ITEGAM - JETIA ISSN 2447-0228 Online
Journal of Engineering and Technology for Industrial Applications (JETIA)

O **ITEGAM-JETIA: Journal of Engineering and Technology for Industrial Applications** is a publication of the Galileo Institute of Technology and Education of the Amazon (ITEGAM), located in the city of Manaus since 2008. JETIA publishes original scientific articles covering all aspects of engineering. Our goal is the dissemination of research original, useful and relevant presenting new knowledge on theoretical or practical aspects of methodologies and methods used in engineering or leading to improvements in professional practice. All the conclusions presented in the articles It should be state-of-the-art and supported by current rigorous analysis and balanced assessment. Public magazine scientific and technological research articles, review articles and case studies.
JETIA will address topics from the following areas of knowledge: Mechanical Engineering, Civil Engineering, Materials and Mineralogy, Geosciences, Environment, Information and Decision Systems, Processes and Energy, Electrical and Automation, Mechatronics, Biotechnology and other Engineering related areas.

Publication Information:
ITEGAM-JETIA (ISSN 2447-0228), (online) is published by Galileo Institute of Technology and Education of the Amazon on a every two months (February, April, June, August, October and December).

Contact information:

SUMMARY

COMPACT SPIRAL TRANSFORMER DESIGN FOR HIGH-EFFICIENCY INTERLEAVED FLYBACK CONVERTERS IN SOLAR POWER SYSTEMS **01**
Benzidane Mohammed Ridha, Namoune Abdelhadi, Benbouzid Zineb, Benyamina Mansour, Meskine Said

DEVELOPMENT AND IMPLEMENTATION OF AN INDUSTRIAL IOT-BASED REAL-TIME PROCESS MONITORING SYSTEM TO IMPROVE OVERALL EQUIPMENT EFFECTIVENESS (O.E.E.) OF BEARING MANUFACTURING PROCESS **11**
Manan Bhavesh Raval, Hirenkumar Indravadan Joshi, Bharat Khatri, Janak Valakl

PERFORMANCE-DRIVEN OPTIMIZATION OF CMOS-BASED TWO-STAGE OPERATIONAL AMPLIFIER USING METAHEURISTIC ALGORITHMS **23**
Sureshbhai Laxmanbhai Bharvad, Pankajkumar Prajapati

NAVIGATING AGILE IMPLEMENTATION IN YEMENI SOFTWARE FIRMS CHALLENGES, BENEFITS, AND STRATEGIC INSIGHTS **32**
Ali Balaid, Hanan Baleid, Nasr Alsakkaf

EXPERIMENTAL VALIDATION OF VIBRO SEPARATOR AND ANOVA TECHNIQUE FOR AMPLITUDE **42**
Pavan Maheshchandra Bhatt, D.H. Pandya

OPTIMIZATION OF PROCESS PARAMETERS FOR HORIZONTAL VIBRO-SEPARATOR WITH DYNAMIC MOTION ANALYSIS **47**
Pavan Maheshchandra Bhatt, D.H. Pandya

ELECTROCHEMICAL POTENTIAL AND CHARACTERIZATION OF $NIFE_2O_4$/CU-1 AND $NIFE_2O_4$/CU-2 **53**
Naveen Chandra Joshi, Khundrakpam Somen Singh, B S Rawat

COMPARATIVE ANALYSIS OF IECC-QKD WITH SEVERAL ACCESS CONTROL AND SECURITY APPROACHES FOR SECURE AUTHENTICATION AND DATA SHARING IN CLOUD ENVIRONMENTS **64**
Akshay Agrawal, Rahul Thour

DEEP LEARNING APPLICATIONS IN AGRICULTURE AND RURAL DEVELOPMENT: TOWARD SMARTER, MORE SUSTAINABLE FOOD SYSTEMS **75**
Mohammed Mostefa Selt, Aymen Dia Eddine Berini, Said Boumaraf, Abelhalim Hadjadj, Ala-Eddine Benrazek

ANFIS-BASED MPPT STRATEGY FOR SOLAR WATER PUMPING SYSTEM **87**
Islam Hachemi, Kamel Haddouche, Ahmed Bouzidane, Mustapha Belarbi

DEVELOPMENT AND FIELD EVALUATION OF AN IOT-BASED SMART IRRIGATION SYSTEM FOR VEGETABLE PRODUCTION IN SEMI-ARID SENEGAL **98**
Pape El Hadji Abdoulaye Gueye, Diery Ngom, Cherif Bachir Deme

AUDITORY LIBRARY GUIDE: A DIGITAL SOLUTION FOR VISUALLY IMPAIRED READERS **108**
V. Thamilarasi

PROGRESSIVE BAT FOR NEURAL TUNING (PBNT): A BIO-INSPIRED HYPERPARAMETER OPTIMIZATION FRAMEWORK FOR SKIN LESION CLASSIFICATION **118**
Shunmuga Priya K., Selvi V.

ITEGAM - JETIA
ISSN 2447-0228 Online
Journal of Engineering and Technology for Industrial Applications (JETIA)

HFMSTMC: IMPROVED BINARY GREY WOLF OPTIMIZATION IN HYBRID FUZZY MINIMUM SPANNING TREE CLUSTERING WITH MANIFOLD LEARNING **131**
Dhanapriya L., S. Preetha

PERFORMANCE OPTIMIZATION OF EV MOTOR THROUGH NOVEL MODULATION TECHNIQUES IN SIC MULTILEVEL INVERTER **139**
K. S. R. Deepika, Shaik Abdul Ahad, R. Srinivasa Rao

IMPROVING DEPTH IMAGE QUALITY VIA SUPER-RESOLUTION AND ARTIFACTS REMOVAL: CNN-BASED APPROACH VS. TRADITIONAL METHODS **150**
Yagneshkumar Jayantilal Parmar, Paresh M. Dholakia

PERFORMANCE EVALUATION OF SOLAR PV-BATTERY HYBRID SYSTEM POWERED BLDC MOTOR SPEED CONTROL USING ULTRA-LIFT LUO-CONVERTER **160**
G Dilli Harsha, Vyza Usha Reddy

IOT-BASED REMOTE VITAL SIGNS MONITORING AND TEMPERATURE FORECASTING FOR PREGNANT WOMEN **173**
Bilal Mokhtari, Fairouz Graine, Abdelhak Merizig

DEVELOPMENT OF A REAL-TIME MONITORING AND CONTROL SYSTEM FOR AN INDUSTRIAL PLANT USING PLC AND SCADA TECHNOLOGIES **184**
Benarabi B., Achbi MS., Rouabah B., Boutalbi MC.

A SHORT REVIEW ON BATTERY THERMAL MANAGEMENT FOR EV APPLICATION **194**
B Musthafa, Bharath H, P.D. Jeyakumar, T.R. Tamilarasan, C. Dineshkumar, C.K. Arvinda Pandian, A. Gurusamy

MODELLING, VERIFICATION, AND OPTIMIZATION OF PROCESS PLAN GENERATION IN SUSTAINABLE RECONFIGURABLE MANUFACTURING SYSTEMS USING EVOLUTIONARY-GENERATED PETRI NETS **209**
Fareh mohamed elkabir, Laid Kahloul, Manel Femmam

LEVERAGING TUMOR INDUCED FREQUENCY SHIFTS BY A 24 GHZ MICROSTRIP ANTENNA WITH HIGH SENSITIVITY FOR BREAST CANCER DIAGNOSIS **224**
Yaqdhan Mahmood Hussein, Tabarek Alwan Tuib, Baydaai Hadi Saoudi, Thulfiqar H. Mandeel

SMART CLASSIFICATION OF SUBMERSIBLE PUMPS **235**
Mourad Abed, Ali Bedjaoui Bedjaoui, Abdelmoutia Telli

GROUNDEDNESS-AWARE RETRIEVAL IN GOVERNMENT DOCUMENT CHATBOTS: SYSTEMATIC LITERATURE REVIEW AND SEMANTIC ALIGNMENT SCORE (SAS) FORMULATION **242**
Frendy Rocky Rumambi, Didik Dwi Prasetya, Triyanna Widiyaningtyas

DEEP LEARNING-BASED DETECTION OF VERNACULAR HERITAGE HOUSES IN SUMBA ISLAND USING BSTO-VGG16-ALNN AND BIG DATA ANALYTICS **258**
Nandhini P

AN INTEGRATED RECOMMENDATION SYSTEM FOR CUSTOMISED E-LEARNING USING THE BERT MODEL **273**
Jatin Singh, Nirbhay Gautam, Amul Bharti, Priyanka Sharma, Vibha Gaur

LIFTING-BASED BLOCK FRACTIONAL WAVELET FILTER COMPRESSION OF HYPERSPECTRAL IMAGES OVER WIRELESS MULTIMEDIA SENSOR NETWORK PLATFORMS **284**
Purushottam Lal Nagar, Shrish Bajpai

ITEGAM - JETIA
ISSN 2447-0228 Online
Journal of Engineering and Technology for Industrial Applications (JETIA)

ARTIFICIAL INTELLIGENCE STRATEGIES IN ENHANCING CYBERSECURITY: AN ANALYSIS OF ADVANCED APPLICATIONS AND TECHNIQUES **296**
Ali Chasib Alhasnawy, Nibras Yousif Algburi, Tara Sabah Mehdi

ENHANCED DEEPFAKE IMAGE DETECTION VIA SWIN-B TRANSFORMER WITH VISUAL ATTENTION ANALYSIS **304**
Vineela Krishna Suri, Prasad GVSNRV

EFFECT OF CVD-COATED MULTILAYER CARBIDE INSERT ON SURFACE FINISH OF CRYOGENICALLY TREATED EN31 HARDENED ALLOY STEEL USING BOX-BEHNKEN DESIGN **315**
Shivaji Vithal Bhivsane, Arvind L Chel, Siraj Sayyed

EXPERIMENTAL INVESTIGATION OF ROTARY FRICTION WELDING OF AL2017A ALLOY REINFORCED WITH ALUMINA (AL_2O_3) PARTICLES **325**
Raouache elhadj, Ahlem Mechta, Aissa Laouissi

REAL-TIME PATH REROUTING AND OBSTACLE AWARE NAVIGATION IN AUTONOMOUS VEHICLES: A SIMULATION AND DATA ANALYSIS APPROACH **334**
Lakshmi Narayana I, TMN Vamsi

A DEVELOPMENT OF FUZZY-PID CONTROLLER APPLIED ON AN AUTONOMOUS SURFACE VEHICLE **342**
Thien M. Tran, Tien V. Tran

OPTIMIZATION OF ENERGY CONSUMPTION BY HVAC SYSTEM IN BUILDINGS USING DEEP LEARNING-BASED CONTROL STRATEGIES **356**
Rajalakshmi K, R. Thirumalai Selvi

INVESTIGATION OF FRACTURE BEHAVIOR IN MODE I AND II FOR REPAIRED EDGE-INCLINED CRACKS WITH TRAPEZOIDAL COMPOSITE PATCHES **367**
Toufik Achour, Cherrad Mohamed Lotfi, Chaour Mohamed, Boucherma Djamel, Boulkroune Sofiane, Hamadi Billel Billel

DIGITAL TWIN IMPLEMENTATION STRATEGIES FOR COMPLEX MANUFACTURING ECOSYSTEMS: A MULTI-LEVEL INTEGRATION FRAMEWORK **373**
Suchita B. Jadhav, Kirti A Patil, Kavita Tukaram Patil, Mokshda Nandkishor Kachave, Sharmila P Zope

IMPACT OF ROUGHNESS ON THE EMPTYING TIME OF A TANK: EXPERIMENTAL AND NUMERICAL ANALYSIS **381**
Belaid Larbi, Bessanane Nabil, Tebbi Fatima Zohra

EXPERIMENTAL VALIDATION OF A NOVEL DUAL-SLOT SIW BANDPASS FILTER FOR 5G KA-BAND APPLICATIONS **389**
Fatiha Louakhche, Ahcene Abed, Redha Bendoumia, Ahmed Bouchekhlal

AES-ENHANCED BLOCKCHAIN INTRUSION DETECTION SYSTEM FOR SECURE NETWORKS **399**
Hemanth Uppala, R. Renuga Devi

DEEP LEARNING APPROACH FOR OIL PALM LEAF DISEASE CLASSIFICATION USING VGG16 ENHANCED WITH ADAM OPTIMIZATION **411**
Hafiz Irsyad, Muhammad Rizky Pribadi, Indrajani Sutedja, Yulistia Yulistia

ITEGAM - JETIA
ISSN 2447-0228 Online
Journal of Engineering and Technology for Industrial Applications (JETIA)

COMPREHENSIVE ANALYSIS OF ENERGY AUDIT STRATEGIES FOR ENHANCING ENERGY EFFICIENCY IN HIGHER EDUCATIONAL INSTITUTES **419**
Seema V Vachhani, Dharmesh J. Pandya

QUALITY ENHANCEMENT TECHNIQUES FOR BREAST CARCINOMA IN EPITHELIAL TISSUE IDENTIFICATION PROCESS **424**
Bharathi K, A. S. Arunachalam

AUTOMATION OF THE FOOD DEEP-FREEZING PROCESS USING A PLC-CONTROLLED FREEZING TUNNEL. **434**
Washington Stalin Jácome Bastidas, Franklin Wilfrido Salazar Logroño, Byrón Paúl Huera Paltán, María Belén Paredes Regalado

SYSTEMATIC REVIEW OF COFFEE AND RICE ASH IN PHYSICAL-MECHANICAL PROPERTIES AND CONCRETE DURABILITY **442**
Michael Whitman Quiñones Mas, Socrates Pedro Muñ, Victor Manuel Valdiviezo Sir

A NOVEL TWINNET TRANSFORMER-BASED DEEP LEARNING MODEL FOR ACCURATE AND EFFICIENT PADDY LEAF DISEASE DIAGNOSIS USING EXPLAINABLE AI **453**
Daniel Raj K, Ponseka G, JeyaPreetaEmima J, Ananthakumari A, Karthi S, KumaraSundari V.

SMART AI-INTENSIVE SOFTWARE DEFECT PREDICTIONS BASED ON OPTIMIZED DEEP FEATURE CLASSIFICATION USING GWO-CODE2VEC CNN LEARNING **460**
Ruckmani V. S, Rajan John, J. Jebamalar Tamilselvi, Surya Susan Thomas

A YOLO-BASED AUTOMATIC BANGLADESHI VEHICLE LICENSE PLATE RECOGNITION SYSTEM **475**
Ashraful Islam, Naimul Amin, Ali Ahmmed, Nushrat Jahan Nishita

EXPERIMENTAL EVALUATION OF MULTI-SENSOR AI-BASED FAULT DIAGNOSIS FOR INDUCTION MOTORS IN INDUSTRIAL APPLICATIONS **487**
Saranya M, Archana N, Udhayakumar S

DEEP LEARNING APPROACHES FOR DETECTING AND CLASSIFYING TOMATO DISEASES: A COMPREHENSIVE OVERVIEW **498**
Youssef M Laatiri, Mohamed Ali Mahjoub, PROF

WELL-POSEDNESS IN M-ULTRADIFFERENTIABLE SPACES FOR WEAKLY HYPERBOLIC CAUCHY PROBLEMS WITH HÖLDER CONTINUOUS COEFFICIENTS **515**
Said Bouaziz, Khaled Benmeriem, Laid Gasmi

FIREFLY-BASED OPTIMIZED LINK STATE ROUTING PROTOCOL FOR ENERGY-EFFICIENT VEHICULAR AD HOC NETWORKS **526**
Mustafa Tareq, Saad Adnan Abed, Yasir Hadi Farhan, Boumedyen Shannaq, Said Almaqbali, Oualid Ali

CONSISTENCY VALIDATION OF TRANSFORMING UML STATECHART MODELS TO FLAT STATE MACHINE MODELS WITH USE APPROACH **538**
Ali lalouci

POWER QUALITY IMPROVEMENT THROUGH HARMONIC FILTERS USING TASMANIAN DEVIL OPTIMIZATION ALGORITHM **560**
Ashokkumar Parmar, Mehul Dansinh Solanki, Jaydeepsinh Sarvaiya, Divyesh Keraliya, Ashokkumar Lakum, Maqbul Ghanchi

ITEGAM - JETIA
ISSN 2447-0228 Online
Journal of Engineering and Technology for Industrial Applications (JETIA)

COST-EFFECTIVENESS AND EFFICIENCY OF PV PUMPING SYSTEMS UTILIZING ARTIFICIAL INTELLIGENCE ALGORITHMS **567**
Zoubir Chelli, Tarek Khoualdia, Skander Bouraghda

EVALUATION OF METHYLENE BLUE REMOVAL USING A FOOD-INDUSTRY BYPRODUCT VIA SIMULATION AND MODELING **575**
Salah Eddine Bencheikh, Mohamed Bilal Goudjil, Ladjel Segni

DESIGN OF A HYBRID ENSEMBLE FEATURE SELECTION FRAMEWORK FOR BIG DATA TEXT MINING **589**
Smah Smari, Barigou Fatiha, Belalem Ghalem

EXPERIMENTAL INVESTIGATION AND OPTIMIZATION ON ABRASIVE WATERJET DRILLING OF INCONEL -939 ALLOY **602**
Praveen Jayapalan, Rajesh Munusamy, Sandhya Jayakumar

EFFICIENT EXTRACTION OF PATTERNS AND INSIGHTS FROM LARGE-SCALE DATA FROM DISTRIBUTED SYSTEM USING DEEP LEARNING AND LSTM **610**
Syed Kousar Niasi K, K. Saravanakumar, Anand Viswanathan, K. Ravikumar

RED-TAILED HAWK (RTH) ALGORITHM FOR OPTIMAL PV RECONFIGURATION IN IRRIGATION SYSTEMS UNDER PARTIAL SHADING CONDITIONS **621**
Abdelouadoud Loukriz, Abderrahim Zemmit, Ahmed Bendib, Moadh Kichen

IMPROVEMENT IN BER PERFORMANCE OF GFDM-BASED 5G COMMUNICATION SYSTEM USING NEW HYBRID ERROR-CORRECTING CODE **635**
Divya Jain, Debendra Kumar Panda, Smita Prajapati

A PROPOSED MODEL FOR DESIGNING A METAMATERIAL UNIT CELL 9 - 14GHZ FREQUENCY BAND COMMUNICATIONS **643**
Jamal Mohammed Rasool, Ahmed Al Asadi, Ali Kahdum Abd, Omar Alnaseri

ABSTRACT

This paper explores the design, modeling, and optimization of a spiral transformer integrated into an interleaved flyback converter tailored for photovoltaic (PV) applications. The transformer features two square planar spiral coils with an outer diameter of 9000 µm and an inner diameter of 6000 µm, yielding primary and secondary inductances of 0.128 µH and 0.226 µH, respectively, at a 5 MHz operating frequency. The miniaturized design includes 3 primary turns and 4 secondary turns, with conductor widths of 500 µm and 300 µm, respectively. An electrical model accounts for parasitic effects, such as series resistances (0.195 Ω for primary, 0.282 Ω for secondary) and capacitances (inter-turn and oxide layer), which are minimized to boost efficiency. Frequency-dependent behavior is analyzed using MATLAB, identifying a resonance frequency of 20 MHz and a coupling coefficient of 0.87. The interleaved flyback converter, simulated in PSIM, delivers a stable 48 V output voltage and 3.2 A output current from a 162 W input, achieving 95% efficiency. This work validates the potential of compact, high-efficiency transformers for advancing PV energy conversion systems.

I. INTRODUCTION

Interleaved Flyback converters, incorporating miniaturized transformers, are versatile and find application in various sectors such as solar energy, wireless chargers, and electric vehicle equipment [1], [2]. Compact and efficient, they are favored for their suitability in environments where space and energy efficiency matter [3], [4]. The miniaturization of photovoltaic converters offers significant advantages: improved energy efficiency, reduced foot print, increased power density, and enhanced integration into complex systems [4], [5]. These advancements facilitate the accessibility and adaptability of solar energy for various applications [6], [7].

However, the miniaturization of flyback converters involves that of their transformers, there by requiring the reduction of coil dimensions [8], [9]. These coils necessitate sophisticated technological advancements, particularly in high-flux-density magnetic materials, to increase energy density and minimize losses [10], [11].Planar spiral coils are studied for their potential for miniaturization and electronic versatility. Research focuses on optimizing their design, materials, and manufacturing techniques to meet the requirements of compactness and integration into advanced systems [12], [13].

In this study, we present the geometric dimensioning of a transformer consisting of two square planar spiral coils. This transformer plays a crucial role within a flyback converter specifically designed for a photovoltaic system. Our main objective in this geometric design is to reduce the transformer size while minimizing energy losses. These efforts align with the specific requirements outlined in the flyback converter's specifications. The geometric dimensioning process is meticulously conducted, taking into account the converter's specifications. Our aim is to define the values of geometric parameters to subsequently calculate the technological parameters. This will ensure that parasitic effects are maintained at a negligible level, thereby ensuring optimal efficiency of the transformer.

In addition to the geometric sizing step, we undertake an in-depth study of the impact of frequency on various transformer parameters, namely, the inductances of the primary and secondary coils, their series resistances, as well as the quality factors and the coupling coefficient. This study will determine the sensitivity of the transformer at different frequencies. To validate our approach, we will conduct comprehensive simulations of the voltages and currents involved in the converter's operation. These simulations will confirm the proper functioning of the transformer integrated into the flyback converter, there by guaranteeing its efficiency and overall performances.

II. PRESENTATION OF INTERLEAVED FLYBACK CONVERTER

The interleaved flyback converter is used in the photovoltaic system in order to reduce the input current and increase the output power, as it includes two equal flyback converters connected in parallel and each of them includes the following components: the transformer, power electronic switch and diode, but they share the source *Vin* and capacitance *Cout* as shown in Figure 1. When operated, the phase between the two switches is set at 180 degrees.

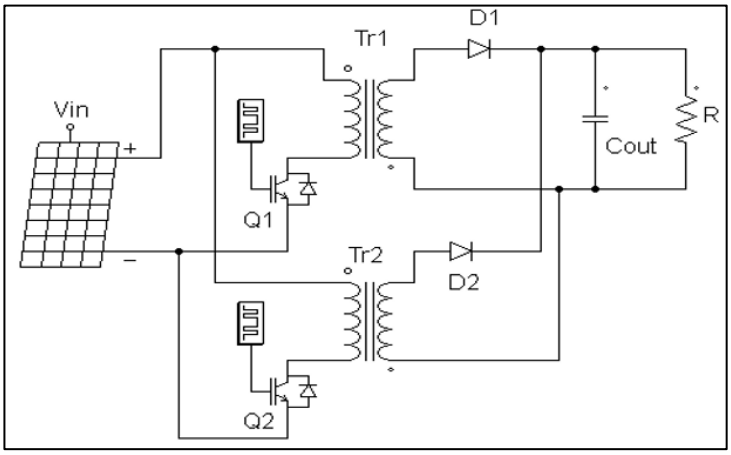

Figure 1: Schematic of an interleaved flyback converter.
Source: Authors, (2026).

To evaluate this type of DC/DC converter in a micro solar system, the spiral transformer will be studied when integrated into an interleaved flyback converter enhanced with the following specification: Input voltage, Vin = 24 [V]. Input power, Pin = 162 [W]. Output voltage, Vout = 48 [V]. Energy efficiency, η = 95%. Operating frequency, f = 5 [MHz], α = 0,6. Since the two micro transformers are equal, the primary inductances Lp of the micro transformers are calculated by the relation (1):

$$L_p = \frac{V_{in}^2 * \alpha^2}{2P_{in} * f} = 0{,}128\ [\mu H] \tag{1}$$

The turns ratio for the micro transformers (m) is calculated by the equation (2).

$$m = \frac{V_{out}}{V_{in}} * \frac{(1-\alpha)}{\alpha} = 1{,}33 \tag{2}$$

Using equation (3) the secondary inductances Ls of the micro transformers are calculated.

$$L_s = m^2 * L_p = 0{,}2264\ [\mu H] \tag{3}$$

The load resistance is calculated according to equation (4):

$$R = \frac{V_{out}^2}{P_{in} * \eta} = 14{,}97\ [\Omega] \tag{4}$$

The output voltage ripple ΔVout/Vout is estimated at 1%. By means of relation (5), the value of the output capacitor Cout is extracted:

$$C_{out} = \frac{\alpha}{\left(\frac{\Delta V_{out}}{V_{out}}\right) * R * f} = 0{,}8016\ [\mu F] \tag{5}$$

III. DIMENSIONING OF THE SQUARE COILS SPIRAL TRANSFORMER

Geometrically, the spiral transformer with square shape of windings is described by the parameters shown in Figure 2 as follows: do and di are the outer and inner diameter, tp and ts are the thickness of primary and secondary coils, Np and Ns are the number turns of primary and secondary coils, Wp, Sp, Ws and Ss are the width and spacing of adjacent turns of primary and secondary coils.

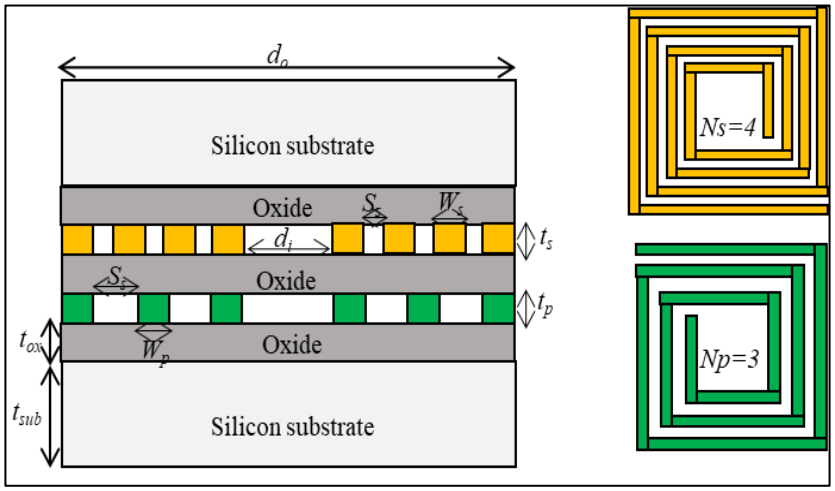

Figure 2: Geometric parameters of micro transformer spiral coils.
Source: Authors, (2026).

From the literature publications, there are several methods to calculate the inductance value. By choosing Wheeler method, the primary and secondary inductances of the transformer are expressed in the relations (6) and (7) [14], [15].

$$L_p = \frac{k_1 * \mu_0 * \left(\frac{d_o + d_i}{2}\right) * N_p^2}{1 + k_2 * \left(\frac{d_o - d_i}{d_o + d_i}\right)} \tag{6}$$

$$L_s = \frac{k_1 * \mu_0 * \left(\frac{d_o + d_i}{2}\right) * N_s^2}{1 + k_2 * \left(\frac{d_o - d_i}{d_o + d_i}\right)} \tag{7}$$

The coefficients k_1 and k_2 depend on geometrical structure of two coils. For the square geometry: $k_1 = 2.34$, $k_2 = 2.75$. To calculate all the geometrical parameters, we set the outer and inner diameters of the primary and secondary windings, respectively: $do = 9000$ [µm], $di = 6000$ [µm]. Based on relations (6) and (7), we extract the number of primary and secondary turns of the transformer as follows: $Np = 3$, $Ns = 4$. To determine the conductor thickness for each of the two inductors, the following condition must be met: $t_p = t_s \leq 2\delta$. Where δ is the skin thickness and is expressed as (8) [16]:

$$\delta = \sqrt{\frac{\rho_{Cu}}{\pi * \mu * f}} = 29{,}36\ [\mu m] \tag{8}$$

The width of individual winding W of both the primary and secondary windings of the transformer are calculated using relations (9) and (10) [17]. Where, the constant pitch P is the sum of the width of single turn and the distance between it and the next turn. We have chosen pitch values P for the primary and secondary coils respectively: $P_p = 600$ [µm], $P_s = 400$ [µm]

$$W_p = \frac{d_o - d_i - 2(N_p - 1) * P_p}{2} = 300\ [\mu m] \tag{9}$$

$$W_s = \left(\frac{d_o - d_i}{2}\right) - (N_s - 1) * P_s = 300\ [\mu m] \tag{10}$$

Also to calculate the distance S between adjacent coils of the two inductors of transformer, the relations (11) and (12) are used:

$$S_p = P_p - W_p = 300\ [\mu m] \tag{11}$$

$$S_s = P_s - W_s = 100\ [\mu m] \tag{12}$$

The expression used to calculate the conductor length of the primary and secondary windings of a transformer is given by (13) and (14) [18]:

$$l_p = 2 * N_p * \left[2 * d_i + \left(4 * N_p - 1\right) * W_p\right] = 86{,}4\ [mm] \tag{13}$$

$$l_s = 2 * N_s * [2 * d_i + (4 * N_s - 1) * W_s] = 124{,}8\ [mm] \tag{14}$$

All geometric dimension values of the tapered spiral transformer obtained after calculation are summarized in Table 1.

Table 1: Geometric dimension values of the tapered spiral transformer.

Geometric parameters	Primary coil		Secondary coil	
	Symbol	Values [µm]	Symbol	Values [µm]
Outer diameter	*do*	9000	*do*	9000
Inner diameter	*di*	6000	*di*	6000
Number of turns	*Np*	3	*Ns*	4
Width of conductor	*Wp*	300	*Ws*	300
Thickness of conductor	*tp*	58	*ts*	58
Spacing between turns	*Sp*	300	*Ss*	100
Length of conductor	*lp*	86400	*ls*	124800

IV. ELECTRICAL PARAMETER OF THE SQUARE COILS SPIRAL TRANSFORMER

Based on the physical model of Yue and Yong [19], the equivalent electrical circuit of a square coils spiral transformer is derived which shows all the parasitic effects when integrated into silicon. At high frequencies, the inductor is represented by three passives components where the series inductance *Ls* is related to the series resistance *Rs* and both are related to the capacitance series *Cs* of the inductor in parallel. Losses in the dielectric layer are represented by parasitic capacitance *Cox*. Substrate losses are represented by resistance and capacitance in silicon *Rsub, Csub*. *Cc* is the coupling capacitance between the primary and secondary windings of the transformer. According to the integrated spiral transformer in Figure 3, the expressions analytical for all electrical parameters of the equivalent circuit model are also given below [20], [21]:

$$C_c = \frac{d_o^2 * \varepsilon_{ox}}{t_{ox}} \tag{15}$$

$$R_{s-p} = \frac{\rho * l_p}{\delta\left(1-e^{-\left(\frac{t_p}{\delta}\right)}\right) * W_p} \quad , \quad R_{s-s} = \frac{\rho * l_s}{\delta\left(1-e^{-\left(\frac{t_s}{\delta}\right)}\right) * W_s} \tag{16}$$

$$C_{s-p} = \frac{t_p * l_p * \varepsilon_{ox}}{2 * S_p} \quad , \quad C_{s-s} = \frac{t_s * l_s * \varepsilon_{ox}}{2 * S_s} \tag{17}$$

$$C_{ox-p} = \frac{\varepsilon_{ox} * l_p * W_p}{2 t_{ox}} \quad , \quad C_{ox-s} = \frac{\varepsilon_{ox} * l_s * W_s}{2 t_{ox}} \tag{18}$$

$$C_{sub-p} = \frac{\varepsilon_{sub} * l_p * W_p}{2 t_{sub}} \quad , \quad C_{sub-s} = \frac{\varepsilon_{sub} * l_s * W_s}{2 t_{sub}} \tag{19}$$

$$R_{sub-p} = \frac{2 * \rho_{sub} * t_{sub}}{l_p * W_p} \quad , \quad R_{sub-p} = \frac{2 * \rho_{sub} * t_{sub}}{l_s * W_s} \tag{20}$$

Where, ρ_{cu}, ρ_{sub}: resistivity of conductor and substrate (ρ_{cu}=1,72 10^{-8} [Ωm], ρ_{sub} = 18,5 [Ωm]), t_{sub}, t_{ox}: thickness of substrate and SiO2 insulator (t_{sub} = 600 [µm], t_{ox} = 100 [µm]) , ε_{ox}, ε_{sub}: permittivity of SiO2 insulator and substrate ($\varepsilon_{r,ox}$ = 3,9 , $\varepsilon_{0,ox}$ = 8,85 10^{-12}[Fm^{-1}], ε_{sub} = 11,8).

IV.1 INTERPRETATION OF RESULTS

The objective of this study is to reduce energy losses within the transformer by addressing capacitive and resistive effects introducing parasitic currents. The calculated values of technological parameters, which are closely tied to geometric parameters, align seamlessly with the desired objectives. We notice that, they obtained results show particularly low values for the series resistances (*Rs-p* and *Rs-s*) of the primary and secondary coils. It is the same for the values of the inter-turn capacitances (*Cs-p* and *Cs-s*) and the capacitances (*Cox-p* and *Cox-s*) from the oxide layer. On the other hand, the substrate resistances (*Rsub-p* and *Rsub-s*) have high values, thus preventing the circulation of the low parasitic currents induced by the capacitive effect in the substrate. Figure 4 shows a simplified model of a micro transformer including two inductors, where the primary inductance and resistance are denoted by *Lp* and *Rp*, while the secondary inductance and resistance are denoted by *Ls* and *Rs*, as well as the coupling coefficient *k* and quality factors for the primary and secondary windings *Qp* and *Qs*.

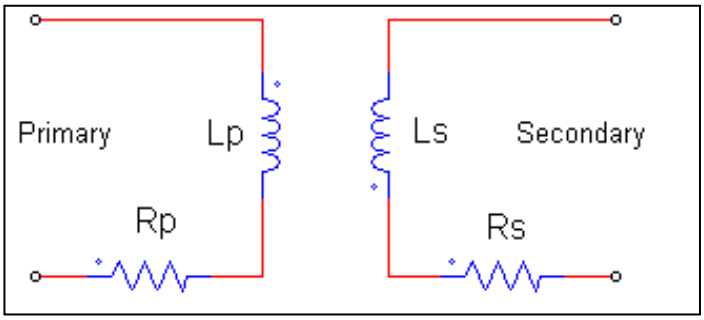

Figure 4: Simplified micro transformer model.
Source: Authors, (2026).

These elements, which represent the transformer specifications, are extracted from the Z-parameters, which are expressed as follows [22], [23]:

$$L_p = \frac{Im(Z_{11})}{2\pi f} \tag{21}$$

$$L_s = \frac{Im(Z_{22})}{2\pi f} \tag{22}$$

$$R_p = Re(Z_{11}) \tag{23}$$

$$R_s = Re(Z_{22}) \tag{24}$$

$$Q_p = \frac{Im(Z_{11})}{Re(Z_{11})} \tag{25}$$

$$Q_s = \frac{Im(Z_{22})}{Re(Z_{22})} \tag{26}$$

$$k = \sqrt{\frac{Im(Z_{12}) * Im(Z_{21})}{Im(Z_{11}) * Im(Z_{22})}} \quad 27)$$

V. SIMULATION AND RESULTANTS

V.1 INFLUENCE OF FREQUENCY ON THE INDUCTANCES OF THE PRIMARY AND SECONDARY

Based on relations (21) and (22) that were extracted from the imaginary part of the impedances, the variations of the primary and secondary inductances as a function of frequency were shown as shown in Figure 5. This figure gives a noticeable contrast between the primary and secondary inductors, which go through two stages: before the resonance frequency from 1 to 23 [MHz], the two inductors behave inductively, where the inductance values at a frequency of 5 MHz are 0,128 [µH] for the primary coil and 0,226 [µH] for the secondary coil, and with increasing frequency the inductances reach values climax at 20 [MHz]. But after the resonant frequency they behave capacitive.

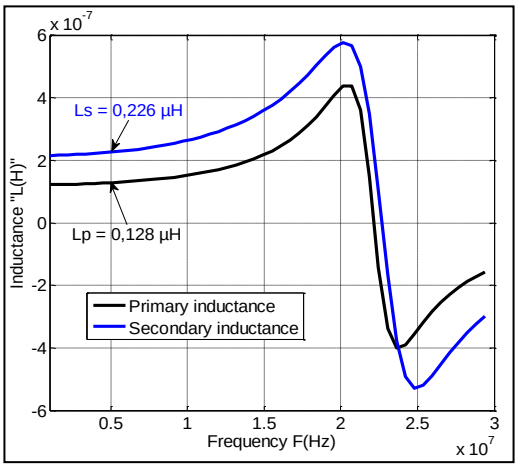

Figure 5: Variation of the primary and secondary inductances as a function of frequency.
Source: Authors, (2026).

V.2 INFLUENCE OF FREQUENCY ON THE SERIES RESISTANCES OF THE PRIMARY AND SECONDARY

Figure 6 depicts variation the series resistances of primary and secondary inductors as function of frequency, which was extracted from the real parts of the impedances according to two relations (23) and (24). At 5 [MHz], the resistances of the primary and secondary windings give low values of 0,195 [Ω] and 0,282 [Ω], respectively, due to the losses resulting from very low Joule effects. As the frequency increases, the series resistances of both windings begin to increase until they reach a peak at a frequency of 20 [MHz], which is known as resonance.

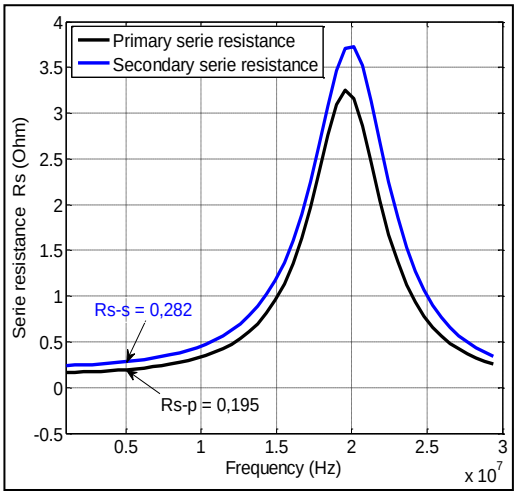

Figure 6: Variation of the primary and secondary series resistances as a function of frequency.
Source: Authors, (2026).

V.3 INFLUENCE OF FREQUENCY ON THE QUALITY FACTOR OF PRIMARY AND SECONDARY INDUCTANCES

Figure 7 shows the effect of frequency on variations in the quality factors of the primary and secondary inductors, which were previously expressed by relations (25) and (26) extracted from the real and imaginary parts of the impedances. In the first stage, it was observed that as the frequency increased, the quality factors increased until they reached the maximum values corresponding to the frequency of 13 [MHz], where the maximum value for the primary inductor is 25 and 20 for the secondary inductor. In the second stage, the quality factors decrease with increasing frequency until they reach zero, which is known as the resonant frequency point.

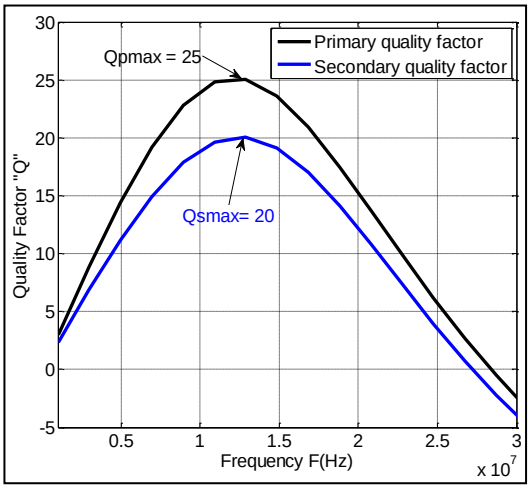

Figure 7: Variation of the primary and secondary quality factor as a function of frequency.
Source: Authors, (2026).

V.4 INFLUENCE OF FREQUENCY ON THE COUPLING COEFFICIENT

The curve shown in Figure 8 gives the evolution of the coupling coefficient between the two windings of the transformer as a function of frequency, which was previously expressed by relation (27) deduced from the imaginary parts of the impedances. We can notice that the coupling coefficient increases significantly at low frequencies, but after a frequency of 10 [MHz] this increase is very small until it reaches approximately 87 %.

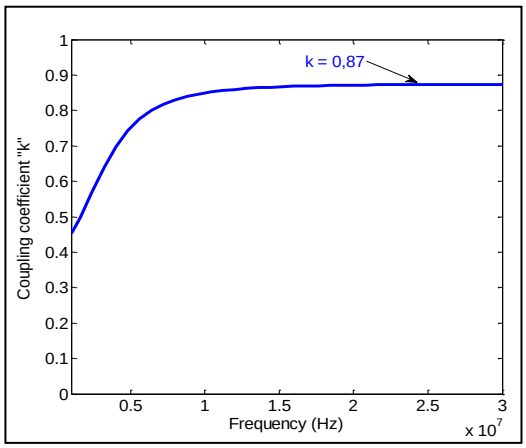

Figure 8: Evolution the coupling coefficient as a function of frequency.
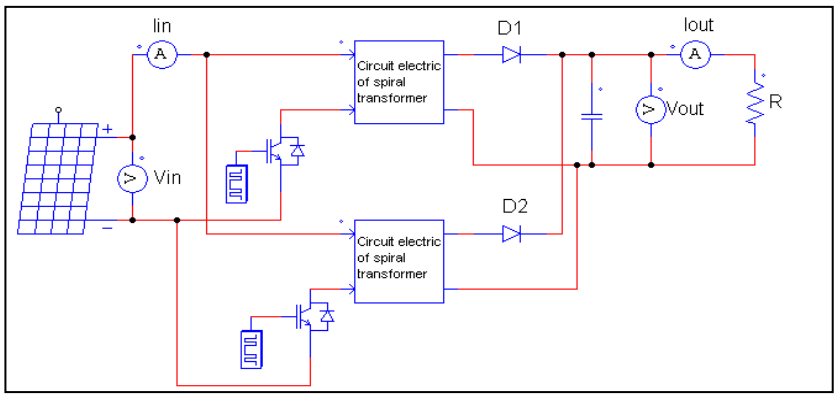
Source: Authors, (2026).

V.5 SIMULATION OF INTERLEAVED FLYBACK CONVERTER WITH INTEGRATED SPIRAL TRANSFORMER IN PHOTOVOLTAIC SYSTEM

In this section, we simulate the operation of the photovoltaic system of interleaved flyback converter containing two spiral transformers using the PSIM program. This simulation aims to see the voltage and current graphs at the output of a DC/DC converter. Figure 9 shows a comprehensive diagram of the PV system at PSIM consisting of a solar panel, interleaved flyback converter with a integrated spiral transformers and the required load.



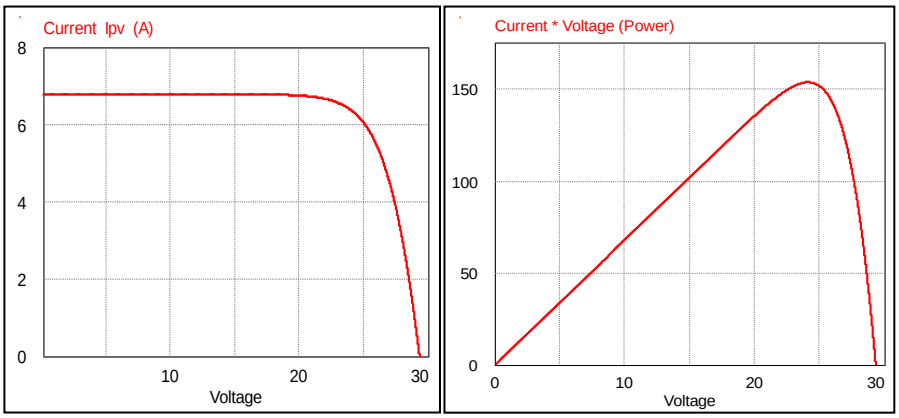


Figure 9: photovoltaic system consisting of interleaved flyback converter with integrated two spiral transformers.
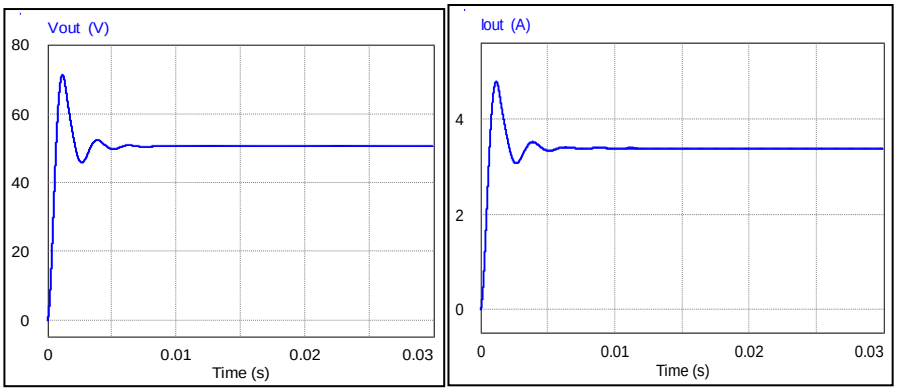
Source: Authors, (2026).



Figures 10 show the current and power to voltage characteristics of the photovoltaic module with standard parameters (S = 1000 [W/m^2]. T = 25 [°C]). The maximum photovoltaic current reaches 6.75 [A] and the maximum power is about 153 [W] for a voltage of 24 [V].

(a) **(b)**

Figure 10: Characteristics of the module photovoltaic, (a)current–voltage, (b) Power-voltage.
Source: Authors, (2026).

Figure 11 (a) show the output voltage form of interleaved flyback converter with integrating two spiral transformers stabilized at value 48 [V] starting from moment 6 [ms]. The value of the output current is about 3.2 [A] as shown in figure 11 (b), which indicates a stable and continuous transfer of power to the load.

(a) **(b)**

Figure 11: (a) Output voltage and (b) Output current form of interleaved flyback converter with two spiral transformers integrated.
Source: Authors, (2026).

Since the interleaved flyback converter consists of two identical transformers connected in parallel and operating in alternating mode, simulation results for one of these transformers give the voltage and current for the primary and secondary windings, as shown in Figure 12.

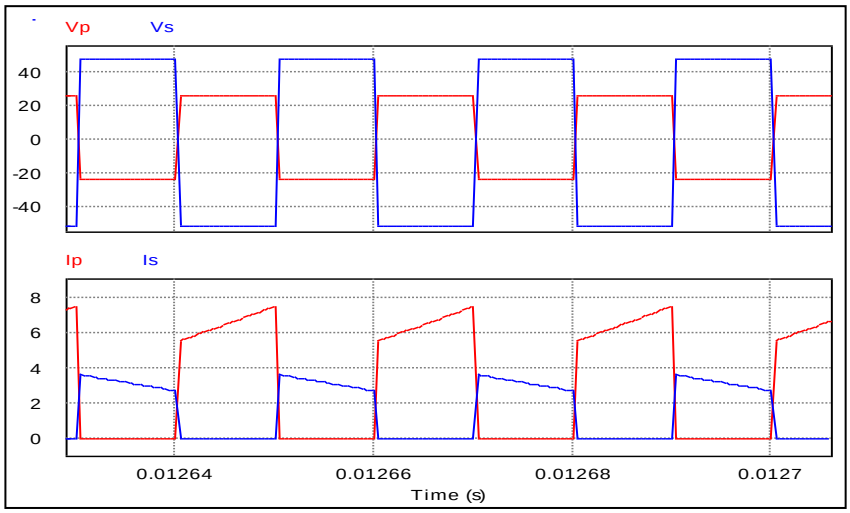


Figure 12: Voltage and current of the primary and secondary windings of the transformer integrated into the interleaved flyback converter.

VI. CONCLUSION

In the context of this study, we investigated the possibility of incorporating two spiral transformers within an interleaved Flyback converter specifically designed for photovoltaic applications. Our main goal is to reduce the dimensions of converters, fundamental components in photovoltaic systems, where the footprint in terms of size and weight poses a significant challenge. Reducing the dimensions of an interleaved Flyback converter necessarily involves decreasing the size of its transformers. In this regard, our work primarily focused on the miniaturization of coils. Initially, adhering rigorously to the converter specifications, we calculated crucial values of transformer parameters, including primary and secondary inductances, as well as the transformation ratio.

These parameters served as the basis for calculating all geometric parameters of primary and secondary coils (inner and outer diameters, conductor dimensions, number of turns, and inter-turn distance). The geometric sizing results were within integration standards. However, this step proved insufficient to ensure the proper functioning of the two transformers. So, it was imperative to precisely calculate the values of electrical parameters, responsible for various parasitic effects, to guarantee optimal operation. The obtained results reveal particularly low values for the series resistances (*Rs-p* and *Rs-s*) of the primary and secondary coils, as well as for inter-turn capacitances (*Cs-p* and *Cs-s*) and capacitances (*Cox-p* and *Cox-s*) resulting from the oxide layer.

On the other hand, substrate resistances (*Rsub-p* and *Rsub-s*) exhibit high values, providing significant resistance to the low parasitic current induced by capacitive effects in the substrate. Using the simplified electrical model of the transformer and the Z matrix, we expressed in detail the essential components of the transformer as a function of frequency. This approach allowed us to analyze the variation curves of primary and secondary inductances, *Ls* and *Lp*, with respect to frequency, as well as that of the series resistances, the quality factor *Q*, and the transformation ratio *k*. The results revealed a resonance frequency of 20 MHz, wich is quite high compared to the operating frequency (5 MHz).

However, at the operating frequency, the values of inductances and resistances indicated by the curves perfectly matched those obtained by calculation. The curves also highlighted satisfactory quality factors and a coupling coefficient of 0.87. Simulation results of the voltage and output current of the Flyback converter, incorporating the two dimensioned spiral transformers, were in accordance with the converter specifications. These results attest to the proper functioning of our converter. In conclusion, it is plausible to assert that the miniaturization of equipment in photovoltaic systems is entirely feasible.

Real-time Monitoring

ABSTRACT

The research study presents the design and implementation of an IoT-based real-time monitoring system to enhance Overall Equipment Effectiveness (O.E.E) of External grinding process used in precision bearing manufacturing. The developed system continuously monitors critical parameters such as cutting temperature, machine vibration, noise and cycle time using calibrated sensors. These critical parameters are directly linked to Key Performance Indicators (KPIs) of O.E.E in terms of Availability, Quality and Performance. A systematic layered IoT architecture is developed to enable real-time data acquisition, cloud storage, visualization and alert generation through a customized web application. Controlled experiments were conducted on various batches of bearing races under fixed machining conditions with critical parameter thresholds defined based on ISO standards and historical production data. The system successfully identified deviations, enabling timely corrective actions and reducing unexpected breakdowns. The real-time dashboard and alert system provided actionable insights, improving operational decision-making and minimizing manual documentation. As a result, OEE improved from 86% to 94.70%, demonstrating an 8.70% increase. Additionally, reductions in breakdowns, defects, and downtime were observed. This study confirms that integrating IoT in manufacturing significantly enhances equipment performance and product quality through data-driven process control.

I. INTRODUCTION

Grinding is a abrasive machining process used to remove small amount of material from workpiece, there are two types of grinding process, precision and rough. In Bearing manufacturing precision grinding process is required to achieve markable surface finish in bearing parts as bearings are used in aerospace, automobiles, agriculture machineries, railways and rotary machines like turbine, pump and electric motors.The external grinding process is essential to produce bearing parts and carried out in external grinding machine. To achieve process efficiency and production proficiency, the monitoring of pre-decided optimum process parameters and machining conditions plays important role to achieve quality of bearing parts as well as productivity of external grinding process. In this research study the industrial IoT (Internet of things) web-based monitoring system has been developed to monitor the various production parameters. The process parameters are linked with concern factors of Overall Equipment Effectiveness (O.E.E.) i.e indicates correlation between Process parameters with quality of bearing part, Performance of system and Availability of machine.

The designed IOT based grinding system, sensors collects the data for all three O.E.E elements automatically and the data is visualized using IOT applications. O.E.E is a standard metric which represents the overall production capability, consistency, proficiency, and achievements after completion of manufacturing process. O.E.E represents the various factors i.e Quality, Availability and Performance which effectively evaluates the achievement of manufacturing system. O.E.E indicates in terms of percentage, As per world-class standard the O.E.E should be 85 % [1],less than 85 % OEE represents production inefficiencies. OEE is calculated by multiplying the three OEE factors so the equation will be OEE = Availability × Performance × Quality [2]. In which Availability is the ration of Run Time to Planned Production Time, Performance is calculated by (Ideal Cycle Time x Total Parts Produced)/Actual Operating Time and Quality is found by dividing Good parts count to Total parts count. The focus has been given to achieve maximum OEE by monitoring of critical parameters using IOT web-based system. The designed IOT system is multi-purpose, which can be used for condition monitoring, predictive maintenance, and In-process measurement. The Key Performance Indicators (KPIs) are identified for external grinding process by brainstorming, past production data, various quality, and productivity tools. The major quality measures of bearing parts are surface finish, dimensional accuracy, visual appearance and ovality.

It has been found from observation and past quality data taken from the bearing manufacturing industry that major defects among all defects are size variation and Surface finish, including surface scratches. The significant process parameters affecting parts' surface finish are cutting temperature [3], [4], machine vibration [3], [5], [6], [7], feed and cutting speed. Here, the most affected critical parameters, cutting temperature and machine vibrations are monitored during the entire external grinding process. The performance is a measure of how promptly the machine produces a part as compared to ideal machining time. The identified key performance indicators to monitor performance with an IoT-based system are grinding process time and inspection time. The key performance indicators of availability are machine uptime, machine downtime duration, mean time between failures, setup and changeover time, and number of unplanned downtimes. The machine's actual operating time is continuously monitored in the proposed IOT based system. In an external grinding machine, trail runs and experiments have been performed with IOT web-based monitoring system to improve and measure the O.E.E factors related with bearing manufacturing.Before performing trail runs and experimentation the past one year O.E.E of External grinding machine is calculated and it is 86 %.

II. LITERATURE STUDY

Using advanced technologies to constantly monitor equipment efficiency in the digitalization era, research suggests a digitalized, real-time OEE calculating system. Focusing on availability, performance, and quality measurements helps the system to improve organizational performance by automating manual processes and allowing real-time decision-making [2]. By allowing real-time data collecting and analysis via linked sensors, the IoT is absolutely essential in grinding process monitoring. By means of instantaneous feedback on machine performance, a real-time monitoring system improves production efficiency and enables timely adjustments to avoid failures. Improved product quality and less resource waste resulting from this integration help to maximize the grinding operation in manufacturing plants [7]. To continuously monitor the efficiency of manufacturing equipment, research presents a digital, real-time OEE calculation system that makes use of cloud computing, IoT sensors, and data analytics. The system lowers downtime through predictive maintenance, improves operational decision-making, and optimizes availability, performance, and quality metrics in industrial settings to improve product quality. It does this by automating manual data collection and enabling instant insights.[8]. Through real-time asset monitoring and data-driven insights, research conducted predictive maintenance (PdM) using IoT technology and Six Sigma Define, Measure, Analyse, Improve and Control (DMAIC) methodology, achieving a 95:5 Predictive Maintenance to Corrective Maintenance (PM-to-CM) ratio (from 84:16) and so reduced maintenance costs by 25–30%.

Also eliminated 70–75% of breakdowns, so reducing downtime by 35–45% and so increasing production by 20–25%. The research mostly relies on IoT technology since it allows real-time and continuous data collecting through linked sensors and devices, so improving the accuracy and precision of the observations. In industrial and research environments, it automates data collecting, lowers manual intervention, and lets remote monitoring and predictive analytics possible, so improving operational efficiency, timely decision-making, and best use of resources [9]. In research article examining the development of Overall Equipment Effectiveness (OEE) as a key manufacturing KPI, this systematic literature review highlights growing academic interest, model changes, and new applications in logistics and services, so highlighting rising industrial KPI relevance. It underlines the importance of IoT integration since it improves operational efficiency, predictive maintenance, and real-time monitoring, so providing a strong basis for next studies and intelligent industrial machine control [10]. By allowing early fault discovery and predictive maintenance, the cost-effective IoT system for real-time temperature and humidity monitoring presented in this paper increases Overall Equipment Effectiveness (OEE). Combining edge computing, the system alerts and offers actionable insights by streaming data to a real-time OEE dashboard. This dashboard promotes smart manufacturing operations, enhances equipment availability and performance, and speeds decision-making for ongoing OEE improvement.

For immediate understanding of shop floor operations, shows real-time OEE scores including availability, performance, and quality criteria [11]. The research investigates how real-time monitoring and diagnosis made possible by IoT technologies might improve manufacturing Continuous Improvement (CI). It presents the Automatic Detailed Diagnosis (ADD) system, which tracks operator activity and equipment condition using low-power sensors, so increasing efficiency and lowering waste. In Lean Manufacturing systems, this integration of IoT supports improved problem-solving and decision-making.[12]. The researchers have found that real-time monitoring and data collecting made possible by the Internet of Things (IoT), manufacturing sector productivity is much improved. Condition monitoring, process optimization, and waste reduction made possible by this technology enable in the contactor manufacturing sector, for example, IoT deployment enhanced workplace productivity and safety as well as timely decision-making and knowledge-sharing among team members, so enabling cost savings and quality improvements [13]. Emphasizing the use of Kistler tri-axial accelerometers for vibration sensing in hostile environments, this work addresses the implementation of IoT-based monitoring for lathe machine performance. It describes local recording and cloud transmission as well as the significance of accelerometer data analysis of tool lifetime. Integration of cloud services like GE Predix improves analytics and data management capacities [14].

Track manufacturing efficiency, use real-time data to evaluate performance, quality, and availability, and the OEE monitoring system is absolutely vital. An OEE dashboard lets one quickly make decisions and adjust operations by offering graphic insights into these numbers. The dashboard KPIs allow one to keep a real eye on the current production status. IoT improves this system by means of data collecting from many machines, so promoting flexibility and production quality enhancement. Using IoT helps companies to reach operational excellence by means of ongoing process optimization and monitoring, so enhancing OEE results [15].

III. METHODOLOGY AND DESIGN OF IOT ARCHITECTURE

III.1 SENSORS AND DATA ACQUISITION

The selection of suitable sensors is essential for a cyber-physical system. The sensor should be highly accurate, and the appropriate data collection and data transmission are the most necessary things for any IoT-based system. The calibrated and accurate sensors were chosen for this research work.

Table 1: Details of selected sensors

Sr.No	Monitoring Parameter	Required sensor
1.	Cutting Temperature	Infrared Thermometer
2.	Machine work head, wheel head and bed Vibration	3-Axis Digital Accelerometer unit
3.	Machine Noise	Noise Sensor
4.	Bearing Part Detection	Proximity sensor

Source: Authors, (2026).

III.2 DETAILED NETWORK ARCHITECTURE, DATA STORAGE AND PROCESSING

There are four primary layers designed to establish IOT web-based monitoring system, first layer is Machine with sensors in which the sensors are attached in External Grinding machine to monitor machine conditions and process parameters, Second layer is perception layer in this Controller is designed to receive the data from sensors and takes appropriate actions if any abnormality generates. Third layer deals with network, in this layer, the data is stored in the cloud with using wifi module. The last one is application layer, in this, the O.E.E dashboard is designed and the production data can be visualized, analyzed, and monitored.

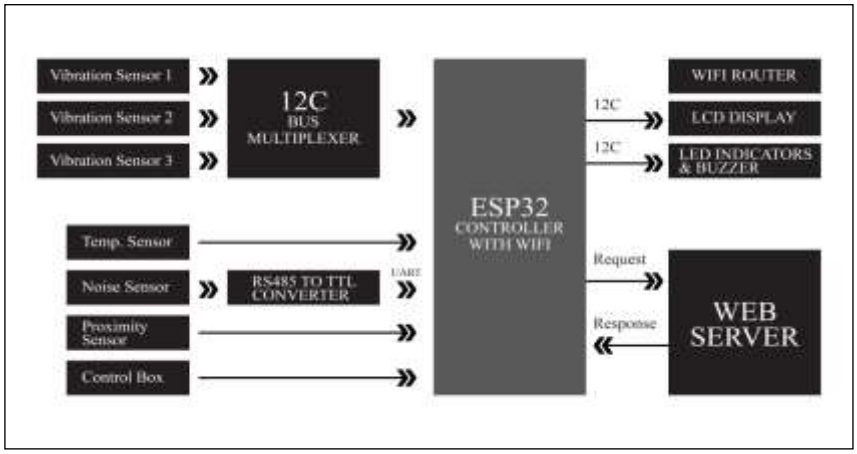

Figure 1: Basic Architecture and Hardware Interconnections.
Source: Authors, (2026).

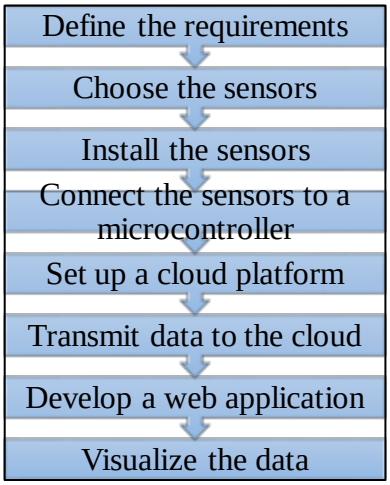

Figure 2: Steps to establish the setup of IOT web based monitoring system in the External Grinding machine.
Source: Authors, (2026).

III.3 INTEGRATION WITH EXTERNAL GRINDING PROCESS

The attached sensors detect and measure the physical quantity, convert these values into an electric signal and transmit the data to the controller and the controller takes the decision about further required actions, if any abnormality is detected in machine conditions and process parameters. It is a close loop system in which feed is given to system about predefined process values. The data is transmitted through a Wi-Fi router and stored in the cloud. The data can be visualized using IOT applications.

IV SYSTEM IMPLEMENTATION

IV.1 HARDWARE SETUP

The hardware elements, electronic components, control unit, wifi router, switches are interconnected and sensors have attached with machines to monitor process paramatrs and machine condition. Inter integrated circuit, Uart (Universal Asynchronous Receiver/Transmitter) and RS485 protocols are used for data communication between sensors and devices. The system is developed as if any abnormality is detected in machine or process parameters the notification will be sent to IOT web application for further improvements.

IV.2 EXPERIMENTAL SETUP AND TRAIL RUNS

The experimental setup has been developed by attaching sensors in machine to monitor external grinding process. The Control box, which contains a controller with voltage converters,I2C (Inter-Integrated Circuit) multiplier, RS485 signal to TTL (Transistor-Transistor Logic) converter, LCD, an active buzzer, Red and blue LED lights and a button Panel connector. Trail runs are conducted to check the response time, functionality testing, integration verification, usability, performance assessment, reliability, and stability of the developed IoT-based monitoring system. During trial runs, the problems faced related to incorrect sensor readings due to improper attachment with the machine, also corrected software bugs and compatibility problems related to IoT platforms, were not integrated smoothly with the machine tool. The experiments are performed after successful trial runs, Experiments are performed in various batches with groups of bearing races. Each batch contains total 38 bearing races. Experiments have been performed for two days with a total of five batches of 38 components. The method of experimentation is control experiments; it's a scientific test in which all machining conditions and process parameters remain constant except for the variables being tested. The hypothesis is a prediction of experimental outcome and an assumption about the relationship between variables. The fig 6. explains the step-by-step procedure of controlled experiments.

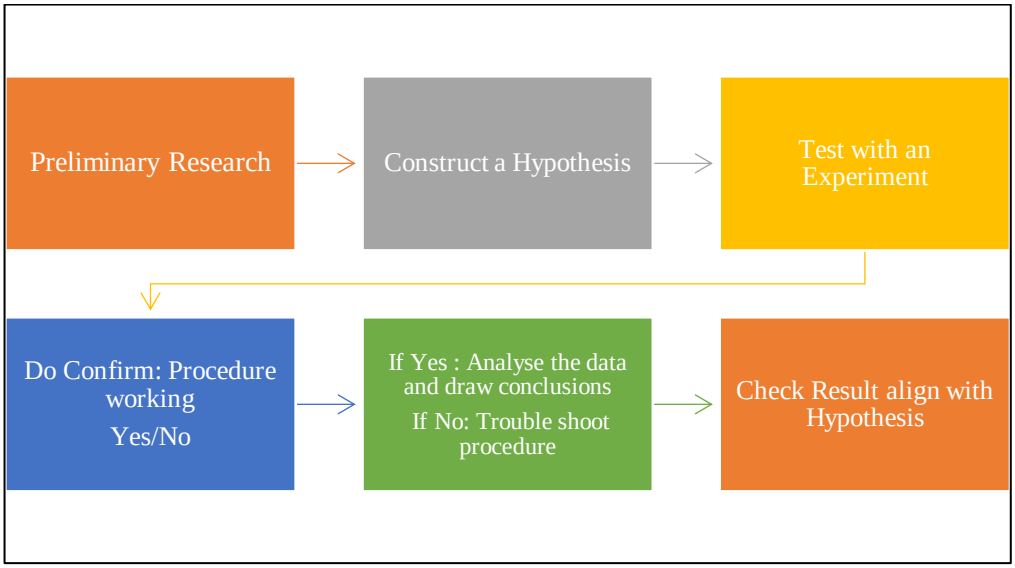

Figure 6: Controlled Experiment Procedure.
Source: Authors, (2026).

The pre-defined optimum threshold values for process parameters and machining conditions have been decided based on ISO standards and past production quality data records. The values of machining time and inspection time are chosen by the standard procedure of industrial engineering. With concerning controlled experiments the Independent variables (Controls during the experiment) are Vibration of Work head, Wheel head and Machine Bed, Cutting Temperature, and Noise. The Dependent Variables (Measured during the experiment) are surface finish, size accuracy, machine working time, machining time, and inspection time. The controlled variables Controlled Variable (Need to be constant for accurate results) are Feed, cutting speed, and depth of cut.

Table 2: Threshold values during experiment.

Sr. No	**Critical Parameter**	**Threshold values**	**Reference**
1	Maximum Cutting Temperature	25°C	---
2	Machine Vibration (Wheel head, work head and machine Bed)	1.8 mm/sec	ISO 10816-1
3	Noise	85 db	[16]
4	Cycle Time	126 sec.	--
5.	Inspection Time	4 sec.	--

Source: Authors, (2026).

The parameters mentioned in Table No.2 are monitored by IoT web-based monitoring system during the external grinding process for a bearing race. If the value exceeds the threshold, there is a chance of poor bearing race quality as well as machine inaccuracy and abnormal conditions.

Table 3: Machining Conditions that remain constant during controlled experiments.

Sr. No	**Parameter**	**Value**
1	Grinding Wheel RPM	2200
2	Work Piece RPM	16
3	Depth of Cut	0.05 mm
4	Material of Grinding wheel	RAA120L5VF8/60
5	Material of Work Piece	SAE 52100
6	Cutting Fluid Flow rate	20 Liter/Min
7	Feed	0.05 mm per pass
8.	Cutting Speed	46.05 m/s

Source: Authors, (2026).

Figure 7: Experimental setup.
Source: Authors, (2026).

The bearing race holds in work holding device of the external grinding machine. during external grinding, the cutting temperature is monitored, as well as the vibration and noise of the machine is monitored. After completion of the grinding operation, the machining time and inspection time are noted by a proximity sensor. The bearing size accuracy is measured by a measurement setup using a dial gauge. At last, the quality of the part is confirmed by pressing the Green or Red button push switch.

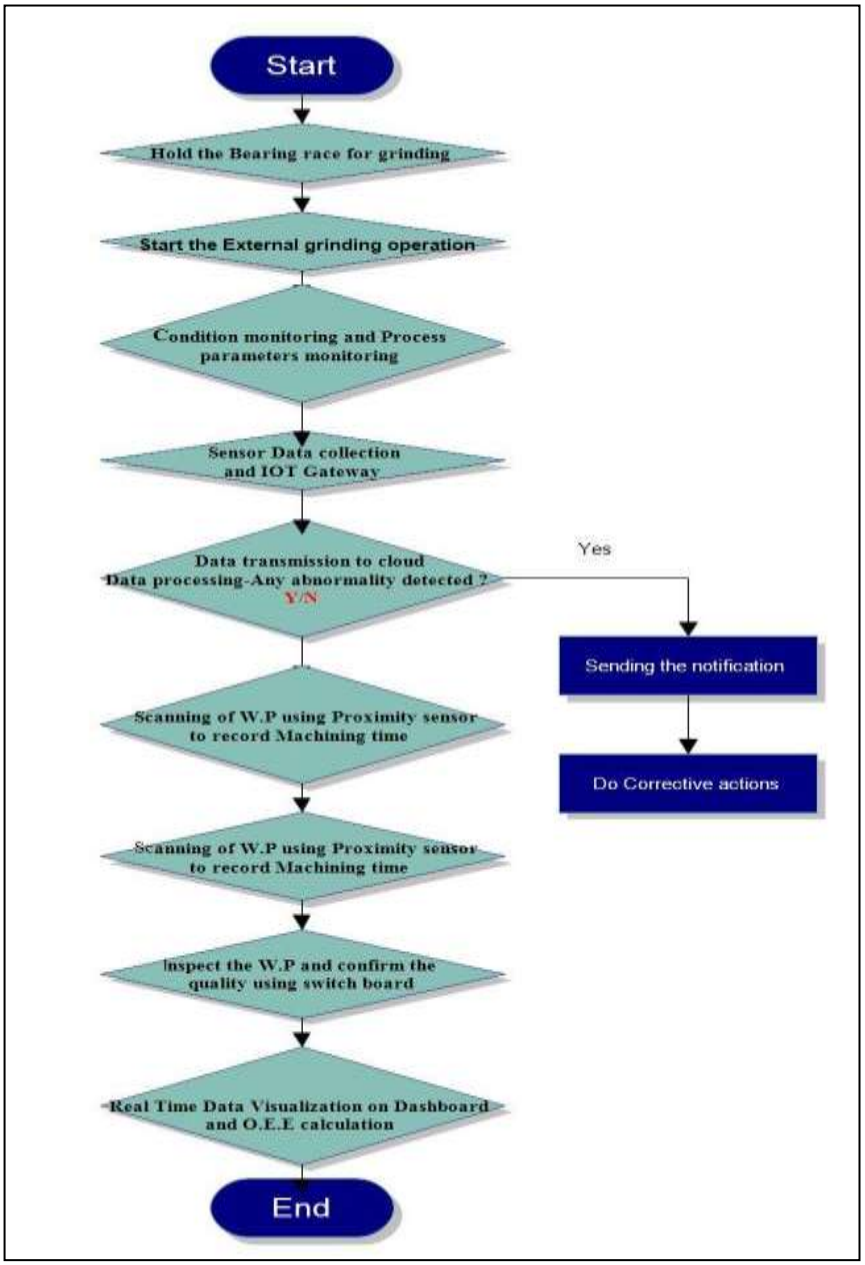

Figure 8: Flow chart of Experimental procedure.

IV.3 REAL-TIME MONITORING AND O.E.E DASHBOARD

The process variables are monitored by IoT-based system, and if any abnormality is detected, the notification will be mentioned on IOT web application.

IV.4 PROCESS CONTROL PLAN

Table 4: Process Control plan for IoT-based External Grinding Process.

KPI	Thresh-old Values	Relevant O.E.E.Factor	Required Corrective actions (If variable values exceed threshold values)
Cutting Temperature	25°C	Quality	Maintain cutting fluid temperature.
Vibration of the Machine bed, wheel head, and work head	1.8 mm/ sec	Quality and Availability	Balance machine parts, repairing Spindle misalignment, Repairing Loose machine parts, managing cutting speed, and feed.
Machine Noise	85 db	Availability	Controlling friction, unbalancing, overloading, malfunctioning, and misalignment between machine parts.
Process Time and Inspection Time	126 sec. and 4 sec.	Performance	Continuous improvement, corrective actions and standardizing working procedures.

Source: Authors, (2026).

IV.5 IOT WEB APPLICATION AND O.E.E DASHBOARD

The IoT web application is developed to analyze, monitor, and visualize the real-time production data. The stored data from the cloud is sent to the web application through the wi-fi module. The O.E.E Dashboard is developed to monitor the O.E.E of the external grinding process. O.E.E. is visible after the completion of a shift. The record of past production data and O.E.E. is visible in the web application.

