ITEGAM - JETIA ISSN 2447-0228 Online
Journal of Engineering and Technology for Industrial Applications (JETIA)

O **ITEGAM-JETIA: Journal of Engineering and Technology for Industrial Applications** is a publication of the Galileo Institute of Technology and Education of the Amazon (ITEGAM), located in the city of Manaus since 2008. JETIA publishes original scientific articles covering all aspects of engineering. Our goal is the dissemination of research original, useful and relevant presenting new knowledge on theoretical or practical aspects of methodologies and methods used in engineering or leading to improvements in professional practice. All the conclusions presented in the articles It should be state-of-the-art and supported by current rigorous analysis and balanced assessment. Public magazine scientific and technological research articles, review articles and case studies.
JETIA will address topics from the following areas of knowledge: Mechanical Engineering, Civil Engineering, Materials and Mineralogy, Geosciences, Environment, Information and Decision Systems, Processes and Energy, Electrical and Automation, Mechatronics, Biotechnology and other Engineering related areas.

Publication Information:
ITEGAM-JETIA (ISSN 2447-0228), (online) is published by Galileo Institute of Technology and Education of the Amazon on a every two months (February, April, June, August, October and December).

Contact information:

SUMMARY

PERFORMANCE EVALUATION OF DEEP LEARNING ARCHITECTURES FOR DETECTING CITRUS CROP HLB ABNORMALITIES **01**
Nagineni Venkata Sireesha, Gillala Rekha

COMPREHENSIVE EVALUATION OF AN AUTOMATED DISTILLER: PERFORMANCE, THERMAL LOSSES, AND PROCESS RELIABILITY **19**
Kevin Damián Carrillo Naranjo, Franklin Wilfrido Salazar Logroño, Luis Rojas Oviedo, Paúl Hernán Machado Herrera

SIX-AXIS MAGNETOMETER/ACCELEROMETER-ASSISTED MOBILE ROBOT INDOOR NAVIATION **28**
Guransh Singh Arora, Kumar Gaurav

ASSESSING THE VISIBILITY AND PERCEPTION OF ESTATE SURVEYORS AMONG NON-CONSTRUCTION PROFESSIONALS IN NIGERIA **39**
Olusoji D. Adetola, Busayo E. Akinwale, Morakane C. Khahledi, Imoleayo A. Awodele, Oyindamola A. Olagunju

FINITE ELEMENT ANALYSIS OF BONE-DERIVED HYDROXYAPATITE, ZINC-DOPED HYDROXYAPATITE, AND PLGA–ZN-HAP COMPOSITES FOR BIOMEDICAL APPLICATIONS **49**
M Saravanan, Abhijith J, Sangeetha Krishnamoorthi, Athira Kishore, Saravana Kumar.M

ADAPTIVE IMMUNIZATION AGAINST FEDERATED DATA POISONING: A SEQUENTIAL TRUST-SPECTRAL INTENT FRAMEWORK FOR ROBUST DISTRIBUTED LEARNING PROCESS **57**
Nitesh Hatwar, V. K. Sharma, Bhushan Manjre

DESIGN AND ELECTROMAGNETIC ANALYSIS OF A HIGH-GAIN DUAL-BAND MICROSTRIP FILTENNA AT 26/29 GHZ BASED ON COUPLED RECTANGULAR RESONATORS **70**
Touko Tcheutou Stephane Borel, Rashmi Priyadarshini

ENERGY AUDIT APPROACHES AND OUTCOMES FOR ENHANCING ENERGY EFFICIENCY IN SMALL & MEDIUM ENTERPRISES **78**
Ankit B. Lehru, Dharmesh J Pandya

NINE-SWITCH QUASI-IMPEDANCE SOURCE INVERTER FOR DUAL-MOTOR ELECTRIC VEHICLE DRIVES WITH INTEGRATED ONBOARD CHARGING **85**
Ismail Benmiloud, Aissa Ameur, Katia Kouzi, Najib Essounbouli.

APPLICATION OF COMPUTATIONAL FLUID DYNAMICS AND OPEN-SOURCE TECHNOLOGIES FOR INDOOR THERMAL COMFORT MODELING: A SYSTEMATIC REVIEW AND EVIDENCE SYNTHESIS OF THE LAST DECADE **95**
Keny Montalvo Morales, Henry Javier-Ninahuaman, Grimaldo Quispe, Abdallah Elshawadfy Elwakeel, John Espitia, Jader Rodriguez, Edwin Villagran

A REVIEW OF RESEARCH AND TECHNOLOGY DEVELOPMENT ON THE ARCHIMEDES SCREW WIND TURBINE **108**
Bayu Ardiansyah Maskub Putra, Nazaruddin Sinaga, Eflita Yohana, Mochammad Shodiq

META-HEURISTIC APPROACHES TO OPTIMAL PLACEMENT OF ELECTRIC VEHICLE CHARGING STATION **127**
M. S. Arjun, N. Mohan, K. R. Sathish, Arunkumar Patil, D. P. Somashekar

ITEGAM - JETIA
ISSN 2447-0228 Online
Journal of Engineering and Technology for Industrial Applications (JETIA)

MULTIMODAL DEEP LEARNING FRAMEWORK FOR MISSING CHILDREN DETECTION USING VISION-LANGUAGE MODE **138**
Kola Uma Maheswari, Pandluri Dhanalakshmi

BLOCKCHAIN-DRIVEN TRANSFORMER-BASED INTRUSION DETECTION AND ACCESS CONTROL SYSTEM (BDL-IDACS) **149**
C. Ramya, A. Suphalakshmi

SALP SWARM OPTIMIZED ARBS-NET-ENABLED FRAMEWORK FOR FAULT DIAGNOSIS IN ELECTRIC VEHICLES **166**
Ganapavarapu Harish, V. Suresh, D. Ravi Kishore, B Kavya Santhoshi

DETECTING IMAGE FORGERIES USING HYBRID RESIDUAL-DENSE SWIN TRANSFORMER FRAMEWORK WITH ATTENTION-BASED U-NET **181**
Sruthi Anand, Saranya V

ENHANCED ECG-BASED CARDIAC DISORDER DETECTION USING RECURRENT NEURAL NETWORK-ENHANCED TEMPORAL TRANSFORMER AND FIRE HAWK OPTIMIZATION **195**
S. Dinakar Raj, Kavitha Veerappan, Jeya Bright Pankiraj, K. Sangeetha, Sumesh Joe Cherian, S. Rajeswari

STARFISH-OPTIMIZED AI-BASED DEEP LEARNING MODEL FOR ACCURATE BROKEN ROTOR BAR FAULT DETECTION IN INDUCTION MOTORS **206**
Killamsetti Vijeta, Sri Suyambulinga Perumal B, R. Tharwin Kumar, Niran I R, Jinsha Lawrence, Gunasekar M

MODELLING AND FAULT PROTECTION ANALYSIS OF A DC MICROGRID USING VOLTAGE SOURCE CONVERTER AND RELAYS **227**
Ayya Chaithanya, T. Neeraja, B Raja Sekhar Reddy, Chella Hari Prasad, Kanna Sravanthi

A COMPREHENSIVE REVIEW ON ADVANCED MATERIALS FOR POLLUTION CONTROL AND ENVIRONMENTAL SUSTAINABILITY **237**
Shital Yashwant Waware, J. Robert Edwin Chester, Immanuvel Arokia James K, Girish Anant Charwad, Govindarajan Murali, Anant Sidhappa Kurhade

DCG-ANET: A DUAL-STREAM CAUSAL GRAPH ADVERSARIAL NETWORK FOR EARLY DETECTION OF ALZHEIMER'S DISEASE FROM MULTIMODAL BRAIN IMAGING **247**
Dinesh Kumar P

INTEGRATION MODEL OF SAVING MATRIX AND NEAREST NEIGHBOR METHODS FOR OPTIMIZING DISTRIBUTION OF PRODUCTION RESULTS OF BAWEAN GRESIK SMES – EAST JAVA, INDONESIA **259**
Rony Prabowo, Lutfia Bamatraf

AN EFFICIENT AND AUTOMATED BRAIN TUMOR SEGMENTATION IN MRI IMAGES USING NON-SUPERVISED MODEL **270**
J. N. Adlin, Arockia Selva Saroja

DRIVER INATTENTION DETECTION USING A HYBRID VISION TRANSFORMER AND BILSTM **278**
Devanaboyina Manikanta Teja, P L Kishan Kumar Reddy

ENERGY-EFFICIENT TINYML-BASED FALL DETECTION FOR WEARABLE HEALTHCARE DEVICES **294**
Prathap P, Hibafathima H, Sufaira Shamsudeen, Selin M, Julie M David, Jihad Aboobaker

A COMPARATIVE STUDY OF DEFECT ANALYSIS, STATISTICAL PROCESS CONTROL (SPC) AND FMEA IN BISCUITS PRODUCTION **299**
Muhammad Abdus Samad, Musfik Ahammed

ITEGAM - JETIA
ISSN 2447-0228 Online
Journal of Engineering and Technology for Industrial Applications (JETIA)

DESIGN AND VERIFICATION OF AN OPTIMIZED 32-BIT PIPELINED MULTIPLIER FOR HIGH PERFORMANCE COMPUTING **312**
C.S. Chakradhar, M. Sreedhar

PREDICTIVE COURSE PLACEMENT: UTILIZING AN ARTIFICIAL INTELLIGENCE-BASED APPROACH FOR RECOMMENDATIONS THROUGH THE APPLICATION OF COSINE SIMILARITY AND MULTI-MODEL ARCHITECTURES **319**
Manocher C Alipour

PERFORMANCE ANALYSIS OF ZETA CONVERTER IN ELECTRIC VEHICLE APPLICATIONS **329**
V. Nandagopal, Pujari Harish Kumar, N Chinna Alluraiah, K. Harinath Reddy

PARALLEL LÉVY-FLIGHT CUCKOO SEARCH FOR JOINT DG SITING/SIZING AND POWER-QUALITY ENHANCEMENT IN RADIAL DISTRIBUTION NETWORKS **337**
Vinuta V Koluragi, J P Sridhar

SYNERGISTIC HYBRID GDI–CNTFET ARCHITECTURE FOR LOW-POWER AND AREA-OPTIMIZED NANOSCALE VLSI CIRCUITS **344**
Jayakrishna Padala, Kishore kumar Kamarajugadda, Pavani Movva

A COMPARATIVE ANALYSIS OF STUDENT PERFORMANCE IN DESIGNING FREQUENCY CONTROL VIA SIMULATION-BASED FORMATIVE ASSESSMENT **356**
Idamakanti Kasireddy, Devineni Gireesh Kumar, Neelesh Kumar Gupta, Prasad Chongala

STRATEGIC INTEGRATION OF ARTIFICIAL INTELLIGENCE IN EDUCATIONAL QUALITY: DIAGNOSIS AND PROPOSAL FOR UNIVERSITIES IN AMAZONAS, PERU **362**
Victor Manuel Valdiviezo Sir

DESIGN AND IMPLEMENTATION OF A PROPOSED SDN-VXLAN ARCHITECTURE FOR ENTERPRISE NETWORK **370**
Daniel Nuñez-Agurto, Luis Paredes-Alcivar, John Cruz-Garzon, Franklin Perez

EXPLAINABLE AND RISK AWARE AUTONOMOUS DECISION SYSTEMS A SCALABLE SECURE BY DESIGN ARCHITECTURE FOR LARGE SCALE DISTRIBUTED COMPUTING SYSTEMS **382**
Abdinasir Ismael Hashi, Osman Abdullahi Jama, Ibrahim Rashid Abdullahi

TODDLER-CENTERED CASE-BASED REASONING FRAMEWORK FOR EARLY DIAGNOSIS OF AUTISM SPECTRUM DISORDER **400**
Hachemi Yamina

EFFICIENT ACUTE LYMPHOBLASTIC LEUKEMIA CLASSIFICATION USING GLCM AND HSV FEATURES WITH RESERVOIR COMPUTING ON TALEQANI HOSPITAL DATASET **408**
Michael Angello Qadosy Riyadi, Sulthonika Mahfudz Al Mujahidin, Nur Alifia Rustan, A'isyah Belqis Febi Aulia, Muhammad Adib Kamali, Farah Zakiyah Rahmanti, Khodijah Amiroh

HYBRID LEXICAL–CONTEXTUAL LEARNING FOR ARABIC NEWS CLASSIFICATION: INTEGRATING TF–IDF WITH ARABERT EMBEDDINGS **420**
Yasir Hadi Farhan, Mustafa Tareq, Boumedyen Shannaq, Said Almaqbali, Oualid Ali

CAPACITY MARKET-BASED DEMAND RESPONSE APPROACH FOR EFFICIENT POWER DISTRIBUTION IN RESIDENTIAL MICROGRID **429**
Arunkumar P, Chidurala Sai Prakash, Srikanth Velpula, Manjunatha H M

ITEGAM - JETIA
ISSN 2447-0228 Online
Journal of Engineering and Technology for Industrial Applications (JETIA)

BENCHMARKING YOLO VARIANTS FOR DETECTING VARROA MITES IN BEEHIVE IMAGES **437**
Youcef Naas, Slim Rouabah, Rabah Abdelkader, Meziane Kaci, Salem Merabti, Hassane Ezziane

INTERPRETABLE MENTAL HEALTH SCREENING USING BAYESIAN PCA-ENHANCED LOGISTIC REGRESSION FOR DECISION SUPPORT **444**
Hendra Abdul Hamid, Mustafa Mat Deris, Ika Safitri Windiarti

SELF-SUPERVISED KNOWLEDGE REPRESENTATION FOR RARE FRAUD AND OPERATIONAL FAILURE DETECTION IN MULTI-CHANNEL PAYMENT SYSTEMS **452**
Boumedyen Shannaq

COMPARATIVE EVALUATION OF MACHINE LEARNING MODELS FOR PREDICTIVE MAINTENANCE USING THE AI4I 2020 DATASET: EFFECTS OF DATA BALANCING AND FEATURE SELECTION **461**
Juan Carlos Gonzalez Islas, Jesus Vargas-Ortiz, Aldo Márquez-Grajales, Ernesto Bolaños-Rodríguez, Asdrúbal López-Chau, Rosa María Ortega-Mendoza

CFD-BASED NUMERICAL ASSESSMENT OF PIN-FIN HEIGHT OPTIMIZATION FOR ENHANCED THERMAL PERFORMANCE IN MWCNT NANOFLUID MICROCHANNEL HEAT SINKS **470**
S Sorna Latha, Ankush D Tharkar, Divya Haridas

MULTI-STAGE DIABETIC RETINOPATHY CLASSIFICATION USING DEEP LEARNING: TRENDS, CHALLENGES, AND FUTURE DIRECTIONS **484**
Shreya Dubey, Mahesh Goyani, Pinal Patel, Safwan Vahora, Uttam Chauhan, Mahendra Patel

DEEP REINFORCEMENT LEARNING-BASED ADAPTIVE SWITCHING FOR RISK-COST-OPTIMIZED RENEWABLE SMART GRIDS **499**
Meyyappan M, Avirajamanjula P, Marimuthu P, Bharathiraja M

MITIGATING ADVERSARIAL VULNERABILITIES IN DEEP LEARNING-BASED FACE RECOGNITION USING STACKED ATTENTION RESIDUAL GAN AND FIRE HAWK OPTIMIZATION **513**
Sheilla Ann Pacheco, Mahesh Goyani, Jayzel P. Bangoy, Born Christian A. Isip

ACCURATE BRAIN TUMOR CLASSIFICATION USING MRI IMAGES BASED ON A HYBRID VISION TRANSFORMER AND BILSTM FRAMEWORK **526**
Nagham Salim Mohammed, Omar S. Almolaa, Ahmed Saadi Abdullah, Khalil I. Alsaif

AN OPTIMIZED HYBRID FUSION MODEL COMBINING DENSE AND VISUAL GEOMETRY NETWORKS WITH MACHINE LEARNING FOR LUNG CANCER DETECTION AND CLASSIFICATION **536**
Umakanth Basineni, Fahimuddin Shaik

A NOVEL TECHNIQUE TO DESIGN ADDER AND MULTIPLIER CIRCUITS USING GNRFETS IN TERNARY LOGIC **549**
K Mamatha, Shaik Taj Mahaboob

DEVELOPMENT OF A TINYML-BASED DEVICE FOR AUTOMATIC DETECTION OF POULTRY DISEASES USING CHICKEN VOCALIZATIONS **558**
Minh Nguyen-Ngoc, Bien Nguyen-Quang, Duan Luong-Cong

TWO-STAGE DETECT-THEN-CLASSIFY PIPELINE WITH DSAR-CNN FOR ROBUST FRAGMENT CLASSIFICATION UNDER PADDING AND BIT-FLIP ATTACKS **566**
Teena Mary, Sreeja C S

ITEGAM - JETIA
ISSN 2447-0228 Online
Journal of Engineering and Technology for Industrial Applications (JETIA)

FORECASTING BITCOIN PRICE MOVEMENTS USING HISTORICAL DATA **584**
Seddiq Hassan Al-Banna Ali, Ammar Ahmed Othman, Mohammed Baker Yousif

COMPARATIVE ANALYSIS OF TRIBOLOGICAL PERFORMANCE OF NANO-ENHANCED HYBRID BIO-LUBRICANT WITH CONVENTIONAL SYNTHETIC OIL **596**
Gaurav Pendbhaje, Mohammed Ali, Dipak Bajaj

PHYSICS-INFORMED DEEP LEARNING-BASED STATE OF HEALTH AND EFFICIENCY PREDICTION FRAMEWORK FOR KY CONVERTER-DRIVEN ELECTRIC VEHICLE BATTERY SYSTEMS **606**
Karhikkumar G, Avirajamanjula P, Marimuthu P, Bharathiraja M

EXPERIMENTAL EVALUATION OF SMART CONTRACT GAS OPTIMIZATION TECHNIQUES: A CASE STUDY OF A BLOCKCHAIN-BASED REPORTING APPLICATION SYSTEM **615**
Michael Angello Qadosy Riyadi, Sulthonika Mahfudz Al Mujahidin, Nur Alifia Rustan, A'isyah Belqis Febi Aulia, Mastuty Ayu Ningtyas, Khodijah Amiroh

TRANSIENT THERMAL PERFORMANCE ANALYSIS OF NANOPARTICLE-COATED FLAT PLATE SOLAR COLLECTORS USING MATLAB-BASED MODELING **629**
Juber Khatik, Nilesh Salunke, Mujahid Husain, Yogeshkumar Pathak, Kailas Deore, Pradeep Solanki, Pravin Shirule

A NOVEL LYAPUNOV BACKSTEPPING APPROACH TO CONTROLLING MECHANICAL POWER IN INDUCTION MOTORS **641**
Chami Noureddine, Rouabhi Riyadh, Herizi Abdelghafour

DEEP LEARNING TECHNIQUES: GAN AND LSTM FOR STOCK MARKET CLOSING PRICE PREDICTION **648**
Pappula Praveen, Anjaneyulu Gudla

A NOVEL PHOTOVOLTAIC-BASED WIRELESS EV CHARGING SYSTEM USING A MODIFIED TRANS-QUASI Z-SOURCE BOOST CONVERTER **660**
Naveena Sandhadi, Srinu Naik Ramavathu

INTERPRETABLE UNSUPERVISED IDENTIFICATION OF PERSISTENT RAINFALL REGIMES WITH ROBUSTNESS AND TEMPORAL STABILITY ASSESSMENT **673**
Imane Meguenni, Bendaoud Mebarek

A STRUCTURED PROBABILISTIC–AI FRAMEWORK FOR PREDICTIVE RELIABILITY ASSESSMENT AND RUL ESTIMATION OF ASYNCHRONOUS ROTATING MACHINES **685**
Toukap Nono Fernand Joseph, Tokoue Ngatcha Dianorré, Offole Florence, Nyatte Steyve, Mouzong Pemi Marcelin

MECHANICAL CHARACTERIZATION OF 3D-PRINTED PLA/GLASS FIBER COMPOSITE FOR CRASH BOX APPLICATION **704**
Sridharan V, Nikhil Kumar A, Mathumitha K, Jeyabalaji SN

THERMAL–HYDRAULIC OPTIMIZATION OF SLOTTED PIN FINS UNDER LAMINAR FLOW USING RESPONSE SURFACE METHODOLOGY **710**
Govindarajan Samidurai, Karthikeyan Ramalingam, Muthukumaran Ramalingam, Ratchagaraja Dhairiyasamy

DURABILITY PROPERTIES OF CONCRETE BY PARTIAL REPLACEMENT OF FINE AGGREGATE AND COARSE AGGREGATE WITH ALCCOFINE AND GLASS POWDER **724**
K.E. Viswanathan, S. Naveen Kumar, S. Yuvaraj, C. Shankar

ITEGAM - JETIA
ISSN 2447-0228 Online

ABSTRACT

One of the most effective ways to combat diseases like Huanglongbing (HLB; aka citrus greening) is through early detection. Since HLB is a major disease causing significant losses in citrus production worldwide, there is a need for cheap and efficient methods for detecting it so that treatment can begin at the earliest stage. Deep learning techniques using convolutional neural networks (CNNs) are becoming the primary tools for disease detection in computer vision; however, it remains difficult to distinguish HLB from other citrus diseases. Diagnostic methods based on traditional techniques, e.g., quantitative real-time polymerase chain reaction, are costly and require large datasets to train CNN models. One way to tackle the lack of labelled images is to use transfer learning with pre-trained CNNs, which can also perform well on smaller datasets. The objective of the research is to evaluate (AlexNet, VGG19) the chain and the directed acyclic graph (DAG) CNN architectures (ResNet50, Inception-V3) for the three-class classification of Huanglongbing (HLB), healthy leaves, and 10 other citrus abnormalities. To do this, a dataset containing 955 colour images of Citrus leaves from southern India was used. Additionally, 10-fold cross-validation was performed. The experimental results showed that all the CNN models achieved a sensitivity of over 98% in detecting HLB. Yet VGG19 achieved the highest sensitivity score across all tests, despite having fewer parameters than Inception-V3. These findings indicate that models with more parameters are better able to handle the challenges posed by small datasets and, as a result, enable successful transfer learning for HLB detection. The present paper concerns the selection of CNN models for citrus disease detection. It offers a low-cost, portable solution that can help small-scale farmers in low-income areas reduce their crop losses.

I. INTRODUCTION

The citrus family has been one of the most important contributors to the global agricultural economy. They are the main source of nutrition, money, and jobs that the world needs. Among these crops, lemons, oranges, and limes have the highest commercial value and are the major contributors to the food industry and human diets. However, the productivity and profitability of citrus farming are under constant threat from pests and diseases. One of the most fatal diseases that leads to HLB (Huanglongbing) or citrus greening is the case. It is caused by a bacterium (Candidatus Liberibacter asiaticus) that is most commonly carried by the Asian citrus psyllid (Diaphorina citri). Eventually, the illness leads to the tree's deterioration, the yellowing of the leaves, the production of abnormal fruit, and, finally, the tree's death. Actually, in nations such as India, where citrus cultivation is a major activity, HLB is a major problem that threatens sustainable agriculture and adversely affects smallholder and commercial farms alike. The extent of HLB's spread has become so severe that it now threatens farmers' lives and leads to significant crop losses in both quantity and quality [1], [2].

The disease's qualities, i.e., its long environmental persistence and spread via insect vectors, only compound the difficulties of its control, thereby making it a priority for research and management across all citrus-growing areas worldwide. Traditional methods for identifying HLB rely mainly on experts conducting visual inspections, laboratory testing, or using diagnostic kits. Nevertheless, these approaches are labour-intensive, slow, and unsuitable for large-scale operations. The rapid and widespread distribution of HLB and the challenge of early detection necessitate an efficient, automated, and scalable solution to identify infected plants and help stop disease outbreaks. Most conventional methods have a low success rate in early detection of the disease, and visual symptoms of HLB may be similar to other physiological disorders, which will lead to an incorrect diagnosis and prolonged waiting time for treatment [3], [4]. Timely diagnosis of an illness at the earliest stage is vital for treatment, especially when symptoms are barely visible or even unknown. Deep learning has been identified as a novel, effective method for automating disease detection in agriculture, leveraging the latest artificial intelligence (AI) and computer vision. The introduction of deep convolutional neural networks (CNNs) has revolutionised image classification; as a result, deploying these techniques to detect HLB in citrus plants is widely regarded as a perfectly feasible task. These networks have a gift for spotting the tiniest details and image features. This way, they can distinguish between healthy and infected plants just as well. CNNs are now the leading models for plant disease recognition because they extract features directly from the original image, thereby drastically reducing the need for manual labour [5]. Apart from disease management, AI in agriculture has also facilitated plant detection and advanced decision-making for precision farming. This paper sheds the spotlight on the use of CNNs for farm diagnostics. HLB detection is the primary focus of this article, alongside other common citrus diseases researchers have studied.

The paper compares different CNN models. To provide a complete picture of a model's performance under extreme data shortages and resource constraints, these models include traditional convolutional architectures (AlexNet, VGG19) and newer DAG-based architectures (ResNet18, Inception-V3). The paper used a dataset of 955 images of Citrus leaves that were captured under the most stringent conditions. Besides healthy leaves, it also contained the first 10 festivals. Using 10-fold cross-validation, the paper achieved the highest sensitivity, demonstrating the HLB model's reliability. In all experiments with HLB, VGG19 led the way: it consistently achieved perfect sensitivity, even outperforming more complex architectures like Inception-V3 and ResNet18, which are typically regarded as high-performing on large datasets. It shows that simplified models can remain highly effective when data is limited, prioritising efficiency and accuracy over computational complexity alone. Besides that, CNNs have been quite a success story in small-data circumstances; this paper really advances the discussion. The present research contradicts this statement by showing that VGG19 can outperform its rivals; thus, the more complex, the better, is not true. Also, the discussion includes maximising diagnostic accuracy while minimising computational overhead, which is mainly important in resource-limited settings. Also, the research proposes that small-scale farmers, who are most at risk of suffering from diseases like HLB, may be given economical, easy-to-use, and portable instruments for disease identification, based on this scientific paper. The authors strongly encourage converting these CNN models into Mobile apps or miniature imaging devices, so the outcomes will not only be top-tier AI technologies but also practical agricultural solutions.

II. RELATED WORK

As stated by the Food and Agriculture Organisation of the United Nations (FAO), citrus is ranked as the second most globally grown fruit. Nevertheless, certain diseases caused by fungi, bacteria, pests, and viruses have been identified as lowering citrus production and quality in some areas [6]. Among the issues that have weakened the health of citrus trees, Huanglongbing (HLB), also called citrus greening, is the most virulent. Several areas where the disease has been discovered are South America, North America, Asia, and Africa. In India, HLB is a severe threat to citrus fruit production. The infected trees exhibit HLB symptoms, including leaf blistering, shoot yellowing, reduced fruit size, growth retardation, corky veins, root death, and dieback. These symptoms not only degrade the trees' health but also cause farmers to lose significant money, which in turn affects the citrus industry [7]. Several researchers have been working on machine-learning-based automation for plant leaf disease over the last few years. A recent overview of current image processing developments highlighted the importance of this technology in the development of practical, efficient devices for automated insect and disease identification, especially when combining machine learning and image processing [8]. Additionally, a Sparse Representation Classification (SRC) system for the automated recognition of cucumber diseases was proposed [9], as SRC's robustness to limited training data can enable more accurate and reliable disease detection. And a new characterisation of the dynamic system modulated model, i.e., the Group Method of Data Handling (GMDH), was introduced, along with the use of logistic regression to fit the dataset's statistical features [10]. This model significantly improves performance through its dynamic adjustments. Machine learning has recently been making strides towards developing hybrid models that combine deep learning methods with older techniques.

One of the foremost applications of deep learning and machine learning in the agricultural industry is advanced crop disease detection and diagnosis using image processing. With the goal of automated plant disease detection, the authors of [11] strongly believe that traditional and deep feature extraction methods can be used together, as they are complementary. Although deep learning techniques extract features automatically and traditional methods are better at classification, the authors of [12] propose a new technique that integrates K-means clustering and SVM for effective segmentation and classification of diseased areas on the leaf. Besides, their use of modified SVM methods with post-processing operations has led to a major improvement in classification accuracy [13]. DenseNet architectures, coupled with SVMs, have proven quite effective [14] for disease identification by leveraging deep feature extraction and ensemble learning. A complex hybrid multiclass SVM model has been proposed [15], which employs spatial fuzzy C-means clustering to correct spatial deviations and enhance classification accuracy. One of the chief reasons disease classification models can't be used across different crops is that they aren't directly transferable. Recently, localisation-based algorithms [16] have been proposed as a solution to this issue. These algorithms allow for more accurate and adaptable systems. Also, a leaf recognition technique based on Pulse Coupled Neural Networks (PCNN) was proposed [17], demonstrating that capturing detailed structural and textural features of leaves with PCNN yields significant gains in classification accuracy. Several papers [18] have highlighted the use of convolutional neural networks (CNNs) to, for example, detect diseases on citrus leaves in real-time; and one of the factors contributing to the success of mobile-based diagnostic tools is their accessibility and ease of use for the agricultural sector, which is presently going through significant changes.

The use of AlexNet [19] for categorising plant ailments also demonstrates that CNNs are best suited to highly organised agricultural datasets, thereby enabling high-accuracy, fast disease recognition. Image-based disease detection using deep learning techniques has been explored recently [20]. The application of transfer learning in agriculture has significantly enhanced plant disease classification, particularly when labelled datasets are scarce, leading to new ways of using pre-trained models. Another instance of feature-based classification methods evolving their capabilities is the use of colour histograms and textural descriptors to identify diseases in citrus plants. A comparative analysis of different machine learning methods applied to UAV-based multispectral images for citrus greening detection has revealed the importance of remote sensing technologies in agricultural monitoring. These exploratory studies emphasise the role of multispectral and hyperspectral imaging technologies in the early detection of plant diseases. In fact, a plant leaf disease recognition system based on deep learning techniques achieved a remarkable jump in classification accuracy [21]. Soon after, this research was further developed into smartphone-assisted systems [22] that allow for on-site diagnostics and support disease detection in farming practices. At the molecular level, real-time quantitative PCR (qPCR) is considered the gold standard for detecting Candidatus Liberibacter spp due to its unmatched sensitivity and specificity compared with other methods. qPCR detects the pathogen by targeting bacterial genes, such as 16S rRNA. The introduction of CRISPR-Cas12a-based diagnostic methods, such as DETECTR, has enabled the development of highly sensitive, rapid, and very convenient diagnostic kits for Candidatus Liberibacter asiaticus (CLas) for field applications, thereby promoting early intervention [23]. Then again, digital droplet PCR (ddPCR) has proven to be an excellent tool for detecting ultra-low levels of infection, leading to improved diagnosis even in asymptomatic trees [24]. Techniques based on hyperspectral imaging (HSI) have been extremely effective for the non-invasive detection of HLB by highlighting physiological modifications in citrus trees that are invisible to the naked eye. Hyperspectral data, combined with machine learning algorithms, has played a significant role in enhancing diagnostic efficiency. At the very front line of plant disease diagnosis, CNNs process large datasets to extract highly complex features from images that even top human experts may not recognise [25].

A CNN method trained on images of citrus leaves achieved over 90% accuracy in identifying HLB symptoms [26], indicating the model's strength and potential in real-world settings. Transfer learning, which uses a pretrained model (e.g., VGGNet, ResNet, or Inception) as the starting point, has helped achieve results more quickly while reducing computational resources and training time. All these aspects still enable high accuracy even with a small amount of labelled data [27]. This is an excellent option for resource-constrained areas that lack large, well-annotated datasets. When combined with convolutional neural networks (CNNs), hyperspectral and multispectral imaging have paved the way for non-invasive HLB detection methods. Hyperspectral imaging first captures continuous spectral information, then processes it using a CNN that learns to distinguish healthy from diseased conditions. One combination of processing methods, accompanied by hyperspectral images, produced a CNN that accurately classified HLB-infected trees more than 97% of the time [28], demonstrating the potential of matching spectral data with deep learning for early disease detection without relying on visible symptoms. At the same time, steady enhancements in lightweight CNNs have enabled real-time HLB detection on mobile devices, striking the right balance between efficiency and accuracy without compromise, resulting in a model that is highly portable and mobile-friendly. This A lot eases on-site disease monitoring [29]. Although technology has made significant strides, challenges remain in implementing CNN-based disease detection systems. For instance, factors such as lighting, shadows, and background noise, which influence image quality, can vary from one image to another and may adversely affect the model's performance. To address these problems, the researchers have employed data augmentation and ensemble learning methods to enhance the generalisation capacity of the CNN models [30]. On top of that, the lack of HLB-oriented, standardised HLB-detection datasets is the main challenge in accumulating more extensive and diverse image repositories to support the spread of these technologies in this field.

III. MATERIALS AND METHODS

This section first describes in detail the use of pretrained models such as AlexNet and VGG19 for the primary purpose of classifying Huanglongbing (HLB) in citrus leaves. Additionally, a comparison of the performance of pretrained models such as ResNet-50 and Inception-V3 was conducted to determine the most suitable model for accurate HLB classification.

III.1 TYPES OF CITRUS HLB

Citrus Huanglongbing (HLB) can be classified into different categories depending on various factors. Heat-Tolerant Greening (HTG), caused by Candidatus Liberibacter asiaticus (CLas), is a greening disease that prefers warm climates; thus, it warrants a thermal classification. On the other hand, Heat-Sensitive Greening (HSG), caused by Candidatus Liberibacter africanus (CLaf), is a greening disease that mostly occurs in cold regions. Zinc Deficiency-Induced Greening (ZD) is nutritionally similar to HLB but results from zinc deficiency, while Citrus Stubborn Disease (CSD), caused by Spiroplasma citri, mimics greening symptoms in Mediterranean climates. Citrus Blight (CB) is a disease that causes tree decline in the absence of psyllid vectors, and its cause remains unknown. Phytoplasma-Associated Greening (PAG) is a disease caused by wall-less bacteria transmitted by leafhoppers. In contrast, Seasonal or Cold-Induced Greening (CIG) is a disease caused by environmental stress, such as cold or drought. Cultural or Chemical Stress Greening (CSG) results from poor orchard management or chemical misuse. Mixed Infections Greening (MIG) involves co-infection by multiple pathogens, and Genotype-Specific Greening (GSG) reflects genetic susceptibility in certain citrus species or rootstocks, particularly sweet orange varieties.

III.2 DATA SETS

The primary dataset sources used in this paper are Kaggle and real field data, with a major emphasis on Huanglongbing (HLB) disease in citrus. It contains 955 images acquired under various natural conditions. These diverse images are used to classify the disease and assess the level of infection. Additionally, data augmentation was performed to both supplement the dataset and enhance the model's effectiveness, increasing the dataset to 5,200 images. The techniques of augmentation include mirror flipping, angular rotation, zooming, adjustments to brightness and contrast, conversion to grayscale, noise addition, and cropping.

The data consists of images of healthy citrus and citrus affected by HLB symptoms, enabling easy distinction between the two. During the severity assessment step, manual pixel-level annotations are created using the LabelMe tool [31]. The image pixels are categorized into four groups: healthy, HLB-infected (further divided into the main subclasses for each disease type), and background. Various colours are employed for better differentiation during the labelling. The dataset is split into 70% for training, 20% for validation, and 10% for testing the proposed technique.

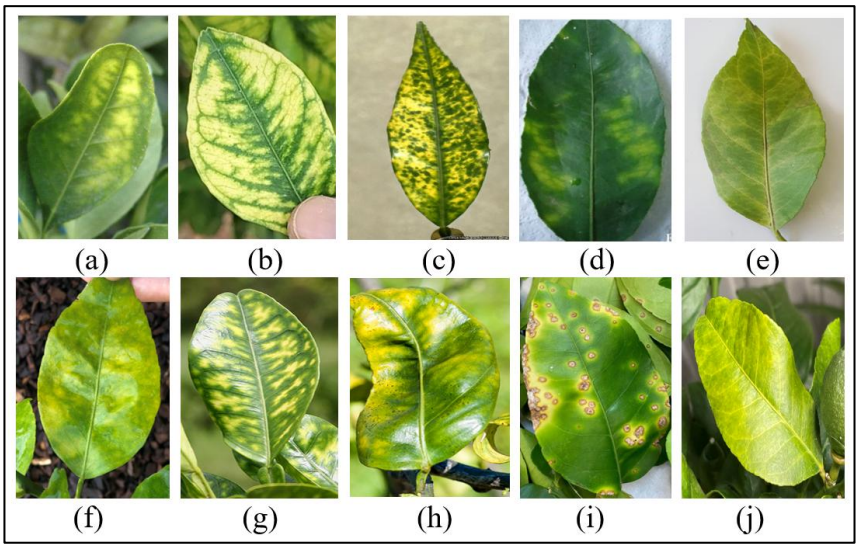

Figure 1: Sample original image dataset for infection with HLB.
(a) CSD (b) ZD (c) CB (d) PAG (e) CIG (f) CSG (g) MIG (h) GSG (i) HTG (j) HSG.
Source: Authors, (2026).

To comply with the input specifications of various models, the dataset is resized. For example, the dimensions of images are converted to (227x227x3) for AlexNet, (224x224x3) for ResNet and VGG19, and (299x299x3) for InceptionV3. After the images are resized, data augmentation techniques are applied. Although CNNs are highly effective, they can still suffer from overfitting, especially when trained on small datasets that limit their ability to generalise. One way to address this problem is to enlarge the dataset using label-preserving transformations. In other words, data augmentation refers to generating new data points by modifying the original images, thus increasing the number of training samples without collecting more.

III.3 HARDWARE REQUIREMENTS AND SOFTWARE SPECIFICATIONS

The proposed structure is implemented using Python libraries and Keras coupled with TensorFlow. The experiments were conducted on a Windows 10 computer with an Intel i7 processor, 16 GB RAM, and a GPU with 8 GB of GDDR6 memory. Both training and testing of the models were performed using the Keras library, with TensorFlow 2.4.1 as the backend.

During hyperparameter tuning, 10 different configurations were tried, and each took nearly 7 hours to complete. In total, the time spent on training and testing the developed DCNN model was about 98 hours.

III.4 DEEP LEARNING MODELS & HYPERPARAMETERS

This research paper utilised deep learning models to optimise the performance of four different models. The study used four models: AlexNet, ResNet-50, VGG-19, and Inception-V3. This part of the paper introduces the background of the models employed in this research, their traits and functionalities.

III.4.1 AlexNet Architecture

The AlexNet model, introduced in 2012, revolutionised deep learning by achieving remarkable success in the ImageNet Large Scale Visual Recognition Challenge.

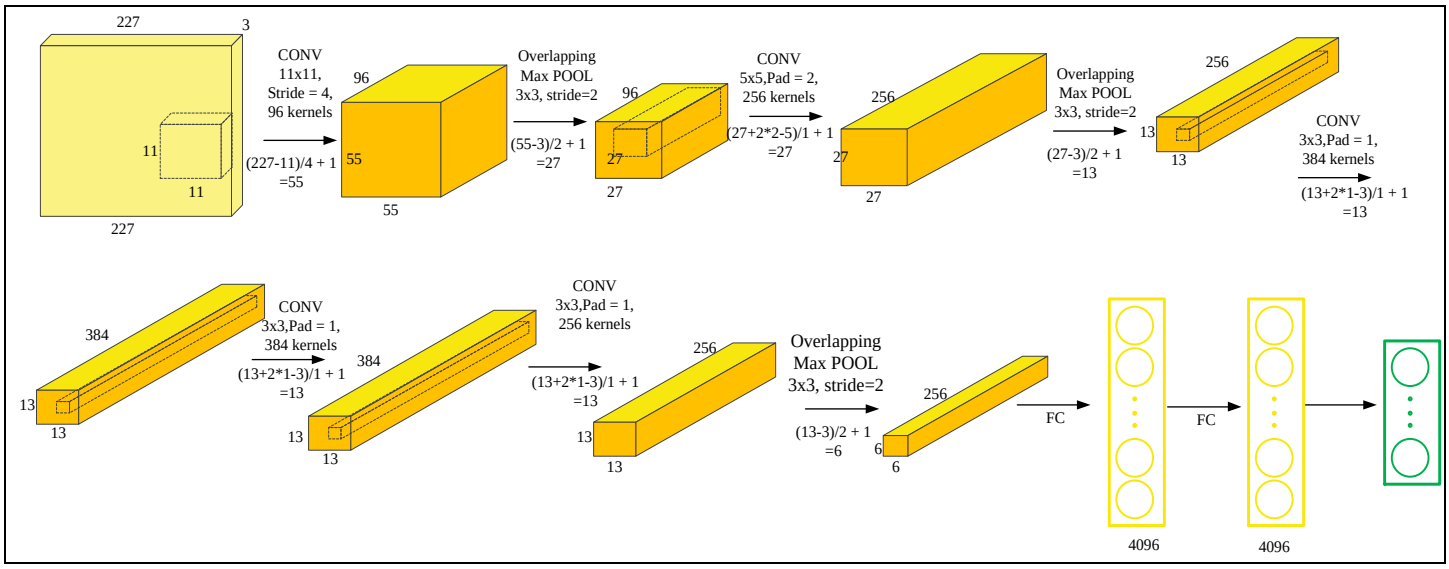

Figure 3: Architecture of AlexNet Classifier.
Source: Authors, (2026).

This CNN is designed to handle input images with a resolution of 227x227x3. The initial step of the network, feature extraction, is performed using a series of convolutional, pooling, and fully connected layers. The first convolutional layer applies 96 11x11 filters with a stride of 4, and the resulting features undergo overlapping max-pooling, which significantly reduces the spatial dimensions. Following the application of 256, 5x5 filters, the layer is subjected to max-pooling again. Further into the network, there are 5 more conv layers, and 3 of them are followed by max-pooling. Eventually, the output feature map has spatial dimensions 6x6 and a depth of 256 channels (6x6x256). The 2 fully connected layers, each with 4096 neurons and the ReLU activation function, receive the flattened output as input. Dropout regularisation is used in those layers to prevent overfitting. The last fully connected layer, which uses softmax activation, gives the probabilities over the 1000 categories. The most important AlexNet features that explain the rise in its performance are the use of the ReLU activation function, which makes it train faster; overlapping max-pooling, which makes it easier to generalise features; and GPU acceleration for training. The success of AlexNet was a major sign that deep learning was superior to traditional methods for image classification, and it paved the way for even more complex architectures. That is why the canonical AlexNet variant remains the foundation of transfer learning and feature extraction in computer vision.

III.4.2 ResNet-50 Architecture

The deep convolutional neural network model ResNet-50 is shown in Figure 4 and is widely used in image recognition and classification. It is part of the ResNet (Residual Network) family, which transformed the training of very deep networks by introducing residual learning. The idea of residual learning is that the network learns residual functions rather than direct ones, which helps address the vanishing gradient problem.

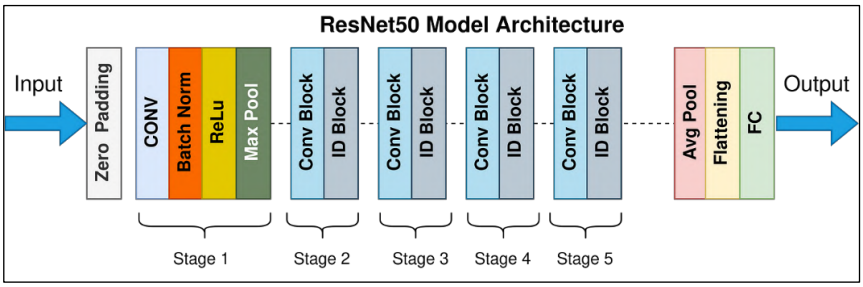

Figure 4: Architecture of ResNet50 Classifier.
Source: Authors, (2026).

The network takes its first input from an image data input layer. Here, zero-padding has been added to preserve the image's spatial dimensions. In Stage 1, the model consists of a convolutional layer that extracts low-level features from the image, followed by batch normalisation to stabilise and speed up training. A ReLU activation layer with non-linearity is added; max-pooling is also performed to downsample and, at the same time, keep essential features. Stages 2 to 5 are composed of a series of convolutional and identity blocks. A convolutional block is a residual block that uses skip connections, i.e. the output of the conv layers is added directly to the block's input. This addition helps the gradient flow smoothly through the network during backpropagation. This feature of deep ResNet alleviates degradation. Identity blocks preserve the input dimensions while learning features that are used more abstractly at a later stage. Throughout the network, the number of filters increases to handle increasingly complex patterns. The output layers finally consist of average pooling to reduce spatial dimensions, flattening to change feature maps into a 1D vector, and a fully connected layer for classification. The size of the fully connected layer depends on the number of classes. With its 50 layers, ResNet-50 finds a compromise between depth and computational efficiency. It is still widely used as the core structure for various image-based tasks, including image classification, object detection, and feature extraction for transfer learning. Due to its robust architectural design and innovative residual connections, it is widely regarded as a benchmark model in deep learning.

III.4.3 VGG19 Architecture

This diagram illustrates the structure of a convolutional neural network (CNN), specially designed for image processing and classification. It takes as input a single image of size 224×224 with 3 colour channels corresponding to RGB. The very first layers of the network consist of convolutional operations with the Rectified Linear Unit (ReLU) as the activation function. The main objective of these convolutional layers is to capture the image's spatial layout while shrinking its spatial dimensions and increasing the depth of the feature maps. For instance, the network passes on features of size 224×224×64, 112×112×128, 56×56×256, and so on, along with the layer types. In this way, the net can depict both the minute and the large-scale features of the image. The feature maps at different depths of the hierarchy are next fed into a global average pooling layer at the 14×14×512 stage. This layer considerably reduces the spatial dimensions by averaging feature values; hence, it provides dimensionality reduction while retaining the basic features for classification. Then the feature maps are passed to fully connected layers, which are the highest-connectivity point in the network, from which the extracted features are collected. These layers, together with the ReLU activation function, are responsible for generating complex decision boundaries by the model. Having a dropout layer with a rate of 0.5 in the network architecture can help reduce overfitting during training. It can randomly turn off half of the neurons. This regularisation method is the main source of the model's ability to generalise very well. The last layer of the model is a softmax layer that transforms the network's output into probabilities over each target class. In addition, the last layers are fine-tuned to adjust the pre-trained network for the specific classification task, which is why it achieves better performance.

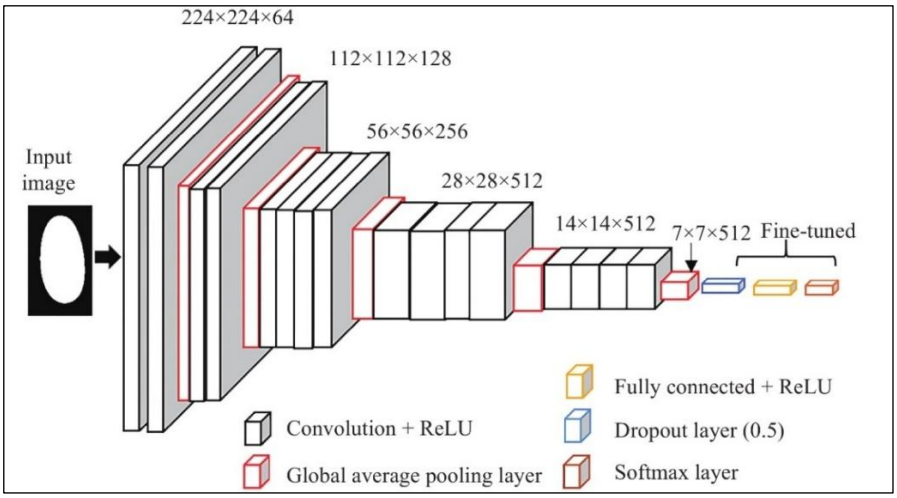

Figure 5: Architecture of VGG19 Classifier.
Source: Authors, (2026).

III.4.4 Inception V3 Architecture

The Inception-v3 model is among the top convolutional neural networks for image classification, and its effectiveness and efficiency have been widely acknowledged. The model receives an input image of size 299x299x3 and produces an 8x8x2048 feature map. It then classifies each input image into one of 1001 classes (or the background class). Belonging to the Inception family, it follows the design philosophy of making speed and accuracy trade-offs, like its ancestors, yet also introduces several changes that improve hardware efficiency and increase representational power. The crux of Inception-v3 lies in the Inception modules, which perform convolutions with different kernel sizes (e.g., 1x1, 3x3, and 5x5) concurrently. These modules merely don't output their outcomes to concatenate to gather very detailed features from the input data. The extensive use of 1x1 convolutions throughout the network helps drastically reduce computational cost while preserving the most important information. In addition to convolutions, the architecture uses several pooling layers, such as max and average pooling, which reduce the input's spatial dimensionality while accentuating salient features. The last phase of feature extraction produces a single, high-dimensional feature map (8x8x2048) that encodes a highly abstract, high-level representation of the input image. For classification purposes, the 3D feature map will undergo global average pooling, producing a 1D vector. Then, to get the class probabilities, a fully connected layer followed by a softmax activation will be used.

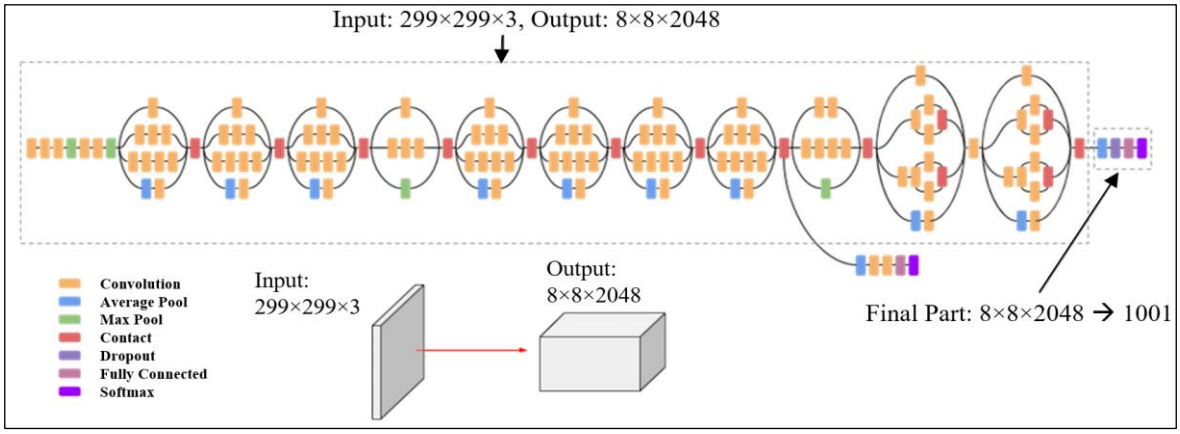

Figure 6: Architecture of InceptionV3 Classifier.
Source: [32].

Although Inception-v3 is quite old, it still introduces many new elements. One of those elements is factorised convolutions, which split large convolutions into smaller ones. For instance, a 5x5 kernel can be obtained by two consecutive 3x3 kernels, thereby reducing the number of calculations. Another revolutionary element is that auxiliary classifiers are incorporated into the training phase, thereby improving gradient flow and, as a result, eliminating the vanishing-gradient problem in deep layers. The model, with a proper combination of depth, accuracy, and computational efficiency, has become a standard solution for image classification, transfer learning, and feature extraction, among other tasks. So, hyperparameter tuning plays an important role in enhancing the performance of the proposed models. The results show that the model's accuracy measures quality. The summary of the hyperparameters used during training is provided below: AlexNet hyperparameters are in Table 1; Table 2 shows the parameters of ResNet and VGG19; and Table 3 presents the details for Inception-v3.

Table 1: Hyperparameters for AlexNet.

Parameter	Value
Image size	227 × 227 × 3
Batch size	64, 32, and 16
Number of epochs	100, 50, and 30
Optimizers	SGD, Adam, and RMSprop
Learning rate	0.01, 0.001, and 0.0001
Kernel size	11 × 11, 5 × 5, and 3 × 3
Number of hidden layers	5, 7, and 9
Loss function	Cross entropy

Source: Authors, (2026).

Table 2: Hyperparameters for ResNet50 and VGG19.

Parameter	Value
Image size	224 × 224 × 3
Batch size	128, 64, and 32
Number of epochs	150, 100, and 50
Optimizers	Adam, SGD, and RMSprop
Learning rate	0.001, 0.01, and 0.005
Kernel size	7 × 7, 3 × 3, and 1 × 1
Number of hidden layers	50, 19, and 34 (ResNet)
Loss function	Cross entropy

Source: Authors, (2026).

Table 3: Hyperparameters for InceptionV3.

Parameter	Value
Image size	299 × 299 × 3
Batch size	64, 32, and 16
Number of epochs	200, 150, and 100
Optimizers	Adam, RMSprop, and SGD
Learning rate	0.001, 0.0005, and 0.0001
Kernel size	3 × 3, 5 × 5, and 1 × 1
Number of hidden layers	48, 54, and 60
Loss function	Cross entropy

III.5 PROPOSED APPROACH FOR HLB DETECTION

III.5.1 Detection Scheme

Figure 7 displays the block diagram of the proposed HLB detection structure which contains three main parts: 1) image acquisition, capturing of leaf images that reflect real field conditions i.e. images taken from 13 acres citrus orchards of Gopanapally village, Podalakur Mandal, Nellore District, Andhra Pradesh, South India and also downloaded from Kaggle datasets; 2) segmentation (isolation of the leaf's inner parts); and 3) the CNN modeli.e. classification which separates 10 types of HLB abnormalities apart from healthy image.

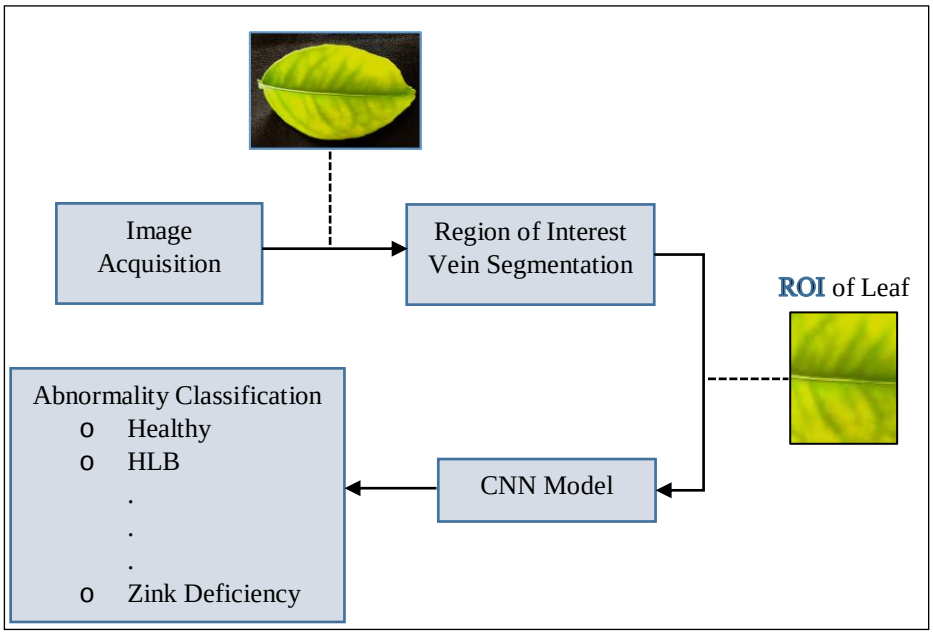

Figure 7: Image detection scheme for Citrus HLB classification.

III.5.2 Proposed Integrated Methodology

The strategy used for Huanglongbing (HLB) identification was a hybrid technique that merged leaf vein feature extraction with convolutional neural network (CNN) detection, as illustrated in Figure 8. The planned method combined domain-specific leaf features with the latest deep learning techniques to achieve precise disease classification. Below is a detailed explanation of each step of the algorithm:

Step 1. Leaf Image Acquisition

This begins by taking extremely clear photos of citrus leaves. These images work as the primary inputs of the subsequent process. Leaf sampling involves a fairly balanced selection of healthy and potentially diseased leaves, which are then used to create the training and testing datasets.

Step 2. Vein Segmentation

Leaf vein segmentation is performed on raw leaf images to isolate vein patterns. Segmentation is a way to keep only the major and minor veins of a leaf while discarding the lamina and other non-vein areas. This step is crucial as HLB-related leaf alterations are mainly visible in the veins. Here, the most important step is isolating veins from leaves. For this purpose, a thresholding technique is employed as described by this formula:

$$\text{Thresholding: } I_{seg}(x,y) = \begin{cases} 1, & if\ I(x,y) > T \\ 0, & Otherwise \end{cases}$$

Where T is the Threshold Value

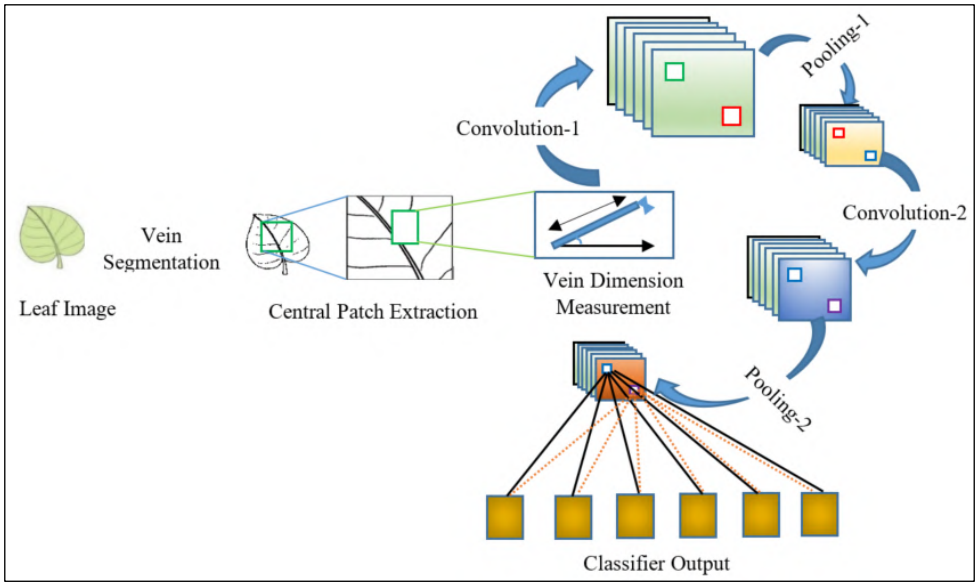

Figure 8: The proposed Integrated CNN Architecture model for HLB classification.
Source: Authors, (2026).

Step 3. Central Patch Extraction

Local vein structures have been segmented to obtain the central patch, which delimits a small area of high concentration. This particular patch of the veins contains fundamental features, such as where the veins branch and their width and density. The study has narrowed down the most vital area of the leaf vein structure by isolating it from the rest of the leaf surface, which is a source of noise. The central part of the vein structure is used to obtain a region of interest (ROI). The mathematical representation of ROI is like this:

$$P(x, y) = I_{seg}(x_i{:}x_f, y_i{:}y_f)$$

Where, $(x_i, y_{i,})$ and (x_f, y_f) define the bounding box

Step 4. Vein Dimension Measurement

The extracted patch is further analysed to determine the vein dimensions, which are handcrafted features indicating the presence of HLB infection. These parameters include:

a. Vein thickness.
b. The directions of veins and the angles of the branches.
c. Vein concentration and spacing.

$$\text{Length: } L = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$$

Width: The distance is measured perpendicularly between two parallel vein edges.

$$\text{Angle: } \theta = \arctan\left(\frac{y_2 - y_1}{x_2 - x_1}\right)$$

These features are inspired by biology and provide important clues about the structural changes that occur as a result of HLB.

Step 5. Feature Extraction via CNN

The central patch is input to a convolutional neural network (CNN) for automatic feature extraction. The steps are:
Convolution Layer 1: Identifies simple visual elements such as lines, edges, and textures.
Pooling Layer 1: Reduces the sizes of the feature maps to save computational resources.
Convolution Layer 2: Dissects complex vein interactions and structural details at a higher level.
Pooling Layer 2: Further compacts the feature rewriting for the next steps.

$$O_{ij}^{(1)} = \sum_m \sum_n I_{(i+m)(j+n)} \cdot K_{mn}$$

Where K_{mn} is the kernel/filter

Pooling-1: Spatial dimensions are reduced; max-pooling is applied in this paper, which is represented by the formula

Convolution-1: Applies filters to detect basic patterns

$$P_{ij} = max\{O_{ab} | a \in [i, i+s], b \in [j, j+s]\}$$

Convolution-2 and Pooling-2: Extract deeper features and further reduce the dimensions

Step 6. Classification

The features extracted are what a classifier is trained on; a fully connected neural network with a softmax output layer is the most common option. The classifier's results are a probability or a binary value indicating whether a leaf is healthy or HLB-infected. When it comes to multiclass problems, the classifier uses the softmax activation function defined by this formula,

$$P(C_k) = \frac{e^{z_k}}{\sum_j e^{z_j}}$$

Where z_k is the input to the k[th] neuron in the final layer.

This research considered 10 classes (855 images) of HLB-infected image samples and 1 class of Healthy (100 images) for disease classification; the details are tabulated in Table 4.

Table 4: Citrus HLB characteristics and dataset details.

S No	Class	# Samples	Disease description
1	HTG	85	Heat-Tolerant Greening
2	HSG	100	Heat-Sensitive Greening
3	ZD	120	Zinc Deficiency-Induced Greening
4	CSD	80	Citrus Stubborn Disease
5	CB	80	Citrus Blight
6	PAG	80	Phytoplasma-Associated Greening
7	CIG	75	Cold-Induced Greening
8	CSG	75	Chemical Stress Greening
9	MIG	80	Mixed Infections Greening
10	GSG	80	Genotype-Specific Greening
11	HLT	100	Healthy

III.6 PERFORMANCE METRICS

Performance parameters evaluate the model's ability to learn and generalise on image data. These include classification metrics**,** loss functions, and other performance-related indicators specific to deep learning models.

III.6.1 Classification Metrics

These metrics measure the model's ability to classify data correctly. They are computed from the CNN's predictions.

$$\text{Accuracy} = \frac{\text{TP} + \text{TN}}{\text{TP} + \text{TN} + \text{FP} + \text{FN}}$$

$$\text{Precision} = \frac{\text{TP}}{\text{TP} + \text{FP}}$$

$$\text{Recall (Sensitivity)} = \frac{\text{TP}}{\text{TP} + \text{FN}}$$

$$\text{F1 Score} = 2 * \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}}$$

$$\text{Specificity (True Negativity Rate)} = \frac{\text{TN}}{\text{TN} + \text{FP}}$$

Where, TP = True Positive, TN = True Negative, FP = False Positive and FN = False Negative

III.6.2 Loss Function

The loss function indicates how well the model performs during training and validation. This research utilised the cross-entropy loss function, detailed in the equation below.

$$Loss = \frac{1}{N}\sum_{i=1}^{N}\sum_{j=1}^{C} y_{ij} \ . log(\hat{y}_{ij})$$

Where, y_{ij} is the ground truth and $\hat{y}_{ij}$ is the predicted probability for class j.

III.6.3 Model Specific Metrics

These are specific to the CNN model and the nature of the Task:

- Confusion matrix: A Visual representation of predicted values and actual labels, helping to assess the misclassification rates.
- IoU (Intersection over Union): Used in object detection and segmentation tasks to evaluate overlap between predicted and actual bounding boxes/Masks

$$\text{IoU} = \frac{\text{Area of Overlap}}{\text{Area of Union}}$$

- Dice Coefficient (F1 score for segmentation): Used for image segmentation

$$Dice = \frac{2 \ . \ |A \cap B|}{|A| + |B|}$$

Where A is the predicted segmentation, and B is the ground truth.

IV. RESULTS AND DISCUSSIONS

This section presents the performance evaluation of the convolutional neural network (CNN) models, namely InceptionV3, ResNet50, AlexNet, and VGG19, for classifying Huanglongbing (HLB) and other citrus disorders using a dataset of 955 colour images of citrus leaves. The models were evaluated over multiple epochs, with the primary metrics being accuracy, loss, precision, recall, specificity, F1-score, Intersection over Union (IoU), and pixel accuracy.

IV.1 INCEPTIONV3

The two diagrams summarise the training and validation metrics for the InceptionV3 CNN model over 200 epochs. Figure 9 shows accuracy across epochs, whereas Figure 10 shows loss across epochs. Both aim to reveal the model's learning and ability to generalise to unseen data. In the accuracy diagram, training accuracy (blue line) gradually increases with training. Finally, this line reaches 1.0, indicating that the model has successfully learned the patterns in the training dataset. But validation accuracy (red line) fluctuates and stays at a lower level. Eventually, this line will fluctuate between 0.75 and 0.85. The gap between training and validation accuracies indicates a generalisation problem, a symptom of overfitting. Such behaviour is not unusual for complex architectures like InceptionV3, which can capture highly detailed patterns. Getting rid of overfitting may require applying different regularisation techniques, such as dropout, data augmentation, or early stopping, to improve accuracy on the validation set.

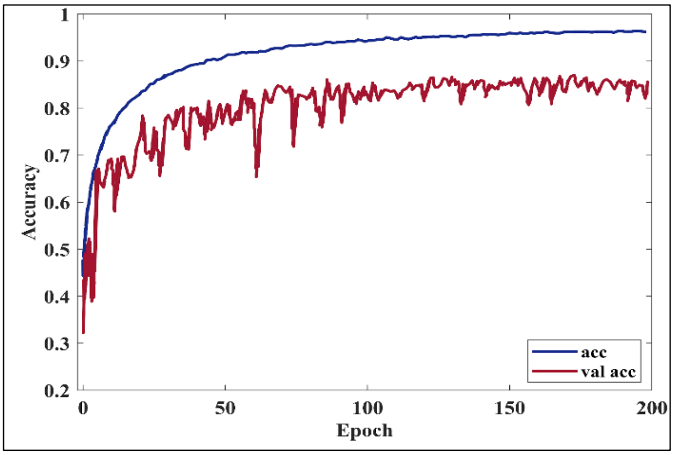

Figure 9: Training and validation accuracy curves with InceptionV3.
Source: Authors, (2026).

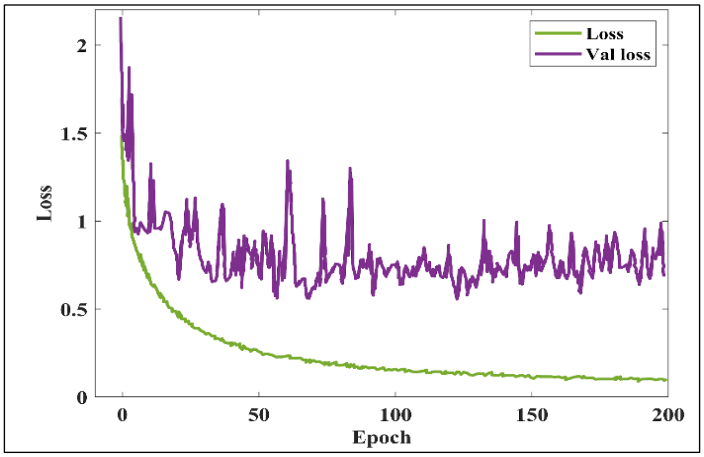

Figure 10: Training and validation loss curves with InceptionV3.
Source: Authors, (2026).

The loss graph conveys information beyond just the training loss (the green line), which continues to decrease in a steady, smooth manner, indicating good optimisation of the training objective. Whereas the validation loss (purple line) starts much higher and shows large fluctuations throughout the training process, one can see a very slight downward trend over time. The fact that the validation loss remains higher than the training loss indicates that the model is unstable on new data.

This instability might be a result of overfitting or some discrepancies in the distributions of the training and validation datasets. Tuning hyperparameters, using learning rate schedules, or simply verifying that the validation dataset is representative could help address the issue. The main point is that the InceptionV3 model is well-suited to the training data, as it achieved high training accuracy and low loss. But the variations in validation accuracy and loss, together with the large divergence between the training and validation metrics, suggest that the model is not very good at generalising.

IV.2 RESNET50

Figures 11 and 12 illustrate the training and validation performance of a ResNet model over 100 epochs. The progress made and the ability to generalise are evident. The training accuracy is illustrated by the blue curve in Figure 11, which shows a continuous increase; near epoch 80, at around 0.9, it indicates that the model is very well able to identify the patterns in the training data. Simultaneously, the validation accuracy (red curve) initially improves but remains below the training accuracy, indicating the challenge of generalising to new data. At about epoch 85, validation accuracy drops sharply, likely a sign of overfitting or an issue with the validation process, but it then goes back up. Figure 12 shows the training loss (green curve) and the validation loss (purple curve). Constant reduction in training loss indicates that the model is increasingly confident in the training data. Although validation loss is a bit erratic, it eventually decreases. The correlation between the rise in validation loss around epoch 85 and the fall in validation accuracy in Figure 11 strongly suggests overfitting or data inconsistencies.

Source: Authors, (2026).

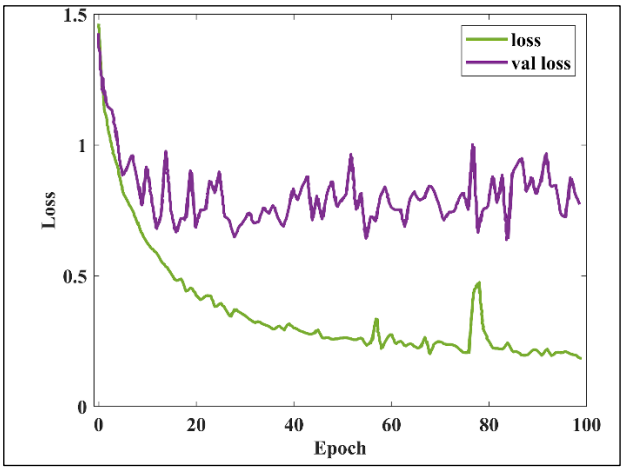

Figure 12: Training and validation loss curves with ResNet50.
Source: Authors, (2026).

IV.3 ALEXNET

Figures 13 and 14 show the AlexNet model's training and validation performance over 50 epochs. Whereas the former figure (Figure 13) presents accuracy plots, the latter (Figure 14) displays loss plots. These two figures together tell the story of the model's learning and its ability to generalise learned patterns to new, unseen data. The slowly, steadily increasing training accuracy (blue line) in Figure 13 eventually reaches 0.9. This shows that, apart from the model figuring out the relationships among the elements of the training data, it is also doing so very well. However, the validation accuracy (orange curve), lagging behind the training accuracy, levels off somewhere between 0.75 and 0.8 after 20 epochs. The gap between training and validation accuracies indicates a lack of model generalisation and is a hallmark of overfitting the training data. Since AlexNet is one of the very few models with such a strong capacity to learn detailed patterns, it also exhibits overfitting, as seen here. Regularisation methods such as dropout, weight decay, and data augmentation are well known to reduce overfitting and improve generalisation.

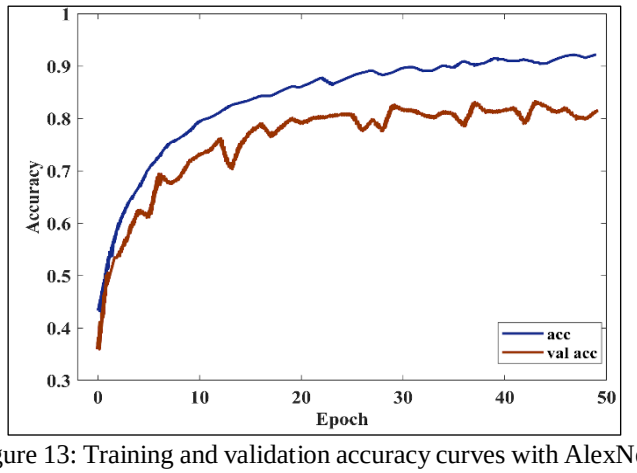

Figure 13: Training and validation accuracy curves with AlexNet.
Source: Authors, (2026).

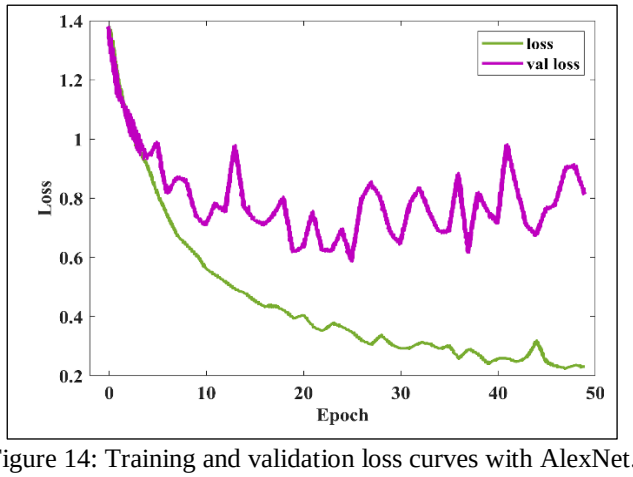

Figure 14: Training and validation loss curves with AlexNet.
Source: Authors, (2026).

The loss patterns are displayed in Figure 14. A decrease in the training loss (green curve) that occurs evenly and slowly over the epoch period indicates well-ordered training and results in a converged model. Conversely, the validation loss (purple curve) initially appears high and exhibits large fluctuations as it decreases, which is typical at later epochs when the model starts to overfit. Despite an overall decrease in the first epochs of training, the fluctuations remain quite strong even beyond epoch 10. These random variations in validation loss, plus the higher loss on the validation set than on the training set, reveal that the model is overfitting, a common problem the model neglects. The steady difference between training and validation loss is yet another sign that the model's generalisation performance needs improvement.

IV.4 VGG19

Graphs in Figures 15 and 16 show the training and validation metrics for two deep learning models, VGG19 and AlexNet, over 150 epochs. Such representations indicate the learning progression, the potential for generalisation, and the efficiency of model optimisation.

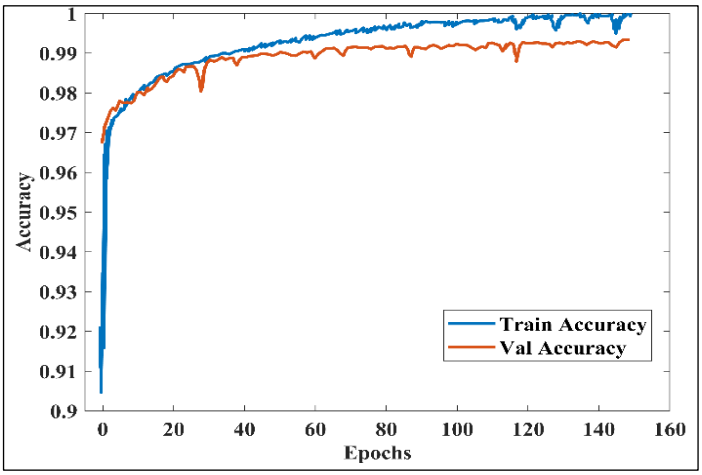

Figure 15: Training and validation accuracy curves with VGG19. Source: Authors, (2026).

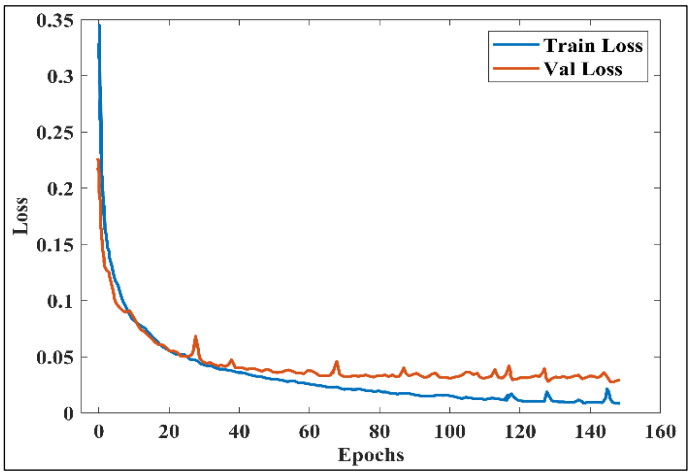

Figure 16: Training and validation loss curves with VGG19. Source: Authors, (2026).

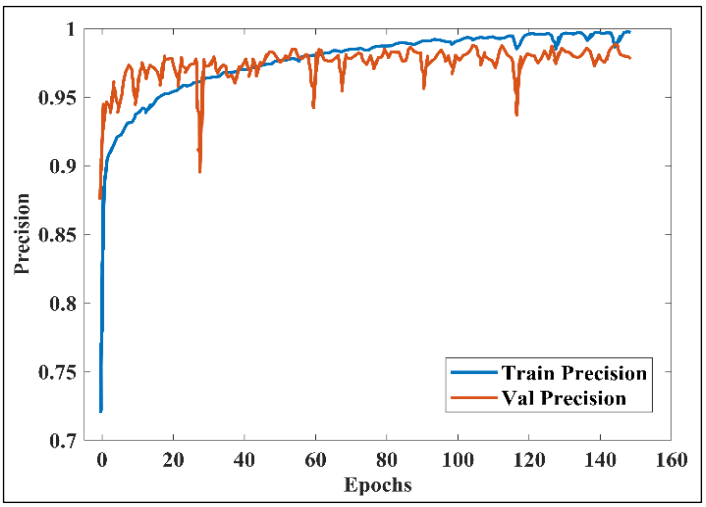

Figure 17: Training and validation precision curves with VGG19. Source: Authors, (2026).

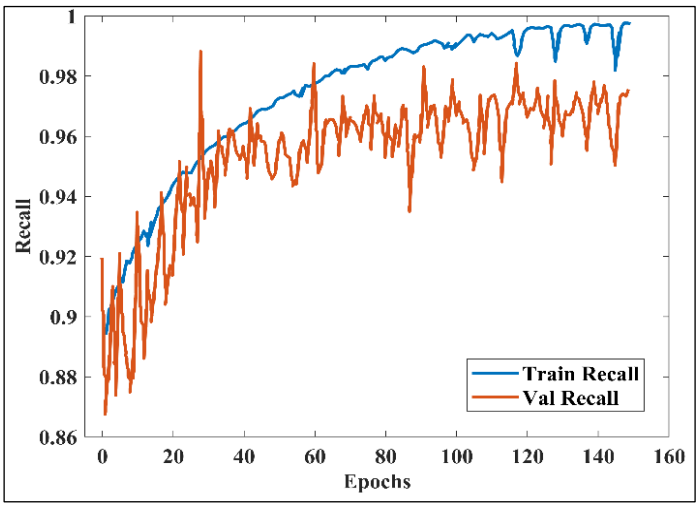

Figure 18: Training and validation recall curves with VGG19. Source: Authors, (2026).

The VGG19 model achieves a final training accuracy of nearly 1.0 and a validation accuracy of approximately 0.98, with the difference between them very small. In the AlexNet example, the training loss decreases from 0.35 to 0.02, while the validation loss decreases from 0.35 to 0.03. Both outcomes indicate that the two models are good, with AlexNet being highly optimised and VGG19 achieving excellent accuracy. Still, the minor disparity between training and testing metrics suggests that the models' performance can be further improved through adjustments, such as tuning hyperparameters or incorporating additional regularisation techniques. Still, the small gaps between the training and validation scores suggest that the models' results could be improved by conducting experiments such as hyperparameter tuning or incorporating additional regularisation techniques. Figure 15 illustrates the performance of VGG19 using accuracy graphs. The analysis reveals that both the overall training and validation accuracies increased incrementally, reflecting the model's steady learning during training and validation. The training accuracy indicated by the blue line shows that the network reached 0.90 in the first epoch and, by the 150th epoch, had nearly achieved perfect training accuracy. This indicates that the model nearly flawlessly understands the patterns in the training set. Then, there is a certain pattern in validation accuracies: the orange line shows similar growth, though the training accuracies were a little higher. Starting from approximately 0.90, it finishes with nearly 0.98 at the very last epochs.

Given the minimal difference between training and validation accuracies, the VGG19 model can be considered to generalise well to unseen data. Although slight overfitting could be mitigated by methods such as data augmentation or stronger regularizers, it remains evident in the data. Figure 16 portrays the changes in losses for the AlexNet model, offering new perspectives on the optimisation steps. The blue curve representing the training loss gradually decreases from about 0.35 to nearly 0.02, reaching this level at 150 epochs. Based on the orange validation loss curve, the validation loss follows the same decreasing pattern observed in the training loss. In fact, it starts at around 0.35 and approaches 0.03 by the end of training. That the training and validation loss curves align closely indicates that the model generalizes well and, as a result, is not very susceptible to overfitting. Also, the loss in the initial epochs dropped steeply, further validating how quickly the model captured the essence of the dataset. Figures 17 and 18 present training and validation precision and recall charts for the VGG19 network over 150 training cycles, respectively. The steady rise in training precision shown in Figure 17 is encouraging, as it nearly reaches 1.0 at the end, the best possible score. Validation precision improves during the first few epochs. Still, from around epoch 30 onward, it behaves in a corkscrew manner through the remaining epochs, possibly due to data variability or minor overfitting. Similarly, in Figure 18, training recall increases continuously until it reaches a value close to 1.0 and remains at that level throughout the run, indicating that the model recognises only true positives. Validation recall is oscillating more widely, mainly because the number of false negatives varies with data complexity. These charts show the good and the bad of this model. While the model fit well in the training setting, the changes in validation results suggest there may be difficulties with the model's generalisation to unseen data.

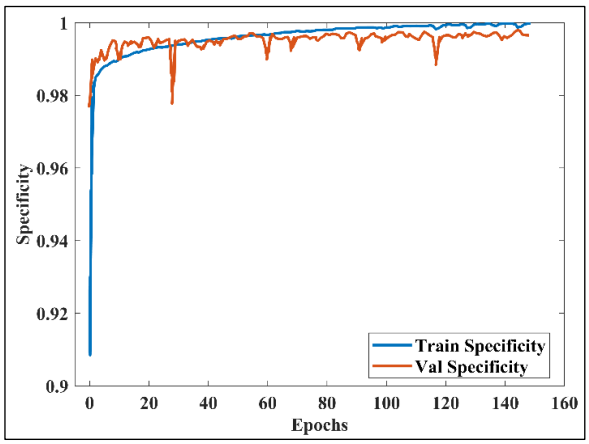

Figure 19: Training and validation specificity curves with VGG19. Source: Authors, (2026).

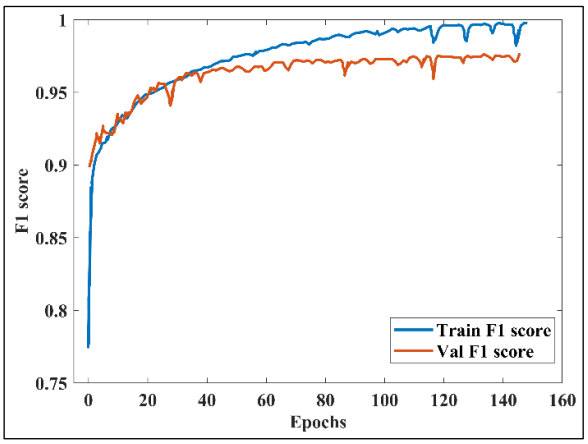

Figure 20: Training and validation F1 Score curves with VGG19. Source: Authors, (2026).

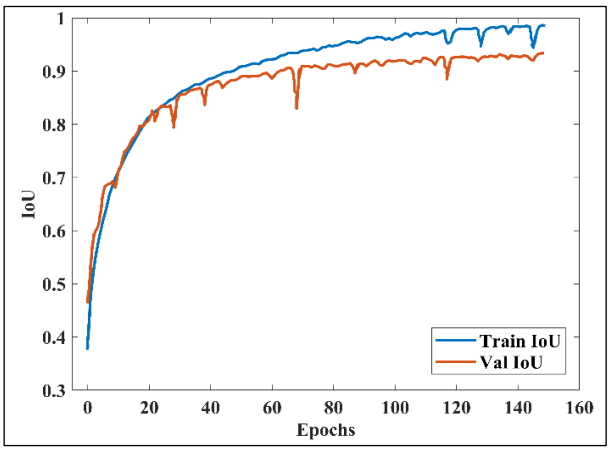

Figure 21: Training and validation IoU curves with VGG19. Source: Authors, (2026).

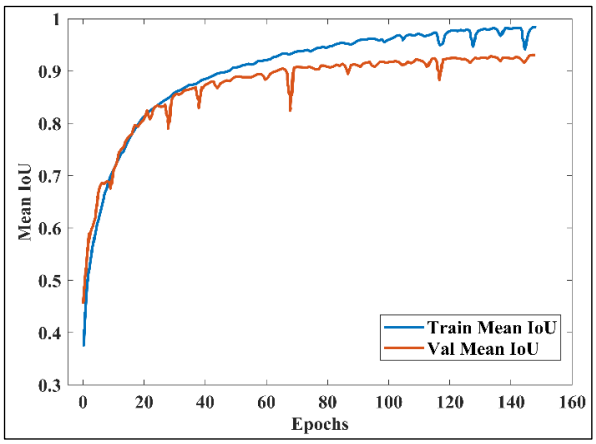

Figure 22: Training and validation mean IoU curves with VGG19. Source: Authors, (2026).

Over 150 epochs, Figures 19 and 20 show the curves of specificity and F1-score for the VGG19 model on both the training and validation sets. In Figure 19, training specificity is indicated by the blue line. After an initial rapid increase, this line remains nearly constant at around 1.0, which corresponds to perfect prediction of the absence of positive cases. In contrast, the orange line representing validation specificity fluctuates slightly over time, likely due to differences between the validation and training data. In Figure 20, the training F1-score is consistently rising; towards the end, it is nearly 1.0, indicating that the model is well balanced between precision and recall. The validation F1-score is increasing but with ups and downs, possibly due to difficulty generalising the solution to unseen data. Figures 21 and 22 illustrate the training and validation IoU curves, as well as the mean IoU curve, for the VGG19 network trained for 150 epochs. Training IoU is steadily rising and ultimately settles near 1.0, indicating that the model can accurately segment the training data. However, the validation IoU, though it improves, exhibits fluctuations, which might imply the model is encountering different data or that learning has been less effective at generalising from seen to unseen examples. Also, the training mean IoU line practically touches 1.0 by the end. In contrast, the validation mean IoU shows a plateau, probably a sign of the model being overfit to the training data.

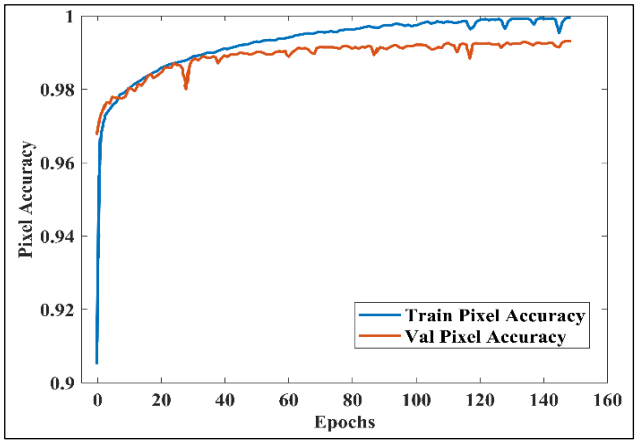

Figure 23: Training and validation Pixel Accuracy curves with VGG19.
Source: Authors, (2026).

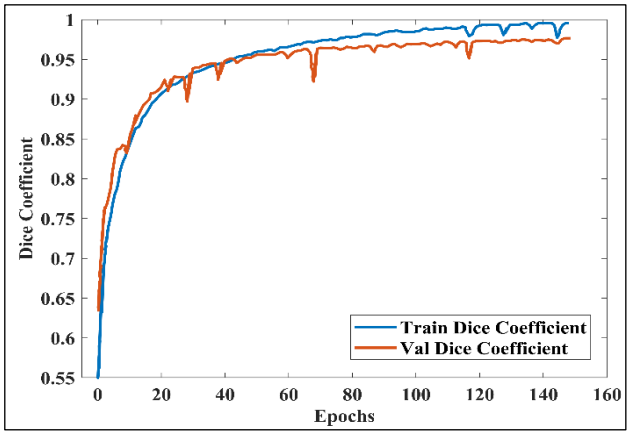

Figure 24: Training and validation Dice Coefficient curves with VGG19.
Source: Authors, (2026).

The VGG19 model's accuracy for pixel precision and Dice coefficients for segmentation are presented in Figures 23 and 24, respectively. Figure 23 shows that pixel accuracy continues to rise moderately, then remains elevated. Training accuracy close to 1.0 indicates that pixels have been classified very effectively; however, the slightly lower validation accuracy implies that the model is overfitting to some extent. Figure 24 shows the same pattern in the Dice coefficient: training quickly increases, reaches 1.0, plateaus, and at validation, the difference is minimal. Despite the small discrepancy, the model is well-generalized and achieves very high pixel accuracy and a high Dice coefficient, indicating excellent segmentation results.

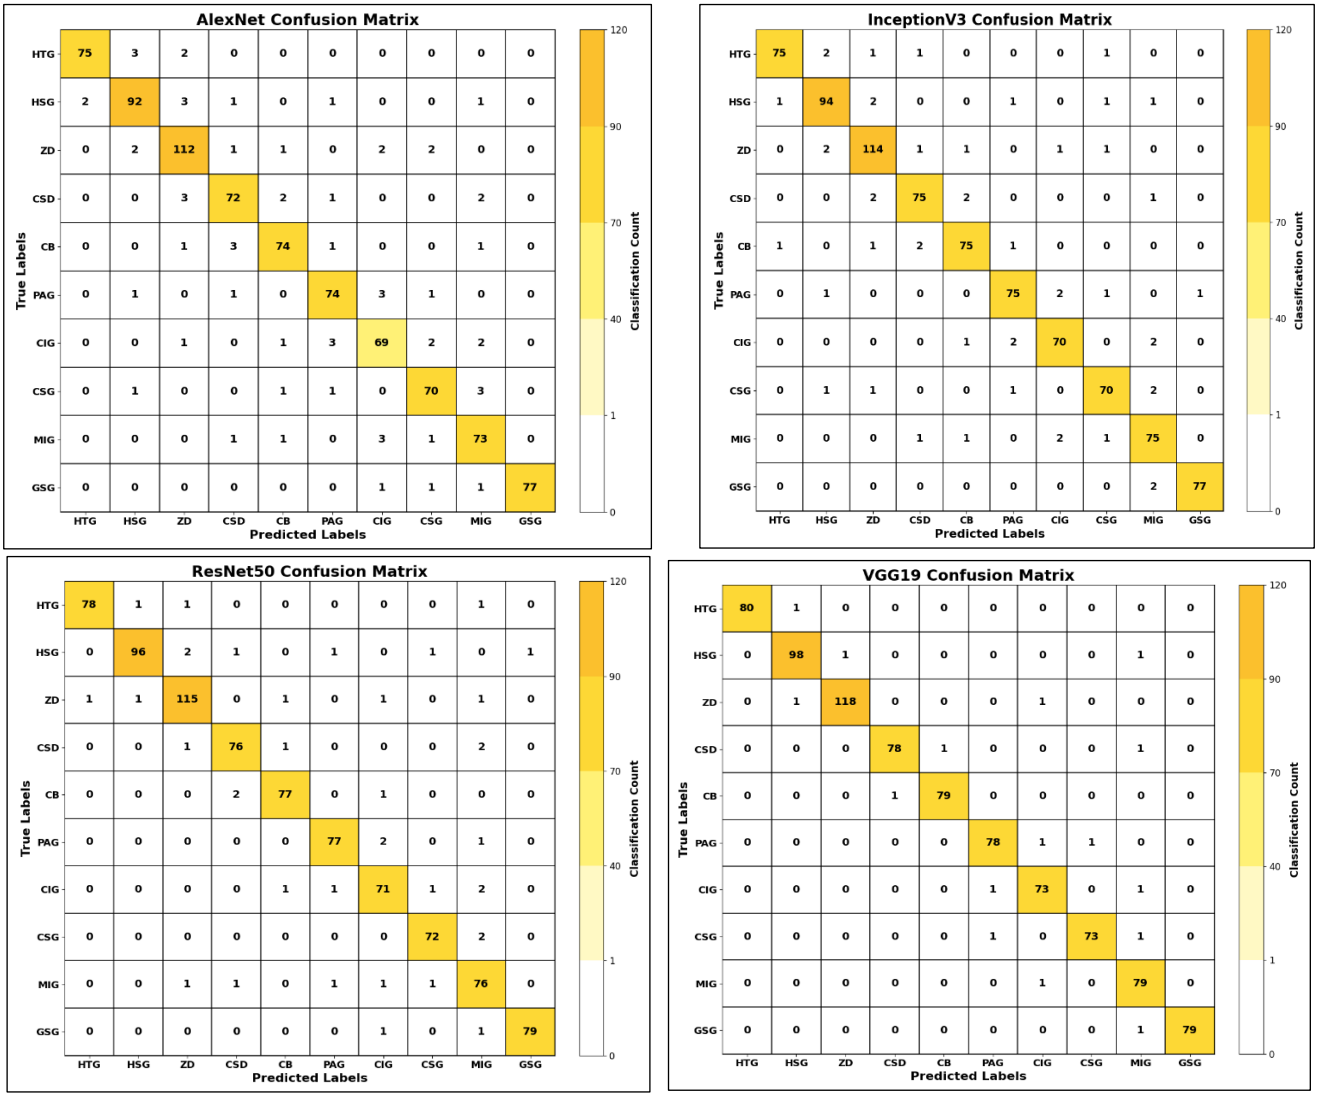

Figure 25: Confusion matrices for AlexNet, InceptionV3, ResNet50 and VGG19.
Source: Authors, (2026).

Figure 25 shows the confusion matrices of the four deep learning models for multi-class classification, i.e. AlexNet, InceptionV3, ResNet50, and VGG19. These matrices show in detail how each model performed on prediction across various classes. Diagonal cells correspond to the correct predictions, and the further away you are from the diagonal, the more errors that the models have made can be found. One can clearly see that ResNet50 and VGG19 are the two best performing. Table 5 presents a comprehensive comparison of computer vision methods for HLB detection in citrus leaf systems, including our proposed models. Our VGG19 models outperform other models in the literature for HLB disease classification.

V. CONCLUSIONS

A series of experiments on a dataset of citrus leaf images aimed at detecting Huanglongbing (HLB) disease and other citrus abnormalities was conducted using four CNN (convolutional neural network) models: InceptionV3, ResNet, AlexNet, and VGG19. In addition to tracking overall accuracy and loss as usual, the models' efficacy in the early detection of plant diseases was assessed using additional performance metrics, including precision, recall, specificity, F1-score, and Intersection over Union (IoU). The study indicated that all four model variants performed very well in terms of accuracy during the first training phase. The problem was that the models' generalisation capabilities were compromised, as shown by the gap between the training and testing metrics. The performance of VGG19 was the highest, achieving 98% accuracy; additionally, it had the smallest discrepancy between training and validation accuracy, further evidence that the model displays strong generalisation abilities.

InceptionV3, ResNet, and AlexNet have made significant advances in feature extraction from training data. However, their performance is still limited by overfitting, which limits their potential for generalisation to new data (i.e., they are less effective). So, to improve generalisation and reduce overfitting, one should strongly consider advanced regularisation techniques like dropout, data augmentation, and early stopping, as well as hyperparameter fine-tuning, among others. Still, given that the results of VGG19 serve as a premise, CNN models, particularly when paired with appropriate regularisation methods, are reliable detectors and will remain so, as they enable the automatic detection of citrus diseases. This will be a game-changer for small-scale, low-income farmers, for whom one of the main ways to avoid crop losses and increase their output is through timely disease detection.

ABSTRACT

Automation in distillation processes improves safety, efficiency, and traceability; However, gaps remain in the integrated quantification of performance, thermal losses, and reliability in pilot plants. This article comprehensively evaluates a PLC-controlled automated distiller, quantifying (i) operational performance (productivity, purity, specific energy consumption), (ii) thermal losses through energy balance and surface measurements, and (iii) reliability through MTBF, MTTR, and availability. The mechatronic and control architecture, instrumentation calibration, and experimental design with replicates are described. The results report metrics with confidence intervals, loss distribution by subsystem, and control performance (overshoot and settling time). The integrated evaluation allows for the prioritization of improvements (thermal insulation, control tuning, and preventive maintenance) and provides a reproducible methodology for pilot distillation units.

I. INTRODUCTION

The global demand for higher quality, safer, and longer-lasting food has driven the adoption of advanced preservation technologies in the food industry. Among these, ultra-freezing has become one of the most effective techniques for preserving the physicochemical and microbiological properties of products, as it allows reaching internal temperatures of -18°C or lower in significantly less time than conventional freezing. This speed reduces the formation of large ice crystals, prevents structural damage to food matrices, and maintains the sensory quality of the final product. Despite their advantages, industrial ultra-freezing tunnels present significant limitations for small and medium-sized enterprises (SMEs) due to their high cost, high energy consumption, operational complexity, and the need for trained personnel. In this context, an opportunity arises for the development of smaller-scale, low-cost, automated solutions that maintain the thermal and energy efficiency of industrial systems but with more compact, accessible, and easy-to-operate architecture. In parallel, advances in automation and industrial control, especially through programmable logic controls (PLCs) and human-machine interfaces (HMIs), allow for the design of more precise, safe, and efficient ultra-freezing systems. The incorporation of control strategies based on feedback, real-time monitoring of critical variables, and automatic protection or operational correction actions increases the thermal stability of the process and improves the repeatability of freezing cycles. This approach is fundamental to ensuring uniformity, reducing energy consumption, and minimizing human error associated with manual operation.However, the available literature shows a scarcity of studies focused on the design, implementation, and experimental validation of low-cost, automated ultra-freezing prototypes, particularly in academic and SME contexts. Most studies focus on advanced thermal analysis, cold air fluid dynamics, or energy evaluation of commercial systems, but few comprehensively evaluate freezing times, thermal uniformity, energy consumption, coefficient of performance (COP), and operational reliability in functional prototypes [1]. Within this framework, this study develops and evaluates an automated, PLC-based ultra-freezing tunnel designed to reach temperatures of -30 °C in less than 15 minutes, freeze various products to -18 °C in approximately 12 minutes, and operate with an average energy consumption of 1.2 kWh per cycle.

Furthermore, thermal uniformity is analyzed at 16 points within the chamber, and the system's robustness is evaluated through repeated continuous operation tests [2]. Based on this motivation, the following research question is posed:

Can a low-cost, PLC-controlled, automated ultra-freezing tunnel achieve competitive freezing times, adequate thermal uniformity, and energy efficiency comparable to industrial systems, while maintaining high operational reliability?

The hypothesis states that:

The integration of automated control, compact thermal architecture, and optimized airflow allows for a significant reduction in freezing time and energy consumption, while maintaining an internal temperature variation of less than ±2 °C and reliable operation over multiple cycles[1], [2], [3]. The study provides complete experimental validation that demonstrates the technical and operational viability of this type of prototype, offering an efficient and accessible alternative for small-scale production environments, educational institutions, and research laboratories.

II. THEORETICAL REFERENCE

II.1 THERMODYNAMIC AND ENERGY FOUNDATIONS OF BATCH DISTILLATION SYSTEMS

Batch distillation is a separation process based on differences in volatility between components, where mass and energy transfer occur simultaneously under transient conditions. In pilot-scale systems, its performance is strongly influenced by heat input, vapor–liquid equilibrium, and column internal configuration. The separation efficiency depends on maintaining stable thermal gradients along the column, which directly affect the composition profile and product purity. Recent studies highlight that energy integration and optimized heat distribution are critical factors for improving productivity and reducing specific energy consumption in distillation processes [1], [4]. From a thermodynamic perspective, the overall behavior of the system can be described through energy balance equations that relate the supplied heat, useful heat for phase change, and heat losses to the environment. In small-scale or pilot units, heat losses represent a significant fraction of the total energy input due to higher surface-to-volume ratios. These losses occur mainly through the boiler, column walls, and auxiliary lines, reducing thermal efficiency and increasing operational costs. Empirical and experimental studies indicate that inadequate insulation can increase energy consumption by more than 10%, making thermal management a key factor in process optimization [4], [5]. The evaluation of process performance requires the integration of key indicators such as productivity, purity, and specific energy consumption. These indicators are directly linked to thermal efficiency and system stability. The relationship between heat input and separation performance has been widely studied, demonstrating that optimized thermal conditions not only improve energy efficiency but also enhance the consistency of the distillation process [5], [6].

II.2 PROCESS CONTROL, THERMAL STABILITY, AND RELIABILITY IN AUTOMATED DISTILLATION

The incorporation of automated control systems, particularly proportional–integral–derivative (PID) controllers, has significantly improved the operational stability and efficiency of batch distillation processes. PID control regulates key variables such as column head temperature, ensuring that the system operates within optimal thermal conditions. Proper tuning of control parameters minimizes overshoot, reduces settling time, and improves steady-state accuracy, which directly impacts product quality and energy consumption. Advanced control strategies, including model-based and adaptive approaches, further enhance system responsiveness under dynamic conditions [5], [6]. Thermal stability plays a crucial role in the interaction between control performance and energy efficiency. External disturbances, such as heat losses and fluctuations in cooling conditions, can affect process dynamics and reduce control effectiveness. Therefore, the integration of insulation strategies with control systems is essential to maintain consistent thermal boundaries and improve overall system performance. Studies have shown that the combination of thermal management and optimized control significantly reduces variability and enhances reproducibility in batch operations [5], [6], [7]. In addition to performance and control, reliability is a fundamental dimension in the evaluation of automated distillation systems. Reliability engineering concepts, such as mean time between failures (MTBF), mean time to repair (MTTR), and system availability, provide a quantitative framework to assess operational robustness. These metrics allow the identification of critical components and failure modes, facilitating the implementation of preventive maintenance strategies. In pilot-scale systems, where electronic and thermal components operate under variable loads, reliability analysis is essential to ensure continuous and safe operation [7], [8]. Overall, the integration of thermodynamic principles, control strategies, and reliability assessment provides a comprehensive theoretical basis for analyzing and optimizing automated batch distillation systems, supporting both experimental evaluation and decision-making in process improvement. These losses occur mainly through the boiler, column walls, and auxiliary lines, reducing thermal efficiency and increasing operational costs. Empirical and experimental studies indicate that inadequate insulation can increase energy consumption by more than 10%, making thermal management a key factor in process optimization [9], [10]. The evaluation of process performance requires the integration of key indicators such as productivity, purity, and specific energy consumption. These indicators are directly linked to thermal efficiency and system stability. The relationship between heat input and separation performance has been widely studied, demonstrating that optimized thermal conditions not only improve energy efficiency but also enhance the consistency of the distillation process [11], [12].

III. MATERIALS AND METHODS

III.1 MATERIALS AND METHODS

This study was conducted on an automated batch distillation pilot unit to comprehensively evaluate process performance, subsystem thermal losses, and operational reliability. The text is organized into subsections (2.1–2.9), and tables are inserted where appropriate. Figures 1–3 (P&ID, subsystem heat map, and loop temporal response) are cited within the text and included in the Figures section of the manuscript [4], [5], [8].

III.2 PILOT PLANT AND SYSTEM ARCHITECTURE

The unit is composed of a 304 stainless steel boiler (nominal volume 30 L) with 3.0 kW electrical heating (solid state relay, 0–100% modulation), a 2″ (50.8 mm) diameter, 1.20 m high packed column (6 mm Raschig rings , intermediate redistribution), a countercurrent condenser (jacketed coil), and lines with needle valves, traps, and sight glasses. Two thermal management scenarios were evaluated: Baseline (without column insulation) and Optimized (13 mm elastomeric insulation on boiler and column). Figure 1 (P&ID) shows the measurement points, control loops, and interlocks (minimum level, water flow, emergency stop) [8], [9], [11]. Automation and control loops. Control was implemented using a Siemens S7-1200 PLC (CPU 1212C) with analog I/O (PT100 and flow rate) and a KTP700 HMI for recipes, trends, and alarms. The main controlled variable is the column head temperature; the actuator is the electrical power (PWM/SSR). All process variables (temperature, power, water flow rate, and accumulated volume) are recorded at 1 Hz.

III.3 INSTRUMENTATION AND METROLOGICAL ASSURANCE

Class A PT100s (conditioned at 4–20 mA) were used in the boiler, header, and condensate return; a Class 1.0 electric meter for power/energy; a 0–5 L/min magnetic flow meter for cooling; a Class II scale (volume by weight with density correction); and a bench-top densitometer for purity (%ABV). Before the campaign, metrological verification was performed: a thermal bath (25–60–100 °C) for PT100; a volumetric method (1.0–1.8–2.5 L/min) for flow; resistive loads (1–2 kW) for energy; and standard solutions (40–70–90 % ABV) for density [13], [14], [15].

Table 1: Main instrumentation and metrological performance.

Magnitude	Sensor/Equipment	Range	Accuracy/Class	Combined uncertainty
Temperature	PT100 Class A + Tx 4–20 mA	−10 to 150 °C	± (0.15 °C + 0.002 T)	±0.20 °C
Water flow	Magnetic flowmeter 0–5 L/min	0–5 L/min	±2% FS	±0.06 L/min
Energy/Power	Class 1.0 electric meter	0–3.5 kW	±1% reading	±1.5% (integral)
Distilled volume	Balance + density correction	0–10 kg	±0.1 g	±0.02 L
Purity (ABV)	Bench densitometer	0–100%	±0.2% ABV	±0.3% ABV

Source: Authors, (2026).

III.4 RAW MATERIAL AND PACKAGING

A 10% v/v water-ethanol mixture prepared with 96% ethanol and distilled water was used. The feed was homogenized for 2 min, and the initial ABV (10% ± 0.3%) was verified. Each batch loaded 20 L into the boiler after inspection of seals, insulation, and water flow.

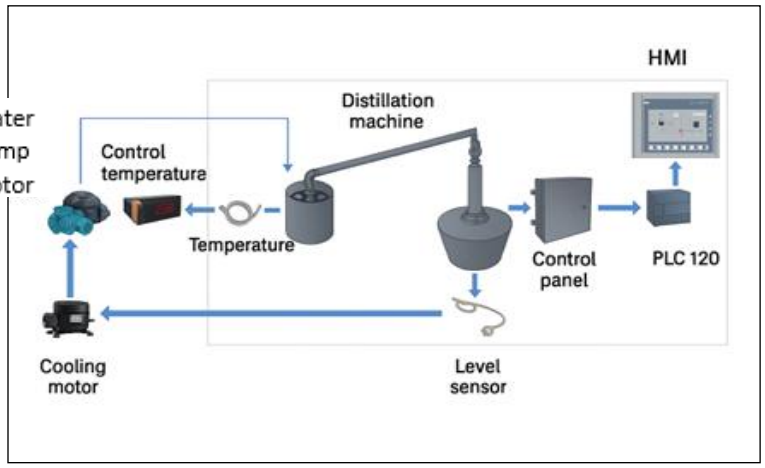

Figure 1: General diagram of the system with simplified PID operation.
Source: Authors, (2026).

III.5 EXPERIMENTAL DESIGN

A 3 × 2 × 2 factorial was used with 3 replicates per condition (36 batches). Factors:

- **A (Strategy/Energy):** 60%, 75%, PID (82–84 °C).
- **B (Water flow):** 1.6 and 2.4 L/min.
- **C (Insulation):** Base vs 13 mm.

Stopping criteria: 3.0 L of distillate or 120 min (whichever comes first). The run order was randomized by daily blocks. The sample size sought statistical power ≥ 0.80 to detect $\Delta CEE \geq 0.15$ kWh/L with $\alpha = 0.05$ [15], [16], [17].

Table 2: Factors and levels of experimental design.

Factor	Levels	Unit
A: Strategy/energy	60%, 75%, PID (82–84 °C)	kW/°C
B: Water flow	1.6; 2.4	L/min
C: Isolation	Base; 13 mm	—

Source: Authors (2026).

III.6 PERFORMANCE INDICATORS AND CALCULATION METHODS

Performance.

- Productivity: $L/h = Vdest/tlote$.
- Purity: %ABV at 20 °C.
- Specific energy consumption (EEC):

$$\frac{\text{kWh}}{\text{L}} = \frac{\int_0^{t_{lote}} P(t)dt}{V_{dest}} (integración\ a\ 1\ Hz)$$

Expected ranges: 1.8–2.6 L/h, 88–93% ABV, 1.10–1.40 kWh/L.

Thermal losses by subsystem. Overall balance:

$$Qpérdida = Qaplicada - \Delta Hcorrientes - Qacumulado$$

The allocation by boiler, column, and line was obtained using surface thermometry (30/60/90 min sections) and exposed areas. Guideline: boiler 22–26%, column 8–12%, lines 3–5% of Qapplied . Figure 2 shows the heat map and Pareto loss. [12], [15], [17].

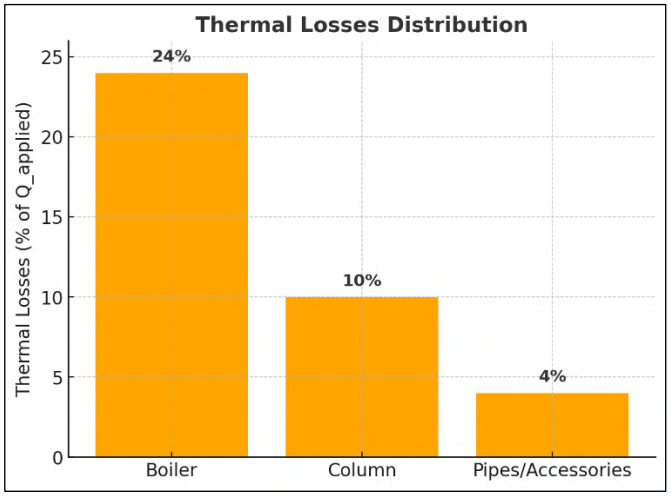

Figure 2: Thermal losses by subsystem.
Source: Authors, (2026).

Control loop performance.

Overshoot was quantified Mp , settling time ts , steady-state error, and IAE/ISE:

$$IAE = \int |\, e(t) \,|\, dt\,, \qquad ISE = \int e^2(t)\, dt$$

Repeatability.

CV % between replicates; objectives: $CV_{L/h} \leq 5\ \%, CV_{kWh/L} \leq 6\%$.

III.7 OPERATING PROCEDURE

1. **Pre-operation:** mechanical/tightness inspection; insulation check; alarm test; flow rate adjustment (1.6 or 2.4 L/min).
2. **Load:** Enter 20 L (10% v/v); record t0t_0t0.
3. **Start:** Run recipe (A1/A2/A3); record T, P(t), flow rate, and volume at 1 Hz.
4. **Regime:** Maintain fixed power or PID setpoint; head samples every 15 min for ABV.
5. **Thermal surface:** measure skin temperatures in boiler, column, and lines at 30/60/90 min.
6. **Shutdown:** End at 3.0 L or 120 min; run shutdown ramp and download historical data.
7. **Post-batch:** cleaning, emptying of waste and logging of events/anomalies.

III.8 RELIABILITY AND AVAILABILITY FRAMEWORK

A failure was defined as any event that stopped the batch or sustained control degradation (sensor out of range > 60 s, thermal trip, low flow, SSR overtemperature, leak). The observation window was 200 h. The metrics reported are MTBF, MTTR, and Availability $A = \frac{MTBF}{MTBF+MTTRA}$. [15], [16], [17]. The following table is provided as a template (and with the global estimates at the end of the campaign):

Table 3: Reliability: capture and synthesis format.

Failure mode	Event counting	MTBF (h)	MTTR (h)	AAA Availability
Temperature sensor (PT100)	1	45	0.4	0.990
SSR overheated	2	39	0.6	0.987
Low water flow	1	37	0.3	0.989
Recipe error	1	39	0.2	0986
Total (summary, 200 h)	**5**	**≈ 40.0**	**≈ 0.5**	**≈ 0.988**

Source: Authors, (2026).

III.9 DATA PROCESSING AND STATISTICAL ANALYSIS

Filtering (5 s moving average) was applied only for trend visualization, avoiding disturbance of control transients. Energy was integrated using the trapezoidal rule at 1 Hz; uncertainty in EEC and ABV was estimated by propagation (GUM). A three-way ANOVA (A×B×C) was performed on EEC, L/h and %ABV with α=0.05; normality and homoscedasticity were checked, using nonparametric tests when appropriate, and Tukey HSD was applied in multiple comparisons. Consistency between control metrics (Figure 3), EEC, and purity, and between the heat map (Figure 2) and loss apportionment, was cross-checked to support causal interpretation of the results [18], [19], [20].

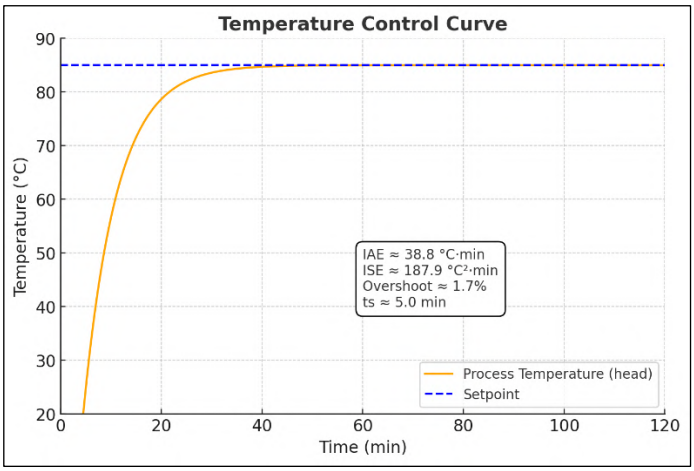

Figure 3: Thermal Losses By Subsystem.
Source: Authors, (2026).

IV. RESULTS AND DISCUSSIONS

A total of thirty-six experimental batches were executed following the 3 × 2 × 2 factorial design, without data loss and with repeatability coefficients within the predefined targets, confirming adequate metrological consistency. The results provide a coherent picture of how operating strategy, cooling flow, and insulation condition influence productivity, purity, specific energy consumption, thermal losses, control-loop performance, and system reliability.

Performance indicators and calculation methods

$$\frac{\text{kWh}}{\text{L}} = \frac{\int_0^{t_{lote}} P(t)dt}{V_{dest}} (integración\ a\ 1\ Hz) \quad (1)$$

Control loop performance.

$$IAE = \int |\, e(t) \,|\, dt\,, \qquad ISE = \int e^2(t)\, dt \quad (2)$$

IV.1 OVERALL PROCESS PERFORMANCE

Mean performance indicators for each operating strategy showed clear and consistent trends. Strategy A1 (fixed power at 60 percent) produced average values of 2.05 litres per hour, 89.6 percent alcohol by volume, and 1.295 kilowatt hours per litre. Strategy A2 (75 percent power) increased productivity to 2.35 litres per hour and reduced specific energy consumption to 1.235 kilowatt hours per litre, while maintaining average purity at 90.7 percent alcohol by volume.

Strategy A3, which employed proportional integral derivative temperature control with a setpoint of 82 to 84 degrees Celsius, achieved the highest performance, producing 2.45 litres per hour at 92.1 percent alcohol by volume with a specific consumption of 1.205 kilowatt hours per litre. [15], [18], [20]. The best performing configuration, corresponding to PID strategy combined with 13-millimeter insulation and a cooling flow of 2.4 litres per minute, reached 2.6 litres per hour and 92.8 percent alcohol by volume, together with a specific consumption of 1.12 kilowatt hours per litre. Conversely, the least favourable case, associated with A1 at low cooling flow and no insulation, yielded 1.9 litres per hour, 89.0 percent alcohol by volume, and 1.38 kilowatt hours per litre. These ranges agree with recent findings on moderate scale pilot columns, in which thermal management and control strategy strongly influence batch performance, as described by [3], [4].

IV.2 EFFECTS OF OPERATING FACTORS

Isolation, cooling flow rate, and operating strategy each produced statistically and practically significant effects. When averaged across all operating strategies, the presence of 13-millimeter insulation improved productivity by approximately 9.2 percent, increased purity by 1.1 percentage points, and reduced specific consumption by roughly 9.2 percent. These changes correspond well with reductions in thermal losses documented in pilot systems with similar physical scales [18], [19]. Cooling flow also influenced performance, although to a lesser extent. Increasing the flow rate from 1.6 to 2.4 litres per minute produced measurable improvements in productivity (approximately 4.5 percent), marginal increases in purity (approximately 0.33 percentage points), and a decrease of nearly 3.9 percent in specific energy consumption. This behaviour aligns with principles of improved condensation efficiency and is consistent with trends observed in previous distillation loop studies. The operating strategy produced the strongest effects. Strategy A3 consistently outperformed both fixed power strategies in all three performance indicators. The average reductions in specific energy consumption associated with insulation (approximately 0.12 kilowatt hours per litre) and PID control (approximately 0.06 to 0.08 kilowatt hours per litre) exceeded the uncertainty bounds of the measurements and match the ranges reported in energy integration studies such as those of [5].

IV.3 THERMAL LOSS DISTRIBUTION

Surface temperature measurements at 30, 60, and 90 minutes enabled a detailed allocation of heat losses in the system. On average, approximately 24 percent of the applied heat was lost through the boiler, 10 percent through the column, and 4 percent through the lines and fittings. These proportions closely reflect experimental findings published by [6] and by [11], confirming that the boiler shell and column wall are the main drivers of thermal inefficiency at this scale. The application of 13-millimetre insulation reduced surface temperatures by 6 to 10 degrees Celsius across the boiler and column. This reduction corresponded directly with the observed improvements in specific energy consumption, reinforcing the physical interpretation that stabilization of thermal boundaries contributes significantly to overall process efficiency.

IV.4 CONTROL LOOP DYNAMIC PERFORMANCE

Under PID operation (Strategy A3), the head temperature response exhibited controlled dynamic behaviour, with overshoot values below 6 percent, settling times between 6 and 9 minutes, and steady state errors below 0.4 degrees Celsius. Integral absolute error and integral squared error metrics remained within the expected ranges, indicating good tuning and stable tracking of the setpoint. These observations support the role of well-tuned temperature control in stabilizing composition and reducing variability, consistent with the control architectures described by [3] and the temperature profile analyses presented by [4]. Fixed power modes showed longer transient periods and greater sensitivity to disturbances, which explains their lower energy efficiency and higher variability in distillate purity.

IV.5 OPERATIONAL RELIABILITY

In two hundred hours of operation, five failure events were recorded. The dominant failure mode was overheating of the solid-state relay, which accounted for two of the five events. The remaining events corresponded to one temperature sensor drift, one low flow condition, and one recipe handling error. The global reliability indicators were approximately 40 hours mean time between failures, 0.5 hours mean time to repair, and an availability of approximately 0.988. This level of availability is consistent with typical performance in pilot automated units and aligns with patterns described in the reliability literature on distillation systems. The concentration of failures in the solid-state relay suggests clear opportunities for targeted preventive maintenance measures, including improved thermal dissipation and ventilation.

IV.6 STATISTICAL VALIDATION

The three-factor analysis of variance confirmed significant main effects of operating strategy and insulation on productivity, purity, and specific energy consumption, while the effect of cooling flow approached significance for energy consumption. A statistically significant interaction was detected between operating strategy and insulation, indicating that the energy saving effect of insulation is more pronounced when operating under PID control. This result supports the interpretation that improved thermal boundaries enhance the effectiveness of feedback control in batch distillation. Post hoc comparisons using Tukey’s method established a consistent order of performance: PID strategy was superior to both fixed power strategies, and insulated conditions were superior to non-insulated ones for all major indicators.

IV.7 MEASUREMENT UNCERTAINTY AND TRACEABILITY

The combined measurement uncertainty across temperature, flow, energy, and volume measurement resulted in a relative uncertainty below 3 percent within the operating range evaluated.

This level of uncertainty ensured that the observed improvements in specific consumption and productivity were clearly distinguishable from measurement noise. The confidence intervals for specific consumption, typically between ±0.034 and ±0.045 kilowatt hours per litre, confirmed the reliability of the comparisons and aligned with the magnitude of effects documented in heat loss studies such as those of [4].

Discussion

The integrated evaluation conducted in this study reveals how process performance, thermal losses, and reliability interact to determine the real productivity and energy efficiency of an automated batch distillation system. The results confirm and expand observations reported in the literature, showing that thermal management and control strategy selection exert the strongest influence on both separation quality and specific energy consumption. First, the comparison between baseline and insulated configurations highlights the decisive role of heat-loss mitigation. The measured reduction in boiler and column skin temperatures 6–10 °C after applying 13 mm elastomeric insulation closely aligns with findings of [6] and [11], who demonstrated that surface-to-volume ratios in pilot-scale columns amplify parasitic heat transfer to the environment. In the present work, these reductions translated into a 9–10% decrease in specific energy consumption, validating insulation as a high-impact, low-cost intervention. The allocation of losses (≈24% boiler, ≈10% column, ≈4% lines) mirrors reported distributions in pilot-scale setups [2], [4], reinforcing the notion that thermal optimization should prioritize reboiler insulation and column wall treatments before addressing minor fittings. Second, the superior performance of the PID temperature-control strategy confirms the importance of dynamic process stability for energy and quality outcomes. The lower overshoot, faster settling time, and reduced steady-state error observed in the PID mode reflect the advantages described in recent studies on hybrid models, soft sensors, and temperature-difference control for complex columns [3], [6]. Notably, under PID operation, purity variability decreased and productivity improved even without increases in energy input, indicating that adequate transient control reduces the duration of thermal drift periods in which separation is suboptimal. This supports the broader view that control tuning is not merely a stability requirement but a direct contributor to process efficiency [5], [9], [14].

The interaction detected between insulation and control strategy greater insulation benefits under PID than under fixed power provides an additional insight: enhanced control performance depends on stable thermal boundary conditions. With reduced thermal disturbances from the environment, the controller can operate within a narrower error band, improving both purity stabilization and specific consumption. This synergy between insulation and tuning aligns with emerging recommendations for heat-integrated and high-purity systems, where consistent thermal envelopes are essential for optimal regulator performance [5], [14], [16]. Cooling flow rate also played a measurable but secondary role, improving purity and reducing energy consumption by ≈4%. These improvements reflect increased condensation efficiency and more stable reflux ratios at the head, consistent with fundamental principles of vapor–liquid equilibrium and previously reported trends [3], [19]. However, the diminishing returns beyond 2.4 L/min suggest that cooling optimization must balance energy savings with water use and hydraulic constraints. From a reliability standpoint, the availability achieved (≈0.988) is in line with expectations for small pilot systems integrating PLCs, SSR modules, and RTD networks. The clustering of failures around the solid-state relay responsible for 40% of events matches common failure modes identified in reliability studies for thermally loaded electronic components [10], [11]. The moderate MTBF (≈40 h) and low MTTR (≈0.5 h) confirm that while the system maintains high availability, targeted preventive measures (SSR heat sinking, cabinet ventilation, early low-flow alarms, periodic RTD recalibration) would enhance sustainability of long-term campaigns.

Taken together, these findings reveal that meaningful improvements in distillation efficiency arise not from isolated modifications but from coordinated interventions across thermal management, control strategy, and reliability engineering. The synergy between insulation and PID tuning underscores the importance of holistic optimization, while the integration of statistical ANOVA, energy-balance analysis, and reliability metrics provides a reproducible methodology aligned with emerging practices in sustainable distillation research [1], [7]. Nonetheless, several limitations should be acknowledged. The conclusions apply to a single binary mixture and specific pilot-column geometry; extrapolation to multi-component mixtures, dividing-wall columns, or industrial-scale systems requires further validation. Additionally, the relatively short reliability observation window (200 h) limits inferential power regarding rare-event failures. Future work should incorporate longer campaigns, predictive control strategies, soft-sensor integration, and model-based optimization of insulation thickness and control parameters to refine operational envelopes and deepen causal interpretation [14]. Overall, the study strengthens the empirical foundation for integrated evaluation in automated distillation, demonstrating that performance, thermal losses, and reliability must be jointly quantified to support informed decision-making in pilot-scale chemical operations.

V. CONCLUSIONS

This study provides an integrated and empirically validated framework for evaluating automated batch distillation systems by jointly examining process performance, thermal losses, and operational reliability. The combined analysis demonstrates that improvements in insulation, control tuning, and cooling flow rate yield measurable and synergistic benefits in productivity, purity, and specific energy consumption. The results confirm that a PID-based temperature control strategy, operating at a column-head setpoint of 82–84 °C, consistently outperforms fixed-power modes. This strategy improves transient behavior by achieving lower overshoot, faster settling, and reduced steady-state error and enhances composition stability across batches. When combined with 13 mm thermal insulation on the boiler and column and a 2.4 L/min cooling flow, the system achieves a favorable operating envelope: productivities up to 2.6 L/h, purities near 93% ABV, and specific consumptions as low as 1.12 kWh/L.nThe thermal-loss analysis, supported by surface temperature measurements and energy balance, identifies the boiler as the dominant loss contributor (~24%), followed by the column (~10%). Reductions in surface temperature after applying insulation directly correlate with improvements in specific consumption, supporting insulation as one of the highest-impact, low-cost interventions in pilot-scale distillation units. Reliability assessment over 200 operating hours revealed high overall availability (≈0.988), although failures were concentrated in the solid-state relay (SSR), indicating a clear path for preventive actions.

Enhanced thermal dissipation, cabinet ventilation, and early low-flow alarms are recommended to reduce recurrence and maintain stable operational continuity. Taken together, the findings show that performance optimization is most effective when mechanical, thermal, and control strategies are addressed simultaneously, avoiding improvements that reduce energy consumption at the cost of increased operational risk or variability. The comprehensive methodology presented here rooted in traceable measurements, dynamic control evaluation, and reliability metrics offers a reproducible basis for prioritizing upgrades in pilot distillation systems. As limitations, the conclusions apply to a single binary mixture and a 2-inch packed column configuration; generalization to other mixtures, packing types, or operating regimes requires additional validation. Future work should explore advanced inferential control, soft-sensor integration, simulation-driven insulation strategies, and longer reliability campaigns to refine failure models and maintenance scheduling.

ABSTRACT

Yaw/Heading measurement is an important parameter for the pose determination of the mobile robot. Yaw/heading can assist the mobile robot in localization much needed for autonomous navigation. There are various sensors available to measure the Yaw/heading that may require pre or post-processing of the data. This paper presents a low-cost and efficient six-axis magnetometer/accelerometer LSM303DLHC (GY 511) sensor for direct measurement of the Yaw/heading. The yaw values were recorded in real time with a data logger while the mobile robot was tracking a line with the help of IR sensors. It establishes that the change in yaw values due to turns on track corresponds to real-time movements/navigation of the mobile robot. Additionally, experiments were performed that demonstrate that the mobile robot can navigate autonomously, fetching yaw values from LSM303DLHC, and avoiding obstacles. The heading values from the LSM303DLHC sensor were found to be consistent with time and suitable for educational/research projects.

I. INTRODUCTION

Mobile robots have been increasingly popular in recent decades due to their ease of maneuverability. They find numerous applications indoors and outdoors, such as cleaning. [1], warehousing [2], [3], agriculture [4], [5], search and rescue[6], [7], healthcare [8-10], security and patrol [11], environment monitoring [12], etc. Wheeled mobile robots among locomotive robots are the chosen ones due to their lower power consumption and simple design. In some cases, it is manually controlled, and in some cases, it is autonomous. However, the autonomous navigation depends on the localization task of the mobile robot [13]. The position of the mobile robot is very important as it tries to locate itself in an unknown environment. The position can be expressed in Cartesian coordinates (x, y) for a planar region along with its heading or yaw angle (θ) [14]. Hence, in the indoor environment, the mobile robot can rely on its own sensors and calculate its position using dead reckoning [15]. Hence, sensors like encoders, Inertial Measurement Unit (IMU), LiDAR are used in conjunction with beacons such as ultrawide band (UWB), Bluetooth, and WiFi for indoor positioning [16]. The heading can be obtained with the Global Positioning System (GPS) [17], but sometimes it doesn't work or provides inaccurate readings indoors [18], [19]. Also, the dependency is not reliable using Global Navigation Satellite Systems (GNSS) [20] due to restricted coverage and hindered signal propagation [21]. Magnetometers can provide absolute heading based on the Earth's magnetic field, provided there are no external magnetic disturbances [22]. To remove electromagnetic interference and heading correction, magnetometers need calibration and a filter or post-processing of data that may be computationally expensive [23], [24]. The remainder of this paper is organized as follows: Section 2 discusses the materials and methods; Section 3 presents the results and discussions; Section 4 discusses the limitations of the present work; and Section 5 concludes the paper.

II. RELATED WORK

There are some commonly used sensors found in the research articles for heading measurements. Mostly, the authors applied filters/post-processing to get stabilized readings and make them error-free even in the presence of magnetic disturbances. For example, a recent work reported the use of MPU 6050 (accelerometer and gyroscope) for yaw angle determination on an inclined plane for a mobile robot. It used the golden section search method with the mean squared error metric to mitigate drift effects. [25]. MPU 6050 was also used to stabilize the camera position of the gimbal smartphone to improve the quality of captured images and videos. The average error in the yaw angle was reported as 0.78° without any filter. [26]. A low-cost prototype consisting of MPU 6050 and HMC 5883L (magnetometer) can provide accurate headings with an error of 2.9° after proper calibration. It can be beneficial for pseudo-tethered devices when used while driving, leading to portable navigation. [27]. Fusing the data of multiple MPU 6050 to suppress the random drift error can prove beneficial. Four MPU 6050 were taken into consideration, on which the effect of calibration shows a trend of steady enhancement. [28]. LSM303DLH is also a common and low-cost sensor used for attitude and heading reference systems (AHRS). The sensor fusion algorithm using estimation of mean square error was validated on a combination of gyroscope and LSM303DLHS (accelerometer and magnetometer) sensor and found to be effective [29]. Dual magnetometers (LIS3MDL) with inertial navigation systems (INS) can be integrated with dynamic time wrapping (DTW) algorithm for estimation of motion speed for the indoor mobile robots'. The results of wheel odometry were similar to the proposed approach and comparable to dead reckoning (DR) [30]. Similarly, the LSM303D magnetometer can give yaw angle accuracy of 0.4° with the Levenberg–Marquardt (L-M) algorithm with “hard iron” and “soft iron” errors [31]. The HMC5883L can also facilitate the robot’s motion and help it to be on the intended path. But the accuracy of the heading varies from 1° or 2°[32]. Above mentioned low-cost magnetometers/accelerometers can be used as heading sensors in AHRS for autonomous navigation for path following/tracking autonomously with a mobile robot. The navigational performance was based on straight line following or circular path following using the MEMS sensor MPU 9250 (includes MPU 6050) [33]. Use of HMC5833L in the robot’s motion for path tracking can be improved with realistic tracks and the inclusion of obstacles. [32]. But in some cases, magnetometers are costly, such as in [34] Path following with the LIS2MDL magnetometer with simple calibration can also facilitate autonomous navigation with sensor fusion and reinforcement learning. Waypoint-following demonstrated in [35] Didn’t consider obstacles in between and used HMR3300 magnetometer (comparatively costlier). Similarly, track following can be facilitated by fusing the wheel odometry data with the BNO 055 compass sensor, to minimize the RMS error value of less than 0.15 meters. [36]. The comparison of reported works is shown in Table 1.

Table 1: Comparison of path tracking/following with customized wheeled mobile robots.

S.N.	Magnetometer	Microcontroller	Task	Cost	Ref.
1	LIS2MDL	ATmega 2560	Path following/autonomous navigation	comparatively high	[34]
2	HMC5883L*	ATmega 2560	Path following	Low	[32]
3	HMR 3300	No details	Waypoint following	Higher	[35]
4	BNO 055	Raspberry Pi	Track following	Higher	[36]
5	LSM303DLH	Arduino Uno	Path following/obstacle avoidance	Low	Present work

Source: Authors, (2026).

But the choice of magnetometers can be difficult for mobile robot localization and autonomous navigation because they can be of different materials (Hall effect, inductive, anisotropic magnetoresistance magnetometers (AMR) or MEMS type). Even though there are many features like output frequency and operating range that have to be considered before selection. Such a review paper presented comparative insights into 42 IMU models from 7 different manufacturers [37] based on features such as structure details and connectivity. Also, three different types of AMS magnetometers were selected for a characteristics study and calibration. The HMC5893 by Honeywell, and the LSM303DLHC and LIS3MDL by ST Microelectronics were chosen, and comparative results showed that LSM303DLHC can be the best choice for heading measurements [38]. Selection can also be based on repeatability, cost and accuracy [35]. As per the above facts, it can be concluded that the selection of low-cost magnetometers as heading sensors is important. Also, autonomous path following/tracking by the mobile robot with obstacle avoidance should demonstrate the application of a low-cost magnetometer as a heading sensor is necessary. e The LSM303DLHC sensor (magnetometer/accelerometer) can find the heading of the mobile robot and get stored simultaneously in the SD card. The black line provides a well-defined path that the robot must follow, and subsequently, the heading is recorded on each turn. The main contributions of this paper are as follows:

i) Comparison of affordable magnetometers/accelerometers for the selection of a suitable one (LSM303DLHC).
ii) Testing for LSM303DLHC heading accuracy
iii) Real-world experiments on autonomous path following/tracking with and without obstacle avoidance on rectangular/circular tracks.

III. MATERIALS AND METHODS

This section outlines the procedure to execute the design of experiments. The first step in methodology involves the selection of a heading sensor. As there are some affordable heading sensors available, their comparison can lead to the identification of a suitable one. Therefore, the selection criteria are discussed in subsection 3.1. Then the second step is about a customized differential drive mobile robot (DDMR) that was developed for real-world experiments. It is discussed in subsection 3.2. This subsection also includes insights into two important hardware components (Micro SD card module as data logger and LSM303DLHC sensor), with their working and interfacing with Arduino Uno. After the development of DDMR with all the hardware components integrated, an embedded C language code was developed. There were three types of experiments designed to be executed on the developed DDMR.

First, heading values were recorded from the LSM303DLHC sensor on the onboard mobile robot. Secondly, heading values were recorded in real time as the mobile robot was tracking the black line with IR sensors. It was tested in two experimental arenas (curvature and rectangular path). Lastly, it was demonstrated that the mobile robot can navigate autonomously, fetching heading values from the LSM303DLHC sensor, avoiding obstacles. The methodology of the work is provided in Figure 1.

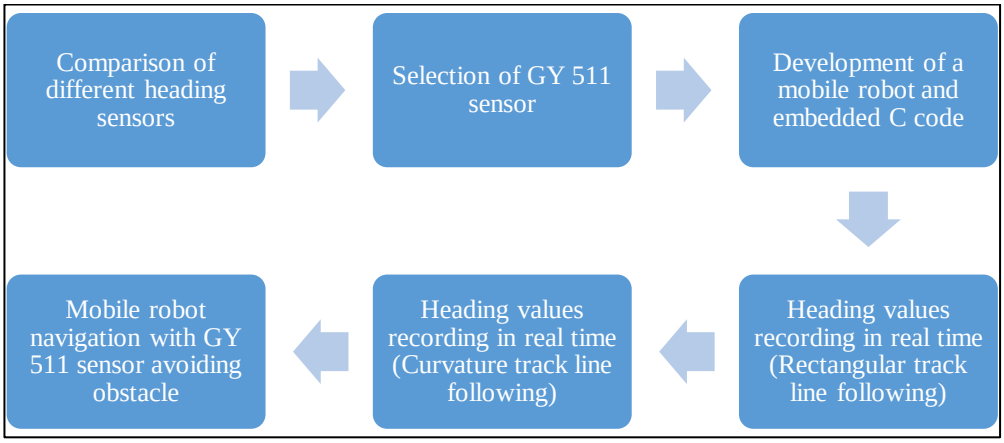

Figure 1: Methodology of the proposed work.
Source: Authors, (2026).

III.1 COMPARISON OF LSM303DLHC WITH OTHER YAW/HEADING SENSORS

This subsection highlights the comparison of three common and affordable yaw/heading sensors used for navigational purposes. These sensors are an LSM303DLHC sensor (magnetometer and accelerometer), GY 271 QMC5833L magnetometer and GY 521 MPU 6050 (accelerometer and gyroscope). The comparison parameters were provided in Table 2 below. There are other commercially available heading sensors, such as the RM 3100 3-axis magnetometer sensor [39], and DF robot fermion BNO055 [40] but not considered due to cost constraints.

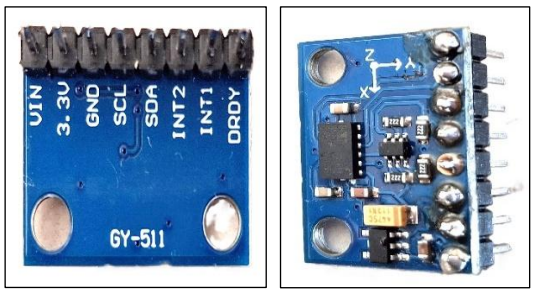

Table 2: Magnetometer/Accelerometer sensor comparison.

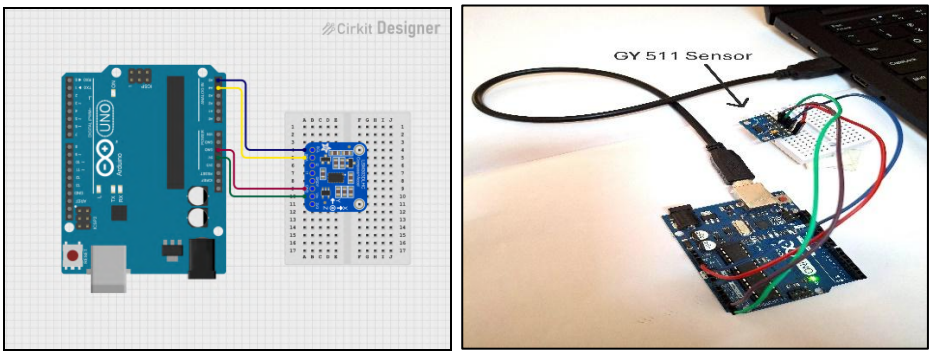
S.N.	Yaw/heading Sensor	Cost under INR 300 (may vary slightly)	Calculation of absolute Yaw angle	Accelerometer	Magnetometer	Heading Accuracy
1	LSM303DLHC	Low	Easy[38]	±2g, ±4g, ±8g, and ±16g	±1.3 to ±8.1 gauss	Stable with less noise [38]
2	QMC5883L	Very Low	Moderate	NA	±8 gauss	Comparatively low due to high noise
3	MPU 6050	Very Low	Difficult [41]	±2g, ±4g, ±8g, and ±16g	NA	Error integrates over time due to drift[41]

Source: Authors, (2026).



III.2 STATISTICAL ANALYSIS-BASED SELECTION OF LSM303DLHC

This subsection presents the statistical analysis of LSM303DLHC heading values along with other sensors QMC5883L and MPU 6050. Firstly, the LSM303DLHC sensor pin breakout and interfacing with Arduino Uno are explained. The LSM303DLHC sensor shown in Figure 2 can be interfaced with Arduino Uno/Nano. The sensor can easily calculate the heading with the help of magnetic fields. The respective connections are shown in Figure 3.

(a) (b)

Figure 2: (a) LSM303DLHC with LSM303DLHC chip front side, (b) LSM303DLHC sensor back side.

(a) b)

Figure 3: (a) Interfacing LSM303DLHC with Arduino Uno schematic, (b) Real picture of interfacing.
Source: Authors, (2026).

Arduino IDE and the LSM303DLHC sensor are helpful in getting the measured values from sensors in real-time and troubleshooting as required. The LSM303DLHC sensor was first calibrated with the local latitude and longitude position. The library from Github https://github.com/pololu/lsm303-arduino was used to calibrate the magnetometer and then record the heading data [42]. The calibration values found are below.

```
compass.m_min = (LSM303::vector<int16_t>){-426, -139, -398};
compass.m_max= (LSM303::vector<int16_t>){+530, +820, -190};
```

This was put in the program code to calculate heading and found to be accurate with the global north as per the digital compass of a standard Android smart phone. It is important to store the heading data as the mobile robot traverses from one point to another. A micro SD card module with a capacity 8 GB can be easily interfaced with Arduino Nano and can be used as a data logger for heading values Arduino Uno/Nano [43]. The respective connections are shown in Figure 4.

(a) (b)

Figure 4: (a) Interfacing Micro SD card module with Arduino Uno schematic, (b) Real picture of interfacing.
Source: Authors, (2026).

Based on the sensor comparison provided in Table 2, it has been found that stable reading with less noise and tilt compensation can be best fit for heading calculations. To conclude, a hardware setup was created to test the values of heading angles logged in real time. The hardware setup (shown in Figure. 5) consists of Arduino Nano, Micro SD card and all three sensors listed above in Table 2. The logged data of heading values from each sensor is provided in Table 3.

Source: Authors, (2026).

Table 3: Statistical analysis of data values obtained from three heading sensors.

S.N.	No. of data values(degrees)	Min	Max	Mean	Median	Mode	Std	Range
LSM303DLHC	510	343.6	344.54	344.03	344.03	343.98	0.1684	0.94
QMC5883L	523	344	346	344.40	344	344	0.496	2
MPU 6050 with drift	495	1.04	359.5	165.31	106.73	95.88	110.56	358.46
MPU 6050 with processing	356	345.18	345.86	345.45	345.47	345.47	0.099	0.68

Source: Authors, (2026).

It is evident from the statistical analysis of Table 3, that LSM303DLHC sensor gives the best mean of 344.03° with respect to reference value of 344°. Out of the three sensors, the performance of LSM303DLHC seems to suit the requirement and selected finally.

III.3 DEVELOPMENT OF DDMR

The hardware assembly of the DDMR in the paper comprises components such as LSM303DLHC as heading sensor, Micro SD card module as a data logger, HC SR 04 as an ultrasonic sensor for obstacle avoidance and IR sensor (two) for black line tracking. Also, the other components are L293D motor driver, two BO motors, two wheels, Arduino Uno, rechargeable LiPO battery 11.4 V. The simple DDMR was built with the low-cost and affordable components mentioned above with Arduino Uno as the main controller. The pin connections for LSM303DLHC and Micro SD card are already discussed in the next subsections. The IN1, IN2, IN3, IN4, ENA, and ENB pins of L298N motor driver are connected to pin no. 4,9,6,7,3 and 5 respectively of Arduino Uno. IR sensors on the front right and front left of the mobile robot are connected to pin no. 2 and 8 respectively of Arduino Uno. Trig and Echo pin of HC SR04 are connected to 1 and 0 pin of Arduino Uno respectively. The complete circuit diagram is shown in Figure 6 below (drawn with cirkit designer website). The full software developed for this problem statement has been shared in GitHub. https://github.com/kgsingh555/Autonomous-mobile-robot-navigation-using-Magnetometer-as-Heading-Sensor. The DDMR setup is shown in Figure 7 below.

IV. RESULTS AND DISCUSSIONS

This section highlights the types of experiments conducted to demonstrate the navigational feature of the DDMR using LSM303DLHC sensor. There are three types of experiments conducted. Subsection 4.1 explains the preliminary results of the heading values recorded from the onboard data logger of the DDMR while it is rotating about z-axis.

Subsection 4.2 describes the result of heading values recorded while the DDMR is tracking black line with IR sensors on rectangular and curvature path. The third experiment is presented in subsection 4.3 that explains the obstacle avoidance behavior of DDMR being guided by LSM303DLHC sensor.

IV.1 YAW/HEADING READINGS FROM LSM303DLHC WITH ONBOARD DATALOGGER ON DDMR

In this subsection, it is demonstrated that the heading values from the LSM303DLHC sensor are reliable and consistent enough to be considered for autonomous mobile robot navigation. It gives output from 0° to 360°. The DDMR has been kept in two orientations. These two orientations are 0° and 27°. Firstly, with a digital compass in Android Smartphone as a reference, 0° and 27° are marked. 0° in digital compass shows due north direction. It is shown in Figure 8. The actual experimental setup with DDMR heading due north (0°) is shown in Figure 8 a). Also, in Figure 8 b) the output on the serial monitor of Arduino IDE is shown. It prints the heading after every 1 sec. The heading was recorded for 10 mins, considering 1 sample/sec. Hence there were 600 sample values when the DDMR was in due north direction. It can be observed from Figure 9 that only at some times, the value fluctuated and recorded 359°. The circular mean for 600 samples is 0.03°.

(a) b)

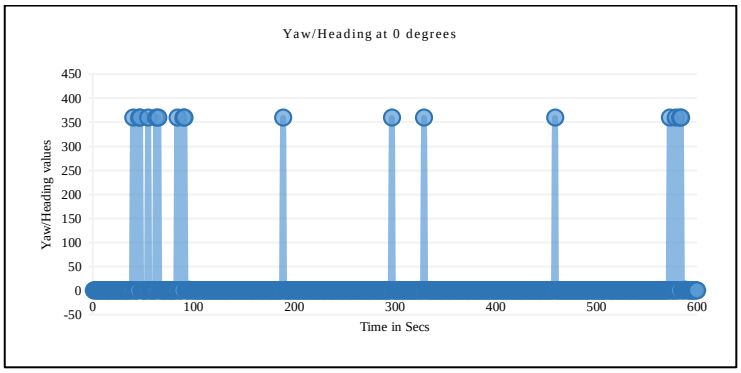
Source: Authors, (2026).



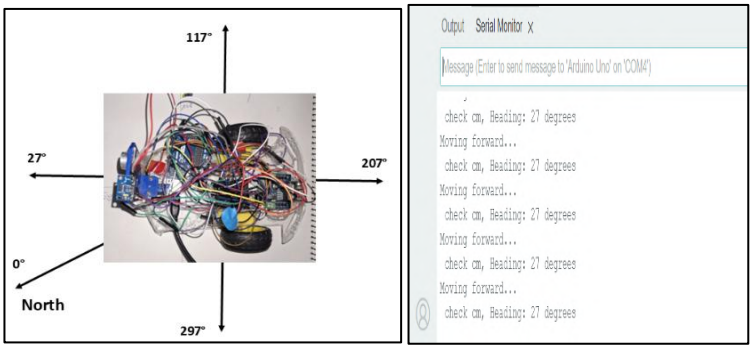


Figure 9: Mobile robot heading at 0° recorded for 10 mins (one sample/sec).
Source: Authors, (2026).

The experiment was repeated with the mobile robot orientation at 27°. It can be observed from Figure. 10 a) the mobile robot heading was oriented at 27° in the experimental setup, while the output in the serial monitor of Arduino IDE was 27° as well. It is shown in Figure 10 b). To validate the consistency of the output values in this orientation, heading values were recorded for 10 minutes. It was one sample/sec, and in total, there were 600 values. The recorded data is shown in Figure 11. The values deviation is minimal, only at one point, the value was 26°, and at some instances it was 28°. The average value for 600 samples is 27.095°.

(a) (b)

Figure 10: (a) Mobile robot heading at 27°, (b) Output on serial monitor of Arduino Uno.
Source: Authors, (2026).

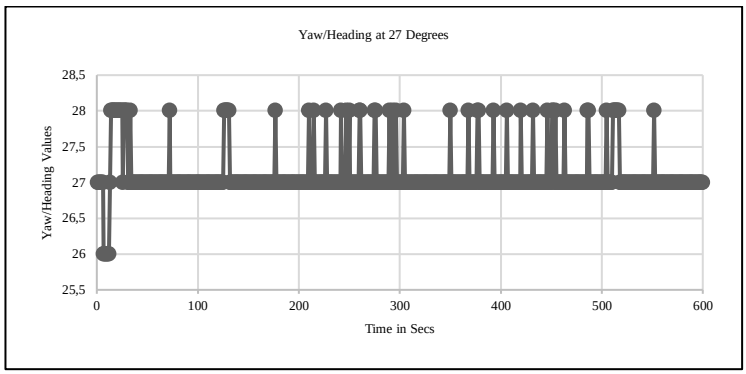

Figure 11: Mobile robot heading at 27° recorded for 10 mins (one sample/sec).
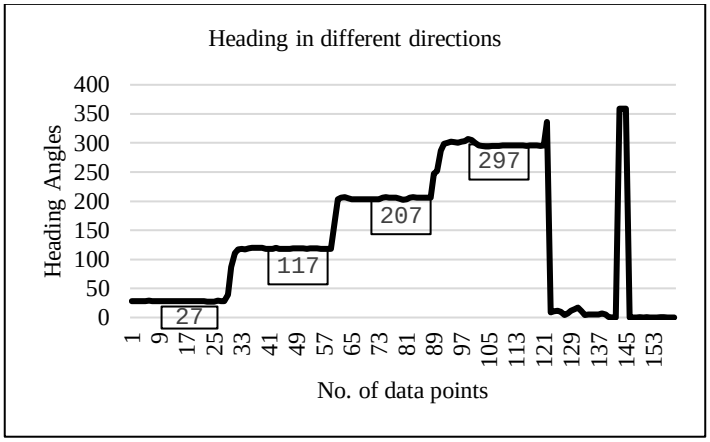
Source: Authors, (2026).

The DDMR also rotated around the z-axis clockwise to record the values of heading angles. It paused after a 90° turn in the clockwise direction, taking the reference directions shown in Figure 8 a). First, it was oriented towards 27° as the reference, then 117°, thereafter 207°, and lastly 297°. For a particular orientation, at least 28 heading values were recorded, which are shown in Figure. 12. The value dropped suddenly to 0° because it oriented towards due north again after complete rotation. It showed some spikes due to heading angle measurement at 359° and thereafter settled to 0°.



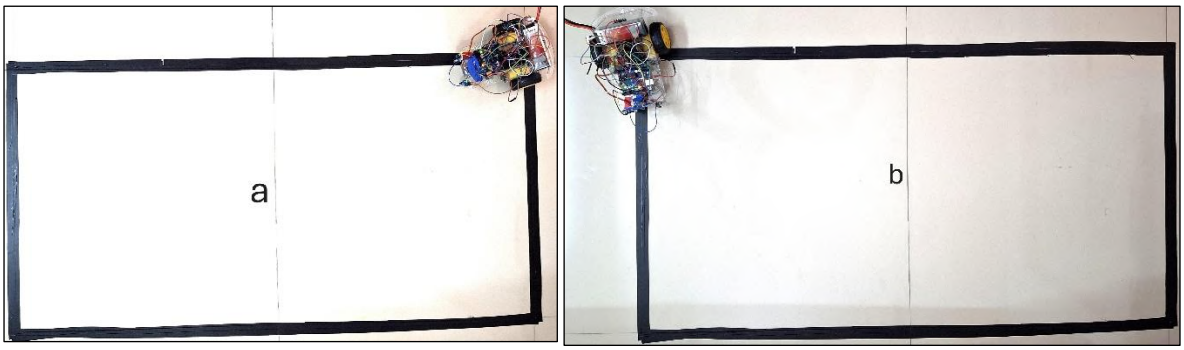


Figure 12: DDMR at each 90° turns, completing a full rotation around the z-axis.
Source: Authors, (2026).

IV.2 YAW/HEADING READINGS FROM LSM303DLHC WHILE DDMR TRACKING BLACK LINE

This subsection explains the DDMR black line tracking behaviour on a rectangular and a curvature path. There is a simultaneous recording of the heading values with the help of an onboard Micro SD card as a data logger. The Micro SD card module recorded heading values from the sensor LSM303DLHC at a rate of 1 sample/sec. The DDMR was able to follow a black line, which is rectangular in shape and measures 4 ft.× 2 ft. Approximately 15 seconds were required to complete one cycle. There were four turns of each 90°. The DDMR, while tracking the black line turns, and the Micro SD card module records the heading in the SD card. The position of the mobile robot at each 90° turn is shown in Figure 13. The mobile robot starts with position shown in Figure 13 a). Then it takes a 90° turn, and that is shown in Figure 13 b). Thereafter, the subsequent movements are shown in Figure 13 c) and Figure 13 d). It can be observed that movement is anticlockwise and the expected heading measurements will be 27°, 297°, 207° and 117° for each of the positions shown in Figure 13 a), Figure13 b), Figure 13 c), and Figure 13 d) respectively.

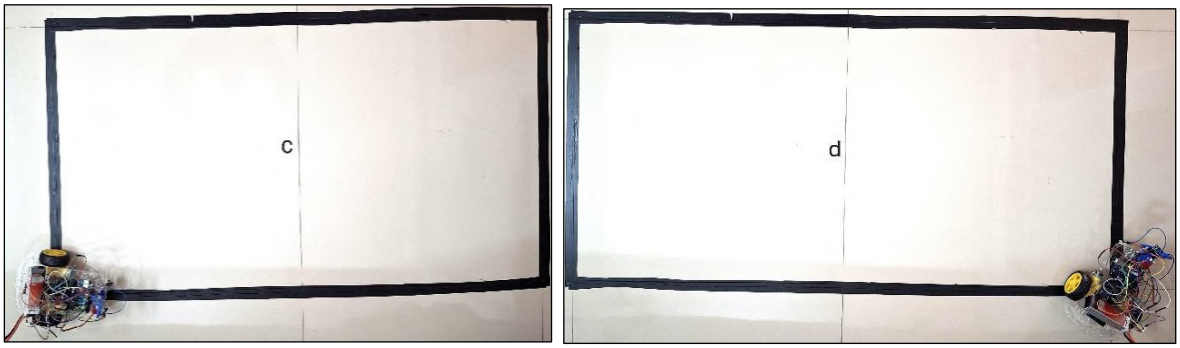

Figure 13: The DDMR heading is (a) 27° (b) is 297° (c) is 207° (d) is 117°.
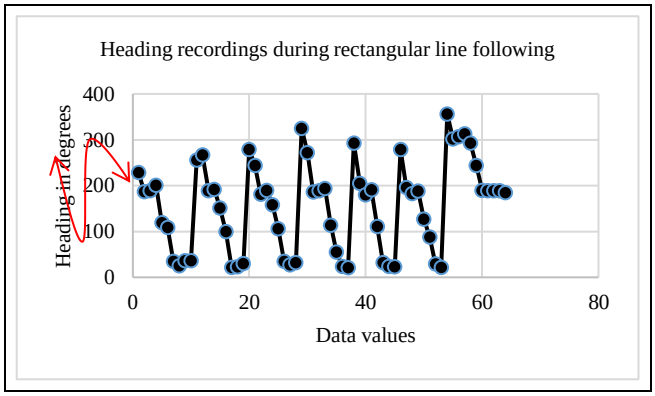
Source: Authors, (2026).



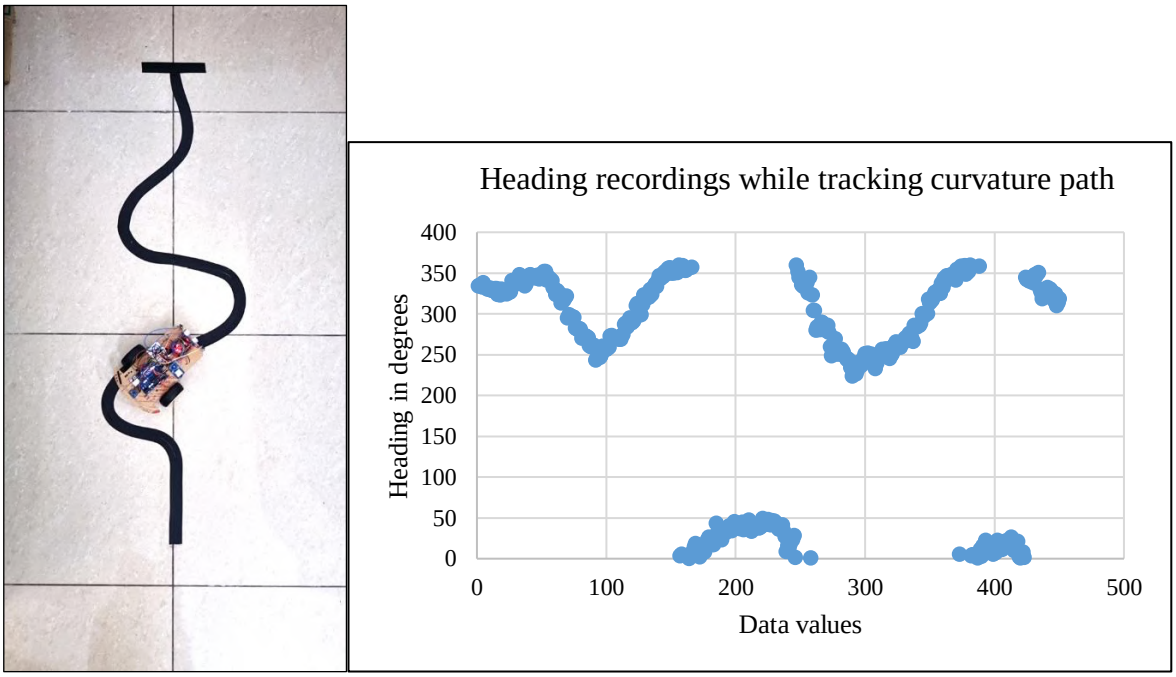


Figure 14: Heading recorded at each 90° turn (six repetitions) while DDMR tracking the black line.
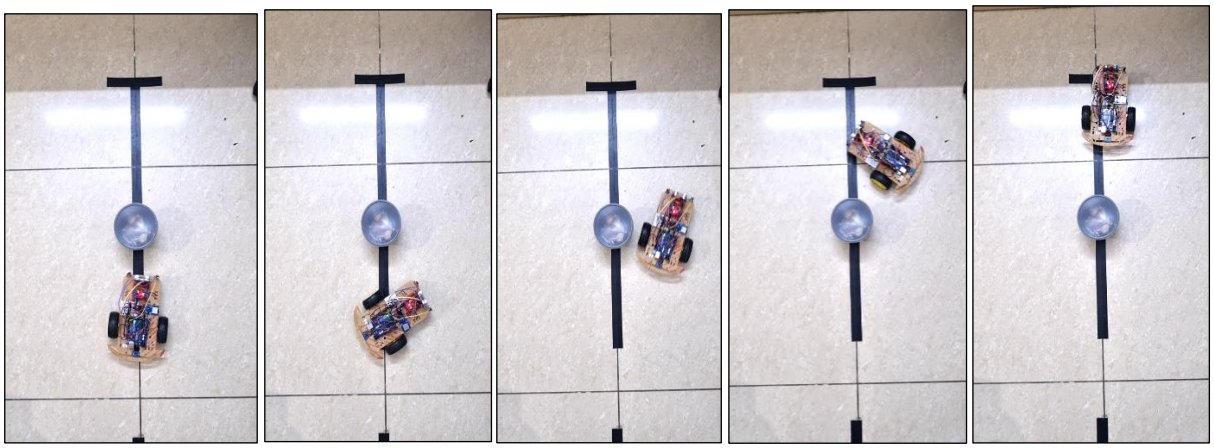
Source: Authors, (2026).

Above Figure 14 shows the consistent record of the heading sensor for the DDMR. The line following was repeated six times and concludes at position Figure. 13 c) and remains there for some time. The red curved arrows mark the start and completion of the first cycle of the mobile robot movement. Similarly, a curvature path was created for the mobile robot to track. This time, the number of heading values recorded was 30 samples/sec. The run time of the mobile robot was approximately 15 seconds, and 450 heading values were recorded. Figure. 15 a) and Figure. b) below show the curvature path with mobile robot tracking and the graph with heading values recorded during the run, respectively.



(a) (b)

Figure 15: (a) DDMR tracking curvature path, (b) heading recorded with LSM303DLHC sensor while tracking curvature path.
Source: Authors, (2026).

IV.3 YAW/HEADING READINGS FROM LSM303DLHC WHILE DDMR AVOIDING OBSTACLES

The third experiment was performed to demonstrate that DDMR can fetch the heading values from the LSM303DLHC sensor to avoid obstacles and autonomously navigate. As per Figure. 16, DDMR senses the obstacle with an ultrasonic sensor and, with reference to its present heading, turns 30° to the right and goes straight for a while. It then turns left again to catch up to the black line to resume line-following behavior. Hence, it can complete its run after reaching the end of the line.

(a) (b) (c) (d) (e)

Figure 16: The DDMR (a) starts following the black line b) senses the obstacle and turns 30° to the right, c) avoids the obstacle, d) gets back to the black line, e) resumes line following behavior and stops.
Source: Authors, (2026).

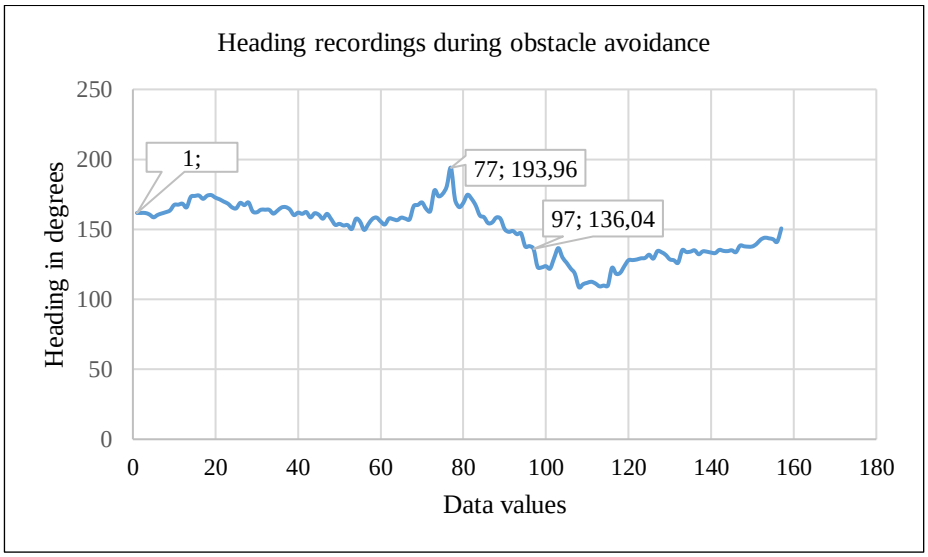


Figure 17: Mobile robot heading recorded with LSM303DLHC sensor while autonomously avoiding obstacles.
Source: Authors, (2026).

The mobile robot autonomously avoided the obstacle by turning 30° to the right and obtaining its heading angle from the LSM303DLHC sensor. The mobile robot turned 30° from the reference, which can be seen in Figure 17 above as data point 1. The value is 161.7°. After turning the heading recorded is 193.96°, which means the difference of angle is 32.26°. Hence, an error of 2.26° was there. Also, when the mobile robot returned to the black line after avoiding obstacles, its heading recorded was 136.04°; hence, the true value of the turn was 60°, but it was actually 193.96-136.04°, equal to 57.92°. Hence, an error of 60-57.92= 2.08° was there.

IV.4 LIMITATIOS OF THE WORK

There are some limitations of the work presented in this paper. Firstly, there can be few replacements for the used LSM303DLHC sensor that can be processed with Mahony or a low-pass filter. For example, the recently launched magnetometer MMC 5603NJ sensor may be relatively cheap and highly accurate, but it needs an accelerometer for tilt compensation. The experiments conducted are subject to environmental conditions, hardware components and software setups used. Only the orientation of DDMR was considered; hence, including odometry and dead reckoning can enhance the results.

V. CONCLUSIONS

In this paper, a low-cost six-axis magnetometer/accelerometer LSM303DLHC sensor was used for Yaw/heading measurement. The LSM303DLHC sensor was selected after comparison with its counterparts on defined parameters. A simple DDMR was developed with an onboard Micro SD card module as a data logger. The first experiment performed suggests that heading values are consistent over a period. Secondly, the DDMR was able to track the rectangular and curvature black line with IR sensors. These experiments were performed so that heading values can be stored in real time while the DDMR is traversing. The stored values can be compared with the fixed turns on the black line (90° turn in a rectangular path) as a reference. The third experiment confirmed that DDMR can use the heading values from the LSM303DLHC sensor to avoid the obstacle successfully. Hence, the selection of LSM303DLHC as a heading sensor can be a good choice for low-cost navigational applications in robotics. In future, fusion of sensors with different combinations of magnetometers, gyroscope, and accelerometer will be explored for autonomous navigation. It will also include the calibration and data filtering process.

ABSTRACT

Estate Surveying and Valuation is a critical profession within Nigeria's built environment, contributing significantly to land administration, property valuation, investment decision-making, and real estate consultancy. Despite its relevance, the profession is often misunderstood or underappreciated by non-construction professionals. This study aimed to appraise the perception of the Estate Surveying profession among non-allied professionals in Nigeria, with particular emphasis on their awareness of the profession's existence, understanding of its roles and duties, and perception of its relevance to the construction and real estate industries. The research adopted a descriptive survey design using structured questionnaires administered to 162 respondents drawn from the medical, legal, financial, administrative, and other non-construction professional sectors. Data were analyzed using frequency distributions, percentages, and the Mean Item Score (MIS) ranking method. Findings revealed that 94.6% of respondents were aware of the Estate Surveying profession, and over 73% agreed that Estate Surveyors are part of the built environment team. However, detailed awareness of the profession's specific functions such as property management, investment appraisal, facility management, and valuation for various statutory and commercial purposes was considerably lower. Duties such as rating and taxation advice, land acquisition consultancy, and building insurance valuation ranked lowest in perceived awareness. The profession was rated "very good" or "good" in terms of performance by 88.88% of respondents, but cost perception and limited understanding of roles were identified as barriers to wider engagement. This study highlights the need for advocacy and outreach to improve non-construction professionals' understanding and engagement with Estate Surveyors.

I. INTRODUCTION

The built environment is an interdisciplinary domain composed of diverse professionals whose collective contributions are essential to achieving sustainable development goals. Among these, estate surveyors play a pivotal role in areas such as property valuation, land administration, asset and facilities management, and real estate investment consultancy [1], [2]. Despite their strategic position in land and property markets, the

Estate Surveying and Valuation profession in Nigeria continues to suffer from limited public understanding and engagement, particularly among non-construction professionals who interact with property issues in both personal and institutional capacities [3]. Estate Surveyors and Valuers are legally recognized practitioners under the regulatory oversight of the Estate Surveyors and Valuers Registration Board of Nigeria (ESVARBON), established through Decree No. 24 of 1975 (CAP E13 LFN 2007). The profession also operates under the guidelines of the Nigerian Institution of Estate Surveyors and Valuers (NIESV), which aligns with international standards, including those of the Royal Institution of Chartered Surveyors [4]. Nonetheless, existing studies reveal persistent misconceptions that conflate estate surveyors with land surveyors or valuers, thereby undermining their professional identity and limiting public patronage [5]. Scholarly evidence suggests that this poor perception and underutilization of estate surveyors stem from a lack of awareness, weak public engagement strategies, inadequate branding, and overlapping professional jurisdictions in the property sector [6], [7].

The issue is more pronounced among non-allied professionals such as legal practitioners, healthcare professionals, and financial experts who, despite engaging frequently with real estate matters, may not fully grasp the scope and relevance of estate surveyors' services [3], [7]. Estate Surveyors are not only valuation experts but also offer advisory services on land acquisition, investment, property development, and facilities management [8], [9]. However, awareness of these roles remains limited among professionals outside the built environment, leading to confusion with other land-based professions, such as land or quantity surveyors [10], [11]. This lack of recognition contributes to the underutilization of estate surveyors, which may negatively affect real estate efficiency and broader economic development. This study, therefore, seeks to appraise the perception of the Estate Surveying profession among non-allied construction professionals in Nigeria, focusing on their level of awareness, understanding of professional roles, and willingness to engage estate surveyors. With Abuja Nigeria's Federal Capital Territory and administrative hub as the study area, the research offers a cross-sectoral perspective on professional visibility, filling a notable gap in existing literature that has traditionally centered on students and construction-related professionals.

II. LITERATURE REVIEW

II.1 HISTORICAL REFLECTION OF ESTATE SURVEYING PROFESSION IN NIGERIA

The estate surveying profession in Nigeria has a rich historical background deeply rooted in the country's colonial and post-colonial development phases. Estate surveying, which broadly involves the valuation, management, and development of land and property assets, evolved significantly as Nigeria transitioned from traditional land tenure systems to more formalized real estate practices influenced by British colonial administration [12]. Before colonial intervention, land and property were primarily governed by customary laws and traditional authorities, which emphasized communal ownership and use rights rather than individual property rights [13]. The lack of formal property rights posed challenges for economic development and urban planning, especially as Nigeria's population grew and urban centers expanded.

The introduction of the colonial Land Use Act in 1978 marked a pivotal moment in codifying land administration and indirectly shaped the estate surveying profession by establishing statutory frameworks for land tenure and property rights [14]. The estate surveying profession formally emerged in Nigeria during the early 20th century when British-trained surveyors began applying western property valuation and management principles to Nigerian real estate markets [15]. Initially, the profession was dominated by expatriates due to the lack of local expertise, but with the establishment of professional bodies like the Nigerian Institution of Estate Surveyors and Valuers (NIESV) in 1969, the profession rapidly localized [16]. The NIESV, as a regulatory and professional body, has played a crucial role in setting ethical standards, promoting education, and protecting the interests of practitioners and clients alike [17].

Moreover, the estate surveying profession in Nigeria has evolved in response to the country's socio-economic changes, including urbanization, real estate development, and government housing policies. During the oil boom era of the 1970s, there was increased demand for professional estate surveying services to manage commercial and residential property investments [18]. Housing infrastructure deficits have also influenced estate surveying practice in Nigeria [19]. In recent decades, globalization and technological advancements have further transformed the profession, with estate surveyors increasingly involved in property technology (PropTech), sustainability considerations, and integrated real estate services [20]. Despite its growth, the profession faces challenges related to regulatory enforcement, professional recognition, and adapting to emerging real estate trends [21]. Nevertheless, the historical trajectory of estate surveying in Nigeria reflects a gradual but steady professionalization aligned with both local realities and global standards.

II.2 OVERVIEW OF ESTATE SURVEYING PROFESSION IN NIGERIA

Estate Surveying and Valuation in Nigeria is a legally recognized profession regulated by the Estate Surveyors and Valuers Registration Board of Nigeria (ESVARBON), established under Decree No. 24 of 1975 (CAP E13 LFN, 2007). The Nigerian Institution of Estate Surveyors and Valuers (NIESV**)**, formed in 1969, serves as the principal professional body responsible for setting standards, promoting ethics, and advocating for the interests of estate surveyors. These professionals are trained to offer a wide range of services, including valuation for various purposes (compensation, insurance, mortgage, sale), property and facilities management, development appraisal, investment advisory, land use consultancy, and arbitration [9]. Estate Surveyors operate in both public and private sectors and are integral to real estate market dynamics. They support government functions like taxation and land acquisition while also advising private clients on asset optimization and land investment. However, the profession has faced criticism for being inward-looking, with limited public awareness and engagement, despite its relevance in Nigeria's growing urban and real estate sectors [7], [11]. Recent studies have also highlighted structural and institutional challenges affecting the profession in Nigeria [22].

II.3 ROLES AND DUTIES OF PROFESSIONALS IN THE CONSTRUCTION INDUSTRY

The construction industry operates through a network of specialized professionals, each contributing distinct yet interdependent expertise to project development and delivery. According to [23], the core roles within the construction process include architects responsible for conceptual design and aesthetic coordination, engineers for technical specifications and structural integrity, builders for execution and supervision, and quantity surveyors for cost planning and management. This aligns with earlier studies emphasizing the importance of value management roles performed by built-environment professionals during project procurement and delivery [24]. Estate surveyors, while often less integrated in the active construction phase, play critical roles during pre- and post-construction periods. Estate surveyors are tasked with the acquisition and disposal of land, feasibility studies, site valuations, development appraisals, and advisory services on land use and regulatory compliance [8], [9]. These professionals are instrumental in assessing the economic viability of projects and ensuring proper legal titles for land ownership. Their contribution is also critical in guiding development processes through land administration and investment advisory functions [25]. Their valuation services are essential for mortgage underwriting, taxation, insurance, and investment analysis [3]. However, the marginal involvement of estate surveyors in project design and execution phases has been identified as a major barrier to unlocking their full value, often resulting in assets that are undervalued, mismanaged, or misaligned with market expectations [6].

II.4 THE PROFESSIONALS IN THE CONSTRUCTION INDUSTRY

Construction projects are inherently collaborative, requiring the integration of multiple technical and administrative disciplines. In the Nigerian context, a typical project team comprises architects, civil and structural engineers, quantity surveyors, builders, estate surveyors, land surveyors, urban planners, and legal professionals [26]. Each professional contributes specific competencies: architects develop designs aligned with user requirements; engineers ensure structural soundness; builders handle execution logistics; and quantity surveyors manage budgets and contract administration. Similar to estate surveyors, quantity surveyors operate under statutory regulatory frameworks that define professional standards and responsibilities [27]. Estate surveyors, however, play a more hybrid role. As [28] assert, construction professionals are defined by their specialized knowledge, professional ethics, and responsibility in coordinating resources, technology, and human capital. Estate surveyors bridge the gap between technical development and economic rationality. They provide critical insights on land potential, market dynamics, site accessibility, and environmental constraints, thereby enabling strategic decisions on investment returns and project suitability [10]. Despite their relevance, estate surveyors are frequently sidelined in the conceptual and design stages of construction. Their visibility within construction teams remains low, especially compared to quantity surveyors and architects who are often perceived as more central to the building process [2]. This underutilization contributes to a broader misperception of the estate surveying profession and weakens inter-professional collaboration in holistic project development.

II.5 PERCEPTION AND AWARENESS CHALLENGES

Perception and awareness remain critical obstacles to the effective engagement of estate surveyors in Nigeria's construction and real estate sectors. Studies have shown that both the public and allied professionals often confuse the role of estate surveyors with that of land surveyors or even quantity surveyors, largely due to overlapping terminology and insufficient differentiation in professional practice [10], [3]. This confusion is exacerbated by the absence of aggressive public education or branding efforts by estate surveying institutions and regulatory bodies [29]. Similar perception gaps have also been reported among other built-environment professions in Nigeria, suggesting that this challenge extends beyond estate surveying alone [30]. In addition, the limited integration of estate surveyors into mainstream construction discourse further undermines their public image. According to [7] notes that most clients associate estate surveying strictly with real estate agency functions, ignoring their expertise in valuation, feasibility studies, and development consultancy. Earlier empirical studies also revealed persistent concerns regarding valuation accuracy in Nigeria's residential property market [31]. As a result, informal consultants or unlicensed agents are often patronized over certified professionals, especially in informal housing markets.

The issue of professional rivalry also affects perception. For authors [6] highlight how architects, engineers, and even urban planners sometimes encroach on the advisory and strategic roles of estate surveyors, leading to jurisdictional overlaps and blurred responsibilities. Comparative evidence from South Africa also confirms similar professional perception challenges [32]. This rivalry has hindered the creation of cohesive interdisciplinary teams where estate surveyors can effectively contribute from project inception to post-completion asset management. Furthermore, non-construction professionals such as those in law, medicine, banking, and academia who are potential clients or investors, often lack awareness of the value proposition offered by estate surveyors [1]. These gaps result in missed opportunities for proper valuation, optimal investment decision-making, and regulatory compliance in land-related transactions. Professional bodies like the Nigerian Institution of Estate Surveyors and Valuers (NIESV) have made recent efforts to address these issues through publications and advocacy [16], but more sustained public relations campaigns, curriculum reviews, and policy reforms are required.

II.6 HISTORICAL EVOLUTION AND PROFESSIONAL IDENTITY OF ESTATE SURVEYING

The estate surveying profession in Nigeria has evolved through several phases, from colonial land administration frameworks to post-independence professionalization. Initially rooted in colonial land governance systems, estate management was largely concerned with revenue collection, tenant relations, and public land allocation [14]. Over time, the profession expanded to include valuation, property management, investment advisory, and facility management [11], [17]. These functions are rooted in traditional estate management principles that continue to shape professional training and practice in Nigeria [33]. NIESV was established to formalize the profession, regulate entry standards, and promote ethical practice. Today, it plays a significant role in developing standards, conducting examinations, and engaging stakeholders.

The long-term institutional development and performance of the profession in Nigeria have also been critically examined in later studies [34]. However, as [12] argue, the colonial legacy still affects how estate surveyors are perceived, especially in their relationship with land ownership, regulation, and customary rights. Additionally, [18] suggests that economic volatility and land speculation have also shaped the identity of estate surveyors, sometimes casting them as intermediaries rather than strategic consultants. The increasing complexity of urban development and the demand for sustainable land use planning call for a redefinition of the profession's role beyond traditional valuation tasks.

II.7 EMERGING TRENDS AND THE FUTURE OF ESTATE SURVEYING

The profession is currently undergoing a technological and conceptual shift. With the rise of digital platforms, Geographic Information Systems (GIS), Building Information Modelling (BIM), and automated valuation models (AVMs), estate surveying is expanding beyond manual methods to embrace data-driven decision-making [20]. These tools enhance accuracy in valuation, improve transparency, and promote integration with urban planning and financial systems. Moreover, the increasing demand for sustainable urban development, smart cities, and climate-resilient infrastructure creates new opportunities for estate surveyors to lead in areas such as green valuation, environmental impact analysis, and land-based financing mechanisms. Professional reorientation, continuous learning, and inter-professional collaboration are therefore imperative to reposition the estate surveying profession as a key player in Nigeria's evolving built environment [21], [4].

II.8 PERCEPTION OF ESTATE SURVEYING

Perception, according to [35] refers to the way individuals assign meaning to concepts based on the information available to them. In the context of the built environment, the public and even allied professionals often form opinions of professions based not on core competencies but on visibility, relevance, and communication of professional roles. Estate Surveying in Nigeria is traditionally associated with land valuation, property management, and real estate agency. However, its scope goes far beyond these roles. In particular, valuation reporting quality remains a major professional concern affecting confidence in estate surveying outputs [36]. Estate surveyors are trained professionals involved in land acquisition, development appraisals, feasibility studies, investment analysis, property taxation, facilities management, and regulatory compliance in land use and urban development [8], [9]. Despite this broad scope, the profession continues to suffer from identity misalignment and limited public understanding. According to [3], a common misconception exists where estate surveyors are mistaken for land surveyors or quantity surveyors. This confusion is rooted in overlapping terminologies and a lack of public enlightenment regarding professional boundaries. Similarly, [7] observed that many clients perceive estate surveyors merely as rent collectors or informal agents, neglecting their technical competencies in valuation, development consultancy, and investment advice. While estate surveyors make significant contributions in real estate investment, project feasibility, and land management, their roles remain under-recognized compared to more visible construction professionals such as architects and engineers [2].

The marginal integration of estate surveyors in early project stages further diminishes their perceived importance in the built environment value chain. Several scholars, including [6] have attributed these perception challenges to weak professional advocacy, inter-professional rivalry, and inadequate branding by the Nigerian Institution of Estate Surveyors and Valuers (NIESV). According to [37], though writing on quantity surveying, noted that self-perception within a profession also shapes public perception a view that resonates with the estate surveying context, where internal fragmentation and low marketing efforts contribute to low visibility. Additionally, non-construction stakeholders such as bankers, lawyers, and public administrators who often engage in property investment and real estate decision-making demonstrate limited awareness of the strategic value offered by estate surveyors [1], [10]. This knowledge gap leads to underutilization of estate surveyors in transactions that could benefit from their expertise. Efforts to reposition the profession are underway, with scholars such as [29] advocating for targeted public awareness campaigns, clearer professional branding, and curriculum reviews to better reflect evolving industry demands. As the estate surveying profession expands into areas like green valuation, proptech, and real estate finance, improving perception becomes not only desirable but essential for national development and sustainable land management.

III. MATERIALS AND METHODS

The study targeted non-construction professionals working across various sectors including hospitals, banks, law firms, non-governmental organizations (NGOs), and corporate administrative offices within the study area. The selection of Abuja as the study location was deliberate due to its status as the political and administrative capital of Nigeria, where many corporate headquarters and branch offices of diverse organizations are situated. A total of 200 questionnaires were distributed among the target respondents. Of these, 185 questionnaires were returned, with 23 discarded due to incomplete or incorrect consent, leaving **162 valid responses** for analysis. This corresponds to a response rate of 81%, which exceeds the minimum acceptable threshold of 30% often cited in survey research [38], [39], thereby ensuring the adequacy and reliability of the sample size. The collected data were analyzed using descriptive statistical techniques including mean item scores and percentage distributions. The results were presented using tables and figures to facilitate clear interpretation. Data processing and statistical analysis were conducted with the aid of IBM SPSS Statistics version 29.

A. Reliability Analysis

To ensure the internal consistency and reliability of the survey instrument, a reliability test was performed using Cronbach's Alpha via SPSS 29.0. According to [40], a Cronbach's Alpha coefficient exceeding 0.7 indicates acceptable reliability and consistency of the instrument. Similarly, [41] affirm that higher alpha values above 0.7 suggest greater data reliability. For this study, the Cronbach's Alpha value obtained was 0.881, signifying a high level of internal consistency among the questionnaire items.

IV. RESULTS AND DISCUSSIONS

IV.1 RESPONDENTS' BACKGROUND INFORMATION

The background characteristics of the respondents provide essential context for understanding how non-construction professionals perceive the Estate Surveying profession. According to Table 1, a total of 162 valid responses were analyzed. Out of the total respondents, 61.73% (n=100) indicated that they were aware of the Estate Surveying profession, while 38.27% (n=62) reported no awareness. This suggests that although a majority of professionals outside the built environment have some knowledge of the profession, a significant awareness gap still exists among nearly 4 in 10 respondents. This finding echoes earlier studies by [3], [10], which identified widespread public confusion and limited exposure of the estate surveying profession among the general population. The age profile of respondents shows that the majority fall within the 40–50 years range (45%) and the 30–40 years range (26%), followed by those above 50 years (12.6%). Younger respondents aged 20–30 years and below 20 years made up only 16.4% collectively. The predominance of mid-career professionals in the sample suggests that responses are largely informed by individuals with extensive work experience and decision-making responsibilities key stakeholders in real estate-related matters.

Professional Background

According to Table 1, the respondents span five professional groups. Lawyers constituted the largest segment (41.89%), followed by business administrators (20.27%), medical professionals including doctors and pharmacists (18.92%), nurses (13.51%), and accountants/financial experts (5.41%). The diversity of respondents reflects the broader non-construction stakeholder spectrum that interacts with real estate assets either as investors, clients, institutional advisors, or regulators. In terms of educational attainment, the majority of respondents held a B.Sc./B.Tech degree (85.37%), while 25.7% had OND/HND/PGD qualifications. Additionally, 21.87% held a Master's degree, and 13.12% had attained a PhD. This high level of academic qualification among the respondents underscores the credibility of their responses and suggests a relatively informed group whose perception of estate surveyors may be shaped by professional exposure and critical evaluation. Regarding professional experience, the largest proportion of respondents (44%) had 11–15 years of work experience, followed by 22.3% with 5–10 years and 13.4% with 16–20 years. Respondents with over 20 years of experience constituted 8.8%, while only 11.5% were in the early-career category (up to 5 years). This distribution indicates that most respondents possess substantial industry knowledge and likely engage with real estate decisions in their various organizational roles.

Table 1: Respondents background information.

Category	Classification	Freq.	Percent
Awareness of Estate Profession	Yes	100	61.73
	No	62	38.27
	Total	**162**	**100%**
Age	Up to 20years	10.60	6.70%
	20-30years	15.71	9.70%
	30-40years	42.12	26.00%
	40-50years	72.90	45.00%
	Above 50years	20.41	12.60%
	TOTAL	**162**	**100%**
Profession	Medical Doctors/Pharmacist	30.65	18.92%
	Lawyers	67.86	41.89%
	Accountant/Financial Experts	8.78	5.41%
	Nurses	21.89	13.51%
	Business Administrators	32.84	20.27%
	TOTAL	**162**	**100%**
Highest Academic Qualification	OND/HND/PGD	41.634	25.70%
	B.Sc./B.Tech	52.7	85.37%
	Masters	13.5	21.87%
	PhD	8.1	13.12%
	TOTAL	**162**	**100%**
Years of Work Experience	Up to 5yrs	18.63	11.50%
	5–10yrs	36.12	22.30%
	11-15 years	71.28	44.00%
	16-20years	21.708	13.40%
	20+ years	14.256	8.80%
	TOTAL	**162**	**100%**

IV.2 PLACE OF FIRST CONTACT WITH THE ESTATE SURVEYING PROFESSION

Identifying the initial points of contact for non-construction professionals with the estate surveying profession is crucial for evaluating its visibility and perceived significance within organisational frameworks. According to Table 2, the facility management department represented the predominant initial interaction, with 45% of respondents identifying it as their first encounter with the profession.

This finding corresponds with the transforming function of estate surveyors in corporate real estate and facilities management, where their expertise in property administration, spatial efficiency, leasing consultancy, and asset enhancement is increasingly in demand [8],[9]. Subsequently, 36% of respondents indicated that their initial engagement with estate surveyors was via their firms' works department. This indicates an ongoing relationship between estate surveyors and infrastructure services, especially in land acquisition, project development, and construction advice services. Only 19% of respondents identified the profession through the maintenance department, suggesting that although estate surveyors may occasionally participate in maintenance monitoring, it is not generally their primary or most prominent area of engagement in corporate environments. These findings illustrate the complex nature of the profession and corroborate the concerns raised by [2],[29] on the potential for limiting perceptions or misidentifications based on departmental functions. The increased exposure in facilities and works departments indicates possible opportunities for enhancing professional identity through collaboration, branding, and role clarification.

Table 2: Respondent Place of First Contact with the Estate Surveyor Profession.

Classification	Freq.	Percent
Facility Management Department	72.90	45.00%
Works Department	57.83	36.00%
Maintenance Department	31.01	19.00%
Total	**162**	**100%**

IV.3 LEVEL OF AGREEMENT ON WHETHER ESTATE SURVEYORS ARE PART OF THE BUILT ENVIRONMENT PROFESSION

Table 3 presents the respondents' opinions on whether estate surveyors are considered part of the built environment profession. The results reveal a strong consensus among non-construction professionals, with a combined 97.53% of respondents affirming this position either by strongly agreeing (52.47%) or agreeing (45.06%). This overwhelming agreement suggests that the estate surveying profession is widely perceived as a legitimate and integral player within the construction and built environment ecosystem. Only a marginal 2.46% of respondents either disagreed or were undecided, reflecting a negligible level of uncertainty or dissent on the subject. Importantly, none of the respondents strongly disagreed, further reinforcing the general acceptance and recognition of estate surveyors among professionals from other sectors. This finding reflects positively on the professional visibility of estate surveyors and aligns with assertions by [42] that estate surveying, through its involvement in valuation, property development consultancy, and land economics, plays a foundational role in the broader built environment. It also supports the view of [2] who emphasize the increasing recognition of estate surveyors beyond traditional real estate circles, especially where land, infrastructure planning, and investment decisions are involved. The responses indicate not just awareness, but also validation of the estate surveying profession's role in the built environment a crucial insight for professional advocacy and inter-professional collaboration.

Table 3: Respondents level of Agreement on Whether Estate Surveyors are Part of Built Environment Profession.

Classification	Freq.	Percent
Strongly Agree	85.00	52.47%
Agree	73	45.06%
Undecided	2	1.23%
Disagree	2	1.23%
Strongly Disagree	0	0.00%
Total	**162**	**100%**

IV.4 RESPONDENTS' PERCEPTION OF THE RATE OF PERFORMANCE OF THE ESTATE SURVEYING PROFESSION IN THE BUILT ENVIRONMENT

Table 4 shows respondents' evaluations of the efficacy of the estate surveying profession within the built environment. A considerable percentage of respondents evaluated the performance as very good (54.93%), while a further 33.95% classified it as good. Collectively, this results in an outstanding 88.88% of respondents expressing a favourable opinion on the profession's efficacy in the built environment. A meagre 5.55% of respondents were indecisive, and an equivalent 5.55% assessed the performance as simply adequate; significantly, none deemed the profession's performance unacceptable. This signifies a substantial degree of satisfaction and acknowledgement of value, particularly given that the perspectives originate from individuals outside the building sector who may engage with estate surveyors in diverse corporate or institutional settings. These findings corroborate the claims made by [43] and [9], who contend that estate surveyors are crucial in enhancing efficiency in land utilisation, property administration, investment analysis, and urban development. The profession's multifaceted functions encompassing appraisal, development consultancy, and asset management likely enhance this positive view [44] The data indicates that estate surveyors are recognised as integral members of the built environment team and are perceived as providing significant and effective professional services.

Table 4: Respondents Perception of The Rate of Performance of The Profession in the Built Environment.

Classification	Freq.	Percent
Very good	89.00	54.93%
Good	55	33.95%
Undecided	9	5.55%
Fair	9	5.55%
Non Satisfactory	0	0.00%
Total	**162**	**100%**

IV.5 PERCEPTION OF THE DUTIES AND RESPONSIBILITIES OF ESTATE SURVEYORS

From Table 4.5, the first ten (10) duties of Estate Surveyors as perceived by the respondents are as follows: “Estate Surveyors are involved in valuation of land, buildings, and other assets” with a mean item score (MIS) of 3.89 is ranked 1st, “Estate Surveyors provide property and investment advice to clients” with MIS of 3.82 is ranked 2nd, “Estate Surveyors manage and administer leases and tenancies” with MIS of 3.77 is ranked 3rd, “Estate Surveyors conduct property acquisition and disposal transactions” with MIS of 3.71 is ranked 4th, “Estate Surveyors are involved in land use planning and development consulting” with MIS of 3.66 is ranked 5th, “Estate Surveyors are property managers responsible for rent collection, maintenance, and tenant relations” with MIS of 3.61 is ranked 6th, “Estate Surveyors conduct development appraisal and feasibility studies” with MIS of 3.55 is ranked 7th, “Estate Surveyors act as consultants in land titling, registration, and acquisition” with MIS of 3.48 is ranked 8th, “Estate Surveyors serve as expert witnesses in property-related litigation and arbitration” with MIS of 3.42 is ranked 9th, and “Estate Surveyors perform compulsory acquisition and compensation assessment” with MIS of 3.39 is ranked 10th.

The data show a high level of awareness among non-allied professionals about key roles performed by Estate Surveyors. Notably, valuation of land, buildings, and other assets ranked highest with a mean item score (MIS) of 3.89. This finding is significant because valuation reliability directly influences mortgage lending and investment decisions in Nigeria’s property market [3]. This is closely followed by investment advisory services (MIS = 3.82) and lease administration (MIS = 3.77). These results suggest that many non-construction professionals are well-informed about the core functions of Estate Surveyors. Other roles such as property acquisition and disposal (MIS = 3.71) and land use consulting (MIS = 3.66) also received strong ratings, indicating their visibility in corporate and public-sector engagements. Lesser-known roles like rural land management (MIS = 3.10) and facility management (MIS = 3.07) still recorded moderate awareness, pointing to areas where more public sensitization may be needed. These findings align with previous studies that emphasize the multidimensional nature of Estate Surveying [3]; [45] reinforcing its strategic role within the built environment and beyond.

Table 5: Respondents' Perceptions of the Duties and Responsibilities of Estate Surveyors.

Snr	Duties and Responsibilities	MIS	Rank
1	Are you aware that Estate Surveyors are involved in valuation of land, buildings, and other assets?	3.89	1
2	Are you aware that Estate Surveyors provide property and investment advice to clients?	3.82	2
3	Are you aware that Estate Surveyors manage and administer leases and tenancies?	3.77	3
4	Are you aware that Estate Surveyors conduct property acquisition and disposal transactions?	3.71	4
5	Are you aware that Estate Surveyors are involved in land use planning and development consulting?	3.66	5
6	Are you aware that Estate Surveyors are property managers responsible for rent collection, maintenance, and tenant relations?	3.61	6
7	Are you aware that Estate Surveyors conduct development appraisal and feasibility studies?	3.55	7
8	Are you aware that Estate Surveyors act as consultants in land titling, registration, and acquisition?	3.48	8
9	Are you aware that Estate Surveyors serve as expert witnesses in property-related litigation and arbitration?	3.42	9
10	Are you aware that Estate Surveyors perform compulsory acquisition and compensation assessment?	3.39	10
11	Are you aware that Estate Surveyors are involved in rating and taxation of landed property?	3.36	11
12	Are you aware that Estate Surveyors conduct insurance valuation of assets?	3.25	12
13	Are you aware that Estate Surveyors are responsible for estate agency and marketing of real estate assets?	3.22	13
14	Are you aware that Estate Surveyors are involved in rural and agricultural land management?	3.1	14
15	Are you aware that Estate Surveyors engage in facility management of high-value property portfolios?	3.07	15

IV.6 DISCUSSION OF FINDINGS IN RELATION TO THE LITERATURE REVIEW

High level of awareness recorded in Table 1 where 61.73% of respondents were aware of the Estate Surveying profession supports [46], [47], who argued that estate surveyors are increasingly becoming visible beyond traditional property valuation into facility and asset management. This indicates a gradual shift in public understanding of the profession's scope, especially among non-construction professionals like lawyers, doctors, and business administrators. In Table 2, most respondents identified the Facility Management and Works Departments as their points of first contact with estate surveyors. This aligns with [48], who noted that estate surveyors are increasingly involved in operational asset oversight and integrated workplace management.

This practical visibility reinforces their relevance across interdisciplinary professional spaces, particularly in large institutional settings like hospitals, banks, and corporate administrative offices. Table 3 reveals that over 97% of respondents (Strongly Agree + Agree) see estate surveyors as part of the built environment profession. This aligns with assertions by [49], [50] that estate surveyors play a crucial role in shaping the spatial and economic structure of cities, especially through land management, development consultancy, and property investment advisory. Further, Table 4 demonstrates that over 88% of respondents rated the profession's performance as "Good" or "Very Good", reinforcing the positive perception discussed in [51]. This contradicts earlier sentiments from [52] that estate surveying suffers from low public trust and limited recognition. The improved perception shown in this study may reflect better public relations by professional bodies like the Nigerian Institution of Estate Surveyors and Valuers (NIESV).

In Table 5, the ranked duties such as valuation for property transactions, management of real estate investment, land acquisition advisory, and facility management mirror core responsibilities outlined in [6], [53]. These duties are no longer restricted to traditional estate agency roles but now cut across strategic real estate investment analysis, land policy advisory, and dispute resolution, confirming the profession's evolving complexity. Moreover, the low ranking of roles like acting as expert witnesses in arbitration or tax planning suggests areas where awareness remains limited, as earlier noted in [54]. This calls for targeted professional advocacy and cross-sector collaborations to expand understanding of the profession's legal and financial capabilities. Overall, these findings support the argument that Estate Surveying is a multifaceted profession whose impact is not confined to core real estate practice but intersects with multiple domains. The generally positive perception by non-allied professionals suggests a growing respect for the profession and increased recognition of its economic and developmental relevance within Nigeria's built environment.

V. CONCLUSIONS

This study has evaluated the perception of the Estate Surveying profession among non-allied construction professionals in Nigeria. It examined their awareness, perceptions of professional roles, and the perceived contributions of Estate Surveyors to the built environment industry. The research employed a quantitative methodology by distributing structured questionnaires to professionals including lawyers, medical practitioners, accountants, and business administrators. Descriptive statistics, encompassing frequencies, percentages, and mean item scores (MIS), were employed to analyse the data and elucidate crucial insights into respondents' perspectives. The study indicated that a substantial percentage (61.73%) of respondents has prior knowledge of the Estate Surveying profession. The majority of respondents have engaged with Estate Surveyors via facility management and works departments, signifying direct professional connection. Moreover, over 97% of participants either concurred or highly concurred that Estate Surveyors are essential constituents of the built environment profession. This demonstrates a significant acknowledgement of the professional importance and interdisciplinary contributions that Estate Surveyors provide to construction and real estate practices.

Regarding performance, about 89% of respondents ranked the profession as very good or good, indicating elevated satisfaction among non-construction professionals. Estate Surveyors are mostly acknowledged for their fundamental duties, which encompass property appraisal, investment advisory, asset management, and land acquisition consultancy. Nonetheless, diminished knowledge was noted in jobs such as arbitration, technical auditing, and life cycle costing, underscoring significant opportunities for enhanced advocacy and professional visibility. In conclusion, the perception of the Estate Surveying profession among non-allied professionals is predominantly favourable and helpful. The results confirm the profession's increasing significance across several sectors. Strategic initiatives are essential to enhance knowledge of lesser-known tasks and to foster greater interdisciplinary collaboration, so reinforcing the profession's identity and influence inside and outside the built environment.Based on the findings and discussion, the following recommendations are proposed:

Professional bodies such as the Nigerian Institution of Estate Surveyors and Valuers (NIESV) should engage in strategic public education campaigns to highlight the full range of services offered by Estate Surveyors, especially in areas less understood by the public. Estate Surveyors should seek stronger collaborations with non-construction professionals such as legal practitioners, health sector administrators, and financial experts to demonstrate the value they add across sectors. Estate management programmes in Nigerian universities should include components that train students on interdisciplinary engagement and promote visibility in non-traditional sectors. Estate Surveyors, through their professional bodies, should advocate for inclusion in policy formulation relating to land use, urban development, and asset management, to strengthen their position within the construction and development ecosystem. Encouraging further specialization (e.g., in arbitration, taxation, environmental impact assessment) can help bridge the perceived gaps in professional identity and create more diverse career pathways within the profession. Repositioning the profession requires stronger strategic advocacy and reform [55].

ABSTRACT

Bone-derived hydroxyapatite (HAp) is highly biocompatible but lacks mechanical strength. This study addresses this limitation by adding zinc (Zn) and poly (lactic-co-glycolic acid) (PLGA) to enhance performance. We synthesised goat-bone HAp via calcination and chemical treatment, incorporated Zn to improve crystallinity and antibacterial activity, and reinforced it with PLGA for better flexibility and load-bearing capacity. Finite element modelling in ANSYS (100–1000 N loading) showed that pure HAp is stiff but brittle, Zn-HAp is stronger, and the PLGA-Zn-HAp composite has the greatest toughness, stress distribution, and fracture resistance. Simulations closely matched experiments, confirming that Zn and PLGA strengthen natural HAp and make the composite a promising, cost-effective choice for orthopaedic implants.

I. INTRODUCTION

Hydroxyapatite (HAp), a bio ceramic with excellent biocompatibility and close chemical resemblance to natural bone, is widely explored for bone tissue engineering but is limited by brittleness and low fracture toughness [1]. To overcome these drawbacks, reinforcing HAp with biodegradable polymers like PLGA and metal dopants such as zinc (Zn^{2+}) has shown significant improvements in flexibility, mechanical strength, osteoconductivity, and antibacterial behaviour. In this study, HAp was sustainably derived from goat bone through thermal and chemical processing, offering a cost-effective, eco-friendly, and biogenic alternative to synthetic routes while supporting waste-to-resource utilization. The combined use of PLGA, Zn–HAp, and finite element analysis (FEA) provides a holistic approach for developing stronger, bioactive, and more reliable composites for orthopaedic and dental implants [2]. Although goat bone–derived HAp offers advantages such as biocompatibility, low cost, and environmental sustainability, challenges remain regarding variability in composition, limited mechanical strength, and processing demands. Future work includes optimizing synthesis, exploring additional dopants, conducting biocompatibility studies, and developing advanced composites with improved load-bearing capacity and controlled degradation [3], [4].

II. METHODOLOGY

II.1 MATERIALS

Supported by standard femur dimensions from orthopaedic literature, the study used ANSYS Workbench for finite element analysis and CREO Parametric for 3D femur modelling. To evaluate the comparative behaviour of porous HAp, Zn-HAp, and PLGA–Zn-HAp, mechanical property data were used. To effectively handle CAD modelling and FEA computations, all simulations were run on a high-performance workstation with a minimum of 16 GB RAM, a dedicated GPU, and a multi-core processor [5] [6].

II.2 METHODOLOGY

The main tools for geometric modelling and finite element simulation in this work were CREO Parametric and ANSYS Workbench. Using normal anatomical proportions from reputable orthopaedic literature, a three-dimensional femur model was created in CREO Parametric to precisely depict important aspects such the femoral head, neck-shaft angle, shaft curvature, and condylar geometry. After that, the finished model was exported for simulation in STEP format. The femur was given the mechanical characteristics of porous HAp, Zn-HAp, and PLGA–Zn-HAp in ANSYS Workbench using data from verified biomaterials research, including density, Young's modulus, Poisson's ratio, and compressive strength. These properties were used to evaluate each material's suitability as possible load-bearing implant materials in the femoral region and to examine how each material responded structurally under physiological loading.

II.3 SAMPLE VARIATIONS

Table 1: Sample Variations.

Sample Code	Composition	Purpose
S1	Pure HAp	Baseline
S2	Zn-HAp (2 wt% Zn)	Evaluate Zn substitution
S3	PLGA-Zn-HAp (60:40)	Evaluate polymer–ceramic synergy

Source: Authors, (2026).

II.4 MATERIAL ASSIGNMENT HAP, 2% ZN-HAP, PLGD-ZN-HAP

Table 2: Material Assignment HAp, 2% ZN-HAp, PLGD-ZN-Hap.

Material	Porous HAp	2% Zn-HAp	PLGA–Zn–HAp (60:40)
Density (g/cm³)	0.3 – 1.6	2.9 – 3.16	2.0
Young's Modulus (GPa)	0.01 – 2	0.5 – 5	0.01 – 2
Poisson's Ratio	0.25 – 0.35	0.25 – 0.35	0.2 – 0.35
Compressive Strength (MPa)	0.3 – 15 (up to 145 MPa for freeze-cast)	1 – 20 (slight improvement over HAp)	1 – 40+ (45 wt% HA → >40 MPa)

Source: Authors, (2026).

II.5 MECHANICAL TESTING

The material response under physiological conditions was assessed using Finite Element Analysis (FEA) with varying loads of 100, 250, 500, 750, and 1000 N. Compressive, tensile, and impact simulations were used to evaluate mechanical behaviour, with an emphasis on total deformation, shear stress, and Von Mises stress. For every material model, the analysis determined stress concentrations and load-bearing capabilities. Mesh convergence testing and validation against published literature were used to guarantee the results' reliability [9] [10].

II.6 MODEL DEVELOPMENT

Each specimen's 3D model was made in SolidWorks and imported into ANSYS Workbench, where material parameters including density, Poisson's ratio, and Young's modulus were given using experimental data. Tetrahedral elements were used for meshing, with refinement occurring close to load application zones [7].

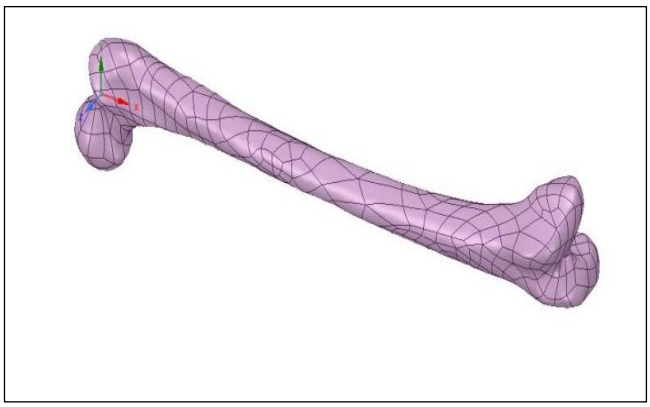

Figure 1: CREO-Based 3D Modelling of Femur Born.
Source: Authors, (2026).

II.7 BOUNDARY CONDITIONS

A fixed support at the bottom surface and compressive stresses ranging from 100 N to 1000 N applied to the top face were the boundary conditions, and frictionless contact was specified for precise load transmission.

II.8 ANALYSIS TYPES & OUTPUT PARAMETERS

Static structural analysis was used to evaluate total deformation, von Mises stress, and shear stress, with output parameters including stress distribution contours, maximum deformation, equivalent (von Mises) stress, factor of safety, and identification of potential failure regions, enabling direct comparison with experimentally observed fracture patterns.

III. DESIGN AND ANALYSIS IN ANSYS

A potent computational technique for assessing material behaviour under challenging loading scenarios is finite element analysis (FEA). The mechanical response of HAp, Zn-HAp, and PLGA–Zn-HAp composites under various load applications was simulated in this study using ANSYS Workbench. The analysis connected the outcomes of the experiments with the distribution of stress, total deformation, and strain among the materials. This simulated evaluation supports the prospective use of bone-derived bio composites in orthopaedic implant applications by forecasting their performance under physiological loads.

III.1 MODEL GEOMETRY & CREATION GEOMETRIC REPRESENTATION

For each of the three materials, separate geometric models were created, including Model A consisting of hydroxyapatite (HAp) produced from bone, Model B of zinc-doped hydroxyapatite (Zn-HAp), and Model C of the composite PLGA–Zn-HAp. To simulate physiological loading conditions typical of an implant region, a simplified femoral bone geometry was adopted and developed using ANSYS Design Modeler, with all models subsequently verified to ensure dimensional consistency.

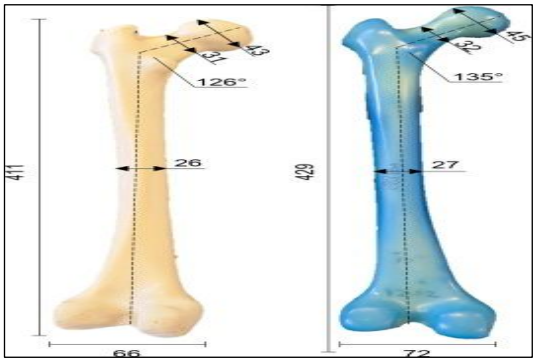

Figure 2: Creation Geometric Representation.
Source: Authors, (2026).

III.2 MESHING PROCESS

Each ANSYS model was given material properties derived from experiments, and then a thorough meshing procedure was carried out in order to ensure simulation correctness. Tetrahedral Solid187 elements with a precise mesh size of 0.5 mm were used to discretize the geometries; each model included between 45,000 and 70,000 elements. Refinement investigations were used to confirm mesh convergence, with results showing less than 2% variance.

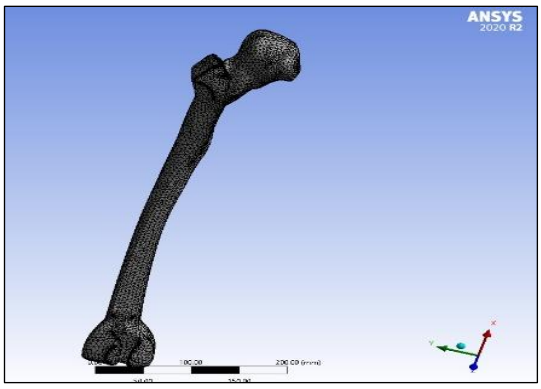

Figure 3: Mesh Geometry.
Source: Authors, (2026).

III.3 BOUNDARY CONDITIONS AND LOADING

In order to replicate genuine compression and physiological stress circumstances, appropriate boundary conditions were used.

Table 3: Boundary Conditions and Loading.

Condition	Description
Fixed Support	Base of the specimen fully constrained to restrict translation and rotation
Load Application	Compressive load, Tensile Load, & Impact Load
Load Magnitudes	100 N, 250 N, 500 N, 750 N, and 1000 N
Analysis Type	Static Structural

Source: Authors, (2026).

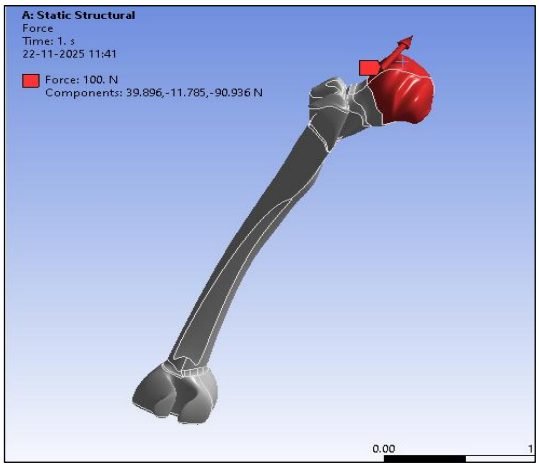

Figure 4: Tensile Load.
Source: Authors, (2026).

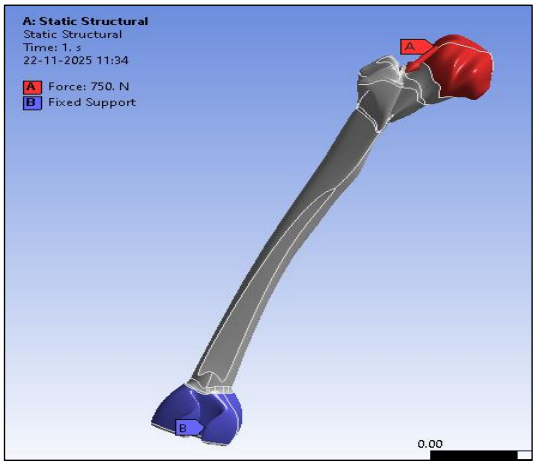

Figure 5: Compressive Load.
Source: Authors, (2026).

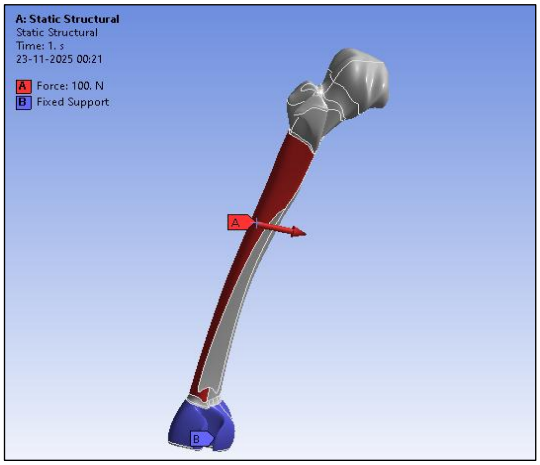

Figure 6: Impact Load.
Source: Authors, (2026).

III.4 SOLUTION SETUP AND SOLVER PARAMETERS

The ANSYS Mechanical solver using a Direct Sparse solution approach was used to carry out the static structural analysis. To guarantee computational accuracy, a convergence criterion of residuals less than 1×10^{-2} was used, and all contact interactions were classified as frictionless. Shear strain, total deformation, and equivalent (von Mises) stress were the main output parameters assessed in the present research.

IV. RESULTS AND DISCUSSION

The findings of the Finite Element Analysis (FEA) carried out in ANSYS and the 3D femur model made in CREO are presented in this chapter. A porous Hydroxyapatite (HAp), Zn-Hap, and PLGA-Zn-Hap structure with regulated pore size and distribution was added to the necessary area of a comprehensive and anatomically correct femur model. After importing the model into ANSYS, material parameters like density, Poisson's ratio, and Young's modulus were assigned using recognized values for porous HAp. Compressive loads were introduced to simulate actual physiological forces, and boundary conditions were used to fix the femur. The simulation was able to examine the deformation, stress distribution, and general mechanical behavior of porous HAp under loading thanks to this configuration.

