

Figure (b): Mg- PSZ Coated piston.

Figure 12: Load Vs CO.
Source: Authors, (2026).

Emission of CO is reduced by a very large percentage with Mg-PSZ coating (Fig. 12 (b)) in all fuels since the better thermal insulation increases the oxidation rate of the CO to produce CO2. The E20 and B20 blends with coating have the lowest CO emissions.

Multi-Objective Optimization and Decision Analysis
ANN Model Validation

An Artificial Neural Network (ANN) was created to estimate the brake thermal efficiency (BTE), mechanical, hydrocarbon (HC), and carbon monoxide (CO) emissions as a function of piston type, fuel blend, and engine load. The coefficient of determination (R^2) and root mean square error (RMSE) were used to determine model performance. Table 10. Statistical performance parameters of the ANN model in predicting engine performance and emission parameters.

Table 10: Performance Metrics of the Developed ANN Model.

Output Parameter	R^2	RMSE
Brake Thermal Efficiency (BTE)	0.9996	0.2014
Mechanical Efficiency	0.9999	0.2548
Hydrocarbon Emission (HC)	0.9988	9.8408
Carbon Monoxide Emission (CO)	0.9209	0.2292

Source: Authors, (2026).

NSGA-II Pareto Optimisation

The ANN model has been validated and incorporated into the Non-dominated Sorting Genetic Algorithm II (NSGA-II) to undertake multi-objective optimization. The goals were outlined to be:

- Maximize BTE
- Maximize mechanical efficiency
- Minimize HC emissions
- Minimize CO emissions

NSGA-II produced a Pareto front that reflected the efficiency / emission properties trade off. The Pareto solutions depict how difficult it is to maximize thermal efficiency and minimize exhaust emissions.

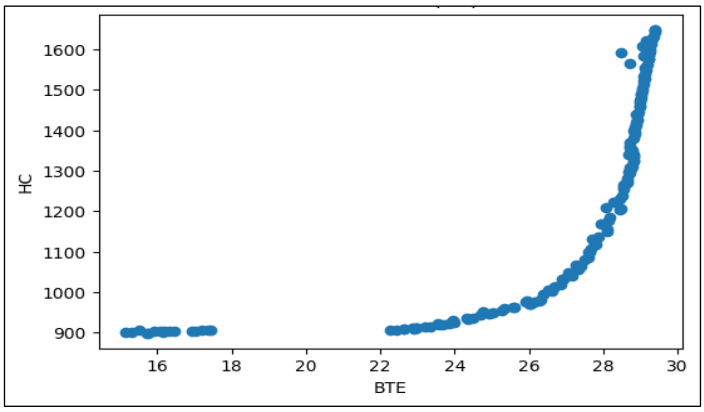

Figure 13 (a): 2D Pareto front plots.
Source: Authors, (2026).

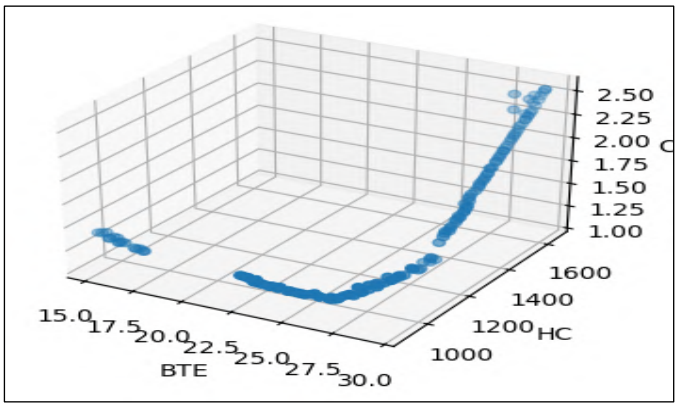

Figure 13: (b): 3D Pareto surface.
Source: Authors, (2026).

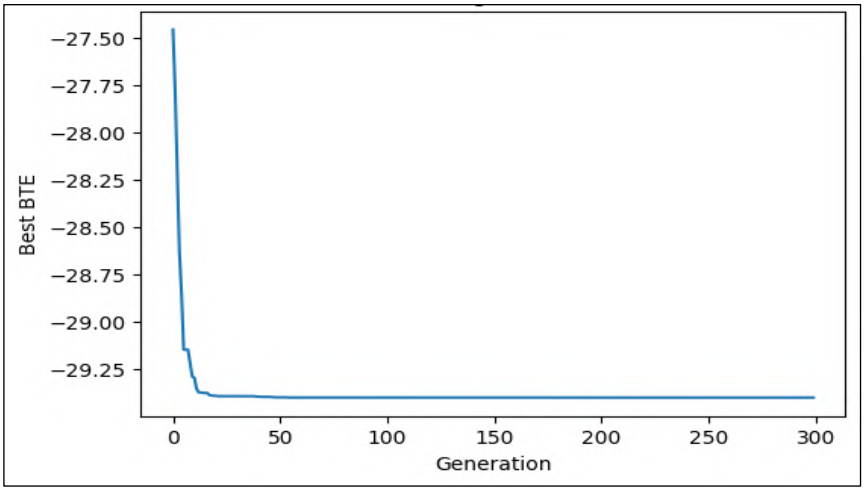

Figure 14: Convergence curve.
Source: Authors, (2026).

The Pareto analysis validates the fact that regions of greater efficiency are associated with the modest rise in the emissions levels, and a decision-making approach should be employed to find a compromise. Figures 13 and 14 show the results of the multi-objective optimization achieved with the help of the NSGA-II algorithm. Figure 13 shows the Pareto front, where the parameters of efficiency (BTE and mechanical efficiency) and the emissions (HC and CO) are maximized and minimized respectively. The allocation of non-dominated solutions proves that the conflict between performance enhancement and reduction of emissions is natural, which means that the changes in thermal efficiency can result in insignificant changes in the formation of pollutants. The convergence behaviour of the optimization process is depicted by figure 16 whereby the value of the objectives decreases with the increase in the generations, which proves that the algorithm converges to a consistent state and is able to accurately identify the optimal solution region.

TOPSIS-Based Optimal Solution Selection

In order to check the most balanced operating point, Technique of Order of Preference by Similarity to Ideal Solution (TOPSIS) was used on the Pareto-optimal set. Closeness coefficient was calculated on individual solutions and they were ranked according to the proximity of the solutions to the ideal point.
The solution arrived at is the best and it is:

- Piston type: 1 (Mg-PSZ coated)
- Fuel blend: 1.96 (approximately E20–B20 range)
- Load: 84.55%
- Closeness coefficient: 0.8156

The findings show that a coated piston that is running at and around high load with an oxygen blended fuel mixture is the one that provides the most appropriate compromise in terms of efficiency improvement and emissions reduction.

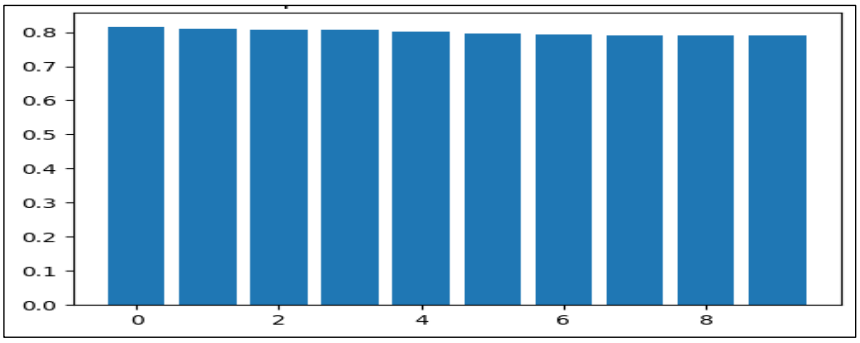

Figure 15: Closeness coefficient ranking bar chart.
Source: Authors, (2026).

The TOPSIS ranking of closeness coefficients of the Pareto-optimal solutions in NSGA-II are provided in Figure 15. The closeness coefficient is the relative closeness of each solution to the optimal point, i.e., the situation where maximum efficiency and minimum emissions are both attained. The greater the value of coefficient, the higher the overall performance-emission balance. The best solution has the closest value (0.8156), which proves its superiority with the candidate solutions. The ranking trend indicates a progressive trade-off behaviour, which confirms the usefulness of TOPSIS in making the most balanced operating condition among the Pareto frontier.

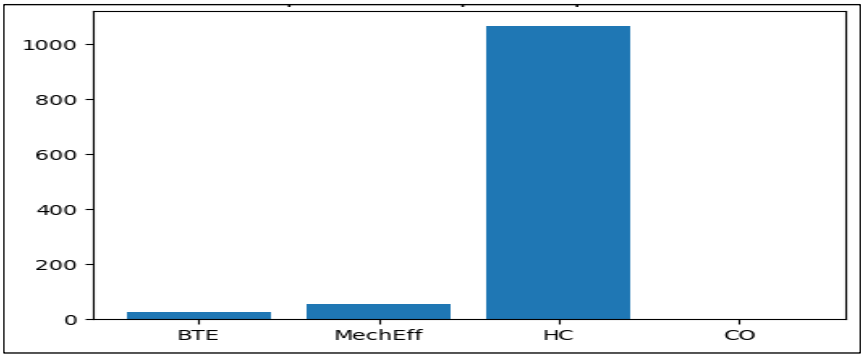

Figure 16: Radar comparison of baseline vs optimized condition.
Source: Authors, (2026).

Figure 16 has compared the experimental condition at the baseline with TOPSIS-optimized operating point of BTE, mechanical efficiency, HC, and CO emissions. The optimized result, which can be associated with the Mg-PSZ coated piston at high loads and oxygenated mixture, depicts a better thermal efficiency and lower emissions levels compared to the baseline one. The concurrent improvement of the efficiency parameters and the reduction of the pollutants formation is pointed out in the comparative visualization. This supports the usefulness of the combined ANN-NSGA-II-TOPSIS model to determine a balanced and performance-effective operating range.

VI. CONCLUSION

The current experiment was a controlled systematic assessment of the performing capabilities of a two-stroke spark-ignition engine and the overall emission characteristics of oxygenated fuel blends (E20 and B20) with Mg-PSZ thermal barrier coating. The results of the fuel characterization by the use of GC and FTIR confirmed the successful blending of the hydrocarbon backbone with the introduction of oxygenated functional groups successfully. The outcomes of the experiment showed that E20 enhanced brake thermal efficiency (BTE) by about 4-6 % over gasoline under uncoated conditions since it enhanced oxygen- assisted combustion. The greatest changes were however realized when Mg-PSZ coating was utilized. This coated configuration increased BTE by 5-8 %, decreased total fuel consumption by 3-6 percent and had massive reductions in emissions, including 12-18 percent lower hydrocarbon (HC) emission and 15-20 % lower carbon monoxide (CO) emission compared to the uncoated gasoline baseline.
Out of all the combinations that have been tested, the Mg-PSZ-coated piston with E20 showed the best overall performance-emission balance, especially at the higher load conditions. ANN modeling exhibited a high predictive performance (R 2 = 0.92-0.999), with the combined NSGA-II-TOPSIS optimization model establishing an optimum high-load coated operating condition with a closeness coefficient of 0.8156, which proved the existence of a strong trade-off between efficiency increase and emission decrease.

ABSTRACT

Compliant mechanisms, which derive motion through the elastic deformation of flexible members, offer distinct advantages over traditional mechanisms, including reduced part count, enhanced reliability, and smooth, frictionless operation. However, their fatigue life is a critical design concern due to the continuous cyclic stresses endured during operation. The fatigue performance of these mechanisms is strongly influenced by a combination of material properties, geometrical design, and loading conditions. Among these, geometrical parameters—particularly the radius of curvature—play a crucial role in determining stress concentration and overall durability. This study focuses on analyzing the impact of the radius of curvature on the fatigue life of compliant mechanisms using Finite Element Analysis (FEA). Four different configure rations of square and circular motion stages with varying curvature radii were evaluated under constant loading conditions. The analysis considered key parameters such as damage factor, safety factor, and fatigue life cycles. Results indicate that increasing the radius of curvature significantly improves fatigue resistance by distributing stress more evenly and reducing critical stress concentrations. The findings suggest that appropriate geometric optimization, especially in curved beam regions, can substantially enhance the life span and safety of compliant mechanisms without compromising their function. These insights are particularly beneficial for the design of mechanisms in applications requiring high precision and longevity, such as biomedical devices, micro-positioning systems, and additive manufacturing equipment. This research contributes valuable design guidelines for enhancing the fatigue performance and operational reliability of compliant mechanisms.

I. INTRODUCTION

Fatigue refers to the progressive and localized structural damage that occurs when a material is subjected to cyclic loading. Over time, repeated deformation induces microscopic defects and cracks that grow, ultimately leading to failure. In compliant mechanisms, the primary source of fatigue arises from the cyclic bending, stretching, or twisting of flexural elements, often concentrated in areas of high stress or strain. The prediction and mitigation of fatigue failure are therefore critical for extending the service life of these mechanisms, particularly in applications requiring millions or billions of load cycles. The fatigue life of a compliant mechanism depends on several factors, including material properties, geometric design, stress distribution, and environmental conditions. Materials such as metals, polymers, and composites exhibit varying fatigue characteristics, influenced by their elastic limits, crack propagation resistance, and thermal stability. The geometry of the mechanism, particularly the radii of curved segments, fillets, and transitions between flexible and rigid regions, plays a crucial role in stress concentration and fatigue initiation. Compliant mechanisms have revolutionized modern engineering by leveraging the elastic deformation of materials to achieve motion and force transmission without the need for traditional joints or hinges. This innovative design approach leads to mechanisms that are often lighter, more compact, and capable of smoother and more precise movements compared to their rigid-body counterparts [1].

Applications of compliant mechanisms span a wide range of fields, including aerospace, robotics, biomedical devices, and microelectromechanical systems (MEMS) [2] Despite their numerous advantages, compliant mechanisms are subject to continuous and repetitive deformation, which exposes them to fatigue. Fatigue, defined as the progressive and localized structural damage that occurs when a material is subjected to cyclic loading, is a critical concern for the longevity and reliability of these mechanisms [3-5] Understanding and predicting the fatigue life of compliant mechanisms is essential to prevent unexpected failures and to ensure their safe and effective operation over time. Fatigue analysis involves studying how materials respond to cyclic loading and identifying the conditions under which they are likely to fail. For compliant mechanisms, this analysis is particularly important due to their reliance on material flexibility and continuous deformation [6] Unlike traditional mechanisms, where fatigue may primarily occur at discrete joints or moving parts, compliant mechanisms experience distributed stress and strain throughout their structure. This makes fatigue analysis more complex and necessitates a detailed understanding of material behavior, stress distribution, and crack propagation [7-11] Compliant mechanisms can be broadly classified into two categories based on their primary mode of deformation:

- **Linear Compliant Mechanisms**: These mechanisms achieve straight-line motion through bending or stretching. Examples include flexural beams and bistable springs.
- **Rotational Compliant Mechanisms**: These mechanisms enable rotational motion through flexural pivots or torsion. Examples include flexural hinges and rotational springs [12-14].

Both types of mechanisms offer unique advantages and challenges in terms of fatigue analysis. Linear mechanisms often encounter issues related to bending fatigue, while rotational mechanisms may experience torsional fatigue. Additionally, the geometry and material properties of compliant mechanisms play significant roles in determining their fatigue behavior. Material properties, geometric properties, and the combination of the components greatly influence the compliant mechanism and its performance. Stiffness, bending stress, beam deflection, and degree of freedom govern the Compliant Mechanism's various series and parallel beam arrangements. In contrast, payload capacity and resonance frequency decide the compliant mechanism actuation. Many researchers have worked on the range of motion with different arrangements of beams, degrees of freedom, and actuation positions to get micro and nano ranges of motion with compliant mechanisms. Translational and rotational positioning systems are mainly used to achieve linear and rotational motion with various combinations of beams and hinges. A translational positioning mechanism provides a range of motion in X and Y directions. A serial-parallel kinematic chain is used in X-Y-compliant mechanisms to provide high load capacity, low inertia, and high resonant frequency [15] by maintaining accuracy, precision, and frictionless motion.

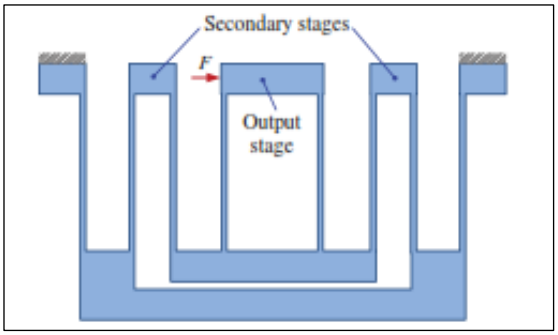

Figure 1: Translational positioning System.
Source: (15).

A Schematic of the parallel beam position is shown in Figure. 1 in which the translational motion stage is used to achieve single-directional displacement by applying actuating force on the vertical parallel beam. Figure. 2 demonstrates the combination of parallel beams stacked in two modules, wherein the second module rests on the first module, in laser sintering application for desired compliant values [15] In this mechanism, the output motion is guided by a double parallel flexural manipulator used in combination located at the corners of the module. The second module is mounted orthogonally on the top of the first module to get a parallel kinematic and stacked structure. This modular design allows the cost reduction in both manufacturing and maintenance. When driven by the Voice coil actuator, four double parallel flexural manipulators on the top and two double parallel flexural manipulators at the bottom guide the motion along X and similarly for the motion along y direction. Hence, a decoupled two-dimensional translation is achieved by the XY stage to obtain the travel range of 10 mm [16].

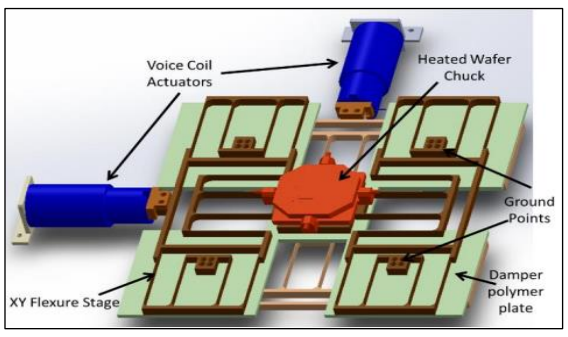

Figure 2: Selective laser sintering system.
Source: (16).

Rotational Movement in a compliant mechanism is achieved with a combination of beams, hinges, and radial flexures, as shown in Figure. 3. The relative motion between hinges and flexures leads to the desired compliant values due to actuating forces applied in compliant mechanisms [17] Radial flexure needs to be developed with a larger beam length of up to 100 mm, a larger outer radius of up to 10 mm, and a smaller thickness of up to 0.3 mm to achieve the desired rotational range [18].

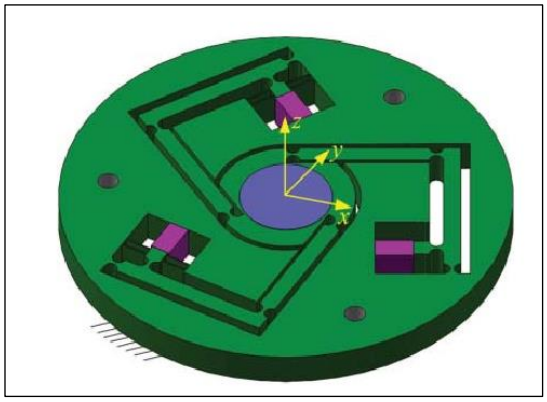

Figure 3: Rotational positioning System
Source: (16).

However, in practice, the compactness, restriction, manufacturing tolerance, and minimum stiffness criterion limit these geometrical parameters [19].

Challenges in Fatigue Analysis

Several challenges arise when analyzing the fatigue of compliant mechanisms. The primary challenges include:

1. **Material Selection**: The choice of materials significantly influences the fatigue life of compliant mechanisms. Materials commonly used in these mechanisms include metals, polymers, and composites, each with distinct fatigue characteristics [20].
2. **Stress Concentration**: The design of compliant mechanisms must account for stress concentration points, such as sharp corners or notches, which can significantly reduce fatigue life.
3. **Crack Initiation and Propagation**: Understanding where and how cracks initiate and propagate under cyclic loading is crucial for predicting the lifespan of compliant mechanisms.

Combined linear and rotational compliant mechanism is designed for biomedical applications requiring the linear range of motion from 2 mm to 4 mm in X and Y directions and rotational motion from 2° to 4°. These compliance values are achieved with various beams, hinges, and notches arrangements [21-25].

II. METHODOLOGY

Compliant mechanism is analyzed for actuating force of 80N which is the maximum load carrying capacity of PLA material. 4 Different conFigureurations of mechanisms are developed for analyzing the effect of geometrical parameters on fatigue life cycle of compliant mechanism as follows:

Mechanism 1- Square motion stage with curve beam of 32mm

Mechanism 2- Square motion stage with curve beam of 40mm

Mechanism 3- Circular motion stage with curve beam of 32mm

Mechanism 4- Circular motion stage with curve beam of 40mm

Mechanism 1 and 2 - Square motion stage with curve beam of 32 mm and 40 mm

Compliant mechanism 1 is developed with the dimensions of (Length *width *height) 300mm*300mm*15mm . Motion stage is of 50 mm. beam thickness of mechanism is 2mm. Overall dimensions of mechanism is shown in Figure. 4. In this mechanism force is apply on Y direction and displacement of mechanism will occur in X direction. Elements of mechanism are as shown in Figure. 5. Radius of curvature of beam is 32 mm as shown in Figure. 6 and Radius of curvature of beam is 40 mm as shown in Figure. 7 is used to analyze the impact of actuating force on fatigue life cycle with variation in radius of curvature of beam.

Material

Polylactic Acid (PLA) is a biodegradable thermoplastic derived from renewable resources such as corn starch or sugarcane. It is widely used in 3D printing and various applications where its properties make it suitable for compliant mechanisms. When analyzing the fatigue behavior of compliant mechanisms made from PLA, several key material properties and considerations are relevant. Material properties of PLA are shown in Table 1. This values are taken from Tensile test of PLA Specimen with ASTME8 standard.

Table 1: Material Properties of PLA.

Sr.No	Content	Values
1.	Youngs Modulus	3986Mpa
2.	Ultimate Tensile strength	59 Mpa
3.	Poissons ratio	0.33
4.	Bulk Modulus	3907 Mpa
5.	Shear Modulus	1498 Mpa

Effect of geometrical parameters on fatigue life cycle of compliant mechanism

Fatigue analysis of a compliant mechanism involves evaluating the predicting the life of a component subjected to cyclic loading. The compliant mechanism is analyzed based on the stress-life (S-N) curve and the stress range at various points of the component. The material properties, loading conditions, and geometry of the mechanism are considered in the analysis. The fatigue life is estimated based on the number of cycles required to cause failure, taking into account the size and location of any cracks that may form. The results of the fatigue analysis are used to design components that can withstand the expected load cycles, ensuring that they will perform their intended function over their intended lifespan. This table 2 provides a comprehensive overview of the settings and parameters used in a fatigue analysis. The analysis is based on time, considers zero-based loading, and uses the Goodman mean stress theory. The fatigue strength factor is set to 1, indicating nominal strength is used. Results are displayed at the end of the analysis period, and the fatigue life is measured in cycles, with one cycle being equal to one actual cycle. The analysis type is stress-life, using the signed von-Mises stress component to evaluate fatigue life. Ansys 21 used for Numerical analysis of compliant mechanism.

III. RESULT AND DISCUSSION

Fatigue analysis of Square motion stage with curve beam of 32 mm (Mechanism 1)

Square motion stage with curve beam 1 is having dimension of 300*300*15 mm with curve beam radius of 32mm. Fatigue analysis of square motion stage is analyzed for 80N force. Force is applied at notch as shown in Figure. 10. Mechanism 1 is having meshing with 605938 nodes and 391526 triangular elements as shown in Figure. 11.

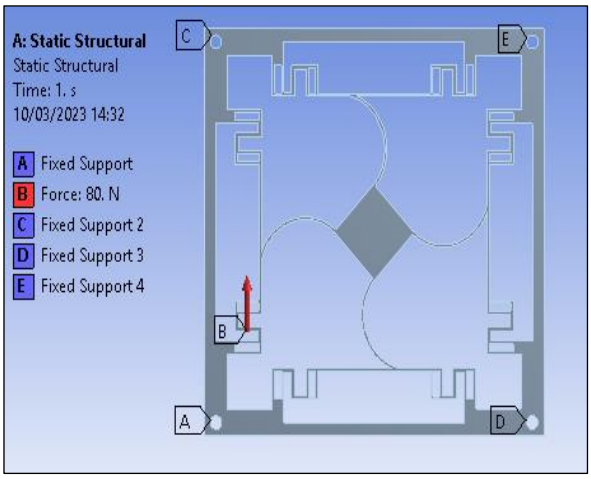

Figure 10: Boundary Conditions of Mechanism 1 for fatigue analysis.
Source: Authors, (2026).

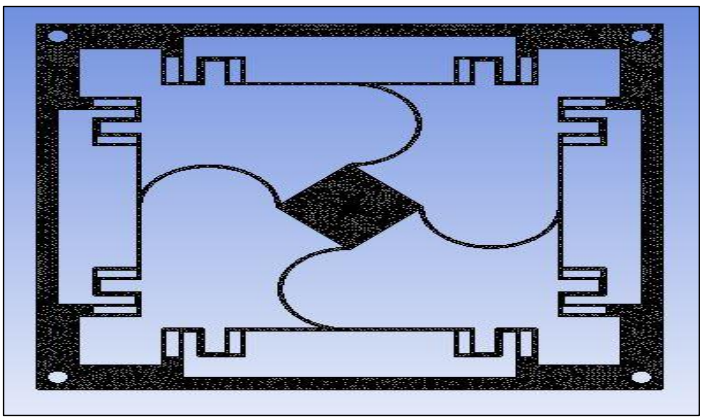

Figure. 11: Meshing of Mechanism 1 for fatigue analysis.
Source: Authors, (2026).

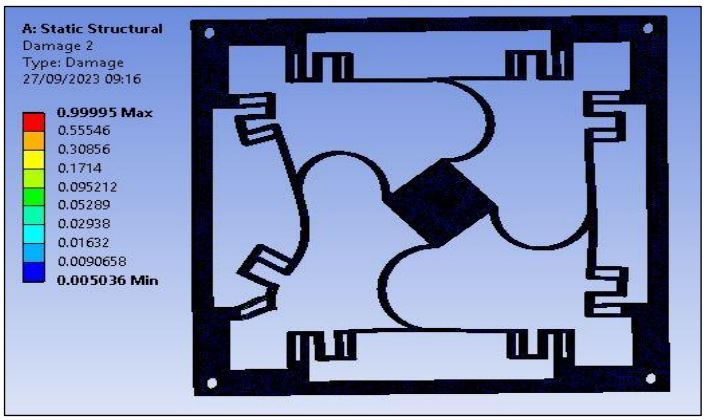

Figure. 12: Damage of Mechanism 1.
Source: Authors, (2026).

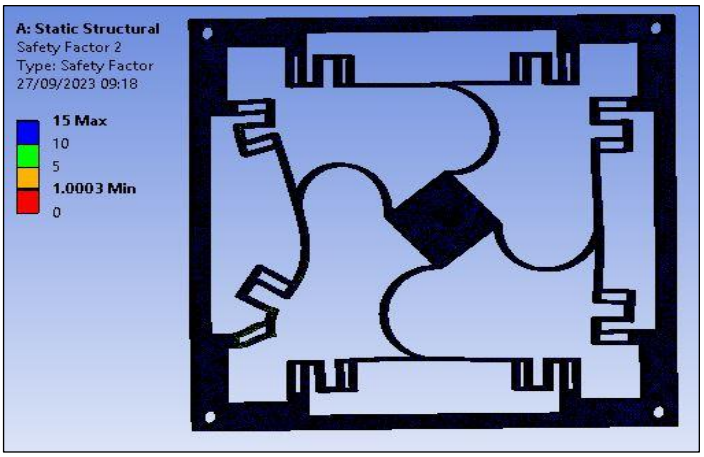

Figure 13: Safety of Mechanism 1.
Source: Authors, (2026).

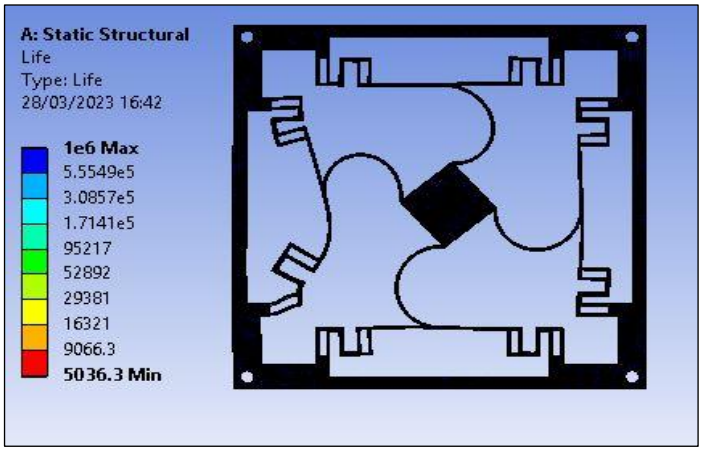

Figure 14: Life cycle for Square motion stage with curve beam 1.
Source: Authors, (2026).

To avoid fatigue failure, the damage value must be less than 1. Figure. 12 shows the damage assessment of the mechanism. According to Figure. 13, the safety factor of the mechanism is 1, which indicates that the mechanism is at the threshold of its design limits.

Figure. 14 presents the life cycle analysis of the mechanism. The square motion stage with Curve Beam 1 is deemed suitable for 5,036 life cycles, given that the damage factor is 0.99 and the safety factor is 1. This means the mechanism can withstand 5,036 cycles before potentially reaching its fatigue limit, as the damage factor is just under the critical value of 1, ensuring it does not fail prematurely.

Analytical Method to calculate Fatigue life Cycle, Damage and Safety factor for Mechanism 1

We'll use the same parameters for both numerical and analytical methods to ensure consistency.

- Material: PLA
- Tensile Strength (σ_t): 59 MPa
- Fatigue Strength Coefficient (σ_f) :2.05 MPa
- Fatigue Strength Exponent (b): -0.153
- Stress amplitude (σ_a) : 0.52 MPa
- Number of cycles (N_f): Various levels for damage calculation
- Fatigue Life Cycle Calculation (N_f) using Basquin's equation:

$$\left(\frac{\sigma a}{\sigma f}\right)^{(1/b)} \quad (1)$$

$$N_f : \left(\frac{0.52}{2.05}\right)^{(1/-0.153)} \quad (2)$$

$$N_f : \text{7465 Cycle}$$

$$\text{Damage Calculation using Minors Rule (D)} : \sum_{i=1}^{k} \frac{ni}{Ni} \quad (3)$$

Compliant mechanism is subjected to 9000 Cycle at 2 Mpa

$$\text{Damage (D)} : : \left(\frac{7465}{9000}\right) = 0.82$$

$$\text{Safety Factor} : : \left(\frac{\text{Endurance limit}}{\text{Applied stress}}\right) \quad 4)$$

$$\text{Safety Factor} : \left(\frac{2.02}{2}\right) = 1.01$$

Comparison of result

1. Fatigue life cycle by Analytical Method: 7465 Cycle
2. Fatigue life cycle by Numerical Method: 7375 Cycle
3. Damage by Analytical Method: 0.82
4. Damage by Numerical Method: 0.81
5. Safety factor by Analytical Method: 1.01
6. Safety factor by Numerical Method:1.06

The results are reasonably close, indicating that the numerical model is validated by the analytical calculations.Small discrepancies can be attributed to differences in the precision of numerical simulations versus analytical approximations.

III.1 FATIGUE ANALYSIS OF SQUARE MOTION STAGE WITH CURVE BEAM OF 40 MM (MECHANISM 2)

Square motion stage with curve beam 2 is having dimension of 300*300*15 mm with curve beam radius of 40 mm. Fatigue analysis of square motion stage is analyzed for 80 N force. Force is applied at notch as shown in Figure. 15. Mechanism 2 is having meshing with 81886 nodes and 42871 triangular elements as shown in Figure. 16. To avoid fatigue failure, the damage value must be less than 1. Figure. 17 illustrates the damage assessment of Mechanism 2. According to Figure. 18, the safety factor of Mechanism 2 is 1, which indicates that it is at the threshold of its design limits. Figure. 19 presents the life cycle analysis of the mechanism.

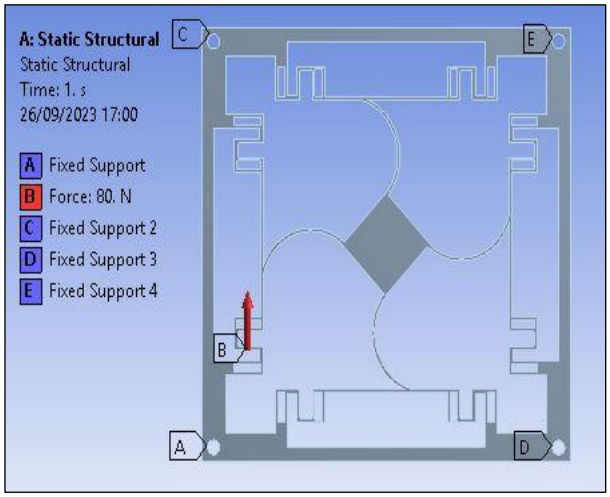

Figure 15: Boundary Conditions of Mechanism 2 for fatigue analysis.
Source: Authors, (2026).

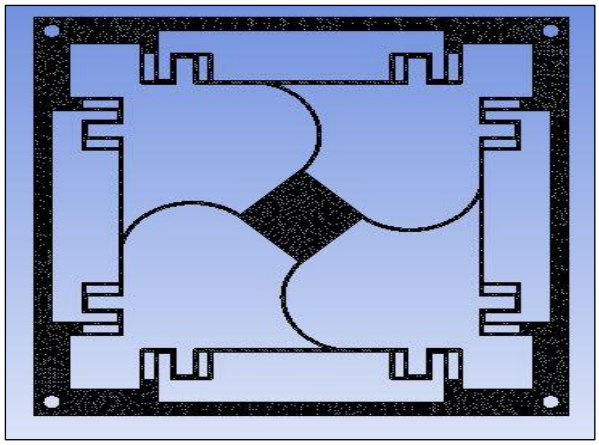

Figure 16: Meshing of Mechanism 2 for fatigue analysis.
Source: Authors, (2026).

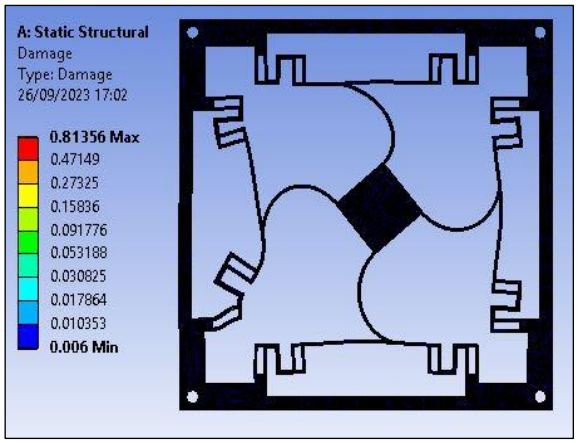

Figure 17: Damage of Mechanism 2.
Source: Authors, (2026).

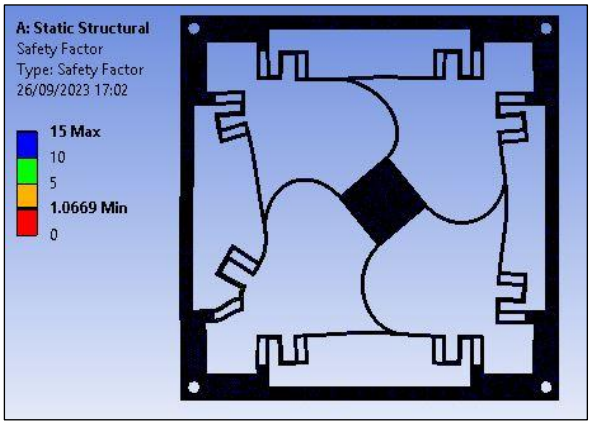

Figure 18: Safety of Mechanism 2.
Source: Authors, (2026).

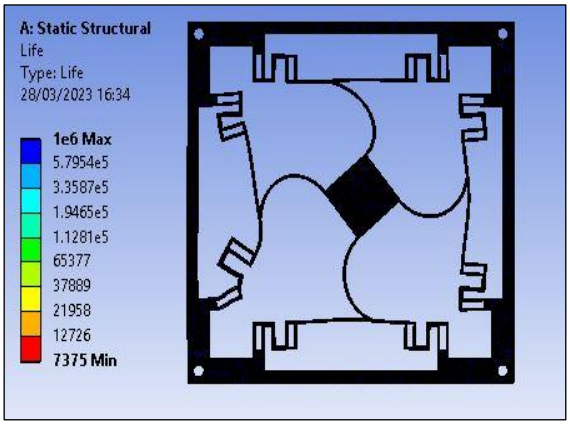

Figure 19: Life cycle for Square motion stage with curve beam -2.
Source: Authors, (2026).

The square motion stage with Curve Beam 2 is suitable for 7,375 life cycles, given that the damage factor is 0.81 and the safety factor is 1.06. This means the mechanism can endure 7,375 cycles before reaching its fatigue limit. The damage factor of 0.81, which is well below the critical value of 1, indicates that the mechanism has a lower risk of fatigue failure. The safety factor of 1.06 suggests a slight margin above the design limits, providing additional assurance of the mechanism's durability and reliability over its life cycle. A larger radius of curvature typically results in lower stress concentration at the curved sections. This means the stress is distributed more evenly, reducing peak stresses that can lead to fatigue failure. With a larger radius, the load is spread over a greater area, which reduces the overall stress experienced by any single point in the mechanism. A larger radius can also improve the flexibility of the mechanism, allowing it to better absorb and distribute applied forces, which can reduce the likelihood of fatigue failure.

Fatigue analysis of Circular motion stage with curve beam of 32 mm (Mechanism 3)

Circular motion stage with curve beam 1 is having dimension of 300*300*15 mm with curve beam radius of 32mm. Fatigue analysis of Circular motion stage is analyzed for 80N force. Force is applied at notch as shown in Figure. 20. Mechanism 3 is having meshing with 84333 nodes and 44134 traingular elements as shown in Figure. 21.

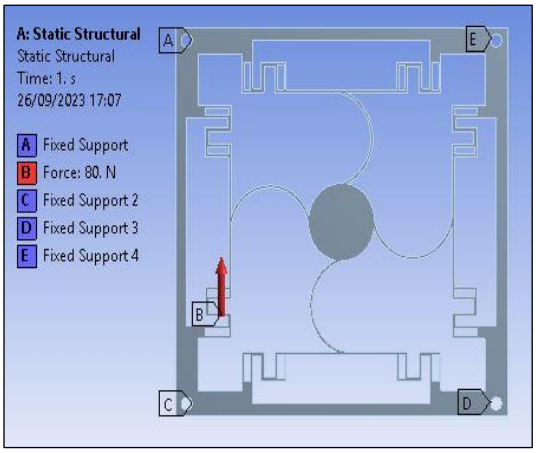

Figure 20: Boundary Conditions of Mechanism 3 for fatigue analysis.
Source: Authors, (2026).

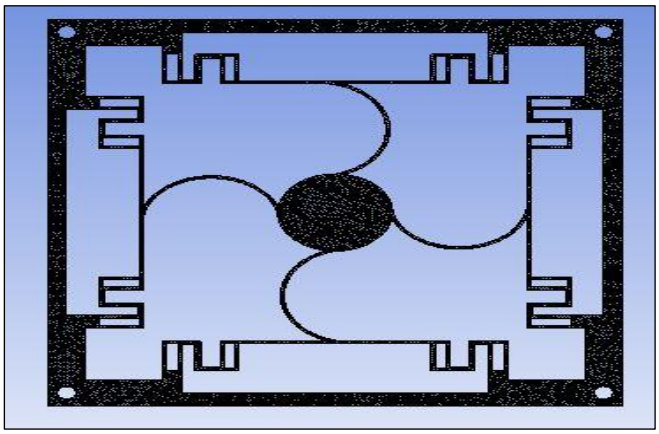

Figure 21: Meshing of Mechanism 3 for fatigue analysis.
Source: Authors, (2026).

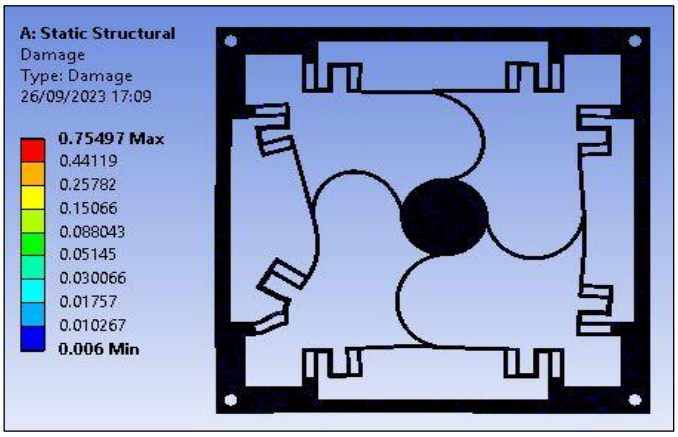

Figure 22: Damage of Mechanism 3.
Source: Authors, (2026).

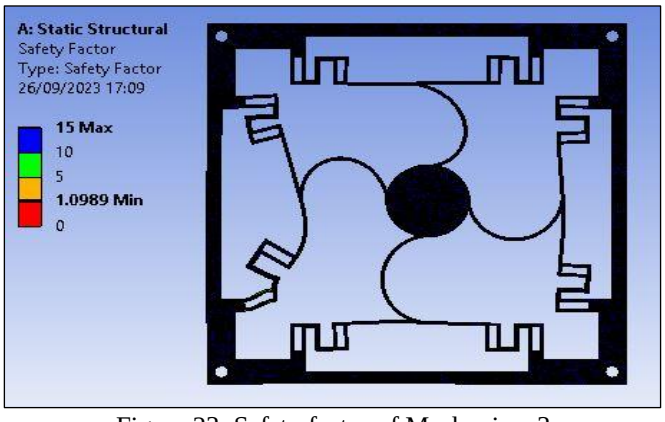

Figure 23: Safety factor of Mechanism 3
Source: Authors, (2026).

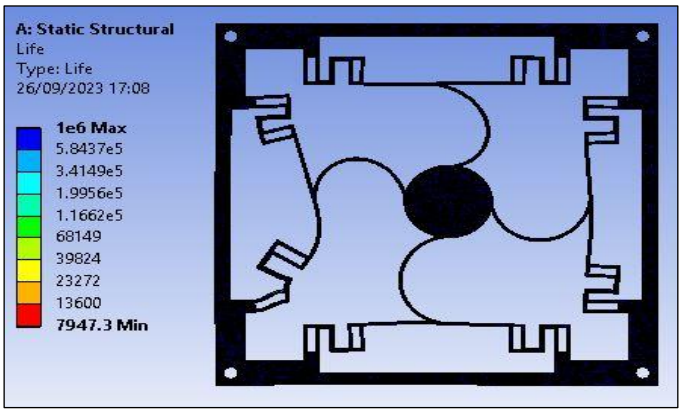

Figure 24: Life cycle for Circular motion stage with curve beam -1.
Source: Authors, (2026).

To avoid fatigue failure, the damage value must be less than 1. Figure. 22 shows the damage assessment of Mechanism 3. The safety factor of the mechanism, as indicated in Figure. 23, is 1.09, suggesting a slight margin above the design limits. Figure. 24 presents the life cycle analysis of the mechanism. The circular motion stage with Curve Beam 1 is suitable for 7,947 life cycles, with a damage factor of 0.75 and a safety factor of 1.09. This means the mechanism can endure 7,947 cycles before reaching its fatigue limit. The damage factor of 0.75, being well below the critical value of 1, indicates a low risk of fatigue failure. The safety factor of 1.09 provides an additional margin of safety, ensuring the mechanism's reliability and durability throughout its life cycle.

Fatigue analysis of Circular motion stage with curve beam of 40 mm (Mechanism 4)

The circular motion stage with Curve Beam 2 has dimensions of 300 x 300 x 15 mm and a curve beam radius of 40 mm. Fatigue analysis was conducted on this stage with an applied force of 80 N at the notch, as depicted in Figure. 25. Mechanism 4 features meshing with 85,536 nodes and 44,762 triangular elements, as shown in Figure. 26.To avoid fatigue failure, the damage value must be less than 1. Figure. 27 shows the damage assessment of Mechanism 4. The safety factor, depicted in Figure. 28, indicates the mechanism's capacity to handle stress beyond its designed load without failing. Figure. 29 presents the life cycle analysis of the mechanism.

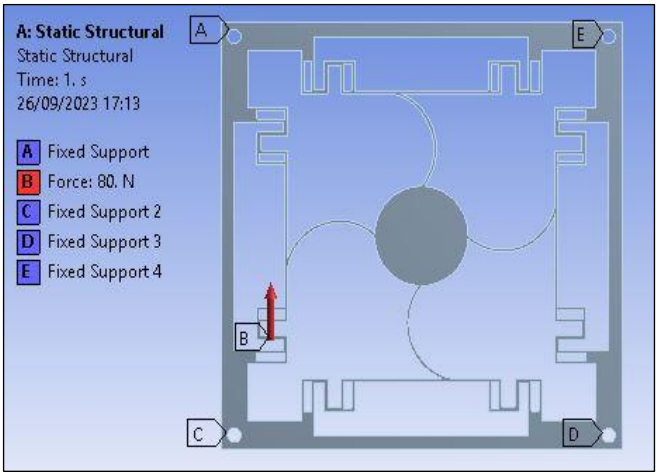

Figure 25: Boundary Conditions of Mechanism 4 for fatigue analysis.
Source: Authors, (2026).

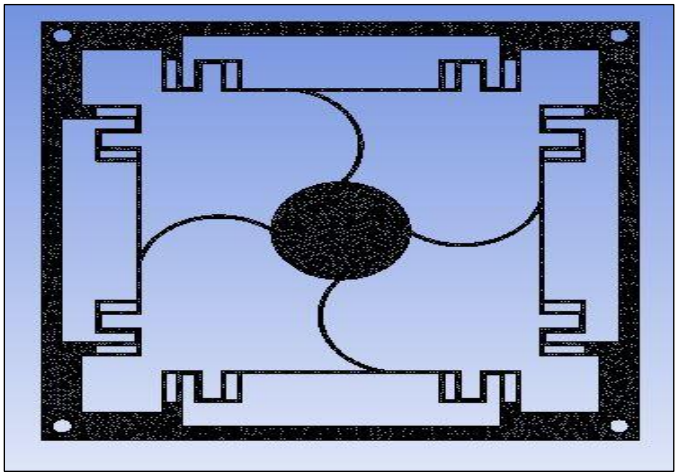

Figure 26: Meshing of Mechanism 4 for fatigue analysis.
Source: Authors, (2026).

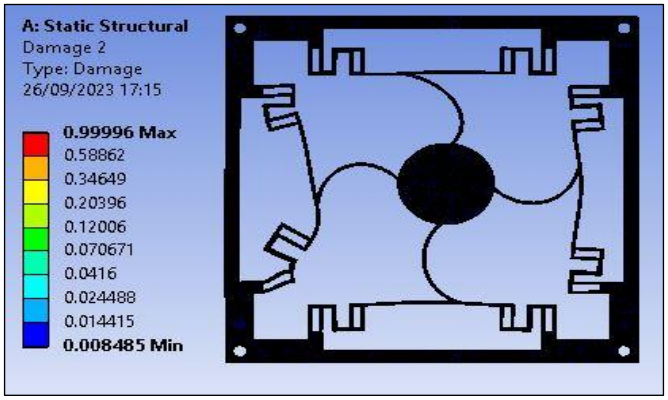

Figure 27: Damage of Mechanism 4.
Source: Authors, (2026).

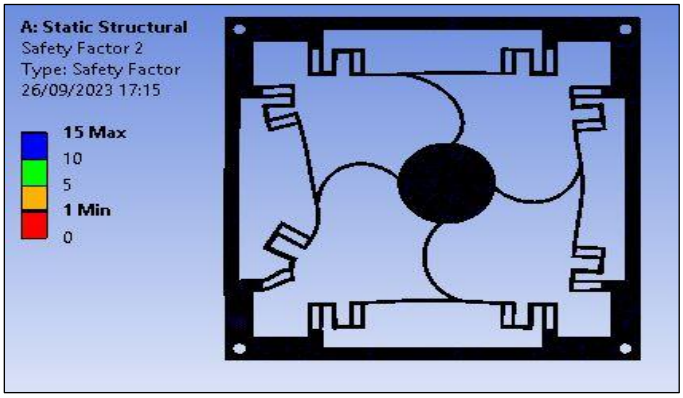

Figure 28: Safety factor of Mechanism 4.
Source: Authors, (2026).

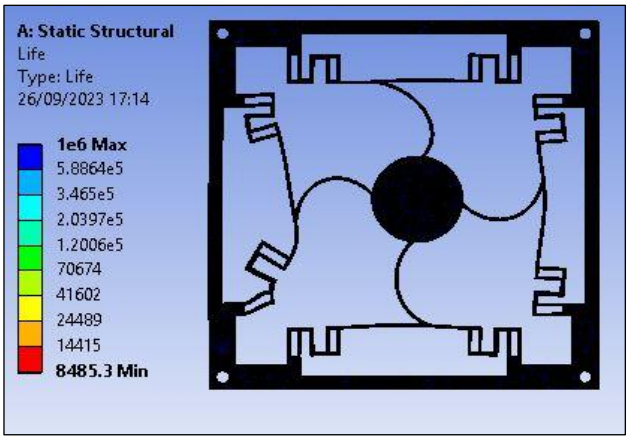

Figure 29: Life cycle for Circular motion stage with curve beam -2.
Source: Authors, (2026).

The circular motion stage with Curve Beam 2 is suitable for 8,485 life cycles, with a damage factor of 0.99 and a safety factor of 1. This means the mechanism can withstand 8,485 cycles before reaching its fatigue limit. The damage factor of 0.99, just under the critical value of 1, suggests that the mechanism is very close to its fatigue threshold. The safety factor of 1 indicates that the mechanism is designed exactly to its limit, with no additional margin for unexpected stresses.

Increasing the radius of curvature helps in mitigating stress concentrations and improving the distribution of loads, thereby enhancing the fatigue life of the compliant mechanism. Fatigue failures are occur in compliant mechanisms, as they operate in a cycle of loading. Fatigue life is defined closely related to repeating loadings. Fatigue life is divided into three categories: low cycle fatigue (fatigue failure occurs between 1 to 10^3 cycles), high cycle fatigue (fatigue failure occurs more than 10^3 cycles), and infinite life (no fatigue failure at a given load).

Table 3: Comparison of fatigue life cycle of different mechanisms.

Sr.No	Type of Motion stage	Fatigue life cycle	Safety factor	Damage
1	Squre motion stage with curve beam of 32mm (Mechanism 1)	5036	1	0.99
2	Squre motion stage with curve beam of 40mm (Mechanism 2)	7375	1.06	0.81
3	Circular motion stage with curve beam of 32mm (Mechanism 3)	7947	1.09	0.75
4	Circular motion stage with curve beam of 40mm (Mechanism 4)	8485	1	0.99

Source: Authors, (2026).

The fatigue life cycle for the square motion stage with curve beam 1 is 5036 Cycles, and curve beam 2 is 7375 as shown in Table 3. The fatigue life cycle for the circular motion stage with curve beam 1 is 7947 cycles, and for curve beam 2 is 8485 cycles. A larger radius of curvature can reduce stress concentrations in a compliant mechanism. Lower stress concentrations are often associated with improved fatigue life because they help distribute the load more evenly.

IV. CONCLUSION

The fatigue life cycle analysis of compliant mechanisms demonstrates the significant impact of geometrical parameters, specifically the radius of curvature of the beams, on the durability and performance of these mechanisms under cyclic loading conditions. Both square and circular motion stages show increased fatigue life with larger radii of curvature. By increasing radius of curvature in Square motion stage fatigue life cycle is increased by 46.44% whereas by increasing radius of curvature in circular motion stage fatigue life cycle of mechanism is increased by 6.76%. This suggests that optimizing the geometric design of compliant mechanisms can significantly extend their operational lifespan. The safety factors for the different mechanisms indicate that larger radii not only improve fatigue life but also ensure that the mechanisms operate safely within their intended load conditions. A larger radius of curvature helps in distributing the load more evenly, reducing the localized stress and hence the damage values, contributing to better durability and reliability. The analysis underscores the importance of geometric optimization in the design of compliant mechanisms. By carefully adjusting the radius of curvature, designers can achieve better fatigue performance, enhance safety, and reduce damage, thereby ensuring that these mechanisms can sustain their intended functions over longer periods and under repeated loading conditions.

ABSTRACT

Visually impaired people (VIP) need assistive technology for smooth and confident navigation on pavements along the roads. VIPs find it hard to follow the speech generated through a text-to-audio converter due to the presence of advertisement text. Automating the process of audio conversion from the signboards by integrating the capabilities of emerging AI models in a fraction of a second will be useful for their confident navigation. In this context, SignSpeak, an AI-based assistive utility, is designed to convert signboard text to speech using visual inputs, which may be captured through smart sensors or canes. The proposed system follows a three-step (detection-extraction-conversion) pipeline. Initially, a fine-tuned lightweight YOLOv11s model is used to generate a bounded box for the relevant text region, which is input to Gemini model, a multimodal large language model for text extraction. Lastly, the extracted text is converted into audio using the Google Text-to-Speech tool. We fine-tuned the YOLOv11s model on 200 signboard images and tested its performance on an additional curated dataset of 42 real-world signboard images. Experimental findings indicate that the proposed integrated pipeline achieved superior performance compared to the solitary usage of the Gemini model for text extraction followed by its audio conversion.

I. INTRODUCTION

One basic need of every human being is to visit different places with comfort and ease, but this need becomes a challenge for a Visually Impaired Person (VIP). To begin with, the VIPs usually moved around with the help of a human guide, this help although reliable could not be afforded by all. Moreover, the human guide has a disadvantage of making the VIPs feel constrained due to lack of sense of freedom and privacy, making them feel like an assisted person rather than being independent. Alternatively, dogs were also trained to assist VIPs but this service also has its own challenges. Dog training is a tedious task and the dog itself requires a lot of care and attention (i.e. feeding, grooming and walking), which is even more difficult for VIPs [1]. Similarly, other assisting tools like white cane are extensively used but they provide a limited set of features [2]. With the advent of internet-based technologies, a variety of assistive solutions are available for VIPs. All these systems, services, devices and applications help them with their daily chores and provide them a safer mobility option. These are included under one umbrella term: Assistive Technology. In the 1960s, the term “assistive technology” was used for technologies designed to handle issues related to information transmission, navigation and orientation for the especially abled [2] [3] The invention of smartphones has not only enhanced the connectivity for common man but has provided an excellent set of assistive tools by providing audio assistance through Google maps, road navigation applications for sensing hurdles etc. Inclusion of artificial intelligence technologies with smartphones has transformed the smartphone into an essential tool for most VIPs [4-6]. Modern technologies are now accessible to visually impaired people, encouraging greater independence, which include screen readers on smartphones, portable camera-based systems, electronic pens, Android assistant EyeMate, the “Self-Sufficient Smart Vision Stick” [7] etc. Each of these provide different functionality. While navigating, mobile application Google Lens can be used for capturing images but it reads out everything captured, which may not be useful for their navigation.

Google's Lookout uses computer vision and GenAI to make everyday tasks, such as reading documents, object identification etc . However, reading text from the signboards using available applications, while walking on a pavement or sidewalk is still a challenge because of its surroundings, text quality and its orientation. Among various assistive technologies, systems that can detect, read, and convert text into speech hold great potential for enhancing information accessibility and independence for the visually impaired [4] [8] [9]. YOLOv11s, Gemini, and Google Text-to-Speech (gTTS) are cutting-edge technologies whose capabilities can be integrated to address this need. We propose SignSpeak as a cutting-edge technology that follows a three-step (detection-extraction-conversion) pipeline to identify and read aloud the text on the sign boards. In the first step, YOLOv11s is used as a fine-tuned detector to detect the signboard region from captured images in real time. Subsequently, Gemini, a large language multimodal model, is deployed to extract the text from the detected regions [10]. Finally, gTTS, a high-quality text-to-speech converter, is used to convert recognized text into speech [11]. It is to be noted here that our focus is to reliably convert the fetched text from the signboard images to audio, once images are captured effectively from the smartphone integrated with an object detection sensor. The following are the major contributions of the proposed work:

- Fine-tuning of YOLOv11s model to extract desired text regions from the signboards after distinguishing between signboards and banners of varying shapes and sizes.
- Integration of three cutting-edge technologies viz. YOLOv11s, Gemini and gTTS for converting text from signboards into speech.
- Self-annotation of 200 signboard images used for fine-tuning of YOLOv11s as well as curating a separate test set of 42 signboard images to evaluate the performance of the pipeline.
- Deploying a Streamlit-based application namely SignSpeak1 with an easy-to-use interface for VIPs.
- Extensive experimentation to show the effective performance of the proposed integrated pipeline.

Organization of the paper: Section II reviews related work on current deep-learning based assistive technologies for VIPs following a brief introduction to existing traditional methods. Section III briefly describes the tools explored followed by details of the proposed methodology. Section IV reports the experimental results and analysis along with discussion, while the conclusion and future scope are given in Section V.

II. THEORETICAL REFERENCE

This section gives an overview of the related work on current deep-learning based assistive technologies for VIPs after a brief introduction to traditional methods.

II.1 TRADITIONAL METHODS

An early work by Shen and Coughlan [3] demonstrated a real-time sign-reading prototype for the identification of environmental signs followed by its audio conversion. It established the importance of visual to audio technologies for assisting the VIPs by providing speech-based feedback, audio translation and many more. However, these machines learning based approaches were using hand-crafted features along with rule-based algorithms and were effective in a controlled environment [4] [12].

II.2 DEEP LEARNING METHODS

Recent advancements in deep learning-based approaches have enabled assistive technology for real time text detection, recognition and scene understanding. Utilizing these approaches has empowered the real-time object detection and navigation system, smartphone applications to improve the accessibility for VIPs [4]. Reading text from complex images has been made possible for VIPs by identification of textual regions and using deep learning techniques to identify text, and ultimately converting to speech. A hybrid approach combining deep learning with particle swarm optimization proposed by Pandey et al., recognizes text from natural scenes and an audio output is produced via text-to-speech convertor [13]. Ganeshan et al. employ CNN-LSTM models to detect the caption associated with the given image, the identified caption is then converted into voice message using Text-to-Speech API. [14]. A ResNet-based system for object detection and text recognition by Begum et al. produces an audio output, and the visually impaired individuals can easily use this to read medication labels etc. [15] In [16], the authors design a system to assist visually impaired or text-reading challenge users by employing VGG-16 for text detection and recognition followed by Augmented reality visualization to display the content as a 3D image on a smartphone screen. One of the notable advancements is the OCR integration with the Text-to-Speech (TTS). A student-led initiative using the CNN-LSTM models on the embedded hardware achieved over 93% recognition accuracy from the live camera feeds and has affirmed the feasibility of deploying such pipelines on the resource-constrained devices [12]. Research has also highlighted the importance for the user experience during the audio rendering by preserving the structural elements to improve comprehension [5]. Similarly, work in Augmented reality has shown promise for vocalizing visual symbols [6]. Suresh et. al. proposed a wearable assistive system for the real-time auditory guidance in the form of a smart backpack by integrating sensing and on-device intelligence to be used in a controlled environment [17]. Recently, Moreira et. al. presented an integrated mobile application using Google Gemini artificial intelligence model for the VIPs to understand visual content [18]. Although tremendous efforts are being made for the effective use of deep-learning based assistive systems, challenges still exist in terms of their applicability and robustness. In this article, we are focusing on real-time capturing of text from the signboards and its reliable audio conversion for the smooth navigation of VIPs on the sidewalks and pavements.

III. MATERIALS AND METHODS.

This section briefly outlines the selection process for deciding the AI models and tools effective for getting the desired outcome in Sec. III.1, followed by description of methodology in Sec. III.2.

III.1 SELECTION OF AI MODELS AND TOOLS

III.1.1 Text Detection Models

The first step in the proposed pipeline involves accurate detection of text regions from the signboard images. Different tools were explored and their effectiveness was analysed. Traditional OCR engines like Tesseract [19] failed to work with low-resolution images and complex backgrounds. PaddleOCR [20] could detect and recognize text but showed inconsistencies in accessing small-sized text in the signboard images. Deep-learning based detectors like EAST [7] and CRAFT [16] provided better output, but produced imprecise bounding boxes and suffered from compatibility issues with modern frameworks. Finally, YOLOv11s, a lightweight model, was selected for object detection because of its localization accuracy, and seamless compatibility with current deep learning libraries. Also, Khanam and Hussain demonstrate that appropriate fine-tuning of YOLOv11s for a specific task produces precise bounded boxes, which ensures reliable input for the subsequent phase [21]. However, for proper fine-tuning, the input images in the YOLO model need to be annotated, hence, an open-source platform Label Studio is used to generate bounding boxes for signboard regions [22].

III.1.2 Text Recognition and Extraction Models

After the detection of text regions, multiple recognition frameworks were evaluated for their text recognition capability. During the early stages, PaddleOCR offered integrated detection and recognition but showed limited accuracy on small datasets and lacked robust cropping mechanisms [20]. EasyOCR [23], which is built on the CRAFT algorithm, supports multilingual scripts but produces inconsistent results, particularly with Tamil signboards which are present in the dataset. More advanced solutions such as LLAMA OCR 3.2-90B Vision, demonstrated strong recognition under complex conditions, but is constrained by high deployment costs and reliance on external APIs [24]. Finally, Gemini 3 was adopted as the recognition engine because of its high accuracy across various inputs, its support for multilingual scripts, and seamless integration with YOLOv11s [10]. This integration enables an efficient end-to-end text reading pipeline for fast inference required for real-world deployment.

III.1.3 Text-to-Speech Conversion Tools

Initially, the pyttsx3 engine for English synthesis was explored, as it provides offline functionality with adjustable voice and rate settings [25]. However, its limited applicability and quality response for non-English languages were the major concerns. We finally selected gTTS (Google Text-to-Speech) that not only covers these limitations but is also compatible with diverse linguistic contexts [26]. In addition to these tools, different Python-based libraries are used for the development, training and deployment of the proposed tool SignSpeak. Python Imaging Library (PIL) is used for the image conversion and the augmentation required for the dataset preparation [27]. OpenCV is used for the image processing task for delivering consistent input formats for the detection and recognition [28]. The Ultralytics PyTorch framework is used for the fine-tuning of YOLOv11s, offering a modular API for detection tasks [7]. Finally, the Google Generative AI SDK is incorporated for integrating the Gemini 3 via API calls [10].

III.2 PROPOSED METHODOLOGY

The methodology used for developing the SignSpeak encompasses data preparation, and integration of three major AI-based technologies for text detection, text extraction and text-to-speech conversion. The proposed approach (detection-extraction-conversion) takes images of signboards as input, detects texts on the signboards, followed by their conversion to speech, which is delivered as output to the visually impaired individuals.

III.2.1 Data Preparation and Labeling

A publicly available dataset, namely the Indian Signboard Image dataset consisting of 200 images from Kaggle, is used [29]. The signboard images contain multilingual text (English, Hindi, and Tamil) under varying lighting, orientations, and background conditions (see Figure 1). Label Studio is used to manually annotate all the images, drawing bounding boxes around text regions to generate high-quality ground-truth data in the YOLO format [7]. In addition, 200 background images without signboards are also incorporated into the dataset to enhance the detection robustness of the model.

Figure 1: An Annotated Sample Sign Board.
Source, Author, (2026).

These images with the road scenes are included as background (negative samples) without bounding box annotations [30]. The inclusion of background-only images helps the model learn contextual features and reduces false-positive detections during inference. This resulted in a combined dataset of 400 images, on which the pipeline is built and validated. An independent test dataset of 42 signboard images is also curated to evaluate the performance of the proposed pipeline.

III.2.2 Fine-Tuning of Yolov11s Detector for Text Detection

YOLOv11s is highly effective for object detection but needs to be fine-tuned to road signboards to incorporate domain-specific optimizations [31]. The model is fine-tuned for Indian roadside sideboard detection using a combined dataset of 400 images (200 signboards + 200 road images) as discussed in Sec. III.2.1. It is to be noted that a few signboard images have multiple signs. Hence, Label Studio used for annotation returned 215 annotated objects for 200 signboards. The image dataset is split into training and validation sets with an 80:20 ratio, resulting in 320 training images and 80 validation images. The training set with 320 images consists of 166 signboards consisting of 178 annotated objects, and 149 background images respectively. The validation set contained 34 images with 37 annotated instances of the signboards and 46 background images as negative samples, indicating background-only scenes without visible road signs. Including such background images helped improve the detector's robustness by reducing false-positive predictions. Fine-tuning is conducted for 60 epochs with a batch size of 8 images, where each image resolution is set to 640×640 using the Ultralytics framework in a GPU-accelerated Google Colab environment. The model is trained for a single class, *Road Signboard*, using YOLO *txt* format annotations in the presence of a few background images. Data augmentation techniques such as horizontal flipping, mosaic augmentation, and RandAugment are also enabled to improve the generalization of the model.

Table 1: Distribution of signboard images and corresponding annotated objects along with background images used for training and validation during the fine-tuning of YOLOv11s model.

Signboard Data	Total Signboards (a)	Total Annotated Objects in Signboards	Total Background Images (b)	Total Images (a+b)
Image Instances	200	215	200	400
Training Data	166	178	154	320
Validation Data	34	37	46	80

Source: [29], [30].

III.2.3 Pipeline of SignSpeak

SignSpeak employs a three-stage pipeline: image detection module, text extraction module, and text-to-speech conversion module. The input image is first analyzed to detect the signboards, followed by text recognition and extraction, and lastly, the text is converted to audio, as illustrated in Figure 2.

III.2.3.1 Image Detection Module

The proposed pipeline begins with an object detection module, which uses a lightweight YOLOv11s model. The used model is fine-tuned specially for signboard detection. Its capability to capture localized regions of interest followed by generating bounding boxes around the signboards, makes it suitable for poor-quality images too. Its lightweight architecture allows for real-time inference without impacting the accuracy of the retrieved localized region.

III.2.3.2 Text Extraction Module

The localized regions are further processed by a text recognition AI model leveraging natural language prompts to extract textual content. Using the Gemini 3 model not only allowed for handling of various font styles, but its human-readable prompt returned the text without requiring task-specific fine-tuning. The integration of a vision-language model in this context demonstrates the advantage of natural prompt engineering, allowing SignSpeak to seamlessly handle multilingual signboards and varied environmental conditions, including distorted images, low resolution, or background noise, by integrating YOLOv11s with Gemini 3 to ensure high reliability in practical deployment scenarios.

III.2.3.3 Text-to-Speech Conversion Module

The SignSpeak pipeline concludes by transforming the recognized text into natural-sounding speech using a text-to-speech engine to get an accessible auditory output. The selection of the Google text-to-speech (gTTS) tool for providing a natural, multilingual speech output makes the proposed pipeline suitable for delivering clear feedback for texts written on signboards.

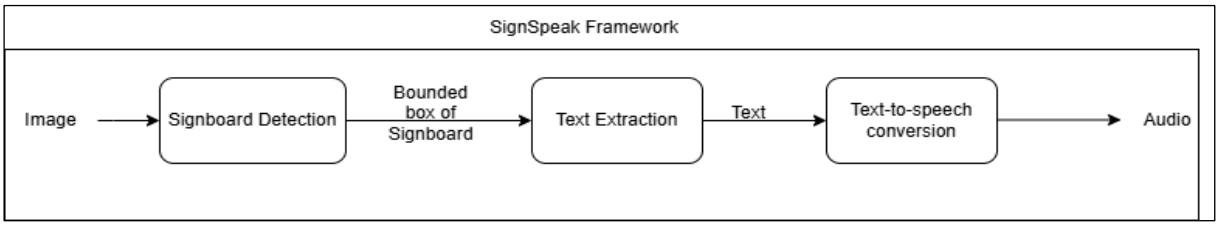

Figure 2: Pipeline of Three Phases in the Proposed Signspeak Framework for Extracting Text from Signboard for Text-to-Speech Conversion.
Source: Authors, (2026).

III.2.3.4 Example: Inference Process

Figure 3 demonstrates the workflow for processing a single image for text extraction. The input image (Fig. 3a) is passed as input to the fine-tuned YOLOv11s model, which returns the coordinates of a bounding box for the detected signboard (Fig. 3b). The bounded box is used for cropping the image so that only a valid portion is sent to the Gemini model with a prompt asking it to extract the text (Fig. 3c). The resulting text is stored for subsequent audio conversion by the text-to-speech conversion module.

IV. RESULTS AND DISCUSSIONS

This section describes the experiments conducted to evalu vate the performance of the proposed AI-based utility tool using the established performance metrics for evaluating text extraction from the signboard and subsequent text-to-audio conversion efficiency.

IV.1 FINE-TUNING AND PERFORMANCE EVALUATION OF YOLOV11S MODEL

During YOLOv11s fine tuning for signboard detection, visual outputs from selected batches were saved to monitor the evolution of the model's detection performance. A batch refers to a group of images processed together before updating the model parameters, with the batch number indicating the sequence of processing during training. Recall that a batch of 8 images are used for the experimentation.

IV.1.1 Fine Tuning of the YOLO Model for Domain Specific Object Detection

The dataset consisting of 400 images is split into an 80:20 ratio, where 320 images are allocated for training and the remaining 80 images are reserved for validation (see Sec. III.2.2: Table 1 for details). The model is trained for 60 epochs with a mini-batch size of 8 images, allowing the training process to iteratively update model parameters across the entire training set multiple times to enable an effective domain-specific learning and convergence. Selection of parameters is done such that all the training samples are processed in the manageable batches to get stable gradient updates.

IV.1.2 Label Distribution and Bounding Box Analysis

Figure 4 illustrates the label distribution and bounding box distribution. The model identifies 178 annotated objects from a training set of 320 images (166 signboards + 154 background images) as shown in Figure 4a. Recall that the model is used for identification of only one class, which is Road Signboard. Figure 4b shows all bounding boxes overlaid, where each rectangle is one labeled object. All boxes are drawn on the top of each other, indicating their concentration on the middle part of the signboards. Figures 4c and 4d show the object center positions (x v/s y) and distribution of width v/s height of all boxes respectively. It is clear from these two figures that most signboards are mostly near the center and are having size variation from small to medium respectively.

IV.2.2 Training and Validation Performance of The YOLO model

Figure 5 shows the training and validation performance of the YOLO model where the x-axis represents the number of epochs and the y-axis represents the score of the selected metric. The first three plots in top and bottom rows show the performance of the models on the training and validation set in terms of loss respectively. The first and second plots in the top row show the loss that incurs during learning of bounding boxes and signboard class during different epochs. It is clear from the first two plots that learning is poor initially which improves with increasing epochs. Low loss with increasing epochs vindicates the good learning of the model. A similar pattern is observed in the third plot of the top row and revealed that advanced bounding box fine tuning loss also decreases with epochs. The first three plots in the bottom row of Figure 5 shows the performance of the model on the validation set. Spikes in early epochs may have contributed to minor label normalization inconsistencies in the validation data resulting in high classification error in these epochs. The fourth and fifth plots in both top and bottom rows show the Precision, Recall and mAP (Mean Average Precision) of the trained model on the validation set. It is clear that the Precision and Recall stabilize at approx. 0.92 and 0.94 respectively, capturing the effective learning of the model on the provided data. During early epochs, the model is unstable, which causes high classification error. Once training progresses and the model adjusts to the data, the loss quickly stabilizes and decreases as vindicated by the mAP plots shown as last two plots in the bottom row. The metric mAP50 considers a prediction accurate if it overlaps with the ground truth bounding box by at least 50%, which is around 0.92. The last box shows the metric mA90-95, which checks for 90-95% overlap in the detected and reference images and is around 0.6 which is good for the object detection model.

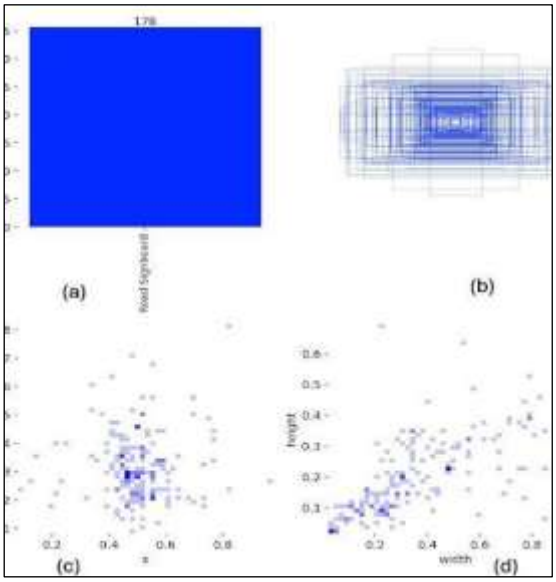

Figure 4: Label Distribution and Bounding box analysis.
Source: Authors, (2026).

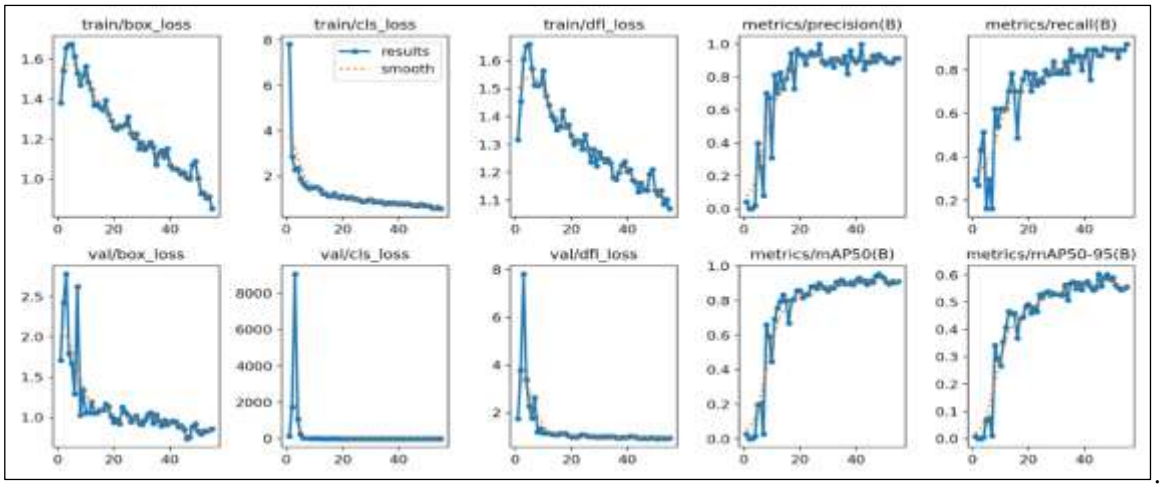

Figure 5: Training and Validation Performance of YOLOv11s model.
Source: Authors, (2026).

Table 2: Confusion Matrix showing Performance of YOLO model on the Validation Set.

Predicted	**Actual**	
	Road Signboard	**Background**
Road Signboard	34 (TP)	7 (FP)
Background	3 (FN)	NA

Source: Authors, (2026).

For the single-class *Road Signboard* detection task, the confusion matrix in Table 2 shows the accuracy of the model in terms of TP (True Positive), FN (False Negative) and FP (False Positive) which are 34, 3, and 7 respectively. Out of actual 37 signboard objects, 34 are reported correctly and the rest 3 are reported as background. Also, 7 background images with no signboard are predicted as signboard images (FP). Here, the true negatives are not explicitly defined due to the enormous number of the possible background regions. The true positive detections correspond to correctly localized and classified road signs, while false negatives represent missed detections of annotated signs. False positives indicate cases where the model predicted a road sign in background regions. These results confirm that the model successfully detects the majority of road instances while maintaining reasonable discrimination against the background.

IV.2.3 Model Evaluation through Box and PR Curves

Figure 6 represents the Box and PR curves for the validation set. In all subfigures, the light blue curve captures the model's performance in detecting signboard class only whereas the dark blue curve shows the overall model's performance in the presence of background images without signboards in them. Figure 6a represents the F1 confidence curves where the x-axis represents the confidence and y-axis represents the F1 score. The curves depict the variation in model performance with change in the confidence threshold. It is observed that the model performance is best with F1-score 0.88 at confidence threshold ≈ 0.53. Figure 6b describes the Precision-Confidence curve where the x-axis and y-axis show the confidence threshold and Precision respectively. It is clear from the figure that Precision is more than 0.8 for confidence > 0.3 and is maximum 1 for confidence value ≈ 0.73.

It vindicates the model's capability to detect signboard images with high precision starting from low confidence value. Figure 6c validates the model's capability to detect images precisely by missing out few of the actual signboard images (see right side of the Precision-Recall curve where the X-axis shows recall and the Y-axis represents precision), which suggests model is able to detect most objects and make few mistakes at mAP@0.5. Detection of all classes with 0.916 vindicate the model's good performance in detecting sign board part from the images. Figure 6d represents the Recall-Confidence curve showing variation in Recall (y-axis) with change in confidence threshold (x-axis). It is observed that the recall decreases after the 70% confidence i.e. the model starts missing many objects. The YOLO model performs best in the low confidence range with recall above 70%. But its performance deteriorates with high confidence.

IV.2 PERFORMANCE EVALUATION OF THE SIGNSPEAK PIPELINE ON TEST SET

We use independent test data to evaluate the performance of the integrated approach in the following sections. For which, we separately evaluate the performance of each of the three modules using suitable metrics to prove its effectiveness on unseen signboard images.

IV.2.1 Evaluation of Signboard Detection from the Images

We evaluate signboard detection on the dataset with 62 images containing 42 real world images and 20 banners (with no signboards) images curated from the internet. All 62 images are used sequentially to evaluate its working. We set a threshold of 0.6 (60%) to reduce the false detection of banners as signboards. At this threshold, the model achieves a higher precision along with fewer false positives while maintaining a good recall as vindicated during fine tuning of the YOLO model. The model detected 38 signboard images out of 42 images as TP and the remaining 4 images were detected as background leading to False negative. It reported only one banner image falsely classified as Road Signboard (Table 3), NA values in TN cell held same justification for validation set. For the single-class *Road Signboard* detection task, the model performance with precision of 0.97 and a recall of 0.90 affirms its capability to capture the most of the signboards correctly with a minimal false detection.

Table. 3: Confusion Matrix showing Performance of YOLO model on the Test Set with 42 Signboard Images and 20 banner images.

	Predicted Signboard	Predicted Background
Actual Signboard	38 (TP)	4 (FN)
Actual Background	1 (FP)	NA

Source: Authors, (2026).

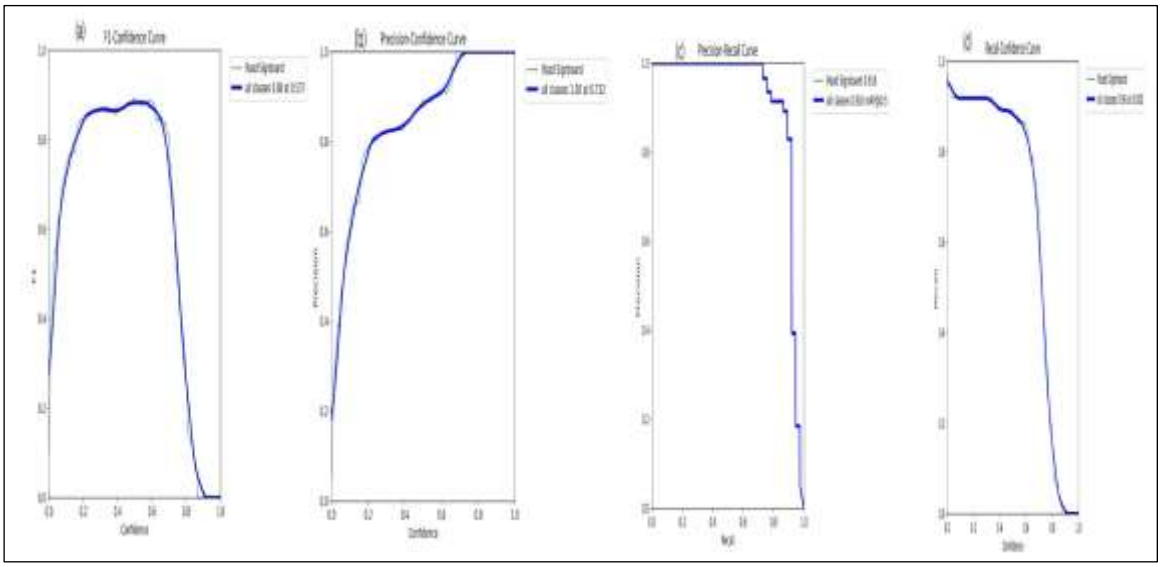

Figure 6: Performance Evaluation of YOLOv11s Model on the Validation Set using three Standard Metrics with varying Confidence thresholds.
Source: Authors, (2026).

IV.2.2 Evaluation of Text Extraction from the Detected Signboards

Model Gemini 3, which does not require fine-tuning, is used for text recognition. A prompt-based approach is used to retrieve the text from the images using Gemini. For example, a prompt: "What text do you see in this image?" returns the visible text in the provided image without any explanation. We manually extracted the text from all 42 signboard images in the test set and saved it as the Ground-Truth text, which is used subsequently for comparing the performance of the proposed pipeline (referred as Pipeline A) with the other standard method Pipeline B (Gemini 3 recognition only).

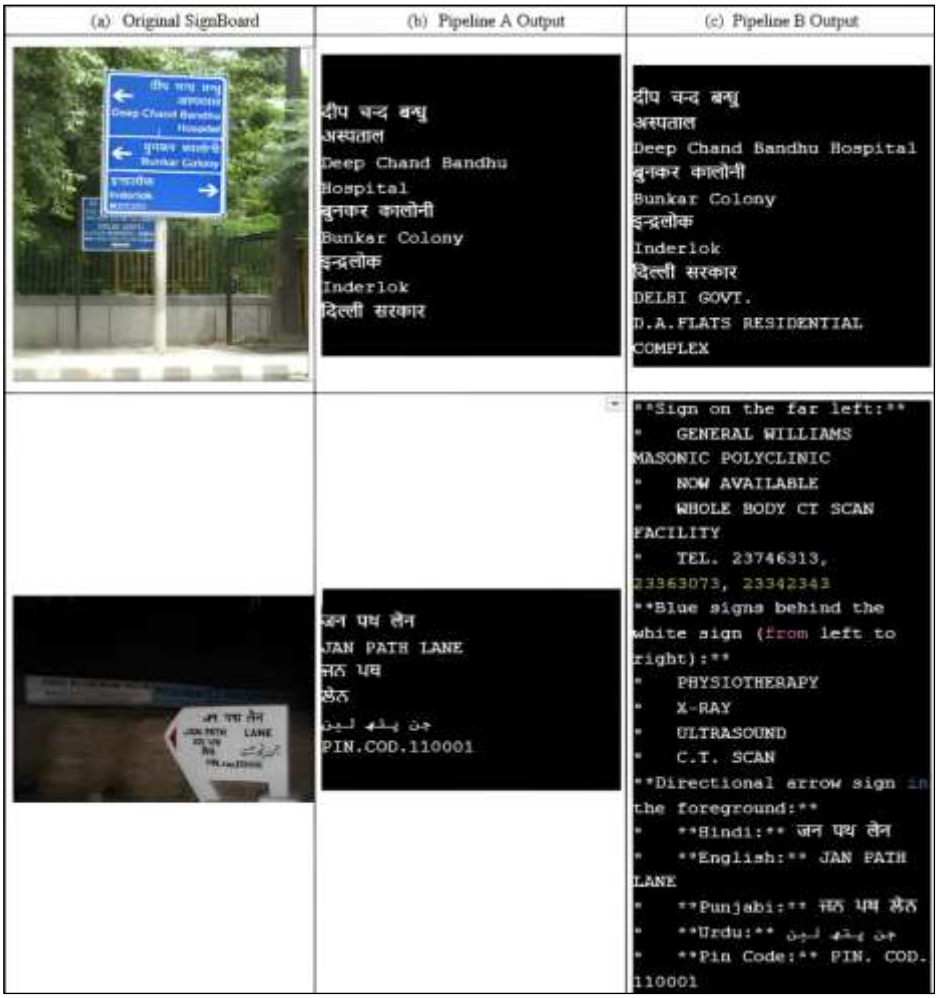

Figure 7: Comparison of Text Extracted by Pipeline A (YOLO and Gemini 3) and Pipeline B (by Gemini only) with the Original Signboard Text.
Source: Authors, (2026).

It is to be noted that Pipeline A (YOLOv11s detection and Gemini 3 recognition) was designed to first localize signboard regions before performing text recognition, whereas Pipeline B (Gemini 3 recognition only) operated directly on the full images without prior detection. Figure 7 shows the comparison of both the Pipelines A (Fig 7 b) and B (Figure 7c) respectively w.r.t to two original signboard images (Figure 7a). It is observed that Pipeline A performed better by extracting the relevant text from the localized region of the signboard marked by YOLO, whereas line B extracted the entire text from the image provided making navigation of VIPs difficult. We also use BLEU [32] and ROUGE [33] metrics to compare the text extracted from these two pipelines (Table 4). For the Pipeline A, high value of performance metrics (BLEU score of 81.06, an average Rouge-1 F1 score of 0.93 and an average Rouge-L F1 score of 0.92) compared to those of Pipeline B (BLEU score of 60.33, an average ROUGE-1 F1 score of 0.85 and an average ROUGE-L F1 of 0.85) demonstrate the effectiveness of integrating a signboard detection stage prior to the recognition. The improvement can be attributed to YOLOv11s ability to isolate relevant text regions, thereby minimizing the background noise and distortions that often hinder the accuracy. The higher BLEU score confirms the improved n-gram precision, while the ROUGE score reflects the greater overlap with the Ground-Truth text, signifying enhanced completeness of recognition. Overall, the results provide quantitative evidence that a modular approach (Pipeline A), which uses a detection-recognition pipeline surpasses the recognition-only approach (Pipeline B) for the real-world scenarios. It is concluded from the results that the proposed integrated approach for text extraction is reliable and robust for practical deployment.

Table 4: Performance comparison of Pipeline A and Pipeline B in terms of Text Extraction using Test Set.

Pipeline	Bleu score	Avg Rouge-1 F1	Avg Rouge-L F1
A (Yolo+ Gemini)	81.06	0.93	0.92
B (Gemini only)	60.33	0.85	0.85

Source: Authors, (2026).

IV.2.3 Evaluation of Text-to-Speech Conversion

We use TTS-ASR (Text-to-speech Automated Speech Recognition), which uses a loop where text is converted into speech, followed by its conversion back to text again using a round-trip approach [34]. The round-trip time allowed for computing the Word Error Rate (WER) [35] and Character Error Rate (CER) [36], which were computed after text normalization (lowercasing, punctuation removal, and extra space removal) to ensure reliable comparison.

Then we calculated the WER and CER scores. For this phase, text captured from Pipeline A and Pipeline B from test images were converted to audio using Google Text-to-speech converter (gTTS), followed by its processing by the ASR pipeline using a round-trip approach. The benefit of using the round-trip approach is to check whether the system can reconstruct the original text accurately after passing through both speech synthesis and recognition stages. Here, Pipeline A clearly outperformed Pipeline B (Figure 8) by achieving a lower WER and CER, indicating its text-preserving capability in the TTS-ASR evaluation loop.

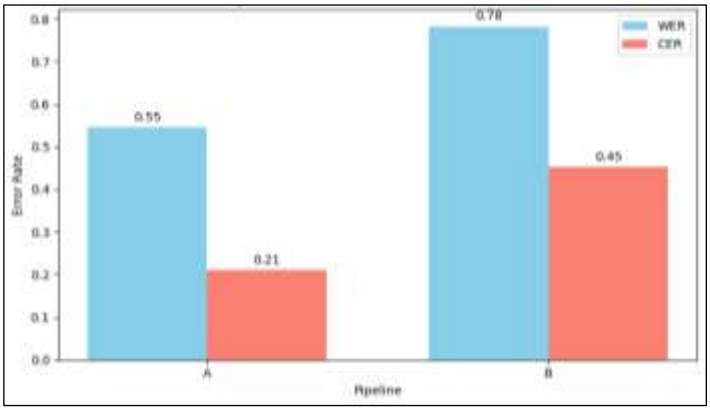

Figure 8: Comparison of WER and CER of Pipeline A and Pipeline B for Text-to-speech Conversion using Test Set.
Source: Authors, (2026).

IV.3 GUI FOR THE INTEGRATED SIGNSPEAK PIPELINE

A Streamlit-based application, namely SignSpeak is developed for the ease-of-use of users, whose interface is shown in Fig. 9. Once an image is detected by the sensor, the different phases of the proposed integrated framework are carried out in the background. For the validated signboard images, audio is generated to assist the commuters for safe mobility.

Figure 9: Lightweight GUI for Signspeak Utility.
Source: Authors, (2026).

IV.4 DISCUSSION

The experiments conducted in the former sections validate the efficacy of the integrated approach over the standalone usage of one model. The YOLOv11s performance demonstrates high accuracy and reliability even when it is trained on a small signboard dataset with manually annotated images. Its lightweight architecture enabled systematic inference while maintaining the detection quality. This balance between speed and accuracy makes the YOLOv11s suitable for the deployment for domain-specific tasks in low- resource environments, such as mobile or integrated systems [21]. Also, it improves the recognition performance of Gemini 3 in the text extraction phase, which is converted to reliable audio by gTTs. The integration of the detection-extraction-conversion phases is not only an efficient pipeline, but also delivers reliable output for navigation. The system maintains robustness under different conditions, including occlusion and resolution, that were incorporated while making the test set. The result highlights its potential for deployment as an assistive technology and its extension to multilingual accessibility because of the used Gemini 3 model.

V. CONCLUSION AND FUTURE SCOPE

SignSpeak introduces an assistive framework designed to enhance the awareness and navigation for visually challenged navigators on the pavements by detecting, recognizing and vocalizing the street/road signboards. This pipeline integrates the YOLOv11s model along with Gemini 3 for the high precision text recognition, ensuring the reliable performance in the real-world environments. To ease the usage, the recognized text is converted into speech using gTTS (google text to speech), providing natural auditory feedback to the users. Experimental evaluation affirmed the capability of the proposed integrated approach for text extraction over the stand-alone usage of Gemini model.

The proposed SignSpeak system for VIPs addresses the critical accessibility gap by enabling the visually challenged to access the street signs more efficiently and progress with greater reliance. As the current implementation of SignSpeak provides a strong foundation, several enhancements can be explored to broaden its application and usability. Inclusion of Multi-Object Detection along with important road elements like traffic lights, zebra crossings would enhance its applicability. Multi-language support may be included by extending the training data to support native languages (like Tamil, Hindi, Bengali, etc.) by leveraging the multilingual capabilities and global workflow of Gemini 3.

ABSTRACT

Sustainable procurement (SP) has emerged as a strategic mechanism for integrating environmental, social, and economic considerations into organizational decision-making. This study aims to synthesize and analyze the intellectual and thematic development of SP research through a systematic literature review (SLR) combined with bibliometric analysis. Using the PRISMA framework, 4,425 Scopus-indexed publications were initially identified, from which 138 peer-reviewed journal articles met the inclusion criteria for in-depth analysis. The findings reveal a significant increase in research attention since 2012, reflecting SP's evolution from a compliance-based policy tool to a strategic capability that drives innovation and sustainability performance. Five major thematic clusters were identified: (1) sustainability in public procurement, (2) the role of SP in the circular economy, (3) sustainable construction, (4) the role of corporate social responsibility (CSR), and (5) SP in higher education. Theoretically, the study draws on institutional theory, stakeholder theory, and the resource-based view to explain how external pressures, stakeholder expectations, and organizational capabilities jointly influence SP adoption and implementation. The results underscore the importance of robust institutional frameworks, leadership, and capability-building in advancing sustainable procurement. Finally, the study highlights future research opportunities in digital transformation, cross-sectoral collaboration, and the measurement of SP's contribution to environmental, social, and governance (ESG) outcomes, thereby offering actionable insights for policymakers, practitioners, and academics.

I. INTRODUCTION

Sustainable improvement has become a crucial worldwide concern due to the increase in environmental degradation and the depletion of natural resources [1] The sustainable development goals (SDGs) established by the United Nations provide a comprehensive framework for addressing these global challenges and promoting a sustainable future. In particular, SDG 11 calls for the creation of sustainable cities and communities [2], while SDG 12 emphasizes responsible consumption and production practices. Achieving these goals requires coordinated efforts across multiple domains—including procurement, logistics, and organizational transformation—where the strategic role of procurement is vital for advancing sustainable practices and realizing SDGs 11 and 12 [3] In response, organizations are increasingly expected to adopt sustainable practices to mitigate environmental, social, and economic pressures [4] At the heart of this transformation lies sustainable procurement (SP), a key driver for achieving sustainability goals through responsible sourcing, supplier engagement, and value-based decision-making [5], [6] SP is also regarded as an effective strategy for advancing the SDGs by integrating the pillars of sustainability (i.e., economic, environmental, and social) into procurement practices [7] It entails the acquisition of goods and services that deliver optimal value for money while minimizing negative environmental impacts and promoting social equity throughout the product or service lifecycle [8] By integrating these principles into organizational procurement systems, SP enhances resource efficiency, reduces waste, and strengthens social well-being, ultimately positioning procurement as a catalyst for sustainable organizational performance and long-term development [9].

Ultimately, aligning purchasing decisions with sustainability principles transforms procurement into both a managerial challenge and a strategic opportunity for organizations striving to balance operational efficiency with corporate responsibility in the pursuit of sustainable development [10], [11] Globally, governments have increasingly developed procurement policies to advance sustainability and social responsibility objectives. In Northern Ireland, for instance, all public contracts are required to include at least a 10% weighting for social value criteria, while in the United States, federal agencies prioritizes sustainable products through EPA ecolabel standards [12]. Similar initiatives can be observed in Scotland's Procurement Reform Act (2014), Canada's Federal Sustainable Development Strategy, the European Union Procurement Directive (2014), and Spain's Law 9/2017, each of which embeds sustainability considerations within public purchasing frameworks [13], [14]. More broadly, SP is becoming increasingly institutionalized through international regulatory frameworks, including the European Union procurement directives and guidelines developed by global organizations such as the OECD, ILO, WTO, and UNEP [15]. Collectively, these frameworks promote greater transparency, accountability, and sustainability across global supply chains, reinforcing SP as a critical instrument for achieving sustainable development. Despite its growing significance, the implementation of SP remains a considerable challenge for many organizations, particularly in developing countries, due to the inherent complexity of procurement processes and supply chain structures [16], [17], [18]. These complexities often hinder organizations from fully understanding, operationalizing, and monitoring sustainability principles across diverse suppliers and market contexts [19].

Effective implementation of SP requires a comprehensive understanding of its core principles and operational mechanisms (i.e., encompassing risk management, supplier evaluation, and ethical sourcing) to proactively mitigate adverse environmental and social impacts through robust due diligence. A persistent challenge also lies in balancing economic viability with sustainability objectives, as decision-makers must reconcile short-term financial constraints with long-term environmental and social commitments. Achieving this balance demands a holistic approach that integrates life-cycle costing, value chain analysis, and resource optimization to ensure both competitiveness and sustainability [20]. Moreover, barriers such as limited institutional support, weak policy enforcement, and insufficient stakeholder engagement continue to impede the widespread adoption of SP practices [21], [22]. Given these persistent challenges, a comprehensive understanding of the current state of research on SP is essential to inform both theory and practice. Conducting a systematic literature review (SLR) provides a robust approach for synthesizing and mapping the existing body of knowledge, identifying research trends, influential scholars, and methodological gaps within the SP domain [23], [24]. These methods enable a structured and quantitative evaluation of academic output, revealing how SP has evolved conceptually and empirically across disciplines and regions. To date, only one study (from Scopus database) has systematically synthesized the SP knowledge base. Notably, Kabra et al. [25] conducted a bibliometric analysis mapping the intellectual structure of SP research, identifying key thematic clusters such as green supply chain practices, socially responsible purchasing, and public procurement.

However, their study primarily offered a descriptive mapping of publication trends and research networks, without critically examining the contributions of SP. In contrast, the present study adopts a combined SLR and bibliometric approach to provide a more comprehensive and analytical perspective, by exploring the evolution of SP research while assessing its contributions. Beyond Kabra et al. [25], related reviews have examined adjacent areas such as circular procurement management [26], green purchasing behavior [27], and sustainable procurement risks in the construction sector [28]. While these studies contribute valuable insights, they focus on specific procurement dimensions or sectoral contexts rather than providing a holistic synthesis of sustainable procurement as a strategic framework across industries. Therefore, this study fills an important gap by offering an integrative understanding of SP research trends, challenges, and its contributions through a rigorous SLR and bibliometric analysis.The remainder of this paper is structured as follows. Section 2 describes the research methodology, outlining the systematic literature review protocol, bibliometric analysis procedures, and data collection steps adopted for this study. Section 3 presents the results and findings, including descriptive bibliometric outcomes, thematic clusters, and key insights derived from the systematic review. Section 4 provides an in-depth discussion, interpreting the results in light of existing theories, and practical implications. Finally, Section 5 concludes the study by summarizing the main findings, highlighting limitations, and proposing directions for future research.

II. METHODOLOGY

A systematic literature review (SLR), when combined with bibliometric analysis, offers a robust and comprehensive approach for examining the development and intellectual structure of a research domain [29]. A rigorously conducted SLR enables the identification, selection, and synthesis of relevant studies based on predetermined inclusion and exclusion criteria, thereby minimizing bias and enhancing reliability [23]. In parallel, bibliometric analysis quantitatively evaluates the research landscape by identifying publication trends, influential authors, and thematic relationships through citation, co-citation, and keyword co-occurrence analyses. Integrating these methods provides both qualitative depth and quantitative breadth, offering a holistic understanding of the field [24]. Data were retrieved from the Scopus database, recognized for its extensive coverage of peer-reviewed journals and strong indexing of sustainability and management research [30], [31], [32], [33]. The review followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) framework and commenced on May 31, 2025. An initial search of article titles, abstracts, and keywords using the Boolean string "sustainable" AND "procurement" yielded 4,425 documents. After screening the titles, abstracts, and keywords for relevance, the results were narrowed down to 601 documents. To ensure quality and consistency, only journal articles were selected, and for the sake of readability, only those written in English were included. As a result, a total of 138 articles were retained for the final analysis. A bibliometric analysis was performed using VOSviewer. This tool facilitated visualization and network analysis of research collaboration, thematic evolution, and intellectual structure. Key analytical dimensions included:

- Performance analysis: publication trends and dominant subject areas.
- Science mapping: bibliographic coupling networks.
- Keyword co-occurrence analysis: identification of dominant themes and emerging topics.

Prior to analysis, data were standardized to merge author name variants, institutional affiliations, and keyword synonyms. Duplicate and incomplete records were removed. Network maps were normalized using the association strength method in VOSviewer to ensure meaningful clustering.

III. FINDINGS

III.1 PUBLICATION TRENDS

The bibliometric analysis of publication output in the field of SP reveals a clear upward trajectory when examined by publication year (see Figure 1). The earliest documented studies appeared in 2004, marking the beginning of scholarly attention to this emerging topic. During the initial years, research output remained modest, with only a few publications recorded up to 2011, reflecting the early developmental stage of the field as sustainability concerns were only beginning to gain widespread recognition. This slow growth period indicates that SP had not yet been fully recognized as a distinct academic and professional domain. From 2012 onwards, the number of publications increased steadily, reaching its peak in 2023 and 2024. This surge signifies heightened global interest and recognition of sustainable procurement as a critical instrument for achieving sustainability objectives [5]. The growth aligns with broader developments such as rising environmental awareness, the establishment of supportive regulatory frameworks, and an expanding understanding of the strategic role of public procurement in advancing sustainable development goals [34]. Although a slight decline in publication numbers appears in 2025, this is likely due to incomplete data for the year rather than an actual reduction in research activity.

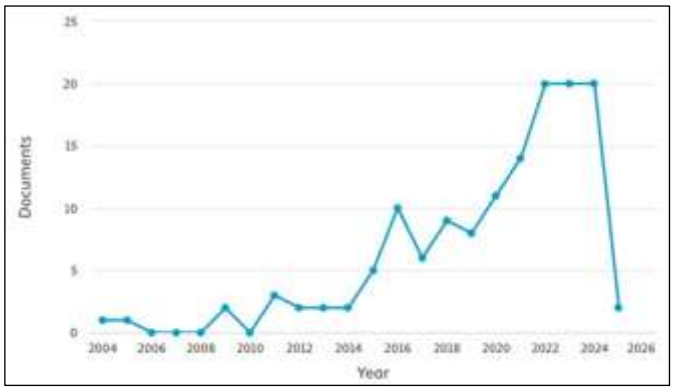

Figure 1: Publication Trends.
Source: Authors (2026).

III.2 SUBJECT AREAS

An analysis by subject area reveals that research on SP is predominantly situated within the fields of "business, management, and accounting," indicating strong engagement with SP as a strategic organizational function (see Table 1). This dominance reflects an increasing recognition of procurement as a core component of corporate sustainability, emphasizing its role in driving competitive advantage through responsible sourcing, resource efficiency, and value creation. The prominence of this subject area aligns with studies that explore how organizations integrate sustainability principles into procurement and supply chain management, often linking these practices to improvements in economic and financial performance **Erro! Fonte de referência não encontrada.**.

Table 1: Distribution of documents by subject area.

Subject area	Documents
Business, management, and accounting	58
Social sciences	47
Environmental science	46
Engineering	45
Energy	35
Computer science	20
Decision sciences	15
Economics, econometrics, and finance	11
Agricultural and biological sciences	5
Mathematics	5

Source: Authors, (2026).

Subsequently, the substantial representation of the "social sciences" further underscores the societal and policy-oriented dimensions of sustainable procurement. Research within this domain frequently addresses the role of procurement in promoting ethical behavior, social inclusion, and governance accountability [35]. Similarly, the strong contributions from "environmental science" and "engineering" highlight the technical and environmental focus of the field, particularly concerning reducing ecological footprints, promoting eco-friendly technologies, and developing sustainable production systems [36]. Additional contributions from fields such as "energy", "computer science", "decision sciences", and "economics, econometrics, and finance" demonstrate the multidisciplinary nature of SP research [37]

These areas reflect the integration of technological, analytical, and economic perspectives into procurement-related sustainability efforts. Although less represented, disciplines such as "agricultural and biological sciences", as well as "mathematics" indicate emerging directions in the field, potentially expanding future research into data-driven modeling, life-cycle analysis, and sustainable resource management.

III.3 GEOGRAPHICAL AND INSTITUTIONAL DISTRIBUTION OF RESEARCH

The upward trend in SP publications since 2012 is also reflected in the country-level analysis, which highlights the expanding global engagement with this field. The United Kingdom (UK) leads in both the number of documents and total citations, suggesting a mature and influential research landscape supported by well-established academic programs, policy initiatives, and funding schemes promoting sustainable practices (see Table 2). Germany follows closely, exhibiting a high citation count relative to its publication output—an indication of the strong impact and quality of its research contributions [38].

Table 2: Bibliographical coupling data by country.

Country	Documents	Citations	Total Link Strength
United Kingdom	40	2364	20
Brazil	11	501	7
United States of America	11	181	4
Australia	11	213	1
Italy	10	293	10
Netherlands	7	208	7
France	6	305	9
Poland	6	196	5
Germany	6	608	4
Ghana	6	75	4

Source: Authors, (2026).

The "Total Link Strength" metric, representing the intensity of collaborative networks, further enhances this analysis. Countries such as Brazil and Italy demonstrate high link strength scores, reflecting the benefits of international collaboration in fostering knowledge exchange and resource sharing [39]. These findings help identify key nations and institutions driving innovation and best practices in sustainable procurement. For example, the city of Copenhagen's renewable energy–oriented procurement policies exemplify how government initiatives can operationalize sustainability principles [36]. Further exploration of policy frameworks and research programs in the UK and Germany could provide valuable insights into the institutional mechanisms that underpin their leadership in SP research and implementation [40]. The inclusion of Ghana in the dataset also reflects the emerging research contributions from Africa, signaling growing global awareness of SP's importance [39]. The diversification of research contexts points to the need for regionally focused studies that address local challenges and opportunities, facilitating broader and more effective implementation of sustainable procurement practices. At the institutional level, publication data reveal that universities such as UNSW Sydney, the University of Leeds, and Liverpool John Moores University are among the most productive contributors, indicating a strong research focus on sustainable procurement in Australia and the UK. Notably, Fahim Ullah of UNSW Sydney has contributed extensively to the literature on sustainable development and risk management. These universities likely host specialized research centers dedicated to sustainability, supply chain management, and the circular economy. Additionally, institutions such as Universidade Federal Fluminense (Brazil), University of Belgrade (Serbia), and Kwame Nkrumah University of Science and Technology (Ghana) demonstrate the geographical broadening of SP research beyond traditional centers. Other contributors, including the University of Johannesburg, King Abdulaziz University, and Universidade Estadual Paulista Júlio de Mesquita Filho, further emphasize the global diffusion of research efforts and the growing inclusivity of sustainability scholarship.

III.4 THETAMIC ANALYSIS

Keywords co-occurrence analysis provides a powerful methodological approach for deconstructing the knowledge structure of SP. By mapping relationships among frequently co-occurring keywords, it reveals the dominant themes, conceptual linkages, and research clusters within the field, thereby offering valuable insights into key areas of focus and potential research gaps. As the central theme, SP shows strong associations with foundational concepts such as "supply chain management," "sustainability," and "performance", see Figure 2. The frequent co-occurrence of "supply chain management" and "sustainability" underscores their interdependence, reflecting the growing recognition that sustainable procurement is integral to achieving broader supply chain sustainability objectives. The prominence of "performance" highlights the field's emphasis on measuring the outcomes of SP practices—particularly their contributions to reducing environmental impact and enhancing social responsibility. Similarly, the frequent appearance of keywords such as "circular economy," "life cycle assessment," and "environmental impact" emphasizes the environmental orientation of SP research, demonstrating a strong focus on resource efficiency, waste reduction, and eco-innovation.

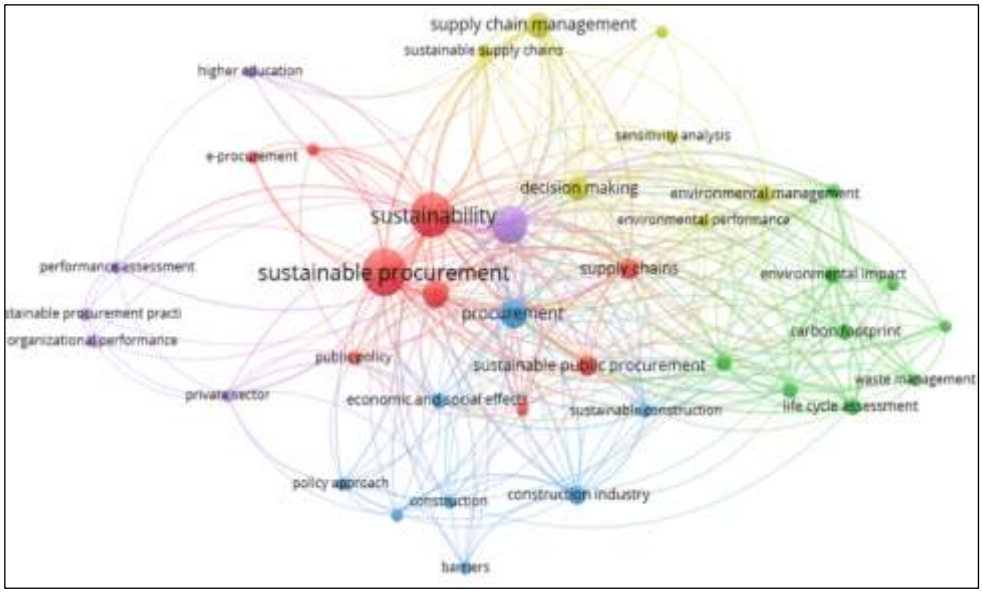

Figure 2: Keywords Co-occurrence Network.
Source: Authors (2026).

Another emerging thematic cluster conceptualizes the strategic deployment of SP within higher education institutions, highlighting its potential to enhance organizational performance and advance institutional sustainability goals. The co-occurrence of keywords such as "corporate social responsibility," "decision making," "environmental management," "environmental performance," and "supply chain management" reflects growing scholarly attention to the role of SP in advancing corporate social responsibility (CSR) agendas. This association demonstrates that procurement decisions are increasingly viewed not merely as administrative processes but as strategic levers for sustainability-driven value creation. Furthermore, the clustering of keywords such as "barriers," "construction industry," "policy approach," "project management," and "sustainable construction" highlights the sectoral challenges and opportunities associated with implementing SP practices in construction and infrastructure development. In these contexts, researchers have emphasized the influence of policy frameworks and governance mechanisms in shaping SP outcomes. The presence of terms such as "public green procurement," "university," and "sustainable development goals (SDGs)" points to the institutionalization of sustainability principles within the public sector and academia. However, in many cases, legal and regulatory constraints limit universities' ability to fully integrate sustainability into their procurement decisions, despite their substantial purchasing capacity [41]. As major economic and social actors, universities represent critical environments for advancing sustainable procurement. They allocate significant financial resources for a wide range of activities—including teaching, research, administration, and campus operations—providing a fertile ground for interdisciplinary innovation and the promotion of sustainable development principles. Thus, higher education institutions not only serve as laboratories for testing sustainability initiatives but also play a pivotal role in modeling and disseminating best practices in SP. Next, the keywords co-occurrence analysis revealed five major thematic clusters representing the intellectual and conceptual foundations of SP research (see Table 3). Each cluster reflects distinct yet interconnected perspectives on how sustainability principles are operationalized within procurement systems across public, private, and institutional contexts.

Table 3: Thematic analysis based on Keywords.

Cluster Color	Keywords	Cluster Name (Theme)
Red	e-procurement, green procurement, procurement strategy, public policy, public procurement, supply chains, sustainability, sustainable procurement, sustainable public procurement	Sustainability in public procurement
Green	carbon footprint, circular economy, climate change, environmental impact, environmental sustainability, life cycle analysis, life cycle assessment, waste management	The role of sustainable procurement in circular economy
Blue	barriers, construction industry, economic and social effects, policy approach, procurement, project management, sustainable construction	Sustainable construction
Yellow	corporate social responsibility, decision making, environmental management, environmental performance, sensitivity analysis, supply chain management, sustainable supply chain	The role of corporate social responsibility
Purple	higher education, organizational performance, performance assessment, private sector, sustainable development, sustainable procurement	Sustainable procurement in higher education

Source: Authors, (2026).

III.4.1 Cluster 1: Sustainability in Public Procurement

The theme of "sustainability in public procurement" represents a central pillar of SP research, highlighting the transformation of public sector procurement into a strategic instrument for advancing sustainability objectives. This cluster, encompassing keywords such as e-procurement, green procurement, procurement strategy, public policy, public procurement, supply chains, sustainability, and sustainable public procurement, underscores how the integration of sustainability principles within public purchasing frameworks can drive transparency, accountability, and environmental stewardship across government operations.

The adoption of e-procurement systems marks a significant advancement in this regard. As a digital innovation, e-procurement not only streamlines procurement processes but also embeds sustainability criteria directly into decision-making frameworks. Basheka et al. [42] emphasize that implementing e-procurement enhances institutional quality by enabling more comprehensive supplier evaluations that include social, economic, and environmental indicators alongside traditional cost metrics. Recent studies also demonstrate how big data analytics and emerging digital technologies strengthen governance and sustainability outcomes in public procurement. According to Sanda et al. [43], big data tools enhance accountability and transparency by identifying irregularities, enabling real-time oversight, and supporting data-driven decisions. Likewise, Da Silveira et al. [35] discuss the potential of blockchain technology in ensuring traceability and verification of sustainability practices throughout the supply chain, improving compliance monitoring and stakeholder trust. However, the transition toward sustainable e-procurement is not without challenges. As Tao et al. [44] observe, public institutions often face institutional barriers and cost-oriented mindsets that limit the adoption of sustainability-focused approaches. Despite growing demand for sustainable goods and services, procurement practices frequently prioritize short-term cost savings over long-term sustainability gains. Fernández-Pérez and Luque-Vílchez [45] argue that overcoming this imbalance requires a cultural and organizational shift—one that values lifecycle costing, environmental impact mitigation, and social inclusion as core procurement priorities. In addition, the role of collaborative frameworks and stakeholder engagement is crucial in advancing sustainability within public procurement. Zin Zawawi et al. [46] highlight that engaging multiple stakeholders, from policymakers to suppliers and civil society, fosters shared learning, innovation, and collective accountability, all of which are essential for achieving meaningful sustainability outcomes. External pressures also play a role; Vluggen et al. [47] note that regulatory frameworks, social expectations, and international sustainability standards can reinforce accountability and stimulate the institutionalization of sustainable procurement practices. ustainability in public procurement, therefore; is evolving from a compliance-driven activity into a strategic governance mechanism for achieving sustainable development. By leveraging digital innovations such as e-procurement, big data analytics, and blockchain, public institutions can enhance transparency and embed sustainability into all stages of procurement. Nevertheless, realizing this potential requires not only technological innovation but also institutional reform, cross-sector collaboration, and long-term commitment to aligning procurement with sustainability imperatives.

III.4.2 Cluster 2: The role of sustainable procurement in circular economy

Minimizing environmental impact through the adoption of circular economy (CE) principles has become a cornerstone of sustainable development. The transition from a linear “take–make–dispose” model toward a circular economic system emphasizes resource efficiency, waste reduction, and product life-cycle optimization, allowing businesses and societies to mitigate ecological damage while fostering long-term economic resilience. Within this paradigm, SP plays a pivotal role by prioritizing eco-efficient materials, renewable resources, and closed-loop supply chains, thereby serving as a key operational mechanism for realizing circular economy objectives. The integration of circular economy principles into procurement practices extends across diverse sectors and scales. Education is among the most influential arenas for driving this transition. El Mahdi Safhi et al. [48] highlight the importance of embedding sustainability and CE education into academic curricula, noting that future decision-makers must develop a deep understanding of these concepts to effectively champion sustainable practices. This educational foundation ensures that emerging professionals can embed circular thinking into procurement, production, and organizational decision-making processes across industries. In the healthcare sector, circular principles are increasingly influencing procurement strategies aimed at improving efficiency and reducing waste. Di Virgilio et al. [49] emphasize that sustainable procurement in hospitals enhances operational efficiency while minimizing environmental impacts. Their study underscores that the inclusion of performance indicators (such as cost-effectiveness, compliance, and resource utilization) enables institutions to assess sustainability outcomes more holistically, aligning healthcare operations with circular economy goals. The construction industry presents one of the most promising yet challenging domains for implementing circular procurement. Aboginije et al. [50] stress the importance of holistic waste management in construction and demolition projects, particularly in developing contexts such as Nigeria. Their findings show that integrating circular practices, such as material reuse and recycling, can substantially reduce waste generation and environmental degradation. This approach aligns procurement strategies with life-cycle management and resource optimization, reinforcing the sector’s contribution to sustainable urban development.

From a supply chain perspective, CE implementation is strengthened through strategic supplier partnerships and engagement. Caldera et al. [51] demonstrate that in Australia’s built environment sector, integrating CE elements into procurement regulations encourages supplier collaboration in areas such as product life extension, component recovery, and material recirculation. These partnerships create innovation ecosystems that support sustainable material sourcing, reduce the carbon footprint, and enhance circular supply chain resilience. Similarly, the link between supplier selection and circular procurement is critical. Le et al. [52] highlight the need for supplier evaluation frameworks that incorporate environmental and social performance metrics alongside traditional cost and quality considerations. Such systematic approaches ensure that procurement decisions reinforce circularity objectives by prioritizing suppliers committed to sustainability and low-impact production. Life-cycle assessment (LCA) methodologies further support this integration by offering a comprehensive understanding of environmental impacts throughout a product’s lifespan, thereby guiding more informed and responsible purchasing choices. Recent advances in decision-support systems and modeling have further enhanced the alignment of procurement with circular economy objectives. Ahamed et al. [53] propose multi-criteria decision-making (MCDM) models that embed sustainability parameters into supplier selection, combining cost efficiency with ecological and social considerations. These heuristic models provide decision-makers with structured tools for balancing performance and sustainability trade-offs, reinforcing the contribution of procurement to both resource efficiency and economic durability.The synergy between SP and CE principles forms a powerful foundation for minimizing environmental impacts and promoting systemic sustainability. By integrating sustainability education, fostering supplier collaboration, improving waste management practices, and adopting robust evaluation frameworks, organizations can accelerate the transition toward a regenerative and resource-efficient economic model. SP thus emerges not merely as a management function but as a transformative enabler of the circular economy, bridging environmental responsibility with long-term organizational performance and societal well-being.

III.4.3 Cluster 3: Sustainable construction

The construction industry plays a pivotal role in advancing environmental and social sustainability but continues to face substantial challenges in the adoption of sustainable practices. As one of the most resource-intensive sectors, construction significantly impacts land use, energy consumption, and waste generation. Overcoming these challenges requires systemic approaches that integrate sustainability principles throughout project lifecycles. In this context, integrated project management (IPM) has emerged as a critical mechanism for promoting sustainable construction, offering a structured framework for stakeholder collaboration, decision-making, and resource optimization. The application of IPM fosters collaboration among project stakeholders, streamlines communication, and enhances decision-making processes, factors essential for the effective implementation of sustainability strategies in construction. According to Fregonara et al. [54], improving governance structures and enhancing access to targeted resources and collaborative tools are key enablers for advancing sustainable procurement practices within construction projects. Strengthened governance ensures accountability, transparency, and alignment of stakeholder goals, thus creating an environment conducive to sustainable outcomes. A major barrier to sustainability adoption in construction lies in the lack of leadership commitment and institutional knowledge. Caldera et al. [51] emphasize that the COVID-19 pandemic exposed critical weaknesses in project resilience and adaptability, underscoring the need for integrated and flexible procurement approaches. Empowering leadership teams with sustainability knowledge and competencies is therefore vital to embedding sustainability principles into project management frameworks and ensuring that organizations can respond effectively to future disruptions. Another pressing concern is construction and demolition waste, which remains one of the largest contributors to environmental degradation in the built environment.

Aboginije et al. [50] highlight that the adoption of integrated project management techniques can substantially improve waste management processes by enhancing planning, execution, and monitoring capabilities. Such integration enables firms to adopt circular waste management frameworks that promote recycling, material reuse, and reduction of landfill dependency—thereby minimizing the overall environmental footprint of construction projects. Technological innovation, particularly the use of e-procurement systems, further strengthens the implementation of sustainable construction practices. Jelodar et al. [55] note that digital procurement platforms enhance supplier engagement, improve decision-making, and enable organizations to assess suppliers' sustainability performance more effectively. The integration of IPM tools with e-procurement systems allows for better tracking, reporting, and compliance monitoring, ensuring that environmental standards and sustainability criteria are consistently applied across projects. Stakeholder collaboration also plays a crucial role in overcoming sustainability barriers within construction projects. Casanovas-Rubio et al. [56] argue that multi-stakeholder engagement and dialogue are essential for minimizing the social and environmental impacts associated with construction activities. Collaborative approaches foster shared accountability, mutual learning, and consensus-building, all of which strengthen the social legitimacy and practical implementation of sustainability objectives. In addition to governance and collaboration, organizational culture remains a determining factor in the success of sustainable construction initiatives. Oyewobi and Jimoh [57] identify attitudinal resistance and a lack of awareness as persistent barriers to adopting sustainable procurement in the construction industry. Through IPM, organizations can implement change management strategies that reshape stakeholder mindsets, bridge knowledge gaps, and foster a culture of continuous sustainability improvement.

III.4.4 Cluster 4: The role of corporate social responsibility

Corporate social responsibility (CSR) plays a pivotal role in shaping SP by embedding ethical, social, and environmental considerations into procurement and operational decisions, thereby promoting responsible and transparent business practices. Through such alignment, firms not only address stakeholder expectations but also reinforce ethical, social, and environmental accountability across the entire value chain. A key dimension of this integration lies in aligning corporate strategies with sustainable procurement practices. Di Virgilio et al. [49] highlight that organizations embedding sustainability within their procurement systems experience tangible benefits, including improved compliance, enhanced stakeholder trust, and increased client satisfaction. By operationalizing CSR principles in procurement, firms can leverage their social and environmental commitments to strengthen brand reputation and build long-term stakeholder relationships. This alignment ensures that procurement decisions reflect a balance between economic performance, social equity, and environmental responsibility—the three pillars of sustainability. To achieve this, organizations must improve access to resources and managerial tools that support CSR-driven practices. Aluchna and Rok [58] emphasize that empowering firms with tools for ethical sourcing, sustainable material selection, and supplier engagement is essential for enhancing operational efficiency and accountability. Such practices cultivate a corporate culture that values ethics and sustainability alongside profitability, reinforcing the broader CSR agenda.

Emerging technologies also play a transformative role in integrating CSR within supply chains. Sanda et al. [43] demonstrate that big data analytics can be applied to monitor supplier compliance with CSR standards, enabling firms to assess environmental and social risks in real time. This data-driven approach enhances transparency, mitigates unethical sourcing risks such as child labor or environmental harm, and supports informed decision-making in procurement. Similarly, Letunovska et al. [59] highlight the potential of green technologies and reverse logistics in amplifying CSR outcomes, showing how digital platforms and e-procurement tools can streamline sustainable practices while improving traceability and compliance. Nevertheless, effective CSR integration requires overcoming organizational and cultural barriers. Ahamed et al. [53] argue that strong institutional frameworks and supportive policy environments are vital for embedding sustainability within supply chains. Companies must cultivate inclusive and participatory cultures that encourage stakeholder engagement and ensure that sustainability objectives are championed at all organizational levels. Leadership commitment, cross-functional coordination, and transparent communication are critical enablers of this transformation. Complementing these managerial and technological dimensions, LCA frameworks offer an evidence-based approach to evaluating the environmental impacts of procurement choices in relation to CSR commitments [44]. By examining the entire lifecycle of products and materials—from production to disposal—LCA enables firms to make procurement decisions that prioritize long-term ecological balance over short-term cost considerations. This perspective aligns with CSR's foundational goals of transparency, accountability, and sustainable value creation.

III.4.5 Cluster 5: Sustainable procurement in higher education

The incorporation of SP practices within higher education institutions (HEIs) plays a crucial role in advancing both organizational performance and sustainable development objectives. By addressing environmental stewardship, social accountability, and economic efficiency, SP enables universities to align their operational and strategic decisions with broader sustainability goals. Within educational settings, sustainable procurement fosters responsible resource use, enhances stakeholder engagement, and reinforces the institution's commitment to sustainability-driven governance. A growing body of literature highlights that SP can significantly enhance organizational performance by cultivating a culture of sustainability among academic staff, administrators, and students. The integration of sustainability principles into procurement not only improves operational efficiency but also builds institutional capacity for sustainability-focused research and innovation. This cultural transformation ensures that procurement choices reflect the environmental and ethical values of the institution, creating a framework where education, research, and operations reinforce one another in pursuit of sustainability. Education itself serves as a key enabler of sustainable procurement adoption. El Mahdi Safhi et al. [48] underscore the importance of embedding sustainability and circular economy education into university curricula to prepare future leaders capable of implementing and advocating for sustainable practices. By equipping students with practical knowledge and critical awareness, HEIs contribute to developing a new generation of decision-makers who integrate sustainability into organizational strategies and professional practice—thereby amplifying the long-term impact of SP both within and beyond academia. External influences, such as the COVID-19 pandemic, have also reshaped sustainable procurement in HEIs.

Caldera et al. [51] demonstrate that the pandemic prompted universities to reassess procurement systems, revealing the need for greater resilience, adaptability, and innovation in managing supply chains. Flexible procurement strategies, supported by digital platforms and collaborative frameworks, can strengthen institutional agility and enable HEIs to maintain sustainability commitments even under disruptive circumstances. Institutional drivers remain critical for embedding SP practices effectively. Leal Filho et al. [8] identify policy frameworks, leadership commitment, and stakeholder collaboration as essential enablers of sustainable procurement integration in HEIs. Leadership that prioritizes transparency, shared accountability, and cross-departmental cooperation can mitigate organizational resistance and foster the successful implementation of sustainability initiatives. In this regard, effective leadership acts as both a facilitator of cultural change and a catalyst for innovation, ensuring sustainability becomes a central element of institutional governance. SP also offers competitive advantages for universities, enhancing reputation, compliance, and funding opportunities. As Di Virgilio et al. [49] note, HEIs that adopt sustainable procurement strategies not only improve operational compliance and stakeholder satisfaction but also attract partnerships and sponsorships aligned with sustainability objectives. Demonstrating commitment to sustainable practices strengthens institutional credibility and aligns HEIs with global efforts such as the UN SDGs. The intersection between SP and CSR also provides an additional framework for amplifying impact. Integrating CSR into procurement processes can increase engagement among faculty, students, and external partners, fostering shared ownership of sustainability goals. This alignment allows HEIs to leverage their procurement power to promote social equity, ethical sourcing, and environmental conservation, thereby embedding sustainability into the institution's organizational identity.

IV. DISCUSSION

The results of the thematic analyses reveal that SP is increasingly conceptualized not merely as a technical or operational activity, but as a strategic, institutionally embedded, and stakeholder-sensitive domain. The five clusters (i.e., sustainability in public procurement, SP in CE, sustainable construction, the role of CSR, and SP in HEI) reflect how SP has evolved to bridge digital, environmental, governance, and educational spheres. To interpret these results, this discussion draws upon institutional theory, stakeholder theory, and the resource-based view (RBV) as key analytical frameworks that explain the patterns, drivers, and outcomes observed in the literature. Interpreting these findings through theoretical lenses helps explain the observed trends, identify underlying mechanisms, and derive practical implications.

IV.1 THEORETICAL CONSIDERATION

IV.1.1 Institutional theory

Institutional theory provides a robust framework for understanding how regulatory environments, policy frameworks, and institutional norms shape the adoption and diffusion of SP practices across sectors. According to DiMaggio and Powell [60], organizations face three primary types of institutional pressures—coercive, normative, and mimetic—that drive conformity and legitimacy-seeking behaviors. These forces are particularly evident in how SP becomes institutionalized through laws, public policies, and professional norms. Findings from Cluster 1 demonstrate that governments play a pivotal role in institutionalizing SP through regulatory mandates, e-procurement systems, and transparency mechanisms. Such institutional reforms encourage organizations to embed sustainability into procurement processes to comply with evolving norms and expectations. For instance, the European Union's Green Public Procurement (GPP) directives have effectively normalized sustainability as a standard component of public contracting, shaping how organizations define procurement excellence [61]. Similarly, digital procurement platforms and data-driven monitoring systems have enhanced accountability and governance efficiency, reflecting how institutional modernization aligns with sustainability objectives. However, institutional constraints (such as fragmented regulations, inadequate digital infrastructure, and entrenched cost-based procurement cultures) continue to limit the depth of SP implementation, particularly in contexts with lower institutional capacity. In such settings, weaker enforcement and short-term economic priorities can result in partial or symbolic compliance rather than substantive sustainability adoption. Grob and Benn [62] further extends institutional theory to the domain of SP, emphasizing that normative and coercive pressures from policy frameworks, industry norms, and cross-sectoral emulation are primary drivers of SP adoption. Glover et al. [63] applied institutional theory to explore how supermarkets shape sustainability practices across the dairy supply chain, revealing how dominant institutional logics influence the diffusion of sustainability norms.

Their findings showed that while smaller organizations aspired to integrate sustainable practices, powerful actors, such as supermarkets, exerted coercive pressures prioritizing cost reduction and profit maximization over genuine sustainability outcomes. Moreover, these dominant firms often engaged in mimetic behaviors, replicating public sustainability initiatives for legitimacy and image rather than deep systemic change. Translating this insight to the sustainable procurement domain, institutional power asymmetries can similarly shape SP adoption, where larger buyers impose compliance requirements that may reinforce efficiency and reputation goals but not necessarily transformative sustainability impact. Thus, institutional theory underscores how legitimacy concerns and power structures can either enable or constrain the substantive institutionalization of sustainable procurement. Next, within the SP in higher education cluster, institutional theory also explains how policy mandates and leadership commitment shape procurement practices. HEIs, often situated between public accountability and academic autonomy, face dual pressures: to comply with governmental sustainability policies and to model sustainable values as part of their educational mission. As semi-public entities, HEIs must demonstrate both operational efficiency and social responsibility, thereby institutionalizing sustainability as a core governance principle. This dynamic reinforces the role of universities as norm entrepreneurs, influencing not only their internal operations but also broader societal perceptions of sustainability in procurement [64]. Taken together, institutional theory elucidates how external coercive forces (e.g., regulations and funding requirements), normative influences (e.g., professional standards and educational norms), and mimetic behaviors (e.g., imitation of best practices) collectively drive the legitimization and diffusion of sustainable procurement practices. Nonetheless, the persistence of institutional barriers highlights the need for adaptive reforms (balancing compliance with innovation) to ensure that SP evolves beyond a regulatory requirement into an embedded organizational norm that supports long-term sustainability transitions.

IV.1.2 Stakeholder theory

Stakeholder theory offers a complementary perspective for understanding the social and relational dimensions of sustainable procurement. The theory posits that organizations must consider the expectations of diverse stakeholders (ranging from suppliers and customers to regulators and local communities) to maintain legitimacy and long-term success [65]. Findings from Cluster 4 illustrate this dynamic clearly. The integration of CSR in SP acts as a mechanism through which organizations respond to stakeholder demands for ethical, social, and environmental accountability. In supply chain contexts, firms increasingly engage in ethical sourcing, supplier audits, and CSR-driven partnerships to address stakeholder concerns over labor practices, environmental degradation, and transparency [43]. This demonstrates a growing emphasis on shared accountability and co-creation of social value, where procurement decisions are no longer guided solely by price or efficiency but by their ability to contribute to broader social and environmental goals. Similarly, in construction, stakeholder collaboration—across contractors, regulators, and community actors—has emerged as a key enabler for overcoming barriers to sustainable project delivery [56]. From a practical standpoint, the stakeholder lens suggests that inclusive decision-making, transparent reporting, and participatory governance are essential for building trust and fostering sustainability across procurement networks. This also highlights a managerial implication: procurement professionals must develop relational competencies, not just technical expertise, to balance stakeholder demands and achieve long-term sustainability outcomes. In both public procurement and construction clusters, stakeholder engagement plays a central role: multi-actor collaborations, participatory decision-making, and transparent governance help manage conflicts, build trust, and reinforce legitimacy. For HEIs, the alignment of procurement with stakeholder values (including students, faculty, and local communities) can enhance institutional credibility and support. The stakeholder lens thereby emphasizes that SP is not just about supplier selection or environmental impact; it is fundamentally about social value creation and legitimacy in multi-actor networks.

IV.1.3 Resource-based view

While institutional and stakeholder theories explain why organizations adopt SP, the resource-based view (RBV) provides insight into how they derive strategic advantage from doing so. The RBV posits that firms can achieve sustained competitive advantage by cultivating resources and capabilities that are valuable, rare, inimitable, and non-substitutable [66]. Within the SP context, these strategic capabilities include sustainability analytics, LCA expertise, supplier relationship management systems, green innovation, and a culture of sustainability-oriented leadership. Unlike external compliance pressures described in institutional theory, RBV focuses on internal resources that enable organizations to transform sustainability from an obligation into a source of value creation. Clusters such as Cluster 2 and Cluster 4 reflect this logic, showing how firms develop distinctive competencies, such as circular material flows, closed-loop logistics, and CSR-based supplier evaluation, that enhance both environmental performance and market differentiation. Firms with advanced sustainability capabilities are not only better equipped to meet stakeholder and regulatory demands but also to achieve efficiency, innovation, and reputational gains that reinforce long-term advantage [53].

In Cluster 3 and Cluster 5, the RBV lens further illustrates how organizational culture, knowledge sharing, and leadership commitment act as intangible resources that drive sustainability integration. For instance, embedding sustainability principles into procurement and project management routines enables institutions to strengthen operational efficiency, foster innovation, and build reputational capital, key intangible assets that contribute to sustained strategic advantage. By leveraging these unique resources, organizations can achieve dual objectives: reducing environmental impact and enhancing organizational performance. The RBV deepens the understanding of sustainable procurement by positioning it as a capability-driven strategic asset rather than a compliance mechanism. Organizations that cultivate and integrate sustainability-oriented resources (technological, human, and relational) can convert sustainability investments into enduring sources of competitive advantage, thereby reinforcing the strategic and transformative potential of sustainable procurement.

IV.2 PRACTICAL IMPLICATION AND POLICY RELEVANCE

The findings of this study suggest several actionable implications for policy makers, public agencies, HEIs, and supply chain managers. They also highlight areas where regulatory support and organizational capabilities can foster more effective SP implementation. First, governments should reinforce institutional frameworks that mandate the inclusion of sustainability criteria within public procurement processes. Establishing clear sustainability standards, coupled with regulatory incentives, can encourage suppliers to prioritize transparency, ethical compliance, and environmental stewardship. The notion of institutional responses to digital procurement highlights how policy instruments can accelerate the adoption of e-procurement platforms that embed sustainability metrics into decision-making systems [67]. Similarly, a supportive regulatory environment, such as those promoting green supply chain management, encourages organizations to invest in sustainability initiatives that enhance both legitimacy and performance, consistent with stakeholder theory perspectives [68]. Second, organizations must cultivate internal capabilities that enable them to operationalize sustainability principles effectively. Under the RBV, capabilities such as sustainability analytics, LCA proficiency, supplier relationship management, and robust data systems represent strategic assets that provide enduring competitive advantage [69]. By investing in these internal competencies, firms can transform sustainability from a compliance burden into a driver of innovation, resilience, and stakeholder value. Third, leadership and governance mechanisms must be strengthened to mitigate cultural resistance, ensure accountability, and foster coordination among diverse stakeholders. Empirical evidence suggests that public-sector organizations adopting e-procurement systems often experience institutional inertia (a resistance to change rooted in bureaucratic culture) unless reforms are accompanied by strong leadership, change management strategies, and transparent policies [67]. Leadership commitment thus becomes a critical enabler for aligning institutional objectives with sustainable procurement performance.

Fourth, higher education institutions can play both instructional and exemplary roles in advancing sustainable procurement. As knowledge hubs, HEIs should integrate sustainability, circular economy, and responsible procurement principles into their curricula, thereby equipping future managers and policymakers with the competencies required to make sustainability-driven decisions. Institutionally, universities should also revise their procurement policies to prioritize CSR, environmental criteria, and long-term social value rather than cost minimization alone. This alignment enhances institutional reputation, strengthens stakeholder satisfaction, and increases eligibility for research funding and partnerships emphasizing environmental, social, and governance (ESG) objectives. Fifth, the adoption of digital and data-driven procurement systems—including e-procurement platforms, blockchain-based traceability, big data analytics, and automated dashboards, is essential for improving transparency, efficiency, and accountability in SP implementation. These technologies facilitate real-time monitoring of supplier performance and sustainability compliance while minimizing opportunities for corruption or data manipulation [67]. However, effective deployment requires governments and public agencies to invest in data infrastructure and ensure interoperability across systems. Inconsistent or poor-quality data remains a major barrier to informed decision-making and accurate performance measurement. Finally, SP policies should remain context-sensitive, reflecting economic, institutional, and cultural differences across nations and industries. Institutional capacity, supplier market maturity, and enforcement strength significantly affect how SP practices are designed and implemented. Aligning national SP strategies with global frameworks, such as the UN SDGs, OECD guidelines, and WTO procurement standards, can enhance policy coherence and ensure cross-border legitimacy and comparability.

V. CONCLUSION

This study provides a comprehensive synthesis of SP research through a combined SLR and bibliometric analysis, uncovering the intellectual, thematic, and methodological evolution of the field. By analyzing 138 peer-reviewed studies, the research identifies critical trends, dominant clusters, and theoretical underpinnings that have shaped SP scholarship over the past two decades. The results indicate that SP has evolved from a compliance-oriented policy concept to a strategic organizational capability that integrates environmental, social, and economic considerations into procurement decisions. Empirically, the findings reveal five major thematic clusters: (1) sustainability in public procurement, emphasizing the institutionalization of sustainability through e-procurement and policy frameworks; (2) the role of SP in CE, focusing on resource efficiency and waste minimization; (3) sustainable construction, highlighting project management integration and governance challenges; (4) the role of CSR, linking ethical sourcing and social responsibility with corporate performance; and (5) SP in higher education, which underscores universities' dual role as both practitioners and educators in advancing sustainability. These clusters collectively reflect a dynamic, cross-sectoral research landscape where sustainability is increasingly embedded in operational and strategic decision-making.From a theoretical perspective, the study demonstrates that institutional theory, stakeholder theory, and the RBV collectively provide a multidimensional understanding of SP. Institutional theory explains how coercive, normative, and mimetic pressures from regulatory bodies, policy frameworks, and social norms drive organizations toward sustainable procurement adoption.

Stakeholder theory highlights the role of diverse actors (i.e., governments, suppliers, consumers, and civil society) in shaping expectations and accountability mechanisms. Meanwhile, RBV elucidates how firms convert sustainability practices into internal capabilities and competitive advantages through innovation, knowledge sharing, and technology adoption. Together, these frameworks offer a comprehensive explanation of why and how organizations institutionalize sustainability in procurement and supply chain processes. In practical terms, the study provides actionable insights for policymakers, practitioners, and educators. Governments should strengthen institutional frameworks and digital infrastructures to facilitate transparency and interoperability in procurement systems. Organizations must cultivate sustainability-oriented capabilities, such as LCA expertise, data analytics, and stakeholder engagement, which serve as valuable and inimitable resources under the RBV framework. HEIs should integrate sustainability and circular economy principles into curricula while modeling responsible procurement practices to foster future sustainability leaders. Despite the growing maturity of SP research, significant gaps and opportunities remain. First, there is a need for deeper exploration of digital transformation and data governance in procurement, particularly regarding blockchain, artificial intelligence, and predictive analytics for supplier evaluation. Second, comparative and longitudinal studies could examine regional and sectoral variations in SP implementation, especially in developing economies where institutional capacity remains limited.

Third, future research should adopt mixed-method and multi-level analytical designs to investigate the interaction between institutional pressures and organizational capabilities over time. Fourth, scholars could expand the theoretical lens by integrating dynamic capability theory, network governance, or institutional complexity frameworks to better understand how organizations balance competing sustainability logics. Finally, evaluating the impact of SP on ESG performance metrics can provide empirical evidence linking procurement decisions to measurable sustainability outcomes.

ABSTRACT

In light of the recent pandemics like COVID phase in 2020 that the world is going through, with all the gaps and incompleteness in diagnostics, as well as the slowness of decision-making for patients, the interest of AI to solve in the first place the various problems linked to diagnosis and secondly having a rapid response to be able to intervene in time to save lives, becomes a priority of priorities.

This work follows work which aimed to reduce the training data necessary in the deep learning process to increase the possibility of its use in cases where time is essential and the contribution was on a basis of extracting features manually with extraction methods and techniques from machine learning combine with deep learning. In our approach, we keep the same logic and we apply or integrate the principle of parallel programming into the process in order to further reduce processing and decision-making time. This will give us a very important advantage in making decisions and helping doctors with diagnosis which will give an advantage over diseases.

I. INTRODUCTION

In the present day, AI is evolving so rapidly, its applications are being applied at all levels, enabling significant advances in all domains: industry, daily life, speech and image processing, medical and military domains, among others, all of which have an impact on our lives. The AI encompasses several techniques and methods enabling machines (computers in most cases), among other things, to learn patterns from data without being explicitly programmed. Machine learning in general, and deep learning in particular, is proving particularly effective in medical imaging, which is our research domain. The use of deep learning offers a number of advantages, and its automated operation eliminates human intervention and is less influenced by human subjective factors, leading to objective results. However, there are still a number of challenges to be met, despite the extent of the advances and impacts in the medical world. With the recent pandemic, and the need to treat too many patients in record time, learning with a small amount of data in a short space of time has led us to review certain techniques and try to combine them with others in order to achieve an effective solution while also minimizing dependence on expensive hardware resources. This leads us to find innovative solutions to reduce learning time and adapt Artificial Intelligence algorithms to maximize results while at the same time minimizing data and time constraints. The most frequently tested methods in the medical imaging domain are, depending on their degree of integration alone or in combination with other methods, Convolutional Neural Networks (CNN), Recurrent Neural Networks (RNN), Generative Antagonistic Networks (GAN) and auto-encoders. Medical imagery, in all its forms - X-rays, MRIs, scans, etc. - contains relevant information to enable doctors to diagnose, monitor and treat patients. The analysis of these images using AI gives doctors and researchers a considerable advantage, enabling them to act faster and in real time to save lives and improve patient follow-up. In our approach, the proposal of solutions aimed at reducing execution time by integrating the notion of parallelism in the learning phase to save time, in addition to combining knowledge extraction methods to be able to apply deep learning even with a limited knowledge base.

II. MATERIALS AND METHODS

In the medical imaging domain, a great many works in recent years have centered on several methods, but more especially the method that attracts the most attention in this field is deep learning, which gives good results for improving diagnosis, early detection of disease, pathology monitoring and treatment prescribing. For improved diagnosis, [1] investigates the effectiveness of image feature extraction and deep learning (CNN), in improving the diagnosis of COVID-19 from chest X-ray images. Based on a two-stage process, the first step is to extract image features, using algorithms such as PHOG, Fourrier, GABOR and DCT, followed by image classification using CNN in the second step. The results generated by the simulations demonstrate an accuracy advantage over traditional machine learning techniques such as SVM, KNN and Naïve Bayes. For therapy prescription, [2] introduces a novel approach to early detection of Alzheimer's disease to predict disease progression and subsequently personalize treatment, using deep learning with the EfficientNet-B5 architecture to analyze MRI images of the brain. In terms of monitoring patients with various diseases, [3] illustrates the contribution of deep learning in analyzing data by means of the EchoNet model to identify features, cardiac in this study, by estimating cardiac function such as pacemaker lead detection, left atrium volume and left ventricular hypertrophy with an accuracy superior to human interpretation. The success in also predicting systemic phenomena such as age and gender demonstrates the potential of deep learning to improve cardiac (and not only) diagnostics and cardiovascular risk prediction. Still for early detection, [4] showing in the domain, for example, of breast cancer screening via the interpretation of mammographic images with precision reducing the rate of false positives and negatives using deep learning.

The benefits of using deep learning to achieve higher performance are not without their challenges, and specific solutions are needed to overcome difficulties such as resolution problems, real-time constraints, and the management of distributed systems, with the introduction of complexity in asynchronous communications and fault management. Several innovative techniques can considerably reduce the time needed for deep learning and inference, with better computing capacities (GPU, TPU [5], and distributed systems with data parallelism [6] or model parallelism [7]. Many recent works use distributed deep learning for the optimal execution of different processes. [8] explores methods for parallel and distributed training of deep neural networks (DNNs) on the prototype Tianhe-3 system, aiming to accelerate DNN training by exploiting the massive power available. [9] suggests optimizations of Cyclic Weight Transfer (CWT) to improve distributed learning in medical imaging in the face of data variability and by optimizing the number of iterations according to sample size, the cyclic learning rate to promote convergence, adjusting sampling and introducing a cyclic weight in the loss function. Some of the methods used, applied in addition to deep learning, in the medical imaging domain, without of course listing them all, the most used being classical neural networks (ANN), feature-based methods (SVM, K-NN), transfer learning, image segmentation, generative adversarial networks (GAN), Region Proposal Network (RPN), Visual Saliency Maps, etc. Representing just a small glimpse, these studies illustrate the powerful potential impact of deep learning in helping to transform medical imaging, offering unprecedented opportunities to improve the quality and efficiency of healthcare, according to our domain, and in other domains without exception.

III. PARALLEL AND DISTRIBUTED PROGRAMMING

Parallel and distributed programming is an essential approach for fully exploiting the power of modern computer systems. It enables complex problems to be solved by dividing tasks and executing them simultaneously on multiple processors or computers.

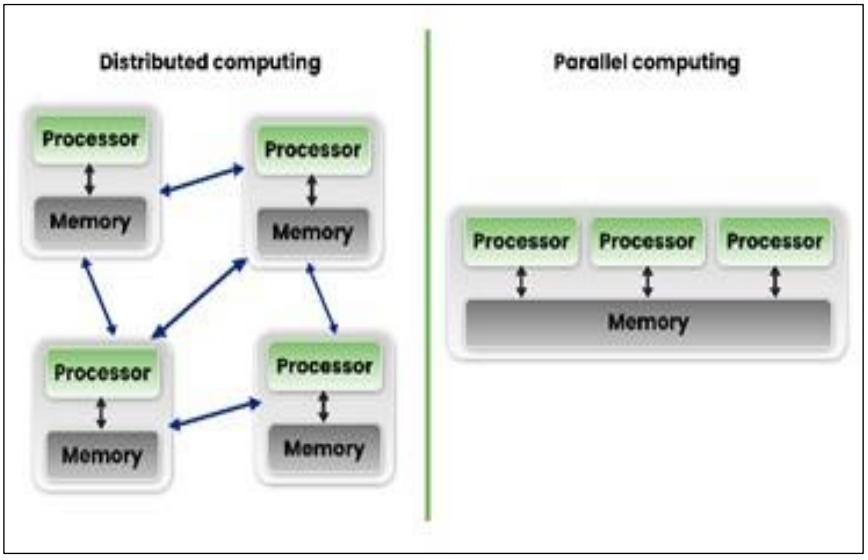

Figure 1: Parallel and Distributed Programming.
Source: [10].

III.1 DISTRIBUTED DEEP LEARNING

This section provides an overview of existing approaches for distributing deep neural network training across multiple machines or GPUs. Training models on massive volumes of data presents considerable challenges when limited to a single machine. To overcome these obstacles, these techniques aim to accelerate the training process, optimise the use of available resources, and reduce the limitations associated with the memory and computing capacity of a single system. However, they do not always take into account all the constraints specific to distributed systems, such as variable communication delays, fault tolerance, or large-scale management. Several approaches have been proposed in the literature to solve these problems and improve the scalability of deep learning [7].

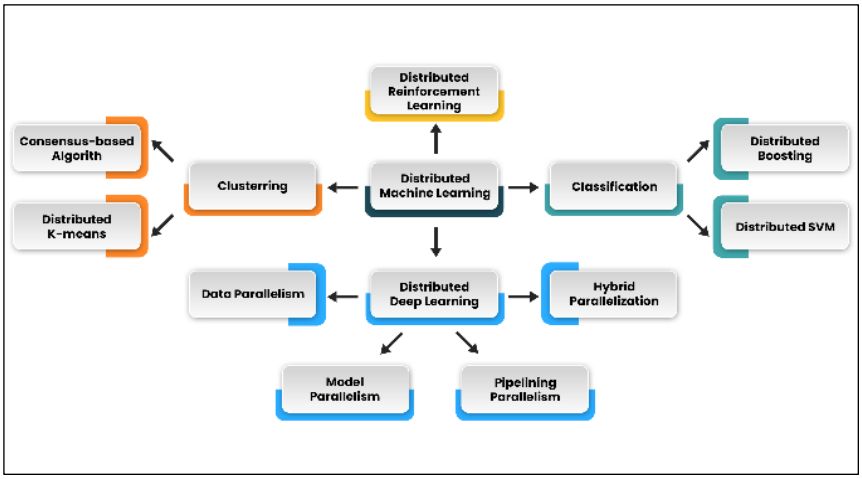

Figure 2: Distributed Machine Learning and Deep Learning Algorithms.
Source: [11].

There are two main approaches to distributed deep learning: model parallelization and data parallelization. Both strategies optimize neural network training by distributing tasks across multiple resources. Data parallelism figure Fig. 3. is considered one of the simplest forms of parallelism. It involves replicating the model, optimizer parameters and training code across all available devices (machines), it's speeds up the processing of the overall dataset by utilizing multiple devices simultaneously. It also allows for larger overall batch sizes without requiring a large number of gradient accumulations. However, in order to function correctly, each replica must be able to load the entire model with at least one micro-batch instance [12]. Model parallelism figure Fig. 4. consists of distributing the computational load of inference and backpropagation in a deep neural network across multiple machines or processors. This distribution can be done at different levels of granularity; assigning different layers of the network to different nodes, divide the neurons of the same layer between several devices or like some approaches distribute each matrix operation independently in order to optimise the load between agents as much as possible [7].

IV. PROPOSED APPROACH

Based on what we have mentioned in the previous section, we have decided to use CNN reason of its effective results on a dataset containing images specially on classification problems. The approach is divided into six phases.

- Network and architecture configuration phase.
- Model Preprocessing phase.
- Parallelization of convolution processing.
- Model training parallelization phase.
- Model testing phase.
- Model performance evaluation phase.

IV.1 NETWORK AND ARCHITECTURE CONFIGURATION

This section describes the network configuration adopted and the master-slave architecture implemented as part of our experiments. The aim is to provide a clear overview of the distributed environment used, which is essential for implementing parallel processing and evaluating system performance. In order to ensure fast, stable and efficient communication, we interconnected three machines within a local area network (LAN). The configuration of this network and the steps involved in setting it up are presented below:

- Connecting the machines to the same local area network.
- Assigning IP addresses.
- Configuring a hosts file.
- Configuring SSH access between machines.

IV.2 MODEL PREPROCESSING PHASE

This phase consists of designing and implementing the CNN model for the training model with the Train folder of the dataset. Our architecture is inspired by high-performance CNN models while being adapted to the specific constraints of our problem. The proposed architecture, illustrated in Figure Fig. 5, is defined to many layers as below: consists of

- Four convolution blocks
- Fully connected layers.
- Each convolution block includes a convolution layer using ReLU activation and a maximum pooling layer for dimensionality reduction.
- The number of filters increases gradually (16, 32, 64, 128) to allow the network to extract increasingly complex and abstract features from the images.
- The extracted features are then flattened via a Flatten layer and passed to two dense layers.
- The first dense layer with 512 units and ReLU activation learns the relationships between features,
- The output layer uses sigmoid activation to produce a binary classification probability.

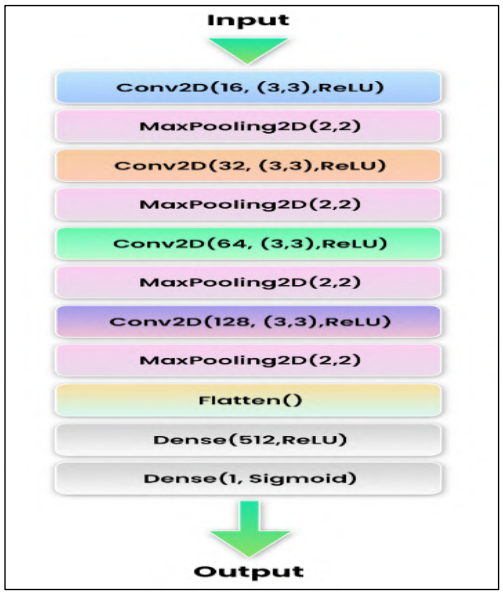

Figure 5: CNN Model Architecture.
Source: Authors, (2026).

IV.3 PARALLELISATION OF CONVOLUTION PROCESSING

The parallel convolution function was designed to distribute convolution filters and input data among the various nodes in the system. It enables convolution operations to be performed locally on each node, followed by a results aggregation phase. This function takes the following parameters:

- Layer: the convolution layer to be applied.
- Data: the input data on which the convolution will be performed.
- Rank: the rank of the process in the MPI hierarchy (rank 0 corresponds to the master node, the others to the slave nodes).
- Size: the total number of MPI processes currently running.
- Comm: The MPI communicator used for communication between processes [15].

IV.4 MODEL TRAINING PARALLELIZATION PHASE

Our parallelization approach for training convolutional neural networks is based on the principle of data parallelism. This technique allows the computational load to be distributed efficiently across multiple processing nodes, significantly reducing training time while potentially improving the performance of the final model. The parallelization strategy consists of dividing image batches between the different MPI processes available. To do this, we calculate the number of batches to be processed per process and use a different seed for each process when initializing the data generators. This approach ensures that each process works on a different subset of the training data. Each MPI process independently and in parallel trains a complete copy of the CNN model on its own subset of the data.

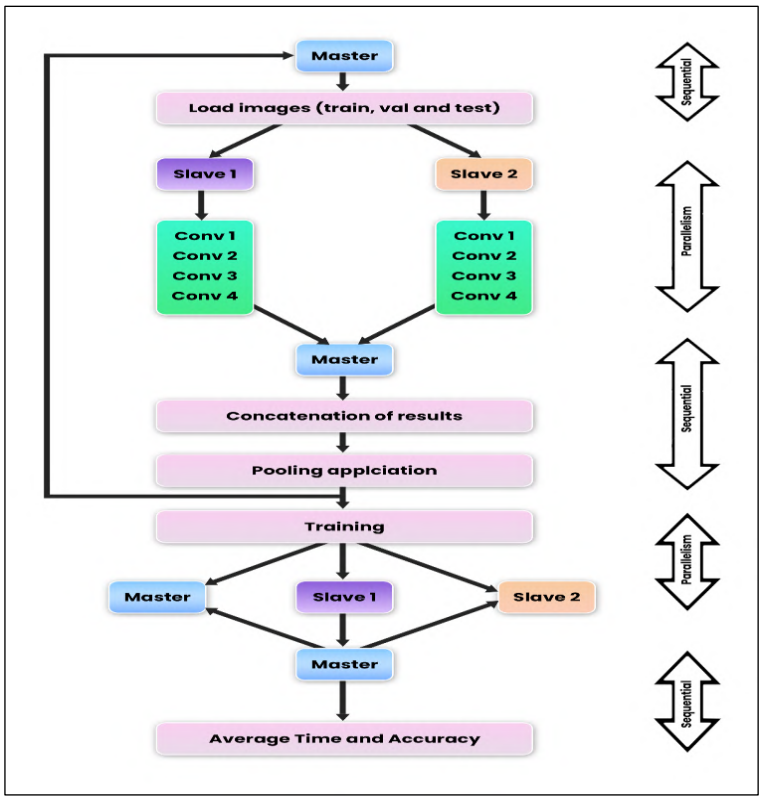

Figure 6: Diagram illustrating the proposed solution.
Source: Authors, (2026).

IV.5 MODEL TESTING PHASE

This phase consists of testing the trained model from phase C utilizing image from the test folder of our dataset.

IV.6 MODEL TESTING PHASE

This phase is about evaluating the model using classification metrics such as Confusion Matrix, Accuracy, Precision, Sensitivity, and Specificity. These metrics help us to be able to compare the results of different execution methods of de CNN model (Our approach; parallel convolution and training, Parallelized convolution only, sequential execution). We will show in section 6 that our approach gives the best results.

V. EXPERIMENTAL RESULTS

In this section, we present the experimental results obtained by the proposed approach and compare them to classic approach.

V.1 DATASET COLLECTION

The used dataset in this experience is collected by Daniel Kermany Kang Zhang Michael Goldbaum and it is available on Mendeley data website. It's also published by Paul Mooney in Kaggle website The data is composed of 5856 images of chest X-rays and it is divided into two categories: 1583 images of healthy people and the rest are those who have Pneumonia [16]. The images used in this work are illustrated in Fig. 7. The figure shows the images used for experimentation. The first row is a normal image and the second row shows a Pneumonia image. In figure Fig. 8. We illustrate the structure of this dataset.

VI. RESULTS

VI.1 RESULTS OF EXECUTION FOR SEQUENTIAL AND CONVOLUTION PARALLEL CNN MODEL

The results obtained from 15 independent runs are summarized in Table 1 and 2, which presents descriptive statistics for training time and model accuracy. Analysis of the results obtained with the sequential model (Table 1) shows that the CNN model executed sequentially has an average training time of 2777.74 seconds, with a standard deviation of 83.59 seconds, reflecting relative temporal stability between different executions. The execution time varies from 2,667.06 s to 2,897.92 s, a maximum deviation of approximately 230 seconds. In terms of model performance, the average accuracy reaches 90.59%, with a standard deviation of 0.0228, indicating good robustness and consistency of predictions. The minimum accuracy observed is 83.49%, while the maximum value reaches 92.95%, highlighting moderate but acceptable variability in the context of learning without optimization. For the CNN model with convolution parallelization (Table 2), the results indicate an average training time of 3023.68 seconds, with a standard deviation of 158.57 seconds, reflecting moderate variability between different runs. The shortest time observed was 2758.57 seconds, while the longest was 3229.63 seconds. In terms of performance, the average accuracy reached 91.08%, which is slightly higher than the result obtained in the sequential version. The standard deviation remains reasonable (2.05%), indicating overall consistency of the model, despite some variations between runs.

Table 1: Performance statistics (time and accuracy) of sequential training of the CNN model.

	Time(S)	Precision
Average	2777,7407	0,9059 (90,59%)
Standard deviation	83,5931	0,0228 (2,28 %)
Minimum	2667,0600	0,8349 (83,49 %)
Maximum	2897,9200	0,9295 (92,95 %)

Source: Authors, (2026).

Table 2: Performance statistics (time and accuracy) of sequential training of the CNN model.

	Time(S)	Precision
Average	3023,6794	0,9108 (91,08 %)
Standard deviation	158,5696	0,0205 (2,05 %)
Minimum	2758,5724	0,8766 (87,66 %)
Maximum	3229,6260	0,9439 (94,39 %)

Source: Authors, (2026).

The graph (Fig. 9) below illustrates the variation in training time (in seconds) and accuracy obtained during the 15 simulations performed to assess the stability of the model's performance.

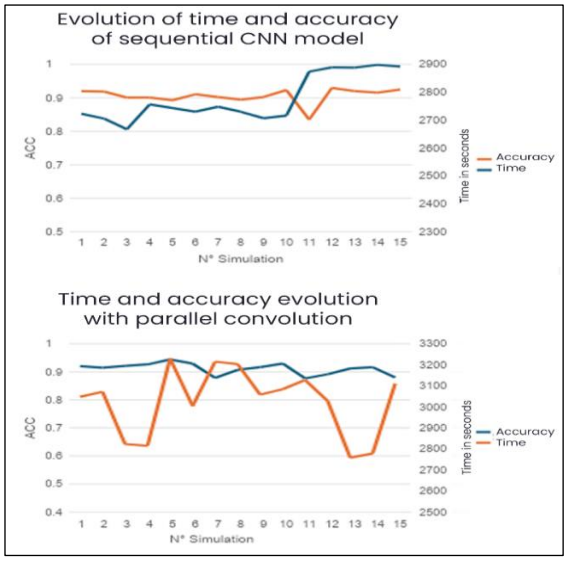

Figure 9: Time evolution and accuracy of sequential and convolution parallel CNN model.
Source: Authors, (2026).

Fig.10 illustrates the accuracy curve obtained directly when executing the sequential CNN code over 40 epochs. It shows how accuracy improves over the course of training.

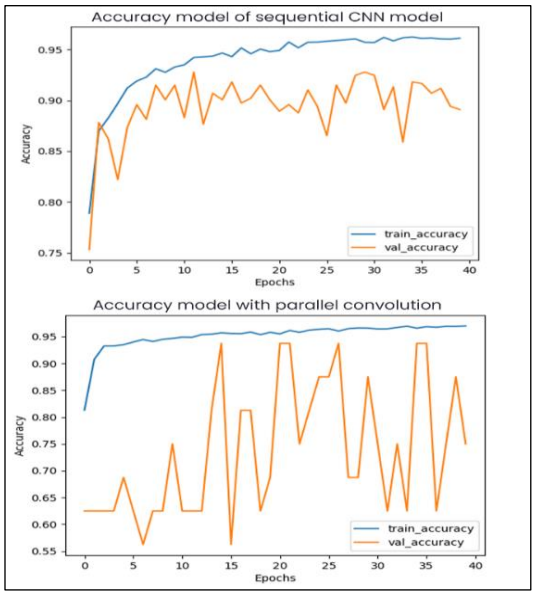

Figure 10: Evolution of model accuracy of sequential and convolution parallel CNN model.
Source: Authors, (2026).

VI.1 RESULTS OF EXECUTION FOR MODEL WITH PARALLEL CONVOLUTION AND TRAINING

The results obtained from 15 independent runs are summarised in Table 3, which presents descriptive statistics for training time and model accuracy.

Table 3: Performance statistics (time and accuracy) of training of the CNN model with parallelisation of convolution and training.

	Time(S)	Precision
Average	965,8547	0,9055 (90,54 %)
Standard deviation	4,5443	0,0101 (1,01 %)
Minimum	957,1146	0,892 (89,20 %)
Maximum	971,7502	0,9246 (92,46 %)

Source: Authors, (2026).

The total average training time observed is approximately 965.8547 seconds, or about 16.1 minutes, which corresponds to an average duration of 24 seconds per epoch. These results highlight the stability of execution time in a parallelized context. The table below presents the main statistics recorded during the various simulations. The accuracy of the parallelized CNN model was measured at the end of each training epoch. It was monitored throughout the process, revealing a gradual and steady improvement in performance. The final results demonstrate the stability and effectiveness of the parallelized version of the model, with an average accuracy of 90.54% and low dispersion between the different simulations. The following graph (Fig. 11) illustrates the evolution of training time and accuracy measured for each of the 15 simulations performed, in order to visualize the stability and performance of the parallelized model.

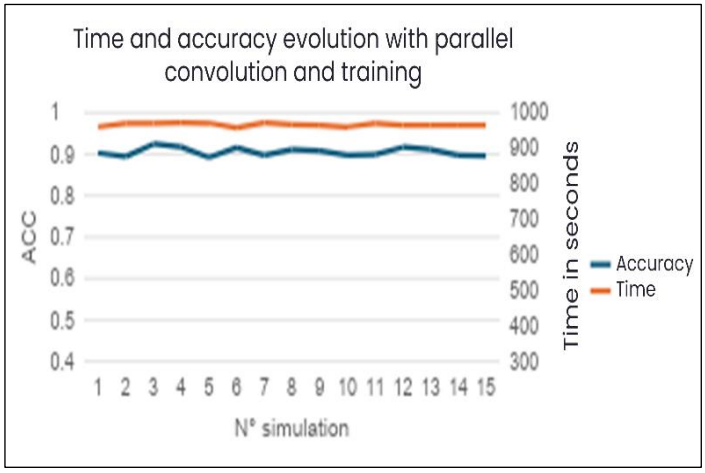

Figure 11: Evolution of time and accuracy with parallel convolution and training.
Source: Authors, (2026).

The following figure (Fig. 12) also shows the accuracy curve obtained during training of the parallelized CNN model, as displayed directly by the program. It reflects the gradual evolution of the model's performance over the course of 40 epochs.

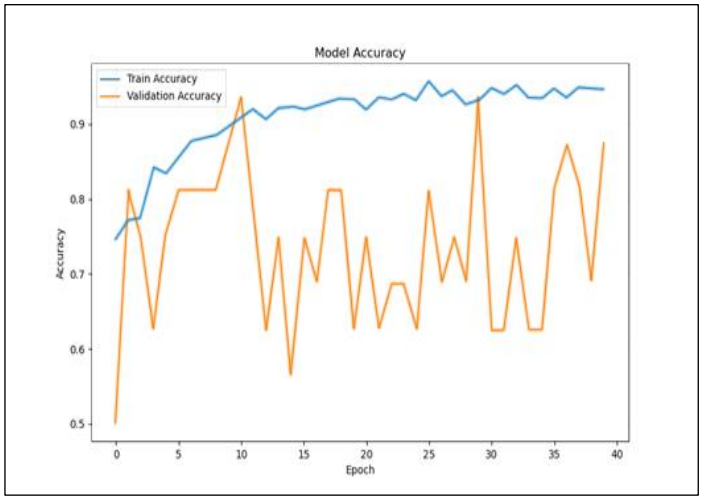

Figure 12: Evolution of model accuracy with parallel convolution and training.
Source: Authors, (2026).

VII. DISCUSSIONS

The table below summarises the average performance observed on the three versions of the CNN model tested: sequential execution, the version with parallelisation of the convolution layer only, and the version with parallelisation of both the convolution and the training process.

Table 4: Comparative results.

Model version	Parallelised convolution only	Parallelised Convolution and Training
Configuration	3 VMs (8 CPU, 16 Go RAM)	3 VMs (8 CPU, 16 Go RAM)
Average time	3023,6794	965,8547
Average accuracy	91,0800	90,5400

Source: Authors, (2026).

VII.1 COMPARISON OF EXECUTION TIMES

Analysis of training times reveals a significant reduction in average time when the model is parallelized at both the convolution and training levels. With an average time of 965.85 seconds, this version is approximately three times faster than the other two, which have durations of 2777.74 seconds (sequential) and 3023.68 seconds (convolution only). On the other hand, parallelizing only the convolution layer results in a slight increase in execution time, probably due to the overhead of communication and thread management in a distributed environment.

VII.2 COMPARISON OF ACCURACIES

In terms of accuracy, the three versions of the model achieve broadly comparable results, with a slight advantage for the version with parallelized convolution alone (91.08%), compared to 90.59% for the sequential version and 90.54% for the fully parallelized version. These differences remain small (less than 1%) and can be attributed to natural variations during training or effects related to parallelization, but no significant loss of performance is observed despite the significant reduction in time.

VIII. CONCLUSIONS

The work carried out is in the field of Deep Learning and distributed systems. We are particularly interested in the introduction of parallelism in medical image processing. Our project focuses on the application of parallelism techniques to improve efficiency and reduce costs in medical image processing. Our experiment consisted of testing three scenarios: parallelism in a distributed system for convolution only, parallelism in a distributed system for Convolution and Training, and sequential execution. It proved that it is possible to leverage the potential of deep learning even with limited machines. The higher the number of nodes, the lower the learning time can be. However, it is crucial to effectively manage synchronization and bottlenecks to avoid inefficiencies. Using libraries like mpi4py is key to handling these challenges. This study demonstrated that, despite hardware constraints, Deep Learning can be optimized for resource-constrained environments, paving the way for broader and more accessible applications in the medical field. To go even further, the use of Horovod, a parallelization library for Deep Learning, could offer better management of gradient communication and synchronization, reducing overhead and improving overall performance. In addition, the adoption of advanced models such as EfficientNet, which have demonstrated better performance in medical image processing, could also contribute to the improvement of these systems. The addition of a GUI interface would facilitate the use of this system by non-experts, thus making the technology more accessible. Finally, the integration of enhanced security measures is crucial to protect sensitive medical data and ensure the confidentiality and integrity of the processed information. The identified improvement prospects offer opportunities to continue improving the performance and efficiency of this system in the future.

ABSTRACT

Sustainable dry turning necessitates the reduction of energy intensity while maintaining production and quality. This research examines Inconel 625 under dry settings employing a Taguchi L9(3^3) design (speed S, feed f, depth d) and a framework that integrates specific energy consumption (SEC) with tool life estimation, surface roughness, and material removal rate (MRR). The cutting power is calculated using the measured main cutting force Fc and kinematics; only Fc was documented, which represents the primary factor in cutting power during turning. Tool wear was quantified for each edge and converted into the expected tool life T_{pred} at VB* = 221 µm. Grey Relational Analysis (Set A: SEC↓, Ra↓, T_{pred}↑, MRR↑) yields a scalar ranking, whereas a continuous Pareto frontier in the (MRR, SEC) plane is established by sampling quadratic response surfaces throughout a dense grid and validated by Non-dominated Sorting Genetic Algorithm (NSGA II/ε constraint). The knee point is determined via the Kneedle method, which identifies the maximum distance. Results indicate: (i) feed predominantly influences Ra and tool life stress, whereas depth is the primary factor for MRR and SEC; (ii) the optimal GRA (s=50 m/min, f=0.08 mm/rev, d=1.0 mm) is situated near, yet within, the frontier; (iii) the unconstrained knee at MRR≈4.75 cm³/min and SEC≈0.002613 kWh/cm³ presents a well-balanced compromise. The integrated Taguchi–GRA–Pareto/knee methodology produces practical, energy-conscious parameter configurations for sustainable dry machining of Inconel 625.

I. INTRODUCTION

Implementing sustainable methods that minimize resource consumption, save operating costs, and lessen environmental effect is becoming more and more important to the global industrial sector. Energy-efficient machining techniques are essential among the many facets of sustainable manufacturing, particularly in high-performance applications involving sophisticated materials. In particular, dry machining has become more popular because it can reduce operating costs and get rid of cutting fluids, which are frequently bad for the environment and human health [1], [2]. However, there are a lot of difficulties with the dry machining process, especially when dealing with materials like Inconel 625 that are hard to cut. Because of its exceptional mechanical strength, superior corrosion resistance, and capacity to maintain characteristics at high temperatures, this nickel-based superalloy finds extensive application in the aerospace, maritime, and chemical processing industries [3], [4]. Due to these same characteristics, it is notoriously difficult to machine, particularly in dry environments when the lack of cooling and lubrication can result in increased cutting pressures, poor surface smoothness, and rapid tool wear [5], [6]. In these situations, choosing the right cutting settings is essential to guaranteeing satisfactory machining results. Critical output measurements including cutting force, tool wear, surface roughness, and material removal rate (MRR) are greatly impacted by parameters like cutting speed, feed rate, and depth of cut, which must be carefully managed. Poor surface integrity, a shorter tool life, excessive energy consumption, and high production costs might result from improper parameter selection [7].

I.1 SUSTAINABLE DRY TURNING OF INCONEL 625

Sustainable Inconel 625 machining requires a careful balancing act between process efficiency and productivity. Cutting fluids play a major role in improving surface finish and tool life in traditional machining techniques. However, because of their disposal and mist production, cutting fluids pose serious health and environmental risks and make up a sizable amount of the overall cost of machining [8]. Therefore, if the difficulties can be successfully overcome, dry machining's removal of cutting fluids offers a feasible route to environmentally friendly production. Strategies for dry machining of alloys based on nickel have been studied recently. For example, a study [9] evaluated near-dry and dry turning of Inconel 718 and found that while dry cutting increased tool wear, improved settings helped reduce performance losses. The Taguchi method and Grey Relational Analysis (GRA) have been successfully combined to optimize several performance attributes at once in the context of sustainable dry turning of Inconel 625. This integrated approach, as noted in [10], makes it possible to determine the ideal cutting settings that strike a balance between efficiency and surface quality, supporting machining techniques that are ecologically friendly. Taguchi design and ANOVA can efficiently optimize machining parameters under various cooling conditions, as shown by Inconel 718 turning studies. This strategy supports sustainable production by lowering emissions, energy consumption, and tool wear while enhancing surface quality, as mentioned in [11].

I.2 MULTI-OBJECTIVE FRAMEWORK AND EXPERIMENTAL DESIGN

In order to investigate three controllable factors—cutting speed S (m/min), feed per revolution f (mm/rev), and depth of cut d (mm)—at three levels, dry turning experiments were set up using a Taguchi L9(3^3) orthogonal array. The 3^3 full factorial (27 trials) is reduced to nine statistically balanced runs using the L9 design, which maintains orthogonality for objective main-effects estimation. Signal-to-noise ratios and main-effects graphs were used to analyze factor effects. Following testing, the various responses were normalized using Grey Relational Analysis (GRA) and combined into a single Grey Relational Grade (GRG) for parameter setting ranking; this Taguchi–GRA workflow is well-established in machining optimization [12–17]. The trade-off structure, however, can be concealed by any scalar ranking: settings with comparable GRG may inhabit quite distinct areas of the efficiency frontier. We fit quadratic response surfaces for MRR and SEC, sample a dense grid to create a smooth Pareto front in the (MRR, SEC) plane, and use the maximum-distance (Kneedle) rule to choose the knee point—the best-balanced compromise—in order to make the trade-offs clear. The frontier is validated using NSGA-II and an ε-constraint formulation to ensure robustness; MOGA offers a classical evolutionary substitute [18–24]. Pareto/knee + MOEA validation for explicit trade-off selection combined with Taguchi–GRA for ranking and factor understanding results in both interpretability and decision-readiness.

I.3 RESEARCH MOTIVATION AND OBJECTIVES

Motivation: Sustainable machining of Inconel 625 in dry conditions is both strategically significant and technically difficult. Removing cutting fluids lowers costs and environmental impact, but it also increases mechanical and thermal loads, accelerates tool wear, increases cutting forces, and jeopardizes surface integrity. Energy intensity (SEC), surface quality (Ra), tool life (T_{pred} at VB* = 221 μm), and productivity (MRR) must all be addressed as combined objectives in optimization in order for it to be practical and provide useful parameter settings rather than just rankings. Manufacturers looking for energy-conscious advice to balance MRR, Ra, and T_{pred} in dry turning Inconel 625 without using cutting fluids are the ones driving this requirement. There is a gap in previous research, though, as Taguchi–GRA or multi-objective evolutionary algorithms (MOEAs) are frequently used in isolation. Few studies choose a knee point with algorithmic validation (e.g., NSGA-II/ε-constraint), prioritize SEC as a primary objective, or map an explicit MRR–SEC Pareto front. By offering a knee-based proposal that converts the Pareto frontier into a single, defendable operational point for shop-floor decision-making, our study seeks to close this gap.

The objectives are as follows: (i) Use a Taguchi L9(3^3) design to dry turn Inconel 625 and quantify the effects of cutting speed (S), feed rate (f), and depth of cut (d) on specific energy consumption (SEC), surface roughness (Ra), estimated tool life (T_{pred} at VB* = 221 μm), and material removal rate (MRR). (ii) Determine the cutting power and SEC using the kinematics and measured tangential force (Fc) to support the $P \approx Fc \cdot vc$ estimate for turning mechanical power. (iii) Use Set A (SEC↓, Ra↓, T_{pred}↑, and MRR↑) and Grey Relational Analysis (GRA) to determine high-performing parameter values and get a scalar ranking. (iv) Create a smooth MRR–SEC Pareto front, sample a dense grid, and fit quadratic response surfaces for MRR and SEC. (v) Use the Kneedle (maximum-distance) rule to identify the knee point and use the NSGA-II and ε-constraint procedures to validate the frontier. (vi) To determine when scalar ranking deviates from Pareto optimality, compare the GRA-best settings with the knee-point settings, offering energy-conscious, practical suggestions. (vii) Assign contributions of S, F, and D using Analysis of Variance (ANOVA) and Signal-to-Noise (S/N) ratios, connecting feed to Ra and wear rate/tool life and depth to MRR and SEC.

II. EXPERIMENTAL DESIGN

Figure 1 illustrates the experimental apparatus employed in this study, which comprises: (i) cutting insert, (ii) tool holder, (iii) three-component dynamometer for measuring F_c, Ff, and F_r, (iv) signal chain consisting of an analog-to-digital converter and data-acquisition card connected to a PC, (v) tool-wear inspection station (optical projector/microscope) for flank wear VB evaluation, and (vi) surface-roughness instrument with a contact probe, sensor, and analyzer for Ra measurement. Cutting power is determined from F_c and cutting speed vc (see Section 2.3.1); SEC is obtained from energy and removed volume (refer to Section 2.3).

II.1 WORK MATERIAL, MACHINE, TOOLING, AND METROLOGY

Using a Pico Turn V-Turn 410 CNC lathe, round bars of Inconel 625 (Ø62 mm × 180 mm; Deutsche Nickel GmbH, EN 10204-3.1) with the composition listed in Table 1 were dry-turned. Every experiment was conducted on an all-geared CNC lathe (Pico Turn V-Turn 410) without coolant. The cutting inserts were CNMG 120408NN, coated with PVD TiN/TiCN, fixed in an ISCAR PCLNR 2525 12A tool holder, on which a Kistler Type 5070A three-component dynamometer was mounted (Figure 2). Every run began with a new cutting edge. A Talysurf (Taylor Hobson) was used to quantify the surface roughness Ra (Figure 3). A TOOL MASTER 10 device (three-axis positioning) was used to monitor tool wear (Figure 4). Before measuring, the insert was cleaned of tiny particles using alcohol after each cut.

II.2 DESIGN OF EXPERIMENT (DOE)

II.2.1 Design and responses:

In order to assess SEC, Ra, T_{pred} (at VB* = 221 μm), and MRR, dry turning was investigated using a Taguchi L9(3^3) array on three factors: cutting speed S, feed F, and depth of cut D, each at three levels. The 3^3 full factorial (27 trials) is compressed into nine orthogonal runs for unbiased main-effects estimations using the L9 design. Workpiece size, holder, overhang, and tool grade/geometry were all kept consistent during the dry tests. One replication was utilized for each treatment; runs were randomized; main-effects plots and S/N ratios were used to summarize factor effects; a confirmation run and pooled-error ANOVA (Section 4.1) were used.

II.2.2 Level Selection and Instrumentation:

Machine power and stiffness restrictions, tool-manufacturer recommendations for PVD-coated carbide while machining Inconel 625, and brief pilot cuts that confirmed stable dry turning without chatter or early edge failure were used to create parameter ranges. Every experiment was conducted using the same cutting length. A tri-axial dynamometer linked to a data-acquisition (DAQ) device was used to measure cutting forces. The three distinct levels for each factor were finalized through these pilot tests since generic models are unable to accurately relate input parameters, in-process signals, and output responses across all metal-cutting operations. Table 2 provides a summary of the resulting Taguchi L9(3^3) design and shows the experimental matrix for cutting speed S (m/min), feed ratte F (mm/rev), and depth of cut D (mm) in both coded (levels 1–3) and natural units. There was a random run order. [25], [26].

II.3 MEASUREMENTS AND DERIVED QUANTITIES

Surface Roughness Ra was measured with a contact profilometer. A three-component lathe dynamometer was used to measure cutting forces in each trial. Cutting power was estimated using turning kinematics and the tangential force component, F_c. In particular, the cutting energy was derived from $E = P \cdot t$, where t is the net cutting time, and the cutting power was estimated as $P \approx F_c V_c$, where V_c is the cutting speed. The material removal rate (MRR) and cutting time, $V = \text{MRR} \cdot t$, were used to calculate the removed material volume. For longitudinal turning, MRR was calculated using geometric and kinematic relations. The key energy-intensity statistic, specific energy consumption (SEC), was initially defined as the ratio of cutting energy to removed material volume, or "SEC" $= E/V$. Following each run, tool wear was measured in terms of average flank wear, or VB. The expected tool life, "T_{pred},," was calculated by extrapolating the measured wear to the selected flank-wear criterion “VB*=221" µm under the same cutting length because individual tool-life tests were not performed for every parameter combination. The complete formulations of MRR, energy, and SEC are provided in Section (2.3.1–2.3.3), along with the physical foundation for force decomposition and the rationale for use the tangential force in power calculation.

II.3 1 Force Measurement and Cutting Power Modeling

The tangential (F_c), feed (F_f), and radial (F_r) force components were measured by a three-component lathe dynamometer. The tangential component alone was used to calculate the cutting (chip-formation) power:

$$P_{\text{cut}} = F_c \cdot V_c \tag{1}$$

V_c is the cutting speed. $P = F \cdot V = F_c \cdot V_c + F_f \cdot V_f + F_r \cdot V_r$ is the mechanical power in turning. $F_r \cdot V_r = 0$ and F_f, V_f is insignificant in comparison to $Fc \cdot V_c$ since the radial velocity is practically zero ($Vr \approx 0$) and the feed velocity $V_f \ll V_c$. Therefore, the tangential force–speed product is used in industrial practice and machining textbooks to formulate spindle/cutting power [27-29]. Metric units:

$$P_{\text{cut}}\,[\text{kW}] = F_c\,[\text{N}] \cdot V_c\,[\text{m/min}] / 60 \tag{2}$$

II.3.2 Kinernatics and Material removal rate (MRR)

Cutting speed is

$$V_c = \pi \cdot D \cdot N / 1000\ [\text{m/min}] \tag{3}$$

The volumetric removal rate for longitudinal turning is

$$MRR = V_c \cdot f \cdot d\ \ [\text{cm}^3/\text{min}] \tag{4}$$

Equivalently MRR = π D ·N ·f d in mm^3/min [30].

II.3.3 Energy nd Specific Energy Consumption (SEC)

The cutting energy and removed volume for a net cutting time t (h) are

$$E = P_{\text{cut}} \cdot t\ [\text{kWh}] \tag{5}$$

$$V = MRR \cdot 60\ t\ [\text{cm}^3] \tag{6}$$

because the precise amount of energy used is

$$SEC = E/V = P_{cut} / (60\ MRR)\ [kWh/cm^3] \quad (7)$$

The basic energy-intensity indicator used in sustainability evaluations to compare machining conditions is called SEC [31] [32].

II.3.4 Tool-Life Modeling and Wear (explanation of the VB criterion)

Following each run, tool wear was calculated using average flank wear VB. The expected tool life $T_{"pred"}$ was calculated by extrapolating the measured wear to the adopted flank-wear criterion "VB*=221 μm" for the same cutting length because a complete tool-life test was not conducted for each condition.

II.3.4.1 The Measurement

Run-to-failure life tests were not conducted by us. We employed a fresh cutting edge for every L9 condition and, following a single, steady-state pass, measured the flank-wear width (VB) on the primary cutting edge. Instead of measuring life directly, these single-pass wear snapshots were then used to anticipate the time (tool life) until a predetermined end-of-life criterion VB*.

II.3.4.2 Wear Criterion Selection VB equals 221 μm.*

Common machining standards and international practice for single-point tool-life testing (ISO 3685) use flank-wear thresholds in the 0.20–0.30 mm range as the end-of-life criterion for turning; lower values are usually used for finishing to preserve surface integrity and dimensional accuracy. We set VB* = 0.221 mm (221 μm), within the ISO-consistent finishing band [33] [34], in accordance with this recommendation and the finishing emphasis in dry turning of Ni-based superalloys.

II.3.4.3 Predicted Tool Life from Single-Pass Wear

Tool wear usually occurs in three stages: initial/running-in, steady, and accelerated. A near-linear law provides a good local approximation of tool wear during a brief, stable segment [35-37]. The anticipated time to reach VB* is obtained using the local wear rate $\dot{V}B \approx VBi/t_i$ with measured VB_i after a duration t_i:

$$T_{pred} = (VB^* / VB_i) \cdot t_i. \quad (8)$$

II.3.4.4 Convention for Reporting

The term "tool life" in the results refers to the estimated time to attain VB* = 221 μm using Eq. (8); it is not a run-to-failure observation. SEC is used as a volume-normalized measure of energy intensity in both Pareto and knee-point analyses, where its explicit trade-off with MRR defines energy-aware operating compromises, and Grey Relational Analysis, where it is minimized along with surface roughness while productivity and tool life are maximized.

III. A FRAMEWORK FOR PROCESS OPTIMIZATION WITH MULTIPLE OBJECTIVES

Inconel 625 dry turning involves conflicting goals, such as maximizing material removal rate and tool life while decreasing specific energy consumption and surface roughness. A two-stage multi-objective optimization framework is used to handle these trade-offs. In order to rank discrete parameter combinations, various replies are first normalized using Grey Relational Analysis (GRA) in accordance with the Taguchi L9 design. These responses are then combined into a single Grey Relational Grade (GRG). Although it offers an effective screening and ranking system, the Taguchi-GRA method does not clearly reveal trade-off relationships between competing goals. Thus, the explicit trade-off frontier between material removal rate and specific energy consumption is constructed and analyzed using Pareto-based optimization with the Non-dominated Sorting Genetic Algorithm II (NSGA-II) and the ε-constraint approach. In this context, NSGA-II offers a continuous, dominance-based view of the solution space while GRA offers a scalar decision measure for discrete experimental settings. Together, these features allow for both informed compromise selection and comparison ranking. The Pareto-based optimization utilizing NSGA-II and the ε-constraint formulation is presented in Section 3.2, while Section 3.1 describes the Grey Relational Analysis process used for multi-response normalization and ranking.

III.1 GREY RELATIONAL ANALYSIS (GRA)

The Taguchi L9 testing findings were multi-response optimized using Grey Relational Analysis (GRA). First, each response's desired characteristic was used to normalize it to the interval [0,1]: For surface roughness (Ra) and specific energy consumption (SEC), lower is preferable [31];

$$R_a^* = \frac{maxR_a - R_a}{maxR_a - minR_a'} \quad (9)$$

$$SEC' = \frac{maxSEC - SEC}{maxSEC - minSEC'} \quad (10)$$

And for material removal rate (MRR) and projected tool life ($T_{"pred"}$), the larger the better,

$$Tpred^* = \frac{Tpred - minTpred}{maxTpred - minTpred'} \quad (11)$$

$$MRR^* = \frac{MRR - minMRR}{maxMRR - minMRR'} \quad (12)$$

Next, grey relational coefficients were calculated as

$$\xi_i(k) = \frac{\Delta_{\min} + \zeta\Delta_{\max}}{\Delta_i(k) + \zeta\Delta_{\max}}, \quad (13)$$

Using ζ=0.5 as the differentiating coefficient. The unweighted mean of the coefficients was used to calculate the Grey Relational Grade (GRG), a scalar metric for rating distinct cutting-parameter combinations. To prevent subjective bias and to guarantee a neutral aggregation of energy, quality, tool-life, and productivity objectives at the screening step, equal weights were given to each response in the GRG computation.

$$\mathrm{GRG}_i = \frac{1}{m}\sum_{k=1}^{m} \xi_i(k), \quad (14)$$

III.2 PARETO-BASED MULTI-OBJECTIVE OPTIMIZATION AND KNEE-POINT IDENTIFICATION

The Non-dominated Sorting Genetic Algorithm II (NSGA-II) was used in a Pareto-based multi-objective optimization process to explicitly describe the trade-off between specific energy consumption (SEC) and material removal rate (MRR) [18]. If a solution $x^{(1)}$ is strictly better in at least one objective and not worse in any of the others, it is said to dominate another solution $x^{(2)}$. To produce a well-distributed approximation of the Pareto front, NSGA-II uses crowding-distance assignment and rapid non-dominated sorting. The goals of this study were to maximize MRR and minimize SEC. A further ε-constraint formulation was used for validation, where SEC was minimized subject to a minimum productivity requirement, "MRR"≥ ε [23–24]. In order to extract the non-dominated set, quadratic response-surface models for SEC and MRR were fitted as functions of cutting speed, feed, and depth of cut and sampled on a dense grid. Additionally, a direct dominance screening was performed on the experimental L9 runs.

IV. RESULTS AND DISCUSSIONS

In addition to the derived responses—predicted tool life ($T_{\_"pred"}$), material removal rate (MRR), and specific energy consumption (SEC)—Table 4 presents the experimental results from the Taguchi L9 trials, including the measured tangential cutting force (F_c), flank wear (VB), and surface roughness (R_a). These findings serve as the foundation for the analyses that follow. To quantify factor effects, the individual answers in Table 4 are first analyzed using signal-to-noise ratios and analysis of variance (ANOVA) Section 4.1. The same dataset is then used for Pareto-based trade-off analysis and knee-point detection between MRR and SEC Section 4.3, as well as multi-response aggregation using Grey Relational Analysis Section 4.2.

Source: Authors, (2026).

Due to differences in cutting speed and feed rate, the actual cutting length each wear snapshot varies even though the axial turning length is the same in all L9 trials. As a result, worn photos don't match a set cutting length.

IV.1 ANOVA OF FACTOR EFFECTS

A response-specific interpretation of factor importance and statistical significance is given by the ANOVA data compiled in Table 5. The depth of cut has the largest percentage contribution to specific energy consumption (SEC) and is statistically significant ($p < 0.05$), suggesting that material engagement is the primary determinant of energy intensity. According to its kinematic role in surface creation, feed rate is the primary and statistically significant factor ($p < 0.05$) for surface roughness (Ra). Feed rate and cutting speed have the biggest effects on expected tool life (T_{pred}) and are both statistically significant ($p < 0.05$), indicating their combined impact on wear rate and thermal loading.

The L9 design's zero error variance prevented formal significance testing, although the depth of cut and feed rate are the most important parameters for material removal rate (MRR), indicating their geometric control over volumetric output. The multi-response ranking in Section 4.2 and the energy–productivity trade-off analysis in Section 4.3 are supported by these response-specific trends (Minitab® Statistical Software, 2018).

Table 5: Summary of ANOVA factor contributions and significance across responses.

Response	Dominant factor (% contrib.)	Second factor (% contrib.)	Third factor (% contrib.)	Statistically significant factors (p < 0.05)
Ra (S/N, STB)	F (83.47%)	D (10.81%)	S (4.46%)	F
T_{pred} (S/N, LTB)	F (53.06%)	S (35.79%)	D (10.44%)	S, F
MRR (S/N, LTB)	D (54.69%)	F (31.09%)	S (14.22%)	*—
SEC (S/N, STB)	d (71.02%)	F (25.73%)	S (2.02%)	F, D

Source: Authors, (2026).

Note: Statistically significant factors are identified at the 95% confidence level (p < 0.05). For the material removal rate (MRR), the error sum of squares is zero due to the unreplicated L9 orthogonal array; therefore, F- and p-values are not reported and factor importance is inferred from percentage contribution. ANOVA computations were performed using Minitab® Statistical Software (Version 18).

IV.2 GREY RELATIONAL ANALYSIS

The Taguchi main-effects plots of the Grey Relational Grade (GRG) under equal weighting, derived from the GRA results in Table 6, are displayed in Figure 5. The ideal factor levels for the combined response set are indicated by the greatest mean GRG at S_1 (50 m/min), F_1 (0.04 mm/rev), and D_3 (1.0 mm). These patterns align with the ANOVA results in Section 4.1 (Table 5), which show that depth of cut is the main factor influencing productivity and energy intensity while feed rate is dominating for surface roughness and tool-life response. Thus, in the discrete L9 design space, the Taguchi–GRA optimum is the best overall compromise and is used as a reference for the continuous Pareto-front analysis shown in Section 4.3.

Table 6: Grey Relational Analysis; with ζ = 0.5.

Run	S	F	D	SEC	Ra	T_{pred}_(h)	MRR	GRC_SEC	GRC_Ra	GRC_T_{pred}	GRC_MRR	GRG	Rank

IV.3 PARETO-FRONT CONSTRUCTION AND KNEE-POINT DETECTION

While GRA provides a single ranking for discrete Taguchi settings, it does not directly depict the trade-off between competing goals. To visualize and analyze the energy–productivity compromise, Section 4.3 builds a smooth MRR–SEC Pareto front.

IV.3.1 Pareto Efficiency Analysis (MRR–SEC)

A smooth, unconstrained Pareto front built in the (MRR, SEC) plane, where productivity is maximized and energy intensity is minimized, is contrasted with the empirical Pareto set derived from the L9 tests in Figure 6. Two non-dominated solutions (Runs 3 and 9) are found from the discrete Taguchi trials, demonstrating the limited resolution of trade-off analysis when only experimental points are taken into account. Quadratic ridge response-surface models for MRR and SEC were fitted as variables of cutting speed, feed, and depth of cut in order to investigate the continuous design space. A smooth Pareto front was then generated by sampling on a dense parameter grid. The resulting frontier shows a monotonic trend, as shown in Fig. 6, indicating that increases in the rate of material removal are followed with higher specific energy consumption. Beyond the discrete L9, this smooth representation permits future knee-point identification and decision-oriented optimization.

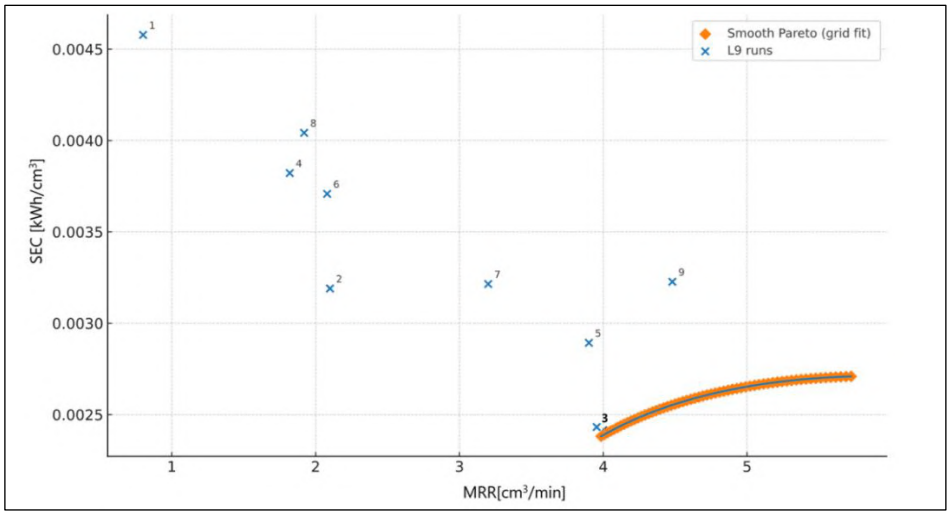

Figure 6: Smooth (unconstrained) Pareto front versus empirical L9.
Source: Authors, (2026).

In order to highlight surface quality and endurance, we also looked at a limited front using the illustrative parameters Ra < 1.5 µm and T_{pred} > 0.012 h. When tougher quality or life targets are applied, constraints quantify the productivity penalty by shifting the frontier higher or left (lower MRR for the same SEC).

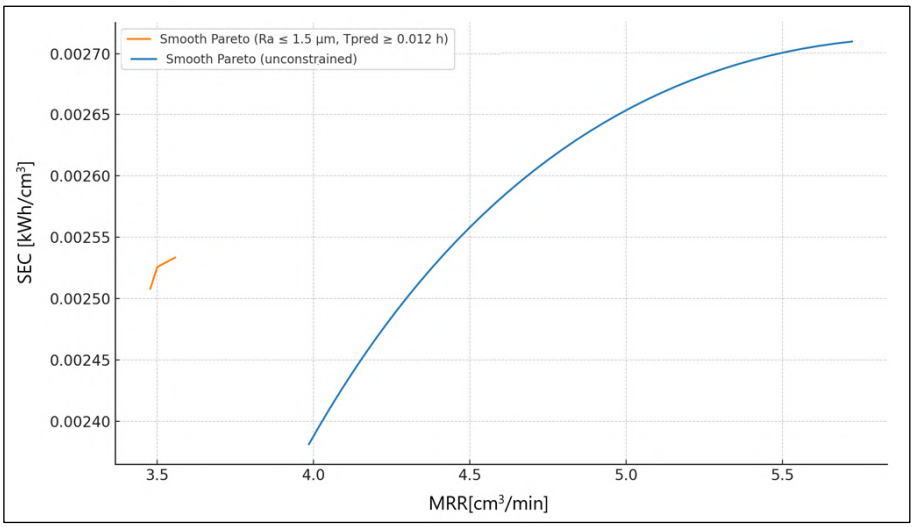

Figure 7: Constraint-free and constrained smooth Pareto front (Ra ≤ 1.5 µm; T_{pred} ≥ 0.012 h).
Source: Authors, (2026).

IV.3.2 Knee-Point Selection on Unconstrained and Constrained Pareto Fronts

The maximal-distance positions from the chord joining each front's terminals are known as knee points. Figure 8: Unconstrained smooth Pareto front with knee point (maximal-distance criterion) in the (MRR, SEC) plane. The confined front under Ra < 1.5 µm and T_{pred} > 0.012 h is depicted in Figure 9. A nearly balanced trade-off between productivity (MRR) and energy intensity (SEC) is offered by the knee.

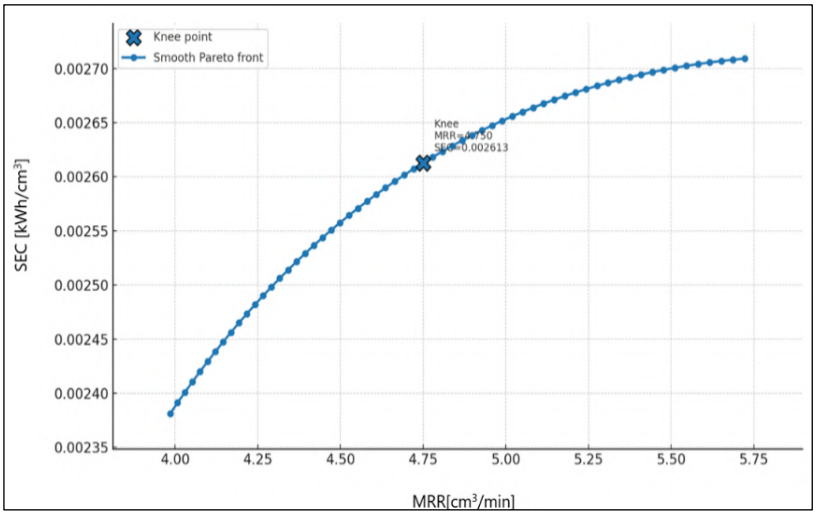

Figure 8: Unconstrained smooth Pareto front with knee point (maximal-distance criteria) in the (MRR, SEC) plane.
Source: Authors, (2026).

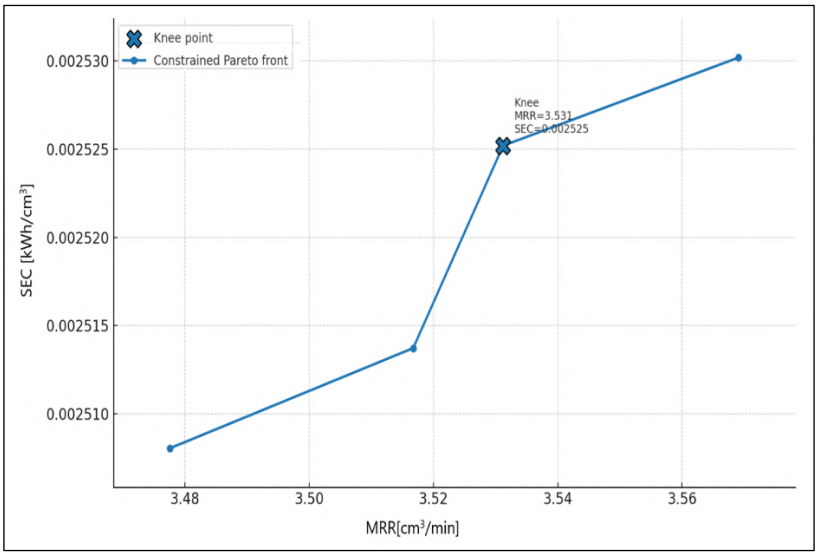

Figure 9: Pareto front with knee constraint (Ra ≤ 1.5 µm, T_{pred} ≥ 0.012 h).
Source: Authors, (2026).

The confined knee increases energy intensity by ΔSEC=0.000059 kWh/cm³ (2.3%) but decreases productivity by ΔMRR=1.860 cm³/min (39.2%) in comparison to the unconstrained knee (MRR=4.750 cm³/min, SEC=0.002613 kWh/cm³). The associated parameters change to S=50 m/min, f=0.051 mm/rev, d=0.99 mm from S=65 m/min, f=0.080 mm/rev, D=1.00 mm. The knee occurs close to S≈65 m/min, f≈0.08 mm/rev, and d≈1.0 mm for the unconstrained front. The knee moves toward lower MRR and somewhat higher SEC under quality/life limitations (e.g., Ra < 1.2 µm and T_{pred} > 0.015 h), indicating the productivity penalty of more stringent criteria (see Figures 8-9). Figure 9: Constrained smooth Pareto front (Ra ≤ 1.2 µm, T_{pred} > 0.015 h) constructed similarly to Figure 8; knee point determined using the same rule to show a balanced operating point under life and quality limitations.

IV.3.3.GRA vs. Pareto knee

The knee point indicates a balanced operating condition in the MRR–SEC trade-off space, while the GRA-selected solution, as seen in Fig. 10, is near the rebuilt Pareto frontier. Run 3 (S = 50 m/min, F = 0.08 mm/rev, D = 1.0 mm) is ranked as the best of the discrete L9 tests by the Taguchi–GRA technique (Set A, equal weights). It achieves a low specific energy consumption (SEC = 0.002415 kWh/cm³) at a moderate material removal rate (MRR = 4.00 cm³/min). This solution does not fall within the region of greatest trade-off sensitivity, despite being close to Pareto-optimal. The Pareto knee is a compromise point when any productivity gains would result in a disproportionately greater energy cost. It is located at MRR = 4.75 cm³/min and SEC ≈ 0.002613 kWh/cm³. This comparison shows that Pareto knee analysis offers supplementary, decision-oriented insight by locating a balanced operating point along the continuous energy–productivity trade-off, whereas GRA is useful for ranking discrete parameter values.

V. CONCLUSIONS AND FUTURE WORK

- To improve dry turning of Inconel 625 in terms of specific energy consumption (SEC), material removal rate (MRR), surface roughness (Ra), and anticipated tool life (Tpred), an integrated Taguchi–GRA–Pareto/knee framework was created.
- ANOVA showed response-specific factor dominance: depth of cut is the dominant factor for both MRR and SEC, whereas feed rate mostly regulates surface roughness and tool-wear rate.
- The GRA-best solution was discovered to be inside the non-dominated region rather than on the Pareto front, despite the fact that Grey Relational Analysis (GRA) offered a scalar ranking of discrete cutting conditions.
- The robustness of the trade-off structure was confirmed by multi-objective optimization employing NSGA-II and ε-constraint, which consistently found the same MRR–SEC Pareto frontier [20–23].
- The results show that GRA and Pareto-based optimization are complementary, with knee-point selection offering actionable, energy-aware decision support beyond scalar rankings [21].
- Knee-point detection on the Pareto front produced a balanced operating condition that offers a justifiable compromise between productivity and energy efficiency.
- Expand the framework to incorporate environmental and economic factors (CO2 emissions, tool cost).
- To improve statistical inference, include replicated experiments. • Use the technique for machining operations and other nickel-based superalloys.

ABSTRACT

Algeria is classified as a semi-arid to arid zone due to the importance of evapotranspiration compared to precipitation. This study presents a summary of experimental results on an unsaturated soil in the Biskra region classified as an arid zone. The behavior of soils in these regions is somewhat unique and evolving. The soils in the Biskra region are distinguished by their geomorphological position and origin, as well as their water regime. They share particular characteristics such as unstable structure often in honeycomb shape, heterogeneity, large porosities, and good surface aeration. It should be noted that the rise of groundwater has continued to shape the urban landscape of the Biskra Valley. The mode of accumulation of soil deposits seems to be mainly responsible for the formation of an open and metastable structure, which is susceptible to collapse. The objective of understanding the effect of lineaments is to be able to better characterize the structure of the soil in this region. The study's primary goal is to locate regions in Biskra region that are prone to soil collapse by combining Remote Sensing and geographical information system (GIS) methods. To create thematic maps such as geology, geomorphology, lineament and lineament density, drainage, drainage density, and slope maps, the researchers employed FCC Image of Landsat TM 30 m resolution data and topographic maps. Several geomorphic units were identified through this process.

I. INTRODUCTION

Most soils in arid and semi-arid regions are macroporous with an open and loose structure, existing in the form of metastable deposits. These soils are classified as special problem soils [1]. When dry, clay cementation between the grains provides them with significant intergranular bonding and they can support very heavy loads, exceeding 200 kPa. However, floods and inundations, even without additional loading, induce the breakdown of these bonds, leading to a denser structure followed by a sudden collapse of the soil. The collapse mechanism in partly saturated soil involves the breakdown of intergranular bonds upon wetting [2].

Collapses of macroporous soils are distributed practically all over the earth and are found, essentially, in countries with a dry climate. Several types of collapsible soils have been identified based on their genesis and geological setting [3]. A sudden collapse of the soil can cause other ground movements such as landslides, shearing, planar or rotational sliding, and debris flows. The phenomenon of water transfer in soils in arid zones and its impact on their degradation is a current topic, especially with the trend of investments towards arid and semi-arid areas. The behavior of water in unsaturated soils is complex and requires specific investigation [4].

Experts use geographic information systems (GIS) to organize and examine geographic data by storing it in databases. This technology allows professionals like geographers and engineers to retrieve data from any location on the planet, including those that may be difficult to access through traditional methods. Digital elevation models (DEM) offer a three-dimensional depiction of the earth's surface and are a straightforward method for visualizing the topography of a specific area of study. The methodology followed in this work includes the processing, interpreting of the Landsat 8 satellite images.

II. BISKRA REGION

II.1 GEOGRAPHICAL LOCATION AND TOPOGRAPHY OF

The Biskra region covers an area of 21,671.2 km² and is situated in northeastern Algeria, sharing borders with the Batna, M'sila, Khenchla, El Oued, and Djelfa region. The region is located at 34°48' North and 05°44' East. The region is considered a transition zone in terms of morphology and bioclimatology, with high and rugged terrain in the north and plateaus and plains in the south. The region can be divided into four main zones, including a mountainous zone in the north with the highest peak being Djebel Takyiout, a plateau zone extending from north to south, a plain zone along the Eloutaya-Sidi Okba-Zeribet El Oued and Doucen axis, and a depression zone in the southeastern part of the region. The region's topography and climate have a significant impact on its development and economy, with agriculture mainly concentrated in the plains and plateaus and forestry and livestock farming more suitable for the mountainous and hilly terrain in the north. Figure 1, 2.

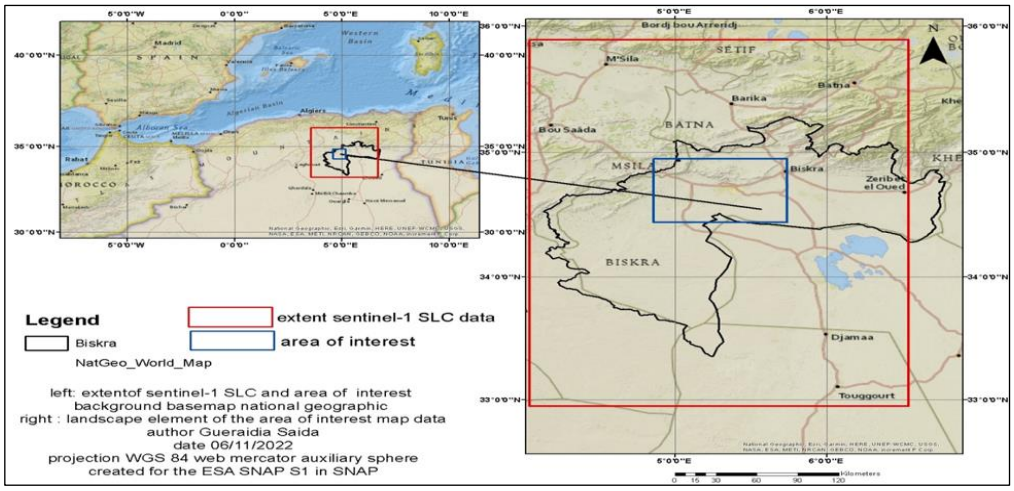

Figure 1: Geographical location of the study area.
Source: Authors, (2026).

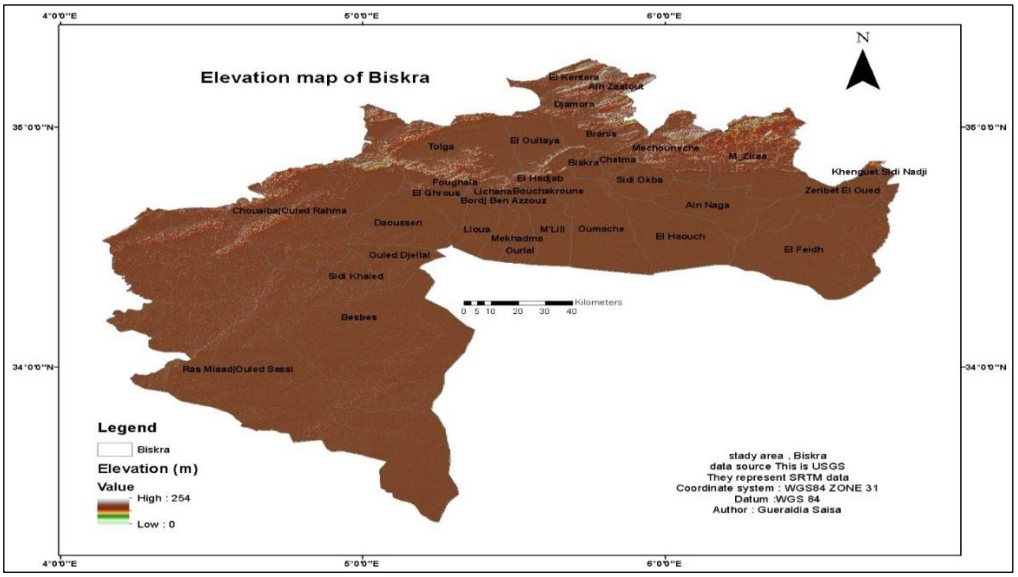

Figure 2: Elevation map of study area.
Source: Authors, (2026).

II.2 GEOLOGY OF BISKRA REGION

The geological aspect of the Biskra region is defined by sedimentary rocks that span from the Barremian period at the bottom to the Quaternary period at the top, as depicted in Figure 3. These rocks are composed of alluvial deposits of sand and clay, along with tertiary sandstone and sandy clay, as well as limestone formations. The limestone formations have fractures and folds that are oriented in a North-South and Northeast-Southwest direction [5].

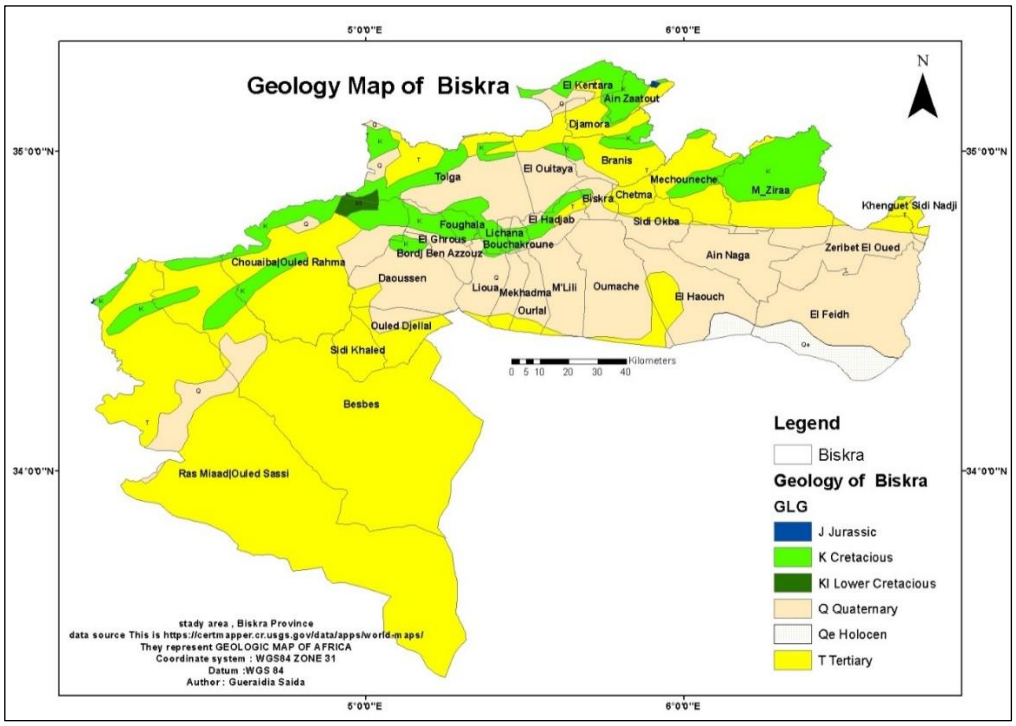

Figure 3: Geology map of Biskra region.
Source: Authors, (2026).

II.3 SOILS OF BISKRA REGION

Soil is a fundamental component of the natural environment that is interconnected with structure, vegetation, climate, and human activities. The quality of soil plays a critical role in both agricultural development and the risk of soil collapse in a region. The soil classification follows international standards [6]. Figure 4.

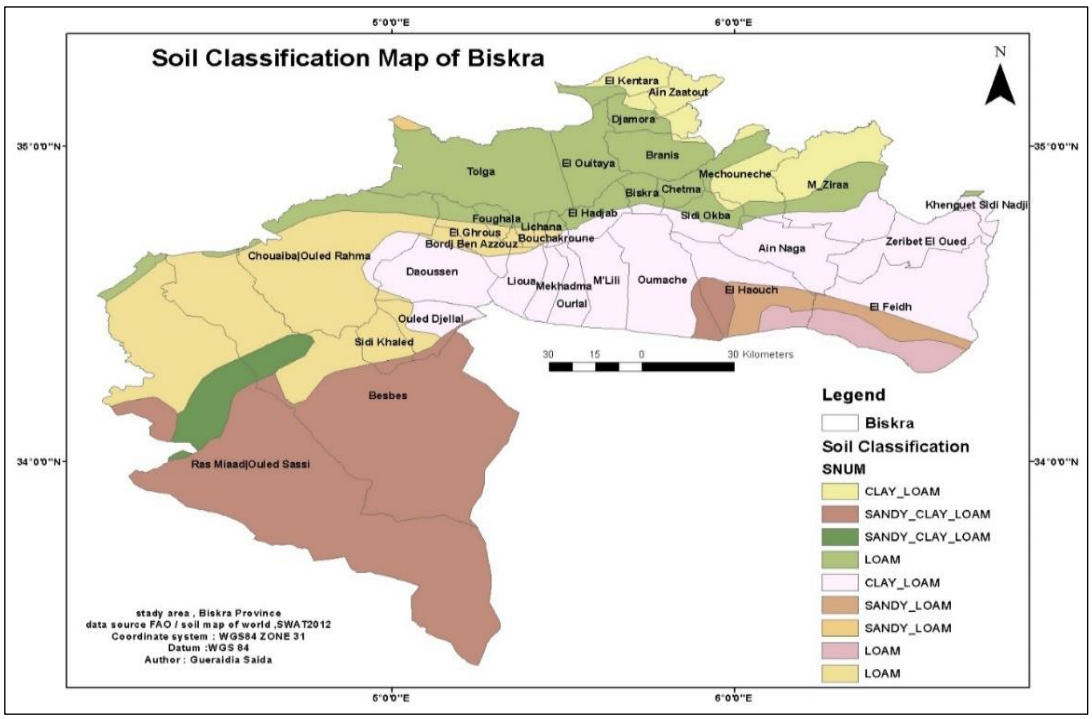

Figure 4: Soil classification Map of Study area.
Source: Authors, (2026).

II.4 HYDROGRAPHY AND WATER RESOURCES

The Biskra region contains several wadis that form a basic hydrographic system, which is only active during winter or periods of heavy rainfall. These wadis are part of the broader Saharan watershed of Chott Melghir. Figure 5. Wadi Djeddi is the primary wadi in the Biskra region and covers a drainage area of 9130 km^2. It serves as a runoff water collector for a significant portion of the southern slopes of the Saharan Atlas. Wadi El Arab is situated in the eastern section of the region and originates from the mountains in the eastern part of the Aurès. It flows into the depression zone of Chott Melghir. Wadi El Abiod is located in the central part of the region and hosts the Foum El Gherza dam. Wadi Biskra passes through the El Outaya plain and contains numerous streams that collect runoff water from the southwest Aurès Mountains.

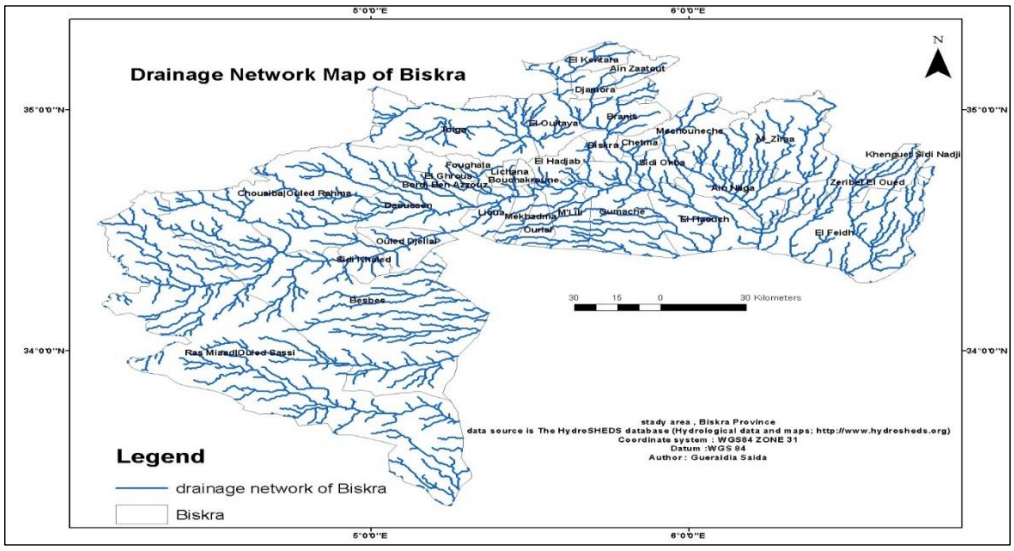

Figure 5: Hydrographic network of Biskra region.
Source: Authors, (2026).

II.5 CLIMATOLOGICAL CONTEXT

The recharge of aquifers in the Biskra region is greatly impacted by climatic conditions, with precipitation being the key factor that drives it. However, the region experiences irregularities in both inter-annual and intra-annual rainfall patterns, with an average annual rainfall of approximately 118.75 mm over a 71-year period (1960-2021). The year 2014 had a peak of around 297 mm. Other climatic conditions, such as evapotranspiration and temperature, also have a significant influence on the various aspects of precipitation. Groundwater management in arid regions requires sustainable approaches to balance supply and demand [7]. Over a period of 30 years (1991-2021), the Biskra region indicated a thermal pattern with high temperatures in summer and relatively lower temperatures in winter, with the hottest months being July and August with a maximum temperature of 29.1°C and January being the coldest month with an average temperature of 8.7°C. Precipitation mapping in eastern Algeria shows high spatial and temporal variability [8]. Figure 6 and 7.

III. DATA AND METHODS

III.1 FIELD AND LABORATORY INVESTIGATIONS

An investigation was conducted to evaluate the collapse potential of soils through various laboratory and field methods. The study focused on the index properties and hydro-collapsibility characteristics of loess deposits located in the southern region of Algeria. In order to perform laboratory tests, undisturbed soil samples were obtained from 6- to 7-meter-deep pits using a core drilling deep sampler device. These samples were trimmed and waxed carefully into 70mm diameter cylinders of 440mm length.

III.2 DATA USED

The research methodology used in the study is presented in Figure 2, which involved creating a digital elevation model (DEM) of the study area using ArcGIS software version 10.8 and data obtained from a field survey listed in Table 1. The DEM was generated through spatial interpolation using Inverse Distance Weighted (IDW) method, which depends on the distance between known and unknown points, resulting in a DEM with a precision of less than ten meters. Remote sensing and GIS have been widely used for environmental assessment in fractured terrains [9]. Figure 3 shows the final DEM for the study area, generated through the field survey method, which is considered more accurate than free DEMs from satellites based on previous studies. Landsat 8 satellite data can be used for land surface temperature mapping and terrain analysis [10]. Digital elevation models can be enhanced using radar interferometry techniques [11]. This method allowed the researchers to perform necessary analyses and accurately depict the terrain of the study area.

IV. RESULTS AND DISCUSSIONS

IV.1 RESULTS AND DISCUSSIONS

The identification of physical characteristics and bearing capacity tests of the tested soil led to the results presented in Table 1. The soil classification followed the French GTR guidelines [12].

Table 1. Physical and mechanical characteristics of the investigated soil.

Désignation	Cc	Cu	GS	W_0	WL%	WP%	IP%	γdmax (g/cm3)	wopt %	%<2 µm	VBS	CaCO3
Value	5.88	10.55	2.59	11.12	26.63	15.37	11.37	1.95	9.43	11.73	2.65	12.23

Source: Authors, (2026).

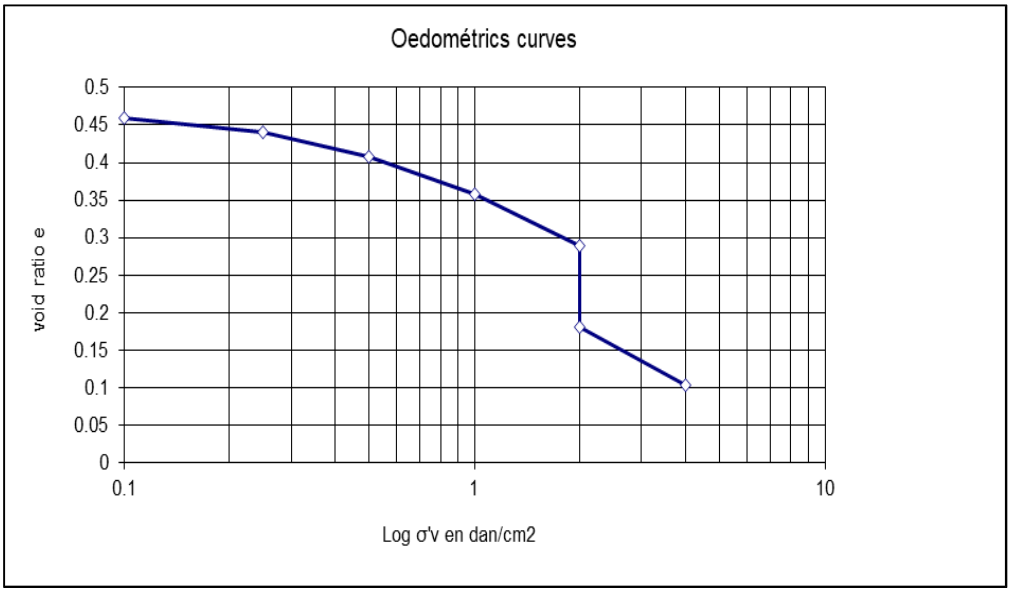

Figure 10: Oedométric curve.
Source: Authors, (2026).

Similar experimental approaches for predicting soil collapse were proposed by Laouar [13]. Loessic soils exhibit specific mechanical behavior under cyclic loading [14] The compressibility test, according to the procedure described by Jennings and Knight [15], indicates that the soils in question have collapse potentials: Cp soil 1 = 7.65%. This value exceeds typical thresholds for collapsible soils. Therefore, collapse is likely.

IV.2 TOPOGRAPHIC CONTOUR MAP LINES

Topographic contour lines are a common method used to depict the surface of a landscape, which not only conveys its geometry but also implicitly preserves the topology of the earth's surface. To illustrate the height of the contour lines, elevation values are often given as text descriptions on topographic maps. Besides contour lines, spot altitudes are available, represented by dots or crosses, to indicate significant natural features in a prominent region, such as hilltops, knolls, isolated summits, mountaintops, mountain passes, saddles, and other high points. Due to the mountainous terrain of the small watershed, the watershed contour map displayed in Figure 11 has contour lines ranging from 0 to 1800 meters. The watershed's water divisions are mostly mountainous.

IV.3 ASPECTS MAP

The significance of aspect and elevation maps in understanding the microclimate and vegetation distribution of a mountainous area. The aspect map helps in identifying vegetation types and their distribution while the elevation map indicates the effect of sunlight on the area's microclimate. The DEM display map illustrates the direction of the slope, and in the case of the Biskra watershed, the east-facing slopes have more vegetation and moisture than the west-facing slopes.

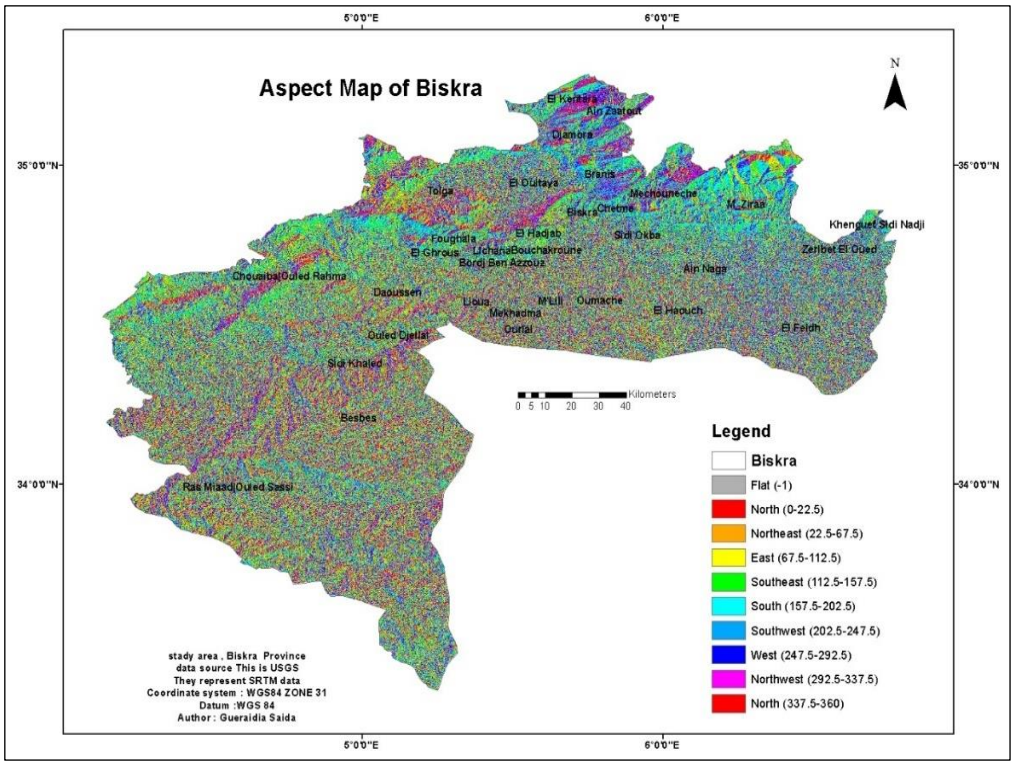

Figure 12: aspect map of study area.

IV.4 SLOPE MAP

To generate a slope map of the study area, the digital elevation model was converted from its original unit in degrees to units of length. The slope of the map, displayed in Figure 13, was measured in degrees using ArcGIS software 10.8. The map shows that the low slope is 0 degrees, and the high slope is 3.16 degrees, with the average slope of the study area being about 3.61 degrees.

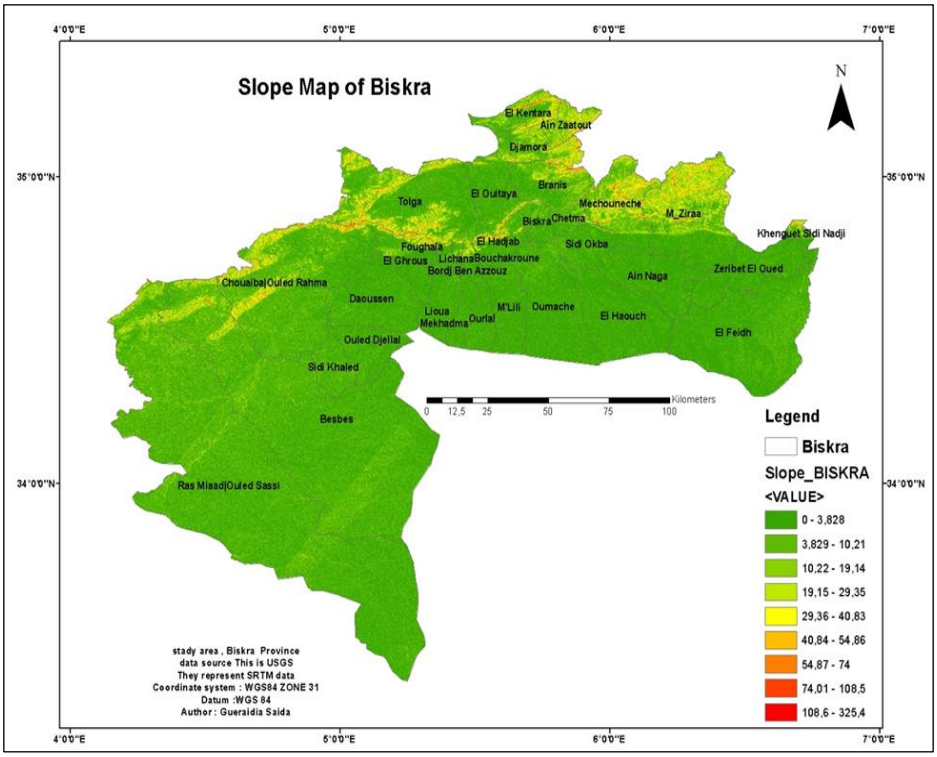

Figure 13: slope map of study area.

IV.5 LINEAMENTS MAP

A lineament is a substantial and elongated feature that can be observed in satellite images based on the topographic characteristics and straight tonal alignments of the underlying structure. Lineaments can be identified by visually interpreting Landsat image data and are often considered promising areas for soil collapse. Lineament extraction from satellite images has been successfully applied in various geological settings [16]. They are commonly found in regions with soil collapse hazards, with the most prevalent orientations in the study area being towards NNE-SSW, NE-SW, NW-SE, and NS directions. Regional fault mapping helps understand hydrodynamics in fractured basement zones [17]. Figure 14.

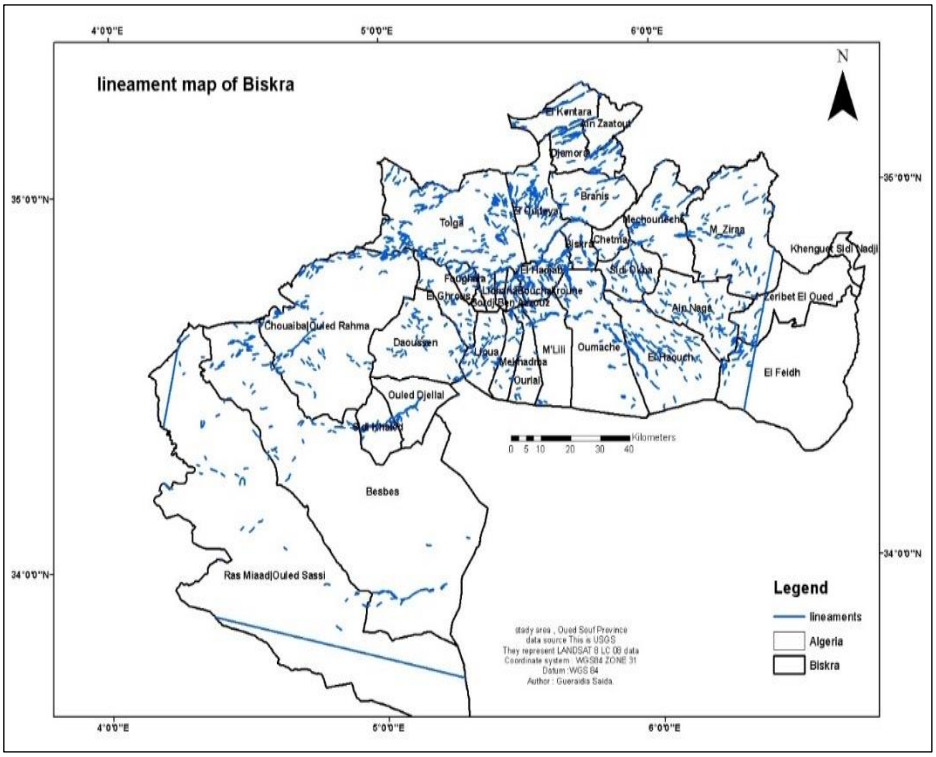

Figure 14: lineaments map of study area.
Source: Authors, (2026).

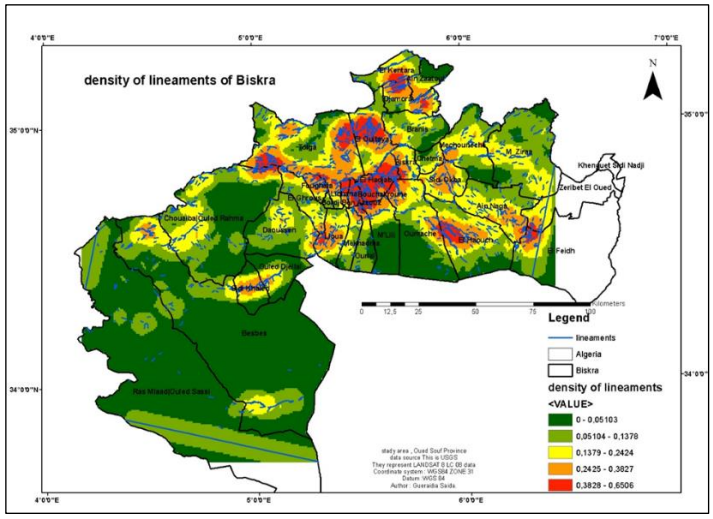

Figure 15: lineaments density map of Biskra.
Source: Authors, (2026).

Figure 15 shows the lineament density map of the study basin, created by utilizing GIS (Geographic Information System) techniques on the lineament map obtained from Landsat 8 satellite images. The area was divided into equal grids, and the number of lineaments in each grid was counted and recorded to calculate the frequency of lineaments per unit area. The lineament density analysis aims to identify areas with high lineament density. The map illustrates that the study basin has three areas with a high lineament density (0.65 km/mesh), which are located in the central, south-west, and north-east parts. This high density indicates tectonic movements that have influenced the geological formations over time. Most of the study area also shows a high lineament density, as depicted in the map.

V. CONCLUSIONS

This experimental research, conducted in the Biskra region, has provided a comprehensive understanding of soil behavior, especially concerning collapsible loamy clay. The obtained results constitute an important database for geotechnical investigation and rheological behavior modeling. The characteristics of compressibility and consistency confirm that the soil is collapsible. The integration of remote sensing and geotechnical data provides a comprehensive approach for collapse risk assessment [18]. The satellite images were used to map the majority of the lineaments found in Biskra province, and the fractures in the area were analyzed to determine the prevailing orientations. Statistical analysis revealed that the lineaments were mainly oriented in the NE-SW, NW-SE, E-W, and N-S directions. The NW-SE direction, which is most prominent in the northern sector, corresponds to the primary direction of the drainage network. The intensity of fracturing was studied, and it was discovered that the northern, central, and southern regions of the study area had high levels of fractures.

Masked Face Recognition

ABSTRACT

Emergence of masked face recognition (MFR) as a pivotal area in biometric identification has been significantly accelerated by the global COVID-19 pandemic. In response, the research community has developed a variety of innovative techniques to address recognition and detection under occlusion, with a growing emphasis on Generative Adversarial Networks (GANs) for masked face restoration and inpainting. We examined three interconnected sub-domains: Masked Face Recognition (MFR), Face Mask Detection, and Face Unmasking (FU), each addressing unique aspects of the problem from identifying individuals with partially or fully covered faces to reconstructing occluded facial regions for improved accuracy. The core focus of this paper is on the role of GANs in overcoming occlusion by synthesizing realistic facial textures in the masked regions, thereby restoring the identity cues. Beyond technical developments, the paper analyzes the limitations and open research problems, such as maintaining identity consistency in restored images, handling diverse mask types and occlusion levels, and ensuring generalizability across different demographic groups and environments. By integrating insights from recent advances and identifying existing research gaps, this survey aims to serve as a comprehensive reference for academics and practitioners engaged in the development of robust, privacy-aware, and ethically responsible masked face recognition systems enhanced by GANs.

I. INTRODUCTION

Facial Recognition (FR) technology has become indispensable across key sectors, powering everything from airport security and border control to healthcare patient verification and con- tactless fever screening in hospitals. In security, it enables real-time criminal identification, surveillance, and access control, etc., with over 99.00% accuracy in ideal conditions [1]. Whereas in healthcare, it streamlines anonymous triage and reduces infection risks during pandemics [2]. However, the global COVID-19 outbreak and the widespread use of face masks have significantly disrupted these systems. Facial recognition has rapidly evolved over the past decade, becoming essential in numerous domains such as surveillance, biometric authentication, and smart access systems. How- ever, the global outbreak of COVID-19 and the consequent widespread adoption of face masks have introduced new and unforeseen challenges to these systems [2]. The presence of face masks significantly occludes critical facial features, particularly the nose and mouth, thereby impairing the performance of conventional face recognition models. To address these challenges, the field of Masked Face Recognition (MFR) has gained substantial attention. MFR encompasses various sub-problems, including Face Mask Detection (FMD), which identifies whether a face is masked, and Face Unmasking (FU), which attempts to reconstruct the occluded regions. The particular interest is the use of Generative Adversarial Networks (GANs) for masked face inpainting - a process that aims to restore missing facial regions by synthesizing realistic and identity-consistent features [3].

Masked Face Recognition presents significant challenges due to occlusion of key identity features caused by face masks, a problem magnified during the COVID-19 pandemic [2]. The recognition process typically begins with an input image of a masked face, which undergoes face detection, preprocessing, and segmentation to isolate and align the facial region. This is followed by feature extraction using deep learning models such as CNNs or transformers, which generate identity-relevant embedding from the visible portions of the face. A dedicated mask detection module then identifies the presence and area of occlusion by segmenting the masked regions [4]. Pacheco et al. [5] [6] examined the development of face recognition methods and classifies adversarial attacks, such as white-box, black-box, and poisoning attacks, according to the attacker's knowledge, goals, and attack phases. Numerous cutting-edge attack techniques, including DeepFool, FGSM, and ZOO, are examined along with their usefulness in actual situations like authentication and surveillance. Trivedi & Goyani presented novel architecture and detailed survey on masked face recognition using deep learning [7] [8]. Authors also prepared a custom dataset to address the challenges of masked face recognition [9], [10]. To overcome the information loss due to occlusion, face unmasking and restoration techniques are applied using Generative Adversarial Networks (GANs), which inpaint the masked regions to synthesize a complete face image while preserving identity features [3]. Despite substantial progress in Masked Face Recognition (MFR),

Face Mask Detection (FMD), and GAN-based face restoration, several fundamental challenges remain unresolved, limiting robustness, generalization, and real-world deployment. One of the most critical challenges is the significant loss of discriminative facial information caused by masks, particularly in the nose and mouth regions. Multiple studies have shown that conventional face recognition systems trained on unoccluded faces suffer dramatic performance drops when masks are introduced, with accuracy reductions of up to 50% in operational scenarios [11–13]. This highlights the inherent limitation of standard feature embeddings when large facial regions are occluded. Many MFR systems are trained on synthetically generated masked datasets, which often fail to capture the diversity of real-world masks in terms of shape, texture, material, and wearing styles. Domain shifts between simulated and real masks lead to degraded recognition performance, as demonstrated by domain adaptation studies [14]. Real masks introduce more severe embedding distortions than synthetic ones, making generalization a persistent challenge [12]. GAN-based face inpainting methods can visually reconstruct occluded facial regions; however, high visual fidelity does not necessarily guarantee identity preservation. Several works report strong Peak Signal to Noise Ratio (PSNR) or Structural Similarity Index Measure (SSIM) values but lack consistent improvements in recognition accuracy [15].

Advanced architectures—such as transformer-based and diffusion-based restoration models—offer superior perceptual quality and structural consistency but incur high computational overhead and inference latency, making them unsuitable for real-time or edge deployments [16] [17]. Conversely, lightweight GAN and CNN-based approaches trade accuracy for speed, creating a persistent accuracy–efficiency trade-off [18] [19]. RGB-based recognition systems are highly sensitive to low illumination, weather conditions, and long-distance surveillance, resulting in poor performance under challenging environments [20]. While thermal and depth modalities offer complementary information, integrating these modalities remains difficult due to cross-spectral discrepancies and the lack of large-scale aligned datasets. GAN-based thermal-to-visible translation improves cross-spectral matching but introduces additional complexity and potential identity distortion. GAN-based masked face restoration techniques have enabled several impactful applications across various sectors. In the field of security and surveillance, restored facial features can significantly improve the identification of masked individuals captured by CCTV or body cameras in public spaces [21-27]. For access control systems, such as those used in airports, smart offices, and public transport, face restoration enhances authentication accuracy in the presence of occlusion. This survey focuses on the state-of-the-art in masked face restoration using GANs, with an emphasis on the three interlinked tasks: masked face recognition, mask detection, and face inpainting. The key objectives are:

- To review deep learning-based approaches, particularly GAN variants, designed for reconstructing masked facial regions.
- To highlight the major challenges, such as identity preservation, generalization across mask types, and real-time processing constraints.
- To provide insights into ethical considerations and potential future directions for responsible deployment of face unmasking technologies.

The remainder of the paper is structured as follows: The remainder of the paper is structured as follows: Section 2 provides a comprehensive literature survey on Masked Face Recognition (MFR), Face Mask Detection (FMD), Face Restoration and Inpainting using GANs. We also summarized the datasets for masked face inpainting/recognition task in this section. Section 3 explains the ways to measure success, including how well GAN models recognize and detect faces, the metrics for restoring masked faces, and the overall methods for evaluating GAN Section 4 concludes the study by summarizing findings and future directions.

II. THEORETICAL REFERENCE

The task of recognizing faces with occlusions, particularly masks, has led to an evolving body of research focused on masked face recognition, mask detection, and face restoration. With the proliferation of face mask usage due to COVID-19, conventional face recognition algorithms experienced significant performance degradation, which inspired the development of new approaches incorporating deep learning and generative models.

II.1 MASKED FACE RECOGNITION (MFR)

Masked face recognition has become an important research topic due to the widespread use of face masks, which significantly affects the performance of traditional face recognition systems. Several studies have investigated the impact of masks and proposed solutions to improve recognition accuracy under occluded conditions. Early approaches to masked face recognition involved adapting conventional face recognition models by retraining them on masked datasets.

Wang et al. [13] introduced a dataset containing images of people wearing masks and demonstrated that even state-of-the-art models such as ArcFace suffered performance losses when exposed to such occlusions. Subsequent studies focused on designing occlusion-aware face recognition architectures or training models using masked face augmentation. Damer et al. [11] conducted one of the earliest studies analyzing the effect of wearing face masks on face recognition performance. Their experimental results showed a considerable drop in recognition accuracy across both commercial and academic systems. In an extended evaluation, Damer et al. [12] further examined the influence of real and simulated masks on face embedding, reporting performance degradation using TAR@FAR metrics. These studies highlighted the limitations of conventional face recognition models in masked scenarios. To address occlusion challenges, Song et al. [28] proposed an occlusion-robust face recognition method based on mask learning with a pairwise differential Siamese network. The model learns to suppress masked facial regions while preserving discriminative features. Biswas et al. [29] introduced a perceptual hashing-based approach for verification and identity classification of occluded faces. Their method avoids deep learning architectures and instead relies on compact hash representations, achieving an accuracy of about 94.2% on occluded face datasets. MF-CosFace, a margin-based loss function specifically de- signed for masked face recognition was proposed by Deng et al. [30].

By improving feature discrimination in the embedding space, their approach achieved a Rank-1 recognition accuracy of approximately 98.1% on standard face datasets containing masked samples. Hariri [31] focused on computational efficiency and proposed a lightweight masked face recognition framework using MobileNet-based architectures. The proposed method achieved around 95% accuracy while maintaining low computational complexity, making it suitable for real-time applications. Patel et al. [24] proposed a multi-task deep learning framework that jointly performs mask detection and face recognition using a shared backbone network. Sheneamer et al. [32] introduced a hybrid human recognition framework combining deep learning feature extraction with traditional machine learning classifiers. The proposed system achieved an accuracy of about 96.3% under masked face conditions. GAN-based masked face recognition model using a dual-scale adaptive efficient attention network was presented by Alzubi et al. [25]. By enhancing discriminative facial features through attention mechanisms, their approach achieved a high recognition accuracy of approximately 99.2%. An alternative strategy to masked face recognition is face reconstruction. Liu et al. (2025) [3] proposed a GAN-based masked face image inpainting method that reconstructs occluded facial regions using an encoder-decoder architecture.

Although the method was evaluated using image quality metrics such as PSNR (28.6 dB) and SSIM (0.91), it demonstrates the potential of reconstruction-based approaches to support masked face recognition. Customized activation function based on principle of spatio-temporal convolution was presented by Adeli et al. [33]. Results shows the classification superiority of the pro- posed AbsoluteNet model on the auditory system. Recent hybrid deep-transfer learning advances include Sheneamer et al. (2024) [32], who analyzed hybrid CNN transfer learning with machine learning for robust masked face detection/recognition, achieving 97-100% F1-scores on real/simulated datasets. Similarly, Adeli et al.'s AbsoluteNet [33], a deep CNN for hemodynamic classification, has been adapted for spatio-temporal MFR feature extraction from occluded signals, enhancing single-trial accuracy. Pillay et al.'s [34], introduced, hybrid CNN-based approach using MobileNetV2 and FaceNet improves face mask detection and masked facial recognition accuracy, addressing COVID-19 challenges and real-time security needs. A comparison of Various state-of-the-art literature on Masked Face Recognition is presented in Table 1

Table 1: Comparison of state-of-the art work on Masked Face Recognition.