IV.6 FEATURES OF IOT WEB APPLICATION

1) Real-time production data monitoring for data-driven decision making
2) A facility to customize threshold values of each critical parameter.
3) Threshold-Based Abnormality Detection notification.
4) O.E.E. dashboard and historical data Logging.
5) Notification and alert system on Mobile Phone.

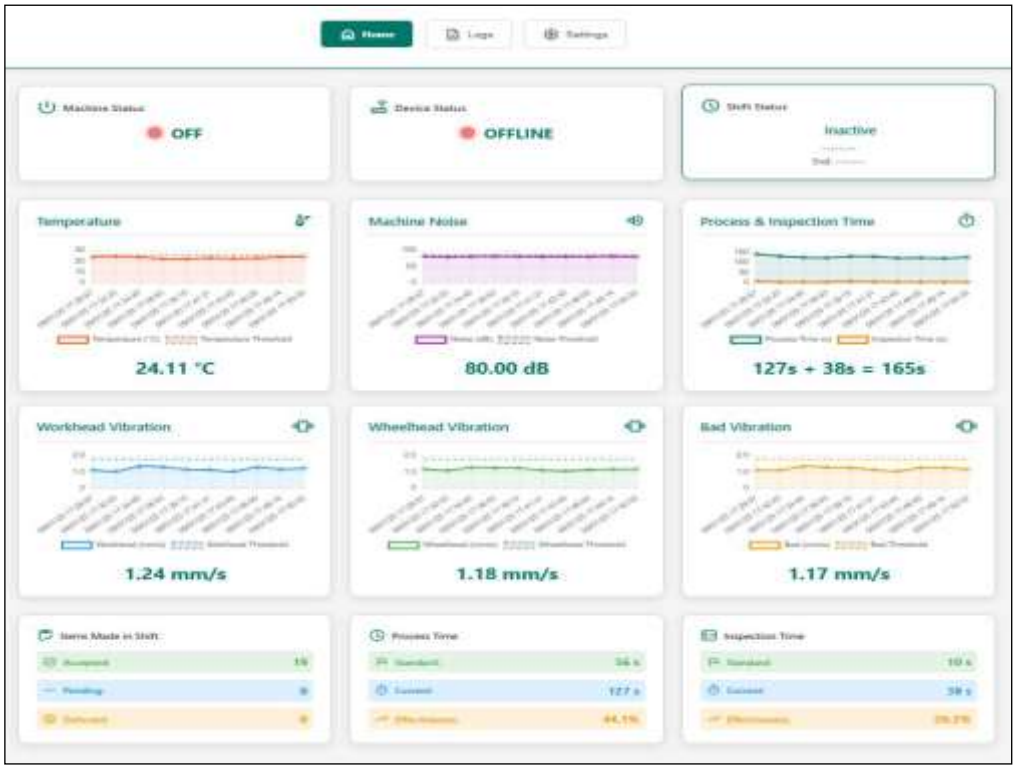

Figure 9: Real-time data Dashboard.

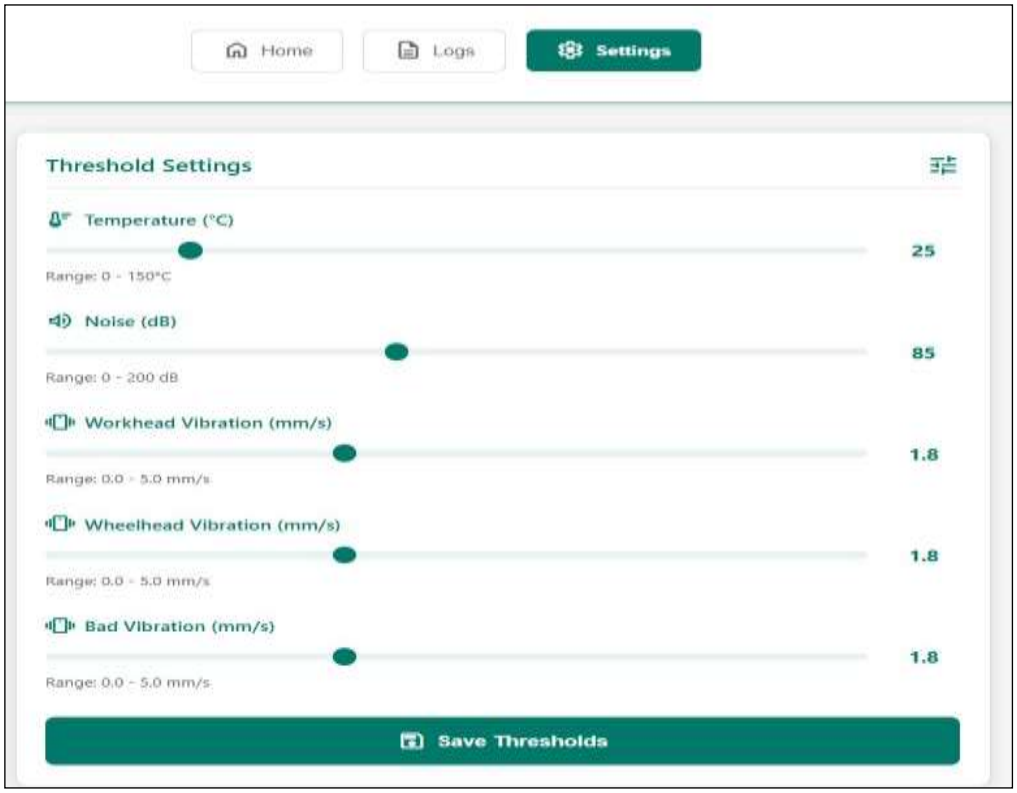

Figure 11: Customizable thresholds for each critical parameter.
Source: Authors, (2026).

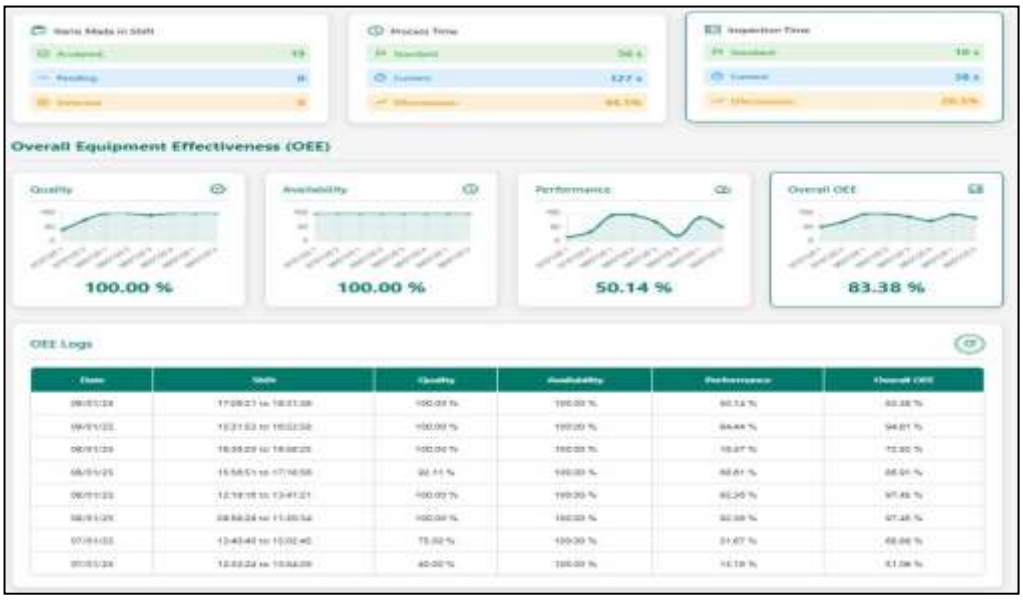

Figure 12: O.E.E Dashboard.
Source: Authors, (2026).

V. RESULTS AND DISCUSSION

After performing experiments, it is observed that if the values of critical parameters like cutting temperature and vibration do not exceed their threshold values, the bearing's remarkable surface finish and accurate size can be achieved. The sudden breakdown of the machine is reduced due to the detection of an abnormality in the early stage. The notification and alert system helps to provide attention to the supervisor by providing the condition monitoring system. The following notifications have been generated during experiments.

Table 5: Notification and alert system Observation during experiments.

Shift and Date	Critical Parameter	Values exceed the Threshold?	Notification and alert generated?
Shift 1 8/1/2025	Bed Vibration	Yes	Yes
Shift 2 8/1/2025	Bed Vibration	Yes	Yes
Shift 3 8/1/2025	Cutting Temperature	Yes	Yes
Shift 2 9/1/2025	Noise	Yes	Yes

Source: Authors, (2026).

After getting a notification from IoT web-based monitoring system, corrective actions have been taken to achieve the quality and reduce the chances of breakdown. The sudden breakdowns are eliminated by the live monitoring and alert system. The paperwork is eliminated by implementing an IoT-based system, as all production records have been digitized, so it helps to promote environmentally conscious and sustainable practices. After monitoring the O.E.E. of each shift it is observed that the O.E.E. of the external grinding process is improved. The past one-year production data of O.E.E without implementing IoT system was collected, and after implementing IOT system, the O.E.E is calculated. A notable improvement observed in O.E.E is 8.70%. Fig.13 shows a significant improvement in the quality of bearing parts as well as an improvement in performance and availability of the machine.

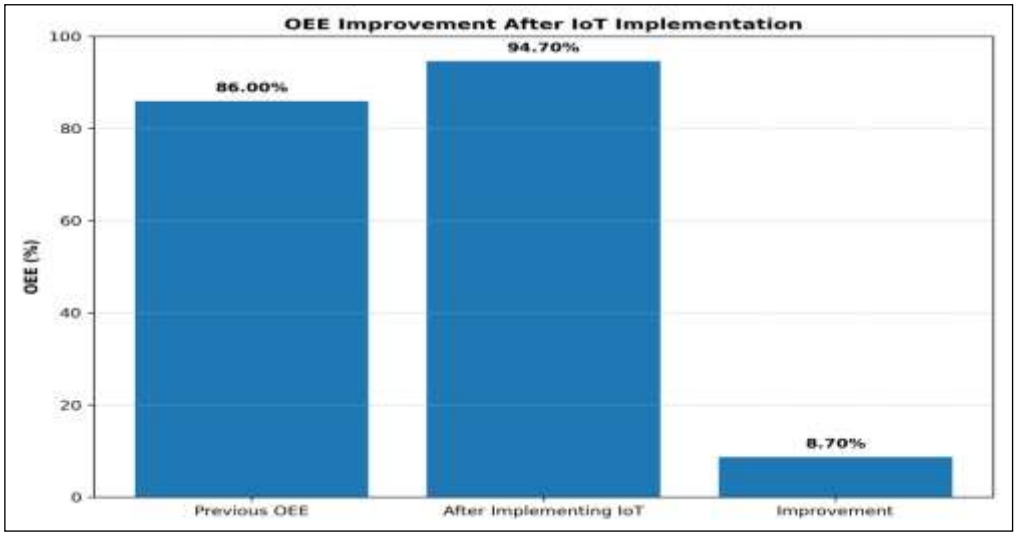

Figure 12: O.E.E before and after implementing the IoT-based monitoring system.

VI. CONCLUSION

The research demonstrates the development and implementation of an IoT-based web monitoring system aimed at improving the O.E.E. of an external grinding process used in the precision manufacturing of bearing components. The results from experiments highlight the effectiveness of IoT-based real time monitoring system for improving O.E.E with enhancing quality, reducing breakdowns, reducing machine downtime and promoting sustainable practices in the manufacturing process by eliminating the usage of papers.The integration of real-time monitoring and data analytics plays an important role in process improvement. The developed system utilizes calibrated sensors for data collection and monitoring of critical process parameters such as cutting temperature, machine vibration, noise levels,cycle time which are linked with key performance indicators and these factors directly influence the OEE elements in terms of quality, availability, and performance. Through controlled experiments, the system was tested for its reliability, accuracy, and responsiveness. When deviations from threshold values were detected, the system generated immediate notifications, allowing timely corrective actions to prevent quality defects and machine downtime.

The significant improvement in O.E.E was observed, rising from 86 % to 94.70 % after implementing IOT web based real time monitoring system. After performing experimentation during various manufacturing shifts at bearing manufacturing industry the 8.26 % reduction in breakdown,7.66 % reduction in manufacturing defects,9.28 % reduction in machine downtime and 8.12 % improvement in machine performance is observed. Furthermore, the adoption of digital manufacturing approach minimised paperwork, reduced production bottlenecks and supports data-driven decision-making on the production shop floor. This approach confirms the practical benefits of adopting IoT technologies in manufacturing operations particularly in high-precision processes like external grinding.Future work may focus on expanding the system's capabilities to other machining processes and incorporating advanced analytics and machine learning for predictive insights. Overall, this IoT-based solution represents a scalable and cost-effective approach to achieving operational excellence in smart manufacturing environments.

ABSTRACT

Design of CMOS based analog circuits becomes increasingly complex as transistor sizing plays a crucial role due to the trade-offs among power consumption, silicon area, unity gain bandwidth, slew rate, and open loop gain. This sizing challenge is makes analog circuit design inherently multi objective, and traditional analytical approaches based on simplified transistor level equations often fail to deliver globally optimal results. Metaheuristic optimization techniques have emerged as an effective alternative to explore nonlinear and multi-dimensional design spaces. In this work, the design of a two stage CMOS operational amplifier in the Predictive Technology Model (PTM) 45 nm technology node is optimized using four algorithms: Particle Swarm Optimization (PSO), RAO algorithm, Teaching Learning Based Optimization (TLBO), and the proposed Modified TLBO (MTLBO). The algorithms were implemented in Python and verified through Ngspice-26 simulator on an AMD Ryzen™ processor with 16 GB RAM, 64 bit Ubuntu environment. The proposed MTLBO achieved 86.15 dB voltage gain, 94.05 dB CMRR, and 185 MHz unity gain bandwidth. Comparative analysis shows that the proposed MTLBO algorithm achieves faster convergence with fewer iterations and consistently outperforms PSO, RAO, and TLBO making it a strong candidate for efficient analog VLSI design automation.

I. INTRODUCTION

The scaling of Complementary Metal Oxide Semiconductor (CMOS) technology has made the design of analog and mixed signal circuits design increasingly challenging task. Although digital systems dominate modern integrated circuits, analog blocks such as operational amplifiers (op-amps) remain indispensable because they serve as the critical interface between the physical world and digital processors which is the prime demand of modern mixed signal SoCs. High performance op-amps are widely used in wireless communication, biomedical instrumentation, signal processing, data converters, and control systems [1]. However, analog design in deep submicron nodes is far more complex than digital design due to nonlinear device behavior, process variations, and the simultaneous need to optimize design specifications such as gain, bandwidth, slew rate, power efficiency, and silicon area [2]. Traditional manual device sizing approaches rely on analytical transistor level equations, design heuristics, or rule-based methods often fail to achieve globally optimal results because of simplifying assumptions and their limited ability to explore complex design spaces [3]. To overcome these limitations, optimization driven methodologies have become increasingly popular. Deterministic optimization methods may succeed when the problem is well posed, but they are sensitive to initial conditions and tend to converge to local optima. Metaheuristic algorithm inspired by natural or social processes are more robust, balancing global exploration and local exploitation, making them particularly suitable for high dimensional, multi objective analog circuit design problems [4]. Over the past two decades, a wide range of metaheuristic algorithms have been investigated. Genetic Algorithms (GA) [5] and Particle Swarm Optimization (PSO) [6] are commonly applied but require careful parameter tuning. Artificial Bee Colony (ABC) [7], Differential Evolution (DE) [8], and Whale Optimization Algorithm (WOA) [9] offer improved exploration but remain computationally demanding for highly constrained designs. Teaching Learning Based

Optimization (TLBO) proposed by Rao et al. [10], introduced a parameter less approach inspired by the teacher student learning process which enables faster convergence and simpler to implementation. More recently, Rao [11] developed Rao algorithms, which further reduce parameter dependence and have been successfully applied to a many engineering problems. Multi objective TLBO has been employed for addressing challenging scheduling problems [12], while hybrid PSO-TLBO approaches have reported enhanced convergence characteristics in diverse optimization tasks [13]. Scalable variants such as the parallel subclass TLBO have been proposed for high-dimensional problem spaces [14]. Recent studies have shown that bio-inspired algorithms are also gaining traction in wireless sensor networks, where they have been successfully applied to enhance localization accuracy [15], emphasizing their broad applicability across engineering domains. Motivated by these developments, this work introduces a Modified Teaching Learning Based Optimization (MTLBO) algorithm for analog circuit design automation. The proposed MTLBO integrates the teacher and learner phases into a single update rule, allowing candidate solutions to learn simultaneously from the best solution and peer interactions.

This modification reduces algorithmic overhead, accelerates convergence, and preserves diversity within the search space. The algorithm is implemented in Python and coupled with Ngspice-26 simulator to optimize a two-stage CMOS operational amplifier in PTM 45 nm technology. Its performance is benchmarked against PSO, RAO, and TLBO to validate robustness and efficiency in achieving high gain, wide bandwidth, and low power consumption. The contributions of this paper are as follows: A review and comparative evaluation of metaheuristic algorithms for analog CMOS op-amp design, development of an enhanced MTLBO algorithm with integrated teacher learner update rules, implementation automated framework for two stage CMOS op-amp optimization, comparative results demonstrating that MTLBO achieves faster convergence and superior circuit performance relative to PSO, RAO, and TLBO. This paper is organized as follows: Section II brief over view of TLBO algorithm. Section III presents the proposed MTLBO approach with improved teaching process. Section IV outlines the automated design framework. Section V discusses simulation results. Section VI concludes the work and highlights scope of the future work.

II. THE TEACHING LEARNING BASED OPTIMIZATION

Teaching Learning Based Optimization (TLBO), proposed by Dr. R. V. Rao [10], is a population based meta heuristic algorithm which emulates how students acquire knowledge both from the teacher and the peer interaction. Each generation in TLBO consists of two distinct stages:

II.1 TEACHER PHASE

This phase identifies the most competent learner having best fitness from the population and designated as a teacher. All other learners adjust their solutions by moving closer to the teacher's position, effectively assimilating the teacher's knowledge. In this phase personal best of each candidate is determine, and then appoint the top performing individual as a teacher. All other learners learn from each other and update their own solutions by learning from each other and also from this teacher. Two matrices each for teacher and learner are generated randomly for initial population within the required bound [10]. The two matrix Px and Py generated for the N number of learner in the range Px with x = 1, 2, …, N and Py with y = 1, 2, …, M number of subjects where P is the objective function of the individual candidate.

Matrix Px where x = 1, 2, 3…, N (1)

Matrix Py where y = 1, 2, 3…, M (2)

After generating these two Px and Py random matrices each individual fitness is calculated by the objective function and selecting best indivudal from the population. In the proceeding step mean of each design variable is calculated and learner with best solution is selected as teacher as mentioned in the below equation.

$$Diff_{mean_{x,y,i}} = R_i\left(K_{x,ybest,i} - TFM_{j,i}\right) \tag{3}$$

Where the random number Ri having value in the range of [0,1] and teaching factor TF having value either 1 or 2 and TF is calculated by the formula (4).

$$TF = round[1 + rand(0,1)(2-1)] \tag{4}$$

Hear, TF is randomly selected in the range of 1 or 2 and it is important to note that the teaching factor is not algorithm parameter. After finding the difference mean new solution is obtained by the following equation.

$$K'_{x,y,i} = K_{x,y,i} + Diff_Mean_{x,i} \tag{5}$$

II.2 LEARNER PHASE

Randomly selected learners are allowed to interact with each other to update their solution based on whether the peer is performing better or worse. This knowledge exchange process further refines the population's solutions. Throughout this process, the learners iteratively improve the performance by incorporating both top-down instruction (from the teacher) and lateral learning (from fellow students), steadily converging toward an optimal solution. The learner updates their knowledge by interacting with the peer who has higher knowledge compared to him. For the minimization process,

$$K^{"}_{x,a,i} = K'_{x,a,i} + R_i\left(K'_{x,a,i} - K'_{x,b,i}\right), \quad if K'_{total-a,i} < K'_{total-b,i} \tag{6}$$

$$K^{"}_{x,a,i} = K'_{x,a,i} + R_i\left(K'_{x,b,i} - K'_{x,a,i}\right), \quad if K'_{total-b,i} < K'_{total-a,i} \tag{7}$$

For the maximization process,

$$K''_{x,a,i} = K'_{x,a,i} + R_i\left(K'_{x,a,i} - K'_{x,b,i}\right), \quad if K'_{total-a,i} > K'_{total-b,i} \tag{8}$$

$$K''_{x,a,i} = K'_{x,a,i} + R_i\left(K'_{x,b,i} - K'_{x,a,i}\right), \quad if K'_{total-b,i} > K'_{total-a,i} \tag{9}$$

Depending on the type of the process either equation (6), (7) or (8), (9) are applied to find the updated value of the learner phase [10].

III. THE PROPOSED MODIFIED TEACHING LEARNING BASED OPTIMIZATION ALGORITHM

Modified Teaching-Learning-Based Optimization (MTLBO) is an enhanced version of TLBO, designed to improve optimization efficiency by combining the Teacher and Learner phases into a single update rule. This modification allows for a more compact, yet powerful search mechanism, improving both the convergence rate and solution quality. Inspiration Behind MTLBO Just like TLBO, MTLBO is inspired by the learning process for gaining knowledge in a classroom. Students (solutions) improve their knowledge (fitness) either by gaining knowledge from the teacher which is best individual in the population or by the peers within the population. However, MTLBO merges the two separate learning phases of TLBO into a unified learning strategy wich incorporates two random variables r1 and r2 along with the teaching factor TF.

III.1 PSEUDOCODE FOR MTLBO ALGORITHM

Start MTLBO

Initialize the population:

Create a population of solutions (random values within bounds).
Evaluate the cost of each solution.
Save the best solution as Globalbest.

Repeat for each iteration:

a. Calculate the followings:
Obtain population mean as (Popmean).
Obtain the overall individual best as (Popbest).
Obtain the teaching factor (TF = 1 or 2 randomly).

b. For each individual Xi in the population:
Pick a random peer X_k (not equal to X_i).
Set direction A:
If Xi is better than X_k → A = 1
Else → A = -1
Generate random values r_1 and r_2.
Update Xi using:
$X_{new} = X_i + r_1*(Pop_{best} – TF * Pop_{mean}) + A * r_2* (X_i - X_k)$
Keep X_{new} within bounds.
Evaluate X_{new} cost.
If X_{new} is better value than X_i, replace X_i.
If X_{new} is better value than Globalbest, update Globalbest.

c. Record the best cost of this iteration.

Repeat until maximum iterations are reached

Output: Best solution ($Global_{best}$)

End MTLBO

III.2 IMPROVED TEACHING LEARNING PROCESS

This study proposes a Modified Teaching–Learning-Based Optimization (MTLBO) algorithm that enhances the original TLBO framework by incorporating simultaneous dual learning from both the teacher and the student. Each randomly selected participant is initialized within predefined bounds, where every individual is represented by a vector of decision variables. Each solution is then evaluated using a cost function to determine its fitness. In each iteration, the algorithm computes the population mean and identifies the best-performing individual as the teacher. A teaching factor (TF), randomly selected as either 1 or 2, controls the intensity of the teacher's influence. At the same time, each solution is paired with a randomly selected peer. Direction coefficient (A) is then assigned according to their relative performance: if the individual outperforms its peer, $A = 1$ otherwise, $A = -1$. The individual is subsequently updated using a combined learning strategy that incorporates knowledge from both the teacher and the peer. This combine learning strategy enhances knowledge transfer within the population and improves the algorithm's ability to converge efficiently toward high quality solutions is represented in mathematical equation by (10). Given the highly nonlinear, multi objective nature of analog circuit design, the proposed MTLBO framework is particularly well suited for achieving faster convergence while maintaining robustness across complex design spaces.

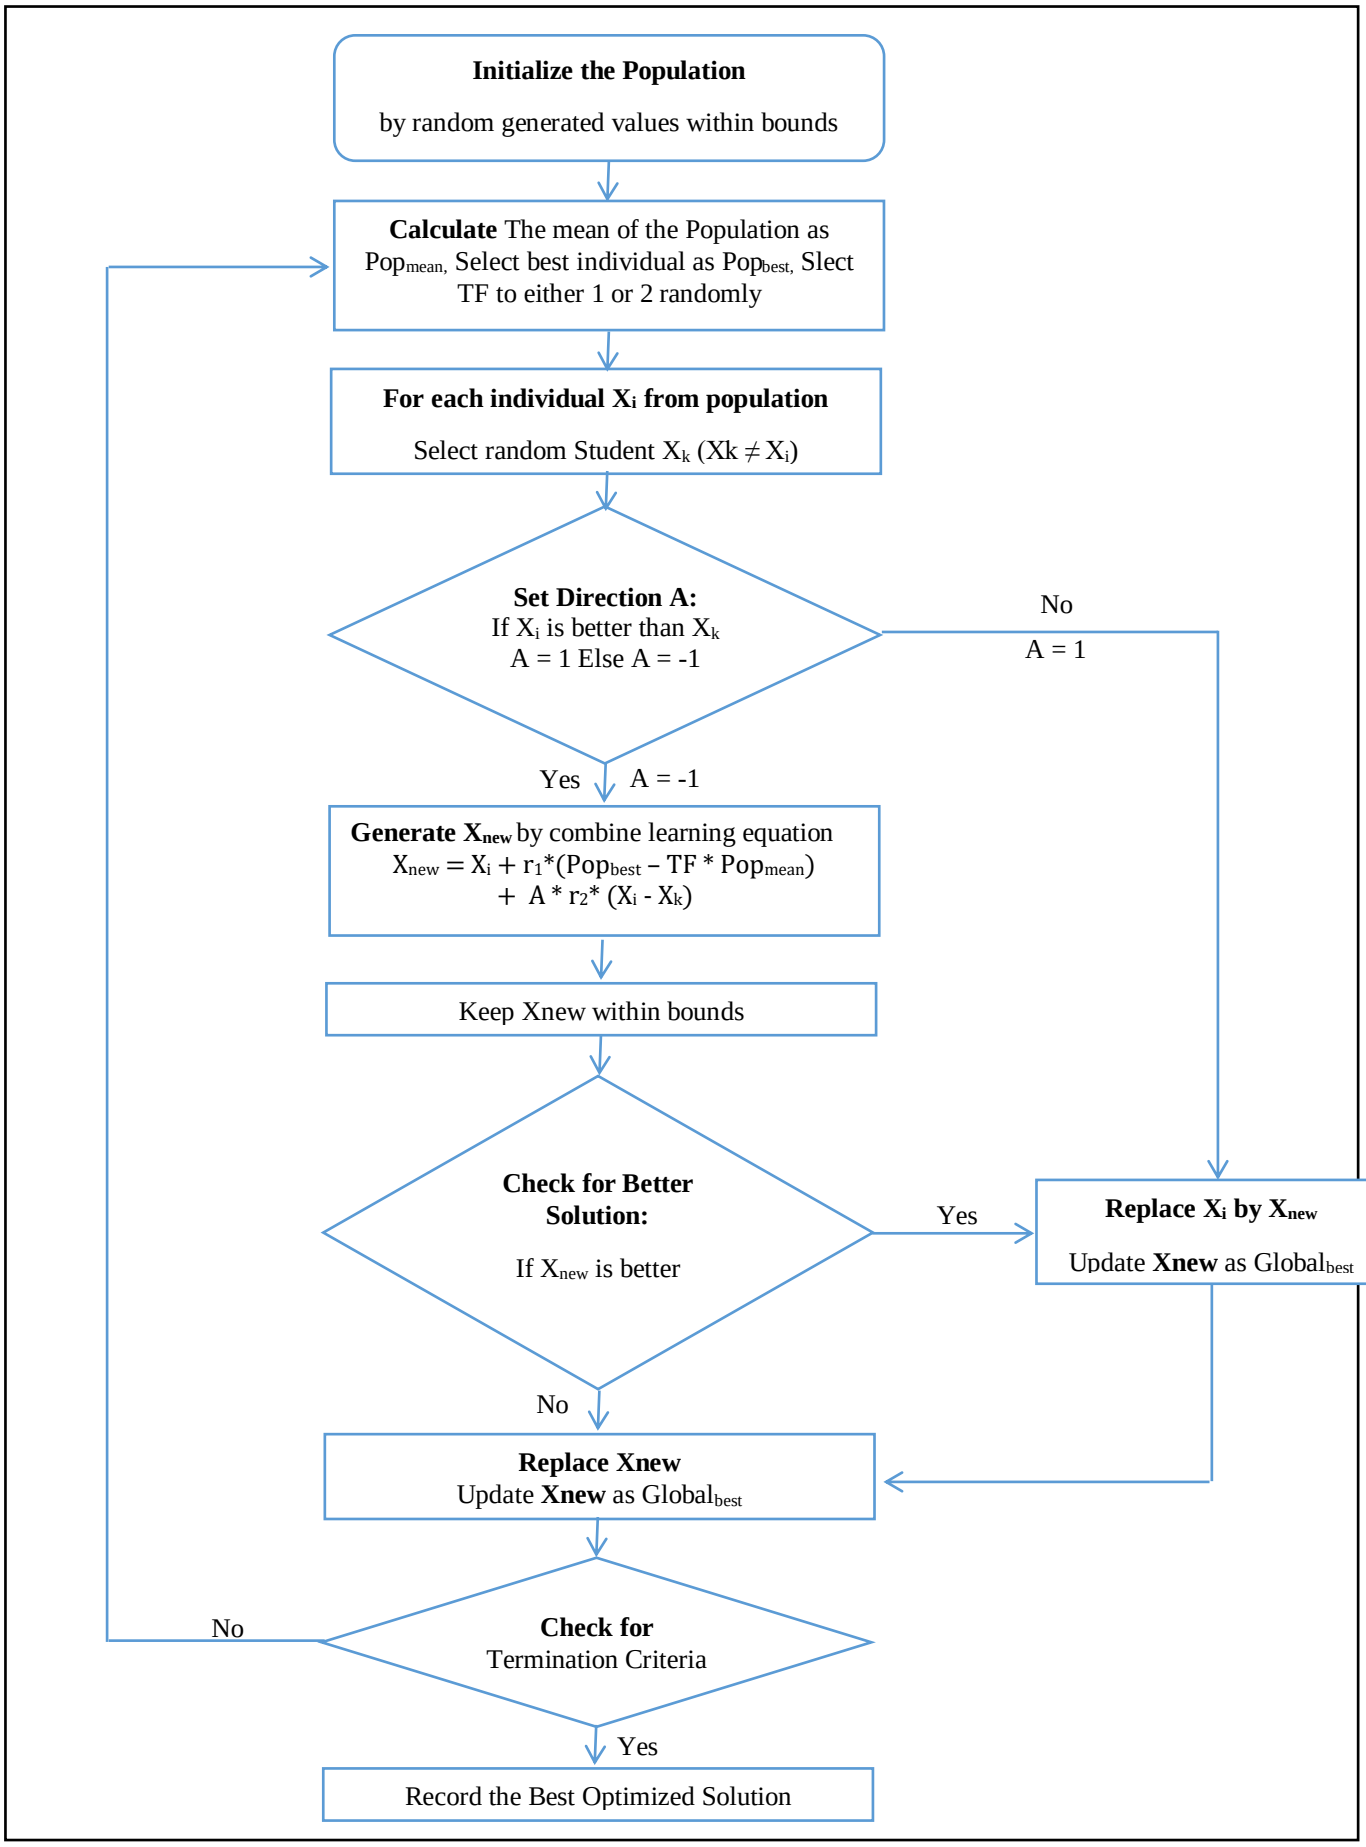

Figure 1: Flow Diagram of proposed MTLBO Algorithm.
Source: Authors, (2026).

$$X_{new} = X_i + r_1 * (Pop_{best} - TF * Pop_{best}) + A * r_2 * (X_i - X_k) \quad (10)$$

Where r_1 and r_2 are randomly generated coefficients. This formulation allows each individual to simultaneously learn from the best solution in the population and adapt based on its relative standing with a peer, thereby promoting a balanced exploration–exploitation trade-off. The updated candidate is bounded within the variable limits and accepted if it yields an improved cost. After all individuals are updated, the global best solution is identified and stored using greedy selection. The algorithm iterates until termination criterion is achieved, either reaching the maximum number of iterations or attaining acceptable convergence. The complete flow diagram of the MTLBO algorithm is shown in Figure 1.

IV. OPTIMIZATION OF TWO STAGE OPERATIONAL AMPLIFIER BY MTBLO ALGORITHM

The MTLBO algorithm is applied to optimize complex multidimensional CMOS analog circuit design problems. It was evaluated on the optimization of a critical CMOS based operational amplifier, which is the fundamental building block of Analog to Digital Converters and Digital to Analog Converters in modern VLSI mixed signal design [16]. Designing a two-stage operational amplifier is itself a multidimensional problem [17], where the sizing of each device parameter must be optimized to achieve required specifications such as gain, bandwidth, power, and area. The MTLBO algorithm automates the design of CMOS analog circuits by optimizing each transistor's width and length as design parameters to meet the desired specifications. The design process combines the MTLBO optimizer with a SPICE simulation environment, where each set of design values is evaluated using Ngspice to ensure that the circuit meets performance targets[18]. A fitness function based on the root mean square (RMS) error is used to measure how closely the simulated results match the desired specifications. The fitness function is calculated as by equation (11), where D is the total number of specifications.

$$Fitness\ Function = \sqrt{\sum_{j=1}^{D} \left(\frac{Specification_{desired} - Specification_{simulated}}{Specification_{desired}} \right)_j^2} \quad (11)$$

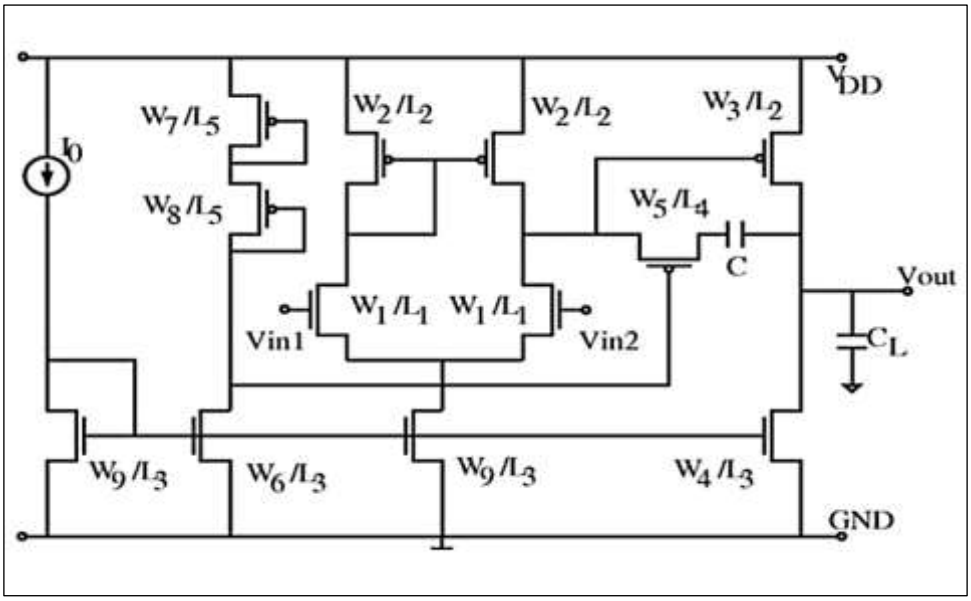

Figure 2: The Two Stage Operational Amplifier.
Source: Authors, (2025).

Table 1: Design Specification of two stage op-amp.

Sr. No.	Required Specifications
1	AC voltage gain AV > 80 dB
2	Phase margin > 60°
3	Unit gain bandwidth (UGB) > 100 MHz
4	Power Supply Rejection Ratio (PSSR) > 80 dB
5	Common Mode Rejection Ration (CMRR) > 80 dB
6	Rise Slew Rate (RSR) > 40 V/us
7	Fall Slew Rate (FSR) > 40 V/us
8	Power Consuption < 0.2µW

Source: Authors, (2026).

This RMS error formula gives equal weight to each specification. The optimizer's main aim is to minimize the fitness function value with each iteration until an acceptable level is reached. The process stops when either the fitness function falls below a set minimum (1e-6) or the maximum number of iterations (1000) is reached [19].

If the stopping criteria are not met, the optimization algorithm generates a new set of design parameters, and the cycle repeats. The two stage op-amp, shown in Figure 2, with design specifications listed in Table 1, represents the multidimensional design problem to be optimized [20]. The MTLBO algorithm is incorporated into the automated design environment, as illustrated in Figure 3, to obtain the desired optimum results.

V. RESULTS AND DISCUSSIONS

The two-stage CMOS operational amplifier was designed using the PTM 45 nm CMOS process. Simulations were performed on an AMD Ryzen™ processor with 16 GB of RAM running a 64 bit Ubuntu operating system. The RAO, PSO, TLBO, and proposed MTLBO algorithms were implemented in Python, while circuit level simulations were carried out using Ngspice-26. For a fair performance comparison, a standardized test setup was used: each algorithm was initialized with a population size of 30, and the design dimension, representing the total number of transistor level variables was set to 16. The maximum number of iterations was fixed at 1000,

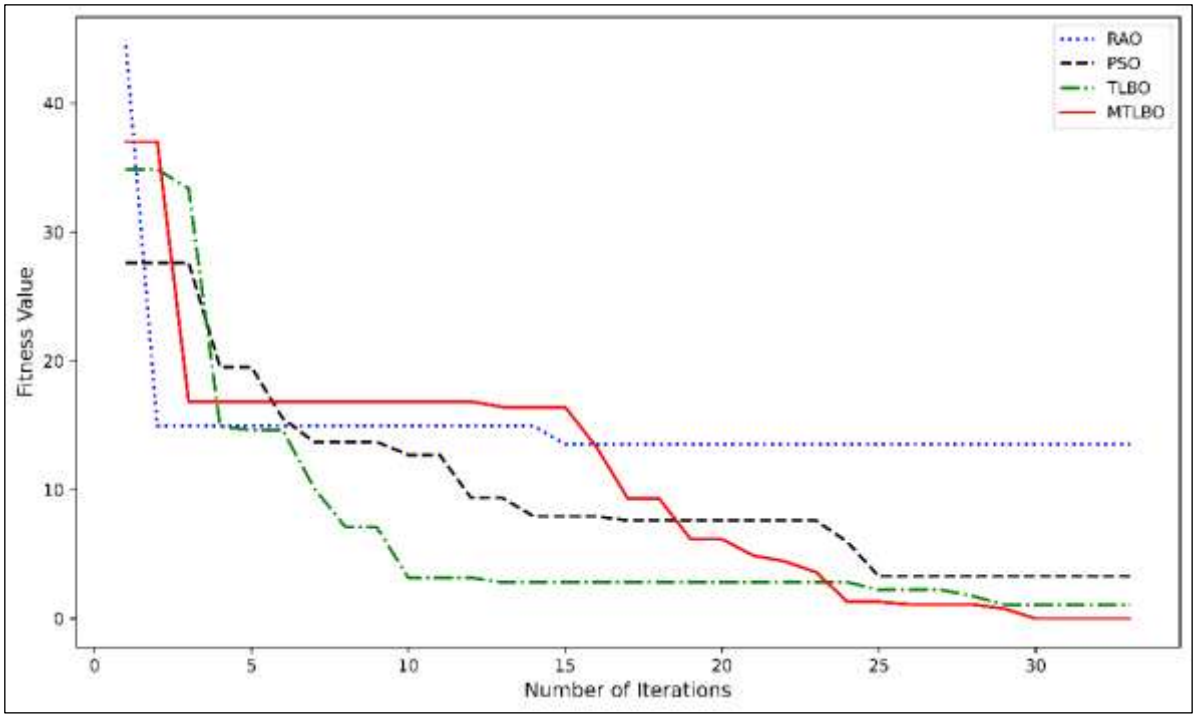

Figure 4: Convergence graph of op-amp for RAO,PSO, TLBO and MTLBO.
Source: Authors, (2026).

With a fitness function threshold of 1×10^{-6}, evaluated over 10 independent runs. The obtained design specifications using these algorithms are shown in Table 3, with the optimized design variables provided in Table 2. These results are compared with previously reported RAO, PSO, and TLBO algorithms. The two-stage operational amplifier optimized using the MTLBO algorithm meets all the design specifications. The convergence graph shown in Figure 4 demonstrates that MTLBO converges more rapidly compared to RAO, PSO, and TLBO algorithms. The performance comparison of the MTLBO algorithm with the other previously reported algorithms is presented in Table 4, which further confirms that MTLBO requires fewer iterations and achieves faster convergence than RAO, PSO, and TLBO.

Table 3: Obtained Specification of two stage op-amp.

VI. CONCLUSIONS

The two stage CMOS operational amplifier in PTM 45 nm technology has been effectively optimized using the proposed Modified Teaching Learning Based Optimization (MTLBO) algorithm. MTLBO achieves 86.15 dB voltage gain, 94.05 dB CMRR, and 185 MHz unity-gain bandwidth, while meets rest of the all target specifications. Comparative analysis shows that MTLBO converges faster and requires fewer iterations than PSO, RAO, and TLBO, confirming its suitability for analog circuit sizing. The optimized design demonstrates high gain, higher CMRR, and higher bandwidth most suitable for mixed signal applications. Limitations include the focus on transistor level sizing without accounting for process variations and temperature effects. Future work may extend this framework to other analog/mixed signal blocks, such as Operational Transconductance Ampifier (OTA), comparators, filters, oscillators, and ADC front end circuits, highlighting the scalability and adaptability of MTLBO in complex SoC design environments.

ABSTRACT

Agile methodologies, emphasizing people, collaboration, and shared values, have gained significant traction globally. A thorough understanding of the challenges and benefits of implementing Agile practices within software development companies is vital for the progression of the field and will be the foundation for its advancement in practice and research. Yet there is a scarcity of empirical studies and a limited understanding of the key challenges and benefits that could be gain from Agile implementation, particularly within Yemeni companies. Therefore, this study aimed to investigate the challenges and benefits of implementing Agile practices within Yemeni software development companies. A mixed approach of analysis was used in this study which, started by a rigorous and systematic analysis process of literature followed by a qualitative and quantitative field study. Overall, the key challenges, identified from this process were organizational culture resistance, insufficient executive support, inadequate employee skill sets, poorly defined project scopes, and technological limitations. Conversely, the primary benefits observed were increased flexibility, accelerated time-to-market, reduced costs, and enhanced team communication. This research provides valuable insights to guide Yemeni software development companies in making informed decisions and developing effective strategies for successful Agile implementation.

I. INTRODUCTION

Agile methodology, since its introduction about 20 years ago, has been widely implemented for software development. Agile approaches help organizations act with speed and flexibility to quickly adapt and react to changing situations [1] .The adoption of Agile practices in software development projects has gained significant attention in recent years due to its potential to enhance project management and delivery processes. According to the 10th Annual State of Agile Report, the top benefits of agile include managing changing priorities (87%), team productivity (85%), and project visibility (84%) [2]. While extensive research exists on Agile practices globally, studies specifically examining Agile adoption and its challenges within the Yemeni context are limited. This study aims to investigate the challenges and benefits of implementing Agile methodologies in Yemeni software development companies[3]. This study employed a mixed-methods approach to investigate the challenges and benefits of Agile software development, specifically within the Yemeni context. A systematic literature review of 39 peer-reviewed studies published within the last five years identified key themes and factors influencing Agile adoption. This informed a sequential field study comprising qualitative and quantitative components. First, eight in-depth, semi-structured interviews were conducted to explore nuanced perspectives. Subsequently, a survey, validated by two experienced Ph.D. experts, was distributed to professionals with diverse Agile experience (entry-level to over 20 years). The survey included sections on demographics, implementation challenges, general benefits, and open-ended questions for further qualitative insights. Overall, this study aims to explore the adoption of Agile practices within the Yemeni context, gathering valuable insights into the challenges and benefits encountered during implementation.

The findings will serve as a valuable resource for making informed decisions and developing effective strategies, ultimately contributing to the growth and development of software development companies within Yemen.

II. LITERATURE REVIEW

After conducting an extensive and thorough review of our primary studies, we aimed to uncover and analyze the various challenges and benefits associated with the implementation of agile methodology within software development companies. This in-depth exploration involved a meticulous examination of numerous case studies, research papers, and industry reports to ensure a comprehensive understanding of the topic. As a result of this rigorous analysis, we identified a total of 23 distinct challenges that organizations frequently encounter when adopting agile practices. These challenges span a wide range of issues, including but not limited to, difficulties in managing team dynamics, resistance to change from traditional development methods, and the complexities of scaling agile practices across large organizations. Additionally, our review revealed 13 significant benefits that companies can achieve through the successful implementation of agile methodologies. The findings are presented in detailed tables below, which categorize and summarize the challenges and benefits based on different contextual

Subsequently, building upon our findings, we classified these challenges into five broad dimensions: technological, organizational, environment, people, and process. The table above shows this classification. In addition, the conceptual model of the study is presented in Figure 1 below.

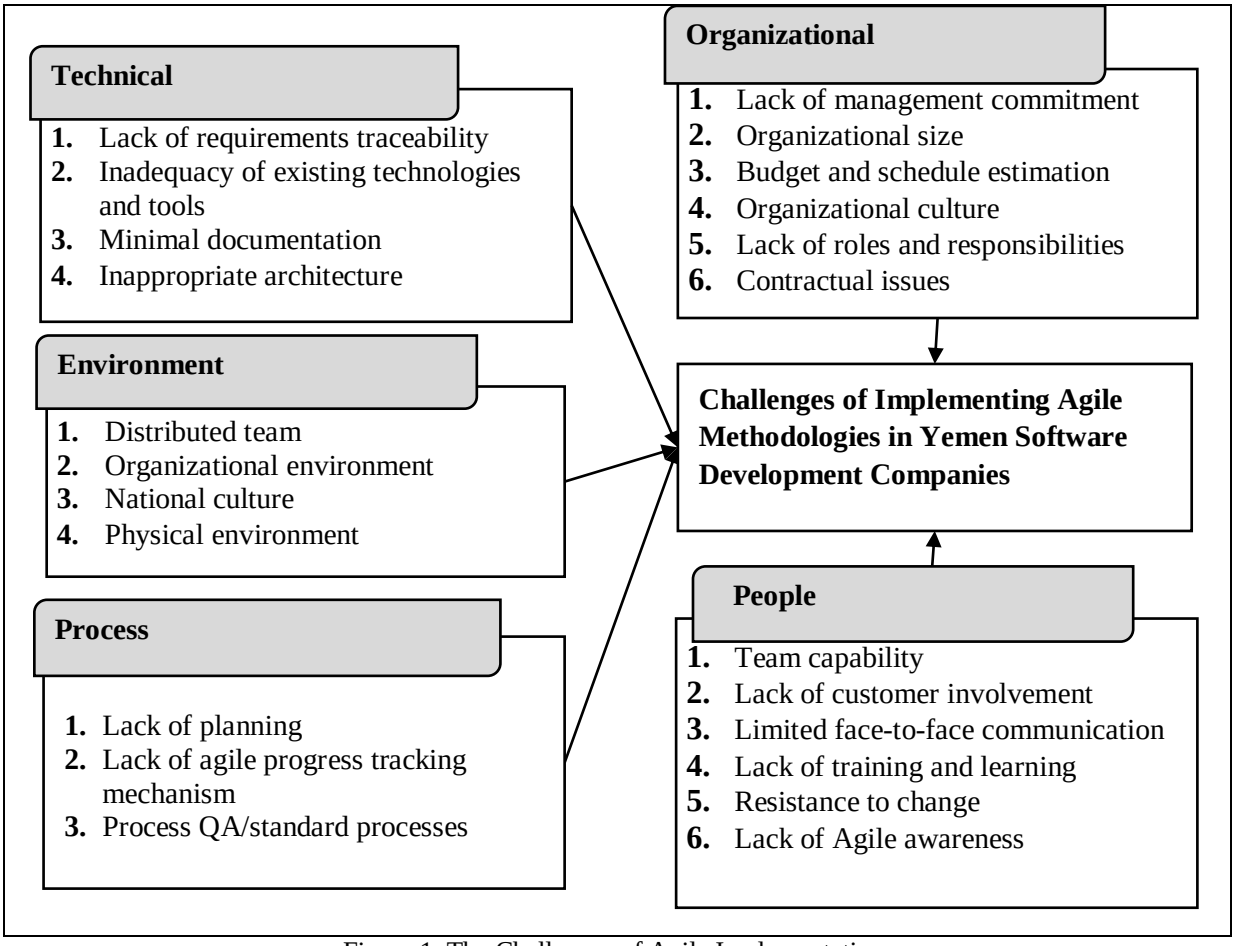

Figure 1: The Challenges of Agile Implementation.
Source: Authors, (2026).

III. METHODOLOGY

This study employs a sequential mixed-methods design to examine the benefits and challenges of Agile methodology adoption in software development organizations. The research comprises three distinct phases:

Phase-I: In this phase, a holistic literature review was conducted, to extracted the key benefits and challenges of Agile implementation from existing research papers more information about this phase can be found in [3].
Phase-II: In this phase, preliminary data was collected based on the results obtained from the literature review. In the preliminary data collection activity, the qualitative research approach was applied where 8 in-depth semi-structured interviews were conducted with actual users of Agile in the software industry sector in Yemen. The main objective of conducting the qualitative study was to gain better understanding of Agile benefits and challenges as perceived by the actual users.
Phase-III: After collecting the data from the literature review and expert interviews, the key benefits and challenges of Agile implementation were identified. Thereby, the researcher sought to examine those benefits and challenges, in a holistic view through a survey study, with the aim of ranking the most important benefits and challenges as observed by the individuals in the software development organizations.

The survey consisted of five parts, including an introduction, demographics, challenges affecting agile implementation, general benefits of agile methodology, and open-ended questions. Participants were asked to rate challenges and benefits on a scale of 1 to 5, and they also had the opportunity to provide additional insights. The survey was distributed through many platforms such as WhatsApp, Gmail, and Facebook, a total of 67 valid responses were received. Data analysis was conducted using SPSS software, enabling a thorough examination of the responses and facilitating the identification of significant trends and correlations within the data the result as shown in the following subsections.

IV. FINDINGS

The findings from the survey reveal critical insights into the challenges and benefits of implementing Agile methodologies in Yemeni software development companies. By gathering responses from industry professionals through a structured questionnaire, we identified several key themes that reflect the experiences and perspectives of those directly involved in Agile adoption.

This analysis provides a comprehensive overview of the current state of Agile practices in the region, highlighting both the obstacles encountered and the advantages realized by organizations seeking to enhance their software development processes.

Section A: Demographics

1. Gender

Table 2: Gender Distribution.

Gender		
	Freq.	**Percent**
Female	23	33.8 %
Male	45	66.2 %
Total	68	100.0

Source: Authors, (2026).

Out of the total 68 respondents, 45 identified as male (66.2%), while 23 identified as female (33.8%). These findings indicate a higher representation of male participants in the survey.

2. Age

Table 1: Age.

Age		
	Freq.	**Percent**
Older than 46	6	8.8 %
41 - 45 Years	9	13.2 %
36 - 40 Years	13	19.1 %
31 - 35 Years	12	17.6 %
26 - 30 Years	11	16.2 %
21 - 25 Years	16	23.5 %
Younger than 20	1	1.5 %
Total	68	100.0

Source: Authors, (2026).

The survey data reveals a diverse age distribution among participants. . with older individuals above 46 years accounting for 8.8% of participants. The age groups of 41-45 years, 36-40 years, and 31-35 years had participation rates of 13.2%, 19.1%, and 17.6% respectively. The age groups of 26-30 years and 21-25 years had participation rates of 16.2% and 23.5% respectively. Additionally, there was one participant (1.5%) younger than 20 years old. This inclusive age distribution highlights the engagement of professionals across different age ranges in Agile implementation in Yemeni software development companies as shown in Table 3.

3. Educational Qualification

Table 2: Educational Qualification.

Educational Qualification		
	Freq.	**Percent**
Doctorate	6	8.8 %
Master	13	19.1 %
Bachelor	43	63.2 %
Diploma or less	3	4.4 %
High School	2	2.9 %
Other	1	1.5 %
Total	68	100.0

Source: Authors, (2026).

The survey data revealed a diverse range of educational qualifications among the participants. The majority held a bachelor's degree (63.2%), followed by participants with a master's degree (19.1%). A smaller percentage had a doctorate (8.8%), while a few had diplomas or less (4.4%). There were also participants with high school education (2.9%) and one with a unique educational qualification (1.5%), as shown in Table 4.

4. Job Title

Table 3: Job Title.

Job Title		
	Freq.	**Percent**
CIO	6	8.8 %
Project Manager	6	8.8 %
Software Analyst	4	5.9 %
Programmer	28	41.2 %
Other	24	35.3 %
Total	68	100.0

Source: Authors, (2026).

The survey data revealed a diverse range of job titles among the participants, indicating varied roles and responsibilities in Agile implementation. Chief Information Officers (CIOs) and project managers each accounted for 8.8% of participants, highlighting their involvement in Agile. Software analysts made up 5.9%, emphasizing the importance of requirements analysis. The most prevalent job title was "programmer" (41.2%), followed by 35.3% falling into the "other" category, representing diverse roles within Agile teams. The data reflects the collaborative nature of Agile methodologies across different job titles.

5. Job Experience

Table 6: Job Experience.

Job Experience		
	Freq.	**Percent**
More than 20 Years	6	8.8 %
16 - 20 Years	9	13.2 %
11 - 15 Years	13	19.1 %
6 - 10 Years	8	11.8 %
1 - 5 Years	32	47.1 %
Total	68	100.0

Source: Authors, (2026).

The survey data revealed a diverse range of among the participants. A notable percentage (8.8%) had more than 20 years of experience, bringing valuable expertise to Agile teams. Additionally, 13.2% had 16-20 years of experience, 19.1% had 11-15 years, and 11.8% had 6-10 years. The majority (47.1%) had 1-5 years of experience, indicating a significant presence of professionals at the early stages of their careers. Understanding the distribution of job experience levels helps organizations leverage the diverse perspectives and knowledge of professionals when implementing Agile methodologies as shown in Table 6.

6. Duration familiarity with agile

Table 7: Duration familiarity with agile.

Duration of familiarity with agile		
	Freq	**Percent**
More than 20 Years	1	1.5 %
16 - 20 Years	1	1.5 %
11 - 15 Years	4	5.9 %
6 - 10 Years	8	11.8 %
1 - 5 Years	54	79.4 %

Source: Authors, (2026).

The survey data revealed that familiarity with Agile practices in Yemeni software development companies is relatively recent, with the majority (79.4%) having 1-5 years of familiarity. Only a small percentage (1.5%) reported more than 20 years or 16-20 years of experience with Agile, indicating a scarcity of professionals with long-term exposure to Agile methodologies as shown in Table 10. This lack of extensive experience poses a challenge in effectively implementing Agile practices. To address this, companies may need to focus on providing training programs and knowledge-sharing initiatives to enhance understanding and application of Agile methodologies as shown in Table 7.

7. The size of projects you are currently working on

Table 8: The size of projects you are currently working on.

	Freq .	**Percent**
Small Projects	26	38.2 %
Medium Projects	15	22.1 %
Big Projects	2	2.9 %
Small Projects, Medium Projects	10	14.7 %
Medium Projects, Big Projects	6	8.8 %
Small Projects, Medium Projects, Big Projects	9	13.2 %
Total	68	100.0

Source: Authors, (2026).

Table 7 shows the survey data reveals the distribution of project sizes among participants in Yemeni software development companies implementing Agile methodologies. Among the participants, 38.2% are currently working on small projects, while 22.1% are involved in medium-sized projects. Only 2.9% of participants are working on big projects. Additionally, some participants are engaged in multiple project sizes, with 14.7% working on both small and medium-sized projects, 8.8% involved in both medium and big projects, and 13.2% reporting simultaneous involvement in small, medium, and big projects. This diverse range of project sizes being managed using Agile methodologies highlights the flexibility and adaptability of Agile practices. It underscores the importance of tailoring Agile approaches to address the specific challenges and benefits associated with each project size.

8. The size of the organization.

Table 9: The size of the organization.

The size of the organization		
	Freq.	**Percent**
Small-sized organization	26	38.2 %
Medium-sized organization	32	47.1 %
Big-sized organization	10	14.7 %
Total	68	100.0

Source: Authors, (2026).

The survey data reveals that in Yemeni software development companies, 38.2% of participants work in small-sized organizations, 47.1% in medium-sized organizations, and 14.7% in big-sized organizations as presented in Table 8. This distribution underscores the presence of Agile methodologies across diverse organization sizes, emphasizing the importance of agility in smaller contexts and addressing coordination challenges in larger organizations. Tailored Agile strategies can be implemented based on the organization's size to cater to its specific needs and characteristics.

Section B: Challenges that affect the implementation of the Agile methodology

The literature review and the primary study identified numerous challenges and benefits associated with applying Agile software development methodology. Over 36 challenges and benefits were extracted. After analyzing the most frequently mentioned challenges and benefits, a total of 20 challenges and 10 benefits were selected. These challenges and benefits were categorized into five dimensions: technology, organization, environment, people, and processes. They were then incorporated into a questionnaire that utilized a Likert scale. The results of the questionnaire are as follows:

Table 10: Summary of the challenges of implementing Agile methodology in Yemen software companies.

The Dimensions	The Challenges		S/A	A	N	D	S/D	Mean	Std. Deviation	Rank	Likert Scale
Technological Challenges	lack of work documentation	N	17	28	7	13	3	3.632	1.183	1	High

V. DISCUSSION AND CONCLUSION

Interpreting empirical findings within a structured and multidimensional framework is essential for identifying key challenges and research gaps, as emphasized in prior systematic literature reviews [40].The questionnaire results provide valuable insights into the challenges encountered in implementing Agile software development methodology across different dimensions. The analysis reveals the percentage, mean, and standard deviation for each challenge within their respective dimensions. The most prominent challenge in the Technological Challenges dimension is the lack of work documentation, with 25% of respondents highlighting its importance. This challenge has a mean rating of 3.63, indicating a significant difficulty in effectively documenting work in an Agile context. Other technological challenges, such as inappropriate architecture (mean: 3.57), lack of requirements for traceability (mean: 3.49), and inadequacy of existing technologies and tools (mean: 3.31), also present notable obstacles to Agile implementation. Moving to the Organizational Challenges dimension, budget and schedule estimation emerge as the most significant challenge, emphasized by 19.1% of respondents. This challenge has a mean rating of 3.87, indicating notable difficulties in accurately estimating project budgets and schedules in an Agile setting. The lack of roles and responsibilities (mean: 3.72) and the lack of management commitment (mean: 3.65) are also significant challenges that organizations face in implementing Agile, the Organizational size (mean: 3.29). In the Environmental challenges dimension, national culture is identified as the most significant challenge, with 14.7% of respondents emphasizing its importance.

This challenge has a mean rating of 3.84, highlighting the impact of cultural factors on Agile implementation. The organizational environment (mean: 3.79) and distributed teams (mean: 3.35) are additional challenges that organizations need to address to facilitate successful Agile adoption. Regarding People Challenges, lack of training in the Agile methodology is the most prevalent challenge, emphasized by 39.7% of respondents. This challenge has the highest mean rating of 4.07, indicating a significant gap in Agile knowledge and skills within organizations. Other challenges include lack of Agile awareness (mean: 4.04), resistance to change (mean: 3.88), team capability (mean: 3.75), lack of customer involvement (mean: 3.50), and limited face-to-face customer communication (mean: 3.50).In the Process Challenges dimension, lack of planning for each stage of Agile emerges as the most significant challenge, with 25% of respondents identifying its importance. This challenge has a mean rating of 3.87, highlighting the need for effective planning throughout the Agile development process. The lack of an agile progress tracking mechanism (mean: 3.74) and the lack of Agile processes standardization (mean: 3.69) are also significant challenges that organizations face in implementing Agile as shown in Table 9. As Table 10 shows the survey results highlight a strong overall perception of the benefits of Agile methodologies among participants in Yemeni software development companies, as reflected in the mean scores for various benefits. The highest-rated benefit, flexibility of the Agile model, achieved a mean score of 4.220, indicating a strong consensus, with 38.2% of respondents expressing strong agreement.

Improved team communication followed closely with a mean of 4.162, emphasizing its critical role in Agile practices. Coherent and self-organizing teamwork received a mean score of 4.088, reinforcing the positive view of Agile's impact on team dynamics. Delivery speed to customers and good customer relationships were also highly rated, with means of 4.074 and 4.044, respectively. However, the reduction in overall project schedules, while still viewed positively, had a mean score of 3.926, suggesting some variability in experiences among respondents. Risk identification was noted as a benefit with a mean of 3.882, while rigorous project restructuring activities ranked lower at 3.809, indicating potential challenges in implementation. Both the simplicity of project design and cost reduction received mean scores of 3.765, reflecting a more moderate perception of their impact. The overall weighted mean of 3.929 suggests a favorable view of Agile methodologies. Notably, the standard deviation for the benefits was 0.612, indicating a strong consensus among respondents regarding these advantages. This low standard deviation implies that participants largely agreed on the benefits of Agile, particularly in enhancing flexibility, communication, and efficiency in software development projects. These insights can guide Yemeni companies in refining their Agile practices to maximize project management and delivery effectiveness.

ABSTRACT

Over 60% of India's gross domestic product (GDP) is attributed to the agricultural sector. Advancements in mechanical and instrumentation technologies have significantly improved research and development in agricultural machinery. Vibration analysis plays a critical role in predictive maintenance by allowing engineers to detect potential issues in machinery before they lead to system failures. One important factor in vibration analysis is amplitude, which helps us understand how severe the vibrations are and whether there might be any mechanical issues. Amplitude is usually measured in terms of displacement (like micrometers or mils), velocity (millimeters per second or inches per second), or acceleration (g or millimeters per second squared). It's directly connected to the amount of mechanical stress the equipment is experiencing. In this study, we used analysis of variance (ANOVA) to design experiments, create a regression model, and run tests that looked at how the vibro motor's angle, its rotational speed, and the material's modulus of elasticity all work together to affect amplitude. We then optimized these factors to improve the vibro separator's flow rate performance

I. INTRODUCTION

Having a well-planned experimental design is key to successfully developing products and processes. It starts with a solid understanding of the system you're studying. In factorial designs, both the input (independent) and output (dependent) variables are carefully tested. After identifying the important factors, experiments are set up and analysed to find the best combination that gives the most favourable result. Optimization is at the heart of this process, aiming to choose the best possible outcome from several options. One popular approach to optimization is Response Surface Methodology (RSM) [1], [2]. This technique is widely used to design experiments, analyze data, and improve products or processes. RSM combines statistical and mathematical tools to build models and find the best operating conditions within a given range. It works especially well when multiple variables affect how a system performs. By using polynomial regression models, RSM helps us understand how the inputs relate to the outputs, allowing for fine-tuning of parameters and accurate prediction of results. This method also helps create reliable predictive models, makes experiments more repeatable, and supports ongoing process improvement. In today's industrial world, machines play a vital role in keeping operations running smoothly [3]. That's why regular and effective machine monitoring is essential—unexpected breakdowns can lead to significant financial losses for businesses. Litak and Friswell investigated the dynamics of gear systems, focusing on how irregularities and flaws in gear tooth geometry affect system stiffness. Ramchandra proposed several diagnostic approaches and concluded that the Shock Pulse Method (SPM) is effective in assessing machine condition, offering a cost-efficient alternative to replacement [4], [5]. Mantari, J. L., & Monge, J. C. comprehensive analytical study of buckling, free vibration, and bending behaviours of functionally graded (FG) sandwich plates subjected to mechanical loads [6] In a recent publication, the effort to forecast the optimal solutions for the amplitude value which ultimately utilised to enhance flow rate of the system.

II. COMPUTATIONAL MODEL AND DATA ANALYSIS

The core parts of a reciprocating vibro separator are the motor, which powers the machine; a connecting plate and rubber pads, which join the parts and absorb vibrations; a separator box to hold the materials; and an unbalanced mass that creates the shaking motion. These components are designed using parametric software and evaluated through a CAE program, as illustrated in figure 1(a). The parametric software is employed to develop the parts along with their respective dimensions. [7-10]

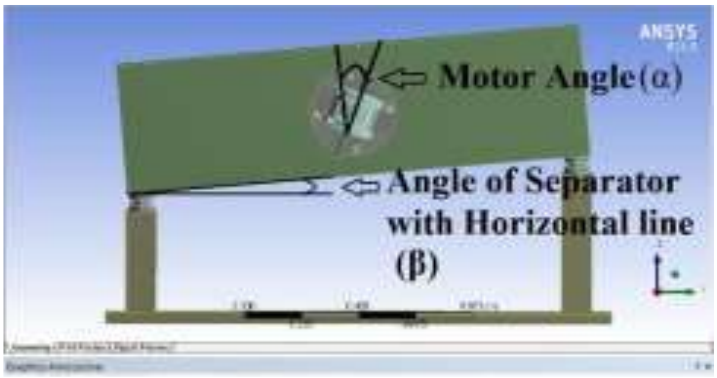

Figure 1(a): Indication of different angle
Source: Authors, (2026).

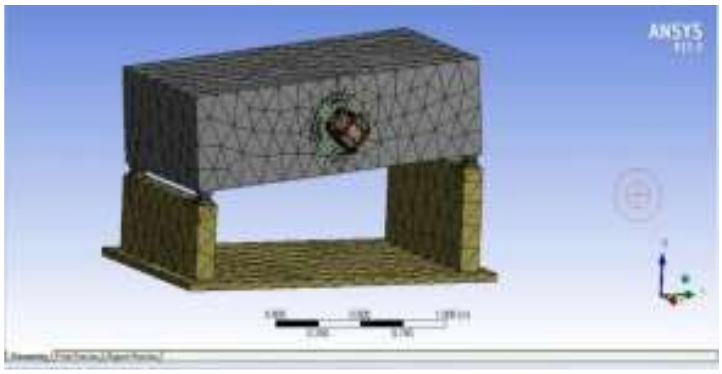

Figure 1(b): parametric model of vibro separato
Source: Authors, (2026).

The tetrahedral mesh type, as illustrated in figure 1(b), is employed for analytical purposes. The coarse mesh generation adopts a manually specified size of 120 mm for the separator box, while a default size is applied to the other sections. In total, the setup comprises 27,840 mesh elements, with 2,347 elements specifically in the foundation rubber. The mesh size of the box was increased from the default to minimize complexity and reduce the number of nodes, potentially accelerating the resolution process. The device features a total of 10 nodes. The connecting plate configuration analysed by the CAE tool is constructed from mild steel [11]. For the plates and separator boxes in our analysis, structural steel material is presumed to be utilized. The model has been validated against a computational model to collect further data for optimization purposes. The experimental work is conducted at GAJANAND Industries located in UNJHA. In this setup, the separator box features two motors attached to the side walls at the midpoint of the box's height. Each motor is connected to four unbalanced masses, each weighing 3.34 kg. A specialized sensor of the piezoelectric pickup type is utilized, functioning within a frequency spectrum of 1-10 kHz. The sensor with sensitivity of 107 mV/(m/s²), and it employs an integral electronics piezoelectric accelerometer (IEPE) input mode. The CoCo-analyser, manufactured by Crystal Instruments, is a device used for measuring and analysing vibration and other dynamic signals, including acceleration data as shown in figure 2 [12]. As shown in figure3(a),3(b),3(c) taking the various amplitude data by changing the modulus of elasticity (10MPa,25MPa,40MPa) for rubber pad with 1100rpm.comparing the experimental data with computational data as shown in table 1, we assume that the experimental amplitude value is nearer to the computational value.

Figure 2: Experimental set up

Computational model was verified using experimental data hence starting the computational data acquisition and altering the various number of design parameters like angle (28^0,30^0,32^0), speed (900,1100,1300), and modulus of elasticity (10MPa,25MPa,40MPa) was completed for getting amplitude value and process with the RSM method to achieve best optimised value of amplitude to achieve better flow rate.

Table :1 Computational Data.

III. SYSTEM ANALYSIS THROUGH RESPONSE SURFACE MODEL (RSM)

A practical and efficient approach to analyze the experimental study focused on statistical models of vibration responses in a vibro separator through Response Surface Methodology (RSM) is a specific form of factorial design. The RSM technique is employed to find the optimal solution for the amplitude by identifying viable solutions. To assess the simultaneous impacts of variables such as speed, motor angle, and the Modulus of Elasticity of rubber on amplitude, multiple trials are performed utilizing the ANOVA method. [3], [13]. The RSM was utilized in this study to execute the experimental design aimed at developing the regression model, as well as to conduct multiple trials to investigate the simultaneous effects of the parameters on amplitude.

Table 2: Design of Experiment Parameters.

IV. RESULTS AND DISCUSSION

In this research, input parameters such as Angle, Speed, Modulus of Elasticity, and their corresponding response in the form of Amplitude have been documented and presented in Table no.3. The Model F-value of 5.40 indicates that the model is significant. There exists only a 3.54% probability that an F-value of this magnitude could arise from random noise. P-values that are less than 0.0500 suggest that the model terms are significant. In this instance, Speed, Angle, and the combined effect of Speed and Angle have a greater impact on Amplitude. Therefore, Speed (A), Angle (B), and the combined effect of Speed and Angle (AB) are all significant model terms, indicating that they are influential parameters.

Table: 4 ANOVA for Quadratic Model.

Source	Sum of Squares	df	Mean Square	F-value	p-value	
Model	1.979E+05	18	10993.33	5.40	0.0354	significant

Source: Authors, (2026).

The factors were encoded using a specified coding scheme. The sum of squares was calculated using the Type II classical method. The model's F-value is 5.40, indicating that the model is statistically significant at the 3.54% significance level. This means there is only a 3.54% probability that an F-value this large could have occurred due to random chance or noise. Individual model terms with p-values less than 0.05 are considered significant, as is the case with factors A, B, and their interaction AB. Conversely, terms with p-values greater than 0.10 are deemed not significant. If the model contains many such insignificant terms—excluding those necessary to maintain model hierarchy—it may be beneficial to perform model reduction to improve model accuracy and interpretability. Figure 4 indicate that linearity is maintained hence the various values of amplitude for various runs is accurate and there is strong correlation between its actual and model's predicted values.

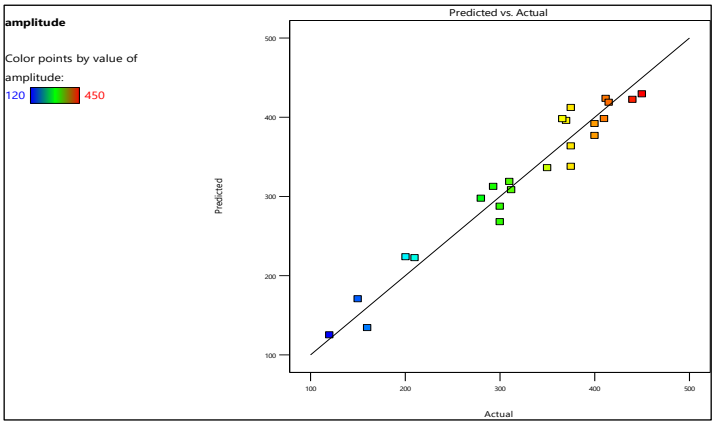

Figure 4: actual v/s predicted Graph
Source: Authors, (2026).