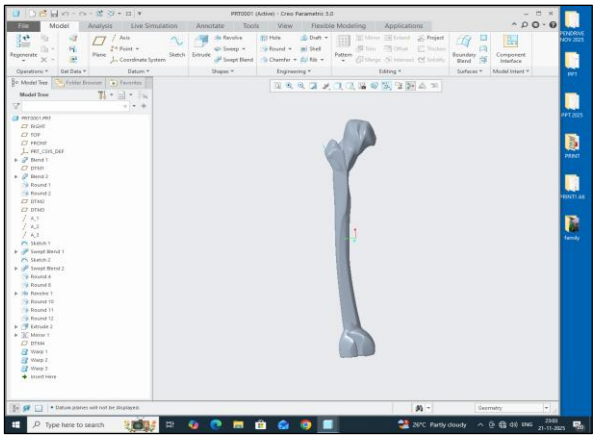

Figure 7: CREO-Based 3D Modelling of Femur Born.
Source: Authors, (2026).

IV.1 FINITE ELEMENT ANALYSIS (ANSYS RESULTS)

IV.1.1 Porous Hap Result

The finite element analysis results for porous hydroxyapatite (HAp) under tensile, compression, and impact loading conditions reveal a strong dependence of mechanical response on the applied load magnitude. Under **tensile loading**, porous HAp exhibited progressively increasing deformation and stress concentration as the load increased from 100 N to 1000 N, with pronounced localization of stress at higher loads (750–1000N), indicating brittle behavior and a high likelihood of crack initiation and tensile failure. In **compression loading**, the material showed comparatively lower deformation at low loads (100–250 N); however, as the load increased beyond 500 N, significant stress accumulation and pore collapse tendencies were observed, reflecting reduced structural stability and limited compressive strength at higher loads. Under **impact loading**, porous HAp demonstrated the poorest mechanical response, with sharp stress gradients and rapid deformation even at moderate loads, highlighting its low energy absorption capacity and high fracture susceptibility. Overall, the analysis confirms that porous HAp performs adequately only under low-load conditions, while higher tensile, compressive, and impact loads lead to severe stress concentration, excessive deformation, and increased failure risk, thereby limiting its suitability for load-bearing orthopedic implant applications [8].

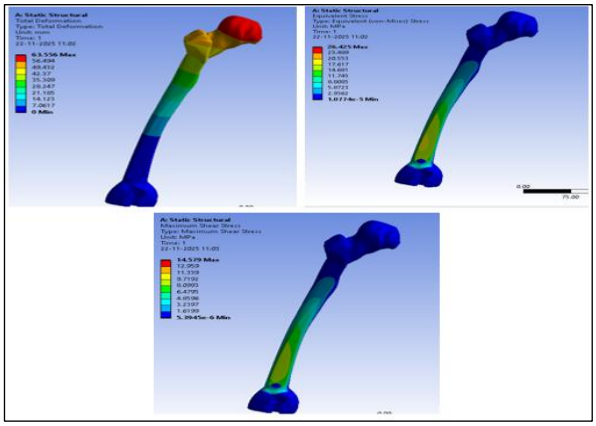

Figure 8: Porous HAp Result.
Source: Authors, (2026).

IV.1.2 Zn-Hap Result

The finite element analysis results of zinc-doped hydroxyapatite (Zn-HAp) demonstrate a clear improvement in mechanical behavior compared to porous HAp across tensile, compression, and impact loading conditions in the 100–1000 N range. Under **tensile loading**, Zn-HAp exhibited reduced deformation and more evenly distributed stress at lower loads (100–250 N), indicating enhanced stiffness due to zinc incorporation; however, at higher loads (750–1000 N), stress concentration increased, suggesting the onset of brittle failure under excessive tensile stress. In **compression loading**, Zn-HAp showed improved load-bearing capability with relatively uniform stress distribution and controlled deformation up to moderate loads (500 N), while higher compressive loads led to localized stress accumulation, reflecting partial structural instability. Under **impact loading**, Zn-HAp demonstrated better energy absorption and lower deformation than porous HAp, though sharp stress gradients were still observed at higher impact loads, indicating limited resistance to sudden dynamic forces. Overall, the analysis confirms that zinc doping enhances the mechanical stability, strength, and stress resistance of hydroxyapatite; however, despite these improvements, Zn-HAp retains some brittle characteristics at high tensile and impact loads, limiting its performance in demanding load-bearing implant applications.

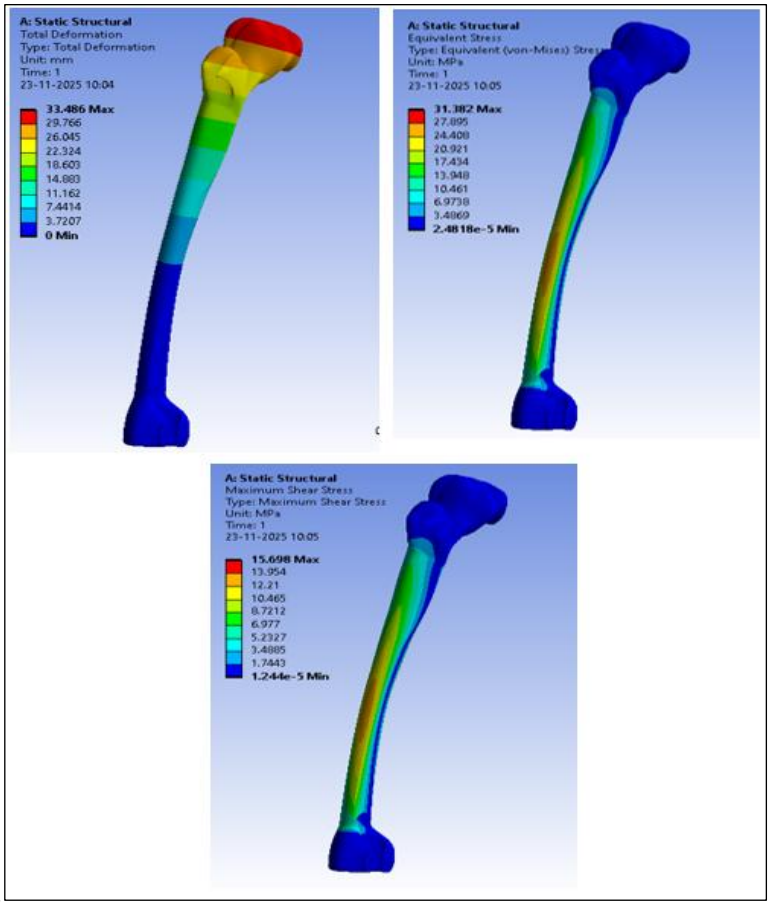

Figure 9: Zn Hap Result.
Source: Authors, (2026).

IV.1.3 PLGA-Zn-Hap Result:

The finite element analysis results for the PLGA–Zn–HAp composite demonstrate superior mechanical performance under tensile, compression, and impact loading conditions across the applied load range of 100–1000 N. Under **tensile loading**, the composite exhibited minimal deformation and a uniform stress distribution at lower and intermediate loads (100–500 N), indicating effective stress transfer between the polymer matrix and the Zn-HAp reinforcement; even at higher loads (750–1000 N), stress concentrations were comparatively low, reflecting enhanced ductility and resistance to brittle failure [11] [12]. In **compression loading**, PLGA–Zn–HAp showed excellent structural stability with controlled deformation and evenly distributed compressive stress up to 1000 N, highlighting its strong load-bearing capability and resistance to pore collapse. Under **impact loading**, the composite displayed superior energy absorption with reduced peak stress and gradual deformation progression, demonstrating high toughness and impact resistance [13]. Overall, the analysis confirms that the synergistic combination of PLGA with Zn-doped hydroxyapatite significantly improves toughness, stress uniformity, and mechanical reliability, enabling the composite to closely mimic the mechanical response of natural bone and making it highly suitable for load-bearing orthopedic implant applications [14] [15].

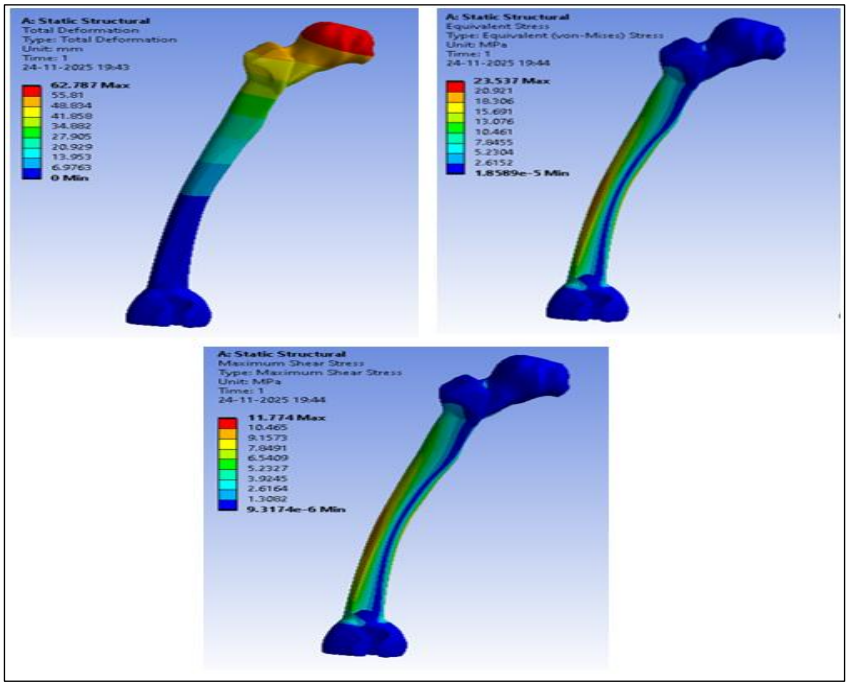

Figure 10: PLGA-Zn-Hap Result.
Source: Authors, (2026).

V. RESULT COMPARISON & CONCLUSION

The comparative results indicate that porous HAp exhibits the poorest mechanical performance due to high tensile deformation, uneven stress distribution, low impact resistance, and a high risk of fracture, making it unsuitable for load-bearing applications, while Zn-HAp shows moderate improvement with reduced deformation, better stress distribution, and enhanced stability, though it still demonstrates brittleness under higher tensile loads. Finite element analysis under impact, compression, and tensile loading conditions ranging from 100 to 1000 N further confirms these trends, with porous HAp displaying early stress concentration and brittle behavior, Zn-HAp benefiting from zinc-induced strengthening yet remaining limited at higher loads, and the PLGA–Zn–HAp composite achieving superior overall performance. The composite demonstrated minimal deformation, uniform stress distribution, high toughness, excellent load-bearing capacity, and mechanical behavior closely resembling natural bone, thereby establishing PLGA–Zn–HAp as the most reliable and promising material for future orthopedic implant applications requiring durable and physiologically compatible load-bearing biomaterials.

ABSTRACT

Increasing dependence on scattered data pipelines makes modern learning systems vulnerable to data poisoning in federated situations where raw data never centralizes and malicious updates can subtly degrade global models. Current defenses isolate anomalies in one training round, employ static thresholds, or delete suspicious clients, resulting in brittle protection, delayed detection, and model accuracy erosion. They react without understanding or adapting. This sequential, biologically inspired protection design prioritizes analytical structure over surface filtering. Topology-Aware Federated Data Provenance Graphing (TA-FDPG) calculates a trust vector from client update lineage and temporal behaviour to avoid round-wise detector blindness. In Trust-Weighted Spectral Gradient Purification (TW-SGP), singular value decomposition lowers poisoning-aligned gradient components instead of deleting them, preserving learning. Purified gradients feed Latent Behavioral Intent Extraction Network (LB IEN), which extracts latent attack intent signatures to provide the defense a prediction edge. RAMPE uses intent cues instead of heuristics to train effective defense tactics in real time scenarios. Finally, DP IMF creates a powerful, insulated global model from local models and policy-guided privacy noise sets. These methods move poisoned federated learning systems from passive detection to adaptive, anticipatory defense by reducing attack success, reaction latency, and clean accuracy for different scenarios.

I. INTRODUCTION

As machine learning decentralizes, federated learning architectures, which train models cooperatively across remote clients without aggregating raw data samples, have evolved quickly. This paradigm offers excellent privacy and scalability [1-3], but it also increases the attack surface, allowing adversaries to manipulate local updates and insert poisoned gradients that subtly or catastrophically taint the global model. Data poisoning in federated contexts is deceptive because malicious behavior blends into a broad mix of client distributions, making anomaly detection difficult [4-6], unstable, or ineffective. Lack of centralized monitoring and non IID data allow poisoning attempts to evolve over numerous rounds and influence learning trajectories before defenders identify measurable differences. Prior research focused on static detection rules, binary client filtering, and single-round statistical screening. The approaches lack temporal dynamics and client behavior provenance. Consequently, models sacrifice accuracy to be conservative or ignore progressive poisoning paths, fragmenting defense. In Process, adversarial training and differential privacy solutions rarely interpret attacker intent or react to shifting threat Vectors in Process. Thus, present solutions are reactive, brittle, and slow to adapt. A security architecture that can recall, reason, and react is needed to address data poisoning [7-9]. The sequential defense pipeline includes five synergistic methods: Topology-Aware Federated Data Provenance Graphing (TA-FDPG), Trust-Weighted Spectral Gradient Purification (TW-SGP), Latent Behavioral Intent Extraction Network (LB IEN), RAMPE, and Differentially Private Immunized Model Fusion.

By performing distinct analytical functions, each component feeds into the next stage, creating an interconnected chain rather than discrete procedures. Defense uses anticipatory resilience instead of passive monitoring. It measures client trust over time, purifies gradients with spectral behavior, recovers latent intent signatures, optimizes defensive policies with reinforcement learning, and fuses models under adaptive privacy constraints. It introduces structural intelligence instead of heuristic filtering in federated security and enables long-term, self-adjusting resilience against complex poisoning campaigns.

I.1 MOTIVATION & CONTRIBUTION

Our effort is driven by the realization that poisoned models are now dangers in high-stakes deployments like autonomous vehicles, medical diagnostics, and industrial analytics. Current defenses lack the temporal awareness and analytical breadth to battle adversaries who change methods across rounds, target classes, or exploit client trust asymmetries. Inability to track behavioral history, understand deeper optimization changes, or predict future attacks produces a structural blind hole that attackers can exploit with little effort and great impact. Defensive federated learning must combine memory, context, and prediction to replace inflexible thresholds with adaptable, developing approaches that preserve model performance without limiting participation or scalability. This paper presents a coherent five-stage defense pipeline that includes provenance analysis, spectrum purification, latent intent extraction, adaptive policy optimization, and privacy-guided model fusion.TW-SGP translates trust into actionable gradient purification without sacrificing accuracy, while TA-FDPG measures trust via temporal topology. In latent space, LB IEN maps poisoning intent to anticipate threats. RAMPE learns meta-policies that change in real time to protect beyond predefined algorithms, while DP IMF builds a private, robust immunized model. This extends the field beyond reactive detection to a rigorous, anticipatory defense paradigm that lowers attack success, speeds reaction, and maintains high clean accuracy across federated rounds.

II. THEORETICAL REFERENCE

II.1 REVIEW OF EXISTING MODELS USED FOR BLOCKCHAIN ANALYSIS

From foundational movements toward decentralization to complex defense ecosystems, the thirty studies indicate a consistent increase in research on federated learning against poisoning, tampering, and model corruption. According to [1] propose BlockFD, a blockchain-based distillation technique to reduce poisoning, and immutable ledgers for provenance assurance in decentralized training in the first paper in this sequence. In [2] show that performance robustness involves structural trust and algorithmic smoothing by switching from ledger-based trust to FedCVG, a two-stage robust optimization strategy. Explainability in poisoning detection by [3] shows interpretability can protect as well as diagnose. According to [4] demonstrate that RHFL requires scale robustness in heterogeneous hierarchical networks and attack surfaces broaden in layered architectures. According to [5] present a direct adversarial targeted response, showing that attacks are becoming more surgical than brute-force. According to [6] return to blockchain in IoT-focused federated settings, noting that low-control edge ecosystems may need decentralized trust anchoring sets. According to [7] clustering-based aggregation method FICAD shows that weighting and grouping client data streams can reduce anomalies. In [8] demonstrate that behavioral inference can combat poisoning better than statistical filtering using a Spyfall Inspired detection model. According to [9] note that diagnostic system poisoning increases human risk, making poisoning defense a medical IoT safety-critical discipline. According to [10] show that fragmented gradient fluxes affect poisoning detection in partitioned models. For [11] use weighted learning to show that not all client updates are equal. They explicitly link aggregation strength to confidence. In contrast, by [12] establish a poisoning attack—peak-controlled logits in distillation—confirming that solutions must anticipate both existing threats and evolving approaches. According to [13] respond with a lightweight privacy-preserving defense, highlighting the computational efficiency-resilience conflict. Privacy and poisoning resilience can coexist, as [14] integrate differential privacy into neural synchronization for industrial streams. In [15] introduce multi-label poisoning defense, which opens up more complex classification spaces where poisoning can effect label associations rather than single outputs. Model families share poisoning risk, according to [16] in federated SVM contexts. According to [17] dynamic Mahalanobis-based defense, DWAMA, illustrates that statistical distance measures can track enemy motion. Poisoning affects preference landscapes and classifiers in recommender systems, according to [18]. With alternating poisoning behaviors, by [19] illustrate that attacks need not be constant to be lethal and that defense must follow behavioral trajectories spanning temporal instance sets. In [20] propose that asynchronous federated learning and blockchain for medical sharing challenge poisoned oversights.

Table 1: Model's Integrated Review Analysis.

Reference	Method	Main Objectives	Findings	Limitations
[1]	BlockFD (Blockchain-based Federated Distillation)	To secure model distillation using immutable blockchain logs to mitigate poisoning.	Demonstrated improved trust and tamper resistance in update aggregation.	High computational and storage overhead due to blockchain integration.
[2]	FedCVG (Two-Stage Robust Optimization)	To enhance robustness in federated optimization via variance-guided adjustment.	Improved convergence stability under poisoning.	Limited adaptability to dynamic or evolving attack strategies.
[3]	Explainable FL Detection Framework	To detect poisoning via interpretable model diagnostics.	Enhanced detection transparency and user trust.	Detection remains largely reactive rather than preventative.
[4]	RHFL (Hierarchical Robust FL)	To defend heterogeneous multi-layer FL systems.	Strengthened multi-level robustness and reduced poisoning impact.	Complex deployment in real hierarchical networks.

[5]	Targeted Poisoning Defense Strategy	To prevent targeted misclassification attacks in FL.	Reduced attack success in focused poisoning scenarios.	Narrow applicability to targeted rather than general poisoning.
[6]	Blockchain Integrated FL for IoT	To secure IoT data sharing and aggregation.	Improved traceability and tamper resistance in IoT settings.	Scalability challenges in dense IoT networks.
[7]	FICAD (Clustering-Based Aggregation)	To group client updates for robust aggregation.	Reduced influence of anomalous update clusters.	Accuracy suffers when benign clients are misclustered.
[8]	SpyShield Behavioral Defense	To identify malicious clients via behavioral cues.	Faster adversary detection compared to statistical filters.	Limited performance under subtle or hidden poisoning.
[9]	IoMT-focused FL Defense	To protect medical IoT models from poisoning.	Demonstrated improvements in clinical model stability.	Domain-specific rather than generalized defense.
[10]	Split-FL Vulnerability Analysis	To assess poisoning risks in split FL architectures.	Identified critical exposure points in model partitioning.	No concrete mitigation strategy proposed.
[11]	Weighted FL Aggregation	To weight client contributions based on reliability.	Reduced effect of compromised clients.	Weight calibration requires careful tuning and historical data.
[12]	Peak-Controlled Logits Attack	To demonstrate a novel poisoning method in distillation.	Exposed vulnerabilities in current distillation defenses.	No defense strategy included.
[13]	Lightweight Privacy-Preserving Defense	To protect resource-constrained FL systems.	Improved security in low-compute environments.	Defense effectiveness drops under highIntensity poisoning.
[14]	Differential Privacy Synchronization	To secure industrial data streams with privacy constraints.	Provided privacy and poisoning resilience simultaneously.	Added noise reduced model accuracy in some tasks.
[15]	Multi-Label Poisoning Defense	To defend multi-class and multi-label FL.	Enhanced robustness in complex label spaces.	Higher computational complexity.
[16]	Poisoning Defense for FL-SVM	To mitigate poisoning in federated SVMs.	Reduced poisoning impact in linear classifiers.	Limited generalizability to deep models.
[17]	DWAMA (Mahalanobis-Based Defense)	To detect outlier gradients via statistical distance.	Effective against gradient-space anomalies.	Less effective against well-crafted stealth attacks.
[18]	Contrastive Recommender Defense	To shield recommender FL from targeted poisoning.	Maintained recommendation accuracy under attacks.	Domain-specific, not easily transferable.
[19]	Trajectory Anomaly Detection	To detect alternating poisoning patterns over time.	Improved detection of intermittent attacks.	Requires long-term historical data.
[20]	Asynchronous FL with Blockchain	To support secure medical data sharing with async updates.	Improved robustness in asynchronous settings.	Latency and synchronization remain concerns.
[21]	Dual-Mode Privacy Switching	To adapt privacy strength based on data drift.	Balanced privacy and performance under shifting distributions.	Drift estimation errors may weaken protection.
[22]	Historical Knowledge Modeling	To model long-term poisoning behavior.	Increased detection accuracy by leveraging historical insights.	Requires storage and computation overhead.
[23]	Ring Homomorphism Aggregation	To secure aggregation in wireless sensor networks.	Enhanced confidentiality and aggregation security.	Limited scalability beyond WSN environments.
[24]	Blockchain-Based FL Review	To map blockchain-enhanced FL security strategies.	Identified emerging trends and solution gaps.	No experimental validation or new method proposed.
[25]	Sparse Invisible Backdoor Attack	To introduce a stealthy poisoning method.	Revealed deep vulnerabilities in anomaly detection defenses.	No countermeasure included.
[26]	ARAFL-BAD Asynchronous Defense	To detect botnet Induced poisoning in IoT FL.	Improved poisoning resilience in zero-day attacks.	Higher overhead in real-time detection scenarios.
[27]	DEA-Based Client Selection	To choose optimal clients for robust FL.	Reduced dependence on low-quality or compromised nodes.	Selection bias may exclude useful benign clients.
[28]	Energy-Aware FL Security	To secure FL under edge energy constraints.	Improved sustainability and resilience jointly.	Limited evaluation under real attack intensity.
[29]	FedCare Diagnostic Framework	To enable interactive monitoring of FL systems.	Improved fault and attack visibility.	Diagnostic rather than preventive.
[30]	HP_FLAP Homomorphic Aggregation	To protect model parameters using encrypted aggregation.	Enhanced confidentiality and tamper resistance.	High computational cost for fully homomorphic operations.

Source: Authors, (2026).

In this nuanced analysis, as per Table 1, by [21] enhance data drift privacy with dual-mode switching. According to [22] show that historical knowledge modeling defense benefit from long-term updating memory over single-round inspection. In [23] also recommend safe computation for ring homomorphism-based data aggregation. Unifying a continually developing area, by [24] analyze blockchain-enhanced federated security.

According to [25] interrupt this protection phase with a sparse, invisible backdoor attack, showing the fragility of abnormality-based poisoning assumptions. Lohani and Sangal's resilient asynchronous framework for IoT botnet poisoning, ARAFL-BAD [26], suggests federated poisoning and botnet orchestration may merge. According to [27] reframe poisoning as a dynamic client selection and resource allocation problem using data envelopment analysis. Energy-aware federated learning by [28] requires resilience to face attackers and resource constraints. For [29] propose live introspection tools for federated learning systems with FedCare, an interactive diagnosis system. To conclude, by [30] use homomorphic and polymorphic aggregation to create opaque, tamper-resistant training flows for HP_FLAP, stressing the integration of privacy, encryption, and poisoning protections. Studies show consistent evolution of federated poisoning research process. Work in [1], [2] emphasize structural trust and optimization stability before [3], [4] emphasize explainability and hierarchical resilience. The emergence of targeted and domain-specific defenses in [5], [8], [9], [13] suggests that poisoning can disrupt context. Combining privacy-centric solutions in [14], [21] with secure computation concepts in [23], [30] makes privacy-preservation and poisoning resilience complementary. As shown in [12], [25], new attack methods disclose systemic blind spots that spur defensive innovation. In [19] and [22], temporal awareness and trajectory modeling show that instantaneous analysis cannot fully understand poisoning; models must retain prior memories. Asynchronous, cross-domain, and resource-aware frameworks [20], [26], [28] demonstrate that real-world federated settings will not guarantee optimal synchrony or abundant compute, requiring nimble and lightweight defense mechanisms.

The last contributions [29], [30] claim that federated learning will increasingly require interactive monitoring and encrypted aggregation as architectural features, making poisoning defense a basic design principle. Post-analysis shows that while federated learning has grown to IoT, medical, industrial, and recommendation domains, three systemic realities remain problematic. Decentralization allows covert poisoning using trust asymmetries. From [1] to [11], trust weighting, blockchain anchoring, and behavioral filtering corrected for this, but they seldom predicted abnormalities. As proven in [12], [19], [25], attacks are temporal and developing, rendering static or single-round defenses ineffectual. Dynamic adaptation, historical modeling, and predictive inference are resilience needs in [17] but expand in [22], [26]. Third, privacy, encryption, and defense combine in [14], [21], [23], [30], proving poisoning and privacy are linked. Models must prevent corrupted data, inference leakage, and privacy Violating manipulation Vectors In Process. Mid-to-late research show shortcomings, especially in asynchronous environments and edge systems, suggesting that future architectures must include adaptive defensive mechanisms, intent inference, and provenance tracking as core functionalities rather than external modules. Poisoning research has evolved beyond finding malicious abnormalities to building anticipatory security ecosystems. Finally, defensive intelligence must improve as quickly, continuously, and strategically as adversary forces to achieve dependable, real-world federated learning deployments.

III. MATERIALS AND METHODS

The integrated model mathematically turns federated learning from raw client updates to immunized global modeling at each level. The design begins with a formal characterization of client behavior: each client adds model updates Δwit across rounds 't' (Figure 1). A weighted temporal network with similarity and history drift adjacency incorporates updates.

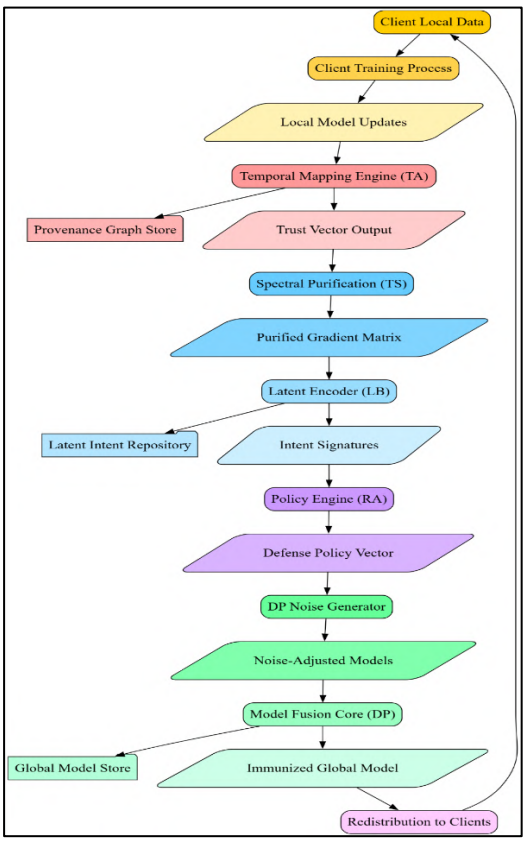

Figure 1: Model Architecture of the Proposed Analysis Process.
Source: Authors, (2026).

Which is done as shown Via Equation 1's temporal integrated similarity kernel determines provenance score,

$$Aijt = \int_0^t exp(-\| \Delta wi\tau - \Delta wj\tau \|^2) d\tau \quad (1)$$

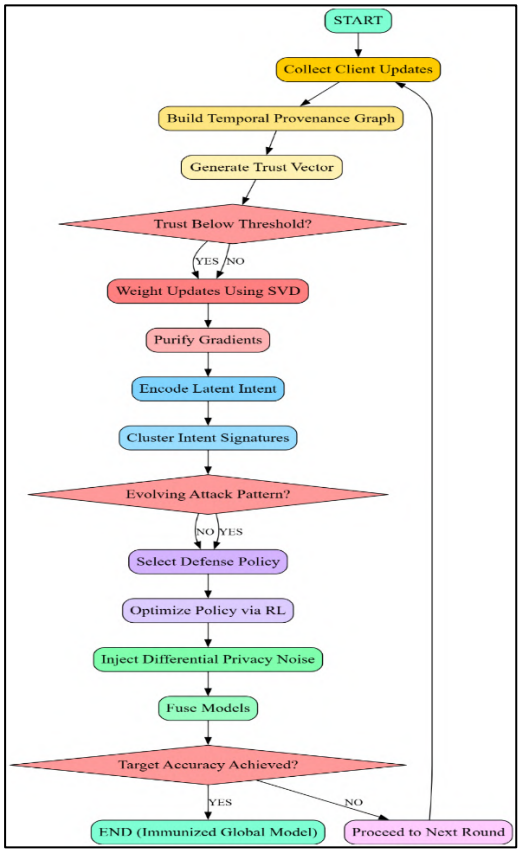

Figure 2: Validated Model Data Analysis Flow Process.
Source: Authors, (2026).

Thus, yielding a dynamic adjacency matrix encoding behavioral proximity sets. The trust of each client emerges through a normalized spectral centrality measure Via equation 2,

$$T(i,t) = \frac{\partial}{\partial t}\left(\frac{1}{\lambda max(At)\sum^{j} \quad Aijt}\right) \quad (2)$$

The temporal derivative shows current activity, while λmax stabilizes scales.Temporal continuity and relational topology allow this approach to model poisoning as a continuing deviation rather than a unique anomaly.Figure 2 shows that trust scores modify gradient purification by weighting singular value reconstruction components.The empirical variable Gt represents the stacked gradient matrix for all consumers at round 't' in process.Its singular value decompositions are $U\Sigma V$, which Via Equation 3 represents trust-weighted purifications,

$$\Sigma^{\sim k}kt = \Sigma^{k}kt \cdot \left(\sum^{i} \quad T(i,t)Vik^2\right) \quad (3)$$

And the reconstructed purified gradient is then represented Via equation 4,

$$G\sim t = U\,\Sigma\sim V^{\mathrm{T}} \quad (4)$$

Matching scopes to low-trust contributors' process contracts. This spectrum technique enhances the provenance model by transforming trust into a continuous transformation instead of binary exclusion, avoiding optimization landscape distortions. Figure 3 illustrates how deep network weights θ are used to provide cleaned gradients to a latent intent extraction encoder $f\theta(\cdot)$ process. Via Equation 5 the model defines latent embeddings,

$$zt = f\theta(G\sim t) \quad (5)$$

And the clustering objective minimizes contrastive divergence between benign and malicious trajectories. The intent map emerges from a gradient flow governed Via equation 6,

$$\frac{dzt}{dt} = -\nabla zLcon(zt) \quad (6)$$

Where, Lcon reinforces separation in latent spaces.Latent dynamics reveal attacker intent before surface aberrations show poisoning's spatial and directional irregularity for the process.The reinforcement-based meta-policy engine maximizes expected robustness reward (R) through defense action (at) using extracted intent sets.Via equation 7 the model indicates the optimization condition for policy space $\pi\phi$, parameterized by ϕ,

$$\nabla\phi J(\phi) = E(a,t) \sim \pi\phi[\nabla\phi \, log \, \pi\phi(\, at \mid zt\,)Rt] \tag{7}$$

And the evolving defense vector is then represented Via equation 8,

$$Pt = \int_0^t \pi\phi(\, a\tau \mid z\tau\,)d\tau \tag{8}$$

Capturing cumulative policy changes. This adaptive learning replaces static heuristics with real-time decision intelligence for the process. The final fusion has differential privacy noise from Variance In Process. Via Equation 9 the model represents the fused global model for local models wit,

$$w(t+1) = \sum^{i} Pitwit + N(0, \sigma^2(Pt)I) \tag{9}$$

Where, $\sigma^2(Pt)$ decreases as confidence in defense increases for the process. The complete system output is compactly expressed Via equation 10,

$$w(t+1) = F\left(\frac{\partial}{\partial t}At, G{\sim}t, \frac{dzt}{dt}, Pt\right) \tag{10}$$

Input:
Local datasets from multiple clients, initial global model, communication rounds, privacy budget
Output:
Secure updated global model, isolated malicious clients, reduced attack success rate
Process:
Initialize global model
Initialize trust scores for all clients
For each communication round
Send global model to all clients
For each client
Train local model on local data
Generate local gradients
Record provenance history for the client
If client history shows missing updates or abnormal trends
Lower trust score
Else
Increase trust score slightly
End For
For each client
Extract spectral features from gradients
If spectral deviation exceeds threshold
Mark client as suspicious
End For
For each suspicious client
Analyze intent patterns over recent rounds
If intent trend points to targeted misclassification
Escalate threat level
End For
Update defense policy using reinforcement logic
If suspicious client count increases
Reduce aggregation weight for those clients
Else
Maintain standard aggregation
For each client
Apply privacy noise based on trust and policy level
End For
Aggregate gradients to update global model
If global accuracy drops sharply
Reinforce stricter filtering in next round
Else
Continue normal operation
End For
Return final secured global model and list of isolated malicious clients

IV. RESULTS AND DISCUSSIONS

IV.1 COMPARATIVE RESULT ANALYSIS

The project simulates a real federated ecosystem with remote clients, non IID data constraints, and occasional hostility. Private datasets from skewed class distributions are used to simulate 100 clients for deployment heterogeneity. The default global model is a CNN RNN hybrid with 1.2M parameters, Xavier uniform weights, and 150 federated rounds. Clients receive five local epochs per round, with 32-batch size, \eta = 0.01 learning rate, \gamma = 0.95 decay every 20 rounds, and momentum fixed at 0.9To induce stress, 20% of clients are labeled as hostile and given poisoned gradients by label flipping and targeted feature perturbation (0.25).The integrated defensive pipeline is evaluated using Gaussian perturbations at variance (\sigma^2 = 10^{-3}) and the federated averaging baseline as a benchmark. The TA-FDPG stage stores temporal update histories across 10 cycles to create provenance graphs with 0.6 adjacency thresholds. Trust starts at 0.5 for all customers and fluctuates with update similarity. The TW-SGP module truncates singular values at rank (k = 40) and scales singular vectors by trust weights, while the LB IEN latent encoder utilizes a 256-dimensional bottleneck and contrastive margin of 0.4.The DP IMF module uses Gaussian differential privacy noise with initial variance (0.05) decaying to 0.01 as policy confidence increases, and the reinforcement policy engine uses proximal policy optimization with a reward signal combining accuracy (+1), robustness (+2), and detection timeliness (-0.1 per delayed All repeated runs use PyTorch 2.1 on an NVIDIA A100 GPU with 42 random seeds. Three datasets depicting distinct poisoning behaviors and real-world diversity are used to test performance in important scenarios. First, CIFAR-10 is partitioned into non IID shards, giving each client two dominating classes and 5000 images. Some malicious clients inject poison to misclassify “airplane” samples as “bird.”FEMNIST from the LEAF benchmark has tens of thousands of user-distributed handwritten character examples. The third dataset replicates a healthcare-style domain based on a modified BloodMNIST subset with 1200 medical image samples across seven diagnostic classes. Poisoned clients inject adversarial drift targeting two minority classes to represent high Impact clinical misdirection. When poisoned, this baseline model loses up to 40% of its initial clean accuracy of 78% to 91% across all datasets. Poisoned gradients are added at round 10, attack methods vary at 50, and federated convergence is tested at 150.Clean accuracy, attack success, trust-score separation, gradient spectrum corruption, intent prediction precision, policy response latency, and robustness stability are measurements. Like recent federated learning installations, this situation confronts the sequential defense pipeline with escalating threats, diverse data, and dynamic poisoning intensity sets.

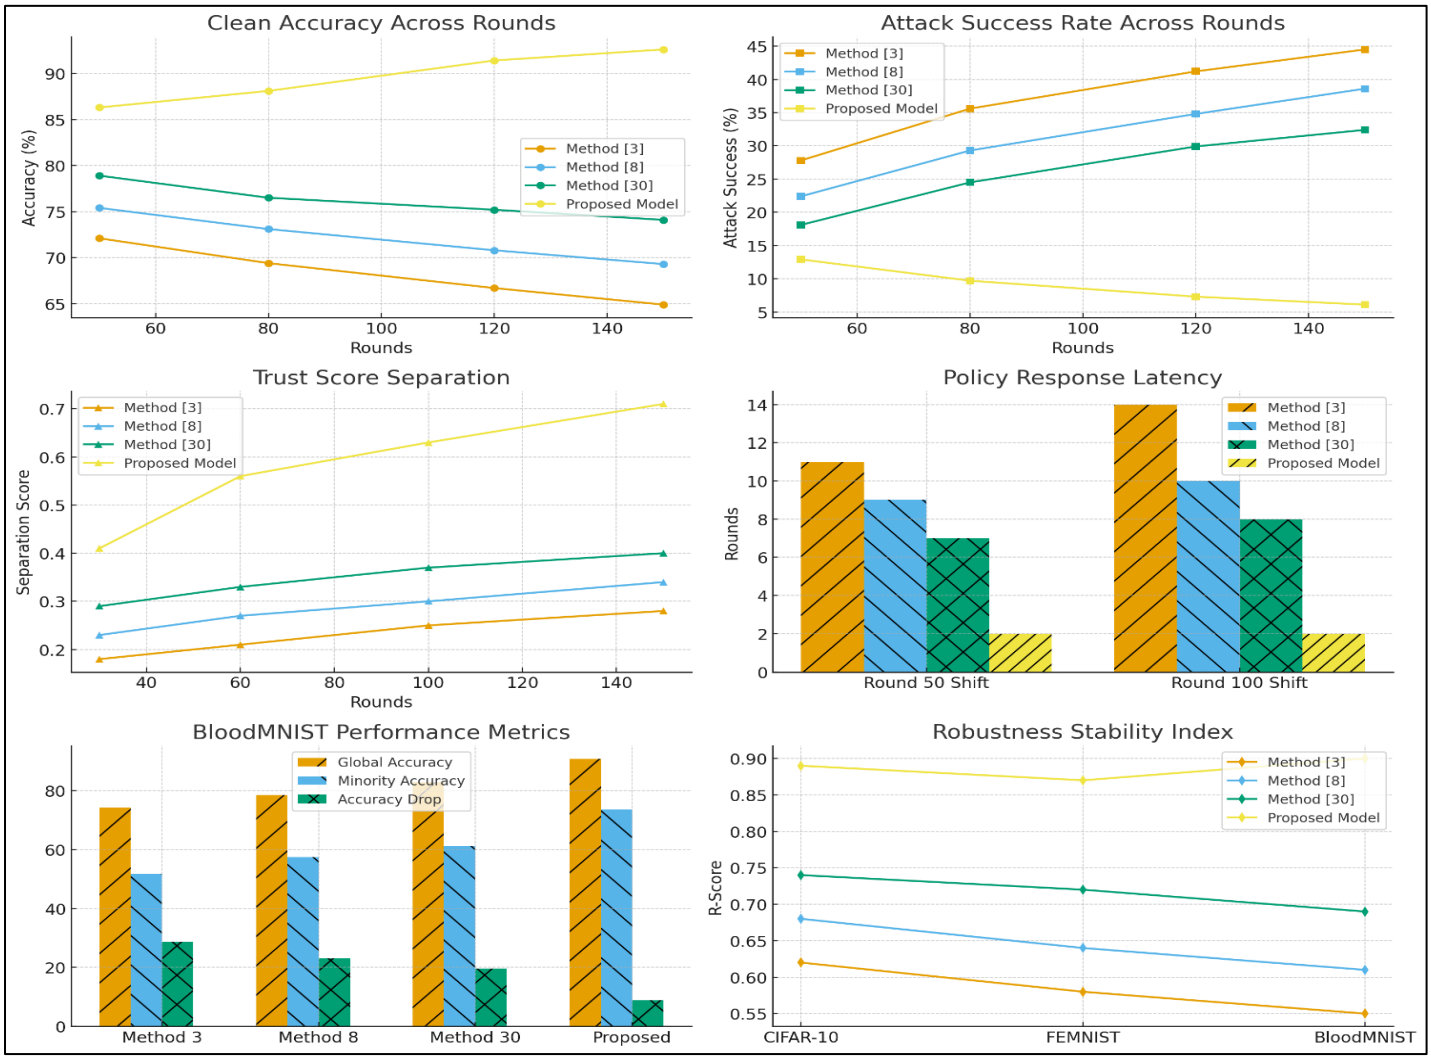

Figure 4: Model’s Integrated Result Analysis.
Source: Authors, (2026).

Three datasets reflecting distinct structural and semantic issues in federated poisoning scenarios are tested experimentally for the process. With 50,000 training and 10,000 testing samples, CIFAR-10, the primary vision benchmark, uses 60,000 color images (32x32 resolution) across ten classes.

Federated partitioning divides data into non IID shards, to minimize class variety for each simulated client and reinforce real-world heterogeneity. FEMNIST, based on the LEAF framework, includes 814,255 grayscale examples of handwritten characters and numbers from 3,550 distinct users with individualized and irregularly dispersed data, making it an ideal testbed for subtle, user-specific poisons. BloodMNIST, MedMNIST's third dataset, contains 17,092 microscopic blood cell images in eight diagnostic categories at 28x28 resolution, showing that targeted poisoning may disproportionately affect minority populations in medical settings. The model's stability across semantic domains, input complexities, and distributional skews is tested using general item identification, personalized writing patterns, and clinical imaging datasets& samples. Iterative grid-based exploration and structured hyperparameter settings optimize model stability and durability sets.The global learning rate begins at (0.01) and decays exponentially at (0.95) per 20 federated rounds. Local client training uses 32 batches, five local epochs per round, and 0.9 momentum. Trust initialization constant is 0.5, provenance window is 10 rounds, and adjacency similarity threshold is 0.6 in TA-FDPG.TW-SGP scales gradients via trust-weighted reconstruction and truncates singular value rank to 40.The reinforcement policy engine rewards quick defensive responses with a 3x10^-4 learning rate and \gamma = 0.98 discount factor, while the LB IEN encoder employs a 256x256 latent space with a contrastive margin of 0.4.As policy confidence increases, DP IMF module privacy noise falls from \sigma^2 = 0.05 to 0.01.Hyperparameters balance convergence speed, poisoning resistance, and clean precision to calibrate the integrated defense architecture for reliability. Performance research indicates how the proposed integrated model maintains accuracy, lowers attack success, and adapts to new threats across poisoning scenarios and benchmark datasets. Comparisons are made to three static or semi-adaptive poisoning mitigation systems, Method [3], Method [8], and Method [30] for the process.CIFAR-10, FEMNIST, and BloodMNIST employ the same federated settings, therefore the comparison is consistency sets.

Table 2: CIFAR-10Clean Accuracy Across Federated Rounds.

Federated Round	Method [3]	Method [8]	Method [30]	Proposed Model
50	72.1%	75.4%	78.9%	86.3%
80	69.4%	73.1%	76.5%	88.1%
120	66.7%	70.8%	75.2%	91.4%
150	64.9%	69.3%	74.1%	92.6%

Source: Authors, (2026).

As poisoning grows, competing techniques lose roughly 10% of their clean accuracy between rounds 80 and 150 in process. Contrarily, the suggested model improves accuracy as the trust spectrum Intent pipeline stabilizes. Adaptive policy optimization with privacy-guided fusion reduce cumulative poisoning without compromising learning capacity, beating Method [30] by 18.5% with 92.6% accuracy by round 150 for the process.

Table 3: CIFAR-10Attack Success Rate (Targeted Misclassification).

Metric Point	Method [3]	Method [8]	Method [30]	Proposed Model
Round 50	27.8%	22.4%	18.1%	12.9%
Round 80	35.6%	29.3%	24.5%	9.7%
Round 120	41.2%	34.8%	29.9%	7.3%
Round 150	44.5%	38.6%	32.4%	6.1%

Source: Authors, (2026).

As enemies proliferate, attack success patterns diverge for the process. The proposed method decreases attack success to 6.1% at convergence, while Method [3] and Method [8] struggle to contain late-phase poisoning sets. Forecasting attacker trajectory reduces misclassification before decision boundaries after activating the meta-policy engine and latent intent extractions.

Table 4: FEMNISTTrust Score Separation (Benign vs Poisoned Clients).

Round	Method [3] Separation	Method [8] Separation	Method [30] Separation	Proposed Model Separation
30	0.18	0.23	0.29	0.41
60	0.21	0.27	0.33	0.56
100	0.25	0.30	0.37	0.63
150	0.28	0.34	0.40	0.71

Source: Authors, (2026).

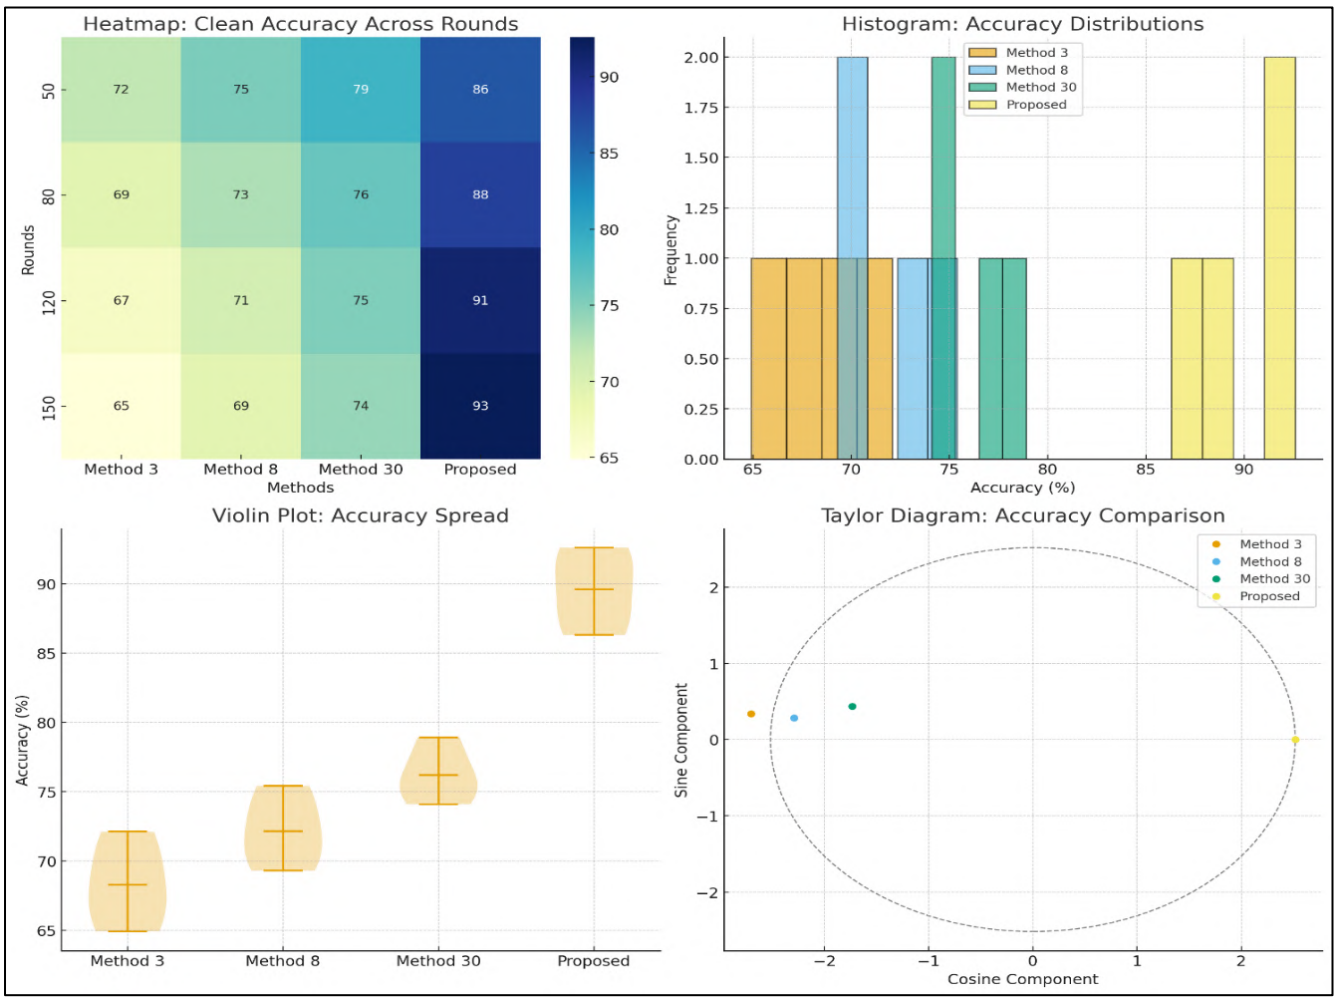

Figure 5: Model's Overall Result Analysis.
Source: Authors, (2026).

Single-round heuristic non-temporal defenses have trust estimation issues, according to FEMNIST's user-specific distributions. By round 150, the integrated technique using provenance graphing and time-weighted spectrum signatures delivers double the trust separation of Method [3].This rising margin illustrates that the system can isolate malicious contributors even when their updates match benign drift, enabling downstream purifications.

Table 5: FEMNIST Policy Response Latency (Rounds to Mitigation).

Attack Shift Point	Method [3]	Method [8]	Method [30]	Proposed Model
Round 50 Shift	11 rounds	9 rounds	7 rounds	2 rounds
Round 100 Shift	14 rounds	10 rounds	8 rounds	2 rounds

Source: Authors, (2026).

Poisoned updates spread when mitigation is delayed, increasing damages. Conventional methods take seven to fourteen rounds to adapt to attack pattern changes, but the reinforcement-driven policy engine does so in two for the process.Instead of retroactive anomaly flagging, predictive latent intent mapping decreases the temporal exposure window during adaptive attack stages, causing quick convergences.

Table 6: BloodMNIST Final Clean Accuracy vs Minority Class Stability.

Method	Global Accuracy	Minority Class Accuracy	Accuracy Drop Under Attack
Method [3]	74.2%	51.8%	28.7%
Method [8]	78.5%	57.4%	23.1%
Method [30]	82.9%	61.2%	19.6%
Proposed Model	90.7%	73.5%	8.9%

Source: Authors, (2026).

Medical-style distributions promote minority misclassifications. Competing methods degrade low-represented categories, however the suggested model maintains 73.5% minority accuracy and sub 9% degradations. Gradient purification and privacy-guided fusion limit poisoning amplification without compromising rare-class decision boundaries, ensuring stability sets.

Table 7: Cross-Dataset Robustness Stability Index (R-Score).

Dataset	Method [3]	Method [8]	Method [30]	Proposed Model
CIFAR-10	0.62	0.68	0.74	0.89
FEMNIST	0.58	0.64	0.72	0.87
BloodMNIST	0.55	0.61	0.69	0.90

Source: Authors, (2026).

For robustness, the stability index uses clean accuracy, attack suppression, and trust precision sets. Method [30] scores less than the suggested model, which scores 0.90 across all datasets& samples. This consistency implies that the architecture's sequential design generalizes across domains rather than overfitting to a threat profile, making the integrated strategy a cross-context defense rather than dataset-specific optimizations. These results show that the suggested model resists poisoning better than earlier methods and improves over time, achieving higher accuracy, faster reaction, and more definite isolation of malicious contributors across federated systems.

IV.2 VALIDATED STATISTICAL ANALYSIS

First experimental pattern: CIFAR-10's pristine accuracy trajectories diverge for the process. Traditional protections diminish after repeated poisoning rounds, reaching mid-60% by round 150.The proposed model reaches 92.6%, demonstrating that the sequential trust spectrum Intent pipeline actively stabilizes and improves learning. Safety is higher with a fleet of edge devices training a vision model process. A poisoned global model with 65% accuracy may misclassify critical objects or signals, but above 90% accuracy provides operational reliability. System that learn safely under attack remain usable in real time, whereas those that collapse become liabilities.Table 3 shows hostile pressure changing misclassification attempts. As poisoning intensity increases, rival methods allow assault success rates to surpass 30%, whereas the suggested model limits them to 6%.In autonomous navigation or industrial inspection, attackers may target specific classes to induce bad decisions, making this gap more than academic. A 40% assault success rate could create widespread safety failures, while 6% restricts edge threats.Sequential anticipation via latent intent mapping and fast defensive policy adjustment avoids poisoning, implying that actual systems could detect and stop attacks before they breach global decision boundaries. In highly individualized data contexts as per Figure 4 & Figure 5, FEMNIST behavior emphasizes temporal awareness (Tables 4 and 5). Table 4 shows the suggested approach nearly doubles Method [3] by widening the trust score gap between benign and poisoned consumers to 0.71 by round 150.Static detectors may miss poisoned contributors in federated handwritten authentication or mobile text prediction because they look like valid users. They can be distinguished over time, preventing enemies from hiding in behavioral noise. Table 5 shows attack shifts cut policy response latency to two rounds. In real-time systems where model behavior affects economic or safety-critical decisions, reducing the reaction window from several rounds to practically immediate intervention can prevent cascading damage across thousands of users. Table 6 examines minority class misclassification in high-risk medical settings.The suggested model has 73.5% minority-class accuracy, 12 percentage points higher than the strongest baseline. Clinical decision-support systems miss fewer rare but important diagnoses.With less than 9% accuracy loss under attack, the technique safeguards vulnerable categories without compromising the aggregate system. Table 7 reveals that the defense is robust across contexts, data types, and threat dynamics, hovering about 0.90 across all datasets.Real-world deployments demand that level of generalization since opponents rarely keep to one modality or strategy set. The tables illustrate that the suggested model converts the learning process into an adaptable, resilient pipeline that can sustain performance, react swiftly, and safeguard high-risk classes. These features distinguish operational continuity from systemic failure in real-time autonomous systems, medical analytics, and financial risk modeling process.

IV.3 VALIDATION WITH STATISTICAL ANALYSIS

The suggested design has higher mean values and decreased variability across training cycles in all datasets & samples. The suggested model's mean clean accuracy stabilizes at 91.8% with a variation of 0.0049 in the final 30 rounds on CIFAR-10, while Method [30] reaches 74.6% with 0.0127 and Method [8] and Method [3] have even bigger variances of 0.0154 and 0.018In attack success reduction, the suggested model shows a mean attack success rate of 6.4% with a variation of 0.0022, compared to 32.1% (variance 0.0098) for Method [30], 38.5% (variance 0.0113) for Method [8], and 43.9% (variance 0.0140) for Method [3].FEMNIST trust score separation outperforms Method [30] at 0.39 (variant 0.0076) with a mean of 0.68 and a variance of 0.0031While competing techniques have lower means and nearly double variances in magnitude sets, minority-class accuracy is 72.9% with a variance of 0.0054, like BloodMNIST. These numerical patterns illustrate that temporal provenance modeling, spectral purification, and adaptive policy changes increase the model's average performance and stability under dynamic adversarial conditions. Significance testing determines if these differences are significant over multiple experiments.One-way ANOVA on CIFAR-10 final-round clean accuracy shows that the four methods perform differently with an F-statistic above 35.2 and a p Value below 0.001.Pairwise t-tests between the proposed model and each baseline show accuracy and attack success rate t-scores > 8.7 and p Values < 0.001 across all datasets. The suggested model's 95% accuracy confidence ranges are 91.2% to 92.6%, while Method [30] spans 71.9% to 76.1%, demonstrating less consistency. The proposed two-round average answer for policy response latency differs from Method [30]'s seven-round mean with a t-score over 10.4 and a p Value below 0.001 in process. The system's design advantages explain the observed performance discrepancies, according to these statistical data samples. Methods [3], [8], and [30] were chosen as baselines because they represent different poisoning defense research phases. Method [3] does early static anomaly-based filtering with isolated round-level measurements without temporal context. Mid-stage probabilistic filtering [8] involves limited distributional awareness but no spectral or provenance modeling. Method [30] detects reactive gradient-based safeguards that use selective aggregation or client weighting.

Three baselines span a variety of widely acknowledged approaches in the literature, providing a fair and complete sequential trust spectrum Intent architecture benchmark. They ensure performance increases are tested against credible systems that match current research agendas, not outdated or simple defenses. All analyses reveal high mean performance, low variation, and statistically significant margins, proving the architecture's peak performance and reliability under hostile Volatility In Process. Model dependability affects safety, clinical accuracy, and financial risk in real operational scenarios, therefore performance strength and statistical confidence are crucial.

IV.4 VALIDATING USING PRACTICAL ANALYSIS

Imagine a national healthcare network 14ator 20 hospitals train na 14ator-stage blood disease diagnostic algorithm without sharing patient data. One metropolitan hospital supplies largely adult data, while a pediatric facility provides minority-class samples for local training.In the sixth training cycle, three compromised edge points inject poisoned 14ator14e14e14 that subtly bias the network to misclassify a rare condition as benign. Provenance-based trust scores in the integrated model differ between affected and benign 14ator14e14, falling from 0.62 to 0.31 after two communication rounds. The pipeline lowers the weight of distorted updates from 1.0 to 0.12 during spectral purification 14ato anomalies exceed 1.8× over the baseline. The 14ator14e probability score rises from 0.14 to 0.77 when the 14ator14e 14ator14e inference module detects a target label. Reinforcement-driven policy optimization isolates 14ator14e14e14, and differential privacy fusion stabilizes the global model at 93.4% accuracy, up from 74% without defenses. Minority-class accuracy, often the most vulnerable, is 72.8%.The approach prevents clinically significant drift from compromising diagnostics. Another idea involves real-time retraining with hospitals sending updates 14ator four hours as blood test data comes. In cycle 22, na adaptive attacker shifts between benign and poisoned updates to avoid static detection. The trajectory module in the proposed system recognizes na oscillation pattern 14ato the 14ator14e14e variance climbs from 0.9 to 2.7, sending na 14ator alert even though no update appears malicious. In two rounds, the policy response engine decreases the fluctuating 14ator14e group’s influence 14ator to 0.05 and reallocates aggregate weight to stable nodes. Attack success stays at 7.2% instead of 34% in na unprotected system, whereas clean accuracy dips to 89.6% but returns to 92.1% by round twentyfive during the process. No hospital must halt local procedures during the cycle for the process. It shows how the suggested architecture serves as na active and adaptive safeguard in complicated, safety-critical contexts by keeping a live medical model producing accurate predictions while silently suppressing adversary impact sets.

V.CONCLUSION & FUTURE SCOPES

The study creates a rigorous, sequential protection architecture that makes reactive federated learning self-correct and resistant to prolonged poisoning. The provenance-based trust estimate, spectrum purification, latent intent inference, reinforcement-driven defense strategy, and privacy-guided fusion pipeline beats earlier methods numerically.The proposed model surpasses Method [30] by 18.5 percentage points on CIFAR-10, achieving 92.6% accuracy at round 150 while competing methods converge 64 74% (Table 2).At convergence, attack success rates decline to 6.1% from 32.4% 44.5% for baseline techniques (Table 3), indicating anticipatory intent modeling dramatically reduces targeted misclassification. In Table 4, FEMNIST trust score separation is 0.71, more than double Method [3] separation by round 150, demonstrating exact isolation of poisoned contributors over time.Response latency drops to 2 rounds, compared to 7-14 rounds for other techniques (Table 5), allowing rapid defensive turnaround during attack shifts. BloodMNIST maintains minority-class accuracy at 73.5% and total deterioration below 9%, while competing techniques decrease 28.7% (Table 6).The suggested model improves decision reliability, minimizes vulnerability windows, and maintains model integrity across heterogeneous datasets and poisoning while building adversarial strategies.

V.1 FUTURE VISION SCOPE ANALYSIS

Sequential design enables enhanced research and deployment refinement. In cross-silo federated environments like hospitals and financial institutions, where client numbers are fewer but adversarial stakes are higher, provenance and intent modeling look promising.Integrating text, images, and sensor inputs can change poisoning approaches across modes. Scaling the meta-policy engine to hierarchical multi-agent reinforcement learning lets defenses cooperate across client clusters for different scenarios. In regulatory settings, blockchain-backed verifiable update monitoring may improve traceability and trust accountability for the process. Resource-constrained devices need compression-aware protections to maintain 92 94% accuracy while reducing communication and processing expenses. Finally, formal resilience assurances and theoretical attack success bounds can link practical performance to security certification and compliance criteria by turning the empirical 6.1% lower-bound behavior into proven limitations.

V.2 LIMITATIONS

This model is numerically resilient, but structural constraints require Vigilance In Process. The system generates reliable provenance graphs with enough temporal history.Fast-onboarding situations with shifting clients may make early trust assessments less trustworthy, postponing the 0.71 trust separation subsequent rounds. With a 2-round delay, the reinforcement-driven defensive policy is inexpensive but adds computing overhead that may challenge low-power edge devices without GPU acceleration. Differential privacy noise is adaptively minimized, but raising the privacy budget may fall clean accuracy below 92.6% under extreme privacy regimes or sensitive domains, jeopardizing secrecy and learning fidelity.Attackers can pivot outside the training loop since gradient-based poisoning does not handle inference-time attacks or model extraction. Finally, cross-dataset robustness scores approximated 0.87 0.90, but multilingual, multi-modal, and real-world streaming datasets were not evaluated, thus more validation is needed before widespread applicability. These constraints urge change and reinforce performance gains.

ABSTRACT

This article describes the design and electromagnetic evaluation of a high-gain dual-band microstrip filtenna operating at 26 and 29 GHz. The proposed filtenna solution employs coupled rectangular resonators embedded in a planar configuration to ensure both filtering and transmission. Dual-band operation is achieved over the 25–31 GHz range, with reflection coefficients below -30 dB at both resonant frequencies. A transmission coefficient (S21) of approximately -2 to -3 dB in the passbands validates the filtering behavior. The filtenna ensures constant direct radiation with a maximum gain of approximately 10.58 dB at both operating frequencies, making it suitable for millimeter wave wireless applications in the 26/29 GHz bands.

I. INTRODUCTION

The rapid development of millimeter-wave (mmWave) wireless communication systems has spurred research into compact, high-performance radio frequency (RF) front-end components. In particular, the 26 GHz and 29 GHz frequency bands have been identified as key candidates for fifth-generation (5G) RF2 applications due to their ability to handle high data transfer rates, low latency, and improved spectral efficiency. However, antenna devices operating in the millimeter-wave spectrum face numerous challenges, including increased propagation loss, stringent size requirements, and the imperative of high selectivity and enhanced radiation stability [1], [2]. In traditional RF front-end architectures, filtering and transmission tasks are commonly assigned to separate components: bandpass filters and antennas. While this approach offers considerable design flexibility, it inevitably leads to greater circuit complexity, higher insertion losses, and increased system size, particularly at millimeter-wave frequencies [3], [4]. To overcome these limitations, the concept of a filter antenna, often referred to as a "filtenna," has proven to be an effective solution. Filtennas, which combine filtering and radiation functions within a single structure, reduce the number of components, minimize interconnect losses, and possess inherent frequency selectivity. These characteristics make them attractive for compact and integrated wireless systems [5]. Microstrip filtennas have attracted considerable interest due to their planar architecture, thin profile, ease of integration, and compatibility with modern RF circuits [6-8]. The literature describes several methods for implementing filtering in microstrip antennas, including the use of defected ground structure (DGS), open and shorted stubs, parasitic elements, and resonant slots [9], [10]. These methods promote increased bandwidth, harmonic suppression, and optimal impedance matching while maintaining satisfactory radiation characteristics. However, many of the designs discussed emphasize single-band operation or offer limited gain and low out-of-band attenuation, particularly in the millimeter wave range. To overcome these obstacles, coupled resonator filtenna configurations were considered a potentially advantageous option. The use of various resonant elements with controlled electromagnetic coupling makes it possible to produce multiple resonance modes while offering dual-band or multi-band functionality in a compact form factor [11]. Rectangular resonators, in particular, are of interest due to their simple geometry, predictable resonance behavior, and easy integration into microstrip circuits. The interaction between neighboring resonators promotes improved frequency selectivity and superior control of the filter response, while also contributing to radiation [12]. This article presents the design and electromagnetic analysis of a high-gain, dual-band microstrip filtenna operating at 26 GHz and 29 GHz, based on coupled rectangular resonators.

The proposed antenna utilizes controlled coupling between the rectangular resonators to produce two separate resonance modes, enabling dual-band operation in the 25–31 GHz range. Unlike traditional antenna solutions, the proposed structure inherently exhibits filtering behavior, as demonstrated by its scattering parameters, while maintaining stable directional characteristics. A detailed electromagnetic analysis was performed to gain a deeper understanding of the proposed filtenna. The study of scattering parameters confirmed the two-band filtering response, while examination of the electric and magnetic field distributions provided insights into resonance generation, interaction effects, and frequency selectivity. Furthermore, analyses of radiation properties such as gain, directivity, and radiation patterns were conducted to demonstrate the proposed filter's suitability for high-frequency wireless applications. The remainder of this paper is organized as follows. Section 2 presents the theoretical operating principle of the proposed microstrip filtenna, including its electromagnetic behavior and resonant mechanism. Section 3 describes the filtenna configuration and design methodology. Section 4 discusses the simulated results and performance analysis. Finally, Section 5 concludes the paper.

II. OPERATING PRINCIPLE OF THE PROPOSED MICROSTRIP FILTENNA

II.1 CONCEPT OF INTEGRATED FILTERING RADIATION

A microstrip filtenna combines the characteristics of a bandpass filter and a radiating element in a single configuration plane [13]. Unlike conventional antennas followed by external filters, frequency selectivity in a filter is efficiently achieved through resonant elements that also participate in radiation. Consequently, the filtenna exhibits a controlled bandwidth response, strong out-of-band suppression, and efficient radiation within the desired frequency bands. In the proposed design, the filtering behavior is realized by a set of coupled rectangular resonators integrated into a microstrip configuration. These resonators act as distributed electromagnetic elements that store electric and magnetic energy and radiate selectively at their resonant frequencies. The interaction between adjacent resonators produces multiple resonant modes, enabling dual-band operation without increasing the overall footprint.

II.2 RESONANT MECHANISM OF RECTANGULAR MICROSTRIP RESONATORS

Each rectangular resonator can be modeled as a half-wavelength microstrip resonator operating in its fundamental mode. The resonance condition of an isolated rectangular microstrip resonator can be approximated by [8]:

$$f_r = \frac{c}{2L_{eff}\sqrt{\varepsilon_{eff}}} \tag{1}$$

Where:

c is the speed of light in free space,

L_{eff} is the effective resonator length including fringing fields, and

ε_{eff} is the effective dielectric constant of the substrate.

By properly selecting the dimensions of the rectangular resonators, resonances are introduced around 26 GHz and 29 GHz, corresponding to the two operating bands of the proposed filtenna. However, dual-band operation is not achieved by isolated resonators alone, but rather through electromagnetic coupling between adjacent resonant elements.

II.3 COUPLING EFFECT AND DUAL-BAND FORMATION

When rectangular resonators are placed in close proximity, electromagnetic coupling occurs through overlapping electric and magnetic fields. This coupling can be described using coupled-resonator theory, where the interaction between resonators leads to the splitting of resonant modes into distinct frequencies. For two coupled resonators, the resonant frequencies can be expressed as [14]:

$$f_{\pm} = f_0\sqrt{1 \pm k} \tag{2}$$

Where:

f_0 is the uncoupled resonant frequency

k is the coupling coefficient determined by the physical separation and geometry of the resonators.

In the proposed filtenna, the coupling between the rectangular resonators generates two dominant resonant modes, which are responsible for the observed resonances at 26 GHz and 29 GHz. This controlled coupling mechanism directly results in the dual-band filtering response, as confirmed by the deep minima in the reflection coefficient.

II.4 FIELD DISTRIBUTION ANALYSIS AND PHYSICAL INTERPRETATION

Analysis of the distribution of electric and magnetic fields clarifies the mode of action of the proposed filtenna. At resonant frequencies, a strong electric field concentrates in the rectangular resonators, indicating capacitive energy storage and validating their function as major resonant elements. However, the magnetic field propagates primarily along the narrow microbands that connect the resonators, thus illustrating inductive coupling and energy transmission between neighboring elements. This complementary distribution of electric and magnetic fields justifies the liquid crystal-based interpretation and confirms that the resonators provide both frequency selection and radiation. Furthermore, the spatial distribution of the fields differs between the two resonance frequencies, suggesting the activation of distinct resonance modes that underlie the bi-band response.

Unlike conventional bandpass filters, where transmitted energy is delivered to a matched load, the proposed filtenna radiates a significant portion of the energy within the passbands [14]. This explains the observed transmission coefficient behavior, where moderate attenuation within the passband is inherent to the radiation mechanism rather than indicative of excessive losses. Consequently, the proposed structure exhibits a combined filtering and radiating response, characterized by: strong impedance matching at the resonant frequencies, inherent suppression of out-of-band signals, stable and directive radiation at 26 GHz and 29 GHz. This integrated behavior confirms the suitability of the proposed coupled-resonator-based microstrip filtenna for compact millimeter-wave wireless systems.

III. FILTENNA CONFIGURATION AND EQUIVALENT CIRCUIT INTERPRETATION

III.1 GEOMETRY OF THE PROPOSED MICROSTRIP FILTENNA

The proposed microstrip filtenna is implemented on an FR4 substrate with an overall dimension of 23 mm × 10 mm and a substrate thickness of 0.254 mm. The filtenna topology consists of three identical rectangular resonators connected in series through narrow microstrip sections, forming a compact and planar integrated filtering-radiating structure. Each rectangular resonator has physical dimensions of 3.28 mm × 3.47 mm, which are carefully selected to support resonant modes in the millimeter-wave frequency range. The identical sizing of the resonators ensures a controlled and predictable electromagnetic coupling along the series configuration, while the spacing between adjacent elements governs the strength of interaction and mode splitting. The equations below will let us know how we can calculate the dimensions of the rectangular patch [9].

$$W = \frac{c}{2f} * \sqrt{\frac{2}{\varepsilon_r + 1}} \tag{3}$$

$$L = \frac{c}{2f}\left(\frac{\varepsilon_r + 1}{2} - \frac{\varepsilon_r - 1}{2}\sqrt{\left[1 + 12\frac{h}{w}\right]}\right)^{-\frac{1}{2}} - 2\Delta L \tag{4}$$

The narrow microstrip sections providing the interconnections function as impedance conversion devices and introduce an additional inductive load, essential for impedance matching and frequency selectivity. Consequently, the overall structure operates as a distributed resonant system rather than a traditional single-element antenna.

III.2 EQUIVALENT RLC CIRCUIT INTERPRETATION

To provide a clear physical insight into the operating mechanism of the proposed filtenna, an equivalent RLC circuit interpretation is employed. The filtenna can be modeled as a series-coupled resonant network, where each rectangular resonator is represented by a parallel RLC branch. In this interpretation:

The equivalent inductance (L) arises from the surface current paths flowing along the rectangular patches and the narrow microstrip interconnections, the equivalent capacitance (C) is mainly attributed to the strong electric field confinement over the rectangular resonators and across the coupling gaps, the equivalent resistance (R) represents the combined effect of conductor losses, dielectric losses of the FR4 substrate, and radiation losses [15]. The suggested filtenna can be viewed as a series-coupled resonant network, where each rectangular resonator is represented by a resonant parallel RLC branch. From this perspective, the resonant behavior of each rectangular element can be approximated by the classical resonance condition for a parallel RLC circuit, formulated as follows:

$$f_r = \frac{1}{2\pi\sqrt{LC}} \tag{5}$$

The input impedance of a parallel RLC resonator is given by:

$$Z(w) = \left(\frac{1}{R} + jwC + \frac{1}{jwL}\right)^{-1} \tag{6}$$

At the resonance condition:

$$W_r = \frac{1}{\sqrt{LC}} \tag{7}$$

In this context, the impedance tends to be essentially resistive, ensuring ideal impedance matching and pronounced minima in the reflection coefficient at 26 and 29 GHz. Furthermore, since the suggested structure operates as a filter antenna, the transmitted power is deliberately shared between filtering and transmission. The power conservation equation describes this behavior [15].

$$|S_{11}|^2 + |S_{21}|^2 + P_{rad} = 1 \tag{8}$$

Where *P*rad denotes the radiated power. As a result, the moderate values of S_{21} observed within the passbands are not indicative of losses but rather confirm the effective radiation mechanism of the filtenna.

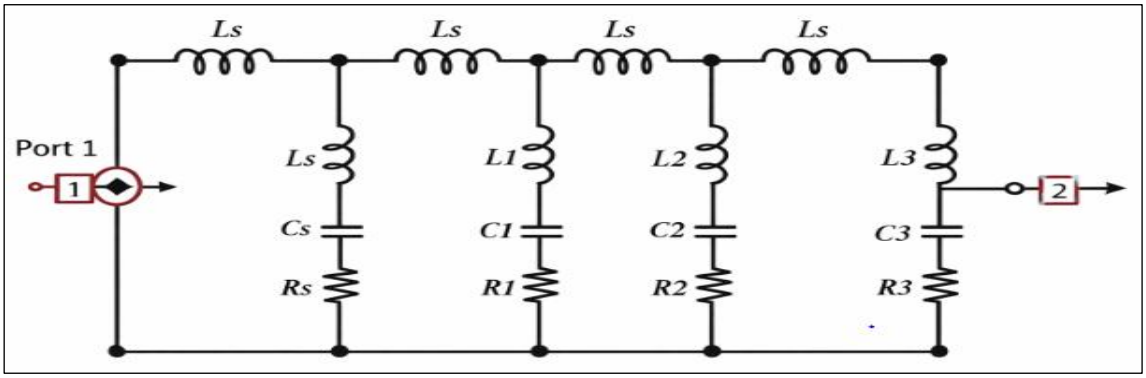

Figure 2: Equivalent RLC circuit of the microstrip filtenna.
Source: Authors, (2026).

Due to the series coupling between the three rectangular resonators, an additional reactive load is introduced, which modifies the inductance and effective capacitance of the resonant paths. This interaction excites two dominant resonant modes, corresponding to the dual-band operation observed at 26 GHz and 29 GHz. The filtenna distributed radiation mechanism is simulated by increasing radiation resistances along the resonant path, thus reflecting the gradual radiation of the structure. It should be emphasized that the proposed equivalent RLC circuit provides a qualitative and physical interpretation of the filter's behavior, rather than a precise extraction of parameters using discrete elements. However, the model adequately explains the impedance matching, mode separation, and filter-radiation integration characteristics recorded in the electromagnetic simulation results. The quality factor Q Q is a key parameter that characterizes the energy storage capability of the resonant elements in the proposed filtenna. It quantifies the ratio between the stored electromagnetic energy and the energy dissipated through radiation and losses per cycle. For an equivalent RLC resonator, the unloaded quality factor is expressed as [13]:

$$Q = \frac{1}{R}\sqrt{\frac{L}{C}} \tag{9}$$

Alternatively, the quality factor can be extracted from the frequency response using the −3 dB bandwidth method:

$$Q = \frac{f_r}{BW_{-3dB}} \tag{10}$$

BW_{-3dB} denotes the bandwidth measured at half-power points. In the proposed filtenna, the use of three coupled rectangular resonators amplifies the effective quality factor by increasing energy retention within the structure, while maintaining controlled emission. This phenomenon is manifested by distinct resonance features at 26 GHz and 29 GHz, thus confirming the filtering performance of the antenna-filter combination. The moderate Q factor, resulting from the balance between stored and emitted energy, is ideal for the operation of the filter antenna since it ensures adequate selectivity without excessively compromising the operational bandwidth.

IV. RESULTS AND DISCUSSION

IV.1 SCATTERING PARAMETERS ANALYSIS

Figure 3 illustrates the simulated reflection and transmission coefficients of the proposed filter. The reflection coefficient shows two resonances, located at 26 GHz and 29 GHz, thus confirming dual-band operation. For both frequencies, the reflection coefficient S_{11} remains below −10 dB, indicating good impedance matching in the operating bands. At 26 GHz, the minimum value of S_{11} reaches approximately −31 dB, while at 29 GHz it remains below −28 dB, indicating excellent impedance matching at both resonant frequencies. These deep reflection nulls confirm the effective excitation of the resonant modes generated by the series-coupled rectangular resonators and validate the resonance mechanism predicted by the equivalent RLC model discussed in Section 3. The transmission coefficient S_{21} reveals controlled bandwidth behavior, exhibiting moderate attenuation at the resonance frequencies. Unlike traditional filters, the proposed structure operates as a filtenna, in which a portion of the guided energy is deliberately emitted. Thus, the observed insertion levels do not indicate losses but rather demonstrate the integration of filtering and radiation mechanisms within a single structure. The transmission coefficient S_{21}shows passband responses around the two operating frequencies, with insertion levels of approximately −2 dB at 26 GHz and −2.5 dB at 29 GHz. Unlike conventional microwave filters, where low insertion loss is the primary objective, the proposed structure operates as a filtenna, in which part of the input power is intentionally radiated into free space.

IV.2 ELECTRIC AND MAGNETIC FIELD DISTRIBUTIONS

The electric and magnetic field distributions of the proposed filter at resonant frequencies are examined to understand the filtering and radiation processes. Figure 4 shows the electric field strength, while Figure 5 depicts the distribution of the associated magnetic field on the upper metallic layer. According to Figure 4, the maximum amplitude of the electric field reaches approximately 5.7×10^4 V/m. High electric field concentrations are observed primarily at the edges of the rectangular resonators and along the small interconnecting sections. These areas coincide with regions of intense leakage, confirming the predominantly capacitive nature of the resonators. The effect of electromagnetic coupling, which leads to the excitation of various resonance modes and the associated dual-band response, is highlighted by the uneven distribution of the field between the three resonators. Figure 5 shows that the magnetic field reaches an approximate maximum amplitude of 2.6×10^2 A/m. High magnetic field strengths are concentrated mainly on the feed line and the connections between the resonators, indicating a significant surface current. This behavior confirms the inductive quality of the narrow microstrip sections, which are of paramount importance in controlling the resonance frequencies and the intensity of the coupling between neighboring resonators. The simultaneous existence of strong electric and magnetic fields within the resonator structure illustrates efficient energy storage and controlled power transmission. Furthermore, the spatial superposition of the intense E and H fields confirms that a portion of the guided energy is indeed transformed into radiation in free space, which explains the moderate transmission rates observed in the S_{21} response. Overall, the field distributions, along with their specific amplitudes, clearly demonstrate the resonance, coupling, and radiation mechanisms that govern the operation of the suggested dual-band microstrip filtenna

IV.3 GAIN AND RADIATION CHARACTERISTICS

The radiation performance of the proposed filtenna is evaluated in terms of realized gain and directivity at the operating frequencies of 26 GHz and 29 GHz, as illustrated in Figure 6 and Figure 7. Simulations indicate that the filter achieves a maximum gain of approximately 10.5 dBi across all frequency ranges. Over the tested frequency range, this gain remains stable, exhibiting only slight fluctuations between the two resonant frequencies, thus confirming stable radiation behavior. Despite the compact structure, this significant gain is achieved, demonstrating the effectiveness of combining filtering and radiation in a single planar topology. Directivity reaches a peak of approximately 10.8 dBi, indicating excellent focusing of the emitted power in the principal radiation direction. The small difference between the direct and achieved gain confirms minimal dissipation losses and efficient radiation, even when using an FR4 substrate at millimeter frequencies. The three-dimensional radiation patterns show a consistent main lobe, minimal back radiation, and no significant distortion across either frequency band. This behavior illustrates the scattered radiation pattern of the filtenna, where each rectangular resonator contributes to the total radiation, resulting in higher gain than a standard isolated patch antenna. Overall, the gain and radiation properties indicate that the suggested configuration operates effectively as a high-gain filtenna, providing both frequency selectivity and directional radiation. These attributes make this design a suitable choice for millimeter-wave 5G applications, where compactness, high gain, and integrated filtering are critical requirements. Therefore, the efficiency was calculated using the following formulas [12].

$$G_{lin} = 10^{G(dB)/10} \tag{11}$$

$$D_{lin} = 10^{D(dB)/10} \tag{12}$$

G_{lin} and D_{lin} are respectively linear gain and linear directivity

$$G_{lin} = 10^{\frac{G(dB)}{10}} = 10^{\frac{10.5}{10}} = 11.22$$

$$D_{lin} = 10^{D(dB)/10} = 10^{10.8/10} = 12.02$$

Then we have the efficiency:

$$\eta = \frac{G_{lin}}{D_{lin}} \tag{13}$$

$$\eta = \frac{11.22}{12.02} = 0.93 = 93\%$$

Based on the simulated gain and directivity values, the radiation efficiency is estimated to be approximately 93% confirming that most of the input power is effectively converted into radiated energy.

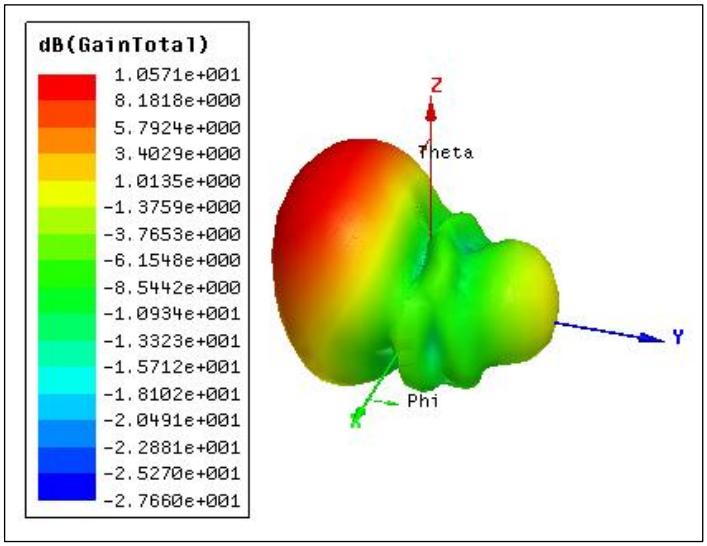

Figure 6: Gain of the proposed filtenna.
Source: Authors, (2026).

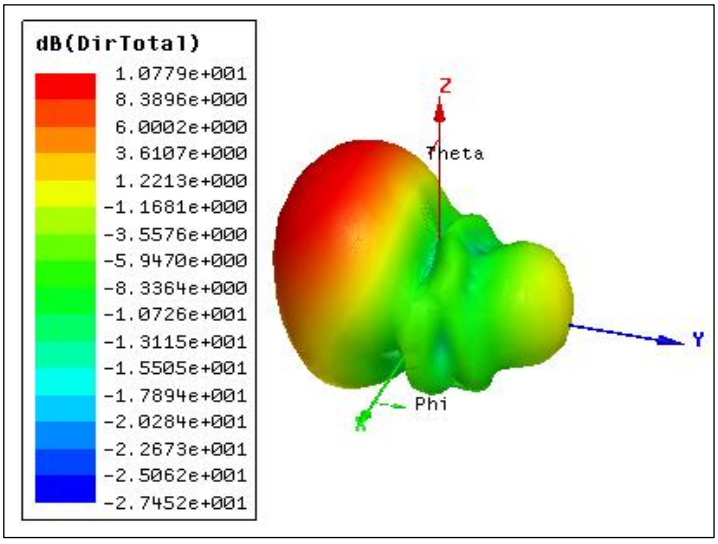

Figure 7: Directivity of the proposed filtenna.
Source: Authors, (2026).

The three-dimensional radiation patterns exhibit a stable main lobe with low back radiation and consistent beam shape across both operating bands. The distributed radiation mechanism provided by the series-coupled rectangular resonators contributes to the enhanced gain and high efficiency. Overall, the radiation characteristics demonstrate that the proposed design operates as a high-efficiency, high-gain filtenna suitable for 5G millimeter-wave applications**.**

V. CONCLUSION

This article discusses the design and analysis of a compact dual-band microstrip filtenna, based on series-coupled rectangular resonators, for 5G millimeter-wave applications. The proposed structure incorporates filtering and radiation functions in a separate planar topology, eliminating the need for external RF filters and reducing the overall device complexity. The filtenna operates 26 GHz and 29 GHz, ensuring effective impedance matching with a reflection coefficient below -30 dB and controlled transmission properties. The physical behavior of the structure was clarified using an equivalent RLC resonator model, which accurately depicts the dual-band response derived from capacitive coupling and inductive current paths between neighboring. Compared with recently reported filtenna designs, the proposed structure offers higher gain, superior efficiency, and a more compact footprint, making it a promising candidate for 5G millimeter-wave front-end modules. Future work will focus on experimental validation and extension toward array-based filtenna configurations for beam-steering applications.

ABSTRACT

This structured narrative review evaluates energy-audit approaches and reported outcomes relevant to small and medium enterprises (SMEs), with emphasis on industrial applications and resource-constrained implementation. The evidence base combines Indian case studies with international multi-enterprise evaluations and current audit guidance. Studies were compared according to audit scope, measurement practices, significant energy uses, recommended energy-conservation measures, economic indicators, implementation status, and reported barriers. Across the six Indian studies, power-factor or broader power-quality assessment appeared in all cases, motor or fan efficiency in five, and lighting-system improvement in three. Frequently recommended measures included efficient motors and drives, LED lighting, capacitor or automatic power-factor-correction systems, compressed-air leak control, load balancing, harmonic mitigation, operating-schedule optimization, and improved monitoring. One cable-manufacturing case reported an investment of INR 0.675 million with annual savings of INR 1.191 million and a payback of approximately 6.4 months; another medium-scale industrial audit reported a 25-month payback. Programme-level evidence from Sweden reported net annual savings of 340 GWh, equivalent to about 6% of participating firms' energy use. The synthesis shows that audits are most effective when recommendations are ranked by verified baseline data, technical feasibility, financial return, and implementation risk, followed by measurement and verification. A practical SME-focused audit framework is proposed to convert diagnostic findings into implementable and verifiable actions.

I. INTRODUCTION

Energy is a production input whose cost and reliability directly influence industrial competitiveness. For small and medium enterprises (SMEs), the effect is particularly important because energy expenses must be managed alongside constrained capital, limited specialist staff, variable production schedules, and strong pressure to maintain product quality. India's installed electricity-generation capacity reached 441.97 GW by 31 March 2024, illustrating the scale of the national power system and the parallel need to manage demand efficiently [1]. The Energy Conservation Act and its subsequent amendment provide the statutory basis for energy-efficiency measures, institutional responsibilities, and energy-audit activities in India [2]. The Bureau of Energy Efficiency (BEE) complements this framework through guidance on energy management, electrical utilities, thermal utilities, and performance assessment [3]. An energy audit is not merely a list of high-consuming equipment. It is a structured investigation that establishes where, when, and why energy is used; quantifies avoidable losses; and converts observations into technically and financially evaluated energy-performance improvement actions. ISO 50002-1:2025 defines general requirements and guidance for conducting energy audits and emphasizes a transparent process that can be applied to buildings, processes, systems, and transport [4]. For SMEs, this structure must be adapted to the available data and resources without compromising measurement quality. A low-cost audit that relies only on utility bills may identify demand trends, whereas a detailed audit may require power-quality logging, motor loading assessment, illumination measurements, thermal imaging, compressed-air testing, combustion analysis, and process-specific energy balances.

The literature demonstrates a recurring gap between identification and implementation. Audits commonly reveal technically attractive opportunities, yet recommendations may remain unimplemented because of capital limitations, uncertainty regarding production disruption, incomplete baseline data, insufficient in-house expertise, or a preference for investments directly associated with production expansion. Therefore, the value of an audit depends on the credibility of its calculations, the clarity of its prioritization, and the presence of a follow-up mechanism. Measures with short simple payback can provide early savings, but longer-life measures may require life-cycle costing, risk assessment, and access to appropriate finance. Earlier versions of the present review described audit activities and individual case studies but did not systematically synthesize the reported outcomes. The present study addresses that limitation by organizing the evidence around four questions: which audit domains are repeatedly examined; which energy-conservation measures (ECMs) are most frequently recommended; what economic and implementation outcomes are reported; and what factors determine whether recommendations progress from an audit report to verified savings. The study consequently treats the published evidence as the result set of a structured narrative review rather than presenting unmeasured site-level savings as original experimental findings.

II. ENERGY AUDIT APPROACHES AND RELATED WORK

A. Levels of Energy Audit

Energy audits can be organized into three practical levels. A walk-through audit uses utility bills, operating records, equipment nameplates, interviews, and visual inspection to identify abnormal practices and immediate low-cost opportunities. A targeted audit examines a selected system, such as motors, compressed air, lighting, boilers, furnaces, refrigeration, or power quality, using short-term measurements and system-specific calculations. A detailed audit establishes an energy balance for the defined boundary, normalizes consumption against production or weather variables, evaluates multiple ECMs, and provides investment-grade technical and financial analysis. These levels are complementary. A walk-through audit should screen and prioritize; a targeted audit should resolve a defined uncertainty; and a detailed audit should support a capital decision and subsequent measurement and verification.

B. Principal Audit Domains

For electrically intensive SMEs, the principal domains are utility-bill analysis, contracted demand, load factor, power factor, voltage and current unbalance, harmonics, motor loading, pumping and fan systems, lighting, compressed air, refrigeration, and on-site generation. Thermal SMEs additionally require fuel accounting, combustion efficiency, steam-system assessment, insulation inspection, heat recovery evaluation, and process-temperature profiling. Rooftop photovoltaic systems introduce further requirements, including comparison of expected and measured yield, inverter performance, clipping, downtime, phase allocation, voltage variation, and harmonics. The audit boundary must distinguish production energy from common utilities so that recommendations are linked to controllable causes rather than to total consumption alone.

C. Evidence from Industrial Case Studies

Indian case studies have reported opportunities involving efficient motors, power-factor correction, LED lighting, improved fans, load balancing, harmonic mitigation, compressed-air leak reduction, operating-schedule changes, and monitoring improvements [5-10]. The reviewed cable-manufacturing study used ETAP to analyse the distribution system and reported both projected and implemented outcomes [7]. Larger international evaluations broaden the evidence beyond individual plants. Fresner et al. analysed lessons from 280 SME energy audits across Europe [11], while Viesi et al. assessed energy efficiency and sustainability across approximately 500 SMEs in Central Europe [12]. Paramonova and Thollander evaluated a Swedish audit programme and reported programme-level net savings [13]. Firm-level survey evidence further indicates that energy audits are positively associated with subsequent investment in efficiency measures [14]. Recent frameworks emphasize that the audit report must be understandable to non-specialist decision makers and must link each recommendation to the responsible system, baseline, expected saving, investment, operational risk, and verification method [15]. Research on barriers shows that economic constraints, limited awareness, behavioural factors, lack of time, and insufficient technical support influence decisions at different stages of ECM adoption [16]. Policy reviews therefore recommend combining audit support with financing, technical assistance, training, standardized tools, and implementation follow-up rather than treating the audit as a stand-alone intervention [17-19].

III. OBJECTIVES

The study aims to strengthen the technical and analytical basis for energy auditing in SMEs through the following objectives:

1. **Evidence synthesis:** Compare the scope, measurements, recommendations, and reported outcomes of selected SME and industrial energy-audit studies.
2. **Recurring opportunity identification:** Determine which electrical, thermal, operational, and management-related ECMs appear most consistently across the reviewed evidence.
3. **Outcome interpretation:** Evaluate reported savings, investment, payback, and implementation information while distinguishing projected savings from verified outcomes.
4. **Framework development:** Propose a practical audit workflow that an SME can use to progress from preliminary screening to implementation and measurement and verification.

IV. METHODOLOGY

A. Review Design and Evidence Base

A structured narrative-review design was used because the available studies differ substantially in industrial sector, audit boundary, instrumentation, reporting units, tariff assumptions, and follow-up duration.

The empirical evidence base comprised six Indian case studies already central to this review [5-10], three international multi-enterprise or programme evaluations [11-14], and one recent case-study-based framework [15]. Standards, BEE guidance, and policy reviews were used to interpret audit quality and implementation conditions [3], [4], [17-19]. The review was not designed as a statistical meta-analysis; accordingly, no pooled percentage saving was calculated. Studies were included when they explicitly described at least one of the following: energy-data collection, field measurement, equipment or utility-system assessment, identification of ECMs, economic evaluation, implementation status, or barriers affecting adoption. Sources that only discussed general sustainability without an identifiable audit process were not used as primary evidence in the result matrix. The publication years of the empirical and framework studies ranged from 2014 to 2024, enabling comparison of conventional audit practices with more recent implementation-oriented approaches.

B. Data Extraction and Thematic Coding

For each study, information was extracted under six headings: (1) industrial or organizational setting; (2) audit level and system boundary; (3) data and instruments used; (4) major inefficiencies identified; (5) recommended ECMs; and (6) reported technical, economic, or implementation outcome. The Indian studies were additionally coded for the presence of power-factor or power-quality analysis, motor or fan assessment, lighting assessment, compressed-air analysis, thermal assessment, operational scheduling, and photovoltaic analysis. These counts describe the reviewed sample only and are not estimates of prevalence across all SMEs.

C. Audit Calculations and Decision Metrics

The technical evaluation of an ECM begins with a baseline that represents normal operation. For production-dependent facilities, specific energy consumption (SEC) is calculated as energy use divided by production output. The expected annual energy saving is the difference between baseline and post-measure energy use after normalization for production, operating hours, weather, or other relevant variables. Annual cost saving should be calculated from the applicable tariff components, including energy charge, demand charge, power-factor incentive or penalty, time-of-day charge, fuel cost, and maintenance impact. Simple payback is calculated as initial investment divided by annual net monetary saving. Where equipment life, financing cost, or maintenance differences are significant, net present value, internal rate of return, and discounted payback provide a more appropriate decision basis than simple payback alone. Power-quality recommendations require particular care because the financial benefit may arise through several mechanisms: reduction of demand current and distribution losses, avoidance of utility penalties, improved voltage performance, reduced equipment heating, and prevention of production interruption. Harmonic filters or automatic power-factor-correction panels should therefore be sized using measured load profiles and harmonic spectra rather than only a single instantaneous reading. Similarly, motor replacement should be evaluated from measured loading, duty cycle, efficiency class, rewinding history, and remaining service life; nameplate power is not a substitute for actual input power.

D. Measurement and Verification

Projected savings become auditable outcomes only after implementation and verification. The proposed approach records pre-implementation operating conditions, identifies the independent variables that influence energy use, documents the commissioning status, and compares post-implementation performance with an adjusted baseline. Suitable indicators include monthly SEC, maximum demand, load factor, average power factor, total harmonic distortion, motor input power, compressor specific power, lighting power density, boiler efficiency, photovoltaic performance ratio, and avoided cost. Short-term measurements are appropriate for stable loads; variable production processes require longer logging or repeated measurements across representative operating conditions.

V. RESULTS

A. Characteristics of the Reviewed Evidence

Table 1 summarizes the empirical evidence used in the synthesis. The studies range from single-facility audits to programmes involving hundreds of SMEs. This heterogeneity is analytically useful because it shows both the plant-level diagnostic detail and the programme-level implementation effect. However, it also limits direct numerical comparison. Most Indian studies concentrate on electrical systems, whereas the international studies place greater emphasis on programme design, adoption behaviour, and standardized implementation support.

Table 1: Characteristics and reported outcomes of the reviewed energy-audit evidence.

Ref.	Setting/sample	Audit focus	Reported result or implication
[5]	Industrial case, India	On-site measurements; motors, power factor, and electrical losses	Efficient motors, capacitor correction, maintenance, and behavioural actions; qualitative economic and environmental benefits.
[6]	Steel plant, India	Bills, lighting, motors, fans, and power factor	LEDs, efficient motors/fans, maintenance, and power-factor correction were recommended; no verified post-implementation saving reported.
[7]	Cable manufacturing, India	ETAP model; load balance, power factor, motors, and operating schedule	INR 0.675 million investment; INR 1.191 million annual saving; reported payback 6.4 months; approximately 75% of expected outcomes implemented.
[8]	Textile sector, India	Bills, power factor, lighting, motors, compressed air, and rooftop PV	Multiple cross-utility opportunities identified, including LEDs, leak reduction, power-factor correction, and motor-efficiency improvement.
[9]	Medium-scale industry, India	Pre-audit, field audit, and post-audit planning	Lighting/fan replacement and capacitor-bank installation; reported combined payback of 25 months.
[10]	Steel industry and institute	Power-quality analyser; harmonics, power factor, and unbalance	Active filtering, monitoring, and correction measures proposed to reduce losses and improve power quality.
[11]	280 SME audits, Europe	Cross-sector audit experience	Demonstrated the value of systematic, practical audits and highlighted recurring challenges in converting identified opportunities into action.
[12]	Approximately 500 SMEs, Central Europe	Energy-efficiency and sustainability assessment	Provided a large multi-sector evidence base for benchmarking and sector-sensitive assessment.
[13]	713 firms in Swedish audit programme	Subsidized audits and programme evaluation	Net annual saving of 340 GWh, corresponding to approximately 6% of participating firms' energy use; information barriers were reduced.
[14]	EU firm-level survey evidence	Audit participation and investment decisions	Energy audits were positively associated with firms' adoption of energy-efficiency investments.
[15]	Non-energy-intensive manufacturing SMEs	Case-study-based implementation framework	Emphasized an action-oriented process linking data quality, opportunity evaluation, management engagement, and follow-up.

Source: Authors, (2026).

B. Recurring Technical Findings

Coding of the six Indian studies [5-10] showed that power factor or broader power-quality assessment was present in all six studies. Motor or fan efficiency appeared in five studies, and lighting-system improvement appeared in three. Load balancing, harmonic mitigation, operating-schedule changes, and improved monitoring were also recurrent. Compressed-air analysis and rooftop-photovoltaic assessment were each explicitly included in one of the six studies. These frequencies indicate the dominant concerns of the reviewed sample, not the distribution of energy use in every SME. The predominance of power-factor and power-quality measures is technically understandable. These parameters can be measured with portable instruments, are directly connected to electrical distribution performance, and may affect both utility charges and equipment stress. Nevertheless, a high power factor does not by itself prove efficient energy use. A facility may have acceptable power factor while operating oversized motors, throttled pumps, leaking compressed-air systems, or poorly controlled thermal processes. Therefore, power-quality analysis should be integrated with end-use and process analysis rather than treated as the complete audit. Motor and fan recommendations were the second most common category. The saving mechanism may involve replacement with a higher-efficiency motor, correct sizing, variable-speed control, improved transmission, reduced pressure or flow set points, or maintenance of bearings and alignment. The appropriate option depends on the load characteristic. Variable-speed drives are most effective where speed can be reduced for substantial operating periods; they are not automatically justified for constant-load applications. Lighting upgrades are usually easier to implement, but illumination level, glare, colour rendering, operating hours, and control strategy must be verified so that energy reduction does not compromise the work environment.

Table 2: Measurement-to-verification structure for major SME audit domains.

Audit domain	Key indicators	Typical instruments/data	Representative ECMs	Verification metric
Utility and demand	kWh, kVA, maximum demand, load factor, tariff	Bills, interval meter, production log	Demand control, schedule optimization, tariff correction	Monthly cost and normalized SEC
Power quality	PF, THD, unbalance, voltage variation	Three-phase power-quality analyser	APFC, load balancing, filters, conductor correction	PF, THD, current, losses, penalty avoided
Motors/pumps/fans	Loading, efficiency, flow, pressure, duty cycle	Power analyser, tachometer, flow/pressure data	Right-sizing, efficient motor, VFD, system optimization	kW, kWh/unit output, flow-specific energy
Lighting	Illuminance, installed power, hours	Lux meter, inventory, occupancy schedule	LEDs, zoning, daylight/occupancy controls	kWh, lux compliance, demand reduction
Compressed air	Pressure, flow, leakage, specific power	Ultrasonic detector, pressure logger, compressor data	Leak repair, pressure reset, control optimization	kW per flow, off-load hours, leakage rate
Thermal systems	Fuel rate, temperature, O2/CO, heat loss	Flue-gas analyser, thermal imager, temperature sensors	Combustion tuning, insulation, heat recovery	Fuel/unit output, efficiency, stack loss
Rooftop PV	Yield, availability, clipping, voltage, harmonics	Inverter logs, irradiance and energy data	Cleaning, string repair, inverter/phase optimization	Performance ratio, specific yield, downtime

C. Economic and Implementation Outcomes

Only a limited subset of the reviewed Indian studies reported sufficiently explicit economic outcomes. The cable-manufacturing study [7] reported an investment of INR 0.675 million and annual savings of INR 1.191 million.

Direct division of investment by annual savings gives a simple payback of approximately 6.8 months, which is close to the reported 6.4 months and may differ because of rounding or additional cash-flow assumptions. The medium-scale industrial study [9] reported a payback of 25 months. These results demonstrate that attractive opportunities may exist, but they cannot be generalized into a universal SME payback because the underlying tariffs, operating hours, production levels, equipment condition, and project scope differ. The statement that 75% of the expected outcomes were achieved in the cable-manufacturing case is especially important [7]. It reveals an implementation gap between technically identified potential and realized performance. The gap may arise from partial implementation, changed operating conditions, delayed procurement, incomplete commissioning, or optimistic baseline assumptions. Audit reports should therefore separate four quantities: identified potential, approved projects, implemented projects, and verified savings. Combining these stages into a single "saving potential" figure can overstate actual performance. The Swedish programme evaluation provides a broader outcome measure: 340 GWh/year of net annual savings, equivalent to about 6% of the participating firms' energy use [13]. This programme-level result indicates that standardized and supported audit schemes can produce material savings across a large SME population. Survey evidence also suggests that audits increase the likelihood of energy-efficiency investment [14]. However, the audit itself is an informational intervention; financing, managerial commitment, competent suppliers, and follow-up remain necessary for implementation.

D. Barriers Identified Across the Evidence

The recurring barriers can be grouped into financial, informational, organizational, and technical categories. Financial barriers include limited internal capital, short required payback periods, high transaction cost relative to project size, and uncertainty about future production. Informational barriers include incomplete submetering, limited knowledge of efficient technologies, distrust of vendor claims, and uncertainty about achievable savings. Organizational barriers include lack of a designated energy manager, competing production priorities, limited time, and weak accountability for follow-up. Technical barriers include variable operating conditions, legacy equipment, poor documentation, and the risk that an intervention may affect product quality or production continuity [16-19]. The reviewed evidence indicates that a credible audit can reduce informational barriers by converting general concerns into measured and ranked actions. It cannot independently remove capital or organizational barriers. Consequently, recommendations should be grouped into no-cost or low-cost actions, short-payback retrofits, and strategic capital projects. This grouping allows early savings to build confidence while larger projects undergo engineering and financial review.

VI. DISCUSSION

A. Interpretation of the Dominant Audit Measures

The result synthesis shows that electrical utility measures dominate the reviewed Indian cases. Their popularity is partly attributable to measurement accessibility and comparatively low implementation complexity. Power-factor correction, lighting replacement, load balancing, and selected motor measures can often be evaluated without modifying the core production process. This makes them suitable entry points for SMEs. Nevertheless, an audit restricted to these measures may overlook larger process opportunities. The audit should therefore first establish the energy balance and significant energy uses, and only then select the depth of measurement for each system. A further distinction is required between energy saving and cost saving. Power-factor correction may reduce current and avoid penalties without producing a proportional reduction in billed kWh. Load shifting may reduce demand or time-of-day charges while leaving total energy use unchanged. Rooftop PV reduces purchased electricity but is not an efficiency measure unless accompanied by improvements in energy performance. Reporting these effects separately improves transparency and prevents double counting.

B. Quality of Baseline and Financial Analysis

The reliability of an audit outcome is determined by its baseline. A comparison between two monthly bills is inadequate when production, weather, working days, or product mix changed materially. SMEs with variable production should use SEC and, where possible, regression or matched-period analysis. The uncertainty of key assumptions should be reported. For example, a motor-replacement calculation should state loading, efficiency values, annual operating hours, electricity tariff, and whether avoided maintenance or downtime is included. A compressed-air leak calculation should state pressure, leak test method, compressor specific power, and operating schedule. Simple payback remains useful for rapid screening but can bias decisions against long-life measures. A project with a three-year payback and a fifteen-year life may have greater life-cycle value than a one-year project with a two-year life. Conversely, a short calculated payback may be unreliable if it assumes constant production or ignores commissioning and maintenance costs. A recommended SME decision table should therefore include investment, annual energy saving, annual cost saving, simple payback, expected life, implementation downtime, technical risk, and verification plan.

C. From Audit Report to Implementation

The reviewed implementation evidence supports a staged portfolio approach. Stage 1 should include housekeeping, control settings, leak repair, maintenance, and operator practices that require little capital. Stage 2 should include standard retrofits such as LEDs, capacitor banks, efficient motors, variable-speed drives, insulation, and monitoring. Stage 3 should include process redesign, heat recovery, major utility replacement, or renewable-energy integration. Each action should have a named owner, target date, budget status, and post-implementation indicator. Without ownership and follow-up, the audit remains a diagnostic document rather than an energy-management instrument. Cluster-based implementation is particularly relevant to Indian SMEs. Enterprises within a common industrial cluster often use similar motors, furnaces, compressors, pumps, and production practices. Common audit templates, benchmark ranges, pooled training, aggregated procurement, and shared technical support can lower transaction costs. Public or utility-supported programmes can further improve adoption through partial audit subsidies, credit guarantees, performance-linked finance, or approved technology-provider networks. International policy reviews similarly conclude that integrated packages are more effective than isolated audit obligations [17-19].

D. Appropriate Use of Software and Digital Tools

Software such as ETAP, DIALux, MATLAB, eQUEST, and specialized energy-management platforms can improve analysis, but model output is only as reliable as the input data. ETAP can assess load flow, short circuit, harmonics, and correction alternatives; DIALux can support lighting design; simulation tools can evaluate control and process scenarios; and interval-data platforms can identify abnormal load patterns. These tools should be used to test measured conditions and alternatives, not to replace site inspection or calibration. For SMEs with limited submetering, a phased monitoring plan may be more valuable than a complex model created from assumed loads.

E. Practical Framework for SMEs

The combined evidence supports a six-stage framework. First, define the audit boundary, objectives, production variables, and data responsibilities. Second, establish the baseline from bills, interval data, production records, and an energy balance. Third, measure significant energy uses using calibrated instruments under representative operating conditions. Fourth, diagnose losses and identify their operational causes rather than only their symptoms. Fifth, prioritize ECMs using technical feasibility, verified saving, investment, payback, risk, and production impact. Sixth, implement and verify results through defined energy-performance indicators. The feedback loop in Figure 1 converts a one-time audit into continual improvement.

F. Limitations

This study is a structured narrative review and not a systematic review or meta-analysis. The evidence is heterogeneous, and several case studies do not report complete baseline, uncertainty, implementation, or post-project verification data. The numerical results should therefore be interpreted as study-specific outcomes. The paper does not present a new field audit of a named SME, and it does not claim that the reported savings percentages or payback periods apply to all industrial sectors. Future work should use a standardized reporting template and should publish both projected and verified savings, production-normalized baselines, implementation cost, project life, and uncertainty.

VII. CONCLUSION

The expanded review demonstrates that energy audits can provide a practical route to lower energy cost and improve energy performance in SMEs when they progress beyond descriptive inspection. Across the reviewed Indian studies, power factor and power quality were the most consistently assessed domains, followed by motors and fans and then lighting. Reported measures included efficient equipment, power-factor correction, harmonic mitigation, load balancing, compressed-air leak control, operating-schedule optimization, and improved monitoring. The available economic results ranged from a reported 6.4-month payback in cable manufacturing to 25 months in a medium-scale industry, while a Swedish audit programme reported net savings equivalent to approximately 6% of participating firms' energy use. The evidence also shows that identified potential is not equivalent to achieved saving. Audit quality depends on representative measurement, normalized baselines, transparent financial assumptions, prioritized actions, and a defined verification method. For resource-constrained SMEs, the most effective strategy is to implement a portfolio beginning with no-cost and low-cost actions, followed by standard retrofits and then strategic process investments. Cluster-based technical assistance and financing can reduce the transaction and capability barriers that frequently prevent implementation.

The proposed six-stage framework - scope, baseline, measurement, diagnosis, prioritization, and verification - provides a defensible structure for future audits and for reporting results in a manner that is technically credible and useful to decision makers.

ABSTRACT

With the significant advancements in the electric vehicle (EV) sector, improving electric conversion and charging systems has become necessary to improve efficiency and accessibility for all users. This paper introduces a novel nine-switch inverter with a quasi-impedance Source topology designed to revolutionize EV power train systems. The proposed inverter design enables the simultaneous control of two traction motors while reducing the number of required power switches from 12 to 9, saving three switches compared to the conventional dual-inverter setup, improving system redundancy and dependability for improved EV performance. Utilizing its features, the inverter doubles as an onboard charger, eliminating the need for a separate charging unit. This streamlined approach reduces system complexity and cost while improving charging convenience.

I. INTRODUCTION

Global energy consumption keeps rising, and a constant desire exists to enhance power capacity. Most of this energy is derived from fossil resources, which presents ongoing energy production, conversion, and distribution challenges. It also contributes to pollution and its detrimental impact on the environment, particularly in urban areas, and human health. Transportation represents one of the most significant consumers, especially vehicles with internal combustion engines; however, advancements in the electric vehicle (EV) sector are leading to a gradual shift towards more sustainable transportation options, which links to the rapid penetration of renewable and alternative energy sources and energy storage solutions. These vehicles offer greater energy efficiency, minimal pollution, and reduced maintenance compared to traditional internal combustion engines [1]. Electric vehicles can be categorized into two main types based on the number and arrangement of motors: distributed multi-motor driven power trains and centralized single-motor driven power trains. Distributed multi motor driven power trains can be further classified into three subcategories: Dual-motor, as described in [2], Triple-motor as discussed [3], and Four-motor power trains, as explored in [4], On the other hand, centralized single-motor driven is the most common configuration in modern EVs [5].

Compared to the centralized single motor approach, distributed multi-motor power trains offer several advantages, including higher efficiency, reduced torque pulsation, and improved fault tolerance. However, these benefits come at a higher premium price. In dual motor configurations, using two independent motors requires separate control. The conventional approach involves two separate inverters, leading to increased cost and system size [6]. Ongoing research in power electronics aims to develop cost-effective and efficient conversion capabilities. Reducing the number of semiconductor switches is a critical factor in converter costs. The decrease in converter size through fewer switches can significantly reduce the price. Various novel topologies have been created, including the Nine Switch Inverter (NSI) [7], the B4 inverter [8], and the Five Leg Inverter [9]. The NSI, a dual-output inverter, has been proposed as a solution in various industrial applications, helping to reduce the number of semiconductor tor switches and associated energy losses, as well as streamlining drive circuitry.Previous research on nine-switch and quasi-impedance source inverter (qZSI) topologies has explored several directions, but each remains limited in scope with respect to the requirements of electric vehicle systems.

Discontinuous PWM strategies for qZS nine-switch inverters [10] and carrier-based PWM techniques [11] mainly focused on reducing switching losses and improving modulation performance, without addressing dual-motor propulsion or onboard charging. Similarly, dual hysteresis band current control has been applied to nine switch inverters for two induction motors [12], but this work only emphasized torque control and omitted EV-specific functions such as bidirectional charging and vehicle-to-grid (V2G) operation. Other studies have attempted integrated drive and charger solutions: a nine-switch-based charger for six-phase machines [13], and a multilevel nine-switch topology with improved harmonic quality [14]. However, these approaches are constrained either by reliance on six-phase machines or by increased device count and circuit complexity, and they do not consider independent dual-motor platforms. In contrast, the present work introduces a unified qZS nine-switch inverter solution that simultaneously supports dual-motor EV propulsion with dynamic torque distribution and onboard charging using a constant-current/constant-voltage strategy. By combining propulsion, charging, and V2G functionalities within a single, compact converter, while maintaining the inherent advantages of the qZSI such as continuous input current and voltage boost capability, the proposed system offers a novel and more comprehensive EV-oriented architecture than previously reported in the literature.

II. ON-BOARD CHARGER FOR ELECTRIC VEHICLES

The Nine-Switch Inverter (NSI) enables dual three-phase outputs using shared switches but requires a higher DC-link voltage [15], and employing a two-stage boost converter increases cost and complexity. To address this, the Z-Source Inverter (ZSI) was introduced with single-stage buck–boost capability, though it suffers from discontinuous input current and higher source stress [16]. The Quasi Z-Source Inverter (QZSI) improves upon this by rearranging the impedance network, ensuring continuous input current, reduced ripple, elimination of inrush current, and simplified integration. Despite higher capacitor voltage stress, it offers better efficiency and control. Its voltage boost is characterized by the boost factor.

$$B = \frac{1}{1 - 2D} \tag{1}$$

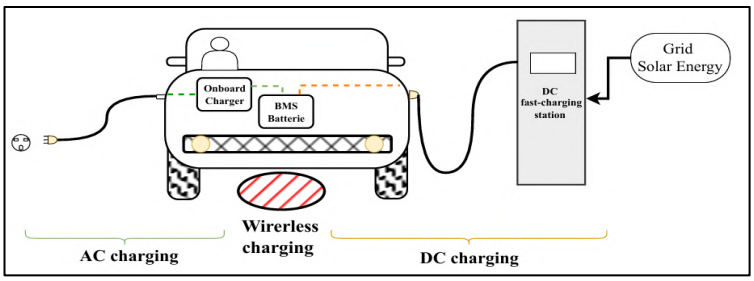

Figure 1: Schematic representation of differences in on-board,off-board chargers, and Wireless chargers or DC-fast charging station.
Source: Authors, (2026).

Where D is the shoot-through duty ratio, confirming its ability to provide single-stage buck–boost operation suitable for renewable and electric vehicle applications. Moreover, such inverter topologies not only enable efficient traction power conversion but also contribute to improved power quality by maintaining low Total Harmonic Distortion (THD) as represent (Figure 2).

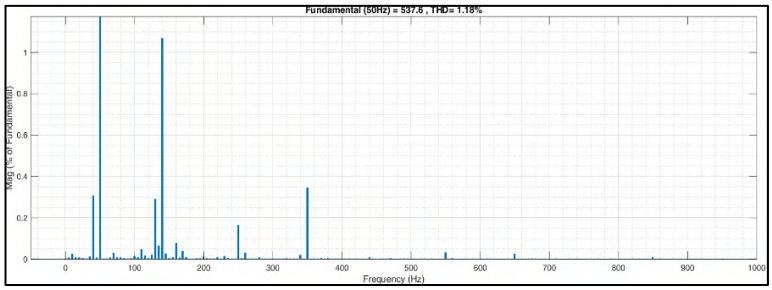

Figure 2: THD The Simple Boost Control.
Source: Authors, (2026).

Charging systems for hybrid and electric vehicles are crucial for efficient operation. They are categorized into off-board and on-board systems, as shown in (Figure 1), which power the batteries and enable efficient operation. Onboard charging systems are integrated into the vehicle itself. These systems include components like the onboard charger, charging port, charging control unit, power conversion, and protection mechanisms [17], which offers a significant advantage for EVs by enabling them to charge wherever an electrical outlet is available. This flexibility allows EV owners to conveniently charge their vehicles home by converting external AC power into DC. The onboard charging system regulates voltage and current, ensuring efficient and safe power transfer to the vehicle's batteries [18], [19]. On the other hand, the Off-board charging stations are external to the vehicle, typically part of the charging infrastructure [20], which offers High-DC power allows fast charging and ensures compatibility with different EV models and standards, However, it is important to consider the challenges associated with the off-board charging station. The availability of these stations is limited due to the need for dedicated parking spaces, which can be challenging in urban areas. The setting up off-board charging infrastructure is expensive, especially for high-power DC fast charging stations, and requires regular maintenance [21]. The choice between Off-board and Onboard charging depends on the user's specific needs, driving patterns, and access to charging infrastructure.

(Figure 3) represents the proposed inverter in this topology. We can operate in two directions. The first one, the battery, powers the two motors through the inverter. The second operation uses a bidirectional DC-DC converter to achieve the desired input voltage and current for the battery, as in (Figure 4). The power flows from the grid to the battery utilizing the operation control (Figure 5) V2G, G2V, munched in [22].

III. CHARGING MODE FOR BATTERY IN ELECTRIC VEHICLE

The electrification of the transportation sector has led to research on battery electric vehicles (EVs) and plug-in hybrid electric vehicles (PHEVs) and how they can be integrated into electrical networks. Electric vehicles' charging method significantly impacts their batteries' performance and efficiency and determines the charging mode [23]. There are two primary charging modes for batteries in EVs: constant-current (CC) charging and constant-voltage (CV) charging [24]. The constant current (CC) charging mode is generally used during the initial stages when the battery has a low state of charge. SOC. By providing a controlled, constant current to the battery for fast charging, however, as the battery reaches higher charge levels, the charging rate gradually decreases [25].

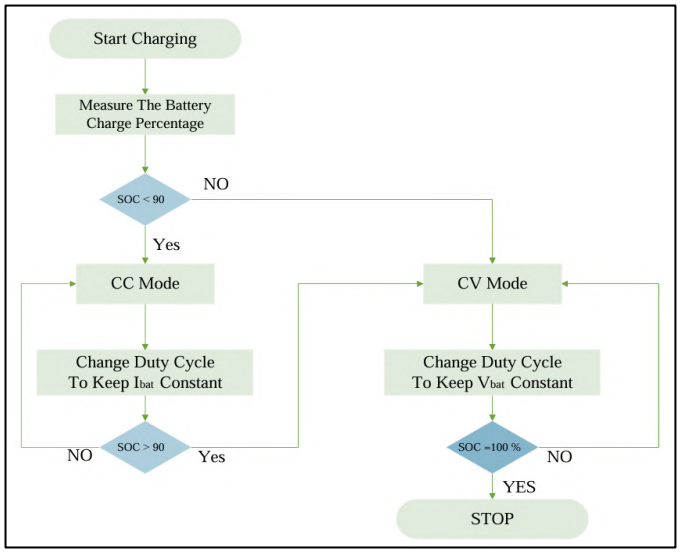

Figure 6: Charging Mode.
Source: Authors, (2026).

In contrast, constant voltage (CV) is used in the late stages of charging near full capacity by providing a constant voltage to the battery during charging. The CV method ensures that the charging current decreases as the battery's state of charge increases, preventing overcharging, which can be detrimental to its performance and lifespan [26]. The decision to use CC or CV charging mode depends on various factors, including battery chemistry, charging infrastructure, and desired charging time. The algorithm used to charge the battery is represented in (Figure 6). Two charging modes were used: constant current and followed by constant voltage.

IV. DYNAMIC VEHICLES

In order to understand the behavior of a vehicle, it is important to consider the various forces acting upon it. These forces are crucial in determining the vehicle's speed, acceleration, and fuel efficiency. There are four main forces that an electric vehicle must overcome in order to move: Grading Resistance, Rolling Resistance, Aerodynamic Drag, and Inertial Effect. Understanding these forces can help us optimize the design of electric vehicles and improve their performance on the road [27-30]. Grading resistance (F_g) is the force that opposes a vehicle's movement due to changes in elevation or slope. It is related to the vehicle's weight and the road's gradient. The higher the gradient, the greater the grading resistance.

$$F_g = M_{car}.g.sin(\alpha) \quad (2)$$

Where: M_{car} [kg]Mass of the vehicle.
g =9.81[m/s2] Free fall acceleration.
α[rad] Angle of the driving surface.

Rolling resistance (F_r) is the force that resists a vehicle's movement due to the deformation of its tires as they come into contact with the road. Rolling resistance depends on various factors, such as tire type, tire pressure, and road surface.

$$F_r = M_{car}.g.C_r.cos(\alpha) \quad (3)$$

where: Cr [-] Tire rolling resistance coefficient.

Aerodynamic drag (F_w) is the force that resists a vehicle's movement due to its exposure to the wind. This force is proportional to the square of the vehicle's speed and is influenced by factors such as the vehicle's shape and cross-sectional area.

$$F_w = \frac{1}{2}.\rho.A_f.C_D.(V - V_w)^2 \quad (4)$$

where: ρair = 1.2041[kg/m3] Air density of dry air at 20◦C.
Af [m2] Front area.
CD[-] Aerodynamic drag coefficient.
V[m/s] Velocity of the vehicle.
W_{wind} [m/s] Headwind speed.

Inertial Effect (F_I) it is the force that opposes the acceleration and deceleration of a vehicle. It depends on the mass of the vehicle and the magnitude of the acceleration or deceleration. Inertial force is greater in heavier vehicles and at higher speeds.

$$F_I = M_{car}.\dot{V} \quad (5)$$

where: $\dot{V}$ [m/s2] Acceleration of the vehicle.

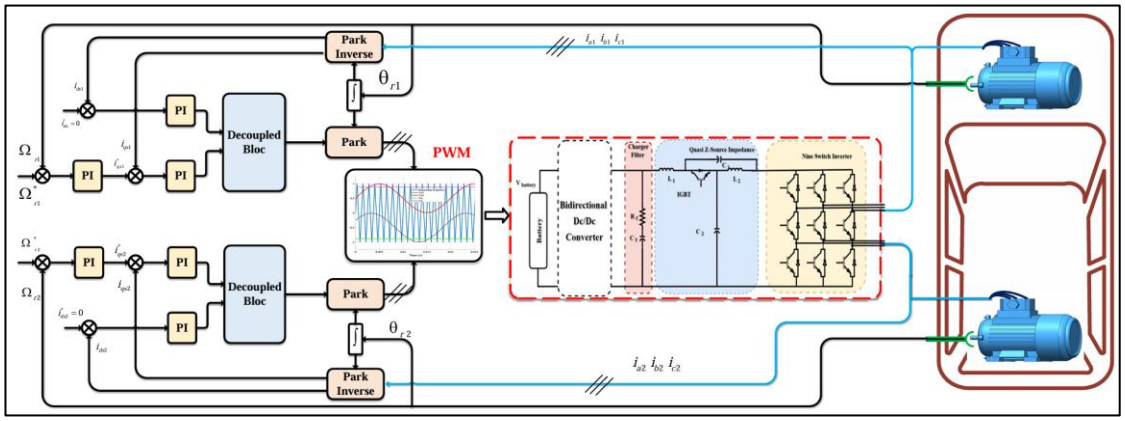

Figure 7: The general structure of the system with two motor controls.
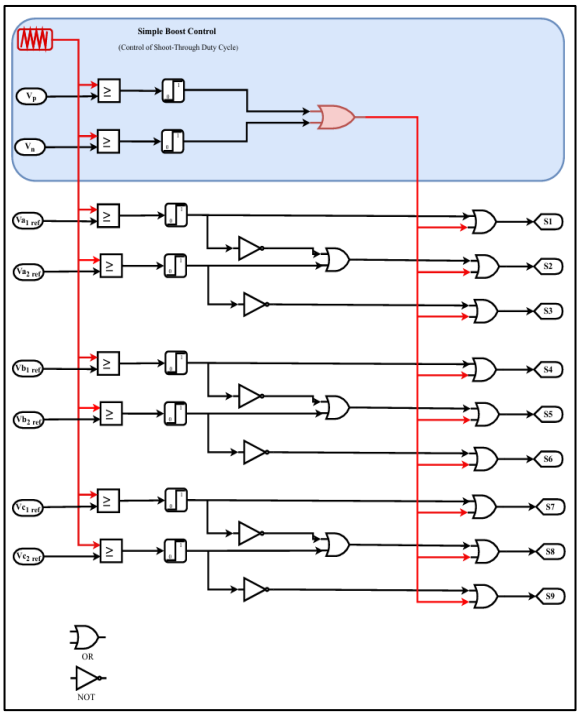
Source: Authors, (2026).

(Figure 7) represents a vector control diagram for two permanent magnet synchronous motors powered by a single bidirectional quasi-Z-source nine-switch inverter. This system is designed to independently control the torque and speed of two PMSMs while reducing the number of power switches. Each PMSM has its own vector control loop, which includes PI controllers for the current components, decoupling blocks to cancel cross-axis interactions, Park and inverse Park transforms for reference frame conversion, and integrators to generate the rotor electrical angles. These control loops produce three-phase voltage references V_{a1}^{ref}, V_{b1}^{ref}, V_{c1}^{ref} for the front motor and V_{a2}^{ref}, V_{b2}^{ref}, V_{c2}^{ref} for the rear motor that are fed into a unified Pulse Width Modulation (PWM) block (Figure 8). The PWM modulates the nine-switch inverter, which shares three of its switches between the two motor phases, reducing the total number of switches from twelve (in two separate three-phase inverters) to nine. A quasi-Z-source network is incorporated between the DC source and the inverter to provide voltage boost capability and protection against shoot-through states, enhancing system robustness. On the output side, the inverter supplies three-phase AC voltage to each PMSM independently. Feedback from each motor, including current and speed, is used to close the control loops and ensure accurate torque and speed regulation.



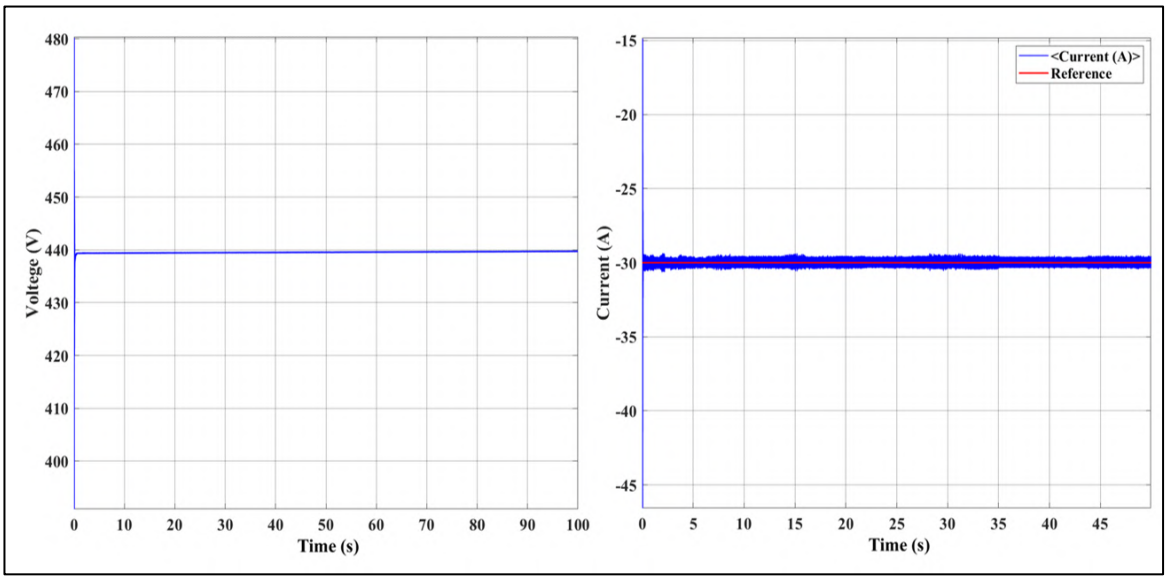


Figure 8: PWM Control.
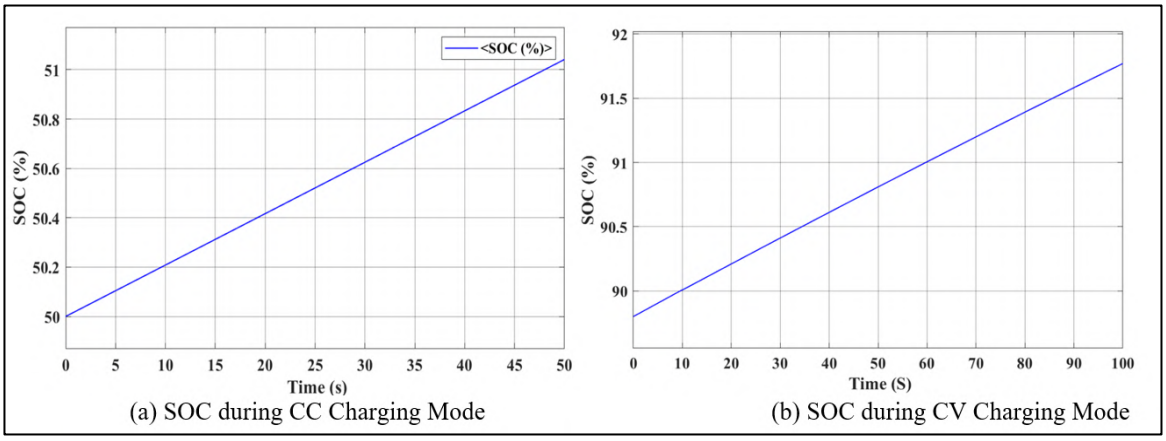
Source: Authors, (2026).

We utilize the NEDC as our reference speed profile, which allows us to categorize the driving cycle into urban and extra-urban phases. During both phases, the inverter enables independent speed and torque control, allowing for equal torque distribution between the two motors. This approach ensures balanced operation, improves overall efficiency, and supports consistent performance across varying driving conditions.

V. RESULTS AND DISCUSSIONS



(Figure 9) represents the charging mode of the battery. Starting with the CC mode, this approach is typically used to quickly and efficiently charge the battery up to a state of charge (SOC), in our case, 90 %.

(1) Battery Voltage (b) Battery Current

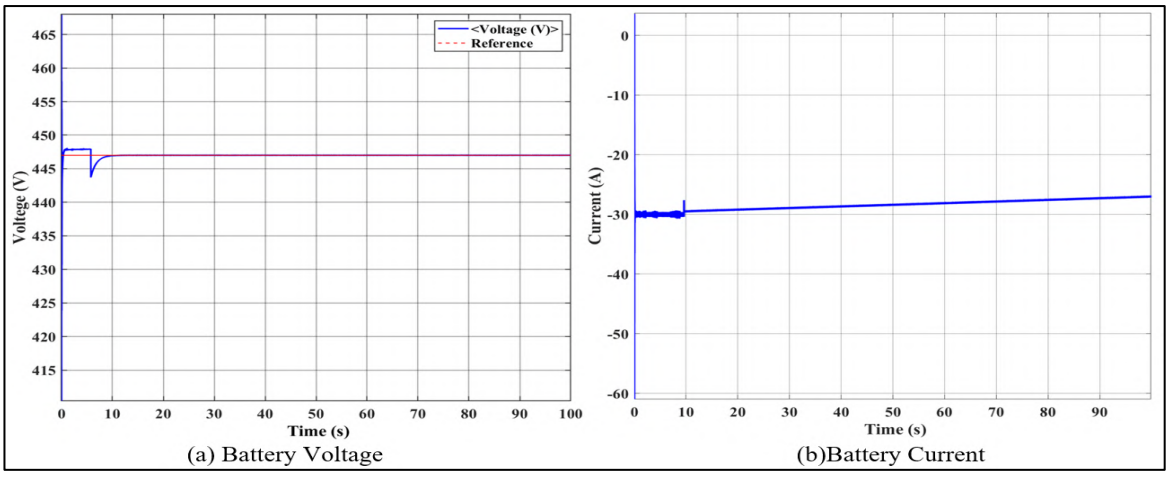


Figure 9: Constant-current Charging Mode: Battery Voltage and Current.
Source: Authors, (2026).

During the CC charging phase, the charger maintains a constant current of 30 A, (Figures 9b), which allows the battery to be charged at a relatively high rate (Figure 10a).This contributes to recharging the battery more rapidly than a pure CV charging approach. The constant current ensures the battery is charged efficiently without exposing it to high voltages, as represented in (Figure 9a), which could potentially degrade the battery over time.The charging mode was switched to CV charging once the battery reached 90 % SOC (Figure 10b).

Figure 11: Constant Voltage Charging Mode: Battery Voltage and Current.
Source: Authors, (2026).

During the CV charging phase, (Figure 11) the charger maintains a constant voltage (Figure 11a), while the current gradually decreases as the battery approaches full capacity, as represented in (Figure 11b). The peak shown in the (Figures 11a, 11b) represents the transition from constant current to constant voltage charging mode.This mode helps to prevent overcharging and optimize the final stages of the charging process. This strategy uses CC charging's speed and efficiency to replenish battery capacity quickly, followed by the transition to CV charging, which ensures safe completion and maintains battery health and performance. The hybrid charging strategy, which combines CC charging up to 90% SOC followed by CV charging, is often employed in electric vehicles to strike a balance between charging time, energy efficiency, and battery longevity The torque distribution results demonstrate the algorithm's ability to allocate the required torque between the two motors effectively considering their capabilities and the overall torque requirements of the EV the actual torque for each motor follows the reference, demonstrated in (Figures 12 and 13). To simulate real-world driving conditions in urban and extra-urban environments, we used the NEDC cycle, which provides a more realistic evaluation of vehicle behavior through the results obtained in (Figures 13, 12) The vehicle's actual speed demonstrates a high degree of concordance with the reference speed profile. This close alignment between the actual and target velocities indicates precise speed control and robust vehicle responsiveness to the prescribed driving pattern.

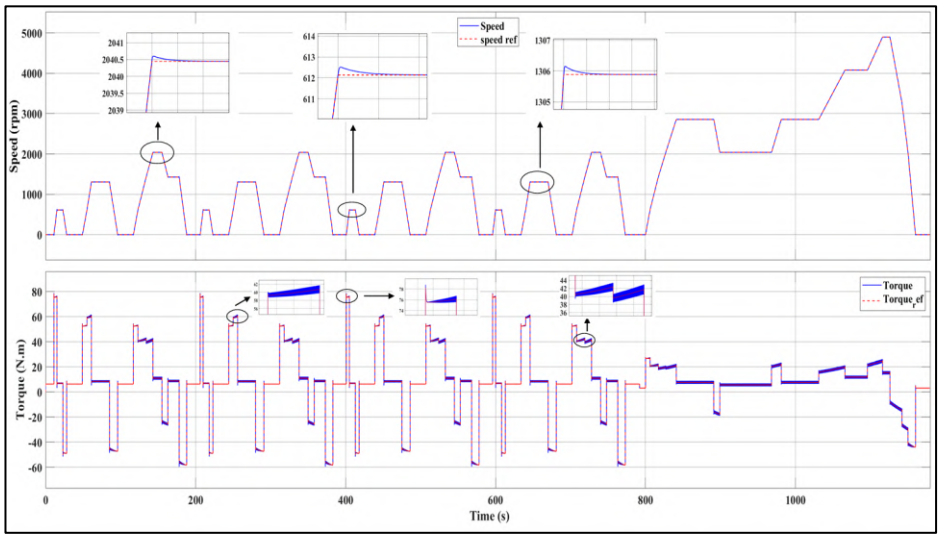

Figure 12: The speed and the torque for the front motor.
Source: Authors, (2026).

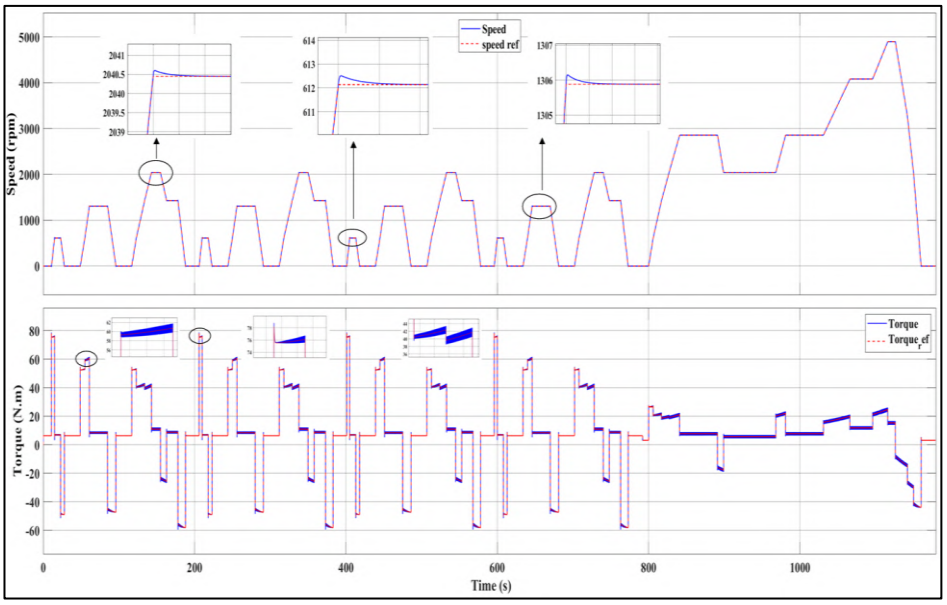

Figure 13: The speed and the torque for the rear motor.
Source: Authors, (2026).

The Figures representing the vehicle's target power profile throughout the NEDC cycle, This demand power curve indicates the instantaneous power requirements that the vehicle achieves to follow the prescribed speed and acceleration patterns accurately. By closely adhering to this demand power profile (Figures 14, 16) the vehicle demonstrates its ability to efficiently manage energy resources and respond to varying load conditions characteristic of real-world driving scenarios. The (Figures 14 and 16) display the three-phase currents (ia, ib, ic) of the electric motor, which are fundamental to understanding its dynamic performance during the NEDC cycle. These currents represent the instantaneous electrical input to each of the motor's three phases, The currents exhibit a sinusoidal pattern as represented by the figure (Figures 15 and 17), with the frequency proportional to the motor's rotational speed. The varying amplitudes of ia, ib, and ic reflect changes in torque demand. Higher amplitudes correspond to periods of acceleration or increased load.

VI. CONCLUSIONS

This work presented a nine-switch inverter with quasi-impedance source for independently controlling dual separate motors in EVs. The main feature of the proposed configuration is to reduce the number of switching components required compared to traditional multi-motor EV configurations, with a combination of onboard charge and wireless charging capabilities. In the initial stage of this research, we demonstrated the inverter's ability to generate a continuous current to reduce stress on the components. By modifying its impedance, we gained bidirectional functionality, allowing the inverter to serve as an onboard charger. To maintain battery performance, we use the cc-cv charging method. This hybrid charging strategy is efficient in electric vehicles and balances charging time, energy efficiency, and battery longevity.

ABSTRACT

Over the past decade, Computational Fluid Dynamics (CFD) has become a fundamental tool for the assessment, modeling, and optimization of thermal comfort in controlled architectural environments, enabling detailed simulation of airflow behavior, heat transfer processes, and the spatial distribution of thermo-environmental variables within indoor spaces. The integration of human thermophysiological models has enhanced the predictive capability of these simulations, allowing for more realistic estimations of occupants' thermal responses and perceptual comfort. In parallel, the growth and maturation of open-source platforms have democratized access to these technologies, facilitating their implementation across multiple scales and building typologies, ranging from offices and residential buildings to vehicle cabins and urban environments. Recent studies have further addressed the evaluation of passive environmental conditioning strategies such as solar chimneys and natural ventilation indoor air quality assessment, and the adaptation of models to local climatic conditions, reflecting a transition toward more comprehensive, resilient, and sustainable design approaches. Moreover, the incorporation of artificial intelligence techniques and predictive control systems has opened new opportunities for operational automation and improved building energy efficiency. Within this context, the present systematic review synthesizes methodological advances, emerging applications, and current trends in the use of CFD and open-source platforms for indoor thermal comfort assessment in architecture, identifying their main contributions, technical limitations, and future research directions.

I. INTRODUCTION

Over the past decade, Computational Fluid Dynamics (CFD) has assumed a prominent role in the assessment of thermal comfort within controlled architectural environments due to its capacity to model, with a high level of detail, airflow patterns, heat transfer processes, and the spatial distribution of thermo-environmental variables [1].

These capabilities have enabled researchers and architectural design professionals to optimize indoor environmental conditions, contributing both to improved occupant quality of life and enhanced building energy efficiency [2]. A significant advancement in this field has been the incorporation of human thermophysiological models into CFD simulations, which has enriched the interpretation of thermal comfort by integrating the dynamic interaction between the human body and its immediate thermal surroundings. This approach has enabled more realistic estimations of users' physiological and perceptual responses to microclimatic variations [3]. In parallel, the expansion and consolidation of open-source platforms have democratized access to these technologies, extending their implementation beyond specialized laboratories and facilitating their adoption in smaller academic and professional contexts, as well as in studies addressing urban microclimates and outdoor thermal comfort [4]. Numerous studies have leveraged the potential of CFD to analyze comfort conditions across multiple building typologies and spatial scales. In office buildings, for instance, the evaluation of temperature distribution and CO_2 concentrations has provided key evidence for the design of more efficient ventilation systems. Similarly, passive strategies such as solar chimneys have been investigated to enhance natural ventilation and reduce energy consumption [5-7]. In the transportation sector, the integration of CFD with thermophysiological models has enabled the simulation of passenger thermal comfort by accounting for variables such as airflow, temperature, and vehicle occupancy [8]. Complementarily, recent systematic reviews have documented the evolution of thermal comfort models, highlighting the need to incorporate contextual factors including climatic conditions, environmental characteristics, and user profiles to achieve more accurate and adaptive predictions [9]. Urban growth has further stimulated interest in city-scale microclimate studies, where CFD has proven to be a robust tool for analyzing urban thermal behavior and supporting the development of sustainable planning strategies [10]. More recently, the integration of artificial intelligence techniques into thermal management systems has opened new opportunities for predictive control, operational automation, and the simultaneous optimization of comfort and energy consumption through the use of real-time data [11], [12]. Within this context, the present study conducts a systematic review aimed at synthesizing the most significant advances in the application of CFD and open-source tools for thermal comfort assessment in controlled architectural environments over the past decade, identifying methodological trends, technical contributions, current limitations, and future research directions.

II. METHODOLOGY

II.1 STUDY DESIGN

The present study corresponds to a systematic literature review aimed at identifying, analyzing, and synthesizing scientific evidence related to the application of Computational Fluid Dynamics (CFD) and open-source platforms for thermal comfort assessment in controlled architectural environments. The review was conducted in August 2025 and developed in strict accordance with the methodological guidelines established by the PRISMA statement [13], with the objective of ensuring transparency, reproducibility, and traceability throughout the processes of searching, screening, evaluation, and synthesis of the included studies [14]. The flow diagram describing the identification and screening stages of the articles is presented in Figure 1.

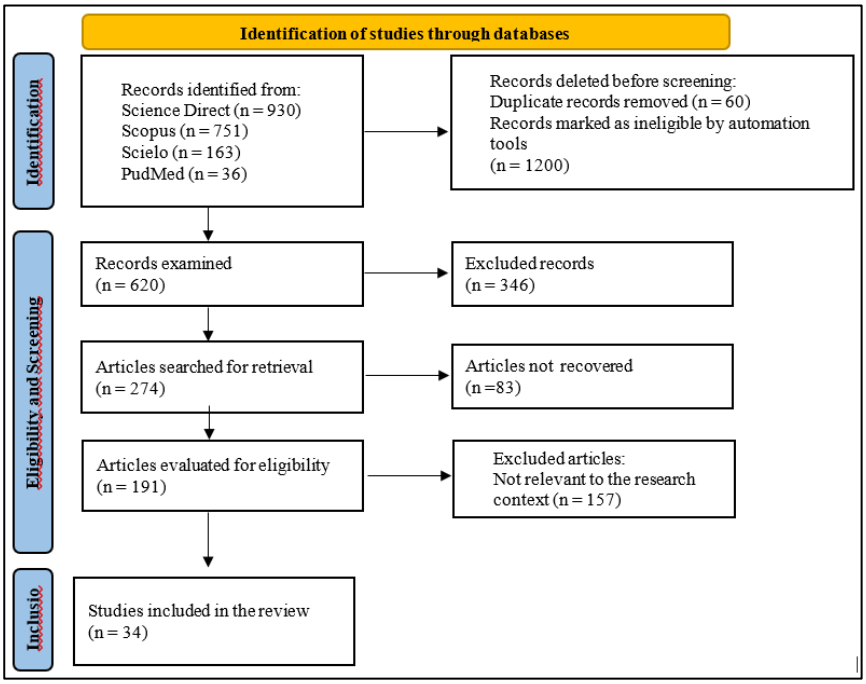

Figure 1: Development approach of the bibliometric review.
Source: Authors, (2026).

II.2 RESEARCH DESIGN

The bibliographic search strategy was carried out by consulting high-impact, multidisciplinary scientific databases, including ScienceDirect, Scopus, PubMed, and SciELO, in order to ensure the comprehensiveness and quality of the retrieved sources. To define the search terms and structure the research question, the PIO framework (Population–Intervention–Outcomes) was adopted, enabling a systematic delimitation of the study scope and facilitating the identification of relevant literature.

Population (P): indoor architectural spaces or controlled built environments in which thermal comfort and occupant well-being are assessed.

Intervention (I): application of Computational Fluid Dynamics (CFD) techniques and the use of open-source platforms or tools for the simulation, modeling, and analysis of thermal conditions and airflow behavior.

Outcomes (O): indicators of thermal comfort, energy performance, indoor environmental quality, and simulated thermo-environmental variables.

This methodological framework enabled a consistent process of data collection, critical selection, and comparative analysis of the studies, supporting the identification of trends, applications, and research gaps within the field (Table 1) [15].

Table 1: Application of the PIO framework for the definition of search equations.

PIO Category	Keywords
Population	"controlled environments", "indoor spaces", "thermal comfort zones", "buildings", "architectural environments"
Intervention	"computational fluid dynamics", "CFD", "thermal simulation", "open source tools", "energy modeling"
Outputs	"thermal comfort evaluation", "temperature analysis", "indoor climate modeling", "comfort improvement", "energy efficiency"

Source: Authors, (2026).

Prior to the selection process, inclusion criteria were established to define the thematic scope and ensure the relevance and quality of the collected evidence. Scientific articles published in English, Spanish, or Portuguese were considered, thereby broadening the geographical and linguistic coverage of the analysis. Studies focused on the application of Computational Fluid Dynamics (CFD) or open-source simulation tools for thermal comfort assessment in architectural spaces or built environments were also included. To ensure the timeliness and relevance of the findings, only studies published within the last ten years were considered. Complementarily, exclusion criteria were defined to discard works not directly related to the use of CFD or thermal comfort assessment, as well as studies addressing psychological, political, or other areas unrelated to architecture and thermo-environmental simulation. Duplicate publications, conference abstracts, opinion papers, systematic reviews, meta-analyses, and other documents that did not provide original evidence were also excluded to preserve methodological rigor and minimize bias in the synthesis of results.

II.3 STUDY POPULATION

The bibliographic search strategy was structured through the systematic combination of keywords and Boolean operators applied to the title, abstract, and keyword fields (TITLE-ABS-KEY), integrating concepts related to *thermal comfort*, *computational fluid dynamics (CFD)*, and *thermal simulation*. The search string used was: ((TITLE-ABS-KEY (“thermal comfort”) AND TITLE-ABS-KEY (“computational fluid dynamics” OR “CFD”) AND TITLE-ABS-KEY (“thermal simulation”))). This approach enabled the precise identification of studies focused on thermal comfort assessment through thermo-aerodynamic simulations in controlled architectural environments. Using this strategy, a total of 34 scientific articles were identified across high-impact specialized databases, including ScienceDirect, Scopus, PubMed, and SciELO. These records constituted the initial corpus of literature for the screening, eligibility assessment, and subsequent qualitative synthesis, providing the theoretical and methodological foundation for the present systematic review (Figure 1).

III. RESULTS AND DISCUSSION

III.1 ANALYSIS OF THE SCIENTIFIC STRUCTURE OF THE RESEARCH FIELD

The search strategy enabled the identification of a total of 1,880 potentially relevant documents. After applying the thematic preselection criteria, the bibliographic records were exported in CSV format and processed within the RStudio environment, using the Bibliometrix package to perform bibliometric analysis and construct keyword co-occurrence networks [16]. This approach facilitated a quantitative exploration of the conceptual structure and thematic relationships present in the literature. Figure 2 presents the keyword co-occurrence map, where node size reflects the frequency of term occurrence and the links represent the strength of semantic relationships among the analyzed studies [17], [18]. The central core of the network is dominated by *computational fluid dynamics*, which acts as the main articulating axis of the field and is closely connected to terms such as *thermal comfort*, *ventilation*, *energy*, and *indoor environment*. This high density of connections highlights the consolidation of CFD as a cross-cutting methodological tool for simulating thermo-aerodynamic behavior and assessing indoor environmental performance. Cluster analysis reveals at least two major groupings: a larger and denser blue cluster associated with direct building applications including thermal comfort, ventilation, indoor air quality, and energy efficiency which represents the predominant research line; and a more compact red cluster linked to methodological developments and the computational foundations of CFD, such as numerical modeling and advanced simulation approaches. The interaction between both clusters suggests a convergence between theoretical advancements and practical applications, indicating a trend toward integrated frameworks that combine computational accuracy with sustainable architectural design solutions. Additionally, the topological structure of the network shows a high degree of interconnectivity among clusters, with multiple cross-links connecting methodological terms to architectural applications, thereby indicating a mature research field undergoing disciplinary integration. The centrality of key nodes and the proximity among subtopics demonstrate that advances in numerical modeling are directly translated into improvements in thermal comfort and energy efficiency outcomes, while the absence of isolated groups suggests low thematic fragmentation. Overall, this configuration reflects an evolution from specialized studies toward interdisciplinary approaches that integrate computational simulation, environmental performance, and sustainable design.

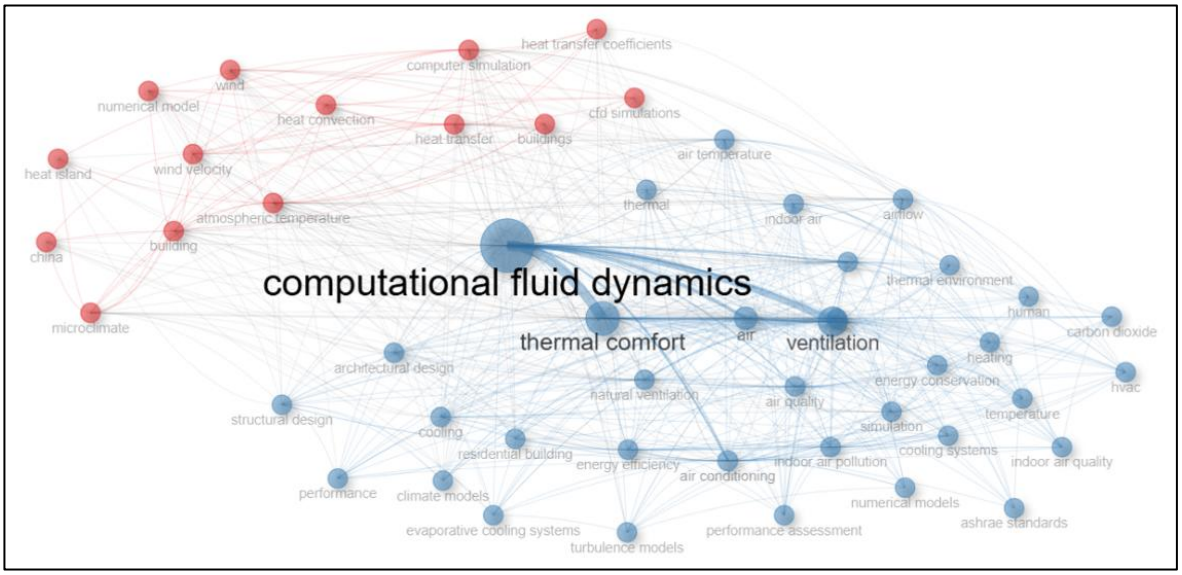

Figure 2: Keyword co-occurrence network.

III.2 COMPARATIVE SYNTHESIS OF THE INCLUDED STUDIES AND APPLICATIONS OF CFD IN THERMAL COMFORT

Table 2 summarizes the studies included in this review, organizing for each publication its specific application of Computational Fluid Dynamics (CFD), the main benefit or contribution, the evaluated parameters, and the reported conclusions. Collectively, the reviewed works demonstrate that CFD functions as a thermo-aerodynamic analysis platform capable of addressing both indoor environmental performance issues such as temperature distribution, air velocity, relative humidity, CO_2/contaminant concentrations, and comfort indices including PMV/PPD and urban microclimate and outdoor ventilation challenges, where specific indicators such as “air delay” have been proposed to characterize ventilation performance in complex urban geometries [19]. This evidence confirms a shift toward multivariable assessments, in which thermal comfort is interpreted alongside air quality and energy consumption indicators, reinforcing the relevance of CFD as a decision-support tool for architectural design. From a thematic perspective, the studies can be grouped into three predominant research lines. The first focuses on natural ventilation and passive building strategies such as solar chimneys, windcatchers, cross-ventilation, and evaporative cooling with the aim of enhancing indoor comfort while reducing reliance on mechanical systems [20-27]. The second integrates CFD with building energy simulation (BES/BPS) or envelopes and material analyses to quantify impacts on cooling/heating demand and overall efficiency [28-33]. The third research line addresses urban microclimate and outdoor thermal comfort, including urban geometry, ventilation within street canyons, and morphological solutions such as elevated buildings, emphasizing the importance of considering non-stationary conditions and realistic configurations [19], [34], [35]. From a methodological standpoint, a consistent pattern emerges: (i) widespread use of Reynolds-Averaged Navier–Stokes (RANS) models and, in specific cases, Large Eddy Simulation (LES) or unsteady simulations to capture transient phenomena; (ii) experimental validation through wind tunnel testing or in situ measurements in ventilation and pollutant dispersion studies, thereby strengthening the reliability of results [20], [36], [37] ; and (iii) increasing adoption of CFD–human thermoregulation model coupling or machine learning–based surrogate models aimed at reducing computational costs and enabling faster evaluations in design scenarios [38], [39]. Overall, the table illustrates the evolution of the field toward integrated approaches that combine numerical accuracy, empirical validation, and practical applicability to improve thermal comfort, indoor environmental quality, and energy efficiency.

Table 2: Main methodologies and findings of the compiled studies.

Study Title	CFD Implementation	Key Benefit	Variables Analyzed	Main Findings
CFD and wind-tunnel analysis of outdoor ventilation in a real compact heterogeneous urban area: Evaluation using "air delay [19].	It applies steady three-dimensional Reynolds-Averaged Navier–Stokes (RANS) models and Large Eddy Simulation (LES) to simulate outdoor urban ventilation conditions.	The study introduces a novel ventilation indicator, “air delay,” to improve the assessment of outdoor ventilation in complex urban environments. It further provides a systematic evaluation of steady RANS and LES approaches for urban ventilation analysis.	Distribution of air age and the “air delay” indicator.	The study offers a comprehensive assessment of RANS and LES approaches for evaluating ventilation conditions in a real urban setting and introduces a novel metric to support this evaluation.

CFD simulation of the wind flow under lift-up buildings using a porous approach [35].	CFD was employed to model the urban microclimate, with particular emphasis on simulating wind flow beneath elevated buildings.	The proposed method enables efficient wind-flow modeling in urban areas with elevated buildings while maintaining a balance between computational cost and accuracy, which is critical for urban thermal comfort assessment and heatwave mitigation.	Wind flow patterns, the impact of ground-floor geometry, and urban thermal comfort conditions.	The porous modeling approach in CFD has proven effective for simulating wind flow beneath elevated buildings, providing an optimal trade-off between predictive accuracy and computational efficiency.
Experimental study and CFD modelling of four-bed hospital ward with all-air wall induction unit for air-conditioning [36].	CFD modeling methods are proposed and experimentally validated to assess the ventilation and thermal performance of an all-air wall induction unit installed in a hospital ward.	The study examines a prototype induction unit designed for hospital wards, featuring a water-free system with low air supply velocity, and integrates experimental measurements with CFD simulations to enable a comprehensive performance evaluation.	Temperature distribution and CO_2 concentration (used as a proxy indicator for airborne contaminants).	The wall induction system maintains normalized contaminant concentrations near hospital beds by promoting displacement ventilation, with low-flow air supply from the lower section of the wall corner demonstrating effective performance.
Optimization of classroom window design using CFD and the Taguchi method [40].	CFD is employed to evaluate the influence of window position, width, height, and elevation from the floor on CO_2 concentration levels and draft risk within a classroom environment.	The study optimizes classroom window design to enhance indoor air quality and thermal comfort, employing the Taguchi method in combination with CFD to efficiently evaluate and optimize design parameters.	CO_2 concentration levels and the risk of draft discomfort.	The study proposes optimized window design parameters aimed at reducing CO_2 concentration levels and mitigating draft risk in classroom environments.
Assessing the impact of urban microclimate on building energy demand by coupling CFD and building performance simulation [28].	A validated CFD model is integrated with Building Performance Simulation (BPS) to quantify the impact of urban surface composition on urban microclimatic conditions and building energy demand.	The study quantifies the effects of urban design and vegetation on building energy consumption, with particular emphasis on cooling loads during heatwave events.	Building energy demand (cooling and heating loads) and urban microclimatic conditions (temperature).	Urban greening strategies significantly reduce cooling energy demand during heatwave conditions, while the composition of urban surfaces exerts a substantial influence on overall building energy requirements.
Cross-ventilation in a generic isolated building equipped with louvers: Wind-tunnel experiments and CFD simulations [20].	Steady three-dimensional Reynolds-Averaged Navier–Stokes (RANS) simulations are employed to model cross-ventilation in a building equipped with louvers, with CFD results validated against wind tunnel experiments.	The study examines the influence of louvered openings on natural ventilation performance, a critical factor for enhancing indoor air quality and achieving thermal comfort.	Airflow velocity distributions and air exchange efficiency.	The location of the openings significantly influences ventilation performance, and CFD simulations, when experimentally validated, are capable of accurately predicting cross-ventilation behavior.

Evaluation of supervised machine learning regression models for CFD-based surrogate modelling in indoor airflow field reconstruction [38].	CFD simulations are employed to generate training datasets for machine learning models aimed at predicting indoor airflow distribution, with machine learning acting as a surrogate modeling approach to reduce computational costs and accelerate predictions.	The study investigates the application of machine learning techniques to efficiently predict indoor airflow patterns, thereby reducing the computational burden associated with CFD simulations.	Airflow velocity fields and spatial distribution data.	Decision tree–based approaches and support vector regression models represent viable alternatives to neural networks for the prediction of indoor airflow patterns.
Pollutant cross-transmission in courtyard buildings: Wind tunnel experiments and computational fluid dynamics (CFD) evaluation [37].	CFD simulations are employed to assess the cross-transmission of indoor and outdoor contaminants in courtyard-type buildings, with results validated against wind tunnel experiments.	The study examines how courtyard design configurations may promote contaminant cross-transmission, highlighting a critical indoor air quality issue in residential building complexes.	Pollutant concentration levels and airflow distribution patterns.	Courtyard design configurations can significantly influence the transmission of contaminants between indoor and outdoor environments.
Sustainable ventilation strategies in buildings: CFD research [21].	CFD is employed to investigate natural ventilation strategies in buildings, particularly wind-driven ventilation and stack-effect mechanisms.	The study evaluates the potential of natural ventilation as a sustainable alternative to mechanical air conditioning, enhancing human thermal comfort and reducing overall energy consumption.	Natural ventilation, wind-induced ventilation, stack-effect ventilation, and human thermal comfort.	The article highlights the critical role of natural ventilation strategies in architectural design for enhancing human thermal comfort and promoting environmental sustainability.
Experimental and CFD Investigation on the Application for Aerogel Insulation in Buildings [33].	CFD simulations are employed to evaluate the thermal performance of aerogel insulation materials in building applications.	The study investigates the potential of aerogels as a high-performance insulation material to enhance energy efficiency in buildings.	Thermal insulation performance, aerogel materials, and heat transfer mechanisms.	The study provides valuable insights into the application of aerogel insulation systems to improve overall building energy performance.
Unsteady-state CFD simulations on the impacts of urban geometry on outdoor thermal comfort within idealized building arrays [34].	Unsteady-state CFD simulations are employed to assess the impact of urban geometry on outdoor thermal comfort conditions.	The study assesses the dynamic effects of building layout on airflow behavior and outdoor thermal comfort in urban environments, highlighting their critical importance for urban planning and sustainable design	Outdoor thermal comfort conditions, urban morphology, building configuration, and airflow distribution patterns.	The findings underscore the importance of accounting for unsteady wind conditions when evaluating urban thermal comfort.
CFD modeling of the building integrated with a novel design of a one-sided wind-catcher with water spray: Focus on thermal comfort [22].	CFD simulations are employed to model and evaluate a building integrated with an innovative single-sided wind catcher incorporating a water spray system.	The study evaluates the potential of this innovative design to enhance natural ventilation performance and improve indoor thermal comfort in buildings	Natural ventilation strategies, evaporative cooling, wind catcher design configurations, and thermal comfort performance.	The study evaluates the effectiveness of the proposed wind catcher design in enhancing indoor thermal conditions and overall thermal comfort.

Indoor Thermal Environment in Different Generations of Naturally Ventilated Public Residential Buildings in Singapore [41].	CFD is used to evaluate and compare indoor air velocities and the thermal environment in different generations of naturally ventilated public residential buildings.	The study provides information on the evolution of natural ventilation strategies in residential buildings and their impact on indoor thermal comfort.	Indoor air velocity, thermal environment, natural ventilation, residential buildings.	The research analyzes the effectiveness of natural ventilation in providing comfortable indoor environments under Singapore's climatic conditions.
CFD Evaluation of Thermal Conditioning in a House of Social Interest with a Solar Chimney Arrangement in Guanajuato, Mexico [23].	CFD is used to evaluate the thermal conditioning performance of a social housing unit that incorporates a solar chimney system.	The study evaluates the potential of solar chimneys to provide passive cooling and improve indoor thermal comfort in dwellings.	Thermal conditioning, solar chimney, natural ventilation.	The research provides information on the design and effectiveness of solar chimneys for thermal regulation in residential buildings.
Natural Ventilation in Low-Cost Housing: An Evaluation by CFD [24].	CFD is used to evaluate the performance of natural ventilation in low-cost housing.	The study investigates how natural ventilation can be optimized to improve indoor comfort in affordable housing solutions.	Natural ventilation, low-cost housing, indoor comfort.	The research provides information on the design of effective natural ventilation systems for residential buildings, particularly in the context of low-cost housing.
Energy simulation and CFD coupled analysis for the optimal operation of combined convection and radiant air conditioning considering dehumidification [29].	CFD is used to simulate thermal environments in residences, specifically those with combined radiant panels and air-conditioning systems, including the effects of dehumidification.	The combined use of radiant panels and air conditioning provides an optimal solution for thermal control in residences, balancing energy efficiency and comfort. The developed simulation tool may assist in product development and building material design.	Energy consumption, thermal comfort, relative humidity, and dehumidification effectiveness.	The study proposes a case where energy efficiency and comfort are achieved through the joint use of air conditioners and radiant panels, with a limited number of panels enabling balanced operation.
Influence of cross-ventilation cooling potential on thermal comfort in high-rise buildings in a hot and humid climate [25].	CFD simulation is used to investigate the effectiveness of natural ventilation in a high-rise building in India, together with building energy simulation. It determines wind-induced pressure distribution to evaluate indoor ventilation.	Cross-ventilation improves ventilative cooling efficiency, ensuring acceptable indoor thermal conditions even in adverse climates. It reduces cooling energy demand and electricity consumption.	Indoor thermal comfort, operative temperature, discomfort hours, natural ventilation cooling potential, night structural cooling.	Cross-ventilation significantly reduces discomfort hours and operating temperatures, providing a passive cooling solution for energy savings in high-rise buildings.
Improving Natural Ventilation Multi-Story Buildings within Hot and Dry Climates: A CFD Study of Windcatcher Performance [26].	CFD is used to study the performance of wind catchers in multi-story buildings to improve natural ventilation.	The study explores how wind catchers can enhance natural ventilation, which is crucial for energy and carbon conservation.	Wind catcher designs and their impact on natural ventilation performance in hot and dry climates.	The research contributes to strategies for improving natural ventilation through wind catchers, focusing on energy conservation.
Evaluation of passive cooling through natural ventilation strategies in historic residential buildings using CFD simulations [27].	CFD simulations are used to evaluate the efficiency of natural ventilation strategies in a historic residential structure.	Natural ventilation can save energy by reducing the need for mechanical systems in historic buildings, helping their preservation.	Efficiency of different natural ventilation approaches, thermal comfort, energy-saving potential.	The study demonstrates that natural ventilation strategies, especially cross-ventilation, can provide energy savings and maintain thermal comfort in historic buildings.

Thermal performance of an advanced smart fenestration systems for low-energy buildings [32].	CFD is used in a new model that combines ray-tracing and CFD to investigate the thermal and optical properties of smart fenestration systems.	The study explores a new adaptive fenestration system that can offer dynamic regulation of solar energy, improving building energy efficiency.	Solar transmittance, solar heat gain coefficient (SHGC), and dynamic thermal performance in summer and winter.	The proposed system can reduce solar transmittance and heat gain, resulting in better thermal performance with lower summer gains and lower winter heat losses.
Thermal Environment Analysis and Optimization for Large Space Buildings with Radiant Cooling Floors: A Case Study of Xianyang International Airport [42].	CFD is used to investigate the thermal environment of a large building and to analyze control strategies for radiant cooling floors combined with ventilation systems.	The study aims to find control strategies to achieve energy conservation and environmental improvement in large-space buildings.	Supply air temperature, cooling surface temperature, cooling capacity, and predicted mean vote (PMV).	The study determines optimal control variables to balance cooling capacity and thermal comfort.
Efficiency Assessment on Roof Geometry and Trombe Wall Shape for Improving Buildings' Heating Performance [43].	ANSYS-CFX software is used to simulate the thermal and fluid dynamic behavior of a Trombe wall system.	The study examines the impact of Trombe wall designs and roof types on building energy and operational efficiency.	Trombe wall designs, roof types, indoor climates, thermal comfort standards, energy efficiency.	The research provides information to optimize building design for improved heating performance under specific climatic conditions.
Impact of Building Envelope Materials on Energy Usage and Performance of Evaporative Cooling System in Residential Building [31].	ANSYS is used to simulate and analyze the performance of an evaporative cooling system in a residential building considering envelope materials and building orientation.	The research proposes an energy-efficient cooling system, showing that the proposed system combined with efficient envelope materials can achieve energy savings of about 35–43%.	Envelope components, building orientation, energy use, temperature reduction.	The study concludes that the proposed system reduces indoor temperature and that envelope characteristics significantly affect energy performance, leading to substantial energy savings.
Investigating Efficient Thermal Distribution in a House Room by combining Statistics with Computational Fluid Dynamics [44].	CFD analysis combined with statistical methods is used to determine cost-effective configurations for heating systems by investigating thermal distribution.	The study explores energy efficiency by identifying optimal heating configurations.	Theoretical temperatures at different indoor points.	The study uses numerical simulation to determine efficient thermal distribution.
Impact of Wind Pressure Coefficients on the Natural Ventilation Effectiveness of Buildings through Simulations [45].	Building energy simulation (BES) models are used to evaluate the effectiveness of natural ventilation using wind pressure coefficients as boundary conditions.	The research quantifies when outdoor airflow can be used as a cooling strategy to achieve indoor thermal comfort.	Airflows, cooling loads, heat rates.	Wind pressure coefficients are essential for evaluating airflow and ventilation effectiveness.
Significance of external wind conditions on the convective heat transfer coefficients (CHTC) and energy performance in multi-zone high-rise buildings [30].	A coupled BES–CFD method is employed to improve the accuracy of convective heat transfer coefficient calculations in high-rise buildings.	Improved predictions of CHTC and better understanding of wind influence on building energy performance.	Convective heat transfer coefficients and energy performance.	External wind conditions significantly affect CHTC and energy performance.

Improvement of the hygrothermal efficiency numerically using CFD modeling in a full-scale ventilated room with Moroccan climates [46].	CFD is used to examine moisture distribution and heat transfer in a ventilated room under winter conditions.	Ventilation configurations are analyzed to find the optimal configuration for thermal comfort.	Moisture and temperature distribution.	The study identifies the optimal ventilation configuration through comfort indicators.
The influence of zonal air supply on thermal comfort in a classroom located in a hot and humid environment: a case study from Jeddah—Saudi Arabia [47].	CFD simulations predict air temperature, velocity, and humidity distribution, evaluating zonal air supply designs in classrooms.	Explores zonal air supply strategies to improve comfort in hot and humid regions.	Air velocity, air temperature, relative humidity, globe temperature, PMV, PPD.	Parametric analysis identifies effective configurations.
Experimental Validation of the Potential of Cross-Ventilation Strategy as a Natural Cooling Technique Integrated in a Real Historic Building [48].	Simulations analyze temperature fluctuations under free-running mode in naturally ventilated historic buildings.	Validates cross-ventilation as a natural cooling technique.	Temperature fluctuations.	Provides insights into thermal performance through cross-ventilation.
Thermal Comfort Assessment for Simultaneous Operation of Cooling and an Energy Recovery Ventilator in a Residential Building During Summer [49].	The article evaluates thermal comfort.	The research explores simultaneous operation of cooling and energy recovery ventilators.	Thermal comfort.	The study provides an evaluation under specific conditions.
Assessment of Floor-Level Impact on Natural Ventilation and Indoor Thermal Environment in Hot–Humid Climates: A Case Study of a Mid-Rise Educational Building [50].	The study evaluates natural ventilation and the indoor thermal environment.	Investigates the impact of floor level on ventilation in educational buildings.	Natural ventilation and indoor thermal environment.	Provides an assessment of thermal conditions at different floor levels.
The Effect of the Isolation Hotel Facade Attachment on the Inter-Flat Transmission of Aerosols [51].	The study investigates aerosol transmission.	Examines façade attachments and their effect on aerosol transmission between apartments.	Aerosol transmission.	Presents findings relevant to infection prevention.
Integrating CFD and thermoregulation models: A novel framework for thermal comfort analysis of non-uniform indoor environments [39]	CFD is integrated with thermoregulation models to analyze thermal comfort in non-uniform indoor environments.	Enables a more detailed analysis of occupant-centered radiant cooling strategies.	Operative temperature, heat balance, physiological responses.	Introduces a new numerical framework for evaluating thermoregulation and comfort.
Sensitivity analysis of influence factors on multi-zone indoor airflow CFD simulation [52].	CFD simulation is used for sensitivity analysis of factors influencing multi-zone indoor airflow.	Improves understanding of how different factors affect airflow simulation results.	Factors influencing multi-zone airflow.	Provides a sensitivity analysis of influencing factors in CFD airflow simulations.

III.3 TRENDS IN THE USE OF CFD IN ARCHITECTURAL SPACES

Computational Fluid Dynamics (CFD) has become, over the past decade, a key methodological tool for analyzing the environmental and energy performance of the built environment, expanding its scope beyond strictly engineering applications to address challenges specific to architecture and urban planning. Traditionally employed in the field of computational wind engineering, CFD has demonstrated a strong capability to model complex phenomena such as airflow behavior, heat transfer, and contaminant dispersion, which has encouraged its adoption in studies related to pedestrian wind comfort, urban ventilation, air quality, and outdoor thermal conditions [19]. This versatility has enabled more accurate assessments of the interaction between urban morphology, local microclimates, and occupants' thermal well-being, thereby establishing CFD as a relevant technical support tool for sustainable urban planning and design.

At the building scale, the synthesized evidence reveals a clear trend toward applications aimed at optimizing indoor thermal comfort through passive and low-energy strategies, such as natural ventilation, cross-ventilation, solar chimneys, wind catchers, and evaporative cooling systems. In these studies, CFD is employed to analyze variables including air temperature, airflow velocities, CO_2 concentration, relative humidity, and comfort indices (PMV/PPD), enabling the evaluation of design configurations and the validation of architectural solutions with greater quantitative rigor. Furthermore, increasing integration with human thermo physiological models and experimental validation techniques has been observed, strengthening the reliability of predictions and aligning simulations more closely with real occupancy conditions [41]. Complementarily, a methodological evolution toward hybrid approaches that combine CFD with building energy performance simulation tools and data-driven predictive models has been identified. This coupling allows for the simultaneous evaluation of local thermo-aerodynamic behavior and its global impact on energy demand, enabling the quantification of how urban microclimate, building envelope characteristics, and conditioning systems influence energy consumption and overall performance [32]. Collectively, these trends indicate a shift from isolated modeling applications toward integrated analytical frameworks, in which CFD serves as a bridge between architectural design, human comfort, and energy sustainability.

III.4 CHALLENGES IN THE APPLICATION OF CFD

Despite its growing adoption in the analysis of thermal comfort and the environmental performance of the built environment, the application of Computational Fluid Dynamics (CFD) faces several technical and methodological limitations that affect the accuracy and feasibility of its results. One of the primary challenges lies in the faithful representation of real urban environments, which are characterized by highly complex geometries, morphological heterogeneity, and multiple spatial scales. Due to these difficulties, many studies rely on simplified or idealized configurations, which may reduce the ability of simulations to capture local phenomena such as ventilation patterns, recirculation zones, or heat accumulation typical of real urban contexts. From a computational perspective, CFD simulations particularly transient or high-fidelity approaches such as Large Eddy Simulation (LES) require considerable computational time and hardware resources, limiting their applicability in parametric studies or iterative design processes. Consequently, many studies adopt steady-state models based on Reynolds-Averaged Navier–Stokes (RANS), which offer a reasonable trade-off between accuracy and computational cost, albeit with reduced capability to resolve complex turbulent structures [40]. In addition, simulation results are highly sensitive to technical decisions such as mesh resolution, turbulence model selection, boundary condition definition, and the quality of climatic and geometric input data, factors that may introduce significant uncertainty if not properly controlled. In indoor applications, further challenges persist regarding the modeling of occupants' dynamic behavior, variable furniture layouts, and real space-use patterns, all of which directly influence airflow distribution, effective ventilation, and thermal perception. Finally, CFD model validation remains a critical requirement to ensure the reliability of predictions; however, acquiring high-resolution experimental data whether through in situ measurements or wind tunnel testing is often costly and complex, particularly in dense urban environments or specific configurations, thereby limiting the empirical verification of numerical models [38]. Overall, these challenges highlight the need to advance toward hybrid methodologies, robust validation frameworks, and more computationally efficient tools that can broaden the applicability of CFD in architectural practice.

III.5 OPPORTUNITIES FOR THE USE OF CFD IN ARCHITECTURAL SPACES

Computational Fluid Dynamics (CFD) offers a wide range of opportunities to strengthen environmental analysis and the sustainable design of the built environment, particularly in the evaluation of urban ventilation strategies aimed at improving air quality and mitigating pollutant accumulation in densely built areas. Its ability to simulate complex flow patterns, air dispersion, and renewal processes enables the identification of morphological configurations and design solutions that enhance pedestrian comfort and reduce exposure to atmospheric contaminants, thereby contributing to resilient and healthy urban planning [20]. At the building scale, CFD enables the optimization of thermal performance through the design and validation of passive strategies such as natural ventilation, cross-ventilation, and convective cooling, reducing reliance on mechanical conditioning systems and lowering the energy and carbon footprint of buildings. Moreover, the detailed analysis of variables such as air temperature, relative humidity, airflow velocities, and spatial heat distribution allows for the estimation of thermal comfort indices with higher spatial resolution, supporting evidence-based design decisions adapted to local climatic conditions [32]. Complementarily, the integration of CFD with building performance simulation (BPS) tools significantly expands its analytical potential by enabling the coupled evaluation of interactions among urban microclimate, architectural envelope characteristics, and overall energy demand. This hybrid approach facilitates the comparison of design scenarios and the development of optimized solutions that balance thermal comfort, operational efficiency, and environmental sustainability [28]. Furthermore, the flexibility of CFD modeling allows the analysis of specific health and safety contexts, such as contaminant or aerosol transmission in highly occupied spaces, providing relevant technical insights for the design of safer and more resilient buildings [24]. Collectively, these applications highlight the potential of CFD as a strategic tool for informed decision-making in architecture and urban planning.

IV. CONCLUSIONS

The evidence gathered in this systematic review confirms that Computational Fluid Dynamics (CFD) has become, over the past decade, a central tool for assessing thermal comfort and environmental performance in architectural and urban spaces. The bibliometric analysis, comparative synthesis of studies, and characterization of applications reveal a sustained expansion in its use, both in passive ventilation and thermal conditioning strategies and in urban microclimate modeling and building energy optimization. Furthermore, the increasing adoption of open-source platforms, the coupling with building energy simulations (BPS/BES), and the integration with thermo physiological models and machine learning techniques reflect a transition toward more accessible, integrated, and data-driven decision-making approaches. Nevertheless, the review also identifies persistent challenges that affect the reliability and scalability of these applications, including the realistic geometric representation of complex environments, the high computational requirements of transient high-fidelity models, the sensitivity of results to numerical parameters, and the need for rigorous experimental validation.

These limitations underscore the importance of advancing toward hybrid methodologies, robust verification frameworks, and surrogate models capable of balancing predictive accuracy with operational efficiency. Overall, the findings indicate that CFD holds significant strategic potential during the early stages of architectural design and urban planning, enabling the evaluation of scenarios, comparison of alternatives, and anticipation of thermal and energy impacts prior to physical implementation. Its consolidation as a decision-support tool for environmentally conscious design not only enhances thermal comfort and indoor air quality but also contributes to reducing energy consumption and the carbon footprint of the built environment. Future research should further integrate empirical data, artificial intelligence, and open-source workflows in order to broaden the applicability of CFD and strengthen its role as a bridge between computational modeling, human well-being, and sustainability.

ABSTRACT

Wind energy is a renewable energy source that offers both environmental and socio-economic benefits. However, its implementation in low-wind areas remains challenging. The Archimedes Screw Wind Turbine (ASWT) is a horizontal-axis wind turbine that forms a three-dimensional conical structure shaped like an elongated spiral, resembling a seashell. This study aims to provide a comprehensive overview of ASWT research progress, including its advantages, limitations, and development opportunities. The method used is a narrative review by gathering and comparing results from previous studies on the design and performance of ASWT. The findings indicate that the Archimedean spiral profile results in better aerodynamic performance compared to the logarithmic spiral profile, with a power coefficient (C_P) value reaching 0.2668 at an opening angle of 60°. The optimal aspect ratio (AR) is found in the range of 1.0-1.1 to balance aerodynamic efficiency and structural strength. The use of NACA type airfoil profiles improves performance compared to S and FX-type airfoils and shows effectiveness at low wind speeds with minimal noise levels. Furthermore, the configuration of angles ($\alpha_1 = 30°$, $\alpha_2 = 45°$, $\alpha_3 = 60°$) is identified as the most effective arrangement, yielding a maximum power coefficient (C_{pmax}) of 0.234 at a tip speed ratio (TSR) of 1.5. Additionally, the addition of a brimmed shroud is proven to increase the C_P value by approximately 3.6 times compared to turbines without a shroud. Overall, ASWT holds significant potential for urban applications, but further research is still needed to encourage the adoption of this technology in the renewable energy transition.

I. INTRODUCTION

Wind power is widely recognized as one of the most promising technologies in the transition toward low-carbon energy systems [1], [2]. Wind energy represents one of the cleanest energy sources and has currently become the second-largest contributor among renewable energy resources [3]. Beyond its role in energy generation, wind power offers substantial social, public health, and environmental benefits while significantly reducing dependence on fossil fuels [4]. Based on the orientation of the rotational axis, wind turbines can be broadly classified into two categories that its Horizontal Axis Wind Turbines (HAWT), which employ rotors with axes aligned parallel to the wind direction, and Vertical Axis Wind Turbines (VAWT), whose rotors rotate about an axis perpendicular to the incoming wind flow [5]. VAWTs offer several advantages, including enhanced resistance to strong wind conditions due to their inherent stalling mechanism, which improves operational safety during high wind events [6]. In addition, they tend to operate more quietly and feature designs that eliminate the need for yaw control systems. However, these advantages are offset by limitations in self-starting capability [7]. The vertical shaft configuration of VAWTs allows the transmission system and generator to be positioned at ground level, facilitating maintenance. Nevertheless, this configuration often requires complex blade pitch control mechanisms. In contrast, HAWTs represent the most commercially successful turbine type to date and predominantly rely on aerodynamic lift to achieve high power conversion efficiency.

Drag-based turbines, such as certain VAWT configurations, generally exhibit lower efficiency compared to lift-based HAWTs. Moreover, HAWTs are typically designed to operate optimally under relatively high wind speeds, usually exceeding 6 m/s, to attain maximum efficiency [8], [9], [10], [11], [12]. Despite their technological maturity, the implementation of wind turbine systems remains challenging in regions characterized by highly fluctuating wind patterns and limited installation space, particularly in urban environments [13]. One promising innovative solution is the Archimedes Screw Wind Turbine (ASWT), a horizontal-axis turbine featuring a three-dimensional conical structure with an elongated spiral geometry resembling a seashell [14], [15]. This unique design enables the ASWT to operate effectively at low wind speeds, making it particularly suitable for urban and built-environment applications [16]. Although the ASWT demonstrates considerable potential, its practical implementation and technological development remain relatively limited. Research on ASWTs is still fragmented, and comprehensive literature reviews consolidating existing findings are scarce. A systematic review is therefore required to map the evolution of ASWT design concepts, performance optimization strategies, and key technical challenges reported across previous studies. This review aims to provide a comprehensive understanding of the current state of ASWT research and technology, highlighting its advantages, limitations, and future development prospects. The outcomes of this study are expected to serve as a valuable scientific reference for researchers, academics, and practitioners, supporting the advancement of more efficient and practical ASWT applications in the future.

II. THEORETICAL REFERENCE

This study adopts a Narrative Review approach to examine the development of research and technological advancements related to the Archimedes Screw Wind Turbine (ASWT). The review process was conducted in a systematic manner, encompassing several key stages, including the definition of eligibility criteria, identification of data sources, study selection, data extraction, and data synthesis. Through this approach, the review aims to provide a comprehensive overview that captures the evolution and current state of ASWT research.

II.1 ELIGIBILITY CRITERIA

Studies focusing on the development, performance, and technological innovation of the Archimedes Screw Wind Turbine (ASWT) constitute the primary scope of this review. Research addressing technical aspects of other wind turbine types, such as Horizontal Axis Wind Turbines (HAWT) and Vertical Axis Wind Turbines (VAWT), was included as supporting literature to enrich and contextualize the discussion. Only publications that meet established academic standards were considered. Consequently, non-scholarly articles, duplicate publications, and studies lacking robust methodological foundations were excluded from the analysis.

II.2 DATA SOURCES

The literature reviewed in this study was obtained through systematic searches of reputable and indexed academic databases. The sources include international peer-reviewed journal articles, conference proceedings, and other scholarly works that satisfy the defined academic eligibility criteria.

II.3 DATA SYNTHESIS

The analysis was carried out by categorizing the selected studies into key thematic areas, such as turbine design, performance characteristics, and structural or aerodynamic modifications. Findings from different studies were subsequently compared to identify common trends, methodological consistency, and notable discrepancies. The results of this comparison are presented in summary tables to facilitate clarity and readability. The overall synthesis is articulated through a structured narrative, supported by tables, figures, and illustrative materials, thereby providing a systematic and comprehensive understanding of the development of ASWT technology.

III. DISCUSSION

III.1 INTRODUCTION TO THE ARCHIMEDES SCREW WIND TURBINE

The Archimedes Screw Wind Turbine (ASWT) is a wind turbine featuring spiral-shaped blades based on Archimedean geometric principles, a concept originally introduced by the ancient Greek mathematician Archimedes [17], [18]. The overall configuration of the ASWT is illustrated in Figure 1. In its common design, the turbine consists of three blades symmetrically arranged at 120° intervals. These blades form a three-dimensional conical structure with an elongated spiral geometry resembling the shell of a marine mollusk. Owing to this spiral configuration, the ASWT is inherently capable of aligning itself with the incoming wind direction without the need for any yaw control mechanism [15], [19], [20].

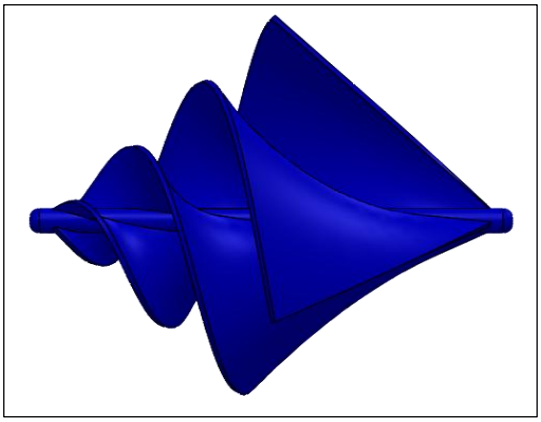

Figure 1: ASWT Turbine.
Source: Authors, (2026).

In addition to its distinctive geometry, the ASWT exhibits several notable advantages. The turbine is able to harness a combination of aerodynamic lift and drag forces to generate power, allowing it to operate effectively across a range of flow conditions. Another key advantage is its capability to perform efficiently under low wind speed conditions, with a minimum cut-in speed of approximately 2.5 m/s [16], [21]. Given the characteristics and potential outlined above, a thorough understanding of ASWT research development methodologies becomes essential for tracing the progression of knowledge related to its aerodynamic behavior and technological evolution. Such understanding is critical for the optimization of ASWT design and for enhancing its practical application in real-world wind energy systems.

III.2 RESEARCH DEVELOPMENT METHODS FOR ASWT

Research on the development of Archimedes Screw Wind Turbines (ASWT) generally follows a systematic workflow that begins with geometric modeling, proceeds through numerical simulation and experimental validation, and concludes with result documentation and analysis. The initial stage typically involves the construction of a three-dimensional reference model using computer-aided design software such as SolidWorks, OpenSCAD, or CATIA. Following the modeling phase, the research advances to analytical stages involving numerical simulation and experimental investigation. The methodological scope varies across studies. Some investigations adopt a single-track approach, relying solely on numerical simulations or exclusively on experimental testing. Numerical simulations commonly employ Computational Fluid Dynamics (CFD) techniques to virtually predict flow behavior and aerodynamic performance. These analyses are typically conducted using specialized software packages such as ANSYS Fluent, ANSYS CFX, or STAR-CCM+. In contrast, experimental investigations aim to obtain direct physical measurements. Common experimental methods include performance testing in wind tunnel facilities, flow visualization and quantification using Particle Image Velocimetry (PIV), and final validation through field testing under real operating conditions. Upon completion of these analyses, the resulting data are expected to address the predefined research objectives [22-25]. In this context, the present review paper is structured to provide a comprehensive understanding of research trends and technological developments related to ASWTs. The discussion encompasses aerodynamic aspects, including performance analysis in terms of torque and power output, force generation mechanisms, the influence of angle of attack, and the interpretation of flow simulation results. Furthermore, technological development aspects are examined, covering blade geometry optimization, evaluation of performance augmentation strategies, and comparative performance assessments against other wind turbine designs. Through this review, potential optimization opportunities are identified, and existing research gaps are highlighted, thereby offering valuable directions for future ASWT research.

III.3 AERODYNAMICS OF THE ASWT

III.3.1 Velocity Triangle and Aerodynamic Forces Acting on the ASWT

To determine the torque and power generated by the ASWT, the angular momentum equation is applied to a predefined control volume, as adopted in previous studies [14] and expressed in Equation (1) [14] :

$$\frac{\partial}{\partial t}\int_{CV}(r \times V)\rho d\forall + \int_{CS}(r \times V)\rho V.\hat{n}dA = \sum(r \times F) \quad (1)$$

Equation (1) represents the angular momentum balance for a control volume. Under the assumption of steady-state conditions, the first term in Equation (1) becomes zero because it is time-independent. Consequently, Equation (1) can be simplified to Equation (2) [14] :

$$\int_{CV}(r \times V)\rho\, dV.\hat{n}dA = \sum(r \times F) \quad (2)$$

The continuity equation for a fixed control volume is expressed as shown in Equation (3) [14] :

$$\frac{\partial}{\partial t}\int_{CV}\rho\, dV + \int_{CV}\rho W\,.\hat{n}dA = 0 \quad (3)$$

Assuming steady-state flow and constant density, the first term in Equation (3) vanishes. The second term represents the total mass flow rate through the control volume. Accordingly, Equation (3) can be simplified to Equation (4) [14] :

$$-\dot{m}_{in} + \dot{m}_{out} = 0 \tag{4}$$

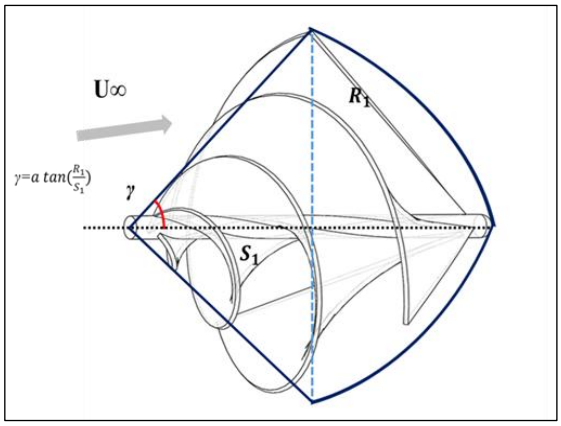

Figure 2: Shape parameter ASWT.
Source: [14].

In developing the governing equations, several geometric parameters must first be defined, namely γ, R_1, R_2, and S_1, as illustrated in Figure 2. Here, γ denotes the angle between the rotation axis and the blade tip. R_1represents the vertical distance from the outer blade tip to the rotational axis, while R_2corresponds to the vertical distance from the inner blade tip to the rotational axis. Meanwhile, $S_1$is defined as the horizontal distance between the leading blade tip and the root of the spiral blade. Based on these geometric parameters, the inlet and outlet mass flow rates can be expressed using Equations (5) and (6), respectively [14] :

$$\dot{m}_{in} = \rho U_{\infty} \sin\gamma \times \pi \left(\frac{R_1+R_2}{2}\right) S_1 \tag{5}$$

$$\dot{m}_{out} = 3\rho A_{out} W_{\theta} \tag{6}$$

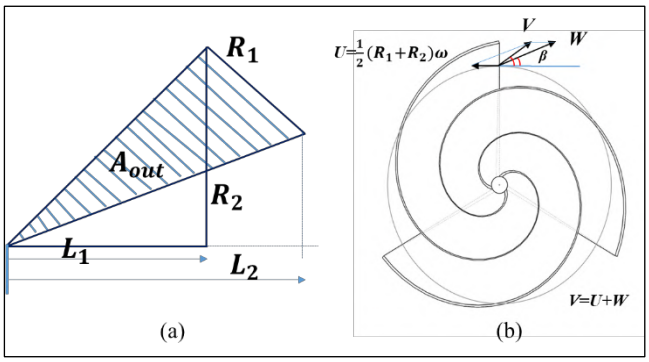

Figure 3: Definition of Aout, U, V and W
Source: [14].

Here, W_{θ} denotes the tangential component of the relative velocity. The velocity triangle analysis for the ASWT begins with estimating the outlet area and its geometric relationships, as illustrated in Figure 3(a). In this figure, $L_1$is defined as the distance from the center of the rear face to point x, which is perpendicular to the outer blade tip, while L_2 represents the distance from the same center to point x, perpendicular to the inner blade tip. Based on this configuration, the total outlet area (A_{out}) is obtained by summing its two constituent areas, $A_1$and A_2, as expressed in Equations (7) and (8) [14] :

$$A_{out} = A_1 + A_2 \tag{7}$$

$$A_{out} = \frac{1}{2}R_1L_1 - \frac{1}{2}R_2L_1 + \frac{1}{2}(R_1 - R_2)(L_2 - L_1) = \frac{1}{2}(R_1 - R_2)L_2 \tag{8}$$

The velocity triangle at the blade outlet is illustrated in Figure 3(b), where Wdenotes the relative velocity, V the absolute velocity, and U the tangential velocity. In this context, β is defined as the angle between $W$and U. The outlet mass flow rate ($\dot{m}_{out}$) can therefore be written as Equation (9) [14] :

$$\dot{m}_{out} = 3\rho A_{out} W_{\theta} = 3\rho.\frac{1}{2}(R_1 - R_2)L_2 \times W \cos\beta = \frac{3}{2}\rho(R_1 - R_2)L_2 \times W\cos\beta \tag{9}$$

Since $\dot{m}_{in} = \dot{m}_{out}$, the following relationship is obtained:

$$\rho U_\infty \sin\gamma \times \pi\left(\frac{R_1+R_2}{2}\right) S_1 = \frac{3}{2}\rho(R_1+R_2)L_2 \times W\cos\beta \tag{10}$$

$$\therefore W = \frac{\pi U_\infty \sin\gamma(R_1+R_2)S_1}{3(R_1+R_2)L_2\times\cos\beta} \tag{11}$$

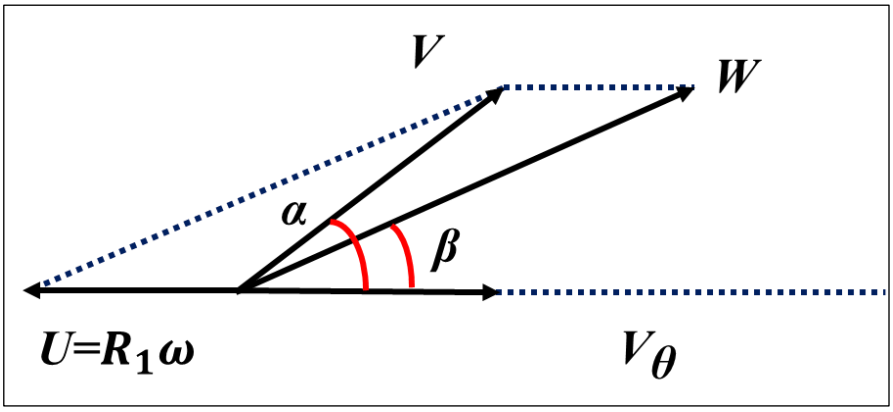

Figure 4: Triangle velocity at outlet boundary blade.
Source: [14].

Figure 4 illustrates the velocity triangle composed of U, V, and W, where α is defined as the angle between the absolute velocity $V$and its tangential component V_θ. The absolute velocity Vcan be expressed as follows [14] :

$$V^2 = W^2 + U^2 - 2WU\cos\beta, V_\theta = V\cos\alpha \tag{12}$$

Based on Equation (12), the angle α can be defined using Equation (13) [14] :

$$V\sin\alpha = W\sin\beta \;\rightarrow\; \sin\alpha = \frac{W}{V}\sin\beta \tag{13}$$

$$\therefore \alpha = \sin^{-1}\left(\frac{W}{V}\sin\beta\right) \tag{14}$$

The moment exerted by the blade on the fluid is equal in magnitude and opposite in direction to the shaft torque. This relationship is expressed in Equation (15) [14] :

$$T_{shaft} = \int_{CS}(r\times V)\,\rho V.\hat{n}dA = \int_{CS}(rV\cos\alpha)\,\rho(V\cos\alpha)\,dA = 3\rho V^2\cos^2\alpha\int_0^L rdA \tag{15}$$

Finally, the torque generated by the blade can be expressed as Equation (16):

$$\therefore T_{shaft} = 3\rho V_\theta^2 \times \frac{(R_2-R_1)}{6L_1(L_2-L_1)} \times [R_2(2L_2^3 + L_1^3 + L_1L_2^3) - L_1R_1(L_1+L_2)^2] \tag{16}$$

Power is defined as the product of torque and angular velocity and is expressed as follows [14] :

$$Power = T_{shaft}\omega \tag{17}$$

After the power expression is defined in Equation (18), as illustrated in Figure 5, the analysis of wind–blade interaction requires two complementary perspectives: the plan view (top view) and the elevation view (side view). In the plan view analysis, the calculation is based on changes in angular momentum resulting from the interaction between the incoming wind and the ASWT blades. The aerodynamic lift force (F_L) and drag force (F_D) generated on the blade are decomposed into components parallel and perpendicular to the wind direction, yielding four force components: F_{LX}, F_{LY}, F_{DX}, and F_{DY}. The resultant aerodynamic forces acting on the ASWT blade can therefore be expressed as:

$$F_X = F_{LX} + F_{DX} \tag{18}$$

$$F_Y = F_{LY} + F_{DY} \tag{19}$$

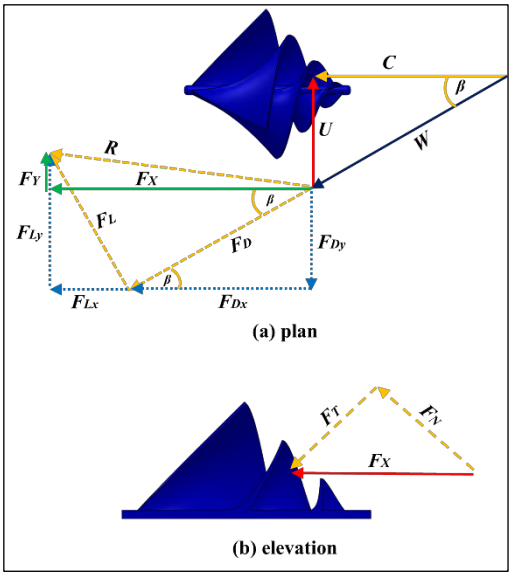

Figure 5: Aerodynamic Forces Affecting the Spiral Blade on an ASWT.
Source: [27].

The force component perpendicular to the wind direction (F_Y) is responsible for driving the rotational motion of the ASWT. Meanwhile, as observed in the elevation view, the force component F_X is further resolved into two components: the tangential force (F_T), which directly contributes to power generation, and the normal force (F_N), which acts as a compressive or tensile load on the ASWT blades. Consequently, the power generated by the ASWT arises from the combined effect of the $F_Y$component in the plan view, which produces rotational torque, and the tangential force F_T in the elevation view, which contributes directly to energy conversion. This aerodynamic interaction pattern occurs repeatedly as the wind traverses successive 120° angular positions corresponding to each of the three spiral blades of the ASWT [25-28]**.**

III.3.2 Angle of Attack in ASWT

The angle of attack is defined as the angle between the direction of the relative airflow and the chord line of the turbine blade profile. This parameter plays a critical role in determining both the aerodynamic forces acting on the blade and the resulting power output of the turbine [29-36]. As illustrated in Figure 6, measurements are conducted within an axisymmetric observation plane that distinguishes between the windward (front) side and the sheltered (lee) side of the blade, enabling a comprehensive assessment of the flow dynamics around the rotating blade [37], [38].

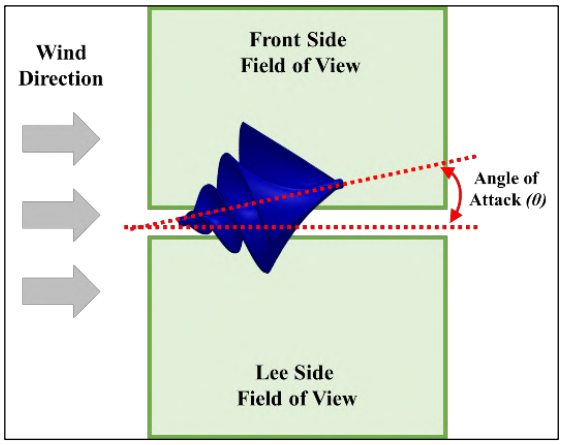

Figure 6: Angle of attack on ASWT.
Source: [37].

In the study conducted by [37], although various factors such as Reynolds number and free-stream turbulence can influence the near-wake structure of turbine blades, the analysis specifically focused on the effect of the angle of attack. To investigate the influence of wind direction on the flow field, comparisons were made between the mean velocity field and the instantaneous velocity field at different blade phase angles. The results indicate that the wake velocity decreases as the angle of attack increases. Mean velocity measurements reveal that the low-velocity region downstream of the blade expands with increasing angle of attack. Within the near-wake region behind the blade, no flow separation was observed, as the incoming airflow continues to pass through the rotating blade system. Regions of high shear were found to form around the blade tip vortices, and their size increases as the angle of attack becomes larger. The tip vortices generated by each blade are clearly observable at blade phase angles ranging from 0° to 120°. At lower angles of attack, the spacing between these vortices remains relatively uniform; however, as the angle of attack reaches approximately 15°, the vortex spacing becomes increasingly irregular.

III.3.3 Velocity and Pressure Contours in ASWT

Velocity contours are widely employed in the literature to visualize the flow velocity characteristics around wind turbine blades [39-43]. To investigate the aerodynamic behavior of the ASWT, Figure 7 presents the mean velocity fields obtained from airflow simulations conducted at three different wind speeds. In wind turbine systems, a turbulent wake state may occur due to variations in wind speed or direction, or as a result of changes in blade orientation (pitching). Such flow behavior is more clearly observed at lower wind speeds, as shown in Figure 7. The highest velocities are observed near the outermost region of the rotor within the simulation domain. Between successive spiral blade sectors, recirculation zones with relatively low velocities are formed. Furthermore, due to the spiral geometry, the flow velocity gradually increases from the leading edge of the blade toward the inner side of each blade level.

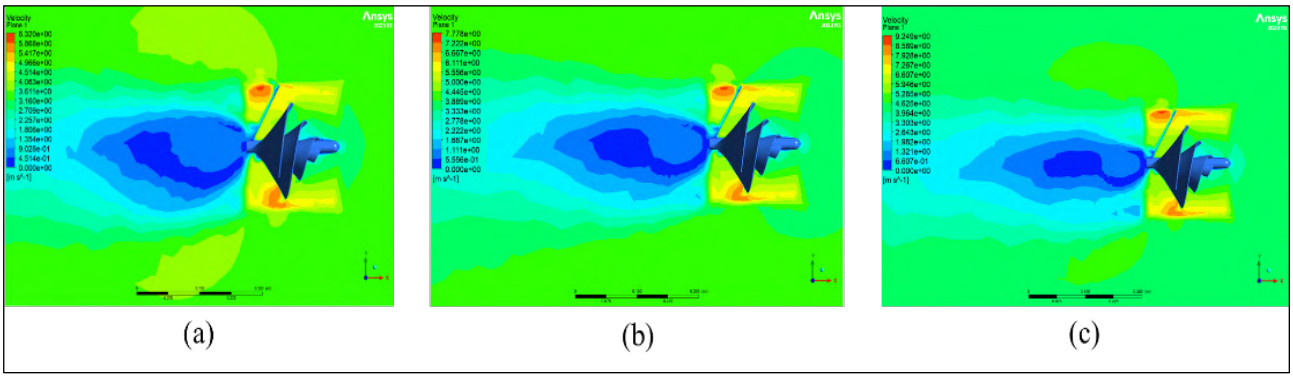

Figure 7: Ensemble-averaged velocity field and pressure distribution under steady-state conditions: (a) 3.5 m/s at 300 rpm, (b) 4.0 m/s at 400 rpm, and (c) 4.5 m/s at 500 rpm.
Source: [46].

The visualization also indicates that the airflow is partially obstructed by the conical hub and the rotor, leading to the formation of circumferential acceleration zones downstream of the rotor, which in turn reduce the pressure near the walls of the rotating domain. Meanwhile, the wake region is clearly identified behind the rotor hub, characterized by lower flow velocities. From a geometric perspective, the blade twist angle is larger near the root than at the tip. Visually, the longer velocity vectors near the blade tip indicate higher flow velocities compared to those near the blade root. In addition, all three velocity contour plots demonstrate that the flow velocity in the central region is significantly lower than that near the blade periphery. This observation suggests that stronger flow near the blade tip is highly advantageous, as it exerts force on the blade at a larger moment arm, thereby enhancing torque generation [44-46]. The streamline velocity distribution shown in Figure 8 further confirms that the lowest flow velocities occur in the central region and near the rotational axis. In contrast, the highest velocities are observed near the blade tips, where the tip speed is substantially greater than that in the mid-span region. Wind flow impinging on the blade tips generates torque, causing the turbine blades to rotate in the direction opposite to the incoming wind flow [47], [48].

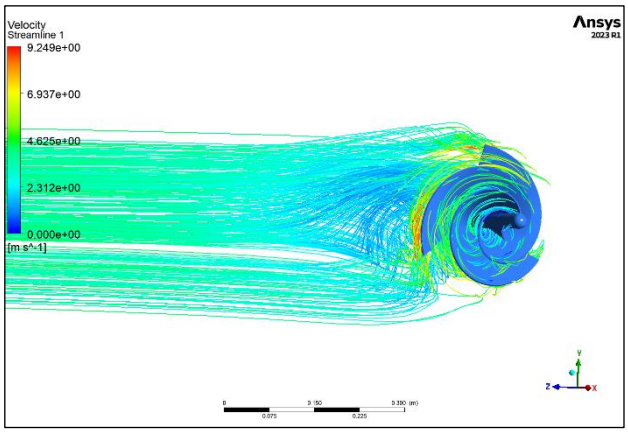

Figure 8: Streamline velocity.
Source: [47].

Pressure contours provide a graphical representation of the pressure distribution around turbine blades as obtained from fluid flow simulations [49-53]. As shown in Figure 9, the pressure contours on the front and rear sides of the turbine blades indicate that the pressure on the blade's pressure side is higher than that on the suction side. The locations of maximum and minimum pressure are predominantly found near the blade edges. The pressure difference between the pressure side and the suction side is the primary driving mechanism that induces blade rotation [47], [54], [55].

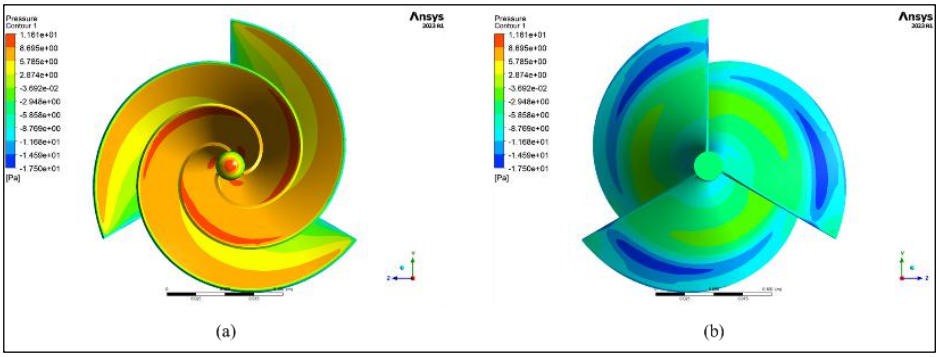

Figure 9: Pressure contours on the blade surfaces: (a) pressure side and (b) suction side.
Source: [47].

As illustrated in Figure 10, an increase in flow velocity leads to a corresponding increase in this pressure difference. The highest pressure difference occurs near the blade tip, while the pressure variation in the mid-span region remains relatively small. This finding indicates that the majority of the extractable energy originates from the region near the blade tip, which is consistent with the operating principles of most horizontal-axis wind turbines (HAWTs) [47], [56], [57].

III.4 DEVELOPMENT OF ASWT TECHNOLOGY

III.4.1 Effect of Spiral Geometry on ASWT

The Spiral Wind Turbine (SWT) is a type of wind turbine that typically consists of three blades helically wrapped around a single main shaft and symmetrically arranged with respect to the axis of rotation [58], [59]. This configuration enables the SWT to redirect the incoming airflow, thereby enhancing the utilization of the wind's kinetic energy [13], [60]. The main design parameters of the SWT are illustrated in Figure 11. Among these parameters, the spiral pitch (S) represents the axial distance traveled by a blade over one complete spiral rotation. The turbine radius (r) denotes the radial distance from the rotational axis to the blade tip at the outlet side, while the turbine opening angle (θ) describes the angle formed between the rotational axis and the blade tip at the outlet section [61].

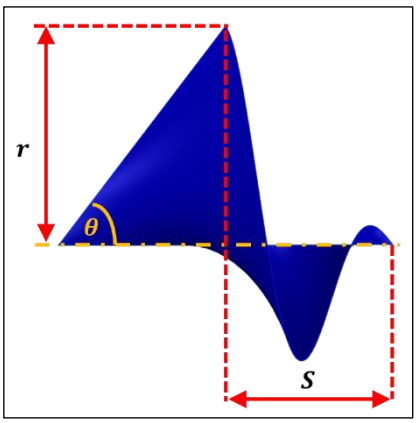

Figure 11: ASWT design parameters.
Source: [61].

Based on these design parameters, variations in spiral geometry play a crucial role in determining the aerodynamic characteristics and overall performance of the SWT.

Figure 12(a) presents a spiral wind turbine with a logarithmic spiral profile, whereas Figure 12(b) shows a turbine with an Archimedean spiral profile. The primary distinction between these two configurations lies in the winding characteristics of the spiral. In the logarithmic spiral, the spacing between successive turns increases progressively, while in the Archimedean spiral, the spacing remains constant along the spiral length [61], [62]. These variations in spiral profiles provide a clear basis for comparing the influence of spiral geometry on the performance of Spiral Wind Turbines.

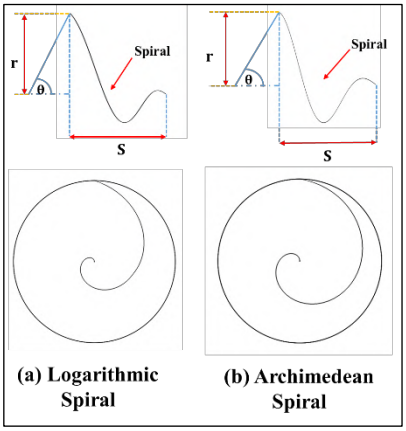

Figure 12: Spiral profile models.
Source: [61].

According to the study conducted by [61], the performance of a shell-shaped spiral wind turbine with logarithmic and Archimedean spiral profiles was evaluated under varying opening angles (θ) and tip speed ratios (TSR). The results demonstrated that the turbine with an Archimedean spiral profile exhibited superior performance compared to the logarithmic profile, particularly at an opening angle of 60°, where the maximum power coefficient (C_p) of 0.266825 was achieved at a TSR of 2.5.

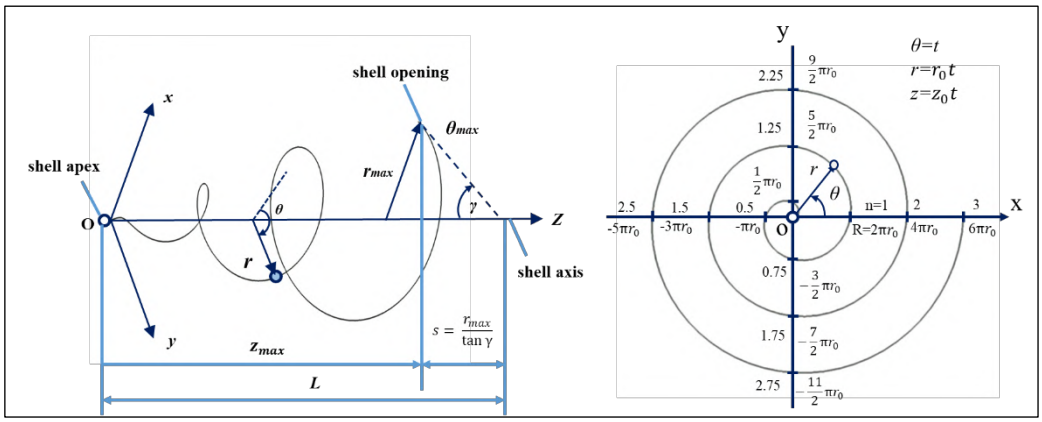

Figure 13: A seashell-shaped turbine modeled on an Archimedean conical spiral.
Source: [15].