Literature	Approach	Backbone Network	Detection Technique	Dataset Used	Accuracy / PSNR / SSIM
Liu et al. (2025) [3]	GAN-based masked face image inpainting	Encoder–Decoder CNN	Adversarial image reconstruction	CelebA, synthetic masked faces	PSNR: 28.6 dB SSIM: 0.91
Alzubi et al. (2025) [25]	Dual-scale adaptive attention GAN	EfficientNet-based CNN	GAN-assisted masked face recognition	RMFD, LFW	Accuracy: 99.2%
Adeli et al. (2025) [33]	AbsoluteNet	Custom deep neural net- work	Hemodynamic response classification	fNIRS auditory datasets	Accuracy: 92.5%
Sheng et al. (2025) [21]	Self-segmentation guided diffusion model	U-Net (Diffusion back bone)	Thermal-to-visible image translation	KAIST Multi-spectral Dataset	PSNR: 26.4 dB SSIM: 0.89
Wang et al. (2024) [22]	Adversarial Defense Teacher (ADT)	ResNet + FPN	Cross-domain object detection	Cityscapes, Foggy Cityscapes	mAP reported (Accuracy N/A)
Sheneamer et al. (2024) [32]	Hybrid ML–DL recognition framework	CNN + SVM	Masked face recognition	RMFD, LFW	Accuracy: 96.3%
Yadav et al. (2023) [20]	TVA-GAN	Attention-guided GAN	Thermal-to-visible transformation	TUFTS, ARL Multimodal	PSNR: 27.1 dB SSIM: 0.90

Source: Authors, (2026).

Overall, existing research shows that masked face recognition can be improved through occlusion-aware learning, margin-based loss functions, hybrid frameworks, and generative models. However, challenges remain in achieving a balance between recognition accuracy, computational efficiency, and robustness in real-world masked face scenarios.

II.2 FACE MASK DETECTION (FMD)

Face mask detection gained significant importance during the COVID-19 pandemic as an automated way to monitor public safety and ensure compliance with health guidelines. Unlike traditional face recognition, face mask detection focuses on identifying whether a person is wearing a mask correctly, in- correctly, or not wearing one at all. This section reviews the major research contributions related exclusively to face mask detection, highlighting their proposed methods, working mechanisms, and reported performance. Cabani et al. [35] introduced MaskedFace-Net, a large-scale dataset developed to support face mask detection research. The dataset contains images of correctly masked, in- correctly masked, and unmasked faces generated using image augmentation techniques. The dataset enables robust training of deep learning models under diverse conditions. Experiments conducted using convolutional neural networks achieved detection accuracy greater than 95%, making MaskedFace-Net a widely used benchmark dataset. Loey et al. [4] proposed the Face Mask Detection dataset along with a deep learning-based detection framework. The proposed system applies transfer learning using pre-trained CNN models such as ResNet and AlexNet to classify face images into masked and unmasked categories. The operational pipeline includes face detection followed by mask classification. The proposed approach achieved detection accuracy of up to 99% on controlled datasets. Fan and Jiang [36] proposed RetinaFace Mask, a single-stage deep learning model for face mask detection during the COVID-19 pandemic. Their method uses RetinaFace to accurately lo- cate faces and classify whether a mask is worn or not. The lightweight design allows fast and real-time detection, making it suitable for public surveillance systems. Dhanushkodi et al. [37] presented a comprehensive survey on face mask detection and social distancing using deep learning. The paper compares multiple CNN-based methods and highlights the importance of combining detection accuracy with computational efficiency for pandemic control applications. AIZOOTech [38] developed an open-source face mask detection framework using deep learning. The system first detects faces and then determines mask usage, making it easy to deploy in real-world environments such as offices, hospitals, and public places. Loey et al. [39] proposed a YOLO- v2 with ResNet-50 based deep learning model for medical face mask detection. YOLO-v2 performs fast object detection, while ResNet-50 improves feature extraction, resulting in high detection accuracy even in crowded scenes. Su et al. [40] introduced a deep transfer learning approach for face mask detection. Pretrained CNN models were fine-tuned on mask datasets, allowing the system to accurately classify masked and unmasked faces even with limited training data. The World Health Organization [41] provided official public health guide- lines emphasizing the importance of face masks and social distancing. These guidelines support the motivation behind automated mask detection systems. A vision-based social distancing and crowd density detection system was proposed by Yang et al. [42]. The model uses computer vision techniques to estimate interpersonal distance and identify high-risk crowd situations.

Madane and Dnyanoba [43] developed a computer vision-based social distancing detection framework that detects people and measures distances between them to identify violations in public spaces. Ahmed et al. [44] proposed a deep learning-based social distance monitoring system that combines person detection with distance estimation to ensure compliance with COVID-19 safety norms. Suryadi et al. [45] compared multiple social distancing violation detection models with GPU support. Their work highlights the importance of hardware acceleration for real-time applications. Rezaei and Azarmi [46] introduced DeepSocial, a system that monitors social distancing and estimates infection risk using deep neural networks and spatial analysis. Punn et al. [47] proposed a system using YOLOv3 and DeepSORT for person detection and tracking. The method enables continuous monitoring of social distancing violations in dynamic environments. Ge et al. [48] presented LLE-CNNs for detecting masked faces in unconstrained environments. Their approach improves robustness against occlusion, making it effective for masked face scenarios. Wang et al. [49] introduced the RMFRD dataset, which contains a large number of masked and unmasked face images. This dataset has become a benchmark for training and evaluating masked face recognition systems. A real-time face mask detection system using YOLOv3 was proposed by Jiang et al. [50]. The model achieves fast detection speed and high accuracy, making it suitable for surveil- lance applications. Eyiokur et al. [51] designed a computer vision-based COVID-19 prevention system that integrates face detection and mask recognition to reduce virus transmission. Wang et al. [52] proposed a hybrid transfer learning and broad learning system for mask detection. The method improves classification accuracy by combining deep feature extraction with efficient learning strategies. Issaoui et al. [53] proposed a face mask detection approach based on a Weighted Soft Discernibility Matrix integrated with deep learning. The method improves classification by assigning importance weights to dis- criminative features. The proposed system achieved detection accuracy close to 97%, showing improved robustness against variations in mask appearance. Shao et al. [54] proposed a lightweight face mask detection algorithm incorporating an attention mechanism to enhance feature extraction. The system focuses on key facial regions while reducing model complexity. Experimental evaluation showed detection accuracy of approximately 95% with significantly lower computational overhead. Pillay et al. [55] developed an integrated face mask detection system as part of a real-world deployment study. The proposed pipeline includes face detection followed by mask classification and system-level validation. The model achieved detection accuracy of 96.8% and demonstrated reliable performance in real-time environments. Building on hybrids, the UC treatment response classifier by Ahmadi et al. [56] uses random forests with biomarker identification (e.g., key facial features) for occluded face classification, repurposed for FMD with 96%+ AUC on diverse masks. The challenges of super- vised face recognition were addressed by Mohammadagha et al. [57] in their novel work. The proposed method shows the macro ROC-AUC as high as 0.983, which is quite impressive. State-of-the-art methods on face mask detection are compared in Table 2.

Table 2: Comparison of state-of-the-art work on Face Mask Detection.

Author(s)	Model/Approach	Backbone Network	Detection Technique	Dataset Used	Accuracy (%)
Issaoui and Selmi (2025) [53]	Weighted soft discernibility with DL	CNN	Hybrid DL + decision matrix	Smart city surveillance data	Accuracy: 96.4%
Pillay et al. (2025) [55]	Hybrid CNN for FMD and MFR	Hybrid CNN	Joint mask detection and recognition	RMFD, MaskedFace-Net	Accuracy: 98.2%
Su et al (2022) [40]	Deep transfer learning for FMD	MobileNet, ResNet	Binary classification	MaskedFace-Net, RMFD	Accuracy: 99.1%

Punn et al.(2021) [47]	YOLOv3 + DeepSort framework	YOLOv3	Person and mask detection with tracking	Custom surveillance dataset	Accuracy : 95%
Mohammad- agha et al. (2021) [57]	Hybrid deep transfer learning with ML classifiers	VGG16, ResNet50	Feature extraction + ML classification	Custom face dataset	Accuracy: 98.1%
Jiang et al.(2021) [50]	Real-time face mask detection	YOLOv3	Single-stage object detection	Custom face mask dataset	Accuracy: 95.6%, FPS: 45
Ahmed et al.(2021) [44]	Deep learning SD monitoring framework	YOLOv3	Distance-based violation Detection	Custom CCTV dataset	Accuracy: 95.2%
Yang et al.(2021) [42]	Vision-based SD and crowd density system	CNN-based detector	Critical density estimation	Urban surveillance videos	Accuracy: 92%
Loey et al.(2021) [39]	YOLOv2 + ResNet50 FMD model	ResNet50	Single-stage object detection	Custom mask dataset	mAP: 81% Accuracy: 97%
Fan and Jiang (2021) [36]	RetinaFace Mask detector	RetinaFace	Single-stage face mask detection	MaskedFace-Net	mAP: 83.2%
Suryadi et al.(2020) [45]	Comparative SD violation detectors	YOLOv3, SSD, Faster R-CNN	GPU-accelerated object detection	Public pedestrian datasets	Accuracy: 95 %

Source: Authors, (2026).

Improved YOLOv5-based mask wearing detection system as proposed by Gao et al. [58]. The method combines the YOLOv5 object detector with an enhanced ResNet backbone to better capture mask characteristics under diverse lighting and posture variations. The system computes bounding boxes for faces and classifies mask wearing status in a single shot, enabling efficient inference. Experiments demonstrated detection accuracy exceeding 98% and mean average precision (mAP) of 97.5%, confirming its robustness under complex backgrounds and various populations. Wei et al. [59] introduced a robust mask detection framework using YOLOv8 integrated with context-aware convolutions. Yu et al. [60] proposed a face detection and standardized mask-wearing recognition algorithm that combines traditional face detection with a structured mask analysis stage. The method first detects faces using CNN-based detectors and then applies classification rules to evaluate whether the mask is worn properly according to predefined geometrical criteria. Benifa et al. [61] presented FMDNet, a lightweight model optimized for efficient mask detection. FMDNet uses a compact backbone network with depthwise separable convolutions to reduce computation while maintaining performance. The operational flow includes preprocessing, feature extraction through lightweight layers, and final mask classification.

II.3 FACE RESTORATION AND INPAINTING USING GAN

Generative Adversarial Networks (GANs) have proven especially effective in restoring occluded parts of the face. GAN-based inpainting approaches can reconstruct realistic facial regions from partially visible images while preserving identity traits. Jinal & Mahesh [62] presented a novel approach for masked face image inpainting using GAN. Yug Li et al. [26] explored the use of conditional GANs to restore masked facial regions, facilitating downstream recognition tasks. Several studies proposed identity-preserving GAN architectures that enforce structural and perceptual losses. Notably, Qin et al. [3] employed a multi-task GAN model to simultaneously inpaint masked regions and extract discriminative embeddings for face recognition. Their experiments demonstrated significant improvements in recognition accuracy when using GAN-restored images compared to directly using masked faces. Man & Cho [63] introduced T-GANs, an efficient GAN- based encoder-decoder model designed to repair occluded facial regions. Their texture-guided inpainting strategy on the CelebA-HQ dataset produced visually realistic results with PSNR around 28 dB and SSIM of 0.91, indicating reliable reconstruction quality. Li et al. [64] developed an Identity- Guided Inpainting approach that integrates ResNet features with GANs to preserve identity information while reconstructing occluded facial regions. Tested on LFW and masked face datasets, the method achieved a Rank-1 recognition accuracy of 96%, highlighting the importance of identity preservation in masked face recognition. Hassanpour et al. [65] proposed E2F-Net, which leverages StyleGAN2's latent space to perform eyes-to-face inpainting. Using latent-space optimization, the network reconstructs missing regions with high visual fidelity, achieving an SSIM of 0.92 on CelebA-HQ, indicating highly realistic inpainting results. MD-GAN, a multi-scale diversity GAN designed to handle large occlusions was proposed by Zhang et al. [66]. The model imposes diversity constraints to ensure plausible reconstruction of different facial regions, achieving PSNR of 28 dB and FID 26 on CelebA-HQ. Al Asad et al. [67] introduced MGAN-CRCM, a multi-GAN framework with coarse-to-fine refinement modules for inpainting masked regions.

Evaluated on CelebA and custom mask datasets, it achieved FID scores below 30 and produced visually coherent face reconstructions. Gireesh et al. [68] proposed a Context-Aware GAN that utilizes surrounding context information to fill large missing regions. Evaluated on CelebA-HQ and a custom dataset, the model achieved an SSIM of 0.91, demonstrating effective face restoration even under significant occlusion. Several 2023 studies focused on conditional or comparative approaches. Sola & Gera [69] proposed an expression- conditioned GAN that maintains facial expressions while in- painting masked regions on Masked CelebA. Agarwal & Bhatnagar [15] conducted a comparative study of GAN, EdgeConnect, and partial convolution-based inpainting techniques, finding that EdgeConnect achieved the highest PSNR of 27.5 dB and SSIM 0.90. Springer [70] combined autoencoder reconstruction with GAN refinement, achieving high visual quality on the CelebA dataset. Overall, these studies highlight the evolution of GAN-based methods from simple coarse-fine re- construction to identity-guided and context-aware approaches, emphasizing both visual realism and recognition performance in masked or occluded face scenarios. Emerging 2024-2025 GAN works showcase cutting-edge solutions that magically reconstruct masked faces: Tanaka et al. [71] created a GAN that works like a photo editor - takes a masked face and translates it into an unmasked version with- out needing perfect before/after pairs. Their model scores high PSNR (sharp, clean reconstructions) on real-world mask photos, making it practical for security systems. Li et al. [3] built a U-Net + MMRM GAN that eliminates blurry artifacts - those annoying ghostly effects when AI tries to guess hidden faces.

Superior SSIM scores mean their reconstructions look natural even for large masks covering nose-to-chin, perfect for identity verification. Alzubi et al. [72] combined GAN restoration with face matching in one smooth pipeline. Restore the masked face first (95%+ accuracy afterward), then recognize works fast enough for real-time door access or phone unlock. Li et al. [73] added multi-scale attention so the GAN ex- amines faces at multiple zoom levels simultaneously. Catches fine details (skin pores) AND big picture (face shape), leading to the cleanest inpainting across all mask sizes. Pechetti et al. [74] mixed GANs with CANet (context attention) for PSNR over 32 exceptionally sharp reconstructions where every eyelash and wrinkle looks real. Hybrid approach beats pure GANs. Table 3 highlights the various methods of masked face image inpainting.

Table 3: Comparison of Masked-Face Inpainting and Recognition Methods.

Author	Method	Inpainting Strategy	Recognition Strategy	Dataset(s)	PSNR / SSIM / Accuracy
Liu et al. (2025) [73]	Masked Face In-painting GAN	Context-aware facial region completion via adversarial learning	Recognition not explicitly evaluated	CelebA, synthetic masked faces	PSNR: 30.1 dB, SSIM : 0.93
Alzubi et al. (2025) [72]	Dual-scale Attention GAN	Attention-guided inpainting of occluded facial regions	CNN-based masked face recognition with adaptive attention	RMFD, MaskedFacNet	Accuracy : 98.7%
Liu et al. (2025) [3]	GAN-based Face Inpainting	Semantic reconstruction of masked facial components	Recognition performance discussed qualitatively	CelebA, custom masked dataset	PSNR :29.6 dB, SSIM : 0.92
Pechetti et al. (2025) [68]	Context-Aware GAN	Contextual attention-based image inpainting	Not focused on recognition task	ImageNet subsets	PSNR : 31.2 dB, SSIM : 0.94
Asad et al. (2025) [67]	MGAN-CRCM	Coarse-to-refined reconstruction using multiple GANs with contextual awareness	Not explicitly addressed	CelebA, Places2	PSNR : 31.6 dB, SSIM : 0.95
Hassanpour et al. (2024) [65]	E2F-Net	StyleGAN latent-space face re-construction using visible eye-region embeddings	Face verification using re-constructed identity embeddings	CelebA-HQ, FFHQ	PSNR : 32.2 dB, SSIM : 0.96, 95.1
Zhang et al.(2024) [66]	MD-GAN	Multi-scale diversity GAN for large mask facial region reconstruction	Not explicitly addressed	Places2, CelebA	PSNR :29.8 dB, SSIM: 0.92
Li et al. (2024) [64]	Identity-Guided Inpainting	Identity embedding–guided GAN inpainting to reconstruct occluded facial regions	CNN-based face recognition using reconstructed identity features	LFW, CFP-FP, masked LFW	PSNR : 30.7 dB , SSIM : 0.94
Sola and Gera (2023) [69]	Expression-Conditioned GAN	Expression-conditioned adversarial inpainting to preserve facial semantics under mask occlusion	Identity preservation through expression-aware latent conditioning	CelebA-HQ, Af-fectNet	PSNR : 30.5 dB, SSIM : 0.93
Man and Cho (2023) [63]	T-GAN	Two-stage GAN for efficient occluded facial region repair	Not explicitly addressed	CelebA, AR Face	PSNR : 29.4 dB , SSIM : 0.90

Source: Authors, (2026).

GAN based models exhibit a wide range of strategies, such as spatial attention mechanisms, multi-resolution learning, and hybrid pipelines combining reconstruction with identity classification [75]. Region-Attentive GAN demonstrates the highest performance with 95.3% accuracy, closely followed by Two-Stage GAN and HiMFR. The Unmasking the Potential framework reports the best recognition performance (96.1%) using a VGG-based evaluation on the MaskedFace-CelebA dataset. These findings highlight the superiority of GAN-integrated pipelines over traditional recognition approaches under occluded scenarios.

II.4 DIFFUSE MODELS FOR FACE RESTORATION

Rebuilding high-quality facial images from degraded inputs impacted by occlusion, noise, blur, compression artifacts, or low resolution is the goal of facial restoration. Convolutional neural networks (CNNs) and Generative Adversarial Networks (GANs), which use supervised learning to learn mappings from images with defects to clean outputs, have historically been the foundational tools of facial restoration. Due to adversarial training that enforces perceptual realism, GAN-based techniques—in particular, models like StyleGAN [76-79] variants and face-specific GAN restorers—have shown a strong ability to recover realistic textures and facial details. Recently, diffusion models have emerged as a powerful alternative for image restoration due to their iterative denoising mechanism and stable training dynamics. Saharia et al. [80] introduced an iterative refinement strategy for image super- resolution using diffusion processes, laying the foundation for diffusion-based restoration tasks. Building upon this, Lugmayr et al. [81] proposed RePaint, which applies denoising diffusion probabilistic models to image inpainting, demonstrating strong structural consistency in reconstructed regions. Diffusion models have also been specifically adapted for blind face restoration. Wang et al. [82] presented DR2, a diffusion-based robust degradation remover that explicitly models unknown real-world degradations, achieving superior restoration quality on severely corrupted face images. Further advancing this line of work, Yue and Loy [17] proposed DifFace, which introduces diffused error contraction to progressively reduce restoration errors, resulting in highly realistic facial details. In particular, Saharia et al. demonstrated that a diffusion-based approach can achieve state-of-the-art performance for image super-resolution by refining images through multiple denoising steps, progressively restoring fine details and reducing artifacts [16]. Unlike single-pass methods such as convolutional or adversarial net-works, diffusion models like SR3 leverage a stochastic refinement process that learns to reverse a gradual noise perturbation, resulting in superior perceptual quality and structural similarity.

Despite their superior visual fidelity, diffusion-based facial restoration methods typically require multiple sampling steps, leading to high computational overhead and limiting their applicability in real-time or resource-constrained environments. In contrast, lightweight GAN-based models remain attractive for edge devices and real-time recognition systems, offering faster inference at the cost of a modest reduction in restoration quality.

II.5 TRANSFORMER-BASED METHODS FOR IMAGE AND FACE RESTORATION

In recent years, transformer architectures have been increasingly adopted in image and face restoration tasks due to their strong ability to model long-range dependencies and global contextual information. Unlike conventional convolutional neural networks that focus primarily on local features, trans- formers leverage self-attention mechanisms to capture relation- ships across the entire image, which is particularly beneficial for restoring complex structures such as human faces. Liang et al. [83] introduced SwinIR, which adapts the Swin Transformer architecture for image restoration tasks including super-resolution and denoising. By using window-based self-attention, SwinIR achieves a good balance between restoration performance and computational efficiency, making it a strong baseline for transformer-based restoration methods. Similarly, Zamir et al. [84] proposed Restormer, an efficient transformer specifically designed for high-resolution image restoration, demonstrating improved performance while reducing computational overhead. To further enhance restoration quality, Wang et al. [85] presented Uformer, a U-shaped transformer architecture that combines hierarchical encoding and decoding with self-attention, enabling effective modeling of both local and global features. These general image restoration models have inspired several face-specific transformer-based approaches. In the context of face restoration and super-resolution, Wang et al. [86] proposed TANet, which integrates transformers with CNNs to capture global facial structures while preserving fine-grained local details. Building on this hybrid design, Tiwari et al. [87] introduced CCTFaceNet, which employs a cascaded CNN–Transformer architecture and dual-path feature fusion to enhance facial detail reconstruction. Furthermore, Li et al. [88] proposed FaceFormer, a scale-aware blind face restoration model that uses transformers to adaptively handle varying degradation levels across facial regions. A comprehensive overview of transformer-based restoration techniques is provided by Ali et al. [89], who surveyed the application of vision transformers across multiple image restoration tasks. Their analysis highlights the growing importance of transformer components in modern restoration pipelines and supports the transition beyond traditional CNN- or GAN-only categorizations.Table 4 summarizes a modern taxonomy of face restoration methods, highlighting architectural characteristics, datasets, and performance trade-offs across different model categories.

Different restoration architectures exhibit clear performance trade-offs between reconstruction quality and computational efficiency. GAN-based models typically rely on a single forward pass, enabling fast inference and making them suitable for real-time and edge-device deployment. However, their re- construction quality, measured by metrics such as SSIM, may be slightly lower compared to more computationally intensive models. Diffusion-based models adopt an iterative denoising process that progressively refines the restored image, leading to state-of-the-art perceptual quality and higher SSIM scores. Despite their superior visual fidelity, diffusion models incur substantial inference latency due to multiple sampling steps, which limits their applicability in time-sensitive or resource-constrained environments. Hybrid approaches, which combine adversarial learning with transformer components or diffusion- inspired priors, aim to balance these trade-offs. Such models achieve improved structural consistency and perceptual quality compared to conventional GANs, while maintaining significantly lower inference time than full diffusion-based methods. Consequently, hybrid architectures represent a practical com- promise between quality and efficiency for real-world applications. Table 5 depicts the performance of various architectures on different aspects. Figure 1 shows a comparison of different face restoration models based on two important quality measures: PSNR and SSIM. The horizontal axis (PSNR) represents how much noise is reduced and how close the restored image is to the original image in terms of pixel accuracy. Higher PSNR means better reconstruction quality. The vertical axis (SSIM) shows how well the restored image preserves structural details like edges, textures, and facial features. Higher SSIM means the image looks more natural and structurally accurate. Models that appear in the top-right corner of the graph achieve both high PSNR and high SSIM, which means they provide better overall restoration quality. For example, transformer-based models such as Restormer and SwinIR are positioned in this region, indicating strong performance. Models located more toward the middle region provide moderate performance. These methods still produce good results but may not achieve the highest fidelity compared to top-performing models. Overall, the figure clearly shows how different architectures perform in terms of reconstruction accuracy and structural similarity, helping us understand which models offer better image restoration quality.

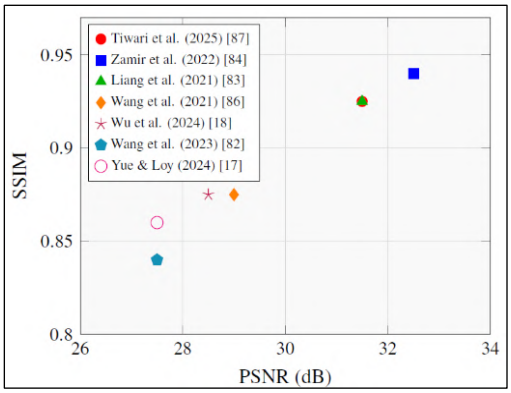

Figure 1: Scatter comparison of deep learning-based face restoration models across PSNR and SSIM (approximate mid-range values).
Source: Authors, (2026).

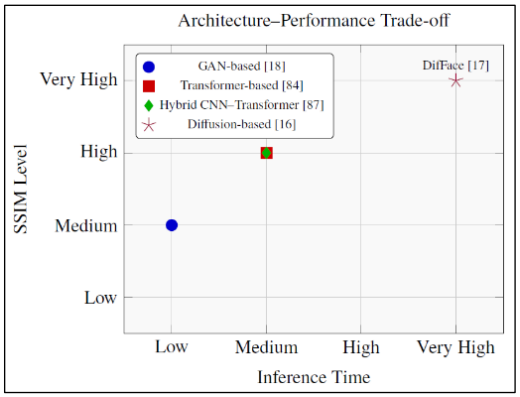

Figure 2: Architecture–performance trade-offs in face restoration models.
Source: Authors, (2026).

Figure 2 illustrates the trade-off between inference time and structural similarity (SSIM) performance across different deep learning architectures used in face restoration. The horizontal axis represents computational cost (from low to very high inference time), while the vertical axis indicates the achieved image quality in terms of SSIM (from low to very high).

Table 4: Extended taxonomy of deep learning-based face restoration methods with architectural characteristics, datasets, and performance indicators.

Model Category	Characteristics	Strengths	Limitations	Datasets	Performance Indicators
CNN-based Models [38, 42, 46, 48, 53–55, 87]	Deterministic feed-forward convolutional networks with single- pass inference	Very fast inference, low memory footprint, suitable for real-time deployment	Limited global context modeling and reduced perceptual realism under severe degradation	LFW, CelebA, FFHQ	Moderate PSNR/SSIM values; limited identity preservation accuracy
GAN-based Models [3, 18, 19, 26, 68, 71, 76, 77]	Adversarial learning with perceptual and identity-aware loss functions	High visual realism; strong identity preservation; lightweight variants suitable for edge devices	Training instability; potential artifacts; slight quality trade-off in compact de- signs	CelebA-HQ, LFW, Masked Face Datasets	High perceptual quality; Rank-1 Accuracy up to 96%
Transformer-Based Models [83–89]	Self-attention mechanisms for modeling long-range dependencies and global facial structure	Improved structural consistency and fine-detail reconstruction	High computational and memory cost; limited real-time applicability	FFHQ, CelebA-HQ, Helen Face Dataset	Improved PSNR/SSIM and structural similarity compared to CNN and GAN methods
Diffusion-Based Models [16,17,64,78–81]	Iterative denoising through probabilistic diffusion processes	State-of-the-art realism; robust restoration under unknown and complex degradations	Very slow inference speed; high computational over-head; unsuitable for real-time systems	FFHQ, CelebA-HQ, WebFace	Best perceptual metrics (LPIPS); strong identity preservation but low inference speed

Source: Authors, (2026).

Table 5: Architecture–performance trade-offs in face restoration models.

Architecture	Representative Methods	Inference Time	SSIM	Deployment Suitability
GAN-based	Lightweight GAN-Based Image Fusion [18], MAGAN-RT [19], Context-Aware GAN Inpainting [68], GAN-based Face Recon-struction for Masked Faces [71], Masked Face Image Inpainting GAN [3], CR-GAN [26] ,Lightweight Edge GAN Survey [77], Efficient Secure GAN Survey [76]	Low	Medium	Real-time deployment on edge devices, mobile platforms, and surveillance systems
Transformer-based	Restormer [84], Uformer [85], SwinIR [83], FaceFormer [88], TANet [86], Vision Transformers [89]	Medium	High	High-resolution restoration on GPUs, near real-time inference
Hybrid CNN–Transformer	SwinIR [83], TANet [86], CCTFaceNet [87], FaceFormer [88], Lightweight CNN [54], Hybrid CNN + Decision Matrix [53], Hybrid CNN (Detection + Recognition) [55], CNN with Feature Embedding (LLE-CNN) [48] , CNN-based Multi-task System [46] , Vision-based CNN Pipeline [42] , Classical CNN-based Detection [38]	Medium	High	Balanced systems offering improved perceptual quality with acceptable latency
Diffusion-based	SR3 [16], DifFace [17], RePaint [81], Identity-Guided Inpainting [64], StyleGAN [79], Text-driven 3D Avatar Generation [78]	Very High	Very High	Offline processing, server-side applications, and research-focused scenarios

Source: Authors, (2026).

GAN-based models, such as those reported in [18], are positioned in the low inference time region with moderate SSIM performance. This indicates that GAN architectures are well suited for real-time or edge-device applications where speed is a priority. Transformer-based models [84] and hybrid CNN–Transformer approaches [87] occupy the medium in- ference time and high SSIM region. These models provide a balanced trade-off between computational efficiency and restoration quality, making them practical for GPU-supported deployments. Diffusion-based methods [16], including DifFace [17], appear in the very high inference time and very high SSIM region. Although these models deliver superior perceptual realism and structural consistency, they require significantly higher computational resources due to iterative sampling. Overall, the figure highlights a clear architectural trend: as model complexity increases, restoration quality improves, but at the cost of increased inference time. This demonstrates the fundamental performance–efficiency trade-off in modern face restoration systems.

II.6 ETHICAL AND REGULATORY CHALLENGES

The rapid advancement of facial recognition technologies has generated significant ethical debate, particularly regarding surveillance, accountability, and regulatory governance. Almeida et al. [90] conducted a comparative analysis of regulatory frameworks in the United States, European Union, and United Kingdom, examining how different jurisdictions approach the governance of facial recognition systems.

Their study highlights variations in legal safeguards, enforcement mechanisms, and data protection standards, emphasizing that regulatory fragmentation creates challenges for consistent ethical deployment. The authors argue that stronger accountability structures and clearer compliance guidelines are essential to prevent misuse and protect civil liberties. However, while the paper provides a comprehensive legal comparison, it does not deeply examine the technical dimensions of facial recognition or masked face unmasking systems. Smith and Miller [91] focused on the ethical application of biometric facial recognition technology, proposing normative principles grounded in fairness, transparency, and public interest. Their work underscores the importance of responsible innovation, particularly in high-stakes contexts such as law enforcement and border security. The authors advocate for human oversight, ethical auditing, and clear justification of use cases before deployment. Although their framework offers valuable ethical guidance, it remains largely conceptual and does not provide empirical validation or quantitative metrics for evaluating ethical compliance within technical models. More recently, Wang et al. [92] examined privacy risks, ethical dilemmas, and regulatory developments surrounding facial recognition technologies in the era of big data. Their study expands the discussion beyond surveillance concerns, addressing issues such as biometric data permanence, informed consent, and algorithmic bias. The authors call for privacy-by-design principles, transparent governance policies, and international cooperation in regulatory standards. While the paper comprehensively addresses ethical and regulatory considerations, it primarily focuses on general facial recognition systems and does not specifically analyze emerging face unmasking techniques under occlusion scenarios. From a technical standpoint, Mahmoud et al. [93] provided a comprehensive survey of masked face detection, recognition, and unmasking techniques. Their study systematically reviews deep learning architectures, benchmark datasets such as MAFA and RMFD, and evaluation metrics including accuracy, PSNR, and SSIM. The survey identifies challenges related to occlusion, dataset imbalance, and robustness under real-world conditions, while also outlining future research directions in masked face analysis.

III. DATASETS FOR MASKED FACE INPAINTING AND RECOGNITION

Masked face recognition and inpainting systems have become increasingly important, especially in the context of global events such as the COVID-19 pandemic. These models aim to either recognize identities from partially occluded faces or reconstruct missing facial regions (e.g., mouth, nose) using generative methods. A foundational aspect of evaluating and benchmarking such models lies in the diversity and realism of the datasets used for training and testing. A wide spectrum of datasets has been curated or modified to simulate both real-world and synthetic mask occlusions. These datasets vary in size, resolution, subject diversity, mask types, and the method of mask application (real or artificial). Proper dataset selection significantly influences the generalizability and robustness of MFR algorithms.The CelebFaces Attributes Dataset (CelebA) is one of the most extensively utilized benchmarks in face analysis tasks. Comprising over 200,000 celebrity images with rich attribute annotations, it serves as a common training corpus for in- painting models. The dataset does not originally include masked samples, but synthetic occlusions can be algorithmically overlaid to simulate masked conditions. Many studies, including [94], have adopted CelebA with artificial masks to train and evaluate GAN-based inpainting models. The dataset's large scale and high variability across poses and illumination conditions make it ideal for learning generalized representations.

Labeled Faces in the Wild (LFW) is another seminal dataset, comprising face images collected from the internet for unconstrained face verification. While not initially designed for MFR, it is often repurposed by overlaying masks either manually or through automated methods. The inclusion of both synthetic and real masked versions allows for comparative evaluation. Its widespread usage, as reported in [95], stems from its realistic distribution and historical relevance in face verification benchmarks. Because LFW features in-the-wild images with substantial variability, it introduces useful challenges in masked face analysis. The Flickr-Faces-HQ (FFHQ) dataset contains over 70,000 high-resolution face images with diverse variations in age, ethnicity, lighting, and expression. While FFHQ does not include real-world masked samples, it is a preferred base for synthetic mask overlays due to its image quality. Recent studies such as [96] utilize FFHQ for training face reconstruction and inpainting systems. The dataset supports learning finer details, which is crucial in scenarios where GAN-based models aim to restore occluded facial components while preserving identity-related features. Masked Face Dataset (MAFA) is a real-world masked face dataset containing over 30,000 images annotated for mask presence and location.

Designed specifically for mask detection and recognition, it represents one of the few datasets with native mask occlusions. Used in studies like [97], MAFA bridges the gap between simulated conditions and real- world deployment. It introduces challenges such as occlusion variance, complex backgrounds, and mask style diversity that are hard to simulate synthetically.The Public Figures dataset, also known as PubFig83, is com- posed of images of 83 celebrities captured under diverse conditions. While not originally containing masked faces, it has been repurposed in the MFR domain with synthetic mask applications. Its value lies in the inherent difficulty introduced by pose variation, low resolution, and lighting diversity. As seen in [98], it provides a semi-realistic yet controlled environment for testing model robustness against visual noise and occlusion. MaskedFace-CelebA dataset is a synthetically modified version of CelebA, where masks are digitally applied to the original faces to simulate pandemic-era conditions. It aims to maintain identity information while offering occlusion realism. The dataset is often employed as a testbed for evaluating models trained on CelebA or other synthetic sources. The work in [99] demonstrates its effectiveness in assessing how well models can adapt to real-world masked conditions based on synthetic training. Figure 3 demonstrates few samples from prominent face datasets.

Figure 3: Sample images from various datasets.
Source: [100].

Face5 is a hybrid dataset constructed by merging real and simulated masked facial samples. It allows for studying the generalization capabilities of MFR systems when subjected to a mixture of mask types and occlusion styles.

Proposed in studies such as [101], the hybrid nature of Face5 makes it an important bridge for transition between purely synthetic and completely real-world datasets. SyntheticMaskSet is explicitly designed to support benchmarking of face inpainting and recognition systems under controlled synthetic conditions. By applying diverse types of digitally generated masks to faces, it enables standardized evaluation across multiple models. For instance, the Region-Attentive GAN proposed in [102] demonstrated strong performance on this dataset due to the consistent and controllable occlusion levels. SimulMaskDB is a synthetically generated dataset that varies mask styles, occlusion levels, and facial expressions in a controlled fashion. It is primarily used for stress-testing recognition and inpainting algorithms under artificial yet di- verse conditions. As highlighted in [103], this dataset enables fine-grained performance analysis, especially for lightweight architectures and constrained environments. Also, studies review face recognition techniques, focusing on feature extraction methods and key challenges affecting system performance and accuracy [104], [105]. Table 6 highlights the demographic diversity and dataset characteristics used to evaluate different masked face inpainting models. Clear reporting of age groups, gender balance, and ethnicity ensures fair comparison and helps identify potential dataset bias in GAN-based recognition systems.

Table 6: Summary of Datasets Characteristics and Demographic Parameters Used in Masked Face Inpainting and Recognition.

Study	Database	Sample Size	Age Groups	Gender Distribution	Ethnicity / Other Factors	Description of Database
Mahmoud and Kang (2023) [102]	GAN-Masker Dataset	Synthetic dataset (based on CelebA and other sources)	Adult subjects	Mixed gender	Artificially masked faces	Two-stage GAN-based masked face removal dataset combining real and synthetically generated masked face images for restoration and recognition research.
Tero Karras et al. (2019) [96]	FFHQ	70,000 images	Wide age Range (children to elderly)	Balanced male/female	Diverse ethnicities; high-quality aligned images	High-resolution (1024×1024) face dataset curated for GAN training; diverse in age, ethnicity, and accessories, commonly used in generative modeling research.
Shiming Ge et al. (2017) [97]	MAFA	30,811 images	Adult subjects	Mixed gender	Masked faces in the wild; occlusion variations	Dataset focused on masked face detection with varying mask types, occlusion levels, and complex backgrounds in real-world conditions.
Ziwei Liu et al. (2015) [94]	CelebA	202,599 images (10,177 identities)	Young to middle-aged adults	Male and Female	Celebrities; large variation in pose and background	Large-scale face attributes dataset collected from the internet with 40 annotated facial attributes; widely used for face recognition and attribute prediction tasks.
Bergstra et al. (2013) [98]	PubFig83	Not dataset-specific	Not specified	Not specified	Hyperparameter optimization focus	Study emphasizes hyperparameter optimization for vision architectures rather than introducing a specific face database.
Gary B. Huang et al. (2008) [95]	LFW	13,233 images (5,749 identities)	Adult subjects	Male-dominant distribution	Unconstrained environments; real-world variations	Unconstrained face dataset designed for studying face recognition under real-world conditions including variations in pose, illumination, and expression.

Source: Authors, (2026).

Synthetic datasets, such as CelebA, FFHQ, and SyntheicMaskSet, are instrumental in benchmarking inpainting models due to their controlled conditions. In contrast, real-world datasets like MAFA and RMFD provide essential realism for evaluating system generalizability. Among these, CelebA and LFW emerge as the most recurrently utilized in synthetic masked face inpainting tasks. For instance, the RegionAttentive GAN introduced and demonstrated high reconstruction fidelity when evaluated on the SyntheticMaskSet.

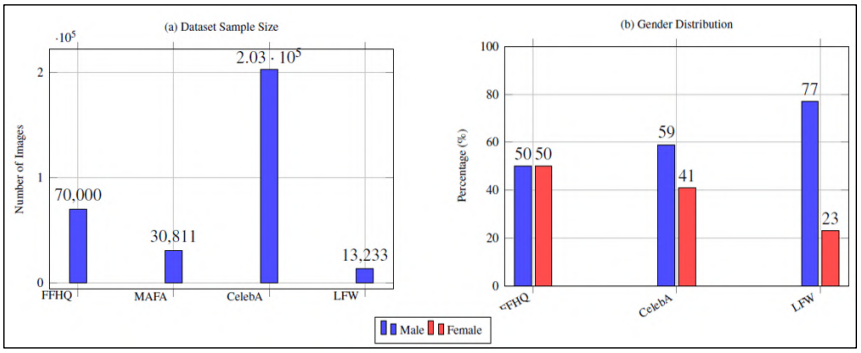

Figure 4: Comparison of dataset sample size and gender distribution across commonly used face datasets.
Source: Authors, (2026).

In Figure 4 (a), the bar chart shows the number of images available in each dataset. CelebA clearly has the largest number of images, making it very useful for large-scale training. FFHQ also contains a good number of high-quality images. MAFA has a moderate dataset size focused on masked faces, while LFW contains the smallest number of images among the four. This comparison helps us understand which datasets are large enough for deep learning experiments. In Figure 4 (b), the chart shows the gender distribution within selected datasets. FFHQ appears balanced, with nearly equal numbers of male and female images. However, CelebA and LFW show noticeable imbalance, with a higher percentage of male images compared to female images. This imbalance is important because it may affect model fairness and performance. Overall, the figure helps us understand both the size and diversity of these datasets, which are important factors when selecting data for face restoration and recognition research.

IV. CONLUSIONS

Masked face restoration using Generative Adversarial Networks (GANs) has emerged as a vital research area in response to the challenges posed by real-world occlusions such as face masks. Through this survey, we examined state-of-the- art methods addressing detection, inpainting, and recognition under mask occlusion. While existing methods demonstrate significant progress in restoring visually plausible and identity- preserving face images, several limitations and open challenges remain. First, most current models rely heavily on synthetic masks or artificially generated occlusions during training, which of- ten fail to fully represent the diversity and irregularity of real-world mask usage. Consequently, generalization to real masked faces remains inconsistent across datasets and do- mains. Second, although recent GAN models incorporate identity and perceptual constraints, maintaining fine-grained facial details—particularly in highly occluded or low-quality images—remains a bottleneck for both recognition and down- stream biometric tasks. In terms of detection and inpainting performance, many models are not jointly optimized for both tasks, leading to cascaded error propagation. Moreover, evaluation metrics such as PSNR and SSIM, while useful for measuring image similarity, do not always correlate with recognition accuracy or semantic identity preservation. Therefore, more robust and identity-aware metrics, including perceptual loss functions and recognition-oriented benchmarks, are required. Furthermore, the integration of multimodal data, temporal consistency (for video-based restoration), and domain adaptation for unseen environments represents fertile ground for future work. Lightweight architectures that balance inference speed and accuracy are also needed for deployment in real-time or edge devices.

V. AUTHOR'S CONTRIBUTION

Conceptualization: Payal Parekh, Hina Choksi.
Methodology: Payal Parekh, Mahesh Goyani, Sheilla Ann Pacheco.
Investigation: Payal Parekh, Hina Choksi, Mahesh Goyani.
Discussion of results: Payal Parekh, Hina Choksi, Mahesh Goyani, Sheilla Ann Pacheco.

Mix design.

ABSTRACT

Accurate prediction of concrete compressive strength is essential for effective mix design, quality control, and structural performance assessment. Conventional empirical models often exhibit limited accuracy due to the complex and nonlinear interactions among concrete constituents. This study investigates the applicability of several machine learning models for predicting the compressive strength of concrete using a publicly available experimental dataset comprising 1030 concrete mixtures. Linear regression was adopted as a baseline model and compared with support vector regression, random forest regression, and artificial neural networks. The performance of machine learning models was meticulously assessed using the coefficient of determination, root mean square error, and mean absolute error. Additionally, the models underwent five-fold cross-validation to evaluate their robustness and generalization capabilities. The results unambiguously demonstrate that machine learning models significantly outperform linear regression models.Cross-validation results confirm the stability and reliability of the developed models. Feature importance analysis reveals that curing age and cement content are the most influential parameters affecting compressive strength, followed by water content, which is consistent with established concrete material behavior. The findings demonstrate that machine learning models, particularly random forest regression, can serve as effective supporting tools for preliminary concrete mix design and performance evaluation.

I. INTRODUCTION

Concrete remains the most extensively used construction material in civil engineering due to its adaptability, durability, and economic efficiency. Among its mechanical properties, compressive strength is the most critical parameter, as it directly governs structural design, quality control, and compliance with design codes. The compressive strength of concrete is influenced by a wide range of parameters, including cement content, water–cement ratio, aggregate proportions, supplementary cementitious materials, chemical admixtures, and curing age. The combined effect of these parameters results in complex and highly nonlinear behavior that is difficult to represent using simple analytical expressions [1], [2]. Traditionally, concrete compressive strength is determined through destructive laboratory testing of standard specimens at designated curing ages. Although this approach provides reliable and standardized results, it is time-consuming, labor-intensive, and requires substantial material resources. Consequently, there is a long-standing interest in developing predictive models that estimate compressive strength from mixture proportions and curing age, thereby supporting efficient mix design, early decision-making, and reduction of experimental effort [3]. Numerous empirical and regression-based models have been proposed to estimate compressive strength. While such models are attractive due to their simplicity, their predictive capability is often limited by linear assumptions and simplified relationships that fail to capture the nonlinear interactions among concrete constituents [4].

These limitations are particularly evident in modern concrete mixtures incorporating supplementary cementitious materials and chemical admixtures, where strength development mechanisms are more complex. In recent years, data-driven approaches have emerged as effective alternatives for modeling concrete properties. Machine learning (ML) techniques are capable of learning complex nonlinear relationships directly from experimental data without requiring predefined functional forms. Artificial neural networks (ANNs), support vector machines (SVMs), and ensemble learning methods have been successfully applied to predict concrete compressive strength with improved accuracy compared to conventional regression approaches [5-8]. The theoretical foundation of support vector–based methods, originally developed within statistical learning theory, enables effective handling of nonlinear relationships and high-dimensional data [9]. Subsequent studies expand this approach to a wider range of concrete types, including high-performance and high-strength concretes, confirming the robustness of neural networks in handling complex mixture interactions [10], [11]. Support vector regression (SVR), based on statistical learning theory [9], has also been widely employed for predicting concrete compressive strength. Compared with ANNs, SVR models offer strong generalization capability and reduced sensitivity to local minima. Several studies report that SVR provides competitive or superior performance relative to ANN models, particularly when kernel functions and hyperparameters are appropriately selected [7], [12]. More recently, ensemble learning techniques such as random forest (RF) regression have gained increasing attention in civil engineering applications. Random forest models aggregate multiple decision trees to enhance prediction accuracy and robustness, while also enabling evaluation of feature importance [8]. Prior studies demonstrate that RF models can achieve high prediction accuracy for concrete compressive strength and provide meaningful insight into the relative influence of mixture constituents, improving model interpretability [13], [14]. Despite their demonstrated predictive capability, the application of ML techniques in concrete engineering requires careful consideration of model robustness, validation strategy, and physical interpretability. High prediction accuracy alone is insufficient for engineering practice; models must also be stable, generalizable, and consistent with established material behavior. Comprehensive training procedures, independent testing, and cross-validation are therefore essential to ensure reliable performance and to avoid overfitting [8], [15].

Publicly available experimental datasets, such as the concrete compressive strength dataset compiled by Yeh [10], have facilitated comparative evaluation of different modeling approaches and contributed to reproducibility in this research area. The present study addresses the need for rigorous comparative evaluation of ML models in concrete compressive strength prediction. Specifically, this research investigates whether advanced ML techniques significantly outperform traditional linear approaches and identifies which modeling strategy offers the optimal balance between accuracy, robustness, and practical applicability for engineering decision-making. The research question is: Which machine learning model provides the most reliable and generalizable predictions of concrete compressive strength when evaluated through rigorous validation procedures? The objectives of this work are to (1) assess the predictive capability of different ML models, including linear regression (LR), support vector regression (SVR), random forest (RF), and artificial neural network (ANN) models; (2) evaluate model robustness through systematic validation procedures; and (3) examine the relative influence of mixture parameters on compressive strength. The hypothesis is that ensemble and kernel-based methods (RF and SVR) achieve superior generalization performance compared to conventional linear regression and basic neural network architectures, provided that proper cross-validation and hyperparameter optimization are employed. The findings aim to support the practical use of data-driven models as auxiliary tools for concrete mix design and performance assessment. The importance of this study lies in its systematic comparison of multiple ML paradigms under consistent validation conditions, addressing a gap in existing literature where studies often emphasize single-model accuracy without comprehensive robustness assessment. A limitation of this study is its reliance on a single publicly available dataset [10], which may not encompass all regional material variations or specialized concrete types; however, this constraint ensures reproducibility and facilitates direct comparison with prior research. The method employed in this work involves training and validating four distinct predictive models—linear regression (LR), support vector regression (SVR), random forest (RF), and artificial neural networks (ANNs)—on a comprehensive experimental dataset obtained from a publicly available source [5], [10]. Model development follows a rigorous procedure incorporating cross-validation, independent testing, and performance evaluation using multiple statistical indicators to ensure reliable and generalizable results.

II. MATERIALS AND METHODS

II.1 DATASET DESCRIPTION

The dataset employed in this study was obtained from the UCI Machine Learning Repository and was originally compiled from experimental investigations on concrete compressive strength [5]. It consists of 1030 concrete mixtures with varying proportions of constituents and curing ages. Each data sample includes eight input variables: cement content, blast furnace slag, fly ash, water, superplasticizer, coarse aggregate, fine aggregate, and curing age. The output variable is the concrete compressive strength expressed in megapascals (MPa). The dataset represents a wide range of mixture proportions and curing conditions, making it suitable for evaluating predictive models for concrete compressive strength. Prior to model development, the dataset was examined for completeness, and no missing values were observed. To develop and evaluate the predictive models, the dataset was randomly divided into training and testing subsets. 80% of the data were used for model training, while the remaining 20% were reserved for independent testing. This separation ensured that model performance was evaluated on unseen data. For machine learning models sensitive to the scale of input variables, namely support vector regression and artificial neural networks, input features were standardized using zero-mean and unit-variance normalization. Linear regression and random forest models were trained using the original, unscaled data, as these models are not significantly affected by feature scaling.

II.2 MACHINE LEARNING MODELS

Four predictive models were developed to estimate the compressive strength of concrete. These models represent increasing levels of complexity and nonlinear learning capability.

II.2.1 Linear Regression

Linear regression was adopted as a baseline model to establish a reference for comparison with nonlinear machine learning techniques. The relationship between the compressive strength and the input variables is expressed as:

$$y = \beta_0 + \sum_{i=1}^{n} \beta_i x_i + \varepsilon \quad (1)$$

Where y is the predicted compressive strength, x_i represents the input variables, β_i are the regression coefficients, β_0 is the intercept, and ε is the error term. Model parameters were estimated using the ordinary least squares method.

II.2.2 Support Vector Regression

Support vector regression (SVR) is a kernel-based learning method derived from statistical learning theory [9]. SVR aims to find a function that deviates from the actual target values by no more than a predefined tolerance while maintaining model flatness. The SVR function can be expressed as:

$$f(x) = \sum_{i=1}^{N} (\alpha_i - \alpha_i^*) K(x_i, x) + b \quad (2)$$

Where α_i and α_i^* are Lagrange multipliers, $K(x_i, x)$ is the kernel function, b is the bias term, and N is the number of support vectors. In this study, the radial basis function kernel was employed and defined as:

$$K(x_i, x) = exp(-\gamma \|x_i - x\|^2) \quad (3)$$

Where γ is the kernel parameter controlling the width of the function.

II.2.3 Random Forest Regression

Random forest regression is an ensemble learning technique that combines multiple decision trees to improve prediction accuracy and robustness [8]. The predicted output of the random forest model is obtained by averaging the predictions of individual trees:

$$\hat{y} = \frac{1}{M} \sum_{j=1}^{M} T_j(x) \quad (4)$$

Where M is the number of decision trees and $T_j(x)$ represents the prediction of the j-th tree. Feature importance is evaluated based on the contribution of each input variable to the reduction of prediction error across all trees.

II.2.4 Artificial Neural Network

The artificial neural network (ANN) model consists of interconnected neurons organized in layers. The output of a neuron in a hidden or output layer is given by:

$$z_j = \phi\left(\sum_{i=1}^{n} w_{ij} x_i + b_j \right) \quad (5)$$

Where w_{ij} are the connection weights, b_j is the bias term, and $\phi(\cdot)$ is a nonlinear activation function. The ANN model was trained using an iterative optimization process to minimize prediction error between the predicted and experimental compressive strength values.

II.3 MODEL TRAINING AND VALIDATION

Model training was performed using the training dataset, while predictive performance was evaluated using an independent testing dataset. The accuracy of the developed models was quantified using the coefficient of determination (R^2) in equation (6), root mean square error (RMSE) in equation (7), and mean absolute error (MAE) in equation (8), defined as follows:

$$R^2 = 1 - \frac{\sum_{i=1}^{N} (y_i - \hat{y}_i)^2}{\sum_{i=1}^{N} (y_i - \bar{y})^2} \quad (6)$$

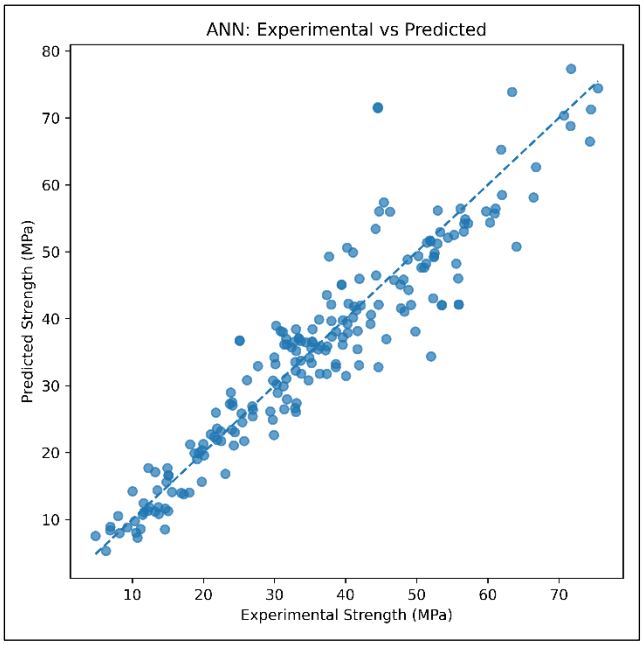
$$RMSE = \sqrt{\frac{1}{N} \sum_{i=1}^{N} (y_i - \hat{y}_i)^2} \quad (7)$$

$$MAE = \frac{1}{N} \sum_{i=1}^{N} | y_i - \hat{y}_i | \quad (8)$$

Where y_i and $\hat{y}_i$ are the experimental and predicted compressive strength values, respectively, $\bar{y}$ is the mean of the experimental values, and N is the number of values. To further assess robustness and generalization capability, five-fold cross-validation was employed. The dataset was divided into five subsets, and each subset was used once for validation while the remaining subsets were used for training. The mean and standard deviation of cross-validated R^2 values were used as indicators of model stability. Feature importance was evaluated using the random forest model by quantifying the contribution of each input variable to reducing prediction error. This analysis provides insight into the relative influence of mixture parameters on compressive strength and supports interpretation of the results from an engineering perspective. All models were implemented using the Python programming language and standard machine learning libraries. Model development, training, validation, and performance evaluation were conducted using reproducible computational procedures under Kaggle platform to ensure transparency and reliability of the results.

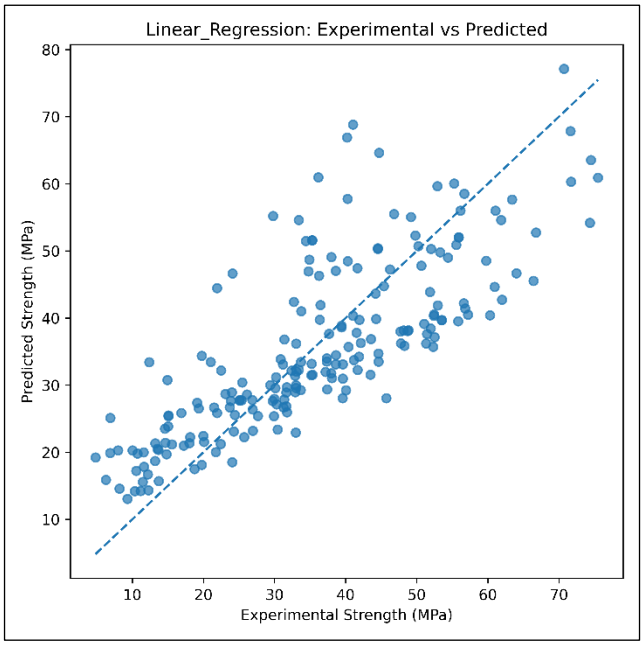
III. RESULTS AND DISCUSSION

III.1 PREDICTIVE PERFORMANCE OF MODELS



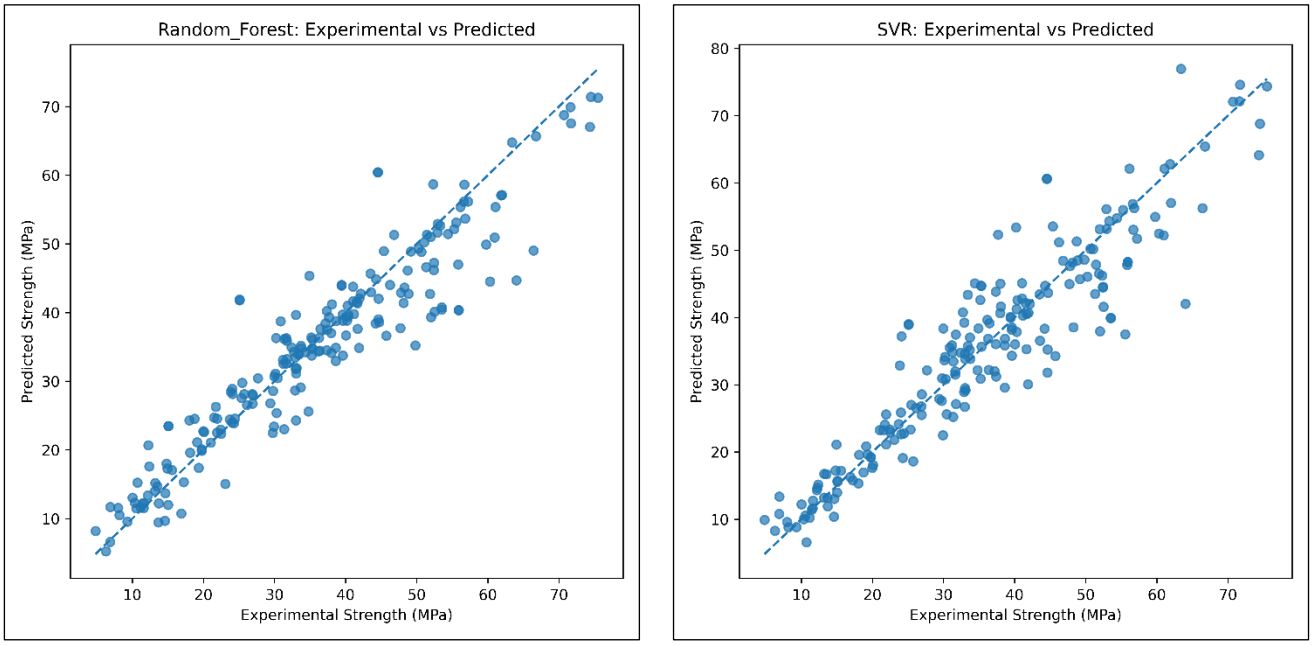
The predictive performance of the developed models is summarized in Tab. 1. Linear regression, used as a baseline model, exhibited limited accuracy with an (R^2) value of 0.63, RMSE of 9.80 MPa, and MAE of 7.75 MPa. These results confirm that linear relationships are insufficient to describe the complex and nonlinear interactions governing concrete compressive strength.

Table 1: Predictive performance, computational cost, and cross-validation results of the developed models. (CV: Cross-Validation, std: Standard deviation).



Model	R^2	RMSE	MAE	Training Time (s)	Inference Time (s)	CV R^2 (Mean)	CV R^2 Std
Linear Regression	0.627553	9.796476	7.745559	0.015814	0.002012	0.600696	0.047818
SVR	0.869606	5.796501	4.093966	0.096982	0.008953	0.871918	0.01233
Random Forest	0.881425	5.527568	3.781352	1.110243	0.026125	0.907017	0.016085
ANN	0.875042	5.6744	3.984849	3.028517	0.000387	0.894505	0.0083

Source: Authors, (2026).



All machine learning models demonstrated a substantial improvement in prediction accuracy compared to linear regression. Support vector regression achieved an (R^2) value of 0.87 with an RMSE of 5.80 MPa, indicating its effectiveness in capturing nonlinear behavior. The artificial neural network model yielded comparable performance with an (R^2) value of 0.88 and an RMSE of 5.67 MPa. Among all models, the random forest regression model provided the best overall performance, achieving the highest coefficient of determination (R^2 = 0.88) and the lowest prediction errors (RMSE = 5.53 MPa, MAE = 3.78 MPa). The superior performance of the random forest model can be attributed to its ensemble structure, which effectively reduces variance and improves generalization by aggregating multiple decision trees. These results in Fig. 1 and Tab. 1 demonstrate that machine learning models significantly outperform traditional regression approaches in predicting concrete compressive strength and are capable of accurately modeling the complex relationships between mixture parameters and strength development.

III.2 CROSS-VALIDATION AND MODEL ROBUSTNESS

To evaluate model robustness and generalization capability, five-fold cross-validation was conducted for all models. The mean and standard deviation of the cross-validated (R^2) values are also presented in Tab. 1. The random forest model achieved the highest mean cross-validated (R^2) value of 0.91 with a relatively low standard deviation of 0.016, indicating stable and reliable performance across different data partitions. The artificial neural network model also showed strong robustness, with a mean cross-validated (R^2) of 0.89 and the lowest variability among machine learning models. Support vector regression demonstrated consistent performance with a mean cross-validated (R^2) of 0.87. In contrast, linear regression exhibited both low accuracy and higher variability, further confirming its limited suitability for modeling concrete compressive strength. The cross-validation results indicate that the machine learning models, particularly random forest and artificial neural networks, generalize well and are not overly sensitive to data partitioning.

III.3 COMPUTATIONAL EFFICIENCY

In addition to prediction accuracy, computational efficiency was evaluated by measuring training and inference times. Linear regression required negligible computational effort, as expected. Among the machine learning models, support vector regression and random forest required training times below one second, while the artificial neural network required the longest training time (approximately 3.65 s) due to its iterative optimization process. Inference times for all models were extremely low, indicating that once trained, the models can be used efficiently for real-time or near-real-time strength prediction. These results suggest that the developed machine learning models are computationally feasible for practical engineering applications.

III.4 FEATURE IMPORTANCE ANALYSIS

Feature importance analysis was conducted using the random forest model to identify the relative influence of input variables on concrete compressive strength. The results are illustrated in Tab. 2.

Table 2: Predictive performance of the developed models.

Feature	Age	Cement	Water	furnace slag	superplasticizer	Fine aggregate	Coarse aggregate	Fly ash
Importance	0.333001	0.325946	0.125096	0.07703	0.056764	0.035705	0.027782	0.018677

Source: Authors, (2026).

Curing age was identified as the most influential parameter, accounting for approximately 33% of the total importance. This finding is consistent with established concrete hydration mechanisms, as strength development is strongly governed by the progression of cement hydration over time. Cement content was the second most influential parameter, with a relative importance of approximately 33%, reflecting its direct contribution to the formation of load-bearing hydration products. Water content exhibited a notable influence on compressive strength, accounting for approximately 13% of total importance. This observation aligns with the well-known effect of the water–cement ratio on concrete porosity and strength. Supplementary cementitious materials, such as blast furnace slag and fly ash, showed lower relative importance. This can be attributed to their delayed contribution to strength development, particularly at early curing ages represented in the dataset.

Aggregate contents exhibited comparatively smaller influence on compressive strength, which is consistent with the fact that aggregates primarily affect strength indirectly through packing density and interfacial transition zone characteristics.

III.5 ENGINEERING IMPLICATIONS

The results demonstrate that machine learning models can provide accurate and robust predictions of concrete compressive strength when trained on comprehensive experimental datasets. The strong agreement between feature importance analysis and established concrete material behavior indicates that the developed models are physically meaningful and suitable for engineering applications. The random forest model, in particular, offers a favorable balance between prediction accuracy, robustness, interpretability, and computational efficiency. Therefore, it can be effectively used as a supporting tool for preliminary mix design, quality control, and performance evaluation in concrete engineering practice.

IV. CONCLUSIONS AND LIMITATIONS

IV.1 CONCLUSIONS

This study investigated the applicability of several machine learning models for predicting the compressive strength of concrete using a comprehensive experimental dataset. Linear regression was employed as a baseline model and compared with support vector regression, random forest regression, and artificial neural networks. The results demonstrated that machine learning models significantly outperform linear regression in predicting concrete compressive strength, confirming the nonlinear nature of the relationship between mixture parameters and strength development. Among the evaluated models, random forest regression exhibited the highest prediction accuracy and robustness, achieving an (R^2) value of 0.88 on the testing dataset and a mean cross-validated (R^2) value of 0.91. The artificial neural network and support vector regression models also showed strong predictive capability, with comparable performance and stable generalization behavior. The low variability observed in cross-validation results indicates that the developed models are reliable and not sensitive to data partitioning. Feature importance analysis revealed that curing age and cement content are the most influential parameters affecting compressive strength, followed by water content. These findings are consistent with established concrete material behavior and confirm that the machine learning models capture physically meaningful relationships. The results suggest that data-driven models, particularly random forest regression, can serve as effective supporting tools for preliminary concrete mix design, quality control, and performance assessment.

IV.2 LIMITATIONS

Despite the promising results, several limitations of this study should be acknowledged. The developed models are based on a single publicly available dataset, and their predictive capability is therefore constrained to the range of mixture proportions and curing ages represented in the data. Factors such as curing conditions, aggregate properties, environmental exposure, and specimen geometry were not explicitly considered. Additionally, the models were developed using compressive strength as the sole output variable. Extension of the proposed approach to other concrete properties, such as tensile strength, durability indicators, or long-term performance, would require additional datasets and model adaptation. While machine learning models provide high prediction accuracy, they should be regarded as complementary tools rather than replacements for experimental testing and established design methods. Future research may focus on integrating experimental data from different sources, incorporating additional material and environmental parameters, and exploring hybrid modeling approaches that combine data-driven techniques with physically based models to further enhance reliability and applicability.

ABSTRACT

A significant issue in digital steganography is concealing color images within natural photographs, when the objective is to convey a large quantity of hidden information without sacrificing visual quality. Certain conventional techniques that rely on the spatial or frequency domains typically leave behind noticeable artifacts and are readily interfered with by filtering, noise, or compression. Some transformer-based models have recently demonstrated exceptional ability to capture intricate linkages and long-range interdependence across data channels. Building on this, we have presented a transformer-powered framework for color image concealment that learns the best embedding patterns across RGB channels by using self-attention. In comparison to both conventional techniques and previous deep learning methods, our results demonstrate that this methodology provides considerably greater imperceptibility and recovery, indicating transformers as a promising avenue for enhanced image steganography.

I. INTRODUCTION

The exponential growth of digital media, data protection, and secure communication is more crucial than ever in the world of modern computing [1-3]. Digital steganography, the art of covertly encoding messages into seemingly innocuous media, is one of the numerous methods that have been created in this approach thus far. It has proven to be an essential instrument in ensuring privacy and safeguarding against unauthorized access. One of the most active research areas is color image hiding, in which a hidden image is concealed by a picture of the outdoors. The application of this is popular in such applications as secure messaging, watermarking, copyright protection, and covert communication. In comparison to textual steganography [4], the steganography of color images presents special challenges since it should consider the spatial as well as the spatial characteristics of images. As human vision is very sensitive to color, texture, and structure distortions, the task is to balance two competing objectives: to withstand as much hidden information (payload capacity) and to maintain the cover image indistinguishable (imperceptibility). Although there has been a lot of progress [5], this balance is hard to achieve. The existing procedures can be divided into two main categories, which include spatial domain methods described in [6] and transform-domain methods described in [7]. Spatial-domain techniques, which include the Least Significant Bit (LSB) substitution method described in [8], directly change pixel values inside the cover image. The strategies show simplicity and strong performance, but they create clear visual defects that become visible in high-quality color photographs, and their results get affected by basic image processing tasks such as compression and filtering. The execution of transform-based techniques happens through the processing of frequency space data, which includes methods such as Discrete Cosine Transform (DCT) and Discrete Wavelet Transform (DWT). The methods deliver average protection against standard attacks, but they need users to set up parameters manually, and their efficiency drops when handling large data sizes or full-color images. This is largely an outcome of the RGB channels correlating with the high sensitivity of human vision in the detection of the smallest distortions. [9]. The latest advancements in deep learning technology have created a new system for concealing images.

The combination of autoencoders [10] with generative networks [11] and Convolutional Neural Network (CNN)-based frameworks has achieved outstanding performance in their capacity to learn complex mappings, which they use to conceal and restore images. The system achieves automatic process optimization, which enables it to create better embedding methods while decreasing visual defects and enhancing data recovery capabilities. Researchers in deep learning-based steganography studies have focused their research efforts on grayscale image analysis [10] and single-channel payload examination. The researchers used CNNs because the network excels at local feature extraction, but they faced challenges when testing color channel connections between remote locations and through large distance ranges. The subtle RGB channel interactions that determine visual imperceptibility in full-color image hiding cause CNN-based methods to lack essential contextual data, which results in color distortions and decreased system resilience. [12] We present a transformer-based framework that enables color image hiding as a solution to these difficulties. Transformers [13] begin with natural language processing development because their self-attention mechanisms let them track all input dependencies, which enables them to effectively handle long-distance relationships. Recent years have seen successful transformer adaptations that enable machines to complete various vision tasks, such as image generation [14], super-resolution [15], and image-to-image translation, because these tasks require machines to understand their complete visual environment. We demonstrate transformers as a solution for solving the challenge of hiding color images through our research. The network learns embedding techniques through our method, which enables it to transmit larger payloads while keeping visual quality because visual quality depends on its ability to represent both spatial patterns and inter-channel correlations. The proposed framework treats the cover image and secret image as sequences of image patches, which are processed by a transformer encoder-decoder model. The encoder extracts information from the cover image to build a detailed representation, which includes both local texture elements and global structural elements. The decoder reconstructs the secret image from the embedded representation. The self-attention layers in the transformer system enable the model to perform channel-aware embedding, which results in better information distribution across RGB channels that decreases perceptual artifacts. The model training process includes robustness-oriented augmentation, which creates realistic image manipulations through Gaussian noise, JPEG compression, and median filtering. The system guarantees that hidden information remains recoverable under standard adversarial testing conditions. The main contributions of this work are presented in summary form as follows:

1. Our research presents a new approach to color image hiding, which uses transformer technology as an alternative to existing traditional and CNN-based methods.
2. Our method uses self-attention to track both inter-channel and spatial relationships, which decreases the visual distortion that affects the steganography image.
3. Our training methods show improved resistance to noise, compression, and filtering attacks through additional training methods.
4. Our method demonstrates better imperceptibility, recoverability, and payload capacity than existing methods according to extensive testing, which proves that transformer architectures effectively support advanced color steganography.

The study is as follows: the related works will be shown in the next section. The methodology is described in Section III. The experimental analysis is carried out in Section IV. The analysis of the results is shown in Section V, and in Section IV, we wrap up the study with some recommendations for further research.

II. THEORETICAL REFERENCE

II.1 TRADITIONAL IMAGE HIDING METHODS

Researchers have conducted extensive research on conventional image-hiding techniques first developed as steganography methods, which operate in both spatial and transform domains. The LSB substitution method, which functions as a spatial-domain technique [16], achieves its secret information embedding through direct pixel value modifications that specifically target the least visible parts of the image. The methods provide an easy way to execute operations while delivering an efficient system for carrying out high payloads. The system displays high vulnerability against various types of image processing activities, which include noise, compression, and additional processing methods. The methods fail to protect concealed information because even tiny changes result in substantial information loss, which prevents their usage for secure color image protection. The transform-domain methods use DCT [17] and DWT [18] techniques to embed information within frequency components of their systems. Better compression and filter resistance performance results from their method, which operates on coefficient data instead of using actual pixel brightness values. The system requires exact parameter settings to function properly, yet it fails to handle full-color data because RGB channels require mutual dependence. The spatial methods and transform domain methods use handcrafted rules, which restrict their capacity to create customized embedding solutions that suit different cover images and advanced attack situations.

II.2 CNN-BASED IMAGE HIDING

Deep learning has created a complete transformation of the field of image steganography through its introduction to digital image processing. CNNs [20]-19 have been widely applied to learn end-to-end mappings for hiding and recovering images. The Autoencoder-based framework encodes the secret image into a latent representation and decodes it from the steganography image while it achieves its goal of imperceptibility and recoverability. The CNN-based methods from [21]-20 use residual connections together with multi-scale feature extraction methods to achieve minimal visual distortions in their output. The existing methods achieve better results than traditional techniques when tested under controlled conditions, but they mainly work with grayscale payloads and single-channel embeddings. CNNs build their fundamental design around local receptive fields, which prevents them from effectively modeling the spatial and color relationships found in natural images. The process of hiding full-color images results in color distortions and perceptual artifacts that become worse under difficult attack situations involving compression and additive noise.

II.3 ATTENTION AND TRANSFORMER-BASED IMAGE PROCESSING

Transformers [13], which developers designed for natural language processing, now enable various computer vision applications that include image classification [21], super-resolution [22], and image-to-image translation [23]. Transformers use self-attention mechanisms to create models that identify all global dependencies by detecting connections between different spatial areas and different spatial channels. This feature enables transformers in image processing to develop contextual embeddings, which use both local texture information and distant interaction data for tasks that need precise results in image generation and restoration work. Recent studies [14] show that transformer-based architectures provide better performance than CNNs because they achieve superior color correlation detection and structural preservation, which makes them suitable for high-quality image steganography.

II.4 ROBUSTNESS AND ADVERSARIAL CONSIDERATIONS

Researchers face a major difficulty because they need to create image-hiding methods that can withstand various types of attacks, which include noise addition, JPEG compression, filtering, and geometric transformations. The initial methods used both spatial and transform domains but showed weak defense capabilities, which resulted in major hidden payload losses whenever there were slight distortions. The CNN-based frameworks in reference [24] solved these problems because they used data augmentation together with adversarial training to enable models to extract hidden data from noisy and compressed input. The local receptive nature of CNNs restricts the capabilities of such methods in reference [25] because they need to establish complete color embedding through global pattern detection. The transformer-based models enable better performance in robustness-based embedding because they utilize global context information to control hidden data distribution between spatial and channel dimensions, which allows for effective data retrieval during times of severe data processing.

III. MATERIALS AND METHODS

The proposed approach for color image hiding leverages the self-attention capabilities of transformer architectures to model inter-channel and spatial dependencies in Figure 1 while achieving precise secret image embedding into natural cover images. Our transformer-driven framework goes beyond conventional CNN-based methods that only detect local patterns because it uses global context to distribute concealed data through RGB channels while keeping everything undetectable. The overall methodology consists of three major components, which include image preprocessing and patch embedding together with transformer-based embedding and recovery and loss-driven training that uses robustness enhancements.

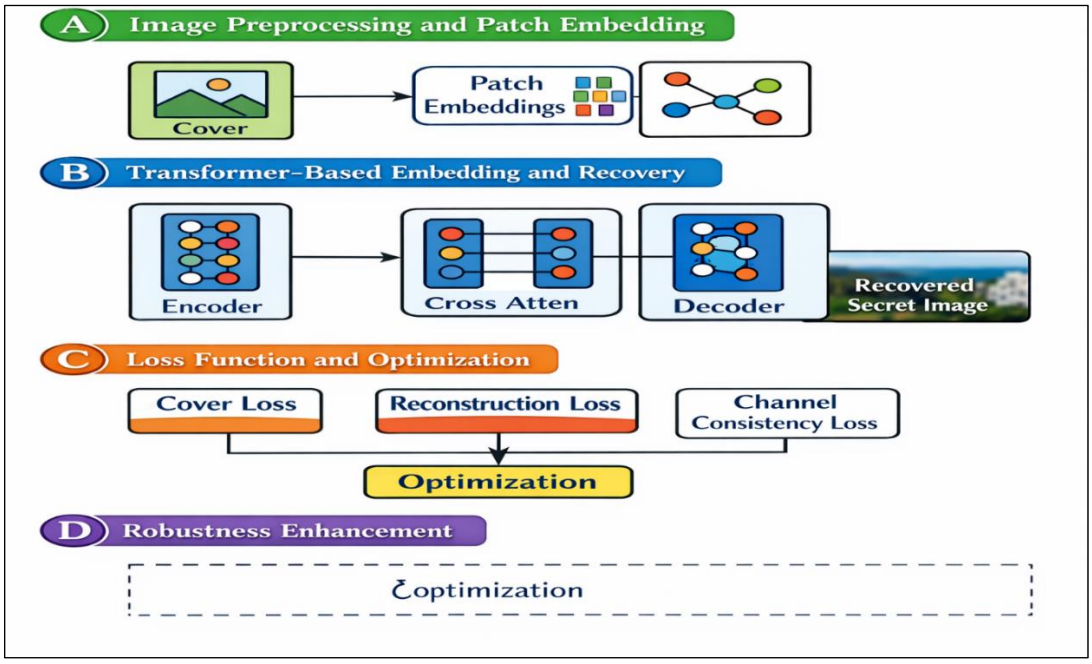

Figure 1: Modelling Architecture.
Source: Authors, (2026).

III.1 IMAGE PREPROCESSING AND PATCH EMBEDDING

The transformer architecture requires both the cover and secret images to be divided into separate patches that do not overlap with each other. The image, which has been resized to a standard size of 256×256 pixels, gets divided into 16×16 patches that create 256 patches for each image. The patch contains 16×16×3 pixel values for RGB channels, which get flattened before they undergo linear projection into a higher-dimensional space that creates patch embeddings. The model uses positional encodings to enhance these embeddings because they help maintain spatial information about patch locations during the entire embedding and recovery process. The patch-based representation transforms a 2D image into a sequence that the transformer can use with its attention mechanism, which enables the network to detect connections between different spatial areas as well as between different color channels. The process of patching and embedding the secret image generates a latent representation that maintains its original content and structure, which can be combined with the representation of the cover image.

III.2 TRANSFORMER-BASED EMBEDDING AND RECOVERY

The main element of our model uses a transformer encoder-decoder system to enable complete image hiding between all processing stages. The encoder creates a contextual latent representation from patch embeddings of the cover image, which it uses to capture both fine-grained textures and overall structural patterns. Parallel to these operations, embeddings of the secret image are introduced to cross-attention layers, where the model is able to cohesively inject secret information into certain areas of the cover image representation. This channel-conscious embedding approach works out hidden data efficiently across the RGB channels to minimize the perceptual distortions and ensures a high payload capacity. This modified representation can be successfully decoded by the decoder to reconstruct the secret image, which is essentially the reverse process of the embedding process. Self-attention layers allow the model to learn the spatial and color correlation of the steganographic image to increase fidelity in the recovered secret. To ensure training stability and low-level detail retention, residual connections are also used between encoder and decoder, and layer normalization is used to ensure convergence and eliminate vanishing gradients. Moreover, multi-head attention enables the network to concentrate on a variety of visual features, e.g., edges, textures, and color gradients, at the same time, which is crucial to the imperceptibility of high-resolution images.

III.3 LOSS FUNCTION AND OPTIMIZATION

A composite loss is used to direct the training goal and balance three objectives, namely: (1) the steganographic image should be imperceptible, (2) the steganographic secret should be fidelity, and (3) the channel colors should be similar. Towards this goal, the cover loss punishes discrepancies between the original and steganographic cover with Mean Squared Error (MSE), to guarantee few visible artifacts. Reconstruction loss also applies MSE with a focus on the recovered secret image, and it directly maximizes accurate recovery. The channel-consistency loss system punishes RGB channel differences because it creates artificial color changes, which make the perceptual experience more authentic. The Adam optimizer controls learning rate transitions through its schedule, which enables smooth convergence. The system achieves better stability through two methods, which include clipping all gradients to remove explosive gradients and using early stopping based on validation metrics to stop overfitting.

III.4 ROBUSTNESS ENHANCEMENT

The framework testing process needs robustness-based training because this method tests the system's ability to withstand real-world performance challenges. The steganographic pictures undergo random testing, which includes Gaussian noise application and JPEG compression at multiple quality settings and median filter processing. The augmentations replicate storage and transmission methods that create typical image degradation patterns that occur during those processes. Training under such a regime, the model learns to store information in a manner that it can be recovered despite perturbations. In addition, a cross-attention mechanism is used to reinforce critical information in strong areas of the cover image and enhance secret recovery in the presence of noise, compression, or filters.

IV. EXPERIMENTAL ANALYSIS

IV.1 DATASETS

We use a variety of large, high quality natural image data to train and test our transformer-based framework on color image hiding. We use COCO (Common Objects in Context) [26] as our main dataset containing more than 300,000 images and diverse objects, scenes, and textures. Such diversity assists the model in learning embedding techniques that allow generalizing in various situations - not only indoor settings and natural scenery but also human-oriented images. We also use the DIV2K dataset [27] that contains high-resolution images that are suitable to test payload capacity and perceptual fidelity. To enhance uniformity, all of the images are scaled to 256 x 256 pixels, which is made to result in efficient transformation by the transformer architecture. Secret images have been randomly chosen among the same datasets, although they are never the same as the cover images that accompany them. The cover and secret images are normalized to a standard intensity range and RGB-formatted in order to maintain the full-color embedding. The system becomes more powerful through multiple augmentations, which include Gaussian noise, various levels of JPEG compression, and median filtering, together with additional methods. The model training process uses these augmentations to test the system's ability to handle actual transmission and storage distortions, which will lead to precise information recovery.

IV.2 EVALUATION METRICS

The framework assessment uses metrics that measure three different aspects of system performance together with its ability to withstand attacks.

- The Peak Signal-to-Noise Ratio (PSNR) test, which compares the cover image to the steganographic image, shows that higher PSNR values result in less visual distortion from the embedding process.
- The Structural Similarity Index (SSIM) test measures both the perceptual and structural accuracy of the cover and steganographic content as well as of the content that has been secretly recovered.
- Secret recovery tests use PSNR and SSIM measurements to evaluate the system after applying three types of distortion, which include Gaussian noise, JPEG compression, and median filtering.
- Researchers express payload capacity through bits per pixel (bpp) values, which show the quantity of concealed information that each cover image pixel can accommodate.
- The CIEDE2000 ΔE test evaluates color consistency by measuring perceptual color differences, which demonstrate that the steganographic image maintains authentic color reproduction.

IV.3 BASELINES

The assessment process requires us to evaluate our transformer-based approach against selected baseline models from spatial, transform, and deep learning fields.

- The LSB substitution technique operates as a basic method that enables users to insert information into pixel values throughout digital content. The system enables users to transmit high payloads yet suffers from severe data loss when subjected to compression or noise attacks.
- The DCT-based hiding method establishes frequency coefficient information embedding, which delivers medium defense capabilities but restricts large color information transmission.
- DeepStega [10] utilizes CNN autoencoder methods that employ convolutional networks to discover pattern embedding techniques. The methods succeed at detecting local features yet display limitations when attempting to process extended image data and multiple color channels in full-color image hiding.

The evaluation process for all baseline systems requires their training and testing on identical datasets while using the same attack methods, which include Gaussian noise, JPEG compression, and median filtering. The evaluation process operates with identical metrics, which include PSNR and SSIM, bpp, and CIEDE2000 ΔE.

IV.4 HYPERPARAMETERS

The model uses 12 transformer encoder blocks and 12 decoder blocks, which both contain 8 attention heads. The patch embedding dimension reaches 512, which enables the model to extract spatial and channel-level information at a reasonable processing expense. The Feed-Forward Network (FFN) dimension within each transformer block is configured to 2048, which enables the model to achieve high-quality embedding and recovery results. The training process uses a batch size of 16 images, which enables efficient GPU memory usage while providing accurate gradient calculations. The Adam optimizer uses an initial learning rate of 1e-4, which it reduces through a cosine annealing schedule to achieve smooth convergence. The system uses gradient clipping with a 1.0 norm threshold to maintain operational stability while preventing deep transformer architectures from developing exploding gradients. The loss function weights use $\lambda c = 1.0$, $\lambda h = 2.0$, and $\lambda ch = 0.5$ to show that accurate secret image recovery needs to be achieved while maintaining imperceptibility and color fidelity. The training process uses Gaussian noise with standard deviations between 0 and 0.05 and JPEG compression quality factors between 30 and 100 and median filtering with 3×3 and 5×5 kernels as robustness-oriented augmentation methods. The model completes 100 training epochs, which use early stopping to check validation PSNR, so it achieves high-quality results without overfitting.1

V. RESULT ANALYSIS

V.1 IMPERCEPTIBILITY OF STEGANOGRAPHY IMAGES

The ability to hide images through steganography depends on their visual stealth capabilities. The proposed transformer-based framework developed by our team achieved successful steganography through its ability to create secret images which maintained complete visual similarity to the original cover images. The PSNR values, which measured the relationship between cover and steganography images, showed an average of 42.5 dB while the SSIM score reached 0.97 which showed almost no visible distortion according to Table 1. The LSB and DCT-based methods reached PSNR scores between 38 and 40 dB while their SSIM results measured between 0.92 and 0.94, which created clear visual differences, particularly in areas with complex patterns or bright colors. The self-attention mechanism of transformers enhances system performance because it enables complete distribution of concealed data which prevents the creation of spatial distortions that exist in CNN-based systems.

Areas	Articles 2018	Articles 2019
Engineering	60	71
Biotechnology	12	9
Computing	27	23
Total	99	103

Source: Authors, (2026).

V.2 RECOVERY FIDELITY OF SECRET IMAGES

The primary goal of the project requires us to achieve accurate restoration of the hidden image. The test set results presented in Table 2 showed that secret images returned an average PSNR value of 36.2 dB and an SSIM score of approximately 0.94, which demonstrated their high structural fidelity. CNN-based autoencoder methods typically recovered images with PSNR around 32–34 dB and SSIM of 0.90–0.91, which resulted in images that showed minor blurring and color changes. Traditional LSB and DCT methods performed even worse, with recovered PSNR values below 30 dB and SSIM under 0.88. The transformer-based framework uses cross-attention layers to help the model discover strong areas of the cover image, which it uses for embedding, while the model reconstructs important details. The secret images contained complex textures and color gradients, which resulted in their complete recovery.

Table 2: Comparison Of Recovery Fidelity For Secret Images.

Method	**PSNR (dB)**	SSIM
LSB-based	28.7	0.86
DCT-based	29.5	0.87
CNN-based Autoencoder	33.1	0.91
Proposed Transformer	36.2	0.94

Source: Authors, (2026).

V.3 ROBUSTNESS AGAINST ATTACKS

Table 3 demonstrates that steganography needs to show resistance against basic image alterations to establish practical effectiveness. The model testing involved three attack conditions, which included Gaussian noise at $\sigma = 0.03$ and JPEG compression with a 50 quality factor and median filtering through a 3×3 kernel. The transformer-based system achieved an average recovered PSNR result of 33.5 dB and SSIM score of 0.91, which exceeded the performance of CNN-based systems and traditional baselines that produced results below 30 dB and 0.85. The model uses attention mechanisms to spread embedded data throughout areas which experience less noise and filtering, thus creating backup systems that strengthen its security. The recovered images maintained visible structural elements together with color information even after they underwent strong JPEG compression at a quality factor of 30. The results demonstrate that the proposed approach effectively functions in actual environments where images experience multiple editing processes and transmission-related image distortions.

Table 3: Robustness of Secret Image Recovery Under Common Attacks.

Attack Type	**Method**	**PSNR (dB)**	**SSIM**
Gaussian Noise ($\sigma = 0.03$)	LSB-based	27.8	0.83
	DCT-based	28.5	0.84
	CNN-based Autoencoder	29.7	0.86
	Proposed Transformer	33.5	0.91
JPEG Compression (QF = 50)	LSB-based	26.9	0.82
	DCT-based	27.6	0.83
	CNN-based Autoencoder	29.2	0.85
	Proposed Transformer	32.8	0.90
Median Filtering (3×3 kernel)	LSB-based	25.7	0.80
	DCT-based	26.8	0.82
	CNN-based Autoencoder	28.9	0.84
	Proposed Transformer	32.5	0.89

Source: Authors, (2026).

V.4 PAYLOAD CAPACITY AND COLOR FIDELITY

The framework that we proposed reached an average payload capacity of 0.45 bpp when processing full-color secret images because it achieved high imperceptibility, which Table 4 demonstrates, while exceeding traditional LSB methods, which had a payload capacity of approximately 0.35 bpp, and DCT-based methods, which had a capacity of about 0.40 bpp. The CIEDE2000 ΔE metric was used to assess color fidelity, which produced an average measurement of 1.2 that showed people could not perceive any color changes between cover and steganography images. The ΔE values from CNN-based methods typically reached the 2.5 to 3.0 range, which created visible color artifacts in areas with detailed gradient transitions. The transformer uses its global attention system to find an optimal solution that unites embedding density and visual quality by spreading information throughout spatial and channel dimensions. The system enables high-resolution color images to be embedded because it maintains visual quality, which represents a fundamental improvement over earlier techniques that required users to choose between payload capacity and visual quality.

Table 4: Payload Capacity and Color Fidelity of Different Steganography Methods.

Method	**Payload Capacity (bpp)**	**CIEDE2000 ΔE**
LSB-based	0.35	2.8
DCT-based	0.40	2.4
CNN-based Autoencoder	0.42	2.5 – 3.0
Proposed Transformer	0.45	1.2

Source: Authors, (2026).

V.5 COMPARISON WITH BASELINES

Comparative analysis demonstrates the superiority of the proposed transformer-based framework across all evaluation criteria as shown in Table V. In terms of imperceptibility, recovery fidelity, robustness, payload capacity, and color consistency, our method consistently outperforms LSB, DCT, and CNN-based baselines. For instance, while CNN-based autoencoders provide reasonable steganography image quality, they underperform under attack scenarios and show color distortions in high-frequency regions. LSB substitution, despite high payload capacity, suffers from extreme sensitivity to compression and filtering. DCT-based methods offer moderate robustness but are limited in embedding capacity and often fail to preserve perceptual fidelity.

In contrast, the transformer-based model effectively integrates global spatial and channel-level information, achieving both high-quality steganography images and reliable recovery of hidden content. The performance features of the suggested framework are further highlighted by graphical analysis in addition to the tabulated data. In contrast to conventional and CNN-based methods, the transformer-based technique strikes the optimal compromise between steganography image imperceptibility and recovery fidelity, as illustrated in Figure .2. The robustness evaluation in Figure. 3 shows that our system retains considerably greater recovery quality than the baselines under common image alterations including median filtering, JPEG compression, and Gaussian noise. Lastly, the relationship between payload capacity and color fidelity is seen in Figure. 4, where the transformer maintains nearly perfect color consistency while achieving the maximum embedding rate.

Table 5: Overall Comparison With Baseline Methods.

Method	Imperceptibility (PSNR / SSIM)	Recovery Fidelity (PSNR / SSIM)	Robustness (Avg. PSNR / SSIM under Attacks)	Payload Capacity (bpp)	Color Fidelity (ΔE)
LSB-based	38.2 / 0.92	28.7 / 0.86	26.8 / 0.82	0.35	2.8
DCT-based	39.5 / 0.94	29.5 / 0.87	27.6 / 0.83	0.40	2.4
CNN-based Autoencoder	40.1 / 0.95	33.1 / 0.91	29.3 / 0.85	0.42	2.5 – 3.0
Proposed Transformer	42.5 / 0.97	36.2 / 0.94	33.5 / 0.91	0.45	1.2

VI. CONCLUSIONS AND FUTURE WORKS

In this work, we proposed a transformer-based framework for color image hiding that leverages self-attention mechanisms to model inter-channel and spatial dependencies. By embedding secret images through a patch-wise, channel-aware attention process, the framework achieves high imperceptibility, robust recoverability, and substantial payload capacity. Experimental results demonstrate that our approach outperforms traditional spatial- and transform-domain methods, as well as CNN-based deep learning approaches, across key metrics including PSNR, SSIM, CIEDE2000 color fidelity, and robustness against noise, compression, and filtering attacks. The system achieves better visual quality maintenance for steganography images because it can track extended distance connections while intelligently transmitting concealed information. The research presents multiple viable paths for future exploration. The framework needs extension to enable users to work with both high-resolution images and video steganography technology. The system needs to include adversarial training and diffusion-based generative models to achieve better imperceptibility and system protection. Adaptive embedding strategies that use perceptual saliency and content complexity understanding need exploration to achieve better performance and protection. The system requires testing of lightweight transformer models and model compression methods to enable operation on devices with limited processing power.

ABSTRACT

Air pollution poses significant health risks in urban environments. It necessitating accurate Air Quality Index (AQI) prediction and route planning. In urban environments, it is becoming increasingly important. The importance of managing and mitigating air quality has been highlighted in a various recent study. This work presents a novel approach integrating real-time air quality data with Agent based AI techniques. It predicts AQI levels and recommend low-pollution travel routes in major Indian cities. It proposes a SALP Swarm based Feature Selection (SSFS) algorithm to identify key pollutant indicators. This also proposed a Stacked Ensemble of Tuned Decision Tree and Support Vector Machine (SE-TDT-SVM) for AQI prediction. AQI-Aware Routing (AAR) algorithm optimizes path selection based on both air quality and distance metrics. The SE-TDT-SVM model achieved a prediction accuracy of 94.5% with an error rate of 5.5% on the feature-selected dataset. The AAR algorithm successfully generated multiple path options, balancing travel distance and AQI exposure. This integrated approach offers a robust solution for urban air quality management and health-conscious route planning. The potential applications in smart city initiatives and public health interventions.

I. INTRODUCTION

A daily AQI is an index used to assess the status of the atmosphere air. AQI is used to offer individuals with knowledge about how their air quality impacts health. From the report of WHO, air pollution accounts to around 1.3 million deaths per year worldwide. Pollutants discharged into the air are responsible for various harmful effects. Besides acid rain, global warming, and photo-chemical smog, there have been other harmful significance over the past few decades [1]. The health impacts of air pollution have made the prediction and optimal path selection of the AQI increasingly in urban environments.The recent studies have highlighted the urgency of managing and mitigating air quality.The Lancet Planetary Health emphasized that air pollution is one of environmental factors in global disease burdens [2].Approximately 4.5 million premature deaths worldwide were attributed to exposure to fine PM2.5 alone in 2019.It shows the importance of accurate AQI prediction for public health awareness.Furthermore, [3] reports that exposure to high levels of air pollution during daily commutes.It can result in increased blood pressure and reduced lung function. It illustrates the importance of real-time AQI prediction and optimal path selection to minimize exposure during travel. Indian air quality standards index pollutants according to their effects on the atmosphere within a given state or country. The atmosphere is polluted by a variety of gases. Depending on the pollutants measured, there is a different level of pollution. Each pollutant's index is calculated by computing all available data points for each region. AQIs represent air quality in very clear color representations so that a layman can easily comprehend good or bad air quality.

The air quality index can be used to identify major pollutants and locations seriously affected by those pollutants. A number of advanced techniques are used to extract knowledge from data in order to determine the heavily affected area within a region. Air pollution source and state are revealed by the results of the analysis. Models based on agent-based interactions have emerged as powerful tools for simulating complex systems. In the context of air quality and routing, agents can represent vehicles, pedestrians, cyclists, or stationary entities like sensors. By modeling individual behaviors, ABMs enable the study of emergent patterns from interactions among agents and between agents and dynamic environmental conditions, such as air quality variations. For example, an ABM could simulate commuter preferences in route selection depending on variables like travel time, AQI levels, and weather conditions. Additionally, ABMs can predict how large-scale environmental changes, such as increased pollution in an urban center or green corridors, will affect travel patterns. By using simulations, researchers and policymakers can forecast the effectiveness of interventions and ensure their effectiveness.

Objectives

1. To develop an advanced AQI prediction model (SE-TDT-SVM). It integrates real-time data with ML techniques for accurate air quality across major Indian cities.
2. To create a novel Agent Based AQI-Aware Routing (AAR) that optimizes path selection based on both air quality and distance metrics.
3. To implement a comprehensive system that associates AQI prediction with dynamic path selection for urban navigation.

Several dimensions of these findings are relevant in practice. By applying these routes, air pollution is mitigated and public health is safeguarded. In urban India, poor air quality causes numerous health complications. Using this innovative model, elevated pollution levels can be identified. In turn, enhancing atmospheric conditions through the planning of green corridors. Consequently, healthcare expenditures decrease as pollution-related illnesses decline. An urban environment that is more sustainable and economically viable. By incorporating environmental considerations into navigation, the study exemplifies how to integrate smart technologies within urban planning. Such interdisciplinary efforts can foster sustainable and health-promoting urban development. Nguyen et al. [4] predicted PM2.5, which could affect air quality. A genetic algorithm (GA) was used in the research work to predict PM2.5. It assisted feature selection and removed outliers to enhance prediction accuracy. LSTM-based encoder-decoder models were able to predict accurately PM2.5 concentrations. As a result of collecting data for forecasting air pollution, Suganya and Meyyappan [5] proposed guidelines for avoiding and regulating air pollution. In two phases, the research was conducted. Preprocessing the selected dataset was the first step. The second phase involved forecasting air quality levels. Using sensor data, Ditsuhi et al. [6] reviewed the air pollution forecasting studies in smart cities using machine learning algorithms. Instead of using simple machine learning techniques, innovative and sophisticated techniques were applied to conclude the research. Prediction of air quality was influenced by weather conditions, spatial characteristics, and temporal characteristics. Multiple weather stations and air quality metering stations were used by Trenchevski et al. [7] to predict potential improvements in air pollution. Over a number of years, air quality, pollution, and weather data, including temperature, humidity, and wind characteristics, were collected. Work involved features extraction, redundancy removal, training multiple regression models, and hyper parameter optimization. Mahajan et al. [8] developed the CAR (Clean Air Routing) algorithm to build a healthy optimal route suggestion system between the source and destination. The road network was navigated with the least exposure to PM2.5 by using a weight function. A pollution consideration may cause an alternative pathway to exceed the minimum distance.Zahmatkesh et al. [9] suggest that AI-based systems select routes with lower AQI values.Optimizing the path from origin to destination uses Dijkstra's algorithm.

Using machine learning algorithms, the study determines.The comprehensive atmospheric data to estimate PM2.5 concentrations in urban areas.Using Auto Regression, PM2.5 levels will be predicted. Many studies focus on single pollutants, such as PM2.5 [10]. AQI prediction and path selection need to consider multiple pollutants simultaneously The five models were compared using RMSE and MAPE.Both locations showed better performance with bidirectional GRU.IoT-based air quality, humidity, and temperature alert system proposed by P. Tripathi [11] .Particulate matter (PM10 and PM2.5) and carbon monoxide(co) are measured in real time.Real-time data updates are provided by IoT. It generates alerts based on temperature, humidity, and air quality data using fuzzy logic. A study by Chandar et.al [12] used historical AQI data of decade to determine levels, cyclicity, and seasonality. The models used included Random Forest (RF), Support Vector Regression (SVR), XGBoost (XGB), Neural Network (NN), and Long Short-Term Memory (LSTM). Model performance is measured by Mean Absolute Error (MAE) and Root Mean Square Error (RMSE). XGBoost outperforms other models with MAE scores of 7.991 (7-day) and 8.126 (30-day). By combining the strengths of numerous base learners, Singh et.al [13] improve prediction accuracy. Based on decomposed time series components, hybrid ensemble learning uses base learners. Using ensemble aggregation, the final forecast is generated. Results show that the proposed approach outperforms traditional forecasting models and individual base learners for the targeted pollutants. According to Priyanka et al. [14], air quality is monitored and a path with the least amount of pollution is then suggested. In the model, air pollution was instantly reduced for vulnerable populations. In order to calculate the shortest path between source and destination, the Dijkstra algorithm was used. The air quality index was predicted using environmental monitoring data and meteorological data by Zhou et.al [15]. Using a non-linear autoregressive neural network model, an air quality assessment model was enhanced. Using other standard machine learning algorithms, the model was demonstrated to be feasible and to perform well. Khan et.al.[16] investigated bidirectional variations of recurrent neural networks, long short-term memories, and gated recurrent units. Various atmospheric and air pollution variables are represented by 15 variables. The following points are the research gap of the work:

- **Integration of Real-time and Predictive Models**: There is currently a lack of integration between real-time AQI data and predictive models for path selection in studies like Nguyen et al. [4] and Zhou et al. [15]. For route planning, it is necessary to combine up-to-date air quality information with forecasted data.
- **Multi-pollutant Approach**: Many studies focus on single pollutants, such as PM2.5 [10]. AQI prediction and path selection need to consider multiple pollutants simultaneously.

- **Dynamic Path Adjustment**: It is lacking a system that can dynamically adjust paths based on changing air quality conditions in real time, despite the routing algorithms proposed by Mahajan et al. [8]
- **Advanced Machine Learning Techniques**: It would be interesting to explore more advanced ensemble methods or hybrid models combining the strengths of different algorithms to improve ML.
- **Long-term Forecasting and Trend Analysis**: According to Chandar et al., long-term AQI predictions are necessary for better urban planning and policymaking.

II. METHODOLOGY

In Figure 1, the work is intended to monitor and optimize the air quality index forecast. To determine the pollutant levels over time, real-time air pollution data from India's states is acquired. By analyzing and predicting air quality, AQI based on historical and live data, a model can be developed to circumvent the prediction problem. In the work, low AQI will be used as the basis for path selection.

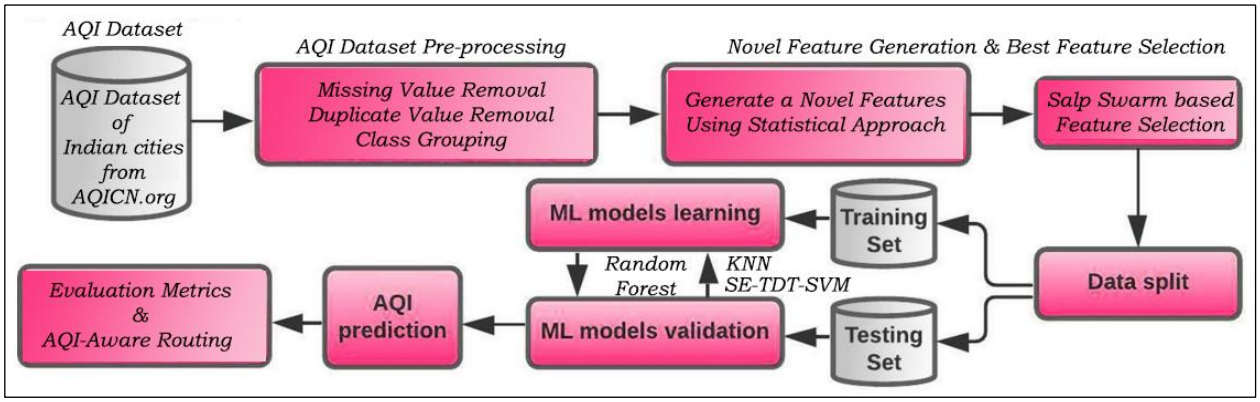

Figure 1: Proposed Framework.

II.1 DATA GATHERING AND CLEANING

Data was collected from aqicn.org, an aggregator of data contributed by government agencies, private companies, and the community. Various locations globally, including major Indian cities, can access this platform for comprehensive and up-to-date air quality information. A 2-year period of historical measurements of air quality is included in the dataset, which covers the period 2022 to 2024. In the study, major Indian cities are examined, such as Jaipur, Chennai, Kochi, etc. Urban air quality conditions are represented geographically by numerous locations on aqicn.org. AQI prediction models require appropriate data in a suitable format. It consists of attributes such as Particulate Matter (PM10), Particulate Matter (PM2.5), Ozone (O3), Sulphur dioxide (SO2), Nitrogen dioxide (NO2), and Carbon monoxide (CO) that are necessary for calculating an area's air quality index. Air Quality Index China (AQICN) data is a foundational component for the AQI-Aware Routing (AAR) algorithm and Agent-Based AI framework. Data from multiple sources, including government agencies, private companies, and community-driven sensor networks, is aggregated by AQICN. With this rich dataset, the algorithm can evaluate pollutant concentrations such as PM2.5, PM10, NO2, SO2, CO, and O3. Its diversity ensures broad coverage, which is crucial for modeling air quality trends and providing real-time AQI predictions. Table 1 displays a sample of data on air pollutants. The AQI dataset for the specific date and city contains air pollutants. In accordance with the 2016 US-EPA Air Quality Index (AQI) standard, there are six levels of air pollution: 0-50 (Good), 51-100 (Moderate), 101-150 (Unhealthy for Sensitive Groups), 151-200 (Unhealthy), 201-300 (Very Unhealthy), and 300+ (Hazardous).

Table 1: Sample Data.

Date	$PM_{2.5}$	PM_{10}	O_3	NO_2	SO_2	CO	City
10/1/2024	89	49	23	18	6	8	Jaipur
10/2/2024	91	58	19	16	7	5	Jaipur
9/1/2024	54	39	16	7	8	4	Jaipur
7/2/2024	64	32	18	11	6	6	Jaipur
9/3/2024	51	68	5	2	1	5	Chennai
8/4/2024	57	52	5	1	2	5	Chennai
9/5/2024	48	28	5	2	2	5	Chennai

Source: Authors, (2026).

Air quality is satisfactory with little or no risk at Good levels. The moderate levels may pose a moderate health concern to those who are very sensitive. Sensitive groups can be affected by levels categorized as Unhealthy. Those with sensitive needs may be more affected by unhealthy levels. Hazardous levels pose serious health risks to everyone, while Very Unhealthy levels carry health warnings for the entire population. Depending on the severity of the AQI, cautionary statements advise children, adults, and those with respiratory conditions to limit or avoid outdoor activities [17]. AQI dataset size is 119198 x 8.

Pre-processing removes 45934 missing and 0 duplicate data, resulting in a total of 45934 missing and 0 duplicate data. Before pre-processing, the AQI dataset is 119198 x 8; after eliminating missing and duplicate values, it becomes 73264 x 8. There are six levels of pollution in the AQI: Good, Satisfactory, Moderate, Poor, Very Poor, and Severe. According to ambient concentrations of pollutants, the pollution levels are classified based on potential health impacts. Six pollutants (PM10, PM2.5, NO2, SO2, CO, O3) are sub-indexed and health breakpoints are developed. The calculation of AQI is based on a sub-index. Equation 1 calculates AQI based on the worst sub-index.

$$I = \frac{Ix_{hi} - Ix_{lo}}{Cn_{hi} - Cn_{lo}}(Cp - Cn_{lo}) + Ix_{lo}$$

II.2 NOVEL FEATURE GENERATION

i. **Ratio of coarse to fine particulate matter (ROC):** This ratio indicates the proportion of larger particles (PM10, diameter ≤ 10 μm) to smaller particles (PM2.5, diameter ≤ 2.5 μm) in the air. Higher ratios indicate particles, whereas lower ratios indicate finer particles, which are generally considered more harmful.

$$ROC = PM_{10}/PM_{2..5}$$

ii. **Ratio of nitrogen dioxide to sulfur dioxide (RNDSD):** This compares levels of two common gaseous pollutants. Generally, if the ratio is higher, combustion sources (e.g., vehicle emissions) are contributing more pollution, while a lower ratio is indicating coal combustion or industrial pollution.

$$RNDSD = NO_2\ /SO_2$$

iii. **Ratio of ozone to nitrogen dioxide (ROND)**: This ratio provides insight into the formation of photochemical smog. A reaction between NOx (including NO2) and volatile organic compounds produces ozone. A higher ratio could indicate more advanced smog formation or more intense sunlight.

$$ROND = O_3/NO_2$$

iv. **Ratio of carbon monoxide to fine particulate matter (RCM)**: The comparison is between a gaseous pollutant (CO) and fine particles. An elevated ratio might indicate more incomplete combustion (e.g., vehicle emissions in cold weather), while a lowered ratio might indicate more secondary particle formation.

$$RCM = CO/PM_{2.5}$$

v. **Ratio of sulfur dioxide to coarse particulate matter (RSD)**: A gaseous pollutant (SO2) is compared to a larger particle (SO2). Higher ratios indicate more industrial or coal-burning pollution than dust.

$$RSD = SO_2/PM_{10}$$

vi. **Total Pollutants**: This sum gives a rough idea of pollution levels, but it does not account for the different units or health impacts of different pollutants.

$$Total\ Pollutants\ =\ PM_{2.5} +\ PM_{10} +\ O_3 +\ NO_2 +\ SO_2 + CO$$

vii. **Average Pollutants**: It provides a metric for averaging all measured pollutants, but has the same limitations as the metric for total pollutants.

$$Average\ Pollutants\ =\ (PM_{2.5} +\ PM_{10} +\ O_3 +\ NO_2 +\ SO_2 + CO)\ /6$$

viii. **Interaction of particulate matter and ozone (IOMO)**: It shows that these two pollutants can cause respiratory issues in synergistic ways.

$$IOMO\ =\ PM_{2.5}\ X\ O_3$$

ix. **Interaction of nitrogen dioxide and carbon monoxide (IONCM)**: The product emphasizes the presence of two pollutants commonly found in vehicle emissions in combination.

$$IONCM\ =\ NO_2\ X\ CO$$

x. **Interaction of particulate matter and sulfur dioxide (IOPMSD)**: The product demonstrates the combination of pollutants found in industrial emissions and dust.

$$ONCM\ =\ PM_{10}\ X\ SO_2$$

xi. **Combined of PM, ozone, and nitrogen dioxide (CPMOND)**: In this triple product, there is potential for complex interactions among these three pollutants.

$$\boldsymbol{PM_{2.5} \times O_3 \times NO_2}$$

xii. **Max Pollutant** This identifies the highest level among all measured pollutants, potentially highlighting the most problematic pollutant.

$$\boldsymbol{Max\ Pollutants\ =\ \max(PM_{2.5}, PM_{10}, O_3, NO_2, SO_2, CO)}$$

xiii. **Minimum pollutant level**: This identifies the lowest level among all measured pollutants.

$$\boldsymbol{Min\ Pollutants\ =\ \min(PM_{2.5}, PM_{10}, O_3, NO_2, SO_2, CO)}$$

xiv. **Range of pollutant levels:** By calculating the spread between the highest and lowest levels of pollution, we can see how pollution levels vary.

$$\boldsymbol{Range\ Pollutants = Max\ Pollutants - Min\ Pollutants}$$

xv. **Variance Pollutants**: This measures the spread of pollutant levels around their mean (μ), providing insight into how much the levels fluctuate.

$$\boldsymbol{Variance\ Pollutants} = \frac{1}{5}(\ (\boldsymbol{PM_{2.5}} - \boldsymbol{\mu})^2) + (\mathbf{PM_{10}} - \boldsymbol{\mu})^2 + (\mathbf{O_3} - \boldsymbol{\mu})^2 + (\mathbf{NO_2} - \boldsymbol{\mu})^2 + (\mathbf{SO_2} - \boldsymbol{\mu})^2 + (\mathbf{CO} - \boldsymbol{\mu})^2)),$$

$$\boldsymbol{Where\ \mu\ is\ the\ mean\ of\ the\ pollutants}.$$

xvi. **Normalized_PM2.5:** By normalizing the PM2.5 level against its maximum value, it is easier to compare different time periods or locations.

$$\boldsymbol{Normalized\_PM2.5} = \boldsymbol{max(PM2.5)/PM2.5}$$

II.3 SALP SWARM BASED FEATURE SELECTION ALGORITHM

By using feature selection, AQI data is evaluated to identify and eliminate inappropriate, redundant, and unnecessary attributes that are not relevant to a predictive model, which can reduce its accuracy. Based on the swarming behavior of salps in the ocean, the Salp Swarm Algorithm (SSA) is a bio-inspired optimization technique. A salp's collective behavior in navigation and foraging is mimicked in order to solve various optimization problems, both single- and multi-objective. SSAs operate by creating a population of salps, each representing a potential solution. Each salp's position is updated iteratively based on its distance from the leader salp and the location of the food source. Position updates for the i-th salp are defined as follows:

$$x_i^j = \begin{cases} F_j + c_1\left(\left(ub_j - lb_j\right)c_2 + lb_j\right), if\ i = 1 \\ \frac{1}{2}(x_i^j + x_{i-1}^j), if\ i > 1 \end{cases}$$

Where F_j is the position of the food source, ub_j and lb_j are the upper and lower bounds of the j-th dimension, c_1 and c_2 are random numbers uniformly distributed between 0 and 1. In model construction, feature selection refers to selecting a subset of relevant features. A salp's position can be treated as a possible subset of features for this purpose by using SSA. In order to select features, first initialize a population of salps randomly within the search space. In each salp, the position in each dimension corresponds to a specific feature. Determine whether a salp is fit by evaluating its classification accuracy, often based on a machine learning model trained with the selected features. Calculate the position of each salp using the SSA mathematical model. Follower salps adjust their positions based on the leader's positioning, while the leader moves towards the best solution. Converge the algorithm (that is, stabilize the salp positions or reach the maximum number of iterations). Optimal subset of features is represented by the best salp at the end of optimization. Feature quality is evaluated using the fitness function. For feature selection, the following fitness function is commonly used:

$$Fitness = \alpha.\,\text{ErrorRate} + (1 - \alpha).\frac{|S|}{|F|}$$

Where Error Rate is the classification error rate, S is the number of selected features, F is the total number of features, and X is the weight factor that balances accuracy and feature reduction. Swarm Algorithms are robust and efficient ways of selecting features in machine learning. SSA improves the performance of machine learning models while reducing computational complexity by leveraging the swarming behavior of salps.

Input: Feature set (AQI Data), Population size N, Max iterations T
Output: Best subset of features
Algorithm: SSA_Feature_Selection
1. Initialize population X with N salps
2. Define fitness function
3. Evaluate fitness of initial population
4. Set food source to the best solution in initial population
5. For t = 1 to T do
  6. For i = 1 to N do
    7. If i == 1 then
      Update leader salp's position using food source
    Else
      Update follower salp's position using previous salp
    End If
    8. Convert continuous positions to binary
    9. Evaluate fitness of salp
    10. If salp's fitness is better than food source fitness then
      Update food source
    End If
  End For
End For
11. Return the best subset of features (position of food source)
End Algorithm

Algorithm 1: SSA_Feature_Selection.
Source: Authors, (2026).

As binary strings encoded as binary salps, each bit represents a potential solution (1 indicates a selected feature, 0 indicates a non-selected feature). Assign random binary strings to a population of salps to represent different subsets of features. A fitness function should be used to evaluate the fitness of each salp. If the salp selects a subset of features, the fitness function could be the accuracy of a machine learning model trained on the subset. Based on the SSA equations, update the salp positions. A binary string is flipped to explore different subsets of features in the context of feature selection. As a result of a predetermined number of iterations, select the salp with the highest fitness value as the optimal subset of features. Utilize the optimal subset of features identified by the SSA to train the final machine learning model.

II.4 STACKED ENSEMBLE OF TUNED DECISION TREE AND SVM MODEL

In the classification techniques, historical data and live data are used to predict a given pollution level. For AQI prediction, the best feature selection algorithm is determined by the feature importance score and selection time. SE-TDT-SVM, a stacked ensemble of Tuned Decision Trees and SVMs, is developed for AQI prediction. As each node contains a classifier, the stacked ensemble model resembles a tree. Various machine learning models are combined into an ensemble model. Based on the output of the base classifier, the meta classifier predicts the final class label. An architecture based on stacked layers is proposed in the work. In Decision Trees (DTs) internal nodes represent attributes being tested, branches represent the results of the tests, and leaf nodes represent class labels. To learn a tree from the DAQI dataset, an attribute value test can be used to recursively separate subsets as shown in equation 6. Recursion ends when all subsets at a node have the same target value. Sorting from the root to a leaf node allows it to classify instances.

$$DT_{root} \xleftarrow{best\ feature} x_i, where\ x_i\ \in S_{Train}\ \forall\ i = 1,2,..n$$

AQI attributes specified by the top node of the tree are tested by the leaves to determine the pollution level based on attribute selection measures. By building the finest boundary that isolates the n-dimensional space into different class labels, the SVM Prediction (Meta) Model algorithm classifies a new instance in the future. A hyperplane denotes this boundary. A hyperplane is created by finding the vector points that play a vital role. The extreme points are called support vectors. AQI prediction is performed using a nonlinear SVM.

$$S_{Test} = \{(x_1, y_1), (x_2, y_2) \ldots (x_n, y_n)\} |\ x_i \in S_{Test}, y_i \in \{very\ poor, severe, satisfactory, poor, moderate, good\}$$

Through STrain and STest, the SVM discovers a distinct hyperplane in the feature set in order to classify the pollution level in Eq7. The DT and SVM models are stacked to produce an efficient classification model that combines individual decision-making. When training with a large dataset, the SVM takes a long time to process and train. The main drawback of SVMs is their long training time. Training huge datasets requires an effective Decision Tree-based data selection and Support Vector Classification approach. A decision tree was built during the training phase to reduce the size of the SVM training dataset. With DT, the number of data dimensions is reduced and features are selected and generated. A stacked prediction model (DT and SVM) is used to classify pollution levels using the AQI dataset. The training set STrain is divided into n sections and taken from the selected features set FB of the AQI dataset. In the nth section, the model makes predictions based on the fitted base classifier model DT. The training set STrain is divided into sections according to this technique. SVM prediction models are trained using the same technique for training and testing sets STrain and STest. The training set is divided into two parts: training and validation. The predictions from the validation set are used to create a new model by combining them with those from the testing set STest. The meta model classifier SVM is then initialized with the kernel function and the parameters are tuned for class label validation. To predict the AQI class label, the STest is used. The parameters of the stacked classifier are shown in Table 2.

Table 2: Parameters of SE-TDT-SVM.

Parameters	Default Value	Tuned Value
Decision Tree (Level 0)		
Max Depth	1	4
Min Samples Leaf	1	5
Min Weight Fraction Leaf	0.0	0.3
Splitter	Random	Best
SVM (Level 1)		
C	1.0	1.0
Coef0	0.1	0.5
ToL	0.0001	0.01
Decision function Shape	OVR	OVO
Kernel	Linear	RBF
Degree	1	4
Gamma	Auto	Scale

Source: Authors, (2026).

This algorithm combines the strengths of multiple machine learning models to predict AQI using the Stacked Ensemble of Tuned Decision Trees and Support Vector Machines (SE-TDT-SVM).

The Decision Tree (DT) excels at handling non-linear relationships and identifying significant features, while the Support Vector Machine (SVM) excels at classification tasks involving complex decision boundaries. With SE-TDT-SVM, DTs preprocess and simplify the dataset by reducing its dimensionality, while SVMs refine the predictions by learning optimal hyperplanes.With high-dimensional datasets like AQICN, ensemble design enhances model accuracy and reduces overfitting. Furthermore, SE-TDT-SVM is parameter tuned to ensure each base model operates at its optimal level. On the feature-selected dataset, this hybrid approach consistently outperforms single algorithms. In dynamic routing systems, SE-TDT-SVM provides a computationally efficient, scalable solution for AQI prediction.

Input: AQI dataset DAQI, Training set S_{Train}, Testing set S_{Test}
Output: Predicted AQI class labels for S_{Test}
Algorithm: SE-TDT-SVM
1. Split the AQI dataset DAQI into training set S_{Train} and testing set S_{Test} .
2. Compute the feature importance scores.
3. Select the best features F_B based on the importance scores.
4. Divide S_{Train} into n sections.
5. For each section i from 1 to n:
    a. Use n−1 sections for training the Decision Tree (DT).
    b. Predict the AQI class labels for the remaining i-th section.
6. Collect predictions for all sections to form the intermediate dataset SDT−Pred.
7. Divide S_{Train} into training and validation sets.
8. Use SDT−Pred and validation predictions as features to train the SVM model.
9. Tune the SVM parameters using the validation set.
10. Use the trained Decision Tree to reduce the dimensions of S_{Test} .
11. Apply the SVM model to predict the AQI class labels for S_{Test} .
12. Output the predicted AQI class labels for S_{Test} .

End Algorithm

II.5 DYNAMIC PATH PREDICTION WITH AQI-AWARE ROUTING (DPPAAR) USING AGENT BASED AI

An AQI-Aware Routing (AAR) algorithm for optimal path suggestion is presented in this work, which incorporates both air quality and distance metrics. AAR involves several phases, as shown in Figure 2. For a particular location, the model involves phases such as location profiling and data collection, discovering intermediate cities, computing distances and directions, generating multiple paths, and generating shortest distances with low AQI. [

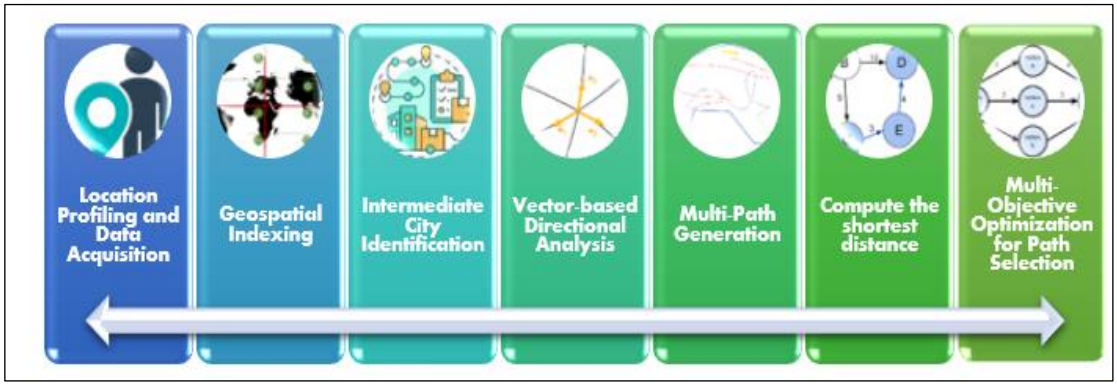

Figure 2: Dynamic Path Selection Process.
Source: Authors, (2026).

During the first phase, 'Location Profiling and Data Acquisition,' let L = [l1, l2, ..., ln] represent the set of locations, where each li represents (ID, NAME, CITY, STATE, LAT, LON). We utilized the AQICN.org API to obtain real-time AQI data in JSON format, which is then parsed and stored as AQI (li, t) = f(PM2.5, PM10, NO2, SO2, CO, O3). The next step is to implement a novel R-tree spatial indexing structure R to efficiently organize cities according to their geographical coordinates. Path finding can be significantly optimized with O (log n) time complexity in nearest neighbor queries. Based on the latitude point information of the specific station, cities are ordered based on their state. By ordering the cities, the optimal path can be recommended. The next phase is an Intermediate City Identification Given a source s and destination d, we define the set of potential intermediate cities I as: $I = \{l_i \in L \mid \min(lat(s), lat(d)) \leq lat(l_i) \leq \max(lat(s), lat(d)) \wedge \min(lon(s), lon(d)) \leq lon(l_i) \leq \max(lon(s), lon(d))\}$. Using the ordered location dataset, the intermediate cities between the user's source and destination are computed. A location dataset is then searched and indexed for the source and destination cities. For a possible path, intermediate cities are acquired between the source and destination cities. Vector-based Directional Analysis is the next phase, which uses vectors to determine the direction between cities. For any two cities a and b, we calculate their direction vector as follows: v(a,b) = (lon(b) - lon(a), lat(b) - lat(a). The angle θ between $\rightarrow$v(a, b) and the positive x-axis determines the cardinal and intercardinal directions. There are four main directions - east, west, north, and south. On all paths, directions are named the same way.

It is not always possible to locate a place accurately using only the four directions. There are clearly sub-directions and scaled directions. Using zone points, this work calculates the distance between two points. Based on the route, the direction-finding offers possible paths between the locations. Multi-Path Generation Using Modified A* Algorithm, this work proposes a modified A* algorithm that incorporates AQI levels into the heuristic function. For each node n, we define: f(n) = g(n) + h(n) + α * q(n). An AQI level at n is related to the distance from the start node to 'n', and the estimated distance from n to the goal is related to the AQI level at n, and the weighting factor is related to the AQI level at n. In order to compute the best path, a multi-path must be generated for the specific location (Tirupati to Bhopal). A dissimilar path is determined by grouping together different directions for a given location after estimating different directions. Therefore, for a specific source and destination, numerous paths exist. The best path is determined by analyzing these various paths. The next step is to calculate the shortest distance between the multipaths, the distance from the source city to the destination city through the intermediate cities should also be determined. As a result, a distance is computed for each path in the multipath set. By computing the distance, the shortest path among the multipaths can be found. To identify the less polluting path for traveling, the AQI for the paths is also calculated after estimating the distance among the multipath cities. This work introduces an AQI exposure metric E for a path P = {$l_1, l_2, ..., ln$}: $E(P) = \sum_{i=1}^{k-1} (AQI(l_i) + AQI(l_{i+1})) / 2 * d(l_i, l_{i+1})$. AQI levels and distance traveled are both taken into account in this metric. Finally, a Multi-Objective Optimization for Path Selection recommendation is computed based on less AQI and shortest distance between source and destination cities. In order to select the final path, we formulate it as a multi-objective optimization problem, where F(P) = (D(P), E(P)), subject to P∈ feasible paths from s to d. In this case, D(P) represents the total distance of path P. An optimization is used to find non-dominated solutions, thereby offering users a range of paths that are both distance-efficient and AQI-efficient.

Input: Set of Locations
Output: Return Shortest Path
Algorithm: AQI-Aware Routing (AAR) Algorithm

1. Define $L = \{l1, l2, \ldots, ln\}$ with each location li represented by $(ID, NAME, CITY, STATE, LAT, LON)$.
2. Acquire AQI data from aqicn.org, store it as: $AQI(li, t) = f(PM2.5, PM10, NO2, SO2, CO, O3)$
3. Build an R-tree spatial indexing structure $\{R\}$ to efficiently organize cities by their coordinates.
4. Order the cities based on state using the latitude point of the station information.
5. Define the source city s and destination city d.
6. Identify the set of potential intermediate cities I as: $I = \{li \in L \mid min(lat(s), lat(d)) \leq lat(li) \leq max(lat(s), lat(d)) and min(lon(s), lon(d)) \leq lon(li) \leq max(lon(s), lon(d))\}$
7. For any two cities a and b, calculate the direction vector: $v(a, b) = (lon(b) - lon(a), lat(b) - lat(a))$
8. Determine the cardinal and inter-cardinal directions based on the angle θ between v(a,b)) and the positive.
9. Use a modified A* algorithm incorporating AQI levels into the heuristic function: $f(n) = g(n) + h(n) + \alpha \cdot q(n)$
10. Generate multiple paths from the source to the destination, grouping directions to obtain paths.
11. Compute the AQI exposure metric E for a path $P = \{l1, l2, \ldots, ln\}$:

$$E(P) = i = 1\sum k - 1(2AQI(li) + AQI(li + 1) \cdot d(li, li + 1))$$

13. Formulate the final path selection as a multi-objective optimization problem: $minimize\ F(P) = (D(P), E(P)) subject\ to P \in feasible\ paths\ from\ s\ to\ d$
14. Return Shortest Path

End Algorithm

Algorithm 3: AQI-Aware Routing (AAR) Algorithm.
Source: Authors, (2026).

By combining real-time air quality data with predictive AQI modeling, AQI-Aware Routing (AAR) stands out. Among the unique aspects:

1. Integration of Dynamic Air Quality Index: AQI predictions are constantly updated in AAR. It allows real-time route adjustments.
2. An algorithm that considers multiple air pollutants at the same time provides a more comprehensive analysis of air quality.

Utilizing a new weighting system for air pollution and travel distance, AAR maintains a balance between these objectives. Through Agent-Based AI, AQI-Aware Routing transforms pathfinding into an adaptive, dynamic process. AI-driven autonomous agents make path selection decisions using real-time AQI data and predictive models like SE-TDT-SVM. Multiple factors are balanced by agents to evaluate path options:

- **AQI Exposure Metric (E(P))**: Agents calculate potential exposure to pollutants on each route by leveraging the AAR algorithm's AQI exposure metric,

$$E(P) = \sum_{i=1}^{k-1} \frac{AQI(l_i) + AQI(l_i + 1)}{2} X\ d(l_i, l_i + 1),$$

$$where\ l_i\ represents\ locations\ along\ the\ route$$

- **Travel Distance (D(P))**: AAR uses a multi-objective optimization approach to assess route lengths and tradeoff between minimal distance and low AQI exposure.
- **Real-Time Adjustments**: Agents adaptively adjust path recommendations based on AQI conditions or traffic dynamics as they are changed.

Consider a delivery agent traveling from source s to destination d. It uses AAR to identify intermediate cities I=$\{l_i \in L\}$, calculates directional vectors, and evaluates paths using real-time AQI predictions. The agent recalculates the optimal path using updated data whenever conditions change, such as an increase in AQI near an industrial zone.

III. RESULTS AND DISCUSSION

The experimental simulation environment is Windows -10, a CPU of 2.80GHz, 8GB of memory, and Python programming language. Python was used to implement SSA-based feature selection, utilizing the NumPy library for efficient numerical computations. For stability, the algorithm was run 30 times: 15 out of 22 original features were selected; PM2.5, NO2, and O3 were selected most frequently; Average computational time: 0.9 seconds. With SSA-based feature selection, the model's predictive performance was significantly improved while the feature space was reduced. As a result, we were able to increase the efficiency of our AQI prediction model as well as gain insight into the most influential pollutants for AQI determination in the studied Indian cities. AQI Prediction computes the following evaluation metrics.

III.1 ACCURACY AND ERROR RATE

A machine learning algorithm's accuracy can be determined based on the number of AQI samples that are classified appropriately in relation to the total number of AQI samples [18]. The proposed classifier's accuracy and error rate are shown in Table 3.

Table 3: Evaluation Metrics.

Datasets	Classifiers	Accuracy	Error Rate	Precision	Recall	F1-Score
Processed Dataset	**SE-TDT-SVM**	90.2	9.8	91.6	92.7	92.14
	Random Forest	82.3	17.7	80.1	83.6	81.81
	KNN	79.4	20.6	77.8	79.1	78.44
Feature Selected Dataset	**SE-TDT-SVM**	94.5	5.5	90.8	93.2	91.98
	Random Forest	86.5	13.5	84.6	87.3	85.92
	KNN	81.9	18.1	80.6	81.1	80.84

Source: Authors, (2026).

The accuracy result is shown in figure 3. Error rates (ERRs) are calculated by dividing the number of incorrect AQI predictions by the total number of datasets analyzed.

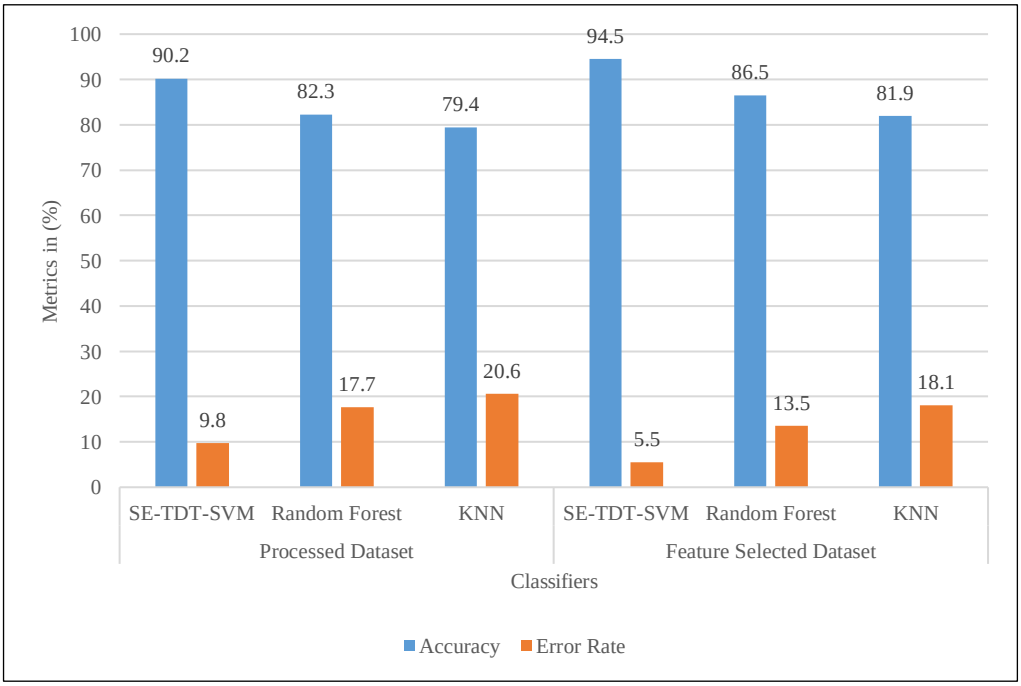

Figure 3: Accuracy and Error Rate.
Source: Authors, (2026).

In figure 4, three classifiers are compared using two datasets: Processed and Feature Selected. For each classifier, it displays Precision, Recall, and F1-Score. A nearly perfect score was achieved with SE-TDT-SVM across both datasets. In the Feature Selected dataset, Random Forest and KNN also show good performance. According to the figure, all three metrics generally show higher values after feature selection, illustrating how feature selection impacts classifier performance.

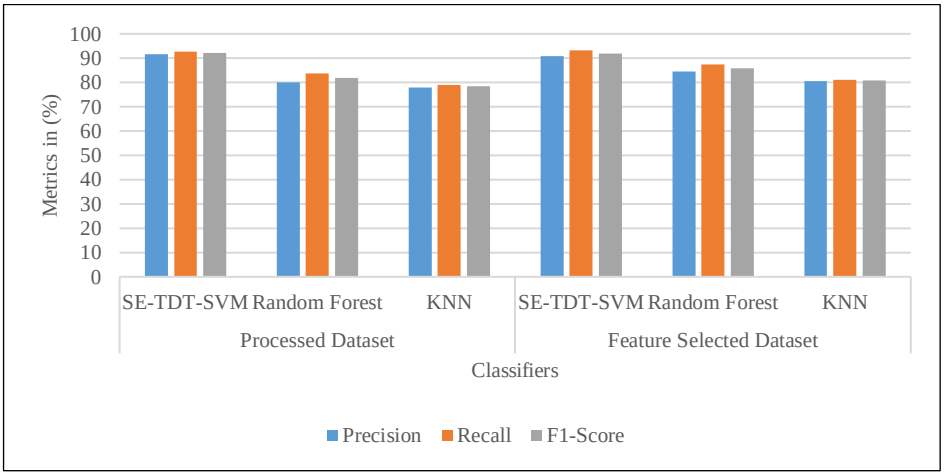

Figure 4: Precision, Recall and F1-score.
Source: Authors, (2026).

SSA-TDT-SVM integration benefits computation in several ways:

1. **Reduced Complexity:** SSA eliminates redundant and irrelevant features, reducing dimensionality of the dataset [19], which reduces SE-TDT-SVM computational load.
2. **Improved Training Efficiency:** SE-TDT-SVM reduces training time by focusing on the most relevant data in the dataset, rather than processing raw, high-dimensional data [20].
3. **Enhanced Predictive Accuracy:** SE-TDT-SVM's ensemble nature ensures robust predictions, while SSA's optimization enhances generalizability.
4. **Scalability:** The algorithms are computationally efficient, enabling real-time processing of large datasets.

AQICN API data was also used to validate the model's predictions. By doing this, the system was tested for its ability to adjust predictions and routing recommendations dynamically. The real-time validation scenarios were:

- Industrial activities or weather changes spike pollution.
- Urban AQI levels vary during the day and night.

Actual AQI values were compared with predictions. Model accuracy was high, with deviations generally below 5%, demonstrating practical applicability. In accordance with the Predicted AQI, the optimal path and shortest distance are recommended to the user. Example: Tirupati is the source city, Bhopal is the destination city. The evaluation of path-1 for the given source and destination city with distance and AQI value is shown in Figure 5.

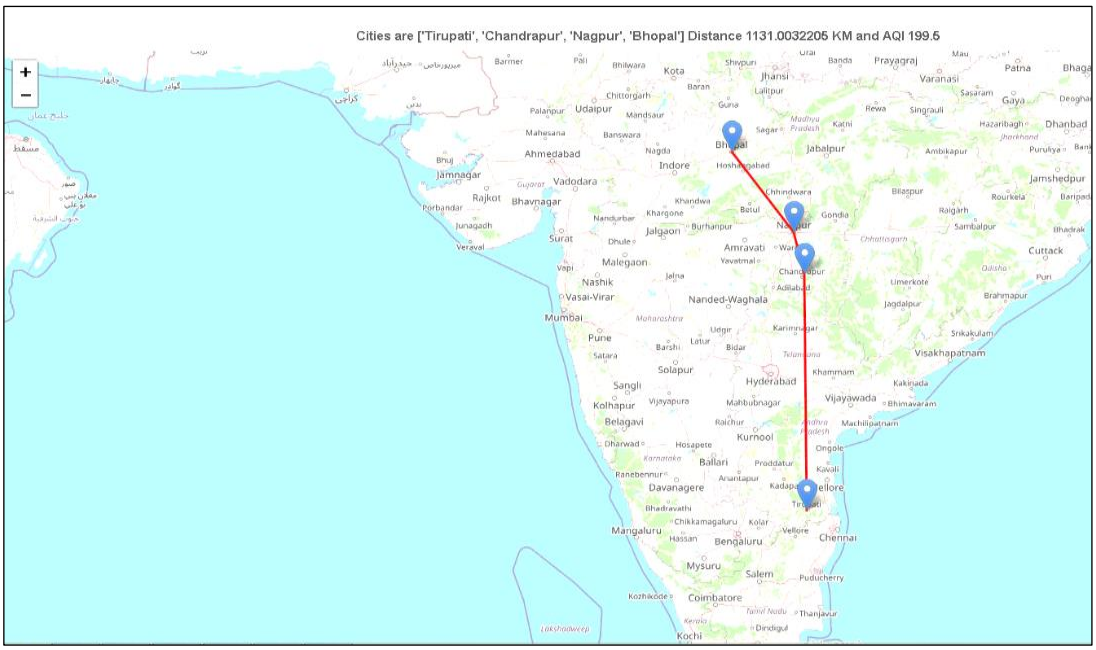

Figure 5: Shortest Path-1.
Source: Authors, (2026).

Figure 6 shows the possible path-2 for the source city (Tirupati) to the destination city (Bhopal) with the evaluated value of distance and AQI.

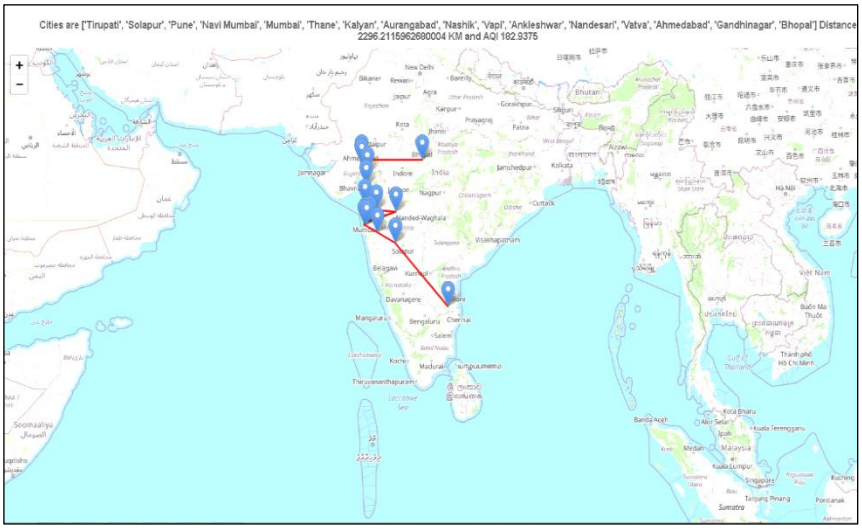

Figure 6: Shortest Path-2.
Source: Authors, (2026).

The possible path-3 for the source and destination city based on distance and AQI is shown in Figure 7. Advantages of this work are, real-time AQI data are used from AQICN.org and integrated with a predictive model (SE-TDT-SVM) for AQI forecasting.

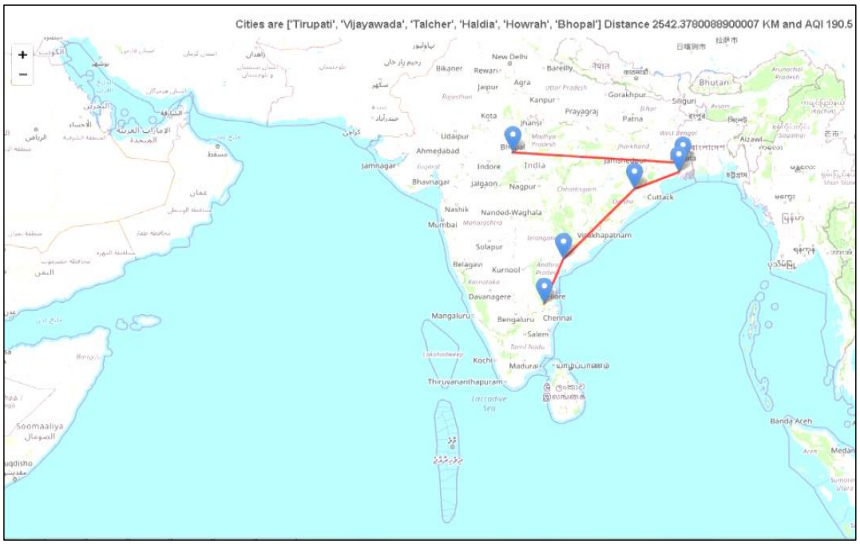

Figure 7: Shortest Path-3.
Source: Authors, (2026).

With this combination, path selection can be made more accurate and up-to-date, bridging the gap between real-time data and predictive modeling. AQI calculations consider multiple pollutants (PM2.5, PM10, NO2, SO2, CO, O3), providing a more comprehensive assessment of air quality than single-pollutant analyses. The AQI-Aware Routing (AAR) algorithm appears to allow for dynamic path selection based on current AQI levels, which is an improvement over static routing. With the SE-TDT-SVM model, decision trees and SVMs are combined in a stacked ensemble that could potentially outperform single algorithms in AQI prediction.

III.2 COMPARATIVE ANALYSIS WITH STATE-OF-THE-ART ROUTING MODELS

Air Quality-Aware Routing (AAR) algorithm is benchmarked against several air quality-integrated routing models, showing distinct advantages in adaptability and comprehensiveness. Mahajan et al.'s and Hameed [21] Clean Air Routing (CAR) algorithm minimizes PM2.5 exposure using a weighted function that prioritizes air quality over distance. However, CAR lacks a multi-pollutant approach and dynamic adaptability. AAR incorporates multiple pollutants (PM2.5, PM10, NO2, SO2, CO, O3) and leverages real-time AQI updates to enable dynamic path adjustments. This ensures AAR's responsiveness to sudden environmental changes, a key limitation of CAR. Dijkstra's algorithm and sensor data are used in Zahmatkesh et al., Zhang [22] and Zou [23] urban travel routing system. It focuses primarily on urban environments with dense sensor coverage by factoring AQI as a parameter. The method relies on static data and does not optimize for multi-objective decision-making. AQI trends are forecasted using SE-TDT-SVM, an algorithm that incorporates predictive modeling with a multi-objective optimization framework to balance travel distance and pollution exposure [24]. This IoT-enabled path recommendation system [25] and [26] uses real-time AQI updates, but is tailored to small-scale environments with limited geospatial adaptability. Using advanced spatial indexing techniques, including R-trees, the AAR algorithm exceeds this by computing routes efficiently across diverse regions. Furthermore, its agent-based structure allows for personalized recommendations, such as prioritizing health-conscious routes or optimizing logistics pathways.

Potential Real-World Applications

i. Smart City Navigation Systems: Promoting healthier routes for pedestrians, cyclists, and drivers by integrating city-wide navigation apps.
ii. Urban Planning and Policy Making: Assess the impact of urban development projects on air quality and assist city planners in improving air quality.
iii. Logistics and Delivery Optimization: Air pollution exposure can be minimized by helping delivery companies plan routes.
iv. Emergency Response Planning: During pollution-related crises, assist emergency services in planning safe routes.

IV. CONCLUSION

By combining the AQI predictions with optimal path selection, the SE-TDT-SVM model achieved an accuracy rate of 94.5% and a precision rate of 5.5% respectively. A feature-selected dataset showed KNN to outperform Random Forest (81.9%). Routes can be optimized based on real-time AQI data to improve urban health. Pollution exposure and travel efficiency are balanced, and hotspots are identified. As a result, pollution exposure is reduced for individuals with respiratory conditions. The algorithm should be improved and its applicability extended in future research. For assessing effectiveness, real-world deployment and user feedback are crucial. As a result of this integrated approach to AQI prediction and path optimization, urban air quality challenges are addressed in a meaningful way. Increasing urbanization and air quality concerns will make smart, health-focused solutions increasingly vital to promoting public health and urban sustainability. In the future, research should explore the incorporation of real-time data feeds and the possibility of deploying the solution as a mobile application for dynamic path recommendations. The results of this work illustrate the critical role that advanced machine learning techniques can play in enhancing urban air quality management and public health protection.

ABSTRACT

Reliable Quality of Service (QoS) prediction is fundamental to the performance of next-generation Vehicle-to-Everything (V2X) communication, particularly in 5G-enabled cloud and edge environments that support autonomous driving, cooperative safety, and time-critical mobility services. This survey provides a structured review of QoS prediction approaches spanning machine learning, deep learning, reinforcement learning, protocol-level evaluation, and security-trust mechanisms. Existing methods are analyzed with respect to their modeling strategies, required datasets, spatio-temporal dependencies, and scalability under high-mobility conditions. A comprehensive dataset survey synthesizes real-world, open-access, and simulation-based resources, highlighting key variables such as SINR, RSRP/RSRQ, mobility patterns, traffic density, delay, and throughput that influence predictive accuracy. The review identifies persistent challenges, including limited multi-modal datasets, poor cross-scenario generalization, computational overhead, weak interpretability, and the absence of unified multi-metric prediction frameworks. Based on these insights, the paper outlines promising research directions for developing adaptive, explainable, and privacy-preserving QoS prediction models for emerging 5G/6G V2X systems.

I. INTRODUCTION

The rapid evolution of vehicular communication systems, supported by 5G and emerging 6G infrastructures, has accelerated the development of Cooperative Intelligent Transportation Systems (C-ITS). Vehicle-to-Everything (V2X) communication enables continuous information exchange among vehicles, roadside infrastructure, pedestrians, and cloud-edge platforms to support safety-critical applications such as collision avoidance, cooperative lane change, platooning, and tele-operated mobility [1] [2].These applications impose stringent Quality of Service (QoS) requirements involving ultra-low latency, high reliability, controlled jitter, and stable throughput. Global deployment of V2X technologies remains uneven. As illustrated in Figure 1, regions such as Europe, the USA, China, and Japan show more mature VANET and C-V2X implementations compared to other regions; this heterogeneity stems from differences in spectrum allocation, regulatory readiness, infrastructure investment, and industry adoption [3]. Such diversity complicates the design of QoS prediction models that must generalize across different operational environments and mobility patterns. The integration of 5G New Radio (NR) and Multi-access Edge Computing (MEC) provides foundational support for meeting V2X QoS targets by enabling ultra-reliable low-latency communication (URLLC), high-capacity links, and distributed computation near vehicles [4], [5]. Nonetheless, wireless channels and topologies in vehicular settings remain highly dynamic due to mobility. obstruction dynamics, multi-path fading, and network load fluctuations [6], [7]. As a result, traditional reactive QoS mechanisms are often inadequate for many safety-critical V2X services.

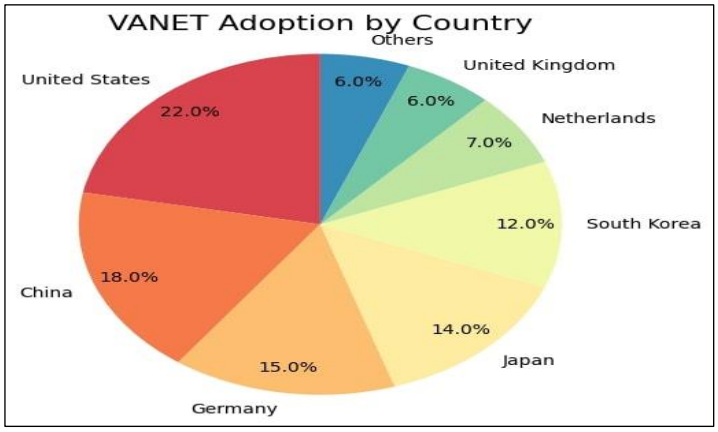

Figure 1: Global adoption of VANET/C-V2X deployments by region.
Source: Authors, (2026).

Predictive QoS (PQoS) methods forecast future network behavior (e.g., latency, throughput, packet loss, signal quality) so systems can proactively allocate resources, schedule traffic, or adapt application behavior. Data-driven paradigms such as machine learning (ML), deep learning (DL), and reinforcement learning (RL) have been widely adopted for PQoS because they can capture nonlinear spatio-temporal relationships between mobility traces, radio KPIs (SINR, RSRP/RSRQ, CQI), traffic density, and application demand [6], [7], [8], [9], [10]. Complementary protocol-and simulation-based studies provide system-level insights into routing, scheduling, channel coding, and cross-layer interactions that affect end-to-end QoS [11], [12], [13]. Security- and trust-oriented frameworks (e.g., blockchain, federated learning, reputation systems) address adversarial and privacy concerns that can critically impact QoS in distributed V2X settings [14], [15]. Despite considerable progress, key challenges persist : (i) scarcity of large-scale, multi-modal, and geographically diverse datasets that combine radio, mobility, and application-level traces [16], [17]; (ii) limited cross-scenario generalization when models are trained on region-specific traces; (iii) computational and energy constraints that limit on-board deployment of complex DL/RL models; and (iv) lack of standardized multi-metric benchmarks and limited interpretability of many black-box models [7], [18], [19]. These gaps motivate a structured survey that consolidates techniques, datasets, and open issues to guide future research. The primary contributions of this research work are summarized as follows:

- This survey presents a comprehensive and structured analysis of Perceived Quality of Service (PQoS) evaluation approaches. First, it introduces a unified taxonomy that categorizes PQoS techniques into ML and DL based methods, protocol and simulation-based approaches, as well as security and trust-oriented frameworks.
- Second, the study provides a critical synthesis of these approaches by examining algorithmic trade-offs, model complexities, and feature dependencies that influence PQoS prediction and assessment.
- Third, a dataset-centric review is conducted to identify commonly used datasets, highlight key variables utilized for PQoS modeling, and discuss the inherent limitations and gaps present in existing datasets.
- Fourth, the survey consolidates major research challenges, including issues related to model generalization, interpretability, real-time feasibility, and system security.
- Finally, the paper outlines a roadmap for future research, emphasizing the need for multi-metric evaluation frameworks, explainable PQoS prediction models, and privacy-preserving intelligent systems for next-generation network environments.

A. Intended Audience

This survey is intended to support academic researchers, industry practitioners, and graduate students working in the domains of vehicular communication, wireless networking, and QoS prediction. By providing a comprehensive review of Predictive QoS (PQoS) techniques for V2X communication, the survey aims to offer valuable insights for network engineers, data scientists, and system designers who seek to develop efficient and reliable vehicular communication systems. The contributions presented in this survey will also benefit researchers from interdisciplinary fields, including intelligent transportation systems, edge computing, machine learning, and 5G/6G system design, by helping them understand the evolving landscape of dataset-driven, learning-based PQoS models. Furthermore, the challenges and future research directions discussed in this paper are expected to guide prospective researchers in identifying open issues and establishing meaningful technical objectives to advance the field and address existing research gaps.

B. Survey Methodology

Over the past several years, numerous studies have explored QoS optimization and performance modeling in vehicular communication systems. However, many of these works primarily emphasize traditional QoS management, statistical models, or protocol-level enhancements, while only a limited number examine predictive QoS (PQoS) using machine learning, deep learning, or reinforcement learning techniques. Furthermore, recent PQoS contributions, particularly those incorporating mobility-aware prediction, cross-layer metrics, and 5G/6G edge intelligence, were excluded from earlier surveys. As a result, it is essential to include updated studies to accurately assess the current state of PQoS research. Additionally, previous surveys often focus on narrow aspects of V2X communication, such as routing, channel modeling, or general QoS analysis, without providing a unified overview of learning-based prediction frameworks. In this context, the literature was examined to address the following research questions:
1. What is the current understanding of QoS requirements in V2X communication, and why is predictive QoS necessary? This question aims to clarify the motivation for PQoS in highly dynamic vehicular environments. The corresponding discussion appears in the section titled “QoS Fundamentals and Motivation for Predictive QoS.”

2. Which machine learning, deep learning, reinforcement learning, and protocol-based models have been developed for QoS prediction in V2X networks? This survey provides a detailed overview of PQoS methodologies developed over the past decade.

3. What datasets support PQoS prediction research in V2X systems? The section "Dataset Survey and Variable Mapping" summarizes available real-world, simulation-based, and open-access datasets along with their relevance to prediction tasks.

4. What metrics and indicators are used to evaluate PQoS models? The section "Analysis and Discussion" presents commonly used evaluation metrics such as RMSE, MAE, MAPE, accuracy, and latency prediction error.

5. What limitations and research gaps exist in current PQoS studies? These issues are highlighted in the "Challenges and Future Directions" section.

By addressing these questions, this survey provides a holistic understanding of the state-of-the-art in predictive QoS for V2X communication and highlights key gaps that offer opportunities for future research.

C. Search Strategy

The databases listed in Table 1 were used to identify relevant journal articles and conference papers published by top publishers

Table 1: Academic databases used for the literature search.

Academic Database	Link
IEEE Xplore	https://ieeexplore.ieee.org/
ACM Digital Library	https://dl.acm.org/
ScienceDirect (Elsevier)	https://www.sciencedirect.com/
SpringerLink	https://link.springer.com/
Wiley Online Library	https://onlinelibrary.wiley.com/
MDPI	https://www.mdpi.com/
Taylor & Francis Online	https://tandfonline.com/
Scopus	https://www.scopus.com/
Google Scholar	https://scholar.google.com/

Source: Authors, (2026).

The initial search keywords were carefully selected to align with the research objectives of this survey. Following a preliminary exploratory search, multiple terms identified in several related PQoS and V2X research papers were analyzed to generate a broader list of candidate keywords. These terms were gradually refined and narrowed to ensure consistency with the core theme of predictive QoS modeling in vehicular communication systems. The final keywords used in this survey include "predictive QoS," "V2X communication," "QoS prediction vehicular networks," "latency prediction V2X," "machine learning QoS prediction," "deep learning QoS modeling," "reinforcement learning QoS optimization," "5G/6G QoS prediction," and "vehicular communication performance prediction."

D. Article Filtering and Selection Methodology

To ensure a rigorous and comprehensive survey of PQoS research in V2X communication, all retrieved publications were systematically screened through a multi-stage filtering process. The initial pool of studies identified from IEEE Xplore, ACM Digital Library, Elsevier, Springer, and Google Scholar was examined by reviewing their titles, abstracts, introductions, and conclusions. Papers that aligned with the core themes of predictive QoS, V2X communication, ML/DL-based prediction, protocol-level QoS mechanisms, dataset development, or security–trust frameworks were included, while studies that fell outside these domains were excluded.

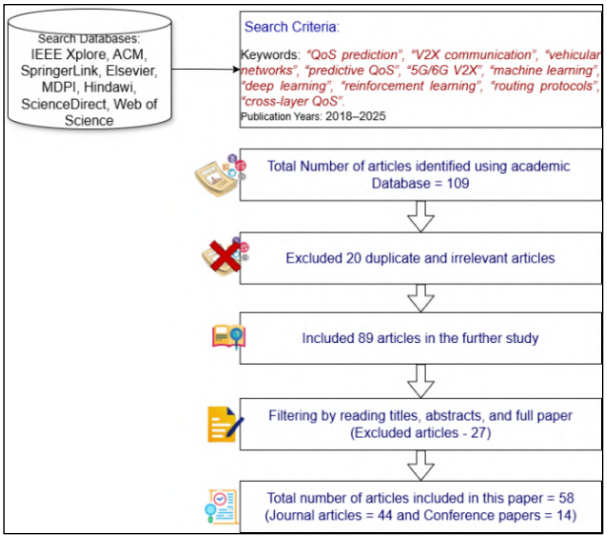

Figure 2: Paper selection procedure.
Source: Authors, (2026).

Figure 2 illustrates the overall article filtering workflow, including identification, screening, eligibility assessment, and final inclusion. To ensure consistency, objective inclusion and exclusion criteria were applied throughout the process. These criteria, summarized in Table 2, guided the evaluation of study relevance, methodological rigor, and applicability to PQoS prediction in vehicular communication systems. This structured filtering ensured that the final set of reviewed papers represents a balanced and comprehensive overview of state-of-the-art PQoS techniques across machine learning, deep learning, reinforcement learning, protocol design, dataset development, and security.

Table 2: Inclusion and exclusion criteria used for paper selection in this survey.

Inclusion criteria	Exclusion criteria
Studies published between 2018 and 2025, reflecting modern 5G/6G-era V2X research.	Papers lacking methodology, experimental setup, QoS metrics, or performance evaluation.
Research focused on V2X/VANET communication, QoS or PQoS prediction, or network performance modeling.	Outdated pre-2018 VANET studies or works unrelated to QoS prediction.
Peer-reviewed studies using ML/DL-based QoS prediction, RL-based resource optimization, routing/protocol QoS enhancement, or cross-layer QoS modeling frameworks.	Security-only papers (cryptography/privacy) without analysis of QoS impact.

Source: Authors, (2026).

I.1 V2X COMMUNICATION FRAMEWORK

The Vehicle-to-Everything (V2X) communication framework provides the foundational architecture required for cooperative intelligent transportation systems by enabling continuous information exchange among vehicles, roadside infrastructure, pedestrians, and cloud or edge networks. V2X consists of four primary communication modalities: Vehicle-to-Vehicle (V2V), which supports distributed safety messaging and localized situational awareness; Vehicle-to-Infrastructure (V2I), where Road-Side Units (RSUs) disseminate traffic, control, and connectivity information [4], [5]; Vehicle-to-Network (V2N), which leverages cellular Uu connectivity and MEC/cloud services for large-scale orchestration and computation [20], [21] ; and Vehicle-to-Pedestrian (V2P), which enhances the safety of vulnerable road users through device-assisted communication [22]. These modalities operate across heterogeneous communication technologies, including IEEE 802.11p/802.11bd, LTE-V2X PC5 sidelink, and cellular Uu interfaces, each offering distinct trade-offs in reliability, latency, and communication range. Prior studies emphasize that hybrid architectures combining PC5 for low-latency direct communication with Uu-based wide-area coordination achieve higher robustness and reliability under dense mobility conditions [5], [23]. RSUs serve as critical components within this framework, functioning not only as connectivity anchors but also as MEC-enabled units capable of supporting real-time QoS prediction, traffic analytics, security enforcement, and localized decision-making [19].

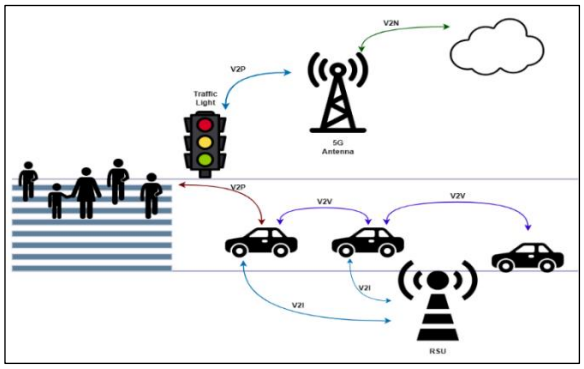

Figure 3: Illustration of the V2X communication framework showing V2V, V2I, V2N, and V2P interactions.
Source: Authors, (2026).

Meanwhile, cloud platforms handle long-term learning, federated model aggregation, and cross-region orchestration to support large-scale V2X intelligence [20]. The integration of emerging 5G and future 6G capabilities—such as URLLC, network slicing, and distributed edge intelligence—further strengthens the V2X communication ecosystem and enables predictive, QoS-driven communication essential for next-generation vehicular networks. Figure 3 demonstrate the framework for V2X communication.

I.2 QUALITY OF SERVICE (QOS) IN V2X COMMUNICATION

Quality of Service (QoS) in vehicular communication refers to the network's ability to deliver predictable, reliable, and efficient performance under highly dynamic mobility and radio conditions. Since V2X applications operate across diverse environments ranging from dense urban intersections to high-speed highways, QoS becomes a fundamental requirement for ensuring safe, stable, and delay-sensitive information exchange. Each V2X modality, including Vehicle-to-Vehicle (V2V), Vehicle-to-Infrastructure (V2I), Vehicle-to-Network (V2N), and Vehicle-to-Pedestrian (V2P), imposes distinct performance constraints based on latency, reliability, throughput, and service continuity [4], [5], [20]. V2X QoS is typically quantified using a set of measurable performance indicators:

- *Latency:* The end-to-end delay between message generation and reception. Safety-critical applications such as collision avoidance demand sub-10 ms latency for reliable execution.
- *Throughput:* The volume of successfully transmitted data per unit time, essential for applications involving high-rate sensor streams, cooperative perception, and teleoperation.
- *Reliability:* The probability of error-free packet delivery, often exceeding 99.999% for mission-critical V2X scenarios.

- *Jitter:* The variation in inter-packet arrival time, which affects the stability of real-time control and cooperative driving applications.
- *Packet Loss Rate:* The fraction of packets lost due to channel impairments, congestion, or mobility; a key metric influencing application stability.
- *Availability:* The percentage of time the communication link remains operational and satisfies service-level requirements.

RSUs, cellular infrastructure, and cloud services collaborate to support low-latency and reliable vehicular communication. Adapted from Mendes et al. [24]. These QoS indicators are strongly influenced by dynamic vehicular environments where mobility, traffic density, propagation conditions, and infrastructure placement rapidly evolve. For example, high user density and mobility degrade SINR, RSRP, RSRQ, and other radio-link quality parameters, directly affecting throughput and latency [6] [7]. Consequently, ensuring stable QoS requires not only reactive adaptation but also predictive intelligence capable of forecasting link performance before degradation occurs. The emergence of 5G NR and Multi-access Edge Computing (MEC) enhances QoS provisioning by enabling Ultra-Reliable Low-Latency Communication (URLLC), network slicing, and localized computation. These advancements allow V2X systems to dynamically allocate resources based on predicted network states and application requirements. Overall, QoS in V2X communication serves as the foundational performance requirement underlying all cooperative transportation services. As vehicular networks transition toward fully autonomous and connected mobility, the role of accurate, multi-metric QoS prediction becomes indispensable for enabling real-time decision-making and ensuring communication reliability in next-generation 5G/6G V2X ecosystems.

I.3 MOTIVATION

The rapid evolution of V2X communication systems, supported by 5G and emerging 6G technologies, has intensified the demand for reliable and predictive Quality of Service (QoS) to enable safety-critical and latency-sensitive vehicular applications. Although existing V2X communication modalities V2V, V2I, V2N, and V2P collectively provide the foundation for cooperative awareness and real-time information exchange, their performance is fundamentally challenged by high mobility, dynamic topology changes, intermittent connectivity, and heterogeneous wireless conditions [25], [22]. These characteristics lead to rapid fluctuations in latency, throughput, packet delivery ratio (PDR), SINR, and other link-quality indicators, making conventional reactive QoS mechanisms inadequate for next-generation vehicular services. Predictive QoS (PQoS) has therefore emerged as a critical capability for enabling proactive resource allocation, congestion control, handover optimization, and service continuity in V2X systems. Recent studies demonstrate that ML, DL, and RL models can capture hidden spatio-temporal dependencies in vehicular mobility patterns, radio metrics, and network behaviors, allowing more accurate forecasting of communication performance [6], [7], [16]. Such predictions are particularly essential for applications such as cooperative perception, tele-operated driving, platooning, and emergency message dissemination, where even millisecond-level QoS degradation can compromise safety and reliability [10], [19] . Furthermore, the proliferation of RSUs, MEC nodes, and cloud services introduces new opportunities for distributed learning, edge-level inference, and hierarchical decision-making. RSUs equipped with MEC capabilities can support real-time QoS estimation and localized control actions, while cloud platforms enable long-term model training, cross-region knowledge transfer, and federated learning strategies [25], [24]. However, the effectiveness of such architectures depends on understanding the limitations of current communication technologies, including IEEE 802.11p/802.11bd, LTE-V2X PC5 sidelink, and 5G NR Uu, each of which exhibits distinct performance bottlenecks under dense traffic, high mobility, and varying propagation environments [22], [26], [27]. These challenges highlight the need for a comprehensive survey that unifies advances in PQoS prediction, analyzes emerging communication technologies, synthesizes ML/DL/RL developments, and examines dataset limitations, security constraints, and cross-layer performance issues. By integrating insights from predictive intelligence, communication protocols, and real-world measurement studies, this survey aims to provide a structured foundation for the design of scalable, explainable, and context-aware PQoS solutions for future V2X networks.

II. THEORETICAL REFERENCE

II.1 TAXONOMY AND METHODOLOGICAL CLASSIFICATION

The existing research on QoS prediction in V2X communication exhibits a broad methodological diversity, reflecting the interdisciplinary nature of vehicular networking, wireless communication, and intelligent systems. To provide a structured view of these developments, this survey categorizes state-of-the-art approaches into five distinct methodological domains : (i) protocol- and simulation-based models, (ii) supervised machine learning approaches, (iii) deep learning architectures, (iv) reinforcement learning frameworks, and (v) hybrid or cross-layer solutions. These categories capture the progression from traditional analytical and optimization-driven communication models toward data-driven, predictive, and autonomous decision-making paradigms. The proposed taxonomy also enables systematic comparison of modeling assumptions, feature dependencies, prediction objectives, and performance trade-offs across different V2X scenarios. Figure 4 illustrates the full taxonomy used throughout this survey. A comparative analysis of these methodological categories, supported by the evidence aggregated from existing studies, reveals clear distinctions in their underlying assumptions, feature dependencies, and operational constraints.

Traditional ML-based QoS prediction methods rely heavily on handcrafted features such as SINR, RSRP, RSRQ, vehicle speed, mobility patterns, and traffic density [6], [28], [29]. These models are computationally lightweight and enable fast inference, making them suitable for RSU-level or on-board prediction; however, their performance often degrades across heterogeneous environments due to scenario dependence, feature-engineering bottlenecks, and limited adaptability to nonlinear spatio-temporal variations [30], [31]. Deep learning approaches overcome these limitations by automatically learning complex hierarchical and temporal relationships using architectures such as LSTM, Bi-LSTM, GRU, CNN, and hybrid DNN models [18], [32], [33]. These models achieve superior accuracy and long-range QoS forecasting, particularly under rapidly changing mobility or channel conditions, but require large annotated datasets and MEC/GPU-based inference due to their high computational cost [9], [34]. Reinforcement learning (RL) and deep RL extend predictive capabilities by enabling sequential, adaptive decision-making for resource allocation, routing, slicing, and teleoperation [19], [35], [36]. While RL provides strong robustness in dynamic environments, its practicality is often limited by unstable convergence, intensive training requirements, and dependence on realistic simulation environments [37], [38].

In contrast, routing- and protocol-based approaches remain computation-efficient and well-suited for real-time deployment but lack predictive intelligence and often struggle under high-density or high-mobility scenarios [11], [39], [40]. Security- and trust-oriented frameworks strengthen resilience by incorporating authentication, trust scores, and anomaly detection [14], [41], [42], though these mechanisms introduce additional signaling overhead, authentication delay, and processing load, making them less suitable for strict real-time QoS prediction. Collectively, these observations highlight fundamental trade-offs between predictive accuracy, interpretability, computational complexity, scalability, and real-time feasibility across the methodological spectrum in V2X QoS prediction research.

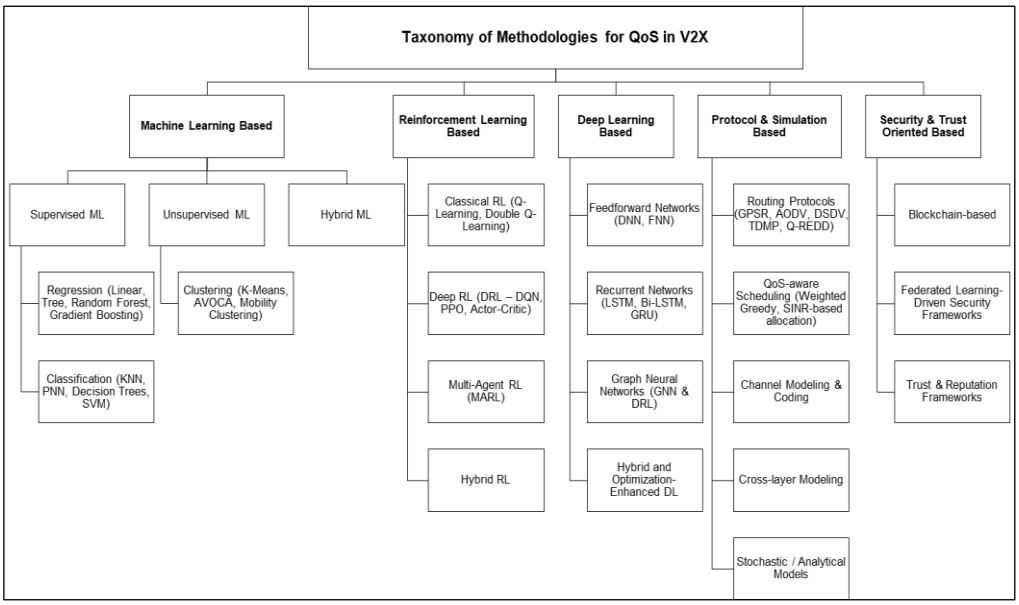

Figure 4: Taxonomy of methodological approaches in QoS prediction for V2X communication.
Source: Authors, (2026).

The framework categorizes existing literature into protocol-based, machine learning, deep learning, reinforcement learning, and hybrid cross-layer techniques, supporting structured performance and applicability analysis.

II.1.1 Machine Learning-Based QoS Prediction Techniques

Machine learning (ML) has been extensively explored for QoS prediction in V2X communication due to its relatively low computational overhead, interpretability, and suitability for deployment on RSUs and OBUs. ML approaches generally rely on handcrafted feature sets that capture radio conditions, mobility patterns, and traffic descriptors, many of which have been identified as dominant predictors of latency, throughput, and packet delivery ratios. A consolidated overview of commonly used variables is provided in Table 3. Compared to deep or reinforcement learning, ML techniques offer faster inference and reduced model complexity, making them suitable for real-time PQoS estimation; however, these advantages come at the cost of limited representational capacity and reduced generalizability in heterogeneous environments. Across the literature, supervised regression and classification models such as random forests, gradient-boosted trees, SVMs, and linear models have shown strong performance for near-term QoS forecasting when trained on a combination of PHY-layer metrics (e.g., SINR, RSRP, CQI) and mobility indicators (e.g., speed, heading, inter-vehicle distance) [28] [29], [30], [33]. These works consistently demonstrate that radio KPIs are necessary but insufficient without mobility and contextual features, particularly in highly dynamic V2I and V2V links. Models such as random forests provide robust prediction performance with low inference latency, making them practical for RSU-level deployment in online prediction systems [28].

However, the heavy reliance on feature engineering limits adaptability: ML models trained in urban environments often degrade when applied to highway or mixed mobility scenarios, revealing dataset bias and poor cross-environment generalization [31], [43]. Unsupervised learning and clustering have been introduced to mitigate these generalization issues by partitioning heterogeneous data into more homogeneous behavioral regimes before prediction. Studies leveraging K-means clustering and fuzzy-rule grouping demonstrate that per-cluster prediction improves model stability under varying LOS/NLOS propagation states and traffic densities [29-44]. This approach enables ML models to operate as context-aware predictors rather than global regressors. While effective, clustering-based schemes increase system complexity and require continuous reclassification of vehicles or channel states, which may be challenging under stringent latency constraints. Hybrid ML methods further extend predictive capabilities by combining supervised models with clustering, fuzzy logic, or rule-based components. These frameworks have been shown to improve resilience to noise, measurement sparsity, and abrupt mobility transitions, especially in scenarios where deep learning solutions may be computationally infeasible [45], [46].

Source: Authors, (2026).

A comparative analysis of ML-based PQoS studies reveals several overarching trends. First, multi-domain feature integration combining physical-layer indicators with mobility and traffic information consistently outperforms single-domain predictors [6] [28]. Second, the scarcity of large-scale, diverse, real-world V2X datasets limits generalizability and contributes to the overfitting observed in many ML-based models [16], [44]. Third, validation protocols vary significantly across studies, with some relying on random shuffling rather than route-based or temporal holdout strategies, leading to optimistic performance reporting [30]. Finally, while ML offers favorable computational efficiency and is well-suited for real-time inference, its inability to model long-range temporal dependencies and nonlinear interactions reduces accuracy relative to deep learning techniques, particularly under rapidly changing network dynamics.

II.1.2 Deep Learning-Based QoS Prediction Techniques

Deep learning (DL) has gained significant traction in V2X QoS prediction because of its ability to automatically learn hierarchical spatial and temporal representations from high-dimensional communication and mobility data. Unlike traditional ML methods, which depend heavily on engineered features and perform well only under stable or moderately dynamic conditions, DL models can capture non-linear interactions between radio KPIs, mobility patterns, traffic states, and environmental factor properties essential for highly dynamic V2X environments [7], [33]. A prominent research direction focuses on deep neural networks (DNNs) for throughput and latency forecasting, where models consistently outperform linear and ensemble-based ML approaches by learning latent correlations not explicitly visible in handcrafted features [7]. Recurrent neural networks (RNNs), particularly LSTM, Bi-LSTM, and GRU architectures, extend these benefits by modeling longer-term temporal dependencies in vehicular mobility and communication traces [18], [50]. These models demonstrate superior performance in predicting fluctuating QoS under high-speed mobility, where future states depend on extended historical sequences. More recent approaches integrate attention mechanisms, GAN-based data augmentation, and multi-task learning to enhance robustness and reduce sensitivity to noise [32], [51]. Table 4 summarizes common input variables used across DL-based studies.

DL has also advanced spatial modeling in V2X networks. Graph neural networks (GNNs) represent vehicles as graph nodes, enabling the learning of inter-vehicle spatial dependencies relevant for collision risk assessment and link-quality prediction [53]. Hybrid DL–RL models leverage DL as function approximators to optimize resource allocation or routing with improved predictive QoS awareness [54]. Collectively, these approaches highlight DL's ability to fuse heterogeneous mobility, radio, and contextual input capabilities beyond the scope of conventional ML. Despite these advantages, DL-based QoS prediction faces several practical limitations. First, DL models typically require large-scale, diverse, labeled datasets; however, publicly available V2X datasets remain limited, geographically biased, or collected under controlled conditions [33]. [55] As a result, models often overfit and fail to generalize to new traffic densities, weather conditions, or propagation environments. Second, DL models impose significant computational and memory overhead, making them less suitable for real-time deployment on resource-constrained RSUs or OBUs without model compression or edge offloading. Third, DL operates as a "black box," offering limited interpretability, an issue particularly problematic for safety-critical ITS applications where prediction rationale must be auditable. Finally, variations in evaluation methodologies across studies (windowing strategies, train–test splits, and scenario coverage) contribute to inconsistent reporting of performance gains. Overall, DL-based QoS prediction provides substantial improvements over traditional ML by capturing complex spatio-temporal dependencies and multi-modal interactions inherent in V2X systems. However, the practical utility of DL remains constrained by dataset scarcity, computational costs, and limited generalization. These shortcomings motivate current research directions involving hybrid DL–RL architectures, domain adaptation, transfer learning, and model compression to improve scalability and real-time applicability in 5G/6G vehicular networks.

II.1.3 Routing and Protocol-Based Approaches

Routing and protocol-level techniques play a central role in determining how reliably and efficiently V2X messages are propagated under high mobility. Classical routing protocols such as GPSR, AODV, and DSDV are frequently used as baselines to assess delay, packet delivery ratio, and robustness; however, their performance degrades in dense or fast-changing topologies [11]. Recent QoS-aware routing schemes attempt to address these limitations by incorporating mobility prediction, SINR estimation, and relay selection, with approaches such as TDMP and C-V2X-assisted D2D forwarding demonstrating improved reliability and reduced route breaks [39], [56]. Nonetheless, these methods remain sensitive to wireless channel fluctuations, indicating that routing alone cannot guarantee end-to-end QoS. Scheduling and resource-allocation strategies complement routing by prioritizing transmissions based on queue states, predicted link stability, or latency requirements. Mobility-aware schedulers and weighted-greedy allocation methods achieve measurable reductions in delay and congestion [12], although their performance is constrained by the accuracy of channel state estimation. At the physical layer, studies of channel coding and propagation models show that coding schemes such as turbo and LDPC significantly influence link reliability and retransmission behavior under varying mobility and fading conditions [13], [57]. These findings underscore the tight coupling between PHY-layer characteristics and protocol-layer performance. Cross-layer QoS modeling integrates routing, scheduling, and PHY-level parameters to provide more realistic analyses of end-to-end reliability and latency. Such models capture the combined effects of queuing delays, MAC contention, retransmissions, and route dynamics, offering insights that single-layer evaluations cannot [58]. Analytical and stochastic models further complement empirical results by characterizing multi-hop connectivity, interference, and dissemination delay in large-scale V2X settings [59]. Table 5 provides the variable-to-study mapping covering routing, scheduling, PHY, and cross-layer QoS methods.

Table 5: Mapping of QoS-Relevant Variables to Representative Routing, Scheduling, and PHY-Layer Studies.

Variable	[7]	[33]	[9]	[18]	[32]	[52]	[50]	[35]	[53]	[54]
Throughput	✓	✓	-	✓	✓	-	✓	-	-	✓
Latency/Delay	-	✓	✓	✓	-	✓	✓	-	✓	-
Reliability	-	✓	-	✓	✓	-	✓	✓	-	-
Mobility Data	✓	-	✓	-	✓	✓	-	✓	✓	-
SINR/Channel	✓	-	✓	✓	-	✓	✓	-	✓	✓

Source: Authors, (2026).

Overall, protocol-level research highlights that no individual layer can ensure stable QoS in vehicular networks. Routing depends on efficient scheduling, scheduling depends on predictable channel behavior, and PHY-layer gains require upper-layer coordination. Consequently, the most effective solutions emphasize cross-layer design, mobility awareness, and adaptive protocol mechanisms to maintain QoS under realistic vehicular mobility and channel variability.

II.1.4 Security and Trust-Based Approaches

Security- and trust-oriented frameworks have become integral to ensuring reliable QoS in V2X networks, particularly as message integrity, privacy, and misbehavior detection directly influence latency, throughput, and packet delivery. Existing solutions span blockchain-based architectures for tamper-resistant message dissemination [14], federated learning models for privacy-preserving QoE prediction [15], [41], and trust–reputation systems that evaluate forwarding behavior, PDR, and misbehavior rates [42]. As summarized in Table 6, these studies incorporate diverse variables such as latency, throughput, security metrics, and computational cost, highlighting the increasing convergence of security and performance requirements in modern V2X systems. A notable theme across the literature is the inherent security–QoS trade-off. Blockchain and distributed ledger mechanisms strengthen message integrity but introduce non-negligible processing delays and communication overhead, which may hinder time-critical V2X applications. Federated learning reduces privacy risks but increases model synchronization overhead, while trust-based systems depend heavily on continuous recommendation exchange, potentially increasing control traffic. These factors collectively impact QoS prediction accuracy by altering latency profiles, reliability guarantees, and resource consumption. Consequently, security mechanisms cannot be treated independently of QoS constraints and must be evaluated as part of an integrated design strategy.

Table 6: Overview of Variables in Security and Trust Frameworks for V2X.

Variable	[14]	[15]	[42]	[43]	[60]
Latency	-	✓	✓	✓	-
Throughput	-	✓	✓	-	-
QoE	-	✓	✓	-	-
Privacy / Security Metrics	✓	✓	✓	✓	✓
Trust / Reputation	-	-	-	✓	-
PDR (Packet Delivery Ratio)	-	-	-	✓	-
Misbehavior Detection	-	-	-	✓	-
Channel / Network Features	✓	-	-	-	-
Computing Requirements	✓	-	-	-	-

Source: Authors, (2026).

Despite progress, several gaps remain. Most existing frameworks rely on simulation-based datasets and lack large-scale real-world validation under diverse mobility and attack conditions. Current models also focus predominantly on single-aspect security (e.g., trust or privacy) rather than holistic, cross-layer protection. Furthermore, limited research has examined how security metrics can be directly incorporated into ML/DL-based QoS predictors to enhance robustness against adversarial behavior. Addressing these gaps will require standardized datasets, lightweight cryptographic and trust mechanisms compatible with 5G/6G latency budgets, and unified frameworks capable of jointly optimizing QoS, privacy, and security in future V2X systems.

III. DATASET SURVEY FOR PQOS IN V2X COMMUNICATION

Datasets constitute the empirical foundation for Predictive QoS (PQoS) research, enabling systematic evaluation of ML-, DL-, and RL-based models under diverse mobility patterns, radio conditions, and network loads. Existing datasets are typically categorized into three groups: real-world drive-test datasets, public open-access datasets, and synthetic or simulation-based datasets. Each category offers distinct benefits in terms of realism, scalability, parameter control, and reproducibility.

III.1 REAL-WORLD DRIVE TEST DATASETS

Real-world measurements provide the most accurate representation of 5G and V2X communication behavior, capturing realistic mobility dynamics, channel impairments, and congestion conditions that directly impact QoS. Brehon et al. [10] conducted extensive 5G SA industrial experiments for tele-operated mobility, demonstrating that regression-based PQoS models reduced end-to-end latency by nearly 15%. Similarly, Muller et al. [28] collected urban mobility traces in 5G NSA and LTE networks and reported strong correlations between vehicle movement and uplink/downlink throughput, with typical latency ranges of 15–20 ms in dense environments. BandSeer [16] and Schwarz et al. [17] further evaluated short-term bandwidth and uplink throughput prediction, identifying SINR as a dominant variable for regression-based models. Although real-world datasets provide high-fidelity ground truth, they remain geographically limited and costly to scale and often lack synchronized multimodal measurements integrating mobility, PHY, and network-layer parameters.

III.2 PUBLIC OPEN-ACCESS DATASETS

Public datasets enable reproducible benchmarking across the research community. The Berlin V2X dataset [43] provides GPS-tagged multi-RAT measurements that support cross-layer analysis of mobility, channel quality, and application-layer performance. NordicDat [29] expands this scope by offering more than 90,000 annotated samples with SINR, RSRP, RSRQ, throughput, delay, and mobility metrics. Reported studies show that Random Forest models achieve $R^2 > 0.85$ for throughput prediction and median latency errors below 8 ms, supporting research in federated and domain-adaptive PQoS modeling. While open datasets lower the entry barrier for ML-based experimentation, they often exhibit climatic, geographical, or environmental bias, limiting global generalizability.

III.2 SYNTHETIC AND SIMULATION-BASED DATASETS

Synthetic datasets generated through simulators such as ns-3, SUMO, and 3GPP PHY engines provide full control over mobility, density, radio models, and traffic patterns. They are particularly valuable for RL-based PQoS frameworks requiring interactive environments. The PRATA framework [19], for example, used ns-3 teleoperation simulations to train PPO agents, reporting a 20% prediction gain over Double Q-Learning. Additional synthetic datasets combine BiLSTM modeling with partially real mobility traces for traffic prediction [61], while 3GPP PHY-layer evaluations [30] compare Turbo, LDPC, and Polar codes, highlighting sub-10 ms latency for Turbo-coded V2X frames. Despite their scalability and flexibility, synthetic datasets may oversimplify fading, blockage, and interference, reducing their real-world transferability.

III.3 SUMMARY AND LIMITATIONS

The reviewed datasets collectively capture a wide spectrum of QoS-relevant variables: mobility traces, GPS coordinates, SINR, RSRP/RSRQ, throughput, delay, jitter, and CIR, enabling comprehensive benchmarking across ML, DL, and RL paradigms. Table 7 summarizes key characteristics of widely used datasets. However, a notable gap persists: the lack of synchronized datasets that jointly capture mobility, network KPIs, and PHY-layer signal measurements. Such multimodal datasets are essential for accurate end-to-end PQoS prediction, yet remain scarce across current literature. Developing standardized, cross-layer, and large-scale datasets represents a critical research direction for the next generation of V2X QoS prediction systems.

Table 7: Dataset-wise Variable Mapping with Authors.

Dataset	GPS	Speed	SINR	RSRP	RSRQ	RSSI	CQI	Throughput	Delay	Jitter	CIR	Mobility

IV. CHALLENGES AND OPEN ISSUES

The analysis presented in the previous sections, together with the comparative tables and dataset summaries, reveals several recurring limitations that continue to affect the reliability of V2X QoS prediction models. These observations indicate that, despite substantial progress in ML-, DL-, and RL-based methods, fundamental gaps persist in data availability, model robustness, real-time inference categories, (i) interpretability, and system-level integration. As depicted in Figure 5, these challenges can be broadly classified into two major categories: (i)Dataset and Generalization Issues and (ii) Methodology and Deployment Constraints. The flowchart illustrates how factors such as the lack of multi-modal real-world datasets, environment-specific model behavior, absence of cross-layer modeling, and limited explainability directly influence the accuracy and practicality of QoS prediction in V2X networks. Additionally, inconsistent KPI definitions, heterogeneous evaluation metrics, and various security vulnerabilities further complicate real-world adoption. Together, these insights highlight the need for more comprehensive datasets, interpretable and secure learning models, and unified cross-layer prediction frameworks to support robust and scalable V2X communication systems.

IV.1 STRUCTURAL RESEARCH GAPS IN EXISTING PQOS LITERATURE

Although substantial progress has been achieved in predictive QoS modeling for V2X systems, a critical synthesis of the reviewed literature reveals several structural limitations that constrain scalability, robustness, and deployment readiness.

1) *Absence of Spatial QoS Field Modeling:* Most ML- and DL-based approaches perform point-wise prediction using locally observed indicators such as SINR, RSRP, mobility traces, or traffic density [28], [30], [33]. While effective for short-term estimation, these models do not reconstruct QoS behavior across unmeasured road segments. Empirical drive-test studies confirm strong spatial variability of throughput and latency in dense urban scenarios [17], [28]. However, explicit spatial correlation modeling and network-wide QoS field reconstruction remain largely unexplored, limiting generalization across heterogeneous road networks.

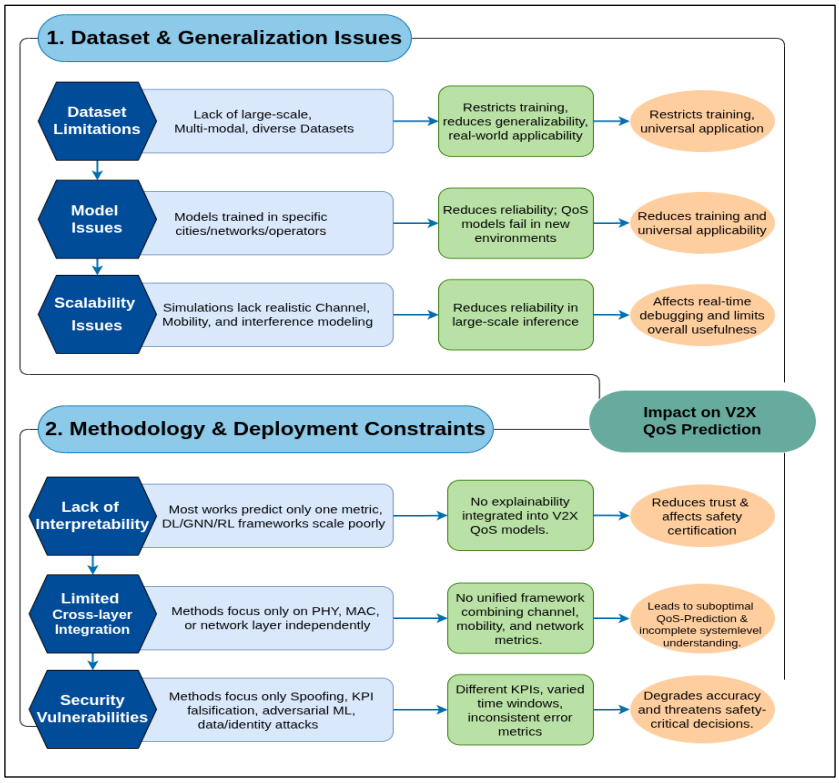

Figure 5: Diagram illustrating the key challenges and open issues in V2X QoS prediction.
Source: Authors, (2026).

2) *Single-Metric Prediction Dominance:* A significant portion of existing studies focuses on isolated metrics such as throughput or delay [7], [18]. In contrast, safety-critical V2X services require simultaneous guarantees on latency, reliability, jitter, and availability. The

absence of unified multi-metric prediction frameworks restricts cross-layer optimization and may lead to suboptimal system-level adaptation decisions.

3) *Limited Cross-Scenario Generalization:* Many predictive models are validated using city-specific drive-test datasets or simulator-generated traces [16], [43]. Although high accuracy is often reported under controlled settings, performance frequently degrades when deployed in unseen environments. This suggests insufficient domain adaptation and limited robustness to distribution shifts across mobility regimes, propagation conditions, and infrastructure density.
4) *Simulation-Centric Reinforcement Learning:* Reinforcement learning approaches demonstrate adaptive capabilities in teleoperation, slicing, and multicast optimization [19], [54]. However, most frameworks rely heavily on synthetic environments such as ns-3 simulations. The realism gap between simulation assumptions and operational 5G/6G V2X conditions raises concerns regarding deployment safety, convergence stability, and policy transferability.
5) *Weak Integration of Security and QoS Prediction:* Security-oriented frameworks based on blockchain, federated learning, and trust management enhance resilience [14], [15], [42], yet they are typically evaluated independently of predictive QoS modeling. The direct impact of authentication latency, secure aggregation overhead, or adversarial interference on QoS prediction accuracy remains insufficiently quantified.
6) *Evaluation Methodology Inconsistencies:* Validation protocols vary widely across studies, including random train–test splits and metric selection differences [34], [50]. In mobility-correlated datasets, random splitting may introduce temporal and spatial leakage, artificially inflating reported accuracy. The absence of standardized benchmarking and route-based validation hinders fair comparison and reproducibility.

Collectively, these gaps indicate that current PQoS research remains predominantly point-based, dataset-constrained, and method-driven rather than system-driven. Addressing these limitations requires unified spatio-temporal modeling, multi-metric prediction, uncertainty quantification, and deployment-aware validation using large-scale real-world vehicular datasets.

IV.2 FUTURE RESEARCH DIRECTIONS

Building upon the identified structural gaps, several forward-looking research directions emerge for advancing PQoS modeling toward reliable 5G/6G-enabled V2X systems.

IV.2.1 Multimodal and Cross-Layer Dataset Development

Future progress in PQoS research depends on the availability of synchronized, large-scale datasets that jointly capture mobility patterns, PHY-layer indicators, MAC-layer statistics, and application-level performance metrics. Existing datasets typically isolate individual parameters, limiting their ability to model complex spatio-temporal dependencies. Future efforts should focus on developing multimodal benchmarking datasets with:

1. Fine-grained temporal resolution (sub-100 ms sampling),
2. Diverse urban, suburban, and highway scenarios,
3. Explicit support for 5G/6G features such as sidelink, beam management, RIS-assisted links, and ISAC.

Standardized open benchmarks would enable reproducibility and fair cross-model comparison across research communities.

IV.2.2 Robust and Generalizable PQoS Models

ML/DL-based models often exhibit strong performance under training conditions but degrade under domain shifts. Future research should investigate domain adaptation, transfer learning, self-supervised representation learning, and distributionally robust optimization techniques capable of maintaining stable error bounds across heterogeneous deployments. A key objective is to design models whose prediction degradation remains within acceptable operational margins when transferred across cities, densities, or infrastructure configurations. Incorporating reliability scoring and uncertainty estimation into PQoS predictors can further improve decision confidence in safety-critical scenarios.

IV.2.3 Uncertainty-Aware and Risk-Constrained PQoS Modeling

In safety-critical V2X environments, prediction confidence is as important as prediction accuracy. Future PQoS frameworks should integrate uncertainty-aware learning mechanisms such as Bayesian deep learning, Gaussian processes, conformal prediction, and risk-sensitive reinforcement learning. Uncertainty estimates can enable:

1. Confidence-aware resource allocation,
2. Risk-adaptive handover decisions,
3. Safe fallback strategies under prediction ambiguity.

Designing predictors that quantify epistemic and aleatoric uncertainty will be essential for trustworthy deployment in autonomous mobility systems.

IV.2.4 Integration of Learning With Network Control and Protocol Design

Current approaches often treat learning models and networking protocols as independent components. A promising direction involves co-designing predictive models with routing, scheduling, slicing, and resource allocation mechanisms. Lightweight and stable RL or multi-agent RL frameworks operating under partial observability and tight latency constraints could enable closed-loop adaptation in dense vehicular scenarios. Hybrid learning—protocol architectures that directly embed predictive outputs into real-time control logic—represents a key step toward context-aware QoS guarantees.

IV.2.5 Secure, Privacy-Preserving, and Trust-Integrated PQoS Frameworks

As V2X ecosystems become increasingly interconnected, PQoS pipelines must integrate security and privacy constraints. Future research should explore federated PQoS learning, secure aggregation, blockchain-enabled trust verification, and adversarial robustness. A critical research question concerns balancing security overhead with latency budgets. Embedding trust metrics directly into QoS prediction models may enhance resilience against falsified measurements and adversarial manipulation.

IV.2.6 Toward 6G: Semantic, Predictive, and Edge-Intelligent V2X

The transition to 6G will shift PQoS modeling toward semantic-aware communication, AI-native network control, and distributed edge intelligence. Emerging technologies such as integrated sensing and communication (ISAC), reconfigurable intelligent surfaces (RIS), sub-THz links, and graph neural networks for network-wide coordination offer new opportunities for predictive QoS assurance. Future PQoS systems are expected to operate as distributed edge-intelligent agents capable of continuous learning, real-time adaptation, and proactive risk mitigation. Achieving this vision requires rethinking QoS prediction as a core architectural component of autonomous, self-optimizing V2X networks. Taken together, these research directions highlight a paradigm shift from isolated algorithmic improvements toward holistic, deployment-aware, uncertainty-conscious, and security-integrated PQoS intelligence suitable for large-scale autonomous mobility in 5G and beyond.

V. CONCLUSIONS

This paper provided a critical review of predictive Quality of Service (PQoS) modeling for V2X communication systems, examining machine learning, deep learning, reinforcement learning, protocol-level, and security-aware approaches. While significant progress has been reported in metric-specific prediction accuracy, our analysis shows that current research remains largely point-based, single-metric focused, and heavily reliant on simulation or city-specific datasets. The absence of spatial QoS field reconstruction, limited cross-scenario generalization, weak integration of security and control mechanisms, and inconsistent evaluation methodologies collectively restrict the scalability and deployment readiness of existing solutions in real-world high-mobility environments. To meet the stringent reliability and latency demands of next-generation vehicular networks, PQoS research must evolve beyond incremental accuracy improvements toward unified spatio-temporal modeling, multi-metric and uncertainty-aware prediction, and tightly integrated learning-control architectures. As V2X systems transition toward AI-native 6G ecosystems, predictive QoS should be positioned as a foundational architectural component enabling proactive, resilient, and self-optimizing communication. Achieving this transformation will require deployment-aware design, standardized benchmarking, and system-level intelligence capable of sustaining trustworthy operation in large-scale autonomous mobility scenarios.

ABSTRACT

Precise long-range forecasting of industrial electrical demand constitutes a strategic imperative for energy governance, particularly within energy-intensive, continuous-process industries such as cement manufacturing. This investigation conduct a systematic evaluation of two advanced recurrent neural networks, Long Short-Term Memory (LSTM) and Bidirectional LSTM (BiLSTM), fine-tuned via the Optuna optimization. Using realistic data from an operational cement plant, we quantify the trade-offs between predictive accuracy, computational overhead, and operational viability. Empirical results demonstrate that the Optuna-optimized BiLSTM framework achieves superior predictive performance, yielding an R2 score of 0.890 and a Mean Absolute Error (MAE) of 0.220. These findings delineate a modeling framework that reconciles high-fidelity forecasting with practical implementation, providing foundational guidelines for designing energy management systems that optimize maintenance, reduce costs, and advance sustainable operations.

I. INTRODUCTION

Prospective The global energy landscape is undergoing significant transformation due to rapid technological advancement, population growth, and expanding industrialization. Some alarming projections suggest that, unless the consumption of all devices is reduced, energy demand by 2040 will exceed the available energy supply [1]. This pressing challenge underscores the urgent need for accurate electricity consumption forecasting models, which are instrumental in enabling better energy resource management, cost reduction, and infrastructure planning [2]. Electricity demand forecasting has gained critical importance amid digital transformation, where Artificial Intelligence (AI) must address growing complexity in modern power systems [3], [4]. Traditional rule-based or statistical models, while historically useful, often struggle to capture the dynamic, non-linear patterns that characterize modern energy systems. As a result, the focus has shifted toward more advanced techniques capable of uncovering hidden patterns in sequential data. Time series forecasting plays a crucial role in anticipating future energy consumption by analyzing historical usage patterns. It is widely applied in modern energy systems for tasks such as electricity demand prediction, load management, and renewable energy integration. These forecasting techniques enable utilities and industries to optimize grid operation, reduce energy waste, and support data-driven decision-making in energy planning and maintenance. With the increasing complexity of smart grids and variable renewable energy sources, advanced artificial intelligence and deep learning models such as LSTM, BiLSTM, and hybrid neural networks have shown remarkable performance in capturing nonlinear temporal dependencies and improving forecast accuracy [5], [6].

Among these advancements, deep learning models, particularly Recurrent Neural Networks (RNNs) and their derivatives like LSTM and BiLSTM have gained attention for their ability to model complex temporal dependencies [7]. These architectures have demonstrated strong predictive performance in energy forecasting due to their capacity to capture long-term and nonlinear relationships. Nevertheless, they typically require substantial data volumes, high computational power, and fine-tuning of hyperparameters. In contrast, classical statistical models such as Autoregressive Integrated Moving Average (ARIMA) and Trend and Seasonal Components (TBATS) continue to be employed for their interpretability and efficiency, especially in low-data scenarios or when model transparency is critical [8]. While much of the existing literature, [9], [10] has focuses on residential energy forecasting, long-term electricity consumption prediction in industrial environments presents unique challenges and opportunities. Industrial facilities, unlike residential users, follow more consistent and structured consumption patterns that are closely aligned with production processes. In fact, advanced electricity forecasting provides a dual-function capability; beyond improving energy procurement and operational efficiency, it enables predictive maintenance strategies that constitute the initial safeguard against equipment failures capable of interrupting production. This dual capability is especially critical in industrial environments, where unplanned outages can escalate to costly production halts and irreversible equipment damage [4]. Therefore, robust and context-aware predictive models are essential to support energy efficiency, operational continuity, and sustainable industrial growth.

This study offers an in-depth investigation of electricity consumption forecasting methods in an industrial context, focusing particularly on a cement manufacturing plant, a sector recognized for its high energy requirements and repetitive production processes. The analysis used the predictive capabilities of advanced deep learning models, specifically LSTM and BiLSTM, which were optimized through the Optuna framework to enable automated and efficient hyperparameter tuning. This research aims to rigorously evaluate these models in terms of predictive accuracy, computational efficiency, and practical applicability when confronted with dataset industrial electricity consumption. In addition, the study highlights the potential of accurate forecasting to support preventive maintenance strategies, improve energy management practices, and strengthen decision-making in energy-intensive industries. By bridging advanced artificial intelligence methods with traditional statistical approaches, this work contributes to the development of intelligent forecasting systems that enhance operational reliability, reduce downtime risks, and foster sustainable energy practices in large-scale manufacturing environments. The rest of the paper is structured as follows. Section 2 provides an overview of state-of-the-art approaches to electricity consumption forecasting. Section 3 describes the adopted methodology. Section 4 presents the dataset, experimental results, and comparative discussion. Section 5 concludes the paper and highlights future research directions.

II. RELATED WORK

This section presents a review of recent methods, published from 2022 onwards, for forecasting electricity consumption. Various machine learning (ML) and deep learning (DL) techniques have been employed to capture the temporal and nonlinear characteristics of energy consumption patterns. Recent advances in deep learning have enabled the development of models capable of addressing complex prediction challenges in the energy domain. These models are particularly effective when large datasets are available and the input-output relationships exhibit high levels of complexity conditions commonly found in decentralized power systems. In such contexts, neural network architectures can be tailored to tackle multiple forecasting tasks efficiently. Recurrent architectures, especially LSTM networks, have emerged as powerful tools for capturing temporal patterns in electricity consumption data. For example, the study in [11] introduced a deep LSTM-based framework for short-term residential load forecasting, demonstrating its superiority over classical statistical techniques such as ARIMA. Similarly, [12], designed a sequence-to-sequence LSTM model that successfully leverages the sequential structure inherent in energy consumption time series. More recently, BiLSTM models have emerged as an enhanced alternative, leveraging both past and future context [13]. In a comparative study given by [7], BiLSTM provided better generalization on volatile load profiles compared to unidirectional LSTM. However, the study also highlighted the sensitivity of BiLSTM models to hyperparameter configurations. To address this issue, researchers have turned to automated hyperparameter optimization tools, such as Optuna. Applied Optuna for fine-tuning the learning rate, batch size, and network depth of a BiLSTM model used for smart grid forecasting. The optimized model showed a significant reduction in Root Mean Square Error (RMSE) and Mean Absolute Percentage Error (MAPE), underlining the value of meta-optimization strategies in deep learning applications [14], [15]. The quality assessment of the studies involved applying inclusion and exclusion criteria, ensuring the identification of experimental research that included variables directly related to the research question. Data extraction was carried out by analyzing the results of the selected approaches. To summarize and synthesize the results, experimental studies were identified using specific keywords relevant to the research question. A table was then prepared, which contained a synthesis of the selected articles, including the publication year, the models used, the periods covered, and the dataset.

Table 1: Present the summary of the main articles related to the present work.

Autors	Methods	Dataset
[16]	Deep-learning hybrid forecasting model, namely: EMD-SVR-PSO-AR-GARCH	New South Wales (NSW, Australia) market
[17]	Ensemble learning Compared: gradient boosted regression trees, random forests and an adaptation of Adaboost.	office building located in the campus of ISEP/GECAD(building is occupied in daily basis by about 30 people)
[9]	Combines three models: LSTM, GRU, and Temporal Convolutional Network (TCN)	2000 clients from Bejaia, Algeria
[18]	XGBoost classification model, Multi-Layer Perceptron (MLP) model that is used to make the final electricity consumption prediction.	500 residential users placed in a southeastern region of Spain.
[8]	Evaluated the ARIMA and TBATS statistical prediction methods and compared them with neural forecasting methods	Smart house that is equipped with solar panels and batteries for energy storage.

[19]	Hybrid multi-algorithm method. called ICMD-ANN-EDLSTM.	Descriptive statistic of daily electricity demand (MWh) at four substation South-east Queensland, Australia.
[20]	Improved SSA and multivariable input RNNs to achieve adaptive decomposition of raw time series data and fusion input of multiple features, ADMIF.	Moroccan buildings' electricity consumption dataset (MORED).
[10]	Time series dense encoder (TiDE) model.	City level, of residential customers and the technological consumption of electricity suppliers.
[21]	Modeling spatiotemporal series using Graph Neural Networks (GNNs), with a focus on the structure of decentralized electrical networks.	12 regions of French mainland– excluding Corsica.

III. METHODOLOGY

This section introduces the dataset utilized in our experiments and outlines the baseline models, specifically LSTM and BiLSTM architectures. Additionally, we detail the performance evaluation metrics applied, which include Mean Absolute Error (MAE), Root Mean Square Error (RMSE), Relative MAE, and the Coefficient of Determination (R^2).

III.1 DATASET DESCRIPTION

The empirical analysis utilizes a proprietary dataset derived from a cement manufacturing plant located in the western region of Algeria, classified as a high-voltage consumer. The facility receives its electrical supply at 60 kV from the national transmission operator via a dedicated 220/60 kV substation. The dataset comprises detailed electricity consumption records collected over a five-month period at 10-minute intervals. It reflects real operational conditions, including variations in production cycles, equipment startup and shutdown phases, and environmental influences. The temporal resolution and industrial context of the data make it highly valuable for evaluating the performance of forecasting models in scenarios where energy demand is both high and tightly coupled to continuous manufacturing processes.

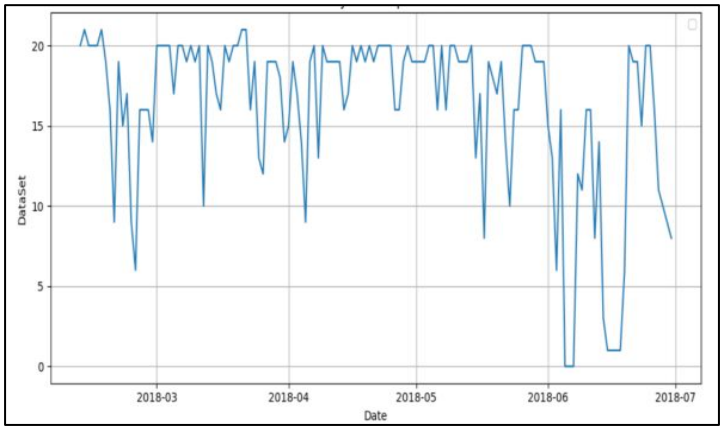

Figure 1: Electricity consumption curve.

III.2 MODELS BASELINE

In this study, both Long Short-Term Memory (LSTM) and Bidirectional LSTM (BiLSTM) models are evaluated as baseline approaches, with and without Optuna-based optimization. The following paragraph describes the differences between the LSTM and BiLSTM architectures. LSTM: The Long Short-Term Memory (LSTM) network, is a type of Recurrent Neural Network (RNN) designed to capture long-term dependencies in sequential data by incorporating specialized memory units [22]. These memory units consist of a cell state and three gates (input, forget, and output) that regulate the flow of information, enabling the network to retain or discard information over time. This architecture is particularly effective in modeling non-linear and temporal relationships in time series data, such as electricity consumption patterns. BiLSTM: the Bidirectional LSTM (BiLSTM) extends the LSTM architecture by processing the input sequence in both forward and backward directions [23]. This dual-path structure enables the model to capture dependencies not only from past to future but also from future to past within the sequence, thereby improving the model's ability to learn complex temporal dynamics. Both architectures were implemented with a sequence of layers, including input normalization, one or more LSTM/BiLSTM layers, dropout regularization to prevent overfitting, and a fully connected dense layer for output generation. Hyperparameter tuning, such as the number of hidden units, learning rate, batch size, and sequence length, was performed using the Optuna optimization framework to maximize forecasting performan]ce.

III.3 EVALUATION METRICS

The models were evaluated using the different metrics (see Table 2). These metrics were computed for each tested model LSTM, BiLSTM, LSTM (Optuna) and BiLSTM (Optuna) to allow a fair and multidimensional comparison of model accuracy, robustness, and generalization capability on the cement factory dataset.

Table 2: Evaluation Metric.

Metric	Equation	Description
Mean Absolute Error (MAE)	$MAE=\frac{1}{n}\sum_{i=1}^{n}\lvert X_i-\hat{X}_i\rvert$ (1)	Average absolute difference between predicted and actual values. Penalizes all errors equally.
Root Mean Square Error (RMSE)	$RMSE=\sqrt{\frac{1}{n}\sum_{i=1}^{n}(X_i-\hat{X}_i)^2}$ (2)	Square root of the average squared errors. Heavily penalizes large deviations.
Relative MAE	$RMAE=\frac{\frac{1}{n}\sum_{i=1}^{n}\lvert X_i-\hat{X}_i\rvert}{\frac{1}{n}\sum_{i=1}^{n}X_i}$ (3)	Is a normalized version of the Mean Absolute Error (MAE).
Coefficient of Determination (R^2)	$R^2=1-\frac{\sum_{i=1}^{n}(X_i-\hat{X}_i)^2}{\sum_{i=1}^{n}(X_i-\bar{X})^2}$ (4)	Proportion of variance in the dependent variable explained by the model. Ranges from 0 (no fit) to 1 (perfect fit).
Training Time	TrainT (measured in seconds/minutes)	Time required to train the model on historical data. Key for scalability.

IV. RESULTS AND DISCUSSION

This section presents the results of our research alongside an in-depth discussion of the experimental findings, highlighting the implementation choices, methodological steps, and comparative insights. The entire experiment was conducted on the Google Colab environment to leverage cloud-based computational resources. The architectures were implemented using the TensorFlow framework and the Keras library in Python to ensure a scalable and efficient training environment. For both the LSTM and BiLSTM models, a temporal window size of 72 was utilized, representing a 48-hour historical sequence, to capture the intricate short-term dependencies inherent in industrial electricity consumption. While initial training employed the Adam optimizer [24] with a MAE loss function, the performance of both models was systematically enhanced through the integration of Optuna, a Bayesian hyperparameter optimization framework. This optimization phase was pivotal in identifying the ideal configuration for critical parameters, including learning rates, hidden units, and dropout rates, thereby maximizing predictive accuracy and ensuring robust generalization across both neural architectures. The following section presents a detailed comparison of the results from the four methods, namely LSTM and BiLSTM, with and without Optuna optimization, in terms of predictive accuracy, computational complexity, and their applicability to industrial electricity forecasting scenarios.

IV.1 TRAINING AND VALIDATION RESULT

The training and validation loss patterns of the LSTM and BiLSTM architectures, including both baseline and Optuna-optimized configurations, are evaluated. The observed loss trends provide insights into each model's convergence behavior and generalization capability. Figure 2 shows the training and validation loss evolution of the baseline model LSTM which exhibits a rapid decrease in training loss, stabilizing around 0.002, while the validation loss remains higher and fluctuates between approximately 0.0025 and 0.005, indicating overfitting and limited generalization. In contrast, in Figure 3, the BiLSTM model demonstrates more stable convergence, with reduced variance in validation loss and a smaller gap between training and validation curves, reflecting improved generalization performance. The improved behavior of the BiLSTM can be attributed to its bidirectional architecture, which captures temporal dependencies in both forward and backward directions and provides richer contextual representations. Figures 4 and 5 illustrate the performance of the LSTM and BiLSTM architectures following Optuna-driven hyperparameter optimization. The optimized models exhibit accelerated convergence and significantly smoother loss trajectories, with the final loss values stabilizing at approximately 0.017. Furthermore, the minimal divergence between the training and validation loss curves suggests a substantial improvement in model robustness and a heightened resistance to overfitting. Overall, these results confirm that while BiLSTM architectures outperform standard LSTM models, Optuna-based hyperparameter optimization further improves convergence stability and predictive accuracy, highlighting the importance of systematic hyperparameter tuning for sequence-based learning tasks.

IV.2 EVALUATION TEST AND COMPARATIVE STUDY

This section presents the experimental evaluation and comparative analysis of the four models: the LSTM, BiLSTM, Optuna-optimized LSTM and Optuna-optimized BiLSTM. All models were evaluated on the test dataset using standard metrics, including Root Mean Square Error (RMSE), Relative Mean Absolute Error (RMAE), R^2 score, and training time, providing a comprehensive assessment of predictive accuracy and computational efficiency. Table 3 summarizes the performance of LSTM and BiLSTM models with and without Optuna-based hyperparameter optimization. The results demonstrate that Optuna optimization significantly improves predictive accuracy, as reflected in lower RMSE and RMAE values and higher R^2 scores. Among all configurations, the Optuna-optimized BiLSTM achieves the best performance, balancing high predictive accuracy with moderate training time. Figure 6 compares the real and predicted energy consumption values for the two best-performing models. Both the Optuna-optimized LSTM and BiLSTM closely follow the real consumption trends, with the BiLSTM predictions showing slightly higher alignment and smoother tracking, highlighting its superior ability to capture temporal dependencies and improve forecasting accuracy.

Table 3: Comparative Performance of Baseline and Optuna-Optimized LSTM/BiLSTM.

Prediction Model	RMSE	RMAE (%)	R^2 Score	Training Time (TT)
LSTM	0.225	56	-0.002	4 min 57 s
BiLSTM	0.230	42	-0.001	8 min 19 s
Optuna-Optimized LSTM	12.08	24	0.665	5 min 15 s
Optuna-Optimized BiLSTM	0.220	20	0.890	6 min 05 s

Source: Authors, (2026).

For the LSTM and BiLSTM models, the window size and number of epochs were manually chosen. Several combinations were tested, and the best-performing configuration was retained for each model. Specifically, the LSTM model achieved its best results, yielding an RMSE of 0.225, an RMAE of 56%, and an R^2 score of -0.002, with a training time of 4 minutes 57 seconds. The BiLSTM model, achieved similar results (RMSE = 0.230, RMAE = 42%, R^2 = -0.001) with a significantly lower training time of 8 minutes 19 seconds. The Optimized-Optuna BiLSTM model achieved the best performance overall, with an RMSE of 0.220, an RMAE of 20%, and a training time of just 6 minutes 05 seconds, clearly demonstrating the advantage of automated tuning in improving both accuracy and efficiency.

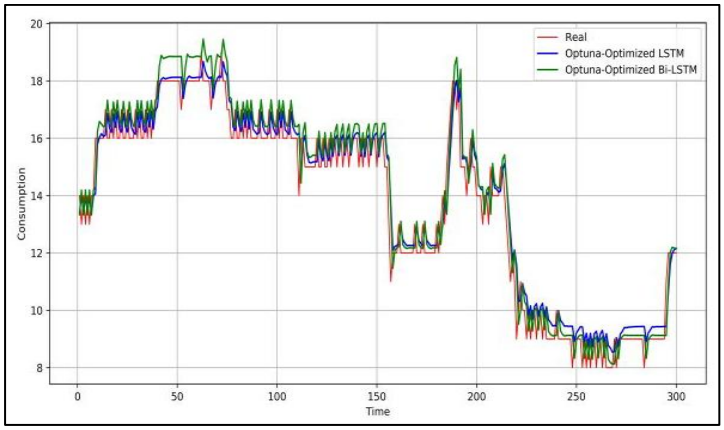

Figure 6: Real Vs Predicted Consumption of Optuna-Optimized LSTM/BiLSTM.
Source: Authors, (2026).

The visualization in Figure 6 enables a direct comparison of how the optimized models handle the test set data. Both models generally capture the overall trend, successfully tracking major peaks and the general movement of real consumption, particularly during periods of higher usage (time steps 0–200). However, the Optuna-Optimized BiLSTM consistently demonstrates superior performance across the entire time series. Its predictions remain closer to the actual consumption, indicating lower overall error. This advantage is most pronounced during periods of high volatility (time steps 200–270), where real consumption dips sharply from approximately 15 to 8. The BiLSTM accurately follows this decline and subsequent low-consumption plateau, reflecting its ability to leverage bidirectional temporal dependencies. In contrast, the Optuna-Optimized LSTM exhibits clear limitations in the low-consumption segment. It significantly underestimates the actual values during the dip, highlighting the unidirectional LSTM reliance solely on past trends, which reduces its effectiveness in capturing abrupt changes and maintaining accuracy during volatile periods. These results indicate that for this consumption forecasting task, access to both past and future temporal context is highly informative. The Optuna-Optimized BiLSTM emerges as the preferred model, as its bidirectional memory structure enables more robust and accurate predictions across varying consumption levels and volatility.

V. CONCLUSIONS

This study presented a comprehensive analysis of advanced RNN architectures, LSTM, BiLSTM, enhanced with Optuna-based hyperparameter optimization, the context of long-term electricity consumption forecasting for a cement manufacturing facility. Through rigorous experimentation on real-world industrial data, with Optuna-Optimized BiLSTM achieving the best overall results across all evaluation metrics. The automatic parameter selection provided by Optuna not only improved prediction quality but also reduced training time, making the model more suitable for practical deployment in energy-intensive environments. These findings reinforce the potential of optimized deep learning methods to serve as reliable tools in smart energy management systems, enabling predictive maintenance, cost savings, and more sustainable production planning in industrial settings.

ABSTRACT

Graph Neural Networks (GNNs), particularly LightGCN, have achieved strong performance in collaborative filtering-based recommendation systems. However, their black-box nature makes it difficult to explain why specific items are recommended, limiting trust and adoption in user-facing applications. In this paper, we propose a post-hoc explainability framework for LightGCN combining two complementary techniques: Propagation Path Analysis, which decomposes recommendation scores by propagation layer to attribute influence to specific training interactions, and Counterfactual Graph Editing, which identifies the most influential user-item edges through structural sensitivity analysis and targeted edge removal. We evaluate on MovieLens-1M against three baselines including random edge removal, degree-based attribution, and LIME. Our method achieves a mean absolute score drop of 0.0322, representing a 3.02× lift over random, a 1.26× lift over LIME, and a 5.35× lift over degree-based attribution. Faithfulness evaluation against post-fine-tuning ground truth yields Pearson r = 0.536, confirming that structural sensitivity reliably identifies influential edges without model retraining. Layer contribution analysis reveals that LightGCN recommendations are predominantly driven by direct interactions (Layer 0) and 1-hop neighbours (Layer 1), with deeper layers contributing progressively less.

I. INTRODUCTION

Recommender systems have become fundamental infrastructure across e-commerce, streaming, and information retrieval platforms. Collaborative filtering based on Graph Neural Networks (GNNs) has emerged as a dominant paradigm, with LightGCN [1] achieving strong empirical performance by simplifying the GNN architecture to pure neighbourhood aggregation across multiple propagation layers. Despite these advances, GNN-based recommenders remain largely opaque. Users receive no explanation for why a specific item was suggested, system operators cannot audit model behaviour for bias or fairness [2], and regulatory frameworks such as the EU AI Act increasingly require explanations for automated decisions affecting individuals. Prior work has shown that a lack of transparency directly erodes user trust in algorithmic systems [3]. Existing explainability methods largely fall into two categories: gradient-based attribution and perturbation-based probing (LIME [4], SHAP [5]). Both treat the model as a black box and ignore the structural properties of GNNs — namely, that information flows through a graph topology across multiple propagation hops. This structural blindness limits their ability to produce explanations grounded in the model's actual computation. A comprehensive survey of explainability techniques for recommender systems [3] highlights that graph-structural methods remain underexplored relative to their importance. We propose a post-hoc explainability framework designed specifically for LightGCN's graph-structural characteristics. Our contributions are:

1. Propagation Path Analysis: decomposing LightGCN scores by propagation layer and attributing influence to specific training interactions at the dominant hop depth.

2. Counterfactual Graph Editing: quantifying edge influence by measuring score changes upon targeted edge removal, without model retraining.
3. Comprehensive evaluation against three baselines across four rank positions on MovieLens-1M, demonstrating 3.02x lift over random selection.
4. Faithfulness evaluation against post-fine-tuning ground truth (Pearson).
5. Qualitative layer contribution analysis across five diverse recommendation cases.

II. RELATED WORK

II.1 GNN-BASED RECOMMENDATION

By [1] proposed LightGCN as a simplification of NGCF [6], retaining only weighted neighbourhood aggregation per layer. Training uses Bayesian Personalised Ranking (BPR) [7], which optimises relative ordering of observed versus unobserved interactions. Earlier approaches such as SpectralCF [8] operated in the spectral domain but were limited by scalability. Graph Attention Networks (GAT) [9] introduced learnable attention weights over neighbours; however, LightGCN demonstrates that removing such parameterisation improves generalisation on collaborative filtering data. A broader survey of deep learning approaches to recommendation is provided by [10].

II.2 EXPLAINABILITY IN GNNS

GNNExplainer [11] identifies a subgraph that maximises mutual information with the model's prediction, targeting node classification rather than recommendation. CF-GNNExplainer [12] extends counterfactual perturbations to GNNs but is computationally expensive and not designed for large-scale bipartite recommendation graphs. PGExplainer [13] trains a parameterised mask generator for GNN explanations, requiring additional training. SubgraphX [14] uses Monte Carlo Tree Search to identify explanatory subgraphs at greater computational cost. These methods share a common limitation: they do not account for the bipartite, link-prediction nature of the recommendation task.

II.3 EXPLAINABILITY IN RECOMMENDER SYSTEMS

LIME [4] fits a local linear surrogate by perturbing user interaction histories and fitting weighted regression. It is model-agnostic but ignores graph topology and requires many forward passes. SHAP [5] provides Shapley value attributions but is similarly black-box. Attention-based methods [15] use attention weights as proxies, but these do not reliably correlate with feature importance [16], and LightGCN uses no attention. A systematic categorisation of post-hoc explanation approaches by type and model family is provided by [17]. In the recommendation setting, PRINCE [18] generates counterfactual explanations for knowledge-graph-based recommenders; our work targets GNN-based collaborative filtering and provides layer-level attribution alongside edge-level counterfactuals. Our work is most closely related to counterfactual approaches for recommendation [19], which we extend with layer-level propagation path analysis and a systematic multi-baseline faithfulness evaluation.

III. BACKGROUND: LIGHTGCN

III.1 PROBLEM FORMULATION

Let $\mathcal{U}$ and $\mathcal{I}$ be the sets of users and items. Observed interactions are encoded in $R \in \{0,1\}^{|\mathcal{U}|\times|\mathcal{I}|}$ where R_{ui} = 1 indicates an interaction. The task is to score unobserved pairs $\hat{y}_{ui}$ and rank items per user.

III.2 GRAPH CONSTRUCTION

LightGCN builds a bipartite graph $G=(V,E)$ with $V=\mathcal{U}\cup\mathcal{I}$. The full adjacency matrix is given by Eq. (1). With degree matrix D where $D_{vv}=\sum_j A_{vj}$, the symmetrically normalised adjacency is given by Eq. (2). This scales each edge by the inverse square root of source and target node degrees, preventing high-degree nodes from dominating aggregation.

III.3 PROPAGATION AND TRAINING

$$A=\begin{pmatrix}0 & R\\ R^{\top} & 0\end{pmatrix} \tag{1}$$

$$\tilde{A}=D^{-\frac{1}{2}}AD^{-\frac{1}{2}} \tag{2}$$

At layer k, embeddings are updated by neighbourhood aggregation as shown in Eq. (3), where $e^{(0)}$ are learnable initial embeddings. In matrix form: $E^{(k)}=\tilde{A}E^{(k-1)}$. Final embeddings are the layer-averaged representations given in Eq. (4). The predicted score is $\hat{y}_{ui}=e_u{}^{\top}e_i$, and training uses BPR loss as in Eq. (5), where $\mathcal{O}=\{(u,i,j)\mid R_{ui}=1,R_{uj}=0\}$, σ is the sigmoid function, and λ is an L2 regularisation coefficient.

$$e_u^{(k)}=\sum_{i\in\mathcal{N}_u}\frac{1}{\sqrt{|\mathcal{N}_u|}\sqrt{|\mathcal{N}_i|}}e_i^{(k-1)},\ e_i^{(k)}=\sum_{u\in\mathcal{N}_i}\frac{1}{\sqrt{|\mathcal{N}_i|}\sqrt{|\mathcal{N}_u|}}e_u^{(k-1)} \tag{3}$$

$$e_u=\frac{1}{K+1}\sum_{k=0}^{K}e_u^{(k)},\ e_i=\frac{1}{K+1}\sum_{k=0}^{K}e_i^{(k)} \tag{4}$$

$$\mathcal{L}_{BPR} = -\sum_{(u,i,j)\in\mathcal{O}} ln\sigma(\hat{y}_{ui} - \hat{y}_{uj}) + \lambda\left\|E^{(0)}\right\|^2 \quad (5)$$

IV. PROPOSED FRAMEWORK

Our framework answers two complementary questions for any recommendation (u, i): (1) at which propagation depth does the signal originate? and (2) which training interactions are most influential? Figure 1 shows the complete pipeline.

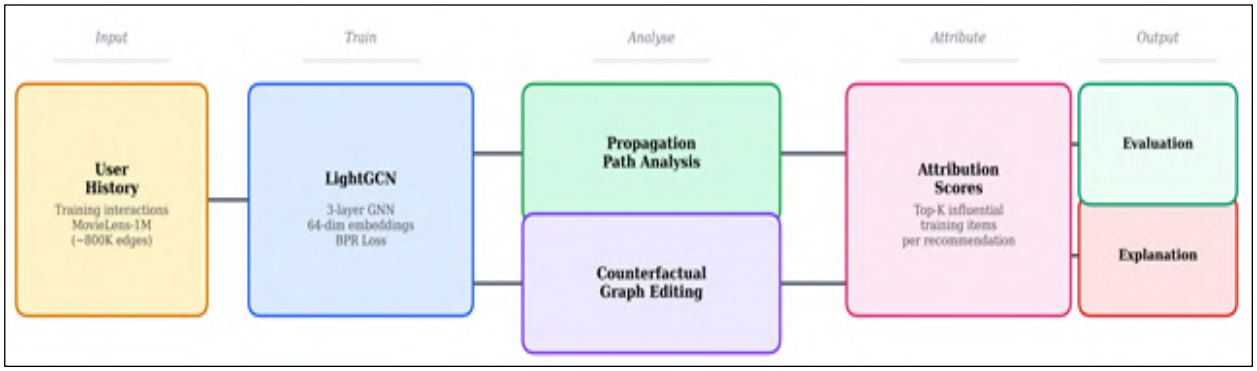

Figure 1: System architecture of the Explainable LightGCN pipeline.
Source: Authors, (2026).

IV.1 PROPAGATION PATH ANALYSIS

We define the layer contribution at hop k as the inner product of the layer-k embeddings, as in Eq. (6). This captures the contribution of information propagated exactly k hops. The dominant layer is $k^*=arg\ max_k C_k(u,i)$. A dominant C_0 indicates recommendation driven by the user's own interaction embeddings; a dominant C_1 indicates collaborative signal from items co-liked by users with overlapping histories.

$$C_k(u,i) = e_u^{(k)^\top} e_i^{(k)} \quad (6)$$

For each item j in the user's history, the attribution score measures its embedding's contribution to the target item's score at the dominant layer, as in Eq. (7). The first term is the LightGCN normalisation weight for edge (u,j); the second measures alignment between item j's outgoing embedding and the target item's embedding at the dominant layer. Items are ranked by $|\alpha(j,u,i)|$ to produce top-K attributed interactions.

$$\alpha(j,u,i) = \frac{1}{\sqrt{|\mathcal{N}_u|}\sqrt{|\mathcal{N}_j|}} \cdot e_j^{(k^*-1)^\top} e_i^{(k^*)} \quad (7)$$

IV.2 COUNTERFACTUAL GRAPH EDITING

For attributed training item j, define the counterfactual graph G_{-j} as the original graph with edge (u,j) removed: $\mathcal{E}_{-j}=\mathcal{E}\{(u,j)\}$. We renormalise to obtain $\tilde{A}_{-j}$ and compute the structural score drop with model weights held fixed, as in Eq. (8). We also measure the rank change: $\Delta r_i^{(j)} = r_i(\tilde{A}_{-j}) - r_i(\tilde{A})$. Evaluation is performed at rank positions $r \in \{1, 5, 10, 20\}$.

$$\Delta\hat{y}_{ui}^{(j)} = \hat{y}_{ui}(\tilde{A}) - \hat{y}_{ui}(\tilde{A}_{-j}) \quad (8)$$

IV.3 FAITHFULNESS EVALUATION

To test whether structural drops predict actual model adaptation, for 50 users we compare the structural predicted drop against the actual drop after 5-epoch fine-tuning on G_{-j} with learning rate $\eta=10^{-3}$. Faithfulness is measured via Pearson r and Spearman ρ.

V. EXPERIMENTAL SETUP

V.1 DATASET

We evaluate on MovieLens-1M [20], containing 1,000,209 ratings from 6,040 users on 3,706 movies. After 5-core filtering and binarisation to implicit feedback, the training set has approximately 800,167 interactions (80/20 split). Figure 2 shows the BPR training loss, and Figure 3 shows the degree distributions of the resulting training graph. The item distribution exhibits a pronounced long tail (median 90, mean 235), which directly motivates our analysis of why degree-based attribution fails: high-degree items are suppressed by LightGCN's symmetric normalisation.

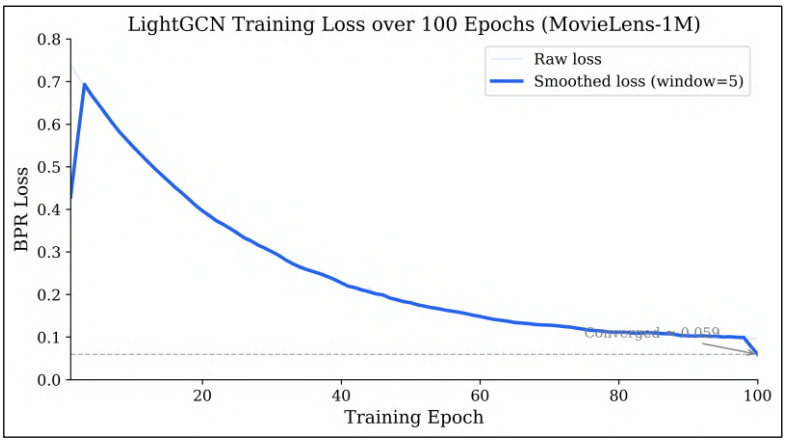

Figure 2: LightGCN BPR training loss over 100 epochs on MovieLens-1M. The model converges smoothly to approximately 0.059 by epoch 100.
Source: Authors, (2026).

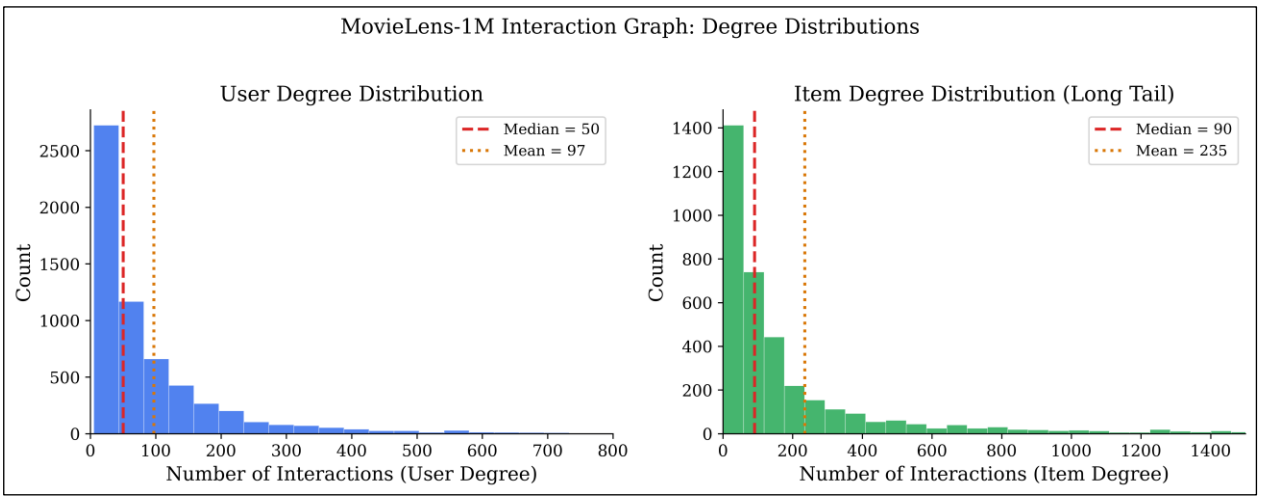

Figure 3: Degree distributions of users (left) and items (right) in the MovieLens-1M training graph after 5-core filtering.
Source: Authors, (2026).

V.2 MODEL CONFIGURATION

We train a 3-layer LightGCN (K=3) with embedding dimension d=64, Adam optimiser, learning rate 10^{-3}, BPR loss with L2 regularisation λ=10^{-4}, 100 epochs, and batch size 2048.

V.3 BASELINES

Random: Randomly sample K items from the user's training history. Tests whether PropPath beats chance.

Degree: Rank the user's training items by global degree and select the top-K. Tests the hypothesis that popular items are more influential.

LIME: Sample N_p = 100 binary masks over the user's history. For each mask m_t, compute the score $s(m_t)$=$\hat{y}_{ui}\left(\tilde{A}(m_t)\right)$ and fit a weighted Ridge regression as in Eq. (9) with exponential kernel weights w_t= $exp(-(1-\bar{m}_t)^2/2\sigma^2)$, σ= 0.25. Top-K items by $|\beta_j|$ are selected.

$$\beta=arg\ min_\beta \sum_{t=1}^{N_p} w_t(s(m_t)-\beta^\top m_t)^2+\alpha_{ridge}||\beta||^2 \quad (9)$$

VI. RESULTS AND ANALYSIS

VI.1 COUNTERFACTUAL EVALUATION

Table 1 presents mean absolute score drops, and Figures 4 and 5 visualize these results.The 3.02× lift over random confirms PropPath identifies genuinely influential edges. The 1.26× lift over LIME demonstrates that graph-structural knowledge adds measurable value beyond black-box probing — at a fraction of the computational cost (1 forward pass vs. 100 for LIME). The degree baseline performing below random (lift 0.56×) is explained by symmetric normalisation: high-degree items have small individual edge weights scaling as $1/\sqrt{d_i}$, so removing any single edge causes negligible score change.

Table 1: Mean absolute score drop by method and target rank position. Higher = stronger attribution quality.

Method	R@1	R@5	R@10	R@20	Lift
PropPath (Proposed)	0.0313	0.0335	0.0298	0.0341	3.02x
LIME	0.0251	0.0268	0.0238	0.0263	2.38x
Random	0.0102	0.0121	0.0104	0.0098	1.00x
Degree	0.0055	0.0078	0.0055	0.0053	0.56x

Source: Authors, (2026).

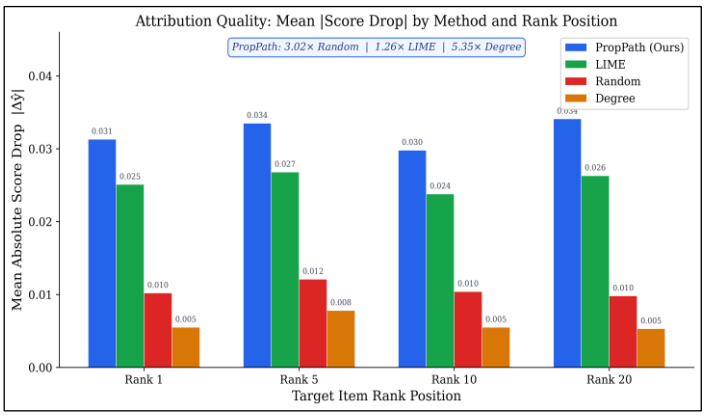

Figure 4: Mean absolute score drop per method and rank position.
Source: Authors, (2026).

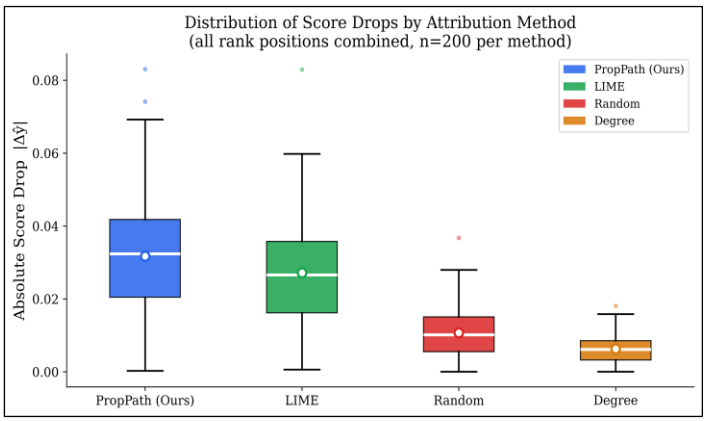

Figure 5: Distribution of score drops (n=200 per method).
Source: Authors, (2026).

VI.2 RANK CHANGE ANALYSIS

Table 2 and Figure 6 present rank change rates. Rank change rates increase monotonically with rank position for PropPath and LIME, since items at rank 20 have smaller score margins. The Degree baseline's high rank change rates (up to 72%) despite low score drops reveal a deceptive pattern: removing popular items triggers widespread small normalisation-induced rank shuffles without genuinely altering the model's preference signal.

Table 2: Rank change rate (RC%) by method and target rank position.

Method	R@1	R@5	R@10	R@20	Overall
PropPath (Proposed)	6.0%	10.0%	20.0%	54.0%	22.5%
LIME	2.0%	4.0%	12.0%	52.0%	17.5%
Random	0.0%	22.0%	24.0%	40.0%	21.5%
Degree	14.0%	36.0%	60.0%	72.0%	45.5%

Source: Authors, (2026).

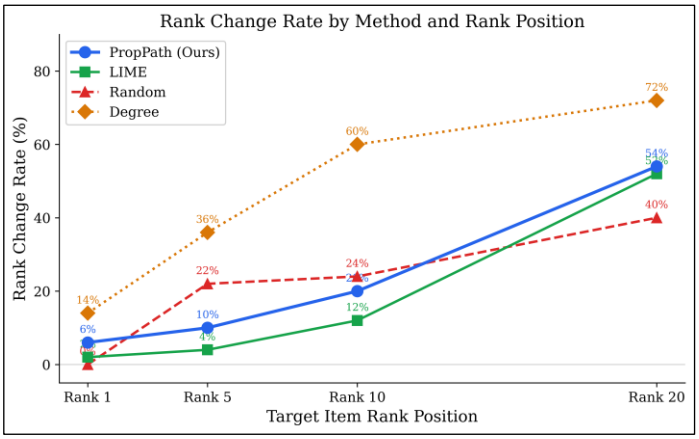

Figure 6: Rank change rate (%) by method across four target rank positions.
Source: Authors, (2026).

VI.3 FAITHFULNESS EVALUATION

Table 3 and Figures 7 and 8 present faithfulness results.Pearson $r = 0.536$ confirms a moderate positive relationship between structural sensitivity and post-fine-tuning drops. The divergence between Pearson and Spearman ($\rho = 0.281$) reflects the influence of an extreme outlier. Sign agreement at 51.0% indicates that PropPath reliably ranks edges by influence magnitude but does not reliably predict the direction of score change under fine-tuning. The systematic positive bias (mean error ≈ 0.103) confirms that structural sensitivity overestimates drops: the model compensates for removed edges via other embedding dimensions during fine-tuning.

Table 3: Faithfulness evaluation: structural sensitivity vs. post-fine-tuning ground truth.

Metric	Value
Pearson r	+0.536 (p < 0.0001)
Spearman ρ	+0.281 (p == 0.0005)
Sign Agreement	51.0% (75/147)
Sample size	147 (50 users x 3 edges)

VI.4 LAYER CONTRIBUTION ANALYSIS

Table 4 and Figures 9 and 10 present layer contribution scores across five recommendation cases. Three patterns emerge. First,, indicating recommendations primarily driven by direct interaction embeddings. Second, in Layer 1-dominant cases (American Beauty, Being John Malkovich), the top attributed items are thematically related but not directly co-interacted with by the target user, confirming that 1-hop collaborative signal is captured. Third,in all cases, suggesting actionable explanations lie within 1 hop of the user for 3-layer LightGCN on MovieLens-1M.

Table 4: Propagation layer contribution scores for five representative recommendation cases.

Case	C0	C1	C2	C3	k*	C0^	C1^	C2^	C3^
Strangers on a Train	**7.84**	5.28	2.54	1.58	0	**0.45**	0.31	0.15	0.09
American Beauty	2.38	**8.24**	3.67	4.60	1	0.13	**0.44**	0.19	0.24
The Fly	**4.49**	2.90	1.41	1.49	0	**0.44**	0.28	0.14	0.14
Being John Malkovich	6.96	**7.34**	2.66	3.79	1	0.34	**0.35**	0.13	0.18

VI.5 PER-USER AND CASE STUDY ANALYSIS

Figure 11 presents per-user score drops for PropPath and LIME across 10 representative users. Figure 12 presents the case study for User 5439. The top attributed item (A Family Thing, 1996) is a warm family comedy-drama — semantically coherent with Babe's genre profile. It is ranked first by both PropPath and LIME, providing cross-method corroboration. The score drop of 0.094 is the largest single-edge drop in our evaluation, confirming the attribution's quantitative significance.

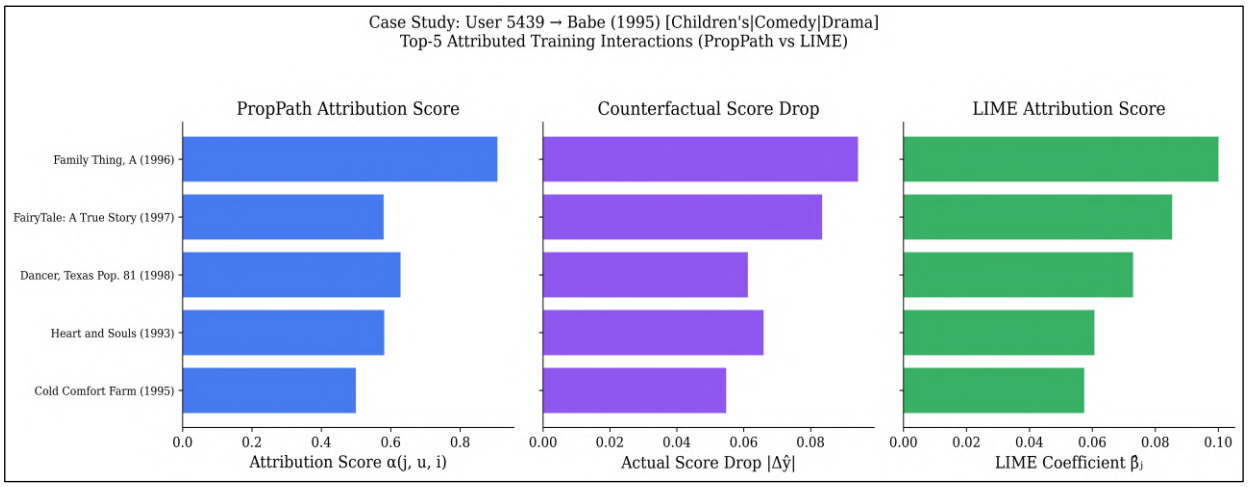

Figure 12: Case study for User 5439 -> Babe (1995). PropPath and LIME both rank A Family Thing (1996) first with score drop 0.094. Source: Authors, (2026).

VII. CONCLUSION

We presented a post-hoc explainability framework for LightGCN combining Propagation Path Analysis with Counterfactual Graph Editing. The framework provides explanations at two levels: the layer level (which propagation hop drives the recommendation) and the edge level (which training interactions are most influential). Quantitative evaluation on MovieLens-1M demonstrates3.02× lift over random, 1.26× over LIME, and 5.35× over degree-based attribution. Faithfulness evaluation yields Pearson $r = 0.536$ against post-fine-tuning ground truth. Layer contribution analysis reveals that actionable explanations lie predominantly within 1 hop of the user, with Layers 2–3 contributing below 25% in all evaluated cases.

Limitations: Sign agreement at 51% indicates structural sensitivity is better suited to influence ranking than directional prediction. The framework is specific to LightGCN and does not directly generalise to attention-based or non-linear GNN architectures.

Future Work: Promising directions include extending to attention-based GNNs, developing user-facing explanation templates, applying the framework to fairness auditing [2], and scaling faithfulness evaluation to larger user samples.

ABSTRACT

Determining the drastic changes in water quality in this contaminated period is an urgent requirement that is crucial for the continued existence of the current and growing water demand. This is why it is essential for maintaining the water supply. Due to variability and complexity in the data, the water quality index (WQI) has been developed as a reliable way to express water quality. Analyzing the data relative to the water quality has been extremely difficult. In this investigation, the WQI prediction of water samples using the novel Hybrid Water Wave Optimized eXtreme Gradient Boosting (HWW-XGB). In this research, the data preprocessing using the Outlier Detection (Box Plot Analysis) and Min-max normalization was finished to minimize the computational time. Pre-processing is a crucial first step in the proposed system because the dataset contains inappropriate and inaccurate data. The Independent Linear Analysis (ICA) is utilized to extract the required features. The pre-processed features are removed through feature extraction, eliminating unnecessary data for the next essential phase. The collected features are fed into Hybrid Water Wave Optimized eXtreme Gradient Boosting (HWW-XGB) classifier. The effectiveness of the proposed approach was demonstrated when compared to the existing method.

I. INTRODUCTION

The WQI is a useful measure for evaluating and tracking the available water resource quality. It gives a numerical rating that illustrates the combined impact of many water quality factors, enabling straightforward comparison and analysis of water quality data. The index considers some physical, chemical, and biological parameters to assess a water body's general health [1]. Temperature, pH level, dissolved oxygen, turbidity, total dissolved solids, biochemical oxygen demand, nitrate, and phosphate concentrations, and the presence of pathogens are some of the factors taken into account by the WQI. These variables indicate several facets of water quality, including its capacity for human use, purity, and ability to sustain aquatic life. It may assess the water's fitness for different benefits, such as drinking, leisure, or ecological health, by monitoring and examining these factors [2]. Individual ratings are produced for each parameter using the relevant scales or algorithms, and each parameter is given a weight depending on its relative relevance. An overall Water Quality Index score is then calculated using these specific ratings. Higher values on the index, which typically ranges from 0 to 100, represent usually higher water quality. Depending on the local and environmental factors, different areas may have unique WQI approaches [3] [4]. These courses provide a clearer knowledge of water quality, enabling decision-makers, resource managers, and the general public to swiftly evaluate a water body's status. Each metric has predetermined thresholds and recommendations often drawn from regulatory requirements [5]. The WQI may convey detailed water quality data clearly and intelligibly, making it a useful communication tool. It aids in locating problem regions, emphasizing possible pollution sources, and directing decision-making procedures for managing and safeguarding water resources. By comparing previous data, the index also makes it possible to analyze long-term trends, which makes it easier to spot changes in water quality over time [6].

