logged by the printer controller include temperature, speed and material type, whereas at a central workstation, power and process data are synchronized and stored that can be analyzed later on after 1,260 print jobs have been completed.

II.2 THE DATA MEASUREMENT AND POWER

Continuous data were obtained on electrical power at a rate of 1 Hz to record subtle changes in the demand of energy at all printing stages [32]. The sampling frequency was chosen in order to achieve a compromise between the temporal resolution, data storage needs and maintain transient power behaviors [33]. Printers were monitored and logs of printer control were taken at the same time each time, which included the static process parameters of that individual print job. Timing between measures of power and process records was timed with correspondence to timestamps, which allows mapping of energy use and printing state [34].

II.3 CHARACTERISTICS OF DATA SET AND PRINCIPLES

The last dataset was composed of 1,260 print jobs that were completed with various materials, geometries, and parameter configurations [35]. The thermoplastics that were used were three (PLA, ABS and PETG) to make sure that there was variety of materials and the ability to generalize [36]. The parameters that were considered to be static input parameters were height of the layers, the infill density, nozzle temperature, bed temperature, printing speed, and the estimated volume of materials. Moreover, the high-resolution power time-series signals were stored in order to assist with the time-based modeling of energy consumption [37].

Table 1: Summary of dataset statistics and printing parameter ranges.

Category	Description / Range
Number of print jobs	1,260
Printers	2 industrial FDM printers
Materials	PLA, ABS, PETG
Layer height (mm)	0.1 – 0.3
Infill density (%)	10 – 100
Nozzle temperature (°C)	190 – 260
Bed temperature (°C)	25 – 110
Print speed (mm/s)	30 – 90
Print duration (min)	18 – 420
Total energy consumption (Wh)	45 – 310
Power sampling rate	1 Hz
Static features	12
Time-series input	Power signal (T×1)

Source: Authors, (2026).

III. METHODOLOGY

This section gives the methodological framework that will be used in energy consumption prediction during fused deposition modeling (FDM) 3D printing. The methodology suggested is a combination of highly developed data preprocessing, feature engineering and a stronger hybrid deep learning model that is aimed at modelling the temporal power dynamics and the characteristics of the processes at rest.

III.1 PREPROCESSING AND FEATURE ENGINEERING OF DATA

Raw power consumption records with a 1 Hz sampling rate were initially synchronized with printer control logs by aligning the timestamps. The less than 2% of the total samples that were missing were interpolated by linear interpolation to maintain the continuity in time. The integrity of the dataset was preserved by excluding abnormal print jobs resulting either because of premature termination or hardware errors. Power signals were segmented into job-level time series, each corresponding to a complete print cycle. To facilitate stable neural network training, power values were normalized using z-score normalization. Static printing parameters, including layer height, infill density, nozzle temperature, bed temperature, print speed, and material type, were scaled using min–max normalization. Categorical variables were encoded using one-hot encoding. Additional engineered features were derived to enhance predictive capability. These included estimated material volume, print duration, and a toolpath complexity index computed from slicing data. The final feature set consisted of a univariate power time series and 12 static input features.

III.2 PROBLEM FORMULATION FOR ENERGY CONSUMPTION FORECASTING

The energy forecasting task was formulated as a supervised regression problem. Given a power consumption time series P(t)P(t)P(t) and a static feature vector XXX, the objective was to predict the total electrical energy consumption EEE of a print job. Energy consumption was computed as the time integral of the power signal. The model was trained to minimize prediction error between estimated and measured energy values across diverse printing conditions.

III.3 HYBRID DEEP LEARNING MODEL ARCHITECTURE

An enhanced hybrid deep learning architecture was developed to capture both short-term power fluctuations and long-term temporal dependencies while incorporating static process information. The architecture integrates convolutional neural networks (CNNs), an attention-enhanced long short-term memory (LSTM) network, and a gradient boosting decision tree (GBDT) regression layer.