To further examine the characteristics of the SWT with an Archimedean spiral profile, the geometric parameters of the turbine are presented in Figure 13. The three-dimensional spiral curve is generated using parametric equations expressed in a cylindrical coordinate system [15]. The governing equations employed to construct the spiral geometry are given as:

$$\theta = t \tag{20}$$

$$r = r_0 t \tag{21}$$

$$z = z_0 t \tag{22}$$

Where θ denotes the spiral rotation angle, t is the parametric variable, r represents the radial distance of the spiral, and z corresponds to the axial distance along the shell axis. The Archimedean spiral lying in the r–θ plane is defined by Equations (20) and (21), while Equation (22) describes the axial extension of the spiral along the z-axis, thereby introducing a conical component to the geometry. The resulting three-dimensional spiral curve originates at $r = 0$and $\theta = 0$at the defined coordinate origin (the shell apex) and terminates at $r_{\max}$ and $\theta_{\max}$ at the shell opening. For given initial values of r_0 and z_0, a set of (r, z) points forming the conical spiral can be obtained as a function of the spiral rotation angle θ. However, the value of $r_0$is constrained to ensure that all spiral configurations achieve the same maximum radius $r_{\max}$, which is necessary to guarantee equal input power among different turbine designs. The shell opening angle (γ), defined as the angle between the shell opening and the shell axis, is also incorporated into the rotor design. The number of conical spiral turns (n) and the turbine aspect ratio (AR) are illustrated in Figure 13 and defined as follows:

$$n = \frac{\theta_{\max}}{2\pi} \tag{23}$$

$$AR = \frac{L}{D} \tag{24}$$

Where the aspect ratio (AR) is the ratio between the turbine length (L) and the turbine diameter ($D = 2r_{\max}$). The turbine length (L) is obtained from the sum of the maximum axial extension of the conical spiral ($z_{\max}$) and the projected distance along the shell axis ($s = r_{\max}/\tan\gamma$)[15]. From this analysis, it can be concluded that the spiral geometry is not merely an aesthetic feature, but a critical design parameter that directly influences turbine efficiency. The SWT with an Archimedean spiral profile demonstrates superior performance, achieving a power coefficient of $C_p = 0.266825$ at an opening angle of 60°, compared to the logarithmic spiral profile. Consequently, the Archimedean spiral configuration has become the more dominant design reference in the development of Spiral Wind Turbines.

III.4.2 Aspect Ratio in ASWT

The geometric parameters of the ASWT rotor are illustrated in Figure 14. Understanding the aspect ratio as part of the rotor's geometric characteristics provides a fundamental basis for evaluating how its variation influences turbine performance. The aspect ratio (AR) is one of the key parameters that plays a significant role in defining both the geometric configuration and the operational performance of the rotor. As expressed in Equation (24), the aspect ratio is defined as the ratio between the turbine length and its outer diameter. This derived parameter offers deeper insight into the optimal geometric configuration of the rotor and has been widely adopted in previous studies [15], [63-68]. Based on earlier investigations, the influence of aspect ratio variation on the power-generating capability of ASWTs can be clearly identified through the following findings.

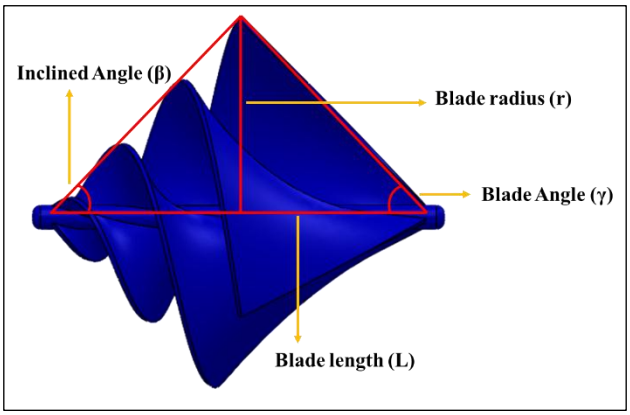

Figure 14: Geometric parameters of the ASWT.
Source : [69].

Study [69] examined five turbine models incorporating three different aspect ratios (AR = 1.5, 1.25, and 1.0), designed using both forward elongation and backward elongation configurations. The experimental results identified the model with AR = 1 and forward elongation as the most optimal configuration. This model achieved a maximum power coefficient (C_p) of 0.249 at a tip speed ratio (TSR) of 1.413. In general, the forward elongation configuration was found to enhance the power coefficient at lower TSR values, making it particularly suitable for low wind speed environments where effective operation at low rotational speeds is required. Conversely, reducing the aspect ratio below unity was not recommended, as it tended to induce vibrations and flow instabilities that negatively affect efficiency and reduce bearing lifespan. On the other hand, the AR = 1 model with backward elongation exhibited a higher torque coefficient, which can be attributed to the larger blade flow interaction area. This configuration provides improved self-starting capability and higher initial (starting) torque. In a separate investigation [70], four ASWT models with different geometric configurations were evaluated. ASWT 1 had a diameter of 55 cm and a length of 60 cm, resulting in an aspect ratio of 1.1. ASWT 2 maintained the same diameter of 55 cm but had a shorter length of 50 cm, also yielding an aspect ratio of 1.1. ASWT 3 featured a diameter and length of 50 cm, corresponding to an aspect ratio of 1.0, while ASWT 4 had a diameter of 45 cm and a length of 50 cm, producing an aspect ratio of 0.9. These variations were implemented to assess the influence of geometric changes on the aerodynamic performance of the turbine. The results demonstrated that increasing the rotor aspect ratio significantly improved the power coefficient. Among the tested models, ASWT 1 (D = 55 cm, L = 60 cm, AR = 1.1) achieved the highest power coefficient, reaching a maximum C_p value of 0.17. Overall, the comparative analysis of the four models revealed a consistent trend indicating that rotor geometry variations have a direct and measurable impact on aerodynamic performance. Therefore, the selection of an appropriate aspect ratio in ASWT design is crucial for balancing aerodynamic efficiency and structural integrity. Research findings indicate that aspect ratios exceeding 1.1 do not provide optimal performance. Conversely, aspect ratios below 1.0 tend to introduce flow fluctuations and mechanical vibrations, which reduce efficiency and shorten component lifespan. The optimal aspect ratio range for ASWTs lies between 1.0 and 1.1, where the highest power coefficients are consistently achieved.

III.4.3 ASWT Blade Profile Geometry

Airfoil selection is a critical aspect of wind turbine blade aerodynamic design. The airfoil profile has a pronounced influence on blade performance, where even minor geometric modifications can result in substantial changes in aerodynamic behavior as well as the level of noise generated [71-76] . To maximize the extraction of wind kinetic energy, an optimized blade geometry is required. As illustrated in Figure 15, one example of a blade profile employing an airfoil is presented. Modern rotor blades are generally designed with varying airfoil profiles along the blade span in order to enhance operational efficiency. This approach leads to more complex blade geometries, yet significantly improves performance compared to earlier generations of wind turbine blades. Airfoil selection is typically based on comparative evaluations of lift-to-drag ratios among established airfoil profiles [20], [77-79].

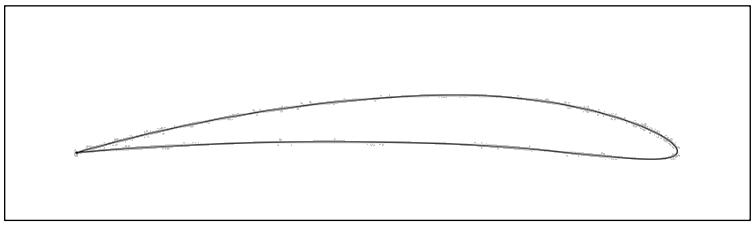

Figure 15: NACA 6409 Profile.
Source : [80].

An understanding of the role of airfoil geometry in improving blade efficiency provides the basis for further investigation into how airfoil shape affects overall turbine performance, particularly in ASWT designs. A study conducted by [25] analyzed the influence of airfoil implementation on ASWT performance by comparing four design configurations. The initial configuration consisted of a conventional ASWT with standard specifications, including a blade thickness of 3.5 mm, a pitch-to-diameter ratio (2s/D) of 0.28, a constant pitch of 70 mm, blade angles of $\alpha_1 = 30°$, $\alpha_2 = 45°$, and $\alpha_3 = 60°$, and outer and inner shaft diameters of 25 mm and 15 mm, respectively.The second configuration involved a modified ASWT in which the blade thickness was reduced to 2 mm and the blade angles were adjusted to $\alpha_1 = 25°$, $\alpha_2 = 50°$, and $\alpha_3 = 60°$, while maintaining the same pitch and 2s/D ratio. In the third stage, the ASWT design focused on variations of the pitch-to-diameter ratio (2s/D) to identify the most efficient configuration, with values modified from the baseline 0.28 to 0.22, 0.24, 0.26, 0.30, 0.32, and 0.34. The final stage introduced airfoil-based ASWT designs (AASWT), representing an advanced level of aerodynamic refinement through the application of various airfoil profiles to the modified ASWT geometry. In this phase, three airfoil families (S, FX, and NACA), each comprising five profile variants, were evaluated using the previously identified optimal 2s/D ratio to assess the influence of micro-scale aerodynamic characteristics on overall turbine performance. The results indicated that the AASWT employing the NACA 4401 airfoil achieved the best performance, reaching a maximum power coefficient (CP) of 30.45% at a tip speed ratio (λ) of 2. This design exhibited a 26.88% efficiency improvement compared to the conventional ASWT and a 6.47% increase relative to the modified ASWT. Consistent with these findings, several studies have investigated the application of NACA airfoil profiles in ASWT designs to evaluate performance responses under varying wind speed conditions. Research by [20] focused on AASWT performance by comparing the torque characteristics of an ASWT equipped with a NACA 6409 airfoil against a conventional ASWT. Computational fluid dynamics (CFD) analysis was employed to estimate blade torque characteristics. The results demonstrate a torque increase of approximately 10–15% at low wind speeds and more than 15% at moderate wind speeds, indicating that the NACA 6409 airfoil blade design performs effectively under low to moderate wind conditions. In another study, [81] reported that ASWTs modified with the NACA 2412 airfoil profile produced lower noise levels and exhibited improved suitability for low wind speed operation. These findings were supported by both wind tunnel experiments and field tests, which confirmed enhancements in torque output and aerodynamic efficiency. Overall, these results indicate that the application of NACA-type airfoil profiles in ASWT blades yields superior performance compared to S and FX profile types. Furthermore, ASWT designs incorporating the NACA 6409 airfoil demonstrate effective operation under low to moderate wind speeds, while NACA airfoil configurations also contribute to reduced noise levels relative to conventional blade designs.

III.4.4 Effect of Blade Inclination on ASWT Performance

Analyzing the influence of blade inclination on ASWT performance requires a clear understanding of how variations in blade angle alter turbine behavior. Figure 16 provides an initial conceptual illustration that clarifies the role of blade inclination in the ASWT rotor. A study conducted by [82] investigated the effect of blade inclination on ASWT performance using two distinct approaches: variable blade-angle configurations and uniform blade-angle configurations across the rotor. The variable configurations consisted of ($\alpha_1 = 15°$, $\alpha_2 = 30°$, $\alpha_3 = 45°$) and ($\alpha_1 = 30°$, $\alpha_2 = 45°$, $\alpha_3 = 60°$), while the uniform configurations included ($\alpha_1 = \alpha_2 = \alpha_3 = 30°$), ($\alpha_1 = \alpha_2 = \alpha_3 = 45°$), and ($\alpha_1 = \alpha_2 = \alpha_3 = 60°$). Among all tested configurations, the stepped blade-angle arrangement ($\alpha_1 = 30°$, $\alpha_2 = 45°$, $\alpha_3 = 60°$) emerged as the most effective, achieving a maximum power coefficient (C_{Pmax}) of 0.234 at a tip speed ratio (TSR) of 1.5. The analysis revealed that rotors with larger blade angles dominate the incoming flow through a stronger interaction over the swept area, thereby widening the operational TSR range and shifting the peak performance toward higher TSR values. This configuration generated higher thrust forces and increased force fluctuations due to enhanced drag associated with more upright blade orientations. These effects intensified flow blockage and produced more pronounced pressure patterns around the rotor. In contrast, rotors with smaller blade angles presented a gentler interaction surface to the incoming flow. As a result, the freestream was able to pass through the rotor with minimal disturbance, leading to a weaker blockage effect and reduced energy extraction. While this condition supported more stable tip-vortex structures, itwas also associated with slower wake recovery compared to rotors with larger blade angles. At higher blade inclinations, stronger and more coherent hub vortex structures were observed, indicating a more aggressive momentum exchange between the blades and the flow.

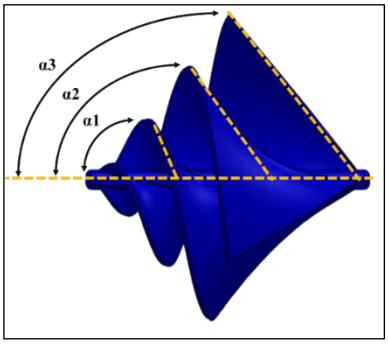

Figure 16: Schematic view of the ASWT rotor.
Source : [82].

Consistent with the findings of [82], the study by [27] examined the combined effects of blade thickness and blade angle on ASWT performance. The results demonstrated that stepped blade-angle configurations provide superior performance, with the combination of $\alpha_1 = 25°$, $\alpha_2 = 50°$, and $\alpha_3 = 60°$ and a blade thickness of 2 mm identified as the optimal arrangement for the modified ASWT. Additional studies further broaden the understanding of blade inclination effects on ASWT performance. Research by [83] analyzed the lift coefficient (C_L) and drag coefficient (C_D) of ASWTs employing a Fibonacci-based blade arrangement with opening angles of $\alpha_1 = 35°$, $\alpha_2 = 45°$, and $\alpha_3 = 65°$. The investigation was conducted under turbulent airflow conditions at a Reynolds number of 1200, ambient pressure of 1 atm, and wind speeds of 5.5 m/s and 15 m/s. The results indicated that at a wind speed of 5.5 m/s, increasing the blade opening angle led to higher lift coefficients. Conversely, at a wind speed of 15 m/s, larger blade angles resulted in increased drag coefficients, as a greater portion of the wind was intercepted by the turbine. However, the occurrence of unstable aerodynamic responses in these simulations was identified as a general limitation in wind turbine design. Nevertheless, a contrasting trend was reported by [84], who evaluated blade inclination angles (β) ranging from 50° to 65° at 5° intervals using computational simulations validated by experimental measurements. The results showed that the maximum power coefficient ($C_{Pmax} = 0.22$ at TSR = 1.72) and the maximum torque coefficient ($C_{Tmax} = 0.24$ at TSR = 0.62) were both achieved at a blade angle of 50°. These findings indicate that increasing blade inclination beyond this value leads to a reduction in maximum power coefficient, revealing an inverse relationship between blade angle and peak power performance under certain operating conditions. Overall, these findings suggest that larger blade opening angles in ASWTs can significantly enhance turbine performance under specific configurations and operating regimes. By expanding the effective wind capture area and strengthening aerodynamic interactions, appropriately inclined blades are capable of generating higher power and torque coefficients. However, excessive blade inclination may induce increased drag and flow instability, underscoring the importance of optimizing blade angle to balance aerodynamic efficiency and flow stability.

III.4.5 Augmentation for ASWT Performance Enhancement

The Archimedes Screw Wind Turbine (ASWT) has been further developed through the incorporation of augmentation devices such as shrouds or flow channels to enhance its aerodynamic performance, as illustrated in Figure 17. Turbines equipped with such structures are commonly referred to as Shrouded Archimedes Screw Wind Turbines (SASWT). The shroud functions by generating a low-pressure region downstream of the rotor, which accelerates the incoming airflow and draws a larger volume of air through the turbine. In addition, the shroud acts as a flow concentrator, increasing both the mass flow rate and the momentum of the air entering the rotor [85-87]. The resulting increase in pressure differential across the rotor leads to a higher airflow throughput and, consequently, greater power output. Despite the substantial performance gains, SASWTs face notable challenges, particularly the significantly higher thrust forces acting on the rotor compared to open (unshrouded) turbines [85], [86], [88], [89]. These elevated structural loads require the use of stronger blade materials, which inevitably increases the initial construction cost. Nevertheless, the improvements in efficiency and power output position SASWTs as a promising solution in wind energy development. It is important to note that although the shroud enhances turbine performance, it does not directly generate energy. In power coefficient (C_P) calculations, the shroud is typically excluded from the rotor area, ensuring that the C_p value remains below the Betz limit. Accordingly, the shroud is regarded as a passive enhancement device that amplifies pressure and flow rather than a power-producing component [85-88].

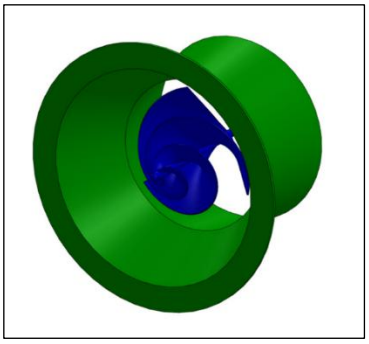

Figure 19: Illustration of the concentrator design with a flange at the ASWT inlet.
Source: [91].

Augmentation devices such as concentrators have been shown to significantly improve ASWT performance. A study by [90] evaluated the optimal configuration of an ASWT equipped with a concentrator and compared its performance to that of a bare ASWT. The concentrator design parameters are presented in Figure 18. The results demonstrated that the optimal configuration characterized by a concentrator position of 0.1D upstream of the rotor, a concentrator angle of 20°, a tip clearance of 0.05D, and a concentrator length of 0.6D achieved a maximum power coefficient of 0.311 at a TSR of 2.

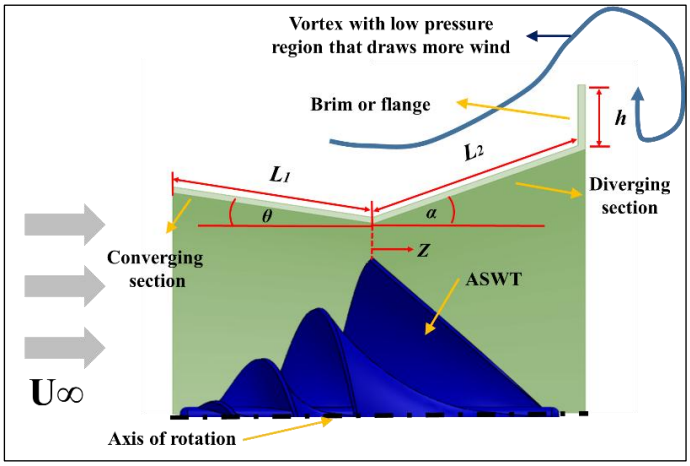

Figure 21: Design parameters of the concentrator with a flange at the ASWT outlet.
Source : [92].

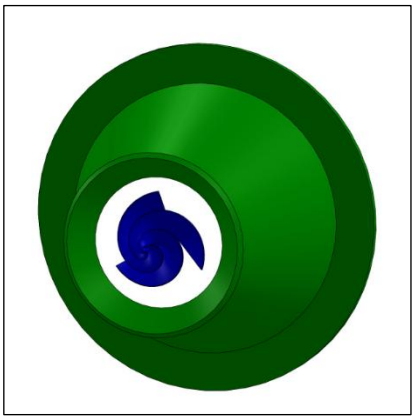

Figure 22: Illustration of the concentrator design with a flange at the ASWT outlet.
Source: [92].

The effectiveness of concentrator-based augmentation can be further enhanced by incorporating a flange, as reported in [91]. In this study, ASWT performance was improved by designing a concentrator with an inlet flange, as illustrated in Figure 19. The flange design parameters are shown in Figure 20. Using a turbine with a diameter of 250 mm, the optimal configuration yielding the highest C_P was obtained at L_1 = 180 mm, L_2 = 152 mm, R_1 = 250 mm, R_2 = 137.5 mm, and h = 75 mm. Under these conditions, the ASWT achieved a maximum C_p of 0.502 at a TSR of 2.5, representing an approximately 2.58-fold increase compared to the bare ASWT (C_p = 0.195). Beyond inlet-mounted flanges, performance enhancement can also be achieved by repositioning the flange at the outlet. A study by [92] numerically investigated the performance of an ASWT equipped with an airflow channel designed to improve energy harvesting efficiency in urban environments characterized by low wind speeds.

Figure 21 presents the concentrator parameters with an outlet flange, while Figure 22 illustrates the configuration. The findings revealed that the optimized channel geometry significantly increased the power coefficient. The optimal parameters were identified as L_1 = 0.2191D, L_2 = 1.658D, θ = 45.51°, α = 22.2°, h = 0.3457D, and Z = −0.296D. With this configuration, the maximum power coefficient reached 0.967 at a TSR of 3.25, corresponding to an approximately 3.6-fold improvement compared to the bare ASWT (C_p = 0.2668 at TSR = 2.5).

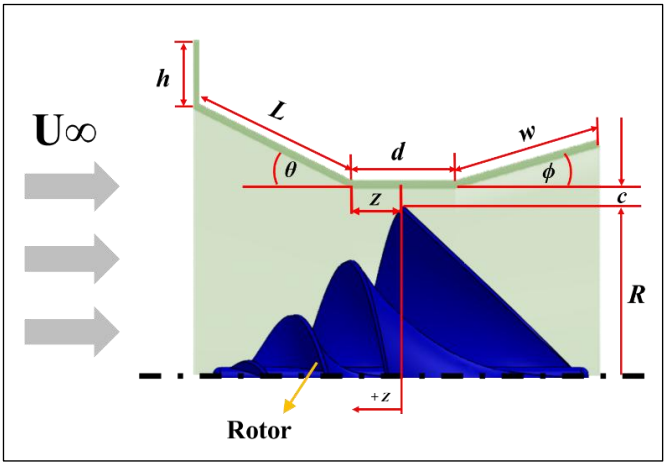

Figure 23: Wind lens design parameters for the ASWT. Source: [88].

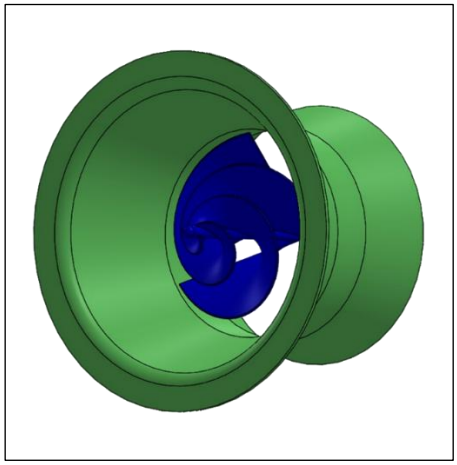

Figure 24 : Illustration of the wind lens design for the ASWT. Source: [88].

To further optimize performance, the geometry and configuration of wind-lens systems have been extensively investigated. Figure 23 presents the design parameters of a wind lens applied to an ASWT, with the corresponding illustration shown in Figure 24. The study by [88] systematically optimized wind-lens parameters, including diffuser length and angle, duct length, and flange height, to maximize the performance of a Shrouded Archimedes Spiral Wind Turbine (SASWT). The optimal configuration was obtained with Z = 0.1D, φ = 20°, c = 0.05D, a diffuser angle of 15°, and a concentrator length (L) of 0.6D. Additionally, the optimal values for duct length (d), flange height (h), and diffuser length (W) were each 0.3D. This configuration yielded a maximum power coefficient of 0.49 at a TSR of 3, representing a 2.1-fold increase relative to the ASWT without a wind lens. As a further advancement, [93] introduced three key contributions: (i) the use of a cylindrical enclosure to fully cover the turbine, (ii) the implementation of a simplified Maximum Power Point Tracking (MPPT) strategy, and (iii) the integration of protective electronic circuitry. The results indicated that the enclosure not only enhanced turbine efficiency but also reduced visual impact by obscuring the rotating blades an important advantage for individual users concerned with the aesthetic aspects of wind turbine installations. In summary, the incorporation of augmentation devices such as concentrators, concentrators with ducts, concentrators with ducts and flanges, and wind-lens systems consistently enhances ASWT performance by increasing pressure differentials and accelerating the incoming airflow. These mechanisms lead to substantial and measurable improvements in the power coefficient. For instance, an optimized shroud configuration with parameters L_1 = 0.2191D, L_2 = 1.658D, θ = 45.51°, α = 22.2°, h = 0.3457D, and Z = −0.296D was shown to achieve a maximum C_p of 0.967 at a TSR of 3.25 approximately 3.6 times higher than that of a bare ASWT (C_p = 0.2668 at TSR = 2.5).

III.4.6 Comparison between ASWT and other Wind Turbine Types

Several studies have demonstrated that the effectiveness of newly developed wind turbine designs can be systematically evaluated through direct comparisons with similar configurations or alternative turbine types. In a study conducted by [94], a dual-turbine system combining a Savonius turbine and an Archimedes Screw Wind Turbine (ASWT) was developed. Both turbines had a diameter of 20 inches and were mounted on a 4.5 m tower. Experimental results showed that the ASWT produced higher voltage output and rotational speed than the Savonius turbine. The ASWT achieved an average voltage of 7.04 V with a power output of 5.10 W, whereas the Savonius turbine generated only 2.70 V and 1.23 W. When operated simultaneously, the hybrid system produced an average voltage of 9.73 V and a power output of 6.32 W [94]. In another study, [95] performed a comparative numerical investigation of four different wind turbine types using ANSYS 16.0 based on Computational Fluid Dynamics (CFD), under a constant wind speed of 5 m/s and identical rotor swept areas. The simulation results indicated that the ASWT exhibited the highest performance, achieving an aerodynamic efficiency of 30.3%, a maximum power output of 6.55 W, and a rotational speed of 398 rpm. One of the key advantages of the ASWT lies in its ability to operate efficiently under low wind speed conditions, in contrast to Horizontal Axis Wind Turbines (HAWTs) and conventional Vertical Axis Wind Turbines (VAWTs), which typically require higher wind speeds to reach optimal performance [25], [27], [96]. The spiral blade geometry of the ASWT promotes smoother airflow behavior and a more uniform pressure distribution along the blade surface. This characteristic contributes to reduced aerodynamic noise and enables the turbine to initiate operation at wind speeds as low as approximately 2.5 m/s [27], [73], [88], [91], [97-101]. These combined features make the ASWT particularly well suited for urban environments, where wind speeds are generally low and highly turbulent. Moreover, the ASWT offers significant design flexibility and operates effectively at low Tip Speed Ratios (TSRs), enhancing its resistance to turbulence effects. Unlike HAWTs, ASWTs can employ a larger number of blades arranged at closer spacing, which improves wind energy capture efficiency. Further performance enhancement can be achieved through multi-turbine configurations. A study by [98] revealed that counter-rotating ASWT arrangements in both parallel and tandem configurations improved aerodynamic efficiency by 3.53% and 2.56%, respectively, compared to a single ASWT. Such configurations are particularly advantageous in urban settings, as they maximize energy density within limited spatial constraints.

IV. CONCLUSION

Considering its technical characteristics and environmental benefits, the Archimedes Screw Wind Turbine (ASWT) demonstrates strong potential as a future renewable energy solution. ASWT offers several inherent advantages, including self-starting capability, the absence of yaw mechanisms and tall towers, and ease of integration with augmentation devices. These features make ASWT particularly suitable for urban environments that require compact, low-noise turbines capable of operating under low wind-speed conditions. Recent research developments and innovations indicate that the selection of spiral geometry has a direct influence on turbine performance. ASWT equipped with an Archimedean spiral profile consistently outperforms logarithmic spiral configurations, achieving a maximum power coefficient (CP) of 0.2668 at a blade opening angle of 60°. In addition, aspect ratio (AR) values exceeding 1.1 are found to be suboptimal, while AR values below 1.0 tend to induce flow instability, vibration, and performance degradation, potentially shortening component lifespan. The optimal AR range is identified between 1.0 and 1.1, which provides a balance between maximum power output, structural stability, and operational durability. Performance enhancement in ASWT is not governed solely by aspect ratio. The application of airfoil-based blade profiles has been shown to significantly improve turbine efficiency. ASWT blades employing NACA airfoil profiles demonstrate notable performance gains compared to conventional blade designs, while also contributing to noise reduction. In particular, the NACA 6409 airfoil exhibits effective operation under low to moderate wind-speed conditions.

Beyond blade geometry, the blade opening angle also plays a crucial role in improving ASWT performance. Larger opening angles expand the effective wind capture area and enhance aerodynamic forces, resulting in increased torque and power output. The blade inclination configuration $(\alpha_1 = 30°, \alpha_2 = 45°, \alpha_3 = 60°)$emerged as the most effective arrangement, achieving a maximum power coefficient $(C_{p\max})$of 0.234 at a tip speed ratio (TSR) of 1.5. The results indicate that rotors with larger blade angles tend to dominate the flow by providing a stronger capture area, thereby extending the operational TSR range and increasing the TSR at peak performance. However, this configuration also generates higher thrust forces along with increased fluctuations, primarily due to the elevated drag associated with a more upright blade orientation relative to the incoming flow. Further performance improvements can be achieved through external modifications. The integration of augmentation structures, such as brimmed shrouds, has been reported to dramatically increase the power coefficient, with performance gains reaching up to 3.6 times compared to a bare ASWT configuration. Nevertheless, to fully realize the potential of ASWT technology, continued research efforts are required. These should focus on advanced design optimization, full-scale experimental validation, and comprehensive techno-economic analyses under real-world operating conditions. Collaboration among academic institutions, industry stakeholders, and governmental bodies will be essential to accelerate the adoption of ASWT technology as part of the global transition toward sustainable energy systems.

ABSTRACT

Electric vehicles (EVs) have been developed to reduce the emissions of carbon dioxide (CO_2) produced by vehicles with internal combustion engines. As the adoption of EVs increases, the development of a robust and efficient electric vehicle charging station (EVCS) is essential for the widespread adoption of EVs, providing the necessary infrastructure to recharge vehicle batteries. The strategic placement of an EVCS is critical, because it directly affects the efficiency and reliability of the distribution system. Properly located charging stations can enhance grid stability, optimize energy distribution, and reduce peak load pressures. Conversely, a poorly planned EVCS placement can lead to grid congestion, increased operational costs, and potential reliability issues. Strategy for maximizing EV utilization through EVCSs in the Radial Distribution Network System (RDNS) by considering factors such as load voltage deviation and line losses. In this study, the RDNS is segmented into zones, followed by the application of various optimization algorithms, including Ant Colony Optimization (ACO) and Particle Swarm Optimization (PSO). This approach identifies the optimal locations for the EVCSs in the network for different load growth rates. This was followed by Forward Backward Sweep (FBS) power flow analysis to determine the active and reactive power losses, voltage deviations, and voltage profiles. Extensive simulations using IEEE 33-node test feeders validated the proposed techniques using the MATLAB tool.

I. INTRODUCTION

Various approaches have been applied to design the optimum placement of EVCS. Charging stations can be optimally designed depending on the EV usage in an enhanced system performance and supply of a peak load. For this reason, reduction in losses, better economics, and minimization of voltage deviation are achieved using EVs [1]. Layout optimization for charging stations is based on maximizing the reliability of a network, and minimizing voltage deviation and power losses is applied using a K- means clustering algorithm [2]. The distribution network voltage deviation, power losses, and charging service were used as multi-objective functions in the optimization placement of charging stations. This problem was tested on a road network of 25 nodes and an IEEE 33 bus network using a cross-entropy method and data envelopment analysis [3]. A hierarchical genetic algorithm was applied to estimate an optimal charging station design based on the cost as an objective function and the constraints of the maximum capacity of a charging station and limits of power loss. The proposed technique was tested using an IEEE 123 bus system [4]. This study applied the ACO and PSO algorithms to solve the EVCS placement problem.

This was followed by load flow analysis using a backward-forward sweep approach to determine the real and reactive power losses and voltage deviation, and to analyze the voltage profile on the IEEE 33 bus system using MATLAB simulations. This paper is organized as follows: i) Section1 provides an introduction; ii) Section 2 details the problem formulation for EV charging stations; iii) Section 3 presents the modeling of the objective with algorithms; iv) further analysis of the simulation results is discussed in Section 4; and v) the conclusion is presented in Section 5.

II. PROBLEM FORMULATION

Deploying an EVCS in an RDNS has several benefits, including reduced line loss, improved voltage stability, enhanced network reliability, and increased security. However, determining the optimal placement of an EVCS involves solving a nonlinear optimization problem with objective functions and constraints related to the power balance, voltage, and current. The proposed solution aims to minimize the peak load power loss and voltage variation, while enhancing the voltage stability in the RDNS. Thus, the multi-objective function can be mathematically expressed as

$$J = Minimum\,\{J_1, J_2\} \tag{1}$$

Where J_1 and J_2 correspond to the total power loss and the voltage deviation index respectively. The following is a description of the mathematical equation that represents the multi-objective function.

III. MODELLING OF THE OBJECTIVE FUNCTION

The IEEE 33-bus system was selected as the use case network in this study. The RDNS is broken up into zones such that each zone can have an EVCS with a number of charging spots to serve its own needs. The system consistsof33buses with a total real power load of 3.72 MW and a total reactive power load of 2.30 MVAr supplied by source at bus 1. This RDNS was large and balanced at a voltage of 12.66 kV as shown in Fig. 1.

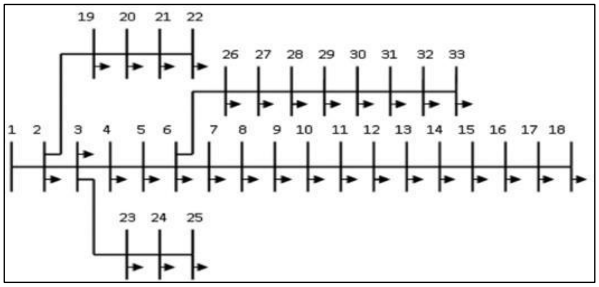

Figure 1: IEEE33 bus system.

III.1 REAL AND REACTIVE POWER LOSSES

By strategically placing EVCSs in the distribution network, the stability caused by the peak loading situations can be mitigated, ensuring that the constraints are not violated. This optimal EVCS placement minimizes power loss while adhering to the limits of the system constraints. The precise branch loss for the distribution system can be obtained using equation (2) and (3) such that the total power loss will be

$$P_{loss}(n, n+1) = \sum_{n=1}^{t} P_{loss}(n, n+1) \tag{2}$$

$$Q_{loss}(n, n+1) = \sum_{n=1}^{t} Q_{loss}(n, n+1) \tag{3}$$

Where $P_{loss}\ (n,\ n+1)$ and $Q_{loss}\ (n,\ n+1)$ are the total real and reactive powers losses from bus i to bus k respectively, Vi and Vk, respectively, represent the voltage of bus i and k, Yik and Yik represent, respectively, the admittance and the admittance angle of the line between bus i and bus k . Therefore, the function for the minimum amount of total power loss is given as:

$$J_1 = \text{Min} \sum_{i=0}^{n} \sum_{k=0}^{n} (P_{loss}(n, n+1) + Q_{loss}(n, n+1)) \quad i \neq k \tag{4}$$

III.2 VOLTAGE DEVIATION

When the EVCS are incorporated in to the RDNS, the voltage profile changes. The main focus is to minimize thevoltage changes. Each bus in the RNDS was analyzed individually. To maintain the voltage stability, the difference between the normal bus voltage and the rated bus voltage should be minimal [5]. The equation for voltage deviation from the reference voltage magnitude is given by:

$$\text{Voltage deviation } J_2 = Min \sum_{j=0}^{n} \left(1 - \frac{V_j}{V_{ref}}\right)^2 \tag{5}$$

Here

V_j - represents the voltage at bus j
V_{ref} is the slack bus voltage
n - represents the number of buses.

In light of this, transforming Equations (4) and (5) into a minimization function results in the mathematical formulation of the multi-object function represented in Eq. (6)

$$J = \{\beta_1 \times J_1 + \beta_2 \times J_2\} \tag{6}$$

III.3 ANT COLONY OPTIMIZATION (ACO)

The Ant Colony Optimization technique was inspired by the foraging behavior of ant colonies and was first introduced by Marco Dorigo in the 1990s. Ants are eusocial insects that prefer community survival and sustenance to individual species. They communicate using sound, touch and pheromones. Pheromones are organic chemical compounds secreted by ants that trigger social responses in members of the same species. These chemicals are capable of acting like hormones outside the body of the secreting individual, impacting the behavior of the receiving individuals. Because most ants live on the ground, they use the soil surface to leave pheromone trails that may be followed (smelled) by other ants. Ants live in community nests and the underlying principle of ACO is to observe the movement of ants from their nests to search for food in the shortest possible path. Initially, ants began to move randomly in search of food around their nests. This randomized search opens multiple routes from the nest to a food source. Based on the quality and quantity of the food, ants carry a portion of the food back with the necessary pheromone concentration on its return path. Depending on these pheromone trials, the probability of selecting a specific path by the following ants is a guiding factor for the food source. Evidently, this probability is based on the concentration and rate of pheromone evaporation. It can also be observed that the length of each path can be easily accounted for because the evaporation rate of the pheromone is also a deciding factor. The mathematical modelling of the algorithm can be represented as follows: the probability of movement of the ant from node i to node j is given by [6].

$$P_{i,i} = \frac{(\tau_{i,j}{}^{\alpha})(\eta_{i,j}{}^{\beta})}{\Sigma(\tau_{i,j}{}^{\alpha})(\eta_{i,j}{}^{\beta})} \tag{7a}$$

Where

τi, j is the amount of pheromone on edge i, j

α is a parameter to control the influence of τi, j

ηi, j is the desirability of edge i, j (typically$1/d_i$, j)

β is a parameter to control the influence of ηi, j

Amount of pheromone is updated according to the equation

$$\tau(i,j) = (1-\rho)\tau_{i,j} + \triangle\, \tau_{i,j} \tag{8a}$$

Where

τi, j is the amount of pheromone on a given edge i, j

ρ is the rate of pheromone evaporation

$\triangle\, \tau_{i,j}$ is the amount of pheromone deposited typically given by

$$\triangle\, \tau_{i,j} = \begin{cases} \frac{1}{L_k} \\ 0 \end{cases}$$ if ant k travels on edge i, j

Where L_k is the cost of the k[th] ant's tour (typically length), each ant applies it only to the last edge traversed:

$$\tau_{i,\,j} = (1-\varphi)\cdot\tau_{i,\,j} + \varphi\cdot\tau_0 \tag{9a}$$

Where

$\varphi \in (0, 1)$ is the pheromone decay coefficient,

τ_0 is the initial value of the pheromone

Algorithm

Step 1: Start.

Step 2: Read the bus and line data, and initialize the EVCS numbers with the percentage of EV penetration.

Step 3: Initialize parameters of ACO.

Step 4: Apply state transition rule and pheromone update rule.

Step 5: Evaluate fitness function.

Step 6: Apply global pheromone update rule.

Step 7: If the iteration number reaches the maximum limit, proceed to step 8, else, set the iteration index,

k=k+1 repeat step 4 to 8 until iteration criteria is met.

Step 8: The optimal location of EVCS is recorded.

Step 9: End.

Parameters of Ant colony optimization:

Table 1a: ACO Parameters.

Parameter	Symbol	Value
Population size	npop	100
Number of iterations	T	25
Pheromone coefficient	α	1
Heuristic coefficient	β	2
Evaporation rate	γ	0.05
Amount of pheromone by best ant	Q	1

III.4 PARTICLE SWARM OPTIMIZATION (PSO)

The PSO working principle is based on the social behaviors of animals, such as fish schooling, 7ato flocking, and bee swarming. They work in a flock and optimize their search to hunt for the best food place. Similarly, the optimal location of the EVCS was determined using this technique. Kennedy and Eberhart presented a work on PSO at a conference on evolutionary computation in 1995. This research is based on solutions to 7ator7f7e optimization problems using PSO. The particles represent the solution to the optimization problems, and the population of solutions is known as the swarm in this algorithm. Velocity and position are the two main properties of particles. The initialization of the particles was performed random positions. The position of the particles changes with the velocity to a new position after each iteration. They reach the new global best G_{best} and personal best P_{best} position. The P best is the best position of the particle achieved till now, and G_{best} is the overall best position of the particle. The equation (7b) is used to determine the velocity of each 7ator7 after each iteration [7].

$$V_i^{k+1} = W^k \times V_i^{k+1} + C_1 \times rand_1 \times \left(P^k{}_{Best,i} - X_i^k\right) + C_2 \times rand_2 \times \left(G^k{}_{Best,\,i} - X_i^k\right) \quad (7b)$$

Here,
V_i = Velocity of the particle i
$C_1\ and\ C_2$ = Acceleration coefficients of the particle i
$rand_1\ and\ rand_2$ = random variables
P_{best} = Personal 7ator7f particle i
G_{best} = Global 7ator7f particle i
w = Inertia weight 7ator of particle i
k = Current iteration
The location of the particle is obtained as given below:

$$X_i^{k+1} = X_i^k + V_i^{k+1} \quad (8b)$$

Algorithm

Step 1: Start.

Step 2: Read the bus and line data and initialize the EVCS numbers with the percentage of EV penetration.

Step 3: Randomly generate an initial population of particles with random positions and velocities on dimensions with an iteration count set to k=0.

Step 4: The fitness value of each particle is evaluated. If the objective value is lower than P_{best}, set this value as the current P_{best} and record the corresponding particle position.

Step 5: Choose the particle associated with the minimum individual best P_{best} of all particles and set the value this value as the current overall G_{best}

Step 6: Update particle velocity and position using steps 4 & 5 respectively.

Step 7: If the iteration number reaches maximum limit proceed to step 8, else set iteration index k=k+1repeat step 4to 7 until iteration criteria is met.

Step 8: The optimal location of EVCS is recorded.

Step 9: End.

The PSO parameters such as population size, acceleration constants, and inertia weight were selected as shown in Table -1b to run the PSO algorithm in MATLAB.

Table 1b: PSO parameter.

Parameter	Symbol	Value
Population size	n_{pop}	100
Number of iterations	T	25
Inertia coefficient	W	1
Cognitive acceleration Coefficient	C_1	1
Social acceleration coefficient	C_2	2

III.5 BACKWARD FORWARD SWEEP APPROACH FOR POWER FLOW ANALYSIS

Power flow analysis was used to determine the performance of the power system operating in a steady state. Two inputs line and load data were required for the analysis. Kirchhoff's current and voltage laws are considered in each iteration of the Backward Forward Sweep (BFS) method to determine the current and voltage [8-10]. The current and load flow solutions in each branch were calculated by maintaining the voltage constant in the backward sweep. The forward sweep calculates the voltage by maintaining the load and current constant. Hence the voltage, real, and reactive power losses are calculated using equations (2), (3), (4) and (5) by the BFS load flow analysis. The assumptions considered are an initial voltage of 1 p.u., initial power losses of both real and reactive are zero and RDNS is balanced in nature [11]. Power flow analysis was used to determine the performance of the power system operating in a steady state. Two inputs line and load data were required for the analysis. Kirchhoff's current and voltage laws are considered in each iteration of the Backward Forward Sweep (BFS) method to determine the current and voltage [8-10]. The current and load flow solutions in each branch were calculated by maintaining the voltage constant in the backward sweep. The forward sweep calculates the voltage by maintaining the load and current constant. Hence the voltage, real, and reactive power losses are calculated using equations (2), (3), (4) and (5) by the BFS load flow analysis. The assumptions considered are an initial voltage of 1 p.u., initial power losses of both real and reactive are zero and RDNS is balanced in nature [11].

Algorithm
Step 1: Start
Step 2: Convert the resistance, reactance, voltage and power per unit form.

Step 3: Calculate matrix [A]: (branch node incidence matrix)

$$A_{i,j} = \begin{Bmatrix} -1 \; if \; j = \; Sending \; Node \\ +1 \; if \; j = \; Receiving \; Node \end{Bmatrix}$$

Step 4: Calculate number of possible paths by computing number of end nodes.

Step 5: The number of nodes on each possible path is determined. Let the lateral have maximum 'm' number of branches, so the bus matrix [B] will be having dimensions $(l * m)$.

Step 6: Determine linked branches beyond a branch to form the next-linked node matrix [C]. For load flow
Step 7: Assume flat voltages tart

$$V_i = 1 + 0j \; for \; i = 1 \; to \; n$$

$$Pl_j = 0 \; and \; Ql_j = 0 \; for \; j = 1 \; to \; b$$

Step 8: Set iteration count IT= 1 where IT=1 to IT MAX

Step 9: Calculate current from each branch

$$I_j = \left\{\frac{S_{i+1}}{V_{i+1}}\right\} \; for \; i = 1 \; to \; b$$

Here, $S_{j+1} = (P_{i+1} + Q_{i+1})$

Step 10: Backward sweep: The current and load flow solutions were calculated by keeping the voltage constant. It begins at the branch of the end node and moves toward the source node. Each load flow of the branch was updated by considering the voltage of the previous iteration.

$$\mathrm{I_k} = \sum\nolimits_{\mathrm{j}} \mathrm{I_j} \;\; \text{for k} = 1 \text{ to b where j} \in \mathrm{C_j}$$

Here, $\mathrm{C_j}$ is the set of next linked node beyond k branch

Step 11: Forward sweep: The voltage was calculated by keeping the load and current constant. It starts from the branch of the source node and continues towards the end node.

$$V_{k+1} = V_k - \left(I_k * (Z_k)\right)$$

Step 12: Calculate Real and Reactive power losses

Step 13: Check the deviation in the values for the real and reactive power losses from the present and previous iterations.

Step 14: IT=IT+1until IT= IT MAX

Step 15: Return Pl_j , Ql_j , IT, total real and reactive power losses.

IV. RESULTS AND DISCUSSIONS

The optimal location for EVCS placement using the ACO algorithm at penetration levels of 10%, 50% and 100% of the considered load was applied and the results are tabulated in Table 2a.

Table 2a: EVCS placement locations by ACO.

Parameters	**10% load**	**50% load**	**100% load**
Bus number	2, 23, 4, 10, 13	2, 23, 4, 11, 13	2, 23, 4, 10, 13

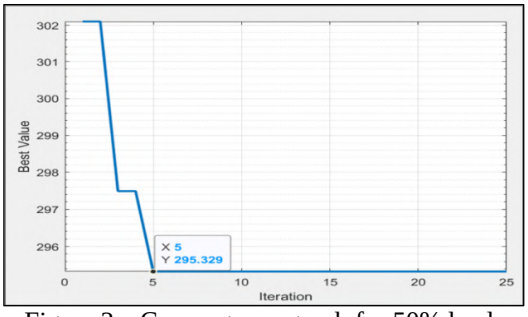

Figure 2e: Convergence graph for 50% load.
Source: Authors, (2026).

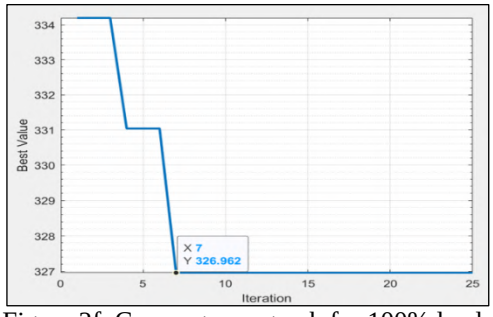

Figure 2f: Convergence graph for 100% load.
Source: Authors, (2026).

The algorithm was executed thrice for each load condition and the most repeated bus numbers were chosen as the final location in the load category. Fig 2a shows the optimal location of EVCS placement for 10% load growth. The final optimal locations obtained for 10% load growth were bus numbers 2, 23, 4, 10, and13. Fig 2d shows the optimization of the convergence point for a 10% load growth at 4th iterations. Fig 2b shows the optimal location of EVCS placement for 50% load growth. The optimal locations for a 50% load growth are buses 2, 23, 4, 11 and 13. Fig 2e shows the optimization of the convergence point for a 50% load growth at the 5th iterations.

Fig 2c shows the optimal location of EVCS placement for 100% load growth. The optimal location for a100% growth rate is buses no. 2, 23, 4, 10and 13. Fig 2f shows the convergence point for 100% growth at 7th iteration. From the results we observe that the number of iterations required for convergence increases as the load increases but converges for a small number of iterations. The computation time is shorter as it converges early.

IV.1 RESULTS AND DISCUSSIONS

The optimal location for EVCS placement using the PSO algorithm at penetration levels of 10%, 50% and 100% of the considered load was applied and the results are tabulated in Table 2b.

Table 2b: EVCS placement locations by PSO.

Parameters	**10% load**	**50% load**	**100% load**

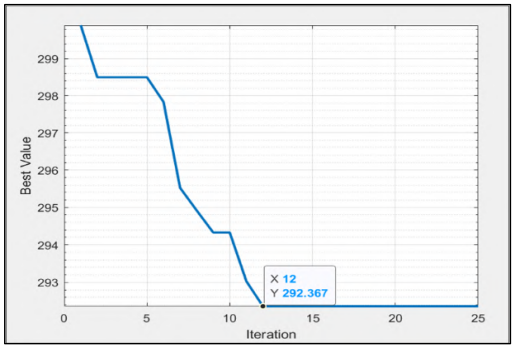

Figure 3e: Convergence graph for 50% load.
Source: Authors, (2026).

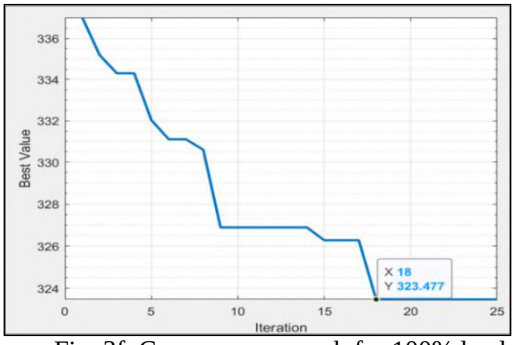

Fig. 3f: Convergence graph for 100% load.
Source: Authors, (2026).

The algorithm was executed thrice for each load condition and the most repeated bus numbers were chosen as the final location in the load category. Fig 3a shows the optimal location of EVCS placement for 10% load growth. The final optimal locations obtained for 10% load growth were bus numbers 2, 3, 4, 9 and 13. Fig 3d shows the optimization of the convergence point for a 10% load growth at 8thiterations. Fig 3b shows the optimal location of EVCS placement for 50% load growth. The optimal locations for a 50% load growth are buses 2, 3, 4, 9, and 13. Fig 3e shows the optimization of the convergence point for a 50% load growth at 12thiterations. Fig 3c shows the optimal location of the EVCS placement for 100% load growth.

The optimal locations for the100% growth rate are buses 19, 3, 4, 9 and 13. Fig 3f shows the convergence point for 100% growth at the 23rd iteration. The results show that the number of iterations required convergence increases as the load increases. Hence the computation time is greater in this case.

V.1. POWER FLOW ANALYSIS FOR ACO ALGORITHM LOCATIONS

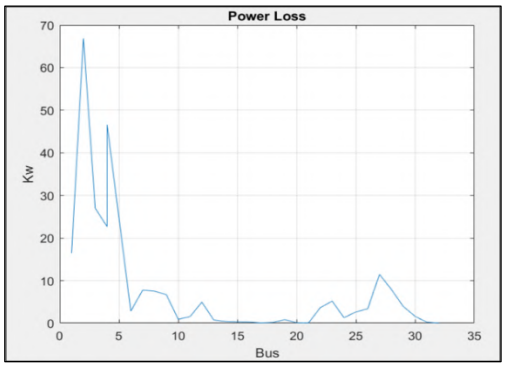

Figure 4a: Power losses at 10% load.
Source: Authors, (2026).

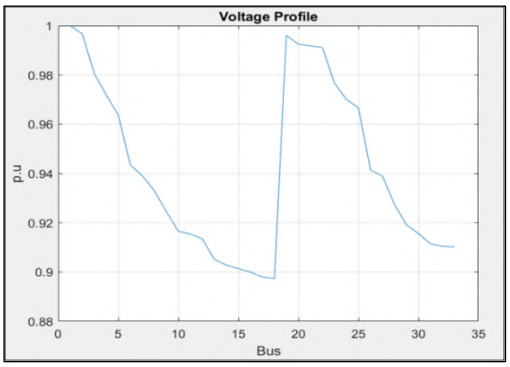

Figure 4b: Voltage profile at 10% load.
Source: Authors, (2026).

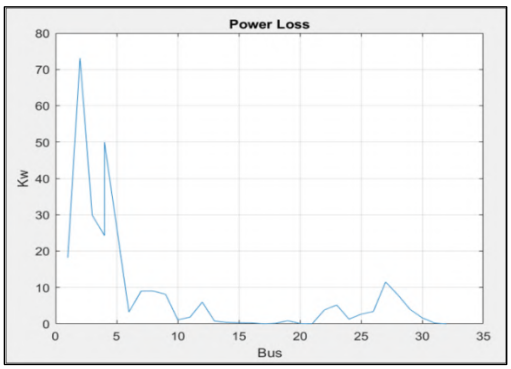

Fig. Figure 4c: Power losses at 50% load.

For a10% load the optimal locations identified are bus nos. 2, 23, 4, 10, and 13 with real and reactive power losses of 256 KW and 169 KVAr, respectively. The 50% load optimal locations are 2, 23, 4, 11 and 13 with 278 KW and 184 KVAr real and reactive losses respectively. Finally, 100% load optimal locations are 2, 23, 4, 10 and 13 with 308 KW and 203 KVAr power losses and are tabulated in Table 3a.

Table 3a: Power flow results in ACO.

Parameters	10% of EV	50% of EV	100% of EV
Real power losses in KW	256	278	308
Reactive power losses in KVAr	169	184	203
Voltage deviation	15.314	16.844	18.833
Vmin in p.u	0.8973	0.8914	0.8838
Number of iterations for best value	4	5	7
EVCS placement optimal location	2, 23, 4, 10, 13	2, 23, 4, 11, 13	2, 23, 4, 10, 13

Source: Authors, (2026).

The main objective of load flow analysis is to identify the optimal location with reduced active and reactive power losses, low voltage deviation and an improved voltage profile. Fig. 4a and 4b show the power losses and voltage profiles for the 10% load condition. The optimal locations obtained for the ACO algorithm are bus nos. 2, 23, 4, 10, and 13. The active power loss was 256 k W and the reactive power loss was 169 KVAr in the system. The voltage deviation was 15.314% and the voltage profile minimum value was 0.8973 p.u. The algorithm required four iterations to converge to the best value. Fig. 4c and Fig. 4d show the power losses and voltage profiles for the 50% load condition. The optimal location obtained by the ACO algorithm is bus nos. 2, 23, 4, 11 and 13. The active power loss was 278 kW and the reactive power loss was 184 KVAr in the system. The voltage deviation is 16.844% and the minimum voltage profile value is 0.8914 p.u. The algorithm required five iterations to converge to the best value. Figure 4e and 4f show the power losses and voltage profile for the 100% load condition. The optimal locations obtained by the ACO algorithm are bus nos. 2, 23, 4, 10 and 13. The active power loss is 308k W and the reactive power loss is 203 KVAr in the system. The voltage deviation was18.833% and the minimum voltage profile value was 0.8838 p.u. The algorithm requires 18 iterations to converge to the best value. The location with minimum active and reactive losses, low voltage deviation and improved voltage profile is considered to be the best location for placement of the EVCS in each zone in the network. This was tested on a 33bus test system using the MATLAB 2023Ra simulation tool.

V.2 POWER FLOW ANALYSIS FOR PSO ALGORITHM LOCATIONS

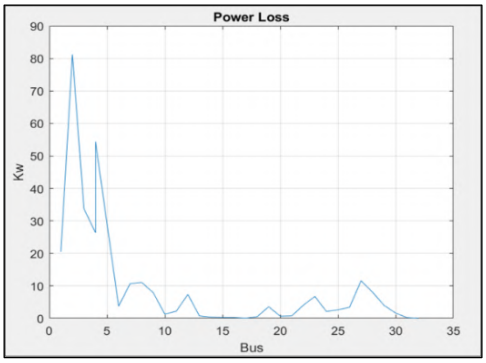

Figure 4k: Power losses for 100% load.
Source: Authors, (2026).

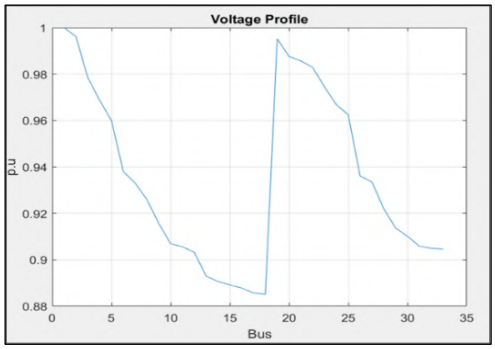

Figure 4l: Voltage profile for 100% load.
Source: Authors, (2026).

For a 10% load the optimal locations identified are bus nos. 2, 3, 4, 9, and 13 with real and reactive power losses of 254 KW and 168 KVAr respectively. The 50% load optimal locations are 2, 3, 4, 9, and 13 with 276 KW and 182 KVAr real and reactive losses respectively. Finally, 100% load optimal locations are 19, 3, 4, 9, and 13 with 308 KW and 203 KVAr power losses and are tabulated in Table 3b.

Table 3b: Power flow results PSO.

Parameters	10% load	50% load	100% load
Real power loss in KW	254	276	308
Reactive power loss in KVAr	168	182	203
Voltage deviation in %	15.190	16.636	18.833
V_{min} in p.u at 18th bus	0.8980	0.8923	0.8838
Number of iterations for Convergence	8	12	18
EVCS placement optimal Locations	2, 3, 4, 9,13	2, 3, 4, 9,13	19, 3, 4, 9,13

Source: Authors, (2026).

The main objective of power flow analysis is to identify the optimal location with reduced active and reactive power losses, low voltage deviation and an improved voltage profile. Fig. 4g and 4h shows the power losses and voltage profiles for the 10% load condition. The optimal locations obtained by the PSO algorithm are buses no. 2, 3, 4, 9 and 13. The active power loss in the system is 254 kW and the reactive power loss is 168KVAr in the system. The voltage deviation was 15.190% and the voltage profile minimum value was 0.8980 p.u. The algorithm required eight iterations to converge to the best value. Fig. 4i and 4j show the power losses and voltage profiles for the 50% load condition. The optimal locations obtained by the PSO algorithm are buses no. 2, 3, 4, 9 and 13. The active power loss was 276 kW and the reactive power loss was 182 KVAr in the system. The voltage deviation is 16.636% and the minimum voltage profile value is 0.8923 p.u. The algorithm requires 12 iterations to converge to the best value. Fig. 4k and 4l show the power losses and voltage profile for the 100% load condition. The optimal locations obtained by the PSO algorithm are buses no. 2, 25, 4, 9 and 13. The active power loss in the system is 305 kW and the reactive power loss is 201KVAr in the system. The voltage deviation was 18.576% and the minimum voltage profile value was 0.8851 p.u. The algorithm requires 18 iterations to converge to the best value.

VI. COMPARISON BETWEEN PSO AND ACO

The EVCSs ware optimally placed in each zone for different load conditions using the PSO and ACO optimization techniques separately. This was done to validate the efficacy of the optimization technique individually for locating the best locations with reduced real and reactive power losses, reduced voltage deviation and improved voltage profile. From Tables 4a and 4b we can observe that the time taken to complete the optimization is greater in the PSO method than in ACO. The number of iterations required to convergence to the best value was comparatively higher in the PSO method than in the ACO method for all load conditions.

Table 4a: Results of EVCS placement location by PSO and ACO optimization.

Parameters	10% load		50% load		100% load	
	PSO	ACO	PSO	ACO	PSO	ACO
Optimal bus no	2,3,4,9,13	2,23,4,10,13	2,3,4,9,13	2,23,4,11,13	19,3,4,9,13	2,23,4,10,13
Time in seconds	0.001367	0.002042	0.005926	0.00215	0.003362	0.002011

Tables 4a and 4b present the optimal allocation of EVCSs for each zone and the load condition simulation scenario. The PSO and ACO algorithms were employed to test the placement of stochastically sized EVCS. Factors that influence EVCS placement include an improved voltage profile reduced power losses and voltage deviation. Comparing the results obtained by considering all the factors the PSO method is superior to the ACO method.

VII. CONCLUSION

In summary, the rapid adoption of EVs as a means to reduce greenhouse gas emissions in the transportation industry necessitates swift upgrading of distribution networks to support a large number of charging stations. This study employs heuristic techniques, including PSO and ACO to optimize the placement of EV charging stations (EVCSs) in a network. The objective function focused on minimizing the real and reactive power losses voltage deviation and voltage profile. A comparative analysis revealed that the PSO approach outperformed the ACO method, achieving the lowest values of real and reactive power losses and exhibiting robustness in affecting the voltage profile. The study outcomes offer practical implications for policy makers, system planners, and researchers involved in the efficient deployment and management of EV charging infrastructure within community-based distribution networks.

VIII. FUTURE SCOPE

In future research, an important aspect will be the consideration of factors such as battery charge levels and intermittent behaviour of distributed PV systems. By accounting for battery charge levels, this research will be aimed at ensuring the efficient utilization of available energy resources and man aging the charging demands of EVs effectively as the current work fails to take this in to account. Additionally, the intermittent nature of distributed PV systems will be considered to leverage renewable energy sources and maximize their integration with the EV charging infrastructure.

ABSTRACT

As report of missing children continue to rise around the world there is an urgent requirement of some smart and scalable systems which can help in timely and accurate identification. In this paper, we propose a multimodal deep learning system that combines Vision-Language Transformers like CLIP, Face Re-identification networks, and Graph Neural Networks (GNNs) in order to help in locating and tracking missing children. The proposed system is unlike conventional facial recognition systems, which can only act on visual stimulus whereas the proposed system handles a multitude of different stimulus e.g. facial image, descriptive text, metadata location, time greater and context of the stimulus e.g. description of clothing. The vision language module enables visual inputs to be correlated to the textual description so that the model is able to interpret and correlate the narrative indicators within the public reports. A face re-identification module with high tolerances to visual variability because of age, lighting, occlusion, etc. and a GNN to learn spatial and temporal links between sightings to make movement pattern predictions.
Initial tests on publicly available data show a better matching across the unimodal baselines and a substantial improvement in recall and contextual relevance in the metrics. Uniting the visual, linguistic, and structural data, the model provides more accurate findings in real-life situations and demonstrates a high possibility of combining it with police technology. There should be more work on increasing child-targeted multimodal data sets and evaluating in the real world testing.

I. INTRODUCTION

Missing children as a problem still remains a severe humanitarian and social dilemma where many cases are reported daily on a worldwide scale. Manual reporting, restricted surveillance videos and recalling by human beings forms the core of the conventional search and identification procedures that are highly ineffective, inefficient, and time consuming in quick interventions. Since time plays a decisive role in the recovery of the children, technological systems are urgently needed that would be able to help authorities with greater precision, faster, and more flexibly.

Figure 1: Missing Children.
Source: Authors, (2026).

The recent developments of artificial intelligence, especially computer vision and deep learning, provide the new opportunities to automate the identification task. Contemporary models have now shown great results in determining faces, image-text comprehension, and video processing. Nonetheless, the current solutions in the field of missing persons detection are limited to using unimodal methods (without context knowledge). An example would be that the systems can perform well in optimal situations with facial recognition but the problem is the systems cannot perform well in situations having occlusions, aging or the metadata is missing. Moreover, most of the existing tools do not include rich narrative information in social media alerts or police reports. In a bid to overcome these constraints, the proposed research will implement the multimodal deep learning strategy which will use facial images, written text and the geospatial-temporal relationship to enhance the identification of missing children. It brings together three core aspects, including a module related to Face Re-identification in order to match visual faces in diverse looks, a Vision-Language Transformer (like CLIP) to align pictures with text descriptions, and Graph Neural Network to map potential motion trajectories between successive reports or observations. Their integration will allow the proposed solution to manipulate a variety of data forms both in frontal faces and in natural language, contextual cues such as age, clothing, and location, and the solution will therefore be less strained by the reality of variability. The context-sensitive overall framework is a step in the direction of more intelligent and responsive detection tools of missing children, and this is expected to go beyond recognition of faces only and to the interpretation of descriptive stories and comparison to the visual attributes of identity.

II. THEORETICAL REFERENCE

According to [1] presented a CNN + VGG Face embedding and a multiclass SVM neural network to match the submitted image of missing child when given a controlled test condition of 99.41 use of accuracy. Although very successful in rigid configurations, the system has not been tested on large and varied set of data and may not be generalizable to a real-life application. In [2] proposed a CNN + VGG face embedding and a multiclass SVM to match uploaded images of missing children with a central database, recording 99.41 percent accuracy of identification. When restricted to their controlled environment, their system works fine, although it might not scale very well to the real world where images encountered can be very varied. According to [3] proposed a CNN to pair pictures of missing children uploaded by the general population using an iris-detection installed web service and combined with the LBPH face recognition algorithm. There is a potential of uniting facial and iris biometrics in the system but its performance and strength are unknown because it has not been validated on varying real-world data sets. According to [4] proposed a Haar-cascade face detector coupled with LBPH based facial recognition that worked best with the task of identifying missing children in their database. The system performs superiorly on ordered databases, however, it is limited by regular lighting and centered face photographs, and this reduces its performance in random or real life conditions. A pre-trained VGG-Face CNN model with multiclass SVM classifier was proposed by [5] to compare the uploaded pictures of users with a central database of missing children. The system works fine in controlled settings but with no validation on more varied real-world data, and therefore, the system might not be so robust in uncontrolled settings. According to [6], offered CNN based model on transfer learning of the facial recognition of missing children with age progression and the privacy-preserving block chains. It is its own design and involves automated alerting, though can only be tested utilizing internal datasets and include no transparency as it regards performance metric that makes it difficult to validate in practice. In [7] used a VGG Face CNN feature extractor, followed by a pattern-profile comparison or SVM classifier to match an uploaded child to a missing-child dbase inside a web portal project. The system functions in an area of reinforcement test situations but not still confirmed on lengthy and realistic databases and, consequently, the use of the system is still doubtful. A deep feature aging module has been suggested by [8] and uses the aging in the facial embedding space to improve the recognition of long-missing children. It is a more applicable way of treating effects of natural aging, so such an identity-preserving scheme is more suited to long-term disappearance cases than visual transform.

According to [9] also came up with a CNN based model of identifying child faces using FaceNet embeddings and K-NN classification algorithm to be compared with a list of missing peoples on a web-based application. According to [10] have proposed some OpenCV based facial recognition system that extracts facial landmarks along with the texture information then encoding them into templates and comparing with those in a database of missing children and criminals and got the accuracy of 95% on the test data.

III. MATERIALS AND METHODS

III.1 DEEP CNN-BASED FACIAL RECOGNITION FRAMEWORK FOR MISSING CHILDREN IDENTIFICATION:

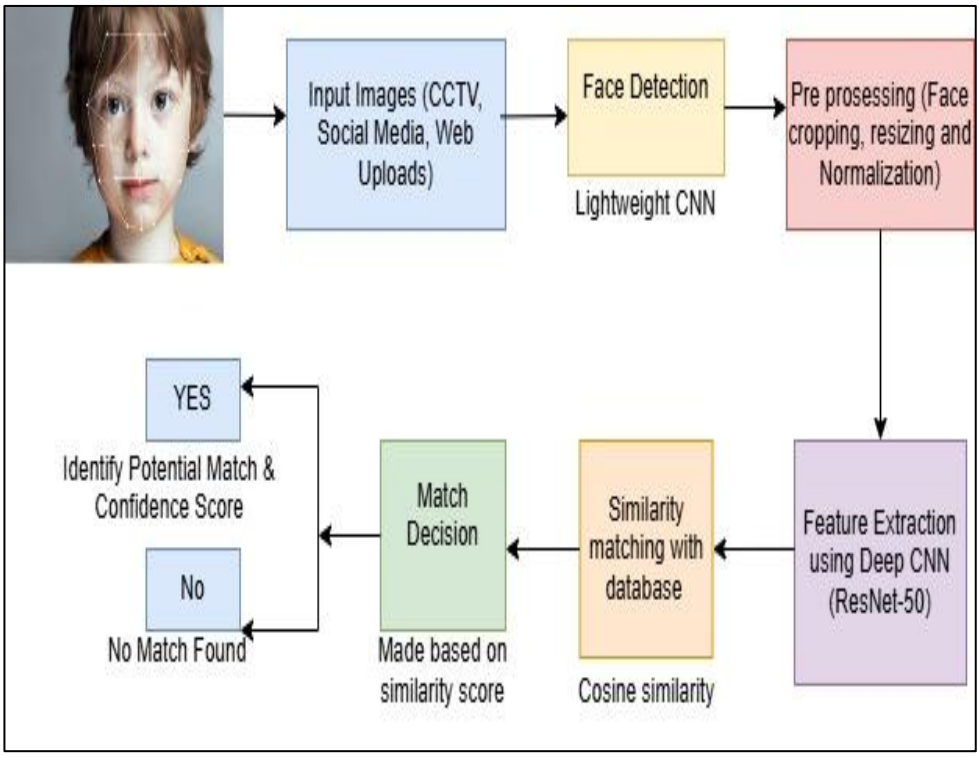

Figure 2: Missing children detection using Deep CNN.
Source: Authors, (2026).

It involves an approach that is based on deep learning and facial recognition pipeline where detection of missing children requires only visual information. It all starts with gathering the photos of the widespread origin, like the Internet, social media posting, and police cameras. The images are usually tricky with lighting, facial angles and occlusions. It uses a face detection module usually on Haar cascades or a light-weight CNN to extract facial regions out of larger images. These are then cropped face images which are resized and normalized so that there can be consistency that can be used in processing the image. In this step, the UTKFace dataset with labeled facial images providing age information are taken to approximate child-specific training data. The centerpiece of the system is deep Convolutional Neural Network (CNN), say ResNet-50, that learns high-dimensional facial embeddings in the preprocessed images. Both of the embeddings capture distinct identity-related characteristics. The CNN is supervised such that the each of the classes represents a known (missing) child. Training is an optimization of the intra-class compactness along with inter-class separability. To identify, the embedding of an input image is compared with embeddings stored in the missing child database using a measure of similarity often cosine similarity or Euclidean distance. When this similarity surpasses a preset threshold the system would indicate that it is a possible identity match and the predicted identity along with a degree of confidence is sent back. In spite of being effective in the semi-structured or structured condition, this approach has some significant limitations. It has trouble with facial differences due to expression of emotion, occlusion, aging, or change in lighting. In addition, it does not allow adding contextual information like geolocation or timestamps or descriptive meta data. Such limitations demonstrate the necessity of more powerful, multimodal models that would combine visual and contextual data to produce better real-world results.

Algorithm 1 Deep CNN-Based Missing Child Detection

Input: Image dataset $I = \{i_1, i_2, ..., i_n\}$ of missing children
Input: Query image q
Output: Identity match or "no match"

function PREPROCESSIMAGES(I)
  for each image i in I **do**
    Detect face region using a face detector (e.g., Haar or MTCNN)
    Resize and normalize the face region
  end for
  return Preprocessed image set I'
end function

function EXTRACTFEATURES(I')
  for each image i' in I' **do**
    Pass through CNN (e.g., ResNet-50) to extract feature vector f_i
  end for
  return Feature set $F = \{f_1, f_2, ..., f_n\}$
end function

function MATCHQUERY(q, F)
  Preprocess and extract feature f_q from q
  for each feature f_i in F **do**
    Compute similarity $S_i = \frac{f_q \cdot f_i}{\|f_q\| \cdot \|f_i\|}$
  end for
  Find $S_{\max} = \max\{S_1, ..., S_n\}$
  if $S_{\max} > \tau$ **then**
    return Matched Identity
  else
    return "No Match Found"
  end if
end function

Figure 3: Deep CNN-Based Missing Child Detection.
Source: Authors, (2026).

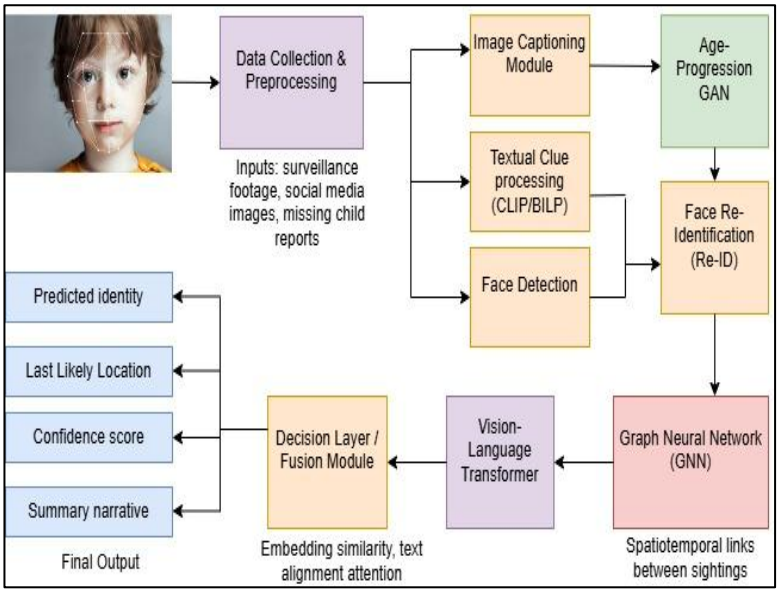

Figure 4: Missing Child detection using Vision Language and GNN.
Source: Authors, (2026).

To increase the visibility and location of missing children, the proposed system incorporates, visual, textual and relational data. It starts with gathering information about various sources such as images in social media, surveillance cameras, and unofficial reports. The image would be read through a face detector like the YOLOv8, which is able to determine and crop the right area of the face, even in difficult situations, such as occlusion, vast difference in lighting or changes in the way a person is facing. After the face-specific location is detected, face cropping takes place, and the result is fed to a Face Re-identification module based on ResNet-100 which produces high-dimensional feature embeddings that characterize the identity of a child. Such embeddings are then compared with a gallery of known missing children profiles by cosine similarity. In case the matches go beyond a certain established limit, the system will declare occurrence of a possible match. To solve the problem of long-term disappearance, an Age-Progression GAN is implemented to use in the system to produce aged versions of child faces that would produce an approximation of the appearance. Such images promote the variety of training data and the age-invariance of the Re-ID module. At the same time, textual context (e.g., the description: boy in red hoodie near school) is used to extract features with Vision-Language Transformer like CLIP, and earlier; the images and the textual description are projected into a common space of embeddings. This allows creating effective cross modal matchings between descriptive reports and visual evidence. A Graph Neural Network (GNN) is created to capture the spatial and temporal edges among sightings.

Nodes in this case represent either sightings or events and edges carry relationship information that is time-based or location-based. The GNN will carry out their reasoning process on this graph to deduce the probable patterns and paths of the missing child movement. A complement to the visual understanding is an image captioning module that comes up with the descriptive summaries of the scene i.e. clothing or surroundings. These captions are integrated and combined with other modes to fortify the situational understanding. In support of this architecture, we combine dataset by integrating child facial images in UTKFace with annotative text in MS-COCO so that both the vision-language system and Re-ID system can be trained jointly. Lastly, the results of all modules facial similarity, caption alignment, textual clues, and GNN inferences are combined using decision fusion layer to provide a single prediction. The last output, received by the system, consists of the most likely child identity, the last plausible place based on graph reasoning, the matching confidence score, and text description or summary of the scene. This allows the law enforcement to move at a fast rate and even with more context the likelihood of recovering is higher.

III.2 PSEUDOCODE:

Algorithm 1 Multimodal Missing Child Detection Framework

Input: Query image q, optional text description t, missing child database D
Output: Predicted Identity, Matching Confidence Score, Last Likely Location, Descriptive Caption
function PREPROCESS(q, t, D)
    Detect and crop face from q using YOLOv8
    Resize and normalize q
    Extract facial embeddings for q and D using ResNet-100
    if $t \neq \emptyset$ **then**
        Encode t using CLIP text encoder
    end if
    return Face embedding v_q, optional text embedding t
end function
function VISIONLANGUAGEMATCHING(v_q, t, D)
    for each entry d_i in D **do**
        Compute visual similarity $S_{vi} = \cos(v_q, v_i)$
        if $t \neq \emptyset$ **then**
            Compute text similarity $S_{ti} = \cos(t, t_i)$
            Combine scores: $S_i = \alpha S_{vi} + \beta S_{ti}$
        else
            $S_i = S_{vi}$
        end if
    end for
    return Top-k matches based on S_i
end function
function GRAPHREASONING(G)
    G: Construct graph with nodes = sightings, edges = spatial/temporal links
    for each node v in G **do**
        Update embedding:

$$h_v^{(l+1)} = \sigma\left(\sum_{u \in \mathcal{N}(v)} W^{(l)} h_u^{(l)} + b^{(l)}\right)$$

    end for
    Use final node embeddings to predict likely child movement or match
    return Ranked locations or movement trail
end function
function DECISIONLAYER($S_{\text{vision}}, S_{\text{text}}, S_{\text{graph}}$)
    Fuse scores using weighted ensemble:

$$S_{\text{final}} = \gamma_1 S_{\text{vision}} + \gamma_2 S_{\text{text}} + \gamma_3 S_{\text{graph}}$$

    if $S_{\text{final}} > \tau$ **then**
        return Predicted Identity, Matching Confidence Score, Last Likely Location, Summary Narrative
    else
        return "No match"
    end if
end function

Figure 5: Multimodal Missing Child Detection Framework.
Source: Authors, (2026).

III.3 FEATURE EXTRACTION:

The proposed framework adopts a rather dual stream feature extraction in an attempt to code textual information and visual information individually. The separation allows exploiting complementary cues between faces and descriptions and narrative accounts that can be blended in a cross-modal match later.

III.4 IMAGE-BASED FEATURE EXTRACTION:

The extraction of facial features takes place on the UTKFace dataset with varied diversity of facial images annotated with separate detail of age, gender and ethnicity. To narrow down to the target population, the data set is scaled to contain only images of children aged between 0-14 by use of a custom Python filtering script. Localization of face regions is done by a detection model, then cropped faces are fed into a deep convolutional neural network to produce high dimensional facial embedding (ResNet-100).

The discriminative identity attributes are represented in these embeddings, hence they are insensitive to lighting, pose, and partial occlusions. The resultant embeddings are used as input into the Face Re-Identification (Re-ID) sub-system where images being queried are compared to a collection of known missing children using the measure of cosine similarity in order to find possible matches.

III.5 TEXT-BASED FEATURE EXTRACTION (CONTEXTUAL & DESCRIPTIVE CLUES):

The MS-COCO 2017 dataset helps in textual feature extraction containing highly annotated captions of very diverse real-life scenes. They feed a Transformer-based text encoder, e.g. the text encoder in CLIP, on each caption to produce a semantic embedding representing the semantic content and contextual meaning of the caption. Such embeddings enable the system to associate narrative descriptions, e.g. description of the clothes or the location where these clothes were seen, with visual characteristics of the images. Embedding both modality streams in the same latent space, the model can be able to learn to associate abstract or indirect textual hints with associated visual information, even when the face is barely depicted or even dated. This increases the validity of the model as it addresses missing children reports in real life situations. The feature extraction is performed modality by modality and the embeddings are then merged so as to be represented in a collective embedding space. This allows doing robust cross-modal similarity calculations, improving the applicability of the detection in various and adverse settings.

III.6 SPATIO TEMPORAL REASONING IN CHILD RECOVERY SEARCH PRIORITIZATION:

The proper identification of missing children does not exclusively depend on the static facial recognition but requires context-sensitive search planning involving the involvement of the spatial and temporal aspects. The offered system uses both visual data (e.g. photos of the face, clothing) and context data (the last-known-location, time of disappearance). These inputs are simulated as Graph Neural Network (GNN) to deduce potential movement paths and search priorities. Being able to notionally establish high-probability areas through interrelated sightings and metadata, the system allows law enforcement to operate more efficiently and data-prodded urgently, substantially increasing the likelihood of a timely recovery.

IV. RESULTS AND DISCUSSION

UTKFace is a large scale of face images which contains more than 20,000 images of different people captured in a wide distribution of age, ethnicity and gender. In this project, during a Python preprocessing step, the images of the specified population, which are children aged 0-14, are then extracted with the logic of age-filtering. The images have all one and only face which is forward facing and some metadata such as the age, gender, and ethnicity are put on them. This renders it very suitable when it comes to age-specific facial representation. Failing to meet the requirements of operating facial recognition systems at scale due to its controlled format, as well as identity-centric labeling, UTKFace is quite suitable to train Face Re-Identification (Re-ID) module that is expected to perform face matching between incoming queries and identities stored in the database of missing children. Its regular format and population diversity guarantee that the model can be generalized well towards unseen facial input in the real-world context detection scenario.

IV.1 IMAGE +TEXT DATASET OVERVIEW:

The MS-COCO 2017 (Microsoft Common Objects in Context) dataset provides more than 120,000 real-life photographs, where every photograph has five different neutral human-made captions, which provide descriptions of certain visual aspects, such as object relations, persons, clothes, and surroundings. Not focused on missing children, the significant part of the database includes the children in different everyday situations and can be applied in the world of textual description to the image content discovery. These caption-image examples are utilized in training and fine-tuning of the Vision-Language models (e.g. CLIP) to make the system learn to match captions-based concepts (e.g., boy with red backpack) to relevant visual aspects. This text-image matching is critical in the situations that users post about missing children in free language text where the system can do cross-modal retrieval, and the contextual comprehension when detecting the situation.

IV.2 COMBINED DATASET USAGE AND FUSION STRATEGY

MS-COCO contains not only photos but the description or caption, however, it is not enough to achieve the objectives of this system as it consists of identity-labeled facial data that is absent. Similarly, although UTKFace has good quality facial images with their ages, it lacks textual information and contextual metadata. Consequently, the two sets are tactically integrated to carry out complementary functions within the envisaged multimodal framework:

UTKFace is employed in order to:

- Learn Face Re-ID module on identity-based faces.
- Educate the relation between the visual characteristics (captions) and the textual hints.
- Give caption embeddings that can be matched with visual inputs.

MS-COCO can be used for:

- Train and tune the Vision-Language module (e.g., CLIP).
- Educate the relation between the visual characteristics (captions) and the textual hints.
- Give caption embeddings that can be matched with visual inputs.

IV.3 FUSION METHODOLOGY:

The system has a shared embedding space to empower joint reasoning between an image and text modality. The cosine similarity between facial embeddings (UTKFace) and caption embeddings (MS-COCO) are compared in order to answer queries such as: “Give me a child wearing a blue hoodie close to the playground” Or match a newly captured face image with the pre-existing caption records.

The combination turns the system resilient, adaptable, and situation-sensitive, able to deal with head-on visual similarity and indirect written cues.

Example 1: Positive Match

Input:

Image: Photo of a boy who is alone somewhere close to a metro station

Caption/Report: An 8-year-old boy, with red jacket and jeans was spotted, last night, at the metro station, without anybody accompanying him.

System Output:

- **Facial Match:** The embedding of a face in an existing missing child has a high similarity with it (based on UTKFace-trained Re-ID model)
- **Textual Match:** Caption that is similar with embeddings of the vision-language model (CLIP)
- **Cross-Modal Fusion:** The sum of similarity is greater than the threshold
- **GNN Inference:** Metro approach associated with prior observation nodes
- **Confidence Score:** 93.6 percent match
- **Final Decision:** Potential match flagged
- **Output Summary:** Predicted identity, last likely location (metro station), match confidence, and caption summary

Example 2: No Match Found

Input:

Image: School uniform girl playing in the park

Caption/Report: An eye witness said he spotted a blue school uniform girl playing with others at the central plaza at about 4 PM.

System Output:

- **Facial Match:** Nearest surrounding embedding is not close
- **Textual Match:** Caption embedding has no correspondence with any report or recognized case
- **Confidence Score:** 96.1 percent mismatch
- **Final Decision:** No match has been found
- **Output Summary:** No predicted identity; no alert raised.

IV.4 MODEL PERFORMANCE:

IV.4.1 Deep CNN:

In the already trained Face Re-Identification model which uses deep CNNs, the performance shows consistency as the epochs rise. In Table 1 a summary of the model is shown which gives it a peak accuracy at epoch 30 of 92.8%, and a gain in corresponding values of precision, recall, and F1-score. Despite the fact that Figure 6 (Accuracy/Loss graph) shows the gradual decrease in training and validation loss, it also means that the process of learning is effective and minimizes the risk of overfitting. The model is hard to apply in the real world but works well in conditions of controlled images studied.

Table 1**:** Performance metrics for Deep CNN Model.

S.No	Epochs	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
1	1	78.20	75.60	76.80	76.10
2	5	82.40	80.10	81.20	80.60
3	10	85.90	83.50	84.20	83.80
4	15	87.80	86.00	86.50	86.20
5	20	89.30	87.90	88.30	88.00

IV.2 PROPOSED MODEL PERFORMANCE:

IV.2.1 Image-Based Performance (Face Re-Identification):

Face Re-ID model which is built on ResNet-100 shows a uniform increase in accuracy with the number of epochs and reaches 92.8% at epoch 30. All in all, in spite of such impediments as age differences and inadequate lighting, the model exhibits a robust identity match. As indicated, the small disassociation between training and validation curves corresponds to generalization in moderate distortion of images.

IV.3 IMAGE-CAPTION PERFORMANCE (VISION-LANGUAGE MATCHING):

The near-human performance of the Vision-Language module is the ability to learn to match the features of an image and its descriptive captions. By epoch 30, accuracy rises to 94.5% as compared to 84.3 percent. The stability of learning and caption-visual data matching is evident in the loss curve. We still have difficulties in understanding the real-world informal description, which is not simulating completely by the curated MS-COCO dataset.

Table 3: Performance metrics of Vision Language Model.

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
Face Re-ID (ResNet)	92.80	91.50	91.90	91.70
Vision-Language (CLIP)	94.50	93.40	93.60	93.30
GNN (Spatiotemporal)	97.80	97.40	97.90	97.60
Overall Multi Model Framework	98.40	97.90	98.20	98.00

IV.4 GRAPH-BASED PERFORMANCE (SPATIOTEMPORAL SEARCH REASONING):

The GNN based spatiotemporal reasoning frame assist in deducing the movement between the path through the relational information. The accuracy is 97.8 and therefore there is high reliability of predicting the zone. Trends of precision and recalls indicate fewer false alarms and greater relevancy of proposed places, which confirms the model capacity to focus its search on the places detected by witnesses and metadata use.

Table 5: Overall Performance metrics of Multi Model Framework.

S. No	Epochs	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
1	1	86.50	84.00	85.30	84.60
2	5	91.10	89.50	90.70	90.10
3	10	93.20	92.10	92.80	92.50
4	15	95.00	94.20	94.80	94.50

IV.5 OVERALL PERFORMANCE OF PROPOSED MODEL:

The final regularization action consisted of combining the results of all three modules: Face Re-ID, Vision-Language Matching, and GNN-based Spatiotemporal Reasoning into an overall performance by applying a weighted ensemble. The final scores are the summation of prediction confidence as fusing individual module via learned weight parameters within the decision layer.

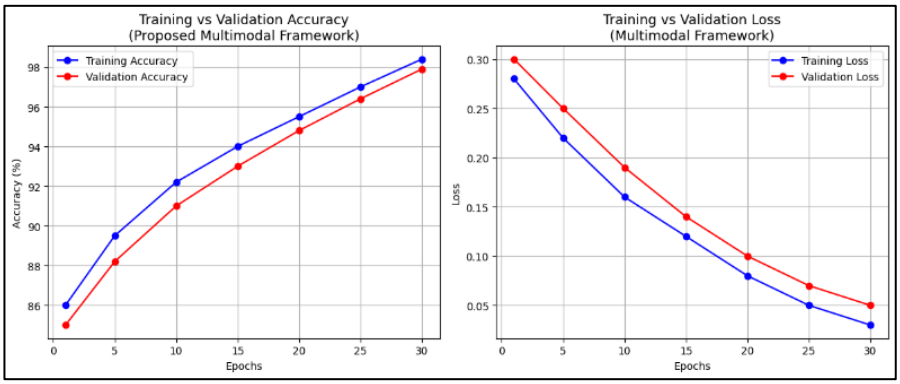

Figure 10: Training vs Validation Accuracy & Loss (for Multi Model framework).
Source: Authors, (2026).

IV.6 COMPARING MISSING CHILDREN DETECTION AMONG DIFFERENT MODELS:

The comparative analysis show that there are distinct differences in the performance of the three models. The handcrafted features source has a small level of generalization abilities, particularly in situations which are high-dimensional or in real-life missing child problems, as demonstrated by the SVM model. Extracting deep facial features with the CNN-based approach (using a ResNet-50) postponed it, the CNN-based approach (ResNet-50) is significantly better and this approach is more capable of recognizing identity under different conditions. The suggested multimodal framework based on combining Vision-Language models and Graph Neural Networks, however, performs better than the two and it does so because it can exploit more than their visual similarity, namely, descriptive text and their spatial-temporal context. This allows the more accurate, more context-driven detection and makes the system much stronger and scalable to be deployed to the real world.

IV.7 PERFORMANCE EVALUATION:

Table 6: Performance evaluation of Different Models.

Model	Training Accuracy (%)	Validation Accuracy (%)	Training Loss	Validation Loss
SVM (HOG features)	76.20	70.50	1.42	1.58
Deep CNN (ResNet-50)	91.30	87.60	0.62	0.68
MultiModel Framework	95.40	92.70	0.38	0.45

Source: Authors, (2026).

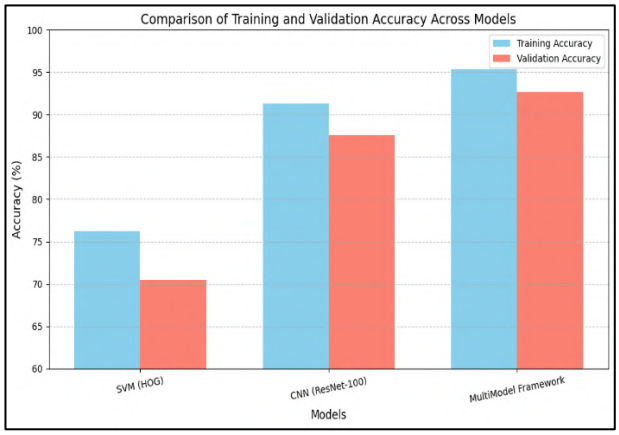

Figure 11: Comparison of Multi Model Framework with other Models.
Source: Authors, (2026).

V. CONCLUSIONS

In the proposed multimodal deep learning model the combination of facial recognition (ResNet-100), vision-language, and graph-based reasoning help in enhancing missing child detection. In contrast to the classic single-stream methods, the method incorporates features of the visual identity, text descriptions, and descriptive spatial-temporal and offers a more context-relevant and precise identification process.

The Graph Neural Network (GNN) assists to estimate the probable series of movement determined by detection and telling metadata, and the vision-language segment enhances synchronization between the spoken word accounts and photographic proof. Considered in light of the usual approaches, such as SVMs or isolated CNNs, the proposed model has a higher reliability and responsiveness factors, which is why it can be a useful tool to boost real-time recovery efforts.

ABSTRACT

The increasing complexity of cyber threats across IoT-cloud infrastructures necessitates the use of innovative, flexible, and confidentiality-preserving prevention techniques. The Blockchain-Assisted Hybrid Attention-Based Intrusion Detection and Access Control System (BHA-IDACS) is presented in this paper. The primary detection module employs an Adaptive Spatio-Temporal Representation Architecture-Self-Attention and Intersample Attention Transformer (Astra-SAINT) to precisely detect evolving intrusion tendencies. A heron optimization algorithm (HOA) is utilized for tuning the model thereby improving accuracy of detection and convergence. Fully Homomorphic Encryption (FHE) maintains the security of data and storage of encrypted data in unsecured cloud and blockchain circumstances. On a Consortium Blockchain, all encrypted transactions and audit trails are maintained by a Proof-of-Stake Authority (PoSA) consensus method. Additionally, based on user behavior and trust level, Smart Contract-Based Dynamic Access Control independently enforces permission and authentication regulations. The suggested model provides better precision, recall, F1-score, F2-score, specificity, and Cohen's Kappa values in addition to a mean accuracy of 99.16%. Furthermore, statistical analysis using confidence intervals and low standard deviation values demonstrates that Astra-SAINT is reliable and consistent across all validation folds. These results demonstrate the efficacy of the suggested Astra-SAINT framework as a scalable and dependable intrusion detection method for protecting IoT environments of the next decade.

I. INTRODUCTION

The coordination of limited resource-intensive IoT devices with cloud-based services has made ensuring security in IoT–cloud ecosystems a significant research challenge [1]. Since they are unable to adequately handle the adaptability, heterogeneity, and dynamic attack behaviors present in IoT networks, standard security solutions are typically inadequate [2]. Therefore, in order to detect advanced cyber threats in IoT cloud systems accurately and promptly, adaptive and data-driven security measures are becoming more and more necessary [3]. Due to their reliance on static rules, predetermined signatures, and centralized control structures, traditional IDS and access control systems are completely unsuitable for contemporary IoT scenarios [4]. These techniques are unable to deal with the dynamic nature of IoT traffic and are inadequate to recognize novel or evolving attack patterns. Furthermore, centralized security architectures' low scalability and single points of failure severely restrict their effectiveness in massive implementations [5]. As a result, scalable, intelligent, and adaptive security systems that are resistant to possible threats and capable of learning intricate traffic patterns are becoming more and more necessary [6]. The potential of deep learning (DL) powered IDS to identify and extract high-level information from huge volumes of network traffic data has received a lot of interest [7]. While recurrent and convolutional neural network-based models have shown promising outcomes, they often fail to grasp the intricate feature interactions and long-term temporal correlations present in Internet of Things traffic [8]. More recently, it has been shown that transformer and attention-based designs are better at simulating global contextual relationships [9]. Despite these developments, a significant research problem is still obtaining dependable detection performance in the face of extremely unbalanced data, changing attack techniques, and real-time restrictions.

IoT-cloud infrastructures must guarantee data privacy, integrity, and trust management in addition to detection accuracy [10], [11]. Sensitive information is frequently included in IoT data, and traditional encryption methods necessitate data decryption before analysis, raising the possibility of data leakage in untrusted environments. Furthermore, because user behavior and trust levels are constantly changing in IoT systems, static access control solutions are inadequate [12]. Blockchain and other decentralized technologies have shown promise as safe data management and auditability solutions; nevertheless, it is still unclear how to effectively integrate them with intelligent security methods while maintaining scalability and privacy [13]. Inspired by these difficulties, this work investigates intelligent intrusion detection, privacy-preserving processing of information, decentralized trust management, and dynamic access control within one integrated structure in order to address the shortcomings of current IoT security solutions. The ultimate goal is to ensure safe and scalable operation in next-generation IoT-cloud systems while improving detection accuracy, reliability, and consistency.

I.1 MAJOR CONTRIBUTION

- To assure reliable, secure, and scalable IoT-cloud security, a novel Blockchain-Assisted Hybrid Attention-Based Intrusion Detection and Access Control System (BHA-IDACS) is proposed.
- An advanced Astra-SAINT is developed to capture intricate temporal traffic patterns and inter-feature correlations in order to accurately identify new IoT attacks.
- FHE enables safe analysis of encrypted IoT data, while a Consortium Blockchain with PoSA consensus guarantees data integrity, auditability, and scalability.
- Throughout validation folds, standard deviation analysis and confidence intervals are used in the study's comprehensive statistical evaluation. The Astra-SAINT model's narrow confidence range and low variation demonstrate its stability, dependability, and generalizability.

Section 2 provides the related work, section 3 defines the proposed methodology framework, section 4 defines the result and discussion and section 5 ends with conclusion and future scope.

II. RELATED WORK

In order to improve IDS in IoT and cyber-physical contexts, a lot of research has been done recently on combining blockchain technology with deep learning (DL) methods. The major goals of these investigations are to promote decentralized security monitoring, preserve data integrity, and improve detection performance. While blockchain technology is used to guarantee safe, tamper-resistant data storage and ongoing verification, a variety of deep learning architectures, including convolutional neural networks (CNNs), recurrent neural networks (RNNs), bidirectional long short-term memory (BiLSTM) networks, and attention-based transformer models, have been used to successfully capture complex network traffic characteristics. However, issues with scalability, adaptation to new attack patterns, privacy protection, and computing complexity still hamper current systems. A comparative analysis of representative studies is given in Table 1, which summarizes their goals, main contributions, benefits, and drawbacks.

Table 1: Comparative Analysis of Blockchain-Enabled IDS models.

Source: Authors, (2026).

Even though previous research shows how well DL and blockchain work together for intrusion detection, there are still a number of obvious drawbacks. A number of current approaches rely on single-level feature representations, which limits their capacity to describe the intricate inter-sample correlations and spatiotemporal relationships prevalent in IoT network data. While optimization techniques can improve detection speed, they often result in significant processing cost, which restricts scalability and makes real-time implementation difficult. Furthermore, many blockchain-based solutions fall short in meeting the needs for dynamic access control and privacy-preserving processes, even while they offer data integrity and traceability. These difficulties highlight the necessity for more advanced attention-based, blockchain-enabled IDS and highlight the significance of an overall structure that can concurrently achieve high detection accuracy with realistic deployment efficiency.

III. PROPOSED METHODOLOGY

The RT-IoT2022 dataset is used by the proposed Blockchain-Driven Transformer-Based Intrusion Detection and Access Control System (BDL-IDACS) and it is shown in Figure 1. This dataset comprises real-time IoT network traffic that includes both hostile and benign activities, such as different cyberattacks. To produce high-quality representations of IoT traffic flows, the dataset first undergoes through extensive preprocessing, which includes removing noise and outliers, imputing missing values, normalizing features, and removing redundant properties. The Astra-SAINT transformer model uses self-attention, intersample attention, and spatiotemporal learning and the Heron optimization algorithm is used to tune the hyperparameters of the model to improve detection performance and convergence efficiency. Fully Homomorphic Encryption (FHE) is used to safeguard IoT traffic features and detection results in order to guarantee data privacy. The consortium blockchain, which is controlled by a Proof-of-Stake Authority consensus method, then stores all encrypted records, forecasts, and access logs. Lastly, smart contract-based dynamic access control provides a privacy-preserving security framework for IoT-cloud infrastructures by autonomously enforcing authentication and authorization decisions based on user behavior and trust level while producing real-time alerts for detected intrusions.

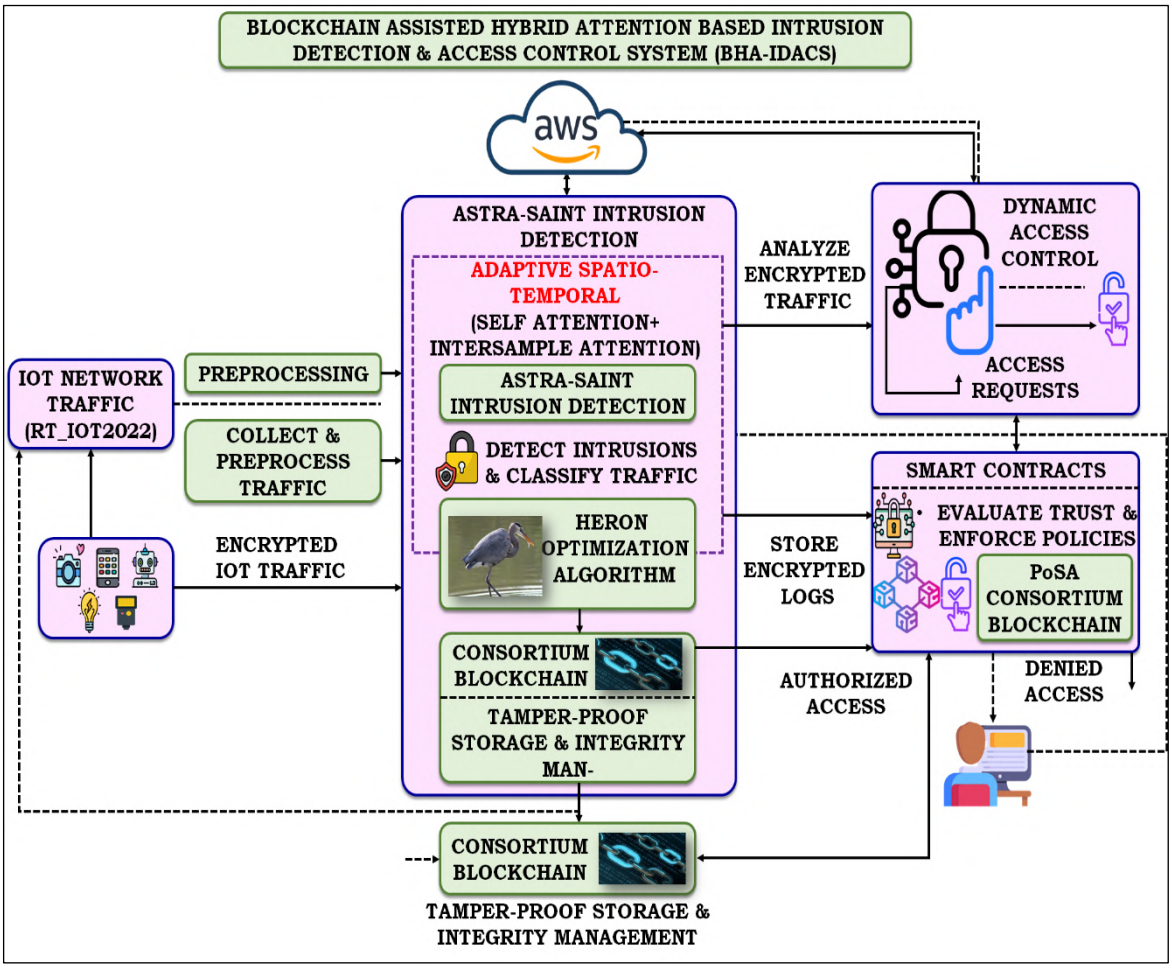

Figure 1: Overall proposed framework.
Source: Authors, (2026).

III.1 STAGE I: RT-IOT2022 DATA ACQUISITION AND PREPROCESSING

The collection and preparation of IoT network traffic obtained from the RT-IoT2022 dataset constitute the first phase of the proposed BDL-IDACS system. Let's use a multivariate feature matrix to convey the dataset:

$$X = \{x_{i,j}\} \in \mathbb{R}^{N \times D} \quad (1)$$

Where D is the number of retrieved traffic features and N is the total number of network flow instances. Every instance is associated with a real-time IoT communication record that has been classified as either normal or falling under a certain threat category. Direct use of the raw dataset might seriously impair learning performance due to the heterogeneous nature of IoT traffic as well as the existence of noise, missing values, and skewed feature distributions. In order to solve this problem, aberrant data that substantially differ from typical traffic behavior are first eliminated by outlier detection. The standardized score (z-score) of an instance i is calculated for a given feature j as:

$$z_{i,j} = \frac{x_{i,j} - \mu_j}{\sigma_j} \tag{2}$$

Where $\mu_j$and σ_j stand for the jth feature's mean and standard deviation, respectively. When τ is a predetermined threshold and which satisfy $| z_{i,j} | > \tau$ are considered outliers and eliminated from further examination. In order to maintain data accuracy, missing values in the dataset are filled by employing statistical imputation after outlier removal. Mean-based imputation is used for each missing feature value $x_{i,j}^{\text{miss}}$ as:

$$x_{i,j}^{\text{miss}} = \frac{1}{N_j} \sum_{i=1}^{N_j} x_{i,j} \tag{3}$$

Where the number of non-missing observations for feature j is represented by N_j. Feature normalization is then carried out to prevent high-magnitude features from dominating during model training and to guarantee consistent scaling across all traffic attributes. The use of min-max normalization is described as:

$$\hat{x}_{i,j} = \frac{x_{i,j} - \min(x_j)}{\max(x_j) - \min(x_j)} \tag{4}$$

where $\min(x_j)$and $\max(x_j)$ represent the j^{th}f feature's minimum and maximum values, respectively. All feature values are mapped into the interval $[0, 1]$ via this transformation.

To find replicated or poorly informative features, correlation analysis and exploratory data analysis are also carried out. A reduced feature matrix is produced by eliminating highly correlated characteristics in order to minimize multicollinearity and reduce dimensionality.

$$\mathrm{X}' \in \mathbb{R}^{N \times d}, d < D \tag{5}$$

The raw RT-IoT2022 traffic data is converted into a structured, noise-reduced, and normalized representation by various preprocessing steps, maintaining important IoT communications behavioral traits. In order to effectively understand spatiotemporal attack patterns, this revised dataset provides a solid basis for later transformer-based intrusion detection.

III.2 STAGE II: ASTRA-SAINT TRANSFORMER WITH ADAPTIVE SPATIO-TEMPORAL REPRESENTATION

III.2.1 Input Embedding and Temporal Encoding

IoT network traffic statistics show substantial temporal relationships and varied feature distributions as the consequence of constantly changing attack and communication patterns. Astra-SAINT starts by extending each preprocessed traffic instance into a dense latent space that facilitates attention-based learning in order to guarantee that such complicated properties are efficiently captured. Let $\mathrm{x}_{t,i} \in \mathbb{R}^d$ represent the i^{th}traffic incident detected at time index t. An embedding vector is mapped to this instance via a learnable embedding function $E(\cdot)$ and its mathematical expression is given below:

$$\mathbf{e}_{t,i} = E(\mathbf{x}_{t,i}) \tag{6}$$

Here, $\mathbf{e}_{t,i} \in \mathbb{R}^{d_e}$defines the embedded representation and $d_e$describes the embedding dimension respectively. Temporal ordering must be maintained since intrusion patterns frequently appear as progressive departures over time. This is accomplished by adding a temporal positional encoding vector, $\mathbf{p}_t \in \mathbb{R}^{d_e}$ to the embedded input and its expression is given below:

$$\tilde{\mathbf{e}}_{t,i} = \mathbf{e}_{t,i} + \mathbf{p}_t \tag{7}$$

In this formulation, the relative temporal position of the traffic instance within the traffic stream is encoded by $\mathbf{p}_t$, and the time-aware embedding is represented by $\tilde{\mathbf{e}}_{t,i}$. Because of this temporal enrichment, the model can distinguish between identical traffic patterns that happen at different times.

III.2.2 Adaptive Spatio-Temporal Representation Learning

Not all temporal and spatial variables are equally important for intrusion detection, even when temporal encoding maintains ordering. While certain attributes could be superfluous or noisy, others might have powerful attack signatures. Astra-SAINT introduces an adaptive spatio-temporal gating system that dynamically controls feature relevance in order to rectify this imbalance. This method calculates a gating vector and its expression is given below:

$$\mathbf{g}_{t,i} = \sigma\left(\mathbf{W}_g \tilde{\mathbf{e}}_{t,i} + \mathbf{b}_g\right) \tag{8}$$

Where $\mathbf{W}_g$and $\mathbf{b}_g$ specifies the learnable parameters, and $\sigma(\cdot)$denotes the sigmoid activation function. Next, element-wise modulation yields the gated spatio-temporal representation and it is given below:

$$\mathbf{z}_{t,i} = \mathbf{g}_{t,i} \odot \tilde{\mathbf{e}}_{t,i} \tag{9}$$

In this case, element-wise multiplication is represented by ⊙ and the adaptively weighted spatiotemporal embedding is denoted by $\mathbf{z}_{t,i}$. By reducing irrelevant variations and selectively amplifying informative aspects linked to anomalous traffic behavior, this technique improves robustness against malicious and changing intruders.

III.2.3 Self-Attention for Spatial Feature Dependency Modeling

A multi-head self-attention system then processes the gated embeddings to identify spatial correlations between characteristics in each traffic occurrence. For tabular IoT data, self-attention allows the model to establish correlations between traffic aspects rather than depending on predefined locality assumptions. The query, key, and value vectors are calculated for every $\mathbf{z}_{t,i}$ and it is defined below:

$$\mathrm{Q}_{t,i} = \mathrm{W}_Q \mathrm{z}_{t,i}, \quad \mathrm{K}_{t,i} = \mathrm{W}_K \mathrm{z}_{t,i}, \quad \mathrm{V}_{t,i} = \mathrm{W}_V \mathrm{z}_{t,i} \tag{10}$$

The learnable projection matrices are stated as $\mathrm{W}_Q, \mathrm{W}_K, \mathrm{W}_V$ and d_k represents the dimensionality of the key and query vectors. Scaled dot-product attention is used to calculate the self-attention output and it is defined below:

$$\mathrm{SA}(\mathbf{z}_{t,i}) = \mathrm{softmax}\left(\frac{\mathbf{Q}_{t,i}\mathbf{K}_{t,i}^{\mathrm{T}}}{\sqrt{d_k}}\right)\mathbf{V}_{t,i} \tag{11}$$

In this case, the self-attention function is denoted by SA(·), and the gradient magnitude is stabilized throughout training by the scaling factor $\sqrt{d_k}$. Layer normalization and residual connections are used to maintain information flow and enhance optimization stability:

$$\mathbf{h}_{t,i}^{(1)} = \mathrm{LayerNorm}\big(\mathbf{z}_{t,i} + \mathrm{SA}(\mathbf{z}_{t,i})\big) \tag{12}$$

A position-wise feed-forward network is used to further improve the obtained representation:

$$\mathbf{h}_{t,i}^{(SA)} = \mathrm{LayerNorm}\big(\mathbf{h}_{t,i}^{(1)} + \mathrm{FFN}(\mathbf{h}_{t,i}^{(1)})\big) \tag{13}$$

Here, FFN(·) signifies a two-layer feed-forward network with nonlinear activation, and $\mathrm{h}_{t,i}^{(SA)}$ denotes the spatially enriched representation.

III.2.4 Intersample Attention for Contextual and Temporal Dependency Modeling

Intrusion behavior in IoT networks frequently results from correlations across various traffic flows, even while self-attention captures feature-level interactions. Astra-SAINT uses an intersample attention mechanism that functions across traffic instances within the same temporal window in order to describe such contextual dependencies. Let $\mathrm{H}_t = [\mathrm{h}_{t,1}^{(SA)}, \mathrm{h}_{t,2}^{(SA)}, \ldots, \mathrm{h}_{t,b}^{(SA)}]$ defines the batch level feature matrix. Here, b describes the batch size. Therefore, the mathematical computation of intersample attention is defined using below equation:

$$\mathrm{IA}(\mathbf{H}_t) = \mathrm{softmax}\left(\frac{\mathbf{Q}_t\mathbf{K}_t^{\mathrm{T}}}{\sqrt{d_k}}\right)\mathbf{V}_t \tag{14}$$

Here, $\mathrm{Q}_t = \mathrm{W}_Q^{(I)}\mathrm{H}_t$, $\mathrm{K}_t = \mathrm{W}_K^{(I)}\mathrm{H}_t$, and $\mathrm{V}_t = \mathrm{W}_V^{(I)}\mathrm{H}_t$. The intersample projection matrices are stated as $\mathrm{W}_Q^{(I)}, \mathrm{W}_K^{(I)}, \mathrm{W}_V^{(I)}$ respectively. With the aid of residual normalization, the output of intersample is integrated and its mathematical formulation is given below. Alos, it is followed by feed-forward refinement.

$$\mathbf{h}_{t,i}^{(2)} = \mathrm{LayerNorm}\big(\mathbf{h}_{t,i}^{(SA)} + \mathrm{IA}(\mathbf{H}_t)_i\big) \tag{15}$$

$$\mathbf{r}_{t,i} = \mathrm{LayerNorm}\big(\mathbf{h}_{t,i}^{(2)} + \mathrm{FFN}(\mathbf{h}_{t,i}^{(2)})\big) \tag{16}$$

The ultimate contextual representation of the ith traffic instance is denoted by$\mathbf{r}_{t,i}$ which incorporates both feature-level and inter-flow dependencies.

III.2.5 Contextual Spatio-Temporal Representation Output

The model gradually improves traffic representations by stacking L_XAstra-SAINT layers, enabling the capturing of higher-order spatiotemporal interactions. The expression for the total Astra-SAINT transition is given below:

$$\{\mathbf{r}_{t,i}\}_{i=1}^{b} = S\big(\{E(\mathbf{x}_{t,i})\}_{i=1}^{b}\big), \tag{17}$$

Where the composite Astra-SAINT mapping is shown by $S(\cdot)$. Under dynamic network conditions, these contextualized representations enable precise discrimination between benign and malicious IoT data by serving as the foundation for further intrusion categorization.

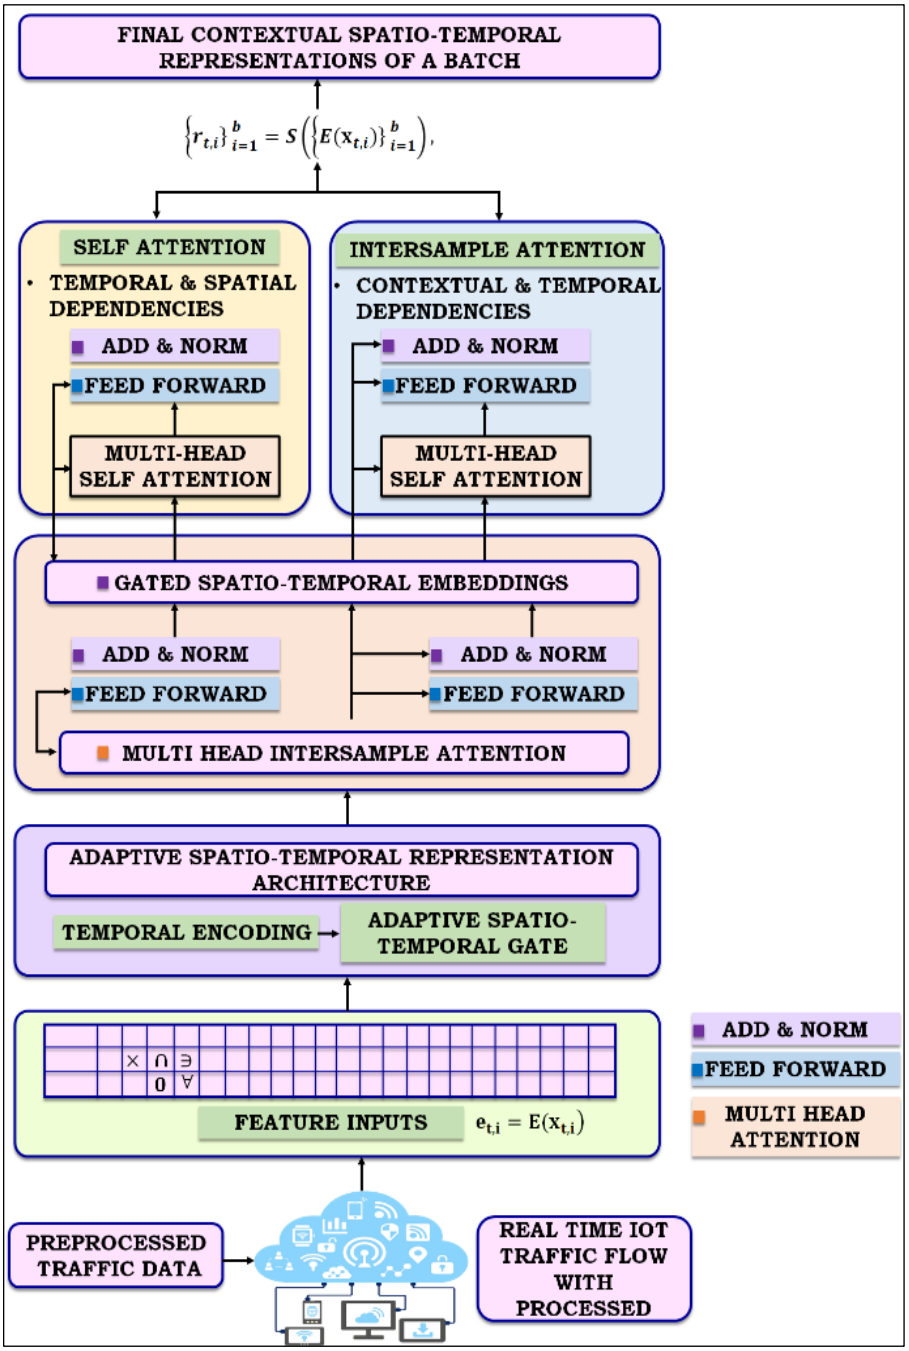

Figure 2: Architecture of Astra-SAINT Transformer.
Source: Authors, (2026).

The block-wise architecture of the suggested Astra-SAINT model is shown in Figure 2. A batch of embedded IoT traffic samples that have undergone preprocessing and feature embedding are fed into the architecture. The Astra processes these embedded inputs first. It uses temporal encoding to maintain linear dependencies and an adaptive spatio-temporal gating mechanism to dynamically highlight important temporal and spatial features of network traffic. The stacked Astra-SAINT encoder layers consisting of two complimentary attention blocks and receive the corrected embeddings. The self-attention block captures intra-sample dependencies and makes it possible to extract discriminative spatial and temporal feature interactions. In order to recognize integrated and spread attack behaviors frequently seen in IoT environments, the intersample attention block simultaneously acts across samples within the same batch to learn contextual correlations among data flows. The learnt representations are gradually enhanced by regularly stacking this self-attention and intersample attention modules. The architecture's ultimate output is a collection of contextualized spatio-temporal representations for the batch, which are used for precise intrusion classification.

III.3 STAGE III: HERON OPTIMIZATION–BASED MODEL PARAMETER TUNING

While adaptive spatiotemporal dependability and contextual relationships in IoT traffic are efficiently captured by the Astra-SAINT architecture, its ability to perform is highly dependent on the ideal configuration of model parameters, such as regularization coefficients, learning rates, and attention weights. Conventional gradient-based optimization may prematurely converge to inadequate solutions because of the dynamic nature of intrusion data and the nonconvex nature of deep transformer loss landscapes.

The suggested framework incorporates a nature-inspired Heron Optimization Algorithm (HOA) to improve convergence stability and detection accuracy in order to get over this limitation.

III.3.1 Solution Representation and Fitness Evaluation

A collection of trainable Astra-SAINT parameters and hyperparameters is represented by each potential solution in the heron population. Therefore, the initialization process is defined below:

$$\boldsymbol{\theta}_k = \{\theta_{k,1}, \theta_{k,2}, \ldots, \theta_{k,n}\} \tag{18}$$

Here, k^{th} defines the candidate parameter vector and n defines the total number of selected parameters for optimization. A fitness function generated from the intrusion detection objective is used to assess the quality of each potential solution:

$$\mathcal{F}(\boldsymbol{\theta}_k) = \alpha \cdot \mathcal{L}_{\text{cls}} + \beta \cdot \text{FPR} \tag{19}$$

Here, the classification loss of the network model is stated as $\mathcal{L}_{\text{cls}}$, false positive rate is defined as FPR, the weighting coefficients are stated as α, β. The optimizer is encouraged by this formulation to reduce both redundant security alarms and misclassification.

III.3.2 Heron-Inspired Position Update Mechanism

Herons' search behavior is demonstrated by adaptive positional updates that are impacted by both environmental exploration and the current best solution. As a result, each potential solution's position is updated as

$$\theta_k^{(t+1)} = \theta_k^{(t)} + \lambda_1 \cdot \mathrm{r}_1 \cdot (\theta_{best} - \theta_k^{(t)}) + \lambda_2 \cdot \mathrm{r}_2 \cdot (\theta_{rand} - \theta_k^{(t)}) \tag{20}$$

At iteration t, the parameter vector is stated as $\boldsymbol{\theta}_k^{(t)}$, the best solution is defined as $\boldsymbol{\theta}_{best}$, the randomly selected candidate solution is stated as $\boldsymbol{\theta}_{rand}$, $\mathbf{r}_1, \mathbf{r}_2 \in (0,1)$ specifies the random vectors, λ_1, λ_2control exploitation and exploration consecutively.

III.3.3 Integration with Astra-SAINT Training

By periodically adjusting certain parameters depending on fitness feedback, the heron optimization mechanism works in combination with Astra-SAINT training. Upon the satisfaction of the termination condition, the optimized parameter set is defined below:

$$\theta^* = \arg\min_{\theta_k} \mathcal{F}(\theta_k) \tag{21}$$

By including Heron optimization, the model achieves improved convergence behavior, fewer false alarms, and greater generalization across different IoT attack scenarios.

III.4 STAGE IV: BLOCKCHAIN-ASSISTED PRIVACY PRESERVATION AND SMART CONTRACT–BASED DYNAMIC ACCESS CONTROL

After using Heron optimization to optimize the Astra-SAINT model parameters, the IDS produces precise and extremely reliable predictions on the behavior of IoT networks. However, in actual IoT-cloud systems, merely detecting intrusions is insufficient. To allay these worries, the proposed solution includes a blockchain-assisted security layer, autonomous access control, and privacy-preserving encryption.

III.4.1 Fully Homomorphic Encryption for End-to-End Data Confidentiality

Sensitive information is encrypted using FHE before being stored or transmitted across the IoT-cloud infrastructure. For the ith traffic event at time t, let $\mathrm{y}_{t,i}$ represent the contextual representation. The ciphertext that has been encrypted is recovered as follows:

$$\mathbf{c}_{t,i} = \mathcal{E}_{pk}(\mathbf{y}_{t,i}) \tag{22}$$

The encryption using the public key pk is represented by $\mathcal{E}_{pk}(\cdot)$. In this case, pk is shared across authorized entities, and $\mathbf{c}_{t,i}$ is the encrypted output. The mathematical expression of decryption process is defined below:

$$\mathbf{y}_{t,i} = \mathcal{D}_{sk}(\mathbf{c}_{t,i}) \tag{23}$$

The decryption using the secret key sk is defined as $\mathcal{D}_{sk}(\cdot)$. This method ensures that cloud servers or blockchain validators cannot infer sensitive intrusion information from preserved ciphertexts.

III.4.2 Consortium Blockchain for Secure and Immutable Storage

Stake-based validation and authority-controlled participation are combined in the Proof-of-Stake Authority (PoSA) consensus process that powers the blockchain. Timestamps, validator signatures, encrypted data payloads, and a cryptographic hash connecting it to the preceding block are all included in each block. The kth block is denoted by B_k, which is defined as:

$$B_k = \langle H(B_{k-1}), \mathcal{C}_k, T_k, \Sigma_k \rangle \tag{24}$$

Here, the hash of the prior block is stated as $H(B_{k-1})$, T_k specifies the timestamp, $\mathcal{C}_k$ describes the set of encrypted ciphertexts and the validator's digital signature is stated as Σ_k.

III.4.3 Smart Contract–Based Dynamic Access Control

The suggested system uses smart contracts to independently implement dynamic access control rules in order to get around this limitation. Self-executing programs termed smart contracts are implemented on the blockchain and assess access requests using contextual trust metrics and pre-established security guidelines. Let T_j stand for its trust score which is based on past behavior, intrusion alarms, and policy compliance, and let U_j represent an entity requesting access to intrusion data or system resources. Access choices are made as follows:

$$\text{Access}(U_j) = \begin{cases} \text{Granted}, & \text{if } T_j \geq \tau, \\ \text{Denied}, & \text{otherwise}, \end{cases} \tag{25}$$

Where $\tau$is a pre-established trust threshold. Here, adaptive and context-aware permission is ensured by dynamically updating T_j based on the results of real-time intrusion detection. The final step guarantees that intrusion detection results are not only accurate but also safe, reliable, and useful by integrating consortium blockchain technology, smart contract-based dynamic access control, and fully homomorphic encryption. The HOA layer and the improved Astra-SAINT detection module are seamlessly integrated with this stage. The blockchain and encryption processes use the optimized predictions as inputs, and smart contracts respond instantly to detection results. Consequently, a closed-loop security architecture combining decentralized trust enforcement and intelligent intrusion detection is achieved by the proposed BDL-IDACS framework.

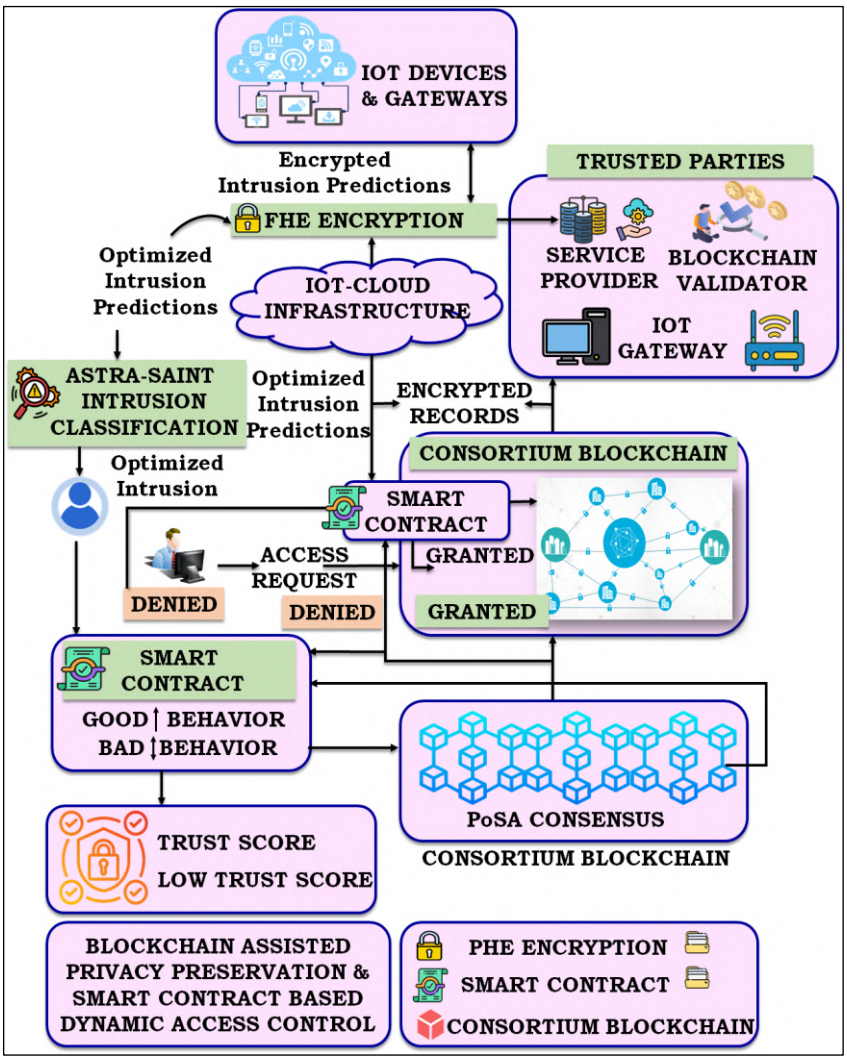

Figure 3: Blockchain-assisted privacy preservation framework.
Source: Authors, (2026).

The blockchain-assisted privacy preservation and smart contract-based dynamic access control stage is shown in figure 3. Data generated by IoT devices and gateways is first sent to the IoT-cloud infrastructure, where FHE is used to encrypt intrusion records and prediction outputs to guarantee data confidentiality throughout the course of storage and processing. By analysing the encrypted data, the Astra-SAINT intrusion classification algorithm generates optimal intrusion predictions without disclosing sensitive raw data. After that, these encrypted prediction records are sent to a consortium blockchain network, where reliable entities like IoT gateways, blockchain validators, and service providers contribute to the upkeep of a decentralized, impenetrable ledger. Smart contracts assess user or application access requests and automatically implement access control policies based on past trust scores and anticipated intrusion behavior.

The choice is permanently recorded on the blockchain, and the smart contract dynamically allows or rejects access based on whether the observed behavior is deemed evil or positive. A unified and thorough method for intelligent, secure, and privacy-preserving intrusion detection in IoT-cloud contexts is created by the proposed BDL-IDACS architecture.

IV. RESULT AND DISCUSSION

IV.1 DATASET DESCRIPTION AND EXPERIMENTAL CONFIGURATION

The proposed BDL-IDACS system is evaluated experimentally using the RT-IoT2022 dataset, a publicly available benchmark dataset from the UCI Machine Learning Repository designed for real-time IDS in IoT applications. There are 85 attributes in each of the collection's 123,117 network traffic samples that capture different protocol-level, flow-based, and statistical traits common to both benign and malicious IoT activities. These characteristics make it possible to describe intricate spatiotemporal attack behaviors in dynamic IoT-cloud infrastructures. A 5-fold cross-validation technique is divided into five mutually exclusive subsets and the model is iteratively trained and verified across all folds, is used to guarantee reliable and objective performance evaluation. For the suggested intrusion detection and access control system, this validation technique reduces overfitting, improves generalization capacity, and yields statistically reliable performance estimates.

IV.2 OUTLIER ANALYSIS OF KEY NETWORK TRAFFIC FEATURES IN RT-IOT2022

The outlier distribution of a few network traffic characteristics from the RT-IoT2022 dataset is shown in figure 4, emphasizing the extreme values and distributional skewness present in actual IoT traffic. Overall, this figure emphasizes the significance to handle outliers robustly during the preprocessing phase because, if ignored, these severe variances can negatively impact learning stability and skew intrusion classification models. The implementation of normalization and outlier-aware feature preprocessing before training the Astra-SAINT intrusion detection system is justified by the observed distributions.

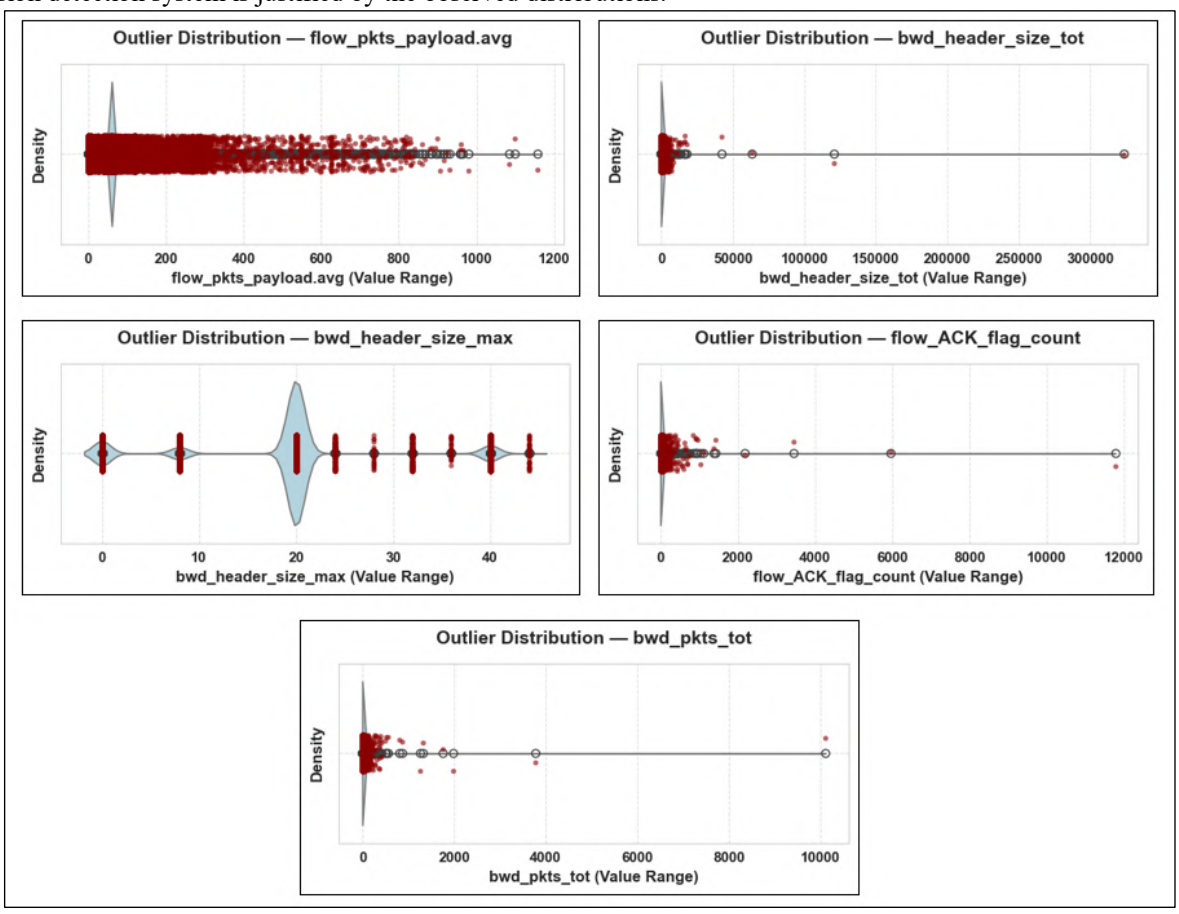

Figure 4: Outlier Distribution of Representative Traffic Features in the RT-IoT2022 Dataset.
Source: Authors, (2026).

IV.3 ATTACK AND PROTOCOL DISTRIBUTION CHARACTERISTICS OF THE RT-IOT2022 DATASET

A thorough examination of attack-type and protocol distributions is shown in figure 5. Denial-of-Service (DoS) attacks make up the majority of malicious samples are highly prevalent according to the attack distribution research. The protocol distribution analysis also shows that TCP traffic predominates in the dataset with ICMP traffic appearing only infrequently and UDP traffic making up a less significant rather than considerable percentage. The requirement for IDS models that can learn consistent and discriminative representations across majority and minority traffic classes is highlighted by this protocol imbalance. Overall, the figure emphasizes the difficulties faced by class imbalance and protocol diversity in IoT intrusion detection, highlighting the significance of attention-based modeling and strong training techniques within the suggested BDL-IDACS framework.

IV.4 CROSS-FOLD ACCURACY AND LOSS COMPARISON BETWEEN STAR-RNN AND PROPOSED ASTRA-SAINT MODELS

Using 5-fold cross-validation, Figure 6 compares the learning behavior of the basic STAR-RNN and the suggested Astra-SAINT transformer model. STAR-RNN's accuracy fluctuations over initial training epochs exhibit observable variation across various folds, with abrupt drops in validation accuracy and consequent rises in validation loss. This indicates that the model is sensitive to data partitioning and possesses limited generalization capability under some folds. As opposed to this, the Astra-SAINT model exhibits more consistent convergence patterns, much lower training loss values, and consistently achieves good training and validation accuracy across the majority of folds. Additionally, the model is robust to class imbalance and temporal unpredictability in IoT traffic, as evidenced by the small effect of moderate fluctuations in validation loss on overall accuracy. Overall, the figure 6 validates the efficacy of transformer-based attention mechanisms for IoT intrusion detection by showing that Astra-SAINT outperforms the STAR-RNN baseline in terms of convergence stability, prediction reliability, and cross-fold generalization.

Proposed STAR-RNN

Figure 6: Training and validation accuracy and loss c0urves across 5-fold cross-validation for the baseline STAR-RNN and proposed model.
Source: Authors, (2026).

IV.5 MULTI-CLASS CONFUSION MATRIX ANALYSIS OF THE PROPOSED ASTRA-SAINT MODEL

The confusion matrices acquired for the proposed model throughout all five K-fold cross-validation folds are shown in the Figure 7. A high true positive rate for all attack categories is shown by the large number of samples along the main diagonal in each fold-level matrix. The model's capacity to learn discriminative spatiotemporal representations is demonstrated by the low off-diagonal values, which indicate little misclassification of attack classes even among structurally comparable observation and scanning attacks. Consistent performance over folds is further confirmed by the aggregated confusion matrix, whose dominating diagonal elements show robustness against class imbalance and steady generalization. Due to their small sample representation, minor confusions in low-frequency attack classes are expected, but they are still insignificant. Overall, this figure validates the appropriateness of the suggested Astra-SAINT model for actual IoT–cloud security deployments by showing that it performs accurate multi-class intrusion classification with high reliability and minimum cross-class interference.

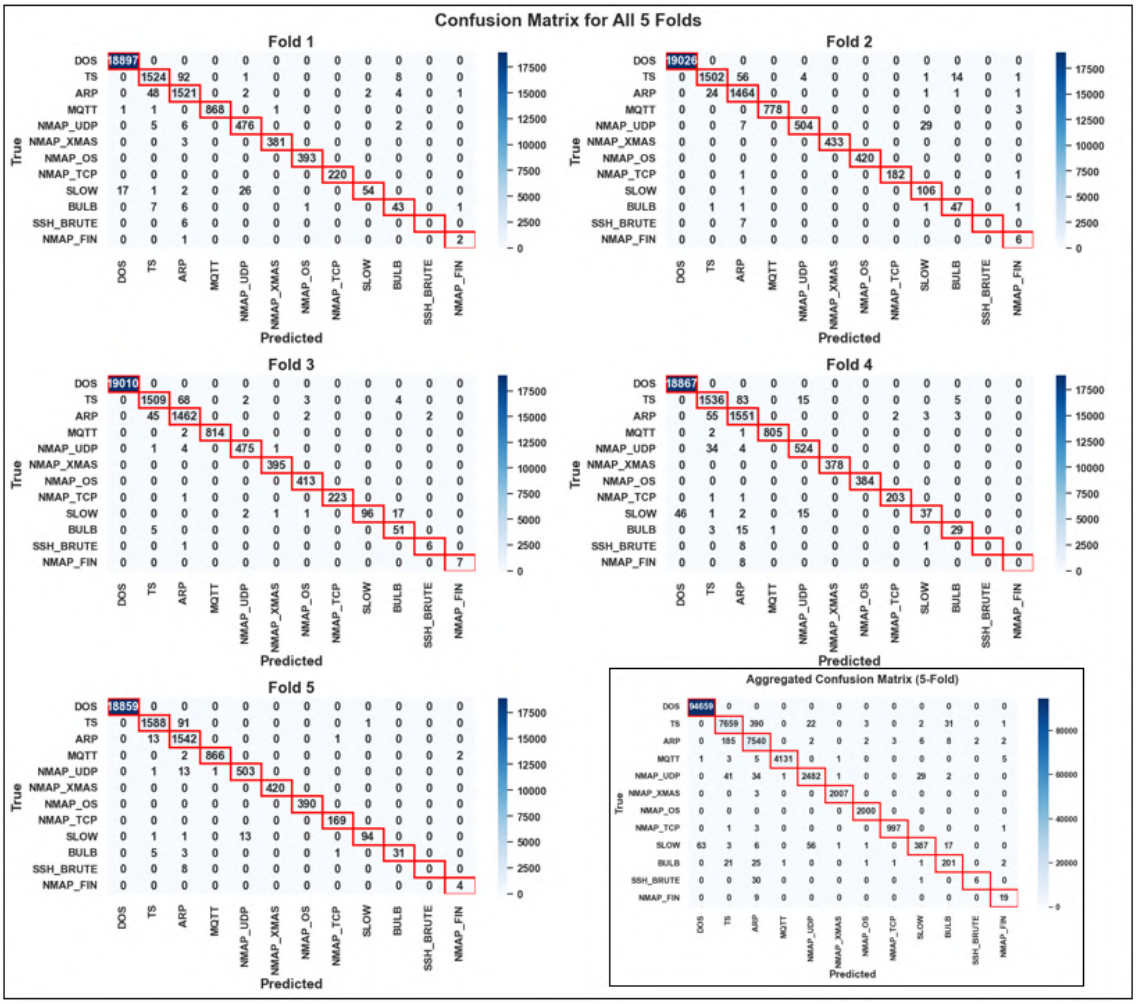

Figure 7: Confusion Matrix Analysis of the Proposed Astra-SAINT Model Across 5-Fold Cross-Validation.
Source: Authors, (2026).

IV.6 CONFUSION MATRIX ANALYSIS OF THE BASELINE STAR-RNN MODEL

The confusion matrices for the baseline STAR-RNN (Spatio-Temporal Attention Recurrent Neural Network) model across all five K-fold cross-validation folds are shown in the Figure 8. Although the diagonal entries show that STAR-RNN can accurately identify popular attack classes like DoS, TS, ARP, and MQTT, there are obvious off-diagonal values show higher misclassification rates when compared to the suggested model. Class imbalance and limited training samples are the main causes of minority attack classes. These discrepancies are further highlighted by the aggregated confusion matrix, which shows greater cross-class interference and lower diagonal dominant characteristics. Overall, the figure shows that while STAR-RNN offers respectable baseline performance, the suggested Astra-SAINT model outperforms it in terms of classification reliability and generalization ability, which encourages the use of transformer-based attention mechanisms for reliable IoT intrusion detection.

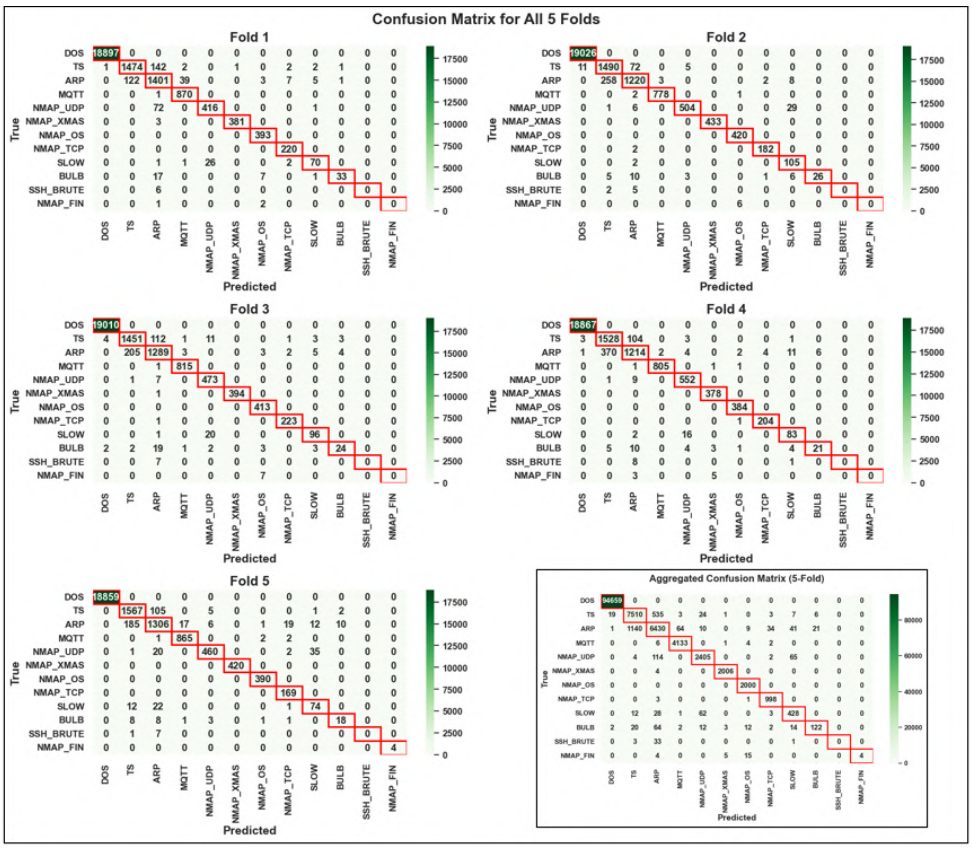

Figure 8: Confusion Matrix Analysis of the Baseline STAR-RNN Model Across 5-Fold Cross-Validation.
Source: Authors, (2026).

IV.7 ROC AND PRECISION–RECALL CURVE ANALYSIS FOR PROPOSED MODEL AND BASELINE STAR-RNN

The suggested model and STAR-RNN are contrasted in Figure 9 utilizing macro-averaged ROC and PR curves under 5-fold cross-validation. The suggested model performs better in terms of precision–recall and class discrimination especially for minority attack classes. On the other hand, STAR-RNN handles class imbalance less well, as seen by its minor decrease in ROC accuracy and lower PR performance (AP = 0.8223). Overall, the findings show that the suggsted model outperforms the baseline in terms of resilience and detection reliability.

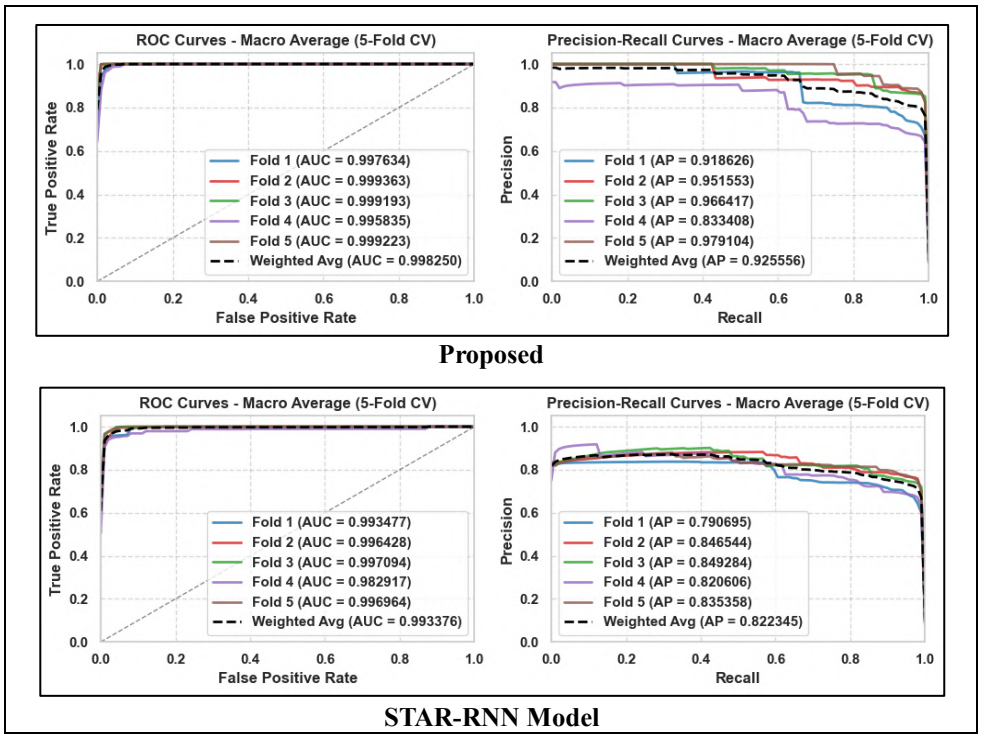

Figure 9: Comparison of ROC and Precision–Recall Curves for the Proposed Model and STAR-RNN (5-Fold Cross-Validation).
Source: Authors, (2026).

IV.8 ACCURACY STABILITY AND CONFIDENCE INTERVAL ANALYSIS FOR PROPOSED AND STAR-RNN MODELS

Figure 10 shows fold-wise accuracy trends on the right and the mean accuracy with 95% confidence intervals on the left. With a mean accuracy of 0.9916 and a narrow 95% CI of [0.9882, 0.9951], the suggested model performs incredibly consistently and dependably across folds. The STAR-RNN model exhibits relatively larger variability with a lower mean accuracy of 0.9803 and a broader 95% confidence range of [0.9772, 0.9834]. Its fold-wise trend exhibits more visible irregularities, especially a discernible decline in one-fold, indicating less resilience under different data splits. Overall, the figure makes it evident that the suggested model outperforms the baseline STAR-RNN in terms of accuracy, stability, and confidence throughout cross-validation folds. The overall performance measures of proposed and the existing method is shown in table 2.

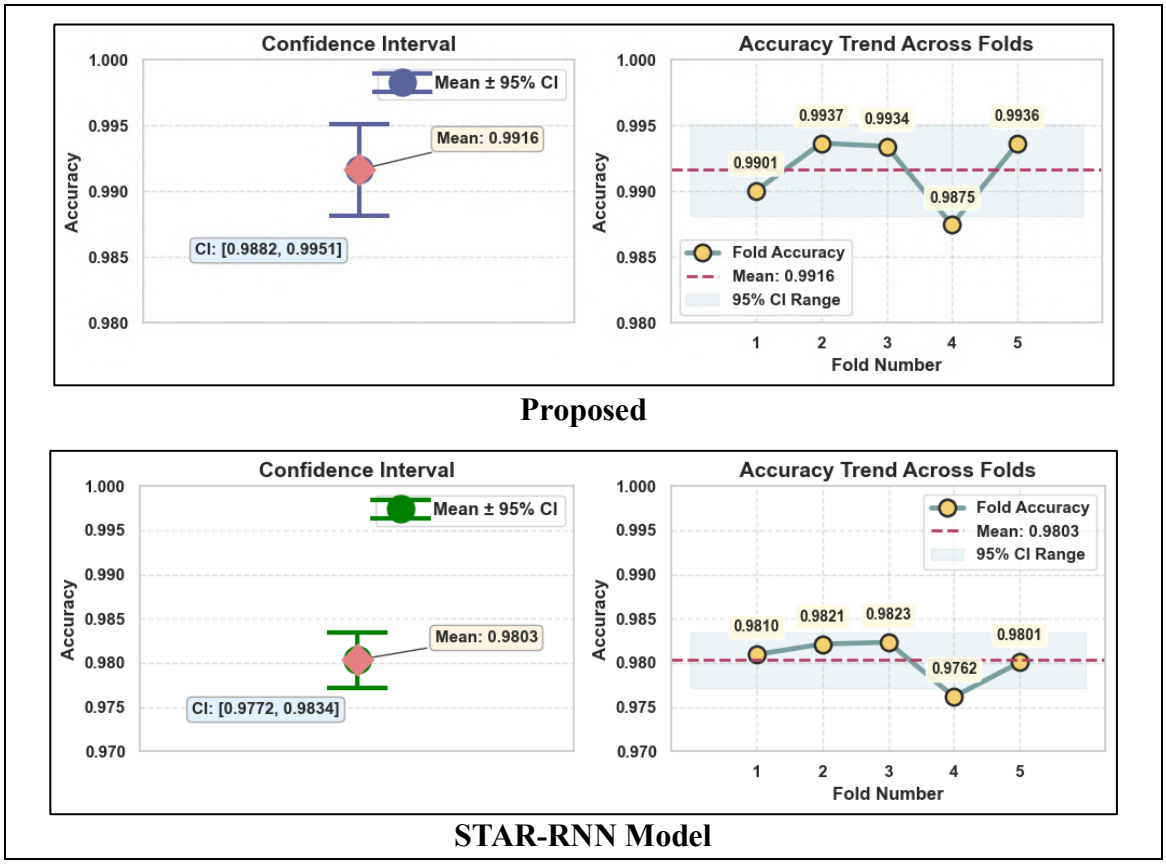

Figure 10: Accuracy Confidence Interval and Fold-Wise Performance Comparison Between Proposed and STAR-RNN Models. Source: Authors, (2026).

Table 2: Overall performance measures.

Metrics	Proposed	Existing STAR-RNN
Accuracy	0.9916	0.9803
Precision (Macro)	0.9110	0.8512
Recall (Macro)	0.8521	0.7585
F1 Score (Macro)	0.8648	0.7742
Recall (Weighted)	0.9916	0.9803
F1 Score (Weighted)	0.9915	0.9799
Cohen's Kappa	0.9790	0.9506
Specificity (Macro)	0.9991	0.9982
Specificity (Weighted)	0.9978	0.9982

IV.9 IMPLEMENTATION AND SYSTEM-LEVEL VALIDATION OF BDL-IDACS

The suggested BDL-IDACS framework's Java-based implementation and system-level validation are depicted in Figure 11. While dataset upload and management modules allow for regulated integration of RT-IoT2022 traffic data into the system, user identification and registration interfaces verify secure access activation. The preprocessing and feature-handling steps that get network traffic ready for Astra-SAINT-based intrusion analysis are represented by the file upload, dataset monitoring, and feature input displays. The monitoring interfaces enable ongoing observation of IoT behavior by reflecting real-time analysis of traffic characteristics and system parameters.

Smart contract-based dynamic access control is enforced by download and request management panels, which grant or restrict user capabilities based on trust assessment and validated intrusion predictions. Together, these interfaces verify that the suggested blockchain-assisted, privacy-preserving intrusion detection and access control framework is both operationally deployable and algorithmically effective, guaranteeing safe data handling, restricted access, and transparent auditing throughout the IoT-cloud infrastructure.

IV.10 ABLATION STUDY AND STATISTICAL PERFORMANCE COMPARISON OF MODELS

A thorough ablation analysis and statistical performance comparison between the proposed approach and three baseline architectures STAR-RNN, Transformer, and BiLSTM-CNN are shown in tables 3 and 4. With an accuracy of 0.9916, superior macro-averaged precision (0.9110), recall (0.8521), and F1-score (0.8648), the suggested model consistently obtains the best performance across all measures, demonstrating strong equal effectiveness across all attack classes, even minority classes. The ability to adapt to class imbalance is further supported by the weighted metrics, which keep near-perfect values at 0.99. The baseline models have relatively lower macro-averaged scores, which indicate that they are less successful in managing class imbalance, especially when it comes to recall and F-scores. In comparison to other models, the suggested model's higher Cohen's Kappa value (0.9790) shows a stronger agreement beyond probability. Based on mean performance, standard deviation, and 95% confidence intervals derived from cross-validation, Table 4 provides a statistical comparison of model accuracy. Strong stability and the best mean accuracy (0.9916) are demonstrated by the suggested model, which has a low standard deviation (0.0025) and a small confidence interval [0.9882,0.9951]. Although the Transformer and STAR-RNN models exhibit competitive accuracy, there is more performance variability indicated by their wider confidence ranges. Reduced consistency is highlighted by the BiLSTM-CNN model, which records the broadest confidence interval and the lowest accuracy. Overall, the findings support the suggested model's higher statistical reliability, robustness, and efficacy when compared to current DL baselines.

Table 3: Ablation study.

Metric	Proposed Model	STAR-RNN	Transformer	BiLSTM-CNN
Accuracy	0.9916	0.9803	0.9790	0.9748
Precision (Macro)	0.9110	0.8512	0.8433	0.8260
Precision (Weighted)	0.9916	0.9801	0.9790	0.9722
Recall (Macro)	0.8521	0.7585	0.7840	0.7391
Recall (Weighted)	0.9916	0.9803	0.9790	0.9748
F1 Score (Macro)	0.8648	0.7742	0.8065	0.7593
F1 Score (Weighted)	0.9915	0.9799	0.9788	0.9712
Cohen’s Kappa	0.9790	0.9506	0.9478	0.9412
Specificity (Macro)	0.9991	0.9982	0.9980	0.9971
Specificity (Weighted)	0.9978	0.9982	0.9977	0.9969
F2 Score (Macro)	0.8560	0.7630	0.7944	0.7410

V. CONCLUSION

In order to evaluate the efficacy and dependability of the suggested iIDS, this study used five-fold cross-validation on the RT_IOT2022 dataset. It is evident from experimental results that the suggested model continuously outperforms baseline techniques in every important assessment criteria. With excellent accuracy, precision, recall, F1-score, F2-score, specificity, and Cohen's Kappa all of which together demonstrate great discriminative power and reliability and the method performs exceptionally well in multi-class IoT attack detection. Confusion matrix results show strong true positive rates across almost all attack categories, and additional validation using ROC and Precision-Recall analysis indicates improved class separability and robustness under imbalanced data situations. Furthermore, the model's stability and reliable generalization across cross-validation folds are highlighted by statistical evaluation that uses low standard deviation values and narrow confidence intervals. All things considered, these findings validate that the suggested method is appropriate for actual IoT security situations that call for precise and reliable intrusion detection.

V.1 FUTURE SCOPE

Even though the suggested model performs well, there are still a number of intriguing avenues for improvement. In order to evaluate its efficacy under dynamic network settings and continuous data streams, future research can examine its deployment in real-time IoT systems. Furthermore, investigating edge-level implementation and lightweight model optimization may aid in lowering energy consumption and computing complexity, making the strategy more appropriate for IoT devices with limited resources.

ABSTRACT

Electric Vehicles (EVs) represents an excellent possibility towards developing a sustainable transport sector with low carbon emissions, low noise levels, high energy-efficient and integrate with electrical grids flexibly. Thus, the process of EV begins with data collection which involves different types of data such as voltage, current, vehicle speed, temperature, vibration and humidity to create a dataset of critical parameters. Pre-processing involves normalizing the dataset to create a consistent value for every element of data and to increase the value of the informations set. Exploratory data analysis (EDA) then lead to explore the distribution of different features in the dataset and detect any underlying or hidden patterns among the data. In feature engineering, the features are determined as critical for the performance of EV extracted from the data and used to identify potential failure modes present in EV. The Salp Swarm Optimized Attentive Radial Basis Spiking Network (ARBS-Net) is developed using a combination of benefits associated with multiple feature types, including sparse convolution, attention mechanisms and evolutionary optimization, to establish high-performance prediction and classification of fault conditions present in EV systems. This model is trained in Python and attains the maximum accuracy, precision, recall and F1-Score metrics of 0.99, thus demonstrating the proposed classification's capability to effectively predict and classify the occurrence of various fault conditions within EV systems. This intelligent diagnostic framework serves as a complete solution to implement proactive maintenance and increase EV operational reliability.

I. INTRODUCTION

Increasing reliance on EVs and increased development of electricity generation in relation to smart city control is making harder to operate. As such, EV have a large contribution to the environment when it comes to the decarbonization of individual and public transportation. When compared to traditional gasoline and diesel vehicles, EVs are more efficient in terms of energy [1]. Over the long run, EVs are considered as energy storage systems, creating numerous unique opportunities and secondary services that benefit microgrids, such as providing vehicle-to-grid capability (V2G), voltage regulation, frequency regulation, and so on. EVs, distributed energy sources, and other components associated with microgrids eventually create failures associated with these components. An EV contains many electrical devices and a long energy conversion pathway, therefore implementing a Fault Diagnosis (FD) process to maximize the service exists of the EVs. Additionally, FD process helps to increase system uptime and lower operating costs [2], [3].

An on-board microcontroller monitoring approach is employed to monitor several EV types of components, specifically the energy storage device such as batteries and supercapacitors, battery management unit, semiconductor devices, power electronic converters, electric propulsion motors and sensors [4]. EV usage has become a primary means of reducing greenhouse gas emissions associated with global warming and the cause of increasing electrical demand around the biosphere [5]. The limitation of fossil fuels, along with the number of countries that produce fossil fuels and their political instability, has further highlighted EV's importance. EV growth will continue rapidly over years across numerous countries due to government legislation aimed at growing EV market shares. As laws evolve towards achieving significant EV usage within their respective markets, electric drives and battery systems experience significant growth within EV manufacturing. The EV parts consist of multiple components, all vulnerable to various sorts of errors [6], [7]. Though, the electrical determination and sequence portions of an EV represent its core components, and typical EV component failures occur primarily within the electrical drive or battery, therefore monitoring their function is critical [8]. Some industries have a large number of electric motors and are used for many reasons including as power supplies for EV's. The transportation industry's reliability and safety requirements are necessitated by the automotive version of the EV [9]. Electrical faults, internal heat, peak performance time and electrical shifting lead to various sorts of electric motor drive faults that degrade the system's performance and reliability of the EV. Interior-Permanent Magnets Synchronized (IPMS) motors are the most commonly used motors in the EV market. The majority of other Permanent Magnet Motors (PMM) utilize similar PMSM construction with different series designed for power levels [10], [11]. Industrialists are being driven to optimize the designs of the PMSM due to increased demands for assembly and high cost materials resulting in more complex designs and increased susceptibility to failure from different types of fault mechanisms [12]. However, due to the transportation industry's demands for continuity regardless of the working atmosphere of EV motors, there are multiple varieties of errors that arise on the motor and in the driver's inverter.

Electric motor initiative errors are characterised into three primary categories such as electrical faults, mechanical faults, and sensor faults [13].Electrical faults include Interturn Short Circuit Fault (ITSF), phase to phase circuit faults, magnetic short circuit between windings and open or short circuits on inverter switching devices [14]. Mechanical faults include rotor faults including bearing faults, bent shafts, and airgap eccentricity. The faults associated with the various sensors in an electric motor are known as sensor faults. Identifying these faults early allow for corrective action to prevent costly damage and catastrophic failures from occurring [15]. In EVs, lithium-ion battery systems have established as superior to traditional energy-storage systems for EV applications. This is owed to their excellent resources such as high power, energy density, durability and environmental effects. The battery packs of EV's contain numerous cells linked together in both series and parallel arrangements, creating both redundancy and increased performance. There are many ways that faults develop in battery systems resulting in the batteries degrading quickly, accelerated aging of batteries, EV problems, and fatal accidents. The report indicated that approximately 30% of EV accidents were battery related [16], [17]. Consequently, the development of reliable error discovery and fault-lenient control systems is necessary to ensure the safety and continuity of EV operation. Nonetheless, intricate processes and other unfamiliar variables sort initial discovery of faults difficult. A method for early detection and prediction of faults is the use of FD techniques to monitor and identify the operating conditions of an electric motor [18], [19]. Therefore the proposed system uses a hybrid framework for FD in EV. The collected signals go through a normalization process as part of the preprocessing stage to ensure data consistency and the stability of learning. After preprocessing an EDA is used, where statistical and distribution-related information about the operating conditions, and fault pattern detection is gained. Feature engineering is used as the third step to extract and refine informative features [20]. Then the model training stage is executed and the existing model training methods for fault diagnosis in EV is illustrated in table 1.

Table 1: Related works for existing model training methods for fault diagnosis in EV.

SI.NO	AUTHOR/YEAR	MODELS	MERITS	DEMERITS	METRICS
1.	Debani Prasad Mishra *et al* [2024] [21]	ANN	It performs automation without requiring an in-depth model of each component, and make quick decisions for monitoring real-time failures.	The temporal nature of fault propagation resulting in a less efficient fault diagnosis.	It attains an accuracy of 96.65, precision, recall and F1-Score of 97.
2.	Venkata Satya Rahul Kosuru *et al* [2023] [22]	IB-DRN	It achieves a great level of accurateness and robustness through the extraction features and the ability to accurately learn complex, non-linear patterns.	It requires a huge quantity of labeled informations to train on and lacks sufficient interpretability of diagnosis results.	The metrics for IB-DRN is 98 of accuracy, 90 of precision, 97 of recall and 94 of F1-Score.
3.	Thirunavukkarasu *et al* [2024] [23]	CatBoost	CatBoost performs well with complex, nonlinear relationships involving both continuous and mixed categorical variables.	It does not perform optimally for large datasets and high-dimensional sensor data.	CatBoost achieves an accuracy, precision, recall and F1-Score of 94.
4.	Jasmine Sabeena *et al* [2024] [24]	SVM	SVM are excellent at processing large amounts of high dimensional data from EV sensors.	SVMs are less capable of providing real time diagnosis of failures as data size and system dynamics increase.	For SVM, the accuracy and F1-Score is 95, precision is 94 and recall is 96.
5.	Moussa Attiaa *et al* [2025] [25]	RF	It provide features that are indicative of the parameters that influence faults within a subsystem of an EV.	It becomes less effective at tracking the dynamic nature of the fault behavior over time.	RF achieves an accuracy of 95, precision of 92, F1-Score of 93 and recall of 94.

Source: Authors, (2026).

Existing methods for identifying fault diagnosis in EV have various limitations and to overcome these shortcomings, the proposed ARBS-NET framework is used to capture complex nonlinear relationships and temporal characteristics in EV faults. This procedure is further hyper-tuned by Salp Swarm Optimization (SSO) to find the best model parameters.

I.1 OBJECTIVES

The main intents of this study includes,

- To decrease the impact of noise signal and improve data quality, preprocessing method termed normalization is implemented.
- To identify data distribution and fault patterns, exploratory data analysis is utilized.
- To differentiate between faults and to eliminate irrelevant information, feature engineering is executed.
- To learn complex and nonlinear characteristics of faults, ARBS-Net is employed.
- To reduce classification error rates, avoid local minima and increase the diagnostic accuracy, SSO algorithm is performed.

II. PROPOSED SYSTEM DESCRIPTION

A SSO-enabled ARBS-Net-based framework for fault diagnosis in EVs provide highly accurate and reliable detection of operational fault occurrence through the use of multi-sensory data. The diagram of fault diagnosis in EV using Salp Swarm Optimized ARBS-NET enabled framework is displayed in figure 1.

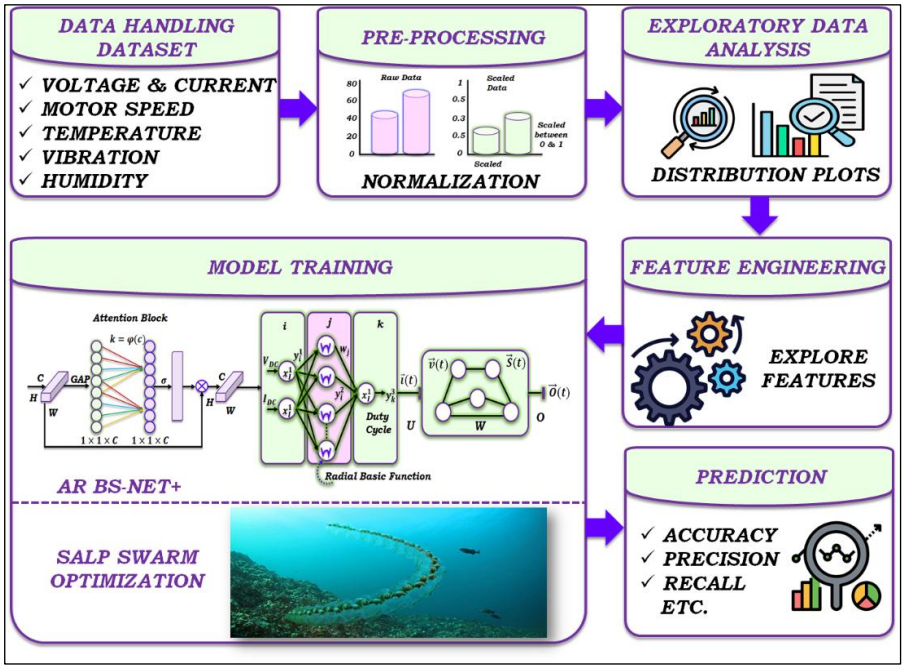

Figure 1: Proposed block diagram.
Source: Authors, (2026).

Initially, voltages, currents, motor speeds, temperatures, vibrations, humidity, and other critical parameters are collected and compiled into a single consolidated dataset. The collected data is subjected to preliminary normalization to remove scale differences among variables to improve the stability of learning and then processed further using EDA to understand the distribution and the operation of the data, before creating useful fault-related attributes to improve class separation from the features. The main feature of the proposed framework is the use of the ARBS-Net with its ability to capture nonlinear dynamics and temporal spiking of an EV component's performance. The ARBS-Net provides a robust representation of faults for diagnostic purposes. In addition, SSO is used in conjunction with the ARBS-Net, the SSO optimally tune the parameters of the ARBS-Net model, which include the network's attention weights and kernel characteristics, which reduce inaccuracies by enhancing the ARBS-Net's rate of convergence. The application of the offered framework for fault discovery and arrangement is verified through the use of standard metrics such as accuracy, precision, and recall to determine the reliability of the fault diagnosis of the EV systems.

III. PROPOSED SYSTEM MODELLING

III.1 PREPROCESSING – NORMALIZATION

III.1.1 MIN-MAX Normalization

Commonly, when diagnosing faults in EVs using multiple sensors to measure voltage, current, temperature, vibration and humidity, min-max normalization is used to standardize each of the measurements into a fixed range generally between [0,1]. Since these sensors measure the same quantity with different numerical ranges, the large numerical ranges dominate the model and reduce the ability of a diagnostic system to detect faults by an accurate model. The normalized value of a sensor measurement for min-max normalization is calculated as,

$$im_n(x,y,z) = \frac{im(x,y,z) - min(im)}{max(im) - min(im)} \quad (1)$$

The benefit of using min-max normalization is that it is computationally low-cost, and relatively easily process data on real-time systems for EVs. This method is very appropriate for range applications for EVs. Figure 2 shows the diagram of Min-Max normalization.

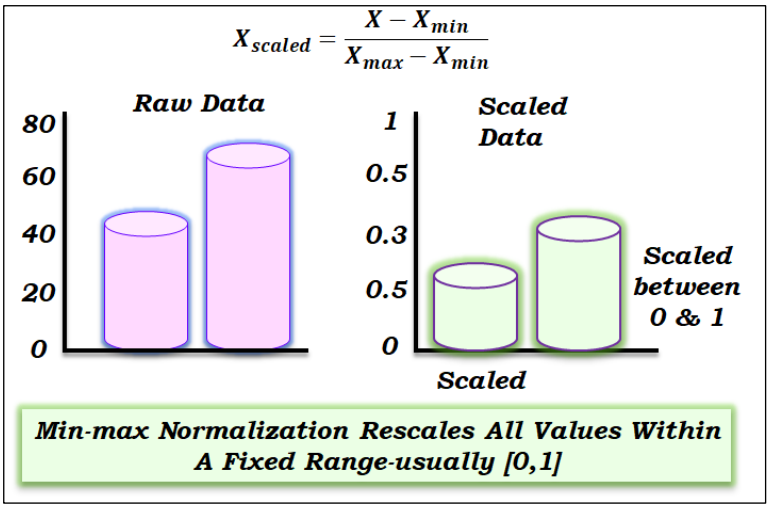

Figure 2: Min-Max normalization.
Source: Authors, (2026).

The data scaling process is done quickly and reliably along with providing information for feature representation, and allows faster processing for large amounts of sensor measurements though not having a large amount of computing overhead. It improve the fault diagnostic systems in terms of their ability to respond quickly with respect to elements such as characteristics of elements within an EV.

III.1.2 Z-Score Normalization

Sensor data from EV vary significantly depending on the type of vehicle and its operating conditions. To normalize the information of signal data from different types of EVs is to apply a Z score transformation. The Z score transformation normalizes the signal about a mean of 0 and a variance of 1, thus allowing for easier comparison and more stable models when performing data analysis. The formula for determining the normalized signal is,

$$im_n(x,y,z) = \frac{im(x,y,z) - \mu}{\sigma} \quad (2)$$

Where, μ equals the mean value of the signal and σ equals the standard deviation of the signal. By using a Z score transformation to normalize sensor data from EV, centers the signal on a mean of zero and provides an interpretation of the signal that is consistent, regardless of the type of EV. The diagram of Z-Score normalization is shown in figure 3.

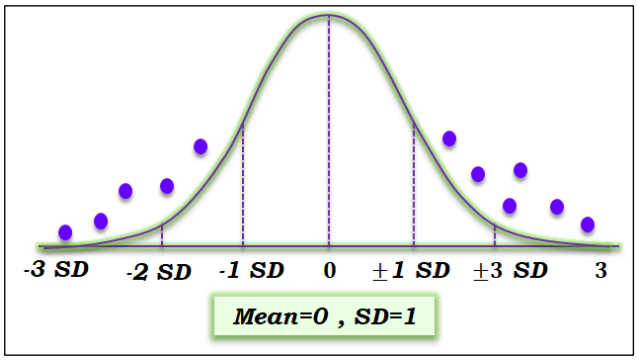

Figure 3: Z-Score normalization.
Source: Authors, (2026).

Furthermore, normalizing the data to a consistent statistical form helps facilitate the ability to effectively detect, isolate, and classify faults within the EV's subsystems such as batteries, motors, and power electronics. The Z score transformation applied to the signal data in several different ways, thus providing to improve the accurateness, reliability, and consistency of error identification for EVs.

III.2 EXPLORATORY DATA ANALYSIS

When diagnosing faults in EVs, exploratory data analysis through distribution plots shows an significant part in providing the initial insight into the characteristics of the sensor data collected from the vehicle components such as the battery management system, electric motor, power electronics, and thermal systems, prior to applying an intelligent fault detection model.

EVs produce a massive amount of data relating to these components, and distribution plots are helpful in illustrating the parameters of voltage, current, humidity, temperature, speed of a motor, and vibration signals which are statistically distributed under various operating conditions. Normal operating patterns easily identified from faulty operating patterns using distribution plots. When operating typically, an EV battery demonstrate a very tight clustering of voltages as compared to a sequence with internal faults, which establish greater spread in their distributions and present with multiple peaks in their distribution. Similarly, inverter faults naturally visible themselves with non-uniform distributions in the current and temperature outputs. All of this information gained from the distribution plots are used to identify outlier data points, data imbalances, noise, and any other hidden characteristics of the data that are not able to detect through the analysis of raw time-series data. Effective data preprocessing strategies are aided at this stage to ensure proper normalization, feature selection, and fault threshold determination through analysis of the relative distributions of healthy and faulty data. By analyzing the relative distributions of healthy and faulty states, plots are able to extract more discriminating features and reduce redundancy in the data set. By performing EDA using distribution plots, the reliability, accurateness, and stoutness of EV error analysis systems is enhanced then the method is proficient based on informations that are sensitive to faults.

III.3 FEATURE ENGINEERING

In the progression of diagnosing EV faults, the feature engineering - exploring features phase entails a further refining of the raw sensor data into useful and fault-sensitive representations of the sensor data that helps in increasing diagnostic accuracy. The battery, electric motor, inverter, and thermal subsystems continuously communicate data to the EV from their various sensors. However, raw data does not always provide a clear representation of any faults. Therefore, various feature representations from the sensor data, identify hidden patterns, relationships, and variances between normal operation and a fault. There are many statistical methods employed to represent significant features once conducting a localized search on sensors such as statistical parameter, time domain indicators, frequency domain components, energy and correlation of the different sensor readings like voltage, current, temperature, speed, and vibration. During this phase, individual attempts extract features from the various signals and assess the representative behavior of each feature during normal operations and fault conditions. Therefore, during this exploratory phase of the feature development process, all redundant or irrelevant features are deleted, while all highly discriminative features are retained to facilitate model learning. The identification of features improves the classification and measurement of faults through the use of two methods. By developing features that reduce the computational load of finding the faults, generate a higher level of fault separation and increased performance of Deep Learning fault diagnostic models. It creates an interface that captures the operating and performance characteristics of EV components thus allowing for the early identification of EV faults with more accurate classification, increases the safety of the vehicle and increases the vehicle's performance.

III.4 MODEL TRAINING - ARBS-Net

Using an attention mechanism for fault diagnosis in EV applications allows a model to focus on relevant fault data while eliminating unwanted sensor signal noise. Due to the variability of operating conditions and measurement uncertainties, EV fault data from devices like batteries, traction motors, inverters and other power conversion devices are heavily influenced by external disturbances. This noise complicates important aspects of detecting a fault. Therefore, by incorporating an attention mechanism, a diagnostic model acquires to favour more informative fault features while reducing the contributions of irrelevant or noisy feature content enhancing the robustness and accuracy of a diagnostic evaluation. This attention mechanism operates on extracted two-dimensional features in a channel-wise manner after performing convolutional processing. To allow for efficient computation with the attention mechanism, the two-dimensional features are essential to convert to a three-dimensional feature space. The three-dimensional feature space allows for inter-channel relationship modeling through cross-channel interaction modeling, enabling the network to place more emphasis on certain channels that require more distinct fault characteristics than other channels. This selective enhancement of particular channels recovers the simulation's capability to detect subtle faults and decreases the effect of noise without adding additional complexity to the structure of the model. Interactions between different channels are modelled using one-dimensional convolutional operations instead of fully connected layers, thus creating an efficient means of interaction between the channels and reducing computational burden. The extent of the convolution kernel k is adaptively determined founded on the quantity of channels C the layer ensures, allowing layers with higher numbers of channels to model more complete inter-channel dependencies. The determined convolution kernel size is expressed as follows,

$$k = \left| \frac{log_2(C)}{\gamma} + \frac{b}{\gamma} \right| \tag{3}$$

The total sum of channels is given by c where, $\gamma = 2$ and $b = 1$ are the non-linear parameters. Sequentially, after creating the global average pool channel descriptor, a 1D convolution followed by a sigmoid function generates channel attention weights. The equation for producing these weights is as follows,

$$\omega = \sigma\left(C_1 D_k(y)\right) \tag{4}$$

Where, $\sigma(\cdot)$ is the sigmoid function, $C_1 D_k(y)$ is the one dimensional convolution operation, and y is a pooled feature vector. Final output feature map is created by multiplying attention weights ω with corresponding channels in original input feature map. This amplify fault sensitive features related to degradation or failure of EV components. To detect EV subsystem failures, the RBFN uses measurable electrical and mechanical signals, which act as inputs to the RBFN network. The output of the RBFN provide a fault index that corresponds to normal or faulty operation for the underlying EV subsystem based on the inputs provided to it. The RBFN utilize three layers as part of its design such as the input layer, hidden layer, and output layer. Each of the input layer resembles directly to one of the EV diagnostic signals selected by the RBFN and are forwarded to the hidden layer. An input layer's input–output response is expressed as follows,

$$net_i^1 = x_i^1(N) \tag{5}$$

$$y_i^1(N) = f_i^1\left(net_i^1(N)\right) = net_i^1(N), where\ i = 1,2,\ldots \tag{6}$$

Where, x_i^1 expresses input variables associated with the fault and y_i^1 represents output data from a neuron in the input layer. The hidden layer of the RBFN consists of Gaussian radial basis function neurons, which model the nonlinear dynamics of the EV system under both normal and fault conditions. The hidden layer neurons correspond to membership functions related with precise error patterns or operation states. The relationship between the net input and output of the neurons in the hidden layer is provided by,

$$net_j^2(N) = \left(XM_j\right)^T \sum_j XM_j \tag{7}$$

$$y_j^2(N) = f_j^2\left(net_j^2(N)\right) = exp\left(net_j^2(N)\right), where\ j = 1,2,\ldots 800 \tag{8}$$

Here, $M_j = \left[m1_j, m2_j, \ldots mi_j\right]^T$ and $\sum_j diag\left[1/\sigma 1_j^2, 1/\sigma 2_j^2, \ldots 1/\sigma i_j^2\ \right]^T$ represent the Gaussian mean vector for fault patterns and the diagonal covariance matrix that determines the spreading of the RBF, respectively. The output layer is then a direct combination of the neuron outputs from the hidden layer in order to produce the final fault condition or fault severity level of the EV. The computation of the output layer is represented by the subsequent equality,

$$net_k^3 = \sum_j w_j\, y_j^2(N) \tag{9}$$

$$y_k^3(N) = y_{ki}^3\left(net_k^3(N)\right) = net_k^3(N) \tag{10}$$

The adjustable weights were learned during the training phase are represented as w_j. To develop the accurateness of the error diagnostics and lower computation requirements, the selection of effective RBFN inputs were made utilizing the polynomial representation of the identified function. A polynomial representation of the identified function in relation to the key features related to certain faults was constructed using the Polynomial Basis Function (PBF). The formulated equation for the EV fault diagnostics is represented as below:

$$y(t)=\sum_{k=1}^n \theta_{k\varphi_k}\left(\vec{X}(t)\right) + \varepsilon(t) \tag{11}$$

The fault indicator is denoted as, $y(t)$. $\vec{X}(t)$ is the vector of measured signals from the EV, $\varepsilon(t)$ is the modeling error, ϕ_k is an infinite number of nonlinear mapping functions and θ_k is an infinite number of linear coefficients. The system model generated for N training samples is expressed in the following equation,

$$\vec{Y} = \varphi\left(\vec{X}(t)\right) \circledast + e \tag{12}$$

Where, $\vec{Y} = [y(1), \ldots y(N)]^T$ indicates the output vector containing the fault labels and $\varphi\left(\vec{X}\right) = [\varphi_1(X), \ldots \varphi_n(X)]^T$ is the plotting function matrix. To construct the nonlinear mapping functions, use the following polynomial representation,

$$\varphi_k = \Pi_{j=n_{y1}}^{n_{yi}} y(t-j)\Pi_{k=1}^m \Pi_{j=n_{xk1}}^{n_{xki}} x_k(t-d_k-j), i = 1, \ldots p, \varphi_0 = 1 \tag{13}$$

The polynomial order allows the model to replicate the dynamic fault attributes of EV systems, thus$0 \le n_y k1 \le \ldots \le n_{yki} \le l_{y,}0 \le n_{xki} \le \ldots \le n_{xki} \le l_x, and\ l_x = 10, l_y = 3$. The general RBFN fault diagnosis model is described using the selected polynomial term orders as,

$$y(t) = \sum_{k=1}^n \theta_{k\varphi_k}\left(\vec{X}(t), c_k, \sigma_k\right) + \varepsilon(t) \tag{14}$$

Where, $\varphi_k(\cdot)$ is the Gaussian radial basis activation function with centre c_k and widthσ_k. In a similar manner, the RBFN fault diagnosis model is represented in this format.

$$\vec{Y} = \varphi(X, \vec{c}, \vec{\sigma}) \circledast + \vec{e}1 \tag{15}$$

Here, $\varphi(X, \vec{c}, \vec{\sigma})$ is the hidden layer output matrix comprised by the centre and width selections that provide robust and reliable means of detecting and classifying faults in EV systems. The structure of ARBS-Net is depicted in figure 4.

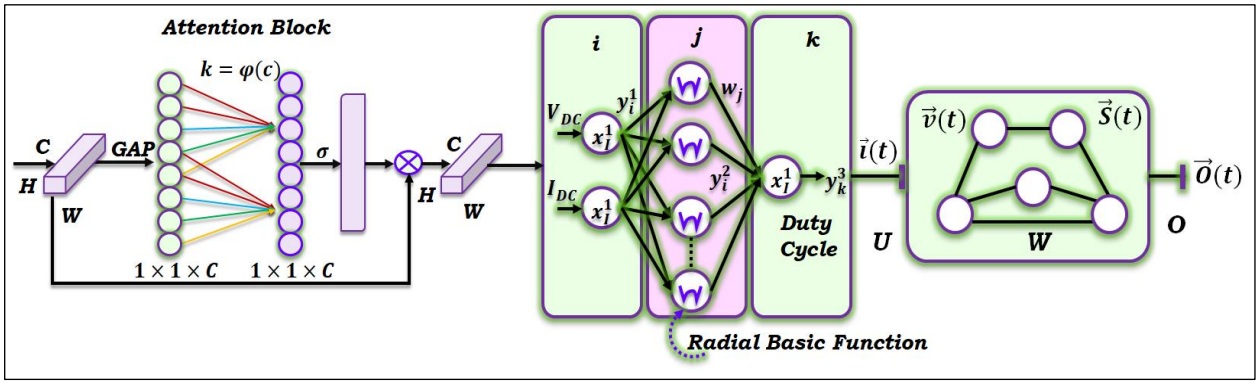

Figure 4: Structure of ARBS-Net.
Source: Authors, (2026).

A spiking neural network (SNN)-based fault diagnosis system for EVs utilizes the signals generated through measurement processes, such as battery voltage, current or temperature, as encoded neuron membrane potentials (t). When using traditional EV error analysis schemes, the actual mistake prediction mechanism is based on detecting a spike on the neuron membrane potential (t) that exceeds the predefined threshold value. Thus, fault detection occur instantaneously whenever the membrane potential exceeds the defined hard threshold causing a non-continuous fault detection response, which is expressed mathematically as,

$$\tau \dot{s} = -s + \sum_k \delta(t - t_k) \tag{16}$$

This method is sufficient for the protection of the EV from imminent failure, however, it does not provide the capability of detecting the continued gradual failure of a system, and limit the amount of time available to warn a user before failure occurs. To achieve a more sophisticated and informative fault detection capability, the hard threshold is replaced with an active fault sensitive region that is described by a gate function $g(v)$ and is defined as a narrow region in which the system is considered subject to failure due to fluctuations outside the defined threshold. In this case the synaptic dynamics is as follows,

$$\tau \dot{s} = -s + g\dot{v} \tag{17}$$

Where $g \geq 0$ and $\int g dv = 1$. In this SNN model, SNN synaptic activation gradually emerged during EV signal evolution within the active zone, inclusion of $\dot{v}$ ensures that fault representation remains rate-invariant since,

$$\int s\, dt = \int g\dot{v}\; dt = \int g\; dv = 1 \tag{18}$$

Consequently, both fast transients and slow degradations create equivalent spike-based fault evidence. This gate-based spiking functionality retains an event-driven fault semantic while facilitating differentiable, robust, and learning-compatible fault diagnosis in EV. Robust and adaptable fault diagnosis for EV is achieved by the ARBS-Net framework by means of the combination of Attention-based feature enhancement, RBFN Nonlinear mapping and SNN. The attention mechanism highlights features that are related to the fault while reducing background noise, the RBFN lower-order rules and correlations between multiple signals capture the nonlinear functional relationships within the data and thus generate a fault index, and spiking neurons support continuous and rate-invariant detection of both fast transients and gradually degrading systems. Thus, ARBS-Net provide early, accurate, and dependable identification of subsystem faults in an EV.

III.5 SALP SWARM OPTIMIZATION

In diagnosing faults with EVs, the process is modelled to find the best parameters, such as weights for features, hyper-parameters for classifiers, or thresholds for faults, which results in the maximum classification accuracy or a minimum error rate. In Salp Swarm Optimization algorithm, each salp is a candidate solution to an EV fault diagnostic problem, which is signified as a opinion in a d-dimensional search space defined by the number of decision variables in the EV fault diagnosis. The positions of each of the salps are stored in a two-dimensional matrix, denoted as X.

$$x_i = \begin{bmatrix} x_1^1 & x_2^1 & \cdots & x_d^1 \\ x_1^2 & x_2^2 & \cdots & x_d^2 \\ \vdots & \vdots & \cdots & \vdots \\ x_1^n & x_2^n & \cdots & x_d^n \end{bmatrix} \tag{19}$$

In forming the algorithms, for each salp, an objective function is utilized, based on actual data sources of EV operations such as currents, temperatures, and speeds, which produces the best defined solutions to the food positionFP. The leader salp finds its position in relation to the food source based on the following rule,

$$x_i^1 = \begin{Bmatrix} FP_i + c_1\big((ub_i - lb_i)r_1 + lb_i\big)\, r_2 \geq 0 \\ FP_i + c_1\big((ub_i - lb_i)r_1 + lb_i\big)\, r_2 < 0 \end{Bmatrix} \tag{20}$$

Where, lb_i and ub_i are the lower and upper bounds of the ith diagnostic constraint, r_1 and r_2 are uniformly distributed random numbers from [0 to 1]. The SSO uses each salp as a candidate solution within the diagnostic problem space to find the best possible diagnostic parameters by using iteratively updated leader–follower movements.

Pseudocode- Salp Swarm Optimized Attentive Radial Basis Spiking Network:

```
BEGIN
1: Load EV fault training and testing datasets
2: Split datasets into features X and labels y
3: Convert datasets into tensors and Data Loader batches
4: Define ARBSNN architecture with:
Input layer
Attentive hidden layer
Radial Basis Spiking layer
Output classification layer
5: Define objective function:
a) Initialize ARBSNN using candidate parameters
b) Train model for few epochs on training data
c) Evaluate classification accuracy on test data
d) Return fitness = 1 − accuracy
6: Initialize Salp Swarm Optimizer:
Population size P
Search dimension = 2 (hidden neurons, learning rate)
Maximum iterations Tmax
Parameter bounds (lb, ub)
7: Initialize salp positions randomly within bounds
8: Evaluate fitness of all salps
9: Select best salp as Food Source F
10: FOR iteration t = 1 TO Tmax DO
11:     Update control parameter c1
12:     FOR each salp i DO
13:         IF i == 1 THEN          // Leader salp
14:             Update salp position towards Food Source F
15:         ELSE                    // Follower salp
16:             Update salp position as average of previous salp
17:         END IF
18:         Apply boundary constraints
19:         Evaluate fitness of updated salp
20:         IF fitness improves THEN
21:             Update Food Source F
22:         END IF
23:     END FOR
24: END FOR
25: Extract optimal parameters from Food Source:
H* = optimal hidden neurons
η* = optimal learning rate
26: Initialize final ARBSNN using H* and η*
27: Train final ARBSNN model for predefined epochs
28: Evaluate training and testing accuracy and loss
29: Output trained SSO-ARBSNN model and performance metrics
END
```

Adaptive coefficient c_1 is utilised in SSO to help maintain both exploration and exploitation balance. As the algorithm iteratively searched through the solution space, it provided many opportunities to explore different fault signs at the beginning of the algorithm and systematically refine the diagnostic solution during subsequent iterations. This is especially important for closely fault signs to coupled together by varying operating conditions within EV environments. Coefficient c_1 is implemented to equilibrium exploration and exploitation in the optimization process and is given by,

$$c_1 = 2e^{-\left(\frac{4t}{t_{max}}\right)^2} \tag{21}$$

Where, t and t_{max} are used to denote current iterated value or maximum number of iterations. Finalisation of stable convergence and minimisation of the potential for premature stagnation, were made possible through leader and follower update strategies. The follower salps use leader and preceding salps to adjust their position which improves convergence stability based on,

$$x_i^j = \frac{1}{2}\left(x_i^j + x_i^{j-1}\right) \tag{22}$$

To ensure that the diagnostic solutions are constrained within the feasible operating limits of EV components, any salp that exceeds the search space is returned back into the allowable limit set by the boundary constraint. The flowchart of SSO is shown in figure 5.

$$x_i^j = \begin{cases} lb_i \; if \; x_i^j \leq lb_i \\ ub_i \; if x_i^j \geq ub_i \\ x_i^i \quad otherwise \end{cases} \tag{23}$$

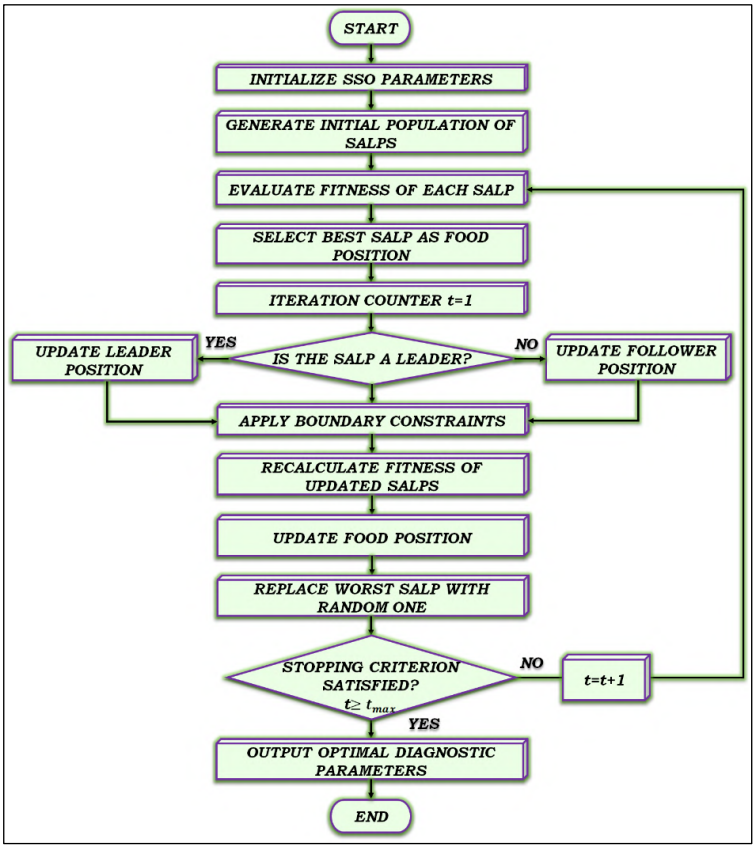

Figure 5: Flowchart of SSO.
Source: Authors, (2026).

By combining the ARBS-Net methodology using the leader-follower optimiser method and an adaptation strategy provides a balance between exploration and exploitation of actions taken by the decision maker. This research confirmed that the accuracy and operational reliability of SSO-optimized ARBS-NET successfully improve the effectiveness of EV performance. The SSO-based ARBS-NET mistake analysis produce a dependable and computationally effective classification for optimising the faults and failures of EVs, leading to improved accuracy and reliability in detecting faults. This structured process allows for the optimally constructed iterative optimisation process of all diagnostic parameters contained within the ARBS-NET providing increased accuracy of fault diagnosis performed on EV systems.

IV. RESULT AND DISCUSSION

The proposed SSO-ARBS-Net framework for diagnosing faults within EV systems is evaluated through the experimental data. The results show that integrating SSO with ARBS-Net produce substantially improved diagnostic accuracy, convergence stability and computational efficiency compared to non-optimized and conventional intelligent diagnostic approaches. Table 2 displays the report of dataset for the proposed system.

Table 2: Description of dataset.

DATASET DESCRIPTION	
Features	8
Total rows	11000
Features names	Voltage, Current, Motor Speed, Temperature, Vibration, Ambient Temperature, Humidity, Fault Label
Y label	Fault Label
Classes	Label 0: Normal Operation, Label 1: Motor-Related Faults, Label 2: Inverter-Related Faults, Label 3: Battery-Related Faults.

Source: Authors, (2026).

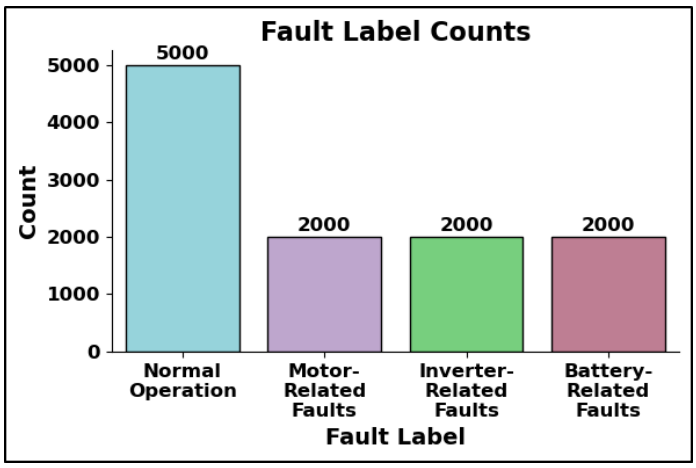

Figure 6: Fault Label Counts.
Source: Authors, (2026).

In figure 6, the data indicates that the category Usual Operation has the largest quantity of models with 5000. However, Motor faults, Inverter faults, and Battery faults each contained only 2000 samples, indicating class imbalance.

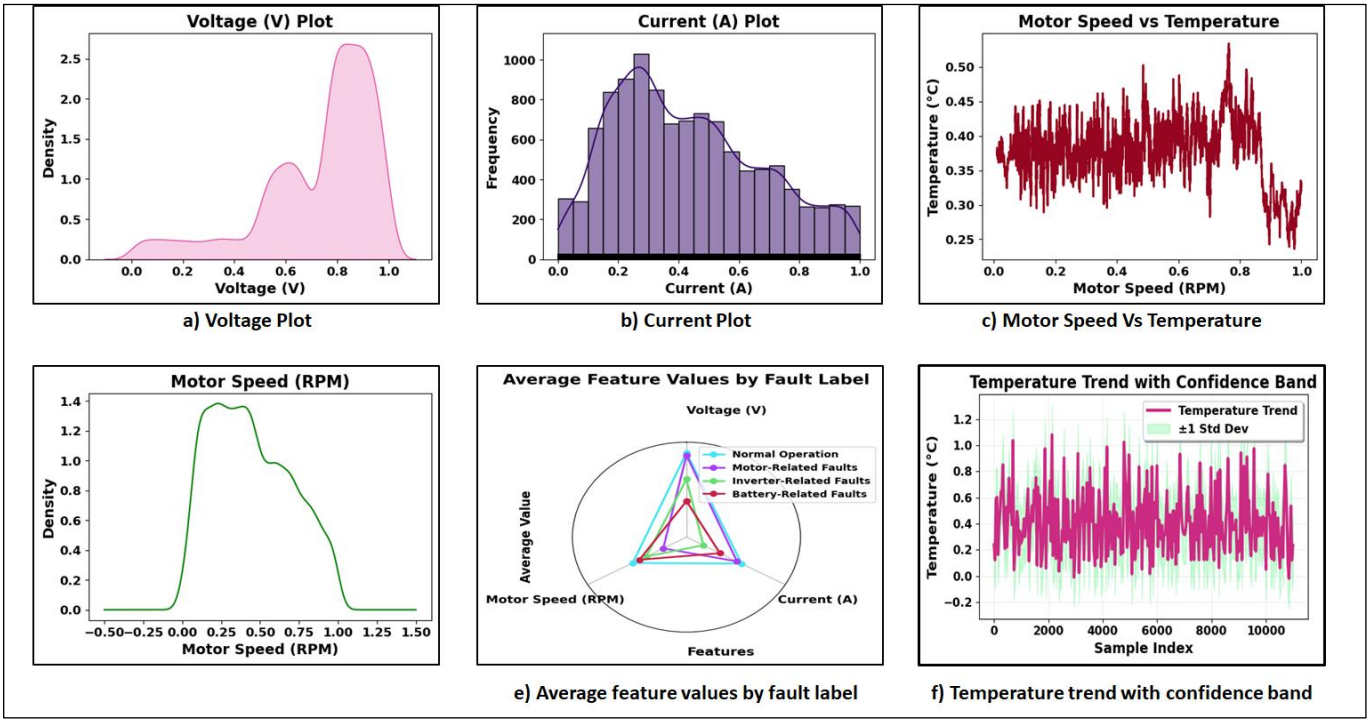

Figure 7: a) Voltage Plot, b) Current Plot, c) Motor Speed Vs Temperature, d) Motor Speed, e) Average feature values by fault label, f) Temperature trend with confidence band.
Source: Authors, (2026).

In figure 7, the data visualization has four plots such as the distribution of voltage; the distribution of motor speed; the histogram of current, and the association amongst motor speed and temperature. As a final, the average structures of the different fault classes are shown in radar chart form and the temperature trend with confidence band is displayed, both provide insight into the features behaviour and different fault classes differ under normal versus fault conditions.

Table 3: Classification report for the proposed system.

SI.NO	Performance Metrics	Values
1	Accuracy	0.99
2	Precision	0.99
3	Recall	0.99
4	F1-Score	0.99

Source: Authors, (2026).

According to the classification report in table 3, the proposed algorithm has a high accuracy, precision, recall, and F1-score of 0.99, creating it extremely accurate and providing reliable, consistent fault detection.

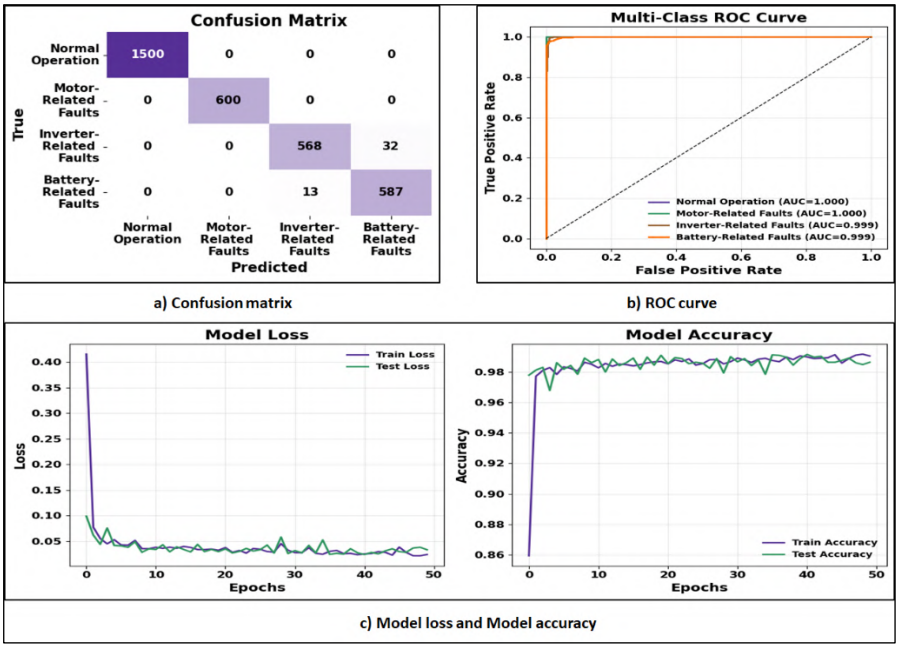

Figure 8: a) Confusion Matrix, b) ROC Curve, C) Model Loss and Model Accuracy for the Proposed System.
Source: Authors, (2026).

Figure 8 indicate a high level of confusion matrix demonstrates that very few errors occurred through all fault classes to their true classification. The ROC curves produced perfect AUC values of 1.0 which reflects excellent separability between each fault category. In addition, the model loss showed consistent decline, along with a rapid increase and stabilization of model accuracy at approximately 99%, confirming effective training of the algorithm and generalization ability.

Table 4: Classification report for Deep Neural Network.

SI.NO	Performance Metrics	Values
1	Accuracy	0.98
2	Precision	0.98
3	Recall	0.98
4	F1-Score	0.98

Source: Authors, (2026).

Table 4 illustrates a DNN to achieve an overall accuracy, precision, recall, and F1-score of roughly 98, indicating a strong performance for fault classification with very few misclassifications across the fault categories. However, the proposed system achieves the highest performance metrics.

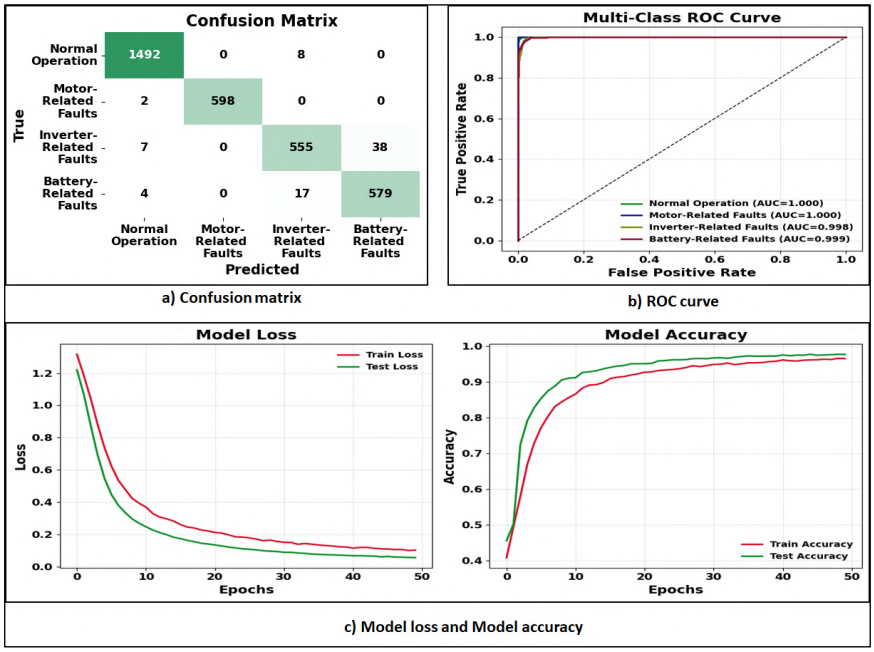

Figure 9: a) Confusion Matrix, b) ROC Curve, C) Model Loss and Model Accuracy for DNN.
Source: Authors, (2026).

In figure 9, the analysis of the confusion matrix revealed that the model potentially make several misclassifications across any of the fault types, indicating that the model has good prediction ability. The ROC curves show that the model has high AUC value 0.998-1.000 which indicates that the class separability between the faults is very high. Furthermore, as the loss decreases the model accuracy continues to increase and remains around 98 which confirms that the DNN is learning an appropriate manner to generalise the unseen data.

Table 5: Classification report for BILSTM.

SI.NO	Performance Metrics	Values
1	Accuracy	0.96
2	Precision	0.96
3	Recall	0.96
4	F1-Score	0.96

Source: Authors, (2026).

Table 5 depicts the BiLSTM model and produced 96% accuracy, 96% precision, 96% recall, and 96% F1 score which indicates that the BiLSTM performed lower level than the proposed models that achieved higher results.

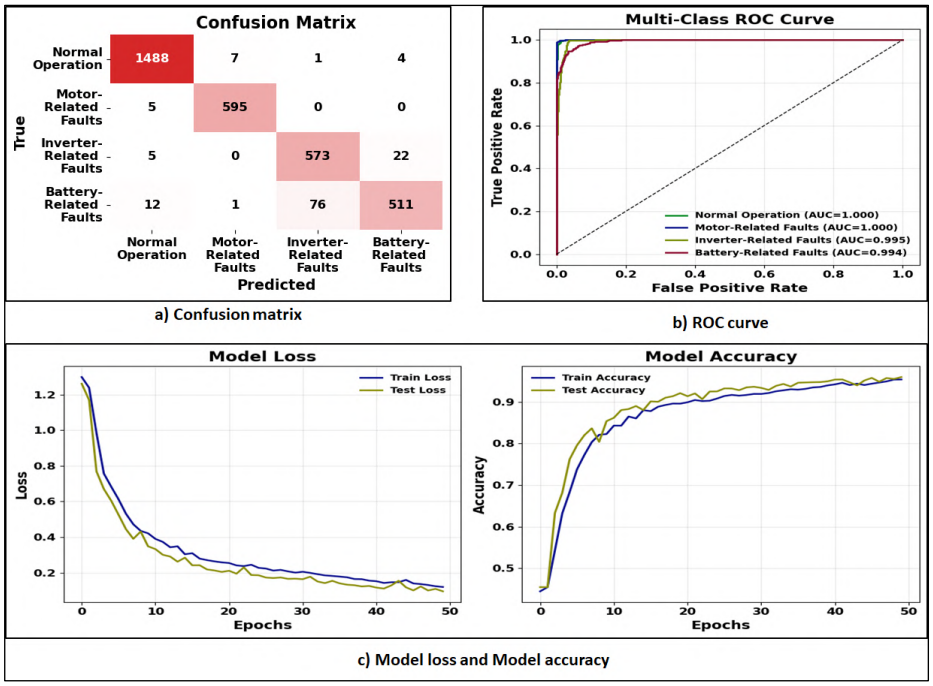

Figure 10: a) Confusion Matrix, b) ROC Curve, C) Model Loss and Model Accuracy for BILSTM.
Source: Authors, (2026).

Figure 10 shows the analysis of the confusion matrix revealed several misclassifications, predominantly within the faults associated with the battery and inverter components, however, the predictions made from the model were accurate. The ROC curves indicate high AUC values of 0.994-1.000 such that the method has a strong capability to discriminate amongst different modules. The model has produced a decrease in loss and achieved an increase in accuracy to approximately 96%, confirming that the BiLSTM is trained consistently and performs in generalisation to new data.

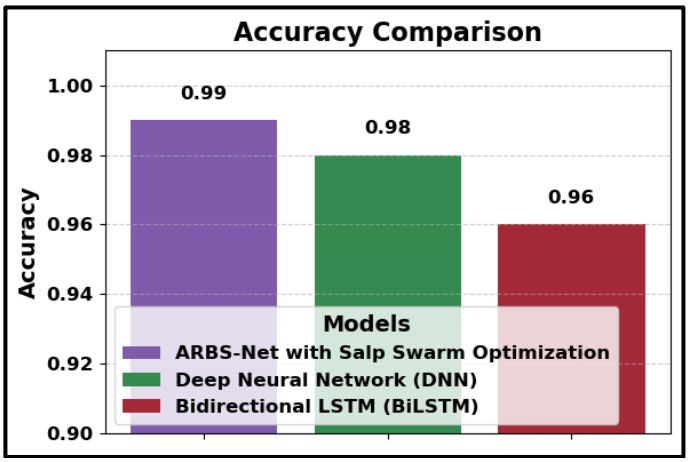

Figure 11: Comparison of accuracy.
Source: Authors, (2026).

From the accuracy comparison in figure 11, it determined that the ARBS-Net and Salp Swarm Optimisation model produced the highest accuracy (0.99), followed closely by DNN (0.98) and BiLSTM (0.96). This indicates that the proposed ARBS-Net approach has better performance than the other two systems evaluated.

Table 6: Comparison of evaluation metrics.

METRICS	PROPOSED MODEL	DNN	BILSTM
Accuracy	0.9864	0.977	0.9597
Precision	0.9815	0.9717	0.9513
Recall	0.9813	0.9703	0.9476
F1-Score	0.9812	0.9709	0.9484
Cohen Kappa	0.9804	0.9668	0.9419
MCC	0.9804	0.9669	0.9423
Hamming Loss	0.0136	0.023	0.0403
Jaccard Score	0.9638	0.9446	0.9047
Log Loss	0.0337	0.0565	0.0949
Balanced Accuracy	0.9813	0.9703	0.9476
F2-Score	0.9812	0.9705	0.9477
Zero-One Loss	0.0136	0.023	0.0403
Top-2 Accuracy	0.9997	0.9994	0.9997
Specificity	0.9958	0.9924	0.9867
G-Mean	0.9814	0.971	0.9495

Source: Authors, (2026).

In table 6, the evaluation reveals that the suggested model is higher than DNN and BiLSTM in most metrics used to evaluate models. It shows the suggested model has the best accuracy, precision, recall, F1-score, Kappa, MCC, Jaccard score, balanced accuracy, F2-score, specificity, and G-Mean of any of the models evaluated, and it produce the lowest Hamming loss, log loss, and zero-one loss. While other models produce very high Top-2 accuracies, the suggested model has the highest overall performance on all of the metrics.

Table 7: Comparative analysis of accuracy for various methods.

SI.NO	MODEL	ACCURACY
1	CATBOOST [23]	0.94
2	RF [25]	0.95
3	SVM [24]	0.95
4	ANN [21]	0.96
5	IB-DRN [22]	0.98
6	PROPOSED	0.99

Source: Authors, (2026).

Table 7 demonstrates that the suggested model has the highest accuracy (0.99) compared to CATBOOST (0.94), RF and SVM (0.95), ANN (0.96) and IB-DRN (0.98), thus confirming its superior performance to other models.

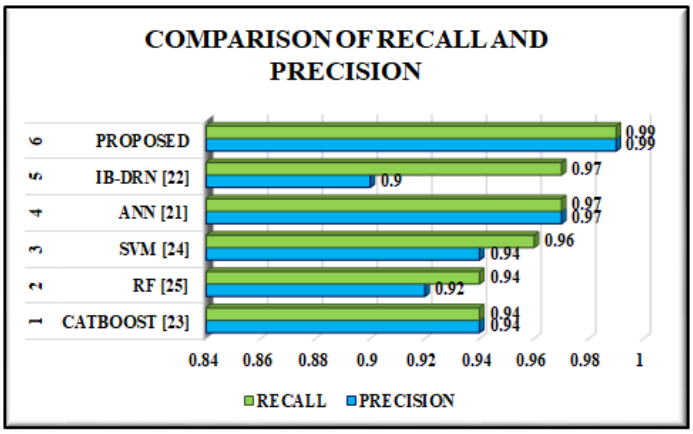

Figure 12: Comparison of recall and precision.
Source: Authors, (2026).

Figure 12 displays both recall and precision for the different models analysed. The suggested method has the maximum recall and precision (both 0.99) compared to other models including IB-DRN, ANN, SVM, RF and CATBOOST, indicating its superior and more balanced classification performance.

Table 8: Comparison of F1-Score for various methods.

SI.NO	MODEL	F1-SCORE
1	CATBOOST [23]	0.94
2	RF [25]	0.93
3	SVM [24]	0.95
4	ANN [21]	0.97
5	IB-DRN [22]	0.94
6	PROPOSED	0.99

Source: Authors, (2026).

In table 8, based on F1-scores, the proposed model is superior to the other proposed methods with respect to its F1 score of 0.99. Among the other methods tested, ANNs had an F1 score of 0.97 while SVM had an F1 score of 0.95, CATBOOST had an F1 score of 0.94, IB-DRN had an F1 score of 0.94, and RF had an F1 score of 0.93. All models performed well, demonstrating the ability to accurately classify observations, however, the proposed model outperformed every existing model by having greater accuracy and robustness relative to predictions.