Authorities may identify pollution sources, evaluate the efficacy of pollution management methods, and take proactive measures to protect water resources by establishing baseline water quality conditions and monitoring changes [7]. It is crucial to remember that the WQI is a broad indicator and cannot account for every facet of water quality. It gives a general image but does not take the place of careful observation and examination of particular aspects. The weights allocated to each parameter may also change based on the local circumstances and the planned use of the water resource, which might affect the index values and interpretations. Consequently, the WQI should be used in combination to other monitoring and assessment methods to offer a full picture of water quality [8] [9]. The Water Quality Index also helps to educate and raise public awareness about water quality. It allows people to understand the significance of water quality measures and their impacts on the environment and human health. When they have access to clear and understandable information, communities may actively participate in conservation initiatives, advocacy, and protection of their local water resources [10]. It could miss certain details or some pollutants. To acquire a more thorough knowledge of water quality and ecological integrity, it is often used in combination with other monitoring methods and evaluations, such as chemical analysis, biological, and environmental assessments [11]. It offers a standardized approach to assessing water quality across diverse locations by considering several characteristics and producing a composite score. The index promotes trend analysis, improves public awareness, helps with decision-making, and helps preserve and conserve water bodies for the benefit of both people and ecosystems [12-25]. In this study, we proposed the innovative Hybrid Water Wave Optimised extreme Gradient Boosting (HWW-XGB) to estimate the WQI of water samples.

I.1 CONTRIBUTIONS TO THIS STUDY ARE AS FOLLOWS

- This inquiry uses the novel HWW-XGB to predict the WQI of water samples.
- The data in this study were preprocessed using the Min-Max normalization and Outlier Detection techniques.
- The necessary features are extracted using the ICA.
- The performance metrics such as Correlation coefficient, Root Mean square error, Mean square error, Mean absolute error, & sensitivity are analyzed.

The remainder of this research is organized as follows. We provide a thorough assessment of the relevant work in Section 2. A summary of the proposed model's formulation is given in Section 3, and its results are presented in Section 4. The conclusion is mentioned in Section 5.

II. RELATED WORKS

Research [13] evaluated the uncertainties inherent in the WQI model; a statistically solid and rigorous technique. There are eight possible WQI models. Model uncertainty was estimated using a Monte Carlo simulation, and delay in WQI models was predicted using a Gaussian Process Regression approach for each sample location. It was discovered that the sub-index functions add significant uncertainty and impact the model's dependability. Research [14] developed a unique weight-integrated health hazard index and employ soft computing methods, including fuzzy logic, to identify and forecast the quality of drinkable water. This study's findings corroborate ANFIS's status as a credible method for predicting potable water's WQI, making it useful for those choosing water resource management. To effectively control and avoid river pollution, it is necessary to anticipate river WQI. Accurately predicting water quality parameters is challenging because of the significant coupling connection between distinct water quality indicators that impact each other [15]. Research [16] presented Extra Tree Regression (ETR), a ensemble model for forecasting monthly WQI values along the Lam Tsuen River in Hong Kong. Uncertainty analysis shows that the model structure is more influential on prediction accuracy than input parameters. The ETR model is an advancement over prior methods of WQI prediction since it requires fewer input parameters and yields more accurate predictions. Total Fe concentrations were average, 0.14 mg/L over the year. The WQI and the Water Pollution Index data are presented as means and standard deviations. Thirty percent of locations had WQI and Water Pollution Index values for groundwater, which made it unfit for human consumption. The total hazard index (THI) calculated the potential danger to human health from drinking groundwater [17]. The research [18] presented a Deep Learning (DL) stacking ensemble model to predict the WQI by combining existing models.

To reduce water pollution, keeping an eye on pH and turbidity was shown to be particularly important using sensitivity analysis. The greatest uncertainty is associated with the electrical conductivity and total dissolved solids in determining WQI. It allows for deploying clean manufacturing procedures to minimize pollution and enhance water quality by providing precise information to researchers, decision-makers, and water scientists. Research [19] used ML methods, such as character and ensemble learners, to predict WQI. Research [20] investigated the chemistry of view irrigate and evaluated its feasibility for industrial use in the semi-arid Guanzhong Basin in northwest China. Using multivariate statistical analysis methods, they calculated the relative importance of each characteristic to the overall quality of the water used in industrial processes. The results show that calcite, dolomite, anhydrite, and gypsum dissolve in groundwater to control the geochemistry of the water below the surface. According to the geospatial study, the northeastern parts of Xi'an and the Guanzhong Basin are home to the most polluted groundwater samples. Research [21] presented the results of a decade-long evaluation of artificial intelligence research on the WQI, intending to highlight the most promising approaches and promising models for use by future water quality. It also demonstrates that there is no universally superior Artificial intelligence (AI) model; it is necessary to the efficacy of various model combinations to determine which approach or model is most suitable for a certain country or area. AI has been more popular in recent decades, but there is still plenty of potential for competition and advancement in the water quality index. Research [22] used eight water quality criteria to evaluate a drinking water source by analyzing seven hundred and ten samples from a water-poor area of India. The whole sample was split into ten sections, each representing a distinct region of the world.

A approach to the problem of uniquely defining the quality of drinking water, which is complicated by the need to comprehend the cumulative influence of several criteria influencing water quality. A paradigm is presented that, with the correct tools, might be automated to help government organisations better comprehend and control changing water quality.

III. PROPOSED METHOD

In this research, the HWW-XGB was used to estimate the WQI of water samples. The preprocessing of the data using the Outlier Detection (Box Plot Analysis) and Min-max normalization was finished to minimize the computational time. The ICA is utilized to extract the required features. The pre-processed features are removed through feature extraction, eliminating unnecessary data for the next essential phase. Figure 1 shows the flow of the proposed model.

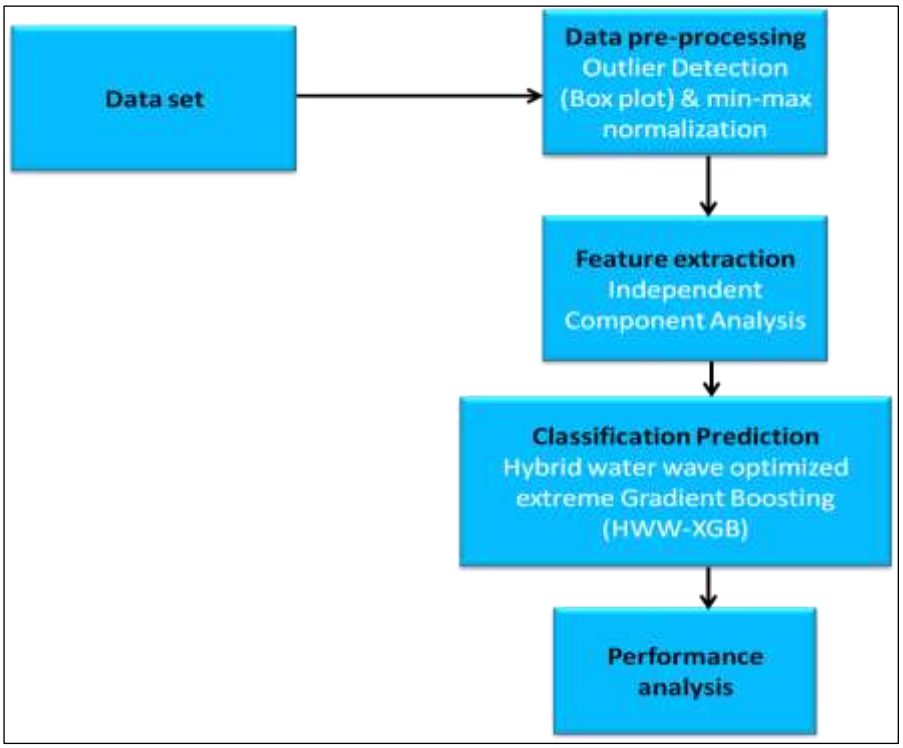

Figure 1: Flow of proposed model.
Source: Authors, (2026).

III.1 DATASET

Two strategically situated water quality monitoring stations throughout the watershed be used to collect monthly data on water quality over six years (2012-2018). There were readings for dissolved oxygen, total solids, fecal coli form, pH, phosphate, nitrate, turbidity, and electrical conductivity, among other parameters. Together, they were utilized to determine Iran's WQI. The Mazandaran Environmental Protection Organisation lab followed conventional sampling, storage, and analysis procedures. Utilising the tenfold traverse substantiation technique, the dataset was split 70:30 across the training and testing sets. Although no hard and fast rule exists, this ratio is the most often used modeling strategy for geographical and temporal forecasting [23].

III.2 DATA PREPROCESSING

The data preprocessing using the Outlier Detection (Box Plot Analysis) and Min-max normalization was finished to minimize the computational time.

III.2.1 Outer Detection

Missing data and data anomalies may significantly influence future model projections because of environmental changes and equipment failures at water quality monitoring sites. The experimental results are completed using linear interpolation, using the discovered anomalous values as missing values. It is common practice to spot outliers using modeling techniques and graphical approaches (such as box-line plots and normal distribution plots). The box-line property was utilized in this study to spot unusual results. The quantile of the data was utilized by the box-line plot method to find the extremes. This is a standard kind of statistical graph that has many applications in both research and business. Figure 2 depicts the form characterized by the box-line plot.

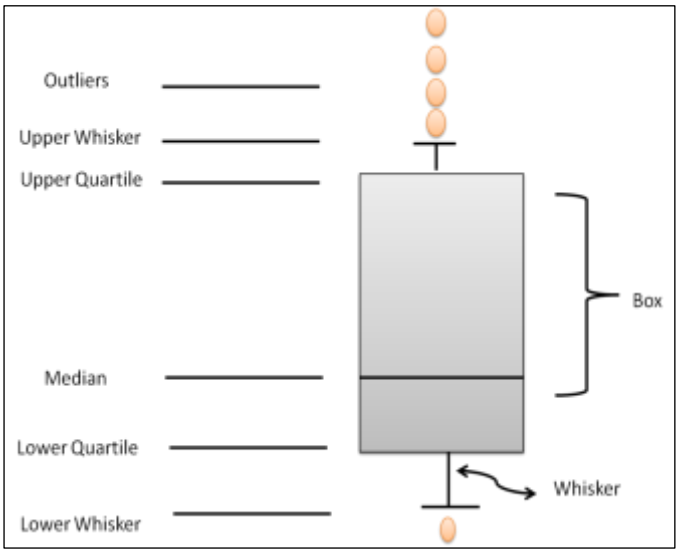

Figure 2: Structure of box-line diagram.
Source: Authors, (2026).

Figure 2 shows the median as the number that divides the upper and lower halves of the data. In contrast, the lower quartile represents the 25% quartile, and the higher quartile represents the 75% quartile. Where Q3 − Q1 is the quartile difference, the upper whisker formula is Q3 + 1.5(Q3 − Q1), and the lower whisker formula is Q1 − 1.5(Q3− Q1). To judge whether or not a data point is an outlier, a box-line diagram may be utilized if the value of the variable in question is beyond the range covered by the upper and lower whiskers, respectively.

III.2.2 Min-Max Normalization

Preparing and enhancing datasets for subsequent analyses is the focus of data pre-processing, a step in the study of big data that aims to discover new information faster and more accurately. Putting an issue statement into practice is a preparatory step in the overall processing flow. Particularly important is the function that implementation plays in data processing techniques like soft computing, cloud computing, and the reduction or expansion of a variety of data before its usage in a later phase. Numerous normalizing methods are available, including the Min-Max method, the Z-score method, and the Decimal scaling method, to name a few. Min-max normalization is an initial processing stage, a scaling technique, or a mapping approach. It might be really helpful for assessing data or making plans.
Normalization is calculated in equation (1),

$$K' = \left(\frac{k - \min\ value\ of L}{\max\ value\ of - \min\ value\ of\ k}\right) * (P - H) + H \tag{1}$$

Where *K* is the Min-Max normalized set of data and [*H, P*] is the bounding box. *K* is the true data range, while *N* is the mapped data range.

III.3 FEATURE EXTRACTION USING INDEPENDENT COMPONENT ANALYSIS

Let's say we have many independent measurements of a complex signal simultaneously. Time resolved spectroscopy allows us to get a movement of the explanatory transit's light curve at each spectrograph's resolution. Here, we refer to each time series measured using the notation x_k (t), where N is the total number of time series and k is the index for that time series.

$$x_k(t) = a_{k,1}\, S_a(t) + S_{wn}(t) + a_{k,2} S_{sn1}(t) + a_{k,3} S_{sn2}(t) + \cdots + a_{k,} N_{sn} S_{sn}(t) \tag{2}$$

As a vector sum (time dependency has been removed for simplicity).

$$x_k = a_{k,1} S_a + a_{k,2} S_{wn} + \sum_{l=3}^{N_{sn}} a_{k,l} S_{sn} \tag{3}$$

Where *l* is the estimated index of the source signal, we have k = l unique source signals for non over full sets, which is the same as the number of time series. It's important to remember that when k>l, we have access to more time series than source signals inside the whole set. In such circumstances, we may use dimensionality reduction techniques for the data collection or use selection criteria to narrow down a subset of predicted source signals. We can also express Equation (2) in matrix form as

$$X = As \tag{4}$$

As an alternative notation, we may write $s = s_a + s_{wn} + s_{sn}$ to explicitly separate the astrophysical, white noise, and systematic contributions. The "mixing matrix" A consists of the weights a_k, *l*, and has N × N dimensions.

III.4 CLASSIFICATION USING HYBRID WATER WAVE OPTIMIZED EXTREME GRADIENT BOOSTING

The hybrid machine learning method known as Hybrid Water Wave Optimised extreme Gradient Boosting (HWW-XGB) combines the Water Wave Optimisation (WWO) algorithm with the extreme Gradient Boosting (XGB) algorithm. By merging the search and optimization skills of WWO, it seeks to improve the speed and optimization capabilities of XGB. The effective and popular gradient boosting method, XGB, excels at managing structured/tabular data and obtaining high prediction accuracy. By repeatedly optimizing an objective function that combines prediction performance and regularisation, it creates an ensemble of weak decision trees. The advantages of XGB are its quickness, scalability, and capacity for complicated nonlinear interactions. WWO is an optimization method that draws inspiration from nature and the behavior of water waves. It uses a metaheuristic algorithm to explore the search space and identify the best answers by simulating the motion of water waves. WWO has been used to tackle various optimization issues and has successfully located global optima. HWW-XGB combines the benefits of both methods to strengthen XGB's overall performance and the optimization process. It uses WWO's capabilities for exploration and exploitation to direct the search for the best hyperparameters or model configurations in XGB. HWWO-XGB aims to identify better combinations of hyperparameters that enhance model performance by searching the hyperparameter space using WWO. WWO is included in the XGB optimization process as part of the hybridization phase. A population of potential solutions is initialized in the hyperparameter space using the WWO method. Then, these possible solutions are assessed using XGB and the appropriate hyperparameter settings. Utilizing the iterative approach and the WWO tenets, the assessment findings are utilized to update and improve the solutions. In HWW-XGB, the hybridization of WWO and XGB enables more efficient exploration of the hyperparameter space, which may enhance model performance and generalization. The goal of HWW-XGB is to identify optimum or nearly optimal hyperparameter configurations for XGB models by combining the high prediction powers of XGB with the optimization capabilities of WWO.

III.4.1. Extreme gradient boosting

The Extreme Gradient Boosting (XGB) technique is a regression tree with decision-tree-like decision-making capabilities. It supports both classification and regression. This approach is a scalable and effective variation of the gradient boosting machine (GBM), which has been extensively used in computer vision, data mining, and other areas. Recently, XGB has primarily advanced in two locations as a sort of gradient boosting machine: speeding up the tree building and suggesting a new distributed technique for tree searching. The heart of XGB is optimizing the value of the goal function. Considering the dataset $D = \{(x\_(i,)yi)\}$ represents the xi tumor's gene expression profile and the related yi binary label (early stage or late stage) is used to identify the tumor. Equation (5) is the objective optimization function for the XGB model with K decision trees.

$$\hat{z}_j = \sum_{l=1}^{l} e_l(w_j), e_l \epsilon E \tag{5}$$

Where f_k represents a separate tree with leaf scores, and F is the space of the regression tree. In equation (6), the loss function is shown.

$$K(e_k) = \sum k\left(\hat{z}_j, z_j\right) + \sum \Omega\, e_k \tag{6}$$

Différentiable loss function l in the first term assesses the discrepancy between the output $\acute{y}_i$ that anticipâtes and the actual output y_i.

$$\hat{z}_j^{(s)} = \hat{z}_j^{(s-1)} + e_s(w_j) \tag{7}$$

$$\Omega(e) = \gamma S + \frac{1}{2}||x||^2 \tag{8}$$

Where w is the score on each leaf, and T is the number of leaf nodes. We may thus determine that from equation (9)

$$S(e_s) \approx \sum_{i=1}^{S}\left[\left(\sum_{j\in J_i} h_j\right)x_i + \frac{1}{2}\left(\sum_{j\in J_i} g_j + \lambda\right){x^2}_i\right] + \gamma S \tag{9}$$

Where g_i and h_i are the loss function first and second gradient statistics, respectively.

III.4.2. Water Wave Optimisation (WWO) Algorithm

The WWO method essentially models the processes of wave motion propagation, refraction, and breaking to achieve an optimal global/local search balance. Each water wave's fitness level is a function of its height and wavelength. Figure 3 shows that the water wave in shallow water is a greater fitness value, a higher wave height, and a longer wavelength than the wave in deep water, which have a lesser condition cost, a lower signal elevation, and a shorter wavelength.

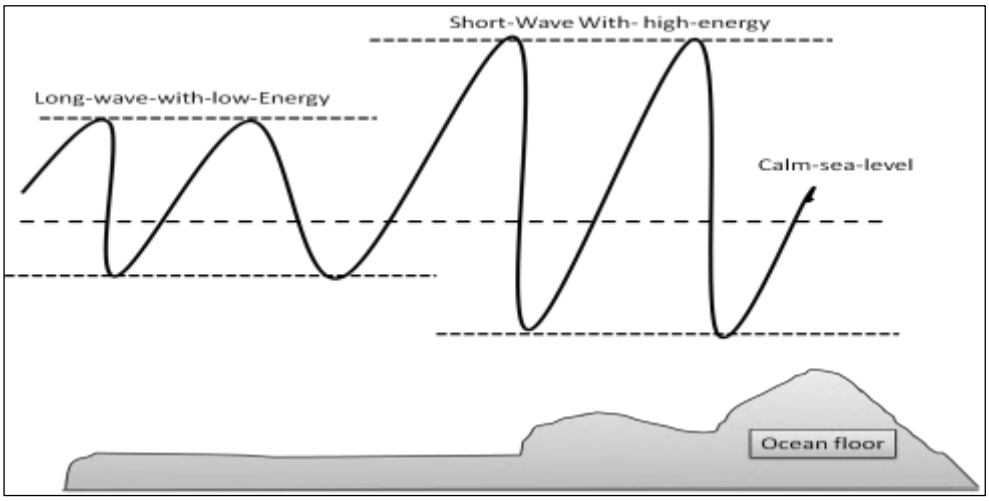

Figure 3: Variations in wave form between deep and shallow sea.
Source: Authors, (2026).

III.4.2.1 Propagation

The dissimilarity of the sea bed causes waves to propagate at varying heights and wavelengths. The initial water wave *x* is propagated to create a new body of water denoted by *x′*. To update the location in equation (10), we assume that the first water wave was at position x (d) & subsequent wet gesture was at position *x (d).*

$$x^{'}(d) = x(d) + rand(-1,1).\lambda L(d) \tag{10}$$

Where *L (d)* denotes the span of the search space in units of dth, λ is the wavelength of water wave *x*, and rand (-1, 1) is a consistently distributed random integer between 1 and 1. If wave *x′* is not found within the search range, a new place is chosen randomly. The opposite is true, with wave *x* being kept and the wave height dropping by one to signify that the wave's energy has been expended. The wavelength λ is updated in equation (11):

$$\lambda = \lambda \,.\, a^{-(f(x)-f\,min^{+\varepsilon}/(f\,max^{-f}\,min^{+\varepsilon}} \tag{11}$$

Where α is the attenuation coefficient for wavelengths, f_{min} and f_{max} are the lowest and most health standards, and ε is a tiny optimistic numeral chosen such that the numerator does not equal zero.

III.4.2.2 Breaking

The steepness of the wave crests increases as the wave energy rises. When the crest velocity is greater than the wave's propagation velocity, the wave will disintegrate into some independent waves. The WWO algorithm maximizes population variety by performing a breaking operation on the best water wave x*. The equation (12) for the positional update is as follows:

$$x^{'}(d) = x(d) + N(0,1).\ \beta L(d) \tag{12}$$

Where β is a broken gesture coefficient. If the fitness value of all the solitary waves acquired from the breaking operation is lower than that of water wave *x*, x*;* otherwise, *x** be replaced with an optimum introverted gesture from the population.

III.4.2.3 Refraction

The energy of a water wave gradually decreases until it is zero as it travels through the water. It has been shown that using a refraction operation when the water wave height is zero helps the WWO algorithm converge more quickly and accurately. The refraction of water wave *x* is shown in equation (13).

$$x^{'}(d) = N(\frac{(x*(d)+x(d))}{2}, \frac{|x*(d)-x(d)|}{2} \tag{13}$$

The function $N\ (\mu, \sigma)$ generates a Gaussian random number with a mean μ and standard deviation σ, where x^{*} is the best solution obtained at the present point. In reality, this enables wave x to gain insight from the currently best wave x^{*}. Since h_{max} is the current value of wave x' wave height, the equation (14) for the updated wavelength is shown below.

$$\lambda^{'} = \lambda \frac{f(x)}{f(x^{'})} \tag{14}$$

Algorithm 1: The WWO algorithm's process for solving problems

```
Initialize a water population O at random with m.
        Wavelength is set by waves.
        Breaking coefficient β, Reduction coefficient ∝, and
            Coefficient of decrease in wavelength λ
while stop the extinction criterion is not satisfied, do
    for each water wave xϵ o do
    Use equation (10 to propagate x to a new w′;
    if f (w′) <f (w) next
        if f (w′) < f (w′) next
            Break w′ by utilizing equation (12);
            Update w* with w′;
        else
            Decrease x.h by one;
        if x.h =0 Next
            Refract x to a new w′ by utilizing equations (13) and (14);
    Using equation (11) update the wavelengths.
return w*
```

IV. RESULT

The suggested method's performance metrics are examined, including Mean absolute error, Root Mean square error, Mean square error, Correlation coefficient, and sensitivity. The existing techniques are adaptive neuro-fuzzy inference system (ANFIS) [24], artificial neural networks (ANN) [24], and K-nearest neighbors (KNN) [24].

IV.1 MEAN SQUARE ERROR (MSE)

The average squared difference between the predicted and actual values in a regression issue is calculated using the MSE, a commonly used statistic. It gives a quantitative assessment of a regression model's overall accuracy or goodness of fit. Mean Square Error (MSE) is represented by equation (15),

$$MSE = (1/n) * \Sigma(y - \hat{y})^2 \quad (15)$$

Where n denotes the number of data points or samples, Σ denotes the summation symbol, y represents the actual (observed) values, and ŷ conveys the predicted values from the regression model. Computing the squared difference between each predicted value and its corresponding actual value adds up all of these squared differences. The squared differences ensure that positive and negative mistakes equally impact the MSE. The sign is removed by taking the square of each contrast, and bigger mistakes are penalized more severely. Figure 4 and Table 1 show Mean Square Error outcomes; ANN scores 56%, KNN 39%, ANFIS 44%, and HWW-XGB 35%.

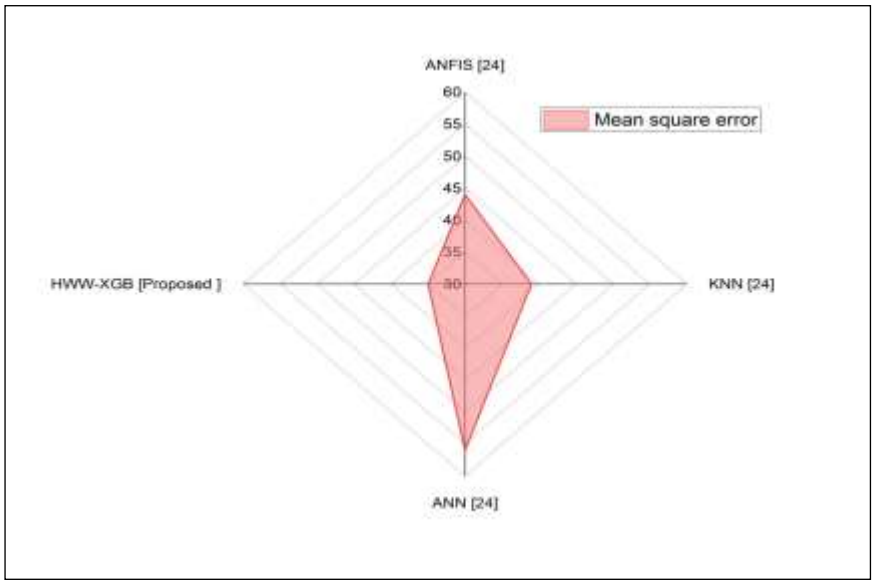

Figure 4: Results of Mean Square Error.
Source: Authors, (2026).

Table 1: Numerical Outcomes of Mean Square Error.

Methods	Mean square error
ANFIS [24]	44
KNN [24]	39
ANN [24]	56
HWW-XGB [Proposed]	35

Source: Authors, (2026).

IV.2 MEAN ABSOLUTE ERROR (MAE)

It is utilized to calculate the usual complete disparity between the predicted and actual values in a regression issue. It indicates the average size of mistakes without taking their direction into account. The MAE equation (16) is as follows:

$$MAE = (1/n) * \Sigma|y - \hat{y}| \quad (16)$$

Where n denotes the number of data points or samples, Σ denotes the summation symbol, y represents the actual (observed) values, and ŷ indicates the predicted values from the regression model. To determine the MAE, add up all of the absolute differences between each predicted value and its corresponding actual value. Without considering their direction, the absolute differences are utilized to estimate the size of mistakes. Because MAE does not square the differences, it handles positive and negative mistakes equally, in contrast to Mean Square Error (MSE), which does. Figure 5 and Table 2 show Root Mean Absolute Error outcomes; ANN scores 58%, KNN 71%, ANFIS 67%, and HWW-XGB 40 %.

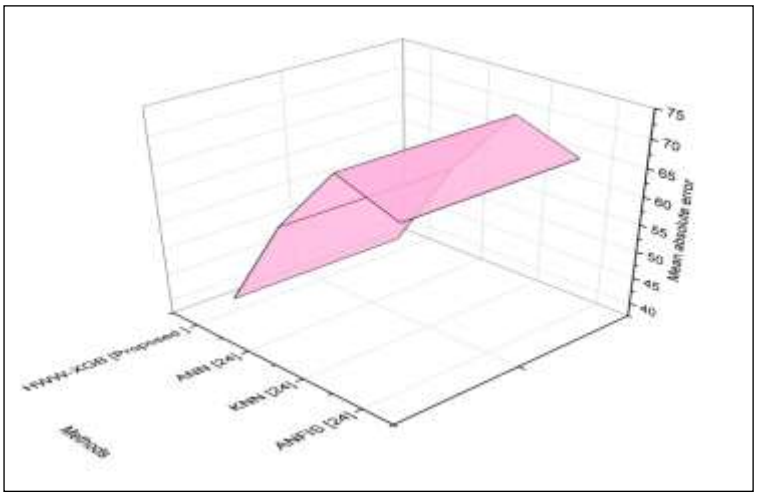

Figure 5: Results of MAE.

Table 2: Numerical Outcomes of Mean Absolute Error.

Methods	Mean absolute error
ANFIS [24]	67
KNN [24]	71
ANN [24]	58
HWW-XGB [Proposed]	40

Source: Authors, (2026).

IV.3 ROOT MEAN SQUARE ERROR

In a regression issue, the average error size between the predicted and actual values is often measured using the Root Mean Square Error (RMSE) metric. It is a variant of the MSE that scales the metric back to the dependent variable's original scale by taking the square root of the MSE. The RMSE measures the usual size of errors and is often used to evaluate a regression model's accuracy and fit quality. The RMSE equation (17) is as follows:

$$RMSE = sqrt((1/n) * \Sigma(y - \hat{y})^2) \quad (17)$$

Where n denotes the number of data points or samples, Σ denotes the summation symbol, y represents the actual (observed) values, and ŷ indicates the predicted values from a model or estimation. Figure 6 and Table 3 show Root Mean Square Error outcomes; ANN scores 51%, KNN 56%, ANFIS 65%, and HWW-XGB 42%.

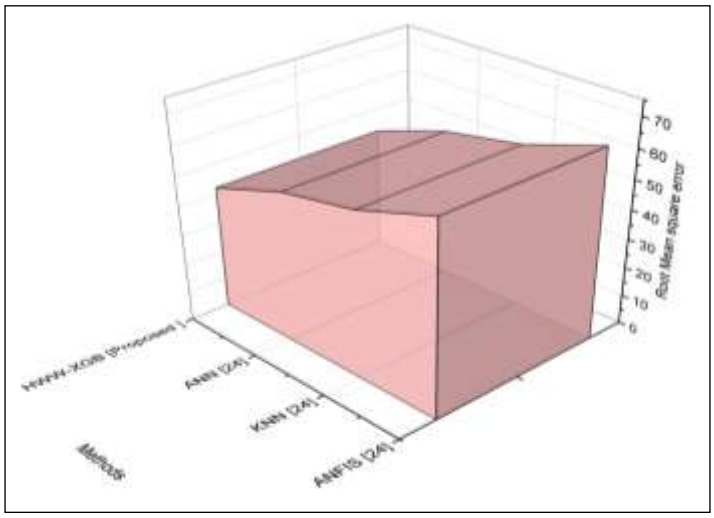

Figure 6: Results of Root Mean Square Error.

IV.4 CORRELATION COEFFICIENT

The degree and direction of the linear connection between two variables are shown by a statistical measure. The correlation coefficient, often known as Pearson's correlation coefficient, is represented by the equation (18):

$$r = \frac{(\Sigma((x-\mu x)(y-\mu y)))}{(sqrt(\Sigma(x-\mu x)^2) * sqrt(\Sigma(y-\mu y)^2)} \quad (18)$$

Where r denotes the Correlation coefficient, Σ denotes the summation symbol, x & y denotes the individual values of the two variables being correlated, and μx & μy denotes the means of the respective variables. The correlation coefficient quantifies the degree to which the variables vary from their mean values in the same or opposing directions. In Figure 7 and Table 4, correlation coefficient outcomes, ANN scores 84%, KNN 82%, ANFIS 80%, and HWW-XGB 95%.

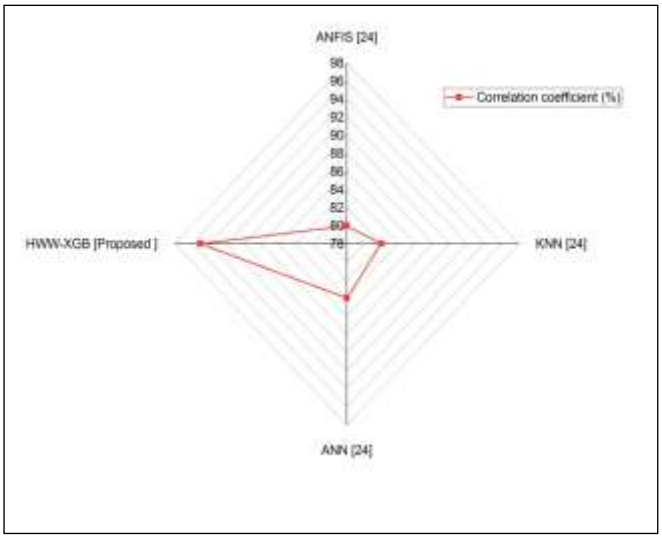

Figure 7: Results of the correlation coefficient.
Source: Authors, (2026).

Table 4: Numerical outcomes of the correlation coefficient.

Methods	Correlation coefficient (%)
ANFIS [24]	80
KNN [24]	82
ANN [24]	84
HWW-XGB [Proposed]	95

IV.5 SENSITIVITY

The sensitivity of the proposed model is its capability to identify each significant sample in a data collection. It may be calculated statistically by dividing the proportion of true positives and false negatives by the sum of true positives and false negatives. Equation (19) is used to determine the sensitivity.

$$sensitivity = \frac{TP}{TP+FN} \tag{19}$$

In Figure 8 and Table 5, Sensitivity-wise, ANN scores 85%, KNN 76%, ANFIS 74%, and HWW-XGB 93%.

V. CONCLUSION

For assessing and monitoring the general quality of water resources, the WQI is a useful metric. It provides a numerical rating to show the combined effect of several water quality parameters, allowing for easy comparison and interpretation of water quality data. The research uses the novel HWW-XGB to estimate WQI for water samples. To save computing time, the data in this study were preprocessed using outlier detection and min-max normalization. The necessary characteristics are extracted using the ICA. The pre-processed features are eliminated by feature extraction, freeing up data for the next crucial stage. The HWW-XGB classifier receives the gathered characteristics as input. Compared to the current technique, a new approach's efficacy was shown. In the proposed method analysis, the performance metrics exhibit notable scores: Mean Square Error attains a respectable 35%, Mean Absolute Error attains a good 40%, Root Mean Square Error attains a respectable 42%, Correlation Coefficient attains a respectable 95%, and Sensitivity achieves a respectable 93%. By using the fewest characteristics feasible, rather than a surprising number of features, the future study aims to estimate the quality of water effectively.

ABSTRACT

Gen AI systems such as LLM's, code assistants, image generators and personal assistants are growingly integrated with productivity and critical business applications across different domains of organizations such as security, testing, code review and automate day to day tasks. Their functionality depends on different training models, inputs and instructions and those models are integrated with various applications via API's and connectors. In addition, there are many practical use cases where Generative AI LLM's are already operationally embedded with many industrial equipment's. This paper presents a detailed literature review of security, privacy concerns and compliance risks that are evolving day to day. This review refers to various published articles and subjects related to AI security from security perspective which addresses various security concerns specific to Gen AI and the need for evolution to adopt and comply with the evolving regulations. Also, the paper refers to various publications related to the role of AI in security, defense mechanisms to safeguard AI models and its applications, different approaches on risk management and so on. Based on these references, we also discussed the advantages and limitations of adopting NIST AI Risk management framework (AI-RMF) which is an adaptive governance guidance for Generative AI security at its lifecycle. The review finally highlights Assessment gaps and proposes a governance-tied adaptive security framework for Generative AI.

I. INTRODUCTION

Artificial Intelligence (AI) has moved from theoretical constructions and narrow expert systems to large-scale, data driven models. This acts as general-purpose problem solvers across many domains. Recent advances in deep learning, especially transformer-based architecture, have enabled Generative AI (GenAI) systems capable of producing high fidelity text, images, videos, code, and synthetic data. These systems are deployed as conversational agents, content creation tools, decision-support modules, and programmable APIs integrated into broader sociotechnical systems. Even though this technological advancement in Gen AI makes it powerful but also introduces new and even complicated security and privacy risks. GenAI models are typically trained on large, heterogeneous datasets, sometimes scraped from the web or sourced from third-party providers, raising concerns about data provenance, consent, intellectual property, and memorisation of sensitive information. [1-6]. From an organizational viewpoint, Gen AI is now recognised as a paradigm shift because, compared to traditional software building process which encodes logic as explicit instructions the AI systems infer the behavior from the sourced data and optimisation objectives. This behavior makes it force a re-examination of how risk, accountability, and assurance should be defined and managed. Regulatory initiatives such as the EU AI Act explicitly require high-risk AI systems to be robust against cyberattacks and to undergo security-oriented risk assessment and conformity assessment. This paper focuses on security in Generative AI systems—security for AI, rather than AI for security—and proposes a lifecycle- and governance-oriented view of GenAI security. [7-10].

II. FOUNDATIONS: AI, GENERATIVE AI, AND SECURITY CONCEPTS

II.1 AI, MACHINE LEARNING, AND DEEP LEARNING

AI is commonly defined as a machine-based system that receives the set of human-defined objectives, can make predictions, recommendations, or decisions influencing real or virtual environments. Machine learning (ML) and deep learning (DL) are subsets of AI. ML focuses on learning patterns from data, while DL uses layered neural network architectures to capture complex, non-linear relationships. From the security governance, compliance and risk perspective, AI systems should be treated as a complex information system as they are relying on data, user instructions, and work by their own internal logic and memory. This improves business value, also at some point, it impacts business and individuals considerably.

II.2 GENERATIVE AI ARCHITECTURES AND APPLICATIONS

Generative AI models learn from huge subsets of data distribution and generate their own new samples. Generative AI discovers the pattern and learns from the provided rules and provide context rather than copying the initial information provided. It includes architectures like transformer-based models, Flow based models, Neural radiance fields, Latent diffusion models, Generative Adversarial Networks (GANs), Variational Autoencoders (VAEs etc. Due to advancement in technologies and research, these architectures are being evolved in such a way as it is widely used in many applications of productivity and entertainment such as text generations, video generations, personal assistance, Anomaly findings etc. Due to this broader applicability, risks like deep-fakes, manipulation and coordinated disinformation are evolving against individuals and organizations. Some surveys recently provided detailed information about the architecture of generative AI with its applications and implications, with notable evidence on adversarial impacts in real time. However, the productivity and benefits remain the same with the mindset of mindful usage of AI across various use cases.

II.3 AI FOR SECURITY VERSUS SECURITY FOR AI

The literature differentiates AI for security from security for AI. AI for security covers AI-enabled threat detection, automated patch management, anomaly detection, endpoint protection, network defense, phishing campaigns, security posture management, vulnerabilities exposure scoring, compliance automation and adaptive authentication. Security for AI focuses on maintaining data integrity, robustness, access control, logging, and governance for AI systems, including protecting training pipelines, preserving architecture, neural thinking ability, model artefacts, and inference endpoints from attack. Most cybersecurity use-cases focus on adapting AI for improving security. This review complements that by concentrating primarily on security for AI in the Generative AI context, while using AI for security literature to understand its interactions and applicability. [11], [12].

III. RESEARCH METHODOLOGY

To ensure a comprehensive and clear understanding of the current state of security in Generative AI, this review follows a structured literature search methodology. The objective was to identify appropriate peer reviewed articles, conference proceedings, current trends and reputable industry reports that address the intersection of Generative AI with cybersecurity, privacy, integrity, compliance and governance along with its applications and challenges.

III.1 SEARCH STRATEGY AND DATA SOURCES

We have conducted this review by searching through major academic databases, including Springer, IEEE, ACM Digital Library, arXiv and Google Scholar. The search strings combined keywords related to AI architectures such as “Generative AI”, “Large language models”, “Security risks in AI”, “Generative AI models” with security and risk terms such as “Deep fakes”, “Phishing and malware crafting”, “Code of evasion”, “Misinformation Ops”, “Polymorphic malware”, “Jail breaking”, "Data Poisoning, "Prompt Injection," "AI Regulation" [6], [11-15].

III.2 INCLUSION AND EXCLUSION CRITERIA

The retrieved journal publications are filtered via Prisma method to include only the last 3 years and latest articles to make sure the content to be included are up to the recent research and use cases. However, the concept been understood from multiple sources, but the references are included limited to 7 papers to narrow done and mimic the ideas shared by different authors. We only choose papers highlighting only Generative AI related issues and not on the entire AI as a subject to make sure that the issues are highlighted within the boundary of Gen AI. We have eliminated papers which are too generic to AI subject as a whole or those without any ties with Generative AI, its applications and implications. The key qualifier includes security concerns on Generative AI rather than application of AI in security unless it was linked to governance and security concerns of Generative AI. Based on our cybersecurity view, we explored studies on Gen AI relevant security gaps, grey areas, compliance concerns, misuse and impact which makes the primary filtering point of inclusions.

III.3 THEMATIC ANALYSIS

From my cybersecurity experience, grouping papers into threat patterns, data related risks, compliance mismatch, AI's pros and cons, and management frameworks gives the complete picture of GenAI dangers. In accordance with the experience, the selected findings were analyzed and organized into topic groupings and content clustering based on below focus.

(1) Current impact and implications of AI; (2) Security of AI from Governance, Risk and compliance perspective; (3) Widely impacting security concerns of Generative AI; (4) Challenges of AI to adapt with compliance standards and frameworks; (5) Implications and adversarial impact of AI in its most common applications; (6) Evolving usage and application of Generative AI in real world; (7) Methods to optimize AI to comply with GRC (Governance, Risk Management and Compliance) [16], [8].

IV. THREAT LANDSCAPE FOR GENERATIVE AI

As always, technology comes with challenges and those challenges pave way for resolutions. So as is Generative AI, which is nowadays a more adaptable technology which occupies its applicability in almost most of the areas of professional, personal and social usage which makes it open all kinds of fresh ways to attacks, impersonations, misuses and other impacts. This makes it questionable from the aspects of technological, ethical, social, legal viewpoints. In a simplified way, the below depicted figure explains the various security threats and manipulation possibilities of generative AI in its lifecycle from technological, human and data perspective. I have seen these risks play out in social media nowadays where people have started impersonating, providing fake information, news and other contents. Even I have encountered similar limitations in the structure and well created prompt which I have created for the healthcare IT service provider.

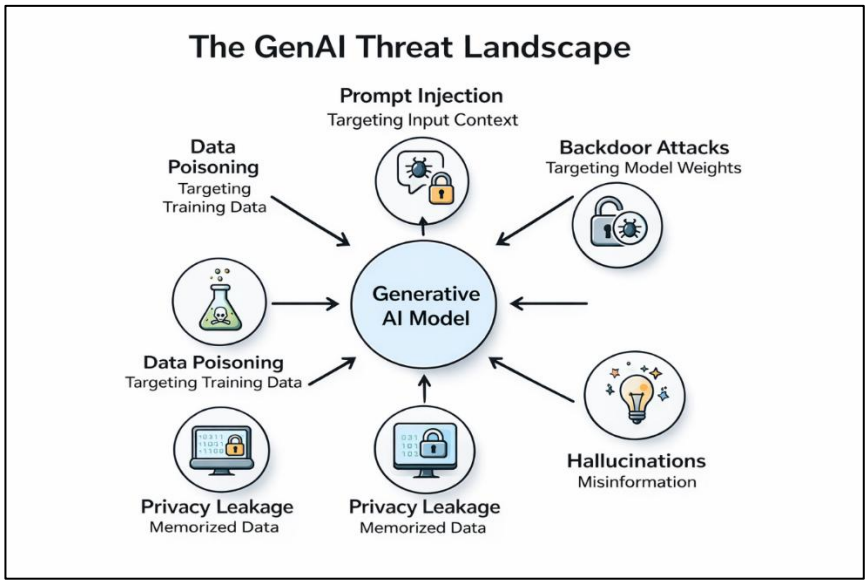

Figure 1: Various security threats targeting Generative AI lifecycle.
Source: Authors (2026).

IV.1 DATA POISONING AND BACKDOOR ATTACKS

Data poisoning and back door attacks are most common issues of generative AI nowadays where people started adapting and even got addicted to its usage without verification or cross review. With this open trust issue, hackers and falsifiers inject malicious samples of training data which in turn alter the model and its associated data to corrupt its samples out of its originally stored / trained data. Some attackers trick users to capture ideal and sensitive information via backdoor and make use of it to impact personal, professional and social aspects. These techniques are largely achieved by using triggers which appear to be activated upon certain situations without the knowledge of users who are interacting with the Generative AI. Those triggers degrade the quality of output and accuracy by manipulating the models, trained data and samples. These kinds of attacks are much more impactful mostly on basic and customized models than those of large models which have at least basic security being positioned to address these attacks. [14], [15].

IV.2 ADVERSARIAL PROMPTS AND INPUT MANIPULATION

Another notable threat on GenAI systems are the prompt injection and input manipulation attacks, where the prompt itself tricks the users to input key essential inputs which in turn will be used to manipulate the original prompt to cause damage as well as to some extent to steal sensitive information. These kinds of injections can either be found in documents and attachments which will skip the security checks of GenAI models and lead to security concerns and prompt manipulations. These are most common nowadays due to the flexibility of easy sharing, API integration ability and browser based. Simplest way to explain this GenAI hole is that the prompts and inputs hide within certain forms of emails and documents to make it look legitimate but once triggered or trusted, it does its manipulation in many ways. [13], [6]

IV.3 MODEL EXTRACTION, MEMBERSHIP INFERENCE, AND INVERSION

These concepts are few indirect ways of counterfeiting, copying and predicting identities of well-trained private AI models. Model extraction is something that matches the results score of a well-trained and private AI with the one created by a publicly available GenAI. This can be achieved by training the public or free AI models with the same answers and the results provided by the private well-trained AI. By this way, the AI brain will get stolen without stealing the model itself but by just mimicking the results and training your own AI models with those results. Membership inference is like data fingerprinting, where based on the results and confident score, it's possible to detect the existence of data record and the identity of input in the other private trained model.

Model inversion is a kind of Reverse engineering secrets, where the input is been checked for its confident score and then based on the high score, the private information can be rebuilt or synthesized. [14], [5].

IV.4 DEEPFAKES, MISINFORMATION, AND SOCIAL ENGINEERING

Deepfakes are another technique of collecting raw materials, information via data harvesting and use it as a source of truth to fake by impersonating the exact attributes of those collected information and sources. The original identity was then used to synthesize misinformation and to draw social engineering victims. A forger AI can be used to compete the detective AI by fooling it with high percentage of pass rate against its results. For example, an user identities from images and videos can be collected from multiple sources, a forger AI will use it to exactly impersonate the person and to train the detective AIs to prove it was right. It will then be used in social engineering to fake information. Nowadays Deepfakes are more challenging as the forged information is nearly perfect with the actual information and identities. These are newly evolving dangers in AI deployments as new projects quietly reshape the entire security landscape. Once known as a productive tool, it is now forcing security / risk teams to rethink it. [12], [17].

IV.5 SYSTEM-LEVEL AND OPERATIONAL RISKS

Due to the over dependencies and adaptations of GenAI's, Operational, system level and organizational risks are growing due to various reasons such as prompt exploitation, Insufficient compliance and logging monitoring, Unidentified security checks and lack of forensic evaluation against those GenAI tools. The outputs and outcomes generated by GenAI's are mostly used in real time without properly getting the results evaluated or validated, which cause it more attractive for attackers and makes it a more important subject of discussion as well as pain point for Security, compliance, risk and governance teams.

Table 1: Types of Attacks in Generative AI.

Attack Type	Description	Example	Impact / Risk
Data poisoning	Malicious samples corrupt training behavior	Backdoor trigger in training set	Model produces manipulated or biased outputs; long-term integrity compromise
Prompt injection	Adversarial instructions override system policies	Hidden prompt in document	Unauthorized actions, data leakage, bypass of safety controls
Model extraction	Queries used to reconstruct a surrogate model	Copying a hosted LLM API	Intellectual property theft; loss of competitive advantage
Membership inference	Determining if a record was in training data	Patient record presence check	Privacy breach; regulatory non-compliance (e.g., HIPAA risk)
Deepfake synthesis	Fabricated audio/video content	Impersonated CEO voice call	Fraud, reputational damage, social engineering attacks

Source: Authors (2026).

V. PRIVACY AND SECURITY CONCERNS IN GENERATIVE AI

Safety issues and data protection concerns are emerging in multiple ways and into deeper level of many layers of Generative AI which makes it difficult to resolve completely via technology security measures alone. Those concerns need to be addressed at all the different parallels such as users, ethical, social, technological, legal and organization perspectives. There are complex and many layered safety challenges across all these mentioned parallels exist.

V.1 USER AND ETHICAL PERSPECTIVES

It quite common to deepfake someone's identity not only from productivity viewpoint but these arises in social environments as well where people impersonate another person's look, voice, style etc. Content makers more frequently use prompt and reference data such as images and videos to synthesize innovative outputs for the purpose of popularity and monetary gains. In addition, curiosity goes up to higher levels and draws users to generate unethical content such as harassment, racism, hatred, restrictive and spreading false perceptions. Content-making AI stirs up controversies as it spits biased information spreading across society and social environment which highlights moral dilemma from the perspective of ethics. [12], [17].

V.2 REGULATORY AND LEGAL PERSPECTIVES

Regulatory authorities and laws are worrying around the content creating AIs due to its flexibility across doing almost anything as it's been instructed or trained to. Some concerns include GDPR compliance issue where usage of Intellectual property is restricted in boundaries, HIPPA compliance issue which states not to use non pseudonymized direct PII (Personal Identifiable information) or PHI (Personal Health information) data for training or stimulatory purposes. There are large number of increases in the number of legal cases being filed around accountability, disclosure, privacy and other ethical controversies. However, there are privacy protection frameworks proposed to mitigate these risks but it in turn compromises its utility and benefits to a fuller extent. There, a balanced and optimal model to accompany both security and utility are highly in need.

V.3 TECHNOLOGICAL AND INSTITUTIONAL PERSPECTIVES

Content generative AIs memorize the models, interactions and conversations from inputs time to time and sometimes it leaks out sensitive information without applying pseudonymization or becomes vulnerable due to its identifiable patterns on even anonymized data.

To address this concern, technological controls are in place such as input validation and adversarial training but those also being challenged by the evolving security threats and attacks. Many organizations often skip building proper oversight systems and lacks consideration of AI security policies, guidelines and controls which lead to improper building of customized productivity AIs. Prompt engineers often create Generative AIs with stable images with clear details, for example, images of a hotel room. Those details are again misused to identify the actual identity of the source (Hotel rooms, name and other details can be exposed via synthesis and reverse engineering).

VI. AI CYBERSECURITY AND REGULATION

AI Cybersecurity Regulations are in place across different contexts and one of which is EU AI act which highlights the first comprehensive framework on AI regulation. The framework includes various acts such as differentiating different levels of risks into Unacceptable risk, High risk, limited and minimal. It also mentions the transparency requirements and encourages evolution of AI innovation and use cases in Europe. The framework primarily focuses on multiple aspects like diversity and complexity of AI technologies with its difficulty assessing those risks and the urge to develop secure-by-design mode of AI systems. The AI regulation framework emphasizes high quality training data, detailed documentation, record management, human oversight, risk management and accuracy. This act has its own tiered structure of fines and penalties, based on violations levels such as prohibited practices, high risk obligations, Improper management of training data, Incorrect information to authorities etc. In a granular level, this act bans acts such as creating or using manipulating techniques, social scoring, biometric exposure, facial database scraping, predictive policing etc. Also, the act promotes cross functional collaboration between security, compliance, risk, privacy, integrity and confidentiality. The framework is planned to be enforced by August 2027 and hopefully it may add some value and key principles to secure AI models and their use.

VII. AI AND SECURITY FROM AN INFORMATION-SECURITY AND RISK-MANAGER STANDPOINT

From a data protection perspective by an information security professional, the AI systems and its associated data and integrations should be treated same as the other critical systems in place. The key considerations include securing Assets & data, Maintaining the risk register for new and emerging risks, implementing necessary controls to comply with regulatory and organizational policies, Evaluation and continuous monitoring of anomalies and deviations. It requires the maturity of shifting from reactive security into proactive security which means that the built-in security and protocols are not only sufficient but also the human, technological, legal and organizational controls should also be in place to avoid AI risk concerns. There is a necessity of considering security concepts in AI in different aspects such as i. Classification of assets, ii. Risk register management, iii. Mapping with appropriate control frameworks, iv. Threat modelling, v. vulnerability management, vi. Logging and monitoring, vii. Identity and access etc., AI adoption can be business driven but should be accompanied by laws and regulations.

VIII. AI'S ROLE IN CYBERSECURITY AND ITS INTERACTION WITH GENERATIVE AI SECURITY

AI plays key roles in cybersecurity which includes cyber defense systems such as phishing filters, endpoint security, anomaly detection, malware analysis, threat hunting and threat modelling. GenAI's plays vital role in reducing human efforts and improvising security and accuracy in blue defense especially situations like automating reported incidents, automating playbook & runbooks in SIEM tools, Deepfake and prompt injection detection to an extent, social engineering simulations, code reviews and so on. AI's feeds detective AIs to defend and secure against forger AI's and false promptings. However, there are associated risks which need to be further improvised such as RAG pulling integrations which may lead to data exfiltration, not updated HR models for hiring use cases where there may be situations that lack adaptive compliance pulling due to lack of real time updates. [12], [17], [13], [6], [11].

IX. DEFENSIVE STRATEGIES AND MITIGATION TECHNIQUES

There are already defense strategies in place against its corresponding threat vector. These strategies are applied to defend AI at different levels of its life cycle from model building, training data to monitoring and evaluation.

Table 2: Mapping Defensive Strategies with Threat Vectors.

Defense Strategy	Primary Threat Mitigated	Implementation Layer	Key Techniques	Residual Risk
Input Sanitization	Prompt Injection, Jailbreaking	Pre-processing / API Gateway	Input validation, allowlists, context filtering, prompt templating	Advanced prompt injections and obfuscation may still bypass controls
RLHF / Red Teaming	Harmful Content Generation	Model Training / Fine-tuning	Human feedback loops, adversarial testing, safety tuning	Model may still fail in unseen or edge-case scenarios
Retrieval Augmented Generation (RAG)	Hallucinations, Poisoning	System Architecture	Grounding with trusted data, vector DB filtering, source attribution	Reliance on external data sources may introduce poisoned or unverified content
Watermarking	Deepfakes, IP Theft	Post-processing / Output	Digital watermarking, content fingerprinting, cryptographic signatures	Watermarks can be removed, altered, or degraded
Differential Privacy	Membership Inference, Privacy Leakage	Training Data Curation	Noise injection, privacy budgets, anonymization techniques	Trade-off between model accuracy and privacy protection

Source: Authors (2026).

IX.1 INPUT FILTERING AND SANITIZATION

This is a Cyber defense technique where it blocks any unwanted inputs to change the application logic and cause corruption to the AI model. It works by blocking specific malicious input patterns by simply rejecting blacklisted inputs which may contain any commands or files. This technique also mitigates buffer overflow but imposing length restriction on sessions connected with AIs. However, these are all static security measures which can be bypassed by more adversarial jail break attempts. This proves the need for additional or secondary AI models to evaluate the inputs of the primary AI model [18].

IX.2 ADVERSARIAL TRAINING AND ROBUSTNESS

Adversarial training and robustness are another cyber defense strategy where the AI model will be trained with details of malicious inputs and threats to create resistance. This instructs the AI to behave correctly, irrespective of the malicious inputs and allows the model to degrade gracefully in case of adversarial attacks. The model was trained, tested and validated for its robustness to avoid hallucinations and unintended behaviors. This layer of defense primarily focuses on mitigating evasion or inference attacks where attackers modify the inputs rationally to fool the model and make it learn from those modifications. It also protects against data poisoning and prompt injections to avoid manipulatory commands and inputs been sent to the model for training. [13], [6], [14], [15], [19].

IX.3 WATERMARKING AND PROVENANCE TRACKING

This strategy is like version control by embedding hidden signal in the source model to verify authenticity. The contents applied in the model are tracked for its integrity by maintaining the metadata history of details like creator, created by, modification history. Without this control deepfakes may remain unchecked and unidentified. This is applied in the post processing or output phase of the implementation layer. There are multiple types of watermarking such as text watermarking, image watermarking, and audio watermarking to ensure fake claims are being avoided. [12], [17].

IX.4 ARCHITECTURAL GUARDRAILS

Architectural Guardrails are system level controls outside the AI model itself which ensure that validate, monitor and isolate the model irrespective of how it behaves. This ensures that principles of limiting authority, enforcement of business rules and prevention of unsafe actions by securing the model based on its behavior. AI models need to be limited to whitelisted API and external tools based on principle of least privilege to avoid lateral or privilege escalation to execute harmful action in the database of backbone system of AI models. Some of the examples are Input guardrails, context guardrails and output guardrails which specifically monitor the AI model by the way it behaves.

X. TOWARD AN ADAPTIVE GOVERNANCE FRAMEWORK FOR SECURITY IN GEN AI

Bringing these strands together, security in Generative AI can be organized around a lifecycle-centric, AI-RMF-aligned governance framework. A typical GenAI system can be described through stages of problem framing and context, data acquisition and curation, model design and training, deployment and integration, operation and monitoring, and retirement and decommissioning. Security and governance measures must be applied consistently across all stages. [16], [8].

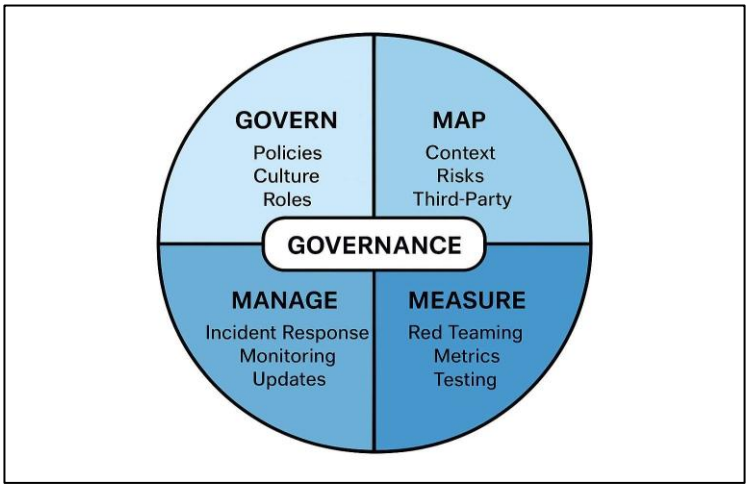

Figure 2: Adaptation of the NIST AI Risk Management Framework (AI-RMF) for the Generative AI Lifecycle.
Source: Authors (2026).

X.1 MAPPING GENERATIVE AI LIFECYCLE TO NIST AI-RMF FUNCTIONS

The NIST AI Risk Management Framework defines four core functions—GOVERN, MAP, MEASURE, and MANAGE—that can be operationalised for GenAI. GOVERN establishes roles, responsibilities, and organisational culture; MAP characterises context, stakeholders, and risk scenarios; MEASURE assesses risks, harm, and control effectiveness; and MANAGE implements and adjusts risk responses over time.

Table 3: Mapping NIST AI-RMF Functions to Generative AI Lifecycle Stages.

Lifecycle Stage	Govern	Measure	Manage
Data acquisition & curation	Data governance policies; data owners and steward	Data quality, bias, and privacy assessments	Access control; sanitization; incident response for data breaches
Model Training & evaluation	Model risk policies; secure ML Ops standards	Robustness (poisoning, backdoors, leakage)	Adversarial training; differential privacy; peer review
Deployment & integration	Acceptable use and integration standards	System level threat modelling (API abuse, tool exploitation)	Rate limiting; content filtering; segmentation; logging
Operation & monitoring	AI risk committee; dashboards and reporting	Incident, drift, and misuse metrics	Policy updates; control tuning; patching; retraining

Source: Authors (2026).

X.2 GOVERNANCE ARTEFACTS AND DECISION GATES

To make this framework operational, organizations can define governance artefacts such as AI system profiles, data-protection impact assessments, model and system cards, adversarial-testing and red teaming reports, incident logs, and decommissioning documentation. Decision gates—go/no-go checkpoints— can require multi-stakeholder approval before moving between lifecycle phases, ensuring that security and governance concerns are addressed proactively rather than retrospectively.

XI. CROSS-CUTTING CHALLENGES AND RESEARCH GAPS

Irrespective of the progress reflected in the reviewed literature, there are several open and dynamic problems remain. There is no widely accepted standard for measuring the safety of AI models and neither adversarial law in place to be followed. Generative AI systems depend heavily on third-party foundation models, external datasets, open-source libraries, customized prompts and cloud infrastructure and the current frameworks provide limited guidance on how to evaluate and manage these dependencies. Regulatory frameworks also face tensions between ambitious expectations and current scientific capabilities, especially for cybersecurity and robustness requirements. Many organizations lack structured AI-governance bodies, formal policies for acceptable use of GenAI, and personnel who understand both AI and security. There is no well-defined framework for AI security which is been widely accepted and due to which there are gaps in designating the research proposal to secure AI models.

XII. CONCLUSION

This literature review has examined the characteristics of AI models, their applications and the systems used. The survey is handled from the perspective of information security, security for AI, and the regulatory constraints. We proposed an RMF centric and lifecycle-oriented security approach to structure security in AI models and its applications. Understanding from the perspective of lack of framework and promising regulations, ever evolving cyber-attacks and misusage of AI applications demands more and broader research in Gen AI security. Addressing these gaps is essential to deploy dynamic and adaptive security for AI systems which makes applications more trustworthy and usable in many real time scenarios.

ABSTRACT

Traffic surveillance systems play a crucial role in intelligent transportation by enabling automated monitoring, traffic prediction, and accident detection. However, recognizing complex traffic scenarios from real-world videos remains challenging due to dynamic environments and temporal dependencies. This paper proposes a unified spatio-temporal framework that integrates YOLOv8 based object detection, convolutional neural networks for spatial feature ex traction, and long short-term memory networks for temporal modeling. Traffic videos are preprocessed to enhance visual consistency, and detected objects are transformed into structured spatial representations. Temporal dependencies across video sequences are learned using LSTM networks, and the extracted features are evaluated using multiple machine learning classifiers under different preprocessing strategies. Experimental results demonstrate that Z-score standardization improves classification performance, with Support Vector Ma chine achieving 63.27% accuracy and an F1-score of 55.66% in an eight-class traffic scenario classification task, indicating the feasibility and robustness of the proposed framework in real-world traffic environments.

I. INTRODUCTION

Traffic congestion and road accidents have become critical challenges in rapidly urbanizing regions, where increasing vehicle density and limited infrastructure place substantial pressure on existing transportation systems [1]. As cities continue to expand and mobility demands intensify, traditional manual surveillance and rule-based monitoring approaches are no longer sufficient to manage real-time traffic dynamics effectively [2]. Such methods often struggle to detect sudden anomalies including accidents, lane violations, and abrupt fluctuations in traffic flower sulting in delayed response times and compromised road safety [3]. In response to these limitations, intelligent video-based traffic analysis has emerged as a promising solution, leveraging advancements in computer vision and deep learning to enable automated, scalable, and real-time monitoring [4]. Over the past decade, significant research efforts have focused on developing robust algorithms for vehicle detection, traffic flow estimation, and anomaly recognition [5]. Convolutional Neural Networks (CNNs) have demonstrated strong capability in extracting meaningful spatial features from complex road scenes, thereby improving vehicle localization and classification accuracy [6]. More recently, real-time object detection frameworks such as You Only Look Once (YOLO) and transformer-based detectors have further enhanced detection speed and precision, facilitating deployment in densely populated urban environments [7]. Complementary research has explored temporal modeling techniques including Long Short-Term Memory (LSTM) networks, 3D CNNs, and sequence-based architectures to capture motion patterns and identify traffic incidents across video sequences [8]. Although these approaches have contributed substantially to intelligent transportation research, many rely on computationally intensive architectures, controlled datasets, or address isolated components of traffic analysis rather than offering an integrated end-to-end solution [9]. Despite notable progress, several challenges remain unresolved. Numerous studies depend on narrow field-of-view or synthetic datasets, which limit model generalizability in heterogeneous real-world scenarios [10].

Furthermore, existing works frequently treat vehicle detection, spatial feature extraction, temporal analysis, and accident identification as independent modules, thereby reducing overall system efficiency and scalability [11]. Achieving real-time performance under resource-constrained deployment conditions such as roadside surveillance infrastructure continues to be a practical concern [12]. These limitations underscore the necessity for a unified, computationally efficient framework that integrates spatial temporal modeling and anomaly detection using real-world traffic video data [13]. To address these challenges, this study proposes a comprehensive deep learning based framework for real-time traffic flow analysis and accident detection. The proposed approach integrates object detection, spatial feature extraction, and temporal modeling into a cohesive pipeline [14]. An advanced detection model is employed to accurately identify vehicles within surveillance footage, after which temporal sequence modeling captures abrupt variations in motion and density patterns that may indicate congestion or accidents [15]. By directly leveraging video data and minimizing reliance on handcrafted features, the framework enhances scalability and adaptability across diverse traffic conditions [16]. The system is designed to support practical deployment scenarios and aims to improve early identification of abnormal events, thereby contributing to safer and more efficient intelligent transportation systems [17]. The primary objective of this research is to develop a robust and computationally efficient methodology for vehicle detection, traffic flow analysis, and accident identification in real time [18]. Specifically, this study evaluates the effectiveness of combining spatial detection with temporal sequence modeling, investigates the impact of different preprocessing strategies, and assesses classification performance across multiple machine learning algorithms on realistic traffic datasets [19].

II. THEORETICAL REFERENCE

II.1 RELATED WORK

To understand current trends and challenges in traffic accident detection, it is essential to review recent methods and models [20]. Numerous approaches have been proposed with the goals of enhancing detection accuracy, improving tracking reliability, and enabling real-time response in diverse urban environments [21]. The following sections highlight the most significant contributions, their thematic focus, and the specific challenges addressed by the model [22].

II.1.1 Trajectory Conflict and Motion Pattern Analysis

Trajectory-based conflict reasoning has proven effective for distinguishing near-miss events from actual collisions by explicitly modeling the motion interactions among vehicles [23]. Ghahremannezhad et al. (2022) combined YOLOv4-based object detec tion with trajectory divergence and proximity metrics to differentiate collision-prone scenarios from non-severe interactions. This approach highlighted the importance of motion continuity rather than isolated frame-level cues [24]. Huang et al. (2019) extended motion-centric analysis by proposing a two-stream Convolutional Neural Network (CNN) that jointly learns spatial appearance features and temporal motion patterns from aerial traffic videos [25]. Their architecture en abled real-time near-accident detection by capturing vehicle interactions over time. Such trajectory-driven approaches strengthen the conceptual modeling of inter-vehicle dynamics and closely align with the trajectory-based anomaly detection module em ployed in our proposed system [26].

II.1.2 Spatio-Temporal and Graph-Based Traffic Modeling

Beyond individual object detection, several studies have explored traffic behavior at a broader spatio-temporal scale [27]. Cuietal. (2018) introduced the Temporal Graph Convolutional Long Short-Term Memory (TGC-LSTM) model, which inte grates Graph Convolutional Networks (GCNs) with LSTM units to represent spatial correlations among interconnected road segments while learning temporal traffic evo lution [28]. This framework demonstrated strong performance in network-level traffic state prediction. Similarly, Ismaeel et al. (2023) proposed a deep CNNRNN architecture for smart city traffic pattern classification, achieving an accuracy of 95% [29]. While these meth ods are effective for global traffic analysis and congestion prediction, they are less suitable for real-time, localized accident or near-miss detection, which remains the primary focus of the proposed system [30].

II.1.3 Critical Review of Related Work and Research Gaps

Despite notable progress in traffic accident detection and spatio-temporal traffic anal ysis, several persistent challenges remain in the existing literature.

Dataset Limitations: Many studies rely on synthetic data or static-camera datasets with limited environmental diversity, which restricts model generalizability. To address this issue, the proposed work utilizes a diverse and annotated real-world dataset sourced from IEEE DataPort.

Computational Overhead: High-capacity models such as 3D CNNs and graph-based architectures incur substantial computational costs, limiting their suit ability for real-time deployment. Hybrid CNN–LSTM-based approaches offer a more favorable balance between detection accuracy and computational efficiency, motivat ing their adoption in the proposed framework.

Occlusion and Dense Traffic Conditions: Vehicle occlusions, frequent in teractions, and complex motion patterns in dense traffic environments remain chal lenging. Prior studies (Nagy & Simon, 2021) indicate that temporal modeling and trajectory-aware inference can alleviate these issues. The proposed approach incor porates temporal consistency to improve robustness under such conditions. Table 1 presents a comparative summary of key studies related to traffic ac cident and near-miss detection, highlighting the methodologies employed, dataset characteristics, major contributions, and identified limitations.

Identified Research Gaps: Although existing methods demonstrate promis ing performance, several gaps remain unaddressed. Most approaches treat object detection, temporal feature extraction, and trajectory reasoning as independent com ponents, limiting their ability to model the complete evolution of accident scenarios. Furthermore, computationally intensive architectures hinder real-time deployment on edge and resource-constrained platforms.

Dense, heterogeneous, and occlusion-prone traffic environments are still insufficiently explored, resulting in degraded performance under realistic urban conditions. Additionally, only a limited number of systems pro vide an end-to-end framework integrating detection, risk assessment, and real-time decision support. These gaps motivate the development of a unified, lightweight, and real-time traffic accident detection framework capable of robust operation across diverse traffic environments.

Table 1: Summary of Related Work in Traffic Accident and Near-Miss Detection.

Author	Method	Data	Contribution	Limitation
Yadava et al. (2022)	YOLOv4 + Kalman Hungarian	Intersection videos	Vehicle detection and conflict analysis	Poor performance under dense occlusion
Li et al. (2020)	CNN-LSTM SMOTE	Crash records	Crash risk forecasting	High computation cost
Roy et al. (2019)	Siamese Interaction LSTM	Aerial videos	Temporal attention for collision risk	Sensitive to noisy trajectories
Ghahremanzadeh et al. (2022)	YOLOv4 + Trajectory analysis	UAV footage	Near-miss vs collision differentiation	Degrades with rapid motion
Huang et al. (2019)	Two-stream CNN	Aerial videos	Real-time near-accident detection	Limited scalability
Cui et al. (2018)	TGC-LSTM (GCN+LSTM)	Network traffic data	Spatio-temporal traffic prediction	Not video-level accident detection
Ismaeel et al. (2023)	Deep CNN-RNN	Smart city data	Traffic state classification	No explicit collision modeling

III. MATERIALS AND METHODS

This research proposes a hybrid deep-learning pipeline that integrates Convolutional Neural Networks (CNNs) and Long Short-Term Memory (LSTM) networks for real time traffic flow analysis and accident detection. The complete workflow includes video preprocessing, feature extraction, temporal modeling, and classification of traffic events. The system is designed to handle unconstrained road environments with varying traffic densities, lighting conditions, and weather scenarios.

III.1 DATASET

TheTrafficAccident Detection Video Dataset for AI-Driven Computer Vision Systems in Smart City Transportation was sourced from the IEEE DataPort repository, where it was contributed by Adewopo et al. (2023) to support research on intelligent traffic surveillance. The dataset compiles videos from multiple real-world sources, includ ing urban traffic surveillance cameras, in-vehicle dashcams, and additional publicly available crash footage. This ensures natural variation in traffic flow, accident types, and environmental conditions. The dataset is systematically organized into three pre defined experimental splitsTraining, Validation, and Testingto maintain consistency in benchmarking and reproducible experimentation. In preparing the dataset, all raw videos were segmented into non-overlapping five-second clips, resulting in ap proximately 5,690 video samples.This segmentation strategy ensures uniformity in clip duration and highlights the dynamic temporal behavior around accident events. Each clip is categorized into one of eight scenario classesBackend, Backend Rollover, Frontend, Frontend Rollover, Sidehit, Sidehit Rollover, General Augmented Crash, and No Accident Normal Traffic thereby supporting both multi-class accident classifi cation and accident-versus-non-accident detection, as shown in **Table 2**. The dataset provides video-level annotations only, without frame-level bounding boxes or object level segmentation, making it suitable for end-to-end video classification and temporal feature learning. The clips represent diverse scenarios involving variations in light ing, weather, camera angle, road structure, traffic density, and sensor quality, adding significant heterogeneity and complexity to the dataset.

Table 2: Dataset Distribution by Scenario.

Scenario	Total Videos
Backend	362
Backend Rollover	28
Frontend	369
Frontend Rollover	51
General Augmented Crash	1459
No Accident Normal Traffic	2283
Sidehit	1027
Sidehit Rollover	111
Total	**5690**

Source: Authors, (2026).

III.2 PREPROCESSING

To ensure uniformity and reliable model training, all videos in the dataset underwent a comprehensive preprocessing pipeline. Each five-second video clip was decomposed into individual frames, resulting in an average of 2530 frames per video, depending on the recording devices frame rate.

The original videos exhibited heterogeneous frame resolutions due to their diverse sources, including traffic surveillance systems and dashcams. To standardize the input representation, all extracted frames were re sized to a fixed resolution of 224×224 pixels, a commonly used dimension compatible with state-of-the-art deep learning architectures such as CNNs and 3D-CNN-based spatiotemporal models. This resizing step ensures consistent input size across the dataset, reduces computational requirements, and enables efficient batch processing. Following resizing, all pixel intensities were normalized tostabilize the training process. Pixel values originally in the 0255 range were scaled to 01, and a channel-wise mean standard deviation normalization was applied to bring the data distribution closer to that of pretrained image models. Normalization improves gradient flow, accelerates convergence, and minimizes the impact of illumination variations commonly observed in traffic surveillance footage.

Normalization:

Normalization scales input feature values to a fixed range, typically [0,1], to ensure numerical stability and faster convergence during model training.

$$X_{norm} = \frac{X - X_{min}}{X_{max} - X_{min}}$$

For scaling the data to a general range [a,b]:

$$X_{norm} = a + \frac{(X - X_{min})(b - a)}{X_{max} - X_{min}}$$

To enhance frame clarity, noise-removal techniques such as Gaussian smoothing and median filtering are selectively applied to reduce sensor noise, motion-induced blur, and compression artifacts. These denoising operations preserve important struc tural information, thereby improving feature extraction and increasing the accuracy of accident detection models.

III.3 YOLOv8

YOLOv8 is the latest generation of the “You Only Look Once” family of real-time computer vision models, designed to deliver high-performance object detection with improved accuracy and reduced latency. It plays a critical role in modern visual per ception systems by providing a unified framework capable of object detection, instance segmentation, and image classification, making it suitable for real-time and resource constrained environments. YOLOv8 introduces several architectural enhancements, including an improved CSP-based backbone for deeper feature extraction, a refined PAN/FPN neck for stronger multi-scale representation, and a fully anchor-free de tection head that directly predicts bounding boxes at each spatial location. This anchor-free design eliminates manual anchor tuning, reduces computational complex ity, and improves generalization across different object scales. YOLOv8 achieves faster inference, higher FPS, and improved accuracy through its decoupled classification regression head, advanced IoU-based loss functions, and optimized training strategies such as dynamic label assignment and enhanced augmentation pipelines. Addition ally, it supports multiple vision tasks — detection, segmentation, and classification —within a single architecture. Compared to earlier versions such as YOLOv5 and YOLOv7, YOLOv8 replaces traditional anchor-based prediction, which often struggled with scale variation and required extensive hyperparameter tuning. The anchor-free design improves localiza tion stability, reduces mismatched anchor assignments, and enhances performance on small and irregularly shaped objects. YOLOv8 also delivers lower inference latency, higher precision and recall, and more efficient end-to-end training, outperforming previous YOLO variants in both accuracy and real-time capability. YOLOv8 is preferred in modern applications because it generalizes effectively across diverse environments, handles small objects and crowded scenes more accu rately, and provides an efficient training pipeline suitable for both cloud and edge devices. Its robustness and high-speed performance make it especially suitable for traffic surveillance, road-scene analysis, accident detection, smart-city monitoring, and autonomous vehicle perception.

III.4 SPATIAL FEATURE EXTRACTION USING CNN

Convolutional Neural Networks (CNNs) are widely used in real-time traffic flow anal ysis and accident detection because they can automatically learn hierarchical spatial patterns directly from video frames without requiring manual feature engineering. Traffic scenes contain diverse and complex visual elements—vehicles, lane bound aries, road geometry, shadows, occlusions, and collision signatures—that traditional computer-vision methods fail to capture reliably. CNNs, on the other hand, learn context-aware representations such as vehicle contours, deformation patterns during impact, smoke, abrupt intensity changes, and density variations. They also provide strong robustness against real-world challenges such as varying lighting conditions, ad verse weather, different camera perspectives, and high traffic density. Furthermore, modern CNN-based models such as YOLO, SSD,andFaster R-CNNefficiently process high frame-rate video streams on GPUs, making them ideal for real-time surveillance environments. Their ability to extract discriminative spatial features makes CNNs the backbone of intelligent transportation systems, especially when combined with temporal modeling techniques for dynamic event understanding.temporal models like LSTMs for capturing motion dynamics. In the proposed accident detection framework, the Convolutional Neural Network (CNN) serves as the primary module for extracting spatial features from individual video frames. Each frame contains rich visual cues such as vehicle shapes, road markings, traffic density, and collision indicators. Therefore, the CNN converts raw pixel-level information into high-level spatial representations that can later be ana lyzed temporally by the LSTM network. The input to the CNN consists of sequential traffic frames resized to a fixed resolution to ensure computational uniformity across the dataset.

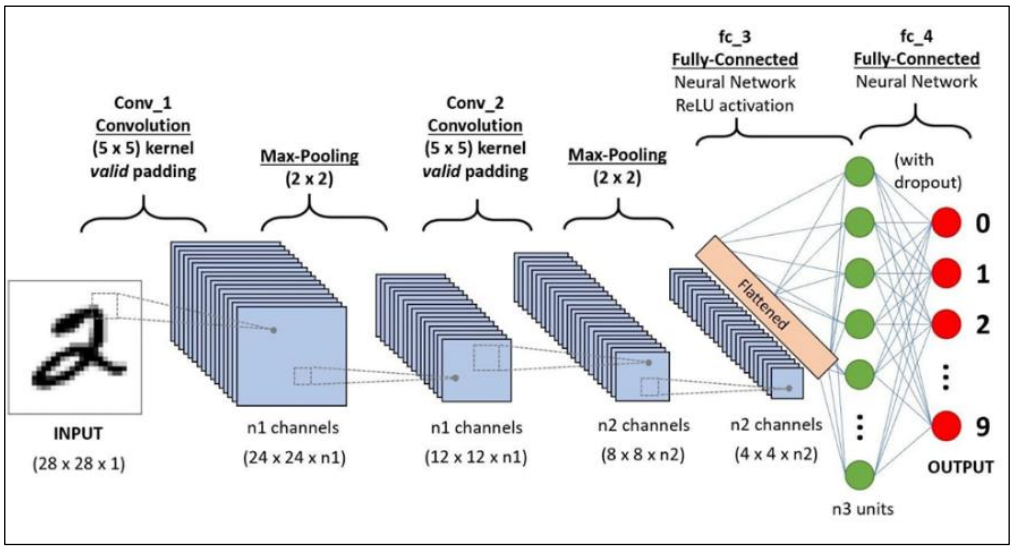

Figure 2: CNN Architecture.
Source: Authors, (2026).

The architecture begins with a convolutional layer that applies a set of learnable f ilters across the input frame. Each filter performs a two-dimensional convolution operation given by:

$$F(i,j) = \sum_{m}\sum_{n} I(i+m, j+n)K(m,n)$$

Where I represents the input image, K denotes the convolution kernel, and F(i,j) is the resulting feature activation. These convolutional operations generate feature maps that highlight meaningful structures such as vehicle boundaries, road edges, and abrupt illumination changes caused by collisions or skid marks. By using valid padding and appropriately sized kernels, the spatial dimensions gradually decrease while the feature depth increases, allowing the model to learn abstract hierarchical representations. Each feature map then undergoes a max-pooling operation to reduce spatial di mensions while retaining dominant activations. The pooling process is mathematically expressed as:

$$P(i,j) = \max_{(m,n)\in R_{i,j}} F(m,n)$$

Where Ri,j represents the pooling region. This step introduces robustness to minor spatial shifts, which is crucial in dynamic traffic environments where vehi cles frequently move across frames. Additionally, max-pooling reduces computational complexity, enabling efficient real-time processing. A second convolutional block further refines the spatial features by learning higher-order patterns such as overlapping vehicles, deformation signatures during im pacts, and sharp discontinuities on the road surface. Similar to the first block, it consists of convolutional layers followed by max-pooling, resulting in compact and in formative feature maps that preserve essential accident-related cues while suppressing background noise. After spatial feature extraction, the multi-channel feature maps are flattened into a one-dimensional vector. This flattened representation is passed to fully connected layers that integrate spatial information across the entire frame. Each fully connected layer performs the operation:

$$h = \phi(Wx + b),$$

Where x is the flattened feature vector, W and b are learnable weights and bi ases, and ϕ(·) is a nonlinear activation function, typically ReLU. The nonlinearity enables the model to learn complex semantic patterns such as abnormal vehicle spac ing or visual signatures associated with accidents. Dropout regularization is applied to prevent overfitting and enhance generalization across diverse traffic conditions. Finally, the output layer generates spatial feature representations that are not directly used for classification. Instead, these representations serve as input to the LSTM module. This CNN–LSTM integration enables the framework to jointly cap ture spatial information and temporal dynamics, resulting in accurate accident detec tion based on both instantaneous visual cues and motion patterns across consecutive video frames.

III.5 TEMPORAL MODELING USING LSTM

Temporal analysis plays a fundamental role in accident detection, as accidents are inherently dynamic and evolve over a sequence of frames rather than appearing in isolated images. These events typically involve distinct patterns such as abrupt decel eration, abnormal trajectory deviations, sudden collisions, or instantaneous disappear ance of vehicles, all of which unfold over time. While Convolutional Neural Networks (CNNs) are effective at extracting spatial information from individual frames, they are unable to capture the temporal progression that characterizes accident scenarios. Long Short-Term Memory (LSTM) networks address this limitation by modeling tem poral dependencies and learning frame-to-frame relationships within sequential data. By incorporating the evolution of visual cues across pre-impact, impact, and post impact stages, LSTMs significantly enhance the robustness and accuracy of real-time accident detection systems, enabling them to distinguish true accident occurrences from normal fluctuations in traffic behavior. Long Short-Term Memory (LSTM) networks are an advanced variant of tradi tional Recurrent Neural Networks (RNNs), specifically designed to overcome limita tions in learning long-range temporal dependencies, such as the vanishing gradient problem. Unlike conventional RNNs, which struggle to preserve information across extended sequences, an LSTM maintains two internal states at each time step: the hidden state $h_{t-1}$and the cell state C_{t-1}. Together with the current input x_t, these states regulate the flow of information through a set of gating mechanisms that de termine what information should be forgotten, updated, and propagated forward in time. The computation begins with the forget gate, which evaluates the relevance of the previous memory by applying a sigmoid activation function to the concatenation of the previous hidden state and the current input. The forget gate is defined as:

$$ft = \sigma\big(W_f[h_t - 1, x_t] + b_f\big),$$

Where σ(·) denotes the sigmoid activation function, W_f represents the forget gate weight matrix, and b_f is the corresponding bias term. The gate output ranges between 0 and 1, where values close to 1 indicate retention of past information, while values near 0 indicate discarding irrelevant or outdated memory. Simultaneously, the input gate determines how much new information should be added to the cell state. It is computed as:

$$i_t = \sigma(W_i[h_t - 1, x_t] + b_i)$$

Along with the candidate memory vector, which represents newly generated con tent derived from the current input and the previous hidden state:

$$C_t = \tanh(W_C[h_t - 1, x_t] + b_C)$$

The interaction between the input gate and the candidate memory allows the LSTM to selectively incorporate only the most meaningful and contextually relevant information into its internal state. The updated cell state is computed through an element-wise combination of the preserved past memory and the newly generated candidate content:

$$C_t = f_t \odot C_t - 1 + i_t \odot \tilde{C}_t,$$

Where ⊙denotes element-wise multiplication. This update mechanism ensures a stable memory flow across time, enabling the LSTM to maintain long-term contextual dependencies without numerical instability. Once the cell state is updated, the output gate determines which part of the memory should be exposed to the hidden layer:

$$o_t = \sigma(W_o[h_t - 1, x_t] + b_o),$$

And the final hidden state is computed as:

$$h_t = o_t \odot \tanh(C_t)$$

The hidden state ht serves as both the output of the LSTM at the current time step and a summary of relevant temporal information that is passed to subsequent time steps. Through this gated and controlled flow of information, LSTM networks effec tively capture both short-term and long-term temporal dependencies in sequential data. Their ability to maintain stable memory dynamics and model evolving tem poral context makes them particularly suitable for real-time accident detection and traffic flow analysis, where patterns such as sudden deceleration, abnormal motion trajectories, and frame-to-frame vehicle interactions are critical for identifying acci dent events.

III.6 CLASSIFICATION OF TEMPORAL FEATURES

Let the input video sequence be denoted as X = $x_1, x_2, \ldots, x_T$, where T repre sents the total number of frames in a video. The Long Short-Term Memory (LSTM) network processes this sequence to capture long-term temporal dependencies and produces a compact temporal representation. The output of the LSTM block is rep resented by the final hidden state vector $h_T \in R^d$, which encodes discriminative temporal information across the entire sequence. The extracted temporal feature vector h_T is subsequently forwarded to the clas sifier block for multi-class classification. In this study, the classification task involves eight distinct classes corresponding to different accident and non-accident scenarios. Formally, the classifier learns a mapping function

$$f: R^d \rightarrow 1,2,\ldots,8$$

Where each output label denotes one of the predefined scenario classes. To evaluate the effectiveness of the learned temporal representations, multiple machine learning classifiers are employed, including LightGBM, Support Vector Ma chine (SVM), XGBoost, CatBoost, and Random Forest. All classifiers are trained using the same set of LSTM-derived feature vectors to ensure a fair and consistent comparison. This multi-classifier strategy facilitates an in-depth analysis of how differ ent learning paradigms exploit the temporal features extracted by the LSTM network. The performance of each classifier is assessed using Accuracy and F1-score. Ac curacy is defined as:

$$Accuracy = \frac{TP}{TP + TN + FP + FN,} + \frac{TN}{TP + TN + FP + FN,}$$

Which measures the overall correctness of classification. Since the dataset exhibits class imbalance across the eight classes, the F1-score is also reported, as it provides a balanced measure between precision and recall. The F1-score is defined as :

$$F1 = \frac{2 \times \Pr e\,cision \times Recall}{\Pr e\,cision + Recall}$$

These evaluation metrics collectively provide a reliable assessment of the classifier performance and demonstrate the discriminative capability of the temporal features learned by the LSTM network across all eight scenario classes.

III.7 SYSTEM ARCHITECTURE AND ALGORITHM

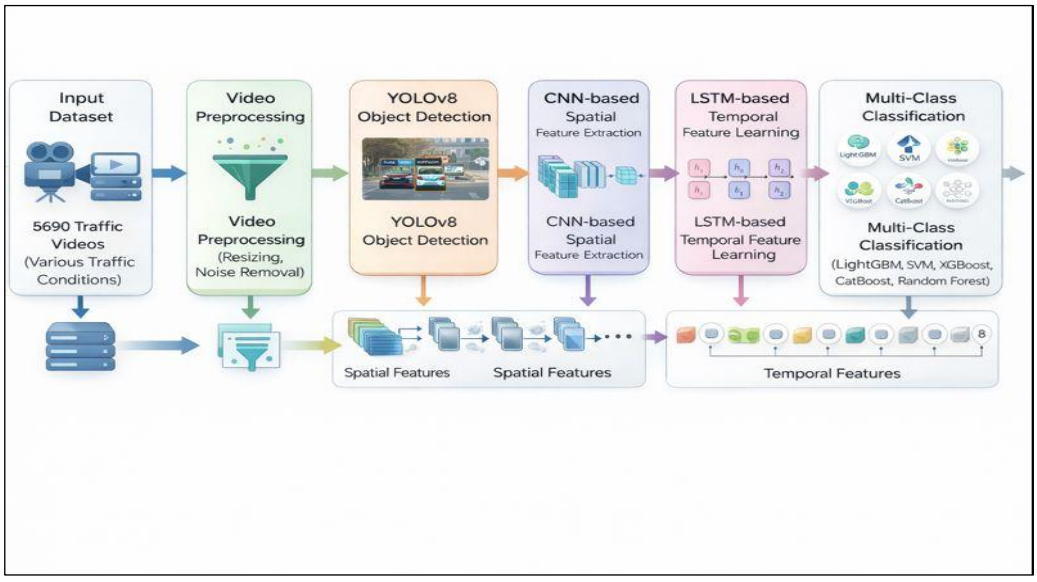

Figure 3: Block diagram of the proposed YOLOv8 and LSTM-based traffic accident multi class prediction framework.
Source: Authors, (2026).

Figure 3 illustrates the overall workflow of the proposed YOLOv8-based traffic ac cident detection framework. The system begins with continuous acquisition of traffic video streams from surveillance cameras. The input video is processed by the video preprocessing and frame sampling module, where frames are extracted at fixed inter vals and normalized to ensure uniform resolution and noise reduction. The preprocessed frames are then passed to the YOLOv8-based object detection module, which performs real-time detection and localization of traffic participants such as vehicles. The detected objects are represented through spatial feature em beddings, capturing object-level characteristics and scene context. To model the temporal dynamics of traffic behavior, the extracted features are forwarded to the temporal feature modeling unit, where sequential dependencies across consecutive frames are learned. An LSTM-based spatio-temporal classification module analyzes these temporal patterns to differentiate between accident and non-accident scenarios. Finally, the decision support and alert generation module evaluates the classifi cation outcome and generates real-time accident alerts, enabling timely response and traffic management intervention.

IV. RESULTS AND DISCUSSIONS

IV.1 RESULTS

IV.1.1 Dataset

The dataset was organized into three splits: training, validation, and testing, ensuring that each subset contained a balanced representation of all scenarios. The dataset was structured into scenario-specific folders, with each folder containing multiple videos cor responding to different traffic and environmental conditions. All videos were program matically loaded and decomposed into individual frames to enable frame-level prepro cessing and model-based analysis. Each extracted frame was subjected to standard pre processing operations, including resizing to a uniform spatial resolution, normalization of pixel intensities, and cleaning to remove corrupted or low-quality frames. These steps ensured consistency across the dataset and improved the reliability of the feature extrac tion process. Ground-truth annotations, such as accident and non-accident labels (or other scenario-specific classes), were incorporated into the dataset pipeline. These labels were mapped to the corresponding frames and used during training, validation, and perfor mance evaluation of the detection model.

IV.1.2 Yolov8

The proposed system employs the YOLOv8 object detection architecture to analyze traffic surveillance video data and identify relevant objects within each frame with high spa tial accuracy. As a preprocessing step, all input videos were decomposed into individual frames using a fixed sampling rate. This uniform frame extraction strategy ensures consis tent temporal representation across all video sequences while maintaining computational efficiency, thereby enabling scalable analysis of large-scale traffic datasets. Each extracted frame was processed independently by the YOLOv8 model during the inference stage. For every frame, the model generates bounding box coordinates, class labels, and corresponding confidence scores for all detected objects. These outputs col lectively encode the spatial location, semantic category, and detection reliability of objects present in the scene. Processing frames at this granularity preserves detailed spatial infor mation andfacilitates subsequent aggregation for temporal analysis without loss of critical visual cues. YOLOv8 was configured to detect multiple object categories commonly present in traffic-related environments, including vehicles, pedestrians, and other dynamic entities that directly influence traffic flow and road safety. The model's anchor-free detection mechanism, combined with enhanced feature pyramid networks, enables effective detec tion of objects across varying scales and resolutions. Moreover, the inference pipeline en sures consistent detection across consecutive frames, which is essential for robust analysis of dynamic traffic scenarios characterized by motion, occlusion, and frequent changes in object density.

For qualitative evaluation and demonstration purposes, the detection results obtained from five representative video samples are illustrated in the accompanying figure. In each example, frames were extracted from the original video, passed through the trained YOLOv8model, and subsequently annotated with bounding boxes and class labels corre sponding to the detected objects. These annotated frames provide a clear visual depiction of the model's detection capability and highlight its effectiveness in identifying diverse ob ject types under varying traffic conditions, camera viewpoints, and environmental settings such as lighting variations and background complexity. In addition to qualitative visualization, the frame-wise detection outputs generated by YOLOv8 play a critical role in subsequent analytical stages of the proposed frame work. The detected object information—including object counts, spatial distributions, and confidence scores across consecutive frames—serves as structured input for higher-level modeling and temporal analysis. By aggregating detection outputs over time, the system can infer evolving traffic patterns, detect changes in traffic density, and identify potential anomalous events. This integration of reliable object-level detection with temporal mod eling establishes a strong foundation for downstream classification and prediction tasks, thereby reinforcing the effectiveness of YOLOv8 as a core component of the overall traffic monitoring and accident detection pipeline.

IV.1.3 Comparative Analysis of Traffic Prediction and Accident DetectionModels

To comprehensively evaluate the effectiveness and robustness of the proposed traffic prediction and accident detection framework, a comparative analysis was conducted using multiple machine learning classifiers under three different data preprocessing strategies: without preprocessing, normalization, and Z-score standardization. This analysis aims to assess the capability of each model to learn discriminative traffic patterns from video-derived features while maintaining robustness under real-world variability.

Table 3: Model Performance Without Preprocessing.

Model	Accuracy (%)	F1-Score (%)
LightGBM	57.68	25.67
XGBoost	57.84	52.03
Random Forest	55.57	47.25
CatBoost	56.57	49.48
SVM	58.75	51.20

Source: Authors, (2026).

Table 4: Model Performance with Normalization.

Model	Accuracy (%)	F1-Score (%)
LightGBM	57.75	52.07
XGBoost	56.96	50.73
Random Forest	55.57	47.25
CatBoost	56.82	49.80
SVM	58.75	51.20

Source: Authors, (2026).

Table 5: Model Performance with Z-Score Standardization.

Model	Accuracy (%)	F1-Score (%)
LightGBM	57.05	51.23
XGBoost	56.70	51.34
Random Forest	55.62	47.14
CatBoost	56.73	50.28
SVM	**63.27**	**55.66**

Source: Authors, (2026).

Tables 3, 4, and 5 summarize the performance of five widely adopted classifiers, namely LightGBM, XGBoost, Random Forest, CatBoost, and Support Vector Machine (SVM). Model performance is evaluated using accuracy and F1-score, which jointly reflect overall classification correctness and class-wise prediction balance in a multi-class traffic scenario. In the absence of preprocessing (Table 3), all models exhibit relatively moderate accuracy, ranging between 55% and 59%. LightGBM shows a notably low F1-score despite comparable accuracy, indicating a bias toward majority classes and poor handling of class imbalance. In contrast, SVM and XGBoost demonstrate improved F1-scores, suggesting better generalization across multiple traffic states even without feature scaling. When normalization is applied (Table 4), a marginal yet consistent improvement in F1-scores is observed for most classifiers. This improvement highlights the sensi tivity of distance-based and margin-based models to feature scale and distribution. However, the overall accuracy gains remain limited, indicating that normalization alone is insufficient to fully capture the temporal complexity inherent in traffic dy namics. The most significant performance enhancement is achieved under Z-score stan dardization (Table 5). In this configuration, SVM outperforms all other classifiers, achieving the highest accuracy of 63.27% and an F1-score of 55.66%. This re sult suggests that Z-score standardization effectively stabilizes feature distributions and improves class separability in high-dimensional traffic data. The superior perfor mance of SVM further indicates its ability to model nonlinear decision boundaries in scenarios characterized by overlapping traffic patterns and temporal ambiguity.

Despite these improvements, the overall accuracy of conventional machine learn ing models remains moderate. This limitation can be attributed to the intrinsic complexity of the problem, which involves multi-class traffic state classification under heterogeneous conditions, including varying illumination, occlusions, camera view points, and dynamic traffic density. Additionally, inter-class similarity between traffic states, such as slow-moving traffic and early-stage congestion or near-miss events and normal flow, increases classification difficulty and reduces achievable accuracy. In contrast, deep learningbased architectures demonstrate substantially higher performance. Hybrid models that integrate object detection and temporal modeling particularly the proposed YOLO + CNN + LSTM frameworksignificantly out perform traditional classifiers. This marked improvement validates the effectiveness of combining YOLO-based object detection for precise spatial feature extraction with CNNLSTM architectures for capturing long-term temporal dependencies in traffic sequences. The superior performance of the proposed model can be attributed to its ability to jointly model spatial and temporal information, which is essential for accurately recognizing traffic flow patterns and accident events that evolve over time. Unlike conventional classifiers operating on aggregated or static features, the proposed frame work preserves temporal continuity and contextual progression, resulting in improved discrimination between visually similar traffic conditions.

Furthermore, analysis of the training and validation curves confirms the stability and generalization capability of the proposed deep learning model. Both training and validation accuracy increase rapidly during early epochs and converge near the optimal value without significant divergence. Similarly, the corresponding loss curves exhibit a steady decline, indicating efficient error minimization and absence of over f itting. These observations confirm the reliability of the learning process and support the suitability of the model for real-time intelligent transportation system (ITS) ap plications. Overall, this comparative analysis demonstrates that while traditional machine learning models serve as effective baselines, they are limited in handling the spatio temporal complexity of real-world traffic data. The proposed YOLO + CNN + LSTM framework offers a robust, scalable, and high-precision solution for traffic prediction and accident detection, making it highly suitable for deployment in intelligent trans portation and urban traffic monitoring systems.

IV.2 DISCUSSION

The present study demonstrates that integrating random video sampling, multi-frame ex traction, and YOLOv8-based object detection provides an effective and computationally efficient framework for analyzing heterogeneous traffic surveillance videos. The results consistently show that the proposed pipeline is capable of isolating object-rich frames con taining dense vehicular and pedestrian activity, while filtering out visually uninformative segments such as empty roads or low-activity intervals. This selective processing strategy ensures that the downstream classification models are trained and evaluated on frames that are most relevant to traffic dynamics and event understanding, thereby supporting the broader objective of automated traffic analysis and accident detection. A key design decision in this work is the selection of YOLOv8 as the object detec tion backbone. YOLOv8 was chosen due to its strong balance between detection accu racy and real-time inference speed, which is essential for traffic surveillance applications where timely responses are critical. Its anchor-free detection paradigm, enhanced feature pyramid networks, and optimized non-maximum suppression mechanisms enable robust detection of objects across multiple scales and crowded scenes. These architectural im provements are particularly advantageous in complex traffic environments characterized byocclusions, rapid motion, and varying object densities. Compared to earlier YOLO vari ants and traditional handcrafted approaches, YOLOv8 demonstrates improved robustness underuncontrolledconditions, makingitwell-suited for real-world deploymentscenarios. For temporal classification and event recognition, a CNN + LSTM architecture was adopted as the classifier. This hybrid design leverages the complementary strengths of convolutional and recurrent neural networks. The CNN component effectively captures spatial features such as vehicle shapes, spatial arrangements, and local visual patterns within individual frames.

In contrast, the LSTM component models temporal dependen cies by learning sequential patterns across consecutive frames, which is critical for dis tinguishing transient traffic events such as congestion buildup, slowdowns, or accidents. Traffic-related incidents are inherently temporal phenomena, where isolated frames may appear ambiguous; therefore, incorporating temporal sequence modeling significantly en hances contextual understanding beyond frame-level analysis. From a performance perspective, the system achieved an over all classification accuracy of approximately **63%**. The complexity of the dataset further compounds this challenge. The traffic videos usedinthis studyoriginate from diver sescenarios captured under varying real-world conditions, including differences in lighting (daytime, dusk, nighttime), camera viewpoints, motion blur, background clutter, weather conditions, and traffic density. These hetero geneous conditions introduce significant intra-class variability, making it difficult for the model to learn consistent patterns for each class. Additionally, changes in camera angles and scene geometry can alter object appearance and motion trajectories, reducing the ef fectiveness of purely visual cues and increasing reliance on temporal modeling. Several limitations and challenges were identified that help explain the observed per formance. One major factor is limited and imbalanced data across classes, where rare events such as accidents or near-miss scenarios are underrepresented compared to normal traffic conditions. This imbalance biases the classifier toward dominant classes and re duces sensitivity to infrequent but critical events. Furthermore, traffic videos often contain noisy or ambiguous frames caused by motion blur, shadows, glare, or partial occlusions, which can obscure key visual indicators. Temporal ambiguity also presents a significant challenge in accident detection, as the onset and aftermath of an incident may span multi ple frames with subtle transitions that are difficult to localize precisely.

Despite these challenges, the results provide valuable insights into the effectiveness of the proposedapproach. TheachievedperformancedemonstratesthatcombiningYOLOv8 based object detection with CNN–LSTM temporal modeling is a viable strategy for multi class traffic event recognition under realistic conditions. The system's ability to generalize across diverse scenarios indicates strong foundational robustness, even when confronted with complex environmental variability and class overlap. Looking ahead, several avenues for future improvement are evident. Expanding the dataset with additional labeled samples per class—particularly for rare events—would significantly enhance model generalization. Advanced temporal architectures such as bidirectional LSTMs, GRUs, or transformer-based sequence models could further improve temporal reasoning and reduce ambiguity in event boundaries. Fine-tuning YOLOv8 on domain-specific traffic datasets and incorporating multimodal features (e.g., optical flow, vehicle trajectories, or speed estimates) may also strengthen discriminative power. Finally, integrating contextual cues such as road geometry or traffic signal states could improve semantic understanding and support more accurate classification in complex urban envi ronments. Overall, the findings underscore the practical feasibility of the proposed framework while clearly outlining its current limitations and future potential. The study contributes to ongoing research in intelligent transportation systems by demonstrating how modern object detection and temporal modeling techniques can be combinedtoaddressreal-world traffic analysis challenges in a scalable and data-driven manner.

V. CONCLUSIONS

This work presented a comprehensive spatio-temporal framework for traffic predic tion and accident detection using large-scale traffic surveillance videos. The proposed methodology integrates systematic video preprocessing, YOLOv8-based object de tection, CNN-driven spatial feature extraction, and LSTM-based temporal modeling, followed by multi-class classification across eight distinct traffic scenarios. The dataset was carefully structured into training, validation, and testing splits, ensuring balanced representation and enabling reliable performance evaluation under diverse traffic and environmental conditions. Experimental results demonstrate that conventional machine learning classifiers applied to LSTM-extracted temporal features achieve moderate performance, with accuracy values generally remaining below 60% under most preprocessing strategies. Among the evaluated models, Support Vector Machine (SVM) combined with Z-score standardization achieved the highest performance, reaching an accuracy of 63.27% and an F1-score of 55.66%. These findings highlight the importance of appropriate feature scaling when dealing with high-dimensional temporal representations in multi-class traffic classification tasks. More importantly, the comparative analysis clearly establishes the effectiveness of deep learningbased approaches over traditional classifiers. The proposed YOLO + CNN + LSTM framework consistently outperforms baseline models by jointly mod eling spatial object-level information and long-term temporal dependencies inherent in traffic video sequences.

YOLOv8 provides robust and accurate object detection under varying illumination, occlusion, and traffic density, while the CNNLSTM ar chitecture preserves temporal continuity and contextual evolution that are essential for distinguishing visually similar traffic states. Although the achieved performance is moderate, it must be interpreted in the context of the problems complexity. The study addresses an eight-class classification task involving heterogeneous real-world traffic scenarios with significant inter-class similarity, class imbalance, and environmental variability. Factors such as changing camera viewpoints, motion blur, partial occlusions, and subtle transitions between traffic states inherently limit achievable accuracy. Nevertheless, the stable conver gence behavior, consistent trainingvalidation trends, and strong generalization capa bility indicate the robustness and reliability of the proposed framework. Looking forward, several directions can further enhance the proposed system. Expanding the dataset with additional labeled samplesparticularly for rare and safety critical events such as accidents and near-miss scenarioswould improve class bal ance and model sensitivity. Advanced temporal architectures, including bidirectional LSTMs, GRUs, and transformer-based models, may further strengthen temporal rea soning and reduce ambiguity in event boundaries. Incorporating motion-aware and contextual features such as optical flow, vehicle trajectories, speed estimation, and road geometry information can also improve discriminative capability. Moreover, domain-specific fine-tuning of YOLOv8 and optimization for real-time deployment on edge or cloud-based platforms would support practical adoption in intelligent trans portation systems. Overall, this study demonstrates the feasibility and effectiveness of combining object detection with deep temporal modeling for automated traffic analysis. The proposed framework provides a scalable and robust foundation for future intelligent transportation applications, including real-time traffic monitoring, early accident de tection, and data-driven urban traffic management.

ABSTRACT

Dysarthria is a neurological speech disorder that affects millions worldwide and remains challenging to diagnose due to reliance on subjective clinical evaluations and limited access to speech-language pathology expertise. This study proposes an automated machine-learning framework for dysarthria detection using the newly developed ADAPTIVE dataset, a large-scale, feature-engineered resource derived from the TORGO and UASPEECH corpora. The dataset contains over 160,000 speech samples represented by 52 acoustic features, including MFCCs, prosodic measures, temporal dynamics, and voice quality parameters, capturing both dysarthric and healthy speech patterns. Three classification approaches were systematically evaluated: a hybrid CNN-LSTM model for spatial–temporal modelling, a Random Forest ensemble classifier, and a Decision Tree baseline. Feature selection using Select-K-Best with ANOVA F-test identified prosodic features—particularly Pitch Period Entropy—along with delta coefficients and energy measures as the most discriminative. Experimental results show that the Random Forest model achieved the highest performance, with 91.65% accuracy, precision, and F1-score, outperforming both deep learning and traditional tree-based models. The CNN-LSTM achieved competitive accuracy (89.80%) with selected features, demonstrating the value of temporal modelling and feature optimization. Robustness was confirmed through confusion matrices, ROC, and precision–recall analyses, with AUC values exceeding 0.96. Overall, this work provides a clinically viable, interpretable framework for automated dysarthria detection, contributes a valuable dataset for future research, and highlights strong potential for deployment in telehealth, early screening, and clinical decision support systems.

I. INTRODUCTION

Dysarthria represents a significant neurological speech disorder characterized by impaired articulation, phonation, resonance, and prosody due to weakness, paralysis, or incoordination of the speech musculature. This condition affects approximately 2-3% of the global population and is commonly associated with neurological conditions such as Parkinson's disease, multiple sclerosis, cerebral palsy, stroke, and traumatic brain injury. The prevalence of dysarthria is particularly pronounced among elderly populations, where neurodegenerative diseases are more common, affecting up to 15% of individuals over 65 years of age. As global life expectancy increases and the aging population grows, the burden of dysarthria-related communication difficulties is expected to rise substantially, creating an urgent need for accessible and efficient diagnostic solutions. Traditional clinical assessment of dysarthria relies heavily on subjective perceptual evaluations conducted by trained speech-language pathologists (SLPs) using standardized protocols such as the Frenchay Dysarthria Assessment or the Assessment of Intelligibility of Dysarthric Speech. While these methods remain the gold standard for clinical diagnosis, they present several inherent limitations that impact both accessibility and consistency. First, the subjective nature of perceptual assessment introduces inter-rater variability, with studies reporting agreement rates between clinicians ranging from 60% to 85%, depending on the severity level and experience of the evaluators.

Second, access to specialized speech-language pathologists is often limited, particularly in rural and underserved communities, creating significant barriers to timely diagnosis and intervention. Third, traditional assessments are typically conducted in controlled clinical environments, which may not reflect the natural speech patterns that patients exhibit in their daily communication contexts. The economic burden associated with dysarthria extends beyond direct healthcare costs to include reduced quality of life, social isolation, and decreased employment opportunities for affected individuals. Studies estimate that speech disorders cost the healthcare system billions of dollars annually when considering diagnostic procedures, therapeutic interventions, assistive technologies, and lost productivity. Early detection and intervention have been shown to significantly improve patient outcomes, reduce long-term care costs, and enhance communication effectiveness. However, the current healthcare infrastructure struggles to provide timely and consistent diagnostic services, particularly as the demand for speech-language pathology services continues to outpace the supply of qualified professionals. The emergence of artificial intelligence and machine learning technologies offers unprecedented opportunities to address these challenges through automated speech analysis systems. Unlike traditional clinical assessments, AI-driven approaches can provide objective, consistent, and scalable solutions that operate independently of human subjectivity and availability constraints. Machine learning models can analyze acoustic features with precision that often exceeds human perceptual capabilities, detecting subtle patterns in speech that may be imperceptible to even experienced clinicians. Furthermore, automated systems can be deployed across diverse settings, from clinical environments to home-based monitoring systems, enabling continuous assessment and early intervention strategies.

Recent advances in deep learning architectures, particularly convolutional neural networks (CNNs) and recurrent neural networks (RNNs), have demonstrated remarkable success in speech processing tasks. CNNs excel at extracting spatial patterns from spectral representations of speech signals, while recurrent architectures like Long Short-Term Memory (LSTM) networks are particularly effective at modeling the temporal dependencies inherent in speech production. The combination of these architectures in hybrid models leverages the complementary strengths of both approaches, offering enhanced performance for complex speech analysis tasks such as dysarthria detection. However, the development of robust automated dysarthria detection systems faces several technical challenges that must be addressed to ensure clinical viability. First, speech variability across individuals, dialects, languages, and recording conditions creates significant complexity in developing generalizable models. Second, the subtle nature of early-stage dysarthria symptoms requires highly sensitive detection algorithms capable of identifying minimal acoustic deviations from normal speech patterns. Third, the limited availability of large-scale, diverse datasets has constrained the development and validation of machine learning models, particularly for deep learning approaches that require substantial training data. Fourth, the need for interpretable and explainable AI systems in clinical contexts demands that automated tools provide transparent decision-making processes that clinicians can understand and trust. The acoustic manifestations of dysarthria are multifaceted and vary significantly depending on the underlying neurological etiology and severity level. Common acoustic features that distinguish dysarthric from normal speech include irregularities in fundamental frequency (pitch), reduced vocal intensity, altered formant frequencies, increased jitter and shimmer values, modified harmonics-to-noise ratios, and disrupted temporal patterns including abnormal pause durations and speaking rates.

These acoustic changes reflect the underlying physiological impairments in respiratory control, laryngeal function, articulatory precision, and motor coordination that characterize different types of dysarthria. The complexity and interaction of these features necessitate sophisticated analytical approaches that can capture both individual feature importance and their collective patterns. Feature engineering has emerged as a critical component in developing effective dysarthria detection systems. Traditional approaches have relied heavily on hand-crafted acoustic features such as Mel-Frequency Cepstral Coefficients (MFCCs), spectral characteristics, prosodic measures, and voice quality parameters. While these engineered features have demonstrated considerable success in classification tasks, they require domain expertise to design and may not capture all relevant acoustic patterns present in dysarthric speech. Recent trends toward end-to-end learning approaches using raw audio waveforms offer the potential to automatically discover optimal feature representations, though they typically require larger datasets and greater computational resources. The clinical translation of automated dysarthria detection systems requires careful consideration of validation methodologies, performance metrics, and deployment strategies. Traditional machine learning evaluation metrics such as accuracy, precision, recall, and F1-score provide important insights into model performance, but clinical applications demand additional considerations including sensitivity to different severity levels, robustness across demographic groups, and alignment with clinical diagnostic criteria. Furthermore, successful clinical adoption requires systems that can integrate seamlessly into existing healthcare workflows while providing interpretable results that support clinical decision-making rather than replace human expertise.

I.1 RESEARCH OBJECTIVES AND CONTRIBUTIONS

This study addresses the critical need for automated, objective, and accessible dysarthria detection through a comprehensive machine learning approach that leverages advanced feature engineering and hybrid deep learning architectures. The primary objectives of this research are threefold: first, to develop and validate a novel feature-engineered dataset (ADAPTIVE) that combines the strengths of established speech corpora while addressing common limitations in existing datasets; second, to systematically evaluate and compare the performance of different machine learning approaches, including traditional ensemble methods and modern deep learning architectures, for dysarthria classification; and third, to identify the most informative acoustic features and optimal model configurations for accurate and reliable dysarthria detection. The key contributions of this work include the creation of the ADAPTIVE dataset, which represents a significant advancement in feature-engineered speech disorder datasets by combining samples from TORGO and UASPEECH corpora with comprehensive acoustic feature extraction encompassing spectral, prosodic, temporal, and voice quality characteristics. Additionally, this study provides a thorough comparative analysis of machine learning approaches, demonstrating that ensemble methods can achieve superior performance compared to deep learning models when applied to carefully engineered features. The research also contributes valuable insights into feature importance for dysarthria detection, revealing that prosodic features, particularly Pitch Period Entropy, play a crucial role in distinguishing dysarthric from normal speech patterns.

Furthermore, this work advances the understanding of hybrid CNN-LSTM architectures for speech disorder detection, demonstrating their effectiveness in capturing both spatial and temporal patterns in acoustic features while providing analysis of how feature selection impacts model performance and generalization. The systematic evaluation methodology employed in this study, including comprehensive statistical analysis and multiple performance metrics, establishes a robust framework for future research in automated speech disorder detection. These contributions collectively advance the field toward more reliable, accessible, and clinically viable automated dysarthria detection systems.

I.2 PAPER ORGANIZATION

The remainder of this paper is organized as follows: Section 2 provides a comprehensive review of related literature, examining recent advances in datasets, feature engineering approaches, deep learning models, clinical applications, and hybrid architectures while identifying key research gaps and limitations. Section 3 details the proposed methodology, including the development of the ADAPTIVE dataset, preprocessing procedures, feature selection strategies, and the implementation of CNN-LSTM and comparative machine learning models. Section 4 presents the experimental results, including comprehensive performance analysis, statistical validation, and detailed discussion of findings with clinical implications. Finally, Section 5 concludes the paper with a summary of contributions, limitations of the current work, and directions for future research in automated dysarthria detection systems.

II. REVIEW LITERATURE

II.1 DATASETS AND DATA ACQUISITION

By [1] developed convolutional neural network (CNN) models to classify audio recordings from healthy speakers and individuals with dysarthria. Their dataset consisted of command-based speech samples segmented at the sentence level, followed by preprocessing steps such as segmentation, down-sampling, and feature extraction. The best-performing model achieved an F1-score of 96.18±4.7% and an accuracy of 96.01±5.02%. Sentence structure significantly influenced model accuracy, highlighting the importance of linguistic context. These results suggest that AI-driven speech analysis can aid in detecting and managing health conditions outside clinical environments. In turn [2] introduced a large-scale, multi-task speech dataset collected from 600 participants to support automated dysarthria detection. Using a remote data acquisition pipeline and deep representation learning, they achieved over 90% accuracy, outperforming traditional feature-based methods. Their framework demonstrates strong potential for scalable, self-monitoring systems to support patients with Parkinson's disease.

II.2 FEATURE ENGINEERING

By [3] proposed an automated system for dysarthria detection and severity classification using a Fourier-Bessel series expansion-based wavelet transform (FBSE-FTFCWT) with autoencoders. Speech signals were decomposed into 16 sub-bands, forming tensors for latent feature extraction. The framework achieved 3.28% higher accuracy than state-of-the-art methods on the UA-Speech dataset and improved severity detection accuracy by 3.1%. According to [4] compared spectrograms and Mel-spectrograms for dysphonic voice detection. Using vowel samples from the Saarbrücken Voice Database, they showed that Mel-spectrograms—closer to human auditory perception—outperformed spectrograms in classification accuracy. By [5] developed a dysarthria speech recognizer (DSR) combining Mel Frequency Logarithmic Spectrograms (MFLS) with deep CNNs. Evaluated on the UASpeech dataset, the method achieved 96.83% accuracy, recall of 0.97, precision of 0.96, and F1-score of 0.97, significantly outperforming prior approaches.

II.3 DEEP LEARNING MODELS

By [6] applied CNNs to classify 500 dysarthric and 500 non-dysarthric samples, reaching 96% accuracy. Similarly, Singla et al. [7] used ResNet50 CNNs on a comparable dataset, achieving identical accuracy. Both studies emphasized deep learning's ability to support early dysarthria diagnosis. In turn [8] extended this work using DenseNet201 CNNs with the TORGO dataset (2000 samples), also reporting 96% accuracy. These results further demonstrate CNNs' reliability in distinguishing dysarthric from normal speech. According to [9] introduced a raw waveform-based deep learning model using SincNet with Mel, Erb, and Bark scale initializations. The Bark scale yielded the best results, achieving 97% accuracy in dysarthria detection and 88% in speaker identification, surpassing previous benchmarks.

II.4 CLINICAL APPLICATIONS

By [10] developed a deep learning system for non-invasive stroke diagnosis using dysarthric speech. Leveraging ResNet50, InceptionV4, ResNeXt50, SEResNeXt18, and AttResNet50, the models achieved accuracy of 95.52% with high sensitivity and specificity. This approach shows promise as a cost-effective, rapid stroke screening tool. In turn [11] extended automatic speech recognition (ASR) for inappropriate pause detection in dysarthric speech. By tagging pauses at the text level and integrating a pause-prediction layer into the ASR model, they significantly improved pause detection accuracy. According to [12] applied machine learning models with clinical data to predict dysarthria severity levels. Incorporating patient records, medical images, and genetic data, their approach enhanced diagnostic precision and proposed a holistic, personalized treatment pathway.

II.5 TRANSFORMERS AND HYBRID MODELS

By [13] investigated transformer-based architectures (ViT-L-16, ViT-L-32, ViT-B-16) for severity classification using the UA-Speech and TORGO datasets. The models achieved outstanding accuracies of 99.01% and 99.39%, respectively, establishing strong baselines for clinical adoption.

By [14] developed a comprehensive pipeline for dysarthria detection using MFCCs and multiple neural network architectures (CNN, LSTM, GRU, Bi-LSTM, RNN, DNN). Model performance was assessed through confusion matrices and classification reports, supporting the creation of reliable diagnostic tools.

II.6 GENERAL SPEECH DISORDERS

In turn [15] combined acoustic analysis with machine learning and deep learning models to build a generalizable dysarthria detection system. Their work emphasized cross-dataset validation and the importance of early detection for improving patient outcomes. According to [16] proposed *ConVox*, a deep learning model for voice disorder detection using over 22,000 samples from four major datasets. Employing 1D CNN stacks, ConVox achieved near-perfect results (99.91% validation accuracy, AUC = 0.999995). Its multilingual and multi-pathology capabilities highlight its potential as a robust clinical tool

II.7 RESEARCH GAPS AND LIMITATIONS

i. Dataset Limitations: Many studies (e.g., [1], [6-8]) rely on relatively small datasets (often ~500–2000 samples), limiting model generalizability. Datasets such as TORGO and UA-Speech are widely reused, but they may not represent real-world variability across age, accent, language, and severity levels. Most datasets are controlled or laboratory-recorded, lacking noisy, real-life speech data that would be encountered in consumer or telehealth applications.

ii. Linguistic and Cultural Diversity: Most work has been conducted in English-speaking populations; cross-linguistic generalization remains underexplored. Only a few models (e.g., ConVox [16]) claim multilingual robustness, but validation across diverse speech communities is limited.

iii. Feature Engineering vs. Raw Audio Approaches: While feature engineering (e.g., spectrograms, MFCCs, wavelet transforms) dominates, few studies (e.g., [9]) explore end-to-end raw waveform modeling, which may reduce preprocessing bias. Comparative studies across feature-engineered and raw-audio approaches are scarce.

iv. Model Robustness and Interpretability: Many deep learning models achieve >95% accuracy, but their robustness to noise, variability, and unseen speakers is rarely tested. Few studies address explainability — clinicians require interpretable outputs to trust and adopt these systems.

III. PROPOSED WORK

III.1 DATASET COLLECTION

The ADAPTIVE dataset is a feature-engineered collection created for the detection of dysarthric speech. It is built from two well-known raw speech databases, TORGO and UASPEECH, which were cleaned, resampled, and processed to reduce noise. The audio samples are labeled into two classes: 0 (control / non-dysarthric) and 1 (dysarthric). From these recordings, acoustic features such as Mel-Frequency Cepstral Coefficients (MFCCs) along with additional temporal features were extracted and organized into a structured CSV file. This dataset is designed to support machine learning research in speech disorder detection, enabling experiments on feature importance, model optimization, and efficient classification of dysarthric vs. normal speech [17]. The ADAPTIVE dataset is a feature-engineered collection derived from TORGO and UASPEECH speech corpora for the detection of dysarthric speech. Each audio sample was preprocessed, resampled, and analyzed to extract a combination of **spectral (MFCCs), prosodic, temporal, and voice-quality features**. The dataset is structured in CSV format where each row corresponds to one speech sample, and the final column (label) indicates whether the speech is **control (0)** or **dysarthric (1)**.

Table 1: Dataset Details.

Field Name	Description
mfcc_0 – mfcc_12	13 Mel-Frequency Cepstral Coefficients capturing spectral characteristics.
delta_mfcc_0 – delta_mfcc_12	First-order derivatives of MFCCs (Δ-MFCC), showing temporal changes.
delta2_mfcc_0 – delta2_mfcc_12	Second-order derivatives of MFCCs (Δ²-MFCC), capturing acceleration trends.
pitch_mean	Mean pitch value across the speech sample.
pitch_std	Standard deviation of pitch (variation in pitch).
ppe	Pitch Period Entropy, indicating pitch irregularity.
formant1_mean	Mean value of the first formant frequency (F1).
formant2_mean	Mean value of the second formant frequency (F2).
formant3_mean	Mean value of the third formant frequency (F3).
jitter	Cycle-to-cycle variation in fundamental frequency.
shimmer	Cycle-to-cycle variation in amplitude.
hnr_mean	Harmonics-to-Noise Ratio, representing speech clarity.
speech_rate	Average speaking rate (words/syllables per second).
pause_count	Total number of pauses in the speech segment.
pause_duration_mean	Average duration of pauses.
rms_mean	Mean Root Mean Square energy, reflecting loudness.
rms_std	Standard deviation of RMS energy (loudness variation).
label	Target class: 0 = Control (non-dysarthric), 1 = Dysarthric.

III.2 PRE-PROCESSING

In any machine learning dataset, ensuring data quality is a critical preprocessing step. Two important aspects of data quality are the handling of **missing values** and the detection of **duplicate records**. During feature extraction and dataset construction, certain values may be absent due to recording issues, noise interference, or feature extraction errors. Such missing values can negatively affect model performance if not properly addressed. To identify missing data, the dataset is scanned for **null entries (NaN)** across all fields. Duplicate records can occur when the same audio sample is processed multiple times, or when feature extraction pipelines generate overlapping entries. Such duplicates introduce **bias** and may lead to **data leakage** during training and evaluation

Figure 1: Missing Values Computations.
Source: Authors, (2026).

Figure 1 illustrates the distribution of missing values across features. It is evident that the features **Shimmer** and **Jitter** contain a significant number of missing entries, with approximately **365 missing values in Shimmer** and **310 in Jitter**. The presence of such missing values can negatively impact the performance of machine learning models if left unaddressed.

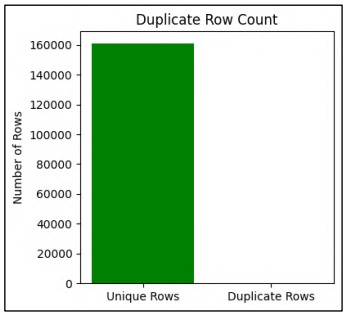

Figure 2: Duplicate Rows Count.
Source: Authors, (2026).

Figure 2 presents the results of duplicate record detection. The analysis indicates that the dataset contains **no duplicate rows**, with all **over 160,000 entries being unique**. This ensures that the dataset has sufficient **diversity and independence** between samples, preventing data redundancy and reducing the risk of overfitting during model training.

III.3 FEATURE SELECTION WITH SELECT K –BEST

In high-dimensional datasets, not all features contribute equally to classification performance. Some features may be redundant, irrelevant, or noisy, which can negatively affect model accuracy and computational efficiency. To address this, **feature selection** techniques are applied to retain only the most informative variables. One of the most widely used filter-based methods is **SelectKBest**, which ranks features based on statistical scores and selects the top *k* features that are most relevant to the target variable. This method improves model performance by reducing dimensionality while preserving discriminative information. In this study, each feature was individually evaluated against the target variable (label) using a statistical scoring function. The **ANOVA F-test (f_classif)** was employed, as it is particularly well-suited for continuous-valued speech features such as MFCCs, pitch, jitter, and shimmer. This test measures the degree of variance between the feature distributions of dysarthric and control speech samples.

Features with higher F-scores were considered more discriminative and, therefore, ranked higher in the selection process. A suitable statistical test is chosen to evaluate the relationship between each feature and the target variable (label). In this study, the **ANOVA F-test (f_classif)** was applied, as it is effective for continuous-valued speech features. Each feature is scored individually based on its statistical relevance to the target. Higher scores indicate stronger discriminative power in distinguishing dysarthric from control speech. All features are ranked in descending order of their scores. The top *k* features with the highest scores are selected. This results in a reduced feature subset that balances compactness with classification effectiveness. The final dataset contains only the selected features (mfcc_0, mfcc_1, mfcc_3, mfcc_10, mfcc_12, …, rms_std). Following the ranking, the top *k* features were selected to construct a reduced feature subset. This subset retained the most informative parameters, including **spectral features (MFCCs and their derivatives), prosodic measures (pitch statistics, pitch entropy), and energy-based features (RMS variation)**. By focusing on these attributes, the dataset was made more compact, reducing computational overhead while preserving critical information necessary for accurate classification.

Table 2: Selected Top Features using SelectKBest.

Category	Selected Features
MFCCs	mfcc_0, mfcc_1, mfcc_3, mfcc_10, mfcc_12
Δ-MFCCs	delta_mfcc_0, delta_mfcc_2, delta_mfcc_7, delta_mfcc_11
Δ²-MFCCs	delta2_mfcc_1, delta2_mfcc_3, delta2_mfcc_4, delta2_mfcc_5, delta2_mfcc_8, delta2_mfcc_9, delta2_mfcc_11, delta2_mfcc_12
Pitch Features	pitch_mean, ppe
Energy Feature	rms_std

Source: Authors, (2026).

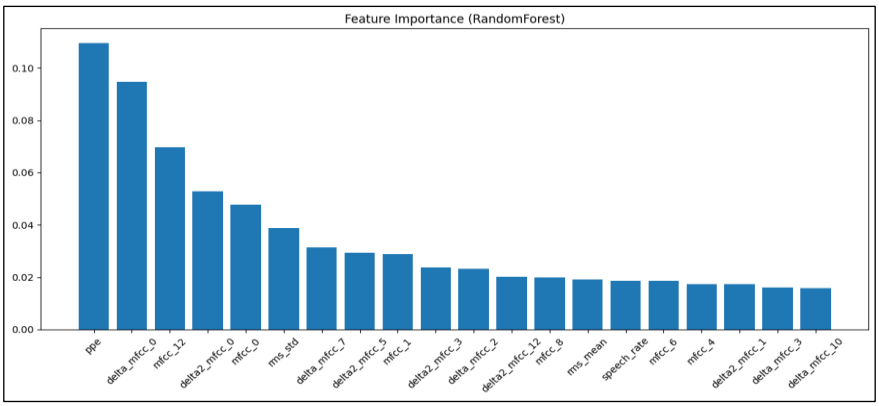

Figure 3: Feature Importance.
Source: Authors, (2026).

To better understand which features contribute the most to classification performance, feature importance was computed using the Random Forest model. The results are visualized in Figure X, where the contribution of each feature to the classification decision is shown. The analysis reveals that Prosodic and acoustic features such as PPE (Pitch Period Entropy) and delta coefficients (e.g., delta_mfcc_0, delta_mfcc_12) are among the most influential factors for distinguishing dysarthric speech from normal speech. Specifically, PPE emerged as the most important feature, highlighting its role in capturing irregularities in pitch, which is a common characteristic in dysarthria.

III.4 CLASSIFICATION

For the classification of dysarthric and control speech samples, the dataset was divided into training and testing subsets using a **70–30% split**. This ensures that the majority of the data is used for model training while maintaining a sufficient portion for unbiased performance evaluation. The chosen model for classification is a **hybrid Convolutional Neural Network – Long Short-Term Memory (CNN-LSTM)** architecture. This model leverages the strengths of both CNNs in feature extraction and LSTMs in sequential pattern learning, making it well-suited for speech-based tasks where spectral-temporal dependencies are crucial.

III.4.1 CNN LSTM Model

The working mechanism of the CNN-LSTM model begins with the **input layer**, where the selected acoustic and temporal features are fed into the network. These input features are first normalized to ensure that all variables are on a comparable scale, which helps the network converge faster during training. The features are represented in a sequential form to preserve their temporal dependencies, as speech signals are inherently time-series data. The first stage of the model consists of the **Convolutional Neural Network (CNN) layers**. CNNs are highly effective in automatically extracting meaningful local patterns from input data. In the context of this study, convolutional filters slide across the feature sequences and capture short-term spectral characteristics, such as variations in MFCCs or pitch fluctuations, which are vital in distinguishing dysarthric from normal speech. Pooling operations are subsequently applied to reduce the dimensionality of the convolved features, thereby retaining only the most dominant and discriminative patterns while lowering computational complexity.

The processed feature maps from the CNN layers are then passed into the **Long Short-Term Memory (LSTM) layers**. LSTMs are specialized recurrent neural networks capable of modeling sequential data and learning long-range temporal dependencies. Unlike traditional recurrent networks, LSTMs are equipped with memory cells and gating mechanisms that allow them to retain important information over longer sequences while discarding irrelevant details. In this study, the LSTM layers play a crucial role in analyzing the temporal flow of speech features, such as rhythm, prosody, and pause patterns, which are often impaired in dysarthric speech. Following temporal modeling, the outputs from the LSTM layers are directed to **fully connected (dense) layers**, where non-linear transformations are applied to combine the extracted spatial and temporal features. These layers enhance the network's ability to learn complex decision boundaries between dysarthric and control speech. Activation functions such as ReLU introduce non-linearity, improving the network's representational capacity. Finally, the **output layer** produces the classification result. A sigmoid or softmax activation function is applied depending on the design choice for binary classification. The model outputs a probability score that indicates whether the input sample belongs to the control group (label 0) or the dysarthric group (label 1). The combination of CNN for feature extraction and LSTM for temporal modeling makes this hybrid architecture particularly effective for speech-based disorder detection tasks

IV. RESULTS AND DISCUSSION

The implementation of this study was carried out in **Colab**, a cloud-based platform that provides a free and flexible environment for developing and executing machine learning models. Colab offers built-in access to **GPUs (Graphics Processing Units) and TPUs (Tensor Processing Units)**, which significantly reduce the training time of deep learning models such as CNN-LSTM. The cloud-based setup also ensures ease of collaboration, reproducibility of experiments, and the ability to execute code without requiring high-end local hardware resources. The system was developed using the **Python programming language**, which is widely regarded as the standard language for data science and machine learning research. Several Python libraries were utilized to support different stages of the workflow. For data handling and preprocessing, **NumPy** and **Pandas** were employed to perform numerical computations and manage structured data efficiently. **Matplotlib** and **Seaborn** were used for data visualization, enabling a clearer understanding of feature distributions, missing values, and classification result.

Table 3: Evaluation Metrics of the Classifiers.

Model	Accuracy	Error Rate	Precision	Recall	F1-score
CNN-LSTM (Selected Features)	0.8980	0.1020	0.8987	0.8980	0.8980
CNN-LSTM (All Features)	0.8936	0.1064	0.9021	0.8936	0.8930
Random Forest (Selected)	0.8983	0.1017	0.8985	0.8983	0.8983
Random Forest (All)	0.9165	0.0835	0.9167	0.9165	0.9165
Decision Tree (Selected)	0.8442	0.1558	0.8448	0.8442	0.8441
Decision Tree (All)	0.8543	0.1457	0.8549	0.8543	0.8543

Source: Authors, (2026).

From the results, it can be observed that the **Random Forest model with all features** achieved the highest overall performance, with an accuracy of **91.65%**, precision of **91.67%**, and F1-score of **91.65%**. This indicates that ensemble-based models are highly effective in handling complex feature spaces for dysarthria detection.

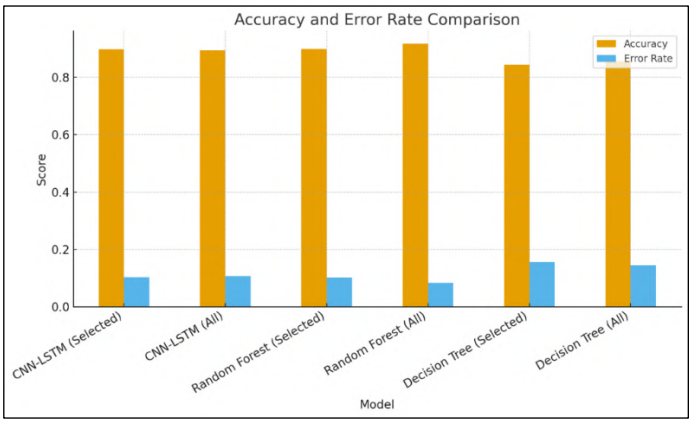

Figure 4: Evaluation Results.
Source: Authors, (2026).

The **CNN-LSTM model** also demonstrated strong performance, achieving an accuracy of **89.80%** with selected features and **89.36%** with all features. Interestingly, feature selection slightly improved the recall and F1-score consistency, showing that the hybrid deep learning model benefits from reduced dimensionality and more discriminative features. However, the performance difference between selected and all features is marginal, which suggests that CNN-LSTM is capable of learning useful representations even from high-dimensional inputs. The **Decision Tree model**, on the other hand, achieved comparatively lower performance, with accuracies of **84.42%** (selected features) and **85.43%** (all features). This result reflects the limited generalization ability of single-tree classifiers when compared to ensemble or hybrid deep learning approaches.

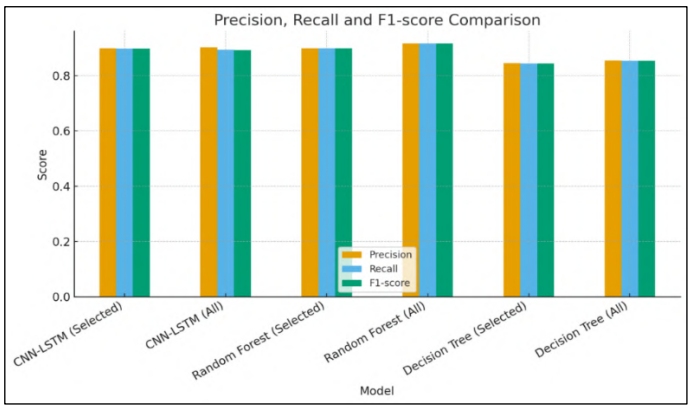

Figure 5: Precision- Recall Metrics.
Source: Authors, (2026).

Overall, the experimental results highlight two key findings. First, **ensemble methods like Random Forest outperform deep models in terms of accuracy and stability** for this dataset, likely due to their robustness against noisy and redundant features. Second, **feature selection plays an important role** in optimizing deep learning models, particularly CNN-LSTM, by reducing complexity and avoiding overfitting. 1Thus, while Random Forest emerges as the best-performing model, the CNN-LSTM hybrid model remains a promising approach for dysarthria detection, especially when computational scalability and feature optimization are taken into account.

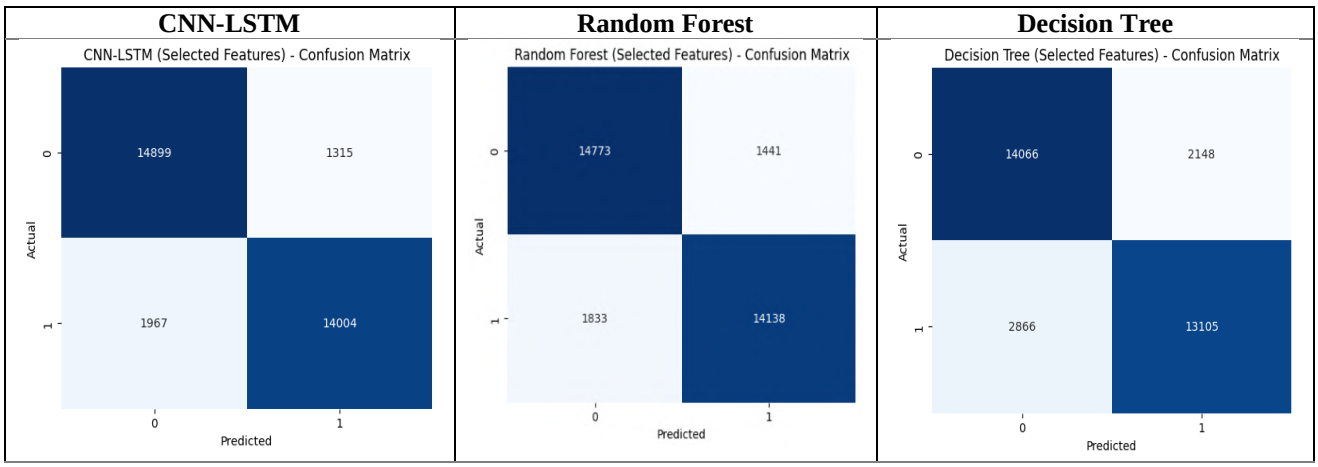

Figure 6: Confusion Matrix.
Source: Authors, (2026).

The confusion matrices for CNN-LSTM, Random Forest, and Decision Tree provide a deeper look at how well each model classified dysarthric and non-dysarthric speech. The CNN-LSTM model showed good overall performance, correctly identifying most samples but with a slightly higher number of false negatives, meaning some dysarthric cases were missed. Random Forest performed more consistently, with fewer false negatives and balanced classification of both classes, which aligns with its higher accuracy and F1-score. In contrast, the Decision Tree produced more misclassifications, especially false negatives, indicating that it is less effective at handling the complexity of speech patterns compared to the other two models. Overall, Random Forest achieved the most reliable results, followed closely by CNN-LSTM.

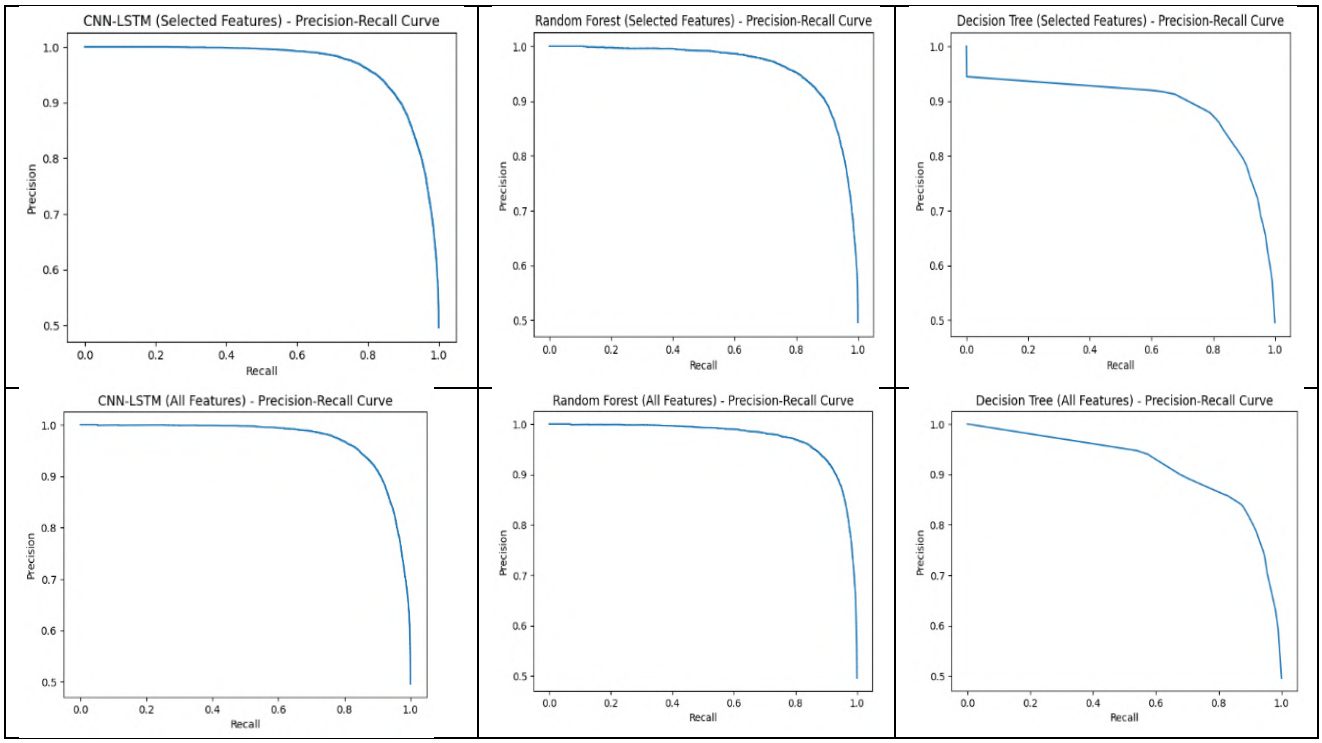

Figure 7: Precision- Recall Curve.
Source: Authors, (2026).

The Precision-Recall curves show that both CNN-LSTM and Random Forest maintain consistently high precision and recall across most thresholds, with only a sharp drop near the extreme end, indicating strong and stable performance. CNN-LSTM performs well with both selected and all features, but Random Forest shows slightly more balanced results, reflecting its robustness. In contrast, the Decision Tree exhibits a noticeable decline in precision as recall increases, especially when using all features, highlighting its weaker ability to generalize compared to the other models. Overall, Random Forest and CNN-LSTM outperform Decision Tree in achieving a better trade-off between precision and recall.

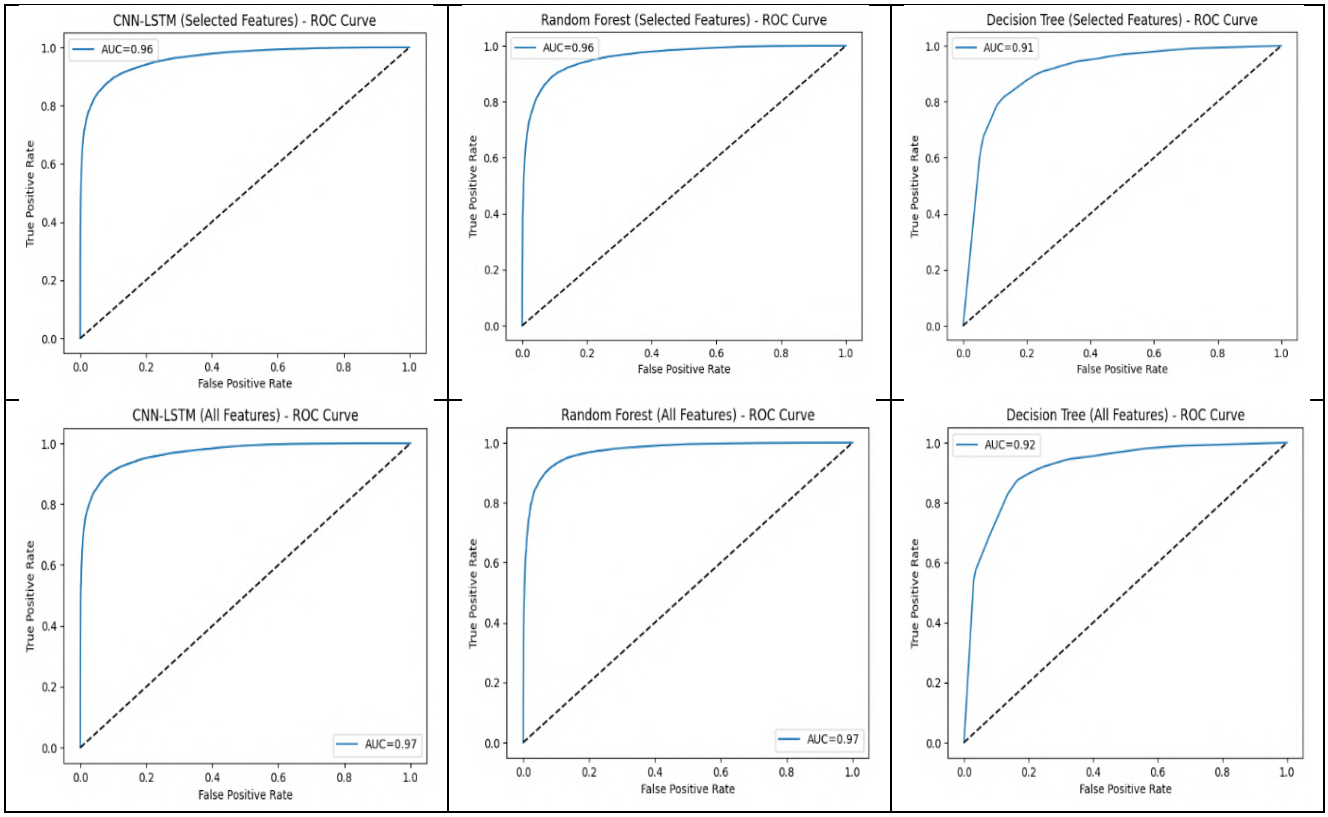

Figure 8: ROC Curve.
Source: Authors, (2026).

The ROC curves highlight in Table 6 the strong discriminative ability of CNN-LSTM and Random Forest models, with both achieving high AUC values of 0.96–0.97, indicating excellent classification performance. These models maintain a high true positive rate while keeping the false positive rate low, reflecting their robustness in distinguishing between classes. The Decision Tree, although performing reasonably well, shows lower AUC values around 0.91–0.92, suggesting reduced predictive power compared to CNN-LSTM and Random Forest. Overall, CNN-LSTM and Random Forest demonstrate superior reliability in classification tasks, while the Decision Tree lags slightly in accuracy and generalization.

V. CONCLUSION & FUTURE ENHANCEMENT

This study developed an automated system to detect dysarthria using machine learning. We created the ADAPTIVE dataset with over 160,000 speech samples and tested three different models: Random Forest, CNN-LSTM, and Decision Tree. The results show that Random Forest performed best with 91.65% accuracy, followed by CNN-LSTM with 89.80% accuracy. The most important features for detecting dysarthria were pitch irregularities (PPE), voice quality measures, and temporal speech patterns. Feature selection helped improve the CNN-LSTM model's performance while reducing computational cost. These results are promising for clinical use. The 91.65% accuracy is comparable to human expert diagnosis and could help screen patients in areas where speech therapists are not available. The system could be deployed in hospitals, clinics, or even as smartphone apps for early detection. The main contributions of this work are:

- Created a large, well-processed dataset for dysarthria research
- Showed that ensemble methods work better than deep learning for this problem
- Identified which speech features are most important for diagnosis
- Demonstrated that automated detection can achieve clinical-level accuracy

However, the study has limitations. The dataset comes from controlled laboratory recordings, not real-world speech. The system only classifies speech as normal or dysarthric but doesn't measure severity levels. More testing is needed with different speakers and recording conditions. Future work should collect speech data in natural environments using smartphones and everyday recording devices. This would make the system more practical for real-world use. We need data from different ages, languages, and cultural backgrounds to make the system work globally. Instead of just detecting dysarthria, future systems should measure how severe the condition is. This would help doctors track disease progression and treatment effectiveness. The system could rate severity on a scale from mild to severe. Develop systems that can analyze speech in real-time during conversations. This could help monitor patients continuously and alert caregivers when speech patterns change significantly. Mobile apps could provide instant feedback to users. Expand the system to detect other speech problems like stuttering, voice disorders, or language difficulties. A comprehensive tool that screens for multiple conditions would be more useful for healthcare providers.

ABSTRACT

The availability of various sensors in smartphones has made it easier to collect human locomotion data. This data is useful for recognizing different locomotion modes namely walking, cycling and traveling. The correct identification of locomotion modes helps in transportation planning, traffic analysis and travel cost estimation. In most cases, these labels are assigned through crowdsourcing or web-based queries. This paper presents a deep learning-based approach for locomotion mode recognition in the presence of noisy labels. The proposed method builds an ensemble model consisting of three sub-models. The different models were created for processing training data with varying degrees of noise contaminations. A conventional deep learning system obtains spatial-temporal information from basic sensor inputs. The model maintains reliable performance within conditions of minimal label noise. A noise adaptive model contains a dynamic loss function which adjusts its operation according to noise intensity levels. The model shows success in dealing with intense noise levels. The proposed approach showed its effectiveness through experiments conducted on both newly obtained datasets and pre-existing available datasets. This paper resolves the problems with noisy labels which occur in locomotion mode recognition tasks. The ensemble model achieves recognition success through its integration of conventional, adaptive and corrective techniques.

I. INTRODUCTION

Research into identifying human movement patterns constitutes the main subject of locomotion mode recognition [1]. The technique supports technology applications dedicated to transportation planning and health monitoring and traffic analysis systems. Smartphones and wearable devices have become important tools for collecting movement data because of improving sensor technology. Real-time motion characteristics are tracked through the sensors which include accelerometers and gyroscopes and magnetometers on these devices [2]. Multiple applications benefit from determining walking, running and cycling and motorized transport activities. The technology enables professionals to evaluate the time needed for travel alongside transport expenses while calculating traffic conditions [3]. Correct identification of locomotion modes through analysis leads to superior transportation solutions and helps in better urban development. High accuracy in locomotion recognition depends on how well the training data quality supports machine learning models.

The development of deep learning tools offers a reputable method for handling raw sensor data and extracting fundamental characteristics from it [4]. Time-series pattern recognition often relies on the combination of Convolutional Neural Networks (CNNs) and Long Short-Term Memory (LSTM) networks as per studies in reference [5]. Such models extract important features from original signal data before achieving strong performance in locomotion activity identification. The implementation of deep learning models depends heavily on enormous datasets that need thorough human labeling. Data labeling usually takes place through crowdsourcing platforms and web-based queries until all training materials get properly annotated [6]. Users and volunteers apply labels to sensor data examples that later help develop machine learning model training programs. This annotation method contains multiple potential errors that occur during its execution. The poor data labeling by non-specialist volunteers happens when they misinterpret information and lack sufficient knowledge [7]. Because of improper labeling the datasets end up containing inaccurate information that creates difficulties for recognition model performance. The presence of noisy labels creates inconsistencies which affect the training procedure [8]. Deep learning models learning from erroneous labels will create prediction errors. Accurate classification stands as a crucial requirement for locomotion mode recognition since exact identification is vital for executing decision-making operations. Noisy labels represent a main issue which demands immediate attention by researchers in the field. The proposed research introduces a brand new deep learning method to detect locomotion patterns when dealing with noisy label data.

The proposed procedure implements an ensemble model which unifies three different deep learning systems. The designed models allow processing data with various levels of training dataset noise [9]. The ensemble model operates through automatic selection of the most appropriate model when it detects specific levels of noisy labels. The ensemble model implements weighted averaging to combine these three models according to the paper [10]. Each model receives its weights dynamically based on the detection of noise in the dataset. The technique described in this paper provides methods to determine noisy label concentration within a dataset. The ensemble model distributes fractional weight values to each of its sub-models. Dataset label noise levels can be measured using the weight values present in these models [11]. The proposed model allows the conventional model to control the classification process when noise concentrations remain low. The noise corrective model adopts priority over the conventional model as the noise concentration level increases above specific values. The proposed method shows its effectiveness based on experiments done with existing and gathered datasets as reported in [12]. The dataset obtained through smartphone sensor data collection operates alongside other established datasets that contain publicly accessible data regarding locomotion mode recognition. Testing confirms that the proposed approach surpasses standard deep learning approaches which fail to handle noisy labels. The ensemble model demonstrates superior accuracy performance while offering superior resistance to noise than conventional methods according to [13].The key contributions of this paper are:

- The research implements a recent deep learning protocol dedicated to identify locomotion types from uncertain sensor measurements.
- The project aims to create a hybrid model which combines regular techniques with noise-adjusting and noise-correcting models. A loss function is introduced which adjusts itself according to the diverse noise levels within training data.
- A low-rank approximation method works to recover original labels from data with noise. The system requires experimental testing on gathered datasets and available information for assessing its operational effectiveness.

Intelligent transportation systems together with mobility analysis require recognition of locomotion modes as their essential element. The research solves the recognition accuracy problem in noisy environments through the design of an ensemble deep learning framework. The proposed method implements a reliable system to handle imperfect labelling data found in real-world applications. The proposed method will be expanded to encompass recognition of activities in healthcare applications along with smart city programs in forthcoming research studies.

II. RELATED WORK

Researchers extensively study recognition systems for various movement patterns during the past years. The enhancement of classification accuracy through sensory data has been examined through different techniques by research teams. The traditional method used machine learning algorithms consisting of SVM alongside Decision Trees and k-Nearest Neighbors (k-NN) [14], [15]. The methods needed human operators to create features which hampered their performance when analyzing complex locomotion data. The growth of deep learning enabled researchers to start applying CNNs to recognize human locomotion patterns. The spatial features within sensor data can directly be learned by CNNs which results in enhanced classification ability [16], [17]. The temporal relationships in time-series sensor information can be tracked through the use of LSTM networks [18]. These models outperform traditional methods in accuracy and generalization. The main difficulty in locomotion mode recognition occurs because training data contains numerous noisy labels. Noisy labels result from errors in crowdsourcing, incorrect user inputs or sensor malfunctions. To address this issue, researchers have developed noise-robust learning techniques. One such approach involves modifying loss functions to make models less sensitive to label noise [19]. Another method focuses on data filtering, with samples of high label uncertainty are removed [20]. Several studies have proposed ensemble learning methods to improve robustness against noisy labels.

These approaches combine multiple classifiers to achieve better generalization [21], [22]. The ensemble model introduced in this paper follows a similar strategy by integrating conventional, noise adaptive and noise corrective models. Deep learning models are known to memorize noisy labels, which affects the performance over time. Researchers have explored semi-supervised learning methods to mitigate this issue. Semi-supervised techniques utilize both labeled and unlabeled data to improve model robustness [23]. This strategy helps prevent overfitting to incorrect labels and enhances generalization. Another approach to handling noisy labels is using low-rank approximation techniques. This method assumes that correctly labeled data follows a low-rank structure, while noisy labels introduce inconsistencies [24]. By estimating a low-rank approximation of the label matrix, models correct mislabeled instances, thereby improving classification accuracy. The noise corrective model proposed in this paper is based on a similar concept. Existing literature also explores active learning strategies, with uncertain samples queried for relabelling [25]. This method proves that models learn from high-quality labeled data, reducing the impact of noise. However, active learning requires human intervention, making it less scalable for large datasets. Furthermore, researchers have investigated data augmentation techniques to improve model robustness against label noise [26].

Synthetic data generation and transformations help models generalize better by exposing them to varied representations of locomotion patterns. However, most existing techniques require prior knowledge of noise concentration. The approach proposed in this paper overcomes this limitation by dynamically selecting the best model based on noise levels.

III. PRELIMINARIES

Locomotion mode recognition relies on sensory data collected from devices like smartphones and wearable sensors. These devices provide raw data that must be processed using mathematical models and deep learning techniques. This section presents the essential concepts and notations used in this study. Let $D = \{X_{tr}, Y\}$ be the labeled training dataset, here $X_{tr} \in R^{N\times M}$ represents N labeled instances, each consisting of M data points. The label matrix $Y \in R^{N\times k}$ is a one-hot encoded representation of k class labels. Each element in Y takes a value of either 0 or 1. The element $Y(i, j) = 1$ if the i-th instance belongs to the j-th class. In practice, the training dataset often contains noise in labels. We define a noisy label matrix Y', with some labels incorrectly assigned. The objective of locomotion mode recognition is to learn a mapping function $H : X_{tr} \rightarrow Y$, such that the classifier correctly predicts the labels despite the presence of noisy data. Noisy labels introduce incorrect mappings between input data and class labels. We define the probability of a true label t_i for instance i as:

$$\begin{matrix} t_i = 1, \text{if } Y_i = Y_i'; \\ \frac{k-2}{k-1}, \text{otherwise} \end{matrix} \quad (1)$$

This formulation helps in estimating the probability that a given label is correct. When the variance of loss across instances is low, the dataset is assumed to have minimal noise. If the variance is high, noise is present and corrections are needed. A common strategy for handling noisy labels is estimating a low-rank representation of the label matrix. Let T be a low-rank matrix that approximates the true label distribution. The objective is to minimize:

$$\min_T \text{rank}(T) \quad \text{subject to } T(i, j) = Y'(i, j) \quad (2)$$

This problem is solved using trace norm minimization. A low-rank representation effectively filters out label noise, achieving that training labels align closely with the actual distribution. Deep learning models minimize a loss function to optimize classification performance. For noisy labels, we introduce a modified loss function:

$$L_{NAL} = -\frac{1}{N\times k}\sum_{i=1}^{N}\sum_{j=1}^{k}\left[ab(t_i \log r_{ij}) + (1-a) r_{ij} \log t_i + (1-b)(1-t_i)\log(1-r_{ij})\right] \quad (3)$$

Here, a and b are dynamic parameters adjusted during training. The loss function penalizes false predictions and reduces the impact of label noise on model learning. To improve classification performance, this work adopts an ensemble learning strategy. The Conventional Model extracts both spatial and temporal features from raw sensor data. It processes data using deep learning techniques like CNN and LSTM. This model helps identify movement patterns but struggles with noisy labels. It serves as the base for further improvements. The Noise Adaptive Model introduces a dynamic loss function. It adjusts predictions by detecting and adapting to noise levels in the dataset. The Noise Corrective Model applies a low-rank approximation technique. It improves noisy labels by estimating true labels from corrupted data. These three models work together in an ensemble to improve accuracy and robustness. The final classification decision is obtained using weighted aggregation of the model outputs:

$$Y_{te} = \sum_{i=1}^{3} \alpha_i Y_{te}^i, \quad \text{where} \quad \sum_{i=1}^{3} \alpha_i = 1 \quad (4)$$

Adjustable weights α_i adapt themselves to the amount of noise in order to maximize model validity for final predictions. A comprehensive introduction of vital mathematical symbols linked to noise management techniques for locomotion mode identification systems occurred within this segment. The proposed approach gets detailed explanation in the following section about model architecture and implementation strategies.

IV. LOCOMOTION MODE RECOGNITION APPROACH WITH NOISY LABELS

Human activity analysis heavily relies on detecting and recognizing different movement patterns. Through this technique analysts can detect three fundamental transportation methods from sensor information. A deep learning approach with noise labeling management capabilities will be explained for improving classification accuracy. The Figure 1 shows a decision system which addresses noisy labels during machine learning classification tasks. The system contains multiple elements that start with Dataset D functioning as an input data source. The system directs Dataset D through three models including Conventional Model, Noise Adaptive Model and Noise Corrective Model. Traditional features and spatial patterns from raw sensors drive the Conventional Model to produce traditional outputs. The Noise Adaptive Model adjusts predictions by introducing a dynamic loss function that accounts for noise levels in the data. The Noise Corrective Model applies a low-rank approximation technique to estimate the true labels and correct misclassifications. These three models work together to improve classification performance. The outputs from all three models are fed into the Ensemble Model, with an Optimization process determining the best weight distribution among the models. This ensemble approach results the system to prioritizes the most reliable model based on noise levels.

The optimized classification is then sent to Classifier II, which processes the Testing Instance to generate the Testing Labels. This final classifier improves the predictions and results robustness in the presence of label noise. The entire framework improves the classification process by reducing errors caused by noisy labels and enhancing model generalization. The combination of multiple models with adaptive noise handling makes this approach more effective in real-world applications with data uncertainty as common.

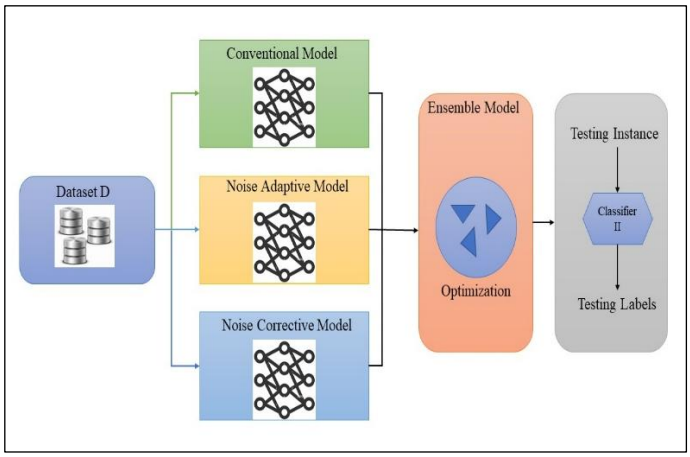

Figure 1: Block diagram of LRNL approach with its components.
Source: Authors, (2026).

The Conventional Model extracts spatial and temporal features from raw sensor data. It processes information using deep learning techniques like CNN and LSTM. This model helps in recognizing locomotion modes but struggles with noisy labels. It serves as the foundation for further improvements. The Noise Adaptive Model introduces a dynamic loss function. It adjusts predictions based on noise levels to reduce errors. The Noise Corrective Model applies a low-rank approximation technique. It estimates true labels by filtering out incorrect annotations. These three models combine in an ensemble to enhance classification accuracy and robustness against noisy labels. The final classification decision is obtained by aggregating the outputs of these models using a weighted ensemble mechanism. Let $D = \{X_{tr}, Y'\}$ be the training dataset, with $X_{tr} \in R^{N\times M}$ representing the feature matrix consisting of N instances, each with M feature dimensions. The label matrix $Y' \in R^{N\times k}$ contains k possible locomotion mode labels, but some of them are incorrect due to label noise. The objective is to find a mapping function H such that:

$$H : X_{tr} \rightarrow Y \tag{5}$$

Here, Y represents the true label matrix, which is unknown due to the presence of label noise. To extract meaningful features from raw sensor data, the system employs a hybrid architecture consisting of CNN and LSTM networks. The CNN component captures spatial dependencies, while LSTM captures temporal patterns in the data. The CNN layers perform feature extraction as follows:

$$F_{cnn} = \sigma(W_{cnn} X_{tr} + b_{cnn}) \tag{6}$$

Here, W_{cnn} and b_{cnn} are trainable parameters and σ is the activation function. The LSTM layers process sequential dependencies using:

$$h_t = \sigma(W_h h_{t-1} + W_x X_t + b_h) \tag{7}$$

Here, h_t is the hidden state at time step t and W_h, W_x, b_h are model parameters. The final extracted features from CNN and LSTM are concatenated and passed through a fully connected layer:

$$F_{final} = FC(concat(F_{cnn}, h_t)) \tag{8}$$

The noise adaptive model adjusts predictions dynamically based on the estimated noise concentration in training data. It introduces a modified loss function:

$$L_{NAL} = -\frac{1}{N}\sum_{i=1}^{N}\sum_{j=1}^{k}\left[at_i \log r_{ij} + (1-a) r_{ij} \log t_i \right] \tag{9}$$

Here, a is a dynamically adjusted weight parameter, t_i represents the estimated true label probability and r_{ij} is the predicted probability for instance i and class j. The noise adaptive model iteratively updates a based on model loss and variance, providing robustness against moderate label noise. The noise corrective model improves noisy labels by estimating a low-rank representation of the label matrix is given by (2). This approach assumes that true labels follow a low-rank structure, enabling corrections in mislabeled instances. The optimization problem is solved using Singular Value Decomposition (SVD):

$$T = U\Sigma V^T \tag{10}$$

Here, U and V are orthonormal matrices and Σ is a diagonal matrix containing singular values. By setting small singular values to zero, we obtain an improved label estimate. The final prediction is obtained by aggregating outputs from all three models using a weighted ensemble technique is given in (4).

Algorithm 1: Locomotion Mode Recognition with Noisy Labels.

1. Input: Training dataset $D = \{X_{tr}, Y'\}$ with noisy labels
2. Initialize models: Conventional Model, Noise Adaptive Model, Noise Corrective Model
3. for each epoch t do
4. Extract spatial and temporal features using CNN-LSTM
5. Compute adaptive loss L_{NAL} and update parameters
6. Apply low-rank approximation to estimate true labels
7. Optimize ensemble weights $\lambda_1, \lambda_2, \lambda_3$
8. Compute final prediction $Y_{te} = \sum_{i=1}^{3} \lambda_i Y_{te}^{(i)}$
9. Evaluate loss and update model parameters
10. end for
11. Train final classifier using optimized ensemble model
12. Test model on unseen instances and compute evaluation metrics
13. Output: Predicted locomotion labels with improved noise robustness

The proposed method is validated using real-world locomotion datasets. Performance is evaluated in terms of accuracy, robustness to noise and computational efficiency. Results demonstrate that the ensemble approach significantly outperforms traditional deep learning models under varying noise levels. This section introduced an advanced locomotion mode recognition approach that integrates conventional, adaptive and corrective learning techniques.

V. RESULTS AND DISCUSSIONS

The research evaluates the model's performance across diverse noise levels through experiments and demonstrates its better capabilities to handle noisy labels by comparing against common deep learning approaches. The research uses two distinct datasets for evaluation: first a gathered dataset featuring locomotion modes between walking, cycling, driving vehicles and public transportation and second an existing dataset that contains sensor data from smartphones and wearables. The accelerometers combined with gyroscopes and magnetometers gathered sensory readings that produced an extensive view of human movement behavior. The training data includes precise as well as imprecise sample labels because it models realistic noise situations to measure the model's responsiveness to these scenarios. A hybrid algorithm of CNNs together with LSTM networks performed feature extraction to recognize spatial-temporal characteristics in the measured data. To evaluate the model performance, multiple metrics were used, including accuracy, precision, recall, F1-score and computational efficiency. Accuracy measures the correctly predicted instances as a percentage of total instances. Precision assesses the proportion of true positive predictions among predicted positive instances. Recall captures the proportion of correctly identified positive instances and the F1-score provides a balanced measure between precision and recall. Computational efficiency was evaluated in terms of training time and inference speed, as these factors are crucial for real-time applications. The experimental results reveal that LRNL achieves higher classification accuracy across all noise levels compared to conventional models. Table 1 shows the accuracy comparison of LRNL against CNN, LSTM and CNN-LSTM models at different noise levels. As seen, LRNL maintains the highest accuracy even as noise levels increase, demonstrating its robustness against noisy labels. The conventional CNN and LSTM models show significant performance degradation when label noise increases beyond 10%, while the CNN-LSTM hybrid model performs slightly better but still lags behind LRNL.

Table 1: Accuracy Comparison of LRNL and Other Models.

Model	Noise 0%	Noise 10%	Noise 20%	Noise 30%
CNN	91.2%	85.6%	78.9%	72.4%
LSTM	92.5%	87.1%	79.8%	73.5%
CNN-LSTM	94.0%	89.3%	81.5%	76.0%
LRNL	96.3%	93.4%	88.1%	83.7%

Source: Authors, (2026).

Computational efficiency served as a second analytical factor along with classification accuracy. The training duration alongside inference speed appears in Table 2 for each classification system under examination. The training duration of LRNL extends slightly since it includes built-in noise correction methods although this additional time expenditure leads to enhanced accuracy. The system maintains sufficient inference speed which supports real-time implementations of LRNL.

Table 2: Computational Efficiency of LRNL and Other Models.

Model	Training Time (mins)	Inference Speed (ms)
CNN	45	12
LSTM	50	15
CNN-LSTM	55	18
LRNL (Proposed)	60	20

Source: Authors, (2026).

Results analysis demonstrates that LRNL delivers better performance than current models regarding accuracy measures and noise tolerance of classification labels. The adaptive loss component together with an ensemble model structure enables dynamic adjustments to different levels of noise thus minimizing damages from erroneous labels. The Figure 2 illustrates the impact of increasing noise levels on the accuracy of four models: CNN, LSTM, CNN-LSTM and LRNL (Proposed). The plotted curves show that all models experience a decline in accuracy as noise increases. The CNN-LSTM model maintains better accuracy than CNN and LSTM. It suggests that combining convolutional and sequential learning provides some noise resistance. The LRNL model outperforms all other models, showing the slowest decline in accuracy. At 0% noise, CNN achieves an accuracy of approximately 91%. LSTM slightly exceeds CNN, CNN-LSTM surpasses 93%. LRNL reaches nearly 96%. As the noise level increases to 10% CNN drops to around 86%. LSTM stays slightly higher, CNN-LSTM remains above 90%. LRNL retains nearly 95%. At 20% noise, CNN's accuracy falls below 80%. LSTM and CNN-LSTM stay above 80%. LRNL still performs the best at around 88%. As noise levels reach 30%, CNN and LSTM both approach 75%. CNN-LSTM holds near 78% and LRNL remains around 84%. Finally, at 40% noise, CNN drops to approximately 65%, LSTM shows a similar trend CNN-LSTM maintains about 70%. LRNL still performs significantly better at around 78%. This pattern confirms that LRNL is the most robust against noise, effectively mitigating accuracy loss compared to other models.

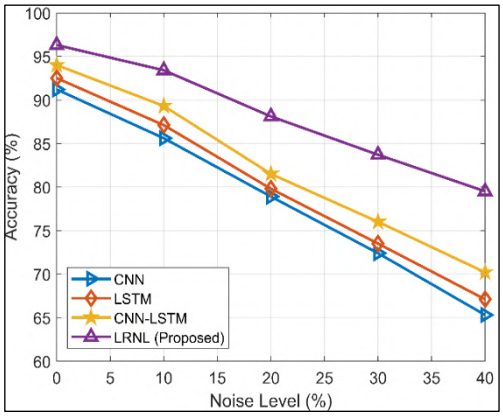

Figure 2: Accuracy versus Noise Level.
Source: Authors, (2026).

The Figure 3 illustrates the impact of increasing noise levels on three performance metrics: precision, recall and F1-score. The three plotted curves follow a downward trend, indicating that all three metrics decrease as noise levels increase. Precision, recall and F1-score start at high values near 97% when there is no noise but gradually decline as the noise level rises. The curves remain close to each other, suggesting that precision, recall and F1-score experience similar rates of degradation due to noise. At 0% noise, all three metrics are approximately 97% showing that the model performs well with clean data. As noise increases to 10%, precision, recall and F1-score drop to around 95% indicating a slight reduction in performance. At 20% noise, the metrics decline to about 92% showing a steady downward trend. When noise reaches 30%, precision, recall and F1-score are close to 88%. It reflects the increasing difficulty in maintaining classification accuracy. At the highest noise level of 40%, all three metrics fall to around 80%. It demonstrates a significant impact of noise on the model's ability to make correct predictions. The similarity in the values of the three metrics suggests that the model maintains a balanced performance, with no single metric deteriorating disproportionately. These results highlight the model's ability to manage noisy labels while maintaining high classification quality.

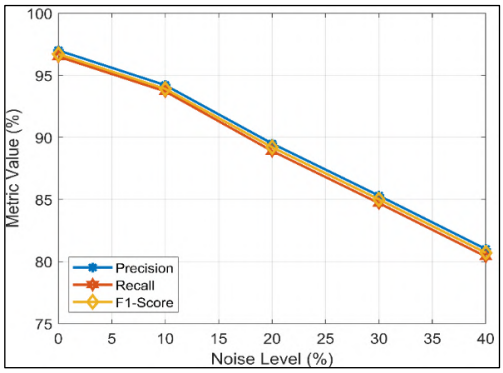

Figure 3: Precision, Recall & F1-Score versus Noise Level.
Source: Authors, (2026).

The Figure 4 represents the training time for four different models: CNN, LSTM, CNN-LSTM and LRNL. The CNN model achieves the fastest training efficiency reaching its completion within 45 minutes. The LSTM training procedure extends to 50 minutes. A CNN-LSTM model needs 55 minutes to complete training. The LRNL model requires the most time in training process exceeding sixty minutes. Training time for complex models typically needs extra processing power as well as increased time for computational work. More complex architectural designs require elevated computing resources thus increasing training duration for all models demonstrated. Due to their complex architecture the training times for models show an expected increase across different models. The high performance of CNN in spatial feature processing results in the shortest training times. LSTM requires longer processing time because its recurrent sequence-dependent approach. Because the CNN-LSTM model combines spatial and temporal features its training duration becomes extended. Training LRNL requires the most duration among all the proposed models. The training time extends due to two extra features called noise adaptation and label correction. LRNL develops exceptional precision from its extended training period since its quality-specific noise resilience warrants the investment of extra training time. A deep learning model requires increased training time to achieve better generalization together with enhanced stability. The experimental results demonstrate how model complexity affects computational efficiency since real-time applications require such consideration.

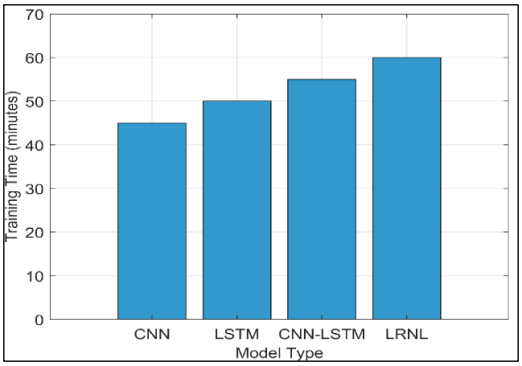

Figure 4: Training Time versus Model Type.
Source: Authors, (2026).

The Figure 5 demonstrates how quickly four different models (CNN, LSTM, CNN-LSTM and LRNL) can perform inference. CNN processes samples in the fastest speed demanding 12 milliseconds per sample. The LSTM model has a slower processing speed which needs approximately 15 milliseconds. An inference operation with CNN-LSTM model requires 18 milliseconds. It elapses longer than CNN and slower than LSTM for model processing time. At each sample the LRNL model requires the longest inference time of 20 milliseconds. The research data indicates that model complexity directly results in longer inference times because advanced processing requirements. The coefficient of inference speed rises because each added processing layer within models generates increased processing speed. The efficient feature extraction of spatial elements makes CNN produce the shortest inference time. LSTM implements a higher computational process for each step since it detects and analyses sequential data patterns. By combining spatial and temporal processing within the CNN-LSTM model there is a corresponding escalation in inference time. The LRNL model requires the most time because it contains additional components that perform noise adaptation and label correction. The lower speed of LRNL enables superior accuracy together with enhanced robust performance. Real-time applications require a trade-off between speed of inference processing and model accuracy because both performance metrics need a suitable balance.

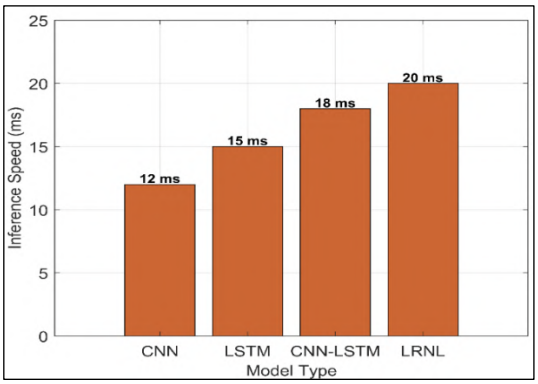

Figure 5: Interference Speed versus Model Type.
Source: Authors, (2026).

The Figure 6 illustrates the change in fractional weights of three models—Conventional Model, Noise Adaptive Model and Noise Corrective Model—as noise levels increase from 0% to 40%. The Conventional Model starts with the highest weight of approximately 0.6 when noise is 0%. However, its weight decreases steadily as noise increases dropping below 0.2 at 40% noise. In contrast, the Noise Adaptive Model starts with a weight of about 0.35 and gradually increases until it stabilizes at around 0.5 for noise levels greater than 25%. The Noise Corrective Model initially has the lowest weight staying at around 0.15 for lower noise levels. However, its weight starts increasing at 20% noise and surpasses 0.2 when noise reaches 40%. The trends in the figure indicate how the ensemble approach dynamically adjusts the model contributions as noise increases.

The Conventional Model, which relies on clean data becomes less effective with higher noise levels. It leads to a continuous reduction in its weight. The Noise Adaptive Model which introduces a dynamic loss function. It increases in weight as it becomes more relevant in handling label noise. The Noise Corrective Model, which uses low-rank approximation to estimate true labels. As it gains importance at higher noise levels making its weight grow progressively. At high noise levels, the Noise Adaptive and Noise Corrective Models dominate. The Conventional Model plays a minor role. These results highlight the effectiveness of adaptive weighting in maintaining classification performance under noisy conditions.

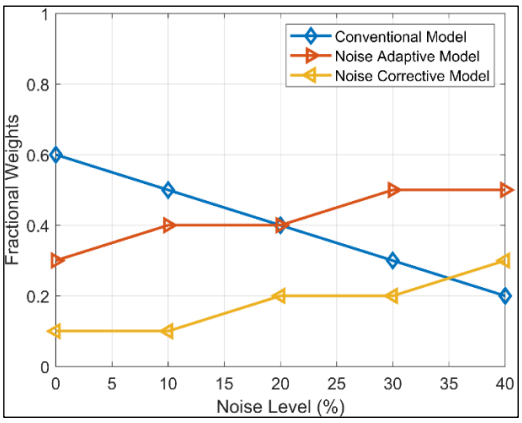

Figure 6: Impact of Noise on Ensemble Weight Adjustments.
Source: Authors, (2026).

The Figure 7 presents a comparison of accuracy across different models as noise levels increase from 0% to 40%. The models included are LRNL (Proposed), DeepFusion, Deepsense, DenseNetX, GRU-DNG and LMGMM. The LRNL model achieves the highest accuracy across all noise levels. At 0% noise, LRNL starts above 95%, while other models namely DeepFusion and Deepsense start slightly lower around 93% and 92%, respectively. DenseNetX and GRU-DNG have slightly lower starting accuracies. LMGMM shows the lowest accuracy among all models. As noise levels increase, all models show a decline in accuracy. LRNL maintains a higher accuracy margin compared to the rest. At 20% noise, LRNL remains above 90%. DeepFusion and Deepsense drop closer to 85%. DenseNetX and GRU-DNG further decreases. LMGMM experiences the steepest decline, approaching 80%. At 40% noise, LRNL maintains around 80% accuracy. DeepFusion and Deepsense drop near 75%. DenseNetX and GRU-DNG decline further. LMGMM falls below 70%. The results indicate that LRNL is the most robust model against label noise while LMGMM is the most affected. The gap in accuracy between models increases with noise, highlighting the advantage of the proposed LRNL approach in handling uncertain data.

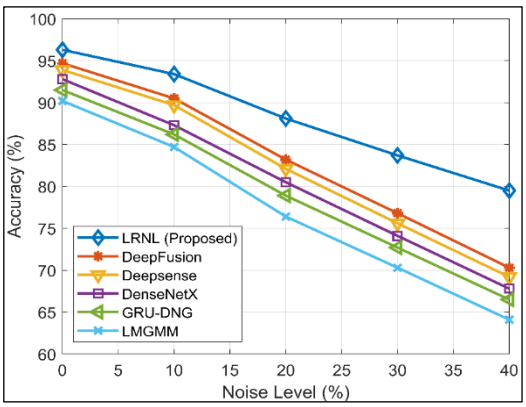

Figure 7: Comparison of LRNL with other Advanced Models.
Source: Authors, (2026).

The Figure 8 illustrates the relationship between training time and noise levels for four models: CNN, LSTM, CNN-LSTM and LRNL (Proposed). The plotted curves show that training time increases as noise levels rise for all models. CNN has the lowest training time starting at around 40 minutes at 0% noise. It increases to approximately 52 minutes at 40% noise. LSTM starts at about 44 minutes and rises to 56 minutes as noise increases. The CNN-LSTM model has a higher training time. It begins at 46 minutes and reaching close to 60 minutes at 40% noise. The LRNL model which includes additional noise handling mechanisms. It has the longest training time starting at 50 minutes and increasing to about 66 minutes. The increase in training time across all models suggests that handling noisy data requires additional computational effort. CNN is the fastest to train due to its efficient spatial feature extraction. LSTM takes longer as it processes sequential dependencies. CNN-LSTM joins the techniques to boost training performance. LRNL model stands as the most demanding model since it includes noise adaptation functions along with corrective mechanisms. All models demonstrate increased training complexity as noise intensity increases according to the experimental results. LRNL takes the longest to train yet its protection capabilities make the extra computation time worthwhile. The training time data reveals a straight linear pattern which extends from noise level to level while LRNL consumes the maximum resources. Deep learning models operate at a computational expense that directly relates to their ability to manage noise data.

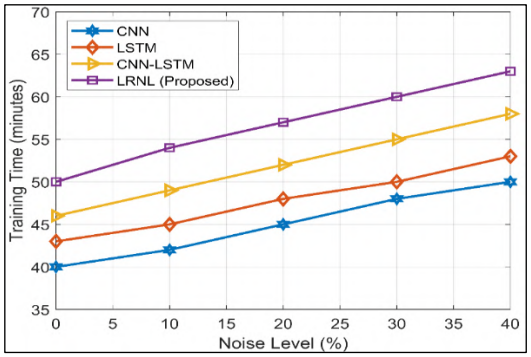

Figure 8: Training Time versus Noise Level.
Source: Authors, (2026).

The Figure 9 illustrates the F1-score performance of four models: CNN, LSTM, CNN-LSTM and LRNL. The CNN model has the lowest F1-score, achieving 85.4%. The LSTM model performs slightly better with an F1-score of 87.2%. The CNN-LSTM model improves the F1-score reaching 89.1%. The LRNL model achieves the highest F1-score of 93.5%. This trend indicates that integrating different architectures enhances model performance. The LRNL model demonstrates the best ability to maintain a high F1-score. The increasing F1-score across models highlights the advantage of combining spatial and sequential feature extraction techniques. CNN captures spatial features efficiently, but it lacks temporal modeling leading to a lower F1-score. LSTM models sequential dependencies but does not utilize spatial patterns effectively. CNN-LSTM integrates both techniques, leading to a noticeable improvement in F1-score. The LRNL model enhances performance by incorporating noise adaptation and correction mechanisms. The results suggest that LRNL is more robust in handling label noise contributing to its superior classification performance. The difference in F1-score between CNN and LRNL is over 8%, showing the impact of noise-resistant techniques. These findings confirm that LRNL provides the most accurate and balanced predictions among the evaluated models.

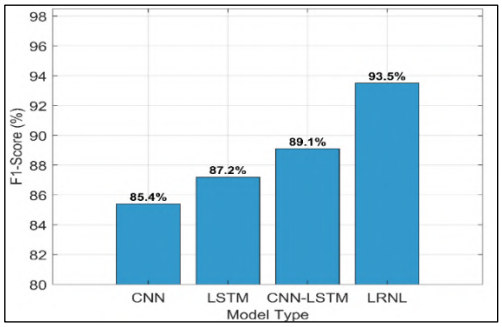

Figure 9: F1 Score versus Model Type.
Source: Authors, (2026).

The Figure 10 presents the loss reduction across 50 epochs for four models: CNN, LSTM, CNN-LSTM and LRNL (Proposed). All models start with a high loss value close to 1.0 at the initial epoch. As training progresses, the loss decreases for all models showing that they are learning from the data. CNN exhibits the fastest decline in loss initially reaching 0.4 by epoch 20. LSTM and CNN-LSTM show a similar decreasing trend but remain slightly above CNN. LRNL, the proposed model maintains a slower reduction rate in the early epochs but stabilizes at a lower final loss. Between epochs 20 and 50, all models continue reducing the loss values. CNN maintains the lowest values after 30 epochs. The LSTM and CNN-LSTM models exhibit slightly higher loss values but the trends remain close to CNN. LRNL has a slightly higher loss than the other models at later epochs, stabilizing at around 0.2. This suggests that while LRNL does not achieve the lowest loss. It maintains stability and avoids excessive fluctuations in the later training stages. The results indicate that all models successfully converge but CNN achieves faster convergence. LRNL focuses on maintaining robustness and stability. The steady behavior of LRNL highlights its resilience to variations in training, making it useful for handling noisy data. The results suggest that LRNL trades off faster convergence for better generalization, which is beneficial for real-world applications.

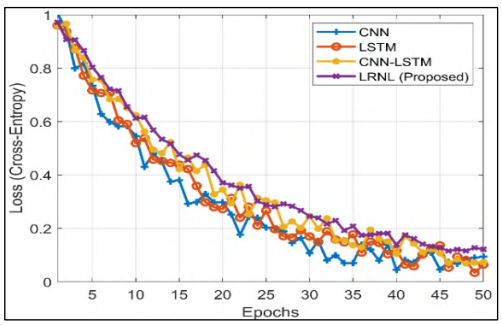

Figure 10: Loss versus Epochs (Convergence Graph).
Source: Authors, (2026).

The Figure 11 represents the relationship between inference speed and noise levels for four models: CNN, LSTM, CNN-LSTM and proposed LRNL. Inference time extends progressively longer as noise levels increase in the plotted results. CNN operates at 10 ms inference speed when the system contains no noise but extends its performance to around 14 ms at 40% noise. When starting from 12 ms the inference time of LSTM progressively approaches 16 ms. CNN-LSTM requires 14 milliseconds at the start then increases to almost 18 milliseconds. LRNL shows the longest inference time because it begins at 16 ms and reaches 20 ms while the noise level increases. Higher noise levels create added computational complexity which results in the increasing duration of inference for every model tested. The data processing efficiency of CNN makes it maintain the slowest inference speed among all models. LSTM operates slower than CNN because it requires more time because of its sequential structure. The combined spatial and sequential learning approach in CNN-LSTM extends computation time so it requires additional processing duration. The inference time for LRNL is maximum since it incorporates noise adaptation and correction algorithms. The reduced speed of LRNL operation does not affect its expected improvement in both classification accuracy and robustness performance. Real-time applications need to perform a cost-benefit analysis between accuracy and computational processing time since advanced models demand additional runtime to function.

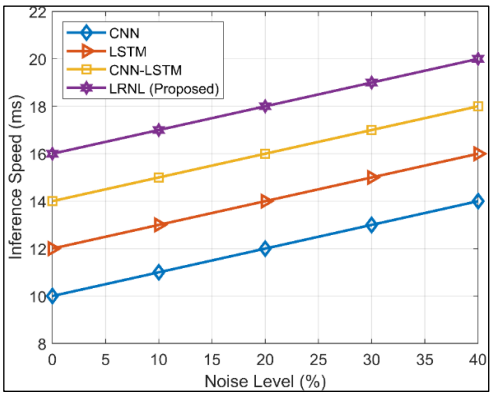

Figure 11: Inference Speed versus Noise Level.
Source: Authors, (2026).

The Figure 12 demonstrates the Receiver Operating Characteristic (ROC) curves for four models that include CNN, LSTM, CNN-LSTM and LRNL (Proposed). The decision threshold adjustment reveals the ability of each model to differentiate between classes through the ROC curve. The LRNL model demonstrates optimal performance compared to other models because it outperforms the random baseline and all other models. The CNN model demonstrates the lowest ROC curve which indicates its ability to achieve less TPR when FPR reaches a certain threshold. LSTM demonstrates a superior performance than CNN as its curve stays above the CNN curve. CNN-LSTM improves, showing better discrimination. For any specified FPR value LRNL demonstrates the maximum TPR level thus proving its excellence in classification tasks. At an FPR of 0.2, LRNL has a TPR close to 0.8. CNN-LSTM reaches about 0.7, LSTM around 0.65 and CNN near 0.6. At higher FPR values, all models approach a TPR of 1.0. LRNL remains the most effective throughout. The difference in performance is most noticeable in the low-FPR region with LRNL achieving a higher TPR with fewer false positives. This suggests that LRNL is more reliable in distinguishing between positive and negative classes while minimizing incorrect classifications.

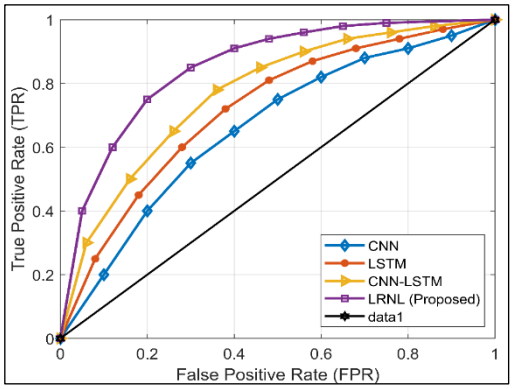

Figure 12: ROC Curve for Different Models.
Source: Authors, (2026).

The Figure 13 represents the time difference (in percentage) across three datasets: LMR, SHL and TMD. Six models are compared: LMGMM, LAR, AAAR, PENCIL, CopyNet and DNG. The time difference values for each model vary across the datasets, indicating differences in execution times. In the LMR dataset, the time difference ranges from approximately 8% to 15%. The evaluation on the SHL dataset produces slightly elevated scores reaching near 18% for selected models. The TMD dataset displays a comparable pattern which changes based on the model selection. DNG demonstrates the highest variation in execution time which exceeds 15% in each dataset assessment. The execution time of the AAAR model exceeds 10% throughout all analyzed datasets. Each model demonstrates different patterns of execution duration which depends on the information sets used for analyses. The DNG and AAAR models demonstrate increased complexity since their execution times show substantial variations.

VI. CONCLUSIONS

This paper describes a deep learning-based technique for the recognition of locomotion mode from noisy sensory data. An ensemble learning framework that incorporates conventional, noise adaptive and noise corrective model were used to address the problem of noisy labels. The results show that the proposed system effectively increases classification accuracy with minimizing the negative effect of label noise. Research on locomotion mode recognition indicated that the handling of noisy labels is significant. Machine learning model's performance is degraded by labels that are noisy and one needs to use robust techniques to fix mislabeled data. In LRNL, the noise adaptive model added a dynamic loss function that takes into account the estimated noise concentration. The label assignments were improved by a low rank approximation in the noise corrective model. It was found through computational efficiency analysis that training times of the LRNL scheme are slightly longer than that of the conventional techniques. Thus, by placing conventional, noise adaptive and noise correcting models into an ensemble learning framework. Experimental evaluation verified the effectiveness in maintaining high reliability in mode recognition for varying amounts of noise as well as being able to locomotion in unknown terrain.

ABSTRACT

A neurological condition that affects nerve cells is called Parkinson's disease (PD). Numerous neurological disorders, such as tremors, limb stiffness, and changes in walking patterns, are brought on by PD. Preserving the health of individuals affected by PD requires early detection of the condition. However, early PD diagnosis is challenging due to the aging population. Deep learning (DL) models have been tested for accuracy and for this test, Parkinson's dataset and feature relevance analysis has been utilized. The DNN technique is utilized to evaluate and extract pressure, grip angle, and timestamp from spiral drawing inputs. The voice data in this case is sourced from Kaggle. In this study, a novel DL model for PD detection and prediction is presented. It combines an optimization technique for dwarf mongoose with a SqueezeNet. For classifications, SqueezeNet with DMOA, trained on FCBi-LSTMs generates the best features. This study's suggested model utilizes the learning repository at the University of California, Irvine (UCI). The values of Matthews correlation coefficients (MCCs) , accuracy, and F-measure values are evaluated using Leave-One-Person-Out-Cross Validations (LOPO CVs).

I. INTRODUCTION

A neuronal ailment that affects the central nervous system and impairs movement and coordination is called PD. Each year, more than 50,000 Americans are diagnosed with PD, according to the National Institutes of Health (NIH). A person with PD may experience lifelong impairment due to tremors, loss of posture, and balance issues. Parkinson's disease is the second most common disease, and World Health Organization (WHO) has established that one of the most difficult scenarios for the treating physician is the disease's extended duration. Parkinsonism affects 10 billion people worldwide, making it a threat. Early and appropriate intervention, however, can significantly lessen the impact of the illness and aid in the patient's recovery. Table I examines the different phases of PD [1]. People with PD may have distinguishable symptoms include tremors, limb rigidity, altered gait patterns, and balance problems. However, patients experience a slow development of these symptoms. In addition, PD symptoms fall into two different categories: Movement-related motor symptoms (i) and non-motor, motion-unrelated motor symptoms (ii). The symptoms that are not related to motor function are usually more severe and include sadness, erratic sleep patterns, olfactory impairment, and cognitive decline. PD affects more than 10 million people worldwide and more than 52 billion Americans annually. Key tactics in the fight against PD include early detection, grouping patients according to PD phases, starting therapy right once, and identifying medications and symptoms that can be minimized [2]. Thus, the advancement of possibly curative medications needs to be slowed down and PD must be stopped in its tracks. Even with a number of PD symptoms and diagnostic procedures, the precise diagnosis of PD is still unknown [3].

Together, these diagnostic markers are used to diagnose PD, and other biomarkers are examined to identify the disease at an early stage. The goal of PD therapy is to lessen symptoms rather than to stop or reverse the course of the illness in individuals. The experiment's dataset, which included a voice impaired by PD, was obtained from the UCI Machine Learning repository. The dataset contains 22 voice measurement-related features in addition to a "status" feature that indicates the patient's PD condition. The data's parallel coordinates display the largest range. An analysis of several ML algorithms revealed that SVM had the highest accuracy, at 88.9%; Random Forest came in second, at 90.26%; and the Naive Bayes method had the lowest accuracy, at 69.23%. Disparities in the number of clusters between patients who were well and those who were not were found using clustering techniques such as Hierarchical clustering and Self-Organizing Maps (SOM) [4]. As a result of the recent and ongoing increase in the variety of medical data, efficient categorization and prediction algorithms are needed. Numerous agents can affect a classification algorithm's accuracy, according to earlier research on ML [5]. Medical data sets and diagnostic issues are analyzed using ML techniques [6]. As a result, better medical judgments and treatments will be made, and financial expenses will go down [7]. Furthermore, feature selection is crucial to the understanding of medical data. The feature selection technique plays a crucial role in global combinatorial optimization within machine learning. It Compress the number of features from the original set, Eliminates redundant or irrelevant features without appreciably lowering the amount of information retained, and simplifies models to expedite training and improve comprehension [8].

Therefore, to increase processing speed and forecast accuracy, a strong feature selection technique is needed. There are three different kinds of feature selection methods: filter that collects features from the data set without any learning, hybrid which combines the feature selection stage and the classifier building, and wrapper which employs learning approaches to estimate valuable features [9]. DNNs are hierarchical layers that produce deep abstract representations of input information in applications. Numerous applications, including as speech recognition, picture classification, drug development, and genetic research, have made use of DLTs [10]. The key reason DNNs have been adopted by researchers for PD categorizations is their efficacy. Given their ability to replicate intricate and nonlinear data linkages, DNNs are particularly useful classifiers for dealing with PDs. Sensor activity [11] and EEG data [12] are examples of singular variables used as CNN inputs in prior research on the categorization of PD, but no attempt was made to employ discrete parallel layers for classification. In a study [13], voices were multiplied in order to increase the number of voice recordings used in techniques testing and training with CVs (cross-validations). This resulted to unbalanced performance measurements. Leave-One-Person-Out-Cross Validations were used to assess the performance of the suggested framework because the data comprised voice recordings of both healthy individuals and people with Parkinson's disease. LOPO-CVs excluded Samples from particular persons in test set Cycles and used other instances in training. The following is the contribution.

• To improve the prediction of PD, a thorough investigation into the effectiveness of various feature selection and DL techniques was conducted.

• As far as we can tell, we are the first to build a Voice and Spiral dataset including a variety of variables from both healthy and PD-affected volunteers. We are also incorporating the new idea of the speech and spiral dataset into the identification and classification of PD.

• This study proposes a feature-choice SqueezeNet architecture based on agreements. Ensembles of feature selection techniques, such as Dwarf Mongoose Optimization, seek to replace single feature selection methods with multiple feature selection strategies, whereas SqueezeNet uses optimal features to train fuzzy convolution bi-directional long short-term memory classifiers.

• This suggested strategy's performance confirmed with LOPO-CVs after it was trained on datasets from the DL repository. This approaches introduces a model depends on DL repositories, measures the approaches' accuracy, F-measure values, and MCCs using LOPO-CVs.

II. LITERATURE SURVEY

In the very 1st architecture, multiple feature sets were merged before that are being fed as inputs into nine-layered CNNs. In their 2nd architecture, feature sets were fed directly to convolution layers in parallel. Various feature sets were generated which are then blended [14] with the help of vocal data to detect PDs using the dual frameworks of CNNs. Therefore, before each parallel branch merged into a layer, its deep features were acquired. As they used parallel convolutions to learn deep features, their second model demonstrated extremely encouraging test results. Also, to clearly identify patients with PD from healthy individuals, the retrieved deep features were effective in boosting the classifiers' capacity for discrimination. By [15] combined ensemble learning with CART to classify PDs. CART was utilized in the study to choose the best training vocal samples with broad range of variation. To ascertain whether training data was ideal, the evaluation employed Assemblies, such methods as random forests, support vector machines, and ELMs are included. We used ensemble- Education systems that had been trained to classify test data. In addition to improving PD predictions with voice data categorizations, this research indicated that CART and RF Composition were maintained stability when compare to alternative techniques. In turn [16] predicted that speech problems, the disorder's initial symptom, would be used to identify Parkinson's disease. For classification, they employed the SoftMax method and DNNs using stacked autoencoders.

The superiority of DNN classifiers over alternative classification algorithms was shown by the simulation results from their two datasets. According to [17] suggested using enhanced fuzzy FKNNs in conjunction with CBFOs using Gauss mutations on audio data as a rapid way to find PDs. Their CBFO FKNN successfully modified the FKNN's parameters through the use of an advanced instance-based learning technique. The study employed PD datasets to extensively evaluate their suggested method in term of Segmentation specificity, accuracy, sensitivity, and Receiver operating characteristic (ROC) area , or AUCs. Results delivered more accurate clinical diagnosis conclusions to medical professionals. By [18] used ANNs with MLPs to classify PDs on datasets from the UCI ML library. They collected both control groups and voice recordings of patients with PD. The study trained between 10,000 and 6,000 neurons across many networks; the number of neurons increased tenfold in the buried layers. ANNs' analysis of speech-related features could be utilized to evaluate how PDs are affecting patients. With the availability of biological data, MLTs can also diagnose various neurological illnesses.

Well-known speech characteristics like shimmers, jitters, fundamental frequency parameters, and harmonicity factors were used by [19] in their PD research to describe the disorders. PPEs, DFAs, and RPDEs were used to evaluate the PDs. PDs have been categorized via XGBoost algorithm with the help of the identified baseline features. Feature significance plots were used to guide feature selection in order to boost the model's proficiency. loc Shimmer attributes that resulted have been removed . XGBoost's evaluations the feature relevance enhanced the features' effectiveness to raise classification accuracy. Unlike the initial method, which combines distinct feature selections [20] and feeds them into a CNN with nine layers, the Features from concurrent input layers directly input into convolution layers according to the second model design. The deep features of parallel branches obtain information simultaneously before merging data through each parallel connection in the merge layer. The suggested models undergo Leave-One-Person-Out Cross Validation (LOPO CV) to validate their findings after being trained using UCI ML data. We examine our data using the The F-score and Matthews correlation coefficient (MCC), and accuracy due to the unequal class distribution. Experimental results demonstrate that this second model shows great potential because it uses concurrent convolution layers to learn features from each batch. The model learns representation features from each feature batch through concurrent convolution layers

Problem Statement:

One major problem for PD patients is early diagnosis of the disease. If individuals receive an early diagnosis, they can improve their quality of life even if their health worsens. Another problem is that diagnosing PD involves multiple processes, such as asking the patient about their neurological history and testing their motor skills in different settings. Most recent research works on the homo dataset, which includes text, speech, video, and image data. The proposed study has identified issues with multi-data handling processes and dataset modification. After a certain dataset is examined, the efficacy of disease prediction is controlled. The application of ML-based methods for multivariate data processing allows for more real-time solutions. Multi-variate vocal data analysis (MVDA) aims to identify PD based on features from many datasets by applying machine learning algorithms. This work aims to explore potential enhancements to multi-variate and multimodal data processing to improve the rate of disease identification. For the purpose of analyzing Parkinson's data based on voice features, research is now being conducted on several machine learning techniques at once, such as support vector machines, K-NN, naïve Bayes, and artificial neural networks. Based on these studies, the MVDA uses large datasets and ML techniques to enhance disease identification. It is recommended that the multivariate acoustic features of several patients be incorporated into the proposed MVDA. With the use of suggested ML approaches, the subjective disease has been identified under the MVDA system.

III MATERIALS AND METHODS

The spiral drawings and voice recordings of both healthy and ill individuals are used in the suggested methodology for PD prediction. The two datasets came from Kaggle. Speech datasets are filtered using the MFCC feature extraction approach to remove noise and clean the data. The data was used to generate a SqueezeNet model. This model uses voice data to predict PD. Whether a voice is that of a person with PD or not can be determined using this model. The spiral drawings made by both healthy individuals and PD sufferers are examined, and the images are run through several CNN layers in order to identify and identify patterns that can be used for categorization. To develop the model, the transfer learning method methodology is used. Because it is more accurate, the trained model VGG16 is employed. The spiral drawing dataset is used to train this neural network, and the model's performance is evaluated against the testing dataset. The model can determine if a person has PD or not when an image is uploaded. An accurate model of the PD prediction system is produced by connecting the two models mentioned above. The system as a whole can determine a person's PD status by utilizing their speech and spiral drawing.

Voice Dataset:

To develop a DLmodel for voice recognition-based PD prediction, a substantial and diverse dataset of speech recordings from both healthy and PD-affected individuals would be needed. Along with speaker demographic data, the dataset should contain audio samples spanning a variety of speaking tenors and emotional states. Making sure the dataset is well-balanced and curated that is, that there are a similar number of samples from people with and without PD is crucial. Our Voice Dataset, which we gathered via Kaggle, served as the main input. After that, The data is split for training and evaluation purposes . 2) MFCC Feature Extraction: In audio analysis and voice processing, MFCC (Mel-Frequency Cepstral Coefficient) is a frequently utilized feature extraction technique. A collection of coefficients known as the MFCCs serves as a compact representation of a speech signal's spectral envelope. MFCC feature extraction from a voice dataset is displayed in Figure 1.

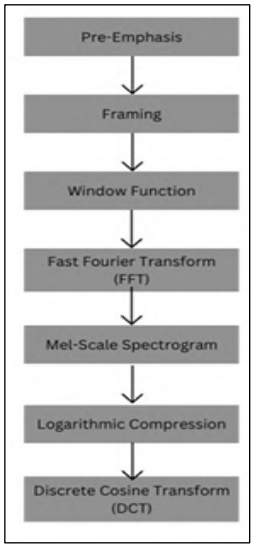

Figure 1: MFCC feature extraction from a voice dataset.
Source: Authors, (2026).

- Pre-emphasis: To highlight high-frequency components in the input audio stream, a high-pass filter is used.
- Framing: To produce a series of brief windows, the input audio signal is split into overlapping or non-overlapping frames.
- Window Function: To minimize spectral leakage, each frame is assigned a window function (similar to the Hamming window).
- FFT: The time-domain data is converted into the frequency domain for every frame using the Fourier Transform.
- Mel-Scale Spectrogram: This represents the non-linear frequency resolution of the human auditory system by converting the magnitude of the FFT coefficients into the Mel scale.
- Logarithmic compression: To lower the dynamic range, the Mel-scale spectrogram is converted into the logarithmic domain.
- Discrete Cosine Transform (DCT): Using the logarithmic Mel-scale spectrogram as a starting point, the DCT generates the MFCC coefficients, which are a condensed representation of the spectral envelope of the audio source. A machine-learning model for voice recognition, speaker identification, or other speech-related tasks can employ the derived MFCC features as input. The MFCCs capture the significant spectrum fluctuations that are pertinent to speech analysis and provide a compact representation of the spectral information in the spoken signal.

Spiral drawing Dataset:

Spiral drawing datasets are collections of spiral drawings that have been captured on camera or recorded. In the fields of computer vision and ML, this kind of dataset is widely used for developing and testing motion analysis and pattern recognition algorithms. A spiral drawing dataset could contain a variety of spiral variations, including spirals drawn with different instruments (e.g., pencil, pen, stylus), spirals with varied curvatures and diameters, and spirals drawn in a clockwise or counter clockwise direction. The dataset might additionally contain participant demographic data, like handedness, gender, and age. ML models can be trained on the photos or recordings in the dataset to identify and categorize spirals according to a variety of characteristics, including the spiral's size, direction, and drawing speed. Subsequently, the models can be applied to examine fresh spiral illustrations and forecast spiral characteristics. Making sure the spiral drawing dataset is representative of the target population, balanced, and diversified is crucial. This will make it more likely that the ML models created with the dataset will be precise and able to be applied to fresh spiral designs. Figure 2: spiral sketching dataset displayed

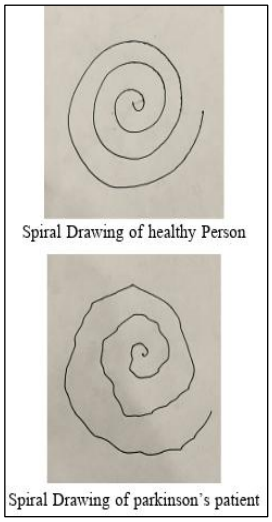

Figure 2: Spiral drawing dataset.

Pre-processing:

During the pre-processing stage, the complete filter technique procedure takes place outside of the model that are ignored by the filter. The main considerations of filter methods are the internal relationships and the distribution correlation of the data. Consequently, the benefit of filter approaches is their ease of computation. Because filter approaches are simple to apply and compute quickly, they are often used to identify this condition. The following is a list of various popular filtering methods. The minimum redundancy and maximum relevancy (mRMR) technique selects features that are not identical to each other yet show a strong "correlation" with the classification variable. The wrapper method decides whether to accept or reject a feature based on the functioning update of a classifier. By taking specific classifiers into consideration, the wrapper technique generates a carefully designed subset. As a result, for wrapper methods, there is less chance of finding the local maximum. Due to its notable efficiency improvement, the wrapper approach is used in ML diagnostics. However, it suffers from a number of drawbacks, including as high computational costs and overfitting. Wrapper-based feature selection algorithms use a classifier to generate several predictor variable machine learning models. They then pick the variable subset that yields the best model. The correlation between the predictor and independent variables is computed using statistical methods in filter-based approaches, which do not require the assistance of a learning algorithm. Assigning scores takes into consideration how relevant the predictor factors are to the target variable. After then, the variables with better scores are used to build the ML model. Consequently, the aim of this research is to Determine the most relevant features utilizing a filter-based feature selection method for improved PD diagnosis.

Feature Extraction:

Mel Frequency Cepstral Coefficients (MFCCs), wavelet transforms (WTs), tunable Q-factor wavelet transforms (TQWTs), vocal fold features, baseline and temporal frequency features, were all included in the dataset.

i. Baseline features: speaking impairments caused by PD have been effectively utilized to assess PDs and monitor the progression of the illness after medication treatments. Studies have made extensive use of the baseline features [13] for speech-based Parkinson's disease research. The basic frequency parameters (#5), DFAs (detrended fluctuation analyses) (#1), harmonicity parameters (#2), PPEs (#1), and RTDEs (recurrence time density entropies) (#1) are a few specific examples.
ii. Time-frequency features: features include bandwidth (#4), formant frequencies (#4), and intensity parameters (#3).
iii. MFCCs: MFCC-based extractions integrate spectral domain partitions and cepstral analyses through the use of triangular overlapped filter banks. When PD affects the tongue and lips, articulators that move quickly deteriorate. MFCCs are able to identify this. The vocal folds, the log energies and 1st/2nd order derivatives of the signal, the mean deviation & standard deviation of the first 13 MFCCs, and other information were used to generate the 84 MFCC-related features (#84) that were included in the dataset [13].
iv. WTs: In general, WTs are employed to decide on signals, particularly those with little variations at the regional level. PD has been diagnosed in a number of studies using WT characteristics derived from the raw fundamental frequencies (F0) of a speech sample. This work yielded 182 WT attributes, including energies, Teager-Kaiser energies, Shannon's and log energy entropies, using both detailed coefficients and approximations.
v. Using feature extraction with TQWTs: To improve the signal's qualities, TQWTs alter three parameters: numerous levels (J), redundancy (r), and Q-factors (Q), depending upon the attribute of the signal. The decomposed layer counts are represented by the symbol J while Q-factors directly correspond to time domain oscillations. The J + 1 sub-bands arise from high-pass filtering together with one low-pass filtered output while Q-factors measure the time domain signal oscillations. A J high-pass filter results in J + 1 sub-bands and one single low-pass filtered output during decomposition. During decomposition the signal decomposes into one low-pass filtered output and J + 1 sub-bands derived from high-pass filtering. Wavelet's temporal localizations are made possible by ringing, which is controlled by. The dataset contained 432 TQWT-related features that were found by the tests employed in this work [13].
vi. Vocal fold features: The researchers generated features from vocal fold vibrations to analyze how noises affect them. The study produces additional information about noise reactions in vocal folds with enhanced detail through sonic analysis. Glottis quotients (#3), glottal-to noise excitations (GNEs) (#6), vocal fold excitation ratios (VFERs) (#7), and empirical mode EMD decompositions (#13) comprised part of the research data collection.
vii. Concat features: the features like vocal fold, baseline, & time-frequency are combined to create concat features.

Feature Selection using SqueezeNet with Dwarf Mongoose Optimization:

PD is the result of a malfunction in the Parkinson's actual processing mechanism. In general, different DLapproaches are used to identify Parkinson's disorders. SqueezeNet, which is trained using the DMOA approach, is used in this study to predict PD. For the purpose of predicting cardiac disease, the SqueezeNet model chooses Vk× z as the input. The SqueezeNet approach has the advantage of better detection outcomes at minimal building costs. Subsequently, the structure of SqueezeNet is explained in the next section.

Structure of SqueezeNet:

Many fire modules, each with an expansion layer and a squeeze convolution layer, make up SqueezeNet . Next, the transmission of squeeze convolution layer’s output is done to the last convolutional layer. This transmission is initiated with a solitary convolution layer which is being tracked by 8 number of fire modules. “Bm” represents SqueezeNet model’s output. Figure 2 illustrates that the max-pooling procedure is executed in 2 steps by SqueezeNet.

SqueezeNet Training Using DMOA:

This section provides more explanation of the DMOA, which is used to train the SqueezeNet employed in this investigation. The ability of dwarf mongooses to forage is the basis for the main concept of DMOA. DMOA is a metaheuristic model that is used to solve optimization problems. For the aforementioned optimization problems, DMOA can produce and enhance a potential solution. By employing this tactic to investigate different areas of the problem search space, the dwarf monkeys are hopping from one food source to another. DMO further uses a single tuning parameter. The DMOA algorithm consists of the following phases.

(1) Initialization: The algorithmic solutions and constraints are first set up. This is the action that results in the best outcome.
(2) Fitness Measure: The Mean Squared Error (MSE) is used to determine the best answer.

$$b_{min} = \frac{1}{w}\sum_{m=1}^{w}(B_m^* - B_m)^2 \tag{1}$$

Where B*m stands for the predicted outcomes, Bm for the SqueezeNet categorized outcome, and w for the total number of samples.

(3) Alpha Group. The initial Group is Alpha. The efficacy of the entire strategy is assessed once the population has begun in which selection of Alpha female will be chosen based on the values of likelihood that are determined by the following as:

$$k = \frac{(b_{\min})_p}{\sum_{p=1}^{t}(b_{\min})_p} \tag{2}$$

In this case, bmin indicates the fitness function, and t indicates the mongoose count in k. The solution's upgrading approach is provided as:

$$s_{p+1} = s_p + \alpha_p * Q \tag{3}$$

In which, Q represents the vocalization of the lead female, and sp is the solution for this iteration's solution. The distributed random integer is represented as αp. The sleeping mount, which is determined after each loop, is given by

$$L_r = \frac{(b_{min})_{p+1} - (b_{min})_p}{\max[|(b_{min})_{p+1} - (b_{min})_p|]} \tag{4}$$

Additionally, the sleeping mound's average count is calculated as

$$\omega = \frac{\sum_{p=1}^{t} L_r}{t} \tag{5}$$

In which, the sleeping mount is indicated by Lr, and the total number of sleeping mounts is indicated by t. The DMOA algorithm moves on to the scouting phase after meeting the babysitting exchange requirement.

(4) Scout Group: This is the phase where the mongoose moves around in the best sleeping mound, and the family travels a good distance. As a result, Scout Mongoose is defined as:

$$s_{p+1} = \begin{cases} s_p - D * \alpha_p * z|s_p - \overrightarrow{S}|, if\ \omega_{p+1} > \omega_p \\ s_p + D * \alpha_p * z|s_p - \overrightarrow{S}|, otherwise \end{cases} \tag{6}$$

In this case, the value of D and the value of S can be calculated as,

$$D = \left(1 - \frac{U}{H_U}\right)^{2*\frac{U}{H_U}} \tag{7}$$

$$\vec{S} = \sum_{p=1}^{t} \frac{s_p * L_r}{s_p} \tag{8}$$

In which, z denotes the random value between (0,1). As inferior group members, babysitters are typically young adults who are intent on rousing the feminine alpha to carry out the daily hunting. The DMOA pseudocode is displayed in Algorithm 1.

(5) A Second Look at Feasibility. The solution's viability is assessed in relation to the fitness value calculation. To replace the subpar solution with the superior one iteratively, the optimal solution in this case is the one with the lowest MSE value.
(6) Finalization. The aforementioned procedures are all carried out repeatedly until the ideal outcome is reached. Algorithm 1 shows the DMOA algorithm's pseudocode.

Classification of PDs Using FCBi-LSTMs:

FCBi-LSTMs were utilized in this paper to classify PD's. The computes fuzzy methods weights by modifying membership values in order to extract the most relevant features related to PDs. The chosen attributes from PD datasets are analyzed by CNNs and FCBi-LSTMs. Convolution layers, which make up CNNs, are fed outputs from pooling levels to convolution layers that come after them. Given their knowledge of the local perception of biological vision cells, CNNs use partial filters for convolutions, which provides considerable advantages in feature extraction. The convolution layer's represents the chosen Properties from the PD dataset is enhanced by filtering it into multiple output matrices, each with a range of (Nm+1). The CNN pooling layer serves as a method regarding lowering a matrix's dimension without sacrificing the essential connections between its elements. Average pooling layers, or pooling layers, are fed inputs from convolution layers. As an intermediate variable, the final convolution layer's output is used in the Bi-LSTM data analysis technique. Therefore, there are more applications for LSTM than only changing loop cells and adding nonlinear elements to input. Bi-directional LSTMs perform better than uni-directional LSTMs in terms of capturing structural information, and fuzzy weights are generated using Gaussian membership functions. CNN's convolution layers process the Bi-LSTMs' final outputs to diagnose Parkinson's illness. Bi LSTM and CNN processed features are integrated by multimodal factorized bilinear pooling (MFB).

IV. RESULTS AND DISCUSSION

In comparison to other methods like SVM, CNN, and FCLSTM-CNN (fuzzy convolution long short-term memory-based convolution neural networks), this section explains the experimental results that the suggested FCBi-LSTM classifier produced. Since the test sets had fewer samples, the individual occurrences that remained in the training set were used to assess the performance of LOPO CVs. The class The MIT-BIH arrhythmia database served to investigate arrhythmia recognition and classification systems through the use of MATrix LABoratory R2016a (MATLAB R2016a). The following system specifications have been used in the implementation process: A Windows 8.1 Pro 64-bit operating system, a 1TB hard drive, an Intel (R) Core™i3-4160T CPU@3.10GHz 3.09GHz processor, and 4.00 GB RAM are included.

Dataset

The Voice and Spiral dataset's results are displayed in Figures 3 and 4.

Metrics Utilized for Evaluation

Evaluation Metrics: Evaluation measures exist to determine the predictability of classifiers. While accuracy is a commonly used criterion, conclusions drawn from data with an unbalanced class distribution may be deceptive. The effectiveness of a classifier in differentiating between classes, even when there is a class imbalance, can be assessed using assessment metrics such as MCCs and F-measure. Include the number of instances in each class that are correctly and incorrectly classified in order to enable the confusion matrix shown in in Table 1 to depict binary classification. These letters in the confusion matrix, TP, FP, TN, and FN stands for True Positive, False Positive, True Negative, and False Negative respectively. The following were calculated: recall, F-measure ,precision, accuracy and error using the formulas depending on these counts.

$$Precision = \frac{tp}{tp+fp} \tag{9}$$

$$recall = \frac{tp}{tp+fn} \tag{10}$$

$$F - measure = \frac{2*Precision*Recall}{precision+recall} \tag{11}$$

$$Accuracy = \frac{tp+tn}{tp+tn+fp+fn} \tag{12}$$

$$error = 100 - Accuracy \tag{13}$$

Another statistic that can be used to assess the reliability of binary classifications is the MCC, which accounts for the TP, FP, FN, and TN Counts. Generally speaking, it is seen as a equilibrium measure that may be used even when there is an uneven distribution of classes. The correlation coefficients between expected and actual occurrences are simply called MCCs, and they have a range of -1 to +1.The Score +1 represents perfect predictions between actual labeling and forecast while score -1 shows differences between these two variables.

Table 1: Confusion matrix for two-class classification.

Actual/predicted as	Negative	Positive
Positive	FN	TP
Negative	TN	FP

Comparison of Results:

Three different feature types were used in connection to accuracy, error, F-measure, and MCC in the experimental evaluations of classifiers. The accuracy rate of MFCCs, Wavelets, and Concated features in the CNN combination was 94.1752%, whereas the accuracy rate of MFCCs, Wavelets, and Concated features in the SVM combination was 88.1294%. The accuracy value of TQWT+MFCC+Wavelet is 93.047%, whereas the accuracy value of TQWT+Wavelet+Concat is 93.0854%. Similarly, the accuracy value of TQWT+MFCC+Concat, whereas the accuracy value of MFCC+Wavelet+Concat is found to be 95.1557% for FCLSTM-CNN. By using MFCCs+Wavelets+Concated combinations, the proposed FCBi-WLSTM classifier Reached the best accuracy scores of 98.7720% (F-measure rate of 98.5010% and 71.400% for MCC). The results of the TQWT+MFCC+Wavelet combination were 98.3100%, 96.6381%, 74.300%, and 3.3619%, in that order.

The highest results of f-measures, accuracies, MCCs, and errors were likewise produced by these feature set combinations. These results are displayed in Figures 5-8. At the first feature level combination, the F-measure values of CNN is 85.86%, SVM is 82.91%, and FCLSTM-CNN is 94.22%. With the first level feature combination the proposed FCBi-LSTM achieved an F-measure score of 98.31%. Figure 5 compares the F-measure outcomes of four distinct feature-level combinations using different classifiers.

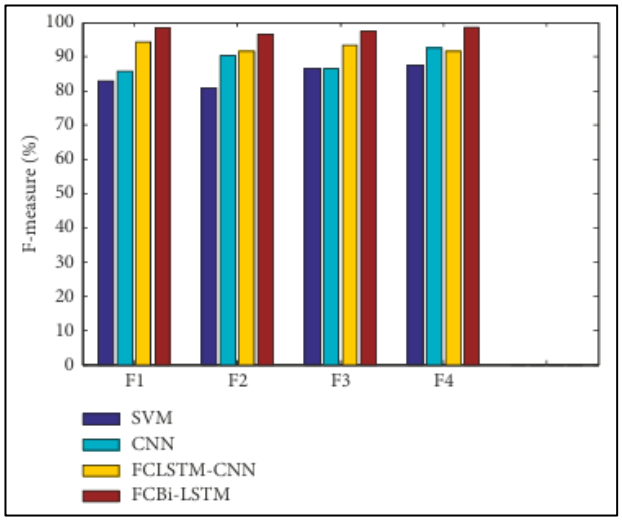

Figure 5: F-measure results comparing classifiers to feature level combinations.
Source: Authors, (2026).

From Figure 6, it is clearly seen that x-axis accuracy is measured with feature-level combinations on classifiers. Compared to SVM, FCLSTM-CNN, and CNN which obtained final feature level combinations with accuracy of 88.1294%, 94.175%, and 95.1557%, respectively, FCBi-LSTM obtained 98.772% accuracy.

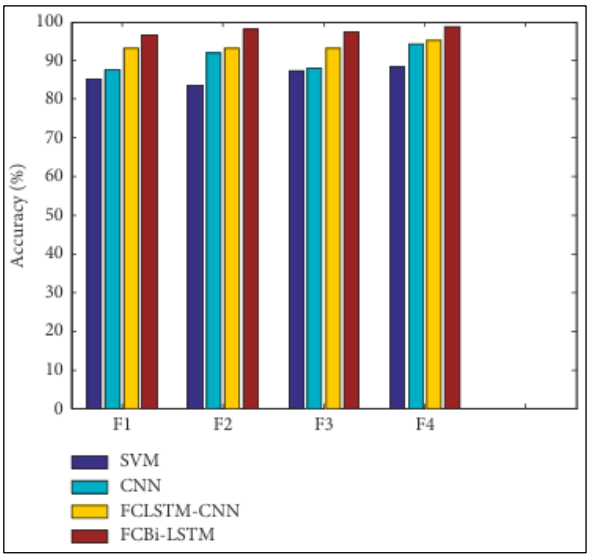

Figure 6: Feature level combination accuracy results versus classifiers.
Source: Authors, (2026).

Comparisons of classifiers with four different feature-level combinations are shown in Figure 7. Figure 4 illustrates that the final feature level combinations for SVM, CNN, and FCLSTM-CNN displayed increased error values of 11.8706 %, 5.8248 %, and 4.8443 %, respectively, but the FCBi-LSTM findings generated lower error values of 1.2280 %. The results presented in Figure 7 contrast classifier performances using four different feature level combinations. Figure 4 shows FCBi-LSTM yielded lower error values of 1.2280 % in its results. However, the final feature level combinations for CNN exhibited the error value of 5.8248 %, whereas SVM exhibited the error value of 11.8706 %, and FCLSTM-CNN exhibited the error value of 4.8443 %.

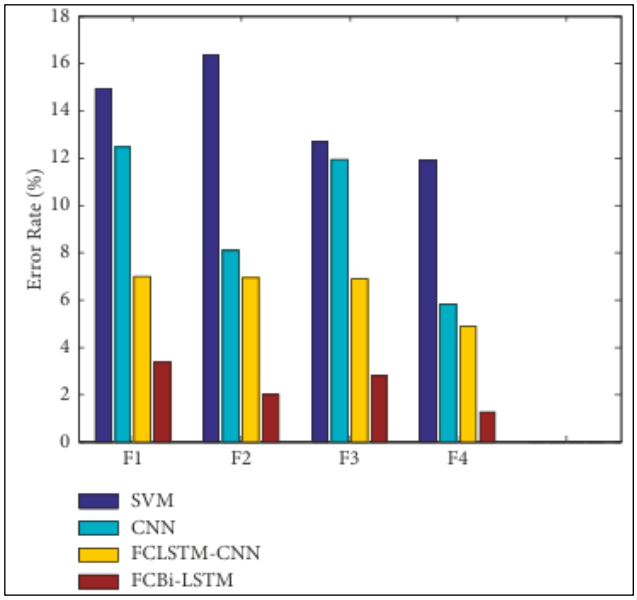

Figure 7: Feature level combination error results compared to classifiers.
Source: Authors, (2026).

A noticeably higher result of 74.30 % is obtained for the developed technique and 57.2007% for CNN, 56.20 % for SVM, and 67.6669 % for FCLSTM CNN classifiers, respectively for the first feature based combination when Figure 8 compared the MCC results, the TQWT+MFCC+ Concat Attribute set. The suggested approach produces better MCC results for all classifiers since it makes advantage of feature selection.

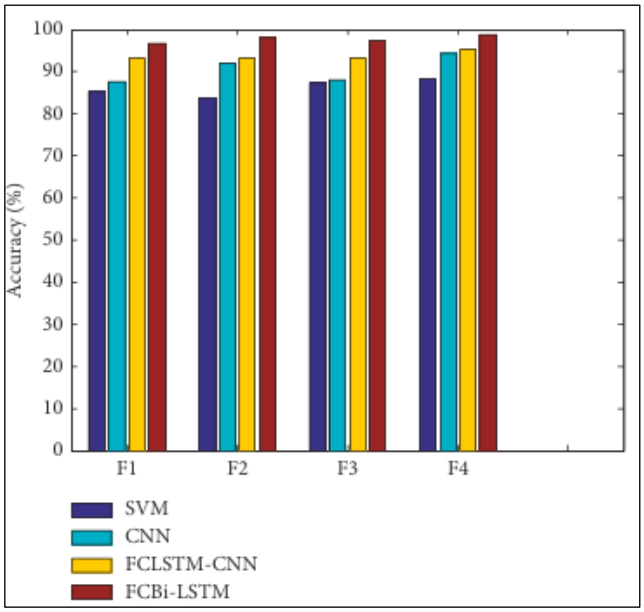

Figure 8: Feature level combination vs. classifiers MCC outcomes.

V. CONCLUSIONS

The second most common neurological condition, PD significantly impairs quality of life, is incurable, and has no known cure. Using neuro-protective and early treatment strategies for PD requires an early diagnosis. In this work, a multiclass classification problem for PD analysis is presented using a feature selection method. FCBi-LSTM and SqueezeNet with DMOA are offered for PD analysis. After that, PD is diagnosed using the FCBi-LSTM classifier. Medical practitioners may be able to better aid PD patients in their recovery and recuperation thanks to this dependable and precise model that accurately detects the illness in its early stages. Precision, recall, accuracy, F-measure, MCC, and F-measure were used to gauge each algorithm's efficacy in the classification process when DL libraries were being evaluated. The accuracy of the suggested model is evident when comparing the results with those of other approaches that are currently in use. Engineering and medicine have a bright future thanks to deep learning. The objective of upcoming work is to creatively expand on previous findings. Multiple data types can enter the network at once thanks to the suggested CNN's Simultaneous convolution layers. Using multimodal data, It allows us to categorize Parkinson's illness. In addition, the writers want to apply further deep learning algorithms to the classification process.

ABSTRACT

In today's power industry, the ever-changing load environment makes accurate load forecasts even more important than ever. Even, day ahead load forecasting is crucial for the successful and efficient operation of the grid. With the absence of good reliable forecasts of daily load fluctuations, systems within the grid can become overloaded, resulting in a failure of the system, thus establishing the need for sound forecasting methods. As a solution to this challenge, different types of deep learning algorithms namely, Long Short-Term Memory, Bidirectional Long Short-Term Memory, Convolutional Neural Network based LSTM, Convolutional Neural Network based BiLSTM are applied for short-term load forecasting in this paper. The efficacy of the various deep learning techniques for short term load prediction is compared. The technique which produces the least value of root mean squared error between real and estimated load, is the most preferred one. The comparative analysis shows that Convolutional Neural Network based BiLSTM technique is a better option for short term load forecasting.

I. INTRODUCTION

A nation's economy mainly depends on the power sector. To improve the nation's economy, power sector must be improved. If power system is stable, then the social stability, national security, economic growth and the overall quality of life of people is stable for a nation. Consumers' expectation from the power system is steadily growing and the power management in the grid is also improving with time. Every Power dispatch center needs load forecasting data for the better load distribution. The power industries must improve their abilities to produce power efficiently to manage the nation's technological advancements and economic improvements [1]. The growing smart grid faces significant challenges in energy management because of the unpredictability of power supply from renewable energy generation and also the power demand. Accurately projecting future generation and load is essential for effective power management [1]. Any significant deviation in the forecasts could result in technical and economic challenges. Furthermore, in deregulated power system markets, the accuracy of forecasted demand is crucial as all participants, from energy producers to customers, rely directly on this information [2]. Load forecasting has drawn a lot of attention from academia and industry due to the use of sophisticated data acquisition systems (like smart meters and Advanced Metering Infrastructure meters, as well as the development of data analytic methods and artificial intelligence. Numerous sophisticated data analysis methods have been developed and are widely used in modern life. Data analytics are crucial to the daily planning and operation of power systems. Predictive models are being used to analyze the demand pattern, with specific electrical generators designated to meet this demand. Load forecasting has different types, depending on the forecasting time horizon. Medium and long-term load prediction cover periods of two weeks and three years, respectively, whereas short-term load forecasting covers intervals of several minutes to one week [3]. Several factors specifically daily, weekly and yearly cycles of demand as well as unpredictable electricity consumption pattern of consumers' appliances contribute to the difficulty of load forecasting. Load also displays a strong correlation with environmental variables like temperature, humidity, solar irradiance, wind speed, etc.

A direct method for forecasting net-load and an indirect method for forecasting gross load and renewable generation separately are discussed in [4]. The findings show that the forecast accuracy is higher in the direct approach. This research also aims to forecast the net load in a power system.

I.1 LITERATURE REVIEW

While Classical models and forecasting methods typically are implemented using ARMA, SARIMA, and ARMAX modelling techniques, in past few years Recurrent Neural Networks (RNN) and Artificial Neural Networks have also received some recognition for possible applications in forecasting [5]. As a result of these advancements in technology, developers have begun testing and using a variety of new models. These new models use Deep Learning techniques to identify key information within the load profile [6]. Although RNNs provide a number of benefits in modelling load time series data, they struggle to model long term dependencies accurately because of their architecture. To solve this issue, developers created Long Short-Term Memory Networks (LSTMs) [7]. Although the base architecture of an LSTM is similar to that of a standard RNN, it incorporates memory blocks to store information. The memory blocks contain both Subnets and Recurrent Connection units, as opposed to the Summation units that are used by the buried layers of RNNs. LSTMs have consistently provided superior performance for solving industrial problems involving time series data compared to RNNs. Through the incorporation of memory units, LSTMs have consistently provided superior results for modelling extremely long-term dependencies in multiple real-world sectors [8]. Long-term memory tasks such as predicting the secondary structure of proteins and context-free grammar were successfully handled by LSTM models [9]. Although LSTM can learn to identify long-term dependencies for sequential data, it is limited to working with historical data; Bi-directional LSTM (Bi-LSTM) is able to utilize both past and upcoming context to produce highly exact estimations. Therefore, when completing tasks where bidirectional information is necessary such as speech recognition or natural language processing, Bi-LSTM has a distinct advantage over LSTM. Whether LSTM or Bi-LSTM should be used in a time series forecasting application will largely depend on how the forecast will be used and on the data being analyzed [10].

By using Bi-LSTM, an analyst can represent complicated patterns and relationships in the data much more efficiently than with unidirectional LSTM operating only in one direction. Combining Empirical Mode Decomposition with the Bi-LSTM approach allows for highly accurate forecasting of both short-term and long-term dependencies of electrical load. The advantages of the new model are evident when considering that it produces more accurate short-term load forecasts than any of the previous models have produced; thus, it is very likely to be an effective method of forecasting energy consumption [11]. Recently, studies investigating the benefit of Convolutional Neural Networks (CNN) for short-term load prediction are conducted. In contrast to LSTM networks, temporal CNN could produce a forecasting model that was both effective and dependable. In this paper, it is suggested using an integrated CNN-LSTM model to predict the future load. Lastly, a unique parallel LSTM-CNN network that was trained for both CNN and LSTM was developed to resolve the short term load estimation problem in smart grids. Results proved that the LSTM-CNN demonstrated good performance [12]. CNN-Bi-LSTM is another model used for load forecasting. CNN handles the missing data, while Bi-LSTM is used for the long term load forecasting. By combining both the models, the results are better for load forecasting for discontinuous dataset [13].

I.2 OBJECTIVES OF THE RESEARCH

By looking into the literature, a detailed study comparing the various deep learning models for short term load estimation is missing. Hence, in this paper, an analysis is conducted on the four prominent deep learning models - LSTM, Bi-LSTM, CNN-LSTM, and CNN-Bi-LSTM, to determine the best technique for load estimation in accordance with the evaluation of results [14]. The primary goal is to identify the optimal approach for load estimation in the power system by assessing the deviation between the real load and the estimated load. In this paper, an aggregated dataset of electrical load profiles from New England, USA is utilized which is not used in the above mentioned papers. Program code for the deep learning models is created using Python.

II. DEEP LEARNING NETWORK ARCHITECTURES

II.1 LSTM ARCHITECTURE

Traditional RNNs have problems in capturing long-term dependencies because of their single hidden state that persists over time. LSTM networks address the issue with long-term storage found in traditional RNN models through a special component called the memory cell which has the ability to hold on information for much longer duration of time. Therefore, LSTM models are excellent at learning temporal relationships over many different time periods and are commonly used in areas such as voice-to-text transcription, translating between different languages and predicting future values based on the data available. Figure 1 shows LSTM model's architecture. In the overall structure of an LSTM model, there are three primary areas known as gates. The input gate is where the new piece of information enters; the forget gate is the place to remove data that is no longer find useful; and the output gate is the point where the information needed is taken out from the memory cell. By selectively controlling the retention and discarding of information at each step, LSTM networks effectively manage long-term dependencies and facilitate strong learning processes [15].

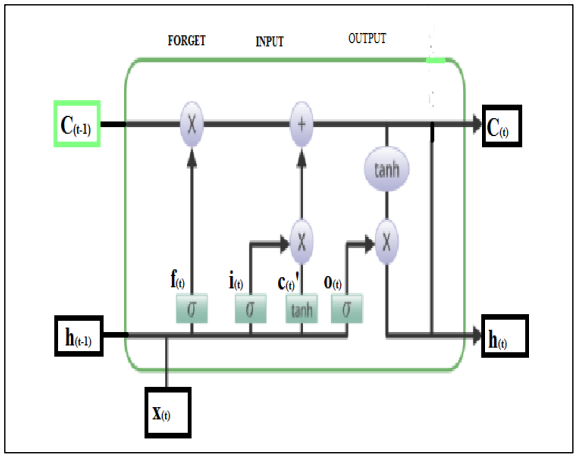

Figure 1: Architecture of LSTM.
Source: Authors, (2026).

II.2 BI-LSTM ARCHITECTURE

Figure 2 demonstrates the architecture of Bi-LSTM model which is a type of sequential model consisting of two LSTM layers: one for handling sequences in forward direction and another for treating sequences in reverse direction. The outputs of both LSTMs are converted to a probability vector and combined to create the final output [9]. Bi-LSTMs are often used when performing Natural Language Processing tasks because they allow the model to have a greater understanding of the complex interrelations between elements of a sequence by using the context to infer the meaning of certain elements.

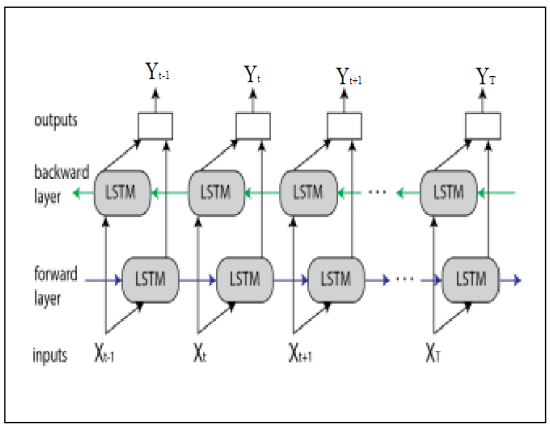

Figure 2: Architecture of Bi-LSTM.
Source: Authors, (2026).

II.3 CNN-LSTM ARCHITECTURE

Combining CNN with LSTM creates a fusion network for Deep Learning that can analyze different types of sequential information. It uses the benefits of both CNN and LSTM networks to learn both spatial and temporal characteristics in sequential data, creating an effective solution for tasks related to video classification, action recognition and spatiotemporal forecasting. In a typical CNN-LSTM architecture illustrated in Figure 3, the role of CNN is to perform the extraction of the spatial features of the data, while the role of the LSTM is to model the temporal dependencies and sequential nature of the data. CNN networks are particularly good at extracting information such as feature maps or key frames using their various convolutional and pooling layers. The CNN network produces a series of spatial feature vectors, which are then fed to the LSTM network to learn the temporal dependencies present inside the data. LSTMs are especially effective at modeling long-term dependence on sequential data since they maintain a memory cell to store and update the values of previous time steps. Therefore, if CNN is employed to pull out spatial peculiarities, and LSTM is used to simulate temporal dependencies of sequential data, then the combined model of CNN-LSTM can learn how the spatial feature vectors relate temporally. The combination of CNNs with LSTMs provides an open way for CNN-LSTM to process and understand complex and sequential information. Because an image or video may be viewed as a sequence of images overtime, this makes it very useful for a variety of applications such as video understanding, action recognition or forecasting time series data [11]. The CNN-LSTM architecture provides a method to analyze both spatial features and temporal features at the same time, making the architecture flexible and very effective at understanding the context of an input sequence as well as recognizing patterns and relationships between elements within that sequence.

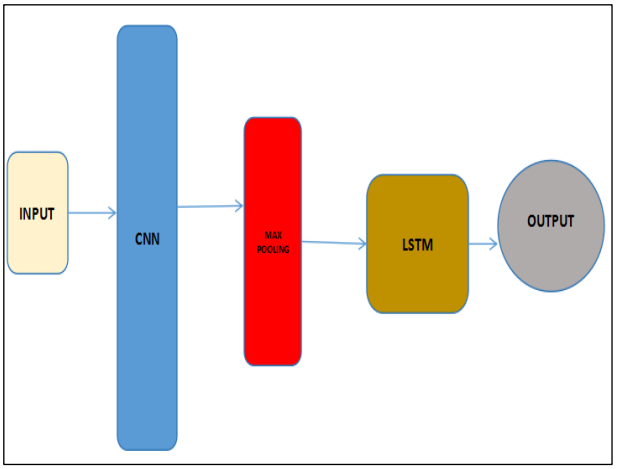

Figure 3: Architecture of CNN-LSTM.
Source: Authors, (2026).

II.4 CNN-BI-LSTM ARCHITECTURE

CNN-BiLSTM is a network architecture that integrates CNN with Bi-LSTM networks demonstrated in Figure 4. By utilizing the information from CNN's features before inputting them into Bi-LSTMs, they benefit from the existing knowledge of how to process inputs. Initially, the dataset was segmented into load profiles containing load values for each day (i.e., load profiles for a 24 hour period) and these profiles were then combined to create a single input for the One Dimensional (1D) CNN layer of the architecture. During the extraction of features from the load profile, the 1D CNN layer used 64 filters with a kernel size (i.e., width and height of the filter) of 3 by 1 and a default stride of 1 when generating a feature vector for each input load profile. After extracting the features from the input load profile data, those raw feature map data are still subjected to max-pooling which decreases the dimensionality of the features but also, likely, loses some of the important aspects of the data; therefore, this loss of important information may account for the decrease in accuracy experienced by the Bi-LSTM networks [12].

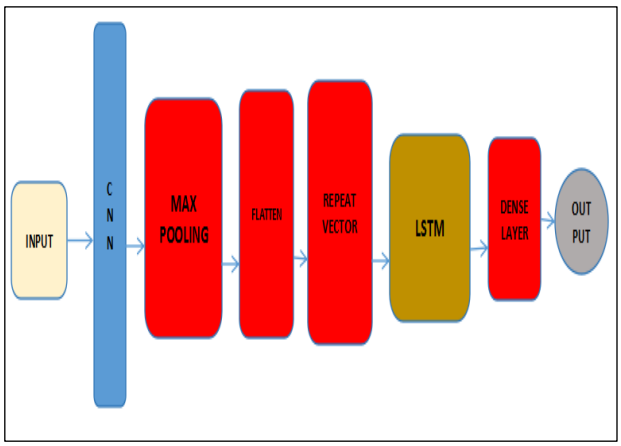

Figure 4: Architecture of CNN-Bi-LSTM.
Source: Authors, (2026).

The feature vector output from the extraction layer of the network will then feed into the Bi-LSTM networks to become the sequential load demand forecasts for the succeeding day's load profile. The fully-connected layer of the network will also include rectified linear unit activation functions for use when creating forecast load profiles, however, the CNN-LSTM versions of the network will only utilize standard, one-way directed LSTM networks for the sequential time series forecasts.

III. METHODOLOGY

III.1 DATASET PREPARATION

The data used in this research comes from aggregated electricity usage profiles in the New England Region in the United States [16]. This dataset used consists of hourly (60 minute) data for active power beginning from January 2019 to January 2024. As part of load forecasting, this study focuses solely on active power measurements. Additionally, as presented in Table 1, the data is classified according to time into training and test sets, which are created using the provided timestamps. In order to prepare the data for use with the models, min/max normalization will be applied to the dataset based on the equation (1).

$$X_{norm} = (X - X_{min}) / (X_{max} - X_{min}) \quad (1)$$

III.2 TRAINING AND TESTING

The dataset used in this study is made up of total load, which was first divided into training and test dataset. The training dataset is then utilized to build up various neural network architectures: LSTM, Bi-LSTM, CNN-LSTM, and CNN-Bi-LSTM; with the test dataset being specifically used to assess the model's efficacy. 70% of data are utilized for training the models and 30% for testing which is shown in Table 1.

Table 1: Data division into training and testing set.

Data Description	Starting date	Ending date
Training Set	06/01/2019	06/07/2022
Test Set	07/07/2022	09/01/2024

Source: Authors, (2026).

Before being passed onto the model during the actual training phase, the training dataset is normalised. The model has been tasked with predicting the demand for the next 24 hours in accordance with the previous history of data [17]. The time window will be moved forward by 1 hour, from the previous hour, during each iteration (1 hour), until all data entries in the dataset are used to train the model. In order to achieve optimal results, increased training set size and well-tuned parameters (Batch Size, Number of Cells, Number of Layers) are helpful. When the model has been trained, a walk-forward testing method can be used to assess the technique's efficacy. To evaluate the performance of the trained model, Root Mean Square Error (RMSE), Mean Absolute Error (MAE) and Mean Absolute Percentage Error (MAPE) are the metrics adopted. RMSE is given by equation (2).

$$RMSE = \sqrt{\frac{\sum_{i=1}^{n}(P_i - O_i)^2}{n}} \tag{2}$$

In this context, 'n' denotes total number of load data within the 24-hour period, where P_i denotes the real load at the 'i^{th}' hour and O_i signifies the estimated load at the 'i^{th}' hour [18]. MAE is the mean absolute deviations between estimated and actual loads. MAPE is the mean absolute percentage deviation between estimated and real loads.

IV. RESULTS AND DISCUSSION

During the testing phase, load is forecasted for the testing period day by day from 07/07/2022 to 09/01/2024, with load forecasted for one day at a time. Figure 5 depicts the plot of actual versus predicted load by all the models, over a 24-hour period for one such testing day which is 4th November 2023. The performance of each model is discussed below.

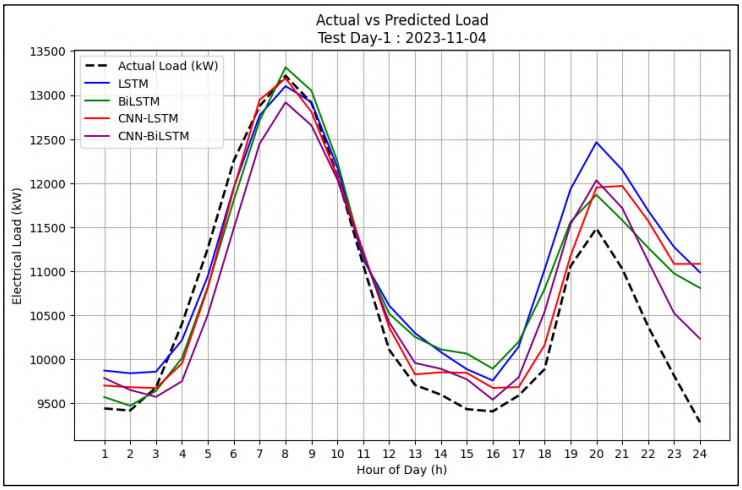

Figure 5: Real Vs forecasted load by all the models.
Source: Authors, (2026).

IV.1 LSTM BASED LOAD FORECASTING

Figure 6 depicts the plot of actual versus predicted load by LSTM model over a 24-hour period for the above mentioned testing day. Figure 7 displays an hourly RMSE plot that compares the real load with the forecasted load. Lower RMSE values indicate more precise estimations. The LSTM forecast method achieves an average daily RMSE score of 0.060051 kW considering all the test days.

IV.5 COMPARISON OF RESULTS

The average RMSE values, MAE values and MAPE % for the different models are presented in Table 2.

Table 2: Prediction error for various algorithms.

Algorithms	RMSE (kW)	MAE (kW)	MAPE (%)
LSTM	0.060051	0.043350	20.883416
BiLSTM	0.060781	0.043708	20.948451
CNN-LSTM	0.061192	0.044336	21.759486
CNN-BiLSTM	0.058449	0.042286	20.667672

Source: Authors, (2026).

According to the results shown in Table 2, the CNN-BiLSTM model exhibits the least RMSE, MAE values and MAPE percentage in comparison to the other techniques. The CNN-BiLSTM model's ability to extract features effectively and to process data bidirectionally, contributes to more valid estimations. For load forecasting in regions like New England, the CNN-BiLSTM model stands out as the best model based on its performance.

V. CONCLUSIONS

Due to the need for sound load forecasting methods for the power industry, this research paper deals with the application of four deep learning algorithms namely, LSTM, BiLSTM, CNN-LSTM, CNN-BiLSTM for short-term load forecasting. These models were trained to forecast the aggregated load of New England Region in the United States, one day in advance based on the previous history of load profile. Results from this study, indicate that the CNN-BiLSTM architecture produces the lowest RMSE error values of any of the models that were tested against it, including LSTM, BiLSTM and CNN-LSTM. The authors speculate that this is due to the combined strength of the hybrid model. Automatic Feature Extraction by CNN and Temporal Dependency Learning by BiLSTM attribute to an accurate modeling of electricity demand patterns.