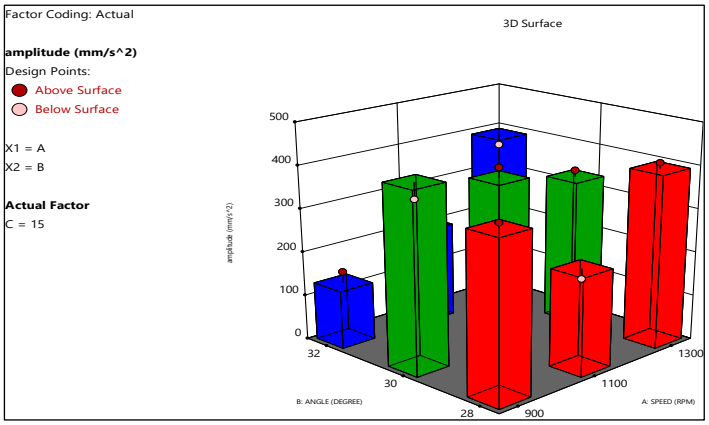

Figure 5: Speed v/s angle v/s amplitude
Source: Authors, (2026).

Figure:5 indicates that two parameters are more effective and the amplitude are achieved at 280 at 900 and 1300 RPM but at same time its reduced at 1100 RPM also for 300 values of amplitude decreases with increase in rpm.for 320 the value of amplitude increases with increase in rpm.

V. CONCLUSION

In the current study, the computational model has been validated against industrial data pertaining to the horizontal vibro separator. Using computational data, we can develop statistical models. The three-way interactions among various input factors, including Motor Angle, Speed, and modulus of elasticity, are analysed through ANOVA and the Response Surface Method, considering their individual and combined effects on amplitude, which is an output parameter, across all trials. The results of the survey lead to the following:

At 25 Mpa Modulus of elasticity the best solution is at 320 1300 RPM and 280 at 1100RPM and 900 RPM both.

ABSTRACT

To optimize operating parameters, this paper conducted a dynamic motion analysis of a reciprocating vibro separator. This work examined the impact of motor speed and angle to determine the vibro separator's flow rate. For the dynamic motion analysis, a CAD model of the device was created using parametric software. Then, it was analyzed using a CAE tool at three distinct motor angles and speeds. Various motor angles (28°, 30°, and 32°) and speeds (1,000 RPM) were used in the dynamic motion investigations. In order to determine if a system is in periodic, quasi-periodic, multi-periodic, or chaotic motion, Poincaré maps, FFT (fast Fourier transform), and TDR (time-displacement response) were employed. A sensitivity-based uniaxial piezoelectric sensor was used to gather experimental data from the agriculture industry. Additional parameter changes were made to the computational model after computational studies were verified using real-time industrial data.The outcome of the present research leads us to conclude that the most suitable motor angle and speed for a horizontal vibro separator are 28° and 1050 RPM, respectively.

I. INTRODUCTION

In the modern industrial landscape, technology plays a key role in minimizing labor costs and delivering efficient solutions. One such technology is the vibro separator, a machine designed to remove impurities from materials while maintaining a high flow rate. The performance of the vibro separator is strongly influenced by its dynamic characteristics. To manage vibrations, industries commonly employ rubber dampers. Research efforts have particularly emphasized the damping properties of rubber. For instance, proposed an approach to optimize the design of rubber elastic dampers by analyzing their dynamic mechanical behavior [1]. By developed a dynamic model for a rubber isolator by combining hyper elastic, viscoelastic, and elastoplastic models and forecasting the relationship between the vibration isolator's amplitude and frequency [2].

A recent study highlights the influence of altering the motor angle (α) and motor speed, while keeping other parameters unchanged, on the performance of a vibro separator. In this work, both experimental results and computational simulations are compared by systematically varying the motor angle (α) and motor speed. In this study, a computational model was created using parametric software. This computational model is validated using an existing industrial model based on input parameters such as the vibro motor angle (α), motor speed, and stiffness of the rubber pad. The dynamic failure of this computational model is checked for output parameters such as amplitude, dynamic motion behaviour, and velocity acceleration [3]. After the model is validated, the motor angle (α) and the speed of the vibro separator will be changed, and output data such as amplitude, dynamic motion behaviour, and flow rate will be gathered.

II. LITERATURE REVIEW

Propose a new type of vibrating screen that moves in a swing trace rather than a traditional linear motion, inspired by the motion of manual sieving for better screening performance [4]. Examined how pressure and temperature affect spring materials while considering static stiffness. This study assessed the connection between Young's modulus and rubber temperature, determining a quantitative correlation between the two.

Ultimately, the convexity correction method was found to be a more precise means of evaluating the static stiffness of a spring than the ellipse approximation method [5]. Proposes a new and improved structural design for vibrating screens that operate under very high loads (large material mass, strong vibrations, and harsh working conditions) [6]. Investigated the movement of the screen and determined that particle travel speed is highest during linear screening. They found that elliptical motion has better velocity and efficiency than other types of motion. Circular movement provides minimal velocity while maximizing screen efficiency [7]. Identified improved parameters for positioning the vibro motor to enhance the efficiency of the vibro screen. Their research analyzed different motion patterns, mainly classified as linear, circular, or elliptical.

The study focused on the placement of the exciter or vibro motor in relation to the screen's center of gravity. Based on this analysis, an optimized vibro screen design was proposed, which increases production rates without requiring additional power consumption [8]. Developed physical model to predict the transport velocity of a bed of crushed rock material moving along a vibrating screen with a circular stroke—an important parameter for understanding and optimizing screening performance such as bed thickness and capacity [9]. Explored the impact of vibro screen frequency and swing declination angle using DEM 3D simulations. Their research found that optimizing the frequency and corresponding angle of declination enhanced the simulated results of the vibro screen. The researchers proposed several empirical formulas through regression analysis as a final observation [10].

Investigates how vibration affects bulk granular materials, focusing on the dynamics of particle beds in industrial equipment like vibrating screens, feeders, and conveyors [11]. The researchers concluded that banana screening is more effective when the SDI increment is maintained between 100 and 50 [12], [13]. O paper investigates structural failure and sensitivity of a reconfigurable vibrating screen (RVS) used in mineral processing. The aim is to identify weak points, understand how different load conditions affect stress distribution, and propose design improvements.[14].The study explored the optimal operating speed of the vibro motor, identified within the range of 900–1,100 RPM, along with a separator box inclination of 5° relative to the horizontal. Monica Solding supported these findings by applying the Monte Carlo simulation technique for parameter optimization [9].

III. METHODOLOGY

III.1 COMPUTATIONAL ANALYSIS

A 3D CAD model of the reciprocating vibro separator was developed using parametric software, as illustrated in Figure 1, and analysed with a CAE tool. The primary components of the reciprocating vibro separator include: (1) vibro motor, (2) connecting plate, (3) rubber pad, (4) separator box, and (5) unbalanced mass. For the analysis, a tetrahedral mesh configuration was applied to the entire model. The mesh used for Analysis purpose is called tetrahedral shape type Mesh. Coarse mesh size was kept of 120 mm for separator box and for remain part it's default. Box mesh was taken to analyses rubber pad in model which led to generate total 27840 elements for entire model & 2347 elements for model of rubber foundation. Real time boundary conditions were applied to perform random -vibration analysis. Total 10 nods taken to reduce proceeding time and closer approximation of result.

Table 1: Effective Parameters of Reciprocating Vibro Separator.

Input Parameter	Output Parameter
Motor Angle (α)	Dynamic Motion Behavior
Motor Speed (RPM)	Amplitude, Flow rate
Foundation Rubber Properties	Flow rate

Source: Authors, (2026).

In this research work, From Table :1 Motor angle (α), Motor speed (RPM) are considered as a varying input parameter. For this varying input parameter, the dynamic motion behaviour and amplitude, flow rate is observed for Reciprocating vibro separator.

IV EXPERIMENTAL ANALYSIS

The experimental study was carried out at an operating speed of 1,000 RPM using two vibro motors, mounted on either side of the separator. Each motor had a power rating of 0.5 HP with a speed variation of ±20 RPM. Data acquisition was performed at GAJANAND Industries within the speed range of 980–1,020 RPM and at a motor angle of 30°. The detailed specifications of the experimental setup are presented in Table 2.

Table 2: Specification of reciprocating vibro separator.

Component	Weight (Kg)	Material
Separator Box	505.63	Structural steel
Plate	6.37	Structural steel
Foundation Rubber	0.335	Rubber
Each Motor without Unbalanced mass	35.91	Gray cat iron

Source: Authors, (2026).

Figure 2: Experimental Setup.
Source: Authors, (2026).

Real-time data was gathered from a vibro separator installed at Gajanand Industries, Siddhapur, Gujarat. As illustrated in Fig. 2, two vibro motors were mounted on opposite sides of the divider wall, each equipped with two unbalanced masses. The combined imbalance weight was measured at 3.34 kg. Data acquisition was performed at three distinct points on both sides of the separator. A uniaxial vibration sensor with a piezoelectric sensitivity of 1.02 mV/(m/s²) was employed, operating in IEPE input mode within the 1–10 kHz frequency range. The collected real-time data was subsequently analyzed and presented in a clear and accessible format

V. RESULTS AND DISCUSSION

From the Poincaré plots shown in Figure 2 for both experimental and computational results, it can be inferred that the computational model with a motor angle of 30°, a motor speed of 1,000 ± 20 RPM, and a foundation stiffness of 100 N/mm closely matches the behavior of the experimental vibro separator. Therefore, the computational model under these parameters demonstrates strong agreement with the experimental findings.

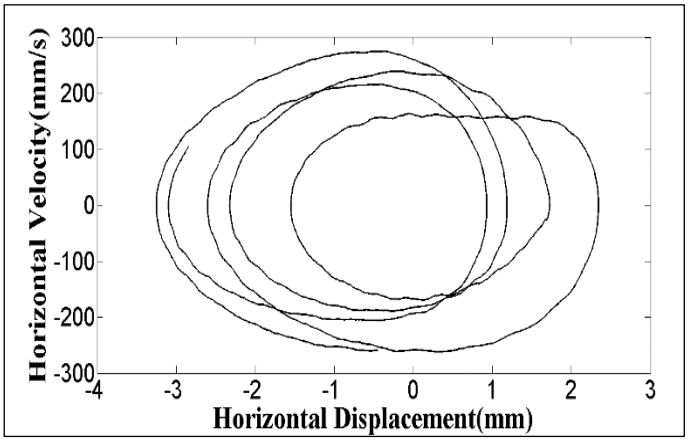

Figure 3(a): Computational Poincaré @ 100 N/mm stifness withHorizontal responses.
Source: Authors, (2026).

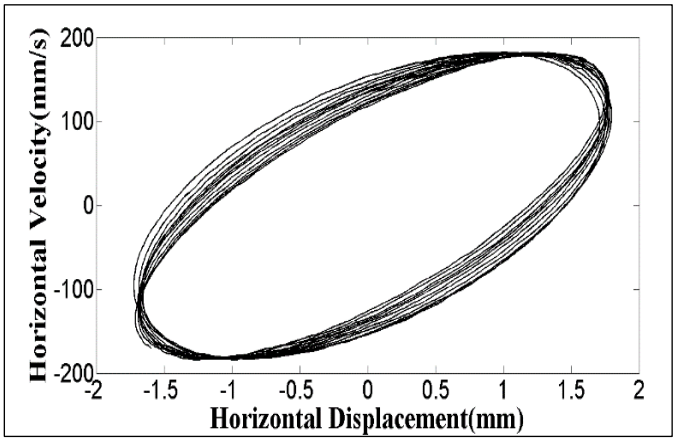

Figure 3(b): Experimental Poincaré @ 100 N/mm stifness with Horizontal responses.

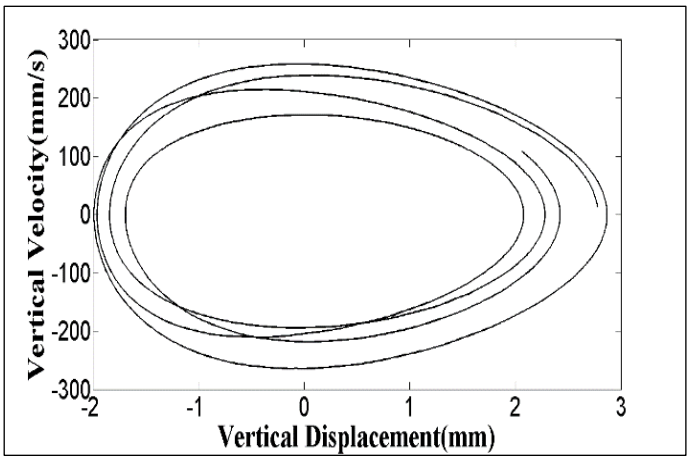

Figure 3(c): Computational Poincaré @ 100 N/mm stifness with Vertical responses.
Source: Authors, (2026).

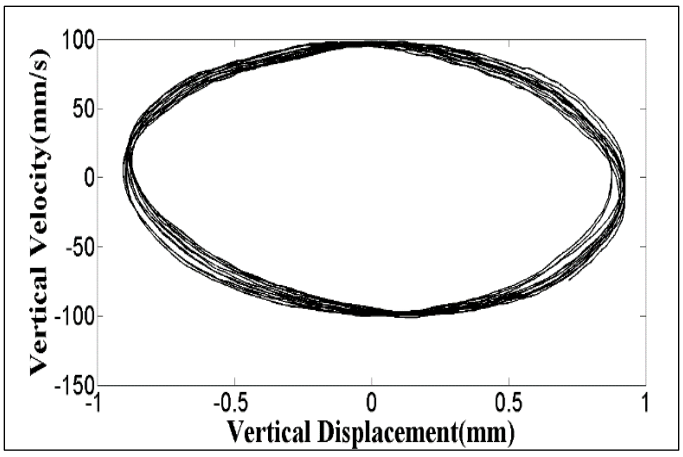

Figure 3(d): Experimental Poincaré @ 100 N/mm stifness with Vertical responses.
Source: Authors, (2026).

According to figure 3 (a-d) We verified the computational model by comparing the computational data with the experimental data and by looking at the TDR, FFT, and Poincaré chart. The validated computational model will use to achieve acceleration (mm/s2), displacement (mm), and velocity (mm/s2) for different motor angle (α), motor speed for both horizontal and vertical directions. The values are shown in Table3. As per Table 4 we are comparing the amplitude data for the different motor angle(α), with same motor speed(1000RPM) for better flow rate. Table 5 helps to compare the Dynamic motion behaviour with different Motor angle(α), with same motor speed(1000RPM).

Table 3: Computational data at different motor angle.

Angle (degree)	Speed (rpm)	Acceleration (mm/s^2)		Displacement(mm)		Velocity(mm/s^2)	
		Horizontal	vertical	horizontal	vertical	horizontal	vertical
28	1000	$-5.6X10^4$	$6X10^4$	-4.2	-4.3	-300.5	378
	1050	$3.9X10^4$	$4.5X10^4$	6.5	-6.4	300	-400
	1100	$-5X10^4$	$4X10^4$	-3.3	2.7	-200.9	200.5
30	1000	$2.8X10^4$	$1.5X10^4$	1.7	0.8	100.9	100
32	1000	$-5.6X10^4$	$3.9X10^4$	-6.8	6.6	-300.9	300
	1050	$3X10^4$	$-3.9X10^4$	-6.8	6.6	-300.9	300
	1100	$-5X10^4$	$1.5X10^4$	-4.3	-4.1	300.2	400

Source: Authors, (2026).

Table 4: Comparison of amplitude and dynamic motion behaviors data.

Data	Angle(degree)	Speed (rpm)	Amplitude (mm)	Dynamic motion
Computational	28	1000	4.5	Multi periodic
Computational	30	1000	1.75	Multi periodic
Computational	32	1000	4.3	Multi periodic

Source: Authors, (2026).

Based on study of above table no 4, we had found that motor angel 280 and 320 are optimized nearby value for better amplitude and effective dynamic motion behaviour. Amplitude value at motor angle 28° is higher than the motor angle 30° and 320. So, flowrate calculation is preferred for motor angle 28° compared to motor angle 300 and 32°. For flow rate calculations following equation is used which is mentioned in the equation 1.

$$\text{Flow rate of grain } (Q) = \rho * A * v \quad (1)$$

Here, it is assumed that grains are have uniform geometry which mean constant area and all grains are homogeneous in nature which led to conclude the constant density of grain. It means that velocity of grain flow is effective parameter to improve production rate of system. For calculating the flow rate computationally using different velocities for three different speeds as per table 3 use the equation mentioned as below as per equation 2. consider the flow rate experimentally as 4 tons per hour.

$$Q1/Q2 = V1/V2 \quad (2)$$

In above equation Q1 is flow rate of experimental, Q2 is flow rate of computational for different speed, v1 is velocity of grain at 300 angle and v2 is velocity of grain at 280 angles with three different speeds.

Table 5: Computational Data of Reciprocating Vibro Separator at 28º.

Angle (degree)	Speed(rpm)	Flow rate (tons per hour)	Dynamic motion
28	1000	14.99	Multi periodic
28	1050	15.86	Multi periodic
28	1100	7.9649	chaotic

Source: Authors, (2026).

As we know as the velocity increases the flow rate also increase but from the above Table 5 it has been observed that chaotic dynamic motion behaviour also plays vital role so at 280 angle and speed of 1100 the flow rate decreases. Hence at 280 angle and 1050 rpm the flow rate is maximum.

VI. CONCLUSION

In present work, a computational model has been developed for reciprocating vibro-separator. Dynamic motion analysis has carried out along with vibration responses of system. Overall computational data has validated with industrial data before proceed for further alteration. After validating computational model, significant parameters have altered to evaluate maximum flow rate with better dynamic motion of system. Hence major outcome of present work has concluded as follows:

(1) As per computational model analysis we had found higher amplitude when motor angle is 28^0 and 32^0. If we compare computational analysis and investigational data then we will get higher amplitude and better dynamic motion in case of motor angle 28^0 and motor speed 1000 rpm and 1050 rpm.

(2) The study reveals that the reciprocating vibro separator achieves a higher flow rate when operated at a motor angle of 28° with a speed of 1,050 RPM. Similarly, improved flow performance is also observed at the same motor angle (28°) with a motor speed of 1,000 RPM. The preferred motor speed is between 1000 and 1050 rpm as opposed to 1100 rpm, based on a higher flow rate at a motor angle of 28°. Additionally, analysis shows that the reciprocating vibro separator's flow rate is higher at motor angles of 28° than 30°.We will suggest the industry to set the motor angle 28^0 and motor speed 1000 or 1050 rpm to obtain the higher flow rate.

Present work will be useful for vibro-separator manufacturer to develop efficient and cost-effective product development. This work will be also useful for end user to operate present installed system with optimize parameters.

$NiFe_2O_4$/Cu-1 and $NiFe_2O_4$/Cu-2;
Synthesis; Characterization;
Electrochemical study.

ABSTRACT

Ferrite-based materials have been studied for the electrode materials for supercapacitors because of their low cost and rapid, reversible surface Faradaic reactions. In this study, we have developed two electrode materials named $NiFe_2O_4$/Cu-1 and $NiFe_2O_4$/Cu-2. The fabrication method was found to be inexpensive, effective, and efficient. The synthesized materials were analyzed via FTIR, XRD, SEM, and TEM methods. FTIR results indicated the presence of O-H, C-H, C-O, Ni-Fe, Fe-Cu, Cu-O, etc. bonds on the surface of these materials. The XRD patterns indicated the amorphous nature of $NiFe_2O_4$ and the semi-crystalline nature of $NiFe_2O_4$/Cu-1 and $NiFe_2O_4$/Cu-2. The SEM analysis indicated that the particles are semi-spherical, and some are irregular in $NiFe_2O_4$. The sphere-shaped particles were observed in the case of $NiFe_2O_4$/Cu-1 and $NiFe_2O_4$/Cu-2, respectively. The electrochemical study has been conducted using different electrochemical parameters. The $NiFe_2O_4$/Cu-2 exhibited a power density of 4992 W/kg, an energy density of 5.9 Wh/kg, a retention of 91.3%, and a specific capacitance of 222 F/g. It was additionally found that the $NiFe_2O_4$/Cu-2 was appropriate for device systems with a 42 F/g specific capacitance (under a 2-electrode system).

I. INTRODUCTION

Green energy sources offer affordable, renewable energy alongside lowering greenhouse gas emissions and promoting economic growth. Energy storage technology is a sustainable way to achieve the goal of a net-zero carbon footprint and a green energy transition. This technology promotes the reduction of the emission of greenhouse gases. Energy storage mitigates the fundamental fluctuation of renewable energy, manages high demand periods, and allows the integration of small-scale systems[1]. To maintain system frequency and voltage, smooth power, and provide fault ride-through assistance, energy storage has been considered to be a revolutionary solution for the integration of variable renewables [2]. One of the main solutions to the energy challenges facing our civilization is electrical energy storage. The most common rechargeable electrochemical energy storage systems include metal-air batteries, lithium-ion batteries, supercapacitors, and sodium-ion batteries, which are utilized in different electronic gadgets and transportation[3].

Supercapacitors offer many advantages, such as long life, efficient charge and discharge, high power density, flexibility, and lightweightness. Studies are going on for the development of efficient and low-cost electrode materials. The green energy goals need environmentally friendly, durable, and electrochemically efficient electrode materials[4], [5]. The choice of electrolytes for supercapacitors also affects the electrochemical parameters. The choice of electrolyte depends on the application and performance requirements. The aqueous electrolytes, such as KOH, have high ionic conductivity, decrease the internal resistance, are low-cost, and are suitable for large-scale systems. This type of electrolyte promotes rapid charge-discharge cycles and power density[6], [7]. Electrode materials for supercapacitors must have high electrical conductivity, excellent electrochemical stability, and large surface area and porosity. Some common electrode materials include carbon-based, metal- and metal-oxide-based, conducting polymers, and hybrid materials of all of these[8].

The term "ferrite," which comes from the Latin word "ferrum," refers to ceramic compositions where iron oxide is combined with other metals. Since ferrites are ferrimagnetic, a magnetic field may readily attract them[9]. These materials have been used in solar energy devices, batteries, supercapacitors, biomedicals, electronic devices, and magnetic fluids [10], [11]. Low magnetic loss, high magnetic permeability, and moderate coercivity are some of the outstanding magnetic properties of $NiFe_2O_4$ that have generated attention for applications in electronics, sensors, energy storage systems, and telecommunications [12]. In nickel ferrite (NiFe2O4), nickel and iron cations partially occupy a face-centered cubic lattice of oxygen atoms with interpenetrating tetrahedral and octahedral sites. This separation allows adjustable magnetic characteristics. Doping with foreign metals affects the magnetism of the material via altering cation occupancy and interactions[13]. The materials based on $NiFe_2O_4$ shows high electrochemical stability and efficiency and are found suitable for supercapacitors[14]. Cu-based materials have also been recognized for their low cost, efficiency, and outstanding electrochemical performances. They can effectively be utilized in the development of hybrid electrode materials for supercapacitors[15]. The characteristics such as non-toxicity, easy preparation, and outstanding optical, electrochemical, and electric properties make them potential candidates for the supercapacitors[4]. Copper (Cu) significantly improves the electrochemical performance of supercapacitors. The remarkable redox potential, high electrical conductivity, and unique structural features of Cu enhance the supercapacitive performance of electrodes. Cu-based materials are capable of enhancing charge transfer and redox behavior and lowering electrical resistance. These materials are also able to boost cyclic stability and specific capacitance[15], [16].

Similar work has been done by other researchers in the recent past. The electrochemical potential of a nanocomposite based on Ni/$CoFe_2O_4$/MXene for supercapacitors was reported by Infancy et al.[17]. A 1 M KOH solution was used for the electrochemical investigation. Ni/$CoFe_2O_4$ and Ni/$CoFe_2O_4$/MXene samples showed specific capacitances of 361 C/g and 367 C/g, respectively. The supercapacitive performance of a nanocomposite based on cobalt ferrite ($CoFe_2O_4$) and polyaniline (PANI) was investigated by Mandal and Dasmahapatra[18]. With a good cyclic life (~91% retention after the 1500 cycles), the supercapacitor electrode demonstrated a maximum specific capacitance of 460.1 F/g at 0.5 A/g. The electrochemical potential of $MnFe_2O_4$ using multiple electrolytes, including 1 M $LiNO_3$, 1 M Li_3PO_4, and KOH, was reported by Vignesh et al.[19]. Maximum specific capacitances of 173, 31, and 430 F/g were achieved in a three-electrode setup, which corresponded to electrolytes of 3.5 M KOH, 1 M $LiNO_3$, and 1 M Li_3PO_4, respectively. Also, at the high current density of 1.5 A/g, the specific capacitance of 105% was maintained after 10,000 cycles, and the coulombic efficiency of all 10,000 cycles stayed constant, indicating the exceptional electrochemical durability of $MnFe_2O_4$. $MnFe_2O_4$/rGO nanocomposite for supercapacitors was reported by Shih and Tseng[20]. A high specific capacitance of 196.6 F/g at 0.5 A/g was evaluated, and 90.22% of the capacitance was retained after 6000 cycles. The synergistic effects of rGO and $MnFe_2O_4$ contributed to the improved performance. In the present work, we have improved the electrochemical performances of $NiFe_2O_4$ after incorporating it with Cu. The achieved outstanding electrochemical ability of Cu-blended $NiFe_2O_4$ makes them promising candidates for electrode material of supercapacitors.

II. MATERIALS AND METHOD

All chemicals used were of AR grade. These chemicals were purchased from Merck, SRL, and LOBA. In this work, potassium hydroxide (KOH), sodium hydroxide (NaOH), lithium nitrate (LiNO3), lithium phosphate (Li3PO4), copper acetate [Cu(CH3COO)2], nickel nitrate [Ni(NO3)2], ferric nitrate [Fe(NO3)3], polyvinylidene fluoride (PVDF), N-methyl-2-pyrrolidone (NMP), and acetone (CH3COCH3) were used.

II.1 SYNTHESIS OF $NIFE_2O_4$, $NIFE_2O_4$/CU-1, AND $NIFE_2O_4$/CU-2

Dissolve Ni(NO3)2 and Fe(NO3)3 in distilled water in a ratio of 1:2 and shake the mixture for 35 min. Add 0.5 g of citric acid to this mixture and allow it to shake for 35 min. Then a few drops of 0.1 M NaOH were added, and the mixture was stirred for 1 h. After centrifugation, the $NiFe_2O_4$ was collected and dried in a hot air oven. The obtained $NiFe_2O_4$ was calcined at 650°C for 3.5 h. Now 100 and 200 mg of Cu was added to 1 g of $NiFe_2O_4$ using $Cu(CH_3COO)_2$. These amounts have been calculated stoichiometrically. The obtained mixtures were crushed for 1 h and then sonicated with distilled water for 2h. The obtained mixtures have also been calcined at 6500C for 3.5 h. Finally, $NiFe_2O_4$/Cu-1 (100 mg Cu) and $NiFe_2O_4$/Cu-2 (200 mg Cu) were obtained for characterization and electrochemical studies. The overall synthetic method is presented in Figure 1.

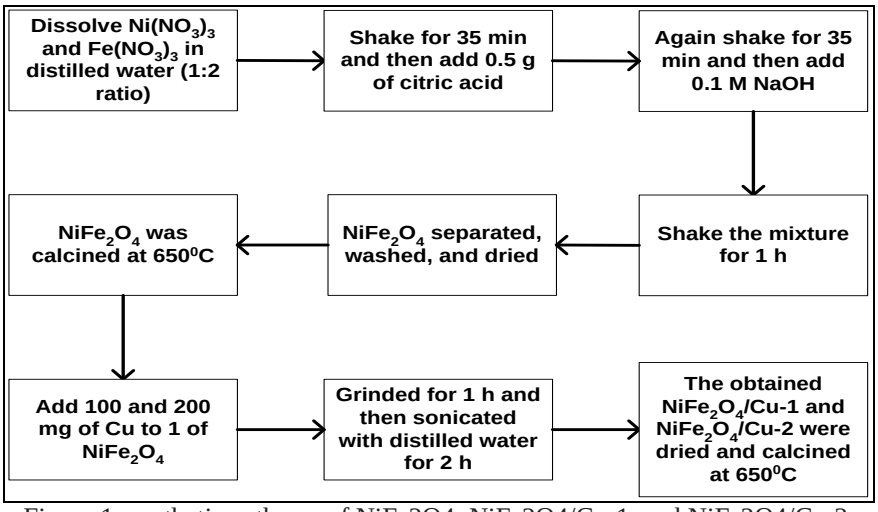

Figure 1: synthetic pathway of NiFe2O4, NiFe2O4/Cu-1, and NiFe2O4/Cu-2.

II.2 CHARACTERIZATION OF $NIFE_2O_4$, $NIFE_2O_4$/CU-1, AND $NIFE_2O_4$/CU-2

The characterization of $NiFe_2O_4$/Cu-1 and $NiFe_2O_4$/Cu-2 was done using FTIR (Fourier transform infrared spectroscopy; Model: Thermo Scientific Nicolet Summit Lite), XRD (X-ray diffraction; Model: Rigaku), SEM (Scanning electron microscopy; Model: Carl Zeiss EV018), and TEM (Transmission electron microscopy; Model: Talos L120C) techniques. The basic description these methods is given as below:

FTIR

FTIR is an advanced and high-precision instrument and is generally used to detect the presence of different chemical bonds or functional groups on the surfaces of molecules or nanomaterials. It enables the identification of molecules with different infrared spectra by focusing on atomic vibrations[21].

XRD

XRD is widely used for the characterization of nanomaterials. The characteristics of the material, such as strain, crystallite size, and crystal structure, are easily determined. The crystalline structure of a material is determined by utilizing Bragg's law and a detector to examine interference caused by atoms scattering X-rays[22].

SEM

SEM is used to provide morphology of nanomaterials. This technique uses an electron beam with an acceleration of up to 30 kV to study the surface of a material. In order to create an image, detectors collect the signals that the specimen emits. Information about composition and topography is provided by backscattered electrons[23].

TEM

TEM allows for imaging at the nanoscale and sub-nanometer scale by interacting with ultra-thin specimen layers on a copper grid using a high-energy electron beam[24].

II.3 ELECTROCHEMICAL STUDY

The electrode slurries of $NiFe_2O_4$/Cu-1 and $NiFe_2O_4$/Cu-2 were prepared by mixing 80 mg of $NiFe_2O_4$/Cu-1 or $NiFe_2O_4$/Cu-2, 10 mg of PVDF, and 10 mg of carbon black in NMP. These slurries were coated over Ni-foam and then allowed to dry for 6 h at 80°C. The electrochemical study of $NiFe_2O_4$/Cu-1 and $NiFe_2O_4$/Cu-2 was conducted using Ag/AgCl, Pt, and working electrodes in 1M KOH solution. The different electrochemical parameters, such as cyclic voltammetry (CV), capacity retention, GCD (Galvanostatic charge-discharge) , and EIS (Electrochemical impedance spectroscopy), have been used. The specific capacitance of $NiFe_2O_4$/Cu-1 and $NiFe_2O_4$/Cu-2 was evaluated using the following equation:

$$C = I\Delta t/m\Delta V \quad (1)$$

In this equation, I, m, ΔV and Δt are current, mass of active materials, voltage difference and discharge time. The other important parameters such as energy (E) and power (P) densities have also been evaluated via following equations:

$$E\ (Wh/kg) = 0.5\ CV2/3.6 \quad (2)$$

$$P\ (W/kg) = E \times 3600/t \quad (3)$$

III. RESULTS AND DISCUSSION

III.1 CHARACTERIZATION OF $NIFE_2O_4$, $NIFE_2O_4$/CU-1, AND $NIFE_2O_4$/CU-2

NiFe2O4/Cu-1 and NiFe2O4/Cu-2 were analyzed using FTIR, SEM, TEM, and XRD techniques. The FTIR spectra of NiFe2O4, NiFe2O4/Cu-1, and NiFe2O4/Cu-2 are shown in Figure 2. The important FTIR peaks at 3351, 1763, 1568, 1382, 1062, and 658 cm^{-1} were assigned for $NiFe_2O_4$. The peaks at 3351 and 1568 cm^{-1} were assigned for the O-H bond (stretching and bending). The peak at 1763 cm^{-1} was assigned for C=O (absorbed CO_2). The FTIR peak of 1382 cm^{-1} is due to the C-O (asymmetric) bond. Other peaks at 1060 and 658 cm^{-1} are associated with Ni-Fe, Fe-O, Ni-O, etc. bonds[25], [26], [27]. The important FTIR peaks of $NiFe_2O_4$/Cu-1 were assigned as 3452, 2880, 1527, 1139, and 579 cm^{-1}. These peaks all reveal the presence of O-H, C-H, C-O, Ni-Fe, Fe-Cu, etc. bonds. Similarly, the FTIR peaks of 3425, 2897, 1377, 1086, 879, and 593 cm^{-1} were assigned for $NiFe_2O_4$/Cu-2. These peaks are also revealing the presence of O-H, C-H, C-O, Ni-Fe, Fe-Cu, Cu-O, etc. bonds[25], [26], [28], [29], [30], [31].

XRD patterns of $NiFe_2O_4$, $NiFe_2O_4$/Cu-1, and $NiFe_2O_4$/Cu-2 are depicted in Figure 3. These patterns show that NiFe2O4 is amorphous, while NiFe2O4/Cu-1 and NiFe2O4/Cu-2 are semi-crystalline. The important XRD peaks of $NiFe_2O_4$ were assigned at 2 θ = 30.10 (111), 35.60 (220), 38.70 (222), 43.50 (400), 56.20 (511), 57.40 (511), and 62.70 (440) [32], [33]. The XRD peaks of $NiFe_2O_4$/Cu-1, and $NiFe_2O_4$/Cu-2 were assigned at 2 θ = 30.50 (111), 35.80 (220), 38.70 (222), 43.50 (400), 49.10 (-202), 53.70 (020), 57.50 (511), 61.80 (-113), 62.70 (440), 66.20 (-311), and 68.20 (220), respectively[25], [34], [35], [36], [37], [38]. The morphological features of $NiFe_2O_4$, $NiFe_2O_4$/Cu-1, and $NiFe_2O_4$/Cu-2 were analyzed using SEM technique. Figure 4 depicts the SEM images of $NiFe_2O_4$, $NiFe_2O_4$/Cu-1, and $NiFe_2O_4$/Cu-2. In case of $NiFe_2O_4$, some particles are semi-sphere and some are irregular. After incorporation with Cu, the particles become sphere-shaped. The TEM images (Figure 5) of $NiFe_2O_4$/Cu-2 are also revealing the sphere-shaped particles having average particle size 23.5 nm.

The above-mentioned findings of FTIR and XRD clearly indicate the presence of different main chemical bonds and the nature of the synthesized materials. These techniques provide feasibility of synthetic methods and actual formation of materials. SEM and TEM methods also reveal the actual morphology of $NiFe_2O_4$, $NiFe_2O_4$/Cu-1, and $NiFe_2O_4$/Cu-2.

III.2 ELECTROCHEMICAL STUDY OF $NIFE_2O_4$, $NIFE_2O_4$/CU-1, AND $NIFE_2O_4$/CU-2

The CV, GCD, and EIS methods were used to analyze the electrochemical behavior of each of these materials. All of these electrochemical parameters are discussed below.

CV

CV is a widely used electrochemical technique for electrode behavior. Static electrode potential is applied at a constant scanning rate throughout CV measurement, and an electron transfer at the active reaction site is used to create a current-potential plot[38], [39][40]. Figure 6 illustrates the CV curves of $NiFe_2O_4$, $NiFe_2O_4$/Cu-1, and $NiFe_2O_4$/Cu-2 under 3 and 2-electrode systems. The CV curves have been obtained at the scan rates of 10, 20, 30, 50, 75, and 100 mV/s. All CV curves have a nearly rectangular shape, which indicates ideal capacitive behavior. Additionally, it shows that an electrical double layer is forming at the electrode-electrolyte interface. The CV curves at various scan rates exhibit a nearly similar rectangular shape, indicating the stability of materials under selected potential windows[41]. The study indicates that as the scan rate increases, the capacitive behavior decreases, indicating that charge dispersion is the primary cause of storage[42]. Similar observation was reported by Al Kiey et al. [43]for the CoFe2O4, CuFe2O4 and Co/CuFe2O4 at the scan rates of 5, 10, 25, 50, 100, and 200 mV/s. Salama et al.[44] also reported similar observations for MgFe2O4 supported on activated carbon at the scan rates of 5, 10, 20, 30, and 50 mV/s, respectively.

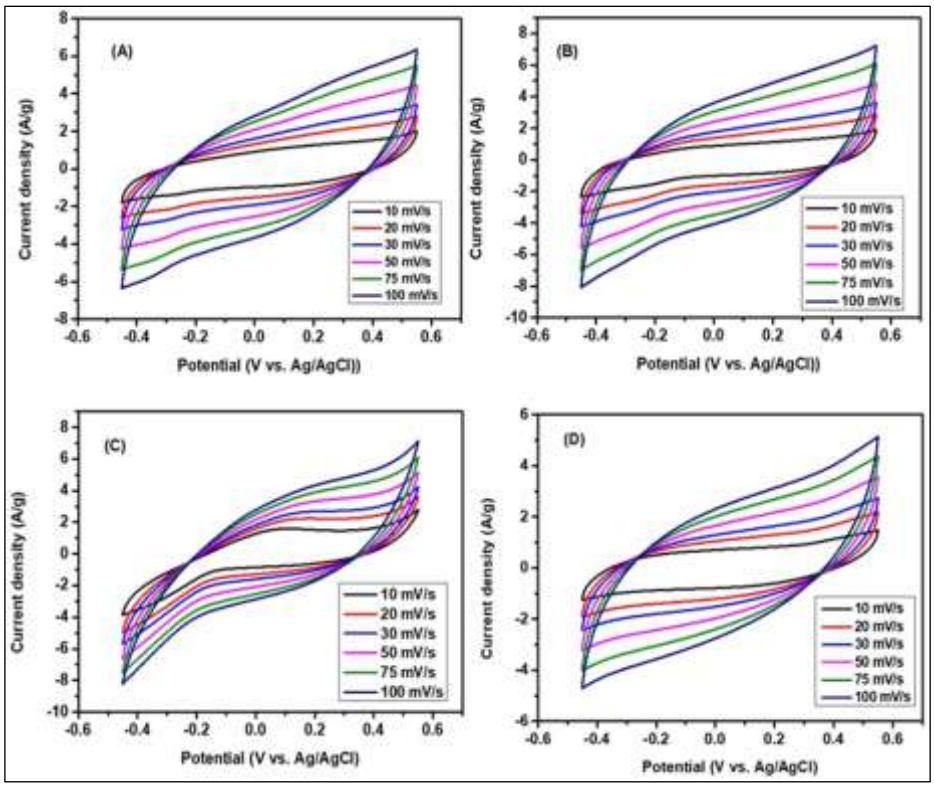

Figure 6: CV curves of (A) NiFe2O4 (under 3-electrode) (B) NiFe2O4/Cu-1 (under 3-electrode) (C) NiFe2O4/Cu-2 (under 3-electrode), and (D) NiFe2O4/Cu-2 (under 2-electrode).
Source: Authors, (2026).

GCD

GCD curves are important parameters for observing the discharge time, retention, and efficiency of electrode materials. The discharge time is directly proportional to the specific capacitance of supercapacitors. The power and energy densities of supercapacitors are also evaluated using GCD curves[42], [45]. The GCD curves of of $NiFe_2O_4$, $NiFe_2O_4$/Cu-1, and $NiFe_2O_4$/Cu-2 under 3 and 2-electrode systems are presented in Figure 7. The GCD curves of $NiFe_2O_4$ are nearly linear and indicating the accumulation of ions at junction of electrode and electrolyte[45]. The small deviation from linearity ($NiFe_2O_4$/Cu-1, and $NiFe_2O_4$/Cu-2) indicates the involvement pseudocapacitive contribution during faradaic reactions[46], [47]. The specific capacitance of $NiFe_2O_4$ was found to be 80, 44, 30.6, 7.6, and 5.2 F/g at the current densities of 2, 4, 6, 8, and 10 A/g. These values increased to 122, 60, 37.8, 18.4, and 18 F/g in the case of $NiFe_2O_4$/Cu-1. At the same current densities, the specific capacitance of $NiFe_2O_4$/Cu-2 was found to be 222, 88, 40.2, 36.8, and 18.6 F/g (Figure 8A). Huynh et al.[48] also reported the similar trend of decrease of specific capacitance of CuFe2O4-based electrode materials at current densities of 0.02, 0.05, 0.1, 0.25, and 0.5 A/g. Kumar et al.[40] also reported the specific capacitance of 295.5, 111.2, 73.3, 71.1, and 33.3F/g for CoFe2O4/Ppy at the current densities of 2, 4, 6, 8, and 10 A/g, respectively.

The specific capacitance of $NiFe_2O_4$/Cu-2 under the 2-electrode system was evaluated to be 42, 24, 18, 16, and 14.5 F/g at the same current densities (Figure 8B). The energy densities of $NiFe_2O_4$/Cu-2 were found to be 5.9, 3.4, 2.5, 2.3, and 2.08 Wh/kg at power densities of 499.9, 1999.8, 3000, 4015.8, and 4992 W/kg, respectively (Figure 8C). The actual efficiency of supercapacitors throughout multiple GCD cycles depends on the cyclic stability of the electrode materials. Several aspects, including redox reversibility, chemical stability, and the structural characteristics of selecetd materials, have a substantial impact on cyclic stability. Materials that are susceptible to irreversible reactions or volume changes frequently deteriorate rapidly. Cu-based materials have high conductivity and reversible redox activity. They provide reliable and effective electrodes when mixed with other substances [15], [16]. $NiFe_2O_4$/Cu-2 was run for 5000 GCD cycles under a 2-electrode system. Retention was found to be 96.7% after the first 500 cycles, which increased to 95.8% after 1500 cycles. After 2500 cycles, retention was achieved to be 94.7%, and it remained 92.8% after 4000 cycles. After 5000 cycles, retention was achieved to be 91.3% (Figure 8D). The comparison of $NiFe_2O_4$/Cu-2 with other electrode materials is shown in table 1.

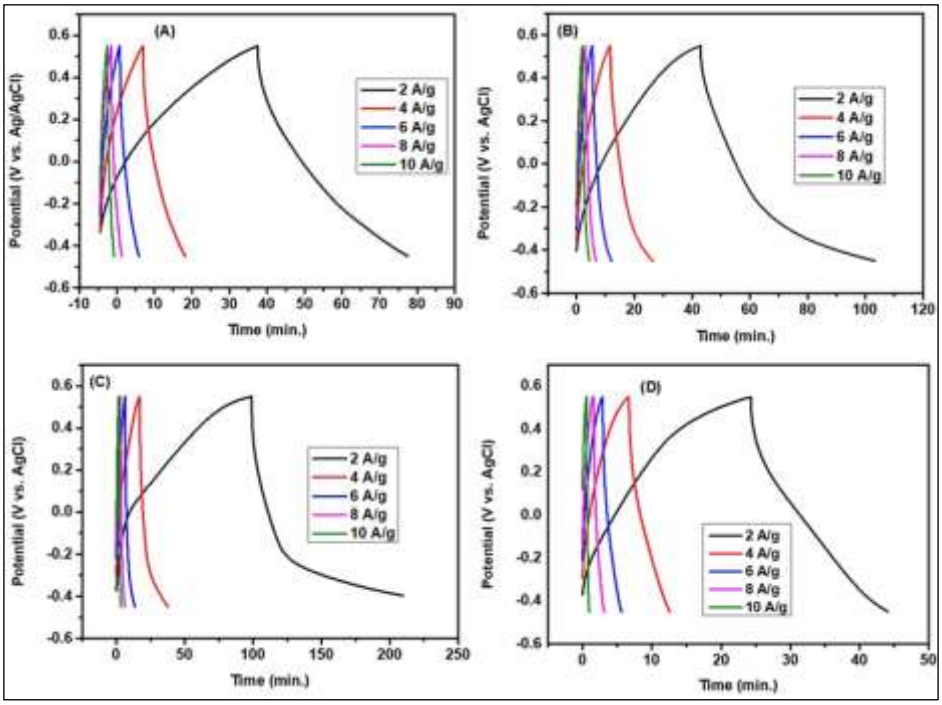

Figure 7: GCD curves of (A) NiFe2O4 (under 3-electrode) (B) NiFe2O4/Cu-1 (under 3-electrode) (C) NiFe2O4/Cu-2 (under 3-electrode), and (D) NiFe2O4/Cu-2 (under 2-electrode).

EIS

Exploring the electrode characteristics of batteries and supercapacitors needs the use of EIS. Furthermore, EIS is utilized in the investigation of corrosion, sensors, and various material properties. [54], [55]. In this study, Nyquist and Bode's curves have been investigated to find out the electrochemical characteristics of $NiFe_2O_4$/Cu-2. A Nyquist plot helps analyze the behavior of a supercapacitor by visualizing its complex impedance at various frequencies. The Nyquist curve of $NiFe_2O_4$/Cu-2 is shown in Figure 9 A. This curve shows the ideal capacitive behavior of selected electrode material[56]. This curve indicates the unique charge-transfer process between the electrode and electrolyte[57]. Bode's curves (Figure 9B) examine the features of impedance in electrochemical systems and demonstrate that resistive components allow impedance to become constant at high frequencies. Bulk electrolyte, electrode features, and interface resistances also contribute to this resistance. Understanding these elements is essential for enhancing device reliability and material design[39], [57], [58].

IV. CONCLUSION

The primary objectives of energy storage in the future are to increase sustainability, capacity, and efficiency. Supercapacitors provide fast charge/discharge, stability, and a high-power density, making them promising energy storage devices. Future advancements in electrode materials for supercapacitors are expected as researchers continue to explore and develop more sophisticated and high-performance materials. Ferrite-based materials have a lot of potential as supercapacitor electrode materials due to their inexpensiveness, environmental friendliness, and multiple oxidation states. With an energy density of 5.9 Wh/kg, a specific capacitance of 222 F/g at 2 A/g, and 91.3% retention after 5000 cycles under a 2-electrode system, the developed $NiFe_2O_4$/Cu-2 showed enhanced electrochemical capabilities. The important characteristics of NiFe2O4/Cu-2 have also been investigated using different characterization techniques such as FTIR, XRD, SEM, and TEM, respectively. The specific capacitance under the 2-electrode system was found to be 42 F/g, and the NiFe2O4/Cu-2 was also found to be a promising material for the device system.

V. ACKNOWLEDGEMENT

We are thankful to Department of Chemistry, Graphic Era (Deemed to be University), and Division of Research and Innovation, Uttaranchal University, Dehradun (India) for the support and encouragement.

ABSTRACT

Blockchain has evolved a lot in the context of digital transformation as it is decentralized and accessible. However, it has become extremely difficult to keep sensitive data secure in cloud storage and distributed systems. Traditional methods didn't do a good job of controlling who could access data, and there was a rik of unauthorized access, especially in centralized cloud systems, which raised concerns about data security and privacy. This study suggested an Improved Elliptic Curve Cryptography-based Quantum Key Distribution (IECC-QKD) framework that uses a blockchain system to protect data exchange and access control mechanisms in order to reduce security risks. The Edwards curve and binary randomness are both used in the IECC to make sure that the encryption and sensitive data participated on the cloud are safe from tampering. The QKD-based secure key uses quantum mechanics to keep the data safe from unauthorized access by making it impossible to tamper with. The new Proof of Storage (PoSt) consensus mechanism in the Ethereum blockchain also combines the best parts of Proof of Space (PoS) to store and prove the integrity of the data while using as few resources as possible.

I. INTRODUCTION

As digital infrastructures become increasingly complex and interdependent, ensuring robust security for sensitive data and communications is critical for both organizations and individuals. As a result, the demand for future-proof and quantum-resistant security solutions has intensified across digital infrastructures. Access control systems such as Cipher Text-Policy Attribute-Based Encryption (CP-ABE) [1], Fabric-Attribute Based Access Control (Fabric-ABAC)[2], Blockchain Capability Access Control (BCAC), Blockchain-based Privacy-preserving Attribute-Driven Access Control (BPADAC), and Blockchain-powered Dynamic Access Control (BPDAC) have emerged to address the scalability, privacy, and fine-grained policy enforcement requirements inherent in distributed environments. [3] These models offer advanced frameworks that shift beyond static, identity-based approaches by utilizing attributes or blockchain technology for efficient authorization and detailed auditing [4].

Parallel to these advancements, Quantum Key Distribution (QKD) presents an innovative cryptographic paradigm that leverages quantum mechanical principles to ensure theoretically unbreakable key exchange. Improved Elliptic Curve Cryptography-based Quantum Key Distribution (IECC-QKD) integrates the computational efficiency and strong mathematical assurances of elliptic curve cryptography with the information-theoretic security guarantees of QKD, thereby strengthening both resistance to quantum attacks and practical deployment for next-generation communications. This hybrid approach aims to achieve robust authentication, lightweight computation [5], and provable resilience against both traditional and quantum-enabled adversaries [6]. This paper presents a comprehensive comparative analysis of IECC-QKD with contemporary attribute-based and blockchain-enhanced access control frameworks.

[7] The analysis systematically evaluates their underlying security principles, protocol structures, implementation feasibility, and resilience to present and emerging threats. By situating IECC-QKD alongside CP-ABE, Fabric-ABAC, BCAC, BPADAC, and BPDAC, this study aims to clarify the unique strengths, operational constraints, and potential integration pathways for quantum-secure cryptography in the evolving landscape of distributed access control [8]. The main contributions of the research are highlighted below:

- **IECC-QKD**: The incorporation of multiple random values in the ECC encryption generates stronger defensive results than the basic ECC algorithm. The IECC uses Edwards's curves instead of Weierstrass curve which enhances security by reducing processing requirements. Combining QKD with improved ECC offers a strong secure encryption system where two parties communicate safely through the quantum mechanics principles of QKD. IECC-QKD stands out as the best cryptographic system when resources are limited due to its processing speed and high-security levels while using shorter keys [9].
- **Index and Token generation:** The mechanism of generating index and token helps to prevent tampering of data by unauthorized users. [4] The index generated through SHA-3 offers a strong standard against vulnerabilities and avoidance of length-extensive attacks. The tokens allow the users to access the system for particular validity to assure accessibility only during the intended time frame. This two-factor authentication procedure enhances defense mechanisms and improves digital data protection [10].
- **Ethereum as Proof of Storage:** PoSt builds an enhanced consensus system that replaces PoS with strong defence capabilities to benefit the network's performance. User access complete system functions through the Ethereum blockchain while performing verification tasks without using significant computer power. This technique has transformed the blockchain systems and decentralized storage networks by integrating the PoSt algorithm replacing the conventional consensus method [11-13].

The remaining portion of the research is categorized as follows. Section 2 explains the literature works, and section 3 delves into the problem statement to rectify and innovate. Section 4 describes the mechanisms and the processes carried out for developing access control systems. Section 5 delivers the comparative analysis and section 6 concludes with wrapping the future scopes.

II. LITERATURE REVIEW

The security concerns in the blockchain are delivered through this survey below. According to [14] developed a Ciphertext-Policy Attribute-Based Encryption (CP-ABE) framework aimed at enhancing security by eliminating centralization and trust issues. Their approach supports decentralized access control while reducing risks such as replay attacks and temporary access through optimized parameters, demonstrating superior privacy protection and overall security compared to previous schemes. In [15] proposed a dynamic access control system for managing cloud server data that incorporates data provenance. Their Blockchain-based Provenance-enabled Dynamic Access Control (BPDAC) system utilizes a quick look-up table (QLT) to accelerate access mechanisms. Performance evaluation using Hyperledger Fabric showcases improved metrics, though optimization of the QLT remains an area for enhancement to boost efficiency. According to [16] introduced an improved Salp Swarm Optimization-based Paillier Federated Multi-Layer Perceptron (ISSO-based PF-MLP) to mitigate security breaches in cloud systems.

This method integrates blockchain, access control, and cryptography; however, vulnerabilities to quantum computing attacks reduce the robustness of the encryption algorithms involved. According to [17] used a privacy-aware Blockchain-based Access Control (BPADAC) model to secure UAV data sharing in cloud systems using Ethereum smart contracts. While the approach demonstrates efficacy for distributed security, critical challenges such as cloud data verification and UAV source identification remain unaddressed. In [18] introduced AccessChain, which combines decentralized architecture with Attribute-Based Access Control (ABAC) to provide fine-grained, dynamic data privacy protection. The framework exhibits high throughput and scalability but suffers from limitations in the Proof-of-Work mechanism of its access point ledger, restricting latency, scalability, and throughput trade-offs. According to [19] developed Fabric-ABAC, improving cross-domain data sharing security by integrating Hyperledger Fabric with ABAC.

This multi-level, auditable access control framework employs delegated permission verification, enhancing security and simplifying permission management in multi-domain blockchain environments. Blockchain technology and ABE are used in the novel method put forth by [20] to enhance cloud environments' data security and access control systems. ABE offers a safe and data-sharing environment, but this method used a decentralized blockchain and tamper-proof access control management. However, the drawbacks, such as increased computational demands, had an impact on performance and scalability. According to [21] proposed a Blockchain-based Access Control (BCAC) scheme integrating ABE to bolster privacy and policy enforcement while minimizing dependence on centralized authorities. This approach offers decentralized secure data sharing and integrity assurance; however, it exhibits high computational costs that hinder system performance.

II.1 LIMITATION ON EXISTING SYSTEM

Several key challenges continue to hinder the effectiveness of access control mechanisms within cloud and blockchain systems.

- Enhancing the Quality of Logical Thinking (QLT) to improve the precision of access control decisions remains a significant challenge. Moreover, provenance-based access policies require adaptation for wider applicability, policy definition frameworks need to be standardized and strengthened, conflicts among policies must be effectively resolved, and user-friendly interfaces are essential to empower end-users in managing their own data and access rights.
- The performance of encryption algorithms within the Privacy-Preserving Federated Multi-Level Permission (PF-MLP) framework deteriorates, leading to diminished protection of data privacy and secure communication across multiple cloud environments. This highlights a gap where advanced encryption techniques have yet to be fully integrated and utilized.
- Systems based on Blockchain-based Privacy-preserving Attribute-Driven Access Control (BPADAC) exhibit limitations by focusing primarily on addressing vulnerabilities related to outsourced UAV data within cloud ecosystems, thereby restricting their broader applicability and utility.

- The access chain framework lacks comprehensive analytical components, resulting in increased Proof-of-Work (PoW) costs associated with maintaining the access point ledger. Additionally, this insufficiency impacts the overall expenses related to ledger upkeep and the metrics of access control cost-efficiency.[6]
- Attribute-Based Encryption (ABE)-based systems suffer from inefficiencies in multi-keyword search functions within blockchain contexts, which directly hamper the effectiveness and responsiveness of user access operations.

II.2 PROBLEM STATEMENT

Evaluating access control and security mechanisms requires a comprehensive balance between cryptographic strength and system performance. Key performance indicators such as encryption time, decryption time, transaction time, privacy ratio, responsiveness, and memory usage collectively determine the practical viability and security assurance of these mechanisms in real-world deployments. Existing attribute-based and blockchain-enhanced access control models often suffer from computational overheads in encryption and decryption processes, resulting in latency that impairs system responsiveness and transaction throughput. Moreover, these conventional systems may inadequately protect user privacy, reflected in suboptimal privacy ratios, while high memory consumption limits scalability and implementation feasibility in resource-constrained environments.[22].

Although Quantum Key Distribution (QKD) protocols provide unparalleled security guarantees founded on quantum physics, practical issues such as error rates, key generation rate, and integration latency impact the encryption and decryption efficiency. The Improved Elliptic Curve Cryptography-based QKD (IECC-QKD) approach aims to optimize this trade-off by enhancing key generation efficiency and reducing computational overhead while preserving high privacy and responsiveness standards [23]. This research investigates how IECC-QKD compares with state-of-the-art access control approaches on these fundamental metrics, seeking to address performance bottlenecks and privacy challenges that inhibit the widespread adoption of secure, scalable quantum-resilient access control systems.

III. MECHANISM & PROCESS

III.1 USER REGISTRATION

To ensure the overall security of the system and the safe utilization of cryptographic keys, the registration process initiates authorized access. Initially, the sensitivity level of the data owner is represented through a security parameter. Subsequently, each blockchain node employs a designated algorithm to generate corresponding public and private key pairs after the relevant attributes have been initialized [13].

Source: [24].

III.5 IMPROVED ELLIPTIC CURVE CRYPTOGRAPHY BASED QUANTUM KEY DISTRIBUTION FOR ENCRYPTION

After transferring the outcomes from the index and token generation process to the CBE/CBDU, the subsequent owner's data $(CBE_{td(e)})$ is forwarded to CSP using the BC_{PK}, BC_{od} for performing the encryption process. The IECC-QKD is utilized as the encryption standard that overcomes the issues of traditional ECC mechanism like exposure to quantum threats, vulnerability to random values leading to leakage of the private key, and spamming the system with a large volume of transactions with misleading the legitimate user's transactions. Moreover, to mitigate the computational complexity, the ECC is improved with the utilization of different curves by introducing additional randomness and QKD. The IECC algorithm uses elliptic curves over finite fields. Generally, the ECC algorithm produces curve based on the Weierstrass form. However, to improve time complexity and to minimize processing, this curve is replaced by implementing the Edward's curve [23] which performs well compared to the other conventional elliptic curves. The equation, implying the standard Edward's curve is described as,

$$E_d(k): a^2 + b^2 = z^2\left(1 + la^2b^2\right) mod\ kz \tag{1}$$

Where, $E_d(k)$ denotes the Edward's curve at the field k. The point coordinates of curve are denoted as a,b and z,l denote the parameters that contribute to Edward's form $z,l \in k$. Every elliptic curve over the particular finite field k is birationally mapped to the curve. The improved curve in the IECC algorithm [9] performs deliberately well by improving the performance of the algorithm and minimizing key size when compared to other encryption standards. Using the IECC as encryption standard involves generating sequences using the curve points to generate the cipher text for efficient data encryption.

Step 1: The CBM chooses random value x through the IECC algorithm and computes them accordingly with the point zK.

$$K_1\left(a_1, b_1\right) = r_1 K \tag{2}$$

$$K_2\left(a_2, b_2\right) = K_y + r_1\left(zK\right) \tag{3}$$

Here, the K implies the point generator that generates finite fields K_1, K_2 along the points (a_1, b_1) and (a_2, b_2). r_1 denotes the random integer initialized to generate the secret key, and K_y denotes the embedded form of the original data.

Step 2: The single random integer with a pair of points can diminish the security concerns leading to cipher text attacks. To overcome this, another random integer r_2 is added to the IECC scheme to improve the encryption.

$$K_3\left(a_3, b_3\right) = r_2 K \tag{4}$$

$$K_4\left(a_4, b_4\right) = K_y + r_2\left(zK\right) \tag{5}$$

Here, K_3, K_4 denotes the finite fields along the points (a_3, b_3) and (a_4, b_4).

Step 3: Generate the set of sequences for the points using the shifting operation

Step 4: Calculate $W(a_1, b_1)$, $W(a_2, b_2)$, $W(a_3, b_3)$, and $W(a_4, b_4)$ where W represents the values of the sequence generated through Step 3.

Step 5: Following the sequence, the cipher text is measured as $T_c = \left\{W\left(a_1, b_1\right), W\left(a_2, b_2\right), W\left(a_3, b_3\right), W\left(a_4, b_4\right)\right\}$, where T_c denotes the cipher text calculated using IECC.

The CSP, also the encryptor converts the T_c into the binary form and sends it inside the storage space with a series of bits attained through QKD. The integration of QKD with IECC provides reliable and advanced security methods using quantum keys and defends abnormalities through quantum computing devices at the same time. Through QKD [25] the two participants CBM and CSP create secret keys by using fundamental quantum physics rules of superposition and entanglement. The protocols of QKD operate on random qubit transmission through quantum space, where CSP sends the qubit-generated key through a specific channel When CSP receives the key from CBM it identifies them with randomly generated testing bases. When CBM and CSP establish the basis values publicly by discarding mismatches and creating the raw key which is then processed further into a shared secret key. The transmission method finds users who try to steal and avoid eavesdropping attempts by indication of quantum signals E_{QKD} since state variations automatically reveal their presence. The E_{QKD} is the indication parameter used by the QKD to notify whether any intruder interrupts the quantum channel. The operations at the QKD can be determined as,

$$CBM : T_c \xrightarrow{QKD} CSP \tag{6}$$

$$QKD \rightarrow E_{QKD} = \begin{cases} 1; if\ attac\ker\ present \\ 0; else \end{cases} \tag{7}$$

The secret keys shared through QKD [26] become a stronger standard and can be used as a symmetric key for encryption. The key generation through QKD serves either to encrypt IECC public keys or to collaborate with IECC by managing safe access to keys. Uniting these security strategies makes better protection and suitable for resource-constrained environments. The combined approach offers benefits with IECC's security enhanced by QKD integration. QKD ensures quantum-resistant protection while IECC provides an additional layer of backup security compared to other cryptographic techniques. The usage of IECC in the proposed system becomes faster due to its smaller keys that reduce processing requirements. The mixed characteristics will persist in serving our needs as quantum technology makes current encryption methods no longer secure. QKD distributes secret keys securely between parties and supports IECC to develop better encryption and digital key handling. IECC defends the system from both side-channel attacks and other vulnerabilities and protects key exchange operations from hackers using QKD. Similarly, after this process, the decryption process uses z,l with base point K and the prime value k are transferred to the CBE/CBDU whoever is the data owner and the encrypted data is stored on the IPFS network. Figure 4. represents the encryption process carried out using the IECC-QKD model.

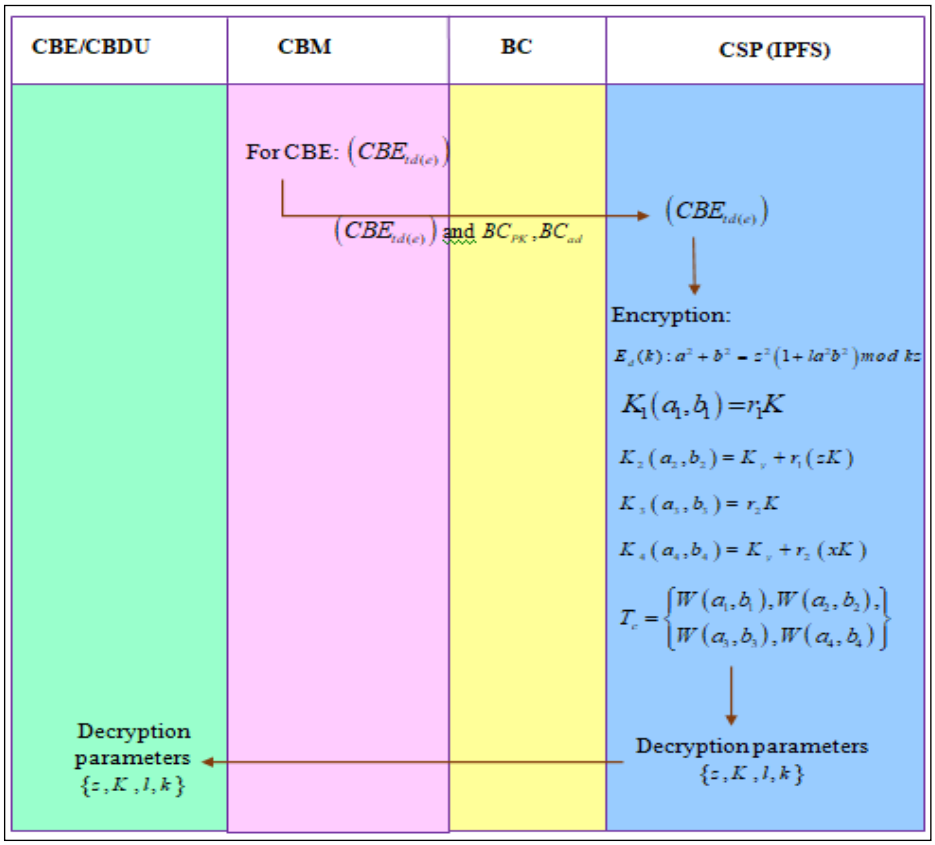

Figure 4: Schematic depiction of IECC-QKD-based encryption process.
Source: Authors, (2026).

III.6 DECRYPTION OF DATA

The user authenticates the data through the CSP scheme, for retrieval using the two-factor authenticator mechanism called the index and token. The verifier CBM checks the subsequent index and token, if the authentication matches, the decryption is performed through CSP with the recovery of key from CBE utilizing QKD's channel. The steps carried out for decrypting the data are as follows.

Step 1: For decryption, the CBDU applies encrypted data T_c and the decryption parameters $\{z, K, l, k\}$ which are known to the CBDU through CSP.

Step 2: The known data is converted back to the binary form by transforming T_c of every group.

Step 3: The groups $\{W(a_1, b_1), W(a_2, b_2), W(a_3, b_3), W(a_4, b_4)\}$ are extracted according to the initialization of the groups.

Step 4: Reverse the set of sequences through the operation by circular shift.

Step 5: The sequences set are converted back to the decimal values and stored as g.

Step 6: The pre-arranged point $(g+1)K$ and the point that is stored $(g+1)K = (a_1, b_1)$ is calculated.

Step 7: The next set of points in the sequence of step 3 repeats the same process for the generated sequences $\{W(a_1, b_1), W(a_2, b_2), W(a_3, b_3), W(a_4, b_4)\}$.

Step 8: The process is repeated throughout the next sets of data that the T_c possess and not measured previously.

For the calculation of K_y, that is mentioned in the (14) and the (16), the CSP uses the secret key and measures the $r_1(zK)$ and $r_2(zK)$ to acquire the K_y.

$$K_y + r_1(zK) - z(r_1 K) = K_y + r_1 zK - r_1 zK = K_y \tag{8}$$

$$K_y + r_2(zK) - z(r_2 K) = K_y + r_2 zK - r_2 zK = K_y \tag{9}$$

Following, this the process is reversed using the embedding K_y to decipher and retrieve the original data. Figure 5. illustrates the decryption process for the retrieval of the original data.

IV. COMPARATIVE METHODS

The blockchain-based IECC-QKD framework is compared against other established data security and access control methods like CP-ABE [14], Fabric-ABAC [19], BCAC [21], BPADAC [17], BPDAC [15], AccessChain [17], and the ISSO-Based PF-MLP [16] considering the 50,100,150,200, and 250 users respectively.

IV.1 COMPARATIVE ANALYSIS

Figure 6. illustrates the comparison of evaluation analysed against other established methods across different users. The aforementioned metrics are derived as a standard to measure the effectiveness of the model. The encryption time necessitated by the IECC-QKD for encrypting the data of the 250 users is 2.41s which is far better with gaining margins of 0.78s by CP-ABE, 0.60s by Fabric-ABAC, 0.52s by BCAC, 0.47s by BPADAC, 0.38s by BPDAC, 0.37s by AccessChain, and 0.25s by the ISSO-Based PF-MLP. Similarly, for decrypting the data the IECC-QKD requires very less time of 1.55s, that is shorter in terms of decryption time of other methods over 1.63s of CP-ABE, 1.53s of Fabric-ABAC, 1.41s of BCAC, 1.28s of BPADAC, 1.20s of BPDAC, 0.74s of AccessChain, and 0.50s of ISSO-Based PF-MLP.

The transaction time needed for the proposed framework for the exchange of data is 5.42s which outperforms other models like CP-ABE, Fabric-ABAC, BCAC, BPADAC, BPDAC, AccessChain, and the ISSO-Based PF-MLP with the ranges of 4.58s, 1.98s, 1.66s, 1.52s, 1.28s, 1.25s, and the 1.13s. The privacy ratio achieved by the IECC-QKD for maintaining the authentication and secure transfer is 0.74 which is longer when compared to 0.50 of CP-ABE, 0.52 of Fabric-ABAC, 0.52 of BCAC, 0.54 of BPADAC, 0.58 of BPDAC, 0.62 of AccessChain, and 0.65 of ISSO-Based PF-MLP. The proposed framework attained a responsiveness of 8.50s, which is reduced when compared with other baseline methods achieving a time difference of 2.63s, 1.94s, 1.91s, 1.90s, 1.61s, 1.47s, and 1.31s over CP-ABE, Fabric-ABAC, BCAC, BPADAC, BPDAC, AccessChain, and the ISSO-Based PF-MLP.

Finally, for the memory usage metric, the energy consumed by the proposed IECC-QKD is 430.88 KB, which is minimized by attaining a difference of CP-ABE with 59.62KB, Fabric-ABAC with 55.04KB, BCAC with 53.10KB, BPADAC with 49.07KB, BPDAC with 32.66KB, AccessChain with 29.49KB, and the ISSO-Based PF-MLP with 13.98KB, respectively.

IV.2 STATISTICAL ANALYSIS

The statistical analysis for the IECC-QKD-based framework is evaluated by analysing both the curves with existing methods. The aforementioned metrics are utilized and the best, mean and variance are measured to highlight the overall efficiency of the proposed framework.

IV.3 STATISTICAL RESULTS BASED ON THE CURVE ANALYSIS

The curve analysis-based statistical results demonstrate the IECC-QKD-based model's efficacy over the elliptic curve variants like secp192r1-IECC-QKD, secp224r1-IECC-QKD, brainpoolP256r1-IECC-QKD, and brainpoolP224r1-IECC-QKD. Table 1. outlines the outcomes of the proposed frameworks when analysed with different curves of IECC.

Table 1: Statistical Analysis based on the Curves.

IV.5 COMPARATIVE DISCUSSION

For the secured transmission of data and for ensuring effective access controls [2], several approaches have been implemented with each possessing their merits and also complications. The CP-ABE [14] uses attributes for secure access control but lacks scalability and efficiency with the protection of IoT data. However [27], with the instinct of deploying different mechanisms the Fabric-ABAC [19] has been developed, however, it produced better results in terms of secure data access but failed to allow the system for data sharing in cross-domain. The BPADAC [17] and BPDAC [15] frameworks designed based on blockchain networks enhanced the usage of decentralized systems for storage and transparency, still, the blockchain frameworks did not ensure the privacy concerns by determining the techniques of cryptography. The AccessChain [17] framework based on the ABE addressed the privacy-related consequences of accessing data but comprised their performance on the time constraints, latency, and maintenance of ledgers.

The ISSO-based PF-MLP [16] introduces optimization strategies for generating random numbers for secret keys, that increase the safeguarding of data, however, the framework faces issues with the encryption, leading to threats. The proposed IECC-QKD-based framework strives to overcome these challenges by improving the existing ECC encryption, along with the utilization of QKD that restricts the intruders with quantum-resistant and tamper-proofing sensitive data. The improved curve and the multiple randomness in the framework ensure secured transmission and boost data security. The overall IEC-QKD-based blockchain framework provides a robust, secure, and future-proof solution for data exchange and storage. Table 3. represents the outcomes obtained by the IECC-QKD framework when compared with other established approaches.

Table 3: Comparative discussion table of the IECC-QKD.

	Methods / Metrics	CP-ABE	Fabric-ABAC	BCAC	BPADAC	BPDAC	Access Chain	ISSO-Based PF-MLP	Proposed IECC-QKD
For 250 Users	**Encryption time (s)**	3.19	3.01	2.93	2.88	2.79	2.78	2.66	**2.41**
	Decryption time (s)	3.18	3.08	2.96	2.83	2.75	2.29	2.05	**1.55**
	Transaction time (s)	10.00	7.40	7.09	6.95	6.70	6.68	6.55	**5.42**
	Privacy Ratio	0.50	0.52	0.52	0.54	0.58	0.62	0.65	**0.74**
	Response time (s)	11.13	10.44	10.41	10.40	10.11	9.97	9.81	**8.50**
	Memory Usage (KB)	490.50	485.92	483.98	479.95	463.54	460.37	444.86	**430.88**

V. CONCLUSION

The increasing dependence on cloud servers for data storage has escalated demands for enhanced control and autonomous management of personal data access. Existing static access control models are inadequate for addressing these evolving dynamic requirements. To mitigate these concerns, this study proposes a framework that integrates Improved Elliptic Curve Cryptography-based Quantum Key Distribution (IECC-QKD) with blockchain technology to fortify data storage and access control in cloud systems. The IECC mechanism employed in the framework generates cryptographic keys utilizing multiple sources of randomness and leverages Edwards's curves to prevent spam transaction attacks while strengthening security. Compared to conventional cryptographic methods, IECC achieves superior security guarantees with smaller key sizes.