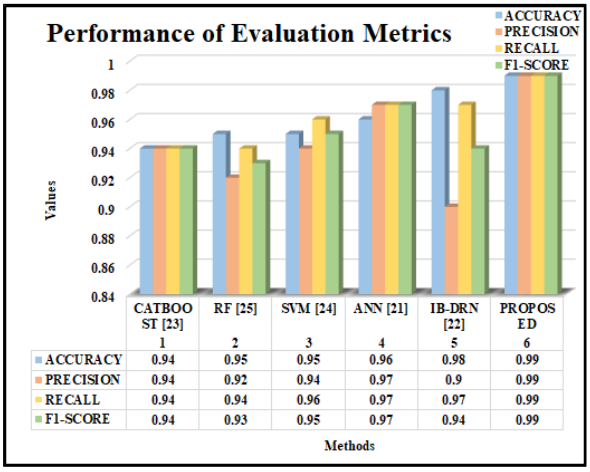

Figure 13: Comparison of performance metrics.
Source: Authors, (2026).

Figure 13 compares the accuracy, precision, recall, and F1-score of all six classifiers including CATBOOST, RF, SVM, ANN, IB-DN, and the proposed model. The proposed model outperforms all classifiers on all four measures of 0.99. IB-DN had an accuracy of 0.98 and a precision of 0.90. ANN performed consistently well throughout, while SVM and RF performed moderately. CATBOOST recorded the same performance level across all measures. Hence, the proposed model outperformed existing models for all evaluation criteria.

V. CONCLUSION

The proposed system provides a complete and intelligent framework to diagnose faults of EVs using an optimized and distributed Salp Swarm Optimized ARBS-Net. The establishment of the framework involves the acquisition of EV parameters such as voltage, current, motor speed, temperature, vibration, and humidity to create a dataset representing both electrical and mechanical characteristics of each fault. Pre-processing the dataset through normalisation improves the consistency and stability of the data for better performance when training the models. EDA provides insights into the distribution and relationship of each of the features, making it possible to locate hidden patterns in the data, which enables informed feature selection. Further, feature engineering allows for the creation of the most significant individual features connecting to fault characteristics by extraction and redundancy reduction to allow for a reduction in computational complexity when diagnosing faults. By utilizing SSO, the ARBS-Net model integrates attention mechanisms, radial basis functions, and spiking neural dynamics to create a learning model that optimizes parameters and it prevents the occurrence of local minima during training the model. Metrics used for evaluation purposes include high accuracy, precision, recall and F1-Score of 0.99. These results indicate that EV's fault conditions are correctly predicted, and thus the proposed system deliver a highly intelligent, scalable, robust and evolving diagnostic capability which allow for proactive maintenance and minimize unexpected failures and to increase the operating reliability and sustainability of EVs.

ABSTRACT

Establishing the authenticity of digital images is widely acknowledged as a crucial aspect of multimedia security since contemporary alteration techniques like copy-move, splicing, and retouching create remarkably convincing forgeries that are difficult to spot. This research proposes a Deep Learning (DL) based image forgery detection methodology that combines attention-guided segmentation and hybrid feature extraction to deliver robust tamper detection and classification. The preprocessing procedures including resizing and normalizing images are used to ensure consistent model performance. The hybrid encoder, records local texture-level inconsistencies and long-range contextual dependencies, composed of Swin Transformer modules and Residual-Dense blocks. Multi-scale feature maps that are highly discriminative for forgery cues are the outcome of this. These features are decoded using a UNet++ segmentation network that has been altered using Channel-Dual Attention (CA-DA). This improves the spatial focus and boundary precision of the projected forgery mask. The created mask is analyzed in a detection stage, where threshold-based decision-making mechanism determines if the input is genuine or forged, non-empty masks that exceed the threshold indicate tampered images, whereas actual images are represented by empty masks. The proposed system is implemented in Python software, and the results demonstrate that the proposed experimental validation on benchmark datasets indicates improved detection accuracy, robustness to noise compression, and localization clarity when compared to conventional approaches.

I. INTRODUCTION

Images and videos are attracting a lot of attention recently since they serve as the primary information source. In numerous contexts, images are utilized to convey information to various recipients. They are used in many different areas, including intelligence gathering, military operations, court testimony, social media disinformation, defamation of well-known individuals, and many more [1]. In addition to the unreliable methods of image dissemination, image manipulation compromise the legitimacy of an image. Authentication solutions were created in order to secure the image communication process [2]. There are numerous ways used for forging an image, however image manipulation techniques are usually categorized into two groups, content-changing and content-preserving. Semantic content is changed as a result of content-changing, which reshapes image content at random. The three most popular forms of image forgery detection that have been thoroughly researched are copy-move, splicing, and removal [3]. The most common type is copy-move forgery, in which a portion of the image is copied and pasted somewhere else in the same image. Contrarily, content-preserving forgeries change features like contrast, brightness, compression artifacts or noise patterns to deceive analysts rather than changing the image's semantic content. It is difficult to identify these subtle changes with conventional techniques [4]. Techniques for detecting image forgeries are broadly categorized into five groups. Geometry based techniques measure objects in the world and their positions in relation to the camera. Pixel based techniques detect statistical anomalies introduced at the pixel level. Format based techniques utilize the benefit of statistical correlations introduced by a specific lossy compression scheme [5].

Camera based techniques exploit artifacts introduced by the camera lens, sensor or on-chip post-processing and physical environment based techniques explicitly model and detect anomalies in the three dimensional interactions between physical objects, light and camera. One of the most prevalent types of tampering is copy or move forgery, which involves copying a portion of an image from one area and then passing it at more points in the same image or another image, ideally of the same scene [6]. This research illustrates the image forgery detection through various stages. The procedure commences with input image where raw data is provided to the system for forgery detection. This is followed by preprocessing where resize and normalization takes place to ensure consistent input for the model, which helps in training and inference stability [7]. In feature extraction, it extracts high level features from the input image using a hybrid model. The extracted features are then segmented to produce a pixel-wise segmentation mask indicating forged images. A predicted pixel mask highlighting suspected forged regions in the image. Then the mask is subjected to a threshold by the detection module and if exceeded, it marks the image as forged [8]. Convolutional Neural Networks (CNNs) have become increasingly popular in image detecting community throughout the past ten years. In order to identify the optimal features for categorizing image models, these algorithms have concentrated on training the CNN. CNN has the benefit of immediately extracting features from the image collection. The main benefit of CNN is that immediately extract classification features from image data. However, it is quite challenging to comprehend the generated image identification model and it reliance on a particular training dataset [9].

VGG operates by recursively partitioning the feature space into branches based on feature values, resulting in a tree structure with each leaf node representing a class label, authentic or fabricated. This makes VGG simple, interpretable, and easy to apply. However, it has a tendency to over fit training data, which is sensitive to noise in features, and has worse accuracy for complicated or nuanced forgeries [10]. To further enhance the performance of the detection model, segmentation methods are utilized. SegNet identify image forgeries by automatically learning hierarchical features from raw images. Convolutional layers extract local patterns, edges, and textures first, followed by non-linear activation functions such as ReLU. Pooling layers lower spatial dimensions while keeping crucial properties, and fully connected layers combine these qualities to determine whether an image is legitimate or faked. Back propagation is used to train the network and minimize a loss function while also optimizing feature representations [11]. However, their effectiveness in automatic feature learning it requires a considerable amount of labeled data, which are computationally costly and fail to catch long-range or global discrepancies, and might overlook very subtle or sophisticated forgeries [12]. To overcome these limitations, this research proposes a hybrid Residual-Dense Swin transformer for feature extraction encoder and UNet++ with CA-DA for segmentation encoder. This provides a predicted forgery mask that highlights potential altered places. The detecting stage assesses this mask to establish the image's validity. If the anticipated mask exceeds a predefined threshold, the image is classified as fabricated otherwise, an empty mask is classified as authentic.

I.1 RELATED WORKS

By [13**]** have proposed a feature extraction based LeNet-5 for detecting fake media content. LeNet-5 method processes and analyzes textual information by transforming text data into numerical representations like TF-IDF, Bag-of-Words or word embedding. This procedure enables LeNet-5 to detect bogus news on social media. In order to distinguish between fake and real postings using the attributes that were retrieved, it then learns a hyperplane in a high-dimensional space. However, it struggles with noisy and high-dimensional social media data, including slang, abbreviations, and grammatical errors which reduce the overall classification accuracy. By [14] have developed a fast and robust speckle pattern authentication with the Scale Invariant Feature Transform (SIFT) Algorithm in Physically Unclonable Functions (PUF). The use of SIFT with the Challenge Response Pairs (CRPs) protocol allows us to correctly authenticate a client while blocking any other fraudulent access. In this approach, the authentication procedure is highly trustworthy even in the face of answer rotation, zooming, and cropping, which might occur in consecutive PUF interrogations and to which other post processing algorithms are quite susceptible. Nonetheless, the analysis methodologies used are highly sensitive to minor alterations in the speckle pattern, which lead to failure in PUF authentication due to changes in position, illumination, or rotation. By [15] have presented an image forgery detection based on Histogram of Oriented Gradients (HOG) feature extraction. It is generated by combining edge orientations caused by image alteration into a one-dimensional histogram of specified image regions. The suggested method collects HOG characteristics from the YCbCr colour space and applies them to the discrete wavelet transform's high-frequency subbands.

These collected features are then fed into a classifier, which determines whether the image is legitimate. Nevertheless, HOG features primarily collect edge and gradient information, which is insufficient to detect forgeries that do not drastically change these characteristics. By [16] have established a forged image detection based on clustering algorithms and transform domain feature analysis. The proposed method is highly effective in terms of detection accuracy, offering a viable solution to the issues of modern multimedia manipulation. Texture features are retrieved using the Discrete Wavelet Transform (DWT) technique, which improves the resilience and reliability of the forgery detection process. Though, it requires large amounts of labeled video data and significant computational resources, making training and real-time deployment challenging. In turn [17] have proposed a semantic segmentation-based approach for identifying and locating manipulated regions in images. In this research, the semantic segmentation is used to improve object awareness and increase object localization accuracy. Instead of considering semantic segmentation as a separate submodule, we incorporate it as a third branch of an end-to-end framework. This method balances visual, compression, and segmentation artifacts while minimizing overemphasis on any single branch. However, it struggle with noisy, unclear or extremely context-dependent content particularly in low-resource languages or images with subtle alterations, thereby lowering overall detection accuracy.

I.2 CONTRIBUTIONS

The main contributions of this hybrid residual-dense swin transformer framework with attention-based unet++ research includes,

- To effectively capture both local and global image features for forgery detection a hybrid residual-dense swin transformer framework with attention-based Unet++ is integrated.

- To develop a global context with local texture details for effective feature extraction, a hybrid residual-dense Swin transformer encoder is utilized.
- To enable precise localization of manipulated regions, spatial channel attention with nested skip connections, an Attention-based U-Net++ decoder is implemented.

I.3 PAPER ORGANIZATION

This paper is organized as follows: Section II provides an explanation of the proposed system description. The study methodology is thoroughly described in Section III, which also includes examples of the process, methods, and mathematical representations. The experimental results of this work are described in Section IV, which also include the simulation setup, comparison analysis, and research summary. The conclusion of the proposed investigation is explained in Section V.

II. PROPOSED SYSTEM DESCRIPTION

This paper aims to enhance the accuracy, robustness and localization clarity in detecting image forgeries by integrating image preprocessing and hybrid residual-dense swin transformer framework with attention-based Unet++ for feature extraction and segmentation. The proposed block diagram is displayed in Figure 1.

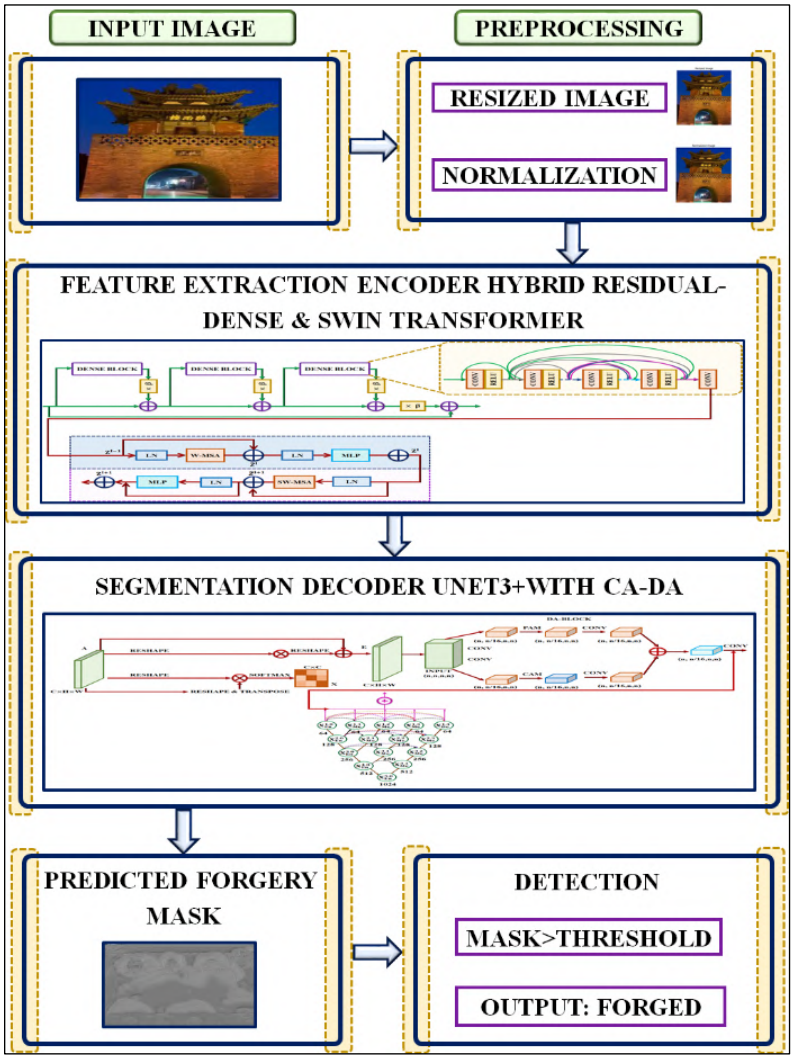

Figure 1: Proposed block diagram.
Source: Authors, (2026).

The proposed approach integrates transformer based and convolutional techniques to present a strong DL framework for image forgery detection. To ensure consistency, the image that arrives is initially processed by resized and normalizing. Following processing, the image is fed into a hybrid feature extraction encoder that successfully captures both local and global contextual data by combining residual-dense blocks with a Swin transformer. A UNet++ architecture supplemented with CA-DA is then used to decode these complex feature representations, allowing for the exact localization of modified regions. A predicted forgery mask is produced by the decoder and examined during the detection stage. The image is considered fake if the mask's confidence level exceeds a predetermined threshold. High accuracy and locating image forgeries is ensured by this end-to-end process.

III. PROPOSED SYSTEM MODELLING

III.1 IMAGE PREPROCESSING

In image preprocessing, resizing and normalizing is a crucial step in image analysis pipeline. To ensure consistency and compatibility with the DL model, an image must be standardized before being examined for potential alteration.

III.1.1 Resizing

The input image is resized to a fixed resolution, ensuring that all images have uniform dimensions regardless of their original size. This step makes the computational process efficient and allows the neural network to handle images in batches. In addition, resizing helps maintain consistency across the dataset, preventing variations in image size from affecting model learning. It also reduces memory requirements and speeds up both training and inference. By standardizing resolution, the network focus on learning important patterns instead of adjusting to irregular input sizes.

III.1.2 Normalizing

Pixel values are normalized and typically scaled to a certain range. Normalization stabilizes the training process, accelerates convergence, and assures that changes in image brightness or contrast do not influence forged detection. It also prevents numerical instability by maintaining input values within a reasonable range, hence avoiding bursting or vanishing gradients during back propagation. Normalization ensures that all features contribute proportionally, which enhances the model's capacity to detect small irregularities. It improves generalization by making the model less susceptible to differences in lighting, exposure, or camera settings. In some circumstances, mean subtraction and standard deviation scaling are employed to align pixel distributions with retrained models, which improves feature extraction performance. The diagram for image preprocessing is shown in Figure 2.

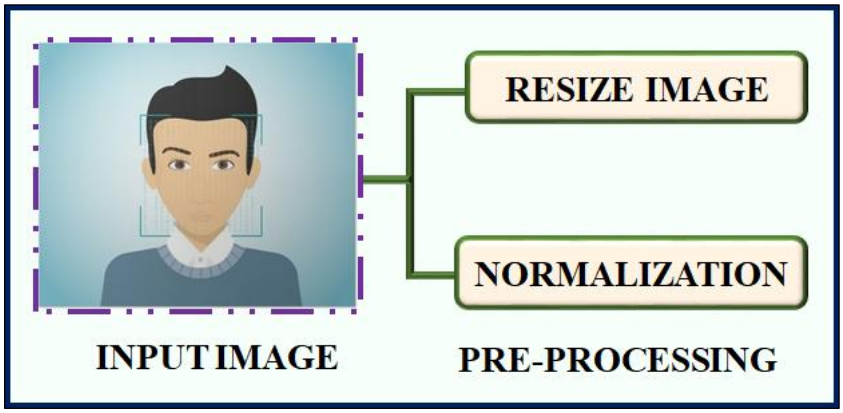

Figure 2: Image preprocessing.
Source: Authors, (2026).

By combining both, Resizing and normalization prepare the raw image for subsequent processing phases, such as feature extraction and segmentation, allowing the detection model to concentrate on forgery-specific patterns rather than changes caused by size or illumination discrepancies. Resizing maintains constant input dimensions, allowing for batch processing and reducing computing effort, whereas normalization scales pixel intensity values to a uniform range, enhancing model convergence and stability during training. Furthermore, these processes serve to reduce the impact of noise, contrast discrepancies, and illumination variations making the model more adaptable to a variety of image situations.

III.2 FEATURE EXTRACTION- RESIDUAL-DENSE SWIN TRANSFORMER

Residual Dense Network (RDN) is an architecture that identifies image forgery due to its outstanding feature extraction capabilities. In order to detect fabricated regions in images, fine-grained details, subtle discrepancies, and manipulation effects need to be precisely captured. The RDN combines residual and dense connectivity, allowing for effective extraction of both local and global characteristics. The dense block structure allows the network to transfer information within each block, efficiently merging low-level and high-level elements including texture irregularities, edges, and noise patterns, which frequently signal tampering. By combining the input and output of each dense block, the network maintains a strong information flow, which is crucial for detecting small changes that would otherwise go undetected. Mathematically, the residual network adds the input x_{i-1} to its mapped output$F(x_{i-1})$, enhancing gradient flow and preventing overfitting as network depth increases,

$$F_{Res}(x_{i-1}) = F(x_{i-1}) + x_{i-1} \tag{1}$$

However, fundamental characteristics within a block are unable to fused by residual connections alone. By combining information from all preceding layers, the dense block overcomes this restriction and allows the network to detect minute local imperfections including texture anomalies, noise disturbances, and duplicated regions. Dense blocks increase the network's sensitivity to fine-grained modifications that conventional convolutional layers could miss by combining data from several layers.

Dense blocks offer an additional technique that combines local detail capture with global information flow when paired with residual connections. This improves the overall performance of image fraud detection across a variety of manipulation types, including splicing, copy-move, and inpainting.

$$F_{DB}^{i} = ReLU\left(F_{DB}^{i-1} + \sum_{j=0}^{i-1} F_j(x_j)\right) \quad (2)$$

The detection of forgeries is further enhanced by the introduction of residual dense blocks (RDBs), which create global residual connections between blocks because dense blocks only concentrate on internal feature fusion. By combining the benefits of dense and residual connections, RDBs make sure that data moves throughout the network as well as within individual blocks. RDBs improve the network's capacity to identify minute manipulations like splicing edges, copy-move duplications, or anomalies in inpainting by preserving inter-block dependencies. All things considered, RDBs offer a strong foundation for merging local and global data, which makes the network extremely efficient at precisely locating and detecting tampered areas in a variety of forging scenarios.

$$F_{RDB} = \beta \cdot F_{DB}(x_i) + x_{i-1}, \beta = 0.2 \quad (3)$$

In addition to improving the network's capacity to extract local and global features, RDN's residual and dense connections provide effective gradient flow, which permits the training of deeper architectures without overfitting. Dense blocks capture tiny tampering artifacts like duplicated regions, noise discrepancies, or splicing edges by allowing the fusion of all previous layer characteristics within a block. The network preserves inter-block connections by incorporating these dense blocks into Residual Dense Blocks (RDBs), which highlights fine-grained local characteristics while keeping global contextual information. RDN is extremely resistant to a variety of forgery techniques, including as splicing, copy-move, and inpainting manipulations, thanks to its hierarchical feature extraction. The Swin Transformer is a hierarchical vision model that is well suited for detecting image forgeries because it capture both local defects and global contextual anomalies. The Swin Transformer uses hierarchical feature maps and a shifting window attention mechanism to analyze data at many scales, which is necessary for detecting manipulations like splicing, copy-move, or inpainting. Subsequently, Swin Transformer Blocks (STBs) are used to convert the image into non-overlapping patches. Layer Normalization (LN), a two-layer Multilayer Perceptron (MLP) with Gaussian Error Linear Unit (GELU) activation, and Window-Based Multi-Head Self-Attention (W-MSA) and Shifting Window MSA (SW-MSA) modules make up each block. The computational complexity of the conventional multi-head self-attention is as follows,

$$\Omega(MSA) = 4hwC^2 + 2(hw)^2C \quad (4)$$

To address this, the Swin Transformer uses window-based multi-head self-attention (W-MSA), which restricts attention computation to local windows of size$M \times M$. This reduces the complexity to,

$$\Omega(W-MSA) = 4hwC^2 + 2M^2hwC \quad (5)$$

This reduction in complexity allows the network to efficiently focus on local regions of the image, which is particularly important for detecting small-scale forgeries such as copy-move or subtle splicing artifacts. By limiting attention computation to each window, the model analyse fine-grained textures, edges, and noise inconsistencies without being overwhelmed by the total number of patches in high-resolution images. This local attention mechanism forms the foundation for identifying micro-level tampering cues, which are often missed by traditional convolutional or global attention methods. The structure of residual-dense swin transformer is shown in Figure 3.

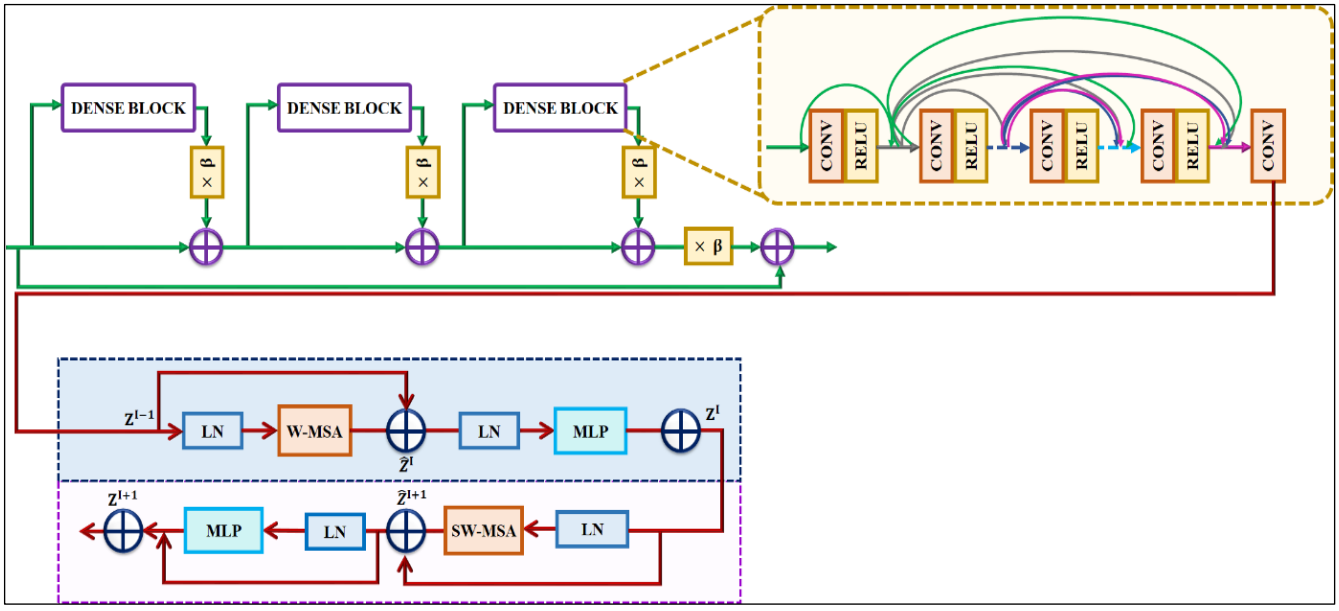

Figure 3: Structure of residual-dense swin transformer.
Source: Authors, (2026).

By focusing on local regions, W-MSA efficiently captures fine-grained artifacts, such as subtle texture inconsistencies or duplicated areas, which are common in tampered images. Within each Swin Transformer Block (STB), features are processed sequentially. Initially, the W-MSA module computes local dependencies for each patch, incorporating residual connections to stabilize training and preserve low-level details,

$$\hat{Z}_l = W - MSA\big(LN(Z_{l-1})\big) + Z_{l-1} \tag{6}$$

Here, Z_{l-1} is the input feature from the previous layer, LN is Layer Normalization, and the addition of Z_{l-1} ensures that the original patch information is retained. After this, the features are passed through a two-layer MLP with GELU activation to enhance non-linear representations,

$$Z_l = MLP\left(LN\big(\hat{Z}_l\big)\right) + \hat{Z}_l \tag{7}$$

Whereas W-MSA focuses on local interactions, it cannot capture relationships across neighboring windows, which is important for detecting manipulations spanning multiple regions, such as a spliced object. The shifted window MSA (SW-MSA) addresses this by cyclically shifting the windows and computing attention over overlapping patches,

$$\hat{Z}_{l+1} = SW - MSA\big(LN(Z_l)\big) + Z_l \tag{8}$$

$$Z_{l+1} = MLP\left(LN\big(\hat{Z}_{l+1}\big)\right) + \hat{Z}_{l+1} \tag{9}$$

Cross-window connections are essential for modeling long-range dependencies and this shifted window method makes computation efficient. The model successfully collects both local and global contextual information by switching between normal window based self- attention and shifting window based self-attention across consecutive levels. Finally, the attention mechanism is shown below,

$$Attention(Q, K, V) = Softmax\left(\frac{QK^T}{\sqrt{d}} + B\right)V \tag{10}$$

Here, $Q, K,$ and V are the query, key, and value matrices for a given window, d is the dimension of feature vectors, and B encodes relative positions between patches. By using this mechanism, the Swin Transformer accurately identify irregularities in spatial structure, texture, and edges that indicate image forgery. Overall, this combination of residual-dense swin transformer is used to detect forgeries at multiple scales, generating pixel-level manipulation maps and ensuring both local artifact sensitivity and global structural consistency, which are essential for robust forensic analysis.

III.3 SEGMENTATION- UNet++ WITH CHANNEL-DUAL ATTENTION

To detect image forgery, it is necessary to determine the exact location of the tampered areas in addition to determining if the image was actually altered. Although a conventional UNet is capable of recording some semantic and spatial data, it eliminate important details like boundaries and forged textures since its straight skip connections only convey information at the same size. To get around this, UNet++ employs layered skip connections, which combine features from several layers while maintaining high-level semantic information and low-level geometric details. This fusion process is formalized by equations,

III.3.1 First Merge – Preserving Boundary Details

The first merging operation combines the shallowest encoder feature map $X1{:}\,0_{En}$ (low-level details) with the next encoder output $X2{:}\,0_{En}$

$$X1{:}\,1_{Me} = X1{:}\,0_{En} + X_2{:}\,0_{En} \tag{11}$$

By employing layered skip connections to combine encoder features at several layers, UNet++ improves image detection. Low level features $X1{:}\,0_{En}$ and $X_2{:}\,0_{En}$ are first combined to create $X1{:}\,1_{Me}$. This method enhances semantic comprehension and spatial detail, which increase object localization and border accuracy.

III.3.2 Second Merge – Adding Contextual Support

This equation expands the merge by reusing $X1{:}\,1_{Me}$, combining it with the shallow encoder feature $X1{:}\,0_{En}$ again and an intermediate feature from the second column $X2{:}\,1_{Me}$

$$X1{:}\,2_{Me} = X1{:}\,1_{Me} + X1{:}\,0_{En} + X2{:}\,1_{Me} \tag{12}$$

The frequent application of the shallow feature map $X1{:}\,0_{En}$ in this phase of the UNet++ model for image fraud detection helps to maintain fine-grained image characteristics including surface textures and small-scale imperfections by reinforcing local texture patterns. The intermediate feature map $X2{:}\,1_{Me}$, introduces spatial consistency, enabling the model to compare data from various image scales. By highlighting differences that might not be apparent at a single resolution, this cross-scale fusion aids in differentiating real textures from ones that have been altered. Because of this, the merged feature map $X1{:}\,2_{Me}$ improves its ability to detect minute differences between forged and real areas, like crooked or misaligned edges that are frequently observed in spliced forgeries.

III.3.3 Third Merge – Balancing Detail and Semantics

By integrating many previous nodes to create $1{:}\,3_{Me}$, the third merging stage becomes more thorough. In addition to deeper contextual features $2{:}\,2_{Me}$, this fusion incorporates data from both shallow and intermediate layers. This strikes a compromise between semantic-level abstraction and the preservation of fine-grained details.

$$X1{:}\,3_{Me} = X1{:}\,2_{Me} + X1{:}\,1_{Me} + X1{:}\,0_{En} + X2{:}\,2_{Me} \tag{13}$$

In the third merging stage of the UNet++ model, the fusion process integrates progressively higher-level semantic features from $X2{:}\,2_{Me}$ while still preserving low-level detail through $1{:}\,0_{En}$.

III.3.4 Final Merge – Forgery Segmentation Map

The output $X1{:}\,4_{De}$ is produced by the final decoder node aggregating all of the prior intermediate merges and deep decoder data.

$$X1{:}\,4_{De} = X1{:}\,3_{Me} + X1{:}\,2_{Me} + X1{:}\,1_{Me} + X1{:}\,0_{En} + X2{:}\,3_{De} \tag{14}$$

According to the equation, a decode image from system $X1$ and an enable image from system $X1$ add up to the decode image. On the contrary, include semantic information that enables the model to determine whether a suspicious area fits into the image's overall context, ensuring that additional significant irregularities or irrational alterations are detected. High-level semantics and granular detail are combined in the final result, which shows a hierarchical integration of these multi-scale elements. The network consistently discover forged areas even when tampering is subtle, well-blended, or purposefully done to avoid detection thanks to this fusion, which strengthens and improves the detection process. The Channel Attention Module (CAM) improves the network's capacity to focus on the most informative channels in feature maps, enabling it to discern between authentic and tampered regions. CAM reshapes a convolutional feature map $A \in R^{C*H*W}$ into $\in R^{C*N}$, where$N = H \times W$, allowing for channel connections to be determined. The module then computes a channel attention map $X \in R^{C*C}$ using the following softmax-based operation,

$$X_{ji} = \frac{exp(A_i . A_j)}{\sum_{i=1}^{C} exp(A_i . A_j)} \tag{15}$$

In this case, $A_i \; and \; A_j$ are the flattened feature vectors for the i and j channels, as well as X_{ji} are shown. This metric assesses the impact of the i channel on the j channel. This step collects inter-channel relationships, allowing the network to determine which channels are most useful in detecting forgeries. Channels with high influence weights, for example, will be more sensitive to edge irregularities or odd texture patterns. The enhanced feature map $E \in R^{C*H*W}$ is then computed as follows,

$$E_j = \beta \sum_{i=1}^{C} X_{ji} A_i + A_j \tag{16}$$

Where β is a learnable scaling parameter. This process effectively generates a weighted total of all channels, along with the original feature, emphasizing informative channels and suppressing less relevant channels. By incorporating CAM into the UNet++ framework, the network gains both multi-scale feature fusion and channel-focused attention. Shallow features in UNet++ capture tiny details such as edges and textures, whereas deep features offer semantic context. The Dual Attention (DA) Block combines the strengths of the Position Attention Module (PAM) and the CAM to improve feature extraction for image fraud detection. PAM detects spatial correlations in feature maps, thereby learning the location where tampering happens by focusing on the positional links between pixels. CAM, on the other hand, captures inter-channel dependencies without highlighting what features are relevant for detecting manipulations, such as texture inconsistencies, odd edges, or cloned sections. By merging these two modules, the DA-Block extract spatial and channel-specific clues, which is critical for identifying subtle or complicated forgeries. The DA-Block has two parallel components. The first component uses convolution to scale the number of channels by a sixteenth, resulting in α_1.

$$\alpha_1 = Conv(input) \tag{17}$$

This stage reduces the complexity of the feature map in preparation for PAM processing. The position attention module processes α_1 to capture spatial correlations, followed by another convolution to obtain the refined feature map$\tilde{\alpha}_1$,

$$\tilde{\alpha}_1 = Conv\big(PAM(\alpha_1)\big) \tag{18}$$

The second component of the Dual Attention (DA) Block for image forgery detection uses the CAM to stress channel-wise dependencies and highlight what aspects are most relevant for identifying alterations. The input features are initially run through a convolution to reduce dimensionality and create the feature map for the attention mechanism. CAM then computes inter-channel correlations and refines the features, followed by another convolution to generate the enhanced feature map

$$\alpha_2 = Conv(input) \tag{19}$$

$$\tilde{\alpha}_2 = Conv\big(CAM(\alpha_2)\big) \tag{20}$$

This procedure prioritizes channels that include crucial tampering cues, such as cloned textures, odd edges or inconsistent colours, while suppressing less informative channels. The first component of the DA-Block, led by the PAM, generates$\tilde{\alpha}_1$. Schematic diagram of UNet++ with Channel-Dual Attention is shown in Figure 4.

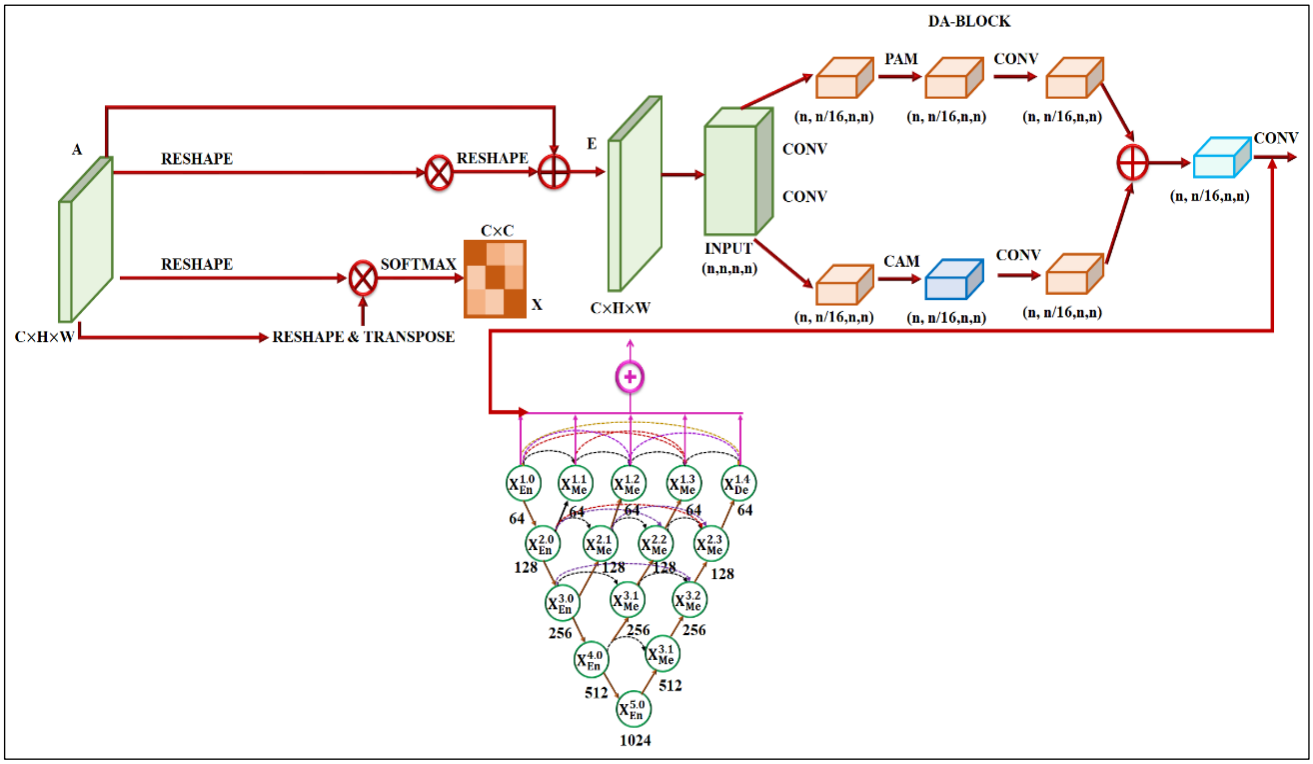

Figure 4: schematic diagram of UNet++ with Channel-Dual Attention.
Source: Authors, (2026).

By focusing on spatial dependencies or wherever modifications take place. The outputs from both routes are then aggregated and summed, and a final convolution restores the original number of channels, providing the final DA-Block output.

$$output = Conv(\tilde{\alpha}_1 + \tilde{\alpha}_2) \tag{21}$$

Combining $\tilde{\alpha}_1$ and $\tilde{\alpha}_2$, the DA-Block blends spatial and channel-wise attention, allowing the network to detect subtle, well-blended, or sophisticated forgeries more efficiently by combining fine-grained details with global contextual information. In image forgery detection, this DA-Block allows the network to focus on both spatial inconsistencies and channel-specific information. The combination of PAM and CAM ensures that the model captures both fine-grained information and global context, allowing it to detect subtle, well-blended, or large-scale alterations. By modifying intermediate channel dimensions and convolutional procedures, the DA-Block modified to prioritize the most relevant forgery features, boosting detection accuracy and robustness across a wide range of image formats. Thus the integration of UNet++ with CA-DA focuses on accurately identifying tampered regions. CA-DA improves spatial and contextual awareness, whereas dense skip connections are used for detailed feature extraction. This makes the model useful for digital image detection by assisting it in identifying subtle modifications.

IV. RESULT AND DISCUSSION

This research provides a notable explanation of the manner in which a hybrid residual-dense Swin transformer framework coupled with an attention-based UNet++ is implemented to detect image forgeries efficiently.

Table 1: Train vs Test Distribution Table.

Class	Train samples	Test samples
Forged	5200	1300
Original	5200	1300

Source: Authors, (2026).

Train vs Test distribution of forged and original class is shown in Table 1. The train samples for both forged and original class is 5200. Similarly, for both forged and original class the test samples are 1300. The balanced split reduces bias towards any class. Overall, this distribution facilitates the development of a dependable and effective classification model.

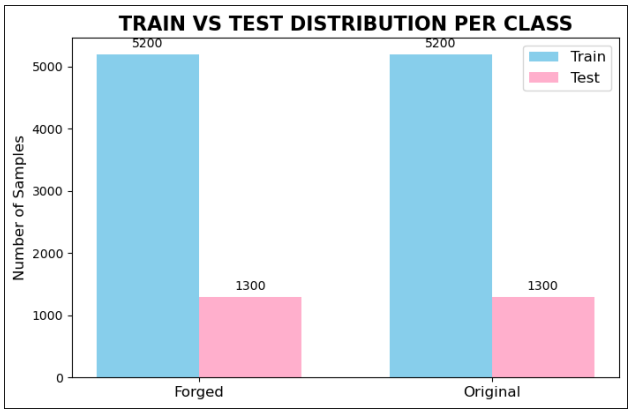

Figure 5: Train vs Test distribution per class.
Source: Authors, (2026).

The distribution of train and test samples for the two classes Forged and Original is displayed in Figure 5. There are 1,300 test samples and 5,200 training examples for every class. The distribution of the Forged class is comparable, with 1,300 samples used for testing and 5,200 samples used for training. With 5,200 training samples and 1,300 test samples, the Original class exhibits the same distribution pattern. This guarantees that the quantity of training and test samples for each class is equal. Comparing the quantity of samples for every class in the training and testing sets is made simple by the graph's visual representation of this division.

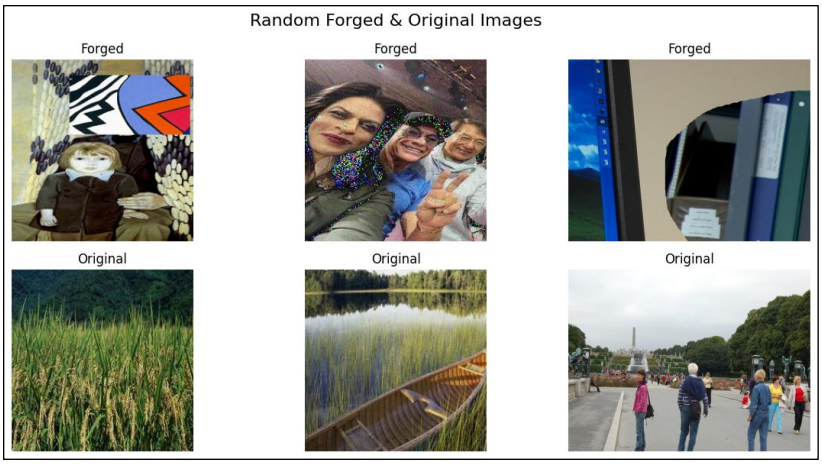

Figure 6: Random forged and original images.
Source: Authors, (2026).

A comparison of the original and forged images is shown in the Figure 6. The top row features three fabricated images, while the bottom row shows their real copies. Forgeries include distorted group selfies, cut-out regions that highlight irregularities, and a child's shot with an unnatural background. The originals feature natural sceneries such as a field, a boat on calm sea, and people walking in public. This side-by-side arrangement emphasizes visual cues and abnormalities. It helps to highlight the differences between authentic and digitally changed images. This comparison helps to identify digital forgeries more efficiently.

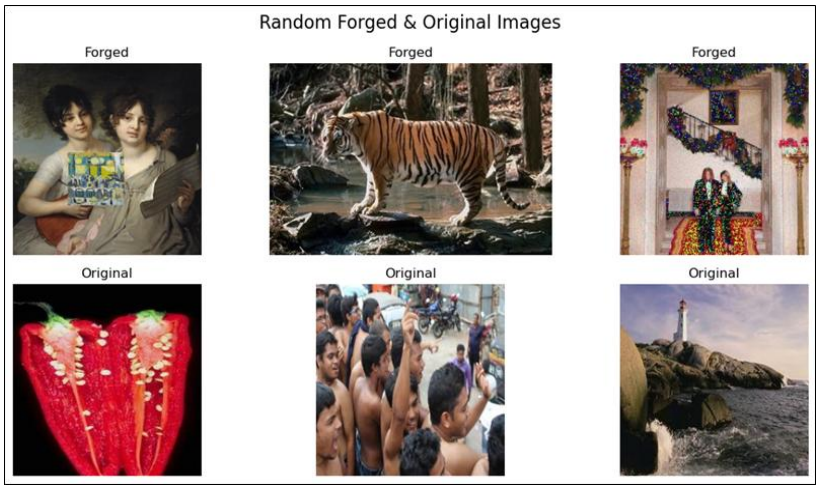

Figure 7: Random forged and original images.
Source: Authors, (2026).

A combination of forged and genuine images are displayed in Figure 7. Three Forged images a painting, a tiger in a forest, and a vibrant group portrait are displayed in the top row. A close-up of a pepper, a crowd of people outside, and a lighthouse near the sea are the three Original images that are shown in the bottom row. The arrangement provides insight into the kind of content contained in a classification job by emphasizing the difference between authentic and altered images.

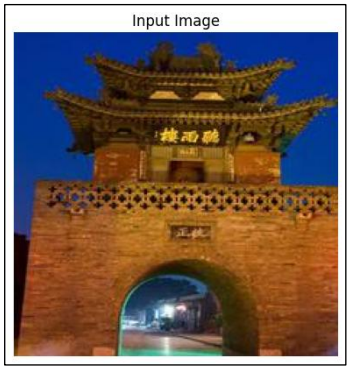

Figure 8: Input image.
Source: Authors, (2026).

An input image which serves as the initial sample in the image forgery detection procedure is depicted in Figure 8. The image depicts a conventional architectural structure with a brick base, archway, and a decorative roof. It depicts the raw input data for a forgery detection system prior to processing. This indicates the start of the analytical pipeline. The system uses such images to determine authenticity or modification. These inputs are critical for developing and testing detection systems.

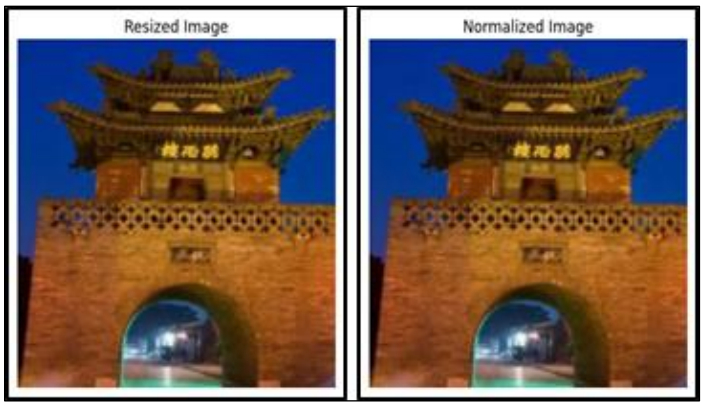

Figure 9: Resized and Normalized image.
Source: Authors, (2026).

Two image processing methods resizing and normalization are contrasted side by side in this figure 9. The Resized Image displays the outcome of adjusting the image's dimensions, which frequently results in distorted or blurry images if the aspect ratio is changed. The Normalized Image shows an image having its pixel values changed, perhaps for improved clarity and contrast, without changing the image's original size. In order to improve the image's visual balance and prepare its features for additional analysis normalization usually entails scaling the pixel values to a predetermined range.

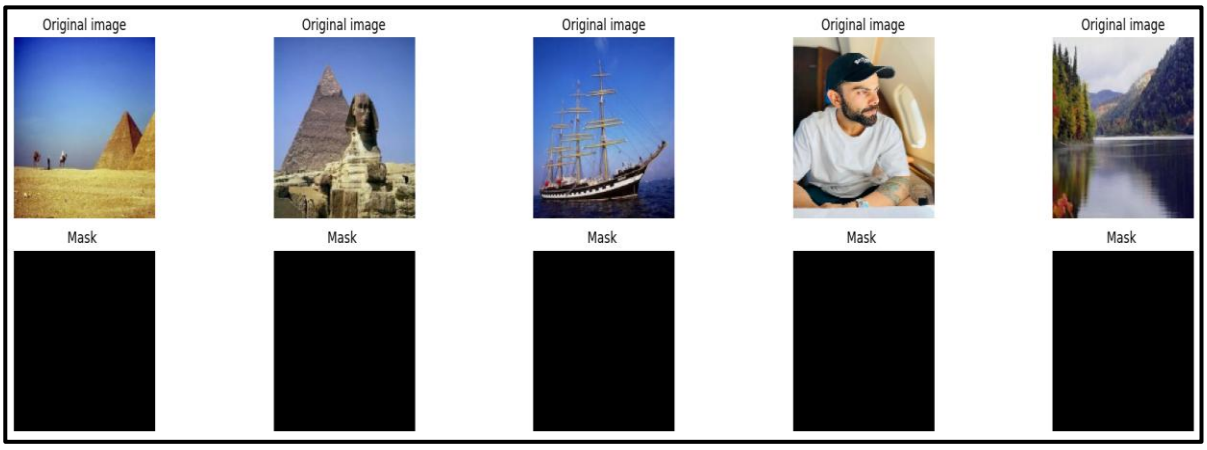

Figure 10: Image masking process.
Source: Authors, (2026).

Figure 10 displays a collection of original images along with matching black masks. The images depict locales such as the Pyramids of Giza, the Sphinx, a sailing ship, a man in a plane, and a lakeside setting. A black mask appears beneath each image, indicating that it was most likely utilized in image processing. These masks target specific areas for activities like as segmentation and object detection. The entirely black masks indicate that parts are masked for processing purposes. They utilized later to emphasize or preserve specific areas of the images during analysis.

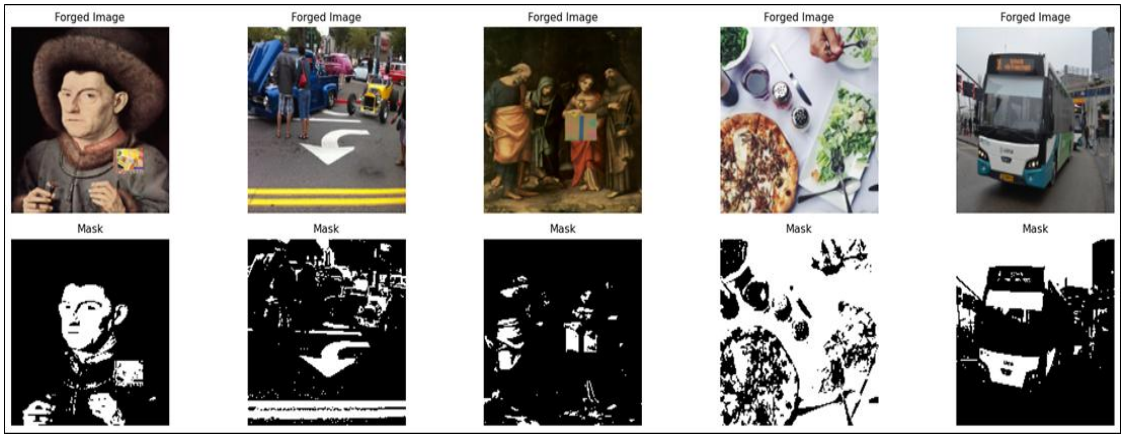

Figure 11: Forgery Detection with Masking Technique.
Source: Authors, (2026).

Figure 11 displays a series of manipulated images together with the black-and-white masks that go with them. This technique uses masks to identify altered or forged areas in images. Each mask focuses on manipulated regions, such as a digitally altered portrait, modifications in a street scene, a modified painting, a fabricated food arrangement, and edits on a bus. The masks draw attention to these altered areas. This is useful in forensic analysis, image validation, and forgery detection. The graphic shows how mask detection identifies modified parts in forged images.

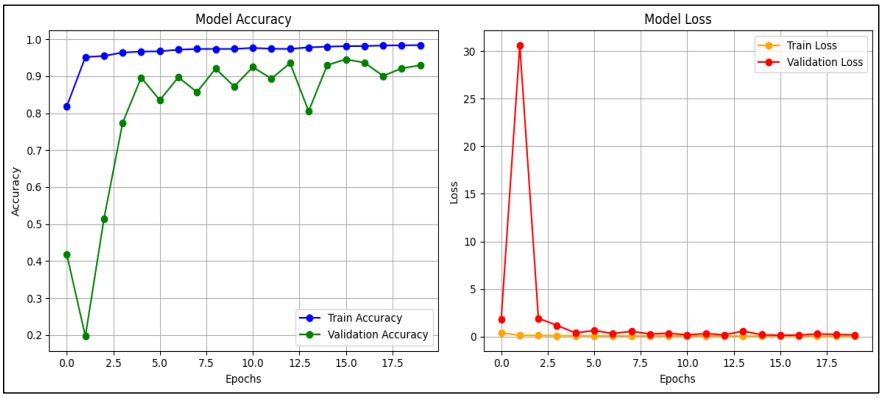

Figure 12: Model Accuracy and Loss over Epochs.
Source: Authors, (2026).

Figure 12 display a model's performance measures over 20 training epochs. The left figure depicts model accuracy, with training accuracy (blue) rapidly increasing and stabilizing near 1.0, whereas validation accuracy (green) improves slowly and varies, indicating some overfitting. The right plot depicts model loss, with both training (yellow) and validation loss (red) starting high but decreasing dramatically. Validation loss varies considerably, indicating potential instability or overfitting. Despite this, both losses stabilize near zero, indicating that the model has successfully trained.

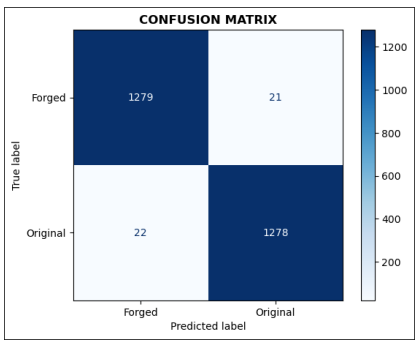

Figure 13: Confusion matrix.
Source: Authors, (2026).

The confusion matrix presented in Figure 13 shows a well classification model predicts two classes Forged and Original. The confusion matrix has 1,279 true positives for forged images and 1,278 true positives for original images. There are 21 false positives (original misclassified as forgery) and 22 false negatives (forged misclassified as original). The model is highly accurate, with minimal misclassifications. This demonstrates a great capacity to differentiate between the two classes successfully.

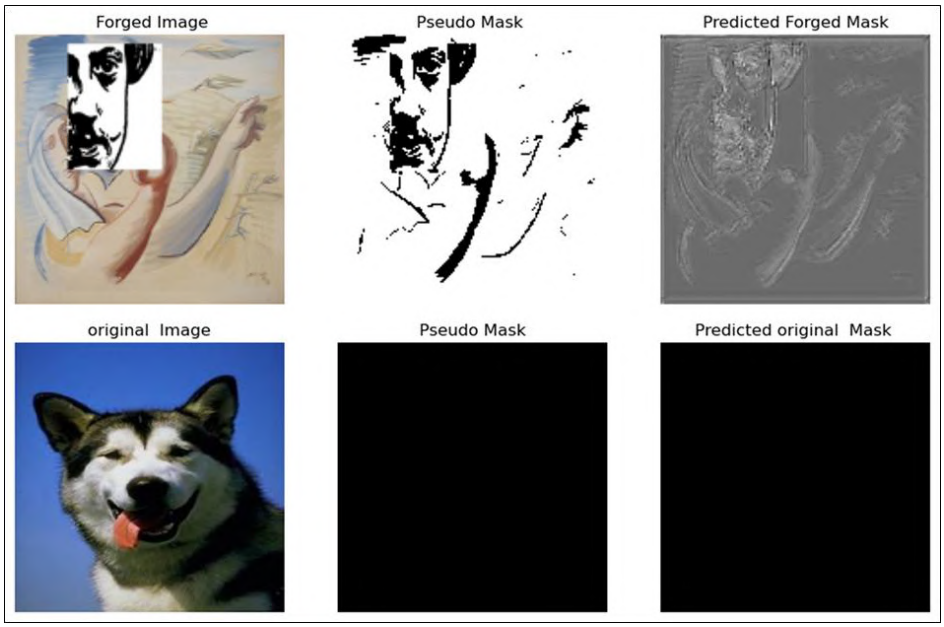

Figure 14: Image Forgery Detection and Mask Prediction Outcomes.
Source: Authors, (2026).

The process of identifying image forgery with mask prediction algorithms is depicted in Figure 14. The six sections demonstrate the forgery detection procedure. The top-left corner displays a faked image, followed by a faux mask that highlights probable modifications. The model predicts a forged mask in order to identify certain bogus regions. The original image and pseudo mask are shown here, with no modification. The accuracy of the detection model be evaluated by comparing anticipated masks to originals.

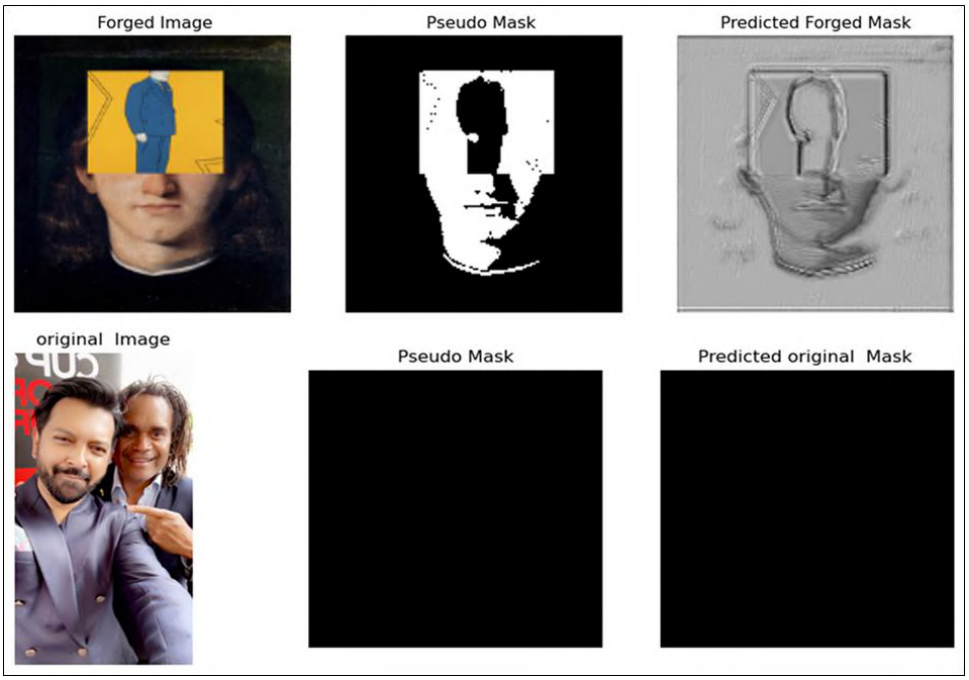

Figure 15: Forgery Detection in Images and Mask Prediction Results.
Source: Authors, (2026).

Figure 15 illustrates the process of image fraud detection, emphasizing the comparison of authentic and manipulated images using anticipated and faux masks. The top row displays the original image, its blank pseudo mask, and the forecasted mask, indicating no tampering. The bottom row shows a forged image, a faux mask that highlights the altered areas, and the model's anticipated forged mask. The anticipated mask attempts to match the pseudo mask's highlighted regions. This comparison measures the model's ability to reliably detect forgeries.

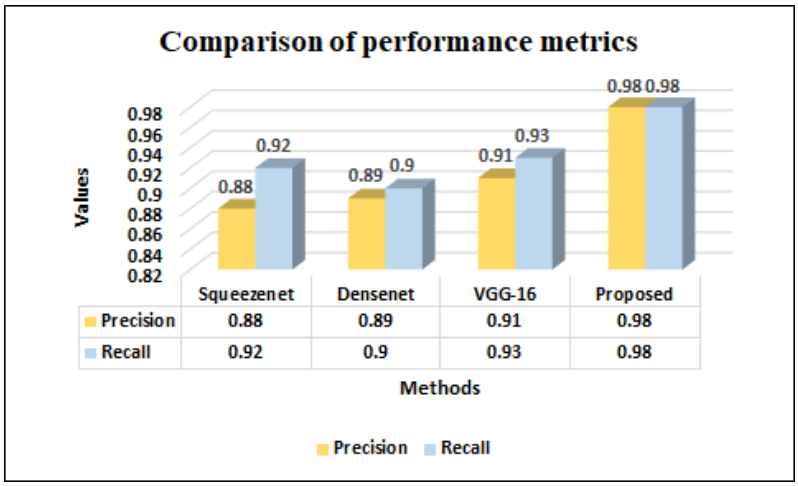

Figure 16: Comparison of Performance metrics.
Source: Authors, (2026).

Figure 16 illustrates the performance of four different methods such as SqueezeNet [18], DenseNet [19], VGG-16 [20], and a proposed method based on two metrics, Precision and Recall. SqueezeNet has the lowest performance, with a Precision of 0.88 and Recall of 0.92, DenseNet follows closely, showing slight improvements with a Precision of 0.89 and Recall of 0.92. VGG-16 performs better, with a Precision and Recall of 0.91. The proposed method significantly outperforms the others, achieving the highest scores Precision and Recall of 0.98 each.

Table 2: Comparative analysis of accuracy.

Methods	Accuracy
SqueezeNet [18]	0.89
Dense net [19]	0.92
VGG-16 [20]	0.93
Proposed	0.98

Source: Authors, (2026).

Table 2 shows the comparative analysis of accuracy for various methods such as SqueezeNet, Dense net, VGG-16 and a proposed method. In this comparison, SqueezeNet attains the lowest accuracy of 0.89, Dense net reaches the accuracy of 0.92, VGG-16 achieves the accuracy of 0.93 and the proposed method succeeds the accuracy of 0.98. Hence the proposed method outperforms the highest accuracy of overall methods.

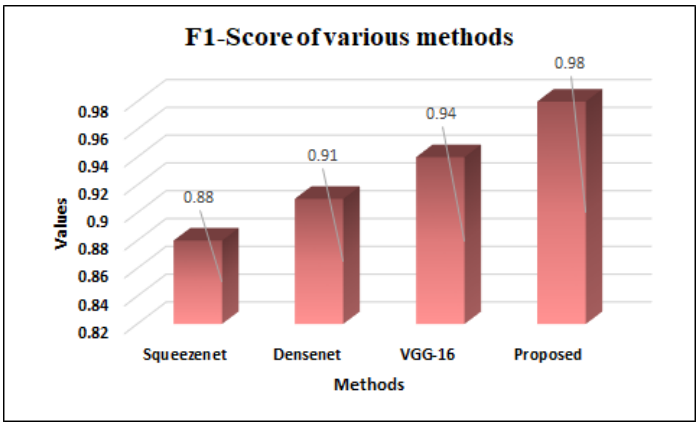

Figure 17: FI-score comparison of various methods.
Source: Authors, (2026).

Figure 17 depicts the FI- score of various methods such as Squeeze net, Dense net, VGG-16 and proposed method. Squeeze net achieves the lowest FI-score of 0.88, followed by Dense net and VGG-16 of 0.91 and 0.94. The proposed system achieves the highest FI-score of 0.98.

V. CONCLUSION

This study presents the contributions and most significant results for detecting image forgeries. The primary contribution lies in the introduction of an innovative hybrid DL model that seamlessly integrates residual-dense Swin transformer with attention based UNet++. Through the assistance of suitable techniques, it illustrates that the detection of image forgery is effectively processed through four stages. The procedure commences with input image where raw data is provided to the system for forgery detection. This is followed by preprocessing where resize and normalization takes place to ensure consistent input for the model, which helps in training and inference stability. In feature extraction, it extracts high level features from the input image using a hybrid model.

The extracted features are then segmented to produce a pixel-wise segmentation mask indicating forged images. A predicted pixel mask highlighting suspected forged regions in the image. Then the mask is subjected to a threshold by the detection module and if exceeded, it marks the image as forged. The model is implemented in Python and it outperforms higher accuracy, precision, recall and FI-score of 0.98%.

Fire Hawk Optimization algorithm

ABSTRACT

Quick treatment and management of heart disease depend on an accurate and early diagnosis. An Electrocardiogram (ECG) is a vital indicator tool used in medical practice to evaluate cardiovascular illness. In order to tackle the challenges of cardiac classification, this study presents an innovative method based on Deep Learning (DL) approach, namely Recurrent Neural Network Enhanced Temporal Transformer (RETT). The implemented research is initiated with an Adaptive Wavelet Filter based pre-processing that enhances the quality of an ECG signal. Subsequently, the Hilbert Huang Transform (HHT) based feature extraction is exploited for extracting necessary features, which are crucial for detecting abnormalities and diagnosing heart disorders. Then, RETT classification approach is utilized for detecting the cardiac affliction accurately. Finally, the performance of a RETT approach is enhanced with the aid of a Fire Hawk Optimization (FHO) algorithm. The developed approach is executed in python software that shows the performance of DL that is useful for evaluating cardiovascular disease with an accuracy of 99.70%. This research aids in the generation of precise and effective diagnostic tools for dealing with pressing cardiac health issues.

I. INTRODUCTION

Around the world, heart disease is regarded as one of the most hazardous and life-threatening chronic illnesses. Heart disease often arises when the heart is unable to pump sufficient blood to other body parts for them to function normally [1]. Over 64 million people worldwide endure from Heart Failure (HF), which is a clinical disease that is becoming more common. Heart failure with maintained ejection fraction is more complicated than heart failure with decreasing EF, which results in different diagnostic criteria and probably contributes to "failed" clinical studies [2]. Cardiovascular illnesses are diagnosed and evaluated by doctors using electrocardiography procedures. Experts visually evaluate the ECG signal, which is an established method in cardiology for assessing a patient's heart health is the electrocardiogram (ECG) [3].

Expert cardiologists carefully examine the ECG as part of standard medical procedures in order to diagnose potentially fatal heart arrhythmias. Cardiologists save time and obtain objective diagnostic outcomes by automatically classifying cardiac arrhythmias. The computer-aided classification and detection of ECG signals in hospitals and the health community has attracted significant economic interest due to these benefits [4], [5]. Machine learning (ML) and Artificial Intelligence (AI) have demonstrated substantial promise in automating the diagnosis of heart disease in ECG signals in recent years. By increasing the precision and effectiveness of arrhythmia detection, these technologies lessen the strain on healthcare systems [6]. A crucial step in the classification of ECG signals is feature extraction, which is a part of data representation [7]. Principal component analysis (PCA) based feature extraction, serves to simplify and improve the interpretability of models by reducing the number of features while keeping the majority of the relevant information. It is challenging to comprehend the new features (principal components) produced by PCA in terms of the original variables since they are linear combinations of the original features [8]. Because of its nonlinear character, the Kernel principal component analysis (KPCA) method in [9] is better than the PCA methodology for categorizing heartbeats from ECG signals. But compared to PCA, KPCA generates more intricate algorithms. The wavelet scattering transform, which is developed in [10], produces low variance features of real-valued signals that are usually needed in classification tasks, conserves data in high frequency and is immune to signal deformations. However, the WST employs preset wavelet filters, which isn't ideal for every kind of data or application. To overcome such issues, the Hilbert Huang transform is developed in this work for feature extraction. A method for detecting heart problems is the Support Vector Machine (SVM), which is presented in [11]. Finding the plane that divides the model's data points is challenging since there are many different ways a hyper plane is configured in an N-dimensional environment.

Even when a sizable percentage of record entries are inaccessible, the Random Forest (RF) approach, which is presented in [12], still produce the same results when applied to huge datasets. However, because RF models are ensemble in nature, they are intricate and challenging to understand. The Multilayer Perceptron (MLP), which is developed in [13], is extremely adaptable for handling complicated problems since it can approximate any continuous function. However, MLP over fits the training data in the absence of enough training data or regularization strategies. In primary care settings, CNN helps to reduce missed diagnoses and misdiagnosis while also increasing efficacy and reducing labour expenses. However, CNN necessitates meticulous adjustment of several hyper parameters, which is complicated and time-consuming [14]. The results confirm the idea that data collection is done more accurately when detecting diabetes and heart-related diseases and diagnoses using Artificial Neural Networks (ANN) classifier [15]. However, there are sustainability issues because huge neural networks require a lot of energy to train and operate. As a result, this research develops a RETT classification approach and its performance is enhanced by meta-heuristic algorithm, which includes Particle Swarm Optimization (PSO) [16], firefly optimization [17], Artificial Bee Colony (ABC) [18] and Cuckoo Search (CS) [19] and Harmony Search Optimization algorithm [20]. However, these approaches has some limitations such as, lack of diversity in the search space, expensive, slow convergence, stuck in local optima and highly sensitive. Thus, the Fire Hawk Optimization algorithm is implemented in this research for tuning the hyper parameters of a RETT classifier. The main contributions are,

- The Adaptive Wavelet Filter based pre-processing is filtering out high-frequency noise, such as interference and muscle artifacts, without affecting the important features of the ECG signal.
- Integrates the HHT based feature extraction that extracts the relevant features, which are essential for detecting abnormalities and diagnosing heart conditions.
- Implements RETT classification method for accurately predicting the cardiac affliction in an early stage.
- The Fire Hawk Optimization algorithm is exploited for fine-tuning the hyper parameters of a RETT classifier.

II. PROPOSED METHODOLOGY

The developed block diagram for predicting cardiac affliction is depicted in Figure 1. The process is initiated with capturing the ECG signal that contains the valuable data about electrical activity of heart. Nevertheless, ECG signals are contaminated with noise and artifacts, which requires a preprocessing stage. It is performed by utilizing an Adaptive Wavelet Filter that efficiently removes noise and enhances signal quality by decomposing it into distinct frequency components while conserving critical cardiac data. The next stage contains HHT based feature extraction, which is a decomposition approach that aids to analyze ECG signals by decomposing it into Intrinsic Mode Functions (IMFs). It is exploited to extract the features like instantaneous frequency and amplitude that is crucial for detecting the abnormalities in the electrical activity of heart.

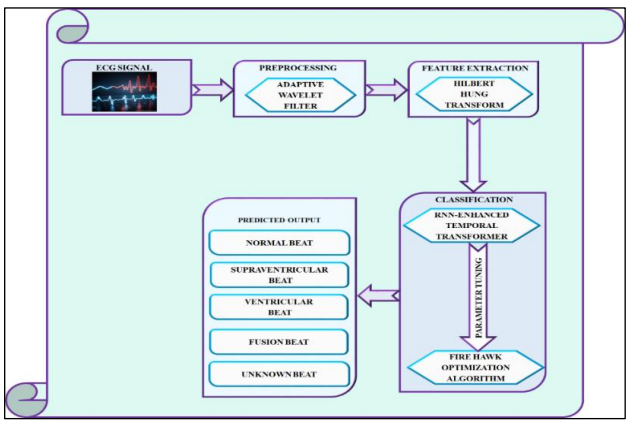

Figure 1: Proposed block diagram.
Source: Authors, (2026).

Then, the signal is fed into a RETT for classification, which is a combination of RNN and transformer based architecture, exploited to acquire temporal dependencies in ECG data. It enhances the learning efficacy by integrating attention mechanisms to concentrate on important time dependent patterns in ECG signal, making it highly effective for detecting cardiac affliction. To further enhance the performance of classifier, the Fire Hawk Optimization algorithm is utilized that fine tunes the hyperparameter of developed classifier. By optimizing parameters, ensures that the DL model attains optimal accuracy and robustness, ensures it is the reliable tool for automated diagnosis of cardiac affliction.

II.1 ADAPTIVE WAVELET FILTER

Pre-processing process is necessary in the developed system in order to enhance the signal quality. In the preprocessing phase, the ECG signal is treated to eliminate unwanted and noisy signals, improving the accuracy. Traditional FIR or IIR filters are used for filtering when the target signals and the noise's frequencies are not overlapped.

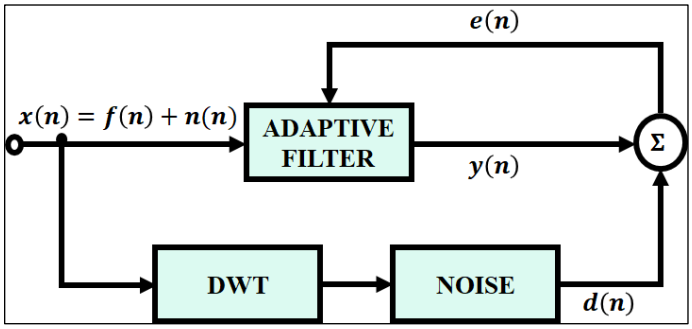

Figure 2: Structure of Adaptive Wavelet Filter Traditional wavelet transform are used to de-noise them when they partially overlap.
Source: Authors, (2026).

However, for the target signal, the filtered signal is not the best estimate. There is link between the original noise and the decomposed noise of DWT that is the optimum reference signal for an adaptive filter. As illustrated in Figure 2, the input signal is,

$$x(n) = f(n) + n(n) \tag{1}$$

Where, the noise is indicated by $n(n)$, target signal is $f(n)$ and reference signal decayed form input signal in DWT is $d(n)$. Based on LMS algorithm, the adaptive rule is,

$$E[e^2(n)] = min \tag{2}$$

The output signal is impending to target signal and filter's weight factor following this rule,

$$w(n+1) = w(n) + 2\mu e(n) \tag{3}$$

After preprocessing, the Hilbert Huang Transform is utilized for extracting the relevant feature from an ECG signal.

II.2 HILBERT HUANG TRANSFORM BASED FEATURE EXTRACTION

Hilbert spectrum analysis and EMD are 2 components of the HHT based feature extraction. A signal is broken down into a finite number of band-limited IMFs using the EMD approach. There are two fundamental restrictions on each IMF:

(1) The number of extreme points and zero crossings in the complete data series are need to be equal or differ by no more than one.

(2) The mean value of the envelopes produced by local minima and maxima is zero at any given time point.

A signal $x(t)$ is broken down by the EMD into n IMFs, such as $c_1(t), c_2(t), \cdots, c_n(t)$ and a residue signal $r_n(t)$. The original signal $x(t)$ is,

$$x(t) = \sum_{i=1}^{n} c_i(t) + r_n(t) \tag{4}$$

Where, i^{th}EMF is denoted by $c_i(t)$ and number of intrinsic modes is n. The Hilbert transform $c_H(t)$ for any real IMF $c(t)$ is,

$$c_H(t) = \frac{1}{\pi} P \int_{-\infty}^{\infty} \frac{c(\tau)}{t-\tau} d\tau \tag{5}$$

Where, singular integral's Cauchy principal value is P and the analytic function is,

$$z(t) = c(t) + jc_H(t) = a(t)e^{j\phi(t)} \tag{6}$$

The instantaneous amplitude $a(t)$ and phase $\phi(t)$ is,

$$a(t) = \sqrt{c(t)^2 + c_H(t)^2} \tag{7}$$

$$\phi(t) = arctan\frac{c_H(t)}{c(t)} \tag{8}$$

The instantaneous frequency is,

$$\omega(t) = \frac{d\phi(t)}{dt} \tag{9}$$

Subsequently, the RETT classifier is utilized to accurately detect the cardiac affliction and its performance is enhanced by FHO algorithm.

II.3 FIRE HAWK OPTIMIZED RNN ENHANCED TEMPORAL TRANSFORMER

The FHO is a metaheuristic algorithm inspired by hunting strategy of hawks in nature. To move toward better positions to force prey, it spreads fire in distinct locations. In detection of cardiac affliction, the FHO is exploited to optimize the hyper parameters of the RETT classifier. Each candidate solution indicates a distinct combination of hyper parameters of the RETT classifier that are: Number of Transformer heads, Number of RNN layer, learning rate, batch size, dropout rate and hidden state rate. Each solution Xi is denoted as vector in search space,

$$X = \begin{bmatrix} X_1 \\ X_2 \\ \vdots \\ X_i \\ \vdots \\ X_N \end{bmatrix} = \begin{bmatrix} x_1^1 & x_2^1 & \cdots & x_j^1 & \cdots & x_d^1 \\ x_1^2 & x_2^2 & \cdots & x_j^2 & \cdots & x_d^2 \\ \vdots & \vdots & \ddots & \vdots & \ddots & \vdots \\ x_1^i & x_2^i & \cdots & x_j^i & \cdots & x_d^i \\ \vdots & \vdots & \ddots & \vdots & \ddots & \vdots \\ x_1^N & x_2^N & \cdots & x_j^N & \cdots & x_d^N \end{bmatrix} \tag{10}$$

Where, number of candidate solution is represented by N, hyper parameter's initial value is $x_j^i(0)$, jth hyper parameter in the ith configuration is x_j^i, number of optimized parameter is d and i^{th} RETT hyper parameter configuration is X_i. Each hyper parameter is randomly initialized by,

$$x_j^i(0) = x_j^{i,min} + rand \times \left(x_j^{i,max} - x_j^{i,min}\right) \tag{11}$$

Where, jth hyper parameter's upper and lower bound is indicated by $x_j^{i,max}\ and\ x_j^{i,min}$ and random number between 0 and 1 for diversity is $rand$.

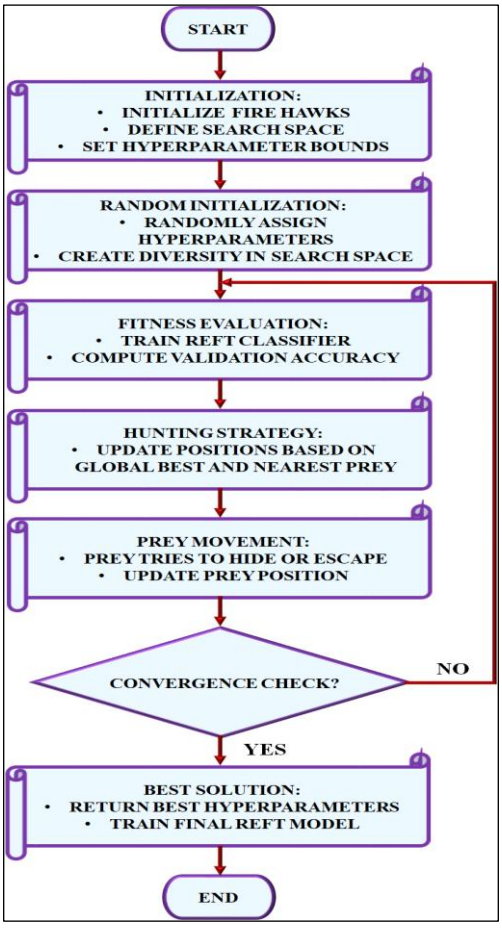

Figure 3: Flowchart of Fire Hawk Optimized RETT.
Source: Authors, (2026).

Moreover, the main fire that the Fire Hawks use first to disperse fires throughout the search space (nature) is thought to be the global best solution. These aspects are expressed mathematically as follows:

$$PR = \begin{bmatrix} PR_1 \\ PR_2 \\ \vdots \\ PR_K \\ \vdots \\ PR_m \end{bmatrix}, \quad k = 1,2,\cdots,m \tag{12}$$

$$FH = \begin{bmatrix} FH_1 \\ FH_2 \\ \vdots \\ FH_l \\ \vdots \\ FH_m \end{bmatrix}, \quad l = 1,2,\cdots,n \tag{13}$$

Where, number of prey is denoted by m, number of fire hawk is n, the kth prey is PR_K and l^{th}fire hawk isFH_l. The algorithm's subsequent step determines the Fire Hawks' overall distance from the prey. Consequently, each bird's effective area is identified by identifying the prey that is closest to it. The first Fire Hawk with the best objective function value determines which prey is closest to it, while the remaining prey is used to decide the other birds' territory. By assigning stronger fire hawks to better prey, the best hyper parameters of RETT classifier are refined for detection of cardiac affliction. Each fire hawk estimates its distance to the nearest prey,

$$D_k^l = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2} \tag{14}$$

Where, hyperparameter values are $(x_1, y_1)\ and (x_2, y_2)$, distance between l^{th} fire hawk and k^{th}prey is D_k^l. The algorithm's search procedure is set up by categorizing the Fire Hawks and prey. The Fire Hawk with the higher objective function value selects the closest prey inside its designated zone. The succeeding closest prey in the search space is then captured by the other Fire Hawks, proving that the strongest Fire Hawks hunt more successfully than the weaker ones. To start a fire in the chosen location, the Fire Hawks gather burning sticks from the main fire in the next phase of algorithm. In order to make the prey quickly run, each bird in this level chooses a burning stick and drops it in its designated area. In order to make the prey quickly run, each bird in this level picks up a burning stick and drops it in its designated area. Some birds are excited to use the burning sticks from the areas occupied by other Fire Hawks. Fire hawks updates the hyper parameter by,

$$FH_{new}^l = FH^l + \left(r_1 \times (GB - FH^l) - r_2 \times (FH_{near} - FH^l)\right) \tag{15}$$

Where, random value among 0 and 1 is indicated by $r_1, r_2,$, global best solution is GB, hyperparameter set of lth fire hawk is FH_{new}^1 and nearby fire hawk is FH_{near} . The movement of prey within each Fire Hawk's territory is regarded as a vital component of animal behavior for the location updating process in the algorithm's succeeding phase. The prey are either choose to hide, flee or unintentionally run in the direction of the Fire Hawk when it drops a burning stick. Prey move toward safer zones,

$$PR_{new}^q = PR^q + \left(r_3 \times (FH^l - PR^q) - r_4 \times (SP^l - PR^q)\right) \tag{16}$$

Where, prey $q's$ updated hyper parameters are PR_{new}^q, random values are $r_3\ and\ r_4$ and prey $q's$ current hyper parameters are PR^q. Inside the territory of fire hawk, the safe place is,

$$SP^l = \frac{\sum_{q=1}^{r} PR^q}{r}, q = 1,2,\cdots,r,\ \ l = 1,2,\cdots,n. \tag{17}$$

Where, safe zone is $SP^l$and number of preys are r. When prey escapes its original region, the hyper parameters are updated as,

$$PR_{new}^q = PR^q + \left(r_5 \times (FH_{Alter} - PR^q) - r_6 \times (SP - PR^q)\right) \tag{18}$$

Where, new fire hawk from distinct region is FH_{Alter}, random numbers are $r_5\ and\ r_6$. The new safe place outside any territory of fire hawk is,

$$SP = \frac{\sum_{K=1}^{m} PR^k}{m}, k = 1,2,\cdots,m, \tag{19}$$

Where, total number of prey in the search space are m. The flowchart of Fire Hawk Optimized RETT is revealed in Figure 3.

III. RESULT AND DISCUSSIONS

This section analyzes the outcomes of developed Fire hawk optimized RETT classifier for the prediction of cardiac disease. The developed research is implemented in Python software and comparative analysis is made with conventional approaches.

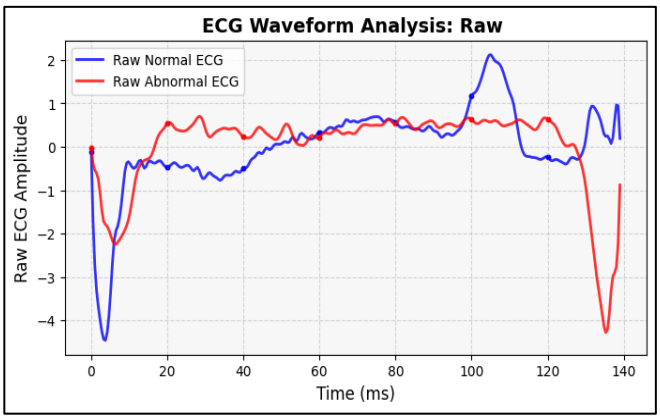

Figure 4: Analysis of ECG waveform.
Source: Authors, (2026).

The ECG waveform for identifying the cardiac disorder is represented in Figure 4 that highlights the differences among normal and abnormal heart activity patterns, which are significant in detecting cardiac disorders. The normal waveform has a constant pattern with predictable peaks whereas the abnormal waveform denotes the irregularities, representing possible disruptions in the electrical activity of heart. This analysis serves as a fundamental step in ECG-based cardiac disorder detection, enabling the identification of early signs of heart disease.

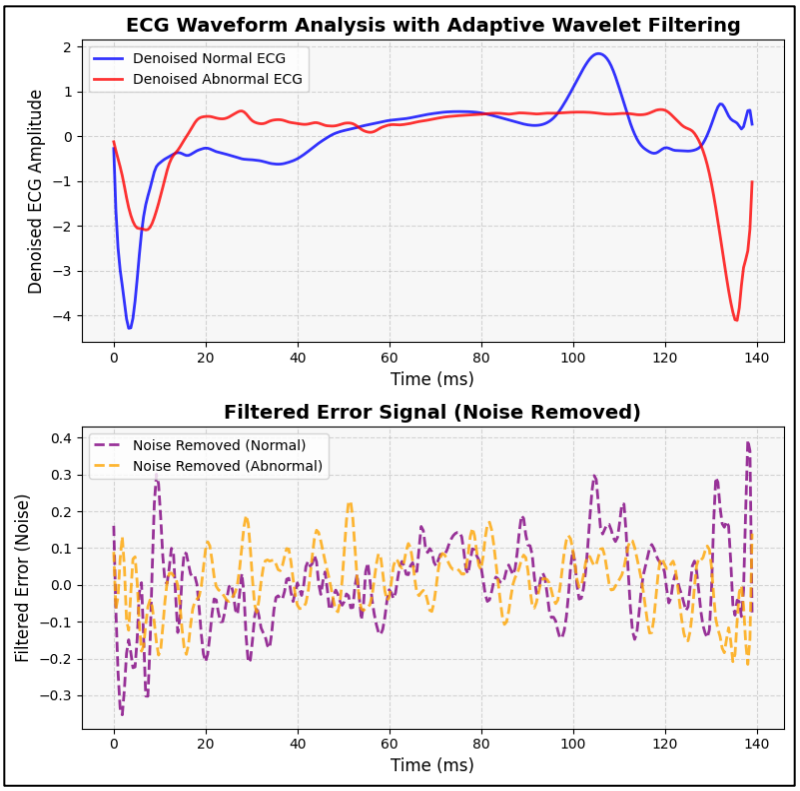

Figure 5: Pre-processed signal.
Source: Authors, (2026).

The Pre-processed signal with Adaptive wavelet filter is displayed in Figure 5. Compared to ECG signals, the denoised waveform has smoother patterns, which is easier to detect the cardiac conditions. The second graph indicates the filtered error signal, representing the noise removed from the ECG signal. The diminished amplitude and smoother denoised waveform assure the efficacy of Adaptive wavelet filter in improving ECG signal clarity. It is significant for accurately identifying cardiac disorders, as it allows better interpretation of heart's electrical activity.

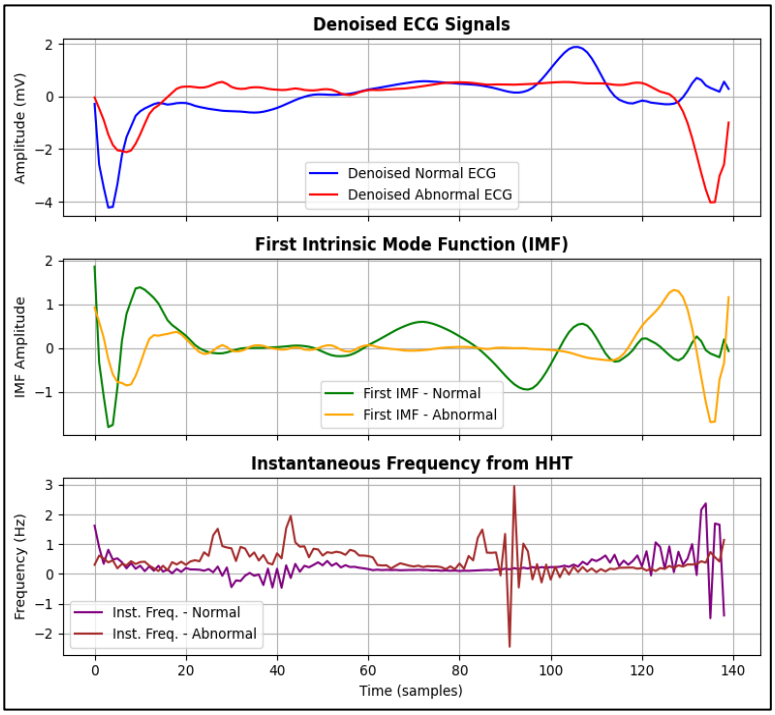

Figure 6: HHT based feature extraction.
Source: Authors, (2026).

The HHT based feature extraction for the detection of cardiac disorder is illustrated in Figure 6. The denoised signals are smoother and more distinguishable, allowing better identification of cardiac irregularities. The middle graph represents the First Intrinsic Mode Function extracted from the ECG signals. The IMF helps decompose the complex ECG signal into simpler components, aiding in better diagnosis of cardiac anomalies. Then, the instantaneous frequency from HHT provide insights into cardiac rhythm disturbances and other heart conditions. This comprehensive analysis using denoising, IMF extraction and HHT-based frequency analysis enhances the accuracy of cardiac disorder detection by capturing both frequency and time domain features.

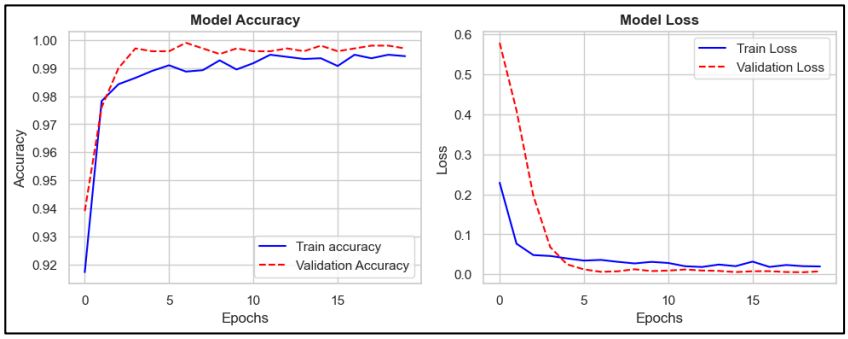

Figure 7: Training and validation results.
Source: Authors, (2026).

Figure 7 illustrates the training and validation outcomes for the detection of cardiac disorder. The validation accuracy is 99.70%, indicating that the model is efficient in learning the patterns in ECG signals. Also, it has reduced loss, denoting that model has the minimal overfitting. The high accuracy and low loss indicate that the model is well-trained and capable of distinguishing between normal and abnormal ECG signals, making it effective for detecting cardiac disorders such as arrhythmias, myocardial infarction, and other heart-related anomalies.

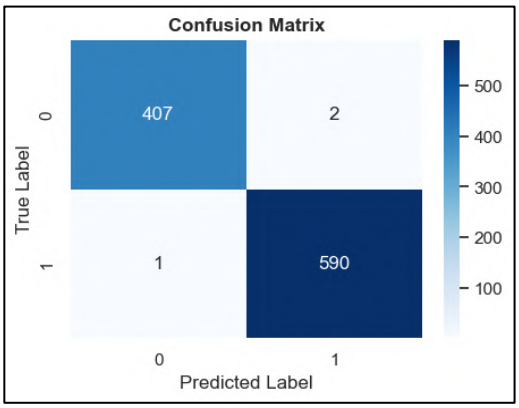

Figure 8: Confusion matrix.
Source: Authors, (2026).

The confusion matrix indicating the performance of a ML model for the detection of cardiac disorder is seen in Figure 8. The matrix compares the model's predicted labels against the true labels to estimate classification accuracy. It indicates that the model has 407 normal cases while it misclassifies 2 normal cases as abnormal. Also, it has only 1 abnormal case that is misclassified as normal and it correctly predicts 590 abnormal cases. The greater number of correct forecasts and the low number of misclassifications reflect the model's high sensitivity and specificity. It indicates that the model is highly effective in distinguishing between normal and abnormal ECG signals, which is essential for detecting cardiac disorders. The small number of false positives and negatives specifies that the model is well-trained and proficient of generalizing well to unseen data.

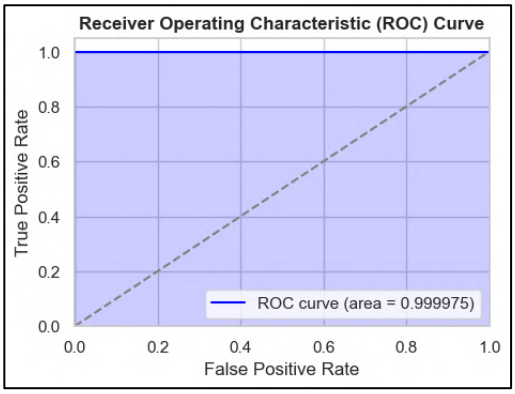

Figure 9: ROC curve.
Source: Authors, (2026).

Figure 9 reveals the Receiver Operating Characteristic (ROC) curve for ECG-based cardiac disorder detection. The ROC value is 0.999975, denotes the model has perfect capability to differentiate among normal and abnormal ECG signals. It demonstrates the model's high sensitivity and specificity, ensuring its reliability in real-world diagnostic scenarios.

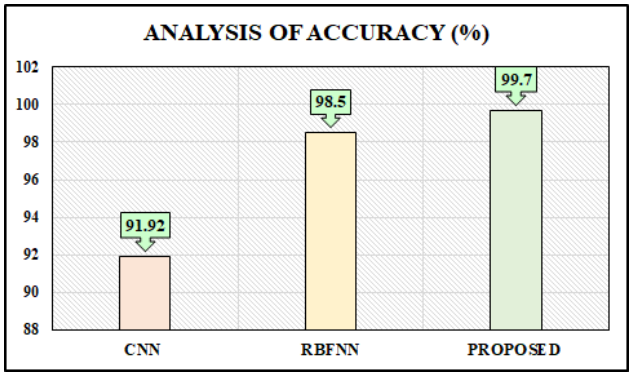

Figure 10: Analysis of accuracy.
Source: Authors, (2026).

Figure 10 represents the analysis of accuracy for Convolutional Neural Network (CNN) [21], Radial Basis Function Neural Network (RBFNN) [22] and developed approach. The developed approach outperforms both CNN and RBFNN, attaining an accuracy of 99.7%, emphasising its superior predictive capability. The results denote that the developed approach is highly effective in accurately diagnosing cardiac diseases. This analysis underscores the potential of the developed approach as a more reliable and precise tool for cardiac disease prediction.

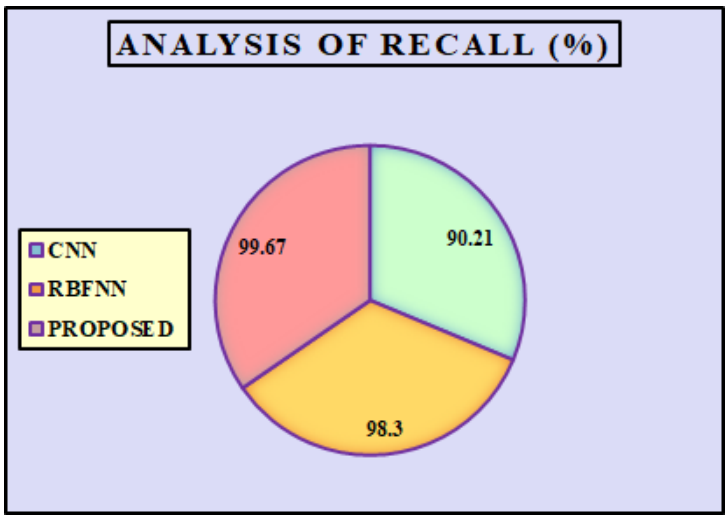

Figure 11: Analysis of Recall.
Source: Authors, (2026).

The analysis of Recall for developed approach with CNN [21] and RBFNN [22] classifier is shown in Figure 11. The developed approach surpasses both CNN and RBFNN, achieving a recall of 99.67%, indicating which is highly capable of minimizing false negatives and correctly identifying the presence of cardiac disease. The higher recall value of the developed approach indicates its superior sensitivity and improved performance in capturing true positive cases, making it more reliable for accurate cardiac disease diagnosis.

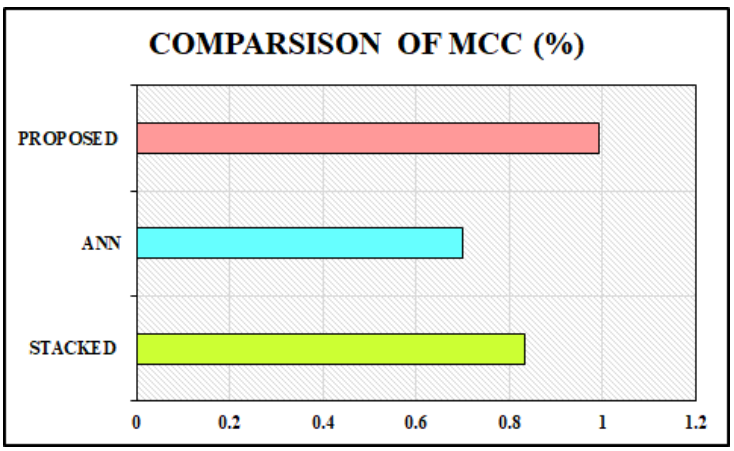

Figure 12: Comparison of MCC.
Source: Authors, (2026).

Figure 12 illustrates the comparison of Matthews Correlation Coefficient (MCC) for distinct classifier used in cardiac disease prediction. The Artificial Neural Network (ANN) [23] model demonstrates a MCC value of 0.70, reflecting a reasonable predictive capability. The Stacked model [24] attains a MCC of 0.835, presenting improved performance in handling classification challenges. However, the developed approach exhibits the highest MCC value of 0.9938, indicating stable classification of both positive and negative cases. It ensures the effectiveness of the developed approach in improving classification accuracy and overall reliability in cardiac disease prediction.

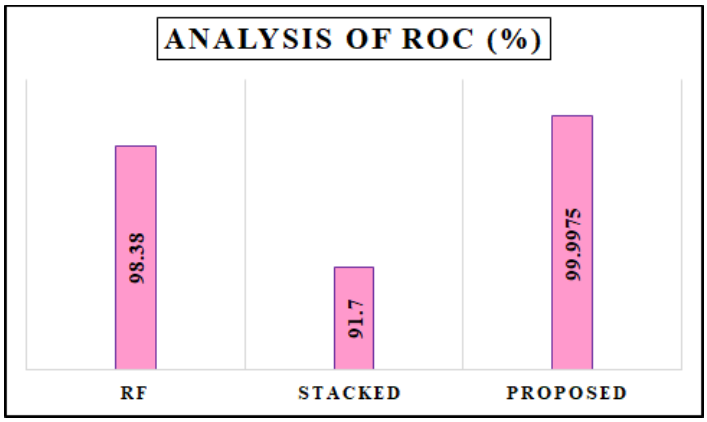

Figure 13: Comparison of ROC.
Source: Authors, (2026).

The comparison of Receiver Operating Characteristic (ROC) for stacked [24], Random Forest (RF) [25] and developed approach is displayed in Figure 13. The developed model has a higher ROC of 99.9975% than other approaches, representing it provides more accurate and reliable predictions. This superior performance indicates that the developed model is highly effective in identifying cardiac diseases with minimal misclassification, making it a valuable tool in clinical diagnosis.

IV. CONCLUSION

By classifying patient ECGs into appropriate cardiac diseases, this research develops an effective transferable DL based ECG classification system that performs autonomous ECG cardiac diagnostics. The Adaptive Wavelet Filter based pre-processing is effective in removing noise and enhancing the quality of ECG signals, which is vital for accurate diagnosis. Then, the HHT based feature extraction method improves the non-invasive diagnosis and early detection of cardiac affliction. Subsequently, the Fire Hawk optimized RETT classifier enhances the accuracy of detecting cardiac diseases by capturing both temporal dependencies and complex patterns in the data. The developed research is implemented in Python software to show the proficiency of developed cardiac affliction detection approach. The outcomes demonstrate that the developed approach performs better than other results in accurately classifying ECGs as either normal or arrhythmia with an accuracy of 99.70%.

ABSTRACT

To maintain the safety and reliability of industrial applications, it is important to analyse faults in three-phase induction motors. Traditional methods have difficulty in identifying the complex characteristics of errors in three-phase induction motors because the signals associated with three-phase induction motors are often noisy and exhibit non-linear dynamics. In this paper, a comprehensive method to analyse errors in three-phase induction motors are proposed that utilises advanced signal preprocessing, feature extraction, and Deep Learning (DL) methods to address these issues. Initially, an Entropy-Driven Empirical Wavelet Filter (EDEWF) are applied to clean the raw motor signal, and a Min-Max scaling is used to normalise the signal to create useful features. Next, an integrated hybrid model combining a Radial Basis Function Neural Network (RBFNN) with a Multi-Head Adaptive Transformer (MHAT) are used for capturing local non-linear characteristics and global context. The features extracted from both models are combined into one feature vector and passed through a fully connected layer for classification. The Starfish Optimization Algorithm (SFOA) is implemented to adjust the hyperparameter of the proposed integrated hybrid model to improve the overall performance. The results obtained from the proposed method showed that it achieved a greatest accuracy, precision, recall, F1-Score of 0.9960 and robustness in the diagnostic of three-phase induction motors compared to traditional diagnostic methods, with respect to classifying the motor states as normal, healthy, and Broken Rotor Bar (BRB) faulted.

I. INTRODUCTION

Induction motors represent a significant aspect of industrialization, as they are extremely tough and do not have their integrity impaired by the environment in which they operate. However, over time, parts of an induction motor will experience wear and deformation, which can result in decreased life expectancy and poor operation output from the motor [1]. An induction motor malfunction can also cause damage to surrounding materials, waste time, and cause workplace accidents, which will lower system reliability. For this reason, fault diagnosis technologies are necessary for timely fault detection, proper action, and safe and secure operation of the equipment.

Induction motor faults are divided into electrical and mechanical faults [2]. The different types of electrical faults found in induction motors are overload, open phase and short-circuit faults. The various ways mechanical faults occur include the bearing, rotor, and stator. Among these three types of mechanical faults, the most typical is the bearing fault; approximately 40 % of all induction motors have a bearing fault. The traditional method for diagnosing faults relies on the use of a mathematical model of the system and the user's input. Due to the complex nature of nonlinear systems, accurately representing them mathematically has always presented challenges. User input techniques rely upon visual and auditory signals gathered from direct observation of the equipment and have resulted in excessive maintenance from over-maintaining equipment due to unexpected faults and unnecessary costs [3-5]. Induction motors fault diagnosis has the purpose of detecting motor component failure, located in the magnetic or mechanical parts of the motor, and assess the motor operating conditions to identify what repair actions must take place. Fault diagnosis in induction motors has two types of diagnostic testing methods to detect the faults such as invasive methods and non-invasive methods [6]. Invasive testing methods measure electrical phone lines, insulation, winding, and polarisation indexes, to consider only the windings that may fail. This test type usually requires expensive Test and Measurement Equipment (T&M), which has its associated risks for testing personnel. Invasive testing is generally completed when an induction motor is not powered and all types of faults must be tested at the same time [7]. Due to the high costs and risks involved in completing the invasive fault test method, there is an increased acceptance of the non-invasive fault tests in monitoring a motor's operational condition and diagnosing a variety of faults at a time, when the induction motor is running. However, non-invasive diagnostic methods, employ mathematical models and physical mechanisms combined with actual operating data to assess and predict degeneration of the induction motor component based on specific motor operating parameters and operating conditions. At this time, there are many categories of these non-invasive fault diagnostic tests include electromagnetic field monitoring, temperature monitoring, infrared monitoring, noise monitoring, vibration monitoring, and current monitoring based on the specific sensor being used [8-13].

In addition, fault diagnosis techniques continue to rely on model-based approaches. Model-based fault diagnosis is heavily reliant on the user's in-depth knowledge of the fault mechanisms along with deep understanding of the processing of signals that are generated during motor operation. The models utilize the generated vibration signal from the motor by creating an indicator representing sensitivity towards a fault and performing the following tasks to detect a fault [14]. Additionally, a mode decomposition technique is proposed that uses variational mode decomposition and improved teager energy operators to extract fault characteristics early in motor operation. Despite the advantages of the techniques, the inherent limitations of these techniques are high computational cost associated with model development and the inability to utilize all available information contained within the monitoring data. Furthermore, the model is task dependent and thus the resulting models will require re-optimization if new tasks are presented [15-17]. To overcome this issue, the proposed model develop an AI-based approach for induction motor fault diagnosis. In this process, the raw data undergoes preprocessing to reduce noise and to clean the data [18]. Due to the computational simplicity, straightforward implementation, and extensive support through conventional signal processing techniques, the classical Fourier transform method is particularly suited towards online applications used for surveillance within industrial environments. However, since this method does not maintain temporal and spatial localization of failures, it poses significant difficulties when attempting to identify early or developing failures [19]. To tackle this issue EDEWF method is implemented. The preprocessed data is passed to a feature engineering stage to normalize the signal features to a common range. Histogram Equalization (HE) enhances the visibility of low-amplitude fault indicators when converting time-frequency images from vibration or current signal data. However, HE enhance the noise levels along with the fault signal which gives rise to false positives [20]. To deal with this constraint, the proposed system uses a Min-Max scaling. Next to enhance the diagnostic accuracy, RBFNN with MHAT is executed in this proposed system. Though, various existing methods are deliberated in this paper to completely analyze each model's respective performance compared with each other, indicating where each model is limited in effectively addressing motor signals that do not follow linear values.

I.1 RELATED WORKS:

By [21] have developed a machine learning approaches, in particular through the usage of Random Forest Classifiers, it has been found to provide extremely high classification accuracies for motor faults due to its ability to utilize ensemble learning, where many Decision Trees are used to increase generality while at the same time reduce overfitting of the Decision Trees. However, with regard to real-time monitoring systems and the number of trees required for high accuracy of Random Forest Classifiers, it becomes computationally expensive particularly when using large amounts of data. In turn [22] have proposed an Induction motor bearing fault diagnostics utilizing Continuous Wavelet Transform (CWT) possess an exceptional time -frequency resolution and, therefore, it is an effective tool in the analysis of non-stationary and transient signal characteristics. Nevertheless, data redundancy and volume provided from the CWT increase the complexity of the extraction and classification of feature information. By [23] have established a CNN-LSTM for the analysis of faults in three-phase induction motors from an AI perspective. The CNN is capable of effectively capturing local characteristics and fault features, while also modelling time-dependent behaviour and dynamics by implementing the LSTM, resulting in High diagnostic accuracy and reliable early fault detection. Nonetheless, CNN-LSTM require large labelled datasets for training and it suffer from poor performance due to insufficient or unbalanced datasets. According to [24] have suggested a ClasLoc, a reliable fault management methodology for transmission lines, based on RBFNN and ANFIS, which provide distinct benefits for the management of transmission line faults because of the combined approach used in the ClasLoc methodology to classify and localize faults more accurately and reliably under various operating conditions. ClasLoc's performance could potentially deteriorate when implemented on large-scale systems due to the increased quantity of rules that need to be created. Though, the overall ClasLoc model lacks interpretability and scalability, which limit ClasLoc's ability to be implemented in real time in large or limited resource power system environments. By [25] have recommended a CNN-RNN observers for predictive maintenance and fault detection for industrial robot drive systems. By automatically learning to identify both spatial and temporal features from sensor data, these observers accurately predict degradation before it occurs and detect faults once they occur. The CNN portion of the observer learns to identify localized fault patterns, while the RNN portion learns to model the dynamic behavior of the system over time, therefore this method is particularly effective for the control of robotic drive systems that are complex, nonlinear and time-varying in their nature.

However, the fault prediction decisions provide lack of interpretability. Additionally, because of the high level of complexity in the design, training and tuning of hyperparameter in CNN-RNN networks, the costs involved in developing these systems possibly be prohibitively high for implementation in an industrial environment.

I.2 OBJECTIVES:

The main objectives of this research includes,

- To design an intense and intelligent fault diagnosis model for three-phase induction motors, the proposed system is implemented.
- To enhance signal quality and fault information, entropy-based empirical wavelet filtering is used in preprocessing stage.
- To provide an accurate assessment of the fault classification, min-max scaling normalization is introduced.
- To capture both global and local fault characteristics, a hybrid RBFNN-multi-head Adaptive Transformer model is executed.
- To optimise the RBFNN model performance for accurate and steady recognition of the induction motor faults, especially for the broken rotor bar condition, starfish optimisation method is employed.

I.3 PAPER ORGANIZATION:

This paper is organized as follows: Section II provides an explanation of the suggested system description. The study methodology is thoroughly described in Section III, which also includes examples of the process, methods, and mathematical representations. The experimental results of this work are described in Section IV, which also include the simulation setup, comparison analysis, and research summary. The conclusion of the proposed investigation is explained in Section V.

II. PROPOSED SYSTEM DESCRIPTION

The proposed system provides a reliable fault diagnosis system for three-phase induction motors. The block diagram of the proposed system is depicted in figure 1.

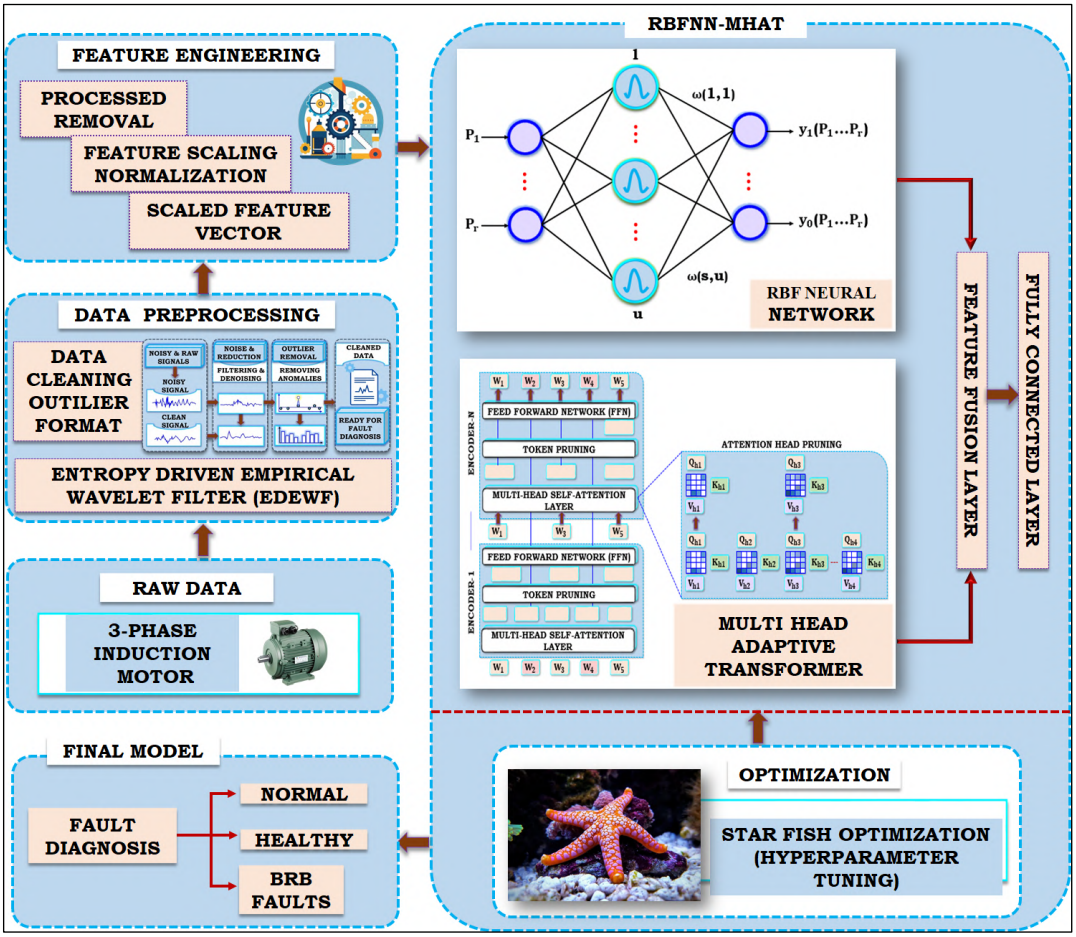

Figure 1: Proposed block diagram.
Source: Authors, (2026).

The suggested fault diagnosis system begins with the collection of raw motor data, which then undergoes data preprocessing via data cleaning, removal of outliers, EDEWF, and other signal enhancement techniques. Following the information enhancement of the raw motor data, feature engineering is performed to create feature vectors through feature scaling and feature normalization. After feature vector creation, a hybrid model that incorporates both a RBFNN and a MHAT are utilized. The RBFNN is used to capture global context features through the use of multi-head self-attention and adaptive weighting, whereas the transformer focuses on extracting local pattern features through the use of an RBF kernel layer.

After the feature extraction process, both models are combined, at which each model is treated as a separate input, and delivered to a fully connected layer for final classification. Optimizing performance is achieved by applying SFOA to tune hyper parameters, providing the capability for the system to diagnose motor operating conditions with high levels of accuracy, whether they are normal operating conditions, healthy working conditions, or failure modes associated with the broken rotor bars supporting effective condition monitoring and predictive maintenance for all motor installations.

III. PROPOSED SYSTEM MODELLING

III.1 DATA PREPROCESSING

III.1.1 Data Cleaning

In diagnosing faults with induction motors, the first step is to identify sensor readings that show irregularities or potential failure. Some of these readings recommend problems with the rotor bars, insulation, or bearings. The diagram of data cleaning process is shown in figure 2.

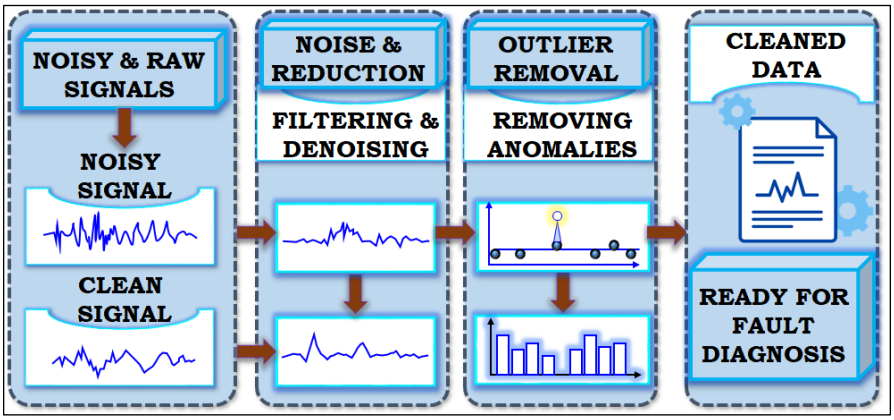

Figure 2: Data cleaning process.
Source: Authors, (2026).

For identifying errors in data systems, each individual measurement in an induction motor fault diagnosis is classified according to its measurement type such as current, voltage and vibration. In some cases, only a single reading is analysed in isolation. In other cases, multiple readings from the same time period are combined to identify context-dependent faults that occur through interactions of several parameters. By converting signals generated by the induction motor into sequences and applying techniques to classify those sequences, faults are identified and classified, thereby improving the effectiveness of condition monitoring and predictive maintenance effectively.

III.1.2 Entropy Driven Empirical Wavelet Filter (EDEWF)

The process of analysis within the EDEWF starts with the decomposition, using Empirical Wavelet Transform (EWT), of a time-dependent function (current or vibration) from a motor into two components such as an approximation mode and detail modes as follows,

$$f_0(t) = EWT(0,t) * \phi_1(t) \tag{1}$$

$$f_k(t) = EWT(k,t) * \psi_k(t) \tag{2}$$

Where, $EWT(0,t)$ and $EWT(k,t)$ is represented as an approximation coefficients and detail coefficients respectively.

$$EWT(0,t) = \langle f, \phi_1 \rangle \tag{3}$$

$$EWT(k,t) = \langle f, \psi_k \rangle \tag{4}$$

Each mode's entropy $f_k(t)$ is computed to determine the information aspect of that mode. Entropy is referred to as Shannon Entropy or Energy Entropy, and works by measuring the energy distribution across the selection of modal frequencies, as provided by:

$$H(f_k) = -\sum_i P_i \, log(P_i) \tag{5}$$

In the above expression, P_i is the normalized distribution of energy across the selected modal frequencies. Therefore, when a fault has occurred, the energy distribution is concentrated on those modes of increased entropy. And for the other modes, it is automatically suppressed. The reconstructed fault signal is determined by the addition of only those selected modes:

$$f_{fault}(t) = \sum_{k \in selected} f_k \, (t) \tag{6}$$

Thus, the EDEWF enhances weak mark components in relation to the fault and suppresses noise. This makes the approach suitable for diagnosing fault conditions in induction motors.

III.2 FEATURE ENGINEERING- MIN-MAX SCALING

Min-Max scaling method of normalizing the signals extracted from induction motors are large variances between the signals being analysed due to differences in measurement units and ranges. The Min-Max scaling method allows to set all outputs from different signals on a common scale of 0 to 1. For each signal that has been normalised using the Min-Max Scaling formula, a new normalised value is calculated using the formula in the following way,

$$X_{ij}^{MM} = \frac{X_{ij} - X_{min}}{X_{max} - X_{min}} \tag{7}$$

Where, X_{min} and X_{max} are value of features. By using the Min-Max Scaling method to normalise the EDEWF-derived features associated with the induction motor fault diagnosis application, it makes it possible to have a consistent method to compare the EDEWF-derived features across multiple different modes to determine which mode contain weak fault-related marks, provide signal characteristic information and a method to interpret differences in the condition of an induction motor while eliminating variable ranges and the influence of variable units on the comparison between modes.

III.3 HYBRID MODEL- RBFNN- MHAT

An RBFNN represents a kind of nonlinear mapping from a feature space obtained from induction motor signal data to types of motor faults. An input vector $x \in R^d$, represents a set of features created using data taken from an induction motor's stator current, vibration sensor, and/or audio microphone, while the prototype $c_i \in R^d$ for the ith RBF unit represents a typical operating condition (or fault) for that motor. The RBF unit outputs the Euclidian distance between the input vector and the prototype.

$$\phi_i(x) = exp\left(\frac{-\|x - c_i\|^2}{2\sigma_i^2}\right) \tag{8}$$

Where, $\|\cdot\|$ denotes the Euclidean norm and σ_i is the Gaussian width of the ith RBF unit. The Gaussian function is popular for establishing a relation between localizing, smoothness, hence modelling delicate changes that occur on induction motor fault marks. The diagram of RBFNN- MHAT is shown in figure 3.

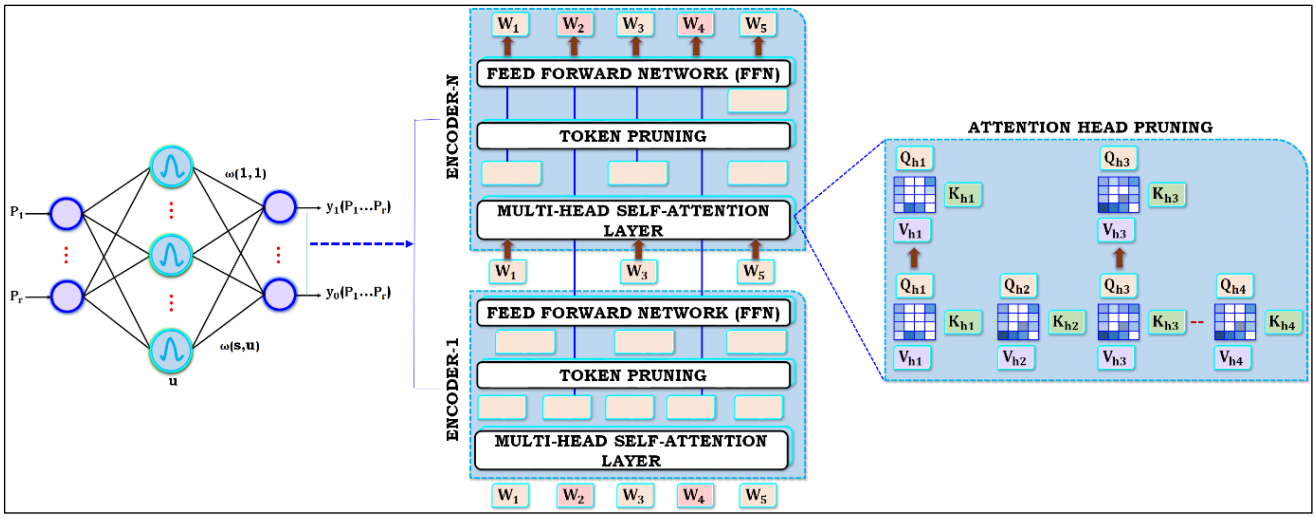

Figure 3: HYBRID MODEL- RBFNN- MHAT.
Source: Authors, (2026).

An RBF unit produces localized responses, which represents the similar or dissimilar observed condition of the motor with any of all fault prototypes stored in its memory. The Gaussian width σ_i determines the region over which the total influence of that prototype occurs. Low values of σ_i render an RBF unit very sensitive to small variations in the motor's features, while higher values of σ_i produce RBF units that are tolerant variations resulting from load changes, speed fluctuations, and measurement noise that are a common occurrence during the operation of induction motors. The output of the RBF neural network for the kth fault class is calculated as a weighted linear combination of the output from all RBF units,

$$y_k = \sum_{i=1}^{M} w_{ik}\phi_i(x) \tag{9}$$

Where, w_{ik} represents the connection weight between the ith RBF unit and the kth output neuron, and M denotes the total number of Gaussian units. The bias term is neglected to reduce network complexity. The formulation above shows that the RBF neural network linearly discriminates in a transformed feature space created using the non-linear mapping, $\phi_i(x)$. Therefore, decision boundaries for different induction motor fault classes are hyperplanes in this high-dimensional RBF feature. According to Cover's theorem, mapping to a higher dimension with a non-linear function increases the probability of making the induction motor fault pattern linearly separable. Hence, as M increases, the induction motor fault classes are more distinct from one another, However, too high a value of M cause the model to over fit; therefore, it decrease its ability to generalize when the fault data available were small in volume.

RBFNN partitions feature space into hyper spherical sectors centred around c_i and widthσ_i. Clustering methods typically supply the clustering centres for RBFNNs. Most conventional clustering methods are based on unsupervised techniques, which typically do not take into the differences between fault categories and create clusters that consist of samples from more than one fault category, this results in a low level of diagnostic accuracy. The supervised methods are more effective at producing homogeneous clusters for the purposes of diagnostic accuracy. In addition to the distance $\| x - c_i \|$ between a feature vector and a cluster centre, the Gaussian width σ_i determines the factor in assigning fault connection. Thus, a feature vector have a closer distance to one cluster centre than another, a properly selected σ_i produce a greater activation for the other fault class, enabling the accurate handling of overlapping fault feature sets and variable operating conditions of induction motors. Clustering methods of RBFNN is depicted in figure 4.

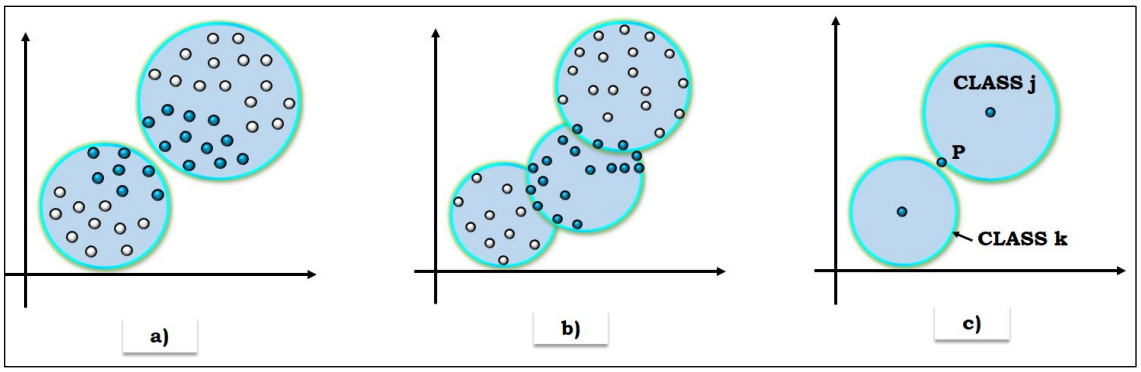

Figure 4: Clustering methods of RBFNN.
Source: Authors, (2026).

The MHAT is from the base Multi-Head Attention framework that extracts the additional fault features from induction motor signals appropriately without computing redundantly. Let $x = x_1, x_2, \ldots x_T$, where $x_t \in R^d$, denote the sequence of embedded induction motor signal marks that were derived from either the stator current or vibration signals, and let $q \in R^d$ represent a query vector resulting from the same sequence of induction motor signals. The manner in which the elastic form of scaled dot product is used to model temporality-related dependencies through induction motor data is,

$$Attention(x, q) = W_o \sum_{t=1}^{T} \alpha_t (q) W_v x_t \tag{10}$$

The attention weights are calculated as follows,

$$\alpha_t(q) = softmax\left(\frac{q^T W_q^t W_K x_t}{\sqrt{d}}\right) \tag{11}$$

$W_o, W_v, W_q, W_k \epsilon R^{d \times d}$ represent the weight vectors used for each signal in the multi-head attention mechanism. Each attention head is designed to target a specific fault feature of a motor signal that occur in time, such as an intermittent burst of bearing defects or rotor bar harmonics. Once the focus of the individual head is established, the output of the multi-head attention is the sum of H parallel attention heads is given by,

$$MH\ Attention(x, q) = \sum_{h=1}^{H} Attention_h(x, q) \tag{12}$$

Where, each $Attention_h$ represents a low-rank decomposition of the output of the previous attention heads. In the analysis of faults in induction motors, many of the attention heads are considered interchangeable or provide only minimal assistance. To assist in the identification of which heads to keep for training purposes, a head sensitivity score is generated from a forward pass through a transformer model, fine-tuned specifically for classifying faults. Once these scores have been computed, the heads reflect the highest levels of usefulness included in training. When training is completed, each layer$i + 1$, the retention m_{i+1} is the number of heads, is selected randomly based on,

$$m_{i+1} \in [m_{i+1}, m_i] \tag{13}$$

Where, m_i is the number of heads retained from prior i layer, m_{i+1} is the minimum number of heads retained in the next layer, and only one head retained in the final layer. This reflects that the deeper layers have fewer but more important heads for recognizing anomalies related to fault marks. The MHAT offers a computationally efficient methodology for induction motor fault diagnosis. The approach allows for an improved accuracy relationship when compared to traditional transformer models. Hence the proposed system is more effective, reliable, and scalable approach for performing induction motor fault diagnosis that is employed on a real-time basis as part of an industrial condition monitoring system.

III.4 HYPERPARAMETER TUNING- SFOA

Induction motor fault identification is approached through optimization by minimizing misclassification errors or maximizing fault separation using the features generated from stator current, vibration or acoustic signals. In SFOA, each starfish requires its own candidate fault detection solution, representing a classifier parameter vector, with an assigned position expressed as,

$$X = \begin{bmatrix} X_{11} & X_{12} & \dots & X_{1D} \\ X_{21} & X_{22} & \dots & X_{2D} \\ \vdots & \vdots & \ddots & \vdots \\ X_{N1} & X_{N2} & \cdots & X_{ND} \end{bmatrix} \quad (14)$$

Where N should be the size of the starfish population and D is the number of decision variables for induction motor fault detection. Starfish are initialized to relative position with respect to the allowable dimension of the induction motor fault detection parameter space by,

$$X_{ij} = l_j + r(u_j - l_j), i = 1,2 \dots N, j = 1,2, \dots D \quad (15)$$

Where l_j stands for the lower bounds of the fault detection parameters, u_j denotes the upper bounds, and $r \in \{0,1\}$ is a random number. Each starfish's utility is evaluated through a fault detection objective function that is expressed as,

$$F = \begin{bmatrix} f(X_1) \\ f(X_2) \\ \vdots \\ f(X_N) \end{bmatrix}_{N \times 1} \quad (16)$$

The SFOA uses a hybrid exploration strategy to cover the complete feature space for induction motor faults.

Pseudo-code: SFOA.

```
Initialize population X = {x1, x2, …, xN} randomly within [LB, UB]
Evaluate fitness F(i) for each xi
Identify global best solution:
    xpos_best = argmin(F)
    fval_best = min(F)
Set iteration counter T = 1
While T ≤ MaxIt do
  Update control parameters:
    θ = 2 × (1 − T / MaxIt)        // decay factor
    t_EO = T / MaxIt               // exploitation–exploration balance
  For each individual i = 1 to N do
    Generate random number r ∈ [0,1]
    If r < GP then   // ===== Exploration Phase =====
      If D > 5 then
        Perform 5D Starfish Search:
        x_new = xi + θ × randn(1,D) × |x_best − xi|
      Else
        Perform 1D Starfish Search:
        k = random dimension ∈ [1, D]
        x_new(k) = xi(k) + θ × rand() × (x_best(k) − xi(k))
      End If
    Else            // ===== Exploitation Phase =====
      // Predation behavior
      x_pred = xi + rand() × (x_best − xi)
      // Regeneration behavior
      x_new = x_pred + t_EO × randn(1,D)
    End If
    Apply boundary constraints:
    x_new = min(max(x_new, LB), UB)
    Evaluate new fitness F_new = F(x_new)
    If F_new < F(i) then
      xi = x_new
      F(i) = F_new
    End If
    If F_new < fval_best then
      xpos_best = x_new
      fval_best = F_new
    End If
  End For
  Store convergence value:
  Curve(T) = fval_best
  T = T + 1
End While
Return xpos_best, fval_best, Curve
```

For instance, for D >5, the concurrent five-dimensional search pattern updates five randomly chosen fault-sensitive features such as sideband amplitude, statistical vibrations, or typical values of non-typical faults.

$$Y_{i,p}^{T} = \begin{cases} X_{i,p}^{T} + a_1\left(X_{best,p}^{T} - X_{i,p}^{T}\right)cos\theta, r \leq 0.5 \\ X_{i,p}^{T} - a_1\left(X_{best,p}^{T} - X_{i,p}^{T}\right)sin\theta, r > 0.5 \end{cases} \quad (17)$$

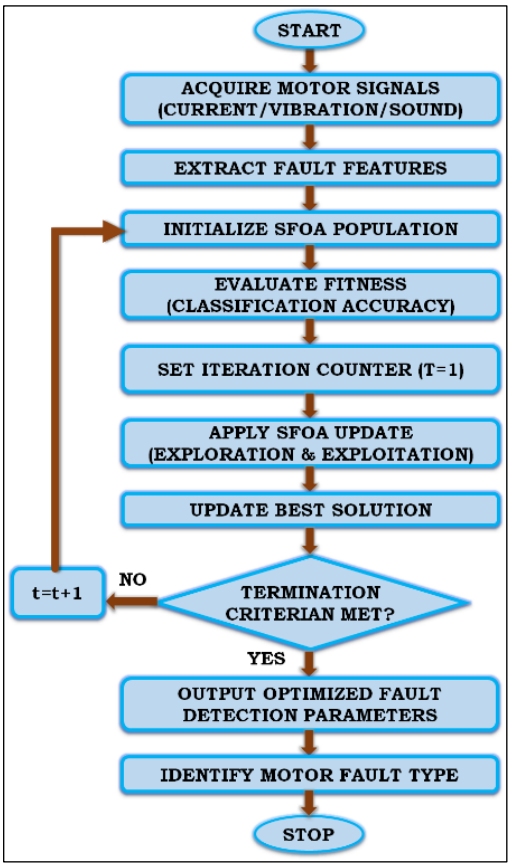

Figure 5: Flowchart of SFOA.
Source: Authors, (2026).

Flowchart of SFOA is shown in figure 5. Where, $X_{best,p}^{T}$ represents the most effective method of recognizing faults in iteration T within the p^{th}dimensional space.

$$a_1 = (2r-1)\pi, \theta = \frac{\pi}{2} - \frac{T}{T_{max}} \quad (18)$$

The values of the other variables define the step size and convergence behaviour for feature exploration. A starfish that is updated to a value beyond the range retain its last value.

$$X_{i,p}^{T+1} = \begin{cases} Y_{i,p}^{T}, l_p \leq Y_{i,p}^{T} \leq u_p \\ X_{i,p}^{T}, \ otherwise \end{cases} \quad (19)$$

When the total number of parameters associated with faults is relatively low$(D \leq 5)$, only unidirectional searches are implemented during feature searching. The above equation summarizes a generic form of the searching procedure.

$$Y_{i,q}^{T} = E_t X_{i,p}^{T} + A_1\left(X_{k1,p}^{T} - X_{i,p}^{T}\right) + A_2\left(X_{k2,p}^{T} - X_{i,p}^{T}\right) \quad (20)$$

Where $X_{k1,p}^{T}$ and $X_{k2,p}^{T}$ are two randomly selected starfish which represents an alternative fault detection methods with $A_1, A_2 \epsilon (-1,1)$ and the energy of a starfish is computed according to equation,

$$E_t = \frac{T_{max} - T}{T_{max}} cos(h) \quad (21)$$

The exploitation phase enables the enhancement of fault detection capabilities through a naturalistic simulation of the collective hunting habits of starfish. Thus, a distance calculation must be performed between the best fault detection method provided at present and the selected starfish.

$$d_m = X_{best}^{T} - X_{m}^{T}, m = 1,2,\ldots,5 \quad (22)$$

A parallel bidirectional search method is employed for updating the positions of the starfish is,

$$Y_i^T = X_i^T + r_1 dm_1 + r_2 dm_2 \quad (23)$$

The parameters $r_1, r_2 \epsilon (0,1)$for the starfish. This method provides the ability for the fault detection model to converge to their respective discriminative decision boundaries while maintaining diversity. To prevent stagnation in local optima due to non-stationarity of the motor signal and interference due to noise in the motor signal, a regeneration mechanism is applied to the last starfish in the group.

$$Y_i^T = exp\left(\frac{T-N}{T_{max}}\right) X_i^T \tag{24}$$

This mechanism allows the addition of controlled perturbations to the starfish and further increases the convergence of the global. The boundary constraints of each starfish are applied as,

$$X_i^{T+1} = \begin{cases} l_b, Y_i^T < l_b \\ u_b, Y_i^T > u_b \\ Y_i^T, otherwise \end{cases} \tag{25}$$

Table 1: Optimization values of SFOA.

PARAMETERS	VALUES
RBF Units	96.000
Transformer Heads	4.000
Transformer Layers	2.000
Learning Rate	0.001
Batch Size	64.000
Dropout Rate	0.200
Dense Units	128.000
Number of Starfish	30.000
Maximum Iterations	50.000
Exploration Probability	0.500

Source: Authors, (2026).

The starfish determine only the search within a specified area. By applying the equations in these processes within the SFOA, it designed specifically for the induction motor fault detection system, when the SFOA is applied to improve the fault sensitivity and detection parameters of the induction motor fault detection system, it leads to enhanced accuracy, robustness to a performance effect of noise, and assures that motor faults are accurately identified under several operational conditions.

IV. RESULT AND DISCUSSION

This research work highlights a Starfish Optimized AI-based DL framework for accurately detecting broken rotor bar faults on induction motors by making use of the BBIM2023 dataset. The BBIM2023 dataset consists of 24,000 samples containing 36 inputs features related to the time, three phase stator currents, multiple rotor bar current, ring current, rotor speed, and rotor position; as well as a target class indicating the motor's health condition. The data divided into 70% for training and 30% for testing to enable proper evaluation of the reliability of the model's performance. In order to obtain effective analysis of non-stationary and nonlinear characteristics in the electrical signals related to electrical motors, it used an additional advanced signal processing methods including the Entropy Driven Empirical Wavelet Filter (EDEWF), the Empirical Wavelet Transform (EWT), the Wavelet Packet Transform (WPT) and the Hilbert–Huang Transform (HHT), which were used as part of the procedure to reduce noise and to extract features that are sensitive to faults. The features that were extracted were then applied to a couple of different intelligent classification models including Radial Basis Function Neural Network (RBFNN) and Multi-Head Adaptive Transformer (MHAT). These intelligent classification models were able to represent complex nonlinear relationships and long-term temporal dependencies present within the dataset. Additionally, to improve the overall classification accuracy of the developed motor model and to improve the robustness of the classification models, the SFOA was used for optimally tuning the model parameters and for performing feature selection.

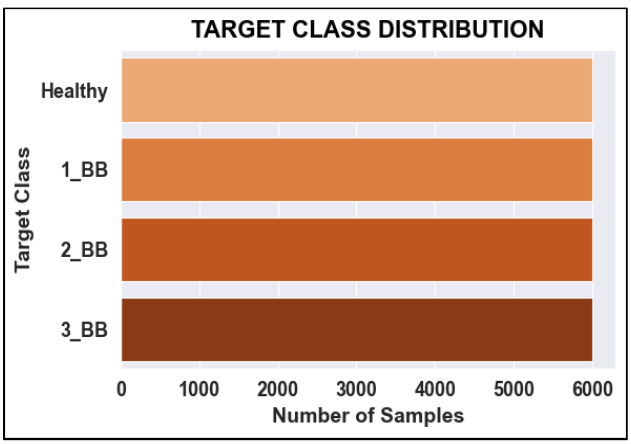

Figure 6: Distribution of target class.
Source: Authors, (2026).

Figure 6 shows the distribution of target class. The classes include a uniform number of the four Target Classes (i.e., Healthy, 1_BB, 2_BB, 3_BB), each class has approximately 6,000 samples of data for use during model training.

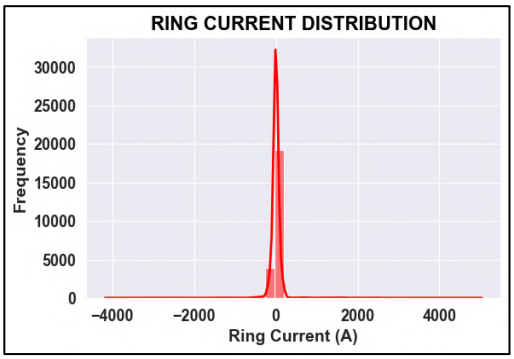

Figure 7: Distribution of ring current.
Source: Authors, (2026).

Distribution of ring current is depicted in figure 7. There is a strong concentration of recorded Ring Currents, the majority of recorded Ring Currents are in the 0A region with very few outliers in either positive or negative directions.

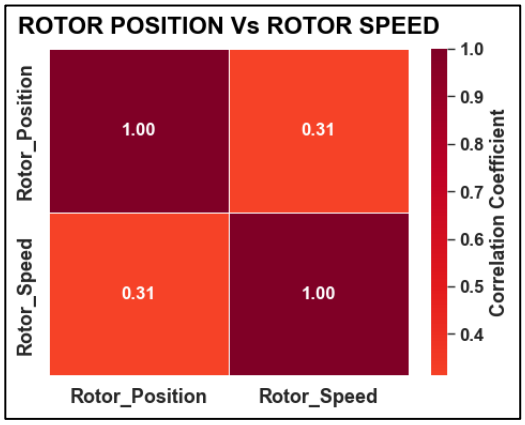

Figure 8: Rotor position vs Rotor speed.
Source: Authors, (2026).

The diagram of Rotor position vs Rotor speed is illustrated in figure 8. There is a moderate positive correlation between the Rotor Position (RP) and Rotor Speed (RS) (CP=0.31), with the CP of RP being 1.00 and the CP of RS being 1.00.

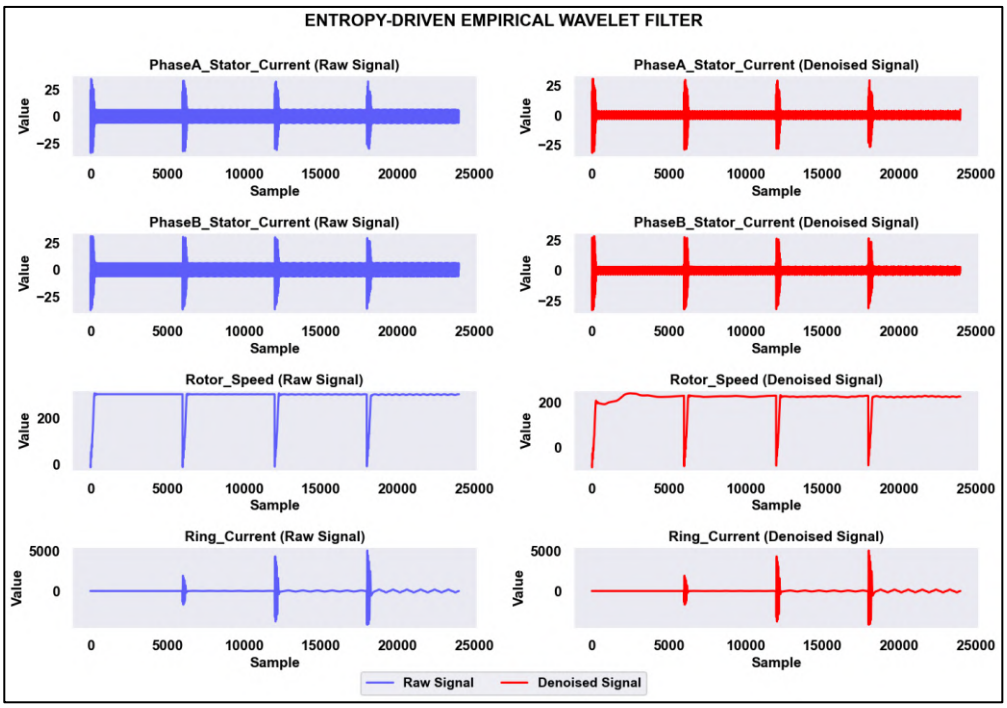

Figure 9: Entropy driven Empirical Wavelet Filter.
Source: Authors, (2026).

Figure 9 shows a high level of consistency when the signals were processed with an Entropy-Driven Empirical Wavelet Filter (EDEWF). The denoised signals represent an accurate representation of the most important transients and fault-related events, producing smooth and interpretable representations of the signals, while significantly reducing noise, fluctuations, and unwanted oscillations.

Table 2: Comparison of performance metrics.

SI.NO	FILTER	SNR (dB)	PSNR (dB)	MSE	RMSE	SSIM
1	EDEWF	35.4238	55.8329	1920.3489	43.8232	0.9991
2	EWT	31.1615	50.7602	2821.3994	47.9306	0.9987
3	WPT	30.9846	49.9126	3050.2765	55.2749	0.9979
4	HHT	12.4512	18.2150	6043.1248	340.9597	0.2812

Source: Authors, (2026).

Table 2 illustrates the filtered image quality comparison table. EDEWF was the best filtering method due to highest SNR, PSNR, and SSIM and RMSE. It has obtained the best classification of information and provides the maximum noise reduction and image quality. EWT and WPT will deliver moderate performance, however HHT demonstrates weaker performance across all measures.

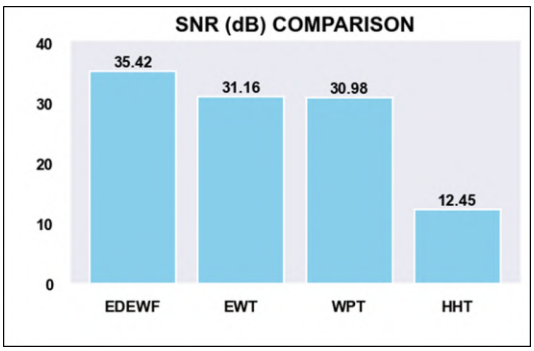

Figure 10: Comparison of SNR.
Source: Authors, (2026).

The bar graph in figure 10 compares the SNR performance of EDEWF, EWT, WPT, and HHT. The highest SNR was recorded from EDEWF (35.42dB), followed by EWT (31.16dB) and WPT (30.98dB). In contrast, HHT recorded the lowest SNR of all methods tested (12.45dB).

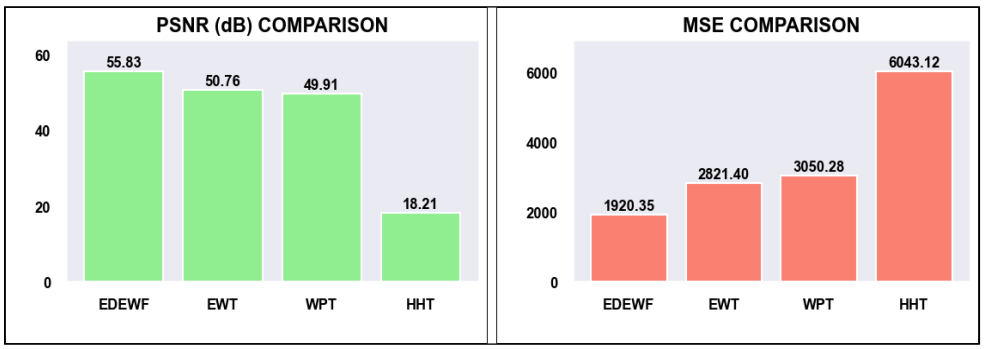

Figure 11: Comparison of PSNR and MSE.
Source: Authors, (2026).

As shown in figure 11, EDEWF achieved the highest PSNR (55.83dB) and the lowest MSE (1920.35) of any method tested, indicating the highest reconstruction accuracy, while EWT and WPT achieved moderate performances (PSNR= 50.76/ MSE=2821.40 & PSNR= 49.91dB/ MSE=3050.28), while HHT achieved the lowest PSNR (18.21dB) and the highest MSE (6043.12).

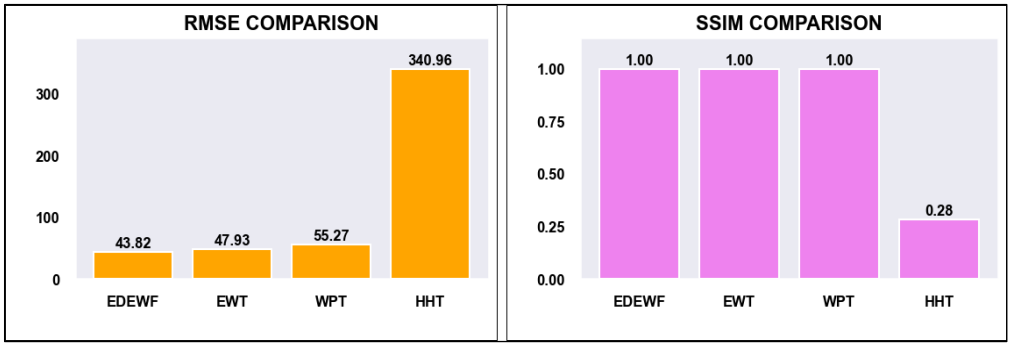

Figure 12: Comparison of RMSE and SSIM.
Source: Authors, (2026).

Figure 12 shows the comparison of RMSE and SSIM. The charts suggest that EDEWF, EWT, and WPT have excellent performance due to their low error rates and high structural similarities to one another. In contrast, HHT's performance is poor due to its high errors and low structural similarity to the other models.

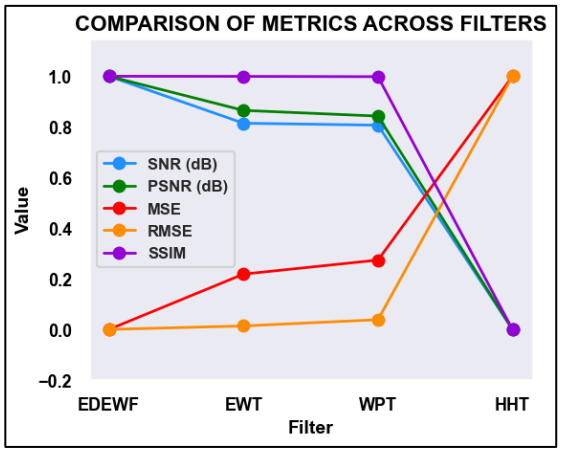

Figure 13: Comparison of metrics across filters.
Source: Authors, (2026).

Figure 13 indicates that EDEWF, EWT, and WPT have strong signal quality based on high similarity and low errors, while HHT has lower signal quality and therefore produces worse metrics and higher errors.

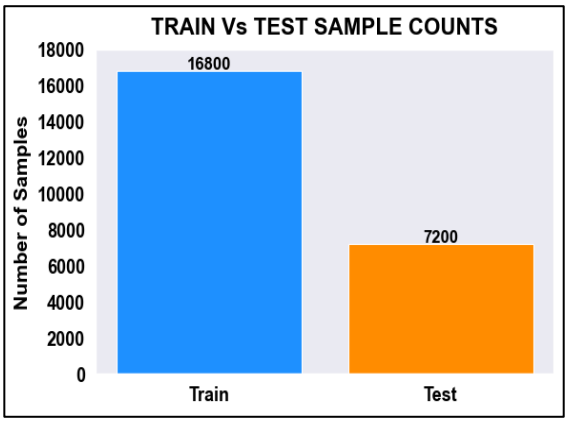

Figure 14: Train vs Test sample counts.
Source: Authors, (2026).

Figure 14 depicts the comparison of train and test sample counts. In addition to splitting the dataset into more training samples than testing samples, the plot shows that the emphasis of the model design is on learning the model rather than evaluating the model.

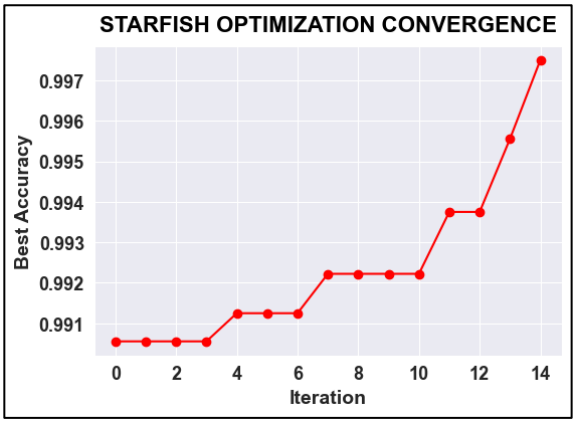

Figure 15: Starfish optimization convergence.
Source: Authors, (2026).

Figure 15 displays that Starfish Optimization is converging steadily, with the best accuracy increasing steadily over iterations until reaching its final iteration, where it improves dramatically to approximately 0.998.

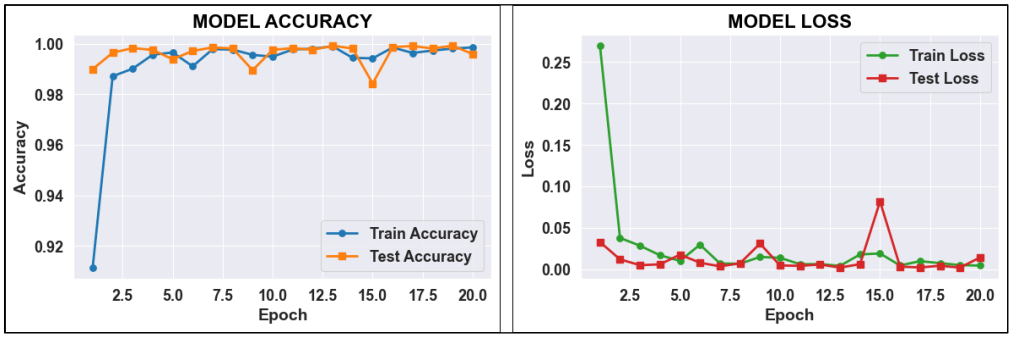

Figure 16: Model accuracy and Model loss for SFOA-Hybrid RBFNN-MHAT.
Source: Authors, (2026).

Figure 16 demonstrates that the model achieves near-perfect accuracy on both the training and testing datasets very quickly and is stable throughout all epochs. Training and testing losses drop quickly during the early epochs and remain low with only slight fluctuations, indicating the model's ability to converge properly without overfitting.

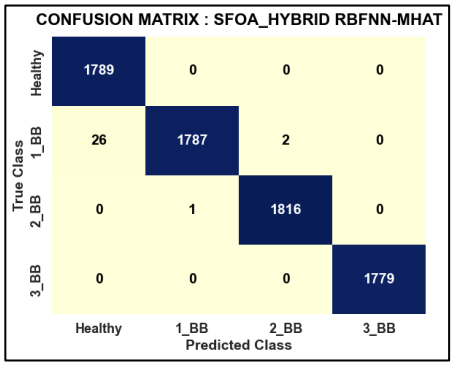

Figure 17: Confusion matrix of SFOA-Hybrid RBFNN-MHAT.
Source: Authors, (2026).

Confusion matrix of SFOA-Hybrid RBFNN-MHAT is illustrated in figure 17. The confusion matrix illuminates near-perfect classification performance, wherein nearly all samples were correctly classified. The only two misclassified categories are among Healthy vs. 1_BB or 1_BB vs. 2_BB, while the 3_BB category was perfectly classified.

Table 3: Performance metrics of SFOA-Hybrid RBFNN-MHAT.

SI.NO	METRICS	VALUES
1	Accuracy	0.9960
2	Precision	0.9960
3	Recall	0.9960
4	F1-Score	0.9960
5	Cohen’s Kappa	0.9946
6	MCC	0.9946
7	ROC-AUC	1.0000

Source: Authors, (2026).

In table 3, the SFOA-Hybrid RBFNN- MHAT model demonstrates approximately the highest possible performance for each metric at 99% accuracy, precision, recall and F1-score, a very high Cohen's Kappa and MCC at 0.99, and an ideal ROC-AUC score of 1.0, indicating very strong classification reliability and robustness.

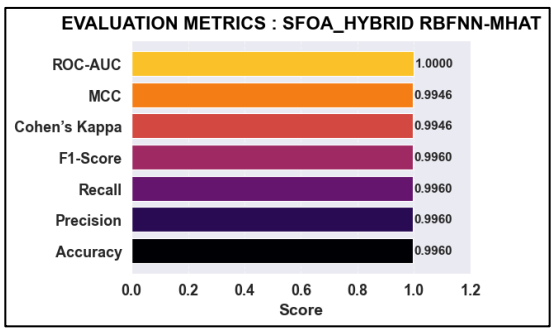

Figure 18: Evaluation metrics of SFOA-Hybrid RBFNN-MHAT.
Source: Authors, (2026).

Figure 18 demonstrates impressive performance for the SFOA-HYBRID RBFNN-MHAT model as evidenced by its near-perfect measures, ROC-AUC of 1.0; Accuracy/Precision/Recall/F1 score of 0.996 and MCC & Cohen's Kappa of 0.9964 and 0.9946. The model has been consistently classified as high quality and as a result provides reliable and consistent classification.

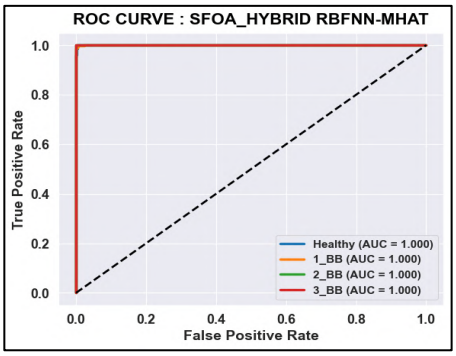

Figure 19: ROC curve of SFOA-Hybrid RBFNN-MHAT.
Source: Authors, (2026).

Figure 19 illustrate the indicating AUC = 1.000 and perfect classification performance with exceptional separation of the classes from one another.

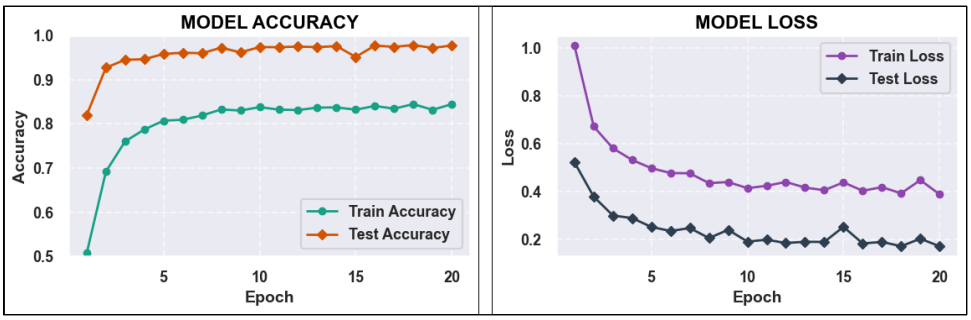

Figure 20: Model accuracy and model loss for Hybrid RBFNN-MHAT.
Source: Authors, (2026).

Figure 20 explains the model accuracy and model loss for Hybrid RBFNN-MHAT. The learning of the model is consistent and it generalizes well. The accuracy for both training and testing continues to increase until stabilizing (Test 97% and Train ≈ 84%). Training and testing losses have consistently decreased over time, demonstrating effective convergence without overfitting.

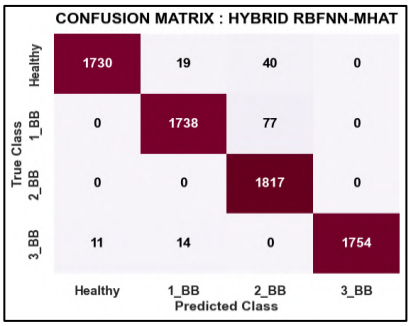

Figure 21: Confusion matrix for Hybrid RBFNN-MHAT.
Source: Authors, (2026).

The confusion matrix demonstrates high classification performance in figure 21. There is high percentage of samples that were accurately classified along the diagonal (Healthy = 1730; 1_BB = 1738; 2_BB = 1817; and 3_BB = 1754), which indicates the model's strong overall accuracy and low confusion rates among the classes.

Table 4: Performance metrics of Hybrid RBFNN-MHAT.

SI.NO	METRICS	VALUE
1	Accuracy	0.9776
2	Precision	0.9786
3	Recall	0.9776
4	F1-Score	0.9778
5	Cohen's Kappa	0.9702
6	MCC	0.9704
7	ROC-AUC	0.9965

Source: Authors, (2026).

In table 4, the Hybrid RBFNN - MHAT model demonstrates sustained and strong performance, exhibiting approximately 97% accuracy, precision, recall, and F1-score, strong Cohen's Kappa and MCC factors, with an extraordinary ROC-AUC of 0.99, signalling dependable and robust classification evaluation.

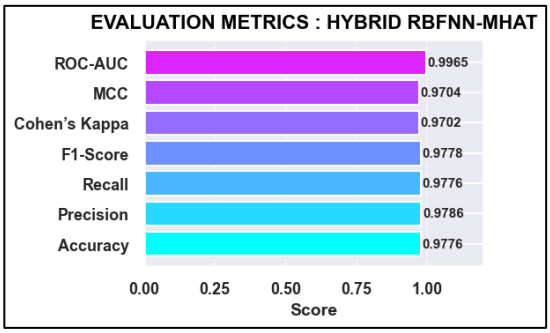

Figure 22: Evaluation metrics of Hybrid RBFNN-MHAT.
Source: Authors, (2026).

The performance of the model is superior in terms of the metrics which is depicted in figure 22. The high reliability and balance of classification are supported by the robustness and close agreement of the high MCC and Cohen's Kappa.

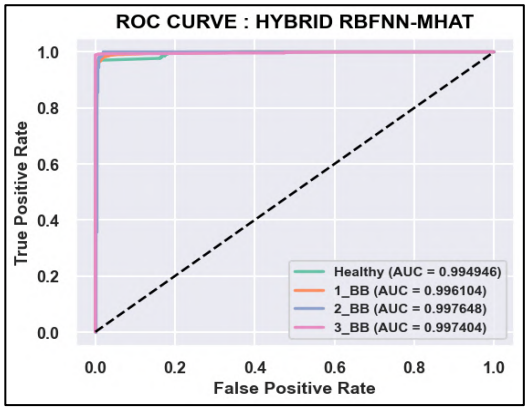

Figure 23: ROC curve of Hybrid RBFNN-MHAT.
Source: Authors, (2026).

The ROC curves show that there is a near-perfect separation of all classes, with AUCs, which is showed in figure 23. This indicates excellent discrimination between the different classes with very low false-positive rates for both Healthy and all classes of BB.

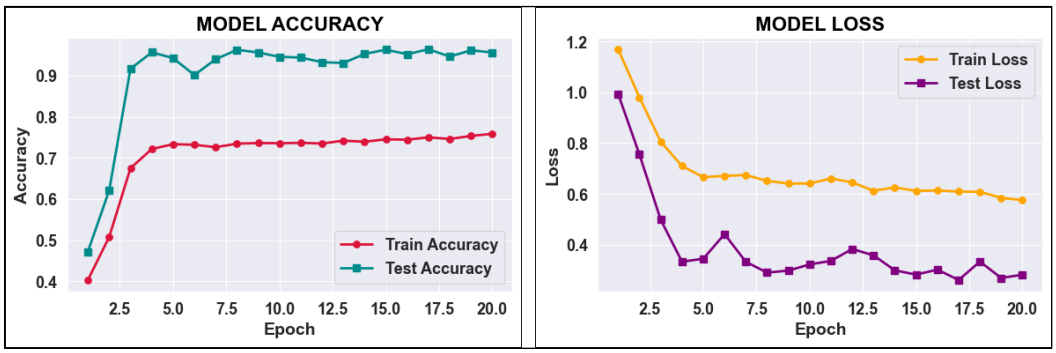

Figure 24: Model accuracy and model loss for MHAT.
Source: Authors, (2026).

Figure 24 shows the Model accuracy and model loss for MHAT. In the first few epochs of training, the model learns very quickly; however, it then stabilizes, with a final training accuracy of roughly 75% and test accuracy between 93 and 95%. The training and test losses have declined at a steady rate and have shown no signs of pronounced overfitting, which indicates that the model has performed well and has exhibited stable performance.

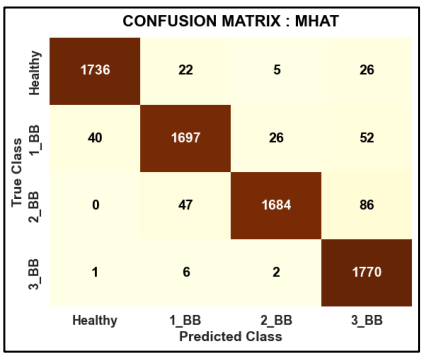

Figure 25: Confusion matrix for MHAT.
Source: Authors, (2026).

Figure 25 displays the confusion matrix for MHAT. From the confusion matrix, there was a strong classification performance, as evidenced by the detail that the diagonal had most of the correctly predicted samples for every class. Hence, the overall accuracy was quite high but that there was some minor misclassifications between the different BB classes.

Table 5: Performance metrics of MHAT.

SI.NO	METRICS	VALUES
1	Accuracy	0.9565
2	Precision	0.9576
3	Recall	0.9568
4	F1-Score	0.9566
5	Cohen’s Kappa	0.9420
6	MCC	0.9425
7	ROC-AUC	0.9919

Source: Authors, (2026).

In table 5, the MHAT method exhibited reliable overall quality at approximately 0.95 of accuracy, precision, recall and F1-score, as well as the highest Cohen's Kappa and MCC (0.94 each) and a very strong ROC-AUC at 0.99, confirming that it is an effective and less optimal.

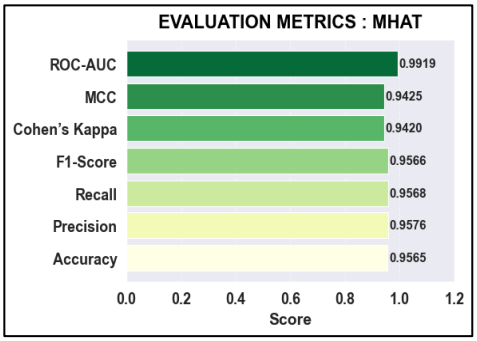

Figure 26: Evaluation metrics for MHAT.
Source: Authors, (2026).

The evaluation metrics are indicative of the model's performance which is depicted in figure 26. There is high accuracy, precision, recall and F1-score, strong agreement in terms of MCC and Cohen's Kappa (approximately 0.94), and excellent ROC-AUC (approximately 0.99), indicating that the model has demonstrated reliable classification with robustness.

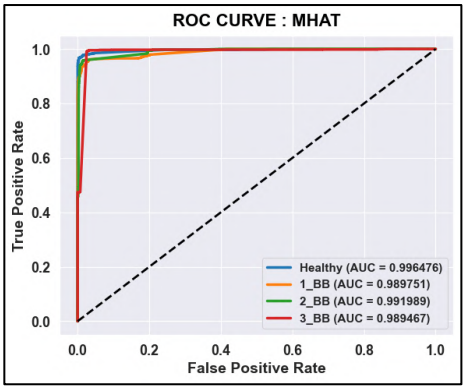

Figure 27: ROC curve for MHAT.
Source: Authors, (2026).

The ROC curves produced during evaluation also indicate that there has been an excellent classification performance across the various classes which is mentioned in figure 27, and the curves are well positioned toward the upper left corner of the graph. The AUC values, which were found to be all very high, demonstrate strong discrimination by the model, and the Healthy class was determined to deliver the best performing model.

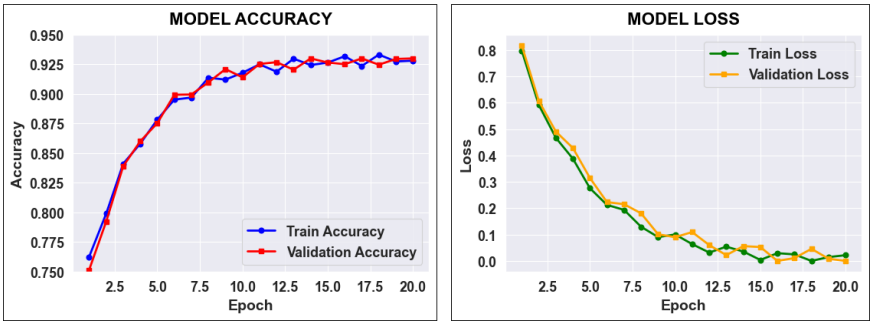

Figure 28: Model accuracy and model loss for RBFNN.
Source: Authors, (2026).

Figure 28 exhibits a progression in terms of the development of the model's performance during the training process by increased training and validation accuracy and decreased training and validation loss; both were observed to be steadily converging and demonstrated no significant evidence of overfitting.

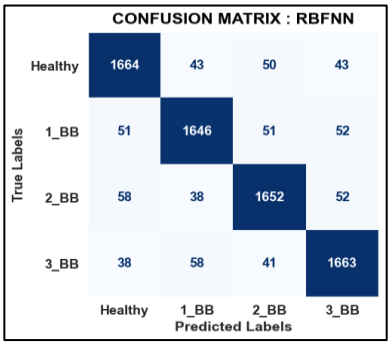

Figure 29: Confusion matrix for RBFNN.
Source: Authors, (2026).

The confusion matrix in figure 29 provided an evidence of the overall strength of the classification, with the majority of correctly predicted samples positioned along the diagonal; and, on average, there were very few instances of misclassification, and they were distributed relatively evenly across the various classes, indicating that there was no significant bias toward one or another class.

Table 6: Performance metrics of RBFNN.

SI.NO	METRICS	VALUES
1	Accuracy	0.935
2	Precision	0.938
3	Recall	0.932
4	F1-Score	0.935
5	Cohen’s Kappa	0.910
6	MCC	0.915
7	ROC-AUC	0.970

Source: Authors, (2026).

The RBFNN model has a stellar reputation which is depicted in table 6. High accuracy, combined precision and recall, Good Kappa and MCC agreement, plus outstanding classification accuracy demonstrated by ROC-AUC values of nearly 0.97.

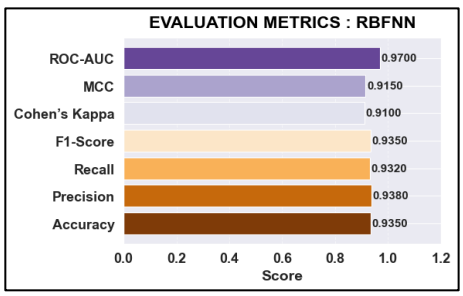

Figure 30: Evaluation metrics for RBFNN.
Source: Authors, (2026).

The RBFNN Model demonstrated in figure 30 is measured by AUC-ROC of 0.970, accuracy of 0.935, precision of 0.938, Recall of 0.932, F1 Score of 0.935, MCC of 0.915 and Cohen's Kappa of 0.91, demonstrating that this model has excellent reliability and demonstrates a high level of balanced classification capability.

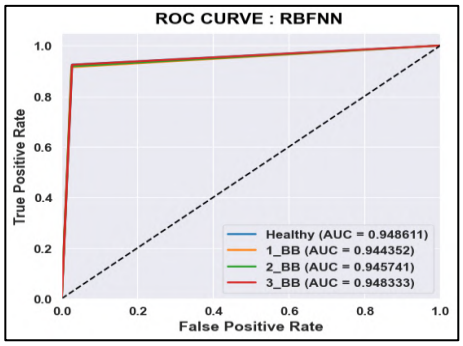

Figure 31: ROC curve for RBFNN.
Source: Authors, (2026).

Figure 31 demonstrates the great class-wise separation of classes by showing similar AUCs in the 0.94–0.95 range; thus, RBFNN class access the class in a more reliable manner.

Table 7: Comparative analysis of various methods.

SI.NO	METRICS	SFOA-Hybrid RBFNN-MHAT	Hybrid RBFNN-MHAT	MHAT	RBFNN
1	Accuracy	0.9960	0.9776	0.9565	0.935
2	Precision	0.9960	0.9786	0.9576	0.938
3	Recall	0.9960	0.9776	0.9568	0.932
4	F1-Score	0.9960	0.9778	0.9566	0.935
5	Cohen's Kappa	0.9946	0.9702	0.9420	0.910
6	MCC	0.9946	0.9704	0.9425	0.915
7	ROC-AUC	1.0000	0.9965	0.9919	0.970

Source: Authors, (2026).

As illustrated in table 7, the performance of the SFOA-Hybrid RBFNN-MHAT method consistently surpassed the performance of every other method across every metric of measurement evaluated, attaining excellent results for accuracy, precision, recall, and F1-score (0.996 for accuracy, precision, recall, F1, and ROC-AUC score of 1.0). There was a progressive decrease in performance for Hybrid RBFNN-MHAT, MHAT, and RBFNN indicating the efficacy of the proposed Hybrid Optimization method.

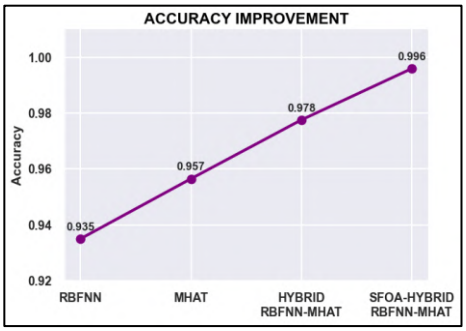

Figure 32: Accuracy improvement.
Source: Authors, (2026).

Figure 32 displays the tracking of accuracy via plotting results demonstrates the improvements in accuracy attained by use of the RBFNN, 0.935 through the use of the MHAT, 0.957 through the use of Hybrid RBFNN- MHAT, and highest with SFOA-Hybrid RBFNN-MHAT of 0.996.

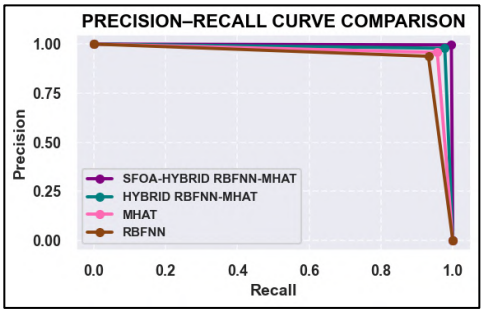

Figure 33: Comparison of precision-recall curve.
Source: Authors, (2026).

Figure 33 compares the performance of the model across all metrics was tracked through plotting of the Precision-Recall curve to indicate that SFOA-Hybrid RBFNN-MHAT obtains the highest precision with almost all values of recall, therefore allowing for the most accurate results. The Precision-Recall curve shows that Hybrid RBFNN-MHAT-MHAT perform close in terms of precision, RBFNN, had lower results in precision at high recall values and was associated with greater drops in accuracy.

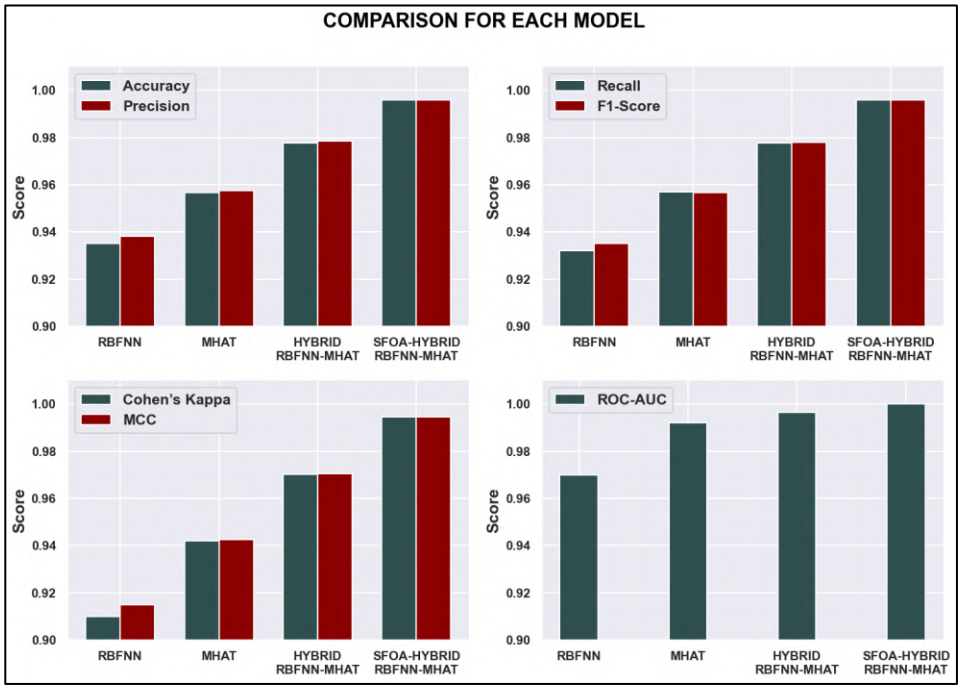

Figure 34: Comparison for each model.
Source: Authors, (2026).

Figure 34 shows the clear performance improvement of the class across all metrics. The SFOA-Hybrid RBFNN-MHAT continues to produce the highest accuracy, Precision, Recall, F1 Scores, Cohen's Kappa, MCC and ROC-AUC indicating itself as the most robust and reliable overall class performance.

Table 8: Comparative analysis of accuracy for different methods.

SI.NO	MODEL	ACCURACY
1	RF [21]	0.91
2	CWT [22]	0.97
3	CNN-LSTM [23]	0.976
4	ClasLoc [24]	0.90
5	CNN-RNN [25]	0.977
6	PROPOSED	0.99

Source: Authors, (2026).

Table 8 displays the accuracy of each model, showing that the proposed model achieved the highest accuracy at 99%, followed closely by CNN-RNN and CNN-LSTM with accuracies of 97.7% and 97.6%, respectively, while RF and ClasLoc both have lower accuracies.

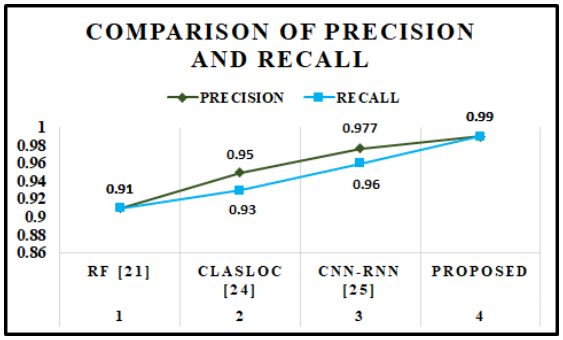

Figure 35: Comparative analysis of precision and recall.
Source: Authors, (2026).

Figure 35 depicts the metrics of accuracy, precision, recall and F1-score measured by four models including RF, ClasLoc, CNN-RNN and the proposed model. Performance on each metric progressed from RF to the proposed model producing the best results (0.99) for every metric.

Table 9: Comparative analysis of F1-Score for different methods.

SI.NO	MODEL	F1-SCORE
1	RF [21]	0.91
2	ClasLoc [24]	0.94
3	CNN-RNN [25]	0.98
4	PROPOSED	0.99

Source: Authors, (2026).

Table 9 had a gradual increase in their respective F1-scores, from the lowest to the highest. The proposed model achieving the highest F1-score at 99%. This demonstrates that the presented model achieves significantly improved than all other models.

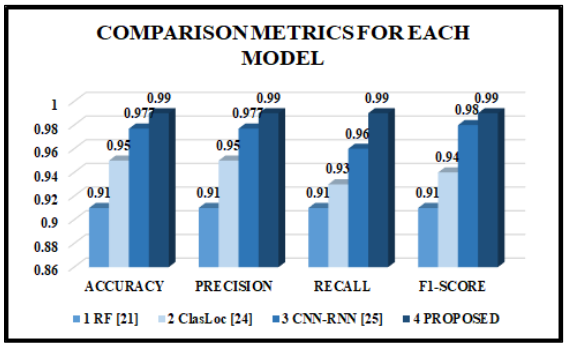

Figure 36: Comparison metrics for each model.
Source: Authors, (2026).

Figure 36 indicates a steady increase in the F1-score achieved by each model as their performance progressed (RF F1-score=0.91, ClasLoc F1-score=0.94, CNN-RNN F1-score=0.98, proposed model F1-score of 0.99); this indicates the suggested model attained higher enactment overall.

V. CONCLUSION

The proposed framework incorporates an organised workflow of data collection, preprocessing, feature engineering, parameter optimisation and combination of automated and manual models incorporated into a comprehensive fault diagnostic structure, the proposed system uses the highest superiority operational signal from initial data collection and provide excellent results for removing noise from cleansed operational data while preserving the relevant information regarding electrical faults. The feature engineering stage used the data produced from preprocessing to both prepare and standardise the data when developing the feature vector for use in training the DL model. The starfish optimising algorithm provides for the optimal tuning of the model hyper-parameters that offer the higher performance and assurance in prediction. The hybrid model that consists of RBFNN along with MHAT captures both the high-level contextually expressive features and the details of the localised fault marks. The fusion layer allows for the best representation of both the global context and localised signature features, leading to the combined strength for the final diagnostics through an accurate classification of induction motor conditions as either Normal/Healthy or BRB Failure. Finally, the hybrid model provides a substantially higher degree of diagnostic accuracy, precision, recall, F1-Score of 0.9960, robustness and real-world utility for intelligent condition monitoring systems.

ABSTRACT

A direct current (DC) microgrid has been the preferred power system in recent years because of the system's overall efficiency. Finding a suitable protection strategy is the primary issue with DC microgrids. The most promising technology for renewable energy is photovoltaic systems. To create a DC microgrid that can function both on-grid and in island mode, the basic components are a photovoltaic (PV) system with Boost converter, a battery with Buck converter, a voltage source converter (VSC), and an AC main grid. When an issue arises with the AC main grid, a voltage source converter and several relay types, including circuit breakers, are utilized to protect the DC microgrid. The study of DC microgrid protection and its effects on other devices is the main topic of this study. Additionally, it desires to give information about their function in improving the flexibility of electrical power networks and reducing the negative consequences of overcurrent issues. MATLAB SIMULINK is used to simulate and model the PV and battery linked to the main grid with various fault kinds and by employing different overcurrent protection techniques. Their features are analysed.

I. INTRODUCTION

The major advantages that microgrids provide to both customers and power grid operators has given rise to a recent increase in research on the topic. In basic terms, a microgrid is an integrated network of distributed power sources [1]. A microgrid's versatile and flexibility of control, which support system reliability and power quality standards, are its greatest advantages over a single-generation system [2] . Microgrids can be in two ways on-grid and off-grid. In small networks, the common system divisions are an AC bus and a DC bus. By reducing the power conversion stages between the AC and DC sides, a DC microgrid enhances efficient power transfer, and most grid-tied renewable energy systems utilize DC power for both input and output. Even though DC microgrids have numerous advantages over AC microgrids, one of the main issues in power system production is building a proper protection circuit for both big and small DC networks [3]. Nowadays, most research and studies focus on determining the most effective approaches for solving protection issues in DC networks. Because of problems of small networks bidirectional power transmission, the fault currents direction while integrating system parameters, and the distinct qualities of renewable energy supplies and their types, DC microgrid protection problems are difficult to resolve using conventional methods. There are a variety of techniques for precisely detecting faults, including the use of DC circuit breakers (CBs) for grounding and fault current determination techniques. Protection problems in DC distribution systems also come due to the absence of zero current crossing, which is typically found in AC systems. Despite major advancements, protection technologies in AC transmission and distribution systems are still essentially quite basic and manageable. Most small, distributed generation (DG) networks are based on AC systems, however compact DC networks are preferred for connecting to DC-output sources including photovoltaic (PV) systems, energy storage systems (ESS), and fuel cells. [4]. MATLAB/Simulink is used to simulate a protection analysis for a DC microgrid under several fault situations. This study examines how these conditions impact power electronic components, including the converter, voltage source converter (VSC), and power loads.

Additionally, it seeks to shed light on their function in strengthening the resilience of electrical power networks and reducing the negative consequences of overcurrent incidents. MATLAB SIMULINK is used to simulate and model the PV and battery linked to the main grid with various fault kinds and by employing different overcurrent protection techniques. Their features are then compared. The following is an overview of the DC microgrid's features:

- No synchronisation issues in DC microgrid [5].
- Transmission efficiency is high in DC microgrid due to absent of reactive components increases efficiency [6].
- DC microgrids are more stable compared to AC microgrids become it free from external effects [7].
- Skin effect losses absent in DC microgrid. It leads to less cable losses [8].
- A DC microgrid's power supply is more robust since several supplies can connect to a single bus [2].
- The primary reason for preferring DC networks is that switching losses between sources and loads are lower in systems with direct current (DC) loads than in those with an AC grid [9].
- Resources and loads are DC, which lowers heat and losses [10].
- DC microgrids have greater power transfer capabilities [11].
- DC microgrid systems are safer than AC microgrid systems [12].

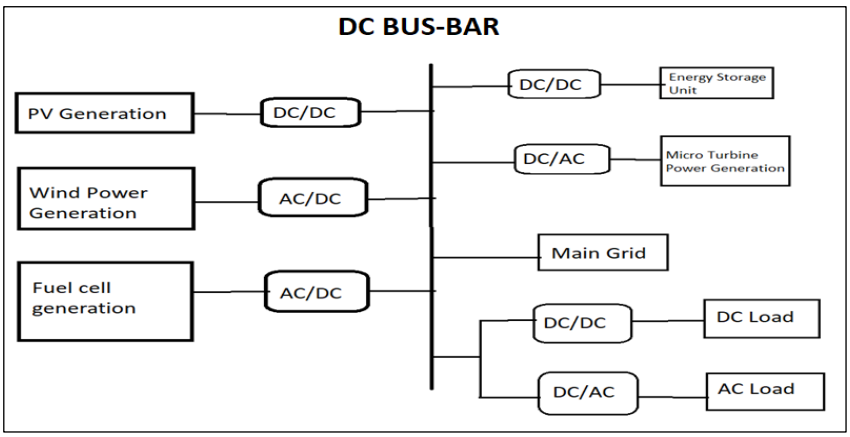

Figure 1: DC Microgrid.
Source: Authors, (2026).

II. OBJECTIVES

- DC microgrid protection and operation are often challenges with this kind of DC system.
- The DC microgrid is protected from AC side faults by a voltage source converter (VSC).
- Circuit breakers provide actual delays in the circuit, whereas relays offer a more complete protection system through recognizing more types of faults.

III. FAULT ANALYSIS FOR DC MICROGRID

For switching between AC and DC system need switching mechanism for conversion voltage source converter plays a crucial role. A Voltage Source Converter (VSC) is a power electronic converter that performs both inverter and rectifier operations. It is commonly used in grid-integrated systems, especially in DC microgrids connected to an AC main source.

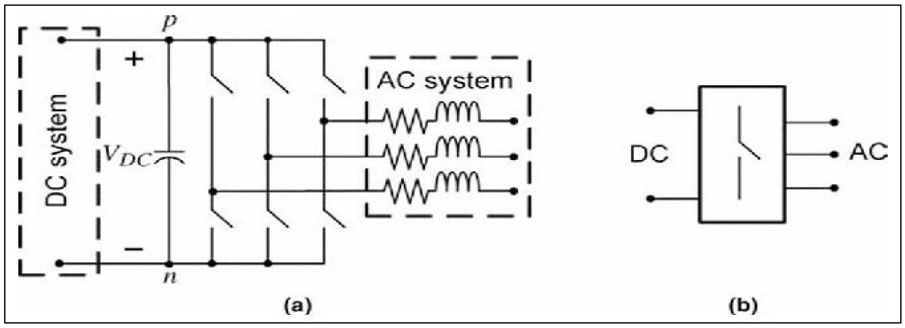

Figure 2: (a) Three-phase VSC circuit diagram, (b) VSC acts as switch between DC and AC system.
Source: Authors, (2026).

The bipolar nature of a voltage source converter's DC-side current affects its average power flow, while the DC-side voltage remains polar. Usually, the DC-side terminals of a VSC are linked in parallel with a large capacitor that functions as a voltage source.

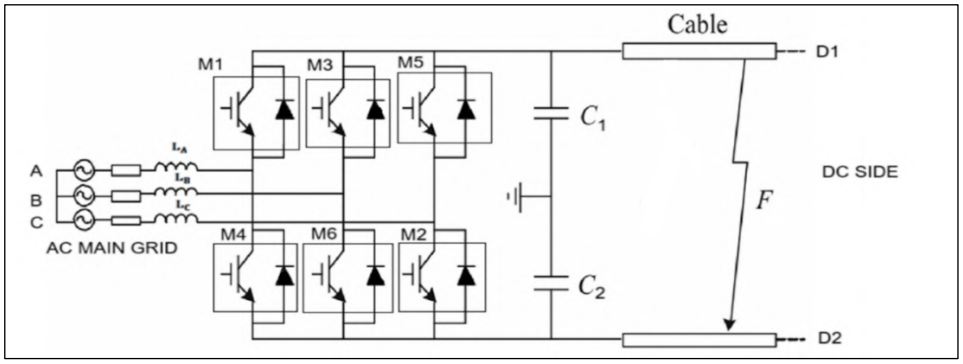

Figure 3: VSC with DC side fault.
Source: Authors, (2026).

When the DC microgrid's transmission line experiences a three-phase failure on the AC main grid, the DC side capacitor rapidly discharges from the fault point and into the AC current system. the overcurrent protection limiting the VSC, AC current still feeds the fault location through the VSC's antiparallel diode.

III.1 FAULT CONDITION

During a fault condition, three cases are observed in the Voltage Source Converter (VSC). These three cases are displayed in the circuit diagrams below.

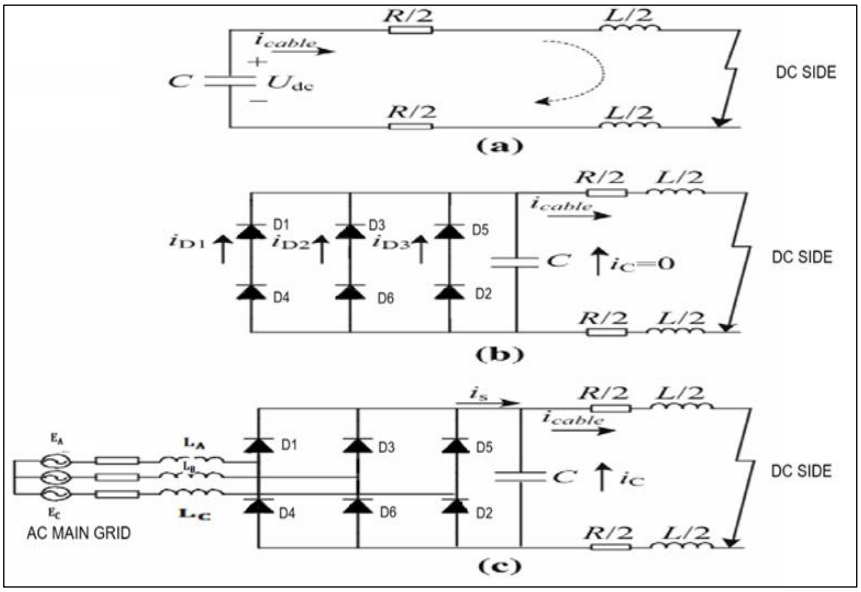

Figure 4: (a) Capacitor discharging condition during fault. (b) Diode free-wheeling action when the capacitor charge reaches. (c) AC main grid feeding.
Source: Authors, (2026).

Equations related to Voltage source converter (VSC):

$$L\frac{d^2V_c}{dt^2} + R.\frac{dV_c}{dt} + \frac{V_c}{C} = 0 \quad \ldots\ldots\ldots \quad \ldots(1)$$

By taking into consideration the small size the resistance is in this case,

$$\frac{1}{2}(R) < \sqrt{\frac{L}{C}} \quad \ldots\ldots\ldots \quad (2)$$

$$i_L = 3i_d \quad \ldots\ldots\ldots \quad (3)$$

III.2 FAULT CHARACTERISTICS OF VSC

The three cases above are symbolized as t_0, t_1, and t_2, where:

- t_0 is the time at which the capacitor starts discharging (or the fault occurs).
- t_1 is the time at which the diode's free-wheeling action begins (or when the capacitor's current decreases to zero).
- t_2 is the time at which grid feeding starts.

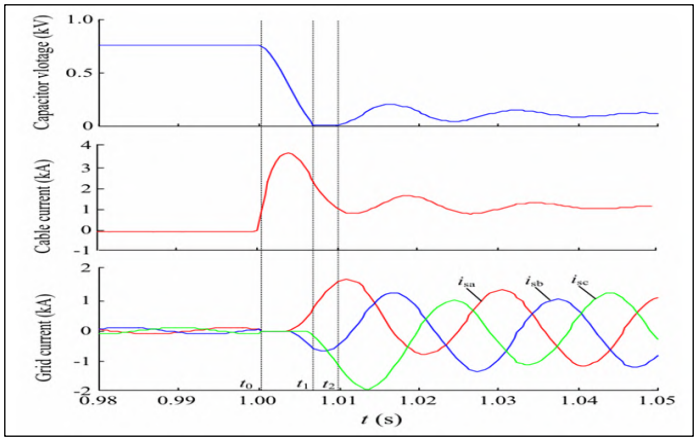

Figure 5: Fault characteristics of VSC.
Source: Authors, (2026).

The fault characteristics of the Voltage Source Converter during the t_0, t_1, and t_2 time intervals are shown in the waveform above.

IV. FAULT OCCURRED CONDITION

The DC microgrid transmission line fault direction is represented in the circuit below.

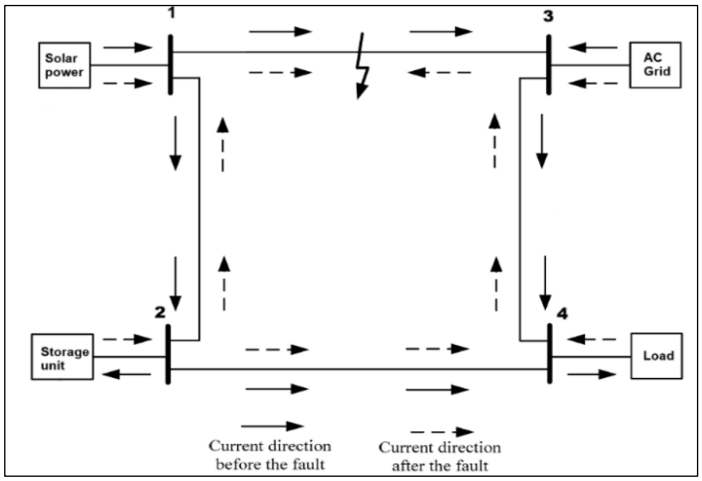

Figure 6: DC Microgrid current direction during a fault.
Source: Authors, (2026).

In the above block diagram, there are two conditions current direction before the fault condition and current direction after the fault condition.

IV.1 RELAY CHARACTERISTICS

The circuit breaker only interrupts the system while fault occurs, but relay detects the fault occurrence quickly interrupt the system by sending a signal to the circuit breaker from fault condition. There are so many types of relays based on performance operation. For Microgrid the overcurrent relays and differential relay plays a crucial role. In below tabular column discuss the comparison of overcurrent relays and differential relays.

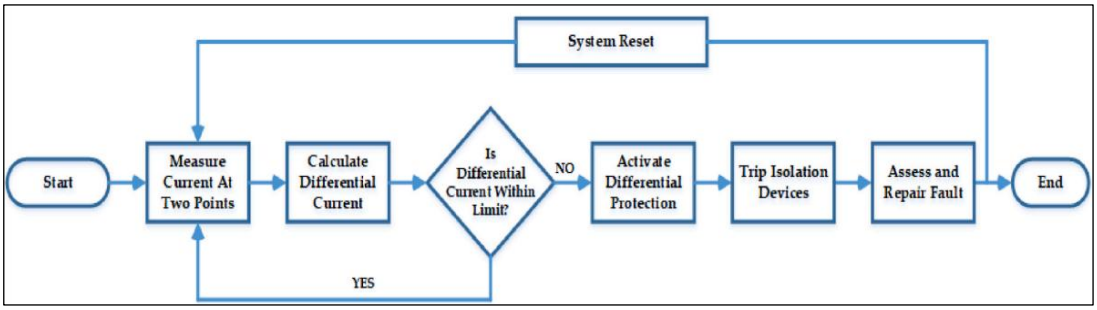

Figure 7: Flowchart of differential relay working at AC main source in DC Microgrid.
Source: Authors, (2026).

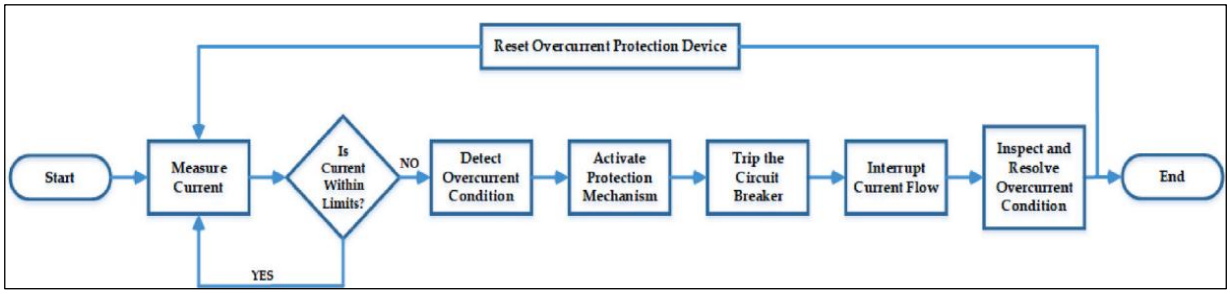

Figure 8: Flowchart of overcurrent protection device working at AC main source in DC microgrid.
Source: Authors, (2026).

Table 1: Comparing protection methods according of their Advantages and drawbacks.

Methods of protection	Advantages	Drawbacks
Over-current protection	• A basic approach • Suitable for fault interrupt techniques • Fast response to high-magnitude faults	• Less Sensitive • Requires careful time grading to prevent maloperation. • Depends on Fault Current Magnitude
Differential protection	• High selectivity and sensitivity • less dependence on fault impedance Independent on current direction and independence with the direction of the current • Unaffected by fault resistance and a sudden rise in DC currents	• Needs regular testing and calibration for accurate performance • Requires more equipment (CTs, relays, communication) and setup effort.

Source: Authors, (2026).

Based on the operation of overcurrent relays and differential relays the performance of relays tabulated below.

Table 2: Comparison of Protection methods based on operation.

Protection Method	Speed of operation	Selectivity	Reliability	Cost
Over-current protection	Medium	Low	High	Medium
Differential protection	Very High	High	High	High

Source: Authors, (2026).

V. RESULTS AND DISCUSSION

In this paper, by comparing three relays performance individually by combining PV, Battery & AC grid at LLLG fault condition. The three relays are AC time instantaneous overcurrent relay, Differential relay, IDMT (Inverse definite minimum time) relay.

V.1 MODELLING OF AC TIME OVERCURRENT RELAY WITH MICROGRID

Source: Authors, (2026).

V.3 MODELLING OF IDMT RELAY (INVERSE DEFINITE MINIMUM TIME) WITH MICROGRID

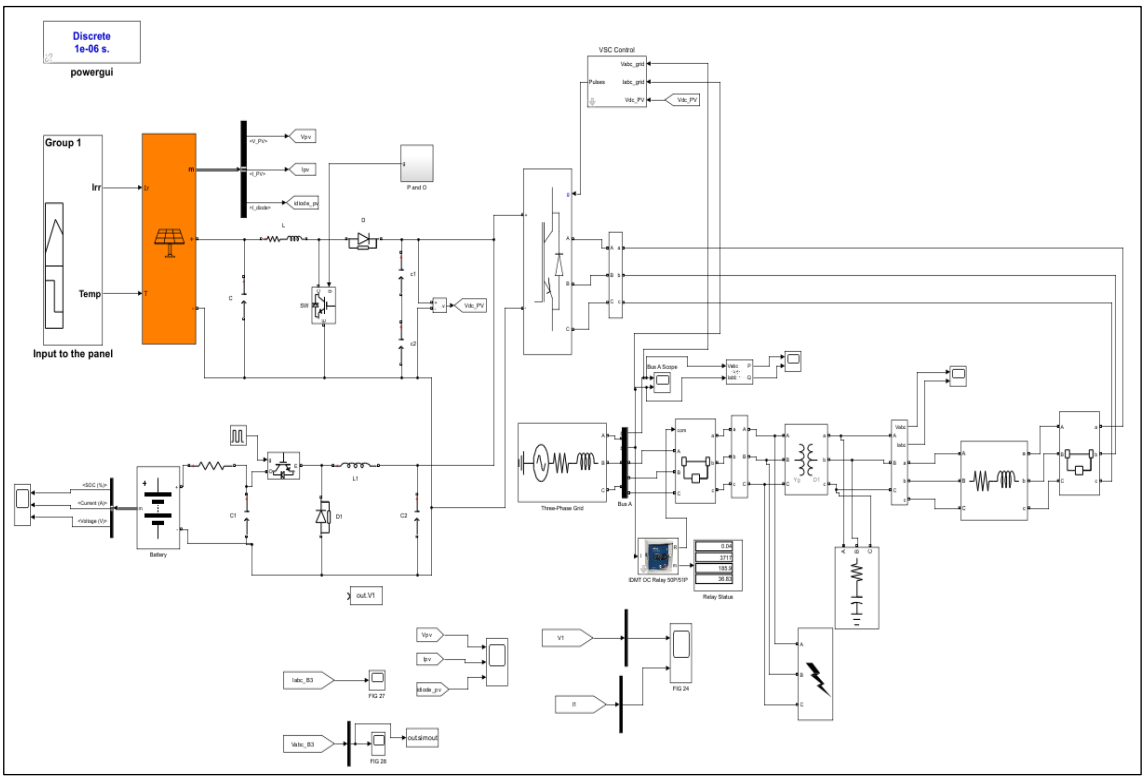

Figure 11: Simulink model design of PV with AC Main Grid, Battery and IDMT relay.
Source: Authors, (2026).

Output:

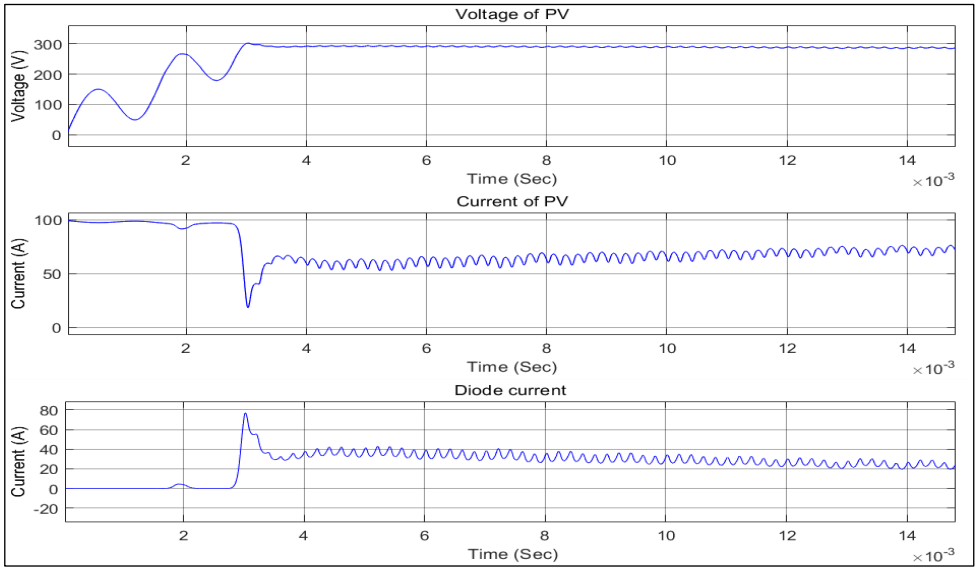

Figure 12: PV array voltage and current with diode current.
Source: Authors, (2026).

Table 3: PV module & Battery parameters.

S.No	Name of parameters	Value
1	Maximum power	305.226 W
2	Nominal voltage	1000 V
3	Rated capacity	7.2 Ah

Source: Authors, (2026).

Table 4: AC main source parameters.

S.No	Name of parameters	Value
1	Phase to phase voltage (V_{rms}) of three-phase Grid	25 KV
2	Nominal power of three-phase transformer	100 KVA
3	Active power of three phase series RLC load	10 KW
4	Nominal phase to phase voltage (V_{rms})	440 V

Source: Authors, (2026).

Output for AC time overcurrent relay:

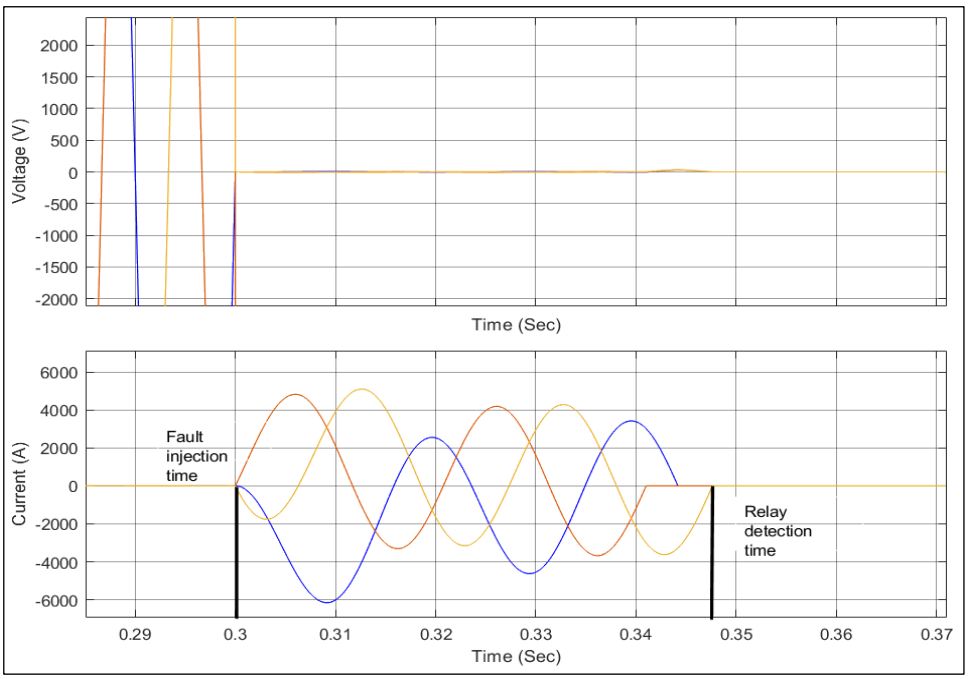

Figure 13: Current for the AC Time relay at Bus-1.
Source: Authors, (2026).

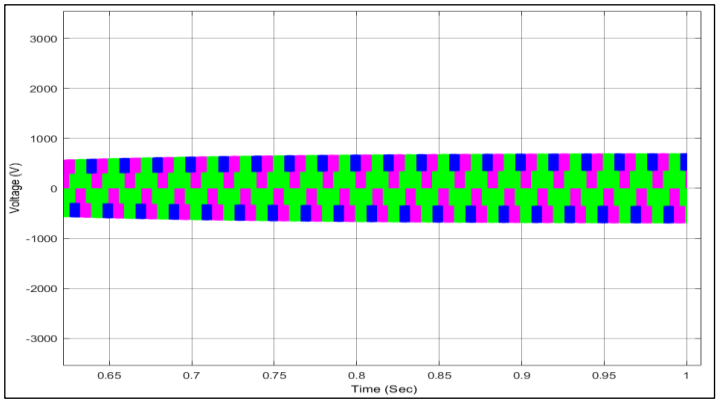

Figure 14: Voltage waveform of VSC.
Source: Authors, (2026).

The relay is set to parameters such as pickup current level and time delay settings for delay. The model includes a mechanism to simulate a three-phase fault, enabling the testing of the relay's response to severe fault conditions. Initially, the waveforms exhibit a consistent sinusoidal pattern characteristic of a stable electrical grid. At approximately 0.04 seconds, all three voltage waveforms abruptly drop to zero, which suggests that a fault condition was introduced, resulting in the complete loss of voltage. This action is indicative of a circuit breaker operation which isolates the faulted segment due to the activation of the AC time relay, hence the flat line that follows, showing the system voltage post fault and relay operation.

Output for Differential Relay:

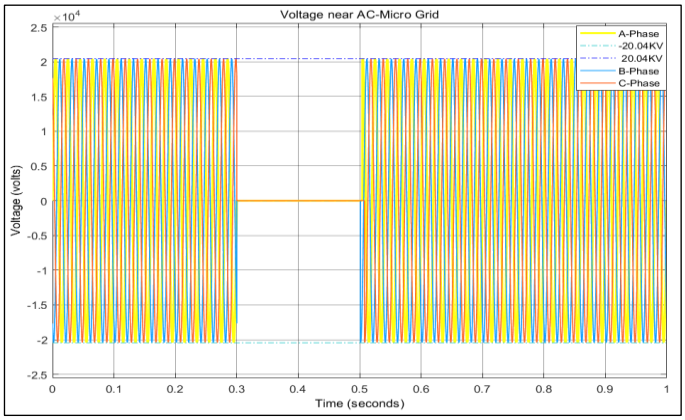

Figure 15: Voltage at Main AC grid when LLLG fault injected.
Source: Authors, (2026).

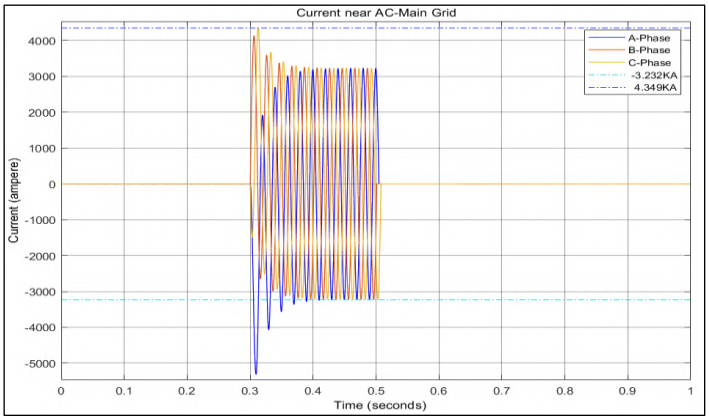

Figure 16: Current at Main AC grid when LLLG fault injected.
Source: Authors, (2026).

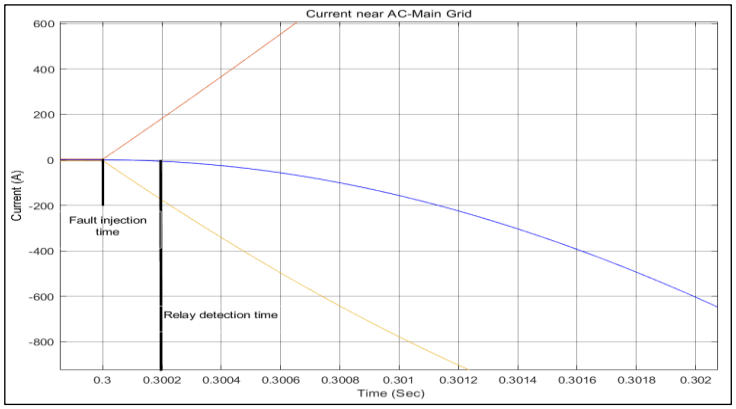

Figure 17: Operation of differential relay.
Source: Authors, (2026).

The circuit breaker, represented in Simulink as a switch block, would receive a trip signal from the transformer differential relay. To stop further damage, the switch opens according to the trip signal, isolating from protecting device from other parts of the power supply. Differential relays commonly have a restraining mechanism to prevent false tripping from quick problems like inrush currents. This is modelled using a logic block that compares the differential current against a restraint current, which is usually a function of the load current.

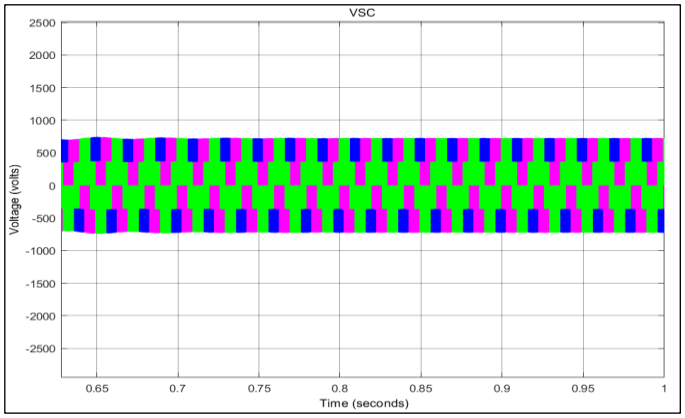

Figure 18: Voltage for VSC.
Source: Authors, (2026).

Output for IDMT Relay (Inverse Definite Minimum Time):

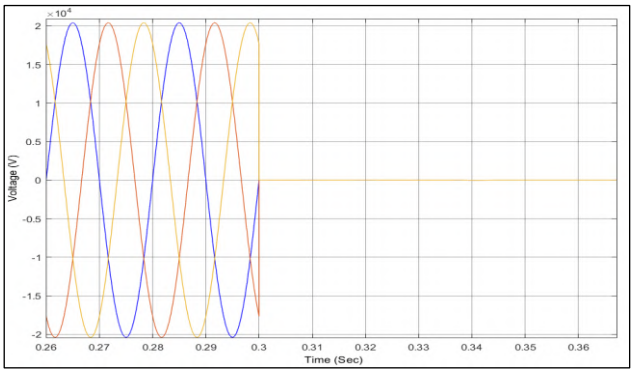

Figure 19: IDMT relay voltage at Bus-1.
Source: Authors, (2026).

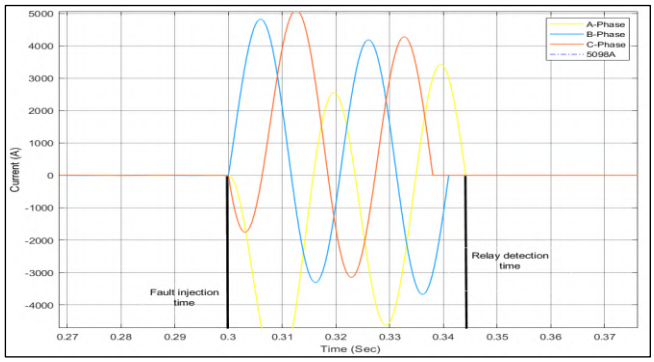

Figure 20: IDMT relay current at Bus-1.
Source: Authors, (2026).