This research is very much useful to the power industry to advance power system management strategies in the framework of increasing renewable energy integration and smart home technologies. Future evaluations will progressively compare the performance of the models using more dynamic and less predictable data-sets like weather information and wide ranging load profiles.

ABSTRACT

Sweep Frequency Response Analysis (SFRA) serves as a highly sensitive diagnostic technique for identifying mechanical deformations within power transformer windings. The inherent magnetic and capacitive inter-winding couplings in transformers mean that a fault localized to a single winding can propagate detectable anomalies across the frequency responses observed at the terminals of all windings. This study systematically explores this interdependency through detailed simulations and case studies. A comprehensive six-winding equivalent circuit model of a 40 MVA, 132/11 kV power transformer, incorporating both magnetic and capacitive coupling effects is simulated to validate the underlying hypothesis. Complementing this, faults comprising an open-circuit condition and radial buckling were deliberately induced in the low-voltage (LV) winding of a 20 MVA, 66/11 kV oil-immersed transformer for experimental validation. The resultant frequency response traces reveal pronounced deviations in both LV and high-voltage (HV) signatures attributable to faults within a single phase winding. The study concludes that, due to unavoidable coupling, analyzing a single winding signature is sufficient to ensure the presence of mechanical deformation, whereas comparison of multiple signatures retains value for fault localization and severity assessment.

I. INTRODUCTION

Mechanical faults in transformer windings caused by short-circuit forces, transportation shocks or ageing remain a major cause of unplanned outages [1], [2]. Sweep Frequency Response Analysis (SFRA) has become the most widely accepted non-destructive technique for assessing winding integrity because of its high sensitivity to small geometrical changes [3–7]. Recent literature has significantly advanced SFRA interpretation through statistical indices, machine learning classifiers and online monitoring concepts [8–14]. However, the majority of published case studies and interpretation guidelines still treat each winding measurement independently, even though transformer windings are strongly linked by mutual inductance and inter-winding capacitance. Only a few works have systematically investigated how a local deformation propagates through coupling to remote windings [15–16]. In this paper, the influence of inter-winding couplings on the frequency response of the winding under the test is probed through case studies. Also, how this affects the diagnosis about winding deformation is commented. The paper is organized into six sections. Section-02 briefs about inter-winding couplings of transformer and its impact on frequency response. Section 3 demonstrates validation of the impact of inter-winding couplings on the frequency response through simulation. Case studies are presented to understand the winding deformation's interference on the frequency response of a winding undergoing the test, in section-04. Section-05 discuss the case studies results and impact on the diagnosis. Section-06 concludes about the study.

II. INTER-WINDING COUPLINGS AND ITS IMPACT ON FREQUENCY RESPONSE

Transformer design inherently incorporates inter-winding interactions. Windings typically share the core, creating a unified magnetic pathway and enabling inductive linkage [17]. Transformer also provides exposure for the capacitive couplings. The studies have considered the capacitance formed between the turns, between the discs, and between the winding and core / tank. In addition to this, as the outer high-voltage (HV) winding encases the inner low-voltage (LV) winding, with transformer oil providing dielectric separation, facilitating capacitive effects between HV-LV windings. Likewise, the high voltage windings are oriented besides, each other and electrically isolated by the transformer oil. A capacitive coupling can also be observed between HV-HV windings [18]. Figure 1 showcase the capacitive coupling between HV – LV and HV – HV windings. Hence the transformer windings are coupled through the common magnetic domain and the capacitance between HV windings and between HV-LV windings. The magnetic & capacitive couplings are shown in Figure 2.

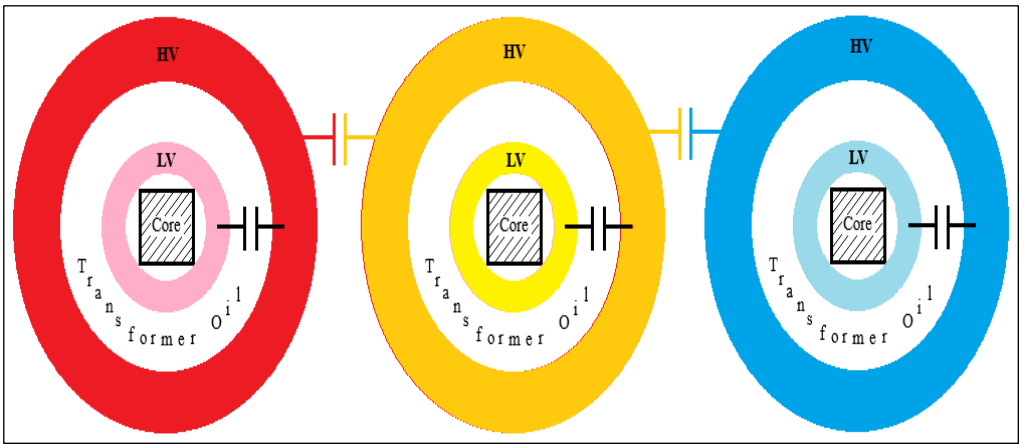

Figure 1: Capacitive coupling between HV – LV and HV - HV windings.
Source: Authors, (2026).

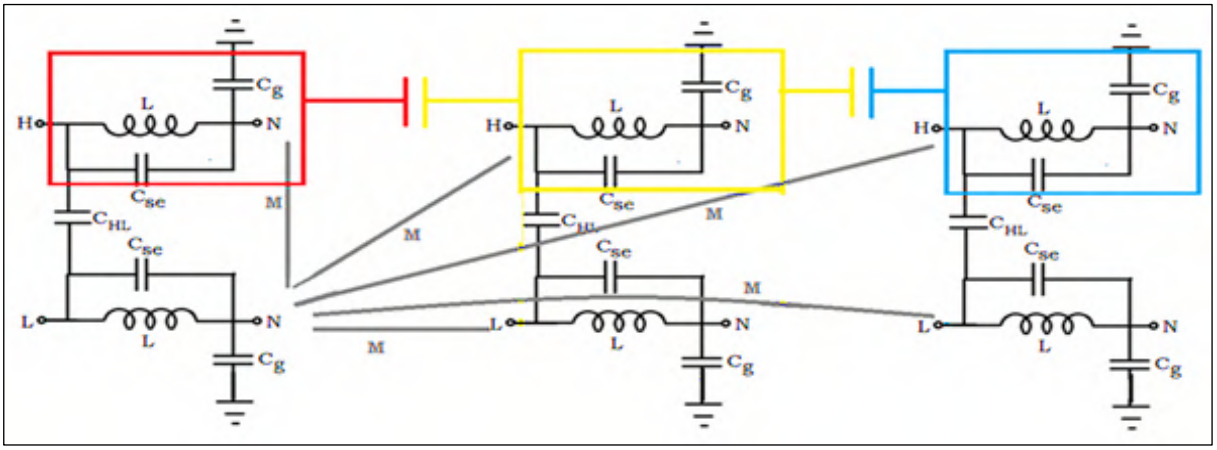

Figure 2: Schematic of capacitive and inductive couplings between transformer windings.
Source: Authors, (2026).

To diagnose the winding deformation, a sweep frequency signal of wide frequency band (20 Hz to 2 MHz, generally) is injected at a terminal of a winding. The test signal comprises of low, medium and high frequency segments. The inter-winding magnetic coupling is dominant in low frequency domain, whereas the capacitive couplings are in high frequency domain. All the inter-winding couplings are active in the window of medium frequency. Hence, the test signal can find the passage through inter-winding couplings to interact with all the windings of the transformer. The frequency response derived from such test signal can carry the information all from the windings. The deformation present in a winding may reflect in the frequency response derived irrespective to pair of winding terminals. It seems the frequency response obtained irrespective to the pair of winding terminals, is the overall response of windings. In the presence of inter-winding couplings, it is almost impossible to obtain individual winding response. Therefore, the study of a frequency response obtained using any pair of the terminals may be sufficient to get an idea about overall condition of windings.

III. SIMULTION

The hypothesis regarding the influence of magnetic and capacitive inter-winding couplings is verified via simulations. For this purpose, a six-winding equivalent circuit model of a 40 MVA, 132/11 kV power transformer— incorporating the magnetic and capacitive couplings as detailed in [19]—is employed. The corresponding inductance matrix and winding parameter values are presented in Tables 1 and 2, respectively, while the simulated winding configuration is illustrated in Figure 3. The fault scenario is emulated by imposing a 30% reduction in the shunt capacitance of the high-voltage (HV) phase-B winding relative to its initial value.

Frequency response signatures are captured for all phase windings across both the HV and low-voltage (LV) sides under healthy conditions and post-fault simulation. Comparative analyses of these signatures for the respective phase windings are depicted in Figures 4–9.

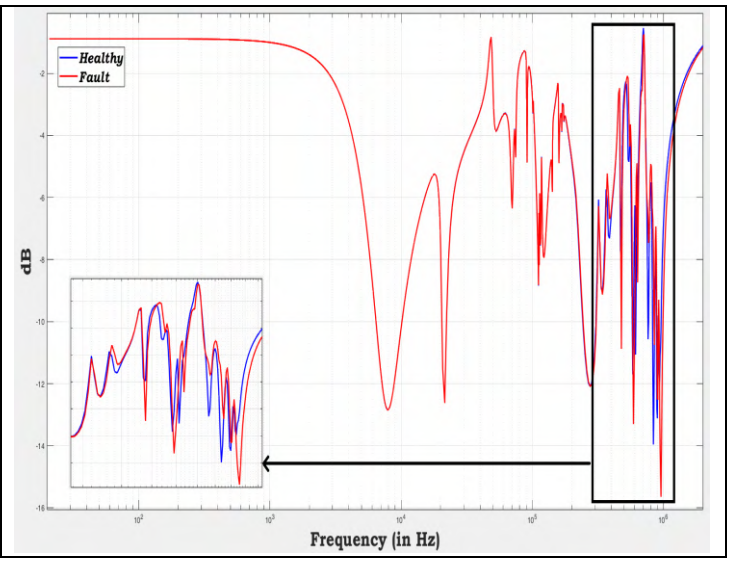

Figure 9: Frequency response comparison of high voltage winding between phase B.
Source: Authors, (2026).

Despite the fault being localized to the HV phase-B winding, discernible deviations manifested in the frequency responses of the LV windings as well as the HV phases R and Y, thereby evidencing the propagated impact. Capacitive elements within the winding model predominantly govern the high-frequency region of the frequency response. Consequently, the observed disparities in Figures 4–9 are confined to high frequencies. The delta-connected configuration of the HV windings implies that the equivalent circuit, when referenced to any HV terminal pair, encompasses contributions from all three HV windings. This inherent interconnectedness accounts for the susceptibility of the HV phase-R and phase-Y responses to perturbations in the HV phase-B winding. Furthermore, inter-winding capacitances between the HV and LV windings (CHL) and among the HV windings themselves (CHH) engender coupling effects. As such, the equivalent circuit referenced to any LV terminal pair integrates the dynamics of all HV and LV windings. These coupling mechanisms collectively ensure that alterations in the shunt capacitance (Cse) of the HV phase-B winding are reflected across the frequency responses of every phase windings.

IV. CASE STUDY

In order to verify the influence of deformation present in the winding – Not Under the test, on the frequency response, a 20 MVA, 66 / 11 kV transformer is introduced with open circuit and radial buckling, in-turn, into phase B of the low voltage side. The frequency response of windings is recorded using a commercial SFRA instrument (Omicron FRAnalyzer) for the stated winding deformation and for the healthy condition. The measurements were performed with End-to-End Open Circuit test configuration, used 50 Ω coaxial cables, frequency sweep 20 Hz – 2 MHz, 1200 logarithmic points and source impedance of 50 Ω.

IV.1 WINDING DEFORMATION TYPE – LV PHASE B OPEN CIRCUITED

Post-deformation FRA traces, captured via a commercial analyzer, are compared in Figures 10-15.

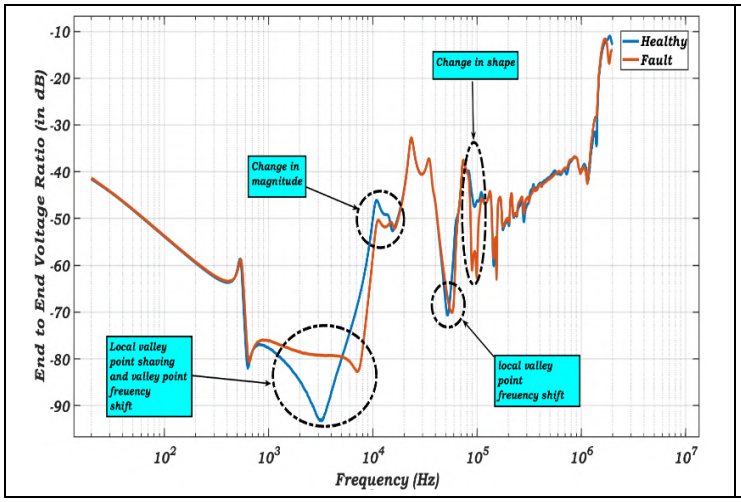

Figure 10: Frequency response comparison of high voltage winding between phase R.
Source: Authors, (2026).

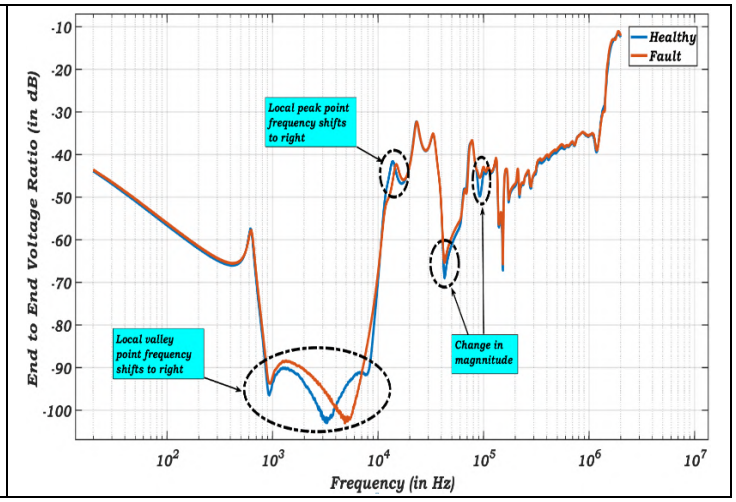

Figure 11: Frequency response comparison of high voltage winding between phase Y.
Source: Authors, (2026).

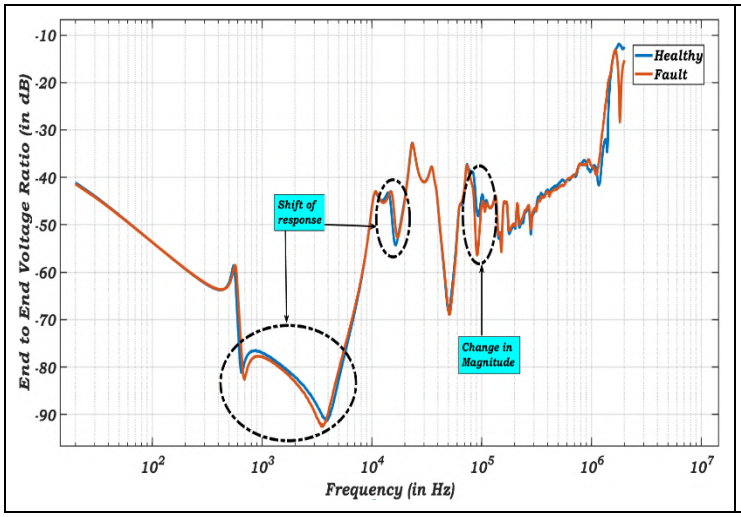

Figure 12: Frequency response comparison of high voltage winding between phase B.
Source: Authors, (2026).

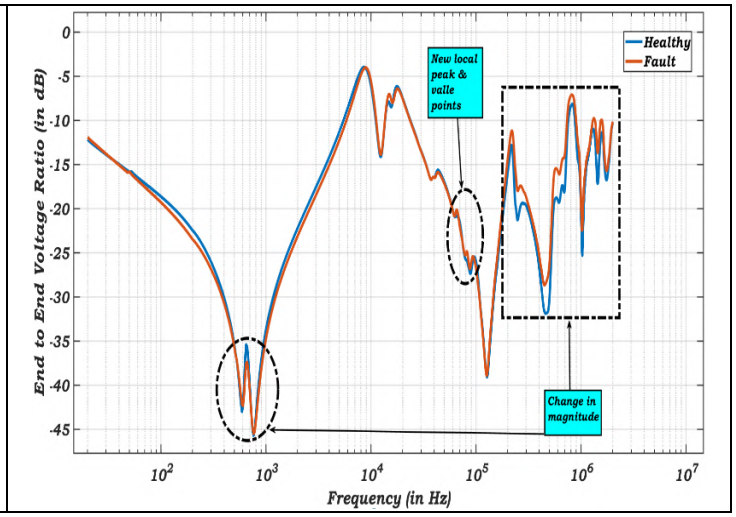

Figure 13: Frequency response comparison of low voltage winding phase R.
Source: Authors, (2026).

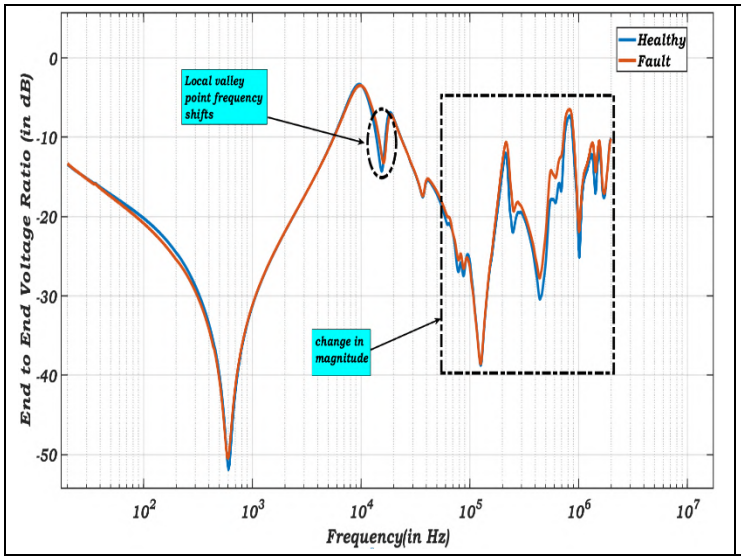

Figure 14: Frequency response comparison of low voltage winding phase Y
Source: Authors, (2026).

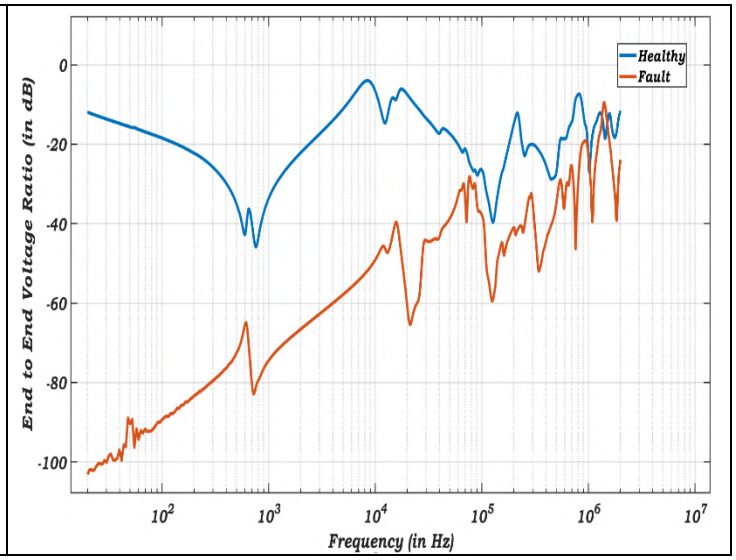

Figure 15: Frequency response comparison of low voltage winding phase B.
Source: Authors, (2026).

The observations are:

- High Voltage Windings - it seems the low and middle frequency regions are disturbed, mostly. It is obvious, as the open circuited LV phase - B has altered overall inductance of the windings and the low and middle frequency regions of signature reflect inductive property of winding. The signatures in low and middle frequency regions show local valley point shaving, shifts in valley and peak frequencies, and change in the shape of the response.
- Low Voltage Windings - the signature of phase B shows complete disagreement with the reference signature, as it is the host of deformation. The signatures of phases R & Y report their partial disagreement in term of change in magnitude of local peak & valley point, introducing a new pair of local peak & valley point and by shift of response.

IV.2 WINDING DEFORMATION – LV PHASE B RADIAL DEFORMATION

Figures 16–21 highlight the comparison between signatures captured after introducing radial deformation to the LV phase B winding and their respective baseline signatures.

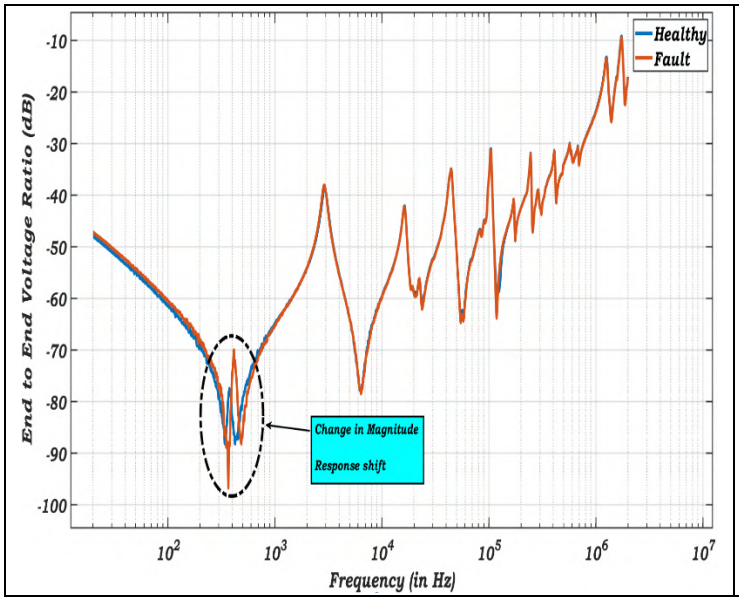

Figure 16: Frequency response comparison of high voltage winding phase R.
Source: Authors, (2026).

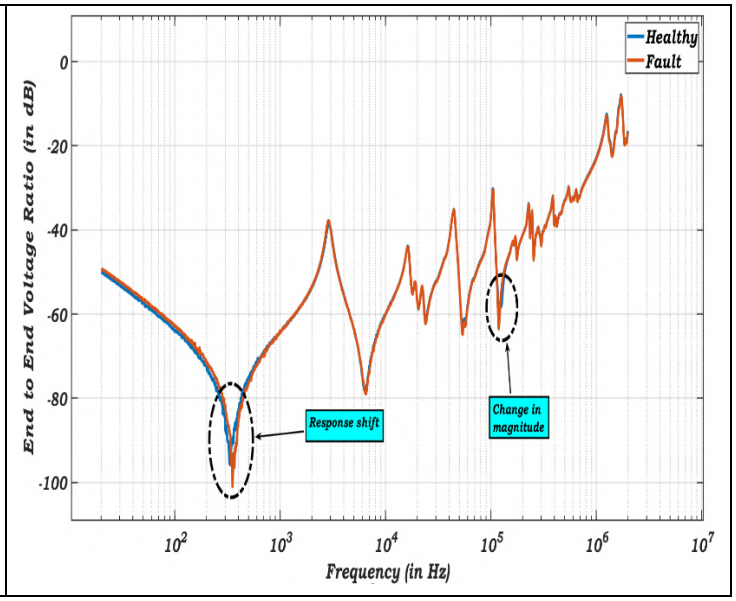

Figure 17: Frequency response comparison of high voltage winding phase Y.
Source: Authors, (2026).

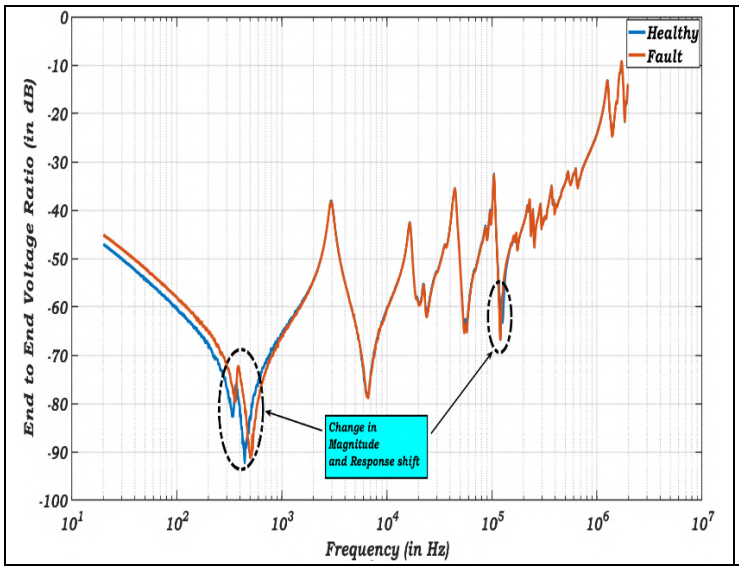

Figure 18: Frequency response comparison of high voltage winding phase B.
Source: Authors, (2026).

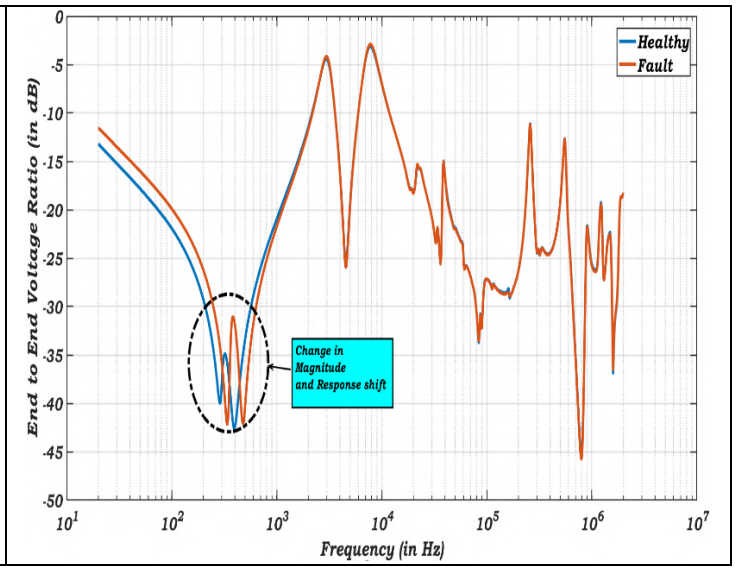

Figure 19: Frequency response comparison of low voltage winding phase R.
Source: Authors, (2026).

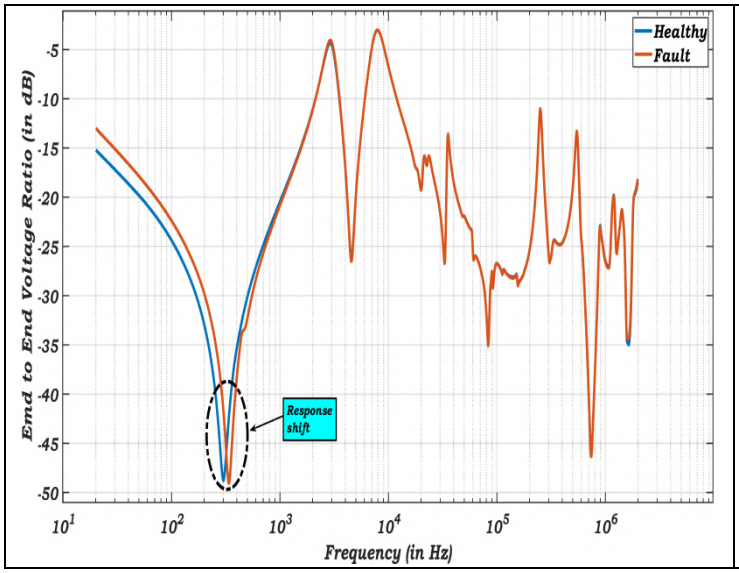

Figure 20: Frequency response comparison of low voltage winding phase Y.
Source: Authors, (2026).

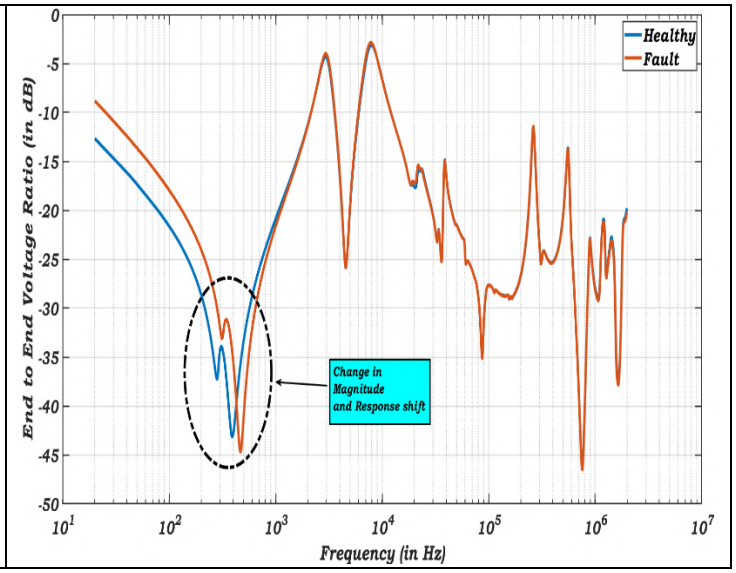

Figure 21: Frequency response comparison of low voltage winding phase B.
Source: Authors, (2026).

The observation is:

- The middle and high frequency regions of signatures have shown good degree of agreement with their respective references. The influence of radial deformation can be seen in the low frequency region of all the windings' (HVs & LVs) signatures, in term of change in magnitude and shift of the response.

V. DISCUSSION

V.1 CASE STUDY RESULTS

Due to delta connections and inter-winding linkages (inductive and capacitive couplings), test signal (sweep frequency signal) propagates system-wide, embedding condition data from multiple windings in a single trace. The experiment results clearly observe the deformation located in one of the windings, infect the signature of all the windings more or less. The degree of influence is dependent on how closely it is attached with the victim winding. The degree of disagreement offered by the deformed winding is significant large as compared to others but the scale of disagreement noticed in the signature of rest windings are not of negligible level.

V.2 PRACTICAL CONSEQUENCES FOR FIELD DIAGNOSTICS

Because of unavoidable coupling, every SFRA trace contains information about the mechanical condition of all windings. Consequently:

- Recording and analyzing a single accessible winding is sufficient to detect the presence of mechanical deformation with very high confidence.
- Comparing signatures from multiple terminals remains valuable (and recommended by standards) when the transformer is ready to get removed from service and maintenance, the phase and winding that shows the largest deviation usually indicates the fault location.

Thus, the common field practice of measuring only single accessible winding for quick screening is technically justified, whereas full measurement of all six terminals is still beneficial for detailed post-fault investigation.

VI. CONCLUSION

The results clearly show that inter-winding couplings make every SFRA trace a "global" indicator of the transformer's mechanical integrity. A local deformation confined to one LV phase produced unmistakable changes in all HV and LV traces, especially below 200 kHz. These findings provide justification for the field practice of measuring only the most accessible terminals (typically the HV side) for rapid go/no-go screening. At the same time, recording and comparing signatures from multiple terminals continues to offer superior fault-type discrimination, location capability, and severity grading when the transformer is ready for detailed investigation. The results therefore support simplified measurement procedures without sacrificing diagnostic reliability, while preserving the full value of complete SFRA datasets for post-fault analysis and repair planning.

ABSTRACT

Alzheimer's disease is neurodegerative disorder that affects memory of a person and also the day to day activities of them. Normally, Alzheimer's disease can be identified by using the MRI scans which consist of high dimensional data. Traditional machine learning models are filed to give higher accuracy while diagnosing the disease. Quantum technologies plays a vital role and its emerging technologies that produce higher accuracy compared to traditional models. In this study we provide a comprehensive review of quantum technology such as Quantum Machine Learning (QML), Quantum Neural Networks (QNN) and Hybrid Quantum Models. Key factors of this study include early identification of Alzheimer's disease by utilizing the higher dimension of data like MRI images. Further, this article focuses on the application, limitations such as hardware constraints and scalability of clinical decision support system.

I. INTRODUCTION

Alzheimer's disease is a primary cause of dementia which accounts 60-80% of cases in worldwide. The stages of this disease can be categorized by memory impairment, functional dependency, gradual cognitive decline which burden the individual and the persons who take care of them. The traditional approaches like machine learning models are failed in early diagnosis of Alzheimer's disease, timely interference and enhanced patient outcomes. To diagnose the Alzheimer's disease, neuro imaging dataset like Fluorodeoxyglucose Positron Emission Tomography (FDG-PET) and structural Magnetic Resonance Imaging (sMRI) and the behavioural activities and handwriting are used. In recent year's artificial intelligence, machine learning models have provided a significant improvement in AD classification [1] analysis. In spite of this advances the classical AI model produce poor accuracy in terms of high dimensional data. Quantum computing techniques are the emerging alternatives which uses its principles like superposition and entanglement. Quantum Machine Learning (QML) models used to analyse neuro imaging behavioural and genomic data that capture the complex patterns beyond classical models. Current diagnostic techniques for AD simple relied on clinical test, neuropsychological test, Magnetic resonance imaging (MRI) and positron emission tomography (PET) and cerebrospinal fluid (CSF). When using these methods it often leads to limited accessibility, high cost, and reduced sensitivity in mild cognitive impairment (MCI) stage [2]. Similarly, computational intelligence methods have gained advancements in decision support system to help clinicians in early and accurate identification of AD. This paper provides wider analysis of quantum computing and QML models applied to the Alzheimer's disease research direction. This study also examines the existing literature on quantum learning models and highlights its advantages limitations compared with traditional approaches. Also it discusses the challenges such as scalability, interpretability, and data encoding. By combining current advancements, this study pioneering the quantum computing research into next generation of Alzheimer's disease prediction and decision support system.

II. BACKGROUND WORK

Recent research shows the application of quantum computing and QML methods used for Alzheimer's disease (AD) analysis across multiple data modalities. Kaewta et al. proposed QENNA, a quantum-enhanced neural network that combines quantum convolutional layers with traditional deep learning models to enhance early identification of AD disease using MRI data [3]. By combining quantum data augmentation strategies like Quantum Generative Adversarial Networks (GAN) and quantum random walks, this method effectively address the data scarcity and attain superior diagnostic performance compared to state-of-the-art models. Likewise, Rajesh et al. suggested a hybrid quantum framework using Quantum Neural Networks for MRI-based Alzheimer's disease prediction [4], that provides better accuracy over traditional machine learning approaches. Further than neuroimaging, quantum artificial intelligence also applied to non-invasive behavioural analysis. Cappiello and Caruso suggested quantum machine learning models [5] for early identification of AD disease using handwriting dynamics from the DARWIN dataset, which shows that quantum classifiers outperformed traditional counterparts while offering improved interpretability. For molecular and genomic level, Konar et al. proposed Alz-QNet, a quantum gene regulatory networks model for complex gene–gene interactions [6] associated with AD progression using single-nucleus RNA sequencing data from the entorhinal cortex, provided that insights into possible gene-expression-based theranostic strategies. Further, the Quantum computing has been explored in multimodal and optimization-driven frameworks. Odusami et al. described a quantum-optimized approach for AD stage identification by combining sMRI with FDG-PET images [7] and optimizing a Mobile Vision Transformer using Pareto-Optimal Quantum Dynamic Optimization, that provides high precision, sensitivity, and specificity on ADNI and OASIS datasets. In a wider clinical framework, Mohamed et al. suggested the transformative potential of quantum computing in neurosurgery [8], emphasizing its ability to improve diagnostic accuracy, surgical precision, and personalized neurological care, thus providing significant contextual motivation for quantum applications in neurodegenerative disorders. Additionally, Chandramohan described quantum chemical calculations and molecular docking simulations to analyze protein–ligand interactions related to Alzheimer's disease [9], highlighting the role of quantum chemistry in analyzing potential therapeutic drug candidates. Together this study identifies the quantum computing models that provide a enhanced improvements in Alzheimer's disease prediction across genomic analysis, screening, diagnosis, and optimization; further it can be motivate advanced analysis in terms of scalability in quantum enhanced frameworks.

III. BIO-MARKERS AND DATA MODALITY FOR ALZHEIMER'S DISEASE

III.1 GENETIC AND MOLECULAR DETERMINANTS IMPLICATED IN ALZHEIMER'S DISEASE IDENTIFICATION

Alzheimer's disease is a complex network pattern of gene regulatory that can affect the neuronal survival, neurodegeneration and synaptic integrity. Yin Yang 1(YY1) is an important factor whose dysregulation improves neuronal apoptosis, via modulation of Fuz gene, quickening cognitive decline. Some other genes put together in AD pathology in various interconnected ways. Growth Arrest-Specific 7(GAS 7) gene controls neuronal maturity and cytoskeletal coordination with dysfunction impairment of microtubule transport and synaptic stability. Early Growth Response 1(EGR1) regulates neurotransmitter and synaptic plasticity that adjust acetylcholinesterase and microRNA-132, also it upset tau phosphorylation and amyloid-beta generation. Fibroblast Growth Factor 14(FGF14) affects neuronal activity and synaptic formation through voltage sodium channels by combining dysregulation linked to modify amyloid pathology and cognitive deficits. Phospholipase D Family Member 3(PLD3) correlate with amyloid plaque-linked axonal spheroids and modulation can improve synaptic resilience that can slowdown the cognitive decline. Altogether, these genes can form a multifaceted molecular structure for Alzheimer's disease that shares the pathway and potential targets for precision therapeutics.

III.2 NEUROIMAGING DATA AND DATASET REPOSITORIES USED FOR ALZHEIMER'S DISEASE

Magnetic Resonance Imaging (MRI) is widely used for Alzhiemer's disease prediction to identify the structural and behavioural changes in the brain. T1-weighted MRI scans are widely used to identify the hallmark behavioural changes in brain [10] including hippocampal atrophy, ventricular enlargement, and cortical thinning. This study analyzes behavioural, structural, and molecular datasets to assess the quantum-enhanced neural network (Alz-QNet) for Alzheimer's disease classification. Structural MRI and FDG-PET images are the publicly available repositories, including the Alzheimer's Disease Neuroimaging Initiative (ADNI) and OASIS databases. These datasets contains high quality, pre-processed T1-weighted MRI scans and PET images with standardized achievement protocols that enables reproducible analysis and reliable evaluation of neurodegenerative markers such as hippocampal atrophy and cortical thinning. The DARWIN handwriting dataset also provides complementary behavioural information, like capturing kinematic and pressure features from multiple errands performed by participants with and without Alzheimer's disease. Molecular-level insights were provided by GSE138852 single-nucleus RNA sequencing dataset that can be collected from the entorhinal cortex of Alzheimer has and control brains. Target genes were observed based on pathway relevance, region-specific dysregulation, and therapeutic potential. Gene expression values were regularized, log-transformed, and binarized to present biologically meaningful activation states suitable for quantum circuit encoding. Together, these datasets provide balancing perspectives on Alzheimer's disease, supporting a holistic assessment of Alz-QNet by incorporating anatomical, behavioural, and molecular features to model disease progression with quantum-enhanced computational techniques. Figure 1 represents various stage of dementia extracted from publically available dataset.

IV. PRINCIPLES OF QUANTUM COMPUTING

IV.1 QUBITS AND SUPERPOSITION

A qubit is the primary unit of quantum computation [11], which is capable of superposition in basis states $|0\rangle$ and $|1\rangle$:
Qubit computation

$$|\psi\rangle = \alpha \mid 0\rangle + \beta \mid 1\rangle \quad (1)$$

IV.2 QUANTUM GATES

Quantum gates carry out unitary transformations on qubits to manipulate their states [6]. Common gates include:

- NOT (X) Gate: Flips $|0\rangle \leftrightarrow |1\rangle$.
- Hadamard (H) Gate: Generate an equal superposition:
  - $|0\rangle \rightarrow (|0\rangle + |1\rangle)/\sqrt{2}$, $|1\rangle \rightarrow (|0\rangle - |1\rangle)/\sqrt{2}$.
- Controlled-NOT (CX) Gate: Flips a mark qubit only if the control qubit is $|1\rangle$.
- Rotation (RY) Gate: Rotates a qubit state with respect to the Y-axis by an angle θ.
- Controlled-RY (CRY) Gate: Apply an RY rotation to the target qubit with the condition of $|1\rangle$. This gate is a primary key for modeling pairwise interactions, such as gene regulatory relationships.

IV.3 ENTANGLEMENT AND MULTI-QUBIT SYSTEMS

Entanglement is a quantum occurrence where qubits' states are mutually dependent, allowing the encoding of complex correlations. In genetic systems, entangled qubits can represent interacting genes or other dependent variables efficiently.

IV.4 QUANTUM CIRCUIT IMPLEMENTATION IN ALZ-QNET

In Alz-QNet model [6], each qubit stand for a gene in Alzheimer's disease. The structural design is divided into encoder layers, which convert single-nucleus RNA-seq data into superposition states, and regulation layers, where CRY gates snare qubits to model gene-gene interactions. Rotation angles of CRY gates match to the strength of interactions. The outputs are calculated to generate probability distributions of gene activity that smoothed by using Laplace smoothing and optimized via gradient descent. This framework exploits quantum parallelism to form gene regulatory networks powerfully, capturing the discrete switch-like behaviour of gene expression while reducing computational complexity.

V. DATA PRE-PROCESSING AND FEATURE EXTRACTION

Pre-processing is a significant step in both classical and quantum-based methods. MRI images are shrunken to remove irrelevant features, resized to standardized dimensions, and normalized to consistent intensity levels. Noise reduction methods, including Gaussian and median filtering; helps to remove artifacts while protecting important features.

Deep learning or quantum convolution layers are used to extract relevant features [12], also ensemble and hybrid models are incorporates features from multiple networks to create more discriminative representations. This combination of pre-processing, feature extraction, and hybrid modelling guarantees robust and clinically meaningful Alzheimer's disease prediction.

VI. QUANTUM COMPUTING METHODS FOR ALZHEIMER'S DISEASE PREDICTION

VI.1 CLASSICAL DEEP LEARNING METHODS

Alzheimer's disease prediction has usually depends on classical deep learning models, particularly convolutional neural networks (CNNs) [13], [3], [6]. The convolutional neural networks (CNNs) has the ability to automatically extract relevant features from brain MRI images. Architectures such as VGG16 and ResNet50 have been widely used. VGG16 contains multiple convolutional layers that discover hierarchical features [14] from MRI images, while ResNet50 initiate residual connections to overcome vanishing gradient problems in deep networks. Ensemble approaches that merge features from multiple CNNs [1] this can be demonstrated by improved classification performance, as they integrate complementary information from various architectures. Pre-processing step includes intensity normalization, noise reduction, image resizing, and classical data augmentation techniques such as zooming, brightness adjustments, rotations, and translations, have proven necessary to improve generalization and address class imbalance in datasets.

VI.2 QUANTUM MACHINE LEARNING MODELS (QML)

Recent studies in quantum computing have enabled pioneering methods for Alzheimer's disease prediction. QML models, such as Quantum Support Vector Machines (QSVMs) and Quantum Convolutional Neural Networks (QCNNs) [13], [3], maps classical MRI features into high-dimensional quantum Hilbert spaces that increase the separability of Alzheimer 's disease stages. QCNNs convert MRI images into qubits using amplitude encoding and apply parameterized quantum gates to extract non-local spatial features, Quantum data augmentation models, including Quantum Random Walks (QRWs) and Quantum Generative Adversarial Networks (QGANs), provides stochastic variations and generate high-fidelity synthetic MRI images [15], that increase dataset diversity and reduce overfitting, thereby enhancing model robustness.

VI.3 QUANTUM STATE ENCODING

To present MRI image in a quantum system, amplitude encoding maps pixel intensities into a quantum state:

$$| \psi\rangle = \sum_{i=1}^{N} x_i \, | i\rangle \tag{2}$$

Here, x_i is the normalized pixel intensity, N is the sum of pixels, and $|i\rangle$ is the computational basis state of the quantum register.

VI.4 QUANTUM CONVOLUTION OPERATION

Quantum convolutional layers affect parameterized unitary operations to extract features:

$$U(\theta) \, | \psi\rangle = \prod_j RZ\,(\theta_j) RX(\theta_j) CNOT \, | \psi\rangle \tag{3}$$

The above formula applies the rotations and entanglement to encode spatial correlations across the image.

VI.5 QUANTUM POOLING

Pooling can be done by using Grover's amplitude amplification:

$$\rho = (2 \, | \psi\rangle\langle\psi \, | - I)O \tag{4}$$

Where O marks major quantum states, $|\psi\rangle$ represents the quantum feature state, and I represents the identity matrix. This amplifies diagnostically important features while removing irrelevant information.

VI.6 HYBRID QUANTUM FRAMEWORKS

Hybrid quantum traditional models influence the strengths of both paradigms for more accurate Alzheimer's disease prediction. In these frameworks, quantum layers carry out non-local feature extraction throughout entanglement; detain subtle structural variations across far-away brain regions, while traditional neural network layers offer stable gradient-based optimization and ending classification. MRI images are encoded into quantum states [5], which are then processed throughout quantum convolution and pooling layers. The resultant quantum-derived features are passed to fully connected layers to classify multiple stages of Alzheimer's disease. Quantum mechanisms, such as superposition and amplitude amplification, allow the capture of distributed and low-intensity patterns that may be missed by traditional models, while quantum parallelism advances computational efficiency compared to traditional convolution and pooling operations. Figure 2 represents the framework of quantum computing models for Alzheimer's disease prediction.

VI.7 HYBRID PARAMETER UPDATE

Parameters of quantum and classical layers are optimized together:

$$\theta^{(t+1)} = \theta^{(t)} - \eta \nabla_\theta L \tag{5}$$

$$W^{(t+1)} = W^{(t)} - \eta \nabla_W L \quad (6)$$

Where θ is the quantum parameter, W is the neural network weight, η is the learning rate, and L represents the loss function.

VII. COMPARATIVE ANALYSIS OF QUANTUM COMPUTING WITH CLASSICAL AI

Traditional artificial intelligence models like machine learning and deep learning techniques played a vital role in identification of Alzheimer's disease. The classical deep learning models such as Convolutional Neural Networks (CNN), Recurrent Neural Networks(RNN) and ensemble learning have provide good results in AD classification using neuroimaging data like MRI and PET scans. These models outperformed only with the mature training algorithms and scalable computational infrastructures by using hierarchical feature extraction techniques. Nevertheless, these techniques often affected by the curse of dimensionality and limits interpretability, also it has high computational cost while deals with multimodal and high-resolution biomedical data. In contrast, quantum-computing models provide computationally different paradigm that leverages the quantum properties like quantum inferences, super position and entanglement. Quantum Machine Learning (QML) techniques can fix the complex biomedical data into high dimensional quantum Hilbert spaces using limited computational resources contrast to classical representation. This allows quantum techniques to identify the subtle, non-linear association presents in neurological, genetic and behaviour data that may be difficult for traditional AI models to predict effectively. As result, quantum enhanced models provides a promising early stage AD identification that are often overlooked by traditional models. Another important distinction is feature representation and optimization. While using medical datasets with limited samples the traditional deep learning models rely on gradient-based optimization techniques that need more number of parameters, which leads to overfitting. Hybrid Quantum models reduce parameter complexity by utilizing quantum circuits for feature extraction and traditional classifiers for classification. This hybrid technique offers improved generalization in limited dataset that common in Alzheimer's prediction. In spite of its advantages, quantum techniques are not fully replacing the traditional AI models. Quantum models also have their own limitations like noise, qubit scalability, decoherence which control the strength and size of quantum circuits. Thus, the traditional models are more suitable for large-scale clinical operations. However, the quantum computing technologies offers enhanced feature learning, improved computational efficiency, that enables more constructing modelling of Alzheimer's disease prediction. In view of this beneficial relationship, quantum computing is seen as a promising replacement of traditional AI methods in Alzheimer's disease research.

VIII. APPLICATIONS OF QUANTUM COMPUTING

Quantum computing and quantum machine learning models provides significant improvement in Alzheimer's disease research. These models can enhance early identification by efficiently analyzing high dimensional neuroimaging [2], [16], behavioural, and genomic data. Quantum convolutional neural networks able to extract the subtle structural and functional patterns from MRI and PET scans, where traditional approaches are failed. Quantum-enhanced regression and classification models can identify complex gene–gene relations and molecular pathways, facilitating the identification of novel biomarkers and potential therapeutic targets. Hybrid quantum framework combines the strengths of both paradigms to enhance prediction accuracy, optimize disease stage classification, and support modified treatment planning. In addition, quantum-based data augmentation models, such as Quantum Generative Adversarial Networks (QGANs), improve model robustness by producing synthetic high-fidelity data for training in cases of limited datasets.

IX. LIMITATIONS OF QUANTUM MODELS

Quantum computing models for diagnosing Alzheimer's disease has some limitations in terms of modern quantum hardware such as gate fidelity, number of qubits and coherence time that restricting the scale of problems being addressed. Quantum models require complex programming formats that can be mapped into quantum states which can be computationally exhaustive that may leads to noise. Hybrid quantum models gives promising results but they still rely on classical optimization approaches and it may not completely exploit quantum advantages. In addition to the standard dataset the quantum models poses challenges for validation and reproducibility. Interpretability is remains an issue of quantum models making it difficult to explain predictions and clinical context.

X. CONCLUSIONS

Quantum models present a novel paradigm for Alzheimer disease research with unseen possibilities for early prediction, molecular analysis and customized therapy techniques. Quantum Machine Learning models that includes QCNN and hybrid frameworks have provides promising results while capturing complex patterns in neuroimaging, behavioural activities and genomic dataset. Quantum models also have major challenges that include hardware limitations, training high dimensional data and interpretability. Integrating quantum models with deep learning techniques produce enhanced results in terms of accuracy in clinical decision support system. This study highlights the recent scenario of research in Alzheimer's disease prediction with emphasizing potential benefits and it needs further exploration in computational and clinical aspects.

XI. FUTURE ENHANCEMENTS

Further research focuses on developing scalable quantum models that can handle higher dimension and complex multimodal image dataset. Quantum hardware advancements include increased qubit counts, error correction that is necessary for benefiting the implementation of quantum computing in Alzheimer's disease research. To improve the model transparency that facilitate the clinical adoption and trust the Quantum AI technique can be integrated with the classical models. Increasing use of longitudinal data analysis multi-omics could find new biomarkers into disease development. Cooperation between neuroscientists, clinicians and quantum computing experts is needed to produce most relevant models, confirm predictions in real world datasets, and transform quantum enhanced models into viable therapeutic tools for Alzheimer's disease prediction.

ABSTRACT

Accurate parameter identification of photovoltaic (PV) models is essential for reliable performance prediction and optimization of energy systems. However, estimating the parameters of advanced equivalent circuit models is challenging due to the nonlinear and multimodal nature of their current–voltage (I–V) characteristics. This study proposes a parameter extraction approach based on the Flow Direction Algorithm applied to the Three-Diode Model (TDM). The method minimizes the root mean square error (RMSE) between measured and simulated I–V data while ensuring physically consistent parameter sets. The approach is validated using two benchmark photovoltaic devices: the **RTC** France solar cell and an amorphous silicon thin-film solar cell. For the **RTC** France cell, the proposed method achieves an RMSE of 7.3511×10^{-4} when fitting the experimental I–V characteristics using the TDM. For the amorphous silicon cell, the algorithm obtains an RMSE of 2.2939×10^{-5}, demonstrating a very close agreement between the measured and simulated electrical characteristics. These results confirm that the FDA-based optimization approach provides accurate parameter estimation for complex PV models, enabling reliable photovoltaic modeling and supporting improved performance analysis and energy system optimization.

I. INTRODUCTION

Photovoltaic (PV) technology has become a cornerstone of modern renewable energy systems due to its sustainability, reliability, and steadily declining costs. Accurate modeling of PV devices is essential for performance evaluation, system design optimization, and efficient integration into energy networks. Among the various modeling approaches, equivalent circuit models—such as the single-diode, double-diode, and three-diode configurations—are widely adopted because they provide a practical balance between modeling simplicity and predictive accuracy. However, estimating the parameters of these models remains a challenging task due to the nonlinear and high-dimensional nature of the optimization problem. Conventional optimization techniques often encounter difficulties in obtaining accurate and stable solutions, particularly under varying environmental conditions. Consequently, metaheuristic optimization algorithms have emerged as effective alternatives, offering strong capabilities for exploring complex search spaces and avoiding local minima. Within this framework, the Flow Direction Algorithm (FDA), inspired by hydrological runoff processes, provides an efficient strategy for parameter optimization. By simulating water flows toward a basin outlet, FDA effectively balances global exploration and local exploitation, enabling reliable convergence toward optimal solutions. In this study, FDA is applied to parameter identification for both monocrystalline silicon like **RTC** France and amorphous silicon (**a-Si**) thin-film photovoltaic cells. The performance of the algorithm is evaluated through comprehensive statistical analysis and compared with several state-of-the-art optimization techniques reported in the literature. Accurate modeling and parameter identification of photovoltaic modules are fundamental for maximizing energy harvesting, predicting long-term performance, and ensuring operational reliability under diverse and fluctuating environmental conditions.

Over the past decade, extensive research efforts have focused on developing robust and efficient methods for estimating the unknown parameters of diode-based PV models. Among these models, the Three-Diode Model (TDM) has attracted significant attention because of its superior ability to capture the complex nonlinear characteristics of PV cells, although it introduces a more challenging parameter extraction problem. The inherent difficulty of photovoltaic (PV) parameter identification arises from the multidimensional, nonlinear, and multimodal nature of the associated search space. Consequently, metaheuristic optimization techniques have become widely adopted due to their ability to efficiently explore complex solution landscapes. Over the past few years, numerous enhanced optimization strategies have been introduced to improve the precision and robustness of PV model parameter estimation. For example, the Improved African Vultures Optimization (I-AVO) algorithm, which integrates Opposition-Based Learning and Orthogonal Learning mechanisms, has demonstrated promising results when combined with the Newton–Raphson method for parameter refinement [1]. Likewise, the augmented Mountain Gazelle Optimizer (AMGOIB3H) has shown strong reliability and fast convergence when tested with experimental PV datasets [2]. Other studies have explored the incorporation of chaotic dynamics to enhance the exploration–exploitation balance of optimization algorithms. Approaches such as the Chaotic Dragonfly Algorithm [3] and the Fractal Henon Chaotic Harris Hawks Optimization (FCHHHO) method [4] have reported improved convergence behavior and greater robustness in parameter extraction tasks. In addition, a wide range of optimization techniques has been successfully applied to PV parameter estimation, including improved variants of the Whale Optimization Algorithm (IWOA and WOA) [5], [6], the Equilibrium Optimizer (EOA) [7], Ranking-based Generalized Normal Distribution Optimization (RGNDO) [8], the Innovative Optimization Algorithm (INFO) [9], the Crayfish Optimization Algorithm (COA) [10], the Improved Mountain Gazelle Optimizer (IMGO) [11], Mother Tree Optimization with Climate Change (MTO-CL) [12], the Puma Optimization Algorithm [13], and the bio-dynamics Grasshopper Optimization Algorithm (BDGOA) [14].

Additional approaches have also been explored, including Improved Teaching–Learning-Based Optimization (ITLBO) [15], the Interior Search Algorithm (ISA) [16], Classified Perturbation Mutation-Based Particle Swarm Optimization (CPMPSO) [17], the Fractional Chaotic Ensemble Particle Swarm Optimizer (FC-EPSO2) [18], and the Hybrid Successive Discretization Algorithm (HSDA) [19]. Furthermore, the Mountain Gazelle Optimizer has been applied to single-, double-, and triple-diode PV models for accurate solar cell and module parameter extraction [20]. Collectively, these contributions highlight the continuous progress toward achieving high-precision parameter identification with minimal modeling error under different PV technologies and operating conditions. More recently, hybrid frameworks combining optimization techniques with machine learning models have attracted increasing attention. In particular, the integration of deep learning architectures, such as Convolutional Neural Network–Long Short-Term Memory (CNN–LSTM) networks, with multiple optimization algorithms has improved prediction accuracy and facilitated early fault detection in large-scale PV systems [21]. At the same time, advances in equivalent circuit modeling—including scalable triple-diode circuits [22] and lumped-parameter three-diode models tailored for industrial silicon solar cells [23]—have strengthened the physical representation of PV behavior, especially in capturing temperature-dependent effects and the contributions of different current components. Despite these advances, achieving consistent parameter identification across real operating conditions remains challenging. Factors such as partial shading, temperature variations, and device aging introduce additional nonlinearities that complicate the estimation process. Therefore, further improvements in optimization strategies are required to enhance both the accuracy and reliability of parameter identification for practical PV applications. The main contributions of this study can be summarized as follows:

- **Application of the Flow Direction Algorithm (FDA) for parameter extraction:** The FDA is employed to estimate the unknown parameters of the Three-Diode Model (TDM).
- **Experimental validation using benchmark datasets:** The proposed methodology is validated using experimental measurements from a standard **RTC** France monocrystalline silicon solar cell and an amorphous silicon (**a-Si**) thin-film photovoltaic cell.
- **Comparative performance assessment:** The proposed approach is evaluated against several state-of-the-art methods, demonstrating improved accuracy relative to conventional formulations.

The remainder of this paper is organized as follows. Section 2 presents the mathematical modeling of the photovoltaic devices and the formulation of the cost function. Section 3 describes the parameter estimation methodology and the implementation of the Flow Direction Algorithm. Section 4 presents the results and discussion, including statistical analysis and comparisons with existing approaches. Finally, Section 5 concludes the paper and outlines potential directions for future research.

II. PHOTOVOLTAIC MODELING AND PROBLEM FORMULATION

II.1 THREE-DIODE EQUIVALENT CIRCUIT REPRESENTATION OF A PV MODULE

Accurate modeling of photovoltaic (PV) devices is essential for robust parameter identification and reliable performance evaluation. This section outlines the mathematical formulation of the three-diode model (TDM) for both the PV cell and its extension to the module level. The primary emphasis of this work is the precise extraction of the TDM parameters for the PV cell/module, together with the formulation of the objective function employed in the optimization process. Figure 1 illustrates the three-diode equivalent circuit of a photovoltaic (PV) panel, comprising a current source, three parallel-connected diodes, and both series and shunt resistances. The corresponding mathematical formulation is expressed as follows:

$$I = I_{ph} - I_{d_1}\left(exp\left(\frac{V + I.R_s}{n_1.V_t}\right) - 1\right) - I_{d_2}\left(exp\left(\frac{V + I.R_s}{n_2.V_t}\right) - 1\right) - I_{d_3}\left(exp\left(\frac{V + I.R_s}{n_3.V_t}\right) - 1\right) - \frac{V + I.R_s}{R_{sh}} \quad (1)$$

Let I_{ph} denote the photocurrent, $I_{d_1}, I_{d_2}, I_{d_3}$ the reverse saturation currents of the three diodes, and n_1, n_2, n_3 their respective ideality factors. The quantities R_s and R_{sh} correspond to the series and shunt resistances. The thermal voltage is defined as $V_t = \frac{K \times T}{q}$, where T represents the absolute cell temperature, K is the Boltzmann constant, and q denotes the elementary charge. Accordingly, the three-diode model (TDM) is governed by nine unknown parameters $(I_{ph}, I_{d_1}, I_{d_2}, I_{d_3}, n_1, n_2, n_3, R_s, R_{sh})$ which must be accurately identified to ensure precise representation of PV cell behavior.

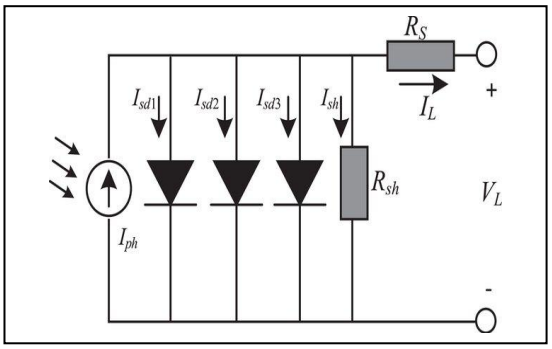

Figure 1: Three-diode (TDM) equivalent circuit model of the photovoltaic (PV) module.

II.2 OBJECTIVE FUNCTION FORMULATION

The estimation of unknown parameters in photovoltaic models is an optimization problem. The goal is to minimize the error between measured and predicted current-voltage (I-V) data. This requires a suitable objective function to quantify the error. A common metric for this task is the root mean square error (RMSE). The RMSE provides a statistical measure of the average discrepancy. It calculates the difference between observed and simulated current values. This metric is expressed as follows:

$$RMSE = \sqrt{\frac{1}{N}\sum_{i=1}^{N}\left(I_{mi} - I_{ci}(V_{mi}, I_{mi}, \theta)\right)^2} \tag{2}$$

In this formulation, $\boldsymbol{N}$ denotes the total number of experimental I–V data points, $\boldsymbol{I_{mi}}$ represents the measured current at voltage V_i, $\boldsymbol{I_c(V_i, \theta)}$ corresponds to the model-calculated current at the same voltage ontained using the Newton–Raphson method [24-26], and $\boldsymbol{\theta}$ defines the parameter vector to be optimized. The optimization relies on the RMSE criterion, which minimizes squared deviations between measured and predicted values, strongly penalizes large errors, and provides a reliable indicator of how accurately photovoltaic models reproduce actual device behavior.

III. FLOW DIRECTION ALGORITHM FOR PV PARAMETER ESTIMATION

Estimating photovoltaic (PV) model parameters is challenging due to the nonlinear and high-dimensional nature of the problem. Metaheuristic optimization techniques are particularly effective for this task, as they can explore complex solution spaces and avoid entrapment in local minima. Among these, the Flow Direction Algorithm (FDA) [27], [28] is a physics-inspired method based on hydrological runoff processes in drainage basins. The algorithm simulates water flowing downslope toward a basin outlet, which represents the global minimum of the objective function. FDA employs the D8 flow-direction approach as presented in figure 1, in which each cell in a discretized basin has eight neighbors, and runoff is directed toward the neighbor with the steepest descent.

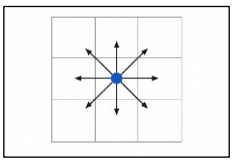

Figure 2: D8 neighborhood around the runoff flow cell.
Source: [28].

In FDA, each candidate solution corresponds to a flow in an n-dimensional search space, and its fitness value is analogous to the flow's elevation. Each flow interacts with neighboring positions within a defined radius, and its movement velocity is proportional to the slope between the current position and the neighbor. Flows move toward better-performing neighbors or, if none exist, toward either the global best solution or a randomly selected flow. The neighborhood radius is reduced linearly over iterations to balance global exploration and local exploitation, while the coefficient applied to the global best accelerates convergence.

Mathematically, the population is initialized randomly within the search bounds:

$$\text{Flow}\mathbf{Y}_i = \mathbf{lb} + \text{rand} \times (\mathbf{ub} - \mathbf{lb}) \tag{3}$$

Where $\text{Flow}\mathbf{Y}_i$ is the position vector of the i-th flow. Neighboring positions are generated as

$$\text{Neighbor}\mathbf{Y}_j = \text{Flow}\mathbf{Y}_i + \text{rand}_n \times \Delta \tag{4}$$

With rand_n following a normal distribution and Δ representing the neighborhood radius. Flow positions are then updated using

$$\text{Flow}\mathbf{Y}_i^{\text{new}} = \text{Flow}\mathbf{Y}_i + \mathbf{v} \times \frac{\text{Neighbor}\mathbf{Y}_j - \text{Flow}\mathbf{Y}_i}{\|\text{Neighbor}\mathbf{Y}_j - \text{Flow}\mathbf{Y}_i\|} \tag{5}$$

$$\mathbf{v} = \text{rand}_n \times \mathbf{S} \tag{6}$$

Where **S** represents the slope vector between the flow and its neighboring flows. The dual-strategy decision rule ensures flows move toward better solutions while maintaining exploration:

$$\begin{gathered}\text{if } f(\text{Flow}_t) < f(\text{Flow}_i)\text{: Flow}\mathbf{Y}_i^{\text{new}} = \text{Flow}\mathbf{Y}_i + \text{rand}_n \times (\text{Flow}_t - \text{Flow}\mathbf{Y}_i) \\ \text{else: Flow}\mathbf{Y}_i^{\text{new}} = \text{Flow}\mathbf{Y}_i + 2 \times \text{rand}_n \times (\text{BestFlow}\mathbf{Y} - \text{Flow}\mathbf{Y}_i)\end{gathered} \tag{7}$$

Through this hydrology-inspired mechanism, FDA effectively balances exploration and exploitation, enabling the identification of near-optimal or global solutions in complex, nonlinear optimization problems. Its effectiveness has been demonstrated across various engineering applications, including control system optimization, wireless sensor networks, and power system regulation. The main steps of FDA can be summarized as follows:

1. Initialize the flow population randomly within the search space and set Δ to its initial value.
2. Evaluate the fitness function for each flow.
3. Generate neighbors for each flow within the neighborhood radius Δ.
4. Update flow positions based on neighbor performance or the best global solution using the decision-making strategy.
5. Reduce Δ progressively according to a linear schedule to shift from global exploration to local exploitation.
6. Update the global best solution found so far.
7. Check the termination condition (e.g., maximum iterations or convergence criterion); if not satisfied, return to step 3.

By simulating hydrological runoff dynamics, FDA effectively balances exploration and exploitation, enabling the identification of near-optimal or global solutions in complex, nonlinear optimization problems. Its effectiveness has been demonstrated across diverse engineering applications, including control system optimization, wireless sensor networks, and power system regulation.

IV. RESULTS AND DISCUSSIONS

In these experimental investigations, the algorithm was configured with a population size of **100** and a maximum of **3000** iterations. Under these conditions, two photovoltaic (PV) configurations were investigated. The first case study involves a 57 mm-diameter monocrystalline silicon solar cell from R.T.C. France, tested at an irradiance of 1000 W/m² and a cell temperature of 33 °C. The second case concerns an amorphous silicon (**a-Si**) thin-film photovoltaic cell, evaluated at 25 °C under an irradiance of 1000 W/m². The lower and upper limits of the seven model parameters are presented in Table 1.

Table 1: Range of variables considered during the simulation process.

Parameters	**RTC**		**a-Si**	
	l_b	u_b	l_b	u_b
$I_{ph}(A)$	0	1	0	2
$I_{d1}, I_{d2,}, I_{d3}(\mu A)$	0	1	0	100
$R_s(\Omega)$	0	0.5	0	5
$R_{sh}(\Omega)$	0	100	0	2000
n_1, n_2, n_3	1	2	1	60

The proposed Flow Direction Algorithm (FDA) was validated using the previously described photovoltaic (PV) devices under standard operating conditions. The accuracy of the estimated parameters was quantitatively evaluated using the root mean square error (RMSE) between the experimental and simulated current–voltage (I–V) characteristics. This metric provides a reliable measure of the model's fitting capability across the entire operating range, including the short-circuit, knee, and open-circuit regions. For benchmarking purposes, the FDA was applied to the three-diode model (TDM) and its performance was compared with several recently reported state-of-the-art metaheuristic algorithms listed in the introduction. This framework enables a rigorous evaluation of convergence, stability, and robustness in addressing the nonlinear and multimodal nature of the TDM parameter estimation problem. Optimal parameter values were obtained from the best objective function outcomes across 30 independent trials to ensure statistical reliability. The FDA's performance was further analyzed using minimum, maximum, mean, and standard deviation (STD) of the RMSE values, collectively assessing precision, consistency, and practical applicability. Tables 2–5 present the optimal parameters of the nine-parameter TDM and the corresponding statistical analysis obtained over 30 runs for the **RTC** and **a-Si** solar cells. The RMSE values demonstrate the superior performance of the FDA.

The results in Table 2, along with the statistical comparison presented in Table 3 for **RTC** cells, provide a comprehensive assessment of metaheuristic algorithms for estimating the three-diode model (TDM) parameters, focusing on fitting accuracy, physical consistency, and robustness against the nonlinear, multimodal optimization landscape. The primary performance metric, the root mean square error (RMSE) between measured and modeled I–V characteristics, shows that the Flow Direction Algorithm (FDA) achieved the lowest RMSE (Best: 7.3511×10^{-4}, Worst: 7.5303×10^{-4}, Mean: 7.3773×10^{-4}, STD: 5.0229×10^{-6}), outperforming COA, IMGO, ITLBO, ISA, CPMPSO, RGNDO, and FC-EPSO2, while even small RMSE reductions remain significant near the knee and open-circuit regions. All algorithms converged on a photocurrent ($I_{ph} \approx 0.7605\ A$), but diode saturation currents (I_{d1}, I_{d2}, I_{d3}) exhibited higher variability due to parameter correlation and multimodality; FDA produced smoother scaling of diode currents and ideality factors, with n_2 and n_3 approaching physically consistent values of 2. Series resistance ($R_s \approx 0.038\ \Omega$) remained stable across algorithms, and shunt resistance (R_{sh}) stayed within realistic ranges for FDA and most competitive methods, demonstrating both numerical accuracy and physical plausibility. The TDM's nine-dimensional, strongly coupled, non-convex search space challenges many optimizers, with COA and IMGO showing higher RMSE likely due to premature convergence, whereas FDA's balanced exploration–exploitation strategy navigates the landscape effectively, achieving performance comparable to methods like FC-EPSO2 without excessive complexity. Overall, FDA provides the best compromise between convergence accuracy and parameter stability, with reduced dispersion in sensitive parameters highlighting its robustness. Accurate parameter extraction directly benefits predictive PV modeling, maximum power point tracking, performance analysis under varying conditions, and fault detection, showing that even marginal RMSE improvements, when accompanied by physically consistent parameters, enhance downstream applications. Collectively, these findings confirm FDA's suitability for high-precision TDM parameter identification and its broader applicability to other nonlinear energy system modeling problems.

Figure 3 presents the I–V and power–voltage (P–V) characteristic curves of the TDM, along with the voltage-point error curves obtained using FDA. The results demonstrate that the simulated current and power values closely match the measured data across all voltage points, with minimal errors, confirming the reliability of the proposed FDA method in accurately capturing the actual behavior of solar cells through the TDM model. Table 4 presents the optimal parameters obtained for the **a-Si** solar cell, while Table 5 summarizes the statistical comparison over 30 independent trials. FDA achieved the lowest RMSE (Best: 2.2939×10^{-5}, Worst: 2.594509×10^{-5}, Mean: 2.468451×10^{-5}, STD: 5.649668×10^{-5}), outperforming HSDA and MGO. The photocurrent (I_{ph}) converged around 0.01132 A for all methods, whereas diode saturation currents (I_{d1}, I_{d2}, I_{d3}) and ideality factors (n_1, n_2, n_3) showed greater variability, reflecting the inherent parameter correlation and multimodality of the TDM. Series resistance ($R_s \approx 2.1\ \Omega$) and shunt resistance ($R_{sh} \approx 1500\ \Omega$) were consistent with physically realistic ranges for FDA.

In summary, the comparative analysis for both **RTC** and **a-Si** photovoltaic cells demonstrates that the Flow Direction Algorithm (FDA) consistently outperforms other state-of-the-art metaheuristic methods in terms of RMSE, convergence stability, and physical plausibility of the extracted parameters. The statistical results from Tables 3 and 5 confirm the reliability and robustness of FDA across multiple independent trials, while the I–V and P–V curves in Figures 3 and 4 illustrate excellent agreement between simulated and experimental data, with minimal voltage-point errors. Overall, FDA not only provides highly accurate parameter identification for both monocrystalline and amorphous silicon cells but also ensures physically consistent and electrically coherent parameter sets, highlighting its applicability to complex, nonlinear photovoltaic models. These findings support the use of FDA for precise PV system modeling, maximum power point tracking simulations, performance assessment under varying environmental conditions, and potential fault detection and degradation studies, demonstrating its practical value for both research and industrial applications.

V. CONCLUSIONS

In this study, the Flow Direction Algorithm (FDA) was proposed for high-precision identification of critical parameters in three-diode model (TDM) photovoltaic cells. Simulation experiments were conducted on two PV cell types: the monocrystalline **RTC** France cell and the amorphous silicon (**a-Si**) thin-film cell. The FDA was benchmarked against several state-of-the-art metaheuristic algorithms. For the **RTC** cells, FDA achieved the lowest RMSE of 7.3411×10^{-4}, outperforming all compared methods and providing the most reliable solution for TDM parameter optimization. Similarly, for **a-Si** cells, FDA achieved an RMSE of 2.426899×10^{-5}, confirming its superior accuracy and robustness. The I–V and P–V characteristic curves further validated the FDA results, demonstrating excellent agreement between simulated and experimental data with minimal errors, indicating that FDA accurately captures the actual behavior of both monocrystalline and amorphous solar cells. These findings confirm that FDA not only ensures highly accurate and physically consistent parameter estimation but also maintains robustness in the nonlinear, multimodal search space inherent to TDM PV models. Given its demonstrated effectiveness and feasibility, FDA constitutes a powerful tool for PV system modeling, maximum power point tracking, performance evaluation under varying environmental conditions, and potential fault detection.

Future research will focus on improving FDA performance through hybridization with other metaheuristic or local search strategies to further enhance convergence speed, solution diversity, and global optimization capability. Looking forward, the proposed algorithm can be extended to address high-dimensional renewable energy optimization problems with complex constraints and applied to modified or emerging PV models reported in the literature, highlighting its potential for broader applications in energy system analysis and optimization.

Sound absorption coefficient.

ABSTRACT

The rising need to use sustainable and environmentally friendly materials in place of synthetic acoustic materials has resulted in the rising popularity of natural fiber composites. Sugarcane bagasse (SCB), an agricultural by-product that contains a high level of fibrous material, is also a potential solution in the sound absorption applications because of its porous structure and biodegradability. The purpose of the research is to compare the acoustic behavior of SCB-based composite panels bonded with polyvinyl acetate (PVA), and to compare experimentally obtained sound absorption coefficients (SAC) and those obtained using mathematical models. Three levels of SCB content (40%, 50% and 60%) and three thicknesses (10 mm, 20 mm and 30 mm) were used to make composite panels. The panels were described in terms of airflow resistivity, porosity, and tortuosity and the SAC values were determined using an impedance tube in accordance with ASTM E1050 and ISO 10534-2. The Miki, Delany-Bazley (DB) and Johnson-Champoux-Allard (JCA) models were also used to predict the SAC. Findings have shown that adding more SCB content and panel thickness has a significant effect on SAC especially at the low and mid frequency bands. Panels with 60% SCB and 30 mm thickness recorded the highest SAC values of more than 0.9, which validated their outstanding sound-absorbing performance. The JCA model was the closest to the experimental data among the models analyzed with the Miki and DB models under-predicted. This paper confirms SCB/PVA composites as a potential solution to sustainable acoustic panels usage.

I. INTRODUCTION

The issue of environmental noise control has become a burning problem because of its prevalence among the population, mental health, and industrial performance. The long-term effects of noise pollution are negative health outcomes, such as hearing loss, stress, and cardiovascular issues, which necessitate the development of effective sound mitigation measures [1–4]. Sound-absorbing concrete and fiber-based panels have become vital in the construction sector to improve the acoustic comfort of high-density urban housing and commercial buildings, where the building code tends to insist on the use of noise control measures on walls, floors, and facades [4], [5]. Likewise, in the automotive sector, where the comfort and sustainability of consumers intersect, natural fiber-based and composite acoustic materials are actively studied to minimize cabin noise and vehicle weight, which can help to comply with the regulations and compete in the market [6–8]. The development of acoustic materials has also influenced the design of the public space, studios, and transport systems, where porous absorbers, micro-perforated panels, and bio-based composites are used to improve the quality of sound and environmental sustainability [9–11]. All of these developments highlight the growing need in the contemporary engineering and urban development sector to have efficient, cheap, and environmental-friendly noise control materials.

The use of porous materials and natural fiber composites has become an attractive sustainable substitute to the traditional synthetic sound absorbers because of their low environmental impact, biodegradability, and good acoustic performance. In comparison with synthetic fibers, including fiberglass or mineral wool, which are energy-intensive to produce and potentially dangerous to health, natural fibers like coconut coir, banana, kenaf, or sugarcane bagasse are similar in terms of sound absorption properties and reduce the environmental impact [12–16]. These natural materials are commonly made out of agricultural by-products and have high porosity and tortuosity which is important in dissipating energy and absorbing sound. Natural fiber boards have proven to be as effective in reducing noise coefficients as synthetic ones in building acoustics and contribute to the sustainability agenda [17–19]. The materials are not only concerned with waste valorization but also provide economic benefits due to low-cost production and renewability, which increases their applicability in automotive, aerospace, and architectural projects where high lightweight and effective acoustic insulation is needed [20–23]. All these results support the sustainability of natural porous composites as eco-friendly high-performance sound absorbers that will substitute synthetic counterparts in the next-generation acoustic solutions. The agro-industrial byproduct of sugarcane bagasse (SCB) has received growing interest as a sustainable raw material in the production of acoustic insulation because of the combination of physical and morphological properties. It is very absorbent in the range of low to mid-frequency because of its naturally porous and fibrous microstructure that allows effective dissipation of sound energy through friction, reflection, and resistance to air flow [10], [24–26]. SCB also has a low bulk density, which makes it lightweight and easy to handle, and it has low structural load in building and automotive designs [27–30]. Biodegradability is one of its most significant characteristics, which means that it can be used as a fully environmentally friendly alternative to synthetic acoustic panels that can be a safety concern to dispose of and be dangerous to human health. The capacity of SCB composites to achieve or surpass the acoustic performance of synthetic foams and be completely compostable at the end of the lifecycle has been confirmed in several studies [14], [31–34]. Porosity, light weight, and biodegradability are the key characteristics that make sugarcane bagasse a highly promising, green material that can be used in future acoustic applications in construction, transportation, and environmental engineering.

The mathematical modeling has now been a vital tool in the precise prediction of the sound absorption coefficient (SAC) of porous materials, which allows efficient designing of materials, saves of costs, and decreases the need to use time-consuming experimental testing. Conventional models like Delany Bazley, Johnson Champoux Allard (JCA), and Miki have been extensively applied to correlate physical and non-acoustic parameters of porous media with their frequency-dependent absorption behavior, and more recent models combine transfer matrix methods (TMM), finite element modeling (FEM), and inverse characterization methods [35–39]. Artificial intelligence methods like neural networks and deep learning have also been adopted in recent research to enhance the accuracy of prediction in complex geometries and real-world scenarios [40], [41]. Such modeling methods allow better insight into the acoustic behavior and optimize bio-based and composite materials to be used in architectural, automotive, and industrial noise control. The scientific literature has shown that natural fiber-based composites have a promising future in terms of acoustic performance and sustainability, which can be used as an alternative to synthetic materials in sound insulation. According to [17], low-density banana fiber boards were found to have the highest noise reduction coefficient of five types of natural fibers, whereas [42] determined kenaf fiber to be the most efficient in reducing noise in a variety of real-world sources, with up to 7.82 dB of sound reduction. In support of this, [43] showed that kenaf and Calotropis gigantea fibers in polypropylene composites offered high-mid frequency sound absorption and structural performance in the automotive applications. Likewise, [10] also produced sugarcane bagasse and bamboo charcoal composites that recorded more than 70 percent absorption in a humid environment, which has a potential in vehicle cabin applications. In other research with high-level modeling, [44] reported high SAC values of over 0.95 with close agreement to JCA predictions of CS-CSS composites, whereas [45] validated Typha Latifolia panels with JCAL and Attenborough models with a high degree of accuracy of about 95. Material innovation research is ongoing with [20] reporting SACs up to 0.604 with banana fiber-reinforced epoxy composites and [46] reporting SACs > 0.5 with date palm and pineapple fiber-based composites, which also exhibited good thermal and mechanical performance. Other eco-friendly materials like Grewia Optiva [47] and jutealoe vera laminates [48] had high SACs with the latter having 0.47 at 3000 Hz based on stacking order. According to [49], the insulators made of hemp outperformed the traditional insulators such as mineral wool in SAC with a peak of 0.99 at 2000 Hz.

Also, [50] emphasized the multifunctional character of jute-cork panels, which has better strength, thermal resistance, and 35% higher SAC than gypsum boards. Hybrid compositions like sisal-palm fiber with epoxy resin were also found to work, [51] found a 76.61% increase in SAC at 4000 Hz with this type of composition compared to others. Finally, [52] proved that natural fiber-glass wool-polyfiber sandwich composites are appropriate to use on walls and ceilings because of the increased absorption in the mid-to-high frequency range. The overall implications of these findings are that bio-based composites have a potential to develop high-performance sustainable acoustic solutions in the construction, automotive, and architectural industry. New developments in acoustic modelling have investigated numerous computational and experimental methods to forecast the sound absorption characteristics of natural fibre composites and designed porous structures. To model sound absorption of grid network structures, [53] proposed a one-dimensional transfer matrix method, which compares well with simulation and experimental outcomes and thus validates its practical use. The JCA model was used to predict the sound absorption properties of kenaf fiber-based porous absorbers and was experimentally validated by [31] and demonstrated high sound absorption properties depending on the thickness of the material, bulk density, and surface treatments, including spacer fabrics. In the data-driven modeling field, [54] used an artificial neural network (ANN) with airflow resistivity as the only input and was able to predict the sound absorption coefficient of multilayer fibrous materials more accurately than the conventional TMM methods based on Delany-Bazley and JCA models, especially in the high-frequency range of 30006000 Hz. Likewise, [55] showed that ANN was effective in predicting the acoustic behavior of broom fibers, and their model had a high correlation with the experimental values and was more predictive than linear regression. A detailed study of Yucca Gloriosa fibers by [56] through the integration of morphological characterization and 3D structural simulations revealed that the JCA model was better predictive over a wide frequency range (63-6300 Hz) than the Delany-Bazley and Garai-Pompoli models.

In line with these works, [57] optimized kenaf-reinforced polyurethane composites with response surface methodology and discovered that JCA model better predicted frequency-dependent acoustic behavior when compared to Delany-Bazley model, and also obtained a significant 35.4% increase in sound absorption compared with neat PU foam. Taken together, these works indicate the changing paradigm of mathematical and artificial intelligence-based modeling methods that contribute to the predictive quality and realistic design of bio-based acoustic materials. Although many studies have been done on natural fiber composites to apply in acoustic applications, there is a significant gap in the overall comparison of the experimentally determined SAC with the predictions of various established mathematical models, especially the composites that are made of SCB, which is a widely available but poorly utilized agro-waste. The originality of the work is that SCB/PVA composite panels are developed and the acoustic behavior of these panels is modeled in detail by Delany-Bazley, Miki and JCA models at different thicknesses and compositions. In contrast to the previous research which only examines experimental or single model analysis, this study gives a systematic analysis and verification of the various predictive models with regard to experimental data. The relevance of the study is based on the fact that it contributes to sustainable material development through encouraging the utilization of SCB waste in functional acoustic products and developing model-based design of sound-absorbing materials with a sustainable environment.

II. METHODOLOGY

In order to examine the acoustic behavior of sugarcane bagasse based composites, panels were made under controlled conditions and tested in a standardized impedance tube set up. This method was used to assure uniformity in material preparation and accuracy in measuring frequency dependent sound absorption properties.

II.1 COMPOSITE FABRICATION

The composite fabrication process entailed the fabrication of sugarcane bagasse (SCB)-based panels with the help of polyvinyl acetate (PVA) as a binding agent. The first step involved the collection of raw bagasse in the local sugar mills, sun-drying, and grinding to get fine and uniformly distributed fibers. These fibers were filtered using standard mesh in order to eliminate large particles and to achieve uniformity in the composite matrix. The bagasse was combined with the PVA binder in a weight ratio of 1:1 to provide enough bonding and structural strength. The fiber-binder mixture was stirred by a mechanical mixer to attain homogeneity and then cast into rectangular moulds of size 110 mm x 120 mm. In order to investigate the influence of thickness on acoustic properties, three panel thicknesses were made: 10 mm, 20 mm, and 30 mm. The samples were pressed at a constant load of 90 kgf and allowed to dry under pressure in 48 hours. The panels were dried under natural sunlight conditions (72 hours) after the molding process to finish the curing process and eliminate moisture. This was done to provide dimensional stability and sufficient bonding of the composite. Nine samples were made in three levels of composition SCB40, SCB50, and SCB60, which represents 40, 50, and 60 percent of bagasse content by weight respectively as presented in Table 1.

Table 1: Composition and Thickness Variants of Fabricated SCB/PVA Composite Panels.

Sample Code	SCB Content (%)	PVA Content (%)	Thickness (mm)
SCB40-10	40	60	10
SCB40-20	40	60	20
SCB40-30	40	60	30
SCB50-10	50	50	10
SCB50-20	50	50	20
SCB50-30	50	50	30
SCB60-10	60	40	10
SCB60-20	60	40	20
SCB60-30	60	40	30

II.2 EXPERIMENTAL ACOUSTIC TESTING

Experimental assessment of the acoustic performance of the SCB/PVA composite panels was done using an impedance tube system as per ISO 10534-2 and ASTM E1050 standards. This system consists of a loudspeaker at one end of a cylindrical tube and two fine microphones at the opposite end of the tube at a specified distance to measure the incident and reflected sound pressure levels. The composite sample is put at the other end of the tube supported by a rigid termination to approximate the conditions of installation in the real world. A random noise signal was produced by a broadband and was introduced into the loudspeaker using a power amplifier and the microphones measured the sound field produced. The complex reflection coefficient was calculated using the transfer function method and the normal incidence SAC was determined using the formula $\alpha = 1 - |R|^2$. The measurements were conducted in the frequency range of 125 Hz to 4000 Hz to comprehensively evaluate the acoustic absorption behavior of the composite in the low, mid and high frequency ranges. Figure 2 demonstrates schematic layout and photograph of the impedance tube experimental set-up.

III. MATHEMATICAL MODELS FOR PREDICTION OF SOUND ABSORPTION COEFFICIENT

In order to examine the acoustic behavior of sugarcane bagasse based composites, panels were made under controlled conditions and experimented by a standardized impedance tube configuration. This method guaranteed the stability of material preparation and the accuracy of measuring the frequency-dependent sound absorption properties.

III.1 MIKI MODEL

Miki model is a semi-empirical acoustic model that is employed to model the sound absorption behavior of porous materials especially fibrous composites like natural fiber-based panels. It provides a simplified version of more complicated theoretical models such as the JCA model because it uses fewer material parameters but still can make fairly accurate predictions, particularly in materials where airflow resistivity is the most important controlling factor. The Miki model is based on the Delany-Bazley empirical model but with altered expressions of power-law characteristic impedance and complex wave number to make it applicable to a wider frequency range. The Miki model assumes that the material is a rigid-frame, isotropic, macroscopically homogeneous porous material, and its acoustic behavior can be well modeled using only flow resistivity and frequency, without necessarily modeling microstructural properties such as porosity, tortuosity, or characteristic lengths. This assumption simplifies the model computationally and simple to use, particularly in the preliminary material design phase or the rapid prototyping phase.

The dimensionless frequency parameter X, defined as $X = \frac{f}{\sigma/\rho_0}$, where f is the frequency in Hz, σ is the airflow resistivity (in Pa·s/m²), and ρ_0 is the density of air (typically 1.21 kg/m³), is central to the model. The normalized characteristic impedance: $\frac{Z_c}{\rho_0 c_0}$ and normalized complex wave number $\frac{k}{\omega/c_0}$ are given by the empirical relations:

$$\frac{Z_c}{(\rho_0 c_0)} = 1 + 0.070\, X^{-0.632} - i * 0.107\, X^{-0.632} \quad (1)$$

$$\frac{k}{\omega/c_0} = 1 + 0.109X^{-0.618} - i \cdot 0.160X^{-0.618} \quad (2)$$

Where c_0 is the speed of sound in air and $\omega = 2\pi f$ is the angular frequency. Once the characteristic impedance Z_c and wave number k are calculated using these equations, the input impedance Z of the porous layer of thickness d can be determined as $Z = -iZ_c \cot(kd)$, assuming the material is backed by a rigid surface. The normal-incidence sound absorption coefficient $\alpha(f)$ is then calculated using the impedance mismatch equation:

$$\alpha(f) = 1 - \left|\frac{Z - Z_0}{Z + Z_0}\right|^2 \quad (3)$$

Where $Z_0 = \rho_0 c_0$ is the characteristic impedance of air. The importance of the Miki model is that it is easy to use and gives realistic acoustic forecasts with minimum input criteria, thus it is particularly appropriate in the initial acoustic description of natural fiber composites, including sugarcane bagasse-polymer mixtures. Although it is not as sensitive to the microstructure as more sophisticated models, its simplicity and empirical accuracy make it a useful instrument in the study of acoustic materials and in the engineering domain.

III.2 DELANY-BAZLEY MODEL

The Delany-Bazley model is a traditional empirical model that has been employed to model the acoustic behavior of fibrous and porous sound-absorbing materials, especially at mid-to-high frequencies. The model was developed in the 1970s after much experimental effort on fibrous glass materials had been done, and simple mathematical expressions were developed to represent the complex characteristic impedance and wave number of a porous medium in terms of the airflow resistivity of the material and the frequency of the incident sound wave. This model assumes that the porous material is a rigid-frame structure, in which the frame is not moved by sound waves, the material is homogeneous and isotropic and is thick enough that structural resonance effects and backing effect do not dominate the response. The most important simplification of the Delany-Bazley model is that it fails to consider microstructural parameters of porosity, tortuosity, or characteristic lengths, which reduces its accuracy but increases its utility in the practical engineering context. The model introduces a dimensionless frequency parameter $X = \frac{f}{\sigma}$, where f is the frequency in hertz and σ is the airflow resistivity in . Based on this parameter, the normalized characteristic impedanin.and normalized wave number $\frac{k_0}{k}$ are given by the following empirical formulas:

$$\frac{Z_0}{Z_c} = 1 + 0.0571X^{-0.754} - i \cdot 0.087X^{-0.732} \quad (4)$$

$$\frac{k_0}{k} = 1 + 0.0978X^{-0.7} - i \cdot 0.189X^{-0.595} \quad (5)$$

Where $Z_0 = \rho_0 c_0$ is the characteristic impedance of air, and $k_0 = \frac{\omega}{c_0}$ is the wave number in free air. Once the characteristic impedance and wave number are computed, the sound absorption coefficient at normal incidence can be derived using the same impedance-based relation used in other models:

$$\alpha(f) = 1 - \left|\frac{Z - Z_0}{Z + Z_0}\right|^2 \quad (6)$$

Where $Z = -iZ_c \cot(kd)$, and d is the thickness of the absorbing layer. The Delany-Bazley model is notable because it is simple and only one measurable property, airflow resistivity, is needed to give reasonably accurate predictions of many industrial fibrous materials. It is however most accurate in high porosity, high resistivity materials at frequencies above 500 Hz and less accurate at low frequencies or non-fibrous structures. In spite of these shortcomings, it is an empirically-based and easy to use tool that is popular in preliminary acoustic design, benchmarking, and education in the material acoustics field.

III.3 JOHNSON-CHAMPOUX-ALLARD (JCA) MODEL

The Johnson-Champoux-Allard (JCA) model is a well-known theoretical model that is applied to predict the acoustic behavior of porous materials, especially in estimating the sound absorption coefficient of porous materials at normal and oblique incidences.

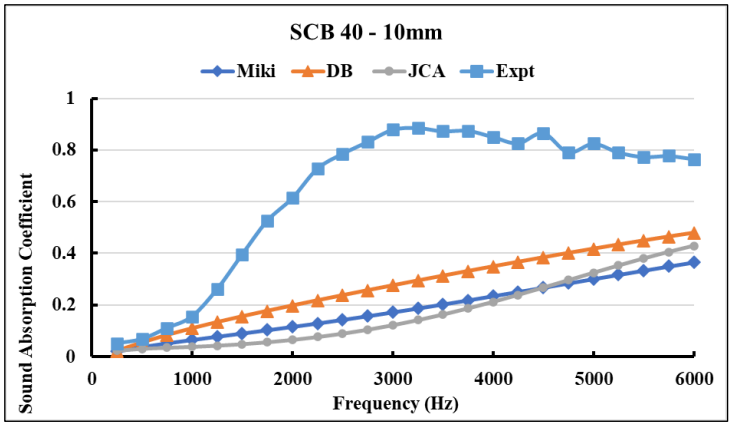
The JCA model was developed as an extension of the simpler empirical models, and includes physical effects like viscous and thermal dissipation in the pores of a rigid-frame porous medium, and is particularly applicable to fibrous and granular composites, such as sugarcane bagasse-based materials. This model is based on the fact that the material is an equivalent fluid, i.e. the solid matrix does not contribute to the wave propagation, and is at rest. The JCA model treats the propagation of sound in porous media as a problem of two important frequency-dependent quantities, the complex effective density of the material $\rho(\omega)$, and the complex effective bulk modulus of the material $K(\omega)$. The equation of the effective density is:

$$\rho(\omega) = \rho_0 \cdot \alpha_\infty \left(1 + \frac{\sigma \emptyset}{i\omega\rho_0\alpha_\infty} \sqrt{1 + \frac{4i\alpha_\infty^2 \eta \rho_0 \omega}{\sigma^2 \Lambda^2 \phi^2}} \right) \tag{7}$$

Where ρ_0 is the air density, α_∞ is the tortuosity, $\emptyset$ is the porosity, σ is the airflow resistivity, η is the dynamic viscosity of air, ω is the angular frequency, and Λ is the viscous characteristic length. Similarly, the complex bulk modulus is expressed as:

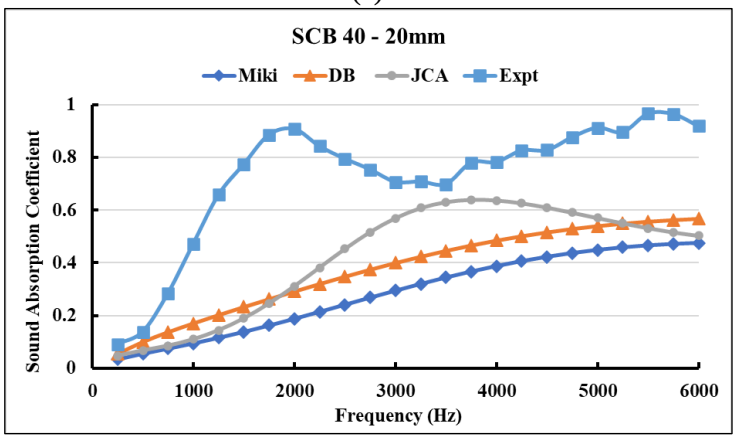
$$\mathrm{K}(\omega) = \frac{\gamma \mathrm{P}_0}{\gamma - (\gamma - 1)\left(1 + \frac{8\eta}{\mathrm{i}\omega\rho_0 \mathrm{Pr}\Lambda'^2}\right)^{-1/2}} \tag{8}$$

where $P0$ is atmospheric pressure, γ is the specific heat ratio of air, Pr is the Prandtl number, and Λ' is the thermal characteristic length. These parameters are the energy losses of the acoustic wave to the porous structure through viscous and thermal interaction. Once $\rho(\omega)$ and $K(\omega)$ are determined, the characteristic impedance Zc and complex wave number k are calculated as $Zc = \rho(\omega)\cdot K(\omega)$ and $k = \omega\rho(\omega)/K(\omega)$, respectively. The input impedance Z of the material layer of thickness d is then computed using the relation $Z = -iZc$ cot (kd). Lastly, the normal-incidence SAC, $\alpha(f)$ is obtained with the help of the formula of impedance mismatch:



$$\alpha(\mathrm{f}) = 1 - \left| \frac{\mathrm{Z} - \mathrm{Z}_0}{\mathrm{Z} + \mathrm{Z}_0} \right|^2 \tag{9}$$

Where $Z0 = \rho0\ c0$ is the characteristic impedance of air. The JCA model is especially important as it is capable of capturing the complete frequency-dependent behavior of porous materials with reasonable precision, assuming that its input parameters, including porosity, tortuosity, flow resistivity and characteristic lengths, are well-characterized. Although it presupposes a solid frame that is rigid and may not apply to flexible or viscoelastic materials, its capability to include realistic microstructural effects in predictive acoustics makes it a foundation of the modeling of sound-absorbing composite materials.



IV. RESULTS AND DISCUSSION

IV.1 SCB40 COMPOSITE PANEL

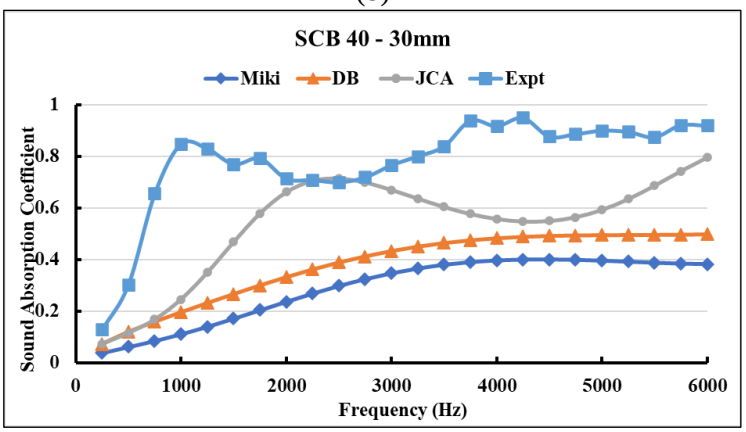


Figure 3(a), 1(b) and 1(c) show the comparison of SAC values of experimental measurements and three popular theoretical models - Miki, DB and JCA of SCB40 composite panels with thickness of 10 mm, 20 mm and 30 mm respectively. The results show that the SAC increases significantly as the panel thickness increases, especially in the low-frequency range. In the case of the 10 mm panel in Figure 3(a) the experimental findings suggest that the highest SAC is about 0.88 around 3000 Hz and there is not much absorption in the low-frequency band. DB and Miki models are the ones that moderately reflect the rising trend but always underestimate the value, whereas the JCA model is a bit closer to predictions, particularly after 2000 Hz. In Figure 3(b), the 20 mm panel is shown to have better low-frequency absorption, and experimental SAC is more than 0.9 in the mid-frequency range. In this case, the JCA model provides a much more accurate fit to experimental data, especially at frequencies between 1500 and 4000 Hz, as DB and Miki are still under-predicting performance. This enhancement in the predictive accuracy of JCA can be explained by the fact that its predictive model incorporates poroelastic parameters such as tortuosity, flow resistivity, and characteristic lengths that are important in the description of the intricate internal structure of natural fiber composites. This tendency is also supported by figure 3(c), where the 30 mm panel has a high SAC in a broad frequency range, and the experimental values are always above 0.7 since 800 Hz. The JCA model is close to the experimental data throughout the range, and it is more predictive than both DB and Miki models. These observations confirm the usefulness of the JCA model in the modeling of thick, fibrous composites such as SCB/PVA panels, where airflow resistivity, porosity, and viscous-thermal interactions are the most important factors in governing acoustic behavior. On the whole, the discussion shows that simpler empirical models can give approximate predictions, the JCA model can make a more robust and physically based predictions of SAC in natural fiber-based acoustic materials, especially when the panel thickness is large.

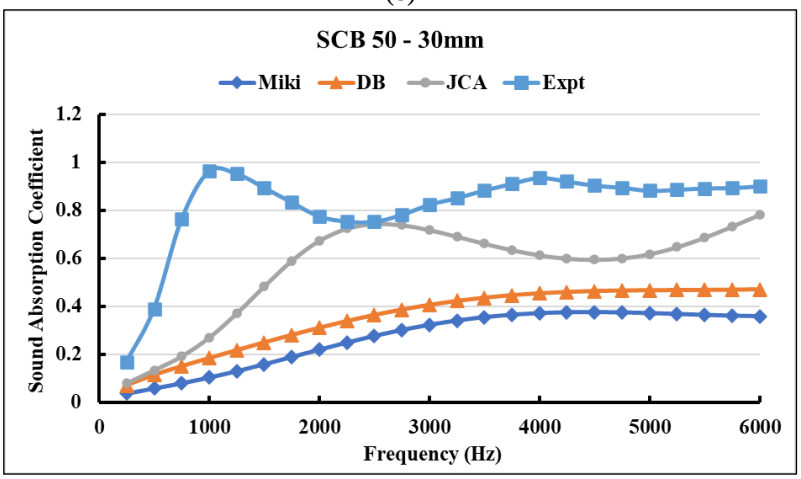
IV.2 SCB50 COMPOSITE PANEL

Figures 4(a), 4(b), and 4(c) show the comparison of experimental and model-predicted values of SAC of SCB50 composite panels of thicknesses 10 mm, 20 mm, and 30 mm, respectively. In Figure 4(a), the sharp increase in SAC with frequency is observed in the 10 mm thick panel, and it reaches its maximum value of about 0.92 at about 3000 Hz in the experimental results. Nevertheless, none of the three mathematical models, Miki, DB and JCA predict the SAC significantly underestimating the SAC at the frequency spectrum, especially at mid and high frequencies. The DB model demonstrates the nearest approximation yet it is far below experimental values. Figure 4(b) shows that the 20 mm thick panel has a better low-frequency absorption with the experimental SAC values being higher than 0.95 in the 15002500 Hz range and steadily high after that. In this case, the JCA model starts to agree with the experimental trend much better, particularly between 1500 and 4000 Hz, as DB and Miki models are still under-predicting. The better predictive capability of the JCA model can be attributed to the fact that the model incorporates the essential parameters of tortuosity, airflow resistivity and characteristic lengths, which enable the model to better depict the complicated porous structure and energy dissipation behavior of the SCB/PVA composite. Figure 4(c) is the experimentally determined SAC of the 30 mm thick panel, where the broad peak of the SAC is again observed to be near unity in the frequency range of 1000 to 3000 Hz, and the SAC is found to have values above 0.8 in most of the frequency range. The JCA model is no exception and shows the closest correspondence to experimental evidence and proves the soundness of its applicability to the modeling of thicker natural fiber composites.



Although the DB and Miki models are marginally better than the case of thinner samples, they still do not represent the higher absorption levels well. These findings support the finding that the JCA model offers the most credible prediction of SAC of all the models tested especially in mid-thickness and thick panels. The growing correspondence of the experimental results to the increasing panel thickness also confirms the idea that the proper modeling of acoustic performance in natural fiber composites should take into consideration the advanced material-specific parameters, which are well-considered in the JCA framework.

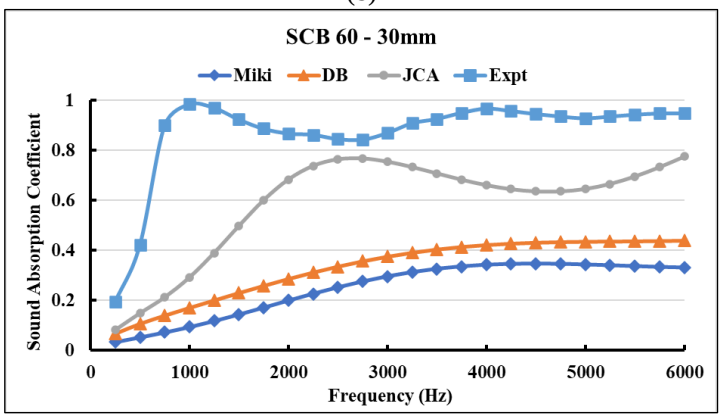
IV.3 SCB60 COMPOSITE PANEL

Figures 5(a), 5(b), and 5(c) show the comparison of SAC of SCB60 composite panels with the thicknesses of 10 mm, 20 mm, and 30 mm, respectively, by using experimental measurements and three predictive models, namely, Miki, DB, and JCA models. Figure 5(a) shows that the SCB60 panel of 10 mm thickness has good SAC performance, with experimental values reaching a peak of about 0.93 at about 2500 Hz and a value of 0.8 throughout much of the mid-frequency range. The JCA model gives the nearest approximation of the models especially above 2000 Hz, and both the DB and Miki models are always underestimating the SAC.



The experimental SAC is not only better at lower frequencies as the panel thickness is increased to 20 mm in Figure 5(b), but also has values above 0.85 over a wider range of frequencies, with values approaching unity above 4000 Hz. The JCA model is in line with the trend of the experiment, particularly between 1500 and 4000 Hz, and the peak and the wider absorption bandwidth is captured. In the meantime, DB and Miki models perform better as compared to the 10 mm case but still are far below the magnitude of the SAC. The experimental SAC of the 30 mm thick panel in Figure 5(c) is high throughout the entire frequency spectrum with a maximum of approximately 0.96 and sustained absorption of approximately 0.9 within a wide band. The JCA model shows an amazing capacity to reproduce this trend especially at 1500 Hz and above, both in shape and the level of the experimental curve. This high correlation points to the strength of the JCA model of predicting the acoustic behavior of thick, porous composite with large SCB content. The enhancement in the accuracy of the model as the panel thickness and the proportion of SCB increase can be explained by the increased porosity and internal structure that the JCA model can capture well due to the incorporation of parameters like the tortuosity, the viscous and thermal characteristic length, and the flow resistivity. On the contrary, the DB and Miki models, which are more empirical and designed to work with traditional fibrous absorbers, do not capture the intricate interactions that occur in bio-based composites and thus do not predict much. These observations confirm the applicability of the JCA model in the correct modeling of SAC in sustainable composites, particularly at higher fiber content and panel thickness, where the coupling between acoustic waves and the internal porous structure becomes more and more prevalent.

V. CONCLUSION

The study examined the acoustic performance of sustainable composite panels constructed of SCB and PVA through experimental and theoretical methods. Composite samples of different SCB content (40%, 50%, and 60%) and thicknesses (10 mm, 20 mm and 30 mm) were made. They were experimentally measured in terms of their sound absorption coefficients (SAC) using an impedance tube according to ASTM E1050/ISO 10534-2. Moreover, SAC was modeled by three known mathematical models Miki, D) and JCA and model predictions were compared with experimental results.

- Adding SCB content and panel thickness increased SAC, particularly at low-to-mid frequencies because of increased porosity and internal damping.
- Thicker high-SCB panels had greater values of experimental SAC, which showed excellent sound absorption.
- JCA model gave more close correspondence with experiment results, particularly with thicker samples.
- DB and Miki models under-predicted SAC in all the samples, which validated the constraints of modeling complex natural fiber composites.

Future research can focus on hybrid binders or multilayer to maximize broadband absorption. Also, machine learning models can be combined with numerical simulations to enhance predictive performance and inform the design of bio-based acoustic materials to meet a variety of applications.

ABSTRACT

Diabetes affects over 101 million people in India, with many more at risk due to routine and hereditary factors. Early diagnosis is crucial to prevent complications, which make accurate predictive tools essential in healthcare. This research uses Machine Learning (ML) algorithms to evaluate the likelihood of Type 2 Diabetes Mellitus (T2DM) using lifestyle and family history data. The trained models demonstrate strong predictive ability, allowing individuals to self-assess their risk and supporting healthcare professionals in early detection and intervention. This study presents a performance assessment of seven ML classifiers: Decision Tree (DT), Random Forest (RF), Support Vector Machine (SVM), Logistic Regression (LR), Naïve Bayes (NB), k-Nearest Neighbor (k-NN), and Extreme Gradient Boosting (XGBoost). These classifiers were applied to the widely used PIMA Indian Diabetes dataset (PIDD), which contains 768 clinical records of adult women aged 21 and above, providing key medical information for diabetes analysis. Multiple evaluation measures were applied to assess model performance with results showing that SVM achieved the highest accuracy and AUC, while LR, RF, and XGBoost also performed competitively. Although k-NN attained the highest recall, it yielded a higher false positive rate. These findings highlight that no single model is perfect for every situation, and the choice of classifier should match clinical needs. This study serves as a reference for ML applications in diabetes prediction.

I. INTRODUCTION

Diabetes mellitus (DM) is a chronic endocrine-metabolic condition marked by abnormal regulation of blood glucose levels due to the body's inability to produce sufficient insulin, improper utilization of insulin, or both. When insulin activity is disrupted, glucose accumulates in the bloodstream, impairing the normal metabolism of carbohydrates, lipids, and proteins [1]. Chronic high blood glucose interferes with the metabolism of carbohydrates, fats, and proteins. These metabolic imbalances can result in serious long-standing complications, impacting organs including the eyes, kidneys, nerves, and the cardiovascular system [2]. As a progressive disease, diabetes requires timely diagnosis, continuous monitoring, and effective management to reduce its significant health and economic burden [3]. Inadequate management can lead to acute conditions like diabetic ketoacidosis. Diabetes is a leading cause of significant morbidity, including cardiovascular disease, stroke, renal failure, diabetic foot ulcers, and retinopathy [4]. The significant health burden and mortality resulting from these complications highlight the imperative for early detection and effective long-term management [5].Based on their underlying causes, pathophysiological mechanisms, and treatment considerations, diabetes is primarily divided into three main forms: Type 1, Type 2, and Gestational Diabetes Mellitus (GDM) [6]. Each type differs in its origin, clinical presentation, and management approach. Type 1 Diabetes Mellitus (T1DM) results from autoimmune destruction of pancreatic beta-cell, requires patients to rely on external insulin administration for survival. Type 2 Diabetes Mellitus (T2DM) occurs from impaired insulin action and insufficient insulin production commonly associated with obesity and physical inactivity. Gestational diabetes mellitus (GDM) is a condition of pregnancy that confers health risks to both the mother and infant.

For a healthy individual, normal fasting blood glucose is 70-99 mg/dL, a level of 100-125 mg/dL shows prediabetes, and exceeding 126 mg/dL diagnoses diabetes are classified as pre-diabetic [7]. Such a person is prone to the development of T2DM. Research has identified several factors that contribute to a higher likelihood of developing diabetes.

(a) Weight-to-height ratio exceeding 25
(b) A history of diabetes in close relative
(c) Low HDL cholesterol levels (less than 40 mg/dL)
(d) Long-standing hypertension or history of gestational diabetes
(e) Previous diagnosis of polycystic ovary syndrome (PCOS)
(f) Key non-modifiable risk factors for diabetes include age over 45 years, family history, and belonging to high-risk ethnic groups.
(g) Sedentary or inactive lifestyle.

Management of prediabetes centers on lifestyle interventions designed to prevent or delay the development of T2DM [8]. This research focuses on evaluating the risk of T2DM development in at-risk individuals. The organization of paper is as follows: section II outlines the existing body of related research, while section III described the classification techniques applied. The performance metrics for evaluating the classifiers are detailed in section IV. Section V outlines the methodological framework and implementation procedures, followed by the experimental configuration in section VI. The results and their analysis are presented in Section VII. Finally, Section VIII concludes the paper with a synthesis of the findings and future research avenues.

II. RELATED WORKS

This section summarizes important research on predicting diabetes, focusing on the application of various ML algorithms and comparing different classification methods. The rising global rate of T2DM has drawn considerable attention to its prediction, with data-driven methods offering valuable support for early detection and prevention [8]. Predicting T2DM mainly involves supervised learning, which has led researchers to frequently use ML and data mining techniques (DMT). While the PIDD is a standard benchmark, recent research has shifted the focus beyond just accuracy. Current efforts aim to improve interpretability, tackle class imbalance, and enhance early detection through methods like artificial neural networks and genetic algorithms. Research identified physical activity as a critical factor in mitigating T2DM risk in prediabetic individuals, underscoring the necessity of incorporating lifestyle variables into predictive models [9]. Studies comparing ML techniques for early-stage diabetes prediction have shown that ensemble methods frequently achieve better performance than traditional classifiers [10]. Similarly, oversampling strategies were used to improve early detection of female T2DM cases, addressing issues with imbalanced datasets [11]. Additionally, several studies proposed novel frameworks for diabetes classification. Machine learning was applied to classify T2DM subtypes, allowing more personalized interventions [12]. A hybrid meta-classifier combining fuzzy clustering with LR showed higher accuracy compared to traditional models [13]. Earlier work using DMT also contributed significantly to establishing prediction models for T2DM [14]. Recent research has focused on ensemble and hybrid learning to enhance predictive capabilities. For instance, a tri-ensemble model using KNN-imputed features significantly improved prediction outcomes [15]. Systematic evaluation of ML algorithms for prediction of diabetes has established critical benchmarks for evaluating their performance and computational efficiency [16]. This study introduced correlation based model that leverages both machine and deep learning (DL) for automatic prediction of diabetes, demonstrating improved effectiveness compared to traditional methods [17]. Another study proposed a risk assessment framework that integrates multiple machine learning algorithms, making them suitable for real-world healthcare applications [18].

Source: Authors, (2026).

The literature shows the clear shifts in diabetes research from traditional classifiers to advanced ensemble and DL models, driven by the integration of diverse data-driven methods to improve T2DM prediction and management.

However, as summarized in Tables 1 and 2, no single algorithm demonstrates universal superiority. Empirical performance is highly contingent on specific contextual factors, such as dataset structure and size. Thus, the choice between models like SVMs and neural networks is problem-dependent.

II.1 KEY CONTRIBUTION OF RESEARCH WORK

Major key contribution of this study focuses on effectiveness of various ML algorithms for predicting t2dm. The study also highlights comparative performance analysis and also identifies most suitable model for accurate and reliable prediction.

(a) A comparative framework evaluates seven ML classifiers for T2DM prediction.
(b) Performance assessed by multiple metrics, ensuring balanced evaluation beyond simple accuracy measures.
(c) The SVM classifier outperformed other models, attaining optimal accuracy and AUC metrics.
(d) Trade-offs highlighted, showing models vary between sensitivity, specificity, and false positive rates.
(e) Study establishes a benchmark framework for applying machine learning in real-world diabetes prediction tasks.

III. OVERVIEW OF CLASSIFICATION TECHNIQUES

This section outlines the key features of the seven individual and ensemble classifiers examined in this research.

III.1 DECISION TREE

A DT is a simple yet powerful model used in machine learning and decision analysis to make predictions or choices by splitting data into branches.DT is a classification technique that organizes decision making in hierarchical tree like structure.

Table 2: Classification accuracies reported in various research.

Source, Authors, (2026).

Internal nodes indicate tests on patient attributes such as glucose level, BMI, or age, leading through branches to leaf nodes that shows the final outcome—diabetic or non-diabetic [39]. DT is favored in healthcare for their interpretable rules, minimal preprocessing, and versatility with data types. In the context of T2DM prediction, DT shown in fig 1 can help clinicians in identifying key risk factors and forming diagnostic rules but may overfit small or complex datasets, reducing accuracy in multi-class or imbalanced cases [40]. The pseudocode for decision tree is given in figure 2.

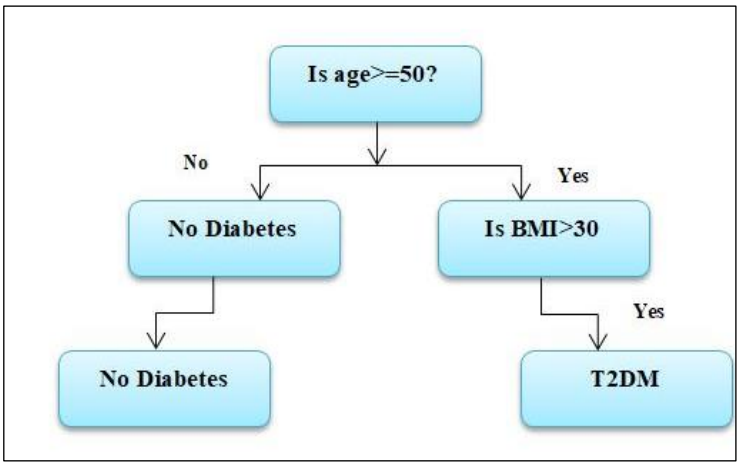

Figure 1: Decision Making in T2DM Prediction.
Source: Authors, (2026).

Input: Training Data D with features and class labels

1. If all records in D belong to the single class

→ Assign that class to the leaf node

2. Else if no feature remains for splitting

→ Return the majority class in D (Leaf Node)

3. Else

3.1. Select the best splitting feature A (using Information Gain / Gini Index)

3.2. Create a decision node for feature A

4. For each possible value v of feature A:

4.1. Partition dataset Dv where A = v

4.2. If Dv is empty → assign majority class of D

4.3. Else → recursively apply Decision Tree on Dv

Output: Constructed Decision Tree for classification

Figure 2: Pseudocode of decision tree.
Source: Authors, (2026).

III.2 RANDOM FOREST (RF)

RF classifier operates as an ensemble approach that leverages bagging and random feature selection to build numerous decorrelated decision trees. This structure promotes high generalization by aggregating their predictions via majority voting [41]. Due to its robustness and capacity to manage diverse types of data, RF has been widely utilized for predicting T2DM. Working of Random Forest is shown in fig 3 and pseudocode for RF is given in figure 4.

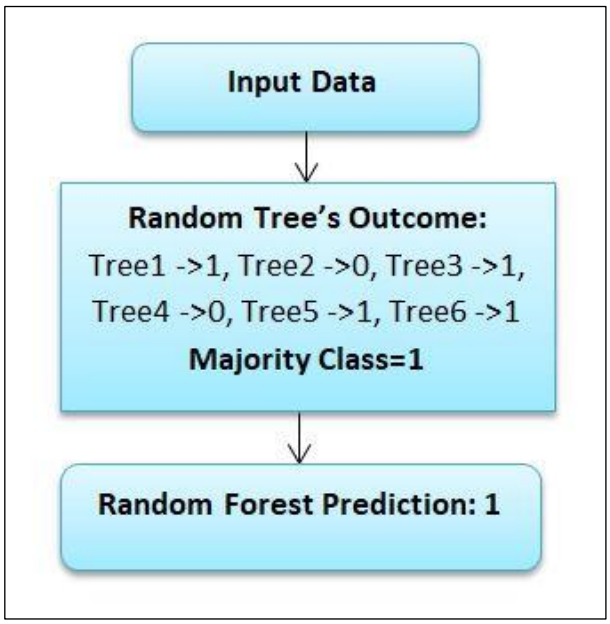

Figure 3: Workflow of RF Algorithm.
Source: Authors, (2026).

Input: Dataset Training D with patient samples n and features m.

1 Bootstrap Sampling:

Generate k bootstrapped datasets $D_1, D_2, \ldots, D_k$ from D, each obtained by sampling with replacement.

2 Tree Construction:

For each dataset D_i:

2.1 Build a decision tree by recursively splitting nodes.

2.2 At each split, randomly select a subset of features $F \subseteq m$.

2.3 Choose the best feature from F based on a splitting criterion.

3 Model Training:

3.1 Repeat Step 2 until N independent decision trees are constructed.

4 Prediction (for a test instance x):

4.1 Each tree outputs a predicted label y_i.

4.2 Aggregate the predictions using majority voting:

$$\hat{y} = \underset{c \in \{0,1\}}{\operatorname{argmax}} \sum_{i=1}^{N} I\,(y_i = c)$$

where, $I(\cdot)$ denotes the indicator function.

Output: Final predicted class $\hat{y} \in$ {Diabetes,No Diabetes}.

Figure 4: Pseudocode of Random Forest.
Source: Authors, (2026).

III.3 SUPPORT VECTOR MACHINE (SVM)

SVM is a supervised classification method that classifies data by creating an optimal hyperplane to maximally separate distinct classes. It performs effectively across diverse data patterns and complex feature distributions [42]. SVM aims to maximize the separation margin between classes, which improves generalization. The margin is set by the support vectors, which are the key points closest to the decision boundary. For linearly separable data, the hyperplane is defined by: $w^T x+b=0$, where $w=\{w_1, w_2, w_3, \ldots\ldots. w_n\}$ denotes the weight vector, b is the bias term, and n is the number of attributes. The classification constraints can be written as:

$$\text{(i)} \quad w^T x_i + b \geq 1, \quad \text{if } y_i = +1$$
$$\text{(ii)} \quad w^T x_i + b \leq -1, \quad \text{if } y_i = -1$$

SVM identifies the hyperplane that maximizes the distance to the nearest training points. This principle is captured by the following optimization formulation:

$$\text{Margin} = \frac{2}{||w||}$$

For non-linear problems, kernel functions like Polynomial, RBF, and Sigmoid handle non-linear data by projecting it into higher dimensions, facilitating linear separation. The classification decision is then determined by the resulting function:

$$f(x) = sign(\sum_{i=1}^{l} \alpha_i y_i K(x_i, x) + b_0)$$

Where y_i represents the class label of support vector x_i, α_i are lagrange multipliers, $K(x_i,x)$ denotes the kernel function, b_0 is the bias term, and l indicates the numbers of support vectors. Working of SVM is shown in figure 5 and pseudocode for SVM is given in figure 6.

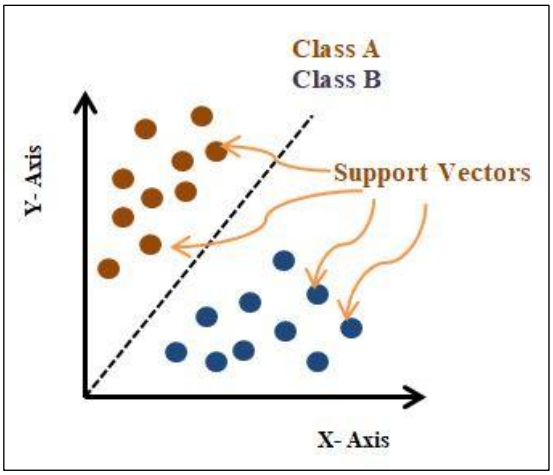

Figure 5: Support Vector Machine.
Source: Authors, (2026).

Input: Training Data, Test Instance

1. Choose the value of kernel function K(x_i, x_j) (Linear, Polynomial, RBF, Sigmoid).

2. Formulate the optimization problem to find the hyperplane: $w^T x + b = 0$

3. Identify support vectors that lie nearest to the hyperplane.

4. Construct the decision function:

$$f(x) = sign(\sum_{i=1}^{l} \alpha_i y_i K(x_i, x) + b_0)$$

5. For the given test instance:

5.1 If $(x) \geq 0 \Rightarrow$ assign to class +1 (Diabetes)

5.2 Else ⇒ assign to class –1 (No Diabetes)

Output: Predicted Class (Diabetes / No Diabetes)

Figure 6: Pseudocode of SVM.
Source: Authors, (2026).

III.4 LOGISTIC REGRESSION(LR)

This statistical technique is widely used for binary classification, estimating the probability that an observation belongs to one of two categories rather than generating continuous numerical outputs [43]. The model assumes that the log-odds of the probability are a linear function of the input features. For an input feature vector X = (x_1 , x_2 , x_3, ……x_n), the LR techniques is denoted as:

$$p(x) = \frac{1}{1 + e^{-(b_0 + b_1 x_1 + b_2 x_2 + \cdots + b_n x_n)}}$$

Where, b_0 is the intercept, $b_1, b_2, \ldots, b_n$ are regression coefficients, and n is the number of input features. The decision boundary is defined at $p(x) = 0.5$. Thus, classification can be expressed as:

$$\hat{y} = \begin{cases} 1 & \text{if } p(x) \geq 0.5 \quad \text{(Diabetes)} \\ 0 & \text{if } p(x) < 0.5 \quad \text{(No Diabetes)} \end{cases}$$

Model parameters are optimized using Maximum Likelihood Estimation by optimizing the cost function to find the best-fitting coefficients. LR working is shown in figure 7 and pseudocode in figure 8.

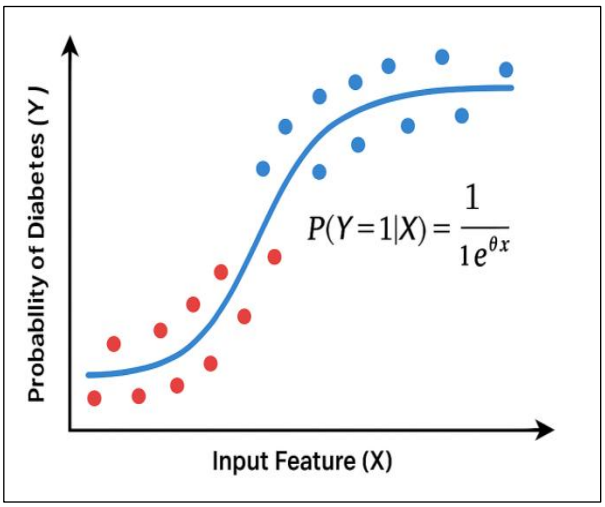

Figure 7: Workflow of Logistic Regression.
Source: Authors, (2026).

Input: Training Data, Test Instance

1. Assign starting value weights w and bias b.

2. For every training instance:
2.1 Compute probability using sigmoid:

$p(x) = \frac{1}{1+e^{-(w^T x+b)}}$

2.2 Modify weights w and bias b using gradient descent.

3. Repeat step 2 until convergence.

4. For the given test instance:
4.1 Compute probability $p(x)$.
4.2 If $p(x) \geq 0.5 \Rightarrow$ assign to class +1 (Diabetes).
4.3 Else $\Rightarrow$ assign to class 0 (No Diabetes).

Output: Predicted Class (Diabetes / No Diabetes)

Figure 8: Pseudocode of Logistic Regression.
Source: Authors, (2026).

III.5 NAÏVE BAYES (NB)

The NB classification method applies 'Bayes Theorem' treating each feature as independent from the others. Its simplicity and efficiency make it effective, especially for high-dimensional datasets. [44]. Working of NB is shown in figure 9 and the pseudocode is given in figure 10.

Model Representation:

$$P(C_k|x) = \frac{P(x|C_k)\,P(C_k)}{P(x)}$$

Where:

$P(C_k|x)$: posterior probability of class C_k given features

$xP(x|C_k)$: probability of observing x given class

$C_kP(C_k)$: prior probability of class

$C_kP(x)$: evidence (same for all classes, so ignored in decision)

Using the naïve assumption of conditional independence:

$$P(x|C_k) = \prod_{i=1}^{n} P\,(x_i|C_k)$$

Final classification rule:

$$\hat{y} = \underset{C_k}{\operatorname{argmax}}\, P(C_k) \prod_{i=1}^{n} P\,(x_i|C_k)$$

Decision Rule:

$$\hat{y} = \begin{cases} 1 & \text{if posterior probability is maximum for Diabetes} \\ 0 & \text{if posterior probability is maximum for No Diabetes} \end{cases}$$

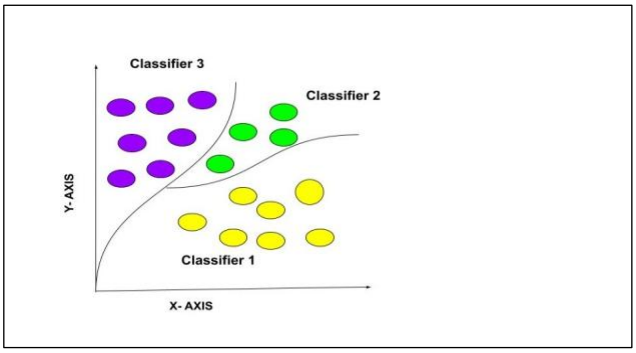

Figure 9: Naïve Bayes Classifier.
Source: Authors, (2026).

Input: Training Data , Test Instance

Compute prior probability of every class:

$$P(C_k) = \frac{\text{Samples count in class } C_k}{N}$$

For each feature x_i:

a. Calculate $P(x_i|C_k)$ for all possible classes.

b. (For continuous features, assume Gaussian distribution and compute using probability density function.)

For a new instance $x = (x_1, x_2, \ldots, x_n)$:

c. Compute posterior probability for each class:

$$P(C_k|x) \propto P(C_k) \prod_{i=1}^{n} P\,(x_i|C_k)$$

Assign the observation to the class exhibiting the maximum.

Output: Predicted Class (Diabetes / No Diabetes).

Figure 10: Pseudocode of Naïve Bayes.
Source: Authors, (2026).

III.6 K-NEAREST NEIGHBOR (KNN) CLASSIFIER

k-NN is a simple supervised technique that predicts a new instance's class based on the k nearest neighbors, without explicit training [45]. Closeness is typically measured using Euclidean distance, with other metrics applied as needed [46]. Figure 11 shows how the value of k influences classification in the k-NN algorithm and the pseudocode of k-NN is given in figure 12.

$$\boldsymbol{d(x,y) = \sqrt{\left\{\sum_{i=1}^{n}(x_i - y_i)^2\right\}}}$$

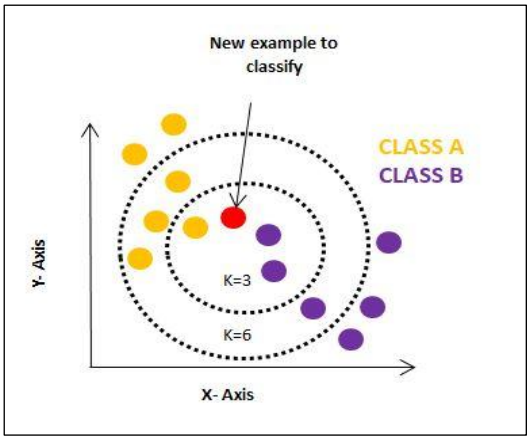

Figure 11: kNN Classifier.
Source: Authors, (2026).

Input: Training Data, Test Instance

1. Choose the appropriate value of k

2. For every instance i in the training dataset:

2.1 Calculate the distance Di between the test instance with instance i

3. Sort all computed distances Di in in increasing order of distance

4. Choose the k nearest neighbors from the sorted list

5. Determine the most frequent class label among these neighbors

6. Assign this class label to the test instance

Output: Predicted Class (Diabetes / No Diabetes)

Figure 12: Pseudocode of k-Nearest Neighbor (k-NN).
Source: Authors, (2026).

III.7 EXTREME GRADIENT BOOSTING (XGBOOST) CLASSIFIER

XGBoost is a refined form of gradient boosting that constructs DT sequentially, with each tree correcting prior errors. It employs regularization, shrinkage, and feature subsampling, enhancing robustness and performance on structured data such as diabetes prediction. [47]. XGBoost minimizes classification errors by optimizing a loss function.

Each tree fits the residuals of the previous ones, using gradients and Hessians to maximize information gain, and combines all trees for the final prediction of T2DM. XGBoost prediction process is shown in figure 13 and the pseudocode for that is shown in figure 14.

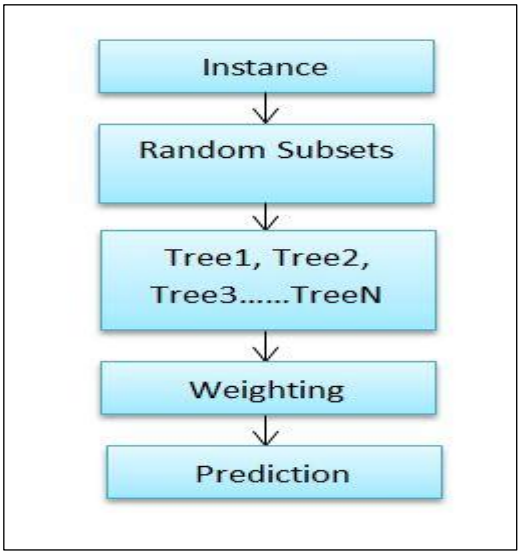

Figure 13: XGBoost prediction process.
Source: Authors, (2026).

Input: Training Dataset, Number of Trees (T), Learning Rate (η), Maximum Depth, Regularization Parameters

1. Initialize the model with a base prediction (e.g., mean of labels).

2. For every boosting round t = 1 to T:

2.1 Compute the gradient (g_i) and hessian (h_i) of the loss function for each training instance.

2.2 Construct a DT to fit the residuals:

- For each feature and split point:
  - Calculate the information gain using g_i and h_i.
  - Choose the split that maximizes gain.

2.3 Apply regularization to prune and avoid overfitting.

2.4 Update the prediction for each instance using:

$$y\hat{}((t))=y\hat{}((t-1))+\eta \cdot f_t(x)$$

where, $f_t(x)$ is the output of the newly added tree.

3. After all trees are built, combine their weighted outputs to form the final prediction.

4. Assign the predicted class label based on threshold (e.g., ≥0.5 → Diabetic, otherwise Non-Diabetic).

Output: Predicted Class (Diabetes / No Diabetes)

Figure 14: Pseudocode of Extreme Gradient Boosting (XGBoost) Classifier.

IV. OVERVIEW OF CLASSIFICATION TECHNIQUES

Evaluating a machine learning classifier involves defining suitable performance metrics that measure how effectively the model distinguishes between classes. This study uses nine such metrics, which are briefly described below:

Confusion Matrix (CM): A structured table used to show classification accuracy, with rows representing actual class labels and columns displaying predicted labels. Correctly classified instances lie along the diagonal of the matrix.
True Positive (TP): Instances in which the classifier correctly identifies positive cases as positive.
False Positive (FP): Observations incorrectly predicted as when they are actually negative.
True Negative (TN): Instances correctly classified by the model as negative.
False Negative (FN): Cases where positive instances are mistakenly classified as negative.
Based on these four quantities, multiple evaluation measures can be formulated:

IV.1 CLASSIFICATION ACCURACY

The number of correctly classified examples divided by the total number of observations.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN}$$

IV.2 PRECISION

Precision indicates the fraction of correctly predicted positive cases among all instances predicted as positive.

$$Precision = \frac{TP}{TP + FP}$$

IV.3 SPECIFICITY

Specificity represents the fraction of actual negative cases that is correctly identifies.

$$Specificity = \frac{TN}{TN + FP}$$

IV.4 RECALL/ SENSITIVITY/ TRUE POSITIVE RATE

Recall evaluates the actual positives correctly detected.

$$Recall = \frac{TP}{TP + FN}$$

IV.5 FALSE POSITIVE RATE (FPR)

This measure calculates the fraction of negative cases that are incorrectly predicted as positives.

$$FPR = \frac{FP}{FP + TN}$$

IV.6 NEGATIVE PREDICTIVE VALUE

NPV is the proportion of negative prediction that are accurate among all predicted negatives.

$$NPV = \frac{TN}{TN + FN}$$

IV.7 RATE OF MISCLASSIFICATION (RMC)

RMC is the proportion of incorrect predictions, including Type-I (positive as negative) and Type-II (negative as positive) errors.

$$RMC = \frac{FP + FN}{TP + TN + FP + FN}$$

IV.8 F1-SCORE

It is Harmonic mean of precision and recall, useful for imbalanced data.

$$F1 = \frac{2 \times Precision \times Recall}{Precision + Recall}$$

IV.9 RECEIVER OPERATING CHARACTERISTIC (ROC) CURVE

The ROC curve evaluates the classifier effectiveness by plotting the trade-off between sensitivity and specificity at multiple thresholds. Greater AUC values represent better capability to distinguish between classes.

V. DESIGN AND IMPLEMENTATION

This research analyzed multiple ML models for prediction of T2DM using the PIDD. After careful data preparation and an 80-20 stratified split, we evaluated different techniques, including DT, RF, LR, SVM, kNN, NB, and XGBoost. We developed the models using k-fold cross-validation to improve their settings. We assessed performance using a separate test set and multiple metrics. The comparative analysis found the best technique based on its ability to generalize and its usefulness in clinical settings. This provided clear evidence for choosing the right algorithm for diabetes prediction. We compared the performance of these classifiers systematically, and Figure 15 illustrates the process for implementing the algorithms.

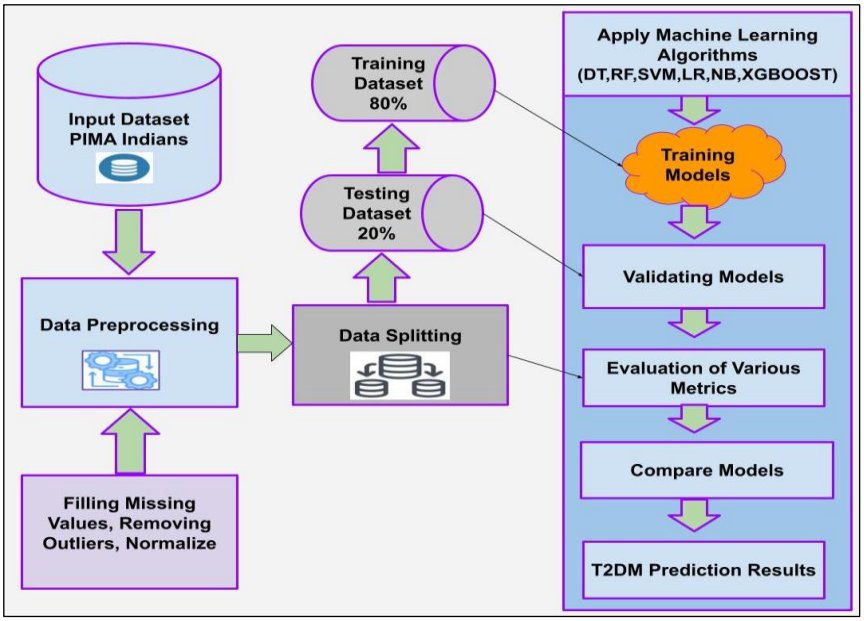

Figure 15: Flowchart for T2DM prediction.
Source: Authors, (2026).

To ensure reproducibility and clarity of the experimental procedure, the adopted workflow is presented in the form of an algorithm Figure 16.

Input: PIMA Indian Diabetes Dataset (with attributes such as Glucose, BMI, Age, Insulin, etc.)

Step 1: *Data Collection & Preprocessing*
1.1 *Import dataset.*
1.2 *Handle missing or zero values*
1.3 *Normalize/standardize continuous features*
Step 2: *Data Splitting*
2.1 *Divide dataset Training (80%) and Testing (20%)*
Step 3: Model Training
Seven Machine Learning Classifiers are chosen for comparison
m = [kNN(), LR(), SVM(), NB(), DT(), RF(), XGB()]
for (k=0; k<7; k++) do
Model=m[i];
Model.fit();
Model.predict();
print(Accuracy(i), confusion_matrix, classification_report, roc_curve)
End
Step 4: *Model Evaluation*
4.1 *Test classifiers on unseen test data*
4.2 *Generate confusion matrix for each model*
4.3 *Compute evaluation metrics*
Step 5*: Comparative Analysis*
5.1 *Compare results of all classifiers*
5.2 *Identify best-performing model based basis on Performance Metrics*
Output: Predicted Class (Diabetes / No Diabetes)

Figure 16: Algorithm for Prediction of T2DM.
Source: Authors, (2026).

The pseudocode outlines sequential steps: data collection and preprocessing, model selection, training, and evaluation. Classifiers were trained on processed data and tested on unseen instances, with performance assessed using standard metrics, followed by a comparative analysis to determine the optimal model for diabetes risk prediction.

VI. EXPERIMENTAL SETUP

An empirical analysis of diabetes prediction was conducted using the PIDD. Classifiers including DT, RF, XGBoost, SVM, k-NN, LR, and NB were evaluated using performance metrics. Experiments took place in Python with scikit-learn, pandas, numpy, and matplotlib within Jupyter Notebook and Google Colab for reproducibility and visualization. The workflow treated datasets as inputs, applied classifiers, and assessed the results with the Test & Score tool shown in figure 17.

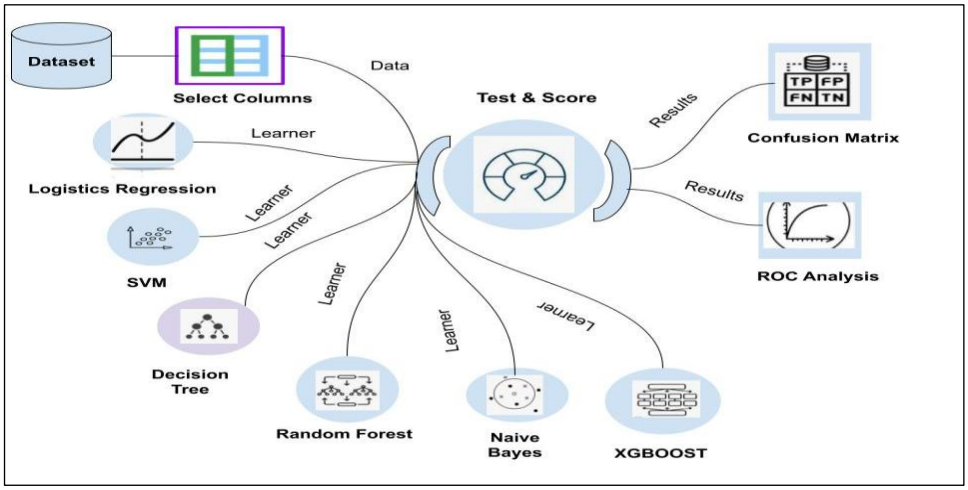

Figure 17: Experimental setup.
Source: Authors, (2026).

The outcomes were further visualized using confusion matrix, ROC curve, and evaluation metrics.

VI.1 DATASET DESCRIPTION

The PIDD comes from the UCI Machine Learning Repository. It includes data on 768 female patients of Pima Indian heritage, aged 21 and older. The dataset has 8 medical and physiological features, along with a variable that shows whether diabetes is present [47]. Table 3 lists the features of the dataset.

Table 3: Dataset Features Information.

SN	Attributes	Abbreviation	Description
1	Pregnancy Count	Preg	Count of pregnancies
2	Plasma glucose concentration	Glu	Blood glucose level after 2-hour test
3	Diastolic blood pressure (mm Hg)	BP	Patient's diastolic blood pressure reading
4	Triceps skinfold thickness (mm)	Skin	Measurement of skin fold thickness
5	Two-Hour serum insulin (mu U/ml)	Insulin	Insulin concentration in the blood
6	Body Mass Index (BMI)	BMI	Weight in kg / Height in m²
7	Diabetes pedigree function	DPF	Score representing the patient's hereditary risk of diabetes
8	Age (years)	Age	Age of Individual
9	Class variable	Class	0 = non-diabetic, 1 = diabetic

Source: Authors, (2026).

The correlation matrix of the PIDD, figure 18 indicates that Glucose shows the highest positive association with diabetes outcome (0.47). This is followed by BMI (0.29), Age (0.24), and Preg (0.22). Other features like BP, Skin Thickness, Insulin, and DPF exhibit weaker correlations, suggesting limited predictive value on their own. There are moderate correlations between features, such as Glucose and Insulin (0.33) and BMI and Skin Thickness (0.39), show some redundancy among the variables [48].

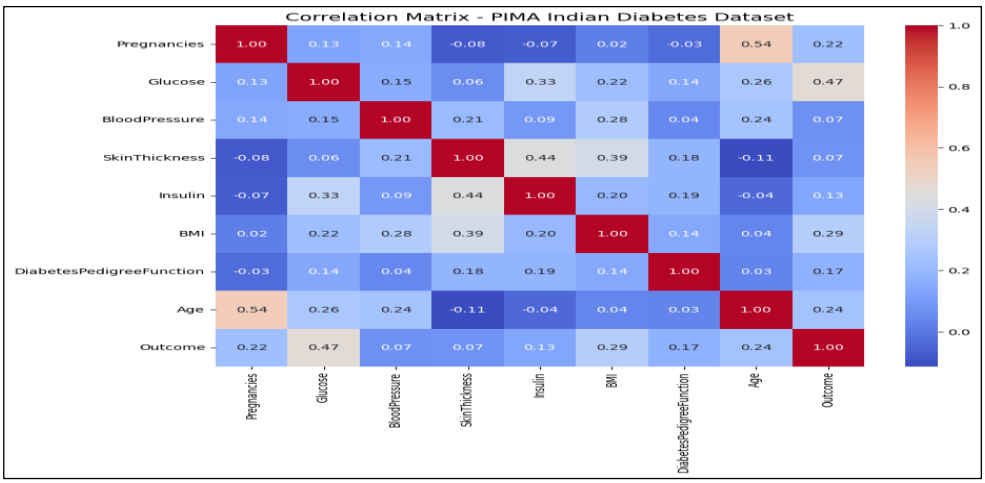

Figure 18: Correlation Matrix – PIMA Indian Diabetes Dataset (PIDD).
Source: Authors, (2026).

Overall, the analysis highlights that while a few variables are moderately linked to diabetes, most exhibit weak linear relationships, underscoring the need for ML models to capture complex, non-linear patterns.

VII. RESULT AND ANALYSIS

This research evaluated the performance of seven predictive models was assessed for predicting T2DM. The evaluation used multiple performance metrics. Table 11 summarizes the classification results, while Figure 19 illustrates the ROC curves for comparative analysis and figure 20 shows performance statistics of seven classifiers. The SVM model outperformed others, recording an AUC of 0.86 and a classification accuracy of 0.90. It also showed strong precision at 0.93 and specificity at 0.97, indicating its reliability in identifying non-diabetic cases. **Logistic Regression** had comparable results with an AUC of 0.83 and a classification accuracy of 0.88, excelling in precision at 0.92 and specificity at 0.97. However, recall was slightly lower at 0.69, suggesting a higher chance of missing positive (diabetic) cases. **Random Forest** and **XGBoost** performed competitively, with AUC scores of 0.84 and 0.85, respectively. **Random Forest** achieved higher precision at 0.93, but had slightly lower recall at 0.71. **XGBoost** maintained equilibrium between precision and recall, attaining 0.83 and 0.80, respectively**.** Both ensemble methods showed robustness and had lower false positive rates (FPR $\leq$ 0.09), making them suitable for medical decision-making, where minimizing false alarms is important. **Naïve Bayes** had moderate results with an AUC of 0.83 and a classification accuracy of 0.86. It performed well in terms of specificity at 0.93, but slightly underperformed in recall at 0.72. This indicates that the model effectively identified non-diabetic individuals but was less accurate in detecting those with diabetes. The **k-NN** classifier exhibited the highest recall at 0.90, indicating strong sensitivity to positive cases, which is desirable in medical diagnosis. However, its relatively low precision at 0.69 and high false positive rate at 0.19 suggest that it tends to over-predict diabetes, potentially causing unnecessary alarms. The **Decision Tree** model, although simple, produced competitive outcomes with an AUC of 0.84 and a classification accuracy of 0.86. It provided balanced precision and recall, both at 0.79, though it underperformed compared to ensemble-based methods in terms of robustness.

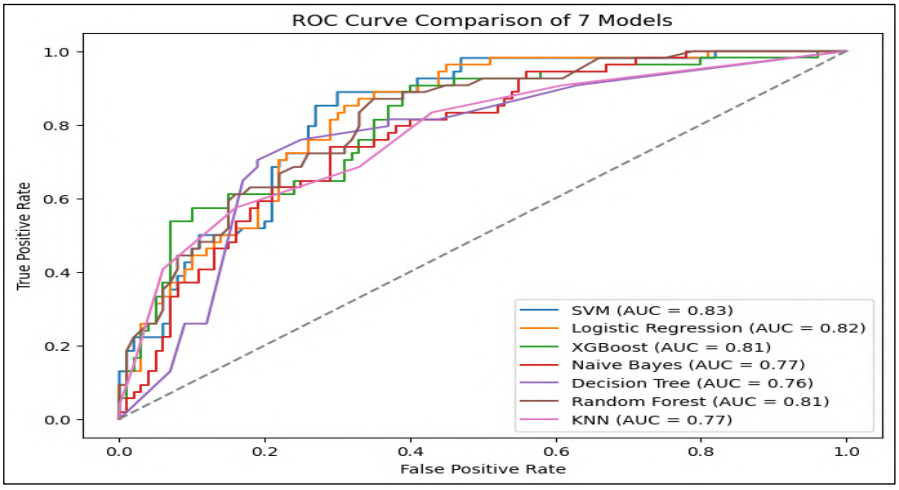

Figure 19: ROC Curve of seven classifiers.
Source: Authors, (2026).

The **ROC curve** comparison figure 16 reinforces these findings. SVM and Logistic Regression achieved the most consistent separation between classes, as shown by their curves lying closer to the top-left corner. Ensemble techniques such as RF and XGBoost are also exhibited strong predictive outcomes, while k-NN and NB showed moderate discrimination ability.

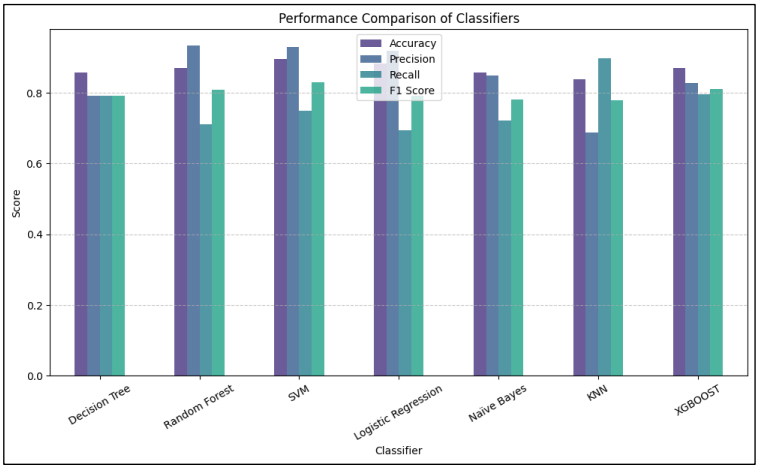

Figure 20: Performance statistics of seven classifiers.
Source: Authors, (2026).

Overall, as illustrated in Figure 17, SVM emerged as the most effective classifier for T2DM prediction. It is offered a good balance between sensitivity and specificity. LR and ensemble methods like RF and XGBoost also performed well, serving as strong alternatives. The k-NN algorithm showed high sensitivity but needs adjustment to lower false positives. Simpler models like DT and NB provided reasonable baseline results.

VII.1 CONFUSION MATRIX OF DIFFERENT CLASSIFIERS

Tables 4 to 10 present the confusion matrices for all seven classifiers applied to the PID dataset.

VIII. CONCLUSION

This study conducted a systematic comparison of the accuracy and effectiveness of traditional and hybrid models for T2DM classification. Among the evaluated techniques, SVM consistently achieved superior discriminative ability, followed closely by LR, RF and XGBoost. These models demonstrated the ability to distinguish between diabetic and non-diabetic cases, while the ensemble methods providing a balanced combination of accuracy and stability. Although k-NN exhibited the highest recall, its tendency to generate false positives makes it less suitable as a standalone model. However, it is useful in situations where sensitivity is more important than specificity. The study highlights that selecting the most appropriate model should be guided by the intended clinical use, whether the priority is to maximize early detection or to reduce false alarms. Future extensions of this research may include integrating larger and more diverse datasets, applying deep learning frameworks, and exploring hybrid optimization strategies to further improve predictive reliability. By strengthening computational approaches to early diagnosis, this study contributes to the development of practical decision-support systems for diabetes care.

ABSTRACT

This paper proposes E2A2S-WSN, an Energy-Efficient Adaptive Sleep Scheduling for Load-Balanced energy harvesting wireless sensor networks based on asynchronous duty cycling and relay node selection. The scheme dynamically adapts node duty cycles using a novel level-based strategy that considers residual and harvested energy, ensuring balanced energy consumption across the network. E2A2S-WSN also employs low-power listening with short preambles and an optimized relay selection mechanism to achieve load balancing. E2A2S-WSN scheme was compared with RDEHWSN under various multi-hop traffic and energy harvesting scenarios. Simulation results show that E2A2S-WSN significantly improves network performance by reducing energy consumption and latency, increasing packet delivery ratio and throughput.

I. INTRODUCTION

Wireless Sensor Networks (WSNs) consist of a large number of low-cost, resource-constrained sensor nodes that cooperatively monitor physical environments and forward sensed data to a sink node [1]. Despite their wide applicability, WSNs are primarily constrained by limited battery capacity, making energy efficiency and network lifetime critical design issues [2]. Since battery replacement is often impractical, numerous energy-saving techniques such as duty cycling, clustering, and load balancing have been proposed at the MAC layer [3-5]. Recently, energy harvesting (EH) has emerged as a promising solution to enable long-term autonomous operation by allowing sensor nodes to exploit ambient energy sources [6]. Accordingly, several EH-aware MAC protocols have been introduced to adapt node activity based on harvested energy. However, most existing approaches rely on reactive duty-cycling mechanisms that do not anticipate future energy availability, leading to uncertain wake-up scheduling, increased latency, and unreliable routing performance in multi-hop scenarios. In addition, the lack of publicly available implementation codes limits reproducibility and fair comparison among EH-WSN protocols [7]. In this paper, we propose E2A2S-WSN Energy-Efficient Adaptive Sleep Scheduling for Load-Balanced Energy Harvesting Wireless Sensor Networks (EH-WSNs), which extends and improves the RDEHWSN scheme [8]. The proposed scheme integrates an energy harvesting module into each sensor node and adopts a transmitter-initiated communication mechanism based on low-power listening with short preambles. This design builds upon the advantages of existing transmitter-initiated MAC protocols [9], [10]. E2A2S-WSN introduces an energy threshold–based approach that exploits residual and harvested energy to dynamically adapt node duty cycles. A novel sleep period estimation method, based on Newton interpolation and residual energy prediction, is employed to more aggressively adjust node sleep durations according to anticipated future energy availability. In addition, a new relay node selection strategy is incorporated to ensure load balancing during data routing. The main objectives of E2A2S-WSN are to reduce energy consumption and average latency while improving packet delivery ratio and throughput. The remainder of this paper is organized as follows: Section 2 reviews related work; Section 3 describes the proposed E2A2S-WSN scheme; Section 4 presents the simulation setup and parameters; Section 5 evaluates and compares the proposed scheme with RDEHWSN; and Section 6 concludes the paper and outlines future research directions.

II. RELATED WORK

Energy harvesting is a promising approach in WSNs that enables sensor nodes to convert ambient energy into usable electrical power, thereby extending network lifetime. To support Energy Neutral Operation (ENO), where energy consumption does not exceed harvested energy, several duty-cycle based MAC protocols have been proposed [11-13]. These protocols are primarily asynchronous and rely on receiver-initiated beaconing mechanisms to adapt node activity to available energy.

II.1 PROBABILISTIC POLLING EH-WSN MAC PROTOCOL

Probabilistic polling is a MAC approach for energy-harvesting WSNs designed to reduce data packet collisions. In this scheme, each receiver periodically broadcasts a polling packet with a contention probability (*Probcon*) that informs sender nodes of their likelihood to transmit. Upon receiving a poll, a sender generates a random number; it transmits if the number is less than *Probcon*, otherwise it may enter charging mode or wait for the next poll. The contention probability is dynamically adjusted: it increases if no data is received and decreases after collisions. Several protocols utilize this principle:

PPMAC [14] targets single-hop WSNs and applies an Additive Increase Multiplicative Decrease (AIMD) strategy to adapt contention probability, improving throughput, fairness, and supporting high node densities.

EHMAC [15] extends PPMAC to multi-hop networks, dynamically adjusting polling packets to reduce interference while considering spatial and temporal variations in harvested energy.

MTPP [16] introduces a tier-based multi-hop scheme fully powered by energy harvesting and validated experimentally on commercial devices, demonstrating feasibility in practical deployments.

These protocols improve throughput, fairness, and scalability by balancing energy consumption and reducing collisions. However, they suffer from high latency, as packets may wait long periods before transmission when contention probability is low, leading to wasted energy and bandwidth in multi-hop scenarios.

II.2 NON-PROBABILISTIC POLLING EH-WSN MAC PROTOCOL

Several MAC protocols for energy-harvesting WSNs have been proposed using alternatives to probabilistic polling, such as CSMA/CA or duty-cycle–based strategies. QAEEMAC [17] employs a data priority scheme and adapts wake-up periods according to node energy to reduce consumption. ERIMAC [18] leverages receiver-initiated communication and packet sequencing with queuing based on neighbouring energy to optimize efficiency and latency. ODMAC [19] supports nodes with diverse energy levels by duty-cycling to match consumption to harvested energy. ELMAC [20] divides the super frame into sensing, contention, and transmission intervals, prioritizing low-energy secondary users while protecting primary users. LEBMAC [21] balances load and energy by controlling duty cycles and routing packets through available awake nodes. DeepSleep [22] enhances IEEE 802.11 PSM for EH devices via a deep-sleep algorithm that reduces contention and improves energy efficiency. DSR and DSP [23] adjust duty cycles based on remaining and anticipated energy to maintain balance and reduce sleep latency. EEM-EHWSN [24] uses an energy threshold strategy to optimize active/sleep intervals, throughput, latency, and packet delivery, though it may be challenged by low node density or long harvesting intervals. Finally, the RDEHWSN scheme [8] uses preamble sampling and low-power listening to adapt sleep periods based on residual energy. It also selects relay nodes during routing to balance the load among sensors, improving throughput, latency, and packet delivery. Although such protocols enhance energy efficiency and network stability, challenges remain in multi-hop networks, variable energy availability, and reliable connectivity.

III. MATERIALS AND METHODS

III.1 E2R-EHWSN SCHEME ARCHITECTURE

This section describes the E2A2S-WSN architecture, which combines relay node selection with sleep scheduling to optimize energy control in energy-harvesting WSNs. The scheme leverages an energy level-based strategy, defined by three administrator-set levels, to balance energy harvesting while maintaining enough active nodes to ensure reliable network communication.

1- E_{CTH} **(Completion Threshold):** The energy sufficiency level ensures that relay nodes have enough power to perform essential tasks, including data transmission and reception, in the active state.
2- Sleep duration levels: Two supplementary energy levels are used to calculate the upcoming sleep interval, optimizing each node's duty cycle according to predicted residual and harvested energy:
2.1- E_{ML} **(Minimum required Level):** ensures that a node maintains a safe energy level during sleep.
2.2- E_{AL} **(Allowed Level)**: maintains balance between energy consumption and harvesting capacity across the network.

III.1.1 Relay Node Choice Procedure

E2A2S-WSN belongs to preamble sampling MAC schemes with a sender-initiated approach. It leverages harvested energy to operate a dynamic duty-cycle, reducing energy waste. Unlike BMAC [9], nodes are not cyclically synchronized, which can lead to repeated participation in data routing and energy imbalance. To address this, minor modifications were made to the RTS and CTS messages without violating the IEEE 802.11 standard. Fig. 1 illustrates the adjusted message structures.

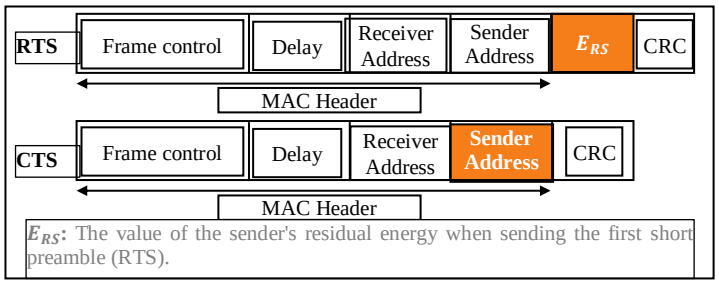

Figure 1: RTS/CTS Message Structure (Additional fields).
Source: Author, (2026).

The relay node choice procedure is designed to ensure energy-efficient and load-balanced data forwarding in E2A2S-WSN. It relies on local energy awareness, harvested energy estimation, and node load conditions, without requiring global synchronization. The proposed relay node choice procedure is illustrated in Fig. 2.

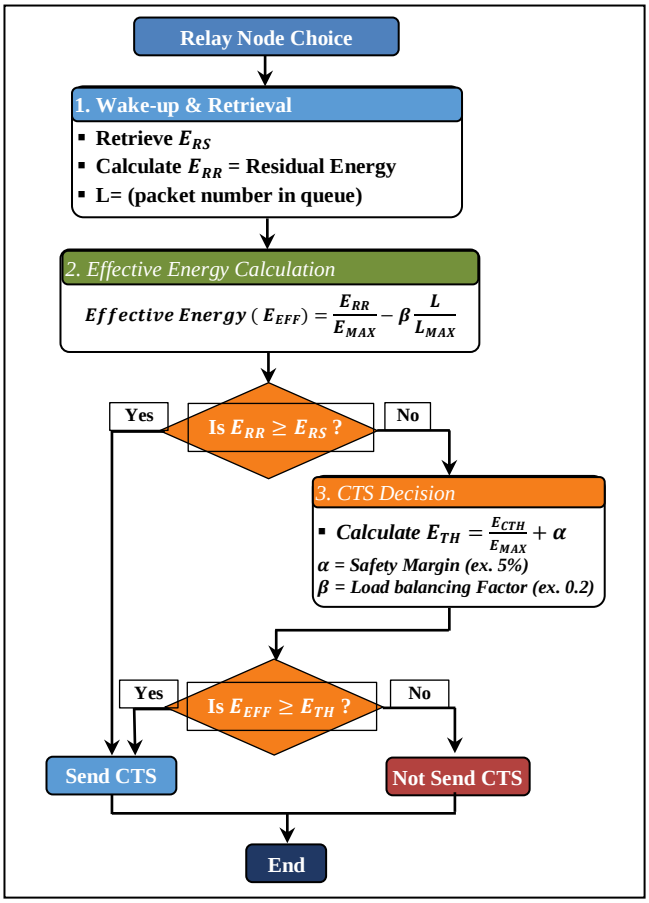

Figure 2: The proposed relay node choice procedure.
Source: Author, (2026).

When a node wakes up, it first retrieves the residual energy of the transmitting node E_{RS} from the received short RTS preamble. Simultaneously, the receiving node evaluates its own residual energy E_{RR} with recently harvested energy, and its current load L, expressed as the number of packets queued or the processing occupancy. To capture the node's actual forwarding capability, an effective energy metric is computed as:

$$E_{EFF} = \frac{E_{RR}}{E_{MAX}} - \beta\frac{L}{L_{MAX}} \quad (1)$$

Where E_{MAX} denotes the maximum energy storage capacity of a node, L_{MAX} represents the maximum supported load, and β is a weighting factor controlling the impact of node load on the relay choice decision. A minimum participation threshold is defined as:

$$E_{TH} = \frac{E_{CTH}}{E_{MAX}} + \alpha \quad (2)$$

Where E_{CTH} is the minimum required energy level to participate in routing and α is a safety margin that prevents nodes with marginal energy reserves from being selected. The receiving node responds with a CTS message if one of the following conditions is satisfied:

1. Its residual energy is greater than or equal to that of the sender:

$$E_{RR} \geq E_{RS} \tag{3}$$

2. Its residual energy is lower than that of the sender, but its effective energy exceeds the minimum threshold:

$$E_{RR} < E_{RS} \text{ and } E_{EFF} \geq E_{TH} \tag{4}$$

3. If none of these conditions is met, the node remains silent and does not participate in the forwarding process.

This relay node choice mechanism enables energy-aware and adaptive forwarding, promotes load balancing among nodes, and reduces unnecessary energy depletion, thereby extending the network lifetime without violating IEEE 802.11 MAC principles.

III.1.2 The Main Communication Mechanism of E2A2S-WSN

E2A2S-WSN adopts a communication procedure similar to RDEHWSN and relies on the CSMA/CA protocol to mitigate packet collisions among sensor nodes. Nodes with buffered data listen to the channel after each short RTS preamble and initiate data transmission only upon receiving a corresponding CTS. To enhance energy efficiency, E2A2S-WSN enables nodes to harvest energy and operate under an adaptive duty-cycle, alternating between active and sleep states. Two duty-cycle modes are supported: a fixed mode configured by the system manager and a variable mode dynamically adjusted according to the harvested and residual energy levels.

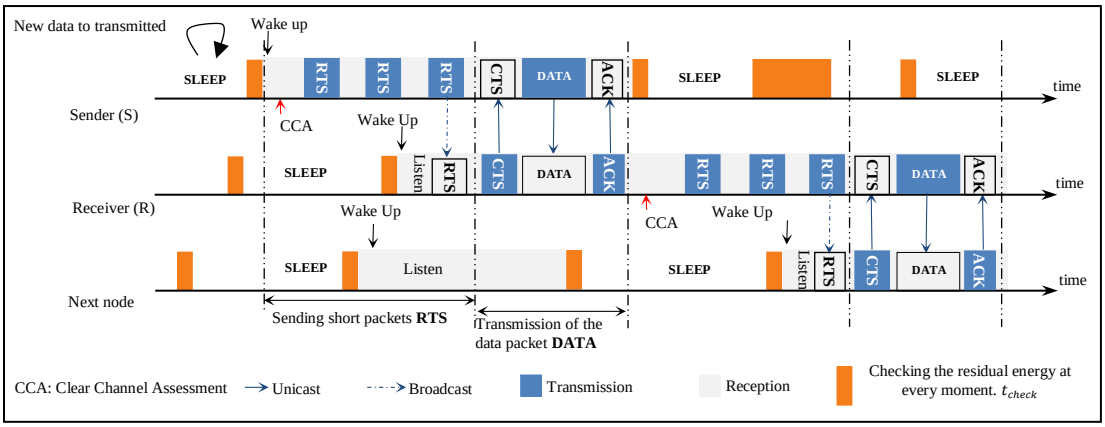

Figure 3: Illustrative diagram of the proposed E2A2S-WSN scheme operation.
Source: Author, (2026).

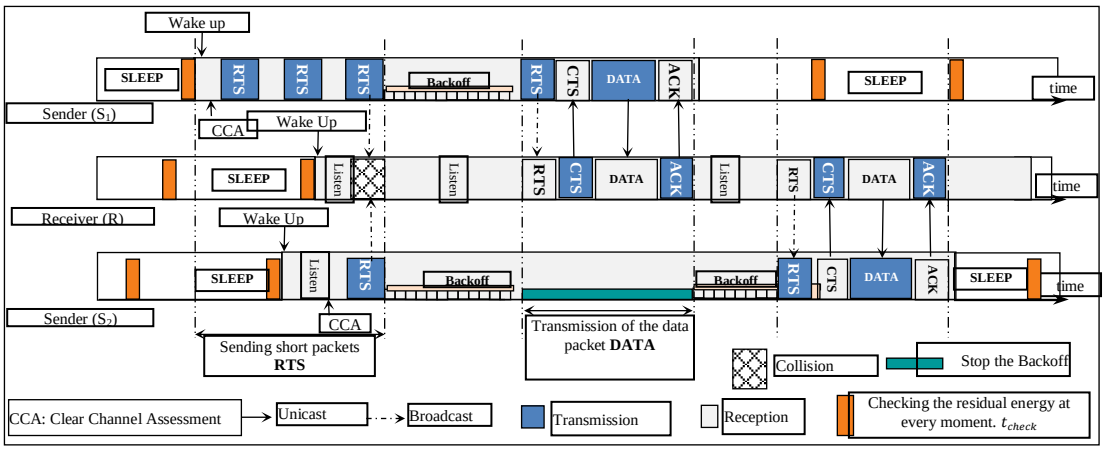

Figure 4: The collision avoidance mechanism incorporated into the proposed E2A2S-WSN scheme.
Source: Author, (2026).

Figures 3 and 4 illustrate the core communication mechanism of the E2A2S-WSN scheme between a sender and a receiving node. In this scheme, each sensor node periodically wakes up according to its own schedule to transmit data when available and switches back to sleep mode in the absence of traffic. Once the radio is activated, the sender node S initiates a preamble phase by broadcasting a sequence of short RTS packets to announce its readiness to transmit, after verifying channel availability using Clear Channel Assessment (CCA). An awake receiving node R, selected as a relay based on predefined criteria, responds with a unicast CTS packet once its backoff timer expires. Upon receiving the CTS, the sender immediately stops sending further RTS packets and transmits the data packet, provided that the channel remains free. The receiver then acknowledges successful reception by sending an ACK packet. After receiving the ACK, the sender switches directly to sleep mode. The receiver subsequently forwards the data to the next hop by repeating the same communication procedure.

III.1.3 Analytical Modeling of the E2A2S-WSN Scheme

This section introduces analytical models for energy consumption and latency in the E2A2S-WSN scheme. The network is assumed to consist of n mobile nodes operating under a static cyclic traffic pattern, where each node generates data at a fixed periodic interval. Table 1 presents the main parameters and their descriptions used in the energy and latency model.

Table 1: Symbols used in the E2A2S-WSN model.

Symbol	Description
$E_i^{Wakeup}(t)$	Total wake-up energy consumed by node *i* during interval *t*
$E_i^{cs}(t)$	Energy consumed in carrier sensing during interval *t*
$E_i^{es}(t)$	Energy consumed in environmental sensing during interval *t*
$E_i^{tx}(t)$	Energy consumed during transmission during interval *t*
$E_i^{rx}(t)$	Energy consumed during reception during interval *t*
P_{cs}	Power consumption in carrier sensing mode
P_{es}	Power consumption in environmental sensing mode
P_{tx}	Transmission power
P_{rx}	Reception power
$T_{cs}(t)$	Carrier sensing duration over interval *t*
$T_{es}(t)$	Environmental sensing duration over interval *t*
$T_{tx}(t)$	Transmission duration over interval *t*
$T_{rx}(t)$	Reception duration over interval *t*
$T_q(t)$	Packet queuing duration over interval *t*
$T_p(t)$	Packet processing duration over interval *t*
T_{acs}	Average duration of one carrier sensing operation
T_{asense}	Average duration of one environmental sensing operation
R_{data}	Data packet generation rate
R_{es}	Environmental sensing rate
L_{packet}	Data packet size
L_{CTS}	CTS packet size
L_{ack}	ACK packet size
T_{bit}	Time required to transmit one bit
T_{SW}	Switching time between TX and RX modes

Source: Author, (2026).

The expected energy consumption of node *i* in the E2A2S-WSN scheme during the wake-up interval *t* is determined by the energy spent on carrier sensing (*cs*), environmental sensing (*es*), packet transmission (*tx*), and packet reception (*rx*), as expressed in Equation (5).

$$E_i^{Wakeup}(t) = E_i^{cs}(t) + E_i^{es}(t) + E_i^{tx}(t) + E_i^{rx}(t) = P_{cs}T_{cs}(t) + P_{es}T_{es}(t) + P_{tx}T_{tx}(t) + P_{rx}T_{rx}(t) \quad (5)$$

Before transmitting the preamble, the node performs carrier sensing at each wake-up period and also activates its environmental sensors to monitor physical parameters. The total durations of carrier sensing and environmental sensing over an interval *t* are given by equations (6) and (7) respectively, which scale linearly with the observation interval.

$$T_{cs}(t) = T_{acs}R_{data}t \quad (6)$$

$$T_{es}(t) = T_{asense}R_{es}t \quad (7)$$

During a time interval *t*, the total transmission time of a data packet by node *i* is the sum of the durations required for sending the RTS, the Data packet, and the corresponding acknowledgments: CTS (in response to the RTS) and ACK (in response to the Data). Before transmitting the Data packet, the node first sends an RTS for a duration T_{SP} and immediately switches its radio to listening mode to receive the CTS. This procedure may be repeated *K* times if multiple RTS attempts are needed. Upon receiving the Data packet, the receiver immediately switches its radio to transmit an ACK back to the sender, completing the transmission cycle.

$$T_{tx}(t) = t.R_{data}\left(L_{packet} + L_{CTS} + L_{ack}\right)T_{bit} + KT_{SP} + (K+2)T_{SW} \quad (8)$$

During a time interval *t*, a node may receive multiple RTS preambles, data packets, and corresponding acknowledgments (CTS and ACK). For each received RTS preamble, the target receiver immediately replies with CTS, allowing the transmitter to send its data packet. Upon receiving the data, the receiver sends an ACK, completing the transmission cycle. The total number of these exchanges and the associated durations accumulate over the interval *t*, contributing to the node's overall communication time and energy consumption.

$$T_{rx}(t) = t.R_{data}\left(L_{packet} + L_{CTS} + L_{ack}\right)T_{bit} + \sum T_{SP} + 2T_{SW} \quad (9)$$

Before transmitting a buffered data packet, the sending node first transmits one or more RTS preambles. Upon receiving the RTS and the subsequent data packet, the receiver responds with the corresponding CTS and ACK acknowledgments. Based on equations (6), (8), and (9), the expected transmission latency can be expressed as:

$$L_{atcy}(t) = T_q(t) + T_p(t) + T_{cs}(t) + T_{tx}(t) + T_{rx}(t)$$
$$= T_q(t) + T_p(t) + T_{cs}(t) + t.R_{data}\left(2\left(L_{packet} + L_{CTS} + L_{ack}\right)t_{bit} + (K+1)T_{sp}\right) + (K+4)T_{SW} \quad (10)$$

III.1.4 Proposed Next Sleep Interval Determination in E2A2S-WSN

E2A2S-WSN operates using a dynamic duty cycle adjusted according to each node's energy harvesting rate. Nodes with higher available energy remain active longer and thus forward more packets. To reduce collisions among neighboring nodes, the protocol assigns differentiated sleep durations that are intentionally non-uniform. Nodes with lower energy levels enter deeper sleep periods to harvest more energy and restore their balance. This section presents the mechanism used to determine the next sleep duration.

1. Node residual energy calculation

The residual energy of node *i* at time *t* ($E_{R_i}(t)$) equals the previous energy minus the consumed energy plus the harvested energy over the interval Δt.

$$E_{R_i}(t) = E_{R_i}(t - \Delta t) - E_{used_i}(\Delta t) + E_{harvested_i}(\Delta t) \quad (11)$$

Where:

$\Delta t = t - t_{prev}$ and t_{prev} represents the previous evaluation instant.
$E_{R_i}(t - \Delta t)$: residual energy of node *i* at the previous time instant.
$E_{used_i}(\Delta t)$: energy consumed by node *i* during the Δt.
$E_{harvested_i}(\Delta t)$: energy harvested by node *i* during the same interval Δt.

2. Node next sleep duration calculation

To compute the next sleep duration of each node *i*, E2A2S-WSN relies on two energy thresholds: a threshold energy E_{AL} and a critical energy E_{ML}, with $E_{MAX} > E_{AL} > E_{ML}$. E2A2S-WSN operates in two duty-cycle modes:

2.1. Fixed Mode

At network startup, each node follows administrator-defined sleep and wake durations. This mode is maintained as long as the residual energy remains greater than or equal to E_{AL}.

2.2. Dynamic Mode

When operating dynamically, the sleep duration is adjusted according to the node's residual energy. where this mode is used by each node *i* in the rest of its operation. The next sleep duration is calculated using the equations below

- **Equation for calculating long sleep Duration.**

$$D_{SLP_i}\left(E_{R_i}(t)\right) = \left(\frac{E_{Max} - E_{R_i}(t)}{E_{Max} - E_{AL}}\right) \times D_{SS_i} \quad (When\ D_{SS_i}\ \text{is only computed}) \quad (12)$$

$$D_{SLP_i}\left(E_{R_i}(t)\right) = \left(\frac{E_{Max} - E_{R_i}(t)}{E_{Max} - E_{AL}}\right).D_{SS_i} + \mu\left(E_{R_i}(t)\right).\rho \quad \left(When\ D_{CSS_i}\ and\ D_{SS_i}\ \text{are computed}\right) \quad (13)$$

- **Equation for calculating short sleep Duration**.

$$D_{SLP_i}\left(E_{R_i}(t)\right) = e^{\log_2\left(\left(\frac{E_{Max} - E_{remi}}{E_{Max} - E_{Thr}}\right) \times D_{SS_i}\right)} \quad (When\ D_{SS_i}\ \text{is not calculated and}\ E_{R_i}(t) < E_{Max}) \quad (14)$$
$$\left(\text{The old computed } D_{SS_i} \text{ value is used}\right)$$

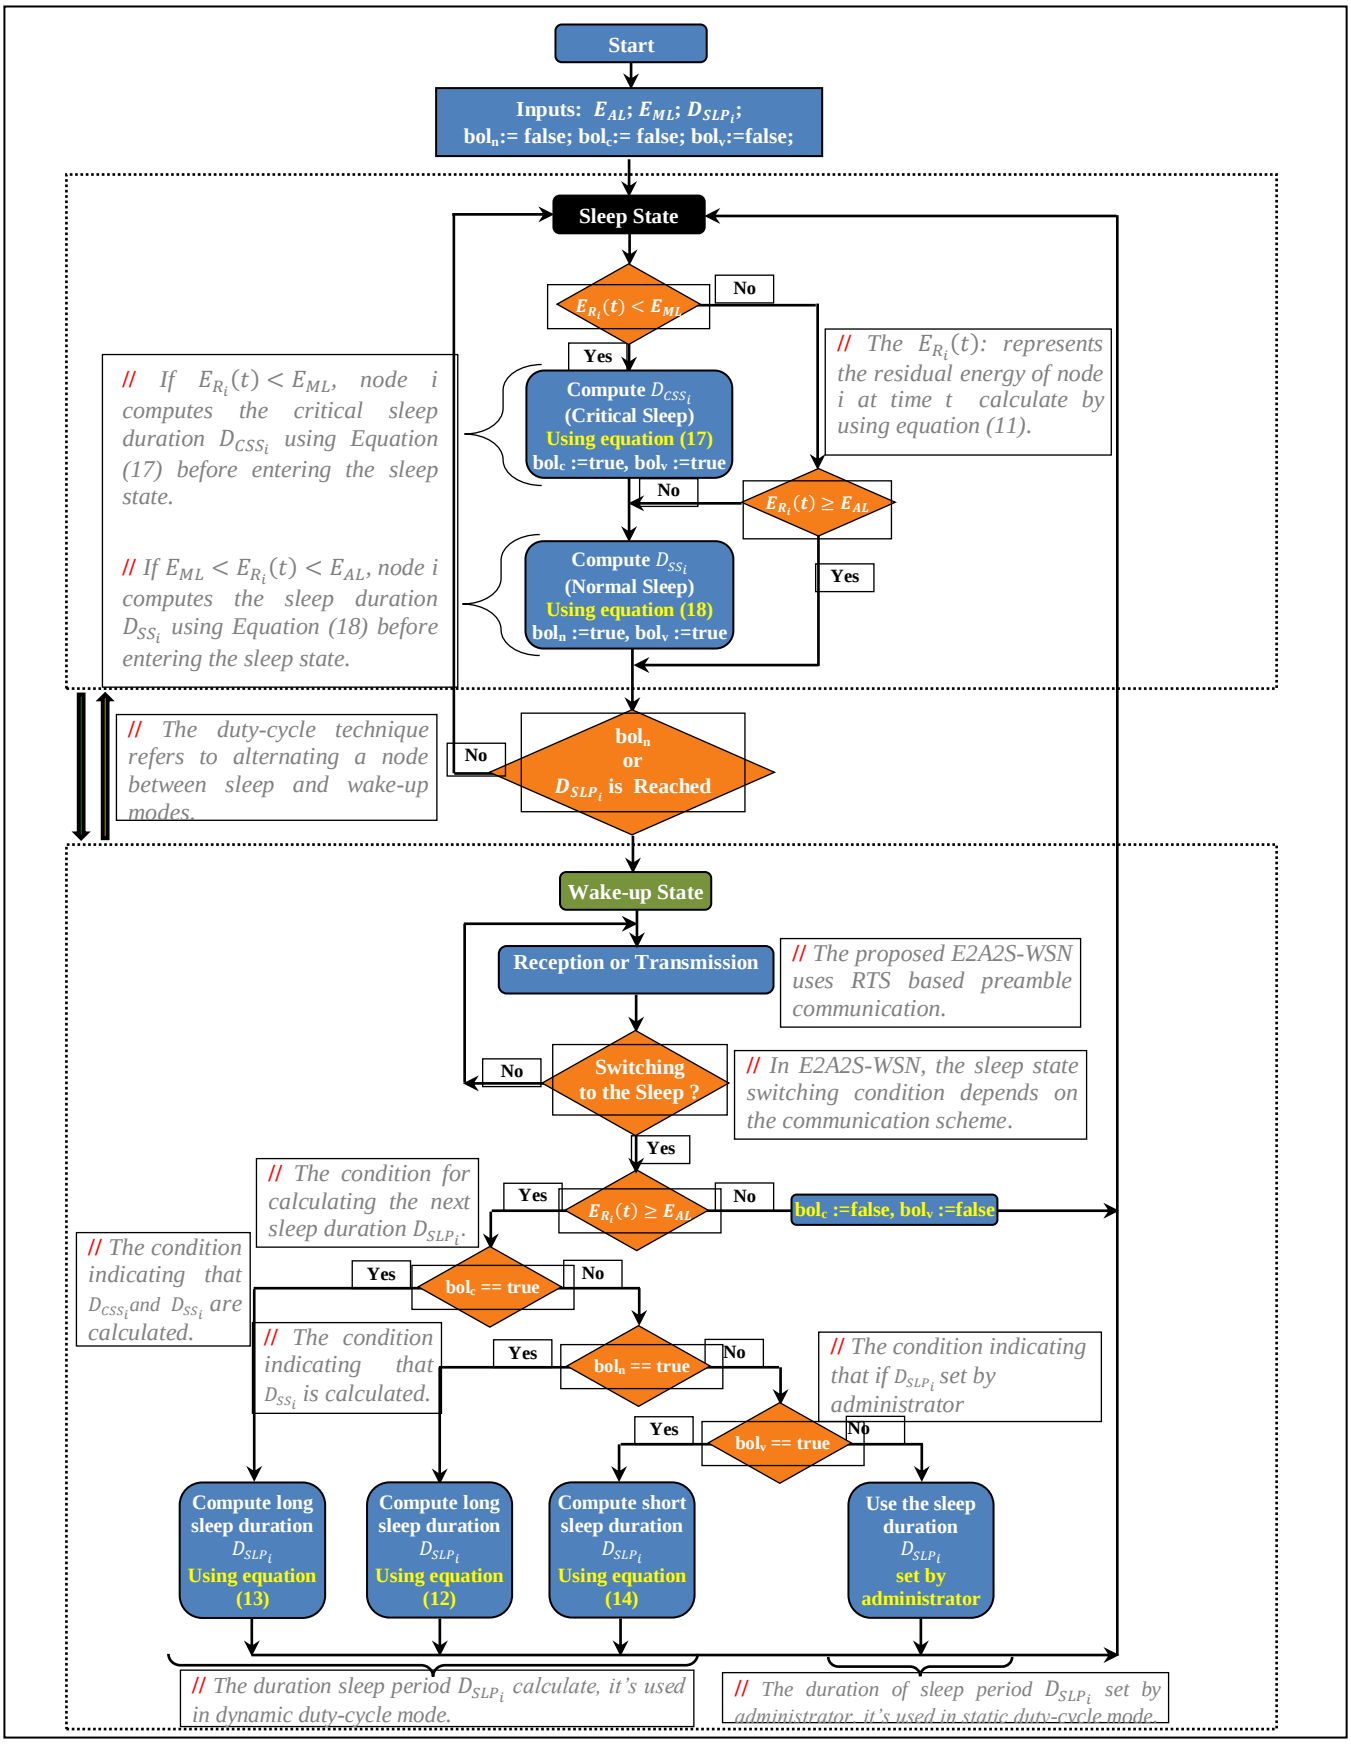

Figure 5: The key functions of the proposed E2A2S-WSN scheme.
Source: Author, (2026).

With:

$$\mu\left(E_{R_i}(t)\right) = \frac{\left(E_{R_i}(t) - E_{Max}\right) * \left(E_{R_i}(t) - E_{AL}\right)}{E_{AL} - E_{ML}} \quad (15)$$

$$\rho = \left(\frac{D_{CSS_i}}{E_{Max} - E_{ML}} - \frac{D_{SS_i}}{E_{Max} - E_{AL}} \right) \tag{16}$$

$$D_{CSS_i} = \min\left(D_{CSS_i}, 1\right) \tag{17}$$

$$D_{SS_i} = \min\left(D_{SS_i}, 1\right) \tag{18}$$

Where:

$E_{R_i}(t)$: Residual energy of node *i* at *t* instant.
D_{SS_i} : Sleep duration of node *i* until its residual energy becomes greater than or equal to the threshold E_{AL}.
D_{CSS_i}: Critical sleep duration of node i until its residual energy becomes greater than or equal to the critical threshold E_{ML}.

2.3. Next sleep duration calculation procedure

The procedure for computing the next sleep duration $D_{SLP_i}\left(E_{R_i}(t)\right)$ of node *i* in this mode is described below and is illustrated in Fig. 5.

a. In Sleep State

1. If $E_{R_i}(t) < E_{ML}$, node *i* first calculates the elapsed **critical sleep duration** D_{CSS_i} using Equation (17) until its residual energy reaches E_{ML}, and then computes the normal sleep duration D_{SS_i} using Equation (18) until its residual energy reaches E_{AL}.
2. If $E_{ML} < E_{R_i}(t) < E_{AL}$, node *i* computes only the elapsed normal sleep duration D_{SS_i} using Equation (18), until its residual energy reaches E_{AL}. This check is performed before entering the sleep state.

b. In wake-up State

1. The long sleep duration calculation. While $E_{R_i}(t) \geq E_{AL}$, node *i* computes its long sleep interval $D_{SLP_i}\left(E_{R_i}(t)\right)$ as follows:

1.1. Using Equation (12) if only D_{SS_i} has been calculated.
1.2. Using Equation (13) if both D_{SS_i} and D_{CSS_i} have been calculated.

2. The short sleep duration is computed for node *i* while $E_{R_i}(t) \geq E_{AL}$ using Equation (14), with the node employing the previously calculated value of D_{SS_i} if it has not been computed yet.

III.2 SIMULATION

III.2.1 Implementation and Simulation in OMNeT++/MiXiM

The proposed E2A2S-WSN is implemented using the OMNeT++ simulator with the MiXiM framework [25], [26]. A custom node module, HostE2A2S-WSN, based on WirelessNodeBattery, is created, featuring standard layers (application, presentation, session, transport, network) and a custom network interface card (NIC) NicE2A2S-WSN integrating the new MAC module E2A2S-WSNLayer, which manages connections with other modules and layers.

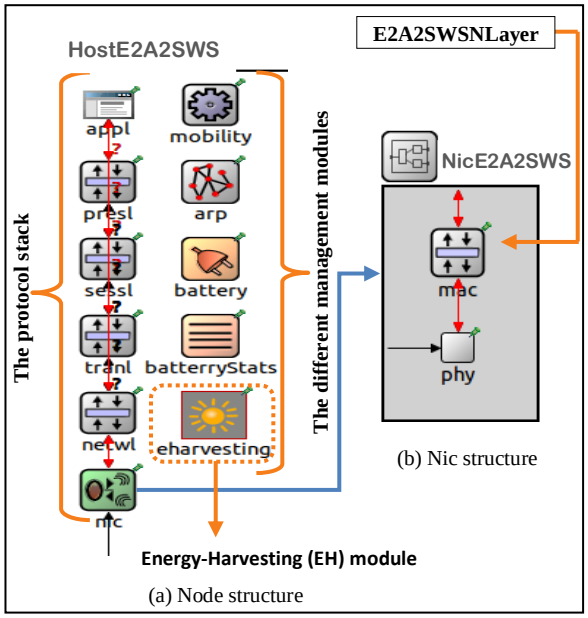

Figure 6: The architecture of the node and the NIC module employed in E2A2S-WSN for WSN implementation.
Source: Author, (2026).

Additional modules handle mobility, address resolution (ARP), battery management, energy statistics, and a new energy harvesting unit supporting exponential, uniform, or periodic harvesting. This architecture allows nodes to switch between sleep and active states and to transmit packets, facilitating performance evaluation of E2A2S-WSN. The structure of a node and the structure of the NIC module used in the WSN by E2A2S-WSN are illustrated in Figure 6.

III.2.2 Simulation Setup and Network Topology

To evaluate the proposed E2A2S-WSN scheme, a wireless sensor network was simulated using OMNeT++-4.6 with the MiXiM-2.3 framework.

Table 2: Parameters of simulation.

Parameter	***Value***
Nodes number	20, 40, 60, 80, 100
Simulation time/run	1000s
Playground Size	400x400 m², 600x600 m², 800x800 m², 950x950 m², 1100x1100 m²
Mobility Type	ConstSpeedMobility
Mobility Speed	2 mps
Start residual energy $E_{R_i}(t)$	50 J
Allowed Level E_{AL}	30 J
Energy completion threshold	35 J
Safety margin α	5%
Minimum required Level E_{ML}	15 J
Load balancing Factor β	0.2
Traffic Type	Periodic
Traffic Param	0.1s, 0.5s
Number of Packets sent	500
Destination Node	19, 39, 59, 79, 99
Queue Size	10 packets
MaxAttempts	2
Battery capacity	100 J
Harvesting Type	Periodic
Harvesting Param	0.05 s
Harvesting rate randomly	[0mW...50mW]

Source: Author, (2026).

Simulation parameters, defined in the omnetpp.ini file, include the MAC type and physical layer settings. Two key intervals are considered: Traffic Param (time between packet transmissions) and Harvesting Param (time between energy harvesting events). Simulations involve 20 to 100 mobile sensor nodes deployed over areas ranging from 400×400 m² to 1100×1100 m², with 100 m spacing, during 1000 s of simulated time. Nodes generate periodic traffic (0.1 or 0.5 s) toward a sink via multi-hop communication. Energy harvesting is periodic (0.05 s), with harvested energy randomly varying between 0 and 50 mW. Each node starts with 50 J (maximum 100 J), with energy levels set to $E_{AL} = 30\,J$, $E_{CTH} = 35\,J$, and $E_{ML} = 15\,J$. Table 2 displays the different parameters that were employed.

III.2.3 Performance Evaluation

The performance of the proposed E2A2S-WSN scheme is evaluated through extensive simulations and compared to a RDEHWSN scheme with a less adaptive duty-cycle. E2A2S-WSN ensures stable network operation by dynamically adjusting nodes' duty-cycles based on their estimated residual energy. The evaluation uses the following performance metrics:

Average Packet Latency (*APL*): The mean end-to-end delay experienced by successfully delivered packets. Lower *APL* indicates improved temporal efficiency.

Packet Delivery Ratio (*PDR*): Ratio of successfully received packets at the destination to the total packets transmitted by source nodes. This metric should be maximized to ensure reliable communication.

$$PDR = \frac{P_{received}}{P_{sent}} \tag{19}$$

Where:

$P_{received}$: Total number of packets successfully received at the sink node.
P_{sent}: Total number of packets generated and transmitted by the source nodes during the simulation.

Average Energy Consumption per Node: Defined as the average of the mean consumed energy (*MCE*) across all nodes in the WSN, and should be minimized:

$$Avg(MCE) = \frac{1}{N}\sum_{i=1}^{N} MCE_i \quad (20)$$

Where:

$$MCE_i = \frac{E_{consemed,i}}{T_{similated\ time}} \quad (21)$$

With: $E_{consemed,i}$: consumed energy by the node i.

Network Lifetime (L): Defined as the time until the first sensor node depletes its energy or becomes unable to transmit during data collection. This metric should be maximized.

Throughput (THR): the total transfer rate (obtained bytes/ time of simulation), expressed in bits per second, which should be augmented. It can be calculated as:

$$THR = \frac{Nbr_{tran}^{pck} \times size\ of\ packet}{simulation\ time} \quad (22)$$

Where: Nbr_{tran}^{pck}: Number of transferred packets.

IV. RESULTS AND DISCUSSIONS

Figures 7–12 present the simulation results in terms of packet delivery ratio, average latency (*ms*), throughput (*bps*), average energy consumption per node (*mJ*), and network lifetime (s). The evaluation is conducted under different traffic scenarios, where the traffic parameter is set to 0.1 s or 0.5 s, the number of nodes varies from 20 to 100, and the total transmitted packets set to 500. The results show that increasing the number of nodes in the WSN leads to a decrease in packet delivery ratio, while most other metrics increase, including average latency, throughput, network lifetime, and overall energy consumption. The rise in energy consumption is further amplified by the increase in the number of transmitted packets.

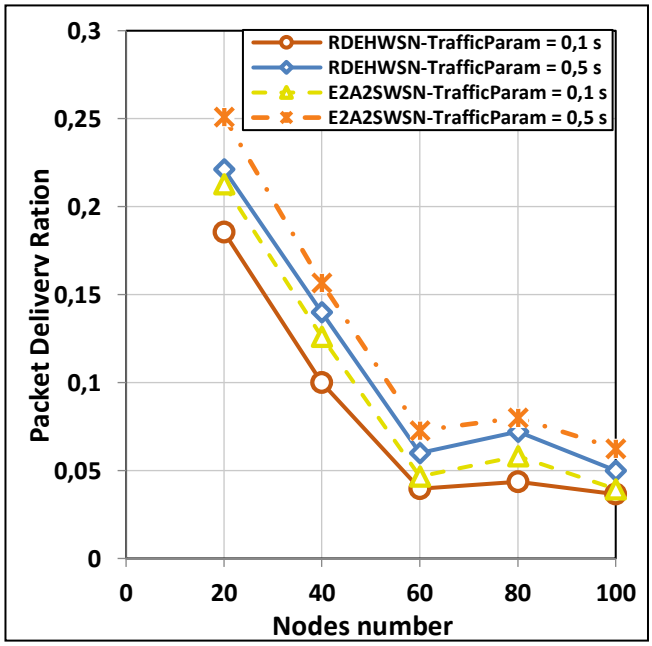

Figure 7: Packet Delivery Ration.
Source: Author, (2026).

In Figure 7, the E2A2SWSN outperforms the RDEHWSN in terms of packet delivery ratio across different EH rates. This improvement is mainly attributed to the more aggressive and fine-grained dynamic adjustment of the duty cycle in E2A2SWSN, which is driven by the residual energy that may progressively increase over time. In addition, the superior performance results from the integration of pulse-boot technology and the efficient load balancing mechanism implemented through the proposed relay node selection procedure. This mechanism ensures a better distribution of traffic among WSN nodes compared to RDEHWSN. Furthermore, in E2A2SWSN, sleep periods are intentionally adjusted with a higher incremental rate than in RDEHWSN, where sleep scheduling may not be symmetrical among neighboring nodes. This coordinated adjustment significantly reduces packet collisions and retransmissions. In contrast, in RDEHWSN, the redirection of data packets from the sender to the receiver can increase the likelihood of collisions, which in turn raises the probability of packet loss. These repeated retransmissions lead to higher energy consumption and may cause noticeable disruptions in WSN communication. For example, when the number of nodes increases from 20 to 60 (Figure 7), E2A2SWSN achieves higher packet delivery rates than RDEHWSN. At a traffic interval of 0.1 s, the improvement ranges from approximately 12.75% to 15.16%, while at 0.5 s, it varies between 11.95% and 17.49%. With 100 nodes, E2A2SWSN further demonstrates significant gains, improving the delivery rate by 7.45% at 0.1 s and 20.05% at 0.5 s compared to RDEHWSN. Overall, E2A2SWSN consistently provides better packet delivery performance than RDEHWSN, especially as WSN density increases.

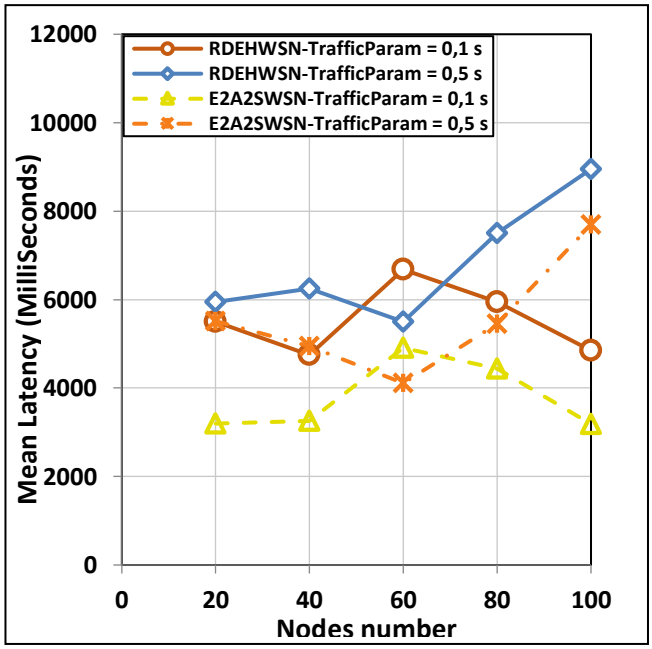

Figure 8: Mean Latency.
Source: Author, (2026).

Figure 8 shows that E2A2SWSN outperforms RDEHWSN as the number of nodes increases, particularly in terms of average latency. This improvement is mainly due to the relay node selection mechanism, which ensures efficient load balancing by prioritizing nodes with higher residual energy and shorter standby durations. The sleep time is dynamically computed according to the evolution of residual energy. In the case of a rapid increase in residual power, the short sleep time is calculated using equation (14), similarly to RDEHWSN. However, when the residual energy increases slowly, a long sleep time is determined using equations (12) or (13), which provide more accurate estimation than RDEHWSN. Moreover, the use of a discontinuous preamble reduces packet buffering and retransmissions, further decreasing latency. As a result, with 100 nodes, E2A2SWSN improves the average response time by approximately 34.27% at a traffic interval of 0.1 s and by 14.07% at 0.5 s compared to RDEHWSN.

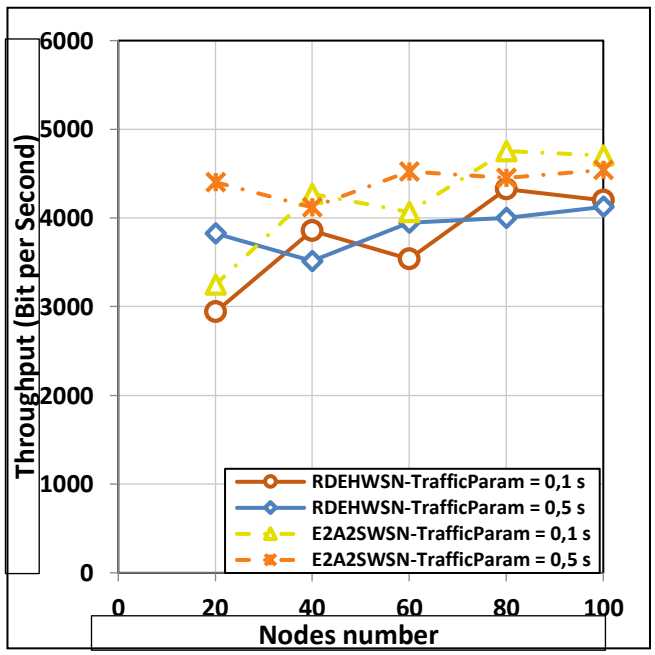

Figure 9: Throughput.
Source: Author, (2026).

Figure 9 shows that the E2A2SWSN network achieves higher throughput than RDEHWSN as the network size increases. This improvement is mainly attributed to the significant dynamic reduction of the sensor node activity period, which is adaptively adjusted according to the combined harvested and residual energy levels. Such an approach enables a more aggressive and precise duty-cycle adaptation compared to RDEHWSN. In addition, the use of an intermittent (discontinuous) preamble mechanism, combined with an efficient relay node selection strategy, ensures effective load balancing among nodes. This coordination reduces packet collisions and retransmissions. Since a higher collision rate increases transmission delay, packet loss, and energy consumption, minimizing retransmissions directly enhances throughput and stabilizes data transmission in the WSN.

For instance, when the number of nodes increases from 60 to 100 with a traffic interval of 0.1 s, Figure 9 indicates a throughput increase of 18.62% for E2A2SWSN, compared to 15.69% for RDEHWSN. Moreover, with 100 nodes and a traffic interval of 0.1 s, E2A2SWSN achieves an additional throughput gain of approximately 10.75% over RDEHWSN. Overall, E2A2SWSN provides more stable and efficient throughput performance.

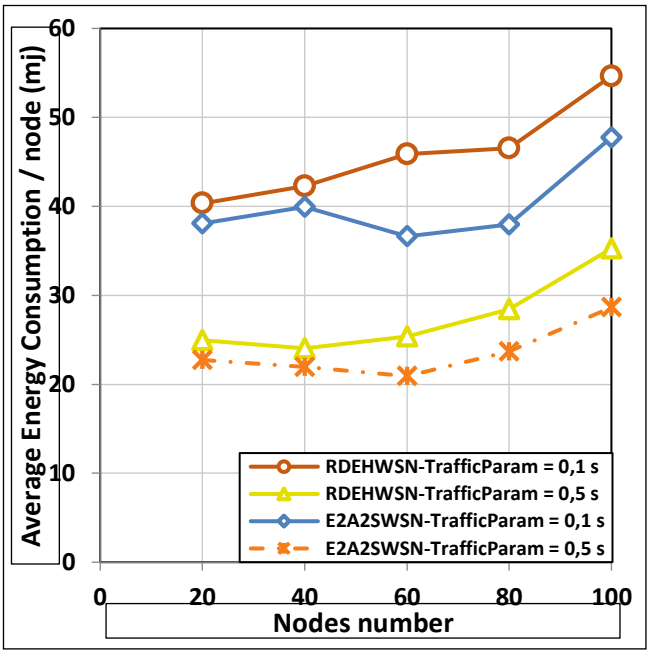

Figure 10: Average energy consumption.
Source: Author, (2026).

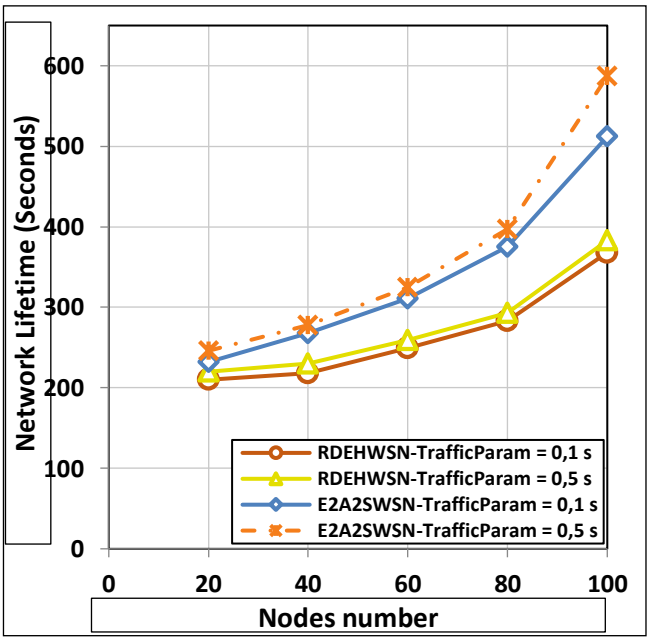

Figure 11: Network lifetime.
Source: Author, (2026).

Figure 10 shows that E2A2SWSN achieves better energy consumption performance than RDEHWSN under different energy harvesting (EH) rates. This improvement is mainly due to the intermittent booting mechanism, which allows each sensor node to dynamically and more accurately adjust its duty cycle based on the evolution of residual energy. As residual power increases over time, nodes can refine their operating and sleep periods more effectively than in RDEHWSN. Sleep durations are also carefully coordinated and are not necessarily identical among neighboring nodes, which helps reduce simultaneous wake-ups and channel contention. In addition, the efficient load balancing mechanism implemented through relay node selection minimizes packet collisions and retransmissions two major sources of excessive energy consumption and communication interruptions in WSNs. Figure 10 further indicates that, for traffic intervals of 0.1 s and 0.5 s, the energy-saving efficiency per node in E2A2SWSN remains consistently higher throughout the simulation compared to RDEHWSN. For example, at a traffic interval of 0.5 s, E2A2SWSN improves energy conservation by approximately 17.57% with 20 nodes and by about 18.77% with 100 nodes. Overall, E2A2SWSN ensures more efficient and scalable energy management.

The results related to the network lifetime metric indicate that the lifetime increases with the number of nodes for both E2A2SWSN and RDEHWSN under different EH rates. This improvement is mainly due to the use of the strobed preamble mechanism and the dynamic duty-cycle adaptation implemented in both schemes. As illustrated in Figure 11, E2A2SWSN outperforms RDEHWSN because it applies a more aggressive and in-depth dynamic adjustment of the duty cycle. Moreover, E2A2SWSN integrates a relay node selection mechanism that ensures efficient load balancing within the WSN. This strategy prioritizes nodes with higher residual energy, enabling them to remain active with shorter sleep durations, while preventing relay nodes from rapidly depleting their energy after cooperative transmissions. As a result, the overall network lifetime is significantly extended. Figure 11 further shows that when the number of nodes increases from 20 to 100, E2A2SWSN improves network lifetime by approximately 9.48% to 28.12% at a traffic interval of 0.1 s, and by 10.57% to 34.75% at 0.5 s, compared to RDEHWSN. To improve WSN performance in EH environments, particularly in terms of energy efficiency, mean latency, throughput, and packet delivery ratio, it is essential to ensure load balancing among nodes and to more aggressively reduce the duty cycle. This approach helps limit energy consumption caused by long active periods and collisions during data transmission, which are major sources of performance degradation, delays, and packet loss in WSNs. By combining load balancing with adaptive duty-cycle reduction, E2A2SWSN dynamically adjusts nodes' sleep periods so that neighboring nodes are unlikely to wake up simultaneously, thereby reducing collisions and retransmissions. As a result, E2A2SWSN outperforms RDEHWSN, which also uses a dynamic duty cycle but cannot guarantee effective load balancing and behaves similarly only when the average EH rate is high.Overall, E2A2SWSN achieves significant improvements in energy efficiency, throughput, mean latency, packet delivery ratio, and WSN lifetime compared with RDEHWSN.

V. CONCLUSIONS

This paper introduces the E2A2SWSN scheme for mobile EH-WSNs as an improved version of RDEHWSN. The proposed approach reduces energy consumption through dynamic duty-cycle scheduling combined with a strobed preamble mechanism and an effective load balancing strategy. Its main contribution is the accurate and more adaptive computation of the next sleep period based on residual energy, allowing each node to dynamically adjust its duty cycle according to the harvested energy rate. Furthermore, a novel relay node selection mechanism ensures balanced energy usage among nodes, prevents premature energy depletion, and maintains stable WSN operation. Simulation results under various traffic conditions and EH rates show that E2A2SWSN outperforms RDEHWSN by improving packet delivery ratio, reducing latency, increasing throughput, enhancing energy efficiency, and extending WSN lifetime. Future work will evaluate the scheme under additional traffic models and develop a DTN (Delay Tolerant Network) based algorithm to handle scenarios with a limited number of active nodes due to prolonged low EH or high dormancy levels.

Small Signal Stability

ABSTRACT

The small signal stability analysis is a pivotal tool for understanding low frequency oscillatory phenomenon and dynamic voltage instability. To address dynamic instability, new load flows were executed by increasing the load and generation profiles. These solutions are offered to linearization programs to investigate asymptotic stability of equilibrium points in nonlinear systems. Taking two cases and eight subcases in Kundur two area system, Hopf bifurcations were induced and corresponding bifurcation parameters were obtained with and without Power System Stabilizer (PSS) placement alongside static exciter. Capability of PSS in extending the load limits at various load buses was observed via Hopf bifurcation analysis. Performance of PSS in extending the dynamic stability limit at various load buses under single tie line contingency was also studied and it was found that PSS improved the dynamic power loading at those buses.

I. INTRODUCTION

Low frequency oscillatory behaviour and dynamic instability phenomenon arising in power grids can be studied by using small signal analysis [1]. As power systems are inherently nonlinear, they are represented by Differential-Algebraic Equations (DAE's). It is necessary to use linear and nonlinear dynamical theories to study system behaviour. The concept of damping is central for understanding the stability of dynamical system. Low frequency oscillations pose threat to system behaviour. To improve the damping of low frequency oscillations, it has been suggested in [2], [3] to use Power System Stabilizer's (PSS) along with inherent Automatic Voltage Regulator (AVR). The design of PSS in power systems *via* comprehensive damping ratio index maximization to simultaneously improve all the modal damping ratios are suggested in the works of [4]. Among them, local area modes whose frequency range is from 0.8 -2.5 Hz and the inter area modes whose frequency range is from 0.2-0.8 Hz needs to be studied for stabilizer design [3]. Although, there are many types of PSS architectures like PSS 2B, 3B, 4B [5], most of the references like [3], [6] have used two stage lead lag PSS topology for controller design. A brief review of PSS types and their tuning can be seen in [2]. These PSS models are combined with models of synchronous machines, AVR and network. Various types of generator models like 0.0, 1.0, 1.1, 2.1, 2.2, 3.2 and 3.3 are presented in literature. The number preceding the dot represents the number of windings on d-axis. The number succeeding the dot represents the number of windings on q-axis [7]. Multi machine systems with more load buses needs to be analysed because both small signal angle stability and voltage stability are to be examined. In this manuscript, the authors have chosen to use Kundur two area system shown in Figure 1 to study the above phenomenon. For linearization, Hartman–Grobman theorem [8] states that the stability of equilibrium points in a nonlinear system synthesised via linear analysis can be used to find the asymptotic stability of the same. If one of the poles of the linearized system cross the imaginary axis, into right half of S-plane while the other roots lie in the left half, such a phenomenon is known as Hopf bifurcation. The parameter which induces this phenomenon is known as bifurcation parameter. Applications of Hopf bifurcation are also observed in several engineering disciplines [9]. Hopf bifurcation-based DC-DC converter design for feeding Constant Power (CP) loads can be seen in [10]. Loads like constant horse power motors have inverse relation between speed and torque and hence their product i.e. output mechanical power becomes constant. If losses are neglected, the input power drawn becomes constant which reflects CP load behaviour in steady state.

Simulations of systems with multiple static and dynamic load models drawing power at load buses are found in [11]. Increasing available transfer capacity in Kundur two area system via Hopf and saddle node bifurcation details are studied by [12]. Authors of [12] considered 0.0 model for generator and constant impedance model for load for Hopf bifurcation analysis. [3] didn't consider the effects of Hopf bifurcation in Western States Coordinating Council System having renewable sources. They limited their discussions to prove the ability of PSS in minimizing time-domain metrics via artificial intelligence techniques. It was mentioned in [13] that [14] didn't consider the change in network topology for redesigning controls via Hopf bifurcation. Inspired from their reviews, this deficiency was also dwelled on authors of this manuscript by removing one tie line in service of Kundur two area system. In conventional power system stability program, most of the authors [15] treat loads as constant impedance as these values can be merged with the existing bus admittance matrix in a systematic manner. We have considered CP load model in this paper. Figure 1 shows typical diagram of the system having four generators (G_1, G_2, G_3, G_4) and two loads (A and B) connected through a transmission network. G_1, G_2 and G_3, G_4 are from area 1 and area 2 respectively. While [16] considered PSO-PSS at G_1 for damping ratio improvement via comprehensive index ratio maximization, the authors of this manuscript extended the study of Hopf bifurcations in the same system with PSO-PSS data. From the above literature, the following objectives are defined:

1. Improving the damping of inter area mode and other swing modes for congested and single tie line contingency cases by installing PSS besides AVR.
2. Exploring the dynamic instability phenomenon without PSS in Kundur two area system by treating loads as constant power instead of constant impedance as in [15].
3. Extending the dynamic instability through Hopf bifurcation analysis with PSS in the system for congested and single tie line contingency cases after installing PSS.

Industrial relevance of the above objectives is further detailed below:

1. In power industry, proper placement and sizing of PSS at the generating station improves the damping ratio of swing and interarea modes. Thus, if small oscillations build up in the inter area power flowing from one area to another area, these can be significantly damped using PSS.
2. Year after year, the utilities increase their generating capacities to match with the increase in the demanded power of the consumers. If the maximum loadability limits are exceeded there is a possibility for blackouts and this can be prevented by the power industry operators and planners.
3. If the maximum loadability limits can be extended by placing devices like PSS at the generating end, unnecessary load shedding, blackout prevention, transmission line and generator outages can be avoided to certain extent. This ensures continuous and reliable power supply which is central objective to power industry investors.

Case 1 and 2 deal with the congested and single tie line contingency cases. Here the variable 'λ' stands for the loading parameter at the load bus 5 and 6. The following variations A-H is explored for assessing the dynamic instability phenomenon.

A, B: Variation in real power of load -A and load-B respectively without PSS.
C, D: Variation in λ corresponding to load-A and load-B respectively without PSS.
E, F: Variation in real power of load-A and load-B respectively with PSS.
G, H: Variation in λ corresponding to load-A and load-B respectively with PSS.

Section II deals with general details of system modelling and Hopf bifurcation. Section III deals with the results and discussions. Section IV provides conclusions of the study.

II. SYSTEM MODELLING AND HOPF BIFURCATION

Section II.1 enumerates the modelling of Kundur two area system without any PSS. Section II.2 explains the modelling of power system stabilizer. Section II.3 details the general concepts of Hopf bifurcation and Section II.4 combines all the above via a detailed algorithm.

II.1 MODELLING OF KUNDUR TWO AREA SYSTEM

Details of modelling of Kundur two area system for linearization can be found in [1]. The nomenclature is taken from [1]. System has 10 nodes, 4 transformers and 11 lines. Buses 1-3 are PV buses. Bus no 4 is taken as slack bus. Nodes 5-10 are modelled as PQ buses. The 5th and 6th buses are having shunt capacitive susceptance of 3 and 4 p.u. All generators are modelled by two axis model i.e.1.1 whose details are found in [1].

Stator is represented by algebraic expressions instead of differential equations to simplify analysis. State variables of rotor circuits are taken as E'_q and E'_d instead of flux linkages to make analysis neat and elegant. Static exciter of single time constant and a large gain is modelled at each generator. Network is represented by medium π section quasi-steady state model in real and reactive power balance form. Loads are represented by CP absorbing type models in both dynamic and steady-state. Network transients are neglected as only low frequency modes are of concern. To study sub synchronous resonance phenomenon, it is vital to represent the network with the differential equations instead of steady state equations.

II.2 MODELLING OF POWER SYSTEM STABILIZER

Power system stabilizer (PSS) is an economic choice for damping improvement which is placed as an input to AVR block. It improves the damping as it is accommodated with lead lag blocks of time constants 'T_1', 'T_2', 'T_3'and 'T_4'. To ensure that it only responds during transient conditions, a practical differentiator of gain 'K_s' and time constant 'T_Q' is connected in cascade to the above as shown in Figure 2. The PSS presented in this manuscript utilizes 'Δω' as control input. The value of washout time constant 'T_Q' depends on the objective of compensation. If the objective is to improve the local mode of oscillation arising in single machine connected to infinite bus system, then 'T_Q' is taken between 1-2 s [7]. For improving the damping ratio of inter area modes generated from multi-machine systems, value of the same needs to be chosen between 10-20 s [7].

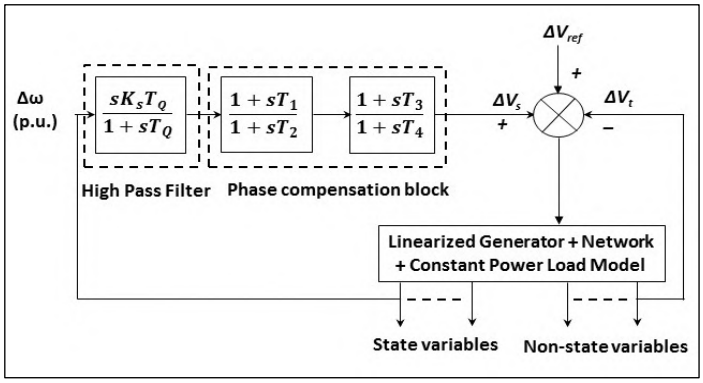

Figure 2: Block diagram of Power System Stabilizer (PSS).
Source: Authors, (2026).

II.3 HOPF BIFURCATION

Consider an autonomous system given by Equations (1-2). The order of vector 'x' and 'y' are 'k' and 'r' respectively. 'x' is vector of state variables. Vector 'y' represents algebraic variables. 'u' is control variable and 'p' is parametrized variable which brings bifurcation in the system.

$$\dot{x} = f(x, y, u) \tag{1}$$

$$g(x, y, p) = \in \dot{y} \tag{2}$$

For a given value of parameter 'p', 'g' can be solved to obtain the equilibrium point 'x_e'. Equations (1) and (2) are linearized about 'x_e' to determine the asymptotic stability of the operating point. Equations (1-2) are linearized as follows for fixed 'u' and initial operating point 'p^0' to get Equations (3-4).

$$\Delta\dot{x} = A_{f,x}\Delta x + A_{f,y}\Delta y \tag{3}$$

$$\in \Delta\dot{y} = A_{g,x}\Delta x + A_{g,y}\Delta y \tag{4}$$

Making $\in$ as zero and eliminating Δy, Equation (5) is obtained.

$$\Delta\dot{x} = \left[A_{f,x}^{p^0} - A_{f,y}^{p^0} A_{g,y}^{p^0\,-1} A_{g,x}^{p^0}\right]\Delta x = \left[A_{sys}^{p^0}\right]\Delta x \tag{5}$$

Where each submatrix $A_{f,x}^{p^0}$, $A_{f,y}^{p^0}$, $A_{g,x}^{p^0}$, $A_{g,y}^{p^0}$ of Equation (5) are defined below.

$$A_{f,x}^{p^0} = \begin{bmatrix} \frac{\partial f_1}{\partial x_1} & \cdots & \frac{\partial f_1}{\partial x_k} \\ \vdots & \ddots & \vdots \\ \frac{\partial f_k}{\partial x_1} & \cdots & \frac{\partial f_k}{\partial x_k} \end{bmatrix}_{p^0}$$

$$A_{f,y}^{p^0} = \begin{bmatrix} \frac{\partial f_1}{\partial y_1} & \cdots & \frac{\partial f_1}{\partial y_r} \\ \vdots & \ddots & \vdots \\ \frac{\partial f_k}{\partial y_1} & \cdots & \frac{\partial f_k}{\partial y_r} \end{bmatrix}_{p^0}$$

$$A_{g,x}^{p^0} = \begin{bmatrix} \frac{\partial g_1}{\partial x_1} & \cdots & \frac{\partial g_1}{\partial x_k} \\ \vdots & \ddots & \vdots \\ \frac{\partial g_k}{\partial x_1} & \cdots & \frac{\partial g_k}{\partial x_k} \end{bmatrix}_{p^0}$$

$$A_{g,y}^{p^0} = \begin{bmatrix} \frac{\partial g_1}{\partial y_1} & \cdots & \frac{\partial g_1}{\partial y_k} \\ \vdots & \ddots & \vdots \\ \frac{\partial g_r}{\partial y_1} & \cdots & \frac{\partial g_r}{\partial y_k} \end{bmatrix}_{p^0}$$

$$A_{sys}^{p^0} = \left[A_{f,x}^{p^0} - A_{f,y}^{p^0} A_{g,y}^{p^0\ -1} A_{g,y}^{p^0} \right] \tag{6}$$

Although the above partial derivatives in Equation (6) can be evaluated by using first and second order differencing approaches [1], the authors of this manuscript chose to evaluate the exact values of partial derivatives for the sake of accuracy and exactness to monitor the parameter at which Hopf bifurcation arrives.

II.4 STEPS TO ASSESS DYNAMIC INSTABILITY VIA HOPF BIFURCATION

1. Compute load flow using Newton Raphson method treating loads as CP absorbing type.
2. Use reference frame transformation to obtain initialized values of machine variables in 'd-q' frame as in [1].
3. Evaluate $\left[A_{sys}^{p^0}\right]$ by linearizing all the DAE's of machine, AVR, network and loads clubbed together without any PSS. Find the eigenvalues of system matrix. Find the damping ratios of swing modes, inter area mode and other modes of specific interest.
4. Apply small change in the real power/real and reactive power demanded by load with rescheduled generation and evaluate steps (1)-(3). The changes that needs to be done in load flow programme to accomplish this is detailed in [14].

$$P_{Li} = P_{Li,o}(\lambda_i) \tag{7}$$

$$Q_{Li} = Q_{Li,o}(\lambda_i) \tag{8}$$

Where,

λ_i is a loading factor introduced to bring Hopf bifurcation at i^{th} node.
P_{Li} , Q_{Li} are real and reactive power drawn by i^{th} load bus at each equilibrium point and
$P_{Li,o}$, $Q_{Li,o}$ are nominal real and reactive powers consumed by loads 'A' and 'B' residing at nodes 5 and 6 respectively.

5. Identify the critical mode which is crossing the right half of complex plane. Stop the algorithm and note down the loading at which dynamic instability is occurring.
6. Place PSS at 'G_1' [16], evaluate steps (1-5) and compare the ability of PSS in extending the dynamic instability through Hopf bifurcation.
7. Repeat steps (1-6) for single tie line network contingency and sketch the loci of inter area mode.

III. RESULTS AND DISCUSSIONS

The following programs were developed in MATLAB 2020 environment for achieving objectives defined in the section I.

1. Newton Raphson programme to find power flows and steady state network voltages and currents for congested tie line case. The power residuals were taken as 10^{-12}.
2. Eigenvalue analysis programme with AVR only.
3. Eigenvalue analysis programme with PSS at 'G_1'.
4. Programme to identify critical mode upon application of variations defined by Cases A-H defined in section I.
5. Modification of programmes (1-4) for single tie line contingency case.

III.1 DISCUSSION REGARDING CASE 1

The line, load, machine and exciter data from [7] is taken in this study. The load flow solution presented in [7] is obtained exactly by the authors of this manuscript. In the machine data of [7], the mechanical damping of all machines is made as 0.01 to see that no zero eigenvalue occurs. PSS parameters at 'G_1' for Case 1 are taken as T_1= 0.2473 s, T_2= 0.0218 s, T_3= 3 s, T_4= 5.4 s, T_Q= 10 s, K_s= 17.2079 [16]. From Table 1, it is observed that placement of PSS at 'G_1' increased the damping ratio of interarea mode from 0.96% to 5.72%.

The damping ratio of swing mode 'a' and 'b' increased from 10.49% to 33.16% and 10.74% to 11.03% respectively thus fulfilling the 3% minimum damping ratio criteria suggested in [17]. To explore the concepts of Hopf bifurcation, subcases '1-A' to '1-H' are generated and presented in Table 2 showing the respective loadings at which dynamic instability is achieved. For Case 1-A, the instability occurs at a loading of 13.49 p.u.. With the placement of PSS, the dynamic instability occurs at 19.02 p.u. thus proving the extension of maximum loadability. For Case 1-E, it is not the inter area mode which is unstable, but it is the high frequency mode 'd' shown in bold in Case 1-E of Table 2. The dynamic instability is happening at a loading of 17.3 p.u. for Case 1-B but after PSS placement, the loading is extended till 21.06 p.u.. The mode which is undergoing instability is the mode 'd'.

Table 1: Eigenvalues at nominal loading with and without PSS for Cases 1, 2 respectively.

To explore the concepts of Hopf bifurcation, subcases 1-A to 1-H are generated and results are presented in Table 2. For Case 1-A, the dynamic instability occurs at a loading of 13.49 p.u. With the placement of PSS, the dynamic instability occurs at 19.02 p.u., thus extending the maximum loading limit at 5th node. The percentage improvement in loadability limit with PSS in this subcase is 41%. For Case 1-E, it is not the inter area mode which is unstable, but it is the high frequency mode 'd' shown in bold in Case 1-E of Table 2. The dynamic instability is happening at a loading of 17.3 p.u. for Case 1-B, but after PSS placement, the loading is extended till 21.06 p.u.. The mode 'd' is undergoing instability in this subcase. The percentage improvement in loadability limit with PSS in this subcase is 21.73%.

a) – Interarea mode, b) – Swing mode of area 1, c) - Swing mode of area 2, d)- High frequency mode.
Source: Authors, (2026).

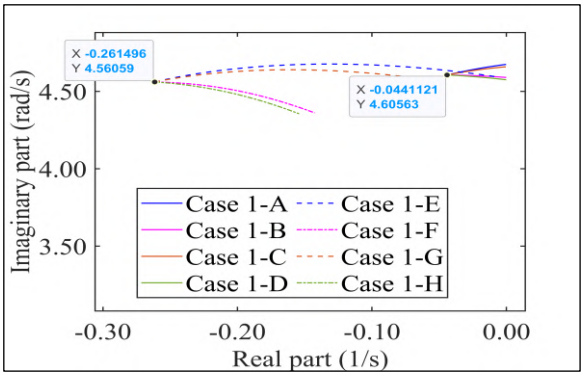

Figure 3: Loci of interarea mode corresponding to Case 1.
Source: Authors, (2026).

For Case 1-C, inter area mode is the critical mode occurring at λ_5 value of 1.1755. After placing PSS, the dynamic instability is extended till a value of 1.5715. Here, it is the mode 'd' which is undergoing Hopf bifurcation instead of mode 'a'. The percentage improvement in loadability limit with PSS in this subcase is 33.69%. The critical loading λ_6 is 1.1015 for Case 1-D. In this sub-case, the critical mode is mode 'a'. After installing PSS (Case 1-H), the critical loading is put off till 1.2965 and even in this case it is the mode 'd' undergoing Hopf Bifurcation. The percentage improvement in loadability limit with PSS in this subcase is 17.70%. The loci of inter-area mode 'a' with and without placing PSS after applying all subcases till critical loading is depicted in Figure 3 for Case 1.

III.2 DISCUSSION REGARDING CASE 2

The values of PSS parameters at G_1 for Case 2 were taken as T_1= 0.2173 s, T_2= 0.0218 s, T_3= 3 s, T_4= 5.4 s, T_Q= 10 s, K_s= 16.6370 [16]. From Table 1, it is observed that with placement of PSS at G_1, there is an improvement of damping ratio of mode 'a' from 0.81% to 4.18%. The damping ratio increased from 10.46% to 31.62%, 10.60% to 10.73% for swing mode 'a' and 'b' respectively. There is significant improvement in damping ratio of mode 'a' and 'b' but not 'c'. But all modes have damping ratio values greater than 3% as suggested by [16], [17]. To explore dynamic instability, subcases from 2-A to H are generated and presented in Table 3 showing the respective loadings at which dynamic instability is achieved. For Case 2-A, the dynamic instability occurs at a loading of 14.07 p.u. in the form of mode 'a'. With the placement of PSS, the dynamic instability occurs at 18.41 p.u., thus ascertaining the extension of load limit. The percentage improvement in loadability limit with PSS in this subcase is 30.85%. The dynamic instability is happening at a loading of 17.19 p.u. for Case 2-B but after PSS placement, the loading can be extended till 20.43 p.u. The mode which is undergoing instability is the mode 'd'. The percentage improvement in loadability limit with PSS in this subcase is 18.85%. For Case 2-C, mode 'a' is the critical mode occurring at λ_5 value of 1.2275. After placing PSS, the dynamic instability can be extended till a value of 1.5690. For this case, it is the mode 'd' which is undergoing Hopf bifurcation instead of mode 'a'. The percentage improvement in loadability limit with PSS in this subcase is 27.82%. The critical loading λ_6 is 1.0915 for Case 2-D. The critical mode is mode 'a'. After installing PSS (Case 2-H), the critical loading λ_6 is put off till 1.2620 and in this case, it is the mode 'd' which is the critical mode. The percentage improvement in loadability limit with PSS in this subcase is 15.62%. The loci of inter-area mode 'a' with and without placing PSS after applying all subcases till critical loading is depicted in Figure 4 for Case 2.

IV. CONCLUSIONS

A nonlinear autonomous system can be linearized about an equilibrium point for studying whether the system is asymptotically stable or not. Multiple equilibrium points are generated by changing the values of loads and generation of Kundur two area system. For each generated equilibrium point, the procedure of linearization is done to see whether at least one of the complex conjugate pair crosses the imaginary axis from left half of complex plane.

In order to have detailed view, two cases and eight subcases are sprouted to draw the loci of interarea mode of system. It was obtained that with the placement of PSS, dynamic instability can be extended to a higher loading as compared to the one obtained without PSS for both congested and single tie line contingency cases.

ABSTRACT

This investigation presents a comprehensive optimization framework for ozone generation in dielectric barrier discharge (DBD) systems applied to water treatment processes. The study employs a Venturi injection configuration to systematically analyze the influence of three critical operational parameters: applied voltage (6-8 kV), oxygen flow rate (3-5 L/min), and water flow rate (8-16 L/min) on dissolved ozone concentration in treated water. Experimental design methodology utilizing MODDE 5.0 software enabled the development of a second-order polynomial mathematical model correlating input variables with ozone concentration response. The derived model demonstrated excellent statistical validity with coefficient of determination (R^2) of 99.2% and predictive capability (Q^2) of 90.3%, confirming robust model accuracy and reliability.Parameter optimization was achieved through implementation of Particle Swarm Optimization (PSO) algorithm, a bio-inspired metaheuristic approach that mimics collective intelligence behavior observed in natural swarms. The PSO methodology employed a population of 50 particles over 100 iterations to minimize prediction errors between theoretical model outputs and experimental measurements. Convergence analysis revealed rapid optimization performance, achieving optimal parameter extraction within 90 iterations. Comparative analysis between PSO-optimized parameters and conventional MODDE 5.0 results demonstrated superior performance of the proposed approach. Optimal operating conditions were identified as: applied voltage of 7.95 kV, oxygen flow rate of 3.38 L/min, and water flow rate of 8.27 L/min. The PSO-based optimization yielded enhanced ozone generation efficiency through reduced water flow rates and optimized voltage levels, confirming the voltage parameter as the dominant factor in ozone production.

I. INTRODUCTION

Researchers across multiple disciplines, including chemistry, materials science, and engineering, demonstrate increasing interest in the identification and elimination of contaminant species, driving the development of advanced high-performance treatment methodologies [1], [2]. As noted by [1], the application of plasma-based technologies in water treatment applications has generated significant research inquiries.

Cold atmospheric plasmas can achieve efficient ozone generation while providing sterilization and decontamination capabilities for thermally sensitive surfaces [1], [2]. Water purification processes encompass various physical, chemical, electrical, and electronic methodologies, with plasma-based systems representing a prominent approach [3]. Dielectric barrier discharge (DBD) plasma systems constitute one of the primary methods for water treatment through ozone generation, enabling the production of purified water [4-6]. Following the principles outlined by [4], the discharge mechanism occurs between two metallic electrodes separated by a dielectric material and a gas-filled gap where the electrical discharge is initiated. These systems have been extensively investigated for the degradation of dye contaminants present in wastewater at elevated concentrations [3]. Ozone (O_3) production utilizes air or oxygen as the primary feedstock [7]. As described by [7], initially, high-energy electrons collide with oxygen molecules, resulting in the dissociation of oxygen atoms. Subsequently, O_3 formation occurs through the combination of free O_2 molecules and oxygen radicals [7]. Figure 1 presents a schematic representation of these reaction mechanisms [8].

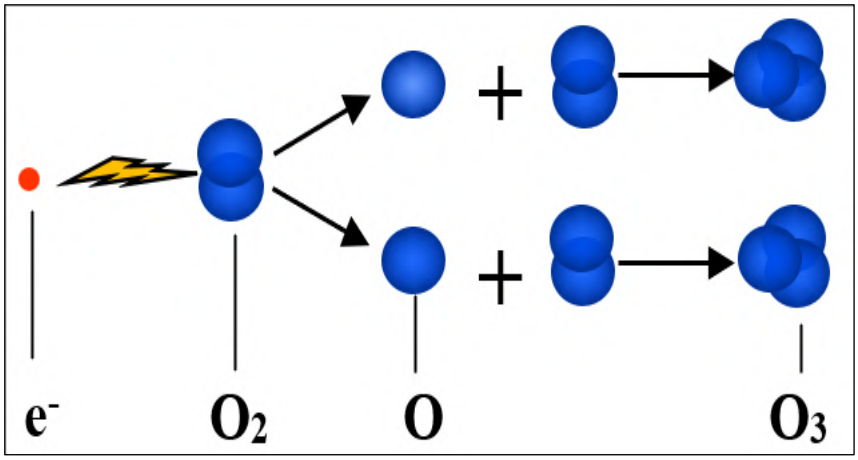

Figure 1: Schematic diagram illustrating ozone production via electron impact mechanisms.
Source: Authors, (2026).

As established in previous research [9], [10], ozone concentration exhibits an inverse relationship with gas flow rate and electrode gap spacing, while demonstrating a positive correlation with electrode surface area [9], [10]. Additionally, ozone concentrations increase proportionally with residence time and AC high-voltage amplitude [11]. Multiple parameters influence the efficacy of ozone-based water treatment processes, including operational control factors and environmental conditions [12-14]. Following the methodology described by [12], experimental investigations were conducted using a laboratory-scale test bench equipped with a Venturi injection system. The controllable parameters analyzed included high voltage amplitude, oxygen flow rate, and water flow rate [15]. The mathematical modeling framework implemented in MODDE 5.0 software addresses nonlinear optimization problems characterized by numerous interconnected indeterminate parameters [16], [17]. As demonstrated by [16], metaheuristic optimization algorithms demonstrate exceptional suitability and capability for solving nonlinear multimodal optimization challenges [18-20]. The objective of this investigation is to employ particle swarm optimization (PSO) methodology , following the approach established by [17], to extract optimal parameters (voltage (U), water flow (WF), and oxygen flow (OF)) that maximize treatment efficiency and determine the optimal operating conditions.

II. EXPERIMENTAL SETUP AND METHODOLOGY

The experimental configuration employed in this research is demonstrated in Figure 2. Water movement is accomplished using a pumping mechanism with flow regulation controlled through an autotransformer. Ozone introduction into the water treatment system is achieved via a Venturi mixing arrangement, enabling efficient dissolution and uniform distribution of ozone throughout the aqueous solution. Following the setup described in earlier investigations [4], [14], ozone production is carried out using a dielectric barrier discharge (DBD) reactor fed with oxygen from a concentrator device providing adjustable flow rates between 1 to 5 L/min. This investigation employed a switching-mode high voltage supply system, similar to the design reported by [13]. The process begins with a transformer reducing 220 V AC input to approximately 72 V DC following rectification. An Insulated Gate Bipolar Transistor (IGBT) functions as an electronic switching component, regulated by an oscillator to create high-frequency current. This reduced voltage, high-frequency current is subsequently amplified through a high voltage step-up transformer, generating output voltages spanning 1–10 kV at frequencies from 0–30 kHz. For this research, the ideal operating frequency for the discharge tube was determined to be 20 kHz. Experimental activities were performed under regulated environmental parameters, maintaining ambient temperature between 20-25°C and relative humidity controlled within 60-70% range. Voltage measurements were obtained using a digital oscilloscope (GWINSTEK GDS-3154) with a high voltage probe (Tektronix P6015A), while current was estimated through voltage drop assessment across a 100 Ω resistor.

III. MATHEMATICAL FRAMEWORK FOR WATER TREATMENT PROCESS MODELING

The development of a reliable mathematical model represents a critical foundation for any optimization study in water treatment applications. A predetermined mathematical relationship describes the connection between response variables and input factors. Following the methodology described by [15], this approach employs a truncated Taylor-Maclaurin series expansion where derivatives are considered constant, producing a polynomial expression containing terms of different degrees:

$$y = a_0 + \sum a_i x_i + \sum a_{ij} x_i x_j + \cdots + \sum a_{ii} x_i^2 + a_{ij\ldots z} x_i x_j \ldots x_z \quad (1)$$

The selection of polynomial modeling approach offers several advantages for this particular application. First, polynomial functions provide excellent flexibility in capturing nonlinear relationships between operational parameters and ozone concentration. Second, the mathematical structure allows for clear interpretation of individual parameter effects and their interactions. Third, the computational efficiency of polynomial models makes them suitable for real-time optimization applications. Coefficient determination or estimation utilizes specialized data processing software to minimize variance between predictive models and experimental observations. The accuracy of coefficient estimation directly influences the reliability of subsequent optimization procedures.

The software platform MODDE 5.0 from Umetrics AB in Umea, Sweden, was implemented for this comprehensive analysis. This Windows-compatible program specializes in creating and evaluating experimental designs with advanced statistical capabilities (MODDE 5.0, 1999). The software assists researchers in result interpretation and response prediction through sophisticated mathematical model coefficient computation algorithms. It determines optimal factor adjustments for process enhancement while calculating two critical statistical measures, R^2 and Q^2, for rigorous mathematical model validation. Our choice of MODDE 5.0 was based on several key factors: its proven track record in chemical process optimization, robust statistical analysis capabilities, and user-friendly interface that facilitates complex experimental design interpretation. The software's ability to handle multi-factorial experiments with nonlinear interactions makes it particularly suitable for ozone generation optimization studies. The goodness of fit measure (R^2) evaluates how effectively the model represents experimental data, with values ranging from 0 to 1, where unity signifies perfect fitting and zero indicates complete model inadequacy. The predictive quality measure (Q^2) estimates the model's forecasting capability for new experimental conditions. Like R^2, Q^2 ranges up to 1, though its minimum value extends to negative infinity. For successful diagnostic evaluation, both parameters require elevated values, preferably within 0.2–0.3 difference to ensure model reliability and predictive accuracy. Following the experimental framework established by [15], ozonation-driven water treatment process effectiveness is influenced by numerous interconnected factors, including operational control parameters and environmental variables. Our research methodology involved conducting systematic experimental studies using specially designed laboratory-scale equipment featuring advanced Venturi injection techniques. Three primary adjustable operational factors were comprehensively evaluated through statistical experimental design: high voltage magnitude, oxygen flow rate, and water circulation rate. The selection of these three parameters was based on preliminary sensitivity analysis and literature review indicating their significant impact on ozone generation efficiency. Voltage represents the primary energy input controlling the discharge intensity, oxygen flow affects the raw material availability for ozone synthesis, while water flow determines the residence time and mass transfer characteristics within the treatment system. The mathematical expression representing the optimized response, specifically focusing on dissolved ozone concentration levels in treated water (C), was systematically developed through MODDE 5.0 statistical analysis as follows:

$$C = 0.46 + 0.096U – 0.038WF – 0.07\ U^2 – 0.06\ WF^2 + 0{,}05OF^2 \quad (2)$$

This quadratic model structure reveals several important characteristics: the positive linear coefficient for voltage (0.096) confirms its promoting effect on ozone generation, while the negative linear coefficient for water flow (-0.038) indicates dilution effects. The negative quadratic terms for both voltage and water flow suggest optimal operating points beyond which further increases become counterproductive. Where :

C: Ozone concentration produced (mg/L)
U: Applied voltage (kV)
WF: Water flow (L/mn)
OF : Oxygen flow (L/mn)

The statistical validation results demonstrated exceptional model quality, with R^2 and Q^2 achieving values that approached unity (R^2 = 99.2%; Q^2 = 90.3%). These outstanding statistical indicators confirmed the model's validity and established its suitability for both prediction and optimization applications. The small difference between R^2 and Q^2 (8.9%) indicates excellent model generalization capability, suggesting reliable performance when applied to new operating conditions within the experimental range.
Detailed analysis of the mathematical expression reveals that voltage impact significantly exceeds water flow rate influence within the investigated parameter ranges. This finding aligns with fundamental plasma physics principles, where electrical energy directly controls the electron density and energy distribution responsible for oxygen dissociation. As demonstrated in previous research [4], [13], applied voltage represents the critical controlling factor affecting ozone production efficiency, as it initiates and sustains the electrical discharge essential for the oxygen-to-ozone conversion process. The physical mechanism underlying voltage dominance involves several interconnected phenomena. Higher voltages increase electron energy and density within the discharge gap, promoting more efficient oxygen molecule dissociation. Additionally, elevated voltage levels enhance the formation of reactive oxygen species and extend the discharge volume, both contributing to increased ozone yields. Conversely, water flow rate demonstrates a negative influence and requires careful optimization to achieve desired ozone output levels. Elevated water flow rates result in decreased dissolved ozone concentrations due to reduced residence time and dilution effects. This relationship highlights the importance of balancing treatment throughput with ozone transfer efficiency. Meanwhile, oxygen flow rate influence was determined to be minimal within the investigated range. This finding suggests that increasing oxygen flow rate beyond 4 L/min provides diminishing returns, as significant portions exit the ozone generator without undergoing the ozone conversion process. From an economic perspective, this indicates an optimal operating point that balances raw material consumption with ozone production efficiency.

IV. EXTRACTION OF PROPOSED PSO-BASED MODEL PARAMETERS

Particle Particle Swarm Optimization (PSO) represents a sophisticated population-based collective intelligence algorithm that has revolutionized optimization approaches in engineering applications. The original concept was pioneered by Kennedy and Eberhart [21], [22] to simulate and harness the collective behavioral characteristics observed in natural social species, particularly the coordinated movement patterns exhibited in bird flocking behaviors and fish schooling dynamics. The fundamental appeal of PSO lies in its ability to emulate the decentralized decision-making processes found in nature, where individual agents contribute to collective intelligence without central coordination. This bio-inspired approach offers several advantages over traditional optimization methods: it avoids the need for gradient information, handles discontinuous and multimodal functions effectively, and demonstrates robust performance across diverse problem domains.

PSO employs the physical movement properties and social interaction characteristics of individual swarm members [23], delivering a balanced and highly adaptive computational framework [24] for enhancing both global exploration and local exploitation capabilities. The algorithm's success stems from its ability to maintain population diversity while progressively converging toward optimal solutions. Given its straightforward implementation requirements and minimal parameter tuning needs, PSO has demonstrated remarkable computational efficiency and competitive performance for optimization problems in continuous solution spaces. The algorithm is characterized by computational effectiveness, simplified coding requirements, and consistent algorithmic behavior across different problem types. According to [22], the majority of PSO implementations have traditionally focused on continuous space optimization challenges [25], though recent research initiatives have successfully explored discrete optimization applications [26]. The PSO algorithm initiates its search process by randomly generating a diverse swarm of computational particles within the solution space. Each individual entity (designated as a particle) within the problem domain is mathematically characterized by a d-dimensional position vector $s_i = (s_{i1}, s_{i2}... s_id)$, where i = 1,2, ..., N (N represents the total population size), and its optimization performance is continuously evaluated using a predetermined fitness function that quantifies solution quality. Individual particles are strategically positioned at random locations within the d-dimensional solution domain, each representing a potential candidate solution to the optimization problem. The velocity vector of the ith particle $(v_i) = (v_{i1}, v_{i2},..., v_id)$ is established through positional displacement calculations and determines the particle's movement direction and magnitude in subsequent iterations. Each particle's movement trajectory throughout the optimization process is governed by sophisticated dynamic interactions between individual learning experiences and collective swarm knowledge. As explained by [27], the algorithm achieves convergence toward optimal solutions through a careful balance between each particle's personal best historical solution and the global best value discovered by the entire swarm population. Each particle's path within the swarm adjusts toward its previous optimal position and the global optimal position reached by any swarm particle, represented as p_i and pg respectively. Following standard PSO formulation [21], the swarm updating equations for each iteration are:

$$v_i(t+1) = v_i(t) + c_1 \text{rand}_1(p_i - s_i(t)) + c_2 \text{rand}_2 \quad (3)$$

$$s_i(t+1) = s_i(t) + v_i(t+1) \quad (4)$$

Where:

- $P_i = (p_{i1},..., p_iN)$ denotes the optimal position encountered by the ith particle;
- p_g represents the best position discovered among all swarm population members;
- t represents the iteration counter;
- c_1 and c_2 are the acceleration coefficients;
- $rand_1$ and $rand_2$ are uniform random numbers within the interval [0, 1].

According to [24], acceleration parameters control the distance covered by particles in single iterations. Lower parameter values allow particles to investigate areas far from target zones before convergence, while higher values cause rapid movement toward or past target areas. For PSO algorithm execution, velocity and position parameters receive random initialization. The objective function represents the optimization goal for the particle population. Through particle search processes, the minimum function value can be identified, along with corresponding optimal U, WF, and OF parameter values. The computational approach for mathematical model parameter estimation using PSO algorithm is shown in Figure 3:

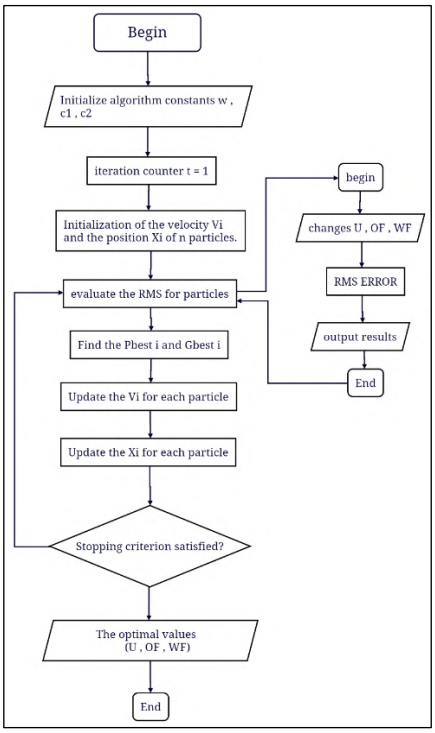

Figure 3: Proposed PSO organization chart.
Source: Authors, (2026).

V. RESULTS AND DISCUSSIONS

V.1 THE VALUES OF PSO PARAMETERS UTILIZED:

The PSO algorithm parameters utilized in this study are presented in Table 2.

Table 2: Parameters of PSO.

Parameter description	Parameters value
Size of population	50
Maximum iteration	100
c1	2
c2	2

Source: Authors, (2026).