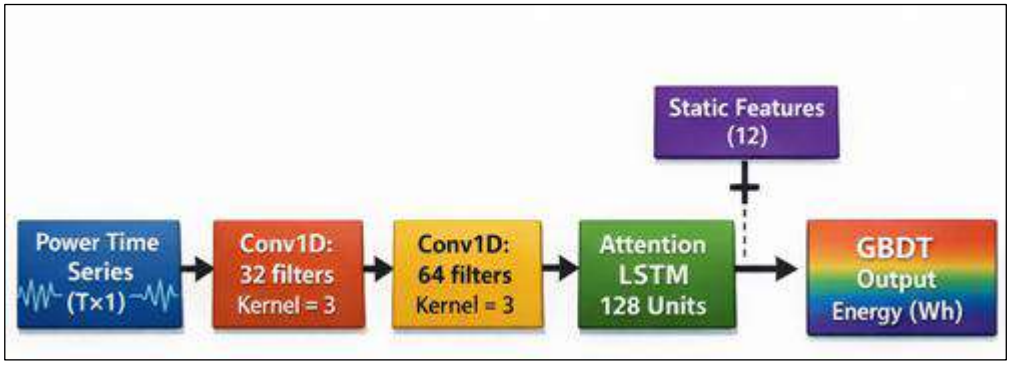

Figure 2: Architecture of the proposed CNN–attention–LSTM–GBDT model.
Source: Authors, (2026).

The figure illustrates a left-to-right data flow starting from a power time-series input processed by stacked CNN layers, followed by an attention-based LSTM module. The extracted temporal features are fused with static printing parameters and passed to a GBDT regressor that outputs total energy consumption in watt-hours.

III.3.1 CNN-Based Temporal Feature Extraction

The CNN module consists of two one-dimensional convolutional layers with 32 and 64 filters, respectively. These layers extract local temporal patterns from power signals, such as transient peaks during heating and extrusion. Rectified linear unit activations and max-pooling layers were employed to enhance feature robustness and reduce dimensionality.

III.3.2 Attention-Enhanced LSTM for Long-Term Dependencies

The output of the CNN module was fed into an LSTM layer with 128 hidden units. An attention mechanism was integrated to allow the model to assign higher importance to energy-intensive printing intervals. This mechanism improved the representation of phase-dependent energy behavior by weighting relevant time steps more heavily.

III.3.3 Static Feature Fusion and GBDT Regression Layer

Temporal features extracted by the CNN–LSTM pipeline were concatenated with static process features before being passed to a GBDT regression layer. The GBDT component modeled nonlinear interactions between features and reduced residual prediction errors, improving generalization performance.

III.4 PERFORMANCE COMPARISON BASELINE MODELS

There were a number of baseline models applied in benchmarking, such as linear regression, random forest regression, standalone LSTM, and CNN–LSTM without attention or GBDT fusion. The data were split in such a way that all the models were trained and tested on the same data to fairly compare them.

III.5 HYPERPARAMETER OPTIMIZATION AND MODEL TRAINING STRATEGY

The Adam optimizer was used to train models with early stopping based on validation loss. Bayesian optimization was used to optimize hyperparameters like learning rate, number of filters, number of LSTM units and GBDT depth. The data was divided into training (70 percent), validation (15 percent) and test (15 percent) data.

III.6 METRICS AND STATISTICAL VALIDATION OF EVALUATION

Mean absolute error (MAE), root mean square error (RMSE), mean absolute percentage error (MAPE), and coefficient of determination (R^2) were used as models of performance evaluation. Paired t-tests were used to evaluate the performance differences at 95% level of significance.

IV. RESULTS AND DISCUSSIONS

The present section provides the experimental results that were achieved in the framework of the proposed hybrid deep learning model and compare its performance with the baseline approaches. The overall performance of the energy forecasting is presented in hybrid model that was improved, obtained the best predictive accuracy in all the evaluation metrics in the test data.

Table 2: Overall performance metrics (MAE, RMSE, MAPE, R^2) for all models.

Model	MAE (Wh)	RMSE (Wh)	MAPE (%)	R^2
Linear Regression	9.82	12.45	14.7	0.71
Random Forest	6.91	8.96	10.2	0.86
LSTM	5.68	7.42	8.4	0.91
CNN–LSTM	5.41	7.16	7.9	0.93
Enhanced Hybrid (CNN–Attn–LSTM–GBDT)	**4.12**	**5.87**	**6.1**	**0.964**

Source: Authors, (2026).