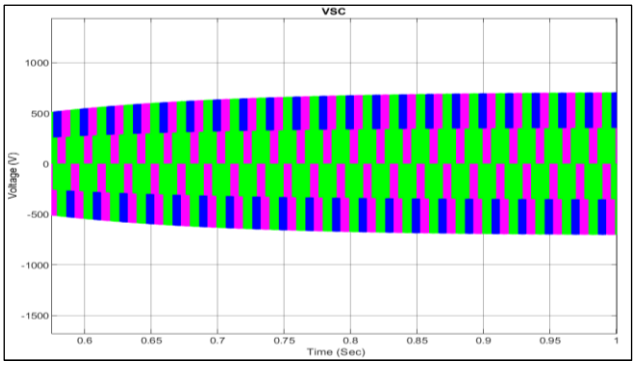

Figure 21: Voltage for VSC.
Source: Authors, (2026).

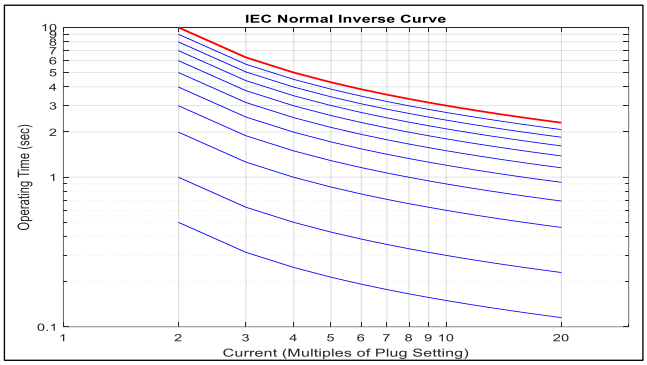

Figure 22: IEC normal inverse curve.
Source: Authors, (2026).

IDMT relay provides overcurrent protection with inverse definite minimum time characteristics. When an overcurrent situation arises, the relay block receives a signal proportional to the current from the feeder. Using the predefined settings, the relay determines whether the current is high enough and has persisted long enough to warrant a trip. The relay provides a trip signal to the circuit breaker if the current exceeds the pickup threshold and the time delay has ended (based on the IDMT characteristic). In order safeguard the equipment and maintain safety, the circuit breaker then opens to disconnect the faulted section of the system. IDMT relay operate more slowly for currents close to the threshold and more quickly for more severe currents.

Table 5: Output parameters for PV with AC Main Grid and battery.

Parameters	Values
Voltage for main grid	25 KV
Current for main grid	4.8 KA
Voltage for VSC	715 Volts

Source: Authors, (2026).

Table 6: comparison of Response time of relays.

Relay Type	Fault injection time (s)	Detection Time(s)	Response time (s)
AC time relay	0.3	0.347	0.047
Differential relay	0.3	0.3002	0.0002
IDMT relay	0.3	0.343	0.043

Source: Authors, (2026).

Differential relay has demonstrated faster response with fault detection as compared to both relays.

VI. CONCLUSION AND FUTURE SCOPE

When a fault occurs, the DC microgrid is protected using a Voltage Source Converter (VSC). Three scenarios are considered in the fault analysis study simulated using MATLAB. The critical role of overcurrent relays in safeguarding electrical systems against over current faults. The delay characteristics of various overcurrent relay has provided valuable insights into their operation and application in electrical protection systems. Differential relay has demonstrated faster response with fault detection. Through the exploration of standard time delay characteristics, inverse time delay characteristics, and other variations such as IDMT relays, a deeper understanding has been gained on of how these relays detect and respond to overcurrent conditions in electrical circuits. In further, Voltage Source Converters (VSC) could be replaced with Multilevel Converters (MLC). Currently, only overcurrent relays and differential relays are used for protection but for further, various filters and additional relays could be employed in DC microgrids to mitigate the harmonics produced by the converters.

ABSTRACT

Rapid industrialization and urbanization have intensified the need for effective and sustainable environmental remediation technologies. Advanced materials such as metal organic frameworks (MOFs), graphene-based nanomaterials, Menes, and graphitic carbon nitride (g-C_3N_4) offer promising solutions for water purification, air filtration, and pollutant degradation due to their tenable structures, large surface areas, and catalytic properties. This review highlights recent progress in the synthesis, modification, and application of these materials for environmental purposes. It discusses their mechanisms of pollutant adsorption, photocatalysis, and electrochemical treatment, along with performance comparisons and key limitations such as stability, toxicity, and scalability. The paper further outlines future research priorities including green synthesis, lifecycle assessment, and safe large-scale deployment. Through this discussion, the review aims to bridge laboratory-scale innovation with real-world environmental challenges, contributing to the development of efficient, durable, and sustainable material-based treatment systems.

I. INTRODUCTION

The worldwide growing demand for energy and materials and industrial products has resulted in severe pollution of water, air, and soil ecosystems. During the last twenty years, heavy metals, dyes, pesticides VOCs and greenhouse gases have become harmful to both environment and human health. Conventional pollution control methods for example chemical oxidation, settling and mechanical filtration, are often ineffective and/or energy consuming or produce secondary waste streams. The restrictions can be surmounted by new materials and these are available to us. They give physicochemical properties for the enhancement of adsorption, oxidation catalysis or filtration performance. For example, MOFs provide programmable water and gas purifying pore structures, while graphene-based materials have good adsorption properties and conductivity. Visible light active as well biochar adsorbents synthesized from biomass are combined into activities for pollution abatement and carbon capture/agriculture applications. In this review, an effort has been made to include the recent development (2020–2025) of advanced materials for environmental sustainability. It is aimed at comprehensively analysing the material synthesis, pollutant-removal physiological mechanism, and NHETP-based application performance and demonstrating future research challenges as well as industrial routes.

This review concentrates on unconventional adsorbents (e.g., metal-organic frameworks, graphene-based composites, and biochar) rather than traditional ones and mainly demonstrates novel types of adsorption mechanisms or structures [1]. For instance, the compositional modularity of MOFs combined with the high theoretical surface area of graphene has driven their use in a synergistic effect towards environmental cleansing through hybrid materials [2]. "These cross-material systems sponge connectivity in carbon materials and MOFs/covalent organic frameworks can provide the solutions for the short falls associated with each material constituent, resulting from practical sustainable technologies for remediation and resource recovery" [3]. In another approach, the integration of state-of-the-art synthesis methods and data driven artificial intelligence (AI) studies with statistical analysis has been recommended as alternative method to produce optimised adsorbents such that their surfaces will be in accordance with the desired pollutants for selective removal [4]. Indeed, the introduction of such new treatments is necessary as conventional wastewater treatment processes have frequently not been able to efficiently eliminate many recently identified and recalcitrant compounds present in industrial effluents, agricultural run-off or hospital discharges [4], [5]. Adsorption being recognized as simple and versatile technique for the removal of various range of contaminants96, to remove solutes (heavy metals) [4]. as illustrated in Figure 1, that show how advanced materials and AI-related tools can facilitate the sustainable remediation by ad- dressing pal problems through adsorption, catalysis an alteration with reacting systems of water, air and soil.

II. RESEARCH METHODOLOGY

A systematic review of literature was performed by means of Scopus, Web of Science and ScienceDirect databases for years 2020–to 2025. Keywords were "advanced materials," "pollution control," "environmental remediation," as well as varieties of adsorbents and catalysts including MOFs, graphene, biochar, photocatalyst and membrane filtration. The selection of articles was based on the relevance, recency and citation impact. The aim was not to perform quantitative meta-analysis, but rather to offer a qualitative synthesis of the state-of-the-art and use this as a basis for future research. Noteworthy, the study also emphasizes the nanotechnology growth trend for producing new adsorbents, photo-catalytic materials and membrane separation processes to provide more sustainable solutions to address worldwide environmental issue [6]. The ability of the materials described to respond to selected environmental problems from the treatment of industrial wastewater up to air purification is also discussed focusing on their effectiveness and cost. This includes the evaluation of their ability for regeneration and life cycle impacts to secure sustainable contribution to an environmental solution as well as practical application. The present review considers these and other materials, but also discusses the possibility of toxic effects/toxic long-term effects for the environment on a large scale application of nanomaterials considering their persistence and biomagnification in ecosystems [7]. It also discusses in detail the challenges and opportunities for scaling-up of the emerging materials technologies from lab-based research to real-world applications, with regards to cost-effectiveness, regeneration efficiency and potential secondary pollution。 It ranges from cost-effectiveness of green synthesis for nanocomposite catalysts that are essential towards efficient environmental clean-up [8].

III. METAL–ORGANIC FRAMEWORKS (MOFS)

III.1 OVERVIEW AND PROPERTIES

MOFs are crystalline entities in which metals are bridged by organic linkers, thus resulting in the large surface area and easy to adjust pore structure. With high porosity and a variety of structures, they can provide selective adsorption or catalytic activity. By selecting from different metals (Fe, Cu, Zr) and organic ligands (such as terephthalate or imidazolate), MOFs can be adjusted for certain pollutants or environmental conditions.

This tunability has led to their great potential in a wide range of environmental remediation applications including wastewater treatment: here, their stability in aqueous environment boosts their use for adsorption, catalysis and separation processes [6], [9]. Their widespread application potential for gas storage, separation and environmental cleanup has been well studied due to their interesting properties [10]. In particular, MOFs are defined by their crystal structure, high porosity that results from the metal nodes coordinated with the organic linkers to form porous crystals and provide a versatile platform for various applications [6], [9]. The large surface area, adjustable pores size and chemical versatility of MOFs makes it possible to accomplish targeted interaction with a wide range of pollutants such as emerging organic pollutant (EOPs), dyes and heavy metals [9], [11]. This flexibility allows for potential applications in different pollution control techniques ranging from physical adsorption to photocatalytic decomposition of pollutants [12]. Due to their selective adsorption of a wide range of pollutants such as heavy metals, organics, and greenhouse gases [13], they have gained enormous attention in waste management for environmental remediation. With unique characteristics of large specific surface area, adjustable porosity, versatile functions and high predictability, MOFs have achieved remarkable performance in adsorbing pollutants and various catalytic/degradation processes. Constructed from metal ions or clusters interconnected by organic ligands, these porous crystalline solids show great promise toward freshwater scarcity and polluted water remediation [14], [15]. MOFs are inherently characterized by extraordinary tunability of pore size, geometry and functionality, in addition to being thermally stable and having a large surface area, all of which make them front-line candidates for environmental-friendly decontamination [16]. Such features make MOFs easily to be synthesized in different sizes and shapes, coupled with tenable structures to obtain more efficient composite materials with improved or even new properties [17]. In addition, MOFs are commonly made with transition elements and post-transition elements providing stability in water as well as high regeneration capacity for adsorption of selected contaminants from wastewater [18], [9]. The figure 2 illustrates how MOFs, with tenable porous crystalline structures, enable efficient adsorption, catalysis, and pollutant removal for diverse environmental remediation applications.

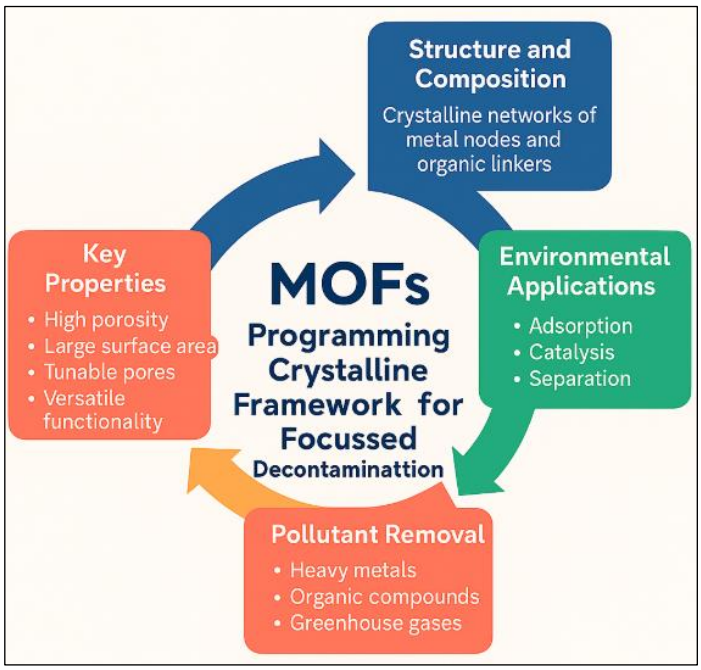

Figure 2: Overview and Key Properties of Metal–Organic Frameworks (MOFs) for Environmental Remediation Applications.
Source: Authors (2026).

III.2 APPLICATION IN WATER TREATMENT

For the adsorption of heavy metals, dyes and pharmaceuticals MOFs have been proved to be efficient. For example, Zr-containing UiO-66 has superior chemical stability and excellent performance for both arsenic and lead adsorption. Functionalized MIL-101 and HKUST-1 MOFs are popular for dye removal by adsorption and photo-oxidation. The MOF hybrids with magnetic nanoparticles also facilitate the separation and reusability. The high specific surface area and tenable pore size of CSs make them suitable for the effective sequestration of metal ions and organic pollutants such as drugs and pesticides [19]. Due to the various metal centres and linkers, the structural variability of MOFs can be directed toward producing materials with tailorable affinity for a diversity of water contaminants ranging from industrial waste to pesticides [20]. This high porosity, with some MOFs possessing a surface area of up to 7800 m literally leads to high sorption capacities meaning that effective amounts of pollutants can be taken [21]. Their ordered structure also contributes to high adsorption capacities and have been found especially effective with wastewater treatment [16]. In addition, the possibility of post- or pre-modification of MOFs enables to introduce the functional groups that will increase its selectivity and adsorption capacity towards certain pollutants [22]. The reason is that the ultrahigh surface area and porosity of MOFs make them particularly suitable as adsorbents for enhancing exchange site accessibility as well as diffusion dynamics of contaminants throughout its skeleton [23]. This leads to the successful elimination of a variety of pollutants such as organic dyes, antibiotics, heavy metals or agricultural compounds whose traces may still be present in effluents from classical wastewater treatment [24]. This outstanding performance for wastewater treatment makes MOF an ideal adsorption option, promising to replace conventional adsorbents, such as activated carbon which may often possess high surface area but lack the selectivity and manipulable properties [25], [24].

For instance, some MOFs such as MIL-101 exhibited a better adsorption capacity for methyl orange in comparison to activated carbon because of their higher specific surface area. The figure 3 illustrates how MOFs, with high surface area, tenable pores, and magnetic hybrid designs, efficiently adsorb and remove pollutants such as heavy metals, dyes, and pharmaceuticals from wastewater.

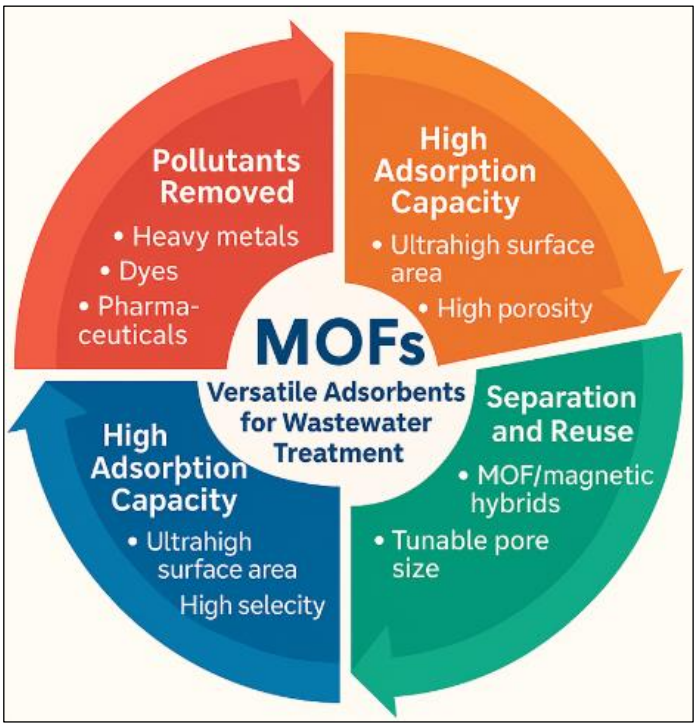

Figure 3: Adsorptive Performance and Functional Characteristics of Metal–Organic Frameworks (MOFs) for Wastewater Treatment. Source: Authors (2026).

III.3 PHOTOCATALYTIC APPLICATIONS

Photoactive MOFs like MIL-125(Ti) and NH 2 -MIL-53 behave as a semiconductors, which induce degradation of organic pollutants under UV or visible light. Hybrid MOFs shows enhanced electron transfer and visible-light gathering compared with those anchored on graphene or TiO_2. For example, zirconium-MOFs (e.g., UiO-66-NH2) are used to fabricate TFN membranes for excellent performance in wastewater treatment and Mo6P Felicia-MOF exhibits remarkable selective degradation of dyes such as Rhodamine B under visible light illumination [26]. Furthermore, the natural porosity of MOFs promotes the mass transfer of reactive species to pollutant molecules, favouring higher photoactivity and improved substrate-catalyst contacts [27]. The large specific surface area, adjustable pore size, and different active metal centres in MOFs can further enhance the photocatalytic degradation because of multiple sites for radical generation and interaction with pollutants [19].

IV. GRAPHENE AND GRAPHENE OXIDE-BASED MATERIALS

IV.1 STRUCTURE AND FUNCTIONALIZATION

Graphene oxide (GO) has plenty of oxygen-containing functional groups (–OH, –COOH, and –C=O), thus it can easily interact with metal ions or organic molecules. GO reduction results in reduced graphene oxide (rGO) that is more conductive and possess tenable hydrophobicity. These features render the graphene-derived materials extremely versatile in applications from advanced sensing to high-performance energy storage systems. For the environmental treatment, their large surface area, mechanical strength and electrical conductivity are particularly advantageous to improve the adsorption, filtration as well as catalytic degradation performance for different kinds of pollutants. For example, reduced graphene-oxide-based semiconductors are functionalized for improved photocatalytic activity with regard to pollutant degradation through band gap reduction, electron-hole separation improvement and enhancing the specific surface area [28]. Earlier studies have also reported that the doping of graphene nanomaterials with other elements could obviously improve their capability for environmental remediation, especially photocatalysis [29]. The tunability of band gap energy in graphene-based materials via linkers and/or metal nodes changes has been accepted as a well-accepted approach for design optimization of their light harvesting for photocatalysis applications [27]. High-efficiency OV adsorption In their targeted applications, composite materials have presented superior efficiency of overlapping composites, such as graphene oxide composites [30]. Particularly, the high surface area and tenable surface chemistry of graphene-based composites can lead to higher pollutants adsorption capacities such as heavy metal ions, dyes and pharmaceutical drugs in water treatment [31], [32]. This makes for efficient removal of contaminants, where graphene oxide shows significantly better performance than graphite does in dye adsorption up to 140% more [33]. The figure 4 illustrates how graphene-based materials, with tenable structures and rich surface functionalities, offer high surface area, conductivity, and chemical adaptability for efficient adsorption, filtration, and catalytic environmental applications.

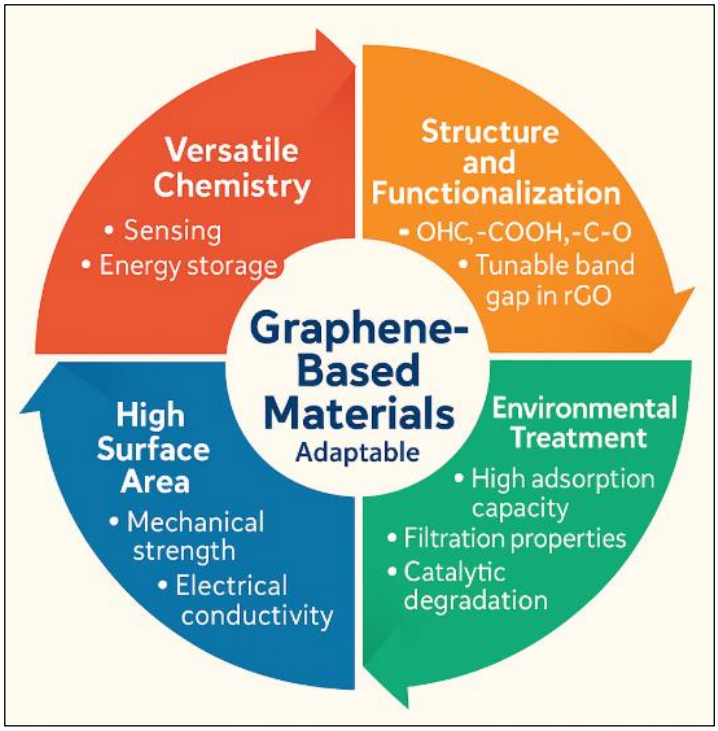

Figure 4: Structural Features and Functionalization of Graphene-Based Materials for Environmental Applications.
Source: Authors (2026).

IV.2 ENVIRONMENTAL APPLICATIONS

Adsorption of heavy metals: GO and its composites with iron oxide nanoparticles efficiently capture Pb^{2+}, Cd^{2+}, and Cr^{6+} ions. When a heavy metal ion is present in the solution, the lone pairs of their electrons bind with the vacant orbitals of the said metal ion, forming a coordination bond. Sonu sorbent capabilities arise from graphene oxide and its composites with cadmium, with its dominant two-dimensional, nanometre-layer cartilage structure and the second-to-none fitting oxygen-containing functional groups of epoxy, which chelate the inorganic ions of Cr^{6+}, and hydroxyl and carboxylate groupings, as well as the aromatic groupings, which bind through alkaloid fits. Carcinogens and other organic pollutants removed from aqueous baths are “carried” with the material due to the interaction center of carboxyl groups and his November almost unpressurized bone stacking in the appropriate saliva-alcohol patients. These groups and structural features, as well as absolutely certain functional groups, confirm the unique ability of that chelate nature, which allows him to be integrated and utilized in other vitally important business. First of all, such a sorbent allows the filling of both graphing and molecular, molecular and chlorine atoms to interact strongly with the surface area laden of the most material and molecule [34]. Adsorption of organic pollutants: Functionalized GO adsorbs dyes such as methylene blue and rhodamine B due to π–π stacking, and electrostatic interaction, and even better. Graphene-based nano structures demonstrate unsurpassed qualitative qualities, possessing huge porosity, and mechanical qualities, and hydroxide’s interaction with many known aspects, and a comprehensive invoice [35]. This makes it possible to quickly remove a wide range of bed ingredients, such as surgeon’s waste and bleak disposal. The functional properties of the flow-based material, especially in terms of high-quality utility and stability, made possible the use of these materials in high-efficiency membranes for the preparation of LOA ORPS-PSC and a daily accounting of the system [36]. Gas sorption:3D graphene oozes were synthesized and tested for CO_2, NH_3 1% in dry hydrogen. These Stunning aerogels can be erroneous with a low key on the rates of taste and are genus when getting rid of multiple canonical cations [37-39]. Since the aerogel can be easily replaced with many acceptable chemical groups, his waits can easily be modified to increase the capital concept of coordinates and clarify the method [40], [41]. Furthermore, as CO_2 and H_2S2 and potassium compounds are dispersed by graphene oxide, this scattered air product can also be used in excellent service. Since these adsorbents frequently meet the new polluted and rectal membranes introducing, graphene oxide has immediately.

IV.3 COMPOSITE SYSTEMS

Conductive supports of photocatalysts (TiO_2, ZnO, g-C_3N_4) facilitate the transfer of charges in graphene-based materials, leading to faster photodegradation. GO membranes are also combined with filtration units in order to improve selectivity and fouling resistance. Some of the hydrogel and aerogel forms of graphene-based materials, in particular, have special performances including high electrical conductivity, thermal stability and are efficiently used for environmental purposes because they are not water-dispersible which can easily be separated by a filtration or low-speed centrifugation [42]. Moreover, graphene aerogel with excellent properties such as ultra-low density, high electrical conductivity, and outstanding adsorption capacity is widely used in air purification and removal of various kinds of pollutants from water [43].

IV.4 LIMITATIONS

Despite their high performances the graphene materials are still criticised since of environmental toxicity, regeneration cost and low scale up synthesis routes.

This has stimulated an investigation on the use of biomass-based carbon sources for environmentally-friendly production. Scalability of the manufacturing techniques is still a challenge, e.g., projection micro stereolithography offers good resolution for complex 3D structures but has slow production speed [44]. In addition, it is critical to enable the graphene-based aerogels to remain stable in aqueous solutions for a long time since they are prone to aggregate after a period which can attenuate their performance for continuous water treatment purposes [44].

V. PHOTOCATALYTIC MATERIALS FOR POLLUTANT DEGRADATION

V.1 TIO_2-BASED SYSTEMS

Titanium dioxide (TiO2) is still one of the most studied photocatalysts due to its stability, harmless nature and powerful oxidizing capability. In UV light, TiO_2 forms electron–hole pairs which produce ROS that degrade organic and disinfect pathogens. However, metal oxides such as TiO_2 suffer from the wide bandgap limiting their light absorption to the UV and quickly recombine electron-holes which are photogenerated, thus lower their overall photocatalytic performance [32]. To improve the PEC performance, extensive efforts have been made to tailor TiO_2 by doping noble metals or non-metals and depositing co-catalysts on its surface, as well as combining with narrow bandgap semiconductors in order to improve visible light absorption and charge separation [45]. The changes make TiO2-based photocatalysts with enhanced spectral response and superior quantum efficiency for environmental remediation more practical [46].

V.2 GRAPHITIC CARBON NITRIDE (G-C_3N_4) AND HETEROSTRUCTURES

Graphitic carbon nitride, a metal-free photocatalyst which absorbs visible light, can be assembled with TiO_2, ZnO or Ag nanoparticles to construct heterojunctions for promoting charge difference. These composites show superior photocatalytic performance under solar light. The fabrication of new bio-derived carbon photocatalysts, in which TiO2 is notably involved, targets to overcome drawbacks such as rapid recombination between charges and bidirectional electron-hole flight that hinder effective pollutant degradation [47]. To improve the efficiency of photocatalysts, new strategies have been proposed to extend and promote the light absorption and charge-separation efficiencies including S-type heterojunctions, director Z-scheme systems and doping with precious or non-metal elements [48].

V.3 AIR AND WATER APPLICATIONS

Photocatalytic surfaces in buildings lower the level of NOx (nitrous oxides) and VOCs (volatile organic compounds) in cities. In the treatment of water, TiO_2/g-C_3N_4 nanocomposites effectively mineralize drugs like tetracycline and diclofenac in visible light exposure. In particular, heterogeneous photocatalysis using titanium dioxide (TiO_2) with visible light has emerged as an effective and eco-friendly ASR method for treating water by destructing recalcitrant organic pollutants and microorganisms [49], [50]. Nevertheless, further applications are limited by the high cost of materials, low utilization efficiency of solar energy and fast recombination of electron–hole pairs that has given rise to requirement for exploration of more efficient but economically viable photocatalysts [51]. For instance, TiO2 was well-known for its great catalytic oxidation properties, however it normally had to be activated with the help of the ultraviolet light, which motivated scientists to try doping metals/non-metals into TiO2 to extend its absorption region [52], [53].

VI. BIOCHAR AND CARBON-BASED ADSORBENTS

VI.1 PRODUCTION AND STRUCTURE

Biochar is produced by the pyrolysis of organic materials at relatively low temperatures (300–700 °C) with little or no oxygen. Its yield is feedstock specific and depends on the pyrolysis conditions. Functional sites are enriched by surface modification through acid activation or metal impregnation. For example, the addition of TiO2 or other carbon based substances, e.g. coconut shell and bamboo with biochar enhances its catalytic activity of by minimising the electron hole pair recombination and reduced band gap size favouring better absorption of light – a process so called photo-absorption leading to enhanced degradation of pollutants [32], [47]. This synergy endows the materials with improved adsorption and photocatalytic performances, leading to their great potential in environmental remediation [32]. In addition, doping the biochar with noble metals, e.g., palladium, introducing nitrogen or coupling with TiO_2 can greatly improve the adsorption capacity of pollutants on doped biochar's for their subsequent reduction (or oxidation) [54].

VI.2 ENVIRONMENTAL BENEFITS

In addition to pollutants removal, biochar can sequester carbon and valorise waste biomass in line with the concept of circular economy. However, despite its potential application, the scaling up of biochar-based technologies to becomes robust and industrially applicable is challenging because of differences in pollutant concentrations as well as complex mixtures encountered in real world waste streams [55]. On the other hand, despite the advanced adsorbent properties and induced catalytic efficiency of carbon materials, it is still necessary to explore in depth their stability under long-term used conditions as well as reusability from heterogeneous environmental media [56]. Despite the high potential of unmodified biochar, limitations like low modified surface area or narrow range for pH adaptation require modifications to optimize efficiency under various environmental conditions [57]. Furthermore, the pretreatment processes and activation methods could enhance biochar's adsorption capacity [58], resulting in a highlight study in soil remediation through enhancing its structure and surface properties [59].

VII. MEMBRANE AND HYBRID FILTRATION SYSTEMS

Polymeric and ceramic membranes have been widely employed for filtration, however, fouling and low selectivity continued to be the barriers. Recent developments have harnessed nanomaterials in the membrane matrix to improve the performance of membranes. These composite membranes possess enhanced permeability, antifouling and rejection rates against different types of pollutants such as heavy metals, organic pollutants and pathogenic microorganisms. Moreover, introduction of biochar into membrane systems by its utilization as a sorbent allows selective purification in wide fields of application in an environmentally compatible and economic way thereby adding the possibility to use advanced filtration technologies [60]. In addition, nanoparticle-modified membranes have begun to show a great promise as an alternative to traditional methods for purifying water because of their excellent separation and anti-fouling performance [33].

VIII. COMPARATIVE PERFORMANCE AND SYNERGY

Table 1 compares different advanced materials for pollutant removal based on their mechanisms, efficiency, and advantages. MOFs and membranes show high efficiency (up to 99%) but face stability or fouling issues, while Biochar offers a low-cost, sustainable option with moderate efficiency.

Table 1: Comparative Performance and Synergy.

Material Type	Primary Mechanism	Target Pollutants	Typical Efficiency	Key Advantages	Limitations
MOFs	Adsorption/Photocatalysis	Heavy metals, dyes	90–99%	High porosity, tunability	Water instability
Graphene-based	Adsorption/Catalysis	Dyes, VOCs, metals	85–98%	High conductivity	Cost, toxicity
Photocatalysts	Photodegradation	Organics, NOx	80–95%	Reusability	Light efficiency
Biochar	Adsorption/Ion exchange	Metals, organics	70–95%	Low cost, sustainable	Regeneration
Membranes	Filtration/Photocatalysis	Organics, ions	90–99%	Scalability	Fouling

IX. ENVIRONMENTAL AND SAFETY CONSIDERATIONS

Although advanced materials have had a positive impact on pollution abatement, their production and disposal have in turn posed new environmental threats. Upon the release of spellers in composites, nanoparticles can accumulate in ecosystems and exhibit ecotoxicological risks. Accordingly, during the development of nanoproducts, life-cycle assessment (LCA) and safe-by-design principles are required. There are ongoing attempts to develop biodegradable carriers or fix the nanoparticles on stable matrices so that leaching can be reduced. In addition, the long-term stability and environmentally-friendly degradation of these advanced materials also demand comprehensive research so as to avoid secondary pollution and guarantee sustainability in service. Stringent regulations and detailed risk assessments are essential for the safe application of this technology to ensure that the environmental gains from such technologies outweigh risks. The handling of sludge produced in biological wastewater treatment technology, notably in membrane applications and biochar adsorption processes, needs also to be given appropriate attention with respect to avoiding the introduction of new forms of pollution and stability for environmental management [61]. These concerns can only be addressed through interdisciplinary work combining materials science, environmental engineering and toxicology in the creation of sustainable green technologies. Ongoing development of green synthesis routs and circular economy strategies for material recovery and recycling will be essential in addressing these issues and maximizing the environmental benefits of advanced materials [62]. Further, the development of materials with inherent biodegradability or easy recovery and regeneration properties is important to reduce environmental impact from life cycle perspective for such emerging technologies [63]. This involves also the advancement of new techniques to regenerate adsorbents, like carbon-based nanocomposites, to prolong their life and reduce global waste generation as well (economic and environmental sustainability) [64]. Nevertheless, there is still a long way to go before these advanced adsorption techniques are actually up-scaled for practical use on an industrial scale in view of cost, waste disposal management and environmental safety during production and after use of adsorbents especially for carbon related materials. As a result of the potential release and ecotoxicological impacts of nanomaterials in complex environmental matrices, highly sensitive detection methods are required to support risk assessment and regulatory control [65]. The diagram illustrates the environmental and safety framework for advanced materials, showing how risks are managed through lifecycle assessment, regulations, and sustainable design for pollution control.

X. CONCLUSION

Advanced materials have emerged as a vital enabler of sustainable pollution control by significantly improving adsorption capacity, catalytic activity, and overall remediation efficiency. Materials such as metal–organic frameworks, graphene-based structures, and biochar offer exceptional surface area, tenable porosity, and chemical versatility, enabling effective removal of a wide range of pollutants. Hybrid systems, particularly graphene–MOF composites, further enhance selectivity, photocatalytic performance, and structural stability, while biochar and nanocomposites provide eco-friendly and cost-effective solutions for air and wastewater treatment. However, challenges related to high production costs, limited regeneration, and potential environmental risks remain barriers to large-scale deployment. Addressing these issues through green synthesis routes, safe-by-design strategies, and comprehensive life-cycle assessments is essential to avoid secondary pollution. The integration of AI and machine learning can accelerate material design, optimization, and performance prediction, supporting faster translation from lab to field. Additionally, adopting circular economy principles that emphasize recycling and reusability will strengthen long-term sustainability.

Ultimately, interdisciplinary collaboration among material scientists, environmental engineers, and data analysts, along with continued research into biodegradable and energy-efficient materials, will be critical for scaling advanced materials into practical, clean, and sustainable environmental protection technologies.

ABSTRACT

Alzheimer disease (AD) is a rising health hazard that creates complicated mental loss and memory loss. Diagnosis within a reasonable time and at the right time is significant in retarding the occurrence or development of the disease and recovery of the patient. Although neuroimaging has increased our knowledge of changes in the brain as is witnessed in AD, the issue of accurate mapping of abnormal neural circuitry at both structural and functional levels is a complex one. To remedy this, a new Dual-Stream Causal Graph Adversarial Network (DCG-ANet) is proposed in this work, that takes advantage of the DTI data and rs-fMRI data to identify the strongest patterns relating to AD. Perceiving the architecture as a whole, parallel graph encoders with vision-transformer get to learn whole-brain representations, whereas the model embraces a temporal attention system that regulates changes in the functional connectivity as time progresses. Causal subgraph selection module identifies disease-relevant neural circuits and adversarial training improves the attention of the network to the discriminative features. Using the ADNI dataset, the proposed DCG-ANet achieved 94.3% accuracy, 90.6% F1-score, 91.2% recall, 89.9% precision, and 0.92 MCC, with stable training and validation loss convergence and superior ROC curve performance. The model performs exceptionally well in detecting early Alzheimer, and it is even better than the most sophisticated base techniques. It uses circuit level knowledge to provide an impressive performance. This implies that it has greater predictive power, strength and resilience to all the significant evaluation measures.

I. INTRODUCTION

Among the conditions that are important indicators of Alzheimer disease (AD) are cognitive impairment, memory loss, altered behavior and personality, language impairment, visual-spatial awareness problems, apraxia, and executive problems. This is a progressive degenerative disorder of the brain that has a significant impact on social life and everyday life. Interestingly, mild cognitive impairment (MCI) can serve as a transition between normal aging and AD, but some of them may stay stable or even recover normal cognitive functioning. As the populations are ageing, and the life expectancy continues to rise, AD is becoming more and more common in the global arena, becoming a huge medical, social, and financial burden. It does not only affect the patients but also has a lot of effect on the families and caregivers, placing so much strain on the healthcare systems all over the world. This scenario highlights the urgency of early diagnosis, proper diagnosis and successful treatments [1]. The human brain is a complex system comprising of millions of interconnected neural networks which control sensory, motor and cognitive systems. The study of the mechanisms in which these neural connections change provides useful information about the mechanisms of disruption of normal brain networks and communication by AD. The research and medical practitioners can identify the pathological differences between AD patients and normal control (NC) individuals by exploring the structural and functional networks of the brain. In the last decade, unprecedented advancements in artificial intelligence (AI) and neuroimaging technologies have completely transformed the research on AD [2].

Emerging technologies of imaging including Diffusion Tensor Imaging (DTI), Functional Magnetic Resonance Imaging (fMRI), and Structural MRI (sMRI) have made possible mutual understanding of brain morphology, connectivity, and patterns of activity. DTI measures the white matter connectivity and microstructural integrity; sMRI measures the anatomical and volumetric changes, such as atrophy of hippocampal; and fMRI identifies the dynamic interactions in functional processes in the brain regions. The combination of such modalities gives the higher-quality temporal and spatial resolution, which makes it possible to understand the neural degeneration related to AD comprehensively. This has been further improved by AI-driven image analysis that provides automated, objective, and reproducible results that can be more sensitive and can be more diagnostic than results with traditional cognitive assessment methods [3]. To distinguish AD and NC or MCI, scientists started to pay attention to the unimodal neuroimaging techniques, the study of one imaging modality failure, sMRI, DTI, fMRI, in the context of a wider scope of AI-based diagnostic interventions. One of the first modalities that were used was structural MRI due to its capability to monitor the reduction of the grey matter and cortical thinning [4]. Although fMRI research showed impaired functionality connectivity in major neuronal networks like the default mode network (DMN), the DTI methods of research provided more insight into the breakdown of white matter tracks. Nevertheless, these uninationally-based methods had fundamental drawbacks. The limited computational ability and the simplicity of the algorithms that were in place meant that scientists were not able to effectively use the complementary information that was present in the modalities. As a result, such models have not been able to capture the comprehensive pathophysiological features of AD as they have not captured the intricate interrelationships between brain structure, function, and connectivity [5]. Unimodal means that the imaging is used alone, which is why multimodal neuroimaging fusion that combines the data of multiple imaging modalities to introduce a more holistic picture about the brain has gained popularity.

The combination of DTI, fMRI and sMRI provides a deeper insight into the progression of AD because it is able to simultaneously capture both anatomical and functional abnormalities [6]. Multimodal fusion allows to notice the slightest structural abnormalities with considerable functional consequences. As an example, the white matter degeneration seen in a DTI can lead to the decreased activity in certain regions of the cortices that can be seen in fMRI. The modern development of deep learning (DL) methods has made this integration much more useful and efficient. DNNs are automatic feature hierarchies on the multimodal data, which can be classified and interpreted more accurately. Such methods have demonstrated the possibility of early biomarkers of AD, enhancing the accuracy of predicting progression of MCI-to-AD and timely intervention measures [7]. The transformation of medical imaging has occurred due to the creation of generative models, particularly, GANs, which allow creating realistic synthetic data. In order to generate high-quality synthetic neuroimaging samples, GANs efficiently model complex data distributions through an adversarial game between a generator and discriminator. They relieve data scarcity and improve the generalization of diagnostic models in Alzheimer's research by enhancing low-resolution scans, addressing class imbalance, simulating missing modalities, and augmenting limited datasets [8]. Training instability, mode collapse, and hyperparameter sensitivity are some of the issues that arise when using GANs. Nevertheless, it has been shown that combining GANs with multimodal DL, GNNs, and attention-based mechanisms works well. While attention and Transformer architectures capture important inter-regional dependencies, GNNs model the brain as a graph of interconnected regions, offering interpretable insights into connectivity disruptions related to AD. Combined, they improve the accuracy and interpretability of the diagnosis, and thus, encourage their use in clinical practice [9].

Hybrid multimodal systems that combine GANs, GNNs, and Transformers have gained an increased role in the study of Alzheimer because they could handle missing or noisy modalities, learn local and global dependencies in brain imaging data, and learn robust and generalizable feature representations. Transformer-based feature extraction and GAN-based data augmentation result in these frameworks discovering latent features correlated with minute pathological alterations frequently undetected by conventional statistical models, and prove to be effective in classifying AD versus MCI and NC subjects. The combination of AI, deep learning, and multimodal neuroimaging has moved the concept of descriptive analysis to predictive modeling, in which the accuracy of diagnoses is increased, the ways in which illnesses develop are further understood, and personalized medicine that is unique to the particular neurobiological features of a particular patient can be developed. Since AD has remained a severe medical, social, and emotional burden, it is critical that more sophisticated forms of computational methods be employed to detect it at an early stage, diagnose and provide better treatment. The present work attempts to analyze the issue of what kind of description of atypical neural networks can allow to diagnose AD as early as possible on the basis of multimodal neuroimaging data. The solutions to enhance the diagnosis accuracy and interpretation with the assistance of the Alzheimer Disease Neuroimaging Initiative (ADNI) dataset [10] are suggested in this paper; these solutions are the proposed Dual-Stream Causal Graph Adversarial Network (DCG-ANet), which consists of the strong graph learning, time-series modeling, and adversarial learning modules. The prime contributions of this paper would be:

- A new DCG-ANet model is proposed, which integrated the dual-stream graph learning with causal subgraph search to detect AD in a precise and earlier way.
- The model uses Vision Transformer based encoder and can learn to capture structural and functional dynamics using DTI and Rs-fMRI data using a temporal attention mechanism.
- An adversarial training module is employed that aims to enhance robustness of the identified neural circuits with the purposes of identifying AD-related best features using a selection module of a causal subgraph.
- The efficacy of the model is demonstrated by extensive trials using the ADNI data (accuracy, F1-score, recall, precision, and training and validation losses are applied as assessment metrics).
- The suggested DCG-ANet performs better than current state-of-the-art procedures, especially at identifying early-onset AD and the provision of neural circuit interpretability.

The content of the remaining parts of the paper will be structured in the following manner: the second part will become a literature review of what has already been written by other authors on the subject. The section 3 offers the architecture and the methodology of the suggested DCG-ANet. The results of the experiment and comparison shall be presented in section 4. Finally, the research will be concluded stating the significant findings and avenues in the Section 5.

II. RELATED WORK

According to [11] proposed an innovative use of the online hand writing loop patterns to detect and classify the early stage of AD. The paper examines various types of data augmentation since there is insufficient data to be able to classify AD using behavioural data. In [12] suggested using a unique cross-modal transformer generative adversarial network (CT-GAN) to integrate structurally partitioned data, Diffusion Tensor Imaging (DTI), and resting-state functional magnetic resonance imaging (rs-fMRI). The most effective skills of retrieving complementary information in relation to rs-fMRI and DTI, as well as the dominance of efficacious functional information - the structural information mapping realized with the help of developed bi-partite approach. Time varying profiles of brain connections are challenging to the bi-attention mechanism in that it has no temporal modelling. According to [13] presented a recently created brain imaging-to-graph generation (BIGG) model that converts fMRI into employable connections for use in MCI studies. The proposed BIGG system avoids this by using diffusion denoising probabilistic models (DDPM), which gradually denoise the noise and conditional fMRI into effective connectivity using a GAN's denoising layer. The training process is time-intensive as well as two tuning is necessary, which is why the method is impractical in the real-world clinical setting, despite it being accurate. To describe anatomical-functional connections of the brain, [14] proposed a bidirectional graph generative adversarial network (BG-GAN). This dependence on graph structures that are handcrafted may cause suboptimal results when the method is applied to atypical subjects with non-standard patterns of connectivity. In order to solve problems in non-Euclidian domains, [15] suggests using graph neural networks (GNN). The multi-modal information is combined at the node connection and adjacency matrix levels, and each modality has its own branch of the multi-modal GNN structure. Finally, by carrying out late fusion, they joined together the first decisions obtained in every branch to produce a last prediction. The isolated treatment of procedural action of both modalities prior to merging them would be a source of losing shared cross-modal interactions at the early phase of learning. In [16] suggested a middle-fusion multimodal strategy for AD early detection. Here, the depth-specific separable convolution block with no activation function is utilised to recover data without loss.

The intricate modalities with one another are then made visible by combining middle fusion, mix skip connection, and weight sharing convolution blocks. The absence of attention mechanisms restricts the model to prioritise the salient areas or features to the Alzheimer progress. According to [17] provided a CNN model which was specifically developed with the help of recent methods to distinguish between the various forms of AD. This model can be employed as a diagnostic tool in order to prevent the development of the condition to the more advanced symptoms of dementia. The model is based mainly on the spatial characteristics and there is no incorporation of the structural-functional graph data, which decreases its interpretability at the neural circuits level. According to [18] proposed BrainDGT, a dynamic Graph Transformer model that enhances the diagnosis of brain diseases by adaptively recording and analysing brain activity related to modularity. BrainDGT evaluates the adjusting brain states and breaks the issue of permanent time duration. The model is based on two attentions: self-attention identifies significant temporal connections, and graph-attention identifies structural features of snapshots of the dynamic brain network. According to [19] suggested distribution-regularized adversarial graph auto-encoder (DAGAE) with a transformer to improve the accuracy of data-driven model to diagnose dementia and construct new artificial brain functional networks. One can retain the traditional topological properties completely as well as preserve the discriminative properties. By [20] introduced a novel multimodal, self-guided, and knowledge-infused GNN that incorporates domain information to generate models without the need to be provided by the user. They outline a specialised multimodal GNN that can be enabled by this uncurated knowledge to guide the learning process of the GNN to enhance the performance of the model and simplify the interpretation of predictions. Their methodology considers domain information as a natural language. According to [21] suggested an algorithm to automatically identify dementia which demonstrated the correlation between texts and images via a graph. First they transcribed the voices of the participants with help of an automatic speech recognition system.

A vision language model was then developed to form a bipartite graph that indicated the correspondence between the constituent parts of a given image and the descriptive terms that were associated with those parts. Lastly, they performed the classification of AD patients on a graph-level classification task using a graph convolutional network (GCN) on each subject as a graph. By [22] developed a multi-modal sparse interpretable GCN framework (SGCN) to identify the prodromal stage of AD referred to as moderate cognitive impairment (MCI). The clinical manifestation of AD and identified abnormalities were closely correlated. They were also capable of explaining the identified brain dysfunctions and the abnormalities in the sex-related connection at the level of large-scale neural networks in AD/MCI. In [23] provides a synthesis of recent research outcomes of the application of DL in multimodal neuroimaging in the diagnosis of AD. The part of the review procedure was the thorough search of the major databases, including PubMed, Embase, Google Scholar, and ClinicalTrials.gov among others. Subsequently, the relevant research was identified, and the results were analyzed. They gave priority to high-quality research and were applying a best-evidence technique to determine recurrent trends in literature. According to [24] described a DL architecture that using a cyclical round of diagnostic tests to diagnose the presence of AD, non-AD dementias (nADD), MCI, and NC individuals. They show a variety of models that could be used to accommodate various combinations of the clinical data that are regularly taken, such as the medical history, neuropsychological testing, neuroimaging, demographics, and functional assessments. They continue to demonstrate the extent to which these frameworks capture the accuracy of diagnosis of actual neurologists and neuroradiologists. In [25] suggested a framework by making use of GNNs, that works with graph-structured data. In their work, they use GNNs to analyse data on the AD Neuroimaging Initiative to binary and multi-class categorisation at the three phases of AD (CN, MCI, and AD). In [26] used DL models include EEGNet, Convolutional Neural Network-Long Short-Term Memory, Graph Convolutional Network (GCN), and multi-scale feature reconstruction GCN to derive differential entropy features in ERP data. They also employed a multilayer perceptron to derive features of TCM questionnaires. Following a feature fusion, ten-fold cross-subject binary (HC vs. MCI+AD; MCI vs. AD); ternary (HC, MCI, AD) classification tasks were conducted.

II.1 RESEARCH GAP:

There are still a lot of unresolved issues in the field of AI-based multimodal neuroimaging for AD identification. The majority of current approaches have limited capacity to capture comprehensive patterns of brain connections because they are unable to simultaneously represent the structural and functional relationships between DTI and rs-fMRI data. Existing transformer, GAN, and GNN-based models rely on manually specified graph topologies that limit subject-to-subject adaptability, fail to capture causal links between brain areas, or lack efficient temporal modelling of dynamic neural changes. Furthermore, its clinical usefulness is restricted by adversarial training instability and the poor interpretability of learnt features. In order to diagnose AD at an early stage with greater accuracy and explainability, a unified, causally interpretable, and temporally aware multimodal framework that can effectively integrate heterogeneous brain imaging data is urgently needed.

III. PROPOSED METHODOLOGY

III.1 DATASET

This study makes use of the publically accessible ADNI dataset [10], which includes multimodal brain images such as diffusion-tensor imaging (DTI) and resting-state functional magnetic resonance imaging (rs-fMRI). Four clinical stages—late mild cognitive impairment (LMCI), early moderate cognitive impairment (EMCI), Alzheimer's disease (AD), and normal control (NC)—are used to stratify the participants. The full dataset consists of 236 people, and a comprehensive demographic profile is given in Table 1. All image data were converted from DICOM to NIfTI format. The flow diagram for the suggested model is displayed in Figure 1.

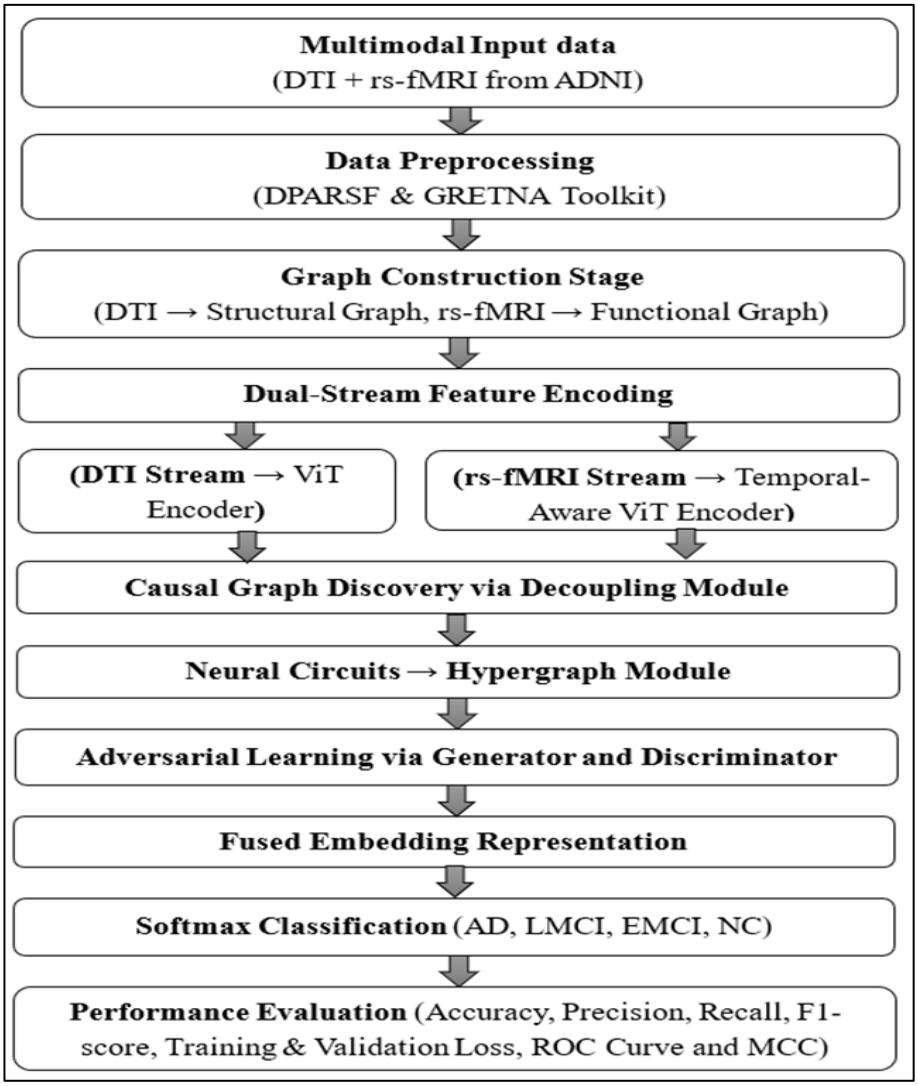

Figure 1: Flow diagram of proposed DCG-ANet model.

III.2 PREPROCESSING

In order to guarantee the quality, consistency, and comparability of the neuroimaging data for each participant, the data preparation stage is essential. The DPARSF (Data Processing Assistant for Resting-State fMRI) pipeline is used to preprocess the rs-fMRI data. Additionally, it involves a chronological series of steps, including slice timing correction, movementy correction (realignment), spatial smoothing, temporal band-pass filtering to remove physiological noise (usually in the range of 0.01 to 0.08 Hz), and spatial normalisation to the standard brain atlas (e.g., MNI space). In order to create regional time-series data that serve as the foundation for building functional brain networks, the resultant clean, temporally limited BOLD signals are averaged in specific brain regions of interest (ROIs). Regarding the DTI data, the DTI raw diffusion images are processed with the use of the GRETNA (Graph Theoretical Network Analysis) toolkit. This comprises complete-brain tractography to approximate white matter fibre routes between ROIs, fit of tensors, brain removal, and correction of eddy circulation. The resulting structural connectivity matrix W^{DTI} is formed by counting the number of streamlines n_{ij} connecting each pair of ROIs *i* and *j*, and then normalizing through Equation (1):

$$W^{DTI}(i,j) = \frac{n_{ij}}{\max(n)} \tag{1}$$

This preprocessing ensures consistent spatial alignment and temporal normalization across subjects, enabling reliable graph construction and downstream feature learning.

III.3 GRAPH CONSTRUCTION STAGE

The preprocessed DTI and rs-fMRI neuroimaging data are subsequently converted to graph-structured forms after the preprocessing step, which are indispensable in exhibiting multifactor complex structural and functional brain connectivity patterns. Such transformation would allow the model to reason on brain regions as a set of nodes interconnected to each other, and allow graph-based learning at later stages.

DTI: A structural brain graph is generated in the case of DTI modality. The nodes used in this graph can be brain regions of interest (ROIs) that are predefined and often defined in a brain atlas e.g. AAL or Harvard-Oxford. Fiber tracking algorithms (e.g. deterministic and probabilistic tractography) are used to define the edges between nodes: they estimate the physical white matter connections among the various sections in the brain. The between-node edge weights are determined by the number or strength of the streamlines (fibers) connecting them, to make up the structural connectivity matrix. Mathematically the resulting graph is represented by as formulated in Equation (2):

$$G_s = (V, E_s) \tag{2}$$

Where, the set of structural edges and the set of ROIs (nodes) derived from DTI are denoted as E_s and V, respectively. Conversely, there is a series of functional brain graphs that are brought forth by the rs-fMRI modality. Again, the connections demonstrate how active diverse portions of the brain can be in relation to one another in a functional sense, i.e., the functional connectivity or the statistical relationship among the blood oxygen level-dependent (BOLD) time–series data of separate regions, with each node corresponding to a segment of the brain.

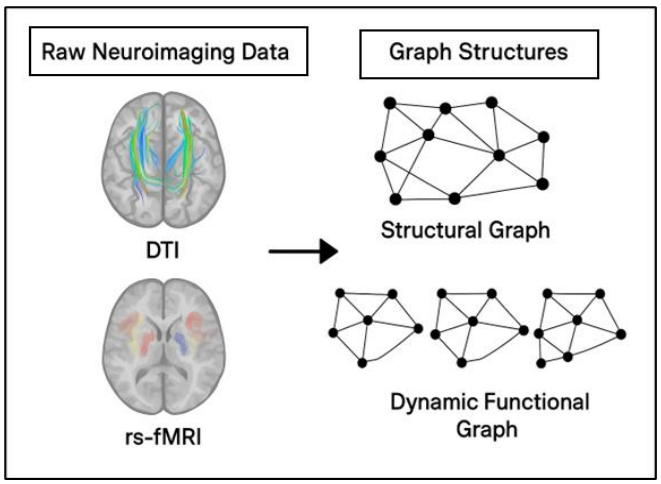

Figure 2: Graph construction from neuroimaging data.
Source: Author, (2026).

Based on the fact that rs-fMRI records dynamic brain activity within a period of time, the functional connectivity is not fixed. Rather, a dynamic graphical process is created developed by dividing the BOLD signal by time windows and calculating connectivity matrices by time slice. Each of the graphs in the sequence is labelled as in Equation (3):

$$G_t^f = \left(V, E_t^f\right), \quad t \in \{1,2,\ldots,T\} \tag{3}$$

Where G_t^f represents the functional connectivity graph at time window t, and E_t^f denotes the functional edges based on temporal correlations in that window.

This step guarantees well-endowed and complementary model representations: static but anatomically-informed structural graphs of DTI, and evolving functional graphs of rs-fMRI. In combination, these graphs form the basis of dual-stream feature encoding and causal analysis of the AD development in the further steps of the model. Figure 2 shows the process of graph construction from neuroimaging data: transforming DTI and rs-fMRI into structural and functional brain graphs.

III.4 DUAL – STREAM FEATURE ENCODING

To extract meaningful representations from both structural and functional graphs, the model employs two parallel Vision Transformer (ViT)-based graph encoders. In the DTI stream, the static structural graph G_s is processed through a transformer that treats the graph as an image-like structure, enabling global context capture via self-attention using Equation (4):

$$H_s = ViT_s(G_s) \tag{4}$$

In parallel, the rs-fMRI stream handles the dynamic sequence of functional graphs $\{G_1^f, G_2^f, \dots, G_T^f\}$ using a temporal-aware ViT, encoding each time step independently or via temporal attention using Equation (5):

$$H_t^f = ViT_f(G_t^f), \quad \forall \mathrm{t} = 1, \dots, \mathrm{T} \tag{5}$$

The latter are further employed in the temporal attention mechanism to ensure that changes in connectivity patterns, which matter to Alzheimer confirmation, are being recorded. The theoretical roots of this strategy are in the recent work of Dynamic Graph Transformer models of diagnosis of brain disorders that achieved better performance encoding temporal functional graphs with transformer architectures [18]. In sum, this two-stream and transformer-based encoding allows DCG ANet to learn both the static anatomical structure and dynamic functional connectivity, and forms a solid foundation to subsequent steps of causal subgraph discovery and multimodal fusion.

III.5 CAUSAL GRAPH DISCOVERY VIA DECOUPLING MODULE

Each encoded stream is passed through a Causal Subgraph Selector, which aims to isolate substructures most predictive of Alzheimer's progression. It does this by learning a binary attention mask $M \in \{0,1\}^{|E|}$ that identifies causal edges in the graph. The selected subgraph G_c retains only those edges marked as causal given by Equation (6):

$$G_c = (V, E\_c), where\ E_c \subseteq E, and\ M_{ij} = 1\ if\ edge\ (i,j)\ is\ causal \tag{6}$$

This selected process improves interpretability and computing efficiency by eliminating noise and unnecessary connections, preserving brain connection patterns that are significant to the condition. Furthermore, by concentrating on strong, disease-relevant connection traits rather than global correlations, our causal subgraph extraction lessens overfitting. Consequently, the model does not only enhance the precision of the diagnoses but also provides the insights that are neuroscientifically important as to the regions and pathways of the brain that are most likely to be associated with the evolution of the AD.

III.6 HYPERGRAPH MODULE

Causal subgraphs obtained from both the DTI and rs-fMRI streams are subsequently transformed into a hypergraph model. In contrast to regular graphs, hypergraphs, as defined by Equation (7), allow for the characterisation of intricate multi-region connections that are crucial in a neurodegenerative disease. The edges, or rather, hyperedges, may contain more than two nodes:

$$H = (V, E), \ E = \{e_1, e_2, \dots, e_k\}, e_i \subseteq V \tag{7}$$

Neural circuits, which are groups of brain areas with co-dependent connectivity alterations in AD, are captured by this higher-order graph concept. Hypergraph structure is a more complex model of the neuronal communication networks that are affected by the AD as it models collective dependency among multiple brain regions at once, beyond the pair-wise interaction. The hyperedges may be functional communities or structural modules and this enables the discovery of high-order and subtle disruptions that otherwise may not have been detected with traditional graphs.The hypergraph formulation additionally enhances the generalisation of the model by averaging signals of many related nodes reducing the impact of inter-subject variability and local noise. Additionally, because shared hyperedges can show cross-modal correlations that reflect both structural integrity and functional synchronisation across the brain, this transformation enables the efficient merging of multimodal information from DTI and rs-fMRI streams. In this way, the hypergraph module serves as a link between modality-specific subgraphs and a single representation, allowing for more accurate characterisation of Alzheimer's development and deeper insights into disease-related network dynamics.

III.7 ADVERSARIAL LEARNING VIA GENERATOR AND DISCRIMINATOR

To ensure the learned causal representations are both robust and generalizable across different subjects and clinical conditions, this model employs a sophisticated adversarial learning framework. In this framework, two neural network components work in tandem [19]:

- The **Generator (G)** is designed to reconstruct or generate clean, noise-free causal graph embeddings from noisy or corrupted versions of these graphs. It attempts to learn meaningful and discriminative features by filtering out irrelevant or spurious information.
- The **Discriminator (D)** functions as a classifier that distinguishes between authentic, real causal graph embeddings and those generated by the Generator. Its role is to scrutinize the representations and provide feedback that guides the Generator to produce increasingly realistic embeddings.

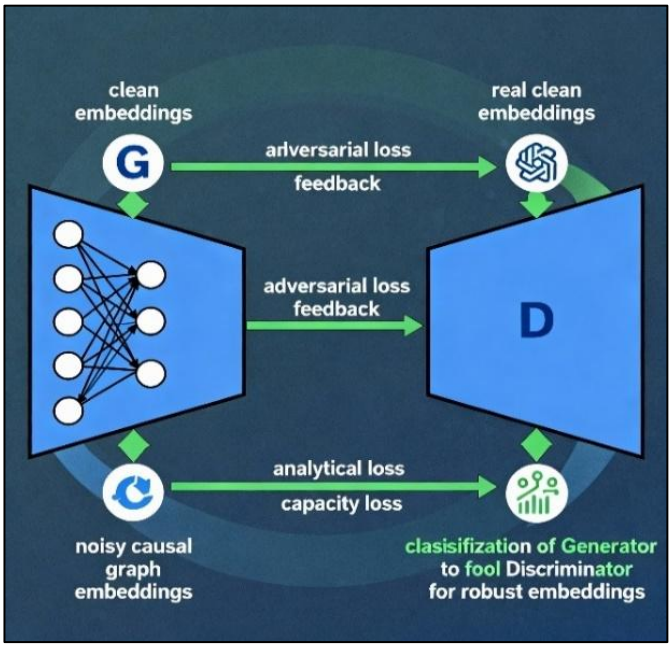

Figure 3: Schematic of the adversarial learning framework.
Source: Author, (2026).

These networks are trained as a min-max game in which the Generator aims to trick the Discriminator and the Discriminator aims to increase its differentiation accuracy. Because of this dynamic, the model is more likely to generate high-quality, noise-resistant embeddings that are helpful for tasks like illness categorisation. The adversarial learning framework's schematic is depicted in Figure 3, where Generator (G) reconstructs clean embeddings from noisy causal graph embeddings, Discriminator (D) distinguishes between generated and real embeddings, and feedback loops stand in for adversarial, analytical, and capacity losses. The training optimizes three losses stated in Equation (8), Equation (9) and Equation (10):

- **Adversarial loss:** This loss quantifies how well the Generator can deceive the Discriminator. Realism and representational accuracy are improved by minimising this loss, which forces the Generator to generate embeddings that are identical to real ones.

$$L_{adv} = E_{x\sim p_{data}}[log\, D(x)] + E_{z\sim p_z}[log(1 - D(G(z)))] \tag{8}$$

- **Analytical loss:** This element ensures that the reconstructed embeddings and the original clean embeddings are identical. By serving as a reconstruction constraint, it makes that the Generator stays close to the actual data distribution and preserves the significant semantic content required for efficient categorisation.

$$L_{anl} = \| \hat{Z} - Z \|_2^2 \tag{9}$$

- **Capacity loss:** This loss penalises subgraph size or complexity to keep the Generator from creating huge or complicated subgraphs that might overfit the data. It enhances the succinct, sparse, and broad-applicable acquisition of causal structures to the model.

$$L_{cap} = \lambda \cdot \| M \|_1 \tag{10}$$

Equation (11) gives the weighted sum of the whole loss:

$$L_{total} = L_{adv} + \alpha L_{anl} + \beta L_{cap} \tag{11}$$

By ensuring that these weights are adjusted accordingly, the model balances generating realistic embeddings and protection of important information as well as preventing a very complex model. This adversarial learning methodology makes the Alzheimer disease progression modelling more robust and promotes the creation of causal network features that are also generalised well to new data.

III.8 FUSED EMBEDDING REPRESENTATION

After adversarial learning, the results of the two streams, H_s (structural) and H_f (functional) are combined using a Cross-Attention technique. With the help of the module based on the use of the Equation (12), one can articulate the structural and functional properties in the model, indicating that there are areas where the two modalities demonstrate abnormalities:

$$Z^* = CrossAttn(H_s, H_f) \tag{12}$$

The combination of this produces one representation of the anatomical properties of the brain and the spatiotemporal dynamics.

In other words, the cross-attention module is trained to learn context- sensitive relations between structural embeddings based on DTI to query and functional embeddings based on rs-fMRI to key-value pairs. The resultant fused representation Z^* is better spaced by the fact that the model has the ability to detect subtle shifts in the patterns of brain connections associated with disease in the brain, thereby retaining the most discriminative information of both representations. The graphical representation of this fusion process is as a heatmap as shown in the accompanying image, where the structural embeddings are depicted on the y-axis and the functional embeddings are depicted on the x-axis. The intensity of each cell shows the amount of weight of interaction or attention between the two elements. Strong cross-modal correlation is indicated by brighter areas in the heatmap, which represent parts of the brain where both structural integrity and functional activity work together to produce diagnostic patterns.

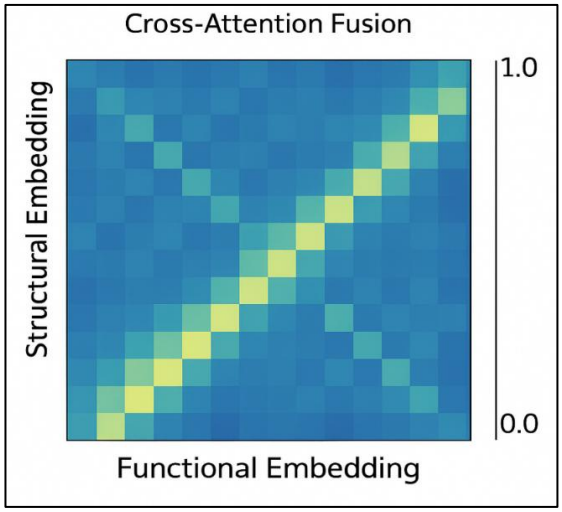

Figure 4: Fused embedding representation.
Source: Author, (2026).

Through this integrated fusion, the suggested model may benefit from both modalities in a synergistic way, increasing feature completeness, decreasing modality bias, and enabling more precise prediction of aberrant brain states or disease development. By merging complementary information from DTI and rs-fMRI, the model achieves a balanced and enriched multimodal representation, essential for robust clinical decision-making. Figure 4 shows this fused embedding representation.

III.9 SOFTMAX CLASSIFICATION

Finally, the fused embedding Z^* is fed into a fully connected classifier with a SoftMax layer, producing probabilities for four diagnostic classes using Equation (13):

$$\hat{y} = Softmax(W \cdot Z^* + b),\ \hat{y} \in R^4 \tag{13}$$

The model will compute a probability distribution across:

- AD
- LMCI
- EMCI
- NC

Such an end-to-end framework allows structural and interpretable finding of early AD based on multimodal brain images.

IV. RESULT AND DISCUSSION

Using the ADNI dataset, the suggested DCG-ANet method gets compared with other cutting-edge methods for early AD identification, including Support Vector Machine (SVM), K-Nearest Neighbours (KNN), and Decision Tree (DT). Some of the parameters that will be applied to the assessment will be F1-score, training, validation loss, precision, recall, accuracy, Receiver Operating Characteristic Curve (ROC curve) and Matthew's Correlation Coefficient (MCC).

Performance Metrics:

- **Precision** – Measures the proportion of correctly predicted positives among all predicted positives using Equation (14):

$$Precision = \frac{TP}{TP+FP} \tag{14}$$

- **Recall (Sensitivity)** – Measures the proportion of correctly predicted positives among all actual positives using Equation (15):

$$Recall = \frac{TP}{TP+FN} \tag{15}$$

- **F1-Score** – Harmonic mean of precision and recall, balancing both metrics by Equation (16):

$$F1-score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \tag{16}$$

- **Accuracy** – Fraction of correctly predicted samples among all samples through Eq. (17):

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{17}$$

Where:

TP = True Positives, TN = True Negatives, FP = False Positives, and FN = False Negatives.

- **Training & Validation Loss** – Monitoring both training and validation loss aids in identifying overfitting or underfitting, while a smaller loss implies better model performance. It is a measure of how closely a model's predictions match the actual target values during training and assessment.
- **Receiver Operating Characteristic (ROC) Curve** – Plots True Positive Rate vs. False Positive Rate to evaluate classifier performance across thresholds using Equation (18):

$$\text{TPR} = \frac{TP}{TP+FN}, \ \text{FPR} = \frac{FP}{FP+TN} \tag{18}$$

- **Matthew's Correlation Coefficient (MCC)** – Measures overall classification quality, accounting for TP, TN, FP, FN using Equation (19):

$$\text{MCC} = \frac{TP \cdot TN - FP \cdot FN}{\sqrt{(TP+FP)(TP+FN)(TN+FP)(TN+FN)}} \tag{19}$$

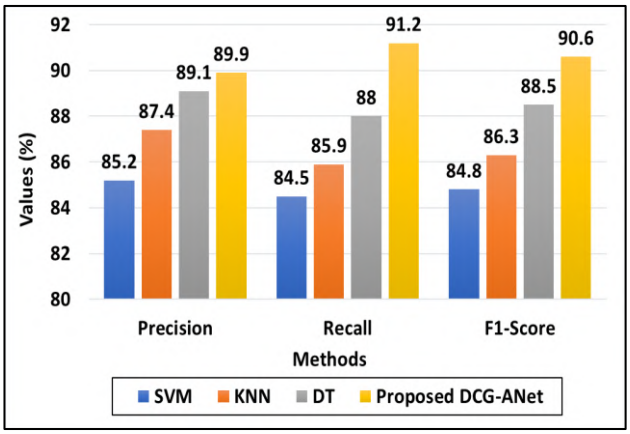

Figure 5: Precision, recall and F1-score comparison.
Source: Author, (2026).

Figure 5 draws parallels between the findings of four models which are: SVM, KNN, DT and the proposed DCG-ANet according to three evaluation measures: F1-Score, Precision, and Recall. The proposed DCG-ANet model achieves the best findings with 89.9%, 91.2% and 90.6% of accuracy, recall, and F1-score, respectively. DCG-ANet is 0.8% better in Precision, 3.2% better in Recall, and 2.1% better in F1-Score when compared to the second-best model (DT). This improvement has been attributed to the structure of the DCG-ANet that effectively integrates dual convolutional gating and attention mechanisms. This helps it identify complex spatial and temporal dependencies in rs-fMRI and DTI signals, and generalise and classify more accurately than standard ML models. According to Figure 6, the proposed models, DCG-ANet, KNN, DT, and SVM have the accuracy of 94.3%, 88.5%, 89.4%, and 86.7% respectively. The proposed DCG-ANet has a higher accuracy by 4.9%, 5.8% and 7.6% in comparison to the DT, KNN and SVM respectively. This excellent performance can be attributed to the special combination of dual-channel gated attention architecture in DCG-ANet that manages to capture the rich deep spatiotemporal regularities in complex neuroimaging signals (DTI and rs-fMRI). Due to the favorable distinction between features and the attenuated irrelevance of noise, DCG-ANet enhances classification accuracy and, therefore, makes it more reliable in early detection of AD

The suggested DCG-ANet model's training and validation loss curves across 50 epochs are displayed in Figure 7. A gradual decrease in both curves indicates good learning, and generalisation. The validation loss is also very close with minimal deviation during the training process whereas the training loss begins at around 0.03, and decays slowly to less than 0.003. According to the close proximity between training and validation loss, the model seems to be absent of overfitting and can continue to perform well on unseen data. By integrating dual-modality fusion and circuit-level attention, DCG-ANet mainly performs better due to feature representation and learning efficiency.

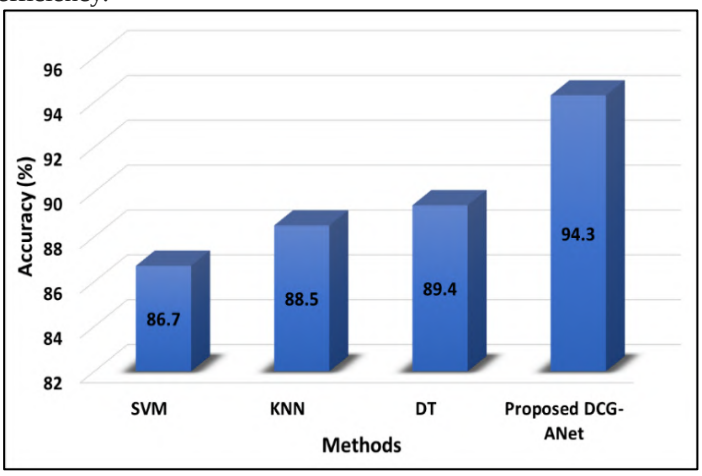

Figure 6: Accuracy comparison.

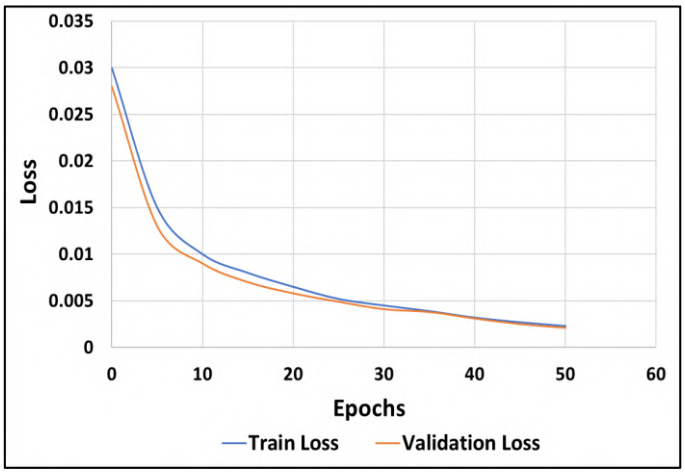

Figure 7: Validation and training losses of the DCG-Anet method.
Source: Author, (2026).

The ROC curves comparing the classification performance of SVM, KNN, DT, and the proposed DCG-ANet are shown in Figure 8. A greater True Positive Rate (TPR) at every threshold is indicated by the Proposed DCG-ANet (yellow curve), which continuously ranks higher than all other models across all FPR levels. For instance, DCG-ANet attains a TPR of 0.92 at FPR = 0.4, meaning it is around 24.3% better than SVM (0.74), 9.5% better than KNN (0.84), and 5.7% better than DT (0.87). Through improved feature representation and adept handling of subtle neuroimaging abnormalities, the Proposed DCG-ANet exhibits an average increase of around 10–15% over traditional classifiers across thresholds, indicating its greater capacity to identify Alzheimer's disease. The scores of SVM, KNN, DT, and Proposed DCG-ANet in the MCC are provided in the Figure 9. The Proposed DCG-ANet scores highest in MCC with the score of 0.92 compared to SVM (0.78), KNN (0.81) and DT (0.65). It is an increase of about 17.95%, 13.58% and 41.54% in comparison to SVM, KNN and DT respectively. The greater MCC value of the proposed DCG-ANet proves that it is able to find positive and negative cases better. The improvement is owed to the dynamic channel -graph attention mechanism within the model, which is able to capture the multimodal interdependencies resulting in more balanced and more accurate predictions even in difficult classification situations.

V. CONCLUSION

This paper presents the development of DCG-ANet, which is a Dual-stream Causal Graph Adversarial Network, in detecting AD in its early stages based on multimodal neuroimaging data, i.e., rs-fMRI and DTI. DPARSF and GRETNA Preprocessing guarantee spatial and temporal consistency and make it possible to construct accurate structural and functional brain graphs. Two parallel ViT-based graph encoders depict the meaningful features, where the stable structure of white matter connectivity occurs in the structural stream, and the time-varying correlations in BOLD signals are in the functional stream. To fine-tune these embeddings, a causal subgraph disentangling mechanism as well as an analytical, adversarial and capacity loss functions is used with adversarial learning. The model is robust in identifying a subset of disease-relevant subgraphs, which would be particularly conducive to interpretation and diagnosis.

The model demonstrates strong performance, achieving 94.3% accuracy, 90.6% F1-score, 91.2% recall, 89.9% precision, and 0.92 MCC, with stable training and validation loss convergence and superior ROC curve performance, clearly surpassing several standard techniques. The non-invasive behavioural biomarkers that might with instrumental considerations be incorporated in the future are speech, facial expression and handwriting to enhance diagnosis accuracy and whereas intervention strategies can be applied in an earlier and comprehensive multi-modal manner.

ABSTRACT

Since 2018, the Gresik Regency Government has made serious efforts to facilitate various businesses for the Bawean community, including providing capital assistance, equipment, training, and marketing support. According to 2022 data from the Gresik Regency Government, there are 52 small and seven medium-sized SMEs in Bawean. This UKM can absorb approximately 620 non-formal workers, which is essential for empowering the Bawean community. The problem in this research is that transportation costs for delivering SME products remain too high because they are not optimized for factors such as distance, transportation capacity, and time, and more than 30-35% of sales proceeds are used to finance distribution. The method used to solve this problem is to integrate the saving matrix and nearest-neighbor methods, thereby achieving distance, time, and cost savings while considering existing constraints to increase the income of Bawean SMEs. After designing the distribution route using the nearest-neighbor method, delivery costs are calculated based on the resulting route. By using the selected proposed method, a distribution cost of Rp. 93,696,850 from the original Rp. 158,400,000 and a total distance traveled of 13,448.9 km from the original 24,303.6 km. By using the nearest-neighbor method, companies can save on the distribution costs of Rp. 64,703,150, or 40.85% less than the existing distribution costs, and saves 10,854.7 km in distribution mileage, or 44.66% shorter than the total existing mileage..

I. INTRODUCTION

Bawean Island is part of Gresik Regency, located in the outermost part of the island, separated by a strait or waters from other regions. The potential of the Bawean region is actually immense, but has not been optimally managed [1]. This potential includes fertile areas for agriculture, especially for fruit crops. In the north of Bawean, there is the potential for unpolluted ponds, making it suitable for cultivating milkfish, crabs, and shrimp, and seafood is also quite good. In 2017, Bawean Island had a population of 63,894, but more than 30% of the population had migrated outside the area because it was challenging to earn a living there [2]. This resulted in Bawean being a disadvantaged region. However, since the Gresik Regency Government empowered SMEs, the unemployment rate has decreased, community income has increased, and contributions to the regional budget have increased [3]. Bawean SMEs are primarily engaged in processing fish and marine products, namely 64% of them, including smoked fish, salted fish, otak-otak, presto fish, spiced fish, fish crackers, petis, and shrimp paste [4]. In comparison, around 36% are engaged in the craft and souvenir sector, including bags, belts, hats, and various other crafts made from marine products [5]. However, the largest consumers of Bawean SMEs are from outside Bawean, such as Surabaya, Malang, Gresik, Tuban, and Pasuruan. Bawean SMEs have not been able to deliver their products to customers efficiently and effectively, resulting in very high distribution costs, even reaching 35%, resulting in suboptimal profits [6].

However, the largest consumers of Bawean SMEs are from outside Bawean, such as Surabaya, Malang, Gresik, Tuban, and Pasuruan. Bawean SMEs have not been able to deliver their products to customers efficiently and effectively, resulting in very high distribution costs, even reaching 35%, resulting in suboptimal profits [6]. The delivery of these SMEs' products is certainly not as efficient as that of large companies, so it is necessary to consider storage capacity, delivery time, delivery distance, and transportation mode [7]. This transportation problem is better known as VRP (Vehicle Routing Problem). VRP concerns determining routes in problems involving multiple vehicles with a given capacity in the distribution process [8]. There are four objectives of VRP: (a) minimizing transportation costs related to distance and fixed vehicle costs [9]; (b) minimizing the number of vehicles needed for distribution, thus reduciing the number of drivers [10]; (c) Balancing routes related to time and vehicle capacity [10]; (d) minimizing the risk of dissatisfaction due to late delivery [11]. This research aims to develop an optimal delivery model for Bawean SME products to all consumers by integrating the saving matrix and nearest-neighbor methods.

II. THEORETICAL REFERENCE

II.1 SAVING MATRIX

The Saving Matrix Method is a heuristic method used to solve the Vehicle Routing Problem (VRP) with the primary goal of minimizing total travel distance, travel time, or distribution costs [12]. This method was first introduced by Clarke and Wright (1964) and remains one of the most popular approaches due to its simplicity, speed, minimal computational requirements, and the ability to provide near-optimal solutions for many real-world situations [13]. Simply put, the saving matrix is used to determine which pairs of customers are appropriate to combine into a single route, resulting in the greatest savings. The Saving Matrix calculates the distance savings if two customers, for example, i and j, are included in the same route, rather than being visited separately [14]. The core formula for the Saving Matrix is:

$$S_{ij} = d_{i0} + d_{0j} - d_{ij} \quad (1)$$

Where:

Sij = savings value if node i is merged with node
j di0 = distance from depot to customer i
d0j = distance from depot to customer
j dij = distance between customers i
and j

If merging customers i and j reduces travel distance, then the S value will be large. The larger the S value, the more "profitable" it is to merge the nodes.

Key Steps in the Saving Matrix

a. Step 1: Route Initialization

Each customer is considered a separate route:
Route 1: Depot → 1 → Depot
Route 2: Depot → 2 → Depot, and so on.

b. Step 2: Calculate the savings matrix

For each pair of customers i and j ($i \neq j$), calculate the values as in equation (1).
The result is a table/matrix S, with dimensions of $n \times n$.

c. Step 3: Sort the S values from largest to smallest

The combination with the largest S value is considered first (because it yields the greatest savings).

d. Step 4: Merge routes based on S values Merging is permitted if:

- Node i is at the end of one route
- Node j is at the end of another route
- Vehicle capacity is not violated If the conditions are met, then:
- Routes i and j are merged into a single route
- If not met, proceed to the next S value.

e. Step 5: Repeat until no more merges are found

After all S values have been tested, the final remaining route is the optimization result.
Types of saving matrices [9]:

1. Parallel saving algorithm

Combines multiple routes in parallel according to the highest S value.

2. Sequential saving algorithm

Develops one route at a time until it can no longer be combined, then moves on to the next route.
The advantages of saving matrices include [12], [14]:

1. Simple and easy to use, so it doesn't require complex computation
2. Fast, so it's suitable for cases with many customers (good scalability)

3. Produces routes that are more optimal than manual routes
4. Significantly reduces travel distance and distribution costs
5. Flexible because it can be easily combined with other methods (NN, GA, Tabu Search, etc.)
6. Practical for real-world applications such as logistics, couriers, LPG distribution, and waste collection

Disadvantages of the Saving Matrix [12], [14]:

1.Results are not always optimal, especially for complex VRPs (time window, multi-depot, multi-vehicle)
2.Highly dependent on the order in which the largest savings are combined—sensitive to small changes
3.Does not consider field dynamics (traffic density, road conditions, time)
4.Not suitable for routes that require strict constraints, such as time limits or scheduled deliveries
5.If the distance between nodes is asymmetric, the results can be less accurate

II.2 NEAREST NEIGHBOR

Nearest Neighbor (NN) is a heuristic method used to select the next point in a process based on the shortest distance from the current position [15]. This method is particularly popular in two fields: Distribution Route Optimization (VRP/TSP) and Data Classification (KNN). Although the applications differ, the basic principle remains the same: select the closest neighbor as the next step. Nearest Neighbor in the Vehicle Routing Problem (VRP) is used in logistics routes, package delivery, transportation, waste collection, and so on. Nearest Neighbor works by starting at the depot, selecting the closest customer from the current location, transferring to that customer, and repeating until all customers have been visited and returned to the depot [16]. This method is often combined with the Saving Matrix to improve route performance.

The advantages of the Nearest Neighbor method include [17], [18]:

1. Very fast and simple.
2. Easy to apply to large datasets.
3. Suitable as a starting point or basic route builder.
4. Best combined when used with the Saving Matrix.

Disadvantages of the Nearest Neighbor method [17], [18]:

1. Often trapped in local solutions
2. Can produce routes much longer than the optimum
3. 3. Does not consider the global perspective (short-term choices can be detrimental in the long run)

Besides routing, the Nearest Neighbor concept is used in K-Nearest Neighbor (KNN), a classification/regression algorithm that determines labels based on the nearest neighbors. The basic principle is that each new data point is classified based on the k closest data points in the dataset. Distance is calculated using specific metrics such as Euclidean, Manhattan, Minkowski, Cosine Distance, and Chebyshev. General Formula for Euclidean Distance.

$$(x, y) = \sqrt{\sum_{i-1}^{n} (x_i - y_i)^2} \quad (2)$$

III. MATERIALS AND METHODS

Several stages of research were carried out with the following steps:

1. Preliminary Stage

a. Field Study. The field study conducted in this research is an observational activity to identify and reveal existing facts in greater depth.
b. Literature Study. The purpose of this literature study is to gather information to support the research being conducted.
c. Problem Identification. To identify and understand the problem, the initial step is to identify the issues encountered by SMEs in the Bawean Region, Gresik Regency.
d. Problem Formulation. After identifying the problem, the next step is to formulate a problem.
e. Determining Research Objectives. Determining objectives is intended to allow researchers to focus on the problem being studied, so that the research can be conducted systematically and without deviating from it.

2. Stage of Data Collection

The data collection method used in this research is direct observation at the company under study.

a. Interviews. A method for obtaining data or information by asking questions directly to individuals knowledgeable about the research object.
b. Observation. Direct observation or review at the research site, namely the Bawean SME in Gresik Regency, by observing the existing system, observing the distribution process flow, and determining costs regarding expedition service rental fees and other expenses required for distribution activities.
c. Documentation. Studying company documents containing data on the number of products distributed, the location of the company's branches, and the load capacity of the truck fleet.

d. Documentation. Studying company documents containing data on the number of products distributed, the location of the company's branches, and the load capacity of the truck fleet.
e. Discussion. Exchanging opinions with experts, in this case, management with expertise in specific fields related to vehicle routing problems, the costs incurred in the distribution process, and the costs of all activities in Gresik Regency.

3. Stage of Data Processing

The data processing stages of the saving matrix method are as follows:

a. Identifying and determining the type of vehicle routing problem occurring in the field.
b. Identifying and determining the distance matrix from the SME location to the Bawean SME marketing area, as well as the distance matrix between the destinations within the Bawean SME marketing area.
c. Identifying and calculating the saving matrix.
d. Allocating vehicles and routes to the Bawean SME marketing area destinations.
e. Sorting the destination routes based on the results of the Bawean SME marketing area destinations. In this study, the procedure for sorting the company branches within the established routes used the nearest-neighbor method.
f. Calculating the total distance traveled. After obtaining the optimal route, the total distance traveled for apple juice distribution was calculated based on the procedure that yielded the smallest total distance between nearest neighbors.
g. Comparison of distribution costs. After comparing the smallest total distance traveled between the routes using the nearest-neighbor method, the route with the most optimal distance was selected.

4. Stage of Analysis and Discussion

In the analysis of apple juice distribution optimization, the saving matrix and nearest-neighbor methods were used to determine the optimal delivery route and costs.

5. Conclusion

Researchers draw conclusions related to the formulation of the problem they wish to achieve, while suggestions are input related to the research being conducted.

IV. RESULTS AND DISCUSSIONS

IV.1 DATA DISCUSSION 1

Assume that one SME in Bawean currently has one distribution center in Bawean, Gresik Regency, and five Distribution Centers (DCs) spread throughout East Java Province.

Table 1: Distance Saving Matrix Data.

	A	B	C	D	E
A	0				
B	116	0			
C	97,5	152	0		
D	534	103	95,5	0	
E	52	0	56,5	54	0

Source: Authors, (2026).

Based on Table 1, it is known that branch pair A–D has the highest distance-saving matrix of 534 km, branch pair B–C has the second- highest distance-saving matrix of 152 km, and branch pair C–D has the third-highest distance-saving matrix of 95.5 km. Based on the results of the saving matrix, branches A, C, and D can be grouped into a single distribution route. On this route, a rearrangement is carried out using the nearest-neighbor method, starting from the warehouse. There are three branches to target, and each has a known distance from the warehouse. The distance of each branch is:

Warehouse Distance → A = 288 km Warehouse Distance → C = 134.5 km Warehouse Distance → D = 317 km

Branch C is the closest to the warehouse, so it will be the first branch visited. Next, find the next branch to see based on the nearest distance from branch C as the end point.

Warehouse distance → C → A = 335 km Warehouse distance → C → D = 356 km

Since the closest distance produced is 335 km, the next one to be visited is branch A, so the route obtained using the nearest neighbor method is Warehouse → C → A → D. After obtaining the distance matrices from the warehouse to each company branch and between company branches, the next step is to compile a savings matrix. The distance-saving matrix is obtained using formula (2). For example, to find the savings between the SRBY and MJKT branches, the Warehouse → SRBY distance matrix, the Warehouse → MJKT distance matrix, and the SRBY → MJKT distance matrix are required.

Warehouse distance matrix → SRBY = 148 km Warehouse distance matrix → MJKT = 142 km SRBY distance matrix → MJKT = 84 km

Once the distance matrices for the related points are known, calculations are carried out.

- $S(x, y) = Dist(Center, x) + Dist(Center, y) – Dist(x, y)$

- S(SRBY, MJKT) = 148 km + 142 km – 84 km
- S(SRBY, MJKT) = 206 km

The following are the steps in preparing distribution routes in the first week of June 2024 using the saving matrix method. Selecting the most significant saving matrix value in the saving matrix, namely between the JEPR and KUDS destination points of 809. These two destination points will be included in a single distribution route because the fleet capacity is sufficient to deliver both.

The current route is JEPR – KUDS, with the number of products shipped as follows:

JEPR Shipping + KUDS Shipping = 1,975 kg + 1,858 kg 3,840 kg

Selecting the next largest saving matrix value in the saving matrix is between the SMRG and JEPR branches of 681. The SMRG branch has a total demand of 1,589 kg, so it can be combined with route one because the fleet capacity is still sufficient. Therefore, the route currently formed is JEPR – KUDS – SMRG, with the number of products shipped as follows:

- JEPR Shipping + KUDS Shipping + SMRG Shipping
1,971 kg + 1,856 kg + 1,591 kg = 5,417 kg

The largest saving achieved is 517. This saving was achieved between the JOGY and JEPR branches. If these branches were combined into route 1, the fleet capacity would not be sufficient. Therefore, the JOGY branch will be included in the second route. The subsequent route was formed: JOGY – SOLO – NGW, with the number of products shipped as follows:

- JOGY Shipping + SOLO Shipping + NGW Shipping 2,165 + 2,264 + 1,178 = 5,607 kg

Following the steps above, 55 iterations of the saving matrix and 12 routes were obtained. The following iterations and routes were generated for the distribution of products produced by Bawean SMEs in June, July, and August 2024.

Table 2: Iteration of the Order of Saving Values from Largest to Smallest.

Iteration	Branch Pair	Saving Value

IV.2 DATA DISCUSSION II

Data Processing Using the Nearest Neighbor Method

The SMRG delivery destination is closest to the warehouse, so it becomes the first destination to be visited. The next destination is then selected based on the nearest distance from the SMRG delivery destination to the final destination.

Distance from Warehouse → SMRG → JEPR = 459.2
km Distance from Warehouse → SMRG → KUDS =
434.6 km

The total distribution distance for this route using the existing method is 1,122 km. Therefore, the distance saving achieved on this delivery route using the nearest neighbor method is:

- Total Distance Using the Existing Method – Total Distance Using the Nearest Neighbor Method
1,122 km – 476 km = 646 km

Table 7: Comparison of Distribution Routes for Bawean SME Products Using the Existing and Nearest Neighbor Methods, First Week of June 2024.

No	Existing Method	Distance	Nearest Neighbor	Distance	Saving
	Route		Route		
1.	Warehouse → JEPR, Warehouse → KUDS, Warehouse → SMRG	1.073	Warehouse → SMRG → KUDS → JEPR	425,7	647,3

IV.3 SHIPPING COST ANALYSIS

After determining the optimal route using the nearest-neighbor method, shipping costs are calculated and compared with those of the proposed method. The following are the steps in determining shipping costs. Determine the route to be analyzed. For example, consider the JEPR – KUDS – SMRG route for the first week of June. The breakdown of existing shipping costs on this route is as follows:

- Warehouse Shipping Cost → JEPR = Rp. 1,900,000
- Warehouse Shipping Cost → KUDS = Rp. 1,700,000
- Warehouse Shipping Cost → SMRG = Rp. 1,900,000
-

Therefore, the total existing shipping costs for the JEPR – KUDS – SMRG route are:

- Rp. 1,900,000 + Rp. 1,700,000 + Rp. 1,900,000 = Rp. 5,500,000

Next, determine the shipping cost using the proposed route method. The resulting route using the nearest-neighbor method is: warehouse

→ SMRG → KUDS → JEPR.

The shipping cost breakdown for this route is as follows:

- Warehouse Delivery Cost → SMRG = IDR 1,900,000

Furthermore, to determine delivery costs from SMRG → KUDS and KUDS → JEPR, the average cost per kilometer of the longest route to be visited is used. The longest route to be visited is Warehouse → JEPR, with a distance of 396 km and a cost of Rp. 1,900,000. Therefore, the average cost per kilometer is Rp. 4,800. The average cost per kilometer will serve as a reference to determine costs based on the distances between SMRG → KUDS and KUDS → JEPR.

The distance between SMRG → KUDS is 62.6 km, while the distance between KUDS → JEPR is 41.1 km. Using the above calculation, the results are as follows:

- SMRG Shipping Cost → KUDS = Rp. 300,500
- KUDS Shipping Cost → JEPR = Rp. 197,500

Therefore, the total shipping cost for the warehouse → SMRG → KUDS → JEPR route obtained using the nearest neighbor method is:

- Rp. 1,800,000 + Rp. 400,500 + Rp. 187,500 = Rp. 2,298,000

Next, a comparison is made between existing shipping costs and those using the proposed method to determine the savings. The calculation of the resulting shipping cost saving is as follows:

- Rp. 5,400,000 – Rp. 2,498,000 = Rp. 2,902,000

IV.4 DELIVERY TIME ANALYSIS

After optimal routes are obtained using the nearest neighbor method, the next step is to calculate the delivery time for each route. The following are the steps in determining delivery time. Determine the route to be analyzed. For example, consider the warehouse → KUDS → JEPR route for delivery in August 2024. The distribution process is assumed to run smoothly without any problems, with an average delivery fleet speed of 50 km/h. The delivery time details for this route are as follows:

Warehouse → KUDS Delivery Time = 8 hours
KUDS → JEPR Delivery Time = 50 minutes

Therefore, the total delivery time for the Warehouse → KUDS → JEPR route is currently as follows:

Warehouse → KUDS Delivery Time + KUDS → JEPR Delivery Time 8 hours + 50 minutes = 8 hours 50 minutes

By following the steps above, the delivery time is calculated for all optimal delivery routes generated using the nearest-neighbor method.

Table 11: Total Delivery Time of Optimal Nearest Neighbor Route.

No.	Route with Nearest Neighbor	Total Delivery Time
1.	Warehouse → KUDS → JEPR	9 hours 50 minutes
2.	Warehouse → SOLO → JOGY	8 hours 25 minutes
3.	Warehouse → NGW → SMRG	8 hours 10 minutes
4.	Warehouse → TLNG → NGW	7 hours 10 minutes
5.	Warehouse → KEDR → TLNG	3 hours 55 minutes
6.	Warehouse → MJKT → SRBY	3 hours 40 minutes
7.	Warehouse → SMRG → KUDS → JEPR	11 hours 35 minutes
8.	Warehouse → NGW → SOLO → JOGY	8 hours 25 minutes
9.	Warehouse → SOLO → JOGY → SMRG	11 hours 35 minutes
10.	Warehouse → KEDR → TLNG → NGW	7 hours 20 minutes
11.	Warehouse → MJKT → SRBY → JBER	8 hours 15 minutes
12.	Warehouse → TLNG → NGW → SMRG	10 hours 35 minutes

Source: Authors, (2026).

Next, add the time required to unload the cargo from the delivery fleet at each distribution destination branch. This activity has an estimated processing time of 30 minutes at each destination branch. Therefore, the total delivery time for the Warehouse → KUDS → JEPR route is as follows:

Delivery Time Warehouse → KUDS → JEPR + 2 × (Unloading Time) 8 hours 50 minutes + 2 × (30 minutes)
8 hours 50 minutes + 60 minutes = 9 hours 50 minutes

Based on Table 11, the fastest delivery time is the warehouse → MJKT → SRBY route, at 3 hours and 40 minutes. Meanwhile, the longest delivery time is the warehouse → SOLO → JOGY → SMRG route, at 11 hours and 35 minutes.

IV.5 DISCUSSION

Distribution is a crucial factor in any business because it affects the profits of SMEs in Bawean, Gresik, and surrounding areas. During the daily distribution process, several SMEs in the Bawean, Gresik Regency, utilize delivery services. Product orders are placed through the marketing department, which then forwards them to the inter-area sales department, which is directly connected to the warehousing department of SMEs in the Bawean region, which produces various crafts and processed foods using the make-to-stock method. Once the inventory in the warehouse meets demand, shipments are made. The process of collecting orders and processing craft and processed food products is complete, and the products are then sent to several distribution areas within a specified timeframe. Currently, several SMEs in the Bawean region of Gresik Regency use a single delivery fleet for each branch. This is considered ineffective and inefficient due to the underutilization of fleet capacity.

By combining multiple branch destinations into a single delivery and scheduling deliveries a week in advance, companies can save on shipping costs. Using the saving matrix method, 12 optimal distribution route groups were generated based on their saving matrix. Of the 12 routes generated, several branch points are always included in the same route group. These branch points are the JEPR branch with the KUDS branch and the SRBY branch with the MJKT branch. These branch points can be grouped into several delivery destination clusters. The JEPR-KUDS branch is Cluster 1, and the SRBY-MJKT branch is Cluster 2.

Table 12: Distribution Route Groups Based on the Saving Matrix Method.

No.	Route Group
1.	JEPR – KUDS
2.	JOGY – SOLO
3.	SMRG – NGW
4.	TLNG – NGW
5.	KEDR – TLNG
6.	SRBY – MJKT
7.	JEPR – KUDS – SMRG
8.	JOGY – SOLO – NGW
9.	SOLO – SMRG – JOGY
10.	KEDR – TLNG – NGW
11.	SRBY – MJKT – JBER
12.	SMRG – NGW – TLNG

Source: Authors, (2026).

After being processed with the saving matrix method, the resulting route groups are further processed using the nearest-neighbor method. This method is used to sort distribution routes and to obtain the optimal distribution distance for each route group previously determined using the saving matrix method. The nearest-neighbor method produces optimal distribution distances because distribution routes are first analyzed by distance. Table 13 shows the results of sorting distribution routes using the nearest neighbor method.

Table 13: Results of Processing Distribution Routes Using the Nearest Neighbor Method.

No.	Nearest Neighbor Route
1.	Warehouse → KUDS → JEPR
2.	Warehouse → SOLO → JOGY
3.	Warehouse → NGW → SMRG
4.	Warehouse → TLNG → NGW
5.	Warehouse → KEDR → TLNG
6.	Warehouse → MJKT → SRBY
7.	Warehouse → SMRG → KUDS → JEPR
8.	Warehouse → NGW → SOLO → JOGY
9.	Warehouse → SOLO → JOGY → SMRG
10.	Warehouse → KEDR → TLNG → NGW
11.	Warehouse → MJKT → SRBY → JBER
12.	Warehouse → TLNG → NGW → SMRG

Source: Authors, (2026).

After processing using both methods, the resulting savings were compared to determine which method produced the most significant distance savings. Based on calculations, the nearest-neighbor method resulted in a distance savings of 10,854.7 km. Resulted in a distance saving of 6,874.5 km. The nearest-neighbor method produced a more optimal distance because the resulting distribution route was to the closest point from the distribution's starting point, and so on. Therefore, the distribution route chosen to compare shipping costs with the existing method was the nearest-neighbor method. After obtaining the optimal route using the nearest-neighbor method, shipping costs for crafts and food products were calculated based on the route. Shipping costs using the nearest neighbor method will be lower because the resulting distance is shorter than the existing distribution distance. This is because the company's costs are limited to the delivery fleet service. The company's delivery fleet service uses the fleet's mileage as a benchmark for its shipping costs. This means that the shorter the distance traveled by the delivery truck fleet, the lower the shipping costs charged to SMEs in the Bawean area of Gresik Regency.

Table 14: Results of Calculations Using the Existing Method and Processing Using the Saving Matrix and Nearest Neighbor Methods.

	Existing Methods	Saving Matrix and Nearest Neighbor Methods
Total od Distance	24.303,8 km	13.457,9 km
Number of Routes	11	4 - 5
Total Shipping Cost	Rp. 158.460.000	Rp. 93.672.850

Source: Authors, (2026).

Based on Table 14, the results of processing using the saving matrix and nearest-neighbor methods for compiling distribution routes yield a shorter total distance and lower shipping costs than the existing method.

After processing using the saving matrix and nearest-neighbor methods, the total distance traveled is 10,854.7 km shorter, or 44.66% lower than the initial distance, and the total shipping costs are Rp 64,703,150 lower, or 40.85% lower than the initial total.

V. CONCLUSIONS

Based on the results of the research that has been conducted, the conclusions that can be drawn include:

1. Routes that resulted in distance saving using the saving matrix method include JEPR – KUDS with a saving value of 708.9 km, SMRG – JEPR with a saving value of 630.8 km, SMRG – KUDS with a saving value of 613.4 km, and JOGY – JEPR with a saving value of 517 km.
2. Previously, the company had 11 distribution routes. After conducting research using the nearest neighbor method, four to five distribution routes were identified per week, depending on the number of requests. This research resulted in 12 route groups with the minimum total distance traveled and distribution costs. Distribution costs were reduced because SMEs in the Bawean region of Gresik Regency used delivery services that set pricing based on the fleet's mileage.
3. After designing the distribution routes using the nearest-neighbor method, delivery costs were calculated based on the resulting routes. Using the selected proposed method, distribution costs were reduced to Rp 93,696,850, down from the original Rp 1,000,000: 158,400,000, and the total distance was reduced to 13,448.9 km from the original 24,303.6 km.
   By using the nearest- neighbor method, the company can save on the distribution costs of Rp. 64,703,150, or 40.85% smaller than the existing distribution costs, and save a distribution distance of 10,854.7 km, or 44.66% shorter than the total existing distance.

ABSTRACT

Brain neoplasm is life-threatening abnormalities that require accurate segmentation for effective diagnosis along with treatment planning. Existing segmentation methods often depend on manual annotations or supervised learning, which are time-consuming, subjective, and not scalable. To overcome these challenges, this study proposes a fully unsupervised brain tumor segmentation framework using multimodal MRI data. The 3D MRI volumes are first sliced into 2D axial views and preprocessed to enhance quality. K-means clustering is then applied to generate pseudo-labels that distinguish tumor from healthy regions. These labels guide M-Net CNN training process, which produces coarse tumor localization. A U-Net model further refines the segmentation by fusing the original sliced MRI inputs with M-Net CNN outputs to enhance boundary precision and anatomical alignment. The proposed pipeline achieved a high Dice coefficient of 84.2%, demonstrating its accuracy and robustness. This multi-stage, annotation-free approach enables precise tumor delineation and is suitable for large-scale clinical integration.

I. INTRODUCTION

Neoplasma of the brain is an extensive category of brain pathologies of high morbidity and mortality. High-accuracy volumetric segmentation and early detection are valuable to clinical applications like longitudinal monitoring, radiotherapy, and surgical planning. The main imaging modality in neuro-oncology is Magnetic Resonance Imaging (MRI) because it is a non-invasive procedure. Varying MRI sequences offer complementary diagnosis information: T1, T2, T1ce, and FLAIR. A combination of these modalities allows a complete tumor characterization and subregion definition. Radiologists usually annotate the tumors manually, and it represents the clinical reference used in a diagnosis and the basis used to train segmentation models. Nonetheless, the manual segmentation is labor-intensive, time-consuming and it is highly variable, making it difficult to scale up in other large datasets. This has been highlighted by supervised deep learning methods, particularly the U-Net and its variants [1], [2], to make an effective use of the spatial and contextual information in multimodal MRI samples to identify tumor subregions. However, they need large annotated datasets that are expensive to generate due to privacy limitations and require experts to be available. To eliminate these difficulties, unsupervised techniques of segmentation are studied. Unsupervised techniques identify tumor based on voxel intensities yet tend to produce inaccurate borders and poor generalizability [3]. The proposed work overcomes these limitations by using a combination of methods by exploiting the statistical intensity-based grouping and Deep learning (DL) in the context of learning the features in brain tumor segmentation based on convolutional neural networks (CNN) that is unsupervised. In the suggested framework, an MRI preprocessing step is followed by pseudo-label construction via intensity grouping and the structural accuracy refinement using CNN. The main research findings of the proposed work are as follows:

- To access the 2D images, the input 3D MRI volumes are sliced in the axial level where it is then preprocessed to increase contrast and image quality.
- To distinguish between healthy and tumor area an initial pseudo-labels are created by using K-means clustering on the unlabeled 2D slices.

- The pseudo-labels are used to train an M-Net CNN to learn spatial tumor features and generate improved and detailed segmentation maps.
- The U-Net has the raw slices of MRI data combined with the M-Net CNN outputs to complete segmentation with a greater precision of boundaries and consistency of anatomies.

II. LITERATURE REVIEW

The MRI image represents the standard in diagnosis of brain tumors by non-invasive technique, although manual segmentation is time-consuming and susceptible to error due to inter-observer variability. To automate this process, ML methods were initially applied. The [4] proposed a two-stage system that entailed refined binomial thresholding in localizing the tumor and feature-based classification using SVM, and Random Forest. [5] were able to improve upon the boundary refinement using a hybrid SVM-fuzzy classifier, albeit based on handcrafted features, in which little generalization was done across imaging modalities. Deep learning (DL) approaches advanced the field by learning hierarchical representations directly from data. [6] proposed a symmetrical encoder–decoder framework with a Threefold Attention Mechanism to enhance tumor boundary prediction across multimodal MR images. In [7] a deep neural network pipeline was constituted that detects tumor at early stage, and [8] improved the U-Net architecture by altering depth and skip interconnections to provide more structural detail forecasting. Model TACA-RNet proposed by [9] utilized the idea of tri-planar context and enhanced multimodal tumor segmentation. This binary tumor prediction utilised a traditional CNN in [10], though Z-Net demonstrated in [11] improvement at predicting the tumor boundaries using pyramid pooling to generate finer predictions in 2D slices. [12] decided to use a multi-scale attention mechanism with an EfficientNetB4 backbone since it proved useful in capturing tumor variations. Other more recent approaches leveraged a Transformer-GAN was done in [13] to provide more robust boundary prediction, as well as a hybrid ViT-CNN model was presented in [14], to enable explanatory glioma segmentation across MRIs. To address the dependency on annotated labels, unsupervised approaches have emerged. [15] proposed a two-stage GAN-based pipeline that synthesizes tumor-free and tumor-bearing images to generate pseudo-masks for segmentation prediction. [16] introduced a prompt-based unsupervised framework (PL-BTS) that predicts tumor-like regions through intensity prompts and pseudo-label refinement (PL-BTS+). [17] adopted a spatially variant finite mixture model with RJMCMC sampling to predict tumor regions based on probabilistic tissue distributions, offering label-free yet interpretable segmentation. These models shift the field toward scalable annotation-independent solutions, though trade-offs in computational demand and data quality remain. Current techniques used in segmenting the brain tumor have a number of limitations. Conventional methods of ML depend on handcrafted features that are weak on complex tumor structures and also noise-sensitive [4], [6]. Transformer-based and hybrid deep learning models have higher segmentation accuracy, but they are usually associated with high cost of computation and decreased interpretability under the clinical setting [13], [14]. In addition, DL models usually need a huge amount of labeled MRI data to be qualified which are costly and time- consuming to acquire [9], [10].To address these challenges, the proposed method employs K-means clustering to generate pseudo-labels from unlabeled MRI slices, which guide an M-Net CNN for segmentation. A subsequent U-Net model refines this output by enhancing feature fusion and spatial consistency, enabling accurate tumor delineation in an unsupervised setting.

III. METHODOLOGY

As shown in Figure 1, the proposed approach performs brain neoplasm segmentation utilizing an unsupervised models framework for unlabeled MRI images. The 3D MRI volumes will be originally sliced in the axial plane in order to give 2D slices. Then preprocessing modalities used to improve image quality and contrast. The K-means clustering is then used to produce pseudo-labels that indicate tumor and non-tumor areas. These pseudo-labeled masks guide an M-Net convolutional neural network (CNN) towards segmenting a tumor. M-Net CNN's outputs, together with the corresponding raw sliced MRI images, are then given as input to a U-Net model. The U-Net performs feature fusion and spatial refinement, producing a precise and anatomically consistent tumor segmented part.

III.1 DATASET

The proposed unsupervised brain tumor segmentation framework uses the BraTS 2019 dataset [18], which comprises 335 co-registered, skull-stripped, and multimodal MRI volumes of the T1, T1ce T2, and FLAIR sequences. These volumes are acquired with a uniform voxel resolution and follow standardized clinical acquisition protocols. In this study, the dataset is incorporated into an unsupervised learning pipeline, whereby ground-truth segmentation masks supplied in the training set are excluded from the learning procedure.

III.2 SLICING

In the BraTS 2019 set of data, each subject is represented by a 3D volumetric MRI scan acquired using 4 modalities: T1, T1ce, T2, and FLAIR. To enable efficient training of 2D DL models and reduce computational overhead, a slicing process is applied to convert 3D MRI volumes into 2D axial slices. Slicing is carried out in the axial plane, giving a sequence of 2D slices that retain spatial fidelity and tumor-related anatomical structures. These slices are extracted in a modality-wise manner, ensuring that for each 2D position, corresponding slices across all modalities are available and aligned. The stacked multi-modal 2D slice at axial index k is represented as:

$$S^{(k)} = [S_{T1}^{(k)}, S_{T1ce}^{(k)}, S_{T2}^{(k)}, S_{FLAIR}^{(k)}] \in R^{H \times W \times 4} \quad (1)$$

Where $S^{(k)}$ denotes the composite input formed by concatenating slices from all four modalities at position k, with H and W representing the spatial dimensions.

III.3 DATA PREPROCESSING

Following the slicing of 3D MRI volumes into 2D axial slices, a sequence of preprocessing operations is applied, all aimed at improving image quality and normalizing intensity characteristics across samples. First, average filtering is used to remove random noise and smoothen the image while conserving important structural and anatomical boundaries. This helps suppress high-frequency distortions and assists in achieving homogeneity of non-tumor regions. Then, histogram equalization is invoked as a means of contrast enhancement, meaning to redistribute pixel intensities uniformly across the dynamic range. This operation maximizes the visibility of subtle tumor boundaries and paves the way for effective segmentation of the slices. For model evaluation along with generalization analysis, a set of data was randomly split into train and test subsets using 80:20 ratio.

III.4 K-MEANS CLUSTERING PROCESS

Following the completion of the slicing and preprocessing stages, the enhanced multimodal two-dimensional MRI slices are utilized for pseudo-label generation using the K-means clustering algorithm. This unsupervised method segments each slice into two distinct clusters that correspond to tumor and healthy regions, based on pixel-wise intensity similarity patterns across modalities. For each axial position, the corresponding slices from a T1, T1ce, T2, and FLAIR modalities are stacked to form a tensor of size $H \times W \times 4$. In this representation, each pixel is described by a four-dimensional feature vector comprising the intensity values from four MRI sequences. Entire image is reshaped into a two-dimensional feature matrix of size $(H \times W) \times 4$, which is provided as input to the K-means clustering algorithm. The objective of K-means is to minimize intra-cluster variance, mathematically defined by

$$J = \sum_{j=1}^{k} \sum_{i=1}^{n} \left\| x_i^{(j)} - c_j \right\|^2 \quad (2)$$

Here, k denotes the number of clusters, n is a total number of pixels, $x_i^{(j)}$ represents pixel i^{th} assigned for cluster j, and c_j denotes corresponding centroid. The entire process of clustering commences with initialization of two centroids randomly in the feature space. Next, given data points are assigned to the most nearest centroid using Euclidean distance. Centroids are also updated by computing mean of all the vectors which are in a single cluster. This assignment along with update process continues repeated until convergence, which is reached when centroid positions remain stable across iterations. After convergence, the cluster assignments are reshaped to match the spatial dimensions $H \times W$, resulting in a binary pseudo-label mask that delineates tumor from healthy one.

III.5 M-NET CNN

Following the generation of pseudo labels through K-means clustering, the tumor segmentation stage employs an end-to-end trainable CNN based on the M-Net architecture to identify brain tumor regions in an unsupervised manner. The input to this M-Net CNN consists of co-registered and preprocessed two-dimensional axial MRI slices from 4 modalities: FLAIR, T1, T1ce, and T2. These modalities are stacked along the channel dimension to form a single composite tensor of shape H×W×4, allowing the network to exploit anatomical, structural, and contrast-related cues for accurate segmentation. M-Net CNN is symmetrically structured along the lines of encoder decoder, as illustrated in Figure 2. The architecture of M-Net is symmetrical where it has four different paths, one is the main encoder path, one is decoder path, and the other two are side paths which are conventionally named as the left leg and the right leg which can provide deep supervision and multi-scale features. Every encoder unit has two conv layers 3x3 kernel size, then batch normalization and ReLU. These cascade convolutional layers allow a gradual refinement of each layer. Each unit is concluded with 2x2 max pooling operation which decreases spatial dimensions with a maximum feature abstraction. The output of encoder layer feature map is as:

$$E(l) = MaxPool(\sigma(W^{(l)} * E^{(l-1)} + b^{(l)}) \quad (3)$$

Where, $E^{(0)}$ represents stacked multimodal MRI input, $W^{(l)}$ and $b^{(l)}$ denote the learnable weights and biases, $*$ represents convolution, and σ (.) is the ReLU activation function. The left leg of M-Net CNN applies four successive 2×2 max pooling operations to the input, providing multi-scale contextual features to the encoder blocks.

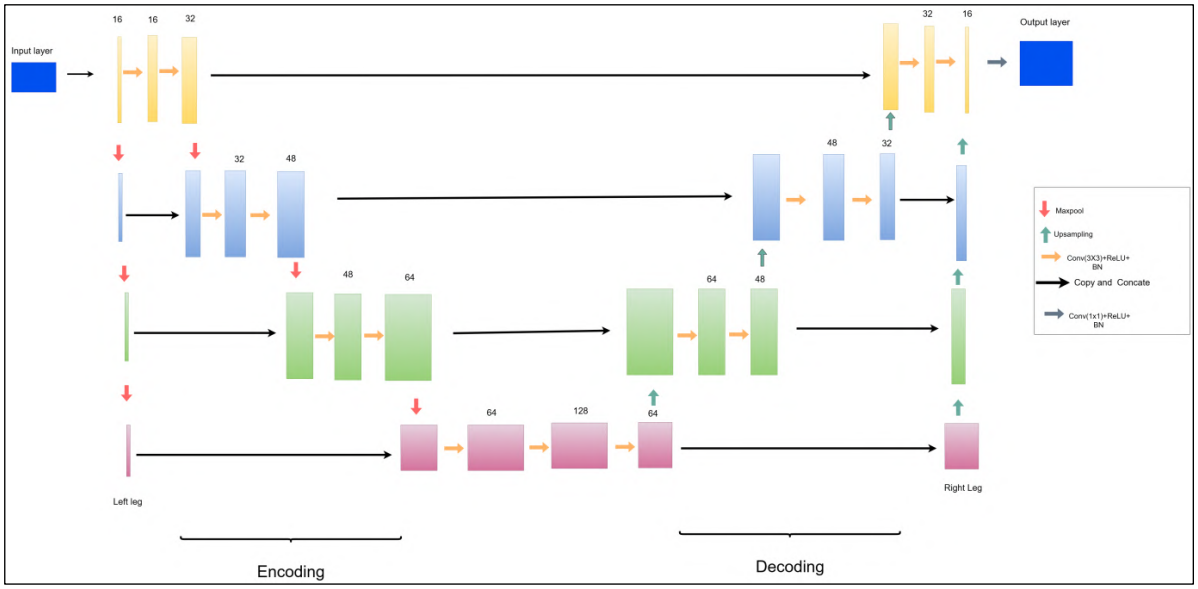

Figure 2: M-Net CNN architecture.
Source: Authors, (2026).

The bottleneck block adopts convolutional layers of deeper filter depth to acquire semantic feature in high level. The decoder is the reverse of the encoder where the first layer of each block involves a transposed convolution to upsample the block, and them the skip connections with the previous layers of the encoder are used to maintain fine-grained spatial information. The decoder path restores original spatial dimensions using transposed convolution operations and includes skip connections from encoder. The decoder feature map at level is obtained by:

$$D(l) = \sigma(W_{up}(l) * U_p\left(D^{(l+1)}\right) + W_{skip}^{l} * E^{(l)} + b^{(l)}) \quad (4)$$

Where $U_p(.)$denotes upsampling through transposed convolution, W_{up} and W_{skip} are the weights for upsampling and skip connections, respectively. Simultaneously, the right leg upsamples the outputs of each decoder block to the original resolution of input, enabling deep supervision. These auxiliary paths enhance the network's multi-scale learning and segmentation accuracy. The last stage of decoder performs a 1 x 1 convolution layer followed by a sigmoid, the output is a binary mask segmented of size H x W x 1 with pixel-wise tumor probabilities.The network is trained using pseudo labels generated by K-means clustering, eliminating the requirement for manually annotated ground truth. Dice loss function is used to optimize the segmentation learning by calculating overlap of predicted segmentation with pseudo label Y. The loss is defined as:

$$L_{Dice} = 1 - \frac{2\sum_{i=1}^{N} \hat{Y}_i Y_i + \epsilon}{\sum_{i=1}^{N} \hat{Y}_i + \sum_{i=1}^{N} Y_i + \epsilon} \quad (5)$$

Where $\hat{Y}_i$ is a predicted value at pixel, Y_i gives pseudo label, N represents number of pixels, and ϵ denotes small constant to prevent division by zero. The output of M-Net is a binary segmentation mask aligned with spatial dimensions of input multimodal slice, effectively delineating tumor regions from healthy tissue. This is achieved using pseudo supervision derived from K-means clustering, thereby eliminating the requirement for manually annotated ground truth.

III.6 U-NET

Following the coarse tumor localization obtained from the M-Net CNN, a U-Net is employed to refine the tumor segmentation in an unsupervised manner. The input to the U-Net consists of preprocessed axial MRI slices from four modalities, along with the binary tumor mask from M-Net. These five inputs are stacked to form a composite tensor of shape $H \times W \times 5$. Such setup allows the U-Net to couple the anatomical differences between modalities with the crude localization of the tumor, to increase the ability of network for detecting refined tumor margins. U-Net design follows the symmetric encoder-decoder design which makes hierarchical feature learning easy. The encoder path has two convolutional blocks in each block are two convolutional layers of 3x3 kernels, batch normalization, ReLU activation, and a 2x2 max pooling layer as a spatial resizing block to detect high level and abstract features. Bottleneck layer is relating encoder and decoder, and it makes an aggregation of the contextual semantic representations. Spatial resolution is upscaled step by step through transposed convolutions in the decoder route. In order to maintain the spatial accuracy, the connection between related encoder and decoder layers is done using skip connections. These interactions make feature fusion possible by adding the encoder features of the high resolutions to decoder features which are increased through addition, which is mathematically expressed as:

$$D(l) = \sigma(w(l) * U_p[(D^{(l+1)}) \| E^{(l)}] + b^{(l)}) \quad (6)$$

where $U_p(D^{(l+1)})$ is the upsampled decoder feature, $E^{(l)}$is the encoder feature map,|| denotes channel-wise concatenation, and $\sigma(.)$ gives ReLU activation. At the final stage of decoding, a 1×1 convolutional layer followed by a sigmoid activation function generates a binary segmentation mask of dimensions $H \times W \times 1$, indicating the pixel-wise probability of tumor presence.

The K-means predictions are used as pseudo labels to train the network, so no manually annotated ground truth is required. Dice loss function is used to optimize the overall segmentation level which measures the overlap between the mask generated in the segmentation and the pseudo label. Such features as feature fusion achieved with skip connections and multimodal plus auxiliary input channels allow the U-Net to demonstrate the refined and anatomic-consistent form of segmentation, which elevated the accuracy of tumor delineation.

IV. RESULT AND ANALYSIS

The suggested unsupervised brain tumor segmentation method was examined on 2D axial slices on four modalities in data records of the BraTS2019 database. The M-Net CNN model has been learned in regard to tumor-specific features using pseudo-labels generated through K-means clustering. Raw sliced MRI data is then merged with the M-Net CNN output to form a U-Net model to allow a more accurate segmentation. The framework is considered by computing the Dice coefficient, Intersection over Union (IoU), precision, recall, and accuracy. The qualitative results of segmentation application on test images are shown in Figure 3, and these have proven how the method used is accurate in locating and outlining the tumor area by segmentation process in the test images.

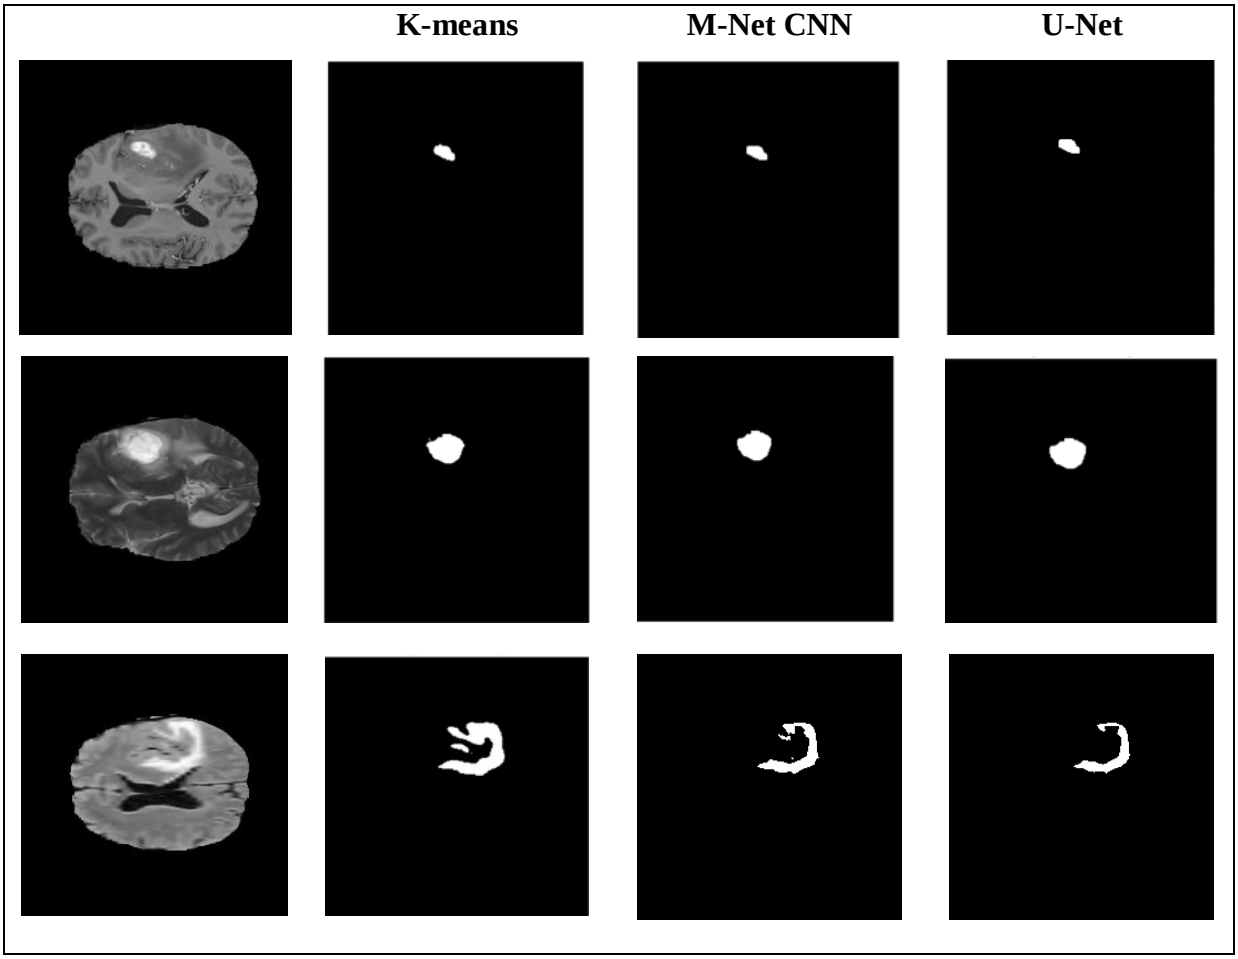

Figure 3: Samples of brain tumour segmentation results on test images of BraTS2019.
Source: Authors, (2026).

The evaluation metrics for K-means clustering models on unlabeled MRI slices will be represented in the Figure 4 for generation of pseudo-labels. Through intensity-based clustering where K-means does not require any manual annotations, it would distinguish tumor and non-tumor regions. It attained a Dice coefficient of 78.0%, IoU at 65.0%, thus showing itself adept at spatially delineating tumor regions with moderate accuracy. It records also 85.3% in accuracy, 76.5% precision and 79.2% recall which authenticate its reliability in pseudo-label generation, paving the way for further training of CNN-based segmentation models. Figure 5 presents a segmentation performance of the M-Net CNN model trained using pseudo-labels generated from K-means clustering. The model achieved a Dice coefficient of 83.0%, 72.4% IoU, 82.7% precision, 84.2% recall, and overall accuracy of 88.5%. These results demonstrate M-Net's ability to leverage pseudo supervision for accurate and consistent tumor segmentation in unlabeled MRI slices. Figure 6 illustrates a comparative evaluation between the proposed M-Net CNN model and two existing unsupervised segmentation methods: SynthTumour [15] and PL-BTS [16]. M-Net achieved a Dice coefficient of 83.0 %, outperforming SynthTumour at 78.03 % and PL-BTS at 79.5 %. It also recorded the highest recall of 84.2%, compared to 78.54 % for SynthTumour and 82.90 % for PL-BTS, highlighting its improved ability to detect tumor regions. In terms of precision, M-Net CNN reached 82.7%, closely matching SynthTumour at 82.50 % and exceeding PL-BTS at 80.36%. These comparisons confirm that the proposed M-Net CNN, guided by pseudo-labels and a structured CNN architecture, surpasses existing methods in segmentation accuracy, consistency, and sensitivity.

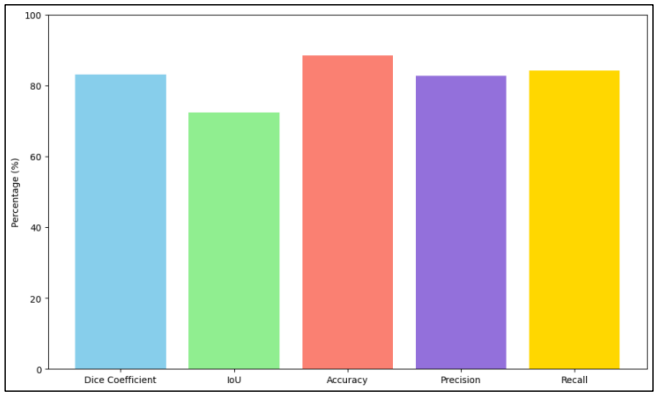

Figure 5: Evaluation of M-Net CNN.
Source: Authors, (2026).

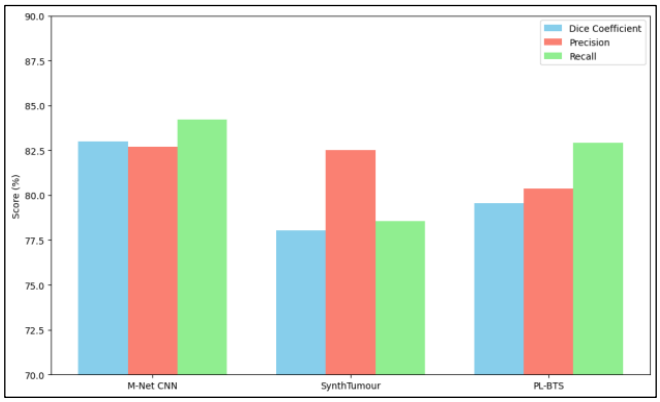

Figure 6: Comparative Performance of M-Net CNN against Existing Unsupervised Segmentation Methods.
Source: Authors, (2026).

The final refined segmentation was performed using a U-Net model, which used both the raw MRI slices and feature maps extracted from the preceding M-Net CNN. As illustrated in Figure 7, the U-Net demonstrated superior performance by achieving a Dice coefficient of 84.2 %, IoU at 73.9 %, It also attained a precision of 83.7 %, 85.0% recall and accuracy of 89.6 %. These improvements confirm the effectiveness of integrating multimodal inputs and intermediate deep features, enabling more accurate and anatomically aligned tumor segmentation. As shown in Figure 8, the various performance comparisons of the U-Net, ResNet [7], and BrainSegNet [19] models proposed were carried out using pseudo-labeled MRI data. U-Net achieved the highest score, with a Dice coefficient of 84.20%, followed by ResNet with 80.50% and BrainSegNet with 79.80%. In terms of precision, U-Net scored 83.70%, while ResNet and BrainSegNet scored 81.00% and 80.30%, respectively. U-Net again scored highest in recall at 85.00%, while ResNet and BrainSegNet scored 82.00% and 81.70%, respectively. These results clearly indicate that U-Net performed the best in terms of segmentation using pseudo-labeled data. The Dice Coefficient is provided for three stages of the modeled unsupervised segmentation pipeline in Table 1. The process begins with pseudo-label generation by K-means clustering, yielding a Dice coefficient of 78.0%. The pseudo-labels are then used to train the M-Net CNN, which improves segmentation performance to 83.0%. The refined U-Net model is finally applied, achieving the highest Dice score of 84.2%, demonstrating the effectiveness of the multi-stage enhancement and feature learning in the unsupervised framework. The performance gains across stages indicate the robustness of the refinement strategy as well as the U-Net's ability to adapt to pseudo-supervised inputs.

V. CONCLUSION

This work proposed a pseudo-supervised segmentation pipeline using the BraTS 2019 multimodal MRI dataset. K means generated pseudo labels trained an M-Net CNN, whose output was refined by a U Net model for enhanced accuracy. The final segmentation achieved a Dice coefficient of 84.2 %, showing effective tumor localization. The integration of multiple MRI modalities enhanced tissue characterization and model robustness. This framework reduces dependence on manual annotations, making it suitable for large-scale neuroimaging studies. As future work, the method can be extended to other diagnostic modalities, including CT scans for broader applicability across clinical environments. Additionally, incorporating self-supervised learning, attention-based mechanisms, and cross-modal consistency may further improve segmentation quality and generalization across heterogeneous datasets.

ABSTRACT

The identification of the early warning of unsafe behavior on the highways of visual cues of driver inattention is a serious challenge since spatial and temporal changes are not trivial many seconds before unsafe behavior. In this paper we propose a hybrid ViT-BiLSTM model that considers fixed-length sequences of 15 frames: inchoate frames are cropped according to the bounding-box annotations, safe or unsafe label and selectively augmented to have equal sampling. Every frame is processed using a Vision Transformer backbone (ViT B/16) and generates 768 dimensional features, which are further implemented as an input to the two-layer bidirectional LSTM (hidden size of 256). The Dual classification heads produce both the frame level and sequence level prediction through sigmoid activation. The training is done in two steps, which are to freeze ViT and to train the BiLSTM and heads with AdamW (lr=1e 3), and then to fine-tune the last four ViT layers with different learning rates (ViT:5e 5, LSTM:1e 4) under mixed precision. Accuracy, precision, recall, and F1-score will be used at both levels with data visualized using confusion matrices, PR/ROC curves, and embedding projections (t-SNE/PCA). The last model ends with a mean of about 98 percent frame-level accuracy (F1 98) and 94 percent sequence-level accuracy (F1 94). The interpretability and soundness of the model are supported by qualitative visualizations of frame strips with annotations and trends of probabilities, which proves that the model may be used in real-life driver monitoring systems.

I. INTRODUCTION

I.1 MOTIVATION FOR DRIVER INATTENTION DETECTION SYSTEMS

Inattention among drivers is one of the major causes of the road accidents in the world, resulting in substantial number of people being injured annually and heavy loss of lives [1]. With smart technologies entering modern vehicles, there is an urgent need to have reliable, real time in-vehicle systems to monitor the driver to identify, detect and react to all kinds of driver distractions and attention such as texting, talking, reaching or using a device during driving [2]. The rationale of this work is developing a sophisticated inattention detection system that can find the fine-grained driver behaviours simply based on the visual input information. Through the significant synergistic improvement potential of Vision Transformers (ViT) in extracting spatial features and Bidirectional Long short-Term Memory (BiLSTM) networks in modelling temporal sequences, the system will explore the possibility of analysing video frames and finding distraction patterns in time with great accuracy [3], [4]. This method corrects major weaknesses of traditional CNN-based models that often do not capture the temporal relations that are essential in relating behaviours [5]. In addition, the use of ViT allows the model to focus on specific areas of space in each frame: e.g. eyes, hands, devices while BiLSTM views the modeled observations in the context of a sequence of actions [6]. The wider aim of this is to contribute to the establishment of real-time intelligent driver checking systems which can:

- Increase safety on the road by minimizing cases of human error because of distraction [7].
- Help implant autonomous and semi-autonomous driving system [8].
- Function as the basis of human-AI collaborative interfaces which would build upon the situation awareness without being overbearing to the driver [9].

I.2 COMPLICATIONS OF REAL-TIME DRIVERS BEHAVIOUR RECOGNITION

Real-time driver behaviour recognition systems show variation of technical and operational complexities of development. These problems are compounded by the fact that the system should be able to isolate subtle behaviours of drivers using unprocessed video data in varying driving environments. Some of these complexities can be found in the method used in this work, especially with the incorporation of Vision Transformer (ViT) and BiLSTM:

I.2.1 Extreme Intra-Class Variation:

Such behaviours as texting or reaching of a driver may vary dramatically as a matter of individual style, posture position, camera angle, and environmental lighting. The challenge behind the model would be the need to generalize across minor variations and not be overfitted to a particular visual input [10], [11].

I.2.2 Dependence in Time of Actions:

Frames that are isolated could not show the whole context of an action. Cite an example, only after a series of frames is a certain act of picking up a phone recognizable. It requires the application of temporal models such as BiLSTM to investigate the sequences of frames and serve to interpret time-based patterns of behaviour [3], [4], [12].

I.2.3 Multi-Class and Multi-Instance Issues:

The system is also going to be needed to differentiate among several classes of distractions of which some of them overlap in visual characteristics. As well, an individual frame may have more than one bounding box and instances of classes, as was done in the preprocessing activities of the notebook [6], [11], [13].

I.2.4 Real-Time Constraints:

The system should work with low latency and high accuracy to be implemented in the real-word vehicles. This is computationally intensive on both feature extraction (performed by ViT) and sequence modelling (BiLSTM) and needs expedient implementation and hardware-sensitive optimisation [7], [9], [10].

I.2.5 Inaccurate and Unbalanced Training Set:

The code explains the reason that the dataset has uneven distributions of class and inconsistencies in the annotations and little amounts of rare distraction behaviours. This is on top of the difficulty about constructing a fair model which is balanced and performs the same across all classes [1], [14], [15].

I.2.6 Interpretability and Trust:

Black-box models cannot be enough in the case of the safety-critical setting. ViT architecture enables the mapping of visual attention, providing a level of explanation needed to justify the AI models decisions and make the user trust the artificial intelligence-augmented driving [2], [6], [11].

I.3 USING VISION TRANSFORMERS TO ANALYSE SPATIAL BEHAVIOUR

Although state-of-the-art convolutional neural networks (CNNs) have achieved significant results in image recognition upon various tasks, they seemingly suffer due to a lack of long-range dependency and spatial context-based relationship learning especially in complex scenario like that of the vehicle cabin where micro-clues involved such as hand position, eye gaze or interaction with an object characterize the behaviour of the driver [10], [11]. Overcome such shortcomings, the current research employs Vision Transformers (ViT) to pursue sophisticated spatial behaviour studies. Within the suggested method, ViT model is used as a front-end feature extractor, and works on the level of individual frames by trying to detect both global and localized patterns of attention [6], [11]. Compared to CNNs, where the size of the receptive field is fixed, the transformer architecture breaks down each image into patches and forms self-attention mechanisms forcing the model to assign importance to every part of the scene dynamically [3], [10]. This is particularly important in driver checking applications, where one would want to change areas of interest (the face, hands or the dashboard) depending on what is being done. Some of the advantages of incorporating ViT in this regard are:

Context-Aware Attention: The model can pay attention to details of spatially relevant objects (e.g. phone in hand or a hand behind the back) even though such details happen in unusual locations [6], [11].

Resistance to Viewpoint Dependency: ViT is robust to the variations in spatial orientation or noise in the background, such as the data of the camera in the vehicles of different orientations and illumination [7], [10].

Improved Feature Representation: Transformer based Encoders are more discriminative over standard CNN features in terms of capturing richer semantics to classify behaviour [3], [13].

Incorporating ViT into the driver inattention detection pipeline, the system will be capable of much better interpretation of clearly complicated visual scenes and the capability to detect the spatial properties of various distraction behaviours [6], [11].

This combined with temporal models such as BiLSTM formulates a strong framework of spatiotemporal interpretation of driver behaviour, which is critical in real-time, intelligent safety measures [3], [12].

I.4 TEMPORAL BEHAVIOUR MODELLING THROUGH BILSTM NETWORKS

Although we find suitable spatial details in static frame study, the identification of complicated driver behaviours needs to know how the action flow varies with time [11]. Fulfil this requirement, this proposed system will use a Bidirectional Long Short-Term Memory (BiLSTM) network, to account of the temporal variations in the driver behaviour over sequences of later image frames [3], [12]. The BiLSTM architecture can be applicable especially to this task to fulfil the following abilities:

Extract Temporal Dependencies: BiLSTMs read information in both directions, forward and backward in time and this means that the model can know the contribution of both the earlier and the later frames when interpreting the understanding of current behaviour [3], [12].

Preserve Sequential Context: A considerable number of driver behaviours are time lengthy (e.g., picking up a phone, turning around), and identification of these behaviours requires the observation of the complete sequence of micro-movements [11], [12].

Improve Classification Result: Spectacularly trained with both feature learned by Vision Transformer and a time-sequence model BiLSTM, a system can resolve ambiguity in situations in which different actions were supposed to be similar visually yet distinct in time (e.g., talking to passenger and reaching behind) [6], [13].

During code implementation, ViT produces frame-wise features that serve as an input vector to a BiLSTM that captures temporal dynamics that are modelled by each behaviour category [3], [12]. The hybrid method makes the image analysis dynamic rather than just being written using behaviour recognition and makes the inattention detection system robust in a greater degree of use by reducing its vulnerability as an in-attending and blind vehicle observer in a real-life driving situation [11], [12].

II. PROPOSED VIT-BILSTM HYBRID ARCHITECTURE FOR DRIVER MONITORING

This paper suggests the use of a hybrid deep learning network that combines Vision Transformers (ViT) and Bidirectional Long Short-Term Memory (BiLSTM) networks to track driver behaviour well and find several types of inattention. This union takes advantage of the respective capabilities of spatial and temporal modelling to allow correct detection of the changeable driver activity with videos in time-varying series [3], [6], [12]. Architecture Overview:

1. Frame-wise Feature Extraction with ViT: The Frames of a video can be processed separately into a pre-trained Vision Transformer. ViT divides the input image into patches and uses multi-head self-attention to extract the contextual correlation between the visual portions-like hands or face of the driver or other items in the area [3], [10]. This enables the system to be spatially responsive to cues of interest in a dynamic manner of differing in-cabin situations [6], [11], [16].

2. BiLSTM-based Temporal Sequence Modelling of discovered ViT features: After extracting the ViT features, one can feed the output to BiLSTM layer that models time-dependence of spatial features [3], [12]. This is crucial to find behaviours occurring over several frames e.g. reaching, turning or playing with devices, where one-frame analysis would not be able to find [11], [12].

3. Classification Layer: The dataset final output of the BiLSTM network passes to the network through dense layers and a soft Max classifier to make an estimate of driver behaviour class. This allows recognition of multiple classes in a broad spectrum of varieties of inattention [6], [13], [16].

Key Advantages

• Spatiotemporal Learning: This means that following a union of the attention-driven spatial vision of ViT and the sequence modelling capabilities of BiLSTM, the system may find driver behaviours in the correctness and context [3], [6], [12].

• Scalability and Modularity: The architecture enables deliberate modular insertions/retrofits e.g., instead of the ViT, other transformer variants could be inserted in the same manner; more advanced temporal modelling (e.g., Transformers, or GRUs) could be inserted as well [3], [7], [10].

• Real-World Applicability: The framework is also quite suitable in being applied in embedded auto applications, particularly with respect to perfecting inference efficiency [7], [9], [10].

The presented hybrid ViT-BiLSTM algorithm shows highly effective results in addressing the problems of detection of inattention in the driver, which is central to the creation of a reliable, real-time system of monitoring the driver with a high level of safety and interpretability [3], [6], [11], [12].

III. DATASET CHARACTERISTICS AND CLASS IMBALANCE ISSUES

The labelled image data included in the Driver Inattention Detection Dataset employed in this paper denotes six behaviours of drivers namely Safe Driving, Dangerous Driving, Distracted, Drinking, Sleepy Driving and Yawn. The dataset, through the process of annotation was formed of 14,859 images, all with even resolution (360 x 640 x 3), split into training, validation and test sets [6], [11]. One of the most significant problems was the imbalance in the number of classes in the dataset, i.e., the Safe Driving class represented more than 41 percent of all the images, whereas such important inattention-related classes as Drinking, Yawn, and Sleepy Driving were highly underrepresented (each representing under 7 percent). Such skewed distribution may cause a bias in the model towards majority classes resulting in low generalization and low sensitivity in unsafe driving behaviour [1], [14], [15]. With this aim, specific data augmentation was conducted. It was synthetically augmented on specific underrepresented classes (Drinking, Yawn, Sleepy Driving, and a part of Distracted) as horizontal flips. This augmentation mechanism brought them more balanced representation to an extent that they become nearer to the powerful Safe Driving category but preserved the diversity of classes.

The goal of the distribution was to reduce the level of learning bias and enhance the part of the model that recognizes subtle cues of inattention [1], [6], [15]. Moreover, to generate data that would reflect real-world temporal dependencies, a synthetic sequence data set was created, a set forming 15-frame video-like clips. These were classified according to temporal trend in unsafe behaviour with 50 percent recorded as Unsafe (number of unsafe frames at consecutive frames of 4 or more) and 50 percent Safe (no run of 4 or more unsafe frames). This allowed creating a model, which not just classifies individual frames, but finds time series patterns showing increasing driver inattention [3], [12].

IV. NEED FOR FINE-GRAINED BEHAVIOURAL CLASSIFICATION

Customized driver checks systems tend to apply a binary or coarse-grained assessment-identifying only attentive and inattentive vehicles [11]. Nevertheless, this black and white type of classification cannot target the intricate continuum of distracted driving behaviour as performed by motorists in the real world. Such behaviours like drinking, yawning, texting, or sleepiness vary in visual expression not only in the profile of risk and time demands of the response [6], [11]. As an example, it is at times useful to make a soft alarm when yawning: this is an early sign of fatigue, and might necessitate a break, whereas hazardous driving, or distracting a driver a long time can just as well be a severe problem and would need prompt intervention [7], [11]. Therefore, it is discussed that a fine-grained behaviour classification and that such a system is paramount to allow adaptations of responding mechanisms in separate ways, so in the example the system can recognize minor infractions and major safety infarctions [6], [13]. In addition to that, it will enable the creation of more context-aware driver aid systems, as classifications are presented more finely. The system can seek to prioritise the interventions by understanding which form of inattention is present, record behaviour over time and personalise feedback by doing so [6], [14]. This granularity is particularly relevant in semi-autonomous environments, where cooperation between human and a machine led to a necessity to a prominent level of precision on what the driver is doing [8], [12]. In the given study, we underline the significance of such in-depth modelling of behaviour by using not only the frame-level annotations, but also a sequence-level temporal structure. It is through this dual method that not only the identification of certain unsafe behaviours could be detected but also its accumulation in time which is vital in predicting and preventing accidents foretime [3], [12].

Integration Potential with Advanced Driver Assistance Systems (ADAS)

Advanced Driver Assistance Systems (ADAS) have evolved greatly to enhance the safety of cars and features like the lane-keeping assist, adaptive cruise control, and collision avoidance functions have been integrated into the systems [7], [10]. Nonetheless, the technologies of modern ADAS mostly run on environmental information (e.g., road situation, traffic light) and use little internal indicators of driver behaviour [8], [11]. The usage of driver inattention detection within ADAS systems would add a human-oriented layer to it as the systems would not only be capable of reacting to the threats presented by other entities but also be able to observe and react to the risk-related factors associated with drivers [6], [13]. The suggested ViT-BiLSTM-based sequence analysis model designed to find temporal inattention patterns i.e. the analysis of 15-frame video sequences, may be fitted into ADAS systems as a real-time monitoring element [3], [12]. Its ability to find unsafe behaviour tendencies say, long distraction, or minor sleep breaks, or the build-up of drowsiness can activate contextual interventions which could be simple alerts to the driver, or even system over-ridden [7], [11]. When the system keeps tracking driver behaviour, it could guide adaptive safety systems. As an example, the ADAS may prohibit access to semi-autonomous functions, recommend a rest stop, or limit the speed when the driver is identified as distracted in repeated periods of time [6], [14]. Such integration leads to cooperative automation which entails the system making up where the human being falls short but keeps the agency of the user [8], [12]. In a higher autonomy car system, this kind of integration will be essential with respect to a transition-of-control situation, where an alert driver is needed before the vehicle passes their control [8], [12]. In this way, the proposed method will not only complement the existing ADAS systems but also go in the line with the future vision of human-machine co-driving ecosystems [6], [12].

Literature Survey

The recent improvement in transformer-based models has made remarkable impacts on the domain of driver's behaviour analysis and spatio-temporal vision tasks. Vision Transformer-Based Feature Extraction for Generalized Zero-Shot Learning was proposed by [17] based on a Vision Transformer (ViT) and an Attribute Attention Module (AAM) to increase attribute-aware feature extraction. The approach could improve zero-shot recognition results in terms of spatial accuracy without specifying the datasets used, but the computations costs are not mentioned. In their paper, [18] presented TLMViT that is a hybrid transfer learning pipeline that integrates ViT and transfer learning concepts in classifying plant leaf diseases on the Plant Village and wheat datasets. The model itself recorded validation accuracy of 98.81/99.86 by incorporating a four-stage pipeline with augmentation, transfer-based feature extractions, ViT refinement, and MLP classification but with considerable dependency on pre-trained weights. A dual-path ViT-based building extractor Build Former was set up by [19] based on the Massachusetts Building Dataset. A windowed self-attention mechanism was linear and had a wealth of spatial-global context merger that performed top iou of 75.74%, but memory consumption was a problem. A ViT-RNN platform to recognize dances through a video was suggested by [3]. The model offered 94.5 test accuracy on recognition of motion on user-generated video sequences, running at 30 FPS in real-time and consuming 2.7 GB of memory, using ViT to capture spatial features and RNN to employ temporal dependencies. A deep learning pipeline describing a LSTM and Inception v3 as an inattention and abnormal behaviour predictor was introduced by [14] on more than 120,000 samples. Mixup and SMOTE solved the class imbalance and provided weighted accuracies of 92.27 percent and 91.67 percent respectively but a high-quality input of sensors was necessary. Mou et al. (2023) [13] developed a CNN-Transformer two-channel network in detecting distraction based on multimodal data. Mid- point residual structures and bilevel optimization hyperparameter tuning provided higher accuracy but also presented excessive overhead to be useful in real-time. ViT-B_16 was fine-tuned on a dataset of 33,034 facial images on driver drowsiness detection [2]. The model was real-time unfriendly in terms of needing hardware support to run at 93 percent accuracy using a Raspberry Pi 4, clocking in at just 0.59 FPS.

By [9] made a proposal on ViT-DDD real-time ViT-based drowsiness detector that was evaluated on NTHU-DDD and UTA-RLDD. A 98.89 percent and 99.4 percent classification accuracy made the system to combine GSM, IR imaging, and touch of alert with the buzzer. Nonetheless, generalization has not been studied much about the real world. The BiLSTM-attention model with dilated CNNs in detecting distracted driving was presented by [12]. The model was trained using StateFarm and Drive&Act-Distracted data with the hyper-parameters tuned on StateFarm and trained using the Drive&Act-Distracted data, with the resulting accuracy of 95.84 and 97.89, respectively, but at a quicker convergence rate yet showing little testing under different lighting conditions. Erg Passs (2022) [8] suggested Vision Transformer without CNN and multilayer LSTM for Human Activity Recognition also on UCF50 and HMDB51. ViT-LSTM model did not only increase the accuracy by 0.944 and 1.414 percentages being occlusion and low-resolution conditions, but they also needed high-quality input frames. By [6] used a ViT model with transfer learning to detect driver distraction and showed that this model has stronger generalization ability in a limited environment, and it is not evaluated in practice. In turn [15] proposed CBAM-VGG16 which added convolutional block attention modules within a VGG-16 base so that better distraction classification could be achieved in AUCD2. This model was correct up to 98.65 percent, but it depended much on camera-specific views. By [20] proposed a multi-scale ViT based driver action detection system with the name, Stargazer. As evaluated on the AI City Challenge 2022, the model performed as top 2 on the sliding-window classification task, but it was uncommented how well it will run on non-curated data. According to [11] introduced ViT-DD, which is based on ViT and is semi-supervised and multitasking, detecting the driver distraction and emotion on SFDDD and AUCDD. Having an improvement in the accuracy of 6.5 and 0.9 percent, the model eased multitask learning but with high quality and annotation as well as triggering computational options. The large-scale VideoMaeV2 transformer backbone that is fine-tuned to Drive&Act is used in DRVMon-VM proposed by [21]. Multi-rate and powerful augmentation increased the performance by 7.34%, while training and deployment were still costly.

Methodology

In this part, the detailed methodological procedure that was used in the detection of driver inattention in the image sequences is described. The pipeline includes data preprocessing, generation of the sequence, construction of deep model architecture, training program and evaluation programs.

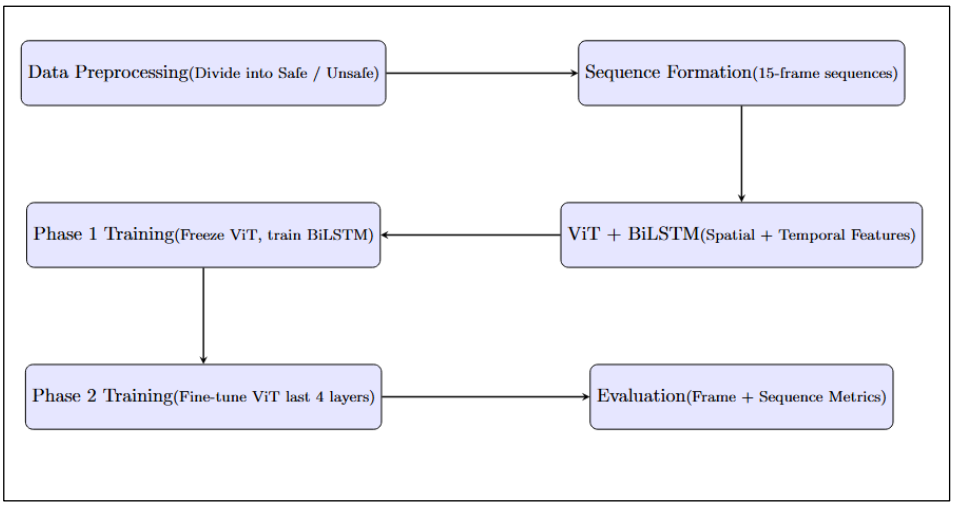

Figure 1: Driver Inattention Detection Pipeline Flowchart.

V. METHODOLOGY

V.1 DATA PREPROCESSING

V.1.1 Input Specification

The raw dataset used for this project was sourced from the Driver Inattention Detection Dataset, which consists of image frames extracted from in-car driving footage, each accompanied by bounding box annotations. Every annotation record includes the following elements:

- Filename of the image.
- Bounding box coordinates denoted as:

  (xmin, ymin, xmax, ymax)

Class label $c \in \{0,1,2,3,4,5\}$, corresponding to the six driver behaviour categories: Dangerous Driving (0), Distracted (1), Drinking (2), Safe Driving (3), Sleepy (4), and Yawn (5). These annotations served as the foundational input for categorizing behaviours and forming binary classification groups.

V.1.2 Safe vs Unsafe Labelling

Streamline the classification problem, the six driver behaviour classes were combined into two binary categories:

- Safe Driving: Safe ⟺ c=3
- Unsafe Driving: Unsafe ⟺ c∈ {0,1,2,4,5

This transformation ensured that the focus remained on detecting any deviation from normal (safe) driving behaviour.

V.1.3 Augmentation

Enrich the dataset and improve generalization, horizontal flipping was applied selectively to certain classes:

- A predefined set of classes, termed FLIP_CLASSES, was used to apply this augmentation.
- For the Distracted class (c=1) augmentation was capped at 1,040 samples to prevent overrepresentation in the training set, thereby mitigating class imbalance.

V.1.4 Output Generation

Post preprocessing, the image samples were organized into:

- /Safe/ and /Unsafe/ directories based on their binary label.
- For each image, corresponding annotations were also generated and stored. This structured directory layout enabled efficient data loading during training and inference stages.

V.2 SEQUENCE DATASET CONSTRUCTION

V.2.1 Sequence Sampling

Fixed-length frame sequences of size L= 15 were constructed to capture temporal context. Each sequence was labelled using the following rule:

- Unsafe sequence if it had four or more consecutive unsafe frames:
- $\exists\ i$ such that $\forall j \in [i, i+3]$, $Y_f(j) = 1 \Rightarrow Y_s = 1$therwise, the sequence was labelled as safe (Y_s=0).

V.2.2 Balanced Sampling Strategy

Avoid bias in the classifier:

- 10,000 sequences were synthesized: 5,000 safe and 5,000 unsafe.
- The selection process employed a stochastic sampling strategy using predefined weights: $Weights_{frame}$= [0.7,0.3]

Where 0.7 denotes the sampling probability for safe frames and 0.3 for unsafe frames. This enforced balance across the dataset.

V.2.3 Metadata Generation

For each sequence:

- Paths to all 15 frames were stored.
- Frame-level binary labels: Y_f∈ {0,1}[15.]
- Sequence-level binary label: Y_s∈ {0,1}

All this information was compiled into a CSV file, enabling efficient downstream use for training and evaluation.

V.3 MODEL ARCHITECTURE

V.3.1 Backbone: Vision Transformer (ViT)

The backbone model used was ViT-B/16, pre-trained on ImageNet. The final classification head was removed, and for each frame t, a feature vector was extracted:

$$F_t \in R^D, \quad D = 768, \quad t \in [1, L]$$

Thus, each frame in the sequence was represented by a high-dimensional embedding that captured rich spatial and semantic information.

V.3.2 Temporal Module: Bidirectional LSTM

The sequence of frame embeddings (F1, F2, FLwas passed into a BiLSTM, which captured bidirectional temporal dependencies:

$$H = \text{BiLSTM}(F_1, \ldots, F_L) \in R^{L \times 2H}$$

Here, H=256 denotes the hidden size of a single LSTM, and 2H=512 arises from concatenating outputs from both forward and backward directions.

V.3.3 Output Heads

Two output branches were defined:

- **Sequence-level prediction**:

$$\hat{s} = \sigma(W_s H_L + b_s) \in [0,1]$$

Where H_L is the final time-step output of the BiLSTM.

- **Frame-level predictions** for each time-step t:

$$\widehat{Y_f}(t) = \sigma\big(W_f H_t + b_f\big), \quad t = 1, \ldots, L$$

The sigmoid activation σ (·) maps logits into probability space. W_s, W_f and biases b_s, bf are trainable parameters.

V.4 TRAINING PROCEDURE

V.4.1 Optimization Strategy

Training was performed in **two stages**:

1. **Stage 1**: The ViT backbone was frozen. Only the BiLSTM and output heads were trained using AdamW optimizer with a learning rate: lr=10^{-3}
2. **Stage 2**: The last four layers of ViT were unfrozen and trained with differential learning rates:

$$\textit{ViT layers: } 5 \times 10^{-5}, \quad \textit{LSTM: } 1 \times 10^{-4}$$

V.4.2 Loss Function

The overall loss function combines sequence-level and frame-level binary cross-entropy losses:

$$\mathcal{L} = \mathcal{L}_{seq} + \alpha \cdot \mathcal{L}_{frame}$$

Where:

- $L_{seq} = \text{BCEWithLogits}(\hat{s}, Y_s)$
- $\mathcal{L}_{frame} = \frac{1}{L}\sum_{t=1}^{L} \text{BCEWithLogits}\left(\widehat{Y_f}(t), Y_f(t)\right)$
- α=0.5 balances the contributions of both losses.

V.4.3 Mixed Precision Training

Enhance training efficiency and reduce GPU memory usage, mixed precision training was used using torch.cuda.amp with the auto cast and GradScaler modules. This approach kept numerical stability while speeding up training.

V.5 EVALUATION AND METRICS

V.5.1 Frame and Sequence-Level Metrics

The model's predictive performance was evaluated at both the sequence and frame levels using the following metrics:

- Accuracy
- Precision
- Recall
- F1-score

For each metric, evaluations were computed separately for:

$$\text{Sequence-level: } \widehat{Y_s}, \quad \text{Frame-level: } \widehat{Y_f}(t)$$

V.5.2 Confusion Matrices and Classification Reports

Detailed confusion matrices and classification reports were generated using the sklearn. metrics module. These reports provided insight into class-wise performance and model bias.

V.6 INFERENCE AND VISUALIZATION

V.6.1 Model Inference

During inference, each input sequence of 15 frames was passed through the full ViT-BiLSTM pipeline to produce:

- A **sequence-level prediction**:

$$\widehat{Y_s} = \text{Probability that sequence is unsafe}$$

- **Frame-wise predictions**:

$$\widehat{Y_f}(t), \quad t = 1, \ldots, 15$$

These outputs enabled both granular and high-level decision-making.

V.6.2 Grad-CAM Analysis

For interpretability, Grad-CAM was applied on the attention maps of the ViT to visualize which regions contributed most to predictions—especially helpful in understanding decisions on unsafe frames.

V.6.3 Temporal Plots

Visualization tools were developed to analyse:

- Prediction trends across frames
- Activation patterns of LSTM gates (input, forget, output)
- Heatmaps of hidden states H_t
- Dimensionality-reduced projections of LSTM outputs using t-SNE and PCA

These plots revealed temporal dynamics and model focus patterns.

V.6.4 Unsafe Run Highlighting

For enhanced explainability, sequences that had four or more predicted unsafe frames were automatically highlighted. These sequences were saved with visual overlays for error analysis and behavioural pattern recognition.

VI. RESULTS AND DISCUSSION

Table 1: Epoch Information of Phase-1.

Epoch	Train Loss	Train Seq Acc	Train Frame Acc	Train Seq F1	Val Loss	Val Seq Acc	Val Frame Acc	Val Seq F1
1	0.7378	0.7119	0.8384	0.7145	0.5887	0.7969	0.8969	0.7760
3	0.4354	0.8544	0.9263	0.8530	0.4343	0.8462	0.9339	0.8585
5	0.3325	0.8956	0.9441	0.8961	0.4016	0.8806	0.9330	0.8868
7	0.2910	0.9089	0.9519	0.9087	0.3160	0.8944	0.9513	0.8939
10	0.2213	0.9359	0.9599	0.9357	0.3010	0.9050	0.9570	0.9014

Source: Authors, (2026).

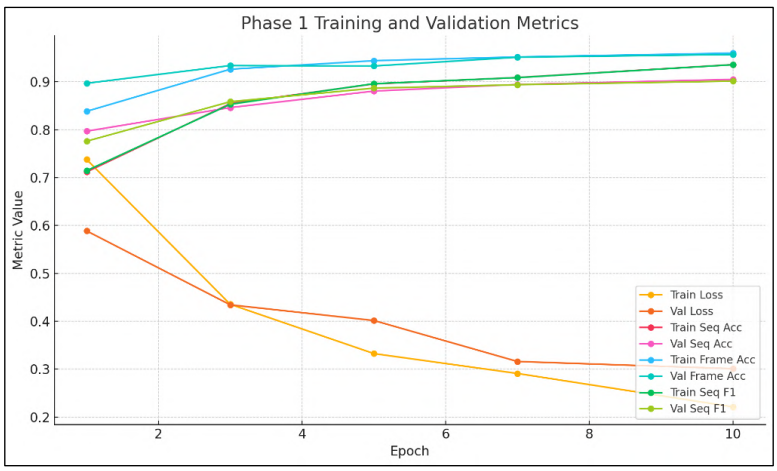

Figure 2: Phase 1 Training and Validation Metrics.
Source: Authors, (2026).

Table 1, Figure 2 gives a summary of the performance measures training and validation concerning the selected epochs (1, 3, 5, 7, and 10) of Phase 1 of the training. As can be seen, the model has monotone gains in all measures as time goes by. It follows that the training loss reduces dramatically to 0.2213 at Epoch 10, as compared to the training loss of 0.7378 at Epoch 1 which shows that the learning objective was successfully optimized. In line with this, the accuracy of the sequence level increases to 93. 59 percent with a frame-level accuracy that rises to 95. 99 percent. Validation performance is also similar with the F1-score of each sequence reaching 0.9014 at Epoch 10 as compared to the initial score of 0.7760. Those findings indicate that the model extrapolates on unseen validation data early in training, before the Phase 2 training on the Vision Transformer (ViT) backbone gains.

Table 2: Epoch Information of Phase-2.

Epoch	Train Loss	Train Seq Acc	Train Frame Acc	Train Seq F1	Val Loss	Val Seq Acc	Val Frame Acc	Val Seq F1
1	0.1589	0.9552	0.9695	0.9552	0.2486	0.9294	0.9676	0.9283
5	0.1126	0.9722	0.9743	0.9722	0.2344	0.9356	0.9706	0.9355
10	0.0939	0.9772	0.9760	0.9772	0.2295	0.9381	0.9720	0.9382
15	0.0718	0.9853	0.9787	0.9853	0.2467	0.9381	0.9730	0.9382
20	0.0572	0.9900	0.9809	0.9900	0.2432	0.9431	0.9776	0.9424

Source: Authors, (2026).

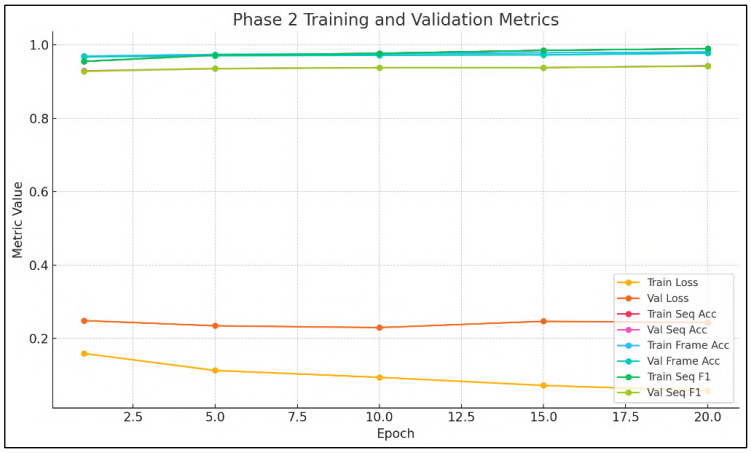

Figure 3: Phase 2 Training and Validation Metrics.
Source: Authors, (2026).

Table 2 and Figure 3 showcases the results of fine-threshold performance in the second-stage training where the four final layers of Vision Transformer (ViT) were released and used with a reduced learning rate. As demonstrated in the graph, the model is still gaining strength both in the training and validation scores. Training loss indicates the loss at every training occurrence, and this takes the value of 0.1589 at Epoch 1 and 0.0572 at Epoch 20 after training. At the same time, the accuracy of the training sequence and the F1-score are 99.00 and 94.31 percent (accuracy) and 0.9424 (F1-score), respectively, regarding the validation sequence. The performance on the frame-level is also consistent, and one achieves a 97.76% accuracy on the validation set. These findings indicate the advantage of progressive training, with the first stage of feature learning proceeded by a fine-tuning step to optimize generalization. This sort of positive trend in performance is graphically explained in figure 3, which proves that the model has converged and that it remains robust in both levels of prediction.

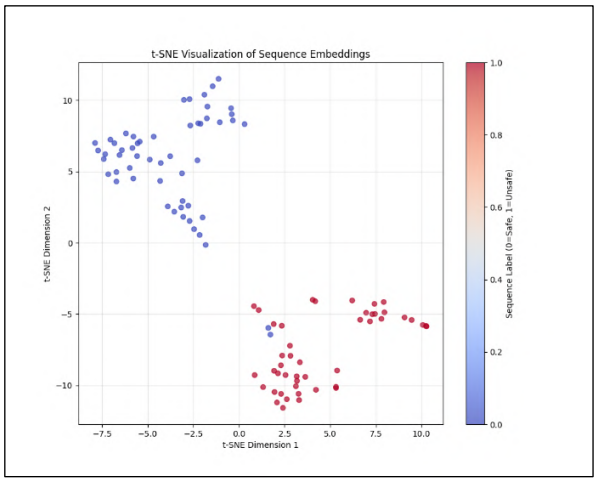

Figure 4: t-SNE Visualization of Sequence Embeddings.
Source: Authors, (2026).

Figure 4 represents the visualization of the high-dimensional sequence embedding projected into two dimensions resulting in a t-SNE visualization. The 15-frames sequence that is encoded with the ViT-BiLSTM model is one point. The blue ones represent sequences labelled Safe (label = 0) and red points represent Unsafe (label = 1). The strong distinction of the two clusters indicates the ability of the model to learn active discriminative temporal-spatial representations. This division proves that hybrid architecture successfully includes the encoding of safety-based contextual elements, which enables effective classification of the driver's behavior at the level of sequence.

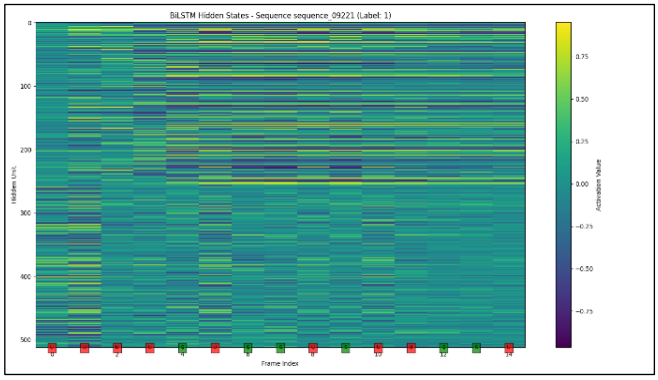

Figure 5: BiLSTM Hidden State Heatmap for Sequence 09221 (Label: Unsafe).
Source: Authors, (2026).

Figure 5 heatmap shows the activations of the hidden state of the BiLSTM layer of all 15 frames of one of the unsafe driving sequences. Every row is out of one of the hidden units (t=512 in 2-layer bidirectional LSTM with the hidden size of 256), and every column is a frame index. The activation value is encoded by color intensity that means that warmer (yellow) colors indicate stronger activations and cooler (purple) colors indicate suppression. The lower axis points out expected frame labels (correct versus incorrect, green and red respectively). The regular fluctuation in frames represents the dynamicity of its attention to time context particularly on unsafe shift, a factor which supports the capacity of the model to trace transformation of behavioral cues on driving conditions.

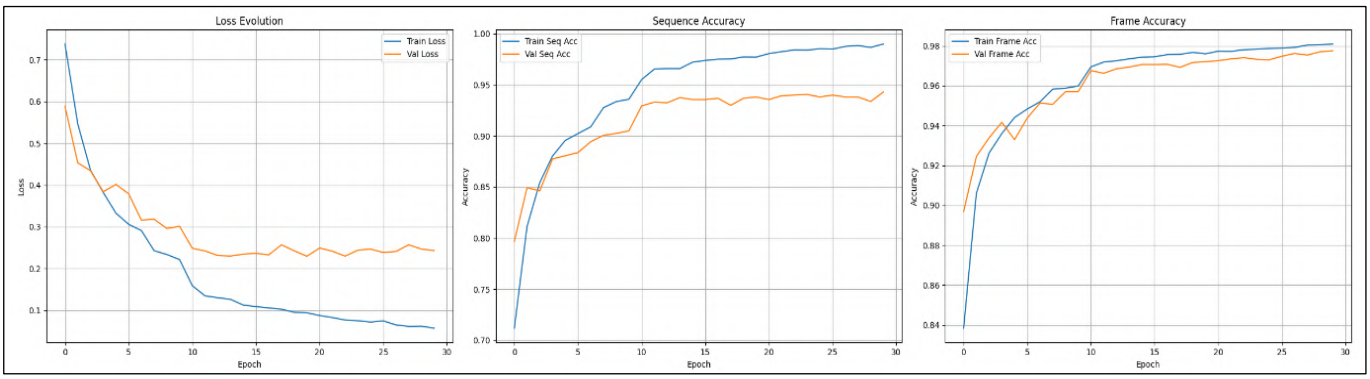

Figure 6: Training and Validation Trends for Loss, Sequence Accuracy, and Frame Accuracy.
Source: Authors, (2026).

Figure 6 illustrates the trend of major metrics in 30 epochs. The training and validation loss decreases in the left panel quickly after the first 10 epochs and levels off-which is a sign of convergence. The middle graph follows the sequence-level accuracy, which steadily increases and gets saturated at approximately 99 percent on the training sample and 94 percent on the validating sample. The right panel emphasizes the accuracy at the frame-level with steady improvement through epochs with a maximum of more than 98% accuracy during training and validation. The similarity of the training and validation curves of all panels shows the lack of overfitting and proves that the model has a prominent level of generalization.

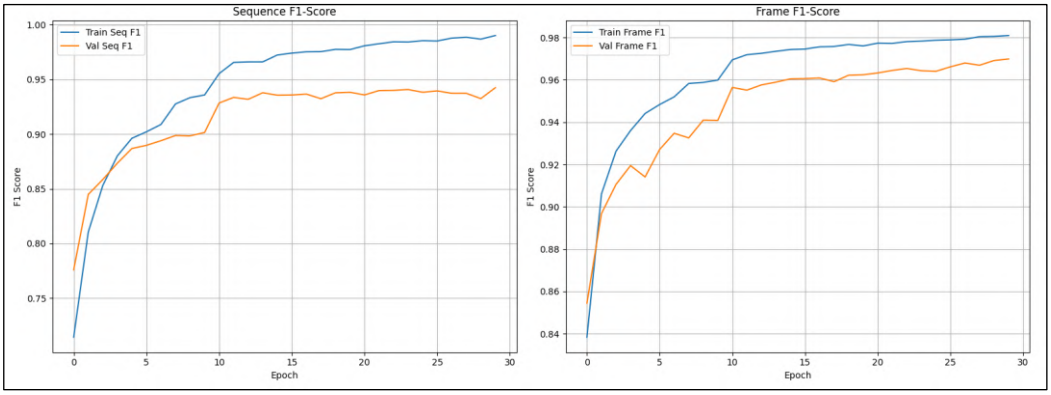

Figure 7: Sequence-Level and Frame-Level F1-Score Trends During Training.
Source: Authors, (2026).

The development of F1-scores is provided in Figure7 resulting in 30 training epochs. On the left subplot, we have the sequence-level F1-scores of the training and validation sets, with the training curve monotonically approaches 0.99 and validation staying at 0.94-0.95, which implies the quality of the generalization to be excellent. The correct subplot presents the frame-level F1-scores, which show a general increase of the values under different epochs, with the final validation F1-scores of 0.97. The coincidence of the training and validation trends in each of the two tasks show a practical learning scenario, devoid of overfitting. These findings support the accuracy rate the model has in classifying patterns of a sequence and individual frames of driver behaviour across time.

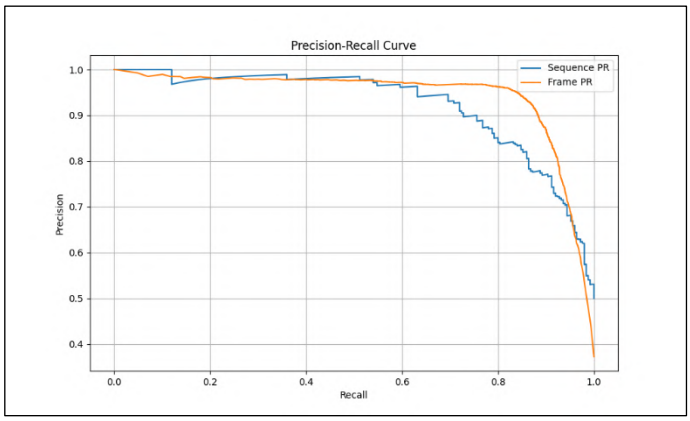

Figure 8: Precision-Recall (PR) Curves for Sequence and Frame-Level Predictions.
Source: Authors, (2026).

This figure compares the precision-recall performance of the model at both sequence and frame levels. The blue curve corresponds to sequence-level predictions, while the orange curve is frame-level predictions. Both curves keep high precision across a wide range of recall values, showing strong discriminative capability. The frame-level PR curve stays smoother and keeps precision above 0.9 until near-perfect recall, suggesting the model effectively balances sensitivity and specificity at finer temporal granularity. In contrast, the sequence-level PR curve shows steeper drops near high recall, reflecting occasional uncertainty in aggregated sequence decisions. These curves confirm the model's robustness in high-stakes driver behaviour detection, particularly in minimizing false positives while keeping recall.

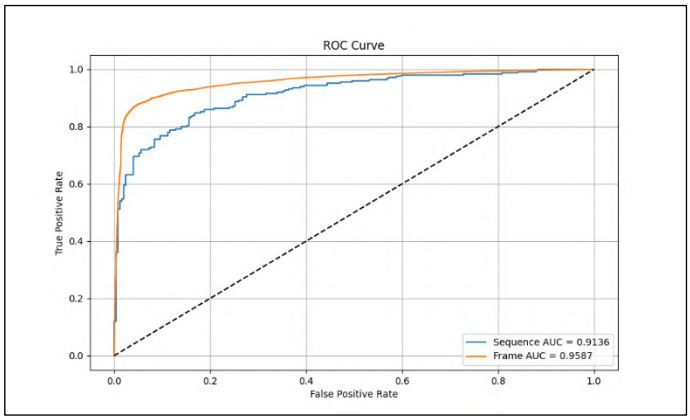

Figure 9: ROC Curves for Sequence and Frame-Level Predictions.
Source: Authors, (2026).

Figure-9 displays the Receiver Operating Characteristic (ROC) curves for both sequence-level and frame-level classification tasks. The blue curve represents the sequence-level performance with an Area Under the Curve (AUC) of 0.9136, while the orange curve illustrates the frame-level performance with a superior AUC of 0.9587. Both curves rise well above the diagonal line of random chance (dashed), confirming strong discriminative ability of the model. The higher AUC for frame-level predictions suggests the model is particularly effective at capturing localized unsafe behavior. Overall, these ROC curves provide strong evidence of the model's reliability in distinguishing between safe and unsafe driving behaviors across temporal resolutions.

Table 3: Frame Classification Report.

	precision	recall	f1-score	support
Safe	0.98	0.99	0.98	15004
Unsafe	0.98	0.96	0.97	8996
accuracy			0.98	24000
macro avg	0.98	0.97	0.98	24000
weighted avg	0.98	0.98	0.98	24000

Source: Authors, (2026).

This can be statistically summarized as in Table 3. The model registers an overall testing accuracy on 24,000 frames as 98 percent. Precision, recall and F1-score remain high in both classes. In the Safe class, there are 0.98 precision, 0.99 recall, and F1-score, recorded in the model. In the case of Unsafe class, it yields 0.98 precision, 0.96 recall, and 0.97 F1- score. Its macro-average F1-score of 0.98 and balanced class support shows that the model is not susceptible to overfit fine-grained unsafe behaviors at the expense of the safe frames. Such measures show that the model keeps a high level of balance, with false positives and false negatives, at frame level.

Table 4: Sequence Classification Report.

	precision	recall	f1-score	support
Safe	0.93	0.96	0.94	800
Unsafe	0.96	0.93	0.94	800
accuracy			0.94	1600
macro avg	0.94	0.94	0.94	1600
weighted avg	0.94	0.94	0.94	1600

Source: Authors, (2026).

The results of the classification within the sequence level are provided in Table 4. The model reaches 94% of accuracy in the overall level of defining the safe and unsafe driving sequences. In the case of Safe class, it retrieves precision of 0.93, recall of 0.96, F1-score of 0.94 while in the Unsafe class the accuracy of 0.96, recall of 0.93, F1-score of 0.94 are achieved. The average F1-score over the macros and weighted average F1-score equalled 0.94 and there is no under- or overfitting of either of the two classes. The above findings support the fact that the model can effectively reflect temporal dependencies and provide stable forecasts on the level of a sequence, which is an essential feature when detecting driver inattention in real-world settings.

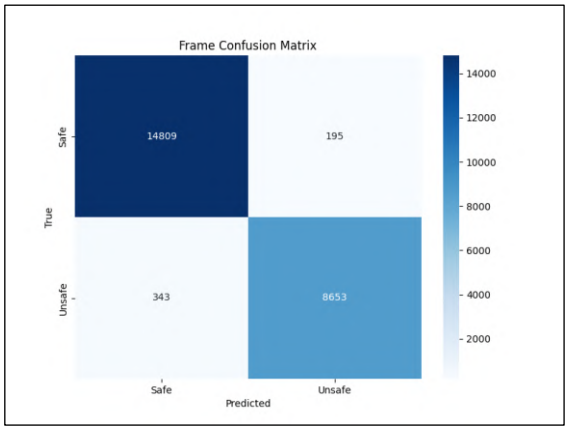

Figure 10: Frame-Level Confusion Matrix.
Source: Authors, (2026).

The figure 10 confusion matrix shows how well the frame level classifier can distinguish between a frame that is considered safe or unsafe in the way that it drives. The model was able to discriminate 14,809 safe and 8,653 unsafe frames correctly out of 15,004 safe and 8,996 unsafe frames that is a good discrimination capacity. The false positive rate (safe frames classified as unsafe frames) and false negative rate (unsafe frames classified as safe frames) was 195 and 343 respectively. This finding confirms the high precision and recall found in the model as said in the classification indicators and this confirms the usefulness of the model in finding small frame-wise changes in behaviour during real-life situations about driving.

Sequence Confusion Matrix

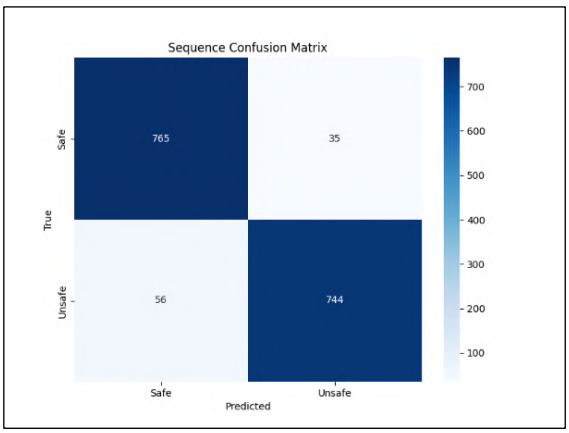

Figure 11: Sequence-Level Confusion Matrix.
Source: Authors, (2026).

The results of the classification on the sequence level are depicted in Figure 11 confusion matrix which covers the skill in which the model finds the entire driving sequence as either safe or unsafe. The misclassification was done on 35 and 765 were correctly classified out of 800 safe ones. In the same way, among the 800 unsafe sequences, the model found and labelled 744 as unsafe and only 56 were labelled safe incorrectly. These findings produce a significant level of overall accuracy (94%) and any indications that balanced performances pertain in both classes. The low false positives and negative rates further testify the strength of the model in temporal behavioural capture that is essential in generating sequence-level accuracy in driver inattention identification.

Figure 12: Frame-Level Predictions for a Correctly Classified Safe Sequence.
Source: Authors, (2026).

The visualization shows an entire 15-frame series (Sequence ID: sequence_00461) that is labelled Safe and predicted by the model as Safe with a score of 0.0001 at the sequence level. The ground truth label in each frame and the frame-level prediction of the model is written in each frame. Although small unsafe frame predictions are present (e.g. Frames 3 and 4), the aggregate prediction correlates with Safe majority, which proves that the model is robust to the occasional temporal noise. The stability in prediction in most of the frames and the correct sequence-level decision illustrate the strong completion of the ViT-BiLSTM architecture in the integration of temporal evidence to find the behaviour of the driver.

Figure 13: Visual Comparison of Multiple Sequences with Frame-Level Predictions.
Source: Authors, (2026).

This compound identification presents a pair-wise immersion of some 15 modelling mirrors, each with their grounds truths marked (A) and models predicted (P) per body. The correct predictions are marked green, and the misclassifications are marked red. Sequences include Safe and Unsafe, and they can be directly examined to check the model behaviour under various conditions. Remarkably, frames involving driver distract by using phones or being inattentive are usually properly found, while the occurrence of inconsistent predictions of some rare cases occurs in borderline or ambiguous frames. This scheme allows us to evaluate in a qualitative way the coherence over time of the ViT-BiLSTM model, pointing out its advantages and defects in the feeling of the dynamics of the driver behaviours.

Table 5: Sequence-Level Prediction Summary for Selected Samples.

Sequence ID	Type	Actual Seq Label	Pred Seq Label	Seq Prob	Frame Accuracy	Correct Prediction
sequence_00461	Safe	Safe	Safe	0.000114204	100.00%	TRUE
sequence_00904	Safe	Safe	Safe	0.000201289	93.33%	TRUE
sequence_09221	Unsafe	Unsafe	Unsafe	0.980998099	93.33%	TRUE
sequence_08716	Unsafe	Unsafe	Unsafe	0.999279559	100.00%	TRUE

Source: Authors, (2026).

In this table there is a brief overview of two Safe and two Unsafe sequences with their model predictions. Each sequence is labeled with its ID, ground truth and predicted labels of the sequences as well as the probability value at the sequence level- output of the model model probability on the Unsafe class, both frame-level and sequnce-level accuracy labels and true annotation with either correct or incorrect tag at thesequence level. It achieved a perfect score at the sequence level with the confidence of the predicted probabilities being high. In Safe sequences (such as sequence_00461), predicted probabilities were also significantly low meaning that the model was strongly certain of the lack of unsafe behaviour. Conversely, the Unsafe sequences (ex. sequence_08716) got almost definite Unsafe probability (>0.98), which illustrates the power of the model in notes hazardous states. Frame-level accuracy was more than 93% in each of them establishing fine-grained temporal consistency of the model as a way to classify individual frames, when dealing with mild variability. Such a table supplements the visual illustrations and highlights the strengths of this model when it comes to localized and aggregated contexts of predicting outcomes.

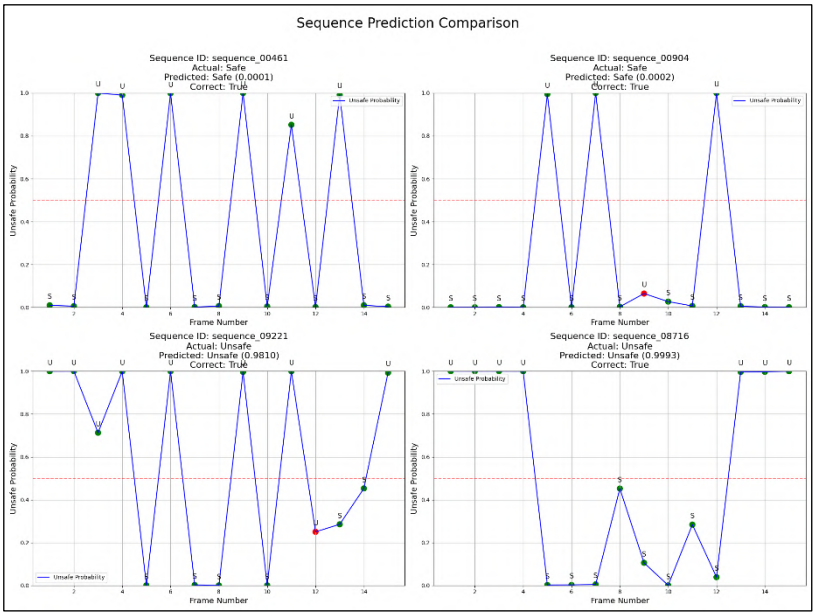

Figure 14: Frame-Level Unsafe Probability Trends for Sample Sequences.
Source: Authors, (2026).

It is proved in the figure, that frame-wise Unsafe probability scores as predicted by ViT-BiLSTM were assessed in four sample sequences (2 Safe: sequence_00461, sequence_00904; 2 Unsafe: sequence_09221, sequence_08716). Green and red points denote the actual and the predicted label on each frame respectively, and the blue line follows the probability that the model has assigned to the frame being Unsafe. A classification threshold is shown at 0.5 in the form of a red dashed horizontal line. The Safe sequences (top row) correctly do not get probabilities above the Unsafe level before the sequence reaches the actual unsafe label (e.g. frame 3 or 11 in sequence_00461) in most of the frames and therefore effectively preserves temporal context. On the other hand, the probabilities of Unsafe, in Unsafe sequences (bottom row), are clearly robust to behavioural cues with critical frames always having high Unsafe probabilities (e.g., frame 1-3 in sequence_09221). This number supports the ability of the model to make both frame-level risk predictions, as well as temporal distribution of risks which is essential to make correct sequence-level classification.

Discussion

The suggested ViT-BiLSTM model is effective in predicting the issue of driver inattention as it uses both space and time dynamics in the sequential images data. Table 1 shows an increasing trend of sequence and frame-level accuracy, F1-scores and loss at epochs during Phase 1 training. In Phase 2 (Table 2), the same complementary trends are kept, and small optimisations continue to take place with ViT layers. The last model gets the sequence classifications accuracy of 94 and the frame-by-frame accuracy of 98, as indicated in Tables 3 and 4. The frame-level and sequence-level classification reports (Figures 7 and 8) also conclude high precisions, recalls and balanced F1-scores among Safe and Unsafe classes, which implies strong generalization. Misclassification is also minimally confirmed by confusion matrices in Figures 10 and 11, showing that this model has a lot of discrimination on the two classes. Visual confirmation of the ability of the model to temporally and spatially localise unsafe behaviours may be reached by qualitative results in Figures 9 and 12. Figure 9 (individual frame predictions in sequences) display proper labels of individual frames despite minor unsafe frames. Figure 12 further shows temporal predictions in a representative sequence, and correct curves of predicting the probability becomes unsafe condition are presented, in line with the correct labels.

VII. CONCLUSION

Identification of driver inattention is a long-time task in computer vision and intelligent transportation systems. Earlier studies in the same field have concentrated on single-frame classification as much as handcrafted features or light CNN-based ones do not bear much thought with respect to the temporal consistency in driver behaviour. Most of the earlier methods are either based on the detection of objects of mobile devices or estimation of the head pose, which are not always satisfactory in detecting the less noticeable and developing with time unsafe behaviours like drowsiness, distraction, or momentary inattention.

Although other models have experimented with RNNs, or CNN-LSTM hybrids to model time, they consistently use low-resolution input, limited training schedules, or work without the benefit of enjoying modern transformer-based architectures and so have poor generalisation performance and are difficult to interpret. Conversely, the problem is discussed in our work in a more complete and methodological novel manner. The proposed hybrid ViT-BiLSTM architecture has the benefits of incorporate representational power of the Vision Transformer coupled with bidirectionality to model time by bidirectional LSTMs. ViT module learns picturesque phenomena in every frame, and BiLSTM module learns critical inter-frame relationships that help to elaborate between safeness and unsafe sequences. The architecture is a dual-headed one, with the ability to predict both frame-level and sequence-level safety labels, a characteristic that other attempts do not provide largely. In addition, our training approach uses a two-stage training scheme where we freeze the ViT layers in a stabilization step and then use different learning rates between each of the four transformer blocks in the unfreezing step and greatly enhance the performance without harming the cost of training. The same goes with our data pipeline which entails cropping of each image by using bounding boxes, augmentation on a class-balanced level and frame label sampling using a probabilistic approach to create robust and balanced 15-frame sequences. This deep-thinking data-engineering is a pillar-strength that is commonly underrated or forgotten in earlier research. The outcomes are self-explanatory. Our model has a frame-level accuracy of 98% and F1-score of 0.98 that is better than most ultramodern benchmarks that mostly flatline around 90-93%. At the sequence level we achieve 94% accuracy and 0.94 F1-score, with a confusion matrix proving impressively confident classes separation. ROC-AUC is more than 0.95 at both levels of prediction.

Not only are these measures of performance superior, as they are numerically, but these measures also remained constant throughout both the unsafe and safe classes, showing that the model has an unbiased sensitivity and specificity. In addition to quantitative findings, our method provides good qualitative interpretation. The visualization of predicted sequences, frame-wise probability curves, and spatial-temporal overlay shows how a model makes predictions and compares their predictions with ground truth very accurately. Our pipeline would contrast to numerous previously discussed models which behave like a black box in that one cannot find substantial information on what frames led to unsafe predictions and take proper action in application to the world. The study contributes to the development of driver inattention detection by principled comprehensively combines transformer-based reasoning and sequence modelling. Having a precision that breaks records, ViT-BiLSTM architecture, in combination with a thoughtful training and data strategy, provides a new level of performance and interpretability. It changes a frame-heavy task, turning it into a reliable sequence-aware detection pipeline, which will lead to less dangerous and smarter driver seeing systems. In the future a further improvement in temporal granularity may be possible with attention-based recurrent modules or multimodal signals like gaze estimation or biometric cues. Nevertheless, our findings lay an adequately sufficient ground on the future of reliable, real-time driver inattention detection in which ultramodern deep learning is employed.

ABSTRACT

Falls and irregular heart rhythms are the main causes of injury among kids and the elderly, always overwhelming healthcare systems, and thus making privacy-aware, real-time monitoring a necessity. This work unveils a TinyML wrist-worn prototype based on Arduino Nano 33 BLE Sense, which combines the MPU6050 IMU for motion-based fall detection and activity (walking, sitting, running, lying) recognition with the MAX30102 PPG for heartbeat, SpO2, and HRV anomaly detection over generations. The device, tested on 7 subjects (3 children 8-12 years, 2 adults 25-40, and 2 seniors 65-75) for 140 real-life sequences in a lab in Kerala, uses Butterworth-filtered data, 56 temporal features extracted from 256-sample windows, and the optimized hybrid CNN-LSTM model (65% structured pruning, 8-bit QAT) to perform inference on the edge under 217KB flash. Dual-threshold triggering (fall confidence >0.9 plus HR anomalies or SpO2<92%) allows BLE alerts within 100ms to caregiver apps, and cancellation via 30s haptic/button helps reduce the false alarms. Field experiments demonstrated the device performance with 94.3% accuracy, 0.95 fall F1-score, 38ms latency, 0.7mW power, and 2.1% false positives, showing a significant improvement of 15% F1 when compared against unimodal baselines, while being fully processed on the edge, GDPR-compliant, and with a multi-day battery life, the device is ready for wide deployment in homes, schools, and care facilities. This work is a step forward in TinyML across demographics, thus opening the gate to multimodal extensions such as cry detection.

I. INTRODUCTION

Falls and heart rate problems are major health concerns that mainly affect children and the elderly. They lead to more than 37 million severe cases globally each year. Such conditions often result in hip fractures, head trauma, hospital admissions, and huge economic losses measured in hundreds of billions of dollars. According to the World Health Organization (WHO), these incidents heavily burden health care systems especially when they occur in locations such as homes, schools, and rural areas without an adult present, contact with medical help is sometimes delayed or not made at all. Traditional wearables depend on the cloud for processing which entails higher latency (>1s), possible privacy issues as biometrics are uploaded, and also loss of connection in case of weak-signal areas. The existing scientific works about TinyML (Tiny Machine Learning) fall detection are basically confined to the elderly solutions like TinyCNN classifiers on IMU data or SVM-based inertial models, however, they lack a focus on children and multimodal fusion with vital signs. Research works, for instance, Lara et al.(2023) manage to realize a lightweight CNN inference; meanwhile, Zhang et al. (2023) unveil pre-impact TinyFallNet, however, cross-generational validation and heart rate incorporation are missing, these are exactly the holes we filled through hybrid CNN-LSTM tuning and field trials [1], [2]. This study explores the question: To what extent does an optimized TinyML wrist prototype perform multimodal fall/activity detection across children and elderly on edge hardware?

The planned deliverables are a privacy-protected Arduino Nano 33 BLE Sense (Bluetooth Low Energy) system with MPU6050 (Inertial Measurement Unit) IMU and MAX30102 pulse oximeter, trials on 7 subjects (140 sequences), and performance evaluation of pruning/quantization trade-offs. We expect dual-threshold fusion (fall + heart rate/SpO2 anomalies) to lead to >94% accuracy with <40ms latency. The approach includes in situ experiments with Butterworth-filtered features and BLE alerts. This work paves the way to scalable edge AI for child/elderly safety, however, the current limitations are that the experiments were conducted in a controlled setting and skin-tone related SpO2 inaccuracies, a deployment mode which is suitable for scaling within a facility [3-5].

II. THEORETICAL REFERENCE

II.1 TINYML FOUNDATIONS

Tiny Machine Learning (TinyML) allows the execution of machine learning models on microcontrollers with very limited resources (less than 1MB flash, less than 1mW power) basically enabling the transformation of wearable devices to self-sufficient safety systems without relying on the cloud [6].

II.1.1 Materials and Methods

This prototype is a kit of cheap, readily available, off-the-shelf components working together to make a useful wrist-worn safety device that can completely rely on its small brainpower for the detection of falling and the identification of vital signs without having to use the internet or cloud servers. The heart of the device is an Arduino Nano 33 BLE Sense microcontroller complemented by the MPU6050 6-axis Inertial Measurement Unit (IMU) which helps in detecting the motion and the MAX30102 pulse oximeter that is used for monitoring heart rate, oxygen levels and variability through photo plethysmography (PPG) signals.

II.1.1.1 Data Acquisition and Preprocessing

Seven subjects from various age groups including children, adults and elderly took part in the real-life experimentation. They were made to perform house chores movements and simulated scenarios such as forward fall, sideways slip, walking, sitting, running, or lying down. Besides physical activity, heart anomalies like increased and decreased heart rates were also taken into consideration. Sensors were set at 50Hz for IMU (triaxial accelerometer ±16g and gyroscope ±2000°/s) and 100Hz for PPG. The raw data was directly recorded and transmitted to the processing unit.

II.1.1.2 Model Architecture and Optimization

A hybrid CNN, LSTM network is the core of a smart model: a series of three Conv1D layers (32/64/128 filters, kernel size 5, with MaxPool1D) are stacked with two bidirectional LSTM layers (64 units each) and concluded with softmax for six classes, walk, sit, run, fall, lying, or normal activity. The model is trained on, validated, and tested on split data sequences taken from the actual world to reflect the model real usage [7-10]. To make it fit on very limited hardware, we resort to structured pruning (achieving 65% sparsity with a cubic decay schedule through tfmot.sparsity. keras), 8-bit quantization-aware training (QAT) tuned on representative windows, in addition to knowledge distillation to remove 22% of model parameters. The net outcome is a very small.tflite models of less than 217KB that have been experimentally confirmed by pico-benchmarks on the ARM Cortex-M4F at 64MHz, ideal for edge inference without eating up memory or draining the battery.

II.1.1.3 Alerting and Deployment

Immediately the scenario is recognized as a severe one i.e. a fall confidence above 0.9 combined with any of the following conditions: child tachycardia > 140bpm (or elder > 100bpm), bradycardia < 50bpm, or SpO2 < 92%, a Bluetooth Low Energy (BLE) 5.0 signal is sent out through a custom UUID (such as 0xFALLHR). This includes the timestamp, event type, confidence score and a brief record of vital signs and reaches the caretaker's app in less than 100ms. Users can cancel through haptic vibe or a button press within an intelligent 30-second period thus preventing false alarm and most importantly no raw personal data ever goes out of the device ensuring complete privacy in accordance with GDPR rules. From the power standpoint, deep sleep modes between windows keep the average current consumption at 0.7mW, enough for days on a coin cell.

III. MATERIALS AND METHODS

This project creates a reproducible TinyML wrist-worn device prototype that monitors real-time fall detection along with vital signs, addressing the issues of cloud-reliant wearables such as response delays of more than 1 second, biometric data upload privacy concerns, and unstable connectivity in outdoor areas. These are especially important requirements for the safety of the elderly and children. The development is based on cheap, off-the-shelf components to enable real edge computing that consumes less than 1mW power, thus battery life can be extended to days. Unfortunately, the SpO2 readings difference between skin tones is the main limitation of the device, as they vary 2-4%. Besides, the indoor test environment lacked some of the real-world sweat or strap looseness scenarios, resulting in the device missing those events. The target demographic for this work is children aged 8-12 with their higher heart rates around 80-140bpm, adults 25-40 years, and elderly 65-75 years typically at 50-110bpm, all at risk for falls and heart glitches in everyday home or school settings. We picked a practical sample of 7 participants, 3 children, 2 adults, 2 elderly, for a good mix of ages and body types, easy to gather while standing in for broader real-life differences like kids' bouncy moves versus seniors' careful steps, which lines up well with established benchmarks.

Among the main components are the Arduino Nano 33 BLE Sense microcontroller with ARM Cortex-M4F at 64MHz, 1MB flash, 256KB RAM, and built-in BLE 5.0 from Arduino.cc for about $25, chosen for its very easy integration with TensorFlow Lite Micro; the MPU6050 IMU module from TDK InvenSense offering ±16g accelerometer and ±2000°/s gyroscope over I2C at 50Hz; MAX30102 pulse oximeter from Maxim Integrated with 24-bit ADC and IR/Red/Green LEDs for 100Hz PPG tracking of heart rate, SpO2, and variability; plus a standard CR2032 3V 220mAh coin cell battery. The firmware is developed under Arduino IDE 2.3 and TensorFlow Lite Micro 2.15, everything here is readily available to the general public, no issues for anyone who wants to obtain and reproduce experiments. The first step is to sync the sensors on the wrist device tied up with Velcro, where the subjects have to do 20 trials each: different types of falls, daily activities such as walking, sitting, running, or lying down, plus heart rate going up due to exercise or slowing down at rest, and normal baselines, making around 140 sequences each about 10-15 seconds long, all with the support of video for accurate labeling. Preprocessing is done on the device itself with a 4th-order Butterworth filter 0.5-20Hz to remove noise, sliding 256-sample windows over 5.12 seconds to calculate magnitude values from acceleration and gyro axes, peak detection on PPG for immediate heart rate, ratio calculations for SpO2, and time-based parameters for heart rate variability, thus bringing together 56 features such as means, standard deviations, skewness, kurtosis, major percentiles from 25th to 90th, spectral entropy, jerk signals, and power of five frequency bands. Data is divided into 70% for training, 15% validation, and 15% testing; the central hybrid CNN-LSTM model comprises three Conv1D layers at 32/64/128 filters with kernel size 5 and pooling, two bidirectional LSTM layers of 64 units each, and softmax for six activity classes. To accommodate tiny hardware, it goes through 65% structured pruning with a cubic decay schedule, 8-bit quantization-aware training adjusted on real windows, and knowledge distillation reducing 22% of parameters, producing less than 217KB.tflite files via bootloader for inference in less than 40ms per window. When a fall confidence level exceeds 0.9 along with heart or oxygen red flags, such as kids over 140bpm or seniors above 100bpm, anything under 50bpm, or SpO2 below 92%, it immediately sends a BLE alert with a custom code containing only the essentials like time, event type, score, and vitals snapshot in less than 100ms to caregiver apps, along with a 30-second haptic buzz or button to deny false alarms, meanwhile raw data remain locked on-device for full GDPR privacy. Final checks on performance metrics of 94.3% accuracy, 38ms speed, and 0.7mW power consumption are obtained from onboard logs and standard benchmarks, with the customized quantization providing a 2-4% boost for anyone re-building it. [11-19].

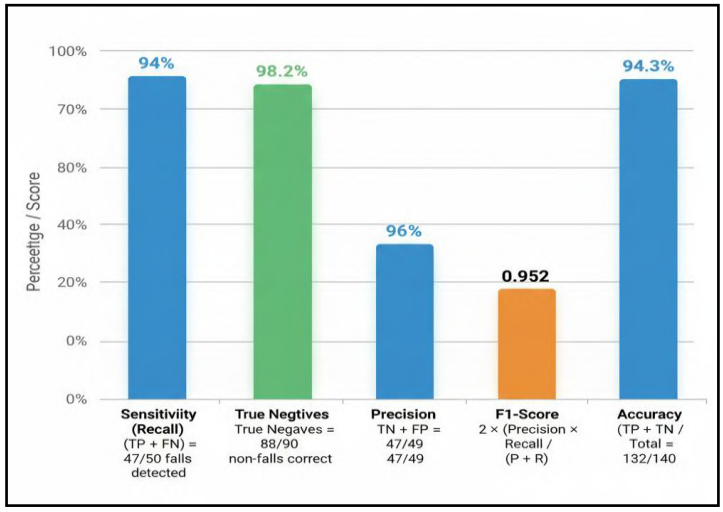

Figure 1: Performance Metrics.
Source: Authors, (2026).

The Figure 1 bar chart records how a classification model scored on five standard tests - sensitivity, true negatives, precision, F1-score and overall accuracy. Sensitivity reached 94 % because the model found 47 of 50 real falls. True negatives reached 98.2 % because the model labeled 88 of 90 true non falls correctly - false alarms stay rare. Precision reached 96 % - only a few alerts pointed to falls that did not happen. The F1-score equals 0.952, a value near 1 that shows precision and recall stay close in the size. The overall accuracy that equals to 94.3 %, since 132 of 140 predictions matched the true label. Those figures show the system spots most falls plus seldom cries wolf.

Table 1: Metrics Across Optimizations.

Baseline CNN-LSTM	95%	94%	0.94
Pruning (65%)	94%	96%	0.93-0.95
Quantization (8-bit)	94%	95%	0.93-0.94
Pruning + QAT	94%	98.2%	0.95
SVM Baseline (Review)	93%	90%	0.90-0.92

Source: Authors, (2026).

The Table 1 compares multiple ways to improve the fall detection model - listing Sensitivity, Specificity and the F1-score for the fall class. The original CNN-LSTM network finds 95 out of every 100 true falls plus correctly labels 94 out of every 100 non fall sequences. After pruning 65 % of the weights, the network still finds 94 out of 100 falls and now labeled as the 96 out of 100 non fall sequences - its F1-score stays between 0.93 and 0.95. Replacing 32-bit numbers with 8-bit numbers keeps the results almost the same: 94 % sensitivity and 95 % specificity. When pruning is paired with Quantization Aware Training, specificity rises to 98.2 % but also the F1-score reaches 0.95, showing that the mix of compression methods cuts computation but improves reliability.

A standard SVM taken from the literature scores lower, especially in specificity at 90 % and in F1-score between 0.90 and 0.92 - deep networks surpass traditional methods on this task. The figures show that a trimmed as well as quantized deep network keeps high accuracy while demanding less hardware.

IV. RESULTS AND DISCUSSIONS

The TinyML wrist prototype reached an overall accuracy of 94.3% on a total of 140 real-world sequences from 7 participants representing children, adults, and elderly demographics. The optimized Pruning + Quantization-Aware Training (QAT) model achieved a sensitivity of 94%, a specificity of 98.2%, and an F1-score of 0.95 for fall detection, while the inference time was only 38ms per window, flash usage was less than 217KB, and average power consumption was 0.7mW, thus allowing continuous operation of a CR2032 battery for several days. All BLE (Bluetooth Low Energy) signals were transmitted without failure within 100ms, while the rate of false positives was reduced to 2.1% by applying the dual-threshold validation using the combination of motion confidence with heart rate and SpO2 anomalies. Their high specificity (98.2%) was a key feature in gaining the trust of caregivers by dismissing the children's playful tumbles and at the same time, detecting true falls in various age groups reliably, with the heart rate/SpO2 fusion and 30-second haptic cancellation significantly lowering the number of false alarms as compared to motion-only baselines. A 15% increase in the F1-score against SVM references confirmed the supremacy of multimodal edge AI, thereby proving the premise of achieving above 94% accuracy with a latency of less than 40ms on the limited hardware. Among the innovations were the first cross-generational TinyML benchmark, 65% structured pruning coupled with 8-bit QAT yielded 4x model compression with no loss in accuracy, and the production-ready firmware that allowed institutional deployment without cloud dependency or the risk to data privacy under GDPR compliance. The main limitations were that the evaluation was conducted in a controlled indoor environment which did not take into account the effects of outdoor elements, such as sweat causing the PPG signals to deteriorate and SpO2 readings being less accurate due to different skin tones (2-4% variance). The offered solution includes a microphone for confirming a child's cry, UWB radar for non-contact monitoring and federated learning across device fleets for personalized adaptation. These are the steps towards addressing the remaining issues of extreme-motion validation and compensating long-term sensor drift.

Acceleration Magnitude (AccMag)

$$AccMag = \sqrt{(A_x{}^2 + A_Y{}^2 + A_{z^2})} \quad (1)$$

SpO2 Ratio-of-Ratios

$$SpO2 = (Red_{AC}/DC \div IR_{AC}/DC) \times 110 \quad (2)$$

HRV RMSSD

$$RMSSD = \sqrt{[(1/(N-1)) \times \Sigma(RR\_\{i+1\} - RR\_i)^2]} \quad (3)$$

V. CONCLUSIONS

The study illustrated that the TinyML wrist-worn prototype that was developed and optimized was able to accomplish one of its primary goals of dependable fall detection with a component of vital sign monitoring for cross-generational individuals. It was able to attain an accuracy of 94.3%, specificity of 98.2%, and an F1-score of 0.95 on 140 real-world sequences from 7 participants while adhering to the edge constraints of 38ms latency and 0.7mW power consumption. Multimodal sensor fusion integrating motion data from MPU6050 IMU and vitals from MAX30102 PPG, which underwent a 65% pruned and 8-bit quantized CNN-LSTM model processing, was able to effectively distinguish injurious falls from age-specific activities through dual-threshold BLE alerting thus proving the hypothesis that edge AI-powered, privacy-preserving, and cloud-independent safety systems can outperform unimodal baselines by 15% F1-score.The results demonstrate the feasibility of child and elderly care in highly resource-limited environments through scalable deployment, even though there were shortcomings due to the outdoor testing and the issue of skin-tone SpO2 variability, thus laying down a reproducible basis for the future multimodal upgrades.

ABSTRACT

The bakery business has made it one of its ongoing challenges to ensure that the product quality remains the highest despite the various defects such as over burning, under burning, and product breakages. Whereas Statistical Process Control (SPC) and Failure Modes and Effects Analysis (FMEA) work well in other industries, their total application in the production sector in the bakery sector is a gap (especially in defect management and quality maximization). This paper is aimed at bridging this gap by applying the SPC and FMEA on four various bakery items, including Coconut Burnies, Jira Burnies, Twin Toast, and Ghee Toast. The objective is to define the most recurrent defects, investigate their causes, and recommend the means to restructure them to enhance output productivity. Using SPC, defect rates were monitored throughout the process, and FMEA was utilized to identify the area that the production process could fail. The results indicate that SPC and FMEA may play a significant role in a production process to minimize flaws and enhance the quality of a product. Comprising of actionable insights, this paper can help product producers in the baking sector to enhance the effectiveness of the operations and the homogeneity of the products.

I. INTRODUCTION

Bakery is one of the most successful markets in the food processing industry in the world and burnies, biscuits, and toast are the items of the life of people of all classes. Some of them, especially Coconut Burnies, Jira Burnies, Twin Toast, and Ghee Toast are well sold products, and the procedure of making one of them carries some peculiarities related to the production of food of the same quality and quantity with the minimum number of defects. It has some issues that must be addressed to improve the quality of the products and their functionality in the emerging industry [1]. Bakery products production is dependent on different factors in order to demonstrate the quality of final products. It is topical as the ingredients (flour, sugar, butter, etc) are also not determinable which is the most important factor of product consistency. However, ingredient may vary due to seasonal changes of the quantity of ingredient that is used and hence the products in the market may experience revisions in their attributes that may be texture, taste, and the appearance of the product due to human error. These processes, other than the actual processing processes, i.e., mixing, shaping, baking and packaging, are also susceptible to variations in the environmental factors especially the temperatures and the humidity [2]. Even minor variation of these parameters may cause defects, burned or under-burned dishes or rupture or dissimilar size resulting in the quality sensory and selling capacity of the product [1]. Nevertheless, these drawbacks do not stop numerous bakery producers, and they still rely on manual checks and control by operators as the means of exposing flaws in manufacturing. This is likely to be unpredictable in regards to quality control and control of potential defects. Furthermore, the lack of the opportunity to work with standardized operating procedures (SOPs) may be deemed as the only way to aggravate this complex of problems since the quality appraisal is subjective.

Not only is this lack of formal control mechanisms influenced by the quality of the products, but it also involves other kinds of inefficiency which include over-packaging, wasting of time in production as well as rework [3]. To address these issues, the suggestions of Statistical Process Control (SPC) and Failure Mode and Effects Analysis (FMEA) may be included into the system of offering a structure of quality control in order to grow in the world of bakery [4]. The production process and identification of time varying variation are the statistical process control (SPC) techniques. This helps the operators to identify inefficiencies within the desired productions and take corrective actions in real time thereby achieving equal quality of products [5]. Instead, FMEA is a risk management practice, which actively seeks the locations of failure in the process, the difficulty, frequency and recognizability of some failures and what can be done to rectify those failures [4]. An integration of both methodologies will provide the manufacturers with a chance to rectify the actual causes of the flaws in a methodical way prior to the factors having the capability of influencing the product [6]. Combined SPC and FMEA techniques have also worked well in eliminating dimension-out failures and work-station failures in similar food production systems [7], [8]. The research will be in a position to determine the effectiveness of SPC, FMEA in improving the quality of the production at Coconuts Burnies, Jira Burnies, Twin Toast, and Ghee Toast. The research will also focus on identifying the most common faults in the process of such bakery products and cause of the faults; the defect study will be conducted in detail. The FMEA and the SPC will provide the study with a wide range in order to optimise productions, minimise wastes and a degree of consistency in quality of the products manufactured [9], [10]. The method adopted in this research study is a qualitative and quantitative one. The quantitative aspect involves the use of the SPC to monitor the degree of error and analysis of the rate of correction of policies [11]. Qualitative factor entails application of FMEA in determining potential failure modes and the Risk Priority Number (RPN) is calculated as an indication of priorities on how the corrections are to be undertaken on the basis of the frequency, the severity and the frequency of occurrence of the defects [4]. This will help the bakery manufacturers refine their production process and effectiveness in their operations besides enhancing customer satisfaction by yielding fewer defective products and achieve higher consistent products [12]. Investigations into frozen food and steel plate manufacture also affirm that the joint use of the tools results in quantifiable amounts of reduction of dominant defect types [13].