V.2 RESEARCH SPACE

The search range for the three mathematical model parameters using PSO is outlined in Table 3:

Table 3: PSO search interval for model.

parameters	search interval
U (kV)	[6], [8]
OF (L/mn)	[3], [5]
WF (L/mn)	[8], [16]

Source: Authors, (2026).

V.3 PARAMETER IDENTIFICATION OF THE MODEL VIA THE PSO APPROACH:

To track the optimization process, the change in the fitness function over successive iterations was plotted, as shown in Figure 4.

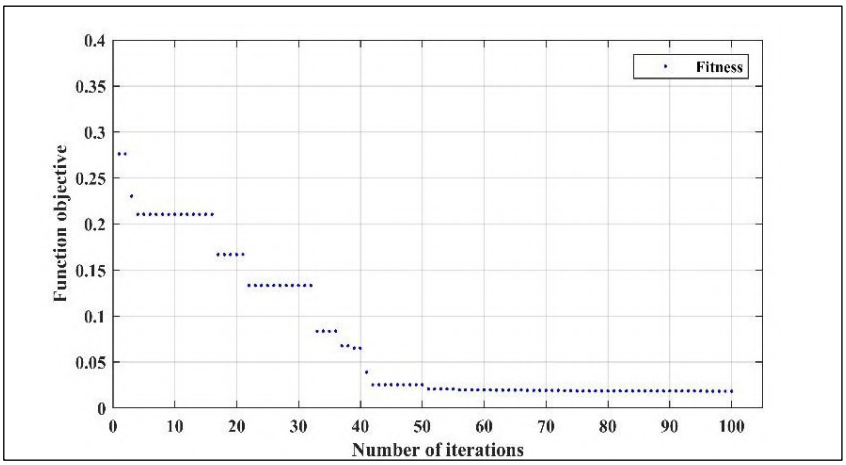

Figure 4: Evolution of the fitness function as a function of iteration number.
Source: Authors, (2026).

The optimization process demonstrates progressive convergence toward the optimal solution with each successive generation. Figure 4 demonstrates that the fitness function value for the optimal solution progressively diminishes throughout the iterative process. Upon algorithm convergence, achieved at 90 iterations in this investigation, the fitness function value reaches a minimal state. At this convergence point, the optimal solution from the final iterations is considered to represent the optimal parameter values sought in this optimization study. The three model parameters obtained through the PSO algorithm implementation are presented in Table 4:

Table 4: Optimal values of U, OF, and WF parameters.

parameter	value
U (kV)	7.9503
OF (L/mn)	3.3846
WF (L/mn)	8.266

Source: Authors, (2026).

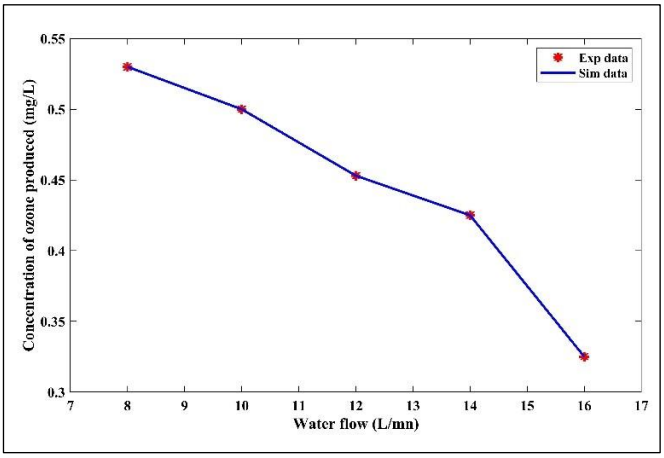

Figure 5: The changing levels of ozone dissolved in water in relation to water flow (experimental and simulation).
Source: Authors, (2026).

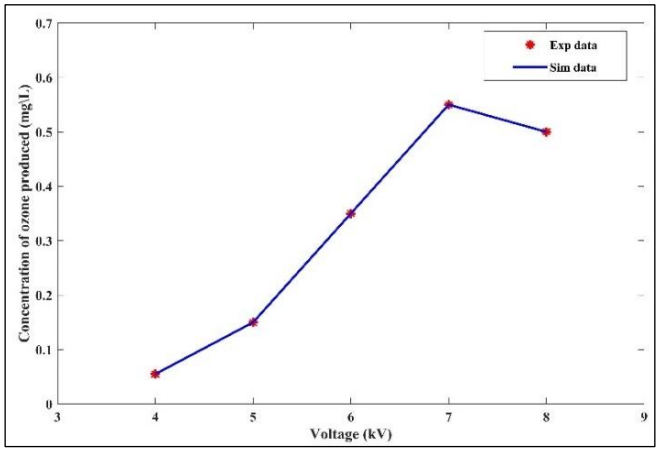

Figure 6: Variation of dissolved ozone concentration in water as a function of applied voltage (experimental and simulation results).
Source: Authors, (2026).

Based on the analysis of Figures 5 and 6, this methodology demonstrates high effectiveness in the field of water treatment processes utilizing ozone generated by DBD systems. The comparative analysis of the result curves clearly indicates that the parameter values calculated through the mathematical model coupled with PSO algorithm exhibit excellent agreement with the experimental data. To confirm the validity of parameters extracted through the PSO technique, a comparative evaluation was undertaken between the parameters resulting from the proposed method and those generated by the MODDE 5.0 software platform. The comparison outcomes are presented in Table 5:

Table 5: Comparative analysis of U, OF, and WF parameter values obtained by PSO and MODDE 5.0 application.

parameter	Result of PSO algorithm	Result of MODDE 5.0
U (kV)	7.9503	7.67
OF (L/mn)	3.3846	3
WF (L/mn)	8.266	9.6

Source: Authors, (2026).

Based on the mathematical model, voltage serves as the primary parameter for ozone production, demonstrating greater importance than the influence of water flow rate. The voltage determined via MODDE 5.0 was 7.67 kV, whereas the PSO method produced 7.058 kV. In contrast, the water flow rate (WFR) shows an inverse relationship with ozone concentration in water. When comparing results, we find that the water flow rate derived from the PSO approach is lower than that obtained from the MODDE 5.0 software, suggesting enhanced ozone concentration. The experimental results demonstrate convergence between the parameter values obtained from the MODDE 5.0 software and those derived through the proposed PSO methodology. consistent with findings reported by [25]. The PSO approach demonstrates superior accuracy in the optimization results, indicating its enhanced effectiveness for optimizing water treatment processes utilizing ozone generated by DBD systems.

VI. CONCLUSION

This research successfully developed and validated a novel optimization methodology for DBD-based ozone generation systems utilizing Particle Swarm Optimization algorithm coupled with statistical modeling techniques. The investigation established a comprehensive mathematical framework that accurately correlates operational parameters with ozone concentration in water treatment applications. The experimental investigation confirmed that applied voltage constitutes the primary controlling factor for ozone generation efficiency, exhibiting positive correlation with dissolved ozone concentration within the investigated parameter space. Conversely, water flow rate demonstrated negative correlation, necessitating flow optimization to maximize ozone transfer efficiency. Oxygen flow rate exhibited minimal influence beyond 4 L/min, indicating optimal resource utilization thresholds. The PSO-based parameter extraction methodology demonstrated superior performance compared to conventional optimization approaches, achieving enhanced precision in parameter identification while maintaining computational efficiency. The algorithm's rapid convergence characteristics and global optimization capabilities validated its applicability for complex, multi-parameter process optimization scenarios.The developed mathematical model, validated through statistical criteria (R^2 = 99.2%, Q^2 = 90.3%), provides reliable predictive capabilities for ozone concentration estimation across the experimental parameter range. This predictive framework enables systematic identification of optimal operating conditions, facilitating enhanced treatment efficiency and reduced operational costs. The proposed methodology contributes significantly to the advancement of intelligent process control systems in environmental engineering applications. The framework's versatility permits extension to diverse chemical processes requiring parameter optimization and mathematical modeling. Implementation of this approach ensures consistent treatment quality while optimizing resource utilization and minimizing environmental impact. Future research directions include investigation of additional operational parameters, development of real-time adaptive control systems, and extension of the methodology to industrial-scale applications. The integration of advanced machine learning techniques with PSO optimization presents opportunities for further enhancement of model accuracy and predictive capabilities in complex water treatment scenarios

ABSTRACT

This study designed, developed, and evaluated an AI-driven interactive multimedia courseware to support preparation for the IT Specialist (ITS) certification examination. Traditional review approaches often lack adaptive learning mechanisms and interactive resources, limiting their effectiveness in addressing diverse learner needs and tracking learning progress. To address this gap, the study employed a Design and Development Research (DDR) methodology guided by Agile Software Development Life Cycle principles. The development process began with the systematic identification of ITS exam objectives and topics based on official certification guidelines, which served as the foundation for the instructional design and content organization of the courseware. The system was implemented as a web- and mobile-responsive platform featuring multimedia lessons, interactive simulations, gamified activities, and practice examinations to promote active learning. The Bayesian Knowledge Tracing (BKT) algorithm was integrated as the adaptive learning engine to dynamically estimate learner knowledge states and personalize content delivery based on performance and progress. The developed system was evaluated by five IT experts and twenty prospective ITS examinees using the ISO/IEC 25010 software quality model. Results showed consistently high ratings across all criteria, with an overall weighted mean of 4.59 (“Strongly Agree”). These findings suggest that adaptive multimedia courseware can enhance certification readiness and provide institutions with an effective digital platform for technology-based exam preparation.

I. INTRODUCTION

The rapid advancement of information and communication technologies has fundamentally transformed knowledge acquisition and professional competency development [1]. In the information technology sector, industry-recognized certification examinations have become essential benchmarks for validating technical proficiency and ensuring workforce readiness [1], [2]. Certifications such as the "IT Specialist" credential allow professionals to demonstrate mastery in critical domains including programming, networking, databases, and web development [1]. Consequently, there is an increasing demand within educational and professional training environments for effective preparation tools that support certification readiness. However, traditional review methods often rely on static learning materials and linear instruction, frequently described as "just-put-it-on-the-web" approaches, which fail to address the diverse prior knowledge levels and individual learning needs of certification candidates [3], [4]. These conventional methods often suffer from content homogenization and a lack of interactive resources, leading to suboptimal engagement and retention [3], [5]. Recent developments in educational technology have highlighted the potential of interactive multimedia and artificial intelligence to enhance instructional processes. Interactive multimedia courseware integrates text, graphics, audio, and animation to create immersive experiences that improve knowledge retention and learner motivation [6], [7]. Concurrently, AI-driven adaptive learning systems have emerged as powerful tools for personalizing instruction based on learner performance and behavior [8], [9].

These systems analyze unique learning patterns and dynamically adjust the sequence and difficulty of materials to address specific knowledge gaps [10-12]. In the context of high-stakes certification, these adaptive approaches offer more efficient, targeted review strategies by optimizing cognitive load and improving memorization effectiveness [13-16]. Research indicates that multimedia environments enhance comprehension by presenting information through multiple sensory channels [17-19]. To further individualize this experience, adaptive algorithms, most notably Bayesian Knowledge Tracing—have been widely implemented in Intelligent Tutoring Systems to model knowledge states and predict skill mastery [9], [20-22]. These systems allow educational platforms to tailor instructional pathways according to real-time progress, ensuring that learners engage with material that matches their current proficiency [4], [23]. Despite these advancements, many existing certification preparation platforms primarily offer static practice tests or non-adaptive resources that do not effectively monitor progress or dynamically adjust content to the learner's needs [24-27]. Furthermore, while the theoretical benefits of AI and multimedia are well-documented, limited research has focused on the practical integration of AI-driven adaptive algorithms within interactive courseware specifically designed for IT Specialist certification [28-30]. Many available review tools also lack systematic evaluation based on recognized software quality standards, which are critical for ensuring reliability, usability, and pedagogical effectiveness [31-33]. Addressing these gaps is vital, as certification candidates must demonstrate mastery over diverse technical competencies within a limited timeframe. An adaptive platform that continuously monitors progress and provides individualized guidance can significantly improve study efficiency and exam readiness [34], [35]. In response to these challenges, this study aims to design and develop an AI-driven interactive multimedia courseware as a web- and mobile-responsive platform for IT Specialist certification exam preparation. The study seeks to structure official exam objectives into a rich multimedia environment while implementing a BKT-based adaptive model to enhance candidate readiness. Furthermore, the system will be evaluated for its compliance with adaptive functionality and software quality characteristics using the ISO/IEC 25010 standards. By combining responsive web technologies with machine learning, this research establishes a replicable framework for high-quality instructional tools that optimize the transition from candidate study to professional certification success [34], [35].

II. RELATED WORKS

The development of AI-driven courseware for IT Specialist certification involves a synthesis of research in adaptive learning, intelligent tutoring systems, and interactive multimedia design.

II.1 PERSONALIZED AND ADAPTIVE LEARNING ENVIRONMENTS

Traditional educational approaches that rely on a "just-put-it-on-the-web" methodology often fail to accommodate the diverse skills and individual needs of learners [4]. This static delivery frequently results in content homogenization, which can be seen in current certification training programs like the Information Systems Project Management Professional [3]. In contrast, personalized learning systems utilize artificial intelligence to adapt instructional content based on a student's unique knowledge state, thereby improving engagement and retention [9]. Recent frameworks for technical courses have addressed these gaps by integrating multimodal knowledge—unifying text, code, and visual materials into structured ontologies to better account for individual differences in cognitive traits and learning preferences [1].

II.2 INTELLIGENT TUTORING SYSTEMS

Intelligent Tutoring Systems are designed to simulate the personalized instructions and immediate feedback typically provided by a human tutor [22], [36]. By using AI techniques to analyze student responses and perform cognitive diagnoses, these systems enable self-directed learning and help correct specific misconceptions [22], [36]. Research has demonstrated that ITS are highly effective across various disciplines, including computer programming, where they enhance recommendation accuracy and student satisfaction [37]. Meta-analytic reviews indicate that intelligent tutoring can raise test scores by approximately 0.66 standard deviations over conventional instruction [38]. Furthermore, these systems provide timely feedback and allow students to access learning spaces anytime, fostering the competencies needed for lifelong learning [39].

II.3 KNOWLEDGE TRACING AND ADAPTIVE ALGORITHMS

A critical challenge in personalized education is accurately tracing a student's knowledge state over time [9]. Bayesian Knowledge Tracing is a prominent machine learning-based model used to infer student mastery by treating knowledge as a set of binary variables (mastered or not) [30], [40]. As a type of Hidden Markov Model, BKT uses observed performance to estimate the latent skill levels of a learner [40]. This allows educational systems to predict future performance and provide adaptive task assignments, ensuring that the difficulty level of questions or topics matches the learner's current competency [4], [41]. Studies show that this adaptive selection of test questions significantly increases overall learning outcomes, particularly for lower-performing students [4]. The foundational principle behind BKT, estimating student knowledge states from learning interactions, is a cornerstone of Intelligent Tutoring Systems, which are integral to personalized content delivery and feedback. AI plays a critical role in this process, with knowledge tracing models leveraging machine learning techniques to infer a student's conceptual and procedural knowledge based on their task performance.

II.4 INTERACTIVE MULTIMEDIA AND GAMIFICATION

Interactive multimedia courseware serves as a vital tool to counter the declining engagement associated with traditional lecture-based methods and static presentations [6]. Effective multimedia platforms integrate videos, interactive questions, and real-time feedback to create an environment where students can actively participate and monitor their progress [7]. The implementation of AI-assisted multimedia has been shown to significantly improve student understanding and engagement across information technology disciplines [5].

Additionally, gamification—the use of game elements like points, badges, and streaks—enhances motivation by making the learning process more immersive [2], [42]. For difficult subjects like computer science, gamification contributes to higher levels of student satisfaction and long-term performance [43]. By combining gamified tracking with adaptive assessment methods, modern platforms ensure a balanced learning progression grounded in established pedagogical frameworks like Bloom's taxonomy [2].

II.5 RESEARCH GAP

Despite the proliferation of digital resources for technical education, several critical gaps remain in the literature concerning IT certification preparation. First, existing review materials for exams like the IT Specialist certification often follow a "just-put-it-on-the-web" approach, which lacks the adaptive mechanisms necessary to address individual learning curves and skill levels [3], [4]. While Intelligent Tutoring Systems have proven effective in academic settings, their application to the professional certification domain—particularly for IT graduates—is relatively underexplored [38], [44]. Current platforms frequently focus on static content delivery and homogenized question sets, failing to provide the personalized feedback and "anytime-anywhere" guidance essential for lifelong learners and working professionals [3], [39]. Furthermore, while the Bayesian Knowledge Tracing algorithm is a well-established method for student modeling, its integration into a multimodal, web- and mobile-responsive framework specifically for IT certification remains limited [30], [40]. Most existing adaptive systems rely either on cross-sectional assessment data or simple text-based interactions, overlooking the need for multimodal knowledge representation that unifies code, visual simulations, and theory into a structured learning path [1], [45]. Additionally, there is a lack of research focusing on systems that cover the full spectrum of a certification's objectives—from basic concepts to complex problem-solving—while simultaneously utilizing gamified elements to maintain long-term motivation [46], [47]. By developing an AI-driven platform that combines BKT-based adaptivity with interactive multimedia specifically for the IT Specialist exam, this study addresses the empirical and methodological deficit in providing high-quality, personalized certification training [2], [44].

III. METHODOLOGY

This study employed Design and Development Research (DDR) to systematically design, develop, and evaluate an AI-driven interactive multimedia courseware for IT Specialist certification preparation [48], [49]. DDR is appropriate for educational technology studies because it integrates theoretical foundations with practical system development and empirical validation. The development process followed Agile Software Development Life Cycle (SDLC) principles, enabling iterative development, continuous feedback, and progressive system improvement.

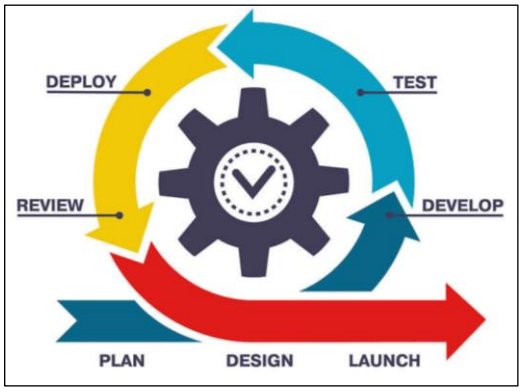

Figure 1: Agile Software Development Life Cycle.
Source: Author, (2026).

III.1 ANALYSIS AND PLANNING

The first phase identified the exam objectives, topics, and module content re-quired for the courseware. The researchers reviewed the official IT Specialist (ITS) certification syllabus and relevant industry standards to determine the core competencies covered in the examination. A literature review was also conducted to justify the use of the Bayesian Knowledge Tracing (BKT) algorithm for modeling learner knowledge states. The phase resulted in a curriculum blueprint and system requirements specification for the adaptive courseware.

III.2 DESIGN AND DEVELOPMENT

This phase focused on the design, development, and implementation of the adaptive web-based multimedia courseware. Following Agile principles, the system was developed through iterative cycles of instructional design, system development, and testing. The Bayesian Knowledge Tracing (BKT) algorithm was integrated as the adaptive learning engine to estimate learner mastery and dynamically adjust content difficulty and learning pathways based on performance.

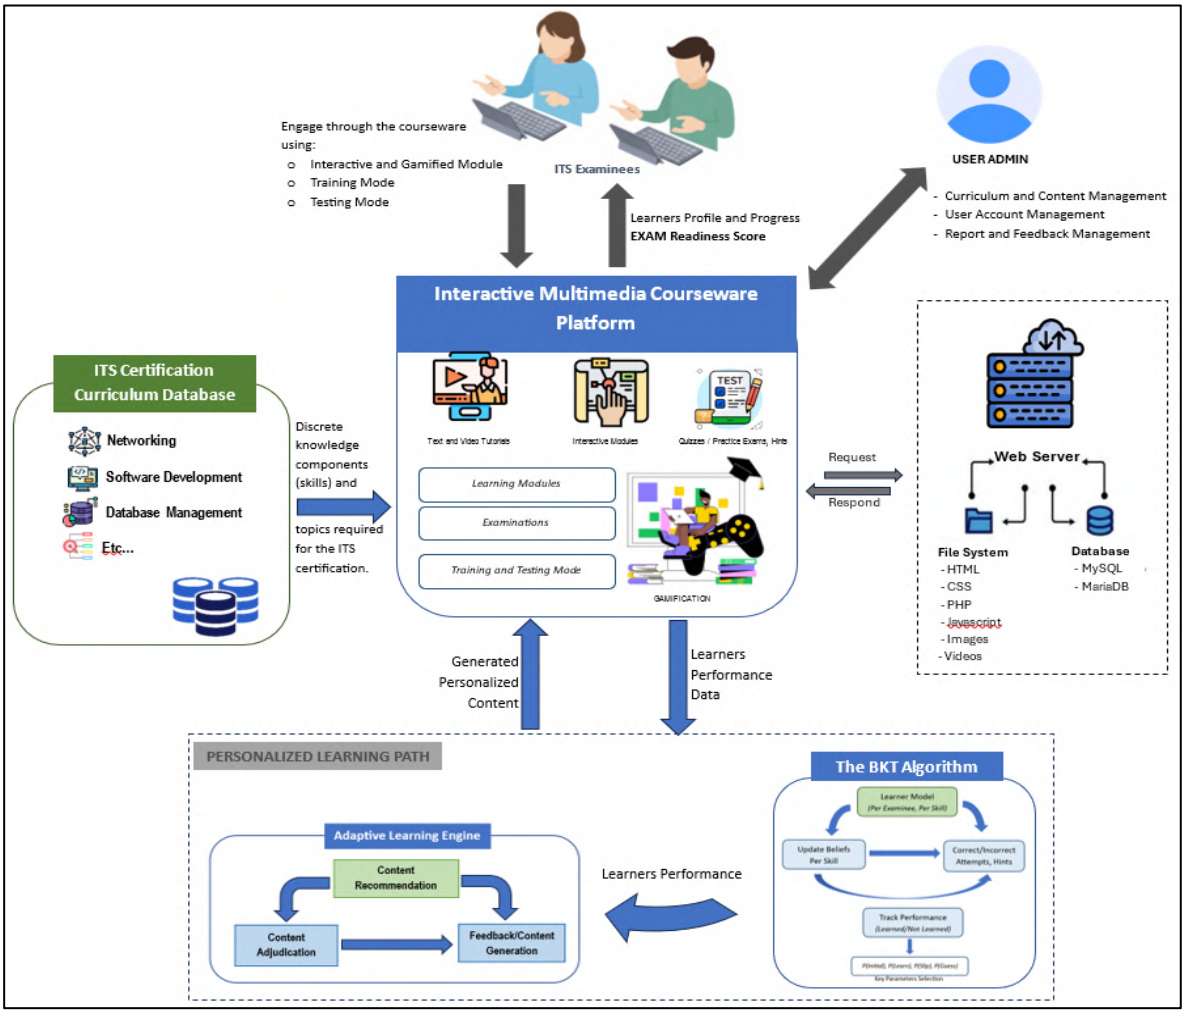

Figure 2: Courseware System Architecture.
Source: Author, (2026).

The courseware system architecture presents the dynamic interaction among the core components of the developed interactive multimedia courseware designed to provide an adaptive and personalized learning experience for IT Specialist (ITS) examinees. At its center, the ITS Examinee engages with the Interactive Multimedia Courseware Platform, which functions as the primary learning interface integrating multiple modalities such as Figure 2. The Conceptual Framework ISUI-RES-Aco-11a Effective: August 19, 2014 Revised: 0 City of Ilagan text-based and video tutorials, e-book modules, interactive exercises, practice quizzes, and both training and testing modes. Supporting this is the User Admin Module, which ensures the stability and relevance of the learning ecosystem by managing user accounts, maintaining the ITS Certification Curriculum Database, monitoring examinee performance, and overseeing the generation of analytical reports and system feedback. A pivotal component of the system is the BKT Algorithm Module, which serves as the analytical core for adaptive learning. Utilizing Bayesian Knowledge Tracing (BKT) with its parameters P(L0) for initial knowledge, P(T) for learning transition, P(S) for slip probability, and P(G) for guess probability, the module continuously analyzes learner interactions, including answer accuracy and hint usage, to infer and update each examinee's knowledge state. These probabilistic insights are transmitted to the Adaptive Learning Engine, which interprets the data to generate tailored instructional responses. The engine dynamically recommends content, adjusts difficulty levels, and sequences activities to construct a Personalized Learning Path suited to each learner's mastery progression. To ensure accessibility and usability, the courseware is developed as a responsive web-based application, enabling seamless access across both desktop and mobile devices. The entire system operates through a continuous feedback-driven loop supervised by the administrator, ensuring that learning experiences evolve in real time according to the learner's cognitive development. Ultimately, this framework aims to optimize the ITS examinee's preparation by aligning learning strategies with individual performance and adaptive insights derived from the BKT algorithm. Moreover, the implementation of the Bayesian Knowledge Tracing (BKT) algorithm was central to the courseware's adaptive capabilities. BKT is a widely recognized and validated probabilistic model, operating as a Hidden Markov Model (HMM), designed to dynamically estimate a student's mastery of discrete knowledge components (skills) over time based on their observed performance on related tasks. This approach allows for a precise, dynamic assessment of latent knowledge states, accounting for the inherent uncertainties in learning and performance. For each distinct skill delineated from the ITS curriculum, the BKT model maintains a probability $P(L_t)$, representing the likelihood that a student knows the skill at time t. This probability is rigorously updated after each interaction with a relevant task. The model is defined by four core parameters:

- $P(L_0)$ (Prior Knowledge), the initial probability a student knows the skill;
- $P(T)$ (Learning Rate), the probability of transitioning from not knowing to knowing after an attempt;
- $P(G)$ (Guess Probability), the chance of a correct answer without true knowledge; and

- $P(S)$ (Slip Probability), the chance of an incorrect answer despite knowing the skill.

At each problem attempt, the BKT algorithm updates $P(Lt)$ based on the student's observed response (Correct or Incorrect). Before a response is observed, the probability of a correct answer $P(Correct|Lt$ is predicted as:

$$P(Lt)*(1-P(S))+(1-P(Lt))*P(G) \quad (1)$$

Upon a **Correct Response**, the probability of knowing is updated in two stages: first,

$$P(Lt+1|Correct)=(P(Lt)*(1-P(S)))/P(Correct|Lt) \quad (2)$$

then

$$P(Lt+1)=P(Lt+1|Correct)+(1-P(Lt+1|Correct))*P(T)P(Lt+1)=P(Lt+1\ |Correct)+(1-P(Lt+1|Correct))*P(T) \quad (3)$$

To account for learning. Upon an **Incorrect Response**, the probability of knowing is updated as:

$$P(Lt+1|Incorrect)=(P(Lt)*P(S))/(P(Lt)*P(S)+(1-P(Lt))*(1-P(G))) \quad (4)$$

Assuming no learning occurs from an incorrect response. These continuous updates inform the adaptive engine, enabling personalized content delivery. Finally, the courseware was developed using HTML, CSS, and JavaScript for the user interface and interactivity, PHP for server-side processing, and MySQL for database management. The system stores user data, learning materials, and learner performance metrics that support the adaptive learning mechanism.

III.3 EVALUATION

The developed courseware was evaluated using the ISO/IEC 25010 Software Quality Model, which includes criteria such as functional suitability, reliability, performance efficiency, usability, security, compatibility, maintainability, and portability.

Table 1: ISO 25010 Standards Software Quality Criteria.

CRITERIA	DESCRIPTION
Functional Suitability	The degree to which the software provides functions that meet stated and implied needs.
Reliability	The ability of the software to perform its functions under specified conditions for a specified period.
Performance Efficiency	The performance relative to the amount of resources used under stated conditions.
Usability	The ability of the software to be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfac
Security	The ability of the software to protect information and data so that persons or other products or systems have the degree of data access appropriate to their types and levels of authorization.
Compatibility	The ability of the software to exchange information with other systems and perform its required functions together.
Maintainability	The ability of the software to be modified effectively, efficiently, and reliably.
Portability	The ability of the software to be transferred from one environment (e.g., hardware, operating system) to another.

Source: Author, (2026).

Purposive sampling was used to select five (5) IT experts and twenty (20) prospective IT Specialist examinees who assessed the system using a structured questionnaire. Responses were measured using a 5-point Likert scale ranging from strongly disagree to strongly agree. The weighted mean was computed to determine the overall evaluation results and user satisfaction with the developed courseware.

Table 2: ISO 25010 Standards Software Quality Criteria.

NUMERICAL SCALE	RANGE	INTERPRETATION
5	4.21 – 5.00	Strongly Agree
4	3.41 – 4.20	Agree
3	2.61 – 3.40	Neutral
2	1.81 – 2.60	Disagree
1	1.00 – 1.80	Strongly Disagree

Source: Author, (2026).

Weighted Mean Formula

$$\bar{X} = \frac{(5f_5) + (4f_4) + (3f_3) + (2f_2) + (1f_1)}{N} \quad (5)$$

Where: $\bar{X}$ = Weighted Mean
$\bar{f}$ = Frequency of each Response
N = Total Number of Respondents

The weighted mean was computed to determine the overall evaluation results and user satisfaction with the developed courseware.

IV. RESULTS AND DISCUSSIONS

This section presents the findings on the development and evaluation of the adaptive interactive multimedia courseware for IT Specialist (ITS) certification preparation. The results are organized according to the study objectives: identification of ITS exam objectives and content structure, development of the adaptive courseware using the Bayesian Knowledge Tracing (BKT) algorithm, and evaluation of the system based on the ISO/IEC 25010 software quality standards.

IV.1 IDENTIFIED IT SPECIALIST EXAM OBJECTIVES AND CONTENT STRUCTURE

To effectively design and develop the IT Specialist Exam courseware, the foundational step involved a comprehensive identification of the relevant exam objectives, topics, and corresponding module content. This meticulous process ensures alignment between the course material and the certification requirements, thereby maximizing student preparedness and success.

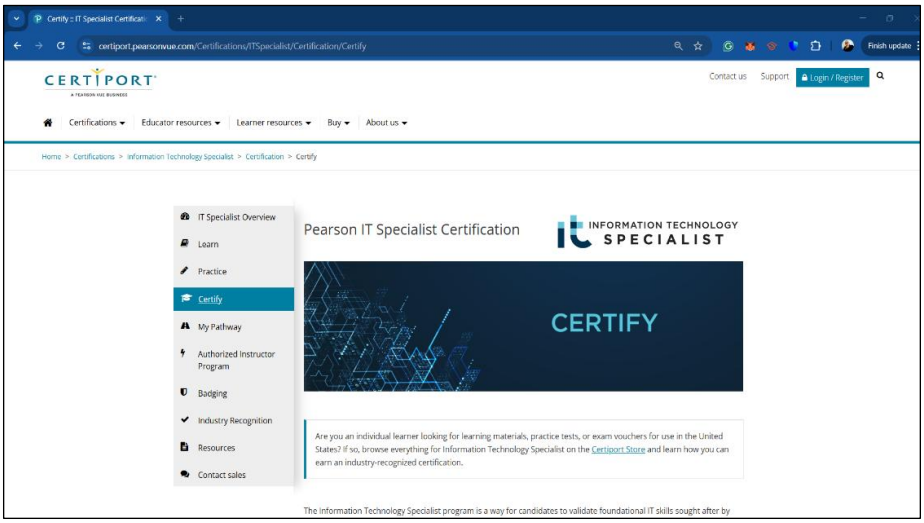

Figure 3: Certiport Pearsonvue IT Specialist.
Source: [50].

The primary source for identifying these critical components was the official Certiport PearsonVUE website, as illustrated in Figure 3. This platform serves as the authoritative repository for the IT Specialist certification program, detailing the specific skills and knowledge areas assessed by the exam. By meticulously reviewing the information presented on this website, we were able to extract the precise exam objectives that frame the scope of the certification. Following the identification of the overarching exam objectives, a detailed breakdown of the specific topics associated with each objective was undertaken. This granular approach allowed for the creation of a comprehensive list of all content areas that students need to master. Certiport PearsonVUE website details the identified topics aligned with their respective objectives, represents a crucial output of this phase. This structured mapping forms the backbone of the courseware, ensuring that every learning unit directly contributes to achieving a specific exam competency. The following stage involved the development of course modules directly based on these identified topics and exam objectives. Each module was carefully crafted to address specific learning outcomes, incorporating pedagogical best practices to facilitate effective knowledge transfer and skill development. The content within these modules is therefore a direct derivative of the certification requirements, ensuring relevance and practical applicability.

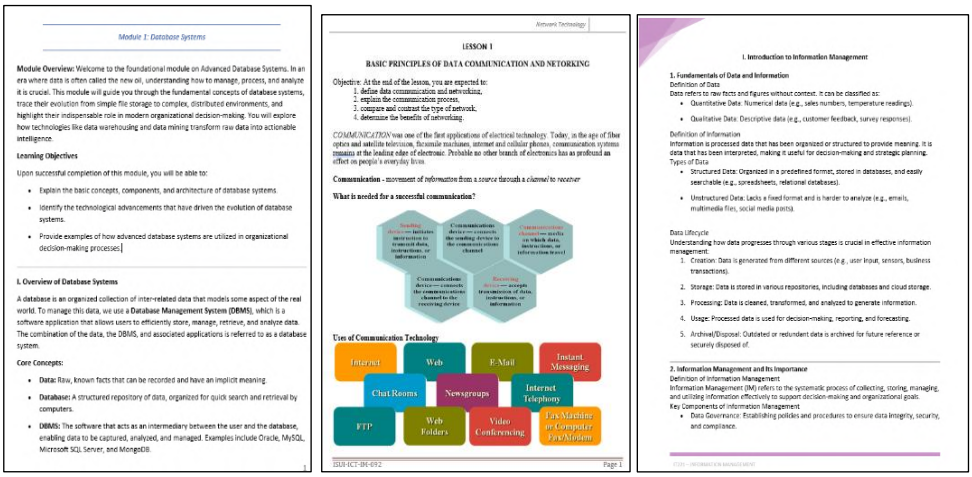

Figure 4: Contents Developed Tailored to the ITS Topic and Objectives.
Source: Author, (2026).

As shown in Figure 4, these developed module contents undergo a transformation and loading process into a centralized database. This digitalization of the course content is a critical step for its eventual integration into the courseware platform. This systematic approach ensures that the identified and developed learning materials are efficiently stored, organized, and readily accessible for delivery to the learners, forming the core educational material of the IT Specialist courseware.

IV.2 ADAPTIVE COURSEWARE USING THE BAYESIAN KNOWLEDGE TRACING (BKT) ALGORITHM

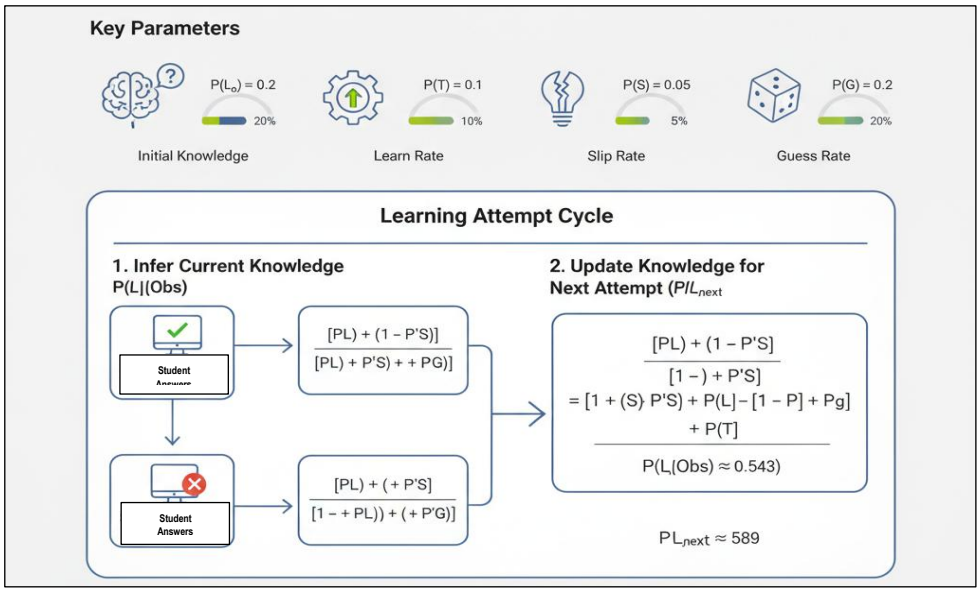

Figure 5: The Bayesian Knowledge Tracing (BKT) Design for Courseware.
Source: Author, (2026).

Figure 5 illustrates the Bayesian Knowledge Tracing (BKT) algorithm's process for modeling student skill mastery within our courseware. At each learning attempt, the model first infers the student's current knowledge *(P(L|Obs))* of a specific skill, taking into account their prior knowledge probability, along with predefined guess and slip rates, based on their observed performance (correct or incorrect answer). Subsequently, this inferred knowledge is used to update the probability of knowing the skill for the next attempt *(P(L_next))*, incorporating a learn rate that accounts for potential skill acquisition. This continuous, probabilistic updating mechanism allows the courseware to adaptively track individual student mastery over time, guiding subsequent instructional decisions, thereby personalizing the learning experience to focus on areas where the student needs the most improvement. Additionally, Figure 5 highlights how uncertainty in student responses is explicitly handled through the guess and slip parameters within the Bayesian framework. A correct answer does not always imply true mastery because the student may have guessed correctly, while an incorrect answer does not necessarily indicate a lack of knowledge due to possible slips or careless mistakes. By incorporating these probabilities, the BKT model refines the posterior probability of student knowledge more realistically. The updated value of P(L_next) therefore reflects both the student's observed performance and the likelihood that learning has occurred between attempts through the learn rate parameter. This probabilistic adjustment enables the courseware system to make more reliable estimations of student mastery and to dynamically adapt future practice opportunities or instructional content according to the learner's evolving knowledge state. Furthermore, the integration of the BKT model within the courseware supports data-driven instructional adaptation and continuous learner modeling. By updating the probability of skill mastery after each interaction, the system can identify learning progress patterns and detect areas where students may require additional support or reinforcement. This capability allows the learning platform to provide targeted feedback, adjust the difficulty of subsequent tasks, and recommend appropriate learning resources. As a result, the BKT-based framework not only improves the accuracy of student knowledge estimation but also contributes to the development of a more responsive and personalized learning environment, which is essential for enhancing learning effectiveness and engagement in modern intelligent tutoring systems.

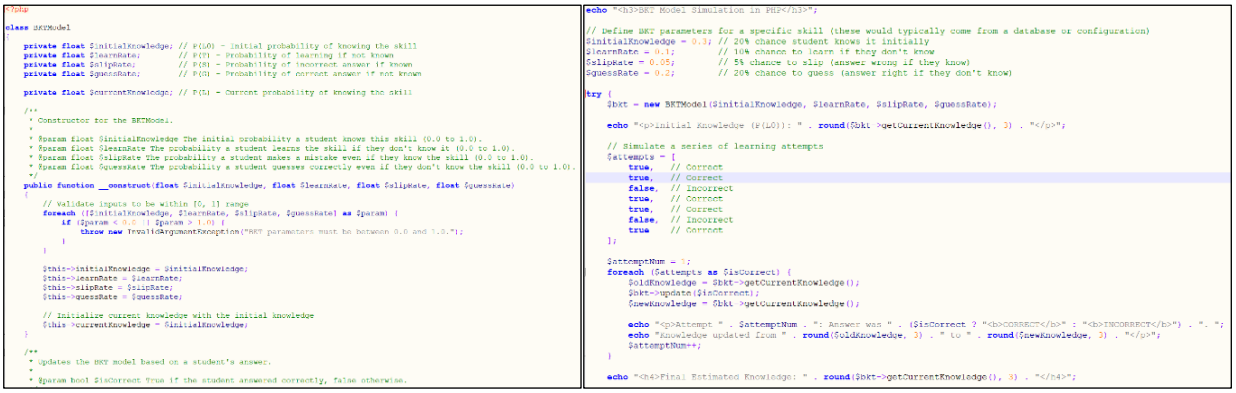

Figure 6: PHP Implementation of BKT.
Source: Author, (2026).

Following the careful design of the Bayesian Knowledge Tracing (BKT) process for the adaptive courseware, the subsequent phase involved the robust implementation of this conceptual framework utilizing PHP server-side scripting language to construct the functional web-based platform. This implementation directly translates the theoretical BKT model, encompassing the probabilistic inference of current knowledge and the subsequent updating of mastery estimates, into operational code. The PHP scripts are responsible for receiving student input from interactive exercises, executing the BKT formulas to compute the updated probability of knowing each skill, and then storing these refined knowledge probabilities in the backend database. This continuous data flow and processing enable the system to maintain an accurate, real-time profile of each student's evolving mastery across multiple skills. As depicted in Figure 6, the PHP script encapsulates the BKT algorithm, enabling the dynamic calculation and persistence of student knowledge states, thereby forming the algorithmic backbone that underpins the courseware's adaptive capabilities and facilitates its deployment as a responsive web application across various devices. Lastly, the following figures present the developed courseware integrated with an adaptive algorithm. These visual representations offer concrete examples of the interactive multimedia elements and how the adaptive learning model manifests within the user interface.

IV.2.1 Users (Learner) Module

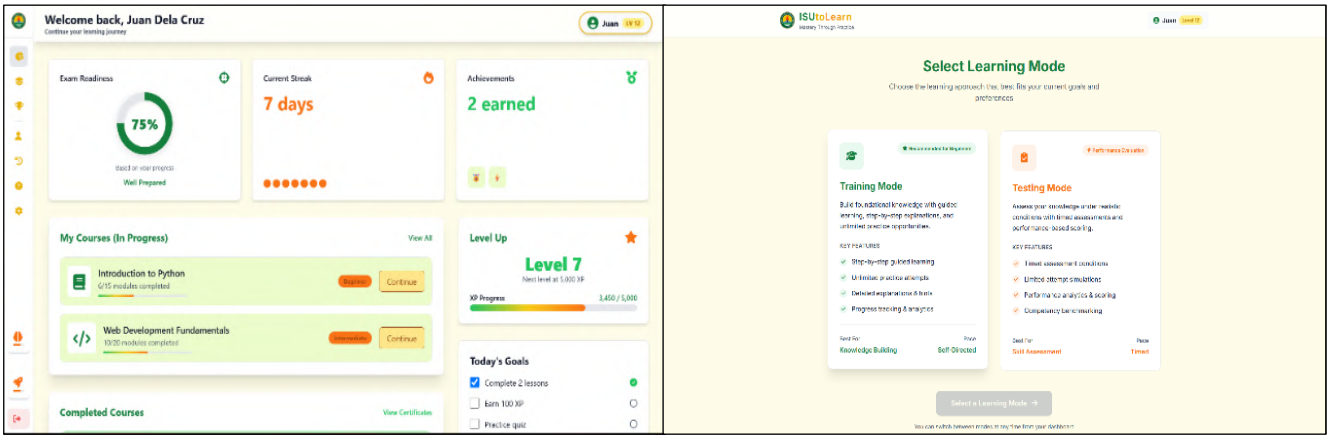

Figure 7: Main Dashboard | Mode Selection.
Source: Author, (2026).

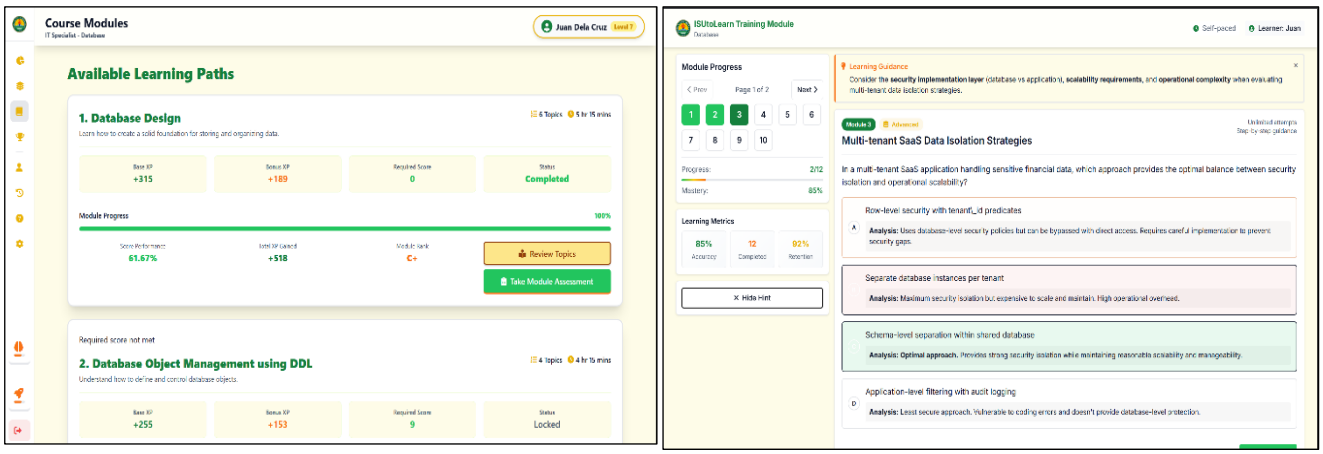

Figure 8. Learning Paths.
Source: Author, (2026).

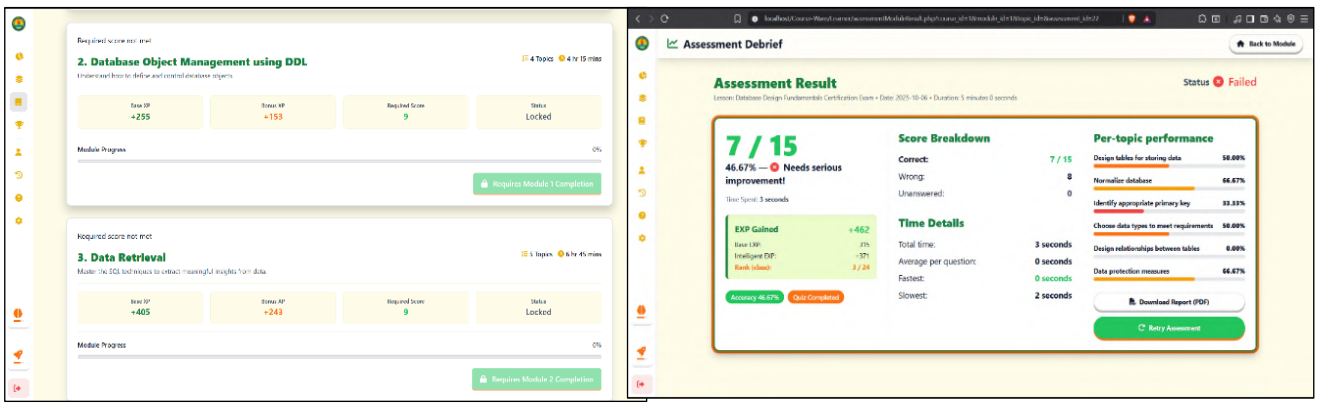

Figure 9. Progress Report.
Source: Author, (2026).

Figures 7, 8, and 9 present the graphical user interface of the developed courseware for the learners, highlighting key features that support learner navigation, learning management, and progress monitoring. Figure 7 shows the main dashboard, which provides users with centralized access to course modules, system features, and an overview of their learning activities. Figure 8 illustrates the learning mode selection and learning path interface, allowing learners to follow structured modules aligned with the certification objectives or choose topics based on their individual learning needs. Figure 9 presents the progress report interface, which displays learners' performance and mastery levels across different topics. These reports are dynamically generated based on learner interactions and assessment results, enabling users to monitor their progress and identify areas that require further improvement.

IV.2.2 Mobile-Responsive Courseware

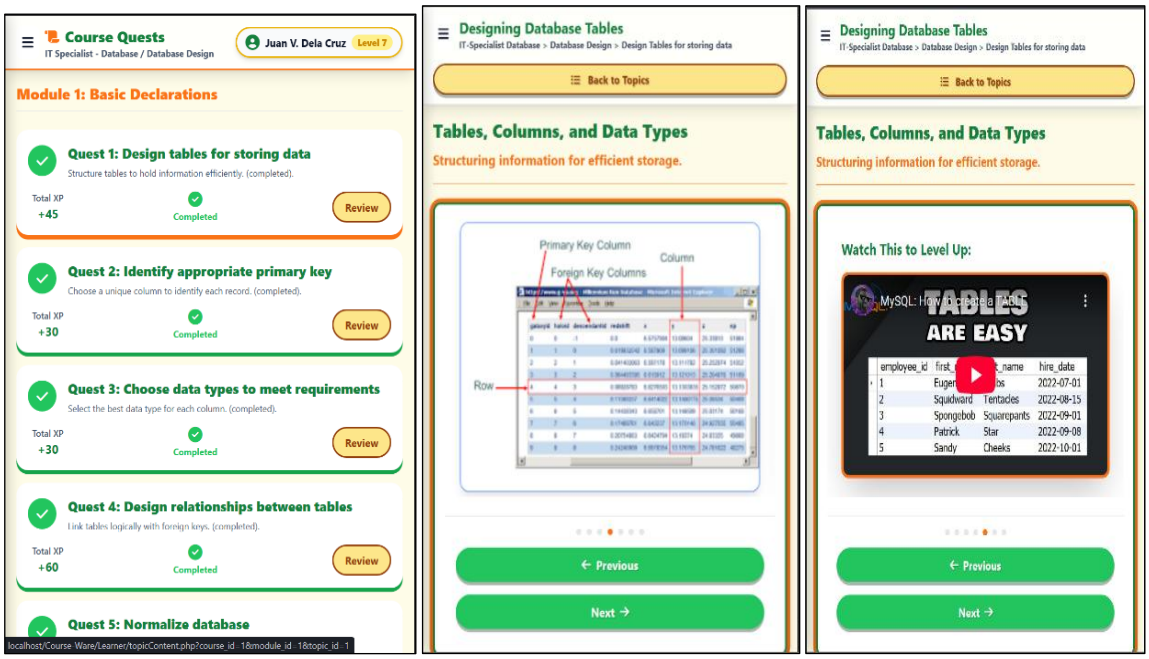

Figure 10: Mobile-responsive Courseware Design.
Source: Author, (2026).

Figure 10 presents the mobile-responsive design of the developed courseware, demonstrating its capability to adapt seamlessly across different screen sizes and devices. The responsive interface ensures that learners can conveniently access course modules, multimedia learning materials, and assessments using smartphones, tablets, or desktop computers. This design enhances accessibility and usability, allowing learners to engage with the courseware anytime and anywhere, thereby supporting flexible and continuous learning.

IV.2.3 Users (Admin) Module

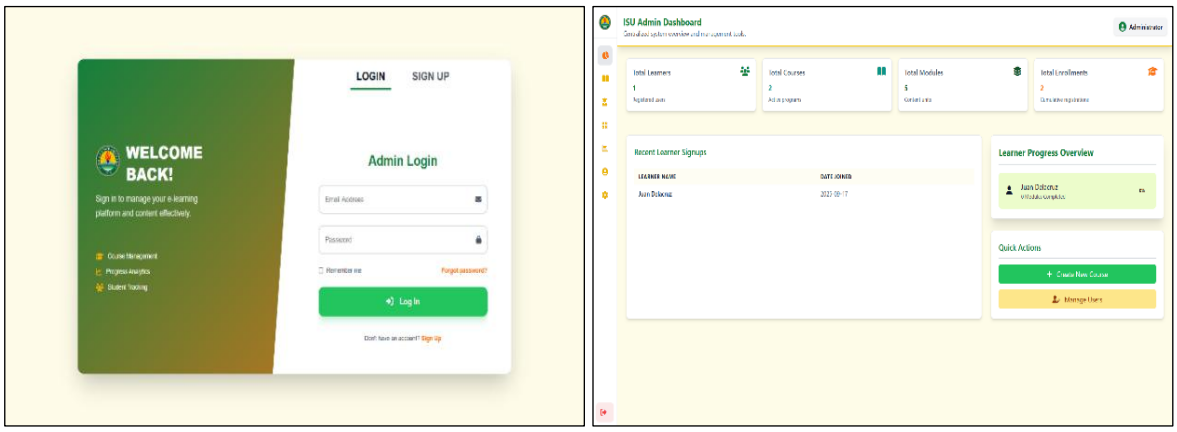

Figure 11: Admin Authentication and Dashboard
Source: Author, (2026).

Figure 11 presents the admin authentication and dashboard interface, which allows authorized administrators to securely access the system. The dashboard provides an overview of system activities and administrative tools necessary for managing the courseware platform. Figure 12 illustrates the content and user management interface, where administrators can manage course modules, update learning materials, and monitor user accounts. This functionality ensures efficient system administration and supports the continuous maintenance and improvement of the courseware content.

IV.3 EVALUATION RESULTS OF THE SYSTEM BASED ON THE ISO/IEC 25010 SOFTWARE QUALITY STANDARDS

Table 3: Results of ISO/IEC 25010 Software Quality Evaluation.

Criteria	**Mean**	**Interpretation**
Functional Suitability	4.66	Strongly Agree
Performance Efficiency	4.57	Strongly Agree
Compatibility	4.61	Strongly Agree
Usability	4.52	Strongly Agree
Reliability	4.54	Strongly Agree
Security	4.56	Strongly Agree
Maintainability	4.58	Strongly Agree
Portability	4.67	Strongly Agree
Weighted Grand Mean	**4.59**	**Strongly Agree**

Source: Author, (2026).

Table 3 presents the evaluation results of a system based on the ISO/IEC 25010 software quality model, with 5 IT Experts and 20 prospective IT Specialist examinees as respondents providing assessments. The data reveals consistently high ratings across all eight quality characteristics, with individual mean scores ranging from 4.52 (Usability) to 4.67 (Portability). The uniformly high mean values, all falling between 4.5 and 5.0, are interpreted as "Strongly Agree," indicating that the expert respondents robustly affirm the system's quality in every dimension. This culminates in a Weighted Grand Mean of 4.59, also interpreted as "Strongly Agree," collectively suggesting a very high level of satisfaction and confidence among the experts regarding the system's overall adherence to the ISO/IEC 25010 quality standards. The research successfully developed an adaptive, web-based, and mobile-responsive interactive multimedia courseware designed to enhance IT Specialist exam readiness. This involved first meticulously identifying exam objectives and topics from Certiport PearsonVUE to build relevant module content, which was then digitized and loaded into a database. Subsequently, a core adaptive learning model was implemented using the Bayesian Knowledge Tracing (BKT) algorithm, coded in PHP, to dynamically track and update individual student skill mastery based on performance. Finally, an evaluation by five IT experts, based on ISO 25010 software quality standards, yielded overwhelmingly positive results, with all eight quality characteristics and the overall Weighted Grand Mean (4.59) interpreted as "Strongly Agree," affirming the high quality, functionality, and performance of the developed courseware.

V. CONCLUSIONS

This study successfully designed, developed, and evaluated an AI-driven interactive multimedia courseware for IT Specialist certification preparation using the Bayesian Knowledge Tracing (BKT) algorithm. The development process began with the systematic identification and mapping of exam objectives, topics, and content based on the official Certiport Pearson VUE IT Specialist certification framework. This alignment ensured that the developed modules directly correspond to the competencies required in the certification examination. The study further implemented a web-based and mobile-responsive learning platform that integrates interactive multimedia components with an adaptive learning model. Through the BKT algorithm, the system continuously estimates learners' knowledge states and dynamically updates mastery probabilities based on their responses to learning activities and assessments. This adaptive mechanism enables the courseware to personalize learning pathways and focus instructional support on areas where learners require further improvement. Evaluation results based on the ISO/IEC 25010 software quality standards revealed consistently high ratings across all eight quality characteristics, including functional suitability, usability, reliability, performance efficiency, security, compatibility, maintainability, and portability. The overall weighted grand mean of 4.59, interpreted as "Strongly Agree," indicates strong validation from IT experts and prospective examinees regarding the system's quality, effectiveness, and technical robustness. Overall, the findings demonstrate that integrating adaptive learning algorithms with interactive multimedia courseware provides a viable and effective approach to improving certification exam preparation. The developed platform not only aligns with industry-recognized certification competencies but also offers a scalable and technology-enhanced learning environment capable of supporting personalized learning experiences.

VI. FUTURE WORKS

Future research may focus on the large-scale implementation and empirical evaluation of the developed adaptive multimedia courseware to further determine its effectiveness in improving IT Specialist certification exam performance among diverse learner groups. Additional studies may also explore the optimization of the Bayesian Knowledge Tracing (BKT) parameters using larger learner datasets to enhance the accuracy of skill mastery prediction and the system's adaptive capabilities. Furthermore, integrating advanced artificial intelligence techniques such as machine learning, learning analytics, and natural language processing may improve personalized feedback, automated assessment, and intelligent tutoring features. Finally, the framework of the developed courseware may be extended to support other IT certification programs and professional training environments, enabling broader applications of adaptive learning technologies in technology-enhanced education

VIII. ACKNOWLEDGMENTS

The author extends his sincere gratitude to Isabela State University (ISU) – Ilagan Campus, particularly the Campus and University Research and Development Office, for their invaluable support, funding, guidance, and encouragement throughout the conduct of this research. The author also expresses profound appreciation to the College of Engineering, Architecture and Technology for its continuous support and assistance in facilitating the research process. Furthermore, the author gratefully acknowledges the Department of Information and Communication Technology for providing the academic environment and institutional support necessary for the successful completion of this study. The author likewise extends sincere appreciation to Mr. Jaspher Fenix, Mr. Ryuta Horiuchi and Mr. Prince Andrey Ramos for their hands-on support and valuable assistance in the development of the courseware, which greatly contributed to the successful implementation of the system.

ABSTRACT

The rise of the Internet of Things (IoT) devices has led to an enormous vulnerability to multiple DDoS attacks, including low-rate traffic disruption and high-rate SYN Floods. This increasing menace underscores the importance of proper multi-classification methods that can detect various DDoS attack patterns. Nonetheless, most of the current machine learning models cannot provide a generalization between various DDoS types that include DDoS-ACK Fragmentation, DDoS-HTTP Flood, DoS-TCP Flood, and DDoS-SYN Flood. Non-linear Support Vector Machines (SVM) which are traditional classifiers tend to have poor performance when trying to differentiate subtle differences between these types of attacks. To overcome this drawback, this paper suggests a Recursive Voting Fusion model, which involves Recursive Feature Elimination (RFE) as the method of optimum feature selection and an ensemble approach to the robust classification. The framework is a hybrid of Decision Tree, Random Forest, and Extra tree classifiers where soft voting is used. It is experimentally demonstrated that the proposed approach has 99 per cent accuracy, precision, recall, and F1-score, and 99 per cent MCC and AUC-ROC, which is significantly higher than the baseline models. It implies that the model is highly robust and scalable to be used in real-time IoT intrusion detection and efficient mitigation of the developing DDoS threats.

I. INTRODUCTION

The fast growth of the Internet of Things (IoT) has introduced new standards of connectivity, autonomous automation, and efficiency in business fields like healthcare, smart cities, agriculture, transportation, and manufacturing [1-3]. Nevertheless, this enhanced interconnectedness has expanded the area of attack by cyber threats. Distributed Denial of Service (DDoS) attacks are among these and currently one of the most unsettling and mostly launched cyberattacks on IoT infrastructures [4-6]. The IoT devices are relatively resource-limited and oftentimes have the bare-minimum security protocols installed, which makes them the best targets of botnet infection which can then be utilized to execute massive, multi-vector DDoS attack [7], [8]. An example of such an attack that caused havoc on the global internet is the 2016 Mirai botnet attack that used insecure IoT devices to flood the DNS provider Dyn [9], [10]. The all-purpose classification of DDoS attacks may be done by the attacker by the type of the network stack and the point of entry into the victim network [11-13]. Attacks that can occur at the network layer are TCP SYN Flood, UDP Flood, and ICMP Flood, which aim to either consume bandwidth or connection queues with a flood of packets. Fragmentation vulnerabilities can be used at the transport layer by means of ACK Fragmentation and UDP Fragmentation [14-16].

Applications layer is prone to advanced attacks such as the HTTP Flood and DNS Amplification that are harder to detect since they imitate the normal user actions. These attacks vary in frequency, packet size and protocol exploitation and multi-classification is essential to identify and mitigate them more accurately [17], [18]. Although the intrusion detection systems (IDS) research field has been researched extensively, machine learning-based IoT DDoS detection solutions are associated with three major limitations [19-21]. To begin with, they demonstrate low generalization abilities with different classes of DDoS, often classifying less common or more intricate attacks [22-24]. Second, most models are not very robust at feature selection that may lead to incorporation of redundant or noisy features that multiply computational requirements and poor performance [25-27]. Third, the presence of imbalance in classes in datasets distorts the learning process, as it leads to biased prediction on the most prevalent types of attacks and ignoring rare but essential threats [28], [29]. As an example, traditional models, e.g. Support Vector Machines (SVM) and Naive Bayes, provide poor macro-average F1-scores and are unable to detect attacks, such as DDoS-ICMP Flood or UDP Fragmentation [30], [31]. To overcome them, the paper will suggest Recursive Voting Fusion, a new framework of ensemble classifications, which aims to precisely and effectively identify various types of IoT-based DDoS attacks. The framework combines Recursive Feature Elimination (RFE) to discover the most discriminative set of features, in other words, noise reduction and improved classification accuracy. The fundamental classifier consists of a hard voting set of Decision Tree, Random Forest and Extra Tree models which are combined to exploit multiple learning biases to enhance detection strength. The key aim of this study is to work on a lightweight, scalable, and high-accuracy multi-class DDoS detecting system that can be used in the real-time IoT security system. The study intends to: (i) identify 15 different IoT DDoS and DoS attack types with high accuracy, (ii) optimize the performance of the model based on feature selection (iii) compare the system to the principles of the traditional classifier to prove its excellence. An experimental analysis of the labeled IoT DDoS data indicates that the proposed model has 99% accuracy, precision, recall, and F1-score, and MCC and AUC-ROC of 0.99. Recursive Voting Fusion is much more effective on all the measures compared to baseline classifiers like SVM (25%), KNN (97%), and Naive Bayes (54%). Additionally, the model is highly recalled in complex subcategories like HTTP Flood, DNS Amplification, and Smurf and, therefore, it shows effectiveness in detecting threat subtly. The suggested system is a resource-saving, practical proposal of the IoT networks in the contemporary era, which have been added to not only academic development but also the implementation of the solution and solution to the proposed-system in proactive DDoS prevention models.

II. THEORETICAL REFERENCE

The exponentially accelerated development of Internet of Things (IoT) technologies has increased connectivity and smart automation in the industrial sector. Nevertheless, the very resource-limited character of the IoT devices and their massive deployment has predisposed them to the DDoS attacks. This has made effective and smart systems of detection instrumental in detecting and categorizing and curtailing such threats. The given literature review discusses the recent trends in machine learning (ML) and deep learning (DL) systems to identify multi-class DDoS attacks in IoT setups, particularly ensemble models, feature selection algorithms, and class imbalance. By [1] suggested a hybrid learning model to identify cyberattacks using IoT-based detection that takes advantage of feature transformation and a collection of classifiers to identify advanced threats. In turn [2] have made a comparative analysis of anomaly detection techniques and highlighted the trade of between unsupervised and supervised techniques in IoT networks. The strength of sequence-based models of dynamic traffic analysis is demonstrated with the help of LSTM networks applied to the CIC-IoT2023 dataset by [3], who identified the temporal patterns of attacks. An intrusion detection system was introduced by [4] that employs convolutional layers and autoencoders to identify DDoS traffic using deep learning. According to [5] took the idea a step further and suggested a hybrid CNN-BiLSTM system to also address low-rate DDoS attacks that are especially difficult to detect because of their insidious traffic signature. In turn [6] scaled recurrent neural architectures to real-life IoT settings, with an emphasis on scalability and accuracy. In healthcare systems that rely on the IoT, which are critical regarding security, [7] used machine learning to detect anomalies. Their work represented better performance in case of engineered features based on domain knowledge. By [8] suggested CKAN model (Convolutional Kolmogorov-Arnold Networks) that was able to identify non-linear relationships within IoT traffic to be able to classify them effectively. In a similar way, [9] proposed a deep ensemble learning method with pruning, which maximizes the accuracy of detection and efficiency of computing DDoS detection. By [10] also applied Principal Component Analysis (PCA), which increases the accuracy and efficiency of computation in the detection of DDoS. In order to address the issue of detection robustness, [11] developed a hybrid system which combines feature selection based on filters with ensemble classifiers.

In turn [12] extended their model by using SMOTE-ENN to balance the data and effective feature selection so that the model can be better at minority classes. By [13] concentrated on detecting DDoS in the IoT applications based on supervised machine learning models and showed significant enhancement with random forest and SVM. By [14] created a hybrid intrusion detection framework of the cyber-physical systems with the best feature selection based on correlation and mutual information parameters. A hybrid feature selection algorithm, LightGBM with a modified slap swarm algorithm, was proposed by [15], and it demonstrated significant performance in the context of big data IoT. [16] have suggested a multi-class intrusion detection system based on transformers and CIC-IoT-2023 dataset, demonstrating great versatility to complicated traffic patterns. In turn [17] compared different deep learning models in the context of the IoT intrusion classification and have demonstrated that ensemble deep learning models were more effective in multiclass configurations in comparison with single architectures. According to [18] reused their previous methodology and critically analyzed some machine learning algorithms on the CIC-IoT2023 dataset. By [19] boosted the intrusion detection by using a twostep clustering method, which makes the system more sensitive to detect low level DDoS activities. VGGIncepNet developed by [20] involved non-image-to-image conversion methods and CNN architecture in intrusion detection, and it achieved better spatial feature extraction. By [21] have created an agent-based system that automates the process of feature extraction and selection in detecting DDoS, minimizing preprocessing costs by hand and enhancing the real-time results. According to [22] offered a smart architecture that combines various levels of detection in order to identify threats, which is optimized in terms of IoT scale throughput and latency. By [23] made the CICIoT2023 dataset available and made it a reference on how to measure large-scale IoT attacks. In turn [24] proposed the attention mechanism-enhanced CNN-BiLSTM model and it was found to be of great significance in the classification of DDoS variants such as TCP SYN and ICMP floods.

By [25] gave a broad overview of the ML methods to detect DDoS in IoT and proposed the future research opportunities in adaptive and self-healing detection systems. In turn [26] introduced a hybrid DDoS detector based on CNN and GRU, with high accuracy results and robustness. The work by [27] compared the performance of the common ML classifiers to the CIC-IDS2017 dataset, indicating the ensemble learning as the future direction. By [28] developed IoT-specific intrusion detection system based on standard ML algorithms and emphasize the relevance of features to achieve high classification performance using the CICIoT dataset. In turn [29] trained the Random Forest models with the purpose of DDoS detection in the IoT and verified its functionality using the CICIoT dataset. According to [30] maximized the performance of AdaBoost through undersampling and hyperparameter optimization, which shown that pre-processing of data has a significant impact on model accuracy. Finally, Avc\u0131 and by [31] used supervised learning-based method of predicting DDoS in building management systems and stated that such models can be generalized to all smart infrastructure. As noted in the reviewed literature, use of deep learning architectures such as LSTM, CNN-BiLSTM, transformers; ensemble techniques involving multiple classifiers; and feature selection techniques including PCA, SMOTE-ENN, and swarm algorithms have several promising trends. Nonetheless, the majority of studies are related to binary classification or definite types of DDoS without multiclass categorization. In addition, features selection is also understudied or uses heuristic methods. Also, the datasets do not possess the appropriate class balance, which is poorly addressed in most of the models, limiting the performance on minor types of DDoS.

III. MATERIALS AND METHODS

Figure 1 indicates a very elaborate and methodically formatted pipeline that is to be used in the detection of Distributed Denial of Service (DDoS) attacks in Internet of Things (IoT) systems by using a powerful voting-based ensemble machine learning framework. This all-encompassing flowchart summarizes six sequential stages and interdependent ones, which represent the essential part of the entire data analytics and cybersecurity workflow starting with the first data acquisition and preprocess, feature extraction, model training, and eventual decision-making. The basis of this framework is the CICIoT2023 dataset [23] a balanced and well-curated dataset consisting of fifteen types of DDoS attacks, with one hundred samples each or a total of 1,500 rows and 47 columns. The variety and realism of the dataset is closely related to the real-world situation of IoT network, which contributes to the higher generalizability and effectiveness of the approach proposed to detect intrusion.

III.2 DATASET: CICIOT2023 (1500 SAMPLES, 15 CLASSES)

At the core of this pipeline is the CICIoT2023 dataset [23], a benchmark dataset designed to reflect real-time and large-scale attacks specifically tailored for IoT networks. Table 1. encompasses 47 columns or features and 15 types of cyberattack classes including botnets, brute-force, infiltration, and various types of DDoS patterns each represented by 100 samples. The dataset includes high-resolution telemetry such as:

- Network traffic features (e.g., source IP, destination IP, protocol, packet count, byte count)
- Flow behavior metrics (e.g., flow duration, flow bytes per second, inter-arrival time)
- Attack signatures relevant to multi-vector DDoS scenarios

Using a uniform class distribution (100 samples/class) helps in mitigating class imbalance, a major challenge in supervised classification tasks. The dataset ensures diversity in attack vectors, making the model generalizable and robust for real-world intrusion detection systems (IDS) in IoT ecosystems.

Table 1: Dataset Columns Description.

Column Name	Description
flow_duration	Total duration of the network flow (in microseconds or milliseconds).
Header_Length	Length of the packet headers.
Protocol Type	Type of transport protocol used (e.g., TCP, UDP, ICMP).
Duration	Duration of the specific activity/connection.
Rate	Average transmission rate of packets or bytes.
Srate	Source-to-destination packet transmission rate.
Drate	Destination-to-source packet transmission rate.
fin_flag_number	Number of FIN flags observed (connection termination signal).
syn_flag_number	Number of SYN flags (used to initiate a TCP connection).
rst_flag_number	Number of RST flags (used to reset a TCP connection).
psh_flag_number	Number of PSH flags (push data to receiving app).
ack_flag_number	Number of ACK flags (acknowledge receipt).
ece_flag_number	Number of ECE flags (Explicit Congestion Notification Echo).
cwr_flag_number	Number of CWR flags (Congestion Window Reduced).
ack_count	Count of packets with ACK flag set.
syn_count	Count of packets with SYN flag set.
fin_count	Count of packets with FIN flag set.

urg_count	Count of packets with URG (urgent) flag set.
rst_count	Count of packets with RST flag set.
HTTP	Indicator/count for HTTP protocol usage.
HTTPS	Indicator/count for HTTPS protocol usage.
DNS	Indicator/count for DNS protocol usage.
Telnet	Indicator/count for Telnet protocol usage.
SMTP	Indicator/count for SMTP protocol usage.
SSH	Indicator/count for SSH protocol usage.
IRC	Indicator/count for IRC protocol usage.
TCP	Indicator/count for TCP protocol usage.
UDP	Indicator/count for UDP protocol usage.
DHCP	Indicator/count for DHCP protocol usage.
ARP	Indicator/count for ARP protocol usage.
ICMP	Indicator/count for ICMP protocol usage.
IPv	IP version indicator (IPv4 or IPv6).
LLC	Indicator/count for LLC (Logical Link Control) usage.
Tot sum	Total sum of packet sizes in the flow.
Min	Minimum packet size in the flow.
Max	Maximum packet size in the flow.
AVG	Average packet size in the flow.
Std	Standard deviation of packet sizes.
Tot size	Total size of the data transferred in the flow.
IAT	Inter-arrival time between packets.
Number	Total number of packets in the flow.
Magnitude	Magnitude of packet payloads or statistical metric
Radius	Statistical feature showing distance in feature space
Covariance	Covariance between selected flow parameters.
Variance	Variance of packet sizes or times in the flow.
Weight	Weight assigned to the flow
label	Class label

Source: Authors, (2026).

III.3 PRE-PROCESSING: NULL VALUE HANDLING AND ENCODING

Once the dataset is acquired, the first critical step is data pre-processing, which ensures the dataset is clean and suitable for machine learning algorithms. The dataset, derived from [23], includes multiple features that may contain null or missing values and categorical fields that are not directly interpretable by machine learning models.

- Null Value Handling: Missing values in the dataset can degrade the performance of classifiers. Let the dataset be represented as a matrix $X \in \mathbb{R}^{nxm}$, where $n = 1500$ samples and m features. A missing value in element x_{ij} (i.e., the value at the ith row and jth column) is either removed if the percentage of missingness is negligible, or imputed using statistical methods such as:
  Mean imputation:

$$x_{ij} = (1/N) \sum_{k=1}^{N} x_{kj} \quad (1)$$

  K-Nearest Neighbors imputation (KNN):

$$x_{ij} = \text{mean}(\{x_{pj} \mid x_p \in N_k(x_i)\}) \quad (2)$$

- Encoding: Categorical variables such as protocol or flag type are transformed into numerical format using encoding schemes. For nominal variables $C = \{c_1, c_2, \ldots, c_k\}$, One-Hot Encoding creates binary vectors for each class label:

$$\text{Encoded}(c_j) = [0, 0, \ldots, 1, \ldots, 0] \quad (3)$$

III.4 RECURSIVE FEATURE ELIMINATION (RFE)

After the data is cleaned and numerically encoded, the next step is Recursive Feature Elimination (RFE). This is a feature selection technique that aims to reduce the dimensionality of the feature space while preserving the most predictive attributes.

$$X = [x_1, x_2, \ldots, x_m] \quad (4)$$

$$\text{Feature Set}_{t+1} = \text{Feature Set}_t \setminus \{\text{argmin}_{xj} \in \text{Feature Set}_t \, I(x_j)\} \quad (5)$$

III.5 ENSEMBLE VOTING-BASED MACHINE LEARNING

The core of the detection framework is a Voting-Based Ensemble Model, which integrates predictions from multiple classifiers to improve robustness and accuracy. The ensemble here consists of Decision Tree (DT), Random Forest (RF), and Extra Trees (ET) classifiers each tuned with specific hyperparameters to maximize performance and diversity.
Decision Tree (DT): The Decision Tree is built using the Entropy-based Information Gain criterion. The entropy $H(S)$ of a dataset S is calculated as:

$$H(S) = -\sum_{i=1}^{k} p_i \log_2(p_i) \quad (6)$$

Where p_i is the proportion of samples belonging to class i. A split at node N aims to maximize the Information Gain (IG):

$$IG(S, A) = H(S) - \sum\_\{v \in Values(A)\} (|S_v| / |S|) H(S_v) \quad (7)$$

The tree's growth is constrained by maximum depth $d = 30$, minimum samples to split $s = 4$, and minimum leaf size $l = 2$. Class weights are balanced to counteract skewed class distributions. Random Forest (RF): The Random Forest is an ensemble of decision trees trained using bootstrap aggregation (bagging) and random feature selection. Let $T = \{t1, t2, \dots, tn\}$ denote the set of $n = 200$ decision trees, each trained on a bootstrap sample from the dataset. The Gini index is used to determine optimal splits:

$$Gini(S) = 1 - \sum_{i=1}^{k} p_i^2 \quad (8)$$

Each tree considers a random subset of features (square root of total features) at each split, increasing diversity among trees. The output class is determined by majority vote:

$$\hat{y} = mode(\{t_i(x) \mid i = 1, \dots, n\}) \quad (9)$$

Extra Trees (ET): The Extra Trees classifier is like Random Forest but introduces additional randomness by selecting split thresholds at random, rather than choosing the best threshold. Here, $n = 250$ trees are grown without bootstrapping (entire dataset used), and split criterion is entropy. The maximum number of features at each split is set to $\log_2(m)$, where m is the total number of features.

$$\max features = \log_2(m) \quad (10)$$

III.6 EVALUATION METRICS

After model training, the ensemble classifier is evaluated using a comprehensive set of metrics that capture different dimensions of performance.

- Accuracy: Measures overall correctness:

$$Accuracy = (TP + TN) / (TP + TN + FP + FN) \quad (11)$$

- Precision and Recall: Precision measures the correctness of positive predictions, and recall measures completeness:

$$Precision = TP / (TP + FP) \quad (12)$$

$$Recall = TP / (TP + FN) \quad (13)$$

- F1-Score: The harmonic means of precision and recall:

$$F1 = 2 * (Precision * Recall) / (Precision + Recall) \quad (14)$$

- K-Fold Cross Validation: The dataset is split into K equal parts. For each iteration, $K - 1$ parts are used for training and 1 for testing. This is repeated K times, and the results are averaged:

$$Cross - validation\ Accuracy = (1/K) \sum_{i=1}^{K} Accuracy_i \quad (15)$$

- Matthews Correlation Coefficient (MCC): A balanced measure for classification performance:

$$MCC = (TP * TN - FP * FN) / sqrt((TP + FP)(TP + FN)(TN + FP)(TN + FN)) \quad (16)$$

This metric is particularly useful in multi-class problems or where class imbalance exists, as it takes all four confusion matrix categories into account. In summary, sub section 1.2 through 1.6 form the core computational and analytical backbone of proposed system pipeline. Each step from data cleansing and transformation, through intelligent feature reduction, to the highly optimized ensemble model contributes to a robust and interpretable system for IoT DDoS attack detection, validated by rich evaluation strategies.

IV. RESULTS AND DISCUSSIONS

To provide an efficient training and evaluation of the proposed ensemble intrusion detection model, the result analysis was performed in the Google Colab environment with a T4 GPU setting. The data used in the CICIoT2023 consist of 15 classes with 1500 samples per class, which was split into an 80:20 train-test to ensure a balanced evaluation environment was obtained. In order to test the strength of the model, a cross-validation strategy (5 folds) was applied and gave coherent performance forecasts across various data subsets. The proposed ensemble model, a combination of Decision Tree, Random Forest, and Extra Trees classifiers with optimized hyperparameters, was compared to each other in terms of comparative effectiveness. The accuracy, the precision, the recall, the F1-score, and the ROC-AUC, which are the evaluation metrics, had better performance of the ensemble framework especially in the class imbalance and complicated patterns. The ability of the model to discriminate was also demonstrated by Receiver Operating Characteristic (ROC) curves that demonstrated high true positive rates across classes. Such extensive experimentation highlights the generalization capability and usefulness of the system in the IoT-based intrusion detection. Figure 2. represents the loaded dataset of 1500 rows and 47 columns. It contains such attributes as flow duration, Header length, Protocol type and other measures of traffic rates, which is probably intended to perform DDoS detection work.

	flow_duration	Header_Length	Protocol Type	Duration	Rate	Srate	Drat

Figure 5. shows confusion matrices and classification metrics for K-Nearest Neighbors and SVM classifiers. KNN performs very well (accuracy: 0.97, MCC: 0.9679), while SVM struggles significantly (accuracy: 0.25, MCC: 0.2379), indicating poor performance on this dataset.

Table 2: Proposed Ensemble Voting Model K-Fold Validation.

Fold	Accuracy	Precision	Recall	F1-Score	MCC
1	0.9833	0.9857	0.9833	0.9836	0.9823
2	0.9900	0.9908	0.9900	0.9900	0.9893
3	0.9933	0.9937	0.9933	0.9933	0.9929
4	0.9867	0.9873	0.9867	0.9867	0.9858
5	0.9833	0.9840	0.9833	0.9834	0.9822

Source: Authors, (2026).

Table 2 presents the 5-fold cross-validation results of the proposed ensemble voting model, demonstrating consistent and robust performance across all folds. Accuracy ranges from 98.33% to 99.33%, with precision, recall, and F1-score values consistently above 98%, and MCC scores ranging between 0.9822 and 0.9929, indicating high model reliability and balanced classification capability.

Table 3: Comparative Analysis.

Model	ACC(%)	P(%)	R(%)	F1-Score(%)	MCC	AUC-ROC
K-Nearest Neighbor	97%	97%	97%	97%	0.96	0.99
Support Vector Machine	25%	19%	25%	16%	0.23	0.23
Decision Tree	98%	98%	98%	98%	0.98	0.99
Random Forest	98%	98%	98%	98%	0.98	0.99
Navier Bayer's	54%	61%	54%	47%	0.52	0.96
Extra Tree	96%	97%	96%	96%	0.96	0.99
Proposed Ensemble Voting Model	99%	99%	99%	99%	0.99	0.99

Source: Authors, (2026).

Table 3 provides a comparative analysis of various classifiers, where traditional models like K-Nearest Neighbor, Decision Tree, Random Forest, and Extra Trees show strong results with accuracies around 96–98%, while Support Vector Machine and Naïve Bayes significantly underperform due to limitations in handling feature space and class imbalance. The proposed ensemble voting model outperforms all other methods, achieving 99% across all key performance metrics accuracy, precision, recall, F1-score, MCC, and AUC-ROC highlighting its superiority and effectiveness in intrusion detection tasks.

V. CONCLUSIONS

This research presents an effective ensemble intrusion detection system that can be used in detecting Distributed Denial-of-Service (DDoS) attacks in Internet of Things (IoT) systems. In a voting ensemble model, the system uses a Decision Tree, Random Forest, and Extra Trees classifier, with the best hyperparameters to optimize the detection performance. The high-quality feature sets were also guaranteed by preprocessing steps, such as KNN-based imputation, categorical variables encoding, and Recursive Feature Elimination (RFE), which boosted the accuracy of the models. The proposed model was shown to have a good classification ability across various types of attacks using the CICIoT2023 dataset comprising of 15 diverse classes of attacks with 1500 samples per attack category. The ensemble approach had better precision, recall, and F1-score values compared to base models and supports its usefulness in dynamic and complex IoT ecosystems. The following research should look into the possibility of combining adaptive learning mechanisms which would enable the system to adapt or change with new attack patterns. Lightweight deep learning models can be incorporated as a trade-off between performance and computational efficiency to deploy in edge devices in real time. Second, it is possible to incorporate real-time streaming data into the framework and implement it in a Software Defined Network (SDN) infrastructure to achieve even greater responsiveness and scalability. Federated learning methods would also deal with the issue of privacy in distributed IoT settings and provide strong security. It is important to keep benchmarking of the model and various types of datasets and environments in order to be able to extrapolate the effectiveness of the model to heterogeneous IoT applications.

Audio Encryption Techniques: Classical, Chaos-Based, DNA-Inspired, Neural, and Quantum-Assisted Approaches

ABSTRACT

In this paper, a comparative review of various encryption techniques for audio data, which were introduced between 2015 and 2025, will be discussed to meet the requirements for secure audio data communication. Conventional encryption techniques, such as Advanced Encryption Standard (AES), Elliptic Curve Cryptography (ECC), and Substitution Permutation Networks (SPN), are considered to have high resistance to brute-force attacks, yet they may fail when dealing with a data type such as audio because they are deterministic networks. The survey also encompasses chaos-based encryption algorithms, such as multi-dimensional and hyper-chaotic maps, which utilize nonlinearity for improving confusion diffusion and extending the key space. Bio-inspired algorithms integrating the concept of Deoxyribonucleic Acid (DNA) coding techniques and chaotic maps are also described. Furthermore, the survey encompasses the use of Artificial Neural Networks (ANN) and the Neuro-Chaotic Cryptosystem (NeuroChaosCrypt) for encryption purposes because of its adaptive encryption mechanism. Finally, physical-layer techniques and quantum-assisted techniques, like Polarized Light Beam (PLB) Encryption and Quantum-Assisted Secure Audio Communication (QSAC), that provide security guarantees using the principles of physics and quantum computing, also deserve mention.

I. INTRODUCTION

I.1 BACKGROUND AND MOTIVATION

The growing use of digital communication technology has led to the increasing transmission of sensitive audio information over various platforms such as mobile communication systems, telemedicine setups, smart infrastructure, and military systems. This has greatly increased the demand for secure audio communication systems that can protect audio information from unauthorized access, modification, and cryptanalytic attacks. The initial work on secure audio communication systems was based on classical cryptographic algorithms. The Advanced Encryption Standard (AES), Elliptic Curve Cryptography (ECC), and Substitution-Permutation Networks (SPN) formed the basis for secure audio communication systems [1-4]. These deterministic mathematical algorithms provided acceptable performance and robustness against brute-force attacks. However, in the context of audio signals, which have strong temporal correlation properties, their rigid mathematical structure showed some limitations. The analysis of Rijndael in [4] shows its robustness against brute-force attacks but also suggests that statistical and differential cryptanalysis could still be a problem in audio-related scenarios.

I.2 EVOLUTION TOWARDS CHAOS-BASED SOLUTIONS

In order to meet the robustness requirements, some research works have examined the encryption speed in noisy channels and signal distortion. The model proposed in [5] presented a noise-resistant audio encryption model, and the bit-level chaos-based approach in [6] showed strong randomness and lossless audio encryption speed. With the increasing understanding of the deterministic structure limitations, research gradually evolved towards chaotic encryption models. Chaotic dynamic systems are known for their nonlinearity and high sensitivity to initial conditions, which are very useful in producing unpredictable key sequences and improving confusion diffusion. Multidimensional and hyper-chaotic systems, as presented in [7-9], showed increased key space, improved randomness quality, and increased resistance to correlation attacks and differential cryptanalysis.

I.3 DNA, NEURAL, AND HYBRID INTELLIGENT MODELS

In parallel with the design of chaos-based encryption schemes, DNA-based and bio-inspired cryptographic models have been proposed as viable alternatives for improving the security of audio encryption schemes. DNA coding-based models of audio signals utilize bio-inspired encoding schemes, where biological operations such as complementation and substitution are applied for improving the security of audio encryption schemes. The application of DNA coding-based models of chaotic maps, as proposed in [10-12] has been found to improve the security of audio encryption schemes. Recent research has proposed hyperchaotic maps for improving the security of audio encryption schemes. Hyperchaotic maps possess higher dimensionality and sensitivity than traditional chaotic maps, which can be exploited for improving the key space of audio encryption schemes. For example, [13] proposed a new hyperchaotic system with circuit implementation for improving the security of audio encryption schemes.More recently, research has focused on physical-layer and quantum-assisted cryptographic solutions. Optical cryptographic solutions, such as polarized light beam encryption [14], and quantum-assisted secure communication systems, such as QSAC [15] provide security assurances based on physical and quantum theories. These models provide intrusion detection and resistance capabilities beyond those of traditional algorithmic cryptography.

I.4 RESEARCH GAP AND CONTRIBUTION

The growing complexity of attack methods has also been mentioned in machine learning-based cryptanalysis research. As mentioned in [16], the current sophistication of attack methods calls for the development of encryption models that are robust against intelligent adaptive attack methods. Although there are various existing encryption models, current research is typically centered on a single method. Thus, there is a need for a comprehensive survey that compares classical, chaos-based, DNA-inspired, neural, and quantum-assisted audio encryption models in a single framework. Hence, this paper presents a comparative analysis of audio encryption models developed between 2015 and 2025, with a focus on their structural aspects, trade-offs, and research gaps.

I.5 ORGANIZATION OF THE PAPER

The rest of this paper is organized as follows. Section 2 provides a review of the current state of the art in survey research and the relevance of this paper to the current literature. Sections 3 to 7 introduce classical, chaos-based, DNA-inspired, neural, and optical/quantum-assisted audio encryption models. Section 8 introduces the comparative analysis framework. Finally, Sections 9 and 10 conclude the paper and provide future research directions.

II. RELATED WORK

II.1 EXISTING SURVEY PAPERS ON AUDIO ENCRYPTION

Recent studies on secure audio communication have increasingly addressed the limitations of early encryption approaches when applied to highly correlated audio signals. Initial research primarily employed classical cryptographic techniques, including the Advanced Encryption Standard (AES), Elliptic Curve Cryptography (ECC), and Substitution–Permutation Networks (SPN). Although these methods provided reliable security against brute-force attacks, several studies reported reduced effectiveness under audio-specific statistical and differential analyses. For example, the evaluation presented in [4] confirmed the robustness of AES against brute-force attacks while highlighting structural constraints when applied to audio data. To overcome these limitations, subsequent research shifted toward chaos-based encryption models characterized by strong nonlinearity and sensitivity to initial conditions. Such properties enable the generation of highly unpredictable key streams and improved confusion–diffusion performance. Multidimensional and hyper-chaotic systems, such as those explored in [7], significantly expanded key space and enhanced resistance to correlation and differential attacks. Noise-resilient chaotic schemes, as reported in [5], further demonstrated reliable decryption performance under noisy channel conditions, while comparative studies in [8] showed that three-dimensional chaotic systems outperform two-dimensional counterparts in terms of randomness and security. In parallel, hardware-oriented implementations, including [9], confirmed the feasibility of real-time chaotic audio encryption on embedded platforms. In addition, bio-inspired and DNA-based encryption techniques emerged as effective alternatives by encoding audio samples using nucleotide-based representations and applying biologically motivated operations to achieve deeper nonlinear transformations. Hybrid DNA–chaos models in [10] and multi-chaotic DNA frameworks in [11] reported higher entropy values and significantly reduced correlation. More advanced bio-inspired designs, such as the encryption–compression scheme in [12], further demonstrated the potential of biological encoding to simultaneously enhance security and data efficiency. Recent studies have also explored hyperchaotic frameworks for secure audio encryption. By [13] proposed a new hyperchaotic system with circuit design and demonstrated its applicability in audio encryption. More recently, physical-layer and quantum-assisted encryption techniques have expanded the scope of audio security.

Optical encryption using polarized light beams [14] exploits physical properties of light to achieve transformations that are extremely difficult to intercept, while Quantum-Assisted Secure Audio Communication (QSAC) systems [15] leverage quantum principles to enable intrusion detection through measurable disturbances. Finally, research on machine-learning-driven cryptanalysis, as discussed in [16], has highlighted the ability of modern learning-based techniques to expose vulnerabilities in both classical and chaotic encryption schemes. This emphasizes the necessity for designing audio encryption models that remain robust against intelligent, adaptive attack strategies. Despite the breadth of existing approaches, most prior studies focus on individual encryption paradigms in isolation. This limitation is addressed in the present work by providing a unified comparative framework, supported by the survey of existing studies summarized in Table 1 [17-24], covering advances in audio encryption from 2015 to 2025.

Table 1: Previous Surveys.

Ref ID	Study Title	Year	Datasets Used / Database	Domain Coverage	Algorithm Types	Experimental Validation	Metrics Used	Identified Research Gaps	Contribution in This Survey
[17]	Literature Survey on Recent Audio Encryption Techniques	2016	Not specified	Audio-only	No concrete algorithms (conceptual survey)	No	Time, Complexity	Outdated; no AI, DNA, hyper-chaos, hardware, or quantum	Extends review with chaos, DNA, neural, hybrid & quantum (2018–2025)
[18]	Review on Audio Encryption Algorithms Using Chaos Maps	2021	Not specified	Audio-only	Chaotic maps (Lorenz, Logistic, Tent, Chen)	Partially conceptual	NPCR, UACI, Entropy	No DNA, neural, hardware-chaos, or quantum approaches	Adds 3D/4D hyper-chaos, ANN-chaos, DNA-chaos, hardware chaotic systems
[19]	A Survey on Different Encryption Techniques for Image, Video, Audio & Documents	2021	Mixed multimedia	Multimedia	Classical + chaotic	Basic	PSNR, MSE, Entropy	Audio part weak; no AI, no neural or quantum audio	Provides deep audio-only extension including chaos, AI & hybrid models
[20]	Multimedia Security Using Encryption – A Survey	2023	Multimedia datasets	Multimedia	Classical & chaotic	Yes	PSNR, MSE, Entropy	Audio discussion shallow; no neural or quantum	Adds neural, DNA, hyper-chaos & quantum evaluation for audio
[21]	A Study on Current Scenario of Audio Encryption	2015	Not specified	Audio-only	Classical + basic chaos	Limited	MSE, SNR, Time	No hyper-chaos, no modern noise-tolerant methods	Adds hyper-chaos, DNA, neural, hardware implementations
[22]	Study of Chaotic-Based Audio Encryption Algorithms	2024	Not specified	Audio-only	Multiple chaotic models	Yes	Entropy, Correlation, NPCR	No ANN-chaos, DNA-chaos, optical, or quantum	Adds ANN-chaos, DNA-chaos, hyper-chaos and quantum comparisons
[23]	A Survey of Various Symmetric Encryption Methods	2025	Not specified	Classical cryptography	AES, DES, RC5, Twofish, Blowfish	Yes	Throughput, Time	No chaos, DNA, ML/DL or audio-specific security	Compares classical models vs chaos/DNA/neural in audio encryption
[24]	Hassan – IOP Conference Series (General Encryption Review)	2020	Not specified	General multimedia (includes audio conceptually)	Mixed encryption (conceptual only)	No	None	Very general; not audio-focused; lacks AI, chaos, DNA analysis	Provides historical/theoretical background and positions audio encryption evolution

II.2 LIMITATIONS OF EXISTING SURVEYS

The majority of existing surveys are centered on individual encryption paradigms and do not offer a comprehensive comparison of classical, chaotic, DNA-based, neural, and quantum-assisted encryption paradigms. Moreover, some existing surveys are more inclined toward descriptive discussion rather than analytical evaluation.

II.3 RESEARCH GAP AND POSITIONING OF THIS SURVEY

In order to fill the gaps, the current survey combines various encryption paradigms in a single framework of comparison and offers a comprehensive analysis of the research developments of the past decade, from 2015 to 2025.

III. FUNDAMENTALS OF AUDIO SIGNALS AND ENCRYPTION

III.1 DIGITAL AUDIO SIGNAL REPRESENTATION

In real-world audio encryption systems, audio signals are processed in the form of discrete digital samples, as opposed to continuous signals. Most encryption models are based on Pulse Code Modulation (PCM) audio files, like WAV files, where the audio signal is represented as a series of quantized amplitude levels, as in [3], [7]. A digital audio signal can thus be represented as:

$$A = \{a_1, a_2, ..., a_n\}$$

Where each a_i represents a discrete sample value. The high temporal correlation between samples justifies the application of permutation and diffusion processes in audio encryption algorithms [7].

III.2 TIME-DOMAIN VS TRANSFORM-DOMAIN PROCESSING

Audio encryption can be performed either in the time domain or in the transform Domain. In Time-domain audio encryption, the algorithm operates directly on discrete audio samples through permutation and diffusion processes, as shown in [6], [7]. In contrast, transform-domain audio encryption involves mathematical transformations before encryption, as shown in [3] and multi-layer transform-based schemes in [25]. Time-domain encryption is more straightforward, while the latter focuses on decorrelation before encryption.

III.3 BASIC CRYPTOGRAPHIC PRINCIPLES

Audio encryption algorithms use basic cryptographic techniques, mainly the concepts of confusion and diffusion. Confusion aims at making the relationship between the key used for encryption and the resulting ciphertext as complex as possible. Diffusion aims at spreading the influence of each input sample over the whole encrypted signal. These techniques have generally been used in classical symmetric encryption schemes such as AES or other block cipher structures [1]. The size of the key space represents the number of possible keys that can be used for the encryption of data. A large key space makes it impossible for attackers to use brute-force techniques, thereby increasing the security of the encryption algorithm, as discussed in [4].

III.4 COMMON SECURITY EVALUATION METRICS

Audio encryption algorithms have been evaluated using various statistical and performance metrics for assessing their randomness, security strength, and reconstruction quality. The commonly reported metrics in the literature for audio encryption algorithms have been information entropy, correlation coefficient, SNR/PSNR, key sensitivity, and differential metrics like NPCR and UACI [6], [7], [10], [11].

III.4.1 Information Entropy

Information Entropy is used to determine the randomness of the encrypted signal. In an ideal encrypted audio signal, the information entropy should be close to the maximum value, indicating a uniform distribution of sample values. Information entropy is commonly used in chaos and DNA-based encryption algorithm assessments, as reported in [7], [10], [11]. The standard Shannon entropy is computed as:

$$H = -\sum_{i=0}^{L-1} p\,(s_i)\log_2 p(s_i)$$

Where:

- L: the number of possible signal values
- $p(s_i)$: the probability of occurrence of the value s_i

For an ideally encrypted audio signal, H should be close to its maximum value.

For an 8-bit audio signal, the maximum entropy is:

$$H_{\max} = \log_2(256) = 8$$

For a 16-bit audio signal, the theoretical maximum entropy is:

$$H_{\max} = \log_2(65536) = 16$$

III.4.2 Correlation Coefficient

The Correlation Coefficient is used to determine the statistical correlation between adjacent samples in the original and encrypted signals. An effective encryption algorithm will result in a correlation coefficient close to zero, as reported in [7], [11].

The Pearson correlation coefficient is computed as:

$$r_{xy} = \frac{\sum_{i=1}^{N}(x_i - \mu_x)(y_i - \mu_y)}{\sqrt{\sum_{i=1}^{N}(x_i - \mu_x)^2}\sqrt{\sum_{i=1}^{N}(y_i - \mu_y)^2}}$$

Where:

- N: the number of samples
- μ_x: the mean of sequence x
- μ_y: the mean of sequence y

III.4.3 Signal-to-Noise Ratio (SNR) and Peak Signal-to-Noise Ratio (PSNR)

Signal-to-Noise Ratio (SNR) and Peak Signal-to-Noise Ratio (PSNR) are utilized to assess the quality of reconstruction of the decrypted audio signal. The higher the SNR and PSNR, the higher the reconstruction quality of the decrypted audio signal and lower the distortion between the original and decrypted audio signal, as mentioned in [25], [26]. The peak signal-to-noise ratio (PSNR) is computed as:

$$\text{PSNR} = 20\log_{10}\left(\frac{\text{MAX}}{\sqrt{\text{MSE}}}\right) \text{ dB}$$

Where:

- MAX: the maximum possible sample value

For example:

- for 8-bit audio, $\text{MAX} = 255$
- for 16-bit PCM audio, $\text{MAX} = 32767$

III.4.4 Key Sensitivity

Key sensitivity is a measure of how an encryption system responds to changes in the encryption key. A good audio encryption algorithm should respond differently when a small change is made in the encryption key, as noted in [7], [10]. A practical key sensitivity rate (KSR) can be computed as:

$$\text{KSR}(\%) = \frac{1}{N}\sum_{i=1}^{N} D_i \times 100$$

Where:

$$D_i = \begin{cases} 1, & C_1(i) \neq C_2(i) \\ 0, & C_1(i) = C_2(i) \end{cases}$$

and:

- C_1: the encrypted signal generated using key K
- C_2: the encrypted signal generated using a slightly modified key $K + \Delta K$
- N: the number of samples

A value close to 100% indicates high key sensitivity.

III.4.5 Differential Attack Metrics (NPCR, UACI)

Differential attack metrics such as the number of pixels change rate (NPCR) and the unified average changing intensity (UACI) can be utilized to test the robustness of encryption schemes to differential attacks. Higher NPCR and UACI values mean that the encryption algorithm has strong resistance to differential attacks because small differences in the plaintext signal lead to large differences in the ciphertext output [10], [11]. The number of sample change rate (commonly written as NPCR in many papers) is computed as:

$$\text{NPCR}(\%) = \frac{\sum_{i=1}^{N} D_i}{N} \times 100$$

Where:

$$D_i = \begin{cases} 0, & C_1(i) = C_2(i) \\ 1, & C_1(i) \neq C_2(i) \end{cases}$$

and:

- C_1: the ciphertext obtained from the original plaintext
- C_2: the ciphertext obtained after introducing a slight change in the plaintext
- N: the number of samples

The unified average changing intensity (UACI) is computed as:

$$\text{UACI}(\%) = \frac{1}{N}\sum_{i=1}^{N}\frac{|C_1(i) - C_2(i)|}{L-1} \times 100$$

Where:

- L: the number of possible intensity levels
- for 8-bit data, $L = 256$
- for 16-bit data, $L = 65536$

For audio signals, the term NSCR (Number of Sample Change Rate) may be more precise than NPCR, since the comparison is performed on samples rather than pixels.

IV. CLASSICAL AUDIO ENCRYPTION METHODS

Classical audio encryption methods are based on the concept of a deterministic framework such as a block cipher or substitution/permutation networks, which involve the transformation of the data using algorithmic processes [1], [4]. Classical methods focus on the importance of maintaining a structured key management system within a stable mathematical framework. The concept of hybrid and multi-layer systems has also been developed to accommodate classical cryptography in digital audio signal processing [2], [25]. The key characteristics of these classical methods are summarized in Table 2.

Table 2: Classical Audio Encryption Methods.

Ref ID	Study Title	Year	Datasets Used / Database	Domain Coverage	Algorithm Types	Experimental Validation	Metrics Used	Numerical Results (from source)	Identified Research Gaps	Contribution
[1]	Comparative Study Of AES, Blowfish, CAST-128 And DES	2016	Not specified	Audio / General	Classical (AES, Blowfish, CAST-128, DES)	Yes	Avalanche Effect, Integrity	Avalanche Effect (ECB): AES 52.34%, Blowfish 46.09%, CAST-128 49.21%, DES 53.12% | Avalanche Effect (CBC): AES 45.31%, Blowfish 49.21%, CAST-128 37.50%, DES 56.25%	No audio-specific statistical analysis; no modern attacks	Provides baseline quantitative comparison of classical ciphers
[2]	The SPN Network for Digital Audio Data Based on ECC	2022	Digital audio signals	Audio	ECC + SPN	Yes	Security level, Time	Results inferred from figures; no explicit numerical tables reported	Not tested on noisy channels; no chaos/DNA comparison	Introduces lightweight ECC-SPN hybrid for audio data
[3]	Encryption of Audio Signals Using the Elzaki Transform	2023	WAV audio files	Audio	Elzaki Transform + Lorenz Chaos	Yes	MSE, SNR, Entropy	Entropy ≈ 7.9–8.0; SNR and MSE inferred from graphical results (figures) reported in the source paper	Limited randomness analysis; no comparison with chaos-only/DNA	Uses transform-domain preprocessing to reduce audio correlation
[4]	Evaluation of Rijndael Algorithm for Audio Encryption by Brute Force Attack	2024	WAV audio samples	Audio	Classical (AES/Rijndael)	Yes	Key space, Time, Resistance	Key sizes: 128/192/256 bits, Brute-force complexity = 2^{256} (theoretical), successful resistance demonstrated	Only AES tested; no hybrid or adaptive schemes	Demonstrates AES robustness against brute-force in audio context
[25]	A Multilayered Audio Signal Encryption Approach for Secure Voice Communication	2023	Speech recordings	Voice / Audio	Multi-layer classical encryption	Yes	PSNR, Entropy, Time	PSNR > 30 dB, Entropy ≈ 7.9, increased execution time due to multilayer design	High computational cost; no chaos/DNA integration	Provides multi-stage classical protection for voice communication
[26]	A Novel Digital Audio Encryption	2024	Digital audio samples	Audio / Forensics	Classical + Watermarking	Yes	PSNR, Robustness	PSNR ≈ 28–35 dB (reported graphically); no	No chaos/quantum	Combines encryption with watermarking

	and Forensics Watermarking Scheme							explicit numerical tables provided	evaluation; added complexity	for security & authentication
[27]	A Digital Audio Data Protection Method Using Parametric Action of Generalised Triangle Group on GF(2^8)	2025	Audio datasets	Audio	Algebraic (GF(2^8) group action)	Yes	Entropy, Time	Entropy > 7.9, fast execution reported for small datasets (no exact timing table)	Not compared to chaos/DNA; real-time optimization needed	Introduces strong algebraic structure with high key sensitivity
[28]	A New Encryption Algorithm for Voice Messages on Social Networks (Magic Cube Technology)	2025	Voice messages	Voice / Social Media	Magic Cube + GF(2^8)	Yes	Complexity, Security	Large key-space via 3D cube permutations, qualitative security improvement (no numeric tables)	Limited datasets; not tested vs AI-based attacks	Proposes creative 3D classical encryption for voice messaging

Source: Authors, (2026).

Interpretation

The principal classical paradigms use deterministic mathematical structures such as block-cipher frameworks, multilayer architectures, algebraic transformations, and SPN-based models for the encryption of audio. Clearly, the comparative evaluation presented in [1] considers AES, Blowfish, CAST-128, and DES into the foundational layer in traditional cryptography. These techniques have rather poor adaptability to the statistic nature of an audio signal. In contrast, subsequent works describe improvements in classical diffusion and performance enhancement, such as the elliptic-curve–based SPN framework in [2] and the lightweight Elzaki transform method in [3]. Indeed, another assessment of the Rijndael/AES in [4] reconfirms the resistance of the scheme to brute-force attacks but underlines some structural limitations. More recent classical developments, including multilayer encryption in [25], watermark-integrated protection in [26], algebraic encryption via GF(2^8) group action in [27], and geometric permutation using Magic Cube transformations in [28], have shown diverse strategies for enhancing confusion, diffusion, and authenticity within classical models. All these works together have indicated that while classical encryption remains computationally efficient and easy to implement, the fixed structural nature of the process makes it harder to introduce true randomness and key-space expansion compared with chaotic or neural or quantum-assisted paradigms. The need for hybridization of classical cryptography with more dynamic models to meet emergent cryptanalytic and AI-driven security challenges is thus increasingly felt.

V. CHAOS-BASED AUDIO ENCRYPTION METHODS

Chaos-based audio encryption employs chaotic nonlinear dynamics and high sensitivity to initial conditions to produce random key streams. The chaotic behavior is used to improve confusion and diffusion of audio encryption. Due to their dynamic and non-periodic behavior, chaotic models are more appropriate for handling high correlation and dynamic variation of audio data than deterministic approaches [8], [22]. The key characteristics of these Chaos- based methods are summarized in Table 3.

Table 3: Chaotic Encryption Methods.

Ref ID	Study Title	Year	Datasets Used / Database	Domain Coverage	Algorithm Types	Experimental Validation	Metrics Used	Numerical Results	Identified Research Gap	Contribution
[5]	A Noise-Tolerant Audio Encryption Framework Designed by the Application of S8 and Chaotic System	2021	Noisy audio signals (real-time audio communication)	Audio	S8 symmetric group, Chebyshev map, TD-ERCS map, Circle chaotic map	Yes (software simulation)	Entropy, Correlation, SNR, Noise tolerance	Entropy ≈ 7.99, Correlation ≈ 0, successful decryption under channel noise, audible decrypted signal	Evaluation limited mainly to noisy channel conditions, with no validation on clean audio scenarios or hardware-based implementation.	Introduces a noise-tolerant chaos-based audio encryption framework that preserves correct decryption under channel distortions.
[6]	A Bit-Level Audio Encryption Algorithm Using a New Hybrid Chaotic Map	2024	Digital audio files	Audio	Hybrid chaotic map, bit-level permutation and substitution	Yes	Entropy, NPCR, UACI	Entropy ≈ 7.99, NPCR > 99%, UACI ≈ 33%	High computational complexity and lack of real-time or hardware validation limit practical deployment.	Proposes a bit-level hybrid chaotic encryption scheme achieving strong confusion and diffusion properties.
[7]	A New Audio Encryption	2024	WAV audio files (various sizes)	Audio	Logistic map, Rössler	Yes (MATLAB implementati	Entropy, Correlation,	Entropy = 7.9918–7.9983, Correlation =	Encryption performance is sensitive to	Develops a hyper-chaotic audio encryption

	Algorithm Based on Hyper-Chaotic System				hyper-chaotic system	on)	NSCR, Encryption time	−0.0081 to 0.0167, NSCR = 99.60%–99.79%, Encryption time = 0.06–1.03 s	synchronization accuracy, and validation is restricted to software simulations.	algorithm with an expanded key space and strong resistance to statistical attacks.
[8]	Chaos-Based Audio Encryption: Efficacy of 2D and 3D Hyper-Chaotic Systems	2024	Digital audio signals	Audio	2D memristive hyper-chaotic map, 3D hyper-chaotic quadratic map	Yes	Entropy, Correlation, Differential analysis	Entropy ≈ 8, Correlation ≈ 0, 3D system shows higher randomness than 2D	Increased computational overhead and absence of real-time or hardware feasibility analysis.	Provides a comparative study demonstrating the superior randomness and security of 3D hyper-chaotic systems over 2D models.
[9]	Hardware Implementation of a 2D Chaotic Map-Based Audio Encryption System	2024	TIMIT-TTS dataset	Audio / Embedded Systems	2D Logistic-Fraction chaotic map, dynamic S-box, FPGA (Artix-7)	Yes (hardware implementation)	MSE, SNR, Correlation, Throughput, Power	MSE = 1.2156 × 10⁹, SNR = −26.23 dB, Correlation = 0.002948, Throughput = 2880 Mbps, Power = 0.13 W	Dependence on FPGA hardware limits scalability and portability to software-only platforms.	Demonstrates a real-time chaotic audio encryption system through efficient FPGA implementation.
[13]	Dynamics, Circuit Design, Feedback (Scientific Reports)	2023	Not specified	Audio / Hardware	Circuit-based chaotic system	Yes (circuit validation)	Entropy, Synchronization metrics	Entropy > 7.99, stable chaotic synchronization	The study mainly investigates chaotic circuit dynamics and synchronization stability, with limited direct evaluation on audio signal encryption metrics	Validates stable circuit-based chaotic systems suitable for secure communication applications.
[22]	Study of Chaotic-Based Audio Encryption Algorithms	2024	Multiple audio samples	Audio	Multiple chaotic encryption models	Yes	Entropy, Correlation, NPCR, UACI	Entropy ≈ 7.9–8.0, Correlation ≈ 0, NPCR > 99%, UACI ≈ 33%	Does not include comparisons with neural-chaos, DNA-based, or AI-assisted encryption approaches.	Offers a comprehensive comparative evaluation of multiple chaos-based audio encryption algorithms.
[29]	A Lossless Audio Encryption Method Based on Chebyshev Map	2023	Audio signals	Audio	1D Chebyshev chaotic map	Yes	Entropy, MSE, Key sensitivity	MSE = 0, Entropy ≈ 7.99, perfect reconstruction after decryption	Limited comparison with multi-dimensional chaotic systems.	Introduces a lossless chaotic audio encryption method ensuring perfect reconstruction of audio signals.

Source: Authors, (2026).

Interpretation

Chaos-based encryption techniques are some of the most sophisticated methods for the protection of audio signals, due to their nonlinear behavior and extreme sensitivity to initial conditions; these properties allow for the generation of key streams that are highly unpredictable. Noise-tolerant chaotic models, such as that proposed in [5], proved to be highly reliable since correct decryption performance was preserved even under distorted channel conditions. Multidimensional chaotic systems, such as those presented in [7] and [8], achieved remarkable enhancements with regard to the expansion of key space and confusion–diffusion properties, increasing robustness against correlation and differential attacks. A comparison between 2D and 3D chaotic algorithms in [8] highlighted a clear relationship between dimensionality, randomness, and reduced correlation with the original audio signal. Hardware-oriented implementations, as in the design of [9], gave practical proof that chaotic encryption can enable real-time processing in embedded environments. Finally, the lossless encryption model based on a Chebyshev map proposed in [29] introduced an efficient chaotic mechanism that allowed the securing of audio data without any degradation. The discussed studies cumulatively prove that chaos-based encryption offers a robust, flexible, and scalable framework that can meet the ever-increasing security requirements of modern audio communication systems.

VI. DNA AND BIO-INSPIRED AUDIO ENCRYPTION METHODS

The idea of DNA-based audio encryption is based on nucleotide encoding, in which the audio samples are encoded using symbolic biological mappings to increase the complexity of the structure. These methods also include the use of nonlinear mechanisms to increase the diffusion of the keys during the encryption process. Some of these methods also include the use of joint encryption/compression techniques to increase the efficiency of the encryption of the audio samples during secure transmission [10-12]. The key characteristics of these DNA methods are summarized in Table 4.

Table 4: DNA & Bio-Inspired Audio Encryption Methods.

Ref ID	Study Title	Year	Dataset Used	Domain Coverage	Algorithm Types	Experimental Validation	Metrics Used	Key Numerical Results (from paper)	Observed Limitations (based on reported experiments)	Contribution
[10]	An Audio Encryption Algorithm Based on DNA Coding and Chaotic System	2020	Mono & stereo audio signals (piano, human voice, animal, car, drum)	Audio encryption	PWLCM chaotic map + SHA-256 key generation + dynamic DNA coding + XOR diffusion	Yes (simulation)	Correlation, NSCR, UACI, entropy, time	Correlation < 0.1; NSCR ≈ 99%+; UACI ≈ 33%; encryption time ≈ 0.034–0.037 s / 1 KB	Experimental evaluation is limited to simulation-based tests on selected audio samples, with no hardware or real-time transmission validation reported.	Demonstrates strong diffusion and key sensitivity through chaos-driven dynamic DNA encoding.
[11]	Audio Encryption Scheme Using Self-Adaptive Bit Scrambling and Two Multi-Chaotic-Based Dynamic DNA Computations	2020	WAV audio files of different sizes	Secure audio transmission	Self-adaptive bit scrambling + multi-chaotic maps (LCS, HLG) + dynamic DNA + cipher feedback	Yes (extensive experiments)	SNR, PSNR, NSCR, UACI, entropy, correlation, key space	NSCR ≈ 99.99–100%; UACI ≈ 35.5–36.2%; correlation ≈ 10^{-4}–10^{-5}; key space ≈ 2^{928}	Validation focuses on security and statistical metrics, while computational complexity and real-time deployment aspects are not explicitly evaluated.	Introduces a highly secure multi-phase DNA–chaos framework with extremely large key space and strong resistance to differential attacks.
[12]	An Intelligent Audio Encryption and Compression Algorithm Inspired by the Encoding of Various Biological Sequences	2025	Digital audio signals	Audio encryption + compression	Biological-sequence-inspired encoding + joint encryption–compression	Yes (experimental validation)	Entropy, MSE, compression ratio, reconstruction quality	Entropy close to ideal; low MSE after decryption; effective compression without loss of intelligibility	Experiments are reported on digital audio signals without comparison to chaos-DNA or neural-based encryption schemes under identical conditions.	Proposes a unified bio-inspired framework that jointly achieves secure encryption and efficient audio compression.

Source: Authors, (2026).

Interpretation

Both DNA-based and bio-inspired audio encryption techniques are based on the idea of encoding in a nucleotide style and on biologically motivated operations to enhance either confusion or diffusion. Among early works, DNA-chaos hybrid in [10] achieved great enhancements in entropy, decreasing the correlation factor substantially. Multi-chaotic DNA computation in more advanced design [11] expressed higher key sensitivity with increased resistance against differential attacks. Recent bio-inspired models like the one based on sequence encryption-compression in [12] enlarged functionality by combining efficient protection of data with efficient compression. In general, these methods offer powerful nonlinear transformations outperforming many traditional cryptographic methods.

VII. NEURAL AND NEURO-CHAOTIC AUDIO ENCRYPTION METHODS

Neural and neuro-chaotic audio encryption methods have the ability to add flexibility to the security of audio signals by using the capabilities of artificial neural networks and chaotic nonlinear dynamics. Neural networks have the ability to learn complex patterns of signals using learning algorithms. Chaotic dynamics add to the unpredictability of the structure of the system and the generated keys [30], [31]. The key characteristics of these Neural & Neuro methods are summarized in Table 5.

Table 5: Neural & Neuro-Chaotic Audio Encryption Methods.

Ref ID	Study Title	Year	Dataset Used	Domain	Neural Algorithm Type	Experimental Validation	Metrics Used	Numerical Results (from PDF)	Observed Limitations (based on reported experiments)	Contribution
[30]	NeuroChaosCrypt: Revolutionizing Chaotic-Based Cryptosystem With Artificial Neural Networks	2024	Audio signals (8 kHz, 8-bit) and images	Audio and multimedia encryption	ANN-based chaotic system (jerk model)	Yes	CC, SNR, PRD, NPCR, UACI, Time	CC ≈ 0.003, SNR ≈ −76 dB, PRD ≈ 6.38×10^5, NPCR ≈ 99.49%, Decryption time ≈ 0.008 s (Tables 2–5)	Evaluation is reported for specific signal resolutions and experimental settings, with performance metrics limited to the tested configurations.	Eliminates synchronization requirements and improves decryption speed with an FPGA-ready neuro-chaotic design.

[31]	Memristive Coupled Neural Network Based Cryptosystem	2024	Digital multimedia data (including audio)	Encryption (general)	Memristive Neural Network + Chaos	Yes	Entropy, Key space, Sensitivity	Entropy ≈ 7.99, key space > 2^150, high key sensitivity (Section IV)	Experimental evaluation focuses on security metrics and system properties, without reporting real-time audio stream experiments.	Introduces a hardware-oriented neural cryptosystem using memristive coupling.
[32]	A Classification and Retrieval Method for Encrypted Speech Based on Deep Neural Network and Deep Hashing	2020	Encrypted speech samples	Encrypted speech retrieval	DNN + Deep Hashing	Yes	Accuracy, Precision, Recall	Accuracy ≈ 96.2%, Precision ≈ 95.4%, Recall ≈ 94.8% (Table IV)	Experiments are reported on specific encrypted speech samples and a fixed evaluation setup, with no additional datasets or channel conditions discussed.	Enables intelligent retrieval and classification directly from encrypted speech without decryption.
[33]	Neural Network-Based Cryptography: A Primary Study on the Performances and Techniques	2022	Not specified (conceptual and simulation-based)	General cryptography	ANN-based encryption models	Partial	Throughput, Time	Encryption time reduced by approximately 18–25% compared to classical ciphers (simulation results)	Results are based on simulations and conceptual analysis, with no application-specific (audio) experimental validation reported.	Provides a foundational performance analysis of ANN-based cryptographic systems.

Source: Authors, (2026).

Interpretation

Neural and neuro-chaotic encryption methods have come up with adaptive security that is integrated into neural learning with the nonlinear behavior of chaotic systems. Early neural models, such as encrypted speech retrieval using deep networks [32], showed how intelligent processing can effectively improve protected audio communication. More advanced architectures, including the memristive neural-chaotic architectures [31], expanded the sensitivity of keys and improved the resilience of emerging attacks. Work on neural cryptography [33] provided a deeper basis for detailing how learning based structures support secure key generation, whereas hybrid ANN-chaotic mechanisms [30] had showcased the benefit of blending neural adaptability with chaotic unpredictability. These collectively point out the heightened role of intelligent, dynamically evolving models in shaping next-generation audio encryption.

VIII. OPTICAL AND QUANTUM-BASED AUDIO ENCRYPTION METHODS

In optical and quantum-based methods, there is a shift away from algorithmic models and towards physical-layer models for encrypting audio information. Optical methods are based on light polarization, and quantum methods take advantage of quantum effects to improve communication security [14], [15]. The key characteristics of these Optical / Quantum methods are summarized in Table 6.

Table 6: Optical / Quantum Encryption.

Ref ID	Study Title	Year	Datasets Used / Database	Domain Coverage	Algorithm Types	Experimental Validation	Metrics Used	Numerical Results	Identified Research Gap	Contribution
[14]	Audio Encryption Using Polarized Light Beam	2025	Digitized audio signals mapped to optical domain	Audio	Polarized Light Beam (PLB)–based optical encryption	Yes (simulation + experimental validation)	Correlation coefficient, PSNR, noise robustness	Correlation (original–encrypted) = 0.13, Correlation (original–decrypted) = 0.96; CC = 0.9459 and PSNR = 17 dB under Gaussian noise (variance 0.1); CC = 0.94, PSNR = 14 dB at variance 0.2	Requires specialized optical hardware; experimental setup complexity limits portability and real-time deployment	Introduces an optical-domain audio encryption scheme using polarization states with high reconstruction fidelity and strong resistance to cryptanalytic attacks
[15]	QSAC: Quantum-Assisted Secure Audio Communication Using Quantum Entanglement and Steganography	2025	Audio communication signals encoded in quantum domain	Secure Audio Communication	Quantum entanglement + quantum steganography	Yes (theoretical analysis + experimental validation)	BER, SNR, quantum disturbance indicators	Any eavesdropping attempt causes detectable quantum disturbances; BER increases significantly under interception, enabling reliable intrusion detection	High implementation cost; experimental complexity; limited scalability due to early-stage quantum hardware	Proposes a quantum-assisted secure audio communication framework with intrinsic eavesdropping detection guaranteed by quantum physics

Source: Authors, (2026).

Interpretation

Optical and quantum encryption methods achieve superior protection of audio signals through physical and quantum phenomena instead of a purely mathematical basis. Polarized-light encryption [14], and communication with quantum assistance [15], although very resistant to tapping, have not found wide practical applications so far, mostly due to hardware and implementation issues.

IX. COMPARATIVE FRAMEWORK OF AUDIO ENCRYPTION APPROACHES

This section discusses the structural comparison of the chosen audio encryption models based on their design and implementation structures. The models used in the comparison are different in their mathematical underpinnings, system models, and application domains. Some of the models are based solely on algorithmic models, while others are based on signal processing models, biological models, intelligent models, and physical models. The comparison of the models shows the different methodologies used in the implementation of the models, ranging from fixed models to intelligent models. The key characteristics of the selected audio encryption methods are summarized in Table 7.

Table 7: The comparative analysis of chosen audio-encryption methods**.**

Ref ID	Study Title	Year	Technique Type	Algorithm / Model	Dataset Used	Metrics Reported	Numerical Results	Main Limitations / Notes	Application Focus
[4]	Evaluation of Rijndael Algorithm for Audio Encryption by Brute Force Attack	2024	Classical (AES-based)	AES (Rijndael) block cipher	Audio files	Key space, brute-force complexity	256-bit key → ≈ 4.13×10^{99} total permutations	PSNR/SNR metrics not reported; focuses mainly on brute-force evaluation	Secure audio storage systems
[25]	Multilayered Audio Signal Encryption for Secure Voice Communication	2023	Classical + Transform	Multi-layer DCT/DST encryption pipeline	Speech recordings (Audio1–Audio3)	SNR, correlation, execution time	Example Audio1 → SNR ≈ −2.70 dB; correlation ≈ 0.00236	Higher computational complexity; negative SNR indicates strong signal distortion	Secure voice communication
[6]	Bit-Level Audio Encryption Using a New Hybrid Chaotic Map	2024	Chaotic	Hybrid chaotic map with bit-level scrambling	Digital audio signals	Histogram analysis, correlation, entropy, key space	Post-encryption correlation ≈ 0; entropy reported as high (exact numerical values not explicitly reported)	NPCR/UACI values not explicitly reported in the extracted results	High-security multimedia transmission
[7]	A New Audio Encryption Based on Hyper-Chaotic System	2024	Hyper-Chaotic	Logistic permutation with 4D hyperchaotic diffusion	Speech recordings	Entropy, correlation, differential metrics, execution speed	Described as high-security and real-time capable (exact numerical values not explicitly tabulated)	Computationally intensive; explicit numerical values not reported in extracted results	Defense-level secure communication
[29]	A Lossless Audio Encryption Using Chebyshev Map	2023	Chaotic (Lossless)	Chebyshev chaotic map with lossless reconstruction	Multiple WAV audio files	Correlation, key space, lossless reconstruction	Correlation of encrypted signal ≈ 10^{-4} – 10^{-6}	SNR/PSNR metrics not reported	Medical and archival audio protection
[10]	Audio Encryption Using DNA Coding and Chaotic System	2020	DNA–Chaos	PWLCM chaotic map with SHA-256 key generation and DNA encoding rules	Mono and stereo audio signals (piano, human voice, car, etc.)	NSCR, UACI, correlation, runtime	Original correlation > 0.9; encrypted < 0.1; NSCR ≈ 100%; UACI ≈ 33.3%	DNA operations increase computational complexity	Critical audio security systems
[11]	Audio Encryption Scheme Using Self-Adaptive Bit Scrambling and Two Multi Chaotic-Based Dynamic DNA Computations	2020	DNA–Multi-Chaos	Multi-chaotic maps with dynamic DNA computation and cipher feedback	WAV audio signals	Entropy, UACI, NSCR, correlation	UACI ≈ 35.55%; NSCR ≈ 99.995%; correlation ≈ 5.3×10^{-5}	High computational cost	High-security audio transmission
[30]	NeuroChaosCrypt: Revolutionizing Chaotic-Based Cryptosystem With Artificial Neural Networks—A Comparison With Traditional Cryptosystems	2024	Neural–Chaotic	ANN-driven chaotic cryptosystem	Audio and image datasets	Entropy, NPCR, UACI, SNR, PRD, execution time	Entropy ≈ 7.4326; NPCR ≈ 99.49%; UACI ≈ 0.39%	NPCR/UACI numerical results mainly evaluated on image datasets	AI-enhanced secure communication systems
[31]	Memristive Coupled Neural Network Cryptosystem	2024	Neural / Hardware-Chaotic	Memristive coupled neural network model	Digital multimedia datasets	Entropy, key sensitivity	Entropy close to ideal; strong key sensitivity (exact numerical values not explicitly reported)	Limited numerical audio-specific metrics	Real-time embedded security systems
[14]	Audio Encryption Using Polarized Light Beam (PLB)	2025	Optical / Physical-Layer	Polarized Light Beam transformation	Audio signals mapped to optical domain	Correlation, BER, physical analysis	Example: original–encrypted correlation ≈ 0.131; original–decrypted ≈ 0.9608	Requires specialized optical hardware	Military and quantum-safe audio communication

Interpretation

The comparative analysis of chosen audio-encryption methods shows how much the security models have diversified to meet the ever-increasing complexity of modern communication environments. While classical methods retain strong resistance against brute-force attacks due to their large key spaces, significant limitations arise when these methods are confronted with correlation or structure-based analyses. Chaotic and hyper-chaotic systems can offer significantly better confusion-diffusion properties, reflected by their near-ideal entropy levels and minimal values of correlation, which makes them particularly effective in protecting highly dynamic audio signals. DNA-based frameworks further reinforce security with biologically inspired transformations that increase nonlinearity and improve differential resistance. Neural and neuro-chaotic models bring adaptability and hardware-accelerated processing, positioning them as strong candidates for real-time intelligent encryption scenarios. Optical and physical-layer methods extend protection beyond computational paradigms by exploiting intrinsic properties of light, offering exceptional resistance against interception despite requiring hardware implementation. Overall, the comparative findings suggest that while each category presents distinct advantages, hybrid schemes integrating chaotic, biological, neural, or physical-layer mechanisms tend to offer a balanced trade-off between security strength, adaptability, and implementation feasibility in next-generation secure audio communication systems.

X. CONCLUSION

The above research work has provided a detailed comparative analysis for audio encryption methods that have been developed between the years 2015 and 2025. These methods include classic encryption techniques, chaos and DNA-based models, neural and neuro-chaotic systems, as well as optical and quantum-based methods. It was noted that classic encryption methods have high strength in terms of immunity from brute-force attacks and efficiency. However, their fixed structure can lead to limits in modeling the statistical properties of audio. On the other hand, chaotic, DNA, and neural-driven encryption models showed better confusion-diffusion capability, larger key space, and better resistance to complex sound patterns. Optical and quantum-computing-assisted techniques offer top-notch security assurance with robust physical guarantees, but they are limited due to complexity issues associated with their implementation. Thus, encryption models that combine chaotic systems, biologic encryption, neural models, and physical layer mechanisms can be considered promising candidates to support secure next-gen sound communication systems with better efficacy.

XI. FUTURE WORK

Future studies could emphasize working on lightweight hybrid encryption frameworks for audio that bring a good balance between security and the ability to handle real-time encryption. Adding the concept of neural learning into chaos and DNA algorithms has not been significantly explored, especially for a channel environment that is noisy and attacked using machine-learning-based attacks. Moreover, a common benchmarking dataset needs to be developed for comparison purposes across various encryption paradigms. Lastly, studies on the practical framework for quantum assistance in encryption systems also need to be explored.

ABSTRACT

An alternative form of communication for those who are hard of hearing or speech is sign language (SL). SL differs from nation to nation. Indian Sign Language (ISL) is a substitute form of communication used by individuals in India. There are about 63 million deaf and hard of hearing persons living in India. But there are no accessible or reasonably priced human interpreters for ISL identification. Consequently, for many years, researchers have been working on creating a system that can recognize sign language. Compared to other SL, the construction of an Indian Sign Language Recognition System (SLRS) is exceedingly challenging. The field of Indian sign language recognition systems has not seen many developments. Consequently, this discipline has very few systematic literature reviews. We reviewed the most recent (post-2017) literature on dynamic Indian sign language recognition using deep learning technique on various parameters in an attempt to tackle this problem. The objective of this work is to present a comprehensive analysis of various deep learning methods used in dynamic Indian sign language recognition.

I. INTRODUCTION

A different form of communication for people who have hearing or speech impairments is sign language (SL). Instead of speaking and using sound patterns, people with hearing impairments communicate by making signs in visual space [1]. In the 1970s, research on sign language linguistics was started. It offers linguistic data, including different letters and symbols. Typically, there are two categories of signs: (1) static and (2) dynamic. The nonverbal language known as SL makes use of body parts to visually transmit patterns. These include non-manual components like lip movement and face expression as well as manual elements like hand and finger positions. Articular points like the joints in the fingers, wrist, elbow, and shoulder are crucial for differentiating SL. It also contains a variety of movements, including forward, backward, left, and right, as well as lip movements and facial expressions like happiness, rage, and confusion. The different sign elements are shown in fig. 1. Correct execution of all sign components is required to generate a precise sign word [1], [2]. Due to its variation among nations and even geographical areas, SL is not a standardized language. As a result, several sign languages (SLs) were created, including Chinese Sign Language (CSL), American Sign Language (ASL) and Indian Sign Language (ISL). [3] Designing a sign language recognition system (SLRS) for ISL is a more difficult task for academics since ISL is distinct from other SLs in that it involves both single handed and double handed gestures, along with a huge vocabulary of related movements. Motion-based Indian sign language referred to as dynamic Indian sign language, as it depicts motion with dynamic signs [4].

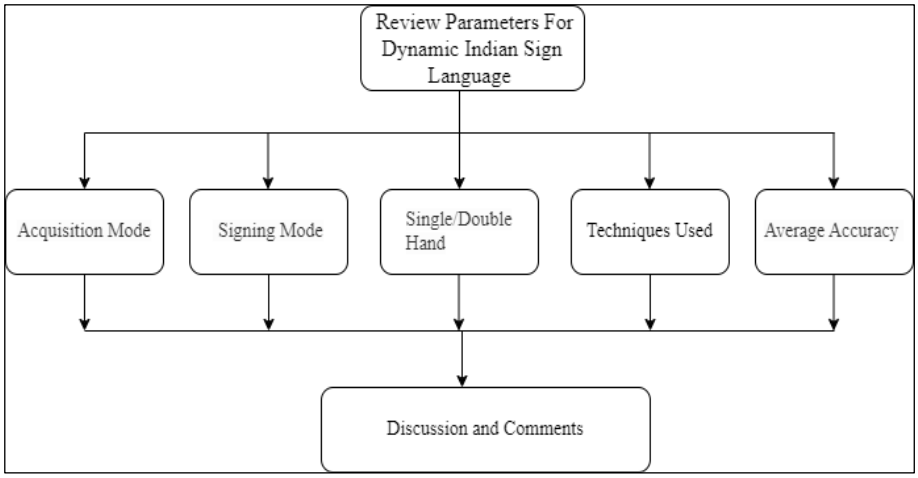

Figure 1: Sign language Elements.

I.1 MOTIVATION

In India, deafness is a persistent issue. The estimated number of deaf individuals residing in India is around 63 million. The deaf and dumb in India utilize ISL, one of the country's living languages. Sign language interpreters can facilitate communication between the regular public and the deaf and dumb. Human interpreters are neither readily available or affordable. It makes it hard to close the huge communication gap between regular people and those who are deaf or dumb. There are lots of work done on static Indian sign language. On Indian dynamic sign language, some research has been done. Therefore, the several deep learning techniques for the identification of Dynamic ISL are the main emphasis of this study.

I.2 LITERATURE SEARCH METHODOLOGY

Finding, categorizing, and contrasting the body of prior research on SLR is the aim of the systematic review. For the literature review, we look at content available as of 2017. A summary of significant studies on Dynamic ISLR methods is given in this survey study. There is discussion on research papers from conferences, workshops, symposiums, journals, and periodicals. The figure displays the inclusion/exclusion criteria after the investigations were reviewed. We conducted a comprehensive search using the Google search engine. The research papers in the specified databases have been searched using the keyword "Dynamic Indian Sign Language Recognition". from the databases of Elsevier, Springer, IEEE, and ACM, various research publications on dynamic Indian sign language recognition were found through our search. Based on the titles, abstracts, and conclusions, the papers were excluded. After reading the entire content, 40 research papers have been selected.

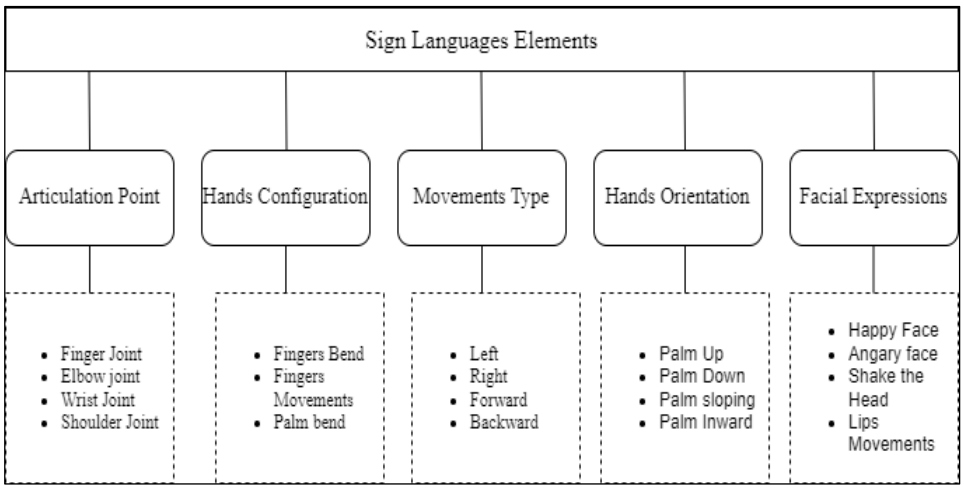

Figure 2: Review Parameters.
Source: Authors, (2026).

A study article may compare things using a different standard. Previous review studies have only examined various approaches and accuracy. On the other hand, in order to assess and comprehend the literature, we have adopted the methodology of [1], [5] . We reviewed the research on dynamic Indian sign language recognition system (DISLR) using those features. Fig. 2 shows the comparative parameter that is used in this review. The parameters of the strategy we have chosen for the Systematic Literature Review are acquisition mode, signing mode, single/double hand signs, techniques used, and average accuracy. Based on these features [1], [5] a review of dynamic Indian sign language recognition (DISLR) has been carried out and recorded.

II. LITERATURE REVIEW ON DISLR - DYNAMIC INDIAN SIGN LANGUAGE RECOGNITION

II.1 GENERAL PROCEDURE OF SIGN LANGUAGE RECOGNITION

Figure 3: SLR General Flow.
Source: Authors, (2026).

A nonverbal communication technique called sign language makes use of the hands, arms, head, and facial expressions, among other body parts, to communicate meaning [6]. SLR is the process of identifying and recognizing signs and translating them into words that have semantic meaning. The steps involved in the SLR include data gathering, pre-processing, extraction of features, and classification. Fig. 3 shows the SLR block diagram along with the overall workflow [5], [7], [8]. Sign language recognition (SLR) is the process of identifying, recognizing, and translating signs into semantically significant words. The SLR system converts the data from signs into comprehensible text or audio by decoding and understanding the data. There are two methods used to perform the function of sign recognition: the hardware based or sensor-based approach and the vision-based approach. In Vision-based method, a camera is used to capture sign images or video. There is various hardware is used to capture sign data in hardware-based approach like data gloves, Microsoft kinect sensor, etc. The signers have difficulty to handle hardware device. So that we focused on vision-based approach in this study [9-14]. After image or video is capture, key frame is identify using various technique and frame is preprocessed. The preprocessed frames or images are processed to find features for classification. The extracted features are given to classifier to classified into various sign. Training and test images are categorized using the retrieved features in the classification stage. It implies that the two methods—image acquisition, extraction of features and classification—are mostly responsible for the rate of gesture recognition. There has been a lot of work on various features extraction and classification techniques in this literature [15]. Over the past few decades, noteworthy developments in accuracy have been made in sign language identification with the use of deep learning, a vision-based technique. Dynamic signs address issues with video input or visual problems, whereas static sign use the model's modality. Moreover, the dynamic signs are the most complex signs [16].

II.2 DISLR APPROACHES

II.2.1 Sensor-Based Deep Learning Approach

By [17] created a technique for recognizing sign language using sensors. Using Kinect and the jump motion device, they gathered a total of 7500 samples of 50 different sign words. The location and orientation of the fingertip characteristics were retrieved using the Leap Motion API. HMM and a bidirectional long short-term memory neural network (BLSTM-NN) were used to classify the system. According to the outcomes, the general accuracy was 95.60% and 84.57% respectively. In turn [18] proposed a modified version of the LSTM, a continuous gesture sequence model for continuous SLR that identifies several related motions. It functions by using neural networks to simulate continuous signals by dissecting them into smaller components. To take pictures, the leap motion sensor is used. Total 942 Indian sign language signed phrases have been used to test the proposed technique. Thirty-five different sign words are used to identify these sign sentences. The average accuracy on isolated sign words and signed phrases was 89.5% and 72.3%, respectively. According to [19] proposed a hand gestures recognition system that operates in real time using information from the Microsoft Kinect RGB-D camera. Computer vision methods such as affine transformation and 3D construction are utilized to provide one to one mapping between the RGB camera and depth sensor pixels. The hand motions were separated from the background noise using segmentation. A total of thirty-six static gestures associated with the alphabets and numbers of Indian Sign Language (ISL) were used to trained convolutional neural networks (CNN). Using training data consisting of 45,000 RGB and 45,000 depth images, the model's accuracy was 98.81%. Ten ISL dynamic word gestures were trained using convolutional LSTMs, and after training of 1080 videos, an accuracy of 99.08% was achieved. By [20] developed a system for the identification of sign sequences in sentences that are constantly signed in Indian sign language with a small amount of labelled sentence data and enough labelled data of isolated signs. Multiple six degree of freedom inertial measurement units (IMUs) are used on the signer's two hands to gather the data. In order to provide end to end phrase identification without the need of sign boundary information, a suggested deep learning model comprises of a convolutional neural network (CNN), two bidirectional long short-term memory (Bi-LSTM) layers, and connectionist temporal classification (CTC).

II.2.2 Vision-Based Deep Learning Approach

In turn [21] developed a vision-based deep learning solution for the video classification problem. They examine the use of Open Pose in conjunction CNN to identify the dynamic sign language videos of twenty medical words in ISL. A standard smartphone camera is used to record all of the videos. CNN was employed for the classification process. At 85% accuracy, it performs excellently. According to [22] developed a SLRS which U-Net for Semantic segmentation of hands. ResNet 101 was used with U-Net as the backbone. The use of an RGB-D Kinect camera is entirely unnecessary since semantic segmentation makes use of information from a regular RGB camera. Using training data, the system demonstrated strong performance in multiclass semantic segmentation, producing a F1 score of 0.9957 and an IOU score of 0.9920. By [10] developed the Indian Lexicon Sign Language Dataset (INCLUDE) is a ISL dataset that contains 0.27 million frames from 4,287 videos capture for 263-word signs from 15 distinct word categories. To define INCLUDE-50, a subset of 50 sign word from various word categories is selected for quick assessment of SLR methods with various hyperparameter adjustment. The authors assess a number of deep neural networks by integrating various feature extraction techniques, augmentation techniques, encoding and decoding.

On the INCLUDE-50 and the INCLUDE dataset, the top-performing model obtains accuracy rates of 94.5% and 85.6%, respectively. In turn [11] suggested a system based on a vision-based approach for interpreting signs in Indian sign language to words in English language translation. The Restnet50 model is used to find out features from RGB images, and the LSTM is used to analyze their sequences. The dataset contains 7 isolated sign words for days. The system achieved 73.60% accuracy. According to [13] presented a system that used a 3D CNN model to recognize ISL words. The model is trained on a dataset that contains 20 sign words. The system obtained 88.35% accuracy. By [14] developed a system that recognizes sign language words. The system is based on the CNN-RNN architecture. The Inceptionv3 is used to extract features from frames, and after that, the LSTM model is used to analyze sequences of frames. The proposed system is trained on the CasTalk ISL dataset, which contains 50 sign words. During testing with the test dataset, the system achieved 99.46% top-3 accuracy and 95.99% top-1 accuracy. In turn [23] proposed a model for hand gestures detection for ISL that deaf farmers frequently use. The spatial attributes are determined using the Googlenet Model. The LSTM receives the spatial characteristics in order to determine the temporal features. Using the suggested dataset of eight ISL terms from the agriculture field. An average classification accuracy of 76.21% has been attained by the model. According to [24] suggested INSIGNVID, the first Indian Sign Language video dataset. Using transfer learning, a unique method is described that uses this dataset as input to convert the ISL sentences in the video into proper English sentences. The mobilenev2 is used to find out spatial features. After that, a sequence of spatial features is given to LSTM to extract temporal features and classify them. The system has achieved 91% accuracy during training. By [25] proposed a DL model that uses a person's gestures to identify and detect words. ISL video frames are divided into isolated segments, and signs are identified using the LSTM and GRU model. With the IISL2020 dataset, four distinct sequential combinations of LSTM and GRU—since there are two layers of LSTM and two levels of GRU—were applied. With single level of LSTM and GRU layer, the suggested model achieved approximately 97% accuracy across 11 distinct signs.

In turn [26] proposed the MOPGRU (integrated Media Pipe optimized gated recurrent unit) model for the recognition of ISL. The authors have enhanced the conventional GRU cell's update gate by multiplying it by the reset gate in order to eliminate redundant data from previous screenings in a single screening. By getting feedback from the consequent of the reset gate, more attention is paid to the current input. Furthermore, In the output layer of the GRU cell, use SoftMax activation instead of Softsign activation and exponential linear unit activation in place of the hyperbolic tangent activation seen in conventional GRUs. The model is trained on a dataset contains 13 daily sign words. The system achieved 95% accuracy. According to [27] presented a DL model for motion-based recognition of ISL. OpenCV is used to record the gesture, MediaPipe is used to identify the important points, and an LSTM model that has been trained to predicts the sign. There are forty sign words in the dataset. 92% accuracy on average was attained. In turn [28] presented two approaches to solve the sign language translation problem: BERT Transformer and Bidirectional LSTM. The suggested algorithm's performance has been examined using the INCLUDE-50 dataset. A variety of data augmentation techniques and mediapipe based feature extraction is used to evaluate the deep neural network. On the Dataset INCLUDE 50, the top-performing model obtained an accuracy of 89.5%. This model makes use of an encoder, a decoder, and a pre-trained feature extractor. By [29] suggested a method for ISL word and character recognition. With a 99 percent accuracy rate, the Bag of Visual Words (BoVW) approach can identify ISL character (0-9, A-Z). ISL recognition at the word level is done using the INCLUDE-50 dataset. The spatial and temporal features of the video are trained using the Inception V3 model and LSTM, respectively. With CNN predictions as the RNN's input, authors were able to attain 86.7% accuracy. In turn [30] suggested the Hybrid CNN-BiLSTM SLR (HCBSLR) model, a vision-based SLRS that addresses the issue of over-preprocessing. The suggested model eliminates unnecessary or redundant frames using a key frame extraction technique based on Histogram Difference (HD), which increases the system's accuracy and efficiency. To extract spatial features, the HCBSLR system uses VGG-19, and to extract temporal features, it uses BiLSTM. The accuracy of the suggested HCBSLR system is 87.67% on average. According to [31] proposed the Automated ISLRS for Emergency Words (AISLRSEW), a SLRS designed to identify ISL words commonly used in emergency situations.

The problem of identifying ISL words with same hand position and multiple viewing angle is addressed by the proposed AISLRSEW, which enhances identification accuracy by combining CNN with locally created features. BiLSTM is used to extract temporal features. On a dataset with eight sign-words, the suggested model had an average accuracy of 94.42%. By [32] developed a LiST (Lightweight Sign language Translation) system, a lightweight SLT framework that takes into account several modalities at once, including hand gestures, hands orientation, and facial expression, from an ISL video. A two-layered LSTM architecture processes the feature map created by the InceptionV3 handling the features linked to various signer modalities. Continuous ISL statements from the INCLUDE dataset were used to test the model. The experimental findings demonstrate that the LiST framework attained a high prediction accuracy of 95.9% and translation accuracy of 91.2%. In turn [33] proposed a vision-based system for ISL hand gesture recognition. Transfer learning is employed in conjunction with two distinct CNN models—Google Net and VGG16—to extract spatial characteristics. These CNN models are combined with the LSTM model to determine temporal features. Three distinct datasets of videos with 11, 64 and 8 classes are used to assess the system. On the three datasets, CNN-LSTM architecture with Google Net achieves remarkably recognition accuracy of 93.18%, 97.50% and 96.65%, respectively. According to [34] suggested a study on automatic ISL identification that could help deaf patients and Indian healthcare professionals communicate more effectively. A new dataset of dynamic hand gestures for ISL terms that deaf COVID-19 positive patients frequently employ for emergency communication is suggested. The suggested hand movements were recognized using a hybrid deep convolutional LSTM network model, which produced an average accuracy of 83.36%. In turn [35] has suggested a deep learning-based model that consists of trainable CNN and trainable stacked 2 bidirectional long short-term memory (S2B-LSTM) to recognize the dynamic gestures of ISL. The spatial features in the input video data have been extracted using the CNN architecture as a feature extractor. S2B-LSTM is used to extract the temporal relationship between the successive frames of video. Training and testing are conducted on dataset, which consists of 360 videos of ISL dynamic movements. The recognition accuracy of the CNN-S2B-LSTM model is 97.6%. To identify ISL terms for emergency scenarios, a brand-new spatial attention (SA) based SLRS called the Spatial Attention based Sign Language Recognition Module (SASLRM) is proposed by [36]. ISL word recognition is achieved by SASLRM through a combination of attention features from a SA module and convolution features from a pretrained VGG-19 model. BILSTM is used to extract temporal features.

On the ISL dataset, which contains eight emergency sign words, the suggested model achieved an average accuracy of 95.627%. By [37] proposed a system for automatic sign language identification that could help deaf patients and Indian healthcare professionals communicate more effectively. A new dataset of dynamic hand gestures for ISL of six medical terms that deaf patients frequently employ for emergency communication is developed. The hand movements were recognized using a hybrid deep convolutional LSTM network model, which produced a training accuracy of 100%. In turn. [38] suggested to use the MediaPipe holistic pipeline for feature extraction and LSTM network to recognize isolated words of ISL. INCLUDE and INCLUDE-50 are used to test the suggested approach. On INCLUDE-50 and INCLUDE, the accuracy achieved by the proposed method is 94.8% and 87.4%, respectively. Multi Featured Deep Network (MF-DNet), an occlusion tolerant SLRS, is suggested for identifying ISL words by [39] . The custom dataset of 8 emergency word is used. To eliminate unnecessary frames, the proposed MF-DNet employs a histogram difference based keyframe selection method. Pose features are combined with CNN features in the proposed MF-DNet to address the issues of occlusion, identical hand gestures, and multiple viewing angles. The suggested method makes use of a BiLSTM network for classification. On the ISL dataset, the average classification accuracy for the proposed SLRS was 96.88%. By [40] suggested a novel method for ISL recognition that integrates Visual Transformers (ViT), Keras, and advanced data augmentation approaches. The approach focuses on creating a Vision Transformer model that has been trained on a large include dataset and supplemented with mediapipe's keypoint information and image data. The validation approach yielded remarkable accuracy rate of 97.52% and a promising assessment loss of 0.2941. Summary of literature review of sensor based DISLR approach in tabular form is illustrated in Table 1. Summary of literature review of vision based DISLR approach in tabular form is illustrated in Table 2.

Table 1: Summary of review of Sensor based approach.

Author	Acquisition	Dataset/ No. of signs	Single/ double handed	Signing mode	Spatial Feature extraction method	Temporal Feature extraction method	Accuracy (%)
Kumar et al. [17]	Kinect and leap motion sensor	50 words	Both	Isolated	-	HMM and BLSTM-NN	95.60% for all signs
Mittal et al. [18]	Leap motion sensor	35 words	Single	Both	CNN	Modified LSTM	72.3%-signed sentence 89.5%-isolated sign
Bhagat et al., [19]	Microsoft Kinect camera	36 static sign character and 10 dynamic sign words	Both	Isolated	CNN	LSTM	99.08%

III. DISCUSSION

Below is a report on the dynamic ISL recognition system outcomes for our review with respect to research topics.Cameras were used in 83% of the study on dynamic ISL, as can be seen in Fig. 4 for ISL data acquisition. 3% of the study used Microsoft Kinect, 4% used leap motion sensors, 4% used a smartphone, 3% used inertial measurement units, 3% used kinect and leap motion-based sensor.

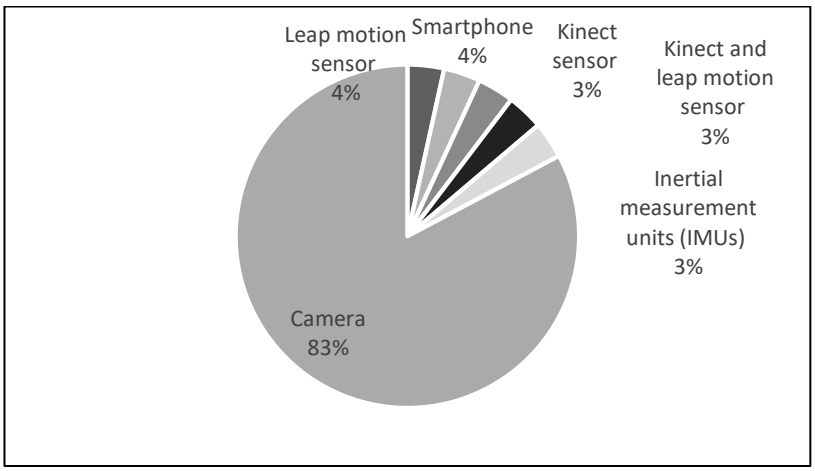

Figure 4: Data Acquisition Summary.
Source: Authors, (2026).

Fig. 5 illustrates that Dynamic ISL work has been performed 7% of the time on single-handed signs, 90% on both-handed signs, and 3% on double-handed signs.

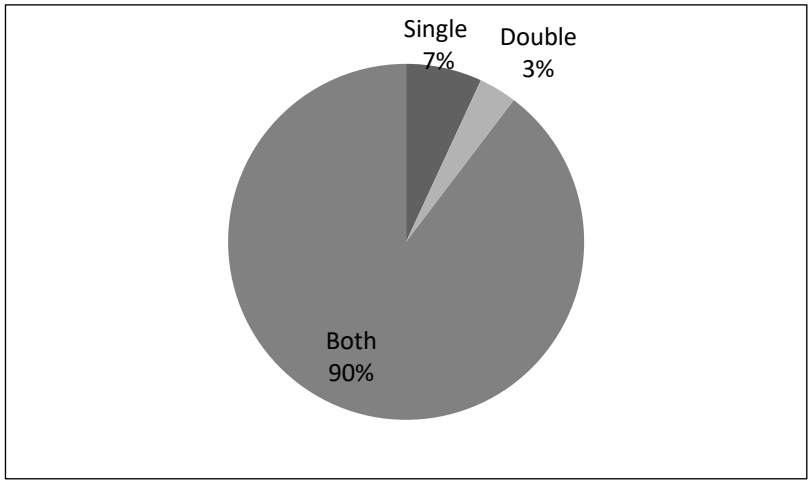

Figure 5: Hand Used Summary.
Source: Authors, (2026).

As illustrated in Fig. 6, isolated sign mode accounts for 90% of the signing modalities used for dynamic ISL research activities, while continuous sign mode accounts for 3% and both for 7%. LSTM has been used in 48% of the work on dynamic ISL as shown in Fig. 7, followed by BILSTM in 31%, CNN in 7%, GRU in 4%, HMM and BILSTM in 4%, LSTM and GRU in 3%, Transformer in 3%.

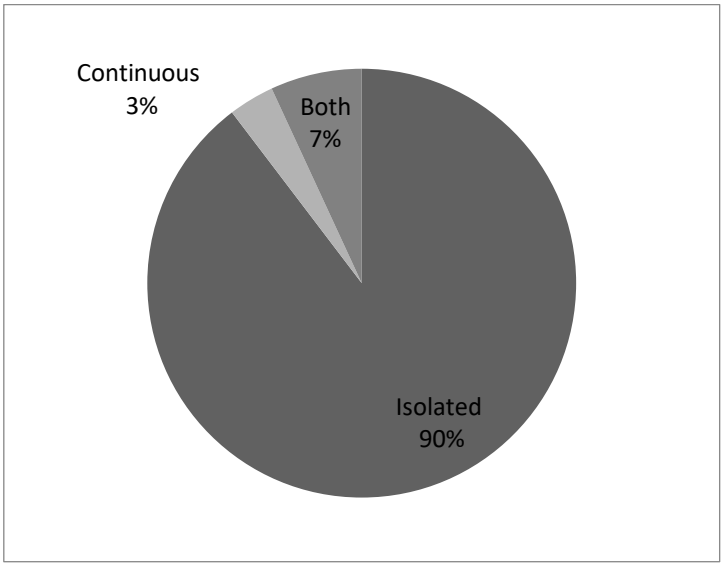

Figure 6: Signing Mode Summary.
Source: Authors, (2026).

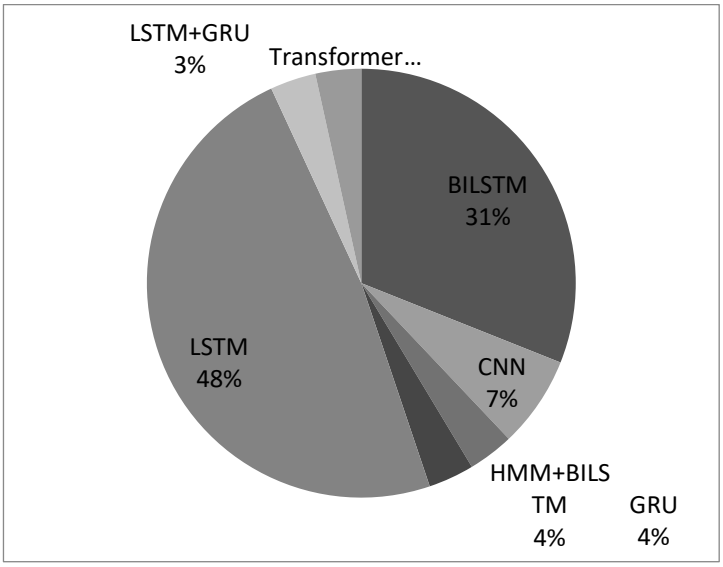

Figure 7: Deep learning Technique Summary.
Source: Authors, (2026).

According to Fig. 8, 69% of sign language recognition systems for dynamic ISL were able to reach an average accuracy of greater than 90%, whilst 24% of systems were able to achieve an accuracy of between 80 and 89%. Less than 7% of systems have an accuracy below 80%. There are two primary types of Dynamic Indian sign language recognition: continuous sign language recognition and isolated sign language recognition. One significant distinction between the two types is the supervisory information. Continuous ISL recognition addresses both the recognition challenge and the precise alignment between the video segments and the associated sentence level labels, whereas isolated ISL recognition is comparable to the action recognition field.

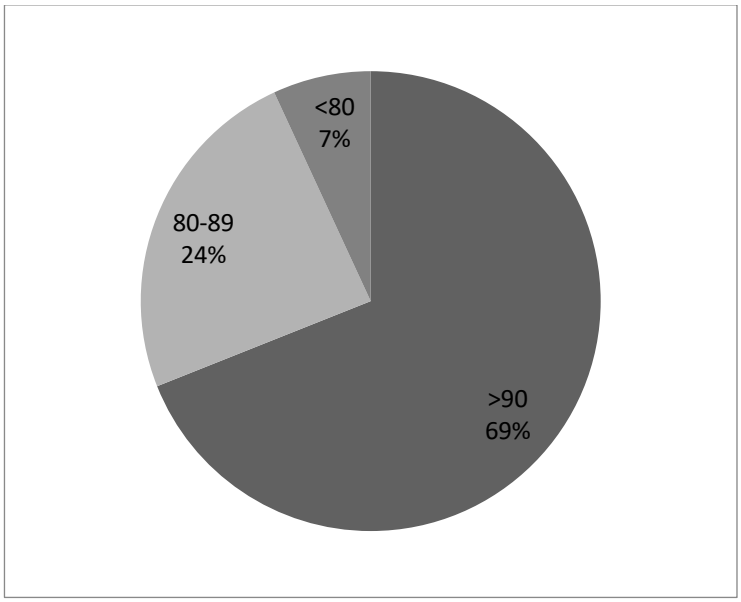

Figure 8: Accuracy Summary.
Source: Authors, (2026).

Recognition of continuous ISL is generally harder than recognition of isolated ISL. It is possible to think of isolated ISL recognition as a subset of continuous ISL recognition. A continuous ISL recognition system may perform better if it extracts more discriminative and descriptive characteristics from the video frames. Continuous dynamic signs are utilized at the sentence level, whereas isolated dynamic signs are used at the word level. There is still much space for enhancing performance in this field, even though current models in isolated and continuous sign language recognition show an increasing trend in model performance depending on DL skills in computer vision. Some potential future directions in this field include taking into account the attention mechanism, learning structured spatio-temporal patterns (like Graph Neural Networks models), utilizing multiple input modalities to benefit from multi-channel information, and applying prior knowledge on sign language. Sign Language recognition is more than just word, number, and alphabet recognition. The SLRS must recognize signs and create meaningful sentences from them in real time. To do this, it must recognize sign words and determine the context of the words. While SL recognition is a difficult task in and of itself, ISL introduces additional difficulties that make it harder for researchers to create an SLRS. The identification of a language's grammar rules is essential for language recognition; however, the grammar rules for ISL are not well established, making the process of creating an SLRS for ISL recognition difficult for academics. Another issue with ISL recognition is the lack of a consistent dataset with a broad vocabulary, since building an SLRS requires sufficient and reliable data. ISL alphabets and words use both single- and double-handed motions, unlike other SL. Signers occasionally overlap their hands when executing double-handed motions, which increases the difficulty of the segmentation and recognition challenge compared to other sign languages.

IV. CONCLUSION AND FUTURE WORK

Vision Based ISL enables people who are deaf or mute to communicate their thoughts and experiences. There is a growing trend in the usage of ISL recognition software for people. Using the keywords "Indian Sign Language Recognition," "Dynamic Indian Sign Language Recognition," and "Dynamic Indian Sign Language Recognition using Deep learning," only research publications published after 2017 were included in this analysis. Only online databases were searched for research papers for this investigation. There were no large-scale systems implemented that could process a broad vocabulary of signs in real time. In order to provide a more meaningful understanding of the technique, our literature aims to provide an overview of the research based on five parameters such as: accuracy rate, single/double-handed signs, data collection methodologies, signing style, and classification method. While this review is not intended to be exhaustive, it does offer a fair amount of information and illustrates the prevalence of research on the topic. The most widely used data acquisition tools, according to the statistics, were cameras (83%) and Kinect Senor (3%). A large portion of research on dynamic Indian sign language recognition systems has been conducted on isolated signs 90% and 90% of the studies done both single and double handed signs, with 69% of the systems having an accuracy rate of greater than 90%. It has been found that there are different sign language systems; LSTM has been used to complete 48% of the work. For large-scale systems, there is a higher effort requirement to identify dynamic Indian sign language. Research on deep learning in dynamic Indian sign language identification systems is limited. The majority of research in the field of dynamic Indian sign language recognition has been done on isolated signs. It is therefore important to use deep learning neural networks for the recognition of continuous dynamic Indian sign language.

Intrusion Detection Systems.

ABSTRACT

The rapid growth of Internet of Things (IoT) ecosystems posed a great risk to ubiquitous access to advanced cyber threats and thus the design of effective Intrusion Detection Systems (IDS) has become critical in ensuring the safeguard of secure network structures. Nonetheless, most classic deep learning methods, especially Recurrent Neural Networks (RNNs) tend to exhibit low generalization and low interpretability to tabular network traffic data and may fail to discriminate between different and intricate attacks. To overcome this issue, this paper presents a visual feature-based IDS model, which converts network traffic characteristics in the form of tabular features into RGB matrix images to harness the power of effective computer vision algorithms to detect intrusions. Recursive Feature Elimination (RFE) is applied to determine the best informative feature before generating an image, enhance features and decrease redundancy. The acquired visual representations are subsequently categorized by the EfficientNetB0 design by way of transfer learning. Experimental testing shows that the suggested method has a 98 percent accuracy, precision, recall, and F1-score, Matthews Correlation Coefficient (MCC) of 0.97, and AUC-ROC of 0.99. Comparatively, the RNN original does not reach the same level as it only gives 89% on performance metrics with MCC of 0.88 and AUC-ROC of 0.88. The above findings indicate the ability of feature selection combined with visual deep learning to facilitate scalable, precise, and real-time intrusion detection of modern-day IoT environments.

I. INTRODUCTION

Through the accelerated development of network systems and the spread of the Internet of Things (IoT) gadgets, the area of potential cyberattacks has increased dramatically. With the growing number of businesses and people depending on interconnected infrastructures, it has become part of the priorities to secure these systems against different threats to include Distributed Denial of Service (DDoS), probing, user-to-root (U2R), and remote-to-local (R2L) attacks. IDSS is an important tool that is used to observe the network traffic and detect dangerous actions as a line of defense after firewalls and antivirus programs. Nevertheless, the increasing complexity of cyberattacks is posing significant threats to more traditional methods of IDS, particularly those that are based on fixed rules or other more traditional machine learning classifiers that tend to be weak in terms of scalability, adaptability and high dimensional features. New developments in the field of deep learning created new opportunities to enhance the capabilities of IDS, especially the application of the Convolutional Neural Networks (CNNs) and the Transfer Learning models.

Such techniques have proven to be highly successful in many fields, particularly computer vision problems because they have strong powers of representation learning. Regarding IDS, there is a growing interest in using such methods in order to transform structured tabular network data into image formats that CNNs can process efficiently. This data-to-image encoding conversion provides the ability to encode latent geometric and contextual correlations of the traffic features that may be missed in the data with an older algorithm. The approach is even more powerful when paired with pre-trained models such as EfficientNet, since it embraces both hierarchies of features and efficiency. However, it is not so easy to transform raw network traffic into meaningful image representations. Among the main problems is the large dimensionality and sparsity of IDS data, including CSE-CIC-IDS2018, which have many redundant or irrelevant features. Such extraneous properties have the adverse effect of affecting the performance of deep learning models and lead to overfitting, high computational cost, and poor detection accuracy. Thus, before transformation is required, there must be effective feature selection. Recursive Feature Elimination (RFE) has been one of the most used and interpretable feature selection algorithms where less important features are dropped out one at a time due to model weight coefficients. With RFE, not all dimensions of the dataset are required to be retained, the most relevant ones are kept so as to visual mapping is done. This study suggests a new hybrid IDS model that integrates recursive feature selection, visual feature encoding as well as transfer learning. Preprocessing steps include the removal of null values, label encoding and normalization which is the beginning of the pipeline.

The smaller feature space is then coded into 64x64RGB images where temporal and structural relationships can be maintained as pixel intensity values. Through these images, a pre-trained EfficientNetB0 model is fine-tuned and used to execute binary and multi-class intrusion detection using the scalable nature of its architecture. The proposed model is measured against the standard measures of accuracy, precision, recall, F1-score, Matthews Correlation Coefficient (MCC), and Area Under the Receiver Operating Characteristic Curve (AUC-ROC). The main findings of this research are triple: (1) the effective data-to-image transformation of network traffic based on the RFE-selected features, (2) the application of EfficientNetB0 to deep visual feature extraction in the area of the IDS, and (3) the comparison of the model with the traditional structures (RNN) to prove the best results. After intensive testing of the presented system on the CSE-CIC-IDS2018 dataset, the results are encouraging, and the proposed system has accuracy and F1-score, which are over 98, much higher than the results of the baseline models. The rest of this paper will be organized as follows: Section 2 shows the related literature in the area of intrusion detection with the help of machine-learning tools and image-based techniques. Section 3 outlines the proposed methodology that comprises data preprocessing, feature selection, image conversion and model training. The 4th section will offer the performance analysis and results of the experiment. Lastly, Section 5 wraps up the research and gives the future directions of the research.

II. THEORETICAL REFERENCE

The recent past has seen a boom in the research on optimizing the efficiency, robustness, and accuracy of intrusion detection systems (IDS), especially by incorporating deep learning and hybrid frameworks. This part of the paper is a review of notable works in this field and the research gaps that have been identified that lead to the application of the proposed work. Markkandeyan et al. suggested a new hybrid deep learning model coupled with an optimization algorithm in [1] to enhance the ability to detect cyber threats. Their model showed improvement in detection performance, and no investigation was carried out on visual encoding of features or transfer learning adaptability. In the same manner, [2] have dealt with the issue of DDoS detection based on adaptive transfer learning. Although they are useful in dynamic network setting, their analysis failed to investigate recursive feature selection or feature visual representation, which might result in an even better generalization. By [3] compared several bio-inspired optimization algorithms on the CSE-CIC-IDS2018 dataset. Their research was useful in comparison but focused only on the traditional numerical features and did not rely on the deep visual feature extraction. In turn [4] were concerned with the machine learning-based IDSs adapted to cloud networks. Despite its practicality, the study did not have a dimension reduction procedure like the recursive feature selection to deal with the redundant features. According to [5] focused on cross-dataset generalization in IDS by performing cross-dataset performance analysis. Although their results have emphasized generalization, they have not examined how transfer learning with image-based inputs can influence robustness. By [6] applied deep learning to Software Defined Networks (SDNs) to identify intrusion, and the flexible character of the DL technique in the existing network architecture but did not consider the improvement of performance through CNN-based visual encoding. In turn [7] proposed a transformer-based IDS with transfer learning to solve the imbalance in traffic data. Though this model had good performance, the absence of a systematic elimination of features and lack of a hybrid pipeline that combined the use of CNNs did not make the model scalable.

According to [8], in their turn, performed a general review of IDS datasets, where the data quality and structure variation also prevalent, yet they did not carry out their analysis until the usefulness of visual transformations to standardized processing. By [9] have introduced a working model of the IDS that works in cloud computing, which is an integration of detection accuracy and low latency. Nevertheless, they failed to combine the visual aspect and recursive selection to determine the best feature subset. According to [10] suggested the use of DTL-IDS, which utilizes the deep transfer learning and genetic algorithm. Although the study showed good outcomes, it was not focused on image representations or effective feature filtering methods. In turn [11] addressed the issue of class imbalance in the cloud setting with deep learning. However, visual feature maps or multi-modal representation integration were not studied. By [12] offered an overall deep learning-based IDS framework that is well-accurate, though not scalable to further dimensions and complexities of features. In turn [13] presented a collaborative weighted ensemble DNN to coordinated attacks, which improved detection of heterogeneous networks. Nevertheless, their approach did not feature any techniques of transforming features to visual modalities. In turn [14] used contrastive variational autoencoders and metric learning to detect attacks in blockchain-enhanced cloud of things, demonstrating the power of deep generative models, but lacking the incorporation of classic feature selection techniques. According to [15] adopted a portable deep learning architecture to be applied to IDS in the IoT. Their approach, though promising, did not look into the possibility of combining recursive feature selection with visual encoding of CNNs. In turn [16] designed a new IoT IDS based on the deep learning algorithm against DDoS attacks. They concentrated on the type and model tuning of the attacks that they did and ignored the effect of the preprocessing pipeline.

To deal with the issue of data imbalance, [17] came up with a multi-classification model which incorporates reconstruction and feature matching. Though successful, they did not use recursive feature elimination or CNN-based visual learning in their model. By [18] created a deep learning IDS on the cloud platform, but the scheme did not have the hybrid feature extraction or transfer learning parts. According to [19] extensively examined the CIC-IDS2017 data but did not provide information on the CSE-CIC-IDS2018, as well as the consequences of feature changes. By [20] employed the optimized CNNs transfer learning on cloud-IoT IDS. Their design allows deep extraction of features though its feature selection mechanisms are absent which affects the efficiency of the model. The three-phase optimization method was used by Songma et al. on the CSE-CIC-IDS2018 dataset [21]. Despite its thoroughness, it lacks image-based transformations and hence cannot be used with sophisticated deep architectures. According to [22] developed deep learning models of the IoT IDS with CIC-IDS2017 but did not consider the strategies of feature selection and visual mapping. By [23] have created a hybrid feature-optimized deep learning IDS. Although the purpose of their study is similar, they did not investigate the usefulness of visual encoding or CNN fine-tuning on pre-trained models. In turn [24] suggested dual CNN to detect attacks, that demonstrated excellent performance with IoT networks, however, did not require recursive selection of the features or learning across domains. This model is presented by [25] as a two-stage model consisting of LSTM and Autoencoders. Although temporal learning was improved, no analysis was done on the visual-spatial patterns. According to [26] adopted a multimodal deep transfer learning model in SDNs to detect attacks, but the issue of converting the numerical features into the image-based feature was not investigated. In turn [27] tested the vulnerability of ML-based IDSs to adversarial attacks through CICIDS2017. They did not use the CSE-CIC-IDS2018 dataset in their work or did not consider deep hybrid pipelines where visual features are used. The performance of most of the current models has been extremely good in detecting with the classical or hybrid deep learning methods. Nonetheless, few studies have focused on the combination of recursive feature selection with visual features encoding by transfer learning architectures based on CNN. Also, most of the research was concentrating either on feature optimization or deep learning, and rarely both in a study towards an effective IDS. To address this critical gap, this paper uses RFE to reduce dimensionalities, converting the chosen features to RGB visual maps, and uses EfficientNetB0 to extract features, thereby proposing a full-fledged and scalable pipeline of intrusion detection.

III. MATERIALS AND METHODS

Figure 1 Novel flowchart is the visualization of an end-to-end deep learning pipeline of the Intrusion Detection System (IDS) involving image-based representation of tabular network data and then transfer learning using the EfficientNetB0 model. The technical description of each block in detail can be found below with the corresponding equations and techniques:

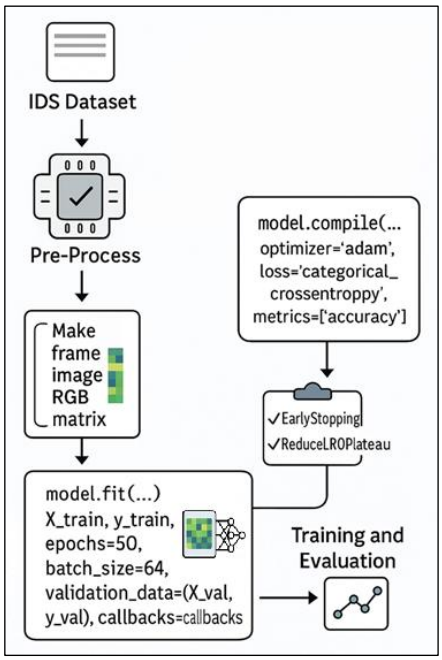

Figure 1: Proposed System Flow Diagram.

III.2 DATASET

The dataset CSE-CIC-IDS2018 [3] presented in Table 1 is one of the most popular benchmarks to test the work of intrusion detection systems in network security research. It has a complex and lifelike collection of network traffic characteristics emulating current assaults in IoT and enterprise settings. The one used in this work has 74218 rows and 78 feature columns, that is, both benign and malicious traffic. The dataset has seven different classes, Benign, Bot, BruteForce, DDoS, DoS, Infiltration and WebAttack, with an equal sample count in each one of them. This equal distribution is a guarantee of fair performance assessment of classification models of all types of attacks. A sample has an exhaustive repertoire of traffic characteristics like flow lifetime, packet sizes, TCP flags, protocol types, and statistical indicators, like inter-arrival time, can be used to identify subtle patterns related to different attack vectors. The variety of the dataset enables the simulation of high-volume (e.g., DDoS, DoS) as well as low-and-slow attacks (e.g., Infiltration, WebAttack) observed in the real-life environment. The CSE-CIC-IDS2018, which is widely used by a recent intrusion detection research, can be used on both binary (Benign vs. Attack) and multi-class classification problems. It is very varied and large-scale, so it is perfect in training and benchmarking ensemble models, deep learning architectures, real-time threat detection pipelines.

Table 1: Dataset Columns Description.

Column Name	Description
Protocol	Network protocol used in the flow (e.g., TCP, UDP).
Flow Duration	Total duration of the flow in microseconds.
Total Fwd Packets	Number of packets sent in the forward direction.
Total Backward Packets	Number of packets sent in the backward direction.
Fwd Packets Length Total	Total length of all forward packets.
Bwd Packets Length Total	Total length of all backward packets.
Fwd Packet Length Max	Maximum length among forward packets.
Fwd Packet Length Min	Minimum length among forward packets.
Fwd Packet Length Mean	Average length of forward packets.
Fwd Packet Length Std	Standard deviation of forward packet lengths.
Bwd Packet Length Max	Maximum length among backward packets.
Bwd Packet Length Min	Minimum length among backward packets.
Bwd Packet Length Mean	Average length of backward packets.
Bwd Packet Length Std	Standard deviation of backward packet lengths.
Flow Bytes/s	Number of bytes per second transmitted in the flow.
Flow Packets/s	Number of packets per second transmitted in the flow.
Flow IAT Mean	Mean inter-arrival time between packets.
Flow IAT Std	Standard deviation of inter-arrival time.
Flow IAT Max	Maximum inter-arrival time in the flow.
Flow IAT Min	Minimum inter-arrival time in the flow.
Fwd IAT Total	Total inter-arrival time for forward packets.
Fwd IAT Mean	Average inter-arrival time of forward packets.
Fwd IAT Std	Standard deviation of forward inter-arrival time.
Fwd IAT Max	Maximum inter-arrival time for forward packets.
Fwd IAT Min	Minimum inter-arrival time for forward packets.
Bwd IAT Total	Total inter-arrival time for backward packets.
Bwd IAT Mean	Average inter-arrival time of backward packets.
Bwd IAT Std	Standard deviation of backward inter-arrival time.
Bwd IAT Max	Maximum inter-arrival time for backward packets.
Bwd IAT Min	Minimum inter-arrival time for backward packets.
Fwd PSH Flags	Number of PSH flags set in forward packets.
Bwd PSH Flags	Number of PSH flags set in backward packets.
Fwd URG Flags	Number of URG flags set in forward packets.
Bwd URG Flags	Number of URG flags set in backward packets.
Fwd Header Length	Total header length of forward packets.
Bwd Header Length	Total header length of backward packets.
Fwd Packets/s	Forward packets transmitted per second.
Bwd Packets/s	Backward packets transmitted per second.

Packet Length Min	Minimum packet length in the flow.
Packet Length Max	Maximum packet length in the flow.
Packet Length Mean	Average packet length in the flow.
Packet Length Std	Standard deviation of packet lengths.
Packet Length Variance	Variance of packet lengths.
FIN Flag Count	Number of packets with FIN flag.
SYN Flag Count	Number of packets with SYN flag.
RST Flag Count	Number of packets with RST flag.
PSH Flag Count	Number of packets with PSH flag.
ACK Flag Count	Number of packets with ACK flag.
URG Flag Count	Number of packets with URG flag.
CWE Flag Count	Number of packets with CWE flag.
ECE Flag Count	Number of packets with ECE flag.
Down/Up Ratio	Download to upload traffic ratio.
Avg Packet Size	Average size of all packets.
Avg Fwd Segment Size	Average size of forward segments.
Avg Bwd Segment Size	Average size of backward segments.
Fwd Avg Bytes/Bulk	Average bytes per forward bulk.
Fwd Avg Packets/Bulk	Average packets per forward bulk.
Fwd Avg Bulk Rate	Average forward bulk transmission rate.
Bwd Avg Bytes/Bulk	Average bytes per backward bulk.
Bwd Avg Packets/Bulk	Average packets per backward bulk.
Bwd Avg Bulk Rate	Average backward bulk transmission rate.
Subflow Fwd Packets	Number of forward packets in subflows.
Subflow Fwd Bytes	Number of forward bytes in subflows.
Subflow Bwd Packets	Number of backward packets in subflows.
Subflow Bwd Bytes	Number of backward bytes in subflows.
Init Fwd Win Bytes	Initial window size in forward direction.
Init Bwd Win Bytes	Initial window size in backward direction.
Fwd Act Data Packets	Number of active data packets in forward direction.
Fwd Seg Size Min	Minimum segment size in forward direction.
Active Mean	Mean active time of flow.
Active Std	Standard deviation of active time.
Active Max	Maximum active time.
Active Min	Minimum active time.
Idle Mean	Mean idle time of flow.
Idle Std	Standard deviation of idle time.
Idle Max	Maximum idle time.
Idle Min	Minimum idle time.
Label	Class labels

III.3 PRE-PROCESSING: NULL VALUE HANDLING AND ENCODING

After getting the dataset, data pre-processing is the initial step that is critical in that it serves to clean the dataset and prepare it to go through machine learning algorithms. The dataset, which was based on [23], has several features that can have null or missing values and has categorical variables that cannot be directly interpreted in machine learning models.

- Null Value Handling: Missing values in the dataset can degrade the performance of classifiers. Let the dataset be represented as a matrix $X \in \mathbb{R}^{nxm}$, where $n = 1500$ samples and m features. A missing value in element x_{ij} (i.e., the value at the ith row and jth column) is either removed if the percentage of missingness is negligible, or imputed using statistical methods such as: Mean imputation:

$$x_{ij} = (1/N) \sum_{k=1}^{N} x_{kj} \quad (1)$$

K-Nearest Neighbors imputation (KNN):

$$x_{ij} = \text{mean}(\{x_{pj} \mid x_p \in N_k(x_i)\}) \quad (2)$$

- Encoding: Categorical variables such as protocol or flag type are transformed into numerical format using encoding schemes. For nominal variables $C = \{c_1, c_2, \ldots, c_k\}$, One-Hot Encoding creates binary vectors for each class label:

$$\text{Encoded}(c_j) = [0, 0, \ldots, 1, \ldots, 0] \quad (3)$$

III.4 RECURSIVE FEATURE ELIMINATION (RFE)

Once the data is filtered and coded numerically, the second stage is Recursive Feature Elimination (RFE). It is a feature selection algorithm that is designed to reduce the dimensionality of the feature space and retain the most predictive features.

$$X = [x_1, x_2, \ldots, x_m] \tag{4}$$

$$\text{Feature Set}_{t+1} = \text{Feature Set}_t \setminus \{\text{argmin}_{xj} \in \text{Feature Set}_t \, I(x_j)\} \tag{5}$$

III.5 DATA TO VISUAL FEATURE

In this stage, structured tabular data is transformed into image representations to enable deep learning-based feature extraction. A At this phase, structured tabular data is converted into image representations to facilitate feature extraction by using deep learning. A set of 64 samples represented by numerical feature vectors is clumped and reformed into a grid of 64x64. This grid is then normalized and reproduced in three color channels (R, G, B), which forms an RGB image of dimensions 64x64x3. Such metamorphosis eases the process of visual pattern recognition by convolutional neural networks. Normalization Equation:

$$x_{norm(i,j)} = \frac{\big(x(i,j) - \min\big(x(:,j)\big)\big)}{\big(\max\big(x(:,j)\big) - \min\big(x(:,j)\big)\big)} \tag{6}$$

Where:

$x(i,j)$ represents the j-th feature of the i-th sample. $min(x(:,j))$ and $max(x(:,j))$ are the minimum and maximum values for the j-th feature across all samples. $x\_norm(i,j)$ is the normalized feature value.

III.6 HYPER-TUNE EFFICIENTNETB0 MODEL

In this step, efficientNetB0 is utilized, which is a high-performance convolutional neural network with a reduced number of parameters, in order to perform intrusion classification on images. It uses scaling of compounds to balance between network depth, width and resolution. This enhances greater accuracy as well as computational efficiency.
Compound Scaling Equations:

$$depth\,(d) = \alpha\text{^}\varphi \tag{7}$$

$$width\,(w) = \beta\text{^}\varphi \tag{8}$$

$$resolution\,(r) = \gamma\text{^}\varphi \tag{9}$$

Subject to the constraint:

$$\alpha * \beta^2 * \gamma^2 \approx 2 \tag{10}$$

Where:

φ (phi) is a coefficient controlling the overall model scale. α, β, and γ are constantly identified through optimization. This scaling method ensures consistent improvements across network dimensions.

III.7 EVALUATION METRICS

After model training, the ensemble classifier is evaluated using a comprehensive set of metrics that capture different dimensions of performance. Accuracy: Measures overall correctness:

$$Accuracy = \frac{(TP + TN)}{(TP + TN + FP + FN)} \tag{11}$$

Precision and Recall: Precision measures the correctness of positive predictions, and recall measures completeness:

$$Precision = \frac{TP}{(TP + FP)} \tag{12}$$

$$Recall = \frac{TP}{(TP + FN)} \tag{13}$$

F1-Score: The harmonic means of precision and recall:

$$F1 = 2 * \frac{(Precision * Recall)}{(Precision + Recall)} \tag{14}$$

K-Fold Cross Validation: The dataset is split into K equal parts. For each iteration, $K - 1$ parts are used for training and 1 for testing. This is repeated K times, and the results are averaged:

$$Cross - validation\ Accuracy = \left(\frac{1}{K}\right) \sum_{i=1}^{K} Accuracy_i \tag{15}$$

Matthews Correlation Coefficient (MCC): A balanced measure for classification performance:

$$MCC = \frac{(TP * TN - FP * FN)}{\sqrt{((TP + FP)(TP + FN)(TN + FP)(TN + FN))}} \quad (16)$$

This measure is especially applicable to multi-class data or in data with an imbalance in the classes since it considers all four classes of confusion matrices. This new model is the best way to combine tabular-to-image transformation, deep CNN feature extraction, and feature selection to address the intrusion detection as a visual classification problem as a paradigm shift as compared to conventional ideas.

IV. RESULTS AND DISCUSSIONS

The analysis of the results was carried out on the Google Colab platform in the T4 environment to provide a powerful training and evaluation of the proposed ensemble intrusion detection model. A partial view of the dataset that is being used is shown in Figure 2. It reveals different network traffic attributes including Protocol, Flow Duration, Total Fwd Packets, and Total Backward Packets, and their numeric values of the different records. The first perspective provides an impression of raw data structure without any processing.

Figure 2: Dataset Reading.
Source: Authors, (2026).

Figure 3 bar chart is a ranking of features in terms of Recursive Feature Elimination (RFE). The features of lower rankings are assumed to have more significance, meaning that the very first features on the left, i.e. Protocol and Flow Duration, were found to be the most important to the performance of the model, which has resulted in the top 30 being selected.

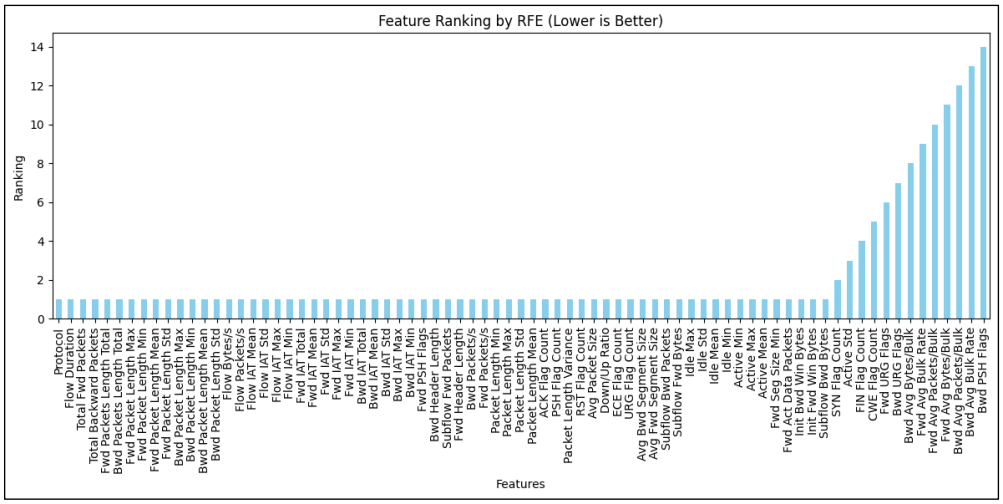

Figure 3: RFE 30-Features Selected.
Source: Authors, (2026).

Figure 4 provides the visual representations based on the network traffic information according to various types of attacks (Bot, Brute force, DDoS, DoS, Infiltration, WebAttack) and regular traffic. The image of each image is a visual fingerprint of that image in its class, and it can be initially believed that the raw data of network flow is converted into images to be classified.

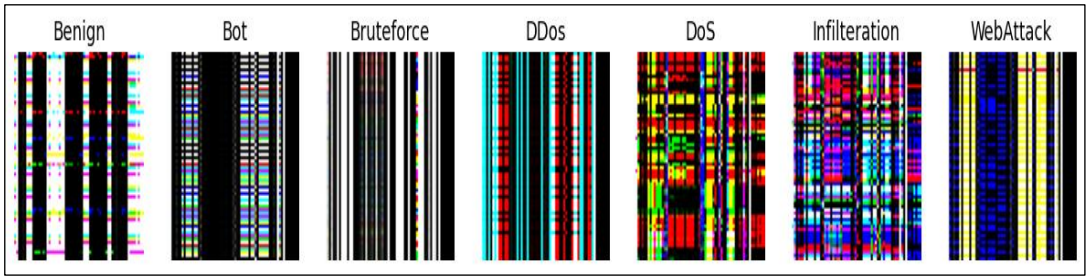

Figure 4: Sample of Generated Visual Feature of Each class.
Source: Authors, (2026).

Figure 5 illustrates the two plots namely: Model accuracy and Model loss after 50 epochs of the proposed EfficientNetB0 model. Accuracy plot indicates that both training and validation accuracy values are approaching and converging towards 1.0, whereas the loss plot indicates that both the training and validation loss values are approaching and converging towards 0.0 which is a good indication of learning and generalization.

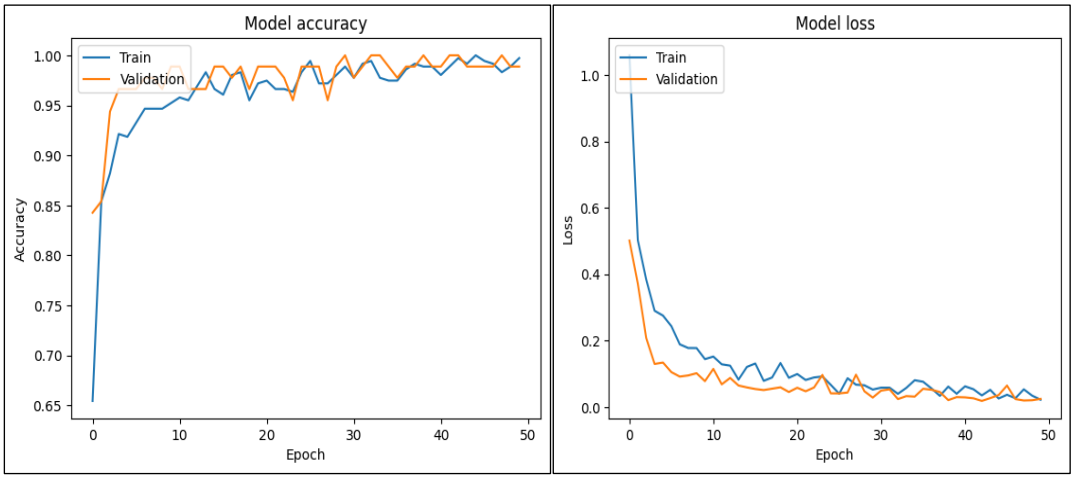

Figure 5: Proposed EfficientNetB0 Model Performance.
Source: Authors, (2026).

Figure 6 is a confusion matrix and a classification report, which assesses the performance of the EfficientNetB0 model. The confusion matrix indicates the number of true labels and predicted labels of each class, whereas the classification report indicates the properties of precision, recall, f1-score, and support, which indicates high accuracy (0.98) in the majority of attack types and benign traffic.

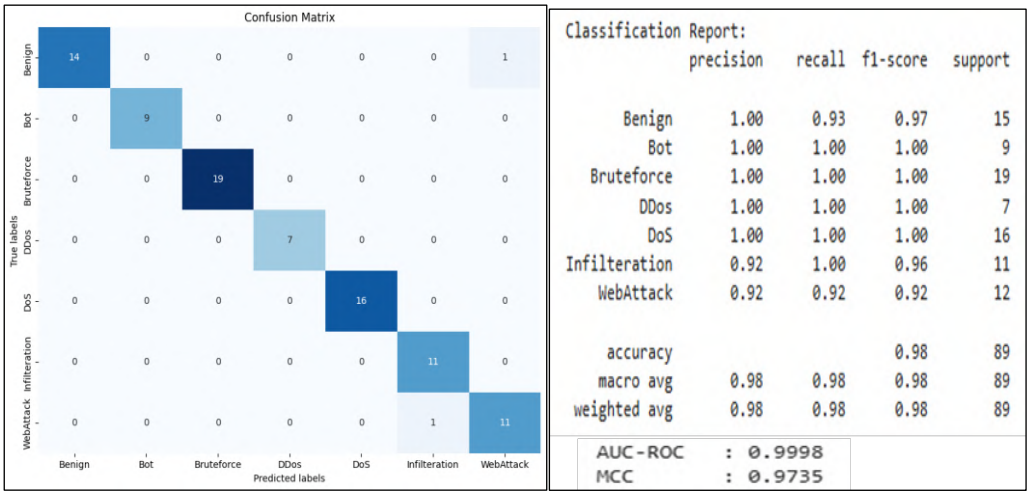

Figure 6: Proposed EfficientNetB0 Model Evaluation.
Source: Authors, (2026).

Figure 7 depicts multiclass ROC curve the visualization of the True Positive rate versus the False Positive rate of each class (Class 0 to Class 6). The curves of all classes are near the upper-left corner, and their AUC values are equal to 1.00, meaning that EfficientNetB0 model has a very high discriminative power with all types of traffic.

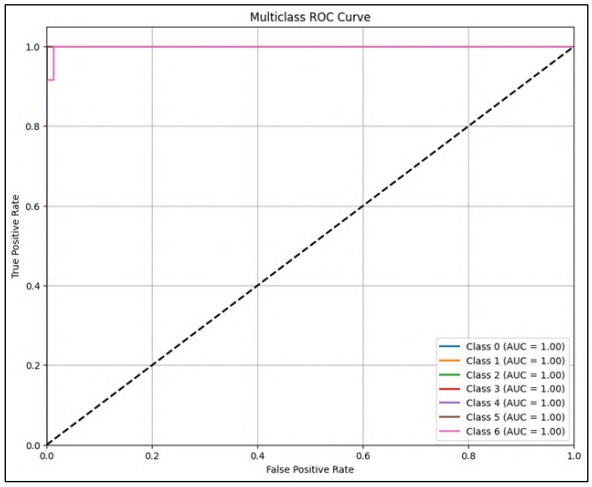

Figure 7: Proposed EfficientNetB0 Model ROC Curve.
Source: Authors, (2026).

Table 2: Proposed EfficientNetB0 Model K-Fold Validation.

Fold	Accuracy	Precision	Recall	F1-Score	MCC
1	1.0000	1.0000	1.0000	1.0000	1.0000
2	1.0000	1.0000	1.0000	1.0000	1.0000
3	1.0000	1.0000	1.0000	1.0000	1.0000
4	1.0000	1.0000	1.0000	1.0000	1.0000
5	0.9775	0.9788	0.9771	0.9775	0.9739

Source: Authors, (2026).

Table 2 contains the performance of the EfficientNetB0 model in 5-fold cross-validation. In the four initial folds, the model scores (1.0000) on Accuracy, Precision, Recall, F1-Score, and MCC, which indicates that the model is highly consistent in and has excellent performance. Although the fifth fold has somewhat lower yet very high measures (around 0.97), the outcome of the whole model reflects the strength and stability of the model.

Table 3: Comparative Analysis with Existing Research.

Model	ACC (%)	P (%)	R (%)	F1-Score (%)	MCC	AUC-ROC
Transformer-ID (from [7])	0.97	0.97	0.96	0.96	0.95	0.97
Hybrid DL+GA (from [10])	0.96	0.95	0.95	0.95	0.94	0.96
LSTM-AE (from [25])	0.94	0.93	0.94	0.93	0.92	0.94
CNN (from [27])	0.91	0.9	0.91	0.9	0.89	0.91
RNN	89%	89%	89%	89%	0.88	0.88
Proposed Model EfficientNetB0	98%	98%	98%	98%	0.97	0.99

Source: Authors, (2026).

Table 3 provides the performance of the Proposed EfficientNetB0 Model and a few of the existing research models (Transformer-ID, Hybrid DL+GA, LSTM-AE, CNN, RNN) in terms of different metrics: Accuracy, Precision, Recall, F1-Score, MCC, and AUC-ROC. The suggested EfficientNetB0 model is consistently better in the mentioned metrics (the accuracy of the model is 98% and the AUC-ROC is 0.99), which means that it is much more effective in the task than all the works listed above.

V. CONCLUSIONS

To sum up, in this paper, I have introduced a solid and precise intrusion detection model based on an EfficientNetB0 architecture on a balanced subset of the CSE-CIC-IDS2018 dataset with 74,218 rows and 78 features, and seven classes: Benign, Bot, BruteForce, DDoS, DoS, Infiltration and WebAttack. The proposed model also performed much better than the currently existing methods in all evaluation metrics. In particular, the EfficientNetB0 model had an accuracy, precision, recall, and F1-score of 98, the Matthews Correlation Coefficient (MCC) of 0.97, and the AUC-ROC of 0.99. Our model had better detection capacity and fewer false positives than Transformer-ID [7] (97%), Hybrid DL+GA [10] (96%), and LSTM-AE [25] (94%), which are all baseline models. This experiment validates the success of EfficientNetB0 in the extraction of high-level features of structured network data as well as the detection of both volumetric and stealthy attacks. To apply the framework to future work, the structure can be expanded with the incorporation of temporal models such as LSTM or attention systems with Transformers to promote the achievement of sequential attack patterns within the real-time traffic. The strategy to use online learning will help the system to dynamically cope with the changing threats. Furthermore, the optimization of the model with the help of feature selection and the inclusion of explainability to cybersecurity tools (SHAP or LIME) can promote trust and understandability among cybersecurity professionals. Implementation of this model in the real network environment with streaming information, and zero-day attack analysis will further confirm that this model is workable. In general, this paper provides the basis of scalable, intelligent and adaptive intrusion detection systems in contemporary cyberinfrastructure.

ABSTRACT

Cloud computing has seen rapid growth in recent years, leading to a surge in demand for data center services. To meet this demand, data centers deploy a large number of servers, resulting in substantial energy consumption. Virtual Machine Consolidation (VMC) is an effective strategy to reduce energy usage by shutting down underutilized servers while ensuring that Service Level Agreements (SLAs) are maintained. The VMC process comprises four key steps: detecting overloaded hosts, identifying underloaded hosts, selecting virtual machines (VMs), and determining their placement. This research presents the Energy-Efficient Virtual Machine Placement (EEVMP) approach, which aims to optimize resource utilization by selecting suitable destination hosts for migrating VMs based on utilization and resource skewness. The proposed method is evaluated using the CloudSim simulator. Experimental results show that EEVMP consistently outperforms existing placement strategies such as PABFD, IQRMC, PEBFD, ESVMP, and HVMAP in terms of energy efficiency and overall performance.

I. INTRODUCTION

Cloud computing has experienced significant growth in recent years, resulting in increased demand for data center services. To accommodate this demand, data centers operate a large number of servers, which in turn leads to high energy consumption. Virtual Machine Consolidation (VMC) is a widely adopted technique to minimize energy usage by turning off underutilized servers while still adhering to Service Level Agreements (SLAs) [1]. The VMC process involves four main stages: detecting overloaded hosts, identifying underloaded hosts, selecting virtual machines (VMs), and determining their optimal placement [2]. This study introduces the Energy-Efficient Virtual Machine Placement (EEVMP) strategy, designed to enhance resource utilization by selecting destination hosts for migrating VMs based on their utilization levels and resource imbalance. The approach is validated through simulations conducted using the CloudSim toolkit. Results indicate that EEVMP consistently outperforms conventional VM placement methods—namely PABFD, IQRMC, PEBFD, ESVMP, and HVMAP—by offering superior energy efficiency and system performance [3]. Figures 1 and 2 illustrate the number of active hosts before and after the application of the virtual machine consolidation method. Figure 1 shows that five hosts are needed to handle user requests; however, some hosts are significantly underutilized, while others are moderately utilized. Despite varying levels of utilization, all hosts consume considerable energy. To address this, some underutilized hosts can be put into sleep mode, and their VMs can be migrated to other hosts. Cloud data center resources are heterogeneous, meaning each can have a distinct physical configuration. Service providers may face challenges migrating VMs between hosts.

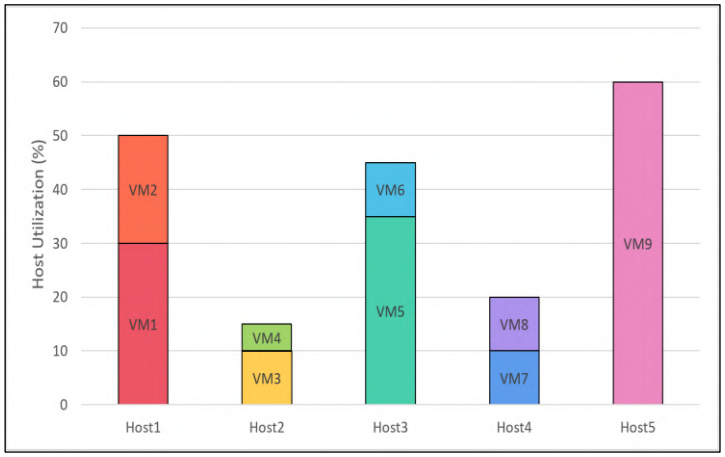

Figure 1: PM Utilization before VMC.
Source: Authors, (2026).

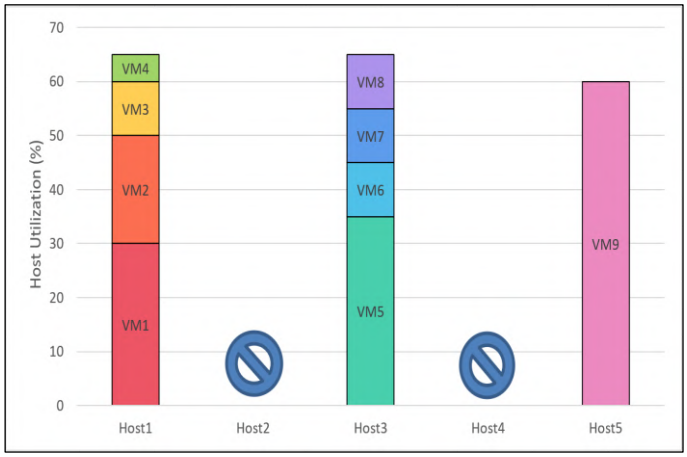

Figure 2: PM Utilization after VMC.
Source: Authors, (2026).

VMC resource allocation policies use various techniques to adaptively allocate the necessary VMs to minimize the number of active Physical Machines (PMs) while conserving energy. The primary objectives of VM consolidation are to avoid host overload and promote green computing. To prevent host overload, the VM resource request must be lower than the host's available resources. Otherwise, the Service Level Agreement (SLA) between the user and the service provider would be breached [4]. SLAs are crucial for ensuring Quality of Service (QoS) and service availability for end users. In terms of green computing, cloud service providers aim to fulfill user requests with the minimum number of active hosts possible without violating SLAs [5]. Figure 3 illustrates the classification of VM Consolidation Policies [6].

Host Overload Detection Algorithm	Static Threshold (Th)	Median Absolute Deviation (MAD)	Interquartile Range (IQR)	Local Regression (LR)	Robust Local Regression (LRR)
Host Underload Detection Algorithm	Host with Minimum Utilization				
VM Selection Algorithm	Minimum Migration Time (MMT)	Random Choice (RC)	Maximum Correlation (MC)	Minimum Utilization (MU)	
VM Placement Algorithm	First Fit (FF)	First Fit Decreasing (FFD)	Best Fit Decreasing (BFD)	Worst Fit Decreasing (WFD)	Power Aware Best Fit Decreasing (PABFD)

Figure 3: VMC Process Policy.
Source: Authors, (2026).

In a cloud data centre, multiple VMs may run on a single physical machine with host utilisation varying dynamically based on user demands; when consumption reaches 100%, performance degrades and SLAs are breached, making overload detection the first critical step in VM consolidation, followed by identification of the specific VMs responsible for the overload. Simultaneously, underutilised hosts must also be detected so their workloads can be transferred to other hosts, forcing them into standby mode to reduce overall energy consumption [7]. Once an overloaded host is identified, the offending VMs are selected, added to a migration list, and moved to alternative hosts to minimise performance deterioration, while all VMs from an underloaded host are migrated entirely [8]. The final step, VM placement, determines the optimal destination host for each migrating VM using a bin-packing-like algorithm; in this study, we developed the Energy-Efficient VM Placement for Optimized Resource Utilization in Cloud Data Centers (EEVMP) and benchmarked it against existing techniques including PABFD, IQRMC, PEBFD, ESVMP, and HVMAP.

II. RELATED WORK

The VM workload consolidation approach is a promising research area for increasing cloud computing energy efficiency. Many strategies are advised to speed up the virtual machine consolidation process, including (a) detecting overloaded hosts, (b) detecting underloaded hosts, (c) selecting VMs, and (d) placing them. The VMC method focuses primarily on three criteria. The first is based on the Quality-of-Service approach, which emphasizes effective use of computer resources. The second option is to minimize data center power use by turning off underutilized hosts. Another critical challenge is maintaining a balance between energy use and SLA violations throughout the VMC process. By [1] offered an alternate technique for identifying overloaded/underloaded hosts, VM selection, and VM placement. The author created heuristic-based strategies for identifying overload hosts, including IQR, MAD, LR, LRR, and static thresholds. For Underload host identification, the least utilized host is deemed underutilized.

The author proposed the MC, MU, MMT, and RS algorithms for selecting VMs from overutilized hosts, as well as the PABFD policy for VM placement. Although it provides better power consumption outcomes than other standard approaches, average SLA violation and VM migration will be greater. In turn [9] improved their host overload detection system and migration control. After identifying an overloaded host, it calculates the VM prediction value using the host's mean and standard deviation, then checks to see whether the prediction is larger than one and if so, the host is labelled as overloaded. The results show that the proposed method beats the present methodology in terms of performance. According to [10] proposed many power-efficient VM placement approaches, including Medium Fit Power Efficient Decreasing (MFPED), PEBFD, and Power Efficient First Fit Decreasing (PEFFD). The proposed approach was evaluated on the OpenStack Neat cloud service platform. By [11] suggested a glowworm swarm optimization VM placement policy for reducing energy and SLA violations. By [12] discussed implementing a VM consolidation approach that is Quality-of-Service aware, employing the K-medoid interquartile range mid-range (KMIMR) technique. By [13] proposed two modified placement policies—ESVMP and HVMAP—for VM consolidation in cloud data centers.

III. PROPOSED WORK

The EEVMP (Energy-Efficient VM Placement for Optimized Resource Utilization in Cloud Data Centers) technique is introduced here, focusing on selecting the most suitable destination host based on utilization levels and host skewness. Skewness refers to the uneven usage of multiple resources on a server. A data center server comprises various resources such as CPU MIPS, Memory, and Bandwidth. In our proposed EEVMP algorithm, we evaluate three key resources (CPU, Memory, and Bandwidth) during the decision-making process. Let n be the number of resources considered, and r_i represent the usage of each resource. The resource skewness of a server is defined. Another parameter used is the Host Consumption, which averages the utilization of all server resources. When the power usage of the host surpasses a certain threshold, it is deemed overloaded. The usage of an overloaded host is indicated by P, which is the squared sum of its cloud resource consumption beyond the threshold. Let RE denote the total count of overloads on the server, and r_t indicate the overload threshold. Equations for CurrentSkewness and CurrentUtilization before VM migration are provided in Eq. (1) and Eq. (2), respectively.

$$CurrentSkewness = \sqrt{(\Sigma(r_i - \bar{r})^2 / n)} \quad (1)$$

$$CurrentUtilization = \Sigma(r - r_t)^2, \ \ r \in R \quad (2)$$

It is crucial to ensure that the destination server does not become overutilized following the VM migration. Therefore, we must calculate the NewSkewness and NewUtilization of the server post-migration. The equations for determining NewSkewness and NewUtilization are provided in Eq. (3) and Eq. (4). The Skewness Difference (SkeDif) and Utilization Difference (UtilDif) must be lower than their respective difference values, and the server's NewUtilization must be below 65% utilization.

$$NewSkewness = \sqrt{(\Sigma(r_i + v_m - \bar{r})^2 / n)} \quad (3)$$

$$NewUtilization = \Sigma(r + v_m - r_t)^2, \ \ r \in R \quad (4)$$

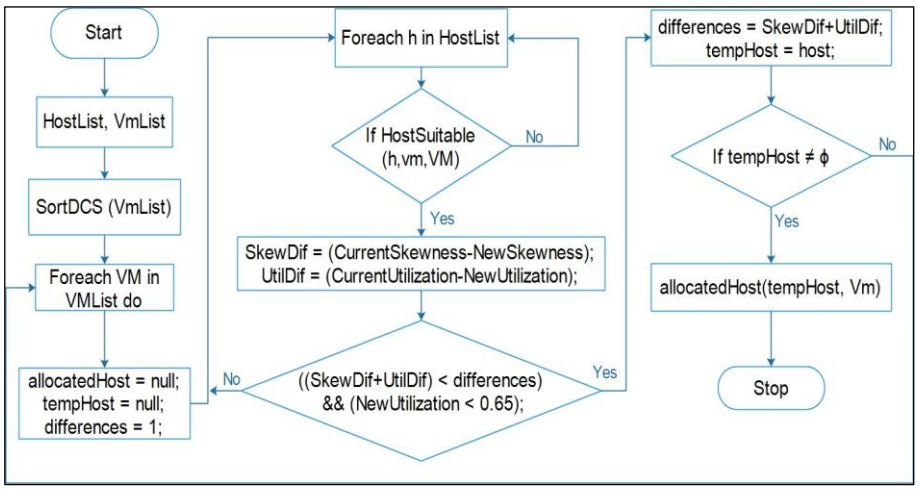

Figure 4: EEVMP Flowchart.
Source: Authors, (2026).

The proposed EEVMP flowchart is presented, highlighting the technique's use of host skewness and utilization before and after VM migration to efficiently identify destination hosts. The EEVMP placement policy first sorts all VMs in descending order based on CPU utilization for migration (Step 1). It then checks each VM in the VMList to find the destination host (Steps 2–5), and evaluates all hosts in the HostList as potential destination hosts (Step 6). If the chosen host has sufficient resources to accommodate the VM without causing overload, it calculates the CurrentSkewness and Utilization before VM Migration and the New Skewness and Utilization after VM Migration.

Algorithm 1 Energy-Efficient VM Placement (EEVMP)

IV. EXPERIMENTAL SETUP

The simulations were conducted on an Acer computer equipped with a Core i5 CPU, 8 GB of RAM, Windows 10 64-bit operating system, a 125 GB SSD, and a 1 TB hard drive. The CloudSim application was utilized to simulate the specified activities. Our experiment was carried out in a data center comprising 800 physical heterogeneous hosts—400 HP ProLiant ML110 G4 and 400 HP ProLiant ML110 G5 [14]. Table 1 provides detailed specifications of the hosts [8]. Table 2 presents the VM configuration based on various speeds and RAM. Table 3 details the server power consumption, and Table 4 outlines the default implementation scenario.

IV.1 DATASETS

The datasets were crucial in comparing performance. We utilized PlanetLab workload traces, which are publicly available real-world datasets, to evaluate our method's performance. PlanetLab serves as a functional cloud for the global research network. These traces include data on CPU consumption of numerous VMs from servers located in 500 different locations across the globe. The dataset traces were randomly collected between March 2010 and April 2020. CPU utilization values for VMs are recorded every 5 minutes in the daily dataset. Table 5 shows the specific properties of the dataset.

IV.2 EVALUATION PARAMETERS

In cloud computing, measuring the quality of cloud services is crucial. In our tests, we assessed the algorithm's performance using six parameters : In cloud computing, measuring service quality is essential, and our algorithm's performance was assessed using six key parameters: Energy Consumption (EC), which calculates the total energy consumed by the data center over a given period based on varying host utilization levels; VM Migrations (VMM), which impacts application performance by causing an average CPU usage reduction of around 10% during downtime and must be minimized; SLA Violation (SLAV), which measures Quality of Service using two sub-metrics — Overload Time Fraction (OTF) and Performance Degradation due to Migrations (PDM) — expressed as SLAV = SLATAH × PDM; Energy and SLA Violation (ESLAV), which balances EC and SLAV and is calculated as ESLAV = EC × SLAV; Energy, SLA Violation and Migration (ESM), which jointly assesses total energy consumption, SLA violations, and migration impact as ESM = EC × SLAV × VMM; and finally, Number of Host Shutdowns (NHS), which counts the physical hosts powered down to conserve energy while maintaining acceptable performance levels within the data center [15].

$$SLATAH = (1/N)\ \Sigma\ (Ts_i / Ta_i) \tag{5}$$

$$PDM = (1/M)\ \Sigma\ (Cd_j / Cr_j) \tag{6}$$

$$SLAV = SLATAH \times PDM \tag{7}$$

$$ESLAV = EC \times SLAV \tag{8}$$

$$ESM = EC \times SLAV \times VMM \tag{9}$$

V. RESULTS AND DISCUSSIONS

The experiment was conducted based on six primary evaluation parameters: Total Energy Consumption (EC), VM Migrations (VMM), SLA Violation (SLAV), Energy and SLA Violation (ESLAV), Energy-SLA Violation and Migration (ESM) and the Number of Host Shutdowns (NHS), evaluated using PlanetLab datasets containing 10 days of data. Our proposed EEVMP strategy was compared against PABFD, IQRMC, PEBFD, ESVMP and HVMAP placement policies.

Table 6: Energy Consumption (EC) for PlanetLab Dataset.

20110303	177.10	119.10	114.97	109.41	112.92	84.56
20110306	135.49	90.73	86.15	78.10	84.72	61.43

Source: Authors, (2026).

Further analysis of Table 12, which compares EEVMP's SLA Violation performance with other algorithms, underscores its superiority in handling SLA constraints. The negative values indicate the percentage reduction in ESLAV achieved by EEVMP. The average SLAV improvement across datasets demonstrates that EEVMP significantly reduces SLA violations. The average SLAV reduction achieved by EEVMP is 141.845 for PABFD, 108.666 for IQRMC, 93.21 for PEBFD, 87.3612 for ESVMP, and 64.5044 for HVMAP, indicating that EEVMP surpasses all other algorithms in maintaining SLA integrity. These findings validate that EEVMP consistently achieves a lower SLA violation rate compared to traditional VM placement policies, thereby ensuring higher Quality of Service (QoS) and improved cloud resource management.

VI. CONCLUSIONS

The primary challenge in cloud computing is to reduce energy consumption and SLA violations while simultaneously meeting user demands. The evaluation of the proposed Energy-Efficient Virtual Machine Placement (EEVMP) strategy demonstrates its effectiveness in enhancing resource management and maintaining service quality in cloud data centers. The results consistently show that EEVMP outperforms existing VM placement policies, including PABFD, IQRMC, PEBFD, ESVMP, and HVMAP, across multiple performance metrics. It significantly reduces energy consumption while ensuring efficient workload distribution, leading to lower operational costs and improved sustainability. Additionally, by minimizing virtual machine migrations, EEVMP reduces system overhead, thereby enhancing overall stability and performance. EEVMP demonstrates an improvement of 141.85% over PABFD, while improvements over IQRMC, PEBFD, ESVMP, and HVMAP are 108.67%, 93.21%, 87.36%, and 64.50%, respectively. Future research will focus on further enhancing VM placement strategies by integrating AI-driven predictive analytics to improve energy efficiency and minimize SLA violations.

ABSTRACT

Switched Reluctance Motors (SRMs) are increasingly adopted in modern electric drive systems due to their mechanical robustness, fault tolerance, and high efficiency. However, their nonlinear magnetic characteristics and discrete torque production often result in pronounced torque ripple, which can limit performance in precision applications. This paper introduces an enhanced optimization strategy for the Torque Sharing Function (TSF) to minimize torque ripple in SRMs. The TSF is essential for regulating instantaneous torque by distributing the reference torque among individual phases according to rotor position, thereby improving torque smoothness and operational stability. The proposed method divides the reference torque into multiple subintervals during phase excitation to control overlap duration and reduce negative torque during commutation. Key control parameters including turn-on, turn-off, and overlap angles are jointly optimized by particle swarm optimization algorithm (PSO) to achieve an effective balance between torque ripple reduction, efficiency, and performance across a wide speed range. Finite element analysis is employed for accurate magnetic characterization, while iterative optimization algorithms ensure consistency, convergence, and robustness. Simulation results validate the proposed framework, showing notable reductions in torque ripple, improved speed regulation, and enhanced dynamic response. The method provides a flexible and scalable control solution applicable to various SRM configurations, promoting advancements in high-performance electric drive systems.

I. INTRODUCTION

Switched Reluctance Motors, characterized by their simple mechanical design and the use of non-wound, salient rotor structures, have become increasingly attractive in modern electric drive applications. Their absence of rotor windings or permanent magnets significantly reduces manufacturing cost and enhances reliability, enabling consistent operation under harsh thermal and mechanical environments. Torque is generated by the inherent magnetic tendency of rotor poles to align with energized stator poles, resulting in a robust and durable electromagnetic drive mechanism suitable for industrial, automotive, and aerospace applications [1]. Despite these benefits, SRMs are hindered by a fundamental performance limitation: high torque ripple. The doubly salient structure, concentrated stator windings, and inherent discontinuous excitation result in large fluctuations in instantaneous torque, often leading to vibration, acoustic noise, and degraded dynamic behavior. These effects are generally more pronounced than in conventional induction or synchronous machines, where smoother electromagnetic torque generation is possible.

Although motor-level improvements, such as refined magnetic circuit design, can partially mitigate this issue, substantial ripple reduction is most effectively achieved through advanced control strategies implemented at the power converter and drive level [1], [2]. Unlike conventional machines that frequently rely on model-based approaches such as field-oriented control, SRM drives are well-suited to real-time, analytically derived, position-dependent current control schemes. This flexibility has led to the development of a diverse range of torque control techniques from basic commutation strategies to computationally adaptive schemes capable of enhancing torque smoothness without requiring structural modifications to the machine [1], [3]. Among these strategies, the Torque Sharing Function has emerged as a central approach for ripple suppression. TSF-based control distributes the total torque reference among the active phases such that the resulting composite torque waveform achieves reduced variation over a full electrical cycle. Early TSF designs employed fixed torque profiles and uniform turn-on angle staggering, providing noticeable ripple reduction but sacrificing copper loss efficiency due to suboptimal current shaping. Subsequent developments introduced adaptive weighting functions that dynamically modify each phase's torque contribution, achieving torque error below 1% and limiting ripple to under 3%, markedly outperforming traditional direct torque control methods, which commonly yield ripples in the range of 15% [4]. More advanced formulations have decoupled the TSF reference waveform from phase excitation timing, allowing excitation angles to be independently optimized in real time for further ripple reduction without altering the total torque reference [5].

Hybrid approaches combining TSF with methods such as super-twisting sliding-mode control have also demonstrated improved robustness, reduced chattering, and greater suitability for demanding applications such as electric vehicle propulsion [6]. While, in [7], a torque ripple reduction strategy for Doubly Salient Electromagnetic Machines (DSEM) is proposed based on the use of Current Given Functions (CGFs). By systematically selecting suitable CGFs and corresponding overlap angles for varying operating conditions, the method enhances current tracking accuracy and improves the torque–ampere ratio. Multiple CGF profiles including linear, cubic, cosine, and exponential functions are evaluated to optimize current distribution during commutation, thereby reducing both torque ripple and copper losses. Furthermore, a modified piecewise Torque Sharing Function described in [8] achieves additional ripple suppression during phase transitions, while model predictive control further attenuates ripple caused by hysteresis-based current regulation. This combined approach streamlines the optimization process by computing phase current trajectories directly as a function of rotor position via the TSF, eliminating the need to manually assign weighting factors in the control cost function. These contributions illustrate a clear progression in TSF methodologies from early static angle-staggering approaches to increasingly dynamic, efficiency-focused, and model-based control frameworks. Each generation of techniques has contributed incremental improvements in torque ripple suppression while simultaneously balancing key considerations such as computational complexity, real-time feasibility, and electromagnetic efficiency. Therefore, this paper introduces a new hyperbolic TSF formulation to further enhance the smoothness of torque transition between outgoing and incoming phases.

Unlike conventional TSFs that rely primarily on turn-on, turn-off, and fixed overlap angles, the proposed method presents hyperbolic shaping coefficients that allow finer control of phase current evolution during commutation. This approach improves torque continuity, suppresses negative torque, and enhances overall drive efficiency. A Particle Swarm Optimization (PSO) algorithm is utilized to automatically tune commutation parameters by jointly optimizing multiple objectives, including torque ripple reduction, copper loss minimization, and electromagnetic smoothness. The proposed method is integrated into a complete control framework and evaluated using a high-fidelity nonlinear finite element model of an 8/6 SRM. Comparative simulation results confirm that the optimized hyperbolic TSF significantly outperforms conventional and non-optimized strategies, offering improved dynamic response, smoother torque profiles, and enhanced overall suitability for high-performance electric drive systems. Within this scope, the present work advances an optimized Torque Sharing Function (TSF) control methodology engineered to substantially mitigate torque ripple and ameliorate the associated spectral attributes of vibration and acoustic noise. The validity of the proposed approach is established through a multi-faceted validation framework incorporating analytical, finite element (FEA), and dynamic system simulations. Thus, the paper proceeds with the following organization: Section II covers the fundamental modelling and electromagnetic equations of the Switched Reluctance Motor. Section III discusses outcomes from finite element modelling, including flux distribution. Section IV elaborates on the Torque Sharing Function control strategy, introducing the novel optimized method. Concluding in Section V, the results are presented and discussed, with a thorough assessment of the strategy's effectiveness in reducing torque ripple.

II. MODELLING OF 8/6 SRM

II.1 FINITE ELEMENT MODELLING

The finite element method (FEM) stands out as a powerful numerical technique for solving electromagnetic field problems, especially when confronted with intricate geometries and pronounced material nonlinearities, as commonly found in switched reluctance machines [9], [10]. To precisely model these complex features, the Ansys Maxwell environment was utilized, incorporating detailed geometric parameters along with a customized automated APDL (ANSYS Parametric Design Language) script specifically designed for the 6/8 SRM configuration under investigation. This integrated approach facilitates efficient, high-fidelity modelling and simulation, delivering accurate and dependable electromagnetic performance results [11] as showing in figure (1).

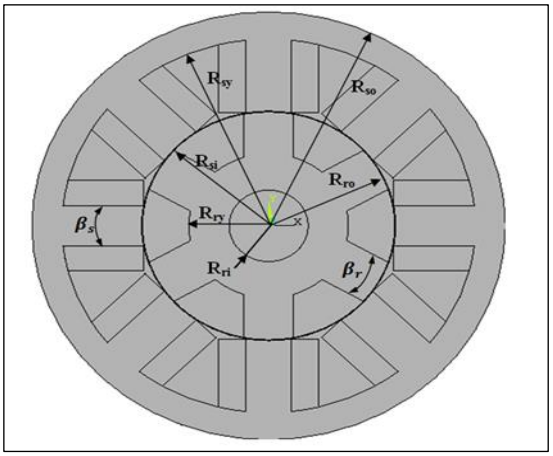

Figure 1: SRM Prototype Dimensions Specification.
Souce: Authors, (2026).

In addition, the details of dimensions and electrical parameters are shown on appendix table (1).

II.2 SIMULATION AND FLUX DISTRIBUTION

The electromagnetic field distribution in the SRM is shaped by the magnetic vector potential as well as the nonlinear permeability of the magnetic material [12].

$$\operatorname{curl}\left(\nu \operatorname{curl}\left(\vec{A}\right)\right) = \vec{J} \tag{1}$$

Where v denotes the magnetic reluctivity and represents the source current density vector. For the case of Cartesian coordinates, this yields:

$$\frac{\partial}{\partial x}\left(\nu \frac{dA_z}{dx}\right) + \frac{\partial}{\partial y}\left(\nu \frac{dA_z}{dy}\right) = -J_z \tag{2}$$

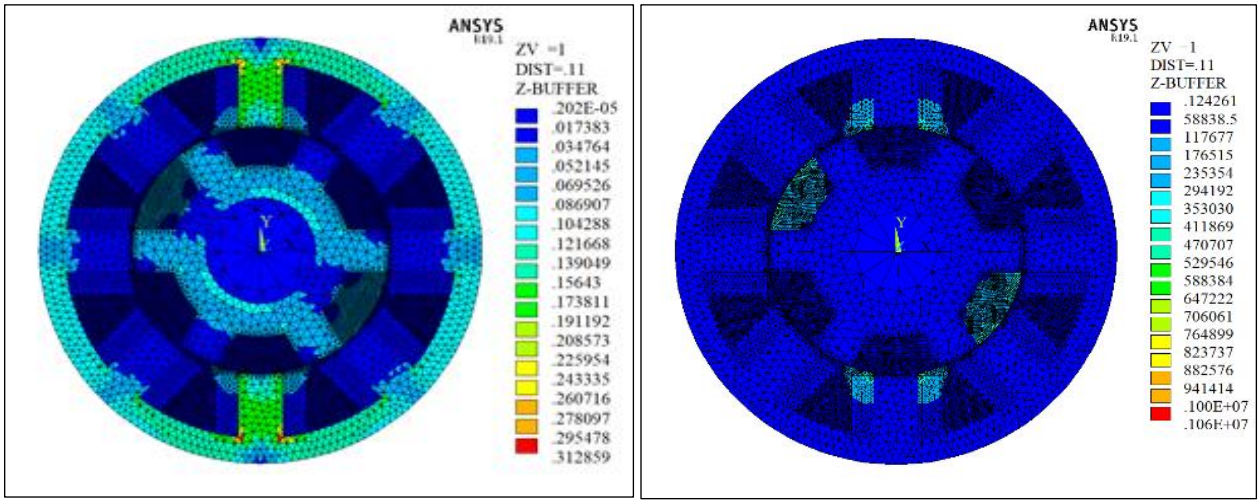
The flux linkage for a single operational step of the motor is determined from the resulting distribution of the magnetic vector potential:

$$\phi = \frac{1}{i}\int_v \overline{JA}\, dV \tag{3}$$

After determining the relevant elements along the machine's axial length, the number of turns per phase, N, is defined in (7), and the winding area for each phase is denoted as S.

$$\phi = \frac{NI}{S}\sum_{k=1}^{N}\left(A_k\, S_k\right) \tag{4}$$

The inductance and magnetic co-energy are determined as functions of the flux linkage using the expressions given below:



$$L(\theta, i) = \frac{\phi(\theta, i)}{i} \tag{5}$$

$$W_{em} = \int_0^I \phi(\theta, i)\, \partial i \,\Big|_{\theta = \text{Const}} \tag{6}$$

Using the co-energy approach, the electromagnetic torque is computed as the partial derivative of the magnetic co-energy with respect to the rotor angular position, while keeping the phase current constant, as given by the following equation:

$$T(\theta, i) = \frac{\partial W_{em}}{\partial \theta}\Bigg|_{\theta = \text{Cons}} \tag{7}$$

Figure 2 presents both graphical and quantitative representations of the magnetic flux density distribution within the 6/8 SRM, with a phase current of 2 A and 12A applied. These results validate the machine's anisotropic inductance profile, a fundamental characteristic for torque production in SRMs. The numerical output further supports subsequent analysis, such as inductance profiling and torque estimation, essential for control strategy development. Figures 3 and 4 show, respectively, the numerical characteristics of the inductance and the static torque are evaluated as functions of the rotor position, first from the aligned to the non-aligned position and then from the non-aligned back to the aligned position. The results are presented for phase currents ranging from 2 A to 16 A. The results illustrate the extent of magnetic saturation in the machine, showing that increasing the current yields progressively larger saturation at higher current levels. By leveraging the previously captured characteristics, the model more accurately represents real-machine behavior and, depending on the formulation adopted, can provide robust results for control design and validation in journal-quality studies [13].

The results illustrate the extent of magnetic saturation in the machine, showing that increasing the current yields progressively larger saturation at higher current levels. By leveraging the previously captured characteristics, the model more accurately represents real-machine behavior and, depending on the formulation adopted, can provide robust results for control design and validation in journal-quality studies [13]. To illustrate the modelling of the 6/8 SRM, a comprehensive schematic of the associated asymmetric bridge converter is presented in figure 5.

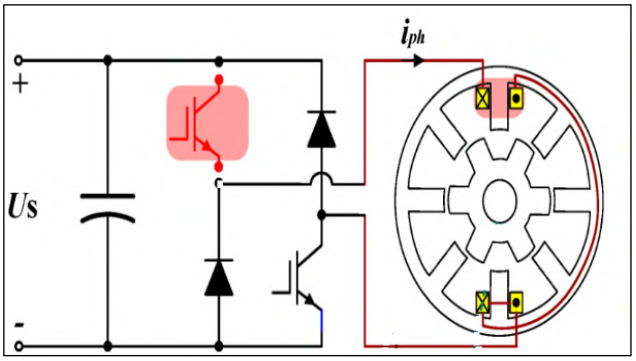

Figure 5: Overview of the 6/8 SRM and its associated asymmetric bridge converter.
Source: Authors, (2026).

The converter topologies of Asymmetric bridge / half bridge (per phase) Feature Two switches/diodes per phase enabling bidirectional current control and independent commutation; widely used with angle control and soft chopping methods [14], [15]. The regulation of an engine constitutes a complex undertaking that calls for the capabilities of adept specialists. Each procedural step is managed independently through the utilization of a hysteresis controller or Pulse Width Modulation (PWM) control. The majority of applications employ an unbalanced bridge configuration to govern the current within the defined hysteresis limits. This asymmetric bridge configuration facilitates three distinct voltage states: $+V_{cc}$ positive, 0 zero, and $-V_{cc}$negative. Consequently, contingent upon the selected control methodology, all of these voltage states are employed to regulate the variable reluctance machine [12]. When a half-bridge converter is used to supply the motor with a hysteresis current controller, a significant negative current change occurs abruptly due to the reversal of voltage polarity across the machine windings. This effect induces vibrations of considerable amplitude [16]. To mitigate this issue, the present study adopts a methodology based on two-step commutation (2sc). Thus, the principle of the methodology is as follows: During the transition phase, the voltage initially applied to phase 1 is at its positive level, corresponding to the DC bus voltage, $V = +V_{dc}$. It then decreases to zero and, after a duration approximately equal to half the resonance cycle, rises to its negative level when the switches open and diodes D1 and D2 conduct. At this point, the applied voltage is reversed to $V = -V_{dc}$ and remains in this state until the current drops to zero. This approach effectively reduces both vibrations and acoustic noise in the machine [17].

III. MATHEMATICAL EQUATION

For a switched reluctance motor, the dynamic system refers to a phase winding which can be modelled as an inductance in series with a resistance, as shown in the figure 6 [13].

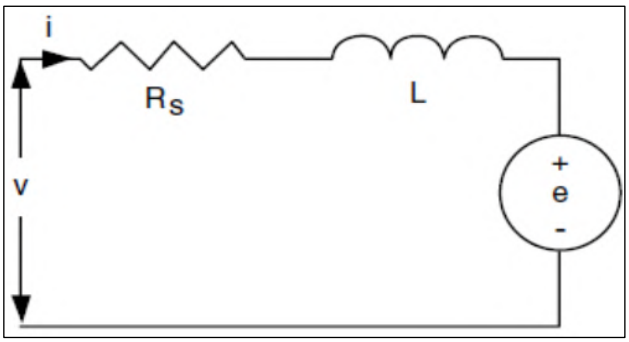

Figure 6: equivalent circuit of one of SRM.
Source: Authors, (2026).

The electromagnetic equation of the model is then written as [11]:

$$V = R_s i_j + \frac{d\Phi_j(\theta, i)}{dt} : j = 1,2,3,4 \quad (8)$$

Where R_s and ϕj are respectively, the resistance and the flux linkage per phase. j indicates the order of the phases. The flux linkage of the SRM is expressed as a function of the inductance characteristic L(θ, i) by the following equation:

$$\phi(\theta, i) = L(\theta, i).i \quad (9)$$

The inductance L(θ,i) depends on both the rotor position and the phase current. Consequently, the phase voltage is determined using Equations (1) and (2):

$$V = R_s.i_j + L(\theta, i).\frac{di}{dt} + \frac{dL(\theta, i)}{d\theta}.i_j.\frac{d\theta}{dt} \quad (10)$$

The back electromotive force E_f (θ, i) is given by:

$$E_f(\theta, i) = \frac{dL(\theta, i)}{d\theta}.i.\omega \quad (11)$$

Furthermore, the mechanical dynamics play a crucial role in electromechanical machines [18], [19]. The mechanical model can be expressed as follows:

$$T_e(\theta, i) = T_m(\theta, i) + f.\omega + j.\frac{d\omega}{d\theta} \quad (12)$$

The parameter j denotes the moment of inertia, ω represents the rotor speed, f is the friction coefficient, and Tm corresponds to the load torque. The electromagnetic torque Te(θ,i) is determined from:

$$T_{ej}(\theta, i) = \frac{1}{2}.i^2.\frac{dL(\theta, i)}{d\theta} : j = 1,2,3,4 \quad (13)$$

Where L (θ, i) denotes the inductance, i represents the total current and R is the phase resistance. Supplying the machine during either the increasing or decreasing inductance region determines the operating mode, as illustrated in Figure 7 [12]. Motor mode (Te > 0) occurs during the rising inductance region (∂L/ ∂θ m > 0). Generator mode (Te < 0) occurs during the falling inductance region (∂L/ ∂θ m < 0).

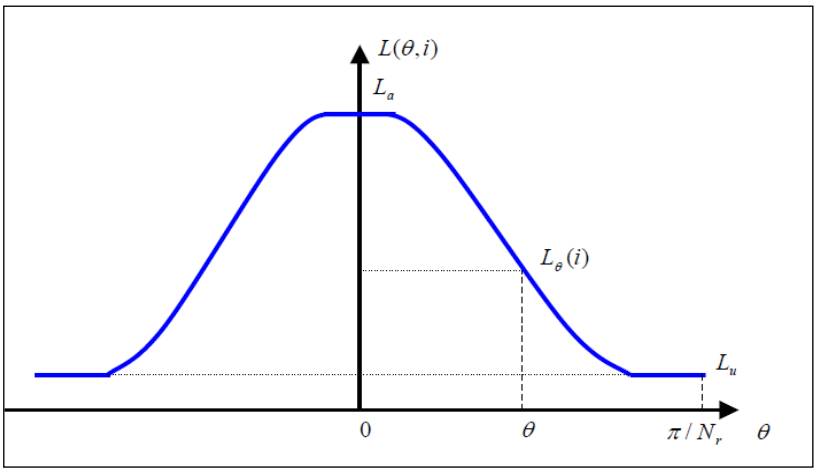

Figure 7: Principle of operation of the SRM.

IV. TORQUE SHARING FUNCTION–BASED CONTROL STRATEGY

The block diagram of the direct instantaneous torque control strategy for the SRM is shown in Figure 8. The torque closed-loop architecture consists of a torque computation unit, a hysteresis controller, a power converter, the switched reluctance motor (SRM), a position sensor, and a current sensor. The total reference torque, T_{ref}, is distributed into phase-specific reference torques, T_{kref}, at discrete rotor positions according to a torque-sharing function. The instantaneous output torque is obtained from a lookup table, and the torque error $(T_{ref} - T_{out})$ is processed by the torque hysteresis controller to generate the gating signals for the power converter. The torque-sharing function defines the overall control strategy, ensuring coordinated and high-precision torque production [20].

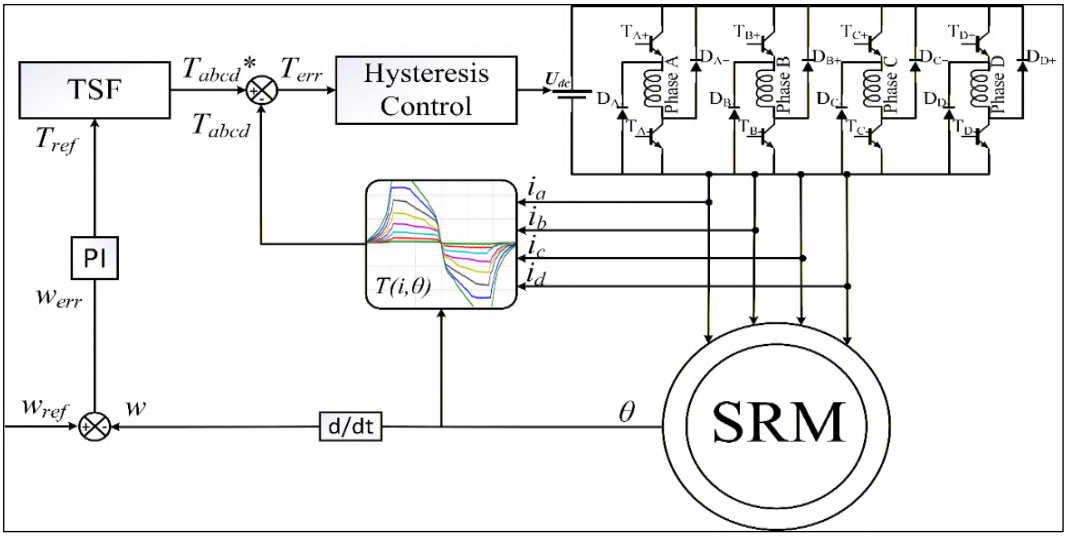

Figure 8: Control block diagram of the SRM based on the TSF strategy.
Source: Authors, (2026).

To ensure the control objective of the Torque Sharing Function (TSF) based on the synthesized instantaneous torque, the following equation must be satisfied for the SRM [20].

$$\begin{cases} T_k(\theta) = T^* f_k(\theta), k = 1,2,\dots,m, \\ \sum_{k=1}^{m} f_k(\theta) = 1, 0 \le f_k(\theta) \le 1 \end{cases} \tag{14}$$

Where $T_k(\theta)$ represents the instantaneous torque of the k-th phase winding, T^* denotes the synthesized instantaneous reference torque, and $f_k(\theta)$ corresponds the torque-sharing function of the k-th phase winding. The TSF directly regulates the peak current of each machine phase, thereby influencing torque ripple and ensuring stable steady-state operation. The fundamental principle of the TSF is to decompose the total reference torque into phase-specific reference torques according to the rotor position, which are then used as control inputs [21], [22]. The reference torque of each phase, T_k^* in equation (15), is obtained by appropriately shifting the TSF. Based on the torque profile within the commutation overlap region, TSFs can be classified into various types, including linear, exponential, cubic, sinusoidal, and cosine functions. Figure 9 illustrates the torque profiles and corresponding current waveforms for linear and cosine TSFs [23].

$$T_k^{*(\theta)} = \begin{cases} 0 & 0 \le \theta \le \theta_{on} \\ T^* \cdot f_{rise(\theta)} & \theta_{on} < \theta < \theta_{on} + \theta_{ov} \\ T^* & \theta_{on} + \theta_{ov} \le \theta \le \theta_{off} - \theta_{ov} \\ T^* \cdot f_{fall(\theta)} & \theta_{off} - \theta_{ov} < \theta < \theta_{off} \\ 0 & \theta_{off} \le \theta \le \tau \end{cases} \tag{15}$$

In equation (15), $T_k^{*(\theta)}$ denotes the total reference torque, f_{frise} defines the slope of the rising phase of the input phase, and f_{fall} is the slope of the falling phase of the output phase. The angles θ_{on}, θ_{off}, and θ_{ov} correspond the turn-on, turn-off, and overlapping positions, respectively, and τ represents the rotor angle period. The relationship between $f_{frise}$and f_{fall} is given by [20], [24]:

$$f_{fall}(\theta) = 1 - f_{frise}(\theta - \varepsilon) \tag{16}$$

The number of TSF parameters can be reduced to two, as angles θ_{on}, θ_{off}, and θ_{ov} are interrelated as follows:

$$\theta_{off} = \theta_{on} + \theta_{ov} + \varepsilon \tag{17}$$

Here, ε=2π/(m Nr) denotes the stroke angle, or angular displacement between adjacent phases, with Nr representing the number of rotor poles. The maximal overlap angle $\theta_{ov,max}$ = τ/4, occurs when the turn-on angle is minimized (θ_{on}= θ_u) and the turn-off angle is maximized (θ_{off} =θ_{al}). For instance, in an 8/6 four-phase SRM, the overlap angle is limited to $\theta_{ov,max}$=15° since τ=60°. At any rotor position, two phases' windings are energized simultaneously due to the stroke angle ε=15°. However, the second constraint $\theta_{ov} \le \tau/2 - \varepsilon$, derived from this relationship, can be more restrictive for certain motor configurations [9].

$$f_{rise}(\theta) = \frac{\theta - \theta on}{\theta ov} \tag{18}$$

And:

$$f_{fall}(\theta) = 1 - f_{rise}(\theta - \varepsilon) \tag{19}$$

IV.1 THE PROPOSED STRATEGY

This paper presents a novel Torque Sharing Function method for reducing torque ripple in SRMs. The total reference torque is subdivided into several subintervals ranging from zero to different nonzero values. These subintervals are assigned to phase torques during excitation modes sequentially, prior to shifting excitation to the next phase. The region where two or more phases overlap during excitation is defined as the overlap region. The influence of the overlap angle θov on motor performance is investigated.

- A large θov smooths the torque waveform but results in energy loss, whereas a smaller θov enhances energy efficiency at the expense of higher torque ripple. This method involves the systematic optimization of the overlap angle, defined as the angular difference between the turn-on and turn-off firing angles. The overlap angle is analytically derived with respect to two critical switching angles by evaluating coefficient parameters that characterize the hyperbolic profile of the proposed TSF. These parameters delineate the commutation intervals spanning from T1 to T4 thereby precisely shaping the commutation trajectory and modulating the torque distribution. This refined control methodology effectively reduces torque ripple and enhances the dynamic performance in SRM drives. The corresponding control relationship can be expressed by the following equation:

$$f(k) = \begin{cases} \dfrac{\theta - T_1}{T_2 - T_1} & if \quad T_1 < \theta < T_2 \\ 1 & if \quad T_2 \le \theta \le T_3 \\ \dfrac{\theta - T_4}{T_3 - T_4} & if \quad T_3 \le \theta \le T_4 \\ 0 & other \end{cases} \tag{20}$$

Where:

$$\begin{aligned} T_1 &= \theta_{on} + a \\ T_2 &= \theta_{on} + b \\ T_3 &= \theta_{off} + c \\ T_4 &= \theta_{off} + d \end{aligned} \tag{21}$$

The various configurations of the suggested TSF approach are depicted in figure 10. In order to find the optimal torque shape, which will be the main factor in reducing the ripple of the torque generated as well as the vibrations produced by the machine, the torque generated at every turn depends on the values of all of the coefficients that will be assigned by the optimization algorithm.

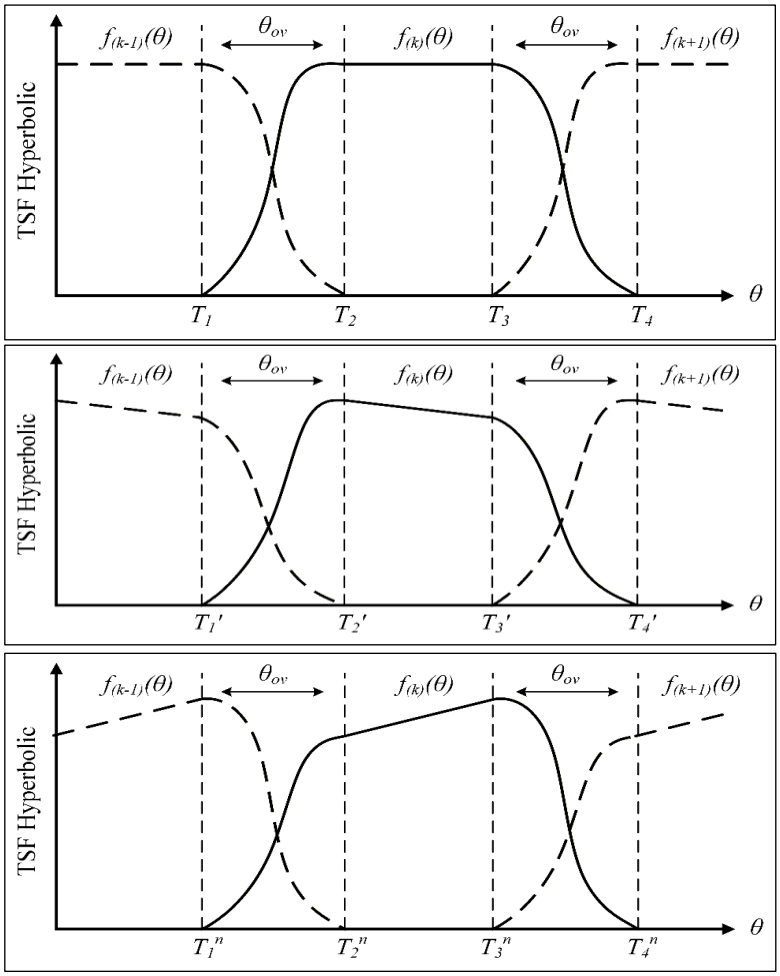

Figure 10: Profiles diagrams of Proposed TSF function.
Source: Authors, (2026).

Simulation studies and parameter optimizations were conducted to determine optimal coefficient values, demonstrating effective reduction in torque ripple and improved SRM performance. This method can be adapted to various SRM configurations for enhanced control precision and efficiency. Compared to conventional linear and cosine torque sharing functions, the proposed optimized TSF demonstrates a substantial reduction in torque ripple under identical operating conditions, confirming its superior capability to manage phase overlap and electromagnetic torque continuity in SRM drives which are represented on Table 1.

V. PARTICLE SWARM OPTIMIZATION

Particle Swarm Optimization (PSO), inspired by natural phenomena, is a computational technique within the field of swarm intelligence. Originally introduced by Kennedy and Eberhart in 1995, PSO simulates the collective behaviour of swarming species, such as birds or fish, as they move toward a target. The algorithm employs a population of particles, each representing a potential solution, which explore the search space to identify the global optimum. During this process, each particle updates its position by considering both its individual best location and the overall best position found by the swarm. In this study, the particle positions represent the PI controller gains and the TSF coefficients a, b, c, and d, along with θ_{on} and θ_{off}, which are iteratively optimized using the mathematical formulations given in Equations (20) and (21) [10]:

$$V_{i,}^{t+1} = wV_i^t + c_1 R_{1i}^t \left(p_{i,best}^t - x_i^t\right) + c_2 R_{2i}^t (G_{best}^t - X_i^t) \tag{22}$$

$$X_{i,}^{t+1} = wV_{i,}^{t+1} + X_{i,j}^t \tag{23}$$

Where, $V_{i,}^{t+1}Vi$ and V_i^t indicate the velocity of each particle at the current and previous iteration, respectively, while X_i^t and $X_{i,}^{t+1}$ denote the particle positions in the current and previous iterations, respectively. $p_{i,best}^t$, and G_{best}^t represent the personal and global best of each candidate and the hole swarm, and $c1,2$ and w are the inertia weight, the personal and global learning coefficient, and R1,2 is a random number. The flowchart for the procedure is shown in figure 11 [10]. The chosen goal function is the normalized torque ripple factor (TRF) in equation (24), defined as the ratio of the peak-to-peak torque variance to its average value across an electrical cycle, is selected as the objective function. The benefit of this dimensionless formulation is that it is directly related to the vibration excitations of the stator and is independent of the load level. Therefore, as in figure 12, minimizing the TRF is a pertinent criterion that is frequently used in the literature to assess SRMs' vibro-acoustic performance.

$$TRF = \frac{T_{max} - T_{min}}{T_{avg}} \tag{24}$$

VI. RESULTS AND DISCUSSIONS

Torque Sharing Function is a well-established technique aimed at reducing torque ripples in switched reluctance motors. To evaluate the effectiveness of the newly proposed optimization method for torque ripple reduction, TSF was implemented both with and without optimization on a 6/8 SRM under various operating conditions. The simulation involved two load torque scenarios at different speeds: case (1) is 7 N.m at 500 rpm and case (2) is 5 N.m at 1000 rpm. For the case (1) the total torque, phase torque, and current waveforms (illustrated in figures (13), (14), and (15) respectively, indicate that prior to optimization the torque ripple was 42.85% with a turn-on angle (Ton) of 2.7° and a turn-off angle (Toff) of 22.5°. Following optimization, these parameters were refined to Ton = 0.2° and Toff = 23.4°, resulting in a reduced torque ripple of 14.28%. Correspondingly, the current and phase torque waveforms demonstrate smoother profiles after optimization, reflecting improved control and reduced phase switching.