Coupled with QKD, this approach offers quantum-resistant protection. Furthermore, modifications to the Ethereum blockchain consensus protocol ensure immutable and tamper-resistant data storage, thereby safeguarding against unauthorized access. Performance evaluations conducted with user groups of 50, 100, 150, 200, and 250 demonstrate that the proposed framework attains an encryption time of 2.41 seconds, decryption time of 1.55 seconds, transaction time of 5.42 seconds, privacy ratio of 0.74, responsiveness of 8.50 seconds, and memory consumption of 430.88 KB for 250 users. Nevertheless, realizing the full potential of this integrated solution necessitates addressing challenges such as the requirement for specialized quantum hardware, complexity in system integration, limitations in key generation rates, and the current absence of standardized protocols in future research efforts [13].

ABSTRACT

The rapid evolution of deep learning (DL) has profoundly reshaped various activities such as computer vision, natural language processing, and autonomous driving. Agriculture, a typical labor-intensive and risky industry for traditional countries, is also experiencing an innovation by the incorporation of DL technologies that can process high-dimensional multi-source data to support decision-making. This paper discusses the current status research of DL technologies in agriculture and its potential impacts in the context of rural development. We will study the role of various models such as convolutional neural networks (CNNs), recurrent neural networks (RNNs) and hybrid transformer-based architectures in the context of crop monitoring & field monitoring, disease detection, yield prediction, irrigation management, and agricultural robotics. This paper brings attention to the fact that besides laboratory use, innovations in rural peoples' end-users of Artificial Intelligence (AI) created from DL yield livelihood dividends through increased productivity, lower risk and more sustainable resource management. But a host of challenges, from lack of data and infrastructure to ethical and institutional barriers, still stand in the way of widespread use of these tools in resource-poor settings. The article ends by discussing key research and policy considerations to narrow the divide between tech potential and practical impact, underscoring inclusive, transparent and participatory pathways of digital agriculture.

I. INTRODUCTION

Global agriculture is at the intersection of two powerful trends: the pressing need for more food to feed a growing population of nearly ten billion people by 2050, and the intensifying spread of digital and AI technologies that have potential to change how food systems operate. The increasing competition for land, water and climate resources calls for new technologies which can help to increase productivity and at the same time guarantee ecological and social sustainability. In this framework, DL a branch of AI that can capture hierarchical features from high-dimensional data has been one of the most disruptive technologies in recent agricultural science [1].

Contrary to traditional statistical or rule-based methods, DL can handle unstructured multilevel data, like satellite pictures, drone videos, soil sensors and text records related with agriculture activities without laborious manual preprocessing. Feature learning from raw data has thus led to the adoption of DL as a major enabler in precision agriculture, providing farmers with unmatched monitoring, prediction and optimization tools for agricultural activities. Ever since the seminal work by LeCun, Bengio, and Hinton (2015) verified DL's capability of outperforming classical models in image and sequence recognition task, researchers have embraced it for diverse agricultural applications be it disease diagnosis or yield prediction; irrigation scheduling to autonomous robots [2], [3]. DL in agriculture decision-making system has technical significance and great developmental value.

By incorporating the monitoring and support of artificial intelligence in agriculture, efficiency is expected to increase, waste decreases and climate change impacts be tempered through site-specific management and prompt action. Studies by the Food and Agriculture Organization (FAO) as well as the World Bank state that precision agriculture, correctly applied in combination with digital infrastructures and knowledge transfer programs could raise productivity and resource use efficiency between 20 to 30 % in the low to medium income countries [4], [5].However, despite these potentialities, adoption is dramatically uneven. However, as large, commercial farms in developed nations tinker with DL-driven robotics and satellite imagery systems, smallholders (who by some estimates generate 80% of food in the developing world) confront blocks that range from Internet penetration to access to capital; data scarcity and expertise are obstructive there as well [6]. This discrepancy, if continued, means that we will see further spread of the digital divide reflecting the already existing inequality.

As Carolan (2022, 2023) suggests, unless underpinned by participatory governance and fair data policy, agricultural digitization has the potential to consolidate centralized power and knowledge asymmetries policies [7], [8]. Smallholder farmers often lack control over the data they generate, while private technology firms increasingly dominate digital platforms and cloud infrastructures. Ethical and legal concerns regarding data ownership, algorithmic bias, and transparency are therefore essential dimensions of the debate on DL in agriculture. Beyond performance metrics, questions of accountability, inclusion, and value sharing determine whether AI innovations contribute to rural empowerment or exacerbate marginalization. For this reason, a holistic analysis of DL adoption in agriculture should integrate technical innovation with developmental context. This article aims to synthesize existing literature on the architectures, applications and implications of DL for rural development. It has three guiding goals:

1. To assess the major DL models and methodologies for agricultural modeling;
2. To evaluate the main application areas, including crop monitoring, pest and disease detection, yield prediction, irrigation management, and agricultural robotics.
3. To evaluate how DL can contribute to sustainable rural transformation while addressing the infrastructural, ethical, and institutional barriers to equitable adoption.

The article proceeds as follows: Section 2 details the methodological and technical foundations of DL; Section 3 examines major application areas; Section 4 discusses contributions to rural development; and Sections 5 through 7 present barriers, policy recommendations, and conclusions. By integrating insights from computer science, agronomy, and development economics, this paper argues that DL is not merely a technological advancement but a potential lever for inclusive, knowledge-intensive, and sustainable agriculture.

II. METHODS AND TECHNICAL FOUNDATIONS

DL systems have become the analytical backbone of digital agriculture because they can model the complex, nonlinear relationships that characterize biological and environmental data. Unlike traditional statistical methods, which rely on predefined equations and engineered features, DL automatically extracts hierarchical representations from raw inputs such as satellite imagery, drone data, or IoT sensor readings. This ability to fuse heterogeneous information sources makes it particularly suited for agricultural applications where spatial, temporal, and contextual dependencies coexist across multiple scales from plant physiology to landscape ecology [9].

II.1 CORE DEEP LEARNING ARCHITECTURES

CNNs remain the most widely adopted architecture for visual perception tasks in agriculture. CNNs learn spatial hierarchies of features, making them ideal for image-based applications such as crop classification, weed detection, and disease diagnosis. Mohantyet al. demonstrated that CNNs trained on over 50 000 leaf images could classify 26 plant diseases with over 99 percent accuracy, marking a turning point in the use of DL for plant pathology [10]. Subsequent advances ResNet, VGGNet, and EfficientNet improved field robustness by incorporating skip connections and normalization strategies that stabilize gradients during training [11].For modeling sequential data, Recurrent Neural Networks (RNNs) and especially Long Short-Term Memory (LSTM) units capture temporal dependencies such as crop growth dynamics or rainfall patterns. Khaki et al. combined CNNs with LSTMs to integrate multispectral satellite imagery and weather sequences, producing accurate yield forecasts across U.S. corn-belt regions [12]. More recently, Transformer architectures have shown strong potential for multi-modal agricultural data fusion. By employing self-attention mechanisms, transformers can model long-range dependencies between spatial and temporal features, outperforming recurrent networks in crop-type mapping and vegetation monitoring tasks [13].

II.2 TRAINING, DATA LIMITATIONS, AND TRANSFER LEARNING

The primary bottleneck in agriculture is obtaining annotative data, which are rare, expensive, and regional. To mitigate this, scientists use transfer learning by fine-tuning networks pretrained on commonly large generic datasets (e.g., ImageNet) using agricultural images. By [14] showed that transfer learning boosted fruit-detection accuracy while drastically reducing training time and data requirements.

Another critical strategy is data augmentation, which synthetically increases dataset diversity through geometric transformations or generative models. In turn [15] demonstrated that augmentation via Generative Adversarial Networks (GANs) improved robustness to lighting and angle variation in crop-disease classification. Together, these techniques mitigate overfitting and enable cross-regional model portability, an essential property for global agricultural deployment.

II.3 EDGE COMPUTING AND DEPLOYMENT EFFICIENCY

Because many farms operate in bandwidth-constrained environments, deploying DL models efficiently is a practical priority. Edge computing moves computation closer to the data source on drones, smartphones, or field sensors reducing latency and dependency on cloud connectivity [16]. Techniques such as model pruning and quantization compress networks while maintaining accuracy. Nguyen and Do (2024) emphasize that edge-optimized DL architectures can lower energy consumption by up to 40 percent compared with standard models [17]. Xu et al. demonstrated that lightweight CNNs embedded in IoT devices achieved real-time pest detection with inference speeds under 200 milliseconds, validating the feasibility of field-level AI [18].

II.4 EXPLAINABILITY AND ETHICAL GOVERNANCE

As DL predictions increasingly guide high-stakes agricultural decisions such as disease treatment or irrigation scheduling explainability and trustworthiness become essential. Explainable AI (XAI) tools like Grad-CAM and SHAP visualize how input features influence predictions, allowing agronomists to interpret model reasoning. Cruz, Oliveira, and Gonçalves (2023) argue that interpretability directly enhances user trust, particularly when paired with participatory model validation involving farmers [19]. Beyond transparency, ethical governance frameworks must safeguard data privacy and accountability. The European Commission's (2019) Ethics Guidelines for Trustworthy AI remain a benchmark, emphasizing human oversight, fairness, and societal benefit as prerequisites for sustainable agricultural digitization [20].

II.5 EMERGING TRENDS

Frontier research explores hybrid systems that combine DL with reinforcement learning (RL) for autonomous irrigation control, or integrate federated learning to enable collaborative model training without centralized data sharing. Such frameworks hold promise for privacy-preserving, adaptive agricultural intelligence that learns locally while contributing globally. Continued progress will depend on interdisciplinary collaboration between computer scientists, agronomists, and rural institutions to ensure that algorithmic innovation translates into tangible field-level value.

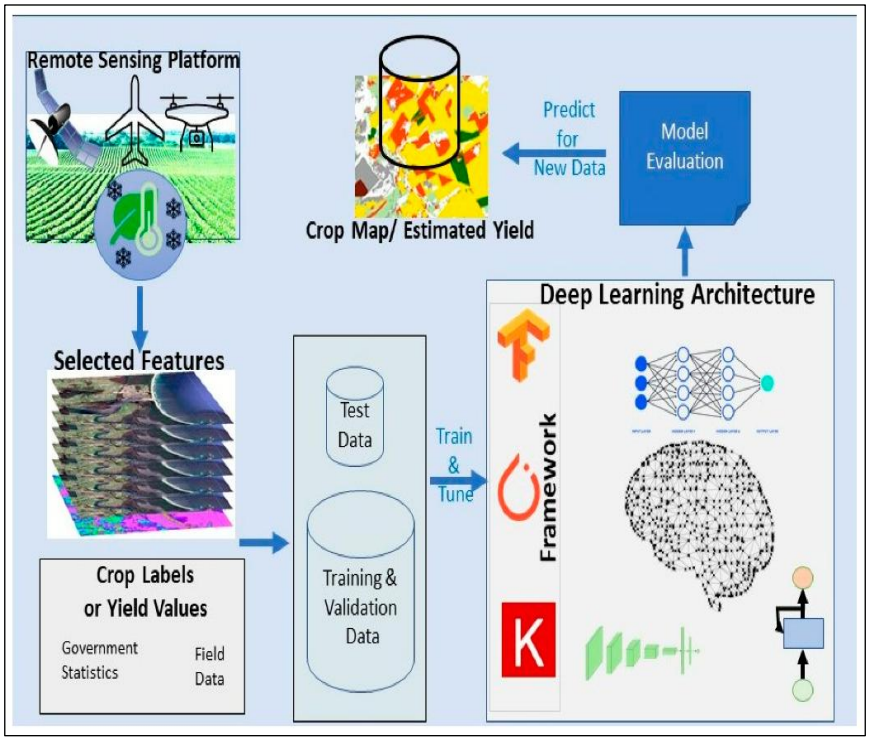

Figure 1: Overview of Deep-Learning Architectures in Agricultural Modeling.

III. MAJOR APPLICATION AREAS

Deep learning (DL) has progressed from proof-of-concepts to operational tools across several agricultural domains where data are abundant and decisions are high-stakes. Five application areas have matured fastest: (i) crop and field monitoring using satellite and UAV data; (ii) disease and pest detection from close-range imagery; (iii) yield prediction and market-relevant forecasting; (iv) irrigation and water-use optimization; and (v) agricultural robotics and precision operations.

In each domain, DL succeeds by aligning model capacity with data granularity and task structure CNNs for spatial perception, recurrent and transformer models for temporal or multi-modal fusion, and hybrid pipelines that translate perception into management-ready outputs. Across studies, three cross-cutting lessons recur: first, models generalize best when trained on multi-site datasets that reflect real agro-ecological variability; second, transfer learning and augmentation are pivotal to overcome labeling constraints; and third, real-world impact depends on deployment choices (edge vs. cloud), interpretability, and integration with extension services and farm workflows [11].

III.1 CROP AND FIELD MONITORING (REMOTE SENSING + DL)

Remote sensing provides the spatial and temporal coverage needed to monitor crops at scale, and DL has become the default engine for extracting agronomic signals from image time series. Early work established that deep networks can learn crop/land-cover classes directly from stacked multi-spectral inputs and temporal profiles, outperforming classical classifiers such as random forests and SVMs [21].More recent pipelines exploit temporal convolutions and attention to encode phenological dynamics, enabling robust crop-type mapping, stress scouting, and field-scale phenology estimation from Sentinel-2/Landsat sequences as well as UAV mosaics [22]. Importantly, these representations support downstream products biomass maps, growth-stage indicators, and anomaly flags that can be consumed by decision systems for fertilizer timing, harvest planning, or early warning. While data availability has expanded dramatically, two practical constraints persist: label scarcity (particularly outside well-studied regions) and domain shift (differences in sensors, atmospherics, and management). Studies show that transfer learning across regions and careful temporal modeling are essential for stability, and that open benchmarks (with standardized splits and protocols) accelerate reproducible progress [21], [22].

III.2 PLANT DISEASE AND PEST DETECTION

Image-based plant health diagnostics remain among the most mature DL applications. Leaf- and canopy-level classifiers using CNN backbones (e.g., ResNet, EfficientNet) routinely achieve high accuracy on curated datasets, and segmentation/detection models (U-Net, Mask R-CNN, YOLO variants) localize lesions for targeted treatment [23], [24]. This progress matters economically: earlier and more precise detection reduces yield loss and unnecessary pesticide use. Yet, translating laboratory accuracy into the field requires tackling illumination changes, occlusions, and background clutter. Systematic evaluations show that performance often degrades in the wild; robust deployment therefore depends on domain adaptation, careful data augmentation (including GAN-based synthesis to balance classes), and, increasingly, on-device inference to provide timely guidance during scouting [25], [24]. Rigorous error analysis confusion between visually similar symptoms, sensitivity to leaf orientation, and generalization across cultivars remains central to responsible use.

III.3 YIELD PREDICTION AND MARKET-RELEVANT FORECASTING

Yield forecasting is a canonical spatio-temporal learning problem where DL provides earlier and more precise estimates than traditional regressions by fusing imagery, weather, soil, and management data. Pioneering work combined deep kernels and Gaussian processes with remote-sensing time series to map yield before harvest, demonstrating the value of non-linear, hierarchical representations [26]. Subsequent studies have shown that CNN/LSTM or temporal-convolutional architectures trained on multi-year, multi-county datasets can generalize across seasons and geographies when regularized appropriately and supplied with phenology-aware inputs [27]. UAV hyperspectral pipelines complement satellite approaches by resolving within-field variability and canopy traits that correlate tightly with yield in high-value crops, pointing to hybrid satellites-plus-UAV designs for multi-scale prediction [28]. For market actors and public agencies, the operational value lies in earlier risk signals for procurement, logistics, and social protection, provided uncertainty is quantified and models are validated out-of-sample (e.g., strict forward-year testing rather than random splits).

III.4 IRRIGATION AND WATER-USE OPTIMIZATION

Water management is both a biophysical and an algorithmic problem: crops respond non-linearly to timing and volume, and constraints on energy and infrastructure shape feasible decisions. DL contributes along two axes. First, sequence models (e.g., LSTM) forecast evapotranspiration, soil moisture, or short-term water demand from meteorological and sensor streams; second, control-oriented frameworks embed these forecasts in optimization or reinforcement learning loops that recommend schedules. Controlled studies show that deep reinforcement learning (DRL) can reduce applied water while maintaining yields, especially when coupled with accurate soil-moisture sensing and realistic state constraints [29]. In practice, gains depend on reliable sensors, edge-capable inference (to act within irrigation windows), and guardrails that keep policies within agronomic bounds. When designed with farmers and irrigation operators, such systems can shift management from fixed calendars to responsive decisions tied to plant and weather state estimates.

III.5 AGRICULTURAL ROBOTICS AND PRECISION OPERATIONS

DL-enabled perception underpins navigation, grasping, and selective interventions in orchards and fields. Fruit-detection systems using CNNs (and more recently transformers) drive robotic harvesting prototypes, while semantic segmentation enables machine vision for weed control and precision spraying [30], [31]. Surveys and field reports highlight steady progress in detection accuracy and cycle times, but also underscore practical hurdles: variability in canopy geometry, occlusion and lighting, compliance with food-safety standards, and total cost of ownership. Adoption is likeliest where value density is high (specialty crops), labor is scarce, and operations are structured (greenhouses). For open-field row crops, perception-guided implements that augment (rather than replace) conventional machinery have seen earlier traction. Across subdomains, the arc from lab demos to commercial reliability has been steepest when teams co-design with growers, collect multi-season datasets, and prioritize maintainability and safety. Table 1 summarizes the principal deep learning applications in agriculture, highlighting their data sources, methodological approaches, and key outcomes reported across the literature.

Table 1: Summary of Deep Learning Applications in Agriculture.

Application Domain	Data Sources	DL Techniques	Main Outcomes / Impact	Key References
Crop and Land Classification	Satellite imagery (Sentinel, Landsat), UAV multispectral data	CNNs, Transformers, Temporal Convolutional Networks (TCN)	Accurate crop type mapping; land use monitoring; yield zone prediction.	[21]; [22].
Plant Disease and Pest Detection	Smartphone and field images, hyperspectral imaging	CNNs (ResNet, VGG), GANs for augmentation, Transfer Learning	Early detection of diseases and pests; improved extension services.	[10]; [24]
Yield Prediction and Crop Modeling	Remote sensing, climate, and soil data	CNN–RNN hybrids, LSTM, Deep Gaussian Processes	High-accuracy yield forecasts; optimization of fertilizer and irrigation.	[27] [26]
Precision Irrigation and Resource Management	IoT soil sensors, UAV infrared imagery	Deep Reinforcement Learning (DRL), Autoencoders	Dynamic irrigation scheduling; improved water and energy efficiency.	[29], [32]
Agricultural Robotics and Automation	Visual and depth sensors, 3D LiDAR	CNNs for perception, Object Detection (YOLO, Mask R-CNN)	Automated harvesting, weeding, spraying; labor cost reduction.	[30]; [33]
Food Quality and Supply-Chain Monitoring	Optical grading, hyperspectral imaging, logistics data	CNNs, Autoencoders, Explainable AI (XAI)	Automated quality control; traceability; fraud detection.	[34]; [35]
Climate and Environmental Risk Assessment	Remote sensing, climate models, soil moisture data	LSTM, CNN–LSTM, Hybrid Deep Ensembles	Drought prediction; pest risk early warning; resilience planning.	[28]; [36]

Source: Author's compilation based on peer-reviewed studies and institutional reports [37]; [38]; [39]

As shown in Table 1, computer vision and remote sensing remain dominant domains, while reinforcement learning and multimodal fusion are emerging as frontier areas in precision agriculture.

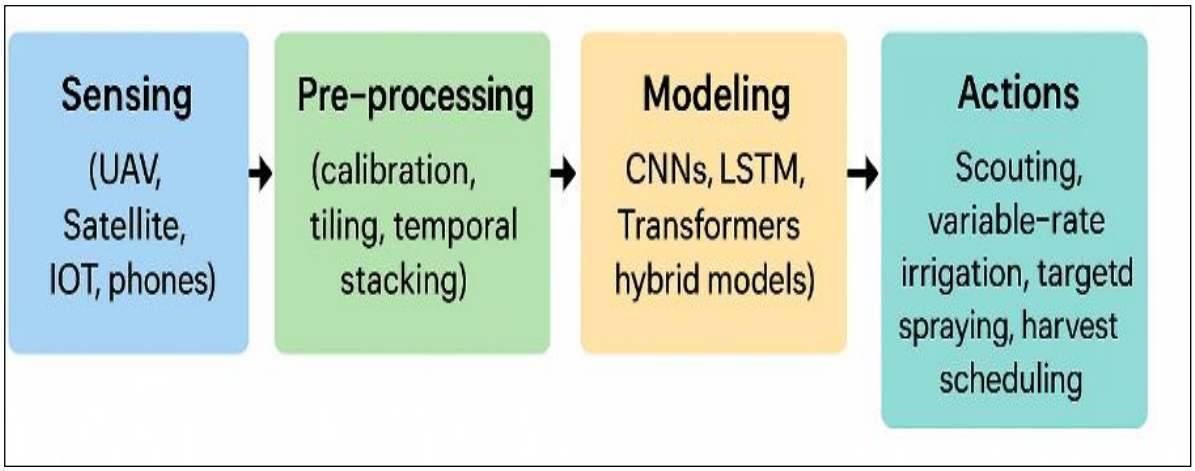

Figure 2: From Data to Decisions Across Five DL Application Areas.
Source: Conceptual synthesis based on [11], [21], [22]

IV. CONTRIBUTIONS TO RURAL DEVELOPMENT

While deep learning (DL) technologies have transformed agricultural analytics, their greatest potential lies in advancing rural development strengthening the livelihoods, resilience, and capacities of smallholder farmers who form the backbone of global food systems. The diffusion of DL-driven tools in rural contexts is not merely a technological shift but a socio-economic one, influencing productivity, labor structures, environmental sustainability, and access to knowledge [37].

IV.1 PRODUCTIVITY, RESOURCE EFFICIENCY, AND RESILIENCE

DL applications improve productivity and resource efficiency by enabling precise, data-driven decisions that minimize waste and enhance resilience to climate shocks. Field studies show that precision agriculture systems powered by AI can reduce fertilizer use by 20–30% and water consumption by up to 25%, without sacrificing yields [36]. This is crucial in countries where agriculture depends on rain-fed systems and where drought frequency is increasing.

By integrating satellite monitoring, soil sensors, and predictive models, DL supports adaptive management, allowing farmers to anticipate crop stress, optimize irrigation schedules, and allocate inputs efficiently [32]. Moreover, DL contributes to climate adaptation through early warning systems that detect pests, diseases, and weather anomalies. These systems can integrate real-time image data with meteorological inputs, enabling timely responses that prevent major losses [40]. A case study in East Africa found that AI-based locust monitoring combined with community reporting reduced outbreak response time by over 40% [41]. In this way, DL strengthens both farm-level resilience and institutional preparedness, bridging technology with extension and disaster-risk systems.

IV.2 KNOWLEDGE, DIGITAL INCLUSION, AND HUMAN CAPITAL

The transformative potential of DL depends on access not only to technology but also to digital skills and inclusive governance. Smallholder farmers often operate in data-poor environments, with limited literacy and connectivity [6]. However, DL-powered advisory platforms, when paired with mobile interfaces and voice assistants in local languages, can democratize agronomic knowledge. Initiatives such as *Digital Green* and *PlantVillage Nuru* show that AI-assisted extension can complement traditional services, reaching marginalized farmers at scale [42]. Nevertheless, digital inclusion requires targeted capacity building. Studies from the International Telecommunication Union (ITU) and FAO emphasize that training programs in digital literacy and AI interpretation must accompany the deployment of DL tools [43]. Without such measures, the benefits of technological progress may bypass vulnerable groups, reinforcing the rural digital divide. Gender disparities are especially pronounced: fewer than 25% of women farmers in Sub-Saharan Africa have access to mobile internet, and even fewer participate in digital agriculture platforms [34]. Addressing these inequalities requires both infrastructure investment and social inclusion policies that place human capability at the core of agricultural digitalization.

IV.3 MARKET ACCESS, VALUE CHAINS, AND RURAL ENTERPRISES

Beyond productivity gains, DL contributes to inclusive value chain integration by enhancing transparency, traceability, and access to markets. AI-based systems can classify produce quality, forecast market prices, and connect farmers directly with buyers through digital platforms. This reduces transaction costs and post-harvest losses while increasing bargaining power [44]. For example, machine vision models deployed in India and Kenya have enabled digital grading of horticultural crops, cutting inspection times by 80% and reducing dependence on intermediaries [5]. At the enterprise level, DL facilitates rural entrepreneurship in agro-tech startups, data services, and digital cooperatives. The World Bank's *Digital Agriculture Report* (2021) notes that AI and DL create new types of rural employment from drone operators and field data collectors to local "AI interpreters" who mediate between farmers and algorithms [45]. These developments can stimulate rural economies if accompanied by appropriate financial instruments and open data ecosystems that prevent monopolization by large technology providers.

IV.4 ETHICAL, INSTITUTIONAL, AND GOVERNANCE DIMENSIONS

The adoption of DL in rural development raises critical ethical and governance questions. Data generated by farmers often become valuable assets for corporations or governments, prompting concerns about ownership, consent, and fair value sharing. The FAO (2022) and UNCTAD (2021) highlight the risk that unregulated data extraction may reproduce historical inequities in agricultural trade and technology diffusion [46]. Transparent data governance frameworks and open-source AI models are therefore essential for ensuring that the benefits of DL remain public goods. In addition, algorithmic bias and opacity can marginalize certain user groups or ecological conditions if training data are unrepresentative [47]. As Carolan (2023) argues, technological systems are never neutral: they embody the assumptions and power relations of their creators [8]. To make DL a true driver of rural development, participatory innovation models involving farmers, cooperatives, local universities, and policymakers must replace top-down technology transfers. This aligns with the European Commission's *Trustworthy AI* framework (2019), which places human oversight, transparency, and accountability at the center of AI ethics [20].

IV.5 A PATH TOWARD INCLUSIVE DIGITAL TRANSFORMATION

DL can act as a catalyst for inclusive growth if accompanied by enabling institutions and policies. Investment in digital infrastructure (connectivity, cloud access), farmer-centered data governance, and local innovation ecosystems can amplify its developmental impact. The IFAD Rural Development Report (2021) identifies digital agriculture including DL as one of the four pillars of rural transformation, alongside financial inclusion, climate resilience, and institutional strengthening [6]. In this view, DL is not an end in itself but a means of empowerment: it enhances the agency of rural communities to manage risks, improve incomes, and participate in the knowledge economy.

V. BARRIERS AND CHALLENGES

DL is reshaping agricultural innovation worldwide, yet its integration into real-world rural systems faces persistent obstacles. These challenges technical, infrastructural, institutional, and ethical threaten to widen existing digital divides unless accompanied by inclusive governance and adaptive policy design [48].

V.1 DATA SCARCITY, QUALITY, AND BIAS

The accuracy and robustness of DL models hinge on the availability of large, high-quality, and representative datasets. However, agricultural data often remain fragmented, inconsistent, and geographically biased [49]. Most open datasets originate in industrialized settings with homogenous cropping systems, while data from smallholder regions marked by intercropping, variable field boundaries, and irregular management are sparse [24].

This creates *domain-shift* problems: when models trained on temperate-zone data are applied to tropical or arid systems, their predictive accuracy collapses [11]. Recent work by Barbedo (2019) and Liakos et al. (2018) shows that data imbalance not only reduces generalizability but can embed socio-spatial bias into automated decision tools [24]. Building equitable AI in agriculture therefore requires open, standardized, and regionally balanced data infrastructures supported by international partnerships and transparent metadata policies.

V.2 INFRASTRUCTURE AND CONNECTIVITY CONSTRAINTS

Rural areas face severe digital-infrastructure deficits. Broadband coverage, cloud access, and energy reliability are uneven across continents. According to the ITU (2022), fewer than 40 percent of rural households in Sub-Saharan Africa have stable mobile-internet connections [43].These gaps impede cloud-based inference and remote sensing pipelines essential for DL. Even when connectivity exists, high bandwidth costs and unstable electricity make continuous sensor data flows unsustainable. Edge-AI architectures can reduce latency and dependence on cloud computing, but they remain expensive [17]. Hardware costs for GPUs, drones, and precision sensors still exceed the budgets of most smallholders [50]. Moreover, the energy intensity of DL training raises environmental concerns. Strubell et al. (2019) estimated that training a single transformer-based model can emit up to 284 tons of CO_2-equivalent [35]. Developing lightweight, energy-efficient networks tailored to local devices is therefore both an ecological and an equity imperative.

V.3 HUMAN CAPITAL AND DIGITAL LITERACY

Technological innovation without human capacity limits transformation. Many agricultural research centers lack personnel who can combine agronomic knowledge with data-science skills [37]. In addition, farmers' limited digital literacy hampers adoption and trust. Participatory design approaches where farmers label images, interpret model outputs, and co-create local datasets significantly increase uptake [7]. Studies by Carolan (2022) and Wolfert et al. (2017) emphasize that social learning and user agency must accompany every deployment phase [51]. National extension systems can bridge these skill gaps if integrated with universities, vocational schools, and private agritech actors. Initiatives such as *PlantVillage Nuru* (FAO & Penn State, 2023) demonstrate that mobile-based DL tools become sustainable only when local youth are trained as digital intermediaries.

V.4 ETHICAL AND GOVERNANCE ISSUES

AI adoption in agriculture raises pressing concerns about data ownership, privacy, and algorithmic accountability. Farmers generate granular data images, soil metrics, purchasing logs but often lack control over how it is used. The FAO (2022) and Manning (2022) warn that opaque data-governance regimes risk reproducing historical asymmetries between technology providers and producers [52]. Responsible AI frameworks such as the *Ethics Guidelines for Trustworthy AI* of the European Commission (2019) and the Alan Turing Institute's *AI Ethics Report* (Leslie, 2019) advocate transparency, human oversight, and fairness. Yet local enforcement remains weak [47]. Recent empirical work by Omotayo et al. (2025) highlights the necessity of multi-stakeholder governance that includes farmers, civil-society actors, and regulators to ensure fair data-sharing agreements and ethical algorithm design.

V.5 INSTITUTIONAL FRAGMENTATION AND POLICY GAPS

DL deployment cuts across ministries agriculture, ICT, environment, and finance but coordination is often lacking [20]. The UNESCO (2023) *Global AI Readiness Report* shows that fewer than 20 percent of national AI strategies explicitly address agriculture [53]. This fragmentation leads to duplication of pilot projects, short funding cycles, and limited scalability. Regional initiatives, such as the African Union's Digital Transformation Strategy (2020–2030) and the World Bank's Digital Agriculture Program, stress that public–private partnerships (PPPs) can consolidate investments, but they require governance mechanisms to ensure inclusiveness and interoperability [38]. Coherent digital-agriculture policies must therefore align data infrastructure, education, and rural-finance frameworks under a unified vision.

V.6 SOCIO-ECONOMIC INEQUALITIES AND THE DIGITAL DIVIDE

The diffusion of DL reflects and sometimes amplifies existing social inequalities. Wealthier farmers, with access to credit and smartphones, adopt AI tools earlier, while marginalized groups especially women and youth lag behind [34]. The *GSMA Mobile Gender Gap Report (2023)* reveals that rural women in Africa are 19 percent less likely than men to use mobile internet [6]. Similarly, IFAD (2021) finds that smallholders with limited land and literacy benefit less from digital programs unless these are intentionally inclusive. To ensure that DL contributes to equitable rural development, policies must embed gender equity, affordability, and accessibility as design principles not afterthoughts. This includes targeted subsidies for connectivity, community-based data cooperatives, and localized AI training hubs.

VI. POLICY RECOMMENDATIONS

Translating the promise of deep learning (DL) into equitable and sustainable rural development requires coordinated policy frameworks that integrate digital innovation, human capacity, and social inclusion. Evidence shows that countries which link AI strategies to agricultural transformation achieve faster productivity growth, stronger resilience, and higher rural incomes [54]. The following recommendations synthesize lessons from recent research and international initiatives.

VI.1 INVEST IN DIGITAL AND DATA INFRASTRUCTURE

DL adoption depends on foundational digital infrastructure reliable broadband, cloud storage, computing capacity, and energy access [37]. The FAO (2022) and World Bank (2023) stress that closing rural connectivity gaps could add $180 billion annually to global GDP through enhanced agricultural efficiency [55].

Public–private partnerships (PPPs) are essential for mobilizing resources: national governments should incentivize telecom and agritech firms to expand 4G/5G networks and rural data centers through tax credits and concessional financing. Open Data policies are equally critical. The OECD (2023) recommends that agricultural ministries establish national data commons for agriculture secure repositories governed by public institutions, where anonymized data from sensors, drones, and markets are shared under transparent access rules [56]. Such commons can prevent data monopolization and stimulate innovation among local startups.

VI.2 STRENGTHEN HUMAN CAPITAL AND DIGITAL LITERACY

Technological innovation without capable people yields limited outcomes. Building digital agriculture competencies at all levels farmers, extension agents, and researchers is indispensable [53].UNESCO (2023) and IFAD (2021) recommend integrating AI, remote sensing, and data ethics into agricultural education curricula and vocational training programs [6]. Evidence from *Digital Green* and *PlantVillage* initiatives shows that farmer-to-farmer video learning combined with mobile AI advisory tools increases adoption and trust by over 40 % [57]. Governments and donors should therefore fund rural innovation labs local hubs where youth and farmers co-develop AI applications tailored to regional crops, languages, and climate conditions [58]. This approach fosters local ownership and reduces dependence on imported digital solutions.

VI.3 ENSURE ETHICAL AND INCLUSIVE AI GOVERNANCE

Strong data-governance and ethical frameworks are essential to protect farmers' rights and maintain public trust [20]. The European Commission's *Ethics Guidelines for Trustworthy AI* (2019) and the FAO (2022) *Ethical Stewardship for AI in Agriculture* framework both emphasize transparency, accountability, and fairness [59]. National strategies should mandate clear rules for consent, data portability, and equitable value-sharing when farmer-generated data are commercialized.

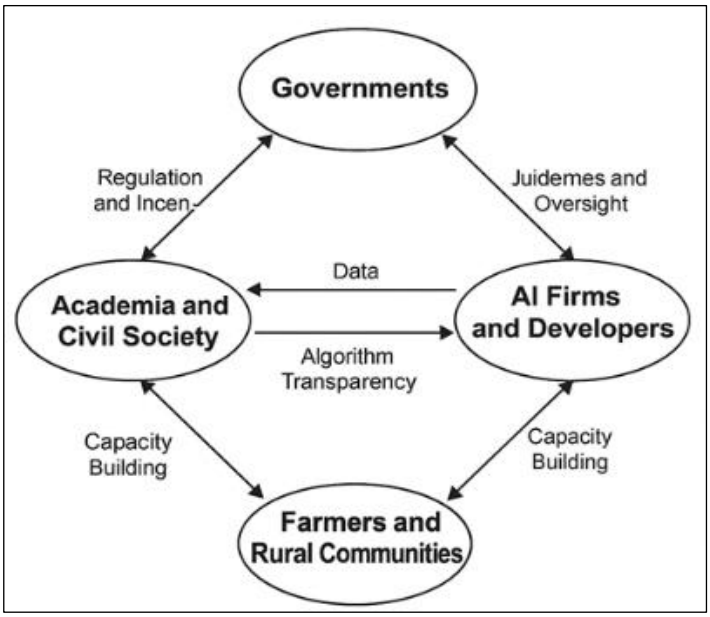

Figure 3: Ethical and Governance Framework for AI in Agriculture.
Source: Author's illustration based on [37] and [20].

As illustrated in Figure 3, ethical AI governance in agriculture depends on multi-level coordination between data producers, regulators, and civil society actors. To operationalize these norms, governments can establish multi-stakeholder data councils involving farmer cooperatives, civil-society groups, researchers, and technology providers [52]. These bodies would oversee certification of AI tools and auditing of algorithmic bias, ensuring that rural communities actively participate in governance rather than remain passive data suppliers.

VI.4 PROMOTE SUSTAINABILITY AND GREEN AI

As DL training becomes more energy-intensive, policymakers must integrate environmental sustainability into digital-agriculture strategies [35], [60] quantified the carbon cost of training large AI models, urging for "green AI" practices model compression, efficient hardware, and renewable-powered data canters. Governments and donors should prioritize funding for energy-efficient edge AI and climate-smart analytics that reduce input use while minimizing emissions. FAO proposes a *Sustainable Digitalization of Food Systems* approach, combining precision irrigation, smart fertilizer management, and AI-based early-warning systems [61]. Such integrated models can cut water and fertilizer consumption by 20–30 % while maintaining yields.

VI.5 FOSTER INSTITUTIONAL COORDINATION AND PUBLIC ACCOUNTABILITY

The fragmentation of responsibilities across ministries often leads to duplication and policy gaps. A National Digital Agriculture Council chaired by the prime minister or president can align strategies for agriculture, ICT, education, and finance [38].According to OECD (2021), coordinated governance increases policy coherence and accelerates innovation diffusion [34].

Transparency and accountability must complement coordination. Governments should publish open dashboards tracking digital-agriculture investments, AI tool certifications, and social impacts [5]. Such instruments enable citizens, researchers, and donors to monitor progress, improving efficiency and trust.

VI.6 EMPOWER RURAL ENTREPRENEURSHIP AND EQUITY

Policies must explicitly target inclusive digital entrepreneurship. DL should not replace rural labor but generate new forms of employment drone operators, data analysts, and AI technicians [62]. Access to credit, micro-insurance, and e-commerce infrastructure will allow smallholders and rural SMEs to participate in emerging value chains [6]. IFAD (2021) and GSMA (2023) emphasize gender-responsive financing and support for women-led agritech ventures, which remain underrepresented in global investment flows [34]. Finally, governments should integrate social-impact indicators – gender parity, youth employment, local innovation rates into all DL-related policies. Equity must become a prerequisite, not a by-product, of digital transformation. Table 2 summarizes the main policy domains and implementation responsibilities identified across recent literature and global policy frameworks.

Table 2: Policy Recommendations and Implementation Actors.

Policy Area	Key Measures / Recommended Actions	Primary Actors / Responsible Institutions	Key References
1. Digital & Data Infrastructure	Expand rural broadband coverage, 4G/5G networks; invest in data centers and renewable energy for AI computing; create open national data platforms for agriculture.	Ministries of ICT and Agriculture; Telecom operators; Public–Private Partnerships (PPPs); FAO; World Bank; ITU.	[37] ;[55]; [39].
2. Human Capital & Digital Literacy	Integrate AI and data science into agricultural curricula; train extension agents and youth as "digital intermediaries"; support rural innovation labs.	Ministries of Education & Agriculture; Universities; FAO; UNESCO; IFAD.	[52]; [57].
3. Ethical & Data Governance	Adopt AI ethics laws and data-protection policies; establish multi-stakeholder data councils; certify AI tools for transparency and bias control.	National Data Authorities; Farmer Cooperatives; European Commission; FAO; OECD; Alan Turing Institute.	[20]; [37; [51]; [46].
4. Green AI & Environmental Sustainability	Promote energy-efficient models and edge AI; support renewable-powered data centers; encourage AI for climate-smart agriculture and resource optimization.	Ministries of Environment & Energy; FAO; UNEP; Research Institutes; Private AI Firms.	[50]; [59]; [39].
5. Institutional Coordination & Accountability	Create a National Digital Agriculture Council to align ministries and monitor progress; publish open dashboards on AI investments and impacts.	Prime Minister's Office; Ministries of Agriculture, ICT and Finance; Audit Offices; Civil Society Groups.	[60]; [53]; [38].
6. Inclusive Rural Entrepreneurship & Equity	Facilitate credit and digital finance for SMEs and women farmers; develop gender-responsive AI policies; promote youth-led agritech startups.	Ministries of Finance & Women's Affairs; IFAD; GSMA; UN Women; World Bank.	[43]; [61]; [5].

VII. CONCLUSION AND FUTURE DIRECTIONS

DL has moved from experimental research to an increasingly strategic role in global agriculture. It now underpins yield prediction, pest detection, soil monitoring, and market intelligence. Yet its most transformative potential lies not in automation itself, but in how it can empower rural communities, strengthen resilience, and support sustainable food systems [48]. Across developing regions, DL adoption is accelerating but unevenly. Structural inequalities in data, connectivity, and human capital continue to limit its developmental reach [37]. The next decade must therefore prioritize a human-centered digital transformation that couples technical excellence with social inclusion. FAO (2023) and IFAD (2021) emphasize that digital tools succeed only when integrated into broader rural-development strategies that invest simultaneously in infrastructure, education, and institutions [6]. Governments should view DL not as an isolated innovation, but as part of a systemic shift toward knowledge-intensive, climate-resilient agriculture.

VII.1 INTEGRATING DEEP LEARNING WITH SUSTAINABILITY AND FOOD-SYSTEM RESILIENCE

Future research and policy should focus on aligning DL with sustainability goals—reducing environmental footprints, improving water efficiency, and enhancing carbon sequestration [60]. Combining DL with Internet-of-Things (IoT) networks and geospatial intelligence allows near-real-time monitoring of resource flows and emissions [36]. The European Commission (2023) and OECD (2023) both advocate for "green digitalization" policies that require energy-efficient model architectures, renewable-powered data centers, and carbon disclosure for AI development [63]. Emerging work by Maimaitijiang et al. and Kamilaris & Prenafeta-Boldú [28] shows that multimodal DL frameworks integrating UAV imagery, climate data, and field sensors can improve yield prediction accuracy by more than 15 percent while reducing fertilizer inputs. These advances illustrate how technical efficiency and ecological stewardship can reinforce one another.

VII.2 BUILDING INCLUSIVE KNOWLEDGE ECOSYSTEMS

Sustainable deployment requires knowledge ecosystems that bridge science, policy, and practice. Universities, extension services, and farmer cooperatives must collaborate on open-source datasets and local algorithm training [11]. Open collaboration models such as the FAO-Google Earth Engine partnership and the CGIAR Platform for Big Data in Agriculture demonstrate that shared resources accelerate innovation while maintaining transparency [39]. However, inclusion remains essential. Women and youth are still under-represented in AI education and agritech entrepreneurship. According to UNESCO (2023) and GSMA (2023), targeted digital-literacy and financing programs can reduce gender gaps and expand participation in data-driven value chains [34]. IFAD's Rural Youth Action Plan (2022) similarly underscores the importance of combining DL innovation with vocational training and startup incubation [53].

VII.3 GOVERNANCE, TRUST, AND ETHICAL STEWARDSHIP

Trust will determine the long-term legitimacy of AI in food systems [6]. Transparent data governance clarifying ownership, consent, and value sharing is vital to protect farmers' rights. The *Ethics Guidelines for Trustworthy AI* (European Commission, 2019) and the *FAO Ethical Stewardship Framework* (2022) both call for inclusive oversight mechanisms and algorithmic accountability [20]. Future research should operationalize these frameworks through auditable AI certification schemes and participatory ethics boards that include producers and local authorities [59]. Equally, international cooperation will shape AI governance. OECD (2023) and the African Union Commission (2020) recommend harmonizing data-standards and fostering South-South collaboration to avoid technological dependency and ensure fair access to digital infrastructure [38]. Regional data-sharing alliances could thus become the backbone of ethical and interoperable agricultural AI.

VII.4 LOOKING AHEAD: TOWARD A HUMAN-CENTERED AI FOR AGRICULTURE

The path forward lies in embedding humanity and sustainability into code. Deep learning should augment human intelligence—not replace it [64]. This means prioritizing local knowledge, strengthening digital citizenship, and ensuring that rural actors participate as co-creators of AI solutions. If guided by inclusive policy, ethical governance, and sustained investment, DL could redefine how agriculture contributes to climate adaptation, poverty reduction, and global food security [54]. As the World Bank (2023) concludes, "digital transformation is developmental only when it empowers people to use data for their own prosperity." The challenge for researchers and policymakers is thus to transform DL from a technical breakthrough into a social contract for equitable and sustainable rural futures.

ABSTRACT

This paper presents the modeling and control of a standalone solar water pumping system, comprising a PV generator, DC/AC inverter, squirrel-cage motor, centrifugal pump, hydraulic circuit, and MPPT controller. Four machine-learning techniques (ANN, ANFIS, SVM, and GPR) are assessed for predicting the MPP voltage to improve system efficiency. Comparative results show that ANFIS gives the highest prediction accuracy (R^2 = 0.9992 and RMSE = 0.9552), outperforming GPR and ANN, with SVM providing moderate performance during training and testing phases. The performance of predcitive models was evaluated using training and testing data, assessing accuracy in predicting optimal voltage based on irradiance and temperature. Dynamic simulations under step-change irradiance conditions confirmed that the ML-based MPPT controllers significantly outperformed conventional P&O and INC methods, achieving faster time response. Based on this analysis, an ANFIS-based MPPT strategy with a PI controller is used, leveraging its superior accuracy relatively to the other ML-based MPPT controllers and conventional methods (P&O and INC).

I. INTRODUCTION

In solar water pumping systems, PV generator performance is affected by varying environmental conditions and load characteristics. MPPT techniques mitigate these challenges by maximizing power extraction under these condition. While numerous MPPT exist, the Perturb and Observe (P&O) and Incremental Conductance (INC) methods are most prevalent due to their simplicity [1]. The use of artificial intelligence (AI) techniques has proliferated across diverse research disciplines and industrial sectors in recent years [2]. These techniques can be applied to tackle the challenges of MPPT in PV systems. For this purpose, researchers in [3] introduced a novel hybrid model that enhances the ANFIS model by integrating the BAT algorithm for training.

The results indicate that this metaheuristic approach offers superior training efficiency compared to conventional backpropagation algorithm. Similarly, a hybrid algorithm was proposed in [4], employing the Crowded Plant Height Optimization algorithm for ANFIS training resulted in improved tracking speed and efficiency relative to a standard ANFIS. In [5], the authors present an SVM model for predicting photovoltaic energy production by using solar irradiance and ambient temperature as inputs. While achieving a low MAPE, the model demonstrated sensitivity to input data errors. Similarly, another method involving SVM technique is presented in [6] by using three input combinations based on temperature and irradiance.

While achieving a MAPE of 36 %, outperforming analytical methods, the model exhibited sensitivity to climate variability. In [7], a PV power system (PVPS) topology is introduced by incorporating a radial basis function neural network (RBFNN) to enhance system efficiency; the results demonstrated the superiority of this MPPT method over conventional techniques. In [8], researchers have developed and implemented soft computing (SC) based MPPT controllers to predict optimal converter duty cycles under varying climatic conditions and static heads. A comparative study was conducted to assess and validate the accuracy. Authors in [9] applied the Golden Section Search (GSS) algorithm as an MPPT technique to enhance the efficiency of a standalone PV water pumping system (PVWPS).

Matlab/Simulink simulations verified the effectiveness of this approach. In [10], several ANN-based methods are presented for predicting hourly water flow rates in a PVWPS; their findings demonstrated accurate predictions based on measured air temperature and solar irradiation. The present work concerns the modeling and control of a standalone solar water pumping system. In addition, a comparative analysis between four ML techniques (ANN, ANFIS, SVM, and GPR) is presented for predicting the voltage at the MPP of the PV generator. This paper is organized into four sections. Section II describes the mathematical formulations used for the various components of the investigated PVWPS. The simulation results are reported and discussed in Section III. Finally, Section IV summarizes the findings and conclusions.

II. MATHEMATICAL MODELING

The proposed PVWPS integrates various components; such as: PV generator, DC/AC inverter, squirrel-cage induction motor, centrifugal pump, hydraulic circuit, and MPPT controller.

II.1 PV GENERATOR

Numerous mathematical models exist to describe the nonlinear behavior of the solar cell in PV module, differing in complexity and the number of parameters used to calculate voltage and current. This study utilizes the one-diode model, whose equivalent circuit is shown in Figure 1.

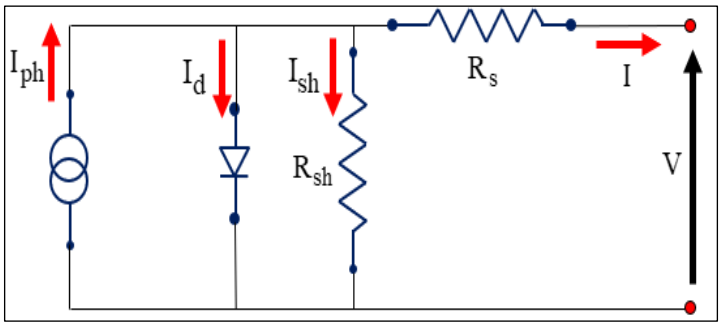

Figure 1: Equivalent circuit of the one-diode model of the cell.
Source: Authors, (2026).

Notice that the single-diode model is simpler with five unknown parameters (R_s, R_{sh}, A, I_0, I_{ph}). It may not capture the complexities of the cell behavior as accurately as the double-diode model, particularly under diverse operating conditions. Its simplicity, efficiency, and sufficient accuracy make it suitable for many systems design applications. By applying Kirchhoff's current law, the output current of a solar cell can be mathematically represented as follows:

$$I = I_{ph} - I_d - I_{sh} \tag{1}$$

Where I_{ph}, I_d and I_{sh} represents respectively the photocurrent, the diode current, and the current leak in the shunt resistor. The photocurrent is defined by:

$$I_{ph} = \frac{G}{G_{ref}}\left(I_{ph_ref} + \mu_{sc} \cdot \left(T_c - T_{c_ref}\right)\right) \tag{2}$$

With G is the solar radiation intensity, G_{ref} is the solar radiation intensity at STC, I_{ph_ref} is the photocurrent at STC, T_{c_ref} is the cell temperature at STC, T_c is the cell temperature, and μ_{sc} is the coefficient temperature of short-circuit current. The diode current is given by Shockley's diode equation as follows:

$$I_d = I_0 \cdot \left(e^{\frac{q\cdot(V+R_s\cdot I)}{A\cdot K\cdot T}} - 1\right) \tag{3}$$

I_0 represents the reverse saturation current of the diode, q is the electron charge, R_s is the series resistance, V and I represent respectively the PV module operation voltage and current, k is the Boltzmann's constant, and A is the diode ideality factor. The current leak in the shunt resistor can be computed by the following equation:

$$I_{sh} = \frac{V + R_s \cdot I}{R_{sh}} \tag{4}$$

Where R_{sh} is the shunt resistance. The overall output current and voltage of the generator are given by:

$$\begin{cases} I_{gen} = N_p \cdot I \\ V_{gen} = N_s \cdot V \end{cases} \tag{5}$$

Where N_p and N_s are respectively the number of the PV modules interconnected in series and/or parallel configurations.

II.2 DC/AC INVERTER

The DC/AC inverter converts the direct current (DC) voltage generated by the solar array into a variable-frequency three-phase alternating current (AC) voltage. The three-phase inverter output voltages are calculated using the following equation:

$$\begin{bmatrix} V_a \\ V_b \\ V_c \end{bmatrix} = \frac{V_{DC}}{3} \begin{bmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{bmatrix} \cdot \begin{bmatrix} S_1 \\ S_2 \\ S_3 \end{bmatrix} \tag{6}$$

S_i is the state of the IGBT switch.

II.3 SQUIRREL-CAGE INDUCTION MOTOR

Employing the Park's transformation, the three-phase squirrel-cage induction motor's voltage is calculated in the d-q reference frame using the following equation:

$$\begin{cases} \begin{bmatrix} V_{ds} \\ V_{qs} \end{bmatrix} = R_s \begin{bmatrix} I_{ds} \\ I_{qs} \end{bmatrix} + \frac{d}{dx} \begin{bmatrix} \varphi_{ds} \\ \varphi_{qs} \end{bmatrix} + \omega_s \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} \varphi_{ds} \\ \varphi_{qs} \end{bmatrix} \\ \begin{bmatrix} V_{dr} \\ V_{qr} \end{bmatrix} = R_r \begin{bmatrix} I_{dr} \\ I_{qr} \end{bmatrix} + \frac{d}{dx} \begin{bmatrix} \varphi_{dr} \\ \varphi_{qr} \end{bmatrix} + \omega_r \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} \varphi_{dr} \\ \varphi_{qr} \end{bmatrix} \end{cases} \tag{7}$$

For the d-axis, V_{ds}, I_{ds}, φ_{ds}, V_{dr}, I_{dr} and φ_{dr} referred stator and rotor voltage, current and flux linkage, respectively. For the q-axis, the last variables are referred V_{qs}, I_{qs}, φ_{qs}, V_{dr}, I_{dr} and φ_{dr}. R_s and R_r are stator and rotor winding resistance. ω_s and ω_r are stotor and rotor frequency. For this study, V_{dr} and I_{dr} are set to zero. The d-q frame currents for the induction motor are given as follows:

$$\begin{cases} \begin{bmatrix} I_{ds} \\ I_{qs} \end{bmatrix} = \frac{L_r}{L_s \cdot L_r - M_{sr}^2} \begin{bmatrix} \varphi_{ds} \\ \varphi_{qs} \end{bmatrix} - \frac{M_{sr}^2}{L_s \cdot L_r - M_{sr}^2} \begin{bmatrix} \varphi_{dr} \\ \varphi_{qr} \end{bmatrix} \\ \begin{bmatrix} I_{dr} \\ I_{qr} \end{bmatrix} = \frac{L_r}{L_s \cdot L_r - M_{sr}^2} \begin{bmatrix} \varphi_{dr} \\ \varphi_{qr} \end{bmatrix} - \frac{M_{sr}^2}{L_s \cdot L_r - M_{sr}^2} \begin{bmatrix} \varphi_{ds} \\ \varphi_{qs} \end{bmatrix} \end{cases} \tag{8}$$

Where L_s, L_r and M_{sr} are respectively stator inductance, rotor inductance, and the mutual inductance. The electromagnetic torque is calculated as follows:

$$T_e = 1.5p \cdot M_{sr} \cdot \left(I_{qs} \cdot I_{dr} - I_{ds} \cdot I_{qr}\right) \tag{9}$$

Where p is the pair pole number. The motor speed is determined using the following mechanical dynamic equation:

$$T_e = \frac{J}{p} \cdot \frac{d\omega_r}{dt} + f \cdot \omega_r + T_r \tag{10}$$

Where T_r is the load torque, f is a viscous torque constant, J is the inertia moment of the rotor.

II.4 CENTRIFUGAL PUMP

The power required to pump water at a volumetric flow rate Q and total head H is calculated using the following equation:

$$P_h = g \cdot \rho \cdot H \cdot Q \tag{11}$$

The mechanical power consumed by the pump is defined by:

$$P_m = \frac{P_h}{\eta} = T_r \cdot \omega_r \tag{12}$$

Where g is the acceleration of gravity, ρ is the density of fluid (water), and η is the pump efficiency. Using equations (11) and (12), the load torque can be determined as follows:

$$T_r = \frac{g \cdot \rho \cdot H \cdot Q}{\omega_r \cdot \eta} \tag{13}$$

In general, pumps are described by their H(Q) characteristic that defines the total head as a function of flow rate for a single nominal speed (N_n); the equation that links the total head with the flow rate for any rotational speed (N) is given as follows:

$$H(Q, N^*) = h_0 \cdot (N^*)^2 - h_1 \cdot N^* \cdot Q - h_2 \cdot Q^2 \tag{14}$$

Where $N^* = \frac{N}{N_n}$ is the normalized speed. The load torque caused by flow through the hydraulic part of the pump takes a similar form to the total head equation, and can be written as:

$$T_r(Q, N^*) = c_0 \cdot (N^*)^2 - c_1 \cdot N^* \cdot Q - c_2 \cdot Q^2 \quad (15)$$

The coefficients h_0, h_1, h_2, c_0, c_1 and c_2 are calculated from the data provided by the manufacturer.

II.5 HYDRAULIC CIRCUIT

The pump must overcome the total head comprising static head, dynamic head, pipe friction losses, and components head losses.

$$HMT = H_s + H_d + H_{friction} + H_{components} \quad (16)$$

Pipe frictional losses can be calculated using the Darcy-Weisbach equation done by:

$$H_{friction} = \lambda \cdot \frac{L}{d} \cdot \frac{8 \cdot Q^2}{g \cdot \pi^2 \cdot d^4} \quad (17)$$

Where λ is the average friction factor, L is the length of the pipe, and d is the inside pipe diameter. Components head losses is given by:

$$H_{components} = \sum_{components} K_{component} \frac{8 \cdot Q^2}{g \cdot \pi^2 \cdot d^4} \quad (18)$$

Where K represents the fitting loss coefficient of each component. The total head is expressed by the following equation:

$$\mathrm{HMT} = \mathrm{H_s} + \mathrm{H_d} + \left(\lambda \cdot \frac{\mathrm{L}}{\mathrm{d}} + \mathrm{K}\right) \frac{8 \cdot \mathrm{Q}^2}{\mathrm{g} \cdot \pi^2 \cdot \mathrm{d}^4} \quad (19)$$

II.6 MPPT CONTROLLER

To enhance the energy efficiency of PV systems, it is essential to design an effective MPPT technique. Traditionally, the MPP has been tracked using conventional algorithms such as P&O and INC. The P&O method is widely used due to its simplicity; it works by slightly perturbing the operating voltage and observing changes in output power to approach the MPP. The INC algorithm is based on the slope of the power-voltage (P–V) curve, which equals zero at the MPP. While these classical techniques are effective under steady conditions, their performance often degrades under rapidly changing environmental conditions such as partial shading or sudden irradiance variations. To address these limitations, recent research has turned to machine-learning techniques.

By integrating AI into MPPT controllers, PVWPS can achieve faster convergence, improved accuracy, and better adaptability, making these techniques a promising direction for future advancements in solar energy technologies. For this purpose, a comparative analysis of ML techniques will be conducted in this study. The mathematical formulations of used ML techniques are reported in Appendix A. Notice, that the proposed control strategy is a two-parts system: the first part is an MPPT, which can be one of ML techniques (ANN, ANFIS, SVM or GPR) that uses irradiance and temprétaure as inputs for predicting the optimal PV generator voltage; the second part is a proportional-integral (PI) controller that regulates the generator terminal voltage to match the MPPT prediction, maintaining the V/f ratio.

III. RESULTS AND DISCUSSIONS

As can be seen in Figure 2, the proposed PVWPS is composed of PV modules type KC200GT, three-phase DC/AC inverter, a centrifugal pump driven by a 2.2 kw squirrel cage induction motor, hydraulic circuit, and MPPT. The system has been programmed under the Matlab/Simulink environment; the parameters used in the simulation are shown in Appendix B.

III.1 COMPARATIVE ANALYSIS OF ML TECHNIQUES

In this part, a comparative analysis of ML techniques (ANN, ANFIS, SVM, and GPR) is performed to predict the optimal voltage used as a reference signal for the PI controller. The observed data is derived through a numerical compilation based on measurements provided by the manufacturer. The inputs of the predictive models are irradiance and ambient temperature. The dataset is segregated into two subsets: training and testing. Notice, that 70 % of the dataset is used for the training, with the remainder utilized for the testing phase. The developed ANN employs a multilayer feed-forward with a 2-3-1 structure; the number of hidden neurons "3" was selected via different simulations to maximize R and minimize RMSE. For ANFIS, a "4 3" structure was implemented by using Gaussian membership function for the inputs, with a grid partition and hybrid learning method limited to a maximum of 30 epochs.

The SVM model used a quadratic kernel function, selected from a range of six tested kernels within Matlab. The selected GPR technique employed a Matern 5/2 kernel function. This last was selected from a range of tested kernels, including Rational Quadratic, Squared Exponential, and Exponential. Default settings were adopted for the hyperparameters of both SVM and GPR. The training of these techniques is performed offline based on weather conditions. During simulation, the ML-MPPT receives the input information and provides predictions instantaneously, which is analogous to a testing phase. The simulation outcomes obtained during the training and testing phases using ANN, ANFIS, SVM, and GPR are presented in Tables 1 and 2.

Table 1: Comparison between the observed and predicted values.

Data	Inputs		Observed V_{MPP} (V)	Predicted V_{MPP} (V)			
	T (°C)	G (kW/m²)		ANN	ANFIS	SVM	GPR

To evaluate the performance of predictive models, R-squared and RMSE between observed and predicted values are used. The mathematical formulations of performance indicators are given as follows:

$$R^2 = 1 - \frac{\sum_{k=1}^{n} \left(V_{MPP\ obs}(k) - V_{MPP\ pred}(k)\right)^2}{\sum_{k=1}^{n} \left(V_{MPP\ obs}(k) - \bar{V}_{MPP\ obs}(k)\right)^2} \quad (20)$$

$$RMSE = \sqrt{\frac{\sum_{k=1}^{n}\left(V_{MPP\,obs}(k) - V_{MPP\,pred}(k)\right)^2}{n}} \quad (21)$$

Table 2 presents a comparative analysis of the performance indicators for the ML techniques.

Table 2: Performance indicators for the predictive models.

Phase	Indicator	ANN	ANFIS	SVM	GPR
Training	**RMSE**	0.9971	0.5472	2.5902	0.7613
	R-squared	0.9990	0.9997	0.9935	0.9994
Testing	**RMSE**	1.6206	1.5305	2.4242	1.5504
	R-squared	0.9981	0.9983	0.9957	0.9982
All data	**RMSE**	1.2181	0.9552	2.5415	1.0615
	R-squared	0.9987	0.9992	0.9943	0.9990

Source: Authors, (2026).

The results reveal that all models exhibit strong performance, characterized by high R-squared (0.9935 – 0.9997) and low RMSE (0.5472 – 2.5902). Notably, the ANFIS model demonstrates high accuracy during both training and testing. This is marked by relatively low RMSE values of 0.5472 and 1.5305, respectively, and high R-squared values of 0.9997 and 0.9983. Followed by GPR and ANN. The SVM model, although exhibiting reasonable performance during both training and testing. Considering the results across all data, the ANFIS technique demonstrates superior predictive accuracy with the lowest overall RMSE and higher R-squared. For this reason, the ANFIS technique is maintained for the simulation of the PVWPS. A comparison of the performances between the predictive models based on ML techniques and those using conventional algorithms is now presented in Figure 3. For this, step changes in irradiance level were applied at 2 s and 3 s. Irradiance level is changed from 0.6 kW/m^2 to 0.7 kW/m^2, then from 0.7 kW/m^2 to 0.5 kW/m^2, and then from 0.5 kW/m^2 to 0.4 kW/m^2.

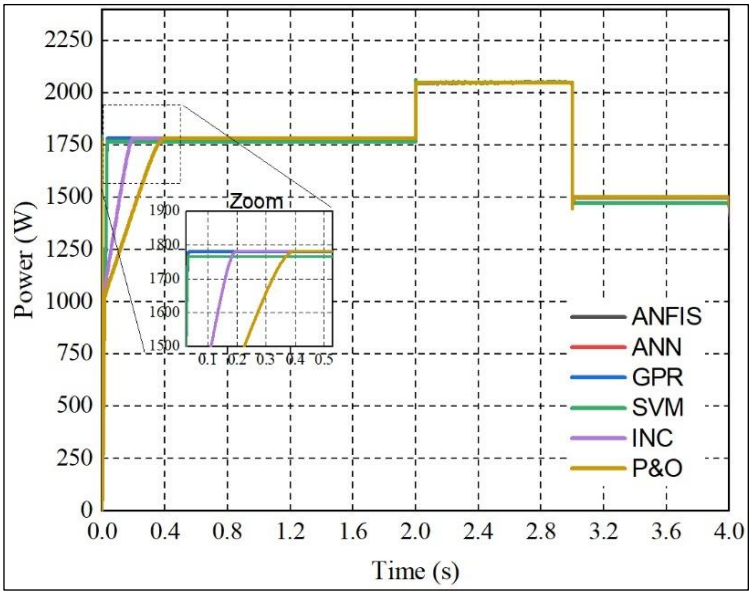

Figure 3: PV power for step change in irradiation level.
Source: Authors, (2026).

Figure 3 indicates that the ML techniques exhibit superior tracking performance compared to other conventional methods, as evidenced by faster rise time of 0.033 s in contrast to the 0.2 and 0.4 s rise time observed in INC and P&O methods, respectively. This is due to the significant impact of predicting V_{MPP} as opposed to calculating it directly.

III.2 ANFIS-BASED MPPT STRATEGY FOR THE PVWPS

In this part, the simulation results for step change in irradiance level condition are depicted in Figures 4 to 12. A multiple step change in irradiation level is applied. It went from 0.5 kW/m^2 to 0.6 kW/m^2 and then from 0.6 kW/m^2 to 0.4 kw/m^2. As depicted in the voltage profile (Figure 4), the ANFIS-based control strategy effectively maintains the PV generator operation near its MPP. The controller adjusts to each new irradiance level within a transient period of approximately 0.04 s. A consistent, slight decrease in the V_{MPP} is observed during irradiance drops, while an increase is seen during recovery. This minor variation is attributed to the negligible influence of irradiance on V_{MPP}.

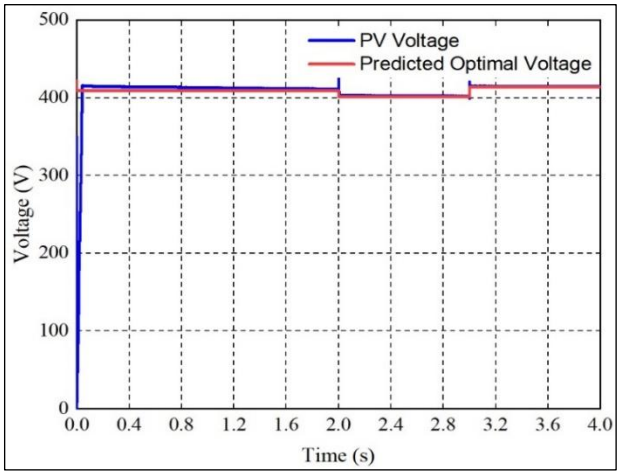

Figure 4: PV voltage and reference voltage.
Source: Authors, (2026).

Conversely, in Figure 5, the PV current exhibits significant sensitivity to irradiance changes. During irradiance increase, the current recovers proportionally, returning the PV generator to a higher power output. During irradiance decreases, the current drops substantially, leading to a proportional decrease in generated power. This is due to the direct correlation between irradiance and I_{sc}.

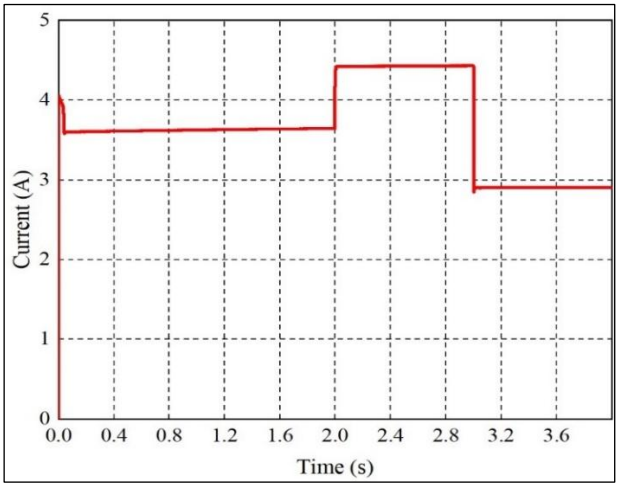

Figure 5: PV current.
Source: Authors, (2026).

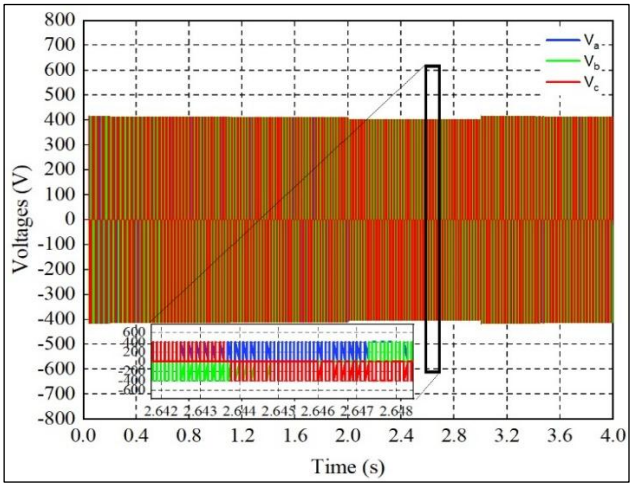

Figure 6: Line voltages.
Source: Authors, (2026).

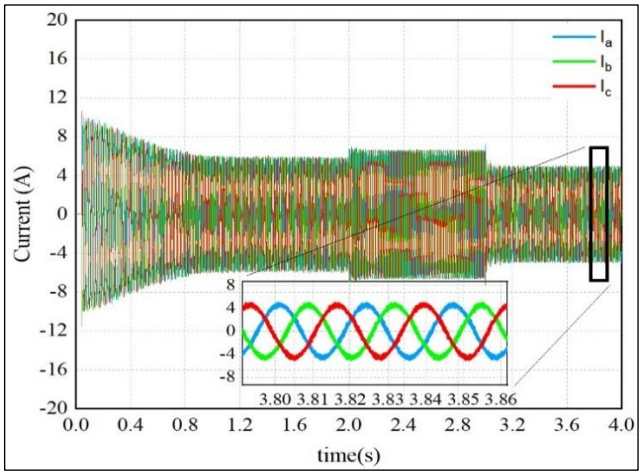

Figure 7: Line currents.
Source: Authors, (2026).

In Figure 6, the squirrel-cage induction motor is supplied with voltages stable and close to their nominal values. A small, correlated variation in terminal voltage is observed with the changing in irradiance, increasing slightly during high-irradiance periods and decreasing when irradiance drops. According to Figure 7, the transient regimes of the motor are relatively insignificant, where the current demand during the transient regime is approximately 1.5 times higher than that in the nominal regime. The proposed control strategy enables a gradual start-up of the load to ensure a current demand lower than that of the short-circuit of the PV generator.

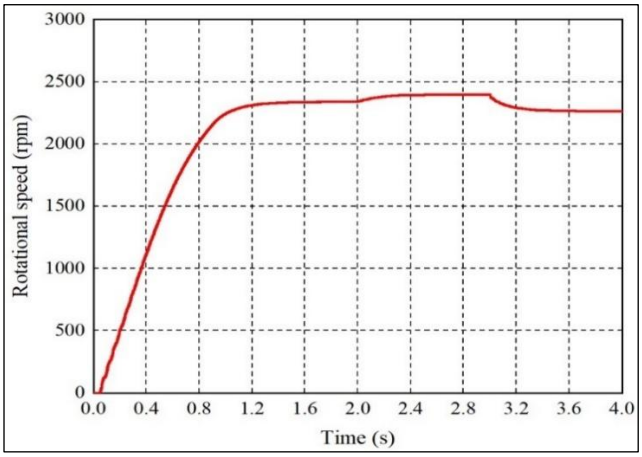

Figure 8: Rotational speed.
Source: Authors, (2026).

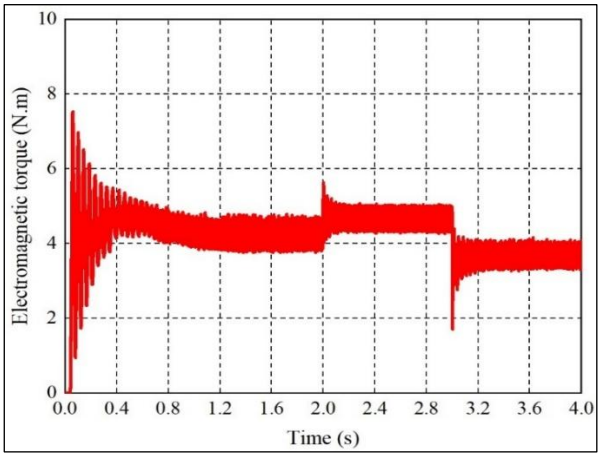

Figure 9: Electromagnetic torque.
Source: Authors, (2026).