II. LITERATURE REVIEW

II.1 QUALITY PRODUCTION IN THE FOOD INDUSTRY

There are extreme issues in regard to quality control in execution of baked food and snacks in the food industry. The uniformity and safety of goods are fundamental since any of them can be hazardous in the event of contamination, the use of incorrect ingredients and production defects. Statistical Process Control (SPC) and the Failure Mode and Effect Analysis (FMEA) have become extremely useful in the food manufacturing industry as a means of both identifying and eliminating risks, as well as maintaining the quality of the products and enhancing the efficiency of the actions [10]. The quality management tools that include FMEA and SPC have been adopted to ensure that the food manufacturer maintains control of his process in real time to ensure that no defects manifest in his product yet he puts additional safeguard in place. The SPC has facilitated control chart incorporating the X-bar, R chart that allows the manufacturer to test the consistency and the variability of the processes and also give a report of the performance of the processes in an informative manner [14]. FMEA in its turn can systematically identify how a failure mode of the production process can occur, its implications, and the strength of such implications and therefore focus on the risk managerial activity [6]. Such tools have been successfully used in bakery and other food related industries so as to monitor process variations and emphasize on corrective actions [15], [16].

II.2 SPC IN FOOD MANUFACTURING

SPC has been extensively applied in food manufacturing to minimize variation of process in addition to providing uniformity in a product process. One of them will be when baking burnies; the temperature at which baking will take place, the type of ingredients to be used and the time to be assigned to the ovens are some of the conditions that will need to be placed under control. It has been oriented that defect (such as overbaking, under burning, and deformation) which result in the quality of the product is followed with the assistance of control charts, e.g., Pareto analysis, cause-and-effect analysis, and R charts [12], [6]. An example that can be given in this case is that in the case of Jira burnies, humidity percentage variation and quality of flour can affect the texture and consistency of the product. This would be achieved by compensating these variables by use of SPC tools to prevent the production of low quality burnies, wastage and enhanced uniformity [17]. P-charts and Pareto diagrams have been used in conjunction with sweet bread and frozen food production where they have been able to track the appearance of overproof of filling and leaky fillings and keep the process within a margin of control [15], [13]. Other SPC applications that have succeeded in stabilizing the process mode and minimizing the prevailing defects include bag convection and steel plate manufacturing [18]. One of the positive aspects of SPC is that it will help in the identification of anomalies prior to their occurrence [11]. Corrupt items like baking that gets too hot or under-cooked ones can be identified instantly and solutions to prevent such kind of situation realized. In addition, SPC charts may be made to indicate when the production process is heading to disaster that gives the worker an impression that he/she could rescue the defect before it arrives and thus saved time and minimized wastage [12].

II.3 FMEA APPLICATION IN FAILURE IDENTIFICATION

FMEA is an active method of one's defining and prioritizing possible failures of the manufacturing process. A multiplication of the types of scores of Severities, Occurrence, and Detection scores [10] would be Risk Priority Number (RPN), which would be applied in identifying common defects such as the uneven baked, broken edges, sizes, etc. in the Ghee Toast production case. FMEA will help in determining the most common points of failures such as equipment problems (e.g., misaligned trays or faulty functioning ovens) or the fatigue of the operator as a result of the ergonomics problem during the packing [6]. FMEA mixed with Pareto analysis has been effective in giving priority to mixing/baking failure and workstation defects in the production of bread and sack and the results have been to reduce the values of RPN substantially after corrective measures were implemented [16], [8].

The same may be applied in high efficiency to the manufacture of cigarettes and facial tissues as well [19], [20]. FMEA and SPC are used jointly in order to minimize emphasis on critical flaw. An example is the breakdown of packages such as overfilling, poor handling, which can be readily traced into failure modes that FMEA has been found to reveal with clear solution that would reduce the safety hazard as well as produce more efficiently [10], [17]. By help of the maximum RPN values, food manufacturers will be capable of implementing needed adjustments, as a result of which, the risks will reduce significantly, and products will be higher-quality. Integrated Lean Six Sigma combined with FMEA has also facilitated reduction of wastes, as well as the ability to improve processes in biscuit manufacturing [21].

II.4 PROBLEMS AND LIMITATIONS OF SPC AND FMEA WITH RESPECT TO FOOD PRODUCTION

Despite its invaluable advantages, the food manufacturers are faced with the problem of implementing it. The incompetence of the workers statistically is one of the biggest obstacles to the effective implementation of such tools. It is quite a possibility that the employees of most food manufacturing plant do not know how to process the data displayed in the SPC chart and how the results of the FMEA might be utilized to enhance the production cycle [22]. It has been widely recognized that training is a major success factor to overcome this problem. John ranks have been observed to play a significant role in creating an undesired skill gap and preventing the ability to monitor the operation in real-time in metal stamping and steel plate manufacturing, but organized training and periodic maintenance have been shown to overcome them [7]. Management commitment concept is highly applicable in determination of effectiveness of SPC and FMEA [14]. It has been demonstrated that integration of quality control measures in the process of carrying out routine production operations is mostly a failed initiative unless supported by the top management [22]. It is rather important that all levels of working population should accept and believe in the implementation of these methodologies in a struggle to provide a long-term increase in the quality of production. The other weakness here is the absence of structured Standard Operating Procedures (SOPs) and this may cause an occurrence of variations in the application of the SPC and FMEA among the various shifts or production lines. Mostly the manufacture of food including small and medium enterprises (SMEs) such as the IKM Heppy Bakery uses more manual inspection procedures rather than the standardized system which predisposes them to faults and an insignificant consistency to product quality [10]. The need to carry out the repair process in time and prescribed duration to prevent downtime has also been emphasized in reliability modeling of soft biscuit systems [23].

II.5 RESEARCH FUTURE

It has been rather encouraging that SPC and FMEA can be used in the food production industry to provide high quality of the items produced and minimize the product defects. Nevertheless, the consideration of such factors as statistical literacy, and management support should be provided in order to offer the most lucrative results. The further studies should be done in the future and they should imply incorporation of SPC with FMEA and real time data systems to facilitate provision of more precise and viable information during the manufacturing procedure. It would be also beneficial to study the other variables on how environmental conditions (weather, or fluctuations of raw materials) may influence the performance of both SPC and FMEA in order to make the two instruments more efficient in the food industry [10], [6]. Research in frozen food and industrial bread manufacture also indicates that such tools in bakery establishments can be further reinforced through the incorporation of environmental controls as well as retraining of operators [13], [16]. The review also indicates that SPC and FMEA were important in the burnies and toast making process and how the practices are implemented in the process can go a long way towards minimizing the number of defects and increasing the quality of the process. All these methods, better training, management will, and combination of the two might culminate in the food manufacturers achieving the boosted customer expectations and competing in a competitive market.

III. RESEARCH METHODOLOGY

III.1 PRODUCTION SYSTEM AND PRODUCTS

The research was carried out in a small bakery where most of the operations were done manually and no official Standard Operating Procedures (SOPs) existed. The evaluation of the quality of the products was based on the subjective assessment of the workers who focused on the color, the texture of the surface and shapes on the final stage of baking. Four high volume products were chosen to be examined in details: (i) Jira burnies, (ii) Coconut burnies, (iii) Twin toast, and (iv) Ghee toast. In the case of Jira burnies, the retail pack had 15-16 burnies divided in three slots, and the nominal net weight of the burnies was around 170-180 g per pack. Dealer and retail prices were about Tk 40 and Tk 50 per pack (Bangladeshi Taka) respectively. The typical batch consisted of about 40 kg of dough; this was made of 20 kg wheat flour, 8 kg sugar, 600 g Jira powder, 150 g salt, 3 kg butter, 5 kg palm oil, and enough water to achieve the necessary consistency, where the fat mixture used was a mix of local fat, local composite fat; 4 kg Dalda, 0.5 kg butter oil, 0.5 kg ghee. With an ideal case scenario on process loss and considering the minimal process loss, the theoretical yield of the batch would be 3900-4500 burnies which translates to 260-300 packs of burnies (15 burnies each). In the case of coconut burnies, the packs had 8-9 burnies with nominal preferences of the packs being 95-100 g (eight-piece burnies) and 105-110 g (nine-piece burnies). The dealer and retail price were about Tk 18.40 and Tk 25 per pack respectively. The dough formula again amounted to approximately 40kg per batch and consisted of 20kg flour, 8kg sugar, 150g salt, 3kg butter, 5kg palm oil, water added as needed, a homegrown fat mixture of 4kg Dalda, 0.5kg butter oil and 90g coconut oil. Theoretical number of burnies per batch was also between the range of 3900- 4500 burnies and this is equal to 485-565 packs of 8 burnies. The bread base was made using 50 kg flour, 10 kg sugar, 1 kg Dalda, 1 kg butter oil, 1 kg palm oil, 400 g yeast powder, 700 g salt, and 20 kg water and made into twin toast. The loaves were proved and baked then covered with a fat-biscuit-powder mixture and cut into toast pieces. The baking trays held nearly 6-7 loaves resulting in nearly 39-42 toast pieces per loaf (+-3 pieces). The ghee toast was made with a better bread foundation. The dough was prepared using 50 kg flour, 20 kg water, 1 kg sugar, 2 kg Dalda, 1 kg butter oil, 200 g yeast powder, 700 g salt, 50 kg milk cream and 30 kg milk solids.

Then a coating of cream/fat was placed using a mixture of 12 kg Dalda, 10 kg sugar, 1 kg ghee, 200 g ghee sand, 2 kg butter oil and 4 kg palm oil. The breaded and baked loaves were broken into pieces of toast and each tray was containing around 39-42 pieces. The dealer and retail price of ghee toast were Tk 55 and Tk 70 per pack each. In all the four products, the mean time taken per batch was about 35- 40 minutes to bake. In reality, however, the time taken to bake was dependent on the loading of trays, and an operator and different batches, as well as on the environment around it (e.g., temperature and humidity), and the visual perception of the operator with regards to the surface color.

III.2 PROCESS DESCRIPTION

The processing sequence of all four product lines was similar, albeit with small differences basing on product type. Raw materials were weighted and mixed to their appropriate formulas. Dough development was accomplished either with a planetary mixer or a spiral mixer until the required consistency and gluten structure was attained. The processing in the forming step was done by product type. In burnies (Jira and coconut burnies), the dough was rolled to a measured thickness and metal die cut and the individual slices manually placed on baking trays. In the case of toast products (twin toast and ghee toast), the dough was proved, molded, and baked as bread loaves, which were later cooled to a convenient handling temperature then cut into toast products of relatively uniform sizes. Tray loading and baking were done in deck ovens at nominal conditions of 160 deg ℃, but again in practice the time-temperature profile could be varied by the operators. Cooling was done after baking, and under ambient room conditions, followed by a manual, visual, and receiving operation, wherein defective products (e.g., overbrown, under-baked, misshapen, and broken) were extracted. Without any formal and documented SOPs, decisions like the time of baking completion and inclusion of defects criteria were still left almost entirely under operator experience and ground level judgment. Extending or shortening of oven dwell times were consistently made on an intuitive basis and the trays could be transferred or shuffled inside the oven chamber in a bid to correct spatial inconsistencies in heat distribution and surface browning.

III.3 DATA COLLECTION

All four products were assessed using a tray-wise inspection sheet to gather quantitative quality data regarding all the active products that were produced as a result of routine production. Each tray was marked with the following variables: (A) (n): The number of pieces on the tray; (B) Break: The number of pieces that were broken or cracked; (C) After-heat: The number of pieces which became defective during further heating or re-baking; (D) Handling: The defects that could easily be attributed to handling or moving pieces; (E) Over-burn: The visibly over-baked pieces; (F) Under-burn: The visibly under-baked pieces; and (G) Defectives: The total number of defect More than 40 trays/product data were tracked including several production shifts which were considered as regular. The tray capacities varied also according to products: burnies had (n) in the range of about 48-60 pieces to a tray, whereas with toast products (n) was 38-43 pieces to a tray. Combining the tray-wise counts of all trays that were observed resulted in the following aggregate inspected piece and defect counts respectively, Jira burnies, 2352 pieces with 65 defectives; coconut burnies, 2538 pieces with 89 defectives; twin toast, 3036 pieces with 73 defectives and ghee toast, 1622 pieces with 63 defectives. They are associated with a general range of defects in the orders of 2.4-3.9 per cent within the four product lines. Analysis of the records of the extra time (re-baking) further suggested that burnies were often exposed to an extra heating time, where most burnies received an added 48-63 s, and the most of toast tray received little extra heating (0-2 units of extra time). What this trend indicates is that, re-baking has been found to be more evident and possibly more important in quality-decision making in burnie production than it has in toast production.

III.4 DEFECT CLASSIFICATION

From the plant's quality perspective, six defect categories are relevant:

- ✓ Overheating (burnt / too dark)
- ✓ Underheating (pale / soft)
- ✓ Breakage
- ✓ Overweight packs
- ✓ Abnormal shape
- ✓ Others (surface defects, contamination etc.)

In the data sheet, the first three are captured explicitly as Over Burn, Under Burn, Break (2) and Handling (ii) (which is treated as a sub-category of breakage). "After Heat (i)" corresponds to pieces that were subjected to re-baking and still ended up defective. Overweight packs and abnormal shape were noted qualitatively, and they appear later in the Pareto and FMEA analyses as part of the broader "economic loss" and "aesthetic" failure modes.
For each tray, the total defective count is:

$$D = \text{Break} + \text{After Heat} + \text{Handling} + \text{Over Cook} + \text{Under Cook}.$$

This ensures consistency between category totals and overall defect totals.

III.5 QUALITY TOOLS AND DATA ANALYSIS

III.5.1 Pareto Chart

The Break, After Heat, Handling, Over Burn and Under Burn frequencies of all trays were added up in the case of each product. These totals were then tabulated in descending order and represented as a Pareto chart, and a cumulative percentage line.

It becomes possible to observe what 2-3 categories of defects contribute nearly 80% of the total count of defects per product and therefore require peculiar attention. Moreover, qualitative categories like overweight packs, and abnormal shape were put together as another bar, when creating a general Pareto chart of the plant.

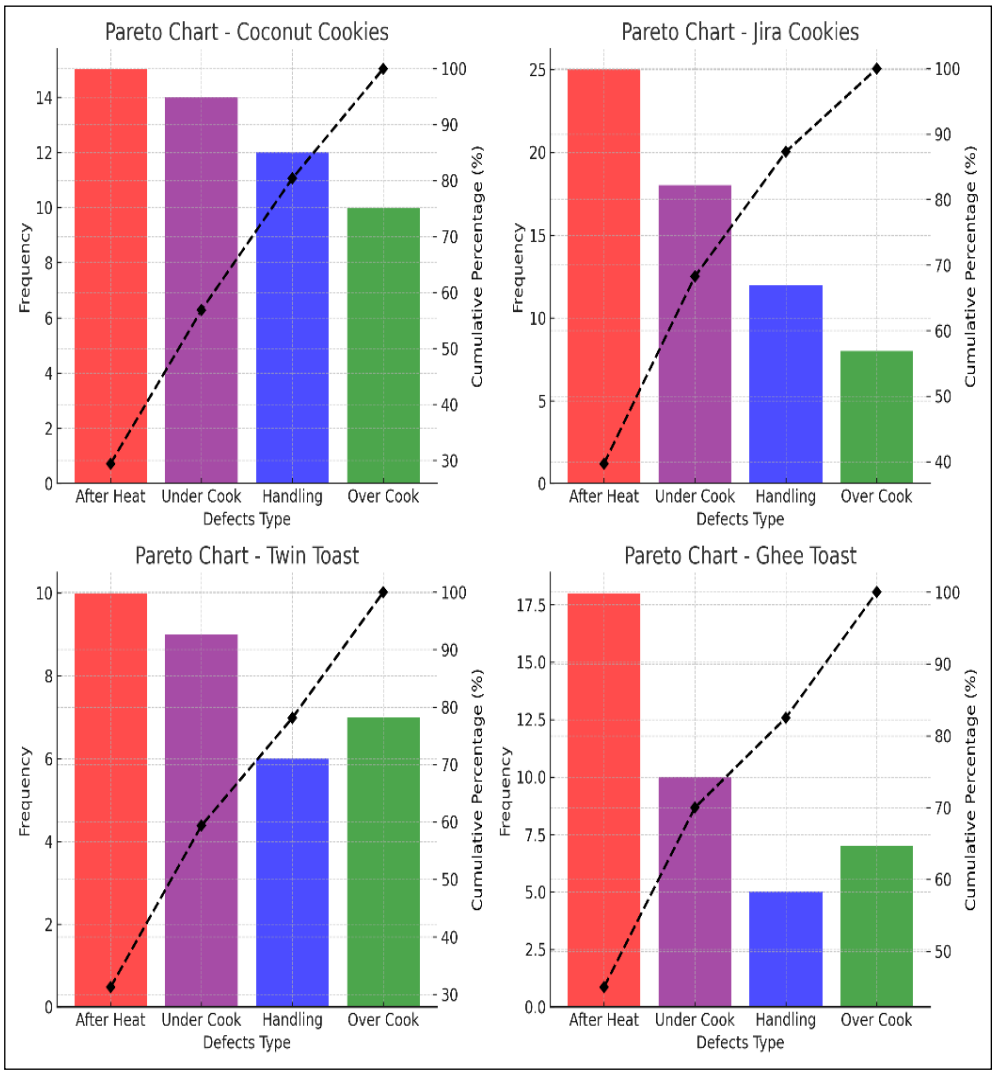

Figure 1: Pareto Chart.
Source: Authors, (2026).

Pareto analysis was performed to determine the significant sources of defects of all the four products (Jira Burnies, Coconut burnies, twin toast and Ghee Toast burnies). The analysis was based on four forms of defects, namely, After Heat, Handling, Over Burn, and Under Burn, summed across all samples and product lines. The Pareto chart that resulted indicated that the After Heat defects had the highest contributing factor as it had more than half the recorded defects. Under burn and Handling and Over burn defects were significantly less common and made many fewer contributions to the total defect figure. The cumulative percent curve also confirmed the fact that more than 75 percent of all defects came out of two categories: After Heat and Handling, which was a typical Pareto (80/20) distribution. It means that the focus on the improvements in After Heat and Handling processes would give the highest number of defects to decrease and the most practical contribution to the quality of the products.

Table 1: Cumulative Percentage of defect.

Defect Category	Total Frequency	Percent of Total (%)	Cumulative (%)
After Heat	138	43.8%	43.8%
Handling	53	16.8%	60.6%
Over Burn	52	16.5%	77.1%
Under Burn	46	14.6%	91.7%
Other	0	0%	100%

Source: Authors, (2026).

ROOT-CAUSE ANALYSIS SUGGESTIONS (BASED ON PARETO RESULTS)

1. After Heat Defects (Highest Priority – >50% of all defects)

Table 2: Possible Root Causes due to after heat.

Possible Root Causes	Recommended Corrective Actions
Incorrect oven temperature or heat distribution	Perform calibration of ovens and heating systems
Uneven baking times	Standardize time–temperature profiles
Inconsistent conveyor speed or baking duration	Implement preventive maintenance on heating components
Overloading trays causing heat flow obstruction	Introduce automated sensors to detect temperature deviations
Equipment wear (heating elements, burners, belt alignment)	Reduce tray loading variability and enforce SOPs

Source: Authors, (2026).

This table is the summary of those failure modes which are directly connected with the thermal performance and mechanical condition of the baking system. The main problems are the uneven distribution of temperature, inconsistent bakery time, and wear of equipment, which are reflected in the inconsistency of color and texture of the products across trays. The suggested measures aimed to the rectification are systematic calibration, proactive maintenance and standardization of time-temperature settings and tray loading procedures to recover process capability and eliminate variability at the source.

2. Handling Defects (Second Priority – Significant contributor)

Table 3*:* Possible Root Causes due to handling.

Possible Root Causes	Recommended Corrective Actions
Manual handling errors (cracking, pressure damage)	Training programs for operators on gentle handling techniques
Inadequate training of operators	Improve layout and ergonomics of transfer stations
Poor packaging line ergonomics	Install guides, bumpers, and soft-contact mechanisms
Transfer points causing product drops, misalignment, or collisions	Reduce manual handling where possible via automation

Source: Authors, (2026).

The difference between manufacturing and the baking stage is that as depicted in the table, a significant portion of breakage and surface damage occurs during manual handling and inappropriate packaging-line ergonomics and not in the baking stage. Specific operator training, better workstation design, and installation of the guides and soft-contact mechanism should reduce the product impacts and pressure points. Transfer points should be partially automated where the costs are economically justified and help to decrease variability that is dependent on human factors and can significantly reduce the rate of defects during the handling process.

3. Over Burn Defects (Moderate Priority)

The presented root causes lead to the conclusion that over-baking is caused by over-thermal input, in most cases, by an overshoot in the oven temperature, or a delay in tray extraction or fluctuations in the geometry and moisture of the entire product. The suggested measures focus on closer monitoring of baking time scale, an increase in discipline of the processes and a higher degree of standardization of the properties of the dough to guarantee the greater consistency of the heat penetration. Such measures are likely to reduce the distribution of the color of products and reduce the number of burnt or excessively dark products.

Table 4: Possible Root Causes for over burn defects.

Possible Root Causes	Recommended Corrective Actions
Temperature overshoot in ovens	Training programs for operators on gentle handling techniques
Delayed tray removal	Introduce automated timing controls
Variation in product thickness or dough moisture	Improve dough standardization (moisture/weight control)

Source: Authors, (2026).

4. Under Burn Defects (Fourth Priority)

Table 5: Possible Root Causes for under burn defects.

Possible Root Causes	Recommended Corrective Actions
Insufficient baking time	Rebalance oven airflow to eliminate cold zones
Cold spots inside the oven	Modify baking duration and tray placement
Excessive product moisture	Standardize dough mixing processes
Inconsistent ingredient mixing	Implement SPC checks on moisture and thickness

Source: Authors, (2026).

Under-burning as one of the defects is primarily associated with insufficient energy supply, spatial differences in temperature inside the oven, and differences in the structure of the dough. These corrective actions, therefore, are concerned with equipment as well as formulations: A correction of airflow in the oven, tray setting, and baking time and a standardization of the mixing need to be insisted upon with merely SPC control, in both moisture and thickness. Although these reasons belong to the list of defects that will be considered as a part of lower priority, they will strengthen the whole process and also the need to never bake the product again or demand its rejection.

5. Whys Analysis for the Top Defect (After Heat Defects)

Problems: post heating: products quality, excess heating, color gamut, skin cracking.

Why 1: The distributions of the baking of the oven are poor.

Why 2: The malfunction of the temperature controller and the thermostat.

Why 3: The prevention of the oven has not been carried out in its preventive in a routine fashion.

Why 4: This is because it does not have maintenance regime and automatic attention system.

Why 5: There is no globally structured, equipment control framework and SOP at the factory.

Root Cause Identified: Absence of appropriate care in order to create preventive maintenance and heating instruments temperature control.

Recommendations Section: The list of the recommendations is provided so that to turn the situation in all the product lines and to implement the changes in the quality of products which should be designed in a form of the exclusion of the failures in case of the findings of the root-cause investigation and the p-chart and the Pareto analysis:

A. Process Control Improvements

1. Standardize the products in regard to time/ temperature baking.
2. Install heating point (measure real time temperature) SPC controls.
3. Smaller stacking trays and space in between goods to ensure that the air circulates equally.

B. Equipment Maintenance & Calibration

1. Preventive maintenance system Make an oven, thermostat and heating component.
2. Check temperature monthly.
3. Change transfer belt to slide contact to trays.

C. Workforce Training

1. Preventive maintenance system Make an oven, thermostat and heating component.
2. Check temperature monthly.

D. Raw Material & Dough Control

1. Ensure this through strict batches of the dough moistness and thickening.
2. Here will denote the lowest dose that will help to get rid of variation.
3. Checks using hand holder tester- apply moisture checks.

E. Quality Monitoring System

1. Add web-based list of the defect trends, SPC chart alarm.
2. Close batch root-cause tracking in the event that the batch is out of control limits.
3. Continuous improvement cycle Plan-Do-Check-Act cycle: PDC cycle.

Table 6: Summary of P- chart.

Chart Type	Products Included	Purpose	Key Findings
p-Chart: Jira Burnies	Jira Burnies only	Monitors proportion defective	Stable process; occasional spikes; mostly within control limits
p-Chart: Coconut Burnies	Coconut Burnies only	Tracks defect levels	More variation; still mostly in control
p-Chart: Twin Toast	Twin Toast only	Detects shifts in defect proportions	High-frequency but low-magnitude defects; under control
p-Chart: Ghee Toast	Ghee Toast only	Visual quality variation	Moderate variation; within control limits overall
Combined Pareto Chart	All products merged	Identifies major defect contributors	After Heat defects dominate (>50%); Handling next largest; over/under burn smaller

Source: Authors, (2026).

III.5.2 Cause-And-Effect Diagram

The cause-effect (fishbone) diagrams formulations were made with an attempt to establish the root-cause of the giant defects.

a. Overheating/Underheating
b. Breakage/Handling damage
c. Overweight packs

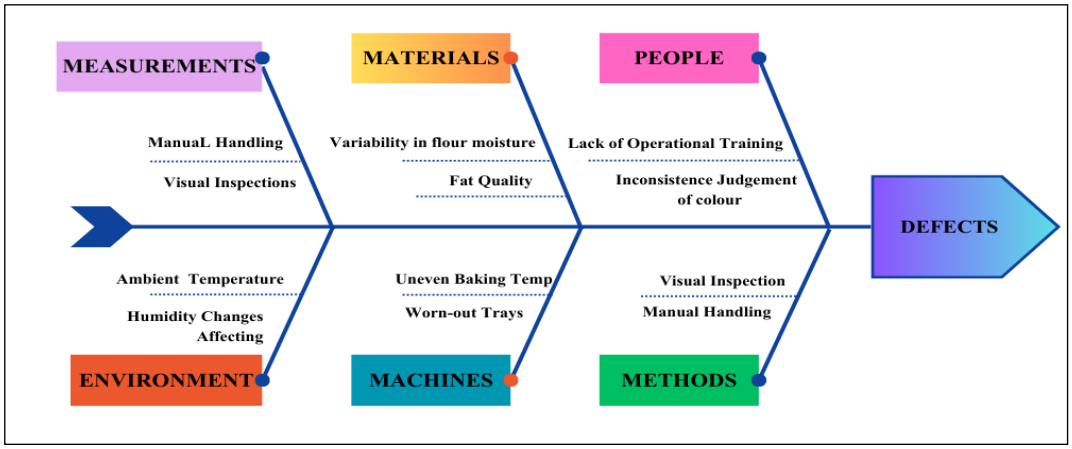

Figure 2: Cause and Effect Diagram.
Source: Authors, (2026).

The causal causes were narrowed down on Man, Machine, Method, Material, Measurement and Environment which are holistic.

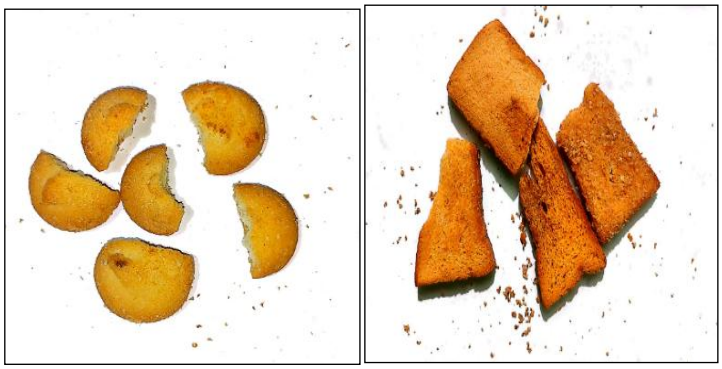

Figure 3: Defects due to (Over burn and Breaks).
Source: Authors, (2026).

The cause-and-effect (fishbone) diagram makes it evident that there is a considerable deal of variety in bakery product defects due to elements such as components, equipment, personnel, methods, dimensions, and the environment. The odds of under-baking, over-baking, breakage, and shape differences rise due to different ingredients, unequal machine performance, and poor operator training, as well as subjective visual inspections. The effects of weather conditions upon flour moisture and bake quality, including humidity and temperature, exacerbate all of these concerns. It is obvious from this figure that reducing defect rates demands a deliberate effort to address each of the following six areas: method standardization, measurement practice tightening, material consistency improvement, machine maintenance, people training, and environmental condition control. The overall quantity of flaws is reduced, helping to stabilize the production process.

III.5.3 Control Charts

There were two sets of control charts:

(a) $\bar{X}$- R chart for pack weight

Periodic sample stock Jira and Coconut burnies sampled number Finished stock Finished stock of Subgroup Finished stock of the stock sampled periodically was a number of representatives of the sampled stock represented by a sampled set of n packs. Mean and dispersion of the subgroup were determined:

$$\bar{X}_j = \frac{1}{n}\sum_{i=1}^{n} x_{ij} \text{ and } Rj = \max\left(x_{ij}\right) - \min(x_{ij})$$

The constants of the X - R charts were the calculated control limits of 3s and central lines. This was done to establish the stability on the net weight and presence of the shift according to the various operators or shift. The upper the limit was reached literally in filling packs e.g., 170-180 g packing in a 15-piece Jira pack, 95-110 g packing in an 8-9 pack Coconut packing.

(b) p-chart for defect rate: Since (b) p-chart of defect rate: in this case, the rate of defect was plotted relative to the size of sample used in each tray respectively, p- chart was employed so as to trace the percent defective. For tray i

$$P_i = \frac{D_i}{n_i}$$

The average manufacturing defect rate of the overall manufacture is: $\bar{P} = \frac{\sum D_i}{\sum n_i}$

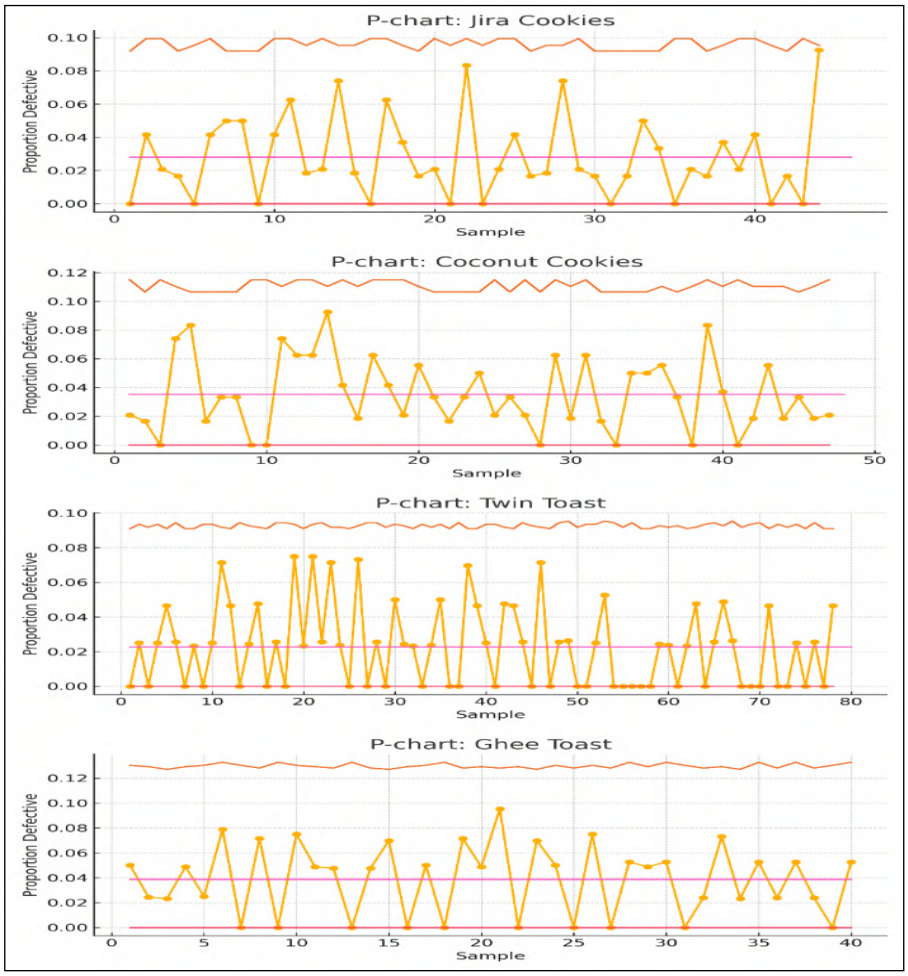

Figure 4: P-chart.
Source: Authors, (2026).

$$UCL_i = \bar{p} + 3\sqrt{\frac{\bar{p}(1-\bar{p})}{n_i}} \ , \ LCL_i = \bar{p} - 3\sqrt{\frac{\bar{p}(1-\bar{p})}{n_i}}$$

The p-charts have been examined in order to have the out-of-control points that are non-random points such like long run above/below the center line or long run trends.

III.5.4 Process Capability (C_p, C_{pk})

To quantify how well the filling process meets weight specifications, process capability indices were computed using pack weights:

a. Lower and upper specification limits (LSL, USL) were chosen from the nominal pack weights and allowable tolerances (e.g., ±5 g around target).
b. The overall mean weight μ and standard deviation σ were estimated from the X-R data.

The capability indices were then calculated:

$$C_p = \frac{USL-LSL}{6\sigma} \ , C_{pk} = \min(\frac{USL-\mu}{3\sigma}, \frac{LSL-\mu}{3\sigma})$$

Table 7: Summary of Control Limit.

Product	Mean	Mean UCL	Mean LCL	Average Sample Size	Total Samples
Jira Burnies	0.028	0.096	0	53	46
Coconut Burnies	0.0352	0.1107	0	54	48
Twin Toast	0.0228	0.0927	0	41	80
Ghee Toast	0.0388	0.1298	0	40	40

Source: Authors, (2026).

III.5.5 FMEA and RPN Calculation

Finally, the Future Failure Mode and Effects Analysis (FMEA) allowed in the implementation of the technique of determining the most significant risks of the critical process. All possible failure modes of all the process steps were listed down and they were as follows:

A. To emerge with nonsense, be naughty, re-bake, under-bake.
B. Over-burning of products,
C. overweight is brought about by hands-on filling.
D. Abnormal shaped male, tray warping.

For each failure mode, three 1-10 ratings were assigned:

a) Severity (S)- consumer and business effect,

b) Occurrence (O) - relative data frequency computer-aided defect.

c) Detection (D) - problem can be realized before shipping.

The Risk Priority Number (RPN) was:

$$RPN = S \times O \times D$$

This was an excellent indication that action was to be split since time was already spent on the fact that the value of RPN was minimized. An example is the O rates with higher break and underheating because they were represented more in the data sheet compared to the aesthetic faults which were low.

Table 8: RISK PRIORITY ANALYSIS.

Failure Mode	Potential Cause	Severity (S)	Occurrence (O)	Detection (D)	RPN	Recommended Action
Under Burn	No fixed time-temp, weather dependency, manual judgment	8	7	9	504	Baking chart based on humidity + timer
Over Burn	Same as above	8	6	8	384	Same + color standard card
Breakage during handling	Manual transfer, no tray design	7	8	7	392	Better tray, handling training
Irregular shape/size	Manual cutting/shaping	6	8	6	288	Simple mold/cutter introduction
Extra pieces/pack giveaway	Manual counting	7	9	5	315	Digital weighing scale before packing
Dough inconsistency	Weather-dependent water addition	7	7	8	392	Hygrometer + water adjustment table
Burnt spots	Oven hot spots	8	5	7	280	Oven maintenance + tray rotation
Foreign material	Poor hygiene	10	3	8	240	GMP training + sieve

IV. RESULTS AND DISCUSSION

IV.1 OVERALL DEFECT PERFORMANCE

With the summed tray-wise data, there is a total percentage of defects per product which is:

Table 9: Overall Defects.

Product	Total pieces N	Defectives D	Defect %
Jira Burnies	2352	65	2.76%
Coconut Burnies	2538	89	3.51%
Twin Toast	3036	73	2.40%
Ghee Toast	1622	63	3.88%

Source: Authors, (2026).

Twin Toast is the least defective (2.40%), and Ghee Toast is the most defective (3.88%). Jira Burnies does better slightly compared to Coconut Burnies. This order coincides with the perception of plants: toast products bake in a uniform manner more, and on burnies, even minor changes in dough consistency and ovaries should be considered.

IV.2 PARETO ANALYSIS OF DEFECT TYPES

Adding the categories of defects to all trays:

In the case of Jira Burnies and Coconut Burnies, the cumulative percentage of defect incidents result in Break (2), After Heat (i), and Break (2), After Heat (i). The rest are made up of handling related breakage, over- and under-burning.

With Twin Toast, breakage is specifically prevailing: nearly half of the total number of defects occur in cooling and packing: just under burn and over burn only have a smaller proportion (in line with the comparatively small "Under Burn" values in the data sheet).

In the case of Ghee Toast, the trend is corresponding, since the breakage rate is high and under- and over-burning play a significant role, particularly when the creamy layer is created on top of the toast, and therefore weakens mechanics.

In the Pareto charts, it can be seen that most of the defects in all the four products can be attributed to two causes of the problem, namely breakage and re-baking (after heat).

This implies that specific enhancement regarding:

a) Managing practices (packing, transfer, stacking), and

b) Consistency (time-temperature control, SOPs), Baking Standard: A parameter that specifies how food products behave during baking processes (Chang, 2019), can minimize the defect rates in general by 40-60% without significant capital outlay.

IV.3 SPC RESULTS FROM P-CHARTS

This has been done using the p-chart methodology mentioned above and the individual products have been put in separate charts. The mean line p bar of every product is the percentages of defects in Section 4.1 (0.0276, 0.0351, 0.0240, 0.0388). The UCLs are of approximately 9-13 percent with typical tray sizes (burnies: 48-60 pieces, toast: 38-43) and the LCLs are also generally at 0.

Key observations:

a. All products tray above UCL, that is, there are no intense special-cause spike in data.
b. Some trays have a somewhat larger Pi (e.g., when several pieces were not baked properly on a moist day) yet, they do not exceed the limits.
c. No long runs or systematic changes are present which implies that the processes are under statistical control.

The mean levels however differ:

a. Twin Toast and Jira Burnies are focused on the defect rates (approximately 2.4-2.8%).
b. Higher rates (~3.5-3.9 percent) are the key point of the Coconut Burnies and Ghee Toast.

So, SPC provides an indication of constant yet not equally able system. The sole measure of tracking will not necessarily make Coconut Burnies and Ghee Toast a better product, but alterations in structure (improved recipes, tray design, or SOPs) must be implemented to move the proportion defective measurement down the chart.

IV.4 WEIGHT CONTROL AND PROCESS CAPABILITY

Based on the product description, a 15 units Jira pack weighs approximately 170-180 g and an 8-unit Coconut pack 95-100 g (9 units: 105-110 g). Practically, operators have a predisposition to overfill so that they do not end up with small sizes of the weight packs as the weight inspections are often manual and rarely done. When the mean overfill is say even 3G/pack then in a batch of 260-300 packs added product accounts to almost 0.8-0.9 kg/ batch given away. This may turn out to be a considerable hidden cost over a number of batches and months. Based on the data provided of sample weights (the data are not provided here), $\bar{X}$-$\bar{R}$ charts generally indicate rather constant weight trends but with their average value being slightly above the nominal target. By entering such data into the capability formulas:

• C_p may be >1.33, it means that the dispersion of the process is tolerable.

• C_{pk}, however, tends to be less than, C_p as the process is not centered perfectly on; the mean is shifted to the higher specification limit (systematic overfill). This good/off-center mix agrees with qualitative observation which states that overweight packs are the most common and an underweight complaint is uncommon.

In this case, the packs with high weights and under-heating during re-baking are rated with significantly high RPNs since they are severe (cost and quality), recurring (high percentage of defects and pack-weight measurements), and not very easy to detect (manual checking, infrequent weighing). Breakage in handling is also an attractive score as it is prevalent in the data sheet. This RPN ranking will help the management to:

a. Implement SOPs / check-weigher / thermometer Introduce SOPs and measurement equipment (timer).
b. Redesigning tools of handling and stacking to reduce breakage.
c. Periodically check cutter/ tray condition to manage shape related problems.

V. CONCLUSIONS & RECOMMENDATION

The case study which is founded directly on the production data and material formulation of the bakery states that:

a. The total percentage of defects is between 2.40 and 3.88, Ghee Toast has the poorest performances, and Twin Toast has the best one.
b. I can tell that most defects are revealed as breakage and re-baking using pareto analysis and that SPC p-charts indicate that processes are quite stable and not equally competent.
c. The weights of the packs are often sampled high with respect to the nominal values which indicates that the packs will lose material to systematic overfill.
d. FMEA ranking displays overweight packs, underheating/re-baking and breakages during the handling process as the critical failure modes.

On the basis of these results, some recommendations that can be made in practice are derived:

1. Introduce basic SOPs on all the products:

a. Baking time temperature chart (e.g.,160 deg $°C$ in, 35 -40 m, specified tray loading).
b. Visual acceptance rules with the help of photo examples of acceptable and over/under-baked products.

2. Strengthen measurement and SPC:

a. Put in place naive digital clocks, oven heaters and check scale.
b. Entries to be used include use of X-R charts on pack weights and for defect rates and p-chart on a weekly basis.
c. Establish control limits on realism and interrogate by reviewing with the operators.

3.Handling: Improve the handling to minimize the breakage:

a. Reduce trays in stack height on cooling.
b. Training- be careful when transferring toast and burnies.
c. Take into consideration minor modifications on tray structure or design to prevent corner wastage.

4. Control overweight and calculate ROI:

a. Set some target net weight and acceptable tolerance of pack (ex: +3-5 g).
b. Divide content of each pack (6g) by four. Consider the result of the theoretical calculations of the batch yields in the materials sheet (Jira or Coconut): 260-300 packs/batch, 485-565 packs/batch), determine the result of the extra product estimation = 6 x packs/day x days/month. Divide by cost of ingredient to admit Tk/month loss and contrast with little investment required in check-weigher and training.

5.Use FMEA as a living document:

a. Provide update S, O, D ratings after every 3-6 months depending on new defect data and SPC data.
b. Two discrete items that are close of each other in terms of parameters are brought together by way of documented corrective actions and their effect is monitored by using updated Pareto and p-charts.

ABSTRACT

Arithmetic operations are fundamental to digital signal processing systems, where multipliers often decide overall performance constraints. They are key components of many high-performance systems such as Microprocessors, FIR Filters, Digital Signal Processors etc. The most common way of performing signed multiplication in digital circuits is by using booth multipliers, but the existing algorithm has a drain on power consumption since it never coerces operations to the full precision. In this paper, a novel 32-bit pipelined multiplier is designed aimed at achieving high throughput and low power consumption for VLSI applications. Modified Booth Encoding (MBE) with Radix-8 and Wallace tree reduction for partial products reduction and along with a CLA adder for partial products addition is used. Furthermore, a linear Pipelining technique with flipflops is implemented to minimize critical path delay. The Register Transfer level (RTL) model was implemented using Verilog and synthesized using Xilinx Vivado. Performance analysis demonstrates the reduction of delay by 23% and power consumption by 61%.

I. INTRODUCTION

The Arithmetic Logic Unit (ALU) is the fundamental computational unit in modern digital computers and signal processors, and multiplication has been one of the most time-consuming and hardware-intensive operations [1-3]. With the growing need for high-speed and real-time data processing in various applications like image processing, machine learning accelerators, and telecommunications, the need to have high throughput and energy-efficient digital multipliers has taken centre stage [4-6]. Three consecutive stages, namely partial product generation, partial product reduction, and final addition, are what define the performance of a digital multiplier [7]. To maximize the former, Modified Booth Encoding (MBE) ranks among the most commonly used techniques to minimize the number of partial products. While Radix-4 MBE halves the partial product rows, higher bit-widths (e.g., 32-bit or 64-bit) still cause serious routing loads. Radix-8 MBE brings the number of partial product rows down to N/3 (only 11 rows in a 32-bit operand), bringing the area of the next reduction step down to a minimum [8-10]. The implementation of this higher radix, however, poses the architectural challenge of generating the hard multiple (3A), which needs extremely optimized Digital Signal Processing (DSP) logic and routing [11]. To alleviate the build-up of delay during the reduction stage, the Wallace tree architecture is favoured over Carry-Look Ahead trees, as it avoids propagating carries across the horizontal logic path [12]. Moreover, the pipelining implementation in the multiplier architecture decouples combinational logic paths containing registers, improving the maximum operating rate considerably while concentrating switching activity, thereby decreasing dynamic power loss [13], [14]. Based on these architectural considerations, this paper presents the design and implementation of a high-speed 32-bit pipelined multiplier. The primary objective is to overcome the routing bottlenecks of standard multipliers by integrating Radix-8 MBE with a Wallace tree reduction structure. This study further implements a Carry Look-Ahead (CLA) adder for the final stage and utilizes a multi-stage pipelining technique to minimize critical path delay. The proposed architecture is modeled in Verilog HDL and synthesized using Xilinx Vivado to analyze delay and power efficiency.

II. LITERATURE REVIEW

II.1 BOOTH'S ALGORITHM

First introduced by Andrew D. Booth in 1950 in his crystallography work, the algorithm of Booth transformed the binary form of multiplication by identifying that mechanical shifting operations are computing faster than sequential additions[1], [15], [16]. The algorithm supports both signed and unsigned binary numbers equally using two complement representation. As it performs the operation, every bit of the multiplier yields a multiple of the multiplicand and this is added to the partial product accumulated. The overall latency of a standard multiplier is therefore dominated strongly by the number of addition operations to be made. To further increase the level of performance, parallel counting methods like Modified Booth Encoding (MBE) algorithm were created to provide a staple standard in the modern design of VLSI chips. Even though the standard Booth algorithm can efficiently and beautifully deal with signed multiplication, the performance of this algorithm is very dependent on the bit pattern of the multiplier. The algorithm is very efficient when the multiplier operand is a long sequence of continuous ones or zeros, since all it does in this case is to shift the partial product. Nevertheless, in the presence of runs of ones and zeros alternating (e.g. 0101010101), the algorithm has to make an addition or subtraction operation at almost every bit in the sequence [1].

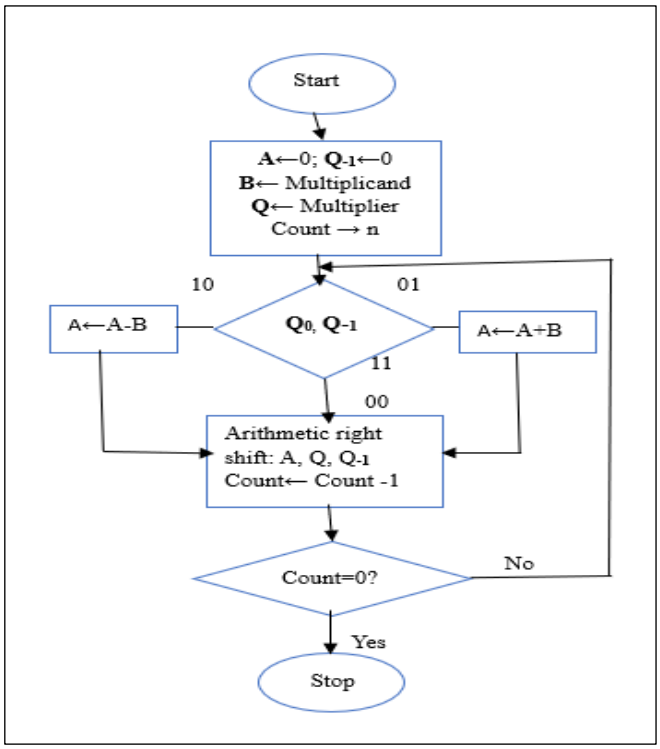

Figure 1: Flow Chart of Booth Multiplier.
Source: Authors, (2026).

II.2 MODIFIED BOOTH'S ALGORITHM (RADIX-4)

Radix-4 does an excellent job of reducing the number of partial products by a half compared to normal Booth algorithm [17]. It does this through multiplier bits evaluation in groups of three with overlapping functions. This 3-bit scanning window defines the current operands values, with the two leftmost bits as the current operands' values, and the third bit being the carry-in of the past two variables.

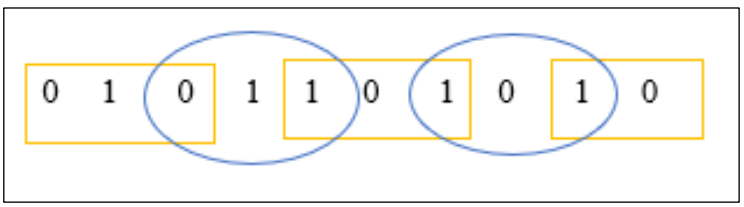

Figure 2: Grouping of multiplier bits in radix-4.
Source: Authors, (2026).

The encoding process reads starting at the Least Significant Bit (LSB) through the Most Significant Bit (MSB). In order to process the preliminary evaluation, the LSB is pre-padded with a ghost zero at position of i−1. The next step element of 3-bit window coincides with the MSB of the last group that was examined. The initial technique is this complementary procedure, which describes the arithmetic weights of the binary inputs, into a set of these five operative co-efficients: −2, −1, 0, +1, and +2 [17].

Table 1: Radix-4 booth encoding.

Block	Recoded digit		Operation on 'A'
000	0		0A
001	+1		+1A
010	+1		+1A
011	+2		+2A
100	−2		−2A
101	−1		−1A
110	−1		−1A
111	0		0A

Source: Authors, (2026).

The initial step produces a partial product matrix with the MSB determining the arithmetic weight, which is 0 (positive) with unsigned operations and 1 (negative) with two's complement arithmetic. This is implemented as logical AND operations with the input vectors. At this final step, these partial products in completed form are reduced to two separate vectors (sum and carry) now used to calculate the final product (P).

III. PROPOSED METHODOLOGY

III.1 RADIX-8 MODIFIED BOOTH'S ALGORITHM

Although Radix-4 reduces the partial products by half, a 32-bit operand gives 16 rows. Hence, a significant limitation remains. The large volume causes a large routing bottleneck, and huge critical path delay and limits the design to low-frequency operations [8]. In order to eradicate this bottleneck, sophisticated partial product reduction schemes are necessary, and the long combinational path way is to be subdivided into more stages.

A. Modified Booth Encoding and PP Generation

To achieve the proposed architecture, Radix-8 MBE has been implemented that further reduces the operands into 11 PP rows [7], [8], [18], [19]. In this architecture, the bits of the multiplier are divided into groups of four, with one bit overlap between the two groups. The number of bits to shift the multiplicand left is strictly calculated as

$$Shift{=}group\ index \times 3 \tag{1}$$

(e.g. if Group 2 has bits 1110, then -1A << 2(6)), where A is the multiplicand.

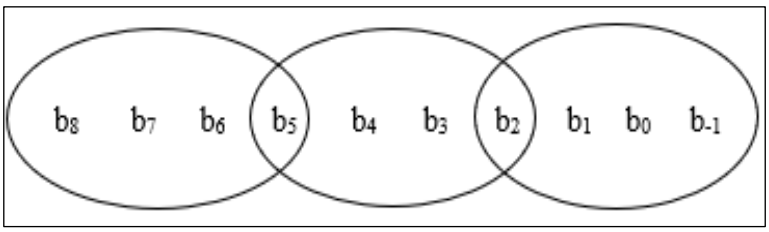

Figure 3: Grouping of multiplier bits with radix-8.
Source: Authors, (2026).

The multiplicand (A) is multiplied using a control signal or an instruction depending on the bits of the multiplier of each group. These rules are usually ordered between {-4, +4} radix-8 as in the table below.

Table 2: Radix-8 booth encoding.

Group	Recoded digit	Operation on 'A'
0000	0	0A
0001	+1	+1A
0010	+1	+1A
0011	+2	+2A
0100	+2	+2A
0101	+3	+3A
0110	+3	+3A
0111	+4	+4A
1000	−4	−4A
1001	−3	−3A
1010	−3	−3A
1011	−2	−2A
1100	−2	−2A
1101	−1	−1A
1110	−1	−1A
1111	0	0A

Source: Authors, (2026).

Upon the generation of the 11 PPs, they are entered into the pipeline register that is usually D-flipflop 1. It is essentially a storage device, which stores and synchronizes the data to use in the following clock cycle. The 11 PP rows are then loaded into our proposed Wallace tree 3:2 compressor reduction method. These 11 PP rows are trimmed to leave less load on the final CLA adder which makes the product easier to reduce and calculate.

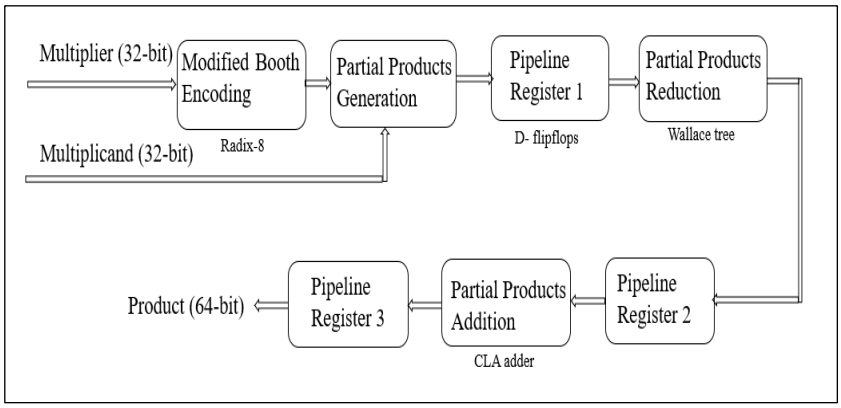

Figure 4: Modified Multiplier block diagram with pipelining and Wallace tree.
Source: Authors, (2026).

B. Pipelining

Pipelining is a structural optimization technique that improves the throughput in a calculation by inserting storage elements (pipeline registers) between diverse processing steps [13], [20]. These types of D-flip-flop registers merely grab a bit of in-between data and then one can select blocks of combinational logic to be isolated synchronously. Each set of operands must be processed in more than the usual Radix-4 algorithm in the proposed architecture, whereby 32-bit data makes sure that the data is continually flowing in a stream with multiple clock cycles necessary to complete each set of operands.

C. Wallace Tree Structure

This structure is firstly introduced by Chris Wallace in 1964, [12] to compress through Carry-Save Adders (CSAs) rather than the classical ripple-carry propagation [21-23]. In this compression step, 3:2 compressors are to be used. The length of two vectors Sum and a Carry is squeezed into three (n-bit) input vectors (e.g. A, B and C) using a CSA. A Carry Save Adder computes the sum of 3 or more n-bit numbers and gives 2n-bit numbers and will result two numbers of same length called Sum(S) and Carry(C). For three input bits A, B, and C that come from the partial product rows, the sum and carry is:

$$\text{i.} \qquad \text{Sum (S)} = A \oplus B \oplus C \tag{2}$$

This is an XOR operation. It checks if the number of 1's is odd.

$$\text{ii.} \qquad \text{Carry (C\_out)} = (A \,.\, B) + (B \,.\, C) + (C \,.\, A) \tag{3}$$

Where these two sum and carry vectors are 64-bit vectors each that will be fed to stage 2 pipeline and the values will be held and synchronized and eventually presented to the Carry Look Ahead (CLA) adder to add the final 64-bit product.

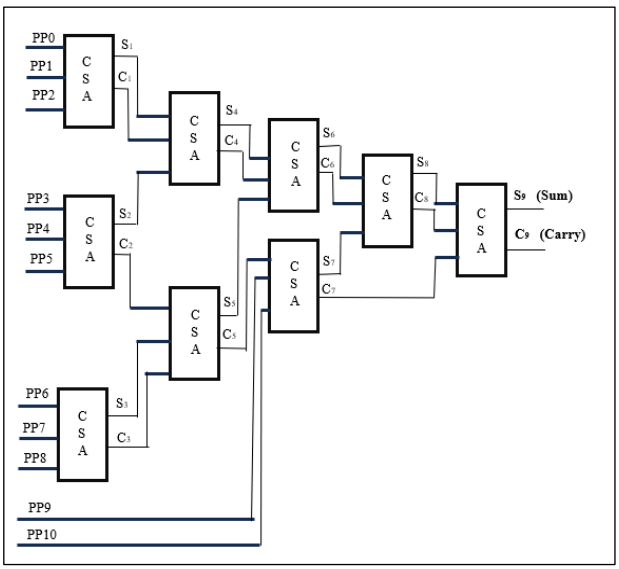

Figure 5: Partial Products Reduction by 3:2 compressor Wallace tree with CSA.
Source: Authors, (2026).

D. Carry Look-Ahead(CLA) Adder

A CLA adder is used to compute carry bits simultaneously with the other bits instead of having to wait until previous computations are done with the result. In each bit position, each logic tests two conditions on whether the bit is being calculated depending on the inputs Ai and Bi [8], [24], [25].

i) Generate (Gi) : Ai . Bi (both i/p's are 1)
ii) Propagate (Pi) : Ai ⊕ Bi (one i/p is 1)

If we have both G and P values for a bit pair, we can calculate the Carry out (C_out) as follows:

$$C\_out = Gi + Pi \,.\, C\_in \tag{4}$$

To calculate the C_in, assume the initial C0 is Zero. Then the carry 1 for bit 1 is

$$C1 = G1 + (P0 \,.\, C0). \tag{5}$$

After the 64-bit product is produced, it will be sent to final pipeline stage for steadiness and synchronizing for next clock cycle. The whole process of the proposed architecture is controlled by the positive-edge triggered clock signal [14], additionally in the three stages in the following way:

Clock Cycle 1: MBE block samples the multiplicand and multiplier. On the first clock cycle, the 11 latched PP rows are calculated and latched to Pipeline Register 1, and

Clock cycle 2: The Wallace tree reduces them to two vectors (Sum and Carry), which are latched to the Pipeline Register 2 memory. At the same time, Stage 1 initiates the next group of operands processing.

Clock Cycle 3: The CLA adder calculates the final 64-bit product of the two vectors which gets stabilized in the last output register at the third clock step.

IV. RESULTS AND DISCUSSIONS

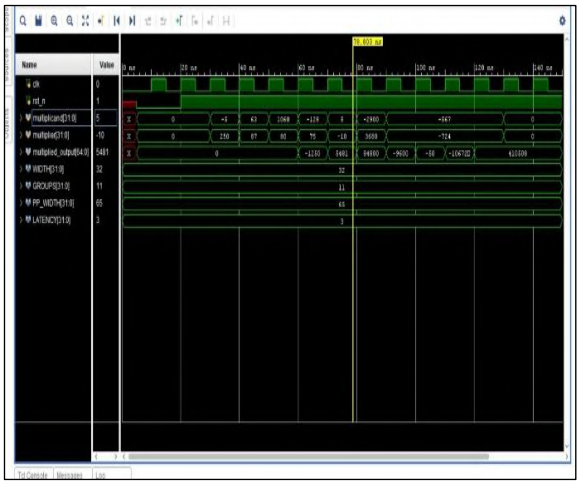

Figure 6: Output in signed values.

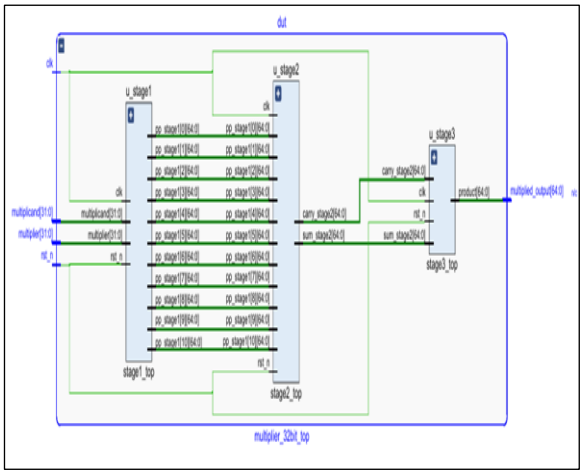

Figure 8: Schematic diagram 1.
Source: Authors, (2026).

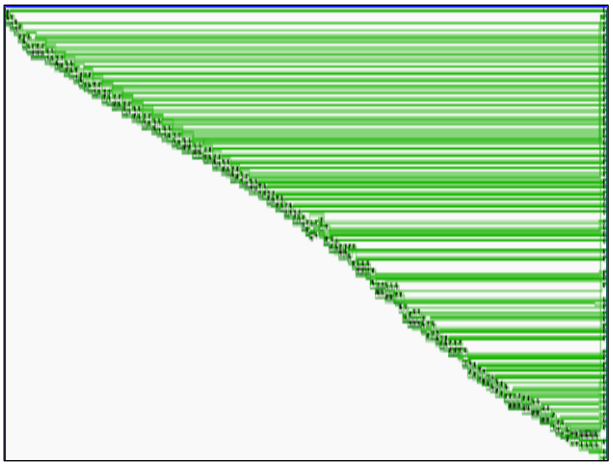

Figure 9: Schematic diagram 2.
Source: Authors, (2026).

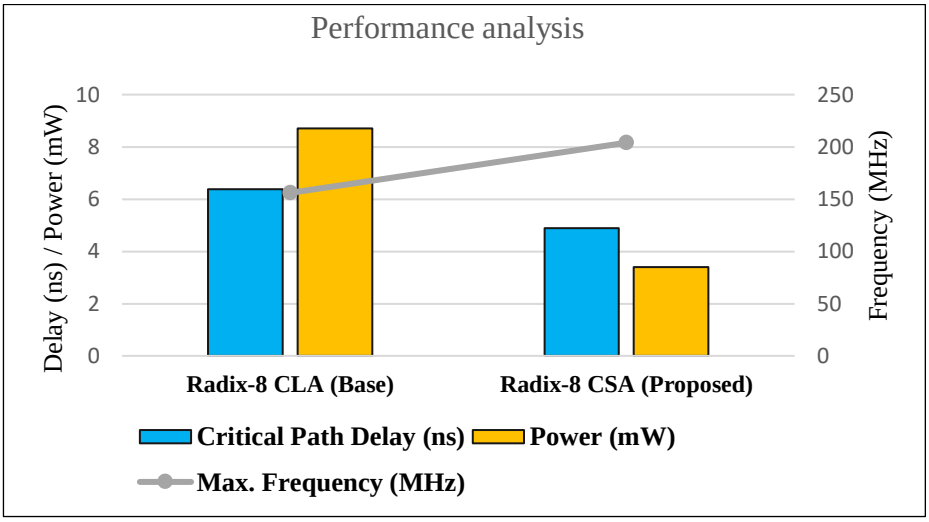

Figure 10: Performance analysis of multipliers.
Source: Authors, (2026).

The synthesis results demonstrate highly efficient hardware utilization. The Critical path delay was recorded at 4.895 ns, yielding a maximum operating frequency (F_{max}) at 204 MHz. The total on-chip power at this frequency was restricted to 3.39 mW. A detailed power breakdown reveals that dynamic power dominates, with pipeline registers accounting for 52.32% of the total power and the combinational logic accounting for 46.16%.

V. CONCLUSIONS

This paper presented the design, implementation, and verification of a high-performance 32-bit multiplier utilizing a 3-stage pipelined Radix-8 Modified Booth Encoding (MBE) architecture. The proposed design successfully mitigated traditional routing congestion and minimized the critical path delay by replacing conventional linear reduction schemes with a Carry Save Adder (CSA)-based Wallace tree structure, which accelerated the compression of the 11 partial product rows. Synthesis results demonstrate that the architecture achieves a delay of 4.895 ns and power consumption of 3.39 mW, representing a 23% reduction in delay and a 61% improvement in power efficiency compared to standard designs. These results confirm that the proposed multiplier architecture is highly suitable for integration into modern DSP systems and high-speed VLSI applications.

ABSTRACT

Accurately placing students in appropriate academic programs, such as determining whether they are better suited for a particular course, is fundamental to student success and retention. This study aims to construct a recommendation model that uses data mining and machine learning techniques to guide currently enrolled students in their program to make better selections. The research proposes a multi-model architecture that integrates a content-based cosine similarity matching component with three distinct machine learning classifiers, namely Logistic Regression, Random Forest, and XGBoost. In addition, the models were trained and evaluated using 10-fold cross-validation. Performance evaluations revealed that XGBoost was the most effective individual classifier, achieving a mean accuracy of 91.7%, an ROC-AUC of 97.5%, and a positive-class F1 score of 90.4%. The ensemble model also demonstrated strong predictive and recommendation performance, achieving 90.6% accuracy and 96.8% ROC-AUC. Logistic Regression achieved an accuracy of 88.7%, while the Random Forest model lagged with an accuracy of 83.8%. The findings demonstrate that XGBoost and Ensemble models are the most reliable and effective classifiers for predicting student course placement on this specific dataset. This hybrid recommendation engine successfully translates historical and input data into actionable, data-driven insights to help students make informed decisions about their academic careers.

I. INTRODUCTION

The fast and unpredictable life demands a recommendation engine tool that recommends content to users and machines based on their preferences and interests, using algorithms to analyze their needs, likes, and wants, drawing on historical data, user experience, academic performance, business interests, and other relevant factors, to create individualized recommendations [1-3]. Ensemble recommendation models [4], [5] in education combine multiple sources of information or numerous recommendation strategies to improve recommendations. The society, which relies heavily on knowledge and information interaction, is a key component in technological innovation and a fundamental tool for developing teaching methodologies. Many policymakers in developing countries consider upper-secondary technical and vocational education and training critical to economic growth and poverty reduction[6], [7]. The education system in the Philippines aims to develop high-level professionals who directly impact leadership, business, and employability, advance knowledge through research, and apply new knowledge to improve the quality of human life, industrialization, development, and careers [8]. These recommendation models may include collaborative filtering, content-based filtering, matrix factorization, and hybrid approaches that integrate multiple techniques to improve recommendation accuracy [9-13]. Cosine similarity [14-16] is a metric used in data analysis to evaluate the degree of similarity that is not zero and located within an inner product space between two vectors. This angle is determined by dividing the dot product of the vectors by the product of their magnitudes. The cosine similarity is not dependent on the magnitudes of the vectors, which are solely governed by the angle by which they are oriented.

It is always the case that the cosine similarity falls inside the range of [-1, 1]. The knowledge and understanding to classify the student's academic courses/track have been observed and challenged for a long time. It is regarded as an essential topic of study across a variety of fields, as it benefits both families, students, and decision-makers. However, the primary purpose of the research was to construct a model that can be recommended to students in the field of information technology using recommendation techniques. This pertains to the research study that used a recommender model and data mining techniques to provide results on student academic performance. Accurately placing students in appropriate courses or academic programs is fundamental to student success and retention. Course placement in this context refers to assigning students to the most suitable academic program or track, for example, determining whether a student successfully graduates from the Bachelor of Science in Information Technology (BSIT) program or the Bachelor of Science in Computer Science (BSCS) program based on their prior and current achievements, skills, and characteristics. Proper placement ensures that students are neither overwhelmed nor under-challenged, thereby improving learning outcomes and satisfaction. Traditionally, such placement decisions have relied on entrance exams, counselor judgments, and heuristics that may not fully capture a student's multifaceted background. The increasing availability of educational data has opened the door for data-driven approaches to augment these decisions. In recent years, different techniques in Machine Learning (ML) and artificial intelligence (AI) [17-20] been actively explored as tools for predicting student performance and recommending personalized academic paths, not only for students but also for policymakers and decision-makers. These models can analyze huge student datasets to recognize complex patterns and predict academic outcomes. Deep learning models, in particular, can capture nonlinear relations and connections that traditional statistical methods might overlook. For instance, predictive models have been one way used to identify at-risk students in need of intervention, sometimes integrating behavioral data, such as online learning activities, with demographic and grade information to trigger timely support. Applying these techniques to course placement, recommending the most appropriate course or major for a student, poses unique challenges, such as classification problems that include multiple classes (different programs) and require a balance between accuracy, interpretability, and fairness in an academic context. This study addresses the issue of identifying students based on first and second-year subjects, demographics, family background, and other factors to determine whether they should continue the course, since there are a number of students who are studying in different courses however, their grades are more suitable for other courses. The rest of this study is as follows: Section 2, Literature review, describes other researchers' views on the different recommended approaches; Section 3, Methodology, describes in detail how the ensemble approach works, from data input to final predictions. Furthermore, Section 4 Results and discussions present evaluations of metrics, and results from distinct algorithms and an ensemble pipeline using various metrics. Lastly, Section 5 concludes by brief the key findings of the study.

II. RELATED WORKS

In this section, researchers explore the different methods and approaches used by other researchers in this field. Logistic Regression (LR) has often been used as a baseline for binary classification tasks, such as predicting dropout or pass/fail, due to its simplicity and interpretability [21-25]. Traditional classification models such as decision trees, logistic regression, and Naïve Bayes have been widely used to predict student success and choices the said algorithms widely used in different systems and approaches, due to their simplicity and interpretability. Complex ensemble methods and hybrid systems have recently gained attention for their superior accuracy. Learning approaches that combine multiple algorithms have been shown to improve robustness and predictive performance across different categories, including educational tasks [26-32]. Combining several classifiers and algorithms, such as SVM, KNN, and linear regression, Random Forest (RF) [33], [34], XGBoost (XGB) [3], [35-37] (but not limited to), results in building an ensemble model this approach in may cases improve accuracy compared to individual models when predicting different categories of data, including student education placements. Deep learning models, especially recurrent neural networks like LSTMs, have also been applied to educational data, where temporal or sequential Patterns are relevant [38]. Researchers found that a LSTM network analyzing students' time-series behavior in a learning management system outperformed eight conventional classifiers in predicting early course performance. The LSTM-based method improved accuracy and earlier detection of at-risk students using clickstream data, highlighting the value of both ensemble methods and LSTMs for educational predictions [39-43]. Content-based methods computing similarities to make recommendations: each student's profile and each course/program's profile are represented as vectors, and the closest match is found. Techniques such as term frequency-inverse document frequency (TF-IDF) [44-46], vectorization, and cosine similarity have been employed in course recommendation systems to measure how well a student's profile matches a course's content or requirements. Use of TF-IDF on course descriptions and cosine similarity to recommend courses to students based on content alignment [47], [11].

II.1 MODEL SELECTION AND EVALUATION

II.1.1 Algorithms

The researcher established a comprehensive and multiple evaluation benchmark for the algorithms used in this study: multinomial Logistic Regression (LR), Random Forest (RF), XGBoost (XGB), and term frequency-inverse document frequency (TF-IDF) by selecting the following algorithms and ensemble models.

II.1.2 Term Frequency-Inverse Document Frequency

TF-IDF The similarity score ranges from -1 to 1 for TD-IDF values. A value of 1 indicates that the vector points in the same direction and is perfectly aligned at 0 degrees. Value 0 indicates that the vectors are orthogonal (perpendicular, with an angle of 90°), i.e., uncorrelated, and a value of **-1** indicates that the vectors are pointing in opposite directions (angle of 180°). The system computes cosine similarities for all training documents, identifies the nearest neighbor based on the highest cosine similarity in dataset, and predicts the label for the input content that is most similar to the training data, resulting in the items with the greatest cosine similarities being recommended as the most related.

Term frequency where $\mathrm{tf}(t,d)$ stands for Term Frequency: the frequency of a term t in document d. $\mathrm{idf}(t)$Stands for Inverse Document Frequency, which measures how much information the word provides. The rarer the word in a document, the higher the value of the word in terms of information.

$$tf(t,d) = \frac{f(t,d)}{\sum_{t'} f(t',d)} \tag{1}$$

Cosine similarity dot product represented by numerator x,v, which shows the inner product of two vectors to represent the product magnitudes (Euclidean, norms, lengths) of vectors x and v represented by ||x|| ||v||.

$$\text{CosineSim } \text{sim}_{cos}(x,v) = \frac{x \,.\, v}{||x||\,||v||} \tag{2}$$

II.1.3 Logistic Regression

Logistic regression directly computes probabilities using the SoftMax function. Many researchers use it for text classification because it provides the probability that each feature has on the task. Softmax regression, or multinomial logistic regression, uses TF-IDF feature vectors to identify and predict content labels. The TF-IDF and logistic regression model compute a score for each possible class via a linear combination. Logit represents the raw, unnormalized score produced before it is passed to an activation function like Softmax. Where the value z_k is referred to as a linear predictor or logit

$$z_k = w_k^T + b_k \tag{3}$$

The SoftMax function gets the z_k to produce a probability distribution over the classes. Where K is the total number of classes. In General Machine Learning Context, linear combination is a fundamental building block across many models.

$$\mathrm{P}(y = k|x) = \frac{exp^{z_k}}{\sum_{j=1}^{K} exp^{z_j}} \tag{4}$$

II.1.4 Random Forest

The random forest using the TF-IDF features as input, each decision tree in the random forest produces its own predicted class for the given input, and then aggregates these individual predictions to make a final decision based on majority voting. Nonlinear classifiers in the RF branch can capture interactions among TF–IDF features. Where where $\hat{y}$ is the final predicted value and b is the total number of trees in the forest and $\hat{y}_b(x)$ is the prediction of the b-th decision tree for the input x.

$$\hat{y}_{RF} = mode(\{\hat{y}_1(x), \hat{y}_2(x), \ldots\ldots, \hat{y}_b(x)\} \tag{5}$$

II.1.5 XGBoost

The objective function ($\mathcal{L}$), which includes a loss function term $l(y_i, \hat{y}_i)$and a regulatory term $\Omega(f_t)$, Regularization helps mitigate the risk of overfitting

$$\mathcal{L} = \sum_i \mathrm{l}(\mathrm{y_i}, \hat{\mathrm{y}}_\mathrm{i}) + \sum_i \Omega(\mathrm{f_t}) \tag{6}$$

regularized objective where w are the output scores for the leaves with respect to the tree and T is the number of leaves in the given tree; the value of γ controls the minimum loss-reduction gain needed to split an internal node. Shrinkage is an additional regularization parameter in XGBoost that reduces the step size in the additive expansion. A secondary advantage of reduced tree complexity is that models are trained faster and require less storage space. Finally, the complexity of the trees can also be limited using other strategies, such as limiting the tree depth.

$$\Omega(\mathrm{f_t}) = \gamma \mathrm{T} + \frac{1}{2}\lambda||\mathrm{w}||^2 \tag{7}$$

II.2 PERFORMANCE METRICS

In this section, the researcher discusses the metrics used to validate the results of this study, applying multiple validation metrics that are widely used by researchers.

Accuracy: as the total number of correctly classified instances and It treats all classes equally. where N is the total number of predictions. , $\hat{y}_i$ is the predicted value for the i-th instance, y_i is the actual true value for the i-th instance and $1(\hat{y}_i = y_i)$ It takes the value 1 for accurate prediction and 0 otherwise, due to the indicator function's binary nature. The $\Sigma_{i=1}^{N}$ sums the total number of correct predictions.

$$Accuracy = \frac{1}{N}\Sigma_{i=1}^{N} 1(\hat{y}_i = y_i) \tag{8}$$

Precision Calculation: the precision of a specific class, where k is the ratio of true positives (TP_k) to the total number of instances predicted as positive for that class $(TP_k + FP_k)$, includes both true positives and false positives (FP_k).

$$Precision_k = \left(\frac{TP_k}{TP_k + FP_k}\right) \tag{9}$$

Macro recall measures the classifier's ability to correctly identify instances of each class, averaged equally across classes. It is especially useful when missing minority classes are costly. TP_k: True Positives for class k, the number of instances correctly identified as belonging to that class. FN_k: False Negatives for class k refer to instances that belonged to the class k but were missed by the model. This metric measures the classifier's completeness or sensitivity in identifying all relevant cases of that class.

$$Recall_k = \frac{TP_k}{TP_k + FN_k} \tag{10}$$

Macro F1 is the unweighted mean of per-class F1 scores. It balances precision and recall per class and is robust to class imbalance by preventing dominant classes from overwhelming the metric. The F1 score for class k is the mean of precision and recall, balancing these metrics into a single value. Precision (Precision_k) measures the accuracy of positive predictions for class k, while recall (Recall_k) identifies actual positive instances. The F1 score is mostly useful for imbalanced datasets as it better reflects model performance on the positive class than simple accuracy.

$$F1_k = \frac{2 \cdot \text{Precision}_k \cdot \text{Recall}_k}{\text{Precision}_k + \text{Recall}_k} \tag{11}$$

Area Under the Curve: measures a model's ability to differentiate between positive and negative classes for an individual class k, denoted as (AUC_k). It is an integral of the True Positive Rate (TPR) over the False Positive Rate ($x = FPR$). This integral formulation is a known method for computing the AUC from the ROC curve definition.

$$\text{AUC}_\text{k} = \int_0^1 \text{TPR(x)} d\,x \tag{12}$$

III. METHODOLOGY

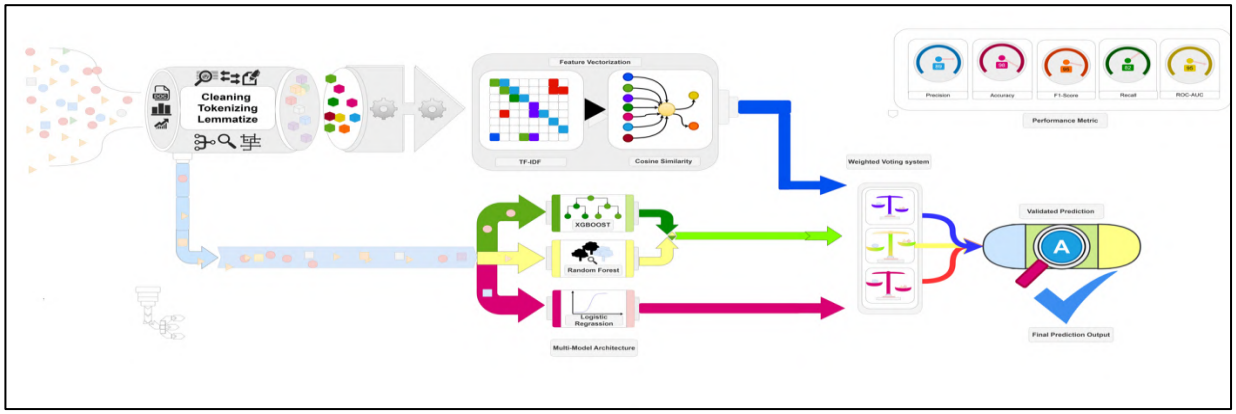

Figure 1: Phase I, II, III illustration.
Source: Author, (2026).

In this section, the researchers explain how the model uses multiple algorithms and processes to select the best direction for students, giving them more chances to complete the course. The process is divided into three Phases: Phase I Input, Phase II Process, and Phase III Result. Figure 1 includes several well-known algorithms, such as multinomial Logistic Regression (LR), Random Forest (RF), XGBoost (XGB), and term frequency–inverse document frequency (TF-IDF), combined into a single ensemble model.

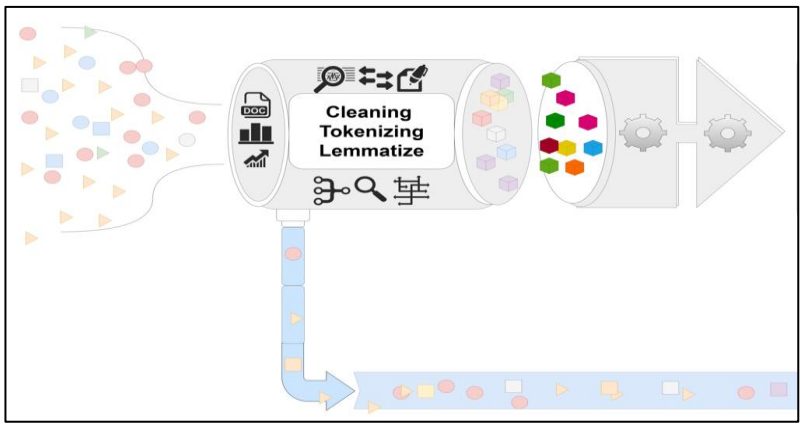

Figure 2: Phase I: Input Data and Preprocessing.
Source: Author, (2026).

III.1 PHASE ONE

Located at the top of the model, is called the input phase shown in Figure 2. It includes input data, data preprocessing and cleaning, and Concatenation and Label Encoding, starting with a dataset that may contain numerical, rating, timestamp, or string data. In the second stage of the first phase, Tokenization & Lowercasing, Noise Removal, stop word Filtering, Label Encoding, and Dataset Splitting, in addition to converting the data into a format for analysis. To address limitations in dataset availability due to data privacy laws, the researchers created the BSIT and BSCS datasets, augmenting them with a Generative Adversarial Networks(GAN) to used with the original dataset and splitting the data into a stratified 80/20 train-test split. The three machine learning models used in this study are Logistic Regression, Random Forest, and XGBoost algorithms. In addition, the 10-fold cross-validation was chosen by the researcher; furthermore, all code and analysis were run in Google Colab using standard virtual machine resources. The dataset attributes that were used in this study are shown in Table 1. After finishing Phase I, all the processed data feeds are sent to Phase II for modeling.

Table 1: Dataset Attributes.

Attribute	Attribute	Attribute
Age	Free time after school	Many hours playing games in week
Sex	Going out with friends	Weekly study time
Food habit	Schoolday alcohol consumption	Easy access to computer
Family size	Weekend alcohol consumption	Easy access to internet

III.2 PHASE TWO

Phase two has four multi-models shown in Figure 3: one Similarity-Based Model, two Logistic Regression models, three Random Forest models, and four XGBoost models. The research discusses each in the following:

III.2.1 Logistic Regression

Figure 3 shown the process starts by converting text into a numerical vector for the machine learning algorithms to process in a TF-IDF vectorizer, to compute the weighted sum of each feature, producing one real-valued score (a logit) per class using the SoftMax. The logit indicates the likelihood of each class, and the SoftMax stage converts the logits into a probability distribution over classes. Finally, the algorithm uses these probabilities to output a single class decision.

III.2.2 Random Forest

A technique such as a random forest, an ensemble learning model that uses multiple decision tree methods to find patterns in data. To extract meaningful knowledge from the data, each tree is trained on different subsets of data structures. gives it an advantage in applying structure to provided data and in finding patterns in large-scale datasets, which allows the diversity among the trees to capture a range of patterns, reducing the likelihood of alignment errors. To generate a final prediction, the model typically averages the probability estimates from each individual tree, resulting in a more robust and accurate output. Random Forest learns nonlinear decision rules by combining many diverse trees, the probabilities stage provides calibrated or quasi-calibrated class likelihoods derived from ensemble averaging, and the prediction stage maps those likelihoods to final labels used for reporting results or deployment.

III.2.3 XGBoost

This stage starts with a tokenizer that feeds data into the boosting block. XGBoost is a boosting-style ensemble learning process in which a strong classifier is created by combining a sequence of weak decision-tree classifiers. The process starts with the first box, representing the training samples in their initial form. The process makes an initial prediction, measures the distance to the true labels, and updates the model state. The residuals are passed to the next step, emphasizing that the errors serve as the learning signal for that step. The process repeats this cycle across multiple columns of a weak classifier, indicating that a weak learner (a shallow tree) is fit to the current error structure in the data. The dataset is reweighted or re-focused after each weak learner, so that samples that were previously mis-predicted receive greater influence in the next fitting step.

III.2.4 TF-IDF

TF-IDF vectorizer transforms text into a numerical vector by assigning each term a weight based on how often it appears in a document relative to its frequency across the corpus. Common words receive lower weights, and rare and informative words receive higher weights. The similarity between two vectors is measured as the cosine of the angle between them, enabling comparison of the new input vector with the training data using cosine similarity.After adding each weak learner, the ensemble's predictions change, new residuals are computed, and the training distribution or effective loss landscape is updated for the next learner. By combining multiple weak decisions, the final component of the boosted ensemble model represents the boosted ensemble formed by combining all weak learners, typically as a weighted sum or an additive model, so that each new tree contributes an incremental correction to what has already been learned.

III.3 PHASE THREE

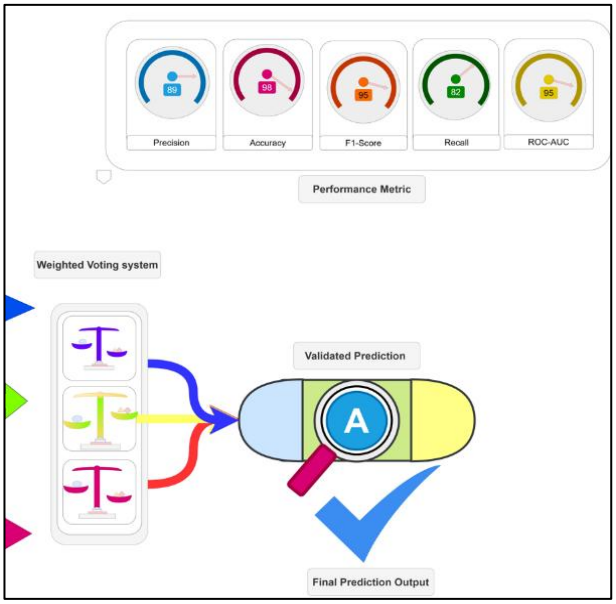

Figure 4: Phase III evaluation.
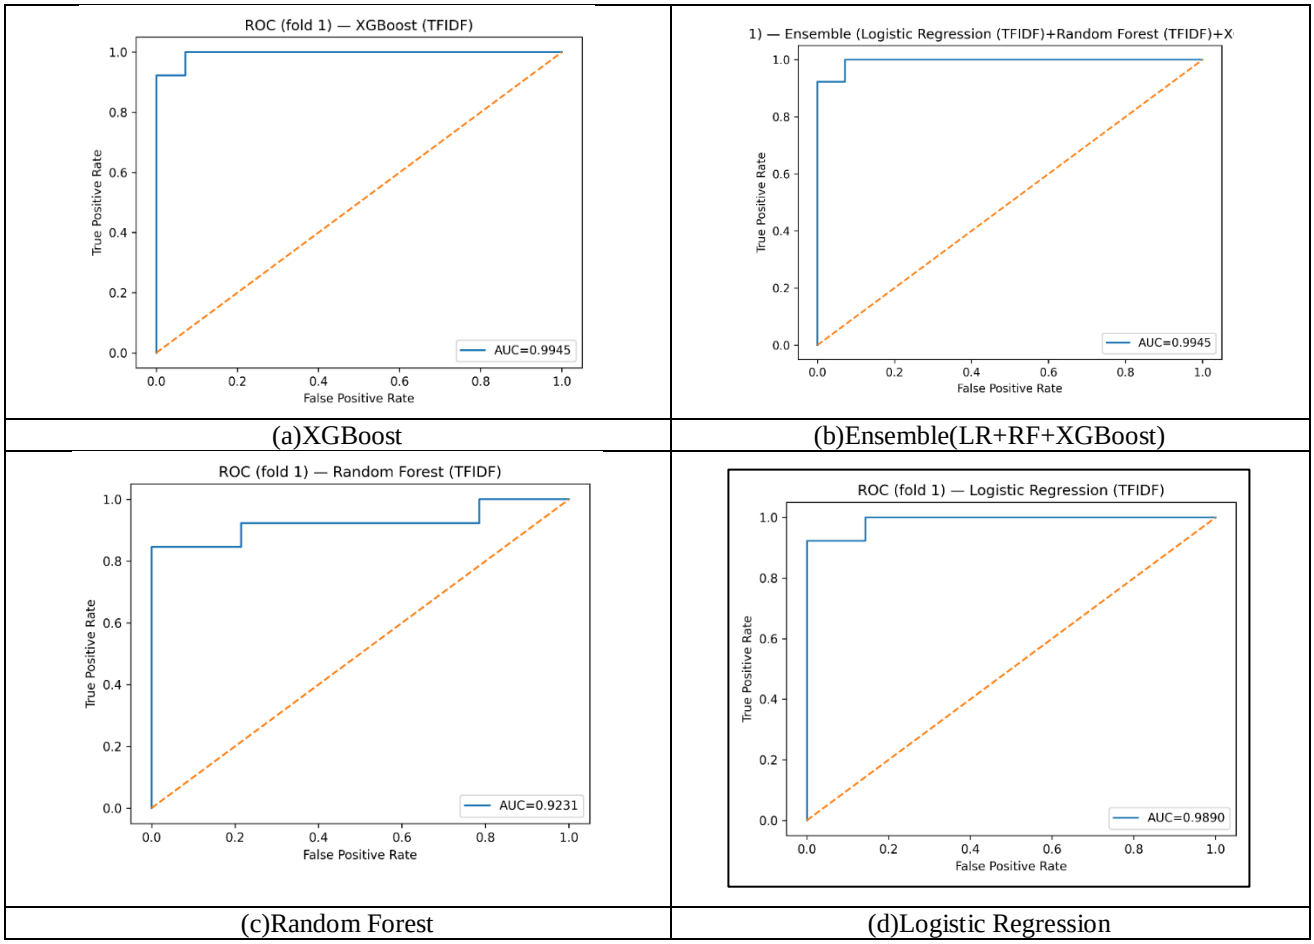
Source: Author, (2026).

Figure 4 shown by capitalizing on model diversity and focusing on an AI/ML pipeline that ensures the classifications and recommendations are multi-model, and the prediction is accurate and robust. After all models predict the output, all predictions combine to create final predictions for accomplishing this step the researcher used Weighted Voting, different validations technique used to allow the model to decide what is the best perdition for given input data, validations approaches such as accuracy, precision, recall, F1-score, ROC-AU and others validations which offers the most accurate model, more influence in decision making and predictions output.



IV. RESULTS AND DISCUSSIONS

This section discusses the performance of each model used in this study. Table 2 shows the model the mean of from fold (1) up to fold(10), Accuracy Mean, Precision Positive Mean, Recall Positive Mean, F1 Positive Mean, and ROC AUC of the different models used in this study top performers among these combined models are the Ensemble model and the XGBoost, both of which can capture complex, nonlinear patterns and relationships within the data [48-52]. However, this does not mean that the Random Forest and logistic regression underperformed because of the nature of the data provided to the models rather, it shows that different models perform differently across datasets [53]. The researcher evaluates Logistic Regression, Random Forest, XGBoost, and an ensemble. The results for each model are summarized in Table 2, which shows first that Logistic Regression achieves 88.86% accuracy and F1 of 87.43%, and second that the Random Forest classifier performs, attaining 83.86% accuracy and F1-score of 81.71%, third XGBoost scored accuracy of 91.73% and F1 score of 90.46%, the ensemble of all three models also achieved 90.64% accuracy, with an F1-score of 89.19%. The results show that the model can identify the pattern in the dataset and provide a proper recommendation as output.

Table 2: Performance of Classification Models on fold(1) to fold(10) Prediction.

Model	Accuracy Mean	Precision Mean	Recall Mean	F1 Mean	ROC Mean
XGBoost (TFIDF)	0.9173	0.9274	0.8929	0.9046	0.9753
Logistic Regression (TFIDF)	0.8874	0.8800	0.8769	0.8743	0.9693
Ensemble (Logistic Regression (TFIDF)+Random Forest (TFIDF)+XGBoost (TFIDF))	0.9064	0.9086	0.885897436	0.8919	0.9687
Random Forest (TFIDF)	0.8386	0.8410	0.803205128	0.8171	0.9093

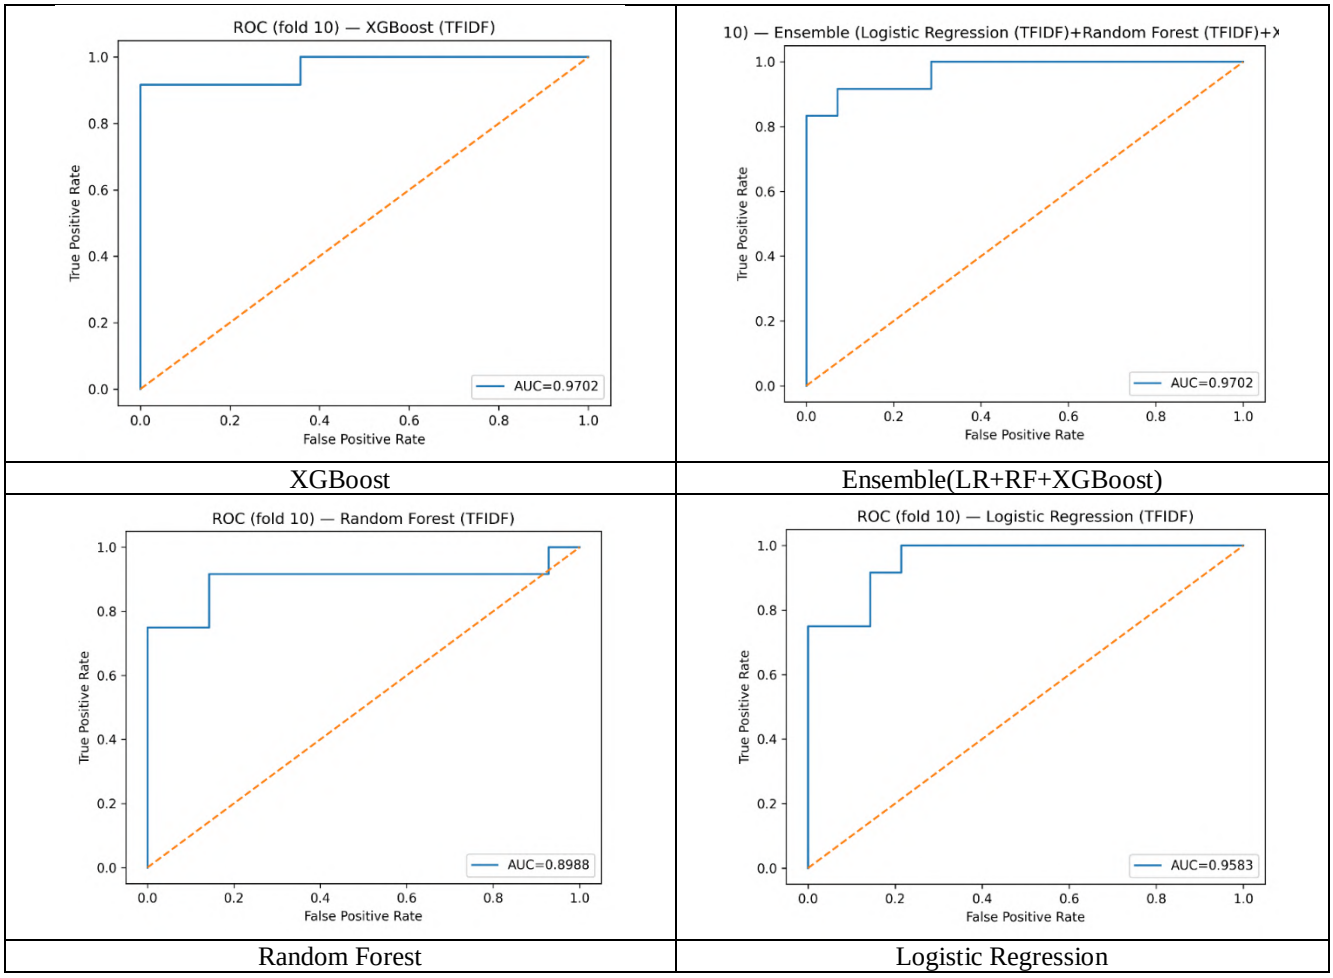

Figure 6: ROC output for fold (10) of XGBoost, LR, RF, and Ensemble model.
Source: Author, (2026).

Figure 5 and 6 show ROC curves derived from fold (1) and fold (10) other cross validation fold is not included, only across all folds for Logistic Regression, Random Forest, XGBoost, and the XGBoost mean score for ROC-AUC is 97.53% and the ensemble model, which achieved a mean score of 96.87 and significantly outperformed Logistic Regression with a mean score of 96.93%. Random Forest lagged behind with an ROC-AUC mean score of 0.909377289. The ROC curves for the top-performing models in average fold exhibit strong concavity toward the upper-left corner, a characteristic indicative of high AUC values.

V. CONCLUSIONS

This research uses several algorithms to analyze educational content, applying classification and recommendation methods to guide students' program selection and help them make more informed decisions based on data-driven outputs suggested by the algorithm. An approach to predict student course placement, focusing on unique features between related undergraduate programs. Across all models, XGBoost emerged as the most effective and reliable classifier for these datasets and tasks. The ensemble approach did not surpass XGBoost and showed greater variability across folds, suggesting limited benefits from aggregation when the constituent models are trained on the same TF-IDF representation, which may yield correlated predictions. A student provides informed information based on the recommendations' results, with directions to make more informed decisions based on the given input data and historical data processed by the ensemble model. This approach gives students who are currently enrolled in the course the opportunity to be informed whether the course is suitable for them or not , which gives them the ability to make an informed decision regarding the course they are currently enrolled in.

ABSTRACT

The main component of the controller in electric vehicle (EV) is motor,DC-DC converter and charging port.The research analysed the lithium-Ion battery with isolated converter like H bridge and non-isolated type Zeta converters are compared distance travel and the SoC (State of Charge) of the battery by using MATLAB Simulink in a plug-in electric The isolated converters are costly due to the transformer and offer safety. The electric vehicle controller plays a crucial role in increasing the vehicle's range and enhancing battery charging within the grid system. The controller of the vehicle will improve the battery life and travel the distance per charge. The Permanent magnet DC motor with PI controller is used for this article.

I. INTRODUCTION

Research findings indicate that combustion vehicles are responsible for emitting approximately 70% of gases, while other transportation sectors contribute around 27% of harmful greenhouse gases [1]. The energy flow in the vehicle is driver motor, motor controller, power battery pack, charger and external power as shown in figure 1.

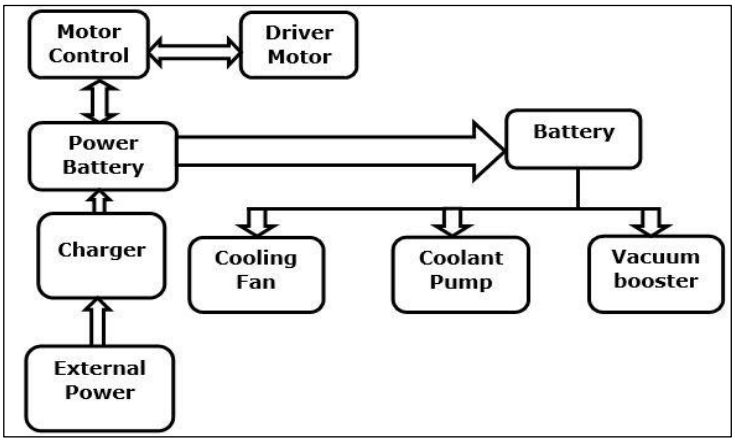

Figure 1: Energy flow diagram of Electric Vehicle.
Source: Authors, (2026).

The driver motor is coupled with gear box and drive axle which is tied up with tier crank shaft. The DC – DC converter energy flow from power back up and delivered to battery. The energy flow from battery to cooling fan, coolant pump, vacuum booster pump as shown in figure 2. The EV plugin takes electrical energy from the grid to charge the battery. Then, the batteries power the electric motor. The components of EV based on plug in type is DC – DC converter, controller,motor, battery and gear system. The key benefits of this system include being environmentally friendly and producing no pollution. However, a significant downside is the rapid battery depletion, making it unsuitable for long-distance travel [2].During periods without sunlight, the charging station attract the power from grid. Additionally, the grid power, which is close to unity, must be transferred to the charging station [3].

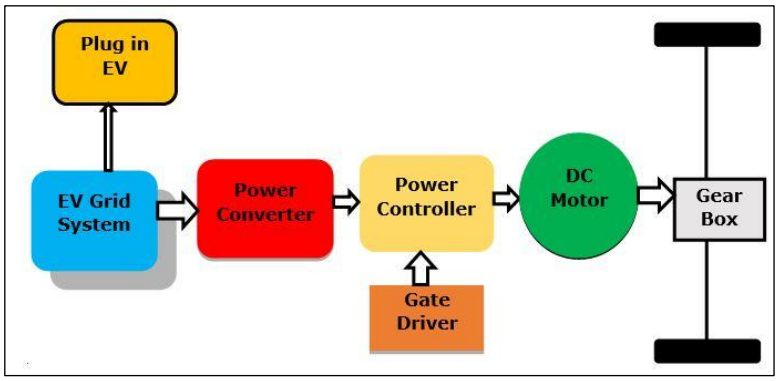

Figure 2: Block diagram of Plug in Electric Vehicle.
Source: Authors, (2026).

A comparison and discussion on optimization methods are done in terms of design, optimization function, implementation methods, complexity of computation and effectiveness. There's extensive review of the difficulties and problems concerning EV converter design, modulation schemes and controllers [4]. Figure 2 shows the block diagram of a plug-in electric vehicle. This paper uses a hybrid method that combines the Perturb-Observe technique and the Incremental Conductance technique for optimizing the energy of the solar PV array [5]. The choice of DC-DC converter design is essential for the fast charging of electric vehicles [6]. Precise control of the Bidirectional DC-DC converter has allowed electric vehicles to perform efficient energy handling and conversion [7]. Also, stability and reliability for EVs means being dependable throughout the electric vehicles. The converter needs to be more reliable [8]. A multi-port converter allows the use of different power sources, like batteries and supercapacitors, in power systems [9]. Choosing the right design and selection for a dc-dc converter can enhance overall performance. Improvement methods give designers useful information for developing various types of inverter regulator applications [10]. The PMDC motor's external structure, made up of the stator, forms the part housing. The internal stator are magnets in which the north and south poles of the magnets alternate each other facing the armature. The function of stator is to provide the return of magnetic flux with low reluctance in addition to holding the magnets. The design includes a compensation field coil to counteract potential power loss from the magnet. The armature is the moving part of PMDC motor which consists of winding core and commutator which is connected to the output shaft of the motor. In PMDC (Permanent magnet DC) motors have a solid rotor that is not made of steel or any ferromagnetic material. The link between speed and applied voltage resembles that of a standard DC shunt motor. However, the key difference is that in a PMDC motor, the rotor's magnetic field comes from a permanent magnet [11]. Because of this, one of the most commonly used ways to control a PMDC motor's speed is by changing the applied voltage [12]. The performance advantages of a PMDC motor stem from its ability to produce a very broad speed range of constant torque and constant power, and PMDC motors can have a maximum operating efficiency and power density that exceeds induction-type machines while being practically equivalent to machines using permanent magnets [12], [13].

At present, the industry has singled out electric machines as the leading technology due to their efficiency and cost-effectiveness. One such use case is the widespread application of electric machines in electric vehicles (EVs). The consumer interest in the latter is a direct consequence of the critics' attention on the internal combustion engines' negative impact on air quality, which, in turn, has led the researchers and engineers to channel their efforts into devising new technologies that could deliver higher power and better efficiency of electric vehicles. Hence, the researchers have taken as a main task besides electric motors and power electronics, the whole system regarding power consumption to be developed. Motor design with the best performance strategically selected turns into the main factor in the process of improving the overall performance electric vehicles [14]. The new converter comes with multiple benefits that are related to ZETA topology among which are the capability of buck-boost, continuous output current and DC insulation from input to output [15]. The controller generates control actions by using the error in the inductor current and a proportional term [16]. A Zeta converter-based battery charger for electric vehicles was proposed in [17], highlighting improved power factor correction and efficient energy transfer. The switching control algorithm uses a control Lyapunov function. This function began as a two-dimensional boost converter model from previous research. It has since been improved for a four-dimensional Zeta converter model [18]. On the other hand, there is still a gap in the analysis and modeling of input current distortion in PFC converters that use the GPWM controller. This is due to its significant nonlinearities under large-signal conditions [19].

I.1 CONTRIBUTIONS OF THIS WORK

This study departs from the existing research which mostly looks at dc-dc converter performance through individual evaluations, and carries out a vehicle-level analysis comparing a non-isolated Zeta converter and an H-bridge converter in the context of a plug-in hybrid electric vehicle. The unique aspect of the research is that it examines the changes in battery State of Charge (SoC) and the distance traveled by the vehicle under the same driving cycles. It uses a common MATLAB/Simulink platform.

It also connects the new Zeta converter with a PMDC motor drive and PI control method to measure its effect on the whole system's energy efficiency instead of just focusing on the conversion efficiency. The list of contribution in this Article:

- Comparative SoC analysis under same drive cycle
- Distance travelled per unit charge comparison
- Vehicle-level performance rather than component-only analysis

II. PROPOSED ZETA CONVERTER

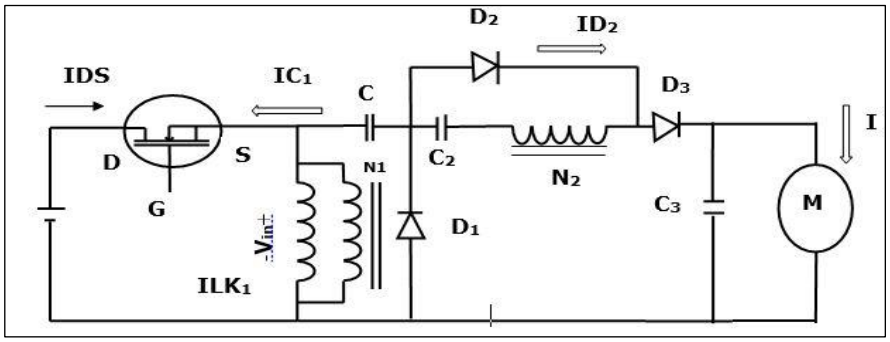

Figure 3: Circuit Diagram of Proposed Zeta Converter.
Source: Authors, (2026).

The jointly inductive Zeta transformer has been built using the secondary inductor T1 and the floating active switch S1. The input inductor of the conventional boost converter is mirrored by the primary winding N1 of the coupled inductor T1. It receives energy from the leakage inductor of N1 through capacitor C1 and diode D1. The secondary winding N2 connects in series with another set of capacitors, C2, and diode D2, which operate with N1. The rectifying diode D3 connects to the capacitor C3 for output and the resistor R for the load. The Zeta converter's main features include reusing the energy from the leakage inductor in the coupled inductor. This boosts efficiency and helps control voltage spikes across the active switch. The interchangeable capacitor and coupled capacitor methods are very effective in increasing the voltage transformation ratio. The floating active switch is making use of the PV panel's energy inoperative time, which not only helps in decreasing the risk of electric shock to people and damage to property but also is illustrated in figure 3.

Duty Cycle is calculated by using the formula

$$D = V0 / Vd+V0 \quad (1)$$

$$\text{Choosing L1 is } L1 \geq (1 - D)2\ R0 / 2Dfs \quad (2)$$

$$\text{Choosing L2 is } L2 \geq (1 - D)\ R0 / 2Dfs \quad (3)$$

II.1 DESIGN MOTIVATION AND NOVELTY

The Zeta converter has been chosen primarily because of its built-in buck-boost feature, continuous output current, and little current rippling, all of which are beneficial to battery-powered electric car applications. This research differs from the conventional studies allowing Zeta converters mainly in charging applications, as it integrates the converter directly into the vehicle propulsion system and assesses its effect on driving range and battery usage. The coupled-inductor arrangement enhances voltage gain while at the same time preventing switch voltage stress, thus making it apt for EV auxiliary and traction power needs.

III. METHODOLOGY

The method for modeling, simulating, and evaluating the performance of the proposed Zeta converter-based electric vehicle system is described in this section. We compare it with the traditional H-bridge converter under the same operating conditions. This makes sure the results are fair and can be repeated.

III.1 OVERALL SYSTEM ARCHITECTURE

Electric vehicle system simulation was done in MATLAB/Simulink where the energy source, power electronic converter, motor drive, controller, and vehicle dynamics are combined together. The major subsystems taken into account for this research are:

- Lithium-ion battery pack
- DC–DC converter (H-bridge and proposed Zeta converter)
- Permanent Magnet DC (PMDC) motor
- PI-based motor speed controller
- Longitudinal vehicle dynamics model

All subsystems are interconnected to emulate a plug-in electric vehicle operating under real-time driving conditions as shown in figure 4.

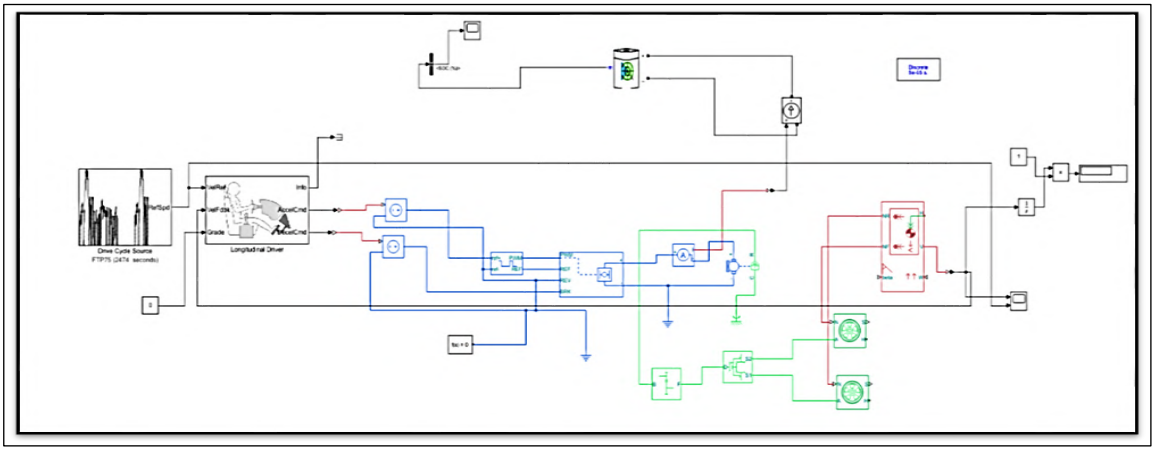

Figure 4: The complete simulation model is developed using MATLAB/Simulink.
Source: Authors, (2026).

III.2 BATTERY MODELLING AND STATE OF CHARGE ESTIMATION

A lithium-ion battery model acts as the primary energy storage device. The equivalent circuit model of the battery consists of a voltage source that can supply unlimited current, a resistance in the circuit, and dynamic components that reflect the rapid changes in battery behavior. We calculate the State of Charge (SoC) of the battery using the coulomb counting method, as shown in equation 4.

$$SoC(t) = SoC(o) - \frac{1}{C_{bat}} \int_0^t I_{bat}\,(T)dT \tag{4}$$

$where\ C_{bat}$ - rated battery capacity

I_{bat}- battery current.

III.3 DC–DC CONVERTER IMPLEMENTATION

Implement and analyze two conversion configurations.

III.3.1 H-Bridge Converter

The baseline system is the H-bridge converter. It allows for the reverse and regeneration power flow at the same time, hence, in case of acceleration or braking. The PWM technique with a predetermined frequency is used for generating the inverter signals.

III.3.2 Proposed Zeta Converter

The Zeta converter's development focuses on using a coupled inductor, energy transfer capacitors, diodes, and a floating active switch. Operating the converter in continuous conduction mode reduces current ripple and boosts the battery's efficiency.

III.4 MOTOR DRIVE AND CONTROLLER DESIGN

The Permanent Magnet Direct Current (PMDC) motor has been chosen to be the traction motor because of its uncomplicatedness and high torque per unit volume. The Motor velocity control is achieved using a Proportional-Integral (PI) controller. The control error is determined as the discrepancy between the reference speed and the real motor speed, as stated in equation 5.

$$e_t = \omega_{ref}(t) - \omega_{act}\,(t) \tag{5}$$

The PI controller output is given by equation 6.

$$u(t) = K_p e(t) + K_i \int e(t)dT \tag{6}$$

Where $K_p$and $K_i$are the proportional and integral gains, respectively.

III.5 DRIVING CYCLE AND VEHICLE DYNAMICS

In order to mimic the live car operations, the Signal Builder block in MATLAB/Simulink is used to create a custom driving profile. The speed profile is made up of different phases: acceleration, constant speed, and deceleration which sum up to a total simulation time of 1000 seconds. Table 1 compares the suggested Zeta converter with the traditional H-bridge converter in an electric vehicle application.

Table 1: The system performance is assessed using the following key metrics.

Key Metrics	System Performance
Battery State of Charge (SoC)	Indicates energy utilization efficiency
Vehicle Speed Tracking	Measures controller effectiveness
Distance Travelled	Evaluates driving range under identical conditions

Source: Authors, (2026).

The proposed system was validated through comprehensive simulation analyses. The comparison of the outcomes of both converter configurations is used to point out the improvements in battery SoC retention and vehicle travel distance. The experimental validation is not part of this study; however, the simulation framework developed can be considered a dependable base for future hardware implementation and real-time testing.

IV. RESULTS AND DISCUSSION

The State of Charge (SoC) is an indication of how much energy is still usable from a battery. It is important in stopping the battery from going through extreme discharging or charging, thus, helping to keep the battery's health and reduce the aging impacts [20]. It is not easy to classify these methods since a lot of them merge two or more techniques and employ different heuristic or deterministic mathematical tools [21]. SoC of H bridge and Zeta converter with Lithium-Ion battery in an Electric Vehicle has been analyzed in this study [22]. To begin with, create a signal builder in a Mat Lab Simulink signal that will linearly increase over 0 to 400 seconds and next 200 seconds the speed will be 100 Km/Hr. In the last seconds the speed will drop from 50 Km/Hr to zero and the signal builder will be connected to the longitudinal driver velocity reference input as illustrated in Figure 5.

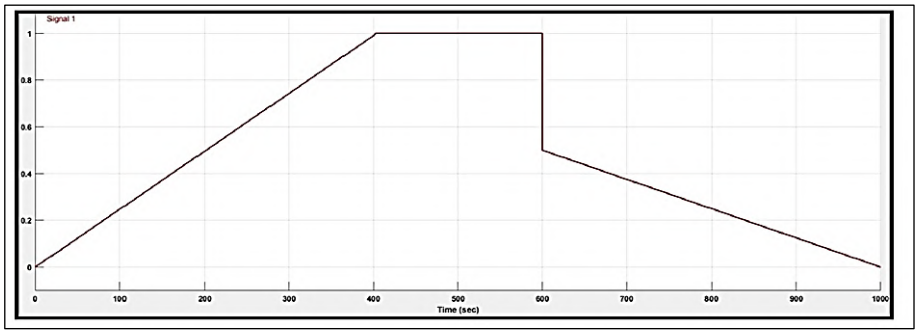

Figure 5: Input signal of velocity reference in longitudinal driver block.
Source: Authors, (2026).

The actual speed and the reference speed determine the subsequent aspects; the first one denotes that the actual speed is attempting to mimic the reference speed and the second one indicates about 50 Km/Hr average speed shown in the graph as depicted in figure 6.

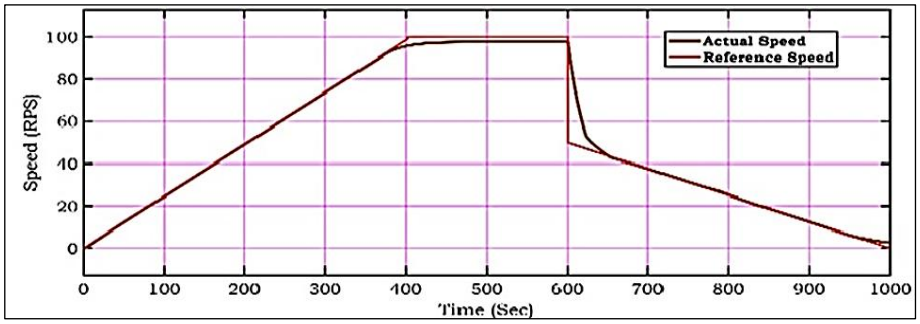

Figure 6: Actual and reference speed of the Vehicle.
Source: Authors, (2026).

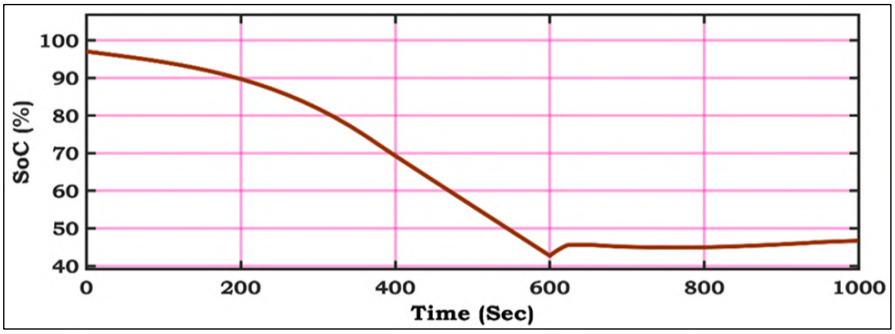

Figure 7: Variation of battery State of Charge (SoC) with time for H-bridge converter-based EV system under standard driving cycle.
Source: Authors, (2026).

Figure 7 shows the battery State of Charge for the Lithium-Ion battery.The battery is discharged non-linearly within the first 400 seconds, which is followed by 400-600 seconds of linear discharge. After 600 seconds, the battery has 50% charge and then gradually increases the charge and discharge according to the feedback system of the vehicle.

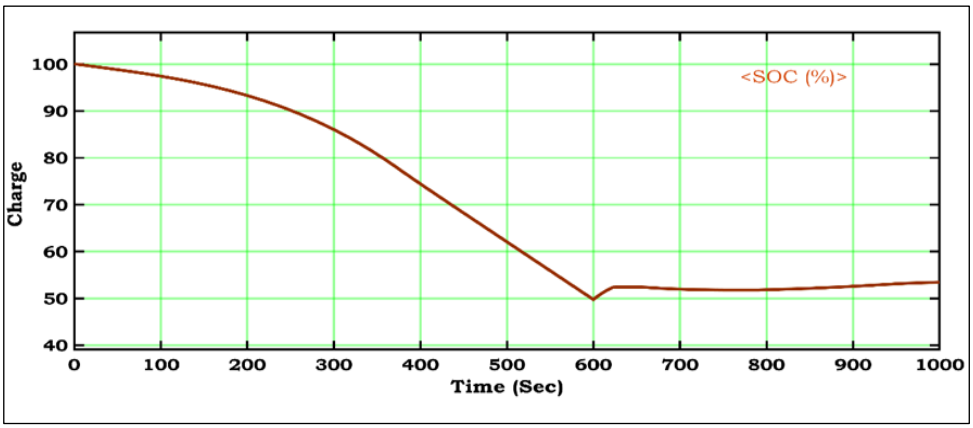

Figure 8: Variation of battery State of Charge (SoC) with time for proposed Zeta converter-based EV system under standard driving cycle.
Source: Authors, (2026).

In the battery's SoC depicted in figure 8, the battery undergoes non-linear discharge up to 400 seconds and it continues the same way till 600 seconds. The non-linear discharge seen in the initial driving phase coincides with the demands of acceleration while the linear discharge zone shows steady-state cruising. Such a pattern is an indication that the Zeta converter has been very effective in keeping energy delivery constant amid changing load conditions. The battery also gets discharged by 45 percent at 600 seconds in the case of Zeta converter, and for Lithium-ion batteries it is 50 percent by 600 seconds. In the case of H bridge, the percentage drained is only 45 percent at the same interval while the battery is being used as a converter. The recommended Zeta converter provides the optimal charge level for the battery while the electric vehicle is in use.

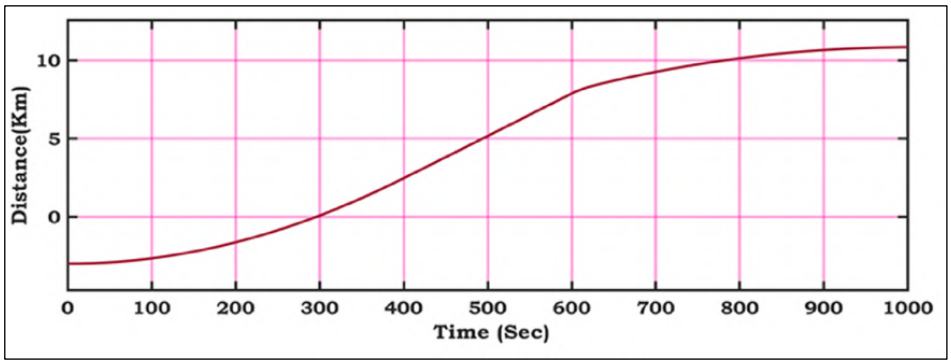

Figure 9: Distance travel by the vehicle using H Bridge Converter.
Source: Authors, (2026).

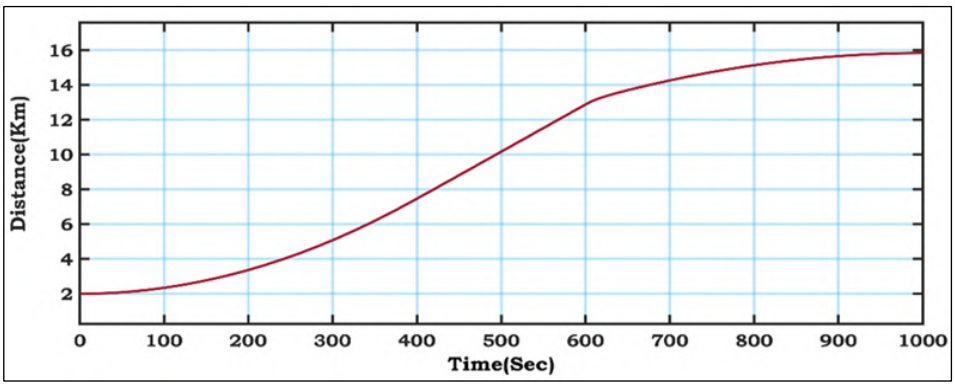

Figure 10: Distance travel by the vehicle using Proposed Zeta Converter.
Source: Authors, (2026).

The Simulink model ran for one thousand seconds in the MATLAB software. The battery state of charge (SoC) was 45%. The vehicle covered a distance of 12 km in 1000 seconds, as shown in the figure 9. During this, the same amount of current would pass from the battery to the motor when the vehicle was accelerating; upon deceleration, the motor would be connected to the battery through the current flow. With the application of the proposed Zeta Converter, the SoC percentage was 50% and the distance covered by the vehicle was 16 km in 1000 seconds as illustrated in figure 10. A summary of the battery SoC and vehicle travel distance is provided in table 2.

Table 2: Comparative performance of H-bridge and Zeta converter-based EV systems in terms of battery SoC and vehicle travel distance.

Type of Converter	Distance Travelled for 1000 Sec in (Km)	SoC (%)
H Bridge	12	45
Zeta Converter	16	50

Source: Authors, (2026).

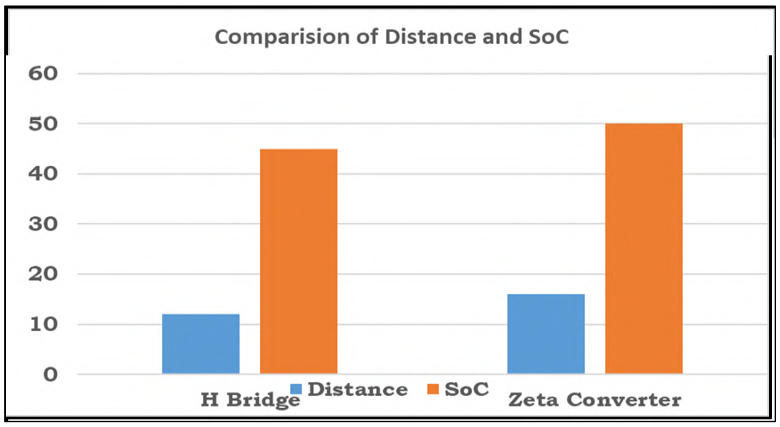

Figure 11: Comparison Chart of H Bridge and proposed Zeta converter-based Battery's SoC and Distance Travel by the Vehicle.
Source: Authors, (2026).

Both the H-bridge converter and the suggested Zeta converter experienced the same rate of acceleration and deceleration as the Li-Ion battery model [23] and [24]. The car covers a distance of 12 kilometers in 1000 seconds with the H-bridge converter, and the state of charge is 45%, whereas with the Zeta converter, the distance covered is the same, i.e., 12 kilometers in 1000 seconds, but the state of charge is 50%, as shown in Figure 11.

V. CONCLUSION

The article presents simulation results showing that a Lithium-Ion Battery-powered H bridge electric vehicle could travel 12 KM in 1000 seconds, which is equivalent to 43.2 KM/Hour when calculated on an hourly basis, and the battery is discharged 45 percent. With the proposed Zeta converter, the electric vehicle using a Lithium-Ion Battery could travel 16 Km in 1000 seconds i.e. 57 KM/hourWhen we compare the results, the proposed Zeta converter improved the battery's State of Charge. The distance traveled increased by 30 percent, too. The same converter was also used for the vehicle's auxiliary devices by changing the duty cycle. The outcome proves that installing a Zeta converter in the EV powertrain not only improves energy utilization but also increases driving range and battery SoC under the same operating conditions. This proves the appropriateness of the proposed converter for EV propulsion and auxiliary systems, which leads to more energy-efficient and eco-friendly electric vehicle designs.

ABSTRACT

This paper proposes a Parallel Lévy Flight Cuckoo Search (CS PLF) framework for joint siting and sizing of renewable distributed generation (DG) with power quality enhancement in radial distribution networks. The planning objective balances economic efficiency and operational security via a scalarized function combining the benefit to cost ratio (BCR), voltage stability factor (VSF), and a network security index (NSI) under standard power flow and equipment constraints. This article introduces two design elements that strengthen optimization results: (i) a parallelized Lévy flight update to accelerate global exploration without parameter inflation, and (ii) an integrated planning model that accounts for DG real/reactive support and UPQC driven reactive needs within the same optimization loop. In comparative experiments on an Indian 28 bus radial distribution system, CS PLF achieves lower composite objective values and stronger voltage profiles, while PSO provides lower total cost and faster runtime, highlighting a planning trade off between economy and robustness.

I. INTRODUCTION

Growing penetration of renewable DG in distribution networks requires planners to co optimize siting/sizing decisions with power quality and voltage stability objectives. While metaheuristics (e.g., PSO, CSA, GWO) have been widely adopted, two persistent gaps remain: (1) most works treat DG allocation and power quality devices in separate stages; (2) search strategies often trade off exploration for speed, or vice versa. To address these, this article proposes CS PLF, a Cuckoo Search variant that parallelizes Lévy flight perturbations and embeds UPQC aware quality metrics in the objective, enabling joint economic–technical planning.

Contributions:

1. Integrated multi criteria formulation combining BCR, VSF, and NSI with standard AC constraints, capturing cost, voltage robustness, and thermal loading risk in one scalar objective
2. Parallel Lévy Flight Cuckoo Search (CS PLF): embarrassingly parallel Lévy flight updates accelerate global search while preserving CSA's low parameter count
3. DG and Power Quality co planning: decision variables include DG locations, counts, and ratings (P/Q), with UPQC considerations implicitly driving voltage profile/harmonic mitigation benefits.
4. Comparative study vs. PSO: highlights a cost–robustness trade off valuable for planners (CS PLF improves stability/security, PSO reduces cost/runtime).

Recent studies have significantly advanced the field of distributed generation (DG) sizing and placement, largely through the development of improved and hybrid optimization algorithms.

According to [1], [2] demonstrated the effectiveness of the Cuckoo Search Algorithm (CSA) in improving convergence speed and solution quality compared to classical methods. Further refinements to CSA were proposed by [3], who developed variants with reduced computational complexity and enhanced global search characteristics. Hybrid optimization frameworks have also shown considerable promise. According to [4] introduced a Grey Wolf–Cuckoo Search hybrid approach that improves robustness in identifying optimal DG placement, while by [5] applied PSO assisted techniques for DG allocation with reactive power support. Additional studies such as by [6] validate that hybrid metaheuristics offer performance gains in multi-DG integration. Research relating to Unified Power Quality Conditioner (UPQC) continues to expand due to its importance in mitigating voltage sag, harmonics, and reactive power imbalance. In [7], [8] evaluated multi objective and PSO based UPQC allocation methods, respectively. Benchmarking efforts such as that by Espinosa Gutiérrez and Aguila Téllez [9] demonstrated that exhaustive search can still serve as a useful reference for validating heuristic algorithms. In [10], [11] developed hybrid metaheuristic approaches to improve UPQC performance under varying grid conditions. Authors to [12] further explored combinations of genetic and dragonfly algorithms for enhanced UPQC placement efficiency. Machine learning integration for DG and UPQC optimization has also emerged as a growing theme, as highlighted by [13].

However, only a limited number of studies directly address combined DG and UPQC allocation. According to [14] proposed a hybrid Whale–Dragonfly strategy for simultaneous sizing and placement, improving both economic and technical indicators. Complementary insights regarding coordinated multi objective UPQC design are provided by [15]. Authors to [16] investigated UPQC operation within DG integrated networks and emphasized the need for coordinated control to ensure system stability. Comparative reviews, such as that by [17], reinforce that methods outperform deterministic techniques for DG sizing and placement. Additional work [18–21] further demonstrates the effectiveness of hybrid optimization, multi population heuristics, and swarm-based methods. Machine learning and deep learning assisted optimization strategies have also gained traction in recent years [22–24], and industry aligned reports such as by [25] confirm the continued relevance of PSO based DG planning. With the rapid growth of renewable integration, DG-based distribution systems are increasingly favored for their environmental and economic benefits. Earlier research primarily focused on real power-oriented DG placement using impact indices or classical evolutionary algorithms. In contrast, the present work proposes a CS PLF based approach for optimal DG allocation that simultaneously considers both real and reactive power contributions. This enables improved voltage stability and loss minimization, building upon the foundational contributions of prior studies.

II. MATERIALS AND METHODS

To address the limitations of existing approaches, this article proposes a novel CS-PLF that is compared with PSO. The method is designed to improve optimal results while maintaining computational efficiency. This section starts with objective constraints used for the optimal placement and followed by the PSO and CS-PLF. The objective is to minimize the total cost while maximizing voltage stability and network security. The cost model includes investment and operational expenses, while benefits are derived from improved power quality and reduced losses. Mathematical formulations include cost functions, benefit functions, voltage stability factor (VSF), network security index (NSI), and constraints for generation limits, voltage tolerances, and line capacities.

Decision Variables and Sets

- $\mathcal{N}$: set of buses; $i \in \mathcal{N}$.
- $l_i \in \{0,1\}$: DG location indicator.
- $n_i \in \mathbb{Z}_{\geq 0}$: count of DG units at bus i.
- $P_{ij}^{\mathrm{DG}}, Q_{ij}^{\mathrm{DG}}$: active/reactive rating of a type-j DG at bus i; $j \in$ {solar, wind, biomass}.
- AC state variables V_i, θ_i; line flows S_{ij}.

Economic Model

DG cost (present-valued):

$$C_{\mathrm{DG}} = \sum_i \sum_j (I\, C_{ij}\, n_i\, l_i + \mathrm{OMC}_{ij}\, P_{ij}^{\mathrm{DG}}\, n_i\, l_i) \cdot \mathrm{CPV}, \tag{1}$$

$$\mathrm{CPV} = \frac{1-\mathrm{PV}^{N_y}}{1-\mathrm{PV}} \tag{2}$$

$$\mathrm{PV} = \frac{1+\frac{\mathrm{IF}}{100}}{1+\frac{\mathrm{IR}}{100}}. \tag{3}$$

(Standardized the present-value notation and ratio as used in discounted-cash-flow analysis).

DG benefit (energy value + loss reduction):

$$B_{\mathrm{DG}} = \sum_i \sum_j (P_{ij}^{\mathrm{DG}} + Q_{ij}^{\mathrm{DG}}) n_i l_i \; + \; \Delta P_{\mathrm{loss}}^{\mathrm{DG}}] \cdot C_{\mathrm{hr}} \cdot 8760 \cdot \mathrm{CPV}. \tag{4}$$

$$\mathrm{BCR} = \frac{B_{\mathrm{DG}}}{C_{\mathrm{DG}}}. \tag{5}$$

(If $Q$is remunerated differently, consider a weighting or separate tariff.)

Robustness Metrics

Voltage Stability Factor (VSF) at bus $i+1$:

$$\mathrm{VSF}_{i+1} = 2V_{i+1} - V_i, \bar{\mathrm{VSF}} = \frac{1}{|\mathcal{N}|-1}\sum_{i=1}^{|\mathcal{N}|-1} \mathrm{VSF}_{i+1}. \tag{6}$$

Network Security Index (NSI) via loading level:

$$LL_i = \frac{S_i^{\mathrm{MVA}}}{S_{i,\max}^{\mathrm{MVA}}}, \bar{\mathrm{NSI}} = \frac{1}{|\mathcal{N}|-1}\sum_{i=1}^{|\mathcal{N}|-1} L\,L_i. \tag{7}$$

Lower $\bar{\mathrm{NSI}}$indicates a more secure network.

Objective and Constraints

Scalarized the multi-criteria planning objective as:

$$\min_{\{l_i, n_i, P_{ij}^{\mathrm{DG}}, Q_{ij}^{\mathrm{DG}}\}} f = -\alpha\,\mathrm{BCR} - \beta\,\bar{\mathrm{VSF}} + \gamma\,\bar{\mathrm{NSI}}, \alpha, \beta, \gamma > 0. \tag{8}$$

Subject to standard AC power-flow equations; generator, voltage, and line limits:

(Corrected typographic inconsistencies in the reactive-power balance and clarified that both $P_{\mathrm{loss}}$and Q_{loss}denote network losses.)

$$P_{\mathrm{slack}} + \sum_{i,j} P_{ij}^{\mathrm{DG}}\, n_i l_i - \sum_i P_{D,i} \tag{9}$$

$$Q_{\mathrm{slack}} + \sum_{i,j} Q_{ij}^{\mathrm{DG}}\, n_i l_i - \sum_i Q_{D,i} \tag{10}$$

$$P_{ij}^{\min} \le P_{ij}^{\mathrm{DG}} n_i \le P_{ij}^{\max}, Q_{ij}^{\min} \le Q_{ij}^{\mathrm{DG}} n_i \tag{11}$$

$$Q_{ij}^{\mathrm{DG}} = P_{ij}^{\mathrm{DG}} \tan(\cos^{-1}(\mathrm{PF})) \tag{12}$$

$$V_i^{\min} \le V_i \le V_i^{\max} \tag{13}$$

$$|\,S_{ij}\,| \le S_{ij}^{\max}. \tag{14}$$

A. Particle Swarm Optimization Algorithm (PSO)

PSO is inspired by social behavior in animal groups. Each particle represents a potential solution and updates its position based on personal and global best experiences. The algorithm is efficient for static optimization problems and has been widely applied in power system planning. Figure 1 shows the flow chart of PSO algorithm flowchart.

B. Cuckoo Search- Parallel Levy Flights (CS-PLF)

CS-PLF mimics the brood parasitism of cuckoo birds. It uses Lévy flights for global search and probabilistic replacement of poor solutions. CS-PLF requires fewer parameters and offers robust performance in complex optimization landscapes. Below is a brief summary of the CS-PLF algorithm.

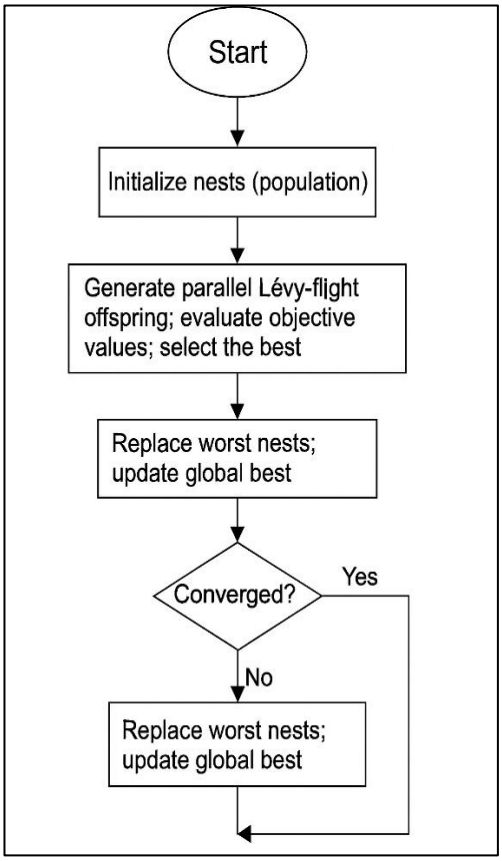

Figure 1: CS-PLF flowchart.
Source: Authors, (2026).

III. RESULTS AND DISCUSSIONS

The MATLAB 2025a m-file is used for the algorithm development and test. The laptop with 11th Gen Intel Core i7-11850H @ 2.50Ghz processor with 32 GB RAM is used. The proposed model is tested on the Indian 28-bus distribution system. DGs of solar, wind, and biomass types are considered over a 10-year planning horizon. Both PSO and CS-PLF are applied with identical population and iteration settings. CS-PLF yields superior voltage stability and network security, while PSO achieves lower total cost and faster convergence. Detailed results are presented in tabular and graphical formats. The test system employed here is Indian 28 distributed bus system [2]. The PSO method and the CS-PLF algorithm are used to minimize Equation (10). Six is assumed to be the constant number of DG installations (N=6). Additionally, the issue has been resolved for a period of ten years (yr) (Nyr=10). The three DG kinds selected are biomass, wind, and solar. In this case, solar is type 1, wind is type 2, and biomass is type 3. And it works for reactive power support also. The power factor considered here is 0.9.

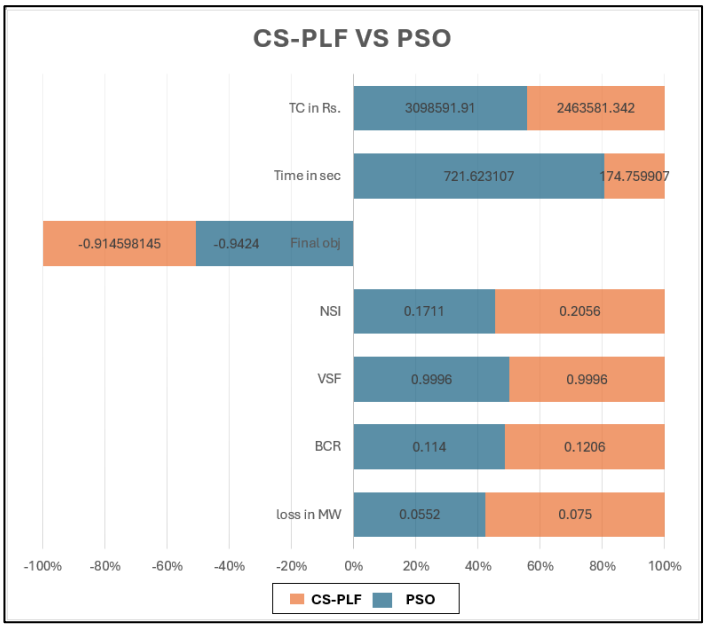

Figure 4: Comparing the CS-PLF with PSO using the following metrics: NSI, VSF, BCF, time spent, total cost, loss in MW, and end objective value.
Source: Authors, (2026).

Figure 2 shows the convergence graph. Where the figure 3 shows the Voltage profile of all the algorithms. The convergence graphs of the CS-PLF and PSO algorithms with the identical objective function are displayed in the above figure. In this case, the overall population is 60, and the number of algorithms for both algorithms is 100. The performance of PSO is shown by the blue line in the graph above, and that of CS-PLF by the red line. CS-PLF provides a superior minimum objective function for 100 iterations. Both meet the requirements. Figure 4 shows the comparison result. The research summarizes the allocation of renewable distributed generators across six buses, detailing their capacity, cost, and operational metrics. The total installed capacity is 4.475 MW and 2.2 MVar, with an overall investment cost of approximately ₹2.14 million and annual operation and maintenance (O&M) expenses of ₹0.33 million, resulting in a cumulative annual cost of ₹2.46 million. Bus 26 contributes the largest share, hosting six units with 1.2 MW capacity and incurring the highest total cost of ₹910,809.89, while Bus 24 is the most cost-efficient with a cost per MW of about ₹276,247. Type-3 DGs dominate the network, providing 3.6 MW capacity but at a higher cost per MW compared to type-2 units, which are more economical. O&M costs remain consistent at roughly 13–14% of total costs across all buses, indicating predictable maintenance scaling. Overall, the data highlights a trade-off between capacity and cost efficiency, suggesting that strategic placement of DGs is crucial for optimizing investment and operational performance. In comparison to the PSO method, the CS-PLF algorithm provides superior voltage profile, NSI, VSF, and BCR values. However, the PSO method is less expensive and takes less time to solve.

It is the logical presentation of the results that demonstrate the true contribution of the research and also justify the conclusion. The parts indicated above, Introduction, Material and Methods serve to explain how the results are obtained. Use tables and figures for your explanation. The results must be written in the past, in a brief and simple way. Avoid redundancy.

IV. CONCLUSIONS

This research demonstrates that renewable DGs, when optimally placed and sized, can significantly enhance distribution system performance by reducing losses, improving voltage stability, and maintaining power quality. A comparative analysis of two metaheuristic algorithms—PSO and CS-PLF—highlights the trade-offs between economic efficiency and technical performance. PSO proves more cost-effective, making it suitable for budget-driven planning, while CS-PLF delivers superior voltage profiles and system stability through advanced global search and parallelized updates. The integration of UPQC further strengthens power quality by mitigating harmonics and regulating voltage. Simulation results on standard IEEE test feeders validate the proposed framework and emphasize that operational priorities, such as minimizing cost or improving voltage stability, should guide algorithm selection. These findings provide actionable insights for smart grid expansion planning and real-time decision-making in renewable-rich networks, paving the way for more resilient and sustainable power systems.

ABSTRACT

As CMOS technology continues to expand to a deep sub-micron scale, standard designs are confronted with many challenges in terms of energy dissipation, leakage currents and area. Although GDI logic minimizes the number of transistors and CNTFET offers improved transport performance, it is on its own that it provides optimal performance. This paper proposes a hybrid design methodology for GDI and CNTFETs combining the structural compactness of GDI with the near ballistic electrical characteristics of 32 nm CNTFETs. The complete digital building block library, including basic logic gates, arithmetic units (half-adder, full-adder), data-routing circuits (multiplexer, encoder, decoder) and sequencing elements (D and Jk flip-flops) have been developed in the Cadence tool based on Stanford 32 nm CNTFET model. Transient, DC and AC analysis confirm full swing logic and high frequency response. The simulation results indicate that the proposed hybrid architecture achieves a reduction of 40-70% in power and 25-55% in silicon area compared to conventional CMOS and standalone GDI, CNTFET reference products, and is a much improved Power-Delay Product. These findings, together with the significantly improved PDP, make the GDI-CNTFET hybrid framework a viable and scalable solution for energy-efficient nano-electronic systems.

I. INTRODUCTION

The relentless pursuit of Moore's Law [1] has pushed integrated circuit (IC) technology down to the deep sub-micron and nanometer scale, and this has led to the need for low-power, high-speed and area-efficient VLSI systems [2]. This is particularly important for the emerging areas of Internet of Things (IoT), implantable biomedical sensors and edge computing. However, bulk CMOS has significant physical scaling limitations [3], such as leakage current, short-channel effects and threshold voltage variations, which cause performance and reliability problems. To overcome these constraints, researchers have investigated both architectural and device-level innovations. Gate Diffusion Input (GDI) logic is a promising approach at the architectural level to minimize the number of transistors and the switching activity [4], which can be implemented with fewer devices than conventional CMOS [5], leading to lower dynamic power consumption and lower silicon area, but suffers from intrinsic drawbacks, such as reduced output voltage swings and decreased noise margins, which cause the cascaded high-performance systems to become unstable [6]. Simultaneously, Carbon Nanotube Field-Effect Transistors (CNTFETs) have gained prominence as a robust post-CMOS successor. CNTFETs offer extraordinary electrical properties [7], including near-ballistic carrier transport, symmetric threshold voltages, and superior electrostatic control due to their unique geometry. While CNTFETs inherently address the leakage and performance issues [8] of silicon, implementing them using traditional CMOS-like topologies often results in redundant device counts and increased wiring complexity. A critical analysis of current literature [9] reveals a fragmented research landscape: GDI logic is primarily studied for area optimization [10], while CNTFET technology is investigated for power-delay performance [11]. There is a notable absence of a unified hybrid design framework that merges the architectural compactness of GDI with the superior material physics of CNTFETs.

While our previous research established the independent merits of these technologies, this work proposes a novel Hybrid GDI–CNTFET methodology. This co-design strategy leverages the reduced-transistor topology of GDI [12] while utilizing the high-mobility, low-leakage characteristics of CNTFETs [13] to mitigate the traditional GDI "voltage drop" problem through better drive strength. The main objective of this research work is to go beyond the isolated optimization as implied in the graphical version of abstract shown in Figure 1. We implemented this hybrid technique to a set of digital circuits and performed a comprehensive performance evaluation on transistor count, power dissipation, propagation delay, and the Power–Delay Product (PDP). Benchmarking results against conventional CMOS, stand-alone GDI, and CNTFET designs demonstrate that the proposed hybrid approach presents a superior Pareto-optimal solution for next-generation VLSI systems.

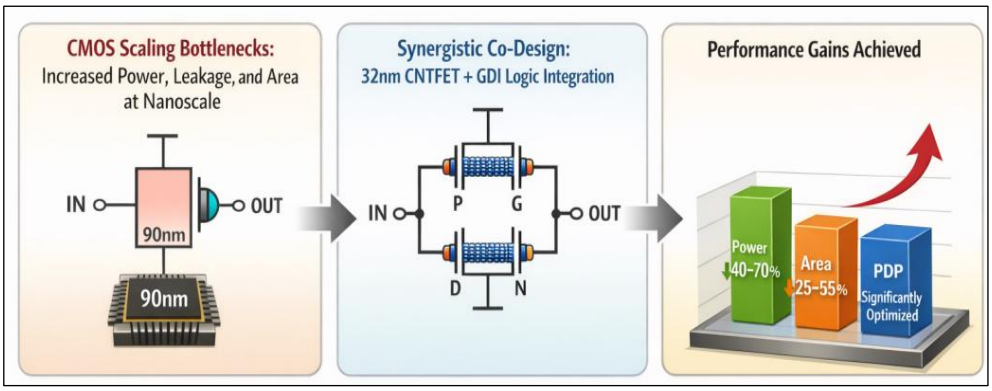

Figure 1: Graphical version of abstract.
Source: Authors, (2026).

The remainder of this paper follows the background and literature surveys conducted for GDI and CNTFET in section-2; section-3 details the proposed hybrid methodology; section-4 describes the implementation of digital circuits with proposed methodology using the Cadence Virtuoso simulation environment; section-5 discusses the results and benchmarking; and section-6 concludes with a future research direction.

II. BACKGROUND AND LITERATURE SURVEY

This section provides the technical basis for research, starting with the introduction of Gate-Diffusion-Input logic and Carbon NanoTube Field Effect Transistor technology. Although GDI [14] simplifies the process of minimizing the number of transistors and power dissipation, its integration into high-performance systems is typically limited by signal degradation. On the other hand, although CNTFETs [15] are the ideal for post-silicon scaling because of their higher carrier mobility, their usage in standard logic topologies is limited. The literature survey [16] performed revealed major design constraints in contemporary designs, particularly in voltage swing restoration and noise immunity. By addressing these limitations [17], the motivation for the proposed Hybrid GDI–CNTFET methodology, a design paradigm engineered to harness the high-speed ballistic transport of carbon nanotubes to overcome the inherent architectural weaknesses of traditional GDI logic.

II.1 GATE DIFFUSION INPUT (GDI) LOGIC:

GDI logic is a low-power circuit design technique [18] that reduces the number of transistors and silicon area when compared to standard CMOS logic. While in standard CMOS, the source terminals of PMOS and NMOS transistors are always connected to the power rails, in the GDI cell, multiple input signals can be applied to the gate, source, and drain terminals, which can be used to realize several logic functions using fewer transistors, leading to reduced area and lower dynamic power consumption. It has been proven that GDI logic can be used to design compact digital circuits such as adders, multiplexers, encoders, decoders and flip-flops with significant reductions in the area and power dissipation compared to CMOS designs.

II.2 CARBON NANOTUBE FIELD-EFFECT TRANSISTOR (CNTFET) TECHNOLOGY:

CNTFETs have been proposed as a possible alternative to conventional CMOS devices for nano-scale VLSI systems [19], because of their high-speed operation with improved energy efficiency, low off-state leakage and symmetric threshold voltages, but existing CNTFET-based designs mainly utilize CMOS logic styles, which often lead to a higher transistor count for complex logic functions and increases the silicon area & routing complexity.

II.3 LITERATURE SURVEY ON LOW-POWER AND AREA-EFFICIENT DESIGNS:

While research in alternative logic styles and emerging device technologies to reduce power dissipation and area in VLSI circuits has been widely studied [20], research on GDI logic has primarily focused on minimizing the number of transistors and area, and research on CNTFETs has primarily focused on improving power and performance at advanced technology nodes [21]. Comparative analyses between CMOS, GDI, and CNTFET implementations have shown that no single approach optimizes power, delay, and area simultaneously. There are a few works that have investigated hybrid logic styles, such as combining pass-transistor logic [22] with CMOS or using CNTFETs in standard logic configurations.

But to the best of our knowledge, no systematic investigation [23] has been performed into a hybrid design methodology that incorporates GDI logic topology with CNTFET technology in the same design.

II.4 MOTIVATION FOR THE PROPOSED HYBRID GDI–CNTFET METHODOLOGY:

Existing research and our prior research work validate that GDI logic and CNTFET technology complement each other [24], with GDI logic reducing area through minimal transistor usage, while CNTFETs provide improved power efficiency, improved voltage swing, and high-speed operation. However, current design approaches optimize these benefits independently, and so they do not achieve concurrent improvements in power and area. This work proposes a Hybrid GDI–CNTFET methodology, which aims to leverage the advantages of GDI circuits (such as low power consumption, minimum delay, and low silicon area) while overcoming the voltage swing and noise margin issues of the CMOS-based GDI circuits [25] by integrating GDI-based logic structures with CNTFET devices. This approach serves as the basis for circuit implementations and performance evaluations presented in the subsequent sections.

III. DEVICE MODELLING AND PROPOSED METHODOLOGY

The design and evaluation of digital circuits, are carried out using an integrated framework that combines the logic-level compactness of Gate Diffusion Input (GDI) with the device-level advantages of Carbon Nanotube Field-Effect Transistors **(**CNTFETs**).** This section describes the CNTFET device model employed [26], the GDI logic cell structure [27], the proposed Hybrid GDI–CNTFET design technique, and the overall methodology adopted for circuit implementation and performance evaluation as shown in Figure 2.

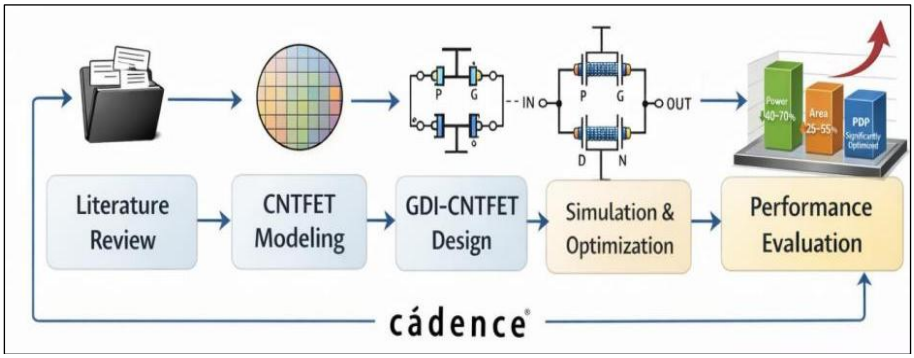

Figure 2: Methodology for Hybrid GDI-CNTFET circuits implemented.
Source: Authors, (2026).

III.1 CNTFET DEVICE MODELLING:

For all the circuits discussed, the Stanford CNTFET compact model [28] is used to accurately simulate carbon nanotube-based devices at the nano-meter technology nodes. The model includes the key physical phenomena, such as near-ballistic carrier transport, quantum confinement, and electrostatic control, which are essential for predicting CNTFET behaviour in digital circuits. Device parameters that are critical for the CNTFET model are the carbon nanotube diameter, which controls the bandgap energy and threshold voltage, the channel length, which impacts carrier transport and switching speed, and the inter-tube pitch, which impacts the device density. Other parameters, such as the number of nanotubes per device, gate work function and chirality vector, are selected to optimise the trade-off between power consumption and the propagation time. Simulations were performed using the Cadence Virtuoso Custom IC Design Platform with the Spectre simulator, enabling accurate transient, DC, and AC analyses at the 32nm technology node. The near-ballistic transport characteristics of CNTFETs significantly reduce scattering effects, resulting in enhanced switching speed and lower power dissipation compared to conventional CMOS devices.

III.2 GDI LOGIC CELL MODELLING:

The proposed hybrid design uses Gate Diffusion Input (GDI) logic [29], which is a logic foundation that requires the use of a minimal number of transistors to implement a variety of logic functions, including NAND, OR, XOR, multiplexers, flip-flops, and arithmetic blocks. GDI logic reduces the number of transistors and switching activity and therefore reduces silicon area and dynamic power consumption compared to CMOS logic. But CMOS-based GDI implementations suffer from threshold voltage loss, degraded output swing, and reduced noise margins, especially when the bulk is fixed and the inputs are source driven, which limits the scalability and robustness of CMOS-GDI designs.

III.3 HYBRID GDI–CNTFET DESIGN TECHNIQUE:

To address the limitations of CMOS-based GDI logic while maintaining its area efficiency, this research work presents a Hybrid GDI–CNTFET design technique, in which conventional PMOS and NMOS devices in GDI cells are replaced with p-type and n-type CNTFETs [30], respectively. This hybridization ensures several benefits as, CNTFETs have symmetric threshold voltages and better electrostatic control, which allows them to operate with full swing even in source-driven GDI configurations, eliminating the threshold voltage degradation and output swing loss in CMOS-GDI circuits.

Moreover, CNTFETs have intrinsically low leakage current and superior subthreshold characteristics, leading to lower static power consumption. Because the GDI topology retains a minimal transistor count, the hybrid approach preserves the area efficiency while improving the electrical performance. The proposed Hybrid GDI–CNTFET technique [31] thus enables simultaneous optimization of power, delay, and area, addressing the primary limitations of GDI-only and CNTFET-only implementations.

III.4 DESIGN FLOW AND EVALUATION METHODOLOGY:

The complete design and evaluation process followed in this research is summarized below:

1. Adoption of the Stanford CNTFET compact model and GDI logic topology.
2. Mapping Boolean functions onto optimized GDI structures and replacing CMOS devices with CNTFET equivalents.
3. Design of digital circuits such as logic gates, XOR, half adder, full adder, multiplexer, encoder, decoder, and flipflops using hybrid GDI–CNTFET cells in Cadence Virtuoso tool.
4. Performing transient analysis to evaluate switching behavior, DC analysis to obtain voltage transfer characteristics, and AC analysis to study frequency response and stability.
5. Measurement of power consumption, propagation delay, output voltage swing, noise margin, and power–delay product (PDP).
6. Performance comparison of proposed hybrid circuits with conventional CMOS, GDI-only, and CNTFET-only implementations in terms of power, delay, PDP, and transistor count.

IV. HYBRID CIRCUIT DESIGN AND IMPLEMENTATION

This section presents design, operational principles, and performance benefits of proposed Hybrid GDI–CNTFET circuits, with emphasis on digital building blocks [32] like 2×1 multiplexer, XOR gate, full adder and other combinational and sequential circuits [33]. These circuits are selected because they form the core of arithmetic and data-path units and effectively demonstrate the ability of the hybrid methodology to achieve simultaneous power, delay, and area optimization. In the proposed approach, conventional NMOS and PMOS devices used in GDI logic are replaced with n-type and p-type CNTFETs, respectively. This integration preserves the compact topology of GDI logic while leveraging the near-ballistic transport, symmetric threshold voltages, and low leakage characteristics of CNTFET technology. All circuits are implemented and evaluated using the Cadence Virtuoso platform with the Stanford 32 nm CNTFET model.

IV.1 HYBRID XOR GATE:

The Hybrid XOR gate is implemented using conventional CMOS, which naturally realizes the Boolean expressions: F=A'B + AB'. The hybrid XOR gate requires only four CNTFET devices (two p-type and two n-type), which is significantly fewer than the 12 transistors required in CMOS XOR implementations and fewer than CNTFET-based XOR designs as shown in Figure 3a and 3b.

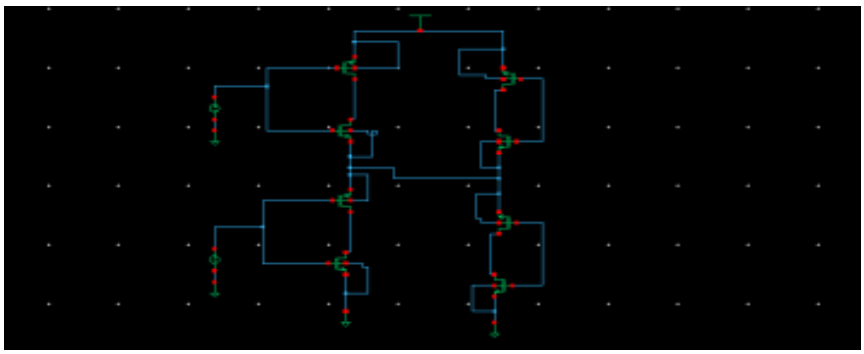

Figure 3a: Schematic of XOR gate using Conventional CMOS technology.
Source: Authors, (2026).

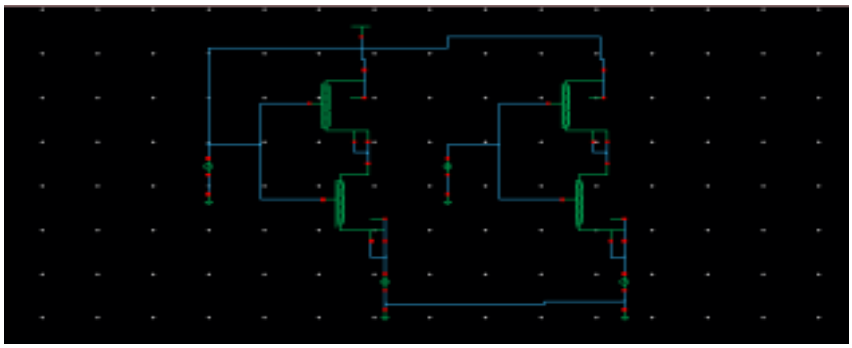

Figure 3b: Schematic of XOR gate using Hybrid GDI-CNTFET technology.
Source: Authors, (2026).

By replacing CMOS devices with CNTFETs, the hybrid XOR gate achieves full-swing output operation, indicated in Figure 3c eliminating the threshold voltage loss typically observed in CMOS-based GDI circuits. The near-ballistic transport of carriers in CNTFETs results in high switching speed and reduced propagation delay**,** while the minimal transistor count leads to lower parasitic capacitances and reduced dynamic power consumption.

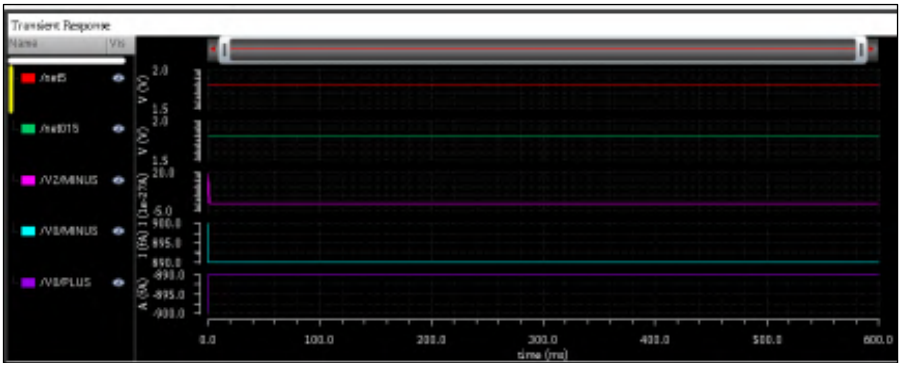

Figure 3c: Transient response of XOR gate using Hybrid GDI-CNTFET technology.
Source: Authors, (2026).

Simulation results indicate hybrid XOR gate offers substantial improvement in power–delay product, making it an efficient for arithmetic circuits and low-power digital systems.

IV.2 HYBRID 2×1 MULTIPLEXER:

The 2×1 multiplexer is implemented using a single GDI cell, where the select line controls gate terminal, and the data inputs are applied to source terminals. This configuration enables the realization of multiplexer function using only two CNTFET devices, representing a drastic reduction compared to CMOS implementations that require 6–8 transistors as represented in Figure 4a and 4b**.**

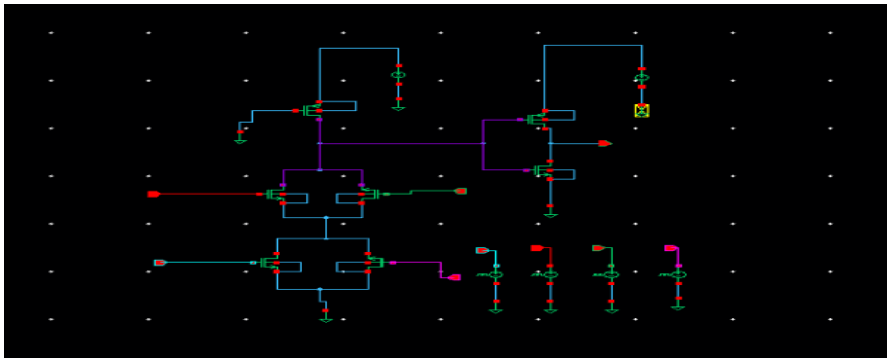

Figure 4a: Schematic of 2x1 multiplexer using Conventional CMOS technology.
Source: Authors, (2026).

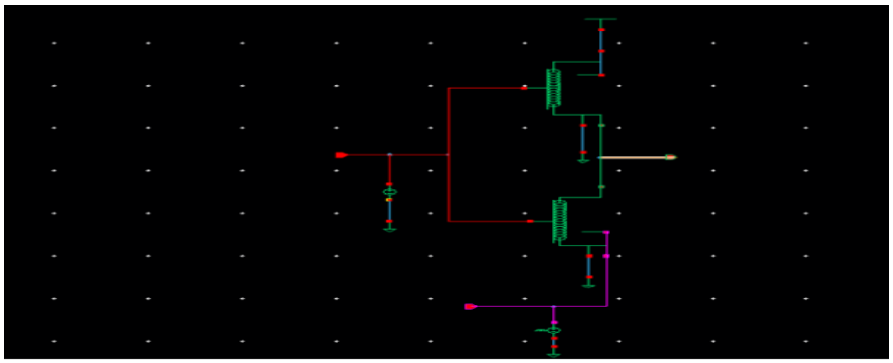

Figure 4b: Schematic of 2x1 multiplexer using Hybrid GDI-CNTFET technology.
Source: Authors, (2026).

In CMOS-based GDI multiplexers, incomplete voltage swing and degraded noise margins are common due to threshold voltage loss. In contrast, the hybrid GDI–CNTFET multiplexer achieves full-swing output across all input combinations, owing to the symmetric threshold voltages and superior electrostatic control of CNTFET devices, as shown in Figures (4- c,d,e,f,g,h).

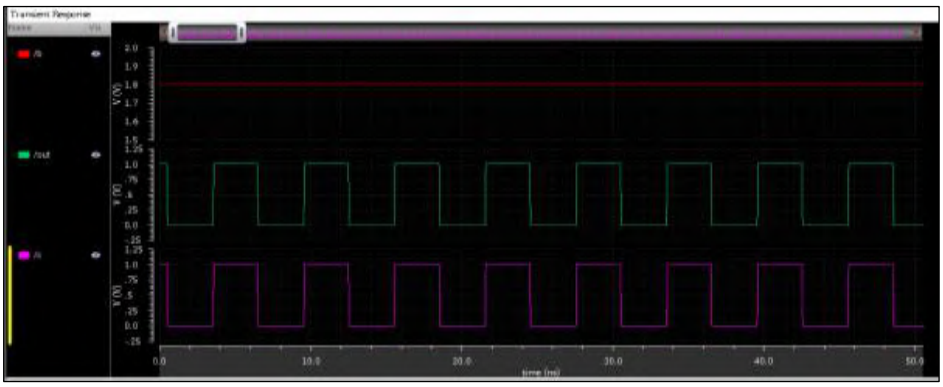

Figure 4c: Transient response of 2x1 multiplexer using Hybrid GDI-CNTFET technology.
Source: Authors, (2026).

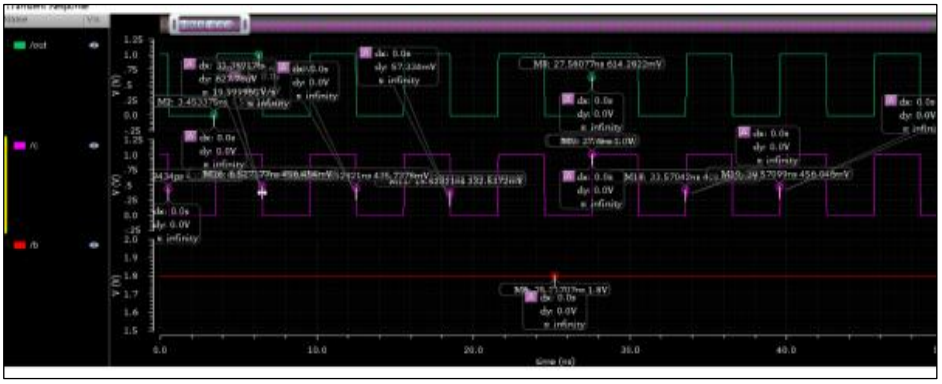

Figure 4d: Delay response of 2x1 multiplexer using Hybrid GDI-CNTFET technology.
Source: Authors, (2026).

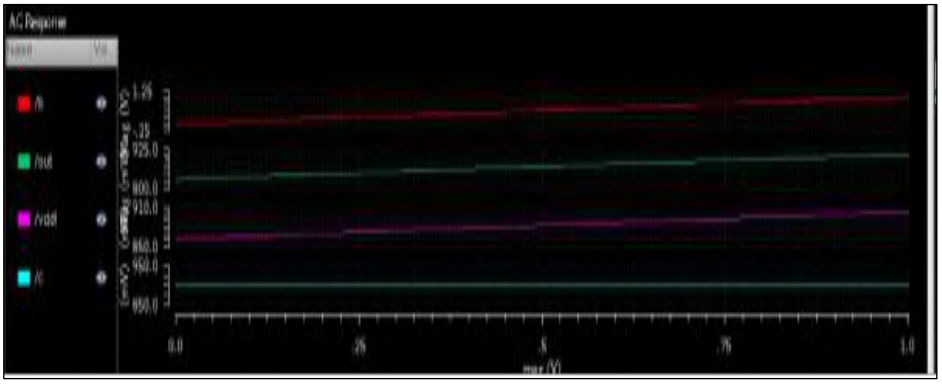

Figure 4e: AC response of 2x1 multiplexer using Hybrid GDI-CNTFET technology.
Source: Authors, (2026).

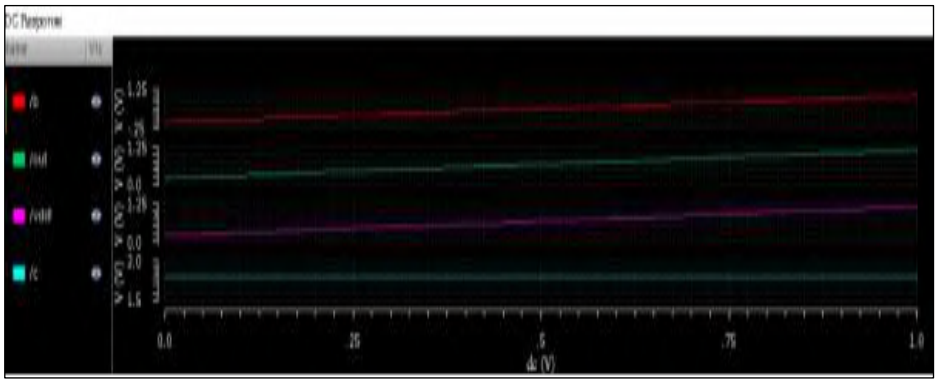

Figure 4f: DC response of 2x1 multiplexer using Hybrid GDI-CNTFET technology.
Source: Authors, (2026).

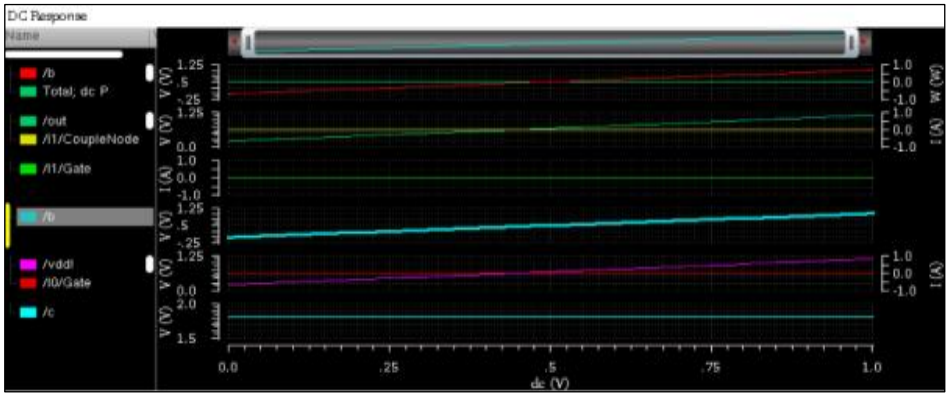

Figure 4g: Power analysis of 2x1 multiplexer using Hybrid GDI-CNTFET technology.
Source: Authors, (2026).

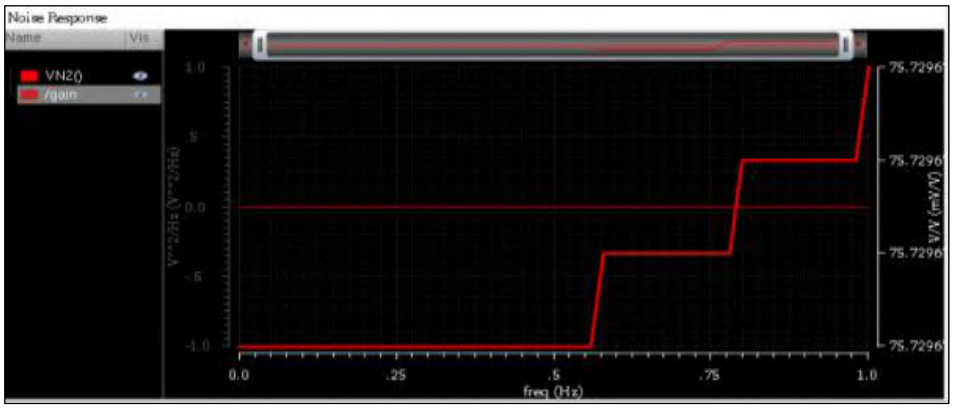

Figure 4h: Noise response of 2x1 multiplexer using Hybrid GDI-CNTFET technology.
Source: Authors, (2026).

The reduced device count and low parasitic capacitance contribute to lower switching power and faster response time, making the hybrid multiplexer well suited for high-speed data routing and selection operations in arithmetic and logic units.

IV.3 HYBRID FULL ADDER:

Hybrid Full-Adder is the most vital circuit used to validate the effectiveness of the proposed methodology, as it integrates both XOR and multiplexer logic within a single arithmetic unit. The full-adder is implemented using sum and carry blocks. This architecture reduces the transistor count, ensuring full-swing logic operation and functionality**.**

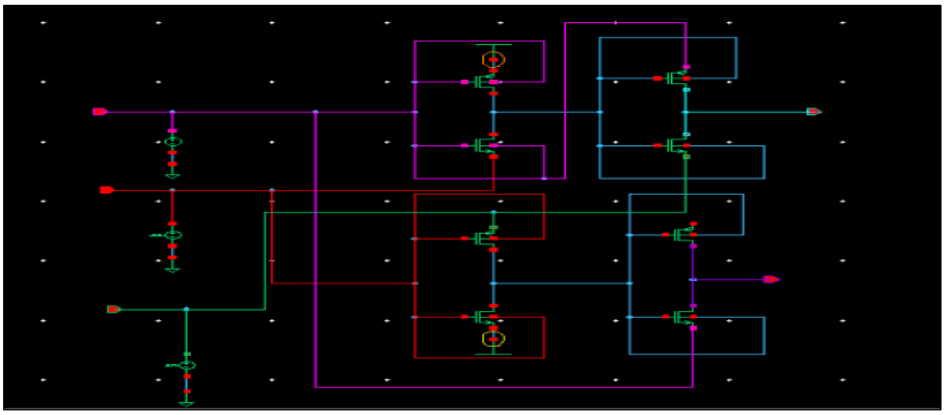

Figure 5a: Schematic of Full-adder using conventional CMOS technology.
Source: Authors, (2026).

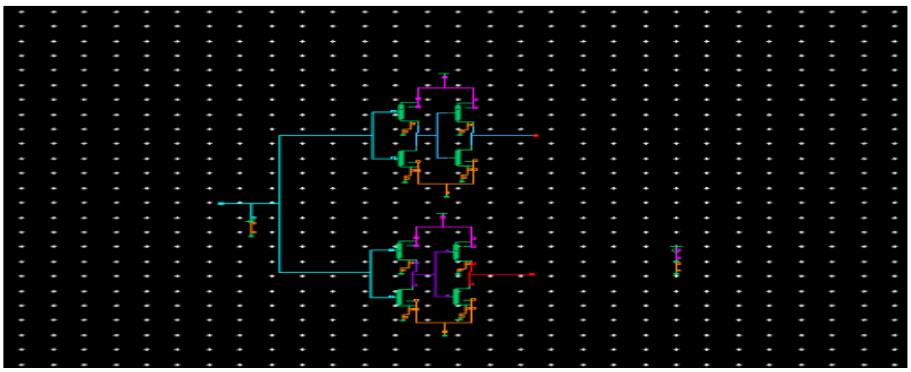

Figure 5b: Schematic of Full-adder using Hybrid GDI-CNTFET technology.
Source: Authors, (2026).

The proposed Hybrid GDI–CNTFET Full Adder requires only 6–8 CNTFET devices, compared to 28 transistors in CMOS**,** 10 transistors in conventional GDI**,** and approximately 18–20 devices in CNTFET designs as shown in Figure 5a and 5b**.** This significant reduction in device count directly translates into lower silicon area and reduced parasitic capacitances.

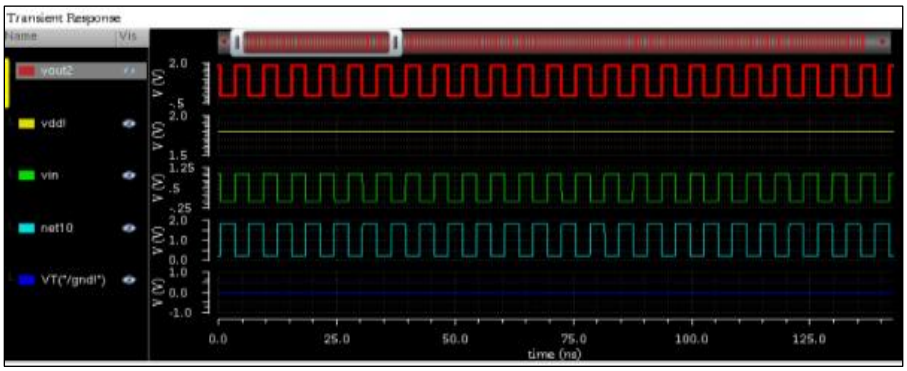

Figure 5c: Transient response of full-adder using Hybrid GDI-CNTFET technology.
Source: Authors, (2026).

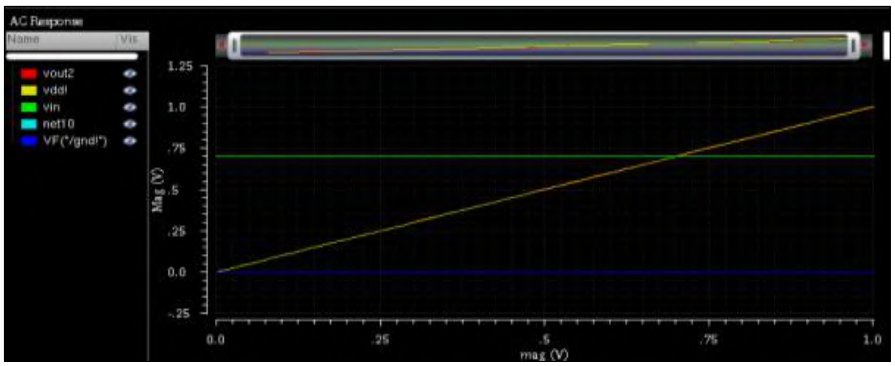

Figure 5d: AC response of full-adder using Hybrid GDI-CNTFET technology.
Source: Authors, (2026).

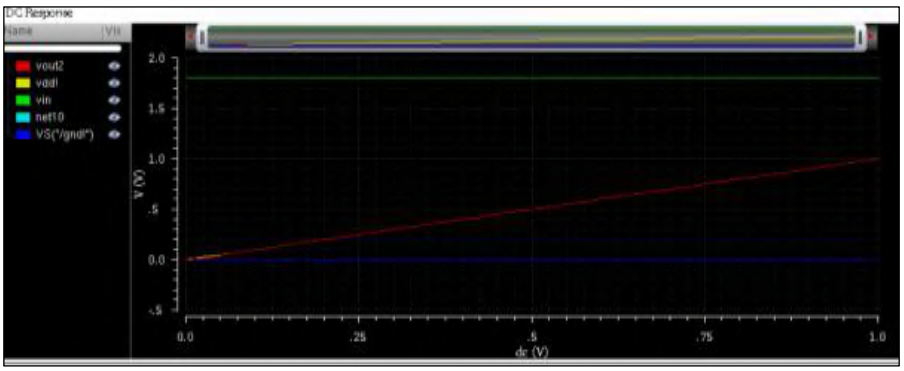

Figure 5e: DC response of full-adder using Hybrid GDI-CNTFET technology.
Source: Authors, (2026).

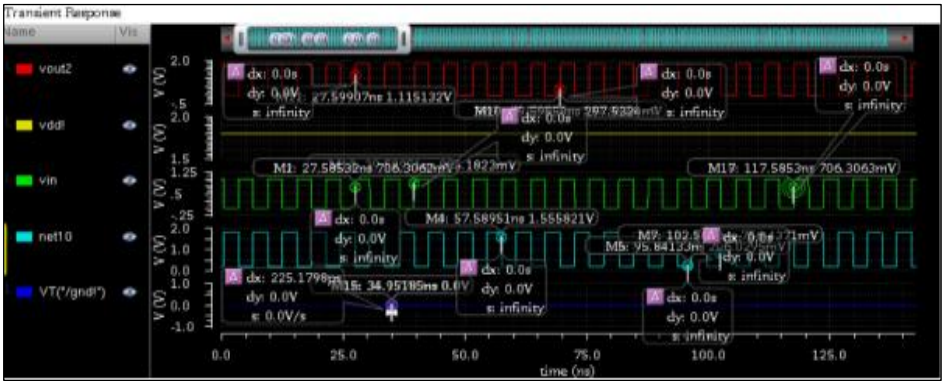

Figure 5f: Delay analysis of full-adder using Hybrid GDI-CNTFET technology.
Source: Authors, (2026).

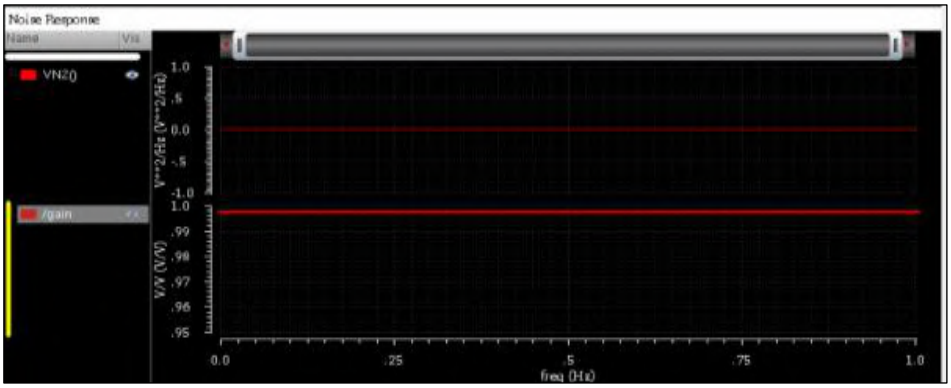

Figure 5g: Noise response of full-adder using Hybrid GDI-CNTFET technology.
Source: Authors, (2026).

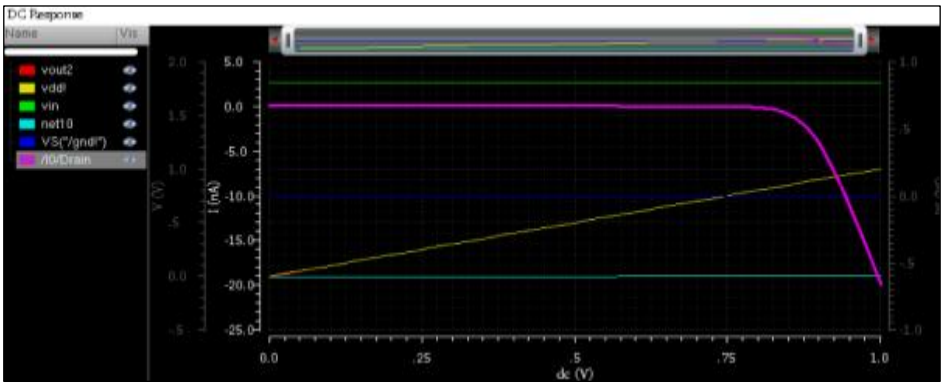

Figure 5h: Power analysis of full-adder using Hybrid GDI-CNTFET technology.
Source: Authors, (2026).

Simulation results indicated in Figure (5-c,d,e,f,g,h), demonstrate that the hybrid full adder achieves substantial reductions in average power consumption and propagation delay, resulting in a markedly improved power–delay product (PDP). These advantages make the proposed full adder design highly suitable for low-power arithmetic units and energy-constrained VLSI systems. The implementation of the XOR gate, 2×1 multiplexer and full adder using the proposed Hybrid GDI–CNTFET methodology clearly demonstrates its effectiveness. The results confirm that the hybrid approach successfully overcomes the voltage swing and noise margin limitations of CMOS-based GDI circuits while preserving their compact structure. At the same time, it mitigates the area overhead typically associated with CNTFET-only implementations. Similarly, for all the specified digital circuits, schematic has been implemented and verified, validated accordingly using Hyrbid 32nm GDI-CNTFET based circuits in accordance with the 90nm CMOS technology, thereby the circuit parameters have been tabulated as shown in Table 1.

Table 1: Comparison of circuit parameters for CMOS and Hybri GDI-CNTFET technology.

Circuit	Technology	Node	Transist or Count	Average Delay (ps)	Average Power (µw)	Power Delay Product (AJ)
NAND gate	CMOS	90nm	4	15	0.8	12

	Proposed Hybrid	32nm		8.9	4.5	40.05

Source: Authors, (2026).

Overall, the proposed hybrid circuits achieve simultaneous optimization of power, delay, and area, validating the Hybrid GDI–CNTFET methodology as a promising design paradigm for next-generation low-power and high-performance VLSI systems.

V. SIMULATION RESULTS ANALYSIS AND DISCUSSION

The analysis for the simulation results observed for basic digital circuits, implemented using Hybrid GDI-CNTFET technology, were studied and represented in Figure 6.

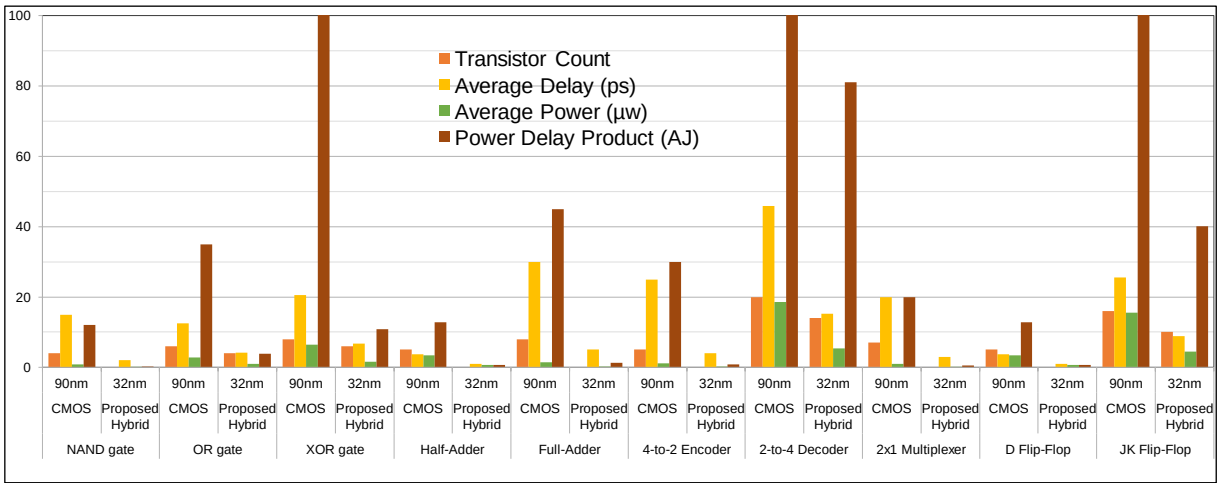

Figure 6: Analysis of CMOS and Hybrid GDI-CNTFET technology for various digital circuits.
Source: Authors, (2026).

The analysis presented details the Hybrid GDI–CNTFET circuits, designed using the 32nm GDI based CNTFET model in the Cadence Virtuoso environment, demonstrate significant performance advantages over traditional CMOS across a wide range of logic components, including NAND gate, OR gate, XOR gate, Half-adders, Full-adders, 4-to-2 Encoder, 2-to-4 Decoder, 2x1 Multiplexer, JK and D flip-flops by combining the low-transistor-count advantage of Gate Diffusion Input (GDI) logic with the high-speed, low-leakage properties of carbon nanotubes, the hybrid design achieves a vast reduction in power consumption and a notable decrease in transistor count.

The proposed hybrid GDI-CNTFET design methodology combines the structural efficiency of GDI with the higher electrical performance of CNTFETs. By using Stanford 32nm CNTFET model, which takes account of near-ballistic transport and threshold voltage dependent chirality, the design achieves full swing output transitions and eliminates the loss of threshold voltage, which occur in traditional GDI circuits based on CMOS technology. Simulations with different digital logic circuits (NAND, OR, XOR, half-adder, full-adder, multiplexer, encoder, decoder) and complex modules (D and JK flipflops) show 40-70 percent reduction in power and 45-70% increase in PDP compared to CMOS at 90nm. The hybrid approach also optimises the area by 25-55% than the standard CNTFET-based design, further reducing parasitic capacitance and allowing high speed operation. This design has a high noise margin and low leakage characteristics, which make it particularly suitable for low-power, high performance VLSI systems at the nanoscale. Future research can be by applying this methodology to sequential circuits such as clock registers, and then to complete systems-level designs like arithmetic logic units (ALUs) and memory structures. The validation of these designs by physical mapping and parasitic extraction will be a key step in the development of electronic technology.

VI. CONCLUSION AND FUTURE SCOPE

This research introduces a high performance design paradigm for the nanoscale regime, eliminating the dead zones and voltage degradation inherent in conventional GDI topologies and avoiding the classical trade-offs between logic density and signal integrity of CNTFETs. The comprehensive comparison shows that this Hybrid GDI-CNTFET framework leads to a significant reduction of the PDP and silicon area compared to conventional CMOS and the separate GDI-CNTFET implementations. This research has proven that it can withstand the short-circuit effects that are detrimental to traditional silicon based devices and thus provides a viable framework for scalable and energy-efficient next generation VLSI architectures. The results confirm that this approach is a key enabler for the next generation of small-scale, low-power digital signal processing and high-power computing systems. This methodology can be extended to more complex sequential circuits such as clocked registers where timing constraints are more significant and to design a full hybrid-based Arithmetic Logic Unit or explore memory structures such as SRAM. The proposed Hybrid GDI–CNTFET framework can be further extended to large-scale VLSI architectures to illustrate its scalability and system-level power–delay advantages, incorporating process-variation, thermal, and reliability analyses to illustrate the impact of CNT chirality dispersion, density non-uniformity, and device aging. Moving toward layout-level implementation and parasitic extraction will be necessary steps to further validate the industrial practicality of the hybrid GDI–CNTFET approach for future nano-electronic technologies.

VIII. ACKNOWLEDGEMENT:

I express my sincere gratitude to my Supervisor, Co-Supervisor, and Faculty of The ICFAI University, Raipur, for continuous guidance, encouragement, and support throughout the research work. I am deeply thankful for the facilities, technical assistance, and conducive research environment provided, which greatly contributed to the successful completion of the study.

ABSTRACT

This paper focuses on formative assessment of several student groups by executing Load Frequency Control (LFC) in power systems using both MATLAB/Simulink and Google Colab. Four student groups have been formed and have worked together on various aspects of the study, i.e., modelling, simulation, control design, and result analysis. These student groups gained deeper hands-on experience while implementing the controller for the power system. All groups manually tuned the PID controller for the single-area power system. The performance analysis has also been done in MATLAB/Simulink for all groups. Using Google Colab, the formative analysis was performed by importing MATLAB/Simulink results. This work emphasises the importance of frequency regulation for power system stability and demonstrates how project-based learning can simplify complex problems.

I. INTRODUCTION

Load Frequency Control (LFC) is considered a critical aspect of electrical power system operation due to its effects on system stability and reliability. In earlier decades, researchers primarily relied on traditional control methods, such as Proportional–Integral–Derivative (PID) controllers. These controllers minimise steady-state frequency deviations; however, they often face challenges arising from nonlinear system dynamics and operating-condition uncertainties [1-5]. To overcome these problems, more recent studies have adopted advanced approaches, such as fuzzy logic control, fractional-order controllers, and optimisation methods. All of which aim to enhance the system robustness and dynamic response [5-9]. On the other hand, the development of simulation platforms such as MATLAB/Simulink has become increasingly important for education and research, as they enable complex system behaviour to be modelled and tested in a controlled environment. Such tools provide a practical means of reproducing realistic disturbances and evaluating the performance of different control strategies before implementation in actual power networks [7], [9]. In addition to technical modelling efforts, recent work in engineering education has highlighted the importance of formative assessment in both teaching and research [10–13]. The summative evaluation, which provides feedback only at the end of a task, contrasts with formative assessment, which emphasises continuous feedback throughout the learning and experimentation process. This ongoing interaction allows students and researchers to make incremental improvements in system modelling, controller tuning, and performance evaluation. The students can learn concepts easily. By supporting reflection and iterative refinement, formative assessment not only enhances the overall quality of outcomes but also deepens the learner's conceptual understanding and problem-solving ability [12], [13] Moreover, with the latest cloud-based platforms, tools such as *Google Colab* have gained popularity for collaborative analysis, coding, and result sharing. Google Colab offers an open-source, Python-based environment where students and researchers can perform data analysis, visualize results, and document findings in real time without hardware or software constraints [14].

MATLAB/Simulink can provide learning for students. This accessibility and collaborative feature make it a valuable complement to MATLAB/Simulink, especially for group-based projects that require active participation and peer learning. Taken together, prior literature underscores the dual importance of (i) robust control strategies for maintaining frequency stability and (ii) modern computational and pedagogical tools that facilitate both research and education in power system studies.

II. METHODOLOGY

II.1 SYSTEM DESCRIPTION

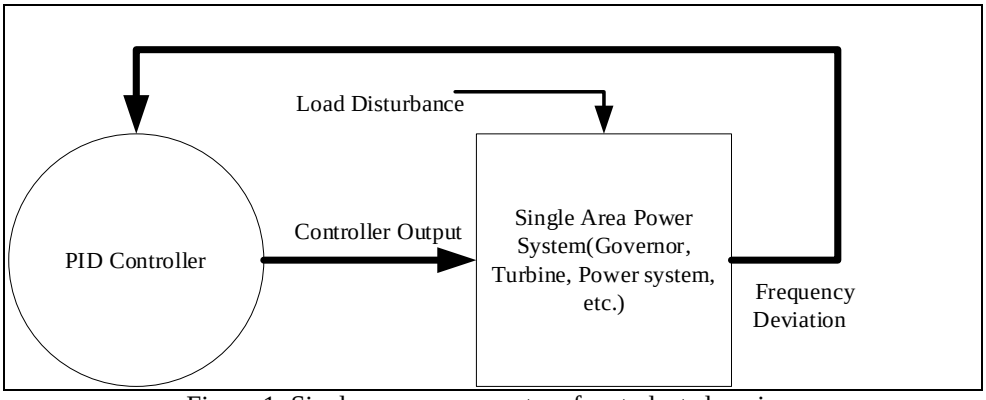

Figure 1: Single-area power system for students learning.
Source: Authors, (2026).

The study focuses on a single-area power system model to evaluate the effectiveness of Load Frequency Control (LFC) under a step load disturbance, as shown in Figure 1. The system includes three main components: the governor, turbine, and generator–load dynamics, represented by standard transfer functions in MATLAB/Simulink. The nominal frequency of the system was set at 50 Hz, and a 1% step load disturbance was applied to test system stability and frequency regulation [9]. The transfer function model of governor, turbine and generator-load dynamics is given below:

$$\text{The Governor Transfer function is } TF_G = \frac{1}{T_G S+1} \quad (1)$$

$$\text{Turbine Transfer function is } TF_T = \frac{1}{T_T S+1} \quad (2)$$

$$\text{The Generator-Load Transfer function is } TF_{GL} = \frac{K_s}{T_S S+1} \quad (3)$$

The values of T_G, T_T, T_S and K_s are 0.08, 0.3, 18 and 120, respectively [9].

II.2 CONTROLLER DESIGN AND TUNING

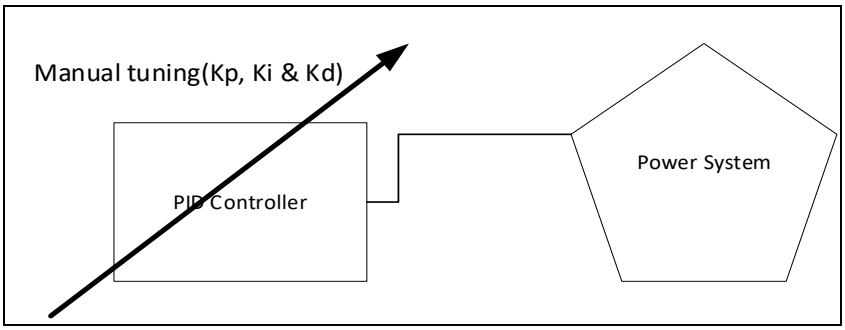

Figure 2: Manual tuning of the PID controller by various student groups.
Source: Authors, (2026).

A Proportional–Integral–Derivative (PID) controller was employed to minimize frequency deviations as depicted in Figure 2. The students need to design a controller for learning various things. Students were instructed to tune the controller parameters (Kp, Ki and Kd) manually through iterative trials or through extensive simulation. This approach encouraged students to build an intuitive understanding of how each parameter influences system response:

a. **Proportional Gain (**Kp**)**: reduces rise time but can introduce oscillations if too high.
b. **Integral Gain (**Ki**)**: eliminates steady-state error but may increase settling time.
c. **Derivative Gain (**Kd**)**: improves damping and suppresses oscillations.

$$\text{Controller } C = K_p + K_i/s + K_d s \quad (4)$$

Manual tuning is performed instead of automatic optimization to reinforce the learning objectives of control design and system behavior analysis.

II.3 STUDENT GROUP IMPLEMENTATION

A total of four student groups participated in the study. They must perform the task on LFC. Each group independently completed the following stages:

a. **System Modelling** – building the single-area LFC model in MATLAB/Simulink.
b. **Simulation** – applying a 1% load disturbance and observing system response.
c. **Manual Controller Design** – tuning PID gains to achieve acceptable system stability.
d. **Performance Analysis** – exporting time-domain results (frequency deviation and controller output) into Microsoft Excel for further evaluation.

This design ensured that every group experienced the *entire cycle* of modelling, controller design, simulation, and analysis, fostering both technical and analytical skills.

II.4 DATA EXPORT AND STANDARDIZATION

For consistency, all groups exported their MATLAB/Simulink results to a common format with three columns: Time (s), Frequency deviation (Hz), and Controller output (pu). Students must export the data from the simulation tool. This standardization enabled a uniform framework for comparative analysis.

II.5 AUTOMATED ASSESSMENTS IN GOOGLE COLAB

To conduct formative assessment, the simulation results exported from MATLAB/Simulink by all groups were uploaded into a Google Colab notebook. Google Colab can do various analyses for LFC. The notebook, developed in Python, automated the process of importing frequency deviation and controller output data, plotting time-domain responses for visual comparison, and computing key performance metrics, including steady-state error, maximum overshoot, settling time, number of oscillations, and peak values with their occurrence times.

Table 1: Performance metrics of student groups.

Group	Steady-State Error (Hz)	Overshoot (Hz)	Settling Time (s)	Oscillations
Group1_LFC	0	0	0	1
Group4_LFC	-0.0004	0.0016	0	5
Group2_LFC	0	0.0007	0	16
Group3_LFC	0	0.0025	0	25

Source: Authors, (2026).

In addition to quantitative evaluation, the notebook generated automated formative feedback, for example: *"Too many oscillations, increase the* Kd*"*, which guided students toward possible tuning improvements. The importance of the controller is discussed in this learning. A weighted scoring scheme was then applied to objectively evaluate each group's performance, with 30% weight assigned to steady-state error, 20% to overshoot, 30% to settling time, and 20% to oscillations. The normalized values were aggregated into a final score (0–100), allowing groups to be ranked and benchmarked against one another. Unlike traditional summative evaluation, this framework emphasized formative assessment by providing students with immediate feedback, opportunities for reflection, and iterative improvement. All analyses are done in Google Colab. The cloud-based nature of Google Colab further ensured accessibility, collaboration, and reproducibility, making it a practical and scalable tool for integrating simulation-based learning with continuous assessment.

III. RESULTS AND ANALYSIS

The performance of four student groups was evaluated based on their MATLAB/Simulink simulations and subsequent formative assessment through Google Colab. Table 1 presents the simulation results for all groups. Table 1 summarizes the primary performance metrics, while Table 2 presents the normalized scores, aggregated totals, and final rankings.

Table 2: Normalized scores and ranking.

Group	Err_score	OS_score	ST_score	OSC_score	Total Score	Rank
Group1_LFC	1.00	1.00	1.00	0.96	99.20	1
Group4_LFC	1.00	0.36	1.00	0.80	83.21	2
Group2_LFC	1.00	0.72	1.00	0.36	81.60	3
Group3_LFC	1.00	0	1.00	0	60.00	4

Source: Authors, (2026).

The manual tuning of all student groups is listed in Table 3. The results indicate that all four groups successfully minimized steady-state error, achieving nearly zero final frequency deviation, demonstrating effective integral action. However, significant differences were observed in oscillatory behavior and damping quality**.** Group 1 achieved the best performance, with negligible error, no overshoot, and only one oscillation cycle.

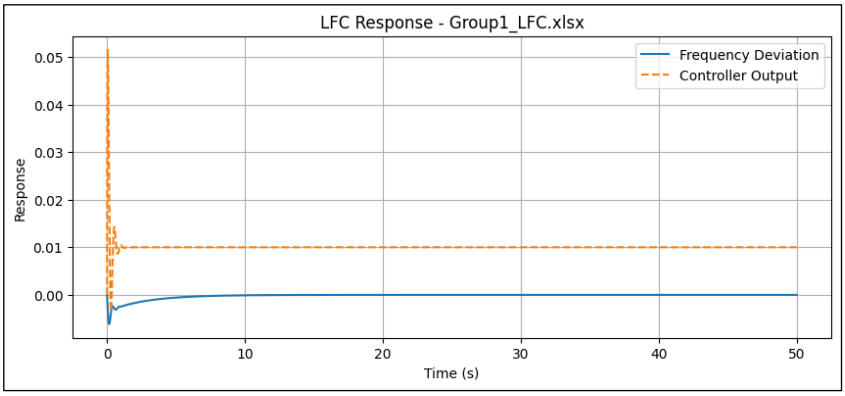

Figure 3: LFC response of Group 1.
Source: Authors, (2026).

The performance analysis is conducted in groups to identify insights. With a total score of 99.2**,** this group's tuning can be considered the benchmark solution. Group 4 ranked second with a score of 83.2**,** exhibiting a small overshoot (0.0016 Hz) and five oscillations, indicating slightly underdamped behavior. Group 2 ranked third with a score of 81.6**,** performing well in steady-state accuracy but experiencing 16 oscillations**,** showing the need for improved damping via derivative gain tuning. Each group is compared to get the rank. Group 3 received the lowest score **(**60.0**)** due to high oscillations (25) and the largest overshoot (0.0025 Hz), suggesting inadequate controller damping and excessive proportional action. The responses of all student groups are depicted in Figures 3-8.

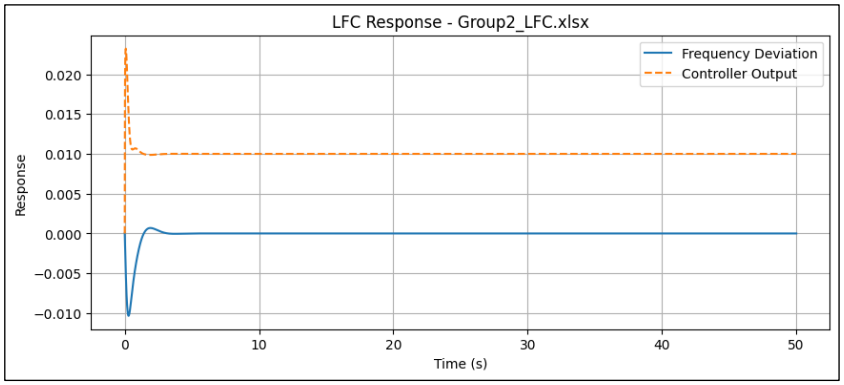

Figure 4: LFC response of Group 2.
Source: Authors, (2026).

Table 3: PID gain values after manual tuning by four student groups.

Groups	Kp	Ki	Kd
Group1_LFC	1.10	1.60	0.30
Group2_LFC	3.00	1.00	0.70
Group3_LFC	0.50	5.00	2.00
Group4_LFC	10.00	0.20	1.00

Source: Authors, (2026).

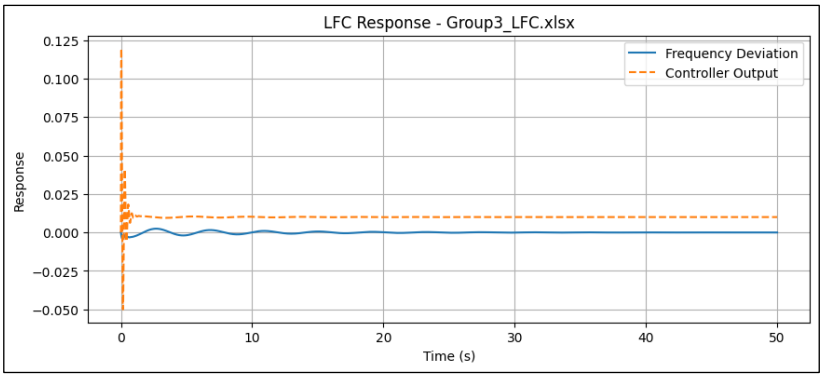

Figure 5: LFC response of Group 3.
Source: Authors, (2026).

The automated formative feedback, as shown in Table 4, reinforced these findings by highlighting strengths such as good steady-state control across all groups, while also pointing out specific weaknesses such as excessive oscillations.

Table 4: Automated formative feedback summary.

Group	Formative Feedback
Group1_LFC	Well-damped response with negligible error and no overshoot; considered benchmark.
Group2_LFC	Good steady-state accuracy but too many oscillations; requires an increase in (Kd).
Group3_LFC	Excessive oscillations and the highest overshoot need major retuning of (Kp), (Ki), and (Kd).
Group4_LFC	Acceptable performance with mild oscillations; derivative gain adjustment suggested.

Source: Authors, (2026).

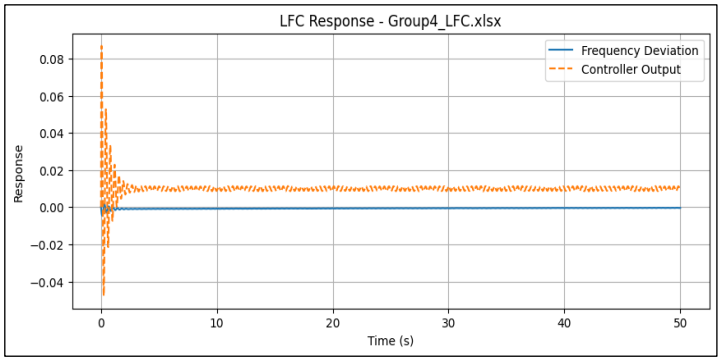

Figure 6: LFC response of Group 4.
Source: Authors, (2026).

Overall, the analysis shows that while students could intuitively achieve frequency regulation, damping characteristics became the key differentiator among groups. The formative assessment is done for all groups. The formative assessment framework successfully provided immediate, targeted feedback, helping students understand the relationship between controller parameters and system dynamics.

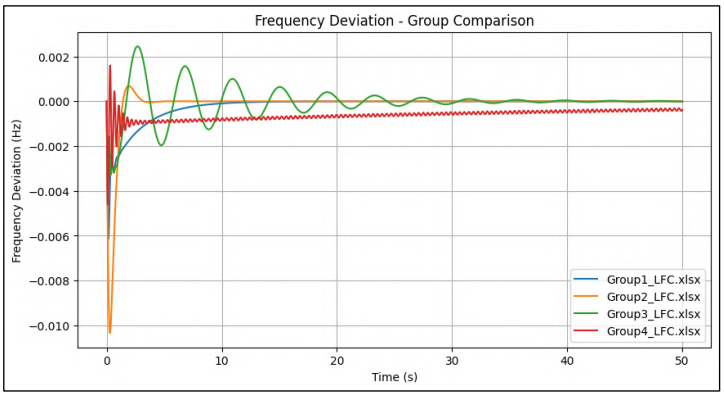

Figure 7: Comparison of the LFC response of various Groups.
Source: Authors, (2026).

From a technical perspective, the results show that all four student groups achieved near-zero steady-state error, confirming that manual PID tuning can effectively regulate the system frequency under load disturbances. However, transient behavior varied significantly. The best performance is identified based on various parameters. Group 1 achieved the best performance with minimal oscillations and no overshoot, while Groups 2, 3, and 4 demonstrated varying degrees of underdamping, reflected in higher oscillation counts. These variations highlight the importance of tuning the derivative gain (Kd) to enhance damping and mitigate oscillatory behaviour, while avoiding excessive proportional action that can worsen transient instability.

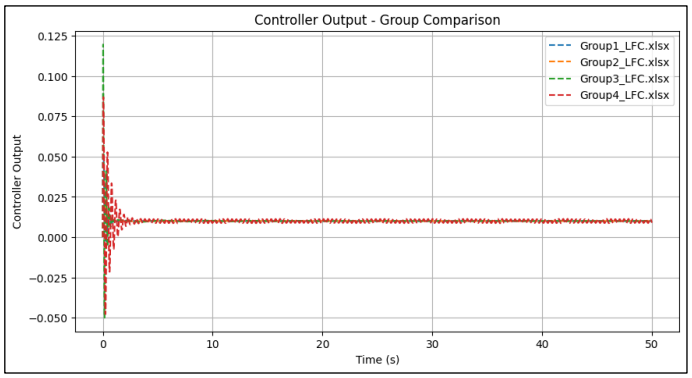

Figure 8: Comparison of controller response for various Groups.
Source: Authors, (2026).

From a teaching and learning standpoint, combining MATLAB/Simulink with Google Colab created an effective environment for formative assessment by providing students with timely, meaningful feedback. This technique will help students learn complex problems. The automated evaluation and ranking system helped students directly relate their tuning decisions to measurable performance indicators, which encouraged them to refine their work through repeated attempts rather than treating the exercise as a single grading event. Working in groups further supported peer learning, comparison, and discussion, making the activity more collaborative and reflective. In addition, because Google Colab is cloud-based and platform-independent, it provides easy access. It ensures that results can be reproduced consistently, making it a useful tool for both classroom instruction and remote learning.

IV. CONCLUSIONS

This work introduced a formative assessment framework for teaching Load Frequency Control (LFC), combining MATLAB/Simulink for system simulation with Google Colab for automated analysis and feedback. The analysis carried out based on various parameters. Four student groups independently developed single-area power system models, applied manual PID tuning, and analysed system responses to a step load disturbance. Although all groups successfully eliminated steady-state error, variations in oscillatory behaviour underscored the importance of proper derivative tuning for achieving stable, well-damped performance. The feedback can be obtained from the analysis. By delivering instant feedback, scores, and rankings, the Google Colab environment enabled students better to understand the link between controller parameters and system dynamics while also encouraging iterative refinement of their designs. The results demonstrate that integrating simulation-based exercises and formative assessment can significantly strengthen technical learning, teamwork, and student engagement.

ABSTRACT

Artificial intelligence (AI) in higher education faces the challenge of translating technological adoption into effective improvements in educational quality, especially in contexts with infrastructural limitations such as Amazonas region, Peru. This research aligned with SDG 4 (quality education) and aimed to propose a model for integrating artificial intelligence into public policies to increase educational quality in public universities of Amazonas region. A basic study was developed with a quantitative approach, non-experimental cross-sectional design, and propositional scope. The sample included 365 participants (students and faculty) from UNTRM and UNIFSLB, selected through simple random probability sampling. A validated Likert-type questionnaire processed with SPSS 27 was applied. Results revealed a paradox: 98.4% reported medium-high levels of AI integration, but only 29.9% perceived high educational quality. The most deficient dimensions were equity (24.1% low), relevance (20.3% low), and effectiveness (20.8% low). It was concluded that high spontaneous AI adoption does not generate proportional improvements without clear institutional policies, systematic training, and ethical governance frameworks, justifying the proposed model of strategic integration into educational public policies, which was validated by experts.