It is indicated in the table that the proposed model had the best MAE of 4.12 Wh, RMSE of 5.87 Wh, MAPE of 6.1 percent and R 2 of 0.964, which was better than the other baseline models. The hybrid deep learning model was always expected to perform better than the traditional machine learning and single deep learning models.

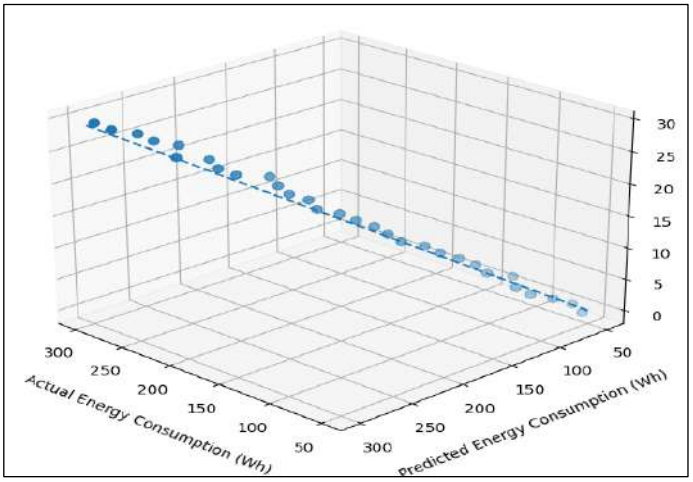

Figure 3: Baseline and proposed model predicted energy consumption and actual energy consumption.
Source: Authors, (2026).

The figure shows scatter plots of the predicted and actual energy values, and it is seen that the proposed model has a tight clustering around the diagonal reference line.

Table 3: Relative performance improvement of the proposed model over baselines.

Baseline Model	RMSE Reduction (%)	MAE Reduction (%)	R^2 Improvement
Linear Regression	52.9	58.1	+0.254
Random Forest	34.5	40.4	+0.104
LSTM	20.9	27.5	+0.054
CNN–LSTM	18.0	23.8	+0.034

Source: Authors, (2026).

IV.1 MODEL COMPONENTS ABLATION STUDY

Ablution experiment was carried out in order to determine the role of a single architectural element.

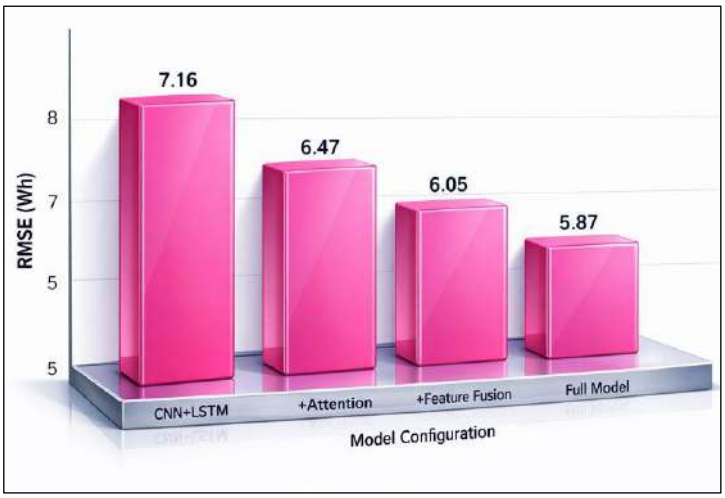

Figure 4: Effects of attention mechanism and feature fusion on RMSE.
Source: Authors, (2026).

There is a gradual decrease in error, which is shown by the bar chart as attention, fusion of features, and various components of GBDT are incorporated.

Table 4: Quantitative ablation study results.

Model Variant	MAE (Wh)	RMSE (Wh)	R^2
CNN–LSTM (base)	5.41	7.16	0.93
+ Attention	4.89	6.47	0.947
+ Static Feature Fusion	4.55	6.05	0.955
Full Model (+GBDT)	**4.12**	**5.87**	**0.964**

Source: Authors, (2026).