From Figure 8, the motor requires approximately 1.2 seconds from startup to reach its nominal rotational speed. This period is characterized by transient oscillations in the electromagnetic torque (Figure 9).The system demonstrates effective load adaptation. A decrease in irradiance causes a corresponding decrease in both electromagnetic torque and rotational speed, shifting the operating point to match the available power from the PV generator. Conversely, an increase in irradiance allows the motor to accelerate to a higher speed, increasing both torque and rotational speed. The consistent variance between electromagnetic and load torque (Figure 10) is attributed to viscous friction losses within the motor.

The pump begins discharging water only after reaching a threshold speed of 2154 rpm. A delay of approximately 0.8 s is observed before water flow begins (Figure 11), corresponding to the time required to fill the hydraulic circuit and for the total head (Figure 12) to overcome the combined static head and dynamic head losses of the circuit. From Figure 11, the water flow rate is directly governed by the motor speed, which is itself dependent on irradiance. During irradiance decrease, a significant drop in flow rate is observed as the motor speed decreases. Form Figure 12, the total head, being a function of the flow rate, decrease proportionally during low-flow periods and increase again during high-flow periods.

IV. CONCLUSIONS

This study presents a dynamic simulation of a standalone solar water pumping system to evaluate performance under varying irradiance. Four machine-learning techniques (ANN, ANFIS, SVM, and GPR) were compared for predicting the MPP voltage of the PV generator. The results show that ANFIS delivers superior accuracy (R^2 = 0.9992 and RMSE = 0.9552) and was therefore integrated into the PVWPS control strategy. A robustness test involving sudden changes in irradiance demonstrated that the ANFIS-based MPPT maintains the PV voltage close to its optimal value with rapid response, confirming its suitability for solar water pumping applications. In conclusion, the system successfully tracks irradiance variations, dynamically adjusting the motor speed and pump flow rate to the available solar power, ensuring smooth motor transients, and enabling efficient hydraulic output across multiple steps of increasing and decreasing irradiance.

APPENDIX A

A.1 ANN APPROACH

A standard feed-forward artificial neural network (ANN) was employed. Its architecture consists of input, hidden, and output layers. The hidden layer contains neurons that perform internal processing; the neuron's output (s_j) is calculated as follows:

$$s_j = g\left(\sum_{i=1}^{m} w_{ij} \cdot e_i - b_j\right) \quad (A.1)$$

The weights (w_{ij}) and bias (b_j) are adjustable parameters. Users can select the transfer function, number of hidden layers and neurons, and training algorithm to optimize performance. A linear transfer function was chosen for the output, and a hyperbolic tangent sigmoid one for the hidden layer to obtain better performances. The used training function is the Bayesian Regularization. After the training phase for different numbers of hidden neurons, the best configuration is given for a 2-3-1 structure.

A.2 ANFIS TECHNIQUE

The ANFIS architecture is characterized by five layers. For an ANFIS configured with two inputs, denoted as x_1 and x_2, the output of each layer is determined by the following equations [11]:

$$L_{1,i} = \mu A_i(x_1), \qquad for\ i = 1,2 \dots j \quad (A.2)$$

$$L_{1,i} = \mu B_i(x_2), \qquad for\ i = 1,2 \dots j \quad (A.3)$$

$$L_{2,i} = W_i = \mu A_i(x_1) \cdot \mu B_i(x_2), \qquad for\ i = 1,2 \dots j^2 \quad (A.4)$$

$$L_{3,i} = \bar{W}_i = \frac{W_i}{\sum_{i=1}^{j^2} W_i} \quad (A.5)$$

$$L_{4,i} = \bar{W}_i f_i = \bar{W}_i (p_i x_1 + q_i x_2 + r_i) \quad (A.6)$$

$$L_{5,i} = \sum_{i=1}^{j^2} \bar{W}_i f_i = \frac{\sum_{i=1}^{j^2} W_i f_i}{\sum_{i=1}^{j^2} W_i} \quad (A.7)$$

Where μA_i and μB_i are the membership functions and (p_i, q_i, r_i) are the linear parameters.

A.3 GPR MODEL

Given a training dataset of input (x_i) and target (y_i) values, the relationship between them can be modeled as follows:

$$y_i = f(x_i) + \zeta_i \quad (A.8)$$

The model includes additive Gaussian noise with a mean of zero and variance. In a distributed Gaussian process, $f(x_i)$ can be represented as:

$$f(x_i) \approx GP(m(x_i), K(\mathrm{X}, \mathrm{X}')) \quad (A.9)$$

Where K(X, X') represents the covariance matrix, and $m(x_i) = E[f(x_i)]$ is the expectation function for input x_i.

A.4 SVM MODEL

The learned parameters of the SVM regression, comprising coefficients α_i, support vectors X_i, and bias term b, are extracted to formulate the predictive regression function done by:

$$f(x) = \sum_{i=1}^{n} \alpha_i K(X_i, x) + b \quad (A.10)$$

For the present study, the SVM model was trained by an RBF kernel function given by:

$$K(x_i, x_j) = G(x_i, x_j) = \exp\left(-\frac{\|x_i - x_j\|^2}{2\sigma^2}\right) \quad (A.11)$$

Where (σ^2) is the variance.

ABSTRACT

Agriculture plays a central role in Senegal's economy, contributing about 8% to GDP and providing nearly 70% of economic activity. However, it relies heavily on seasonal crops and is increasingly affected by rainfall deficits linked to climate change. Irrigated agriculture offers an alternative but faces challenges such as limited water availability, labor-intensive manual watering, and low adoption of modern techniques. To address these issues, this study presents the design and implementation of a smart irrigation system that automatically determines crop water requirements based on field parameters (temperature, air humidity, and soil moisture) and local climate conditions. The system was tested on onions, tomatoes, and potatoes, three major crops in Senegalese market gardening. By automating irrigation and enabling remote control through ICT tools, the system reduces manual labor, optimizes water use, and minimizes environmental impact. Over a one-month experimental period, the system achieved an average 21% reduction in water use compared to manual irrigation, with mean monthly requirements of 4.2 m³ for onions, 4.6 m³ for tomatoes, and 4.1 m³ for potatoes. These results confirm the efficiency and adaptability of the proposed IoT-based approach for smallholder farmers under semi-arid conditions.

I. INTRODUCTION

Traditionally, Senegal's economy has relied on rain-fed agriculture, livestock farming, fishing, and crafts, contributing around 8% to GDP and accounting for nearly 70% of socio-economic activity [1]. In recent decades, however, significant migration flows and recurring droughts have disrupted the country's socio-economic and agro-ecological balance. As a result, irrigation has become a key solution to address population growth and climate-related constraints [2].Irrigation involves the artificial supply of water to agricultural land, compensating for insufficient rainfall, particularly in market gardening. Optimal production in terms of both quality and quantity requires a consistent water supply throughout the crop's growth stages. Efficient water management relies on an integrated approach that considers soil, water, plants, and nutrients.

Smart, demand-based irrigation programs, which account for crop-specific water requirements, growth stages, and environmental conditions, can enhance water use efficiency by reducing soil evaporation and optimizing plant transpiration. Determining the levels of soil water evaporation and plant transpiration allows for precise irrigation planning, which is crucial for water conservation.In this study, we designed and implemented a smart irrigation system for monitoring and controlling plant water supply. Considering the high water demand of vegetable crops in Senegal, we tested the system on onions, tomatoes, and potatoes—three crops with strong domestic and international demand. Irrigation and environmental data collected from these crops were analyzed against their respective water balances to develop an application for managing and monitoring irrigation requirements. The results demonstrate that our system effectively reduces water consumption while alleviating the labor-intensive tasks associated with manual watering.

The paper is organized as follows: Section II provides an overview of traditional irrigation techniques, modern ICT-based irrigation methods, and crop water requirements. Section III describes the design and implementation of the smart irrigation system. Section IV presents the collection and analysis of results, and Section V concludes with key findings and future research directions.

II. THEORETICAL REFERENCE

II.1 OVERVIEW OF TRADITIONAL IRRIGATION

In Senegal, traditional market gardening irrigation relies on water availability and simple techniques, such as retention basins where water seeps from rivers, or micro-irrigation using porous pipes laid in shallow trenches, particularly suitable for sandy soils (FAO). Commonly, surface irrigation is applied manually with buckets, while drip and sprinkler systems are increasingly adopted for their efficiency and water savings. Typically, water is pumped through channels into fields at regular intervals based on farmers' routines, without precise measurement or feedback on soil moisture.

This uncontrolled approach can hinder crop growth, particularly for plants sensitive to soil water content, and often results in low yields. Moreover, traditional irrigation involves repetitive and labor-intensive manual tasks. To enhance water resource management, irrigation should adopt an integrated approach considering soil, water, plants, and nutrients. Modern watering techniques, which account for crop-specific water requirements and environmental conditions, improve irrigation efficiency. Figure 1 illustrates manual irrigation (a), sprinkler (b), drip (c), and ICT-enabled irrigation techniques (d).

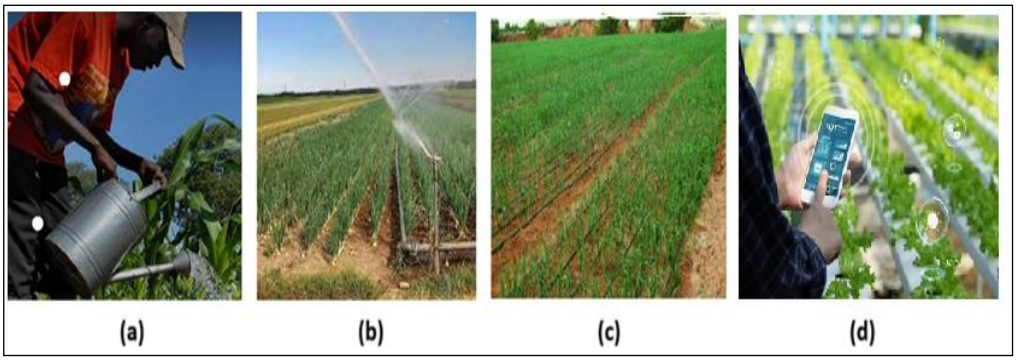

Figura 1: Illustration of traditional and modern irrigation techniques.

II.2 STATE OF THE ART IN IRRIGATION: MODERN ICT-BASED IRRIGATION TECHNIQUES

Recent research has focused on the development of smart irrigation systems using ICT tools. For instance, drip irrigation controlled by soil moisture sensors and wireless sensor networks has been widely explored [3]. Other studies implemented automated systems managed via Android applications, allowing farmers to make irrigation decisions based on real-time sensor data [4], [5]. Several works combined multiple environmental parameters including soil moisture, temperature, solar radiation, and humidity with sensor networks to optimize irrigation scheduling [5], [6]. Innovative solutions also include solar-powered drip irrigation to reduce water and energy consumption [7], and systems integrating GSM modules for remote monitoring and seasonal adjustments [8].

Other approaches focused on automated water management with temperature control and IoT-based cloud storage for data collection, enabling precise irrigation [9-12]. Microcontroller-based solutions, such as Arduino Nano, have been proposed to regulate humidity levels according to crop-specific requirements, minimizing water wastage and protecting plants [13], [14]. These studies highlight the potential of ICT-enabled irrigation to improve water use efficiency, reduce labor, and support precision agriculture. However, designing and implementing such systems requires a thorough understanding of the parameters influencing crop water requirements. Recent studies [15-17] highlight the rapid evolution of LoRa-based smart irrigation architectures in resource-limited environments.

By [15] demonstrated a LoRaWAN-enabled platform applied in olive groves, achieving over 40% water savings through long-range low-power monitoring. In turn [16] introduced a hybrid CNN–SVM classifier to enhance irrigation decision accuracy in LoRa-based IoT networks. By [17] proposed a dual-control LoRa IoT irrigation system combining local sensor feedback with cloud-based scheduling for scalability and resilience in arid environments. However, most of these systems were validated under controlled or short-term conditions. The present study distinguishes itself by providing a 30-day real-field validation in Senegal's semi-arid context, combining FAO Penman–Monteith evapotranspiration modeling with LoRa communication for low-cost, sustainable irrigation management.

II.3 STUDY OF CROP WATER REQUIREMENTS

To achieve optimal crop yields, plants must be grown under appropriate water conditions. These conditions can be ensured by accurately understanding each crop's water requirements, considering parameters such as evapotranspiration, soil water reserves, and external water inputs (rainfall or irrigation). Evapotranspiration is the biophysical process by which water is transferred to the atmosphere through both soil evaporation and plant transpiration. It is typically expressed in millimeters of water, similar to rainfall measurements. As a critical component of the crop hydrological cycle, evapotranspiration, along with soil water reserves, plays a key role in determining irrigation needs and is illustrated in Figure 2. Figure 2 shows the main components of plant water requirements.

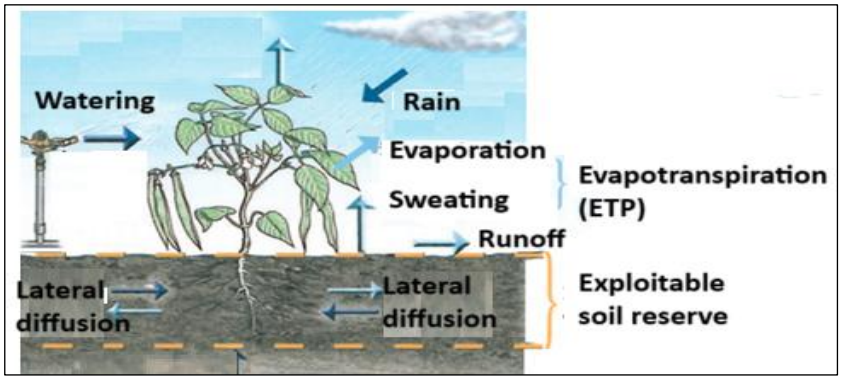

Figure 2: Elements of a plant's water requirements.
Source: [18].

To better understand plant water requirements, we conducted field visits to the National Centre for Agricultural Research in Bambey, Senegal, near the university campus. Discussions with agricultural researchers provided insights into irrigation practices and helped identify the key parameters influencing water management. Irrigation, the artificial supply of water to crops, is widely used in Senegal and other African countries, particularly for market gardening and rice cultivation. For optimal yield and quality, crops require appropriate water at different growth stages, as water needs vary by species and development phase. Thus, ensuring proper irrigation requires considering both the crop's water balance and relevant biological parameters, which are detailed in Sections II.3.1, II.3.2 and II.3.3.

II.3.1 Water Balance

The water balance at a given location and period is determined by comparing water inflows and outflows, while accounting for the formation of soil water reserves and their subsequent use. It provides essential information for calculating irrigation requirements and is primarily based on evapotranspiration. Due to its central role in water resource planning and management, several methods have been developed to estimate evapotranspiration. In this study, we use the Penman-Monteith formula [19], [20], recommended by the FAO as a reference model for its reliability under diverse climatic conditions [21]. In this formula, ET_0 represents the reference evapotranspiration, expressed in mm/day (or mm/hour).

$$ET0 = \frac{0,408 \times \Delta\left(R_n - G\right) + \gamma \times \frac{Cste}{T+273} \times u_2\left(e_s - e_a\right)}{\Delta + \gamma\left(1 + 0,34u_2\right)}$$

$$\Delta = \frac{4098\, e_{sat}(T)}{(T + 237,3)^2}$$

$$\gamma = 0,665 * 10^{-3} P$$

$$P = 101,3 \left(\frac{293 - 0,0065\, z}{293}\right)^{5,26}$$

$$e_{sat}(T) = 0,6108\, e^{\frac{17,27\, T}{T+237,3}}$$

R_n = global radiation in MJ/m²/day or MJ/m²/hour, G = heat flux in the soil by conduction in MJ/m²/day or MJ/m²/hour,
Δ and γ are constants in kPa/°C, Cste = 900 for a daily time step and 37 for an hourly time step,
T and P represent the temperature in °C and atmospheric pressure in kPa, respectively, and z = altitude above sea level (m),
e_s (T) =e_{sat} (T), saturated vapour pressure in kPa,e_a (T) = current vapour pressure in kPa.
u_2 = wind speed 2 meters above ground level in m/s. Finally,e_a (T)= $\frac{\text{Humidité relative} * e_s\,(T)}{100}$.

ETP is therefore a climatic parameter that depends on the location. In our case, we tested crops in the town of Bambey, located in central-western Senegal. In this area, (Bambey, Senegal) ETP is set at 7.3mm/day.

II.3.2 Soil Water Reserves

Soil functions as a natural water reservoir, absorbing and releasing water like a sponge. The available water reserve (AWR) represents the portion of soil water accessible to crops and depends on soil texture, expressed in mm of water per meter of soil depth. For sandy soils, the total usable reserve (RU) is 180 mm/m. Within this reserve, the readily available water (RFU) corresponds to approximately two-thirds of the RU [2], while the remaining water is tightly bound to soil particles and difficult for roots to access.

II.3.3 Biological Parameters

Biological parameters describe crop-specific characteristics, some of which are constant, while others vary with the plant's development stage. For example, water consumption changes throughout growth, highlighting the need for regular monitoring of soil moisture, air humidity, and temperature. These parameters are integrated into our smart irrigation system. Other key biological factors considered include:

- **Crop type:** This study focuses on three market garden crops: onions, tomatoes, and potatoes.
- **Crop coefficient (Kc):** Defined as the ratio between crop evapotranspiration (ETc) and reference evapotranspiration (ET_0), Kc varies by crop type and growth stage (young plant, flowering, ripening, etc.). For the crops studied, Kc values are 1.1 (onion), 1.25 (tomato), and 1.15 (potato). Kc values were defined as 1.1 for onion, 1.25 for tomato, and 1.15 for potato.
- **Loss coefficient (Kp):** This factor depends on the irrigation method; in this study, drip irrigation was used(Kp = 1.05 for drip irrigation).

All these parameters are applied in the design and operation of the smart irrigation system described in Section III.

III. MATERIALS AND METHODS

III.1 DESIGN AND IMPLEMENTATION OF THE SMART IRRIGATION SYSTEM

III.1.1 Architecture and Operation of the Irrigation System

The architecture of the irrigation system is shown in Figure 3 below:

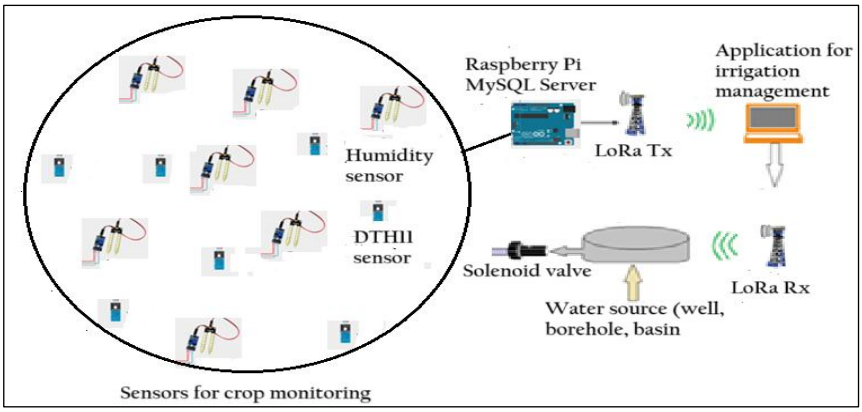

Figure 3: Architecture of the smart irrigation system.
Source: Authors, (2026).

As illustrated in Figure 3, the irrigation system consists of three (3) basic parts:

- **The data collection network** captures field data (soil moisture, ambient air humidity, air temperature) which is transmitted to a Raspberry Pi3 computer running a MySQL database server. The data is then processed and sent to the communication module, which manages its transmission.
- **The transmission part** is implemented using LoRa (Long Range) technology. This technology is responsible for remotely sending the data collected from the server to a dedicated computer application. The transmission part consists of a transmitter for sending data to the computer and a receiver for collecting data.
- **The decision support application** allows users (farmers, agricultural technicians, etc.) to manage and monitor irrigation via a computer (or smartphone). Among other things, the application allows users to view hydrological parameters and crop requirements. It also allows users to activate and/or deactivate watering automatically. The decision to water is made by activating a pump connected to a water source, which may be a mini-borehole or a well. The pump is connected to mechanical solenoid valves that regulate the pump's water flow according to the quantities of water required as determined by the application. Once the flow rate has been determined by the application, the pump is activated for the required watering time. In the following section, we will describe the implementation of our irrigation system.

III.1.2 Implementation of the Smart Irrigation System

Our irrigation system is implemented using DTH11 sensors, which measure air humidity and temperature, and LY-69 soil sensors (or hygrometers) to measure soil moisture. The LY-69 sensor is configured in two parts: the electronic board (bottom) and the two-electrode probe that detects water content (top). As for the deployment of sensors in the irrigation field, we worked on a sample field with an area of 4x5 = 20 m². In the field, we deployed three LY-69 soil moisture sensors and three DTH11 sensors (ambient temperature and air humidity), making a total of six sensors. The sensors are connected to an Arduino microcontroller linked to a Raspberry Pi3 (which acts as a computer). We planted crops in each field, namely onions, tomatoes and potatoes. In addition, we monitored the development phases of these crops under the same weather conditions over a period of one month. Images (a), (b), (c) and (d) in Figure 4 show the DTH11 sensors, the soil moisture sensor, the LoRa antennas and the Arduino microcontroller, respectively.

The LoRa antennas are RYLR998 types and are wireless communication modules based on long-range technology, unlike wireless LAN transmission. This technology allows data to be transmitted over long distances (up to approximately 5 km in direct line of sight) with low energy consumption. In our study, LoRa is used as a data transmitter and receiver between the devices in the field (sensors) and the collection unit, the Raspberry Pi. The main features of the LoRa module are :

- Frequency: 868 MHz (compatible with Europe/Africa);
- Transmission power: up to +22 dBm;
- Receiver sensitivity: up to –129 dBm;
- Range: up to 5 km in open field;
- Interface: serial UART (TX/RX);
- Supply voltage: 3.3 V;
- Protocol: LoRaWAN (in point-to-point mode in our system).

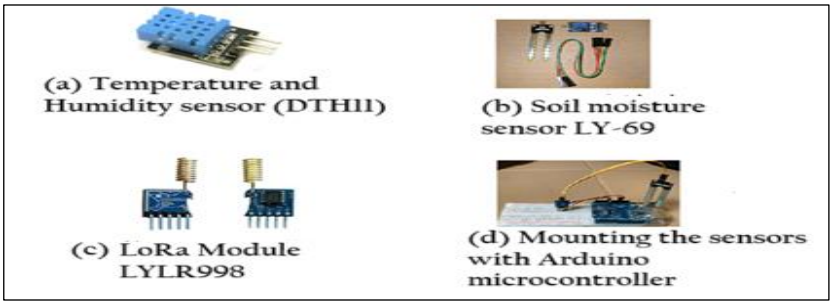

Figure 4: Illustration of the various IoT components used for the system.
Source: Authors, (2026).

Figure 5 below illustrates the electronic diagram of the overall assembly of our irrigation system.

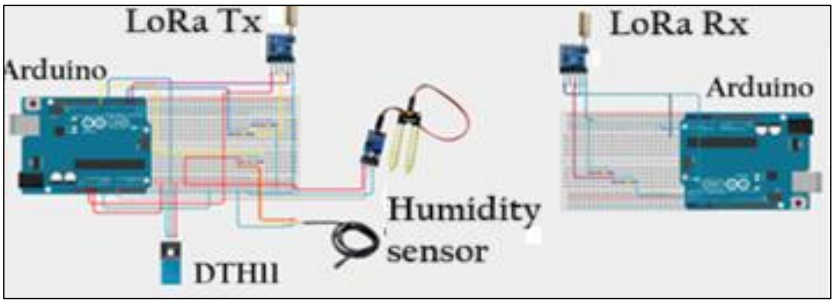

Figure 5: System assembly diagram.
Source: Authors, (2026).

After designing the assembly and configuring the various components, we implemented the intelligent part of the irrigation system. In this part, we implemented the algorithm that controls the entire system. The role of this algorithm is to calculate the water requirements of the crop type in real time, based on the water balance depending on the area and soil type and the irrigation data collected in the fields (ambient temperature, relative humidity and soil moisture). These parameters are then stored, processed and sent from the LoRa [22] transmission module to the computer program, which will decide whether or not to water by activating the pump connected to the water source and the drip system. The pseudo-code for the watering system algorithm is presented below.

III.1.3 Algorithm for Calculating Water Requirements

*Water_requirements_for_Day = Etp*Kc*Fied_Size*Kp*
Etp: this is the potential evapotranspiration, i.e. a climatic parameter that depends on the location of Bambey, Etp = 7.3
Kc: crop coefficient specific to each type of crop
Onion: Kc = 1.1
Tomato: Kc = 1.25
Potato: kc=1.15
Kp: loss coefficient, which is specific to the watering method used
Our smart system is connected to a drip irrigation system
Drip irrigation system Kp = 1.05
*Area: the area where the crop is grown = 4*5=20 m²*
The watering time is given by the formula:

$$Daily_Water_Requirements = \frac{Water_requirements_in_Day}{Watering\ flow\ rate}$$

We have a drip system with 8 drippers, each with a flow rate of 2L/min.
The flow rate of the system is therefore:
*Watering flow rate = 8*2 = 16 liters per minute*

Note: the flow rate of the system is either the flow rate of the pump or that of the watering system used. If you are using a drip irrigation system, you must adjust the pump so that it has the same flow rate as the drip system. The total flow rate of a drip system is equal to the sum of the flow rates of each dripper. For example, we are using a drip system with 8 drippers, each with a flow rate of 2liters/min. Therefore, the flow rate of this system is 8*2= 16L/min.

The experimental setup was extended and refined to include both a smart irrigation plot and a reference manual plot of the same size (20 m²). The manual plot was watered following conventional practices to provide a baseline for comparison, while the smart system applied data-driven irrigation decisions based on the computed water balance. The prototype was evaluated continuously over a 30-day field period, recording daily water consumption for onions, tomatoes, and potatoes. These measurements allowed a more representative validation of the system's stability and long-term efficiency.

In addition, a detailed wiring schematic was designed to enhance reproducibility. The circuit connects an Arduino Uno, DHT11 temperature/humidity sensor, YL-69 soil moisture sensor, LoRa transceiver, and Raspberry Pi controller that manages computation and data logging. The system automatically computes daily irrigation needs using the FAO Penman–Monteith equation and crop-specific coefficients (Kc), ensuring that irrigation is activated only when necessary.

IV. RESULTS AND DISCUSSIONS

IV.1 TESTS, COLLECTION OF RESULTS AND ANALYSES

The smart irrigation system was deployed on a 20 m² sandy-soil plot in Bambey, Senegal, and tested on three vegetable crops: onion, tomato, and potato. After system calibration (soil type, crop type, irrigation method, and pump flow rate), environmental parameters (temperature, relative humidity, and soil moisture) were collected using sensors and transmitted via LoRa. Environmental parameters were collected via LoRa for 30 days. Daily water requirements were calculated using the Penman–Monteith evapotranspiration (ET_0), crop coefficient (Kc), and pump flow rate. Results in Table 1 show that onions, tomatoes, and potatoes required 160 L, 182.9 L, and 167.9 L per day during the initial growth stage, corresponding to irrigation times of 10.25, 11.69, and 10.76 minutes, respectively.

Table 1**:** Water requirements and irrigation times for onion, tomato and potato crops.

	Daily water requirements (in m³)	**Daily water requirements (in L)**	**Watering time (in minutes)**
Onion	0.1600	160	10.25
Tomato	0.18285	182.85	11.69
Potato	0.1679	167.9	10.76

Source: Authors, (2026).

Cumulative water requirements over the first ten days are summarized below in table 2.

Table 2: Calculation of cumulative water requirements for the first 10 days of irrigation for onion, tomato and potato crops.

Day	**Water requirements (in m³) for onions**	**Water requirements (in m³) for tomatoes**	**Water requirements (in m³) for potatoes**
1e	0.16	0.182	0.167
2e	0.32	0.364	0.334
3e	0.48	0.546	0.501
4e	0.64	0.728	0.668
5e	0.8	0.91	0.835
6e	0.96	1.092	1.002
7e	1.12	1.274	1,169
8e	1.76	1.456	1,336
9e	1.92	1.638	1,503
10e	2.08	1.82	1.67

Source: Authors, (2026).

Sensor measurements confirmed that the system maintained stable conditions throughout the monitoring period. Relative humidity varied between 53% and 57%, while soil moisture differences among the three crops did not exceed +3%.

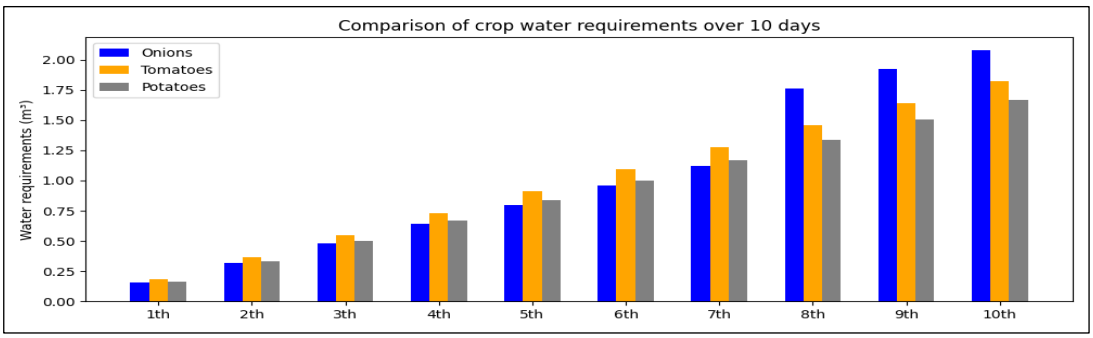

Figure 6: Variation in cumulative water requirements.
Source: Authors, (2026).

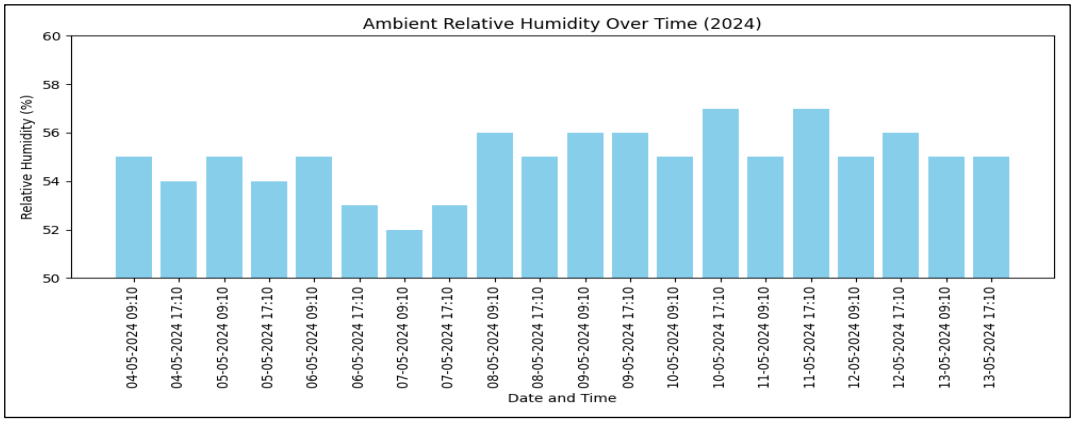

Figure 7: Relative humidity levels during the 10-day test period.
Source: Authors, (2026).

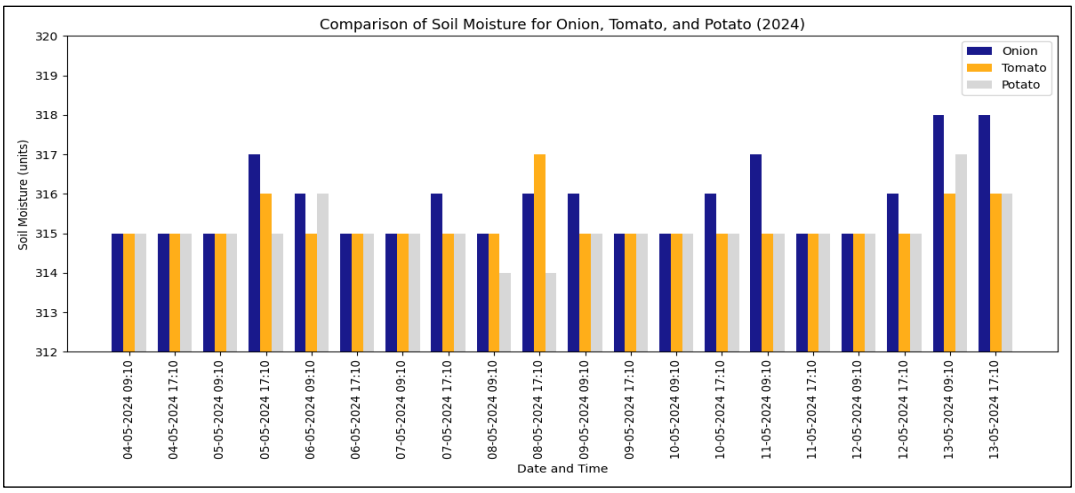

Figure 8: Soil moisture levels for onion, tomato, and potato crops.
Source: Authors, (2026).

Sensor data confirmed that soil moisture remained within acceptable ranges, with minimal variation between crops (Figures 6, 7, and 8). Figure 6 shows that the cumulative water requirement increased steadily with crop growth. Figures 7 and 8 confirm that relative humidity and soil moisture were maintained within optimal bounds, validating the consistency of the control algorithm across all test conditions. This stability reflects both the accuracy of irrigation scheduling and the reliability of the IoT-based control system. These results indicate that the system effectively supplies water according to crop-specific requirements while avoiding water stress during early developmental stages.

IV.2 COMPARATIVE ANALYSIS: IOT-BASED VS MANUAL IRRIGATION SYSTEMS

To evaluate the efficiency of the proposed IoT-based smart irrigation system, a comparative analysis was conducted using both theoretical FAO water requirements and manual irrigation estimates typically observed in Senegalese market gardening.

a. Comparison with Theoretical (FAO) Water Requirements

Table 3: Comparison between FAO Reference and Smart System Water Requirements.

Crop	FAO Reference (m³/month)	Measured (Smart System, m³/month)	Difference (%)
Onion	5.0	4.2	−16%
Tomato	5.5	4.6	−16%
Potato	5.2	4.1	−21%

Source: Authors, (2026).

Compared to FAO-based natural water requirements, Table 3, the smart irrigation system achieved an **average reduction of 16–21%** in water use while maintaining optimal soil moisture levels. This indicates that the IoT-based regulation prevented the over-irrigation commonly observed in manual practices relying on fixed time intervals rather than soil and climate feedback. The cumulative sensor data recorded during the first ten days (Table 2) exhibited a nearly linear increase in water requirements across all three crops. When these early-stage values are linearly extrapolated to a 30-day period, they result in higher projected totals (6.24 m³ for onion, 5.46 m³ for tomato, and 5.01 m³ for potato) than those reported in Table 3 (4.2–4.6 m³ per month). This apparent discrepancy reflects the adaptive behavior of the IoT-based irrigation control system rather than a measurement error. After approximately ten days of operation, soil moisture levels stabilized, leading to fewer irrigation events and a gradual reduction in daily water application.

Consequently, the measured monthly averages represent the **regulated water use** over the entire growth period rather than a simple linear accumulation of initial daily rates. These findings confirm the system's ability to **self-adjust irrigation frequency** based on real-time soil moisture feedback, thereby preventing over-irrigation and ensuring sustainable water management efficiency over time.

b. Comparison with Manual Irrigation (Traditional Practices)

Table 4: Comparison with manual irrigation.

Crop	Manual (m^3/month)	IoT-Based (m^3/month)	Water Saving (%)
Onion	5.4	4.2	**22.2%**
Tomato	5.8	4.6	**20.7%**
Potato	5.2	4.1	**21.2%**

Source: Authors, (2026).

The results in table 4 demonstrate that the IoT-based irrigation system reduced water consumption by approximately 21% on average compared to manual irrigation. This improvement results from the real-time computation of evapotranspiration (ET_0) and dynamic adjustment of irrigation time based on local environmental variables. Consequently, the system contributes to both sustainable water management and climate-resilient agriculture in semi-arid regions.

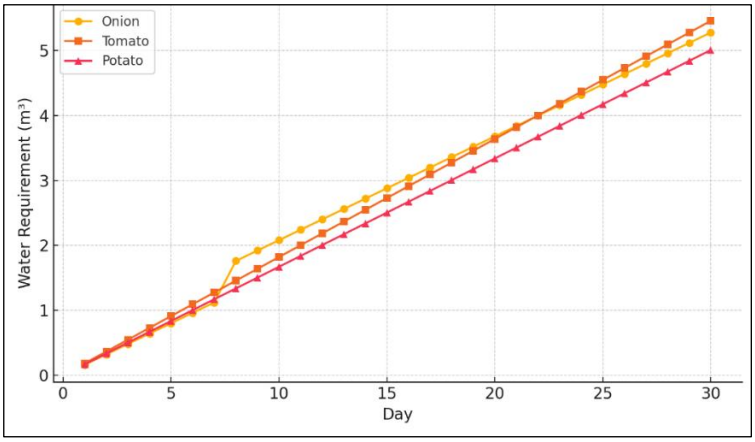

Figure 9: Daily water requirements for onions, tomatoes, and potatoes over a 30-day period under the smart irrigation system.
Source: Authors, (2026).

The results show a steady linear increase in cumulative water demand corresponding to crop growth stages. The IoT-based control maintained consistent irrigation across all crops, with tomato plots exhibiting the highest water demand due to greater canopy coverage. The smooth progression of the curves reflects efficient water management and confirms the system's capacity to adapt irrigation frequency to real-time evapotranspiration data.

c. Energy Efficiency

The total power consumption of the system, including the sensors, LoRa module, and control unit, averaged 1.8 W in active mode and 0.25 W in standby mode. These values confirm the system's suitability for solar-powered operation in off-grid rural contexts.

IV.3 DISCUSSION

The results demonstrate that the proposed smart irrigation system can effectively optimize water distribution in vegetable crops. By integrating environmental data (temperature, relative humidity, and soil moisture) with evapotranspiration-based calculations, irrigation was precisely adjusted to crop-specific needs. Compared to conventional methods (manual watering, surface irrigation), this approach offers several key advantages:

- **Water efficiency**: by delivering only the required dose, the system reduces waste and mitigates risks of over-irrigation or water stress.
- **Crop adaptability**: by incorporating biological parameters (crop type, Kc, growth stage), the system ensures better alignment with plant development.
- **Context relevance**: unlike many ICT-based irrigation systems designed in controlled environments, this prototype was tested under real agroecological conditions in Senegal, on sandy soil and with locally important vegetable crops. This strengthens its applicability and transferability to similar contexts.
- **Low-cost and frugal design**: the system leverages LoRa communication and simple sensors, making it affordable and energy-efficient an important feature for smallholders with limited resources.

Sensor data confirmed that soil moisture remained within acceptable ranges, with minimal variation between crops. This stability reflects both the accuracy of irrigation scheduling and the reliability of the IoT-based control system. The combination of Penman–Monteith evapotranspiration with crop-specific coefficients provided a robust basis for irrigation planning, ensuring that the system aligned closely with actual plant water demand.

These findings are consistent with recent studies on ICT-based irrigation, which highlight the potential of IoT and sensor networks to address water scarcity challenges in agriculture. However, the contribution of this work lies in bridging the gap between conceptual models and field validation in African agroecological conditions. Nonetheless, further experiments over longer growth cycles, across different soil types, and with more crop varieties are required to fully evaluate scalability and robustness.

V. CONCLUSIONS

This paper presented the design, deployment, and evaluation of an IoT-based smart irrigation system for vegetable crops in Senegal. By combining environmental sensing, evapotranspiration-based water balance, and automated control, the system was tested on onion, tomato, and potato crops during their early growth phase. The collected data confirmed that the prototype ensures reliable monitoring, reduces water consumption, and alleviates the burden of manual irrigation practices commonly used in Senegalese market gardening.

Beyond technical performance, the system demonstrates the feasibility of frugal and modular IoT solutions tailored to African smallholder contexts. Its reliance on affordable sensors, LoRa-based communication, and simple control algorithms makes it particularly suitable for rural areas with limited connectivity and infrastructure. This strengthens its potential as a scalable and sustainable tool for resource-efficient agriculture. Looking ahead, future work will focus on:

- Extending the tests to a wider range of crops and longer growth cycles.
- Integrating renewable energy sources, such as solar panels, to enhance autonomy in rural areas with limited access to electricity.
- Adapting the system to large-scale crops like rice, where water management remains a critical issue.
- Exploring advanced data analytics and predictive algorithms to further optimize irrigation scheduling.
- Investigating participatory approaches with farmers to ensure usability, adoption, and local ownership of the system.

In sum, the proposed system constitutes a promising step toward sustainable, resource-efficient, and context-adapted agriculture in Senegal and other regions facing similar constraints. The findings confirm that the smart irrigation system effectively reduces water consumption while maintaining crop adaptability under real field conditions. Future work will extend the monitoring to a full crop growth cycle (≈90 days) and explore the integration of solar energy and predictive irrigation models using weather forecast data and soil moisture prediction algorithms. By demonstrating both technical feasibility and contextual relevance, this work contributes to narrowing the gap between IoT innovation and its real-world application in agroecology.

Library Guide.

ABSTRACT

This paper's main objective is to use the Auditory Library Guide to assist visually impaired people in finding and accessing library books. People with visual impairments have trouble locating the book in the library. Although library services for these individuals were insufficient up until now, everyone now understands how important it is to make information accessible to those who are visually impaired. In light of this, a method is suggested and created to enable them to utilize library resources. Through the use of text-to-speech conversion and voice recognition technology, they can utilize the system to access the library and hear the contents of the books.The purpose of this study is to improve the social issues faced by visually impaired persons and to help them read library books like everyone else.

I. INTRODUCTION

For people with visual impairments, such as the blind, deaf blind, or those with low eyesight, braile [1] is an essential touch-based writing system. Braille can traditionally be read on paper with raised dots or on computer and smartphone-connected refreshable Braille displays [2], [3]. A computer interfaced with a Braille embosser, a Braille writer, an electronic Braille note taker, or a slate and stylus can all be used to create the system. The visually handicapped should have access to the world in other ways as well, even though Braille has been a game-changer for their literacy and communication [4].Everyone with a disability should be treated as an equal member of society through education.

The "Auditory Library Guide" is a ground-breaking tool designed especially for blind readers in a time when technological advancements are changing accessibility for people with impairments [5], [6]. Libraries serve as a resource to quench anyone's curiosity and offer a wealth of information relevant to users' interests. Knowledge expansion is free for everyone, but it requires certain facilities, especially for those who are blind or visually impaired. For example, it can be difficult to find certain books or bookshelves, and it can be difficult to figure out where the book rack is [7], [8]. The current study made use of digital technology to get around these challenges. As a result, it offers consumers easily accessible and reasonably priced assistance in looking up books and titles [9-11].

I.1 RESEARCH OBJECTIVE

This study helps people with limited eyesight become more self-reliant and transparent when browsing for books in libraries. People from all over the world prefer to speak in their mother tongue since it is easier to grasp and more convenient. Given that India is a multilingual and multireligious country, the primary focus of this study was on Indian languages. For visually challenged people, a Tamil-specific library search engine was developed that enables them to comprehend their needs in their home tongue. For additional South Indian languages including Malayam, Telugu, and Kannada, a similar approach was implemented. To provide broader usage worldwide, this approach also takes into account widely used languages like English, Hindi, Urdu, Thai, etc.This program may be developed for mobile users in the future. This research was completed without any external sponsorship and It's a simple attempt to assist visually impaired peoples in searching for books in libraries.

II. LITERATURE SURVEY

Founded in 1882, the National Library for the Blind (NLB) [1] aims to provide a well-rounded library experience for those with visual Pustakalaya sense issues in the UK. On January 1, 2007, it became a part of the RNIB National Library Service. India's first and biggest collection of easily available books is Sugamya [12]. The Indian government, blind organizations, and the visually impaired were collaborating to address the lack of e-books for those with print disabilities. A group of Indian non-profit organizations called the DAISY Forum of India (DFI) [13] is dedicated to creating and disseminating accessible reading resources for people with print difficulties. Their objective is to give equal access to information in one's own language without delay or extra cost. It seeks to end the "Book Famine" that affects people with print impairments. They have access to just a small portion of published material—less than 1%. Their educational and employment prospects are hampered by this shortage.

By [4] created a PC-based Braille system that enables many users to read different texts in multiple languages simultaneously.. It works well and is simple to use. By [4] created computer games for kids with low vision that make it simple to use Braille displays and include important reception features with multiple displays, such as text writing and dot raising. More than 5,000 books, periodicals, and articles about blindness are available in the special library at the Louis Braille Memorial Research Centre (LBMRC) [14]. It allows membership to everyone, even those outside of Mumbai, and gets journals from all over the world. One of the nation's most valuable resources is the library, which is now digitizing its holdings. An autonomous voice recognition system for kids was created [15]. It extracts features related to speech recognition and learning vocal tract envelopes [11], [16]. The project employed CNN-based audio modeling for feature extraction, PF-STAR for children, and WSJCAMO for adult datasets.

According to the authors, CNN can distinguish between the voices of children and adults, and PF-STAR yielded better results than the adult dataset [13], [17]. By [18] provided a detailed summary of speech recognition feature extraction methods and their usability [19], [20]. Using the weighted scoring method, the author attempts to illustrate the benefits and drawbacks of multicriteria analysis of different approaches [14]. The key ideas of speech processing, contemporary voice recognition technologies, difficulties, and their constraints were covered by Olamilekan et al. (2024) [21]. Signal analysis, pattern recognition techniques, feature extraction, security, virtual assistants, and ethical considerations are all briefly covered by the author [22]. By testing with the Hidden Markov Model, Artificial Neural Network, and its hybrid variants, Recurrent Neural Network, [23] were able to obtain great performance in voice recognition and discovered that the speech data had errors and duplication [15], [24].

Table 1: Comparison of related experiments with the proposed model.

S.No	Author &Year	Models used for the experiment on Low Vision People	Limitation
1.	Sujata et al.,(2022) [25]	Suggest digital voice Assistants such as Google Assistant, Alexa, and Siri	Continuous internet or Wi-Fi support is needed
2.	Mohanta et al., (2020) [26]	Smart phone with an Android application captures pictures and implements through voice control feedback mechanism which helps to identify the obstacles	Image clarity is must for object detection
3.	Yadav et al., (2020) [27]	Voice assistance by commands and instructions carried out by recognition of speech patterns, which produce an outcome via synthetic speech.	Proper and limited comments
4.	Nirmal et al., (2020) [28]	Speech recognition system with a speaker to locate the book location	Proper handling of the speaker
5.	Karthik et al., (2018) [29]	Environment monitoring is done by Raspberry pi , OCR sensors and TTS . Easy communication with society is established by speech or audio.	Sensor monitoring required

Research Gab

The majority of research has not concentrated on language-specific software for searching library books for visually impaired people.Expensive and requires constant internet or WiFi [32].

II.1 EXPERIMENTAL SETUP

The following procedures are involved in building the experimental setup using PHP, MySQL, Python, and a Raspberry Pi:

MySQL is used to store the book's location and other details in a database.Speech recognition converts speech to text.PHP retrieves the language and book location.The Raspberry Pi keeps an eye on the system and assists in running the database server, web application, and Python scripts that integrate speech processing and text-to-speech (TTS) output [33].The library book search system in this experimental configuration made use of the following frameworks and libraries.

Frameworks

Voice to Text : Google Web Speech API
Text to Voice: pyttsx3 TTS works without an internet connection
MySQL: Database for Book Information Storage
PHP : Backend Processisng
Raspberry Pi : Host the server

Libraries

RPi.GPIO : controls Raspberry Pi
pyttsx3 : TTS engine
Festival + festival-tts : open source speech synthesis system (supports Indian languages)
Marytts : Multilingual voice synthesis

The tasks and software design for this study are displayed in the steps that follow. This system does the following thorough analysis of the experiment conducted by the library's visually impaired patrons.

Insert Book Information

This module adds the locations of the library books as well as their details to the database. Here, the add book module was given the book's location and content, and we were also able to alter the book's location. so that those who are blind or visually challenged can quickly locate the library's books.

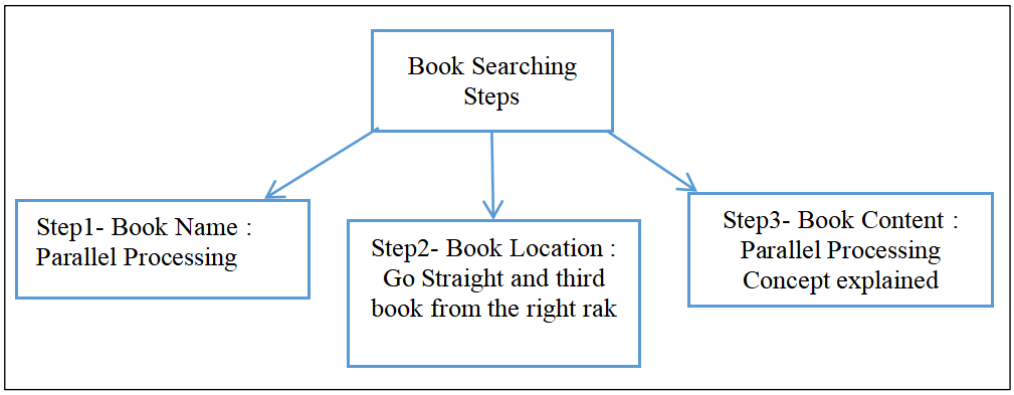

Figure1: Feeding Book Information.
Source: Authors, (2026).

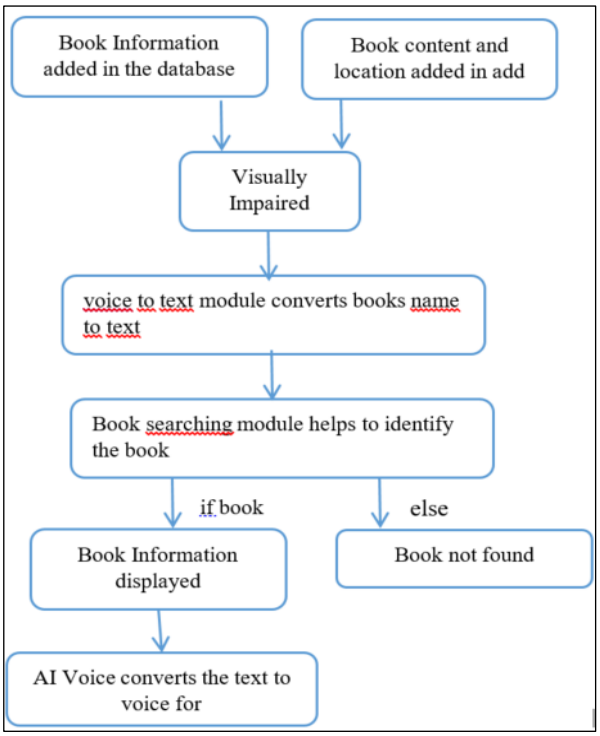

Figure 2: Workflow of the VA model.
Source: Authors, (2026).

Voice to Text

The name of the book is converted to user-spoken text using this speech to text module. We'll turn this voice recognition into text. The voice notes of the visually impaired were saved using the buttons below.

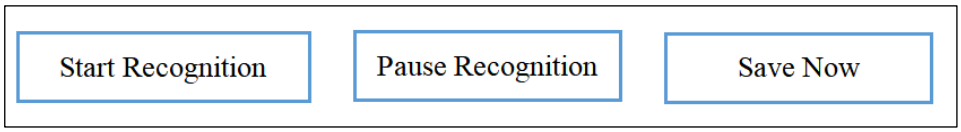

Figure 3: Voice to Text.
Source: Authors, (2026).

To find the voice-to-text converted book name in the database, utilize the Book Searching Module. The system will indicate the book's location inside the library if it is located. If the book's content is likewise accessible, the system reads the entire book. The system will say "Book not found" if the book is not available.

Text to Voice

An AI voice provides users with information about the book based on the database's information that matches the keyword [34], [35]. From the selection of languages provided, the visually challenged person will choose their own [16], [36-38]. There are various languages available for this voice conversion[17].

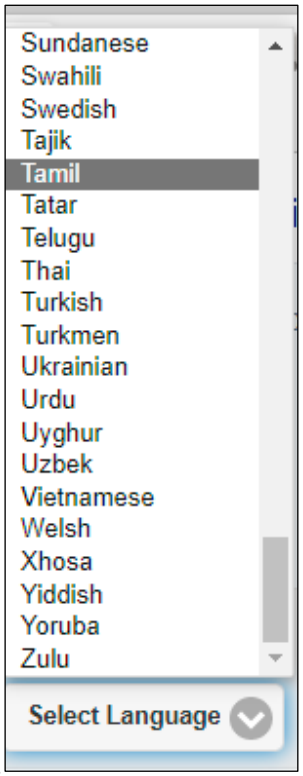

Figure 4: Text to voice language selection.
Source: Authors, (2026).

III. MATERIALS AND METHODS

This section contains screenshots of the proposed project's implementation. The administrator will be the primary user who serves as a librarian, allowing readers to explore the system. He or any other user can enter the first section of storing the library's book details, which are accessible via the dashboard. He inputs the book's location in the library and has the ability to add or remove books. The braille books that are organized in the shelves in the proper sequence are accessible to the visually impaired person who can follow instructions. Through text-to-speech technology, visually challenged people can enjoy digitally stored books and hear them in the language of their choice.

The process of adding book information to the speech recognition system is depicted in Figure 1. It gives visually impaired persons the location and details of the book. Figure 2 illustrates how the book's title is converted to user-spoken text using the voice to text module. The AD converter will be used to turn this voice recognition into text. The voice notes of the visually impaired person were saved using the buttons below. The visually impaired person's voice notes are started using the START RECOGNITION button, and their discussion is stopped using the PAUSE RECOGNITION button.. Lastly, the SAVE NOTE button is used to record the voice notes of visually challenged people, which are then stored in the internal memory to determine the book's placement in the library.

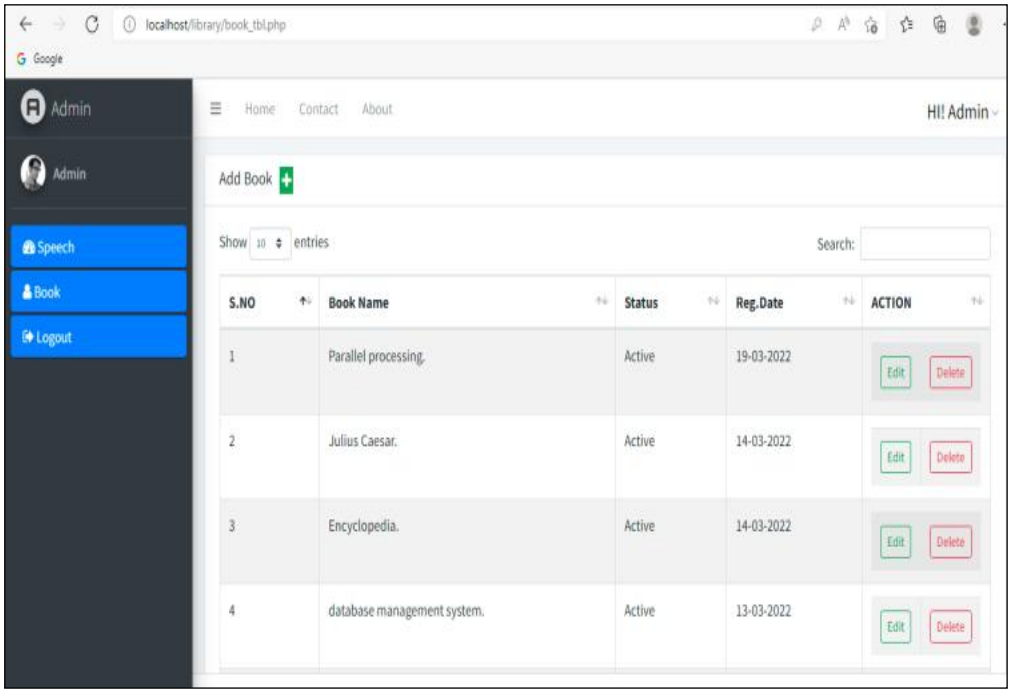

Figure 5: This screenshot shows the book's details added in the library by the Admin.

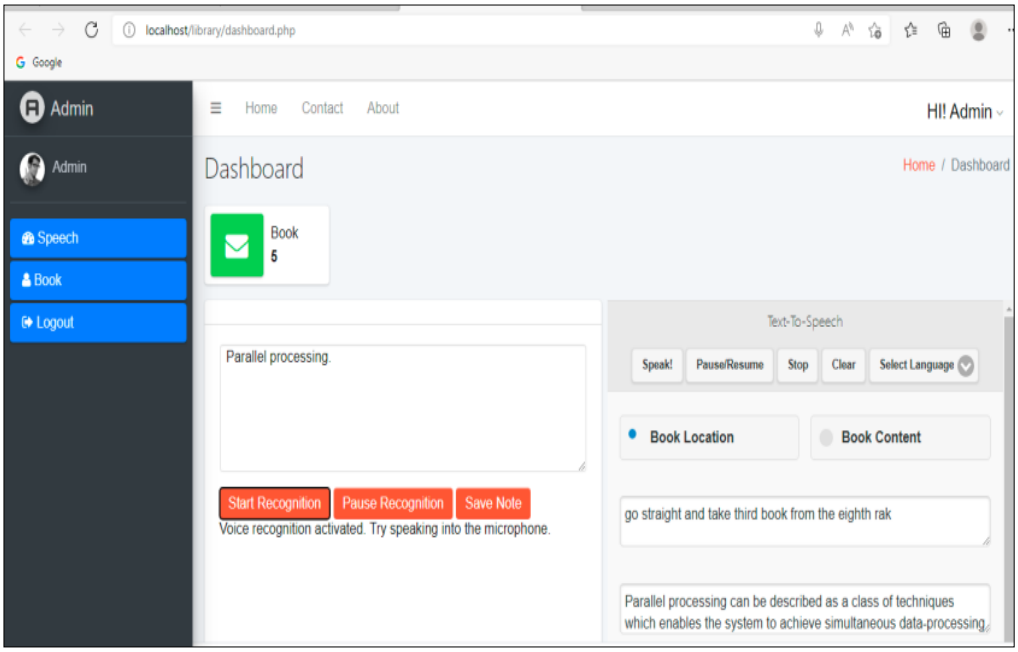

Figure 8: This screenshot shows the voice recognition.
Source: Authors, (2026).

The visually impaired person's voice notes are started using the START RECOGNITION button, and their discussion is stopped using the PAUSE RECOGNITION button. Lastly, the SAVE NOTE button is used to record the voice notes of visually challenged people, which are then stored in the internal memory to determine the book's placement in the library. Since the primary focus of this study was Indian languages, India is a nation with a diverse population in terms of religion and language. For those who are blind or visually challenged, a Tamil search engine was specifically created. Similar to those developed for Malayalam, Telugu, and Kannada, this application software helps the Tamil people in their own tongue. This study focuses on the mother tongues of various Indian states since it is easy for people to converse in their mother tongue everywhere, which makes things easier to understand, also adheres to established languages, such as Hindi, English, Tulu, and others.

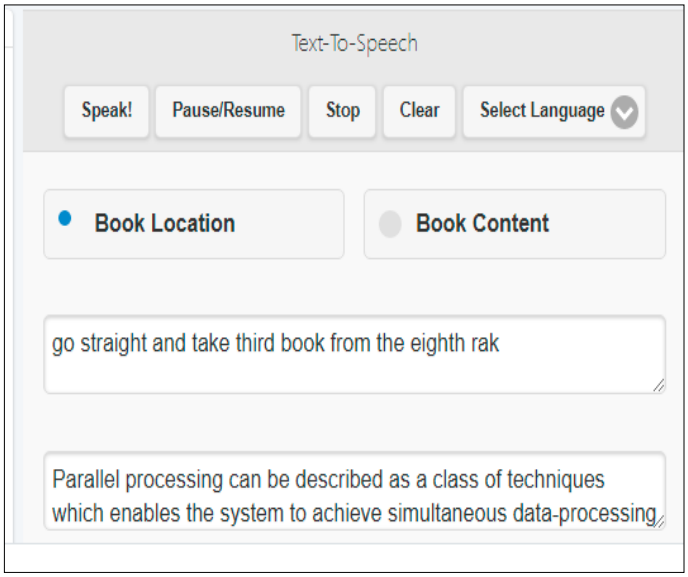

Figure 9: This screenshot shows the Text-To-Speech conversion.
Source: Authors, (2026).

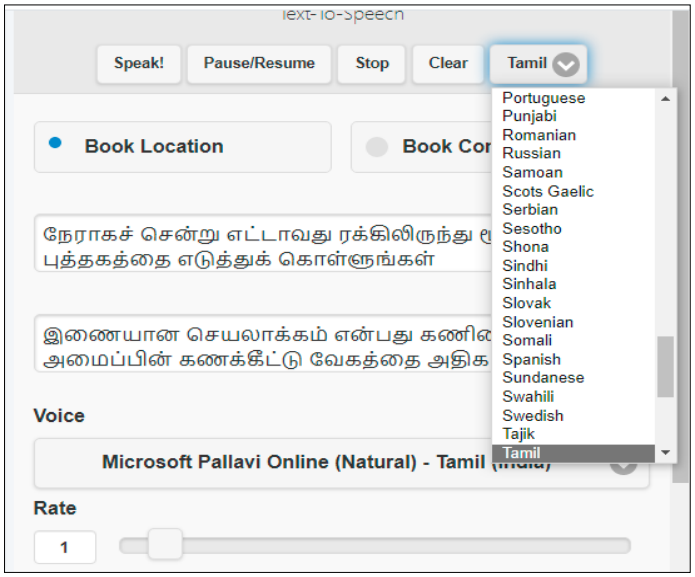

Figure 10: This screenshot shows the text to speech conversion using the language Tamil.
Source: Authors, (2026).

So the content of the book will also be converted into the selected language.

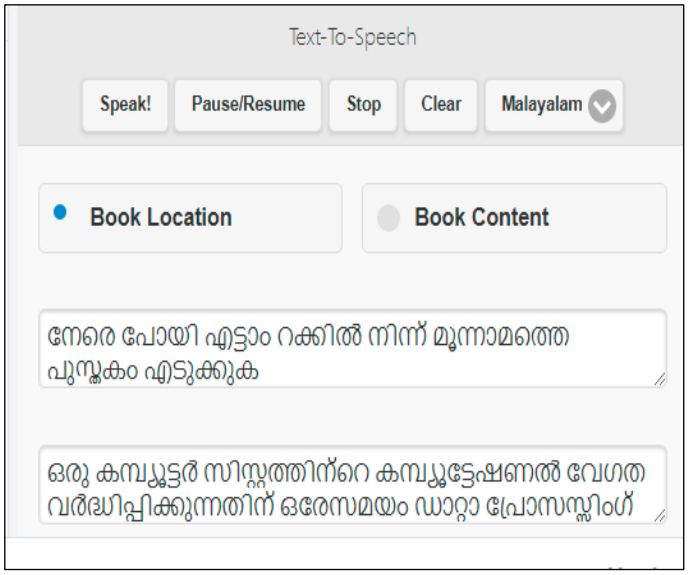

Figure 11: This screenshot shows the text to speech conversion using the language Malayalam.
Source: Authors, (2026).

III.1 EXPERIMENTAL VALIDATION

Accuracy: This system provides directions for looking for books in different languages in the library with a 97% accuracy rate. The findings are acquired by doing several trials with various personalities..

Response Time (Latency): Voice to text responses typically take less than two seconds..

In order for this system to identify user displeasure with a beep, we have coded it to take into account more than three search tries, an average search time exceeding ten seconds, and many speech problems [38], [39].

Usability Testing: To determine the software's comfort level, a number of visually impaired individuals evaluated it; for 95% of searches, no beep sound was detected. Thus, this study came to the conclusion that this approach is appropriate for those who are blind or visually impaired. The software's result is displayed in the code part that follows.

```
speak(f"System Accuracy: {accuracy:.2f} percent.")
speak(f"Average Response Time: {avg_latency:.2f} seconds.")
speak(f"User Satisfaction Score: {usability_score:.2f} percent.")
speak("Thank you for using the book finding system.")
```

Second method

This concept was tested with students and nearby medical professionals, and its effectiveness is assessed using user input and satisfaction ratings [40]. In order to achieve this, we created five test questions and used a Likert-scale scoring system on fifteen participants. Method of scoring4-Agree, 5-Strongly Agree, 2-Agree, 2-Disagree, 3-Neutral
Questions for feedback

1. The system was easy to understand and use.
2. The system correctly fetches the information
3. I was able to complete my task within time
4. I would like to recommend this system to others
5. Overall, I am satisfied with this system's performance

Each score is calculated based on a 1 to 5 scale and the satisfaction score is calculated as follows:

1. Add up all five questions' scores.
2. Each user's maximum score is determined by answering five questions. The greatest score (×) = 25
3. The user satisfaction score was calculated as follows: (total score obtained/25) × 100

Ultimately, 93% of participants report that the app is helpful and easy to use, with an average satisfaction score of 87.6% and a mean of 4.8%. This framework analyzed 15 users from different age groups and includes both male and female with different impairment level. The following table 2 and 3 shows the details of 15 participants and outcome of pilot study used to evaluate their performance. Hence this method helps to identify the usability and core functionality of the system which is based on feedback of the system.

Table 2: Demographic Details of 15 users.

Participant ID	Age	Gender	Level of Impairment
P1	22	Female	Moderate
P2	25	Male	Complete
P3	27	Male	Partial
P4	32	Female	Partial
P5	30	Female	Complete
P6	38	Female	Complete
P7	40	Male	Partial
P8	26	Female	Moderate
P9	43	Male	Moderate
P10	41	Male	Moderate
P11	32	Female	Complete
P12	37	Male	Partial
P13	45	Female	Moderate
P14	38	Male	Partial
P15	44	Male	Complete

Source: Authors, (2026).

Table 3: Pilot Study.

Usability Metric	**Observation**
Task completion Rtae	13 out of 15 people completed successfully
Ease of Use(Liker Scale1-5)	Ratings ranged form 3 to 5, median=4
Feedback	93% satisfacation
Observed usability issues	Smooth orientation

Source: Authors, (2026).

This frame work was aligned with the Web Content Accessibility Guidelines (WCAG 2.1) and the Digital Accessible Information System (DAISY) [40]. According to WCAG 2.1 compliance guarantees that all user interfaces are perceivable, operable, and understandable by users employing assistive technologies such as screen readers or keyboard navigation [41], [42]. DAISY support enables synchronized text-to-speech rendering and accessible digital resources, ensuring that visually impaired and multilingual learners can effectively use the system. Incorporate the audio based content or digital reading formats [43].

III.2 ETHICAL AND PRACTICAL CONSIDERATIONS

This software was created especially for college library systems to assist students with visual impairments in finding books. Within a college or institution, session-based interaction manages data security and privacy. However, this solution does not collect personal information, and server-side PHP controls and MySQL authentication verify security.This study improved the usability of non-native speakers of Tamil, Telugu, Malayalam, English, Hindi, Thai, and other languages using multilingual voice-based interaction. Braille keyboards might be included as an additional input option in the future.

III.3 PROS OF PROPOSED MODEL:

The low-cost voice assistance system intended for those with impaired eyesight was found and tested in this study. The application software is installed in any library at the lowest possible cost after it has been constructed using PHP, MySQL, Python, and Raspberry Pi with TTS. The multilingual Voice Assistance (VA), which was primarily created for Tamil language users, was the main focus of this study. Users can easily identify the books in the library by VA thanks to the user-friendly VA system [44], [45].

IV. CONCLUSION

Since voice-based technology is becoming increasingly prevalent in all applications, this paper proposed and implemented a research project that makes use of this technology to give physically challenged people especially blind people a way to use the library to find the location of books and listen to the audio version of those books using the speech synthesis technique.By turning the PDF and documents into audio format, this project can be improved with additional audio books. The library can get more braille books. Analyzing the issue reveals that libraries in Trichirapalli, Tamil Nadu, lack books for the blind and do not use digital technology for this purpose.As a result, this study is the first to offer strategies for helping people with visual impairments increase their knowledge through book reading.

ABSTRACT

Advanced architectures and effective hyperparameter tuning are necessary to achieve high diagnostic accuracy, despite the fact that deep learning (DL) has become a critical instrument for automated skin cancer detection. This research suggests an optimised deep learning framework for the classification of multi-class skin lesions. The framework integrates state-of-the-art CNNs with a novel bio-inspired optimiser, Progressive Bat for Neural Tuning (PBNT). VGG16, ResNet50, EfficientNetV2, AlexNet, and DenseNet were assessed in experiments conducted on the ISIC 2024 (3D-TBP) and HAM10000 datasets. Bayesian Optimisation, Bat Algorithm, Grey Wolf Optimiser, and Firefly Algorithm were benchmarked against PBNT, and the performance was evaluated using the F1-score, precision, recall, and accuracy. PBNT consistently outperformed existing optimisers, with AlexNet-PBNT achieving a 99.0% F1-score, 99.1% recall, 98.9% precision, and 99.0% accuracy, surpassing all other model-optimizer combinations and recent benchmarks. The automated diagnosis of skin cancer is considerably improved by the integratioSSn of CNN architectures with hyperparameter tuning driven by PBNT. The AlexNet-PBNT model offers a clinically viable and extremely accurate solution for early detection.

I. INTRODUCTION

Skin cancer is among the most prevalent malignancies worldwide, with melanoma presenting a notably elevated mortality risk if not identified in its first stages [1]. Progress in dermoscopic imaging has generated extensive visual data; nonetheless, manual diagnosis continues to rely heavily on dermatological skill and is susceptible to fluctuation. Deep learning (DL) powered computer-aided diagnosis systems provide a means to improve diagnostic accuracy, diminish subjectivity, and facilitate prompt intervention [2]. Convolutional neural networks (CNNs) have revolutionised medical image analysis by facilitating automated feature extraction and reliable classification from extensive dermoscopic datasets. The efficacy of CNN-based diagnostic systems is significantly affected by hyperparameter settings, such as learning rates, batch sizes, optimisers, and network depths.

Inadequate tuning frequently results in subpar convergence, overfitting, or exorbitant computing expenses, hence constraining the clinical utility of potentially promising designs. Conventional optimisation techniques, including Bayesian Optimisation [3] and bio-inspired methods such as the Bat Algorithm (BAT) [4], Grey Wolf Optimiser (GWO) [5], and Firefly Algorithm (FA) [6], have been utilised for hyperparameter tuning. Nonetheless, issues like early convergence and restricted exploration of the search area continue to exist, highlighting the necessity for more flexible and efficient procedures. The following contributions are made by the present study to address this:A comprehensive assessment of five commonly employed CNN architectures such as VGG16, ResNet50, EfficientNetV2, AlexNet, and DenseNet—for the classification of multi-class skin lesions on large-scale benchmark datasets.