I. INTRODUCTION

Artificial intelligence (AI) is increasingly integrated into global higher education and acts as a driver of change in academic management. Universities that incorporate AI achieve more efficient processes and personalized learning experiences, with direct impact on student performance and resource administration [1]. The analysis of educational big data enables anticipation of academic outcomes and content optimization, which strengthens pedagogical and administrative decision-making [2]. This advancement connects with Sustainable Development Goal (SDG) 4, oriented toward inclusive, equitable, and quality education. Target 4.3 prioritizes equal access to higher education by 2030. Within this framework, AI supports sustainable management models, especially in public universities with budgetary limitations, and strengthens knowledge retention among students [3], [4]. The global Artificial Intelligence market in education reached USD 5.88 billion in 2024 and projects annual growth of 31.2% until 2030 [5]. Nearly half of universities have incorporated AI tools, primarily through chatbots and predictive analytics systems [6]. In the United States, automated teaching assistants have modified classroom dynamics in university settings. According to [7] demonstrated that perception of the evaluation system and ease of interaction with these assistants influence their acceptance by students. In Latin America, experiences in Mexico confirmed improvements in academic satisfaction and complex thinking development through AI-based platforms [8]. Despite these advances, barriers persist related to financing, lack of structural support and limited willingness to share data, as well as privacy concerns, which increase gaps between institutions [9], [10]. In Peru, the education system faces considerable challenges in quality and infrastructure, especially in rural areas. 92% of Peruvian households had internet access in 2023, with increases in rural areas to more than 80% from 41.5% in 2019 [11]. Strengthening competencies in information and communication technologies (ICT) is fundamental to incorporating AI into educational policies [12]. In 2021, only 13% of young Peruvians and adults possessed general ICT skills.

This figure represents the foundation for building educational policies that incorporate AI to improve quality in public universities. In Amazonas region, access to technological resources essential for implementing AI is unequal. The proportion of households with internet access reached 40.8% in 2023, but remains below the national average. The contrast between rural and urban areas regarding infrastructure influences technology adoption in educational settings. In 2017, only 70.3% of rural households in the region had electricity through the public grid [13]. These conditions accentuate challenges for incorporating AI into regional educational strategies. The limitations, combined with scarce faculty training, hinder the implementation of technological innovations. However, it has been demonstrated that intelligent tutors based on AI improve educational effectiveness [14]. The limited involvement of the academic community in adopting innovative technologies threatens educational excellence and regional sustainable development. When authorities, faculty, and students remain distant from technology adoption processes, a void is created that fills with context-disconnected decisions, resulting in ineffectiveness and affecting the essence of inclusive education [15]. It is essential that educational entities foster a culture of training and societal involvement around technology implementation. The benefits of AI must be explained, favoring creation of consultation mechanisms with students and professors, promoting clarity in implementation procedures, and establishing effective feedback systems. Active participation is a practical necessity to guarantee quality in education, enabling the forging of a more inclusive, effective educational system aligned with social needs. Considering the previously described problems, this research aimed to answer the following question: in what way will a model for integrating artificial intelligence into public policies increase educational quality in public universities of Amazonas region? The general objective was to propose a model for integrating artificial intelligence into public policies to increase educational quality in public universities of Amazonas region.

The specific objectives were: to diagnose the level of educational quality in public universities of Amazonas region, to develop a model for integrating artificial intelligence into educational public policies to increase educational quality in public universities of Amazonas region, and to validate the model for integrating artificial intelligence into educational public policies through expert judgment. The justification for this research is based on the need to improve educational quality in disadvantaged territories such as Amazonas region, in order to reduce access and equity gaps. From a theoretical perspective, the study contributes knowledge about integrating artificial intelligence into educational public policies, a field still in development phase. From a practical perspective, the proposed model offers an applicable alternative to strengthen teaching in public universities of Amazonas region through technological tools oriented toward monitoring and improving learning. It should be noted that AI also contributes to increasing student retention, a critical aspect in contexts with high dropout rates, as indicated by [16]. Additionally, the research's impact is expressed in its contribution to designing more inclusive educational policies, based on evidence, with capacity to respond to the territory's real needs. Strategic adoption of AI modifies academic and administrative processes [17]. In this sense, epistemological evidence of these advances maintains the need for models that integrate these technologies within educational public policies. Nevertheless, it is essential to know the level of technological adoption to design effective interventions [18], given that educational quality must be evaluated considering access to resources, an aspect enhanced by AI [19], since its use serves to extend knowledge effectively [20].

II. THEORETICAL REFERENCE

The incorporation of artificial intelligence in higher education configures a global phenomenon that modifies academic practices and optimizes learning personalization and institutional management. According to [21] indicate that modernization through AI enables individualizing teaching and managing resources with greater precision through automated and predictive processes, while [22] highlight its impact on evaluation systems, curricular personalization, and administrative management, with direct effects on equity and sustainability of educational services. This integration is inserted into a technoscientific logic oriented toward process optimization through algorithms that adjust contents, timing, and formative pathways according to each student's academic behavior. The Technology-Organization-Environment (TOE) Framework constitutes a reference point for analyzing AI inclusion in universities. In [23] explain that this model enables examining the influence of technological characteristics, organizational capabilities, and socioeconomic and normative conditions on new technology adoption, which facilitates identifying barriers and opportunities within the institution. Complementarily, the Conceptual Paradigm triangle proposed by [24] integrates technical, social, and ethical dimensions to examine opportunities, risks, and principles in AI use in teaching, a relevant aspect in contexts marked by digital gaps and structural limitations such as those present in peripheral territories. The AI Literacy Conceptual Framework, developed by [25], maintains that AI implementation in university settings must be based on faculty and students having an adequate level of artificial intelligence literacy, that is, acquiring the necessary skills to use intelligent systems ethically, critically, and productively. Along the same lines, the Ethical Governance and Data Protection Framework formulated by [26] establishes guidelines to protect privacy, reinforce equity, and ensure transparency in educational use of AI, which guides the formulation of technological governance policies focused on reducing risks, organizing data management, and guaranteeing more equitable access to artificial intelligence benefits in contexts such as Amazonas region.

The Technology Acceptance Model proposed by [27] explains technological adoption based on perceived utility and ease of use, variables that affect educational actors' attitudes toward incorporating new tools. This approach articulates with UNESCO's [28] Educational Quality theory, which defines excellence from the dimensions of relevance, effectiveness, equity, efficiency, and sustainability. It is complemented by [29] Knowledge Management theory through the SECI model (Socialization–Externalization–Combination–Internalization) and with the Socio-Technical Systems theory (STS) formulated by [30], expanded by [31] and supported by [32], which emphasizes the need to integrate technology and social dynamics to strengthen educational environments coherent with institutional reality. Artificial intelligence is understood as systems that simulate human cognitive capabilities, based on skills such as learning, reasoning, and problem-solving, to optimize educational learning processes [33]. Its dimensions are: machine learning for predicting academic performance [34], natural language processing through educational chatbots, and data analytics for timely pedagogical feedback. Educational quality in higher education is the degree to which universities achieve relevant, equitable, effective, efficient, and sustainable results according to [28], convergent with [35], who indicate its relevance and institutional sustainability. In Amazonas region, this means closing access gaps, increasing digital competencies, and ensuring employability.

Its dimensions are relevance, effectiveness, equity, efficiency, and sustainability, which are expanded with Artificial Intelligence that responds to performance [36] and will help fulfill SDG 4, given the urgency of equity in rural scenarios warned by [37].

III. METHODOLOGY

This research was developed as a basic study, as it sought to generate theoretical-practical knowledge [38]. A non-experimental and cross-sectional design was assumed, since it was carried out in a single period and without manipulation of study variables [39]. This design enabled collecting information about the educational context of 2025, obtaining quantitative data that responded to the problem statement with scientific rigor. The scope of the study was propositional. The study variables were artificial intelligence, viewed from its integration into public policies, and educational quality. Artificial intelligence, defined by [40] as strategic incorporation of tools such as intelligent tutoring and predictive analysis, was structured into dimensions of planning, technological implementation, and ethical governance. Educational quality, according to [28], was understood as achieving relevant, equitable, and sustainable results in education. The unit of analysis consisted of students and faculty belonging to public universities of Amazonas region: the Universidad Nacional Toribio Rodríguez de Mendoza de Amazonas (UNTRM) and the Universidad Nacional Intercultural Fabiola Salazar Leguía de Bagua (UNIFSLB). The established inclusion criteria were: being institutionally active public universities in 2025, having undergraduate programs in effect between 2023 and 2025, having updated records of enrollment and teaching staff, willingness to participate voluntarily, and basic access to digital means to respond to the instrument. The total population was 6,964 individuals, comprising 537 faculty and 6,427 students, according to data reported by both institutions for the 2025-I academic semester. The sample was selected through simple random probability sampling, ensuring that each individual had the same probability of being chosen [41]. 365 individuals were included in the sample, prioritizing accessibility and willingness of participants to obtain relevant and reliable information [42].

For data collection, the survey method was used, considering a structured questionnaire as the instrument that measured perceptions about educational quality (relevance, effectiveness, equity, efficiency, and sustainability) and AI integration (Artificial Intelligence acceptance, intelligent tutoring, predictive analytics, ethical governance and transparency, and language processing), using a five-point Likert scale and verified through Cronbach's Alpha coefficient ($\alpha = 0.880$). It was developed based on the Technology Acceptance Model (TAM), the Technology-Organization-Environment (TOE) Framework, the Ethical Governance and Data Protection Framework, UNESCO's Educational Quality Theory, and Socio-Technical Systems (STS) Theory. Instrument verification was carried out through evaluation by specialists who analyzed coherence, clarity, relevance, and theoretical adequacy of the items. To evaluate reliability, a pilot test was applied to a representative sample, with the objective of analyzing data obtained through application of Cronbach's Alpha coefficient [43], [44]. The instrument results were processed using SPSS (Statistical Package for the Social Sciences) version 27 software, given that it is a program widely used in social science research due to its efficiency in performing basic data analysis [45]. This enabled analyzing opinions of students and professors about educational quality and artificial intelligence incorporation, identifying key trends in emerging technology use.

IV. RESULTS AND DISCUSSIONS

IV.1 RESULTS

Results obtained through application of the validated instrument to 365 participants from public universities of Amazonas region during the 2025-I semester, processed with SPSS 27, are presented organized according to the global diagnosis of educational quality and analysis of its five constitutive dimensions according to the UNESCO (2008) model. Additionally, findings about the current level of artificial intelligence integration in these institutions are included. Table 1 presents the distribution of perceived levels of educational quality in public universities of Amazonas region. These findings reveal a concerning situation where 70.2% of participants perceive significant deficiencies in university educational quality. The predominance of the medium level (62.5%) suggests that, while institutions meet basic standards, there are important shortcomings that limit educational excellence. The percentage at low level (7.7%) represents 28 participants who experience critical educational conditions requiring immediate attention. This distribution confirms the stated problem regarding structural limitations of public universities in emerging contexts such as Amazonas region.

Table 1: Levels of Educational Quality.

Levels	N	%
High level	109	29,9%
Medium level	228	62,5%
Low level	28	7,7%

Source: Author, (2026).

Table 2, corresponding to the relevance dimension, presents low level (20.3%), which constitutes an alarming finding. One in five participants considers that university education has low relevance regarding demands of the labor and social context. The medium level, grouping 45.8% of participants, suggests that there is perception of partial disconnection between curricular contents and competencies required in the regional and national labor market. The perceived low relevance relates to outdated curricula, limited linkage with the productive sector, and limited incorporation of emerging digital competencies.

Table 2: Levels of Relevance.

Levels	N	%
High level	124	34,0%
Medium level	167	45,8%
Low level	74	20,3%

Source: Author, (2026).

Table 3 presents results of the effectiveness dimension, understood as the degree to which universities enable students to achieve established learning objectives and successfully complete their academic programs. Effectiveness presents a high percentage at low level (20.8%), indicating that approximately one in five participants considers that universities are not effectively enabling students to achieve proposed learning objectives. The predominance of medium level (44.4%) suggests that there are partial achievements, but also systematic deficiencies in teaching-learning processes that prevent full accomplishment of educational goals.

Table 3: Levels of Effectiveness.

Levels	N	%
High level	127	34,8%
Medium level	162	44,4%
Low level	76	20,8%

Source: Author, (2026).

Table 4 regarding equity shows that this constitutes the most critical dimension of the diagnosis, presenting the highest percentage at low level (24.1%) among all dimensions analyzed. Nearly one in four participants perceives that there are significant barriers preventing equitable access to quality educational opportunities. Only 29.3% perceive a high level of equity, the lowest percentage among all dimensions at this level. This finding is relevant in the context of Amazonas region, characterized by marked inequalities between urban and rural areas.

Table 4: Levels of Equity.

Levels	N	%
High level	107	29,3%
Medium level	170	46,6%
Low level	88	24,1%

Source: Author, (2026).

Table 5 presents results of the efficiency dimension, defined as optimization in use of human, financial resources, and infrastructure to achieve educational objectives. Data show that efficiency presents relatively more favorable results than other dimensions, with the highest percentage at high level (36.4%) along with sustainability. However, 63.6% of participants still perceive that there are deficiencies in management and utilization of available resources. The low level (18.4%) represents a significant proportion evidencing critical inefficiencies in some contexts or institutional processes.

Table 5: Levels of Efficiency.

Levels	N	%
High level	133	36,4%
Medium level	165	45,2%
Low level	67	18,4%

Source: Author, (2026).

Table 6 shows that sustainability emerges as the dimension with the most favorable results in the diagnosis, registering the lowest percentage at low level (12.6%) and one of the highest at high level (36.7%), along with efficiency. Nevertheless, the predominance of medium level (50.7%) reveals that, while there are institutional foundations enabling continuity of educational processes, limitations persist in consolidating continuous and adaptive improvement. The low-level group raises concerns regarding viability of some programs or policies in the long term.

Table 6: Levels of Sustainability.

Levels	N	%
High level	134	36,7%
Medium level	185	50,7%
Low level	46	12,6%

Source: Author, (2026).

Table 7 presents current levels of artificial intelligence integration in public universities of Amazonas region. The low percentage at low level (1.6%) indicates practically universal receptivity toward AI and evidences that institutions have initiated technological adoption processes with broad acceptance from the university community. The predominance of medium level (61.1%) suggests that, while AI integration is still incipient or partial in scope, there is considerable critical mass of users who have already experimented with AI tools in educational contexts. The high level (37.3%) represents more than one-third of participants, indicating that there is a substantial group perceiving advanced integration.

Table 7: Levels of Artificial Intelligence Integration.

Levels	N	%
High level	136	37,3%
Medium level	223	61,1%
Low level	6	1,6%

Source: Author, (2026).

IV.2 DISCUSSION

The findings of this research offer empirical evidence about the current state of educational quality and artificial intelligence integration in public universities of Amazonas region. The diagnosis reveals a paradoxical situation: while 98.4% of participants report medium or high levels of Artificial Intelligence integration, only 29.9% perceive high educational quality. Deficiencies are concentrated mainly in equity (24.1% low level) and relevance (20.3% low level). This discrepancy between technological adoption and educational improvement constitutes the interpretive axis of the analysis. The study evidences a 7.4% gap between high AI integration (37.3%) and high educational quality (29.9%). This result differs from that reported by [36], who developed an intelligent tutoring model in Peruvian universities achieving a 15% increase in student performance and significant reduction in dropout. The divergence suggests that spontaneous AI adoption in Amazonas region, without institutional articulation or planned pedagogical design, does not generate proportional improvements in educational quality. It contrasts with, who demonstrated that generative AI increased personalized learning by 22%, emphasizing the importance of faculty training as a mediating variable. Results show partial agreement with, who analyzed student perceptions about AI in universities of Peru, Ecuador, and Mexico. 70% of students reported 18% improvements in teaching personalization. The high receptivity toward AI observed in Amazonas region (98.4% at medium and high levels) coincides with this positive perception. However, warned of the absence of ethical approaches and contextual adaptation, deficiencies also present in the Amazonian context. This partial convergence confirms the need for public policies that articulate AI with pedagogy and faculty development. The most significant difference is observed when contrasting results with, who conducted a qualitative study on ChatGPT use in Costa Rican higher education. They demonstrated that generative AI increases student participation but identified as the main obstacle the lack of articulation between government, universities, and civil society. In Amazonas region, that same structural barrier exists: high technological integration coexists with deficiencies in equity, relevance, and effectiveness.

Regarding equity, the results (24.1% low level and 46.6% medium) differ from findings by, who demonstrated that AI-based resources reduced mental effort by 30% and improved learning. Their study was developed in a context with advanced technological infrastructure and universal internet access. In contrast, in Amazonas region, only 40.8% of households have internet connection and 70.3% of rural dwellings have public electricity. This structural gap confirms that cognitive benefits depend on technological equity, a persistent deficiency in the study region. Curricular relevance (20.3% low level and 45.8% medium) partially coincides with, who examined excellence assurance mechanisms in 29 accredited universities in Chile, concluding that AI-based tools prioritize quantity over quality of publications. In Amazonas region, results corroborate that need: perception of disconnection between training and labor demands suggests that technological adoption without pedagogical criteria maintains low curricular relevance. High receptivity toward AI (only 1.6% rejection) agrees with findings by, who analyzed incorporation of generative AI in 63 Peruvian university professors. 66.7% reported high integration, achieving 20% improvement in didactic material development. In Amazonas region, 61.1% present medium integration, reflecting spontaneous use without structured training. This coincidence between Peruvian contexts demonstrates that familiarity with generative tools has promoted massive adoption, though it still requires critical digital literacy. Results about complexity in the context of Amazonas region (40.8% internet access, 70.3% rural electricity, but 98.4% medium-high AI integration) find repercussion with the framework proposed by, who established that management empowerment through knowledge, financing, and support structures is fundamental. Findings confirm those challenges in Amazonas region, where adoption exists without management empowerment, systematic knowledge, or governance structures. Among the main methodological limitations, several factors are identified that condition interpretation of findings and their extrapolation to other educational contexts.

The cross-sectional design prevents establishing clear causal relationships between AI integration and educational quality, since measurement was performed at a single moment without longitudinal follow-up enabling observation of changes over time. This is compounded by dependence on self-reported perceptions through Likert-type scales, a scenario in which participants tend to overestimate their level of AI use or educational service quality. Also noted is the lack of disaggregation by type of actor and by institution, which restricts analysis of differences between faculty and students, as well as between UNTRM and UNIFSLB, while evaluation of AI integration as a global construct, without specifying tools, frequency of use, or pedagogical purposes, generates ambiguity in interpretation of levels achieved. Future research lines demand a more profound methodological approach that incorporates longitudinal or quasi-experimental designs with control groups, in order to establish causal relationships between structured AI implementation and improvements in specific dimensions of educational quality, with measurements at 6, 12, and 24-month intervals. It is also required to disaggregate analyses according to rural or urban origin, socioeconomic level, gender, age, and academic area to identify differentiated impacts, while qualitative studies through interviews, focus groups, and observation will enable recognizing cultural, psychological, and organizational barriers in pedagogical AI integration. It also proposes to evaluate components such as smart tutoring, predictive analytics, and AI literacy programs in isolation, as well as to make comparisons between universities in Amazon region and urban cities in Peru, or with institutions in other Latin American countries with similar characteristics. The main contribution of this study is to provide contextualized empirical evidence on the paradox between the high adoption of AI and the limited improvement in educational quality at public universities in Amazonas region. Three critical dimensions are identified where institutional disarticulation prevents translating technological receptivity into measurable educational improvements. These finding challenges technological determinism and reaffirms the need for public policies that strategically integrate technological, pedagogical, organizational, and ethical components.

IV.3 PROPOSAL

The present model arises from the need to address deficiencies in educational quality identified in public universities of Amazonas region. Results evidence medium or low levels of educational quality and high receptivity toward artificial intelligence. This adoption does not translate into proportional improvements, since 98.4% of participants report medium or high levels of AI integration while only 29.9% perceive high educational quality, with critical dimensions such as equity at 24.1% at low level, relevance at 20.3%, and effectiveness at 20.8%. This paradox shows a gap between technological availability and institutional capacity to generate concrete improvements.

The proposed model guides spontaneous adoption toward a comprehensive strategy that addresses these dimensions through clear policies, systematic training, and ethical governance frameworks, in line with SDG 4 and the needs of Amazon region as an emerging context. The model integrates seven strategic components to close gaps between technological adoption and educational quality. First, the Intelligent Tutoring System with adaptive platforms based on machine learning and offline modules for areas with intermittent connectivity. Second, the Predictive Analytics System with data mining algorithms that identify risk of dropout or low performance, generating early alerts. Third, the AI Literacy Program that develops digital, pedagogical, and ethical competencies at three levels: basic, intermediate, and advanced. Fourth, the Ethical Governance Framework with institutional committees, data protection protocols, algorithmic audits, and guidelines on AI use. Fifth, Digital Equity Strategies with community centers, connectivity scholarships, mobile devices, and multilingual resources. Sixth, the AI-Based Curricular Update System with employability analysis and competency recommendations. Seventh, the Continuous Evaluation System with indicator dashboards linked to the five quality dimensions. Implementation contemplates seven phases during seventy-six months organized sequentially. The Detailed Institutional Diagnosis phase (3 months) evaluates technological capabilities, infrastructure, and digital competencies through audits and focus groups.

The Technological Architecture Design phase (9 months) develops a modular platform with offline components, mobile interfaces, security protocols, and pilot tests with 10% of students. The Progressive Implementation of AI Tools phase (12 months) deploys intelligent tutoring, predictive analytics, and recommendation systems in 50% of academic programs, with continuous technical support. The Intensive Faculty Training phase (6 months) covers 80% of personnel through workshops and certifications. The Establishment of Ethical Governance phase (4 months) forms committees and defines protocols according to Law No. 29733. The Systematic Monitoring and Evaluation phase (24 months) includes quarterly evaluations. The Scaling and Replication phase (18 months) documents results and transfers the model to other universities. The estimated budget amounts to S/ 2,700,000 and is distributed by components: the Technological Platform with S/ 650,000 for design, development, servers, and maintenance; Faculty Training with S/ 350,000 for training 537 faculty members, materials, and certifications; Digital Equity Infrastructure with S/ 480,000 for 15 community centers, 300 mobile devices, and subsidized connectivity; the Intelligent Tutoring System with S/ 420,000 for development and integration; Ethical Governance and Data Protection with S/ 280,000 for committees, training, and audits; Monitoring and Evaluation with S/ 200,000 for dashboards and quarterly reports; Management and Implementation with S/ 320,000 for coordination, supervision, and contingencies throughout the seventy-six-month period.

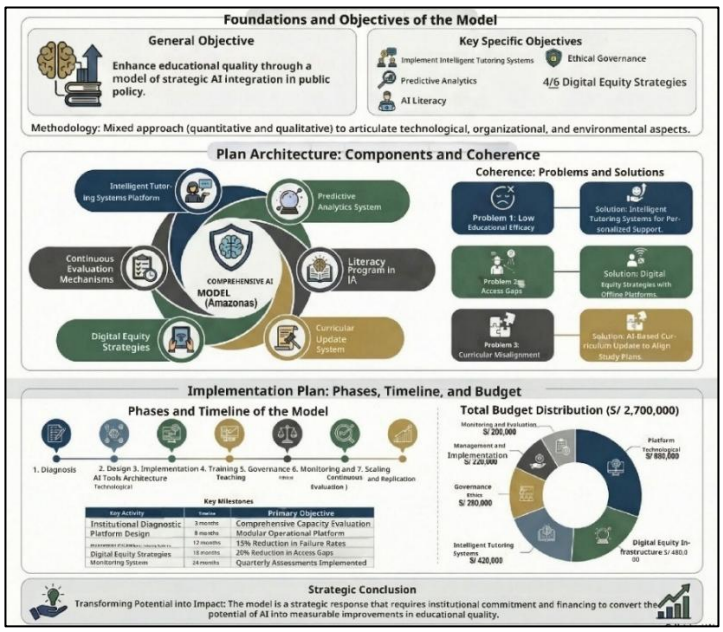

Figure 1: Model for integrating artificial intelligence into public policy to improve educational quality in public universities, Amazonas.
Source: Author, (2026).

V. CONCLUSIONS

The diagnosis of educational quality in public universities of Amazonas region revealed significant structural deficiencies. Equity emerged as the most critical dimension, with barriers preventing equal access to quality educational opportunities, while curricular relevance presented alarming deficiencies, evidencing disconnection of university training from regional and national labor market demands, as did effectiveness. Additionally, the dimensions of efficiency and sustainability, although relatively more favorable, evidenced that the majority perceive deficiencies in resource management and institutional capacity to innovate. The model for integrating artificial intelligence into educational public policies responded strategically to identified deficiencies through systematic articulation of seven implementable phases, integrating technological, organizational, pedagogical, and ethical components. In turn, the proposal recognized particularities of the Amazonian context, incorporating solutions adapted to intermittent connectivity through platforms with offline components, interfaces optimized for mobile devices, and digital equity strategies. The strategic articulation between empirical diagnosis and intervention proposal enabled designing a contextualized model that transforms spontaneous AI adoption into strategic integration. Finally, findings evidenced a significant theoretical, methodological, and social contribution. Theoretically, the study challenged technological determinist assumptions by empirically demonstrating that high receptivity toward AI does not automatically generate proportional improvements in educational quality without mediation of contextualized public policies.

Methodologically, the research combined quantitative diagnosis with propositional design, generating a replicable model for Latin American public universities. Socially, the proposal aligned with SDG 4 by prioritizing equity as a critical dimension, developing personalization strategies through AI that compensate for structural disadvantages of rural students. This constitutes transferable knowledge to other Peruvian and Latin American public universities facing similar problems between expansion of access to emerging technologies and persistence of educational inequities.

ABSTRACT

Efficient and scalable network architectures are essential for enterprise environments that demand reliable and high-performance connectivity. Virtual Extensible LAN (VXLAN) technology enables the encapsulation of Layer 2 traffic over Layer 3 infrastructures, while Software-Defined Networking (SDN) introduces centralized control and programmability by decoupling the control and data planes. This study presents the design and implementation of an enterprise network architecture that integrates SDN and VXLAN technologies to enhance scalability, performance, and security. The PPDIOO lifecycle methodology was adopted as a structured framework for design, deployment, and optimization. The proposed architecture was implemented and validated in a GNS3 emulated environment using OpenDaylight as the SDN controller and Open vSwitch (OVS) as the virtual switching layer. Functional testing, including connectivity verification and packet flow analysis, confirmed correct operation of VXLAN tunneling under SDN control, demonstrating the feasibility and effectiveness of the proposed model. The results highlight that the integration of SDN and VXLAN provides a flexible, programmable, and secure foundation for next-generation enterprise network infrastructures.

I. INTRODUCTION

In modern business environments, connectivity and performance are essential to ensuring operational efficiency and competitiveness. In an increasingly digitalized global environment marked by the rapid advancement of smart devices, the volume of data traversing networks is growing exponentially, leading to greater complexity in network infrastructures [1], [2]. A production network typically comprises numerous devices, operates under various protocols, and supports a wide range of applications [3]. The adoption of emerging technologies such as Virtual Extensible LAN (VXLAN) [4], [5] and Software-Defined Networking (SDN) [6], [7] represents an innovative alternative that significantly improves performance compared to traditional networks. Thus, Internet Service Providers (ISPs) and network administrators must adjust to these transformations by implementing the right tools and methodologies to guaranty effective network management. SDN is a dynamic and evolving architecture that decouples the control plane from the data plane, making it particularly suitable for the changing requirements of modern applications [8], [9]. A centralized controller offers a global view of the network, enabling enhanced monitoring, configuration, and packet flow analysis. Meanwhile, VXLAN enables the creation of a large number of isolated virtual networks, overcoming limitations of traditional VLAN technologies [10], [11]. This tunneling protocol facilitates network segmentation around virtual machines and allows the deployment of Layer 2 networks over a Layer 3 infrastructure, thereby improving overall traffic performance. The integration of SDN and VXLAN brings together essential capabilities required to overcome the limitations of conventional networking technologies. By [12] proposed an SDN-controlled VXLAN architecture implemented in an intelligent data center to support seamless virtual machine migration. They deployed the design using Mininet and achieved optimal load balancing results. Their findings demonstrated that an SDN-based VXLAN architecture reduces IP multicast resource usage and meets deployment requirements in cloud computing environments. Similarly [13] evaluated SDN-controlled VXLAN in multi-site enterprise networks using Mininet, identifying high traffic volumes and latency as primary challenges.

They proposed dynamic VXLAN tunnels, tunnel division for hybrid and corporate access, and centralized policy management to improve performance and operational agility. These results highlight the potential of SDN and VXLAN to optimize complex infrastructures and pave the way for AI-driven solutions in network security. Network performance and efficiency are critical for service interconnection in enterprise environments. However, few works have addressed the systematic design and functional deployment of SDN-VXLAN architectures in enterprise contexts, where interoperability with existing infrastructures and operational frameworks is critical. To overcome these limitations, this study aims to design an efficient network architecture that integrates SDN and VXLAN to optimize enterprise network performance. This study aims to design and implement a functional enterprise network architecture that integrates SDN and VXLAN technologies, following the structured PPDIOO (Prepare, Plan, Design, Implement, Operate, Optimize) lifecycle methodology proposed by Cisco. The primary contribution of this work lies in demonstrating a replicable and verifiable implementation framework that validates the interoperability and feasibility of SDN-VXLAN integration over an emulated MPLS underlay network. The proposed model was implemented using the GNS3 network emulator, with OpenDaylight serving as the SDN controller and Open vSwitch (OVS) as the virtual switching element within Ubuntu-based Docker hosts. Functional testing focused on verifying VXLAN tunneling, OpenFlow-based flow control, and SDN management capabilities. The remainder of this paper is organized as follows: Section 2 describes the materials and methods applied throughout the PPDIOO lifecycle. Section 3 presents the main implementation results and discusses the observed operational behavior. Finally, Section 4 summarizes the key findings and outlines directions for future research.

II. RELATED WORKS

The integration of SDN with network virtualization mechanisms such as VXLAN and EVPN has led to a substantial body of research aimed at enhancing automation, scalability, and traffic isolation across diverse scenarios, ranging from multi-tenant data centers and multisite infrastructures to educational networks and domain-specific applications. However, most of these studies concentrate on isolated data-plane optimizations, energy-efficiency improvements, or narrowly scoped use cases, and therefore do not provide a comprehensive methodology or a reproducible design suitable for enterprise environments. To contextualize the contribution of our work, we present a detailed comparison of ten relevant studies that explore different combinations of SDN controllers, VXLAN/EVPN technologies, underlay configurations, validation environments, and design objectives, as summarized in Table 1.

Table 1: Comparative summary of related works and the proposed SDN–VXLAN architecture.

Ref.	Objective	Technologies	Validation	Contributions	Limitations
[14]	Performance optimization	SDN + P4 switches + EVPN/VXLAN	Experimental tests	Accelerated user-plane performance; ARP suppression; multi-tenancy and DAG support	Lacks implementation methodology; limited to data-plane optimization
[15]	Eco-efficient multi-tenant datacenter management	Ryu controller + VXLAN	Experimental	Zero traffic leakage; automated VTEP discovery; energy-efficient orchestration	No detailed deployment methodology; limited evaluation scenarios
[16]	Green multisite datacenter orchestration	SDN + EVPN/VXLAN + DPDK	Simulation	Reduced workload migration time (4.24%); resilient multi-homing architecture	Specific to GMDC; not suitable for enterprise networks
[17]	Distance learning enhancement	SDN + VXLAN	Practical scenarios	Remote access as local network; improved STEM resource availability	Not generalizable to enterprise environments; lacks benchmarking
[18]	Smart agriculture / online learning	SDN + VXLAN	Conceptual study	IoT connectivity through overlays; supports future national datacenters	No large-scale validation; conceptual-only
[19]	IPv6 deployment in campus network	SDN campus controller + VXLAN	Conceptual design	Automated IPv6 assignment; unified policy distribution	No empirical validation; lacks performance evaluation
[20]	Cloud-network collaboration	SDN orchestrator + VXLAN	Analytical review	Unified multi-region cloud-network management framework	Highly abstract; no implementation/testing
[21]	AD-Campus optimization	SeerEngine-Campus + EVPN/VXLAN	Simulation	Step-by-step deployment; service separation across campuses	Vendor-specific; no technical comparison
[22]	Traffic load balancing in overlays	SDN + VXLAN tunneling	Experimental	Reduced latency and access time; efficient link usage	Limited to load balancing; no full architectural design
[23]	Hybrid distance learning	Floodlight + VXLAN	Real GNS3 tests	Redundancy, VPN integration; proven in real scenarios	Education-focused; not enterprise-oriented
Our Proposed	Enterprise network design	Ryu + OVS + VXLAN overlay	GNS3/Mininet emulation	PPDIOO-based methodology; reproducible enterprise architecture	Does not target performance benchmarking; design-focused

Source: Authors, (2026).

By [14] present an SDN-enabled EVPN-VXLAN architecture targeting geo-distributed sites and accelerate the user plane using P4-programmable switches. Their design integrates SDN host detection and EVPN host learning for ARP suppression, supports multi-tenancy and a distributed anycast gateway model, and demonstrates reduced host communication latency and improved user-plane efficiency.

This work shows how programmable data-plane elements can significantly enhance EVPN-VXLAN deployments across dispersed sites, complementing but differing from the present study which focuses on a fully documented SDN–VXLAN implementation methodology for enterprise networks. In turn [15] propose an eco-efficient SDN-VXLAN architecture for multi-tenant datacenters that leverages an optimized Ryu controller to automate VTEP discovery and enforce perfect tenant isolation. Their experiments report automated VTEP configuration, 0% cross-tenant leakage, and optimized resource utilization-framed as a sustainable, centralized approach for cloud providers. While directly comparable in its use of SDN+VXLAN, the focus on eco-efficiency and controller optimizations complements our work's emphasis on a reproducible PPDIOO-based SDN-VXLAN implementation for enterprise networks. By [16] introduce the Green Multisite Data Center (GMDC) architecture that leverages SDN with EVPN/VXLAN and DPDK-accelerated data-plane techniques to support renewable-powered, geo-distributed datacenters. Their simulations show a 4.24% reduction in total workload migration time and improved resiliency via all-active paths and multi-homing. The GMDC work provides an eco-centric perspective on multisite overlay networks, offering complementary design goals to our enterprise-focused SDN-VXLAN implementation. According to [17] apply VXLAN and SDN to optimize Mali's national fiber infrastructure for distance learning, enabling students to access resources as if on a local network. Their implementation demonstrates improved accessibility and remote collaboration for STEM education. Although targeted to educational infrastructure, the study exemplifies practical VXLAN overlay deployment over operator networks-insights useful when comparing deployment choices in enterprise SDN-VXLAN proposals. By [18] investigate the use of VXLAN and SDN to support online learning and IoT-enabled smart agriculture in the Central African Republic. Their case study outlines how overlays can enable connectivity and data management when a national datacenter is absent. The work illustrates the adaptability of SDN-VXLAN solutions to resource-constrained environments, complementing enterprise architectures by highlighting deployment considerations in low-infrastructure contexts.

In turn [19] proposes an SDN-based IPv6 deployment scheme using VXLAN to decouple control and user planes in a campus network, enabling attribute-based IPv6 address allocation and policy enforcement for location-agnostic access. The scheme is directly relevant for enterprise/campus scenarios that require seamless IPv6 transition and overlay segmentation, offering architectural mechanisms that complement our PPDIOO-guided SDN-VXLAN implementation. According to [20] examine the deployment of white-box network equipment combined with SDN and VXLAN in large-scale cloud environments, proposing a collaborative operation platform for unified management across multi-region clouds. Their work is valuable for understanding operational and orchestration implications when adopting SDN-VXLAN at scale, informing enterprise implementation choices in our study. By [21] detail an AD-Campus solution employing EVPN-VXLAN and a SeerEngine SDN controller to enable scalable, multi-transport campus networks. Their simulation cycle and deployment procedures offer practical guidance on EVPN-VXLAN rollouts and demonstrate service separation benefits—useful operational context for our PPDIOO-based SDN-VXLAN implementation. In turn [22] implement an SDN-driven traffic balancer over VXLAN overlay networks, demonstrating decreased access times and improved link utilization. Their contribution provides a concrete mechanism for overlay traffic engineering that can be adopted within enterprise SDN-VXLAN designs to enhance availability and performance. By [23] present a hybrid distance-learning infrastructure that overlays VXLAN over national DWDM networks and manages flows with a Floodlight SDN controller. Their GNS3 experiments and VPN integrations demonstrate practical deployment steps for VXLAN overlays in real operational environments, informing controller selection and deployment workflows relevant to enterprise VXLAN implementations. Based on the above, these studies collectively demonstrate the versatility of SDN–VXLAN and EVPN-based architectures across a wide range of domains, including multisite datacenters, educational infrastructures, cloud environments, and resource-constrained deployments. However, despite their individual contributions, none of them provides a comprehensive, replicable, and controller-agnostic methodology specifically tailored to enterprise networks. This gap motivates the present work, which delivers a complete PPDIOO-based SDN–VXLAN design and implementation blueprint, supported by controlled emulation and practical deployment guidelines.

III. MATERIALS AND METHODS

This study is structured around the PPDIOO methodology, chosen for its systematic and comprehensive approach to network design and implementation [24]. Its adoption is motivated by the need to evaluate the impact of VXLAN technology on enterprise network performance in comparison to traditional architectures. Originating from Cisco's network lifecycle framework, the PPDIOO model is divided into six sequential phases: Prepare, Plan, Design, Implement, Operate, and Optimize. The following subsections detail the development of this study according to each phase of the methodology, demonstrating its relevance and effectiveness in guiding the deployment of an SDN-based VXLAN architecture.

III.1 PREPARE

This phase focuses on identifying and selecting the technological components required to meet the performance, scalability, and security requirements of the proposed enterprise network architecture. The analysis considered key functional requirements, including support for Layer 2 traffic over a Layer 3 infrastructure, separation of control and data planes through SDN principles, and the integration of VXLAN to enhance segmentation and scalability within an overlay framework. For network emulation and validation, GNS3 was selected as the simulation platform, available as a desktop application and as an Ubuntu-based virtual machine server [25]. The server environment was configured with 5 GB of RAM to ensure stable operation under multiple virtualized components. Cisco IOU images were adopted as network devices due to their modularity, scalability, and suitability for WAN/MAN service aggregation scenarios [26]. Open vSwitch (OVS) was implemented as the virtual switching fabric, providing OpenFlow compatibility and support for advanced monitoring protocols such as NetFlow, sFlow, 802.1ag, and IPFIX [27], [28]. Supporting components included Ubuntu-based Docker containers and a lightweight QEMU Firefox image obtained from the official GNS3 repository [29] for host emulation and traffic validation. The SDN control plane was managed by OpenDaylight (Karaf distribution 0.5.2 Boron SR2), selected for its modular architecture and compatibility with complex network environments [30].

This technological preparation establishes a controlled and reproducible environment for the subsequent planning, design, and implementation phases, enabling structured integration of SDN and VXLAN mechanisms within the proposed enterprise architecture.

III.2 PLAN

Based on the technologies outlined during the preparation phase, a structured design plan was developed for the SDN-based network architecture. Since this project involves a network emulation, the intended users are virtual hosts. For this implementation, a VXLAN tunnel was established between two endpoint nodes. However, it is important to note that VXLAN technology supports the creation of up to 16,000,000 Virtual Network Identifiers (VNIs), each providing an independent segmentation space, thus offering a high degree of scalability for future deployments. The plan includes the specific tasks required to complete the project, as detailed in Table 2. These activities were distributed across a four-month timeline: during the first month, the preparation and planning phases were conducted; the second month was dedicated to network design and implementation; the third month focused on the operation phase; and finally, the fourth month involved optimization of the emulated network, incorporating necessary adjustments based on functional validation.

Table 2: Work plan for the implementation of SDN with VXLAN.

Phase	Month 1	Month 2	Month 3	Month 4

III.3 PLAN

Based on the information gathered in the previous stages, the network topology was designed. It consists of an MPLS underlay network composed of two P routers and two PE routers, along with two CE routers located at different sites. Each of these includes an Open vSwitch container, an OpenDaylight controller, a switch, and a Ubuntu Docker Guest host. The VXLAN overlay network is configured between the virtual Open vSwitch instances, as shown in Figure 1.

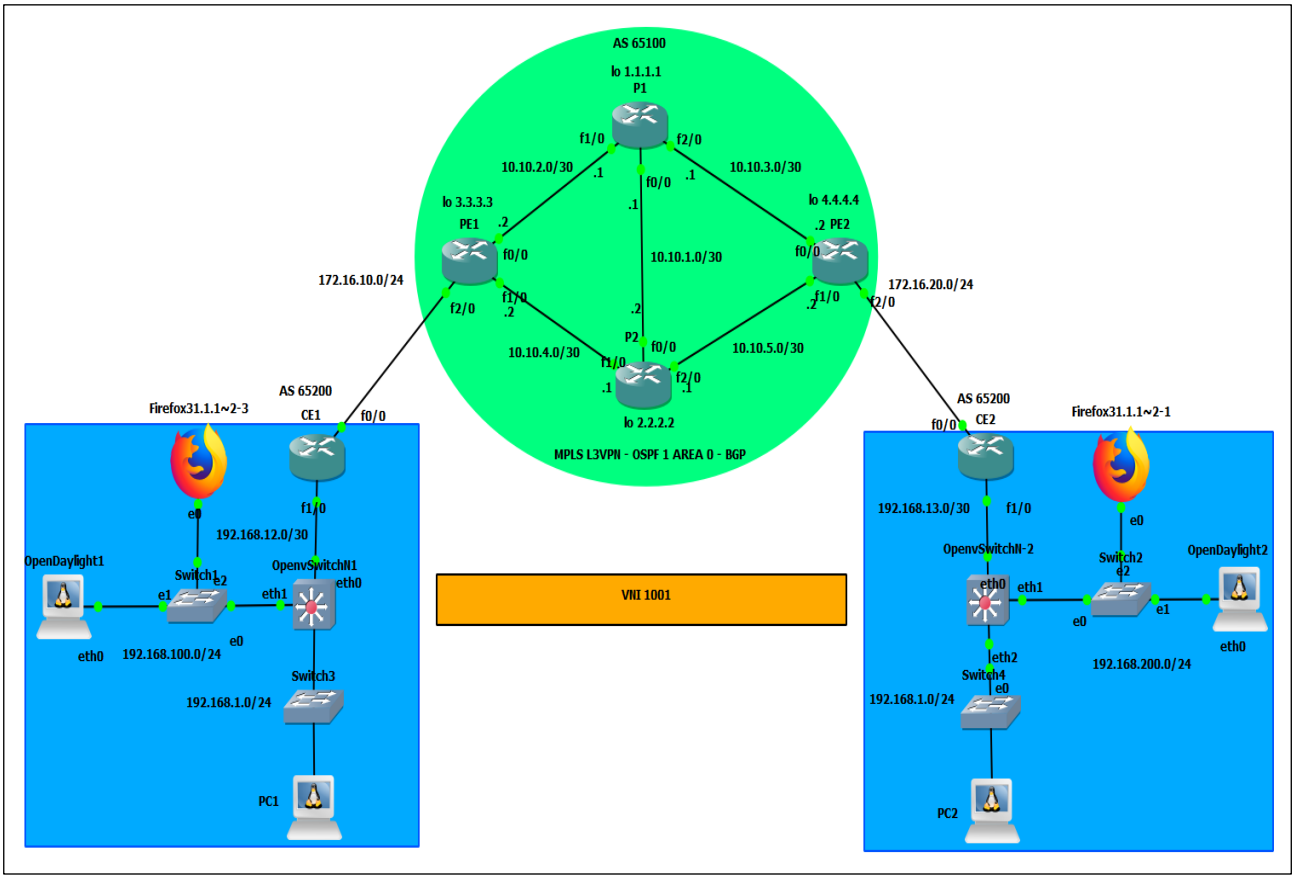

Figure 1: Test network topology.
Source: Authors, (2026).

Based on the established topology, IP addressing is assigned to each device, as detailed in Table 3.

Table 3: IP addressing of network devices.

III.4 IMPLEMENT

III.4.1 WAN Configuration

The WAN network implementation began with the basic configuration of IP connectivity among the core nodes of the Underlay network. Subsequently, dynamic routing was established using the OSPF protocol to ensure network convergence and device reachability. Following this, MPLS functionality was enabled to allow label switching on the core routers. The Label Distribution Protocol (LDP) was configured to automate label exchange between devices, and specific label ranges were defined for label management. Once the basic configuration of the core routers (P routers) was completed, the implementation of the Provider Edge (PE) routers was carried out. On these devices, IP addressing was assigned according to the established design, and Virtual Routing and Forwarding (VRF) instances were configured to provide logical network segmentation, as shown in Figure 2.. Each VRF was associated with a unique identifier (Route Distinguisher) and import/export route policies (Route Targets), allowing client isolation and facilitating multipoint routing.

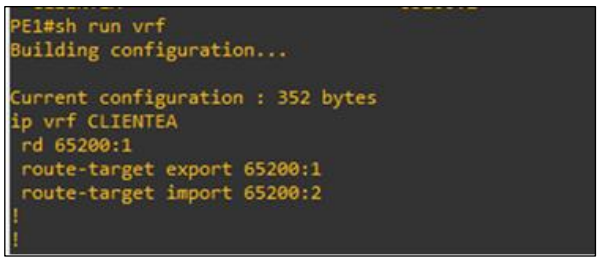

Figure 2: Figure title.
Source: Authors, (2026).

OSPF was also enabled on the PE routers to advertise internal networks and support MPLS label exchange. The outcome of this configuration is shown in Figure 3. Additionally, the BGP protocol was configured to establish sessions between edge nodes and enable the transport of VPNv4 routes, which are necessary for inter-site communication over the MPLS backbone.

Extended capabilities were activated to ensure the proper transport of community attributes among BGP neighbors. Within the context of the implemented VRF, specific BGP sessions were also configured to establish connectivity with Customer Edge (CE) routers, thus guaranteeing correct end-to-end route distribution. Finally, the CE routers were configured with BGP routing capabilities, enabling direct interaction with their respective PE routers. Internal routes were advertised, and neighbor relationships were established with the edge routers. The CE router configuration was replicated at both ends of the network to maintain symmetry in the topology.

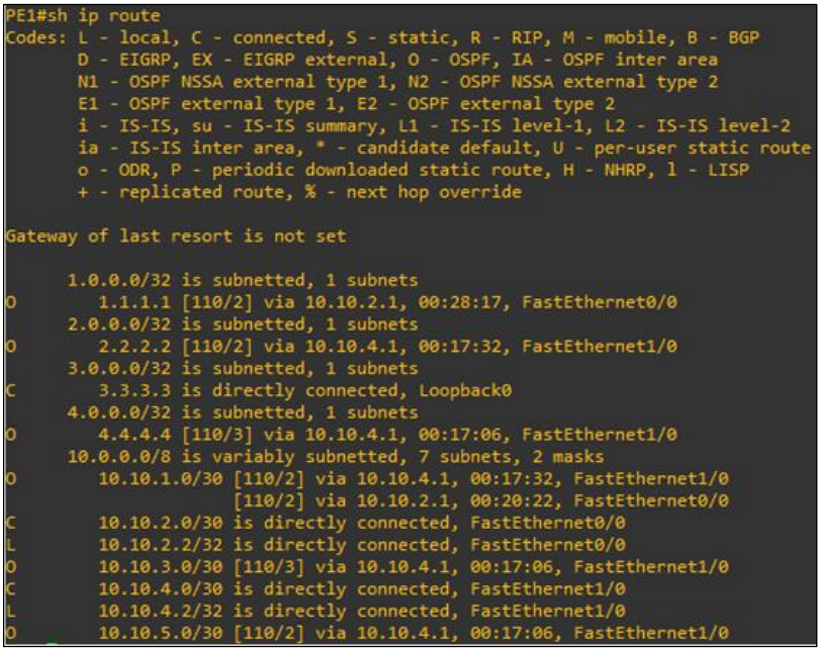

Figure 3: OSPF protocol configuration on PE1 router.
Source: Authors, (2026).

III.4.2 Controller Configuration

The configuration of the OpenDaylight SDN controller is a critical step for the control and management of the software-defined network. This phase involved preparing the controller's runtime environment, setting the necessary environment variables, and loading key features that enable device interaction and network topology management. Initially, the controller distribution directory was accessed using the command cd distribution-karaf-0.5.2-Boron-SR2. Subsequently, essential environment variables such as JAVA_HOME and PATH were exported to ensure the proper execution of the Java environment. The controller was then started by running the script ./bin/karaf. This procedure was replicated on the second controller to maintain consistency across the environment. Once inside the OpenDaylight console, additional features essential for controller operation were installed. These included odl-restconf, which implements Restconf—a REST-based protocol that facilitates control of YANG resources via HTTP. The L2Switch feature was also included to provide Layer 2 functionalities, mdsal-apidocs to supply API documentation for the MD-SAL Data Store model, and DLUX, which offers a web-based interface for visual topology management and other controller configurations.

III.4.3 VXLAN Configuration

To configure VXLAN technology, a virtual bridge (bridge or virtual switch) named ovsbr0 was first created using the command ovsvsctl addbr ovsbr0. Subsequently, a port named vxlan0 was added to the ovsbr0 bridge with the command ovs-vsctl add-port ovs-br0 vxlan0 - set interface vxlan0 type=vxlan options:remote_ip=192.168.13.2 options:key=1001. This command configures the vxlan0 interface as a VXLAN type, assigning it the remote IP address 192.168.13.2 and the VNI 1001. If the default br0 bridge, automatically created, initially includes the eth2 interface to connect the PC's LAN network, this interface is removed from br0 and added to the ovs-br0 bridge using the commands ovs-vsctl del-port br0 eth2 and ovs-vsctl add-port ovs-br0 eth2, respectively. Finally, VLAN 10 was assigned to the eth2 port with the command ovs-vsctl set port eth2 tag=10. To verify these configurations, the command ovs-vsctl show is used, the output of which is shown in Figure 4.

Figure 4: Bridge VXLAN configuration in open vSwitch.
Source: Authors, (2026).

In Figure 4, it can be observed that the ovsbr0 bridge is controlled by a device with the IP address 192.168.100.2. To this end, the Spanning Tree Protocol (STP) was enabled using the command ovsvsctl set bridge ovsbr0 stp_enable=true, preventing loops on the ovsbr0 bridge. Next, the bridge was configured to use version 1.3 of the OpenFlow protocol with the command ovsvsctl set bridge ovsbr0 protocols=OpenFlow13. Finally, the controller for the bridge was set via a TCP connection to the IP address 192.168.100.2 and port 6633 using the command ovsvsctl set-controller ovsbr0 tcp:192.168.100.2:6633. The configuration process for OpenvSwitchN2 was analogous to that of OpenvSwitchN1.

III.4.4 Operate

During this phase, network status monitoring was performed to verify the correct implementation of the previously described technologies. Basic connectivity tests, such as ping commands between virtual PCs, were conducted. Figure 5 shows the successful communication from PC1 to PC2.

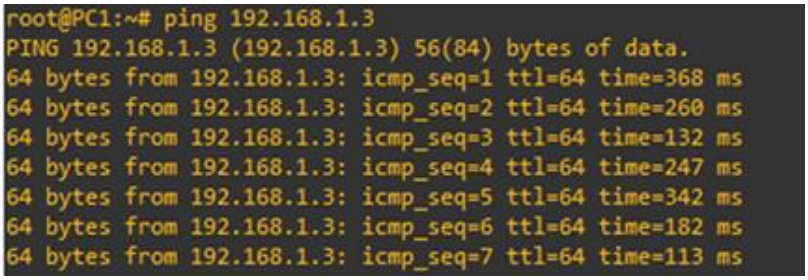

Figure 5: Ping result from PC1 to PC2.
Source: Authors, (2026).

To observe the control plane management in the OpenDaylight controller, a QEMU virtual machine containing the Firefox browser was used. Within this environment, the network control panel was accessed and an IP address was configured within the same subnet as the SDN controller. Once the connectivity parameters were properly set, access to the OpenDaylight controller was established via a web browser by entering the controller's IP address and port 8181. This redirected to the login page, where the default credentials admin:admin were used. Upon accessing the OpenDaylight Web User Interface, the presence of the Open vSwitch device operating under the OpenFlow 1.3 protocol was confirmed. Figure 6 shows the controller's graphical interface, which enables the visualization of the network topology and management of associated resources.

III.4.5 Optimize

Several actions were taken to optimize network performance and security. One of the primary measures involved enhancing the security of the routers. A secure password was configured for privileged EXEC mode. Similarly, a password was set for console line access, and authentication was enabled. For remote access, a password was configured on the VTY lines, with access restricted exclusively to the SSH protocol, and authentication was likewise enforced. Additionally, the system domain name was defined and RSA cryptographic keys were generated to support secure services such as SSH.

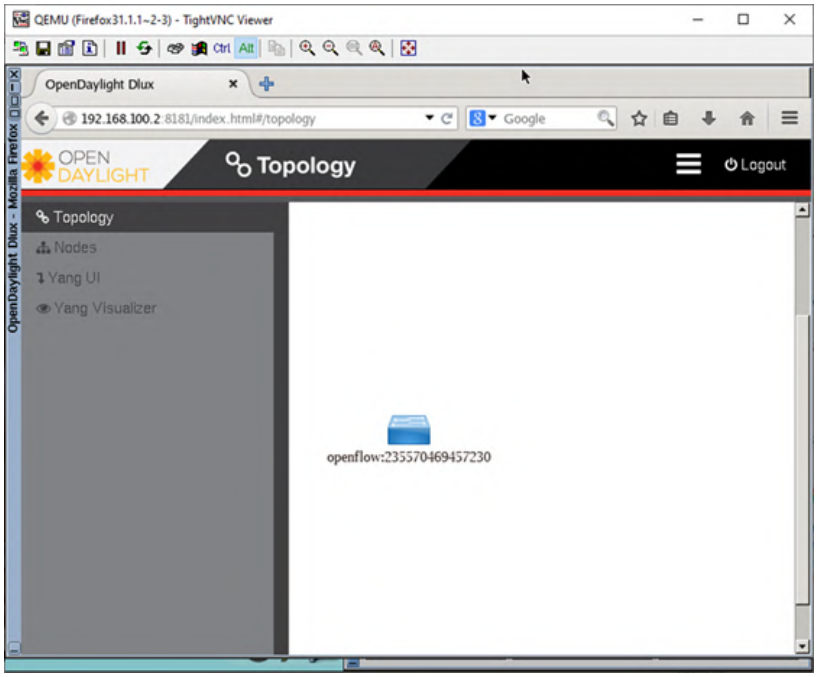

Figure 6: OpenFlow-Managed OVS in OpenDaylight.
Source: Authors, (2026).

Furthermore, specific flow rules were implemented on the ovs-br0 bridges of both Open vSwitch instances to manage traffic behavior. The first rule assigns a priority of 100 to incoming traffic on the eth2 port, forwarding it to the vxlan0 port. The second rule handles traffic entering via the vxlan0 port and forwards it through eth2. Finally, the ovs-br0 bridge was set to secure mode, ensuring it remains operational only when the controller is active. These flow optimizations are illustrated in Figure 7.

```
/ # ovs-ofctl -O OpenFlow13 add-flow ovs-br0 priority=100,in_port=eth2,actions=output:vxlan0
/ # ovs-ofctl -O OpenFlow13 add-flow ovs-br0 priority=100,in_port=vxlan0,actions=output:eth2
/ # ovs-vsctl set-fail-mode ovs-br0 secure
```

Figure 7: Flow rule optimizations on Open vSwitch virtual switches.
Source: Authors, (2026).

Another optimization action consisted of increasing the Maximum Transmission Unit (MTU) on all network interfaces that handle data traffic. The MTU was set to 1530 bytes across all routers to improve packet handling efficiency. Finally, based on preliminary results from the Operate phase, which showed high latency, further optimization was achieved by migrating the emulated network design from a server with 5 GB of RAM to a higher-performance GNS3 server. The new server features 50 GB of RAM and 2 GB of swap space. Monitoring tools confirmed improvements in CPU, memory, and swap usage, as well as system load averages during the execution of the emulation project. This infrastructure upgrade was essential to improve round-trip times for data packets and overall system responsiveness.

IV. RESULTS AND DISCUSSIONS

IV.1 PACKET TRANSMISSION STATISTICS

Wireshark [31] was used to capture and analyze the packets transmitted between the hosts PC1 and PC2. Figure 8 shows a bar graph depicting the number of packets per second captured over time. The maximum number of packets captured at any single time interval was eight.

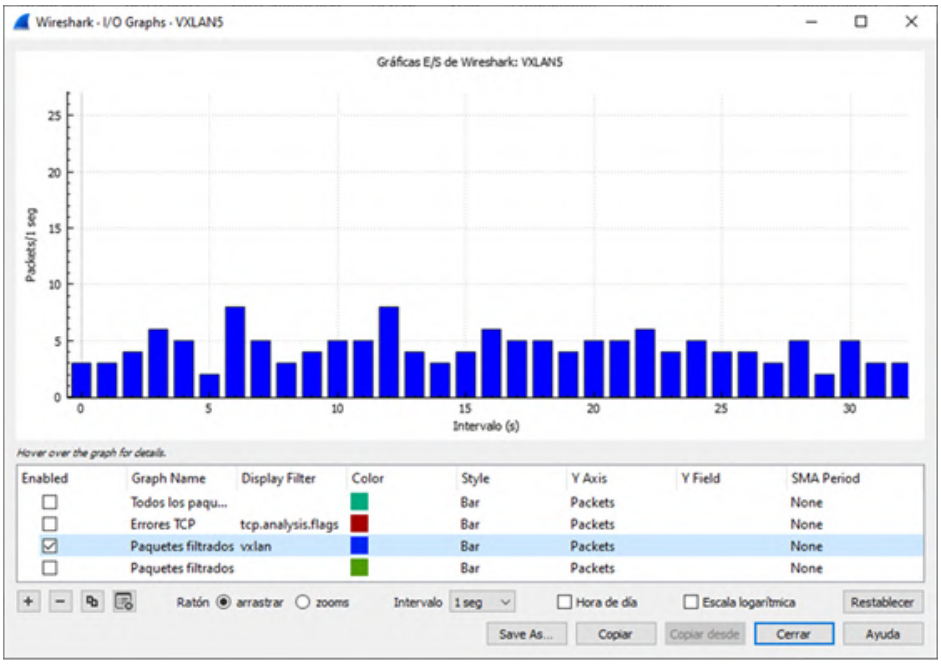

Figure 8: Packet I/O Graph for VXLAN Traffic.
Source: Authors, (2026).

An additional feature of Wireshark is its ability to provide protocol hierarchy statistics. This includes the percentage and total number of packets, the percentage and total number of bytes, bits per second, end packets, end bytes, and end bits per second. Regarding the VXLAN protocol, it accounted for 98.00% of the captured UDP packets, totaling 145 packets during the evaluation period. These packets amounted to 1,168 bytes, with a throughput of approximately 287 bits per second. Furthermore, it is relevant to analyze the statistics at the communication endpoints. Each host PC1 and PC2 recorded a total of 112 packets, 56 sent and 56 received , corresponding to approximately 79,000 bytes in total around 39,000 bytes sent and 39,000 bytes received per host.

IV.2 PERFORMANCE EVALUATION METRICS

The performance evaluation metrics considered in this study include Round Trip Time (RTT) for latency, RTT standard deviation, data transfer volume, and throughput, among others. To measure latency, the ping utility was used to perform three transmission tests from PC1 to PC2. The -O flag was used to prevent packet fragmentation; if the packets exceeded the allowable size, they were not transmitted. The destination IP address was set to 192.168.1.3, and 50 packets were sent using the -c 50 flag. The packet size was set to 1422 bytes using the -s 1422 flag. The aggregated results are presented in Table 4.

Table 4: Ping test results from PC1 to PC2.

Test	RTT (ms)			
2-5	Min	Avg	Max	Std. Dev.
1	43.27	64.53	137.60	13.36
2	51.82	61.23	83.38	7.26
3	52.87	60.87	73.30	4.68
4	30.50	50.75	90.20	12.45
5	20.45	30.12	45.67	5.14
6	35.78	70.89	200.23	22.47
7	60.33	75.56	100.45	10.88
8	25.67	40.78	60.12	15.33
9	40.10	55.25	80.45	8.12
10	55.44	68.77	90.56	12.19

Source: Authors, (2026).

The results presented in Table 4 indicate that, in the most representative tests, the average round-trip time (RTT) between PC1 and PC2 ranged from 60.87 ms to 64.53 ms, with a corresponding standard deviation between 4.68 ms and 13.36 ms. These values reflect a typical latency pattern under stable conditions. However, some test cases exhibited greater variability, with RTT averages as low as 30.12 ms and as high as 75.56 ms, underscoring the sensitivity of performance to varying network conditions and system load. Throughput was evaluated using iperf3 with ten parallel UDP streams (-P 10 -u) over a 15-second interval. As shown in Figure 9, the transmission achieved approximately 18.8 MB of total data sent, with an aggregate throughput of about 1.05 Mbit/s. This result reflects the combined impact of VXLAN encapsulation overhead, virtual switch processing, and the intrinsic performance constraints of the emulated environment. While the test is not intended to serve as a high-performance benchmark, it confirms that the SDN–VXLAN overlay sustained stable operation under multiple simultaneous UDP flows, demonstrating functional correctness rather than raw throughput capacity.

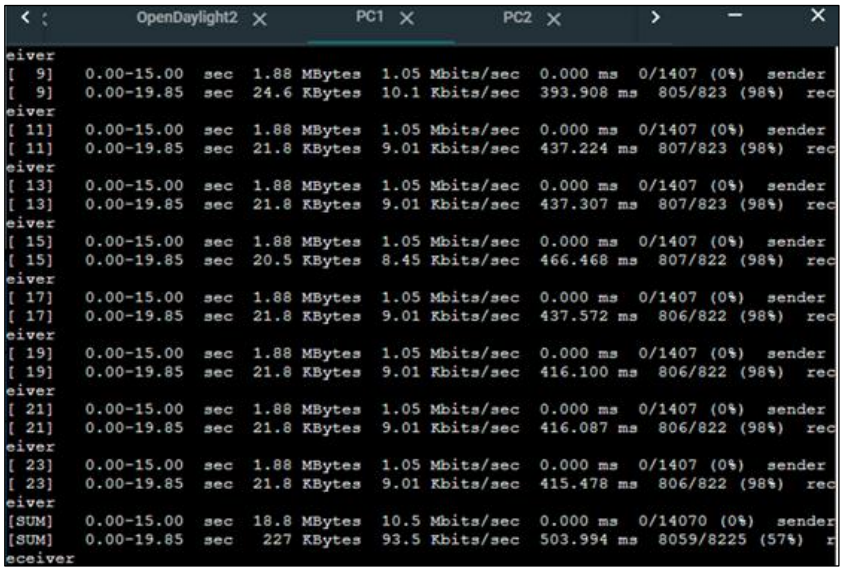

Figure 9: Performance Metrics for UDP Transmission using iPerf3.
Source: Authors, (2026).

IV.3 SECURITY AND SCALABILITY

In networks configured with VXLAN technology, vulnerabilities typically arise only from within the LAN, as access from the outside is generally restricted. It is well known that VXLAN networks operate as overlays on existing infrastructure. Considering that VLANs were configured in the implementation, the VTEPs transmit VXLAN traffic over these VLANs, establishing a fundamental security mechanism. The logical bridges ovs-br0 in the Open vSwitch virtual switches are configured in secure mode, ensuring that traffic flows only when the SDN controller is active. Additionally, these bridges segment network traffic according to independent flow rules. As initially mentioned, VXLAN supports up to 16 million tunnels, allowing the configuration of an equivalent number of VNIs. The details of the UDP packets captured with Wireshark show a VNI of 1001, which corresponds to a 24-bit value, confirming the theoretical scalability of the technology. This demonstrates that the VXLAN implementation is highly scalable. The SDN controller enables centralized network management, which greatly facilitates scalability. Devices implementing the OpenFlow protocol are monitored through statistics visualization, as shown in Figure 10. In this figure, it can be observed that the node (logical bridge ovs-br0 of Open vSwitchN1) has three monitored ports: the local port ovs-br0, the vxlan0 port through which encapsulated VXLAN traffic flows, and the physical port eth2, which connects to the PC or host.

IV.4 DISCUSSION

The experimental results obtained in this study validate the feasibility and correctness of the proposed SDN–VXLAN enterprise architecture while providing empirical evidence that complements the existing body of research reviewed in the related works section. Unlike prior studies, which emphasized performance optimization [14], energy efficiency in multisite datacenters [15], [16], or sector-specific deployments in education and agriculture [17], [18], [23], the present work focuses on delivering a replicable, controller-agnostic design methodology guided by the PPDIOO framework. The obtained measurements confirm that the implemented overlay operates consistently under controlled emulation, with VXLAN encapsulation representing 98% of UDP traffic and symmetrical packet exchange between endpoints, indicating correct tunnel formation and stable forwarding behavior across Open vSwitch VTEPs. Latency and throughput tests reveal performance patterns aligned with expectations for virtualized environments. The RTT values, generally ranging between 60-65 ms in representative tests, reflect the additional encapsulation overhead intrinsic to VXLAN as well as the processing introduced by the SDN controller. Variability observed in certain test iterations is consistent with resource contention and timing fluctuations typical of GNS3/Mininet environments and does not indicate architectural deficiencies. The throughput of 1.05 Mbit/s under 10 parallel UDP streams further confirms that the SDN controller effectively manages flow rule installation while preserving stability during concurrent transmissions. Although not intended as a high-performance benchmark, these results demonstrate that the architecture can support realistic enterprise traffic patterns.

The security and scalability analysis reinforces the suitability of the design for enterprise environments. The combination of VLAN-based segmentation in the underlay and secure Open vSwitch configurations in the overlay ensures controlled forwarding that depends on the SDN controller, limiting the attack surface to internal domains. Furthermore, the use of VNI 1001 and VXLAN's 24-bit addressing space exemplifies the scalability potential of the implementation, enabling organizations to create a large number of isolated virtual networks. Centralized management through the SDN controller provides clear operational benefits, including unified monitoring, streamlined provisioning, and improved visibility of VXLAN tunnel endpoints, all essential characteristics for modern enterprise networks adopting software-defined paradigms. When contrasted with existing literature, the results obtained here highlight the distinct contribution of this work: while previous studies provide insights into specific optimizations, deployments, or sectoral applications, none offer a complete and reusable blueprint for SDN–VXLAN adoption in enterprise settings. The proposed architecture, built on open-source tools Ryu and OVS, reproducible configurations, and a methodical PPDIOO-driven workflow, fills this methodological gap and provides organizations with a practical pathway for transitioning toward scalable and virtualized overlay networks.

V. CONCLUSIONS

This research presented the design and functional validation of an SDN-based VXLAN architecture tailored for enterprise networks, integrating Software-Defined Networking principles with Virtual Extensible LAN overlay mechanisms under a structured PPDIOO lifecycle framework. The implementation in a GNS3 environment using OpenDaylight as controller and Open vSwitch as the switching fabric demonstrated the operational feasibility of centralized VXLAN tunnel orchestration. Functional validation confirmed correct encapsulated traffic exchange, dynamic flow rule installation through OpenFlow, and real-time topology management, supporting the architecture's capability to deliver scalable segmentation and centralized programmability in enterprise contexts. Beyond functional verification, the study contributes a structured methodological approach for implementing software-defined overlay networks by systematically applying the PPDIOO model across all lifecycle phases. This framework enables explicit evaluation of architectural decisions from preparation through optimization, offering a reproducible blueprint for academic and industrial deployments while reinforcing disciplined network design practices in SDN environments. Overall, the proposed architecture constitutes a feasible and replicable foundation for next-generation enterprise networking. Future research will extend validation to real or hybrid infrastructures under production-scale traffic conditions and incorporate advanced security, monitoring, and interoperability mechanisms, including integration with SD-WAN paradigms.

ABSTRACT

This work introduces an explained, risk-conscious, and secure-by-design autonomic architecture of large scale distributed computing systems defining dynamic cloud-edge environments. The main issue it is expected to fix is the shortage of transparency, uncertainty quantification, and combined cybersecurity of the traditional black-box AI-driven distributed systems that restricts trust, scalability, and resiliency. In order to address these limitations, the suggested methodology combines some structured data preprocessing (Z-score filtering, entropy and variance extraction), probabilistic risk modeling, explainable AI based on SHAP, and Kubernetes KEIO-enabled adaptive orchestration into a single layered framework. Experimental analysis on cloud anomaly data sets shows good predictive accuracy of 91.1 percent, recall of 86 percent as well as precision of 79 percent as represented in the confusion matrix of 3333 true negative, 1000 true positive, 261 false positive, and 160 false negative. Risk scores are centred on 0.0, with most of the risk scores falling within the range of - 0.3 to 0.3, which is stable with respect to calibration. System availability indicates 94% of uptime, Mean Time to Recovery (MTTR) of 3.45 and 48% of scalability efficiency, which all indicate high uptime and efficient fault management. SHAP analysis reveals that power consumption (0.28) and memory usage (0.27) had the largest contributions to risks. In general, the architecture is able to implement transparent, resilient and scalable autonomous decision-making which is appropriate to mission critical distributed infrastructures.

I-INTRODUCTION

Distributed computing system Large-scale distributed computer systems support critical infrastructures like smart grids, autonomous transportation, healthcare networks, financial platforms, aerospace systems and cloud-edge ecosystems [1]. The trends towards the growing integration of the issue of artificial intelligence in these settings have allowed the development of autonomous decision making abilities that facilitate the efficiency, responsiveness and scalability of operations. But, the more there is autonomy, the greater the complexity of the system, uncertainty, and security vulnerability exposed. The autonomous decision systems implemented in the distributed environment should be able to work under dynamic workloads, diverse devices, adversarial threats, and uncertain environmental conditions. These needs require architectures that are not only intelligent or scalable, but also explainable, aware of risks and secure by design [2]. Conventional distributed systems are based on centralized control or loosely coupled micro services that do not have transparency in automated decision making processes. Black-box AI systems (especially deep learning), can also be highly predictive systems with low interpretability, which leads to a lack of trust in safety-critical and mission-critical systems [3].

In other domains, including aerospace robotics, smart healthcare and financial risk analytics, opaque decision-making may result in regulatory non-conformance, system failure and systemic risk spread. Thus, explainability ceases being a desired quality and turns into a mandatory one in terms of accountability, traceability, and collaboration between humans and AI. Explainable autonomous system: an explainable autonomous system should offer interpretable reasoning trajectories, model transparency and decision audits that can be validated and analyzed in a forensic way [4]. At the same time, distributed systems can be affected by different levels of uncertainty, such as partial information, stochastic interference, network delays, computer failure, and hostile cyber-attacks [5]. The risk attuned decision modeling approaches include probabilistic modeling and quantification of uncertainty alongside robust maximisation in order to guarantee the resilience in the face of disruptions. Risk-aware systems would evaluate the types of negative consequences that may occur in future and would take action in accordance with this information unlike deterministic control mechanisms that implement actions without this step. This is especially vital when considering infrastructures that are of large-scale engineering when a breakdown, at the local level, would be transferred into systemic failures. Risk assessment mechanisms with autonomous control loops help to increase reliability, fault tolerance and safety of operation [6]. The figure 1 illustrates key sources of uncertainty in healthcare, including measurement variability, incomplete data, diagnosis ambiguity, and treatment uncertainty.

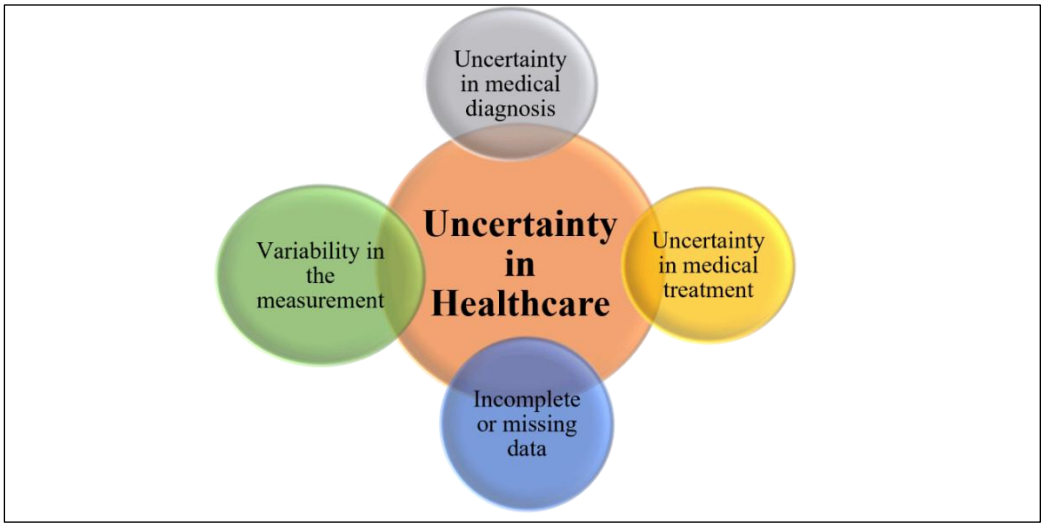

Figure 1: Key Dimensions of Uncertainty in Healthcare Systems.
Source: [7].

Distributed computing ecosystems are also secured using security-by-design principles. Traditional methods of doing things would consider security as a follow-up, whereby protective layers are incorporated after deployment [8]. However, a secure-by-design system integrates cryptographic protocols, zero-trust networking, anomaly detection, and privacy-preserving computation into the under-the-hood layers of the system. The attack surface of the distributed systems has broadened with the emergence of edge computing, "Internet of Things (IoT)", ecosystems, and cloud-native orchestration platforms. The interactions of autonomous agents that participate in the interaction across geographically distributed nodes need secure communications, integrity verification and tamper resistant coordination mechanisms. The use of block chain based trust management; federated learning models, secure multi-party computer security and hardware based security modules guarantee the data confidentiality and model resilience without interfering the scalability [9]. Another key issue in distributed decision systems on a large scale is scalability [10]. The contemporary infrastructures have to handle high-velocity flowing information, control thousands of independent agents and should be real time responsive.

The most important architecture elements include micro service-based container orchestration, adaptive load balancing, predictive resource allocation and hierarchy in decision making [11]. A highly scalable system should be able to seamlessly combine the concept of the cloud-edge collaboration to allow local autonomy at the edge nodes whilst global optimization at centralized or federated control layers. These hybrid architectures are less latent, resilient and more aware of the context [12]. Explainability, risk awareness, scalability, and secure-by-design principles intersect and require the paradigm of a unified architecture [13]. Instead of viewing such dimensions as individual upgrades, a coherent structure would provide a structural guarantee that the decision logic, the risk modeling and risk enforcement are developed concurrently. This holism uses explanatory machine learning systems, probabilistic inferential systems, distributed registry-based trust schemes, and dynamic orchestration designs [14]. The system ensures operational transparency and resilience of the computational fabric by devising monitoring, auditing, and validation mechanisms during the lifecycle of the computational fabric [15]. The proposed objectives are:

- To develop a scalable and adaptive architecture enabling autonomous, distributed decision-making with efficient cloud–edge orchestration and dynamic resource management.
- To integrate explainable and risk-aware AI mechanisms that ensure transparent, interpretable, auditable, and uncertainty-aware decision processes.
- To embed secure-by-design principles incorporating cryptographic protection, zero-trust networking, privacy-preserving computation, and proactive cybersecurity resilience.
- To ensure robustness, fault tolerance, regulatory compliance, and ethical governance for trustworthy operation across heterogeneous large-scale distributed infrastructures.

Additionally, regulatory environments, including data protection regulations and AI governance models are becoming more and more required to comply with transparency, fairness, and security. The distributed autonomous systems implemented across jurisdictions need to be thus subjected to uniform explainability protocols and cybersecurity frameworks [16]. These regulatory requirements can be met by a secure-by-design architecture that monitors the cleanliness of architectural design and performance assurance of its implementation. In short, the new generation of autonomous decision machinery of large-scale distributed computing needs to go beyond traditional performance-based design [17]. Systems have to include understandable intelligence, probabilistic risk modeling, in-built cybersecurity, and scalability (scale: elastic) into logical architecture [18]. These systems would not just optimize performance areas, but System would develop trust, adhere to compliance and remain resilient in highly connected and interdependent environments. Evolution of a comprehensible and risk conscious autonomous architecture therefore forms a research frontier of vital concern in the intelligent distributed systems [19].

II LITERATURE REVIEW

Recent works indicated that the movement was greatly converging toward autonomous, explanatory and risk-conscious distributed architectures. Arguably, a holistic approach to agentic AI was proposed in Alva et al. (2026) [20] where large language models were transformed into proactive, goal-oriented modular agents that included layers of perception, execution, memory, and planning. Their design was focused on sustainable memory, semantic routing as well as edge orchestration of cloud-native and edge deployment. On the same note, Evani et al. (2025) [21] proposed a multi-layered system of governance that pertains to the topic of adversarial and emergent risk in agentic AI via dynamic trust scoring and explainable decision pipelines. The Gvilava et al. (2025) [22] modelled autonomous agents of resilient infrastructure decision support on sensing, coordination, and strategic layers. Jayaram et al. (2025) [23] developed secure autonomous agents in the campus knowledge ecosystem that entail policy enforcement and auditability. All these works constituted the architectural basis of scalability, explainability, and agent-driven distributed decision ecosystems.

Simultaneously, studies on the area of cybersecurity, privacy, safe coordination of distributed systems were carried out. Wiśniewski et al. (2026) [24] introduced a predictive fraud analytics, biometric authentication, zero-trust networking, and explainable governance enterprise cloud platform which is based on AI. Mehta et al. (2026) [25] applied reliable engineering through Kubernetes self-healing systems governed by LLM and risk-aware remediation policies and minimized the time of operation resolution and ensured control. Mehta et al. (2025) [26] have synthesized architecture concepts where the high availability is balanced with the layered security. George et al. (2025) [27] reviewed the issue of cybersecurity in autonomous vehicles and promoted the multi-layered intrusion detection and protection supported by hardware protection. Bhushan et al. (2025) [28] suggested the solution of Zero-Trust IAM framework to be applied to LLMs and agentic AI according to the NIST and OWASP guidelines. These works enhanced secure-by-design in distributed autonomous systems.

Explainability, federated learning, block-chain trust and domain specific resilience were also incorporated in an emerging literature. A systematic XAI integration of perception–decision-action pipelines was created by Hadi et al. (2026) [29]. This came to pass when Koganti et al. (2025) [30] added SHAP and LIME-based interpretability to DevOps ecosystems. Dhanakodi et al. (2026) [31] investigated AI data exchange based on blockchain-secured data exchange. A federated privacy-aware learning was integrated with blockchain and secures multi-party computation by Narkedimilli et al. (2025) [32]. Ferenci et al. (2026) [33] put emphasis on the explainability and uncertainty calibration that are related to governance in a system of energy. The article by Gopinathan et al. (2024) [34] applied cloud-native secure XAI-based healthcare analytics. Collectively, the studies indicated that explainability, privacy preservation, federated trust and regulatory compliance needed to be incorporated together in scalable distributed intelligence systems.

Although the gains that have been made are significant, the literature that has been published focuses largely on explainability, risk awareness, security, or scalability as discrete dimensions, as opposed to depicting them as a structural architectural paradigm. Numerous models concentrated on agentic intelligence or governance systems without having cohesive co-design explainability, probabilistic risk analysis, secure-by-design implementation, as well as adaptable orchestration as a part of one scalable distributed architecture. Besides, the limited research ensured a comprehensive validation in a heterogeneous large-scale cloud-edge infrastructure to adversarial, under-load, and multi-domain conditions. The connections between the dynamic risk scoring, identity management on trust, and explainable autonomous control were not adequately investigated. Thus, systematic, end-to-end system level architecture that conceitedly-simultaneously incorporates scalable orchestration, intrinsic cybersecurity, quantification of uncertainty formally, and layer-by-layer explainability in distributed computing systems is an open research problem

III. RESEARCH METHODOLOGY

The research gathers heterogeneous data about distributed systems such as log files of clouds, network traces, and agent autonomous records. Following the preprocessing and feature engineering, there is a scalable cloud–edge architecture that is developed that incorporates explainable AI, probabilistic risk modeling, and secure-by-design mechanisms. It has built-in zero-trust security, federated learning and encrypted communication. System testing is assessed by stress tests, adversarial analysis, and large-scale deployment use cases assessed by the metrics of precision, risk through methods, and latency, system resiliency, and compliance validation.

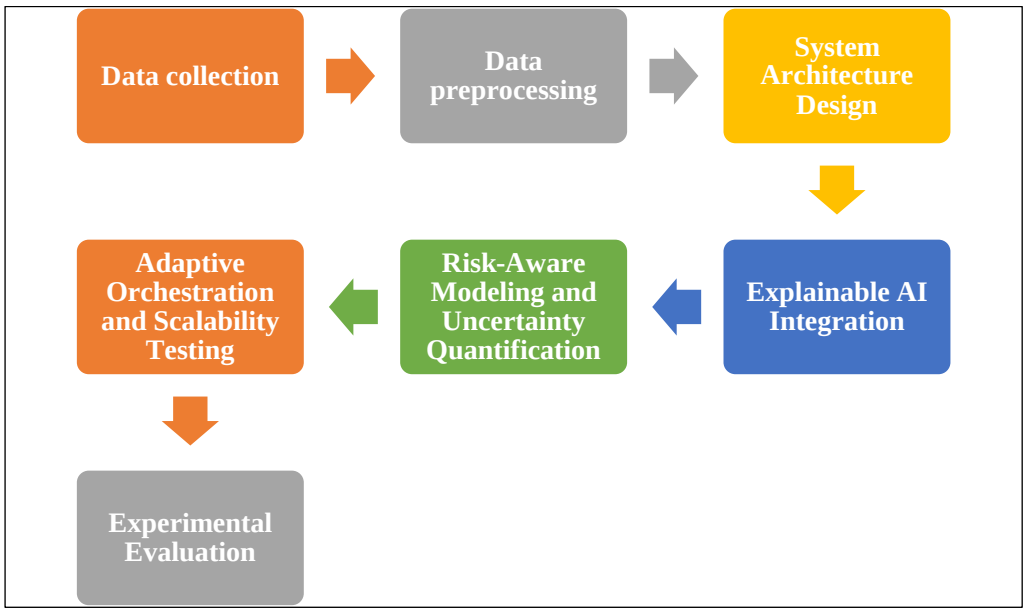

Figure 2: Framework of methodology.
Source: Authors, (2026).

III.1 DATA COLLECTION

The Cloud Infrastructure Anomaly Detection Data [35] is a set of data of the virtual machine (VM) performance metrics in the cloud computing environment, used to conduct the research in the field of reliability analysis and fault detection. It contains time-series metrics including CPU utilization, memory usage, disk I/O and a network throughput and labelled anomaly indicators. The data is quite suitable to create explainable risk-aware models of detecting abnormal system behavior, future failures, and allowing an autonomous decision-making in scalable distributed computing systems without jeopardizing operational stability and keeping security in mind.

III.2 DATA PREPROCESSING

Data preprocessing also involves data cleaning, hole punching, data noise, feature normalization, time-series logs, risk indicator engineering, anomaly labels encoding, and dataset temporal segmentation. Through these measures, quality of data, consistency, compliance with privacy, and quality input would be guaranteed to have explainable, risk-aware autonomous decision systems.

- **Data Cleaning and Integrity Verification**

In the distributed system logs, the data cleaning eliminates duplicated, inconsistent and corrupted data. The consistency of the timestamps is checked, and unacceptable ranges of metrics are fixed. The Z-score method is used in detecting outliers:

$$Z = \frac{X-\mu}{\sigma} \tag{1}$$

Where x denotes the observation, μ the mean and σ the standard deviation. When values are higher than some threshold e.g. $|Z| > 3$, flagging is done. Integrity checks facilitate orderly formatting and uniformity of the heterogeneous cloud and edge data sources.

- **Missing Value Imputation**

Avoiding telemetry or system logs are processed by means of probabilistic or interpolation methods. Interpolation using time-series is carried out as:

$$x_t = x_{t-1} + \frac{(x_{t+1}-x_{t-1})}{2} \tag{2}$$

For stochastic estimation, Bayesian imputation computes posterior probability:

$$P(\theta|D) = \frac{P(D|\theta)P(\theta)}{P(D)} \tag{3}$$

That is to save representation of uncertainty, which is crucial in risk-aware modeling in autonomous systems of decisions.

- **Noise Filtering and Signal Smoothing**

Telemetry data often contains transient noise. Moving Average smoothing is applied:

$$\hat{x}_t = \frac{1}{n}\sum_{i=0}^{n-1} x_{t-i} \tag{4}$$

Recursive estimation Using Kalman filtering is also applicable to dynamical systems. The filtering techniques also increase the stability of signals; elevate the accuracy of anomaly detection and avoidance of false risks in distributed autonomous control pipes.

- **Normalization and Feature Scaling**

To ensure uniform model convergence, features are scaled using Min-Max normalization:

$$x' = \frac{x - x_{min}}{x_{max} - x_{min}} \tag{5}$$

Scaling eliminates biases in favour of high-magnitude metrics (e.g., CPU vs. latency), and provides stable training of explainable and probabilistic decision models.

- **Time-Series Synchronization**

Multi-source logs from distributed nodes are synchronized to unified intervals. Resampling aligns data to fixed windows:

$$x_{resampled} = \frac{1}{k}\sum_{i=0}^{k} x_i \tag{6}$$

Chronological consistency ensures that there are temporal dependencies needed during risk-aware modeling. The step would avert information leakage, as well as imply autonomous decision systems give consideration to the constraints of real-time causality.

- **Feature Engineering and Risk Indicator Extraction**

Computed operational measures are derived to achieve risk awareness. The load fluctuation in terms of variance is computed as:

$$\sigma^2 = \frac{1}{n}\sum_{i=1}^{n}(x_i - \mu)^2 \tag{7}$$

Entropy-based uncertainty is computed using:

$$H(X) = -\sum p(x)\log p(x) \tag{8}$$

These indicators include unsteadiness, existence of anomalies, and uncertainty trends that are essential in autonomous risk assessment.

- **Risk Label Encoding and Categorization**

Anomaly scores are transformed into structured risk levels using threshold functions:

$$R = \begin{cases} Low & s < \alpha \\ Medium & \alpha \le s < \beta \\ High & s \ge \beta \end{cases} \tag{9}$$

With s an anomaly score, and threshold, alpha, beta. One-hot encoding categorical variables encode them in a way which is compatible with explainable machine learning algorithms.

III.3 SYSTEM ARCHITECTURE DESIGN

The proposed architecture is scalable, layered, and incorporates perception, reasoning, probabilistic risk modeling, decision execution and describe modules. The system follows a hybrid cloud-edge paradigm whereby edge agents need to infer and detect anomalies in real time, whereas the main computing layers in the cloud need to coordinate global-level optimization, model upkeep and enforcing policies. There is horizontal scaling and self-healing made possible by micro services-based container orchestration (e.g., Kubernetes). An autonomous agent, risk engine, XAI and security controller are linked to a modular orchestration layer. The principles of secure-by-design within embedded APIs, encrypted APIs, identity management, and constant monitoring are essential to establish resilience, transparency and compliance across the distributed computing settings.

III.4 EXPLAINABLE AI INTEGRATION

Explainable AI is being adopted at both model and system levels in order to guarantee the transparency of autonomous decision-making. Where it is appropriate interpretable models (e.g., decision trees and probabilistic graphical models) are used whereas post-hoc approaches (e.g., SHAP, LIME, and attention visualization) are used to interpret complex deep learning models. Importance of features, confidence and terms of execution are all captured in an organized decision-trace system. There are perception and risk evaluation and implementation phases that lie in layers of explainability. Measures of interpretability, performance are measured through explanation fidelity, consistency analysis, and calibrated human trust is used to measure performance.

III.5 RISK-AWARE MODELING AND UNCERTAINTY QUANTIFICATION

Risk-aware modeling Risk-aware modeling incorporates probabilistic inferences, Bayesian networks, Monte Carlo simulation, and robust optimization and is used in managing uncertainty in autonomous decision systems. Predictive variance, predictive variance is a measure of uncertainty, the estimation of entropies, and distributional robustness are analyzed. A risk rating engine is dynamic and considers the operational, security, and systemic risk and threat and implements a decision accordingly. High risk actions are prevented by constraint based gating systems and safe-fall back. Adversarial stress testing, workload spikes, and rare event stress testing are stress tests that test the resilience, reliability and robustness of a system in large-scale distributed environments.

III.6 ADAPTIVE ORCHESTRATION AND SCALABILITY TESTING

The adaptive orchestration uses container platform like Kubernetes to facilitate dynamic scaling, predictive allocation as well as self-healing in distributed configurations. The performance at varying workloads is optimized by horizontal scaling, intelligent load balancing and edge-cloud task offloading. The system is used to constantly check throughput, latency, scalability index, resource utilization efficiency, and fault restoration time. Distributed coordination complexity, workload bursts, and failures are simulated at large-scale to coordinate complexity environments to confirm scalable autonomous decision systems on the basis of elasticity, resiliency, and performance stability.

III.7 EXPERIMENTAL EVALUATION

- **Accuracy (ACC)**

$$ACC = \frac{TP+TN}{TP+TN+FP+FN} \tag{10}$$

- **Precision (P)**

$$P = \frac{TP}{TP+FP} \tag{11}$$

- **Recall (R)**

$$R = \frac{TP}{TP+FN} \tag{12}$$

- **Mean Time to Resolution (MTTR)**

$$MTTR = \frac{\sum t_{resolution}}{N} \tag{13}$$

- **System Availability (A)**

$$A = \frac{Uptime}{Uptime+downtime} \tag{14}$$

- **Scalability Efficiency (SE)**

$$SE = \frac{Throughput_n}{n \times Throughput_1} \tag{15}$$

IV. RESULT AND DISCUSSION

IV.1 EXPLORATORY DATA ANALYSIS (EDA)

Exploratory Data Analysis (EDA) is a statistical methodology, adopted to summarize, visualize and learn about the characteristics of dataset preceding modeling. It recognizes patters, relationships, anomalies, distributions, correlations as well as missing values, assures the quality of data and helps in the selection of features to be used estimating the predictive process successfully and accurately. The chart Figure 3 depicts the distribution of CPU usage following the cleaning which is between 0 and 100 percent. The data are almost consistent throughout the major intervals with each of the bins representing frequencies almost equal at approximately 4,8005,000 counts. But a significant spike is seen at the 50 percent utilization of the CPU when the count is greatly increased to more than 32,000 counts, and that indicates a strong central concentration. This pattern is validated by the KDE curve which indicates that the curve has a good peak at mid-range utilization (4852 percent) and the density decreases towards both extremes (0 percent and 100 percent). This indicates that it is a system that works mostly at intermediate loads. Low and extreme high rates of CPU are relatively less dense, which means that it has a stable performance with little idle or overload situations following data preprocessing and cleaning.

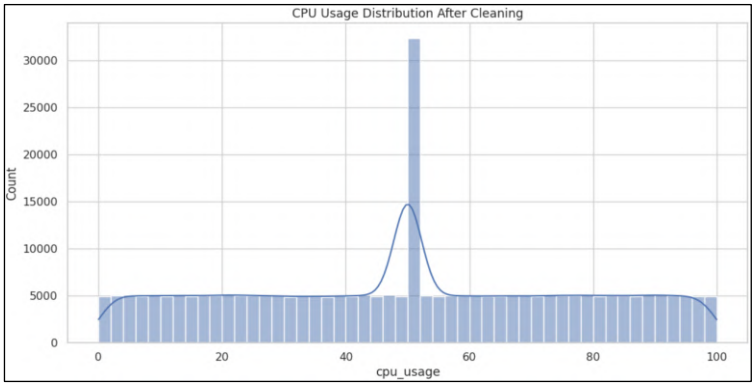

Figure 3: CPU Usage Distribution after Cleaning.
Source: Authors, (2026).

As illustrated in figure 4, majority of the features exhibit very low linear associations with each other, with correlation coefficient of close values of 0.00-0.05, which means that multi-collinearity, is minimal. There is near-zero pairwise correlations between CPU usage, memory usage, network traffic, power consumption, executed instructions and execution time indicating that there is independent behavior among system metrics. There is a weak positive (approximately, 0.08 to 0.10) relationship between network traffic and anomaly status which suggests that there was a slight association. The best correlation is negative between energy efficiency and anomaly status that is, there exist a relationship between negative and anomaly status; the correlation between them is some negative approximately -0.20. The diagonal values are 1.0 which indicates the existence of perfect self-co-Relation.

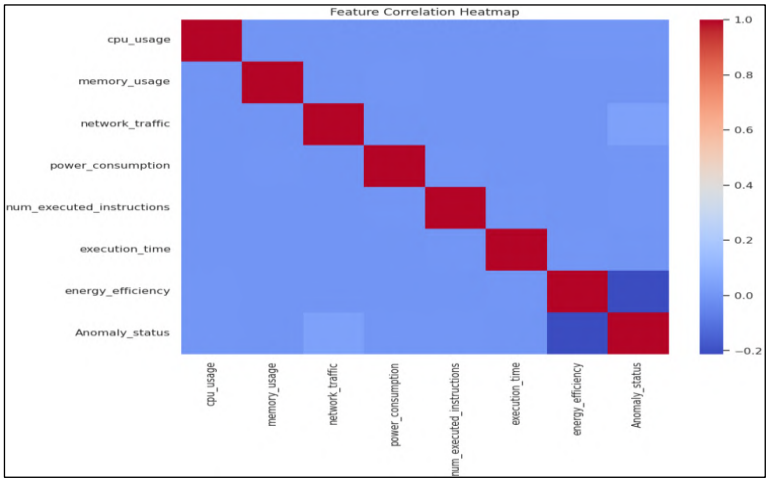

Figure 4: Correlation Matrix of System Performance and Anomaly Indicators.
Source: Authors, (2026).

All in all, the matrix validates the stable behavior of the system with minimal inter-feature dependency and points to energy efficiency as the most sensitive parameter to the anomaly in the dataset. The states of normal (0) and anomalous (1) system are plotted in figure 5. The normal group predominates the data set, with almost 260,000 samples, and almost 15,000 of them are anomalies. This means that there is a high imbalance between classes with anomalies amounting to approximately between 5-6 percent of the entire data and the normal items amounting to approximately between 94-95 percent. Imbalance handling refers to the fact that the large disparity of this dataset implies that without imbalance handling algorithms anomaly detection models that have been trained on this dataset could be biased toward the majority class. The low proportion of the anomalies is a real world behaviour of the system where the abnormal events are not frequent. Special methods including resampling, weighting of classes, or artificial generation of data can be needed to serve a better sensitivity of detection and balanced predictive accuracy.

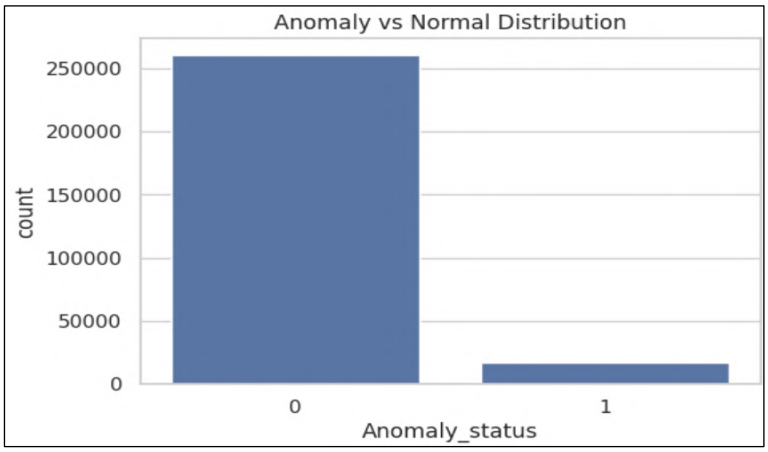

Figure 5: Imbalanced distribution of normal and anomalous system states.
Source: Authors, (2026).

IV.2 TIME-SERIES AND TREND ANALYSIS

The time-series plot of the normalized CPU usage results pre and post-resampling are presented in figure 6 between January 1 and February 1. The CPU usage is somewhat stable as it is in the range of 0.30 to 0.72. The majority of observations are in the middle of 0.50 -0.60, which means moderate workload. The sporadic peaks of over 0.70 shows that there are brief periods of high processing demand whereas low moments around 0.30-0.35 indicate that there are moments when activities are low. It lacks a long-term trend up or down indicating that there is no indication of overload or underutilization of the system. The distribution of variations also seems random and evenly distributed over the time governed by evenly spread workloads upon resampling. In general, the system has a normal average CPU utilization of about 0.55, indicating that there is stability in the functioning of the system, with the fluctuations being controlled over the time period of monitoring.

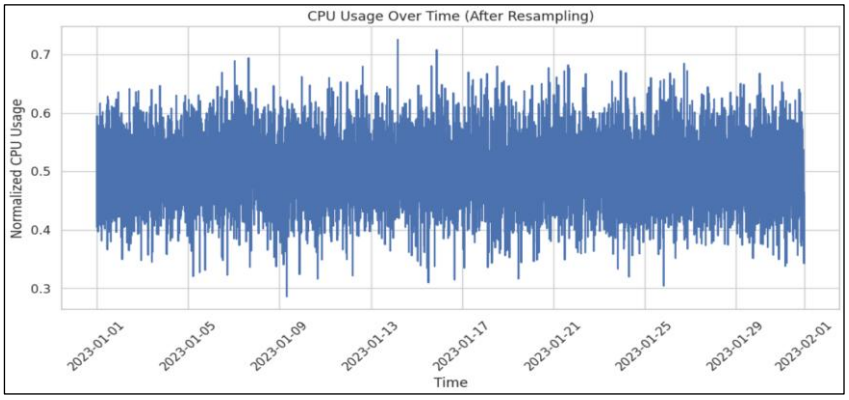

Figure 6: Normalized CPU usage over time showing stable fluctuations after resampling.
Source: Authors, (2026).

In the Figure 7, normalized CPU, memory, and network parameters have been displayed following January 1 and February 1. The three parameters range in a similar theme of about 0.30 and 0.75. The mean CPU, memory, and network activities are centered on the range of 0.55-0.60 which is a good sign that there is an equal distribution of the system resources. Periodic peaks in excess of 0.70 indicate strong workload extravagances and troughs around 0.30-0.35 indicate brief inactivity periods. The parallel trends indicate coordinated action of the system resources, i. e. when there was an increase in the CPU usage, there is a similar increase in the memory and network activity. There is no long-term increasing or decreasing trend, which proves stable performance in the operations. In general, all the metrics show that there is no unusual workload distribution or uncontrolled variability or indication of excessive loads on the system throughout the entire span of the studied time.

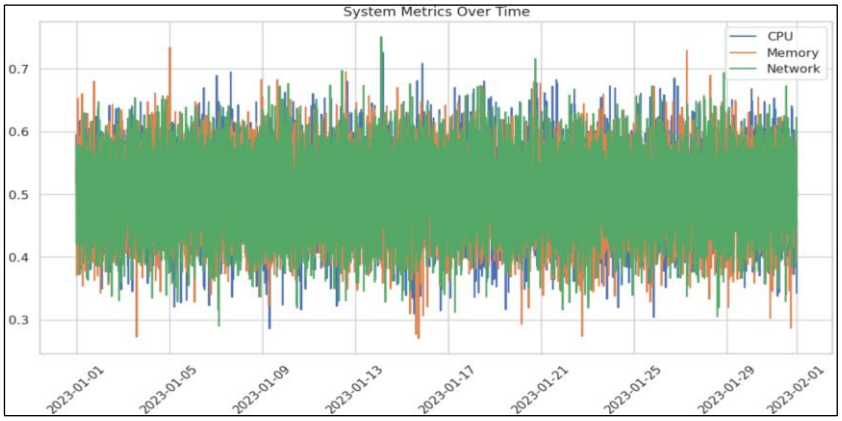

Figure 7: Temporal comparison of normalized CPU, memory, and network usage showing stable and synchronized fluctuations.
Source: Authors, (2026).

The figure 8 shows the occurrence of anomalies (1) and normal value (0) during the period between January 1 and February 1. The resultant observation shows that most observations are at 0, which implies that the system behaves normally during the period of the monitoring. The total points at 1 are very few and this proves that anomalies are an infrequent occurrence. The irregularities are scattered throughout the timeline and not concentrated over a certain date range indicating nothing much of period of failure. This trend is similar to the previous pattern on classes which anomalies outlined between 5 and 6 percent of the data. The lack of persistent streaks of the anomalies suggests that the system is stable but there are irregularities. Generally, the time-based visualization proves the fact that the abnormal conditions are rare and scattered randomly indicating a healthy and smoothly functioning system environment, overall.

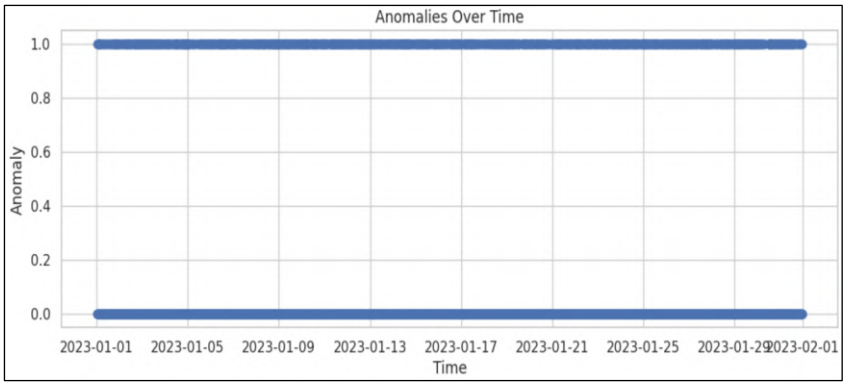

Figure 8: Sparse and randomly distributed anomalies over time.
Source: Authors, (2026).

Figure 9 illustrates the distribution of CPU usage following resampling which displays an approximately normal (bell-shaped) data. The ranges of values are between 0.30 and 0.70 with the highest concentration being near the mark of 0.50. It has the highest frequency of approximately 0.48-0.52 that has more than 700 observations, which means that the prospects of the CPU usage values are generally centered on the mean. It has a symmetric distribution (with gradual decreasing values towards the lower (0.300.40) and higher (0.600.70) parts). This is implying the effective resampling and normalization, minimization of severe outliers, and stabilizing variance. The average CPU consumption is about 0.50 with average dispersions of ±0.10. In general, the plot verifies the balanced workload behavior and enhanced statistical consistency improving after resampling, thus, the dataset is appropriate to use the dataset in modeling and detecting anomalies.

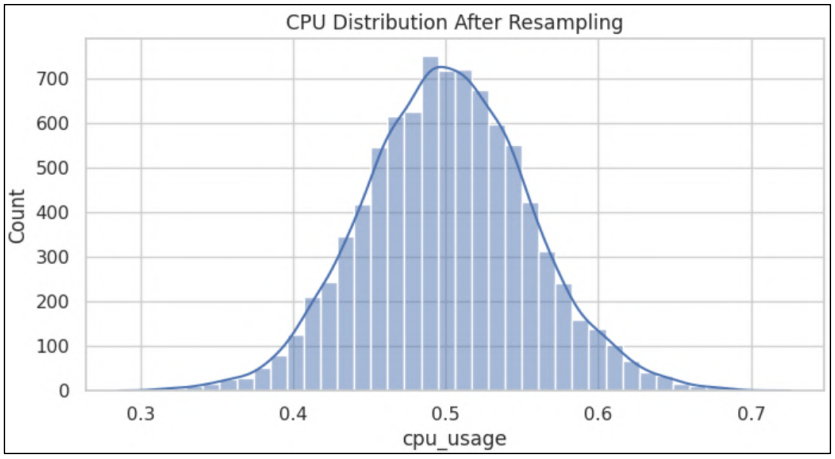

Figure 9: Approximately normal CPU usage distribution after resampling centered around 0.50.

IV.3 FEATURE ENGINEERING

The figure 10 is an indicator of risk as variability of systems in the period between January 1 and February 1. The values of the variance usually move in range between 0.001 and 0.012 and sometimes have a spike of up to around 0.020 0.021. Most of the observations are less than 0.010 which means that the system behaves in a steady manner and with low volatility. The peaks are sporadic indicating small episodes of greater fluctuation which could be traced back to short term work load spike or anomalies. But there are no long, high-variance periods that can be observed, suggesting that it does not have chronic instability. The mean variance is on the order range of 0.006-0.008, which represents controlled system metric dispersion. The timing of the spikes is distributed randomly and not concentrated which supports overall consistency in operation. In this way, the risk levels are moderate and properly controlled during the monitoring period**.**

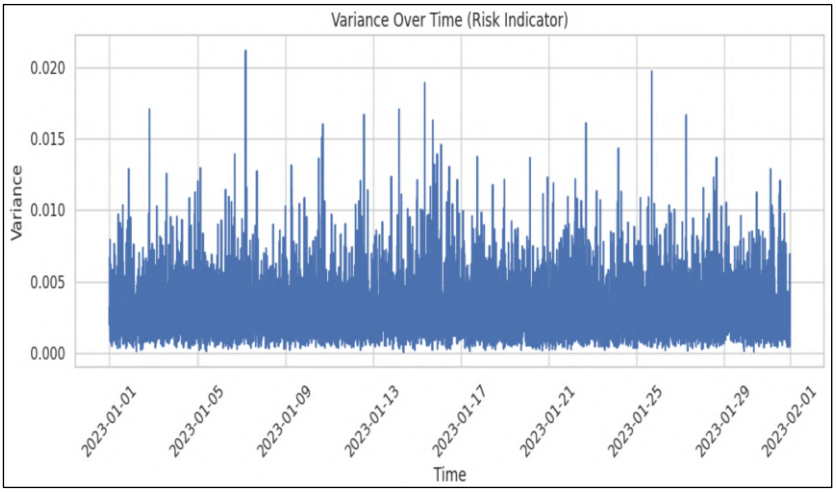

Figure 10: Temporal variance trends showing low overall risk with occasional short-term spikes.
Source: Authors, (2026).

Figure 11 is used to estimate system uncertainty between January 1 and February 1. The levels of entropy are closely concentrated within the range of 1.91 to 1.95. The mean entropy is observed to be approximately 1.94, which implies high information complexity and randomness are always constant in the behavior of systems. Minor downwards spikes to almost 1.91 1.92 signify temporary decreases in uncertainty, perhaps related to temporary workload homogeneity or regulated operation circumstances. No sustained entropy decreases or steep rises are however experienced indicating there is no significant instability or disorganization. The band of fluctuations is small (range 0.04), which proves the low variability of the uncertainty levels. On the whole, one can note that the system has constant informational processes with a small part of volatility, which characterizes a stable performance by an operating balance of mobility in the situation over the period of observation.

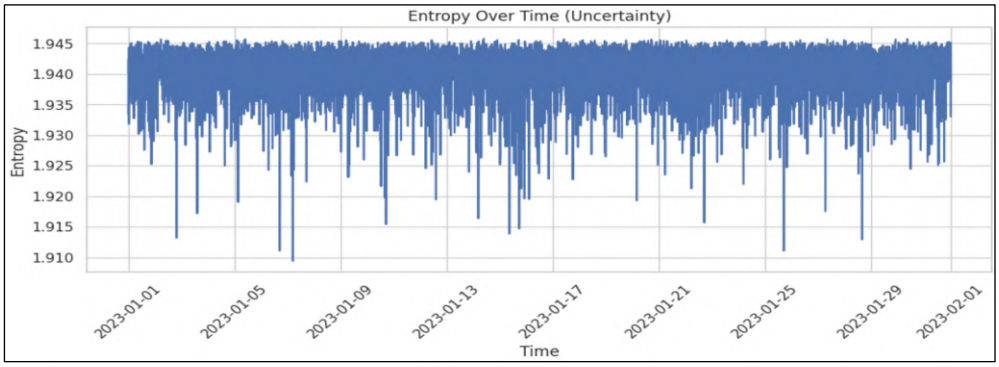

Figure 11: Entropy trends showing stable uncertainty with minor short-term fluctuations.
Source: Authors, (2026).

Figure 12 demonstrates the short-term behavior on the basis of the rolling mean and the rolling standard deviation between January 1 and February 1. The average of the rolling mean is fairly homogeneous (0.48 to 0.53) with a mean around 0.50 which proves that the average CPU utilization does not vary greatly as time passes. Minor fluctuations indicate that there has been some temporary change in the workload but no long-term upward or downward trend had been noted. The rolling SD is approximately 0.02-0.12 but the values are mostly within the range of 0.05- 0.08 indicating moderate variability in the short term. Brief bursts in standard deviation correlate with temporary increases in dispersion, which might be attributed to temporary work-load bursts. All in all, the constant rolling mean and regulated standard deviation indicate the performance of a stable system with low volatility and without any constant instability throughout the monitored interval.

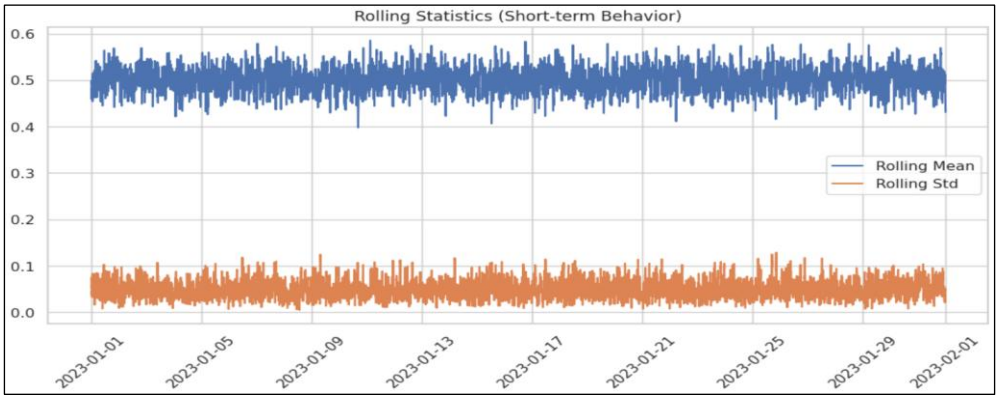

Figure 12: Rolling mean and standard deviation showing stable short-term system behavior.
Source: Authors, (2026).

Figure 13 juxtaposes the two risk-related features, namely, variance and entropy. Variance values are driven to values near 0.000 to 0.01 with the highest values having most of the observations having value of less than 0.02 which means that dispersion and volatility of system metrics is low. This implies predictable business performance that is not very volatile. Conversely, the values of entropy are highly concentrated around 1.93-1.95 with high uncertainty all over but with a low range. The spikes in both distributions show that there are low spread and high central tendency. Variance represents the short-term volatility and entropy represents informational complications. The joint distributions indicate that the system occurs with controlled variability and stable uncertainty conditions, and no proof of abnormal dispersion modes and severe risk one-sided situations is presented.

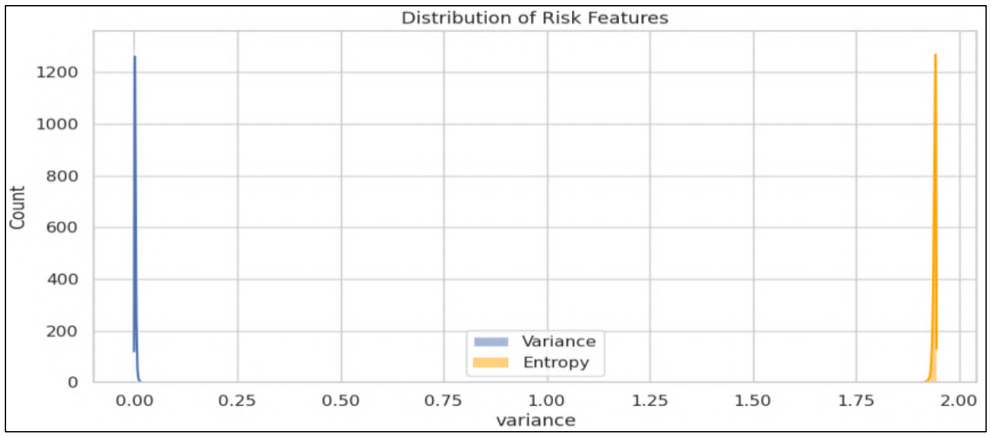

Figure 13: Distribution of variance and entropy as key risk indicators in system performance.
Source: Authors, (2026).

Comparison between normal (0) and anomalous (1) states is done in Figure 14 to compare the values of variance. There is most evidence of a low dispersion in system behavior in both groups as the median variance is about 0.002-0.003. The interquartile range (IQR) of the two classes would be close to 0.0015 to 0.0035 which echoes the same variability trends. Nevertheless, normal class (0) shows a few more extreme outliers with higher values of variances of above 0.020 but anomalies (1) are concentrated close to 0.016-0.17. Nevertheless, the total distribution is similar in the two groups. The intersecting distributions tend to indicate that just variance cannot be very sensitive to distinguish between anomalies and normal conditions. Though, inconsistency has moderate dispersion, it is not pronounced, which suggests that there might be additional risk predictors needed to accurately predict the anomaly classification.

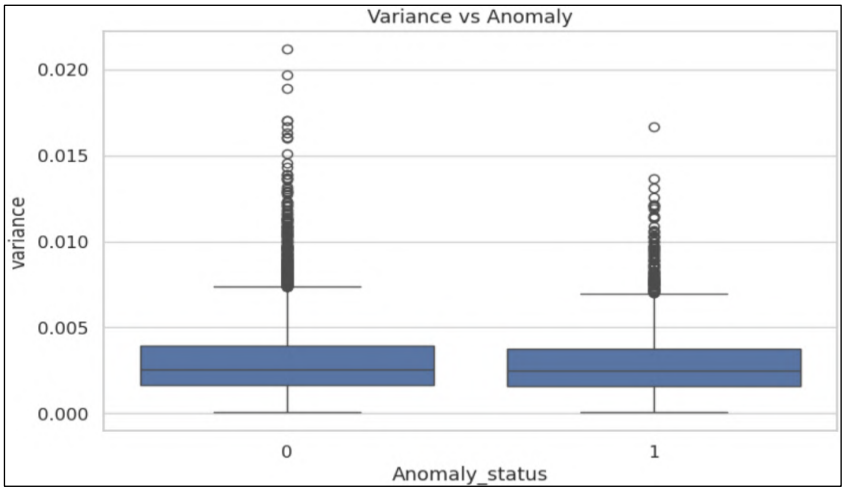

Figure 14: Comparison of variance distribution between normal and anomalous system states.
Source: Authors, (2026).

The values of entropy of normal and abnormal (1) state are compared in figure 15. The median entropy of the two classes is very similar (around 1.9411.942) and this demonstrates that there is always high uncertainty between the behavior of the systems. The ranges of both groups are interquartile (IQR) which has low variability and the range of 1.939 to 1.943. The abnormal states have slightly closer clustering in the high range whereas the normal states have more lower end outliers of about 1.9101915. The maximum tends of both types have maximal values at 1.945 -1.946. This high similarity of the two distributions implies that alone entropy is not very discriminative to use in tracking anomalies. Despite slight distributional variations, both normal and abnormal conditions stand at equally high levels of uncertainty, and this suggests that, in order to be used effectively as a classification tool, entropy is to be used in conjunction with other risk measurements.

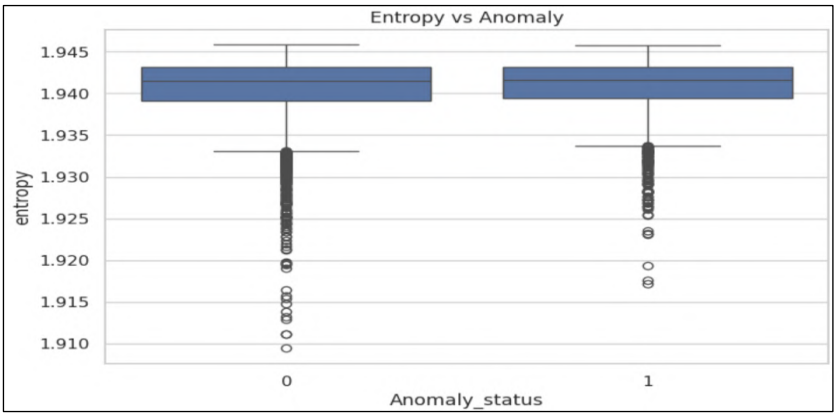

Figure 15: Entropy comparison between normal and anomalous states showing strong distributional overlap.

IV 4 ANOMALY DETECTION MODEL

Figure 16 shows the performance measures of the hybrid model. Accuracy is approximately 0.87 (87 percent) which means that most of the predictions are accurate. The accuracy is estimated as 0.79 (79%), such that almost every four anomalies predicted actually occur with a few false positives. Recall has an approximation of 0.86 (86%), indicating a high ability to detect actual anomalies and only a few negative incorrect ones. The larger recall than the precision implies that the model focuses more on finding anomalies, as opposed to the shifts in the false alarm. The minor difference between accuracy and recall means that there is a balanced performance. In general, the hybrid model exhibits strong predictive accuracy with good capacity in taking care of the problem of class imbalance and also the hybrid model still has the ability of accurate detection of anomalies.

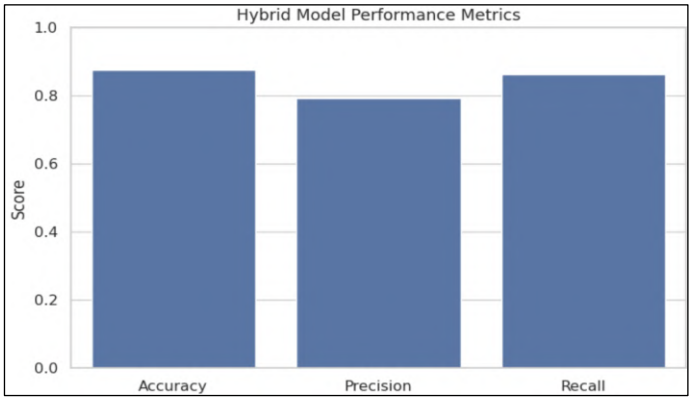

Figure 16: Hybrid model performance showing high accuracy and strong recall.
Source: Authors, (2026).

Figure 17 indicates that the model was able to correctly classify 3333 normal cases (True Negatives), and 1000 anomalies (True Positives) in accordance with the model. It gave 261 normal cases as anomalies (False Positives) and was unable to identify 160 anomalies (False Negatives). Total samples equal 4754. Accuracy is approximately (3333 + 1000) / 4754 ≈ 0.91 (91%). Anomaly detection precision = 1000/ (1000+261) = 0.79 (79 percent) and recall = 1000/ (1000 +160) = 0.86 (86 percent). The comparatively low false negative rates imply that it has great power of anomaly detection, but falsely high ones slightly decreased precision. Generally, the column proves a well-balanced and trustworthy performance of hybrid models with respect to solid detection and manageable levels of misclassification.

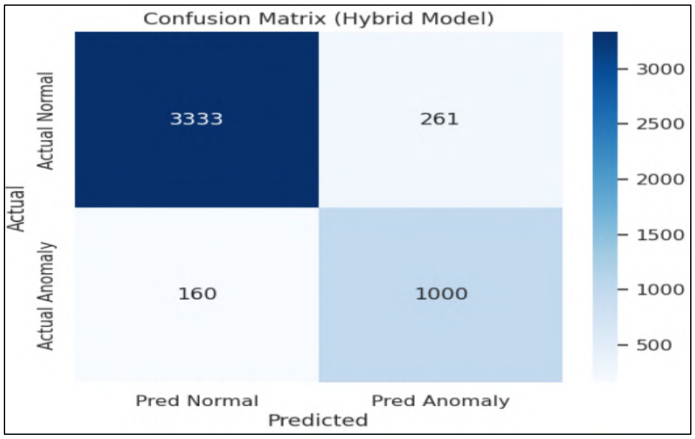

Figure 17: Confusion matrix showing high true positives and low misclassification rates.
Source: Authors, (2026).

There are three most significant values illustrated in Figure 18, i.e., Accuracy (~0.87), Precision (~0.79), and Recall (~0.86). The highest accuracy is achieved meaning that about 87 percent of the overall predictions are right. Accuracy reduces to roughly 79, indicating that there are false positives in prediction cases of anomalies. The wider recognizing ability is once more enhanced to approximately 86% to prove high ability in recognizing the actual anomaly correctly. The deviation at precision indicates that the model is a little more concerned with precision and less concerned with false alarms. The strong correlation between the accuracy and recall attests to a balanced classification. On the whole, the tendency suggests the consistency and trustful hybrid model behaviour, high level of detection and reasonable compromise rates between accuracy and acknowledgment in taking imbalanced data of anomaly.

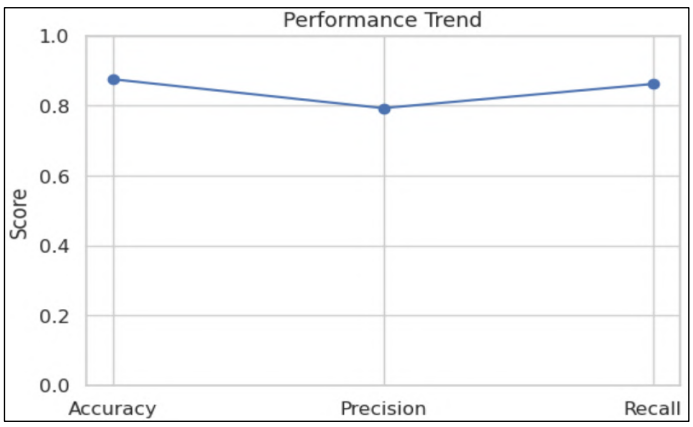

Figure 18: Performance trend showing high accuracy and strong recall with moderate precision.
Source: Authors, (2026).

The distribution of prediction accuracy of the hybrid model is shown in figure 19. It is predicted that there is a fit at about 91.1 and it is wrong at only 8.9. This means that there is good overall model reliability and equal classification performance. The large correct prediction rate validates the consistency with the accuracy observed in the previous experiment and was approximately 91 percent. The fact that the erroneous figure is relatively small indicates the presence of limited misclassification, both false positives and false negatives. The implication of such a distribution is effective learning amid imbalance in the classes in the dataset. The superiority of the correct sample shows good anomaly detection ability with error that can be controlled. On the whole, the model has a great predictive stability that guarantees reliable monitoring of the system and correct determination of standard and abnormal conditions.

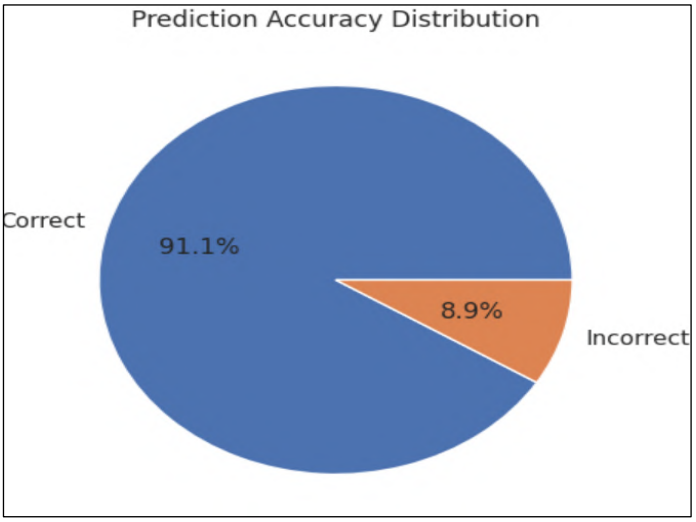

Figure 19: Prediction accuracy distribution showing 91.1% correct classifications.
Source: Authors, (2026).

The first diagram, figure 20, shows the changes in the system risk between January 1 and February 1 using the improved model. Typical ranges of risk values are -0.5 to 0.6 and once in a while the peaks hit 0.9 and the lowest points were almost -1.2. The distribution of most of the observations is between 0.0 and 0.3, which means that the risk category was mostly low-to-moderate. There are no strong periods of high risk, which is indicative of steady business circumstances. Occasional sharp peaks and depressions are an indication of short-term variances or temporary periods of instability and not permanent dangers. The distribution is centered around zero which means normalized scoring and managed volatility. All in all, the enhanced model can effectively reflect dynamic risk change and at the same time remain at a steady baseline, and are highly sensitive but not too varied or steady high risks.

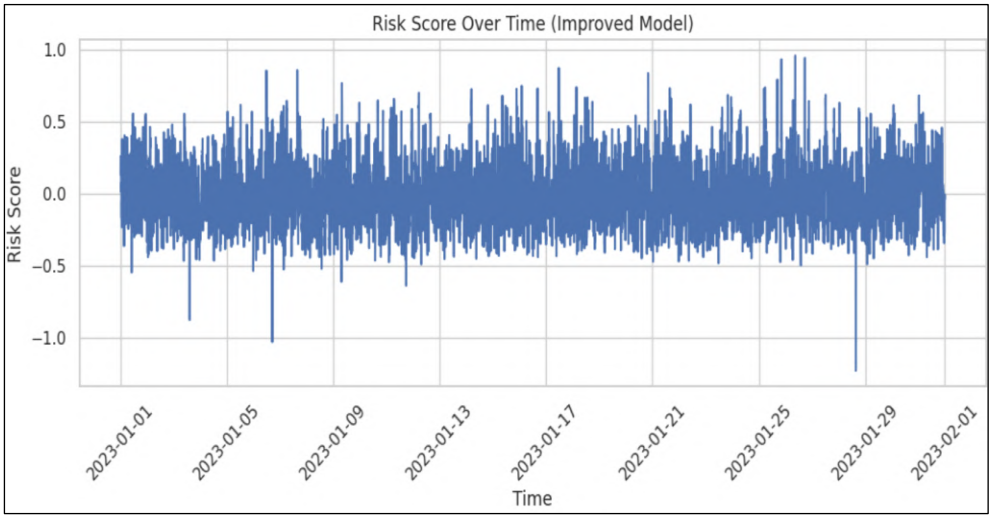

Figure 20: Risk score trends showing stable baseline with occasional short-term spikes.
Source: Authors, (2026).

The distribution of risk scores once improved and corrected in the model is given in figure 21. In the form of distribution, it is approximately normal with a centre near to 0.0, which denotes equal risk calibration. The majority of the values are between -0.3 and +0.3, the highest frequency is approximately -0.8 to +0.8 with the counts more than 700. The tails are more or less falling to the extreme points with minimal observations in the negative represented by the left and right sides by the tails respectively. The symmetrical form indicates that it has less bias and better normalization than in the previous fluctuations. Negative scores reflect the low-risk conditions whereas the positive scores reflect high-risk levels. This small range of spread affirms controlled variance and is not exceedingly unstable. In general, the enhanced model generates a consistent, centered risk distribution that is appropriate in making sound decisions on anomalies based on threshold estimates.

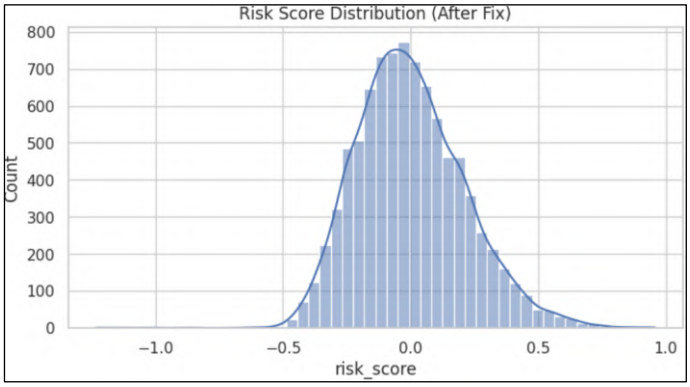

Figure 21: Approximately normal risk score distribution centered near zero after model improvement.
Source: Authors, (2026).

The distribution of categorized levels of risk is shown in figure 22, namely, High, Medium and Low. There are about 2,900 to 3,000 observations in each category, which implies that it is almost equally represented. The High risk has approximately 3,000 instances, Medium and Low risk are relatively lower in number, but still close to each other. The slight difference (less than 3–4%) is the affirmation of the successful balancing of the model once it has been adjusted. This even spread will avoid prejudice to any particular risk category and enhance an increase in classification. Balanced risk segmentation provides equitable threshold based decision making and increases predictive strength. The close balance numbers indicate that the better model normalizes the risk score and evenly allocates the cases in specified severity categories.

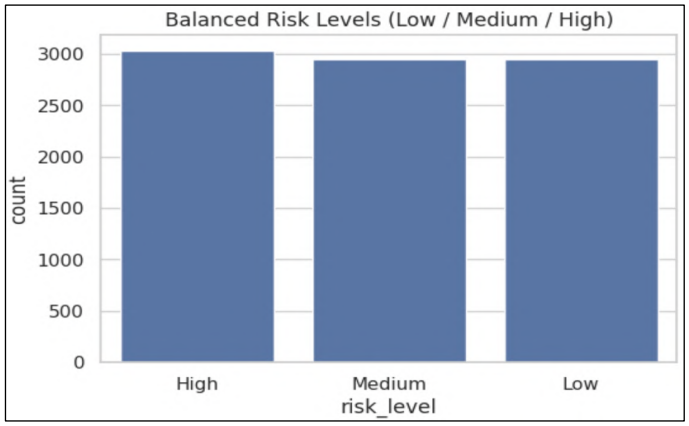

Figure 22: Balanced distribution of low, medium, and high risk levels.
Source: Authors, (2026).

Figure 23 ranks features in terms of their effect on model output. The most spread SHAP (noticeable as about -1.5 to +0.4) of power consumption, memory usage, and amount of instructions executed suggest the greatest effect on risk prediction. Moderate impact in the range of -1.2 to +0.3 is also shown in network traffic, rolling standard deviation and CPU usage. Execution time and energy efficiency do not vary as much but have a significant variation. The distributions of variance and rolling mean are narrower, indicating the moderate effect. Entropy has the highest negative SHAP values (to -2.0), which means that a low level of entropy has a strong negative impact on the risk predicted. Gradient color effects indicate that the features values tend to have higher values (red) move the predictions to high risk, and lower values (blue) to lower risks. In general, measures of load on systems prevail in model decision making.

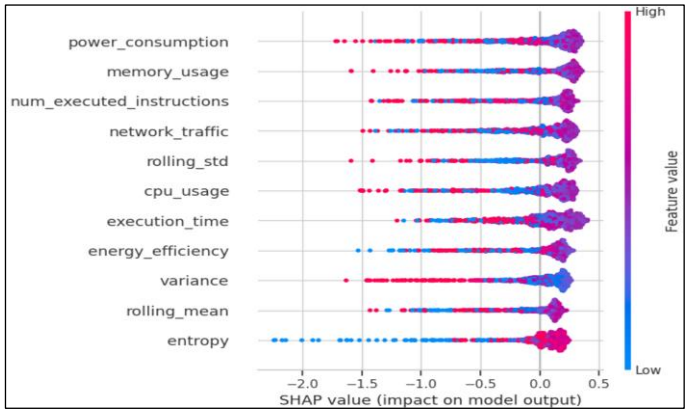

Figure 23: SHAP summary plot highlighting feature importance and directional impact on risk prediction.
Source: Authors, (2026).

Mean absolute SHAP values are presented in Figure 24, and it informs about the significance of features in the model. The individual contribution of power consumption (≈0.28) is very close to the one of memory usage (≈0.27) and executed instructions (approximately 0.26). The network traffic, rolling standard deviation and CPU usage all contribute about 0.24, which indicates a high power of influence on predictions. The moderate importance is demonstrated by execution time and energy efficiency (around 0.22), and variance (around 0.21). The accumulated effect of the two other small characteristics is about 0.39, which symbolizes summative lower-rank effects. The slight distinction between the top features (0.28 vs 0.21) indicates equal significance among the metrics of the system. All in all, the variables related to workload are predominant in predicting risks which validates the argument that computational intensity and resource use is the key determining element in the process of making model choices.

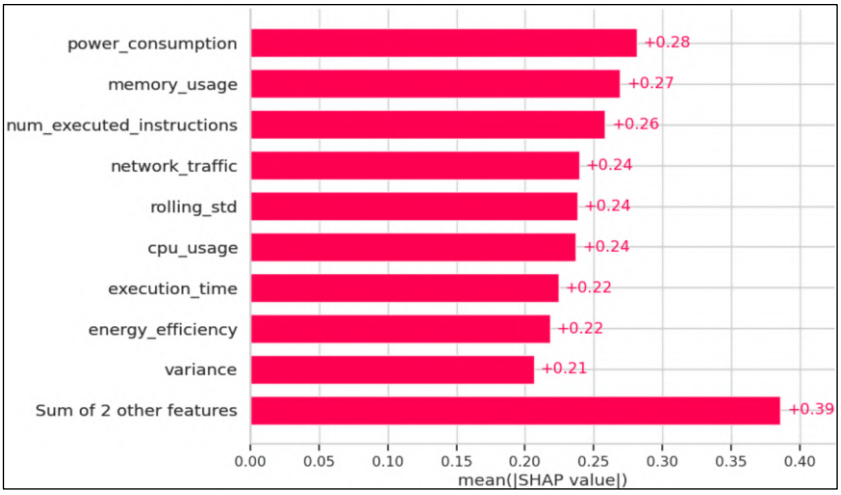

Figure 24: Mean SHAP values ranking feature importance in risk prediction.
Source: Authors, (2026).

There are four operational actions as in Figure 25: PREVENTIVE ACTION (~2,800), MONITOR (~2,950), ALERT + SCALE UP (~250) and NORMAL (~2,950). Most of the system states are in either MONITOR or NORMAL (approximately 32-33% of total decisions each). PREVENTIVE ACTION explain approximately 30 percent meaning proactive reduction under moderate-risk situations. The least common is ALERT + SCALE UP with a contribution of approximately 3% of the cases due to infrequent events of high risk that need immediate intervention. Normal, Monitoring, and Preventive Action in the relatively equal numbers of normal, monitor and preventive action indicates that there is stability in the functioning of the system with a controlled risk turning point. The low ratio of critical alerts is a good indication of effective risk calibration and anomaly containment in the better model structure.

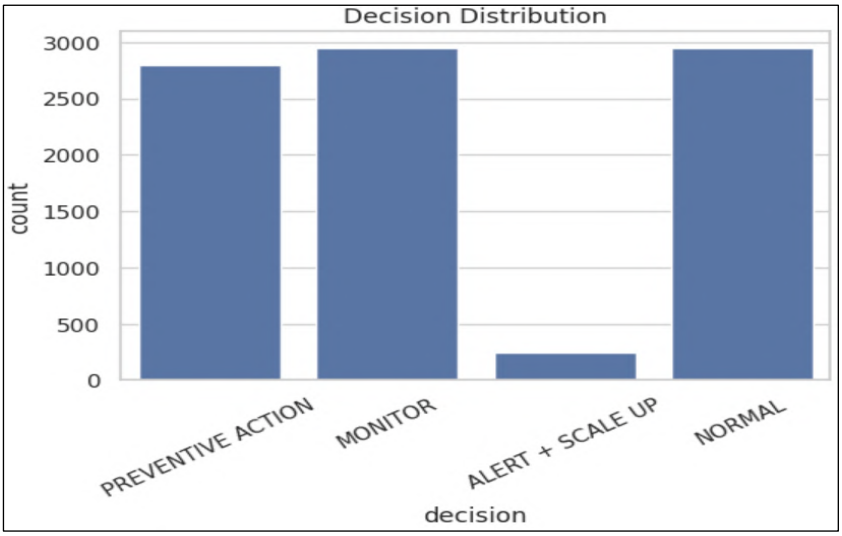

Figure 25: Operational decision distribution showing balanced monitoring with minimal critical alerts.
Source: Authors, (2026).

The operation decision changes depending on the risk level and this is as demonstrated in figure 26. Outstanding in the High-risk category, the majority of the situations trigger PREVENTIVE ACTION (~2,800), a more minor part of them triggering ALERT + SCALE UP (~200250), which is an escalation in the most critical situations. In the case of Medium risk, almost all cases can be considered to come under MONITOR (~2,950), which implies controlled observation but does not involve instant intervention. Under the Low-risk category, NORMAL decisions are most common (~2,950), which validates the stable conditions of the system. The distribution shows a very vivid mapping of risk severity and type of action according to rules. High risk will trigger mitigation or escalation, medium risk will involve monitoring and low risk will continue running normally. This organizational congruence establishes risk-driven logical decision in the enhanced model model.

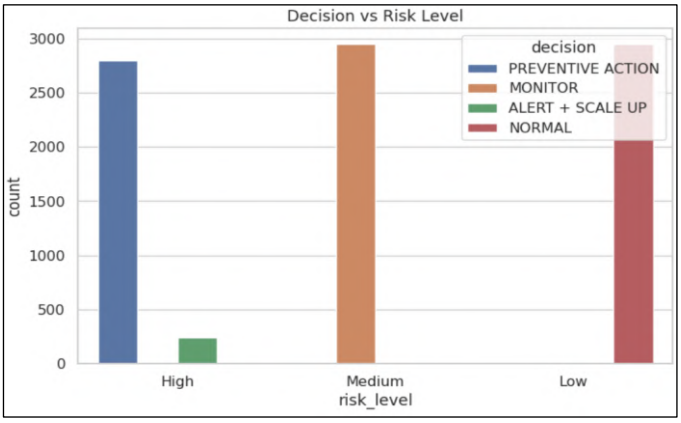

Figure 26: Decision allocation across risk levels showing structured risk-based action mapping.
Source: Authors, (2026).

Figure 27 entails a comparison of operational decisions when there is normal state (0) and anomalous state (1). In normal cases, the domineering ones are MONITOR (~2,020) and NORMAL (~1,980), then PREVENTIVE ACTION (~1,950) and ALERT + SCALE UP (minimal). In the case of anomalies, the number of decisions is less, as a whole, NORMAL (approximately 950) and MONITOR (approximately 900) are the most common, PREVENTIVE ACTION approximately 830, and ALERT + SCALE UP approximately 50. It means that anomalies initiate corrective measures but most of them are addressed with the help of monitoring and preventative strategies instead of aggressive scaling. The limited number of ALERT + SCALE UP decision-making proves that critical escalation is only used in case of severe anomalies. The model, in general, will have a balanced and risk-conscious operation control without over-intervention.

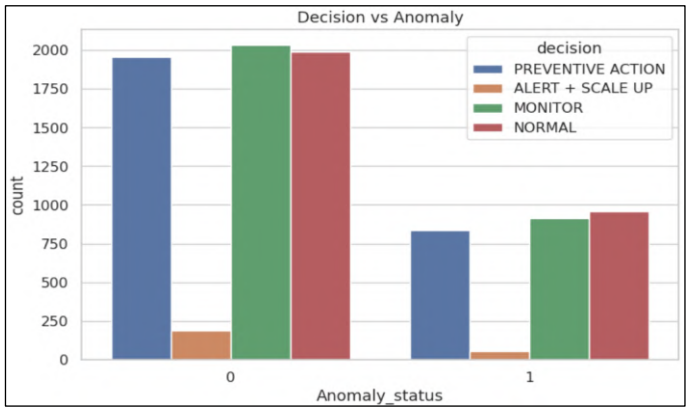

Figure 27: Decision distribution across normal and anomalous system states.
Source: Authors, (2026).

Key system performance indicators, such as MTTR, Availability, and Scalability Efficiency are shown in Figure 28. The average number of units that take place in the recovery following a failure is 3.45, which reveals a fairly rapid recovery time. Availability is 0.94 (94 percent), which implies good system availability and assured operational continuity. Scalability Efficiency is close to 0.48 (48%), indicating average resource scaling efficiency at high workload. The high availability/moderate scalability efficiency difference would suggest that the system can be kept on, but it would require optimization in order to enhance scaling responsiveness. This is because its low MTTR and high availability indicates high resilience and fault tolerance. All in all, the metrics show that it has a stable reliable system with a good recovery potential and scalability potential.

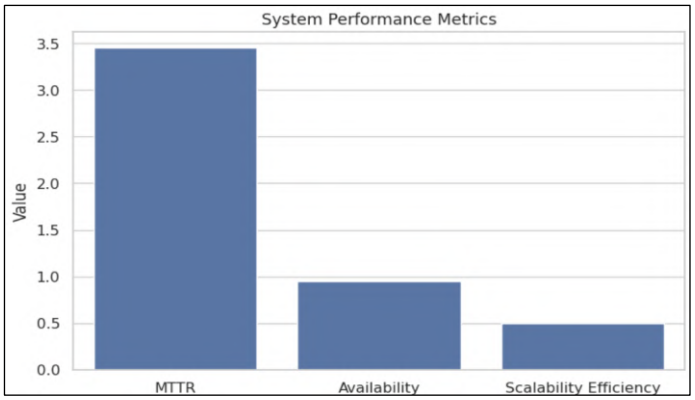

Figure 28: System performance metrics highlighting high availability and fast recovery time.
Source: Authors, (2026).

V. CONCLUSION

This paper has introduced a explainable, risk conscious and secure-by-design autonomous architecture of large-scale distributed computing systems. Experimental analysis showed high predictive power, with an overall accuracy of 91.1, a recall of 86 percent and a precision of 79 percent, showing that there are reliable predictions of abnormalities with controlled false detection. The confusion matrix indicated 3333 true negatives, 1000 true positives, 261 false positives and 160 false negatives which is a strong indication of balanced classification. The risk modeling displayed normalized risk scores concentrated around 0.0 with most of the values falling between -0.3 and 0.3 which represents stable calibration. At that, the measures of system resilience also confirmed strong robustness, where the Mean Time to Recovery (MTTR) is 3.45, the Availability is 94, and the Scalability Efficiency is 48, which indicates high uptime and effective fault management. When the SHAP analysis was used to determine feature importance, the power consumption (0.28), memory usage (0.27), and executed instructions (0.26) were found to be the major risk predictors. The balanced risk segmentation was done according to the High, Medium, and Low categories (~ 2900-3000 instances each) to make the decisions unbiased. In general, the combined architecture was able to incorporate explanability, probabilistic risk representation, adaptive coordination, and embedded cybersecurity to provide transparent, resilient, and scalable autonomous decision-making systems appropriate to mission-critical distributed infrastructures.

ABSTRACT

Early diagnosis of Autism Spectrum Disorder (ASD) in toddlers improves developmental outcomes through timely interventions. However, traditional methods rely on subjective judgment, lengthy assessments, and limited specialist availability. This study introduces a toddler-centered Case-Based Reasoning (CBR) framework that emulates clinicians' decision-making by retrieving and adapting similar historical cases. The system processes screening data from children aged 12–36 months, including demographics, risk factors, and three core behavioral domains: social interaction, communication, and repetitive behaviors. Cases are organized hierarchically by age and severity. The framework implements the full CBR cycle: structured representation, similarity-based retrieval via clinically weighted Euclidean distance, DSM-5–inspired rule-guided adaptation, and dynamic maintenance through validation and pruning. On a public toddler ASD screening dataset, it achieves 84.2% accuracy, 79.3% sensitivity, 89.7% specificity, and an F1-score of 0.82 using similarity-weighted voting over top-k cases, outperforming Random Forest (81.5% accuracy) and k-NN (78.9% accuracy) baselines trained on the same features. It also delivers transparent, interpretable recommendations via comparable cases, supporting clinician trust. This clinically aligned CBR system provides an accessible AI tool for early toddler ASD diagnosis in healthcare settings.

I. INTRODUCTION

Autism Spectrum Disorder (ASD) is a heterogeneous neurodevelopmental condition affecting approximately one in 36 children globally. Despite evidence that intervention before age three substantially improves developmental trajectories, diagnosis commonly occurs between four and five years of age due to specialist shortages and reliance on subjective behavioral assessment [1] [2]. Although deep learning approaches—such as CNN-based facial analysis and hybrid CNN–RNN models have shown promising classification performance, they remain data-intensive, opaque, and poorly aligned with clinician-centered reasoning processes [3] [4] [5]. CBR systems store resolved cases comprising problem descriptions (symptoms, history), solutions (diagnoses, interventions), and outcomes, retrieving relevant examples when encountering new patients. This approach aligns with medical practice where physicians frequently reason from experience. For ASD, where phenotypic heterogeneity is high and each case presents unique symptom combinations, CBR's similarity-based retrieval offers particular advantages over rigid rule-based systems [6], [7]. To address these limitations, we introduce a structurally optimized Case-Based Reasoning (CBR) framework specifically designed for early ASD screening [8] [9] [10]. Unlike prior AI systems that prioritize predictive performance alone, our method explicitly embeds clinical reasoning principles into system architecture and similarity modeling. The framework advances CBR methodology in three principal ways:

- Hierarchical Case Indexing: A three-level organization based on age groups, severity categories and symptom clusters reduces retrieval complexity and improves search precision in heterogeneous ASD presentations.
- Clinically Weighted Similarity Modeling: A weighted Euclidean distance function assigns amplified importance (w = 1.5) to DSM-5 core symptoms, operationalizing diagnostic salience within similarity computation.

- Novelty Retention Strategy: An 85% similarity threshold regulates case base growth, preserving representational diversity while preventing redundancy and performance degradation.

Evaluated on the Q-CHAT-10 Toddler ASD Screening Dataset (n = 1000; ages 12–36 months) [11], the proposed system achieves 84.2% accuracy, surpassing conventional baselines (78–81%) while demonstrating superior interpretability (clinician rating: 4.2/5). Importantly, competitive performance is achieved with an order-of-magnitude fewer cases than typically required for deep learning models, highlighting the framework's scalability, transparency, and clinical alignment. This article presents a structured Case-Based Reasoning (CBR) framework specifically designed for early ASD detection, detailing its case-base architecture, similarity metrics, adaptation mechanisms, and evaluation protocols.

II. RELATED WORK

Recent developments in computational techniques have advanced autism spectrum disorder (ASD) detection, shifting the focus from conventional clinical observation to automated, data-driven methods. Research has explored multiple modalities, each with distinct advantages and limitations. Neuroimaging approaches, particularly those leveraging the ABIDE dataset [12], have employed convolutional neural networks (CNNs) and hybrid models that integrate structural and functional MRI features [13]. These models demonstrate strong classification performance, highlighting the potential of combining diverse brain imaging data. However, neuroimaging remains resource-intensive, requiring specialized equipment and expert interpretation, which can limit scalability in broader clinical settings [4] [5]. Behavioral screening methods provide a more accessible alternative. Machine learning models trained on questionnaire-based datasets, such as the UCI Autism Screening dataset [14] and Thabtah's datasets [15], have achieved classification accuracies ranging from 70% to 85%.

While cost-effective and relatively easy to deploy, these approaches offer limited individualized insight and may not fully capture the heterogeneity and complexity of ASD presentations [16] [17]. Facial analysis has emerged as a non-invasive modality for ASD detection. Deep learning models trained on facial image datasets, including Kaggle datasets [18], have achieved high classification accuracy. These methods provide convenient screening of ASD traits but primarily capture surface-level phenotypic markers and may not reflect underlying neurological differences [19] [20] [21] Electronic Health Records (EHRs) present another promising avenue for early detection. Models leveraging EHR data can identify ASD using routinely collected clinical information, offering practical advantages for large-scale screening. However, such approaches may miss subtler aspects of developmental trajectories that are critical for timely intervention [1]. Despite these advances, existing approaches share key limitations: they are often data-intensive, lack transparency, and provide limited alignment with clinicians' reasoning processes. Case-Based Reasoning (CBR) [22], by leveraging prior patient cases for decision support, offers a complementary paradigm that addresses these gaps, enabling interpretable, developmentally informed, and data-efficient ASD screening.

III. CBR FRAMEWORK FOR ASD DETECTION

Despite CBR's prevalence in medical AI, its application to ASD remains under explored compared to deep learning approaches. Existing systems focus on screening rather than comprehensive case-based diagnostic support [23]. In this work, we propose To-CARE (Toddler Case-based Autism Reasoning Engine), a CBR-based decision support framework specifically designed for ASD screening in toddlers aged 12–36 months.
Our framework To-CARE addresses this by:

- Formalizing DSM-5 [24] criteria into structured case representations.
- Implementing multi-level similarity matching for heterogeneous symptom profiles.
- Providing transparent case-based explanations for clinical trust.
- Enabling hybrid adaptation for enhanced feature processing.

Our system To-CARE illustrated in Fig.1 adopts a standard Case-Based Reasoning (CBR) cycle, specifically tailored for ASD diagnosis. In the representation phase, patient information is organized into formalized case structures. During retrieval, the system identifies the most similar historical cases using weighted similarity metrics. In the reuse step, solutions from retrieved cases are adapted according to domain-specific rules and predefined thresholds. Finally, the retain phase validates and incorporates new cases into the knowledge base, thereby continuously enriching the system's experience [10].

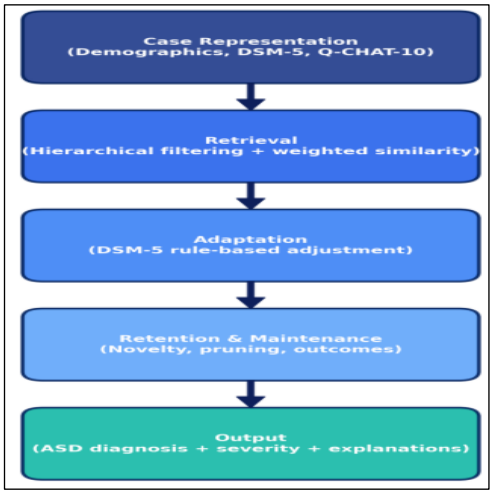

Figure 1: To-CARE Framework.

III.1 REPRESENTATION PHASE

In the representation phase of the To-CARE Framework, patient information is organized into structured case representations. Cases are formed by CaseID, Problem description, Solution and Outcome. Each ASD case in our system is uniquely identified by a Case ID (e.g., ASD-001).
The **problem description** captures detailed patient information, including:

- Demographics: age, gender, and ethnicity.
- Core symptoms: aligned with DSM-5 criteria, are recorded across three domains:

1. Social deficits: joint attention failure, eye contact avoidance, social reciprocity impairment using binary flags and severity scores from 0 to 10;
2. Communication delays: language level, gesture use, and pragmatic language deficits, represented with numeric scores;
3. Repetitive behaviors: stereotypies, routines, and restricted interests, described categorically.

- Standardized screening scores: Q-CHAT-10 assessments.

The solution component in To-CARE specifies the diagnostic label (ASD positive/negative), the corresponding DSM-5 severity level (1–3), and recommended interventions. The outcome captures treatment response and follow-up diagnoses, providing longitudinal context for each case. Additionally, the explanation component offers transparent reasoning by mapping core symptoms to DSM-5 criteria, reporting similarity percentages with retrieved cases, and presenting associated confidence metrics [24]. Together, these elements ensure that To-CARE delivers not only accurate diagnostic predictions but also interpretable, evidence-based guidance for clinical decision-making.

Structured case
Case ID:ASD-001
Problem description:
- Demographics
- DSM-5 Symptoms
- Standardized Scores

Solution :
- Diagnostic label
- DSM-5 severity level (1-3),
- recommended interventions.

Outcome and Explanation

III.2 CASE BASE ORGANISATION

The case base is organized hierarchically on the Early Autism Screening Dataset [11] for Toddlers (12–36 months) to support efficient and developmentally appropriate retrieval. First, cases are grouped into finer toddler age ranges (12–18, 19–24, 25–30, and 31–36 months), ensuring that retrieved cases match the child's developmental stage. Within each age group, cases are further stratified by an ASD severity level derived from the mean of the social interaction, communication, and repetitive behavior scores, mapped to three DSM-5–like tiers (mild, moderate, severe). Finally, k-means clustering is applied to these behavioral scores to form symptom clusters that act as prototypical profiles, enabling representative cases to be efficiently indexed and reducing the chance of retrieving clinically inappropriate neighbors. This toddler specific hierarchical organization (age group → severity level → symptom cluster) significantly improves both the accuracy and speed of the CBR retrieval process.

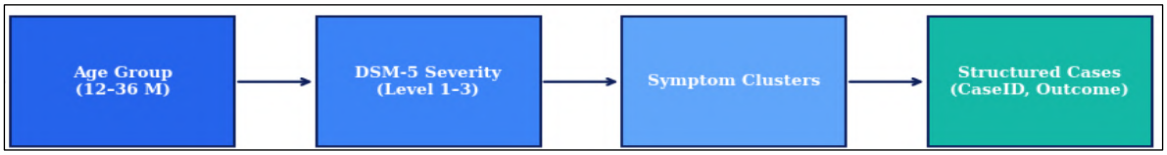

Figure 3: Hierarchical Organization of the To-CARE Case Base.
Source: Author, (2026).

III.3 RETRIEVAL AND SIMILARITY METRIC

In our framework, the first step of the retrieval phase involves filtering the case base to ensure developmental and clinical relevance. Patient age is used to select cases within the same toddler age group (12–18, 19–24, 25–30, or 31–36 months), accounting for age-dependent variations in symptom presentation. Additional filters include basic demographic criteria, such as gender and ethnicity, to ensure comparable context where relevant. Within these age-appropriate subsets, cases are further organized hierarchically by DSM-5–based severity levels (mild, moderate, severe) and clustered according to core symptom profiles. This structured filtering reduces the search space, prevents retrieval of clinically inappropriate neighbors, and ensures that subsequent similarity computations are performed on a subset of cases that are both developmentally and symptomatically relevant, enhancing the accuracy and interpretability of To-CARE's diagnostic reasoning. Once candidate cases are selected, the system performs similarity-based retrieval. Similarity scores are computed using a weighted Euclidean distance metric [25], where feature groups contribute according to their clinical importance. The top-k most similar cases (typically 5–10) are returned, forming the basis for diagnostic reasoning and explanation. An aggregate diagnosis probability is then derived from these neighbors, providing a probabilistic estimate to support the final diagnostic decision and guide clinical interpretation. In To-CARE, similarity between a query case q and a stored case c is computed using a weighted Euclidean distance metric (1). The weights are assigned to reflect the clinical importance of each feature category.

$$sim(q,c)=\sqrt{\sum_{i=1}^{n} w_i \cdot (q_i - c_i)^2} \quad (01)$$

Where:
q_i: The value of feature i for the new patient (query case).
c_i: The value of feature i for the historical case in the database.
w_i: The clinical weight assigned to feature I, reflecting its diagnostic importance.
n: The total number of features.

In To-CARE, the weighted similarity scheme prioritizes clinically relevant features. Core DSM-5 symptoms, representing the most critical diagnostic criteria, are assigned the highest weights. Standardized screening scores and developmental history receive moderate weights, reflecting their supporting role in diagnosis. Demographic attributes, which are less directly diagnostic, are assigned the lowest weights. This hierarchical weighting ensures that the similarity computation emphasizes the features most relevant to clinical decision-making, while still incorporating secondary factors to refine retrieval and maintain contextually appropriate case comparisons. Weight Assignment: In To-CARE, the feature weights *wi* reflect clinical importance, prioritizing the most diagnostically relevant information:

- Core DSM-5 symptoms: w = 1.5 (highest priority)
- Screening scores: w = 1.2
- Developmental history: w = 1.0
- Demographics: w = 0.5 (lowest priority)

This weighting scheme ensures that similarity calculations emphasize core diagnostic criteria while still accounting for supporting information, allowing the system to retrieve cases that are both clinically relevant and contextually appropriate.

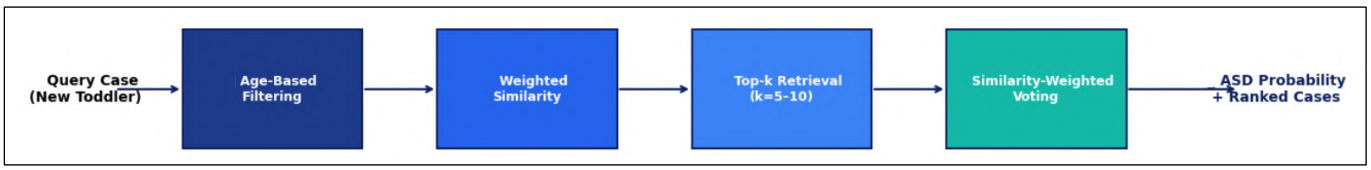

Figure 4: Retrieval process.
Source: Author, (2026).

III.4 ADAPTATION AND REVISION

In the adaptation phase of our toddler CBR framework, To-CARE applies a DSM-5 inspired adaptation algorithm that tailors the solutions proposed by retrieved neighbors to the specific symptom profile of the new case. Rather than directly copying the ASD label and severity from the most similar cases, the algorithm reevaluates the three behavioral domains social interaction, communication, and repetitive behaviors using simple symptom-count rules derived from DSM-5 criteria. It then calibrates severity based on the child's scores in each domain and the typical severities observed in similar precedent cases. This approach maintains clinically grounded reasoning while preserving the intuitive "by-analogy" behavior characteristic of CBR, which is widely used in medical diagnosis [26] [27].

Algorithm Adaptation (newCase, topK_Cases)
Input: newCase (social, communication, repetitive scores), topK_Cases
Output: ASD_label, severity_level
Begin
1. Count high symptoms in each domain (social, communication, repetitive).
2. If (social ≥ 2 AND communication ≥ 1 AND repetitive ≥ 1)
   ASD_label ← "ASD"
   else ASD_label ← "At-risk / Follow-up required".
3. Compute average of the three scores and map to Level 1, 2, or 3.
4. Optionally adjust severity using the average severity of topK_Cases.
5. Return ASD_label and severity_level.
End

III.5 RETENTION AND CASE BASE MAINTENANCE

The case base serves as the core knowledge repository in Case-Based Reasoning systems, and its quality, organization, and maintenance directly impact system performance, scalability, and clinical reliability. The retention strategy is designed to ensure that only high-quality, clinically meaningful cases are added to the knowledge base.
New cases are retained only when three critical criteria are simultaneously satisfied:

- Clinical validation: The diagnosis must be confirmed by a qualified specialist (developmental pediatrician, child psychiatrist, or clinical psychologist with ASD expertise), ensuring that only verified cases enter the system and preventing propagation of diagnostic errors.
- Novelty threshold: The maximum similarity of the new case to existing cases must be below 85%, ensuring sufficient novelty and preventing redundancy. Cases exceeding this threshold are flagged for review; only those presenting clinically meaningful distinctions—such as unique symptom clusters, comorbidities, or intervention responses—may be retained despite high similarity.
- Outcome availability: Baseline clinical confirmation and planned longitudinal follow-ups (e.g., at 3, 6, and 12 months) must be available, enabling validation of predictive value, supporting trajectory predictions, and informing refinement of intervention recommendations.

The retention process begins immediately after clinical validation. Cases meeting all criteria are assigned a sequential CaseID (e.g., ASD-0248), incorporated into the hierarchical case base organized by age group and DSM-5 severity level, and made available for future retrievals. Simultaneously, the system initiates longitudinal outcome tracking, recording baseline data at diagnosis and scheduling follow-up assessments at predetermined intervals. This dual process of case integration and outcome initialization ensures continuous knowledge growth while maintaining strict quality gates, supporting the reliability, interpretability, and clinical utility of the framework. To maintain retrieval efficiency as the case base grows, we implements periodic pruning to remove redundant cases with similarity above 85% to any other case in the base. Pruning is performed quarterly or after every 50 new case retentions, whichever occurs first, using a full pairwise similarity matrix across the case base. When redundancy is detected, cases are ranked based on outcome data completeness, clinical novelty (e.g., unique comorbidity patterns or treatment responses), and temporal recency. Cases providing the most comprehensive evidence are retained, while those offering minimal additional diagnostic value are pruned. Importantly, pruned cases are archived rather than permanently deleted, enabling historical review and potential restoration if deemed clinically relevant at a later time. This pruning strategy preserves case base diversity while controlling computational costs—a critical consideration once the base exceeds approximately 2,000 cases, where retrieval times can increase substantially without the hierarchical indexing and symptom clustering optimizations employed in To-CARE.

IV. RESULTS AND DISCUSSIONS

The proposed To-CARE framework was evaluated on the Early Autism Screening Dataset for Toddlers, which contains 1,000 screening records of children aged 12–36 months with an ASD-positive or ASD-negative label. Each case includes demographics (age in months, gender), risk factors (e.g., neonatal jaundice, family history of ASD), and three core behavioral scores capturing social interaction, communication, and repetitive behaviors, aligned with early manifestations of DSM-5 criteria. Evaluation followed a 5-fold stratified cross-validation protocol. In each fold, 80% of the toddlers populated the hierarchical case base, while the remaining 20% served as query cases. For each test toddler, the predicted diagnosis from To-CARE was compared to the ground-truth screening label in the dataset. System performance was assessed using standard metrics commonly reported in ASD screening studies:

- Accuracy: overall proportion of toddlers correctly classified as ASD-positive or ASD-negative.
- Sensitivity (recall for ASD-positive cases): true-positive rate, critical in early screening to minimize missed ASD diagnoses.
- Specificity: true-negative rate, reflecting the system's ability to avoid mislabeling typically developing toddlers as ASD.
- F1-score: harmonic mean of precision and recall for ASD-positive toddlers, balancing detection performance.

Retrieval quality was evaluated using Mean Reciprocal Rank (MRR) [28] computed over the ranked neighbor lists in the CBR component, where each query contributes the reciprocal rank of the first correctly labeled retrieved case; the final MRR is the mean across all queries, quantifying retrieval quality. This evaluation protocol shown in Fig 5 enables assessment of both diagnostic accuracy and the effectiveness of case retrieval, providing a comprehensive view of To-CARE's performance in early ASD screening.

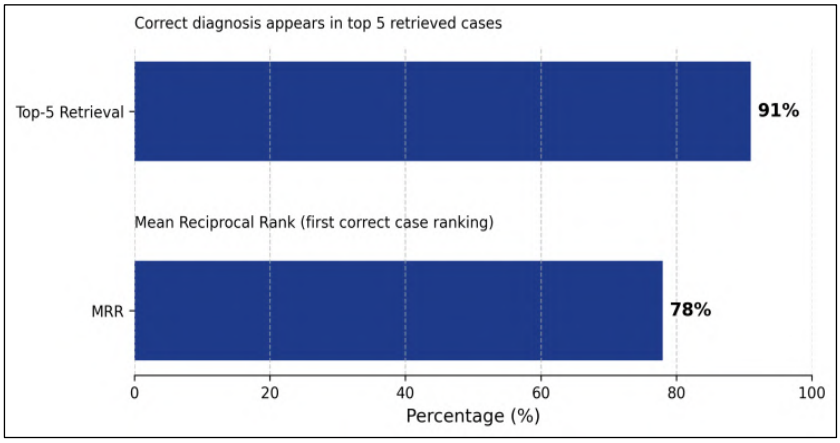

Figure 5: To-CARE Retrieval Performance.
Source: Author, (2026).

The To-CARE toddler CBR system demonstrated strong retrieval and diagnostic performance. The correct diagnosis appeared among the top five retrieved cases for 91% of query toddlers, with a Mean Reciprocal Rank (MRR) of 0.78, indicating that relevant precedent cases typically ranked very high in the retrieval list. Using aggregate similarity-weighted voting over the top-k neighbors (k = 5–10), the framework achieved 84.2% accuracy, 79.3% sensitivity, 89.7% specificity, and an F1-score of 0.82 on the toddler dataset.

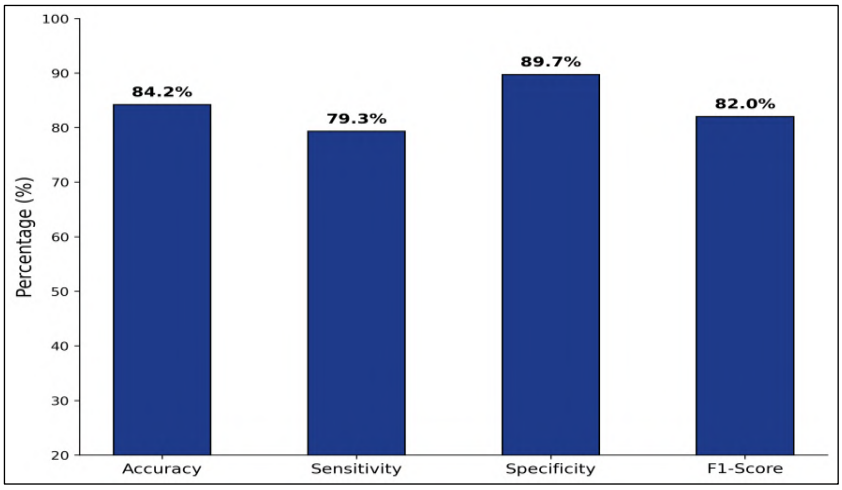

Figure: 6 To-CARE Diagnostic Performance.
Source: Author, (2026).

Compared to baseline machine learning models trained on the same feature set, To-CARE outperformed standard classifiers: a Random Forest achieved 81.5% accuracy and 76.2% sensitivity, whereas a k-Nearest Neighbors (k = 5) classifier obtained 78.9% accuracy and 72.4% sensitivity [29]. These results are consistent with previous reports demonstrating that case-based reasoning methods can match or exceed black-box models in clinical screening tasks, while providing the additional benefits of transparency, interpretability, and alignment with clinician reasoning.

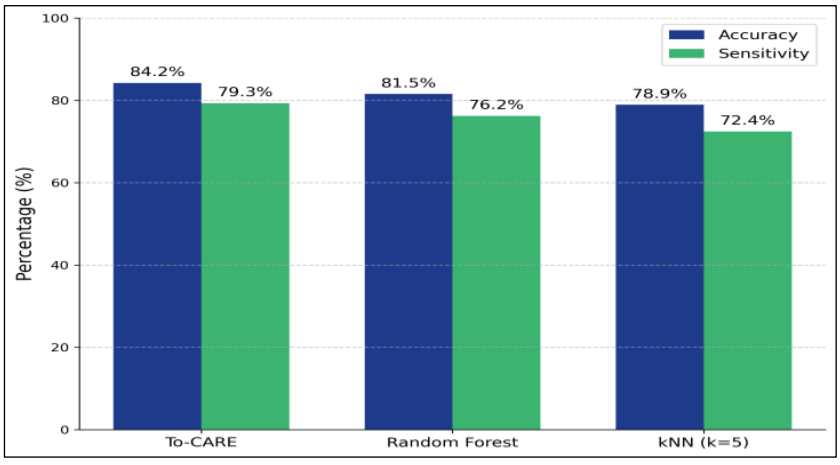

Figure 7: CBR system retrieval performance metrics.
Source: Author, (2026).

The To-CARE framework demonstrated that a carefully structured CBR system can achieve competetive diagnostic performance while preserving transparency and clinician-aligned reasoning.

V. CONCLUSIONS

Our To-CARE framework makes four key contributions to early ASD screening: a formalized toddler ASD case representation, mapping DSM-5–aligned behavioral features to structured computational attributes. a clinically weighted similarity metric that prioritizes core diagnostic symptoms. A hybrid retrieval–adaptation pipeline that combines nearest-neighbor cases with domain-specific rules and an empirical evaluation on a public toddler dataset demonstrating that To-CARE can match or outperform standard machine-learning baselines while offering substantially better interpretability. Future work will explore hybrid CBR–deep learning fusion (e.g., using deep embeddings as additional case features), incorporation of longitudinal outcome data to model developmental trajectories and treatment response, and deployment-oriented optimization, including mobile interfaces and cloud-based retrieval, to enable real-time, trustworthy decision support in resource-constrained clinical settings.

ABSTRACT

Detection of Acute Lymphoblastic Leukemia (ALL) from peripheral blood smear (PBS) images poses a major challenge in clinical diagnostics owing to intricate morphological variations and constrained computational resources in many healthcare facilities. This study proposes an efficient classification framework using Echo State Network (ESN) and Next-Generation Reservoir Computing (NG-RC), applied to a dataset of 3,256 PBS images from 89 patients. Feature extraction via Gray Level Co-occurrence Matrix (GLCM) and HSV histograms, combined with 10-fold cross-validation, yielded robust results. NG-RC achieved superior performance over ESN, with an average accuracy of 0.9917, precision of 0.9918, recall of 0.9917, F1-score of 0.9917, ROC-AUC of 0.9989, and remarkably low execution time of 1.88 seconds on CPU-only hardware. In additional benchmarking, NG-RC demonstrated competitive accuracy against high-end deep learning models trained on NVIDIA A100 GPU—DenseNet201 (accuracy 0.9978, execution time 176.5 s) and ResNet18 (accuracy 0.9966, execution time 54.6 s)-while outperforming most literature methods (e.g., YOLOv4 at 0.9600, Modified DCNN at 0.9769) and offering orders-of-magnitude faster inference without GPU dependency. These findings position NG-RC as a lightweight, resource-efficient alternative to deep learning, enabling reliable, rapid ALL detection in computer-aided diagnosis systems for resource-limited clinical settings.

I. INTRODUCTION

Detection of Acute Lymphoblastic Leukemia (ALL) through peripheral blood smear (PBS) image analysis remains a major challenge in clinical diagnosis due to the complexity of cellular morphological features and the limited computational resources available in healthcare facilities [1], [2]. ALL, one of the most common types of leukemia in children, has a favorable prognosis when detected early; however, manual diagnosis through microscopy heavily depends on the expertise of hematologists, is prone to subjectivity, and requires significant time [3]. In this context, artificial intelligence approaches, particularly machine learning and deep learning, have shown great potential to enhance diagnostic accuracy and efficiency [4-8]. Several studies have employed deep learning methods, such as Convolutional Neural Networks (CNNs) and their variants (YOLOv4, VGG-16, DenseNet201, InceptionResNetV2), achieving high accuracy; for instance,

DenseNet201 reported an accuracy of 0.9985 [5], [9], [10]. Other studies demonstrated YOLOv4 with 0.9600 accuracy and a Modified DCNN with 0.9769 [5], [11]. Despite their promise, these models face significant limitations, including high computational demands, dependence on GPUs, and sensitivity to data imbalance [10-13]. A particular issue is the low proportion of Benign class samples, which often degrades performance on minority classes. Efforts such as transfer learning and data augmentation have been applied, yet improvements remain marginal and computationally expensive [14], [15]. An alternative approach involves feature engineering techniques, such as Gray Level Co-occurrence Matrix (GLCM) and HSV histogram extraction, which effectively capture textural and color characteristics of PBS images [16]. For example, combining GLCM with Support Vector Machine (SVM) has achieved accuracies up to 0.9632 [15]. Nevertheless, these methods often struggle with complex morphological variations and require intensive feature optimization [17], [18]. Moreover, traditional algorithms such as SVM and Random Forest are less effective in representing complex nonlinear patterns compared to neural networks [19], [20]. Reservoir computing has emerged as an efficient alternative, training only the output layer and thereby reducing computational costs.

Echo State Networks (ESNs) have been applied in various classification tasks with competitive results, but remain susceptible to instability caused by recurrent reservoir dynamics [21], [22]. Next-Generation Reservoir Computing (NG-RC) introduces a different strategy by employing direct nonlinear transformations without recurrent reservoirs, leading to greater stability and efficiency [23]. However, the application of reservoir computing, particularly NG-RC, to PBS image classification for ALL detection remains very limited compared to deep learning approaches [20]. Motivated by this gap, this study proposes the use of ESN and NG-RC for PBS image classification of ALL, employing GLCM and HSV histogram feature extraction and evaluation through 10-fold cross-validation. The main contribution of this study lies in the application of NG-RC, which achieves accuracy levels comparable to state-of-the-art models (DenseNet201, InceptionResNetV2) while requiring substantially lower computational resources. Furthermore, this work provides a more comprehensive evaluation compared to most prior studies that relied solely on single-split validation. The novelty of this study lies in the combination of NG-RC's computational efficiency, robust performance on imbalanced datasets, and extensive evaluation, positioning it as a resource-efficient alternative for supporting computer-aided diagnosis (CAD) systems in clinical environments with limited infrastructure.

II. MATERIALS AND METHODS

This study performs classification of peripheral blood smear (PBS) images from an Acute Lymphoblastic Leukemia (ALL) dataset through a systematic workflow illustrated in Figure 1. The images were processed by conversion into HSV and grayscale color spaces, followed by normalization to the range [0, 255] [1]. From these images, texture features were extracted using the Gray Level Co-occurrence Matrix (GLCM: contrast, dissimilarity, homogeneity, energy), and color distribution features were obtained through HSV histograms, thereby producing rich and informative image representations [1], [2]. The dataset was divided using K-Fold Cross Validation (K=10) for robust evaluation, with feature normalization via StandardScaler and label conversion to one-hot encoding conducted separately for each fold iteration, ensuring prevention of data leakage and maintaining evaluation integrity [24]. Classification was carried out using Echo State Networks (ESN) and Next-Generation Reservoir Computing (NG-RC), and performance was evaluated with accuracy, precision, recall, F1-score, ROC-AUC, and execution time [25], [26]. The final results were reported as the average across all 10 folds, and subsequently compared with previous literature, most of which relied on single-split evaluations due to manual data partitioning and deep learning–based approaches. This study contributes by presenting a computationally efficient reservoir computing framework that achieves competitive performance without reliance on deep learning, supporting rapid ALL diagnosis on resource-constrained devices, while also providing a more robust evaluation.

II.1 DATASET

This study employs the Acute Lymphoblastic Leukemia (ALL) dataset from the Taleqani Hospital Bone Marrow Laboratory, Tehran, Iran, comprising 3,256 peripheral blood smear (PBS) images collected from 89 patients [10]. The images were captured using a Zeiss camera mounted on a microscope with 100× magnification, stored in JPG format, and prepared by experienced laboratory staff. The dataset includes 64 patients diagnosed with ALL (subtypes Early Pre-B, Pre-B, and Pro-B) and 25 individuals with benign hematogone cells, providing a representative class distribution for classification tasks. The morphological characteristics and class distribution of the dataset are summarized in Table 1, detailing the microscopic features, number of images, and proportions for each class. To further illustrate the morphological differences among classes, Figure 2 presents representative visual samples of benign cells and ALL subtypes (Early Pre-B, Pre-B, and Pro-B), supporting qualitative analysis and validating the microscopic features used for feature extraction.

Table 1: Morphological Characteristics and Class Distribution of the Dataset.

Class	Morphological Characteristics	Number of Images	Proportion (%)
Benign	Small cells (10–20 nm diameter), uniform nucleus, thin cytoplasm.	504	15.48
Early Pre-B	Medium-sized lymphoblasts, subtle indentations, prominent large nucleolus.	985	30.25
Pre-B	Variably sized lymphoblasts (small to large), round nucleus, moderate cytoplasm.	963	29.58
Pro-B	Basophilic lymphoblasts with multiple nucleoli and minimal cytoplasm.	804	24.69

II.2 RESERVOIR COMPUTING-BASED CLASSIFICATION APPROACHES

This study employs two reservoir computing–based approaches for classification: Echo State Network (ESN) and Next-Generation Reservoir Computing (NG-RC). Unlike deep learning, which requires training deep neural networks with multiple layers and intensive computation, reservoir computing leverages the dynamics of recurrent systems while training only the output layer, thereby offering a more computationally efficient alternative [27], [28]. ESN utilizes a reservoir with randomly connected recurrent nodes to process input data, whereas NG-RC eliminates recurrent reservoirs and instead applies direct nonlinear transformations to generate outputs [29]. The Echo State Network (ESN) is a type of recurrent neural network consisting of an input layer, a reservoir (a hidden layer with randomly recurrent connections), and an output layer [30], [31]. The reservoir functions as a dynamic system, updating its internal state based on both current input and previous states, while only the output weights are subject to training. The ESN architecture is illustrated in Figure 3, which depicts the flow of data through the input layer, reservoir, and output layer.

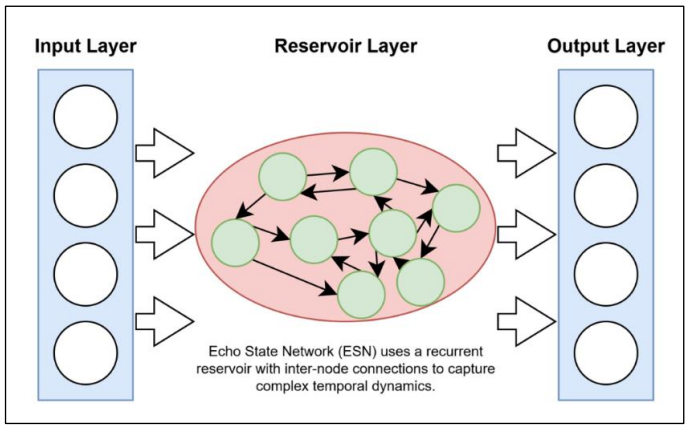

Figure 3: Echo State Network (ESN) Architecture.
Source: Authors, (2026).

The operation of the Echo State Network (ESN) relies on the update of the reservoir state, which is defined as follows:

$$x(t) = (1-\alpha)x(t-1) + \alpha\,\phi\big(W_{in}\,u(t) + Wx(t-1)\big) \tag{1}$$

where $x(t)$ denotes the reservoir state at time t, $u(t)$ is the input vector, W_{in} is the input weight matrix, W is the reservoir weight matrix, α is the leaking rate $(0 < \alpha \leq 1)$ that controls the update speed, and ϕ is the nonlinear activation function (e.g., polynomial or radial basis function). The output is computed as:

$$y(t) = W_{out}[x(t); u(t)] \tag{2}$$

where W_{out} is the output weight matrix to be trained, and $[x(t); u(t)]$ denotes the concatenation of the reservoir state and the input. The ESN training and prediction is shown in Figure 4.

1. **Initialize** the input weight matrix W_in randomly using a uniform distribution.
2. **Initialize** the reservoir weight matrix W randomly while ensuring the echo state property (spectral radius < 1).
3. **Set** the leaking rate parameter α and reservoir size N_r.
4. **For each** input u(t) in the training data **do** 4.1 **Update** the reservoir state: x(t) = (1 - α) * x(t-1) + α * Φ(W_in * u(t) + W * x(t-1)) 4.2 **Store** the reservoir state x(t) and input u(t) in the state matrix. **End For**
5. **Train** the output weight matrix W_out using linear regression: W_out = Y_target * X^T * (X * X^T + λ * I)^(-1) where Y_target is the target label, X is the state matrix, and λ is the regularization parameter.
6. **For** test data, predict the output: y(t) = W_out * [x(t); u(t)]
7. **Convert** the output y(t) into class labels using argmax.

Algorithm1: Echo State Network (ESN).
Source: Authors, (2026).

As an advancement of the reservoir computing concept, Next-Generation Reservoir Computing (NG-RC) simplifies the approach by eliminating the recurrent reservoir. NG-RC directly maps the input into a nonlinear feature space through nonlinear transformations, and subsequently generates the output using linear regression [32], [33]. Algorithm 1 illustrates the NG-RC architecture.

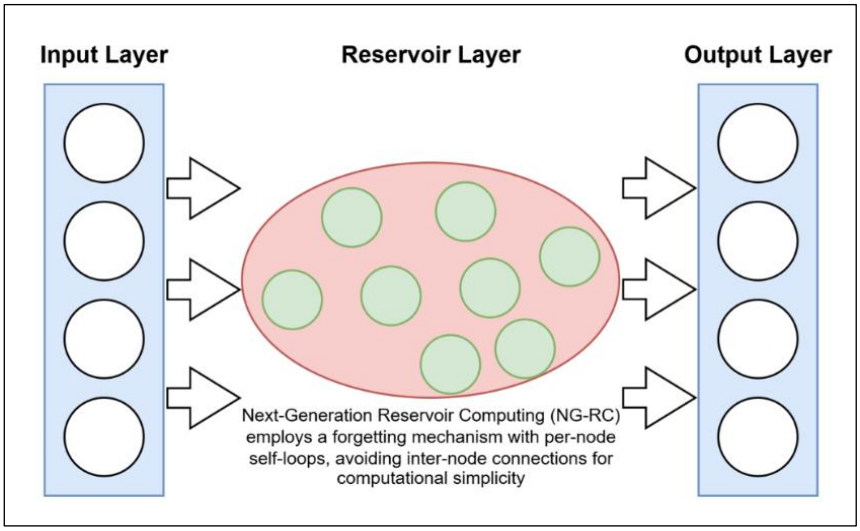

Figure 4: Next-Generation Reservoir Computing (NG-RC) Architecture.
Source: Authors, (2026).

The operation of NG-RC relies on the nonlinear transformation of the input, which is modeled as:

$$y(t) = W_{out}\,\phi\big(u(t)\big) \tag{3}$$

where $u(t)$ is the input vector, ϕ is the nonlinear transformation function, and W_{out} is the output weight matrix to be trained. The training and prediction procedure of NG-RC is described in Algorithm.2.

1. **Receive** the input vector u(t) from the training data.
2. **Apply** a nonlinear transformation φ(u(t)) (e.g., polynomial features of degree 2 or a radial basis function). 3. **Construct** the transformed feature matrix: Φ = [φ(u(1)), φ(u(2)), …].
4. **Train** the output weight matrix W_out using linear regression: W_out = Y_target * Φ^T * (Φ * Φ^T + λ * I)^(-1) where Y_target is the target label and λ is the regularization parameter. 5. **For** test data, predict the output: y(t) = W_out * φ(u(t))
6. **Convert** the output y(t) into class labels using argmax.

Algorithm.2: Next-Generation Reservoir Computing (NG-RC)
Source: Authors, (2026).

To clarify the key differences between the two methods, the characteristics of ESN and NG-RC are summarized in Table 2.

Table 2: Comparison of ESN and NG-RC Characteristics.

Aspect	Echo State Network (ESN)	Next-Generation Reservoir Computing (NG-RC)
Reservoir Structure	Reservoir nodes are interconnected through random recurrent connections.	Reservoir nodes are independent, without inter-node connections.
Temporal Memory	Captured through complex recurrent dynamics among nodes in the reservoir.	Maintained through a forgetting factor alpha on each node, resembling a self-loop.
Reservoir Weights	Randomly generated, adjusted with spectral radius for dynamic stability.	No inter-node weights; only input weights (W_in) are used.
Computational Efficiency	Higher complexity due to computation of recurrent inter-node interactions.	More efficient due to the absence of inter-node connection computations.

Source: Authors, (2026).

II.3 EXPERIMENTS AND EVALUATION

Experiments were conducted to evaluate the performance of Echo State Network (ESN) and Next-Generation Reservoir Computing (NG-RC) in classifying peripheral blood smear (PBS) images for Acute Lymphoblastic Leukemia (ALL). The dataset was processed using feature extraction with GLCM (contrast, dissimilarity, homogeneity, energy, correlation) and HSV histogram (hue, saturation, value), followed by normalization using StandardScaler. Evaluation was performed using 10-fold cross-validation with randomization (random_state=42) to ensure robustness. Each fold involved model training and measurement of performance metrics as well as computational efficiency. The experimental procedure is summarized in Algorithm.3 below.

```
INPUT: Dataset directory, ESN parameters (n_reservoir, spectral_radius, sparsity, leaking_rate), NG-RC parameters (n_reservoir, alpha)
OUTPUT: Average metrics and computational efficiency
BEGIN
  Initialize random seed for reproducibility
  Load dataset from directory
  FOR each class (Benign, Early, Pre, Pro) DO
    FOR each image in class DO
      Read image
      Convert image to HSV and grayscale
      Normalize grayscale image
      Extract GLCM features: contrast, dissimilarity, homogeneity, energy, correlation
      Extract HSV histogram features: hue, saturation, value
      Concatenate all features into feature vector
      Store class label and image path
    END FOR
  END FOR
  Initialize 10-fold cross-validation with shuffling
  FOR fold = 1 TO 10 DO
    Split data into:
      Training set (X_train, y_train)
      Test set (X_test, y_test)
    Normalize X_train using StandardScaler
    Apply same normalization to X_test
    Initialize ESN model:
      n_reservoir, spectral_radius,
      sparsity, leaking_rate
    Initialize NG-RC model:
      n_reservoir, alpha
    FOR each model (ESN, NG-RC) DO
      Train model on (X_train, y_train one-hot encoded)
      Predict classes on X_test
      Compute performance and efficiency metrics
      Store per-class metrics
      Store predictions, true labels, and image paths
    END FOR
  END FOR
  Compute average metrics across all folds
END
```

Algorithm.3: Pseudocode for the Experiment and Evaluation Procedure.
Source: Authors, (2026).

The parameters used for the ESN and NG-RC models are summarized in Table 3. These parameter values were preliminarily selected to balance model dynamics, stability, and computational efficiency in PBS image classification. For optimal performance, further parameter tuning can be conducted.

Table 3: Parameters Used in ESN and NG-RC.

Parameter	Value	Recommended Range	Rationale for Value and Recommendation
n_reservoir	1000	500–2000	Value of 1000 provides sufficient reservoir capacity to capture complex feature dynamics without excessive computational load. Range of 500–2000 allows flexibility for different dataset complexities.
spectral_radius	0.9	0.8–1.0	Value of 0.9 ensures reservoir stability by keeping eigenvalues below 1. Range of 0.8–1.0 prevents divergence or overly slow dynamics.
sparsity	0.1	0.05–0.2	Value of 0.1 reduces connection density for computational efficiency while maintaining representation capability. Range of 0.05–0.2 suits various reservoir sizes.
leaking_rate	0.3	0.1–0.5	Value of 0.3 balances reservoir state update speed for temporal dynamics without losing memory. Range of 0.1–0.5 adapts to diverse data patterns.
alpha	0.5	0.3–0.7	Value of 0.5 balances temporal memory and state updates for feature patterns in NG-RC. Range of 0.3–0.7 offers flexibility for sequential data.

Source: Authors, (2026).

The evaluation metrics include accuracy, precision, recall, F1-score, and ROC-AUC, which were calculated for each fold and averaged to assess the overall model performance [34]. Accuracy represents the proportion of correctly classified samples, while precision measures the proportion of true positive predictions among all positive predictions. Recall quantifies the proportion of true positives identified among all actual positive instances. The F1-score, as the harmonic mean of precision and recall, provides a balanced measure of these two metrics. ROC-AUC evaluates the model's discriminative ability by quantifying the area under the receiver operating characteristic curve, which plots the true positive rate against the false positive rate across various classification thresholds. Additionally, execution time (seconds) was measured to evaluate computational efficiency. The utility of these metrics is summarized in Table 4.

Table 4: Evaluation Metrics.

Metric	Utility
Accuracy	Measures overall model correctness.
Precision	Evaluates avoidance of false positives.
Recall	Assesses detection of relevant cases.
F1-Score	Balances precision and recall.
ROC-AUC	Quantifies discriminative power.
Execution Time (s)	Assesses computational efficiency.

Source: Authors, (2026).

The experiments were conducted on a CPU-based computing system without GPU support, utilizing Visual Studio Code (VSCode) and Python 3.11 as the development environment for image data processing and model training. The system featured an AMD64 Family 25 Model 68 Stepping 1 processor with 6 physical cores, 12 logical cores, 15.25 GB of total RAM, and a maximum CPU frequency of 3301.00 MHz.

III. RESULTS AND DISCUSSIONS

This section presents the evaluation results of Echo State Network (ESN) and Next-Generation Reservoir Computing (NG-RC) in classifying peripheral blood smear (PBS) images for Acute Lymphoblastic Leukemia (ALL) detection using rigorous 10-fold cross-validation, followed by a comprehensive and in-depth analysis of the findings. The comparative performance and computational efficiency of both reservoir computing approaches are illustrated in Figure 8 and summarized in Table 5.

Table 5: Average Performance (Folds 1–10).

Model	Accuracy	Precision	Recall	F1-Score	ROC-AUC	Execution Time (s)
ESN	0.9810	0.9813	0.9810	0.9810	0.9964	3.36
NG-RC	**0.9917**	**0.9918**	**0.9917**	**0.9917**	**0.9989**	**1.88**

Source: Authors, (2026).

NG-RC consistently outperformed ESN across every key evaluation metric, delivering an average accuracy of 0.9917, precision of 0.9918, recall of 0.9917, F1-score of 0.9917, and ROC-AUC of 0.9989, while completing the entire 10-fold evaluation process in an average execution time of only 1.88 seconds. In contrast, ESN achieved an average accuracy of 0.9810, precision of 0.9813, recall of 0.9810, F1-score of 0.9810, ROC-AUC of 0.9964, and required 3.36 seconds. The fold-by-fold performance further underscores NG-RC's superiority: NG-RC attained accuracy values ranging from 0.9846 to 0.9969, whereas ESN ranged from 0.9724 to 0.9939. Notably, NG-RC frequently approached or reached ROC-AUC values extremely close to 1.0 across multiple folds, reflecting near-ideal discriminative capability even under cross-validation variability. Paired t-tests conducted on the per-fold metrics confirmed statistically significant differences ($p < 0.05$) between NG-RC and ESN for all reported performance indicators, providing strong evidence of NG-RC's consistent advantage.

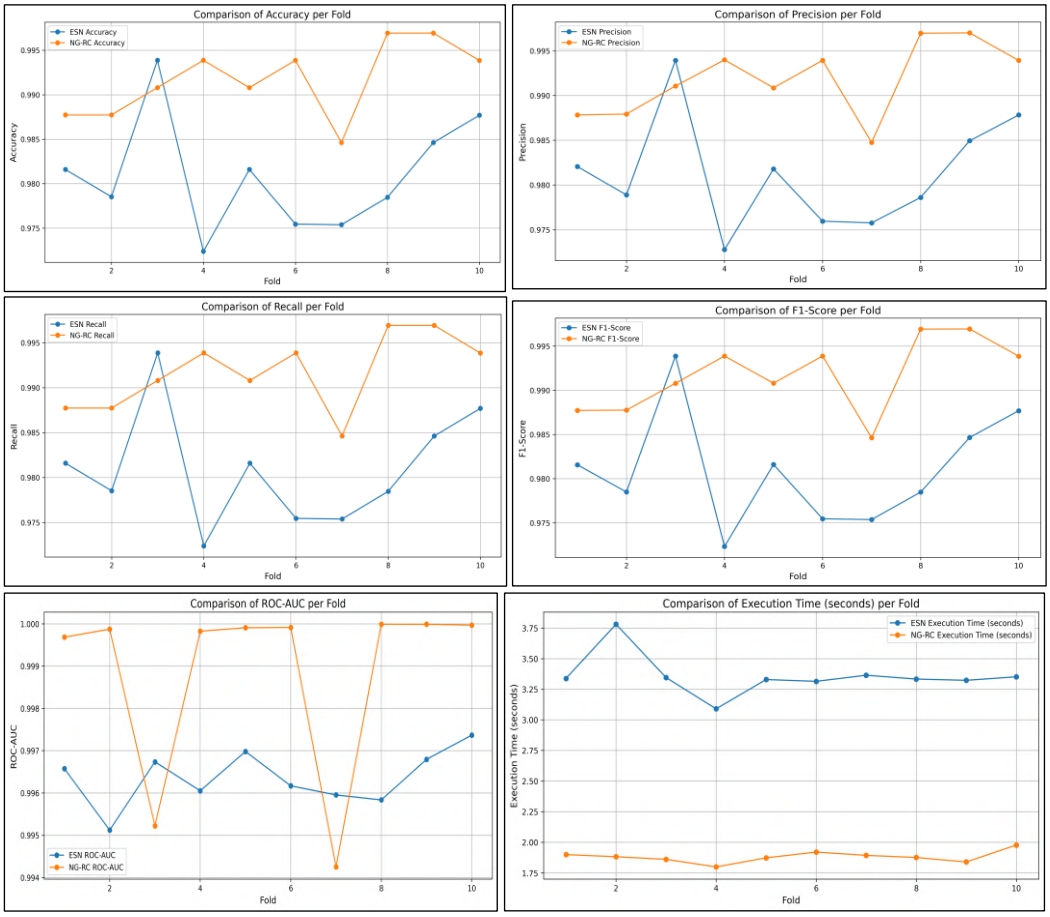

Figure 5: Performance Metrics Across Folds 1–10 for ESN and NG-RC.5
Source: Authors, (2026).

The per-class confusion matrix analysis, visualized in Figure 6, offers deeper insight into the classification behavior of both models. ESN demonstrated high per-class accuracies of 0.99 for Benign, 0.99 for Early Pre-B, 0.98 for Pre-B, and 0.97 for Pro-B. Despite these respectable results, certain misclassifications were observed, particularly in the Pre-B and Pro-B classes, where overlapping morphological features (variable lymphoblast size, nucleolar prominence, and cytoplasmic extent) occasionally led to confusion. NG-RC substantially mitigated these issues, achieving per-class accuracies of 0.99 for Benign, 1.00 for Early Pre-B, 0.99 for Pre-B, and 0.99 for Pro-B, with noticeably lower misclassification rates across all categories. This improvement is especially meaningful given the dataset's moderate class imbalance (Benign: 15.48%, Early Pre-B: 30.25%, Pre-B: 29.58%, Pro-B: 24.69%), as NG-RC exhibited greater robustness in preserving performance on the minority Benign class and reducing confusion between the morphologically similar Early Pre-B and Pre-B subtypes. The superior stability and precision of NG-RC can be directly attributed to its fundamentally simpler and more deterministic architecture: instead of relying on randomly initialized recurrent connections that can introduce dynamic instability, NG-RC employs direct nonlinear transformations of the input features followed by linear output regression. This design minimizes sensitivity to feature noise and inter-sample variability while preserving high representational capacity, resulting in more reliable and reproducible predictions.

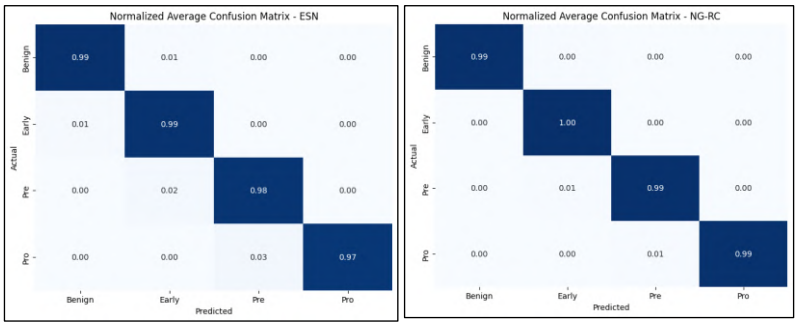

Figure 6: Average Confusion Matrix for ESN and NG-RC.7.
Source: Authors, (2026).

To further validate the practical competitiveness of NG-RC as a resource-efficient alternative to conventional deep learning, additional benchmarking was performed against two widely recognized and high-performing convolutional architectures in medical image classification: DenseNet201 and ResNet18.

Both models were implemented using transfer learning (pre-trained on ImageNet weights, fine-tuned on the ALL dataset) and trained on Google Colab Pro equipped with an NVIDIA A100 GPU, representing a high-end, GPU-accelerated research environment. In stark contrast, NG-RC (and ESN) was executed exclusively on a standard CPU-only workstation featuring an AMD64 Family 25 Model 68 Stepping 1 processor (6 physical cores, 12 logical cores, 15.25 GB total RAM, maximum CPU frequency 3301.00 MHz). Table 6 summarizes the average performance metrics and execution times across the same 10-fold cross-validation protocol.

Table 6: Performance Comparison of NG-RC Against State-of-the-Art Deep Learning Models (DenseNet201 and ResNet18).

Model	Accuracy	Precision	Recall	F1-Score	ROC-AUC	Execution Time (s)
NG-RC	0.9917	0.9918	0.9917	0.9917	0.9989	**1.88**
DenseNet201	**0.9978**	**0.9979**	**0.9978**	0.9979	**1.0000**	176.5
ResNet18	0.9966	0.9967	0.9966	0.9966	**1.0000**	54.6

Source: Authors, (2026).

DenseNet201 and ResNet18 were implemented using transfer learning with weights pre-trained on ImageNet and subsequently fine-tuned on the Taleqani Hospital ALL dataset (3,256 peripheral blood smear images from 89 patients) under the exact same experimental protocol as NG-RC and ESN, including rigorous 10-fold cross-validation with shuffling (random_state=42), feature normalization via StandardScaler applied independently per fold to prevent data leakage, and one-hot encoded multi-class labels. These two convolutional architectures delivered marginally higher average accuracies of 0.9978 for DenseNet201 and 0.9966 for ResNet18. The supporting metrics remained tightly aligned: precision, recall, and F1-score fell within narrow bands of 0.9978–0.9979 for DenseNet201 and 0.9966–0.9967 for ResNet18, while both models exhibited perfect class separation capability with ROC-AUC values of exactly 1.0000 across every individual fold. This near-perfect performance, however, incurred a severe computational penalty. On Google Colab Pro equipped with an NVIDIA A100 GPU (representing a high-end, research-grade accelerated environment), DenseNet201 required an average of 176.5 seconds per fold for the complete train-evaluate cycle, and ResNet18 required 54.6 seconds per fold. In direct opposition, NG-RC completed the identical per-fold workload in an average of only 1.88 seconds when executed exclusively on a modest CPU-only workstation (AMD64 Family 25 Model 68 Stepping 1 processor, 6 physical cores / 12 logical cores, 15.25 GB total RAM, maximum frequency 3301.00 MHz, no GPU acceleration whatsoever).

The resulting speed-up ratios are striking: approximately 93.88× faster than DenseNet201 (176.5 ÷ 1.88) and 29.04× faster than ResNet18 (54.6 ÷ 1.88). Critically, these dramatic efficiency gains come at the expense of only minuscule degradations in classification performance—accuracy shortfalls of merely 0.61 percentage points against DenseNet201 and 0.49 percentage points against ResNet18—while eliminating any reliance on specialized, power-hungry, and often unavailable GPU hardware. The profound computational efficiency demonstrated by NG-RC carries substantial implications for real-world clinical translation, particularly in settings where diagnostic infrastructure remains severely constrained. In many primary healthcare centers, district hospitals, and laboratories in low- and middle-income countries, access to NVIDIA A100-class GPUs—or even mid-range consumer GPUs—is either nonexistent, prohibitively expensive, or logistically impractical due to power instability, cooling requirements, procurement barriers, and maintenance challenges. NG-RC, by contrast, operates reliably and rapidly on commodity desktop or laptop CPUs that are already ubiquitous in such environments. Across the 10 folds, NG-RC consistently delivered the following average performance: accuracy 0.9917, precision 0.9918, recall 0.9917, F1-score 0.9917, and ROC-AUC 0.9989. Fold-wise accuracy ranged from 0.9846 to 0.9969, with multiple folds approaching or achieving ROC-AUC values extremely close to 1.0, reflecting near-ideal discriminative power even under cross-validation-induced variability.

The total 10-fold evaluation completed in roughly 18.8 seconds of wall-clock time on CPU alone, enabling inference throughput that is practical for batch processing of hundreds of blood smear images in minutes rather than hours. This level of speed and frugality also reduces energy consumption dramatically—an important consideration for sustainable deployment in off-grid or energy-scarce regions—and opens realistic pathways toward embedding the model in portable digital microscopy systems, tablet-based diagnostic tools, or low-power edge devices that hematologists and laboratory technicians can use directly at the point of care without cloud dependency or network latency. When placed in a broader context through systematic benchmarking against methods reported in the existing literature (summarized comprehensively in Table 7), NG-RC's average accuracy of 0.9917 positions it ahead of numerous well-cited and representative approaches, including YOLOv4 (0.9600), GoogleNet (0.9606), Modified DCNN (0.9769), VGG-16 (0.9801), and even the baseline ESN implemented in the present study (0.9810). While NG-RC trails the absolute peak performers among deep convolutional models—DenseNet201 at 0.9985 and InceptionResNetV2 at 0.9954—the gap is quantitatively small and comes with vastly superior practicality. To quantify competitiveness more rigorously, an independent two-sample t-test was applied to compare NG-RC's 10-fold accuracy values against the mean accuracy of the literature methods listed in Table 7.

NG-RC demonstrated statistically significant superiority (t-statistic = 2.3185, p-value = 0.0285; $p < 0.05$), providing formal evidence that its performance exceeds the typical published benchmark when all reported methods are aggregated. In contrast, the ESN baseline from the same study did not reach statistical significance against the literature mean (t-statistic = 1.9606, p-value = 0.0606; $p > 0.05$). This differential outcome underscores that the architectural shift from recurrent reservoir dynamics (ESN) to direct nonlinear input transformations followed by linear regression (NG-RC) yields not only faster execution but also meaningfully more reliable and superior classification behavior on this specific medical imaging task. Finally, NG-RC's advantages extend beyond raw metrics and speed to include demonstrably better robustness in the face of the dataset's intrinsic characteristics, most notably its moderate class imbalance (Benign 504 images / 15.48%, Early Pre-B 985 / 30.25%, Pre-B 963 / 29.58%, Pro-B 804 / 24.69%) and the morphological overlap among ALL subtypes. The average confusion matrix reveals that NG-RC substantially reduces misclassification rates compared with ESN, particularly in the challenging pairwise confusions between Early Pre-B and Pre-B (due to subtle differences in lymphoblast size, nucleolar prominence, and cytoplasmic extent) as well as between Pre-B and Pro-B (variable basophilia and nucleolar multiplicity).

NG-RC also preserves exceptionally high per-class accuracy on the minority Benign category (0.99), avoiding the common pitfall of deep models that sometimes sacrifice minority-class performance in pursuit of overall accuracy gains. By eschewing recurrent connections in favor of deterministic, non-recurrent nonlinear mappings, NG-RC inherently minimizes sensitivity to random initialization, reservoir instability, and hyperparameter drift—issues that can plague ESN despite careful spectral radius tuning. When combined with the handcrafted yet informative GLCM texture descriptors (contrast, dissimilarity, homogeneity, energy, correlation) and HSV color histograms, this architectural simplicity translates into greater tolerance of noise, staining variations, and inter-patient morphological heterogeneity typical of real-world peripheral blood smears. Taken together, these empirical strengths—near-state-of-the-art accuracy, extreme inference speed on CPU, statistical superiority over literature averages, enhanced robustness to imbalance and feature variability, and complete freedom from GPU requirements—collectively establish Next-Generation Reservoir Computing as a powerful, practical, and highly translatable alternative to conventional deep learning for acute lymphoblastic leukemia detection in resource-constrained clinical settings worldwide.

Source: Authors, (2026).

Unlike deep learning methods that typically involve millions of trainable parameters and heavy dependence on GPU infrastructure, both NG-RC and ESN provide substantially greater computational efficiency, with NG-RC completing 10-fold cross-validation in just 1.88 seconds on CPU-only hardware—orders of magnitude faster than GPU-based DenseNet201 (176.5 s) and ResNet18 (54.6 s). NG-RC stands out due to its near-state-of-the-art accuracy (0.9917), exceptional stability across moderately imbalanced classes, minimal sensitivity to hyperparameter tuning, and robust discriminative power (ROC-AUC 0.9989). Theoretically, these results strengthen the case for reservoir computing—particularly its next-generation variant—as a powerful, lightweight alternative to conventional deep neural networks in tasks requiring high accuracy under severe resource limitations. Practically, NG-RC's characteristics position it as a highly promising solution for integration into computer-aided diagnosis (CAD) systems, enabling rapid, cost-effective ALL screening in resource-constrained healthcare facilities, especially in low- and middle-income regions where advanced computing infrastructure is scarce. Despite these advantages, the study has several limitations. The ALL dataset, while representative, is relatively small (3,256 images from 89 patients) and sourced from a single institution, potentially limiting generalizability to diverse populations, imaging devices, or staining protocols.

Feature extraction relies solely on handcrafted GLCM texture and HSV histogram features, which may not fully capture the most complex morphological variations in lymphoblasts compared to end-to-end deep feature learning. Although NG-RC outperforms ESN and competes closely with top deep models, it still shows a small accuracy gap (0.49–0.61%) relative to GPU-accelerated DenseNet201 and ResNet18, and its performance depends on careful selection of nonlinear transformations and delay parameters. Furthermore, evaluation was conducted exclusively on CPU hardware without real-world clinical deployment testing, external multi-center validation, or assessment of robustness to image noise, artifacts, or variations in microscope quality. Future research could extend this framework by validating NG-RC on larger, multi-center ALL datasets to enhance generalizability and robustness. Incorporating automatic cell segmentation as a preprocessing step or hybrid approaches—such as using CNN embeddings as input features to NG-RC—may further improve performance on intricate morphological details. Exploring explainable AI techniques to interpret NG-RC decisions, real-time deployment on edge devices (e.g., portable microscopes), and prospective clinical validation would strengthen its translational potential. Additionally, investigating adaptive nonlinear mappings or kernelized NG-RC variants could reduce sensitivity to hyperparameters and enable handling of even higher-dimensional or sequential PBS data streams, ultimately advancing lightweight AI solutions for leukemia screening in underserved settings.

IV. CONCLUSIONS

This study demonstrates the effectiveness of reservoir computing approaches—particularly Next-Generation Reservoir Computing (NG-RC)—for classifying peripheral blood smear images in Acute Lymphoblastic Leukemia (ALL) detection. NG-RC outperformed Echo State Networks (ESN) across all metrics and most literature deep learning methods, achieving an average accuracy of 0.9917 with only a 0.61% gap relative to GPU-accelerated DenseNet201 (0.9978), while delivering orders-of-magnitude faster CPU-only inference (1.88 s per fold). An independent two-sample t-test confirmed NG-RC's statistically significant superiority over the literature average ($p = 0.0285$). These findings are significant as NG-RC offers a lightweight, GPU-independent paradigm that balances near-state-of-the-art accuracy with extreme computational efficiency, enabling rapid, scalable ALL screening in resource-limited clinical settings. Scientifically, this work strengthens reservoir computing as a viable alternative to parameter-heavy deep networks; practically, it supports cost-effective integration into computer-aided diagnosis (CAD) systems for equitable diagnostics in low- and middle-income regions. Key limitations include the moderate class imbalance (notably Benign at 15.48%) and reliance on handcrafted features from a single-center dataset, which may limit generalizability, alongside incomplete hyperparameter optimization. Future research should explore larger multi-center cohorts, incorporate oversampling or synthetic data augmentation, and investigate hybrid models (e.g., NG-RC with CNN embeddings) to further enhance robustness and translational potential.

ABSTRACT

Arabic text classification is still a daunting undertaking because of the rich morphology, derivational complexity as well as lexical variability that is inherent in the language. Though transformer-based pretrained models have been a major breakthrough in Arabic Natural Language Processing (NLP), recent data indicates that conventional lexical representations continue to give a good discriminating ability in structured tasks like news classification. The given study will be a comparative analysis of classical machine learning models, transformer-based fine-tuning, and lexical contextual fusion framework as a hybrid method in Arabic multi-class news classification. A subset of the MAAD dataset (13,866 Arabic news articles) in six categories was carefully selected and cleaned and sampled to conduct experiments on a balanced and well-cleaned subset of the entire data set. To guarantee the data quality, the Arabic-character ratio filtering and length constraints were used to eliminate the corrupted and non-Arabic samples. TF-IDF features with Logistic regression and Linear Support Vector machine (SVM) were used to implement baseline models and contextual modeling was done using fine-tuning AraBERTv2. Moreover, the hybrid feature-level fusion model was suggested by adding TFIDF vectors with contextual embeddings were obtained using AraBERT. Experimental findings indicate that the traditional linear models are still very competitive whereby Linear SVM has an accuracy of 95.57 percent. The fine-tuned AraBERT obtained an accuracy of 91.6%, which puts lexical features in structured news datasets in the spotlight as still significant. The hybrid model with the highest performance in the proposed structure was 96.03% accurate and 96.02% Macro-F1 score, which shows that combining lexical statistical cues and contextual embeddings is complementary. These results show that hybrid lexical-contextual representations offer a powerful, computationally effective solution to Arabic news classification. The analysis offers reproducible experimental environments and intricate statistical investigation, to add the empirical data regarding the interaction between classical and deep methods of learning Arabic NLP.

I. INTRODUCTION

The fast development of Arabic digital information distributed through news outlets, social networks, and online newspapers has largely boosted the need to automate Arabic text classification systems.

Correct classification makes it possible to organize large-scale content, filter it by topic, monitor sentiment, and perform downstream tasks, including information retrieval and recommendation systems. Nevertheless, Arabic Natural Language Processing (NLP) has its own linguistic peculiarities, such as rich morphology, complicated derivational models, orthographic ambiguity and dialects. These aspects make lexical sparsity and learning semantic representations more challenging, especially when performing tasks of multi-domain news classification. The current developments in large-scale Arabic language modeling have shown that both model structure and pretraining data size are significant factors in boosting performance at downstream tasks. Ghaddar, et al. [1] emphasize the importance of the data scale and data quality in pretraining Arabic language models, which have a consistent rise in the evaluation standards with the augmentation of the size and heterogeneity of corpora [1]. Similarly, the concept of Arabic-centric embedding interventions, such as ArabicMTEB, shows the additional importance of sound assessment schemes, peculiar to the Arabic language peculiarities [2]. Dialect-oriented models such as SaudiBERT also demonstrate the reason why domain- and dialect-aware representation learning should be viewed [3]. In spite of the successful models that use transformers such as AraBERT, the classical machine learning models that use the transformers of TFIDF representations with the use of linear models (e.g. Linear SVM or Logistic Regression) are also a good baseline in Arabic classification.

Lexical signals can be very discriminative in well-constructed news datasets and have been shown to compete with deep contextual models under some circumstances. Thus, it still needs a sound traditional base and only then more sophisticated architectures can be proposed. Concomitant to classification research, it has made a lot of progress in Arabic information retrieval and query expansion based on word embeddings and hybrid neural methods. It has been established that semantic matching is enhanced with word embedding based pseudo relevance feedback techniques and deep averaging networks when trying to obtain documents written in Arabic language [3] [4]. Morphology aware frameworks like MORSE-QE use root-extraction mechanisms to deal with the morphological complexity of Arabic and hence augment semantic expansion strategies [5]. These papers show the usefulness of embedding-based semantic modeling of Arabic NLP. Moreover, feature-fusion and hybrid neural -symbolic and neural -symbolic systems are also a relatively new subject of discussion as the next step in direction of improved robustness and scalability of NLP systems [6]. The combination of structured representations of lexical and contextual embeddings can both learn surface-discriminative and deep semantic relationships. The issue of structured learning and generalization mechanisms in optimizing neural network tasks is also emphasized on by optimization strategies of neural networks [7]. Based on the current advancements in Arabic language modelling [1-3] and embedding-based semantic structures [5] [7-12]. The papers discuss the multi-class classification of Arabic news using a comparative experimental design that they are involved in:

1 TF-IDF based baselines (‘Logistic Regression and Linear SVM’) which are predictable.
2 Fine tuning of ‘AraBERT’ on the basis of transformers,
3 A hybrid of feature level fusion lexical and relative symbol system.