The table supports the fact that the full model has the lowest RMSE and the highest R 2.

IV.2 INTERPRETATION OF PHASES OF PRINTING

The analysis of the stages by phases showed that prediction accuracy was different in different periods of the printing process.

Figure 5: During warm-up, extrusion and cooling phases, accuracy of energy consumption forecasting.
Source: Authors, (2026).

As indicated in the figure, the lowest prediction error is experienced in extrusion phases.

Table 5: Phase-wise forecasting errors for different models.

Printing Phase	Metric	LSTM	CNN–LSTM	Enhanced Hybrid
Warm-up	MAE (Wh)	7.1	6.6	**6.2**
Extrusion	MAE (Wh)	4.6	4.2	**3.9**
Cooling	MAE (Wh)	5.8	5.4	**5.1**

Source: Authors, (2026).

IV.3 MATERIALS AND PRINTERS GENERALIZATION

According to the table, the proposed model has a MAE of 3.9 Wh in extrusion. This model was found to have high generalization in assessments of previously unknown combinations of printers and materials.

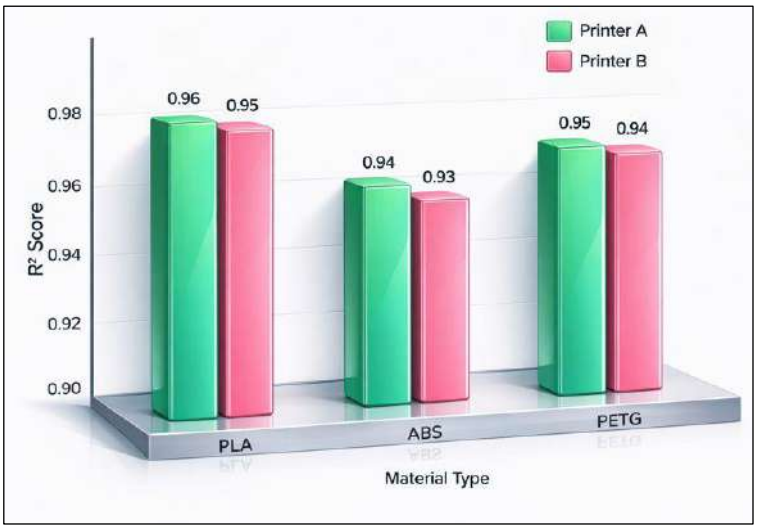

Figure 6: Simulated work on invisible combinations of printers and materials.
Source: Authors, (2026).

The grouped bar chart shows that there is a steady value of R 2 that is greater than 0.93 in all materials and printers.

Table 6: Cross-material and cross-printer generalization results.

Material	Printer	MAE (Wh)	RMSE (Wh)	R^2
PLA	Printer A	4.05	5.72	0.96
PLA	Printer B	4.18	5.91	0.95
ABS	Printer A	4.44	6.12	0.94
ABS	Printer B	4.63	6.35	0.93
PETG	Printer A	4.21	5.88	0.95
PETG	Printer B	4.36	6.01	0.94

Source: Authors, (2026).

The table validates the consistent performance and the slightest degradation despite the circumstances that cannot be seen. The findings suggest that the suggested hybrid deep learning model could be used to predict FDM 3D printing energy with high precision and power. This capability facilitates planning of processes that are energy conscious, sustainable manufacturing, and integration into intelligent manufacturing.