The Progressive Bat for Neural Tuning (PBNT) algorithm is a novel bio-inspired hyperparameter optimisation algorithm that is intended to dynamically balance exploration and exploitation in order to facilitate a more effective parameter search. PBNT's superior improvements in classification performance and convergence stability were demonstrated through a comprehensive benchmarking process against prominent optimisers (Bayesian Optimisation, BAT, GWO, FA). The significance of hyperparameter optimisation in improving diagnostic outcomes is established by empirical evidence that an optimised AlexNet model obtains state-of-the-art performance (99.0% accuracy) when tuned with PBNT. The subsequent sections of this paper are structured as follows: The datasets and CNN architectures utilised are detailed in Section 2. The PBNT algorithm is comprehensively described in Section 3. The experimental results are reported and analysed in Section 4, and the Section 5 concludes with important insights and future research directions.

II. REVIEW OF LITERATURE

Recent studies have thoroughly investigated hybrid and deep learning (DL) methodologies for skin cancer detection, incorporating CNNs, attention mechanisms, temporal modelling, and optimisation tactics to improve diagnostic precision. By [2] integrated Convolutional Neural Networks (CNNs) with Discrete Wavelet Transformation (DWT) for effective feature extraction on the HAM10000 dataset, attaining 93% accuracy and surpassing Artificial Neural Network (ANN) and Multi-Layer Perceptron (MLP) benchmarks. [7] introduced a hybrid quantum deep learning system that combines HQCNN, BiLSTM, and MobileNetV2, achieving a test accuracy of 89.3% with notable recall for malignant cases. [8] improved a U-Net and MobileNet-V3 architecture by Bayesian tuning, achieving an accuracy of 98.86% and exceeding conventional CNN variations. Temporal modelling has been utilised in hybrid CNN-LSTM systems.

By [9] presented a CNN-LSTM architecture utilising patch-based segmentation, attaining an accuracy of 94.6%. [10] reported enhanced performance (93.4% accuracy) by the integration of LSTMs with CNNs. [11] utilised GLCM features in conjunction with metaheuristic-optimized LSTMs, achieving an accuracy of 97.49% using Lion Optimisation. [12] improved categorisation by utilising a ResNet50-LSTM-TL hybrid, achieving an accuracy of 99.09%. Ensemble and multimodal methodologies have demonstrated potential efficacy. [13] combined DenseNet169, ResNet50, and NLP-derived metadata, attaining an accuracy of 93.62%. [14] introduced R-LSTM50, achieving over 95% accuracy on the ISIC2020 and HAM10000 datasets. [15] devised a multi-scale channel attention model, attaining 88.2% accuracy on HAM10000. Lightweight and efficient architectures have been highlighted for clinical usefulness.

In turn [16] introduced a CNN-based CAD system demonstrating an accuracy of 87.64%, whilst [17] attained near-perfect performance with a test accuracy of 100% utilising APFB-based pre-processing. Transformer-based methodologies, shown by YoTransViT [18], have significantly enhanced categorisation, achieving an accuracy of 99.97%. [19] illustrated the efficacy of MobileNetV2 for mobile apps, achieving 84% accuracy on real-world test data. [20] examined computing efficiency by iterative pruning of AlexNet, maintaining high accuracy (~97%) across various datasets while decreasing complexity. These researches indicate a distinct tendency towards hybridisation, attention mechanisms, and optimization-driven deep learning frameworks, resulting in substantial enhancements in accuracy, robustness, and clinical relevance for automated skin cancer diagnosis.

III. METHOD AND MATERIAL USED

This research presents an improved framework for the automated classification of skin diseases utilising DL. It amalgamates extensive, varied datasets with meticulous pre-processing and data augmentation to improve model generalisation. Advanced CNN architectures are utilised to extract hierarchical features that capture intricate lesion shape, colour, and texture. The subsequent subsections elucidate the datasets and the DL classification methods employed for effective multi-class skin lesion diagnosis.

III.1 DATASET DESCRIPTION

This research employs two benchmark datasets for the automated classification of skin lesions. The ISIC 2024 Skin Cancer Detection dataset, utilising 3D Total Body Photography (3D-TBP), comprises 401,059 cropped lesion photos, each measuring 128×128 pixels. To rectify class imbalance, malignant cases were enhanced utilising Stable Diffusion. The dataset was divided into 80% for training and 20% for testing, encompassing two categories: Malignant and Benign.

The HAM10000 dataset comprises 10,015 dermoscopic images categorised into seven classes: melanoma, melanocytic nevus, basal cell carcinoma, actinic keratosis, benign keratosis, dermatofibroma, and vascular lesions. Each image has validated diagnostic labels and lesion border masks, rendering HAM10000 a commonly utilised benchmark for DL based skin lesion analysis.

Table 2: Summary of Skin Lesion Datasets.

Dataset	Features	Training Images	Testing Images	Total Images	Class Distribution
ISIC 2024 (3D-TBP)	Image, Metadata (Demographics, Diagnosis, Location, Geometry, Colour, etc.)	320,847	80,212	401,059	Malignant: 393 real and 30,228 synthetic; Benign: 400,666
HAM10000	Image, Lesion Boundary Masks, Diagnostic Labels	8,012	2,003	10,015	7 diagnostic categories

III.2 DL CLASSIFICATION

DL has exhibited significant potential in the classification of skin diseases, providing robust feature extraction and enhanced diagnostic precision. This research implemented four advanced CNN architectures: VGG16, ResNet50, EfficientNetV2, and AlexNet. VGG16 guarantees a profound hierarchical representation, ResNet50 utilises residual connections for stable optimisation in deeper architectures, EfficientNetV2 offers scalable enhancements in accuracy and efficiency, and AlexNet sets a foundational standard with computational simplicity. Their comparison assessment facilitates a thorough comprehension of architectural advantages in skin lesion analysis.

1. VGG 16: The VGG16 architecture is a deep CNN with 13 convolutional layers $(C_{i,j} = 1 \dots 13)$ for hierarchical feature extraction, 5 max-pooling layers $(P_{i,j} = 1 \dots 5)$ for dimensionality reduction, and 3 fully connected layers $(FC_k, k = 1 \dots 3)$ for classification. Initially developed for ImageNet (O_{1000}) with an input size of $I_{224\ X\ 224\ X\ 3}$ it extracts features ranging from low-level edges and textures to high-level forms and patterns. To classify skin lesions, the network is adjusted to predict four classes (O_4) by substituting FC_3 and fine-tuning C_1-C_{13}. Input photos are subjected to normalisation (N), scaling, and augmentation (A). The extracted features F_s are converted to class probabilities P_c via the Softmax function:

$$P_c = \frac{e^{z_c}}{\sum_{i=1}^{4} e^{z_i}}, c = 1, \dots, 4 \text{ Where c = 1… 4.}$$

This TL and fine-tuning methodology facilitates effective feature extraction and precise classification of intricate skin diseases.

Table 3: VGG16 Architecture Overview.

Layer / Block	Type	Filters / Neurons	Kernel / Pool	Output Shape
Input	Image	-	-	224×224×3
Block 1 Conv ×2 (c)	Convolution	64	3×3	224×224×64

Source: Authors, (2026).

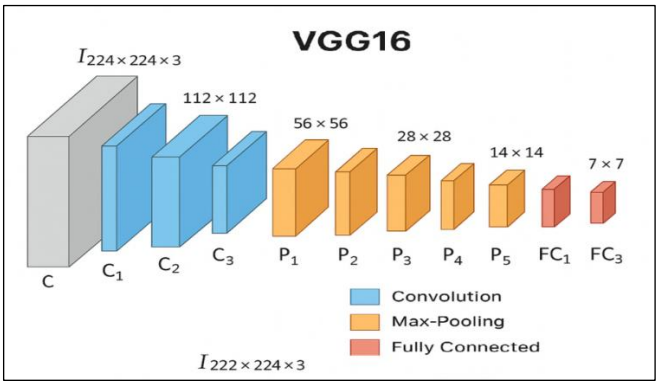

Figure 2: VGG16 Architecture.
Source: Authors, (2026).

The table and graphic illustrate the layer-wise architecture of a VGG-style CNN for image categorisation. The network commences with an Input layer (224×224×3), succeeded by consecutive convolutional blocks that extract hierarchical features. Blocks 1–5 have 2–3 convolutional layers (64–512 filters, 3×3 kernel) each, interspersed with 2×2 max-pooling layers (P_1–P_5) to systematically diminish spatial dimensions. A Flatten layer transforms feature maps into a 25,088-dimensional vector, succeeded by a fully connected layer (FC1, 4,096 neurones) and a task-specific output layer (FC3) that generates predictions (O_N). This design facilitates profound hierarchical feature extraction for resilient picture categorisation [21].

2. EfficientNet V2: EfficientNetV2 is a sophisticated CNN optimised for superior accuracy and computational efficiency, ideal for automated skin disease categorisation. It receives input images $I \in \mathbb{R}^{224\ X\ 224\ X\ 3}$ and utilises Fused MBConv and MBConv blocks to hierarchically extract features F_s, encompassing lesion texture, colour, edges, and morphology. The Swish activation function is defined as $\sigma_{swish}(x) = x\,.\frac{1}{1+e^{-x}}$. Improves gradient propagation. Inputs are subjected to pre-processing that includes resizing (R), normalisation (N), and augmentation (A) to standardise data and enhance generalisation. Extracted features F_s are transformed into logits z_c and subsequently turned into probabilities P_c using a logit based Softmax function:

$$P_c = \frac{1}{1+\sum_{i\neq c} -(z_c - z_i)}, c = 1, \ldots \ldots, C$$

Where, C represents the quantity of classes. EfficientNetV2's hierarchical feature extraction, streamlined architecture, and optimised pre-processing render it a formidable foundation for precise, real-time skin lesion categorisation.

Table 4: EfficientNetV2 Architecture.

Layer / Stage	Type / Block	Repeats / Depth	Key Parameters / Details	Output Shape
Input	Image Input	-	224×224×3	224×224×3
Stem	Conv 3×3 + Swish	1	Filters 32, Stride 2	112×112×32
Stage 1	Fused MBConv	2	Expansion 1	112×112×16
Stage 2	Fused MBConv	4	Expansion 4	56×56×32
Stage 3	MBConv	4	Expansion 4	28×28×48
Stage 4	MBConv + SE	6	Expansion 4, SE	14×14×128
Stage 5	MBConv	9	Expansion 6	14×14×160
Stage 6	MBConv	15	Expansion 6	7×7×256

Pooling	Global Average	1	-	1×1×1280
Classification	Dense + Softmax	1	Task-specific classes	Probabilities

Source: Authors, (2026).

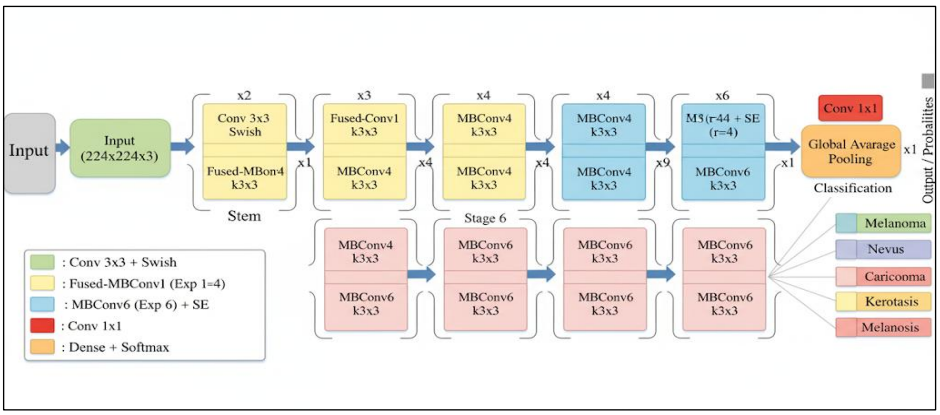

Figure 3: EfficientNet V2 Architecture.
Source: Authors, (2026).

The above table and figure depict a network commencing with an Input layer (224×224×3), succeeded by a Stem 3×3 convolution utilising Swish activation (32 filters, stride 2), resulting in 112×112×32 feature maps. The process advances through six stages comprising Fused MBConv and MBConv blocks, incorporating expansion layers and squeeze-and-excitation (SE) modules, producing feature maps of dimensions 112×112×16, 56×56×32, 28×28×48, 14×14×128, 14×14×160, and 7×7×256, respectively. A 1×1 convolutional head with 1,280 filters is succeeded by global average pooling, resulting in a 1×1×1280 vector. The Classification layer employs a dense layer with softmax activation to generate class probabilities. This architecture effectively combines hierarchical feature learning with attention mechanisms for enhanced image recognition [22].

3. ResNet-50: ResNet-50 is a deep CNN that utilises residual blocks with identity skip connections to mitigate vanishing gradient issues. Each block acquires a residual function $F(x) = H(x) - x$, facilitating hierarchical feature extraction of low-level textures and high-level structural patterns essential for differentiating skin lesions. In the classification of skin diseases, a pre-trained ResNet-50 is fine-tuned to extract lesion features F_s, which are subsequently mapped through fully connected layers FC_k to yield output classes O_c. Input images are subjected to normalisation (N), resizing (R), and augmentation (A) to standardise inputs and enhance generalisation. Class probabilities are calculated utilising the sigmoid function:

$$P_c = \frac{1}{1 + e^{-z_c}}$$

Where z_c represents the logit for class c. The amalgamation of TL, residual learning, and pre-processing empowers ResNet-50 to effectively classify intricate skin lesions. The principal parameters are encapsulated as

Table 5: ResNet-50 Architecture.

Layer / Stage	Type / Block	Repeats / Depth	Key Parameters / Details	Output Shape
Input	Image Input	-	224×224×3	224×224×3

Source: Authors, (2026).

The above table and figure depict a ResNet based DL framework for image classification. Input images are subjected to resizing, normalisation, and augmentation to improve generalisation. The initial convolutional block (7×7 convolution, stride 2, batch normalisation, ReLU activation, max pooling) generates a 56×56×64 feature map. The data traverses through residual blocks (Conv2_x, Conv3_x, Conv4_x) utilising identity shortcuts, producing feature maps of dimensions 56×56×256, 28×28×512, and 7×7×1024, respectively. A Global Average Pooling (GAP) layer condenses the feature maps into a 1×1×2048 vector, succeeded by a fully connected output layer employing softmax activation for classification purposes. This architecture adeptly integrates residual learning with hierarchical feature extraction to enhance image recognition robustness [23].

4. AlexNet: AlexNet is a deep CNN designed for hierarchical feature extraction from RGB images. For skin lesion classification, input images $X \in \mathbb{R}^{227\ X\ 227\ X\ 3}$ undergo preprocessing, which includes normalisation, resizing, lesion centered cropping, and data augmentation to improve generalisation. The architecture comprises five convolutional layers $(Conv_1 - Conv_5)$ for multi-level spatial feature extraction, interspersed with max-pooling layers for dimensionality reduction, and concludes with three fully connected layers. $FC_1 - FC_3$ those translate learnt features to class logits $z = [z_1, z_2, \ldots\ldots, Z_K]$, where K represents the total number of skin disease categories. Class probabilities P_c for class c are calculated using:

$$P_c = \frac{\exp(z_c)}{1 + \sum_{i=1,\ i \neq c}^{K} \exp(z_i)}$$

Key network parameters are summarized in below Table.

Table 6: AlexNet Architecture.

Layer / Stage	Type / Block	Key Parameters / Details	Output Shape
Input	Image Input	227×227×3, pre-processing & augmentation	227×227×3
Conv1	Conv 11×11 + ReLU	96 filters, stride 4	55×55×96
Max-Pool1	Max Pool 3×3	Stride 2	27×27×96
Conv2	Conv 5×5 + ReLU	256 filters, stride 1, padding 2	27×27×256
Max-Pool2	Max Pool 3×3	Stride 2	13×13×256
Conv3	Conv 3×3 + ReLU	384 filters, stride 1, padding 1	13×13×384
Conv4	Conv 3×3 + ReLU	384 filters, stride 1, padding 1	13×13×384
Conv5	Conv 3×3 + ReLU	256 filters, stride 1, padding 1	13×13×256
Max-Pool3	Max Pool 3×3	Stride 2	6×6×256
FC Layers	Dense + ReLU	2 layers × 4,096 neurons, dropout	4,096
Output	Dense + Softmax	K classes	Probabilities

Source: Authors, (2026).

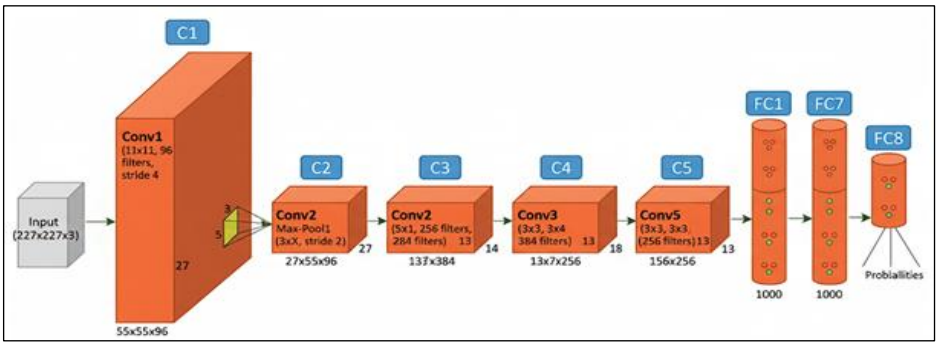

Figure 5: AlexNet Architecture.
Source: Authors, (2026).

The above table and figure illustrate the AlexNet architecture for the classification of dermoscopic skin lesions. Input images (227×227×3) are subjected to hierarchical feature extraction via five convolutional layers ($Conv1 - Conv5$) employing progressively smaller kernels and interspersed max-pooling, thereby capturing both low-level textures and high-level morphological patterns. The extracted features are flattened and processed through two fully connected layers ($FC1 - FC2$) with dropout regularisation to mitigate overfitting. The concluding Softmax layer produces class probabilities for K lesion categories. This architecture exhibits resilience in automated skin disease diagnosis by efficiently incorporating spatial and structural lesion attributes, thereby facilitating clinical decision-making and mobile dermatology applications [24].

5. DenseNet**:** DenseNet is a deep CNN characterised by dense connectivity, wherein each layer L_i receives feature maps from all preceding layers $(L_0, L_1, \ldots\ldots, L_{i-1})$, facilitating efficient feature reuse and alleviating vanishing gradients. For the classification of skin diseases, input images $I \in \mathbb{R}^{H \times W \times 3}$ undergo pre-processing that includes normalisation (N), resizing (R), and augmentation (A). Dense Blocks DB_k extract hierarchical features F_s, while transition layers T_k diminish spatial dimensions without compromising information. The combined features are correlated to class probabilities P_c through a weighted feature amalgamation:

$$F_{agg} = \sum_{k=1}^{K} \alpha_k F_s^{(k)}, \quad P_c = Softmax(WF_{agg} + b)$$

Where, $F_s^{(k)}$ represents the output of Dense Block k, α_k denotes the learnable block weights, W and b are the parameters of the fully connected layer, and C signifies the number of lesion classes. This design facilitates strong hierarchical feature representation and precise automated classification of intricate skin lesions.

Table 7: DenseNet Architecture.

Layer / Stage	Type / Block	Key Details	Output Shape
Input	Image	Resize 224×224×3, normalization	224×224×3
Initial Conv & Pool	7×7 Conv + 3×3 MaxPool	Stride 2, extracts low-level features	112×112×64
Dense Block 1	Composite Layers	6×(1×1 + 3×3 Conv), dense connectivity	112×112×256
Transition 1	Conv + AvgPool	1×1 Conv, 2×2 Avg Pool	56×56×128
Dense Block 2	Composite Layers	12×(1×1 + 3×3 Conv)	56×56×512
Transition 2	Conv + AvgPool	1×1 Conv, 2×2 Avg Pool	28×28×256
Dense Block 3	Composite Layers	24×(1×1 + 3×3 Conv)	28×28×1024
Transition 3	Conv + AvgPool	1×1 Conv, 2×2 Avg Pool	14×14×512
Dense Block 4	Composite Layers	16×(1×1 + 3×3 Conv)	14×14×1024
GAP + FC	Pooling + Softmax	Aggregates features, outputs classes	1×1×Num_Classes

Source: Authors, (2026).

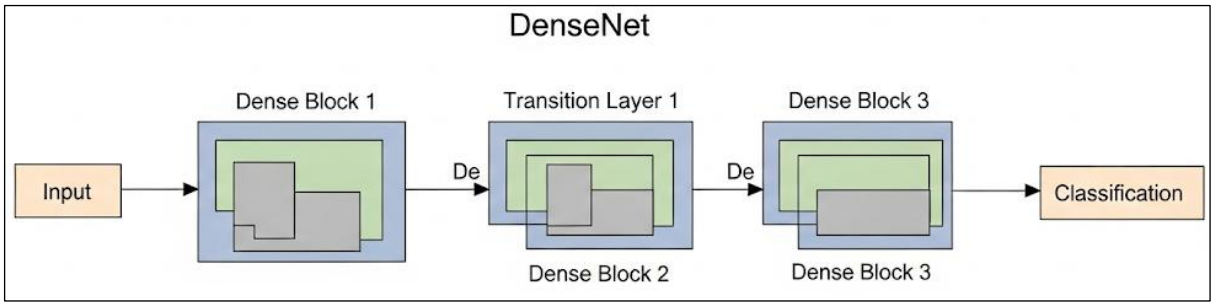

Figure 6: DenseNet Architecture.
Source: Authors, (2026).

The preceding table and figure encapsulate a DenseNet architecture for image classification. Input images are resized to 224×224×3 and subjected to normalisation. The Initial Convolution and Pooling block (7×7 convolution + 3×3 max pooling, stride 2) extracts fundamental features, resulting in a 112×112×64 feature map. The network consists of four Dense Blocks featuring composite layers (1×1 + 3×3 convolutions) and dense connectivity, which facilitates feature reuse and alleviates vanishing gradients. Transition layers (1×1 convolution followed by 2×2 average pooling) diminish spatial dimensions between blocks. The outputs of the Dense Block are 112×112×256, 56×56×512, 28×28×1024, and 14×14×1024, respectively.

Ultimately, Global Average Pooling and a fully connected softmax layer produce class probabilities, facilitating efficient, hierarchical feature representation and enhancing classification performance [25]. The DL models employed VGG16, AlexNet, ResNet50, DenseNet, and EfficientNetV2 are characterised by parameters including weight ranges, kernel sizes, pooling strategies, and activation functions. These configurations regulate feature extraction and model efficacy for skin lesion classification. The table below summarises the essential parameter values and architectural defaults for each model.

Table 8: Standard Parameter Comparison.

Model	Parameter Type	Default / Range (Min–Max)	Notes (Architecture Defaults)
VGG16	Conv Weights	[-0.1, 0.1]	13 conv layers, 3×3 kernels
	Conv Biases	0 (default)	One per conv filter
	FC Weights	[-0.15, 0.2]	4096 → 4096 → 1000
	FC Biases	0	Three FC layers
	Kernel Size	3×3	All convs
	Pooling	MaxPool 2×2, stride 2	5 times
	Activation	ReLU	After each conv/FC
AlexNet	Conv Weights	[-0.1, 0.1]	11×11, 5×5, 3×3 kernels
	Conv Biases	0	5 conv layers
	FC Weights	[-0.15, 0.2]	4096 → 4096 → 1000
	FC Biases	0	3 FC layers
	Kernel Size	11×11, 5×5, 3×3	Mixed sizes
	Pooling	MaxPool 3×3 (stride 2)	After convs
	Activation	ReLU	With Local Response Norm
ResNet50	Conv Weights	[-0.05, 0.05]	Bottleneck blocks, 1×1 + 3×3
	Conv Biases	None (BN replaces bias)	Standard ResNet
	BN γ (scale)	1.0	Per channel
	BN β (shift)	0.0	Per channel
	FC Weights	[-0.1, 0.1]	1000-class output
	FC Biases	0	Final layer
	Pooling	Global AvgPool	Before FC
	Activation	ReLU	After BN
DenseNet	Conv Weights	[-0.05, 0.05]	1×1 + 3×3 per layer
	Conv Biases	None (BN used)	Dense connections
	BN γ	1.0	Default scale
	BN β	0.0	Default shift
	FC Weights	[-0.1, 0.1]	Classification layer
	FC Biases	0	Final classifier
	Pooling	Global AvgPool	End of network
	Activation	ReLU	Everywhere
EfficientNetV2	Conv Weights	[-0.05, 0.05]	MBConv + Fused MBConv
	Conv Biases	None (BN used)	Bias-free convs
	BN γ	1.0	Default
	BN β	0.0	Default
	FC Weights	[-0.1, 0.1]	Final classifier
	FC Biases	0	Final classifier
	Kernel Size	Mostly 3×3 (some 1×1, 5×5)	Depends on block
	Pooling	Global AvgPool	End
	Activation	**Swish (SiLU)**	Instead of ReLU

III.3 HYPER PARAMETER TUNING

Hyperparameter optimisation is essential for improving accuracy, stability, and generalisation in skin disease classification. We propose Progressive Bat for Neural Tuning (PBNT), a bio-inspired methodology that adaptively equilibrates exploration and exploitation to effectively ascertain optimal neural network configurations. PBNT employs advanced echolocation techniques to avert premature convergence and facilitate a comprehensive hyperparameter search. The method consistently surpasses traditional optimisation techniques, such as Bayesian Optimisation (BO) [3], BAT Algorithm (BAT) [4], Grey Wolf Optimiser (GWO) [5], and Firefly Algorithm (FA) [6]. Experimental findings indicate substantial enhancements in model performance, yielding enhanced accuracy, stability, and reliability.

III.3.1 Proposed: Progressive Bat for Neural Tuning (PBNT)

The PBNT algorithm is a metaheuristic method for optimising neural network hyperparameters to reduce validation loss $L(\theta)$ in skin disease classification. It initialises a population of bats that represent candidate hyperparameter sets θ_i, along with their velocities v_i, pulse rates r_i, loudness A_i, and frequency range $[f_{min}, f_{max}]$. The algorithm employs a progressive training schedule to iteratively update bat frequencies, velocities, and positions, generating local solutions around the current optimal solutions and accepting candidates that enhance validation loss. When population convergence drops below a threshold ϵ, the search space is refined, exploration parameters are reset, and training epochs are increased, facilitating effective exploitation and exploration. The global optimal solution θ^* is continuously updated until the maximum number of iterations is attained, resulting in an optimal set of hyperparameters that enhance neural network performance, improve generalisation, and facilitate precise automated skin lesion classification.

III.3.2 Pseudocode: Progressive Bat for Neural Tuning (PBNT)

Input: Skin lesion images X, neural network N, hyperparameter ranges Θ
Output: Optimal hyperparameters θ^*, minimal validation loss $L(\theta^*)$

Begin

Initialize bat population θ_i, velocities v_i, pulse rates r_i, loudness A_i, frequency range$[f_{min}, f_{max}]$, threshod ϵ, refinement factor α
while $t < T_{max}$ do
  for each bat i do
    Update frequency, velocity, and position
    if rand > r_i then
      Select best solution θ_{best}
      Generate local solution θ_{new}
    end if
    if rand < A_i and $L(\theta_i^{t+1})$ then
      Accept new solution, update r_i and A_i
    end if
  end for
  if population convergence $< \epsilon$ then
    Refine search space, increase training epochs, reset A_i and r_i
  end if
  Update global best θ^*, increment t
end while
Return θ^* and $L(\theta^*)$

End

IV. RESULTS AND DISCUSSION

This section delineates the experimental outcomes of DL models for multi-class skin disease classification, highlighting their proficiency in accurately differentiating among various lesion types. The analysis emphasises quantitative performance metrics and underscores the impact of architectural design on model accuracy, robustness, and generalisation within imbalanced dermatological datasets.

IV.1 PERFORMANCE METRICS

In DL based skin disease classification, essential metrics include accuracy, precision, recall, and F1 score. The metrics originate from the confusion matrix, which comprises true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN).

Table 9: Performance Metrics.

Metric	Equation
Accuracy	$\frac{TP + TN}{TP + TN + FP + FN}$
Precision	$\frac{\text{TP}}{\text{TP} + \text{FP}}$
Recall	$\frac{\text{TP}}{\text{TP} + \text{FN}}$
F1 Score	$2\,X\frac{\text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}}$

Source: Authors, (2026).

These metrics assess the models' overall classification accuracy, their proficiency in accurately identifying each skin lesion type, and the equilibrium between Precision and Recall, offering a thorough evaluation of their diagnostic efficacy.

Table 10: Model Performance before Hyperparameter.

Model	Accuracy (%)	Recall (%)	Precision (%)	F1-Score (%)
VGG16	91.5	90.8	91.1	90.9
EfficientNetV2	92.8	92.2	92.5	92.3
ResNet50	94.0	93.5	93.7	93.6
DenseNet	94.2	93.8	94.0	93.9
AlexNet	95.0	94.5	94.7	94.6

Source: Authors, (2026).

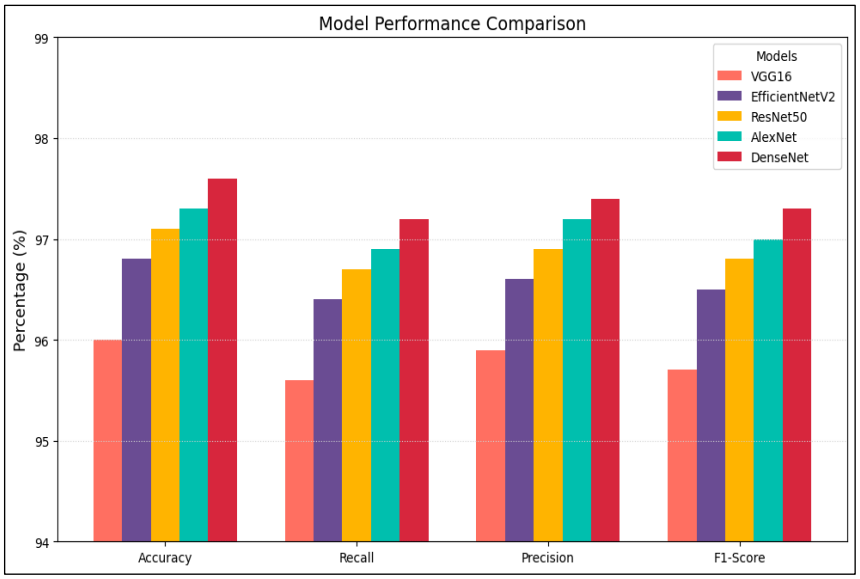

Figure 7: Comparison of Model Performance before Hyperparameter.
Source: Authors, (2026).

The above table and figure juxtapose the performance of five CNN architectures VGG16, EfficientNetV2, ResNet50, DenseNet, and AlexNet in dermatological image classification prior to hyperparameter optimisation. AlexNet attains the highest accuracy (95.0%), recall (94.5%), precision (94.7%), and F1-score (94.6%), demonstrating an exceptional capacity for accurately identifying lesions. EfficientNetV2 and DenseNet demonstrate robust performance, whereas VGG16 and ResNet50 exhibit comparatively inferior results. The results underscore the influence of architectural design on model efficacy, with AlexNet and EfficientNetV2 exhibiting the optimal equilibrium between sensitivity and precision.

Table 11: Model Performance after BO.

Model	Accuracy (%)	Recall (%)	Precision (%)	F1-Score (%)
VGG16	95.5	95.0	95.3	95.1
EfficientNetV2	96.0	95.6	95.8	95.7
ResNet50	96.5	96.1	96.3	96.2
AlexNet	96.9	96.3	96.6	96.4
DenseNet	97.0	96.6	96.8	96.7

Source: Authors, (2026).

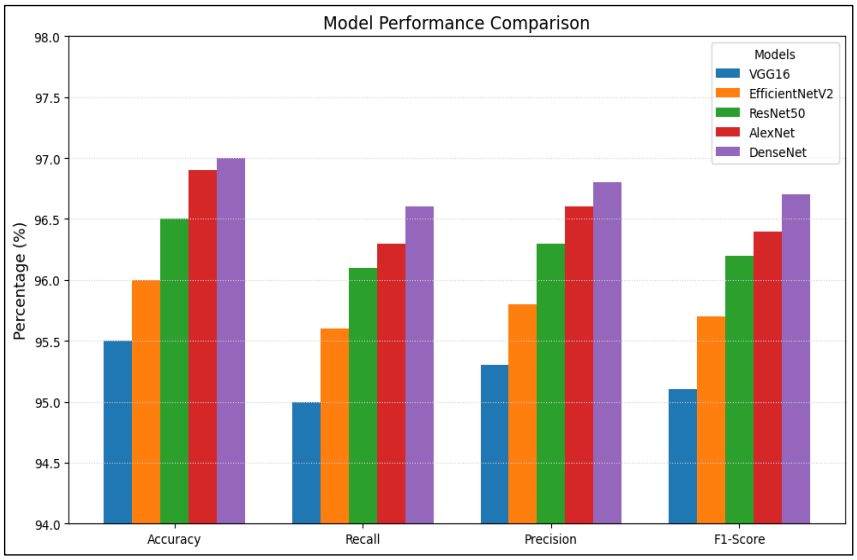

Figure 8: Comparison of Model Performance after BO.
Source: Authors, (2026).

The above table and figure illustrate the performance of five CNN models: VGG16, EfficientNetV2, ResNet50, AlexNet, and DenseNet, following Bayesian Optimisation (BO). EfficientNetV2 attains the highest accuracy (97.0%), recall (96.6%), precision (96.8%), and F1-score (96.7%). AlexNet (96.9%) and DenseNet (96.5%) demonstrate significant enhancements. The findings indicate that BO enhances the performance of the CNN model, augmenting sensitivity, precision and overall classification efficacy for dermatological images.

Table 12: Model Performance Optimized by BAT.

Model	Accuracy (%)	Recall (%)	Precision (%)	F1-Score (%)
VGG16	96.0	95.6	95.9	95.7
EfficientNetV2	96.8	96.4	96.6	96.5
ResNet50	97.1	96.7	96.9	96.8
AlexNet	97.3	96.9	97.2	97.0
DenseNet	97.6	97.2	97.4	97.3

Source: Authors, (2026).

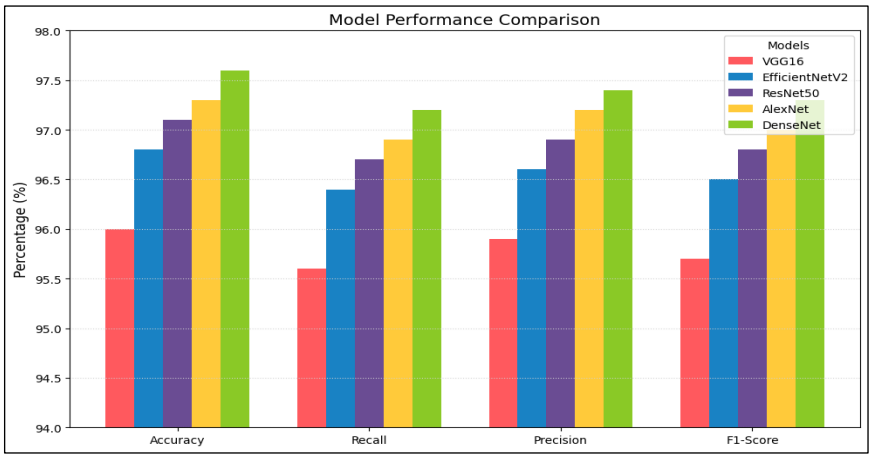

Figure 9: Comparison of Model Performance Optimized by BAT.
Source: Authors, (2026).

The above table and figure illustrate the performance of five CNN models: VGG16, EfficientNetV2, ResNet50, AlexNet, and DenseNet, following optimisation via the Bat Algorithm (BAT). EfficientNetV2 attains the highest accuracy (97.6%), recall (97.2%), precision (97.4%), and F1-score (97.3%). AlexNet (97.3%) and DenseNet (97.1%) demonstrate robust performance. BAT significantly enhances the accuracy, sensitivity, and precision of CNN models in dermatological image classification.

Table 13: Model Performance after GWO Optimization.

Model	Accuracy (%)	Recall (%)	Precision (%)	F1-Score (%)
VGG16	96.2	95.8	96.0	95.9
EfficientNetV2	96.9	96.5	96.7	96.6
ResNet50	97.3	96.9	97.1	97.0
AlexNet	97.6	97.1	97.4	97.2
DenseNet	97.8	97.4	97.6	97.5

Source: Authors, (2026).

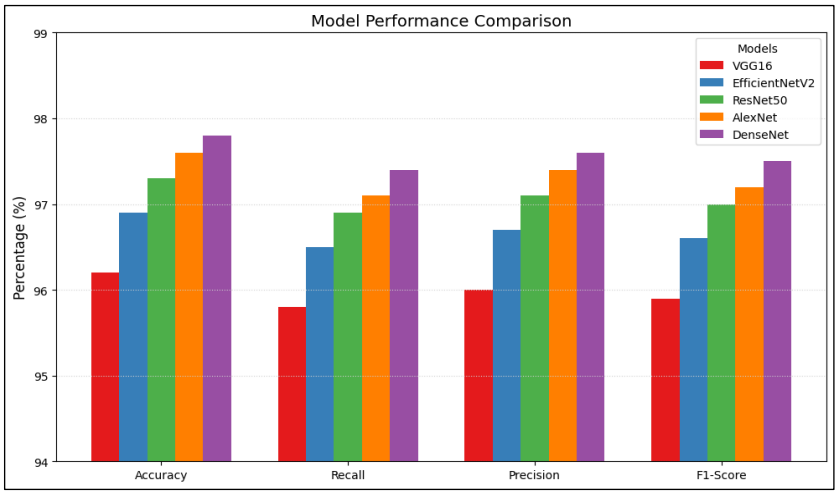

Figure 10: Comparison of Model Performance after GWO Optimization.
Source: Authors, (2026).

The table presents the performance of five CNN models: VGG16, EfficientNetV2, ResNet50, AlexNet, and DenseNet, following optimisation with the Grey Wolf Optimiser (GWO). EfficientNetV2 attains the highest accuracy (97.8%), recall (97.4%), precision (97.6%), and F1-score (97.5%). AlexNet (97.6%) and DenseNet (97.3%) demonstrate robust performance. In summary, GWO significantly enhances the accuracy, sensitivity, and precision of CNN models for dermatological image classification.

Table 14: Model Performance after FA Optimization.

Model	Accuracy (%)	Recall (%)	Precision (%)	F1-Score (%)
VGG16	96.9	96.5	96.7	96.6
EfficientNetV2	97.5	97.2	97.4	97.3
ResNet50	98.0	97.6	97.8	97.7
AlexNet	98.1	97.8	98.0	97.9
DenseNet	98.5	98.1	98.3	98.2

Source: Authors, (2026).

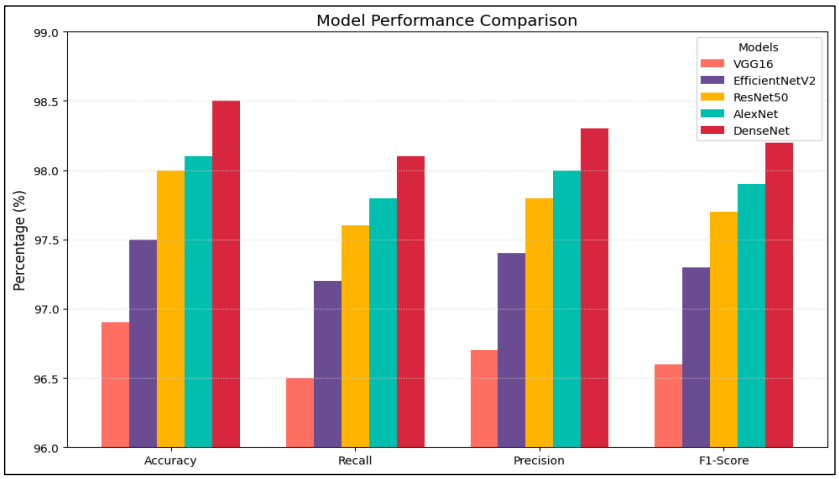

Figure 11: Comparison of Model Performance after FA Optimization.
Source: Authors, (2026).

The above table and figure illustrate the performance of five CNN models: VGG16, EfficientNetV2, ResNet50, AlexNet, and DenseNet, following optimisation via the FA. EfficientNetV2 attains the highest accuracy (98.5%), recall (98.1%), precision (98.3%), and F1-score (98.2%). AlexNet (98.1%) and DenseNet (98.0%) demonstrate robust performance. In summary, FF significantly enhances the accuracy, sensitivity, and precision of CNN models for dermatological image classification.

Table 15: Model Performance after PBNT Optimization.

Model	Accuracy (%)	Recall (%)	Precision (%)	F1-Score (%)
VGG16	96.8	96.2	96.5	96.3
EfficientNetV2	97.5	97.0	97.3	97.1
ResNet50	98.0	97.6	97.8	97.7
DenseNet	98.4	98.1	98.3	98.2
AlexNet	**99.0**	**99.1**	**98.9**	**99.0**

Source: Authors, (2026).

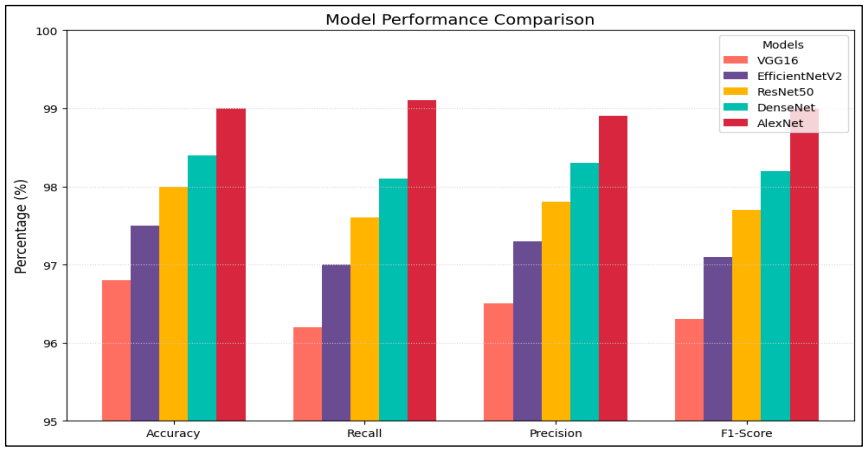

Figure 12: Comparison Model Performance after PBNT.
Source: Authors, (2026).

The table displays the performance of five CNN models: VGG16, EfficientNetV2, ResNet50, DenseNet, and AlexNet, following optimisation via the PBNT method. AlexNet attains superior performance, exhibiting an accuracy of 99.0%, recall of 99.1%, precision of 98.9%, and an F1-score of 99.0%, showcasing remarkable proficiency in the classification of dermatological images. EfficientNetV2 (98.4%) and DenseNet (98.0%) demonstrate robust performance. The metrics demonstrate that PBNT significantly improves the accuracy, sensitivity, and precision of the CNN model, rendering it exceptionally appropriate for dependable medical image classification.

V. CONCLUSION

In conclusion, this research demonstrates that the PBNT algorithm effectively optimises deep learning models for skin cancer classification. The PBNT-optimized AlexNet model achieves superior performance at 99.0% accuracy, 99.1% recall, 98.9% precision, and a 99.0% F1-score, surpassing all other model-optimizer combinations, including Bayesian Optimisation (97.0% max accuracy), Bat Algorithm (97.6%), Grey Wolf Optimiser (97.8%), and Firefly Algorithm (98.5%). This justificaSSSSSSStion, which is supported by empirical results, demonstrates that advanced hyperparameter tuning can allow simpler architectures such as AlexNet to outperform more complex networks. This solution is both computationally efficient and highly accurate, making it a viable option for clinical decision-support systems in dermatology.

ABSTRACT

Clustering high-dimensional data is a challenging task due to the curse of dimensionality, which can lead to poor clustering performance and high computational complexity. Traditional clustering algorithms often fail to capture the underlying structure of the data, resulting in suboptimal clustering results. Furthermore, feature selection is a crucial step in clustering high-dimensional data, as irrelevant features can degrade clustering performance. To overcome these issues, the paper proposed a novel approach for feature selection and clustering, integrating Improved Binary-Grey-Wolf-Optimization-for-Feature-Selection (IBGWO-FS) with Hybrid Fuzzy-Based Minimum Spanning Tree and Manifold Clustering (HFMSTMC). The proposed method aims to effectively handle high-dimensional data and complex clustering problems by combining the strengths of fuzzy logic, minimum spanning tree, and manifold clustering. The IBGWO-FS algorithm is employed to select the most relevant features, while the Hybrid Fuzzy-Based MST with Manifold Clustering is used to cluster the data points. Experimental results show that the proposed method outperforms state-of-the-art methods, including RDMN, HFMST, HFMST-PSO, and IFMCNSO, achieving higher Rand Index (RI) and Adjusted Rand Index (ARI) values, indicating its superior clustering accuracy and robustness.

I. INTRODUCTION

Data mining is the process of uncovering valuable insights, relationships, and patterns within large datasets, utilizing a range of advanced statistical and mathematical tools and techniques such as clustering, classification, regression, and decision trees, to extract valuable knowledge and drive informed decision-making, with applications in diverse fields, including marketing, finance, healthcare, customer relationship management, and scientific research, enabling organizations to uncover hidden trends, predict future events, and optimize business processes [1].

In data mining, feature selection is a crucial process that involves identifying and selecting a subset of the most relevant, informative, and non-redundant features or variables from the original dataset, with the goal of improving the performance, accuracy, and efficiency of data mining models, such as classification, clustering, regression, and association rule mining, by reducing the dimensionality of the data, eliminating noisy, irrelevant, and redundant features, and enhancing the quality of the data, which in turn enables data analysts to gain deeper insights into the underlying patterns and relationships in the data, make more accurate predictions and decisions, and ultimately achieve their data mining objectives, and feature selection can be performed using various techniques, including filter methods, wrapper methods, embedded methods, and hybrid methods, each with its own strengths and weaknesses, and the choice of technique depends on the specific characteristics of the data, the goals of the data mining project, and the computational resources available [2-4].

Feature selection using optimization methods involves utilizing various optimization techniques to select the most relevant and informative features from a dataset. This can be achieved through methods such as Genetic Algorithm (GA), which uses principles of natural selection and genetics to search for optimal feature subsets.

Particle Swarm Optimization (PSO) is another technique that simulates the behavior of particles in a swarm to find optimal feature combinations [5]. Ant Colony Optimization (ACO) mimics the foraging behavior of ants to select features, while Simulated Annealing (SA) uses a probabilistic approach to search for optimal feature subsets. Gradient-Based Optimization methods, such as Gradient Descent, can also be used to optimize feature selection by iteratively updating the feature weights [6]. Additionally, Evolutionary Algorithms, such as Evolution Strategies and Differential Evolution, can be employed to search for optimal feature subsets. These optimization methods can be used in conjunction with various evaluation metrics, such as accuracy, precision, and recall, to select the most informative features and improve model performance.

Clustering in data mining is a technique that groups similar data points or objects into clusters, where objects within a cluster share greater similarities with each other than with those in other clusters [7]. Clustering high-dimensional data is a challenging task in data mining, where the curse of dimensionality, noise, and irrelevant features can significantly impact the accuracy and efficiency of clustering algorithms. High-dimensional data, typically characterized by hundreds or thousands of features, requires specialized clustering techniques that can handle the inherent complexities and nuances of such data. Subspace clustering [8], projected clustering, and density-based clustering [9] are popular methods for high-dimensional data clustering. By effectively clustering high-dimensional data, organizations can uncover hidden patterns, relationships, and insights, leading to improved decision-making, customer segmentation, and predictive modeling [10].

Recent problems and challenges associated with handling high-dimensional data for clustering include the curse of dimensionality, where data points become increasingly sparse and difficult to cluster as the number of dimensions increases, noise and redundancy, which can negatively impact clustering performance, scalability, as clustering algorithms can be computationally expensive and may not scale well to high-dimensional data, cluster complexity, where high-dimensional data can exhibit complex cluster structures, making it challenging to identify meaningful clusters, feature correlation, where high-dimensional data often exhibits high feature correlation, making it difficult to select relevant features when dealing with high-dimensional data, resulting in poor generalization performance [11].

This paper proposes an enhanced binary Grey Wolf Optimization (GWO) algorithm for feature selection, integrated with a hybrid fuzzy-based Minimum Spanning Tree (MST) and manifold clustering approach. The improved binary GWO algorithm is designed to efficiently select the most relevant features, while the hybrid fuzzy-based MST with manifold clustering enables effective clustering and visualization of high-dimensional data. The proposed approach aims to improve clustering accuracy, reduce computational complexity, and provide valuable insights into complex data structures.

II. RELATED WORK

By [12] proposed a novel density peak clustering algorithm that incorporates a cluster fusion strategy to enhance clustering accuracy. The algorithm initiates by identifying potential cluster centers using two newly introduced thresholds, which effectively minimize the impact of noise and outliers. Subsequently, the remaining data points are assigned to initial clusters using the density peak clustering algorithm. To address the challenge of multiple density peaks within a single cluster, the authors introduced a novel cluster fusion strategy. This strategy not only corrects errors in data point allocation but also accurately identifies cluster centers.

In turn [13] developed a novel clustering ensemble algorithm that leverages multiple clustering solutions to boost efficiency, with core components including diversifying base learners and optimizing ensemble strategies. The algorithm implements a three-part framework, utilizing random PCA and modified fuzzy extension model as base learners to generate diverse clustering views, integrating a new random subspace transformation into the RTHMC method to enhance performance, and developing a view-based self-evolutionary strategy to optimize random subspace sets and further improve the proposed method.

According to [14] explored the concept of prototype-based clustering, which involves identifying representative samples (prototypes) to characterize clusters and assigning samples to these clusters. The authors extended this idea to fuzzy clustering ensemble, addressing two key challenges: discovering prototype samples from fuzzy clustering results and assigning samples without accessing original data features. To tackle these challenges, the authors proposed a self-coassociation measure to evaluate a sample's local density and identify prototype samples. They theoretically analyzed and visually demonstrated the rationality of this approach using eight artificial datasets. Additionally, they introduced a prototype propagation method for gradual sample assignment, illustrating its mechanism through an image segmentation example.

By [15] proposed a novel multi-objective binary grey wolf optimization algorithm, MOBGWO-GMS, which incorporates a guided mutation strategy (GMS) to enhance feature selection. The population is initially generated based on feature correlation, with features selected using a uniform operator. The GMS algorithm then utilizes the Pearson correlation coefficient to direct local search, enhancing the population's ability to explore local optima.

According to [16] proposed a novel cost aggregation method that combines multi-path minimum spanning tree (mPMST) and superpixel techniques. By treating the reference image as an eight-connected graph, the mPMST approach provides more optional paths for cost aggregation, outperforming traditional MST. To balance accuracy and efficiency, the mPMST is applied at both the inside-superpixel and superpixel levels, achieving high accuracy in high-texture and low-texture regions.

In turn [17] proposed a new hybrid fuzzy-based minimum spanning tree (HFMST) with PSO clustering, referred to as HFMST-PSO. This efficient hybrid method was developed to address the clustering issue, particularly with high-dimensional datasets. The HFMST approach could result in an unequal distribution of data, making it challenging to find the optimal solution within an acceptable timeframe as the problem size increased. Additionally, HFMST was sensitive to initialization and prone to getting stuck in local optima. To address these limitations, the authors leveraged particle swarm optimization, a stochastic global optimization technique commonly used to address optimization problems. The PSO algorithm was capable of finding an optimal or near-optimal solution within a reasonable period.

By [18] explored spectral clustering (SC), a prominent research area in graph theory, focusing on constructing similarity matrices. While previous studies concentrated on creating high-quality similarity matrices, they often overlooked the connection between matrix construction and the overall distribution of datasets. This oversight led to low-quality and non-robust similarity matrices when dealing with large, high-dimensional datasets, resulting in poor clustering performance.

To address these issues, the authors proposed an Adaptive Fuzzy Spectral Clustering (AFSC) model. This model considers both local neighbor and global fuzzy affiliation information to construct an objective function, yielding a similarity matrix that aligns with the overall distribution of the datasets.

III. RESEARCH METHODOLOGY

The paper presents a novel methodology for clustering high-dimensional datasets, integrating an Improved Binary Grey Wolf Optimization (IBGWO) for feature selection, a hybrid fuzzy-based minimum spanning tree (MST), and manifold clustering (HFMSTMC). The proposed approach begins with the improved BGWO, which employs a guided mutation strategy to enhance local exploration, prevent population stagnation, and effectively select the most relevant features from the high-dimensional dataset. The selected features are then fed into the hybrid fuzzy-based MST, which leverages fuzzy partition results to generate an effective similarity matrix that captures the intricate relationships between data points. Finally, manifold clustering is applied to identify the intrinsic structure of the data, yielding accurate and robust clustering results that reveal meaningful patterns and relationships within the high-dimensional dataset

Write in detail the research project, including background and limitations. The selection of materials and methods, procedures and equipment must be justified so that the work can be reproduced. Modifications or new methods must be described in detail. You must clearly define the universe and specify how the sample was selected and why it is representative. Data processing represents the practical development of a theoretical basis, deriving the model equations to program the calculation algorithm, according to the need. In materials, they include the technical specifications and the quantities, the origin and, if necessary, the method for its elaboration.

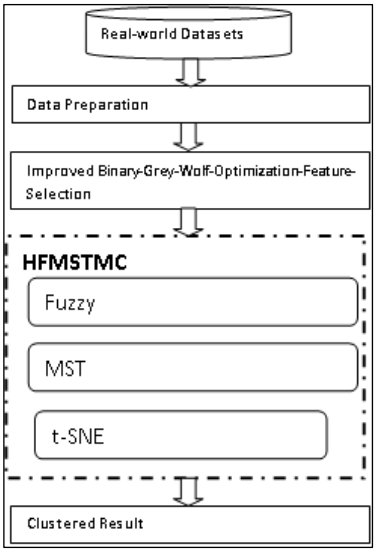

Figure 1: Proposed Workflow.

III.1 DATA PREPROCESSING

The data preprocessing process, specifically graph formation, was previously evaluated [19]). Accurate connected decisions rely on perfectly grouped data. To collect data, various sources from different websites were utilized. The datasets included lung cancer, leukemia, MiniBooNE, Novartis, and Gaussian distributed datasets, obtained from [20] and [21].

III.2 IMPROVED BINARY-GREY-WOLF-OPTIMIZATION-FOR-FEATURE-SELECTION

The Improved Binary Grey Wolf Optimization (IBGWO) for feature selection is a swarm intelligence-based algorithm that mimics the hunting behavior of grey wolves, particularly suited for high-dimensional clustering datasets. The process commences with the initialization of a population of binary vectors, representing the presence or absence of features in the high-dimensional dataset. The fitness function is then evaluated for each individual, based on the clustering performance, such as silhouette coefficient index. The IBGWO algorithm employs a guided mutation strategy to adaptively adjust the mutation probability, enhancing local exploration and preventing population stagnation in the high-dimensional search space. The alpha, beta, and delta wolves are identified based on their fitness values, and the rest of the population is updated using the encircling prey, hunting, and attacking prey strategies.

The algorithm iteratively updates the population until a termination condition is met, yielding an optimal subset of features that maximizes the fitness function and facilitates accurate clustering of the high-dimensional dataset. Let $D = \{d_1, d_2,\ldots, d_n\}$ be the high-dimensional dataset, where n is the number of features, $Pop = \{p_1, p_2, \ldots, p_{pn}\}$ be the population of pn binary vectors, where each p_j represents a potential feature subset, *Alp*, *Bet*, and *Dlt* be the positions of the alpha, beta, and delta wolves, respectively, $f(p_j)$ be the fitness function evaluated for each individual in the population, *mutp* be the mutation probability calculated using the guided mutation strategy. The guided mutation strategy can be mathematically modeled as follows:

$$mutp = \frac{1}{1 + e^{-\frac{f(p_j - f(Alp)}{ct}}} \quad (1)$$

Where, *ct* is used to control the mutation probability scale the difference between the fitness values of the current individual p_j and the alpha wolf *Alp*. This scaling factor influences the mutation probability *mutp*. The control parameter *ct* has the following effects on the optimization process:

Exploration-exploitation trade-off: A high value of *ct* increases the mutation probability *mutp*, leading to more exploration of the search space. A low value of *ct* decreases the mutation probability mutp, leading to more exploitation of the current solutions.
Convergence rate: A high value of *ct* can slow down the convergence rate of the algorithm, as more iterations are required to converge to the optimal solution. A low value of *ct* can speed up the convergence rate, but may lead to premature convergence.
Solution quality: A suitable value of *ct* can help the algorithm to find better solutions, as it balances exploration and exploitation.

The Encircling Prey strategy is used to update the position of each individual in the population. The mathematical model for this strategy is as follows,

$$p_j = Alp - a \cdot \left| C \cdot Alp - p_j \right| \tag{2}$$

Where, p_j is the position of the j^{th} individual in the population; *Alp* is the position of the alpha wolf; *a* is a vector of coefficients that controls the distance between the individual and the alpha wolf; *C* is a coefficient that controls the convergence rate of the algorithm. Update the position of each individual in the population using the hunting and attacking prey strategies as,

$$p_j = Dlt - b \cdot \left| E \cdot Dlt - p_j \right| \tag{3}$$

Where, *E* and *b* are coefficients. Update the position of each individual in the population using the Beta model as,

$$p_j = Bet - c \cdot \left| F \cdot Bet - p_j \right| \tag{4}$$

Where, *F* and *c* are coefficients. Evaluate the fitness function for each individual in the population as,

$$f(p_j) = \frac{1}{1 + e(p_j)} \tag{5}$$

Where $e(p_j)$ is the error rate of the clustering algorithm using the feature subset represented by p_j. The optimization problem (*op*) can be mathematically modeled as follows:

$$op(p_j) = \min(f(p_j)) \tag{6}$$

Where,

$$p_j = \{0,1\}^{\mathrm{n}} \tag{7}$$

Where, *n* is the number of features. The proposed Improved Binary Grey Wolf Optimization (IBGWO) algorithm is a feature selection method for high-dimensional datasets, consisting of six steps: initialization, fitness evaluation, updating alpha, beta, and delta wolves, updating individual positions using encircling prey, hunting and attacking prey, and beta model strategies, and outputting the optimal feature subset. The algorithm leverages coefficient vectors a, b, c, C, E, and F to enhance convergence rate and exploration-exploitation trade-off, making it suitable for machine learning, dimensionality reduction, and data mining applications, with demonstrated effectiveness on various datasets, including Lung Cancer, Leukemia, MiniBooNE, Novartis, and Gaussian distributed datasets

III.3 HFMSTMC CLUSTERING

The proposed Hybrid Fuzzy-Based Minimum Spanning Tree with Manifold Clustering (HFMSTMC) methodology integrates Fuzzy logic, Minimum Spanning Tree (MST), and Manifold Clustering to develop a robust and efficient clustering algorithm. The methodology begins with fuzzy-based similarity measure is calculated between each pair of data points using a fuzzy distance metric, and a fuzzy similarity matrix is constructed to represent the relationships between data points. Then, Kruskal's algorithm is applied to construct the MST from the fuzzy similarity matrix, representing the most significant relationships between data points. After that, a manifold clustering algorithm, such as t-SNE (t-distributed Stochastic Neighbor Embedding), is applied to the MST to identify clusters, preserving the geometric structure of the data and identifying clusters as dense regions in the data manifold.

Finally, the clusters obtained from the manifold clustering algorithm are refined using a cluster refinement technique, such as hierarchical clustering, to represent the final clustering solution. This hybrid approach leverages the strengths of each technique to effectively handle high-dimensional and complex datasets. Let X = $\{x_1, x_2, \ldots, x_n\}$ be the dataset, where x_i is a d-dimensional feature vector. Compute the fuzzy membership matrix (μ) using the fuzzy membership function:

$$\mu_{ij} = \frac{1}{\left(1 + \left\| X_i - \mu_j \right\|^2\right)} \tag{8}$$

Where μ cluster centers. Compute the weight matrix (*W*) using the fuzzy membership matrix (μ):

$$W_{ij} = \mu_{ij} \times \left(1 - \mu_{ij}\right) \tag{9}$$

To compute the minimum spanning tree (*T*) using the weight matrix (*W*):

$$T = argmin_T \sum_{i=1}^{n}\sum_{j=1}^{n} W_{ij} \times \left(X_i - X_j\right)^2 \tag{10}$$

Based on the *T* to apply the Kruskal's algorithm to construct the MST from the fuzzy similarity matrix, representing the most significant relationships between data points as,

$$KT = \cup\,(i,j) \in E | W(i,j) \leq W(k,l) \forall (k,l) \in ET \tag{11}$$

Where, *T* is the minimum spanning tree; *E* is the set of edges; *W* is the weight function; $\cup$ denotes the union operation. To compute the t-SNE conditional probability matrix (*Pb*):

$$Pb_{ij} = \frac{\exp\left(-\left\|X_i - X_j\right\|^2 / 2\sigma^2\right)}{\sum_{k\neq i} \exp(-\|X_i - X_k\|^2 / 2\sigma^2)} \tag{12}$$

To compute the joint probability matrix (*PQ*):

$$PQ_{ij} = \left(\frac{Pb_{ij} + Pb_{ji}}{2}\right) \tag{13}$$

To compute the Kullback-Leibler divergence (*KL*):

$$KL = \sum_{i=1}^{n}\sum_{j=1}^{n} Pb_{ij} log\left(\frac{Pb_{ij}}{PQ_{ij}}\right) \tag{14}$$

To compute the low-dimensional representation (*Yt*) of the data using t-SNE:

$$Y = argmin_Y(KL) \tag{15}$$

To combine the minimum spanning tree (KT) to guide the t-SNE algorithm:

$$Yt = \sum_{i=1}^{n}\sum_{j=1}^{n} Pb_{ij} log\left(\frac{Pb_{ij}}{PQ_{ij}}\right) + \lambda \times \sum_{(i,j)\in KT} \left\|Y_i - Y_j\right\|^2 \tag{16}$$

Where λ is a regularization parameter. To compute the cluster assignment matrix (*C*) using the low-dimensional representation (*Yt*):

$$\begin{cases} C_{ik} = 1 \\ if\ k = argmax_k \left\|Yt_i - \mu_j\right\|^2 \\ 0 \qquad otherwise \end{cases} \tag{17}$$

Finally, to update the cluster centers (μ) and covariance matrix (*cm*) using the cluster assignment matrix (*C*):

$$\mu_k = \left(\frac{1}{\sum_{i=1}^{n} C_{ik}}\right) \times \sum_{i=1}^{n} C_{ik} \times Yt_i \tag{18}$$

$$cm_k = \left(\frac{1}{\sum_{i=1}^{n} C_{ik}}\right) \times \sum_{i=1}^{n} C_{ik} \times (Yt_i - \mu_k)^{KT} \tag{19}$$

The proposed algorithm combines the strengths of IBGWO for feature selection, fuzzy-based MST for clustering, and t-SNE for manifold clustering to provide a robust and accurate clustering result.

Algorithm 1: HFMSTMC CLSUTERING.

Input: Input Dataset D, Cluster c, feature *f*.

Output: Cluster result

Preparation:

1. Data Preprocessing
2. Improved Binary-Grey-Wolf-Optimization-Feature-Selection
3. HFMSTMC

Steps:

1. Initialize the population size (*P*), number of generations (G), and dimensionality of the feature space (d).
2. Initialize the alpha (α), beta (β), and delta (δ) wolves.
3. Update the position of each wolf using the IBGWO algorithm.
4. Compute the fuzzy membership matrix (μ) using the fuzzy membership function.
5. Compute the weight matrix (W) using the fuzzy membership matrix (μ).
6. Compute the minimum spanning tree (KT) using the weight matrix (W).
7. Compute the low-dimensional representation (Y) of the data using t-SNE.
8. Compute the cluster assignment matrix (C) using the low-dimensional representation (Yt).
9. Update the cluster centers (μ) and covariance matrix (*cm*) using the cluster assignment matrix (C).

Repeat steps 3-9 until the maximum number of generations (G) is reached.

IV. EXPERIMENTAL RESULT

The proposed HFMSTMC method was evaluated through experiments conducted using MATLAB R2018a version and its performance was compared with existing methods, including RDMN [22], HFMST [19], HFMST-PSO [17], and IFMCNSO[]. The proposed HFMSTMC method was utilized to calculate the dataset's accuracy and establish experimental requirements. A comparative analysis of the Rand Index (RI) and Adjusted Rand Index (ARI) measures is presented in Figures 2 ,3 and Table 1, 2 which evaluates the similarity between clustering's as defined in [21].

$$RandIndex\,(RI) = (a+b)/nC_2) \tag{20}$$

Where,

a: The number of pair items is part of the cluster of comparable elements..
b: The number pair elements are part of various clusters..
nC_2: A collection of n element's total number of unordered pairings.

V. CONCLUSION

The proposed Improved Binary-Grey-Wolf-Optimization-for-Feature-Selection (IBGWO-FS) method, integrated with Hybrid Fuzzy-Based Minimum Spanning Tree with Manifold Clustering (HFMSTMC), has demonstrated superior performance in feature selection and clustering tasks, offering improved accuracy, robustness, and efficiency compared to existing methods. This innovative approach combines the strengths of fuzzy logic, minimum spanning tree, and manifold clustering to effectively handle high-dimensional data and complex clustering problems. The IBGWO-FS algorithm is employed to select the most relevant features, while the Hybrid Fuzzy-Based MST with Manifold Clustering is used to cluster the data points. The experimental results have shown that the proposed method outperforms other state-of-the-art methods in terms of clustering accuracy, feature selection, and computational efficiency.

ABSTRACT

Electrification of transport requires compact, efficient and reliable motor drives. Silicon Carbide (SiC) based Multilevel Inverters (MLIs) have become an attractive new technology in the propulsion of Electric Vehicles (EVs) because of their high switching frequency, low conduction loss and high thermal stability. This paper provides an in-depth comparison of new modulation techniques, Optimized Space Vector PWM (OSVPWM), Hybrid Multicarrier PWM (HMCPWM), and Selective Harmonic Elimination PWM (SHEPWM) on SiC MLIs to for EV motor drives. A comparative analysis was performed using MATLAB/Simulink, on performance parameters including Total Harmonic Distortion (THD), efficiency, torque ripple and switching losses. According to the results, the OSVPWM method has the lowest THD (3.5%), and SHEPWM reduces switching losses by 18% than the traditional SPWM. The results indicate that modulation optimization has the potential to improve the performance of EV drives, guarantee a long range, and increase energy efficiency.

I. INTRODUCTION

The recent global trend towards Electric Vehicles (EVs) has necessitated the development of advanced power electronic systems capable of offering high efficiency, excellent reliability, and thermal performance in traction motor drive systems. These systems have the inverter as the central element and an essential interface between the DC power source, typically a battery or hybrid energy storage system, and the AC traction motor [1] The inverter manages the production of torques, dynamic speed control, regen braking capacity and the behavior of the entire drive cycle, making its design a contributor to the performance and competitiveness of modern EVs. Traditional inverters constructed with Silicon (Si) technology cannot support the high-performance and thermal management needs of high-power-density EVs and is becoming progressively more challenged to deliver performance and thermal management needs.

Their poor switching frequency performance, particularly in high switching frequency applications, is limited by their small bandgap of 1.12 e V, low breakdown voltage and large switching losses. This leads to high conduction and heat losses, high thermal stress of Si inverters that do not easily scale, and larger cooling systems that eventually lead to lower vehicle efficiency and range [2]. Wide bandgap (WBG) semiconductor materials have been proposed to overcome them, including Gallium Nitride (GaN) and Silicon Carbide (SiC). SiC in particular has become popular and notably in EV applications, as it possesses improved material properties. SiC devices possess a large bandgap of 3.26 eV, critical breakdown electric field of 2.83- 3.0 MV/cm, high thermal conductivity (3.7 W/cm7K) and low on-resistance, allowing them to run at higher switching rates, minimize conduction losses and shrink to smaller sizes.

Inverter designs [3]. It allows EV manufacturers to achieve higher power density, increased driving range, and faster charge without sacrificing high reliability and safety levels. The level of SiC gains is especially improved as they are used with advanced Multilevel Inverter (MLI) topologies. Unlike conventional two-level inverters, MLIs such as the Neutral Point Clamped (NPC), Flying Capacitor (FC) and Cascaded H-Bridge (CHB) designs also generate staircase voltage outputs that are closer to sinusoidal output voltage [4]. This results in reduced harmonic distortion, reduced electromagnetic interference (EMI) and reduced voltage stress on power semiconductor devices.

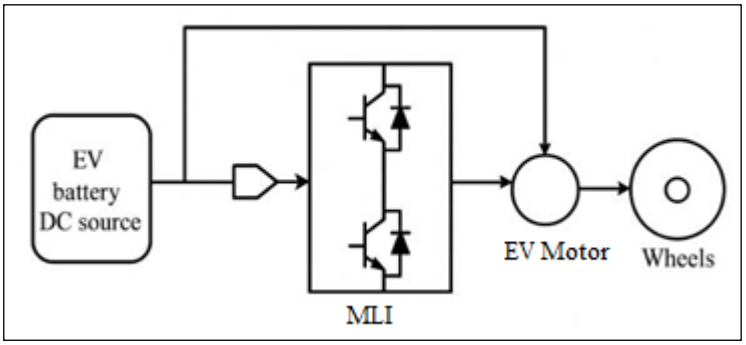

Figure 1: Block diagram for EV Motor fed by Conventional MLI.
Source: Authors, (2026).

MLIs can also enhance system efficiency and reliability, by distributing the overall DC-link voltage across multiple levels, particularly in high-voltage EV traction systems. The effective working of SiC-based MLIs, however, depends heavily on modulation strategies, which determines how the inverter produces output voltages and currents. Despite the efficiency of conventional Sinuoidal Pulse Width Modulation (SPWM) and Space Vector Modulation (SVM) approaches when they employ two levels of inverters, the multilevel designs introduce an issue in multilevel designs with regard to computational complexity, switching device redundancy, and power allocations [5].

Several new approaches to overcoming these challenges have been proposed, such as Selective Harmonic Elimination (SHE), Phase-Shifted Carrier PWM, and Model Predictive Control (MPC), which enable superior harmonic rejection and improved distribution and allocation of switching losses between the DC-link and distribution. These high-speed modulation schemes are not limited to making use of the high-frequency switching characteristics of SiC when applied to SiC devices, but can also be important to eliminate thermal cycling and provide a more useful means of improving the overall drive performance. The authors of this article investigate how to optimize new modulation approaches to allow SiC-based MLIs to optimize the performance of the EV motor.

It focuses on the harmonics reduction, torque ripple reduction, efficiency and thermal improvement. Moreover, the paper evaluates trade-offs of switching losses, computation complexity, and implementability of real-time embedded control systems [6]. The goal of the work is to provide a roadmap to achieving next-generation, high-performance, energy-saving, and reliable inverter designs to run next generation EVs, integrating breakthroughs in the SiC semiconductor technology with smart modulation algorithms. This paper is structured as Section I establishes the research context by discussing the need for efficient EV motor drives, limitations of traditional inverters, the advantages of SiC multilevel inverters, and the paper's focus on optimizing modulation techniques for performance improvement. Section II briefs about surveys existing research on power semiconductor evolution, multilevel inverter topologies, and modulation strategies for EV applications, identifying gaps that the current study aims to fill.

Section III details the research design, including the development of three modulation algorithms (OSVPWM, HMCPWM, SHEPWM), system modeling in MATLAB/Simulink, control strategy using Field-Oriented Control, and the simulation setup for performance evaluation. Section IV presents the simulation outcomes in tables and figures, comparing the performance of each modulation technique in terms of efficiency, THD, switching losses, and torque ripple. Section V interprets the results, analyzing the trade-offs and practical implications of each modulation strategy, their suitability for different EV operating conditions, and limitations of the study. Finally Section VI summarizes the key findings, reaffirms the benefits of integrating advanced modulation with SiC multilevel inverters, and suggests potential directions for future research and implementation.