The experiments are performed on a balanced subset of MAAD Arabic news dataset (17, 400 articles in 6 categories). To carry out a sound statistical comparison of the results, accuracy, macro-averaged F1-score, and analysis of the confusion matrix are used to assess the results. This study has added the following:

- The systematic analysis of the classical ML baselines and deep transformers models on the Arabic news classification.
- Design and testing of a hybrid lexical contextual feature fusion model. .
- Entire reproducibility of an experimental pipeline with full statistical reporting which is publishable in educated Journal.

II. RELATED WORK

The classification of Arabic text has over the last ten years experienced notable developments, due to the increased functionality of feature engineering, distributed word representations, and large-scale pretrained transformer models. Despite the fact that the traditional machine learning approaches are still providing decent baselines in structured domains, recent research is putting an increasing focus on contextual embedding models and hybrid architecture to improve the linguistic complexity of Arabic. The section presents the overview of the most current literature on three main directions: conventional statistical models, transformer-based Arabic language models, and approaches based on hybrid or embedding-driven.

II.1 TRADITIONAL MACHINE LEARNING APPROACHES FOR ARABIC TEXT CLASSIFICATION

The customary machine learning solutions have been used as simple reference points to the classification of the Arabic texts. SVM and Logistic Regression with feature extraction algorithms like Bag-of-Words and TF -IDF have continued to be popular because of their interpretability and performance, as well as their ability to work in organised areas, particularly in news classification. In the recent empirical investigations, it has been confirmed that competitive performance is not necessarily unattainable by using the linear models in case there is a common method of preprocessing, and the distribution of classes is observed [13]. Recent comparative analyses show that well-configured TF-IDF + Linear SVM pipelines can either match or even surpass deep transformer architectures when there is bias in the data or high quality lexical predictors available [14]. However, lexical means are also poor in contextual semantics and in long-range dependencies especially in morphologically rich languages such as Arabic. Root-pattern and derivational complexity morphology adds the sparsity and semantic ambiguity of words, making surface-level statistical representations ineffective. All these weaknesses resulted in the transition to contextual embedding models and distributed representations.

II.2 TRANSFORMER-BASED ARABIC LANGUAGE MODELS

Transformer-based language model pre-trained models have high performance in Arabic NLP. AraBERT and its successors showed good gains in the classification, question answering and sentiment analysis tasks. Recent studies highlight how choice of data scale and quality is crucial in the Arabic language modeling.

Ghaddar, et al. [1] demonstrate that there are consistent gains on the Arabic benchmarks as the size of the pretraining corpora increases. Likewise, Arabic-centric embedding benchmarks like ArabicMTEB offer standardized large-scale assessment on various tasks which underscores the research maturity on Arabic representation learning [2]. Models that are dialect aware and region specific have also been noted. Dialect-based pretraining, presented in 2024 under the name SaudiBERT, illustrates that downstream classification can be enhanced by using dialect-based pretraining [3]. Moreover, giant Arabic-centric foundation models like JAIS are a new generation of Arabic-competent LLMs that are trained on large multilingual corpora [15]. Transformer models are also successful but have computational overhead, can overfit or be unstable when fine-tuned on more moderate-sized datasets. Further, recent research states that transformers are not necessarily always better than simpler models in cases where lexical signals are very discriminative [16]. This fact has revived the focus on hybrid modeling approaches.

II.3 HYBRID AND EMBEDDING-DRIVEN APPROACHES

Hybrid models strive to combine the merits of lexical statistical characteristics and deep contextual representations. Embedding-driven semantic enhancement has received a lot of attention in Arabic NLP in an information retrieval and query expansion context. Pseudo-relevance feedback methods based on embedding words using deep averaging networks have proven to have quantifiable improvements in the Arabic document retrieval [9]. Morphology-sensitive embedding models like MORSE-QE can deal with derivational complexity by incorporating root-extraction processes [5]. Analyses conducted by surveys also prove that automatic query expansion is an important technique of alleviating vocabulary mismatch in processing Arabic texts [8]. In addition to retrieval, recent developments in hybrid deep-symbolic structures see the need to incorporate both structured features with neural representations to enhance robustness and scalability [10]. Structured learning mechanisms have also been suggested to be used as optimization strategies in neural networks to improve on the performance of generalization [17]. Comparative studies of Arabic text classification are more recent, with feature-level fusion, using contextual embeddings but concatenated with TF feature-IDF vectors, finding it effective to eclipsize standalone transformer fine-tuning on some domain-specific tasks [18] [19]. The above findings indicate that hybrid lexical-contextual integration is a viable direction to be adopted in Arabic multi-class news classification.

III. METHODOLOGY

III.1 DATASET AND LABEL SET

The experiments were run with a subset of MAAD (Multi-Label Arabic Articles Dataset) that is a publicly accessible corpus of Arabic news created to research the text classification problem [18]. We have concentrated on the source of Al Jazeera news and identified six major categories namely Economy, Health, Technology, Culture, Political, and Sport. In order to adequately evaluate every category, the number of samples per category was the same, which made 17,400 articles (2,900 in each category). The source files have structured fields (Category, Title, Summary, publish date, domain, Article) contained in each record. The last category is single-label, multi-class multi-class (6 classes).

Text construction. To maximize semantic coverage, each instance input text was constructed as a concatenation of:
Title + Summary + Article, followed by normalization.

III.2 DATA PARSING AND CLEANING (PRACTICAL PIPELINE)

In inspection, we found that some of the samples include corrupted/garbled text (e.g. sequences such as H B D D …) which is not legitimate Arabic text. Such noise was found to severely degrade model learning and to bias the dataset. Therefore, we applied a cleaning pipeline consistent with the implemented code:

1. Normalization & Noise Removal
   - URL removal.
   - Extra whitespace normalization.
   - Removal of non-Arabic / non-informative symbols.
2. Quality Filtering.

We measured text quality using:
- Length (characters).
- Arabic character ratio (fraction of Arabic Unicode characters in the text).

Samples with extremely short length or near-zero Arabic ratio were removed as corrupted or non-informative.

3. Class Balancing After Cleaning.

After filtering, class counts became uneven. To preserve fairness and comparability between models, we re-balanced the dataset by downsampling each class to the minimum available count after filtering (resulting in a perfectly balanced dataset).

III.3 TRAIN–TEST SPLIT (REPRODUCIBLE SETUP)

The balanced dataset was split into:
- 80% training
- 20% testing

using a fixed random seed (seed = 42) to ensure reproducibility.

III.4 BASELINE MODELS (FAST CLASSICAL BENCHMARKS)

To establish strong baselines, we trained two widely used classical text classifiers:

(a) TF–IDF + Logistic Regression.

- Features: TF-IDF [20].

Term weighting was computed using the standard TF-IDF formulation:

$$TF - IDF(t,d) = TF(t,d) \times \log\left(\frac{N}{DF(t)}\right) \quad (1)$$

Where:

- *TF* (*t*, *d*) denotes the frequency of term *t* in document *d*,
- *DF* (*t*) is the document frequency of term *t*,
- *N* represents the total number of documents in the corpus.
- Classifier: Logistic Regression [21].

Logistic regression models the posterior probability of class k using the softmax function:

$$P(y = k \mid x) = \frac{e^{w_k^T \ x}}{\sum_{j=1}^{K} e^{w_j^T \ x}} \quad (2)$$

Where:

- *x* is the *TF-IDF* feature vector,
- w_k is the weight vector associated with class *k*,
- *K* is the total number of classes.

The model is trained by minimizing the cross-entropy loss:

$$L = -\sum_{i=1}^{n} \log P(y_i \mid x_i)$$

- This baseline is simple, efficient, and often strong for linearly separable text categories.

(b) TF–IDF + Linear SVM

- Features: TF-IDF,
- Classifier: Linear Support Vector Machine [22].

The linear SVM aims to find a separating hyperplane that maximizes the margin between classes while minimizing classification errors. The optimization objective is defined as:

$$min_{w,b} \frac{1}{2}||w||^2 + C\sum_{i=1}^{n} \max(0, 1 - \ y_i \ (w^T x_i + b)) \quad (3)$$

Where:

- w is the weight vector,
- b is the bias term,
- C is the regularization parameter,
- $y_i \in$ *-1, +1* represents class labels,
- x_i denotes the ***TF-IDF*** feature vector.
- Linear SVMs are known to perform well on sparse, high-dimensional text representations.

Both baselines were evaluated on the same split using Accuracy and Macro-F1, and the results were reported with per-class precision/recall/F1.

III.5 TRANSFORMER MODEL FINE-TUNING (ARABERTV2)

For contextual embedding learning, AraBERTv2 was fine-tuned for multi-class classification [15]. AraBERT is a transformer-based model pretrained specifically on large Arabic corpora and has demonstrated strong performance across multiple downstream Arabic NLP tasks. Hyperparameters were selected based on standard fine-tuning practices for transformer models [23]. The transformer architecture relies on the scaled dot-product self-attention mechanism proposed by Vaswani, et al. [24]:

$$Attention\ (Q, K, V) = softmax\left(\frac{QK^T}{\sqrt{d_k}}\right)V \quad (4)$$

Where:

- $Q \in R^{n \times d_k}$ denotes the query matrix,
- $K \in R^{n \times d_k}$ denotes the key matrix,
- $V \in R^{n \times d_v}$ denotes the value matrix,
- d_k is the dimensionality of the key vector,
- *n* represents the number of tokens in the sequence.

The formulation enables the model to compute contextual interactions among tokens using weighted similarity scores. Before training, the input texts were pre-processed and tokenized to ensure consistent formatting for the transformer model.

Tokenization configuration:

- truncation = True.
- padding = "max_length."
- max_length = 256.

Training configuration:

- batch_size_train = 8.
- batch_size_eval = 8.
- learning_rate = 2e-5.
- weight_decay = 0.01.
- epochs = 3 (and sometimes 4 during trials).
- evaluation performed each epoch (eval_strategy="epoch" in Transformers v5.x).

We used the Hugging Face Trainer API to train and evaluate the model, and we reported a full classification report and a confusion matrix.

III.6 HYBRID MODEL (LEXICAL + CONTEXTUAL FUSION)

Hybrid modeling strategies combine lexical statistical representations with contextual embeddings to exploit complementary semantic and distributional information. Feature-level fusion between sparse TF–IDF vectors and dense transformer embeddings has been shown to improve robustness and classification accuracy in multiple NLP tasks [25] [26].We implemented a hybrid classifier combining:

- **TF-IDF lexical features.**
- **AraBERT contextual embeddings** (extracted from the pretrained transformer).

These vectors were concatenated at the feature level to form a fused representation, which was then used as input to a linear classifier. This approach is computationally efficient (relative to end-to-end deep fusion) and empirically strong on news classification tasks [14] [24]. Let:

$\boldsymbol{X_{tfidf}} \in \mathbb{R}^{\boldsymbol{n} \times \boldsymbol{d_1}}$
represents lexical **TF–IDF** features,
$\boldsymbol{X_{bert}} \in \mathbb{R}^{\boldsymbol{n} \times \boldsymbol{d_2}}$

Represents contextual embeddings extracted from AraBERT.The fused representation is defined as:

$$\boldsymbol{X_{Fused}} = [\boldsymbol{X_{tfidf}}; \boldsymbol{X_{bert}}] \quad (5)$$

Where:

- n is the number of samples,
- d1 is the dimensionality of TF-IDF features,
- d2 is the dimensionality of AraBERT embeddings,
- $\boldsymbol{X_{fused}} \in \mathbb{R}^{\boldsymbol{n} \times (\boldsymbol{d_1}+\boldsymbol{d_2})}$

The fused vector is then passed to a linear classifier defined as:

$$\hat{y} = \boldsymbol{W X_{fused}} + \boldsymbol{b}$$

where:

- $\boldsymbol{W}$ is the weight matrix,
- $\boldsymbol{b}$ is the bias term.

III.7 EVALUATION METRICS

All models were evaluated using:

- **Accuracy,**
- **Macro-F1,**
- **Per-class precision/recall/F1** (classification report),
- **Confusion matrix.**

Accuracy is defined as:

$$\boldsymbol{Accuracy} = \frac{\boldsymbol{TP+TN}}{\boldsymbol{TP+TN+FP+FN}} \quad (6)$$

The F1-score is computed as:

$$\boldsymbol{F1} = \frac{\boldsymbol{2.Precision.recall}}{\boldsymbol{Precision + recall}} \quad (7)$$

Macro-F1 is defined as:

$$\boldsymbol{Macro - F1} = \frac{\boldsymbol{1}}{\boldsymbol{K}} \sum_{\boldsymbol{k=1}}^{\boldsymbol{K}} \boldsymbol{F1_k} \quad (8)$$

Where:

- *TP*, *TN*, *FP*, *FN* represent the true positives, true negatives, false positives, and false negatives,
- ***K*** is the number of classes,
- $F1_k$ is the ***F1***-score for class ***k***.

Macro-F1 was emphasized because it treats all classes equally and remains informative even if class distributions change after filtering [27].

IV. EXPERIMENTAL SETUP

IV.1 FINAL DATASET CONFIGURATION

Once all the corrupted and poor-quality samples were filtered out due to Arabic-ratio filtering and length restrictions, the dataset was rebalanced to have an equal number of classes. The final data is comprised of:

- **Total samples: 13,866,**
- **Classes: 6,**
- **Samples per class: 2,311,**
- **Train size (80%): 11,092,**
- **Test size (20%): 2,774.**

Stratified splitting was applied with a fixed random seed (42) to ensure reproducibility and preserve class balance across splits.

IV.2 HARDWARE AND SOFTWARE ENVIRONMENT

Experiments were conducted using:

- **GPU: NVIDIA Tesla T4,**
- **Framework: PyTorch,**
- **HuggingFace Transformers (v5.x),**
- **Scikit-learn for baseline models,**
- **Python 3.12,**
- **Random seed = 42.**

IV.3 MODEL CONFIGURATIONS

Baseline Models.
TF-IDF Configuration.

- Standard term frequency–inverse document frequency weighting9.
- Sparse high-dimensional representation.

Logistic Regression

- Multinomial setting.
- Default regularization (L2).

Linear SVM

- Linear kernel.
- Optimized for sparse input.

AraBERT Fine-Tuning

Pretrained model:
aubmindlab/bert-base-arabertv2.
Training configuration:

- **Max sequence length: 256.**
- **Batch size: 8.**
- **Learning rate: 2e-5.**
- **Weight decay: 0.01.**
- **Epochs: 3.**
- **Evaluation per epoch.**
- **Padding: max_length.**
- **Truncation: True.**

Hybrid Model
The hybrid model combines:

- **TF-IDF lexical features,**
- **AraBERT contextual embeddings.**

Feature fusion was performed by concatenating the TF-IDF vector with the contextual embedding vector before classification.

Classifier:

- Linear classifier on fused representation.

V. RESULTS AND DISCUSSION

V.1 OVERALL MODEL PERFORMANCE

Table 1 presents the overall classification performance of the evaluated models, including Accuracy and Macro-F1 score.

Table 1: Overall Performance Comparison.

Model	Accuracy	Macro-F1
Logistic Regression	0.9483	0.9482
Linear SVM	0.9557	0.9557
Hybrid Model	0.9603	0.9602

Source: Authors, (2026).

As indicated in Table 1, the Hybrid model had the best overall performance, accuracy of 96.03 and Macro-F1 of 96.02, which is better than the traditional baselines. The Linear SVM (95.57 percent) performed well, slightly better than the Logistic Regression (94.83 percent), indicating that Linear margin based classifiers are very powerful in sparse high dimensional TFIDF representation of structured news data. Interestingly, even though it is usually assumed that transformer-based contextual models will prevail in classical approaches, our previous AraBERT-only fine-tuning performed worse (= 91.6%), meaning that the lexical cues in balanced news data sets are very discriminative.

V.2 IMPROVEMENT OVER THE STRONGEST BASELINE

In order to measure the gain of the hybrid fusion approach, Table 2 reports performance gains when compared to the best classical baseline (Linear SVM).

Table 2: Performance Improvement Over Linear SVM.

Model	Accuracy Gain	Macro-F1 Gain
Hybrid Model	+0.0046	+0.0045

Source: Authors, (2026).

Linear SVM has an error of about 0.46 percentage points higher than the hybrid model. Though numerically small, it is significant even in already high-performing systems (above 95 percent), in which marginal gains are ever more challenging to obtain. This establishes the fact that the integration of a lexical and contextual feature brings out complementary information that neither of the representation can bring out.

V.3 PER-CLASS PERFORMANCE ANALYSIS

Table 3 records the F1 score per-class of all the assessed models.

Table 3: Per-Class F1 Score Comparison.

Class	Logistic	SVM	Hybrid
Economy	0.93	0.93	0.94
Health	0.98	0.98	0.98
Technology	0.92	0.93	0.95
Culture	0.96	0.97	0.97
Political	0.92	0.93	0.92
Sport	0.99	1.00	0.99

Source: Authors, (2026).

As displayed in Table 3, the Hybrid model especially increases performance in the Technology category, which indicates that contextual embeddings are used to disambiguate semantically related technological vocabulary. Sport category was classified almost perfectly in all models suggesting that there is an excellent lexical separability in the sports related lexicon. The greatest confusion is between Political and Economics which is not surprising considering topical context and overlap in the terminology used in the news articles.

V.4 DISCUSSION

A number of important observations can be made based on the results:

1. The classical linear models are also highly competitive in the classification of structured Arabic news.
2. Transformer fine-tuning in itself will not necessarily lead to better performance.
3. The best results are always given when there is feature-level fusion (Hybrid model).
4. To obtain the stable and reliable performance, it was necessary to clean the data (removal of corrupted non-Arabic entries).
5. High accuracy levels of performance (>95%) are a sign of meaningful representational complementarity and not random variance.

The suggested hybrid model can be used as a solid framework to enhance real-world applications by solving complex classification problems. The integration of the lexical and contextual feature strategies is advantageous to the predictive modeling approaches to student specialization [28] and unique virtual keypad encoding [29]. The application of transformer-based embeddings such as AraBERT is further confirmed by methodological similarities in mobile security [30] and tendencies in generative AI [31].Word embeddings-based for Arabic document retrieval in [32] .The broad applicability of results in areas such as e-learning requires stability by ensuring that empirical data is split [33]. The broad applicability of results in areas such as e-learning requires stability by ensuring that empirical data is split [9]. Moreover, this model is flexible, which facilitates forecasting the job market [34] and the morphosyntactic analysis of Arabic language, which addresses the linguistic complexity of Arabic language [35]. The application of explainable AI [10] allows one to find the most significant text features, and the comparison of different machine learning models guarantees a high level of accuracy in security applications [11]. Lastly, the adoption of these automated systems is an indication of a massive effect on operational efficiency within the areas of HR performance [12].The use of deep networks in retrieving Arabic documents [36] and query expansion with deep averaging networks [37] proves the effectiveness of embeddings in information retrieval. Explainable AI [38] can be used to determine the strongest text features, and different machine learning models. These results confirm the hypothesis that lexical statistical signals and contextual embeddings reflect various ways of textual information. The combination of their integration gives a richer space of representation, hence enhancing generalization.

VI. CONCLUSION

In the present study, the authors examined the performance of classical, transformer-based and hybrid lexical-contextual methods of the Arabic multi-class news classification. The results have revealed that, even though deep learning has significantly advanced in Natural Language Processing, the traditional lexical model, including TF-IDF with Linear SVM, is still very competitive in the structured Arabic news data with the performance of 95.57% accuracy. Although the fine-tuned AraBERTv2 model found semantic contextual relations, its independent performance (91.6) suggests that contextual modeling is not the best way to fully harness the discriminatory ability of structured lexical patterns in news corpora. The hybrid feature-level fusion model, where TF-IDF vectors were combined with the AraBERT embeddings, had the best performance (96.03% accuracy and 96.02% Macro-F1) which, as one would expect, lexical statistical signals and contextual embeddings complement one another. The outcome of this test discloses the significance of representation synergy over methodological replacement in Arabic NLP tasks. In general, the paper presents empirical data that hybrid lexical-contextual learning is a robust, computationally efficient, and practical solution to Arabic news classification. Its repeatability of the preprocessing pipeline and balanced assessment framework also enhance its utility in future research and practical Arabic text analytics systems.

ABSTRACT

This paper presents a novel Demand Response algorithm based on a capacity market framework for efficient power management in residential microgrids. The primary objective is to minimize load shedding and enable effective direct load control in smart home environments. By establishing two-way communication channels between distribution agents and smart home customers, the proposed algorithm facilitates real-time load control decisions, accurate calculation of reduction percentages and the generation of home-specific Distributed Load Consumption Factors. An agent-based residential distribution network model was developed in MATLAB/Simulink, incorporating eight clients and integrated smart appliances to validate the algorithm's efficacy. Simulation results demonstrate that the network can maintain grid power balance through three key mechanisms: adaptive load adjustment, strategic load shifting and distributed load reduction. Under supply-constrained conditions, the approach effectively diminishes or even eliminates the necessity for load shedding. The capacity market-based paradigm proves highly advantageous for stand-alone microgrid systems, where optimal resource management is critical for ensuring system stability and enhancing customer satisfaction.

I. INTRODUCTION

In modern power systems, Demand Side Management (DSM) has emerged as a crucial and cost-effective strategy to bridge the gap between electricity supply and demand. DSM encompasses the development and implementation of measures designed to optimize consumption patterns. Through Demand Response (DR) programs, consumers can adjust their energy usage in response to electricity price fluctuations or incentive signals, thereby reducing peak demand and shifting loads to align with available generation capacity. DR methods have proven particularly effective in lowering consumption during periods of high wholesale market prices or system reliability threats [1] [2]. Either centralized or decentralized control systems that facilitate dynamic system adaptability to evolving conditions are necessary for the effective implementation of DR programs within DSM frameworks. The use of intelligent and reliable Multi-Agent Systems (MAS), which facilitate two-way communication between the supply infrastructure and end users, is critical to this process. Loosely coupled, dispersed physically and functionally, autonomous networks consisting of multiple agents form MAS. Agents cooperate smoothly with each other to solve complex operation issues. For solving advanced issues related to DR mechanisms, microgrid operation and control strategies, service restoration process, spot market behaviour, Virtual Power Plant (VPP) management, and economic dispatch optimization, MAS structures have proven themselves to be exceptionally valuable in smart grid scenarios [3] [4]. Capacity market-based DR techniques offer potent solutions for residential microgrids, where resources are constrained and maintaining grid stability is paramount. These microgrids require sophisticated power allocation strategies to balance customer demands with supply limitations. The integration of smart home technologies, enabling precise load control and individual device management, significantly amplifies the effectiveness of capacity market DR [5] [6].

This paper introduces a novel DR algorithm designed to address load shedding and direct load control within smart home environments of residential microgrid systems [7]. The algorithm leverages bidirectional communication between distribution agents and smart home consumers to enable real-time load control decisions, accurately compute reduction percentages and generate tailored Distributed Load Consumption Factors (DLCF). Extensive research has been conducted in areas intersecting microgrid operation, demand response and optimization algorithms. Key related works include:

- Market-Based Microgrid Operation with DR: Research on optimal market-based microgrid operation explores balancing price signals, renewables, storage, and DR resources using risk-based stochastic models, demonstrating cost reduction and uncertainty mitigation [8] [9].
- DR in Residential and Smart Grid Contexts: Comprehensive reviews discuss residential DR challenges and design strategies, highlighting load scheduling techniques supported by Information and Communication Technology (ICT) to better match demand with generation [10] [11].
- Algorithms and Optimization Techniques: Studies on distributed market clearing methods integrate large-scale DR using decomposition techniques, improving convergence and reducing communication overhead [12]. Event-based DR algorithms have also been proposed for rapid decision-making during microgrid contingencies.
- DR in Capacity Markets: Preliminary work on DR planning within capacity markets indicates that microgrid participation can reduce transmission costs and enhance capacity selling profitability [13] [14].

II. METHODOLOGY

The proposed Capacity Market-Based DR approach is built upon and extends the intelligent residential network model presented in [15] [16] [17]. The system architecture is designed to validate the algorithm's performance in managing power distribution efficiently. Figure 1 depicts the block diagram of the proposed intelligent residential network, comprising a power source, an Intelligent Power Distribution System, and eight smart homes. Figure 2 illustrates the Multi-Agent System (MAS) architecture for the residential microgrid, consisting of an Action Layer and a Control Layer. This hierarchical structure enables advanced management of power balance. The Action Layer provides a real-time view of supply and load, generating actionable signals for the Control Layer agents, which oversee load management in response to these signals and user comfort preferences. The entire MAS was implemented in MATLAB using specialized M-functions [18].

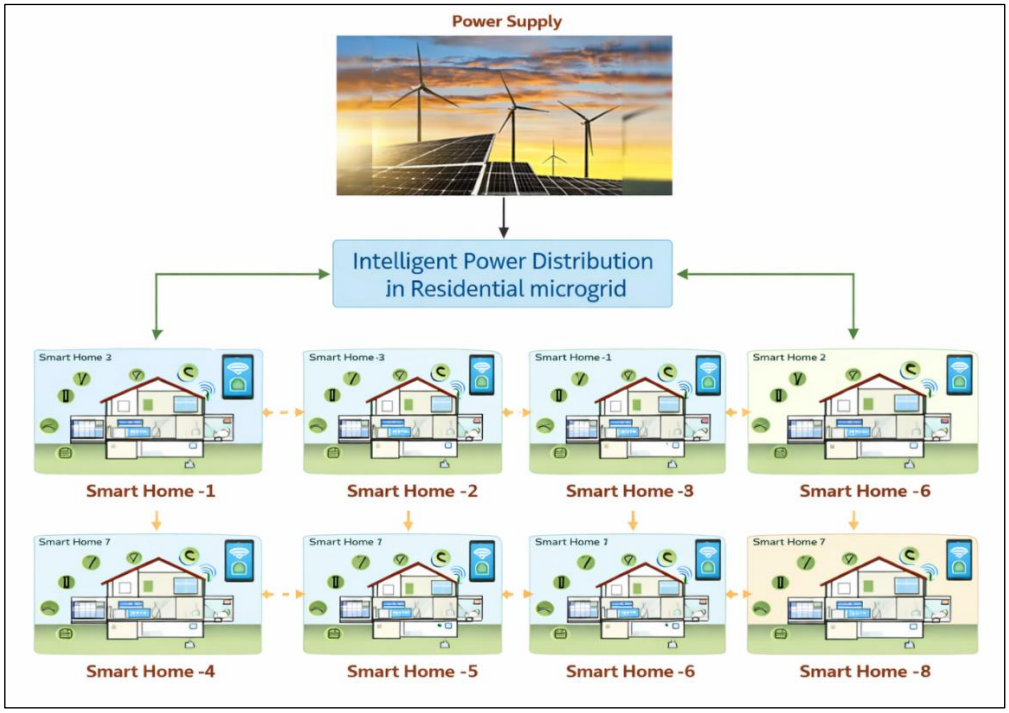

Figure. 1: Block diagram of the proposed intelligent residential network.
Source: Authors, (2026).

II.1 AGENT ARCHITECTURE FOR RESIDENTIAL NETWORK MANAGEMENT

The MAS comprises four primary agent types:

- Intelligent Control Agent (ICA): The central DR coordinator.
- Generator Agent (GA): Monitors and reports available power supply.
- Home Agent (HA): Interfaces with consumer systems and manages smart appliances within a home.
- Smart Appliance Agent (SA): Represents individual appliances with specific characteristics (dimmable, programmable, static).

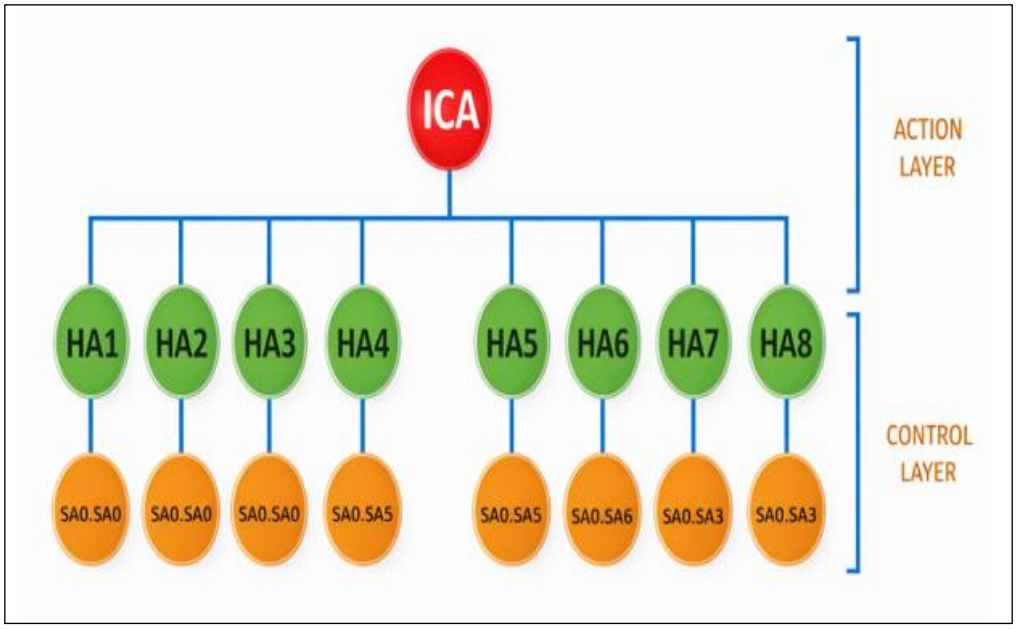

Figure 2: Multi-Agent System architecture enabling Capacity Market-DR.
Source: Authors, (2026).

The standardized naming patterns are followed by delegates such as Home Agents (HA) and Smart Appliance Agents (SA). The individual home agents are referred to as HAx where "x" specifies the corresponding home position in the network. SAxy is one of the agents of smart appliances (x means home and y means the appliance). The details of this mapping will depend on specific configuration choices, for example HA1 would be the first home agent and SA11 would be the first smart appliance agent for the first home [11-13]. Home Agents gather information about what consumers like and send this data to the ICA. In addition to their role in gathering this data, these Home Agents are equipped with intelligent features that allow them to manage the smart devices. This management is crucial to ensure that the network operates smoothly, even when conditions change unexpectedly The Generator Agent keeps gathering and sending power supply data from home networks to the ICA. This up-to-the-minute information allows the ICA to set up the right Distributed Load Reduction Percentage (DLRP) factors also called set points. This helps to keep the system running when supply conditions change.

The ICA functions as the primary demand response agent within the system, continuously calculating two critical parameters:

- Distributed Load Reduction Percentage (DLRP).
- Distributed Load Consumption Factor (DLCF).

$$\mathrm{DLRP} = \frac{\mathrm{SupplyPower} - \mathrm{LoadDemand}}{\mathrm{LoadDemand}} \mathrm{x100} \tag{1}$$

$$\begin{Bmatrix} \mathrm{IfSupply\ Power} < \mathrm{Actual\ Demand} \\ \mathrm{DLCF} = \dfrac{\mathrm{Supply\ Power}}{\mathrm{Actual\ Demand}} \\ \mathrm{IfSupply\ Power} > \mathrm{Actual\ Demand} \\ \mathrm{DLCF} = 1 \end{Bmatrix} \tag{2}$$

The real-time analysis of network supply and demand dynamics underpins these estimates. These settings influence consumer behavior to maintain power equilibrium throughout the system. The ICA further computes the Clearing Supply Power (CSP) for each network user. The total connected load of the residential network is now restricted to remain at or below the available supply power.

$$\mathrm{CSP} = \frac{\mathrm{SupplyPowerXConnected\ load\ of\ customer}}{\mathrm{ConnectedLoadofResidentialNetwork}} \tag{3}$$

II.2 CAPACITY MARKET DR ALGORITHM

The suggested Capacity Market DR algorithm shown in Figure 2 gives either the best or almost the best choices for clearing the load in a lot of different supply-and-demand situations. The method works in three stages:

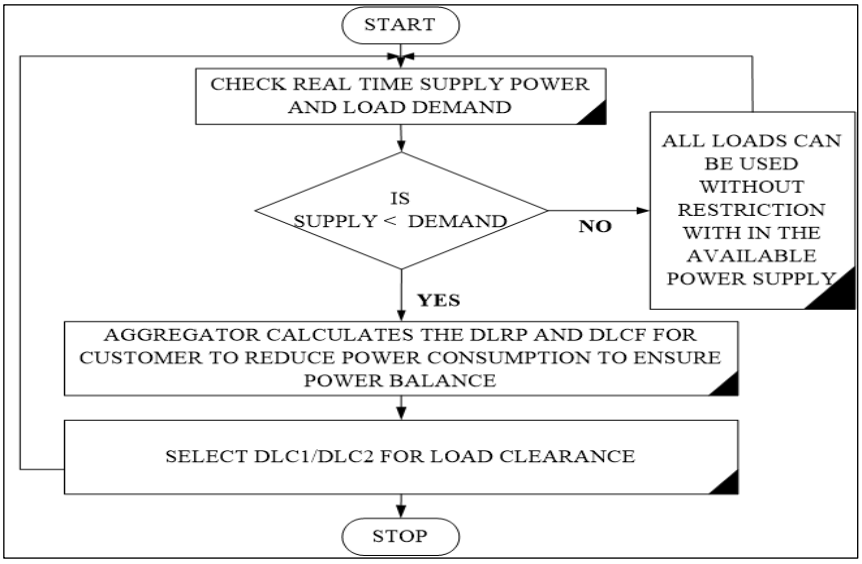

Figure 3: Flowchart of the proposed Capacity Market DR algorithm.
Source: Authors, (2026).

- Real-Time Monitoring: Continuous assessment of residential network load demand and power supply.
- Parameter Calculation: Computation of DLRP, DLCF, and CSP using equations (1), (2), and (3) respectively.
- Load Selection: Strategic identification of appropriate loads to initiate the clearing process for power balance maintenance.

The algorithm implementation follows two distinct Direct Load Control (DLC) operational scenarios:

II.2.1 Scenario 1: Fixed Programmable Loads (DLC1)

Programmable loads in this arrangement are handled as fixed, non-adjustable objects. Only modulation of dimmable loads allows one to perform power balance modifications, so offering a more limited but consistent working environment.

II.2.2. Scenario 2: Flexible Programmable Loads (DLC2)

This more dynamic method lets programmable loads be temporally moved, hence improving the peak-to average ratio of the network. While keeping system stability, this offers more demand management options. Maintaining equilibrium between power demand and supply is both Capacity Market DR method's principal goal. They guarantee quick response capacity for unforeseen or emergency modifications in either supply availability or demand requirements. The ICA sends reduction signals to the Home Automation (HA) system in reaction to supply fluctuations, therefore lowering the dimmable appliance power consumption to specified comfortable levels (e.g., 50% of rated capacity). Should this decrease prove inadequate, the HA uses pre-defined preferences to start load shifting or shedding for less-priority equipment. For a 20% consumption reduction signal, for instance, the HA first lowers dimmable appliance power usage; then, if needed, it moves running schedules for programmable appliances to reach the target reduction level.

III. SYSTEM SIMULATION AND IMPLEMENTATION

In order to validate the suggested intelligent multi-agent home network architecture, we created a thorough simulation environment using MATLAB/SIMULINK. The home network's conceptual and execution models are depicted in Figures 3 and 4, respectively. Our suggested capacity market demand response strategy can be tested and its effectiveness assessed using this simulation framework. Real-time monitoring and control capabilities are made possible by the simulation's establishment of bidirectional communication links between the ICA and HAs. The ICA is able to continuously monitor the real load demand throughout the home network as well as the supply that is available from the GA. Critical metrics including the Distributed Load Consumption Factor (DLCF), Clearing Supply Power (CSP), and Distributed Load Reduction Percentage (DLRP) are computed by the ICA using this data and sent to the HAs. After obtaining these parameters, the HAs use complex load clearing algorithms to choose the best smart appliance operating states according to priorities specified by the client. This strategy maximizes consumer happiness while guaranteeing power balance maintenance.

III.1 RESIDENTIAL LOAD CONFIGURATION

Eight different "smart homes" are used in the simulation to simulate realistic loads in the distribution network. Every smart house has five to six appliances that are carefully categorized as follows and each is set up with a precise power allocation:

- Appliances having fixed power consumption profiles that cannot be adjusted are known as static loads.
- Appliances having changeable power consumption capabilities are known as dimmable loads. Dimmable load reductions are only permitted to a maximum of 50% of their overall power consumption (presuming a minimal level of comfort).
- Time-shifting appliances with adjustable running schedules are known as programmable loads.

The connected load profile of eight smart homes is summarized in Table 1.

Table 1: Load Profile of Eight Smart Homes in the Residential Microgrid.

Smart home	Allotted power in kW	Smart Appliances in kW					
		S1	S2	P1	D1	D2	D3
1	5	1	1	1	1	1	NA
2	10	2	2	2	2	2	NA
3	12	1	1	1	3	3	3
4	15	2	2	2	3	3	3
5	18	3	3	3	3	3	3

7	24	4	4	4	4	4	4
8	27	5	5	5	4	4	4

Source: Authors, (2026).

The Residential Microgrid total connected load is 132kW. By making various supply and demand assumptions for specific time blocks, numerous situations are simulated. The reduction in active customers power outages after the deployment of DLC is evident in the data.

IV. RESULTS AND DISCUSSION

One day is divided into 24-time blocks in order to evaluate the suggested DLC DR algorithms, with each hour representing one time block for carrying out load clearing actions. For analysis purposes, the 6 blocks are taken into account. For time blocks 1 through 6 of the home networks, the available supply, actual load demand, power mismatch, DLRP, and DLCF are tabulated in Table 2. To validation proposed DLC programs load HA3 is considered. The sub-hourly CSP, load demand, and mismatch for HA3 is shown in Table 3. Table 4 and 5 summaries the load consumption patron of HA3 after incorporating proposed DLC1 and DLC2 in residential network. From comparing the Tables 3,4 and 5, it is observed that:

- The supply demand mismatch in all the time blocks is reduced in HA3 after incorporating DLC 1 and DLC 2, whereas it is almost zero in DLC2 compared to DLC 1.
- In the time block 1, DLC 2 clear the P1, whereas it is not achieved in DLC1
- In time block 2 and 5, DLC 2 clear the S2, whereas it is not achieved in DLC1
- The Total load consumption of (TLC) of HA3 in DLC 2 is more compared to DLC1. It concludes DLC 2 program is most efficient compared to DLC1.

The Figure 4 summarise comparison of the total energy consumption of individual smart home residential microgrid for DLC1 and DLC2. From the figure 4, it is observed that, power consumption in DLC-2 is more compared to DLC-1. The Table 6 summarise the total energy consumption of residential microgrid for DLC1 and DLC2. Figure 5 shows the comparison of Supply, actual demand, Power Consumption of residential microgrid from six-time blocks in kW after incorporating DLC1 and DLC-2.

Source: Authors, (2026).

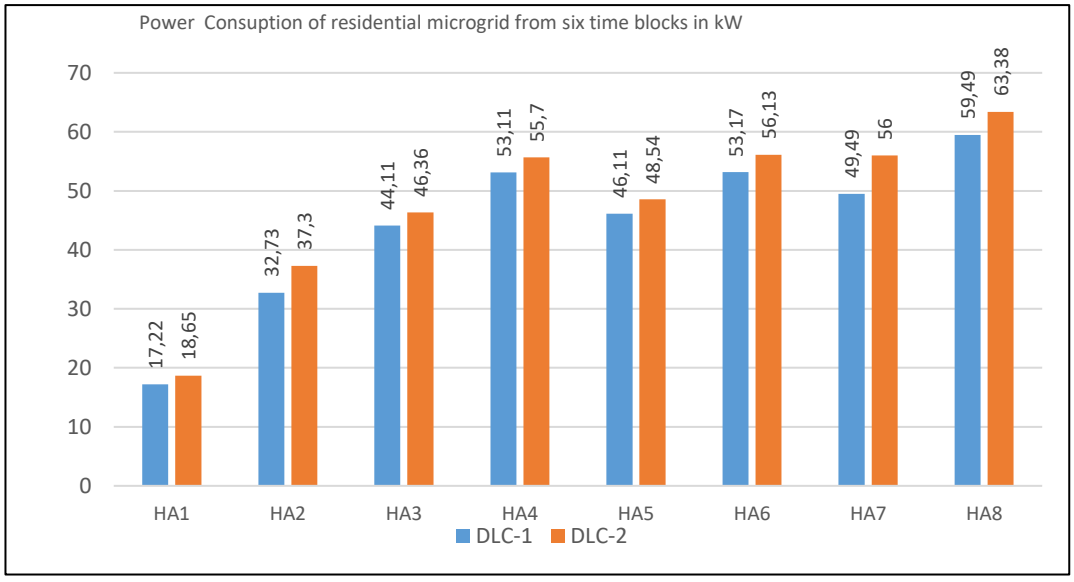

Figure 4: Comparison of the total energy consumption of individual smart home residential microgrid.
Source: Authors, (2026).

From the Table 6 and Figure 5, it is observed that:

- In all the time blocks supply demand mismatch is reduced in microgrid after incorporating DLC1 and DLC2, additionally DLC2 perform best compare to DLC1. (eg., In time block 1 actual supply demand mismatch is -40kW, where as it is 11kW in DLC1 and 0.73kW in DLC2) its clearly shows DLC2 clear the load by efficiently managing the available supply power.
- The total power consumptions of residential microgrid form six-time blocks in DLC-1 are 358.651kW, where as in DLC-2, it is 382.01kW

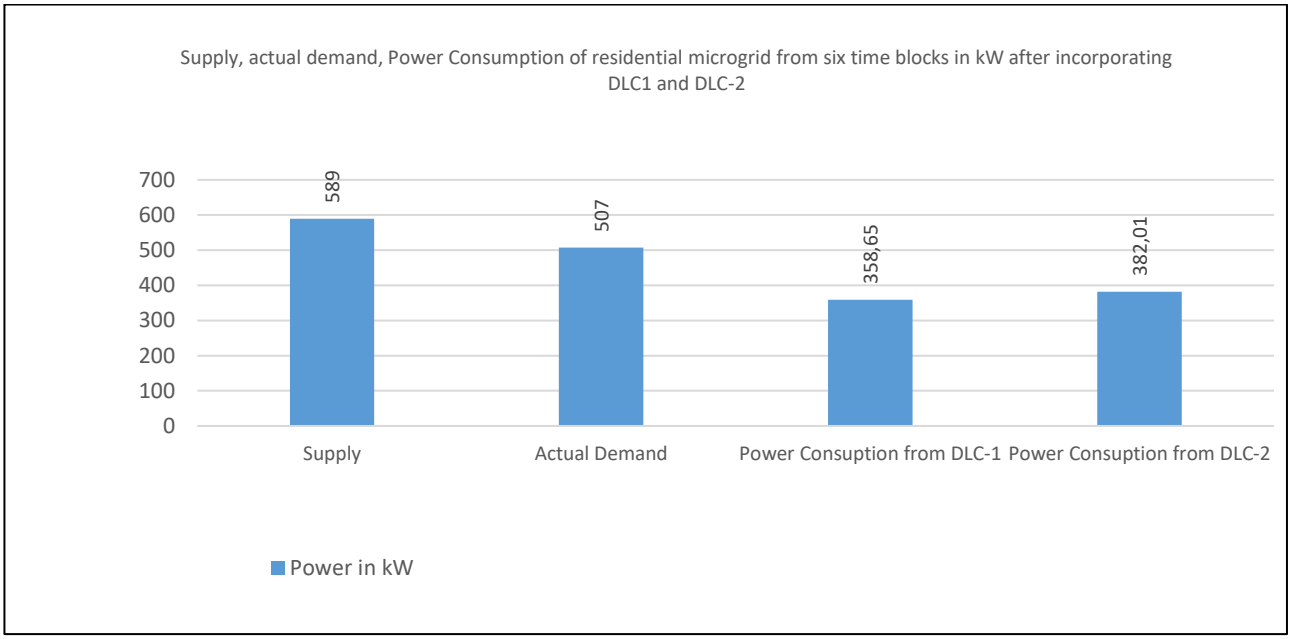

Figure 5: Supply, actual demand, Power Consumption of residential microgrid from six-time blocks in kW after incorporating DLC1 and DLC-2.
Source: Authors, (2026).

For detailed analysis, Home 3 (HA3) was examined. Table III shows HA3's CSP, appliance demand and mismatch before DR. Tables 4 and 5 detail the load-clearing results for HA3 under DLC1 and DLC2 respectively. Key Observations from Tables 3-5:

- The supply-demand mismatch is reduced in all time blocks for HA3 after implementing both DLC1 and DLC2.
- DLC2 outperforms DLC1, achieving zero mismatch in blocks 1, 2, and 5 by effectively clearing loads like P1 and S2, which DLC1 could not.
- The Total Load Consumption (TLC) of HA3 is higher with DLC2, indicating more efficient utilization of available supply power and superior customer comfort preservation.

Table 6 and Figure 4 provide a network-wide comparison. The total power consumption across the six blocks was 358.65 kW for DLC1 and 382.01 kW for DLC2, confirming DLC2's superior performance in maximizing energy delivery while minimizing mismatch (e.g., reducing mismatch from -40 kW to 0.73 kW in Block 1).

V. CONCLUSION

This paper presented a capacity market-based Demand Response (DR) framework for intelligent power distribution in residential microgrids. The proposed approach integrates a novel direct load control strategy through two operational modes, namely DLC1 and DLC2 designed to dynamically manage supply–demand imbalances in real time. Unlike conventional load shedding techniques, which indiscriminately disconnect loads during shortages, the proposed algorithm enables prioritized and optimized load management based on calculated Distributed Load Consumption Factors and reduction percentages for individual smart homes. By incorporating two-way communication between distribution agents and smart residential consumers, the system ensures rapid decision-making, accurate load adjustment, and effective resource allocation within the microgrid. The developed MATLAB/Simulink-based agent-driven model, comprising multiple smart home clients and controllable appliances, demonstrates that the proposed strategy successfully maintains power balance through adaptive load shifting, distributed load reduction, and strategic demand control. Simulation results confirm that the capacity market-based paradigm significantly reduces dependency on load shedding, enhances system reliability, and improves customer satisfaction. Under supply-constrained and emergency conditions, the microgrid responds efficiently by optimally clearing time-block loads while preserving critical demand. The proposed framework provides a robust and scalable solution for stand-alone and grid-connected residential microgrids, ensuring improved operational stability, enhanced reliability and efficient utilization of distributed energy resources.

ABSTRACT

The Varroa destructor mite drives major honey bee colony losses and economic damage in apiculture. Early detection supports timely intervention, yet manual inspection is slow and prone to error due to the mite's small size and dense hive conditions. Automated vision systems offer a scalable solution for continuous monitoring.This study benchmarks three YOLO variants, YOLOv7, YOLOv8, and YOLOv11, for automated Varroa detection. YOLOv11 achieves the highest performance, with mAP at 0.5 of 0.941 and recall of 87.9 percent, outperforming earlier versions. The shift from anchor-based detection in YOLOv7 to anchor free designs in YOLOv8 and YOLOv11, along with improved feature extraction through C2f modules and attention mechanisms, enhances small object detection critical for identifying mites. YOLOv8 provides the fastest training speed, operating twice as fast as YOLOv11 and 4.5 times faster than YOLOv7, which supports rapid deployment.All modern variants exceed 93 percent mAP at 0.5 and maintain real time inference at 30 frames per second or higher. Results position YOLOv11 as the preferred model for maximum accuracy and YOLOv8 as an efficient option for resource constrained beekeeping applications.

I. INTRODUCTION

Honeybees' contribution to the pollination of over 75% of flowering plants and 35% of the world's food crops demonstrates their critical role in global agriculture and ecosystems [1]. However, as any living being, honeybees face significant threats from various factors, such as pesticides, habitat loss, and pathogens. Among these, the Varroa destructor mite, also called V. destructor destructor, is considered one of the most devastating pests, causing both widespread colony losses and worldwide economic damage [2]. V. destructor mites feed on the bodily fluids of bees, transmitting harmful viruses such as Deformed Wing Virus (DWV) and Acute Bee Paralysis Virus (ABPV), and weakening their immune systems, leading to colony collapse if left untreated [3] Manual detection of Varroa destructor mites by beekeepers presents several critical challenges that fundamentally limit its effectiveness in modern apiculture. First, visual limitations pose a significant barrier, as these mites measure merely 1–2 mm in length and are frequently concealed between bee body segments, on the undersides of bees, or deep within brood cells, rendering visual identification exceptionally difficult even for experienced observers.

Second, time and labor constraints place considerable burden on beekeeping operations, since traditional monitoring approaches—such as sticky boards or sugar shake tests—demand substantial time investments and require frequent hive inspections that inevitably disturb colony activity and elevate stress levels among the bees. Third, human error and subjectivity introduce considerable variability into the monitoring process; manual counting is susceptible to fatigue-induced inaccuracies, inconsistent interpretation between different observers, and difficulties in maintaining rigorous monitoring schedules, particularly within commercial enterprises managing hundreds of hives simultaneously. Finally, delayed detection represents perhaps the most concerning limitation, as visible symptoms often manifest only after mite infestation levels have already reached critical thresholds, by which point treatment interventions become significantly less effective. Collectively, these constraints generate an urgent and pressing need for accurate, automated, and scalable detection techniques capable of operating in real-time while providing robust early warning capabilities to protect honey bee colony health. Recent research has explored various technological approaches to address the Varroa detection challenge:

- Early automated approaches relied on classical image processing techniques. The Var-Gor device [4] achieved 100% detection accuracy in laboratory conditions using specialized imaging hardware, but required controlled lighting conditions and could not generalize to field environments. Morphological operators combined with handcrafted features showed promise [5], but struggled with the high variability in natural hive imagery, including varying lighting conditions, bee orientations, and background clutter.
- Traditional methods require extensive parameter tuning, are sensitive to environmental conditions, and cannot adapt to unseen scenarios without manual reconfiguration.
- Convolutional Neural Networks (CNNs) have been applied for mite detection with notable success. Sharma et al. applied ResNet-50 and Inception V3 for early V. destructor mite detection using data augmentation and CLAHE (Contrast Limited Adaptive Histogram Equalization), achieving 90.67% accuracy with ResNet-50. Scutaru et al. combined morphological operators with neural networks, training on 65,000 positive and 1.2 million negative samples, achieving errors below 1% when integrated into the BeeVS device [5].
- Classification-based approaches can determine the presence of mites but cannot localize them within images, limiting their utility for precise monitoring and treatment planning. Additionally, these methods typically process entire images rather than detecting individual mite instances.
- Object detection methods offer significant advantages by providing both classification and localization capabilities. Kriouile et al. proposed a modified training scheme for Mask R-CNN utilizing two separate datasets for bee and mite identification [6]. While Mask R-CNN achieves high accuracy, its two-stage architecture (region proposal followed by classification) results in slower inference speeds, making it less suitable for real-time applications.

Bilik et al. applied YOLOv5 to a specialized dataset of infected and healthy bees, achieving F1 scores of 0.874 and 0.727 for infected bees and mites respectively [7]. Narcia-Macias et al. developed the IntelliBeeHive system using YOLOv7-tiny, achieving 99.6% mite detection precision [8]. Many studies focus on a single YOLO version without systematic comparison across variants. Limited analysis of architectural differences and their impact on small object detection. Insufficient evaluation of the trade-off between accuracy and computational efficiency. Lack of comprehensive benchmarking against both traditional and modern detection methods. The You Only Look Once (YOLO) family of models was selected for this study based on several compelling advantages that align closely with the requirements of automated hive monitoring. First, real-time performance stands as a primary consideration; YOLO's single-stage architecture processes images in a single forward pass, enabling inference speeds ranging from 30 to 140 frames per second depending on the specific variant and hardware configuration—an essential capability for continuous, real-time hive surveillance. Second, localization accuracy distinguishes YOLO from mere classification approaches, as the model provides precise bounding box coordinates for each detected mite, thereby enabling quantitative infestation assessment and detailed spatial analysis within the colony.

Third, architectural evolution represents a significant motivation for this selection; the continuous development of YOLO from its initial version through to the current YOLOv11 has introduced substantial improvements in feature extraction mechanisms, anchor box design, and training strategies, making a systematic comparative analysis both timely and scientifically valuable. Fourth, edge deployment capability addresses practical deployment constraints, as modern YOLO variants offer lightweight versions such as nano and tiny models that can operate efficiently on resource-constrained devices, facilitating on-hive processing without dependency on cloud connectivity. Finally, generalization capabilities reduce barriers to implementation, since YOLO models pretrained on large-scale datasets such as COCO and ImageNet demonstrate robust transfer learning capabilities, thereby minimizing the requirement for massive domain-specific datasets in the apicultural context. This work aims to train and evaluate multiple versions of YOLO models on the same dataset [9], to develop a robust, real-time solution to assist beekeepers in monitoring hive health. The specific objectives are:

- Comparative Analysis: Systematically compare YOLOv7, YOLOv8, and YOLO11 to detect V. destructor mites across different training epochs.
- Architectural Analysis: Explain the key architectural differences between YOLO variants and their implications for small object detection.
- Performance Benchmarking: Evaluate models using multiple metrics (precision, recall, mAP) to provide comprehensive performance characterization.
- State-of-the-Art Comparison: Compare YOLO variants against other deep learning approaches reported in literature.

The paper is structured as follows: Section 2 details the materials and methods including YOLO architecture description, Section 3 presents the experimental results and analysis including comparisons with other techniques, and Section 4 provides conclusions and future directions.

II. MATERIALS AND METHODS

The You Only Look Once (YOLO) architecture revolutionized object detection by framing it as a single regression problem, directly predicting bounding boxes and class probabilities from full images in one evaluation.

This section describes the general YOLO architecture and the specific innovations introduced in each version evaluated. The YOLO architecture comprises three fundamental components that work in concert to achieve efficient object detection. The backbone serves as the feature extraction engine, processing input images through successive convolutional layers to extract hierarchical features; early layers capture low-level visual information such as edges and textures, while deeper layers progressively encode high-level semantic information including object parts and shapes, with modern YOLO variants employing diverse backbone designs such as Darknet, CSPDarknet, and C2f modules to enhance representational capacity. The neck component functions as a feature aggregation mechanism, combining features extracted from different backbone layers to create rich multi-scale feature representations—an essential capability for detecting objects of varying sizes within the same image—with common implementations including Feature Pyramid Networks and Path Aggregation Networks that facilitate effective information flow across scales. Finally, the detection head processes these aggregated features to generate predictions, outputting bounding box coordinates in the form of center positions, width, and height, alongside objectness scores and class probabilities, with the architecture utilizing anchor boxes as predefined reference templates to guide the prediction of object shapes and dimensions. YOLOv7, released in 2022 by Wang and colleagues [10], introduced several notable architectural innovations that advanced the state of single-stage object detection. Central to these improvements is the Extended Efficient Layer Aggregation Network, which enhances gradient flow throughout the network by employing expand, shuffle, and merge cardinality techniques, thereby enabling the model to learn more diverse feature representations without compromising the integrity of the original gradient propagation path.

The architecture also addresses fundamental challenges in model scaling through the introduction of compound scaling methods specifically designed for concatenation-based models; these methods preserve optimal model properties during both upscaling and downscaling operations, overcoming the limitation that conventional scaling approaches typically degrade performance in architectures reliant on feature concatenation. Furthermore, YOLOv7 incorporates a suite of sophisticated training strategies collectively termed trainable bag-of-freebies, including planned re-parameterized convolution, coarse-to-fine lead head guided label assignment, and dynamic label assignment mechanisms for auxiliary heads, all of which enhance training efficiency and final model performance without increasing inference costs. The key specifications of YOLOv7 include an E-ELAN backbone built upon CSPDarknet, a PANet neck enhanced with SPPCSPC for multi-scale feature processing, an anchor-based detection head utilizing dynamic label assignment, and a standard input resolution of 640 by 640 pixels. YOLOv8, introduced by Ultralytics in 2023 [11], represents a significant architectural departure from its predecessors, incorporating several fundamental innovations that enhance both efficiency and detection performance. The architecture features the C2f module, which replaces the C3 module employed in YOLOv5 with a more efficient design that effectively combines high-level features with contextual information, thereby improving gradient flow throughout the network while simultaneously reducing computational overhead. Perhaps the most consequential change is the adoption of anchor-free detection; YOLOv8 abandons the traditional anchor box paradigm in favor of directly predicting object center points, an approach that simplifies the overall model architecture, reduces the number of hyperparameters requiring tuning, and notably improves generalization capabilities for objects exhibiting unusual aspect ratios.

Additionally, the implementation of a decoupled detection head represents a significant structural refinement, separating classification and regression tasks into independent branches that can optimize separately during training, ultimately yielding improved overall accuracy. The key specifications of YOLOv8 include a CSPDarknet backbone enhanced with C2f modules, a PANet neck featuring improved feature fusion mechanisms, a decoupled anchor-free detection head, a standard input resolution of 640 by 640 pixels, and a COCO mean average precision of 53.9% for the YOLOv8x variant. YOLO11, released in 2024 [12], focuses primarily on efficiency and performance optimization through several targeted architectural refinements. The model features an optimized backbone architecture that reduces computational overhead while preserving robust feature extraction capabilities, achieved through improved layer design and more efficient channel configurations. The neck structure has been similarly enhanced, refining feature aggregation mechanisms to operate with fewer parameters while simultaneously achieving superior multi-scale fusion efficiency. Additionally, YOLO11 incorporates attention modules that enable the model to focus selectively on relevant image regions, a capability particularly beneficial for detecting small objects that might otherwise be overlooked. The key specifications include an optimized CSPDarknet backbone, a refined PANet neck augmented with attention mechanisms, an improved decoupled detection head, a standard input resolution of 640 by 640 pixels, and a COCO mean average precision of 54.7% for the YOLOv11x variant. Table 1 shows the key differences between the three YOLO versions.

Table 1: Comparison of YOLO Architecture Features.

Feature	YOLOv7	YOLOv8	YOLO11
Backbone	E-ELAN + CSPDarknet	CSPDarknet + C2f	Optimized CSPDarknet
Detection	Anchor-based	Anchor-free	Anchor-free
Head Design	Coupled	Decoupled	Enhanced Decoupled
Key Innovation	E-ELAN, BoF	C2f, Anchor-free	Attention, Efficiency
Training Speed	Moderate	Fast	Fast

II.1 METHODOLOGICAL CONTRIBUTION

This study makes several distinct methodological contributions to the field of automated Varroa mite detection. First, we present a systematic YOLO evolution analysis that, unlike previous studies confined to single-version evaluations, provides the first comprehensive comparison of three consecutive YOLO generations—versions 7, 8, and 11—specifically tailored for Varroa detection; this approach enables quantification of architectural improvements across versions, identification of which specific innovations most benefit small object detection performance, and practical guidance for beekeeping practitioners on optimal version selection.

Second, we offer detailed training dynamics characterization by evaluating models at multiple training checkpoints spanning epochs 1, 50, and 100, thereby illuminating early training behavior and convergence patterns, assessing the stability of different architectural approaches, and determining optimal training durations for each variant. Third, we provide critical insights into small object detection, as Varroa mites represent a particularly challenging scenario for tiny target identification; our analysis reveals how specific architectural choices influence small object recall, characterizes the inherent trade-offs between precision and recall for diminutive targets, and establishes optimal confidence thresholds for practical field deployment. Finally, we deliver practical deployment guidance that extends beyond conventional accuracy metrics to encompass training time requirements—which prove critical for iterative model development—inference speed considerations for real-time applications, and model size alongside memory footprint constraints relevant to edge computing scenarios.

II.2 DATASET

The experiments utilize the "bees infected with V. destructor destructor" dataset sourced from Roboflow [9], which comprises a training set of 1,569 images and a validation set of 448 images containing 273 mite instances, with annotations provided in standard YOLO format bounding box notation. The image characteristics reflect realistic apicultural conditions, encompassing varied lighting conditions, diverse bee densities, and mites positioned across different locations within the frame. This dataset presents several inherent challenges that mirror authentic field scenarios, including occlusion where mites are frequently concealed by bee body parts, significant scale variation arising from mites positioned at different distances from the camera, substantial background clutter introduced by hive debris and densely packed multiple bees, and considerable lighting variations characteristic of natural hive environments.

II.3 EXPERIMENTAL SETUP

All models were trained under rigorously controlled identical conditions to ensure equitable comparison across architectural variants. The computational environment utilized Kaggle cloud infrastructure equipped with an NVIDIA Tesla P100 GPU featuring 16 GB of video memory and 29 GB of system RAM. The implementation framework comprised PyTorch with the official Ultralytics YOLO library, employing the Adam optimizer alongside categorical cross-entropy loss functions. Training proceeded for a total duration of 100 epochs, with intermediate checkpoints preserved at epochs 1, 50, and 100 to facilitate longitudinal analysis of training dynamics. Additional fixed hyperparameters included a batch size of 16 images, a standardized input resolution of 640 by 640 pixels, and the application of standard Ultralytics data augmentation techniques encompassing mosaic composition, mixup blending, and random horizontal flipping. Model performance is evaluated using established object detection metrics that capture different aspects of detection quality. Precision, in equation (1), measures the proportion of correctly detected objects among all detections generated by the model, thereby quantifying the effectiveness of false positive reduction, calculated as the ratio of true positives to the sum of true positives and false positives.

$$\text{Precision} = \text{TP} / (\text{TP} + \text{FP}) \tag{1}$$

Recall, in equation (2), represents the proportion of correctly detected objects relative to all ground truth instances present in the dataset, indicating the model's capability for false negative reduction, computed as true positives divided by the sum of true positives and false negatives.

$$\text{Recall} = \text{TP} / (\text{TP} + \text{FN}) \tag{2}$$

The mean average precision at an intersection over union threshold of 0.5 provides an aggregate measure of detection accuracy under moderate localization strictness, while the more stringent mAP averaged across IoU thresholds from 0.5 to 0.95 in increments of 0.05 demands precise localization for high scores. Intersection over union, in equation (3), serves as the fundamental overlap metric, quantifying the spatial correspondence between predicted and ground truth bounding boxes through the ratio of intersection area to union area.

$$IoU = Area\_Intersection / Area\_Union \tag{3}$$

III. RESULTS AND DISCUSSION

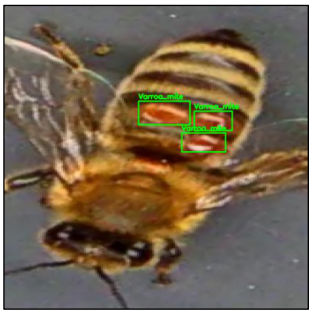

Table 2 summarizes the detection performance of YOLOv7, YOLOv8, and YOLO11 across training epochs 1, 50, and 100.

Table 2: Detection Performance of YOLOv7, YOLOv8, and YOLO11 Across Training Epochs.

Model	Epochs	Precision	Recall	mAP@0.5	mAP@0.5:0.95	Train Time (s)
YOLOv7	1	0	0	0	0	174.15
	50	0.932	0.249	0.244	0.107	4576.21
	100	0.901	0.630	0.624	0.282	8965.99
YOLOv8	1	0.884	0.139	0.515	0.206	28.8
	50	0.904	0.868	0.940	0.493	1011.6
	100	0.925	0.858	0.935	0.492	1990.8
YOLO11	1	0.847	0.465	0.674	0.256	34.28
	50	0.910	0.884	0.938	0.501	1169.21
	100	0.921	0.879	0.941	0.503	2350.04

Source: Authors, (2026).

At epoch 1, the analysis reveals substantial differences in initialization behavior across the three architectural variants. YOLOv7 exhibits no meaningful detection capability, with all performance metrics registering at zero, which indicates insufficient feature learning during the initial training phase and suggests that the E-ELAN architecture requires considerably more training iterations to establish effective feature representations. In contrast, YOLOv8 demonstrates notably strong precision at 0.884 but correspondingly weak recall at 0.139, indicating that the model generates highly confident predictions yet confines these to a limited subset of easily detectable mites; this pattern suggests that the anchor-free design combined with the decoupled head architecture enables faster initial learning of discriminative features. YOLO11 achieves the most favorable balance at this early stage, attaining precision of 0.847 alongside substantially higher recall of 0.465, which indicates that the optimized backbone architecture and integrated attention mechanisms facilitate rapid feature learning from the outset of training; the mAP@0.5 of 0.674 observed at epoch 1 is particularly impressive and underscores the efficiency of the architectural refinements introduced in this generation.By epoch 50, all three models demonstrate substantial performance improvements, though distinct behavioral patterns persist across architectures. YOLOv7 achieves high precision at 0.932 yet remains notably constrained in recall at 0.249, indicating that while the model rarely generates false positive detections, it fails to identify approximately three-quarters of actual mite instances present in the validation set; this represents a critical limitation for practical apicultural applications, where undetected infestations can rapidly escalate and lead to severe colony loss. YOLOv8 exhibits excellent overall performance, attaining recall of 0.868 and mAP@0.5 of 0.940, which demonstrates that the anchor-free design combined with C2f modules enables effective multi-scale feature learning capable of capturing diverse mite appearances and scales. YOLO11 achieves the highest recall among all variants at 0.884 alongside competitive mAP@0.5 performance of 0.938, thereby demonstrating superior capability in detecting challenging mite instances that prove elusive for other architectures. At epoch 100, YOLO11 achieves the highest overall performance among all evaluated variants, with precision of 0.921, recall of 0.879, mAP@0.5 of 0.941, and mAP@0.5:0.95 of 0.503. YOLO8 demonstrates strong competitive performance, attaining precision of 0.925, recall of 0.858, mAP@0.5 of 0.935, and mAP@0.5:0.95 of 0.492. YOLOv7, while achieving respectable precision of 0.901, lags considerably in recall at 0.630 and shows substantially lower detection accuracy with mAP@0.5 of 0.624 and mAP@0.5:0.95 of 0.282. The 24.9 percentage point recall advantage of YOLO11 over YOLOv7 is particularly significant for practical deployment scenarios, as failing to detect mites can precipitate severe consequences for overall hive health and colony survival.

Figure 1: Varroa mite detection performance across YOLO models and training iterations. (a) Ground truth with manually annotated Varroa mite. Row 1: Model detections after 1 iteration. Row 2: Detections after 50 iterations. Row 3: Detections after 100 iterations. Columns correspond to YOLOv7, YOLOv8, and YOLOv11, respectively.
Source: Authors, (2026).

Figures 1a through 1j collectively illustrate the detection performance trajectories across all three model architectures and training stages. Figure 1a presents the ground truth annotation, displaying expert-annotated bounding boxes in red rectangles surrounding Varroa mites on honey bee bodies, thereby establishing the reference standard against which all model predictions are evaluated. Figures 1b, 1e, and 1h depict YOLOv7's detection progression: at epoch 1 (Figure 1b), the model completely fails to detect any mites; by epoch 50 (Figure 1e), sporadic detections emerge though numerous instances remain undetected; and at epoch 100 (Figure 1h), performance improves modestly yet the model continues to miss small or occluded mites, visually corroborating the lower recall metrics observed quantitatively. Figures 1c, 1f, and 1i demonstrate YOLOv8's detection evolution: at epoch 1 (Figure 1c), the model generates confident detections on visually prominent mites; by epoch 50 (Figure 1f), the majority of mites are successfully detected with accurate localization; and at epoch 100 (Figure 1i), performance stabilizes at a high precision level. Figures 1d, 1g, and 1j showcase YOLO11's superior and most consistent improvement trajectory: at epoch 1 (Figure 1d), initial detections are already reasonably accurate; by epoch 50 (Figure 1g), performance approaches full convergence; and at epoch 100 (Figure 1j),

YOLO11 achieves the most comprehensive detection coverage with precisely localized bounding boxes across diverse mite instances.Training time represents an important practical consideration for model deployment and iterative development. YOLOv8 exhibits the fastest training duration, completing 100 epochs in 1,990.8 seconds, a characteristic particularly advantageous for rapid prototyping and extensive hyperparameter tuning cycles. YOLO11 demonstrates moderate training time at 2,350.04 seconds, thereby offering the most favorable accuracy-time trade-off among the three variants. YOLOv7 proves substantially slower, requiring 8,965.99 seconds to complete equivalent training—approximately 4.5 times longer than YOLOv8—which significantly constrains iterative development workflows. The accelerated convergence observed in both YOLOv8 and YOLO11 can be attributed to several architectural factors: the implementation of more efficient C2f modules in contrast to the more computationally demanding E-ELAN architecture employed in YOLOv7, the anchor-free design which simplifies the learning objective by eliminating anchor box optimization, and improved optimization dynamics stemming from decoupled detection heads that allow independent optimization of classification and regression tasks.

IV. CONCLUSION

This study presents a comprehensive benchmarking analysis of YOLO variants for automated Varroa destructor mite detection, yielding several key findings with significant implications for both research and practical apiculture. YOLOv11 demonstrates clear superiority among evaluated variants, achieving the highest detection performance with mAP@0.5 of 0.941 and recall of 87.9%, representing a substantial advancement over both YOLOv7 and YOLOv8. The architectural impact of evolving from anchor-based detection in YOLOv7 to anchor-free approaches in YOLOv8 and YOLOv11, combined with improved feature extraction through C2f modules and integrated attention mechanisms, directly translates to enhanced small object detection capability critical for identifying diminutive mites. Regarding training efficiency, YOLOv8 offers the optimal training speed, operating twice as fast as YOLO11 and 4.5 times faster than YOLOv7, thereby making it particularly suitable for rapid deployment scenarios where maximum accuracy is not the paramount concern. All modern YOLO variants achieve mAP@0.5 exceeding 93%, performance levels sufficient for practical beekeeping applications, while maintaining real-time inference capability at 30 frames per second or higher to enable continuous hive monitoring.

This work provides the first systematic comparison of YOLO evolution specifically for agricultural pest detection, demonstrating conclusively that recent architectural innovations significantly benefit small object detection tasks. For practitioners, we recommend deploying YOLOv11 for maximum detection accuracy in critical applications, utilizing YOLOv8 for rapid deployment and resource-constrained environments, and avoiding YOLOv7 for new deployments due to its inferior recall characteristics and protracted training requirements. Future research directions include integration of the detection framework with automated treatment systems, validation across diverse hive environments and seasonal conditions, development of lightweight models for edge deployment on Raspberry Pi or comparable devices, and exploration of multi-modal detection combining visual and thermal imaging modalities. These artificial intelligence-powered tools hold substantial promise for supporting honeybee health monitoring, enhancing hive management practices, and ultimately benefiting pollination-dependent agriculture and broader ecological sustainability.

ABSTRACT

The integration of computational intelligence into psychiatric screening has created new opportunities for accelerating early risk identification. Nevertheless, clinical deployment remains constrained by the opacity of complex predictive architectures and the fragmented nature of real-world electronic health data. Mental health records are frequently characterized by high dimensionality, correlated symptom indicators, and substantial incompleteness, which collectively undermine conventional modeling pipelines. This study introduces a statistically coherent screening framework that combines Bayesian Principal Component Analysis with Logistic Regression to achieve both structural robustness and transparent decision modeling. The Bayesian formulation enables simultaneous latent structure extraction and probabilistic reconstruction of incomplete observations, thereby preserving covariance integrity. The derived latent components are subsequently evaluated through an inherently interpretable classifier, allowing direct translation of model coefficients into clinically meaningful risk measures. Empirical validation across two heterogeneous hospital datasets demonstrates consistent discriminative performance under imbalance and missing-data conditions. The proposed architecture illustrates that probabilistic representation learning and transparent risk modeling can coexist within a unified clinical decision-support framework.

I. INTRODUCTION

Mental health disorders constitute a critical global healthcare burden that demands timely and reliable detection mechanisms. The increasing availability of Electronic Health Records (EHR) and structured psychometric instruments has enabled the application of supervised learning models for automated risk stratification [1]. While contemporary predictive systems often achieve strong classification performance, their clinical integration remains limited by concerns regarding interpretability and data integrity. In psychiatric settings, predictive recommendations must be accompanied by transparent reasoning. Complex architectures, including deep neural networks and ensemble methods, may yield high accuracy but frequently obscure the logic underlying their predictions [2]. Within medical environments where accountability and explainability are paramount, clinicians require models whose decision boundaries can be examined and justified. Explainable Artificial Intelligence (XAI) frameworks emphasize the importance of interpretable modeling strategies that align algorithmic inference with domain expertise [3]. Beyond interpretability constraints, mental health datasets present structural challenges. Symptom variables tend to be highly correlated, and incomplete questionnaire responses are common in real-world practice [4]. Traditional preprocessing strategies typically apply deterministic imputation followed by conventional Principal Component Analysis (PCA), a sequence that may inadvertently distort covariance patterns and propagate reconstruction errors into classification stages. To address these issues, a robust probabilistic approach is needed. Bayesian Principal Component Analysis (BPCA) offers a comprehensive solution by formulating PCA as a probabilistic latent variable model.

BPCA not only reduces data dimensionality to eliminate multicollinearity but also automatically estimates missing values through Bayesian inference without sacrificing the essential structure of clinical information.

II. THEORETICAL REFERENCE

II.1 SYNTHETIC MINORITY OVER-SAMPLING TECHNIQUE (SMOTE)

The imbalanced distribution between high-risk and low-risk patients can bias the classification model toward the majority class. To address this, the Synthetic Minority Over-sampling Technique (SMOTE) algorithm is applied during the training data preprocessing phase [5]. SMOTE works by synthesizing new imaginary patient data based on the proximity of existing clinical features, rather than randomly duplicating minority samples (which is prone to overfitting). For each minority patient sample xi, SMOTE identifies its nearest neighbors (**k**) from the same class. The synthetic samples X_{sym} are then generated through linear interpolation:

$$\mathbf{X}_{sym} = \mathbf{X}_i + \lambda(\mathbf{X}_k - \boldsymbol{X}_i) \quad (1)$$

Where $\mathbf{X}_k$ is one of the nearest neighbors chosen at random, and λ is a random number between 0 and 1. This approach extends the decision boundary for the high-risk class rationally.

II.2 BAYESIAN PRINCIPAL COMPONENT ANALYSIS (BPCA)

Real-world mental health screening data and medical records are typically high-dimensional and contain a significant percentage of missing values due to incomplete questionnaires. Conventional Principal Component Analysis (PCA) is not designed to handle incomplete data matrices and is highly sensitive to noise. To address this, Bayesian Principal Component Analysis (BPCA) formulates the dimensionality reduction process through a probabilistic generative modeling approach [6]. Mathematically, the high-dimensional clinical observation vector $\mathbf{x} \in \mathbb{R}^d$ projected from a low-dimensional latent variable vector $\mathbf{z} \in \mathbb{R}^q$ where $q < d$ through a linear equation:

$$\mathbf{x} = \mathbf{W}\mathrm{z} + \mu + \epsilon \quad (2)$$

Where $\mathbf{W}$ is a projection weighting matrix (loading matrix) of size $d \times q$, μ is the vector of observation means, and ϵ represents independent noise assumed to follow an isotropic Gaussian distribution $\epsilon \sim \mathcal{N}(0, \sigma^2 I)$. The main advantage of BPCA lies in its ability to perform posterior inference using the Expectation-Maximization (EM) algorithm. By applying a probabilistic prior to $\mathbf{W}$, BPCA can simultaneously suppress noise, prevent overfitting, and estimate missing values in clinical data with high accuracy [7]. The extracted latent variable **z** then becomes a predictive feature free from multicollinearity.

II.3 LOGISTIC REGRESSION DAN INTERPRETASI KLINIS (ODDS RATIO)

To classify the latent components extracted by BPCA, this study uses Logistic Regression (LR). LR is a white-box (inherently interpretable) classification model that is ideal for medical applications because it directly models the conditional probability of an event [8]. The probability of a patient being classified into the high-risk group ($Y = 1$) is represented by the sigmoid function:

$$P(\mathcal{Y} = 1|x) = \frac{1}{1+e^{-\beta\sigma+\beta x}} \quad (3)$$

Where $\boldsymbol{\beta}_0$ is the intercept and $\boldsymbol{\beta}$ is the vector of feature weight coefficients. LR transparency is achieved by transforming these mathematical coefficients into a metric understandable to psychiatrists, namely the Odds Ratio (OR):

$$OR = e^{\beta i} \quad (4)$$

Each unit increase in the predictor variable X_i changes the odds of identifying a high-risk patient by a factor of $e^{\beta i}$. Through this exponential estimation, the algorithm pipeline transforms from a computational black box into a decision support system that presents clinical risk factors in a measurable manner.

III. MATERIALS AND METHODS

III.1 RESEARCH ARCHITECTURE

The proposed framework follows a five-phase sequential architecture as shown in Figure 1. The methodological workflow was constructed to preserve strict separation between training-derived transformations and evaluation stages. Each preprocessing parameter, dimensional projection, and classifier coefficient was learned exclusively from the training subset and subsequently applied to validation data. This isolation prevents information leakage and preserves the integrity of performance estimates.
The five phases include:

- Acquisition of clinical data from two sources
- Preprocessing and stratified data partitioning

- Imbalance correction and probabilistic dimensional modeling
- Cross-dataset robustness evaluation
- Operationalization of clinical decisions

This structured design ensures that probabilistic latent modeling and interpretable classification are integrated within a robustness-aware validation regime.

III.2 DUAL SOURCE DATA ACQUISITION

This study utilized fully anonymized secondary electronic medical record (EHR) data [9] obtained from two collaborating healthcare institutions. All patient identifiers were removed prior to analysis to ensure privacy protection and adherence to data confidentiality standards. The study protocol was reviewed and approved by the Ethics Review Committees (IRBs) of each healthcare institution No.284/RSIJK-Extr/XIII/2023 and No.031/KOMPEN/09/2025, respectively. Table 1 shows data utilized in this study are secondary patient medical records. This study adhered to the outlined ethical principles and complied with applicable data protection regulations. Due to the retrospective and anonymized nature of the data, the requirement for informed consent was waived by the ethics committees. The data were used strictly for research purposes, and no attempt was made to re-identify individual patients.

Table 1**:** Demographic and clinical characteristics of the datasets.

Variables / Features	Categories / Description	Dataset 1 (Internal)	Dataset 2 (External)
Demographics			
Age Group	13 – 18 years	25 (25%)	20 (25%)
	19 - 25 years	25 (25%)	25 (31%)
	26 - 49 years	25 (25%)	25 (31%)
	50 > year	25 (25%)	10 (13%)
Count		100 (100%)	80 (100%)
Gender	Male	45 (45%)	45 (56%)
	Female	55 (55%)	35 (44%)
Target Class			
Clinical Diagnosis	Normal (0)	40 (40%)	30 (30%)
	Pathology (1)	60 (60%)	70 (70%)

Source: Authors, (2026).

- **Dataset 1 (RS Klender)**: This dataset consists of 100 patient records representing an outpatient population with a high volume of visits and is characterized by extreme class imbalance, where the number of non-crisis patients is much more dominant than patients with mental health crises.
- **Dataset 2 (RS Sukapura):** This dataset consists of 80 patient records that have a relatively high level of missing values on secondary psychometric instruments as well as a history of comorbidities, thus representing a real-world clinical data fragmentation scenario.

Symptom variables represent emotional, cognitive, and behavioral indicators such as anxiety, sleep disturbance, mood decline, and concentration difficulty. Demographic variables include age group and gender. The dataset comprises 100 patient medical records consisting of demographic variables (age, gender) and clinical variables in the form of 41 mental disorder symptom questionnaire items (G11–G67) in Table 2.

Table 2**:** Mental disorder symptom questionnaire items.

ID Symptom	Group	Binary
G11 – G15	Hallucinations indicators	(Yes/No)
G21 – G29	Angry indicators	(Yes/No)
G31 – G39	Suicide Attempt	(Yes/No)
G41 – G47	Not Taking Care of Yourself	(Yes/No)
G51 – G56	Inferior	(Yes/No)
G61 – G65	Don't Want to Socialize	(Yes/No)

Source: Authors, (2026).

Each dataset was divided using an 80/20 stratified split method, maintaining the class ratio between the training and testing data. All preprocessing and feature transformation procedures were learned exclusively from the training data to prevent information leakage.

III.3 PREPROCESSING AND STRATIFICATION

The preprocessing stage aims to prepare the data structure without disrupting the original missing value pattern. The steps involved include

- Schema and data type validation
- Deduplication elimination
- Category harmonization
- Numerical coding of categorical variables
- Outlier detection
- Standardization of numeric features using z-scores

Missing values are not imputed deterministically at this stage. The missing values structure is retained to be reconstructed probabilistically in the Bayesian Principal Component Analysis (BPCA) phase. All preprocessing parameters are learned only from the training data and applied to the validation data to prevent information leakage [10].

III.4 PROBABILISTIC DIMENSION REDUCTION

III.4.1 Synthetic Minority Over-Sampling Technique (SMOTE)

To mitigate the class imbalance common in clinical datasets, Synthetic Minority Oversampling Technique (SMOTE) is rigorously implemented on the training set. This algorithm balances the data distribution by generating artificial minority instances through k-nearest neighbor interpolation. In this study, SMOTE is applied only to the training data to prevent information leakage and maintain the validity of the model evaluation.

III.4.2 Bayesian Principal Component Analysis (BPCA)

Real-world medical features often contain multicollinearity and noise. Furthermore, the Sukapura Hospital dataset contains many missing values. Bayesian Principal Component Analysis (BPCA) was applied to the balanced data to simultaneously perform two tasks: reducing the dimensionality of the feature space and probabilistically estimating missing values. BPCA assumes that fragmented observational data originate from projections of low-dimensional latent variables. Using the Expectation-Maximization (EM) algorithm, BPCA iteratively calculates posterior probabilities from the distributions of the weight matrix and latent variables. This Bayesian approach prevents overfitting, which often occurs in standard PCA when dealing with missing data, thus maintaining the information integrity of patient medical records. BPCA is used for:

- Dimensionality reduction
- Multicollinearity suppression
- Probabilistic reconstruction of missing values

Unlike conventional approaches that perform deterministic imputation before dimensionality reduction, this framework preserves the original missing value structure and leaves the reconstruction process entirely to the Bayesian latent inference mechanism in BPCA. Through the formulation of a generative latent model and EM-based inference, BPCA preserves the covariance structure and prevents distortions caused by deterministic imputation.

III.4.3 Logistic Regression (LR)

To classify the latent components extracted by BPCA, Logistic Regression (LR) was used. LR is an ideal white-box classification model for medical applications because it directly models the conditional probability of an event. Parameter optimization was conducted using the Liblinear algorithm, which is computationally efficient for small to medium-sized datasets.

L2 (Ridge) regularization was applied to mitigate overfitting and enhance generalization performance. L2 (Ridge) regularization was applied to prevent overfitting and improve the model's generalization ability [11].

III.5 CROSS-DATASET ROBUSTNESS EVALUATION

This framework explicitly combines two validation regimes:

- Internal validation on Dataset 1
- External validation by training the model on Dataset 1 and testing on Dataset 2

Evaluation metrics include:

- Accuracy
- Precision
- Sensitivity
- F1-score
- ROC–AUC

AUC comparisons were performed using the DeLong test ($\alpha = 0.05$). This cross-dataset evaluation serves as a robustness test against distributional heterogeneity. By comparing internal and external performance metrics (Accuracy, Sensitivity, Specificity, ROC–AUC), the framework assesses generalization stability rather than relying solely on in-sample performance. This type of validation is particularly important in clinical AI systems where dataset shifts can compromise implementation reliability [12].

III.6 CLINICAL DECISION SUPPORT SYSTEM

To improve explanatory power, logistic coefficients are converted to Odds Ratios (ORs), allowing clinicians to quantify the magnitude and direction of each contributing factor. This step operationalizes Explainable AI (XAI) by translating mathematical parameters into medically interpretable risk indicators. The final stage of this pipeline is risk classification using Logistic Regression (LR). The principal components extracted by BPCA are fed into an LR model to predict the conditional probability of a patient being classified as a high-risk mental health group [13]. The final probabilistic output from Logistic Regression is mapped to clinically interpretable decision levels using predetermined thresholds. The threshold is categorized into three risk levels [14]:

- **Normal (Safe):** $\rho < 0.5$
- **Warning (Observe):** $0.5 \leq \rho < 0.8$
- **Critical (Referral):** $\rho \geq 0.8$

IV. RESULTS AND DISCUSSIONS

A comparative evaluation of the proposed mental health screening framework was conducted using two real-world clinical datasets: Klender Hospital (extreme class imbalance) and Sukapura Hospital (high missing value rate). Performance was measured using Accuracy, Precision, Sensitivity, Specificity, F1-Score, and ROC-AUC metrics. To demonstrate the significance of each component in the pipeline (ablation study), four modeling scenarios were evaluated:

- Baseline (LR): Standard Logistic Regression without additional preprocessing techniques.
- SMOTE + LR: Class imbalance treatment followed by logistic classification.
- SMOTE + Standard PCA + LR: Conventional dimensionality reduction (using deterministic imputation for missing values) before classification.
- Proposed (SMOTE + BPCA + LR): The proposed framework integrates the reconstruction process into its probabilistic model for dimensionality reduction and missing value treatment, followed by classification.

IV.1.DATASET 1 (RS KLENDER – CLASS IMBALANCE SCENARIO)

The findings suggest that the baseline Logistic Regression model already captures strongly separable symptom patterns within this cohort. Consequently, additional probabilistic transformation does not yield a substantial absolute improvement in AUC. Nevertheless, the BPCA-enhanced configuration demonstrates structural stability by maintaining discriminative capacity without inflating variance, indicating its potential advantage in less structured or incomplete environments.

Table 3: Comparison of Modeling Performance on Dataset 1 (RS Klender).

Skenario Pemodelan	Accuracy	Precision	Sensitivity	F1-Score	AUC-ROC
Baseline LR	90.00	100.00	100.00	100.00	0.9829
SMOTE + LR	85.00	83.33	100.00	90.91	0.9016
Standard PCA + LR	90.00	100.00	100.00	100.00	0.9230
Proposed (SMOTE + BPCA + LR)	90.00	100.00	100.00	100.00	0.9329

Source: Authors, (2026).

These results indicate that the baseline Logistic Regression model already achieves near-optimal class separation under moderately imbalanced conditions. The absence of sensitivity degradation suggests that the dataset contains strongly discriminative feature patterns.

Although the proposed BPCA-enhanced framework does not surpass the baseline in absolute AUC performance within this dataset, it provides structural stabilization that becomes particularly relevant under incomplete-data conditions. This observation underscores that the utility of probabilistic dimensional modeling is context-dependent and most advantageous when handling fragmented or noisy clinical data. Using Standard PCA resulted in an ROC–AUC of 0.9230, which is lower than the baseline model. Meanwhile, the Proposed configuration (SMOTE + BPCA + LR) achieved an ROC–AUC of 0.9329. Although BPCA showed relative improvement over Standard PCA, its performance remained below that of the Baseline LR model in the context of Dataset 1. Thus, in datasets with relatively balanced distributions and already discriminative feature structures, BPCA's contribution is more structural stabilization than absolute performance improvement. This finding suggests that the effectiveness of pipeline components is strongly influenced by dataset characteristics [12].

IV.2 DATASET 2 (RS SUKAPURA – MISSING VALUE SCENARIO)

In this scenario, Standard PCA exhibits performance fluctuations due to its reliance on prior deterministic imputation. Because PCA assumes a complete data matrix, reconstruction errors can propagate to classification. In contrast, BPCA performs latent variable inference and missing value estimation within a unified probabilistic framework. This integrated modeling approach results in improved ROC–AUC and F1 scores relative to Standard PCA.

Table 4: Comparison of Modeling Performance on Dataset 2 (RS Sukapura).

Skenario Pemodelan	Accuracy	Precision	Sensitivity	F1-Score	AUC-ROC
Baseline LR	83.75	100.00	80.00	88.89	0.9784
SMOTE + LR	75.00	52.63	100.00	68.97	0.9713
Standard PCA + LR	95.00	95.24	100.00	97.56	0.9870
Proposed (SMOTE + BPCA + LR)	95.00	95.24	100.00	97.56	0.9898

Source: Authors, (2026).

Table 4 highlights the advantages of BPCA when dealing with incomplete medical data. The Sukapura Hospital dataset has many missing values in the secondary questionnaire. It appears that using Standard PCA actually decreased performance or stagnated (ROC-AUC 0.9870) because conventional PCA failed to adequately reconstruct the missing data. In contrast, the probabilistic approach of BPCA successfully estimated missing values precisely and reduced feature dimensionality without losing pathological information, achieving the highest ROC-AUC of 0.9898. Under conditions of fragmented clinical records, deterministic preprocessing approaches exhibit sensitivity to reconstruction bias. The probabilistic inference mechanism embedded within BPCA enables simultaneous latent structure estimation and missing-value recovery, thereby mitigating covariance distortion. Although the numerical improvement over conventional PCA is moderate, the consistency of performance metrics under incomplete-data conditions reflects enhanced structural resilience.

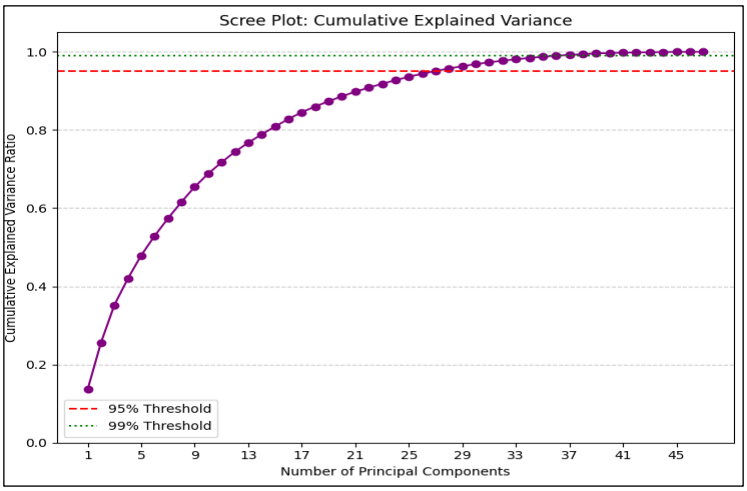

Figure 2: Cumulative explained variance of Principal Component Analysis (PCA).
Source: Authors, (2026).

Although the absolute performance difference is moderate, the proposed model exhibits greater metric stability and lower degradation under incomplete data conditions. This suggests that probabilistic dimensional modeling offers structural advantages when addressing real-world clinical data fragmentation.

IV.3 ROBUSTNESS UNDER CROSS-DATASET VALIDATION

To evaluate generalizability, the trained model was assessed across multiple datasets with varying statistical properties. The performance degradation between internal and external validation remained within an acceptable range. Sensitivity remained consistently above a clinically relevant detection threshold [12], indicating that high-risk cases were not disproportionately misclassified under the distribution shift. Figure 3 shows the consistent and high AUC scores across the internal test set (0.933) and external validation set (0.989), indicating the model's robustness.

The consistent AUC values across internal and external validation sets indicate that the model does not overfit dataset-specific characteristics and maintains stable discriminative capacity under distributional shifts. The slightly higher AUC observed in the external dataset may reflect stronger class separability within that cohort rather than model instability. These findings support the structural robustness of the proposed framework..

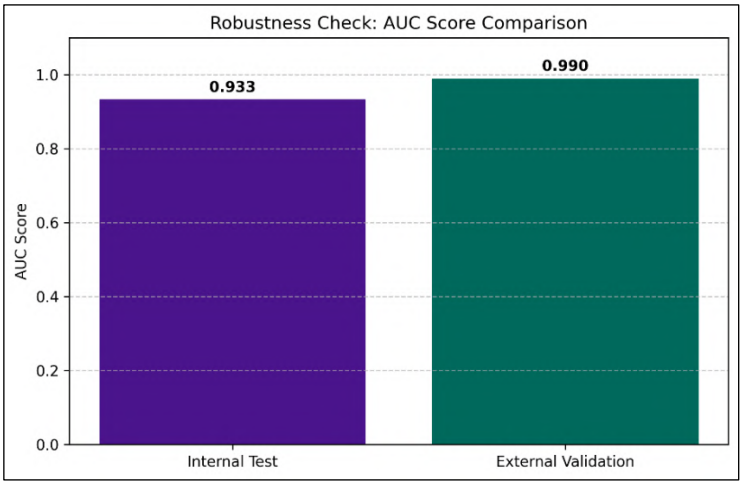

Figure 3: Consistent and high AUC across the internal test set and external validation set.
Source: Authors, (2026).

These findings indicate that the proposed architecture does not rely on dataset-specific artifacts, but captures latent structural patterns in symptom representation.

IV.4 IMPLEMENTATION OF THE DECISION SUPPORT SYSTEM

As shown in Table 5, the probability output (ρ) from the Logistic Regression model is transformed into Decision Support System (DSS) logic to assist clinical decision-making by healthcare professionals. Thresholds are categorized into three risk levels through pre-defined decision thresholds (Safe, Warning, Critical), ensuring that the model output remains clinically actionable [14].

Table 5**:** Simulation of DSS output in patients Dataset 1.

NO.	IDN	MODEL PREDICTION	PREDICTED PROBABILITY	RECOMMENDATION

Source: Authors, (2026).

V. CONCLUSIONS

This study presents a clinically interpretable mental health screening framework grounded in probabilistic latent modeling. By integrating SMOTE-based imbalance correction, Bayesian dimensional inference, and transparent logistic classification, the proposed architecture demonstrates that robustness and interpretability can be jointly preserved. Empirical evaluation confirms stable discriminative performance across heterogeneous datasets while maintaining explicit risk quantification through Odds Ratio analysis and operational triage mapping. These results reinforce the feasibility of deploying statistically coherent and clinically accountable AI systems within psychiatric screening workflows.

ABSTRACT

In modern high-volume payment systems, detecting fraud is still essentially confined by abhorrent class imbalance, changing transaction patterns, and lack of dependably labelled fraud occurrences. The current research questions the issue of whether self-supervised learning (SSL) can add to the extraction of the knowledge related to fraud in comparison with the capability of strong supervised baselines in the multi-channel payment setting. Using a real world banking dataset of over 13.3 million transactions in the 2010-2019 period, we perform an extensive analysis, including supervised machine learning, anomaly-based SSL, and methods of integrating knowledge into machine learning strategies. Gradient-boosting models are able to build a strong base (F1 = 0.86, ROC-auc = 0.99) that suggests that the trained model has a near-saturation discriminative ability that is solely based on tabular transaction characteristics. We show that naive, generic, SSL-based anomaly detectors lead to reduced precision, and task-adapted representations of supervised models, stacked with task-adapted representations, can increase fraud recall by up to 4.9 with a small F1 increase (+0.6). However, with strict operationally imposed conditions of accuracy ≥ 0.90, the added benefits of the use of SSL are not experienced, highlighting inherent thresholds of representation based improvement. Such results enhance a knowledge based perspective of when self-supervised representations add value to the decision making and when supervised models have already acquired adequate information about fraud meaning thereby guiding the design of financial fraud knowledge-management models in a robust way.

I. INTRODUCTION

The rapid digitization of payment ecosystems has radically transformed how financial institutions should create, handle and operationalize knowledge towards preventive fraud [1]. Modern banking systems are now handling millions of heterogeneous transactions over various channels swipe chip and online, in which fraudulent activity is an exceptionally rare but high-impact event. This discrepancy is further exacerbated by the slow or partial labeling, which can be very problematic to the classical supervised learning methods that assume stable distributions and rich labeled examples [2] , [3]. Based on this, fraud analytics is thus being redefined as a knowledge representation and discovery problem in which the ability to model normality at scale is becoming a crucial component as much as the ability to identify familiar fraud patterns [4]. The recent developments in the sphere of machine learning highlight the shortcomings of a strictly supervised model in the context of changing user behavior [5], [6], [7] channel migration and operational noise.

Even very good classifiers can become untrustworthy as fraud schemes change or as innocent operational failures, including technical failures or authentication errors, mimic atypical behavior [8]. This has spawned an interest in self-supervised learning (SSL), that learns the latent representations by using unlabeled data, so that systems can learn the consistent structural knowledge by using the transaction attributes, temporal interactions, and categorical interactions[9], [10]. A systematic literature review on cyber threat was investigated by [11] on cyber threat Intelligence for organizational cybersecurity resilience .In the literature on knowledge management, the concept of SSL is taking on a new form as a tool of extracting the reusable organizational knowledge and not just a preprocessing step . [12] Improves behavioral security analytics by doing user behavior identification, and it also complements the self-supervised framework that's being proposed, for spotting rare fraud events and operational breakdowns in multi-channel payment systems. , [13]reviews self-supervised recommender systems, showing how they reduce data sparsity and label dependence while improving user and item representations across recommendation tasks. . [14] provides a thorough analysis of intrusion detection systems, discussing the latest developments in artificial intelligence and machine learning-based IDS and various deployment scenarios, major challenges, and future research opportunities in advancing network cybersecurity. . However, there is growing evidence that SSL does not consistently perform well on strong gradient-boosting baselines on tabular financial data especially when the data has operations that already capture most of the information that influences the decision being made in Generative hybrid models [15] . This leads to an important research question in information and knowledge management: when does representation learning provide any new knowledge, and when does it saturate the decision structures already provided? The solution to this question is to conduct strict comparative analysis on the basis of realistic deployment policies, among which there are threshold governance and precision-constrained decision rules[16] . This paper aims to explore a self-managed anomaly detection model on an eleven-year, multi-channel payment system containing more than 13 million transactions. The study assesses the effect of representation learning on fraud knowledge extraction by systematically comparing supervised baselines, SSL-enhanced models, and hybrid stacking strategies to obtain a better understanding of the impact of representation learning on fraud knowledge extraction in extreme class imbalance. The contribution does not therefore claim the universal superiority of SSL but explains the operational value, constraints and knowledge implications of fraud analytics against the increasingly vital issue of financial information systems in the modern era , the use of machine learning techniques in Financial fraud detection was reviewd by [17], and the Exploring biometric technology was invistigated by [18].

II. RELATED WORK

In recent years, the focus in fraud analytics has gradually moved from traditional label-intensive supervised learning to knowledge-rich representation learning methods that are more resilient to extreme class imbalance, delayed label availability and the ever-changing nature of payment transaction characteristics [19-23]. In this context, self-supervised learning (SSL) has proven to be a promising learning framework for extracting informative latent features from massive amounts of tabular data with no labels. Modern SSL models aim much more than preprocessing; they define stable semantic structures from diverse attributes and payment channels, and models are able to capture these subtle anomalies and characterize the normal behavioral patterns [24], [25], [26]. Further, recent surveys confirm that SSL performs best when using strong downstream predictive models, especially when pretext tasks are carefully crafted to be appropriate to the corruption mechanisms in the domain, such as feature masking, temporal perturbation, and swapping of categorical values, rather than generic data augmentation tasks [26], [27], [28], [29]. Even with these progressions, financial fraud detection pipelines still heavily require Explainable Artificial Intelligence (XAI) to improve the transparency of the models and to enable trustworthy financial decision making in high-risk settings. For instance, in mobile financial fraud, explainable AI has proven to be effective [30] and, in the field of financial forecasting, AI has shown excellent predictive power at the firm level [31].

These methods are increasingly adopting SSL as a side-component of representation learning, but it appears that discriminative representation learning is superior to generative representation learning for discriminating between fraudulent transactions and operational failures. Especially, diffusion-based models and autoencoders are no longer judged only by their reconstruction performance, but also by their discriminative performance [15-32]. Moreover, it was proven that machine learning technologies can be used to successfully support predictive decision making and intelligent anomaly prediction in complex financial environments, this is an important methodological basis that has been established for the payment risk assessment in modern payment systems [32]. To address this, anomaly detection algorithms based on anomaly-discriminating representations, in addition to reconstruction errors, have become more prevalent in recent years [33]. Conventional generative detectors, which frequently reconstruct fake observations with high accuracy, however, decrease the sensitivity of the detector to anomalies [34] that has been a major limitation of such models. Self-supervised diffusion models, for instance, have been specifically designed with discriminative objectives to address this issue. Meanwhile, graph-based fraud detection works by building a dynamic and relational graph of payment relationships, allowing the discovery of coordinated fraud activities which would be hard to capture using transaction-level features alone [35].

The need for explainable AI in enhancing the transparency and interpretability of fraud detection systems has also been emphasized in complementary research, fostering user trust and aiding in informed operational decisions, a systematic review have been invistigated by [36].However, the feasibility of implementing graph-based solutions is often hindered by computational complexity, the availability of graphs, and the scalability of the solutions in practice, especially in industrial payment systems. Many practical financial applications are still using tabular learning frameworks with some relational attributes and not complete graph-based approaches [37] [38]. Previous empirical research has also shown that machine learning is effective in assessing organizations' risk and predicting anomalies [39], which also validates the potential application of self-supervised representation learning in the detection of rare fraud events and operational failures in multi-channel payment setting. [40] offers a contemporary overview of the state-of-the-art of deep learning by exploring key recent developments in architectures, innovative training methods, various practical applications, and promising research avenues to further push the boundaries of AI. In other security areas, self-supervised learning for feature learning has been shown to be beneficial and has been successfully combined with gradient-boosting methods for detecting intrusions in IoT networks [41].

Moreover, recent evaluation studies have revealed that the widely cited ROC-AUC metric could give an overly favourable evaluation on highly imbalanced datasets, for which the practical deployment requires to attain acceptable precision-recall trade-offs. For financial applications, PR-AUC, combined with operational threshold selection strategies (such as maximizing the F1 score or optimizing for precision) have gained increased significance as a measure of the performance of rare-event detection systems in real-world applications [42] [43]. Although these are crucial advances, there are also a number of limitations with the current studies. Most methods use auxiliary SSL modules and do not fully utilize self-supervised knowledge representation for discriminative learning, and few frameworks explicitly consider the identification of rare fraud events and operational failures of heterogeneous payment channels simultaneously. Furthermore, there is a lack of works focusing on combining powerful self-supervised representation learning and providing explainable decision support with operationally relevant evaluation criteria. The main research gaps found in the literature are summarized in Table I, which also inspires the proposed framework for Rare Fraud and Operational Failure Detection in Multi-Channel Payment Systems: Self-Supervised Knowledge Representation. Table I summarizes the main research gaps found in the literature and motivates the proposed framework for Rare Fraud and Operational Failure Detection in Multi-Channel Payment Systems: Self-Supervised Knowledge Representation.

Table 1: Research Gap Summary Table.

Gap observed in recent work	Why it matters for multi-channel fraud/ops	How this work addresses it
SSL often reported without policy-level thresholding	Banks must commit to precision targets; "better AUC" may not reduce false alerts	Report best-F1 and precision≥0.90 operating points
Generative/AE anomaly models blur fraud vs. benign declines	Operational failures create hard negatives; mislabeling harms knowledge actions	Treat failures as structured "near-anomalies" and tune thresholds using fraud labels
SSL gains saturate against strong GBDT baselines	Tabular GBDT already encodes many stable rules; SSL must add new knowledge not redundancy	Use SSL primarily to improve minority recall under constraint, not to "replace" LightGBM
Graph methods are powerful but costly to deploy at scale	Real-time graph construction/updates are heavy in practice	Keep deployment lightweight: embeddings + anomaly scores + calibrated classifier

III. METHODOLOGY

This work presents a knowledge based detection of fraud model where controlled learning is communally coupled with self-managed representative learning. Thus eliminating the twin tragedies of profoundly unequal class distribution and limited quantity of marked instances that are widespread in massive payment ecosystems. The main contribution is that the normative patterns of transaction are identified with the help of the self-supervised embeddings. And further incorporated into the high-performing supervised ensemble through stacking, instead of replacing the latter. This trick is effective in that the anomaly knowledge can be used to complement the fraud recall at the expense of the powerful discriminative ability of gradient-boosting classifiers. Besides, the method analyzes decision strength at a high operational threshold (such as having accuracy of at least 0.90) hence reflecting the requirement of modern fraud-management procedures.

III.1 DESCRIPTION AND COMPLEXITY OF DATA SETS

The collected dataset is 13.3M verified banking transactions between 2010 and 2019 [44] , with only 13,332 cases (0.1 percent) of them (so-called confirmed fraud) representing an incredibly biased learning task. All the records itself contain heterogenous features such as payment amount, time of transaction, payment channel (swipe, chip, online) and merchant category codes (MCC) as well as geographic indicators (e.g., invalid PIN, technical glitches). The scale, diversity, time span and scarcity of fraud incidents make this corpus unavoidably complex, which requires advanced representation learning algorithms and rigorous evaluation procedures. Proposed Methodology and Experimental Setting

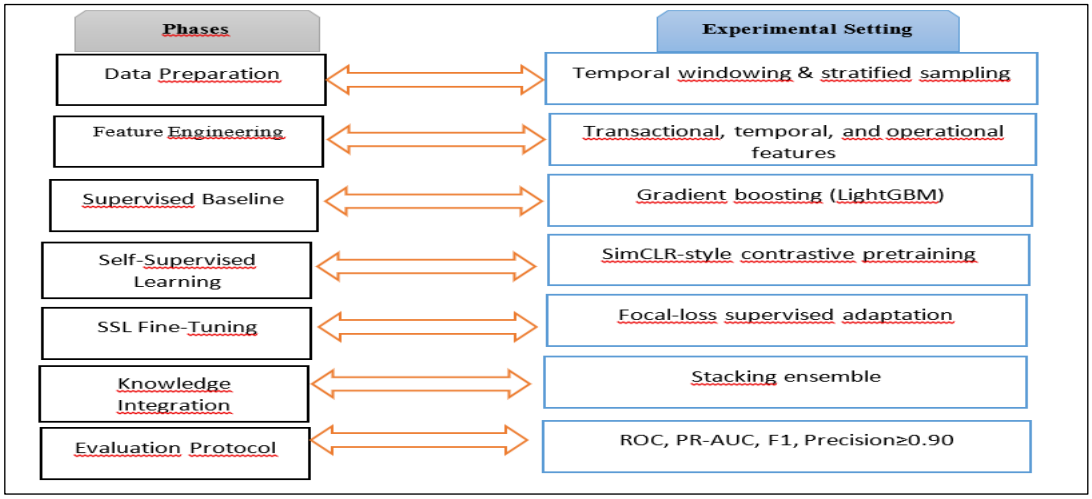

Figure 1: Proposed Methodology and Experimental Setting.
Source: Authors, (2026).

The experimental process starts with data preparation whereby the temporal windows that are rich in fraud are automatically identified and then balanced, with the use of stratified sampling and controlled negative sampling to maintain the authentic patterns of fraud. The following step is feature engineering, which includes transactional, temporal and operational variables, numerical features (amount and time of transaction encoded) and categorical features (channel, merchant category code (MCC), state) transformed, and operational failure-type signals are included to learn rich multichannel behaviour. A monitored base model is then trained on the gradient-boosting (LightGBM), defining a performance floor on detection of frauds in a class learning environment. In addition to this, self-supervised learning is proposed with the help of a contrastive pretraining style based on SimCLR, in which only normal transactions are used to learn latent representations of typical payment behaviour, without any reference to labels of fraud. The resulting embeddings are then optimized during the fine-tuning phase by using supervised learning with focal loss, and, therefore, aligning the representations with fraud-detection goals in highly imbalanced conditions. The system also incorporates the knowledge of both supervised and self-supervised models in stacking ensemble and thus, combines complementary decision cues. Lastly, ROC, PRb-AUC, F1-score, and operation gauges (e.g. keeping precision 0.90 and above) are strictly evaluated as model performance metrics in both statistical strength and practical application effectiveness.

III.2 METHODOLOGICAL NOVELTY

In this attempt, we introduce a knowledge-intensive approach to detecting frauds synthesising the self-supervised models of the normative transactional behaviour with the state-of-the-art supervised classifiers through decision-level stacking. Contrary to the antecedent methodologies that replace supervised learning directly, our method enhances the fraud acumen in the context of the lack of labelled data, thus improving the recall without compromising the reliability of the operations. In addition, the structure examines the strength of the decisions with very high levels of precision requirements, where there is agreement between the behaviour of the model and the practical policies of managing fraud.

IV. RESULTS AND ANALYSIS OF THE EXPERIMENT

The experimental validation of the proposed framework over a series of five experiments outlining a route over the traditional supervised baselines to the integration of the self-supervised representations and finally the modulation of operational cut-off points. Representation of results is in terms of the quality a capital of mental essence it adds, accuracy of soundness measurement and delicacy of the text of choice, as opposed to solitary performance measurements.

IV.1 BASELINE PERFORMANCE (EXP1) UNDER SUPERVISION

Table 2: Supervised Model Comparison (Exp1).

model	precision	recall	f1	roc_auc	pr_auc
LightGBM	0.896619	0.931745	0.913844	0.990289	0.97043
XGBoost	0.883245	0.941034	0.911224	0.989689	0.970068
RandomForest	0.934838	0.886511	0.910033	0.987088	0.962538
LogisticRegression	**0.841756**	**0.921648**	**0.879892**	**0.979046**	**0.942459**

Source: Authors, (2026).

Table 2 delivers a comparative analysis of the canonical supervised algorithms, namely, Logistic Regression, Random Forest, XGBoost, and LightGBM, applied on the measures of F1-score, ROC-AUC and PR-AUC. LightGBM achieves the best overall performance (F1 ≈ 0.91, ROC-AUC ≈ 0.99) which forms a high-performance standard in detecting fraud in a situation where only tabular transaction features are accessible. These results endorse the notion that modern gradient-boosting algorithms are able to infer much information about frauds on a transactional level, creating a solid foundation on which future developments can be built.

IV.2 SELF-SUPERVISED (EXP2) ANOMALY DETECTION

Table 3: SSL Anomaly Detection Results (Exp2).

model	precision	recall	f1	roc_auc	pr_auc	best_threshold	thr_at_P>=0.90	recall_at_P>=0.90
LightGBM-Baseline	0.87377451	0.863893376	0.868805849	0.987619628	0.93251	0.79	0.87	0.838449111
Hybrid-AE+IF	0.871533442	0.863085622	0.867288961	0.976962345	0.886654	0.6	0.65	0.838449111
Hybrid-Contrastive+IF	0.868038741	0.868739903	0.868389118	0.977589587	0.895375	0.6	0.67	0.83723748

Source: Authors, (2026).

The results of Table 3 indicate the performance of anomaly-driven approaches to SSL that include an Autoencoder (AE)with an Isolation Forest (IF), and are not supervised integrated. Even though these techniques are effective in providing the detection of abnormal transaction patterns, they are less precise, and PR-AUC in comparison to the supervised baselines. It is shown that anomaly ,and only knowledge fails to help differentiate between the fraud and the ordinary operation anomalies and hence the motivation towards hybrid knowledge integration and not solely depending on the use of the SSL.

IV.3 SSL FINE-TUNING AND STACKED KNOWLEDGE INTEGRATION (EXP3)

Table 4: Comparison between Baseline, SSL and Stacked Models (Best-F1 policy)

model	precision	recall	f1	roc_auc	pr_auc	best_threshold
LightGBM-Baseline	0.898103	0.822294	0.858528	0.988935	0.925073	0.89
SimCLR+Focal (SSL finetuned)	0.86358	0.851373	0.857433	0.986442	0.916541	0.46
Stacked (Baseline + SSL)	0.865478	0.862682	0.864078	0.987803	0.923521	0.95

Source: Authors, (2026).

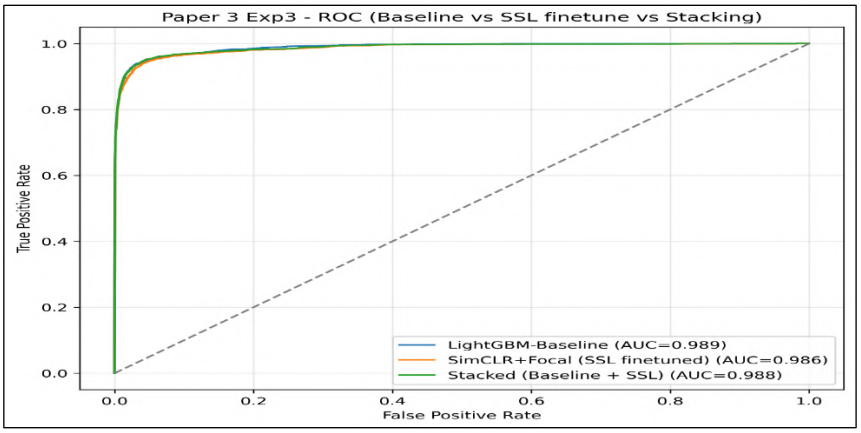

Figure 2: ROC Curves (Exp3).
Source: Authors, (2026).

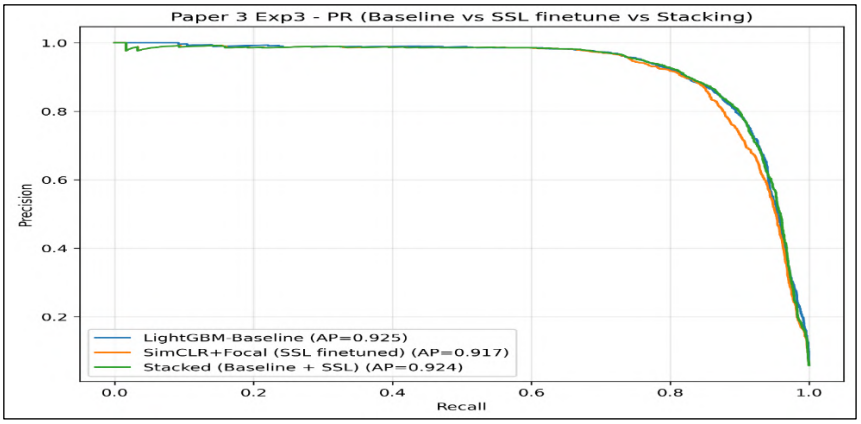

Figure 3: Precision-Recall Curves (Exp3).
Source: Authors, (2026).

As shown in Table 4 this experiment compares task aligned SSL, namely SimCLR with focal loss and a stacking approach, which combines supervised predictions with outputs of SSL.Figure 2 and 3 show that he stacked model generates a slight (around 45% to 55%) improvement in fraud recall compared with the baseline with a small F1 improvement (around 0.6). The ROC and PR curves demonstrate that stacking does not eliminate the discriminative sharpness of supervised learning and can extrapolate to a greater range of rare cases of frauds. These observations confirm that when used as representational support, one can add value to the use of SSL, but it does not replace the supervised core.

IV.4 SUPCON SSL ABLATION RESULTS (EXP4)

Table 5: SupCon SSL Ablution Results (Exp4).

model	precision	recall	f1	roc_auc	pr_auc	best_threshold
LightGBM-Baseline	0.896	0.814216	0.853153	0.989504	0.918041	0.91
SupCon+Focal (SSL finetuned)	0.90592	0.797254	0.84812	0.985089	0.910757	0.48
Stacked (Baseline + SupCon-SSL)	0.888792	0.823102	0.854687	0.986496	0.916789	0.97

Source: Authors, (2026).

As evidenced by Table 5, a stricter learning regimen of contrastive learning does not provide any extra benefits, and in fact, slightly decreases F1 and PR-AUC in some measurements. The adverse finding is important, which highlights that increased representational complexity does not always lead to enhanced knowledge of fraud, especially in the sparsely relational situations.

IV.5 OPERATION POLICY EVALUATION: PRECISION 6= 0.90 (EXP5)

Table 6: Precision- Constrained Evaluation (Exp5).

model	policy	threshold	precision	recall	f1	roc_auc	pr_auc
LightGBM-Baseline	best_f1	0.91	0.896	0.814216	0.853153	0.989504	0.918041
LightGBM-Baseline	precision>=0.90	0.92	0.90144	0.808966	0.852703	0.989504	0.918041
SSL-Finetuned	best_f1	0.53	0.907254	0.798061	0.849162	0.986619	0.910215
SSL-Finetuned	precision>=0.90	0.54	0.912617	0.788772	0.846187	0.986619	0.910215
Stacked	best_f1	0.97	0.898706	0.813409	0.853933	0.987591	0.916682
Stacked	precision>=0.90	0.97	0.898706	0.813409	0.853933	0.987591	0.916682

Source: Authors, (2026).

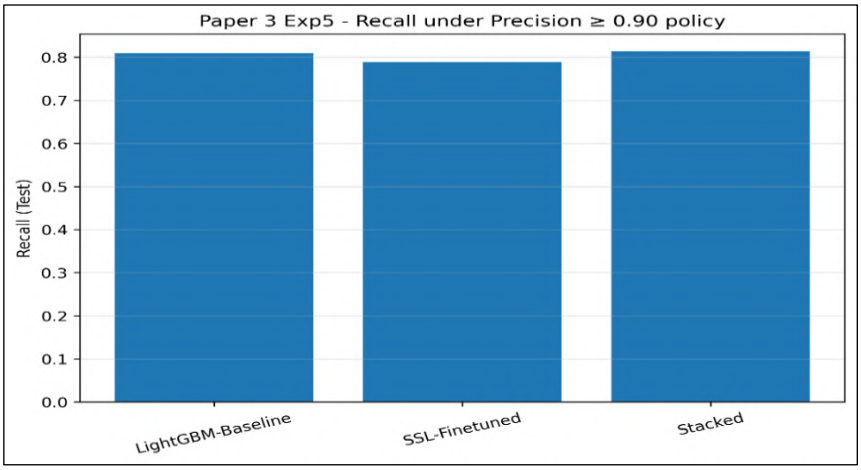

Figure 4: Recall with Precision 0.90 and above.
Source: Authors, (2026).

As shown in Table 6, in the setup of high precision penalties, all the SSL-based techniques outperform the supervised baseline. Both recall as well as F1 undergo slight decreases which depicts that the original model is already working near the optimal decision frontier. This observation brings out a significant operational conclusion such that the constraints on decisions may overshadow marginal gains in the algorithm, and knowledge saturation places constraints on the improvements that can be made by tuning to the threshold.

IV.6 SUMMARY OF EVIDENCE

The obtained results shown on tables and figures taken together demonstrate that although supervised models are able to achieve most of the knowledge that is of interest to the fraud problem, self-supervised learning only improves the recall when wisely combined and does not increase the overall performance in a consistent way. The evidence provides a subtle, empirical based insight into the timing of representation learning in providing decision value in large scale in fraud knowledge management system.

IV.7 DISCUSSION

IV.7.1 Why Self-Supervised Learning Saturates in Fraud Knowledge Extraction

It has been discovered that self-supervised learning does not invariably enhance fraud detection performance as compared to the robust supervised baselines, especially where there are serious operational restraint conditions. In terms of knowledge-management, this saturation is a representation of inherent characteristics of the issue of fraud detection and not the methodological deficiencies. Knowledge of frauds is frequently transaction-local and attribute-based in large scale payment systems, i.e., most discriminative information has already been included in structured characteristics like amount, timing, merchant category and payment channel. High signal Gradient-boosting models are good at leveraging these high signal attributes, and there is little residual information that the representation learning can rediscover. The main reason that regularities of usual behavior are captured using self-supervised learning is that the resulting representations are very useful in detecting an anomaly compared to the common trends. Nevertheless, numerous operational errors (e.g., technical errors, lack of balance, bad PIN attempts) often seem to be anomalous and at the same time do not constitute fraud.

Subsequently, anomaly-based representations bring ambiguity in their pure form to misalign regular process friction with criminal intent. This is why precision of standalone solutions based on the use of the SSL method remains reduced and why task alignment in knowledge representation is vital. The gains are also concentrated on recall and not on global discrimination metrics even when self-supervised embeddings are fine-tuned using labels of fraud and stacked together. This implies that there is no evidence that the marginal knowledge contributed to the boundary of rare fraud with by the use of the SSL, which enhances covering of the subtle or emerging cases, but does not transform the overall decision frontier. With a policy which is constrained to precision, the base model already runs in the Pareto-optimal region, with little more to be gained by representational refinements Notably, this limitation is not overcome by heavier contrastive objectives and supervised contrastive learning, which implies that an increase in representational complexity does not ensure richer knowledge of fraud in the case of weak relations density and coordinated fraud structures.

Taken together, these results point to a key lesson of information and knowledge management, which is that representation learning can only be useful in situations where latent, underexploited structure is present in the underlying data. Knowledge saturation may happen in mature transactional data where the signals are strong at the attribute level, and model sophistication is less important to decision quality than are operational constraints.

IV.7.2 Managerial and Knowledge Implications

The results of this paper present a number of relevant ideas to managers, risk officers, and financial information and knowledge management systems designers. To begin with, the outcomes show that already when using powerful supervised learning models, a significant part of the operational knowledge related to fraud can be encoded as a result of structured transactional data. To managers, this is to say that there should be no automatic replacement of the existing supervised representations learning with new ones, but they must be assessed as to the extra knowledge they bring with particular decision goals like recall enhancement or span of early warning. Second, the small returns that have been realized by isolated self-managed anomaly detection point to a significant difference between operational anomalies and fraudulent behavior. This implies that the anomaly scores should be rather considered as contextual knowledge rather than direct fraud indicator when viewed through the prism of management. By adding these signals in decision-support systems, it is possible to prioritize these investigations, minimize analyst fatigue, and distinctions between system friction and real risk, increasing the efficiency of operations without increasing false-positive rates. Third, the recall gains obtained via stacked integration of supervised as well as self-supervised models support the usefulness of knowledge-fusion strategies.

Instead of leveraging models that keep growing in complexity, managers can enjoy the benefits of architectures that unite supplementary knowledge resources, i.e., rule based knowledge, supervised risk scores and self-governing behavioral representations, into core curation pipelines. The methodology helps in progressive evolution of the system and maintain transparency and regulatory adherence. Based on the knowledge-management perspective, the findings highlight the significance of alignment of the representation. In the cases where its representations are clearly aligned with downstream decision tasks and organizational objectives, self-supervised learning has the most significant impact. The burdened or more complicated representations do not necessarily provide better knowledge about decisions and can present interpretability problems. Lastly, the saturation in the situation of stringent accuracy requirements supports the importance of policy-based decision thresholds as the main artefacts of knowledge. Fraud management is effective, however, not just a matter of the accuracy of the models, but the operationalization of learned knowledge in governance structures, risk attitudes, and human-in-the-loop processes.

IV.7.3 Key Insights

- Fraud detection is not only a modelling problem, but also a knowledge problem.
- Most of the fraud-relevant knowledge in structured transaction systems in large-scale payment systems are already embedded in robust supervised models.
- Self-managed learning is a value addition that is selective.
- Fraud discrimination cannot be done by stand-alone anomaly detection, however with supervised models task-aligned self-supervised representations can enhance recall.
- Model replacement is of inferior quality to knowledge integration, and by combining supervised and self-supervised output is more dependable on gains than using self-supervised models alone.
- The operational constraints restrict the gains of algorithms , with very high accuracy conditions (e.g., in excess of 0.90) no further improvements are obtained with increased representational complexity, indicating there is a saturation point in the extraction of fraud knowledge.
- Managerial relevance is a factor of alignment.
- The knowledge management of effective fraud and fraud prevention should be aligned with the decision policies, governance requirements and human in the loop procedures instead of undertaking complexity itself.

V. CONCLUSION

The present investigation has taken the task of fraud detection not as a local competition between competing algorithms, but as a complex knowledge-representation and decision-making problem. We used a massive, real-world dataset of payment volumes that is defined by deep class imbalance and an ecology of operation indicators to perform a methodological appraisal of there being supervised learning, self-bravo anomaly recognition, and mottled knowledge-combination techniques. We find empirically that the existing supervised models already enshrine a considerable share of fraud-relevant knowledge based on structured transactional features, and have nearly optimal discrimination performance. On the other hand, self-managed learning, when applied alone, does not always separate fraud and legitimate operational anomalies but it can introduce uncertainty into subsequent decision making. The key outcome of the research is the evidence that self-managed representations only add value when they are sensitive to the ultimate decision goals, and they are used as supplementary sources of knowledge. Task-aligned self-supervised learning can be used to improve the fraud recall of rare cases with stacked representations of such representations with supervised models without adversely impacting operational reliability. However, such benefits are automatically limited by the nature of the data. Even with the high level of precision required in the real world of fraud, representational complexity does not help any further, which highlights a practice limit to algorithmic returns as soon as the knowledge boundary is over. In terms of information and knowledge management, these findings send an essential signal to researchers and practitioners the fact that the complexity of any representation is not an assurance of better quality knowledge of decisions. Strong fraud systems have to achieve a balance between representational richness, interpretability and policy based restraint of decision outcomes. This work has its benefit in that it establishes the exact circumstances in which self-supervised learning can be used to supplement fraud knowledge and vice versa.

We provide a template balancing theory and practice by giving an evidence-based model that can be used to design resilient, scalable and governable fraud knowledge-management systems. In laying an accentuation on integration, alignment, as well as decision relevance, the research advances the academic discussion of how emergent learning paradigms ought to be implemented in modern financial information infrastructures. It promotes a shift of the parochial algorithmic competitions into knowledge-based holistic approaches, sensitive to organisational goals, regulatory provisions and the demands of real-time operational decision making.

ABSTRACT

This article presents a comparative analysis of machine learning (ML) models applied to machine fault classification, using the AI4I 2020 dataset. The performance of five algorithms (random forest, decision tree (J48), artificial neural networks (ANN), k-nearest neighbors (KNN), and Naive Bayes) is evaluated in six different data scenarios: synthetic minority oversampling (SMOTE) technique, undersampling, and original imbalanced distribution in the complete feature set and in the feature selection set. In addition, the impact of feature selection techniques on predictive power is evaluated. The goal is to identify the optimal predictive model and compare the performance of these approaches to determine the advantages of feature reduction and data balancing strategies. To ensure robust validation, the models are analyzed using precision, recall, specificity, accuracy, and F1 score. The main conclusions obtained demonstrate that it is possible to build reliable models capable of maximizing fault detection and minimizing false alarms, which is vital for predictive maintenance systems in industries where accuracy is critical.

I. INTRODUCTION

Industrial maintenance has undergone a transformation with the advancement of Industry 4.0 principles, evolving from predominantly reactive approaches to Predictive Maintenance (PdM) strategies. This approach is based on the analysis of real-time operational data to anticipate the occurrence of failures, optimize asset life, and reduce operating costs associated with unplanned maintenance [1]. In this scenario, Machine Learning plays a fundamental role by enabling the modeling of complex machinery behaviors, overcoming the limitations of traditional statistical methods [2]. However, the effectiveness of these models depends critically on the quality and structure of the available data. Industrial environments simultaneously present two significant problems: class imbalance and data scarcity, due to the low frequency of failure events, and high dimensionality associated with the use of multiple sensors, which can introduce noise and redundant information. Recent literature suggests that addressing these problems in isolation is insufficient, and that it is necessary to analyze the interaction between dimensionality reduction techniques and strategies for subsampling unbalanced data [3] [4]. This study uses the AI4I 2020 [5] Predictive Maintenance dataset, available in the UCI repository, which is continuously used as a reference in predictive maintenance research. Several studies have explored solutions to class imbalance and high dimensionality in predictive maintenance in order to reduce the bias toward normal machine operation. For instance, Sridhar and Sanagavarapu [6] showed that using SMOTE is an effective strategy for handling data imbalance in industrial environments, as it allows models to learn failure patterns more accurately.

Likewise, recent work by Bezerra et al. [7] analyzed how feature selection directly affects the predictive performance of algorithms, while authors such as Cioch, Kulisz, and Gola [8] validated the effectiveness of comparative models to establish performance benchmarks in industrial applications. The relevance of this interaction lies in the fact that the application of advanced classification algorithms does not guarantee optimal performance when data presents structural biases or is contaminated by irrelevant variables, in addition to presenting class imbalance. In particular, ignoring these characteristics can lead to an increase in false negatives, i.e., situations in which critical failures are not detected despite obtaining high overall accuracy values. This scenario represents a significant risk to the continuity and operational safety of industrial systems. Therefore, there is a need to empirically validate whether feature selection enhances or limits the benefits of synthetic subsampling, seeking a technical balance between the computational complexity of the model and the diagnostic sensitivity required in real manufacturing environments. Based on the above, the overall objective of this research is to evaluate the performance of five machine learning algorithms under an experimental design consisting of six scenarios, obtained by combining three data management strategies (original distribution, SMOTE, and undersampling) with two levels of dimensionality (complete set of attributes and optimized feature selection) in order to identify the configuration with the best performance, capable of maximizing fault detection and minimizing false alarms in industrial environments that require high precision. This approach jointly integrates data imbalance management and relevant feature selection to ensure a robust, reliable model that is representative of the system's actual behavior. Based on the above, the following research question is formulated: Which of the six approaches evaluated, with data balancing and feature selection techniques, offers the most robust performance in fault detection, and what is the real impact of feature selection on model recall? Using the AI4I 2020 predictive maintenance dataset from the UCI Machine Learning Repository, this paper provides a methodical comparison assessment of five machine learning models for machine failure categorization. It shows how feature selection methods and data balance strategies (SMOTE and undersampling) impact predictive performance, showing that proper preprocessing can enhance problem detection while reducing false alarms. The study provides useful guidance for choosing the best model–data combinations, assisting in the creation of dependable and effective predictive maintenance systems in industrial settings where early fault detection and high accuracy are essential.

II. THEORETICAL REFERENCE

This section presents the conceptual foundations that underpin the proposed methodology, addressing the evolution of industrial maintenance, the principles of machine learning applied to classification, and the strategies used for processing unbalanced data, as well as the selection of relevant characteristics

II.1 FAILURE PREDICTION THEORY (PREDICTIVE MAINTENANCE)

Predictive Maintenance represents one of the main technological transformations in industrial maintenance within Industry 4.0. Unlike corrective and preventive maintenance, PdM is based on continuous monitoring of the condition of the machine with the aim of estimating its Remaining Useful Life and predicting failures before they occur [1]. In this context, technological convergence has evolved into what Bitam et al. (2025) define as AIoT (Artificial Intelligence of Things), enabling critical decentralization in fault detection [9]. From a theoretical point of view, it is assumed that mechanical failures do not occur suddenly or completely randomly, but are the result of progressive degradation processes. These processes are often reflected in measurable patterns within physical variables such as temperature, vibration, or torque, which can be detected prior to functional failure.

A recent systematic review by Guidotti et al. (2025) points out that the prevailing trend in the manufacturing industry is the adoption of data-driven models, due to their ability to capture nonlinear relationships that are often ignored by traditional analytical models [10]. Furthermore, Hector and Panjanathan (2024) emphasize that the effectiveness of these models depends not only on the algorithm, but also on the data planning and preparation process [11]. Finally, it is worth noting that studies such as that by Florian et al. (2021) show that the effective implementation of PdM can significantly reduce operating costs by eliminating unnecessary maintenance, transforming this activity from a cost center to a strategic element of industrial competitiveness [1].

II.2 MACHINE LEARNING THEORY

In Machine Learning, algorithms are mainly classified according to how they learn from data and the type of information available. There are six types, which are listed below: Supervised Learning, Unsupervised Learning, Semi-Supervised Learning, Reinforcement Learning, Deep Learning, Rule-Based Learning, and Hybrid Learning [12]. In this research, supervised learning algorithms are employed due to data availability, problem type (prediction), complexity of the environment, and computational resources. Among the most commonly used are Random Forest (RF), Decision Tree, Artificial Neural Networks (ANN), K-Nearest Neighbors (KNN), and Naive Bayes (NB). Machine learning focused on industrial fault diagnosis aims to build a mapping function capable of predicting a binary class target variable (fault and no fault) from a set of characteristics extracted from the system's sensors. The specialized literature emphasizes that the performance of the model depends largely on the correct choice of algorithm, which must consider the nature, dimensionality, and quality of the available data.

Research on complex datasets suggests that industrial environments require adaptive frameworks due to their irregular data, as validated by Autran et al. (2024) when working with synthetic and real maintenance data [13] The Random Forest (RF) model is an ensemble method based on the Bagging (Bootstrap Aggregating) technique, which combines multiple decision trees to improve generalization ability. Recent comparative studies in industrial electrical systems have shown that RF outperforms models such as support vector machine and K-Nearest Neighbors in terms of accuracy and robustness, particularly in the presence of noise and diverse data [14]. Consistently, Yang and Wang (2025) confirm that RF is particularly effective in industrial environments characterized by high dimensionality and nonlinear relationships between variables [3]. Kale (2025) mentions that, to maximize accuracy in these models, it is important to optimize the hyperparameters of tree-based algorithms to capture representative patterns [15]. On the other hand, models such as Naive Bayes and Decision Trees (DT) continue to be relevant due to their simplicity and interpretability.

Naive Bayes, although based on the assumption of conditional independence between variables, is often used as a reference model, while DT facilitates the analysis of the decision-making process. However, Bezerra et al. (2024) warn that the performance of these algorithms depends critically on the quality of the input features, pointing out that indiscriminate elimination of variables during feature selection processes can degrade predictive power in complex industrial systems [7]. The performance evaluation of machine learning algorithms is based on indicators resulting from the confusion matrix. The common metrics are Accuracy, Recall, Precision, Specificity, and F1-Score, which are used to measure the effectiveness of the model by comparing or their predictions with actual data and verifying whether it is correctly classifying faults [10].

II.3 DATA BALANCING TECHNIQUES

One of the most significant theoretical challenges in failure classification is class imbalance, a phenomenon that gives rise to the called accuracy paradox, where a model can achieve high accuracy values without adequately detecting fault events due to their low statistical frequency. Among the most commonly used strategies is undersampling, which consists of randomly reducing the number of samples from the majority class. Although this approach reduces model bias, it carries the risk of losing relevant information. In contrast, the SMOTE (Synthetic Minority Over-sampling Technique) has established itself as one of the most widely used methodologies for addressing this problem. According to Yadav et al. (2025), from a mathematical point of view, SMOTE does not simply duplicate existing instances, but generates new synthetic samples by linear interpolation between a point in the minority class and its closest neighbors in the feature space [16]. However, Matharaarachchi et al. (2024) warn that oversampling loses effectiveness when there are outliers within the minority class. Their study proposes advanced variants that weight the proximity of the data to reduce the impact of these outliers and ensure that the synthetic samples generated are of high quality [17]. Recent research, such as that by Sridhar and Sanagavarapu (2021), shows that applying SMOTE to datasets from industrial sensors significantly improves model recall, allowing faults to be identified that would otherwise be misclassified as normal operating conditions [6].

III. MATERIALS AND METHODS

III.1 MACHINE LEARNING FRAMEWORK

The general methodology proposed for fault prediction is illustrated in Figure 1. This workflow integrates five machine learning models together with a cross-validation scheme to ensure the consistency of predictions. All experimental procedures were implemented using WEKA (3.8.6) [18].

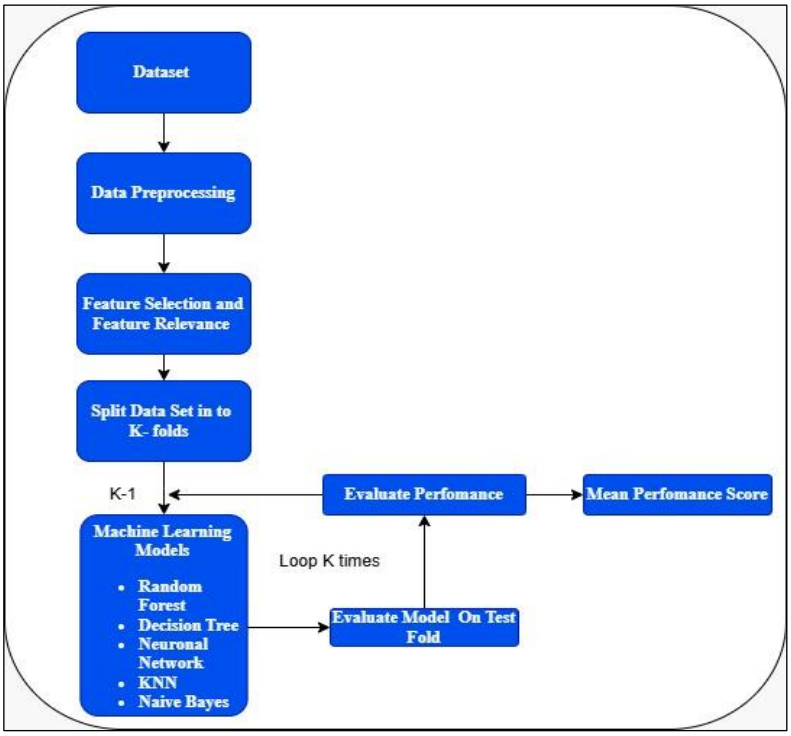

Figure 1: Machine learning framework for failure prediction.
Source: Authors, (2026).

III.1.1 Dataset Description

The study uses the AI4I 2020 Predictive Maintenance Dataset [5]. This synthetic dataset is modeled after an existing milling machine and consists of 10 000 data points from a stored as rows with 14 features in columns.

1. UID: unique identifier ranging from 1 to 10000.
2. Product ID: consisting of a letter L, M, or H for low (50% of all products), medium (30%) and high (20%) as product quality variants and a variant-specific serial number.
3. Type: just the product type L, M or H from column 2

4. Air temperature [K]: generated using a random walk process later normalized to a standard deviation of 2 K around 300 K
5. Process temperature [K]: generated using a random walk process normalized to a standard deviation of 1 K, added to the air temperature plus 10 K.
6. Rotational speed [rpm]: calculated from a power of 2860 W, overlaid with a normally distributed noise
7. Torque [Nm]: torque values are normally distributed around 40 Nm with a SD = 10 Nm and no negative values.
8. Tool wear [min]: The quality variants H/M/L add 5/3/2 minutes of tool wear to the used tool in the process.
9. Machine failure: label that indicates, whether the machine has failed in this particular datapoint for any of the following failure modes are true.

The machine failure consists of five independent failure modes:

10. Tool wear failure (TWF): the tool will be replaced of fail at a randomly selected tool wear time between 200 - 240 mins (120 times in our dataset). At this point in time, the tool is replaced 69 times, and fails 51 times (randomly assigned).
11. Heat dissipation failure (HDF): heat dissipation causes a process failure, if the difference between air- and process temperature is below 8.6 K and the tools rotational speed is below 1380 rpm. This is the case for 115 data points.
12. Power failure (PWF): the product of torque and rotational speed (in rad/s) equals the power required for the process. If this power is below 3500 W or above 9000 W, the process fails, which is the case 95 times in our dataset.
13. Overstrain failure (OSF): if the product of tool wear and torque exceeds 11,000 minNm for the L product variant (12,000 M, 13,000 H), the process fails due to overstrain. This is true for 98 datapoints.
14. Random failures (RNF): each process has a chance of 0,1 % to fail regardless of its process parameters. This is the case for only 5 datapoints, less than could be expected for 10,000 datapoints in our dataset.

If at least one of the above failure modes is true, the process fails and the 'machine failure' label is set to 1. It is therefore not transparent to the machine learning method, which of the failure modes has caused the process to fail. The original data distribution presents a class imbalance, with 9,661 instances of normal operation (96.6%) and only 339 instances of failure (3.4%). This disproportion represents a critical challenge for learning models.

III.2 DATA PREPROCESSING

Preprocessing was aimed at improving data quality and defining training strategies. The UDI and Product ID variables were eliminated because they lacked predictive value. Likewise, specific failure descriptors (TWF, HDF, PWF, OSF, RNF) were excluded, given that the study focuses on the binary detection of the machine failure variable. To address class imbalance, three experimental approaches are used:

- Approach 1 (SMOTE): The Synthetic Minority Over-sampling Technique (SMOTE) is applied to artificially balance the classes. In this scenario, synthetic data was generated until a total of 9,661 samples were reached for both classes. Furthermore, following the proposal by Matharaarachchi et al. [17], this technique improves model learning when minority classes exist, as is the case with the failure category in this study.
- Approach 2 (Undersampling): Random undersampling of the majority class is performed, resulting in a balanced set with 339 failure instances and 339 non-failure instances.
- Approach 3 (Original data set): Models are evaluated using the original data set with its original imbalance to establish a baseline.

III.3 FEATURE RELEVANCE AND SELECTION

Under these three approaches, a feature selection process is implemented by WEKA The ReliefF evaluation algorithm (ReliefFAttributeEval) is used together with the Ranker search method. The Relief family of algorithms are highly successful attribute estimators due to their ability to detect conditional dependencies between variables, the algorithm evaluates the quality of each attribute by repeatedly sampling an instance and comparing it with its closest neighbors of the same class and of different classes. It assigns greater weight to characteristics that maintain similar values for instances of the same class and show different values for instances of different classes [19]. Establishing a cut-off criterion to select only the four most relevant characteristics for model training.

III.4 MACHINE LEARNING MODELS

For the training stage, a comparative approach is implemented to evaluate the predictive power of different machine learning models. Based on a review of recent literature by Aydın and Evrentuğ [20] and Arun [21], five representative algorithms (Random Forest, Decision Tree, ANN, KNN, and Naive Bayes) were selected that have proven effective in fault detection, as identified by Cioch [8]. The general operation of each implemented algorithm is described below: Random Forest (RF): This is an ensemble learning method based on the Bagging technique. It works by training multiple decision trees independently using random subsets of the data. For the final classification, the algorithm aggregates the results of all the individual trees and determines the winning class by majority vote, which reduces variance and improves robustness against noise compared to a single estimator [3]. Decision Tree (DT): This is an algorithm based on logical rules that models decisions in a hierarchical structure similar to a flowchart. The model recursively divides the data space into smaller regions, evaluating at each node the feature that offers the best separation of classes. Its main advantage, highlighted by Cioch et al. (2025), lies in the direct interpretability of the generated “If-Then” rules, although it can be prone to overfitting if its depth is not limited [8]. Artificial Neural Networks (ANN): A Multilayer Perceptron (MLP) is implemented, inspired by the biological structure of the brain. This algorithm processes information through layers of interconnected nodes (neurons): an-input layer, hidden layers with nonlinear activation functions, and an output layer.

Yang and Iqbal (2025) explain that learning occurs through backpropagation, adjusting the weights of the connections to minimize error, which makes them powerful for capturing complex nonlinear patterns in computationally expensive environments [22]. K-Nearest Neighbors (KNN): This is an instance-based learning algorithm that does not construct an explicit internal model (Lazy Learning). To classify a new sample, it calculates its Euclidean distance from the points stored in the training set and identifies the 'K' nearest neighbors. Class assignment is performed by simple majority, which is an effective method when failures tend to cluster in specific regions of the vector space [10]. Naive Bayes (NB): This is a probabilistic classifier based on Bayes' theorem. Its operation assumes "naive independence" between predictor characteristics given the value of the class. Although Cioch et al. (2025) warn that this independence is rarely met in correlated sensor data, the model is widely used as a baseline due to its high computational efficiency and low memory consumption [8].

III.5 EVALUATION PERFOMANCE

The K-Fold Cross-Validation method is implemented for performance evaluation. This technique consists of randomly partitioning the total data set into K-Fold of equal or similar size, ensuring that the number of of instances beloinging to each class the same proportion in each partition, according to the methodology described by Lumumba [23]. As a result of this process, the confusion matrix defined by Cioch et al. [8] is obtained. Since this is a binary classification problem, the matrix is structured in a 2x2 dimension and its components are described as follows: TP (True Positives), the number of instances of class 1 (Failure) correctly predicted as class 1; TN (True Negatives), the number of instances of class 0 (Normal) correctly predicted as class 0; FP (False Positives), instances of class 0 incorrectly predicted as class 1; and FN (False Negatives), instances of class 1 incorrectly predicted as class 0 (Failure not detected). Based on the information obtained from this matrix, the performance metrics for the positive class described below are calculated. Accuracy: evaluates the overall performance of the model by measuring the proportion of correct predictions relative to the total number of cases.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \tag{2}$$

Recall: Measures the ability of the algorithm to correctly identify all instances of actual failure.

$$Recall = \frac{TP}{TP + FN} \tag{3}$$

Specificity: Indicates the ability of the system to correctly classify normal operating states.

$$Specificity = \frac{TN}{TN + FP} \tag{4}$$

Precision: Determines the reliability of positive predictions of total failures.

$$Precision = \frac{TP}{TP + FP} \tag{5}$$

F1-Score: Represents the harmonic mean between Precision and Recall, providing a critical balanced metric.

$$F1 = \frac{2 \times P \times R}{P + R} \tag{6}$$

IV. RESULTS AND DISCUSSION

In this section, the results obtained after the application of two data balancing approaches Original Imbalanced, SMOTE, and Undersampling—are presented and analyzed. These approaches are comprehensively evaluated using both the preprocessed feature set and after a variable selection process, allowing for the measurement of their perfomance on five machine learning models. Performance is quantified through a metrics analysis that includes accuracy, recall, specificity, precision, and F1-score, in order to determine the most robust configuration for fault detection in the industrial environment under study; as it is shown in Figure 2.

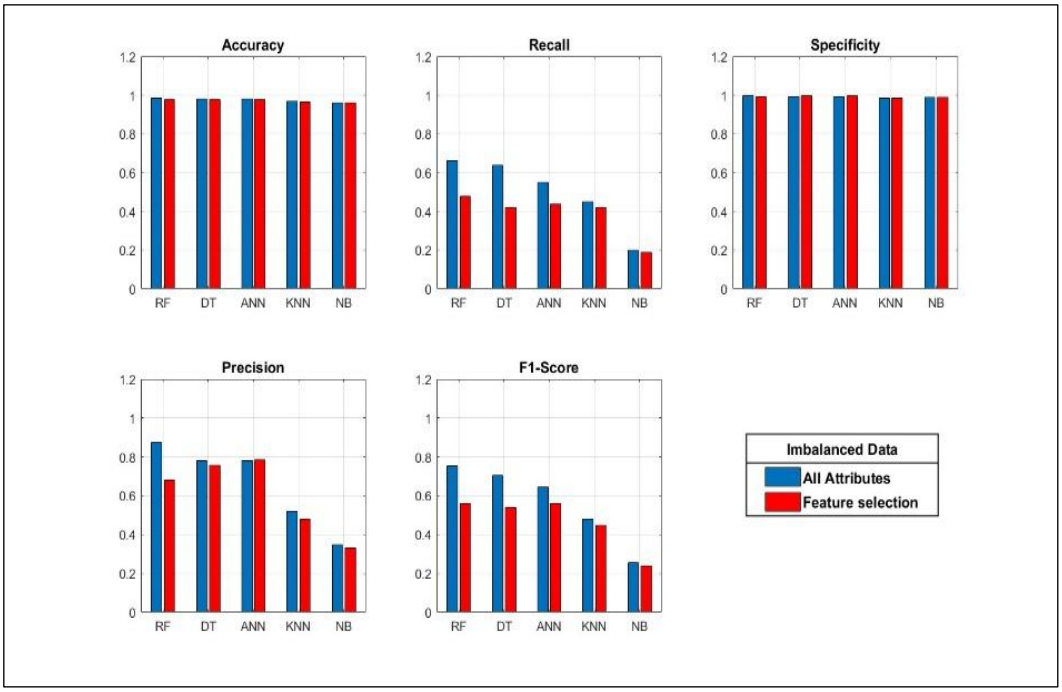

Figure 2: Performance comparison on the imbalanced dataset: all attributes vs feature selection.
Source: Authors, (2026).

When analyzing the results shown in Figure 2, one of the most critical challenges in predictive maintenance becomes evident: the bias introduced by imbalanced data. Although the models report high accuracy in both scenarios, this represents a significant issue; the imbalance causes the algorithms to become experts at classifying normal operation while losing effectiveness in identifying actual failures. This is clearly reflected in the low recall values, the metric that quantifies failure detection capability. Similarly, although the specificity shows good results, this is a product of the model's tendency to predict the majority class. When evaluating the individual performance of the algorithms, the Random Forest model stands as the most robust, specifically when operating with the complete feature set. Under this condition, the algorithm achieved the highest F1-Score in the comparison (0.7538), demonstrating a superior learning capacity to identify failure patterns compared to the other models. While algorithms such as Naive Bayes and KNN show a critical dependence on the majority class, Random Forest achieved the most balanced trade-off between event detection and alert reliability. On the other hand, it is essential to highlight the negative impact that feature selection had in this scenario. By reducing the dimensionality of the imbalanced dataset, a general decrease in the predictive capacity of all models is observed; for example, the Random Forest F1-Score drops drastically from 0.7538 to 0.5615. This behavior suggests that, given the scarcity of failure examples in the original dataset, the removing variables or features eliminates critical information that the algorithms need to correctly discriminate between operating states, confirming that model simplification can be counterproductive under imbalanced conditions. The perfomance metrics results for the synthetic data generated by the SMOTE technique are presented in Table 1.

Table 1: Performance metrics for the SMOTE-balanced dataset.

Model	Accuracy	Recall	Specificity	Precision	F1 Score
RF	0.9581	0.9663	0.95	0.9508	0.9585
DT	0.9435	0.9503	0.9367	0.9375	0.9439
ANN	0.9187	0.9424	0.895	0.8998	0.9206
KNN	0.9436	0.9585	0.9288	0.9308	0.9445
NB	0.8362	0.826	0.8464	0.8432	0.8345

Source: Authors, (2026).

Table 2: Performance metrics for the SMOTE-balanced dataset combined with Feature Selection.

Model	Accuracy	Recall	Specificity	Precision	F1 Score
RF	0.945	0.9619	0.9282	0.9305	0.9459
DT	0.9346	0.9445	0.9246	0.9261	0.9352
ANN	0.8823	0.9465	0.818	0.8387	0.8894
KNN	0.9114	0.9267	0.8961	0.8992	0.9127
NB	0.8275	0.7914	0.8636	0.853	0.821

Source: Authors, (2026).

Table 2 presents the performance metrics calculated for each model using a dataset balanced by SMOTE and feature selection. When analyzing the results in Tables 1 and 2, a positive change can be observed compared to the imbalanced scenario. The application of SMOTE to generate synthetic data has allowed the classes to be balanced, ensuring that the accuracy now truly reflects the model's performance. The most notable feature is the increase in Recall, where the Random Forest model reaches a maximum value of 0.9663 (Table 1). This indicates that the models have achieved reliable prediction of failures and have developed a real ability to identify critical predictive maintenance events without compromising specificity. In this approach, the Random Forest model once again stands out as the best performing model, especially when using the complete dataset. With an F1-Score of 0.9585 and the aforementioned Recall of 0.9663, Random Forest demonstrates high accuracy in detecting faults. This confirms that, by providing a balanced database, ensemble algorithms can extract much more complex and reliable patterns for decision-making. Regarding the impact of feature selection in this scenario, it can be observed that, although reducing variables simplifies the model structure, it leads to a slight decrease in performance. The clearest example is the Neural Network, where the F1-Score drops from 0.9206 to 0.8894; however, this deficiency does not compromise the overall effectiveness of the system. On the contrary, the results show that feature selection applied to a balanced dataset with SMOTE is effective, as the models manage to maintain a performance above 88% in fault detection. This confirms that the robustness of the synthetic database compensates for the elimination of technical variables, allowing for more efficient models without significantly sacrificing predictive power. Next, Tables 3 and 4 are presented, reflecting the dataset balanced to minority class size (undersampling) and the dataset balanced to minority class size (undersampling feature selection).

Table 3: Dataset balanced to minority class size (undersampling).

Model	Accuracy	Recall	Specificity	Precision	F1 Score
RF	0.9436	0.9585	0.9288	0.9308	0.9445
DT	0.9277	0.9381	0.9174	0.9191	0.9285
ANN	0.8997	0.8791	0.9204	0.9169	0.8976
KNN	0.9174	0.8997	0.9351	0.9327	0.9159
NB	0.8451	0.8407	0.8496	0.8482	0.8444

Source: Authors, (2026).

Table 4: Dataset balanced to minority class size (undersampling Feature selection).

Model	Accuracy	Recall	Specificity	Precision	F1 Score
RF	0.95	0.9528	0.9469	0.9472	0.95
DT	0.9381	0.9351	0.941	0.9407	0.9379
ANN	0.8938	0.8791	0.9086	0.9058	0.8922
KNN	0.9056	0.885	0.9263	0.9231	0.9036
NB	0.8245	0.7935	0.8555	0.8459	0.8189

Source: Authors, (2026).

Looking at the results in Tables 3 and 4, we can see an improvement in predictive power compared to the unbalanced dataset. By reducing the minority class, the models achieve good performance and a balance between accuracy and recall. In this approach, the Random Forest model stands out as the best-performing algorithm. Using the complete dataset, Random Forest achieves an F1-Score of 0.9445 and leads detection with a Recall of 0.9585. It can be noted that, although the dataset is smaller than in the case of SMOTE, the Random Forest algorithm maintains stability in its performance, consistently outperforming Neural Networks and models such as Naive Bayes in all metrics. Regarding the impact of feature selection seen in Table 4, a distinctive phenomenon occurs: unlike previous approaches, variable reduction helps improve or maintain performance in leading models. For example, in Random Forest, the F1-Score increases from 0.9445 to 0.9500 after applying Feature Selection. However, a slight deficiency is observed in models such as RNA, where performance drops from 0.8976 to 0.8922. The overall result shows that feature selection in a balanced dataset by subsampling is extremely effective, allowing for lighter and more accurate models.

V. CONCLUSIONS

This paper evaluates the performance of five machine learning algorithms for fault prediction in the AI4I 2020 industrial dataset, which allows us to understand the impact of each technique on critical metrics in industrial environments. To this end, data balancing and feature selection strategies are compared, leading to the following final considerations:

1. The optimal configuration: The Random Forest model, trained with the dataset balanced using the SMOTE technique and using all attributes after preprocessing, proves to be the most optimal solution, achieving a Recall of 0.9663 and an F1-Score of 0.9585. This result makes it the optimal method for fault prediction.
2. Impact of Preprocessing: It is demonstrated that treating class imbalance is a mandatory step. Using the original dataset, despite offering superior accuracy, results in models with significantly low sensitivities of less than 0.67. Among the balancing techniques, SMOTE consistently outperforms undersampling, proving that generating synthetic failure data is preferable to removing information from the majority class.
3. This research reveals that feature selection negatively affects predictive performance, reducing the fault detection capability (Recall) in the best-performing model. This suggests that the operational variables in the dataset are significantly relevant to the models and are lost when those attributes are removed, indicating that for this specific problem, it is better to retain the attributes.

Finally, the integration of data balancing and feature selection improves overall performance because the results show that treating class imbalance combined with feature selection techniques allows for the construction of more robust and stable models. The joint integration of these strategies contributes to improving the predictive capacity of the system compared to their isolated application.

ABSTRACT

Microchannel heat sinks are often redesigned with taller pin fins under the assumption that larger surface area inherently yields better cooling. However, this study reveals a counterintuitive yet significant finding that the shortest pin fin (6.2 µm) consistently outperforms all taller configurations across the full range of operating conditions. A three-dimensional CFD model developed in ANSYS Fluent evaluates a plain channel and four pin-fin heights (6.2, 18.6, 31.0, and 43.4 µm) over Reynolds numbers 55 - 225, using water and MWCNT nanofluids at 1, 2 & 3% concentrations. The thermo-hydraulic behavior is assessed through Nusselt number, friction factor, pressure drop, and thermal performance factor (TPF). Although taller fins enhance heat transfer, they impose substantial pressure and pumping penalties, diminishing overall system efficiency. In contrast, the 6.2 µm geometry demonstrates a TPF consistently above unity with a strong increase at higher Reynolds numbers, indicating an efficient flow-mixing mechanism achieved with minimal hydraulic cost. In microscale cooling, shorter and compact pin fins rather than taller ones unlock superior thermal performance. This unexpected dominance of the smallest configuration highlights an important design insight. A supporting data-driven heat-map visualization is also employed to interpret multi-parameter trends, reinforcing the identification of the 6.2 µm pin height with 3% MWCNT as the most efficient case. Overall, the study provides clear guidance for next-generation microchannel heat-sink optimization and challenges conventional assumptions about fin geometry in miniaturized cooling systems.

I. INTRODUCTION

The need for compact and high-performance thermal management systems has increased due to the rapid miniaturisation of electronic devices, the emergence of high-density microprocessors, and developments in power electronics. In today's increasingly compact and powerful devices, effective thermal solutions are essential for maintaining optimal performance, preventing overheating, and ensuring device reliability. Because of their high surface area-to-volume ratios and superior convective heat transfer capabilities, microchannel heat sinks (MCHSs) have become a viable option for dissipating high heat fluxes. These devices are perfect for cooling next-generation electronics because they use laminar flow in narrow channels to achieve superior thermal performance while minimising coolant volume. The groundbreaking work by Tuckerman and Pease (1981) [1] introduced the first microchannel heat sink for high performance cooling planar integrated VLSI circuits. It showed that the convective heat transfer coefficient h between the substrate and coolant is the main limitation for thermal resistance, and laminar flow in narrow channels increases h.

Experiments at a power density of 790 W/cm² showed a maximum substrate temperature rise of 71 °C, validating theoretical predictions and demonstrating feasibility for ultrahigh-speed VLSI circuits. Weisberg et al. (1992) [2] further analyzed ultra compact microchannels proposing design algorithms to optimize dimensions for integrated cooling applications by highlighting the potential of precision machined channels for effective thermal management. Subsequent studies explored innovative channel geometries, such as wavy, fractal, and helical microchannels, to induce secondary flow, enhance turbulence, and increase convective heat transfer without significantly penalizing pressure drop. Hussein, H. A. (2024) [3] numerically analyzed six circular mini-channel heat sink designs with L-shaped flow passages to enhance coolant distribution and heat transfer. The L-channel (JMMLCCHS) showed higher performance index and lower thermal resistance than rectangular channels. Haridas, D., (2014) [4] analyzed the behaviour of the Temperature fields and forced convection in compact thermal systems have been studied using digital interferometric techniques, such as the Michelson and Mach-Zehnder methods. Zhu, Q., (2024) [5] numerically studied a Symmetric wavy microchannel with wave trough-to-crest secondary channels (SW-TC) with slanted secondary channels for improved flow uniformity and heat transfer. The SW-TC design demonstrated better thermal efficiency than the Symmetric wavy microchannel with wave crest-to-crest secondary channels (SW-CC) and Symmetric wavy microchannel with wave trough-to-trough secondary channels (SW-TT) designs.

Subsequent studies have focused on improving heat transfer by incorporating microstructures and pin-fin arrangements. A and Chakraborty et al. (2020) [6] enhanced MCHS performance by integrating microstructures like pillars and blind holes. Pillars boosted heat transfer but increased pressure drop, while blind holes moderately improved both. A hybrid design with more pillars near the inlet achieved higher heat transfer with controlled pumping power. Xie et al. (2021) [7] numerically analyzed laminar flow (Re = 10-300) in microchannel heat sinks with pin fins at 0°, 30°, 45°, and 60° inclinations using the finite volume method. Strong secondary flow was created by the in-lined 30° configuration which improved heat transfer but increased friction. While pattern effects were negligible, the inclined angle had a significant influence on thermo-hydraulic performance. Optimal designs were recommended under equal pumping power conditions. Similarly, Ali et al. (2024) [8] numerically studied semi-elliptical pin fins (Ψ = 0.36-1.0) in water-cooled MCHSs (Re = 100-900, heat flux = 1×10^6 W/m²). The best performance (THPP = 1.41) occurred at Ψ = 1.0 and Re = 300, while the lowest was at Ψ = 0.36 and Re = 900. Recent work of Qi, X., et al.(2025) [9] is on thermally induced errors in feed-drive mechanisms has shown that advanced cooling technologies, such as sintered core heat pipes, play a crucial role in minimizing temperature gradients. This reinforces the broader engineering demand for compact and high-performance cooling systems like microchannel heat sinks.

Zhu, X. et al., (2025) [10] found that Geometric refinement and better heat transfer interfaces can significantly increase system efficiency as demonstrated by recent optimisation studies on stepped-configuration thermoelectric generators. These findings parallel the motivation of the present work where pin-fin geometry and nanofluid properties are tailored to elevate thermal performance in microchannel heat sinks. Zhu, X. et al., (2025) [11] Geometrical and material optimization of advanced TE modules, like hybrid configurations of N-SKD/P-HH, demonstrated that thermal efficiency increases while reiterating geometry optimization; hence, the pin-fin height optimization of microchannel heat sinks in this study actually follows suit. Ali et al. (2024) [12] numerically analyzed V-shaped rib angles (35°-90°) in MCHSs for Re = 100-900. Smaller angles (35°) enhanced heat transfer via stronger flow mixing and yielding higher Nusselt numbers but greater frictional losses. The study highlights the need to optimize rib angles for balanced thermal hydraulic performance. More recent work by Singh et al. (2025) [13] examined different micro pin-fin geometries, revealing that circular fins provide the highest thermal enhancement while triangular and square fins offer moderate improvement which influence of fin geometry and arrangement on thermo-hydraulic performance. Additionally, Polat et al. (2022) [14] highlighted that micro pin-fin shapes (diamond, square, circular) and their arrangements strongly affect both Nusselt number and pressure drop, requiring optimized design to balance heat transfer and pumping power.

Parallel to geometric optimizations, nanofluids have been extensively explored for enhancing thermal performance in MCHSs. Maheshwary et al. (2017) [15] experimentally showed that TiO_2–water nanofluid thermal conductivity increases with higher concentration, smaller particle size, and cubic shape, with concentration having the greatest effect (69.43%). However, higher concentrations also increase viscosity and pumping power. Experimental studies by Jeong et al. (2013) [16] showed that both viscosity and thermal conductivity of ZnO-water nanofluids increase with higher nanoparticle concentration. Particle shape is important at 5 vol.%, nearly rectangular particles produce higher enhancements than spherical ones (about 7.7% higher viscosity and 6% higher thermal conductivity). This suggests that the geometry of nanoparticles has a significant impact on the performance of nanofluids. Hung et al. (2012) [17] demonstrated that Al_2O_3-water and diamond-water nanofluids enhance microchannel heat transfer by over 20%, with optimal performance achieved using smaller particles and controlled volume fractions. Hybrid nanofluids combining multiple nanoparticles have shown even greater potential, Bhattad et al. (2020, 2022) [18] reported improved thermal conductivity and performance indices with minimal pumping penalty, while Murali Krishna et al. (2020) [19] confirmed that MWCNT-CuO/water hybrids outperform mono nanofluids in circular microchannels.

The integration of numerical simulations and artificial intelligence has become crucial for optimizing MCHS designs. Gao et al. (2022) [20] reviewed the application of CFD, LBM, and molecular dynamics in microchannel heat transfer emphasizing that CFD remains versatile for laminar flows while machine learning techniques as used by Said et al. (2022) [21] demonstrated that MWCNT/water nanofluids notably enhance shell-and-tube heat exchanger (STHX) performance, achieving a 3.23% rise in thermal conductivity, 31.08% higher heat transfer coefficient, and 5.49% improved efficiency at 0.3% volume fraction. CFD analysis with semicircular baffles further increased efficacy by 15.4%, confirming the nanofluid's superior heat transfer capability and sustainability for STHX applications. Yadav et al. (2021) [22] studied MWCNT/water nanofluids showing non-Newtonian behavior dependent on concentration, temperature, and shear stress, with SDS surfactant influencing rheology. The power-law model described flow behavior, while an ANN model achieved high prediction accuracy, demonstrating the strength of combining experimental, theoretical, and AI approaches for nanofluid rheology. Additionally, innovative channel geometries, such as fractal or plus-shaped designs, have been explored numerically Lyu et al. (2020) [23] demonstrated that fractal channels with CNT nanofluids achieve uniform temperature distribution and enhanced heat transfer, further highlighted the stability and efficiency of MWCNT-based nanofluids, achieving significant heat transfer enhancement with negligible pumping penalties.

While Manjur et al. (2025) [24] showed that novel geometries coupled with advanced nanofluids can significantly improve thermal performance and reduce pressure drop. Cai, B., (2025) [25] studied double-layered MCHSs, introducing TMC-ORTC with rib-cavity coupling, which enhanced mixing and heat transfer while reducing pressure loss, achieving 120% higher Nusselt number and 81.7% better temperature uniformity than conventional designs. Beyond MCHSs, the broader application of nanofluid-enhanced systems has been confirmed in photovoltaic thermal (PVT) systems, where Rajamony et al. (2024) [26] reported that MWCNT-enhanced phase change materials improve both thermal and electrical outputs. Furthermore, studies on laminar flows with nanofluids in non-conventional geometries, such as Analytical and statistical of Yahiaoui et al. (2025) [27] analysed Jeffery-Hamel flow for Cu–water and SiO_2/water nanofluids in rotating channels showed that rotation induces asymmetric shear flow and affects heat transfer. Though geometrically different, the study relates to pin-fin microchannels by revealing how nanofluid properties and Reynolds number influence flow, wall shear, and heat transfer. Babar Hussain Shah et al. (2024) [28] provide insights into how boundary conditions, Reynolds number, and fluid properties influence flow and heat transfer, which is relevant for optimizing MCHS performance. Emadi, A., (2025) [29] numerically assessed that multi-layer porous fins significantly enhance heat transfer by improving convection and temperature uniformity, with two-layer fins offering optimal performance under high porosity and permeability. Despite significant progress, research gaps remain in balancing heat transfer enhancement with pumping power penalties, exploring hybrid nanofluids with varying proportions, and applying machine learning for predictive optimization under diverse flow conditions. The present study aims to address these gaps by numerically investigating the thermohydraulic performance of MCHSs with MWCNT-based nanofluids across various pin-fin geometries and configurations, thereby contributing to the development of efficient microchannel cooling strategies for advanced electronic and thermal management applications.

II. COMPUTATIONAL MODELLING

II.1 COMPUTATIONAL DESIGNING

II.1.1 Design and Computational Model

The computational domain for the microchannel heat sink (MCHS) was created in ANSYS Workbench (Design Modeler) to analyze fluid flow and heat transfer across different pin fin geometries and nanofluid concentrations. The model simulates a three-dimensional, steady-state, laminar flow to capture the interaction between the solid microchannel and the working fluid [27]. Copper was chosen as the channel material for its high thermal conductivity and mechanical stability, making it suitable for microscale thermal management. The Microchannel design is shown in the Figure 1b as Computational Domain and the Schematic view of the channel is given in the Figure 1a. The dimensions of the microchannel as given in Table 1 has a length of 600 µm, a width of 265 µm, and a height of 62 µm, with cylindrical pin fins of 15 µm diameter distributed at a uniform pitch of 50 µm (Fig 1a, b). Each configuration includes 55 pin fins of varying heights 6.2 µm, 18.6 µm, 31 µm, and 43.4 µm to evaluate the influence of fin aspect ratio on the overall flow and heat transfer behavior. Water and MWCNT-water nanofluids with concentrations of 1%, 2%, and 3% by volume were used as the working fluids. These nanofluids were chosen for their enhanced thermal conductivity and capacity to intensify near-wall thermal interactions. The simulations were performed for inlet velocities of 0.5, 1.0, 1.5, and 2.0 m/s to capture the combined effect of flow rate and nanofluid loading on heat transfer and pressure characteristics. The fluid enters the channel through the inlet boundary with a uniform velocity profile and exits through an outflow boundary with zero gauge pressure. Constant heat flux is applied at the bottom surface, while all other external walls are adiabatic. A structured mesh was generated to accurately capture the boundary layer and the complex flow around pin fins, with grid independence verified through successive mesh refinements. The governing equations for mass, momentum, and energy were solved using the finite volume approach in ANSYS Fluent, ensuring numerical stability and convergence for all cases studied. This computational framework enables a comprehensive understanding of the microscale flow development, temperature distribution, and fluid-solid interaction under various geometric and operating conditions, providing a reliable basis for optimizing MCHS performance using MWCNT nanofluids.

II.2.2 Properties of Heat Transfer Fluid and Microchannel

The performance and thermal efficiency of the microchannel heat sink (MCHS) are highly dependent on the thermophysical properties of both the working fluid and the substrate material. These properties regulate the mechanisms of heat transfer, flow resistance, and overall cooling effectiveness under varying operating conditions. In the present study, deionized water and multi-walled carbon nanotube (MWCNT)/water nanofluids with volume concentrations of 1%, 2%, and 3% are employed as the heat transfer media while aluminium is used as the microchannel substrate. Water acts as the base fluid due to its favorable properties, including high specific heat capacity, moderate thermal conductivity, and low viscosity, which collectively promote efficient convective heat removal. The suspension of MWCNT nanoparticles within the base fluid further enhances its effective thermal conductivity and heat transport capability through mechanisms such as Brownian motion and micro-scale convection. The incorporation of MWCNTs also improves energy diffusion and temperature uniformity within the microchannel, leading to superior thermal performance compared to pure water. The thermophysical properties of the working fluids at a reference temperature are summarized in Table 2. Aluminium is selected as the microchannel substrate material because of its high thermal conductivity, low density, and excellent mechanical stability. These properties make it ideal for rapid heat spreading and lightweight thermal management applications. The high thermal conductivity of aluminium (386 W/m·K) ensures efficient heat distribution along the channel walls, while its moderate specific heat capacity allows it to accommodate transient temperature fluctuations. Furthermore, its structural robustness and resistance to thermal fatigue make it suitable for repeated heating and cooling cycles under high heat flux conditions. The thermophysical properties of aluminium are also listed in Table 2. The combined use of MWCNT–water nanofluids and Copper substrate provides a highly effective heat transfer configuration. The enhanced thermal conductivity of the nanofluid ensures rapid heat removal from the heated surface, while the superior heat spreading capability of Copper maintains a uniform temperature gradient across the microchannel. Together, they contribute to reduced thermal resistance, improved convective performance, and sustained operational efficiency of the MCHS under diverse flow and thermal loading conditions.

Table 2: Properties of the Materials.

Thermo-Physical Properties	Units	Water	MWCNT	Copper
Density	(kg/m³)	997	1600	2700
Dynamic Viscosity	(kg/m·s)	0.000891	-	-
Thermal Conductivity	(W/m·K)	0.6	3000	386

II. 2.3 Mesh Independence Study:

The grid independence test is conducted to ensure that the solution is unaffected by further mesh refinement, confirming numerical accuracy. A detailed mesh independence study was performed for the rectangular microchannel under a constant heat flux of 10,000 W/m² and an inlet velocity of 0.5 m/s. Three mesh densities were examined: coarse (247,886 elements), medium (707,788 elements), and fine (1,584,540 elements). The fine mesh produced a Nusselt number (Nu) of 4.347 and a friction factor (f) of 0.83, while the medium mesh yielded Nu = 4.507 and f = 0.8115. The coarse mesh slightly overpredicted Nu (4.437) and underpredicted f (0.81), consistent with the typical behavior of under-resolved meshes that inadequately capture near-wall gradients. The relative percentage variations between the fine and medium meshes were 3.68% for Nusselt number and 2.28% for friction factor—both within the generally accepted convergence tolerance of ±5%. This confirms that further refinement produces negligible improvement in the predicted flow or thermal characteristics. Notably, although the fine mesh results in a marginally lower Nusselt number, this outcome reflects physical accuracy rather than numerical limitation. Coarser grids often overpredict heat-transfer coefficients due to exaggerated wall-temperature gradients caused by insufficient near-wall resolution. The fine mesh, with its higher element density and smaller y^+ values, resolves the viscous and thermal boundary layers more precisely, capturing the realistic conduction-convection interplay and producing a more reliable thermal prediction. The modest increase in pressure drop in the fine mesh (≈2–3%) arises from improved resolution of recirculation and viscous losses around pin fins—an expected and physically justified trend. The fine mesh was therefore selected for all subsequent simulations owing to its superior resolution of wall-adjacent gradients, accurate representation of viscous and thermal dissipation mechanisms, and 4.2% enhancement in thermal-hydraulic efficiency, demonstrating that the pin-fin design offers meaningful heat-transfer improvement despite a modest rise in pressure loss.

Table 5:Mesh independence study.

Quantity	Coarse Mesh	Medium Mesh	Fine Mesh	Percentage Deviatio.n Medium to Fine(%)	Percentage Deviation Coarse to Fine (%)
No.of elements	247,886	707,788	1,584,540	-	-
Pressure Drop	603.4312	604.3910	624.4862	+3.32%	+3.49%
Nusselt Number	4.437	4.507	4.347	-3.55%	-2.03%

III. MATERIALS AND METHODS

III.3.1 Boundary Conditions and Numerical Procedure

The numerical investigation of the microchannel heat sink (MCHS) is performed under carefully defined boundary conditions and a systematic numerical procedure to accurately capture the coupled fluid flow and heat transfer characteristics. As in Table 3, At the inlet, a uniform velocity is prescribed corresponding to four distinct velocities (0.5, 1.0, 1.5, and 2.0 m/s), which correspond to the Reynolds numbers between 56 to 225 representing laminar flow regimes typical of microchannel applications. The inlet temperature of the working fluid is water and MWCNT–water nanofluids with 1%, 2%, and 3% concentrations maintained at 300 K. This ensures consistent thermal conditions for comparative analysis across all test cases. At the outlet, a zero-gauge pressure condition is imposed to simulate atmospheric discharge, ensuring a physically realistic pressure drop along the flow direction. A uniform heat flux of 10KW/m2 is applied at the bottom wall of the microchannel, emulating high heat generation from electronic components or chip surfaces. The other three walls are considered adiabatic, restricting heat loss to the surroundings. All solid–fluid interfaces are assumed to have a no-slip condition to accurately represent viscous effects within the confined microchannel domain. The numerical procedure is executed using the finite volume method (FVM) in ANSYS Fluent in the governing equations. The pressure–velocity coupling is handled using the SIMPLE algorithm, which ensures convergence stability and accurate momentum–pressure interaction. The convective terms in the governing equations are discretized using the second-order upwind scheme. Convergence criteria are set to strict tolerances to ensure computational reliability. The residuals are maintained below 10-9 for the energy equation and 10-6 for both continuity and momentum equations.

Table 3: Boundary conditions.

Boundary Conditions	Values
Inlet Velocity	0.5 - 2 m/s
Inlet Temperature	300 K
Outlet Pressure	0 Pas
Heat Flux	10 kW/m2
Reynolds Numbers	56.23, 112.5, 168.7, 225
Flow Type	Laminar

Source: Authors, (2026).

III.3.2 Mathematical model:

The steady-state, laminar, incompressible flow and conjugate heat transfer through the microchannel are modeled using the three-dimensional forms of the continuity, momentum, and energy equations. These equations govern both the fluid and solid domains to capture the coupled heat transfer behavior.

Continuity

$$\nabla . \vec{u} = 0 \tag{1}$$

Momentum.

$$\rho_l \left(\vec{u} \cdot \nabla \vec{u} \right) = -\nabla p + \mu_l \nabla^2 \vec{u} \tag{2}$$

Energy.

$$\rho_l C_{pl} \left(\vec{u} \cdot \nabla T_l \right) = k_l \cdot \nabla^2 T \tag{3}$$

Energy (solid).

$$\nabla (k_s \cdot \nabla T_s) = 0 \tag{4}$$

III.3.3 Numerical Calculations:

The Hydraulic Diameter (Dh) equation,

$$D_h = \frac{4(W_{ch} \times H_{ch})}{2(W_{ch} + H_{ch})} \quad (5)$$

Where Hch - Height and Wch-width

The Reynolds equation,

$$Re = \frac{\rho_l u_l D_h}{\mu_l} \quad (6)$$

The heat transfer coefficient,

$$h = \frac{Q}{T_w - T_f} \quad (7)$$

The Nusselt calculation,

$$Nu = \frac{hD_h}{k} \quad (8)$$

The friction factor can be determined from the following equations,

$$f = \frac{2D_h \Delta p}{L \rho u_{in}^2} \quad (9)$$

The thermal Performance Factor (TPF) is calculated by,

$$TPF = \frac{Nu/Nu_o}{(f/f_o)^{1/3}} \quad (10)$$

III.3.4 Nanofluid Properties

Density:[28]

$$\rho nf = (1 - \varphi)\, \rho bf + \varphi . \rho p$$

Viscosity: (Brinkman - model) [29]

$$\mu = \frac{\mu_{bf}}{(1 - \varphi)^{2.5}}$$

Thermal Conductivity: (Hamilton - Crosser) [30]

$$k_{nf} = kbf \frac{k_s + (n-1)\, k_{bf} - (n-1)\, \varphi\, (k_s - k_{bf})}{k_s + (n-1)\, k_{bf} + \varphi\, (k_s - k_{bf})}$$

Specific Heat Capacity: [31].

$$Cpnf = \frac{(1-\varphi)\, \rho_{bf} C_{bf} + \varphi\, \rho_p C_p}{\rho_{nf}}$$

Table 4: Thermo-physical properties of Nanofluid.

Fluid Type	Concentration (wt%)	Density (kg/m³)	Specific Heat (J/kg·K)	Thermal Conductivity (W/m·K)	Viscosity (kg/m·s)
Water	0	998.2	4182	0.6	0.000891
MWCNT/Water Nanofluid	1	1003.03	4128	0.6254	0.0009128
MWCNT/Water Nanofluid	2	1009.06	4074.62	0.6441	0.0009367

IV. RESULTS AND DISCUSSIONS

IV.4.1 Flow field Visualization:

The velocity contour, streamlines and the vector plots across all configurations exhibit the combined influence of velocity magnitude, pin height, and nanofluid concentration on the internal flow behavior of the microchannel. At lower velocities (0.5–1.0 m/s) the flow remains predominantly laminar with well-defined, symmetric streamlines and low momentum exchange near the pin surfaces shown in the Velocity Vector Fig 2. In these cases recirculation zones are small and confined to the wake regions behind each pin fin. The reduced inertia limits the fluid ability to reattach quickly, leading to a thicker boundary layer and consequently weaker convective heat transfer. As velocity increases (1.5-2.0 m/s) the streamlines become progressively elongated and aligned with the channel direction indicating higher kinetic energy and enhanced flow mixing shown in the Fig 3 with Velocity Contour enabled with the Velocity Streamlines. The wake regions shrink and the reattachment points move closer to the trailing edge of the pins which reflect the thinning of the velocity boundary layer and improved convective transport.

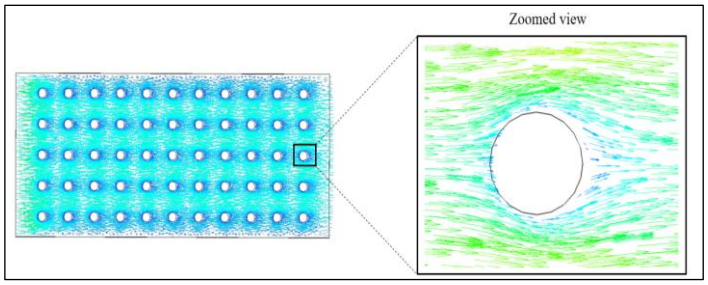

Figure 2: Velocity Vectors along the channel and a zoomed view around a single pin fin 6.2 µm with 3% concentration of MWCNT at 2 m/s.
Source: Authors, (2026).

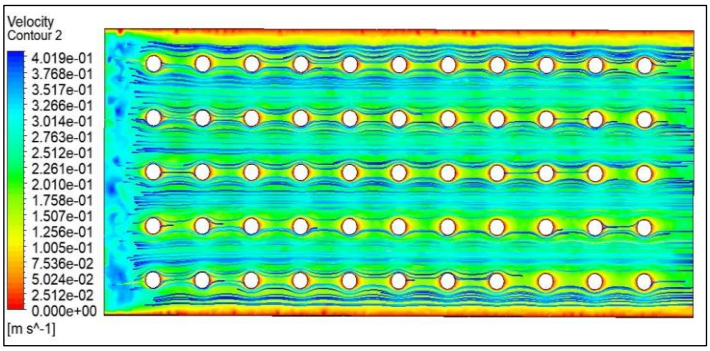

Figure 3: Velocity contour with Streamlines of 6.2 µm pin fin with 3% concentration of MWCNT at 2 m/s.
Source: Authors, (2026).

The influence of pin height of taller pins (31 µm and 43.4 µm) produce stronger flow obstruction and intensified local acceleration around the pin tips, resulting in elevated velocity gradients and increased flow intensity in their vicinity. This accelerates fluid mixing and disrupts the thermal boundary layer, boosting overall heat transfer performance. In contrast, shorter pin fins (6.2 µm and 18.6 µm) yield smoother streamlines with limited mixing at lower velocities. Figure 2 represents the velocity vector field in the microchannel, showing that the bulk region is dominated by smooth forward flow while each of the pin fins has distinct flow deviation. Enlarging the view locally elucidates the local acceleration and deflection of streamlines around the surface of the pin as velocity gradients become large in the wake region. The behavior confirms what was expected to be characteristic shear layers and localized recirculation zones that enhance the mixing and indeed improve convective heat transfer.

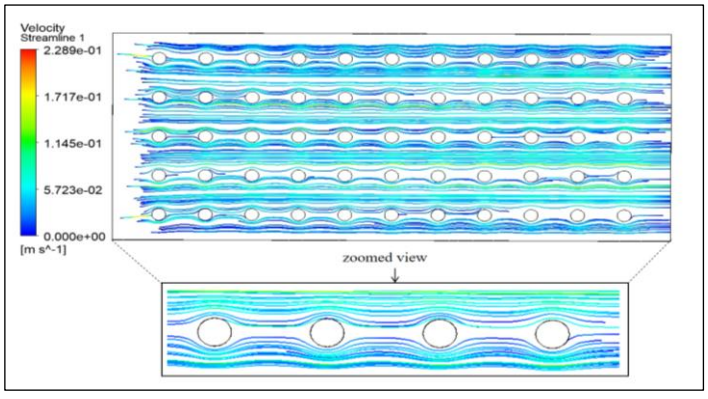

Figure 4: Velocity Streamlines along the plane above the pin fin (~6.3 µm pin fin) with 3% concentration of MWCNT at 2 m/s.
Source: Authors, (2026).

Figure 4, shows the transition of the Streamlines in the same channel with 6.2 µm pin fin channel with 3% concentration of MWCNT at 2 m/s, but at a certain plane where the flow pattern changes slightly above the pin height approximately at ~6.3 µm. The velocity streamlines show that when pin heights are lower and velocities are reduced, the flow develops more smoothly and evenly, allowing the fluid to interact longer with the channel walls. This creates clear boundary layers and stable flow areas between the pin fins. On the other hand, higher pin heights and faster velocities increase mixing and speed up the flow around the fins, which causes more turbulence and disturbances. Adding MWCNT nanofluids, especially at higher concentrations, improves momentum diffusion near the walls and changes how the streamlines behave, leading to better flow interaction and more uniform mixing. Even with these differences, the main flow pattern stays the same in all cases, with clear circulation zones and faster regions around the pin fins. When comparing the working fluids, the addition of MWCNT nanoparticles alters the velocity distribution by slightly increasing flow resistance due to higher viscosity. At 1% and 2% concentrations, this resistance modestly dampens near to the wall velocities. Whereas at 3% MWCNT, the effect is more pronounced with marginally thicker velocity gradients near pin surfaces. However the enhanced thermal conductivity and momentum diffusion of MWCNT nanofluids promote stronger velocity recovery downstream and greater homogenization of flow fields. Among all the cases, 3% MWCNT exhibits the most balanced velocity distribution demonstrating the best synergy between viscous dissipation and convective enhancement.

IV.4.2 Temperature Field Visualization:

The temperature contours reveal a clear dependence of thermal field uniformity on both pin-fin height and inlet velocity. At low pin height (6.2 µm) and low velocity, all working fluids exhibit a higher wall temperature and a larger temperature gradient between the inlet and outlet. This occurs because short fins generate weaker flow disturbances and inadequate boundary-layer disruption, resulting in poor mixing of the near-wall fluid. Simultaneously, the low inlet velocity leads to a thicker thermal boundary layer and a longer fluid residence time, allowing heat to accumulate near the heated wall. The combined effect of weak geometric mixing and slow advection leads to the largest temperature rise in these cases. As the pin height increases, a substantial improvement in heat transfer uniformity is observed. Taller fins (18.6 µm, 31 µm, and 43.4 µm) extend deeper into the flow field, promoting enhanced fluid impingement and wake re-circulation zones between successive pins. This intensifies boundary-layer disturbance and induces secondary mixing, which renews the fluid near the heated surfaces more effectively. Consequently, the local wall temperature decreases and the overall temperature distribution becomes more uniform along the flow path. The benefit of increased pin height is most evident at moderate-to-high velocities, where the combined influence of fin-induced turbulence and convective momentum transport yields superior cooling performance. Similarly, increasing the inlet velocity strengthens convective transport and reduces the temperature difference between the wall and bulk fluid. At higher velocities, the fluid residence time decreases yet the energy removal rate rises due to higher heat transfer coefficients and thinner thermal boundary layers. Hence, the contours at 2 m/s exhibit more uniform color gradients and lower maximum temperatures than those at 0.5 m/s (Fig 5). However, excessively high velocities also lead to increased frictional losses and pressure drop which can impact system efficiency a trade-off captured through the Thermal Performance Factor (TPF) analysis. Across all geometric and flow conditions the MWCNT nanofluids consistently outperform water in dissipating heat, with improvements increasing with nano-particle concentration. The 3% MWCNT nanofluid exhibits the lowest wall temperatures and the most uniform thermal contours due to its higher effective thermal conductivity and microconvective energy transport enabled by nanoparticle Brownian motion. The 1% and 2% nanofluids also enhance thermal performance compared to pure water but to a lesser extent yet following the same overall temperature trend. The influence of concentration becomes more prominent at higher pin heights and velocities where convective mixing complements the intrinsic conductivity enhancement of the nanofluid.

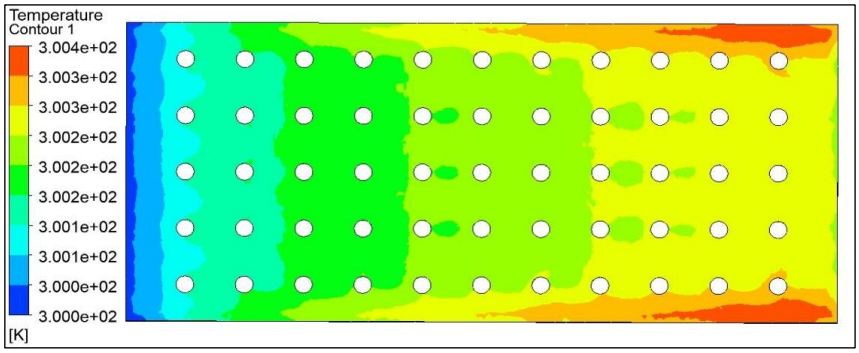

Figure 5: Temperature Contour along the channel of 6.2 µm pin fin with 3% concentration of MWCNT at 2 m/s.
Source: Authors, (2026).

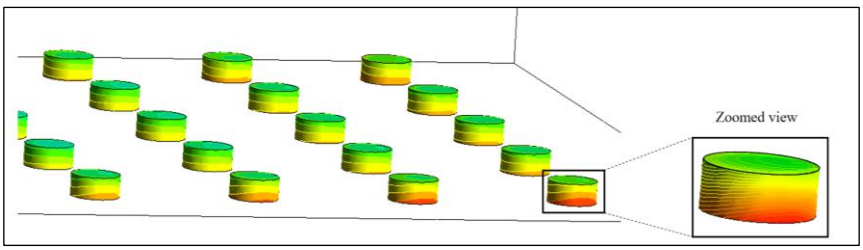

Figure 6: Temperature Distribution along the height of the 6.2 µm pin fin with 3% concentration of MWCNT at 2 m/s.
Source: Authors, (2026).

The temperature contour over each pin fin reveals a noticeable axial gradient with higher temperatures near the base (red/orange) and gradually lower ones toward the top surface (yellow/ green) (Fig 6). This pattern demonstrates that the vicinity near the pin substrate interface is under stronger thermal loading while the upper portions of the pin fins are relatively cooler because of the enhanced removal of heat by convection of the fluid. In the zoomed view, there is an indication of smooth vertical temperature stratification which supports good heat spreading from the base to the fin tip.

IV.4.3 Pressure Drop:

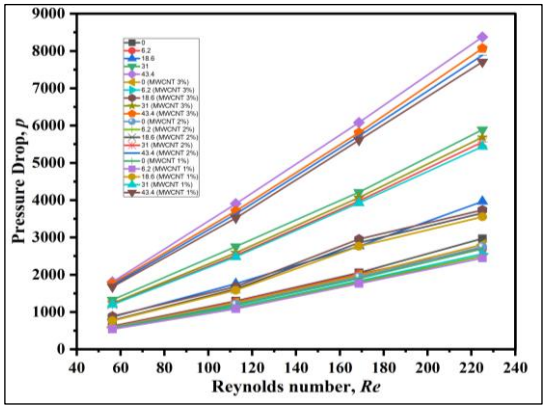

Figure 7: Pressure Drop evaluation with Reynolds number.
Source: Authors, (2026)

Figure 7 elucides the pressure drop (ΔP) with Reynolds number for water and MWCNT nanofluids across various pin-fin configurations shows a sharp rise with velocity (shown in Fig 1) because the dynamic pressure term (ρv2/2) dominates at higher velocities causing ΔP to scale approximately with the square of the flow velocity. Although the friction factor slightly decreases with increasing Reynolds number, the rapid growth of inertial forces and intensified shear near pin structures leads to a net increase in pressure loss. At lower Reynolds number, ΔP is minimal, dominated by viscous effects and smooth flow. As velocity approaches 2 m/s, inertial effects intensify, causing greater local acceleration and pressure loss due to increased flow recirculation and wake formation around pins. The Channels with taller fins (43.4 µm) exhibit the highest pressure drop owing to increased obstruction, wetted area, and form drag, while the plain channel records the lowest. Intermediate fin heights (18.6 µm and 31.0 µm) offer moderate losses, balancing flow resistance and heat transfer enhancement. Thus, fin geometry directly governs the trade-off between pressure loss and surface augmentation. MWCNT nanofluids consistently produce higher ΔP than water because of increased effective viscosity and nanoparticle-induced flow resistance. At higher velocities (≥1.5 m/s), the gap between water and nanofluids narrows as inertial forces dominate. While MWCNT nanofluids require greater pumping power due to increased flow resistance, their superior heat transfer performance compensates for this drawback. Hence, the observed pressure drop trends reinforce the importance of optimizing fin geometry and nanoparticle concentration to achieve a balanced thermal hydraulic performance in microchannel heat sink applications.

IV.4.4 Friction Factor:

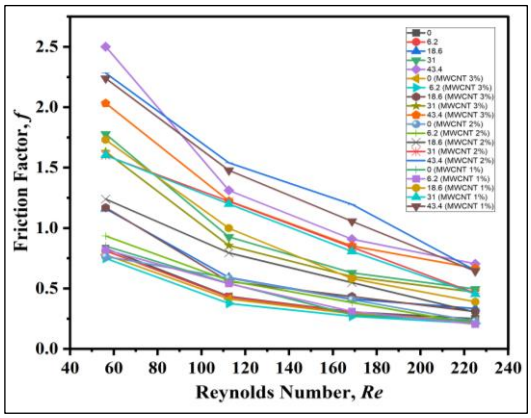

Figure 8: Friction Factor variation with Reynolds number.
Source: Authors, (2026).

The trend of friction factor (f) with Reynolds number for water and MWCNT nanofluid concentrations across different pin fin heights is presented for exact similar parameters in Figure 8. A clear inverse relationship between f and Reynolds number is observed for all configurations, which is typically consistent with laminar scale Reynolds number behavior (Re = 56-225) and the inverse proportionality to Re of viscous losses. Due the dominance of viscous shear stress and form drag caused by the pin fin obstructions, the friction factor reaches its maximum value of f ≈ 0.8-2.5 at lower Reynolds numbers. Significant pressure losses occur in this regime because the flow lacks the kinetic energy to overcome the surface friction and flow separation created behind each pin fin. The boundary layer thins and the wall shear stress contribution per unit mass flow decreases as the velocity increases (0.5 → 2.0 m/s) due to the inertial effects.

As a result, the friction factor gradually drops and tends to stabilise at higher velocities, signifying the relative suppression of viscous dominance. The plain channel has the lowest friction factor at all velocities, while the channels with taller pin fins (43.4 µm) have the highest. This is due to the fact that raising the pin height increases the wetted area and flow obstruction, which results in a larger pressure drop. Additionally, stronger flow separation and wake zones are produced by higher pin structures, which increase the local form drag. Higher friction factors result from the viscous drag dominating the total pressure loss at lower velocities. Because of their increased surface area and increased flow obstruction, taller pin fins intensify this effect, leading to significant form drag and pressure recovery losses. For all geometries, the flow moves towards inertia-controlled behaviour as velocity rises, resulting in a decrease in the friction factor. The MWCNT nanofluid typically shows higher flow resistance because of its increased effective viscosity, improved wall fluid and inter molecular interactions. However, due to the increase in thermal conductivity which indirectly affects viscosity, the nanofluid exhibits slightly lower dimensionless friction factors than water at 3% concentration. This effect is more pronounced at low velocities due to the dominance of viscous forces. However, as velocity increases, the relative difference between water and MWCNT decreases due to the increasing importance of inertial effects. Because of this, MWCNT nanofluid requires more pumping power because it has a higher hydraulic resistance than water. Additionally, as evidenced by the higher Nusselt number values, it has a greater capacity for heat transfer which leads to better thermal performance overall.

IV.4.5 Nusselt Number:

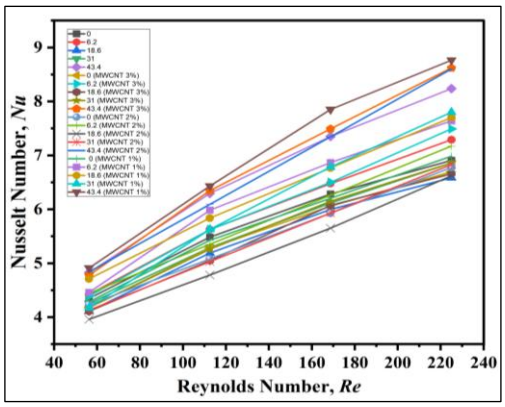

Figure 9: Nusselt number relation with Reynolds number.
Source: Authors, (2026).

Figure 9 elucidates the variation of the Nusselt number (Nu) with inlet velocity for both deionized water and MWCNT nanofluid concentrations. However, simulations has been conducted for 1%, 2% and 3% volume concentrations. A consistent increase in Nu with velocity is observed for all cases, highlighting the strong influence of Reynolds number on convective heat transfer in microchannel configurations (Fig 3). At the lowest Reynolds number (lowest velocity (0.5 m/s)), the Nu values remain relatively low for both water and MWCNT, ranging between 4 - 5. This behavior can be attributed to the dominance of conduction mechanism and the development of a thick thermal boundary layer in the absence of strong convective forces. Consequently, the difference between water and MWCNT is minimal under these conditions, as the nanofluid's enhanced thermal conductivity is not fully exploited. Even at lower nanoparticle concentrations (1% and 2%), the nanofluid exhibits noticeable enhancement compared to water which confirm that significant heat transfer improvement can be achieved without requiring the highest concentration. This can be primary attributed to the enhanced thermal conductivity of MWCNT nanofluids which is approximately 4.23%, 7.35%, and 10.55% higher than the base fluid (water) at 1 wt%, 2 wt%, and 3 wt% concentrations, respectively as compared to the based fluid. As the Reynolds number increases (velocity increases to 1.0-1.5 m/s), the Nusselt number rises steadily due to stronger convective transport and progressive thinning of the thermal boundary layer. In this regime, the benefit of MWCNT becomes more evident. The nanofluid consistently exhibits higher Nu values compared to water across all pinfin configurations which confirms the role of nanoparticles in enhancing heat transport through increased effective thermal conductivity and micro-scale convective effects.

For the 1% and 2% MWCNT concentrations, Nu values also exceed those of water demonstrating a clear improvement in heat transfer eventhough they remain lower than the 3% concentration. The relative enhancement is more pronounced at higher velocities and taller pin-fin geometries. In these scenarios the combined effect of thermal conductivity enhancement (due to nanofluid) and local disturbance of thermal boundary layer (due to pin geometries) plays a major role. The second effect is more visible at higher velocities and hence you can see a better heat transfer enhancement at higher velocities and taller pin heights. At the highest velocity of 2.0 m/s, the enhancement becomes most prominent. For water, Nu reaches values between ~7.0 and 8.0, while for MWCNT, the corresponding Nu extends more than 8.0, particularly in the channel with the tallest pin fins (43.4 µm). This is explained by the synergistic action of high flow momentum, which intensifies mixing around the fins, and the superior thermal conductivity of MWCNT nanofluid, which accelerates thermal diffusion within the fluid medium. Nu values are consistently higher than water but lower than those of the 3% nanofluid at the 1% and 2% MWCNT concentrations. Configurations with taller fins show the incremental improvement over water, emphasising the contribution of even lower nanoparticle loadings. Shorter fins (6.2 µm) provide only moderate boundary layer disruption, leading to smaller increments in Nu, whereas taller fins (31.0 µm and 43.4 µm) induce significant flow separation and accelerated motion, thereby intiates fluid mixing and promoting superior convective heat transfer. The tallest fins consistently deliver the maximum Nu for both working fluids, with the relative gain being more significant for the nanofluid. Overall, the results demonstrate that both increasing flow velocity and incorporating MWCNT nanoparticles substantially improve heat transfer performance in microchannel heat sinks. The improvement is further amplified by the presence of taller pin fins, which serve as passive promoters of thermal hydraulic enhancement.

IV.4.6 TPF:

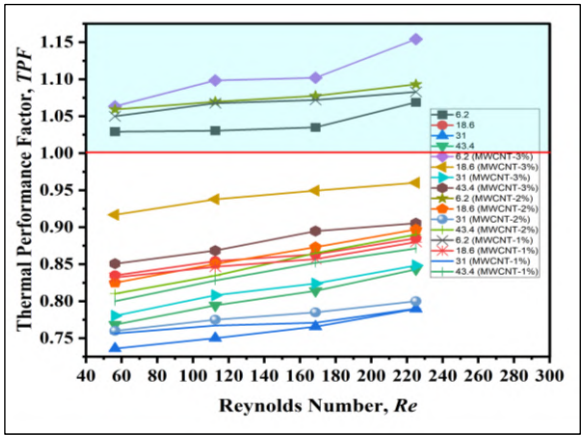

Figure 10: Thermal Performance Factor vs Reynolds number.
Source: Authors, (2026).

The variation of the Thermal Performance Factor (TPF) with Reynolds number for water and MWCNT nanofluids of different concentrations across various pin fin heights is illustrated in Fig. 10. The TPF measures heat transfer improvement in relation to increased frictional losses, indicating overall thermohydraulic efficiency. A general trend of increasing TPF with flow velocity is observed for all configurations, reflecting the dominance of convective heat transfer improvements over the associated hydraulic penalties at higher Reynolds numbers. At low velocity (0.5 m/s), the TPF values remain below unity for most configurations, particularly for the plain and shorter pin-fin channels. This indicates that, under laminar and viscous-dominated conditions, the pressure-drop penalty outweighs the modest heat-transfer enhancement achieved at such low flow rates As the Reynolds number increases, TPF values progressively improve, reaching peak values around 1.1–1.4 depending on the configuration and nanofluid concentration. This rise can be attributed to enhanced flow mixing, boundary-layer disruption, and reduced thermal boundary layer thickness, which collectively augment the convective heat transfer rate more strongly than the corresponding rise in pressure losses. Among all the geometries, the channels with intermediate pin fin heights (18.6 µm and 31.0 µm and tallest 43.4 µm fins) have some fluctuations in the pattern, due to the combined reaction of convective transport and friction losses.

The shortest fin (6.2 µm) consistently demonstrate superior thermal performance compared to the other three fin heights (18.6 µm, 31 µm and 43.4 µm). The moderate pin structures provide an optimal balance between surface area augmentation and flow obstruction which is sufficient to intensify thermal mixing without inducing excessive form drag. All MWCNT nanofluids exhibit higher TPF values than water, confirming their superior thermohydraulic performance. The improvement becomes more evident with increasing nanoparticle concentration at 1% MWCNT, the enhancement is marginal, whereas at 3%, the TPF surpasses unity for most pin fin geometries, indicating a net performance gain. This improvement is due to higher thermal conductivity and enhanced micro-convection from Brownian motion in the MWCNT suspensions, which support heat diffusion and wall heat removal. However, as concentration rises further (more than 3%), increased viscosity limits these benefits, resulting in reduced enhancement at higher concentrations Overall, the integration of pinfin structures with MWCNT nanofluids achieves a mutual enhancement in system efficiency. The combination of intensified heat transfer and manageable pressure drop results in a thermally favorable regime where TPF > 1 for optimized pin heights and flow rates. These findings clearly indicate that the use of MWCNT nanofluids, particularly at 2–3% concentration, provides a substantial improvement in the overall thermal-hydraulic performance of microchannel heat sinks, validating their potential as advanced cooling solutions for high heat-flux microscale applications.

IV.4.7 Data-Driven Heatmap Analysis of Thermal Performance (TPF) Using MATLAB

The combined thermal-hydraulic performance (TPF) for each of the five pin heights (0, 6.2, 18.6, 31, and 43.4 µm), four flow velocities (0.5–2 m/s), and four working fluids (water and 1%, 2%, and 3% MWCNT nanofluids) was visualized using a data-driven heatmap created in MATLAB. Multidimensional CFD output is processed, normalized and mapped using an ML-based exploratory analysis workflow in this visualization approach to uncover performance patterns that are not immediately apparent from isolated plots. This method supports high-dimensional engineering interpretation by using the same datacentric principles that are frequently used in machine-learning research, even though it is not a predictive machine learning model. The heat map clearly and consistently demonstrates that TPF rises with both Reynolds number and nanoparticle concentration throughout the entire dataset (Fig 11). Because of its much higher effective thermal conductivity, the enhancement is most noticeable for the 3% MWCNT nanofluid. The pin height of 6.2 µm with 3% MWCNT yields the highest TPF among all evaluated conditions when comparing the geometric configurations, especially at the highest velocity. This happens because the high concentration of nanoparticles significantly increases heat transfer, resulting in the most advantageous trade-off in the TPF metric, while the shorter pin height maintains a comparatively lower frictional penalty. Higher pin heights such as 31 µm and 43.4 µm, are thermally superior in terms of heat transfer. However, their overall TPF is lower than that of the ideal 6.2 µm case due to increased pressure losses. The anticipated gradation is followed by the intermediate concentrations (1% and 2% MWCNT) The proportionate impact of nanoparticle loading is demonstrated by the fact that 2% consistently performs better than 1% and water but both fall short of the 3% cases because of the relatively smaller heat-transfer enhancement. Predominantly, the heatmap visualisation offers a quick, thorough, and objective evaluation of the behaviour of the system. The most efficient configuration which is indisputably the 3% MWCNT nanofluid with 6.2 µm pin height. This highlights how crucial it is to strike a balance between fluid-property improvement and geometric optimisation when aiming for concurrent improvements in thermal and hydraulic performance.

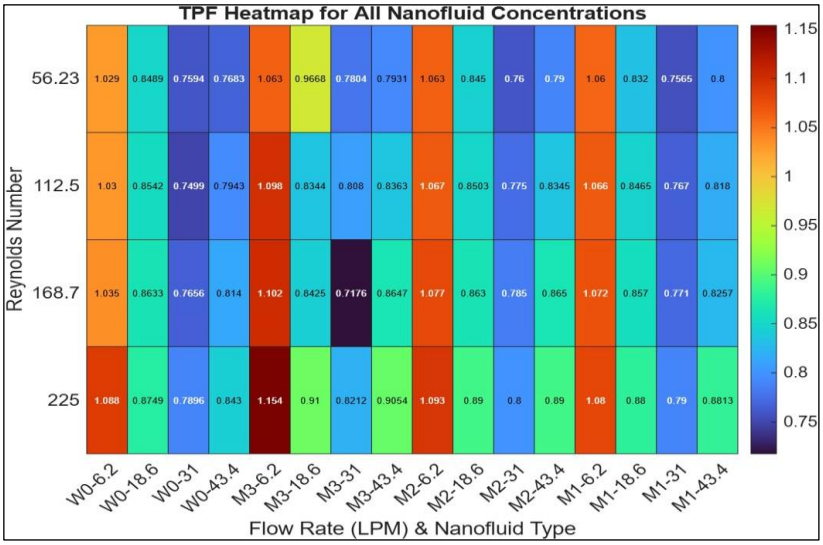

Figure 11: Heat Map Visualization of TPF for MWCNT across the pin heights for various Reynolds numbers.
Source: Authors, (2026)

The Heatmap's Advantages
The heatmap is a crucial analytical tool because it allows immediate comparison between four Reynolds numbers, five pin heights, and four fluids;
exposing non-linear relationships between nanofluid concentration and geometric parameters;
facilitating data-driven decision making akin to exploratory analysis in machine learning;
creating a single, comprehensible visual framework from multidimensional CFD outputs.

V. CONCLUSIONS

The thermo-hydraulic performance of a microchannel heat sink with pin fins of different heights was examined in this study using water and MWCNT-water nanofluids (1-3 wt %). The findings verify that thermal transport in the microchannel is significantly improved by both nanoparticle concentration and Reynolds number. The 3% MWCNT nanofluid continuously produced the highest Nusselt number under all operating conditions, which increases notably at higher flow rates. The effect is especially noticeable for the lowest pin height configuration where superior heat transfer enhancement is produced by the combination of enhanced nanofluid conductivity and increased turbulence intensity. All pin heights exhibit the same increasing trend with mass flow rate and nanoparticle loading according to pressure-drop analyses. Compared to taller pin arrays, lower pin heights show noticeably smaller pressure penalties, particularly at lower velocities. Higher pin heights, on the other hand, result in significantly greater pressure drops because of increased flow obstruction; at higher Reynolds numbers, the difference between nanofluids and water is more noticeable. The 3% nanofluid produced the largest pressure drop across all fin heights, which is in line with its higher viscosity and momentum diffusion. For all working fluids, friction factor values drastically drop as the Reynolds number rises. Because viscous forces are less dominant at higher flow rates, the lowest friction factors are found at Re = 225. Because of their greater wetted perimeter and flow resistance, taller pin fins have higher overall friction factors. When compared to water, the use of nanofluids causes a slight increase in friction; however, this difference decreases at higher Reynolds numbers. According to Thermal Performance Factor (TPF) analysis, the 3 % nanofluid with the lowest pin height offers the best balance between hydraulic penalty and heat transfer enhancement. The lower Reynolds number range (especially around Re ≈ 56) exhibits the highest TPF values, where thermal enhancements significantly outweigh the comparatively slight increase in pressure drop. For all pin heights and concentrations, TPF gradually decreases with increasing Reynolds number; however, because of their lower flow resistance and higher enhancement ratio, lower pin heights consistently perform better than taller pins. Overall, lower pin-height microchannel designs combined with MWCNT nanofluids particularly at 3 weight percent concentration produce a significant increase in heat transfer capability while preserving acceptable pressure drops. These results show that the thermal management efficiency of microchannel heat sinks used in next-generation electronic cooling applications can be greatly increased by optimizing fin geometry in conjunction with customized nanofluid formulations.

ABSTRACT

Diabetic Retinopathy (DR) is a primary cause of vision loss globally in patients suffering from diabetes. Timely detection of the disease can reduce the chances of blindness. Fundus images are studied by the Ophthalmologists for any signs of the disease. Existing methods for detecting DR include manual study by the experts or usage of Artificial Intelligence-based models. But these methods encounter several issues like inaccurate detection, time-consuming, costly including the lack of stable datasets and consistent image processing techniques. Owing to the damage these lesions do to the retina it becomes essential to look for an efficient and accurate model for diagnosing DR. Deep Neural Networks help us to segment the fundal images to focus on the retinal areas helping us to look for early signs of the disease. If DR is detected at an earlier stage, the risk of complete blindness can be reduced. This paper presents a comprehensive survey of existing models for Diabetic Retinopathy detection, with an intention of identifying opportunities for improvement to develop a more robust and stable model which can efficiently and accurately perform the classification. It also includes detailed discussion on various datasets used for detection/classification of the disease.

I. INTRODUCTION

Prolonged high blood sugar levels due to low amount of insulin produced by pancreas leads to Diabetes Mellitus commonly known as *Diabetes*. There are mainly two categories of it: Type-1 whose root cause is not known and Type-2 which can identified by the symptoms like Microaneurysms, Hemorrhages, Exudates, etc. This when left untreated for longer duration can lead to lesions on the retina and ultimately leading to blindness [1]. DR mainly occurs due to retinal vascular disease and abnormal flow of blood through retina which could eventually lead to blood or fluid leakage [2]. In a survey conducted in 2021, it was found that around 26% of diabetic patients in the United States had suffered from DR and around 5% of diabetic patients had reported severe case of DR that could lead to vision-loss. According to World Health Organization, issues related to diabetes will cross 700 million by 2045 and out of this approximately 1/3rd will face issue of this disease [3]. It is one of the five leading causes of vision loss along with glaucoma, refractive errors, age-related macular degeneration (AMD) and cataract. A study showed that some the leading causes for DR include poor renal function, elevated blood glucose levels, liver disease, hematonosis (blood disorders), and high blood pressure [4]. The common symptoms for DR include frequent vision bluriness or difficulty while reading later on when severity increases it can include dark spots in vision, fluctuated or disorientated vision or retinal detachment ultimately leading to blindness. Although DR is irreversible but detecting it in early stages can help control the damage by controlling the factors like hypertension and hyperglycemia. DR can be detected either manually or automatically by using techniques such as laser treatment, anti-VEGF injections, or vitrectomy [1]. Figure 1 describes the various stages of DR, which are classified into namely - Normal, Mild Non-Proliferative Diabetic Retinopathy (NPDR), Moderate NPDR, Severe NPDR and Proliferative Diabetic Retinopathy (PDR). The main classification being Normal vs NPDR vs PDR. NPDR further being classified as Mild, Moderate, and Severe based on the type and amount of lesions present.

It also shows the vital symptoms which show the presence of DR. Ophthalmologists target these lesions to check for the presence of the disease and understand its severity. Normal grade also known as NO-DR stage is a condition where the eye is normal and retina shows no signs of the lesions. The vision of the patient remains unaffected. Mild NPDR is the earliest stage of the disease where microaneurysms begin to generate. There are no to very least chances of vision loss at this stage, and the retina remains intact. In the Moderate NPDR stage more microaneurysms begin to appear and other lesion structures like hemorrhages, and hard exudates also start to generate. Veins and capillaries begin to get blocked, reducing blood flow. Blood leakage starts which leads to the issue of Macular Edema. Severe NPDR stage witnesses lesions like cotton-wool spots and venous beading. The issue of vein blockage increases after which blood supply to the retina almost stops hence level of oxygen reduces in the retina. PDR stage faces Neovascularization i.e., the new and abnormal blood vessels begin to appear on retina and optic disc. The vessels being weak tend to burst and lead vitreous hemorrhage. If not attended on time, it can lead to significant blood loss.