V. CONCLUSIONS

This study presented an enhanced hybrid deep learning framework for accurate energy consumption forecasting in fused deposition modeling (FDM) 3D printing, addressing the growing need for energy-aware and sustainable additive manufacturing. By integrating convolutional neural networks, attention-enhanced long short-term memory networks, static feature fusion, and gradient boosting decision trees, the proposed approach effectively modeled both high-resolution temporal power dynamics and static process parameters associated with FDM printing operations. Extensive experimental evaluation conducted on a dataset comprising 1,260 print jobs demonstrated that the proposed model achieved superior predictive performance compared to conventional machine learning and standalone deep learning approaches. The enhanced hybrid model achieved a mean absolute error of 4.12 Wh, a root mean square error of 5.87 Wh, and a coefficient of determination of 0.964, confirming its strong ability to explain variations in energy consumption across diverse printing conditions. These results indicate that combining temporal deep learning with ensemble regression provides a robust solution for complex energy prediction tasks in additive manufacturing environments. The ablation analysis further validated the contribution of individual architectural components. The inclusion of an attention mechanism significantly improved the model's ability to focus on energy-intensive printing phases, while the fusion of static process features enhanced predictive stability. The addition of the gradient boosting decision tree regression layer effectively captured nonlinear interactions among extracted features, resulting in reduced residual errors and improved generalization. Phase-wise analysis revealed that the proposed model achieved the lowest prediction error during the extrusion phase, which represents the dominant contributor to overall energy consumption in FDM processes.

Generalization experiments across different materials and printers demonstrated that the proposed framework maintains stable performance under unseen conditions, with R^2 values consistently exceeding 0.93. This robustness highlights the practical applicability of the model in real-world manufacturing settings, where variability in machines, materials, and process parameters is unavoidable. The ability to accurately forecast energy consumption prior to printing enables manufacturers to compare alternative parameter settings, schedule jobs more efficiently, and reduce operational energy costs without compromising part quality. Overall, this work demonstrates that enhanced hybrid deep learning techniques offer a powerful and scalable approach for energy consumption forecasting in 3D printing. The proposed methodology provides a foundation for future energy-aware optimization, real-time monitoring, and intelligent control strategies in additive manufacturing systems, supporting the broader goals of sustainable and smart manufacturing. The results obtained in this study demonstrate that accurate energy consumption forecasting in fused deposition modeling (FDM) requires simultaneous consideration of both temporal power dynamics and static process characteristics. Traditional regression-based and single-model machine learning approaches struggle to capture the strongly nonlinear and phase-dependent nature of FDM energy behavior. The superior performance of the proposed hybrid framework highlights the importance of combining complementary modeling paradigms rather than relying on a single predictive structure.

A key observation from the results is the significant contribution of temporal feature learning to prediction accuracy. The convolutional neural network effectively captured short-term power fluctuations associated with heating cycles, extrusion onset, and transient load variations, while the attention-enhanced LSTM successfully modeled long-term dependencies across the entire print duration. The attention mechanism played a critical role by assigning higher importance to energy-intensive intervals, particularly during sustained extrusion phases, which dominate total energy consumption. This selective focus explains the notable reduction in prediction error compared to standard CNN–LSTM architectures without attention. The integration of static process features with temporal representations further improved model stability and generalization. Parameters such as material type, layer height, infill density, and temperature settings introduce systematic shifts in baseline energy demand that cannot be inferred from power signals alone. By fusing these features, the model was able to contextualize temporal patterns within the physical and operational constraints of the printing process. This fusion proved especially beneficial in cross-material and cross-printer evaluations, where consistent performance was maintained despite variations in hardware and material properties. The gradient boosting decision tree regression layer contributed additional gains by modeling higher-order nonlinear interactions among extracted features. Unlike purely neural approaches, the ensemble-based regressor reduced residual errors and mitigated overfitting, resulting in improved robustness under diverse operating conditions. The ablation study confirms that each architectural component provides a measurable and cumulative benefit, reinforcing the value of hybridization in complex manufacturing prediction tasks.

Phase-wise analysis offers further insight into the practical implications of the model. The lowest prediction errors were observed during the extrusion phase, which is the most energy-dominant and operationally stable segment of the print cycle. Higher errors during warm-up and cooling phases can be attributed to shorter durations and greater variability in transient power behavior. These findings suggest that future work could incorporate phase-aware modeling or adaptive weighting strategies to further refine prediction accuracy during transient stages. Overall, the study underscores that energy consumption in FDM 3D printing is governed by intertwined temporal and parametric factors that demand advanced, interpretable, and generalizable modeling approaches. The proposed hybrid deep learning framework not only achieves high predictive accuracy but also provides meaningful insights into energy-driving mechanisms, supporting its applicability in energy-aware scheduling, parameter optimization, and sustainable additive manufacturing practices.