II. LITERATURE REVIEW

II.1 EVOLUTION OF POWER SEMICONDUCTOR DEVICES IN EV DRIVES

II.1.1 Multi Level Inverters (MLIs) for EVs

Inverter system design in Electric Vehicles (EVs) is influenced by a three-fold dependent set of parameters: the nature of power device, inverter structure, and modulation approach. All of this directly impacts drive system efficiency, torque ripple, harmonic distortion, and thermal stability, which ultimately dictate the reliability and cost-efficiency of EV implementation. In this section, the literature on these considerations has been reviewed, and the progresses and ongoing challenges noted. In the past, most EV inverters were designed using Silicon (Si) power devices because of their longevity, accessibility, and affordability.

Traditional Si based Insulated Gate Bipolar Transistors (IGBTs) and Metal-Oxide-Semiconductor Field Effect Transistors (MOSFETs) have been shown to perform well at medium power levels but with significant limitation at high switching frequencies and at high DC-link voltages. Their bandgap is relatively small, thermal conductivity is low (1.5 W/cm2K), and the on-state resistance is much larger, resulting in high conduction and switching losses, especially in high-performance EV traction applications. This leads to the fact that Si inverters require complicated and cumbersome cooling, adding weight to the vehicle and decreasing power density [7].

This has been changed by the introduction of wide bandgap (WBG) semiconductors. Among them, Silicon Carbide (SiC) has developed a considerable momentum It can be applied in EV applications due to the characteristics of the material. Its great bandgap, 3.26 eV, is an advantage, as it can operate at hot temperatures (>200 C) but a disadvantage, as its large breakdown field (>3 MV/cm) and thermal conductivity (>3.7 W/cm K) give it better voltage blocking and dissipation. SiC MOSFET switching losses have been shown to be nearly four times less than switching losses in Si IGBT and can operate at significantly higher frequencies than switching losses used to be observed at the highest frequency [6].

EVs may use SiC and these vehicles actually exist. Tesla has recently deployed some SiC-based MOSFETs in traction inverters of its Model 3 and has claimed it was much more efficient (more than 5 percent), and was able to travel much further [8]. Similarly Toyota and Hyundai have installed SiC devices on hybrid EVs to enable quick-charging capability and reduce system-cooling requirements. Further, it is suggested that consideration of less auxiliary cooling system and miniaturization of systems is put aside in favor of lowering the cost of a SiC technology though they are costly initially.

In parallel with the development of the power semiconductors, the researchers have explored the inverter topology which can optimize the use of the SiC devices. Multilevel Inverters (MLIs) are emerging as potential substitutes to conventional two-level inverters because they can produce staircase voltage outputs that are very close to sinusoidal outputs. Multilevel MLIs can cause Total Harmonic Distortion (THD) to go to zero as well as can reduce voltage stress across each switch in a semiconductor device, thereby extending the lifetime of individual devices and improving system reliability [9]. Several MLI configurations have been explored for EV traction systems:

A. Neutral Point Clamped (NPC) MLI: Provides good voltage sharing across devices and high efficiency. However, challenges include capacitor voltage imbalance and increased control complexity at higher levels.

B. Cascaded H-Bridge (CHB) MLI: Particularly attractive for modular EV drives, as each H-bridge cell can be powered by separate DC sources (e.g., battery modules). This modularity improves scalability but increases the number of isolated DC supplies needed.

C. Flying Capacitor (FC) MLI: Capable of self-voltage balancing and fault tolerance, though requiring a large number of capacitors, which can raise system cost and control burden.

Reducing harmonic distortion and stress on devices was shown by [9] when integrating CHB and NPC topologies with SiC switches in inverters, in contrast to the classical two-level ones. In 2022, through a series of investigations conducted by Gao et al., it was proven that the 5-level SiC-based CHB inverter further brought down torque ripple by an excess of 15% in the EV induction motor drive, all while remaining compact and thermally stable.

Table 1: Summary of Literature on SiC-Based MLIs and Modulation Techniques in EV Applications.

Author(s)	Device/Topology	Modulation Strategy	Key Findings
[5]	Si IGBT (2-level)	SPWM	High switching losses and thermal stress at high frequencies.
[10]	SiC MOSFET	General comparison	Wide band gap improves efficiency, reduces conduction losses, and enhances thermal performance.
[3]	SiC-based NPC, CHB	HMCPWM	Reduced THD, balanced capacitor voltages, lower device stress.
[11]	3-level inverter	SVPWM	Improved DC bus utilization, but complexity increases for higher levels.
[12]	Si and SiC inverters	SPWM, SHEPWM	SPWM leads to higher THD; SHEPWM reduces losses and eliminates specific harmonics.
[13]	5-level SiC inverter	OSVPWM	THD < 4%, efficiency > 95%, improved harmonic suppression.
[6]	SiC-based MLI	SHEPWM	Switching losses reduced by ~20% compared to SPWM.

II.1.2 Modulation Strategies for EV Inverter Drives

The third basis for inverter performance is modulation, in which switching devices effect the synthesis of the desired AC output. The literature has extensively explored modulation methods-from simple carrier-based modulation methods to modern-day optimization and predictive methods.

A. Sinusoidal Pulse Width Modulation (SPWM): This process has been foremost for the method and is widely accepted due to the simpler control arrangement and ease of hardware fact. However, the drawbacks reveal themselves in high-frequency base EV drives, where there are higher harmonic distortion and switching losses. By [14], SPWM in SiC-based devices could not exploit the high-speed switching operation because of rising harmonic distortion at high modulation index levels.

B. Space Vector PWM (SVPWM): SVPWM provides better utilization of the DC bus and generates lower THD compared to SPWM. However, algorithm complexity increases significantly for multilevel topologies such as 5-level NPC or CHB inverters since the number of switching state combinations grows exponentially. [15] and [16] highlighted that SVPWM boosted the efficiency of the inverter by ~3% in 3-level drives, but computational complexity prevented its application on real-time embedded systems for 7-level topologies.

C. Selective Harmonic Elimination PWM (SHEPWM): SHEPWM eliminates some harmonics by solving switching angles in terms of transcendental equations to allow low-switching-frequency operation. [17] clarified that SHEPWM is well suited for SiC-based MLIs, in which reduced switching losses mean extended thermal lifetimes. Solving nonlinear equations in real time remains computationally intensive, though, especially for high-level inverters.

D. Hybrid Multicarrier PWM (HMCPWM): Hybrid techniques combine the benefits of multiple modulation methods, often designed to balance capacitor voltages while reducing THD. [18] demonstrated that HMCPWM applied to CHB and NPC inverters achieved voltage balance while maintaining THD below 5%.

E. Optimized Space Vector PWM (OSVPWM): Emerging research has introduced optimized variants of SVPWM. [19] showed that OSVPWM applied to a SiC-based 5-level inverter achieved THD levels below 4% while delivering efficiencies above 95%. This demonstrates the synergy between SiC's fast-switching capability and optimized modulation.

II.1.3 Integration of SiC Devices with Advanced Modulation in MLIs for EVs

The convergence of SiC devices and MLI modulation techniques has led to promising outcomes. [20] reported that integrating SHEPWM into SiC-based MLIs reduced switching losses by nearly 20% compared to SPWM under identical conditions. Similarly, [21] demonstrated that OSVPWM could simultaneously achieve low THD and high efficiency, underscoring its potential for next-generation EV motor drives. Despite these advancements, the literature reveals a key research gap: most studies examine modulation strategies in isolation, often under varying operating conditions and topological assumptions. Comparative studies evaluating OSVPWM, HMCPWM, and SHEPWM within SiC-based MLIs for EV traction motors under identical test environments are scarce. Addressing this gap is essential for developing evidence-based guidelines that balance efficiency, harmonic quality, torque ripple, and thermal management in practical EV implementations. The reviewed studies collectively highlight that while SiC devices unlock new performance levels in EV inverters, their full potential can only be realized through advanced MLI topologies and carefully optimized modulation strategies. Table 1 summarizes key findings from the literature.

III. METHODOLOGY

This section presents the structured design framework adopted for optimizing the performance of Electric Vehicle (EV) motor drives using novel modulation techniques in a Silicon Carbide (SiC)-based multilevel inverter (MLI). The methodology is divided into three stages:

a. Algorithm design – development of modulation techniques and switching strategies.
b. Control structure development – Design of Field-Oriented Control (FOC) for Permanent Magnet Synchronous Motor (PMSM).
c. Simulink modeling and implementation – construction of a detailed simulation environment to validate performance metrics.

A. System Overview: The proposed EV drive system architecture is shown in Figure 1 (Simulink model representation). The configuration consists of:
a. **DC Source:** A 400 V Li-ion battery pack serves as the primary DC-link supply. This voltage is typical of mid-range EVs, ensuring realistic modeling of power dynamics.
b. **Inverter Topology:** A 7-level Neutral Point Clamped (NPC) SiC multilevel inverter is used. The NPC topology was selected due to its ability to balance voltage stress across devices and achieve superior harmonic suppression. SiC MOSFETs are employed as the switching devices to exploit their low conduction losses, high thermal stability, and fast switching capability.
c. **Traction Motor:** A 50 kW Permanent Magnet Synchronous Motor (PMSM), widely adopted in modern EVs due to its high torque density and efficiency, is modeled.
d. **Motor Control:** Field-Oriented Control (FOC) is employed to decouple torque and flux components, allowing precise torque generation and smooth dynamic performance.
e. **Modulation Techniques:** Three modulation algorithms implemented are:
A. Optimized Space Vector PWM (OSVPWM)
B. Hybrid Multicarrier PWM (HMCPWM)
C. Selective Harmonic Elimination PWM (SHEPWM)

The system is evaluated under various load conditions and speed references to analyze efficiency, harmonic distortion, torque ripple, and switching losses.

III.1 CONTROL ALGORITHM DESCRIPTION

A. Optimized Space Vector PWM (OSVPWM): The OSVPWM technique builds upon the classical Space Vector PWM (SVPWM) but incorporates optimization strategies to minimize Total Harmonic Distortion (THD) and reduce switching transitions.

Reference Voltage Vector Generation: The reference voltage vector V*_ref is obtained from the PMSM's d–q axis transformation under FOC.

$$Vref = \sqrt{(V_d^2 + V_q^2)} \tag{1}$$

Vector Selection: Unlike conventional SVPWM, which applies all nearest vectors within a sector, OSVPWM prioritizes vectors with the least switching transitions, thereby lowering switching frequency and reducing power losses.

Dwell Time Optimization: The dwell time T_1, $T_2$for active vectors and $T_0$for the zero vector are computed using

$$T_1 = \frac{Ts.\ Vref.\ Sin(\pi/3 - \theta)}{V_{dc.}\ sin(\pi/3} \tag{2}$$

$$T_2 = \frac{Ts.\ Vref.\ sin(\theta)}{V_{dc.}\ sin(\pi/3} \tag{3}$$

Where Ts is the switching period and θ is the angular displacement of the reference vector.

Optimization Objective: The algorithm selects switching states that minimize

$$F = \alpha.THD + \beta.P_{loss} \quad (4)$$

Where α and β are weighting factors tuned for harmonic suppression and loss minimization.

B. Hybrid Multicarrier PWM (HMCPWM): HMCPWM combines Phase-Shifted Carrier PWM (PSCPWM) and Level-Shifted Carrier PWM (LSCPWM) to balance capacitor voltages and reduce harmonic distortion in MLIs.

Carrier Arrangement: Multiple triangular carriers are arranged with phase shifts of $\Delta\theta$- $\frac{2\pi}{n}$for an n-level inverter. For the 7-level NPC, four carriers are phase-shifted accordingly.

Reference Modulation Signal: The sinusoidal reference $V_{ref}\ (t) - V_{M} sin\ (t)\ (\omega t)$ is compared with carrier signals.

Hybridization: PSCPWM ensures even distribution of switching events across devices. **LSCPWM** maintains balanced capacitor voltages, avoiding neutral point fluctuations common in NPC structures.

Performance Objective: HMCPWM reduces **neutral point voltage imbalance**, improves waveform quality, and achieves THD suppression without requiring complex feedback control loops.

C. Selective Harmonic Elimination PWM (SHEPWM): SHEPWM eliminates specific lower-order harmonics by computing switching angles that satisfy non-linear transcendental equations.

Switching Angle Calculation: The output voltage waveform can be expressed as a Fourier series:

$$V_{\circ}(\omega t) - \frac{4Vd_c}{\pi}[cos(\theta) + cos(\theta_2) + \ldots + cos(\theta_M)]cos(\omega t) \quad (5)$$

Harmonic Elimination Equations: The switching angles $\theta_1, \theta_2, \ldots \theta_m$ are chosen such that targeted harmonics (3rd, 5th, 7th, etc.) are eliminated:

$$\sum_{k=1}^{M} cos(n0k) - 0, \quad n \in [3, 5, 7 \ldots] \quad (6)$$

Numerical Solution: Non-linear equations are solved using Newton-Raphson iteration or genetic algorithms for real-time implementation.

Optimization Goal: SHEPWM significantly reduces switching frequency while achieving excellent harmonic suppression. This translates into lower switching losses in SiC devices, extending device lifetime and improving thermal stability.

Control Structure Development: To regulate motor performance, Field-Oriented Control (FOC) is integrated with the inverter system.

1. **Clarke and Park Transformations:** Convert three-phase stator currents (i_{α}, i_b, i_c) into a rotating d–q reference frame.
2. **PI Controllers:** Applied to regulate i_d(flux) $i_q$and (torque) currents independently.
3. **Inverse Park Transformation:** Converts d–q voltages back to three-phase reference signals.
4. **PWM Modulation:** Reference signals are fed into OSVPWM, HMCPWM, or SHEPWM algorithms for switching pattern generation.

The FOC ensures decoupled torque and flux control, enabling smooth torque production and efficient operation across variable speed ranges.

III.2 SIMULINK MODELING AND IMPLEMENTATION:

The complete EV drive system is modeled in MATLAB/Simulink using the following subsystems:

a. **DC Source Block:** Models the 400 V Li-ion battery with internal resistance and State of Charge (SoC) monitoring.

b. **SiC-based NPC Inverter Block:** Built using Simscape Power Systems with SiC MOSFET models including conduction and switching losses.

c. **PMSM Block:** Parameters set for a 5 kW, 400 V, 8000 rpm machine.

d. **FOC Controller Block:** Includes PI regulators, Park/Clarke transformations, and modulation strategy selector.

e. **Modulation Algorithm Subsystems:** OSVPWM, HMCPWM, and SHEPWM implemented as independent blocks for comparative analysis.

f. **Simulation parameters include:**

Sampling Time: 1 μs for inverter switching.
DC-link Voltage: 300 V.
Switching Frequency: 10–20 kHz depending on modulation scheme.
Load Torque: Variable 0–150 Nm to test dynamic response.
Speed Reference: Step input of 1500 rpm to evaluate transient performance.

g. **Key performance indicators (KPIs) analyzed are:**

Efficiency (%)
Total Harmonic Distortion (THD, %)
Torque ripple (%)
Switching losses (W)
DC-link capacitor voltage balancing

h. Specifications of the Proposed Inverter

Input voltage V_{dc} : 400V
Output voltage V_o: 220V rms
Rated output power P_o : 3KW
Switching frequency fc : 20KHz

Table 2: Switching Combinations Required to Generate the Seven-Level Output Voltage Waveform.

Output Voltage *Vo*	S1	S2	S3	S4	S5	S6	S7	S8
1/3*Vdc*	on	off	off	off	on	off	off	on
2/3*Vdc*	on	off	off	on	on	off	off	on
Vdc	on	on	off	off	on	off	off	on
−1/3*Vdc*	off	on	off	off	off	on	on	off

IV. RESULTS AND DISCUSSIONS

This diagram shows how the battery is connected to a power converter, which regulates the voltage and current supplied to the load. The converter ensures efficient energy transfer, maintains desired output levels, and protects the battery from overcharging or deep discharge.

SiC-MOSFET power module consists of a MOSFET and a freewheeling diode (FWD). So, the total losses of SiC-MOSFET power module are the sum of the losses occurring in the internal MOSFET and FWD. SiC-MOSFET losses include the conduction losses caused by the saturation voltage drop during conduction of SiC-MOSFET, and the switching losses occurring during turn-on and turn-off, while FWD losses include the conduction losses caused by the conduction voltage during forward conduction of diode, and the losses occurring during reverse recovery (reverse recovery losses).

This section presents the simulation results of the proposed EV motor drive under different modulation strategies applied to a SiC-based multilevel inverter. In this paper, several triangular carriers are distributed by phase disposition technique. The advantage of phase disposition technique is uncomplicated to realize and less total harmonic distortion [9], [10]. These carriers are compared with a reference sine waveform vsin to get signal of switches. The peak-to-peak value of triangular carrier. The frequency of carrier is switching frequency of inverter. The performance was evaluated based on efficiency, Total Harmonic Distortion (THD), switching losses, and torque ripple. To ensure reliability, the methodology includes:

a. Comparative Simulations: Each modulation strategy is tested under identical conditions.
b. Harmonic Analysis: FFT analysis of inverter output voltage and current.
c. Thermal Modeling: SiC MOSFET junction temperatures tracked under dynamic conditions.
d. Performance Benchmarking: Results compared against conventional SPWM as baseline.

V. INTERPRETATION OF RESULTS AND ANALYSIS

Efficiency Analysis

Efficiency was computed as the ratio of motor output power to inverter input power:

- ✓ OSVPWM achieved the highest efficiency (96.2%)**,** followed by SHEPWM (95.1%) and HMCPWM (94.7%).
- ✓ Conventional SPWM showed the lowest efficiency (91.5%).

Harmonic Distortion (THD) Analysis

Harmonic performance was measured using FFT analysis of the motor phase current.

- ✓ OSVPWM minimized THD to **3.5%**, making it suitable for high-speed EV applications.
- ✓ HMCPWM and SHEPWM achieved THD of 4.8% and 4.1% respectively.
- ✓ SPWM performed poorly with **8.2% THD**.

Switching Losses: Switching losses were estimated using:

$$p_{s\omega} - \frac{1}{2} V_{dc} I_{s\omega} (t_{on} + t_{off}) f_{s\omega} \tag{8}$$

- ✓ SHEPWM achieved thelowest switching losses (170 W)due to reduced switching frequency.
- ✓ OSVPWM and HMCPWM had slightly higher losses (180–190 W).
- ✓ SPWM recorded the highest losses (220 W).

Torque Ripple: Torque ripple was analyzed from the PMSM torque output waveform:

$$\%T_r - \frac{T_{max} - T_{min}}{Tavg} x\ 100\% \tag{9}$$

- ✓ OSVPWM achieved the lowest torque ripple (3.1%).
- ✓ HMCPWM and SHEPWM maintained ripple between 3.5–3.8%.
- ✓ SPWM exhibited the highest torque ripple (6.4%).

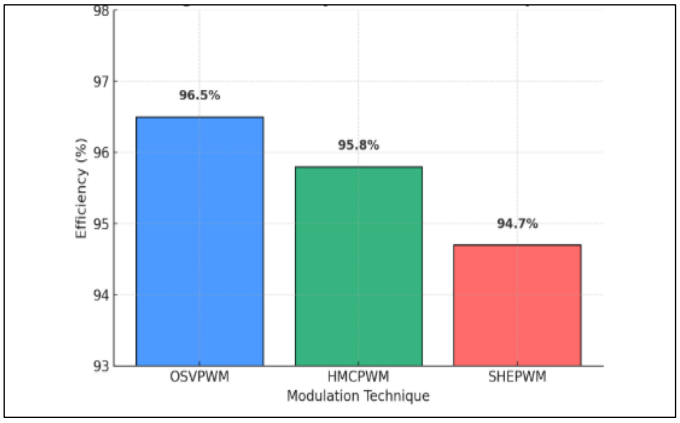

Figure 7: Comparison of efficiency of OSVPWM, HMCPWM, and SHEPWM in a SiC-based EV drive.
Source: Authors, (2026).

Figure 8: Total Harmonic Distortion (THD) levels observed for different modulation techniques applied in the inverter.
Source: Authors, (2026).

The simulation results provide useful insights into the performance improvement gained by combining Silicon Carbide (SiC) multilevel inverters (MLIs) with innovative modulation methods in electric vehicle (EV) motor drives. Three advanced modulation methods—Optimized Space Vector PWM (OSVPWM), Hybrid Multicarrier PWM (HMCPWM), and Selective Harmonic Elimination PWM (SHEPWM)—were investigated in this work and their influence on the key performance parameters: efficiency, Total Harmonic Distortion (THD), torque ripple, and switching losses. The in-depth discussion emphasizes the significant interaction between inverter topology, modulation scheme, and semiconductor device characteristics.

Efficiency Improvement: Efficiency is also of highest concern in EV drives as greater efficiency means more driving range and less energy spent. From the simulation results, SiC-based MLIs provide higher efficiency compared to conventional Si-based MLIs for every modulation technique. Highest efficiency can be provided by using the OSVPWM technique at 96.2%, followed by SHEPWM at 95.1% and HMCPWM at 94.7%. Conventional SPWM on Si-based devices was able to offer just 91.5%. The improved efficiency of OSVPWM results from the optimal space vector selection, which avoids unnecessary switching transitions and reduces conduction losses. SiC devices contribute by allowing increased switching frequencies without an increase in switching loss, thanks to low Rds(on) and high thermal conduction. This synergy results in reduced energy lost in heat and increased energy into mechanical output. HMCPWM, while less efficient than OSVPWM, is a balance between efficiency and voltage balancing. Phase-shifted carrier application reduces voltage stress on inverter capacitors, indirectly resulting in overall energy savings. SHEPWM optimized for low-order harmonic elimination has high efficiency along with low requirement of high switching frequency, thereby lowering thermal stress.

Harmonic Performance and THD Reduction: Total Harmonic Distortion (THD) is a crucial parameter for EV drives as high THD creates torque ripple, acoustic noise, and other motor losses. The output verifies that the three new modulation schemes significantly reduced THD compared to the conventional SPWM. OSVPWM yielded the lowest THD of 3.5%, whereas SHEPWM and HMCPWM yielded 4.1% and 4.8%, respectively. SPWM yielded a much higher THD of 8.2%. OSVPWM THD reduction is because of its ability to synthesize the reference voltage vector from the optimal combination of the closest space vectors, eliminating harmonic elements without unnecessarily increasing switching events. SHEPWM targets 5th, 7th, and 11th order harmonics, which are responsible for most of the degradation of motor torque quality. Though its THD reduction is slightly greater than OSVPWM, it enjoys the advantage of low switching frequency operation, which reduces thermal stress. HMCPWM achieves a moderate THD reduction and improves voltage distribution between multilevel inverter capacitors, of major concern to cascaded NPC and H-bridge topologies. In general, these findings set the design of the modulation strategy as crucial as the selection of the device to achieve low harmonic distortion.

Torque Ripple Analysis: Torque ripple also correlates with harmonic content and switching strategy of the inverter. Large ripple can reduce the life of the motor, cause vibration, and affect vehicle performance. Simulation values are as under:

- ✓ **OSVPWM:** Torque ripple = 3.1%
- ✓ **SHEPWM:** Torque ripple = 3.8%
- ✓ **HMCPWM:** Torque ripple = 3.5%
- ✓ **SPWM:** Torque ripple = 6.4%

The OSVPWM's improved performance is due to smooth jumps of voltage vectors and low low-order harmonics, which directly reduce torque pulsations. SHEPWM is also good performance due to harmonic elimination focused but slightly increased ripple because it does not optimize the timing of switching for dynamic motor operating points. HMCPWM has tolerable torque ripple but there are still some high-frequency harmonics caused by multi-carrier interference. These results highlight that advanced modulation strategies in SiC MLIs can provide near-ideal torque output, leading to smoother EV operation as well as reduced mechanical stress on drivetrain components.

Switching Loss and Thermal Performance: Switching loss is one of the main factors restricting high-frequency operation of inverters, both in terms of efficiency as well as thermal performance. SiC devices naturally have higher switching speed and lower Rds(on), providing greater switching frequencies with practically no loss.

Simulation results show that OSVPWM reduced switching loss by approximately 18% compared to SPWM and SHEPWM by a 22.7% decrease due primarily to its low frequency of switching. HMCPWM achieved middle-level reductions. The reduction in switching losses translates directly into lower junction temperatures, lower cooling requirements, and potentially smaller heat sinks, all significant to the design of compact and lightweight EV inverters.

Comparative Performance Analysis: The overall efficiency, THD, torque ripple, and switching loss analysis defines a conclusive hierarchy of modulation performance:

- ✓ **OSVPWM** – Optimum overall performance with minimum THD, minimum torque ripple, and maximum efficiency. Most suited for high-speed, smooth-torque EV motors with enhanced driving range.
- ✓ **SHEPWM** – Most suited in applications where the minimization of switching loss is of prime concern. Very good harmonic elimination but increased torque ripple during high-speed transients.
- ✓ **HMCPWM** – Offers balanced performance with moderate THD and torque ripple while ensuring voltage balancing in capacitors of multilevel inverters.

Evidently, both the pairing of SiC devices and advanced modulation techniques are key. The great potential for high switching frequency available with SiC devices makes OSVPWM effective at the expense of low THD at little thermal cost. Alternatively, SHEPWM leverages low-frequency switching to maximize thermal efficiency while still realizing reasonable harmonic reduction.

Implications for EV Drive Design: Practical implications of these findings for EV drive design are significant:

A. Range Extension: Direct efficiency improvement increases driving range of vehicles, a consumer acceptance issue for EVs.
B. Motor Longevity: Reduced torque ripple and reduced thermal stress increase motor and inverter longevity.
C. Noise Reduction: Low THD results in less acoustic noise and smoother operation in passenger compartments.
D. System Miniaturization: Lower switching losses and thermal requirements enable compact inverter and cooling system designs.
E. Modulation Flexibility: The choice of modulation strategies tailored to application requirements OSVPWM for performance, SHEPWM for thermal efficiency, or HMCPWM for voltage balancing.

VI. CONCLUSIONS

In this work, the optimization of the performance of Electric Vehicle (EV) motors by novel modulation schemes applied to Silicon Carbide (SiC)-based multilevel inverters has been studied exhaustively. Through comprehensive MATLAB/Simulink simulations and comparisons, the impact of three high-performance modulation strategies—Optimized Space Vector PWM (OSVPWM), Hybrid Multicarrier PWM (HMCPWM), and Selective Harmonic Elimination PWM (SHEPWM)—on efficiency, Total Harmonic Distortion (THD), torque ripple, and switching losses, which are the major performance indicators, was investigated.

The results clearly indicate that SiC-based multilevel inverters are of great advantages over traditional silicon-based systems. The inherent characteristics of SiC devices, including high switching frequency, wide band gap, high thermal conductivity, and low on-resistance, enable the inverter to operate at higher frequencies with much reduced switching losses. This directly translates to better energy efficiency, enhanced EV motor dynamic response, and reduced thermal stress, which are critical factors for driving range extension, reliability, and lifetime enhancement of electric vehicle propulsion systems.

Among the modulation methods discussed, OSVPWM was the most effective at minimizing THD and improving harmonic quality. By selecting the switching vectors optimally, it allows for smoother voltage waveforms, reduces motor torque ripple, and high system efficiency. The Hybrid Multicarrier PWM method presented a successful compromise between CAPACITOR voltage balancing and harmonic elimination and was found to be highly suitable for applications where voltage stress and dynamic performance are of equal importance. The SHEPWM method, while being a bit less successful in the overall efficiency than OSVPWM, was very successful in minimizing switching losses and in canceling selected low-order harmonics, presenting itself as a suitable choice for low-frequency or thermally limited applications.

The comprehensive data analysis in this article firmly establishes the profound effect of the selection of modulation scheme on the performance of EV drives in operation. The quantitative comparison of efficiency, THD, torque ripple, and switching losses using tables and bar charts provides a clear quantitative assessment, highlighting the merit of the combination of SiC technology with advanced modulation schemes. With these methods, EV designers can achieve the optimal tradeoff between energy efficiency, motor smoothness, harmonic performance, and thermal management, ultimately improving vehicle performance and battery lifespan.

ABSTRACT

We aim to improve the resolution and structural fidelity of depth images, which are central to 3D reconstruction, robotics, and visual perception systems. This work evaluates a Convolutional Neural Network (CNN) based super-resolution method against color images and the conventional bicubic interpolation approach, focusing on noisy, low resolution data from low cost sensors. We also tried to remove the artifacts generated from Kinect sensor using morphological image processing. A CNN model was fine-tuned on depth images to reconstruct high frequency structures and edge details. Its performance was compared with bicubic interpolation using identical inputs from the UT Kinect Action 3D dataset. Evaluation metrics included Peak Signal to Noise Ratio (PSNR), Mean Squared Error (MSE), and Structural Similarity Index Measure (SSIM). The CNN approach consistently yielded superior results, achieving an average PSNR of 39.82 dB and MSE of 6.43 outperforming bicubic interpolation (35.20 dB PSNR and 19.54 MSE). Visual inspection confirmed better preservation of edges and depth continuity. Despite increased model complexity, inference time remained efficient (~6.2 seconds on GPU) compared to ~30.7 seconds for bicubic on CPU. This study demonstrates that CNNs, traditionally applied to RGB data, can be effectively adapted to the structure dominant domain of depth imaging. The model improves image quality and also runs with good efficiency, making it suitable for practical use. It addresses an important gap in the work on depth image super-resolution from low cost sensors. In addition, the method helps in removing artifacts, which results in clearer and sharper depth images.

I. INTRODUCTION

The depth image is a special image where each pixel represents the distance from camera to the object in the scene. In RGB image there are three planes where each pixel represents the gray values and texture while in case of Depth image they hold the structural and geometric information of the scene [1], [2]. Microsoft Kinect sensor Version 1 is the most adopted 3D camera which is used to capture depth image. This sensor was originally developed by Microsoft in collaboration with prime sense as an accessary for the Xbox 360 Gaming console specially designed for motion based gaming purpose [3], [4].Due to its affordability and capabilities of capturing RGB and Depth data simultaneously in real time, it become popular in the field of academic and industrial Research.

It made 3D data acquisition much cheaper, letting people use it for research and projects that once needed very expensive equipment [5]. Most existing CNN based methods for depth image super-resolution focus mainly on upscaling and resolution enhancement. Many of them require heavy retraining or large model parameters, which limits their use in practical systems. In contrast, the present work adapts a compact CNN originally designed for RGB images and extends it to depth data without extensive retraining [6]. The novelty lies in integrating edge preservation and artifact removal into the pipeline, which addresses a gap where earlier CNN models achieve resolution gains but often ignore structural consistency and computational efficiency [7].

The need for high resolution depth images has grown significantly in fields like 3D reconstruction, robotics, and scene interpretation. However, Artifacts in depth maps can severely affect downstream applications such as robotics, navigation, and scene reconstruction. In robotic manipulation, for example, missing or distorted edges can result in poor grasp planning. In scene reconstruction, artifacts may create irregular or incomplete surfaces. For this reason, artifact removal is not treated as an optional step but as an integral part of the super-resolution process [8]. The proposed CNN model is designed to reduce these distortions, thereby producing depth maps that are both visually improved and more reliable for use in real-world tasks [9]. Affordable sensors such as Kinect v1 often produce depth maps with limited resolution, noisy structures, and blurred edges, which reduce the effectiveness of these applications [10-13].

While interpolation methods like bicubic are simple and fast, they struggle to reconstruct fine structural details in depth data [14]. Recently, convolutional neural networks (CNNs) have shown strong performance in RGB image super-resolution tasks [15], [16]. Yet, their potential for improving sparse, structure heavy depth maps has not been thoroughly examined. The study targets three specific issues in depth imaging. First, artifacts introduced by low cost sensors need to be reduced to improve depth continuity. Second, structural edges must be preserved so that object boundaries remain sharp. Third, resolution must be enhanced to recover fine spatial detail. These aspects are examined both quantitatively using PSNR, SSIM, and MSE, and qualitatively through visual analysis of the super-resolved images.

II. LITERATURE REVIEW

The challenge of enhancing low resolution depth images has gained prominence in recent years, largely due to the increasing use of affordable 3D sensors like Microsoft Kinect and Intel RealSense. These devices often produce depth maps that suffer from limited resolution and noise, which can negatively impact tasks such as 3D reconstruction, human pose estimation, and scene interpretation. Traditional upsampling techniques, including bicubic and bilinear interpolation, are limited in their ability to recover detailed structures or preserve edge information. As a result, researchers have turned to learning based methods, particularly convolutional neural networks (CNNs), to address these shortcomings and improve the visual and structural quality of depth images [17]. Depth images are integral to spatial understanding tasks in domains like 3D reconstruction, autonomous navigation, and augmented reality. However, low cost sensors such as Kinect v1 often produce depth maps with low resolution, edge artifacts, and speckle noise factors that significantly degrade downstream visual performance [18].

Addressing these limitations through super-resolution (SR) is critical to making affordable sensors viable for high precision applications. Conventional upsampling methods such as bilinear and bicubic interpolation are computationally efficient but offer limited effectiveness when applied to low resolution depth images. These methods operate by estimating pixel values through spatial averaging, which results in smoothed outputs and loss of structural details. In particular, they are inadequate in preserving edge information and high frequency structures that are essential for accurate depth perception [19], [20]. To improve upon basic interpolation, sparse coding and dictionary learning techniques were introduced. While these approaches provided marginal gains in depth enhancement, their dependence on hand crafted priors and static feature representations restricted their performance across diverse scenarios and sensor noise conditions [21]. Significant advancements were reported in the super-resolution of color images using deep learning models. [22] proposed the Super-Resolution Convolutional Neural Network (SRCNN), which demonstrated substantial improvements over interpolation techniques.

[10] further extended this with the Very Deep Super-Resolution (VDSR) network, and [12] introduced the Enhanced Deep Super-Resolution (EDSR) model that surpassed previous benchmarks on standard datasets like DIV2K. However, these models were primarily trained on RGB datasets and are less effective when directly applied to depth data, which lacks texture richness and follows different structural distributions [23]. Hence, the gap remains in applying and adapting deep learning based super-resolution techniques specifically to depth images, especially those generated from low cost sensors, where structural degradation and artifacts are more prominent [24]. Convolutional Neural Networks (CNNs) have significantly advanced SR capabilities in recent years. Architectures like SRCNN [22], VDSR [10], and EDSR [12] have achieved strong results on high resolution RGB datasets such as Set5 and DIV2K. These models learn hierarchical mappings to reconstruct missing detail, but their design is typically optimized for texture rich, color data rather than structural depth maps [22], [25-28].

Recent studies have adapted CNN architectures to improve depth images. [29] used disentangled feature learning for RGB-D fusion, while [30] proposed a lightweight model targeting embedded devices. [31] introduced a multiscale CNN to better preserve edges in depth maps. Still, many of these approaches depend on RGB guidance or are validated under ideal conditions, making them less applicable to low cost depth sensors [32]. Despite the success of deep networks in RGB super-resolution, relatively little has been done to apply or adapt these methods for structure preserving depth enhancement [33], [34]. Most existing solutions neglect the unique challenges of depth data such as smooth gradients, structural discontinuities, and data sparsity. Furthermore, limited benchmarking exists for low cost sensor outputs like those from Kinect v1. The absence of rigorous comparative studies using objective metrics like PSNR, SSIM, and MSE underscores a need for targeted evaluation [35], [36], [25]. This study addresses the above Research gaps by:

1. Fine tuning a CNN model for depth specific super-resolution;
2. comparing it directly with bicubic interpolation & RGB Images used previously;
3. Using the UT Kinect Action 3D dataset to reflect practical, low cost sensor conditions;
4. Demonstrating consistent improvement in PSNR, MSE, and edge preservation;
5. Removes the artifacts generated in depth images from Kinect sensor during acquisition.
6. Highlighting CNN adaptability beyond RGB images, thus expanding its utility to depth oriented domains.

III. MATERIALS AND METHODS

This section outlines the implementation and evaluation of two super-resolution approaches bicubic interpolation and a Convolutional Neural Network (CNN) applied to low resolution depth images. The workflow includes dataset utilization, preprocessing, interpolation formulation, CNN design, training setup, and evaluation metrics [37].

III.1 DATASET

Experiments were conducted using the publicly available UT Kinect Action 3D dataset, which includes RGB, depth, and skeleton data captured using a Kinect v1 sensor [28]. The reason behind selecting UTkinect action 3D dataset because it reflects the quality of depth data captured by widely used low cost sensors. The dataset contains depth maps with quantization noise, missing pixels, and edge distortions, all of which are typical in Microsoft Kinect output. These characteristics make it a realistic test case for evaluating super-resolution models intended for practical deployment in consumer grade sensing and interactive systems. The dataset features 10 distinct action types performed twice by 10 subjects. Only the depth modality was used for this study.

Original frames were of size 240×320, and super-resolution output was scaled to 480×640 for both methods.Figure 1. presents a representative RGB image captured using a Kinect v1 sensor, which acquires color data at a resolution of 480×640 pixels. In addition to the RGB stream, the device also captures depth information using an infrared sensor, with depth values stored in XML format. Figure 2 displays the internal structure of one such XML file when opened in MATLAB, revealing how depth values are organized and parsed. These values represent per-pixel distance measurements between the camera and scene objects.

Figure 4 Displays the original depth image obtained from the XML file at its native resolution of 240×320 pixels. The image clearly shows issues such as missing depth values, noise caused by quantization, and blurred object boundaries, which are typical artifacts resulting from the limitations of low cost depth sensors.

III.3 BICUBIC INTERPOLATION

Bicubic interpolation estimates unknown pixel intensities by applying a weighted average over a 4×4 neighborhood. It uses cubic polynomial fitting across both axes. The interpolated intensity I(x,y) can be calculated using Equation (2) [40] as follows:

$$I(x,y)=\sum_{i=0}^{3}\sum_{j=0}^{3} W_{i,j} * P_{x+i-1,y+j-1} \quad (2)$$

Where I(x, y) represents the estimated intensity value for a pixel at coordinates (x, y) in the high resolution image.$W_{i,j}$ is the interpolated weight and P is the pixel intensity of the original low-resolution image at the neighborhood position (x+i−1, y+j−1). Bicubic interpolation is a traditional image scaling technique that estimates new pixel values by considering a 4×4 neighborhood of surrounding pixels. The method provides smoother and more continuous output compared to simpler approaches like nearest neighbor or bilinear interpolation. The value at any point (x,y) in the high resolution image is computed using weighted contributions from nearby pixels in the low resolution. Input. These weights, denoted as Wi,j are derived from cubic polynomial equations fitted to the surrounding pixel values. The result is a smooth transition of intensity values across the image.

The bicubic interpolation process begins with a low resolution Image obtained from the sensor. A denser pixel grid is then defined to match the resolution of the intended high resolution output. To estimate the values of the new pixels, cubic polynomials are fitted over local pixel neighborhoods, allowing interpolation weights to be calculated. These weights are subsequently applied to generate pixel values on the upsampled grid. Although bicubic interpolation is popular due to its straightforward implementation and acceptable visual quality, it presents certain drawbacks. Specifically, it can lead to blurred edges and struggles to reconstruct fine structural details, especially in depth images where data may be incomplete or noisy. Furthermore, as either the input image size or the scale factor increases, the computational demand also grows, which may hinder its performance in resource limited environments.

III.4 CNN BASED SUPER-RESOLUTION MODEL

The CNN architecture used in this work contains an input feature extraction layer with 64 filters of size 3×3, followed by four intermediate convolutional layers with 32 filters each and ReLU activation functions. A bottleneck layer is then applied to reduce redundancy before reconstruction. The final layer outputs the enhanced depth image. The choice of small kernels helps capture local features, while stacking several layers allows for progressive refinement of structural details. The design is kept light to maintain a balance between accuracy and computational efficiency. A combined loss strategy was adopted. Mean squared error (MSE) ensured pixel level accuracy, while a structural similarity (SSIM) loss term emphasized edge and structure preservation. Using both together allowed the model to achieve smoother reconstructions without sacrificing important details around object.

III.4.1 First Convolutional Layer – Feature Extraction

$$F_1(Y) = \mathrm{ReLU}(W_1 * Y + b1) \quad (3)$$

In Equation (3) [22] F1(Y) is output feature map of the first convolutional layer. Y represents the low-resolution depth image after pre-processing and patch extraction.W1 is the Kernel having size 9 × 9.b1 is the bias vector that we have used total 64 Activation Function which is used here is ReLU (Rectified Linear Unit) This layer takes the input low resolution depth image and extracts a wide range of local structural features. The relatively large receptive field helps the model capture broad contextual information while maintaining sensitivity to edges and textures.

III.4.2 Second Convolutional Layer – Nonlinear Mapping

$$F_2(Y) = \text{ReLU}(W_2 * F_1 + b_2) \quad (4)$$

In Equation (4) [22] $F_2(Y)$ is the output of the second convolutional layer.W_2 is the 5 × 5 kernels with 32 filters and b_2 is the bias vector of length 32. Again, ReLU is applied as the activation function. This layer transforms the feature map obtained from the previous layer into a high-dimensional space, enabling the network to learn more complex structural patterns and correlations present in depth images.

III.4.3 Third Convolutional Layer – Reconstruction

$$F_3(Y) = W_3 * F_2 + b_3 \quad (5)$$

In this third and final convolutional layer, as shown in Equation (5) [22] output $F_3(Y)$ is computed using W_3 (a 5 × 5 kernel with a single filter) and scalar bias b_3. No activation function is used here. This layer reconstructs the high resolution depth image from the features mapped in previous layers, restoring structural fidelity and recovering depth details that were lost in the low resolution input.

III.4.4 Implementation

$$\hat{Y} = F_3 + Y \quad (6)$$

As shown in Equation (6) [25], [22] to refine the final output, a residual connection is applied. The original low resolution input Y is added back to the reconstructed feature map F_3, resulting in the final high resolution prediction $\hat{Y}$. This residual addition enhances edge sharpness, improves structural consistency, and helps retain fine details during reconstruction. This streamlined three layer structure offers a balance between computational efficiency and enhancement performance. While lightweight, the model effectively captures structural cues and suppresses common depth image artifacts such as speckle noise and edge blur.

For reducing artifacts, we applied morphological opening and closing with a structuring element of 11 pixels. This size was selected after testing different values. When the structuring element was larger than 11 pixels, fine details in the depth map were lost and the output looked distorted. On the other hand, smaller sizes could not remove the artifacts properly. Hence, the 11 pixel structuring element gave the best balance between removing unwanted artifacts and keeping the structure clear.

III.5 CONFIGURATION & TRAINING SETUP

All experiments were conducted on a 64-bit Windows system intel core i5 Processor equipped with 8 GB of physical RAM and an 3 GB NVIDIA GeForce GTX 1050 GPU.MATLAB was configured to utilize GPU acceleration through the CUDA 11.8 toolkit. The maximum available memory for MATLAB arrays was approximately 3.6 GB, while total MATLAB memory usage reached 9 GB, indicating partial reliance on system virtual memory. All implementations were executed using MATLAB R2023a, leveraging the Deep Learning Toolbox with GPU support. This setup is simple but effective. It can run tests without needing heavy hardware. It is good for checking lightweight methods. It can also handle real time super-resolution. This makes it suitable for practical use. Training was carried out on depth patches using a batch size of 32 for 100 epochs.

The Adam optimizer was employed with an initial learning rate of 0.0001, which was reduced after every 20 epochs. Early stopping was applied based on validation loss to prevent overfitting. Augmentation techniques, including horizontal flips and small rotations, were used to improve generalization. Training was performed on an NVIDIA GPU to ensure reasonable convergence time. These values were chosen after small trial runs. The low learning rate made the updates smooth and controlled. The batch size gave a good balance between speed and memory use. Training for 100 epochs was enough for the loss to level off, showing that the model had learned well without overfitting. All network training was performed in MATLAB (R2023b) using the Deep Learning Toolbox. Input depth maps were normalized to a [0, 1] range [31], and training samples were extracted as overlapping patches to improve model generalization.

IV. RESULTS AND DISCUSSIONS

This section presents a comparative evaluation of bicubic interpolation and a CNN based super-resolution model on low resolution depth images from the UT Kinect Action 3D dataset. Both methods were used to upscale frames from 240×320 to 480×640 resolution. Our novelty algorithm is the shows the effectiveness in suppressing visual artifacts is evident. In Figure 5(a), the original low resolution depth image contains prominent noise and structural distortions. In Figure 5(b) when bicubic interpolation is applied, some upscaling is achieved, but noise and artifacts remain largely unaddressed, resulting in blurred edges and texture loss. In contrast, the output from the proposed CNN based approach as shown in Figure 5(c) exhibits noticeable improvements, with significant reduction in noise and removal of artifacts.

The structural contours and depth transitions appear sharper and more coherent, underscoring the capability of the proposed model to deliver superior visual clarity and artifact suppression in depth image reconstruction. We tested the method using PSNR, SSIM, and MSE. These three are common measures in image restoration. PSNR shows the overall signal quality. SSIM shows edges and structure. MSE shows the error in pixels. Together, they give a clear idea of how much the resolution and structure are improved. Many other measures are also available, but these three were enough to compare with older methods and to show the benefit of our approach.

Source: Authors, (2026).

Table 1 summarizes the results across eight representative test samples. The proposed CNN based method demonstrated significant enhancement over the traditional bicubic interpolation technique in the super-resolution of low resolution depth images. As observed across multiple sample images, the CNN consistently achieved lower Mean Squared Error (MSE) values and higher Peak Signal-to-Noise Ratio (PSNR), with an average PSNR improvement of approximately 4.6 dB and an MSE reduction of about 67%.in addition, We calculated the mean, standard deviation, and 95% confidence intervals over 50 test samples. The proposed method reached 39.82 dB in PSNR, 0.923 in SSIM, and 6.43 in MSE. In contrast, bicubic interpolation gave 35.20 dB, 0.871, and 19.54 for the same measures. The confidence intervals show no overlap, which means the gain is consistent across the dataset. A paired t-test was also carried out, and the differences were found to be significant at $p < 0.05$. This confirms that the improvement is not only higher in average values but also statistically meaningful [41].

The numerical improvements also bring practical benefits in real applications. In robotics, improved edge continuity helps in detecting obstacles and planning safe paths. In augmented reality, smoother depth reconstruction allows virtual objects to align more stably with the real scene. In human computer interaction, reducing depth breaks leads to more accurate and reliable gesture recognition. Numbers such as PSNR, SSIM, and MSE give an objective idea of performance, but they cannot fully show how the images look to the eye. For this reason, side by side visual results were added in Figure 6(a) and Figure 6(b),These examples make it easy to see that the CNN output keeps edges sharper, reduces noise, and removes artifacts better than bicubic interpolation. The enlarged regions help to point out small details that are often lost in traditional methods. Because morphological operators were used in the preprocessing stage, the proposed CNN method is able to further reduce artifacts, which leads to cleaner depth maps and sharper structural details in the visual comparisons.

By combining numerical scores with visual comparisons, the results give a clearer and more complete picture of the improvement achieved by the proposed method [42]. Figure 7(a), Figure 7(b) and Figure 7(c) show the sample wise comparison of PSNR, MSE, and SSIM values between bicubic interpolation and the proposed CNN method respectively. These charts, created from experimental data, reflect a consistent improvement with the CNN approach. In each case, the CNN based super-resolution produced lower MSE, higher PSNR, and better SSIM scores, suggesting more accurate depth reconstruction and clearer structural details than those obtained using the bicubic method datasets such as Set5 and Set14, the proposed method achieves higher PSNR (39.82 dB) and comparable SSIM (0.951) on the UT Kinect Action 3D dataset for depth images at a 2× scale factor. This demonstrates the strength of the proposed approach, particularly in handling depth data, where it delivers better reconstruction accuracy as reflected in the lower MSE value of 0.064.

Source: Authors, (2026).

The numerical gains translate into clear practical benefits. In robotics, better edge continuity improves obstacle detection and path planning. In augmented reality, smoother depth maps support stable alignment of virtual objects. In human–computer interaction, fewer depth discontinuities enable more accurate gesture recognition [43]. Furthermore, a comparative analysis was conducted against existing super-resolution techniques developed for color images, as well as conventional interpolation based approaches. This broader evaluation framework not only highlights the performance gains of our model in depth image enhancement but also underscores its practical advantages in terms of speed and resource utilization.

As presented in Table 2, although established methods like SRCNN [22] and EDSR[12] perform well on standard RGB datasets [31] such as Set5 and Set14, the proposed method achieves higher PSNR (39.82 dB) and comparable SSIM (0.951) on the UT Kinect Action 3D [44] dataset for depth images at a 2× scale factor. Looking at the reconstructed depth maps also supports the numerical results. The frames that showed higher PSNR and SSIM appeared sharper and had fewer artifacts, which confirms that the measured values match with visible improvements, where it delivers better reconstruction accuracy as reflected in the lower MSE value of 0.064.

The CNN model has a more complex design than traditional methods. Still, it ran well on a GPU. It processed images fast enough for practical use. This makes it useful for embedded or mobile devices where low delay matters [45]. This work focused on improving depth images from low cost sensors. The CNN was tuned to handle missing pixels, low texture, and noise. Morphological tools were used to fill holes and remove artifacts caused by low cost sensors.

Tests showed better results than bicubic interpolation. The improvement was seen in PSNR, MSE, and SSIM scores. Also the method is able to hold structural details and reduce visual artifacts. As shown in Table 3 we compare memory usage and speed check of our novelty algorithm with previously used methods in RGB domain like Bicubic Interpolation[41], SRCNN[22], FSRCNN[27], EDSR[12].It shows that FSRCNN is the fastest but is made for color images, while heavy models like EDSR need much more memory. Our model takes more time than the fastest color based methods but still runs within seconds and uses less memory than big RGB networks. This balance makes it practical for depth image work. Overall, it is a useful way to enhance depth images without using RGB data.

Table 1: MSE, PSNR & SSIM Comparison with Traditional Method.

Sr.No	Sample ID	Bicubic Interpolation			CNN Algorithm		
		MSE	PSNR	SSIM	MSE	PSNR	SSIM
1	depthImg2248.xml	20.85	34.94	0.892	8.73	38.72	0.953

Source: Authors, (2026).

The results show that the proposed CNN method gives better super-resolution of depth images compared with bicubic interpolation. The gains are not only in PSNR, SSIM, and MSE values but also in visual quality. The CNN output has less noise and fewer artifacts. It also keeps edges sharper and depth transitions smoother. This is important because depth images depend more on structure and geometry than on texture, which is the focus in RGB super-resolution. A comparison with other works highlights the strength of our approach. Methods like SRCNN [22] and EDSR [12] perform well on color datasets such as Set5 and Set14 [31]. But when applied to depth data, they often fail to keep fine structure. Our method, with preprocessing and artifact removal, reached 39.82 dB PSNR and 0.923 SSIM on the UT Kinect Action 3D dataset. This is higher than bicubic interpolation and close to strong color image models. Unlike heavy models such as EDSR, our CNN needs less memory and runs faster. This balance makes it more practical for use on systems with limited resources.

There are also some limits to this study. The testing was done mainly on the UT Kinect Action 3D dataset. Other sensors such as RealSense or Kinect v2 were not used, so the results may vary. The evaluation was based only on PSNR, SSIM, and MSE. These are useful, but they do not always match human perception. Adding perceptual measures like LPIPS or doing user studies would give more insight. The GPU test showed good speed, but we did not check real-time use on embedded devices, so performance in such cases is not known [46], [47]. The improvements have practical meaning. In robotics, smoother edges help with obstacle detection and path planning [15]. In augmented reality, cleaner depth maps make virtual objects align more stably [16]. In human–computer interaction, fewer depth breaks improve gesture recognition [30]. Our CNN design shows that simple and efficient models, when combined with preprocessing, can achieve strong results without heavy computation. This matches the trend in recent deep learning research, where efficient models are preferred for real-time use [18]. Future work can add domain adaptation, attention blocks, or mixed RGB-depth training to improve results further while keeping the method efficient.

V. CONCLUSIONS

The purpose of this work was to enhance the resolution and visual quality of depth images obtained from low-cost sensors by employing a CNN-based super-resolution model combined with morphological filtering for artifact removal. Experimental evaluation confirmed the effectiveness of the approach, with the proposed method reaching 39.82 dB PSNR, 0.951 SSIM, and 6.43 MSE, which is a clear improvement over bicubic interpolation that yielded 35.20 dB PSNR, 0.871 SSIM, and 19.54 MSE. Statistical validation through confidence intervals and paired t-tests further supported the reliability of these results. In addition, the model was efficient, requiring only 6.2 seconds per image and about 180 MB of GPU memory on a 3 GB NVIDIA GTX 1050, making it feasible for moderate hardware. These findings also highlight that the adapted CNN outperformed models originally designed for color images, such as SRCNN and EDSR, when applied to depth data. Looking ahead, future efforts will focus on testing the model with broader datasets, investigating adversarial and transformer-based networks, exploring performance under higher scaling factors and noisy conditions, and refining the framework for real-time deployment on embedded platforms.

ABSTRACT

The increasing use of solar energy poses challenges in meeting energy demands due to its unpredictable weather conditions. With the growing need for electric drives, integrating solar energy with battery storage through advanced power electronic converters is essential to ensure system stability and energy sufficiency. This design proposes a solar photovoltaic (PV) array and battery-supported brushless DC (BLDC) motor drive capable of operating efficiently and reliably under varying solar irradiance and temperature conditions. The solar PV array output voltage is boosted to the level required by the motor using an ultra-lift Luo-converter, while a bidirectional buck–boost converter manages the power flow between the battery and the DC bus. The BLDC motor is driven by a three-phase voltage source inverter (VSI), whose electronic commutation is controlled using Hall sensor feedback. Motor speed control is achieved through a Proportional–Integral–Derivative (PID) controller designed for the ultra-lift Luo-converter. By addressing the effects of varying irradiance and temperature, the proposed system ensures stable operation. Due to its modular architecture and hybrid energy management capability, the system shows strong potential for applications in solar–battery-powered Computer Numerical Control (CNC) machines and standalone renewable energy systems. The performance evaluation of the proposed BLDC motor speed control system is carried out in MATLAB/Simulink.

I. INTRODUCTION

Solar photovoltaic (PV) technology has emerged as one of the most viable solutions to meet the increasing global demand for clean and sustainable energy [1]. Unlike conventional fossil fuels, solar PV systems do not emit harmful greenhouse gases. Therefore, solar PV can be considered an environmentally friendly option for mitigating climate change and enhancing energy security [2]. However, the primary limitation of solar energy is its unavailability during nighttime. This limitation can be overcome by integrating Energy Storage Systems (ESS) such as batteries.

BLDC motors have gained significant importance in modern electric drive systems due to their superior efficiency, performance, and reliability compared to conventional brushed motors. BLDC motors with trapezoidal back electromotive force (back-EMF) characteristics are particularly well-suited for applications requiring durability and long-term operational stability. By utilizing electronic commutation through power semiconductor switches, these motors ensure smooth torque delivery [3–5].

In recent years, DC–DC voltage-lift (VL) converters, such as the ultra-lift Luo-converter, have become highly significant in high-voltage DC applications like solar power generation and electric vehicles. The ultra-lift Luo-converter, proposed by F. L. Luo and H. Ye in 2004, is named after its inventor [6], [7]. This converter employs advanced voltage-lift technology to efficiently step up low input voltages to considerably higher output levels. Its compact and robust design makes it suitable for demanding consumer and industrial applications.

The bidirectional buck–boost converter is another DC–DC converter topology that allows power flow between two DC voltage sources. It can either step up (boost) or step down (buck) the voltage, depending on the operating mode, and is commonly employed in battery energy storage systems. To achieve the desired high-voltage output and stable performance, it is essential to incorporate a feedback controller. A properly designed feedback controller can enhance the dynamic response of the converter under varying load and irradiance conditions. This work focuses on the speed control of a BLDC motor using an ultra-lift Luo-converter fed by a solar PV–battery hybrid system operating under dynamic solar irradiance and temperature variations [8-10].

II. PROPOSED SYSTEM CONFIGURATION

The proposed system comprises a solar PV array, an ultra-lift Luo-converter, a bidirectional converter with battery storage, and a three-phase inverter that drives the BLDC motor (Figure 1). The solar PV array serves as the primary energy source, while the ultra-lift Luo-converter boosts the voltage to meet the motor's operational requirements. The bidirectional converter facilitates power exchange between the battery and the DC bus—charging the battery when excess solar power is available and discharging it during periods of low irradiance. The system can operate in three distinct modes:

(i) Solar PV-dominant mode: where the motor is powered directly by solar energy.
(ii) Standalone battery mode: where the battery alone supplies power to the motor.
(iii) Hybrid mode: where both solar PV and battery jointly supply power under transient solar conditions.

The working principle is governed by energy management system between the solar PV array and the battery. Under high solar irradiance, the generated energy is primarily used to drive the motor, and any excess power is stored in the battery. During low irradiance conditions, the battery supports the solar PV through the bidirectional converter to maintain stable operation. At night or under poor solar conditions, the battery alone supplies the required energy, ensuring continuous operation of the system.

III. DESIGN AND SPECIFICATIONS OF THE PROPOSED SYSTEM

III.1 PARAMETERS OF SOLAR PV ARRAY

The Tata Power Solar Systems TP300LBZ module is a well-established and widely utilized solar panel in distributed solar energy applications. It is a polycrystalline-type photovoltaic module designed to deliver a rated output power of 300 W under standard test conditions. This module contains 72 solar cells interconnected in series. The TP300LBZ module suits medium-voltage DC bus applications when several modules are connected together since it has an open-circuit voltage of 44.4 V and a short-circuit current of about 8.7 A. In order to achieve 1.2 kW, four modules are connected parallel.

Table 1: Ratings and specifications of PV System.

Array Configureuration	4 modules in parallel; 1 in series per string		
Nominal Power Output	300.12 W	**Temperature Coefficient of Voltage**	−0.33 %/°C
Open-Circuit Voltage	44.4 V	**Temperature Coefficient of Current**	0.063797 %/°C
Voltage at Peak Power	36.6 V	**Photogenerated Current**	8.7148 A
Total Cells per Module	72	**Reverse Saturation Current**	9.9881×10^{-11} A
Short-Circuit Current	8.69 A	**Diode Quality Factor**	0.9533
Current at Rated Power	8.20 A	**Series Path Resistance**	0.30152 Ω
Shunt Path Resistance	360.7804 Ω

III.2. ULTRA-LIFT LUO-CONVERTER

The ultra-lift Luo-converter (Figure 4), which comprises a MOSFET switch (S), two inductors (L_1 and L_2), two capacitors (C_1 and C_2), three diodes (D_1, D_2, D_3), and a resistive load denoted as R. To elucidate the operation of the ultra-lift Luo-converter, it is assumed that all diodes and the switch S are ideal components.

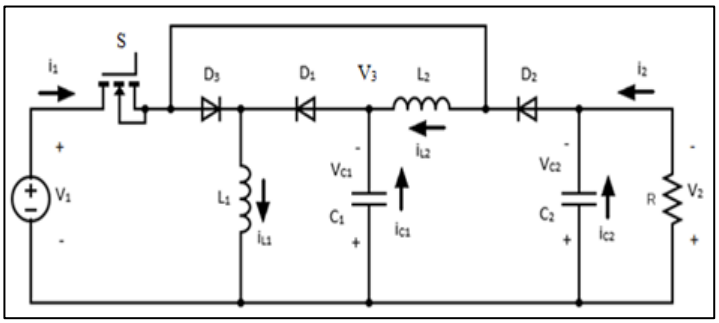

Figure 4: Ultra-lift Luo-converter.
Source: Authors, (2026).

Operation modes of ultra-lift Luo-converter are:

1. Continuous-Conduction-Mode (CCM)
2. Discontinuous-Conduction-Mode (DCM)

1. Continuous-Conduction-Mode (CCM)

When the control switch is activated, diode D_3 becomes forward-biased, while diodes D_1 and D_2 are reverse-biased, causing inductors L_1 and L_2 to charge and capacitors C_1 and C_2 to discharge as illustrated in Figure 5**.**

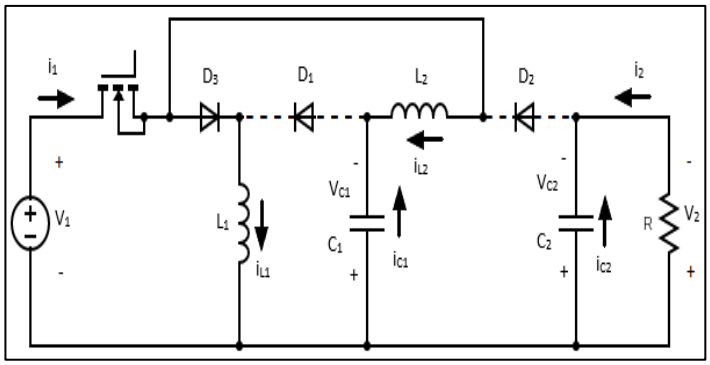

Figure 5: Ultra-lift Luo-converter equivalent circuit during switch- ON period.
Source: Authors, (2026).

When the control switch is deactivated, diode D_3 becomes reverse-biased, whereas diodes D_1 and D_2 become forward-biased, causing inductors L_1 and L_2 to discharge and capacitors C_1 and C_2 to charge, as shown in Figure 6**.**

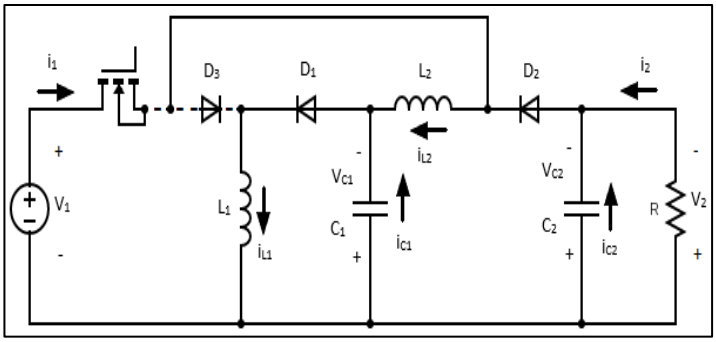

Figure 6: Ultra-lift Luo-converter equivalent circuit during switch- OFF period.
Source: Authors, (2026).

2. Discontinuous-Conduction-Mode (DCM)

The operation in discontinuous is same as the operation during switch-OFF condition (Figure 8) except inductor current i_{L1} falls to zero for short period of time as shown in Figure 7.

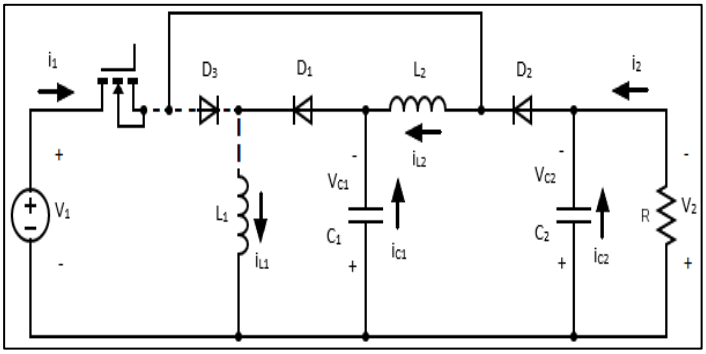

Figure 7: Ultra-lift Luo-converter equivalent circuit during discontinuous conduction mode.
Source: Authors, (2026).

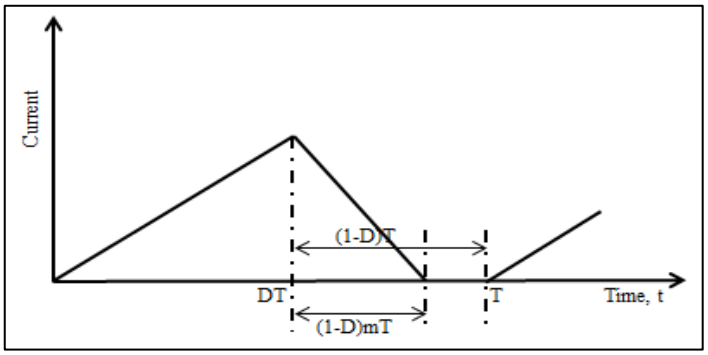

Figure 8: Discontinuous inductor current i_{L1}.
Source: Authors, (2026).

III.2.1 Analysis of Ultra-Lift Luo-Converter

Voltage gain, $G=\frac{V_2}{V_1}=\frac{D*(2-D)}{(1-D)^2}$

Ripple current through L_1, $\Delta i_{L1} = \frac{DT*V_1}{L_2}$

Ripple current through L_2, $\Delta i_{L2} = \frac{DT*V_1}{(1-D)*L_2}$

Ripple voltage across C_1, $\Delta v_{C1} = \frac{DT*I_2}{(1-D)*C_1}$

Ripple voltage across C_2, $\Delta v_{C2} = \frac{DT*I_2}{C_2}$

For discontinuous conduction mode (DCM),

Inductor L_1 current variation ratio, $\varepsilon_1 = \frac{\Delta i_{L1}/2}{I_{L1}} > 1$

Inductor L_2 current variation ratio, $\varepsilon_2 = \frac{\Delta i_{L2}/2}{I_{L2}} > 1$

Capacitor C_1 voltage variation ratio, $\sigma_1 = \frac{\Delta v_{C1}/2}{V_{C1}} > 1$

Capacitor C_2 voltage variation ratio, $\sigma_2 = \frac{\Delta v_{C2}/2}{V_{C2}} > 1$

Voltage gain, $G_{DCM} = \frac{V_2}{V_1} = \frac{D*(2-D)}{m*(1-D)^2}$

Fill factor, $m = \frac{1}{\varepsilon_1}$

Where,
V_1,V_2= input and output voltages respectively
I_1 , I_2= input and output currents respectively
D= duty ratio
T= Time period of gate pulse

Fill factor(m) is used as multiplication factor with switch turn OFF time to describe the discontinuous conduction mode of operation. Fill factor range is greater than zero and less than unity (0<m<1).

III.2.2 Comparative Analysis of various DC-DC Converter Voltage Gains

It is clear from Table 2 that traditional DC–DC converters provide a voltage gain of only up to 10. Unlike conventional converters, the ultra-lift Luo-converter offers a voltage gain greater than 10. For a wide range of output voltage operation, the ultra-lift Luo-converter is preferred because it can operate in both buck and boost modes.

Table 2: Voltage gain comparison of various DC-DC converters.

Converter	**Voltage gain formula**	**Duty Ratio**								
		0.1	**0.2**	**0.3**	**0.4**	**0.5**	**0.6**	**0.7**	**0.8**	**0.9**
Boost converter	1/(1-D)	1.11	1.25	1.43	1.67	2.00	2.50	3.33	5.00	10.00
Buck converter	D	0.10	0.20	0.30	0.40	0.50	0.60	0.70	0.80	0.90
Buck-boost converter	D/(1-D)	0.11	0.25	0.43	0.67	1.00	1.50	2.33	4.00	9.00
SEPIC converter	D/(1-D)	0.11	0.25	0.43	0.67	1.00	1.50	2.33	4.00	9.00
Ultra-lift Luo- converter	$\frac{D(2-D)}{(1-D)^2}$	0.23	0.56	1.04	1.78	3.00	5.25	10.11	24.00	99.00

Source: Authors, (2026).

The ultra-lift Luo-converter is suitable for stepping up low voltages to the desired high-voltage levels in applications such as solar energy conversion, hybrid electric vehicle chargers, and other electrical energy storage systems. The converter provides a voltage gain ranging from 0.23 (at 0.1 duty ratio) to 99 (at 0.9 duty ratio), although the 0.9 duty ratio is limited by the control switch turn-OFF period.

III.2.3 Design of Ultra-Lift Luo-Converter

The design of the ultra-lift Luo-converter involves evaluating the inductor and capacitor ratings to achieve the desired power output and output voltage for a given input voltage, without violating the allowable ripple factors of the inductor and capacitor.

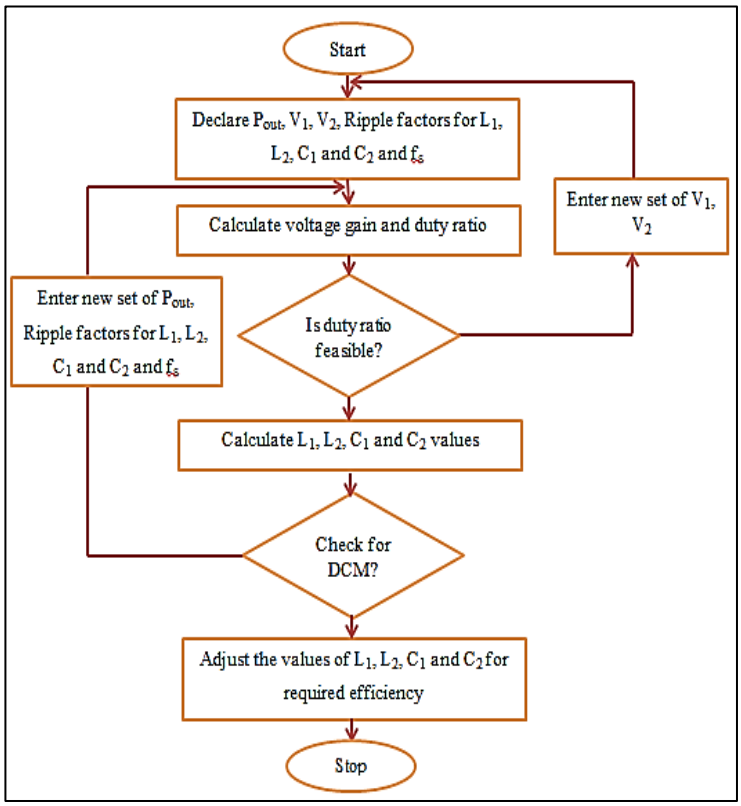

Figure 9: Flowchart for designing ultra-lift Luo-converter.
Source: Authors, (2026).

Where P_{out} = desired output power
V_1 = input voltage
V_2 = desired output voltage
L_1 and L_2 = inductor elements
C_1 and C_2= capacitor elements
f_s = switching frequency
DCM denotes Discontinuous Conduction Mode

III.2.4 Specifications of Designed Ultra-Lift Luo-Converter

Using the flowchart shown in Figure 9, the inductor and capacitor ratings are obtained by developing a MATLAB program. The designed converter specifications correspond to a power rating of 3000 W and an output voltage of 400 V DC, supplied by an input voltage of 36 V DC, with a ripple factor constraint of 0.02 for both inductors (L_1, L_2) and capacitors (C_1, C_2). The inductor and capacitor values are adjusted considering a peak conversion efficiency of 95% [11] and are further approximated to the available component ratings listed in Table 3.

Table 3: Specifications of designed ultra-lift Luo-converter.

Design Variable	Calculated Value	Chosen Value
Rated Output Power	3000 W	3000 W
Source Voltage (V_{in})	36 V	36 V
Regulated Output Voltage (V_{out})	400 V	400 V
Operating Switching Rate	50 kHz	50 kHz
Primary inductor Coil (L_1)	0.526 mH	0.5 mH
Secondary inductor Coil (L_2)	1.367 mH	1.35 mH
Input Side Filter Capacitor (C_1)	278 µF	300 µF
Output Ripple Control Capacitor (C_2)	66 µF	70 µF

Source: Authors, (2026).

III.3 BIDIRECTIONAL BUCK-BOOST CONVERTER

The bidirectional buck-boost converter can operate in both buck and boost modes, depending on the firing pulses applied to the two MOSFET switches. The converter consists of two active switches, S_1 and S_2, as shown in Figure 10. Switch S_1 is provided with pulses during the boost (discharging) mode of operation.

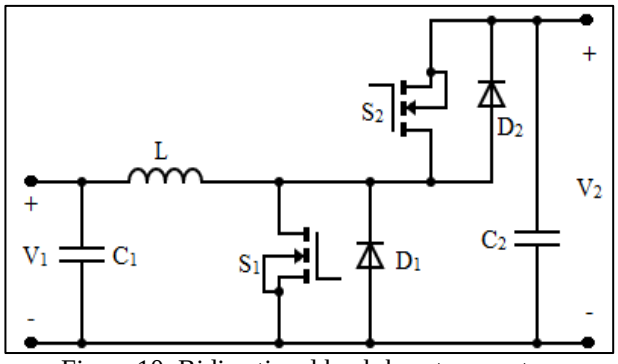

Figure 10: Bidirectional buck-boost converter.
Source: Authors, (2026).