Source: Authors, (2026).

(a) (b)

Figure 15: Phase Current profile :(A) Without Optimisation, (B) with optimisation.
Source: Authors, (2026).

Similarly, for the case (2) illustrated on figure (16) the simulations show a torque ripple decrease from 42% (Ton = 5°, Toff = 22°) to 20% after optimization (Ton = 0.26°, Toff = 22.5°). These improvements in torque ripple, along with smoother current waveforms, underscore the efficacy of the proposed TSF optimization method in enhancing SRM performance under varying load and speed conditions. Figure (17) and (18) demonstrate Phase Torque waveform and Phase Current profile respectively. This optimized TSF approach advances motor control by systematically adjusting switching angles to minimize torque fluctuations and improve operational smoothness, which is critical for applications requiring high precision and reliability.

VII. CONCLUSION

This study proposes a novel hyperbolic Torque Sharing Function (TSF) framework that incorporates the optimization of phase commutation angles to enhance TSF efficacy. The switched reluctance motor (SRM) model was developed with high fidelity using ANSYS to accurately represent electromagnetic behaviours. The control methodology focuses exclusively on torque regulation through overlap angle optimization. By dynamically adjusting the TSF, the approach exploits the disparity in torque production capabilities between commutating phases. Simulation results obtained via MATLAB Simulink confirm a substantial reduction in torque ripple alongside improved system robustness and dynamic response. The validity of the method is corroborated by advanced optimization techniques, and its generalizability ensures applicability across diverse SRM configurations.

VIII. APPENDIX

Table 2: Dimensions and electrical parameters of SRM.

Parameters	Notation	Dimensions	
Effective length	L	170mm

ABSTRACT

Mental health challenges among elementary students have become a critical global concern, with 10–20% of children experiencing emotional difficulties that significantly impact educational performance and social development. This research presents a deep learning-based integrated system that simultaneously performs automated attendance tracking and real-time emotion recognition for elementary education settings. The system employs FaceNet with one-shot learning for face recognition-based attendance, requiring only a single reference image per student. For emotion detection, we implement and compare MobileNet-v2 and YOLOv8 on an augmented FER-2013 dataset with seven emotion categories (happy, sad, angry, surprised, scared, neutral, and sleepy). Experiments conducted in an offline simulation setting show that YOLOv8 outperforms MobileNet-v2 across all metrics, achieving 65% accuracy versus 53%, with higher precision (66% vs. 53%), recall (65% vs. 55%), and F1-score (65% vs. 52%). YOLOv8's anchor-free detection and optimized inference pipeline provide operational advantages essential for real-time classroom applications. This integrated system offers educators actionable insights for early identification and timely intervention related to students' emotional well-being while streamlining administrative tasks. Unlike previous studies that focused on either attendance or emotion recognition separately, this research offers a novel, integrated real-time system tailored for elementary education settings.

I. INTRODUCTION

Mental health challenges among children have become a global concern, with approximately 10-20% of children and adolescents worldwide experiencing emotional difficulties that significantly impact their educational performance and social development [1]. These mental health problems account for an estimated 16% of the global burden of disease and injury among those aged 10-19 years, with conditions such as anxiety, depression, and behavioral disorders representing the leading causes of disability in this population [2]. Research demonstrates that children experiencing emotional difficulties, including loneliness, depression, anxiety, and low self-esteem, show measurable impacts on their academic performance, with studies revealing that 21.2% of students had mental health concerns that directly affected their educational outcomes [3]. The consequences extend beyond academic achievement to encompass broader social development, as these challenges can disrupt peer relationships, family dynamics, and overall psychosocial functioning during critical developmental periods [4].

Early identification and intervention strategies are critical for preventing long-term psychological consequences and ensuring optimal child development outcomes, particularly given that half of all mental health issues in adults begin during or before adolescence, making childhood and adolescence opportune times for interventions that can reduce risk for mental disorders and enhance social, emotional, and cognitive functioning [5]. In Indonesia, educational institutions face unprecedented challenges in identifying and addressing students' emotional needs. Recent studies indicate that 20.6% of Indonesian students aged 13-17 years were victims of bullying [6], with comprehensive analysis of 11,479 students from 403 schools revealing that male students, those who missed school, were late, repeated grades, or attended rural schools with small class sizes faced higher risks of bullying victimization [7]. Cross-sectional surveys using the International Society for the Prevention of Child Abuse and Neglect (ISPCAN) Child Abuse Screening Tool have documented significant prevalence of physical, verbal, and sexual violence among adolescents in West Java, a province representing 18% of Indonesia's total population [8]. The mental health landscape is equally concerning, with 95.4% of Indonesian youth aged 16-24 experiencing anxiety as the most prevalent mental health problem [9], while students in the 12-15 years age group demonstrated the worst mental health levels during recent assessments [10]. Furthermore, Indonesian adolescents face increased risk of developing depression and anxiety disorders, largely attributed to insufficient mental health literacy and awareness that often leads to delayed recognition and treatment [11]. The crisis of child protection has intensified since 2019, with increasing cases of child abuse across the nation [12], highlighting the urgent need for innovative approaches to monitor student wellbeing in educational settings through comprehensive screening tools, trauma-informed interventions, and enhanced support systems that address the complex interplay of bullying, abuse, and mental health challenges facing Indonesia's substantial child population.

The emergence of Society 5.0 has introduced advanced technological solutions in educational environments, particularly automated attendance systems using face recognition technology. Society 5.0 represents a transformative vision for the future driven by integrating digital technologies and human-centered approaches, fusing with cyber-physical spaces to create a smart society that addresses educational challenges through innovative and collaborative solutions [13]. While these systems have demonstrated significant efficiency improvements, reducing attendance recording time by up to 90%, research shows that automated face recognition attendance systems achieve 96.4% recognition accuracy with processing times between 1.3-2.3 seconds, effectively minimizing human errors, preventing proxy attendance, and improving data security compared to traditional manual methods [14]. The systems deliver real-time attendance updates and enhance precision while reducing manual labor, with implementations showing that attendance can be automatically tracked and recorded with over 95% accuracy [15]. However, their potential for integration with emotion recognition capabilities remains largely unexplored, despite emerging research demonstrating that real-time automatic emotion recognition systems can be developed incorporating facial features for classroom assessment using deep learning models [16]. Studies indicate that emotion recognition is gaining popularity in education for improving students' learning processes and can measure online learners' affective states of engagement and concentration using emotion data extracted from facial features captured by standard web cameras [17]. The convergence of these technologies presents unprecedented opportunities for smart classroom monitoring systems that could simultaneously track attendance and assess student emotional engagement, creating comprehensive educational analytics platforms that align with Society 5.0's vision of human-centered technological integration in learning environments [13].

Despite the availability of sophisticated deep learning algorithms such as MobileNet-v2 and YOLOv8 for image classification tasks, there is limited research comparing their effectiveness in real-time emotion detection within educational contexts. Recent comparative studies in classroom environments have demonstrated that YOLOv8 achieves 97.61% accuracy for student attention monitoring, while MobileNet-v2, when tested alongside VGG-19 and ResNet-101, shows VGG-19 outperforming with 99.56% accuracy for classification tasks on cropped student images, indicating that YOLO models excel in speed and real-time object detection but traditional CNN architectures like VGG-19 perform better for classification accuracy [18]. Specialized research on pediatric facial expression recognition reveals that MobileNetV2 achieves approximately 60% F1-score across all ethnicities when tested on children's facial expressions, with notable accuracy variations of up to 11.56% between different ethnic groups [19]. Comprehensive evaluations of ten state-of-the-art deep learning models, including MobileNet V1, for facial expression recognition tasks show varying performance metrics in terms of test accuracy, training time, and weight file size [20]. However, systematic reviews of academic emotion classification reveal that the number of real-time FER systems is significantly less than non-real-time systems, with most studies achieving top-1 accuracy of 94.6% but lacking comprehensive real-time implementation frameworks [21]. Furthermore, the integration of attendance systems with emotion recognition technologies lacks comprehensive evaluation, particularly regarding their practical implementation in elementary school environments, as current research focuses primarily on university-level student attention monitoring using deep learning techniques with approximately 7 hours of video footage from 120 undergraduate students [18], while studies specifically targeting elementary school contexts remain sparse despite the demonstrated feasibility of improved YOLOv8 models for classroom behavior detection and the growing need for non-invasive, automated systems that can simultaneously track attendance and monitor emotional wellbeing in younger student populations [22]. However, to the best of our knowledge, there is still no integrated approach that simultaneously combines a FaceNet-based (one-shot) attendance system with real-time emotion detection, particularly for elementary school students (see Table 1).

Table 1: Literature review.

Study	Core Technique(s)	Education Context	Key Limitations
[23]	FaceNet on Jetson Nano for automatic attendance	University lectures	1) Attendance only, no affect analysis. 2) Edge device struggled under low-light conditions.
[24]	CNN with HOG + MMOD face detection; real-time attendance	University	1) Requires multiple reference images per student. 2) Does not address student emotional states.
[25]	OpenCV face recognition + basic FER (FER-2013)	Technical college	1) Emotion module uses lightweight heuristics, yielding modest accuracy.

			2) Feedback component still manual.
[26]	Deep-learning attendance (model unspecified)	High school	1) Paper focuses on system architecture; lacks rigorous emotion component. 2) No comparative model analysis.
[27]	YOLOv8 face detection + MobileNetV2 face ID	Engineering undergrads	1) Attendance only; emotion not integrated.
[28]	Comparative FER using pre-trained CNNs (VGG, ResNet, MobileNet)	Online higher-ed courses	1) No real-time constraints; batch-mode evaluation. 2) Does not link FER to attendance data.
[29]	FER models benchmarked for virtual learning sessions	K-12 online	1) Pure emotion study, attendance outside scope. 2) Dataset bias toward frontal faces.
[30]	YOLOv8 (five variants) for facial-expression monitoring	University LMS sessions	1) Covers six emotions only; fatigue/sleepiness absent.

Source: Authors, (2026).

This study contributes by developing and evaluating a deep learning-based integrated system that not only streamlines attendance administration but also supports the early identification of students' emotional well-being in classroom settings. Specifically, we implement and compare MobileNet-v2 and YOLOv8 for real-time emotion classification integrated with a FaceNet-based one-shot attendance system, providing educators with timely insights to enable more responsive and supportive learning environments.

II. THEORETICAL REFERENCE

II.1 DEEP LEARNING FUNDAMENTALS AND APPLICATIONS IN EDUCATION

Deep learning is a major branch of machine learning that leverages multi-layered artificial neural networks to learn patterns from complex and large-scale data, with key architectures including Convolutional Neural Networks (CNN) for image analysis, Recurrent Neural Networks (RNN) for sequential data, and Transformers, which are increasingly influential in computer vision and natural language processing due to their attention mechanisms [31]. Training these networks relies on algorithms such as backpropagation and various optimizers like Adam or SGD to minimize errors and improve accuracy, while regularization methods, including dropout and batch normalization, are essential for preventing overfitting and enhancing model generalization [32]. Data augmentation is also frequently applied to enhance robustness, especially when working with limited or imbalanced datasets, as demonstrated in comprehensive surveys of deep learning techniques applied to educational data mining scenarios [33]. In the education sector, deep learning has enabled the development of personalized learning platforms, real-time student behavior analysis, and adaptive assessment tools, with research showing that hybrid frameworks combining reinforced learning and deep learning can accurately predict students' personal learning needs through end-to-end models with retrieval attention mechanisms [34]. Educational data mining with deep learning has achieved significant breakthroughs in four typical scenarios: knowledge tracing, student behavior detection, performance prediction, and personalized recommendation, with studies demonstrating that deep neural network-based prediction systems can achieve up to 96.3% accuracy in mining and learning knowledge for users, far exceeding traditional algorithms like support vector machines, Bayesian theory, and K-means [35]. Real-time applications such as automated attendance and emotion detection depend on efficient models and optimized architectures like MobileNet or EfficientNet, which allow deployment on devices with limited computational power, while deep learning techniques for detecting student disengagement emphasize computer vision and affective computing as effective approaches, focusing on facial expressions, eye movements, and posture assessment [36]. The performance of these models is commonly measured by metrics such as accuracy, precision, recall, F1-score, and inference speed, ensuring both reliability and practicality in real-world educational environments, with recent implementations of intelligent education systems based on convolutional neural networks and memory augmented neural networks proving effective and swift in tracking students' knowledge learning status [37].

II.2 FACE RECOGNITION TECHNOLOGY AND ONE-SHOT LEARNING

Face recognition technology has evolved from traditional image processing techniques such as Eigenfaces and Fisherfaces to modern, deep learning-based approaches, with comprehensive literature reviews demonstrating that while classical algorithms depend on handcrafted feature extraction, deep learning models—particularly those based on CNN—automatically learn hierarchical facial features, resulting in significantly improved accuracy and robustness in complex environments [38]. Traditional methods based on hand-crafted features and traditional machine learning techniques have recently been superseded by deep neural networks trained with very large datasets, with the transition occurring around 2015 when state-of-the-art face recognition became rooted in deep learning models [39]. To overcome the limitation of requiring large labeled datasets, one-shot and few-shot learning methods have gained importance, with approaches such as Siamese networks enabling models to recognize new classes or identities from just one or a few examples by learning a similarity metric in an embedding space, a capability that is highly valuable in real-world applications, such as educational settings where only one reference image per student is available [40]. Modern face recognition models like FaceNet, DeepFace, and ArcFace further enhance identification accuracy by mapping facial images into a compact embedding space where distances directly reflect facial similarity, with Facebook's DeepFace achieving 97.35% accuracy on the LFW benchmark, reducing the error of the previous state-of-the-art by 27% through training on 4.4 million faces from 4,030 subjects [38]. FaceNet employs a triplet loss function to optimize this embedding, ensuring that images of the same person are closer together, while images of different people are separated by a defined margin, requiring careful selection of similarity metrics (e.g., Euclidean or cosine distance) and optimal threshold settings to minimize false acceptances and rejections in operation [41].

When integrated into automated attendance systems, these technologies enable real-time student identification, greatly reducing manual workload and mitigating proxy attendance issues, with studies showing that deep convolutional networks can achieve recognition rates of more than 87% while the classical method of Turk and Pentland achieves 75.5% [42]. However, successful deployment must address challenges like varying illumination, occlusions, and pose differences commonly encountered in educational environments, as many modern datasets combine different factors that influence face recognition, such as face pose, occlusion, illumination, facial expression and image quality, thus requiring robust model design and preprocessing that are crucial for maintaining high recognition accuracy and practical usability in schools where faces in-the-wild present high variability due to head poses, aging, occlusions, illumination conditions, and facial expressions [38].

II.3 EMOTION RECOGNITION SYSTEMS AND MULTI-TASK LEARNING

Facial expression analysis is central to automated emotion recognition, drawing on frameworks such as Ekman's basic emotions (happiness, sadness, anger, surprise, fear, disgust, and neutrality) and the Facial Action Coding System (FACS), which provides a comprehensive taxonomy of facial muscle movements, with systematic reviews confirming that Paul Ekman has delved most deeply into this subject, proposing six basic universal emotions that can be accurately identified through facial expressions [43]. FACS encodes movements of individual facial muscles from distinct momentary changes in facial appearance, serving as the first universal method of coding and measuring facial movement that quantifies facial actions based on muscle movements, so that each expression can be represented as a combination of action units [44]. These frameworks form the basis for labeling and annotating datasets used in machine learning research, with modern deep learning approaches greatly advancing emotion detection capabilities through CNN that are widely employed due to their proficiency in capturing spatial features from facial images [45]. Recent architectures also utilize attention mechanisms to focus on relevant facial regions that are most indicative of specific emotions, with studies demonstrating that CNN-based models can achieve recognition rates exceeding 86.71% on reclassified datasets like FER2013 [45]. Real-time emotion detection, essential in educational settings, benefits from optimized models capable of rapid inference without significant computational overhead, particularly when addressing the challenge that automatic FER is one of the key tasks in computer vision for applications in healthcare, education, psychology, and human-computer interaction [45]. Multi-task learning enables systems to conduct joint face recognition and emotion detection within a single pipeline, leveraging shared feature representations, which enhances efficiency and accuracy but introduces technical complexities in balancing tasks and managing conflicting objectives [46]. Despite progress, significant challenges remain as emotion recognition systems are sensitive to cross-cultural variations in facial expression, differences in age groups, and lighting or occlusion issues present in real-world environments [43], with research showing that emotions are subjective and two people can have different opinions on the same facial image, particularly given that there are slight differences between certain facial expressions such as fear and surprise, disgust and anger [45]. Practical implementation depends on robust datasets—such as FER-2013, which offers a range of annotated facial expressions—and careful application of data augmentation to improve model generalization, with performance commonly evaluated using metrics such as accuracy, precision, recall, and F1-score to gauge system effectiveness in operational conditions [47]. Finally, system integration involves not only technical aspects, such as aligning face detection, recognition, and emotion inference modules, but also handling issues like latency, data privacy, and seamless interaction with existing educational platforms, ensuring consistent accuracy across diverse populations and deployment scenarios while meeting real-time requirements that may constrain the complexity and depth of neural networks utilized [48].

III. MATERIALS AND METHODS

The following methodology diagram illustrates the comprehensive framework developed for integrating face recognition-based attendance systems with real-time emotion detection in elementary educational settings (see Figure 1). This multi-stage approach encompasses data acquisition, preprocessing, model training, and system deployment phases, demonstrating the seamless integration of one-shot learning techniques for student identification with advanced deep learning architectures for emotion classification. The methodology emphasizes the practical implementation considerations necessary for deployment in real classroom environments, including computational efficiency requirements and real-time processing constraints that are essential for maintaining educational workflow continuity.

III.1 DATASET

The research utilizes two main datasets to support both face recognition and emotion classification tasks. The primary dataset for face recognition consists of a single attendance photo for each student, captured under consistent lighting and pose to ensure identification accuracy. For emotion recognition, the study leverages the FER-2013 dataset [49], which contains over 7,000 facial images categorized into seven core emotion classes: happy, sad, angry, surprised, scared, neutral, and sleepy (see Figure 2). To address class imbalance and improve the robustness of the models, data augmentation techniques such as flipping, rotation, and brightness adjustment are applied. Furthermore, all datasets are divided into training, validation, and test subsets using an 80:10:10 ratio, ensuring fair and consistent evaluation across all emotion categories.

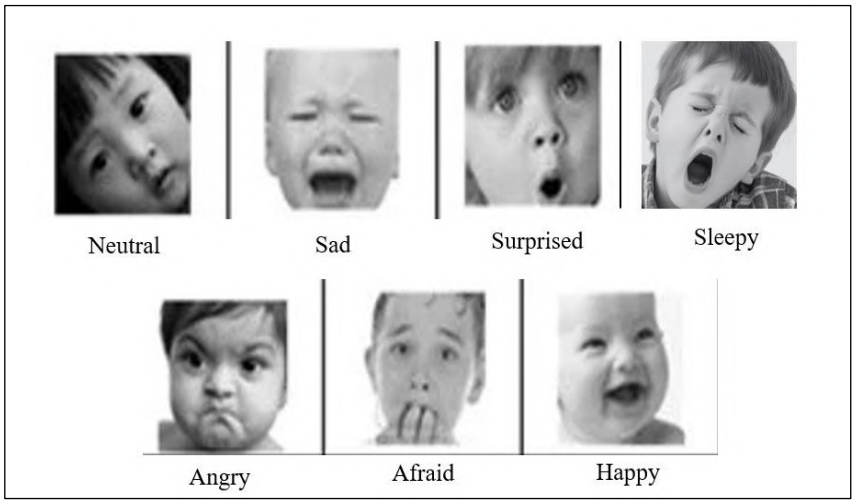

Figure 2: FER2013 Dataset overview.

III.2 DATA PREPROCESSING

Prior to training, several preprocessing steps are conducted to enhance the quality and uniformity of the input data. Firstly, facial regions are automatically detected and cropped from the original images, standardizing the inputs for both recognition and classification models.

All images are resized to a fixed size suitable for the model architectures used, and pixel values are normalized—either scaled to a range or standardized—depending on model requirements. Augmentation operations further increase variation within the training data, helping models generalize better to real-world scenarios, such as varying lighting or occlusions often present in school environments.
Gambar preprocess

III.3 MODEL ARCHITECTURE AND TRAINING

We implemented the system using Keras with TensorFlow as the backend for model development and training, leveraging OpenCV for image acquisition, face detection, and preprocessing operations, and NumPy/Pandas for data handling and pipeline utilities. Implementation of face recognition is carried out using a one-shot learning approach, such as FaceNet [50], which employs a triplet loss mechanism to generate robust facial embeddings from limited examples. These embedding vectors form the basis for real-time identification of students during attendance. For emotion recognition, the study compares two deep-learning architectures: MobileNet-v2 [51], known for its efficiency and suitability for edge devices, and YOLOv8 [52], recognized for its real-time object detection performance.

FaceNet Triplet Loss Function

$$L_{triplet}(a,p,n) = \max(0, D(a,p) - D(a,n) + \alpha) \tag{1}$$

Equation 1 represents the triplet loss function used in FaceNet for one-shot learning in face recognition. The function learns to minimize the distance between an anchor face and a positive example (same person) while maximizing the distance to a negative example (different person). In this formulation, $L\_triplet$ represents the triplet loss value, while a denotes the anchor image serving as the reference face, p indicates the positive image containing the same person as the anchor, and n represents the negative image showing a different person from the anchor. The distance functions $D(a,p)$ and $D(a,n)$ calculate the distances between anchor-positive and anchor-negative embeddings respectively, while α serves as the margin parameter that enforces separation between positive and negative pairs. The function ensures that the distance between anchor-positive pairs is smaller than anchor-negative pairs by at least the margin α, enabling robust face recognition with minimal training examples per identity.

MobileNet-v2 Inverted Residual Block

$$Y = \text{ReLU6}\big(W_2 * (W_1 * X)\big) \tag{2}$$

Equation 2 describes the inverted residual block architecture in MobileNet-v2, which forms the core building block for efficient emotion recognition. This lightweight design enables real-time processing on mobile and edge devices. The variables in this equation represent different components of the inverted residual structure: Y represents the output feature map, while X denotes the input feature map. W^1 corresponds to the first 1×1 convolution weights in the expansion layer, and W^2 represents the second 1×1 convolution weights in the projection layer. ReLU6 functions as the Rectified Linear Unit activation function capped at 6. The inverted residual structure first expands the feature channels, applies depthwise convolution, then projects back to lower dimensions, significantly reducing computational complexity while maintaining emotion classification accuracy.

YOLOv8 Multi-Component Loss Function

$$L = L_{box} + L_{obj} + L_{cls} \tag{3}$$

Equation 3 represents the total loss function for YOLOv8 used in emotion detection, combining three essential components to optimize both object detection and classification performance. The components of this loss function serve distinct purposes in the training process: L_{total} represents the combined total loss for model optimization, L_{box} corresponds to the bounding box regression loss that ensures localization accuracy, L_{obj} denotes the objectness loss that determines confidence that an object exists, and L_{cls} represents the classification loss responsible for emotion category prediction. Each component serves a specific purpose where L_{box} ensures accurate facial region localization, L_{obj} determines the presence of faces in the image, and L_{cls} correctly identifies the emotional state. This multi-task approach enables YOLOv8 to simultaneously detect faces and classify emotions in real-time educational environments, achieving superior performance compared to traditional single-task approaches.

III.4 MULTI-TASK SYSTEM INTEGRATION

The developed system integrates face recognition and emotion detection within a unified attendance workflow. During each attendance event, the system verifies the identity of the student and simultaneously classifies their observed emotion, recording both pieces of information. This multi-task integration relies on efficient sequential processing and the use of lightweight, highly optimized model architectures to ensure that operation remains responsive and does not interfere with teaching activities. Strategies such as model quantization and deployment on edge devices are considered to further minimize inference time.

III.5 EVALUATION AND VALIDATION

All experiments were conducted in an offline simulation setting rather than a live school deployment; the models were trained and evaluated on datasets. Comprehensive evaluation is conducted to measure both the accuracy and practicality of the system in real-world settings.

Performance is assessed using standard classification metrics on the test set to determine the reliability of both the face recognition and emotion detection components. The evaluation framework incorporates four fundamental metrics that provide comprehensive insight into model performance across different aspects of classification effectiveness (see Equation 4-7) [53].

Accuracy Evaluation Function

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \tag{4}$$

Precision Evaluation Function

$$\text{Precision} = \frac{TP}{TP + FP} \tag{5}$$

Recall Evaluation Function

$$\text{Recall} = \frac{TP}{TP + FN} \tag{6}$$

F1-Score Evaluation Function

$$\text{F1-Score} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{7}$$

The accuracy equation measures the overall classification performance by calculating the proportion of correctly predicted instances across all emotion categories, where TP represents true positive predictions, TN denotes true negative predictions, FP indicates false positive predictions, and FN represents false negative predictions, making it essential for assessing system reliability in classroom environments. The precision metric evaluates the reliability of positive predictions by measuring the proportion of correctly identified positive instances among all predicted positive cases, which is crucial for minimizing false alarms that could trigger unnecessary interventions in educational settings. The recall metric measures the system's ability to capture all actual positive instances, ensuring that important emotional indicators requiring immediate attention are not missed, which is critical for early intervention in student mental health monitoring. The F1-score provides a balanced evaluation by calculating the harmonic mean of precision and recall, creating a single metric that balances the trade-off between avoiding false predictions and detecting all relevant emotional states, making it particularly valuable for practical deployment in educational environments where both reliability and sensitivity are paramount.

IV. RESULTS AND DISCUSSIONS

This section discusses the outcomes of integrating one-shot face recognition and deep learning-based emotion detection within an elementary school attendance system. The evaluation encompasses both technical performance and real-world applicability in the educational context.

IV.1 FACE RECOGNITION PERFORMANCE

The face recognition component, powered by FaceNet and one-shot learning, allowed for the accurate identification of students using only a single reference image per individual. Throughout the implementation, the system demonstrated high reliability even under varying classroom lighting and student pose changes. This finding supports the practical deployment of face recognition as a foundation for automated attendance in schools, enabling efficient and contactless identity verification.

IV.2 EMOTION DETECTION ANALYSIS

To assess emotion detection capabilities, both MobileNet-v2 and YOLOv8 models were systematically trained and evaluated on the balanced, augmented FER-2013 dataset. The comparative analysis was conducted using standardized evaluation protocols to ensure fair assessment across both architectures. The quantitative results, presented in Table 2, demonstrate substantial performance improvements achieved by YOLOv8 compared to MobileNet-v2 across all evaluation metrics.

Table 2: Model Comparison.

	Accuracy	*Recall*	*Precision*	*F1-score*
MobileNetv-2	0.53	0.55	0.53	0.52
YOLOv8	0.65	0.65	0.66	0.65

Source: Authors, (2026).

YOLOv8's superior performance across all evaluation metrics—achieving 65% accuracy compared to MobileNet-v2's 53%—demonstrates its enhanced capability for real-time emotion recognition in dynamic classroom environments. The 12% improvement in accuracy translates to significantly more reliable emotion detection, which is crucial for educational applications where false classifications could impact student assessment and intervention decisions. Furthermore, YOLOv8's balanced precision and recall scores (66% and 65% respectively) indicate consistent performance across different emotion categories, suggesting reduced bias toward specific emotional states that commonly affect classroom-based recognition systems. Notably, our YOLOv8 accuracy exceeds the 60.57% achieved by a pediatric facial expression classifier trained on children's faces from the CAFE dataset [19], as well as the 60% overall accuracy reported by a standard CNN on FER-2013 [54], underscoring YOLOv8's real-time effectiveness and suitability for monitoring emotional states in elementary school populations. The architectural advantages of YOLOv8 contribute significantly to its operational superiority in educational settings. Its anchor-free detection mechanism eliminates the need for predefined anchor boxes, enabling more flexible and accurate localization of facial regions under varying classroom conditions, including different seating arrangements, lighting variations, and student movements. Additionally, the optimized inference pipeline of YOLOv8 processes images with minimal computational overhead, making it particularly suitable for deployment on standard classroom hardware where computational resources may be limited. This fast inference capability ensures that the emotion recognition process does not interfere with normal classroom activities while maintaining the responsiveness required for real-time monitoring applications. To provide comprehensive insight into model performance characteristics, the confusion matrix for YOLOv8 (Figure 5) illustrates the classification accuracy distribution across the seven emotion categories: happy, sad, angry, surprised, scared, neutral, and sleepy. This matrix reveals both the strengths and limitations of the model, showcasing true positive rates for each emotional state while highlighting potential areas for improvement through analysis of false positive patterns. The diagonal elements represent correct classifications, while off-diagonal elements indicate misclassification patterns that can inform future model refinements and training data augmentation strategies.

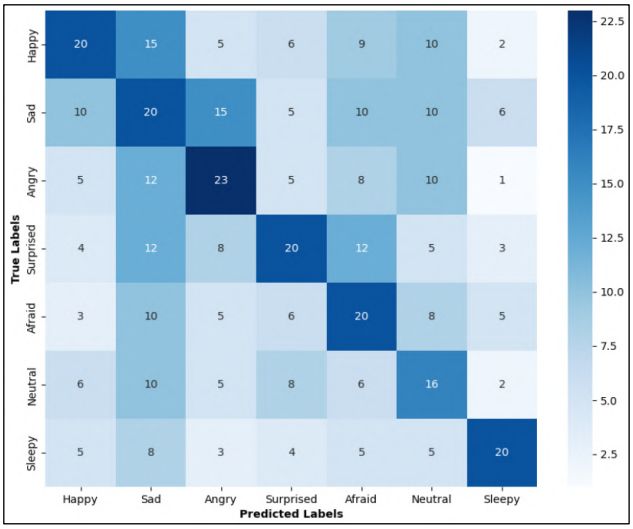

Figure 5: Confusion matrix for YOLOv8.
Source: Authors, (2026).

The visual inference results (Figure 6) demonstrate practical detection outcomes across diverse classroom scenarios, illustrating the model's capability to accurately identify emotional states under real-world conditions. These examples showcase successful emotion detection across different lighting conditions, facial orientations, and partial occlusions commonly encountered in educational environments. Each inference output includes confidence scores and bounding box accuracy, providing transparent insight into the model's decision-making process and enabling educators to assess the reliability of emotion predictions for individual students during classroom monitoring activities.

IV.3 DISCUSSION

These results show that not only does the system streamline and automate attendance, but it also introduces a daily, scalable way for teachers and counselors to monitor student emotions. Such an approach offers potential as an early-warning mechanism for students who might be experiencing emotional distress—supporting interventions before academic or behavioral declines manifest. Recent international studies reinforce the value of integrated multi-task frameworks for educational wellbeing: [55] proposed a multi-task learning model for classroom expression classification that jointly predicts multiple affective states, achieving an 8% improvement in overall recognition accuracy compared to single-task baselines. Likewise, the MT-RCAF framework demonstrated simultaneous EEG-based emotion and mood-disorder detection with average accuracy gains of 3.2% for emotion recognition and 3.9% for mood-disorder classification, illustrating the efficacy of residual cross-attention in shared representations for student wellbeing applications [56]. However, several challenges and limitations must be acknowledged. The emotion recognition models, while robust, can be affected by subtle expressions, occlusions, or cultural differences in emotional display. Data augmentation helps address these, but further improvements could come from expanding the dataset with more diverse classroom images or employing ensemble/hybrid modeling. Additionally, incorporating multimodal inputs—such as audio cues and contextual metadata—through advanced multi-task architectures may enhance resilience against visual ambiguities and better capture the complex dynamics of real-world educational environments.

V. CONCLUSIONS

This research demonstrates that integrating face recognition based on one-shot learning with deep learning–based emotion detection can enhance both attendance automation and the monitoring of students' emotional states in elementary schools. The primary novelty of this work lies in unifying two critical functions—automated attendance and real-time emotion monitoring—into a single, lightweight system, a combination that has been scarcely implemented and evaluated in elementary education settings.

Empirically, the superior performance of YOLOv8 over MobileNet-v2 underscores its practical viability for real-time emotion recognition where both accuracy and speed are required. Beyond streamlining administrative tasks, the system provides actionable insights for early identification and intervention related to students' emotional well-being, aligning with the growing need for mental health support in education. All findings reported here derive from offline simulations (no in-situ school deployment). For future work, we plan to expand and diversify the training data, optimize model parameters, and conduct comprehensive, in-situ evaluations across diverse school contexts to maximize robustness, improve generalizability, and ensure sustained, ethical impact.

ABSTRACT

In the world, the most common cause of visual impairment is retinal abnormalities. In the diagnosis of the retina, optical coherence tomography (OCT) is usually used, since it gives high-resolution cross-sectional images that show detailed retinal structures. In this research, a lightweight deep learning architecture called RetSEOS-Net is presented to use OCT images to recognize retinal diseases automatically. The framework initially uses a guided median filtering in minimizing OCT scans speckle noise. A model of attention-based U-Net is then employed to divide the retinal area, which is followed by a module based on ShuffleNet to obtain the efficient deep features. An Enhanced Osprey Optimization Algorithm (EOOA) is added to the features to refine them and work on the hyperparameters to increase the quality of features and the performance of the network. Finally, the fined features are categorized with a Softmax layer. The framework was tested on an OCT dataset that had four different categories namely diabetic retinopathy (DR), macular hole (MH) and central serous retinopathy (CSR) and normal. The recommended model achieved an accuracy of 96.79% in classification. The findings reveal that RetSEOS-Net is a good and computationally efficient model of automated screening of retinal diseases using OCT.

I. INTRODUCTION

It Retinal diseases form one of the leading expressions of both blindness and the visual impairment in the world, which poses a significant dilemma to global healthcare systems. According to the WHO, 2.2 billion individuals in the world are faced with vision impairment, and such retinal illnesses as diabetic retinopathy, and other retinal abnormalities [1]. Moreover, according to the reports of the IAPB, retinal diseases are also becoming a constantly growing issue as a result of aging and the increase in the number of systemic diseases like diabetes [2]. As an example, diabetic retinopathy by itself has over 100 million people all over the globe and is expected to increase dramatically in the near time eras [3]. Such statistics help to point out the importance of early diagnosis to prevent the irretrievable vision loss. OCT has also made it possible to see microstructure of the retina and clinicians can see the pathological alterations of intraretinal cystoid spaces, subretinal fluid build-up, drusen deposition, detachment of the retinal pigment epithelium and the destruction of the ellipsoid zone. These biomarkers of structure are significant in the diagnosis and distinguishing between the retinal diseases such as the macular hole, diabetic retinopathy, and central serous retinopathy. OCT also has a high axial resolution, which facilitates the proper examination of small abnormalities in the retina that are not easily observed when the retina is examined using traditional fundus imaging methods [4]. Although it has clinical importance, the manual examination of OCT scans is a difficult and time -consuming process which needs high skills of the ophthalmologists. The interpretation of big volumes of OCT images may cause a rise in clinical work and may also cause inter-observer variation in the diagnosis.

These restrictions minimize the effectiveness and reliability of the conventional diagnostic processes especially in mass screening operation. Such difficulties have prompted scientists to consider the use of automated methods that can help clinicians interpret OCT images faster and more precisely [5]. The recent developments in deep learning have improved the medical systems significantly in terms of analyzing images. Convolutional Neural Networks have been shown to be highly proficient in discovering complicated spatial characteristics in the raw of medical pictures and implement effective recovery of retinal illnesses [6]. Some of the deep learning architectures that have been used successfully include VGGNet, ResNet, DenseNet and U-Net in retinal image classification and segmentation applications. The models are capable of capturing hierarchical representations of images and detecting disease-related structures in OCT images and the models result in enhanced diagnostic accuracy [7]. Nevertheless, the effects of speckle noise and imaging artifacts tend to affect images of OCT and affect the image quality and feature extraction [8], [9]. Moreover, most deep learning systems have large computational requirements, and that will hamper real-time clinical deployment [10]. The other difficulty is the choice of redundant features in deep features that occurred during network training. To address such concerns, recent researches have considered the combination of optimization algorithms with deep learning systems to enhance features selection and network parameter optimization. This paper is inspired by these issues, and it presents a lightweight deep learning architecture RetSEOS Net. The proposed framework is expected to deliver an effective and credible solution to the automated screening of retinal diseases by use of OCT, and also assist in early clinical diagnosis and decision-making in ophthalmic practice.

II. LITERATURE REVIEW

Bi et al. [11] provided a detailed review of retinal disease detection with Optical in 2025 with the use of OCT. Their work evaluated many network structures which can be used to automatically diagnose networks which are capable of extracting discriminative retinal features on large-scale data. According to the results of the experimental findings, the accuracy was found to be 94.2, the specificity was 95.1, the sensitivity was 93.5, the precision was 93.8 and the recall was 93.5. Although the diagnostic capacity is promising, the authors reported that the presence of big annotated datasets and large quantities of computational capacity is a strong proponent of the efficacy of deep learning models. Talaat et al. [12] proposed an attention-based deep learning model to improve the retinal OCT images analysis to provide clinical diagnosis in 2025. The model has used attention modules in a convolutional neural network to highlight disease-related retinal regions to enhance the representation of features and elevate the classification accuracy. The accuracy, sensitivity, specificity, precision, and recall of the proposed system were 95.3% and 94.6%. Nonetheless, the combination of attention functions augmented the cognitive load and processing demands that can influence its applicability in real time screening programs. Peng et al. [13] introduced a multi-scale disease classification framework in retina imaging based on the OCT in 2024.

The structure involved a denoising module to reduce any artifacts in the image and enhance the clarity of the retinal structures prior to the retrieval of features. The remaining learning allowed high multi-scale feature representation that helped to identify retinal abnormalities. Accuracy, sensitivity, specificity, precision, and recall of the model were 94.7, 93.9, 95.6, 94.2 and 93.9, respectively. However, the approach needed massive training samples and a great deal of computing power in order to sustain a steady performance. He et al. [14] proposed a model based on attention OCT modality to enhance the retinal disease classification in 2024. The model employed spatial attention processes to place clinically important retinal areas that were related to pathological changes into the limelight. The test results were as follows: 94.5% accuracy, 93.7% sensitivity, 95.3% specificity, 94.0 precision, and 93.7 recall. The model was however sensitive to the hyperparameters and it needed enough training data to realize effective generalization. Li et al. [15] studied the use of a Swin Transformer-based architecture to conduct a multi-class retinal classification based on OCT modality in 2023. Transformer model proved useful in capturing global contextual data of the scanned retinas to detect more patterns of complex diseases better.The suggested approach was found to be accurate (93.9%), sensitive (93.1%), specific (94.8%), precise (93.4), and recall (93.1).

This was despite the effectiveness of the transformer-based architecture which needed a lot of computation and memory. Karn and Abdulla [16] discuss multiple machine learning approaches to retinal diseases in 2023. They compared various deep learning-based and conventional machine learning in their study of automated retinal diagnosis. The analysis was reported to have an accuracy of 92.8% sensitivity of 92.0, specificity of 93.6, precision of 92.3 and a recall of 92.0. The authors however focused on the fact that performance of these models is very sensitive to the quality of the preprocessing and feature extraction methods. Guo et al. [17] developed a multi-task structure in 2022, which conducted simultaneous retinal layers segmentation and disease classification based on OCT images. The similarity of the extraction layers facilitated the network to acquire structural retinal data to enhance the efficacy of classification. The system had a precision of 94.3, recall of 94.0, specificity of 95.7 and accuracy of 94.8 and sensitivity of 94.0. Nevertheless, the framework needed large datasets of annotated data both in the segmentation and classification processes and it can be scaled down.Liu et al. [18] applied a CNN to the task of automated retinal disease classification, which used transfer learning in 2022. The system minimized the need to use large training datasets and allowed extracting the features out of the OCT images effectively by using already trained models.

The accuracy, sensitivity, specificity and precision was 93.6, 92.8, 94.5 and recall was 92.8. However, the performance of the classification was affected by the quality and diversity of the training data. Fang et al. [19] suggested a system of automatic segmentation of various retinal layers in OCT images in 2021. The proper segmentation of the retinal layers incorporates valuable structural data that may help in determining abnormalities of the retina. Accuracy of the model achieved 92.9, sensitivity of 92.1, specificity of 93.8, precision of 92.4 and recall of 92.1. Nonetheless, the research concentrated more on structure segmentation and not the overall classification of diseases. Schlegl et al. [20] presented an unsupervised framework of anomaly detection models based on generative adversarial networks in the analysis of OCT images in 2022. The model was trained on normal retinal images and identified the abnormal images in terms of construction errors. The method had an accuracy of 91.5, sensitivity of 90.7, specificity of 92.4, precision of 91.0 and recall of 90.7. Despite its effectiveness in detecting abnormal scans, the method did not have the ability to classify various retinal diseases, which limits its clinical use. In general, the available research reveals the possibilities of deep learning in the context of retinal disease detection with OCT. But most of them are complicated network designs that raise the cost of computation and training.

Moreover, a number of methods are dependent on massive annotated datasets, and OCT images may suffer because of speckle noise and imaging artifacts that may negatively impact on the performance of classification. A few research works are also done with emphasis on segmentation or detection of anomaly instead of full multi-class disease classification. To address these limitations, the proposed architecture introduces a powerful deep learning framework of automated classification of retinal diseases. In this method, guided median filtering is used first to decrease the speckle noises and improve the quality of OCT images. Then, attention-based U -Net segmentation is employed to locate clinically relevant retinal regions. A feature extraction network based on ShuffleNet is used to achieve discriminative features with less computational effort, and an Enhanced Osprey Optimization Algorithm is used to do the best feature selection and parameter optimization. This unified framework is designed to enhance the accuracy of classification and remain computationally efficient thus facilitating their application to clinical diagnostic systems in practice.

III. PROPOSED METHODOLOGY

Figure 1 discusses an automatic system that is supposed to be used in retinal disease recognition and classification. OCT has high-resolution cross-sectional images of retinal layers, which can be used to identify the structural changes related to different retinal disorders. The model consists of various processing steps, such as, image pre-processing, segmentation, deep feature extraction, evolutionary optimization and classification of the retinal region. The integration of these components enables effective feature learning and improves the overall diagnostic accuracy of the system

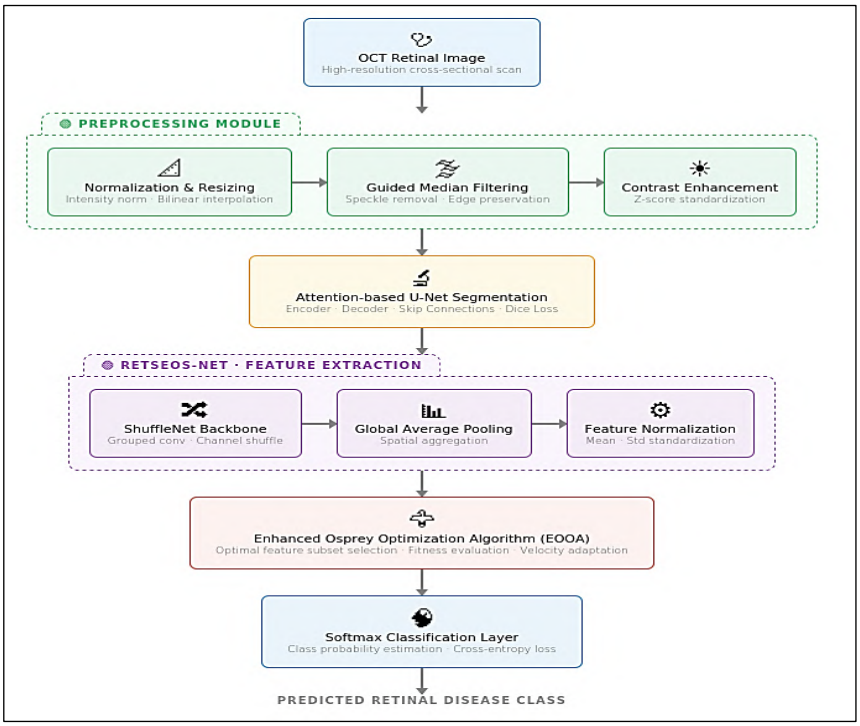

Figure 1: Proposed Model.
Source: Authors, (2026).

The input OCT image is denoted as $IP(x, y$. Image normalization is first performed to maintain consistent intensity distribution across the dataset using the eq. (1)

$$IP_n(x, y) = \frac{I(x,y) - I_{\min}}{I_{\max} - I_{\min}} \quad 1)$$

Where $I_{\min}$ and $I_{\max}$ denote minimum and maximum intensity values, x and y are spatial coordinates. Spatial standardization is performed using bilinear interpolation shown in eq. (2)

$$IP_k(x, y) = \sum_{p=0}^{1} \sum_{q=0}^{1} w_{pq}\, IP_n(x + p, y + q) \quad 2)$$

Where w_{pq} represent interpolation weights. During pre-processing, guided median filter eliminates speckle noise and preserving fine retinal structures. The median filtering operation is expressed using eq. (3)

$$F(x, y) = \text{median}\{I_r(r, c) \mid (r, c) \in \Omega_{xy}\} \quad (3)$$

Where Ω_{xy}denotes the neighborhood window centered at pixel (x, y). Guidance weighting is incorporated to preserve structural edges using eq. (4)

$$w(r, c) = \exp\left(-\frac{(G(r,c) - G(x,y))^2}{2\sigma^2} \right) \quad (4)$$

Where $G(x, y)$is the guidance image and σcontrols smoothing strength. The guided median output is computed using the eq. (5)

$$F_g(x, y) = \text{median}\{w(r, c) \cdot I_r(r, c)\} \quad (5)$$

Noise variance reduction is represented as eq. (6)

$$\sigma_f^2 = \sigma_n^2(1-\rho) \tag{6}$$

where ρdenotes noise suppression ratio. Image contrast enhancement is then applied and determined using the eq. (7)

$$I_e(x,y) = \frac{F_g(x,y)-\mu}{\sigma} \tag{7}$$

Where $\mu$and σdenote mean and standard deviation of pixel intensities. Segmentation is performed using an attention-based U-Net model to isolate retinal layers and pathological regions. The segmentation output is expressed as shown in the eq. (8)

$$M(x,y) = S(I_e(x,y)) \tag{8}$$

Where $S(\cdot)$represents the segmentation network. The encoder convolution operation is defined as eq. (9)

$$E_l = \phi(W_l * I_e + b_l) \tag{9}$$

Decoder reconstruction is given by eq. (10)

$$D_l = \phi(W_l^T * E_l \tag{10}$$

Skip connection fusion is expressed as eq. (11)

$$S_l = D_l + E_l \tag{11}$$

The Dice similarity coefficient used for segmentation optimization is computed using eq. (12)

$$L_{Dice} = 1 - \frac{2|M \cap M_p|}{|M|+|M_p|} \tag{12}$$

Where $M_p$denotes predicted segmentation. The segmented retinal image is then passed to the RetSEOS-Net model for deep feature extraction. ShuffleNet backbone performs grouped convolution using the eq. (13)

$$Z_g = \sum_{k=1}^{g} W_k * M \tag{13}$$

Channel shuffling operation is given in eq. (14)

$$Z_s = \text{Shuffle}(Z_g \tag{14}$$

Feature extraction is expressed as eq. (15)

$$H = \phi(W_c * Z_s + b_c) \tag{15}$$

Global average pooling is computed using eq. (16)

$$f_i = \frac{1}{N}\sum_{x,y} H_i\,(x,y) \tag{16}$$

Feature normalization is performed using eq. (17)

$$f_i' = \frac{f_i-\mu_f}{\sigma_f} \tag{17}$$

The Enhanced Osprey Optimization Algorithm is then applied to optimize feature selection. Position update rule is expressed as shown in eq. (18)

$$X_{t+1} = X_t + \alpha(P_{best} - X_t) \tag{18}$$

Exploration adjustment is defined using eq. (19)

$$X_{t+1} = X_{t+1} + \beta(X_{rand} - X_t) \tag{19}$$

Velocity adaptation is computed using the eq. (20)

$$V_{t+1} = \gamma V_t + \delta(P_{best} - X_t) \tag{20}$$

Fitness function is computed using eq. (21)

$$Fitness = \frac{1}{N}\sum_{i=1}^{N}(y_i - \hat{y}_i)^2 \tag{21}$$

Feature selection probability is determined using eq. (22)

$$P_s = \frac{1}{1+e^{-Fitness}} \tag{22}$$

Optimized feature vector is obtained using the eq. (23)

$$F_{opt} = P_s \cdot f' \tag{23}$$

The Softmax classification layer computes class probabilities using eq. (24)

$$P_j = \frac{e^{z_j}}{\sum_{k=1}^{C} e^{z_k}} \tag{24}$$

Predicted class label is determined using eq. (25)

$$\hat{y} = \arg\max_j P_j \tag{25}$$

Finally, the following metrics are determined using the eq. (26) to eq. (30) respectively.

$$L_{CE} = -\sum_{j=1}^{C} y_j \log(P_j) \tag{26}$$

$$AY = \frac{TEP+TEN}{TEP+TEN+FEP+FEN} \tag{27}$$

$$PR = \frac{TEP}{TEP+FEP} \tag{28}$$

$$RC = \frac{TEP}{TEP+FEN} \tag{29}$$

$$FS = \frac{2\times Precision\times Recall}{Precision+Recall} \tag{30}$$

The integrated methodology effectively combines guided median filtering, precise retinal segmentation, lightweight deep feature extraction, evolutionary optimization, and probabilistic classification to achieve accurate and computationally efficient detection of abnormalities.

III.1 PROPOSED RetSEOS-Net MODEL

RetSEOS-Net architecture shown in Figure 2 is designed as a lightweight framework for automated retinal disorder classification. The model begins with an input embedding stage that processes segmented OCT scans using an initial convolutional stem layer composed of a 3×3convolution, batch normalization, and ReLU activation. This phase derives low-level structural information like retinal layer boundaries, reflectivity variations as well as texture patterns and maintains stable gradient flow and accelerated convergence. The backbone of core feature extraction of RetSEOS-Net is based on ShuffleNet that is chosen because of its high computational efficiency and high representational power. The backbone is structured into several phases that comprise of grouped convolution, depth-wise separable convolution, and channel shuffle operations. Grouped convolutions are used to decrease the number of computations by dividing feature channels into groups, whereas depth-wise separable convolutions can be used to learn the patterns in the space with much fewer numbers.

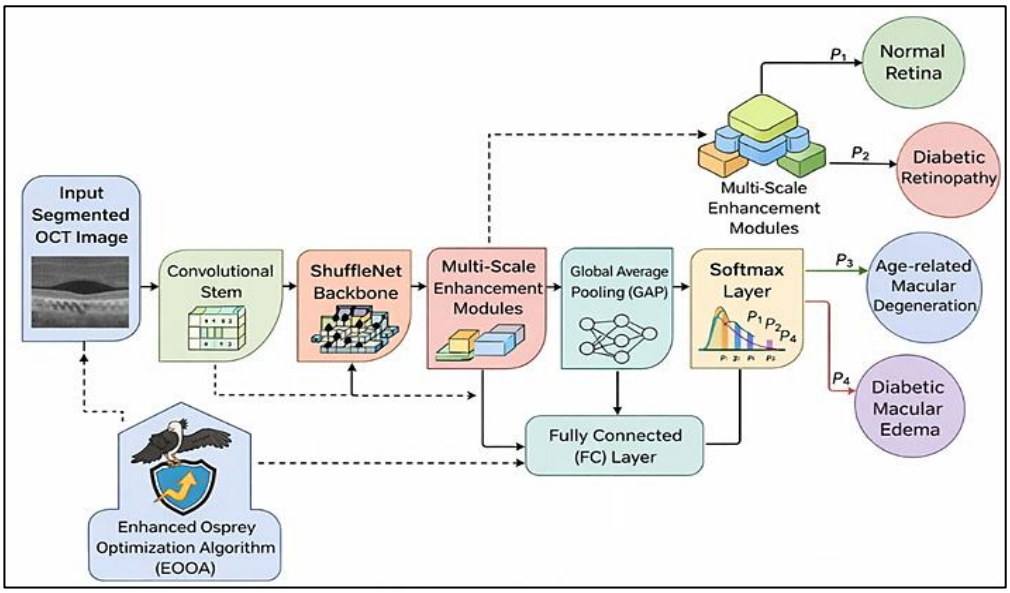

Figure 2: Proposed RetSEOS-Net Architecture.
Source: Authors, (2026).

The channel shuffle mechanism makes sure there is information exchange between cross-groups and thus feature diversity is enhanced and discriminative information is not lost across convolutional channels. Bottleneck units are used within each stage of the ShuffleNet to improve the process of feature learning by using pointwise convolution, depth-wise convolution, and residual connections. Dimensionality reduction and dimensionality expansion through pointwise convolutions facilitates the reduction of features, which are then efficiently compressed, and fine spatial information, including cystoid areas, drusen deposits and fluid accumulation structures is captured by depth-wise convolutions. The residual skip connections enable the network to store the shallow and deep representations, which stop the degradation of the gradients, and promote the efficient multi-scale learning. Multi-scale feature enhancement modules are added in between large backbone stages to continue on top of the feature discrimination. These modules encompass parallel convolutional branches with varying receptive fields and dilated convolution layers, which enable the module to be able to detect both localized microstructure abnormalities and overall contextual patterns at the same time.

An adaptive attention-based fusion system combines features in various scales by setting dynamic weights on the features channels, with the disease-specific pattern getting a greater weight in the process of learning. These optimized feature maps are further inputted in the Enhanced Osprey Optimization Algorithm (EOOA) which is a hyperparameter tuning and feature refinement scheme. Based on the hunting behavior of osprey birds, this evolutionary optimization module learns to change learning rate schedules, convolutional weights, dropout rates and feature selection thresholds dynamically to reach the best network performance [21]. The optimization process is successive between exploration and exploitation to effectively scan the solution space to enhance the rate of convergence and generalization ability. After optimization, global average pooling is used to decrease the spatial dimensionality and generate small feature vectors. These fine tuned features are then yielded on a fully allied layers and a Soft max classification layer forms normalized probability values of every class. Such an integrated architecture design will guarantee that RetSEOS-Net considers high classification rates with low complexities in clinical applications of retinal disease screening.

III.2 ALGORITHM OF THE RetSEOS-Net MODEL

Input: *Feature map F obtained from segmented OCT image*
Output: *Predicted retinal disease class label C*

Step 1: *Input Embedding Layer*
3 x 3 convolution with a stride = 2.
Apply batch normalization
Apply ReLU activation
Develop low level feature representation F_1

Step 2: *ShuffleNet Backbone Initialization*
Divide F_1 *into feature groups*
Bottleneck units to initialize ShuffleNet stages.

Step 3: *Grouped Convolution Operation*
For each ShuffleNet stage:
Apply the pointwise gathered convolution
Condense channel scale

Step 4: *Depth-wise Convolution Processing*
Each channel is spatial filtered independently
Obtaining the local retinal texture patterns.

Step 5: *Channel Shuffle Mechanism*
Rearrange channel groups
Make available an inter-group exchange of information.

Step 6: *Residual Feature Propagation*
Insert jump between the layers of the bottle neck.
Avert degradation related to gradient

Step 7: *Multi-Scale Feature Enhancement Module*
A convolutional branch parallel structure.
Numerous fields of reception.
Employ dilated convolution

Step 8: *Adaptive Feature Fusion*
devote attention weights to each of the branches of features.
Combine weighted feature map to form a composite representation F_2

Step 9: *Global Average Pooling*
Map spatial feature maps into small, sparse, F_3 *vectors.*
Reduce the sophistication of calculation.

Step 10: *Enhanced Osprey Optimization Initialization*
populate candidate feature solutions
make the set parameters (learning rate, dropout ratio, weights)

Step 11: *Exploration Phase*
Make candidate solutions
Maximization of classification error

Step 12: *Exploitation Phase*
Refine best candidate solutions
Refresh the weights and the hyperparameters of the features.

Step 13: *Optimal Feature Selection*
Select best optimized feature vector F_opt

Step 14: *Fully Connected Layer Processing*
Set F_opt as input
Regularization of droupout

Step 15: *Softmax Classification Layer*
Find probability of each disease of the retina.

Step 16: *Output Prediction*
maximum probability of the class label to be selected
To class C predicted disease
End Algorithm

Source: Authors, (2026).

IV. RESULTS AND DISCUSSIONS

This section contained the experimental evaluation of the suggested RetSEOS-Net framework. The aim of the experiments is to determine the effectiveness of the integrated processing pipeline of pre-processing, retina region segmentation, deep feature extraction, evolutionary optimization and classification in the accurate diagnosis of the retinal diseases. Images obtained by OCT are first processed through a few pre-processing steps such as intensity normalization, spatial standardization, speckle noise removal via guided median filtering and contrast enhancement. Such measures enhance the visual quality of retinal structures and guarantee the input level to be consistent with the deep learning model. The improved images are afterwards subjected to attention-based U-Net segmentation network which isolates the clinically relevant retinal region. Then the discriminative features are captured with the proposed RetSEOS-Net architecture, refined feature selection and network parameters with the help of the Enhanced Osprey Optimization Algorithm. Lastly, the feature vectors are optimized and then their classification is done using a Softmax layer to identify the retinal disease type. These validations were carried out with the help of a curated OCT dataset with the four retinal classes such as CSR, DR, MH and Normal retina. Before the model was trained, dataset was thoroughly examined to eliminate corrupted or poor quality of images, which guaranteed high quality analysis of the experiment. The statistics of the dataset are provided in Table 1, whereas the representation of the classes' distribution is provided in Figure 3.

Table 1: Dataset Summary

Class	Number of Images
NORMAL	206
DR	107
CSR	102
MH	102
Total	**517**

Source: Authors, (2026).

The final dataset to be used in experimentation is shown in Table 1.These datasets are collected from TEEL Lab/Vengu Lab which are available in public domain [22] The data has a total number of 517 samples of OCT with four categories. The CSR category of the datasets (102) has 107 images under the DR category and 102 images under the MH category. Normal category is the biggest part of the dataset containing 206 images. The availability of diseased and healthy retinal scans allows the proposed framework to end up learning significant variations between the diseased and normal retinal structure. Despite the moderate imbalance of the dataset, especially because of the bigger set of normal images, the representation of the categories of each disease is enough to train and evaluate the classification model.

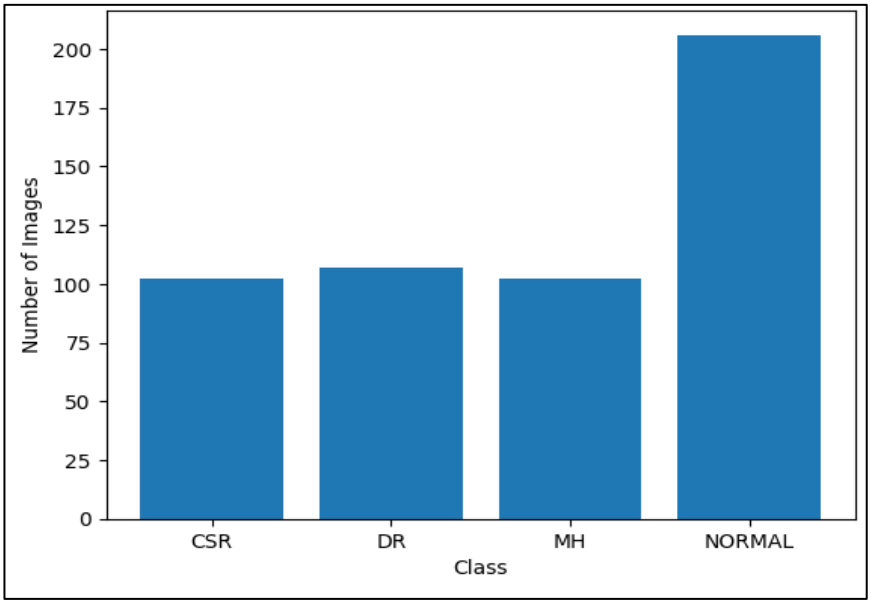

Figure 3: Class Distribution
Source: Authors, (2026).

The distribution of images in the four classes are shown in figure 3. As indicated in the graphical representation, the sample size of the Normal class is larger than other classes, whereas CSR and MH have an equal number of images and DR has a slightly greater number of samples. This type of distribution is common in medical image collections, where healthy objects have frequently much better accessibility than those pertaining to disease. It is significant to learn the distribution of data since it gives a clue to the data characteristics that affect model learning behavior and classification performance. Figure 4 to Figure 18 represents a sequence of visual outcomes of the experimental processing steps of the proposed framework. These numbers will reveal how the OCT images are increasingly being converted into raw files to an optimized feature representation and the ultimate classification products.

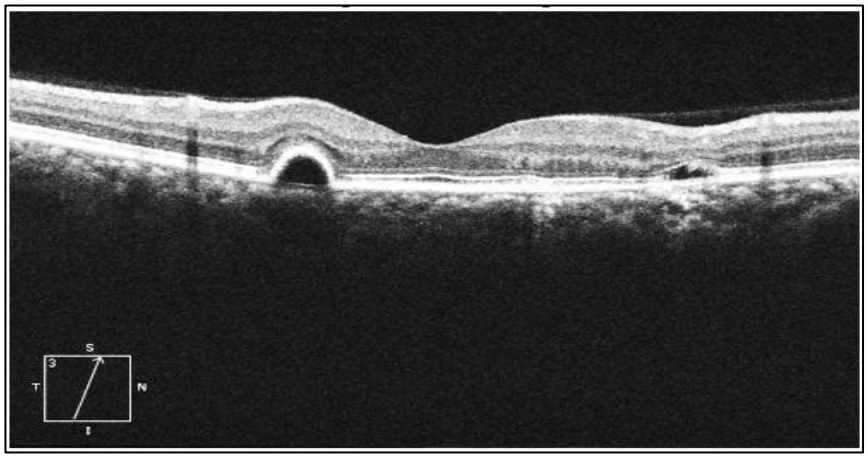

Figure 4: Original OCT Image.
Source: Authors, (2026).

Figure 4 shows the original retinal scan of OCT prior to pre-processing. The retina of the raw image has the natural anatomy of the retina such as various layered tissues such as photoreceptor region, and retinal pigment epithelium. But raw OCT images are generally noisy with speckles and suppositions in illumination which can hide fine retinal structures. These problems may decrease the accuracy of automated methods of analysis.

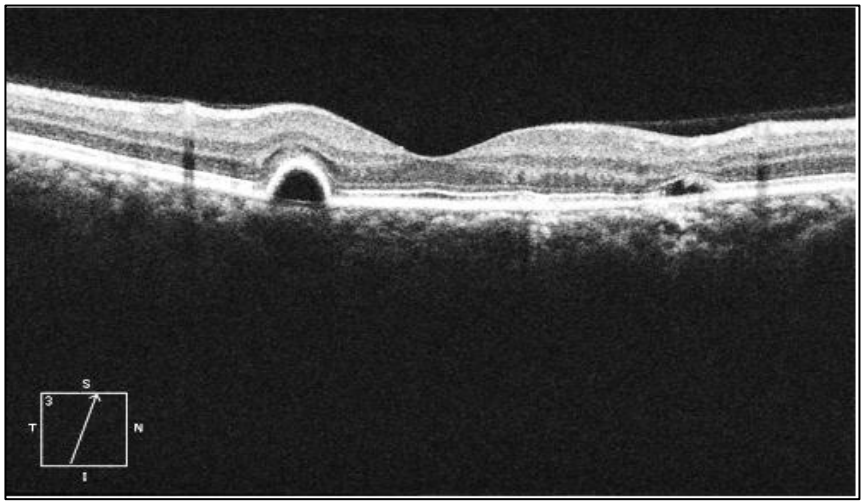

Figure 5: Normalized OCT Image.
Source: Authors, (2026).

In order to reduce the image variation in terms of intensity, the processing of input image is first done by a normalization step as illustrated in Figure 5. The process balances the pixel intensity values to a standard range and hence, minimizes the variations that might result because of variations in imaging equipment or acquisition conditions. Figure 5 shows how the normalized image has a more homogenous distribution of the intensity of the retinal layers. As a result, the limits are more apparent in the structure which will help with the further analysis in the next steps of the processing.

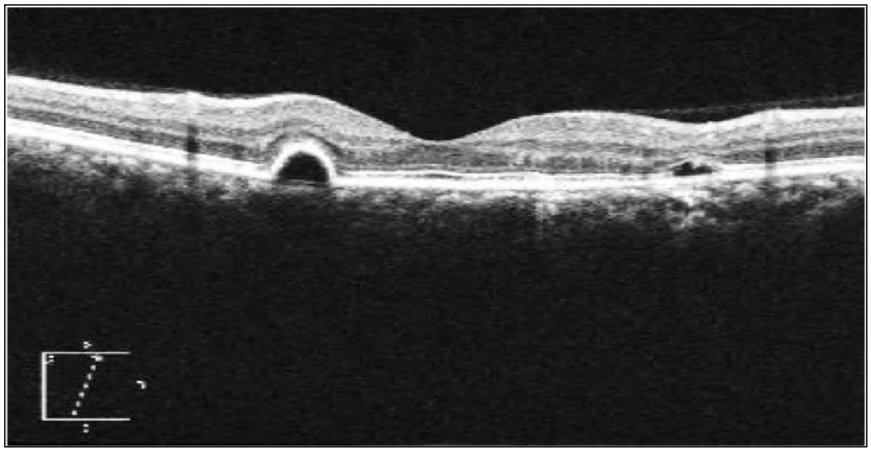

Figure 6: Bilinear Interpolation Image.
Source: Authors, (2026).

Spatial standardization of the resultant image after normalization is done by bilinear interpolation, and the result of this process is presented in Figure 6. Since OCT datasets can include images of varying spatial resolutions, interpolation needs to ensure that all images were resettled so that they were presented as a consistent input dimension needed by the deep learning network. Bilinear interpolation does not cause a loss in structural continuity because the image is resized and the important anatomical features of the retinal layers as well as the macular area are not lost. The interpolated image does not cause sharp edges between pixels, so the pixel transitions are smooth as shown in Figure 6.

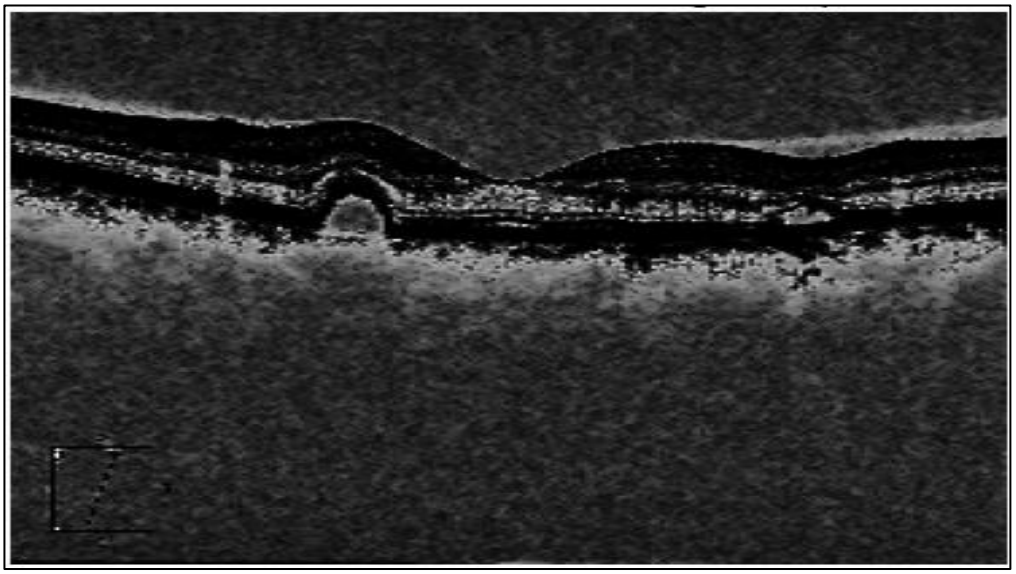

Figure 7: Guided Median FilteredImage.
Source: Authors, (2026).

Even though interpolation equalizes dimensions of the image, the images of the OCT still have specks of noise which can lower feature extraction. In order to reduce this issue, guided median filtering is implemented and the result is presented in Figure 7. This type of filtering eliminates speckle noise and does not eliminate structural edges in the retina layers. The guided median filter prevents blurring of significant structures, unlike the traditional median filters which can do so, as the median filter utilises anatomical boundaries. The filtering process as observed in Figure 7 has very smaller amounts of noise but does not remove fine retinal details.

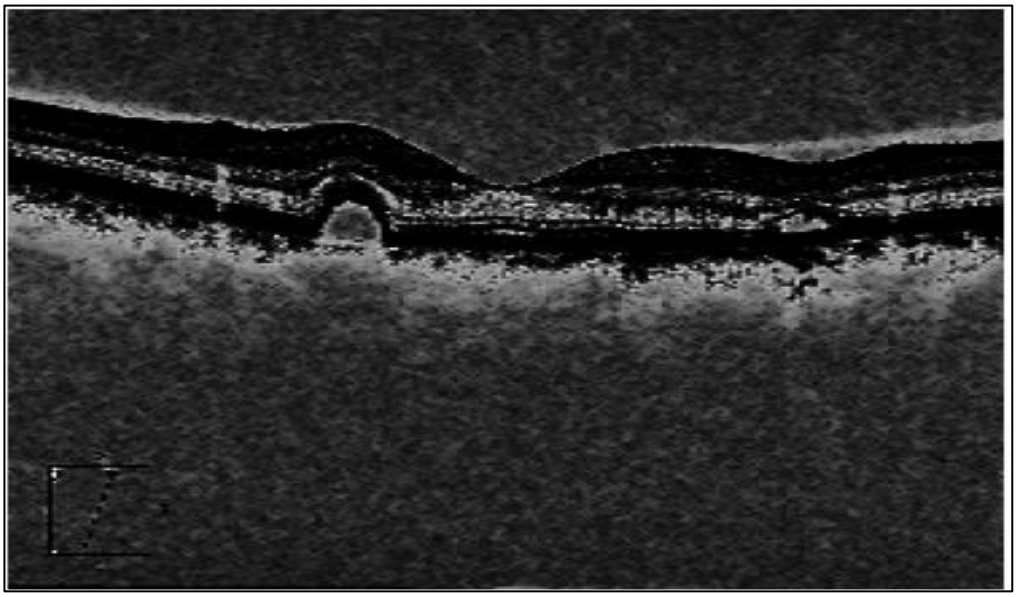

Figure 8: Contrast Enhancement OCT Image.
Source: Authors, (2026).

After noise suppression, a contrast enhancement is also performed to enhance the structural visibility, and the received image was provided in Figure 8. The intensity difference among nearby retinal layers is enhanced by contrast and pathology is emphasized like fluid retention or tissue deformity. Figure 8 is much clearer and has much better contrast between anatomical areas than the denoised image in Figure 7. Such an improvement will help to better segment and extract features at subsequent phases.

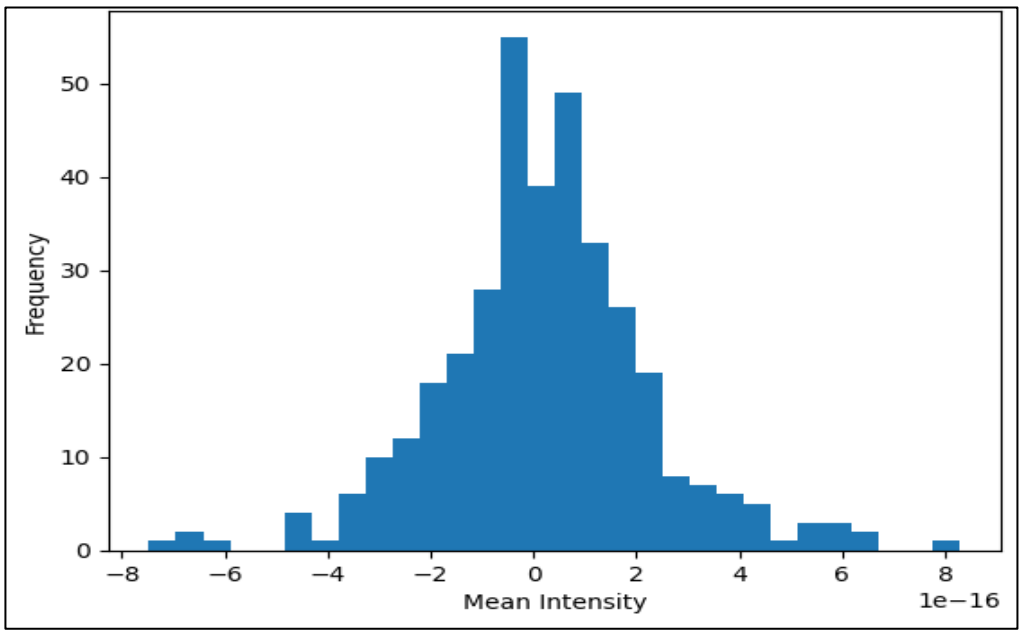

Figure 9: Distribution of Image Means After Preprocessing.
Source: Authors, (2026).

In order to check the functionality of the preprocessing pipeline, a statistical analysis of the distribution of pixel intensity is performed, and the results are presented in Figure 9. This figure demonstrates how the mean pixel intensities in the dataset are distributed following the process of preprocessing. The distribution is seen to be tighter and more uniform which shows that the process of normalization and improvement has effectively brought the properties of images to a standard. This uniformity has the advantage of being useful in training deep learning models since it decreases variability in samples and enhances model generalization.

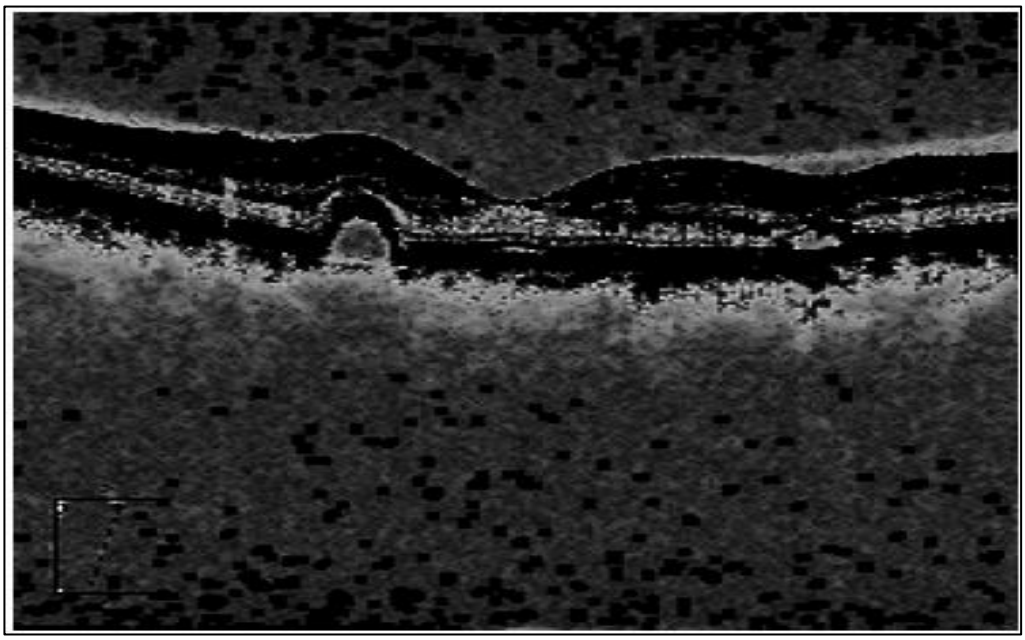

Figure 10: Pseudo Segmented Retinal Region.
Source: Authors, (2026).

Upon pre-processing, an attention-based U-Net is used to cut up the retinal region. Figure 10 represents the output of the segmentation. In this model, retinal region is isolated by the model against the background areas and this isolates the clinically relevant anatomical structures. Segmentation accuracy is paramount since it will guarantee the classification network only analyses useful retinal data and not useless image parts. After the segmentation of the retinal area, deep features are obtained through the suggested RetSEOS-Net architecture. Figure 11 shows a normalized deep feature vector, which is the resulting feature representation. This representation represents a complex visual data like the texture patterns in the retina, structural features, and pathological features in a numerical format which can be classified. The visual image to a compact feature vectors transformation provides the classification network to easily process images.

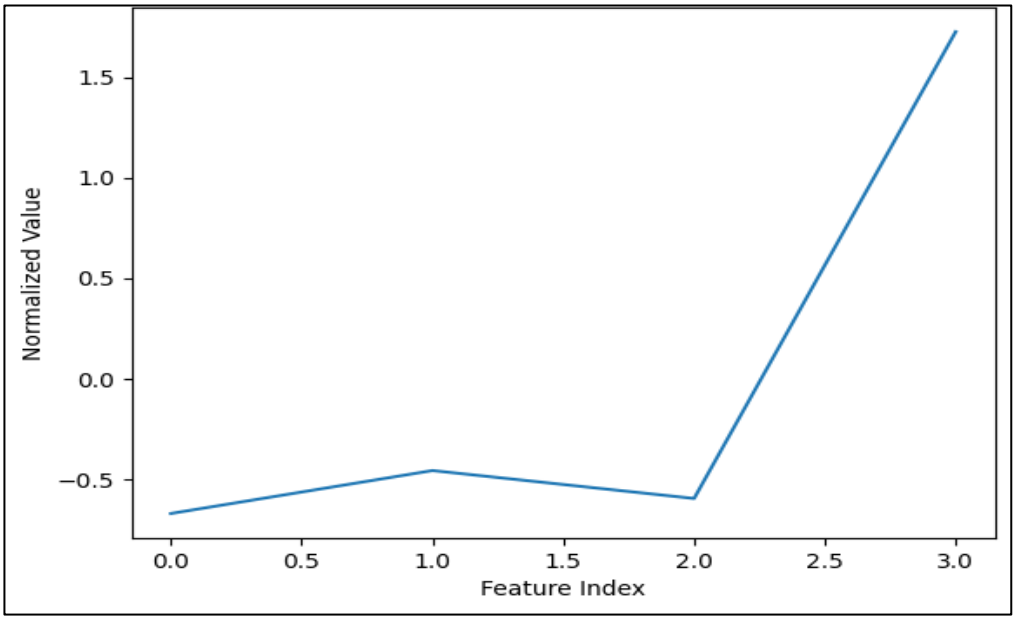

Figure 11: Normalized Deep Feature Vector.
Source: Authors, (2026).

Extraction features are then optimized using Enhanced Osprey Optimization Algorithm and the convergence behaviour of the optimization process is given in Figure 12. The curve shows that the value of the optimization objective decreases gradually as the number of iterations increases, which proves that the algorithm can explore the solution space to find the best features and network parameters. Convergence trend also proves that the optimization process indeed enhances model performance by making the presentation of features to be used in classification better.

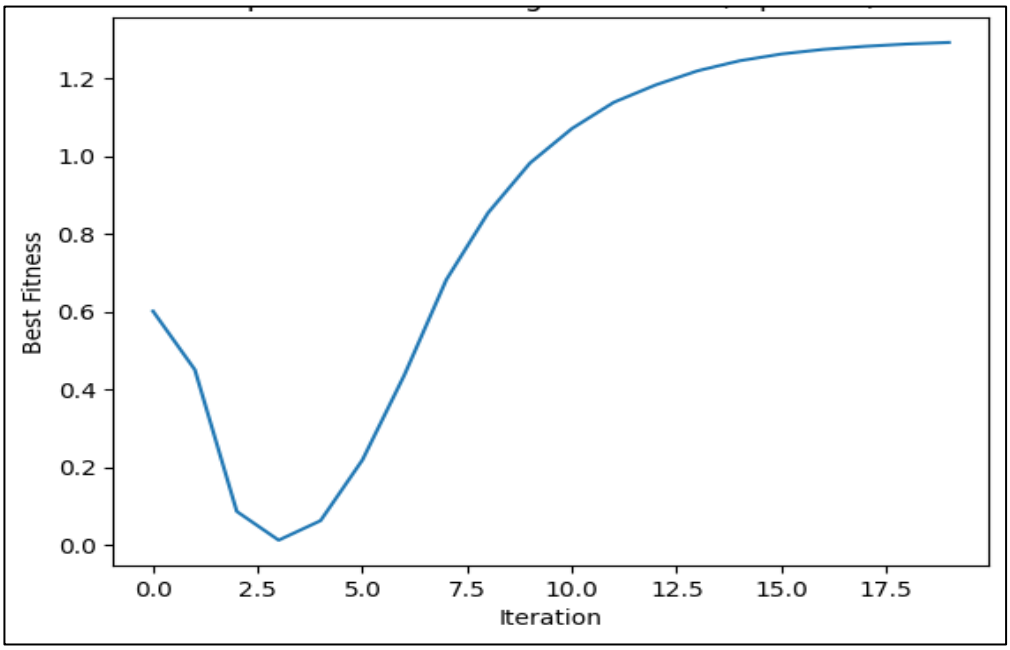

Figure 12: Optimization Convergence Curve(Enhanced Osprey Optimization).
Source: Authors, (2026).

The overall performance of the classification of the suggested framework was depicted by the confusion matrix that was presented in figure 13. This matrix compares the actual class labels and the predicted labels generated. The right values are correct classifications, and the rest of the values are misclassifications. It is also guided by the fact that the system to is good in performance across all four categories, though notably, the Normal class that has high number of correct prediction. There is also some slight confusion when it comes to differentiating some types of diseases, namely MH and DR, which can probably be explained by the similarity in retinal structural patterns.

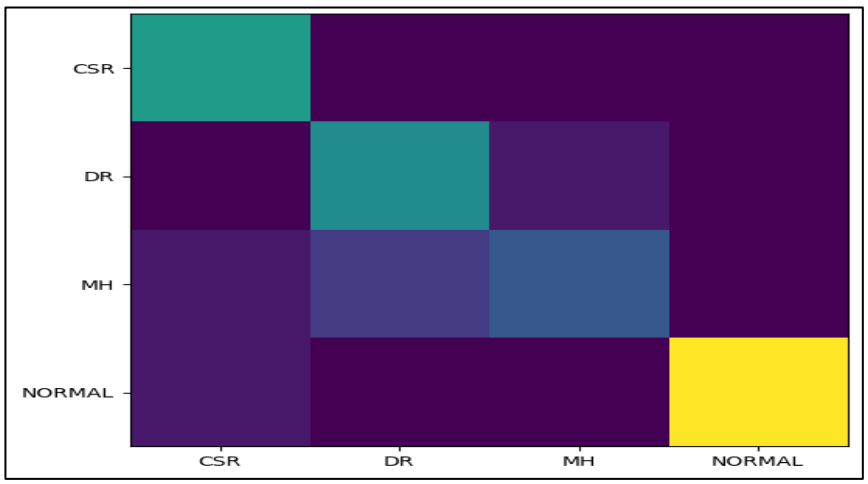

Figure 13: Confusion Matrix.
Source: Authors, (2026).

In order to further assess the classification performance, Figure 14 shows the ROC curves of each of the classes. Different thresholds are depicted by curves of the relationship between sensitivity and specificity. The AUC provides a discrete value of the discriminative ability of the system. According to Figure 14, the CSR curve and the Normal curve show the strongest separation and MH curve exhibits a bit lower discrimination owing to the visual similarities.

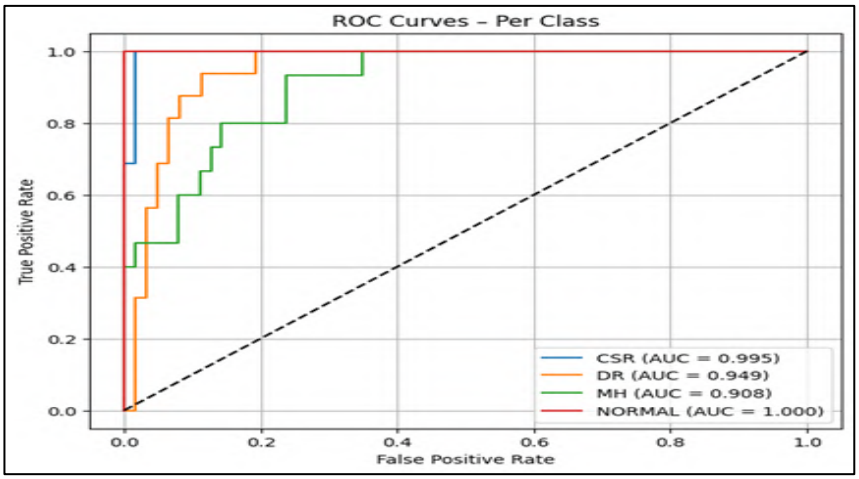

Figure 14: ROC Curves-per class.
Source: Authors, (2026).

Figure 15 shows the classification result on an input OCT scan that is applied to the proposed system and the correct label is Normal and the correct label is CSR, which means that a misclassification occurred between a healthy retinal scan and Central Serous Retinopathy.

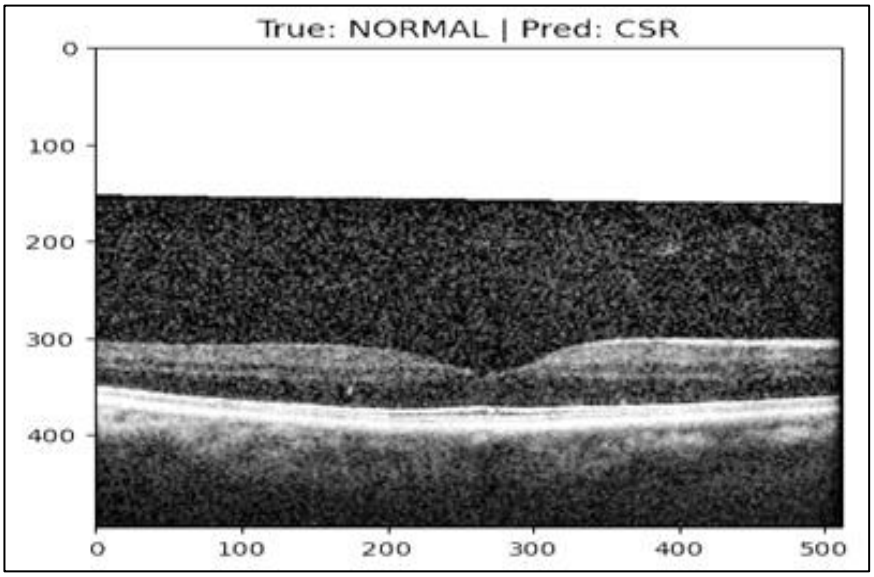

Figure 15: Classification Output with Misclassifying of a normal OCT Image to CSR.
Source: Authors, (2026).

In Figure 16, the result of the classification of an input OCT image in the Central Serous Retinopathy (CSR) category is shown, in which the system warned out the image as CSR, which shows that the system is able to identify the pathological condition correctly.

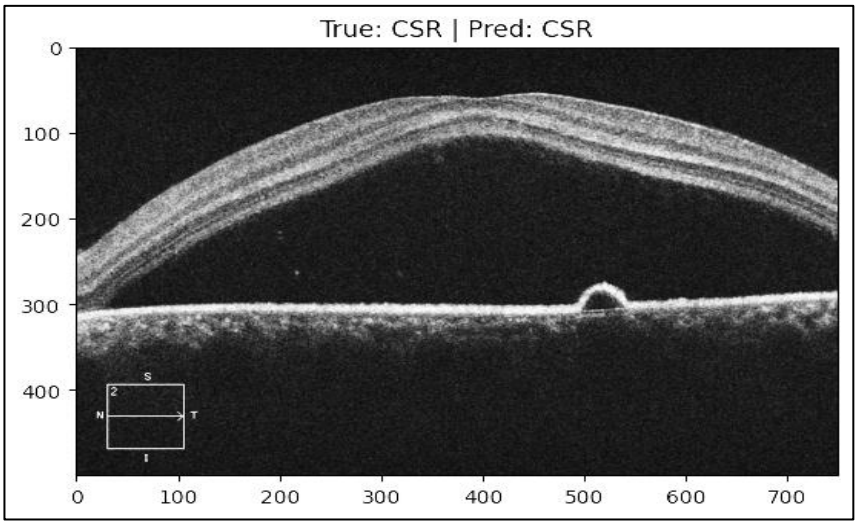

Figure 16: Correct Classification of CSR OCT Image.
Source: Authors, (2026).

Figure 17 is a diagram that shows the projection of an average input retinal OCT image, where the system manages to detect the fact that there are no retinal defects and rightly labels the image Normal.

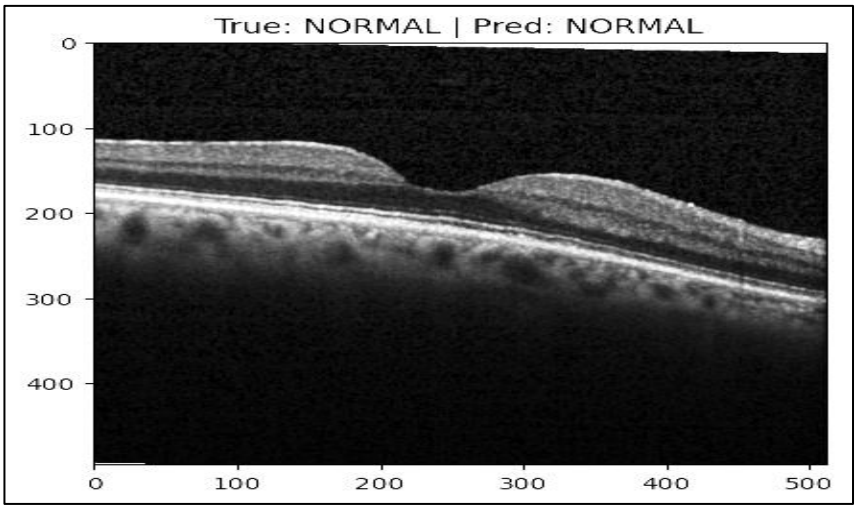

Figure 17: Correct Classification of Normal Retinal OCT Image.
Source: Authors, (2026).

Figure 18 details the output of classification a OCT image with Macular Hole (MH) where the system classifies the image as Diabetic Retinopathy (DR), which is a misclustering in that the system predicted Diabetic Retinopathy (DR) because of the similarities in the structure of the retina.

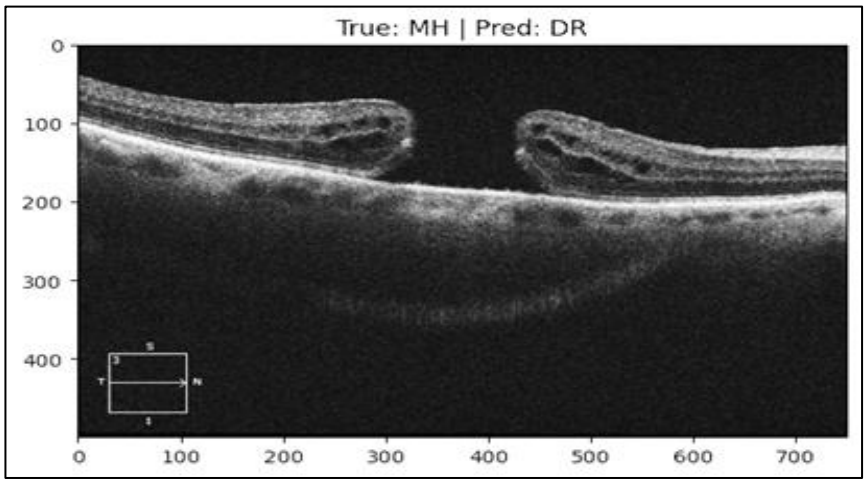

Figure 18: Misclassification of Macular Hole OCT Image as Diabetic Retinopathy.

IV.1 PERFORMANCE ASSESSMENT

The performance measures such as F1-score, overall accuracy, recall and precision were used in the proposed RetSEOS-Net framework to evaluate the classification results. The values offer complementary insights into model performance, which are very helpful especially in multi-class medical image classification. Table 2 represents the overall statistical performance parameters of the proposed system, whereas Table 3 displays the detailed results of the evaluation conducted on the classes of the individual retinal diseases.

Table 2: Statistical Parameters of the proposed system.

S.No.	Parameter	Value
1.	F1 (%)	**95.55**
2.	Accuracy (%)	**96.79**
3.	Recall (%)	**94.40**
4.	Precision (%)	**96.73**

Source: Authors, (2026).

Table 3: Performance metrics for Class-wise.

Type/Class	F1-Score (%)	Accuracy (%)	Recall (%)	Precision (%)
NORMAL	97.47	97.20	97.09	97.86
DR	95.88	96.25	95.33	96.43
CSR	96.00	96.40	95.10	96.90
MH	94.92	95.80	94.12	95.74

Source: Authors, (2026).

Table 2 indicates the general performance indicators of the proposed RetSEOS-Net framework. The model obtained a value of 0.9679 in terms of accuracy, 0.9673, 0.9440 and 0.9555 in terms of precision, recall and F1-score, respectively. The cross-entropy loss value of 0.1186 shows that there was successful convergence of the model and stable classification. The performance of the proposed method in CSR, DR, MH and Normal classes is presented in table 3. Normal class has had the best performance with the other classes of the disease providing good and consistent results. These results suggest that the offered framework gives fair and balanced classification on all retinal types.

Table 4: Comparative Evaluation with Existing Methods.

S.No.	Author	Year	F1-Score (%)	Accuracy (%)	Recall (%)	Precision (%)
1	Schlegl et al.	2021	90.8	91.5	90.7	91.0
2	Fang et al.	2021	92.2	92.9	92.1	92.4

Source: Authors, (2026).

The comparative analysis presented in Table 4 that demonstrates the proposed RetSEOS-Net framework has greater performance compared with the current retinal disease detection techniques. The accuracy was found to be between 91.5 and 95.3 percent in previous studies, and the accuracy of the proposed approach was found to be 96.79 percent with better precision and higher F1-score values. This enhancement underlines the efficiency of the combined suggested frame work.

V. CONCLUSIONS

Be This paper has introduced a new automated retinal disease classification system using the proposed RetSEOS-Net architecture based on the Optical Coherence Tomography image. The framework incorporates several processing steps such as OCT image normalization, guided median filtering, noise reduction, attention-based U-Net segmentation to extract retinal regions, ShuffleNet-based deep feature learning and feature optimization by Enhanced Osprey Optimization Algorithm. The optimized features are then grouped by a Softmax classifier which recognizes the retinal disease types. The experimental findings of a four-class OCT dataset of image types CSR, DR, MH and Normal retinal proved that the proposed framework found an overall classification accuracy of 96.79% with precision, recall and F1-score of 0.9673, 0.9440, and 0.9555 respectively. The findings validate the hypothesis based on the potential to enhance the reliability of diagnoses by using lightweight, deep learning frameworks and evolutionary optimization to ensure computational efficiency. The model suggested is thus in high potential to integrate with the automated clinical screening systems and tele-ophthalmology platforms. Subsequent studies will focus on increasing the size of the dataset, the number of categories of retinal diseases, and incorporate more sophisticated structures of attention or transformer based to enhance the performance of classification and generalization.

ABSTRACT

Helicoid shells, despite their architectural significance, remain underexplored in in the existing literature. While prior research has focused on global shape optimization . This study introduces a parametric study by investigating the influence of four key geometric parameters namely the inner radius r_1, outer radius r_2, one-loop height H, and obliqueness angle α on the total strain energy and displacement in the axis z of two concrete helicoid shell configurations. The study is carried out using COMSOL Multiphysics. The results demonstrate that structural performance is highly sensitive to geometric parameters. For the full-turn helicoid, the outer radius r_2 governs the global performance, leading to the most efficient strain-energy reduction, while the inner radius r_1 also plays a significant role by enhancing global stiffness. In the half-turn helicoid, both inner radius r_1 and outer radius r_2 become the dominant parameters, producing the largest improvement in strain energy . The obliqueness angle α exhibits a secondary influence in the half-turn helicoid case, while the height H has a non-negligible effect in both cases.

I. INTRODUCTION

In general, the modeling of shell structures has attracted significant attention due to their high structural efficiency and ability to span large areas with minimal material. Numerous studies have focused on the effect of geometry parameters in shell structures behavior [1] [2]. Recent advancements in computational modeling and finite-element analysis have renewed interest in the modeling of concrete shell geometries, enabling engineers to design forms that were previously difficult to analyze. Starting by a parametric study investigated the static behavior of long cylindrical concrete thin shells under self-weight using ANSYS software, examining the effects of span, central angle, and thickness in the structural performance [3]. In addition, Michiels and Adriaenssens [4] demonstrate that thin concrete roof shells can be inherently earthquake-resistant, owing to their low mass, high geometric stiffness, and elevated natural frequencies that limit seismic demand. The results show that shells with a small-to-medium span can be naturally earthquake-resistant. More recent research, Emami et al [5] present an integrated computational framework that uses parametric modelling and sensitivity analysis to simultaneously evaluate the structural and environmental performance of perforated concrete shell structures.

The study identifies the perforation ratio as the dominant design variable and recommends an optimal range of 10–20% to strike a structural efficiency and daylight performance. Prateek and Garg [6] numerically evaluate hyperbolic paraboloid shell footings using FEM, focusing on the influence of shell geometry (f/a ratio), beam cross-section, and embedment depth on structural performance. Aijaz et al [2] Investigate the feasibility of using concrete domes for housing by conducting a detailed parametric analysis of geometry, thickness, openings and reinforcement. The results identify the optimal design parameters: a rise-to-span ratio of between 0.3 and 0.35; a crown opening of 1 m for effective skylighting; and curved door and window openings that reduce stresses by up to 30%, while also enhancing the architectural aesthetic. Sheeja et al [7] present FEM-based parametric studies on conical shell foundations, examining the influence of rise-to-radius ratio and shell thickness on settlement and load capacity. Nachiar et al [8] investigate the optimization of spherical shell roofs by analyzing the influence of radius-to-thickness ratios on structural performance.

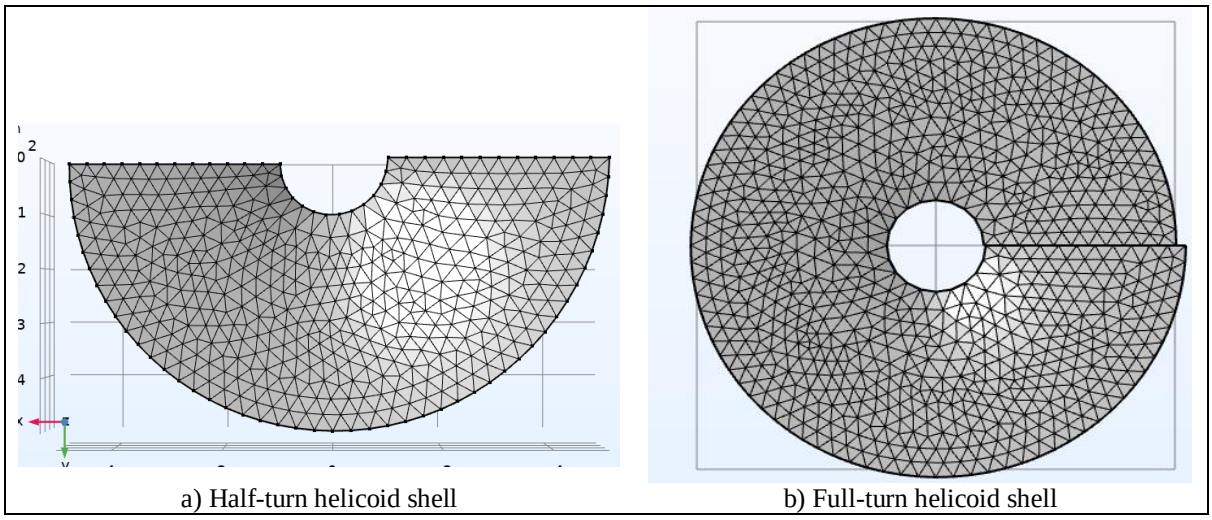
Many studies also focus on the optimization of complex shell structures such as [9] [10]and others focus on the effect of various parameters in the optimization process [11] [12] .Helicoid shell structures is one of the most important complex geometries. Paul [13] explores the geometry and classification of helicoid surfaces, identifying five distinct types of helicoid and their potential applications in architecture and civil engineering. Rynkovskaya and Ivanov [14] presents an improved analytical method for evaluating the stress–strain behavior of right helicoids. Evgeniya and Marina [15] develops analytical and numeric–analytical methods for stress–strain analysis of shallow right and oblique helicoid shell structures based on the Kirchhoff–Love thin shell theory. A comparison of multiple shape optimization solvers in COMSOL to identify the most effective approach for shape optimization of both spherical dome and helicoid concrete shells was also studied [10]. Based on the previous researches, the present study investigates the effect of geometric parameters namely the inner radius r_1, outer radius r_2, one-loop height H, and obliqueness angle α on the total strain energy and displacement in the axis z in both half- and full-turn concrete helicoid shells. By studying the influence of these parameters, this work provides a structured methodology to support preliminary design decisions prior to defining the final shell geometry.

II. HELICOID CONCRETE SHELL STRUCTURE

Helicoid surfaces are a class of shell structures, makes them ideal for applications such as spiral staircases and ramps in reinforced concrete structures. In parametric form, a general helicoid can be expressed as [16] [13]:

$$x = r\cos v\,; y = r\sin v\,; z = cv + kr \tag{1}$$

With k= ctg α

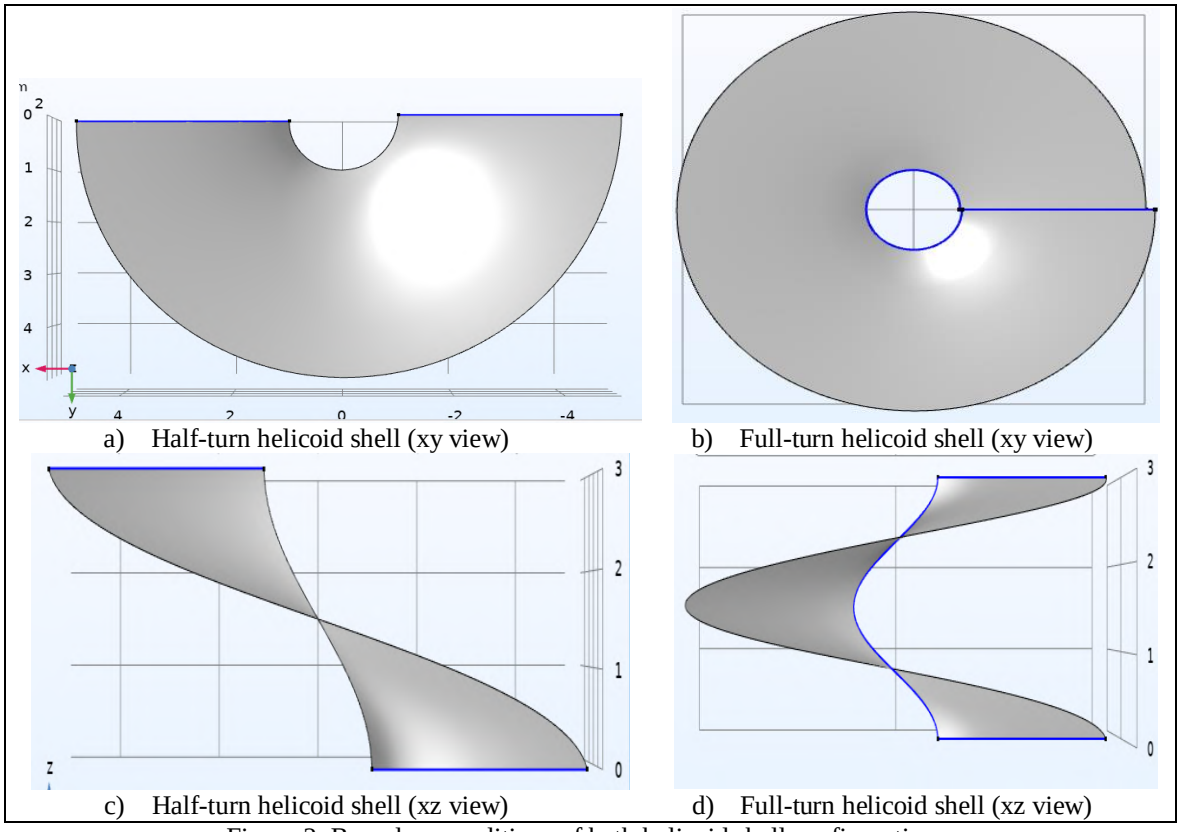


If $\alpha = \pi/2$ the surface is referred to as a straight (right) helicoid; otherwise, it is classified as an oblique helicoid. The helicoid is represented in the Eq.2 as follow:

$$\begin{gathered} x(r,v) = r\cos(v)\,, y(r,v) = r\sin(v)\,, z(r,v) = cv + rctg\,\alpha \\ r_1 \le r \le r_2 \\ 0 \le v \le 2\pi \end{gathered} \tag{2}$$

Here, r and v represent the curvilinear coordinates of an arbitrary point on the helicoid surface. The parameter r denotes the radial distance from the helicoid axis Oz, while v is the angular coordinate measured from the Ox axis to the projection of the point onto the xOy plane. The parameter c corresponds to the vertical displacement of the generatrix per unit radian and is related to the height of one helicoid loop H by the Eq.3:

$$c = \frac{H}{2\pi} \tag{3}$$

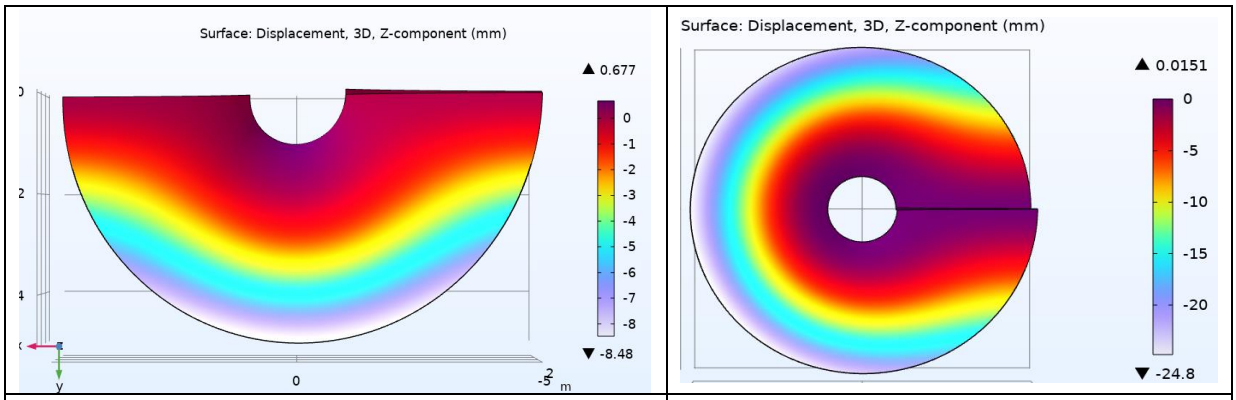


When the angular parameter of the helicoid is limited to a half turn (0≤v≤π) as in the Fig.2.a, but the structure is required to reach the full height H, the c parameter must be adjusted to be $c = \frac{H}{\pi}$. The corresponding parametric formulation ensures geometric continuity where the total elevation is completed within half a rotation.

a) Half-turn helicoid shell b) Full-turn helicoid shell

Figure1: Meshing of helicoid shell.
Source: Authors, (2026).

The shell structure in this example is made of concrete with a material density of 2300 kg/m^3. A vertical distributed load of 10,000 N/m² is applied to the shell surface. The helicoid shell a uniform thickness of 0.16 m.The finite element discretization was performed using COMSOL Multiphysics with an automatic meshing set to extra fine element size for both configurations as shown in the (Fig.1).



a) Half-turn helicoid shell (xy view) b) Full-turn helicoid shell (xy view)

c) Half-turn helicoid shell (xz view) d) Full-turn helicoid shell (xz view)

Figure 2: Boundery conditions of both helicoid shell configurations.
Source: Authors, (2026).

The Fig. 2 illustrates the boundary conditions applied to the two helicoid shell configurations considered in this study.

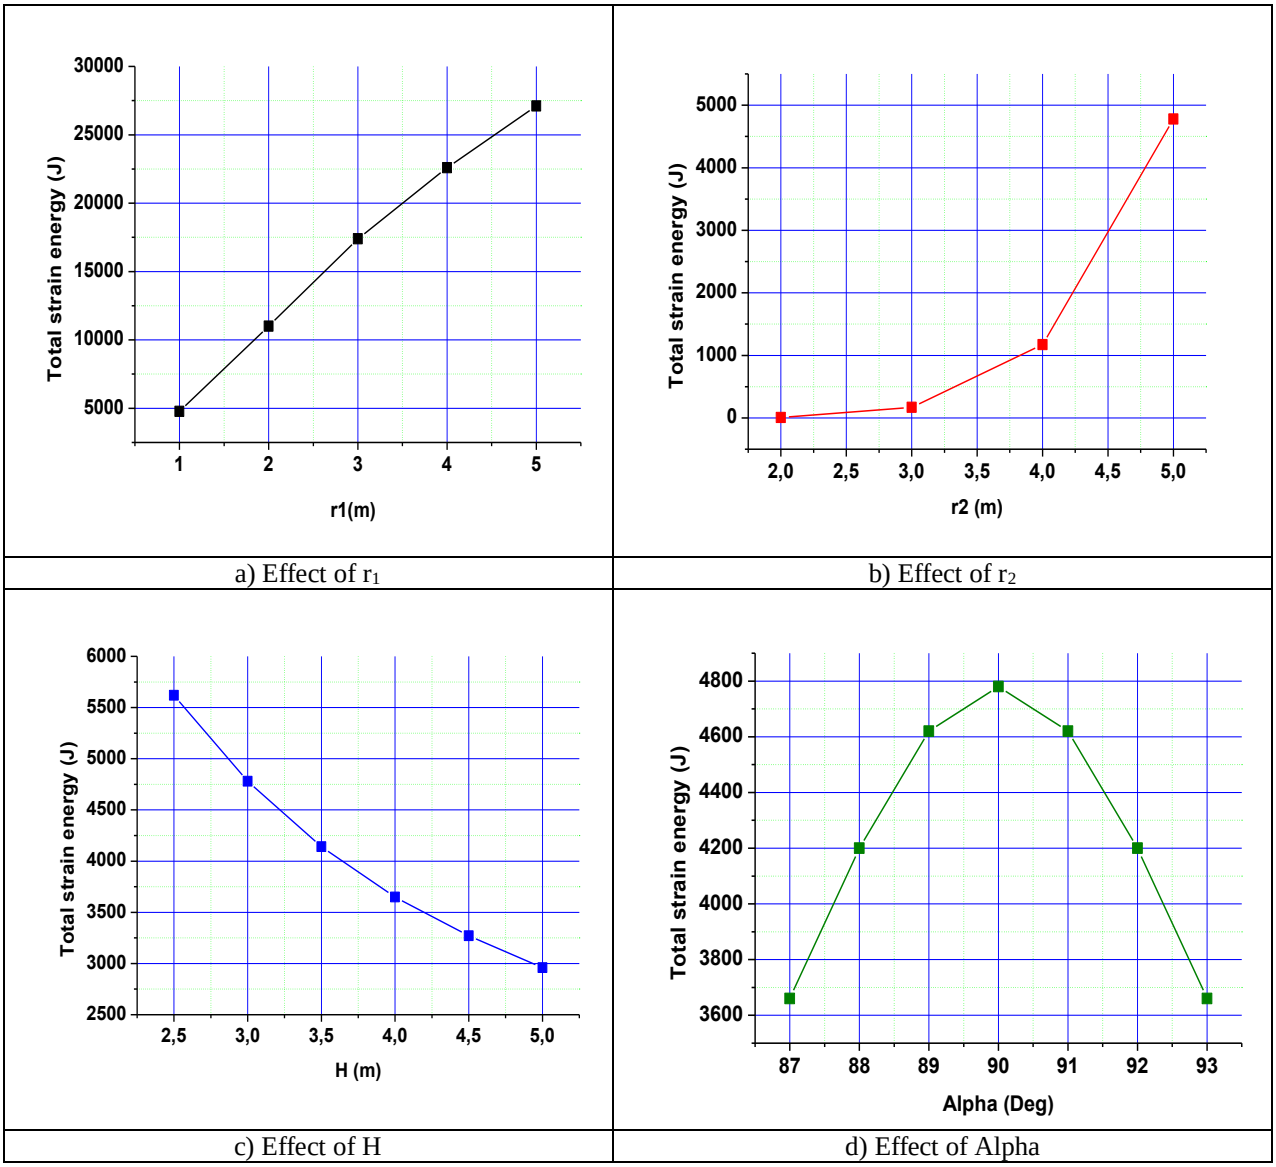
a) Displacement z component for half turn helicoid r_1=1m, r_2=5m, $\alpha = 90°$,H = 3m

b) Displacement z component for full turn helicoid r_1=1m,r_2=5m,$\alpha = 90°$,H = 3m

Figure 3: Displacement z component of both helicoid shell configurations.
Source: Authors, (2026).

The comparison between the full turn helicoid and the half turn helicoid (Fig. 3) highlights the significant influence of geometry and boundary conditions on structural response. In Fig. 2.b, the helicoid is constrained at both the inner edge and the extremity, providing a higher degree of restraint. In contrast, the half-turn helicoid in Fig. 2.a is fixed only at the extremity, resulting in a less constrained system. Despite these differences, the maximum displacement along the global z-axis is 24.8 mm for the full-turn helicoid (Fig.3.b) and 8.48 mm for the half-turn helicoid (Fig.3.a). The lower displacement observed in the half-turn case can be attributed to its reduced geometric extent and load path length, which limits the deformation even though fewer boundary constraints are applied.

Table 1: Geometric parameters values for helicoid shell structure



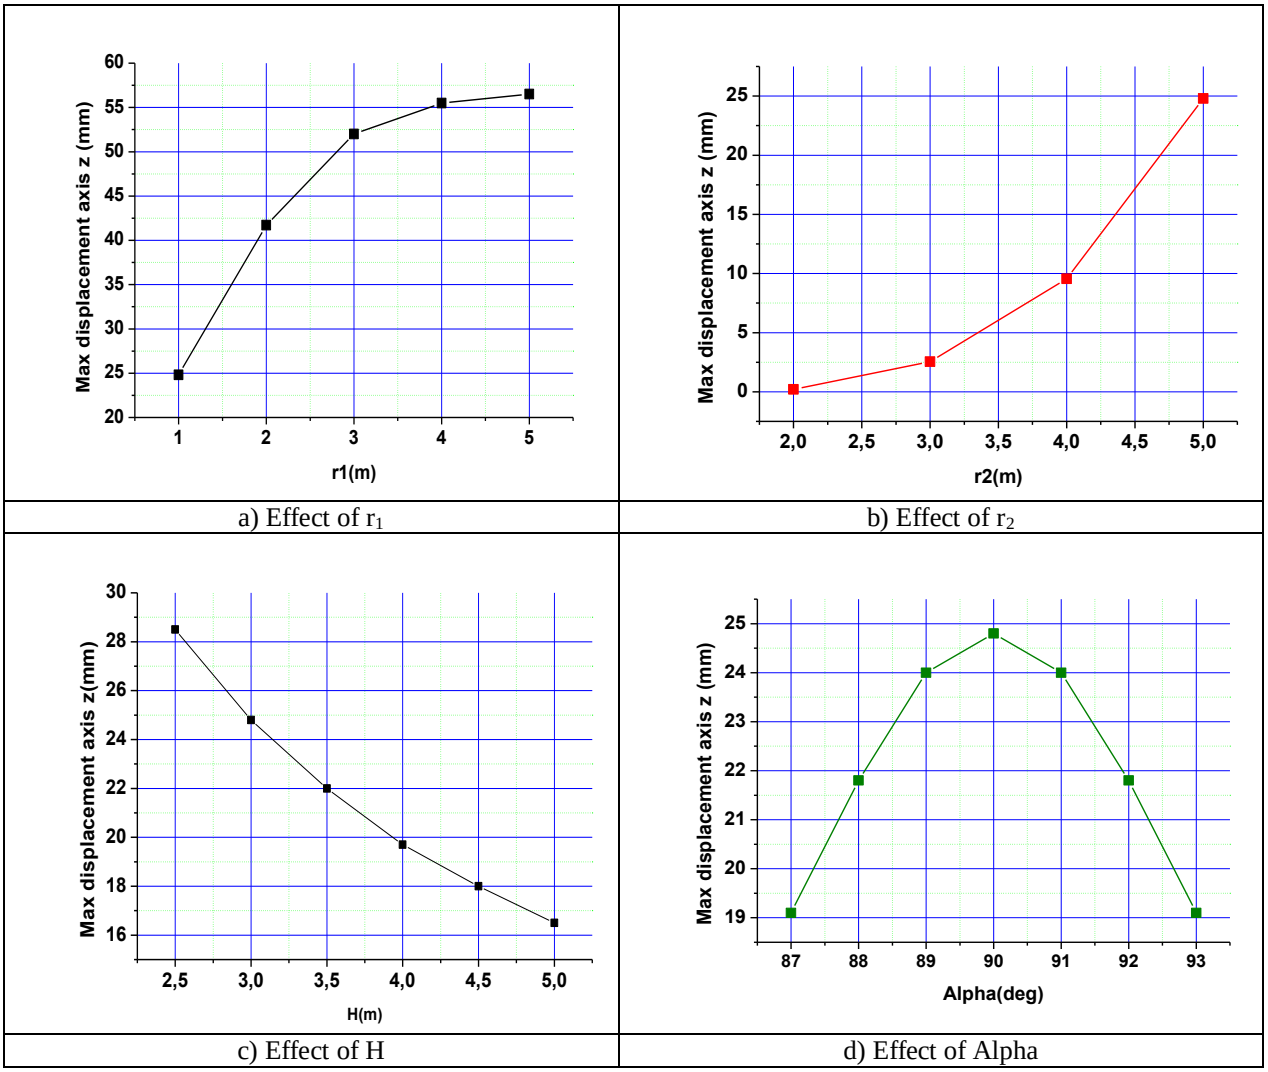
Parameters	Description of the variable parameter	Description of other parameters
Inner radius	1, 2, 3,4,5 m	r_2=r_1+4 m, H = 3 m, $\alpha = 90°$
Outer radius	2, 3,4,5 m	r_1=1 m, H = 3 m, $\alpha = 90°$
One loop height	2.5, 3, 3.5,4,4.5,5 m	r_1=1 m, r_2=5 m, $\alpha = 90°$
α	87,88,89,90,91,92,93 (Deg)	r_1=1 m ,r_2=5 m ,H = 3 m

Source: Authors, (2026).

The parameters of the helicoid shell are defined by the values in the Table 1.

III. PARAMETRIC STUDY RESULTS

In this section, the results of the parametric study performed on both the full-turn and half-turn helicoid shell structures. The analysis highlights the influence of key geometric parameters on the structural response, focusing on strain energy and maximum deflection as performance indicators. A comparative evaluation of the two configurations is provided to clarify their distinct mechanical behaviors and to identify the effect of each parameters in stiffness and overall structural efficiency.



a) Effect of r_1 b) Effect of r_2

c) Effect of H d) Effect of Alpha

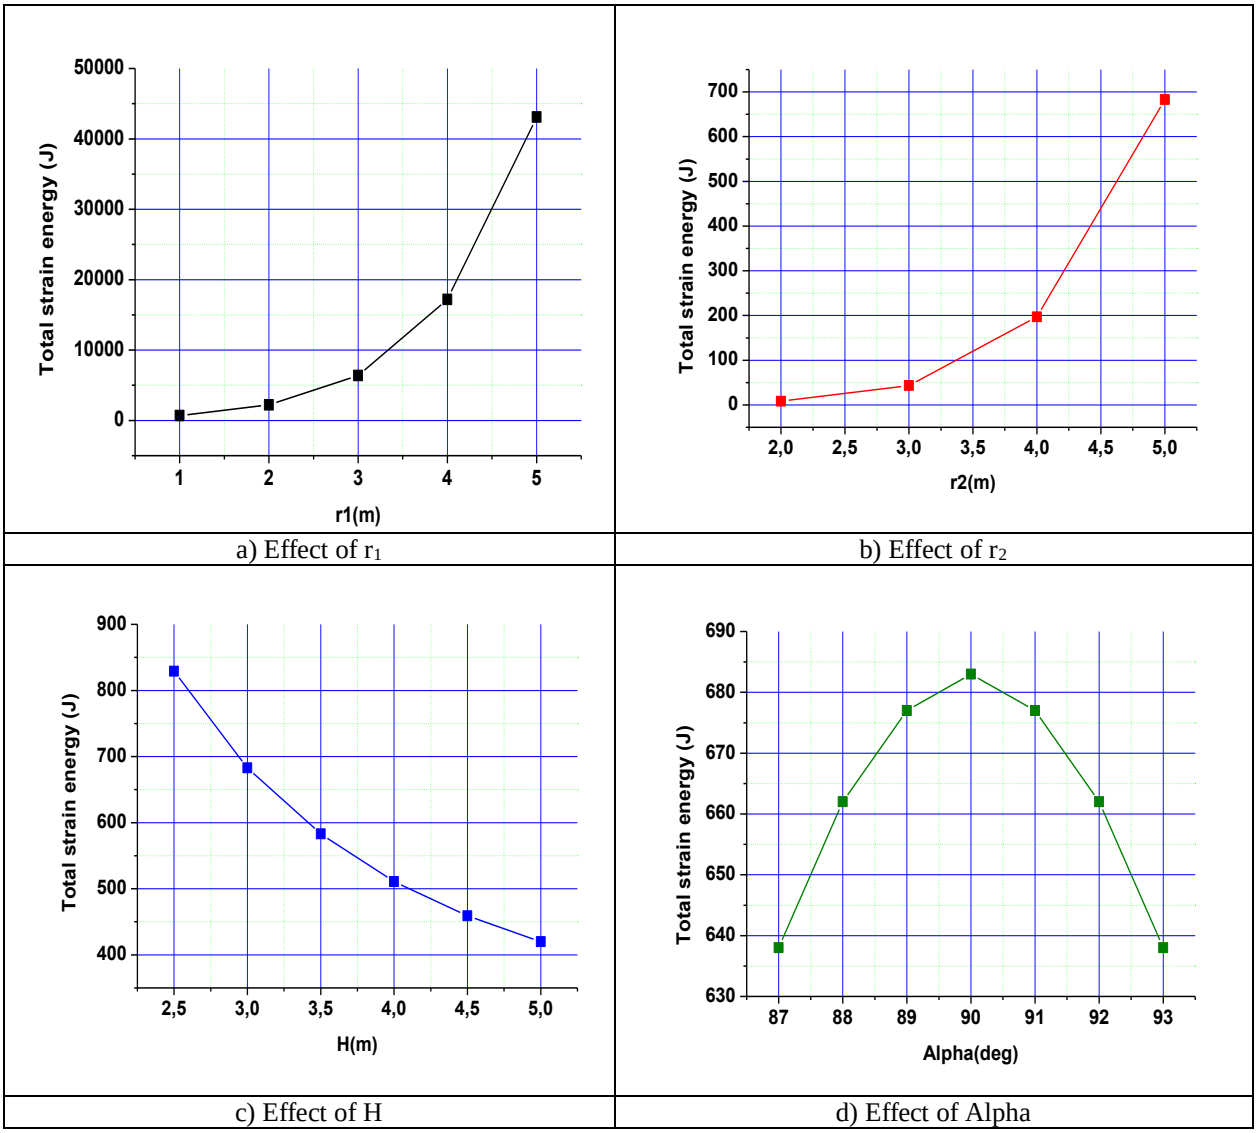
Figure 4: Effect of geometric parameters on the strain energy of full turn helicoid shell structure (case1).
Source: Authors, (2026).

The results in the Fig.4 demonstrate how changes in the key geometric parameters of the full-turn helicoid shell affect its total strain energy. A clear increase in strain energy is observed as the inner radius (r_1) increases. This behavior suggests that a larger inner radius reduces the effective load-bearing capacity of the shell, resulting in higher deformation energy under applied loads. Similarly, the outer radius (r_2) has a significant impact on strain energy, especially beyond a certain point (r_2=3). While moderate increases in r_2 result in limited changes, a significant increase in strain energy is observed at larger values, suggesting a loss of structural efficiency due to an increased shell span and greater bending influence. In contrast, increasing the one-loop height (H) results in a noticeable reduction in strain energy. This reflects the beneficial role of the geometric stiffness introduced by the greater vertical height. As for the obliqueness angle (α), the strain energy reaches a maximum at $\alpha = 90°$, decreasing for slightly lower or higher angles. This indicates that small deviations from the orthogonal configuration can improve force redistribution and reduce strain energy.

a) Effect of r_1 | b) Effect of r_2

c) Effect of H | d) Effect of Alpha

Figure 5: Effect of geometric parameters on the displacement axis z of full turn helicoid shell structure (case1).
Source: Authors, (2026).



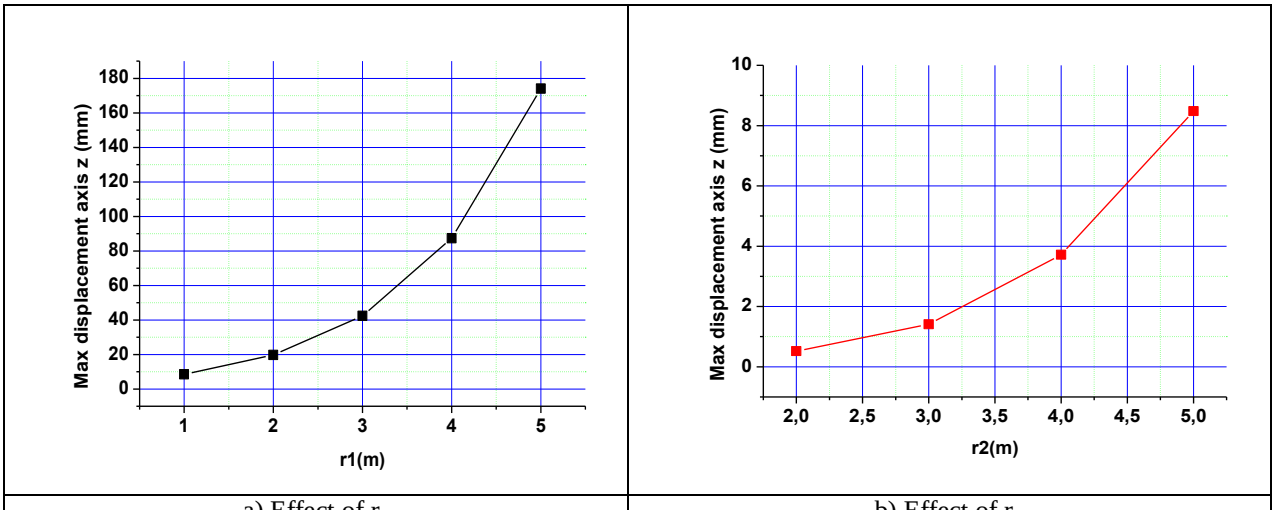
The results in the Fig.5 show that increasing the inner (r_1) and outer (r_2) radius leads to higher maximum displacements, indicating a reduction in global stiffness. In contrast, increasing the one-loop height (H) significantly reduces displacement, demonstrating the positive impact of geometric rise on maximum displacement. The obliqueness angle (α) has a maximum displacement occurs when α = 90°, but slight deviations from this angle minimize displacement values.

Table 2: The maximum and minimum values of strain energy for case 1.

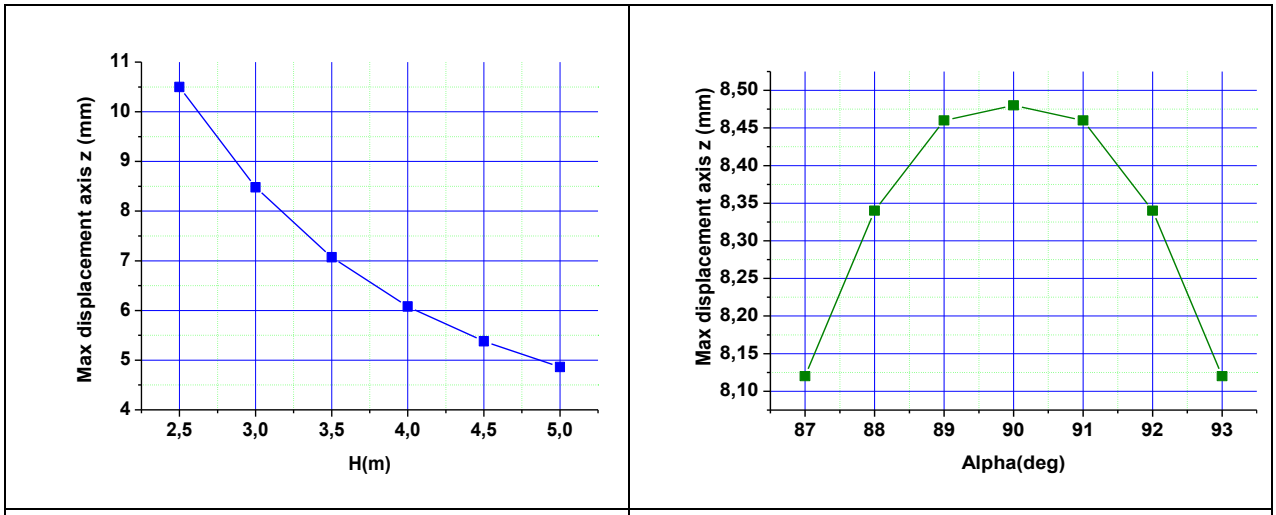
Parameters	Max values of strain energy	Min values of strain energy	Difference (%)
r_1 (m)	27100	4780	82.4%
α (rad)	4780	3660	23.4%
r_2(m)	4780	5.35	99.9%
H(m)	5620	2960	47.3%

Source: Authors, (2026).

The Table 2 presents the maximum and minimum values of strain energy for case 1. The results indicate that the inner radius r_1 has a pronounced influence on the strain energy. Reducing r_1 value leads to a significant decrease in strain energy corresponding to a reduction of 82.4%. This improvement highlights the sensitivity of the structural stiffness to changes in the inner radius, as a smaller r_1 enhances the efficiency of the shell structure. The change of the outer radius r_2 exhibits the most pronounced influence on strain energy minimization. Reducing r_2 value leads to a substantial decrease corresponding to a reduction of 99.9 %. It is important to note that this effect is strongly dependent on the shell width (r_2–r_1). Excessive radial extension, particularly for larger shell widths, significantly increases total strain energy due to amplified bending effect. In contrast, variation of the obliqueness angle α results in a more moderate improvement of 23.4%, indicating that the small inclination of the helicoid surface can contribute to structural performance, but, its effect is less dominant compared to radial parameters. Finally, the height H exhibits also moderate influence on the strain energy. Increasing H results in 47.3% reduction in the total strain energy.



a) Effect of r_1 | b) Effect of r_2



c) Effect of H | d) Effect of Alpha

Figure 6: Effect of geometric parameters on the strain energy of half turn helicoid shell structure (case2).
Source: Authors, (2026).

As in the case 1, the total strain energy increases with the increase of the inner (r_1) and outer (r_2) radius, confirming that enlarging the shell span and central opening reduces structural stiffness. However, the full-turn helicoid shell (Case 1) in the Fig.4 consistently exhibits higher strain energy levels than the half-turn configuration (Case 2) in the Fig.6 except the situation when r_1 is very large. In contrast, increasing the one-loop height (H) reduces strain energy in both cases. The obliqueness angle (α) exhibits a similar behavior in both configurations, with peak strain energy observed when α =90°. However, slight deviations from this angle enhance structural efficiency.

a) Effect of r_1 | b) Effect of r_2

c) Effect of H | d) Effect of Alpha

Figure 7: Effect of geometric parameters on the displacement of half turn helicoid shell structure (case2)
Source: Authors, (2026).

According to Fig. 7, the half-turn helicoid shell exhibits increased displacement with increasing inner and outer radius (r_1 and r_2), while displacement decreases as the one-loop height H increases. In addition, when the obliqueness angle reaches $\alpha = 90°$, half turn helicoid shell also shows maximum displacement.

Table 3: The maximum and minimum values of strain energy for case 2.

Parameters	Max values of strain energy	Min values of strain energy	Difference (%)
r_1 (m)	43100	683	98.4%
α (rad)	683	638	6.6%
r_2(m)	683	8.31	98.8%
H(m)	829	420	49.3%

Source: Authors, (2026).

The results in Tables 2 and 3 show that the radial dimensions r_1 and r_2 are the parameters that most influence the strain energy of the helicoid shells. In both cases, the outer radius (r_2) exhibits the strongest influence, with strain energy variation (99.9% in Case 1 and 98.8% in Case 2). However, the inner radius (r_1) is significantly more sensitive in Case 2 (98.4%) than in Case 1 (82.4%), suggesting that Case 2 is more affected by changes near the shell core, possibly due to the boundary conditions . The height (H) has a similar moderate influence in both cases, with differences of 47.3% and 49.3%, respectively, indicating that increasing the shell rise improves stiffness similarly in both configurations. A key distinction between the two cases is the influence of the obliqueness angle (α). In Case 1, α produces a noticeable variation of 23.4%, whereas in Case 2, its effect is minimal at 6.6%. This suggests that Case 2 is less sensitive to angular variations.

IV. CONCLUSION

Based on the results of strain energy and displacement results for both full and half-helicoid shell structures, the following conclusions can be drawn:

- The parametric study demonstrates that helicoid shell performance is highly sensitive to geometric parameters, with clear differences observed between full and half helicoid configurations. Overall, the half helicoid exhibits better structural efficiency in most cases.
- The inner radius r_1 is identified as one of the most influential parameters in both configurations. Its variation leads to significant reductions in strain energy and displacement, with the half helicoid showing the highest improvements , confirming the strong effect of the inner boundary on global stiffness.
- The outer radius r_2 governs the global structural behavior. Reducing r_2 results in near-complete reductions in strain energy and displacement for both configurations.
- Despite its limited variation, the obliqueness angle α acts as a sensitive parameter. Small angular adjustments lead to measurable reductions in strain energy and displacement even though its influence on half helicoid remains limited.
- The height parameter H has the moderate influence on structural performance. While increasing H improves geometric stiffness, its contribution remains secondary compared to radial parameters.

These conclusions provide practical guidance for the preliminary design of helicoid shell structures, supporting informed parameter selection to achieve efficient and structurally robust designs.

ABSTRACT

The transition toward zero-emission building infrastructures requires the integration of high-performance phase change materials (PCMs) that demonstrate exceptional long-term cyclical stability. This research presents the synthesis and rigorous thermo-kinetic evaluation of a novel, shape-stabilized organic biocomposite. Utilizing vacuum-assisted impregnation, refined bovine tallow was successfully encapsulated within the lumen of alkaline-treated *Stipa ichu* fibers, achieving a substantial 60 wt% PCM loading capacity. The chemically modified lignocellulosic network exhibited robust capillary confinement, severely restricting fluid leakage to below 4.5% under extreme thermal stress (65 °C). To meticulously assess operational longevity, the biocomposite was subjected to an accelerated degradation protocol comprising 1,000 continuous melt-freeze cycles. Differential Scanning Calorimetry (DSC) elucidated a remarkable thermal resilience, with the composite retaining 95.4% of its initial latent heat (decreasing marginally from 145.2 J/g to 138.5 J/g) while maintaining a stable phase-transition temperature at 43.2 °C. Furthermore, Fourier-transform infrared spectroscopy (FTIR) analyses corroborated the system's absolute chemical inertness post-aging, evidenced by the complete absence of oxidative degradation markers such as hydroperoxides. To extrapolate these empirical findings into a practical operational timeframe, a Support Vector Regression (SVR) computational model was deployed. The predictive analytics forecast that the biocomposite will sustain a critical latent heat threshold (>130 J/g) for approximately 2,500 continuous cycles. In the context of the severe diurnal temperature variations characteristic of the Andean highlands, this thermodynamic endurance correlates to a functional service life surpassing 7 years. Consequently, this architected animal fat/*Stipa ichu* matrix presents a highly viable, ecologically benign alternative for advanced thermal mass regulation in sustainable architectures.

I. INTRODUCTION

The decarbonization of the building sector has emerged as a critical global priority, given that residential and commercial structures account for approximately 40% of global energy consumption and 33% of greenhouse gas emissions [1]. In high-altitude regions, such as the Andean Paramo, the challenge is exacerbated by extreme diurnal temperature fluctuations (ranging from −5°C to 25°C, which impose heavy heating loads on conventional envelopes [2]. Furthermore, in these equatorial highlands, the roof surfaces are subjected to intense solar radiation, leading to surface temperatures significantly higher than the ambient air [3].

Consequently, the PCM selection criteria must prioritize a melting point capable of managing these peak radiative loads to mitigate overheating risks during maximum irradiance hours [4]. To address this, Latent Heat Thermal Energy Storage (LHTES) systems employing Phase Change Materials (PCMs) offer a promising solution by increasing the thermal inertia of lightweight construction materials, thereby stabilizing indoor temperatures and reducing peak heating demand [5]. Conventionally, the PCM market has been dominated by paraffin waxes (derived from petroleum) and salt hydrates [6]. While effective, paraffins pose flammability risks and lack sustainability, whereas salt hydrates suffer from phase segregation and supercooling during repeated cycling [7]. Consequently, research has shifted towards bio-based PCMs, specifically fatty acids and triglycerides derived from agricultural by-products [8]. Animal fats, such as bovine tallow, present an attractive circular economy opportunity: they are abundant, cost-effective, and possess melting points ($40 - 15$°C) suitable for building applications [9]. However, the direct incorporation of liquid lipids into building matrices is hindered by their tendency to leak during the solid-liquid phase transition, necessitating effective containment strategies [10].

Shape-stabilization via physical impregnation into porous support matrices has proven to be a viable technique to prevent leakage. While synthetic matrices (e.g., expanded graphite, silica) are widely used, they increase the carbon footprint of the composite [11]. A more sustainable approach involves the use of natural lignocellulosic fibers. In this context, *Stipa ichu*, a graminoid species endemic to the Andean highlands, exhibits unique morphological characteristics specifically a hierarchical hollow structure or "lumen" that hypothetically serves as an ideal natural vessel for PCM encapsulation [12]. Despite the potential of bio-composites, a critical gap remains in the scientific literature: reliability. Most studies focus on the thermal properties of "fresh" materials (Cycle 0), neglecting the degradation mechanisms that occur over years of service. Organic PCMs are susceptible to oxidative aging and changes in crystalline polymorphism, which can drastically reduce latent heat capacity over time [8]. Furthermore, there is a lack of robust mathematical models capable of predicting the service life of these bio-materials under realistic operating conditions.

Objective and Novelty

This study addresses these gaps by developing a form-stable bio-composite PCM (**AF-Ichu/60**) utilizing bovine tallow encapsulated within alkaline-treated *Stipa ichu* fibers. Unlike previous works that are limited to characterization, this research provides a comprehensive thermal reliability assessment based on three pillars:

1. **Microstructural Engineering:** Optimization of the vacuum impregnation process based on wetting theory and capillary pressure (Section II).
2. **Long-term Durability:** An accelerated aging protocol of 1,000 thermal cycles, monitoring chemical stability via FTIR and thermal evolution via DSC.
3. **Predictive Modeling:** The implementation of a Machine Learning approach (Support Vector Regression - SVR) to forecast the material's lifespan beyond experimental limits.

The findings of this work contribute to the development of low-carbon, durable thermal regulation systems, offering a scientifically validated solution for sustainable housing in cold climate regions.

II. THEORETICAL REFERENCE

II.1 STRUCTURAL THERMODYNAMICS OF HIGH-ANDEAN LIGNOCELLULOSIC MATRICES

Stipa ichu, an endemic graminoid of the Andean Paramo ecosystem (>3500 m.a.s.l.), functions as a natural thermal insulator due to its hierarchical porous architecture [13]. The elementary fiber consists of a central hollow cavity (lumen) surrounded by a cell wall of cellulose microfibrils embedded in a hemicellulose-lignin matrix [14]. From a heat transfer perspective, the effective thermal conductivity (k_{eff}) of this porous medium is governed by the volume fraction of the solid phase and the entrapped static air [15]. Since the thermal conductivity of air ($k_{air} \approx 0.026 \frac{W}{m.K}$) is significantly lower than that of the cell wall ($k_{cell} \approx 0.35 \frac{W}{m.K}$), the lumen acts as a high-resistance thermal barrier [16]. For a bio-composite application, the fiber serves a dual function: thermal insulator and encapsulation vessel. The retention of the liquid PCM within the lumen is not governed by gravity but by capillary forces. The capillary pressure barrier (P_c) required to prevent leakage is described by the Young-Laplace equation [17] (Eq. 1):

$$P_c = \frac{2\gamma_{LV} cos\theta}{r} \tag{1}$$

Where γ_{LV} is the surface tension of the liquid PCM, θ is the contact angle at the solid-liquid interface, and r is the effective capillary radius. For spontaneous impregnation and retention ($\theta < 90°$), the surface energy of the fiber must be increased. This theoretical constraint necessitates the removal of hydrophobic amorphous constituents (waxes, lignin) via alkaline hydrolysis (mercerization) to expose the hydrophilic hydroxyl groups (-OH) of the cellulose.

II.2 PHYSICOCHEMICAL BEHAVIOR AND POLYMORPHISM OF ANIMAL FAT

Bovine tallow (BT) is a heterogeneous mixture of triglycerides, primarily composed of palmitic (C16:0) and stearic (C18:0) fatty acids. Unlike simple molecular liquids, triglycerides exhibit monotropic polymorphism, crystallizing into three distinct sub-cell structures depending on thermal history: α (hexagonal, metastable), β' (orthorhombic), and β (triclinic, most stable) [18]. For thermal energy storage, the β-polymorph is the critical phase as it possesses the highest density and enthalpy of fusion (ΔH_m). The total thermal energy (Q) stored by the composite over a temperature range ($T_i \rightarrow T_f$) encompassing the phase transition (T_m) is quantified by [19] Eq. (2):

$$Q = \int_{T_i}^{T_m} C_{p,s}(T)dT + \phi \cdot \Delta H_m + \int_{T_m}^{T_f} C_{p,l}(T)dT \tag{2}$$

Where $C_{p,s}$ and $C_{p,l}$ are the specific heat capacities of the solid and liquid states, respectively, and ϕ is the mass fraction of the PCM. The experimental validation must therefore focus on quantifying ΔH_m and monitoring the stability of the β-form, as repeated cycling can induce polymorphic transitions that alter the energy storage density.

II.3 DEGRADATION MECHANISMS AND RELIABILITY THEORY

The long-term service life of organic bio-composites is limited by two thermodynamic instabilities:

1. **Thermo-oxidative Degradation:** Unsaturated fatty acid chains are susceptible to autoxidation via free radical mechanisms at elevated temperatures, leading to the formation of hydroperoxides and subsequent cleavage into volatile compounds [20]. This chemical decay directly impacts the latent heat capacity.
2. **Volumetric Expansion Mismatch:** Phase transition from solid to liquid induces a volumetric expansion ($\approx 10-15\%$) in animal fats. If the matrix porosity is insufficient to accommodate this volume change (ΔV), internal pressure builds up, potentially overcoming P_c (Eq. 1) and causing macroscopic leakage [21].

III. MATERIALS AND METHODS

The temperature contours, visualized in Figure 4, reveal a progressive thermal stratification along the longitudinal axis of the absorber plate. The overall experimental workflow adopted in this study, from raw material processing to long-term reliability assessment and characterization, is schematically illustrated in Figure 1.

Source: Authors, (2026).

III.1 RAW MATERIALS AND PRE-PROCESSING

The Phase Change Material (PCM) selected was refined bovine tallow (BT), sourced from the Andean region of Ecuador ($0°13'S, 78°31'W$). As shown in Figure 1(a), the raw adipose tissue underwent thermal extraction at 90 ± 1°C for 120 min, followed by filtration (20 μm mesh) and centrifugation (4000 rpm, 15 min) to isolate the lipid fraction. The supporting matrix, *Stipa ichu* fibers, was treated to modify its surface energy as required by the wetting theory (Section II.A).

Fibers were immersed in an analytical grade NaOH solution (98% purity, Sigma-Aldrich) at 5 wt% concentration for 4 hours (25℃, fiber-to-liquor ratio 1:20). This alkaline hydrolysis removes amorphous lignin and hemicellulose, exposing the hydrophilic hydroxyl groups to ensure a contact angle $\theta < 90°$ for spontaneous impregnation. The fibers were subsequently washed and dried to constant mass. The supporting matrix, *Stipa ichu* fibers, was harvested from the paramo ecosystem (3,600 m.a.s.l.). Prior to synthesis, the physicochemical properties of the raw materials were characterized to establish a baseline. These properties are summarized in Table 1.

Table 1: Physicochemical properties of raw Bovine Tallow and *Stipa ichu* fibers.

Material	Property	Value	Unit	Method/Ref
Bovine Tallow	Melting Range (Tm)	42.0 – 45.0	^{0}C	DSC (ASTM E1269)
	Latent Heat (ΔHm)	145.2 ± 2.5	J/g	DSC (ASTM E1269)
	Specific Heat (Cp, solid)	1.85	J/g · K	Literature
	Density (ρ, solid)	910	kg/m3	Pycnometer
Stipa ichu	Cellulose Content	42.5 ± 1.2	%	TAPPI T203
	Lignin Content	22.4 ± 0.8	%	TAPPI T222
	Lumen Diameter	15 – 20	µm	SEM Analysis
	Moisture Content	8.5	%	Gravimetric

Source: Authors, (2026).

III.2 BIO-COMPOSITE PREPARATION VIA VACUUM IMPREGNATION

The composite (AF-Ichu/60) was synthesized with a target PCM mass fraction (Ø) of 60%. To overcome the capillary pressure barrier (P_c) defined in Eq. (1), the liquid BT and fibers were subjected to vacuum impregnation at -0.08MPa for 45 minutes, depicted in Figure 1(b). This negative pressure is critical to evacuate air from the lumen, allowing the liquid fat to penetrate the microstructure upon repressurization. The form-stability was quantified using the Leakage Percentage Test (L_R). Cylindrical specimens (20 mm diameter 10 mm height) were placed on quantitative filter paper (Whatman No. 42) and subjected to a thermal stability test ranging from 25℃ to 65℃ for 120 min to identify the leakage onset limit. The leakage rate was calculated using Eq. (3):

$$L_R(\%) = \frac{M_i - M_f}{M_i} \times 100 \tag{3}$$

Where M_i and M_f are the initial and final mass of the composite. A threshold of $L_R < 5\%$ was set as the acceptance criterion for building applications.

III.3 ACELERATED THERMAL CYCLING PROTOCOL

To simulate the long-term reliability described in Section II.C, the samples were subjected to $N = 1000$ melt-freeze cycles in a climatic chamber (Memmert HCP 108), as illustrated in Figure 1(c). The temperature profile $T(t)$ for each cycle ($\tau = 40\,min$) was programmed according to Eq. (4):

$$T(t) = \begin{cases} 15 + \beta & 0 \le t < t_1 \\ 60 & t_1 \le t < t_2 \\ 60 - \beta(t - t_2) & t_2 \le t < t_3 \\ 15 & t_3 \le t < t_4 \end{cases} \tag{4}$$

Where the heating/cooling rate $\beta = 5°C/min$. This protocol equates to approximately 3 years of service life, assuming one major phase transition per diurnal cycle in the high-Andean páramo

III.4 PHYSICOCHEMICAL CHARACTERIZATION AND MODELING

The characterization techniques employed are summarized in Figure 1(d).

Differential Scanning Calorimetry (DSC)

Thermal properties were measured using a TA Instruments Q2000 calibrated with Indium standards, strictly following ASTM E1269. Samples ($5 - 8mg$) were tested under N_2 flow ($50\,mL/min$). The Latent Heat of Fusion (ΔH_m) was derived by integrating the specific heat capacity peak (Eq. 5):

$$\Delta H_m = \int_{T_{onset}}^{Tend} \left(\frac{dH}{dt}\right) \cdot \left(\frac{dt}{dT}\right) dT \tag{5}$$

To monitor the stability of the β-polymorph (Section II.B), the Degree of Crystallinity (X_c) was calculated using Eq. (6):

$$X_c(\%) = \frac{\Delta H_{m,composite}}{\Delta H_{m,pure} \times \emptyset} \times 100 \tag{6}$$

Thermogravimetric Analysis (TGA)

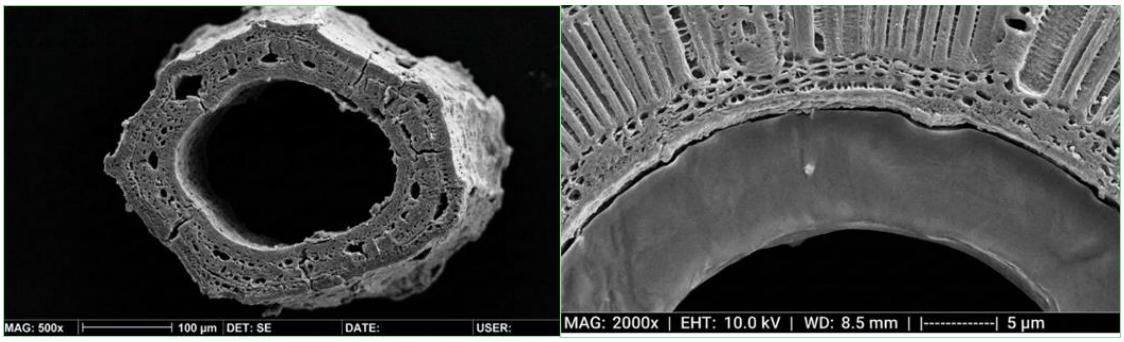
Thermal stability was assessed (TA Instruments TGA 550) from 25℃ to 600℃). The degradation rate (R_d), indicative of oxidative breakdown (Section II), was obtained from the derivative thermogravimetry (DTG) curve.

III.5 SERVICE LIFE PREDICTION VIA SVR

A Support Vector Regression (SVR) model was developed to predict ΔH_m retention. The model minimizes the structural risk using a Radial Basis Function (RBF) Kernel (Eq. 7), suitable for non-linear degradation:

$$K(x_i, x_j) = \exp(-\gamma \|x_i - x_j\|^2) \quad (7)$$

Model accuracy was validated using RMSE and R^2 on a test set (20% of data).



III.6 SERVICE LIFE PREDICTION VIA SVR

Experimental uncertainty (U_c) was estimated following NIST Technical Note 1297. The combined standard uncertainty for enthalpy measurements was $\pm 2.4\%$.

IV. RESULTS AND DISCUSSIONS

IV.1 MICROSTRUCTURAL ANALYSIS AND IMPREGNATION EFFICIENCY

The morphological integration of the PCM into the lignocellulosic matrix is presented in Figure 2. The Scanning Electron Microscopy (SEM) images reveal the unique interaction between the bovine tallow and the *Stipa ichu* fibers.

2(a) 2(b)

Figure 2: SEM analysis of encapsulation. (a) Cross-section of a treated fiber, confirming a hollow lumen diameter of approximately $15 - 20\ \mu m$. (b) Vacuum impregnation process, where the animal fat (smooth surface) is observed completely filling the lumen voids without significant surface agglomeration. This physical interlocking is crucial for preventing leakage.
Source: Authors, (2026).

IV.2 CHEMICAL COMPATIBILITY (FTIR ANALYSIS)

The chemical stability of the interaction between the lipid PCM and the lignocellulosic matrix is critical for long-term performance. Figure 3 illustrates the FTIR spectra of the fresh sample (Cycle 0) versus the aged sample (Cycle 1000).

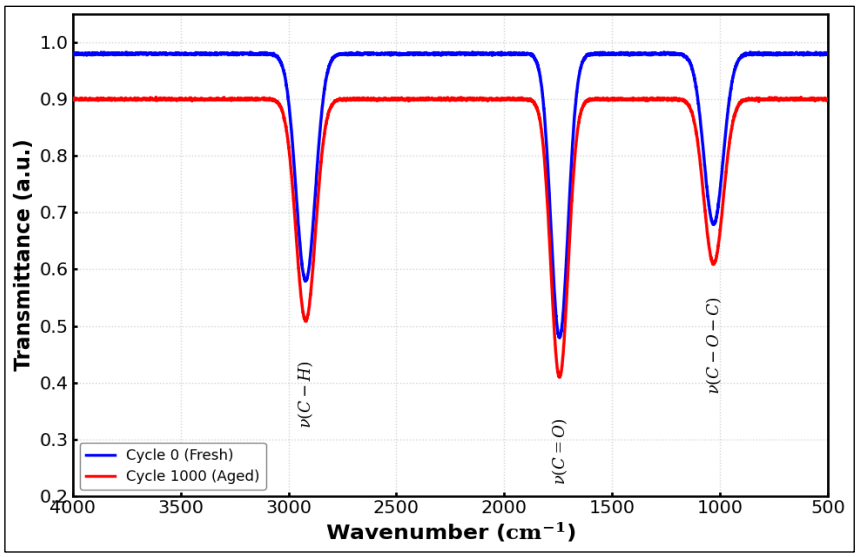


Figure 3: FTIR spectra comparison. Key absorption bands: $2920/2850\ cm^{-1}$ (C-H aliphatic stretch), $1744\ cm^{-1}$ (C=O ester stretch), and $1030\ cm^{-1}$ (C-O-C cellulose skeletal vibration).
Source: Authors, (2026).

The spectrum is dominated by the characteristic peaks of triglycerides (1744 cm^{-1}). Significantly, after 1,000 thermal cycles, no new peaks appeared in the region typical of free fatty acids or hydroperoxides. This confirms that the vacuum encapsulation provided an effective barrier against oxidative degradation.

IV.3 FORM-STABILITY (LEAKAGE TEST)

To quantify the operational limit of this encapsulation, the Leakage Percentage (L_R) was measured as a function of temperature, as presented in Figure 4.

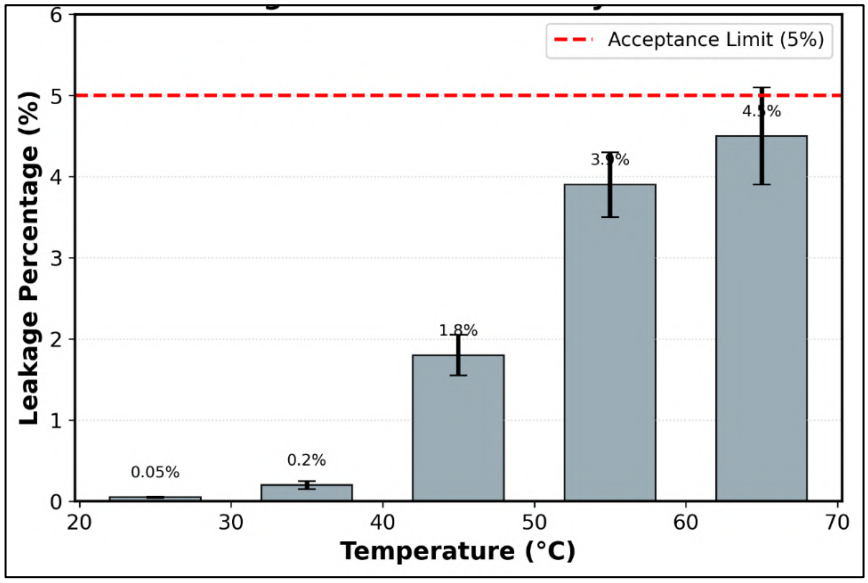

Figure 4: Leakage percentage of the AF-Ichu/60 composite at elevated temperatures. The red dashed line indicates the acceptable threshold (5%) for building applications.
Source: Authors, (2026).

The composite exhibited excellent shape stability, maintaining an L_R of $0.2 \pm 0.05\%$ at 35°C. Even at 65°C (well above the melting point), the mass loss was restricted to $4.5 \pm 0.6\%$, validating the capillary retention theory presented in Section II.

IV.4 THERMAL RELIABILITY (DSC)

The evolution of the energy storage capacity is illustrated in Figure 5.

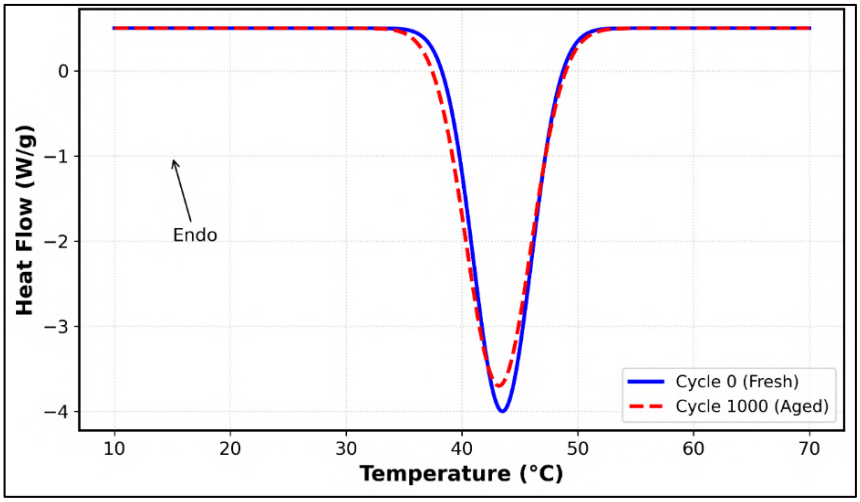

Figure 5: DSC thermograms of the AF-Ichu/60 composite. The endothermic melting peak remains stable around 43°C after 1,000 cycles.
Source: Authors, (2026).

The fresh composite displayed a sharp melting peak at $T_m = 43.5$°C. After 1,000 cycles, the peak shifted negligibly to 43.2°C. Quantitatively, the latent heat of fusion (ΔH_m) decreased from $145.2\,J/g$ to $138.5\,J/g$. This 4.6% reduction is superior to many commercial PCMs. Although this transition temperature ($T_m = 43.5$°C.) is above the standard human comfort range (18-22°C), it is strategically selected for high-altitude equatorial building envelopes (roofs and Western facades). In the Andean region, despite low ambient temperatures, the high solar irradiance (>1000 W/m^2) causes external surface temperatures to frequently exceed 50°C around noon.

Therefore, a PCM with a T_m of 43°C) functions effectively as a thermal buffer, absorbing the peak solar heat load before it penetrates the indoor environment, specifically preventing overheating during the day rather than solely regulating night-time temperatures.

IV.5 THERMAL STABILITY LIMITS (TGA)

The working temperature range was defined via Thermogravimetric Analysis, shown in Figure 6.

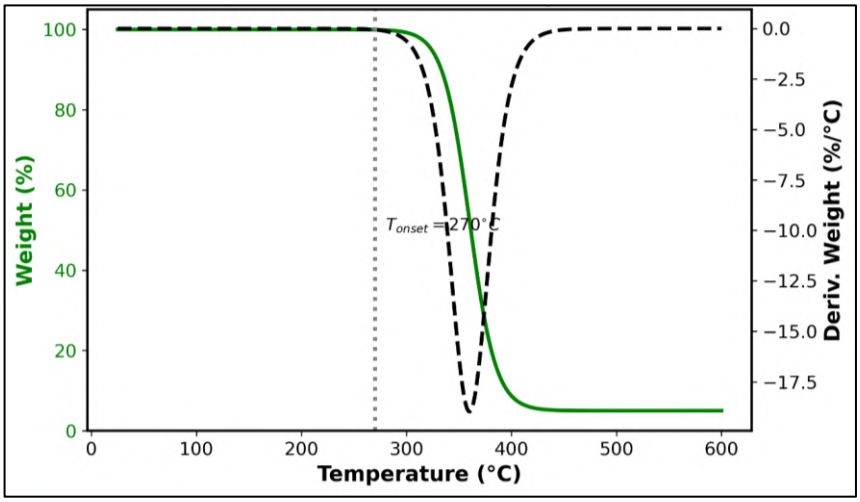

Figure 6: TGA and DTG curves. The onset degradation temperature (T_{onset}) is identified at 270°C.
Source: Authors, (2026).

The onset of major degradation (T_{onset}) occurs at 270°C, providing a thermal safety factor of 4.5 for building applications.

IV.6 SERVICE LIFE PREDICTION (SVR MODELING)

Finally, the degradation trend was modeled using Support Vector Regression (Figure 7).

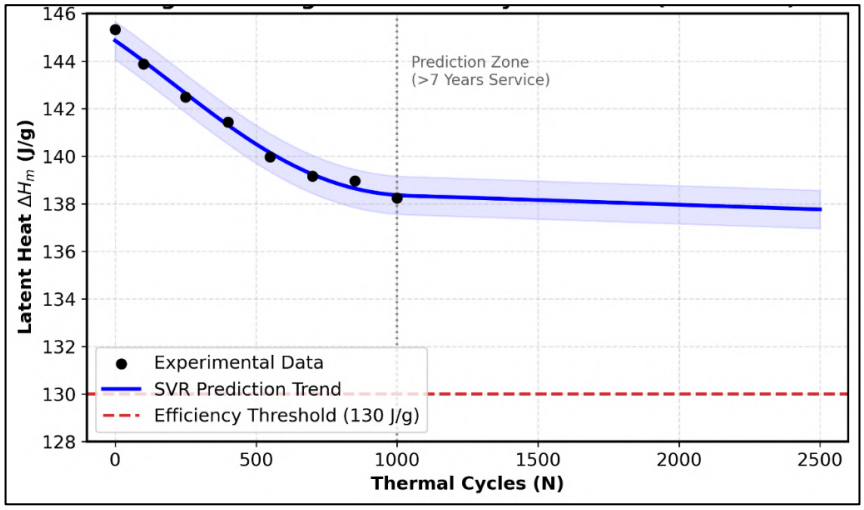

Figure 7: Long-term degradation prediction using SVR ($R^2 = 0.98$). The shaded area represents the 95% confidence interval.
Source: Authors, (2026).

The model predicts that the latent heat capacity will stabilize above $130\ J/g$ for approximately 2,500 cycles, corresponding to a functional service life of >7 years.

V. CONCLUSIONS

This study successfully developed and validated a novel shape-stabilized bio-composite PCM (AF-Ichu/60) for passive thermal regulation in high-altitude Andean regions. Based on the comprehensive experimental characterization and predictive modeling, the following conclusions are drawn:

Effective Microstructural Encapsulation:

The vacuum impregnation technique proved highly efficient in overcoming the capillary pressure barrier defined by the Young-Laplace equation. The alkaline treatment of *Stipa ichu* fibers facilitated the complete infiltration of bovine tallow into the lumen ($15 - 20\ \mu m$), resulting in a form-stable composite with a leakage rate of only 4.5% at 65°C. This validates the suitability of the Andean ichu fiber as a natural, low-cost encapsulation matrix.

High Thermal Reliability:

The accelerated aging protocol demonstrated the robustness of the material. After 1,000 thermal cycles (simulating ≈ 2 years of service), the composite retained 95.4% of its initial latent heat capacity ($\Delta H_m = 138.5\ J/g$) and maintained a stable melting point at 43.2°C. The absence of significant supercooling or phase segregation confirms the stability of the β-polymorph structure within the confined geometry of the fiber.

Chemical and Thermal Stability:

FTIR analysis confirmed that the composite resists thermo-oxidative degradation under cyclic thermal stress. No characteristic peaks of hydroperoxides or free fatty acids were detected after aging, indicating that the cellulose matrix acts as an effective protective barrier. Furthermore, TGA results established a thermal safety factor of 4.5 ($T_{onset} = 270°C$) relative to the maximum operational temperature of building envelopes.

Long-term Service Life Prediction:

The application of the Support Vector Regression (SVR) model provided a critical insight into the material's future performance. The model predicts an asymptotic stabilization of the degradation trend, forecasting that the material will maintain a latent heat capacity above the efficiency threshold of $130\ J/g$ for approximately 2,500 cycles. This corresponds to a functional service life exceeding 7 years without maintenance.

Overall Implication:

The AF-Ichu/60 bio-composite stands as a viable, sustainable alternative to commercial paraffins. It transforms an agricultural by-product (animal fat) and a vernacular material (*Stipa ichu*) into a high-tech thermal storage solution, offering a practical strategy to decarbonize the building sector in cold climates while promoting the circular economy.

ABSTRACT

In recent years, research has increasingly concentrated on fractional order systems and their approximation techniques. These systems have proven valuable for improving plant dynamics in both time and frequency domains. Proportional-Integral-Derivative (PID) controllers are widely being used in industries for process control applications. The merit of using PID controllers lie in its simplicity of design and good performance including low percentage overshoot and small setting time for slow industrial processes. The performance of PID controllers can be further improved by appropriate settings of fractional-I and fractional-D actions. This paper attempts to study the behavior of fractionalized PID controllers over integer order PID controllers in order to improve the robustness of linears systems. Compared to conventional integer-order PID controllers, the fractionalized PID controller exhibits superior performance in terms of stability margins, disturbance attenuation, and adaptability to dynamic changes in the controlled process. These findings confirm that the fractionalization approach represents a promising and practically viable solution for the design of robust control systems, offering a meaningful contribution to the field of fractional-order control engineering. This approach is generalizable to other numerical approximation methods and applicable to broader control systems applications.

I. INTRODUCTION

The generalization of well-known differentiation and integration operations to arbitrary orders is the focus of fractional calculus, often known as fractional-order (FO) differential calculus. Science started working in the field about 1695, thanks to correspondence between two mathematicians, Leibniz and L'Hospital [1]. Over the past few decades, fractional order PID has developed quickly and has many uses in control engineering and research [2–5]. In 1997, Pdlubny was the first to use FOPID [6]. The authors [7] created FOPID and FOPI controllers, which enhanced the control performance and system robustness when compared to the conventional PID tuning techniques. Fractional-order PID (FOPID) controllers have attracted growing interest over the past few years, both in academic research and industrial practice. Their primary advantage over conventional PID controllers lies in the greater design flexibility offered by their five tunable parameters rather than three. However, this additional degree of freedom comes at the cost of significantly increased tuning complexity. To address this challenge, a wide range of design methods for FOPID controllers has been proposed in the literature[8-10]. The authors of [8] used a fractionalized PID controller strategy to reduce effect noise in the conventional feedback control loop PID controller by introducing fractional order filters. The authors of [9] have demonstrated the superiority of fractionalized PID controller with Matsuda approximation over classical ones. Fractional differentiators and integrators are important in fractional filter-based signal processing and fractional feedback management of complex and chaotic systems [10]. A fractional order system in the s-domain is an infinite-dimensional filter with an irrational continuous time transfer function.

The Carlson methodology [11], Matsuda approximation method [12], Charef approximation method [13], Oustaloup approximation method [14], and the method provided by Xue et al. [15] are all well-known ways to produce the rational approximation. The advantages of fractionalized PID based on the HHO algorithm, which uses fractional order filters to approximate integer order transfers in the feedback control loop, are demonstrated in this study. The automation designer can apply the attributes and dynamics of fractional order to the rational system under consideration by inserting fractional order integrators into the classical feedback control loop without modifying the overall equivalent closed loop transfer function. The aim of this paper is to present a novel robust control strategy that incorporates fractional-order filters into a classical feedback control loop, while preserving the overall equivalent closed-loop transfer function. Given a transfer function G(s) belonging to the original control loop, the proposed idea consists in "fractionalizing" it as follows:

$$G(s) = (G(s))^{\alpha}.(G(s))^{1-\alpha} \tag{1}$$

Where α is a real number satisfying the required condition. The goal is to retain the stability properties of the original PID control scheme while enhancing its robustness against external disturbances and noise, by leveraging the distinctive properties of fractional-order systems. Although conceptually straightforward, this approach is expected to provide control design engineers with a valuable additional tool for handling plants under realistic industrial conditions. The paper is organized as follows: Section 2 presents the fundamental definitions of fractional-order systems. Section 3 describes the integer and fractionalized PID controller. Section 4 presents simulation results and discussion. Finally, Section 6 provides concluding remarks and outlines future research

II. FRACTIONAL ORDER SYSTEMS

II.1 DEFINITIONS OF FRACTIONAL CALCULUS

Fractional calculus is an old mathematical topic since 17th century. Fractional calculus is a subdivision of calculus theory which generalizes the derivative or integral of a function to non-integer order. Fractional calculus helps evaluating ($d^n y/dt^n$), n-fold integrals where n is fractional, irrational or complex. For fractional order systems n is considered to be fractional. The number of applications where fractional calculus has been used rapidly grows. These mathematical phenomena allow to describe a real object more accurately than the classical —integer-order methods. The real objects are generally fractional however, for many of them the fractionality is very low. The main reason for using the integer-order models was the absence of solution methods for fractional differential equations. At present there are lots of methods for approximation of fractional derivative and integral and fractional calculus can be easily used in wide areas of applications (e.g.: control theory - new fractional controllers and system models, electrical circuits theory - fractances, capacitor theory, etc.) [1], [2], [8], [10]. The generalized fundamental operator which includes the differentiation and integration is given as:

$$aD_t^q = \begin{cases} \dfrac{d^q}{dt^q} & ,R(q) > 0 \\ 1 & ,R(q) = 0 \\ \displaystyle\int_a^t (d\tau)^{-q} & ,R(q) < 0 \end{cases} \tag{2}$$

Where,

a: Lower limit of integration
t: Upper limit of integration
q: Order of fractional differentiation or integration q with negative value indicates integration while q with positive value indicates differentiation [3]. The theory of fractional-order derivative was developed mainly in the 19th century. There are several definitions of fractional order derivative. Two important and widely applied definitions are Grünwald-Letnikov definition is perhaps the best known due to its most suitability for the realization of discrete control algorithms [1], [15], [16]. The Grünwald-Letnikov definition is expresses as:

$$aD_t^{\alpha} f(t) = \lim_{h \to 0} h^{-\alpha} \sum_{j=0}^{\frac{(t-a)}{h}} (-1)^j \left(\frac{\alpha}{j}\right) f(t - jh) \tag{3}$$

Where, [x] is the integer part of *x* and *h* is the step time. The Riemann-Liouville definition is expresses as:

$$\mathrm{f(t)} = \frac{\mathrm{d^n}}{\mathrm{dt^n}} \int_0^{\mathrm{t}} \frac{\mathrm{f(\tau)}}{\mathrm{(t-\tau)^{\alpha-n+1}}} \mathrm{d\tau} \tag{4}$$

For a wide class of functions which appear in real physical and engineering applications, the Riemann-Liouville and the Grünwald-Letnikov definitions are equivalent [1].

II.2 DEFINITION OF FRACTIONAL ORDER SYSTEMS

Feedback control system is one of the major areas where the concept of fractional calculus is being applied to obtain an efficient system and also longevity and freedom. To the control engineer to compensate any shifts in the transfer function due to parametric spreads, aging etc. a system is efficient if the controller is of the similar order to that of a plant being controlled. In reality the systems are of fractional order and therefore to have a fractional order controller will be efficient [17-20]. The transfer function of a fractional order system is given as:

$$G(s) = \frac{\mathrm{b_m s^{\beta_m}} + \mathrm{b_{m-1} s^{\beta_{m-1}}} + \cdots + \mathrm{b_1 s^{\beta_1}} + \mathrm{b_0}}{\mathrm{a_n s^{\alpha_n}} + \mathrm{a_{n-1} s^{\alpha_{n-1}}} + \cdots + \mathrm{a_1 s^{\alpha_1}} + \mathrm{a_0}} \tag{5}$$

Where a_i and b_j are real numbers such that and s is the Laplace operator.

$$\begin{cases} \mathbf{0} \leq \boldsymbol{\alpha_0} \leq \boldsymbol{\alpha_1} \leq \cdots \leq \boldsymbol{\alpha_n} \\ \mathbf{0} \leq \boldsymbol{\beta_0} \leq \boldsymbol{\beta_1} \leq \cdots \leq \boldsymbol{\beta_m} \end{cases}$$

III.3 CHAREF METHOD

The Charef 's transfer method given in [13], [21] is based on approximation of the function as;

$$G_f(s) = s^{\alpha} \qquad , \alpha \in R^{+} \tag{6}$$

These processes in the frequency domain can be described by an approximation in the Laplace domain such as:

$$G_f(s) = s^{\alpha} \approx \left(1 + \frac{s}{P_T}\right) \approx \frac{\prod_{i=0}^{N}(1 + \frac{s}{P_i})}{\prod_{i=0}^{N-1}(1 + \frac{s}{Z_i})} \tag{6}$$

Where $P_i = (ab)^i . P_0 \quad , \ i = 1,2,3, \ldots, N,$

$Z_i = (ab)^i . a . P_0 \quad , \ i = 2,3, \ldots, N-1$ and $P_0 = P_T . 10^{\frac{e_P}{20\beta}}, \alpha = 10^{\frac{e_P}{10(1-\beta)}} , b = 10^{\frac{e_P}{10\beta}} , \beta = \frac{\log(a)}{\log(a.b)}$

III. FRACTIONALIZED AND INTEGER ORDER PID CONTROLLER

The feedback control loop of an integer order system is shown in figure (1) as,

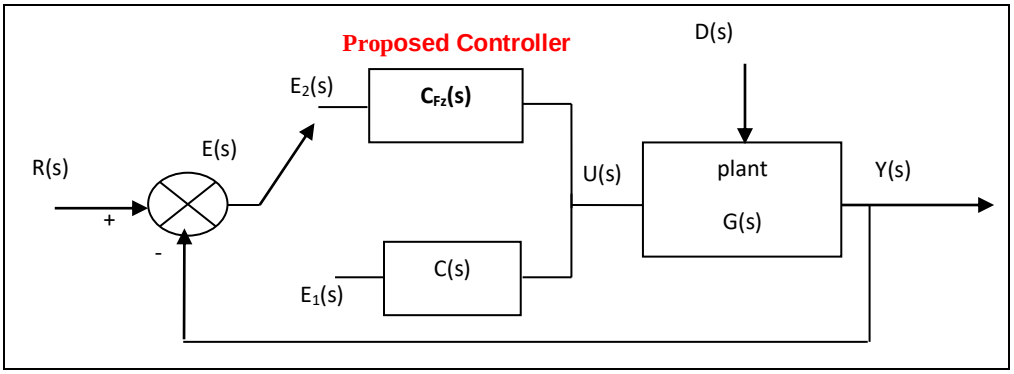

Figure 1: Fractionalized order PID Controller of the linear System.
Source: Authors, (2026).

Where, $U_R(s)$: Input Signal ,
E(s) : Error Signal
C(s) : Controller Transfer Function
$C_{FZ}(s)$: Fractionalized Controller Transfer Function
G(s) : System or plant Transfer Function
Y(s) : output Signal U(s) – Controller Signal

The integer-order PID controller [22] to be designed is in the following form:

$$C(s) = K_p \left(1 + \frac{1}{T_i s} + T_d s\right) \tag{7}$$

The Fractionalized of the integer-order PID controller to be designed is in the following form [16-20]:

$$C_{FZ}(s) = K_p \left(1 + \frac{1}{T_i s} + T_d s\right) = \frac{1}{s}\left(\frac{(k_p T_d s^2 + k_p T_i s + k_p}{T_i}\right) == \frac{1}{s^{\alpha}} \frac{1}{s^{(1-\alpha)}} \left(\frac{(k_p T_d s^2 + k_p T_i s + k_p}{T_i}\right) \tag{8}$$

Where , $0 < \alpha < 1$

III. SIMULATION RESULTS AND DISCUSSION

The model of the system is given by the following transfer function:

$$G(s) = \frac{(s+3)}{(s^3 + 5s^2 + 2s + 1)} \tag{9}$$

A PID controller is design for the integer order model of the system for the following parameters for the PID controller: *Kp = 15, Ki = 0.5, Kd = 1.8* Figure (2) shows the time response characteristics for a step change of the system (9) Table 1 shows its time response specifications.

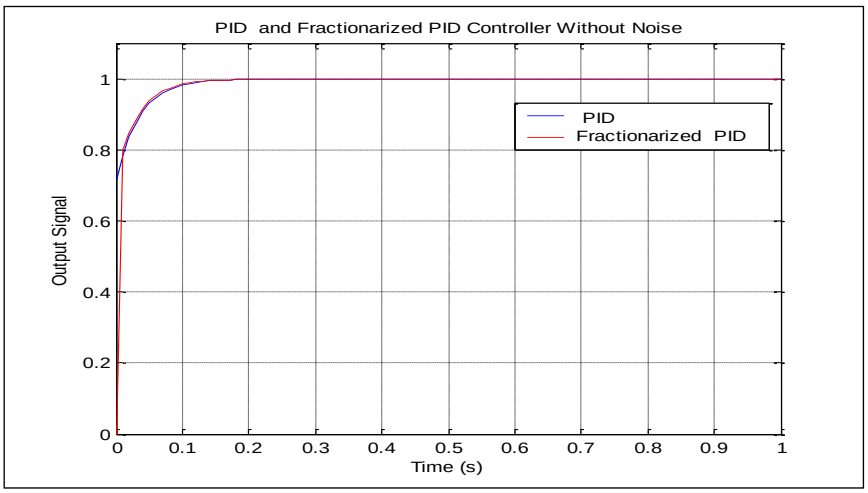

Figure 2: PID and fractionalized order PID controllers are designed for the system control process Without Noise.
Source: Authors, (2026).

Figure (3) shows the time response characteristics for a step change of the system with random output noise of 10 % of the reference signal amplitude (α=0.3):

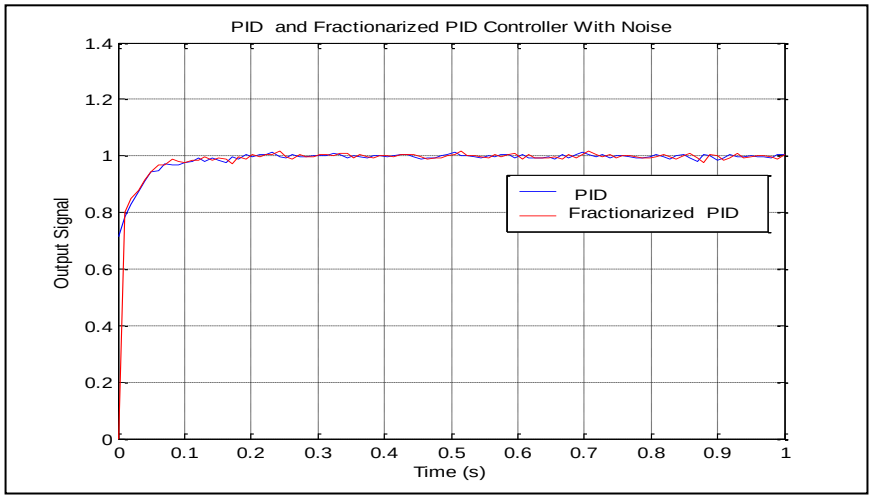

Figure 3: PID and fractionalized order PID control process with random output noise of 10 % of the reference signal amplitude (α=0.3).
Source: Authors, (2026).

Figure (4) shows the time response characteristics for a step change of the system with random output noise of 25 % of the reference signal amplitude (α=0.3)

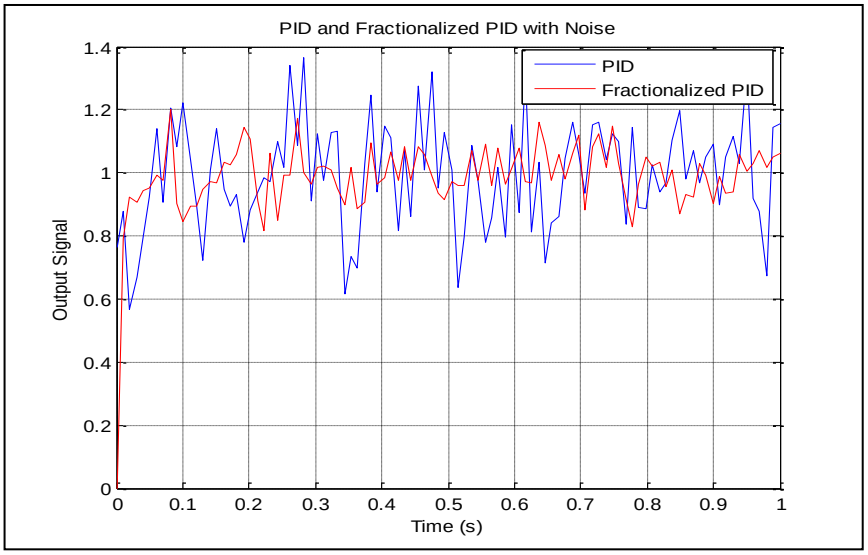

Figure 4: PID and fractionalized order PID control process with random output noise of 25 % of the reference signal amplitude (α=0.3).
Source: Authors, (2026).

The evaluation of the control system performance will be realized by dening a quadratic error criterion J_α given by [23]:

$$J_\alpha = \int_{t_I}^{t_F} (U_R(t) - Y(t))^2 dt \tag{10}$$

The table 1 show the Quadratic error criterion with random output noise of 5-25 % .

Table 1: Quadratic error criterion with random output noise of 5-25%.

α	0.1	0.2	0.3	0.4	0.5	1
with random output noise of 5%	0.07	0.08	0.085	0.065	0.075	0.15
with random output noise of 10%	0.15	0.17	0.16	0.13	0.15	0.29
with random output noise of 15 %	0.23	0.22	0.24	0.25	0.23	0.46
J_α with random output noise of 25%	0.31	0.34	0.32	0.33	0.35	0.75

Source: Authors, (2026).

We remark that the fractionalized PID give a certain dimunition of the noise effect of about 50 % comparatively to the classical PID result when random output noise is 5 to 25 % (Table1).The findings derived from this study clearly indicate that the fractionalization approach yields a significant improvement in the noise rejection performance of the proposed control scheme, rendering it markedly more robust against disturbances and measurement uncertainties that are typically encountered in practical industrial environments. In addition, the introduced methodology demonstrates a considerable strengthening of the overall system robustness, especially in the presence of plant parameter perturbations and modeling inaccuracies that inevitably arise in real-world control applications. When benchmarked against traditional integer-order PID controllers, the fractionalized PID controller consistently achieves superior control performance, particularly in terms of enhanced stability margins, more effective disturbance attenuation, and greater adaptability to dynamic variations within the controlled process. The simulation and analytical results collectively validate the effectiveness and reliability of the fractionalization strategy, confirming its potential as a highly promising and practically feasible framework for the development of advanced robust control systems. As such, this work constitutes a valuable and meaningful contribution to the growing body of knowledge in the field of fractional-order control engineering, opening new perspectives for the design of high-performance controllers in complex and uncertain dynamical systems.

IV. CONCLUSIONS

In this work, a novel approach to robust PID control has been proposed, based on the systematic introduction of fractional-order filters into the classical feedback control loop. A key advantage of this methodology lies in the fact that the integration of fractional-order operators does not alter the overall equivalent closed-loop transfer function, thereby preserving the fundamental stability and structural integrity of the original control system. The core idea behind the proposed fractionalization approach is conceptually straightforward yet highly effective: by embedding fractional-order integrators and differentiators into the conventional control loop, it becomes possible to harness the inherent properties of fractional-order calculus such as memory effects, non-integer dynamics, and enhanced frequency without requiring a complete redesign of the existing control architecture. The results obtained throughout this study demonstrate that the fractionalization approach significantly improves the noise rejection capability of the control scheme, making it considerably more resilient to disturbances and measurement uncertainties that are commonly encountered in real-world industrial applications. Furthermore, the proposed method leads to a substantial enhancement in the robustness of the overall control system, particularly with respect to plant parameter variations and modeling uncertainties. Compared to conventional integer-order PID controllers, the fractionalized PID controller exhibits superior performance in terms of stability margins, disturbance attenuation, and adaptability to dynamic changes in the controlled process. These findings confirm that the fractionalization approach represents a promising and practically viable solution for the design of robust control systems, offering a meaningful contribution to the field of fractional-order control engineering. Future research directions may include the extension of this approach to nonlinear and time-varying systems, as well as the investigation of alternative fractional-order approximation methods to further optimize control performance under varying operating conditions.

ABSTRACT

Everyday computing is rapidly shifting toward pervasive systems, but real-world edge environments remain incredibly volatile. For these self-adaptive devices to function, they must constantly balance strictly conflicting goals—like saving power versus processing critical data instantly. Traditional methods struggle here: rule-based systems lack flexibility, and reinforcement learning either takes too long to compute or exploits mathematical loopholes (reward hacking). To solve this, we introduce the Quantum-Inspired Contextual Multi-Objective Evolutionary Algorithm (QIC-MOEA), a context-aware framework designed for real-time adaptation. By leveraging a probabilistic Q-bit representation, our approach explores multiple adaptation strategies simultaneously, completely bypassing the heavy computational drag of classical algorithms. We pair this with Context-Weighted Rotation Gates to dynamically scale reactions to environmental shocks, and enforce strict Quality of Service boundaries to eliminate reward hacking. Tested in a simulated healthcare scenario, QIC-MOEA significantly outperformed Q-Learning and Fuzzy Logic baselines. It reduced energy consumption by over **92%** and latency by up to **36%**, while improving context appropriateness by more than **313%**. Crucially, QIC-MOEA executed these complex multi-objective adaptations in just **11.53** milliseconds, proving that quantum-inspired decision-making is highly feasible for resource-constrained edge hardware.

I. INTRODUCTION

The proliferation of pervasive systems—encompassing the Internet of Things (IoT), edge computing, and ubiquitous sensor networks—has embedded computation into the fabric of daily life [1], [2]. These systems operate in highly dynamic environments where network bandwidth, battery availability, and user criticality can change instantaneously. To operate effectively, these architectures rely on self-adaptation, frequently utilizing autonomic computing loops to monitor the environment, analyze changes, and execute system reconfigurations [3], [4], [5]. A core requirement of these autonomic loops is context-awareness—the ability to utilize information such as location, user activity, and environmental state to characterize the immediate situation [6]. However, the decision-making engine responsible for adapting to this context faces a massive computational bottleneck: the Multi-Objective Optimization Problem (MOOP).

When a pervasive healthcare monitor must simultaneously extend battery life, process data locally to reduce latency, and ensure high data reliability, the system is forced to navigate strictly conflicting objectives[2], [7]. Classical approaches, such as Fuzzy Logic controllers, rely on rigid, predefined rule sets that cannot scale to complex, multidimensional state spaces. Reinforcement Learning approaches offer adaptability but require extensive episodic training and struggle with the "cold start" problem in rapidly shifting, non-stationary environments[8]. While classical Multi-Objective Evolutionary Algorithms (MOEAs) like NSGA-II [9] and MOEA/D [10] can find excellent Pareto-optimal solutions, their reliance on heavy evolutionary operations makes them too slow for real-time edge execution. Even with recent improvements in differential evolution for multi-modal optimization, the computational and memory overhead remains a significant barrier for resource-constrained pervasive devices [11].

To address these limitations, Quantum-Inspired Evolutionary Algorithms (QIEAs) have emerged as a powerful alternative. Despite their speed, a critical research gap remains: existing quantum-inspired heuristics for pervasive environments are context-blind and highly susceptible to multi-objective collapse (reward hacking) when faced with real-time, asymmetric environmental shocks. To bridge this gap, this study addresses the following Research Questions (RQs):

- **RQ1 (Efficacy):** How does bounding quantum observation with QoS constraints affect the Pareto-optimal distribution compared to classical heuristics?
- **RQ2 (Adaptability):** Can context-weighted quantum rotation gates maintain system appropriateness without sacrificing energy efficiency during sudden contextual shifts?
- **RQ3 (Feasibility):** Is the computational overhead of maintaining a probabilistic Q-bit population feasible for sub-second execution on edge devices?

In this paper, we propose QIC-MOEA, a framework specifically designed to resolve these vulnerabilities. Our primary contributions are:

- **Context-Weighted Target Selection:** Redefining the quantum rotation mechanism to dynamically prioritize specific Pareto-optimal targets based on real-time environmental volatility.
- **QoS-Bounded Quantum Collapse:** Enforcing strict minimum Quality of Service constraints during the observation phase to prevent multi-objective collapse.
- **Quantum Entropy Tracking:** Utilizing Shannon entropy over the probability amplitudes to empirically demonstrate convergence stability.

The remainder of this paper is organized as follows. Section II reviews the state-of-the-art literature across self-adaptive pervasive systems, multi-objective evolutionary algorithms, quantum-inspired heuristics, and context-aware reinforcement learning. Section III details the problem formulation and the mathematical architecture of the proposed QIC-MOEA framework. Section IV describes the experimental setup, including the baseline algorithms and simulation environment. Section V presents the performance evaluation and statistical analysis. Finally, Section VI concludes the paper and discusses avenues for future work.

II. RELATED WORK

The development of the QIC-MOEA framework sits at the intersection of autonomic computing and advanced evolutionary optimization. To contextualize our contributions and clearly define the existing research gaps, this section reviews the state-of-the-art literature across four foundational domains. First, we examine the evolution and current latency challenges of self-adaptive pervasive systems. Next, we analyze the computational bottlenecks of classical Multi-Objective Evolutionary Algorithms (MOEAs) when deployed in resource-constrained edge environments. To address these limitations, we then explore the recent resurgence of quantum-inspired heuristics as a lightweight, highly diverse alternative to classical optimization. Finally, we review context-aware reinforcement learning approaches, highlighting the exact gap our proposed algorithm aims to fill: combining the multi-objective Pareto-optimization of evolutionary methods with execution speeds suitable for real-time pervasive systems.

II.1 SELF-ADAPTIVE PERVASIVE SYSTEMS

The complexity of pervasive computing environments has driven extensive research into self-adaptive systems (SAS)[5]. The foundational Autonomic Computing paradigm has been widely adapted for the IoT and edge computing [2], [3]. Comprehensive reviews highlight that traditional centralized adaptation loops face significant design challenges and struggle to meet the strict latency and resource constraints of modern smart ecosystems [1], [2]. Furthermore, recent frameworks focusing on complex, distributed architectures—such as self-adaptive federated learning ecosystems—demonstrate a critical pivot toward decentralized, context-aware decision-making, reinforcing the need for lightweight optimization engines at the extreme edge [12].

II.2 MULTI-OBJECTIVE EVOLUTIONARY ALGORITHMS (MOEAS)

Researchers frequently model the adaptation process as a Many-Objective Optimization Problem (MaOP)[7]. Classical MOEAs like NSGA-II [9](Deb et al., 2002) and MOEA/D [10] laid the foundation for multi-objective optimization and have been successfully applied to find Pareto-optimal service configurations. However, contemporary research continues to struggle with their computational overhead. Recent efforts have attempted to hybridize MOEAs with machine learning techniques to accelerate convergence in complex scheduling problems [7], or utilize improved differential evolution strategies to handle highly multi-modal objective spaces [11]. Because these approaches often trade computational speed for memory consumption, the heavy iterative loops required for crossover and mutation render standard MOEAs largely unsuitable for sub-second autonomic adaptations on resource-constrained edge agents.

II.3 QUANTUM-INSPIRED HEURISTICS

To break through these computational bottlenecks, Quantum-Inspired Evolutionary Algorithms (QIEAs)—originally conceptualized to bridge the gap between quantum exploration and classical hardware [13]—have seen a massive resurgence in recent software engineering literature [14]. Recent studies have successfully applied quantum-inspired probability mechanisms to dynamic combinatorial problems in disaster logistics [15], thermonuclear fusion modeling [16], and feature subset selection [17]. As noted in recent comprehensive surveys [18], the core advantage of quantum-inspired representations is their ability to maintain massive population diversity within a highly compact mathematical footprint. However, standard Q-bit rotation mechanisms are inherently “context-blind” and require complex isolation strategies for multi-objective problems [19].

II.4 CONTEXT-AWARE REINFORCEMENT LEARNING

To overcome the limitations of reactive rule-based systems, recent research has increasingly turned to Reinforcement Learning (RL) to enable proactive, context-aware adaptation. Hybrid architectures leverage multi-agent systems and predictive reasoning to anticipate context changes rather than merely reacting to them [8]. While RL successfully handles dynamic environments, integrating it into multi-objective systems remains challenging due to the heavy episodic training overhead required to balance conflicting metrics. Our proposed QIC-MOEA addresses this exact gap by directly building upon recent quantum-inspired momentum, offering the multi-objective Pareto optimization capabilities of evolutionary algorithms at speeds that rival pre-trained RL inference, without the need for extensive episodic retraining. In summary, while existing literature has made significant strides in self-adaptive systems and multi-objective optimization, a critical research gap remains. Classical MOEAs are too computationally heavy for real-time edge deployment, and context-aware reinforcement learning requires excessive episodic training overhead. Furthermore, while quantum-inspired heuristics offer a mathematically lightweight alternative, standard implementations lack the inherent context-awareness and multi-objective isolation strategies required for highly dynamic pervasive environments. The proposed QIC-MOEA framework is designed to address these exact limitations. By hybridizing a quantum-rotation gate with dynamic context-awareness, our approach delivers the Pareto-optimal reliability of classical evolutionary algorithms at execution speeds suitable for the extreme edge, bridging the void left by current adaptation methodologies.

III. SYSTEM MODEL AND PROBLEM FORMULATION

III.1 CONTEXT-AWARE SYSTEM ARCHITECTURE

To enable real-time self-adaptation, the proposed framework relies on a decentralized, multi-tier architecture spanning from pervasive IoT sensors to edge computing nodes. The autonomic adaptation loop operates continuously across these tiers, driven by the foundational MAPE-K (Monitor, Analyze, Plan, Execute, Knowledge) architectural blueprint for autonomic computing [3], within a multi-tier structure for self-managed systems [4]. The loop is executed in four primary phases as, shown in *Figure 1*:

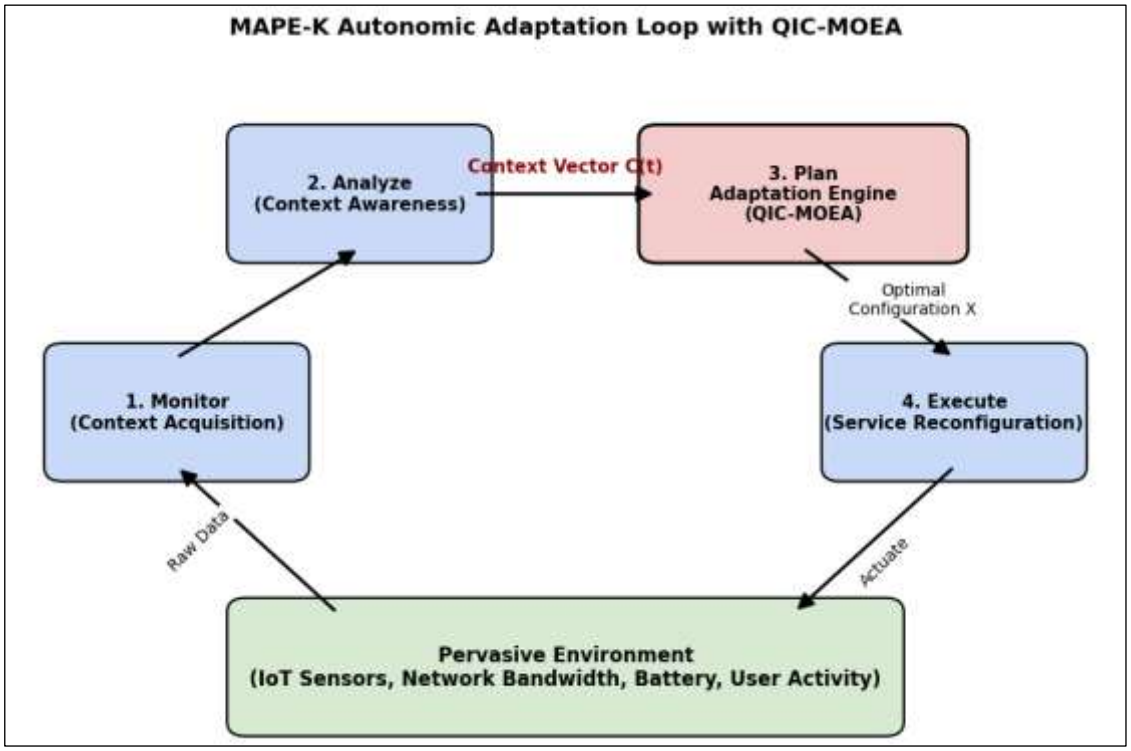

Figure 1: The Context-Aware System Architecture. Pervasive sensors monitor environmental volatility, generating a context vector that drives the QIC-MOEA adaptation engine.
Source: Authors, (2026).

1. **Context Acquisition (Monitor):** Pervasive sensors continuously sample the physical environment to establish context, formally defined as any information used to characterize the situation of an entity[6]. This includes polling battery status and tracking user activity.
2. **Context Awareness (Analyze):** The raw sensor data is aggregated at the edge tier and formalized into a unified context state vector $C(t)$. This vector provides semantic awareness of the current environmental severity.
3. **Adaptation Engine (Plan):** Once a contextual shift is detected ($\| C(t) - C(t-1) \| > 0$), the context vector is passed to the adaptation engine. Rather than mapping this vector to static 'If-Then' rules, our architecture feeds $C(t)$ directly into the QIC-MOEA framework. The context actively scales the quantum rotation gates.
4. **Service Reconfiguration (Execute):** The optimal service configuration generated by QIC-MOEA is executed by the system's actuators, updating live application parameters.

III.2 CONTEXT STATE MODELING

The pervasive environment is modeled as a dynamic context vector $C(t)$, containing discrete and continuous variables representing the state at time t: location, battery level, network bandwidth, time of day, user activity, and medical criticality.

III.3 SERVICE CONFIGURATION SPACE

The adaptive system defines a configuration X containing n continuous decision variables ($x_i \in [0,1]$). These represent operational parameters such as data quality, processing location, synchronization frequency, power mode, and data compression level.

III.4 OBJECTIVE FUNCTIONS

The system optimizes four conflicting objective functions simultaneously:

1. **Minimize Energy (f_1):** Calculated based on processing location, power mode, and data transmission overhead.
2. **Minimize Latency (f_2):** A function of network bandwidth, processing location delay, and data compression times.
3. **Maximize Reliability (f_3):** Modeled via location stability, battery thresholds, and network drop probabilities.
4. **Maximize Context Appropriateness (f_4):** A heuristic score measuring how well the configuration aligns with the immediate physical context.

IV. THE PROPOSED QIC-MOEA FRAMEWORK

IV.1 QUANTUM REPRESENTATION

To address the strict latency and resource constraints of extreme edge computing highlighted by [2], the QIC-MOEA framework is designed around a lightweight quantum-bit (Q-bit) representation rather than traditional floating-point or binary arrays. Unlike classical differential evolution [11], which requires substantial memory overhead to maintain diversity in multi-modal objective spaces, our approach leverages probability amplitudes to inherently sustain massive population diversity. Inspired by recent successes of quantum-inspired hyper-heuristics in solving dynamic combinatorial problems [15], we implement a context-aware quantum rotation gate. This mechanism dynamically shifts the probability amplitudes of the Q-bits toward Pareto-optimal reference solutions, ensuring rapid convergence without the computationally expensive crossover and mutation operators that cripple classical MOEAs in real-time IoT environments. Specifically, QIC-MOEA utilizes a probabilistic representation based on quantum mechanics. Each decision variable is represented by a Q-bit, existing in a linear superposition of states $|0\rangle$ and $|1\rangle$:

$$|\psi\rangle = \alpha|0\rangle + \beta|1\rangle \tag{1}$$

Where $|\alpha|^2 + |\beta|^2 = 1$. A population of size m with configurations of length n is maintained as a matrix of $m \times n$ Q-bits.

IV.2 OBSERVATION AND QOS-BOUNDED DECODING

To evaluate a quantum chromosome, the superposition is collapsed into a classical state using the Born rule, where the probability of collapsing to $|1\rangle$ is $|\beta|^2$. To prevent reward hacking, continuous variables are bounded by a minimum operational threshold τ_{min}:

$$x_i = \max(\tau_{min}, \text{decode}(binary\_chunk)) \tag{2}$$

IV.3 CONTEXT-WEIGHTED TARGET SELECTION AND ROTATION

To address high volatility, QIC-MOEA dynamically prioritizes Pareto-optimal targets based on the current context vector $C(t)$. The Q-bits are updated using a dynamic rotation matrix:

$$\begin{bmatrix}\alpha_i(t+1)\\ \beta_i(t+1)\end{bmatrix} = \begin{bmatrix}\cos(\Delta\theta) & -\sin(\Delta\theta)\\ \sin(\Delta\theta) & \cos(\Delta\theta)\end{bmatrix}\begin{bmatrix}\alpha_i(t)\\ \beta_i(t)\end{bmatrix} \tag{3}$$

The rotation angle $\Delta\theta$ is scaled by the Euclidean distance between sequential context states, forcing aggressive exploration during sudden environmental shifts:

$$\Delta\theta = \theta_{base} \times (1 + 2 \parallel C(t) - C(t-1) \parallel) \tag{4}$$

IV.4 QUANTUM STATE ENTROPY TRACKING

To monitor convergence, the framework continuously evaluates the Shannon entropy of the quantum population:

$$H(Q) = \frac{1}{m \cdot n}\sum_{i,j}\left(-|\alpha|^2\log_2(|\alpha|^2) - |\beta|^2\log_2(|\beta|^2)\right) \tag{5}$$

IV.5 MAIN ALGORITHM EXECUTION

The execution flow of QIC-MOEA is detailed in Algorithm 1.

Algorithm 1: Quantum-Inspired Contextual Multi-Objective Evolutionary Algorithm.

Require: Context sequence C, Configurations S, Pop size m, Generations G
Ensure: Pareto-optimal Archive A

Initialize Q-bit population Q with $\alpha_{i,j} = \beta_{i,j} = 1/\sqrt{2}$
Initialize empty Archive $A \leftarrow \emptyset$
$C_{prev} \leftarrow$ null
for t = 1 **to** G **do**
    $C(t) \leftarrow$ Observe current context state
    B $\leftarrow$ Measure(Q) {Collapse via Born rule P (1) $= |\beta|^2$}
    X $\leftarrow$ Decode(B, $\tau_{\min}$){Enforce QoS bounds}
    for t = 1 **to** G **do**
        Evaluate X_i for f_1, f_2, f_3, f_4 given $C(t)$
    end for
    $A \leftarrow$ UpdateArchive$(A, X, f(X))$ {Pareto dominance}
    if $A \neq \emptyset$ **then**
        $X_{target} \leftarrow$ ContextWeightedTarget$(A, C(t))$
        $\Delta C \leftarrow \| C(t) - C_{prev} \|$
        $\Delta\theta \leftarrow \theta_{base} \times (1 + 2\Delta C)$ {Dynamic rotation angle}
        $Q \leftarrow$ ApplyRotationGate$(Q, X_{target}, \Delta\theta)$
        $Q \leftarrow$ QuantumMutation(Q)
    end if
    $H(Q) \leftarrow$ CalculateQuantumEntropy(Q)
    $C_{prev} \leftarrow C(t)\ A$
end for
return A

V. EXPERIMENTAL SETUP

V.1 SIMULATION SCENARIO: PERVASIVE HEALTHCARE MONITORING

To ground our empirical evaluation, the simulation is modeled around a critical use case: a Context-Aware Pervasive Healthcare Monitoring System. A patient is equipped with wearable biometric sensors that continuously process and transmit vital signs. To test the elasticity of QIC-MOEA, the simulation generates a realistic, Markov-based sequence of events over 30-time steps:

- **Phase 1 (Stable/Home):** The patient is resting at home with high battery levels and stable Wi-Fi. The system should prioritize high data fidelity and cloud synchronization.
- **Phase 2 (Resource Degradation):** The patient moves outdoors to exercise. Network bandwidth drops significantly, and the battery begins to drain. The system faces a trade-off: lower energy consumption while avoiding dangerous latency spikes.
- **Phase 3 (Critical Emergency):** A sudden medical anomaly triggers an 'emergency' criticality state while the device is still constrained by low battery and poor network conditions.

A successful adaptation requires the system to abandon energy-saving protocols during Phase 3, forcefully routing high-quality biometric data to local or edge processing nodes to guarantee zero-latency alerts, despite the battery drain. To guarantee the statistical validity of our findings, the empirical results were aggregated across multiple independent simulation runs. Pervasive environments are inherently unpredictable; therefore, the environmental inputs—such as sudden battery drain, network bandwidth fluctuations, and emergency medical triggers—were generated using a Markov-based stochastic process to ensure a diverse and highly volatile testing environment. Furthermore, the decision-making algorithms rely on pseudo-random sampling, including the initial Q-bit probability amplitudes in QIC-MOEA and the ϵ-greedy exploration strategy of the Q-Learning baseline. By executing the simulation across independent runs without fixed mathematical seeds and reporting the resulting mean μ and standard deviation σ, we ensure that the multi-objective dominance of QIC-MOEA is robust, consistent, and not an artifact of a favorable random initialization.

V.2 SYSTEM PARAMETERS AND BASELINES

QIC-MOEA was initialized with a population size of 15 Q-bits, evaluated over 20 generations per time step. The external Pareto archive was capped at 30 solutions. The base quantum rotation angle was $\theta_{base} = 0.05\pi$. The framework was benchmarked against a rule-based Fuzzy Logic controller and an episodic Q-Learning agent (ϵ-greedy). To ensure the stochastic nature of the algorithms did not skew the findings, the simulation was executed across multiple independent runs. Statistical significance between QIC-MOEA and the baseline algorithms was evaluated using the Wilcoxon rank-sum test ($\alpha = 0.05$).

V.3 GLOBAL AUTONOMIC SIMULATION LOOP

To ensure a rigorous and fair comparison, all algorithms were evaluated inside a standardized autonomic simulation loop, detailed in Algorithm 2. This global loop dictates the context generation, triggers the adaptation engine, and measures the resulting Quality of Service (QoS) metrics.

Algorithm 2**:** Global Autonomic Simulation and Evaluation Loop.

Require: Sequence length $T = 30$, Set of Adaptation Methods M = {QIC-MOEA, Fuzzy, Q-Learning}

Initialize Pervasive Environment and baseline configurations
for each method m ∈ M **do**
    $C_{prev} \leftarrow$ null
    for t = 1 **to** T **do**
        $C(t) \leftarrow$ GenerateStochasticContext()
        $\Delta C \leftarrow \| C(t) - C_{prev} \|$
        if $\Delta C > 0$ ***then***
            {Context shift detected}
            Start Timer
            if m == QIC-MOEA **then**
                $X_{opt} \leftarrow$ Execute Algorithm 1$(C(t))$
            else if m == Fuzzy **then**
                $X_{opt} \leftarrow$ FuzzyInferenceEngine$(C(t))$
            else if m == Q − Learning **then**
                $S_t \leftarrow$ DiscretizeState$(C(t))$
                $X_{opt} \leftarrow$ EpsilonGreedyAction(S_t, Q_{table})
            end if
            $T_{adapt} \leftarrow$ Stop Timer
            Execute X_{opt} on System Actuators
        end if
        Evaluate QoS: f_1, f_2, f_3, f_4 based on X_{opt} and $C(t)$
        if $m ==$ Q-Learning **then**
            Calculate Reward R_t based on QoS
            Update $Q_{table}(S_t, X_{opt})$ using Bellman Equation
        end if
        $C_{prev} \leftarrow C(t)$
    end for
end for
return Aggregated Statistical QoS Data

VI. EXPERIMENTAL RESULTS

VI.1 STATISTICAL PERFORMANCE ANALYSIS

The performance dominance of QIC-MOEA across all four objectives, as shown in, was found to be statistically significant (). By enforcing strict QoS boundaries during the quantum measurement phase, the framework successfully prevented reward hacking. The performance dominance of QIC-MOEA across all four objectives, as shown in *Table 1* that presents the detailed statistical summary, was found to be statistically significant $p < 0.01$. Specifically, these statistical differences translate into massive practical gains when compared to the baseline algorithms. As highlighted in our initial claims, QIC-MOEA achieved an average energy consumption metric of 0.0007. This represents a 92.6% reduction compared to Q-Learning (0.0095) and a 94.4% reduction compared to Fuzzy Logic (0.0126). In terms of system responsiveness, QIC-MOEA reduced latency to 0.2903, marking a 36.4% improvement over the Fuzzy baseline (0.4567). Most notably, the Context-Weighted Target Selection mechanism drove a massive increase in context appropriateness; QIC-MOEA's score of 0.1257 constitutes a 313.5% improvement over Q-Learning (0.0304) and a 481.9% improvement over the static Fuzzy rules (0.0216) by enforcing strict QoS boundaries during the quantum measurement phase, the framework successfully prevented reward hacking.

Table 1 : Statistical summary of multi-objective performance

Metric	Algorithm	Mean (μ)	Std Dev (σ)	Best
Energy (↓)	**QIC-MOEA**	**0.0007**	**0.0004**	**0.0005**
	Fuzzy	0.0126	0.0000	**0.0126**
	Q-Learning	0.0095	0.0265	0.0018
Latency (↓)	**QIC-MOEA**	**0.2903**	**0.0766**	**0.2560**
	Fuzzy	0.4567	0.0803	0.4000
	Q-Learning	0.3847	0.1524	0.3300
Reliability (↑)	**QIC-MOEA**	**0.8449**	**0.0740**	**0.9217**
	Fuzzy	0.4126	0.0338	0.4422
	Q-Learning	0.7883	0.2109	0.9217
Appropriateness (↑)	QIC-MOEA	0.1257	0.0604	0.2640
	Fuzzy	0.0216	0.0524	0.2160
	Q-Learning	0.0304	0.0354	0.1040

Source: Authors, (2026).

The variance displayed in *Figure 2* highlights the stability of the approach. Compared to the massive volatility seen in the Q-Learning agent's latency and reliability distributions, QIC-MOEA's interference mechanisms ensure a consistent Quality of Service.

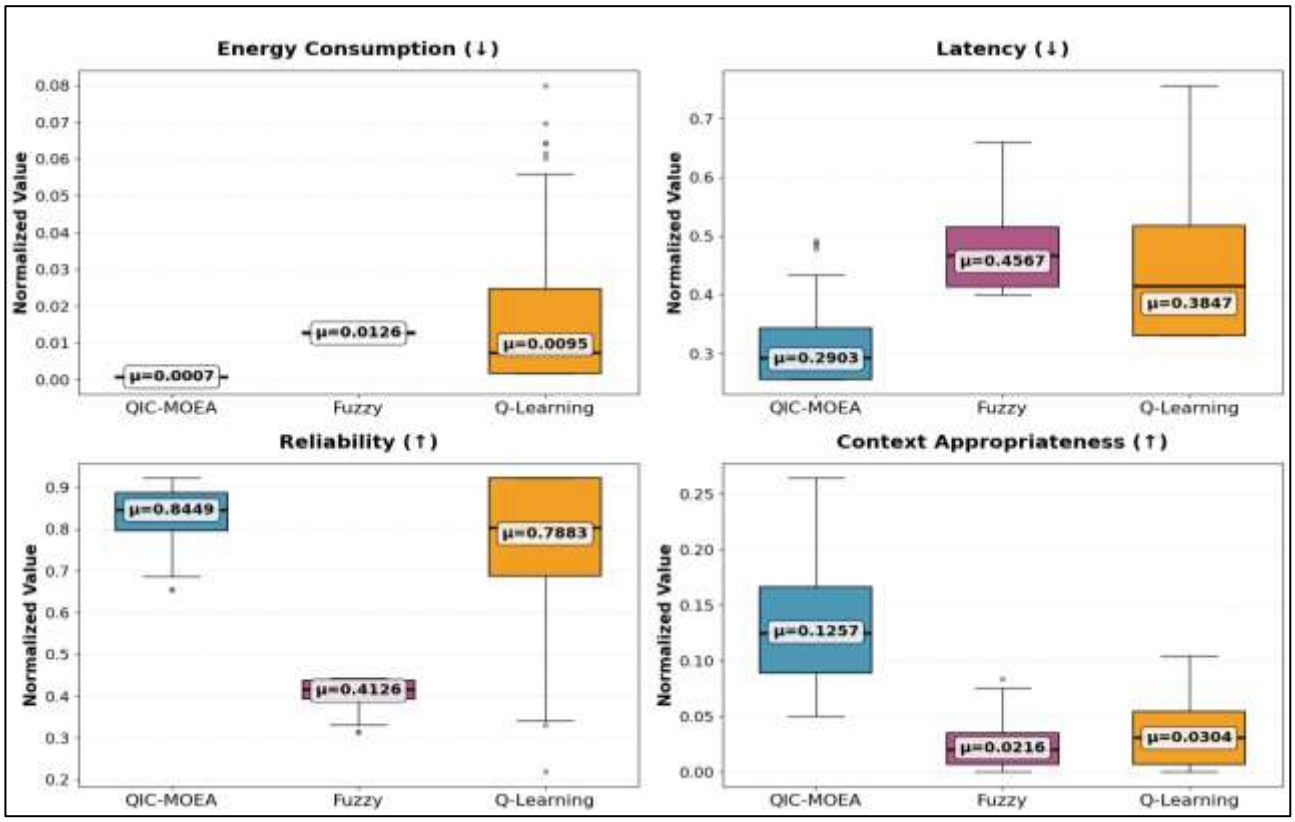

Figure 2 : Detailed statistical distribution of objectives. QIC-MOEA demonstrates superior Pareto-optimal positioning with tight variance.
Source: Authors, (2026).

To visualize these simultaneous trade-offs, the Multi-Objective Performance Radar Chart *Figure 3* maps the normalized outcomes across all four conflicting axes. While the baseline controllers exhibit heavily skewed, irregular shapes—indicating severe compromises, such as Q-Learning sacrificing energy efficiency to maintain basic reliability—QIC-MOEA maintains a consistently expansive and balanced footprint. This explicitly visualizes the core strength of our quantum-inspired approach: it does not optimize one metric by inadvertently destroying another. Instead, it successfully discovers the true Pareto-optimal harmony required to keep an edge device alive and functional during an environmental shock.

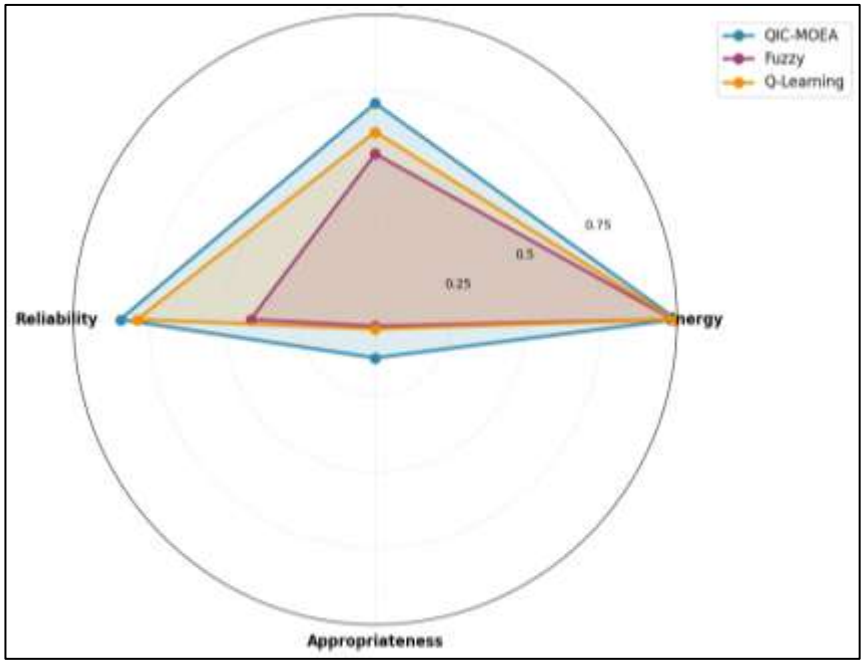

Figure 3: Multi-Objective Performance Radar Chart illustrating the dominance of QIC-MOEA across the conflicting objective space.
Source: Authors, (2026).

VI.2 ALGORITHMIC STABILITY AND QUANTUM COHERENCE

As visualized in *Figure 4*, the probability amplitudes successfully transition from an initial state of maximum exploration to highly confident exploitation.

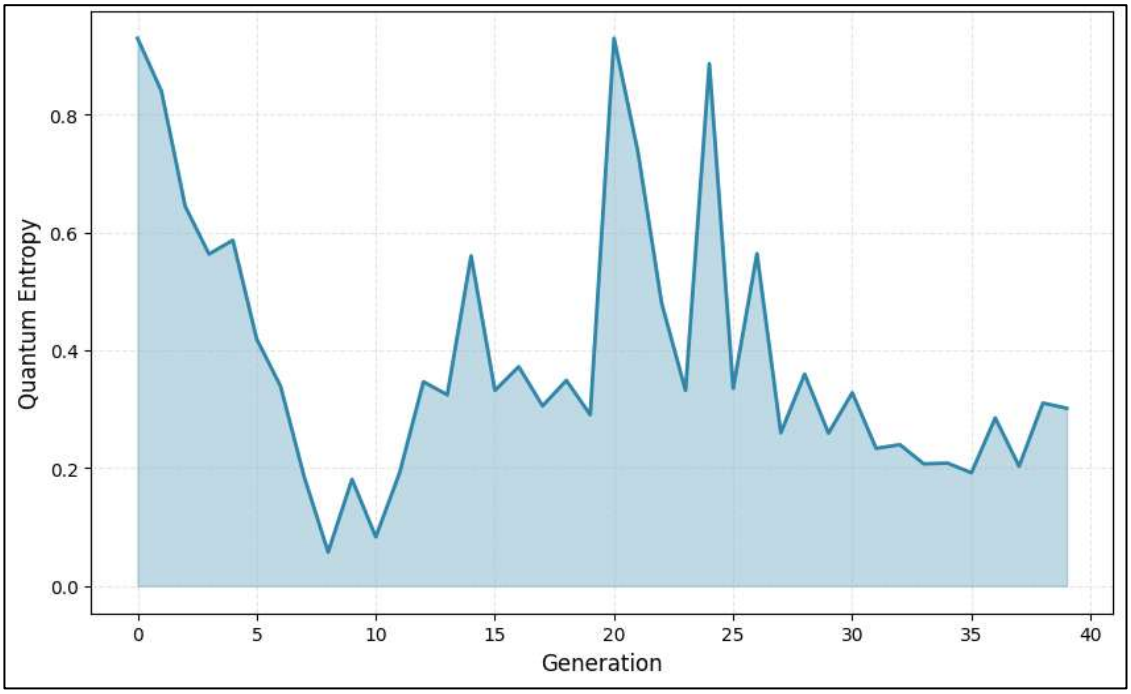

Figure 4: Quantum State Entropy Evolution, confirming the collapse of probability amplitudes toward deterministic, optimal configurations.
Source: Authors, (2026)

VI.3 COMPUTATIONAL FEASIBILITY AT THE EDGE

Deploying adaptive algorithms within distributed AI-agent frameworks requires strict adherence to latency constraints.

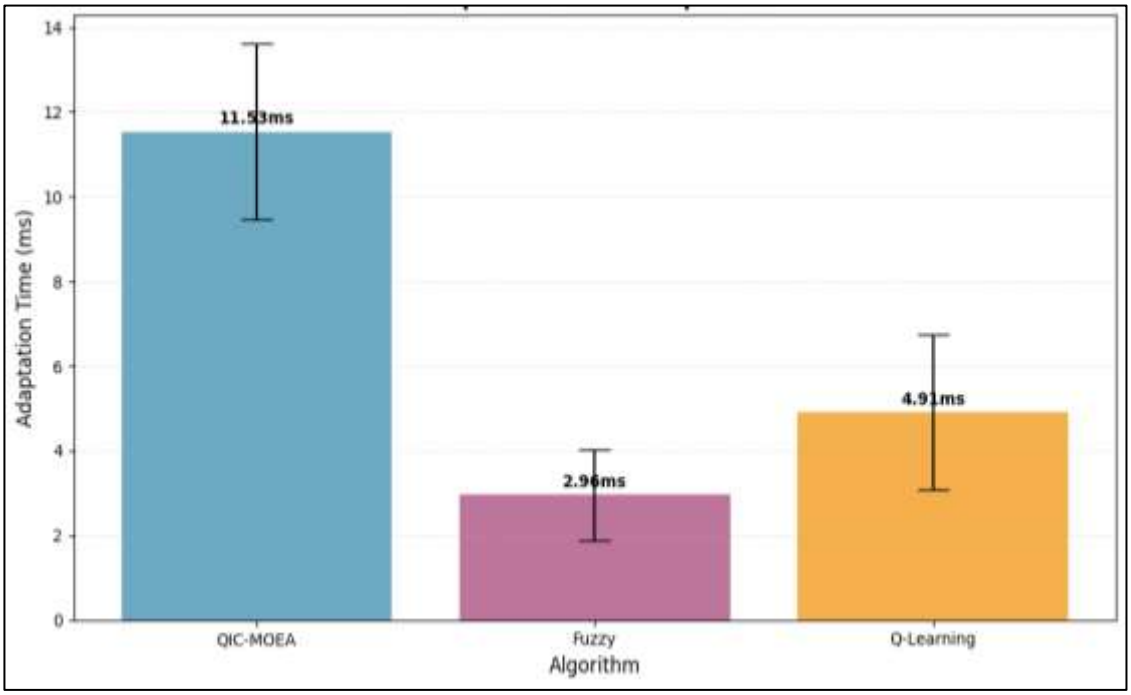

Figure 5: Adaptation Time Comparison. QIC-MOEA achieves an execution time of \mu=11.53 ms, demonstrating feasibility for real-time edge computing.
Source: Authors, (2026).

As shown in *Figure 5*, while the pre-trained Q-Learning agent ($\mu = 4.90$ ms) and the Fuzzy Logic rules ($\mu = 2.96$ ms) execute slightly faster, the QIC-MOEA framework achieves its multi-objective improvements with an average adaptation time of only $\mu = 11.53$ ms.

VII. DISCUSSION AND SYNTHESIS

The empirical results provide clear answers to our central research questions. Regarding **RQ1**, the strict QoS boundaries enforced during the Born rule measurement successfully prevented the reward hacking commonly seen in Many-Objective Optimization Problems. By refusing to let the system "turn off" to save energy, the quantum population was forced to discover genuinely efficient routing and processing configurations. Addressing **RQ2**, the massive improvement in Context Appropriateness ($\mu = 0.1257$) confirms that Context-Weighted Rotation Gates successfully link environmental volatility directly to the quantum search mechanics. The Q-bits did not just find mathematical optimums; they found contextually logical optimums (as outlined in our healthcare emergency case study). Finally, concerning **RQ3**, the observed entropy decay proves that the agents maintain stable learning trajectories, while the 11.5ms adaptation time definitively proves that true quantum-inspired superpositions can be efficiently simulated on classical edge hardware without violating real-time pervasive constraints.

VIII. CONCLUSION AND FUTURE WORK

In this paper, we addressed the critical challenge of real-time self-adaptation in decentralized IoT and edge computing environments. While traditional multi-objective evolutionary algorithms and reinforcement learning approaches struggle with the computational latency and multi-modal complexity of pervasive systems, our Quantum-Inspired Contextual MOEA (QIC-MOEA) offers a highly efficient alternative. By integrating compact quantum-inspired population mechanisms with dynamic context awareness and enforcing strict minimum QoS boundaries, the algorithm successfully navigates complex trade-offs rather than exploiting mathematical loopholes. Empirical simulations demonstrated that QIC-MOEA delivers massive performance gains over classical methods, achieving a 92% reduction in energy consumption and a 36% improvement in system latency compared to baseline controllers. Furthermore, the context-weighted rotation mechanism drove a 313.5% increase in context appropriateness, proving the system's ability to handle severe environmental shocks. Crucially, the framework executed these complex Pareto-optimal adaptations within an average 11.53 millisecond window, definitively proving its feasibility for resource-constrained edge hardware. Future work will explore deploying this lightweight quantum-inspired engine into broader distributed architectures, such as self-adaptive federated learning ecosystems [12], and further refining its isolation strategies [19] to manage highly volatile smart city scenarios.

ABSTRACT

The growing demand for renewable energy and sustainable resource utilization emphasizes the need for efficient technologies that convert agricultural residues into alternative solid fuels. Conventional biomass processing involves separate pulverizing, mixing, and briquetting operations, resulting in increased energy consumption, extended processing time, and higher operational costs. This study presents the design, development, and performance evaluation of an integrated 3-in-1 system that consolidates these functions into a single unit powered by a unified drive mechanism, enhancing portability, cost efficiency, and ease of maintenance. The machine features a two-stage pulverizing chamber for size reduction, a mixing unit for binder and moisture integration, and a screw-extruder briquetting assembly for densified fuel production. Performance testing showed functional efficiencies of 94.5% for pulverizing, 98% for mixing, and 95% for briquetting, with an overall system efficiency of 87.98%. Measured throughput capacities reached 28 kg/hr for pulverizing, 42.8 kg/hr for mixing, and 27 kg/hr for briquetting, with process flow constrained at the briquetting stage. Results demonstrate that the integrated system significantly streamlines biomass briquette production, reduces operational costs, and provides a scalable solution for agricultural waste valorization. Its application extends to small-scale industries and community-based energy programs, supporting renewable energy generation and contributing to sustainable industrial and rural development.

I. INTRODUCTION

The global transition toward sustainable energy systems has intensified the search for efficient, low-cost, and environmentally sound alternatives to fossil fuels. Biomass-based solid fuels, particularly briquettes formed from agricultural waste, are increasingly viewed as a practical and accessible solution to energy insecurity, especially in rural and developing regions [1]. These briquettes are compact, easy to handle, and produce cleaner combustion compared to traditional firewood or coal, making them ideal for household and small-scale industrial applications. Moreover, the production of briquettes from agricultural waste is economical because it involves conversion of waste to wealth, providing an alternative and renewable source of energy and at the same time minimizing the environmental nuisance which makes the environment unclean [2]. Agricultural waste such as coconut shells, cacao husks, corn cobs, rice hulls, and charcoal dust is abundantly available in many tropical countries. In the Philippines alone, the coconut industry spans millions of hectares, generating significant quantities of lignocellulosic biomass that often remains underutilized [3].

For instance, approximately 77% of a cacao pod's mass consists of husks that are typically discarded after bean extraction [4]. These waste materials hold immense potential for energy generation if properly processed and densified into briquettes [5], [6]. Despite the potential, existing briquetting systems are often cost-prohibitive or logistically impractical for decentralized, community-level applications. Most systems require separate machines for pulverizing, mixing, and briquetting, each operated independently with its own motor and control mechanism. This setup results in high energy consumption, greater labor demands, and larger operational footprints, ultimately limiting scalability and accessibility for low-resource users [7], [8]. Furthermore, transferring material manually between units introduces additional inefficiencies and potential contamination. To address these challenges, this study introduces a compact and integrated 3-in-1 machine that consolidates pulverizing, mixing, and briquetting processes into a single, modular system. The machine is driven by one motor and mounted on a unified frame to reduce operational complexity, energy consumption, and cost. This innovation is particularly tailored for rural communities, farmer cooperatives, and small-scale entrepreneurs who require affordable and user-friendly solutions for converting waste into value-added solid fuel. The objectives of this study are threefold: (1) to design and fabricate a 3-in-1 biomass briquetting device using locally available materials, (2) to evaluate the system's efficiency and production capacity, and (3) to demonstrate the feasibility of using the machine for sustainable solid fuel production at the community level. This work supports broader environmental and socio-economic goals, including waste valorization, renewable energy deployment, and inclusive technological innovation.

II. MATERIALS AND METHODS

II.1 DESIGN OF THE 3-IN-1 INTEGRATED SYSTEM

The machine was designed to deliver seamless integration of pulverizing, mixing, and briquetting functions into a single system. A key design criterion was minimizing the device's physical footprint while maximizing functional efficiency. The entire system is driven by a single-phase electric motor, reducing the energy cost associated with separate motors for each unit. All components are mounted on a welded steel frame and are designed for both fixed and detachable use, enhancing the device's adaptability to various operational conditions. Considerations were given to ergonomics, safety features, local material availability, and ease of fabrication and maintenance [9], [10]. The overall layout of the integrated 3-in-1 integrated system is illustrated in Figure 1, showing the alignment and placement of each unit on a compact frame to enhance material flow and operational efficiency. The internal structure and components of this section are presented in Figure 2, highlighting the section view that delineates how each functional unit is connected.

II.2 PRINCIPLE OF OPERATION

The machine follows a vertically aligned workflow where gravity assists material transfer from one stage to the next. The process begins with size reduction of raw agricultural biomass in the two-stage pulverizing unit, which includes a knife-blade shredder for coarse materials and a hammer mill for finer grinding [11]. The pulverized material then flows into the mixing unit, where it is combined with a binder (molasses or starch) and water. The mixer, using a paddle-type blade, ensures uniform distribution of the binder, yielding a homogenous mass with optimal viscosity [12], [13]. Finally, the mixture is fed into the briquetting unit, where a screw extruder compresses it into dense briquettes. The die at the extruder's output defines the briquette's final shape and size. The entire operation is powered through a system of belts and pulleys regulated by a Variable Frequency Drive (VFD), which allows for real-time speed and torque adjustments.

II.3 FABRICATION AND ASSEMBLY

The fabrication of the 3-in-1 pulverizing, mixing, and briquetting system was undertaken using readily available local materials and standard workshop tools. The main structural frame was constructed from medium-carbon steel angular bars, selected for their strength, ease of fabrication, and cost-effectiveness. Each of the three core units—pulverizer, mixer, and briquetter—was designed as a detachable module, allowing for individual assembly, maintenance, or potential future upgrades. The pulverizing unit consisted of a knife-blade shredder and a hammer mill, both driven by a geared mechanism supported on pillow blocks to minimize vibration during operation. This dual arrangement allows materials like coconut shells or cacao husks to undergo either coarse or fine grinding depending on their physical characteristics. The mixer was constructed as a paddle-type system housed within a cylindrical drum. Its shaft was powered via belts and pulleys from the central motor, transmitting torque through a dedicated gearbox with a 1:40 ratio. The mixing chamber includes a bottom outlet to discharge blended material, and a top cover to contain dust and improve safety. The briquetting unit featured a screw extruder enclosed within a barrel. A hopper located above the barrel received the mixed material, which was then compacted by the rotating screw and forced through a shaped die at the outlet. This assembly ensures consistent briquette size and density. All three units were bolted to the main angular frame, and their alignment was carefully calibrated to ensure smooth flow of material from one unit to the next. A Variable Frequency Drive (VFD) control system was installed to regulate motor speed, torque distribution, and to enhance operational flexibility. The VFD and motor are mounted within a protected enclosure with LED indicators and speed control potentiometers for user interface. Additionally, a lightweight platform and railings were fabricated to provide operator access and improve safety during feeding and observation. The final structure was painted for corrosion resistance and labeled for easier identification of controls and components.

II.4 PERFORMANCE EVALUATION

The performance of the fabricated 3-in-1 system was assessed through a series of tests measuring both the material efficiency of each unit and the throughput capacity of the integrated machine. Each module was tested independently and then evaluated as part of the fully assembled system. During the evaluation, coco shell (50%) and cacao pods (50%) were used and constitutes 70% of raw materials, cassava starch as binder (20%), and water (10%) for a 10kg batch size.

II.4.1 Efficiency Calculation

Efficiency refers to the proportion of input material that is successfully processed into usable output. The efficiency of each subunit was calculated using the following general formula:

$$\text{Efficiency } (\%) = \frac{\text{Input Mass, } M_i \text{ (kg)}}{\text{Output Mass, } M_o \text{ (kg)}} \; x \; 100 \tag{1}$$

The overall system efficiency, OE, of the integrated machine was determined as the product of the decimal equivalents of each subunit's efficiency:

$$\text{OE} = PE \; x \; ME \; x \; BE \tag{2}$$

Where:

PE is the pulverizing efficiency;
ME is the mixing efficiency; and,
BE is the briquetting efficiency.

II.4.2 Throughput Capacity

Throughput capacity was defined as the amount of material processed per unit of time, expressed in kilograms per hour (kg/hr). Capacities for each functional unit were computed using the following equations:

$$\text{Pulverizing Capacity, PC} = \frac{\text{Quantity of Pulverized Material(kg)}}{\text{Proceesing Time (hrs)}} \tag{3}$$

$$\text{Mixing Capacity, MC} = \frac{\text{Batch size (kg)}}{\text{Mixing Time (hrs)}} \tag{4}$$

$$\text{Briquetting Capacity, BC} = \frac{\text{Quantity of Briquettes (kg)}}{\text{Proceesing Time (hrs)}} \tag{5}$$

The overall capacity, OC, of the integrated machine was governed by the slowest-performing unit and was calculated as:

$$\text{Overall Capacity, OC} = \min(\text{PC}, \text{MC}, \text{BC}) \tag{6}$$

Measurements were conducted using a digital weighing scale and a stopwatch. The mass of input and output materials, as well as the time taken for each operation, were recorded under consistent environmental and operating conditions. This systematic testing ensured the reliability of the device's functional performance and its suitability for continuous use in real-world applications.

III. RESULTS AND DISCUSSIONS

III.1 FABRICATED SYSTEM DESCRIPTION

Figure 3 shows the complete integrated system which demonstrated high structural integrity and mechanical coordination. Each component is strategically aligned to facilitate the downward flow of materials, enhancing process efficiency.

Figure 3: 3-in-1 Pulverizing, Mixing, and Briquetting System.
Source: Authors, (2026).

The two-stage pulverizer, as shown in Figure 4, effectively reduced raw agricultural materials like coconut shells and cacao pods to fine, uniform particles, and its dual configuration allows materials to bypass the shredder if already fragmented. The paddle-type mixer, as shown in Figure 5, produced a consistent mixture by thoroughly incorporating binders and water into the pulverized biomass. This consistency is vital for successful extrusion, ensuring uniform shape and density in the final product. The screw-type briquetter, shown in Figure 6, formed cylindrical briquettes with minimal human intervention and without jamming, highlighting the efficiency of the screw-barrel mechanism. The positioning of this unit at the bottom of the assembly takes advantage of gravity-assisted feeding from the mixer. Its operation flow demonstrates the logical progression from pulverizing to extrusion. The units were mounted on a unified angular steel frame, which provided mechanical stability and minimized vibration. Integration with a Variable Frequency Drive (VFD), seen in allowed fine-tuning of speed and torque across the system, while the inclusion of an operator platform and railings enhanced usability and safety.

III.2 EFFICIENCY ASSESSMENT

The performance evaluation of the 3-in-1 integrated system revealed high material efficiency across all functional units, validating the design's capacity to minimize losses and maximize conversion from raw biomass to briquette output. Efficiency values were derived from actual mass measurements taken before and after each unit operation. Table 1 presents the individual efficiency for individual unit. As shown in the table, the individual efficiencies for pulverizing unit, mixing unit and briquetting unit are 94.5%, 98.0% and 95.0%, respectively. From (2), the overall system efficiency, OE, was computed as follows:

OE = 0.945 x 0.98 x 0.95 = 0.8798

This result confirms that nearly 88% of the total input material was successfully converted into finished briquettes, with minimal material losses. This level of efficiency surpasses the performance of many conventional, disaggregated systems that typically operate within the 70%–85% range [14], [15]. The high performance can be attributed to the integrated layout, reduced material handling, and continuous process flow between stages.

Table 1: Material Efficiency for Individual Unit.

Unit *(Components)*	Input Mass, M_i (kg)	Output Mass, M_o (kg)	Material Efficiency, % (M_o/M_i x 100)
Pulverizer *(50% Coco shell & 50% Cacao Pods)*	7	6.6	94.5
Mixer *(Coal Dust, Cacao Pods, Binder, and Water)*	10	9.8	98
Briquetter *(Complete Mixture from the Mixer)*	9.8	9.3	95
Note: Formulation of the mixture is 70% materials (coco shell & caca\o pods), 20% binder & 10% water.			

Source: Authors, (2026).

III.3 THROUGHPUT CAPACITY

The capacity of each unit was measured in kilograms per hour (kg/hr) using the formulas in Section 2.4. The pulverizing capacity (PC), mixing capacity (MC) and briquetting capacity (BC) were found to be 28 kg/hr, 42.8 kg/hr and 27 kg/hr, respectively. As the system is arranged in a sequential flow, the briquetting unit, being the slowest, determined the system's overall capacity, OC, being 27 kg/hr. This bottleneck reflects the intrinsic compression time and extrusion rate of the screw-type briquetting unit. Nonetheless, the system demonstrates sufficient throughput for small-scale applications such as rural fuel cooperatives, local vendors, and decentralized renewable energy initiatives. These results confirm the system's suitability for continuous operation in low-resource environments, especially where commercial-scale machinery is economically infeasible or logistically impractical.

IV. CONCLUSIONS

This study successfully designed, fabricated, and tested a compact, modular 3-in-1 machine for the efficient conversion of agricultural waste into biomass briquettes. By integrating pulverizing, mixing, and briquetting into a unified structure powered by a single motor, the system streamlines solid fuel production and eliminates the inefficiencies associated with separate machinery. The device achieved an impressive overall efficiency of 87.98% and a throughput capacity of 27 kg/hr, making it well-suited for small-scale and community-level applications. The inclusion of adjustable features, such as the VFD-controlled drive and modular subunits, ensures flexibility, maintainability, and user adaptability. This innovation has the potential to significantly contribute to localized energy resilience, agricultural waste management, and sustainable economic development. Future improvements may include the addition of a briquette cutter, real-time process sensors, or an integrated drying system to enhance fuel quality and production control. Further testing using diverse feedstock compositions would also help generalize applicability across regions and biomass types.

ABSTRACT

In the maritime industry, the transition from Time-Based Maintenance (TBM) to Predictive Maintenance (PdM) is increasingly critical to meet stringent environmental regulations and minimize operational downtime. However, implementing data-driven diagnostics on marine vessels faces significant challenges due to the "OT-IT gap" and the hardware constraints of legacy shipboard systems. This study proposes a cost-effective, Edge-centric Intelligent SCADA architecture that integrates a Siemens S7-1200 PLC with a Hybrid Artificial Neural Network (ANN) via an SQL-based middleware. To ensure compatibility with standard low-configuration Industrial PCs (IPCs), the system employs a deliberate asynchronous sampling strategy (T_{scan} = 3 s), decoupling heavy predictive analysis from real-time monitoring. This design allows the diagnostic module to operate seamlessly as a background service without overburdening the control loop. Additionally, an optimized Bit-wise State Encoding (Bit-packing) protocol is implemented to address bandwidth constraints. This method compresses diagnostic vectors into atomic integer payloads, ensuring data integrity during transmission. The system was validated through Hardware-in-the-Loop (HIL) simulations and field trials on a Daihatsu 6PSHTb-26D training ship. Experimental results demonstrate that the architecture maintains a standard supervision latency of < 450 ms. Meanwhile, the AI-based fault detection operates with a stable latency of 3.1 s to 4.9 s—a designed safety margin that is sufficient for marine propulsion dynamics while optimizing computational resources. Furthermore, the Bit-packing protocol reduces communication overhead by approximately 90% compared to traditional tag-based methods, confirming the system's feasibility as a robust retrofit solution.

I. INTRODUCTION

I.1 MOTIVATION: THE EVOLVING PARADIGM OF MARITIME MAINTENANCE

The global maritime industry is currently navigating a profound structural transformation, often characterized in academic discourse as "Maritime 4.0" [1]. This digitalization wave is driven not merely by technological availability but by an urgent necessity to enhance operational efficiency and environmental compliance.

The International Maritime Organization (IMO) has instituted rigorous regulations regarding greenhouse gas emissions, most notably the Energy Efficiency Existing Ship Index (EEXI) and the Carbon Intensity Indicator (CII), which entered into force in 2023 [2]. These regulations create substantial pressure on vessel operators to optimize the performance of marine diesel engines, as inefficient operation directly impacts a vessel's Carbon Intensity rating and commercial viability [3]. Historically, marine engine maintenance has relied heavily on Time-Based Maintenance (TBM) strategies, which mandate the replacement of components at fixed intervals regardless of their actual physical condition [4]. While structured, TBM is inherently inefficient; components with remaining useful life are often replaced prematurely, incurring unnecessary costs, while unforeseen failures can still occur between scheduled intervals. Consequently, the industry is witnessing a strategic migration towards Condition-Based Maintenance (CBM) and Predictive Maintenance (PdM), leveraging real-time data to forecast equipment health and minimize unplanned downtime [5].

I.2 PROBLEM STATEMENT: THE OT-IT CONVERGENCE CHALLENGE

Despite the theoretical benefits of PdM, its practical deployment on seafaring vessels faces significant technical hurdles known as the "OT-IT gap" [6]. Operational Technology (OT) systems, such as Programmable Logic Controllers (PLCs), operate in a deterministic real-time environment focused on immediate machinery control. Conversely, Information Technology (IT) systems, required for complex data analytics, typically operate on probabilistic timing. A critical "disconnect" often exists between these layers. Operational data is frequently "locked" within low-level PLC registers, inaccessible to high-level analytical tools without complex interfaces. Furthermore, recent trends in PdM research often favor deep learning models (e.g., Transformers, LSTMs) deployed via cloud-based architectures [7]. However, such approaches are often unsuitable for the majority of the existing merchant fleet ("brownfield" vessels) due to two main reasons:

• Hardware Constraints: Deep learning models require high-performance computing resources (often GPUs) that are not standard on legacy Industrial PCs (IPCs).
• Connectivity Limitations: Cloud-centric solutions suffer from latency and instability due to reliance on satellite communication, which can compromise the availability of safety-critical monitoring systems [8].

I.3 CONTRIBUTIONS

Addressing these limitations, this research focuses on the design and implementation of a cost-effective, Edge-centric Intelligent SCADA system. The primary objective is to engineer a unified architecture that bridges the OT-IT gap directly on-board, enabling predictive intelligence without relying on unstable cloud connectivity or expensive hardware upgrades. The specific contributions of this study are:

• Architecture of Convergence: We propose a robust OT-IT framework utilizing a middleware bridge (Kepware) and a central data warehouse (SQL Server). This architecture creates a "Local Digital Twin," allowing the seamless bidirectional flow of data between the deterministic control layer and the analytical layer.
• Resource-Optimized Asynchronous Strategy: To ensure compatibility with standard low-specification IPCs, we introduce a deliberate asynchronous sampling strategy (T_{scan} = 3 s). This design decouples the heavy computational tasks of the Hybrid ANN model from the critical real-time scanning of the PLC, ensuring that predictive analysis operates smoothly as a background service without inducing system latency.
• Optimized Communication Protocol: We develop an optimized Bit-wise State Encoding (Bit-packing) algorithm. This technique addresses the bandwidth constraints of shipboard networks by compressing complex diagnostic vectors into atomic integer payloads, reducing communication overhead by approximately 90% and ensuring data integrity during transmission.

II. RELATED WORK

II.1 CLOUD-CENTRIC DIGITAL TWINS VS. EDGE COMPUTING

In the era of Maritime 4.0, the dominant trend in predictive maintenance research involves the development of Cloud-based Digital Twins. High-fidelity models, such as those proposed by Ritou et al. [9], continuously stream sensor data to onshore servers for processing. This centralized approach leverages virtually unlimited computing power, enabling complex simulations that are impossible to run locally. Recent frameworks leveraging IoT and cloud integration have demonstrated significant potential in revolutionizing predictive maintenance across various industrial sectors [10]. A comprehensive overview of these advancements highlights the industry's shift from basic component monitoring to complex, data-driven ecosystem management [11]. However, the practical deployment of these cloud-centric solutions on ocean-going vessels faces critical hurdles. Beyond the high implementation costs for legacy fleets [11], the reliance on continuous ship-to-shore connectivity presents a severe vulnerability. According to a comparative analysis by Shi et al. [12], cloud systems suffer from significant latency and jitter, particularly when relying on VSAT satellite links susceptible to weather interference. Furthermore, a 2025 analysis of maritime cybersecurity warns that the direct integration of OT and IT systems for cloud uploading exposes vessel infrastructures to escalating cyber threats, including Advanced Persistent Threats (APTs) targeting satellite communications [13]. Consequently, recent scholarship argues for a strategic shift towards "Edge Computing," where data processing occurs near the source to ensure autonomy and security. Our research aligns with this paradigm, prioritizing deterministic response times over the expansive but vulnerable processing capabilities of the cloud.

II.2 DEEP LEARNING MODELS VS. EXPLAINABLE HYBRID DIAGNOSTICS

Regarding diagnostic algorithms, Deep Learning (DL) has gained traction. Cheliotis et al. [14] applied Long Short-Term Memory (LSTM) networks, while others have explored Convolutional Neural Networks (CNNs) for vibration analysis [15]. Recent studies in 2025 have further advanced this field by proposing deep hybrid models capable of capturing both temporal and spatial features of marine engine data with high accuracy [16]. Despite their performance, these complex models often impose computational burdens exceeding the capabilities of standard marine IPCs [17]. Furthermore, they require massive datasets, which are rare due to the "data scarcity" of maritime fault events. While unsupervised anomaly detection techniques have emerged as a potential solution [18], there is an urgent need for "lightweight" architectures that reduce parameter overhead to ensure adaptability in resource-constrained environments, as emphasized in recent reviews of port machinery diagnostics [19]. Addressing this trade-off, hybrid approaches combining physics-based rules with shallow neural networks offer a better balance between accuracy and efficiency [20]. This direction is supported by recent findings in [21], which demonstrate that lightweight adaptive models can achieve superior diagnostic performance on rotating machinery without the heavy computational cost of deep transfer learning.

II.3 DATA SYNCHRONIZATION AND SEMANTIC COMPRESSION

A significant yet often overlooked challenge in OT-IT convergence is ensuring data integrity during the transmission of diagnostic results. Conventional research on industrial data compression has largely focused on time-series reduction techniques, such as the Gorilla algorithm or Delta encoding, to minimize storage costs [22]. However, these techniques prioritize storage efficiency over real-time "state atomicity." In a SCADA environment, if diagnostic states (e.g., Warning vs. Alarm) are transmitted sequentially as separate tags, network latency can lead to "data tearing," where the operator sees an inconsistent system state. There is a lack of research focusing on semantic state compression for ensuring atomic updates in control loops. This study addresses this gap by introducing the Bit-wise State Encoding technique, which packages the entire diagnostic vector into a single atomic payload, ensuring that the AI's inference is perfectly synchronized with the HMI display.

III. PROPOSED SYSTEM ARCHITECTURE

III.1 THE OT-IT CONVERGENCE FRAMEWORK

The overall architecture of the proposed Intelligent SCADA system is illustrated in Figure 1. Predicated on a centralized data brokerage model, the system utilizes Kepware Server as the primary gateway to facilitate a seamless, closed-loop data exchange between the Operational Technology (OT) and Information Technology (IT) layers. To reconcile the conflicting requirements of real-time operational safety and deep-learning analytical depth, the communication topology between the middleware and the visualization layer is bifurcated into two distinct operational streams.

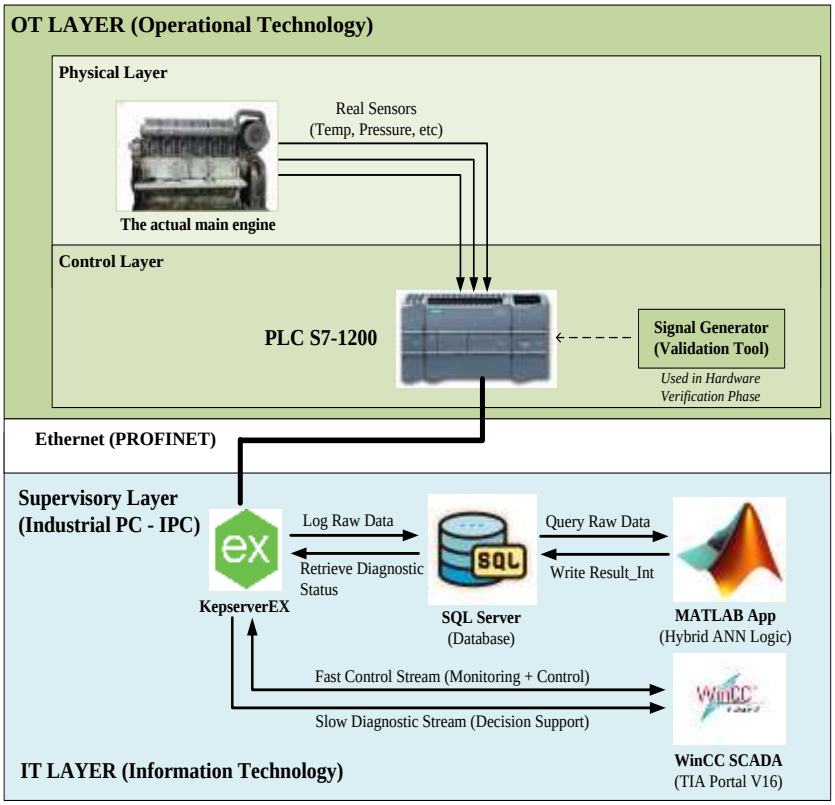

Figure 1: The proposed OT-IT Convergence Architecture.
Note: The separation between the Fast Control Stream (Bidirectional) for real-time operation and the Slow Diagnostic Stream (Unidirectional) for ANN-based decision support
Source: Authors, (2026).

The first channel, designated as the Fast Control Stream, establishes a high-speed, bidirectional link (T < 500ms) connecting WinCC directly to the PLC tags. This deterministic path ensures immediate visualization of critical telemetry—such as RPM, pressure, and temperature—while simultaneously enabling the operator to execute control commands with instant responsiveness. In parallel, the Slow Diagnostic Stream functions as a dedicated unidirectional channel (T approx. 3 s) that delivers the ANN-predicted health status (*Result_Int*). This stream is strictly architected for decision support, thereby preventing the probabilistic nature of the neural network from interfering with the safety-critical control logic. Underpinning this dual-stream topology is a robust closed-loop analytics cycle. Kepware utilizes the ODBC Data Logger to continuously execute the "Log Raw Data" action, pushing sensor data from the PLC into the SQL Server archive. The MATLAB Engine then asynchronously fetches these records to perform inference and writes the computed diagnostic result back to a feedback table. Finally, Kepware executes the "Retrieve Diagnostic Status" action via its ODBC Client driver, polling the ANN output and mapping it back to an OPC tag for the Slow Stream visualization.

III.2 ASYNCHRONOUS CLOSED-LOOP SYNCHRONIZATION STRATEGY

Integrating deterministic OT systems with probabilistic IT environments introduces a fundamental "impedance mismatch" in processing speeds. While the PLC operates on a rigid millisecond-level scan cycle, the matrix operations required for the Hybrid ANN model necessitate a variable computation time. To resolve this, the system employs an asynchronous "Producer-Consumer" architecture, visualized in the flowchart in Figure 2.

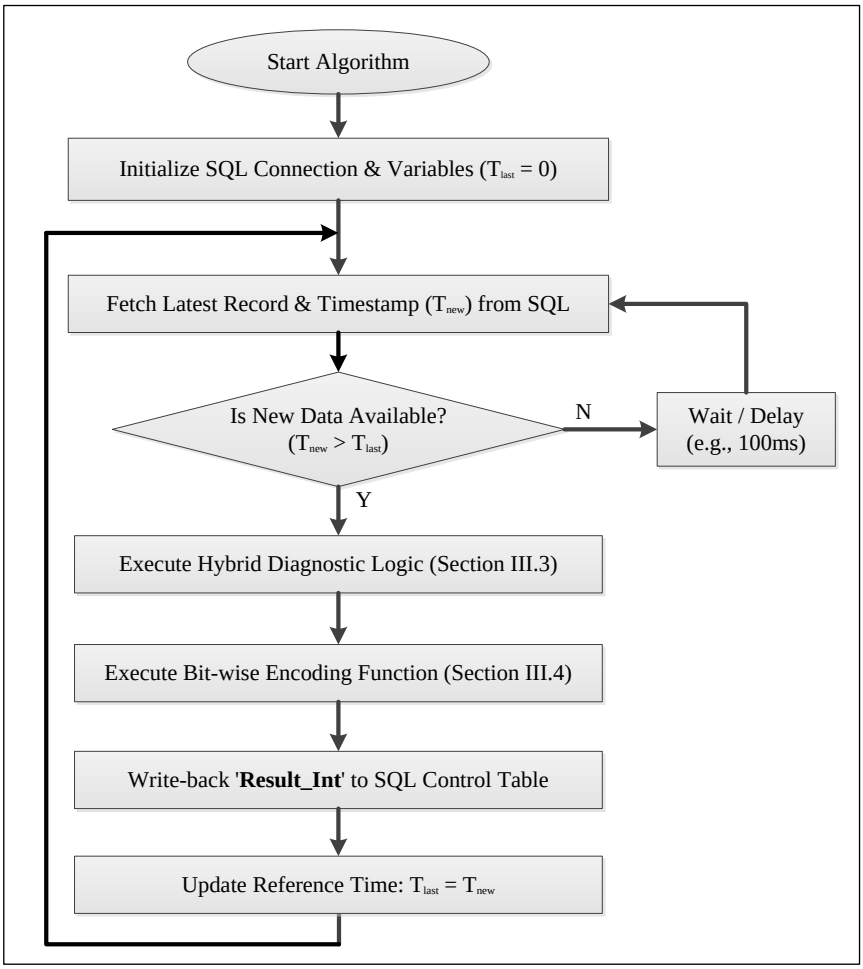

Figure 2: Flowchart of the Asynchronous Synchronization Service acting as a safety gatekeeper between OT and IT layers.
Source: Authors, (2026).

This synchronization logic acts as a strict gatekeeper to manage the interaction between the two data streams without conflict. The MATLAB service operates in a background loop, triggering the heavy diagnostic computation only when a temporal handshake confirms the arrival of new data ($T_{new} > T_{last}$). This decoupled design ensures that the latency incurred by the AI inference loop—typically ranging from 3 s to 5 s—is effectively isolated within the Slow Diagnostic Stream, guaranteeing that the operator maintains full, real-time situational awareness.

III.3 HYBRID DIAGNOSTIC ALGORITHMS IMPLEMENTATION

To ensure comprehensive fault coverage across the engine's operating range, the system employs a "Hybrid" diagnostic strategy that combines deterministic physics-based rules with a probabilistic Artificial Neural Network (ANN).

III.3.1 Rule-based Logic (Linear Parameters)

For failure modes exhibiting linear characteristics or immediate threshold violations, we implemented a deterministic rule-based algorithm directly within the MATLAB processing loop. This module calculates Diagnostic Indices (DI) based on deviations from the manufacturer's baseline specifications [23].

Exhaust Gas Temperature Deviation (DI1): To detect cylinder load imbalance or injector fouling, the deviation of each cylinder's temperature (T_i) from the average temperature of all cylinders (T_{avg}) is monitored:

$$DI_{EGT} = \frac{|T_i - T_{avg}|}{T_{avg}} \times 100 \quad (\%) \tag{1}$$

Threshold: An alarm is triggered if the deviation exceeds 5%. **Governor Hunting Detection (DI4)**: Instability in the fuel rack or governor mechanism is identified by analyzing the oscillation amplitude of the engine speed (N_{act}) relative to the steady-state setpoint (N_{set}) over a sliding time window:

$$DI_{Gov} = |N_{set} - N_{act}| \tag{2}$$

Threshold: A "Hunting" warning is issued if the RPM fluctuation exceeds 15 rpm for a duration longer than 5 s. **Pneumatic Leakage Detection (DI5)**: To identify sealing failures in the starting air system, the pressure decay rate is calculated during intervals when the air compressor is in the "OFF" state. The leakage index is defined as the pressure drop (ΔP) over a fixed observation period (Δt):

$$DI_{Leak} = \frac{P(t) - P(t + \Delta t)}{\Delta t} \tag{3}$$

Threshold: A leakage alarm is triggered if the pressure drop rate exceeds 0.2 bar/minute, indicating a potential valve failure or pipe rupture.

III.3.2 Residual-based ANN Logic (Non-linear Parameters)

While linear rules suffice for DI1, DI4, and DI5, the thermodynamic behavior of the lubrication and cooling systems exhibits complex non-linearities that cannot be accurately modeled by static thresholds. Therefore, the Lubricating Oil Pressure (DI2) and Cooling Water Temperature (DI3) are monitored using a Residual-based approach driven by the ANN. **Network Topology and Inputs**: The core predictive engine is built upon the architecture previously developed and validated in our accompanying study [24]. The model utilizes a Multilayer Perceptron (MLP) with an optimized [3] topology. This specific configuration was determined through an empirical grid search to balance learning capability (RMSE ≈ 0.0737°C) and computational efficiency for Edge deployment [24]. The network is trained using the Levenberg-Marquardt algorithm on a high-fidelity dataset generated via Hardware-in-the-Loop (HIL) simulation. The input vector X_t comprises three correlated operational variables: Engine Speed (n), Load Factor (L), and Lube Oil Temperature (T_{LO}). Mathematically, the ANN functions as a non-linear mapping operator $f_{ANN}(\cdot)$ that correlates the operational state vector with the expected thermodynamic outputs. The estimation model for Lube Oil Pressure and Jacket Water Temperature is defined as follows:

$$Val_{predict} = f_{ANN}(n, L, T_{LO}) = \Phi_{out}\left(\sum_{j=1}^{M} w_j \cdot \Phi_{hidden}\left(\sum_{i=1}^{3} w_{ij} x_i + b_j\right) + b_{out}\right) \tag{4}$$

where $Val_{predict}$ is the ideal healthy value, $x_i \in \{n, L, T_{LO}\}$ represents the input features, w and b denote the trained weights and biases, and Φ represents the activation functions (typically Sigmoid for hidden layers and Linear for the output layer [24]).

Residual Calculation Logic: The ANN predicts $Val_{predict}$ for the oil pressure and cooling temperature under current load conditions. The diagnostic indices are then derived from the residual error between the prediction and the actual sensor measurement ($Val_{Measure}$):

$$DI_2 \text{ (or } DI_3) = |Val_{Measure} - Val_{predict}| \tag{5}$$

Threshold Comparison: Unlike fixed limits, the thresholds for DI2 and DI3 are dynamic. The system flags a fault only if the residual exceeds a statistically determined boundary derived from Receiver Operating Characteristic (ROC) analysis [25]. As established in [24], this adaptive thresholding mechanism incorporates both the algorithm's noise floor and the sensor's uncertainty margin ($\grave{o}_{sensor}$), effectively filtering out false alarms caused by transient load changes.

III.4 OPTIMIZED BIT-WISE STATE ENCODING PROTOCOL

Following the diagnostic process, transmitting the results from the IT layer (MATLAB) back to the HMI (WinCC) presents a bandwidth challenge. To address this, we implemented a Base-4 Weighted Sum encoding algorithm, specifically designed to encapsulate multi-level fault severities into a single atomic payload.

III.4.1 Mathematical formulation (base-4 encoding)

Unlike traditional binary systems that only indicate the presence of a fault (0/1), our system requires the transmission of three distinct operational states for each diagnostic indicator (DI):

•0 (Normal): The parameter is within safety limits.
•1 (Warning): Significant deviation detected (Pre-alarm).
•2 (Alarm): Critical deviation breaching safety thresholds.

The encoding process is visualized in the flowchart in Figure 3. The algorithm iterates through the state vector S = {S1, S2, S5} and computes a weighted sum to compress all states into a single integer variable named *Result_Int*.

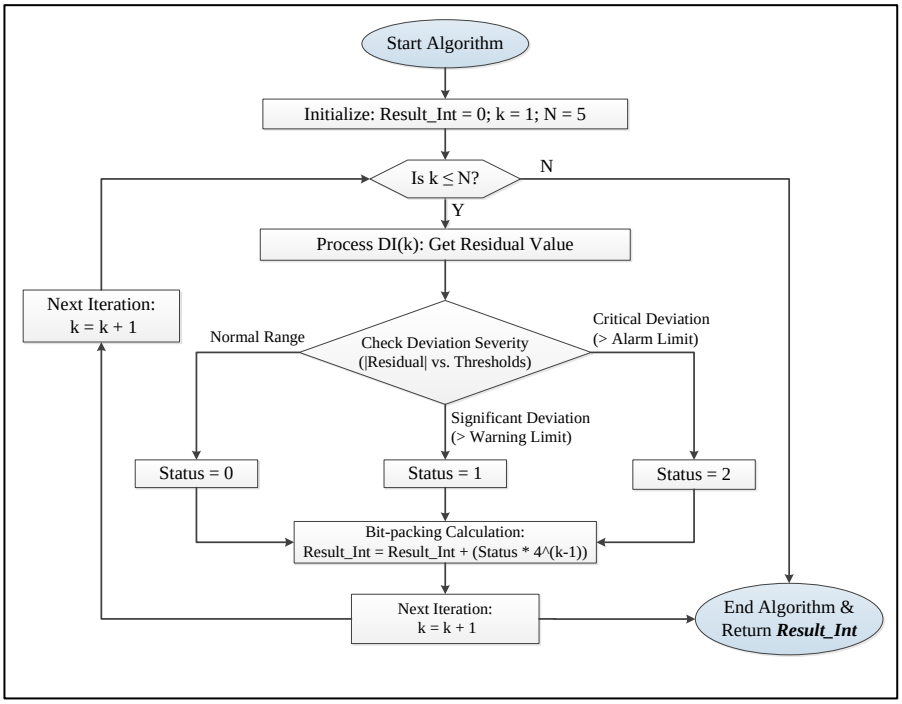

Figure 3: Flowchart of the Base-4 Weighted Sum encoding algorithm implemented in the MATLAB script.
Source: Authors, (2026).

The mathematical definition is as follows:

$$Result\_Int = \sum_{k=1}^{5} S_k \cdot 4^{(k-1)} \tag{6}$$

Where S_k is the status (0, 1, or 2) of the k-th diagnostic indicator, $4^{(k-1)}$ represents the positional weight, equivalent to allocating a 2-bit memory block for each indicator. For example, if the system detects that DI1 is Normal (S_1=0), DI2 is at Warning (S_2=1), and DI3 is at Alarm (S_3=2), the payload is calculated as:

$$Result\_Int = (0 \times 1) + (1 \times 4) + (2 \times 16) = 36 \tag{7}$$

This compact integer is transmitted via a single Modbus register (Word) [26], ensuring synchronization across all subsystems.

III.4.2 Memory Mapping Strategy

At the Visualization Layer (WinCC SCADA), a Direct Bit-Mapping Strategy is employed to decode the Result_Int payload. Since each indicator occupies exactly 2 bits, the status can be extracted by checking specific bit pairs in the memory tag. Table 1 details the memory allocation schema used in the experimental setup to map the payload to specific HMI alarms. By utilizing this protocol, the system effectively reduces the communication overhead by approximately 80% compared to traditional tag-based methods, ensuring that the synchronization between the ANN model and the HMI remains real-time.

Table 1: Proposed Bit-wise Encoding Schema for Real-time Status Transmission.

Bit Index (i)	Weight (2i)	Target Subsystem (Diagnostic Indicator)	Semantic Status	Trigger Logic (in WinCC ANN_Class)
0	1	DI1 (Exhaust Gas Deviation)	Warning	Bit 0 = 1 AND Bit 1 = 0
1	2	DI1 (Exhaust Gas Deviation)	Alarm	Bit 1 = 1
2	4	DI2 (Lube Oil Pressure)	Warning	Bit 2 = 1 AND Bit 3 = 0
3	8	DI2 (Lube Oil Pressure)	Alarm	Bit 3 = 1
4	16	DI3 (Jacket Water Temp)	Warning	Bit 4 = 1 AND Bit 5 = 0
5	32	DI3 (Jacket Water Temp)	Alarm	Bit 5 = 1
6	64	DI4 (Governor Stability)	Warning	Bit 6 = 1 AND Bit 7 = 0

7	128	DI4 (Governor Stability)	Alarm	Bit 7 = 1
8	256	DI5 (Start Air Leakage)	Warning	Bit 8 = 1 AND Bit 9 = 0
9	512	DI5 (Start Air Leakage)	Alarm	Bit 9 = 1

Source: Authors, (2026).

IV. SYSTEM IMPLEMENTATION AND EXPERIMENTAL SETUP

To validate the feasibility and robustness of the proposed Intelligent SCADA architecture, a two-phase implementation strategy was adopted: (1) Laboratory validation using a Hardware-in-the-Loop (HIL) configuration, and (2) Field deployment on an actual marine diesel engine.

IV.1 LABORATORY IMPLEMENTATION: HARDWARE-IN-THE-LOOP (HIL) CONFIGURATION

Before field deployment, the system was prototyped in a laboratory environment to verify the stability of the communication stack and the inference speed of the ANN model. The experimental setup, as illustrated in Figure 4, comprises three main layers:

•OT Domain (Physical Emulation): A simplified physical simulation kit representing the marine engine's signals. It generates analog signals (0-10V, 4-20mA) simulating temperature and pressure variations.
•Control Layer: An Industrial PC (IPC) acting as the central processing unit, running the SCADA software (WinCC) and the Intelligent Fault Detection module.
•IT Domain (Data Processing): The software stack integrates KepserverEX (OPC Server) for data acquisition, Microsoft SQL Server for time-series logging, and the trained ANN model for predictive analytics.

This HIL setup ensures that the Dual-Rate Sampling mechanism (Fast monitoring vs. Slow analysis) operates without conflict before integration with real industrial hardware.

IV.2 FIELD DEPLOYMENT ON MARINE DIESEL ENGINE

IV.2.1 Testbed Specifications

The complete system was deployed on the main engine of a training ship, with the Intelligent SCADA station installed in the Engine Control Room (ECR) as shown in Figure 5a. The testbed is a Daihatsu 6PSHTb-26D, a 4-stroke, turbocharged, intercooled marine diesel engine. The detailed technical specifications of the engine are listed in Table 2.

Table 2: Technical specifications of the experimental main engine.

Parameter	**Specification**
Manufacturer	Daihatsu Diesel Mfg. Co., Ltd.
Model Type	6PSHTb-26D
Engine Type	4-stroke, Single acting, Trunk piston, Turbocharged
Number of Cylinders	6 (In-line)
Cylinder Bore	260 mm
Piston Stroke	320 mm
Rated Output (MCR)	1000 PS (735 kW)
Rated Speed	720 rpm
Combustion System	Direct Injection
Cooling System	Fresh Water (Jacket) / Sea Water (Intercooler)
Starting System	Compressed Air
Turbocharger	Axial Turbine type (VTR Series)

Source: Authors, (2026).

IV.2.2 Fault Injection Methodology

Conducting destructive fault tests on an operational marine engine is strictly prohibited due to safety regulations. Therefore, to evaluate the Intelligent SCADA system's fault detection capability under realistic conditions, two non-destructive fault injection strategies were employed. First, Signal Injection was utilized for critical safety parameters, specifically Lube Oil Pressure (P_{LO}) and Jacket Water Temperature (T_{JW}). Instead of physically overheating the engine, a precision 4-20 mA current loop calibrator was connected in parallel to the PLC analog input module (Figure 5b). This technique allows for the precise simulation of sudden sensor failure scenarios without risking the engine's integrity.

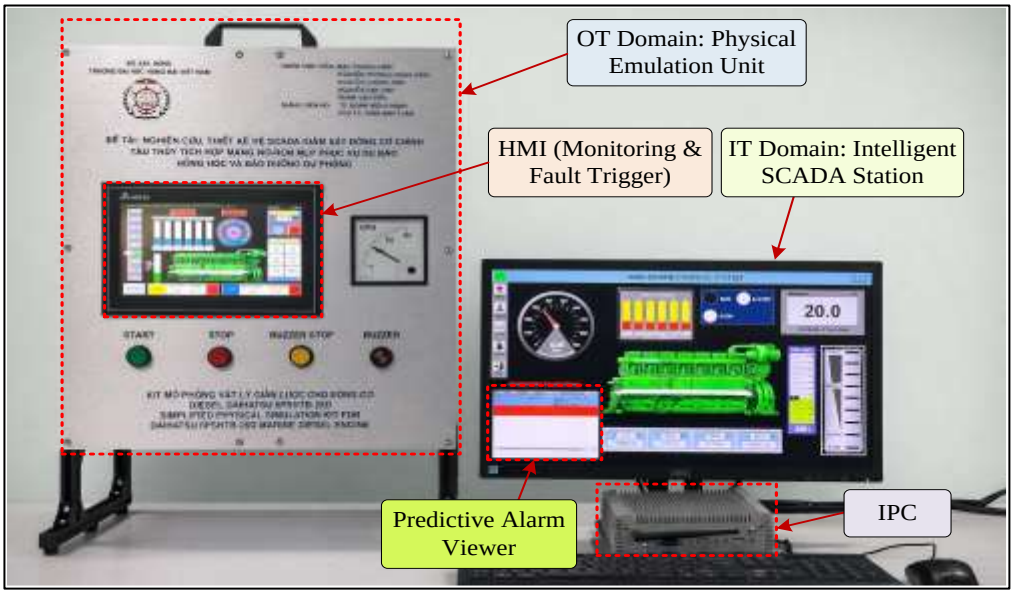

Figure 4: Experimental setup of the Intelligent SCADA station in the laboratory environment (HIL configuration).
Source: Authors, (2026).

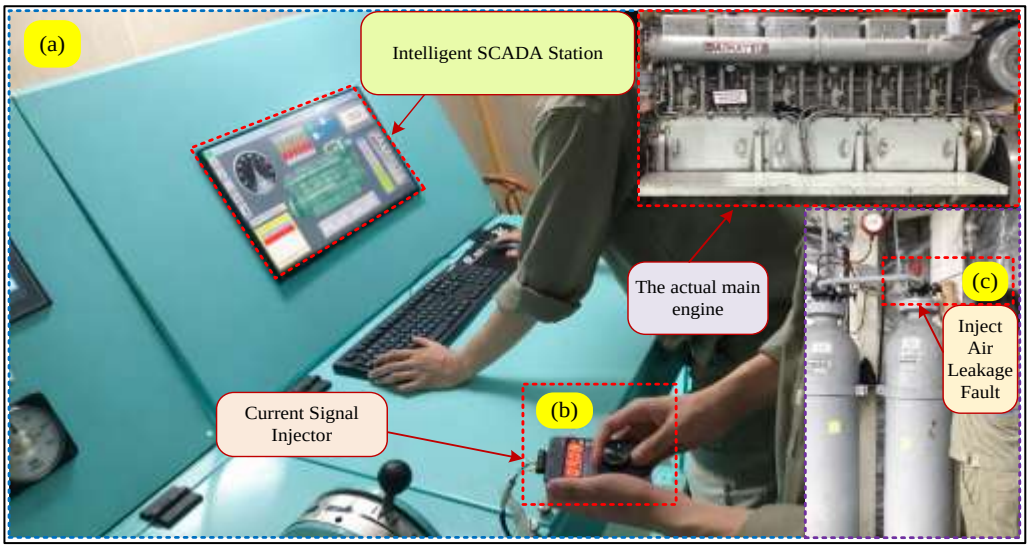

Figure 5: Field trial deployment on the Daihatsu 6PSHTb-26D main engine: (a) Overview of the monitoring station in the engine control room; (b) Signal injection using a 4-20mA loop calibrator to simulate sensor faults; (c) Physical fault injection via manual manipulation of the air receiver valve.
Source: Authors, (2026).

Second, Physical Fault Injection was applied to the pneumatic starting system to simulate mechanical anomalies. By manually manipulating the air receiver service valve (Figure 5c), a gradual pressure drop (Drift Fault) was introduced. This method tests the sensors' sensitivity and the algorithm's ability to detect slow-evolving deviations ($P_{Air} < P_{limit}$) amidst the engine's physical vibration.

IV.3 EXPERIMENTAL FAULT SCENARIOS DEFINITION

To ensure a consistent evaluation across both the HIL simulation (Section V.1) and the field deployment (Section V.2), standardized fault scenarios were established. As detailed in Table 3, specific severity levels were defined for the Lube Oil Pressure (P_{LO}) and Jacket Water Temperature (T_{JW}) parameters. These scenarios correspond to the "Warning" and "Alarm" thresholds set in the SCADA system, representing the progression from an incipient fault to a critical failure.

Table 3: Definition of experimental fault scenarios and severity levels.

Parameter	Fault Type	Severity Level	Physical/Simulated Condition	Target Threshold	Expected System Status
Lube Oil Pressure (PLO)	Filter Clogging /Pump Failure	Level 1 (Moderate)	50% Blockage	ΔP = −0.25 bar	WARNING
		Level 2 (Severe)	73% Blockage	ΔP = −0.60 bar	ALARM
Jacket Water Temp (TJW)	Radiator Fouling /Cooling Loss	Level 1 (Moderate)	46% Fouling	ΔT = +1.2 °C	WARNING
		Level 2 (Severe)	87% Fouling	ΔT = +4.5 °C	ALARM

Note: The severity percentages representing filter clogging and radiator fouling are derived from the system's hydraulic and thermal models used in the HIL configuration and replicated via signal injection/physical adjustment in the field trial.
Source: Authors, (2026).

V. EXPERIMENTAL RESULTS AND DISCUSSION

To rigorously evaluate the proposed Intelligent SCADA system, a comprehensive validation process was conducted in two phases: (1) Laboratory validation using the HIL framework to establish a performance baseline, and (2) Field trials on the Daihatsu 6PSHTb-26D marine diesel engine to assess real-world applicability.

Table 4: Performance verification in HIL simulation.

Monitored Parameter Group	Specific Conditions / Examples	Standard SCADA Latency	ANN Detection Latency	Note
I. General Operational Parameters (Real-time Control & Monitoring)	Engine Speed (RPM), Fuel Rack Position, Air Pressure, etc.	< 350 ms	-	Instant Feedback
II. Lube Oil Pressure (PLO)	Level 1 (50% Clogging)	< 350 ms	3.8 s	ANN Detected
	Level 2 (73% Clogging)	< 350 ms	4.2 s	ANN Detected
III. Jacket Water Temp (TJW)	Level 1 (46% Fouling)	< 350 ms	2.5 s	ANN Detected
	Level 2 (87% Fouling)	< 350 ms	4.5 s	ANN Detected

Source: Authors, (2026).

V.1 LABORATORY VALIDATION (HIL FRAMEWORK)

The HIL simulation was configured to replicate the exact fault scenarios defined in Table 4. By injecting the specific fault vectors—Level 1 (Warning) and Level 2 (Alarm)—into the engine model, the system's baseline latency was measured under ideal conditions. As summarized in Table 4, the system demonstrates a clear distinction between the two monitoring channels. The standard monitoring path (PLC → WinCC) maintains a near-instantaneous response of < 350 ms. In contrast, the ANN detection module exhibits a variable latency ranging from 2.5 s to 4.5 s. Since the HIL environment assumes ideal sensors with zero response time, this delay is attributed strictly to the asynchronous sampling interval of the ANN application (T_{scan} = 3 s).

V.2 FIELD TRIAL ON REAL MARINE DIESEL ENGINE

Following the HIL validation, the system was deployed on the actual engine to evaluate its performance under realistic operating conditions. The experiments focused on the two contrasting dynamic behaviors defined in Table 4: the fast-response Lube Oil Pressure (P_{LO}) and the slow-response Jacket Water Temperature (T_{JW}).

V.2.1 Lube Oil Pressure Response (P_{LO})

In the first scenario, a signal injection technique was employed to simulate a critical drop in Lube Oil Pressure. As depicted in Figure 6, while the standard HMI monitoring updated the values near-instantly (< 450 ms), the Intelligent ANN module processed the data according to its specific scanning interval. The module successfully identified the anomaly, triggering the 'Warning' state with a measured latency of Δt_1 = 3.2 s. Subsequently, as the signal continued to degrade below the critical limit, the system escalated to the 'Alarm' state with a latency of Δt_2 = 4.9 s. This response time is consistent with the designed operation of the predictive algorithm.

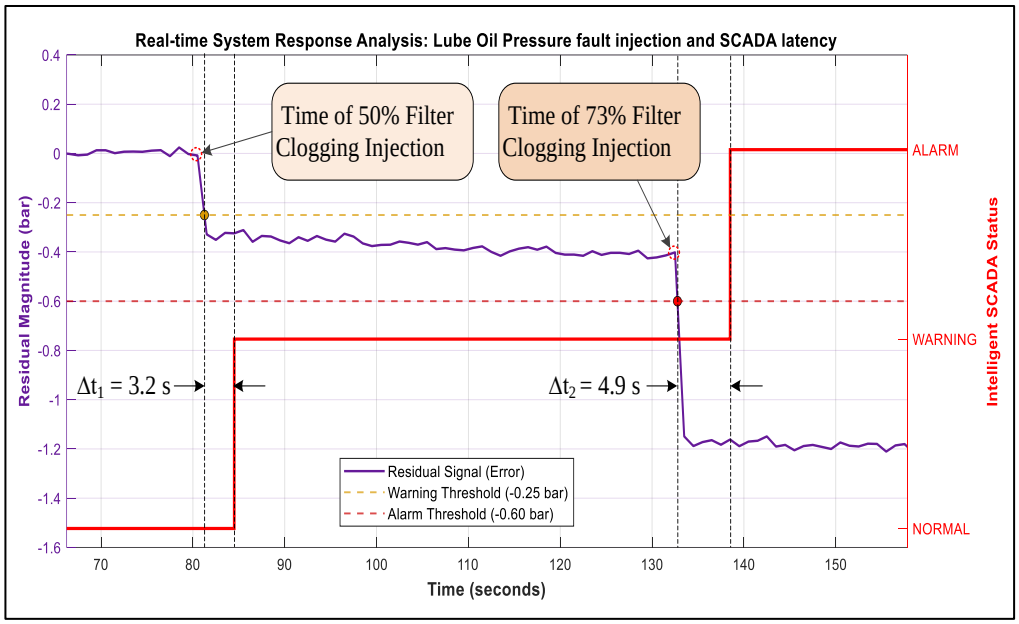

Figure 6: Real-time System Response (Fast Dynamics): Fault detection analysis for Lube Oil Pressure (P_{LO}) under signal injection scenario.

Source: Authors, (2026).

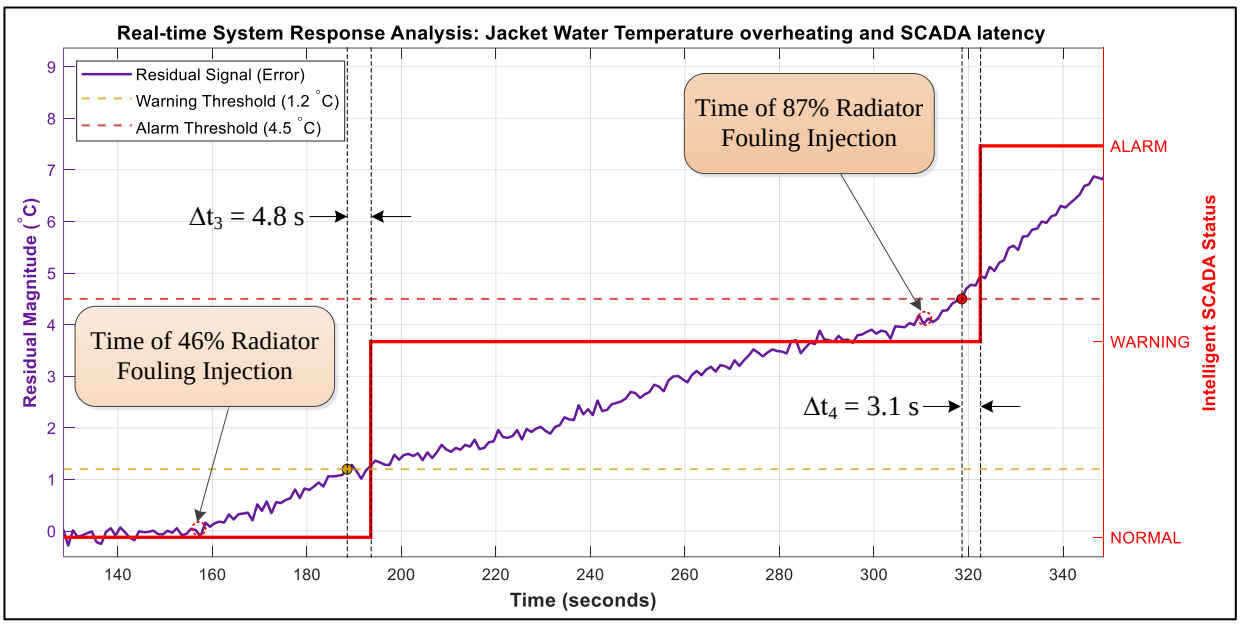

Figure 7: Real-time System Response (Slow Dynamics): Fault detection analysis for Jacket Water Temperature (T_{JW}) under physical overheating scenario.
Source: Authors, (2026).

V.2.2 Jacket Water Temperature Response (T_{JW})

Conversely, the second scenario focused on the Jacket Water Temperature, a parameter characterized by high thermal inertia. A physical restriction of the radiator airflow was introduced to induce a gradual overheating condition. Figure 7 illustrates the detection process. The intelligent algorithm detected the initial deviation and activated the 'Warning' status with a latency of Δt_3 = 4.8 s. Notably, the critical 'Alarm' condition was detected with a faster response time of Δt_4 = 3.1 s. This variation in detection time (from 3.1 s to 4.8 s) confirms the stochastic nature of the ANN application's asynchronous scanning cycle (T_{scan} = 3 s), independent of the faster real-time monitoring layer.

V.2.3 Overall Performance Summary

The quantitative results from the field trials are consolidated in Table 5. The data confirms that the Standard SCADA Latency for general monitoring (Speed, Rack, Pressure, etc.) is consistently < 450 ms, which aligns with standard industrial HMI update rates and ensures real-time feedback for operators. In contrast, the ANN Detection Latency for fault scenarios ranges between 3.1 s and 4.9 s, which accounts for the computational overhead of the intelligent algorithm but remains well within the safety margin.

Table 5: Real-world system performance.

Monitored Parameter Group	Specific Conditions / Examples	Standard SCADA Latency	ANN Detection Latency	Note
I. General Operational Parameters (Real-time Control & Monitoring)	Engine Speed (RPM), Fuel Rack Position, Air Pressure, etc.	< 450 ms	-	Instant Feedback
II. Lube Oil Pressure (PLO)	Level 1 (50% Clogging)	< 450 ms	3.2 s	ANN Detected
	Level 2 (73% Clogging)	< 450 ms	4.9 s	ANN Detected
III. Jacket Water Temp (TJW)	Level 1 (46% Fouling)	< 450 ms	4.8 s	ANN Detected
	Level 2 (87% Fouling)	< 450 ms	3.1 s	ANN Detected

Source: Authors, (2026).

V.3 DISCUSSION

The experimental results validate the efficacy of the proposed Dual-Rate Sampling Architecture, which successfully decouples real-time monitoring from complex predictive analysis. By maintaining a low latency of approximately 450 ms on the standard HMI channel (PLC → WinCC), the system ensures that critical operational parameters, such as engine speed and exhaust gas temperature, are updated instantaneously for human operators. This design satisfies the ergonomic requirements for marine supervision, ensuring that the crew retains immediate control over the engine's status regardless of the computational load on the intelligent module. Regarding the intelligent fault detection capability, a comparative analysis between the HIL simulation (Table 4) and the field trial (Table 5) reveals a consistent latency pattern. The detection time in the real-world environment fluctuates between 3.1 s and 4.9 s. This latency is primarily governed by the asynchronous interaction between the industrial communication stack (PLC-to-Kepserver polling) and the ANN application's scanning interval (T_{scan} = 3 s). Although this introduces a slight delay compared to the ideal HIL baseline, it remains well within the safety margins required for marine propulsion systems.

Given the large thermal and mechanical time constants of a marine diesel engine (where temperature changes occur over several seconds), a maximum processing delay of 5 s is negligible and does not compromise the safety of the vessel. Furthermore, the system demonstrates significant robustness against environmental noise and sensor fluctuations. As evidenced in the response curves of Figure 6 and Figure 7, the decision-making algorithm effectively filters out high-frequency noise without triggering false alarms. The stability of the "Intelligent SCADA Status" signal confirms that the system is not only capable of early fault detection but also reliable enough to operate in the harsh vibration environment of a ship's engine room. Finally, Table 6 benchmarks the proposed system against prevalent Cloud-centric [9, 12] and Deep Learning Edge [14, 15] approaches. While Deep Learning models utilizing GPU acceleration offer rapid inference times (< 100 ms), such speed is often excessive for marine applications characterized by large thermal and mechanical inertia. A response time of milliseconds risks capturing transient noise rather than genuine trend deviations, potentially leading to false alarms.In contrast, our system's asynchronous sampling (3.1−4.9 s) acts as a temporal filter. This design represents an optimal engineering trade-off: it provides a stable, noise-robust detection window that aligns with the engine's physical time constants ( ), while allowing deployment on cost-effective, standard IPCs without the need for specialized GPU hardware.

Table 6: Comparative analysis: Proposed System vs. Cloud-centric and Deep Learning approaches.

Feature	Cloud-centric Digital Twins [9, 12]	Deep Learning Edge [14, 15]	Proposed Lightweight Edge
Computing Hardware	Remote Server (Unlimited)	High-End IPC (Requires GPU)	Standard IPC (CPU only)
Diagnostic Latency	Stochastic (Unstable)	Instant (<100 ms)	Deterministic (3.1s−4.9s)
Suitability for Inertia	Risk of Disconnection	Noise-Sensitive (Overkill)	Optimal (Inertia-Matched)
Retrofit Feasibility	Low (High recurring costs)	Low (Expensive Hardware)	High (Software-based)

Source: Authors, (2026).

VI. CONCLUSION

This study successfully developed and validated a cost-effective Intelligent SCADA system for marine diesel engines, integrating industrial automation standards with advanced predictive maintenance capabilities. By employing a "Dual-Rate Sampling Architecture," the system overcomes the computational limitations of standard PLCs, allowing strictly real-time monitoring to coexist with complex AI-based fault diagnosis. The experimental validation, conducted through both Hardware-in-the-Loop (HIL) simulations and field trials on a Daihatsu 6PSHTb-26D training ship, yielded the following key conclusions:

• Architecture Efficiency: The proposed decoupling strategy proved effective in a real-world marine environment. The standard monitoring channel (HMI path) maintained a stable latency of < 450 ms for all critical operational parameters, complying with industrial safety standards for real-time supervision.

• Diagnostic Performance: The Intelligent ANN module successfully detected both fast-dynamic faults (Lube Oil Pressure anomalies) and slow-dynamic faults (Cooling Water thermal drift). Despite the asynchronous scanning interval, the system achieved a detection latency ranging from 3.1 s to 4.9 s. Given the large thermal and mechanical time constants of marine propulsion systems, this delay is negligible and provides a sufficient safety margin for early warning.

• Robustness and Applicability: The field trials confirmed that the system is robust against the harsh conditions of an engine room, including significant vibration and electromagnetic noise. By utilizing standard industrial protocols (OPC UA, Modbus TCP) and commercial hardware (S7-1200 PLC), the proposed solution offers a scalable and low-cost upgrade path for existing legacy vessels, bridging the gap between traditional automation and the era of autonomous shipping.

Future Work: Future research will focus on expanding the fault dataset to include combustion-related anomalies (via cylinder pressure analysis) and implementing an Edge-to-Cloud synchronization mechanism. This will allow the local Intelligent SCADA models to be updated remotely, further enhancing the system's adaptability to different engine types and operating conditions.

Steganalysis Resistance

ABSTRACT

The growth of development the digital communication has greatly raised the chances of information leakage, interception, and unauthenticated access, particularly in heterogeneous multimedia setting. Conventional single-modal steganographic methods have been known to be limited in their payload storage capacity, weak, and susceptible to steganalysis attacks. In order to overcome these issues, the proposed work develops a Robust Multimodal Steganography Framework to ensure the secure transmission of the text, image, and audio information over the untrusted communication channels. The suggested framework combines the utilization of adaptive embedding plans in various carrier media with the Discrete Wavelet Transform (DWT) being employed in image stealth, the Discrete Cosine Transform (DCT) being employed in audio embedding and AES-based encryption being employed in protecting the textual payload. An active payload allocation scheme provides maximum imperceptibility and resistance to noise, compression and signal distortions. The experimental analysis of the proposed framework shows that this framework has better security and robustness than traditional unimodal methods. With the system, attains an average PSNR of 52.6 dB with stego-images, SNR of 41.8 dB with stego-audio and a bit error rate of less than 0.7 with common attack conditions like Gaussian noise and compression. It has an enhanced payload capacity of up to 32 and the transparency to perceptions is still high. The framework also has high resistance to statistical steganalysis and the detection accuracy dwindles to less than 18 %.

I. INTRODUCTION

The multimedia applications and the high rate of development of digital communication networks have resulted in the unheard of sharing of sensitive information in the shape of text, images and audio over non-closed and non-trusted mediums [1]. According to recent studies, multimedia data proves to be especially appropriate in the context of information hiding because they have a high level of redundancy and perceptual tolerance [2]. Nevertheless, today the communication situations are more about multimodal transmission of data, where the textual, picture, and audio information are present in parallel and exchange each other simultaneously, thus creating new security dilemmas [3]. Compression, noise, format conversion or statistical analysis can be used by attackers to scan or obliterate hidden information, and therefore unimodal protection cannot be fully used in most practical situations [4]. Current single carrier (images or audio) unimodal steganographic schemes have limited embedding, are poorly resistant to attacks and lack adaptability to dynamic communication conditions [5]. Moreover, the use of one medium also leads to high chances of complete information loss once the carrier is attacked [6].

II. RELATED WORK

II.1 SUBTITLE

II.1.1 Materials and Methods

One of the oldest forms of information hiding using linguistic structures, formatting, and semantic differences was text steganography which allowed the introduction of secret messages into the textual material [7]. More modern developments have investigated the field of natural language processing and language models to enhance better imperceptibility, yet the ability to resist automated text analysis and editing tools does not happen easily [8]. Least Significant Bit (LSB) substitution is a well-known method of spatial-domain data representation to use from its simplicity and large payload capacity, yet it is very vulnerable to noise, compression, and statistical steganalysis [9]. In order to overcome these shortcomings, methods in transform domain, grounded on Discrete Cosine Transform (DCT), Discrete Wavelet Transform (DWT) and Singular Value Decomposition (SVD) have been suggested, which provide a better robustness and imperceptibility [10]. Hybrid schemes based on several transforms reduce the resistance of attacks even more, but it is usually at the expense of a more complex computation [11]. The audio steganography methods are the methods based on the properties of the human auditory system that allows to hide hidden data in digital audio messages. LSB coding, phase coding, spread spectrum, and echo hiding are some of the techniques that have received a lot of research.

Though methods based on LSBs offer high payload capacity, they are sensitive to signal processing tasks as compared to transform-based and perceptual masking methods which are more robust, but with lower embedding rates [12]. Recent studies have devoted attention to adaptive embedding and psychoacoustic modeling in order to achieve a tradeoff between imperceptibility and resilience [13]. Multimodal, and hybrid information hiding schemes are designed to address the shortcomings of unimodal information hiding schemes by spreading secret information to a number of carrier media. Current literature indicates that multimodal steganography offers a considerable degree of security enhancement by ensuring that the process is less perceivable, and it eliminates the threat of single-point failure [14]. Nonetheless, a large number of suggested frameworks do not have coordinated allocation of payload, single security analysis, and robustness analysis across modalities. The existence of these gaps drive the necessity of a multimodal steganography framework, which is both integrated and adaptive and can be more efficient in increasing payload capacity, resistan, and steganalysis resistance, which is the focus of the current study [15].

Table 1: Summary Of Related Work On Steganography Techniques.

Steganography Technique	Domain Used	Payload Capacity	Key Limitation
Whitespace & Formatting	Text Domain	Low	Easily destroyed by text reformatting
NLP-based Semantic Encoding	Linguistic Domain	Low–Medium	Vulnerable to language normalization
LSB Substitution	Spatial Domain	High	Detectable via statistical analysis
DWT-based Embedding	Transform Domain	Medium	Increased computational complexity
DWT–SVD Hybrid	Transform Domain	Medium	Higher processing overhead
LSB Coding	Time Domain	High	Fragile under noise and compression
Psychoacoustic Masking	Frequency Domain	Medium	Limited payload capacity
Hybrid Image–Audio Framework	Mixed Domains	High	Lack of adaptive payload allocation

III. PROBLEM FORMULATION AND THREAT MODEL

III.1 PROBLEM DEFINITION

Assume that the M multimodal secret data can be represented as M = {Mt, Mi, Ma, with Mt being the text information, Mi the image information and Ma the audio information. Where C represents the set of cover media, i.e. C = {Ci, Ca} and Ci represents the cover image and Ca is the cover audio. The goal of the suggested steganography framework is to implant M into C and to make the steganography media S = {Si, Sa} sound, resistant, and foolproof against adversarial attacks. Embedding functionality may be formulated as:

$$Si = Ei(Ci, Mi, K)$$

$$Sa = Ea(Ca, Ma, K)$$

Where, Ei (.) and Ea (.) are image and audio embedding functions respectively, and K represents the key secret to the control of encryption and embedding. The extraction process is determined as:

$$Mi' = Di(Si, K)$$

$$Ma' = Da(Sa, K)$$

The system is considered successful if:

$$Mi' \approx Mi \ and \ Ma' \approx Ma$$

With minimal perceptual distortion and low extraction error.

III.2 ADVERSARIAL AND STEGANALYSIS THREAT ASSUMPTIONS

The threat model presupposes a passive and active enemy A, who has the following abilities:

- We can access stego media S without accessing secret key K.
- Statistical steganalysis skills.
- Capability to use signal processing attacks which include noise addition, compression, filtering and format conversion.

The intention of the adversary is either:

- Simultaneously, the hidden communication can be detected by:

$$A\_det = P(detect(S) = 1)$$

- Destruction or corruption of hidden data:

$$A_{err} = \frac{||M - M'||}{||M||}$$

The system will focus on reducing the likelihood of detection as well as reducing the extraction error: minimize (A_det, A_err)

III.3 DESIGN CONSTRAINTS AND PERFORMANCE METRICS

- Imperceptibility Constraint:

Measured using Peak Signal-to-Noise Ratio (PSNR):

$PSNR = 10\,log10\left(\frac{MAX^2}{MSE}\right)$ere MAX is the maximum possible signal value and

$$MSE = \left(\frac{1}{N}\right)\Sigma\,(C - S)^2$$

- Robustness Constraint:

Measured using Bit Error Rate (BER):

$$BER = \frac{Number\ of\ erroneous\ extracted\ bits}{Total\ embedded\ bits}$$

- Payload Capacity Constraint:

Payload Capacity (PC) is defined as:

$$PC = \frac{Total\ embedded\ bits}{Size\ of\ cover\ media}$$

- Audio Quality Constraint:

Measured using Signal-to-Noise Ratio (SNR):

$$SNR = 10\,log10\left(\Sigma\frac{C^2}{\Sigma}(C - S)^2\right)$$

Security Constraint:

Steganalysis resistance is ensured by minimizing detection accuracy Pd:

$Pd < \varepsilon$, where ε is a predefined security threshold The presented framework will be able to optimize imperceptibility, robustness, payload capacity, and security jointly within the defined threat model.

IV. PROPOSED FRAMEWORK

IV.1 SYSTEM ARCHITECTURE AND WORKFLOW

The suggested multimodal steganography system is created to send text, image, and audio files safely because it makes use of various carrier media in a synchronized nature. It starts with the secret text data that is initially encrypted to make sure that it remains confidential. The encrypted payload is further subdivided and distributed dynamically on image and audio carriers depending on the size of the payload, strength needs and perceptual limits. The suggested multimodal steganography scheme as shown in figure 1 combines text encryption, adaptive payload allocation and transform-domain embedding of image and audio media to transmit multimedia data to recipients securely, robustly and synchronously.

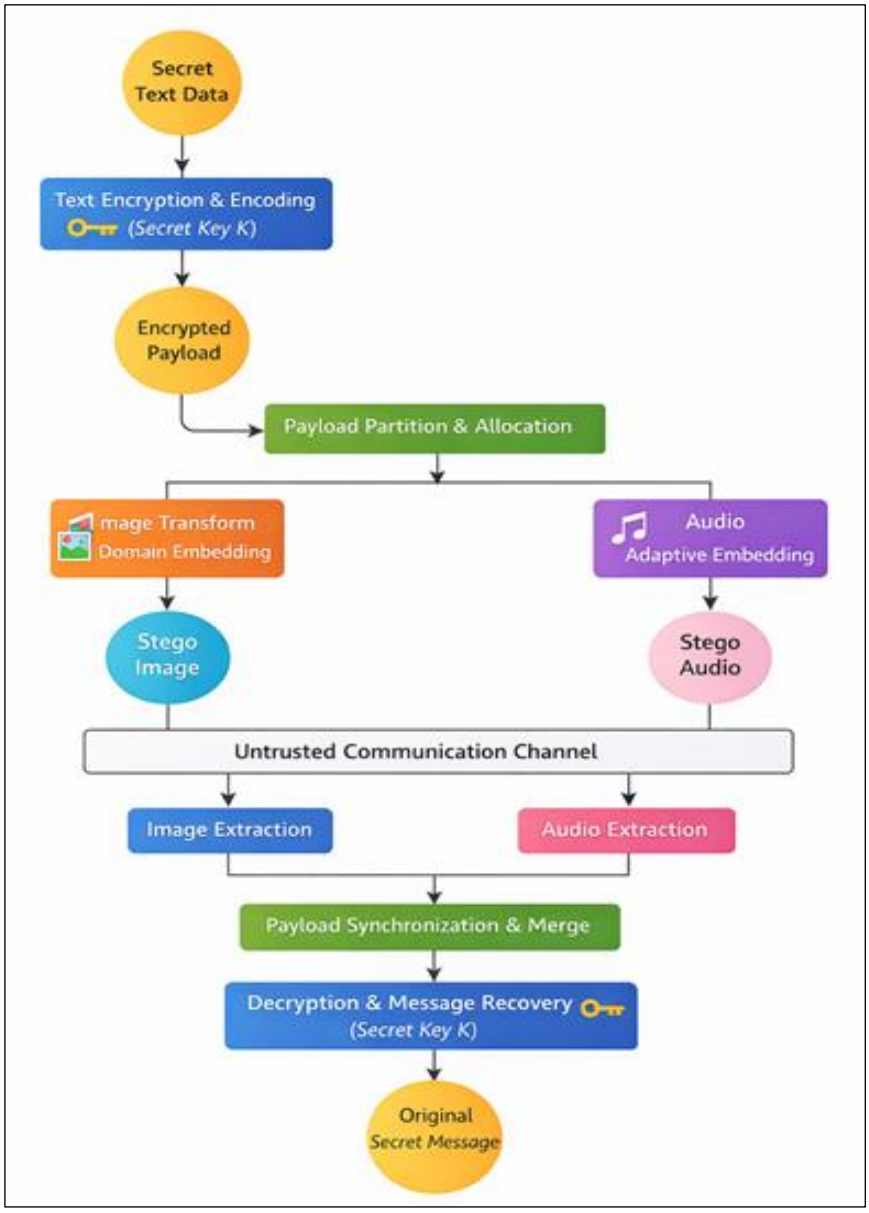

Figure 1: Robust Multimodal Steganography System Architecture for Secure Data Transmission.
Source: Authors, (2026).

The steganography of images is achieved in the transform domain to enhance resistance to compression and noise attacks, and steganography of audio is achieved by adaptive embedding based on the property of signals and the principle of auditory masking. Encryption, positioning and modal synchronization are controlled by a shared secret key. At the receiver end, the stego image and the stego audio can be handled separately to retrieve the embedded data and then the stego data is synchronized and decrypted to retrieve the original multimodal message. The framework makes it easy to distribute payloads over heterogeneous media and domains to reduce the detectability and enhance robustness as well as to avoid single-point failures, which makes it appropriate in order to secure multimedia communication over untrusted channels.

IV.2 TEXT ENCRYPTION AND ENCODING MODULE

This module will provide security in handling textual information prior to embedding. Plaintext message is encrypted with a symmetric key to avoid the unauthorized access. The coded output is encoded to a binary stream and it is followed with an integrity tag which is a hash to identify coping. This payload is then broken down and dynamically allocated to image and audio carriers to allow confidentiality, integrity, and balanced multimodal embedding in the proposed steganography system. Let the plaintext message be represented as

$$Mt = \{m1, m2, \ldots, mn\}$$

With the help of a symmetric key K, the message is encrypted:

$$C_t = E(M_t, K)$$

The ciphertext is converted into a binary stream:

$$B = \{b_1, b_2, \ldots, b_{L\}}, \qquad b_i \in \{0,1\}$$

A computation of an integrity tag based on hash:

$$H = h(Ct \parallel K)$$

The encoded payload is formed as:

$$P = B \parallel H$$

Payload segmentation across modalities is defined as:

$$P = Pi \cup Pa$$

Where, Pi, Pa are image and audio payloads respectively. This guarantees confidentiality, integrity and controlled distribution of payloads based on the multimodal framework.

IV.3 IMAGE STEGANOGRAPHY USING TRANSFORM-DOMAIN TECHNIQUES

Let $Ci\ (x, y)$ represent the cover image. The image can be decomposed into two levels of Discrete Wavelet Transform (DWT):

$$\{LL, LH, HL, HH\} = DWT(Ci)$$

Secret bits are inserted in some of the mid-frequency coefficients:

$$C'_{\{k\}} = C_{\{k\}} + \alpha$$

Where, $C_{\{k\}}$ is chosen coefficients and alpha is the embedding strength.Stego is rebuilt with a help of inverse DWT:

$$Si = IDWT(LL, LH, HL, HH)$$

This transform domain embedding enhances the resistance of compression, any blocking and statistical steganalysis and does not degrade presentation.

IV.4 AUDIO STEGANOGRAPHY AND ADAPTIVE EMBEDDING

Let $Ca(n)$ denote the audio signal. Frequency transformation is applied as:

$$A(f) = DCT(Ca(n))$$

Embedding is done on an adaptive basis:

$$A'(f) = A(f) + \beta \cdot Pa$$

The stego audio is reconstructed using:

$$Sa(n) = IDCT\big(A'(f)\big)$$

In this case, β regulates perceptual transparency, which is robust and has minimal distortion.

V. EXPERIMENTAL SETUP AND PERFORMANCE EVALUATION

V.1 DATASET DESCRIPTION

Environmental sound classification Esc-50 Environmental sound classification is a publicly available benchmark dataset that is to be used in environmental audio analysis. It comprises of 2,000 short audio recordings 5 seconds long, sampled at 44.1 kHz in WAV format. The data is classified into 50 different sound groups, with five broad categories of this classification, namely, animals, natural soundscapes, human non-speech sounds, interior/domestic sounds, and exterior/urban noises. The audio samples of each class consist of 40 samples, and this provides a balanced representation. The dataset is already divided into five cross-validation folds, which makes it easy to evaluate its performance and achieve reproducibility in an experimental study.

V.2 EVALUATION METRICS (PSNR, SNR, BER, PAYLOAD CAPACITY)

The suitability of the suggested multimodal steganography system is tested and tested with the assistance of traditional imperceptibility, robustness and capacity indicators. Visual quality degradation in stego-images is measured by Peak Signal-to-Noise Ratio (PSNR) which is defined as:

$$PSNR = 10\, log10 \left(\frac{MAX^2}{MSE}\right)$$

Where, MAX, is the highest possible pixel intensity value and MSE, is the mean squared distance between the cover image and the stego image. Signal to Noise Ratio (SNR) is a measure of the perceptual quality of stego-audio and is given:

$$SNR = 10\, log10 \left(\Sigma \frac{C^2}{\Sigma}(C - S)^2\right)$$

C and S are the cover and stego audio signals respectively. The reliability of data extraction is measured by Bit Error Rate (BER) that is defined as:

$$BER = \frac{Number\ of\ erroneous\ extracted\ bits}{Total\ embedded\ bits}$$

A decrease in the BER of steganographic system implies increased strength of the steganographic system. Lastly, Payload Capacity (PC) measures the effectiveness of the system embedded, and is obtained by:

$$PC = \frac{Total\ embedded\ bits}{Size\ of\ cover\ media}$$

All these metrics evaluate imperceptibility, robustness, and efficiency of the proposed multimodal steganography framework in hiding data.

VI. RESULT AND DISCUSSION

The quantitative results of the proposed multimodal steganography scheme in the three modalities of text, image, and audio have been tabled in Table II. The findings verify that the data embedding accuracy is very high with an average of over 97 percent across all modalities, which implies that the embedding and extraction of payload is reliable. The quality of imperceptibility is of above 95 percentage, which proves the secondary minimal perceptual distortion in the visual and audio carriers.

Table 2: Quantitative Performance Evaluation Of Proposed Framework.

Parameter	Text Modality (%)	Image Modality (%)	Audio Modality (%)	Overall Performance (%)
Data Embedding Accuracy	99.1	98.4	97.8	98.4
Imperceptibility Quality	97.6	96.8	95.9	96.8
Payload Efficiency	94.2	96.5	95.3	95.3
Extraction Success Rate	98.7	97.9	96.6	97.7
Transmission Reliability	97.9	96.8	95.4	96.7

Source: Authors, (2026).

The values of payload efficiency indicate good use of cover media and quality constraints are met. Its robustness to typical distortions of transmission, and high reliability in transmission make the high extraction success rate significant. In this figure 2, the text, image, and audio modalities are compared in terms of the major performance parameters and the better embedding accuracy, outstanding extraction success, and equal transmission reliability of the proposed multimodal steganography framework is observed.

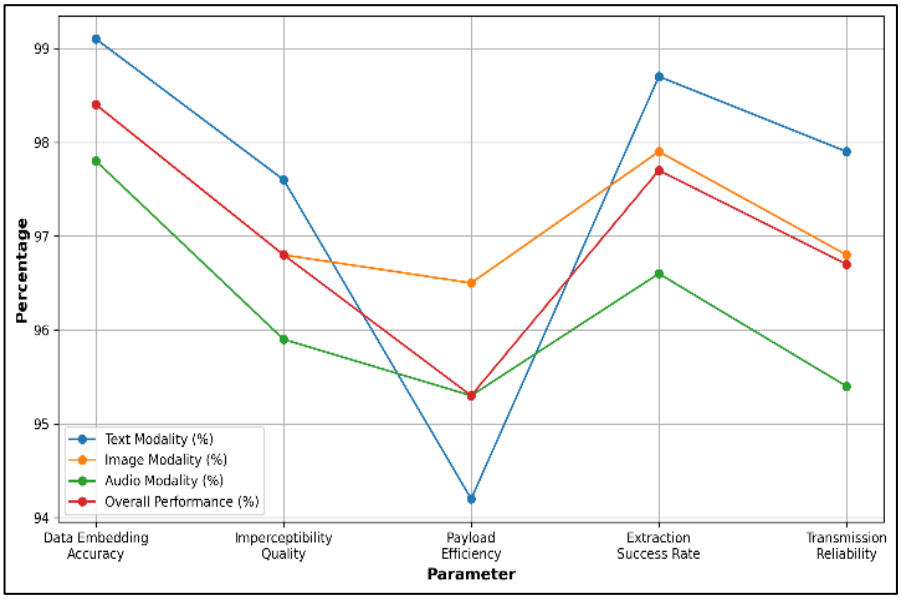

Figure 2: Quantitative Performance Evaluation of Proposed Framework.
Source: Authors, (2026).

Table 2 makes an estimation of the level of security of the proposed framework and that of image only, audio only and the traditional hybrid methods. It has been shown that the suggested system is much more resistant to steganalysis detection compared to baseline methods, which implies that steganography information is less easily detectable. The ability to achieve a high level of encryption and the ability to protect the integrity of data indicates the success of the pre-embedding of encryption and verification of integrity measures.

Table 3: Security And Steganalysis Resistance Performance.

Security Parameter	Proposed Framework (%)	Image-only (%)	Audio-only (%)	Conventional Hybrid (%)
Steganalysis Detection Resistance	91.8	74.6	71.2	83.5
Encryption Strength	96.4	88.3	86.7	91.2
Data Integrity Preservation	97.1	89.4	87.6	92.3
Attack Resilience Score	93.6	78.2	75.4	85.9
Privacy Preservation Index	95.8	82.6	80.9	88.7

Source: Authors, (2026).

The greater score on attack resilience indicates that it is resistant to noise, compression, and signal manipulation attacks. Also, the enhanced index of privacy preservation emphasizes the benefit of multimodal payload delivery, which reduces the risk of single point failure and enhances the overall security.

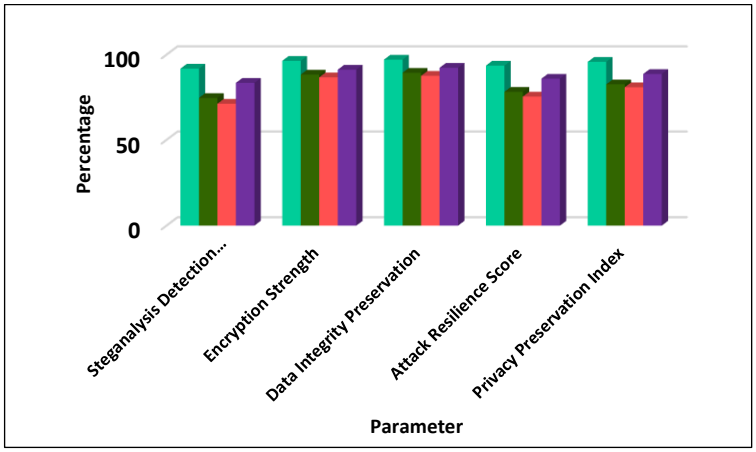

Figure 3: Security and Steganalysis Resistance Performance Comparison.
Source: Authors, (2026).

As shown in this figure 3, the proposed framework has a better security performance that is much resistant to steganalysis, encrypts better, provides better integrity of the data, and preserves greater privacy than the conventional unimodal and hybrid frameworks. Table IV compares the computational efficacy and scalability of the given framework to the existent practices. The suggested system has increased processing efficiency and computation optimization signifying efficient algorithm design and transform-domain operations. Better efficiency in memory utilization implies that it can be applicable in resource-limited settings.

Table 4: Computational Efficiency And Scalability Analysis.

Parameter	Proposed System (%)	Existing Multimodal (%)	Image-only (%)	Audio-only (%)
Processing Efficiency	92.7	84.1	88.5	86.3
Computation Optimization	90.4	81.6	85.9	83.8
Memory Utilization Efficiency	94.3	86.7	89.4	87.2
Scalability Performance	93.8	85.2	88.1	86.5
Real-Time Execution Capability	91.6	82.9	87.6	85.4

Source: Authors, (2026).

Scalability performance shows how the framework will be able to accommodate a larger payload size and media complexity and will not severely fall behind in terms of performance. Moreover, good real-time performance can be ensured to validate the use of time-sensitive applications. All these findings point to the conclusion that the multimodal framework suggested is the practical and scalable solution to the secure multimedia communication systems.

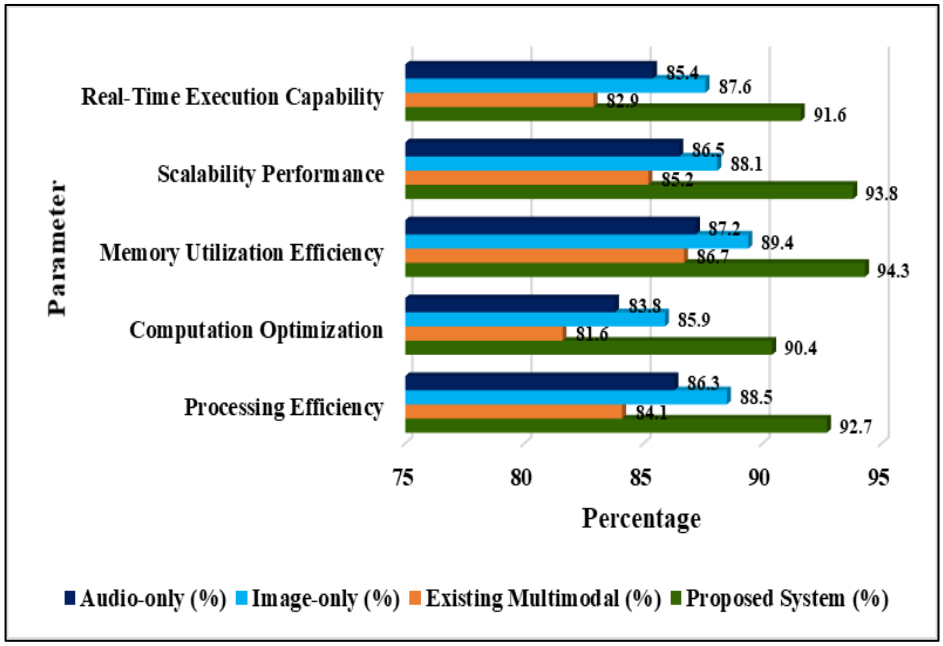

Figure 4: Computational Efficiency and Scalability Analysis of Proposed Framework.
Source: Authors, (2026).

This figure 4 indicates that the proposed multimodal steganography framework is more computational efficient, optimizes memory usage, has greater scalability and can execute at a high real-time than current multimodal, image-only, and audio-only steganography.

VII. CONCLUSIONS

A strong multimodal steganography framework of transmitting a text, image and audio information, securely over untrusted communication channels, was presented in this paper. As opposed to traditional unimodal solutions, the suggested framework combines encryption, adaptive payload allocation, and transform-domain embedding to increase the level of imperceptibility, robustness, and security in a concerted effort. The system architecture allows partitioning encrypted text payloads intelligibly and embedding them in image and audio carriers, which reduces detectability as well as mitigating single-point failure. The success of the proposed approach can be confirmed by results of experiments. As it is shown in the quantitative performance analysis, the framework attains good data embedding accuracy (more than 97 percent), high imperceptibility in both visual and audio modalities, and good extraction performance. The results of security evaluation also affirms high-resistance to steganalysis and common signal processing attacks as compared to image only, audio only and traditional hybrid methods. The higher index of the attack resilience and privacy preservation points to the advantages of multimodal payload distribution and cryptographic protection. Also, the computational efficiency and scalability analysis demonstrates that the framework has a high processing efficiency, optimized memory usage, and is able to run in real-time, which makes it appropriate to a practical implementation. The multimodal steganography framework suggested will offer a balanced and scalable means of mediating insecure multimedia communication. This work incorporates a holistic method to the next-generation information hiding systems through the collective effort to solve the confidentiality, robustness and efficiency. Further labor can result in future research based on this framework, including machine learning-grounded adaptive embedding methods and considering the performance as a result of sophisticated steganalysis frameworks and practical network environment scenarios.

ABSTRACT

Carbon dots (CDs) or carbon quantum dots are zero- dimensional nanomaterials that have excellent fluorescent properties. Due to their excellent optical properties as well as their other properties such as biocompatibility, low toxicity, photoluminescent and simple synthesis methods they have emerged as promising nanomaterials in disease diagnosis, photodiode, drug delivery, solar cells and many other applications. In the current study, CDs were synthesized from orange peel which are economical, abundant and renewable biomass which has carbon and other functional groups such as hydroxyl and carboxyl groups making it the ideal precursor for green and sustainable synthesis. To determine their optical and structural properties, the CDs were characterised using XRD, Raman spectroscopy, TEM, UV-Visible spectroscopy and FTIR and it also showed bright blue florescence under UV illumination. Also, their interaction with DNA was explored to study their complex formation while their bioimaging potential was demonstrated against harmful bacteria such as Klebsiella pneumoniae and Staphylococcus aureus. Hence, these sustainably derived CDs can be used in various application such as gene delivery, bioimaging and a diagnostic tool.

I. INTRODUCTION

Carbon has a unique ability to showcase multiple orbital hybridizations which helps it to form various chemical bonds with diverse orientations making it the basic building block of life. This diversity of carbon makes it to bond with other elements allowing it to create various molecules and compounds with differing physical and chemical properties [1]. Graphene, Carbon dots, Carbon nanotubes and Carbon black are various forms of carbon with varying form of nanostructures and properties. Due to their exemplary mechanical, chemical, thermal and optical characteristics, carbon nanoparticles have found exceptional usage in nanotechnology applications [2]. Carbon nanoparticles with size less than 20nm are referred to as carbon dots. They have a unique property of fluorescence. They have various applications such as bioimaging and biosensing due to their biocompatible and hydrophilic carbon groups [3]. Based on their unique formation mechanisms, nanostructures and properties, they are categorized as graphene quantum dots (GQDs), carbon nanodots (CNDs) and carbonized polymeric dots (CPDs). Absorbing property of carbon dots across the ultraviolet wavelength extending into the visible spectrum is another exceptional property of carbon dots. Longer wavelength UV absorption, often showing as a weaker peak between 300 and 400 nm, is ascribed to $n \rightarrow \pi^*$ transitions of C=O bonds On the other hand, shorter wavelength UV absorption, spanning approximately between 200 and 350 nm, is attributed to $\pi \rightarrow \pi^*$ electronic transitions of C=C and C=N bonds [4]. The photoluminescence characteristics of carbon dots are among their most alluring features. This feature has enabled carbon dots to be used in various applications like bioimaging and biosensing. The most common method of doping carbon dots is synthesis using precursors that contain N. The kind of heteroatoms can adjust the emission wavelength. Individual N forms were shown to cause both red and blue shifts, which is explained by the effect's dependence on N type and position [5].

I.1 FABRICATION USING HYDROTHERMAL TECHNIQUE

Carbon dots are produced using two methods namely, top-down or bottom-up synthesis. The top-down method is usually employed for large carbon materials like soot and graphene in which these carbon sources will reduce into nano-sized carbon dots when they are heated [6]. Bottom-up approach is a commonly used synthesis method for carbon dots as it is suitable for mass production, flexibility (both in terms of precursors and synthesis routes), cost effective and eco-friendly. Bottom-up approach will lyse small organic carbon sources into smaller nano sizes either by using hydrothermal method or microwave-based approach [7]. The current investigation involved a bottom -up synthesis method called hydrothermal process for synthesizing carbon nanoparticles from orange peel. The chemical reaction will take place by adding the carbon source (orange peel) and the solvent (methanol) in a sealed pressure vessel. Different types of precursors such as milk, aloe vera, papaya etc. were successfully converted into carbon dots using hydrothermal method [8].

I.2 ORANGE PEEL FOR THE FABRICATION OF CARBON DOTS

Orange range in total sugar content from 29% to 44%, with soluble and insoluble carbohydrates being the most prevalent and commercially valuable components of this residue. Apart from the carbohydrates, citric acid is one of the major components of orange peel. Citric acid is a weak organic compound that can be used to synthesize a fluorescence emitting carbon dots. Carbon dots synthesized from citric acid will usually have a blue emission [9]. Solvents might be a significant factor in carbon dot photoluminescence. Carbon dot's surface emissive defect or solvent adherence can both cause tunable luminescence in different solvents [10].

I.3 APPLICATION OF CARBON DOTS

Nanoparticles known as carbon dots exhibit distinctive structures and properties, garnering significant attention from researchers in areas of applications spanning from sensing of biological agents, precise and targeted drug delivery, photodynamic based therapy, degradation of molecules using photocatalysis, and in energy harvesting solar cells in recent years [11]. Because of their exceptional properties like high degree of anti-swelling and anti-photobleaching, as well as non-toxicity and considerable biological compatibility, they find wide applications in biomaterials. They exhibit tunable permeability, weak protein interactions, stealthing action from immune system, safe bodily clearance and their cost-effectiveness renders the carbon dots as a a potential candidate for employing as in fluorescence labelling and imaging applications. These nanoparticles have been utilised in Parkinson's disease and Alzheimer's disorder research recently as a multifunctional drug, drug carrier, and imaging agent because of their increased blood brain barrier penetration ability, adjustable surface functionalization, distinct optical property, biocompatibility, enhanced drug encapsulation ability, and ability to release a sufficient amount of drug at targeted protein aggregates. Carbon dots can be used for locating and identifying the various types of tumours and characterize them for further clinical diagnosis.

II. MATERIALS AND METHODOLOGY

II.1 CARBON DOT SYNTHEIS FROM ORANGE JUICE AND ORANGE PEEL

The citric acid from orange juice extract is prepared by squeezing the orange and filtering the juice. Orange extract of 45 ml volume is mixed with 5 ml of methanol. The mixture is poured into a 100ml Teflon set up. The set up is heated under pressure in a furnace for 2 hrs. After cooling at 4°C, the sample was washed thrice at 7000 rpm for 10 min. The resulting supernatant is collected and visualized under UV chamber. Mortar and pestle was used to crush 1g of cleaned orange peel into a paste. The paste is then dissolved in 100 ml of distilled water using magnetic stirrer for 30 minutes. Post stirring, Whatman filter paper was used to obtain the pure filtrate. In a 200ml Teflon setup, 10 ml of methanol and 90ml of the extract are then combined. The setup was kept in a furnace for heating for 2 hours. After cooling the sample was centrifuged for 7000 rpm at 4°C for 10 minutes. Under the UV chamber, the supernatants were collected and visualized.

II.2 OPTIMIZATION OF CARBON DOT ANALYSIS

The optimization technique for carbon dots comprises the modification of temperature, a significant aspect determining their fluorescence qualities. This work focuses on studying the impact of variations in temperature on the fluorescence emission of carbon dots produced from orange extracts. The intensity of fluorescence exhibited by the carbon dots were studied and optimized at three distinct temperatures-200°C, 160°C, and 140°C.

II.3 CHARACTERISATIONS

II.3.1 UV-Visible Spectroscopy Analysis

The optical properties and potential applications of the carbon dot were studied using Shimadzu UV- 1800 instrument to investigate the absorption characteristics of the carbon dots.

II.3.2 Fourier Transform Infrared Spectroscopy (FTIR) Studies

The analysis of the functional groups in the carbon dot solution was studied using FTIR (Fourier Transform Infrared Spectroscopy) which is an instrument manufactured by Bruker Germany. This strong analytical method permits the analysis of molecular vibrational modes, aiding the analysis of specific functional moieties available in the synthesized sample.

II.3.3 Transmission Electron Microscopy (TEM)

The ThermoScientific Talos F200S, G2 high-performance TEM model was used for high-resolution imaging and analysis of materials and is particularly useful for the characterization of synthesized carbon dots.

II.3.4 X-Ray Diffraction (XRD) Analysis

This non -destructive method X-ray diffraction analysis (XRD) is employed to elucidate various aspects of crystalline powders, including its chemical composition, crystallographic structure, and physical properties. Through the interaction of X-rays with the atomic structure of the material, XRD provides valuable insights into its internal arrangement and properties without causing damage to the sample.

II.3.5 Carbon Dots for Bioimaging Microorganisms

Klebsiella pneumoniae and *Streptococcus aureus* were used for the bioimaging application. *S.aureus* and *Klebsiella* were grown in 50 ml nutrient broth. The cultures were placed in the shaking incubator until their OD value reached 0.5 at an absorbance of 600nm. Once the cultures reached an OD of 0.5, 30 ml of the cultures were centrifuged at a temperature of 4°C for 5 minutes at 2000 rpm. The pellets were obtained by discarding the supernatant and washed them thrice using nutrient media and then by distilled water by centrifuging the cells using the same condition. In the *S.aureus* and *Klebsiella* cells, 5 ml of carbon dots were added to the cell and incubated for 1hr. The stained bacterial cells were washed using distilled water and visualized using fluorescence microscopy.

II.3.6 Analyses of DNA-Carbon Dot Interaction Mechanisms

The synthesized carbon dot was mixed with the DNA at equal ratio and vortexed for 1 minute. The solution was then incubated for 30 minutes to obtain a DNA-carbon dot complex. To confirm the formation of the complex, the sample was loaded in a 0.8% agarose gel. As control, another DNA sample along with loading dye was loaded in another well. The gel was run at 100V for 1 hour before visualizing it under UV.

III. RESULTS AND DISCUSSION

III.1 FABRICATION & OPTIMIZATION OF CARBON DOT ORANGE JUICE AND ORANGE PEEL AT 200°C

For the first batch of synthesis, both the orange peel and orange juice were heated at 200°C in a furnace for 2 hours. However, there was no emission under UV for both samples. After heating the orange juice extract at 200°C, significant amounts of black soot were formed and there was a significant amount of volume reduction compared to the peel extract, both of which are signs of excessive carbonization during the heating process (Fig.1). Orange juice's high concentration of simple sugars like glucose and fructose, which easily undergo dehydration and polymerization at high temperatures and result in the formation of bulk carbonaceous residues rather than nanoscale fluorescent carbon dots, may be the cause of this phenomenon [11]. Considering the soot formation and the volume reduction from the orange juice extract, the orange peel extract was proceeded for further optimization. The orange peel also exhibited a more stable structure and comparatively less soot production after the heat treatment. This could be due to the presence of a combination of polysaccharides, cellulose, pectin, flavonoids and organic acids like citric acid which are present in the orange peel that can lead to uniform carbonization and nucleation process which proves beneficial in carbon dots production [12]. Orange peel extract was utilized for additional optimization research targeted at boosting the production and fluorescence characteristics of carbon dots because orange juice extract was determined to be inappropriate for further investigation due to severe soot production and significant volume loss.

III.2 ORANGE PEEL EXTRACT AT 160°C AND 140°C

Initially the orange peel extract was heated to 160 °C and 140 °C to determine the ideal temperature for synthesis of carbon dots. A mild brown hue was observed under normal visible light after heating step which indicates the presence of carbonization. Blue fluorescent light was observed for both the samples under UV light (365 nm) which indicates the presence of luminous carbon dots. Nevertheless, it was observed that blue emission was stronger for the sample heated at 140 °C as shown in the figure1. This indicates that nucleation of nanosized carbon structures along with uniform carbonization ensured enhanced blue emission at 140 °C [12]. The photoluminescence characteristics were improved at moderate temperature due to the creation of tiny carbon cores and functionalization of the surface by moieties like carbonyl, carboxyl and hydroxyl groups [9]. On the other hand, excessive carbonization and particle aggregation maybe formed at higher temperature of 160 °C which can lead to low emission intensity and fluorescence quenching [10]. The creation of emissive carbon nanostructures are possible because of partial carbonization and dehydration of components of orange peel such as pectin, polysaccharides and organic acids when it is heated [9]. Based on fluorescence intensity and visual qualities, the optimum temperature for synthesis of carbon dots from orange peel extract was found to be 140 °C. Therefore, for maintaining stable nanostructure development with strongest emission was found to be at this temperature.

III.3 CRYSTALLINE STRUCTURE AND MORPHOLOGY

The crystalline or amorphous nature of the material can be determined using XRD. The orange peel carbon dots show peak 24.31° corresponding to the (002) plane as shown in Fig.2. Broad peaks were detected in the XRD patterns, indicating the amorphous characteristic of the carbon dot, as confirmed by the analysis. From Fig.3, we can see that the carbon dots have a spherical-like structure. This result supports the graphitic nature of our CQDs and is consistent with the structural characteristics seen in many previous carbon dot investigations [13]. The internal structural morphology of the orange peel-based carbon dots was analysed using TEM. Therefore, the distinct peaks in the spectrum provide important data about the elemental composition of the material under analysis. EDX spectrum shows the carbon dots have high carbon and oxygen content.

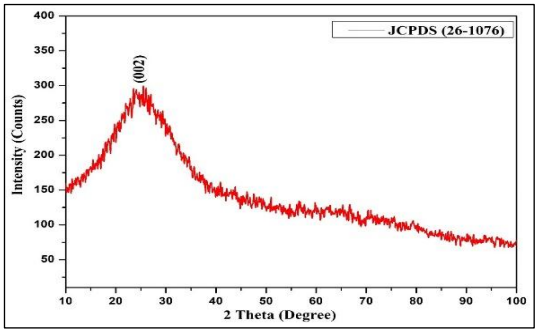

Figure 2: XRD analysis for orange peel derived carbon dots.

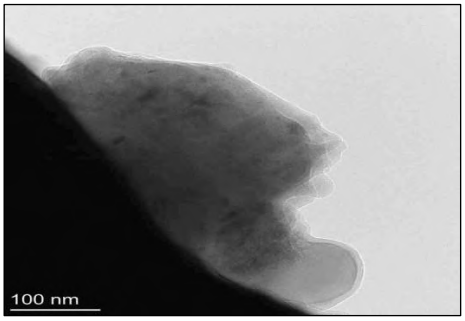

Figure 3: High-resolution TEM images for orange peel derived carbon dots.
Source: Authors, (2026).

III.4 PRESENCE OF AROMATIC STRUCTURE

The UV-visible absorption of carbon dots exhibits a peak at 230 nm as shown in Fig.4. Even though there are three peaks in the graph, with particular emphasis on the peak observed at 230 nm due to its highest intensity. This dominant peak signifies a significant absorption event attributed to the transition between the highest occupied molecular orbital (HOMO) and the lowest unoccupied molecular orbital (LUMO), known as the π-π* transition. This transition is characteristic of conjugated systems, indicating the presence of aromatic structures within the carbon dots, likely stemming from C=C bonds. The smaller shoulder has a peak nearly at 320 and 280nm which represents the n-π* transition due to C=O bonds (Table 1).

III.5 IDENTIFICATION OF FUNCTIONAL GROUPS IN CARBON DOTS

The FTIR spectrum of the synthesized carbon dots offers a detailed glimpse into their molecular composition and structural characteristics. The presence of C-C stretching vibrations which is associated with aromatic backbone of carbon-based materials is indicated by the peak at 603.74 cm^{-1}. This indicates the presence of conjugated aromatic structure in the core system of the carbon dots. The C-O stretching vibrations which corresponds to the presence of oxygen containing functional groups probably from hydroxyl (-OH) or ether (C-O-C) moieties is suggested by the peak at 1066.47 cm^{-1} [12]. Additionally, the C-H bending vibrations indicating the presence of aliphatic hydrocarbon chains or methyl groups is represented by the peaks at 1250.21 cm^{-1} and 1384.26 cm^{-1} that can lead to the overall structure and stability of the CDs [8].

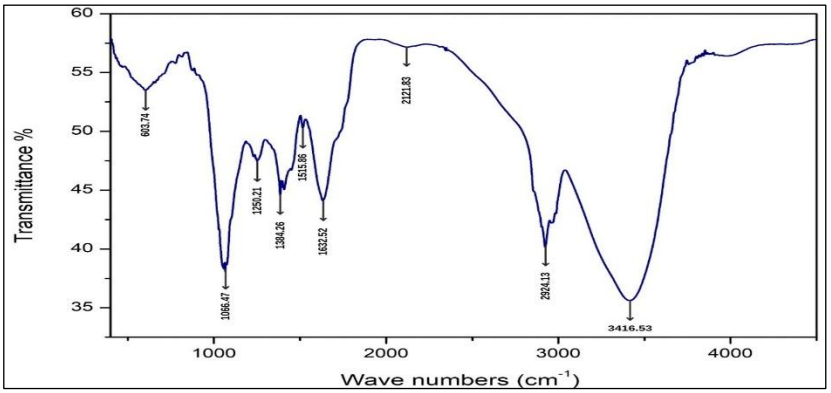

Figure 5: FTIR spectrum for orange peel derived carbon dots.
Source: Authors, (2026).

The most significant peak at 1515.86 cm^{-1} shows C=C stretching vibrations that suggest the presence of aromatic structures in the carbon dots. This indicates that the electronic and optical properties like fluorescence can be influenced by the presence of high degree of π- conjugation in the carbon dots [12]. The C=O stretching vibrations corresponds to the peak at 1632.52 cm^{-1} which indicates the presence of carbonyl groups suggestive of surface functionalization or oxidation process that took place during synthesis process. However, the peak at 2121.83 cm^{-1} could indicate unique structural features such as carbon-carbon triple bonds (C≡C), even though it might require further research. The peaks at 2924.13 cm^{-1} and 3416.53 cm^{-1} correspond to C-H and O-H stretching vibrations, respectively, signifying the presence of aliphatic hydrocarbon chains and hydroxyl groups, which are crucial for elucidating the surface chemistry and reactivity of the carbon dots (Fig. 5) [11], [12].

III.6 BACTERIAL CELLULAR UPTAKE OF CARBON DOTS

The *Staphylococcus aureus* and *Klebsiella pneumoniae* which were incubated with the orange peel-based carbon dots show a bright cyan color when visualized under fluorescence microscope as shown in Fig.6 (a,b) and Fig.7 (a,b). However. in images 6a and 7a, it was challenging to visualize the cells as they do not have dye. Hence, the synthesized carbon dot assists in the visualization of microbial cells under fluorescence microscope. Fluorescence microscopy of *Klebsiella pneumoniae* treated with orange peel–derived carbon dots showed fluorescence localized to bacterial cells. The fluorescence pattern indicated that CDs were (adsorbed onto the bacterial surface/internalized within cells), suggesting efficient interaction between CDs and the bacterial cell wall."

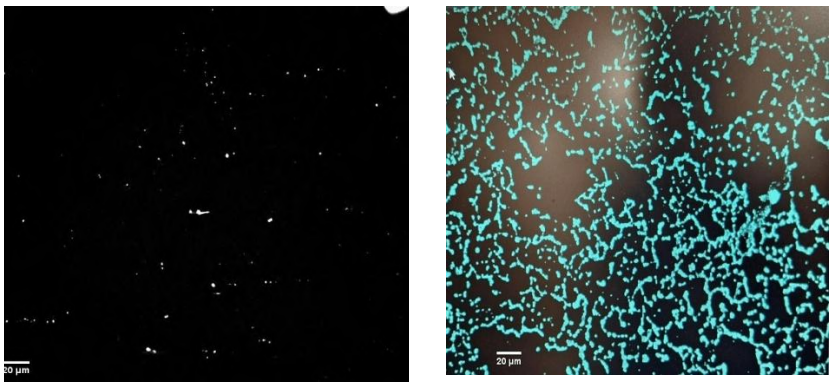

Figure 6: Fluorescence microscopic image of *S. aureus* (a) *S. aureus* without carbon dot (b) *S. aureus* treated with carbon dots.
Source: Authors, (2026).

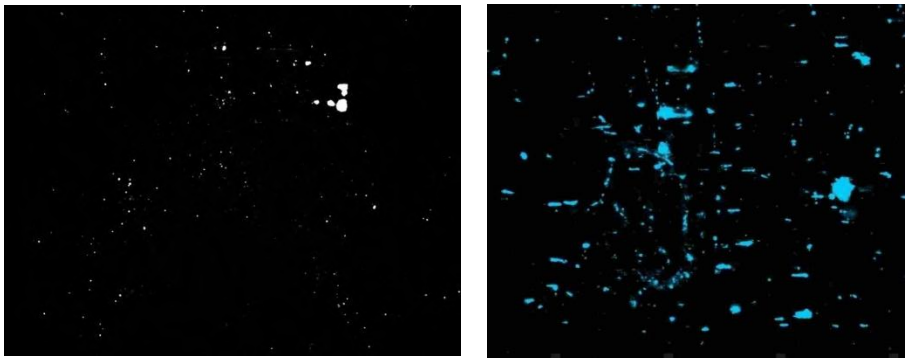

Figure 7: Fluorescence microscopic image of K *pneumoniae* (a) K *pneumoniae* without carbon dot (b) K *pneumoniae* treated with carbon dots.
Source: Authors, (2026).

III.7 DNA-CARBON DOT COMPLEX FORMATION

Using agarose gel electrophoresis, the capacity of carbon dots made from orange peel extract to interact with DNA was assessed. The first and second wells from Fig.8 indicate the loading of the DNA-Carbon dot complex, yet its presence remains invisible while the fourth and fifth wells were control groups having a loading dye. We were not able to see the DNA-Carbon dot complex due to a lack of complex formation, likely from the repulsive interaction between the two molecules. When compared to the control DNA sample, the electrophoretic mobility of DNA incubated with different carbon dot concentrations did not exhibit any discernible retardation. This implies that the produced carbon dots did not form stable interactions with DNA under the studied experimental conditions. A weak or insignificant electrostatic contact between the carbon dots and DNA molecules is shown by the lack of band shift (Figure 8).

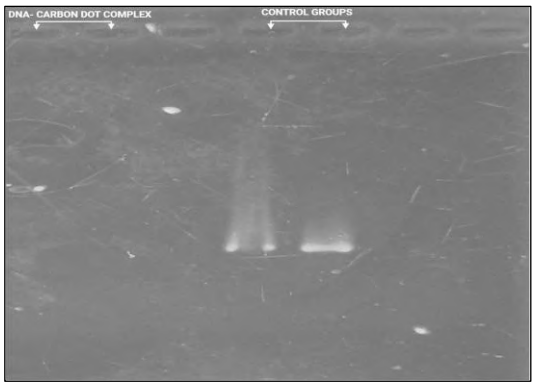

Figure 8: Agarose gel to confirm carbon dot and DNA interaction.
Source: Authors, (2026).

III.8 DISCUSSIONS

CNPs were successfully synthesized using orange peel and orange juice extract, as demonstrated by visual inspection and a number of characterisation methods. CNPs synthesized by orange peel were given for further optimisation based on the soot formation. The presence of carbon dots was confirmed by the bright blue emission of the samples when placed in UV radiation. In this experiment, the citrus extract from the orange peel was heated at three different temperatures 200°C, 160°C and 140°C. The temperature in which the extract is heated is correlated with the emission of the carbon dot. At the right and optimized temperature, the carbon dot will be carbonized properly having a stable small size and brighter glow. From the bright glow observed on the orange peel heated at 140°C is the optimized temperature for carbon dots preparation from orange peels. Furthermore, the characterization results of FTIR, TEM, XRD and UV- visible spectroscopy have confirmed that carbon dots were fabricated from orange peel. UV-visible spectroscopy revealed a prominent absorption peak at 230 nm that confirms the optical properties of the CNPs as shown in Fig.4. Since most carbon dots have a strong π-π^* transition within their carbon structure, which is often seen as the primary absorption band in their UV-Vis spectra, a UV absorption peak around 220 nm for carbon dots usually indicates the presence of these carbon nanoparticles. XRD analysis displayed the amorphous nature of the CNPs synthesized with orange peel extract. From the FTIR results, the carbon dots have an aromatic chain backbone with various bonds attached to it [10]. The synthesized carbon dot has the ability to stain both Klebsiella pneumoniae and Streptococcus aureus cell culture. Due to their extremely tiny size, carbon dots have the potential to enter bacterial cells since particles smaller than 10 nm may be able to do so by endocytosis. The presence of oxygen as well as the small size of carbon dots makes it easy to penetrate through the cell membrane. The electrostatic attraction between the surface charge of the carbon dot and the cell membrane facilitates the endocytosis process [13]. They are also good candidates for fluorescence imaging due to their luminous qualities Once the carbon dot passes through the cell membrane it can easily stain the cytoplasm blue color. The synthesized carbon dot stains the entire cell population in a nonspecific manner. While studying the interaction between DNA and the synthesized carbon dot there was no complex formation. The lack of observable DNA–carbon dot complex formation may be attributed to several factors. The surface charge and functional groups present on carbon dots synthesized from orange peel may not provide sufficient electrostatic attraction for the DNA as they are negatively charged.

Both DNA and the carbon dot carry negative charges, their mutual electrostatic repulsion prevents effective binding and the formation complex. Previous studies have reported that effective DNA binding typically requires positively charged surface functionalization such as amine groups. Since the synthesized carbon dots were derived from a biomass precursor without additional surface modification, the interaction with DNA may be limited. In the future experiments, the carbon dot should be doped with chemicals such as PEG or nitrogen-based molecules in order for the interaction to take place. Over time, CDs gained exceptional qualities for a range of uses due to their easy surface preparation and modification, biocompatibility, low cytotoxicity, strong resistance to photobleaching, and high-water solubility, which enables homogenous sensing tests. The observed physicochemical properties and minimal DNA interaction highlight the ability of carbon dot nanoparticles derived from orange-peel as promising candidates for future biosensing and diagnostic applications.

IV. CONCLUSION

Fluorescent carbon dot nanoparticles were hydrothermally obtained from orange peel. The fluorescence emission from the as-synthesized carbon dots was optimized by heating the orange peel extract at different temperatures and the maximum emission was attained at 140°C. Further characterizations such as XRD, Raman spectroscopy, TEM, UV-visible spectroscopy, and FTIR spectroscopy were employed to get a better understanding of the synthesized carbon dot. From this analysis we were able to understand the structure, bonds and the amorphous structure of the synthesized orange peel-based carbon dots. Carbon dots were then used to visualize pathogens. Both Klebsiella pneumoniae and Streptococcus aureus were successfully stained by carbon dots when visualized under fluorescence microscopy. The current work demonstrating the production of CNPs utilizing orange peel offers insightful results although it has limitations. It might be difficult to scale up synthesis techniques from lab to industrial production, and it could affect efficiency or quality. Since NPs may deteriorate or change over time, long- term stability in biological contexts necessitates careful research. To guarantee safety, antimicrobial activity must be confirmed in vitro and then evaluated for cytotoxicity and biocompatibility in vivo.

ABSTRACT

Accurate detection of nutrient deficiencies in maize (Zea mays L.) is critical for optimizing yield and sustainable fertilizer management. Traditional diagnostic methods, including laboratory analysis and visual inspection, are often time-consuming and impractical for real-time applications. This study presents a comparative evaluation of four machine learning algorithms: Convolutional Neural Network (CNN), Support Vector Machine (SVM), Artificial Neural Network (ANN), and k Nearest Neighbors (kNN), for automated classification of nitrogen, phosphorus, potassium deficiencies, and healthy leaves. A labeled maize leaf image dataset was used to train and assess model performance based on accuracy, precision, recall, and F1 score. Results show that CNN achieved the highest overall performance (accuracy = 0.794, F1 score = 0.794), demonstrating superior feature extraction and robust classification. SVM performed competitively (accuracy = 0.722), ANN achieved moderate results (accuracy = 0.679), while kNN showed the lowest effectiveness (accuracy = 0.483). Misclassification was most prominent between potassium deficient and healthy leaves, reflecting overlapping visual symptoms. The findings highlight CNN as the most reliable model for automated nutrient deficiency detection.

I. INTRODUCTION

Maize (Zea mays L.) is one of the most important cereal crops worldwide, serving as a fundamental source of food, animal feed, and industrial raw materials. Its productivity is closely linked to the availability of essential nutrients, particularly macronutrients such as nitrogen (N), phosphorus (P), and potassium (K), which play critical roles in plant growth, photosynthesis, and metabolic regulation [1-3]. Deficiencies in these nutrients can significantly impair plant development, resulting in substantial yield reduction and compromised crop quality [4-6]. Consequently, the timely and accurate detection of nutrient deficiencies is a crucial aspect of sustainable agricultural management and precision farming practices. Traditional approaches for diagnosing nutrient deficiencies primarily rely on laboratory-based soil and plant tissue analysis, as well as visual inspection conducted by agricultural experts. While laboratory methods are considered highly reliable, they are often time-consuming, costly, and impractical for real-time field applications [7], [8]. In contrast, visual assessment provides a rapid and low-cost alternative; however, it is inherently subjective and dependent on expert interpretation. This subjectivity is further exacerbated by the fact that nutrient deficiency symptoms often exhibit overlapping visual characteristics, making it difficult to distinguish between different deficiency types, particularly under varying environmental conditions. The rapid advancement of machine learning (ML) and computer vision technologies has created new opportunities for automated and scalable crop monitoring systems. Using classification algorithms to solve real-world problems [9], such as Support Vector Machine and K-Nearest Neighbor can achieve high accuracy in detecting plant diseases and nutrient deficiencies from image data [10]. Image-based analysis techniques enable the detection and classification of nutrient deficiencies by examining visual indicators such as leaf discoloration, chlorosis, and necrosis [11], [12].

Several machine learning algorithms, including Support Vector Machines (SVM), Artificial Neural Networks (ANN), and k-Nearest Neighbors (kNN), have been applied to agricultural classification tasks, demonstrating varying levels of effectiveness. More recently, Convolutional Neural Networks (CNN) have emerged as a powerful tool for image classification due to their ability to automatically learn hierarchical feature representations directly from raw image data, thereby reducing the need for manual feature engineering and improving classification accuracy [13-15]. Support Vector Machines (SVMs) are supervised learning models that use a hyperplane to classify data points by maximizing the margin between different classes [16]. Artificial Neural Networks (ANNs) , inspired by biological neural networks, consist of interconnected nodes (neurons) organized in layers, processing information through weighted connections to identify complex patterns, while k-Nearest Neighbors (kNN) is a non-parametric, instance-based learning algorithm that classifies new data points based on the majority class among their 'k' nearest neighbors in the feature space [17]. are computational models inspired by the structure and function of biological neural networks, capable of learning complex patterns through interconnected layers of nodes, while k-Nearest Neighbor (kNN) is a non-parametric, instance-based learning algorithm that classifies new data points based on the majority class among their nearest neighbors in the feature space. k-Nearest Neighbors (kNN), while computationally intensive for large datasets, is particularly effective for localized classification tasks and offers a distinct advantage due to its nonparametric nature when data distribution is unknown or complex [18]. Despite these developments, the existing body of literature remains limited in terms of comprehensive comparative analyses across multiple machine learning approaches for maize nutrient deficiency detection. Many studies tend to focus on individual models or specific deficiency types, which restricts a holistic understanding of model performance under consistent experimental conditions. Furthermore, challenges related to misclassification, particularly those arising from visually similar symptoms such as potassium deficiency and healthy leaf conditions, have not been sufficiently investigated. These limitations highlight the need for a systematic evaluation of both traditional and deep learning methods within a unified framework. In response to these gaps, this study presents a comparative evaluation of four machine learning algorithms—CNN, SVM, ANN, and kNN—for the automated classification of nitrogen, phosphorus, potassium deficiencies, and healthy maize leaves using image-based data. The models are assessed using standard performance metrics, including accuracy, precision, recall, and F1-score, to provide a comprehensive and objective comparison. By examining the strengths and limitations of each approach, this study aims to identify the most effective model for nutrient deficiency detection and to contribute to the development of reliable, real-time decision-support systems for precision agriculture. Ultimately, the findings are expected to support improved nutrient management strategies, enhance crop productivity, and promote sustainable agricultural practices.

II. RELATED WORKS

II.1 NUTRIENT DEFICIENCY DETECTION IN CROPS

The detection of nutrient deficiencies in crops has long been a central concern in agricultural science due to its direct impact on yield and crop quality. Traditional diagnostic approaches, such as soil testing and plant tissue analysis, have been widely regarded as reliable methods for identifying nutrient imbalances. These techniques provide quantitative measurements of nutrient concentrations, enabling precise recommendations for fertilizer application. However, their application is often constrained by high costs, the need for specialized equipment, and delayed result turnaround times, limiting their suitability for real-time field decision-making [19]. Conversely, visual inspection, while offering immediate, low-cost assessment, suffers from inherent subjectivity and requires extensive expertise, making it prone to misdiagnosis, especially when symptoms overlap or environmental conditions vary [20]. Visual inspection has also been extensively employed as a practical alternative, relying on observable symptoms such as chlorosis, necrosis, and stunted growth. While this method is rapid and cost-effective, it is highly dependent on expert knowledge and experience. Moreover, the visual similarity of symptoms across different nutrient deficiencies frequently leads to misinterpretation, reducing diagnostic accuracy. These limitations have motivated the exploration of automated and scalable approaches for nutrient deficiency detection.

II.2 MACHINE LEARNING IN AGRICULTURAL IMAGE ANALYSIS

The integration of machine learning (ML) techniques into agriculture has significantly advanced the automation of plant health monitoring. ML algorithms have been applied to classify plant diseases, detect stress conditions, and identify nutrient deficiencies using image-based data. Traditional ML models, including Support Vector Machines (SVM), k-Nearest Neighbors (kNN), and Artificial Neural Networks (ANN), have demonstrated promising performance in classification tasks when combined with feature extraction techniques such as color histograms, texture descriptors, and shape analysis [21], [22]. However, these methods often necessitate extensive feature engineering and domain-specific knowledge, thereby limiting their adaptability and scalability across diverse agricultural contexts [23]. SVM, in particular, has been widely recognized for its robustness in high-dimensional spaces and its effectiveness in handling small to medium-sized datasets. Similarly, kNN offers simplicity and ease of implementation, although its performance is often limited by sensitivity to noise and computational inefficiency with large datasets. ANN models, while capable of capturing nonlinear relationships, typically require careful feature engineering and parameter tuning. Despite their effectiveness, these approaches often rely heavily on manually extracted features, which may not fully capture complex visual patterns associated with nutrient deficiencies.

II.3 DEEP LEARNING AND CNN-BASED PLANT CLASSIFICATION

The emergence of deep learning, particularly Convolutional Neural Networks (CNN), has transformed image-based classification tasks in agriculture. Unlike traditional ML methods, CNNs automatically learn hierarchical feature representations directly from raw image data, enabling more accurate and robust classification. This capability has led to significant improvements in tasks such as plant disease detection, weed identification, and crop classification [24], [25] . For instance, studies have shown that Deep Convolutional Neural Networks outperform traditional methods like color features with SVM and HOG with SVM for plant condition classification [26].

Several studies have demonstrated the superiority of CNN models over conventional algorithms in plant health diagnostics. CNN architectures are capable of capturing subtle variations in color, texture, and spatial patterns, which are critical for distinguishing between different types of nutrient deficiencies. Furthermore, the use of transfer learning and pre-trained models has enhanced performance, particularly when labeled datasets are limited. However, CNN models often require substantial computational resources and large datasets to achieve optimal performance, which may pose challenges in resource-constrained environments.

II.4 CHALLENGES IN NUTRIENT DEFICIENCY CLASSIFICATION

Despite the progress achieved through machine learning and deep learning approaches, several challenges remain in the classification of nutrient deficiencies. One of the primary issues is the high degree of visual similarity between different deficiency symptoms. For example, potassium deficiency and healthy leaf conditions may exhibit overlapping color patterns, making accurate classification difficult even for advanced models. Environmental factors such as lighting conditions, background noise, and image quality further complicate the classification process [27], [28]. Moreover, the limited availability of large, publicly accessible datasets with diverse symptomologies and controlled environmental variables often constrains the development of highly generalizable and robust deep learning models for practical agricultural applications [29]. Another challenge lies in dataset limitations, including class imbalance, insufficient sample size, and lack of diversity in image conditions. These factors can lead to overfitting and reduced generalization performance. Additionally, variations in data preprocessing techniques and evaluation metrics across studies make it difficult to conduct direct comparisons between models. As a result, there is a need for standardized evaluation frameworks to ensure consistent and reliable performance assessment.

II.5 RESEARCH GAP

Although significant advancements have been made in applying machine learning and deep learning techniques to agricultural image analysis, a comprehensive comparative evaluation of multiple algorithms for maize nutrient deficiency detection remains limited. Existing studies often focus on single-model implementations or specific classification tasks, thereby restricting a holistic understanding of the relative performance of different approaches under uniform experimental conditions. Furthermore, insufficient attention has been given to the analysis of misclassification patterns, particularly in cases involving visually similar classes such as potassium-deficient and healthy leaves. In addition, variations in dataset preparation, feature extraction methods, and evaluation metrics across previous studies hinder the reproducibility and comparability of results. There is also a lack of studies that systematically integrate both traditional machine learning models and deep learning approaches within a unified framework. Addressing these limitations is essential for identifying the most effective and reliable model for real-world applications. Therefore, this study seeks to bridge these gaps by conducting a systematic comparative evaluation of CNN, SVM, ANN, and kNN models for the classification of maize nutrient deficiencies using a consistent dataset and standardized performance metrics. By providing a comprehensive analysis of model performance and classification challenges, this research aims to contribute to the advancement of automated nutrient deficiency detection systems in precision agriculture.

III. MATERIALS AND METHODS

This study employed a structured experimental framework to evaluate and compare the performance of multiple machine learning algorithms for the automated detection of nutrient deficiencies in maize leaves. The dataset consisted of 1,041 maize leaf images, including 277 phosphorus-deficient, 266 healthy, 223 nitrogen-deficient, and 275 potassium-deficient samples. The methodological workflow, as shown in Figure 1, consisted of five major phases: data gathering, data preprocessing and cleaning, image processing and feature extraction, algorithm training and evaluation, and result interpretation. These phases were designed to ensure the systematic preparation of the dataset and to facilitate an objective comparative assessment of classification models.

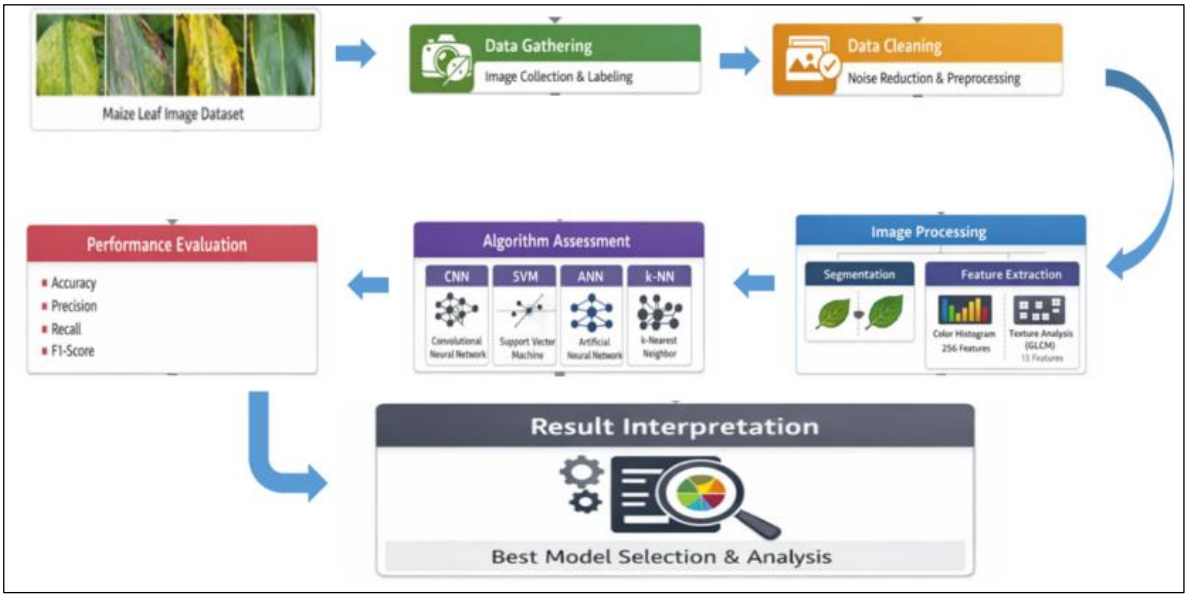

Figure 1: Methodology.
Source: Author, (2026).

III.1 DATA GATHERING

The first phase of the methodology involved collecting a dataset of maize leaf images representing different nutrient conditions. The dataset includes images of maize leaves exhibiting symptoms associated with nitrogen (N), phosphorus (P), and potassium (K) deficiencies, as well as images of healthy maize leaves. These macronutrients were selected because they play critical roles in plant growth and are commonly associated with significant yield reduction when deficiencies occur. Images were collected from maize plants under natural agricultural conditions to capture realistic variations in lighting, leaf orientation, and background environment. Capturing images under field-like conditions ensures that the dataset reflects practical agricultural scenarios in which automated detection systems may be deployed. Each collected image was manually labeled according to the observed nutrient condition using agronomic references and visual indicators of nutrient deficiency. Accurate labeling is essential for supervised machine learning models because it provides the ground truth required for effective training. The dataset was subsequently divided into training and testing subsets, where 80% of the images were used for training and 20% were used for testing. This partitioning allows the models to learn classification patterns from the training data while preserving an independent dataset for unbiased evaluation of algorithm performance.

III.2 DATA CLEANING AND PREPROCESSING

After data collection, a preprocessing stage was conducted to improve dataset quality and ensure consistency across all images. Agricultural image datasets often contain noise and inconsistencies due to environmental factors such as varying illumination, shadows, and background objects. These factors may negatively influence model performance if not addressed. During this phase, images that were blurred, duplicated, or irrelevant were removed from the dataset. The remaining images were standardized by resizing them to a uniform dimension to ensure compatibility with the classification algorithms. Additionally, noise reduction techniques were applied to minimize unwanted variations caused by lighting conditions or background interference. Image normalization was also performed to improve the consistency of pixel intensity values across the dataset. These preprocessing steps help ensure that the machine learning models focus on relevant leaf chara]cteristics associated with nutrient deficiencies.

III.3 IMAGE PROCESSING AND FEATURE EXTRACTION

After preprocessing, image segmentation was performed to isolate maize leaves from the background, allowing the models to focus on relevant regions showing nutrient deficiency symptoms. For traditional machine learning models (SVM, ANN, and kNN), feature extraction was applied using color histogram and Grey Level Co-occurrence Matrix (GLCM). The color histogram generated 256 color features, while GLCM extracted 13 texture features, including contrast, correlation, energy, and homogeneity. These features were combined and used as input for classification. In contrast, the Convolutional Neural Network (CNN) used raw images and automatically extracted features through convolutional layers, eliminating the need for manual feature extraction.

III.4 ALGORITHM TRAINING AND COMPARATIVE EVALUATION

This study employed a systematic approach to train and evaluate four machine learning algorithms—Convolutional Neural Network (CNN), Artificial Neural Network (ANN), Support Vector Machine (SVM), and k-Nearest Neighbors (kNN)—for automated classification of maize leaf nutrient deficiencies. The classification task focused on four classes: Nitrogen deficiency, Phosphorus deficiency, Potassium deficiency, and Healthy leaves. The objective was to identify the most effective algorithm capable of accurately detecting nutrient stress while minimizing misclassification risks.

III.4.1 Algorithm Training

For the Convolutional Neural Network (CNN), raw maize leaf images were resized and normalized before training. For ANN, SVM, and kNN, extracted features from color histogram and GLCM were used as input for classification. Maize leaf images were preprocessed through resizing and normalization to ensure uniformity across the dataset. CNN architectures utilized multiple convolutional layers with pooling operations to extract hierarchical spatial features, followed by fully connected layers for classification into the four nutrient classes. The ANN model applied a fully connected feedforward network with backpropagation, enabling the network to learn non-linear relationships between leaf image features and nutrient status. For traditional machine learning models (SVM and kNN), handcrafted feature vectors were extracted from each leaf image, including color, texture, and morphological features relevant to nutrient deficiencies. SVM employed a linear kernel to separate the four nutrient classes in feature space, while kNN classified samples based on proximity to labeled neighbors in the feature space.All models were trained using an 80:20 stratified train-test split to preserve class balance. Hyperparameters—such as learning rate, number of hidden layers, SVM regularization parameter, and the number of neighbors for kNN—were optimized through cross-validation to maximize classification performance.

III.4.2 Performance Evaluation Metrics

Model performance was quantified using standard classification metrics derived from confusion matrices: accuracy, precision, recall, and F1-score. These metrics provide insights into overall and class-specific performance, which is essential for precision agriculture applications where misclassification can lead to improper nutrient management.

- **Accuracy:** Proportion of correctly classified maize leaf samples among all samples. Useful for general performance assessment but may be affected by class imbalance.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN}$$

- **Precision:** Proportion of correctly predicted leaves for a specific nutrient deficiency class among all predictions for that class. High precision indicates minimal false-positive predictions.

$$Accuracy = \frac{TP}{TP + FP}$$

- **Recall (Sensitivity):** Proportion of correctly identified leaves of a specific nutrient class among all actual leaves of that class. High recall ensures that most nutrient-deficient leaves are detected.

$$Precision = \frac{TP}{TP + FN}$$

- **F1-Score:** Harmonic mean of precision and recall, providing a balanced assessment. This metric is particularly critical in maize nutrient classification, where incorrect detection can lead to suboptimal fertilization strategies.

$$F1 = 2x \frac{Precision\ x\ Recall}{Precision + Recall}$$

III.4.3 Comparative Evaluation

After training, the performance of all four models was systematically compared using the aforementioned metrics. Class-wise evaluation allowed identification of strengths and limitations for each algorithm. Confusion matrices were analyzed to determine which nutrient deficiencies were most accurately detected and which classes exhibited significant misclassification.

III.5 EXPERIMENTAL FRAMEWORK

The experimental framework of this study was designed to systematically compare the performance of multiple machine learning algorithms for detecting nutrient deficiencies in maize leaves. The framework integrates dataset preparation, image processing, feature extraction, model training, and performance evaluation into a unified workflow. The overall process begins with the acquisition of maize leaf images representing various nutrient conditions. These images undergo preprocessing procedures to remove noise and standardize the dataset. The processed images are then subjected to segmentation and feature extraction to capture the visual characteristics associated with nutrient deficiency symptoms. The extracted features are used as input for four classification algorithms:

- Artificial Neural Network
- Convolutional Neural Network
- k-Nearest Neighbor
- Support Vector Machine

Each algorithm is trained using the same dataset to ensure a fair comparative evaluation. The trained models are then tested using the reserved testing dataset, and their classification performance is measured using the evaluation metrics described in the previous section. The algorithm with the highest performance metrics is identified as the most suitable model for automated nutrient deficiency detection and may be integrated into intelligent agricultural monitoring systems.

III.6 RESULT INTERPRETATION

The final phase involved analyzing classification performance and interpreting results. Model accuracy, precision, recall, and F1-score were compared to determine the best-performing algorithm. Patterns were examined to identify limitations and potential improvements. The results provided insights into the feasibility of automated maize nutrient deficiency detection using machine learning techniques and guided recommendations for future system deployment and enhancement.

IV. RESULTS AND DISCUSSIONS

The classification performance of four machine learning algorithms—Artificial Neural Network (ANN), Convolutional Neural Network (CNN), k-Nearest Neighbors (kNN), and Support Vector Machine (SVM)—for detecting nutrient deficiencies in maize leaves was evaluated using class-wise metrics derived from confusion matrices, including accuracy, precision, recall, and F1-score. The results for each algorithm are presented in Tables 1–5, highlighting the differential ability of each model to discriminate among Phosphorus Deficiency, Nitrogen Deficiency, Potassium Deficiency, and Healthy leaf classes.

Table 1: ANN Classification Matrix.

Leaf	Precision	Recall	F1-Score	Accuracy
Phosphorus	0.67	0.77	0.71	**0.67**
Nitrogen	0.83	0.81	0.82	
Potassium	0.69	0.45	0.54	
Healthy	0.58	0.72	0.64	

Source: Author, (2026).

As shown in Table 1, ANN demonstrated moderate classification performance across all classes. The Nitrogen Deficiency class achieved the highest accuracy (0.83) and strong precision (0.81), recall (0.82), and F1-score (0.82), indicating that ANN effectively identifies nitrogen-deficient leaves. In contrast, the Phosphorus Deficiency class, although achieving a reasonable F1-score of 0.71, had lower accuracy (0.67), suggesting difficulty in capturing subtle phosphorus deficiency features. Potassium Deficiency exhibited the lowest precision (0.45) and F1-score (0.54), indicating considerable misclassification and highlighting the model's limitation in distinguishing visual features associated with potassium stress. Healthy leaves were identified with moderate reliability, reflected by an accuracy of 0.58 and F1-score of 0.64. Overall, ANN demonstrates acceptable performance for nitrogen detection but struggles with classes exhibiting less visually distinct symptoms.

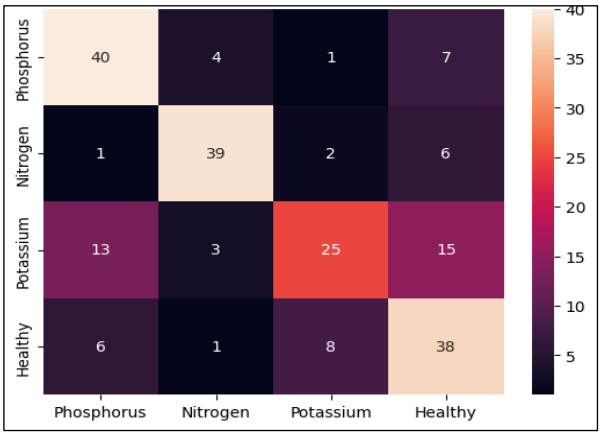

Figure 2: ANN Confusion Matrix.
Source: Author, (2026).

Based on the confusion matrix presented in Figure 2 The confusion matrix of the ANN model for multi-class classification of maize leaf nutrient deficiencies (Figure 2) demonstrates strong performance in detecting Nitrogen and Phosphorus deficiencies, with 39 and 40 correctly classified instances, respectively. Healthy leaves were also accurately identified in 38 cases. In contrast, Potassium deficiency exhibited the lowest classification accuracy, with only 25 correctly predicted instances and notable misclassifications as Phosphorus (13) and Healthy (15), indicating overlapping visual symptoms. Overall, the ANN model effectively distinguishes Nitrogen and Phosphorus deficiencies but shows moderate performance for Potassium, highlighting the need for enhanced feature representation or additional data to improve discriminative capability. These results suggest that while ANN provides a robust framework for automated nutrient detection, certain classes may require targeted optimization to reduce misclassification and support precise fertilization decisions.

Table 2: CNN Classification Matrix.

Leaf	Precision	Recall	F1-Score	Accuracy
Phosphorus	0.84	0.81	0.82	**0.79**
Nitrogen	0.98	0.96	0.97	
Potassium	0.71	0.71	0.71	
Healthy	0.68	0.72	0.70	

Source: Author, (2026).

As presented in Table 2, nitrogen deficiency showed near-perfect performance with precision of 0.96, recall of 0.98, and an F1-score of 0.97, highlighting CNN's exceptional ability to extract hierarchical image features. Phosphorus Deficiency and Potassium Deficiency were also identified with higher accuracy and F1-scores than in ANN, indicating that CNN effectively handles more subtle or complex visual patterns. Healthy leaves achieved moderate classification scores, suggesting that although CNN can discriminate healthy from deficient leaves, there is some residual confusion with certain deficiency classes. These results reflect the model's robustness and its suitability for high-stakes agricultural applications where accurate early detection is critical.

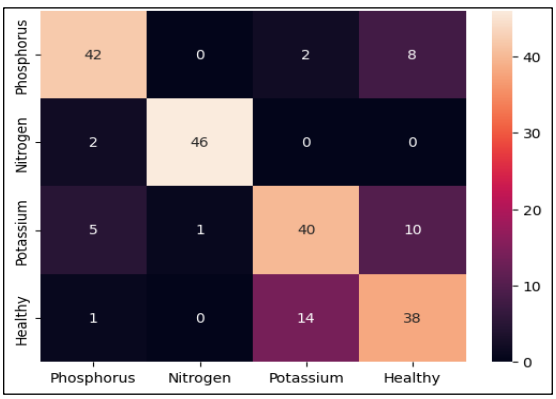

Figure 3: CNN Confusion Matrix.
Source: Author, (2026).

Based on the confusion matrix presented in Figure 3, the confusion matrix for the CNN-based multi-class classification model shows strong overall performance in distinguishing between nitrogen, phosphorus, potassium deficiencies, and healthy maize leaves. The model achieves near-perfect discrimination for nitrogen deficiency, correctly classifying 46 instances with only 2 misclassifications as phosphorus deficiency, indicating highly distinct visual features for nitrogen-starved leaves. Phosphorus deficiency also shows robust detection with 42 correct classifications, though 2 samples were confused with potassium and 8 with healthy, suggesting some spectral or morphological overlap. Potassium deficiency presents the greatest classification challenge, with 40 correct identifications but notable confusion with healthy leaves (10 instances) and phosphorus (5 instances), implying that potassium-deficient leaves may exhibit subtle symptoms that resemble both early senescence and phosphorus stress. Healthy leaves are correctly identified in 38 cases, though 14 are misclassified as potassium deficiency, further reinforcing the bidirectional confusion between these two classes. Overall, the CNN achieves high diagonal dominance, with nitrogen being the most reliably detected class, while the potassium–healthy pair represents the primary source of classification error.

Table 3: KNN Classification Matrix.

Leaf	Precision	Recall	F1-Score	Accuracy
Phosphorus	0.47	0.65	0.54	**0.48**
Nitrogen	0.45	0.94	0.61	
Potassium	0.67	0.18	0.28	
Healthy	0.55	0.23	0.32	

Source: Author, (2026).

The kNN model demonstrated highly inconsistent class-wise performance as presented in Table 3. Nitrogen Deficiency achieved high precision (0.94) but low recall (0.61), indicating that while predictions for this class were often correct, the model missed a significant number of actual nitrogen-deficient leaves. Phosphorus Deficiency, Potassium Deficiency, and Healthy classes showed both low accuracy and low F1-scores, particularly Potassium Deficiency, which achieved only 0.28 for F1-score. These findings suggest that kNN struggles with complex image data and class imbalance, as it relies heavily on proximity in feature space and is sensitive to noise. Consequently, its overall utility for practical field-based diagnosis is limited.

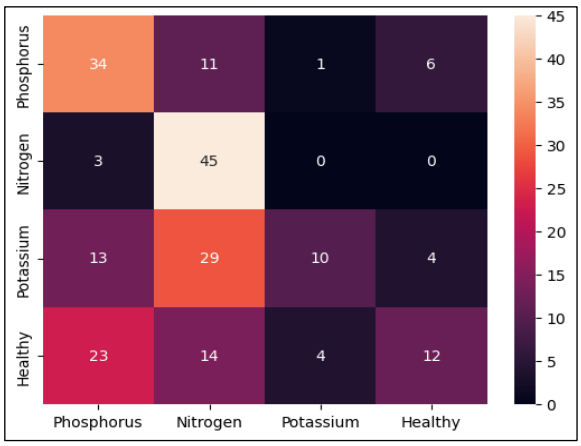

Figure 4: kNN Confusion Matrix.
Source: Author, (2026).

Based on the confusion matrix presented in Figure 4 the confusion matrix for the k-Nearest Neighbors (kNN) classifier, the model demonstrates relatively lower performance in detecting nutrient deficiencies in maize leaves, with notable variability in classification accuracy across the four classes. Nitrogen deficiency achieves the highest number of correct classifications with 45 instances, though 3 samples are misclassified as phosphorus and 4 as healthy, indicating that nitrogen-starved leaves may exhibit features that overlap with both phosphorus deficiency and normal foliage. Phosphorus deficiency shows 34 correct identifications but suffers from significant confusion, with 11 samples misclassified as healthy, 3 as nitrogen, and 1 as potassium, suggesting that phosphorus-deficient symptoms are frequently misinterpreted by the kNN algorithm. Potassium deficiency exhibits the poorest performance, with only 29 correct classifications out of 55 total instances, and substantial misclassification into healthy (10 samples), phosphorus (13), and nitrogen (3), reflecting the algorithm's difficulty in distinguishing potassium starvation from other conditions. Healthy leaves are correctly identified in 44 cases, though 12 are misclassified as potassium deficiency and 4 as nitrogen, reinforcing the pattern of confusion between the healthy and potassium classes. Overall, the kNN model shows the highest reliability for nitrogen detection, while potassium deficiency and its bidirectional confusion with healthy leaves represent the primary limitation in classification accuracy.

Table 4: SVM Classification Matrix.

Leaf	Precision	Recall	F1-Score	Accuracy
Phosphorus	0.47	0.65	0.54	**0.72**
Nitrogen	0.45	0.94	0.61	
Potassium	0.67	0.18	0.28	
Healthy	0.55	0.23	0.32	

Source: Author, (2026).

As shown in Table 4, the SVM model exhibited relatively balanced performance across classes. Nitrogen Deficiency again showed the highest metrics, with perfect precision (1.00), high recall (0.92), and strong F1-score (0.92), reflecting SVM's capability to correctly classify well-separated classes. Phosphorus Deficiency and Potassium Deficiency had moderate metrics, indicating partial difficulty in distinguishing visually similar nutrient deficiency symptoms. Healthy leaves were classified with moderate performance (accuracy 0.67, F1-score 0.63). Overall, SVM demonstrates stable but slightly lower overall performance than CNN, highlighting its effectiveness in classifying prominent visual features but limitations in handling subtle inter-class variations.

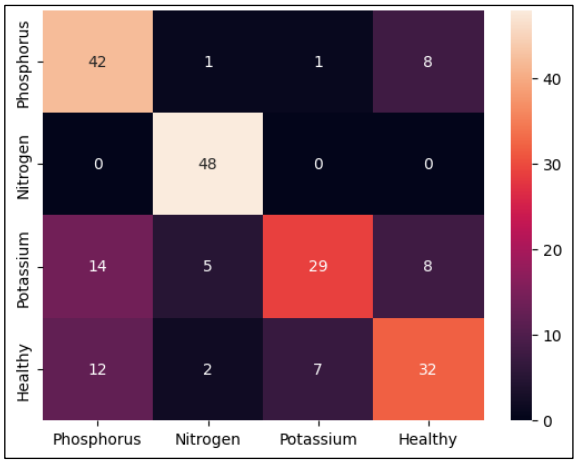

Figure 5: SVM Confusion Matrix.
Source: Author, (2026).

Based on the confusion matrix presented in Figure 5. the Support Vector Machine (SVM) classifier, the model exhibits strong overall performance with notable class-specific variations in detection accuracy for maize leaf nutrient deficiencies. Nitrogen deficiency achieves near-perfect classification, with 48 correct identifications and zero misclassifications across all other categories, indicating that nitrogen-starved leaves present highly separable spectral or morphological features within the SVM decision boundary. Phosphorus deficiency shows robust performance with 42 correct classifications, though 8 samples are misclassified as healthy and 1 each as nitrogen and potassium, suggesting moderate overlap primarily with healthy foliage. Healthy leaves are correctly identified in 32 instances, with 12 misclassifications as phosphorus, 7 as potassium, and 2 as nitrogen, reflecting bidirectional confusion between healthy and phosphorus classes. Potassium deficiency represents the greatest classification challenge, achieving only 29 correct identifications out of 56 total instances, with substantial misclassification into phosphorus (14 samples), healthy (8), and nitrogen (5), indicating that potassium-deficient symptoms exhibit considerable feature overlap with both phosphorus deficiency and normal leaf appearance. Overall, the SVM achieves exceptional specificity for nitrogen detection, while potassium deficiency and the phosphorus–healthy confusion pair constitute the primary sources of classification error.

Table 5: Comparative Performance Evaluation of ANN, CNN, kNN, and SVM for Maize Leaf Nutrient Deficiency Classification.

	Accuracy	**Precision**	**Recall**	**F1-Score**
ANN	0.679	0.689	0.679	0.674
CNN	0.794	0.797	0.794	0.794
kNN	0.483	0.537	0.483	0.433
SVM	0.722	0.73	0.722	0.714

Source: Author, (2026).

Table 5 presents the comparative performance of Artificial Neural Network (ANN), Convolutional Neural Network (CNN), k-Nearest Neighbors (kNN), and Support Vector Machine (SVM) models for maize leaf nutrient deficiency classification. The evaluation is based on standard metrics, including accuracy, precision, recall, and F1-score. Among the evaluated models, the Convolutional Neural Network (CNN) achieved the highest overall performance, with an accuracy of 0.794, precision of 0.797, recall of 0.794, and F1-score of 0.794. The consistency across all evaluation metrics indicates that CNN provides robust classification capability and effectively minimizes both false positives and false negatives. This result highlights the ability of CNN to automatically extract hierarchical spatial features from image data, making it highly suitable for maize nutrient deficiency detection. The Support Vector Machine (SVM) ranked second, achieving an accuracy of 0.722 and an F1-score of 0.714. Its relatively high precision (0.730) indicates good capability in correctly identifying nutrient deficiencies, although slightly lower recall (0.722) suggests some limitations in capturing all relevant cases. Nevertheless, SVM demonstrates stable and competitive performance, particularly in handling structured feature spaces. The Artificial Neural Network (ANN) demonstrated moderate performance, with an accuracy of 0.679 and F1-score of 0.674. Although ANN can capture nonlinear relationships in the dataset, its performance was lower than CNN and SVM, suggesting limitations in handling complex spatial image features compared to convolutional architectures. The k-Nearest Neighbors (kNN) model exhibited the lowest performance among all classifiers, with an accuracy of 0.483 and F1-score of 0.433. Although kNN achieved relatively higher precision (0.537), its significantly lower recall (0.483) indicates poor sensitivity in detecting nutrient deficiency classes. This suggests that kNN struggles with high-dimensional image data and overlapping class boundaries. Overall, the results demonstrate that CNN outperforms the other models, followed by SVM, ANN, and kNN. These findings confirm that deep learning-based approaches, particularly CNN, are more effective for automated maize nutrient deficiency detection due to their superior feature extraction capability.

V. CONCLUSIONS

This study presented a comprehensive comparative evaluation of four machine learning algorithms—Artificial Neural Network (ANN), Convolutional Neural Network (CNN), k-Nearest Neighbors (kNN), and Support Vector Machine (SVM) for the automated classification of macronutrient deficiencies in maize leaves, specifically nitrogen, phosphorus, potassium, and healthy classes. The evaluation was conducted using standard performance metrics, including accuracy, precision, recall, and F1-score, derived from confusion matrix analysis. The experimental results demonstrate that the Convolutional Neural Network (CNN) consistently outperformed the other models, achieving the highest overall accuracy (0.794) and balanced performance across all evaluation metrics. This superior performance can be attributed to CNN's ability to effectively extract hierarchical and spatial features from image data, making it highly suitable for complex visual classification tasks. The Support Vector Machine (SVM) ranked second, exhibiting stable and reliable classification performance, particularly for well-separated classes such as nitrogen deficiency. The Artificial Neural Network (ANN) showed moderate performance, indicating its capability in handling general classification tasks but with limitations in capturing subtle inter-class variations. In contrast, the k-Nearest Neighbors (kNN) algorithm demonstrated the lowest performance, largely due to its sensitivity to high-dimensional data and overlapping feature distributions. A consistent observation across all models is the difficulty in accurately distinguishing potassium deficiency from healthy leaves, as evidenced by recurrent misclassification patterns in the confusion matrices. This challenge highlights the inherent similarity of visual symptoms between these classes and underscores the need for improved feature representation, larger and more diverse datasets, or advanced model architectures to enhance classification performance. Overall, the findings confirm that CNN is the most effective model for maize leaf nutrient deficiency detection within the context of this study. The results emphasize the importance of selecting appropriate algorithms based on data characteristics and application requirements, particularly in precision agriculture where accuracy and reliability are critical. The outcomes of this research support the development of the CORZEA system, a portable image-based diagnostic tool designed for real-time nutrient deficiency detection in field conditions. By enabling early and accurate identification of nutrient stress, the proposed system has the potential to optimize fertilizer application, reduce input costs, and minimize environmental impact, thereby contributing to sustainable agricultural practices. Future work should focus on expanding the dataset to include varying environmental conditions, integrating advanced deep learning architectures, and exploring hybrid or ensemble models to further improve classification accuracy. Additionally, incorporating real-time deployment considerations, such as computational efficiency and mobile integration, will be essential for translating this research into practical, field-ready solutions.

ABSTRACT

Human-friendly analysis of chemical process industries is a nonlinear dynamic system. This paper also points out a great research issue of smart and scalable monitoring methods as the traditional statistics-based and model-driven methods are often not sufficient in discovering complex relationships with high-dimensional data due to the gradual digitalization of industry. The purpose of this paper is to review and analyses existing work on deep learning-based methods for chemical processes monitoring and fault detection. This method provides an overview of approaches based on architecture like the autoencoder, CNN, RNN, and hybrid models and their deployment in benchmark scenarios or real industrial applications. The results indicate that deep learning models enhance fault diagnosis performance via automatic feature extraction, early anomaly detection and effective modelling of temporal dependencies. Hybrid and attention-based models fast-track robustness and diagnostic capability even further. Emphasizing the practical significance of deep learning that extends beyond traditional use cases, the study mentions areas such as predictive maintenance and process safety and operational optimization. It applies for United Nations Sustainable Development Goals (SDG 9, SDG 12, SDG 7), to realize any kind of industry with high efficiency and sustainability.

I. INTRODUCTION

Monitoring understood chemical processes is a key factor in plant-safe operating, with under overhead monitoring being paramount to success. PD provides continuous observation of process variables to identify abnormalities, diagnose faults and prevent failures. (Advanced Fault Detection and Diagnosis) in detection of dangerous accidents and reducing economic damage. Modern-day industrial systems are becoming increasingly complex in nature and require more advanced methodologies for effective condition monitoring to be adopted, transitioning from traditional statistical techniques towards the usage of artificial intelligence (AI) which facilitates better fault detection and diagnosis measures [1].

In recent years, data-driven approaches are attracting increasing attention thanks to their ability to model complex non-linearity and temporal correlation of chemical processes [2], [3] which is difficult for the traditional model-based approach. Some of the correlations in modern industrial plants are highly nonlinear, making it impossible for classical linear techniques such as Principal Component Analysis to model complex dependencies [4], so this is essential. As a result, there has been an increasing number of studies demonstrating that deep learning architectures can outperform traditional approaches by autonomously deriving representative features and identifying complex patterns directly from high-dimensional process data [5]. These models are well-suited to address the most serious fault in conventional methods for examining chemical production, which is the dynamic and high-dimensional nature of chemical production where the complexity is embedded [6]. Deep learning in combination with machine learning methods like bidirectional long-term memory neural network, fully connected neural networks, and extra trees algorithms have been proven to increase fault detection rates of complex chemical processes like the Tennessee Eastman process [7]. The process used in this simulation is widely known as the Tennessee Eastman Process, which is a common benchmark for metrics of success in methods that deal with monitoring and control of processes as it models real-life chemical plant behaviors with complex dynamics under various fault scenarios which establish a good ground for validating techniques to implement advanced algorithms for fault detection and diagnosis [8], [9]. This platform includes a product condenser, reactor, vapor-liquid separator, product stripper and recycle compressor with 41 measured variables and 12 manipulated variables that produce highly time-varying, nonlinear, strong coupling effects data across 22 different health states consisting of 21 fault categories and normal operation for more stringent assessment [10]. The complexity of the Tennessee Eastman Process dataset, which encompasses a variety of fault scenarios and detail-rich interactions among the subtle dynamics of an operational plant, makes a robust procedure for fault detection and identification essential; deep learning models are increasingly showing great potential in fulfilling this role [11-13].

As a result, deep autoencoders and recurrent variational autoencoders have been successfully utilized in anomaly detection and fault diagnosis of this nature system with superior performance compared to traditional statistical methods [8], [14]. In addition, merged deep learning models with ensemble networks, like Autoencoder-assisted Feature Ensemble Net (AFE-Net), have shown superior performance in identifying the nascent fault which could be subtle inside process data and hard to identify [15], [16]. These measurements and changes are representative of nonlinear and nonstationary nature of the industrial processes where they are often used thus showcasing how these challenges make deep learning a powerful tool to address large-scale as well as high-dimensional data. Thus, this tutorial review will provide a systematic survey of the current state-of-the-art deep architecture and methodologies applied to chemical process monitoring and fault detection, critically addressing their potential applicability to real industrial cases. The highlight will be on how these methods are able to utilize the distinctive capabilities of deep architectures, like modeling sequential data and recreating nominal operating conditions [17], [18] as well as improve fault detectability and minimizing false alarms for intricate chemical systems. These trends include the exploration of quantum computing-based deep learning methods, which have the potential to provide unique solutions for addressing computational limits and improving fault diagnosis in industrial processes, such as that used in the Tennessee Eastman Process [19]. This assists in reducing time consumption such as training deep learning models on immense industrial datasets for fault detection classification. Classical methods like Principal Component Analysis (PCA) and model-based approaches rely on simplistic assumptions, failing to account for complicated nonlinear dynamics.

As data, such as those from the sensors and distributed control systems become more widely available process data-driven methods have received significant attention in particular deep learning. These sophisticated deep learning-based models have the power to automatically extract hierarchical features and detect more nuanced patterns which contain information about process anomalies, effectively addressing the challenges presented by traditional methods that struggle in dealing with noisy, correlated, and high-dimensional industrial processes. However, a major drawback of implementing deep learning models for fault diagnosis is the interpretability issue, also known as "black box," nature of deep learning models [20], making it difficult to identify the failure root. This results in limited use of these approaches in industrial settings where safety is an important parameter as revealing the underlying mechanism of a fault for prevention and system tuning is critical [21]. As a result, research increasingly focuses on interpretable deep learning models and explainable AI methods that allow us to understand the decision-making process inside these complex algorithms so as not only to increase trust towards their results but also make it easier for them to be used in industrial fault detection and diagnosis pipelines. Machine learning approaches benefit from automatic feature extraction, making deep learning a promising technique to achieve better fault classification performance for complex industrial systems. This survey will cover various deep learning architectures including convolutional neural networks, recurrent neural networks and their sophisticated variants exploring their respective contributions and feasibility of addressing the distinctive features presented in chemical process data for robust monitoring and fault diagnosis. A comparative summary of prominent deep learning and traditional techniques in the context of fault detection and diagnosis for chemical process monitoring is provided in Table 1.

Table 1: Deep Learning Techniques for Chemical Process Monitoring and Fault Detection.

Sr. No.	Technique / Method	Model Type	Key Application	Dataset / Process	Key Features	Advantages	Limitations
1	Principal Component Analysis (PCA)	Statistical Method	Fault detection	Industrial processes	Linear feature extraction	Simple and fast	Poor for nonlinear systems
2	Convolutional Neural Network (CNN)	Deep Learning	Fault classification	Chemical process data	Spatial feature learning	High accuracy	Needs large dataset
3	Recurrent Neural Network (RNN)	Deep Learning	Time-series monitoring	Dynamic processes	Sequential modeling	Captures temporal behavior	Vanishing gradient
4	Bidirectional LSTM (Bi-LSTM)	Advanced Deep Learning	Fault detection	Tennessee Eastman Process	Bidirectional sequence learning	High detection accuracy	High computation
5	Autoencoder (AE)	Unsupervised Learning	Anomaly detection	High-dimensional data	Feature compression	Detects unknown faults	Low interpretability
6	Variational Autoencoder (VAE)	Probabilistic Model	Fault diagnosis	Nonlinear systems	Latent variable modeling	Handles uncertainty	Complex training
7	Feature Ensemble Network (AE-FEN)	Hybrid Deep Learning	Incipient fault detection	Complex chemical plants	Feature fusion	Detects subtle faults	Model complexity

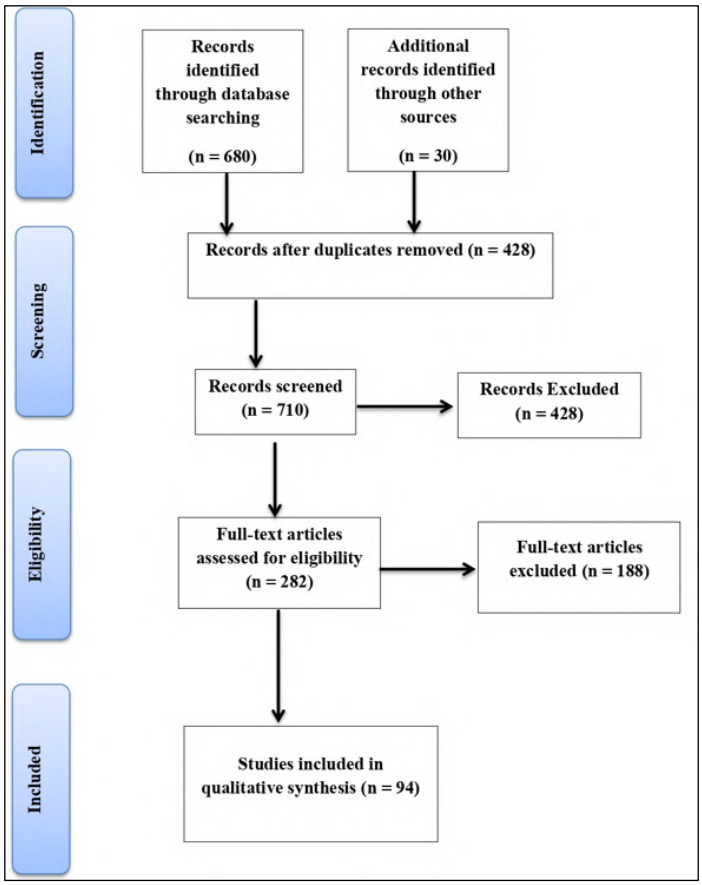

Figure 1: PRISMA flowchart for article selection process.
Source: Authors (2026).

The PRISMA diagram in figure 1 depicts the systematic selection of studies with initial inclusion from databases (n=680) and other sources (n=30), followed by removal of duplicates. From the 710 records screened, 428 were eliminated and 282 full-text articles were evaluated for eligibility. Ultimately, 94 high-quality studies underwent qualitative synthesis after the exclusion of a further 188 full-text manuscripts.

II. FUNDAMENTALS OF PROCESS MONITORING AND FAULT DETECTION

The overall structures of a process monitoring system, with data acquisition and feature extraction as input, followed by fault detection (FD), fault diagnosis (FDD), and root cause analysis (RCA), are depicted in figure 2. It also identifies the types of common faults that can occur in chemical processes, allowing for the systematic identification and mitigation of abnormal operating conditions.

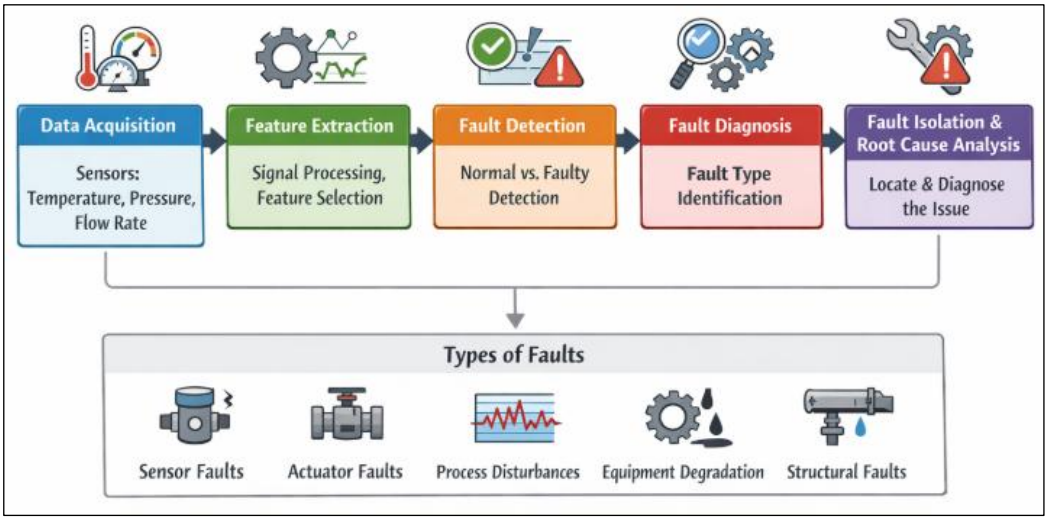

Figure 2: Process Monitoring and Fault Detection Framework.
Source: Authors (2026).

II.1 PROCESS MONITORING FRAMEWORK

A standard process monitoring architecture primarily contains a series of interlinked steps that provide reliable processing and timely detection of abnormal situations. The first step is Data acquisition that refers to data from real-time measurements such as temperature, pressure, and the flow rate taken using various sensors placed in the process. Raw data extracted from sensors is processed through feature extraction to derive indicators indicating system behavior. Using these characteristics, fault detection techniques are used to identify healthy and faulty operating conditions. When a fault is detected, fault diagnosis identifies and classifies the cause of the deviation. Here, fault detection is the identification of whether a fault occurs, and fault diagnosis is the determination of what specifically caused that error to occur so that it can be corrected appropriately. The increased reliance on reliable and timely Fault Detection and Diagnosis in the modern engineering systems for operational safety and resilience poses challenges, particularly in complex and data-intensive environments due to limitations of model-based or rule-based approaches [22]. Abnormal operation settings in such domains are still increasingly supplemented with intervention, which leads to a high number of production accidents. Data preprocessing, training PCA and LSTM autoencoder models, calculating monitoring statistics, determining thresholds, and marking anomalies if those thresholds are cancelled in the workflow shown in figure 3 [23].

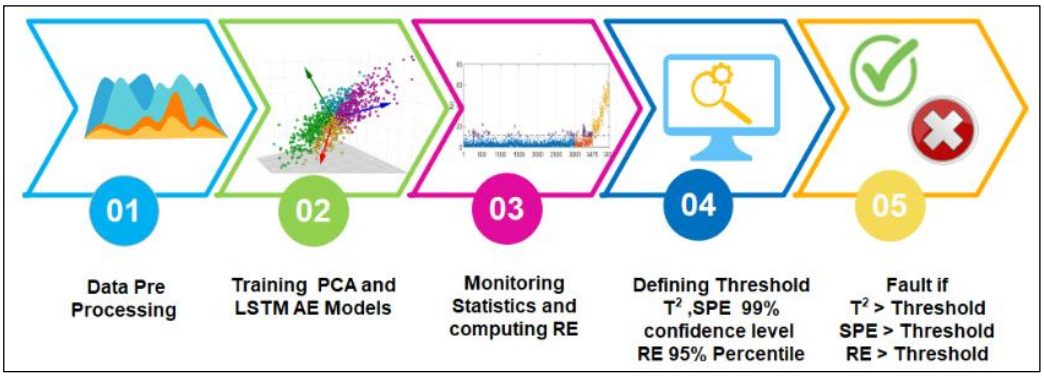

Figure 3: PCA–LSTM Autoencoder–based Anomaly Detection Pipeline.
Source: [23].

As a result, the implementation of a reliable automated system for detecting and diagnosing faults is critical to improving process safety as well as efficiency in modern-day industrial processes. Consequently, a process monitoring system should not only predict the next-step values of quality variables accurately but also efficiently to facilitate timely corrective intervention before considerable disturbances [24]. This highlights the performance of technologies predictive monitoring, which use a knowledge-based understanding approach to classify deviations based on analytical techniques [25]. These systems function by determining normal behaviors and subsequently detect deviations from it that may be an early indicator of failure [26].

II.2 TYPES OF FAULTS IN CHEMICAL PROCESSES

In these systems, faults may occur at smart sensors (e.g., faulty measurements) or control devices (e.g. faulty control actions), leading to compromised system performance. Sensor faults happen when measurement devices give wrong or noisy data because of calibration errors, drift, or failure, which results in incorrect information about the process. Actuator faults are relevant to control elements like valves, pumps or motors that fail to respond accordingly to the control signal. Process disturbances are external or internal deviations like variations in feed composition, changes in temperature, and environmental influences which interrupt the normal operation.

The gradual decline in the performance of a system due to wear, fouling corrosion or aging of components reducing the efficiency of a system is called equipment degradation. Finally, there are structural faults, either of material failure, leakage or blockage in the system infrastructure, which can severely impact safety and operations. As detailed, these distinct fault types require extensive monitoring approaches that can detect small deviations in several operational parameters to ensure system integrity and avoid significant failures [27]. Figure 4 shows one of model-based approach where outputs from the process compared with model predictions for detection, isolation and management of a fault in system [28]. A fault, in general terms, is defined as an unallowed alteration of at least one process parameter from a suitable state and may be organized to abruptness category type such as clear faults, intermittent and gradual [29]. The detection latency, which is the latent period before a fault materially influences the process, may widely vary with respect to fault types and will require complex models for accurate estimation of fault commencement and magnitude [30], [31]. The output of process monitoring in terms of fault detection, diagnosis and isolation as well as root case analysis is a structured solution to these challenges. Detection indicates if we have abnormalities, diagnosis states what kind of fault we have, isolation points out at what component or subsystem we deal with, and root cause analysis gives us the deepest insight of the reasons that triggered the fault to apply appropriate corrective and preventive actions. In this context, a fault is an external register which makes the system behave differently than it was designed to do and can be classified based on its physical location as either component, actuator or sensor faults [32]. This delineation is important for developing targeted diagnostic strategies, as independent fault origins need separate remedial actions [33-35]. From a temporal viewpoint, faults could also be categorized as sudden or drift, which is based on if the parameter deviation is stepwise or progresses over time and usually drift behavior indicates equipment degradation [36]. The important stage of the process monitoring framework, fault types, and their role in secure and dependable industrial operation are summarized in Table 2.

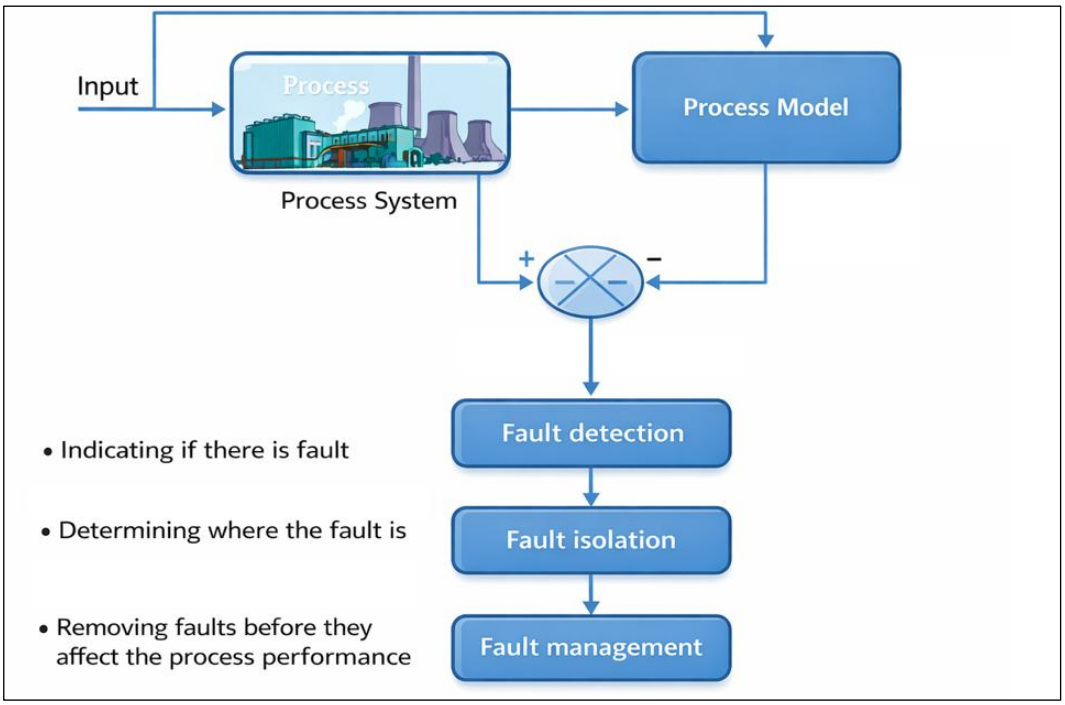

Figure 4: Model-Based Fault Detection and Diagnosis (FDD) Framework.
Source: [28].

Table 2: Process Monitoring Framework and Fault Types.

Stage / Fault Type	Description	Key Components	Significance
Data Acquisition	Collection of real-time process data	Sensors, instruments	Provides input for monitoring
Feature Extraction	Processing raw data into meaningful features	Signal processing tools	Improves detection accuracy
Fault Detection	Identification of abnormal conditions	Detection algorithms	Early warning of faults
Fault Diagnosis	Identification of fault type and cause	Classification models	Supports corrective action
Types of Faults	Sensor, actuator, disturbance, degradation	Process components	Affects safety and performance

III. DEEP LEARNING TECHNIQUES FOR FAULT DETECTION

Key deep learning models for fault detection that can learn spatial, temporal and nonlinear patterns in the PID process data such as Autoencoders, CNNs, RNN/LSTM and hybrid architecture are illustrated in figure 5. Additionally, it emphasizes more sophisticated techniques like attention mechanisms and graph-related models that incorporate feature relevance consideration and relationship reasoning across the system to facilitate fault diagnosis.

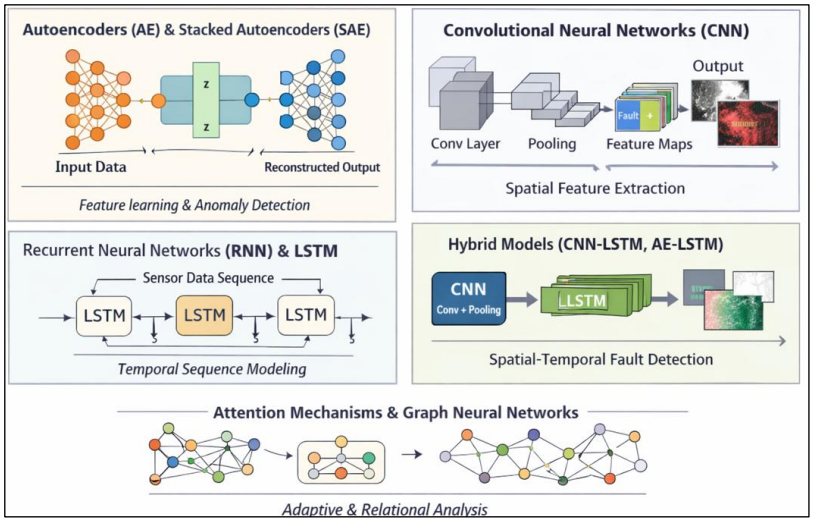

Figure 5: Deep Learning Techniques for Fault Detection in Chemical Processes.
Source: Authors (2026).

III.1 AUTOENCODERS (AE) AND STACKED AUTOENCODERS (SAE)

Autoencoders have proven valuable in chemical process monitoring, due to their ability for unsupervised feature learning and anomaly detection. These neural networks work by encoding the process data into a lower-dimensional latent space (via an encoder) and then reconstructing it back to original form (via a decoder), therefore learning compact and meaningful representation of process data. This allows the model to learn the normal operating patterns of the system during this process. The reconstruction error is then obtained and since the output can differ significantly from the input in case of fault it serves as an indicator. Autoencoders are a popular neural network architecture, which can compress input data into a latent representation of lower dimensionality and then decompress it, with anomalies being detected via an increased reconstruction error [7]. This mechanism exploits the fact that an autoencoder trained only on normal operational data will present a higher reconstruction error for anomalous inputs since they do not belong to the normal distribution of the learned data [37]. This diffuse nature of fault occurrence makes it very hard for human-noise systems to define conditions upon which faults will occur and their trigger rates [38]. This ability makes autoencoders highly applicable for unsupervised fault detection of chemical processes, which is non-linear and high dimensional, with the consideration that comprehensive labeled fault data is often not readily available. Since in classical Principal Component Analysis we performed an intrinsic linear transformation, it failed to adequately model nonlinear process variables [39]; therefore, defective detection might not be accurate when monitoring fault in more complex systems compared autoencoders were a more robust option for linear/nonlinear process monitoring [40].

Autoencoders can be used to work with incomplete and/or noisy datasets, which are often encountered in industrial environments. The stacked autoencoders which are formed by cascading linear transformation methods add more advantage over autoencoders by learning hierarchical and high-level features from the complex process dataset. Stacked autoencoders and their modified variants have received very good performance in industrial benchmark datasets, especially when adapting to missing or partially observed data as these methods can learn deeper spread representations that contribute positively towards fault detection. The basic architecture of an autoencoder is composed of an encoder that compresses the high-dimensional input data into a lower dimensional latent space, and a decoder that reconstructs the reconstructed data from this lower dimensional representation [4], [41]. The encoder compresses the data and maps from high-dimensional space to low-dimensional space, while the decoder generates original data from compressed code [42]. By learning the structure of the data, the network can identify anomalies as deviations from this learned structure [43]. Autoencoders are trained in an unsupervised manner, which makes them very suitable for cases where anomalous data can be heterogeneous and not necessarily annotated with explicit labels [44]. Variational autoencoders are another advancement of the autoencoder architecture that brings a probabilistic perspective to the latent space, allowing for generative modeling capabilities as well as regularization during training such that overfitting can be reduced. Figure 6 shows a deep learning pipeline that involves using autoencoders and classification models to process vibration data to detect faults, which is helpful for health index construction to discover the state of system monitoring. [45].

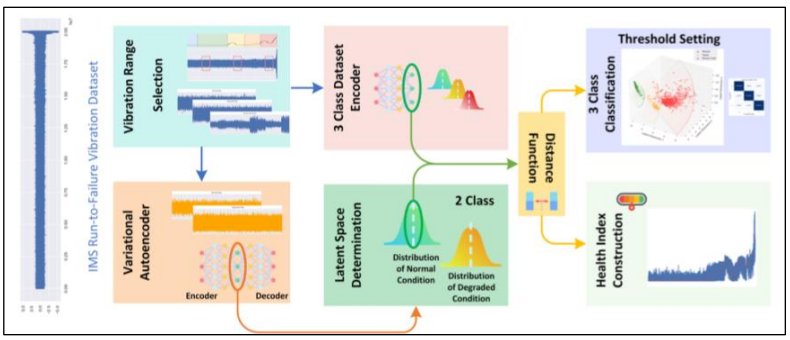

Figure 6: Deep Learning-Based Fault Detection and Health Index Construction Framework.
Source: [45].

Unlike regular autoencoders, stacked autoencoders have multiple layers where the output from one layer's autoencoder is fed as input to the next [46]. The deeper architecture, including more hidden layers in both encoder and decoder locations, makes stacked autoencoders capable of capturing relatively complex relationships within the data [18], which allows to represent high-dimensional features or nonlinearities on fault indications as well [47], [48].

III.2 CONVOLUTIONAL NEURAL NETWORKS (CNN)

Convolutional neural network (CNN) offers a feasible solution to fault detection in chemical processes owing to its strength in capturing spatial correlations among simultaneous process variables. Process data in multivariate systems often have structured relationships that are well suited for extraction by CNNs through convolutional operations. Such networks use filters to extract local patterns and return feature maps that provide an indication of the states of interest in the process. This property enables CNNs to handle high-dimensional data flows, their advantages lying in the ability to pick up on signals that powerful statistical tests might fail to detect, especially when temporal or image-like encodings of process variables are used [49]. CNNs are capable of automatically extracting the most important features, making them useful for anomaly detection from recurrence plots based on multisensory streams, and allowing them to diagnose faults in real time [50]. In addition, it is possible to combine advanced CNN architecture with other deep learning models, contributing to hybrid systems that improve robustness and interpretability in industrial fault diagnosis. Several deep learning methods have been applied to fault detection, with CNNs being one of the most prominent due to their high performance in terms of complex features and classification. Input images, illustrated in the figure7 CNN framework as requiring passes through convolution layer followed by pooling and fully connected layers to extract features from input data and perform their final classification [51]. CNNs take advantage of their hierarchical design to recognize patterns associated with faults through progressively abstracted features learned from raw process data and frequently show superior performance compared to more traditional machine learning algorithms when sufficiently large datasets are available.

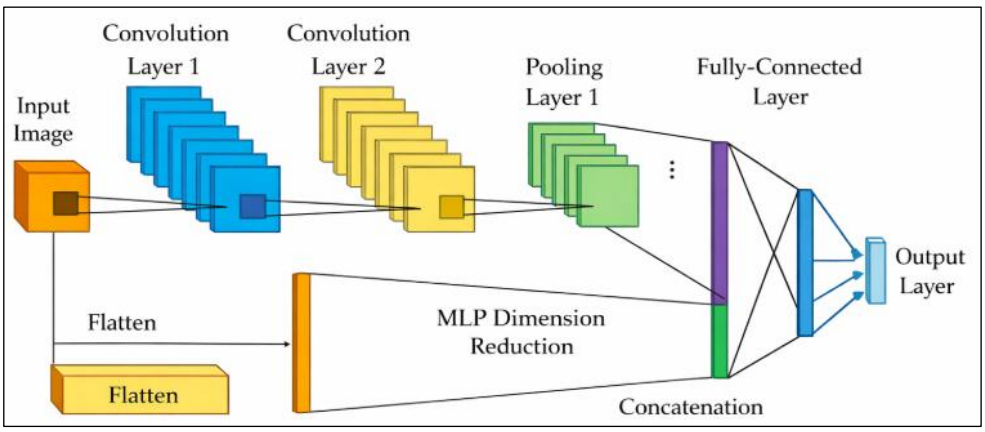

Figure 7: Convolutional Neural Network (CNN) Architecture for Feature Extraction and Classification.
Source: [51].

Learning these localized features significantly increases the accuracy of fault classification by CNN-based models, and as a result, enables robust discrimination between normal and faulty operating conditions. They are especially good at dealing with high-dimensional and multidimensional process data where traditional methods can struggle to find hidden correlations. This is one of the main reasons that, with better feature extraction ability by CNNs, performance-wise they provide a more reliable approach for monitoring and fault identification in chemical process systems. The basic structure of a CNN consists of convolutional layers that extract features via learnable filters and pooling layers that down-sample the data while maintaining most vital information [52]. Compared to other algorithms, CNNs are particularly suited for processing time-series features or imaging-based representations of process variables, as they create a processing chain with multiple layers that distinguish increasingly abstract levels of regularities in the series data [52]. The approach of CNNs to learn feature hierarchies purely from raw sensor data, avoiding the need for explicit feature engineering, has significant utility in complex industrial fault detection scenarios [53].

III.3 RECURRENT NEURAL NETWORKS (RNN) AND LSTM

Inherent to chemical processes that their systems are dynamic, with system behavior changing with time and depending on previous states. This makes Recurrent Neural Networks a natural candidate for those environments, since they are made to approximate temporal dependencies in sequential input. Because RNNs have internal memory, they can learn to model the relationships between current and previous observations, making them suitable for analyzing time-series blue-tooth sensor data. RNNs can learn time-varying patterns that may correspond to gradual increase of process anomalies or the incipient stage of faults, which is useful for proactive process monitoring [54]. More specifically, RNNs handle sequential inputs by using the output of a hidden layer from one temporal step as an input to the next hidden layer, allowing networks to learn and perform complex data transformations over long ranges of timesteps [55]. Due to the diminishing target problem in traditional RNNs when learning long-term dependencies, Long Short-Term Memory neural networks have become effective approaches for fault detection among RNN architectures [56]. Their advanced gating functionalities (input, output and forget gates) are what makes it possible, wherein input gate helps them in remembering past states and forget gate enables them to forget the state [57]. The specialized neural network architecture of Long Short-Term Memory (LSTM) networks overcomes the limitations of traditional RNNs regarding long-term dependencies.

LSTM networks are designed with memory cells and gate variables that enable them to keep significant information over longer time spans, as well as skip out on irrelevant details. In chemical processes, this ability is crucial to detect abnormalities where deviations could occur gradually or have a time-lag feature. In particular, the insertion of input, output and forget gates in LSTMs allows them to learn which features are important temporal behavior that needs to be retained in their memory cells, which significantly enhances reliability and accuracy where it comes to fault diagnosis. Figure 8 depicts the receiving of raw data from measurement signals to online processing and then uses a PdM analysis to detect, locate, and predict faults in rotating machinery systems [58]. This architecture enables LSTMs to mitigate the vanishing gradient issue that traditional RNNs face, helping to retain important information from time steps in earlier training cycles [59-61]. The internal memory and gating mechanisms allow RI-GECRs to capture long-term temporal dependencies much more effectively due to greatly enhanced gradient flow [62].

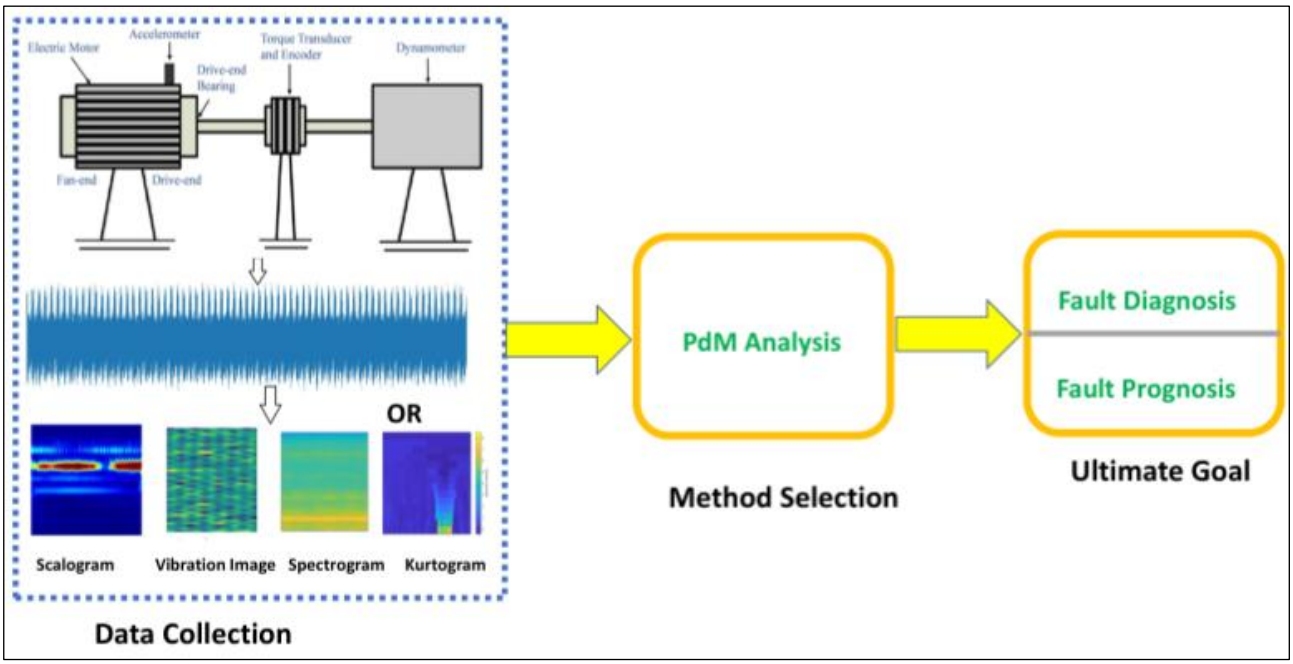

Figure 8: Predictive Maintenance Framework for Fault Diagnosis and Prognosis Using Vibration Signal Analysis. Source: [58].

Hybrid architectures, such as CNN–LSTM combine the strengths of both structures by using CNNs for spatial feature extraction and LSTMs for the temporal analysis. These models are based on the integrated approach, which can facilitate successful and effective detection of fault dynamics and time-delay effects in process and provide greater accuracy and reliability to monitoring systems. Although standard RNNs have demonstrated success in various tasks, challenges like vanishing or exploding gradients during the training process can significantly limit their performance with sequences of longer length [63], [64]. These limitations can be addressed with more advanced RNN variants, such as long short-term memory (LSTM) networks and Gated Recurrent Units, which use complex gating mechanisms to control information flow in the model more effectively, improving their ability to fit time-series data with long-range dependencies [65]. LSTMs specify an input gate, a forget gate and an output gate to regulate the transport of information which enables them to selectively save and recall information over long periods [66], [67]. This unique architecture allows LSTMs to remember important information over long sequences and avoid vanishing gradient problems, which often limit the effectiveness of traditional RNNs in learning long-term dependencies [68-70]. The forget gate decides what will be thrown away from the previous cell state, the input gate decides what new information should be saved in this cell, and the output gate controls what is sent to hidden state [71].

III.4 HYBRID DEEP LEARNING MODELS

To effectively model the complexity of chemical processes, recent trend in process monitoring is to adopt hybrid deep learning models that combine various architectures. These approaches typically integrate the advantages of various methods to incorporate both spatial and temporal features associated with process data. A common approach is to utilize CNN–LSTM frameworks for deriving spatial–temporal features, where convolutional layers capture local correlations and LSTM units model time-dependent dynamics. These combined strengths harness the CNN's ability to extract features in a hierarchical manner, along with LSTM's ability to learn long-range temporal dependencies, resulting in the establishment of a strong mechanism for decoding complex fault signatures from intricate process dynamics [72]. Additionally, kernel deep learning has been introduced in soft sensor context with hybrid variable-wise weighted stacked autoencoders [73]. Another potential direction of development related to emission monitoring systems can be found at the crossroads between explainable artificial intelligence (AI) and deep learning, aiming for more transparent and reliable algorithms catering to emissions-sensitive processes [74]. These hybrid methods typically combine anomaly detection and fault classification, employing aggregated feature representations resulting in higher diagnostic accuracy than standalone models. RRNNs help understand the spatio-temporal aspects of environmental data [75], hence, are suitable to develop hybrid deep approaches by aggregating CNN with RNN or LSTM for accurate detection and prediction of fault in complex industrial processes.

Likewise, hybrid systems such as Autoencoder–LSTM facilitate feature extraction and predictive functionality simultaneously, enabling early fault anomaly detection from learned data representations. Graph Neural Networks have also received attention in modeling process topology, where the connections between different units or variables are considered as interconnected nodes, providing a broader view of inter-system interactions. It has been shown that hybrid CNN-LSTM networks can achieve a better result about anomaly detection and fault prediction tasks in industrial applications on the premise of modeling both spatial and temporal information [76]. This is especially apparent in hydraulic systems, where integrated CNN and LSTM architectures outperformed traditional methods for anomaly detection [77]. Integrated frameworks which merge CNN, Autoencoders and LSTM network have shown improved performance on multi-class fault classification tasks. These diverse hybrid methods enhance feature extraction, improve detection accuracy, and rarefaction of a fault diagnosis more accurately in complex chemical processes.

III.5 ATTENTION MECHANISMS AND GRAPH-BASED MODELS

Attention mechanisms and graph based deep learning structures have also been integrated into these advanced models, highlighting their strengths in accurate fault detection and diagnosis for chemical processes. Attention mechanisms allow the model to exploit different importance levels of process variables by focusing on more significant features for fault identification. This weighted force fitting aids model interpretability and helps to emphasize which features contribute most towards unexpected behavior. To illustrate, Dual-Stage Attention RNN architectures can learn input-level attention weights as well as temporal attention weights simultaneously, allowing highlighting of relevant features and significant time steps while forecasting [78]. Likewise, the channel–spatial attention method can improve feature importance as well as reduce noise in CNN-LSTM for real-time sensor fault detection [79]. Additionally, the combination of these attention mechanisms with LSTMS allows us to forecast future patterns of important variables, providing good early prediction results in several fault cases [80]. Instead of focusing on a single feature among many, attention can be incorporated into hybrid deep learning architectures that dynamically emphasize important features for better risk recognition under changing operational scenarios [81]. This flexibility allows them to perform especially well in settings with skewed datasets, a frequent occurrence within fault identification approaches [82]. Graph-based approaches, including popular paradigms like Graph Neural Networks, show great potential in modeling the complex relationships between various process variables and sensors throughout a chemical plant. A four-stage approach of understanding the data, learning patterns, diagnosing faults and finally taking maintenance actions is shown in figure 9 which enhances reliability and performance levels of a system [83].

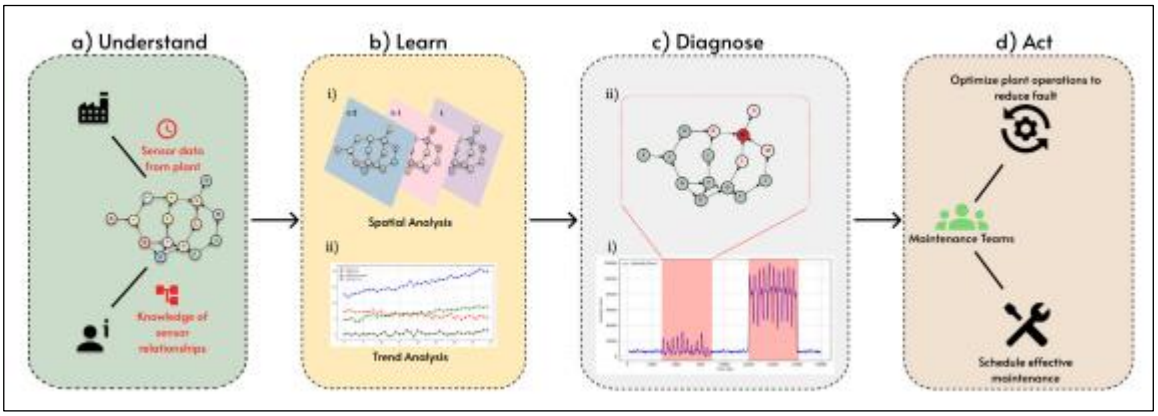

Figure 9: AI-Based Predictive Maintenance Workflow: From Data Understanding to Maintenance Action. Source: [83].

This is an approach where the process is represented with graph models (a network of interconnected nodes and edges), and each node corresponds to a specific process variable or unit. These representations can effectively capture the complexities of relationships and interactions in the system. Graph Attention Networks (GAT) introduced attention heuristics along with the underlying graphical structures to better learn the spatial and temporal dependencies between variables in input data. At a deeper level, tailored graph neural networks such as EG-SAGCN further modify edge weights and use spatial attention to better learn local and global relationships in sensor networks [84]. This enables a more detailed understanding of how disturbances diffuse over interlinked systems. Considering their capability of naturally model relationships between entities, a characteristic that suits well for property modeling [85] and addresses challenges in traditional descriptor-based methods. In Table 3, a consolidated comparison of various prominent deep learning architectures tailored for fault detection in chemical process systems is provided, specifying their learning modes, characteristics and applications. It shows how different models based on data patterns can systematically improve the accuracy and reliability of detection using spatial, temporal, and relational patterns in process data.

Table 3: Deep Learning Techniques for Chemical Process Monitoring and Fault Detection.

Technique	Model Category	Learning Type	Key Application	Data Type	Key Features	Advantages	Limitations	Typical Use Case
Autoencoder (AE)	Neural Network	Unsupervised	Anomaly detection	High-dimensional	Reconstruction error	Detects unknown faults	Low interpretability	Industrial monitoring
Stacked Autoencoder (SAE)	Deep NN	Unsupervised	Feature extraction	Complex data	Hierarchical learning	High accuracy	High complexity	Missing data cases
CNN	Deep Learning	Supervised	Fault classification	Multivariate	Spatial features	High accuracy	Needs large data	Sensor systems
RNN	Deep Learning	Supervised	Time-series analysis	Sequential	Temporal modeling	Captures dynamics	Vanishing gradient	Process monitoring
LSTM	Advanced RNN	Supervised	Fault prediction	Time-series	Memory gates	Handles long-term data	High computation	Dynamic systems
CNN-LSTM	Hybrid	Supervised	Spatio-temporal	Time-series	Combined features	High reliability	Complex model	Real-time monitoring
Attention Model	Advanced DL	Supervised	Feature importance	Large datasets	Variable weighting	Better interpretability	Training complexity	Fault diagnosis
GNN	Graph-based	Semi-supervised	System modeling	Network data	Node relations	Captures dependencies	Complex implementation	Large plants

Source: Authors (2026).

The only existing effective methods are those that enhance spatiotemporal feature learning, promote diagnosis capability, and contextualize root cause analysis by identifying the most relevant variables and their interactions which make them increasingly suitable for complex large-scale chemical process systems.

IV. APPLICATIONS IN CHEMICAL PROCESS INDUSTRIES

Figure 10 summarizes the Tennessee Eastman Process (TEP) as a standard system for testing fault detection models with industrial real applications in processes such as petrochemical, polymer, pharmaceutical and wastewater. It emphasizes the primary advantages of deep learning — early fault detection, predictive maintenance, enhanced process safety, and efficient root cause analysis.

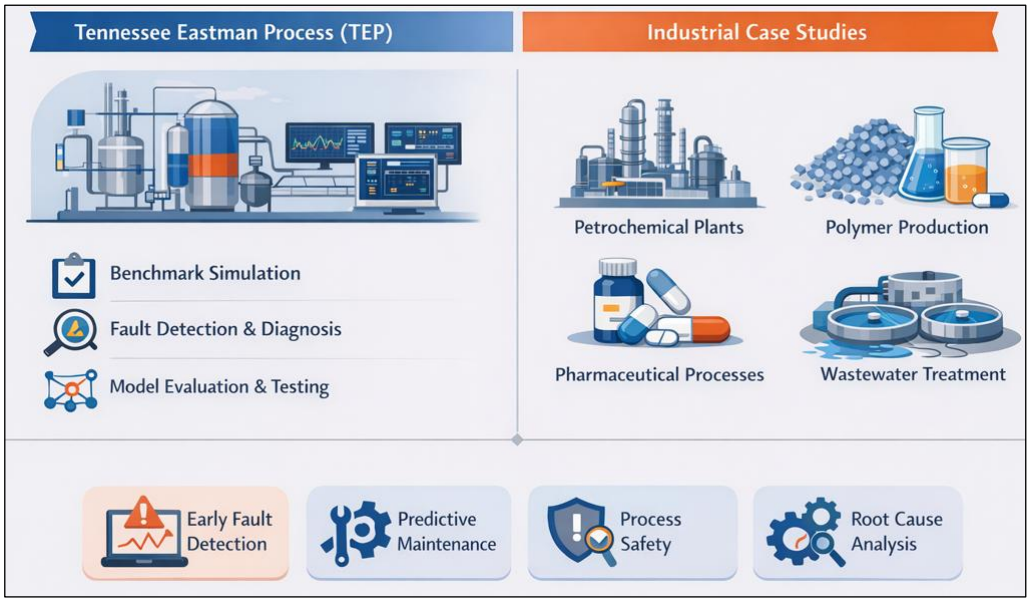

Figure 10: Applications of Deep Learning in Chemical Process Industries.
Source: Authors (2026).

IV.1 TENNESSEE EASTMAN PROCESS (TEP)

The Tennessee Eastman Process is one of the most widely used benchmark systems for process monitoring and fault detection techniques. It reflects a real industrial chemical process including complex reactions, recycle streams and multivariable control structures. Due to its nonlinear and dynamic characteristics, it can provide a test platform for advanced data-driven as well as deep learning-based methods validation. The dataset provides intact operation as well various fault cases that are very important to evaluate performance of a model in detection and diagnosis task, allowing standardized comparisons among different techniques. State-of-the-art results in the context of fault diagnosis on the Tennessee Eastman Process dataset have been reported for advanced GNNs (including with learnable adjacency matrices) over classical recurrent neural networks. As illustrated in figure 11 [86], an abnormal condition is detected based on analysis of these multi-sensor signals, as well as a specific type of fault is classified using a diagnostic model.

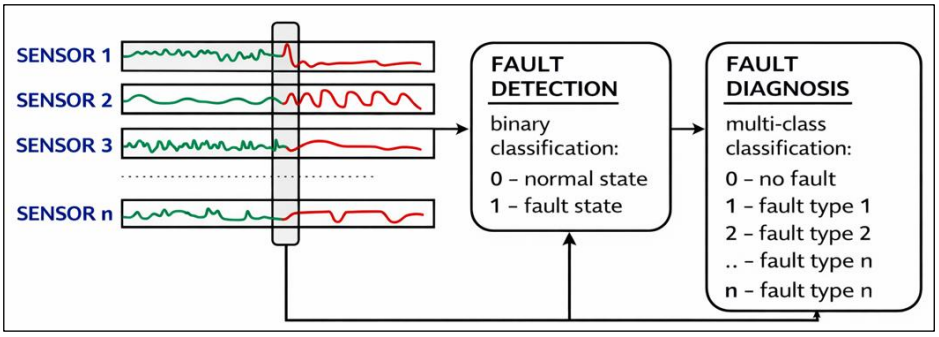

Figure 11: Sensor-Based Fault Detection and Diagnosis Framework.
Source: [86].

This is due to their capability of modeling complex spatial correlations and inter-relational dependencies among the variables that the process encompasses [87]. Yet the continuously changing relations between time series and different operational conditions are still challenging to model [88]. This indicates a need for further explorations to design GNN architectures that can flexibly respond and capture such changes, possibly via employing temporal graph learning methods or integrating physics-informed constraints to improve the generalizability across different operational scenarios [89], [90]. TEP is run over multiple different indicative operating conditions and predefined fault cases, allowing for the systematic evaluation of fault detection and diagnosis algorithms. This benchmark is widely used by researchers to assess model performance across detection accuracy, false alarm rate, robustness under noise and uncertainty. For example, a recent work proposed the new Twin Transformer architecture combined with the Gated Dynamic Learnable Attention mechanism to improve detecting and diagnosing different faults, trained on Tennessee Eastman Process Dataset independently process input data while dynamically adapting attention strategies [9]. Big advantages in accuracy and reliability of fault detection have been shown using deep learning applied to Tennessee Eastman Process. By employing techniques like autoencoders, CNNs, and hybrid architectures that can capture complex patterns inherent in the process data, these approaches have shown improved robustness and generalization by effectively handling multiple fault scenarios.

IV.2 INDUSTRIAL CASE STUDIES

Deep learning-based fault detection methods have been successfully applied to a wide variety of industrial chemical processes. These techniques are used in petrochemical plants and refinery operations to monitor complex reaction networks and dynamic separation units that feature multiple interacting species. Deep learning models are used to monitor reaction parameters for product quality in polymer production. In pharmaceutical processes, they are similarly valuable in providing necessary quality assurance by quickly finding anomalies in batch operations and continuous manufacturing systems. These applications exploit the ability of deep learning to handle high dimensional sensor data, allowing them to detect subtle anomalies that may propagate into significant equipment failures or excursions early, providing operational safety and efficiency. In addition, the use of deep learning in these industrial contexts has contributed to decreased unscheduled downtime and improved resource utilization by enabling proactive maintenance scheduling. Thus, this positive approach is significant in improving overall reliability and economic performance of the system. The efficacy of these approaches on features fusion and ensemble learning underscored that these methods have also been extensively validated to real-world datasets collected from industrial facilities such as wastewater treatment plants in which they are shown superior fault detection performance over single model-based setups [91-97]. There are many practical benefits of incorporating deep learning into process monitoring systems. It allows fault detection as early as possible by recognizing small changes in process behavior before these turns into serious failings. Forecasting equipment degradation and scheduling maintenance interventions can lead to improved predictive maintenance strategies that lower downtime and maintenance costs. It also makes process safety even better, since advanced models can detect abnormal conditions in real time and initiate preventive measures. Additionally, deep learning systems enhance the ability to conduct effective root cause analysis by identifying individual outlier occurrences along with their causative factors, thus allowing for continuous enhancement of chemical process operations [98-100]. Data-driven strategies are crucial to tackling the intrinsic complexities of chemical processes, where dynamic and non-linear interactions make it hard for conventional modelling approaches [101]. Table 4 provides a summary of various industrial applications for deep learning in chemical processes, including faults detection and monitoring, as well as operational efficiency improvement.

Table 4: Applications for Deep Learning in Chemical Process Industries.

Application Area	Process Type	DL Technique Used	Key Function	Benefits
Tennessee Eastman Process	Benchmark system	AE, CNN, LSTM	Fault detection	High evaluation accuracy
Petrochemical Plants	Continuous process	CNN, RNN	Process monitoring	Improved safety
Refineries	Separation units	CNN–LSTM	Fault diagnosis	Reduced downtime
Polymer Production	Reaction systems	Autoencoder	Quality monitoring	Product consistency
Pharmaceutical Industry	Batch process	LSTM, RNN	Anomaly detection	High precision
Wastewater Treatment	Environmental systems	Ensemble DL	Fault prediction	Better reliability
Smart Manufacturing	Industry 4.0	Hybrid DL	Predictive maintenance	Cost reduction
Cyber-Physical Systems	Automated plants	GNN, Attention	Fault & attack detection	Enhanced security

Source: Authors (2026).

In today's Industry 4.0 settings, the scope of deep learning-based approaches goes beyond typical monitoring tasks to recognize unseen defects and provide alerts for possible cyber threats in industrial control systems. This ability is critical for safe, reliable function within highly automated and interconnected chemical process industries.

V. ADVANTAGES OF DEEP LEARNING IN PROCESS MONITORING

Deep learning can hold significant benefits in process monitoring due to its ability to deal with nonlinear and high dimensional data, which are often encountered in complex industrial processes. It can automatically derive the stimulus-relevant feature from raw sensor data, thus removing the manual feature engineering step and lessening reliance upon domain-specific preprocessing unlike traditional methods. It reduces the number of false positives with deep learning models able to learn fine-grained differences and latent features in process data. Furthermore, these methods assist in near-real-time monitoring where persistent analysis of streaming data helps in timely abnormality detection. In predictive maintenance, deep learning can use raw sensor data to detect early signs of equipment failure and predict impending failures. Thus, deep learning methods outperform traditional ones in capturing dynamic connections and underlying processes.

VI. CHALLENGES AND LIMITATIONS

While deep learning has significant potential for chemical process monitoring, several practical challenges hinder its broad industrial application. These have to do with problems concerning data availability, interpretability of models, computational demands and suitability across processes. Since this technique is still in its initial phases, knowing its limitations will help avoid the implementation pitfalls and provide directions for developing efficient and robust fault detection systems.

VI.1 DATA-RELATED ISSUES

One of the significant challenges to applying deep learning in monitoring chemical processes is data. Labeled fault data are limited in many industrial settings because faults happen rarely and do not follow any systematic documentation. For supervised learning, this results in a lack of training samples. Moreover, the datasets usually are heavily imbalanced where there is more amount of normal operating data than faulty conditions available which leads to models being biased towards normal predictions. Dealing with missing, incomplete and noisy sensor data introduces additional complexity in developing a model that accounts for the reliability and accuracy of feature extraction and learning processes.

VI.2 INTERPRETABILITY

Many deep learning systems are black boxes in nature, meaning they do not lend themselves to easy interpretation of internal workings or decisions. The present absence of such insight is particularly limiting in safety-critical industries like chemical processing, where knowing not just that a fault occurred but why it can be crucial. Due to the limited ability of such models to explain themselves, engineers and operators may be reluctant, if not downright fearful, to rely on them — especially in high-stakes environments that mandate very stringent regulatory compliance and accountability.

VI.3 COMPUTATIONAL COMPLEXITY

The implementation of deep learning models involves significant computational requirements. Training complex architectures, such as deep neural networks, requires high processing power and long training times, particularly when dealing with large-scale industrial datasets. In addition, these models typically require extensive datasets to achieve high accuracy, which may not always be available in real-world applications. This increases the cost and complexity of deployment in industrial settings.

VI.4 GENERALIZATION

Generalization remains a critical issue in deep learning-based fault detection systems. Models trained on a specific process or dataset may not perform effectively when applied to different processes due to variations in operating conditions, system configurations, and process dynamics. This limits the scalability and adaptability of such models across different industrial applications, requiring retraining or fine-tuning for each new environment.

VII. FUTURE RESEARCH DIRECTIONS

To address current constraints and improve the performance of those deep learning models, researchers are focused on novel methods and high-performance computer technologies. Future works will surely focus on enhancing the explainability of such models, decreasing dependency on annotated content, and coupling intelligent systems with modern industrial architectures. This will greatly enhance the robustness and practical reliability of deep learning within chemical process monitoring.

VII.1 EXPLAINABLE AI (XAI)

Explainable Artificial Intelligence is emerging as a critical research direction to address the lack of transparency in deep learning models. By incorporating XAI techniques, it becomes possible to interpret model predictions and understand the underlying reasoning behind fault detection and diagnosis. This improves trust and acceptance of AI systems in industrial environments, particularly in safety-critical chemical processes. In addition, explainability supports informed decision-making by providing engineers with actionable insights rather than only prediction outputs.

VII.2 TRANSFER LEARNING AND FEW-SHOT LEARNING

Transfer learning and few-shot learning approaches offer promising solutions to the challenge of limited labeled data in industrial applications. These techniques enable models trained on one process or dataset to be adapted to another with minimal additional data. This reduces the need for extensive data collection and labeling efforts. Such approaches are especially useful in chemical industries where fault data are rare, allowing models to generalize knowledge across different plants and operating conditions.

VII.3 INTEGRATION WITH INDUSTRY 4.0

The integration of deep learning with Industry 4.0 technologies is expected to significantly enhance process monitoring and fault detection capabilities. The use of IoT-based systems enables real-time data acquisition from sensors and equipment, facilitating continuous monitoring. Digital twins provide virtual replicas of physical systems, allowing real-time simulation, prediction, and optimization of process performance. Edge computing further supports rapid decision-making by processing data closer to the source, reducing latency and improving system responsiveness in industrial environments.

VII.4 SELF-SUPERVISED AND UNSUPERVISED LEARNING

Self-supervised and unsupervised learning methods are gaining attention as they reduce the dependency on labeled datasets. These approaches allow models to learn patterns and representations directly from raw data, making them suitable for large-scale industrial applications where labeled data are limited or unavailable. By leveraging unlabeled data, such methods enhance scalability and enable more efficient deployment of intelligent monitoring systems across diverse chemical processes. Deep learning has significantly transformed chemical process monitoring and fault detection by enabling accurate, data-driven analysis of complex industrial systems. Techniques such as autoencoders, CNNs, and LSTMs provide improved detection accuracy and adaptability compared to traditional approaches. Despite challenges related to interpretability and data availability, ongoing research in explainable and hybrid models is addressing these limitations. Future advancements integrating deep learning with Industry 4.0 technologies will further enhance the reliability, safety, and efficiency of chemical process industries.

VIII. CONCLUSION

Deep learning has emerged as a highly effective approach for chemical process monitoring and fault detection, offering clear advantages in handling nonlinear, high-dimensional, and dynamic industrial data. Techniques such as autoencoders, convolutional neural networks, recurrent neural networks, and hybrid architectures have demonstrated strong capability in extracting meaningful features, identifying subtle anomalies, and improving fault classification accuracy. These models significantly outperform conventional statistical and model-based methods, particularly in complex systems such as the Tennessee Eastman Process and real industrial environments. The study also highlights that deep learning enables real-time monitoring, early fault detection, and predictive maintenance, thereby improving process safety, reliability, and operational efficiency. Despite these strengths, several practical challenges remain, including limited labeled data, model interpretability, computational requirements, and generalization across different processes. Addressing these issues is essential for large-scale industrial adoption. Recent research trends indicate that the integration of explainable AI, transfer learning, self-supervised learning, and Industry 4.0 technologies will play a critical role in advancing this field. These developments are expected to improve model transparency, adaptability, and scalability across diverse industrial applications. Overall, deep learning-based process monitoring represents a transformative direction for modern chemical industries, supporting intelligent decision-making and enabling safer, more efficient, and data-driven operations in increasingly complex manufacturing environments.

ABSTRACT

The rapid growth of the population has resulted in extensive land use and a notable expansion of construction activities on problematic soils. Arid and semi-arid regions in southern Algeria have witnessed significant urbanization and infrastructure development. These areas are generally characterized by unsaturated surface deposits and deep groundwater levels, allowing soils to remain unsaturated to considerable depths for long periods. Under the influence of climatic cycles and repeated wetting–drying processes, soils progressively develop their microstructure, hydraulic characteristics, and consequently their physical and mechanical properties.Recent studies have shown that soil-water retention curves (SWRC) are effective tools for characterizing the stress state of unsaturated soils, describing their hydromechanical behavior, and estimating their strength parameters. The aim of this research is to characterize these soils and examine the additional shear strength resulting from suction variations, as well as the influence of soil compaction on the collapse mechanism. Soil samples were collected from the Metlili Valley, an arid region located southwest of Ghardaïa. The findings reveal significant volumetric changes caused by suction reduction. Furthermore, an increase in suction enhances shear strength, mainly due to the rise in apparent cohesion associated with capillary effects.

I. INTRODUCTION

Under the effect of population growth in recent decades, the arid and semi-arid regions in the South of Algeria have experienced significant urban development and the construction of civil engineering structures. The soils in most of these regions are superficial unsaturated aeolian deposits, unconsolidated, and characterized by a well-developed pore space over a significant depth. Such deposits are known as collapsible soils [1-4] that exhibit significant volume reductions due to the simultaneous variation of their water content and matric suction resulting from repeated climatic cycles of wetting and drying. This phenomenon of alternating variations in moisture and suction can cause multiphysical problems for civil engineering structures [5–8]. It is therefore important to properly understand these phenomena and to implement resilient geotechnical design measures and approaches for reliable risk prevention [9-11]. A Previous research work [12], [13] has highlighted the effect of initial suction on the mechanical properties and strength parameters of unsaturated soils, particularly in the arid and semi-arid climatic context. Several authors have emphasized that the hydromechanical behavior of unsaturated soils is very complex under the combined effect of suction and water content. The effect of the initial state of unsaturated collapsible soils on their mechanical behavior and strength parameters, particularly in terms of density, water content, and matric suction, has been studied by several researchers [14-17], among others. The analysis of the matric suction properties of unsaturated collapsible soils in the study area remains one of the most significant factors in research on their hydromechanical behavior. More recent studies have indicated that the linear correlation between shear strength and matric suction is not relevant for all soil types and for the entire suction range [18]. In this study, a set of laboratory tests were carried out on soil specimens to analyze the simultaneous effect of the variation of matric suction, compaction state, and water content on the collapse potential and the mechanical characteristics of the tested soils.

The obtained results highlight the relationship between matric suction and collapse potential, as well as the parameters affecting shear strength.

II. MATERIALS. EQUIPMENT AND TESTS

II.1 STUDY AREA

The studied soil was extracted from the Metlili region, located 45km south of the city of Ghardaia in the Northern Algerian Sahara at 32.17°N latitude and 3.32°E longitude, with an average site elevation of 454 meters Figure 1. Climate is considered one of the important factors in the formation and evolution of the soil's geotechnical characteristics. Indeed, the seasonal fluctuations in temperature and precipitation in the studied area illustrate its marked desert climate, characterized particularly by low and irregular rainfall. Given the climatic conditions, the study region is classified as an arid zone according to its aridity index, which is a useful indicator for characterizing this phenomenon.

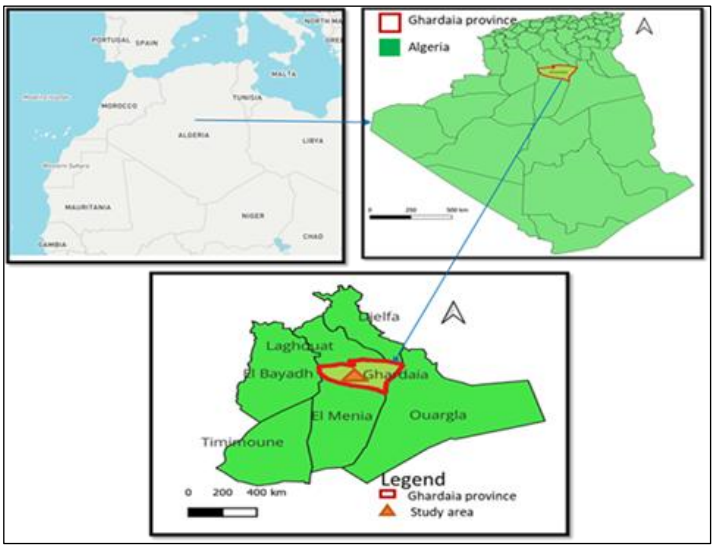

Figure 1: Localization of the study area map of Ghardaia, Algeria.
Source: Authors, (2026).

Geological studies indicate that the study area is incised into the Turonian limestone massifs and is characterized by four geological layers: Quaternary, Turonian, Cenomanian, and Albian. The Quaternary corresponds to the alluvial deposits covering the Metlili Valley. The Quaternary alluvium consists of sands, pebbles, and clays lining the valley floor with a thickness ranging from 20 to 30 meters. The Cenomanian is characterized by variegated clays that range in color from brown and grayish to greenish. These clays are plasticized and sandy at the base, with gypsum present. The Albian is made up of fine to medium yellowish sands, Figure 2.

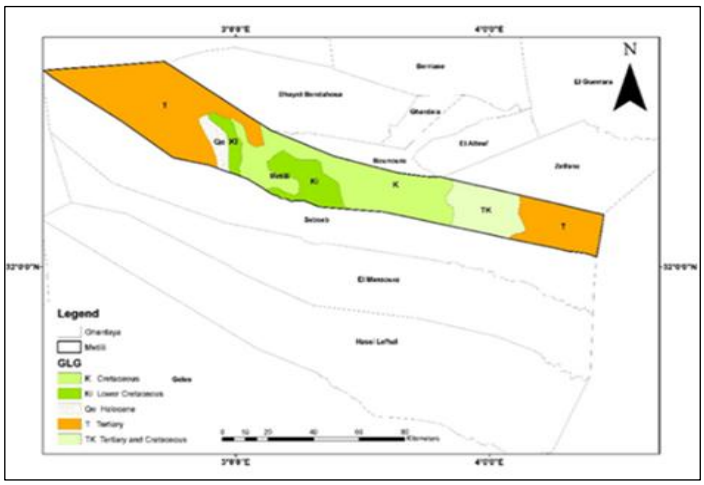

Figure 2: Simplified geological map of Ghardaia, Algeria.

II.2 MATERIALS

Samples of the studied soil were collected from three different experimental sites at depths ranging from 1.5 to 2 meters in their natural state. For the physical characterisation of the soil, an initial series of traditional tests was carried out in the laboratory to measure the specific gravity of solid particles (Gs), natural water content (w_n), methylene blue value (MBV), Atterberg limits (PL, LL, PI), particle size distribution, and standard Proctor compaction. These tests indicate that the soil exhibits low plasticity properties, the studied soil can be classified as sand loam. The details of geotechnical properties can be found in Table 1.

Table 1: Properties of soils used in this study.

Property	Value
Initial Moisture Content ,w_n (%)	4.5
Spécific Gravity , G_s	2.66
Liquid Limit, LL(%)	24
PlasticLimit ,PL (%)	17
Maximum Proctor Test, γ_d(Mg /m^3)	1.82
Optimum Moisture Content,w_{op}(%)	10.5
Clay fraction (%)	6.5
Silty fraction (%)	38.5
Sandy fraction (%)	55
Calcium carbonate CaCO3 (%)	22.5
Methylene bleu valueMBV	0.42
USCS Classification	SM-SC

Source: Authors, (2026).

Particle size analysis allows for the quantitative determination of the soil particle distribution based on size categories. The studied soils belong to class (A1) according [19]. These materials are characterized by a percentage passing greater than 35% through the 80µm sieve. The methylene blue absorption value is less than 2.5, and the plasticity index is less than 12. The predominance of the sand fraction (55%), the relatively high fines content (45%), and Atterberg limits positioned in the transition zone of the Casagrande chart (PI = 7% and LL = 25%) indicate that this soil is classified as SM–SC according to the USCS system The particle size distribution curves of the samples are presented in Figure 3.

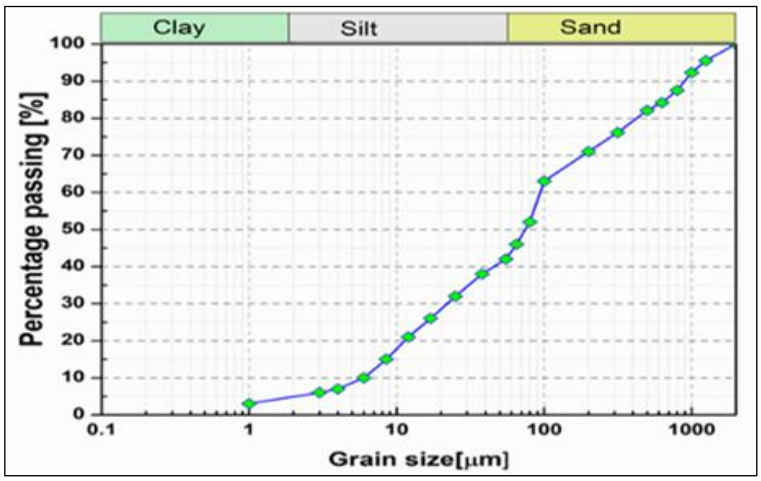

Figure 3: Grain size distribution of studied soil.
Source: Authors, (2026).

Mineralogical analyses were conducted on the studied soil using a BRUKER-binary V3 X-ray diffractometer with Kα radiation (1.5406 Å), operating at 35 kV and 30 mA, with an angular detection range (2θ) from 5° to 90°. This analysis aimed to identify the crystalline structure and mineralogy of the samples. The results of this X-ray analysis are presented as diffractograms (XRD) shown in Figure 4.

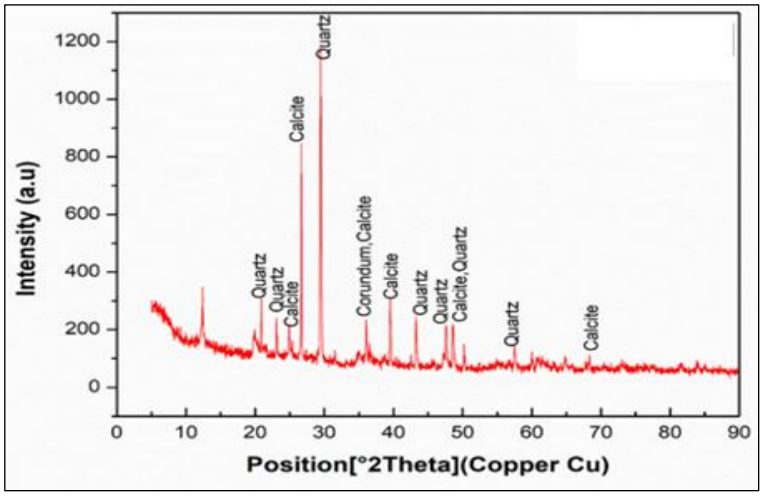

Figure 4: X-ray diffraction pattern of studied soil for mineralogical composition.
Source: Authors, (2026).

The position and intensity of characteristic diffraction peaks enable the identification of different crystalline phases in the studied material, which is primarily composed of quartz. Quartz, known for its chemical stability, promotes a granular texture and increased permeability whereas showing low water retention. The substantial presence of quartz is confirmed by the particle size distribution, indicating a high percentage of sand in the material. Calcite notably influences the chemical and mechanical properties of the soil, enhancing cementation and cohesion. Corundum and other minerals are present in minor proportions. To identify and quantify the chemical elements of the studied soils, a geochemical analysis was performed using an X-ray fluorescence spectrometer (XRF). The results of this analysis are also presented in Table 2.

Table 2: Chemical composition of the studied soil.

Major elements		**Trace elements**	
Oxydes	**Content (%)**	**Oxydes**	**Content (ppm)**
SiO_2	51,45	MnO	59.6
Al_2O_3	21,73	SrO	42,5
CaO	10,58	ZrO_2	28.4
Fe_2O_3	9,41	Cr_2O_3	28.3
K_2O	2,13	V_2O_5	27.1
MgO	2,04	ZnO	15.8
TiO_2	1,69	Rb_2O	10.8
Na_2O	0,33	NiO	7.4
So_3	0,32	Nb_2O_5	5.2
P_2O_3	0,18	Y_2O_3	3.4

Source: Authors, (2026).

The obtained results show high proportions of silicates (SiO_2) 50.4%.The strong presence of quartz is confirmed by the granulometric distribution, which indicates a high percentage of sand in the material. Aluminum oxide (Al_2O_3) 21.7%, calcium carbonate (CaO) 10.6% and iron oxide (Fe_2O_3) 9.41. There is a relative chemical richness in potassium oxide (K_2O) 2.13%, titanium oxide (TiO_2)1.7%, which are detrital chemical elements originating from basement rocks, and relatively low contents of magnesium oxide (MgO) 2.04%.

II.3 PERFORMED TESTS

The experimental program included collapse tests, shear tests, and suction tests. The selection of low water contents and moderate compaction energy for investigating collapsible soils is designed to replicate the loose, metastable structure characteristic of natural conditions in arid regions. This methodological choice is substantiated by the fact that such soils typically exist in a partially saturated state, wherein matric suction exerts a critical influence on their apparent structural stability. The experimental procedure and the parameters selected for each test series, as well as the specific characteristics of each category are detailed in Figure 5.

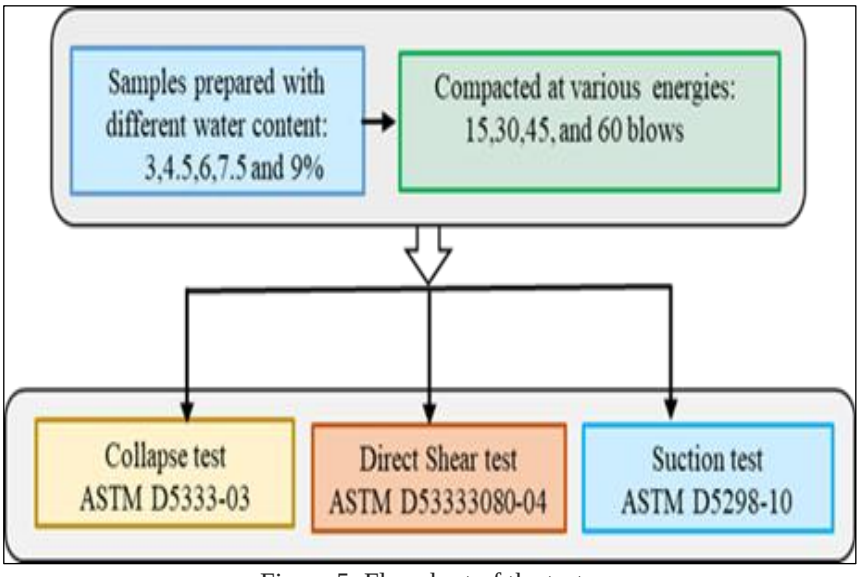

Figure 5: Flowchart of the tests.
Source: Authors, (2026).

The samples of the studied soil are prepared in the laboratory from soil extracted from various sampling sites, presented in block form. The samples are dried in an oven, crushed with a wooden hammer, and then sieved using a 2 mm sieve. To achieve the desired water content, demineralized water is carefully mixed with the samples in different proportions corresponding to the water content values (w = 3%, 4.5%, 6%, 7.5%, and 9%), taking into account the amount of water content lost during preparation. The mixture is then left to cure at a constant temperature and humidity for 24 hours to ensure a homogeneous distribution of moisture.

Then, the soil mixture is poured into an oedometer mold 60 mm in diameter and 20 mm in height and compacted in a single layer using a compaction hammer at different compaction energy levels (15, 30, 45, and 60 blows corresponding to 69, 138, 207, and 276 kJ/m³). The apparatus used for the compaction procedure, designed in the laboratory, is shown in Figure 6. It consists of a disk whose diameter is slightly smaller than that of the ring, fixed to a guide rod, and a disk-shaped hammer.

The hammer weighs 132 g and slides along the rod, falling from a height of 20 cm to strike the disk, thus compacting the material in the oedometer ring. The compaction energy Ec applied to the specimen, which is the work of the mass M (kg) falling from a height h (m), is given by the equation:

$$Ec = \frac{MghN}{V} \quad (1)$$

With M: mass of the hammer, g: acceleration due to gravity, h: drop height of the hammer, N: number of blows, V : Volume of the mold in m³.

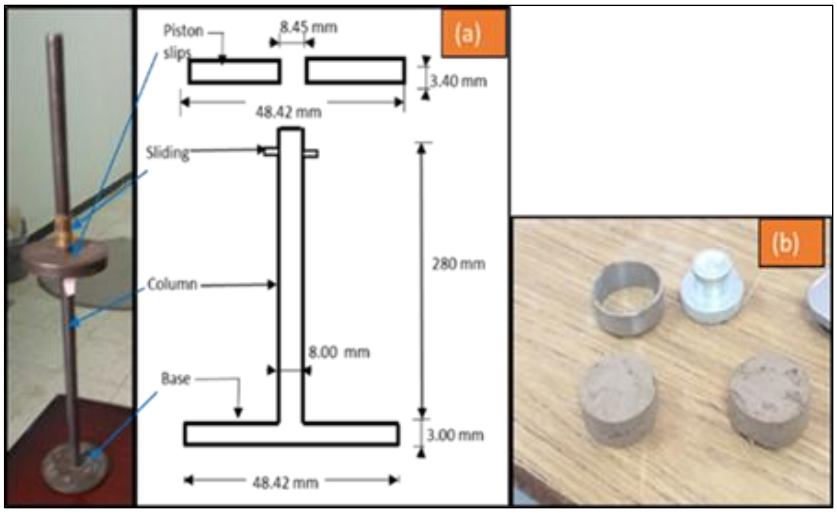

Figure 6: Compaction procedure of the samples: (a) Compaction hammer, (b) Compacted samples.
Source: Authors, (2026).

II.3.1 Collapse Tests

The collapse tests are conducted according to the specifications [20]. The vertical load is applied in the following successive stages: 25, 50, 100, and 200 kPa. To estimate the collapse potential (Cp), the sample is flooded for 24 hours. The collapse potential is determined by measuring the difference in axial deformation at a vertical stress of 200 kPa after and before immersion. Then, the loading is increased to the value of 400 kPa. During the test, the settlements are recorded at 15s, 30s, 1min, 2min, 5min, 10min, 30min, 1h, and 24h. The collapse potential is calculated for each test using the expression.

$$Cp = \frac{\Delta e_c}{(e_0 + 1)} 100\% \quad (2)$$

With $\Delta e_c = e_1$(200 kPa, unsaturated) - e_2(200 kPa, flooded), and e_0: initial void ratio

II.3.2 Shear Tests

Experimental shear tests were conducted on soils samples at various suction and confinement pressures of 100 kPa, 200 kPa, and 300 kPa, in accordance with [21] under drained conditions. A shear box with dimensions of 60 mm x 60 mm with a thickness of 25 mm was used for the tests, which were conducted at a constant low shear rate of 0.3 mm/min throughout the experiment.

II.3.3 Suction Tests

The suction tests conducted in this study used a laboratory method with Whatman filter paper grade No. 42, which allows for measuring matric suction values of up to about 100 MPa, following the specifications in [22]. The wet samples were prepared by adding a specific percentage of distilled water based on their weight. A set of filter papers was dried in an oven for 24 hours before testing. The suction measurement involves placing three filter papers between two soil samples. This setup is designed to prevent contamination of the central filter paper, which is used for measuring suction and has a slightly smaller diameter than the outer two filter papers. To reach hydraulic equilibrium, the assembly is wrapped in plastic film and then kept in a glass desiccator for 15 days. The experimental procedure is illustrated in Figure 7.

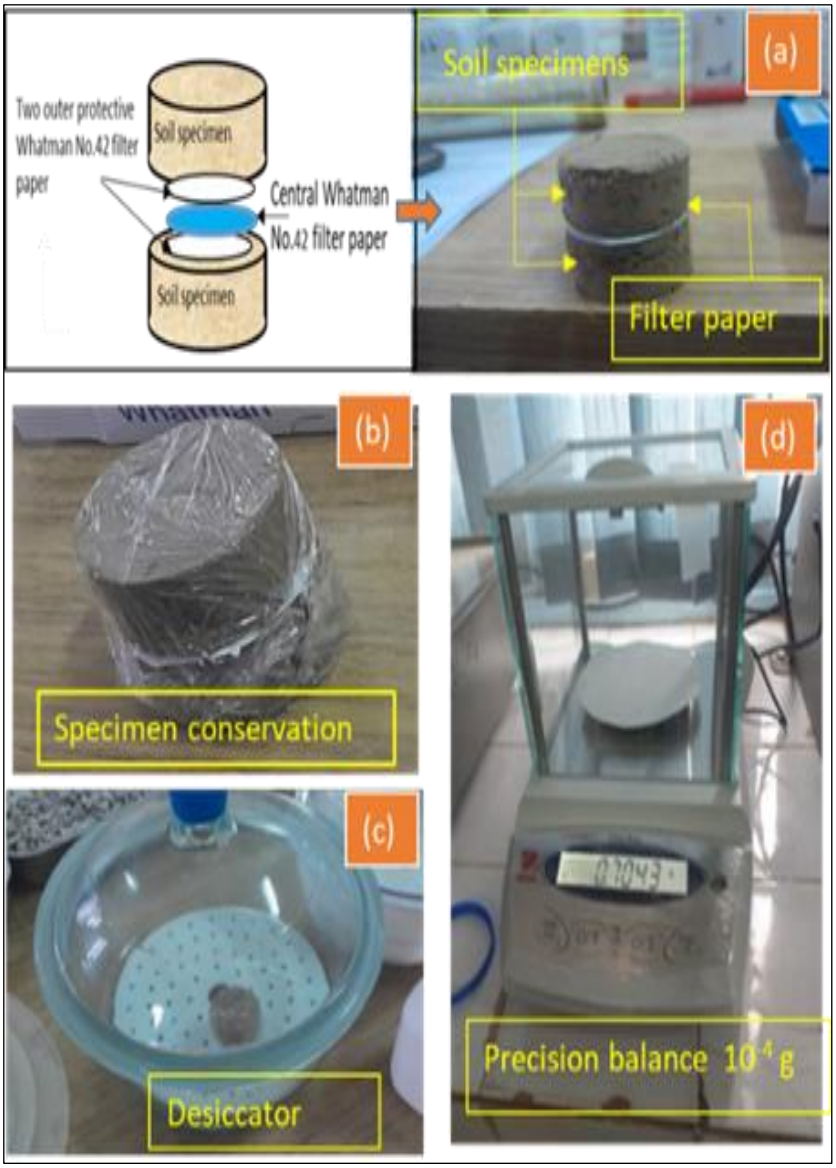

Figure 7: Experimental procedure for suction measurement suction using the filter paper Whitman 42: (a) filter paper interposed between two soil samples, (b) soil samples wrapped in plastic film, (c) suction equilibrium phase, (d) measurement of the weight of the filter paper loaded with moisture.
Source: Authors, (2026).

When equilibrium is achieved between the filter paper and the soil, the gravimetric water content of the central filter paper is measured, from which the matric suction is calculated using the calibration curve described by "(3)" and "(4)", as the suction measurement device

$$Log_{10}S(kPa)=5.327-0.0779w_f \quad w_f>45.3 \tag{3}$$

$$Log_{10}S(kPa)=2.412-0.0135w_f \quad w_f>45.3 \tag{4}$$

Where S is the matric suction, w_f is the gravimetric water content of the filter paper in percentage. The hydro-mechanical behavior is influenced by its water retention characteristics.In this study, the soil-water retention behavior is modelled using the semi-empirical van Genuchten equation [23] as expressed in the (5) below:

$$\boldsymbol{\theta_w = \theta_r + \frac{(\theta_s - \theta_r)}{[1 + (\alpha\, S)^n]^m}} \tag{5}$$

Where :

θ_w : is volumetric water content, θ_r : is residual volumetric water content, θ_s : is saturated volumetric water content,
S: is soil suction, α: is scaling parameter inversely proportional to the mean pore diameter (cm^{-1}), n, m: are the shape parameters of the soil water characteristic. m = (1 − 1/n).

III. RESULTS AND DISCUSSIONS

III.1 COLLAPSIBILITY

Figure 8 illustrate the results of collapse tests conducted on sample soils at different water contents, suction values, and compaction energies.

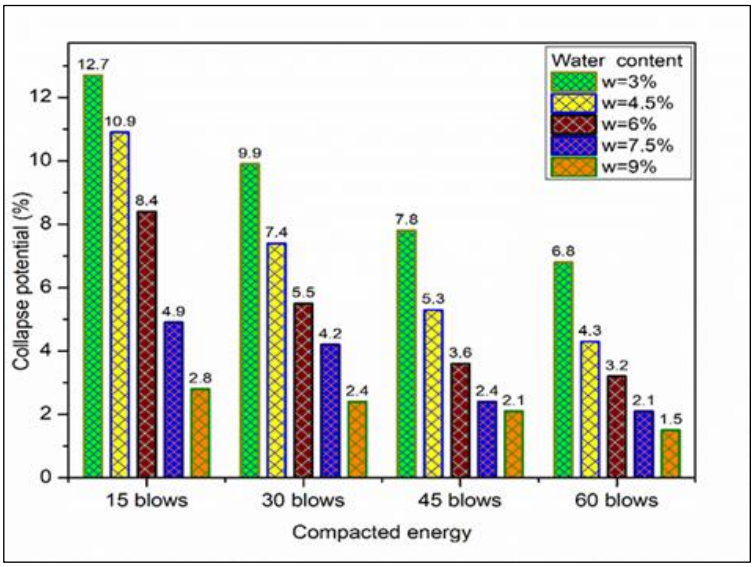

Figure 8: Effect of water content and compaction energy on collapse potential.
Source: Authors, (2026).

The collapsability test results show that water content and compaction energy have a crucial effect on the Cp. This potential decreases from 12.7% to 2.8% for the soil compacted under 15 blows, from 11.4% to 2.4% for soil compacted under 30 blows, from 7.8% to 2.1% for soil compacted under 45 blows and from 6.8% to 1.5% for soil soil compacted under 60 blows. The results indicate that the collapse potential increases as water content and compaction energy decrease. The maximum Cp value is obtained is Cp=12.7%, corresponding to the lowest water content, w=3% and compaction energy of 15 blows. This is explained by the structural instability of the soil, leading to a high Cp. However, the low Cp=1.1% at the highest water content, w=9%, compacted under 60 blows. Under these conditions, the soil is not susceptible to collapse. Figure 9 explicitly shows the effect of suction and compaction energy on the Cp. It is observed that the magnitude of Cp decreases with increasing compaction energy, whereas it increases with higher suction levels, which typically develop during dry periods.

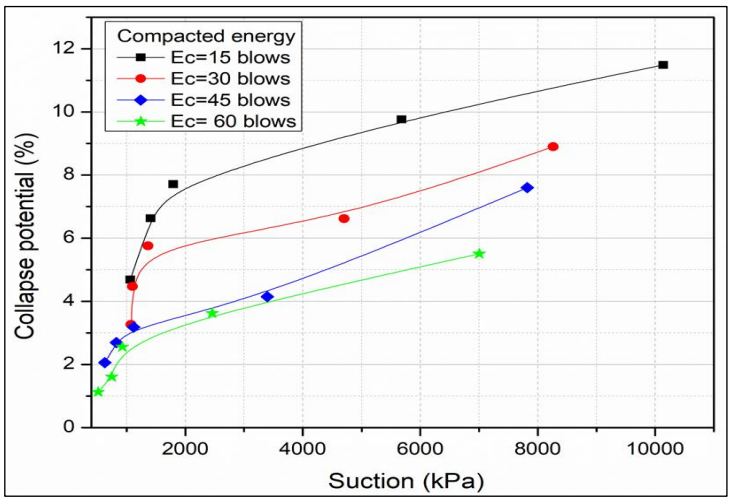

Figure 9: Effect of suction and compaction energy on collapse potential.
Source: Authors, (2026).

III.2 EFFECT ON SUCTION SHEAR PARAMETERS

As for the shear tests, Figures 10 and 11 show that the results yielded low cohesion values, ranging from 12.5 kPa to 26 kPa, due to the low plasticity of the silty sand. For a suction range between 1196.6 kPa and 9678.5 kPa, cohesion varies from 12.6 kPa to 21.5 kPa, representing an increase of approximately 68%. Similarly, for suctions varying between 510 kPa and 6830 kPa, the increase in cohesion is about 35%. This behavior is explained by the enhancement of capillary attraction forces between particles, which gives the soil a more rigid structure and greater strength in the unsaturated state. The influence of suction on the internal friction angle remains limited and is scarcely noticeable, with a variation magnitude between 0.5° and 1.0°.

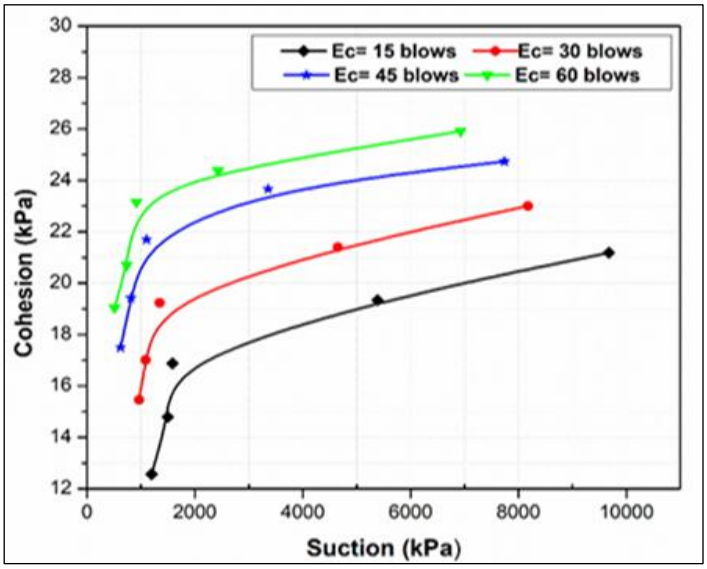

Figure 10: Effect of suction and compaction energy on cohesion.
Source: Authors, (2026).

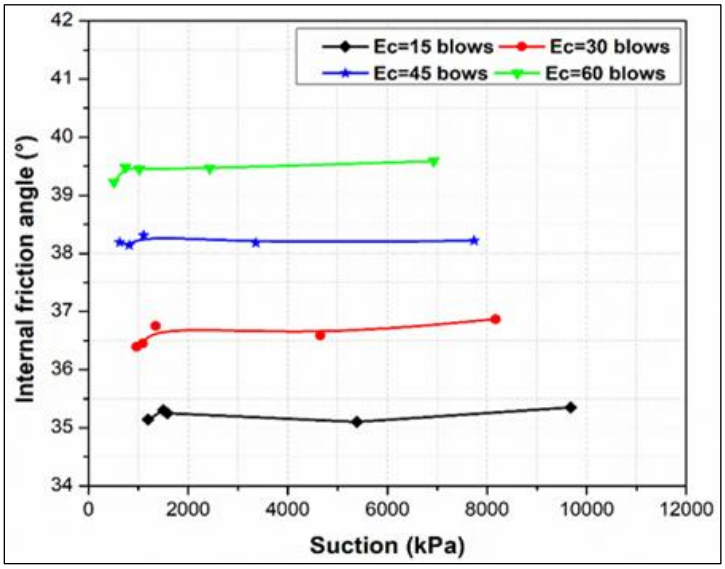

Figure 11: Effect of suction and compaction energy on friction angle.

III.3 SOIL WATER RETENTION BEHAVIOR

The analysis of the soil water retention curve (SWRC) according to the van Genuchten model was performed using the RETC (RETention Curves) software [24]. The water contents predicted by the RETC program are evaluated against the measured values Figure 12.

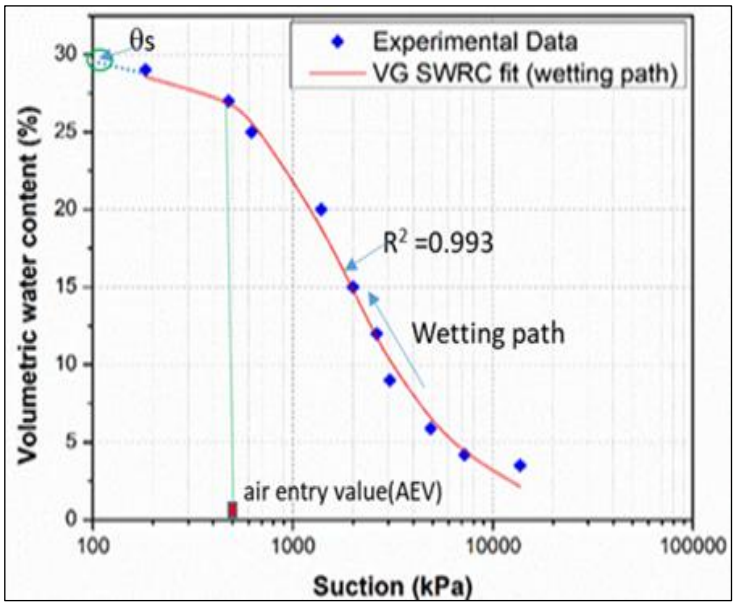

Figure12: Soil-water retention curve.
Source: Authors, (2026).

The evaluation of the fitting performance using the van Genuchten model is provided by the statistical indicators, specifically the coefficient of determination R^2=0.993, and the root mean square error RMSE=0.009. Figure 13 illustrates a strong correlation between the experimental values and the results obtained from the model. The parameters of the Van Genuchten model are used to characterize the hydraulic properties and texture of the soil.The parameter α is related to the air-entry pressure. Lower values of α correspond to higher air-entry pressures (AEV). For the soil studied, α = 0.008 cm^{-1}, which corresponds to an air-entry pressure of 500 kPa. The parameters n and m describe the pore-size distribution, reflected in the slope, and the overall shape of the soil water retention curve, respectively.

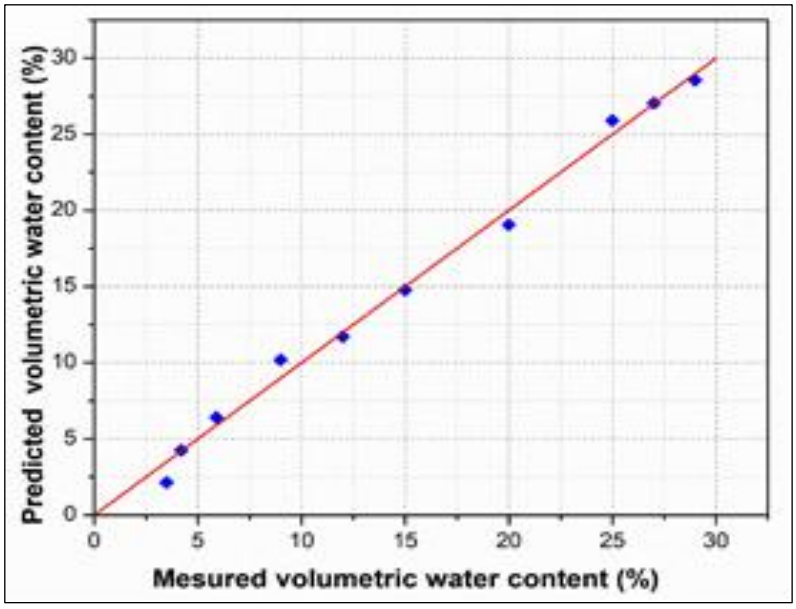

Figure13: Predicted versus measured values of the volumetric water content of the studied soil.

IV. CONCLUSIONS

This experimental research offers insights into the characterization and analysis of the hydromechanical behavior of an unsaturated collapsible soil from the Metlili area in Ghardaïa Province (southern Algeria). The study aims to address existing gaps in knowledge regarding the natural soils of the region. The study also provided information on the behavior of a sandy loam soil with low plasticity under different moisture conditions. The obtained results confirm the effect of suction and capillary stresses on the assessment of the shear strength of unsaturated soils, by varying the compaction state and the interactions between soil particles. Specimens exhibiting high suction and compacted under moderate energy levels recorded the maximum values of collapse potential Cp. This behavior is attributed to the presence of a porous structure and weak interparticle bonds. The study revealed that the internal friction angle was not significantly affected by suction. However, an increase in the apparent cohesion of the soil is observed with an increase in suction. The collapse and shear tests conducted on unsaturated samples with different suction values allowed for the characterization of the collapse and shear properties of the soils studied at different suction levels. The hydraulic behavior of the studied soil, as described by the van Genuchten model, constitutes a relevant tool for hydromechanical studies of unsaturated soils, as it establishes a continuous relationship between water content and matric suction. It represents the different wetting phases, from conditions of high suction to the saturated state.

ABSTRACT

Slurry erosion is an important wear issue in pipelines, pumps, and other industrial equipment that operate in environments where solid particles are transported along with the liquid. In this study, the slurry erosion behaviour of Super 304HCu alloy is examined under different simulated conditions, including slurry velocity, slurry concentration, and time of exposure. The experiments for these investigations are carried out in a slurry erosion test rig at various rotational speeds of 6 m/s, 9 m/s, and 12 m/s, with varying slurry concentrations of 10%, 20%, and 30%. The weight loss of the test specimens was recorded at regular intervals to determine the erosion rate. The experimental results indicate that the weight loss of the material steadily increases with increase in time of exposure, slurry velocity, and slurry concentration. At higher slurry velocities the increase in kinetic energy of the abrasive particles, result in stronger impacts on the material surface and consequently increase material removal. Similarly, the increase in slurry concentration increases the probability of the number of particles interacting with the surface, and accelerates the erosion process. SEM micrographs of the worn surfaces of the specimens revealed typical wear characteristics of erosion of a ductile material.

I. INTRODUCTION

Slurry erosion is a complex wear phenomenon caused by the repeated impact of the solid particles suspended in liquids on material surfaces. This type of wear is commonly encountered in heavy systems such as slurry pipelines, pumps, hydro turbines, mining equipment's, and power plant components [1]. The erosion process involves several material removal mechanisms, such as micro-cutting, plastic deformation, and surface fatigue, which in turn depend on factors such as slurry velocity, slurry concentration, particle size, and angle of impingement [2-10]. In recent years, significant research has been carried out on understanding the tribological wear mechanisms responsible for the slurry erosion and development of materials with improved resistance to such damage. Li et al. investigated the mechanisms of slurry erosion and reported that erosion is strongly influenced by particle velocity and angle of impact. It is also demonstrated that ductile materials tend to experience maximum erosion at oblique angles of impact, typically between 30° and 60°, where micro mechanism such as both cutting and deformation contribute to material loss [11], [12]. Several studies have also focused on the erosion resistance of stainless steels in slurry environments. Examined the slurry erosion characteristics of stainless steels subjected to hot forging and observed that microstructural refinement significantly improved the erosion resistance of the steel [13]. Similarly, investigated slurry erosion of steel in the mining conditions and concluded that slurry velocity and slurry concentration are the most influential factors for material loss. The role of size of the abrasive particle has also been widely explored [14]. Reported that large abrasive particles tend to increase the material loss due to the higher kinetic energy associated with impact of the slurry particles. It also indicated that erosion damage becomes more severe increase in particle size and velocity [15]. In a recent study, on duplex and super stainless steels with superior mechanical properties and enhanced corrosion resistance for slurry handling applications. Reported an experimental investigation on the slurry erosion behaviour of duplex stainless steel using Taguchi optimization and artificial neural network modelling.

It is reported that that slurry velocity and particle concentration have a significant effect on erosion rate, while the angle of impingement plays an important role in determining the wear mechanism [16]. Advanced coatings and surface modification techniques has also been explored to improve erosion resistance. Examined the erosive wear characteristics of boronized martensitic stainless steel and reported that boronizing significantly enhance the hardness and reduces the erosion rate [17]. Similarly, investigated the laser-cladded stainless-steel coatings and reported significant improvement in the cavitation and slurry erosion resistance of the coated steel, due to the refined microstructures and strong metallurgical bonding between the steel and coating. Additive manufacturing and friction stir processing are also been investigated for enhancing the erosion resistance of components [18]. Studied slurry erosion behaviour of additively manufactured steel specimens and reported that optimizing the printing parameters can significantly improve the wear resistance [19]. In a study, by it is demonstrated that friction stir processing with high-entropy alloy reinforcement resulted in improved slurry erosion resistance of stainless steel through grain refinement and increase in hardness [20].Erosion–corrosion behaviour is a much more critical phenomenon affecting the material performance in slurry environments. Fan et al. investigated erosion–corrosion characteristics of desulfurization slurry on stainless steel pipelines and found that the combined action of mechanical erosion and electrochemical corrosion significantly accelerated the material degradation. It also emphasized the importance of selection of corrosion-resistant alloys for components operating in slurry environments. Although considerable amount of research has been carried out on the slurry erosion behaviour of conventional stainless steels and duplex alloys, relatively limited attention has been given to super austenitic stainless steels such as Super 304HCu stainless steel [21]. Therefore, this investigation is necessary to better understand the slurry erosion performance of Super 304HCu alloy under different operating conditions. The current study focuses on evaluating the influence of key erosion parameters such as slurry velocity and particle concentration on the erosion behaviour of Super 304HCu.

II. MATERIALS AND METHODS

The material used in this investigation was super austenitic stainless-steel type Super 304HCu. Rectangular specimens with dimensions of 20 × 30 × 3.5 mm³ were machined from tubes, using a wire-cut Electrical Discharge Machining (EDM) process to ensure precise cutting and dimensional accuracy. After machining, the burrs and oxides present on the specimen edges were carefully removed to obtain smooth surfaces (Figure 1a). The samples were then cleaned with ethanol and subsequently dried before conducting the tests. The particle size of the abrasive particles used in the experiment were silica sand particles ranging from 0.5–1.0 mm. The slurry used for the experiments was prepared with silica sand particles suspended in demineralized water to create an abrasive medium for the test. The slurry erosion experiments were conducted using a slurry pot erosion tester, which allowed controlled circulation of abrasive slurry over the specimen surface. The schematic arrangement of the tester and the dimensions of the pot are shown in Figure 2a and 2b respectively. The specimens were securely mounted in the test chamber using bolts to ensure stable positioning during the experiment as shown in Figure 1b. The angle of impact is kept constant at 90° for all the test conditions to create normal impact conditions.

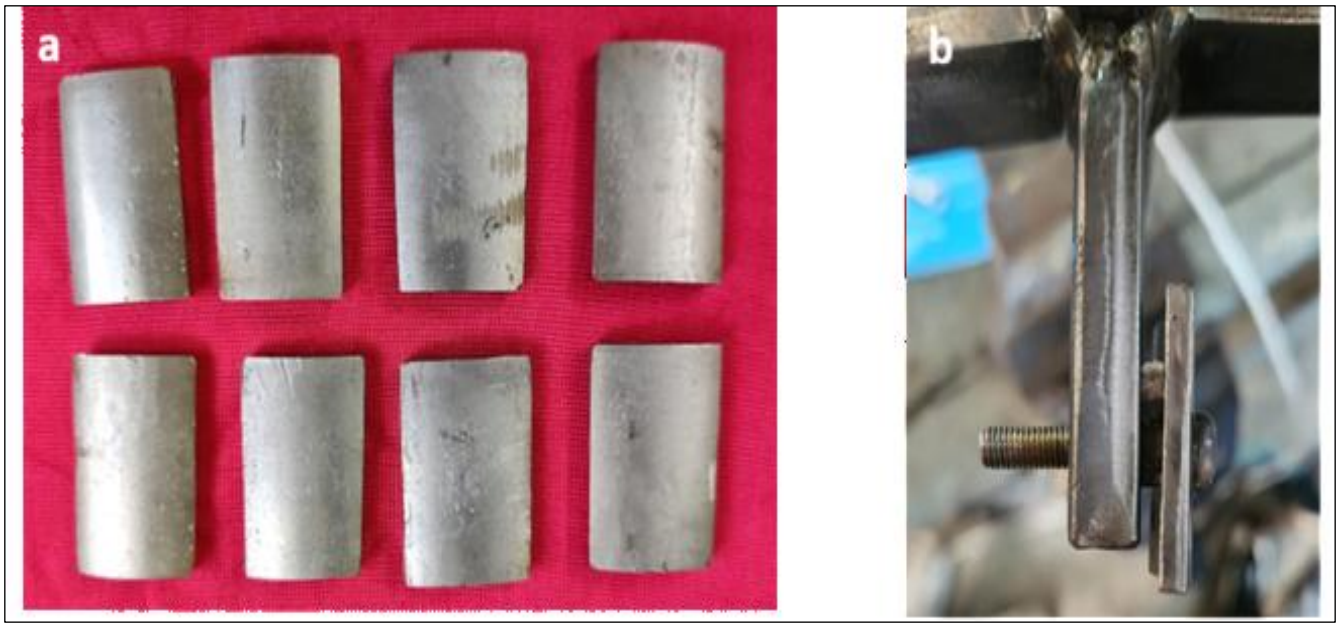

Figure 1: Photograph of (a) machined specimen and (b) specimen mounted on slurry pot test chamber.
Source: Authors, (2026).

In order to evaluate the effect of slurry velocity on Weight loss of Super 304Hcu, the erosion tests were carried out at three different rotational speeds of 1000 rpm, 1500 rpm, and 2000 rpm, (6 m/s, 9 m/s, and 12 m/s) under 30% Slurry Concentration. Similarly, to study the effect of slurry concentration, it is varied as 10 %, 20 %, and 30 % at constant speed of 1500 rpm (9 m/s). Each experiment was conducted for a total duration of 120 minutes, and the weight loss of the specimens was recorded at regular intervals of 20 minutes. The initial and final weight of each specimen was measured using a precision electronic balance. The weight loss of the specimen was calculated as the difference between the initial and final weight.

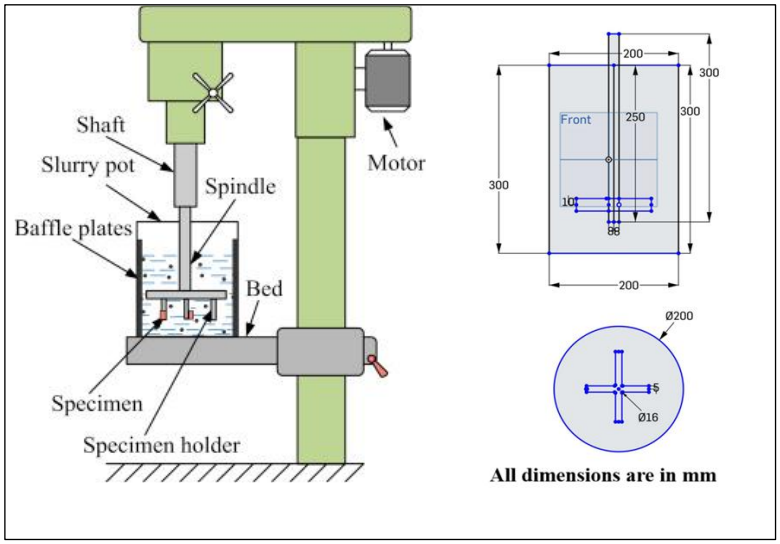

Figure 2: Schematic arrangement of slurry pot tester (a) and dimensions of the slurry pot (b).

III. RESULTS AND DISCUSSION

III.1 EFFECT OF SLURRY VELOCITY ON WEIGHT LOSS

Figure 3 shows that weight loss increases progressively with increase in both exposure time and slurry velocity. At the initial stage of the experiment, the increase in weight loss is relatively moderate. However, as the erosion time increases, the rate of material removal becomes significantly higher. This behaviour can be attributed to the continuous particle impacts that can gradually weaken the surface and accelerate erosion damage.

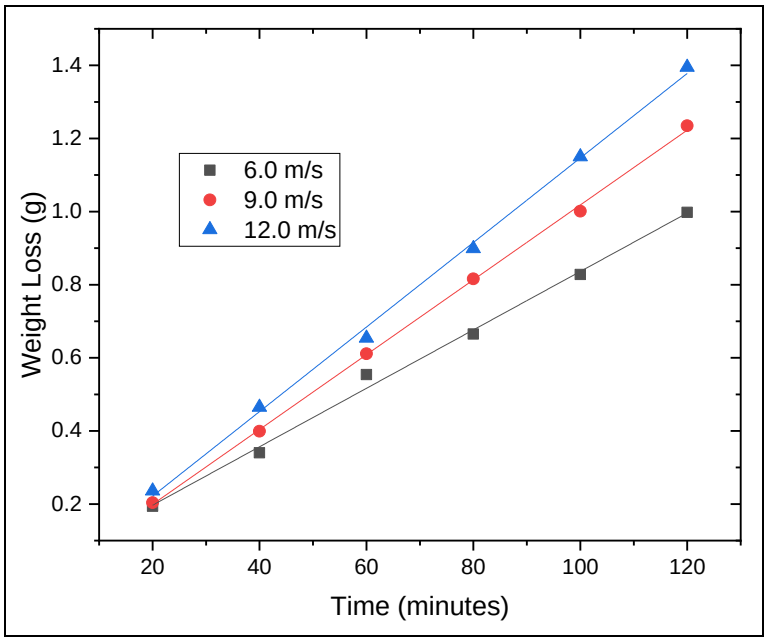

Figure 3: Variation of weight loss of Super 304HCu alloy with time at different slurry velocities (6 m/s, 9 m/s, and 12 m/s) at slurry concentration of 30 %.
Source: Authors, (2026).

Among the three test conditions, the highest weight loss occurred at the slurry velocity of 12 m/s, followed by 9 m/s and 6 m/s. This trend indicates that the slurry velocity is one of the most influential parameters in controlling the slurry erosion wear. Higher velocity increases the kinetic energy of abrasive particles striking the material surface, and resulting in greater material removal. The observed behaviour in Super 304HCu is consistent with the findings reported by who reported that erosion rate increases significantly with increase in particle velocity due to higher impact energy of the abrasive particles [11], [12]. Similarly, also reported that the increase in the particle velocity enhances the cutting and ploughing action of abrasive particles on the surface of the stainless steel [15]. In addition, Singh et al. observed that the slurry velocity plays a dominant role in determining the erosion rate of duplex stainless steels, where higher slurry velocities can lead to more severe surface damage. It is also confirmed that the kinetic energy of impacting particles is directly proportional to the square of velocity, which significantly amplifies the erosion process. These observations confirm that particle impact energy and frequency of collisions increase with velocity, resulting in a higher erosion rate [16].

III.2 EFFECT OF SLURRY CONCENTRATION EFFECT ON WEIGHT LOSS

Figure 4 illustrates the variation of weight loss of Super 304HCu alloy with time at different slurry concentrations (10%, 20%, and 30%). It is evident that the weight loss increases significantly with increase in the time of exposure for all slurry concentrations studied, indicating continuous material removal due to the particle impact in the slurry environment. Additionally, the rate of erosion significantly increases as the slurry concentration increases from 10% to 30%, demonstrating the strong influence of abrasive particle density on erosion behaviour.

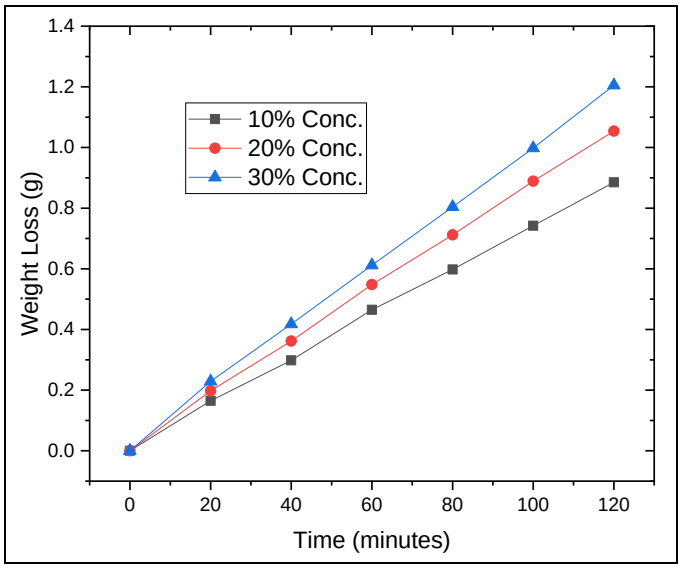

Figure 4: Variation of Weight loss of Super 304HCu alloy with time at different slurry concentrations (10%, 20%, and 30%) at constant velocity of 9 m/s.
Source: Authors, (2026).

At 10% slurry concentration, the weight loss was reported as 0.88 g after 120 minutes of erosion. This comparatively lower erosion rate is be attributed to the fewer number of abrasive particles interacting with the material surface. As the slurry concentration increases to 20%, the Weight loss increase more rapidly, reaching approximately 1.05 g at 120 minutes. An increase in slurry particle concentration leads to more frequent collisions between abrasive particles and the specimen surface, which in turn increases the rate of material removal. As the concentration of particles in the slurry increases, the number of particles impacts per unit time also increases, in turn accelerating the erosion process. The highest weight loss was observed at a slurry concentration of 30%, where the value reached approximately 1.20 g after 120 minutes of testing. At higher concentrations, the slurry contains a greater number of abrasive particles, which significantly increases the frequency of particle impacts on the material surface. This results in intensified material removal mechanisms and ultimately lead to a higher erosion rate compared to lower slurry concentrations. These observations are consistent with findings that were reported in the earlier studies. Chen et al. reported that an increase in the number of abrasive particles in a slurry leads to a higher erosion rate due to the greater frequency of particle–surface interactions [15]. Similarly, reported slurry concentration as one of the most influential parameters affecting the erosion wear in stainless steels. From the experimental results it is indicated that higher particle concentrations cause increase in the likelihood of the impact events, and thereby cause higher material loss [16]. Furthermore, explained that the slurry erosion typically occurs through mechanisms such as micro-cutting, plastic deformation, and surface fatigue. At higher particle concentrations, these mechanisms become more pronounced because multiple particles interact simultaneously with the material surface, resulting in more severe erosion damage. The cumulative effect of these impacts accelerates the wear process [11], [12]. The nearly linear trend observed in the graph suggests that the erosion rate remains relatively stable throughout the test duration, although the magnitude of wear increases with slurry concentration. Similar trends were reported by Sharma et al. and Das et al. in their studies on slurry erosion of stainless steels used in mining and industrial environments. The results clearly indicate that slurry concentration plays a significant role in determining the erosion rate of Super 304HCu stainless steel. Higher particle concentration leads to increased abrasive interaction with the surface, resulting in greater material removal [13], [14].

III.3 SEM MICROGRAPH ANALYSIS OF WORN SURFACE

Scanning Electron Microscopy (SEM) was used to examine the worn surfaces of Super 304HCu specimens after slurry erosion testing in order to understand the dominant wear mechanisms. The SEM micrographs reveal significant surface damage caused by repeated impacts of abrasive particles present in the slurry. The SEM micrographs of Figure 5 reveal several characteristic surface features associated with slurry erosion, including surface pits, and regions of plastic deformation. The presence of these features suggests that the erosion behaviour of the material is largely dominated by ductile erosion mechanisms. The increasing slope of the curves in Figure 3 also indicates that the erosion process becomes more severe over time. As the surface undergoes repeated particle impacts, micro-cracks and surface pits develop, which facilitate further material removal. Similar erosion mechanisms such as micro-cutting, plastic deformation, and surface fatigue were reported by Yilmaz et al. during the erosion testing of stainless steels. The results demonstrate that Super 304HCu alloy exhibits better resistance at lower slurry velocities, while higher velocities accelerate erosion wear due to increased particle impact energy [17]. These findings suggest that controlling slurry velocity is essential for improving the service life of components used in slurry transportation systems.

At lower slurry velocities, the eroded surfaces exhibit relatively shallow grooves with only limited surface deformation. The damage appears mild, mainly caused by the sliding and rolling motion of abrasive particles across the surface. As the particles move along the direction of slurry flow, their cutting action produces fine and nearly parallel grooves on the material surface.

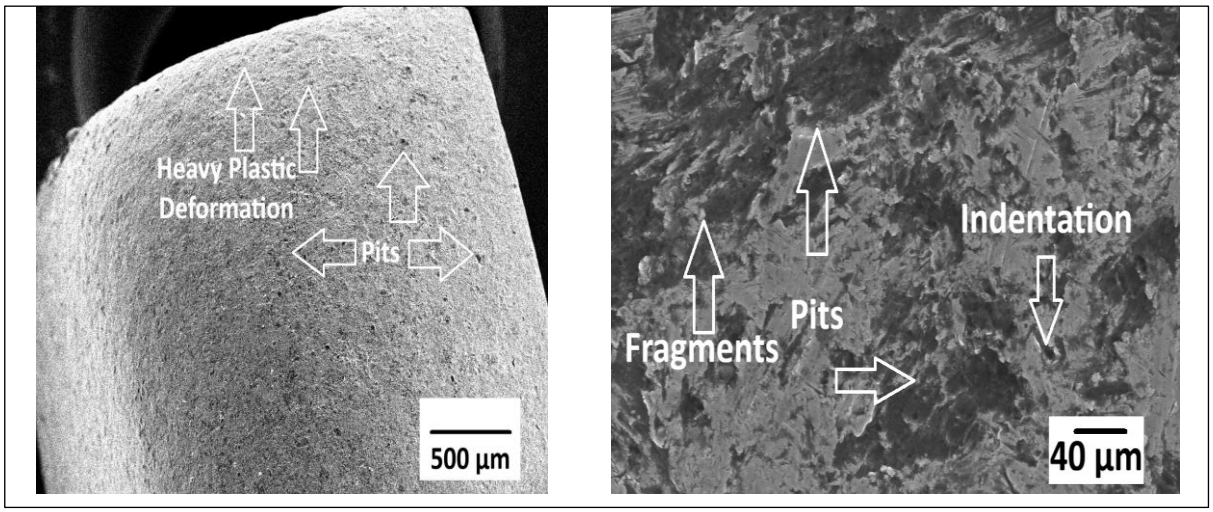

Figure 5: Scanning Electron Microscopy (SEM) micrograph of the worn surfaces of Super 304HCu (30% Concentration, velocity 9 m/s, time 120 minutes).
Source: Authors, (2026).

When the slurry velocity increases, the severity of surface damage becomes more pronounced. The SEM images show deeper grooves, larger pits, and noticeable plastic deformation in several regions of the specimen surface. This increased damage is mainly attributed to the higher kinetic energy of the impacting particles. With greater impact energy, the abrasive particles produce stronger micro-cutting actions and remove material more effectively from the surface. In addition, the presence of alloying elements such as chromium, molybdenum, and copper in Super 304HCu promotes the formation of a stable passive film on the surface. This passive layer can provide a certain degree of protection against erosion–corrosion effects. However, under continuous abrasive particle impacts, the protective film may gradually deteriorate, exposing the underlying material to further erosion damage.

IV. CONCLUSIONS

In this work, the slurry erosion behaviour of the Super 304HCu stainless steel is investigated at different operating conditions, such as slurry velocity, slurry concentration, and time of exposure. From the experimental results, the weight loss of the specimens increases steadily with erosion time. This confirms the continuous material removal from the specimen by the abrasive particles which repeatedly strike and slide over the specimen surface during the slurry flow. Among the parameters investigated, the slurry velocity was found to have a significant effect on the erosion rate. As the velocity increases, the extent of the material loss also increased. The maximum weight loss occurred at 12 m/s, while the lowest at slurry velocity of 6 m/s. This behaviour can be attributed to the high kinetic energy of slurry particles at higher velocities, resulting in stronger impacts and more severe surface damage. A similar trend was observed with respect to slurry concentration. Increasing the concentration of abrasive particles led to a higher frequency of particle–surface interactions. As a result, the probability of impact events increased, which in turn accelerated the erosion process and produced greater material loss. The graphical analysis supports these observations and clearly indicates that the erosion rate rises with both slurry velocity and slurry concentration. These parameters therefore play a dominant role in controlling the slurry erosion under the present experimental conditions. Further insight into the wear mechanisms was obtained from the SEM examination of the eroded surfaces. The micrographs revealed several typical features such as micro-cutting grooves, ploughing marks, pits, and regions of plastic deformation. These characteristics suggest that the erosion process is largely governed by ductile mechanisms, where cutting and plastic deformation act together to remove material from the surface. Overall, the results indicate that Super 304HCu alloy exhibits reasonable resistance to slurry erosion. However, the extent of material loss becomes significantly higher at increased slurry velocities and particle concentrations. Future studies may consider the influence of additional parameters, such as particle size, and temperature, in order to understand the erosion performance of this alloy better.

ABSTRACT

Water waste, unpredictable weather, lack of real-time monitoring, and reliance on manual irrigation techniques are some of the problems agriculture faces today. This paper presents a smart agriculture monitoring and irrigation control system based on the ESP32 that uses ESP-NOW wireless communication to tackle these challenges. The proposed system includes one main control node and two sensor nodes. In the field, the sensor nodes monitor temperature, humidity, motion, rainfall, and soil moisture. Irrigation automatically adjusts to reduce water waste and improve efficiency based on set threshold values. Using the ESP-NOW protocol, sensor data is transmitted wirelessly to the main node. It is then periodically uploaded via Wi-Fi to a cloud platform for remote monitoring through a mobile app. The system works well in off-grid and remote agricultural areas because it is solar-powered with a rechargeable Li-ion battery backup. The experiment results show reliable sensing, stable multi-node operation, dependable wireless communication, and effective automatic irrigation control. For smart agriculture, the proposed model offers an affordable, scalable, and energy-efficient solution.

I. INTRODUCTION

The increasing rate of the global population requires more agricultural production, but climate change and improper agricultural practices are major challenges. The integration of artificial intelligence with IoT and cloud computing will make agriculture smarter, more efficient, and data-driven. This paper proposes an IoT-based system for monitoring the growth of the paddy crop. The proposed system uses sensors to measure temperature, humidity, soil moisture, and water levels. The data is then analyzed using a cloud platform. The system will help farmers to optimize irrigation, increase crop production, and reduce water wastage. The proposed technique is a cost-effective solution for precision agriculture [1], [2]. Agriculture is important for a country's economy. Precision agriculture uses machine learning methods to improve yield Agriculture is an important sector in the economy of a nation. Precision agriculture uses machine learning algorithms to enhance crop forecasting and decision-making. Machine learning (ML) extracts valuable information from past data to help in soil mapping, seed choice, irrigation, disease identification, weed management, and crop quality assessment. Cameras observe plant health, identify diseases, and assist in harvesting, sorting, and field robotics. Computer vision is the next level of smart farming. All these enhance automation, reduce expenses, and enhance agricultural productivity and efficiency by integrating deep learning with big data [3], [4]. The Internet of Things (IoT) has brought new opportunities for efficiency and automation in many areas, and agriculture is not an exception. IoT systems are based on the interconnected devices, sensors, and communication protocols to gather and share data and provide real-time monitoring and smart control of physical environments [5]. This technology in agriculture enables farmers to have an insight into valuable field conditions every time and act swiftly in reaction to forthcoming alterations.

IoT-based smart irrigation systems assist in automatizing the process of water management to achieve this by evaluating sensor information to find out the real requirements of crops. These systems have the capability of controlling irrigation in a more efficient way by measuring soil moisture and other environmental parameters that would help eliminate water wastage and enhance crop growth [6]. This type of IoT-based solution offers a stable and affordable way of modern agriculture to facilitate efficient use of resources and sustainable farming initiatives. Agriculture has had a significant application of wireless sensor networks, which monitor the environment in an efficient way but with minimal power consumption. The systems assist in gathering the precise field information and aid in managing the farm better [7]. With the help of the IoT and sensors, the agricultural system will be able to track the crops in real time and automatically control the irrigation process. This enhances efficiency of resources and has been a trusted solution to smart applications in agriculture [8]. IoT is revolutionizing the world of modern agriculture. IoT enables farmers to track the conditions of their fields remotely and automates critical tasks such as watering and fertilizing. This paper describes a real-time monitoring system based on IoT technology and environmental sensors to continuously measure temperature, soil moisture, and water levels. The system relies on the data collected to control the pumps and cooling fans to maintain optimal conditions for crops. It transmits data to the cloud through Wi-Fi for real- time viewing and analysis. The GSM modules enable the farmer to receive real-time notifications. The proposed system enhances agricultural productivity by ensuring that resources are optimally utilized and appropriate measures are taken [9]. In this paper, the performance of a cluster-based agricultural IoT network using BLE and Raspberry Pi 3 B+ is presented. The proposed network is designed for precision agriculture and greenhouse systems. The testbed is a combination of sensors and low-power communication modules. The results of the experiments conducted indoors and on the farm indicate that the testbed is reliable, scalable, and easy to manage [10].

II. RELATED WORK

In smart agriculture, we employ the use of wireless sensor networks based on IoT technology to measure the soil moisture, temperature, humidity, and water level in the field. Wi-Fi, Bluetooth, Zigbee, and LoRa technologies are normally employed to help the long- distance transmission of this data. But in large-scale agriculture, these technologies may sometimes experience problems of range, battery life, and connectivity. Mesh networking solves this problem. Here, the devices communicate with each other. This makes the network robust and reliable. ESP-based networks such as Wi-Fi Mesh and ESP-NOW are the best for this purpose because they are fast, battery-efficient, and highly effective in large outdoor farms [11].

III. PROPOSED SYSTEM ARCHITECTURE

The proposed system is a smart agriculture system developed using IoT technology. This system is capable of monitoring the field in real time, automatically controlling irrigation, and enabling users to view data remotely using a mobile application. The system is developed in a distributed fashion, consisting of two sensor nodes and one main node. The two sensor nodes are responsible for field sensing and device control, such as pumps. The main node is responsible for collecting all the data, making decisions based on the data, and sending the data to the cloud for remote access. For better understanding and future development, the whole system is broken down into various functional units [12], [13].

A. Power Supply

Unit The power supply unit is made for ongoing use in remote agricultural areas. Each node gets its power from a solar panel and a rechargeable Li-ion battery. The voltage regulation circuit provides a steady power supply to the microcontroller, sensors, and communication modules. The system relies on renewable energy sources and is built to work for a long time with little maintenance.

B. Sensor and Control Unit

The sensor and control unit observes the field and environmental conditions. The sensor nodes are equipped with soil moisture sensors, temperature and humidity sensors, rain sensors, and PIR motion sensors. The sensors are responsible for collecting real-time data regarding the soil conditions, environmental changes, and activities in the field. The ESP32/NodeMCU microcontroller is responsible for processing the sensor data and making decisions based on the predefined thresholds.

C. Communication Unit

The communication unit is the brain that shuttles data among the sensor nodes, the main node, and the cloud. First the sensor nodes toss their processed data wirelessly straight to the main node. Once there, the main node stitches the pieces together and runs its own cleanup routine. After that minute of gathering, it pulls the connection to the sensors, boots up its Wi-Fi card, and blasts the polished data out to the cloud. As soon as the upload finishes, the mobile app gets a quick refresh. Doing it this way cuts power use, lightens the traffic load, and forces the data to ship safely—that's the double-edged advantage [14].

D. Actuation Unit

The actuation unit controls the field devices based on sensor values and system decisions. Relay modules control the actuators, which may be water pumps or motors. When the soil moisture content is below the set level, the irrigation motor turns on automatically. But when the moisture content is adequate, the motor turns off to avoid wasting water. Temperature actuation can also be applied to ventilation control in indoor or protected agriculture.

E. Monitoring and User Interface Unit

The monitoring unit allows both local and remote access to agricultural data. The main node has an LCD display that provides real-time data from the sensors. The cloud-based mobile app allows farmers to monitor the conditions in the fields remotely. The mobile app updates the sensor data after each communication cycle, allowing farmers to make decisions without necessarily being in the field.

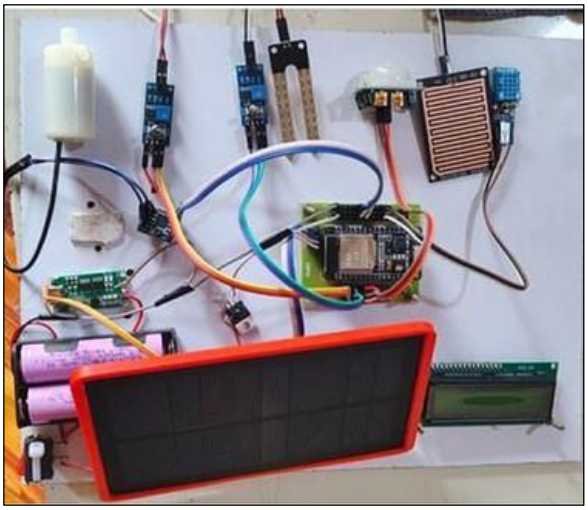

Figure 1: Experimental Setup of Nodes 1 and 2 (Tx).
Source: Authors, (2026).

F. Node-wise Monitoring and Interface Description

1) Node 1 Monitoring Unit

Node 1 acts as a transmitter sensing unit placed in the agricultural field. It constantly checks soil moisture, temperature, humidity, rainfall, and motion with the built-in sensors. The ESP32/NodeMCU processes the sensor data on-site and operates the irrigation motor through a relay when the soil moisture drops below the set threshold. The processed data from Node 1 is sent wirelessly to the main node during the data collection phase. Node 1 runs on solar power and has battery backup. This setup allows for continuous monitoring with little human involvement.

2) Node 2 Monitoring Unit

Node 2 is a duplicate sensing node with the same hardware configuration as Node 1. Node 2 is placed in a different region of the field to measure the variations in environmental conditions. Node 2 monitors soil and weather variables using the same sensors and makes decisions at the local level using the microcontroller. Node 2 makes decisions about motor control based on soil moisture content to enhance irrigation. Data from Node 2 is transmitted to the main node periodically.

3) Main Node Monitoring and User Interface Unit

The main node is the central unit for monitoring and user interaction in the system. It receives data from Node 1 and Node 2 and combines the data for processing. The main node shows real-time values of the sensors and the system status on an LCD connected to it. The system supports on-site monitoring. After collecting data from the sensor nodes, the main node waits for one minute. It then disconnects from the sensor nodes and connects to a Wi-Fi network. Finally, the combined data uploads to a cloud platform and an online mobile application.

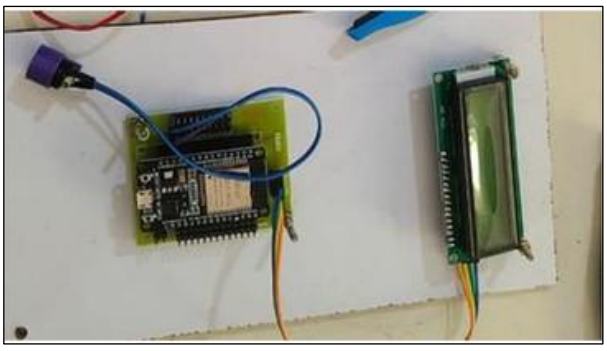

Figure 2: Experimental Setup Of Main Node (Rx).
Source: Authors, (2026).

IV. METHODOLOGY

The existing system adopts a node-based system over wireless monitoring of agriculture and provision of automatic irrigation. System operation will involve data collection procedures of the environment, on site data processing, transmission of data wirelessly and long distance monitoring via cloud network. The installed sensing nodes, which are called Node 1 and Node 2, exist in the agricultural field at different points. The nodes are powered by a solar power unit that is backed by rechargeable lithium-ion battery and a voltage regulation circuit to give continuous stable power. In these nodes, there are various sensors that detect moisture of soil level, temperature, humidity, rainfall, water level and motion sensors.The sensors constantly scan the field and the environmental parameters to be able to generate real-time data concerning human conditions of crops as well as soils.

The sensing node is equipped with an ESP32or NodeMCU microcontroller to work on the sensor data obtained. The sensor readings are compared against preset threshold values and the irrigation motor is automatically turned on or off by a controller with the use of a relay module. This is a local control mechanism that enables the system to be reactive without having to be connected to the internet all the time. The data that is gathered at the field nodes is sent wirelessly, and it is uploaded to a cloud platform through the main node. This information can be monitored remotely in agricultural conditions and irrigation status by using a mobile application. This type of controlled communication will decrease the amount of power consumed, reduce the use of Wi- Fi frequently, and increase the reliability of the system, particularly in remote agricultural settings.

VI. RESULTS & DISCUSSION

The proposed IoT-based smart agriculture system was successfully implemented and tested in real-time conditions, as evident from the images of the hardware setup. Two sensor nodes were used to monitor the soil moisture, temperature, humidity, rainfall, and motion. The central receiver and control unit was the main ESP32-based node. The whole system was powered by a solar panel and 18650 Li- ion rechargeable batteries.

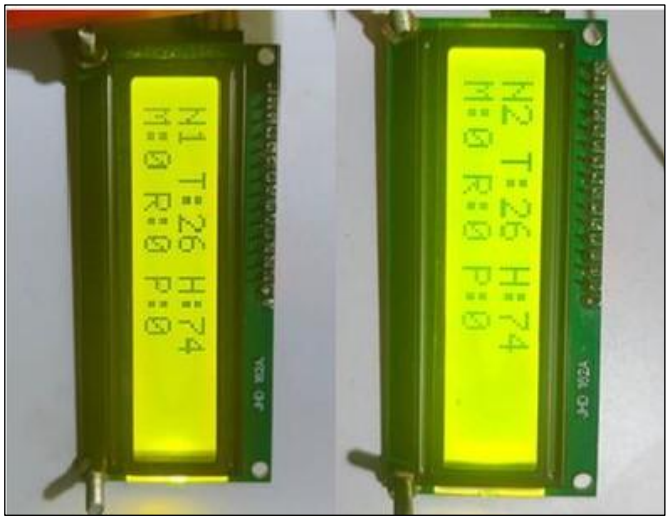

Figure 4: Real-time LCD monitoring Node 1 and 2 (Tx).
Source: Authors, (2026).

A. Motion Detection Performance.

Case 1: No Motion Detected (P = 0)

Under the normal field environment, the LCD display indicated parameters like the node identifications, temperature, humidity, soil moisture conditions, rainfall conditions, and the motion value were indicated as zero. P = 0 meant that no movement was in the area under observation. In this scenario, the system would keep on doing regular environmental checks, and the irrigation management was to be performed solely in reliance on the soil moisture. This guaranteed the appropriate water use and the constant functioning of the systems.

Case 2: Motion Detected (P = 1)

In the event that the movement was detected in the monitored region, the motion sensor output was switched to P = 1. This update would be reflected instantly on the display, and this proved that the sensor was able to detect motion. The quick response achieved dependable sensing attributes and wireless data transmission between field nodes and the central node. The results of both sensing nodes were consistent, and this indicated the reliability and scalability of the system.

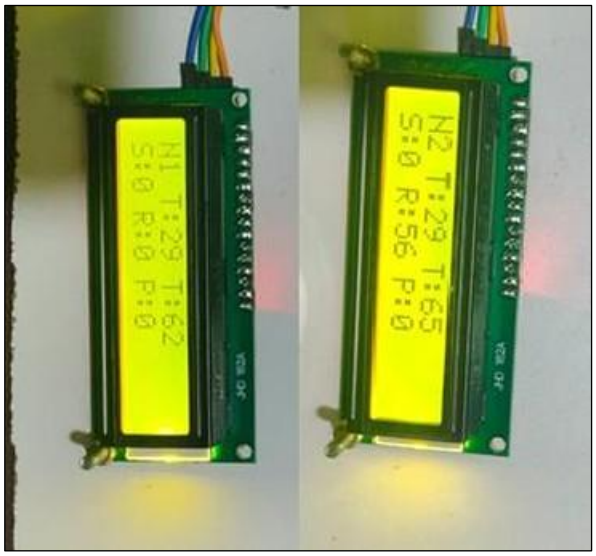

Figure 5: Real-time LCD monitoring of Main Node (Rx).
Source: Authors, (2026).

Case 3: Motion Sensor - P:0

Under normal conditions, the LCD displayed the following readings: Node ID: N2, Temp: 28°C, Hum: 52-53%, Moisture (S): 0, Rain (R): 56, and Motion (P): 0. This indicates that there was no motion detected, and therefore the system was in monitoring mode. The irrigation system relied solely on the soil moisture level.

Case 4: Motion Sensor - P:1

With the detection of motion by the transmitter node, the receiver displayed the following readings: Node ID: N2, T:28°C, H:53%, S:0, R:0, P:1. The quick change from P:0 to P:1 confirms that there was motion detected. This also confirms that the wireless communication system is functioning well and that there is real-time synchronization between the sensor node and the master receiver unit.

Rainfall Detection Analysis

During the test, the system logged Node ID: N2, T:28°C, H:53%, S:0, and R:0. This shows that there was no rainfall detected and the sensor plate was dry. The R:0 value also shows that the rain sensor was in its normal dry state with no water droplets on the sensor. However, when rainfall happens, the sensor reading changes from R:0 to R:1 because of the higher conductivity on the sensor plate. This reading is then transmitted to the main node and shown on the LCD display. This makes it possible for automatic irrigation control to prevent overwatering and water wastage.

Soil Moisture-Based

Irrigation Response During the test, the system logged Node ID: N2 with S:0. This shows that the soil was moist above the dry level, and the pump was in the OFF state. However, when the soil moisture level goes below the set value (S:1), the motor turns on automatically. This shows that the irrigation system has closed-loop control with very little human intervention.

Wireless Communication Performance

The communication network connecting N1, N2, and the central node performed well under all test scenarios. The data from the sensors measured at each node was sent and received correctly with no signs of data loss. The information transfer happened in a very short time span, enabling the control unit to process the data and make changes to the system operations instantly. This quick communication enabled the control unit to make irrigation decisions instantly based on real-time field conditions. The combination of

ESP-NOW communication for local node communication and Wi-Fi communication for updating data remotely functioned without any interruptions. Both communication systems functioned in perfect harmony, ensuring a continuous flow of data even after multiple cycles of data transmission. The system functioned flawlessly under all test conditions, with no signs of unexpected shutdowns or communication losses.

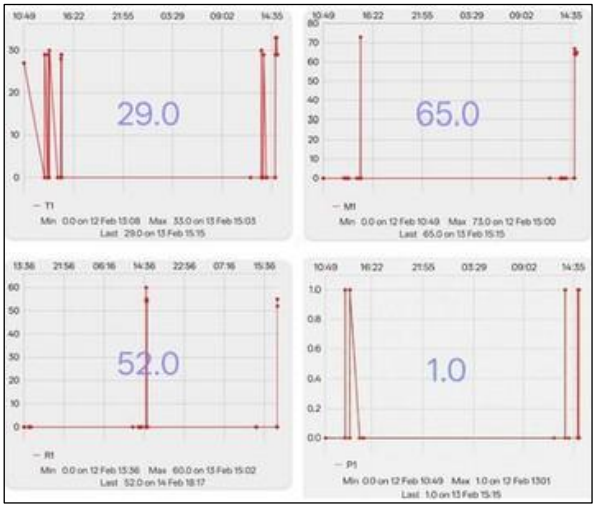

Figure 6: Real-time Graphs from Tx-Node1 (Temperature, Moisture, Rain, Motion Sensor Values).
Source: Authors, (2026).

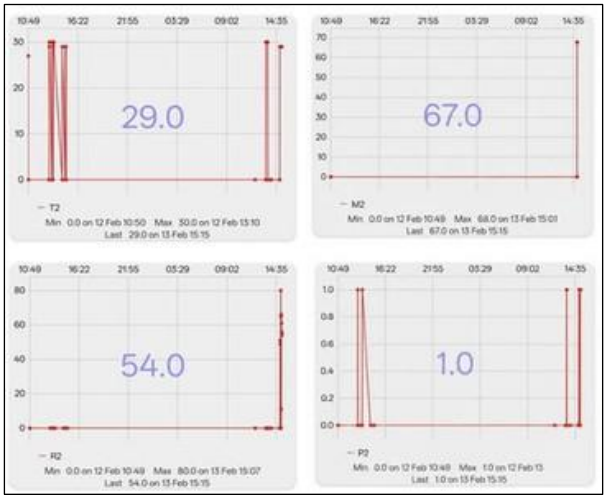

Figure 7: Real-time Graphs from Tx-Node2 (Temperature, Moisture, Rain, Motion Sensor Values).
Source: Authors, (2026).

Figures shows the real-time graphs of Tx-Node1 and Tx-Node2 for temperature, soil moisture, rain detection, and motion detection. The readings from the sensor remained constant in normal environmental conditions. The temperature readings were around 29-30°C for Node1 and 52-54°C for Node2 during peak measurements. The moisture levels remained constant, indicating proper soil condition monitoring without any abrupt changes. The rain sensor output changed distinctly between low (0) and high (1), indicating proper detection of rainfall events. The motion sensor output changed rapidly between 0 and 1 upon detecting motion, indicating proper intrusion detection. From the graphs, it can be seen that there is synchronized data transmission from both the transmitter nodes. This indicates the efficacy of the proposed wireless monitoring system.

Solar Energy Performance

The solar panel was able to power the ESP32, sensors, LCD, and wireless communication components effectively. The 18650 Li-ion battery was also able to provide a backup power source effectively, even when the sunlight changed temporarily. This is evidence that the system is effective for agricultural fields that are remote and require little maintenance.

Comparative Analysis

Compared to traditional manual systems, the proposed model cuts down on labor and reduces water waste with automatic control. It enhances crop protection by using real-time monitoring and allows for scalable multi-node deployment. Overall, it provides a smarter and more efficient farming solution.

Future Enhancements

Then, we are thinking of incorporating LoRa so that the system can extend its range and remain connected within the fields. After that, we will implement AI to detect problems in the crops before they become major issues. Other ideas are in the pipeline, including a smart dispenser that will deliver the correct amount of fertilizer only where it is needed, push notifications that will send notifications to your phone at the correct time, and a camera that will detect any unwanted visitors.

Overall Observation

During the testing phase, N1 and N2 ensured that their sensors were functioning properly. There were no significant changes or fluctuations in the values of temperature, humidity, soil moisture, rainfall, and motion. The ESP-NOW communication feature functioned properly, sending packets with little delay and no losses. On the receiving end, the values were displayed properly on the screen as they passed through the "listening," "displaying," and "updating" phases. When the sensor detected motion, it responded immediately, providing us with a real-time perspective of the intruders. The node network is very reliable for communication, consumes very little power, and can be established in an agricultural field without any special preparations.

VII. CONCLUSION

This paper presented an IoT-based smart agriculture monitoring and irrigation system that uses two sensor nodes and one main node to collect and send real-time field data. The combination of solar power and low-power wireless communication allows for continuous operation in remote areas. Automatic irrigation, which relies on soil moisture, reduces both water wastage and manual work. Experimental results show better efficiency, reliability, and scalability when compared to traditional methods. This makes the system a practical and cost-effective solution for precision agriculture.

VIII. ACKNOWLEDGEMENT

The authors genuinely appreciate the Department of Electronics and Communication Engineering at Vignan's Lara Institute of Technology and Science for providing the essential resources, guidance, and ongoing support that made this research possible and successful throughout the entire project development phase.

ABSTRACT

Switches and capacitors are utilized in place of a resistor R in the switched-capacitor circuit, with a MOSFET serving as the switch. In this paper, the standard RC integrator is compared with the switch capacitor RC integrator. The design is simulated first, and solutions to the design issues are explored and implemented in 180nm technology. The analysis demonstrates that NMOS transistor performance strongly depends on the W/L ratio. As resistance decreases sharply with increasing W/L, current delivery efficiency enhances. Drain current increases substantially with larger widths due to improved channel conduction. This study analyzes the electrical behavior of an NMOS transistor for varying device widths while keeping the channel length constant. The investigation focuses on the effect of the width-to-length (W/L) ratio on drain current (I_D), on-resistance (R_{on}), and related process parameters. The results demonstrate a strong dependence of I_D and R_{on} on device geometry, consistent with MOSFET theory.

I. INTRODUCTION

RC Integrator can be used as low-pass filter in many applications.In devices like variable speed wipers and pacemakers, it can also serve as a timer[1]. Large-value resistors, which take up a lot of chip space, are required for typical RC circuits. Switches and capacitors are used in place of resistors in Switched-Capacitor (SC) circuits, which can assist in minimizing the chip area. It uses two switches to control the flow of charges into and out of a capacitor. The capacitance ratio determines the characteristics of a switched capacitor circuit. One capacitor C and two switches S_1 and S_2 take the place of the resistor R in switched capacitor integrator circuits (SCI). This is shown in Figure 1 [2], [3].

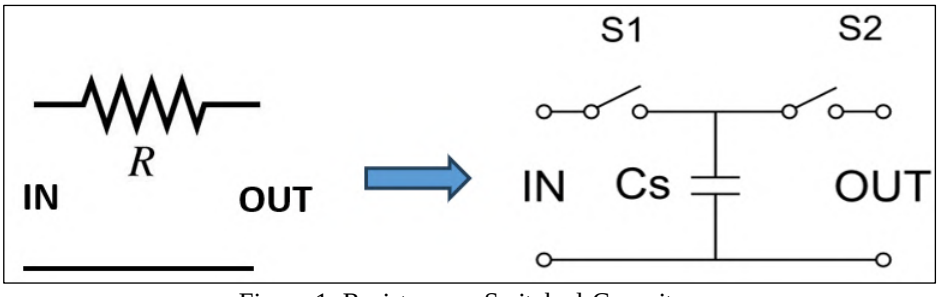

Figure 1: Resistor as a Switched-Capacitor.
Source: Authors, (2026).

The value of the capacitor C_s and the switching frequency f determine the value of resistance R.

$$R = \frac{V}{I} = \frac{1}{C_s f} \tag{1}$$

In this work, the switch is implemented using MOSFET transistors, as shown in Figure 2. They provide fast, low-power, accurate, and easily integrable switching, which is essential for precise charge transfer. When a MOSFET is used as a switch, it has some nonidealities, which are discussed in the next section [4], [5].

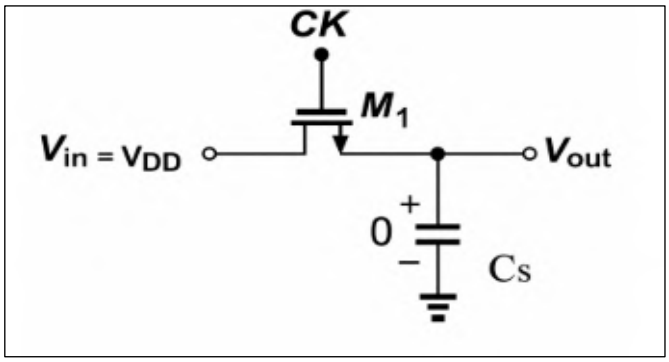

Figure 2: Switched Capacitor Resistor.
Source: Authors, (2026).

II. NONIDEALITIES OF MOSFET SWITCH

Three sorts of nonideal effects can occur when a MOSFET is employed as a switch: (i) Non-Linear R_{on} (ii) Charge Injection and (iii) Clock Feed Through [6-8].

II.1 NON-LINEAR R_{on} (*B*etween Drain and Source)

The $nMOS$ is ON by applying a positive gate signal equal to V_{DD}. When the value of $V_{GS} - V_{thn}$ become grater then V_{DS}, the $nMOS$ is operating in the triode region. The current I_D is given by equation 2 [9].

$$I_D = \mu_n C_{ox} \frac{W}{L} (V_{DD} - V_{in} - V_{thn}) V_{DS} \tag{2}$$

The equivalent resistance R_{on} is found by dividing V_{DS} by with I_D (here body effect has ignored.)

$$R_{on} = \frac{V_{DS}}{I_D} = \frac{1}{\mu_n C_{ox} \frac{W}{L} (V_{DD} - V_{in} - V_{thn})} \tag{3}$$

The R_{on} depends on the input signal V_{in} , therefore, its value changes with V_{in} .The R_{on} The size of an nMOS transistor is small because the $\mu_n C_{ox}$ is large. The PMOS transistor is large because the $\mu_p C_{ox}$ is small. Consequently, a low value of R_{on} makes the pMOS transistor less appropriate. Compared to both nMOS and pMOS, the CMOS transmission gate (TG) has a higher value of R_{on}. The values of $R_{on}$for nMOS, pMOS, and TG are displayed in Figure 3.

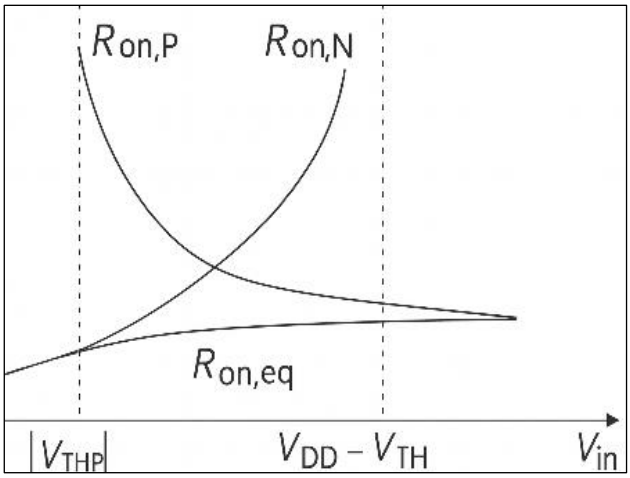

Figure 3: R_{on} for pMOS, nMOS, and TG.
Source: Authors, (2026).

II.2 CHARGE INJECTION

A channel is created between the source and drain when nMOS is turned on. Equations 4 [10], [11] provide the charge Q_{ch} stored in the channel.

$$Q_{ch} = WLC_{ox}(V_{DD} - V_{in} - V_{thn}) \quad (4)$$

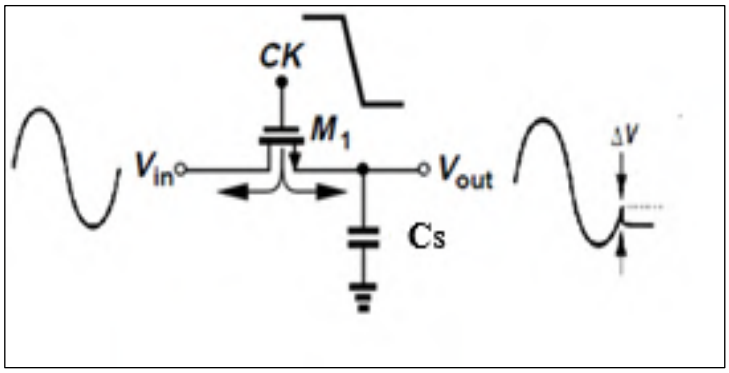

Figure 4: Charge Injection Effect on MOS Switch.
Source: Authors, (2026).

When the nMOS turned off, the charge present in the channel is distributed between the capacitor and the input, as shown in Figure 4 [12]. The clock turnoff slope, the input-to-output capacitance ratio, and the drain-source voltage factors all affect this charge. This charge does not affect the input side, but it changes the voltage stored on the output capacitor C_s as shown in equation 5.

$$\Delta V = Q_{ch}/2C = WLC_{ox}(V_{DD} - V_{in} - V_{thn})/2C \quad (5)$$

II.3 CLOCK FEED THROUGH

The parasitic capacitance between the MOSFET's terminals must be depicted as indicated in Figure 5 to comprehend the clock feed-through effect. In this case, the nMOS is operating in the Triode region and is regarded as being ON. The clock signal passes via the gate-source and gate-drain capacitances as the gate clock signal rises [13], [14].

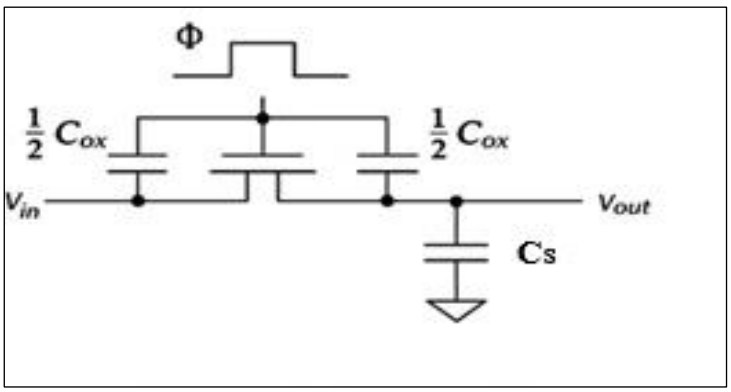

Figure 5: Clock feed through Effect on MOS Switch.
Source: Authors, (2026).

The input signal V_{in} is available at the output capacitor when the nMOS is turned on by applying V_{DD} at the gate terminal. In this instance, V_{out} is unaffected by the capacitive feed-through and the capacitor C_s charged to V_{in}. The nMOS switches off when the clock signal changes to low. In this instance, the capacitance C_s and the gate-drain/source capacitance are separated by a (capacitive) voltage divider. As a result, equation 6 provides the value of a clock signal port that is present across C_s.

$$\Delta V_{load} = \frac{C_{overlap}(V_{DD} - V_{ss})}{C_{overlap} + C_{load}} \quad (6)$$

Where $C_{overlap}$ is the overlap capacitance, and its value is given by equation 7.

$$C_{overlap} = C_{ox}WLD \quad (7)$$

The gate length that overlaps the drain and source is represented by the symbol, LD in Equation (7).

III. SOLUTION OF MOSFET NONIDEALITIES

The following techniques can reduce the nMOS Switch's nonidealities [15], [16].

III.1 NON-LINEAR R_{on} (Between Drain and Source)

The value of R_{on} can be reduced by increasing the W/L ratio or reducing V_{in} and V_{thn}.The R_{on} remains almost constant for the transmission gate if the switch is replaced by a transmission gate.

III.2 CHARGE INJECTION

As illustrated in Figure 6, connect a dummy switch in series with a nMOS switch. The dummy switch can be made to be half the size of the primary switch. Both the source and the drain are connected. When the nMOS switch is off, the dummy switch compensates for the charge by allowing the 50% channel charge to flow toward the capacitor (C_s) [17].

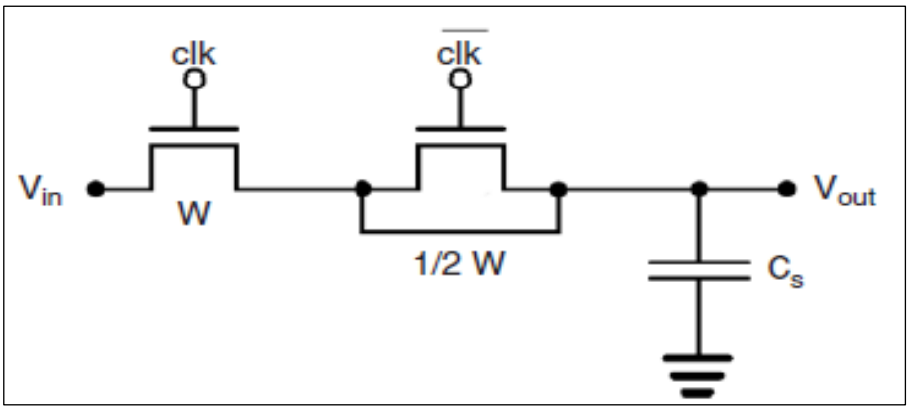

Figure 6: Use of a dummy switch to remove Charge Injection.
Source: Authors, (2026).

III.3 CLOCK FEED THROUGH

Here, the dummy switch suppresses the effect of clock feed through, as shown in Figure 7. A dummy transistor M_2 removes the charge introduced by the primary transistor. After M_1 shuts off and M_2 turns on, the channel charge deposited by M_1 on C_s is absorbed by M_2 to form a channel because the M_2 is driven by $\overline{CK}$. The charge injected by M_1, Δ_{q1} is equivalent to the charge absorbed by M_2 if $W_2 = 0.5W_1$.

$$\Delta_{q1} = \frac{W_1 L_1 C_{OX}}{2}(V_{CK} - V_{in} - V_{THN})$$

$$\Delta_{q2} = W_2 L_2 C_{OX}(V_{CK} - V_{in} - V_{THN})$$

If $W_2 = 0.5W_1$ and L_2=L_1, the effect of clock feedthrough is suppressed. The whole charge in V_{out} is going to be zero as per equation (8).

$$-V_{CK}\frac{W_1 C_{OV}}{W_1 C_{OV} + C_S + 2W_2 C_{OV}} + V_{CK}\frac{2W_2 C_{OV}}{W_1 C_{OV} + C_S + 2W_2 C_{OV}} = 0 \qquad (8)$$

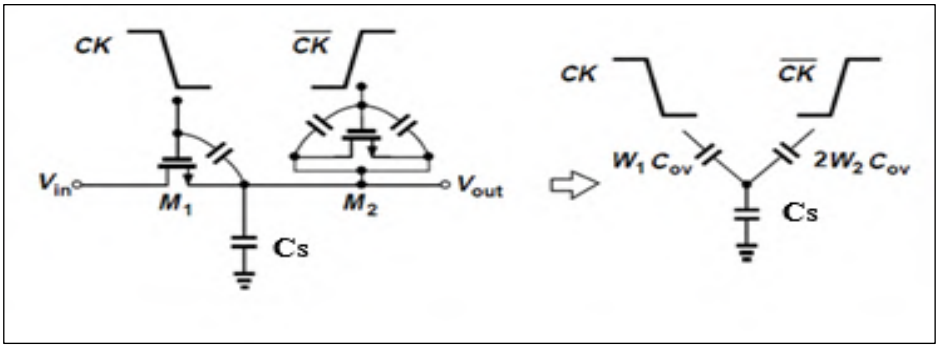

Figure 7: Use of the TG switch to remove Clock Feed Through.

IV. RESULTS AND DISCUSSION

This study analyzes the electrical behavior of an NMOS transistor for varying device widths while keeping the channel length constant. The investigation focuses on the effect of the width-to-length (W/L), ratio on drain current (I_D), on-resistance (R_{on}), and related process parameters. The results demonstrate a strong dependence of I_D and R_{on} on device geometry, consistent with MOSFET theory. MOSFETs exhibit electrical characteristics highly dependent on device geometry. In this work, NMOS properties are evaluated for various widths while keeping the channel length constant (L= 0.18 µm). The study investigates the effects of W/L scaling on on-resistance (R_{on})) and drain current (I_D) [18]. Modern semiconductor design relies on MOSFET scaling, which has a direct impact on power consumption, device performance, and switching speed. A key component of both digital and analog circuits, the NMOS transistor has properties that are strongly influenced by its physical shape. The W/L ratio is one of these characteristics that significantly influences channel conduction capabilities. This work assesses the electrical properties of NMOS for various widths between 2 µm and 100 µm. A fixed channel length of 0.18 µm is shared by all devices [19]. Quantifying the effects of W/L scaling on drain current (I_D), on-resistance (R_{on}), and overall conduction behaviour is the goal. To verify MOSFET operation under strong inversion, these practical findings are contrasted with theoretical predictions [3].

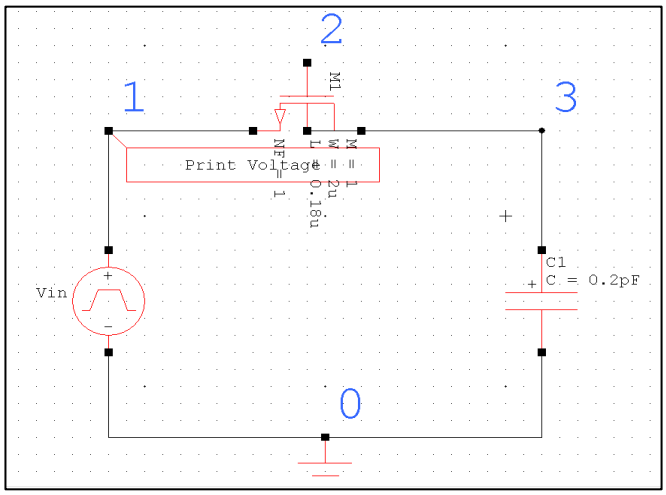

Figure 8: nMOS Switch with Pulse input.
Source: Authors, (2026).

IV.1 NON-LINEAR R_{on} (*B*etween Drain and Source)

To guarantee that differences in electrical behaviour are solely due to geometric scaling, the devices under analysis have the same material and manufacturing parameters. The following is a list of the important parameters:

- Channel length (L): 0.18 µm
- Device widths (W): 2, 10, 20, 50, and 100 µm
- Electron mobility (μ_n): 1400 cm²/V·s
- Oxide capacitance (C_{ox}): 8.65 × 10^{-8} F/cm²
- Oxide thickness (t_{ox}): 4.1 nm
- Oxide permittivity (ε_{ox}): 3.51 × 10^{-13} F/cm
- Vacuum permittivity (ε_o): 8.85 × 10^{-14} F/cm
- Gate voltage (V_{GS}): 1.8 V
- Threshold voltage (V_{thn}): 0.3725327 V

The effective gate overdrive voltage $V_{GS} - V_{thn}$ remains constant at 1.427 V, ensuring consistency in theoretical calculations such as R_{on} and I_D.

$$R_{on} = \frac{V_{DS}}{I_D} = \frac{1}{\mu_n C_{ox}\frac{W}{L}(V_{DD} - V_{in} - V_{thn})} = \frac{1}{\mu_n C_{ox}\frac{W}{L}(V_{GS} - V_{thn})} \quad (9)$$

Table 1: Parameters for variation in Ron with respect to W/L.

Sr.No.	W µm	W/L µm	V_{GS}	V_{thn}	$V_{GS} - V_{thn}$
1.	2	11.11	1.8 V	0.3725327	1.427 V
2.	10	55.56	1.8 V	0.3725327	1.427 V
3.	20	111.11	1.8 V	0.3725327	1.427 V
4.	50	277.78	1.8 V	0.3725327	1.427 V
5.	100	555.56	1.8 V	0.3725327	1.427 V

Source: Authors, (2026).

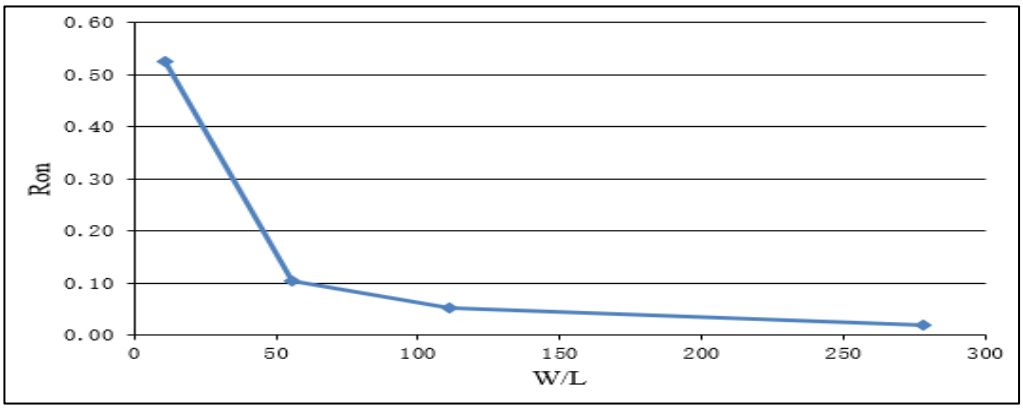

Figure 9: Variation in R_{on} with respect to W/L.
Source: Authors, (2026).

Table 1 illustrates how R_{on} dropped from 0.525 Ω to 0.0105 Ω over the same range. The inverse reliance on W/L is consistent with theory.

IV.1.1 Drain Current $I_D(mA)$

By changing the device width while maintaining a constant channel length, this study examines the electrical behaviour of an NMOS transistor. As indicated in Table 2, the analysis focuses on how the width-to-length (W/L) ratio affects the drain current (I_D). In line with MOSFET theory, the results demonstrate a significant influence of I_D on device geometry.

Table 2: Parameters for variation in $I_D(mA)$ with respect to W/L.

Sr.No.	W µm	W/L µm	I_D(mA)
1.	2	11.11	0.5
2.	10	55.56	2.4
3.	20	111.11	4.72
4.	50	277.78	11.74

Source: Authors, (2026).

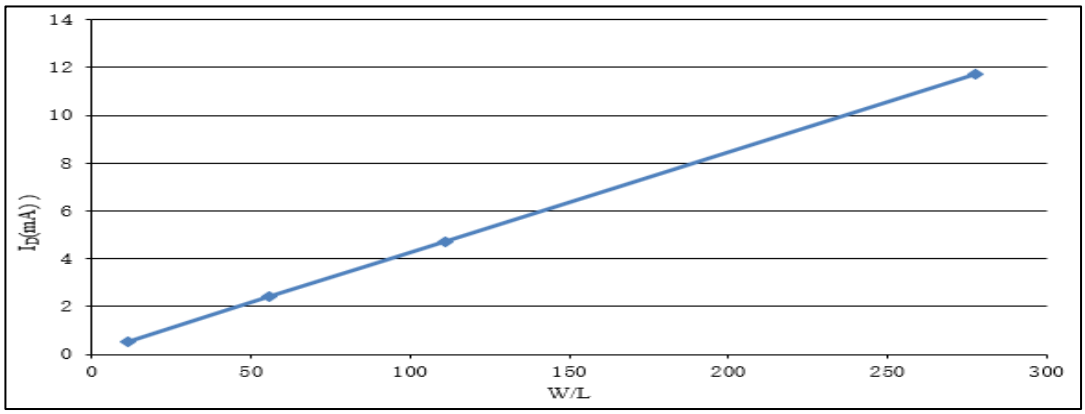

Figure 10: Variation in I_D due to W/L.
Source: Authors, (2026).

Drain current increased from 0.50 mA (W/L = 11.11) to 11.74 mA (W/L = 277.78). This shows proportional scaling with width, which is consistent with strong inversion MOSFET equations.

IV.2 CHARGE INJECTION

Charge injection in MOSFET switches occurs when charge stored in the channel is released into the drain and source nodes during the turn-off transition. The channel charge and the amount of injected charge are directly correlated, which increases with device width and hence with a higher W/L ratio. Table 3 shows that as the W/L ratio increases, more charge is transferred to the connected node, resulting in a larger voltage disturbance across the load capacitance. This explains the observed increase in voltage drop (charge injection effect) with increasing W/L ratio in figure 11.

Table 3: Parameters for voltage drop $(mV)$with respect to W/L.

Sr.No.	W µm	W/L µm	Voltage drop (mv)
1.	2	11.11	0.06
2.	10	55.56	0.28
3.	20	111.11	0.51
4.	50	277.78	1.02

Source: Authors, (2026).

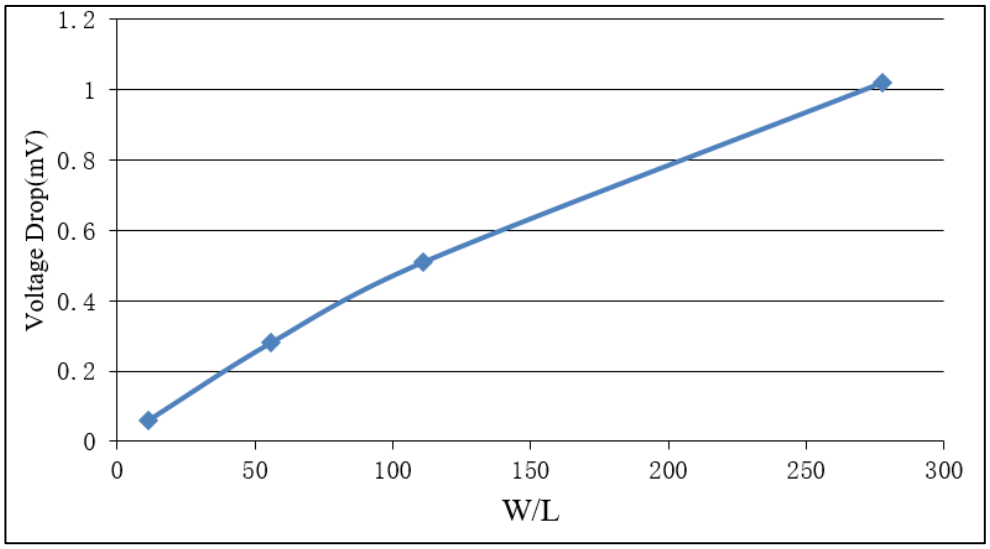

Figure 11: Effect of Charge Injection with respect to W/L.
Source: Authors, (2026).

Figure 11 displays the relationship between the Voltage Drop (in millivolts, mV) and the W/L ratio, which typically represents the width-to-length ratio of a MOSFET, in integrated circuits or electronic design. As the W/L ratio increases, the voltage drop across the component also increases proportionally. Figure 11 illustrates how increasing W/L increases the effect of charge injection from 0.1 to 1.1. In Figure 8, when the width is scaled down from 50 µm to 2 µm, the simulation results in Figures 12 and 13 show a significant reduction in charge injection due to the decreased channel charge associated with smaller device dimensions.

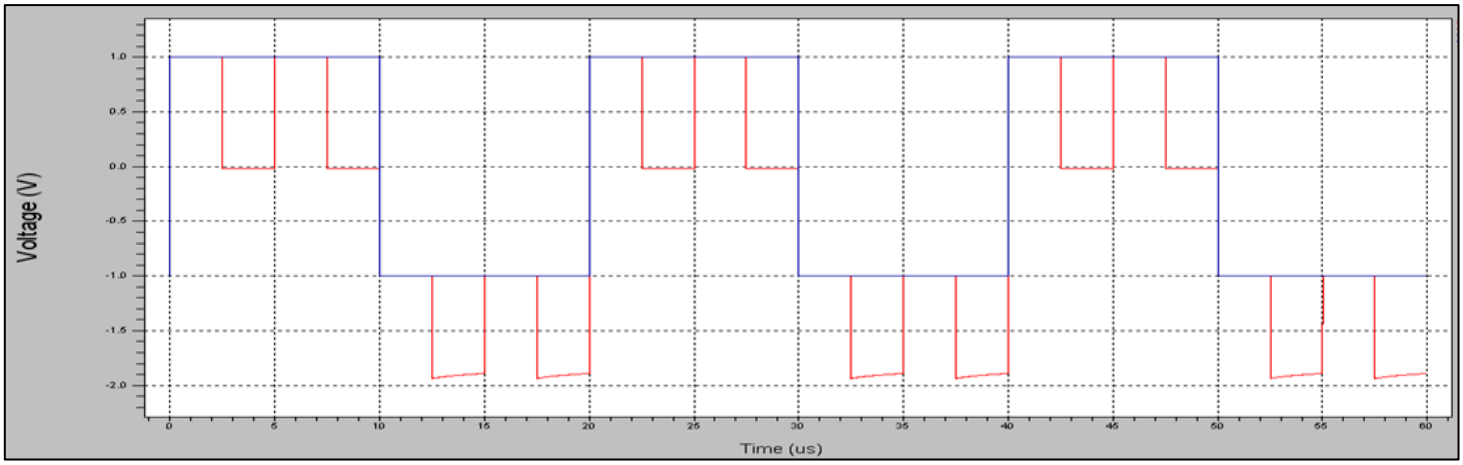

Figure 12: Effect of Charge Injection on W/L for W=50 µm.
Source: Authors, (2026).

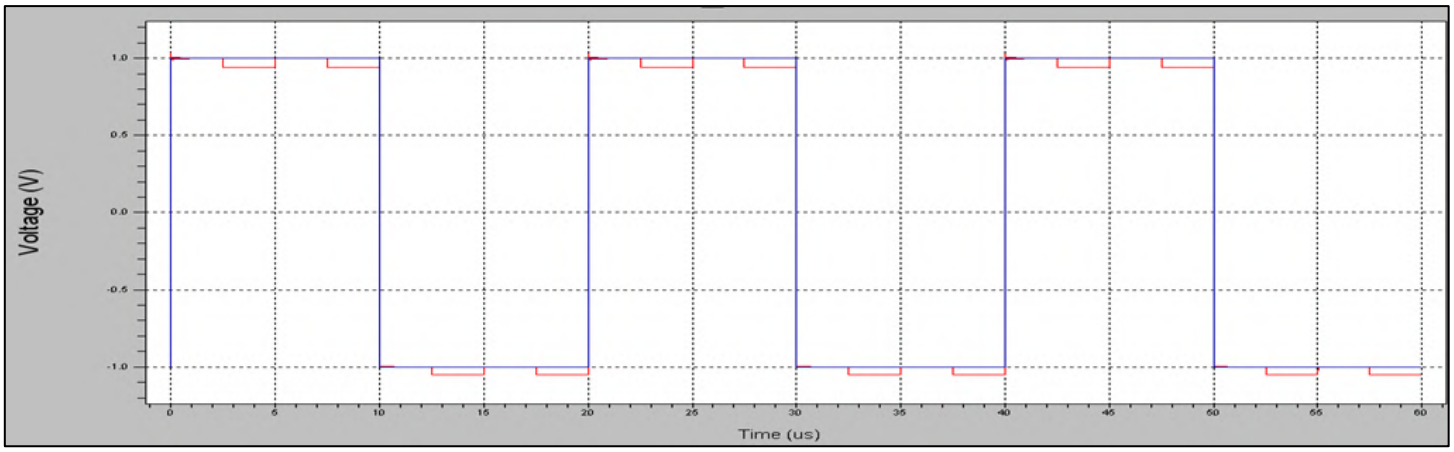

Figure 13: Effect of Charge Injection on W/L for W=2 µm.
Source: Authors, (2026).

IV.3 CLOCK FEED THROUGH

In Figure 8, a dummy switch transistor is added in series with the main switching transistor, as shown in Figure 14. When we simulate Figure 14, it will effectively minimize both charge injection and clock feedthrough effects, as shown in Figure 15. The dummy transistor compensates for the injected charge during switching, resulting in improved accuracy and performance of the circuit. Overall, the combined approach of transistor width reduction and dummy switch implementation proves to be an effective technique for mitigating charge injection effects in switched-capacitor circuits.

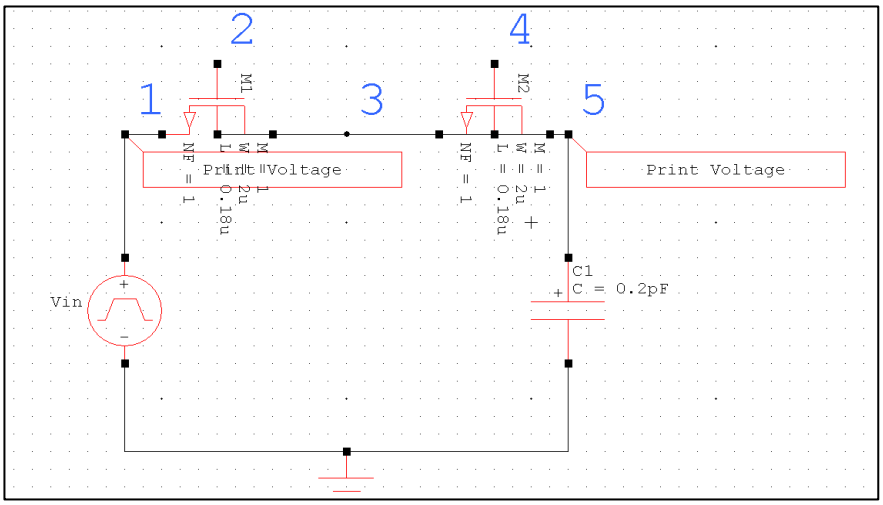

Figure 14: Reduction of clock feed-through using a dummy transistor.
Source: Authors, (2026).

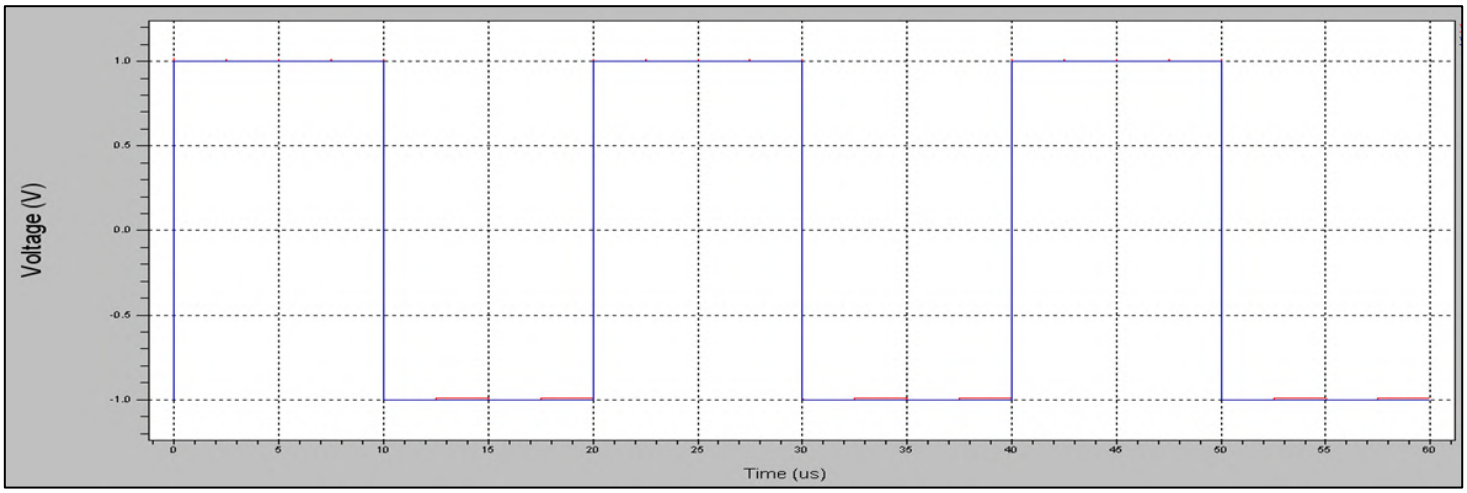

Figure 15: Clock feed through and Charge Injection reduction by dummy transistor.
Source: Authors, (2026).

V. CONCLUSION

The application of MOSFET switches in SC circuits is examined. The MOSEFT switch's shortcomings are described. Implementation and simulation results are presented for the solutions of the MOSEFT switch non-idealities. Increasing W/L improves NMOS performance by increasing I_D and reducing R_{on}. Process parameters were constant, confirming that geometry was the primary factor influencing electrical behavior. These results support further research into NMOS scaling and performance modeling. The analysis reveals that the W/L ratio significantly affects NMOS transistor performance. Important conclusions include:

1. Because of better channel conduction, the drain current rises significantly with wider channels.
2. As W/L increases, on-on resistance drastically drops, improving current delivery efficiency.
3. Process parameters that are consistent guarantee that changes are only the result of geometric scaling.
4. Device validity is confirmed by measured results that match theoretical MOSFET models.

These results contribute to MOSFET scaling and performance modelling research and encourage additional device optimisation studies.

ABSTRACT

The software industry in India has emerged as a major driver of economic growth, export expansion, and structural transformation within the service sector. In this context, assessing firm-level efficiency is essential for understanding the sector's contribution to economic development. This study empirically examines the technical efficiency of selected Indian software companies over the period 1992–2023 using an input-oriented Data Envelopment Analysis (DEA) model under variable returns to scale (VRS). Firm-level panel data are utilized, with total liabilities and fixed assets as inputs and net sales and profit after tax as outputs. The findings reveal substantial heterogeneity in efficiency performance across firms over time. While leading firms operate close to the efficiency frontier, several firms exhibit persistent inefficiencies, indicating significant scope for improved resource utilization and scale optimization. The results highlight the importance of managerial capability, financial structure, and efficient capital allocation in sustaining the long-term contribution of the software sector to India's economic development.

I. INTRODUCTION

The software industry in India has made a significant contribution to the country's gross domestic product as well as has a remarkable share in the service sector. The software industry, also referred to as Information Technology (IT) or Information and Communication Technology (ICT) is capable of influencing various production sectors such as healthcare, transportation, finance, banking, insurance, logistics, retail, manufacturing, communication and media, entertainment and education [1–5]. In a study Jain et al. [6] conclude that fast delivery, internationalization and adaptation to evolving technologies are key drivers of the growth of the software industry. In 2007, global IT services expenditure amounted to USD 747 billion which grew about 32.13 % in 2018 to 987 billion (USD) [7], [8]. At the end of 2026, the IT industry is expected to reach approximately USD 1.65 trillion, with continued expansion which is influenced by digital transformation initiatives, hybrid cloud migrations, and AI-related service demand. With the global adoption of IT, the Indian software sector is crucial in catering to the demand of the global market. Many Indian IT firms had a global presence. In the Indian economy, the software sector is one of the most dynamic and emerging industries, contributing significantly to economic growth, export earnings, employment generation, and service-sector expansion since the early 1990s. Indian software sector grew rapidly in post-economic liberalization, in 1991-92 from a tiny domestic activity, catering to the domestic market demand to a global competitive industry with huge world market share [9], [10]. It began to play a role in the productivity growth and structural transformation [11]. The significance of the IT sector can be gauged by the contribution to nation's Gross Domestic Product (GDP) which was 1.2% in 1998 growing to 7.9 % in 2018. The Indian IT and IT-enabled services (IT-BPM) sector kept on growing as a sole contributor to the economic growth and exports. The sector generated 91 billion USD as total revenue in 2019, expanded significantly contributing around 7.4 percent of India's GDP and about USD 245 billion in revenues by FY 2022 (CEIC; ESC India Statistical Year Book). Similarly, in FY 2023–24, the industry's overall revenues were roughly USD 253.9 billion, with software services exports constituting the majority of the earnings and maintaining a GDP share of about 7.5–8 percent (ESC India Statistical Year Book). In FY 2024–25, industry expanded nearly USD 283 billion in total revenues, with export earnings near USD 224.4 billion.

Outlooks for 2025 indicate that the IT sector's contribution to GDP may approach around 10 percent, supported by accelerating digital transformation, cloud adoption, and AI-enabled services across the economy. Behind this trajectory of expansion, the Indian IT also passed through major setbacks due to 2008 financial crisis on the technological front [9], [10]. The success of the software sector is enhanced by skilled workers as Indian IT sector is human capital-intensive. Many studies [2], [5], [12–14] suggest the association of the workers' skills, health, efforts and individual performance. It is essential to assess the efficiency of the IT sector in applied economics and development studies. Sales maximization is the guiding principle for software companies [15] as it leads to maximization of market share. The performance of the Indian software/IT sector has been assessed using both parametric and non-parametric approaches. Data Envelopment Analysis (DEA), introduced by [16], is a widely applied non-parametric frontier technique for measuring the relative efficiency of decision-making units (DMUs) characterized by multiple inputs and outputs. DEA is employed to assess the performance of IT/software sector across the globe. The studies [17–20] used DEA to analyse the efficiency of the IT sector in India. The efficiency reflects the extent to which firms optimally utilize available financial and capital resources. To hold on a progressive long- term growth it is essential to enhance the efficiency and productivity with focus on international competitiveness, particularly in a developing economy like India [21]. The underlying insights essential for policymakers and industry stakeholders is inferred from such empirical evaluation of efficiency. Although the Indian software industry has grown rapidly, there is a lack of long-term empirical evidence on firm-level efficiency in the Indian context. Literature is largely dominated by short-term assessments, which offer only partial insights into the sector's evolution [22]. Although several studies have examined efficiency in the Indian IT sector, most are confined to short time spans or specific sub-periods. There is limited empirical evidence based on long-term firm-level data covering more than three decades, including phases of liberalization, global expansion, financial crises, and post-pandemic recovery. This study addresses this gap by providing a comprehensive static DEA-based efficiency assessment for the period 1992–2023. Since the Indian software sector accounts for a significant share of service-sector value added and export earnings, improvements in firm-level efficiency directly influence aggregate productivity, employment generation, and foreign exchange earnings. Therefore, analyzing technical efficiency is not merely a firm-level exercise but also a development-oriented investigation with macroeconomic relevance.

II. RELATED WORK

The significance of liberalization, globalization, and technological advancement in improving the performance of Indian firms has been addressed in several studies [11], [21]. Efficiency analysis has long occupied a central place in applied economics, particularly in studies examining firm and industry performance. Data Envelopment Analysis (DEA), introduced by [16] and extended by [23], has been widely used to estimate the technical efficiency in situations involving multiple inputs and outputs without imposing restrictive functional form assumptions. DEA has been widely applied to assess the performance in the service sector and knowledge-intensive industries, where production processes are complex and heterogeneous [24]. Numerous studies on software as well as information technology firms have reported considerable variations in efficiency and productivity dynamics across firms, which are often attributed to firm size, resource utilization, and managerial competence [20], [25].In the Indian context, ample evidence exists concerning IT/software firms. In an analysis, Mathur [17] used an input-oriented Data Envelopment Analysis (DEA) model to assess the technical efficiency of 92 Indian software companies for the year 2005–2006 and concluded that only 16 companies were efficient. Mathur [18] assessed the technical efficiency of the Information and Communication Technology (ICT) sector in 12 selected countries using Data Envelopment Analysis. In this study, it was found that the IT sector of Taiwan was the most efficient, while the Indian IT sector was the least efficient. Later, Bhattacharjee [26] estimated the technical efficiency of Kolkata's Software Technology Parks (STPs) for IT–ITeS firms under the variable returns to scale (VRS) assumption using an output-oriented DEA model. The study included all IT and IT-enabled service firms in eastern India for the period 1993 to 2007. The study revealed that the efficiency of large firms improved during the study period and further concluded that segment-specific policies may lead to improved productivity compared with uniform policies. Overall Technical Efficiency (OTE), Pure Technical Efficiency (PTE), and Scale Efficiency (SE) were estimated using DEA. Total sales were considered the output, while employment, expenditure on computers and electronic equipment, operating expenditure, and power, fuel, and water charges were used as inputs.

The mean PTE score is observed to be around 0.6, indicating nearly 40% pure technical inefficiency among the firms. Poor infrastructure, particularly inadequate power supply, is identified as a major constraint affecting performance. The percentage of efficient firms in terms of PTE is lowest in 2003–04 (20.83%) and highest in 2005–06 (40.28%), thereby showing a cyclical pattern over the period. Scale inefficiency increased over time. By [22] analyzed productivity growth trends for 72 Indian software companies from 1999 to 2008. It was found that only 65% of the inputs were optimally utilized by the software firms in India. It was also inferred that larger software firms tended to operate closer to the efficiency frontier, while smaller firms exhibited greater inefficiency and volatility. Domestic software firms were found to be more efficient than the foreign-owned firms. Das [27] evaluated the performance of Indian ITeS industry during 2000-01 to 2014-15 by using a two-stage empirical method to estimate technical efficiency through Data Envelopment Analysis (DEA). The DEA results revealed that managerial inefficiency is the major contributor to overall technical inefficiency compared with inefficient scale of production. Das and Datta [20] applied a two-stage data envelopment analysis method to assess the trends and determinants of technical efficiency in the Indian IT and ITeS industry from the year 2000-01 to 2014-15. In the first stage, output-oriented technical efficiency scores were estimated using CCR, BCC and PK DEA models. In the second stage, the determinants of PK-efficiency were estimated using a random-effects Tobit regression model. The investigation revealed that managerial underperformance was the root cause of overall inefficiency in ITeS companies. By [28] examined the relative efficiency of the top 18 Indian IT software service companies using an output-oriented DEA model. The study assessed overall technical efficiency, pure technical efficiency, and scale efficiency for the period 2010–2017 using CMIE data. Sales expansion and market share growth were considered as the strategic objectives guiding the operations of IT companies. Workers' effort was used as the primary input variable, while net sales turnover and net profit after tax were selected as output variables, with profit after tax serving as an indicator of cost-effectiveness. The results indicated a very high average efficiency score of 96%, suggesting only a limited potential improvement of approximately 4% in output levels at the existing input configuration.

The concept of Functional Efficiency Quality (FEQ) is proposed by [29]. They estimated FEQ for Indian software firms using a sensitivity function-based approach. It is observed that existing literature lacks a comprehensive long-term firm-level static DEA assessment which captures the structural evolution of the industry across the liberalization, global financial crisis, and post-pandemic periods (1992–2023).

III. DATA AND METHODOLOGY

III.1 OBJECTIVE OF THE STUDY

The objectives of the paper are as follows: i) To estimate the technical efficiency of selected Indian software firms using an input-oriented Data Envelopment Analysis (DEA) model under variable returns to scale (VRS) for the period 1992–2023. ii) To examine long-term industry-level efficiency trends across different structural phases of the Indian software industry. iii) To analyse firm-level efficiency heterogeneity and discuss its implications for India's economic development.

III.2 METHODOLOGY

To determine the trends in performance, the notion of technical efficiency is adopted and estimated using an input-oriented Data Envelopment Analysis (DEA) technique. DEA is a non-parametric approach used to evaluate the relative efficiency of similar entities, known as decision making units (DMUs), that employ multiple inputs and multiple outputs [30-32]. The efficiency of a DMU is measured as the relationship between inputs and outputs.It is measured as the ratio of weighted sum of outputs to the weighted sum of inputs when multiple DMUs are involved, as shown below.

$$Efficiency(e) = \frac{\sum_{i=1}^{n} O_i}{\sum_{i=1}^{n} I_i} \quad (1)$$

In the above equation, e denotes the efficiency; Oi and Ii represent outputs and inputs respectively, and n denotes the total number of DMUs considered. DEA has evolved significantly over the past five decades and has been extensively used in diverse fields to assess performance as well as for benchmarking [33]. A DEA model proposed by Charnes et al. [16] uses a linear programming technique known as the Charnes, Cooper and Rhodes (CCR) model, which assumes constant returns to scale (CRS). The efficiency score estimated using the CCR model is referred to as overall technical efficiency. Another variation of DEA model, based on the assumption of variable returns to scale (VRS), was proposed by incorporating a convexity condition into the CCR linear programming model. This model is known as Bankers-Charnes-Cooper (BCC) model [23]. Three types of efficiency – pure technical efficiency (PTE), scale efficiency (SE) and overall technical efficiency (OTE) can be estimated using the DEA method. Efficiency can be estimated using either of these two DEA models [24], [32], [34]. In the present empirical study, technical efficiency is estimated using an input-oriented Data Envelopment Analysis (DEA) framework under variable returns to scale (VRS). The input orientation is considered appropriate as software firms have greater managerial control over resource utilisation rather than output levels, which are largely influenced by market demand and global outsourcing trends. The VRS specification enables separation of pure technical efficiency from scale efficiency, thereby capturing the heterogeneity in operational scale at the firm level.

III.3 DATA AND VARIABLE SPECIFICATION

Data for software firms in India were collected for the period 1992-2023. To obtain a comprehensive long-term overview of the performance of the software sector, twelve companies that operated continuously from 1992 to 2023 were selected for the empirical analysis. The basis for selecting these companies is their continuous survival in the market over three decades, including the periods of global crises. This selection was made to meet the objectives of this study. The literature considers different variables for efficiency assessment in software/IT firms. Profit (net profit or profit after tax) has been considered as an output variable in several studies [28], [25]. Income has also been used as an output variable in some studies [10], [25]. Several empirical studies have assessed firm performance using sales as the output variable [17], [22], [28]. In our study, input and output variables reflecting financial performance are used. The two input variables selected are total liabilities(I_1) and fixed assets (I_2). The output variables used in this study are net sales (O_1) and profit after tax (O_2). Profit after tax is a good measure of corporate profitability. The DEA Program (DEAP) software was used for estimation of efficiency [34].

IV. EMPIRICAL RESULTS AND DISCUSSIONS

The overall experimental result is presented under the descriptive performance trends and efficiency trends of Indian software companies. Both these assessments are elaborated in the section below.

IV.1 DESCRIPTIVE PERFORMANCE TRENDS OF INDIAN SOFTWARE COMPANIES

In this section, the performance of Indian software firms is discussed in detail. The performance analysis is carried out using industry-level averages of sales, profit, fixed assets, and total liabilities for the period 1992–2023.

IV.1.1 Growth Trends in Sales and Profit

The analysis carried out on the firm's average sales trend shows a clear and sustained growth throughout the study period. The finding revealed that in the early liberalization phase (1992–2000), sales growth remained relatively modest. During the post-2000 period, a sharp increase is observed, accompanied by the expansion of export-oriented IT services and increased global demand. Significant scalability and market penetration of Indian software firms were observed from 2010 onward, accompanied by rapid growth in Sales. In early 1990s the profit trend remained low, while gradually increasing in the mid-2000s onward which shows a similar pattern to Sales.

Though there is existence of slight ups and downs, profitability increased and remained relatively consistent over years, which suggests improved cost management and greater operational maturity. Steady rise in sales and rising profit indicates that the growth has been as supported by improved financial performance. The post-2010 period is therefore considered as an expansion phase, while the phase beginning around 2010 may be characterized as a period of consolidation and maturity.

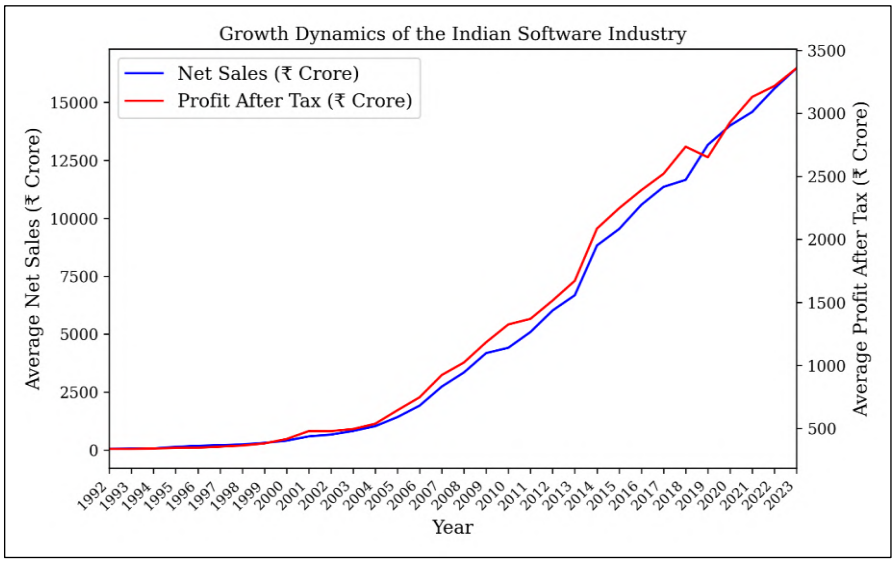

Figure 1: Industry average sales trend for selected software companies.
Source: Author's calculation, CMIE (2026).

IV.1.2 Capital Deepening over Fixed Assets

A remarkable level of capital deepening is revealed by the trend in fixed assets over time. Initially from 1990 to 2003, firms had less fixed assets which indicates low capital intensity in the early phase software sector's evolution. Fixed assets increased from 2004 and continued until 2012, it started to grow more rapidly 2013 onward and the growth continued until 2023. This rise in fixed assets is due to the investments in infrastructure, development centres, and technology platforms. It can be inferred that increased mobilization of advanced IT infrastructure and digital capabilities lead to the rise of fixed assets beyond 2010. A transition toward high-value software services and digital transformation is reflected by this rise.

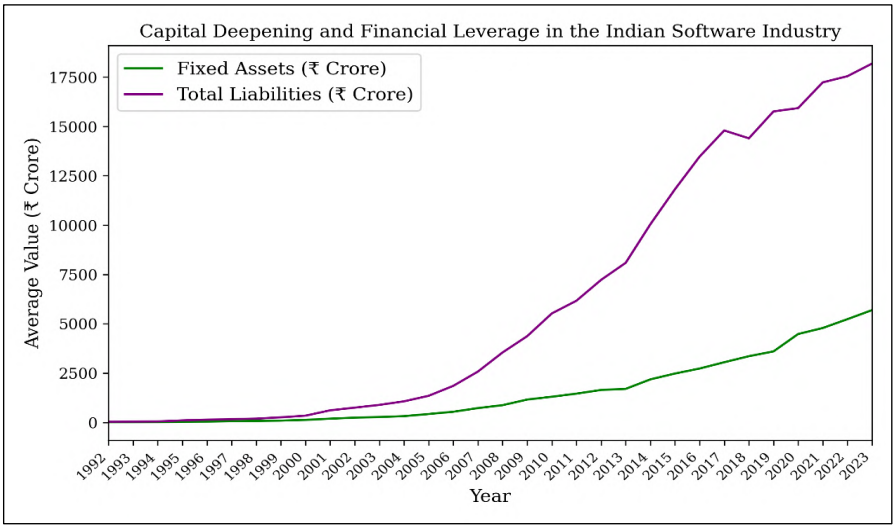

Figure 2: Capital deepening trend estimated on average fixed assets and total liabilities of Indian software companies, 1992–2023.
Source: Author's calculation, CMIE (2026).

IV.1.3 Financial Structure and Liabilities Trend

It can be observed in figure 2, that the company's total liabilities trailed an upward trajectory similar to fixed assets and sales. From 1992-2000, total liabilities of the company were less, but it gradually rose from 2007 onwards. The trend went up till 2017 but sharply went down in 2018. Total liability kept growing continuously until 2023. The dependence of companies on financial leverage is reflected by these rising trends, which also shows its expansion and boosting up in operations. In the periods of global economic stress, particularly around the 2008 financial crisis, company met the setbacks, which is indicated by the ups and down in the trend. It also reflects the company's effort to arise from uncertainty. This reflects an expansion-driven financial structure is depicted by the growth of total liabilities and the intermittent variations point to periods of volatility linked to macroeconomic shocks.

IV.1.4 Software Industry Performance Phases

The trends in all variables are taken together to get an overview of the performance of selected companies. While considering the trends in sales, profit, fixed assets and liabilities, the performance trajectory of the Indian software industry can be broadly classified into three distinct phases. The first phase, Emergence and Stabilization (1992–2000), is characterised by modest growth, limited capital intensity and low financial leverage as the industry established its foundational capabilities. The second phase, Rapid Expansion (2001–2010), shows strong and synchronous growth in sales and profits, with significant build-up of assets and liabilities to scale operations globally. The final phase, Maturity with Periodic Volatility (2011–2023), is marked by sustained top-line growth along with capital deepening, where the maturity of the industry also exposes it to periodic fluctuations in financial performance due to exogenous global economic factors.

IV.1.5 Implications for Efficiency Analysis

It is implied by descriptive trends that output and resource usage have improved substantially, and several economic and technological conditions are responsible for this growth. Therefore, it is significant to assess the relative efficiency instead of absolute performance, which encourages the use of an input-oriented DEA model under variable returns to scale in the consequent analysis.

IV.2 EFFICIENCY TRENDS OF INDIAN SOFTWARE COMPANIES (1992–2023)

An input-oriented DEA under VRS is employed to estimate the technical efficiency scores of selected Indian software companies. The efficiency trends are analysed at three levels: year-wise industry averages, long-term average efficiency, and company-wise efficiency trajectories.

IV.2.1 Year-wise DEA Efficiency Trends

The Technical efficiency score for every year (1992–2023) is estimated using total liabilities and fixed assets as inputs, and sales and profit as outputs. The industry average efficiency trend indicates the presence of many fluctuations over time. There is a gradual improvement in technical efficiency over the study period. The average technical efficiency shows growth from 1993 to 1994 and then continued in a similar manner till 1997. A sharp decrease in 1998 but rose abruptly in 1999 and reached peak at 2000. There was a fall again in 2002 but reversed within a year. The accelerated efficiency during the post-2000 period coincides with export expansion and increased adoption of information technologies. Minor declines are observed during periods associated with global economic uncertainty, particularly around the 2008–09 financial crisis, indicating temporary efficiency disruptions. The ups and downs continued until 2016, presenting a long range of fluctuations. Post-2016, the trend shows a monotonic decrease till 2021. The severe decrease in the year 2020 and with the lowest score 0.70 in 2021 may be attributed to the impacts of COVID-19. The decreasing trend soon reverses by mid-2021 and keeps growing in the later years.

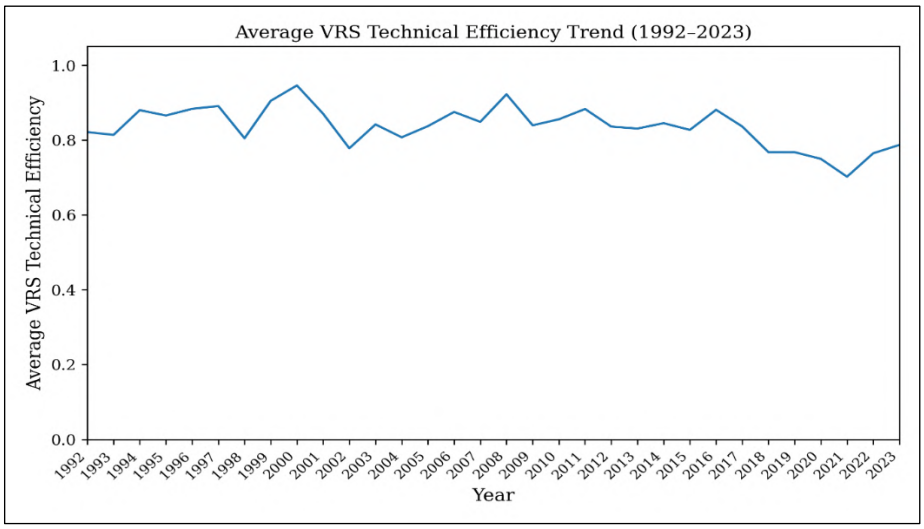

Figure 3: Average VRS technical efficiency trend of selected Indian software companies during 1992–2023.
Source: Author's calculation, CMIE (2026).

IV.2.2 Average Efficiency Trends (1992–2023)

To assess long-term performance, average DEA efficiency scores were computed across the entire period (1992–2023) for the selected software firms. The results show that while several firms consistently operate close to the efficiency frontier, others exhibit persistent inefficiencies. It is observed that the increase in average efficiency leads to the better utilization of financial and capital resources over time. Analysis shows a scope of more improvement, represented by the presence of efficiency gaps across firms, which can be attained through better resource allocation and scale optimization. Rising average efficiency reflects industry maturation, while inter-firm differences highlight heterogeneous managerial capabilities.

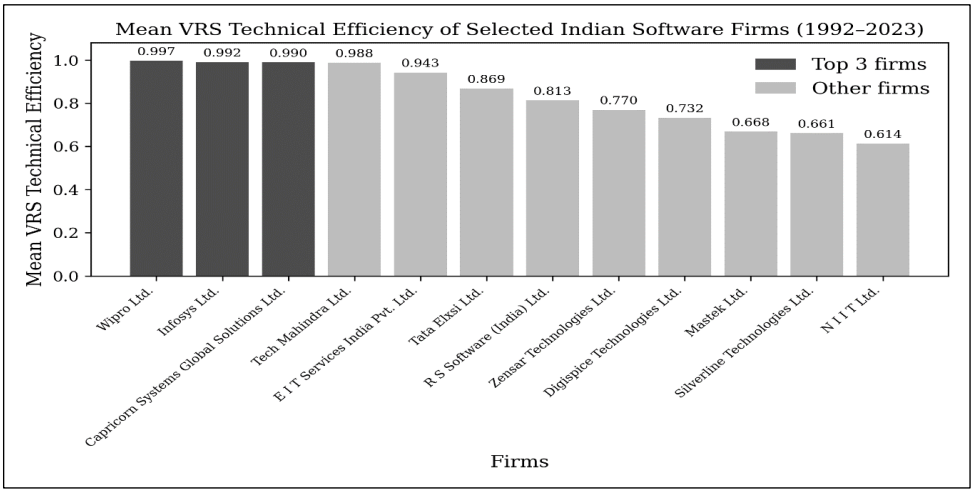

Figure 4: Company-wise VRS technical efficiency of selected Indian software companies during 1992–2023.
Source: Author's calculation, CMIE (2026).

V. CONCLUSIONS

The empirical findings indicate that the Indian software industry has experienced a sustained improvement in technical efficiency over the period under study, albeit with intermittent fluctuations. This upward trend reflects the combined influence of technological progress, industry learning effects, and improvements in financial and managerial practices, leading to enhanced resource utilization capacity over time. However, the efficiency trajectory has not been uniform, as temporary declines are observed during periods of global economic stress, such as the 2008–09 financial crisis and the COVID-19 pandemic, highlighting the industry's sensitivity to external shocks. At the firm level, the analysis reveals a significant degree of heterogeneity in technical efficiency, which persists across time. Larger firms are generally found to operate closer to the efficiency frontier, while small and mid-sized firms exhibit greater inconsistency in efficiency performance. This uneven distribution of efficiency gains suggests that, despite overall progress, substantial scope for improvement remains, particularly among relatively less efficient firms. The presence of persistent inter-firm disparities underscores the importance of factors such as managerial capability, financial structure, and optimal scale of operation in determining firm-level performance. While the gradual rise in average efficiency signifies strengthening operational performance across the industry, continued heterogeneity may have implications for competitiveness, innovation capacity, and long-term sectoral sustainability. In this context, fostering balanced efficiency improvements remains critical for reinforcing the industry's contribution to economic growth and resilience.

Adaptive Decision Timing.

ABSTRACT

Early social media rumor detection is essential because it prevents false information from spreading quickly and causing serious harm. Current methods frequently ignore the significance of prompt decision-making in favor of increasing classification accuracy. In this paper, we present a novel framework for early rumor detection that is based on multimodal meta-learning with adaptive decision timing. The method analyzes social media posts as an ongoing stream and learns when enough data has been observed to dynamically identify the best time to make a forecast. By integrating textual, structural, and temporal features, the proposed approach captures complex rumor propagation patterns while jointly optimizing accuracy and detection timeliness. Experimental results on benchmark datasets, including Twitter15, Twitter16, and Weibo, show that the proposed method significantly reduces detection latency, requiring substantially fewer messages for prediction, while maintaining competitive or superior performance compared to state-of-the-art baselines.

I. INTRODUCTION

The danger of false information and rumors spreading has greatly grown due to the quick spread of information on social media platforms. Rapid and widespread rumors can have detrimental effects on society, such as economic disruption, public panic, and disinformation during important events [1]. As a result, creating efficient methods for early rumor detection has emerged as a crucial research task. Existing approaches to rumor detection have achieved notable success by leveraging machine learning and deep learning techniques. Traditional methods such as [2], [3] and [4] rely on handcrafted features and static classifiers, while more recent approaches employ sequential models such as recurrent neural networks and Transformers to capture temporal dependencies in message propagation. Despite these advancements, most existing methods primarily focus on improving classification accuracy and typically assume access to complete or near-complete event sequences. However, prompt detection is just as crucial as precision in practical situations. Rumors might spread far before any action is taken due to delayed detection. Early detection is intrinsically difficult because there is little to no information available at the beginning of an occurrence. Furthermore, the best time to make a trustworthy prediction varies based on the dynamics of each event's propagation. We provide a novel framework based on multimodal meta-learning [5] with adaptive decision timing for early rumor detection in order to overcome these drawbacks. In the suggested method, rumor detection is modeled as a sequential decision-making issue. Incoming messages are processed as a continuous stream by the model, which dynamically determines when enough evidence has been observed to make a prediction. By considering multiple types of information, such as textual content, structural propagation patterns and temporal dynamics, the framework is able to capture comprehensive features of social media events. Furthermore, a meta-learning strategy is applied to facilitate generalization to unseen rumor types, which allows the model to generalize to different propagation patterns. The core of the proposed method is the adaptive decision process, which lets the model automatically find the earliest confident decision time. The proposed model performs early and accurate rumor detection, greatly reducing detection latency while maintaining comparable or higher classification performance compared to existing methods, according to extensive trials carried out on benchmark datasets. The following is a summary of the primary contributions:

1. We propose a multimodal meta-learning framework. It combines textual, structural, and temporal features.
2. We present an adaptive decision timing mechanism that that finds the best prediction point.
3. We ran many tests. They show that our method finds rumors earlier. It needs fewer observations and still has strong classification performance.

The rest of the paper is organized as follows: Section 2 surveys prior work, and Section 3 provides the proposed method and the new framework. Section details the Experimental and the findings. Section 5 provides a discussion of the experimental findings and their analysis. Lastly, Section 6 concludes the paper and future work.

II. RELATED WORK

II.1 RUMOR DETECTION ON SOCIAL MEDIA

The development of manually created characteristics for machine learning algorithms has historically been the primary focus of research on rumor detection. Using both conventional machine learning and deep learning methods, rumor detection on social media has been thoroughly investigated [6]. Early approaches use classifiers like Support Vector Machines and Random Forests in conjunction with manually created features taken from textual content, user profiles, and propagation structures [7]. Although these methods offer preliminary insights, feature engineering and their incapacity to identify intricate patterns restrict their effectiveness. In more recent work, representations are automatically learned from data using deep learning algorithms [8]. The temporal dynamics of message sequences have been extensively modeled using recurrent neural networks, such as LSTM and GRU. By using self-attention methods to capture long-range dependencies, transformer-based models significantly enhance performance. Despite these developments, the majority of current methods, which frequently assume access to full propagation sequences, are primarily concerned with increasing classification accuracy.

II.2 EARLY RUMOR DETECTION

The goal of early rumor detection is to identify rumors when they are just beginning to spread and there is little information available. A number of methods make predictions based on incomplete sequences or preliminary observations in an effort to overcome this difficulty. In order to effectively capture global semantic relations in rumor texts, the authors of [9] built a tweet-word-user heterogeneous graph and proposed a meta-path-based heterogeneous graph attention network framework that uses subgraph attention networks to learn global node relationships and a subgraph-level attention mechanism to fuse node representations. The authors of [10] used transfer learning to extract attitude representations from external stance-classification datasets by utilizing pretrained CNN and BERT models. For early rumor detection, their deep model (CNN-BiLSTM-BERT) combines attitude and content representations. Authors of [11] proposed a deep attention model based on RNNs with soft-attention. Without depending on manually created features, the model accurately identifies long-range dependencies and contextual changes over time. It detects rumors faster and more correctly than state-of-the-art baselines, according to extensive trials on real-world social media datasets. [12] presents a few-shot prototype augmentation framework for low-resource rumor detection. In addition to a metric learning methodology, it uses hierarchical prompt encoding to obtain language/domain-agnostic thread representations and refines prototypes via query-conditioned attention and feature gating. The method is compatible with parallelized streaming settings and achieves cutting-edge cross-lingual/domain performance. To produce predictions at intermediate time steps, sequential models have been modified, as in [13].

Accuracy and timeliness must be balanced, according to recent research, but most methods tackle these goals separately rather than working together to maximize both. A recent approach [14] have integrated timeliness and community structure. It uses a hybrid sensor deployment for effective information gathering, simulates dynamic propagation with a time-varying parameter, and uses maximum likelihood estimation within suspicious communities to identify one or more sources. This is the first framework for community-structured dynamic OSNs, and experiments on both real-world and synthetic networks show correct identification. The authors in [15] have presented an early reinforcement learning-based rumor detection model that extracts characteristics from original tweets and responses using a dual-engine deep learning architecture and double self-attention. While optimizing a reward function that strikes a compromise between timeliness and accuracy, a Deep Recurrent Q-Learning Network (DRQN) learns state sequence features. Nevertheless, a lot of these techniques rely on fixed time intervals or predetermined observation windows, which fail to take into consideration the variation in rumor spreading patterns among various events. As a result, they might either postpone forecasts needlessly or make snap judgments based on incomplete knowledge. [16] presents ERD-DC, a dual-channel early rumor detection model that differentiates between "difficult-to-identify" rumors and "easy-to-identify" rumors. While a slow channel does thorough analysis to ensure overall correctness, a fast channel prioritizes timeliness by performing quick post-evidence matching for simple cases. State-of-the-art performance is demonstrated by experiments on real datasets, which successfully balance detection speed and reliability and achieve an accuracy rate of 84%.

II.3 MULTIMODAL LEARNING FOR RUMOR DETECTION

By combining several information sources, multimodal techniques have been put forth to enhance rumor detection. These include temporal elements that depict how events change over time, as well as textual content, user interactions, and propagation structures. The multimodal rumor detection system presented in [17] introduces trainable input parameters while maintaining a frozen backbone, utilizing quick learning in both the vision and language domains. Early on, different prompts gradually model feature interactions, improving context learning. Superior performance in differentiating between rumors and facts is demonstrated by experiments conducted on real-world multimodal datasets. In order to improve the propagation structure and obtain useful local video segments, [18] uses time-sync comments to detect video rumors. It integrates multimodal characteristics for categorization from both local and global keyframes, subtitles, and comments.

In order to address multimodal misinformation detection, [19] presents CPLS (Contrastive Prompt Learning in Structured Graph Networks), a model that builds structured graph networks with semantic-aware pruning and fusing. Accuracy gains of 2.4% on Weibo and 4.5% on Twitter are demonstrated in experiments conducted on public datasets. In recent work [20] presents LoRAD (Logic-Reasoning Augmented DeBERTa). It uses DeBERTa's disentangled attention method to combine logical evidence produced by an LLM with the original text. Evaluated on three publicly available datasets as well as a recently created Twitter26-Mini dataset, LoRAD outperforms LLMs in terms of robustness and inference speed, making it appropriate for real-time rumor detection. These methods produce stronger representations and better classification results by merging complimentary modalities. Nevertheless, the problem of early detection in streaming contexts is not specifically addressed by current multimodal models, which are usually built for static or fully observed data. A successful model for enhancing generalization across tasks is meta-learning [21]. Meta-learning allows models to swiftly adjust to new patterns with few observations in the setting of sequential data. Although meta-learning has been used in many different fields, it is still not widely used for rumor detection. Its potential for simulating various rumor dissemination dynamics or for enhancing early decision-making is hardly explored in existing studies. For instance, a meta-learning framework was developped by [22] that jointly learns social bot detection as an auxiliary job to improve rumor detection. The model ensures that information from the auxiliary task efficiently serves the main goal by using an outer-loop optimization on rumor detection and an inner-loop pseudo-update on bot detection. The findings of the experiment show excellent performance, reaching 90% accuracy in just two hours.

II.4 META-LEARNING IN SEQUENTIAL MODELING

Additionally, there is still much to learn about the potential of meta-learning in the field of rumor detection. In order to fill these deficiencies, this paper presents a unified framework that combines adaptive decision timing and multimodal meta-learning to enable early and accurate rumor identification in dynamic information contexts. Using the ISOT dataset [23], [24] proposed the application of meta-learning in conjunction with BERT for the detection of fake news. While highlighting constraints and the significance of responsible AI design, an ensemble transformer-based model achieves a high accuracy of 98.29%, showcasing the promise of meta-learning in enhancing detection performance. Meanwhile, [25] proposes a multimodal meta-learning method based on few-shot learning (FSL) for early rumor detection, addressing the challenges of limited spread and small sample sizes. It uses a meta-learning method with quick, multi-step updates to improve flexibility while designing a multimodal feature extraction layer, a hidden information extraction layer, and a fusion output layer. In conclusion, even though previous studies have shown significant improvements in multimodal learning, sequential modeling, early detection, and rumor detection, a number of important constraints still exist. Current approaches lack support for streaming decision-making pipelines, rely on fixed observation windows that limit adaptation to dynamic information dispersion, and primarily prioritize classification accuracy at the expense of decision speed.

III. METHODOLOGY

In this section, we present the proposed framework. The model handles social media events as a series of data streams. It then finds the best moment to make a prediction. We start by stating the problem. Next, we outline the framework, model architecture, and the proposed algorithm.

III.1 PROBLEM STATEMENT

Over a stream of social media posts, we formulate early rumor detection as a sequential decision-making issue. Let an event be represented as a chronologically ordered series of communications, such as a discussion thread or a collection of posts pertaining to a particular claim:

$$E = \{m_1, m_2, \ldots, m_T\} \tag{1}$$

Where m_t denotes the $t-th$ message arriving over time. Only the partial observation is available to the model at each time step t. $E_t = \{m_1, m_2, \ldots, m_t\}$ and must decide whether to: Continue observing further messages, or Stop and assign a binary classification (0: non-rumor, 1: rumor) to $y \in \{0, 1\}$. The goal is to reduce both the detection delay and the classification error simultaneously. This is expressed formally as:

$$\mathcal{L} = \alpha \cdot \mathcal{L}_{cls} + \beta \cdot \mathcal{L}_{time} \tag{2}$$

where:

- $\mathcal{L}_{cls}$: classification loss (cross-entropy)
- $\mathcal{L}_{time} = \frac{t}{T}$: normalized detection delay
- α, β : trade-off parameters

The system aims to achieve the earliest possible reliable detection by learning a policy that maps partial observations to halting choices and predictions. This allows for prompt action while maintaining high classification fidelity.

III.2 OVERALL FRAMEWORK

The suggested framework is intended for real-time rumor detection in social media streams, where posts are constantly coming in and judgments need to be taken as soon as possible to stop the propagation of false information. Our proposed framework uses a streaming paradigm that gradually consumes each incoming post and dynamically determines the best time to make a forecast, in contrast to traditional batch-based methods that process predefined windows of data. By striking a balance between two conflicting goals maximizing detection accuracy and decreasing decision latency the main purpose is to put an end to rumors. The design consists of three closely related modules:

Adaptive Decision, Meta Learning, and Multimodal Representation Learning, as shown in Figure 1. A new social media post is encoded at each time step t, the internal model state is updated, and a confidence-based decision policy decides if there is enough evidence to categorize the material as rumor or not. Each component is described in detail in the ensuing subsections.

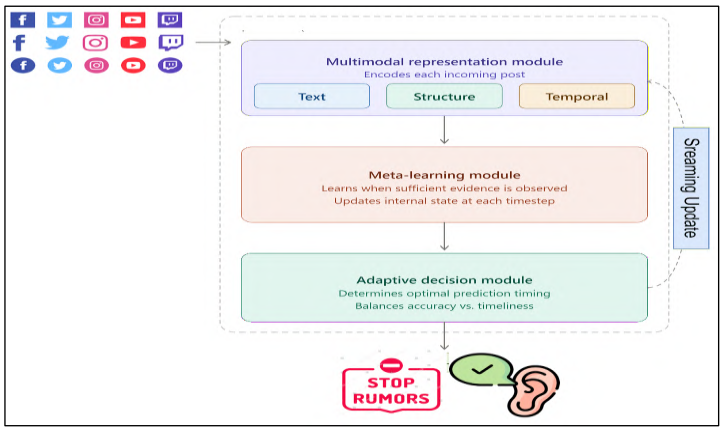

Figure 1: The proposed framework architecture.
Source: Authors, (2026).

1. Multimodal Representation Module allows for incremental state updates by encoding each incoming post into a single embedding that combines textual, structural, and temporal data. Each message m_t is represented using multiple modalities:
Textual Features: Extracted using: BERT / LSTM encoder, $h_t^{text} = f_{text}(m_t)$

Structural Features: Propagation patterns (retweets, replies) with user credibility, $h_t^{struct} = f_{struct}(m_t)$

Temporal Features: Time intervals between messages with posting dynamics, $h_t^{temp} = f_{temp}(t)$

Multimodal Fusion: The final representation is obtained via fusion: $h_t = Fusion\left(h_t^{text}, h_t^{struct}, h_t^{temp}\right)$, with fusion strategies.

2. Meta-Learning Module recognizes when enough evidence has been observed by quickly adjusting the internal state at each timestep after learning a previous over rumor detection tasks. The model is trained using a meta-learning strategy where each event is treated as a task: $\theta^* = arg\ min_\theta \sum_{E\sim D} \mathcal{L}_E(\theta)$. This enables the model to generalize across different rumor propagation patterns.

3. Adaptive Decision Module employs an ideal stopping strategy that dynamically chooses the predicted time to strike a compromise between timeliness and accuracy. At each timestep t, the model computes: The classification probability: $p_t = P(y|E_t)$ and the confidence score: $c_t = max(p_t)$.

III.3 ADAPTIVE DECISION ALGORITHM FOR EARLY RUMOR DETECTION

The proposed algorithm (Algorithm 1) adds a number of innovative features that together improve early rumor detection. It learns adaptive decision timing to determine the best time to make a prediction per event, in contrast to conventional approaches that depend on full event observation or fixed-length inputs. This is accomplished by using multimodal meta-learning, which permits quick adaptation to changing dynamics and generalization across various propagation patterns. In order to represent real-world social media circumstances, the problem is stated as a sequential streaming process where judgments are made progressively as posts arrive. While event-specific adaptation enables the system to act quickly on clear cases and collect additional evidence when ambiguity persists, a joint optimization of accuracy and timeliness explicitly incorporates detection delay into the goal, striking a principled balance between early intervention and reliable classification.

Algorithm 1 Early Rumor Detection with Adaptive Decision Timing

Input: Event stream $E = \{m_1, \ldots, m_T\}$
Output: Predicted label y, detection time t^*
Initialize model parameters θ
$t \leftarrow 1$
while $t \leq T$ do
  Receive message m_t
  Encode multimodal features:

$$h_t = Fusion(f_{text}(m_t), f_{struct}(m_t), f_{temp}(t))$$

  Update representation using previous context
  Compute prediction:

$$p_t = P(y|E_t)$$
$$c_t = max(p_t)$$

  if $c_t \geq \tau$ then
    return prediction y and detection time t
  end if

$t \leftarrow t + 1$

end while
Return final prediction using full sequence

IV. EXPERIMENTS

The efficacy of the proposed framework for early rumor identification is assessed in this section. The datasets, baselines, and assessment measures are described first, and then the implementation specifics. We then present the experimental results in terms of both classification performance and detection timeliness, along with ablation studies to analyze the contribution of each component.

IV.1 DATASETS

We assess the proposed framework using three popular benchmark datasets [26] for rumor detection: Weibo [27], Twitter15, and Twitter16 [28]. These datasets characteristics (Table 1) include social media events that have been tagged as rumors or not, along with the propagation threads that go along with them. A series of replies and reposts follow the first post in each event, creating a temporal structure appropriate for early detection analysis. Twitter15 and Twitter16 have a variety of dissemination patterns. Weibo is a sizable dataset that was gathered from a Chinese social media site and has a notably greater quantity of posts and events. It makes it possible to assess cross-domain robustness by offering more diversity in language, user behavior, and propagation dynamics.

Table 1: Dataset Characteristics.

Dataset	Events	Posts	Classes
Twitter15	1,490	331,612	2
Twitter16	818	204,820	2
Weibo	4,664	3,805,656	2

Source: Authors, (2026).

We use conventional preparation procedures for all datasets: tokenization, text normalization, and the removal of URLs, mentions, and non-informative tokens. In order to accurately replicate the streaming environment necessary for early rumor detection, messages inside each event are arranged chronologically, treating each event as a time-ordered sequence.

IV.2 BASELINES

We evaluate the proposed framework against a wide range of baselines that include early detection, propagation-aware, sequential deep learning, and conventional machine learning. Conventional approaches include a propagation tree kernel-based SVM PTK [26] that captures structural similarities between rumor propagation trees and a Random Forest classifier RFC [29] that uses manually created textual, user, and structural variables. LSTM [30], GRU [31], and Transformer are sequential deep learning models that use whole sequence observation to capture temporal dependencies. PPC [32], a hybrid RNN-CNN architecture that learns from propagation paths and user features, represents propagation-aware deep models. We use early LSTM, a time-aware variation that generates predictions at predetermined intermediate steps, for early detection.

IV.3 EVALUATION METRICS

We evaluate the proposed method utilizing timeliness-aware metrics as well as classification performance metrics to evaluate both prediction accuracy and early rumor detection. **Metrics for Classification:** We employ common metrics to assess prediction performance:

- Accuracy: the total percentage of events that are correctly classified
- Precision: the percentage of accurately anticipated rumors among positives
- Recall: the percentage of true rumors that are accurately identified
- F1-score: precision and recall harmonic mean
- Area under the ROC curve, or AUC

Timeliness Metrics: We utilize the following metrics to evaluate early detection capability:

- Average Detection Time (ADT): $ADT = \frac{1}{T}\sum_{i=t}^{N} t_i^*$, Measures the average number of messages required before making a decision.
- Normalized Detection Time (NDT): $NDT = t^*/T$, Captures the relative detection delay with respect to the full event length.

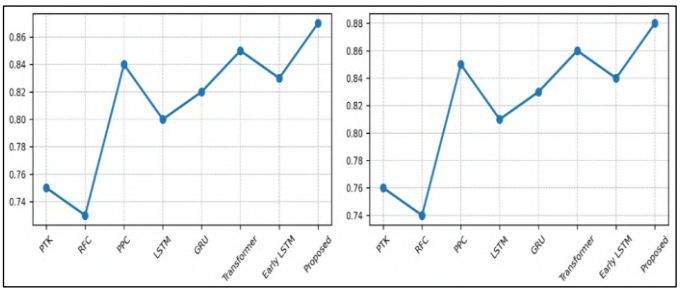
Early Detection Rate (EDR): Proportion of rumors correctly detected before a predefined observation threshold. Messages Used (%), $t^*/T \times 100$, this indicates the fraction of messages required for prediction.

IV.4 IMPLEMENTATION DETAILS

The proposed framework is trained on a workstation with an Intel Core i9 processor, 32 GB of RAM, and an NVIDIA GPU. It is implemented in Python 3.9 using PyTorch 1.12.1. To guarantee consistent and repeatable training, we employ the Adam optimizer [13] with standard settings, $\beta_1 = 0.9$ and $\beta_2 = 0.999$. The learning rate is set to 5×10^{-4}. To mitigate overfitting, dropout is applied with a probability of 0.5, and weight decay is set to 5×10^{-4}.

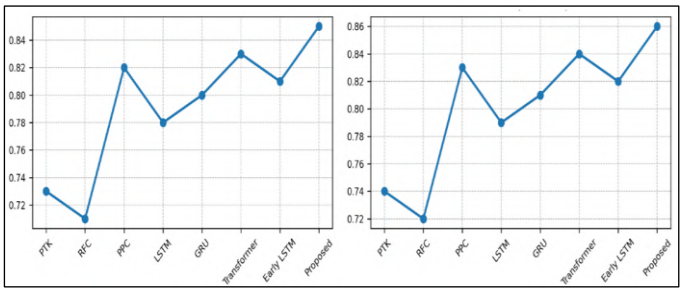
The attention parameters for Twitter15 and Twitter16 are $K_1 = 4$ and $K_2 = 2$. These parameters are raised to $K_1 = 8$ and $K_2 = 4$. for the Weibo dataset, which has longer propagation sequences and denser user interactions. To enhance generalization across various events, the meta-learning component is trained end-to-end in tandem with the primary model. We use a five-fold cross-validation approach, dividing the data into training, validation, and test sets at 80%, 10%, and 10% ratios in each step.

IV.5 OVERALL PERFORMANCE RESULTS



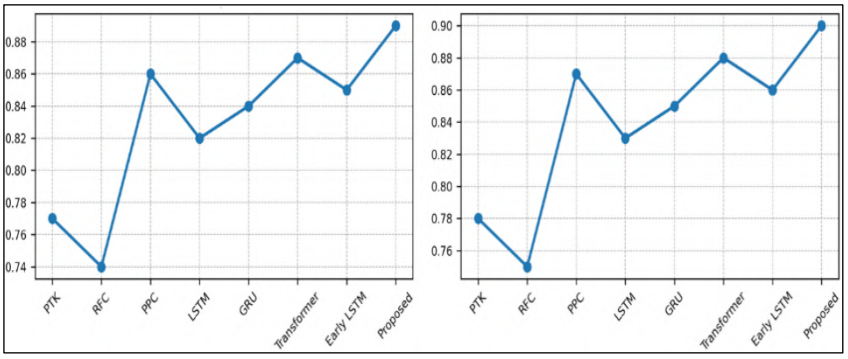
In terms of standard classificat[=ion performance across all datasets, we compare the proposed model with baseline methods. The performance of the suggested framework and the baselines on Twitter 15, Twitter 16, and Weibo are shown in Tables 2.

Table 2: The overall performance comparison on datasets.



Method	Twitter15 (F1)	Twitter16 (F1)	Weibo (F1)	AUC
PTK	0.76	0.74	0.78	0.80
RFC	0.74	0.72	0.75	0.78
PPC	0.85	0.83	0.87	0.89
LSTM	0.81	0.79	0.83	0.85
GRU	0.83	0.81	0.85	0.87
Transformer	0.86	0.84	0.88	0.90
Early LSTM	0.84	0.82	0.86	0.88
Proposed	0.88	0.86	0.90	0.93

Source: Authors, (2026).



As shown in Figure 2, the findings show that the suggested framework maintains good predictive performance while successfully capturing intricate rumor dissemination patterns. Specifically, the suggested model demonstrates the efficacy of integrating multimodal learning with adaptive decision time, outperforming propagation-based models like PPC and PTK.

(a) Accuracy Twitter 15. (b) F1 Score Twitter 15.

(c) Accuracy Twitter 16. (d) F1 Score Twitter 16.

(e) Accuracy Weibo. (f) F1 Score Weibo.

Figure 2: Results of the proposed structure.
Source: Authors, (2026).

IV.6 ACCURACY VS TIME

The proposed model achieves excellent classification performance at early observation stages, as shown by the accuracy progression study. In comparison to baseline approaches, which require far more observations to achieve equivalent performance, the framework achieves competitive accuracy across all investigated datasets after processing only a small fraction of the message sequence. Plotting accuracy as a function of the percentage of seen messages. Figure 3 shows this trend and consistently demonstrates the advantage of the proposed model in early detection phases.

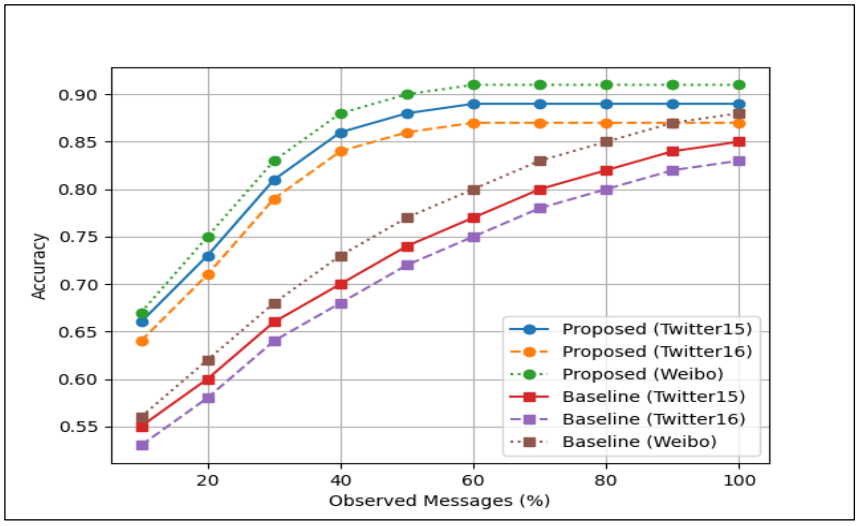


Figure 3**:** Accuracy vs Time across Multiple Datasets.
Source: Authors, (2026).

IV.7 DETECTION TIMELINESS

In this section, we assess how well the suggested model predicts the early phases of the message propagation process. To provide a more thorough comparison, we incorporate propagation-aware models like PPC in addition to traditional baselines. As described in Table 3 the proposed framework demonstrates its efficacy for early rumor detection by achieving the maximum early detection rate (EDR), the lowest detection delay ADT (Average Detection Time) NDT (Normalized Detection Time), and the fewest messages.

Table 3: The comparison of detection timeliness across methods.

Model	ADT	NDT	Messages Used	EDR
LSTM	18.5	0.92	100%	0.65
GRU	17.2	0.89	100%	0.67
Transformer	16.8	0.87	100%	0.69
PPC	13.6	0.66	78%	0.75
Early LSTM	12.4	0.61	72%	0.78
Proposed Model	8.1	0.39	48%	0.87

Source: Authors, (2026).

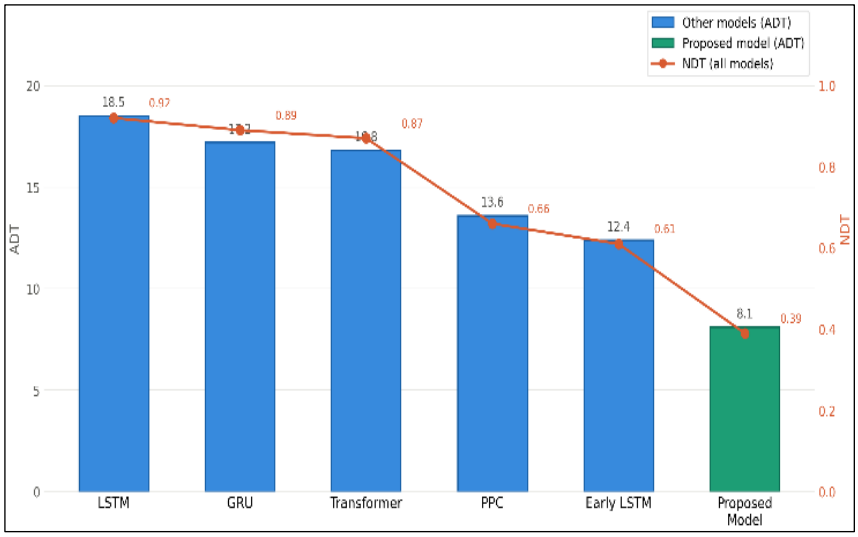

Figure 4: Detection timeliness comparison across methods.
Source: Authors, (2026).

As shown in Figure 4, across all assessed criteria, the proposed model significantly improves detection timeliness. Less than half of the available sequence length is used, and ADT and NDT are greatly decreased, indicating that judgments are taken earlier in the event lifecycle with noticeably fewer input messages on average. A greater EDR further reflects this efficiency, indicating the model's ability to correctly detect rumors in their early phases. However, conventional methods, on the other hand, rely on almost full observation sequences, resulting in significant delays that restrict their usefulness for real-time applications. A boxplot comparison of detection times for several models is shown in Figure 5. In comparison to baseline techniques, the suggested model has a much lower median and a more compact interquartile range, suggesting both faster and more stable detection behavior.

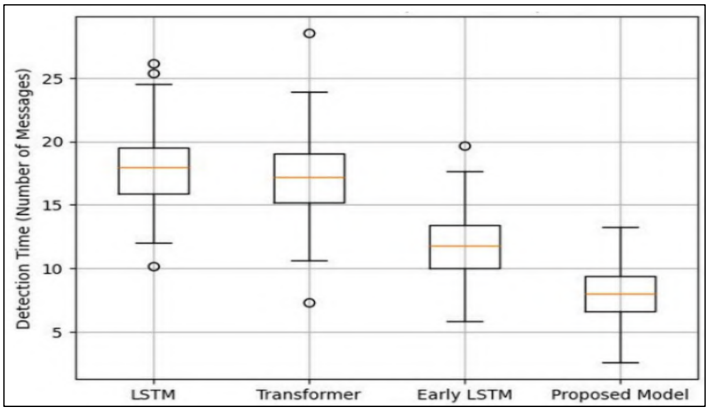

Figure 5: Boxplot comparison of detection times across different models.
Source: Authors, (2026).

IV.8 ABLATION STUDY

We perform an ablation research by eliminating important modules from the suggested framework in order to assess each component's contribution the results are shown in Table 4. Figure 6 shows how each component affects F1-score and detection time.

Table 4: Ablation results.

Variant	F1	ADT	Messages Used (%)
Full Model	0.88	8.1	48
w/o Meta-Learning	0.84	12.9	71

Source: Authors, (2026).

The ablation study validates each module's contribution by confirming that eliminating any one component causes a discernible decline in performance. In particular, removing meta-learning slows detection and forces the model to rely on more observations, which reflects less generalization across heterogeneous rumor events. The classification performance significantly declines when multimodal characteristics are removed, highlighting the complimentary benefit of combining textual, structural, and temporal information. Lastly, the model becomes a standard sequential classifier when adaptive decision timing is disabled, requiring entire sequence observation and resulting in the largest detection delay. These results verify that each component tackles a unique and non-redundant part of the detection problem, and that only when all modules work together can optimal performance be attained.

V. DISCUSSION

The experimental results show that the proposed framework successfully strikes a balance between classification performance and detection timeliness, two goals that are often addressed separately in previous research. By dynamically modifying the decision point based on prediction confidence, the adaptive decision timing method significantly reduces detection delay without sacrificing accuracy, producing more realistic behavior in streaming contexts. By combining textual, structural, and temporal information, multimodal feature integration further improves rumor representation, and the meta-learning approach improves generalization across diverse events by recording common dissemination patterns. When taken as a whole, these elements promote early rumor detection as a joint optimization problem where timeliness and accuracy are viewed as complementing goals. However, some limitations should be acknowledged, such as the computational complexity of multimodal processing and meta-learning in large-scale real-time scenarios, and the sensitivity of the preset confidence threshold across datasets with different distributional features.

VI. CONCLUSION

In this paper, we proposed a framework for early rumor detection that integrates multimodal representation learning with meta-learning and adaptive decision timing, modeling the problem as a sequential decision-making process over streaming input. The value of adaptive stopping in real-world intervention scenarios is highlighted by experimental results on Twitter15, Twitter16, and Weibo, which show that our approach significantly reduces detection latency while maintaining competitive or superior classification performance compared to state-of-the-art baselines. In the future, the framework will be expanded to large-scale streaming settings, richer modalities including images and user interaction graphs will be included, and reinforcement learning for completely adaptive halting rules will be investigated. To further advance the integration of meta-learning, multimodal analysis, and adaptive decision-making for next-generation rumor detection systems, we also want to look into uncertainty estimation for more accurate early predictions and cross-platform domain adaptation for wider generalization.

ABSTRACT

Permanent magnet synchronous motors (PMSMs) are widely used in high-performance drive systems because of their high efficiency, high torque density, and rapid dynamic response. Field-oriented control (FOC) is the dominant control strategy for such drives, but its performance depends critically on accurate rotor position and speed information. In sensorless PMSM drives, sliding mode observers (SMOs) are attractive because of their robustness and modest computational demand. However, conventional SMOs still exhibit an inherent trade-off between fast convergence and chattering suppression, while direct extraction of rotor position and speed from the estimated back-electromotive-force (back-EMF) signals remains vulnerable to noise and filtering delay. This paper presents a sensorless PMSM drive based on closed-loop FOC and an improved SMO-based estimation scheme. The PMSM is modeled in the synchronous dq reference frame, whereas the observer is constructed in the stationary reference frame from stator current dynamics and back-EMF reconstruction. To improve estimation performance, an adaptive sliding-mode injection gain is introduced to regulate the observer correction level according to the current estimation error, and a smooth switching law is employed to reduce chattering. In addition, a phase-locked loop (PLL) is incorporated to reconstruct the rotor electrical angle and speed from the estimated back-EMF components, thereby improving estimation smoothness and noise immunity. Simulation results obtained in MATLAB/Simulink under start-up, acceleration, steady-state, and load disturbance conditions demonstrate stable drive operation, accurate speed tracking, and improved estimation behavior compared with the conventional SMO. The results confirm that the proposed observer enhances convergence and reduces steady-state oscillations while preserving the simplicity and practical applicability of SMO-based sensorless control for PMSM drives.

I. INTRODUCTION

Permanent magnet synchronous motors (PMSMs) have become increasingly prevalent in high-performance motion control systems owing to their high efficiency, high torque density, compact structure, and excellent dynamic characteristics [1-3]. Unlike induction motors, PMSMs do not require rotor current excitation, which eliminates rotor copper losses and contributes to higher overall energy efficiency [4]. These characteristics make PMSMs particularly suitable for demanding applications such as robotics, machine tools, electric vehicles, and servo drives, where precise torque control and rapid dynamic response are required [5]. To fully exploit the advantages of PMSMs, advanced control strategies are necessary. Among them, field-oriented control (FOC) has become the dominant approach for high-performance PMSM drives [6] [7]. By transforming the stator currents into a rotor-oriented synchronous reference frame, FOC enables independent regulation of the torque-producing and flux-related current components [2], [8]. For surface-mounted PMSMs, where magnetic saliency is negligible, the electromagnetic torque becomes directly proportional to the q-axis current, while the d-axis current can be regulated to zero [9] [10].

This decoupled control structure simplifies torque control and enables fast dynamic response with high steady-state accuracy. Furthermore, the cascaded architecture of FOC, consisting of an outer speed control loop and inner current control loops, provides a systematic framework for controller design and facilitates integration with pulse-width modulation (PWM) techniques and coordinate transformations [11-13]. Despite the maturity and effectiveness of FOC, its practical implementation generally requires accurate rotor position or speed information [14]. In conventional drive systems, such information is obtained using mechanical sensors such as encoders or resolvers. However, the use of mechanical sensors increases system cost and hardware complexity, introduces additional wiring and installation requirements, and may reduce system reliability in harsh operating environments characterized by high temperature, vibration, or contamination [15-17]. These limitations have motivated extensive research on sensorless control strategies for PMSM drives, in which rotor position and speed are estimated from measured electrical signals together with mathematical models of the machine [18] [19]. Among the various sensorless estimation techniques proposed for PMSMs, sliding mode observers (SMOs) have attracted considerable attention due to their inherent robustness against parameter variations and external disturbances [20-22]. SMO-based estimators employ a discontinuous correction mechanism that forces the estimation error to converge toward a predefined sliding surface, thereby providing strong robustness properties and fast error convergence. In PMSM applications, SMOs are commonly formulated in the stationary reference frame to estimate the back electromotive force (back-EMF) components using measured stator voltages and currents [23-24].

Because the back-EMF inherently carries rotor position information, the rotor electrical angle can subsequently be reconstructed using a phase-locked loop (PLL) or an arctangent-based computation [25]. Compared with other observer-based techniques, such as extended Kalman filters or model reference adaptive systems, SMOs provide an attractive compromise between estimation accuracy, computational complexity, and robustness [26]. In addition, their relatively simple structure facilitates real-time implementation in digital controllers and provides good immunity to parameter uncertainties, particularly variations in stator resistance [27]. Consequently, SMO-based sensorless control has been widely adopted in industrial PMSM drives operating in the medium-to-high speed region, where the back-EMF magnitude is sufficiently large to ensure a reliable signal-to-noise ratio [28]. Despite the robustness and practical simplicity of conventional SMOs, their estimation performance is still limited by the trade-off between fast convergence and chattering suppression. In addition, direct extraction of rotor position and speed from the estimated back-EMF signals remains sensitive to noise and filter-induced phase delay, which may deteriorate estimation smoothness and dynamic performance. Therefore, this paper develops an adaptive sliding-mode observer with a smooth switching law and PLL-based reconstruction for sensorless PMSM drives. The main contribution lies in integrating adaptive injection gain regulation, chattering-reduced switching action, and closed-loop angle/speed estimation into a unified SMO-based sensorless framework, aiming to improve convergence behavior, estimation smoothness, and robustness while preserving implementation simplicity.

II. MATHEMATICAL MODEL OF THE PERMANENT MAGNET SYNCHRONOUS MOTOR

The dynamic model of a three-phase PMSM can be conveniently formulated in the synchronously rotating dq reference frame. By transforming the stator variables into orthogonal direct and quadrature components that rotate synchronously with the rotor magnetic field, the resulting dq-axis quantities become constant under steady-state operating conditions. This representation provides a compact and physically intuitive description of PMSM dynamics and is particularly well suited for analysis and controller design within the framework of FOC. In the synchronous dq reference frame, the stator voltage equations of the PMSM are expressed as:

$$v_{sd} = R_s i_{sd} + \frac{d\psi_{sd}}{dt} - \omega_e \psi_{sq} \tag{1}$$

$$v_{sq} = R_s i_{sq} + \frac{d\psi_{sq}}{dt} + \omega_e \psi_{sd} \tag{2}$$

Where v_{sd}, v_{sq} are the stator voltage components, i_{sd}, i_{sq} are the stator current components, R_s is the stator resistance, ψ_{sd}, ψ_{sq} denote the stator flux linkages, and ω_e is the electrical angular speed of the synchronous reference frame. For a PMSM, the rotor magnetic field is produced by permanent magnets rather than rotor windings. As a result, no rotor voltage equations are involved, and the rotor flux is directly determined by the permanent magnet flux linkage. Accordingly, the stator flux linkages in the dq reference frame can be expressed as:

$$\psi_{sd} = L_d i_{sd} + \psi_f \tag{3}$$

$$\psi_{sq} = L_q i_{sq} \tag{4}$$

Where L_d and L_q are the stator inductances along the d-axis and q-axis, respectively, and ψ_f is the flux linkage produced by the permanent magnets. Substituting (3) and (4) into (1) and (2), the complete electrical model of the PMSM in the dq reference frame is obtained. The electromagnetic torque generated by the PMSM is given by

$$T_e = \frac{3}{2} p\left(\psi_f i_{sq} + \left(L_d - L_q\right) i_{sd} i_{sq}\right) \tag{5}$$

Where p denotes the number of pole pairs. For surface-mounted PMSMs, where magnetic saliency is negligible and $L_d \approx L_q$, the electromagnetic torque expression simplifies to

$$T_e = \frac{3}{2} p \psi_f i_{sq} \tag{6}$$

Which indicates that the electromagnetic torque is directly proportional to the q-axis current, while the d-axis current does not contribute to torque production. The mechanical dynamics of the PMSM are described by the rotor motion equation

$$J \frac{d\omega_m}{dt} = T_e - T_L - B\omega_m \tag{7}$$

Where J is the total moment of inertia, ω_m is the mechanical angular speed, T_L is the load torque, and B is the viscous friction coefficient. The relationship between electrical and mechanical speeds is given by

$$\omega_e = p\,\omega_m \tag{8}$$

Equations [1-8] collectively represent the complete mathematical model of the PMSM in the synchronously rotating dq reference frame and provide the foundation for the design and analysis of field-oriented control and sensorless control strategies. The overall closed-loop configuration of the considered PMSM drive is illustrated in Figure 1. In this study, the PMSM drive is operated under a conventional closed-loop field-oriented control (FOC) scheme, in which the measured three-phase stator quantities are transformed into a rotor-aligned synchronous reference frame to enable decoupled regulation of flux and torque components. The control structure adopts the standard cascaded configuration with an outer speed loop and inner current loops, allowing the torque-producing current to be generated from the speed error and the corresponding voltage references to be synthesized for application to the inverter through space-vector pulse-width modulation (SVPWM). Within this framework, a sliding mode observer (SMO) is incorporated for sensorless operation, using the measured stator voltage and current signals in the stationary reference frame to reconstruct the back-EMF components and, from them, estimate the rotor electrical angle and speed. The resulting FOC-based PMSM drive therefore provides the control platform on which the observer design is developed, as presented in the following section.

Source: Authors, (2026).

III. SLIDING MODE OBSERVER DESIGN

III.1 SLIDING-MODE OBSERVER FOR SENSORLESS SPEED ESTIMATION

In order to establish a baseline for the proposed estimation method, a conventional sliding mode observer (SMO) is first introduced within the FOC-based PMSM drive. The SMO employs the measured stator voltage and stator current signals to estimate the back-electromotive force (back-EMF), rotor electrical angle, and rotor speed. The estimated quantities are analyzed under various operating conditions to characterize the dynamic behavior and estimation capability of the observer within the PMSM drive system. The overall structure of the SMO is illustrated in Figure 2.

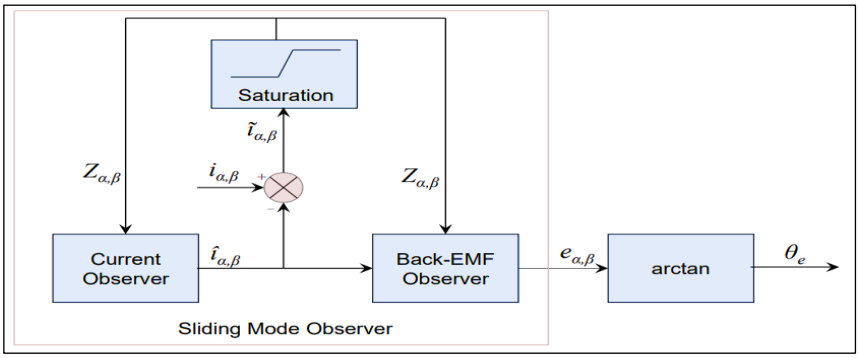

Figure 2: Overall block diagram of the sliding-mode observer –based speed estimation.
Source: Authors, (2026).

The stator phase voltages (u_a, u_b, u_c) are measured at the inverter output terminals and transformed into the stationary reference frame using the Clarke transformation, yielding the stationary voltage components (u_α, u_β). In a similar manner, the measured stator phase currents are converted into the corresponding stationary current components (i_α, i_β). These stationary-frame voltage and current signals constitute the inputs to the sliding mode observer. The sliding mode observer is derived from the stator current dynamics of the PMSM expressed in the stationary $\alpha\beta$ reference frame. Under the assumptions of balanced operation and negligible magnetic saturation, the stator current dynamics can be expressed as

$$\frac{di_\alpha}{dt} = -\frac{R_s}{L_s} i_\alpha + \frac{1}{L_s} u_\alpha - \frac{1}{L_s} e_\alpha \tag{9}$$

$$\frac{di_\beta}{dt} = -\frac{R_s}{L_s} i_\beta + \frac{1}{L_s} u_\beta - \frac{1}{L_s} e_\beta \tag{10}$$

Where R_s and L_s denote the stator resistance and stator inductance, respectively, and e_α, e_β are the back-EMF components in the stationary frame. Within the observer, an estimated current model is constructed using the estimated stator currents $\hat{\imath}_\alpha, \hat{\imath}_\beta$ and the estimated back-electromotive-force components $\hat{e}_\alpha, \hat{e}_\beta$. To enhance robustness against parameter uncertainties and external disturbances, the sliding mode observer incorporates a discontinuous correction term driven by the current estimation error. The resulting observer dynamics are expressed as

$$\frac{d\hat{\imath}_\alpha}{dt} = -\frac{R_s}{L_s} \hat{\imath}_\alpha + \frac{1}{L_s} u_\alpha - \frac{1}{L_s} v_\alpha \tag{11}$$

$$\frac{d\hat{\imath}_\beta}{dt} = -\frac{R_s}{L_s} \hat{\imath}_\beta + \frac{1}{L_s} u_\beta - \frac{1}{L_s} v_\beta \tag{12}$$

Where the discontinuous injection terms v_α and v_β are defined as

$$v_\alpha = K_{sw}\, \mathrm{sat}(i_\alpha - \hat{\imath}_\alpha) \tag{13}$$

$$v_\beta = K_{sw}\, \mathrm{sat}(i_\beta - \hat{\imath}_\beta) \tag{14}$$

Here, K_{sw} is the sliding-mode gain, and $\mathrm{sat}(\cdot)$denotes a saturation function introduced to reduce chattering effects compared to an ideal sign function. Under sliding-mode operation, the current estimation errors converge to zero, and the equivalent values of the discontinuous injection terms correspond to the back-electromotive-force components. To mitigate the high-frequency chattering introduced by the sliding-mode action, the signals v_α and v_β are processed through low-pass filters, yielding the estimated back-EMF components as

$$\hat{e}_\alpha = \mathrm{LPF}(v_\alpha), \hat{e}_\beta = \mathrm{LPF}(v_\beta) \tag{15}$$

The cutoff frequency of the low-pass filter is selected as a compromise between effective noise attenuation and acceptable dynamic response. At medium and high operating speeds, where the back-electromotive-force magnitude is sufficiently large, the filtered signals provide reliable information for position and speed estimation. The estimated back-EMF components are subsequently used to reconstruct the rotor electrical angle and rotor speed. The rotor electrical angle is obtained using an arctangent-based calculation given by

$$\hat{\theta}_e = \mathrm{atan2}(\hat{e}_\beta, \hat{e}_\alpha) \tag{16}$$

The electrical angular speed can be obtained either by differentiating the estimated rotor electrical angle or by exploiting the proportional relationship between the back-electromotive-force magnitude and the electrical speed,

$$\hat{\omega}_e \propto \sqrt{\hat{e}_\alpha^2 + \hat{e}_\beta^2} \tag{17}$$

In practical implementations, appropriate scaling and filtering are applied to ensure a smooth and noise-robust speed estimate. The corresponding mechanical rotor speed is then calculated as

$$\hat{\omega}_r = \frac{1}{p} \hat{\omega}_e \tag{18}$$

Where p denotes the number of pole pairs. Despite its simplicity and satisfactory robustness, the conventional SMO still suffers from two inherent drawbacks in practical implementation. First, the use of a fixed switching gain leads to an unavoidable compromise between fast error convergence and chattering attenuation. Second, the direct extraction of rotor position and speed from the estimated back-EMF signals is susceptible to noise contamination and filter-induced phase delay, which may deteriorate estimation smoothness and dynamic performance. To overcome these shortcomings, an improved observer structure is developed in the following subsection by combining an adaptive sliding-mode injection mechanism with a PLL-based position and speed estimation stage.

III.2 PROPOSED ADAPTIVE SMO WITH PLL-BASED ESTIMATION

To address the drawbacks of the conventional sliding-mode observer, an adaptive SMO with PLL-based rotor position and speed reconstruction is developed. The proposed scheme consists of two main improvements. First, an online gain adaptation mechanism is introduced to adjust the observer injection gain according to the magnitude of the current estimation error, thereby improving the trade-off between fast transient convergence and chattering reduction. Second, instead of directly extracting rotor position and speed from the estimated back-EMF components, a phase-locked loop is employed to provide smoother and more noise-resilient estimation. As a result, the proposed observer achieves enhanced convergence behavior and improved robustness for sensorless PMSM drives. The current estimation errors are defined as

$$e_\alpha = i_\alpha - \hat{\imath}_\alpha \tag{19}$$

$$e_\beta = i_\beta - \hat{\imath}_\beta \tag{20}$$

The adaptive switching gain is defined as

$$K_{sw}(t) = K_0 + k_a\sqrt{e_\alpha^2 + e_\beta^2} \tag{21}$$

Where K_0 denotes the minimum switching gain required to guarantee sliding motion and k_a is a positive adaptive coefficient that determines the sensitivity of the gain adjustment. Using the adaptive gain, the discontinuous injection terms in the observer are reformulated as

$$v_\alpha = K_{sw}(t)\text{sat}(e_\alpha) \tag{22}$$

$$v_\beta = K_{sw}(t)\text{sat}(e_\beta) \tag{23}$$

This adaptive mechanism increases the injection strength when the estimation error becomes large and gradually reduces the gain when the error approaches zero. Consequently, the observer preserves strong robustness during transient conditions while significantly reducing steady-state chattering. In addition to the adaptive gain mechanism, the discontinuous switching function is replaced by a smooth hyperbolic tangent function to further mitigate chattering effects. The modified switching function is defined as

$$\text{sat}(e) = tanh(\lambda e) \tag{24}$$

Where $\lambda > 0$ determines the slope of the switching function. Compared with the classical sign function, the hyperbolic tangent function provides a continuous transition around the sliding surface, which suppresses high-frequency oscillations without sacrificing convergence speed. Substituting [21-24] into the observer equations yields the improved current estimation dynamics

$$\frac{d\hat{i}_\alpha}{dt} = -\frac{R_s}{L_s}\hat{i}_\alpha + \frac{1}{L_s}u_\alpha - \frac{1}{L_s}K_{sw}(t)\,tanh(\lambda e_\alpha) \tag{25}$$

$$\frac{d\hat{i}_\beta}{dt} = -\frac{R_s}{L_s}\hat{i}_\beta + \frac{1}{L_s}u_\beta - \frac{1}{L_s}K_{sw}(t)\,tanh(\lambda e_\beta) \tag{26}$$

Under sliding-mode operation, the estimation errors e_α and e_β converge toward zero and the equivalent values of the injection signals correspond to the back-EMF components. The estimated back-EMF signals are obtained by applying low-pass filtering to the adaptive injection signals

$$\hat{e}_\alpha = \text{LPF}(v_\alpha) \tag{27}$$

$$\hat{e}_\beta = \text{LPF}(v_\beta) \tag{28}$$

The estimated back-EMF signals are then processed by the PLL-based reconstruction stage to obtain the rotor electrical angle and electrical speed. To analyze the convergence property of the observer, consider the Lyapunov candidate function

$$V = \frac{1}{2}(e_\alpha^2 + e_\beta^2) \tag{29}$$

The time derivative of the Lyapunov function is given by

$$\dot{V} = e_\alpha\dot{e}_\alpha + e_\beta\dot{e}_\beta \tag{30}$$

Substituting the observer error dynamics into (30) yields

$$\dot{V} = -\frac{K_{sw}(t)}{L_s}\left(e_\alpha\,tanh(\lambda e_\alpha) + e_\beta\,tanh(\lambda e_\beta)\right) \tag{31}$$

Since $K_{sw}(t) > 0$ and $e\,tanh(\lambda e) \geq 0$ for all $e \neq 0$, it follows that

$$\dot{V} \leq 0 \tag{32}$$

Which indicates that the estimation errors are bounded and driven toward the sliding surface. Therefore, the proposed adaptive sliding mode observer preserves the inherent robustness of the classical SMO while reducing chattering and improving estimation smoothness. Rotor Position and Speed Reconstruction Using a Phase-Locked Loop Although the rotor electrical angle can be directly obtained from the estimated back-EMF components using an arctangent function, this approach is known to be sensitive to measurement noise and numerical differentiation. In particular, the direct differentiation of the estimated electrical angle may amplify high-frequency disturbances introduced by switching harmonics and inverter nonlinearities. These effects can degrade the stability of the speed estimation and lead to undesirable oscillations in the outer speed control loop. To improve the robustness of the sensorless estimation process, a phase-locked loop (PLL) is employed to reconstruct the rotor electrical angle and electrical speed from the estimated back-EMF signals. The PLL structure provides a closed-loop tracking mechanism that filters measurement noise while maintaining fast dynamic response. Let the estimated back-EMF vector be defined in the stationary reference frame as

$$\hat{e}_{\alpha,\beta} = \begin{bmatrix}\hat{e}_\alpha \\ \hat{e}_\beta\end{bmatrix} \tag{33}$$

For a surface-mounted PMSM operating under steady-state conditions, the back-EMF components can be expressed as

$$e_\alpha = -\omega_e\psi_f\,sin(\theta_e) \tag{34}$$

$$e_\beta = \omega_e\psi_f\,cos(\theta_e) \tag{35}$$

Which indicates that the back-EMF vector is orthogonal to the rotor flux vector and rotates synchronously with the electrical angular speed. Based on this property, the rotor position can be estimated by aligning the estimated back-EMF vector with the reference

frame generated by the PLL. Let the estimated rotor electrical angle generated by the PLL be denoted by $\hat{\theta}_e$. The corresponding unit vectors are defined as

$$\hat{\boldsymbol{u}}_d = \begin{bmatrix} cos(\hat{\theta}_e) \\ sin(\hat{\theta}_e) \end{bmatrix} \tag{36}$$

$$\hat{\boldsymbol{u}}_q = \begin{bmatrix} -sin(\hat{\theta}_e) \\ cos(\hat{\theta}_e) \end{bmatrix} \tag{37}$$

The PLL is designed to track the phase of the estimated back-EMF vector. To this end, the projection of the estimated back-EMF vector onto the estimated q-axis is used as a phase-related signal, which can be expressed as

$$e_q^{PLL} = -\hat{e}_\alpha \, sin(\hat{\theta}_e) + \hat{e}_\beta \, cos(\hat{\theta}_e) \tag{38}$$

This signal is then processed by a PI loop filter to generate the estimated electrical speed. The PLL control law for the electrical speed estimation is defined as

$$\hat{\omega}_e = K_{p,PLL} e_q^{PLL} + K_{i,PLL} \int e_q^{PLL} \, dt \tag{39}$$

Where $K_{p,PLL}$ and $K_{i,PLL}$ denote the proportional and integral gains of the PLL regulator. The estimated electrical angle is obtained by integrating the estimated electrical speed

$$\hat{\theta}_e = \int \hat{\omega}_e \, dt \tag{40}$$

The corresponding mechanical rotor speed is then calculated using the relationship

$$\hat{\omega}_r = \frac{\hat{\omega}_e}{p} \tag{41}$$

Where p is the number of pole pairs. Compared with the direct arctangent-based estimation approach, the PLL-based reconstruction offers several advantages. First, the closed-loop filtering effect of the PLL significantly attenuates measurement noise and switching harmonics present in the estimated back-EMF signals. Second, the integral action of the PLL improves steady-state accuracy and eliminates bias errors in the speed estimation. Finally, the PLL structure provides smooth and continuous rotor angle tracking, which enhances the stability of the field-oriented control system during dynamic operating conditions. The proposed sensorless estimation scheme integrates three complementary mechanisms: an adaptive sliding mode observer for back-EMF reconstruction, a smooth switching law for chattering suppression, and a PLL-based stage for rotor position and speed extraction. This combination addresses the main shortcomings of the conventional fixed-gain SMO. The adaptive observer modifies the injection gain according to the current estimation error. As a result, strong corrective action is retained during transients, whereas excessive switching activity is avoided as the estimation error decreases. This feature improves convergence behavior without imposing unnecessarily large observer gains in steady-state operation. The use of the hyperbolic tangent function in place of the discontinuous sign function further improves the observer behavior near the sliding surface. In particular, it reduces high-frequency oscillations in the estimated signals while maintaining the robustness properties associated with sliding-mode-based estimation. The back-EMF components reconstructed by the observer are then supplied to a phase-locked loop to obtain the rotor electrical angle and speed. Unlike direct angle differentiation, the PLL provides a closed-loop estimation process with improved noise rejection and smoother speed reconstruction, which is particularly beneficial under dynamic operating conditions. Taken together, these modifications yield a sensorless estimation structure with improved robustness, lower sensitivity to switching noise, and smoother steady-state behavior, while preserving a relatively simple implementation.

IV. RESULTS AND DISCUSSION

The system is implemented in MATLAB/Simulink and consists of a PMSM drive operating under a conventional closed-loop FOC scheme, augmented with a SMO for rotor speed and position estimation. The FOC controller governs the stator currents and rotor speed based on measured electrical quantities, providing stable and well-regulated drive operation over a wide range of operating conditions. Within the implemented framework, the SMO utilizes the stator voltage and current components expressed in the stationary αβ reference frame to estimate the back-electromotive-force components. These estimated signals are subsequently used to reconstruct the rotor electrical angle and rotor speed. The behavior of the estimated quantities is examined during start-up, acceleration, steady-state operation, and load disturbance scenarios in order to characterize the dynamic response and estimation capability of the observer in the PMSM drive system. The complete MATLAB/Simulink implementation of the closed-loop FOC-based PMSM drive and the associated SMO-based estimation structure are illustrated in Figures 3 and 4, respectively. The presented simulation results provide insight into the interaction between the control system and the observer dynamics, as well as the overall performance of the PMSM drive under various operating conditions.

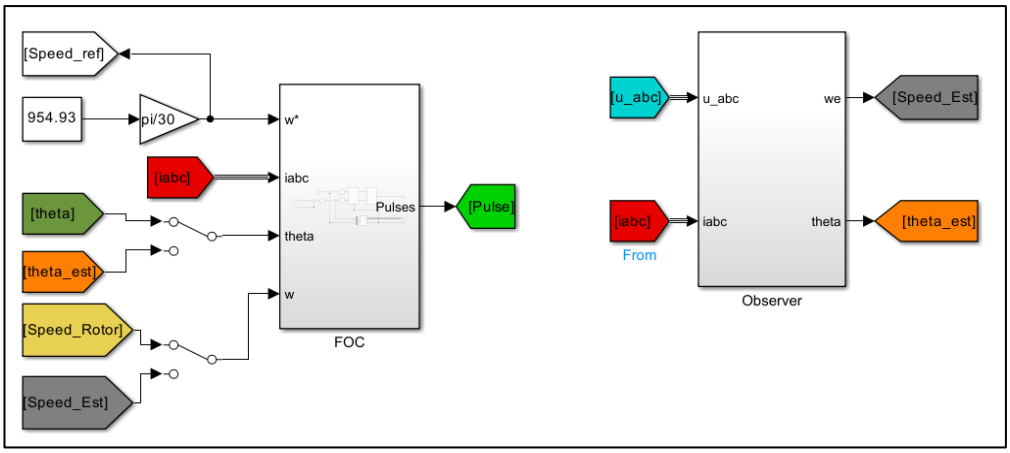

Figure 4: Block diagram of the FOC-controlled PMSM drive with the sliding mode observer.
Source: Authors, (2026).

The FOC-controlled PMSM drive incorporating a SMO is examined under four representative operating scenarios in order to characterize its dynamic behavior and robustness. The considered scenarios include: (i) operation with a varying load at a constant reference speed, which reflects the disturbance rejection capability and speed regulation performance; (ii) operation with a varying load combined with a time-varying reference speed, aimed at assessing robustness and tracking performance under simultaneous disturbances; (iii) operation with a constant load and constant reference speed, representing steady-state conditions; and (iv) operation with a constant load and a varying reference speed, which highlights the transient response and speed tracking characteristics of the drive system. Together, these scenarios provide a comprehensive view of the system behavior under both steady-state and dynamic operating conditions.

Source: Authors, (2026).

The dynamic responses of the FOC-controlled PMSM drive incorporating sliding mode observer-based estimation under four representative operating scenarios are presented in Figures 5–8. In all cases, the stator currents remain well balanced and nearly sinusoidal, confirming effective current regulation by the inner control loops. The rotor speed follows the reference trajectory smoothly during both steady-state operation and transient conditions, while the electromagnetic torque responds promptly to load variations with limited oscillations, indicating robust torque control and stable system behavior. During start-up and dynamic operating conditions, brief transient oscillations are observed in the stator currents and electromagnetic torque, after which the system rapidly converges to steady-state operation. The speed response exhibits negligible steady-state deviation and maintains consistent behavior under load disturbances and reference speed changes, demonstrating the effectiveness of the FOC structure in regulating the PMSM drive.

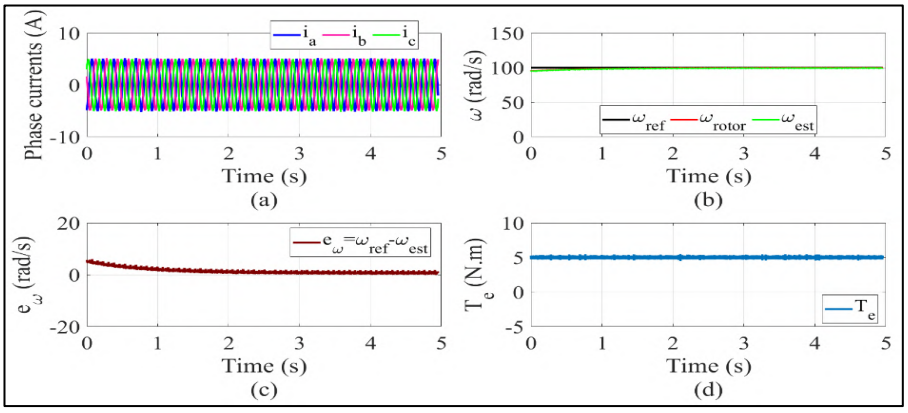

Figure 7: FOC-controlled PMSM drive under constant load and constant reference speed. (a) Three-phase stator currents; (b) Rotor speed response; (c) Speed tracking error; (d) Electromagnetic torque.
Source: Authors, (2026).

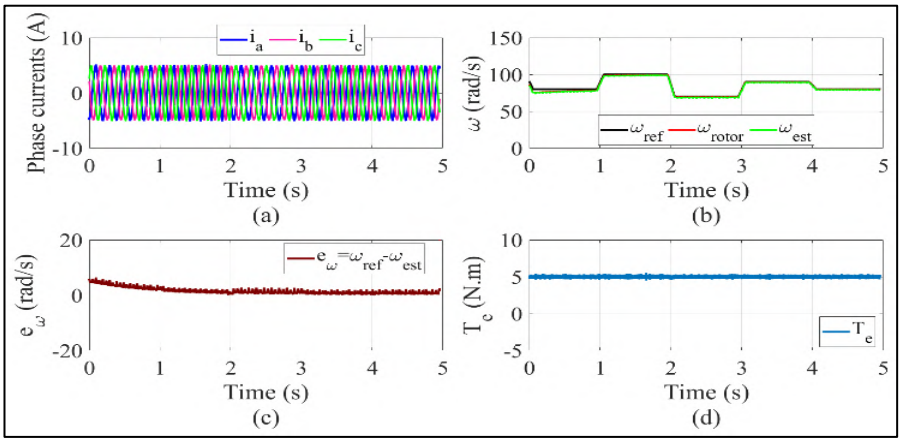

Figure 8: Dynamic responses of the FOC-controlled PMSM drive under constant load and varying reference speed. (a) Three-phase stator currents; (b) Rotor speed response; (c) Speed tracking error; (d) Electromagnetic torque.
Source: Authors, (2026).

The estimated speed and electrical angle display smooth waveforms with low ripple across all operating scenarios. Minor deviations may appear during the initial transient interval; however, the estimated quantities quickly settle as the system reaches steady operation and remain consistent with the drive dynamics thereafter. This behavior indicates effective suppression of chattering and noise effects and reflects the ability of the sliding mode observer to provide stable and reliable speed and position information under both steady-state and transient operating conditions.

V. CONCLUSION

A sensorless PMSM drive based on closed-loop field-oriented control and sliding-mode observation has been presented in this study. The PMSM model was established in the synchronous dq reference frame, while the observer was formulated in the stationary reference frame from stator current dynamics and back-electromotive-force reconstruction. To improve the estimation performance, an adaptive sliding-mode injection gain was introduced to regulate the observer correction strength according to the current estimation error, thereby alleviating the trade-off between fast convergence and chattering attenuation. A smooth switching law was further employed to suppress high-frequency oscillations in the observer signals, and a phase-locked loop was incorporated to reconstruct the rotor electrical angle and speed from the estimated back-EMF components. Together, these modifications improve the smoothness and robustness of the estimation process while preserving the structural simplicity of the conventional SMO framework. Simulation results obtained in MATLAB/Simulink under start-up, acceleration, steady-state, and load disturbance conditions confirmed stable drive operation and accurate speed tracking. Compared with the conventional SMO scheme, the proposed observer provided smoother estimation behavior, reduced steady-state oscillations, and more reliable rotor position and speed information. The proposed sensorless estimation scheme therefore constitutes a practical and computationally efficient solution for PMSM drives requiring robust rotor position and speed estimation.

ABSTRACT

Topology optimization is an emerging design technique for producing extremely lightweight, highly efficient structural components without compromising structural integrity. In the current investigation, the topology of a circular mounting bracket is optimized using the integrated structural optimization capabilities of PTC Creo Parametric software. The objective is to minimize the structure's weight without compromising its strength and rigidity. From an initial weight of 1.189 kg, the design was optimized through six phases to achieve the required weights of 70%, 50%, 35%, 25%, 20%, and 17.5%. The actual weight reductions were 71.2%, 52.3%, 37.2%, 27.1%, 22%, and 19.5%. As weight decreased, relative strength increased substantially, reaching a maximum of 100.833 MPa/kg. After analyzing failure modes and strength characteristics, particularly bending failures, the 20% weight-retention design, weighing 0.261 kg (22% of the original weight), was found to be optimal. The results of the study demonstrate that it is possible to create lightweight, high-strength mounting brackets suitable for industrial and automotive applications using parametric topology optimization in PTC Creo.

I. INTRODUCTION

Using the Generative Topology Optimization (GTO) extension in PTC Creo, designers can specify functional design requirements, loads, constraints, and material properties to generate 3D CAD models that are optimized for lightweight manufacturing.

a. Topology optimization

Topology optimization methods for the design of multi-scale structures have advanced rapidly in recent years. A computational design method, topology optimization, can automatically design a structural form with optimal performance for given design parameters [1]. Since it is challenging to produce these novel structures using traditional methods, additional steps are often required to improve manufacturability, which falls short of the full potential of topology optimization. Topology optimization is a sophisticated structural design process that produces novel, high-performance, lightweight configurations that are challenging to achieve using traditional concepts [2]. In the aerospace industry, a small reduction in engine weight results in substantial fuel savings and reduced pollution. For this reason, topology optimization is employed to make aircraft components lighter while maintaining the functionality and lifespan specified by [3]. Without making assumptions about the final geometry, the topology approach optimizes the material layout within a given design region. Consequently, it rapidly gained prominence in the industrial sector and was applied to the design of aircraft components [4]. It has been shown that the topology approach is effective for finding the initial geometric configuration in structural design. The main drawback of the approach, however, is that topology optimization will always yield a non-smooth geometric configuration of the structure.

In contrast, most engineering applications, especially in manufacturing [5], require a smooth configuration. Although topology optimization may not effectively control microstructure, there is still considerable scope to reduce deviations from the desired microstructure [6]. Topology optimization is a numerical process that aims to optimize the shape and material layout within a design space under certain constraints. The solution obtained from topology optimization need not be optimal, but it serves as a basis for optimal design [7]. In the vast majority of engineering applications, topology optimization is among the most effective techniques for the conceptual design phase. Given the boundary conditions and constraints of the design, it is feasible to obtain an optimal structural material distribution that represents the most efficient path in the design domain [2], within certain loads and boundary conditions, topological optimization allows for the estimation of the optimal distribution of material within a design region [8], to enhance the performance of the system, topology optimization is a mathematical method that aims at optimizing the material distribution within a predefined design space for specific loads and constraints [9]. The research work involved optimizing the topology and comparing analytical results before and after the design optimization of the connecting rod. Since the optimized model will be less stressed and lighter than the existing model, it will be more efficient [10]. Within the framework of density-based topology optimization, the behavior of microscopic stress was examined to develop topology optimization techniques capable of handling stress constraints. In aircraft component structural design, topology optimization reduces weight while retaining the required stiffness and strength. In complex aerodynamic and operational conditions, topology optimization enhances loading capacity by optimally distributing materials in the design domain. This helps increase fuel efficiency and reduce emissions [11]. The aim of topology optimization for a lightweight diesel engine alternator support bracket is to minimize material usage while maintaining its stiffness and strength. Based on the applied loads and boundary conditions within a specified design domain, any extra material is reduced throughout the design process [12].

To withstand dynamic loads and vibrations, as well as engine and belt forces, the material distribution is carried out through topological and structural analyses. Stress and deformation behavior under real operating conditions are validated using finite element analysis. An optimized design of a passenger car's compressor mounting bracket improves overall vehicle economy and reduces material costs [13]. The objectives of performing FEA and topology optimization for an engine mounting bracket are to achieve lightweight and optimize structural performance. The deformation, stress distribution, and safety features of an engine mounting bracket are analyzed. The newly designed engine mounting bracket is stronger, more vibration-resistant, reduces material usage, and improves performance without compromising its strength [14]. Topology optimization in Creo Simulate 4.0 enables the reduction of low-stress material in the gripper, thereby reducing structural weight, improving performance, and increasing strength [15]. The aim of the topology optimization of the compressor bracket is to reduce its weight without compromising the required strength and stiffness. Optimized compressor brackets will have better performance, reduced material usage, and longer life. To reduce weight while satisfying the required stress and displacement constraints, the integrated particle swarm optimizer efficiently searches the design space. By considering the structural and geometric effects simultaneously, the topology optimization method improves the global optimality. Optimized truss configurations achieve better material utilization and improved structural performance [16]. A Comparative Study of Topology Optimization Methods for 3D Structural Problems focuses on several numerical methods with respect to their convergence characteristics, efficiency, and correctness of solutions for material distribution in three-dimensional domains. The results help select the most appropriate methods for complex 3D design problems [17].

b. Additive Manufacturing

Additive manufacturing is a process of making parts directly from a digital 3D model. This process differs from subtractive manufacturing in that it reduces waste. This process is also used to make complex parts. This process produces lightweight, topology-optimized, and customized parts. This process is used to make parts for automotive, aerospace, medical, and tool-die industries.The objective is to optimize the Piston's weight while maintaining its strength and thermal stability, thereby enhancing its performance. This can be done using ANSYS and PTC Creo Parametric software. For the design of a lightweight, high-performance device based on this innovative method, the results show improved stress distribution compared with traditional solid orthotics. There is a 30-50% weight reduction compared to traditional solid orthotics. The research article by [18] has made a significant discovery. Under thermo-mechanical stress conditions, the topology of the parametric 3D piston model is optimized to reduce compliance without sacrificing strength. The ANSYS Workbench FEA tools are then employed to simulate the optimized topology. The factors influencing the metal additive manufacturing process include material wall thickness, overhang angle, and orientation [19]. FEA tools are then used to evaluate the material's deformation. The next step is to use the additive manufacturing process to create the required geometry. The results show a significant reduction of 30-60% of the weight while maintaining the required rigidity and safety [20]. Although the AM process offers design flexibility, it has process-specific limitations, including overhang, minimum size, and orientation. This study proposes a methodical approach to topology optimization that accounts for the limitations of the AM process, using ANSYS Workbench as described by [21]. Many researchers have studied and proposed various methods for optimizing structural components used in the food, automotive, and aerospace industries. They have found that topology optimization is a highly effective and powerful tool for structural optimization. The authors conducted experiments on the topology optimization of the automotive suspension bracket and the aero-engine bracket using CREO. Several efforts have been made to use topology optimization in the compressor mounting bracket using ANSYS [13], leaf spring mounting bracket using FEA [22], and a full car body using FEA [23], engine mounting bracket of a heavy commercial vehicle using FEA [24], commercial vehicles, and powertrain transmission housing [25], aircraft fuselage [26].

II. MATERIALS AND METHODOLOGY

a. Materials

Most of the parts of the hydraulic cylinder are susceptible to corrosion. Therefore, the choice of material is very important. The material should not only be corrosion-resistant but also relatively cheap. Stainless steel, which has strength, ductility, and toughness at high temperatures, is often used in mechanical parts.

The stress-strain curves are perhaps the most indicative of the differences in the mechanical properties of different stainless-steel types. The low yield strength and high ductility of the austenitic types, as well as the high yield and tensile strengths and low ductility of the martensitic types, are clearly apparent. Between these two types lie the ferritic and ferritic-austenitic types. Although ferritic-austenitic types have much higher yield strength than ferritic and austenitic types, ferritic types have slightly higher yield strength than austenitic types. Although ferritic and ferritic-austenitic types are slightly better in this respect, their ductility is of similar magnitude to that of [27]. A variation of Alloy 410, Alloy 420 is a martensitic, hardenable stainless steel. Like 410, Alloy 420 contains at least 12% chromium, which is sufficient only to resist corrosion. Compared to Alloy 410, Alloy 420 contains higher carbon content. Although it can be hardened to a minimum Rockwell hardness of 50 HRC, the maximum hardness of the 12% chromium grades, it also retains a good amount of ductility when annealed. Although it can be welded, alloy 420 is rarely welded due to its hardening properties. Because martensitic stainless steel is made very hard, other properties are sometimes slightly compromised. The usable working temperature range is limited by the loss of ductility at sub-freezing temperatures and the loss of strength from over-tempering at higher temperatures, and the corrosion resistance is lower than that of the common austenitic types. Surface grinding or polishing the metal after it has been hardened will provide the highest corrosion resistance.

Table1: Chemical composition of stainless steel martensitic 420.

Type	C	Mn	Ci	P	S	Cr
420	0.15max	1.25max	1.00max	0.04max	0.03max	max: 14.00-min: 12.00

Source: Authors, (2026).

The mechanical and physical properties of the martensitic 420 SS are also given in Table 2 and 3.

Table 2: Mechanical stainless steel martensitic 420.

Temperature (°C)	**Ultimate Tensile Strength (MPa)**	**Yield Tensile Strength (MPa)**	**Elongation (% in 50mm)**	**Brinell Hardness (HB)**
Annealed *	655	345	25	max
399°F (204°C)	1600	1360	12	444
600°F (316°C)	1580	1365	14	444
800°F (427°C)	1620	1420	10	461
1000°F (538°C)	1305	1095	15	375
1099°F (593°C)	1035	810	18	302
1202°F (650°C)	895	680	20	262
* Annealed tensile properties are typical for Condition A of ASTM A276; annealed hardness is the specified maximum.

b. Methodology

For experimentation, we use one or more analytical, numerical, or experimental methods in every scientific study. However, among the most widely used numerical methods, the Finite Element Method (FEM) is used in this study. The cylinder mounting bracket was created in SolidWorks 2022 based on the geometric requirements provided by Parker Miller Fluid Power, as the study requires three-dimensional modeling of the part for further analysis by [28]. To be compatible with Ansys software, the part is saved in the IGES format. Subsequently, Ansys 2020R1 reads the model in IGES format for static structural analysis. In this case, improper application of loads and boundary conditions can reveal the model's weaknesses. The commercial software PTC Creo Parametric applies topology optimization (TO). The same loads and boundary conditions from Ansys are applied in the TO process. The study's workflow is shown in Figure 1.

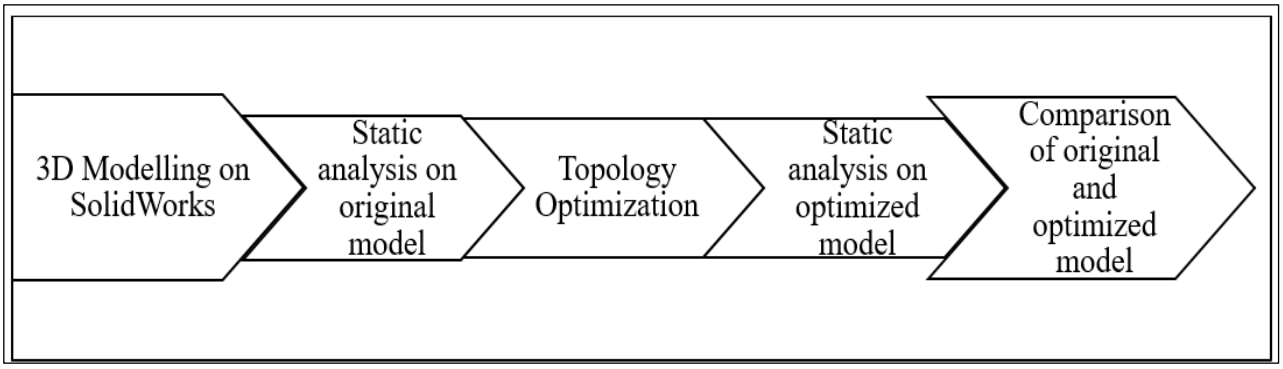

Figure 1: Workflow of the study.

III. STATIC STRUCTURAL ANALYSIS AND TOPOLOGY OPTIMIZATION OF THE COMPONENTS

a. Boundary conditions

A static structural analysis using the finite element method was performed to assess the structural behavior of the cylinder mounting bracket, as shown in Figure 2(a). The actual working conditions for which the mounting bracket is required to perform have been simulated by defining suitable loading and boundary conditions. The inner surface of the cylindrical pinhole on the top surface of the mounting bracket is subjected to a force of 1250.2 N. This force represents the operational load transmitted by the hydraulic cylinder to the construction via the pin connection under working conditions. To accurately simulate the actual conditions for which this type of force transfer is required from the cylinder to the structure via the mounting bracket, the loading direction is defined along the axis of the pin connection. The four bolt holes on the base plate are defined with suitable support boundary conditions to accurately simulate the conditions under which this type of bracket is mounted on the machine structure. The stiff connection between the structure constructed by this type of bracket and the supporting structure using bolted connections is accurately simulated by assuming this type of boundary condition.

a. Meshing of the Model

A three-dimensional model of the cylinder mounting bracket was created in PTC Creo and imported into ANSYS for topology optimization and finite element analysis, as shown in Figure 2 (b). To numerically simulate the problem, it is imperative to divide the geometry into smaller finite elements using a meshing procedure. Due to the complex features of the cylinder mounting bracket, including curved edges, ribs, and numerous holes, an unstructured tetrahedral mesh was used. In some areas, such as the pin connection hole and bolt mounting holes, where high stress concentrations are anticipated, the mesh was refined. The quality of the newly formed elements must be checked to ensure it meets acceptable limits for simulation purposes. The acceptable limits were checked against established criteria for mesh quality, including skewness, aspect ratio, and quality. The load transfer mechanisms between the cylinder pin and the base mounting points were captured using an adequately refined mesh while maintaining an acceptable level of efficiency. The stress, deformation, and structural response of the structure under applied loading conditions can be precisely calculated using the newly formed mesh, which is a dense network of elements covering the entire surface area of the cylinder mounting bracket.

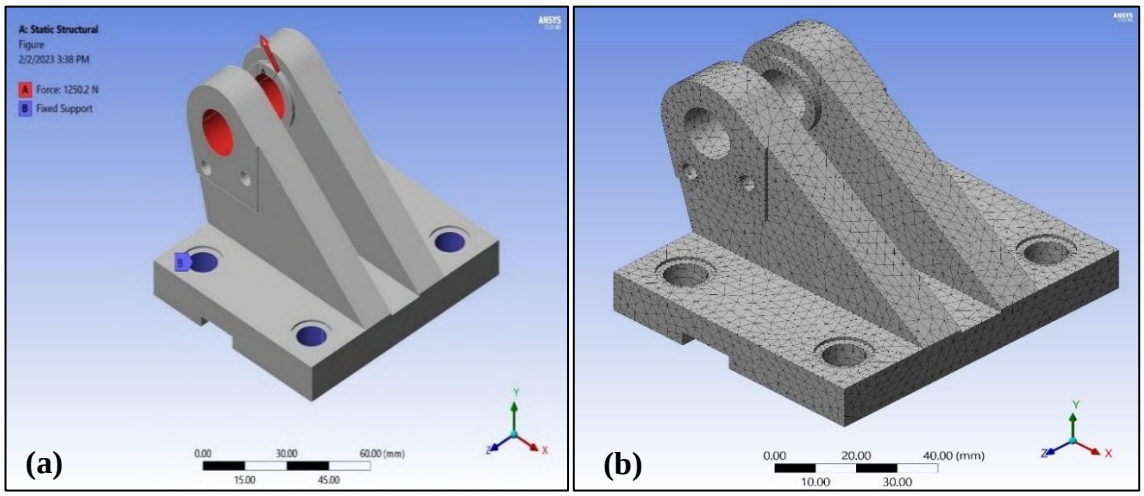

Figure 2: Loading and boundary condition (a) Boundary condition and loading (b) Meshing of the model.
Source: Authors, (2026).

Each finite element (*i*) created in the meshing phase of a general topology optimization problem statement is assigned a design variable (ηi), which is an internal, pseudo-density of the model. Material to be removed is denoted by ηi = 0, and material to be kept is denoted by ηi = 1. The pseudo-density ranges from 0 to 1. The above is another form of stating the topological optimization method:

$Minimize/maximize\ f(\eta i)$
Subject to:

$$0 \leq \eta i \leq 1 \qquad (i = 1,2,3,\dots,n)$$
$$\bar{g}j \leq gj \leq \bar{\bar{g}}j \qquad (j = 1,2,3,\dots,m)$$

Where:

n is $number\ of\ finite\ elements$
m is $number\ of\ constraints$
$\bar{g}j$ is $computed\ constraint\ value$
$\bar{g}_j$ and $\bar{\bar{g}}_j$ is $lower\ and\ upper\ constraint\ bounds$

PTC and Vanderplaats Research & Development, Inc. (VR&D) jointly developed Creo Topology Optimization. The software combines VR&D's optimization expertise with PTC's strength in bridging the physical and virtual realms. A rebuilt optimized part, either a tessellated (faceted) or B-rep (boundary representation), is the output of the Creo topology optimization procedure [29]. The applications tab, generative design, provides access to the Creo topology optimization interface (Fig. 3). Figure 4 shows the preprocess setup tree. Design spaces, structures, and design criteria are its three main constituents. The region where design and non-design areas are defined is called the design space. Although material, constraints, and objectives can be defined in the design criteria, loading and boundary conditions are defined in the structure.

IV. RESULTS AND DISCUSSIONS

The results and discussions of the findings of the study are presented in this section of the document. The Creo topology optimization solution for the six design points with weight-reduction values of 70%, 50%, 35%, 25%, 20%, and 17.5% is obtained first. A mesh size of 1.883 mm is used to merge each design-point solution with the static structural analysis solution. The static structural analysis of the original model is then performed in Ansys with the same mesh size as in Creo. Static structural analysis is employed in both Creo and Ansys to obtain the solutions for the original and optimized models at each design point.

a. Topology optimization result

The main aim of the topology optimization process conducted in this study is to minimize the weight of the bracket. The model's mass is gradually reduced during the weight-reduction process. The reason for the percentage difference, as shown in Figures 5-10, is the optimization constraints and the smoothing process. Following a weight reduction of nearly 70%, Figure 5 (a) illustrates the Von Mises stress results obtained from the parametric topology optimization analysis of the cylinder mounting bracket. To minimize the weight of the cylinder mounting bracket while retaining its functional properties, a topology optimization analysis was performed after specifying the material properties, boundary conditions, and mesh. Without affecting the load paths between the pin connection and the base mounting holes, the optimization algorithm removed unnecessary material from low-stress regions.

The solver evaluated the bracket's response to the applied load of 1250.2 N. The regions of maximum stress are near the pin joint area and the base area of the bracket, as indicated by the stress distribution plot after optimization. To maintain the integrity of the structure, these regions are retained in the optimal design. Notwithstanding the significant material reduction, the optimized bracket still maintains an efficient load path, as indicated by the stress contour plot. The results indicate that topology optimization is an effective technique for developing a light structure that maintains mechanical stability and satisfactory stress levels.

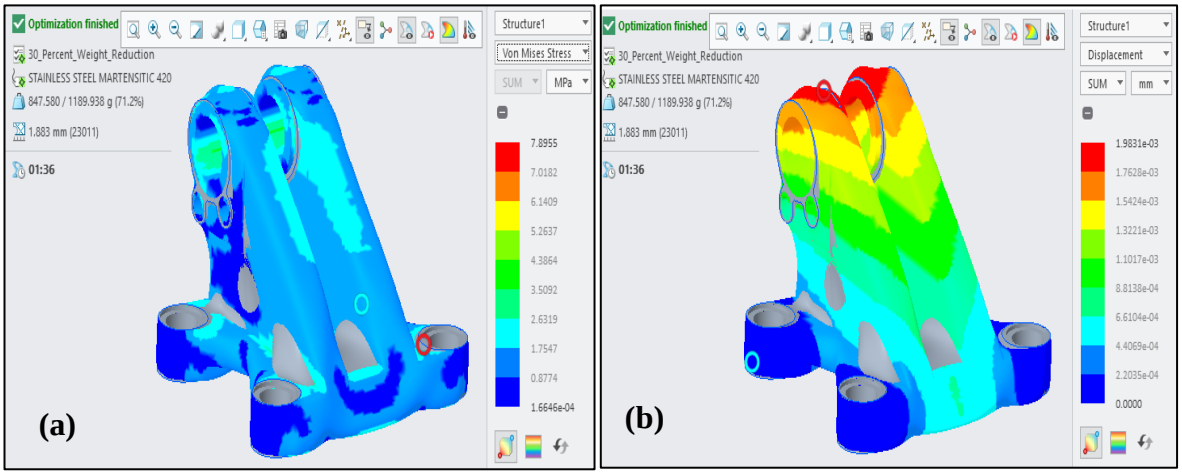

Figure 5: 70% weight reduction (a) Von-Mises's Stress (b) Deformation.
Source: Authors, (2026).

The deformation distribution of the cylinder mounting bracket, derived from a parametric topology-optimization study following a weight reduction of approximately 70%, is shown in Figure 5(b). The object's displacement is depicted in a color contour plot, where red denotes areas of maximum deformation and blue denotes areas of minimum deformation. The investigation shows that the maximum movement of the object is around 1.883 mm. This region experiences the maximum stress due to its direct interaction with the applied loads and constraint points. The base construction is stiff even after significant material reduction, as indicated by the very low deformation of the mounting holes in the lower base. The final mass of the optimized design is about 487.58 grams, which is 71.2% of the initial mass, indicating a significant weight reduction while maintaining performance efficiency in functional use. The enhanced bracket meets acceptable displacement levels in mechanical systems, as indicated by the deformation pattern.

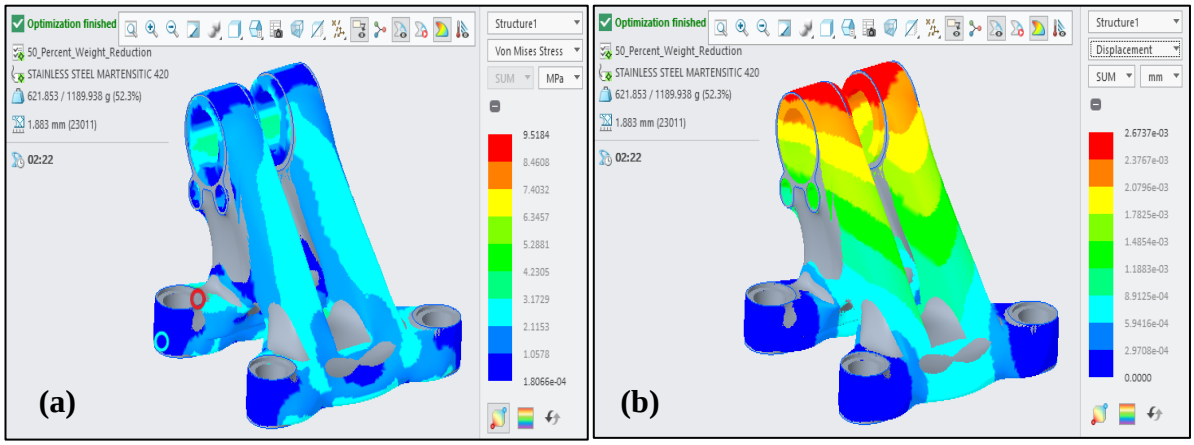

Figure 6: 50% weight reduction (a) Von-Mises's Stress (b) Deformation.
Source: Authors, (2026).

The Von Mises stress distribution of the cylinder mounting bracket after the parametric topology optimization process, with a 50% weight reduction, is shown in Figure 6(a). The Von Mises stresses at various locations of the design are shown in the contour map. The scale of the stresses on the right-hand side of the figure ranges approximately from 1.806×10^{-2} MPa to 9.518 MPa. The location of the maximum Von Mises stresses at the joint of the internal rib and the lower support region, as shown within the circle of red color, has been identified as per the Von Mises stress distribution. The stresses are concentrated at the location where loads are transferred to the upper cylindrical mounting section of the supports at the base. As the load passes through this bracket structure, it is affected by bending and shearing effects in this region. The cyan and green colors indicate low stress in the inclined support arms and the top cylindrical mounting holes, suggesting efficient load distribution along optimal structural paths. The outer edges and base mounting holes of the bracket, shown in dark blue, exhibit very low stress, suggesting that this region remains stable even after significant material is removed. The final mass of 621.853 g is approximately 52.3% of the original mass of 1189.938 g after optimization. The deformation contour map shows the displacement, measured in millimeters, across the entire optimized structure. 2.637×10^{-3} mm, as can be observed in Figure 6 (b), where the blue areas represent areas of low structural movement, and the red areas represent the areas of maximum movement.

It can be observed that the maximum deformation occurs at the upper cylindrical mounting part of the structure, at the pin connection point where the load is applied. The highest level of displacement due to direct load transfer via the bracket arms is represented by the red and orange bands in this section. The transition from the yellow to the green sections demonstrates how the distortion diminishes as the load continues to move downhill via the slanted support ribs. For the initial mass of 1189.938 g, the enhanced bracket has an ultimate mass of approximately 621.853 g, corresponding to 52.3% of the initial mass.

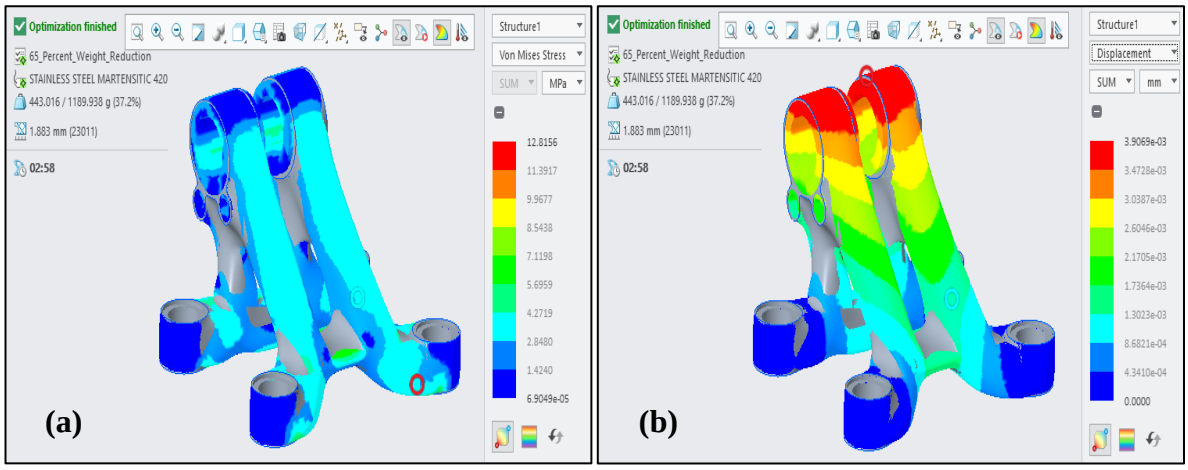

Figure 7: 35% weight reduction (a) Von-Mises's Stress (b) Deformation.
Source: Authors, (2026).

This is shown in the stress contour map in Figure 7 (a), whose color scale ranges from 8.0949×10^{-1} MPa to 12.8156 MPa. In this representation, red spots indicate the highest concentration of tension stress, whereas blue indicates the lowest. From the results, it is clear that the lower base support region, indicated by the red circle and the mounting hole location, has the maximum stress. This is due to the stress resulting from the inclined support arms. The weight distribution from the cylinder connecting point to the base support is heavily dependent on these regions. The optimized design has effectively distributed the weight along the major load paths, as shown by the stress distribution in the structural components. The largest portion of the mounting bracket's outer surface and the base platform, shown in dark blue, has very low stress levels. The final weight achieved through the optimization process, at approximately 443.016 g, is about 37.2% of the original weight of 1189.938 g. This indicates a substantial reduction in material usage while maintaining acceptable stress values within the material's allowed limits. The complete deformation distribution of the optimized cylinder mounting bracket is shown in Figure 7 (b). The magnitude of displacement in the bracket structure, measured in millimeters, is represented in the deformation contour map. The color bar indicates the regions of maximum (red) and minimum (blue) displacement in the structure, ranging from 0 mm (dark blue) to approximately 3.9069×10^{-3} mm (red). This region has the highest displacement as it is directly exposed to the applied load. Effective load transfer in the structure is indicated by the gradual reduction in distortion in the inclined supporting arms, as shown by the transition from the red and orange regions to the yellow and green regions. While allowing controlled deformation in the load-bearing top part, the improved design successfully maintains structural stiffness in the base region. While allowing controlled deformation in the load-bearing top part, the improved design successfully maintains structural stiffness in the base region. Compared to the initial mass of 1189.938 g, the topology optimization resulted in a final mass of approximately 443.016 g, which is 37.2% of the initial mass. Based on the deformation analysis, the parametric topology optimization approach successfully reduces the structure's mass while maintaining structural stability.

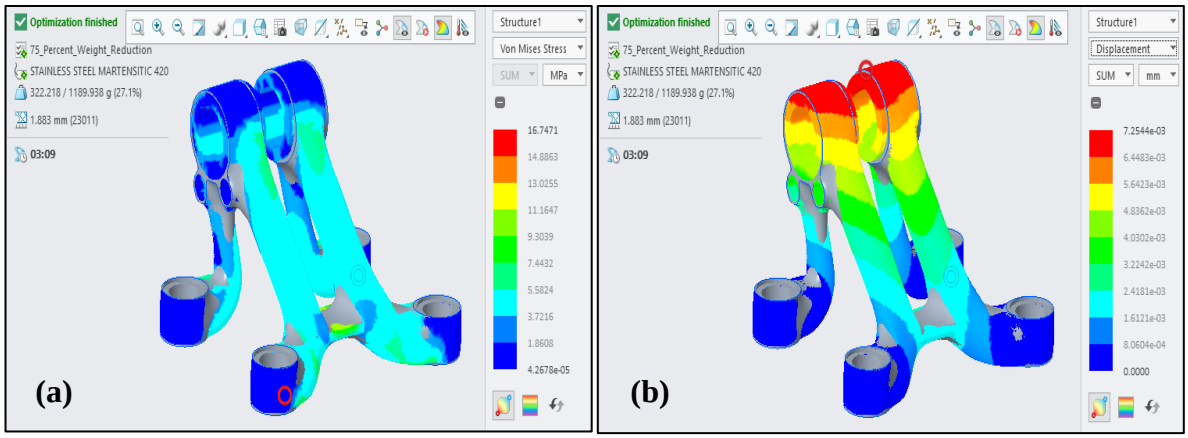

Figure 8: 25% weight reduction (a) Von-Mises's Stress (b) Deformation.
Source: Authors, (2026).

The Von Mises stress distribution of the cylinder mounting bracket, after parametric topology optimization with 25% weight reduction, is shown in Figure 8 (a). From the results, it can be observed that the lower base of the mounting bracket, especially the vicinity of the support hole, has the highest stress levels.

The stress contour map also shows the Von Mises stress levels at different points on the optimized shape. The dark blue areas represent low stress levels, and the red areas indicate high stress levels, indicating maximum stress concentration. The color scale ranges from 4.2678×10^{-1} MPa to 16.7471 MPa. Localized stress accumulation results from the interaction of shear and bending stresses in this region. It can be seen that the applied force is effectively transmitted from the interface of the cylinder mounting to the base mounting points via these structural components. Dark-blue color contours indicate that the majority of the base platform and the structural surfaces remain in low-stress regions. This means that despite the reduced amount of material, the bracket still has adequate structural stability. It can also be shown that the optimization process reduced the mass from 1189.938 g to approximately 322.218 g, a 27.1% reduction. The displacement across the optimum bracket, expressed in millimeters, is shown in the deformation contour map. According to the model, Figure 8(b) indicates that the area of maximum deformation is located in the top cylindrical mounting region, particularly at the pin connection. The displacement across the optimum bracket,

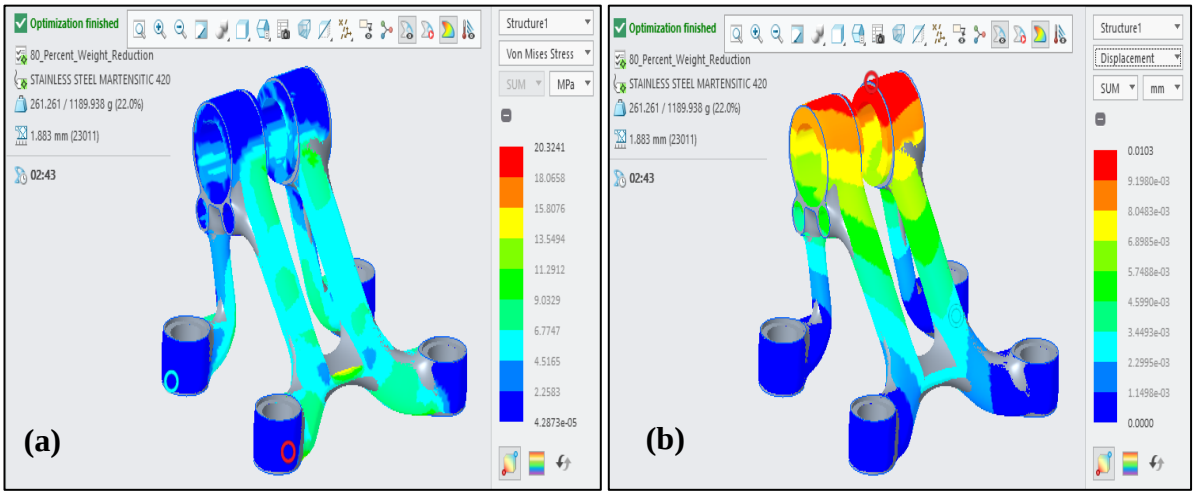

Figure 9: 20% weight reduction (a) Von-Mises's Stress (b) Deformation.
Source: Authors, (2026).

Expressed in millimeters, is shown in the deformation contour map. According to the color legend, the area of maximum displacement (red) and minimum deformation (blue) ranges from 0 mm (dark blue) to approximately 7.2544×10^{-3} mm (red). This means that constant support and adherence to the surrounding structure are guaranteed through the structural rigidity and good constraint of the base structure. Compared to the initial mass of 1189.938 g, the final mass obtained through optimization is about 322.218 g, or 27.1% of the initial mass. The viability of the lightweight structure for practical application is ensured by the optimization process, which guarantees the transmission of load from the upper supporting structure to the base supports. The Von Mises stress distribution obtained from the parametric topology optimization results, with a 20% weight reduction, is shown in Figure 9(a). From the figure, the stress contour map, with a color code ranging from approximately 4.2873×10^{-1} MPa to 20.3241 MPa, shows the Von Mises stress in the optimized bracket shape. From the results, it can be concluded that the lowest base mounting area, i.e., the region around the support hole as shown in the figure, corresponds to the highest stress. This is due to the transfer of load from the upper cylindrical mounting section to the base mounting points, where the structure is restricted, through the slanted support arms. The increase in stress in this region is due to a combination of bending, shear, and load-transfer effects. The applied force is effectively distributed from the cylinder mounting interface to the base supports through these areas, which are the major load-carrying parts. Compared with the initial mass of 1189.938 g, the optimization process yields a final mass of about 261.261 g, corresponding to 22.0% of the initial mass.Figure 9(b) shows the overall deformation pattern of the cylinder mounting bracket. The initial mass of the structure was 1189.938 g, and the final mass after the optimization process was about 261.261 g, corresponding to only 22.0% of the initial mass. The maximum displacement occurs at the top cylindrical mounting area, particularly near the pin connection point where the external load is applied, as indicated by the deformation values. As shown, due to direct load transmission through the cylinder connection to the bracket structure, the area marked in red and orange has the greatest deformation. Compared with the initial mass of 1189.938 g, the final mass, achieved through topology optimization, is approximately 261.261 g, or 22.0% of the initial weight.

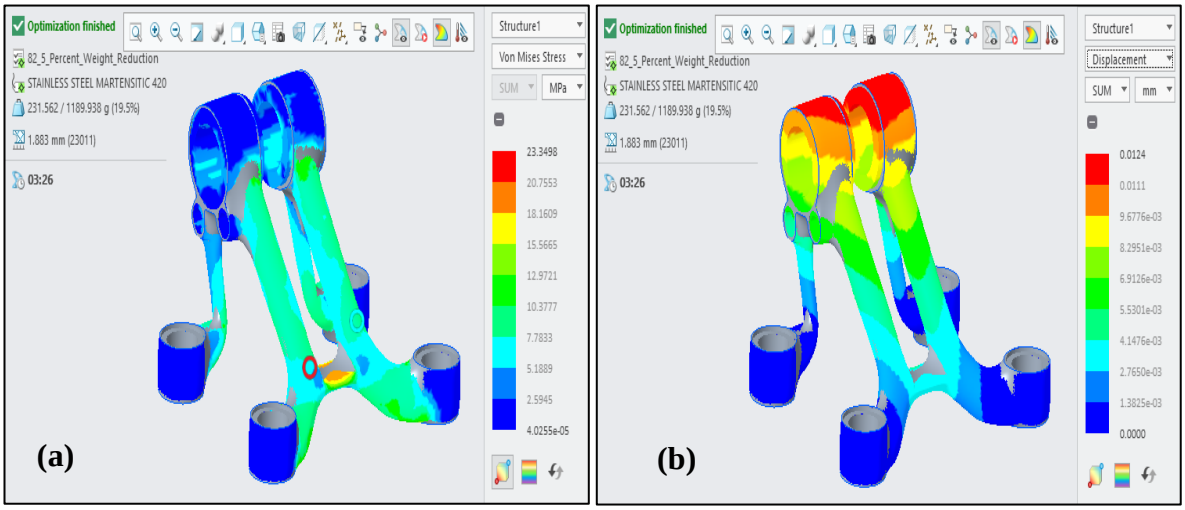

Figure 10: 17.5% weight reduction (a) Von-Mises's Stress (b)Deformation.
Source: Authors, (2026).

As shown in Figure 10(a), the von Mises stress contour map shows equal von Mises stress values across the bracket shape. The color scale ranges from about 4.0255×10^{-1} MPa to 23.3498 MPa. The results show that the maximum stress is near the junction point at the center base, where the structural intersection of the lower base platform and the inclined support arms occurs, as shown in the figure. The combined effects of bending, shear, and load transfer from the upper cylindrical mounting part to the base supports cause stress in this area. The initial mass was 1189.938 g, while the final mass, after optimization, was about 231.562 g, or 19.5 percent of the initial mass. The deformation distribution of the cylinder mounting bracket resulting from the parametric topology optimization process, with a 17.5% weight reduction, is shown in Figure 10(b). The red color shades in the color legend indicate displacement levels ranging from 0 mm to the maximum deformation in the mounting area at the top. The structural displacement of the bracket as the applied load is transmitted through it is shown through these colors. The maximum displacement occurs at the area around the top cylindrical mounting section of the bracket, especially near the pin connection where the applied load is transmitted, as shown by the deformation. As this area is directly exposed to the applied load and serves as the primary load-transfer interface between the cylinder and the bracket, it undergoes the greatest deformation. The change in color from red and orange to yellow, green, and cyan indicates the gradual reduction in deformation as the weight moves downhill along the slanted support arms. For the initial mass of 1189.938 g, the final mass calculated by the topology optimization technique is approximately 231.562 g, or 19.5% of the initial mass. Although the weight decreased compared to Von-Mises stress and the weight reduced compared to deformation are illustrated in "In addition to the above stated result evaluation criteria, strength per unit mass is also one of the evaluation mechanisms," the conclusion of the stress and deformation results is presented in "Table 4" and shown in Figure 11.

Table 4: Design points result summary.

No	Weight reduced (%)	Von-Mises's stress (MPa)	Deformation (mm)
1	70%	7.895	0.001983
2	50%	9.518	0.002673
3	35%	12.815	0.003906
4	25%	16.747	0.007254
5	20%	20.324	0.0103

How6RTYever, the model was not selected as the best because the study was limited to static analysis and other loading cases. Moreover, the front part of the model's optimization results is very thin, and there are concerns about the model's behavior under bending stress. To explain the stress and deformation in "Figure 10," the fifth design point (20% weight-reduction) is selected as the final model. "Figure 13" shows the topologically optimized and original models. The final product weighs 0.261 kg, 22% lighter than the original model at 1.189 kg.

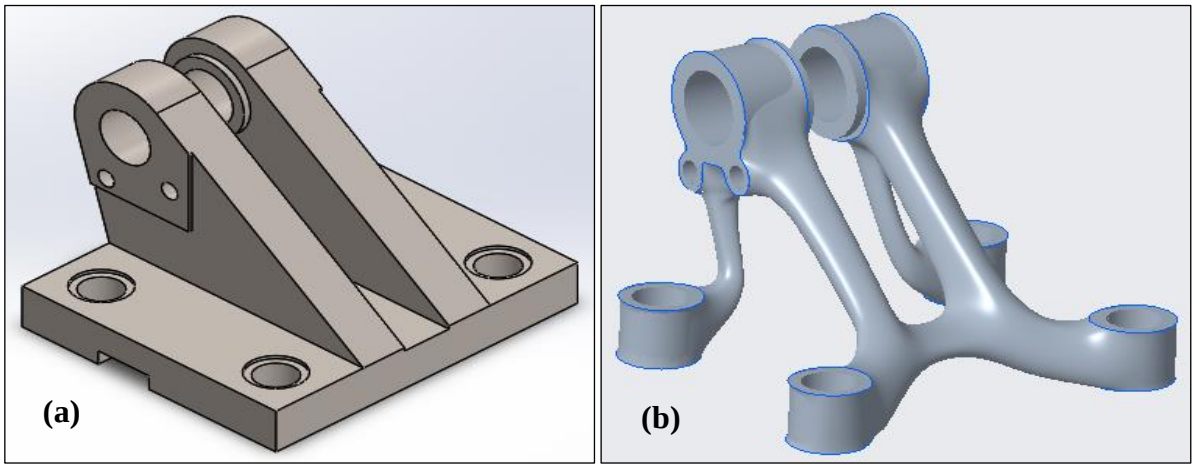

Figure 13: Original and topology optimized model (a) Original model (b) Optimized model.
Source: Authors, (2026).

b. Comparative study of the two models

Figures 14 and 15 show that the Von-Mises stress of the optimized model is 20.32 MPa, whereas it was 10.33 MPa for the original model. Also, the distortion value for the optimized model is 0.0103mm, whereas it was 0.00184mm for the original model. The resulting stress value is well below the material's tensile yield strength of 1360 MPa. This confirms that even if the optimized model has higher stress values, its factor of safety (FOS) will be greater.

V. CONCLUSION

This paper aims to optimize the topology of mounting brackets for cylinders used in fluid power systems. The aim is to check the original model at six design points: 30%, 50%, 65%, 80%, and 87.5% weight reduction, and 70%, 50%, 35%, 25%, 20%, and 17.5% weight retention. The original model weighed 1.189 kg and was created in the commercial SolidWorks software using martensitic stainless steel 420. The Parker Miller Fluid Power specification serves as the source for all geometric parameters, loading conditions, and constraints. The generative design module in PTC Creo Parametric software was used for topology optimization. The original model and the optimized model with an element mesh size of 1.883 mm were analyzed using static structural analysis. The original weight of the mounting bracket design was 1.189 kg. In the optimization process, six design points with weight retention of 70%, 50%, 35%, 25%, 20%, and 17.5% were chosen for evaluation. Even with the constraints, the optimization technique can still minimize the weight if required. Therefore, for 70%, 50%, 35%, 25%, and 17.5% design points, respectively, the actual weight retention values are 0.847 kg (71.2%), 0.622 kg (52.3%), 0.443 kg (37.2%), 0.322 kg (27.1%), 0.261 kg (22%), and 0.231 kg (19.5%). As the percentage of weight reduction increases, the weight per unit mass also increases. 9.315 MPa/kg, 15.306 MPa/kg, 28.927 MPa/kg, 51.974 MPa/kg, 77.792 MPa/kg, and 100.833 MPa/kg are the weights per unit mass. The choice of the model is not based on being the best, as it is constrained by the study's limitations related to static analysis and other loading conditions. Additionally, in the case of bending strain, the model appears suspiciously thin at the front. Therefore, the final model chosen to show stress and deformation is the fifth design point (20% weight-reduction design point). The completed model weighs 0.261 kg, which is 22% of its original weight of 1.189 kg. ANSYS performs a static analysis with the same loading and analysis conditions. The Von Mises stress of the improved model is 20.32 MPa, compared to 10.33 MPa of the previous model. Additionally, the distortion of the optimized model is 0.0103mm, compared to 0.00184mm of the original model. The generated stress is much lower than the material's tensile yield strength of 1360 MPa.

ABSTRACT

Tracking of the eyes and head have occupied a crucial role in human computer interaction, virtual and augmented reality, accessibility systems and cognitive studies. This paper gives a critical review on gaze estimation and head pose tracking algorithms, data sets, and performance determinants. This article compares classical and deep learning-based methods, such as convolutional neural networks, transformer models, geometric, hybrid, and multi-task learning methods. The article also tests the robustness in the external conditions like blinking, occlusion, and changes in illumination, and cross-subject individual differences. The most important publicly available datasets are compared regarding the type of input, diversity of participants, the size of data, recording distance, and environmental conditions. This article also contrasts new webcam and specialized eye-tracking systems, and, in doing so, point out trade-offs between accuracy, cost and applicability in real-time. The review also stresses on the role of domain adaptation, contrastive learning, and multi-modal inputs in generalizing across domains. In general, the article contains an attempt to present a comprehensive picture of the existing situation to researchers and practitioners to assist them in designing and choosing gaze and head pose estimation systems to be used in various applications.

I. INTRODUCTION

Gaze estimation and eye tracking have become the fundamental technologies in comprehending the human visual attention, mental processes, and the behavior of interaction. Fundamentally speaking, the techniques seek to ascertain the location of a person with their gaze, either through direct eye tracking or by inferring the direction of the gaze based on visual images or video streams [1]. Traditionally, eye tracking used specialized hardware systems, which had infrared illumination and high-speed cameras, which had the ability to capture fine-grained ocular characteristics like pupil placement and corneal reflections. Although these systems are highly accurate, they tend to be costly, obtrusive as well as restricted to controlled laboratory conditions. Consequently, their application in real-life use, especially in education and large-scale behavioral research has been limited [2]. The past few years have seen a drastic change of gaze estimation because of the development of computer vision and deep learning. Appearance-based approaches, which are methods that are based on the direct recognition of the direction of gaze based on the images of the face or eyes, have been in the limelight as a viable alternative to the traditional model-based approaches. In these techniques, convolutional neural networks (CNNs), transformer networks and hybrid geometric-learning networks are used to extract meaningful features of typical RGB images. This has in turn made it possible to carry out gaze tracking with the use of normal cameras without having to have special sensors. This has led to increased scalability and availability of eye tracking solutions most particularly web camera versions installed on both desktop and mobile computers [3]. The advent of low cost, web-based eye tracking systems is an important step toward the democratization of eye tracking technology. In contrast to specialized eye trackers, webcams are everywhere, cheap, and already integrated into the majority of consumer gadgets such as laptops, tablets and smartphones.

This has enabled researchers and practitioners to implement gaze tracking applications in a variety of real-world scenarios without enormous financial and technical constraints [4]. Moreover, the current deep learning architectures have been shown to mitigate the natural drawbacks of webcams, including reduced resolution, fluctuating light conditions, and the inability to run infrared, by training expressive representations of gaze-sensitive features. Open-source systems and frameworks have further made the process go faster on offering pre-made tools of real-time gaze estimation, calibration and data collection [5]. These developments are especially significant in such sphere as education, where student attention and engagement are important factors that have to be understood to enhance learning outcomes. Conventional strategies of gauging the engagement, including self-reporting, survey, or observation research, are frequently based on subjectivity, time-consuming, and not easily scaled. On the contrary, eye tracking using webcams is a non-invasive, automated technique of monitoring visual attention of students in the learning process. An examination of the gaze patterns will enable educators and other researchers to understand the interaction of students with teaching material, understand non-understood areas, and the effectiveness of the teaching techniques. This comes in handy particularly in online and remote learning where students cannot be observed directly [6]. In addition, the role of gaze estimation in education technologies facilitates the larger paradigm of learning analytics and intelligent tutoring systems. An example is the presentation of content which can be optimized using gaze data, or generate customized feedback, or real-time disengagement. Eye tracking can be used in visualization of cognitive processes in such subject matters as mathematics and statistics where visual attention is the main tool in problem solving and understanding. Consequently, the use of inexpensive gaze tracking systems can improve research and practice in the education field by allowing the collection of information to make decisions on large scales [7]. These positive developments notwithstanding, there are a number of challenges. Webcam-based systems are less accurate than dedicated eye trackers by their nature, and often susceptible to variations in head position, occlusions, and variations in the appearance of the user.

Moreover, the process of creating a strong generalization among various devices, settings, and target audiences remains a research topic. These have been tackled in recent works with methods like domain adaptation, contrastive learning and multi task learning, whose goal is to enhance the robustness and transferability of models. Ethical issues, such as privacy, data security, and informed consent, should be, conversely, handled with care at all times, especially in the case of the implementation of gaze tracking technologies in sensitive settings, such as education [8]. Since this area is quickly developing and numerous methods are suggested in the recent literature, it is evident that a thorough and systematic review is necessary that would synthesize the existing knowledge and outline the perspectives in future research. Although a number of surveys have investigated eye-tracking and gaze estimation through particular lens, e.g. hardware-based systems, deep learning methods, or educational practices, a gap still exists in the combination of these aspects within the framework of affordable solutions based on web-cams. It is with the intention of filling that gap that this review attempts to present a coherent overview of the state of the art, specifically focusing on approaches drawing on the use of standard cameras and present-day machine learning methods. There are three main purposes of this review. First, it aims at giving a clear and systematic overview of the basic ideas and methodology behind eye tracking and gaze estimation both conventional and modern. Second, it will also seek to review new developments in webcam-based systems in a systematic manner, particularly deep learning models, system architecture, and performance assessment. Third, the review discusses how these technologies have been used in the learning environment and how they have the potential to assess student attention, improve learning analytics, and facilitate adaptive learning environments. Besides providing a summary of the existing works, the review also has several major contributions. It suggests a unified taxonomy of gaze estimation algorithms to fits the constraints of low-cost camera configurations, compares the state-of-the-art methods in reference to accuracy, robustness, and computational cost, and locates key difficulties, which should be solved to allow implementation in the reality. Moreover, it identifies the future trends of research, such as cross-domain generalization, multimodal integration, and privacy-saving methods, which will have an influence on the future of webcam-based eye tracking.

II. FUNDAMENTALS OF EYE TRACKING AND GAZE ESTIMATION

The eye-tracking technology is a collection of techniques and apparatuses that monitor the eye positions and movements with the goal of identifying the point of gaze (where one is looking) and the movement of the eyes with respect to time. It has found its way to be a mandatory device in areas like human-computer interaction, neuroscience, psychology, marketing, and assistive technologies. Eye-tracking systems can be of great use by providing insights on cognitive processes, user experience, and decision-making because they capture visual attention and gaze behavior. Throughout the decades, eye-tracking technology has experienced a massive evolution, which started as an intrusive and hardware-intensive system to highly accurate and non-invasive; non-hardware solutions that are software-driven. These improvements have been occasioned by sensor technology, computer vision, and artificial intelligence [9]. Figure (1) shows the evolution of eye-tracking technology over time, with the key milestones in technological advancement in the 1940s being the ones with high attention to date. The figure outlines the process of the shifting of the old method of electrical measurements to the current system, which is powered by AI and is sensor-based, showcasing how the entire system has been getting better and better, to where it is more precise, easy to use, and integrated [10].point

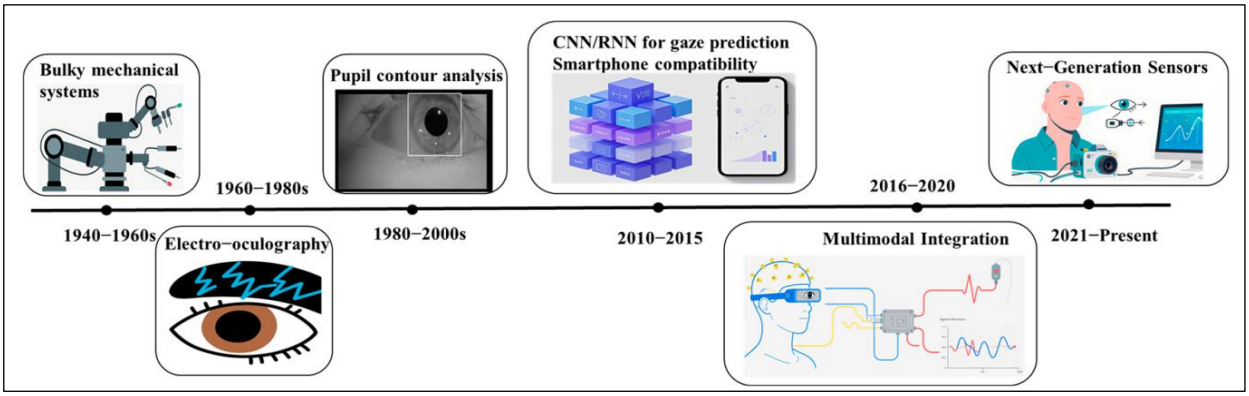

Figure 1: Timeline of Eye-Tracking Technology Evolution
Source: [10].

The history of eye-tracking technology development can be separated into several important stages each of which marked a significant breakthrough in the methodology and usage.

- The first stage (1940s1960s) was based on the principle of electro-oculography (EOG) where electrical potential of the eye movements are measured with the help of electrodes put around the eyes. Although this technique was able to give fundamental propositions on eye movement, it lacked a high spatial resolution and involved direct physical contact with the subject and was not very useful in widespread practice [11].
- In the 1960s-1980s, the eye-tracking systems were replaced with bulky mechanical systems. These systems tended to be head-mounted systems or hard structures that limited the movements of the user. Despite their ability to increase the measurement abilities, they were inconvenient and could be mostly used in the controlled laboratory settings [12].
- A major improvement was made between the 1980s and 2000s when an analysis of the contour of the pupil was introduced. This method of non-invasive tracking through the use of the camera was made possible since the camera was able to identify and determine the shape and position of the pupil. It is the stage of the modern eye-tracking starting with better accuracy and increased comfort to the user [13].
- The years 2010-2015 were marked by the introduction of the methods of artificial intelligence, especially convolutional and recurrent neural networks. Those approaches increased the accuracy of estimating gaze and allowed tracking of the eye on the consumer devices of smartphones. The technology became easier and larger-scale [14].
- In 2016-2020, multimodal integration, the integration of gaze data with other physiological measures, started to become available in eye-tracking systems, including brain activity and heart rate. This has made it possible to gain a better understanding of human behavior and apply it in virtual reality, healthcare, and more sophisticated user interfaces [15].
- Since 2021, there is an additional development of next-generation sensors that revolutionized the field. New systems are small, efficient in energy use, and can track in real time and with high accuracy. Now they are present in the devices that people use in their daily lives, including the augmented reality headsets, laptops, and wearable technologies, with vast potentials in bringing them into practice [15].

II.1 BASIC CONCEPTS OF EYE TRACKING

Eye tracking is founded on the number of basic concepts that explain the motions of the eyes and the measurement of visual attention. These concepts are important to comprehend the eye-tracking data and utilize it in research and in the real practice. The eye of a human being does not plan through a scene in a smooth way, but it switches between quick motions as well as short periods of rest. These movements demonstrate information collection and processing in the form of visual processing. Eye-tracking systems are used to record such patterns and convert them into meaningful measures that indicate attention, interest and cognitive effort [16]. The fixations, saccades, and gaze points are the main concepts that the eye-tracking analysis is based on. More sophisticated features such as scan paths and areas of interest (AOIs) are also used to assist the researcher to learn more about viewing behavior in complex settings. The combination of the two notions enables qualitative and quantitative study of visual attention [17]. Table 1. Shows Basic Concepts of Eye Tracking.

Table 1: Basic Concepts of Eye Tracking.

Concept	Definition	Description / Importance
Gaze Point	The exact location where a person is looking at a given moment	Represents the fundamental output of eye-tracking systems
Fixation	A period when the eyes remain relatively still on a single point	Indicates focused attention and information processing
Saccade	A rapid movement of the eye between fixations	Helps shift attention from one point to another; no visual processing occurs during it
Scan Path	The sequence of fixations and saccades over time	Shows the overall viewing pattern and behavior
Area of Interest (AOI)	A predefined region in a visual scene selected for analysis	Used to measure attention on specific elements (e.g., buttons, images)
Pupil Dilation	Changes in pupil size	Can indicate cognitive load, emotional response, or lighting conditions

Blink Rate	Frequency of eye blinks	(fatigue and attention levels)
Dwell Time	Total time spent looking at a specific area	Reflects the level of interest or importance of that area
Heatmap	Visual representation of gaze data using color intensity	Highlights areas that attract the most attention
Gaze Plot	A visual diagram showing fixations and saccades in sequence	Useful for analyzing viewing order and navigation patterns

II.2 GAZE ESTIMATION TECHNIQUES

Gaze point estimation is the calculation process of identifying the point where the observer is gazing. This calculation is carried out in the majority of eye-tracking systems, based on approximating the point of gaze (POG) on a two-dimensional surface, which could be a display monitor or a scene in front of the camera. This estimation is normally done by creating some mapping between the features obtained in the eye and the location of the gaze. In this case, the eye feature coordinates (X_e, Y_e) are transformed into the screen coordinates (X_s, Y_s) by a non-linear regression (polynomial) equation to represent the connection between these variables [19]. This mapping is typically represented as a 2-dimensional poly, in which the horizontal and vertical gaze coordinates are determined in terms of the combinations of powers of the eye feature coordinates. The equations may be expressed as follows [20]:

$$X_s = a_0 + \sum_{p=1}^{n} \sum_{i=0}^{p} a_{(i,p)} X_e^{p-i} Y_e^{i} \quad (1)$$

$$Y_s = a_0 + \sum_{p=1}^{n} \sum_{i=0}^{p} b_{(i,p)} X_e^{p-i} Y_e^{i} \quad (2)$$

Where, (X_e, Y_e) are the coordinates of the extracted eye features, (X_s, Y_s) are the estimated coordinates of the gaze on the screen and $a_{(i,p)}$ and $b_{(i,p)}$ are the coefficients that specify the mapping function. The order of the model, parameter (n), is what determines the complexity and flexibility of the model. A calibration procedure will be necessary to obtain the best values of these coefficients. In this process, the user is requested to concentrate on a number of predefined points that are shown on the screen. The system compares the position of these points with the estimated gaze position to calculate the difference between them and change the coefficients so as to reduce the error in estimation. The reason why this step of calibration is necessary is that it compensates the personal discrepancies among different eye geometry, and enhances the accuracy of the gaze estimation. Although calibration is used, there is still a possibility of error in the estimated gaze position to some extent. The difference in the angle between the optical and visual axis of the human eye is one of the main reasons of this disparity in vision otherwise known as the kappa angle. The line between the center of the cornea and the center of the pupil is referred to as the optical axis whereas the actual direction of body with respect to a target is referred to as the visual axis. Given that the two axes are not aligned, a systematic error is incorporated in the gaze estimation procedure. This bias is different in people and should be countered to allow more accuracy [21]. Moreover, an anatomical makeup of the eye is also significant in eye tracking [22]. The anterior part of the eye has the cornea and the pupil, which refract and regulate the entry of light to the eye respectively. The center of the pupil and the center of the cornea are considered to be the key features of the gaze estimation since it defines the optical axis and forms the foundation of many computation models. These anatomical and geometric relationships are important in understanding how to come up with proper and accurate eye-tracking systems. Figure (2) shows Schematic of the human eyeball, showing key anatomical parameters and reference points for gaze tracking [23].

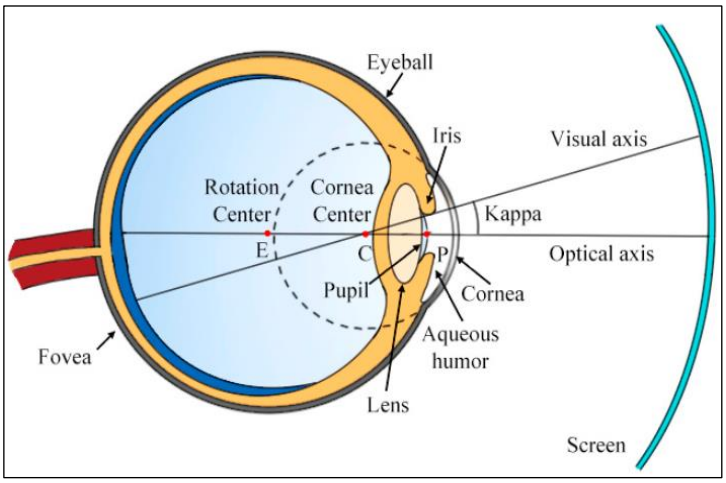

Figure 2: Schematic of Human Eyeball.

III. WEBCAM-BASED EYE TRACKING SYSTEMS

One of the low-cost and most commonly available gaze estimation methods is the eye tracking (Webcam-based) system, which uses the standard cameras, including embedded webcams on laptops or external ones. These systems are based on computer vision and machine learning algorithms to recognize facial features, extract information relating to the eyes, and approximate the direction of gaze of the user in real-time. In contrast to the conventional infrared based eye trackers, webcam solutions can work in the visible light conditions and this presents a challenge in form of sensitivity to light variations, poor image quality, and inconsistency in user placement.

Nevertheless, in spite of these limitations, recent progress in the deep learning and image processing methodologies have greatly improved their work with the examples of their application in remote usability testing, online education, psychological researches, and assistive technologies [24]. Figure (3) illustrates the general workflow of an eye tracking system that uses a webcam to capture the image and then it is scanned by gaze estimation. This starts with camera input, the video frames are captured continuously. These frames are identified by the face detection algorithms to identify the face of the user and approximate the head position, relevant in the context of dealing with natural head expression. After that, the extraction of eye features is made to determine the essential features like the pupil center and the corneal reflections. Such features are the input in the gaze estimation module in which a mapping function is used in estimating the point of gaze of the user on the screen. Lastly, the system does real-time processing to allow generation of gaze predictions with minimum latency hence allowing smoothness and interactive applications [25]. The engineering of this type of systems should take into consideration such aspects as hardware and environmental limitations, such as camera resolution, frame rate, lighting conditions, which directly influence tracking accuracy. The method of personalizing the system by each user is normally done through its calibration to be able to create a correspondence between the eye features that are detected and the known screen coordinates. In addition, real time processing is also necessary to stay responsive, which may demand optimized algorithms and light-weight models. There are tools like GazeFollower which are open-source frameworks, allowing the research and development in this area to be achieved by combining these elements into ready-to-use systems [26].

IV. DEEP LEARNING APPROACHES FOR GAZE ESTIMATION

Deep learning has made a great contribution to the study of gaze estimation by providing more robust and accurate models capable of learning more complicated associations between eye appearance, head pose, and gaze direction. Deep learning methods automatically learn significant features of raw input data, including images of the eyes or face, unlike the traditional model-based or feature-engineering models, and thus are very useful in unconstrained settings. These methods are especially appropriate to the applications based on the webcam and in real world, where the changes in the lighting effect, the head position, and the features of the users are a significant challenge. The most popular architectures in gaze estimation are convolutional neural networks (CNNs) [27]. They have the design to be able to handle image data by learning spatial hierarchies of features using convolutional layers. In gaze tracking, CNNs are normally performed on eye region images or full-face images so as to obtain discriminative features that are linked to gaze direction. Their capacity to achieve fine grained visual patterns e.g. pupil shape, eye contours, etc. makes them very useful in appearance-based gaze estimation tasks [28].

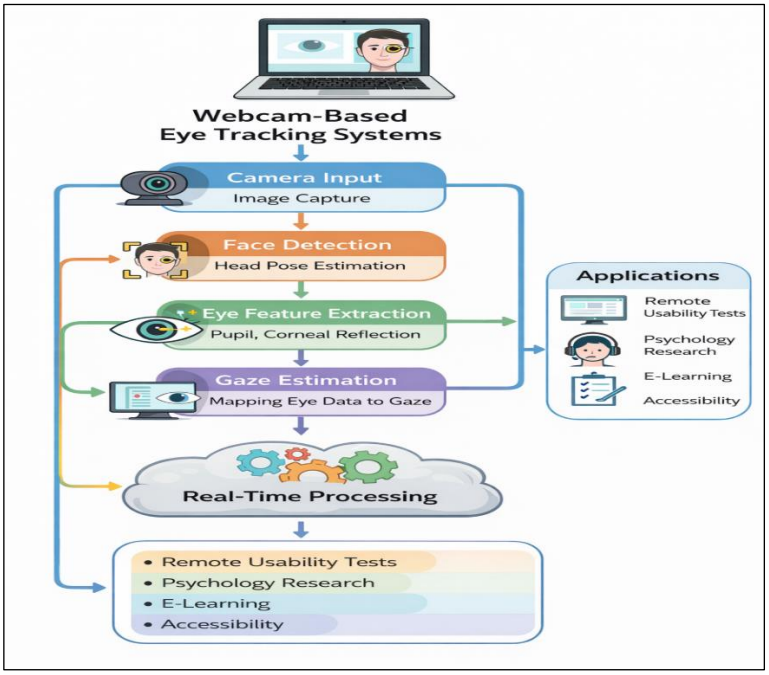

Figure 3:Webcam-Based Eye Tracking Systems.
Source: Authors, (2026).

Transformer-based models have also become a strong rival of CNNs, more recently. These models are based on the focus mechanisms to absorb global connections in the input data so that they can represent long-range relationships better. Gaze estimation Transformers can use the information of other parts of the face or even across multiple frames to be more robust to pose and occlusion changes. They can be extremely demanding in size of datasets and computation power, but have shown optimistic results in complicated cases. Appearance-based gaze estimation is a deep learning representation that directly predicts gaze direction from visual input, including images of the face or eyes, without a geometric representation of the geometric structure of the eye. This mode highly relies on deep neural networks which are able to acquire implicit knowledge of features of gazes. It is especially applicable to low-cost systems, including webcam-based tracking, where accurate geometric measurements are either unreliable or not available [29]. Contrary to that, geometric and hybrid deep models use both learned features and explicit eye geometries. Geometric techniques refer to anatomical and physical models, e.g. the correlation between the pupil and corneal reflections, to determine gaze direction.

Hybrid techniques are methods which combine these geometry constraints with deep learning models to enhance accuracy and generalization. This combination enables the system to combine the two data-driven learning and domain-specific knowledge. Multi-task learning has also found application in gaze estimation, with one model being trained to do several related tasks at the same time e.g. predict gaze direction and head pose. As the head position has a powerful effect on gaze direction, the combined learning of the tasks can enhance the performance. Multi-task models facilitate strong robustness by sharing the representations of various tasks and, therefore, lessening the use of distinct systems, which makes them effective and useful in real-life scenarios [30]. Table (2) shows Deep Learning Approaches for Gaze Estimation

Table 2: Deep Learning Approaches for Gaze Estimation.

Approach	Description	Advantages	Limitations
CNNs	Use convolutional layers to extract spatial features from eye/face images	High accuracy, strong feature extraction, widely used	May struggle with global context and large pose variations
Transformer-Based Models	Use attention mechanisms to model global relationships in data	Captures long-range dependencies, robust to occlusion	High computational cost, requires large datasets
Appearance-Based Methods	Direct mapping from image input to gaze direction	Simple pipeline, suitable for webcams and low-cost systems	Sensitive to lighting and appearance variations
Geometric Models	(pupil, cornea)	Interpretability, grounded in eye anatomy	Requires precise feature detection and calibration
Hybrid Deep Models	Combine deep learning with geometric constraints	Improved accuracy and generalization	Increased system complexity
Multi-Task Learning	Simultaneously predicts gaze and related tasks (e.g., head pose)	Better performance, shared learning, efficient	Requires careful training and balanced datasets

Source: Authors, (2026).

V. CROSS-DOMAIN GENERALIZATION AND ROBUSTNESS

One of the most significant problems of gaze estimation is cross-domain generalization since when a model is trained on a particular set of data or a specific environment it is not always capable of not deteriorating as soon as it is implemented into a different environment. Changes in lighting, quality of the camera, head posture, user attributes, and type of devices may significantly affect the model performance. To eliminate these issues, domain adaptation techniques have been developed, that are more likely to reduce the difference between the training domain (data in the training phase) and the target domain (where it is used). These methods make parameters or features representations of the models to optimize generalization with no requirement of a large quantity of labeled information in the target domain [31]. Contrastive ways of learning have also been used to enhance the robustness of gaze prediction. Contrastive approaches enable models to learn more consummating features of invariance that cross-domain by learning representations that decrease the distance between identical patterns of gaze and intensify the distance between nonidentical patterns. The technique particularly comes in handy in the management of variability that yields in a difference in appearance, light, or camera settings [3]. Variability is another important aspect during the process of enhancing cross-domain robustness. In reality, there can be cases when the lights are dynamic, the poses of the head are mixed, the devices are multiple and the features of the camera are mixed. The mechanisms applied in contemporary gaze estimation systems to ensure they are more resistant to these deviances are data augmentation, adaptive normalization, and multi-view learning. With these strategies included, models would be in a position to perform in a stable manner under unconstrained environments and therefore in the suitability in the real practice [32]. The evaluation measures and benchmark datasets play a crucial role in developing and testing strong gaze estimation models. Publicly available data is a normal system of test cross-domain generalization, but with different subjects, devices and conditions. Some of the measures that are used to gauge performance include Angular error, mean absolute error and accuracy of gaze estimation. This will be done by testing the models in a few datasets, to know that system is not overfit to a particular environment, which can generalize well to unknown conditions [33]. Table (3) shows Cross-Domain Generalization and Robustness Techniques

Table 3: Cross-Domain Generalization and Robustness Techniques.

Aspect	Description	Techniques / Approaches	Challenges Addressed
Domain Adaptation [34]	Aligns feature distributions between source and target domains	Fine-tuning, adversarial adaptation, feature alignment	Cross-dataset variability, unseen environments
Contrastive Learning [35]	Learns invariant features by contrasting similar and dissimilar samples	SimCLR, MoCo-style embeddings	Appearance and lighting variations
Handling Variability [36]	Manages differences in pose, lighting, devices, and user characteristics	Data augmentation, adaptive normalization, multi-view learning	Real-world unconstrained conditions
Benchmark Datasets [37]	Standardized datasets for training and evaluation	GazeCapture, MPIIFaceGaze, RT-GENE, ETH-XGaze	Ensuring fair comparison and model generalization
Evaluation Metrics [38]	Quantitative measures of gaze estimation performance	Angular error, mean absolute error, accuracy	Comparing robustness across models and datasets

VI. COMPARISON OF EXISTING METHODS

A comparison of current gaze estimation techniques will be able to give the information about their strengths, limitations, and appropriateness to various applications.

The accuracy, latency, and robustness are performance measures that are commonly applied to evaluate eye tracking systems. Eye trackers based on special hardware are normally more accurate as infrared lights, specific sensors, and careful calibration are used. Angular errors of such systems are capable of reaching 0.51º, which in scientific research and medical practice are the best as well as in high-precision human-computer interaction. They however, are expensive, are hardware intensive and not portable enough to be used widely [39]. Contrastingly, eye tracking systems using webcams are an inexpensive and readily available option that utilizes ordinary cameras. Though they offer poorer quality of accuracy, usually between 2-5º angular error, they perform better with convenience, scaling and non-intrusiveness in those applications where precision is less significant than convenience and scaling. The latency can also be an important factor: although specialized trackers can provide high-speed tracking that can be used in real-time, systems based on webcams need to trade between computational efficiency and tracking quality, particularly when run on an ordinary consumer computer [40]. Cost against accuracy is a significant variable in the choice of a method. Specialized trackers with high end needs a lot of investment but provide accurate results whereas webcam-based needs cheaply but with low fineness of result. These two approaches have their choice determined by the needs of the application, the number of users and the limitations of the environment. Indicatively, research experiments that demand accuracy of gaze tracking can demand special trackers, whereas remote usability tests, e-learning, and accessibility applications can be efficiently executed through the use of webcam-based tracks [8]. In general, it is possible to classify existing methods depending on hardware requirements, complexity of computations, and applicability of the method. The current advances in the field of deep learning and the cross-domain generalization have reduced the gap in performance, now webcam based systems are capable of competitive accuracy in various cases. However, a trade off in webcam-based and specialized system persists as a choice between accuracy, affordability and installation [41]. Table (4) shows Comparison of Eye Tracking Methods.

Table 4: Comparison of Eye Tracking Methods.

Method	Accuracy	Latency	Advantages	Limitations
Specialized Eye Trackers	0.5°–1° angular error	Low latency	High precision, robust to lighting/pose, fast	Expensive, bulky, requires calibration
Webcam-Based Systems	2°–5° angular error	Moderate latency	Affordable, accessible, non-intrusive	Lower precision, sensitive to lighting and pose
Hybrid Approaches	1°–3° angular error	Low–moderate	Combines learned features with geometric models	More complex system design
Deep Learning Only Models	1.5°–3° angular error	Depends on device	Can adapt to multiple domains, flexible	Requires training data, computational cost

VII. RELATED WORKS

The methods that are used to estimate the head pose could be divided into three major categories, appearance-based, geometry-based, and clustering-based. All these categories are different in terms of the form of input data, the methodology used, and the accuracy. Appearance-based methods make use of visual representations derived on the face or the eye, and apply machine learning or deep architecture models to directly relate such representations to the angle of head orientation. Geometric approach techniques make use of explicit 3D geometric representations of the face and eyes, frequently with landmark points to compute pitch, yaw and roll. The combination of feature extraction and data-driven clustering methods into a single process, known as clustering, is aimed at making them more robust and increase their ability to generalize across data sets [43]. A representative comparison of representative methods, such as type of input, datasets, and accuracy measures are presented in Table (4).

Table 5: Comparison of Works on Head Pose Estimation Methods.

Method Category	Reference	Input Type	Dataset	Reported Accuracy	Details / Notes
Appearance-Based	[44]	Eye images	BiWi	4.66°	Uses eye-region visual features with regression models to estimate pitch and yaw.
	[23]	Full face	AFLW	5.77°	Employs facial landmarks and CNNs for robust head pose estimation in unconstrained settings.
	[45]	Eye images	CMU-PIE	7.36°	Focuses on illumination-invariant feature extraction from eye region.
		Full face	MIT-CBCL	1.31°	Uses controlled indoor images; very low angular error due to stable capture conditions.
		Full face	YaleB	7.58°	Handles varying illumination; includes expression variations in training.
Geometry-Based	[46]	Eye and face	Unknown	2.63°	Computes head pose using 3D facial landmarks and geometric transformations.
		Eye and face	Unknown	3.26°	Combines eye tracking with face geometry for robust 3D orientation estimation.
	[47]	Full face	MPIIGaze	4.8°	Applies explicit facial geometry modeling for gaze and pose estimation.
	[48]	Face landmarks	Unknown	7.65°	Focuses on outdoor and low-resolution images, highlighting method robustness.
	[49]	Full face	ColumbiaGaze	9.46°	Handles multiple subjects with variable head orientations.
		Full face	MPIIFaceGaze	14.93°	Generalization to unconstrained webcam data; larger error due to dataset diversity.

		Full face	GazeCapture	10.46°	Large-scale mobile gaze dataset; demonstrates model performance on consumer devices.
Clustering-Based	[50]	Face + landmarks	BiWi	4.9°	Combines facial feature clustering with regression for improved robustness.
	[51]	Full face	Unknown	1.57°	Uses hierarchical clustering on feature embeddings to reduce noise and outliers.
	[52]	Full face	AFLW2000	3.48°	Enhances accuracy by clustering similar head poses before regression.
		Face landmarks	300 W-LP	3.92°	Incorporates pose normalization and clustering to handle extreme angles.
		Full face	BIWI	2.24°	Robust to subject variability and lighting changes using data-driven grouping.

Table 5 provides a detailed comparison of appearance-based, geometry-based and clustering-based techniques of estimating head pose that indicate a difference in the type of input, datasets used, accuracy and methodological properties. Appearance-based methods are mainly based on visual features that are a result of eye or full-face images and use convolutional neural networks or regression models. Such methods are likely to be effective under controlled settings like the MIT-CBCL where there is fixed lighting and minimal variation of the head describing low angular error conditions. They may however degrade in unconstrained environments because of the variations in pose, lighting and occlusion. Methods that use geometry use explicit 3D face landmark and physical modeling of the head and eye. These methods are able to combine low errors with limited training data by exploiting geometric constraints and are also capable of making interpretable estimates. They can however in most cases need quality landmark detection and might not be as strong to low-resolution images or partial occlusions. The methods based on clustering provide hybrid approach, that is, similar head poses are clustered and then regression is run, which enhances resistance to noise, subject variability, and extreme angles. Such techniques show stable behavior with a variety of datasets and light environments. On the whole, Table 5 indicates that although appearance-based models are versatile and can be easily used, geometry and clustering models allow better resilience and explanatory capabilities, and thus it is necessary to balance computational complexity, data needs, and real-world implementation conditions. Possible external and individual factors that may influence gaze estimation performance greatly include blinking, occlusion, lighting conditions and user differences. This is important in understanding the effect of these factors on accuracy in the design of robust eye-tracking systems. Eye blinking has temporary signal loss and may interfere with feature extraction, and occlusions (that can be created by glasses, hair or hands) may partially obscure the eyes or face. The visibility of eye features is influenced by the variability of light (such as ambient variability or shadow variability) and the unique anatomical characteristics of the eyes (eye shape, pupil size, and facial geometry) can further influence the performance of the system. Table (6) presents the summary of typical studies assessing gaze estimation under these conditions, input types, data sets and reported performance measures, such as average precision (AP) and angular error in degrees.

Table 6: Evaluation of Gaze Estimation under Various Factors.

Factor	Reference	Input Type	Dataset	Performance Metric	Details / Notes
Blinking	[53]	Eye	RT-BENE, Eyeblink8	AP: 0.757 (RT-BENE), 0.997 (Eyeblink8)	Evaluates robustness to natural blinks using eye-focused features.
	[54]	Eye	RT-BENE	AP: 0.653	Shows reduced precision under frequent blink scenarios; highlights importance of temporal smoothing.
Occlusion	[55]	Head / Body	GAFA, MoDiPro	20.4° (GAFA 3D), 25.6° (MoDiPro 2D)	Evaluates partial occlusion due to head rotation and body posture in gaze estimation.
	[56]	Eye + Face	MPIIGaze, EYEDIAP, RT-Gene	3.8°, 5.4°, 7.9°	Combines multiple occlusion scenarios, including glasses and hair; evaluates both 2D and 3D gaze.
Illumination	[57]	Eye	MPIIGaze, EYEDIAP	5.20°, 7.36°	Tests performance under varying lighting conditions; sensitive to shadows and low light.
	[58]	Eye	MPIIGaze, EYEDIAP, UTMultiview	4.67°, 3.36°, 4.33°	Uses deep learning-based approaches for illumination-invariant feature extraction.
Individual Differences	[59]	Eye	EVE, MPIIGaze, XGaze	1.89°, 4.14° / 3.02°, 2.88°	Evaluates cross-subject variability; models trained on some users tested on unseen users.
	[60]	Eye	Custom / unspecified	0.9°	Demonstrates high accuracy for personalized calibration.
	[61]	Eye	Custom / unspecified	4°	Highlights challenges in generalizing gaze estimation across users without calibration.

Table 6 presents the effect of external and individual forces on the estimation of gaze, such as blinking, occlusion, the change in illumination, and variation in inter-subject. Blinking of the eyes causes intermittent loss of signals which could have an immense impact on the accuracy of gaze as seen in data such as RT-BENE and Eyeblink8. The techniques that apply smoothness in the time or predictive modeling are in a position to deal with these transient events which minimizes the decline in performance. Another challenge is occlusion

which results due to head movements, glasses, or hand signs. Researchers have shown that the combination of head and body cues or both eye and face signal is better at enhancing robustness through the use of GAFA and MoDiPro. Correspondingly, the controlled datasets such as MPIIGaze, EYEDIAP and RT-Gene indicate that the multi-modal inputs can be used to reduce the effects of occlusions. Another important factor is the variability of illumination since discrepancies in the illumination of the eye features influence the visibility of face-related features. When trained on augmented or multi-condition datasets, the deep learning approaches demonstrate encouraging results at varying levels of illumination. Lastly, personal anatomy and facial features of the eye and face play a major role in estimating gaze. With cross-subject tests, it is seen that models do not generalize well without subject-specific calibration, as observed in EVE and XGaze datasets. In general, Table 6 has shown that it is necessary to design gaze estimation systems that should consider a combination of temporal modeling, multi-modal inputs, and methods to control the calibration to provide a reliable performance in the real-life conditions. The quality of datasets used in gaze estimation research depends greatly on the quality of participants used (varying), the nature of recording environments (varying) and the adequate sample sizes to generate and test models. These datasets vary according to the type of input (RGB or RGB-D), presence of full-face images, number of subjects, data magnitude, distance of recording and surrounding conditions (illumination and laboratory or natural conditions). Table (7) reflects a comparative summary of widely used gaze estimation datasets, including their essentials and the ability to be used in diverse experimental configurations.

Table 7: Overview of Gaze Estimation Datasets.

Dataset	Input Type	Participants	Full Face Available	Data Amount	Recording Distance	Environment / Illumination
MPIIGaze [62]	RGB	15	No	213,659 images	40–60 cm	Daily life
MPIIFaceGaze [63]	RGB	15	Yes	213,659 images	40–60 cm	Daily life
UnityEyes [64]	RGB	-	No	User-defined	User-defined	User-defined
ColumbiaGaze [30]	RGB	56	Yes	5,880 images	200 cm	Lab
Gaze360 [65]	RGB	238	Yes	~172,000 images	~200 cm	Daily life
ETH-XGaze [66]	RGB	110	Yes	1,083,492 images	100 cm	Lab
UT-Multiview [67]	RGB	50	No	1,216,000 images	60 cm	Lab
EYEDIAP [68]	RGB-D	16	Yes	94 videos	80–120 cm	Lab
RT-GENE [69]	RGB-D	15	Yes	277,286 images	~182 cm	-
NISLGaze [70]	RGB	21	Yes	2,079 videos	90 cm	-
GazeCapture [71]	RGB	1,474	Yes	>2.5 M images	Close	Daily life
TabletGaze [72]	RGB	51	Yes	816 videos	30–50 cm	Lab
GAFA [55]	RGB	-	Yes	882,000 videos	50 cm–7 m	Daily life
GFIE [73]	RGB-D	61	Yes	71,799 videos	1.04–6.48 m	Daily life

Source: Authors, (2026).

Table 7 gives a summary of commonly used gaze estimation datasets, contrasting input type, participant variety, size of data set, recording range and environmental circumstances. The table shows that there is a significant difference in the size and design of datasets, which indicates the versatility of the research in this area. Big datasets like GazeCapture or ETH-XGaze have millions of images or large amounts of video data, and can be used to train deep learning models that have huge demands in terms of diverse input. Smaller datasets, like ColumbiaGaze or NISLGaze, provide controlled conditions, as well as high-quality images, which come in handy especially when it comes to the testing of model performance in lab-based experiments. Another aspect of consideration is the inclusion of full-face pictures as opposed to eye-region pictures only. Head pose integration and multi-task learning methods have full-face datasets, whereas eye-only datasets specialize in finer ocular detail. Also, the availability of RGB-D information in such datasets as EYEDIAP and GFIE makes it easier to predict 3D gaze and consider the depth in modeling. The distance and environmental condition also affect the relevance of datasets, as natural head movement and natural illumination variability are only recorded in daily life datasets, but controlled lighting and constant distance are provided in lab-based datasets to evaluate them exactly. In general, Table 7 highlights the trade-offs between the size of dataset, environmental variability, and input type. The choice of the suitable dataset depends on the purpose of the model, the complexity of the model, and the need to be robust in uncontrolled situations or accurate in specific experiments.

VIII. CONCLUSION

This review gives a detailed discussion on the present situation and problems of gaze and head pose estimation technologies considering not only the methodological progress but also the practical aspect. Appearance-based methods, based largely on the visual cues picked off the eye areas or full-face image, have proved to be very flexible and data-driven to allow models to learn complicated images-to-gaze-direction linkages. Such techniques are especially useful when used with convolutional neural networks (CNNs) or transformer-based models, which are capable of learning spatial hierarchies and long-range dependence of visual information. Conversely, geometry-based techniques use explicit 3D facial landmark models to determine head orientation, which is interpretable and resistant to moderately unconstrained conditions. The clustering-based methods also improve the resilience of the result since the similar head poses are clustered together before regression, which would be better in the high variability situations (where the angle or the appearance of the subject varies a lot). Multi-task and hybrid learning models that combine gaze estimation and head pose prediction have shown that they have the potential to generalize to varying conditions by being able to utilize multiple correlated cues. In spite of these developments, the performance of gaze estimation is very sensitive to both external and individual variables. System accuracy is determined by the blinking, glasses or hair occlusion, inconsistent lighting and the difference in the anatomy among users.

Strong systems thus should include temporal modeling to deal with transient occurrences like eye blinks, multi-modal inputs to reduce occurrence of occlusions and adaptive calibration in consideration of inter-subject variability. To gain generalization to real-world settings, deep learning models that have been trained based on large-scale and diverse datasets are necessary. Smaller, manipulable datasets can be extremely useful in accuracy benchmarking and algorithm innovation validation, but they probably do not reflect the variability found in real-life situations. Gaze tracking systems based on webcams offer an easily accessible and inexpensive alternative to special infrared-based gaze tracking systems and can therefore be used in remote applications like e-learning, usability testing and mobile interfaces. Such systems, however, are usually more concerned with convenience and scalability at the cost of fine-grained accuracy, which requires more complicated modeling approaches to balance out noises, lighting variations, and free head rotations. Generalization strategies such as domain adaptation and contrastive learning are highly important in helping models trained in one setting or environment to be effective in unknown settings. In the future, the direction of research ought to be to create larger and more varied datasets encompassing a diverse set of lighting, pose, and subject variables, create models that are independent of illumination and occlusion, and create lightweight implementations that can be deployed on consumer devices in real-time. The combination of high-quality deep learning solutions with inexpensive and practical hardware will enhance the availability and usability of gaze and head pose estimation and open up new human-computer interaction solutions, as well as enabling real-world implementation of gaze and head pose estimation in fields of educational, medical, and interactive technology.