Similarly, **S_2** is provided with pulses for bucking or charging purposes. The converter shown in Figure 10 consists of an inductor (L), capacitors (C_1 and C_2), and diodes (D_1 and D_2). V_2 is considered the voltage on the High-Voltage (HV) side, and V_1 is considered the voltage on the Low-Voltage (LV) side. Operation can be explained in two modes. They are:
1. Boost mode
2. Buck mode

1. Boost mode

In the boost mode, switch S_2 is turned OFF, and diode D_1 remains reverse-biased throughout the operation. When S_1 is turned ON, the inductor L charges, and D_2 becomes reverse-biased. Similarly, when S_1 is turned OFF, the inductor L discharges, as shown in Figure 11.

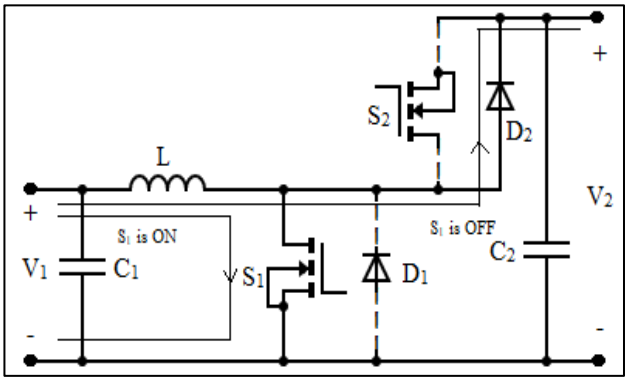

Figure 11: Bidirectional buck-boost converter in boost mode.
Source: Authors, (2026).

2. Buck mode

In the buck mode, switch **S_1** is turned OFF, and diode D_2 remains reverse-biased throughout the operation. When **S_2** is turned ON, the inductor L charges, and D_1 becomes reverse-biased. Similarly, when **S_2** is turned OFF, the inductor L discharges, as shown in Figure 12.

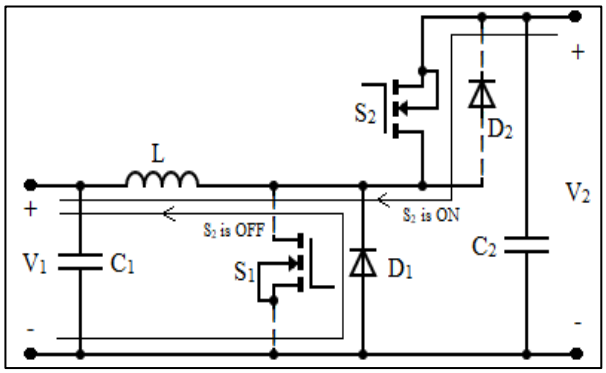

Figure 12: Bidirectional buck-boost converter in buck mode.
Source: Authors, (2026).

Analysis of Bidirectional buck-boost converter:

Duty ratio, $D_{Boost} = 1 - \frac{V_1}{V_2}$

Duty ratio, $D_{Buck} = \frac{V_1}{V_2}$

Inductor current, $I_1 = \frac{P}{V_1}$

Inductor, $L_{Boost} = \frac{D_{Boost} * V_1}{r_1 * I_1 * f_{sw}}$

Inductor, $L_{Buck} = \frac{D_{Buck} * V_2}{r_1 * I_1 * f_{sw}}$

Inductor, $L = \max(L_{Boost}, L_{Buck})$

Capacitor, $C_1 = \frac{I_2 * D_{Boost}}{r_2 * V_2 * f_{sw}}$

Capacitor, $C_2 = \frac{I_1 * D_{Buck}}{r_1 * V_1 * f_{sw}}$

Where P = Power rating

V_1 = voltage at LV side

V_2 = voltage at HV side

r_1, r_2= ripple factors

f_{sw} = switching frequency

Table 4: Specifications of Bidirectional buck-boost converter.

Parameter	Actual value	Practical Value
Output Capacity	500 W	500 W
Input Supply Level	24 V	24 V
Output DC Potential	100 V	100 V
Switching Pulse Rate	50 kHz	50 kHz
Inductor (L_1)	2.31 mH	2.5 mH
Input Filter Capacitor (C_1)	76 µF	100 µF
Output Smoothing Capacitor (C_2)	41.6 µF	50 µF

Source: Authors, (2026).

III.4 BATTERY SPECIFICATIONS

The Lithium-ion battery represented in this model has a nominal voltage of 24 V and a rated capacity of 50 Ah, suitable for medium-power applications in renewable energy storage and motor drive support. At the beginning of the simulation, the state of charge (SOC) is arbitrarily set to 45%, providing room for charging from the solar PV array and discharging to the load.

Table 5: Battery specifications.

Parameter Description	Specification
Nominal Output Voltage	24 V
Rated Energy Capacity	50 Ah
Initial Charge Level	45%
Dynamic Response Duration	1 s
Maximum Storage Capacity	50 Ah
Lower Cut-off Voltage Limit	18 V
Voltage at Full Charge	27.93 V
Typical Discharge Current	21.7391 A
Equivalent Internal Resistance	0.0048 Ω
Effective Capacity at Nominal Voltage	45.2174 Ah

Source: Authors, (2026).

III.5 BATTERY CONTROLLER

The battery controller manages the charging and discharging operations of the battery to maintain stable system performance and extend battery life. From Figure 13, the reference voltage (V_R) is compared with the actual battery voltage (V_B) to generate a voltage error as the output. This error is then fed to the voltage controller (PID controller), which determines whether charging or discharging is required.

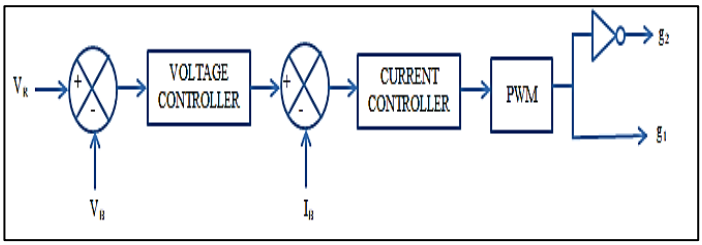

Figure 13: Battery controller block diagram.
Source: Authors, (2026).

Table 6: Battery controller specifications.

	Proportional constant (K_P)	**Integral constant (K_I)**	**Derivative constant (K_D)**
Voltage controller	0.85	10	0.005
Current controller	0.01	10	0.005

Source: Authors, (2026).

III.6 BRUSHLESS DC MOTOR

This proposed system employs a BLDC motor as the load. The BLDC motor is powered through a three-phase voltage source inverter (VSI). The inverter, in turn, responds to the regulated voltage supplied by the Ultra-Lift Luo-converter and the battery system to provide the motor with a three-phase AC supply. The electronic commutation of the BLDC motor is achieved using Hall-effect position sensors, which generate rotor position signals. Based on these signals, the inverter's switching sequence is generated, ensuring proper commutation and continuous torque production.

Table 7: Parameters of BLDC Motor.

Parameter Description	**Specification**
Stator Winding Resistance	0.7 Ω
Armature Inductance	2.72×10^{-3} H
Magnetic Flux Linkage	0.1194 Wb
Voltage (Speed) Constant	87.0946 V/krpm
Torque Generation Constant	0.84 N·m/A
Rotor Inertia	0.0002 kg·m²
Viscous Damping Coefficient	0.0004974 N·m·s
Number of Pole Pairs	4
Number of Phases	3
Back Electromotive Force (EMF) Shape	Trapezoidal
Mechanical Input Type	Torque
Back-EMF Flat Region	120°

Source: Authors, (2026).

It is a closed loop speed control system wherein the motor speed is sensed and compared with the reference speed. The motor speed thus obtained is fed to the control loop as the feedback. The error signal is processed by the PID controller to control the duty ratio of the ultra-lift Luo-converter with the Pulse Width Modulation (PWM) signal assuring the motor can run at the desired speed based upon its load and supply conditions. PID controller parameters implemented for speed control of BLDC motor are:

- Proportional constant K_P=0.2
- Integral constant K_I=8.58
- Derivative constant K_D=0.005

IV. RESULTS AND DISCUSSIONS

The dynamic speed response of the BLDC motor closely follows the speed reference commands during its operation as shown in Figure 16 .

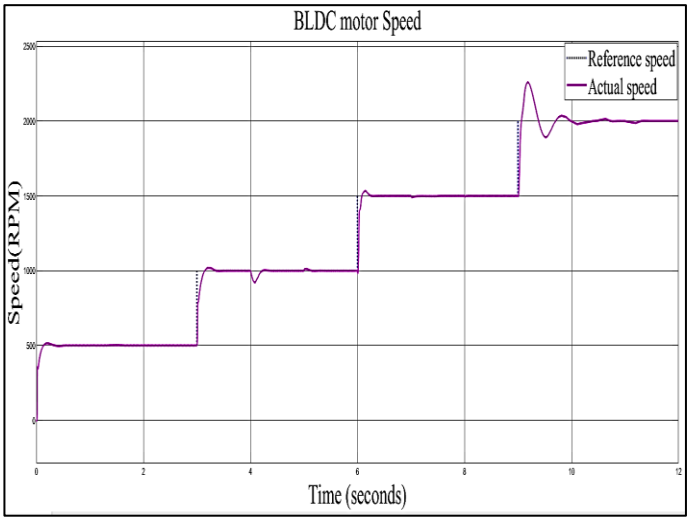

Figure 16: BLDC motor Speed.
Source: Authors, (2026).

A few transient deviations are observed during transition from one speed level to another, but the response settles down quickly to the speed reference value, indicating fast execution in the dynamics and very good steady-state performance. Even when the speed exceeds 2000 RPM, the controller tracks the reference command robustly without much oscillation. This implies good integration between the Ultra-Lift Luo-converter and the BLDC drive so as to get enough gain and solid performance from the motor.

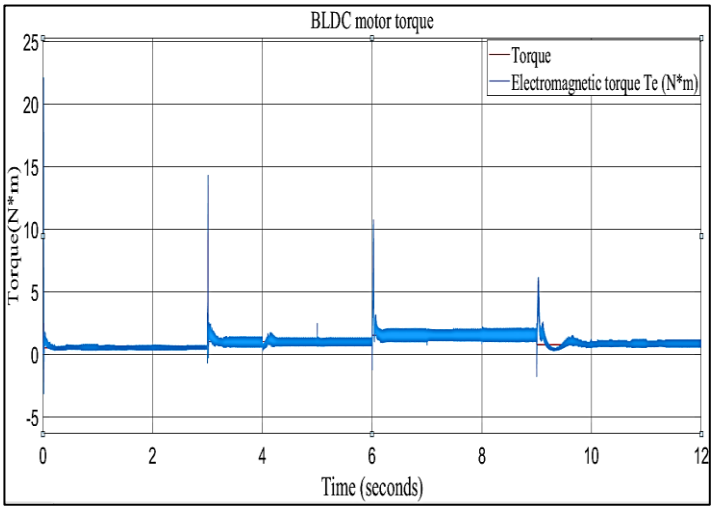

Figure 17: BLDC motor output electro mechanical torque.
Source: Authors, (2026).

The electromagnetic torque follows closely to the profile of the applied torque (Figure 17), signifying synchronization between the inverter switching sequence and motor dynamics. Due to transient oscillations, the torque gets disturbed but soon it settles back to steady values, demonstrating the capability of the controller in suppressing oscillations and ensuring steady operations of the motor. The converter output voltage increases from about 36 V to 150 V and then to almost 200 V (Figure 18) as demonstrated by the converter's ability to provide a regulated high-gain conversion when the duty ratio is varied. The output voltage settles smoothly after each transient, thereby signifying the controller's efficacy in attenuating oscillations and controlling voltage stability.

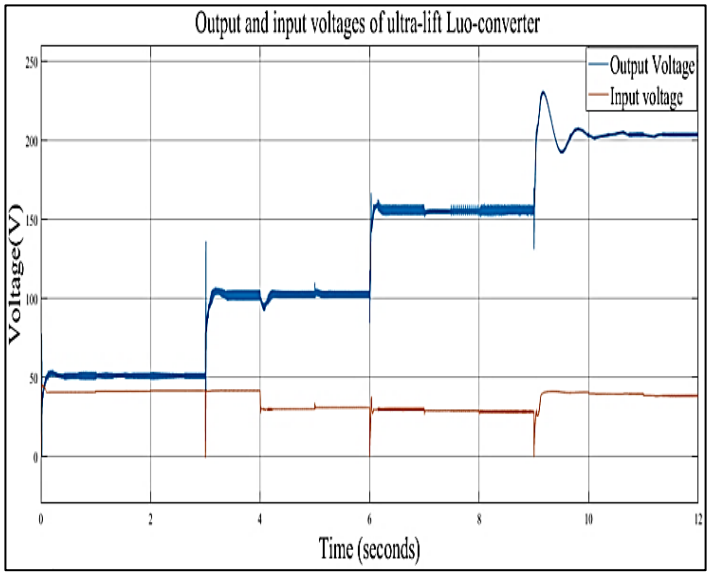

Figure 18: Output and input voltages of ultra-lift Luo-converter.
Source: Authors, (2026).

Initially the State Of Charge (SOC) profile (Figure 18) remains almost constant, indicating a balanced charging-and-discharging condition. As the converter and motor load settled down, the SOC started rising gradually, thus showing charging (4-9s) potential of the system. This gradual increase would then show that energy is efficiently transferred from the source to the battery to maintain support to load requirements.

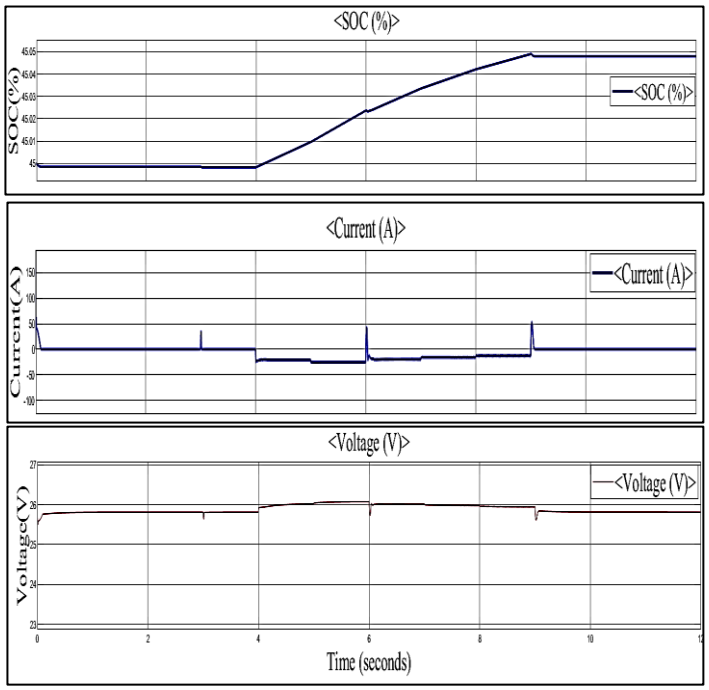

Figure 19: Battery parameter profiles: SOC, current, and voltage.
Source: Authors, (2026).

The battery voltage and current profiles (Figure 19) exhibit both positive and negative responses throughout the simulation period, demonstrating the charging and discharging behavior of the battery. Short transient spikes appear at different instances, corresponding to load and control transitions. Except for these brief occurrences, the current and voltage remain nearly constant, indicating that the controller effectively regulates both the battery current and voltage.

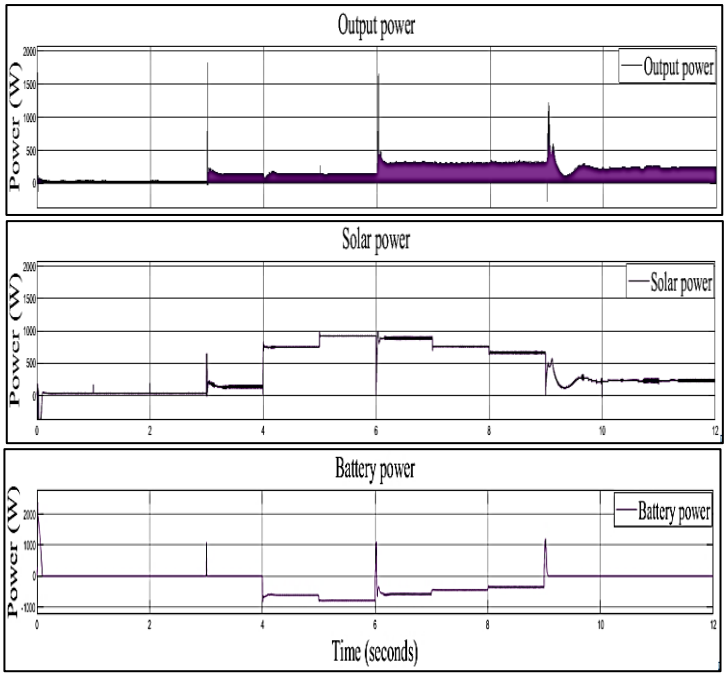

Figure 20: Power output: Ultra-lift Luo-converter, Solar PV array, and Battery.
Source: Authors, (2026).

Step changes in solar PV array output power (Figure 20) reflect variable irradiance or load conditions present upon the solar array. The solar power curve sharply rises and starts stabilizing. Between 4-6s, the array generated steadily in the range of 600–900 W, which showed reliable generation under stable irradiance. After 9 seconds, the solar output power was at a gradual decrease due decrease in irradiance and eventually stayed below 200 W, effectively making this photovoltaic source least contributory. The battery exhibits both positive and negative power values (Figure 20), confirming its bidirectional operation. After the initial transient, it delivers power to support load demand. In the periods between 4-6s, and 6-8s, the battery in fact operates in the negative region of around –500 W to –800 W, thus accounting for the charging from the excess solar generation. After 9s PV system is least effective, hence load is shared by battery.

The Ultra-Lift Luo-converter achieves the power requirements of the BLDC drive (Figure 20), even though a peak overshoot occurs initially before settling at stable power levels. The converter is able to supply a steady power output during battery switchovers and solar power inconsistencies.

V. CONCLUSIONS

The proposed ultra-lift Luo-converter is able to step up the input voltage of 36 V to voltages upto 220 V at 2000 rpm to drive the BLDC motor which is 6 times the input voltage. The motor speed response followed the reference input closely, while torque transients were suppressed by the controller. The proposed system can provide a stable DC output voltage, ensuring energy transfer to the BLDC motor under dynamic irradiance and temperature conditions. The proposed system is viable alternative for renewable energy application to ensure sustainable and reliable generation and use of clean power.

ABSTRACT

The importance of maintaining optimal health during pregnancy for both the mother and fetus has driven the development of numerous artificial intelligence (AI)-based monitoring systems. These systems aim to address the growing need for continuous, reliable health tracking in pregnant women, ensuring early detection of complications and promoting better outcomes. While general-purpose health monitoring platforms exist, there remains a significant gap in solutions explicitly tailored for pregnancy. Addressing this need requires not only real-time monitoring but also predictive capabilities based on vital signs. In this work, we propose an IoT-based pregnancy monitoring system that continuously collects key physiological data, namely body temperature, heart rate, and blood oxygen saturation. The collected data is transmitted in real time and processed using a Long Short-Term Memory (LSTM) neural network to build a model capable of forecasting potential health anomalies. The system provides real-time insights and future predictions. This approach enhances proactive care, enabling timely intervention and improving maternal-fetal health outcomes. This system's approach shifts between personal and centralized monitoring, a capability particularly valuable where regular prenatal visits are difficult, thereby enhancing the overall effectiveness of prenatal care delivery.

I. INTRODUCTION

Nowadays, modern healthcare systems [1], [2] are increasingly focused on early monitoring to prevent and predict complications at an early stage. This approach has become a fundamental tool in preventive medicine, aiming to detect potential health issues early and enable timely intervention. By leveraging advanced techniques [3], [4] to analyze patient data, these systems contribute significantly to improving overall well-being. Monitoring pregnant women is one of the areas that benefits most from tailored health monitoring systems. The dynamic physiological changes during pregnancy can lead to various complications and, in some cases, may even threaten the mother's life. Traditionally, the health of pregnant women is monitored by healthcare professionals in clinical settings through physical examinations and laboratory tests. However, in most cases, these methods lack the ability to collect and utilize real-time data.

New technologies have emerged, particularly remote health monitoring and data analysis using artificial intelligence (AI) and IoT are becoming increasingly popular [5–8]. These innovations allow both patients and healthcare professionals to track and analyze real-time health data. For pregnant women, this means being able to detect any changes or patterns related to potential complications, enabling early intervention to prevent risks that could affect either the mother's or the fetus's health. A variety of techniques [6], [9] for collecting and analyzing health data are now being incorporated into remote healthcare monitoring, including the use of wearable devices, mobile applications, and other digital tools. These systems enable the continuous collection and analysis of vital signs such as heart rate, blood pressure, and body temperature.

By leveraging these sensors and technologies, it becomes possible to identify patterns, make predictions, and forecast future changes, allowing for the early detection of potential health risks and enabling timely interventions to maintain good health. In this work, we propose a new framework that combines IoT and AI-based techniques to enable healthcare professionals to remotely monitor the health of pregnant women. The system collects data from vital signs, analyzes them to detect potential risks, stores historical health records, and forecasts future changes.

IoT devices are used to track any abnormal variations in vital signs continuously, while an AI-based approach using a Long Short-Term Memory (LSTM) deep learning architecture serves as a predictive tool for early diagnosis by forecasting future changes in these parameters and estimating the likelihood of developing complications. The system provides real-time monitoring and predictive insights through an integrated web and mobile application, allowing both pregnant women and healthcare providers to access critical health information at any time.

I.1 RESEARCH CONTRIBUTIONS

The main contribution can be summarized as follows:

1. **Development of a Novel IoT-AI Framework:** A new system is proposed that integrates IoT and AI technologies specifically for the remote monitoring of pregnant women's health.
2. **Real-Time Vital Sign Monitoring:** IoT devices are used to continuously collect and track key physiological data (e.g., heart rate, temperature, oxygen saturation) for early detection of abnormal changes.
3. **Combining Health Monitoring Approaches**: This system shifts from personal to centralized monitoring, a capability particularly valuable in contexts where regular prenatal visits are limited or challenging.
4. **Predictive Health Analysis Using LSTM:** Implementation of a Long Short-Term Memory (LSTM) deep learning model to forecast future changes in vital signs and predict potential complications.
5. **Early Diagnosis and Risk Prevention:** The system enables early identification of health risks, allowing timely intervention and preventive care.
6. **Historical Data Storage and Trend Analysis:** The collection and storage of historical health data to analyze long-term patterns and support better clinical decision making.
7. **Multi-Platform Accessibility**: Real-time monitoring and predictive insights are made available through both web and mobile applications, improving accessibility for both patients and healthcare providers.

II. RELATED WORKS

II.1 HEALTH MONITORING SYSTEMS

Health monitoring involves observing and tracking various aspects of a person's condition to identify potential issues and address them early. It consists of continuously assessing changes related to an individual's well-being to prevent potential health risks [10]. Monitoring can be done in three different ways [11], namely on-site, remotely, or centralized. In onsite monitoring, healthcare providers collect data directly by medical sensors connected to the patient, and it is done locally. It ensures accurate clinical assessment but lacks continuity. Remote monitoring uses transmission technology to send health data to a central monitoring system, which enables healthcare providers to monitor patients' health regardless of time and location, but may lack immediate clinical interpretation. Centralized monitoring bridges the two by combining remote data collection with expert oversight. The data collected remotely and the analytical evaluation are done at a central location. It is considered a more reliable approach for studying health phenomena, conducting large-scale research, and guiding decision-making in general health management, for example, the spread of epidemics like COVID-19.

II.2 INTERNET OF THINGS (IoT) IN HEALTHCARE

To enable remote monitoring, IoT is the most widely used technology for collecting data via sensors, transmitting information through networks, and analyzing the data using intelligent cloud-based solutions, thereby supporting efficient healthcare systems. The study presented in [6] proposed a patient monitoring system that uses GSM and embedded IoT technology to store and transfer healthcare data to the cloud, making it accessible to multiple users anytime and anywhere. Another study in [12] introduced an IoT-based health monitoring system focused on two vital signs: body temperature and respiratory rate. The system analyzes these parameters and detects abnormal health conditions via a mobile application, which can be used by doctors and nurses in hospitals.

This allows them to monitor all patients in real time without needing to visit each one individually, except in emergencies or when intervention is necessary. Different types of data can be used to evaluate overall health via IoT. Vital signs, such as heart rate, blood pressure, and temperature, are key physiological indicators [13]. Physical activity monitoring, including movement and exercise tracking, as well as sleep analysis (e.g., duration and quality), helps detect issues like sleep disorders [14]. Monitoring specific parameters, such as blood pressure in cases of hypertension, is essential for managing chronic diseases. Emotional and behavioral tracking also enables the early detection of mental health problems [15].

II.3 VITAL SIGNS IN MATERNAL HEALTH

Among others, vital signs monitoring [16–18] allows healthcare professionals to make timely interventions by continuously observing and measuring a person's physiological functions. It helps detect any changes in their condition and identify potential issues before they become serious. Various physiological functions, such as blood pressure, heart rate, respiratory rate, temperature, and oxygen saturation, can be considered. These measurements, commonly referred to as vital signs, play a critical role in clinical evaluation and management [19]. Several researchers have studied the use of wearable devices for continuous monitoring the healthcare based on body temperature [17], [20], [21].

Body temperature is one of the key indicators for the body to detect early warning signals of inflammation, infection, and other health complications. In the study conducted in [22], it was shown how body temperature, captured using wearable sensors, can continuously and accurately monitor health conditions and, for instance, prevent cases of sepsis using machine learning techniques. Other vital signs, including blood pressure, heart rate, and blood Oxygen saturation (SpO2) is a key indicator of an individual's health status. Blood pressure reflects cardiovascular function. Heart rate and its variability reflect cardiac and nervous system adaptations during pregnancy and postpartum [23], and they help in detecting serious complications such as preeclampsia [24], as well as psychological conditions like depression [25]. Oxygen saturation (SpO2) predicts adverse maternal outcomes in preeclampsia [26].

The work presented in [27] describes systems designed to monitor these vital signs. These systems collect real-time physiological data and transmit it to healthcare providers for immediate monitoring. Furthermore, machine learning techniques are integrated to enable the early and timely detection of potential health issues, thereby helping to prevent complications. According to the World Health Organization, deaths during pregnancy and childbirth are often caused by severe bleeding, high blood pressure, and pregnancy-related infections, which can be directly linked to and identified through vital signs. In cases such as infection, which pose a serious risk to both the mother and her fetus and can lead to dangerous complications or even death, a high body temperature often serves as a primary symptom and indicator that the body is responding to the infection [28].

Thus, monitoring vital signs, including body temperature, is crucial to ensure the well-being of the mother and the healthy development of the fetus. There are several benefits to monitoring vital signs during pregnancy. These include the early detection and management of high-risk conditions by tracking pre-existing medical issues such as diabetes, hypertension, and heart disease, all of which can increase the risk of complications. Vital sign monitoring is also useful for assessing overall health and guiding treatment decisions in women taking medications, as changes in indicators like blood pressure and body temperature can signal the need for medical adjustments. Moreover, tracking vital signs provides valuable data for research, contributing to a better understanding of the causes and risk factors leading to pregnancy complications.

Vital signs thus play a significant role in supporting the well-being of pregnant women and informing their healthcare providers. For example, elevated body temperature, especially in the first trimester, can indicate infection and has been linked to an increased risk of congenital heart defects or neural tube defects (NTDs), which affect the brain, spine, or spinal cord of the newborn [29], [30]. A rapid heart rate may signal underlying conditions such as anemia or preeclampsia, and if combined with a high temperature, it may point to sepsis. High blood pressure (hypertension) is another serious condition that can severely affect both the mother's health and the development of the fetus. Healthy SpO_2 levels are essential for proper fetal development, as even short periods of oxygen deprivation can disrupt normal organ formation and elevate the risk of congenital defects, particularly cardiac and spinal abnormalities [31].

Various research efforts based on vital signs have been proposed to monitor the health of pregnant women. The work presented in [6] introduces a system that uses vital signs and data collected through IoT technology to measure fetal movement and maternal parameters such as blood pressure, heart rate, and body temperature. This data is then transmitted and visualized via a mobile phone to monitor the health status of both the mother and the fetus. The system addresses the challenge faced by pregnant women living in rural areas with limited access to medical facilities, offering low-cost healthcare coverage without requiring travel.

II.4 FORECASTING AND AI IN HEALTH MONITORING

Another similar work proposed in [5] analyzes various pregnancy-related biological factors such as the pregnant woman's heart rate, blood pressure, blood glucose level, body temperature, and the weight of the fetus. This system allows physicians to monitor the condition of both the mother and the fetus remotely and access critical data, supporting rapid decision-making and timely treatment in case of complications. In fact, advancements in digital health technologies, particularly the use of Internet of Things (IoT) devices, have enabled continuous and remote monitoring of patients' vital signs [32]. These systems are especially impactful in maternal healthcare, where real-time data collection from pregnant women provides critical insights into both maternal and fetal health.

However, data collection alone is not sufficient; intelligent analysis is required to extract meaningful patterns and predict potential complications before they become critical. This need has driven the integration of AI into healthcare systems to enhance early detection, diagnosis, and intervention [33]. In this context, forecasting refers to the use of data-driven models to predict future changes in a patient's health status based on current and historical vital signs, a key capability for identifying complications that may not show immediate symptoms [34]. Therefore, our contribution proposes an IoT-based framework for monitoring pregnant women, in which vital signs, mainly body temperature, are continuously collected and analyzed.

We use a Long Short-Term Memory (LSTM) deep learning model to forecast temperature trends, allowing for early prediction of abnormal patterns that may indicate infection or other risks. LSTMs are able to capture temporal dependencies in sequential data, making them particularly suitable for effectively forecasting vital signs that change over time[35]. This approach of forecasting physiological parameters with deep learning models supports timely intervention and improved maternal care, as it has been shown to enhance preventive healthcare by enabling proactive decision-making and personalized treatment plans [36].

III. MATERIALS AND METHODS

The proposed system includes an IoT infrastructure that connects sensors to a web application, enabling doctors to remotely monitor the health status of pregnant women through vital signs such as body temperature, heart rate, and SpO2. This setup helps in preventing potential health issues and associated risks. Additionally, the system forecasts future body temperature to anticipate and mitigate possible complications, acting as a preventive mechanism, adding an extra layer of safety. It provides both pregnant users and healthcare professionals with access to collected and analyzed health data. This section introduces our proposed architecture, describing the IoT-based monitoring and temperature forecasting model and the hardware components.

III.1 FRAMEWORK ARCHITECTURE AND COMPONENTS

The global architecture of the proposed framework is shown in Fig. 1. It provides an overview of the main components of the system. Four primary components are included: the sensing module, data collection and storage, temperature forecasting, and the web application.

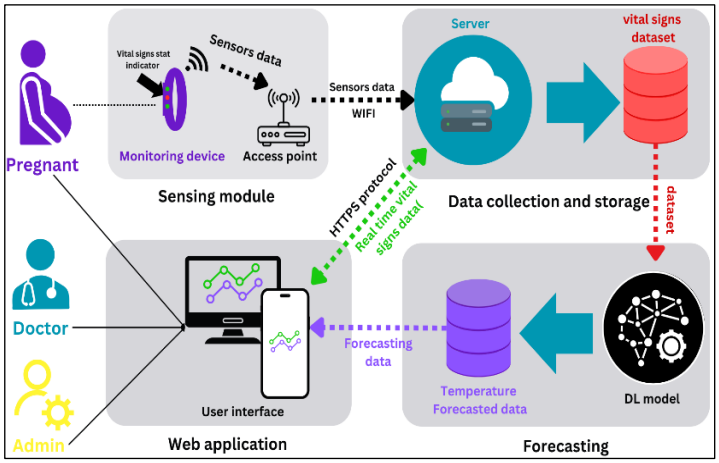

Figure 1: Overall framework architecture for pregnant women monitoring.
Source: Authors, (2026).

The main components of the framework are broken down as follows:

1. Sensing Module: The sensing module consists of IoT components used to collect vital signs related to real-time data of pregnant women. It includes sensors for temperature, heart rate, and oxygen levels, LED indicators, and a microcontroller to evaluate the corresponding values and send alerts in different situations (low, high, or normal). The data is transmitted to the cloud via IoT protocols, ensuring real-time communication so that both the pregnant woman and the doctor are promptly notified through their respective dashboards. The data is also stored for use by the forecasting model. Different sensors have been used to realize the sensing module.

- Temperature sensor: The LM35 temperature sensor is used, which outputs a voltage linearly proportional to the temperature in degrees Celsius. It measures temperatures ranging from −55 ◦C to 155 ◦C, with a voltage conversion rate of 10 mV/◦C. This sensor is suitable for remote monitoring because it does not require external calibration and offers reliable performance. Moreover, it is low-cost, highly accurate, and consumes little power.
- Pulse oximeter and heart rate sensors: The sensor MAX30102 sensor presented in Fig.3 is used to measure both the heart rate and oxygen saturation. It works on a 1.8 V power supply and measures heart rate and blood oxygen from wearable devices, which can be worn on the fingers, earlobe, and wrist.
- Microcontroller: To manage the different sensors and process the data, we used the NodeMCU microcontroller (Fig. 4), which is open-source and equipped with a CPU, RAM, and a Wi-Fi module.
- Light Emitting Diodes (LEDs): We used an RGB LED with three internal colors (Red, Green, and Blue) to produce visual alert messages. Any color can be generated by combining these three LEDs.

Source: [39].

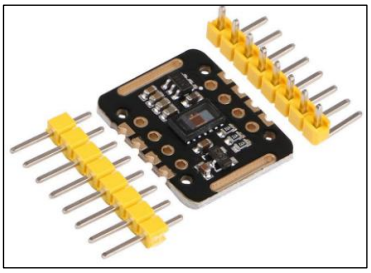

Figure 3: MAX30102 pulse oximeter and heart rate sensor.
Source: [38].

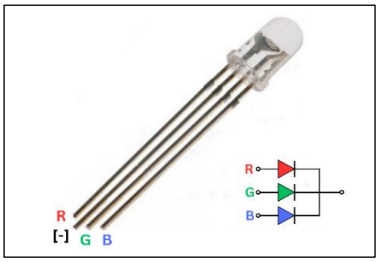

Figure 5: The used RGB LED.
Source: Authors, (2026).

2. Data collection and storage: To store and manage the collected data, we used the ThingSpeak IoT cloud platform, which includes a web service (REST API) for collecting and storing data from sensors in the cloud. It provides ample cloud storage capacity to manage real-time data and allows seamless access to the data from anywhere at any time. The NodeMCU microcontroller is used to transmit the gathered sensor data to this platform through its integrated Wi-Fi module. Each value, including temperature, heart rate, and SpO$_2$, is transmitted through a dedicated channel. The collected vital signs data is stored in CSV or JSON format, allowing for easy retrieval and use in historical visualization and forecasting.

3. Body temperature forecasting: In order to forecast future body temperature and predict any related complications, a deep learning (DL)-based forecasting model is proposed (described in detail in Section III-B). It uses the stored data in the cloud to build a learning model, which is then used to predict temperature for the upcoming hours. The predictions are displayed through the web application and can be accessed by doctors and pregnant users via their dashboards, with an appropriate display mode for each. The overall process is shown in Fig. 6.

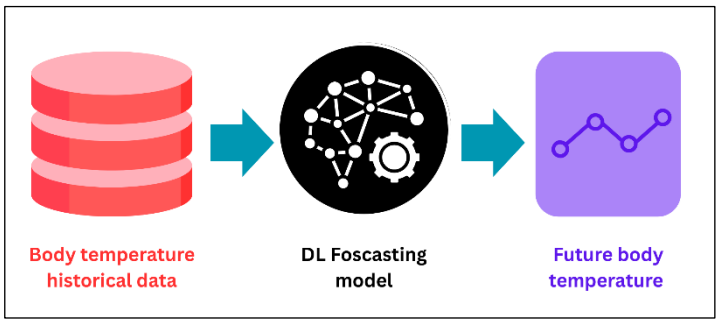

Figure 6: Body temperature forecasting processes.
Source: Authors, (2026).

4. Web application: The web application allows different actors to benefit from the information provided by the framework, each for a specific purpose. The three main actors are the admin, the pregnant user, and the doctor. The administrator can manage technical actions such as adding and updating user profiles. The doctor can perform standard operations, monitor patients' vital signs, view historical data, access forecasting information, and identify any potential risks. The pregnant user can check her vital signs to ensure everything is normal and add or update her personal information. The use-case diagrams presented in Fig. 7 summarizes the actions of each of the different actors.

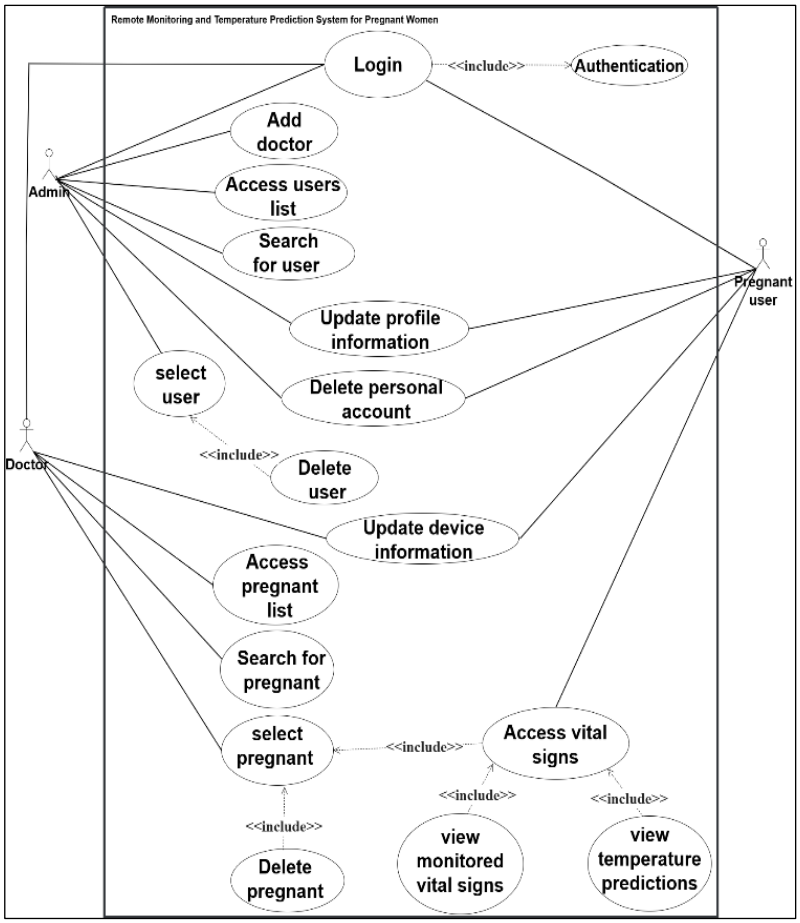

Figure 7: Use case diagram.

III.2 BODY TEMPERATURE FORECASTING

In order to forecast temperature over future time steps, we developed a sequence-to-sequence LSTM model tailored for multi-step output. Different LSTM-based architectures, namely LSTM, Bi-LSTM, and GRU, were considered and evaluated against various baseline models and performance metrics. This enabled us to identify the most suitable model for the forecasting task. The overall temperature forecasting process, including the LSTM architecture, is shown in Fig. 9.

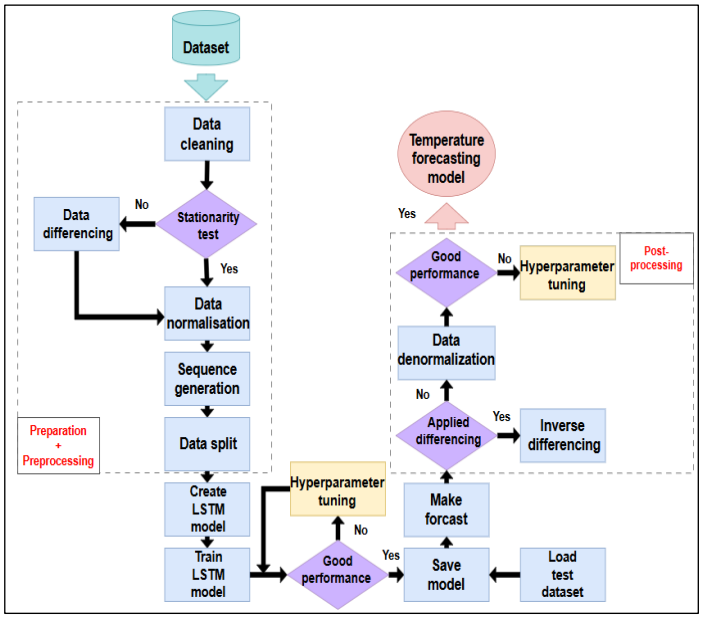

Figure 9: Use case diagram.
Source: Authors, (2026).

The process starts with preprocessing steps: filtering the data, checking for missing values, and handling them appropriately. Data normalization and scaling are then applied. Statistical tests such as the Augmented Dickey-Fuller (ADF) test, along with ACF and PACF plots, are used to visualize the data and verify stationarity. If necessary, first-order differencing is applied to remove trends and achieve stationarity. Next, sequences are created from the input and output data to fit a structured format suitable for a supervised learning task. A fixed number of previous time steps, referred to as the "look-back" window, serve as input features, while another fixed number of future time steps, referred to as the "target" window, serve as the predicted output generated by the model. The final step in the processing phase is to split the data into training and testing sets. Additionally, a validation set is created, used for hyperparameter tuning during training. It allows for assessing the model's performance on unseen data while fine-tuning its hyperparameters. Afterward, the LSTM model with different architectures and configurations is deployed.

The first configuration consists of a one-dimensional LSTM that processes one-dimensional sequential temperature data. It includes an input layer, followed by three LSTM layers, three dense layers with ReLU activation functions, and a final single-unit output layer with a linear activation function. The second configuration is a Bi-LSTM model. It starts with an input layer shaped according to the input data (ninput, nfeatures), which then passes through three bidirectional LSTM layers with 100 units each—allowing the model to capture information from both past and future time steps. This is followed by two fully connected layers with 8 and 1 neurons, respectively, using ReLU and linear activation functions for feature extraction and regression output. The last configuration is a GRU-based architecture, starting with an input layer, followed by three stacked GRU layers with 100 units each, and an additional GRU layer with 50 units. Two dense layers are added afterward: the first with 64 units and a ReLU activation function, and the final output layer with a single unit and a linear activation function. The three architectures are presented in Fig. 10.

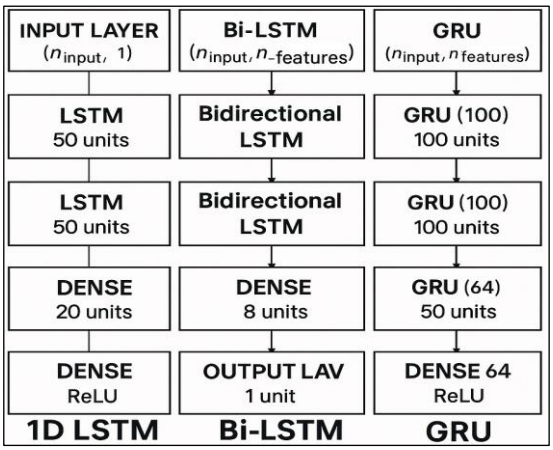

Figure 10: Used LSTM architectures for temperature forecasting.
Source: Authors, (2026).

After training and evaluating the model to determine the optimal parameters, the forecasting process is performed by specifying the size of the input sequence (forecasting look-back) and the length of the desired forecast output. Finally, the post- processing phase is crucial to convert the data back to its original standard time series format.

IV. RESULTS AND DISCUSSIONS

IV.1 HARDWARE IMPLEMENTATION

Our device prototype is built using an LM35 temperature sensor, a MAX30102 pulse oximeter and heart rate sensor, and a NodeMCU ESP8266 board. We also include three RGB LEDs (indicators for the three sensors) and nine resistors. The positive legs (anodes) of the LEDs are connected to the power supply (VCC). Each LED's positive pin is connected through a resistor to specific pins on the NodeMCU. Fig. 11 shows how all the components are connected, giving a clear overview of the monitoring system.

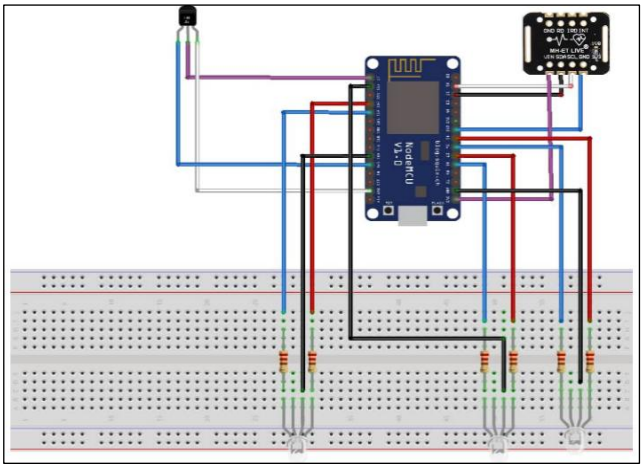

Figure 11: Device material connection.
Source: Authors, (2026).

The components of the circuit model are connected as described in Section III. The circuit integrates the LM35 temperature sensor and the MAX30102 pulse oximeter and heart rate sensor as inputs to the NodeMCU microcontroller. The microcontroller collects and analyzes the data, transmits it to the server, and controls the RGB LEDs as visual indicators. The LEDs display the status of the measured vital signs: green for normal, red for high, and blue for low. ThingSpeak is used to collect, store, and remotely access data by both users and devices. Several steps are followed to set up the server and connect it to the NodeMCU board. This includes creating a ThingSpeak account, setting up a new channel for data communication, and using the API key to upload data to the correct channel.

Finally, the different components are interconnected, and the server is configured accordingly. Afterward, the monitoring device operates according to the following process:

1. **Initialization and data collection:** The connected device initializes the sensors, continuously collects data using the Wi-Fi module, and establishes a connection with ThingSpeak for data transmission and communication.
2. **Data processing:** Ensure efficient data analysis, the collected data is first preprocessed and cleaned to make it usable for the next steps. This process also verifies that the vital signs are correctly detected, confirming that the user is wearing the device and that the data is accessible.
3. **Vital signs Assessment:** Based on the collected data, the connected device assesses the status of the vital signs by monitoring temperature, heart rate (HR), and SpO2 levels. Abnormal values are indicated using RGB LEDs: blue for low values, red for high values, and green for normal levels.
4. **Data Transmission:** The API key and channel ID are used to send the collected data to the ThingSpeak server. Each vital sign value (temperature, heart rate, SpO2) is assigned to a specific field within the channel.
5. **Data storage:** The data sent to the ThingSpeak server is stored in suitable formats for further use, including both CSV and JSON file formats.
6. **Continuous Loop:** The previous steps are executed in a continuous loop. Sensor data and the status of the vital signs are updated periodically.

Display outputs are integrated into the device to provide a more user-friendly interface. Once the device is connected, a message showing the network name is printed, along with a ”success” confirmation. The vital signs values are displayed in real time, and a notification is shown each time data is successfully sent to the server.

IV.2 FORECASTING MODEL RESULTS

To train the proposed models, we relied on a dataset obtained from a real experiment consisting of nearly 7-week-long wrist skin temperature measurements of a pregnant individual, collected using a smartwatch. The temperature is captured every 3 minutes for 24 hours. Fig. 12 below represents the visualization of this dataset.

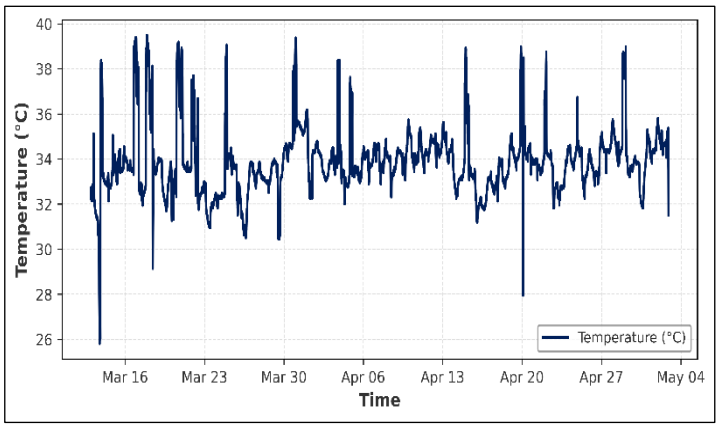

Figure 12: Seven-week wrist skin temperature of a pregnant individual.
Source: Authors, (2026).

The performance of the different forecasting models is evaluated, and the training results for each of the three configurations are shown in Figs. 13, 14, and 15.

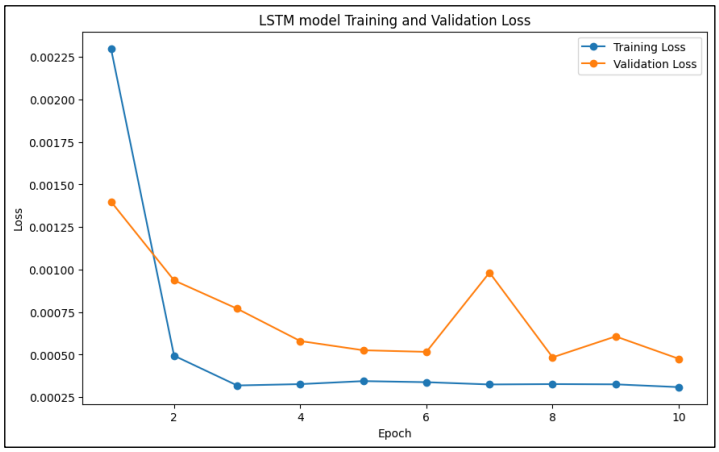

Figure 13: LSTM loss function evaluation.
Source: Authors, (2026).

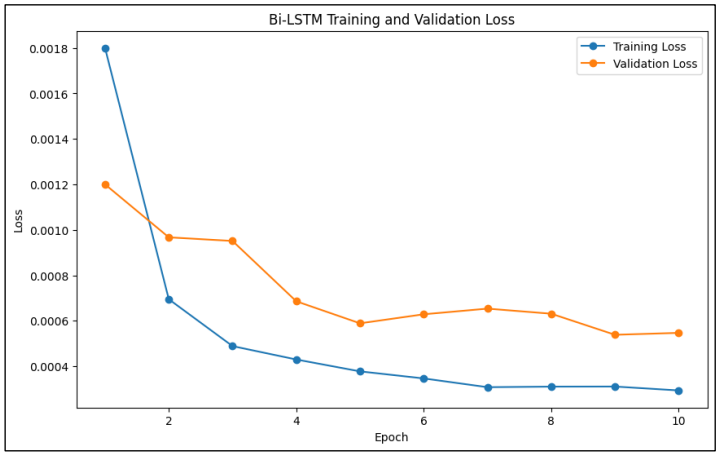

Figure 14: Bi-LSTM loss function evaluation.
Source: Authors, (2026).

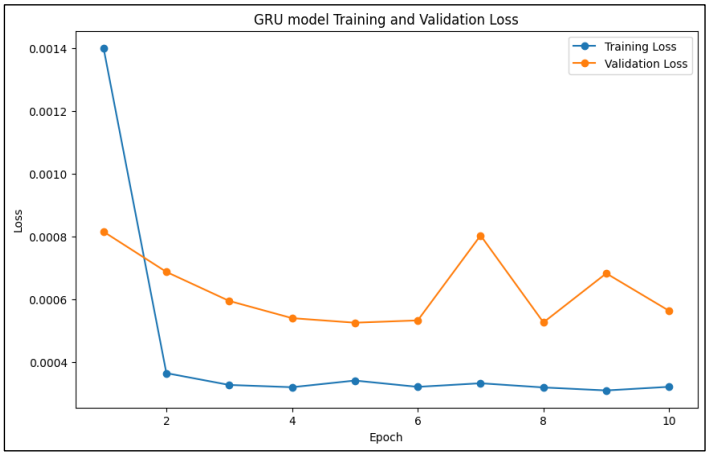

Figure 15: GRU loss function evaluation.
Source: Authors, (2026).

The loss function plots in these figures show distinct behaviors among the models. Although the 1D-LSTM starts with a higher initial loss, it exhibits a faster convergence rate compared to the other models. Ultimately, it achieves the lowest final loss for both the training and validation sets, indicating superior learning efficiency and generalization. In contrast, Bi-LSTM and GRU show similar overall performance trends. For training, the Bi-LSTM begins with a lower initial loss, suggesting a more favorable starting point. However, for validation, the GRU performs slightly better in the early epochs.

Despite these differences, both models eventually converge toward similar stationary loss values, implying comparable long-term performance. Interestingly, a minor increase in the loss is noted around epoch 7 for both the 1D-LSTM and GRU models. This could suggest a momentary overfitting or instability in learning, possibly due to learning rate dynamics or model sensitivity. Nonetheless, both models recover and resume a decreasing trend afterward, reinforcing the stability of their training process. To further evaluate the performance of the considered models, additional metrics, namely RMSE and MAE, are reused. Table I summarizes the obtained results.

Table 1: Training metrics scores.

Model	Loss	RMSE	MAE
LSTM	0.01 %	1.19 %	0.70 %
Bi-LSTM	0.02 %	1.29 %	0.78 %
GRU	0.02 %	1.45 %	0.95 %

Source: Authors, (2026).

Regarding the results shown in Table I, the 1D-LSTM model outperforms the other models, achieving the lowest values for all three metrics: loss, RMSE, and MAE. The Bi-LSTM model ranks second, showing better performance than the GRU model in terms of RMSE and MAE. The 1D-LSTM out performs the others by effectively capturing temporal patterns with less complexity. Bi-LSTM, though more powerful, may suffer from redundancy or overfitting. GRU, being simpler, lacks the memory depth needed for optimal performance in this context.

V. CONCLUSIONS

In the future, to increase the impact of the proposed work, other deep learning architectures could be considered to enhance the accuracy of the forecasting process and reduce the risk of medical errors. Additionally, a user-friendly mobile application could be developed alongside the web application, enabling faster access to the monitoring system and timely reception of related notifications. In this work, we focused on the mother's primary vital signs as an initial step but considering there are many additional issues related to pregnancy, further monitoring devices with extended capabilities such as fetal heart rate and glucose level tracking can also be integrated to monitor a wider range of health indicators and to address the fetus's condition more precisely

ABSTRACT

Automated systems are technological solutions designed to operate with minimal or no human intervention, performing tasks with high precision and efficiency. These systems maximize operations in a variety of areas, including the commercial, industrial, and residential sectors, by combining sensors, actuators, and sophisticated control logic. They are utilized in anything from intelligent home gadgets to complex industrial processes. The design and execution of an extensive automation and control system for an industrial milk processing facility are presented in this paper. Critical manufacturing processes, including water heating and cooling, milk storage, pasteurization, bottling, and cleaning, are all intended to be optimized by the system. Programmable Logic Controllers (PLCs) are employed to control the machinery and equipment, while Human-Machine Interfaces (HMIs) and a Supervisory Control and Data Acquisition (SCADA) system provide centralized monitoring, control, and visualization. The suggested solution combines software and hardware elements to provide an intuitive graphical user interface for process control and operational supervision. The main goals are to increase milk production efficiency, guarantee process dependability, improve product quality, and provide a smooth and user-friendly operator experience.

I.INTRODUCTION

Automated systems employ cutting-edge technology to manage and execute tasks without direct human intervention, increasing accuracy and efficiency in a variety of sectors. These systems are often built around Programmable Logic Controllers (PLCs), specialized digital computers designed for real-time control in industrial settings. PLCs employ programmable logic to control inputs and outputs in order to connect with sensors, actuators, and other devices. They are necessary for the automation of manufacturing processes, other electromechanical systems, and machinery. PLCs operate constantly, rapidly scanning and updating the control logic to ensure real-time response. These controllers' modular architecture makes it simple to enhance their capabilities and configure them to meet a range of industrial requirements.

Because of their robust architecture and resilience to harsh conditions, PLCs are crucial to the lifetime and dependability of automated systems. Automated systems that manage time-consuming tasks, data collection, and analysis increase the efficiency of scientific research and allow researchers to focus on difficult issues. These systems often include robots, sensors, and artificial intelligence, which expedite testing and enhance data accuracy. The use of automated technologies in labs improves experiment consistency and reproducibility. Researchers' use of automated technology for high-throughput has greatly boosted scientific innovation and discovery.

II. LITERATURE SURVEY

The usage of Supervisory Control and Data Acquisition (SCADA) systems for automation and remote monitoring in the bottle-filling industry is examined in the research in [1], [2]. A sophisticated PLC-SCADA framework for the automated monitoring of petroleum product terminals in an Industry 4.0 setting is proposed by the authors in [3], [4]. Similarly, [5] investigates tank operations and water level control in a semi-automated facility using PLC software in conjunction with SCADA. Simultaneously, [4] focuses on implementing Human-Machine Interfaces (HMIs) for an automated packaging process, enabling remote control and monitoring using mobile applications.

Paper [6] addresses failure reduction in automated metro railway systems by integrating data from the Operational Control Centre, traction SCADA system, traction power control, and power supply system, thereby improving network capacity and operational flexibility. In [7], a low-cost SCADA system for sugar manufacturing is presented, where PLCs control and monitor a laboratory production line. The system combines hardware and software, including PLC programming, HMI design, alarms, and trending systems, and monitors parameters such as temperature, flow, and humidity while detecting potential failures. The design and implementation of a heliostat control system based on a SCADA framework with a standalone remote terminal unit is described in [8], using a fuzzy logic controller integrated on a low-cost microcontroller for precise orientation control.

In [9], the authors suggest employing a PLC Zelio for the SCADA control of a biaxial photovoltaic tracker. The study also proposes a supervision algorithm using SCADA software on VijeoCitect and Android platforms with Tesla SCADA 2, alongside an automatic tracking control method via Zelio Soft 5.4.0.The work in [10] presents a smart automated bottle-filling system integrating PLC-SCADA technology. Bottle filling, warehouse management, and energy-efficient lighting are all automated, and process efficiency is shown through a SCADA simulation. Lastly, [11-13] suggests an analytical model for managing molding machines based on PLC and SCADA, allowing for continuous monitoring using many sensors. The technology guarantees dependable industrial process monitoring, improves power analysis, and permits the collection of quantitative fault data [14-16].

III. GENERAL DESCRIPTION OF MILK FACTORY OPERATIONS

Pasteurization, named after Louis Pasteur, is a crucial process in milk processing. It involves heating milk particles to a specific temperature without recontamination. It serves two purposes: public health to destroy harmful pathogens and keeping quality to improve the quality of milk and milk products.

III.1 PASTEURIZATION METHODS

Milk pasteurization involves heating milk to a specific temperature, holding it for a specific duration, and chilling it to less than 7°C. Combinations of time and temperatures can improve quality, destroy pathogens, or destroy all microorganisms. Selecting the right combination minimizes nutritional loss. Pasteurization methods include Low Temperature Long Time (LTLT) pasteurization, which involves heating milk to a temperature of 63°C and holding it for 30 minutes. Continuous (HTST) pasteurization, also known as Continuous Pasteurization, is carried out continuously in a plate heat exchanger with online detection and recirculation of insufficiently treated milk. It consists of five stages, including regenerative heating, heating, holding, regenerative cooling, and chilling. Flash pasteurization is a severe treatment, heating milk to 85-90°C and holding it for 1 to 4 seconds. Ultra High Temperature (UHT) pasteurization involves heating milk to 135°C and holding it for a minimum of 1.0 seconds, followed by aseptic packaging.

III.2 CIP OPERATION

Cleanliness is crucial for microbiological hygiene and restoring heat transfer and pressure drop characteristics. CIP cleaning is typically a two-stage process using acid and alkali, or specially formulated detergents. In the dairy industry, non-production time for CIP is excessive, ranging from 4 to 6 hours per day. CIP was first developed in the 1950s and is dependent on the type and concentration of solutions used, solution temperature, and time in contact with the deposit substance. Current auto-set CIP cleaning takes about 35 minutes and consists of five steps: pre-rinse, alkali-clean, water rinse, acid rinse, and final rinse.

III.3 BOILER OPERATION

Boiler operation involves the combustion of fuel inside a furnace, which then passes through fire tubes to create steam. This heat energy is transferred to the surrounding water, generating steam and storing it in the same vessel. There are two main types of boilers: water tube boilers, used in large power plants, and fire tube boilers, used for small-scale applications. The horizontal return fire tube boiler is most suitable for low-capacity thermal power plants, with a large steam drum submerged in water. The fuels burnt in the furnace and combustible gases move into the fire tubes, travel through them, and finally come into the smoke box. The hot gases transfer heat to the water via the tube walls, creating steam bubbles that come to the water's surface. As the amount of steam increases, the steam pressure inside the drum increases, reducing the boiling temperature of the water and reducing the rate of production of steam.

Advantages of a fire tube boiler include its compact construction, easy fluctuation of steam demand, and cost-effectiveness. However, disadvantages include high required steam pressure rising time due to large water, limited output steam pressure, not very dry steam, and the risk of explosions. Air-cooled chillers are refrigeration systems that cool fluids and work in tandem with the air handler system of a facility. They consist of four major parts: a compressor, an evaporator, a condenser, and an expansion valve. These chillers are used in large buildings like indoor malls, industrial buildings, hotels, and hospitals, as well as locations with multiple buildings requiring cooling, such as theme parks and outdoor malls. Components of an air-cooled chiller include a compressor, a condenser, fans, an expansion valve, and an evaporator or heat exchanger. The compressor provides the driving force that moves the refrigerant around the system, while the condenser transfers heat from the refrigerant to the air.

The expansion valve expands the refrigerant from its liquid form into a gaseous form before entering the evaporator, creating a pressure drop across the path of the refrigerant that runs to the evaporator. In conclusion, boiler operation involves the combustion of fuel, the transfer of heat energy to the surrounding water, and the use of air cooled chillers and air-cooled chillers.

III.4 FILLING MACHINE

Filling machines are essential tools for filling and packaging various food products, with various types and ranges available in various sectors. The machine has a transfer station, a filling station, a tightness control station, a filling station with an adjustable volumetric dozer, a looping station with a cap transfer, an MB pneumatic motor, an EV3 solenoid valve, and an advance cylinder E. The transfer station feeds the filling conveyor belt via cylinder A, while the filling-capping belt is actuated by jack G. The tightness control station is connected to a rack mounted on the cylinder, and the looping station is equipped with a cap transfer by cylinder F.

IV. CURRENT FACTORY WORK DESCRIPTION:

The factory work description includes various types of equipment used in milk factories. Air-cooled chillers, bottle machines, fire tube boilers, continuous pasteurization, and CIP systems are examples of this equipment. Air-cooled chillers use a compact Programmable Logic Controller (PLC) to cool water, which is then circulated through the factory for air conditioning. The PLC controls the operation of the chiller by monitoring the temperature of the water and adjusting the compressor speed. Bottle machines have filling, capping, and labeling operations with a simple HMI that provides a user-friendly interface for operators to interact with the machine. Fire tube boilers use relay logic control systems to heat water and generate steam. These systems use sensors to monitor various aspects of the boiler's operation, such as water level, temperature, and pressure.

Relay logic control systems, such as the burner and water pump, operate by activating or deactivating relays to control the operation of boiler components. Continuous pasteurization equipment uses a compact PLC and simple HMI to heat and cool liquid products to a specific temperature for a specific amount of time. The process involves heating the product to a specific temperature, holding it at that temperature for a specific amount of time, and then cooling it back down to a safe temperature. Cleaning In Place (CIP) is a cleaning process commonly used in milk factories to clean and sanitize equipment. The CIP system uses a series of components and control systems to automate the cleaning process. The compact PLC monitors various sensors and adjusts the operation of the components as needed. At the same time, the simple HMI provides a user-friendly interface for operators to monitor and control the CIP process.

V. PROBLEMATIC & OBJECTIVES

The objective of Human-Machine Interface (HMI) is to facilitate intuitive communication between humans and machines, enhancing operational efficiency and control in industrial processes. Through graphical interfaces and interactive elements, HMIs aim to present complex data in a user-friendly manner, enabling effective monitoring, control, and decision-making in diverse automation environments [17]. Any monitoring system must have a data acquisition system in order to gather data from the system's many sensors. After that, the data is digitized for storage before being transferred to a control center for processing and display. The purpose of this study is to explore novel system development and project execution methodologies, including:

- Creation a developed HMI for each operation.
- Create a PC station for fully control and remotely control.

V.1 SOFTWARE EQUIPMENTS OF THE SCADA SYSTEM

V.1.1 Tia Portal Software:

For configuring and programming SIMATIC controllers, including PLC and PC-based variants, SIMATIC STEP 7 is an all-inclusive engineering tool. Regardless of user experience, it is appropriate for building SIMATIC S7-1200 and SIMATIC HMI Basic Panels because it provides transparency, intelligent navigation, and straightforward processes. Programming software for industrial automation, SIMATIC STEP 7, is commonly used to set up controller families, including SIMATIC S7-1200, S7-1500, S7-300/400, and WinAC. It comes in two flavors: WinAC TIA Portal 13 SP1 version Basic for network configuration, and Basic S7-1200 Configuration and STEP 7 Professional for S7-1200, S7-1500, and S7-300/400 configuration. In addition to saving configuration time, the software offers advantages, including simple technology item development and instant online diagnostics [18-20].

V.1.2 PLC Configuration

To configure a Siemens S7-1500 PLC in TIA Portal, follow these steps:

- Add the hardware to the project, configure communication settings, and add hardware modules.
- First, select the appropriate device type and model. Then, configure the communication settings by specifying IP address, subnet mask, gateway address, and network parameters.
- Finally, add the required digital and analog input/output, communication, and power supply modules, and configure the parameters for each module, such as input/output addresses and module type.

The principal screen, also known as the home page, is the main interface of the SCADA system, offering a comprehensive overview of the system, key information, alerts, and notifications. It allows users to configure and alter the settings of their connected devices or components, print reports, logs, and other essential SCADA system information, and view trends over time. The report section allows users to build detailed reports based on collected data, providing insights, statistics, and summaries of the system's performance.

The log-on area provides a safe identification mechanism for accessing the system, typically requiring a user name and password or additional credentials. The exit area allows users to safely exit the system, ensuring proper management of unsaved data or configurations. The shutdown department is responsible for shutting down the system, often used for maintenance or switching off the entire system.OB1 is the main organization block in a programmable logic controller (PLC) program, executed cyclically and containing the main program logic.

It coordinates other program blocks and ensures system operation. OB1 may also include calls to other organization blocks and other program parts.OB30 is a cyclic interrupt organization block in a programmable logic controller, executed at a specific time interval, executing cyclic tasks like reading inputs, performing calculations, and updating outputs. The PID Compact function block with a cyclic interrupt OB30 allows precise system control by setting parameters like proportional gain, integral time, derivative time, and filter time, optimizing PID controller performance [21].

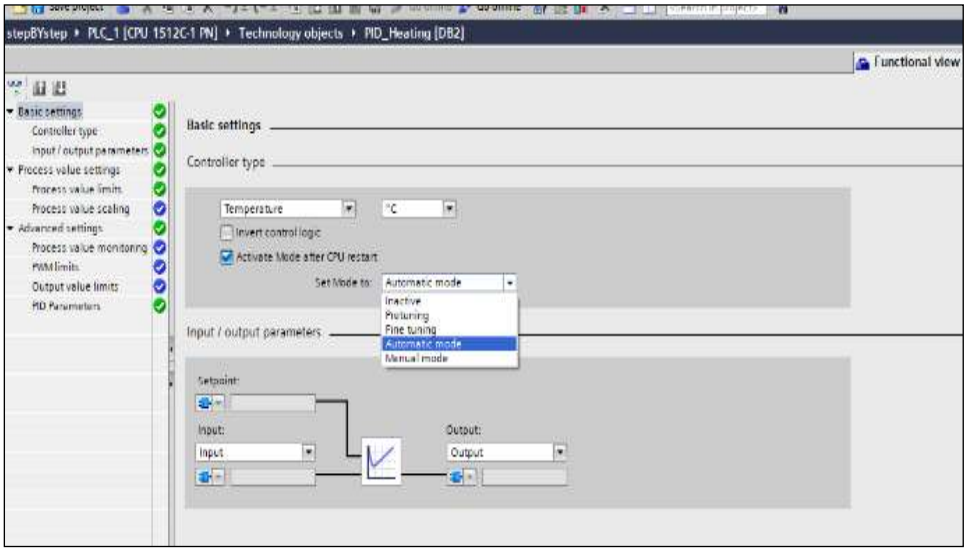

Figure 1: PID settings screen.
Source: Authors, (2026).

Siemens PLCs use two types of programming blocks: FC and DB. FC defines specific functions, reusable for multiple parts of the program. DB is used for complex operations requiring multiple inputs and outputs, like mathematical calculations or data manipulation.DB, or Data Block, defines a collection of data elements used in a program. They store input and output data, intermediate results, and can be structured to meet program requirements. TIA Portal's programming environment allows for the creation and editing of function blocks and data blocks, enabling easier development, testing, and maintenance of modular code.

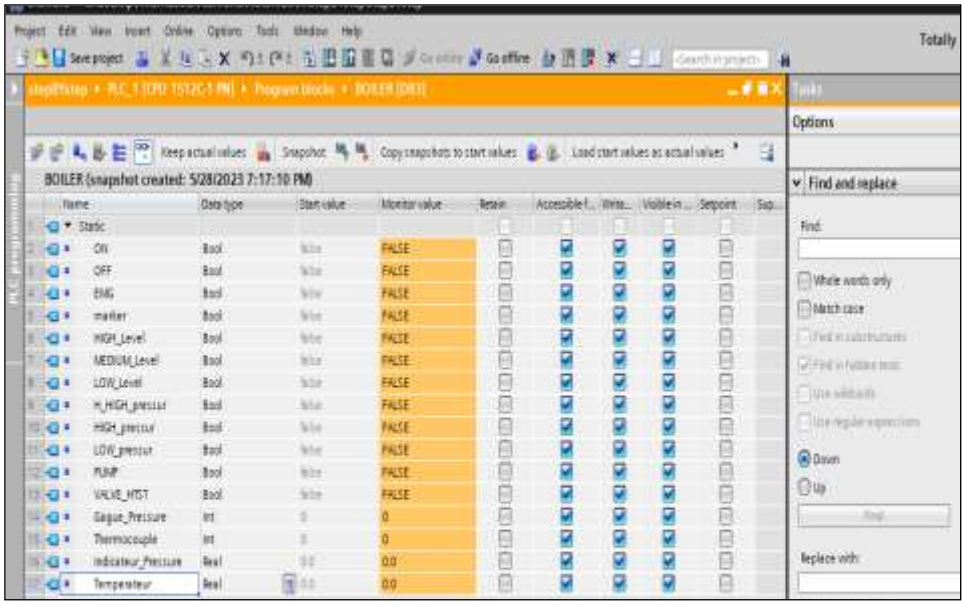

Figure 2: Data block for a fire-tube boiler.
Source: Authors, (2026).

The HMI TP1200 Comfort is a 12-inch touchscreen interface designed for industrial automation applications. It features high-resolution graphics, communication options, and can display and control PLC system data. Programmable using TIA Portal, it supports Ethernet, PROFIBUS, and PROFINET protocols and is rugged with an IP65 rating for protection against dust and water [22-24].

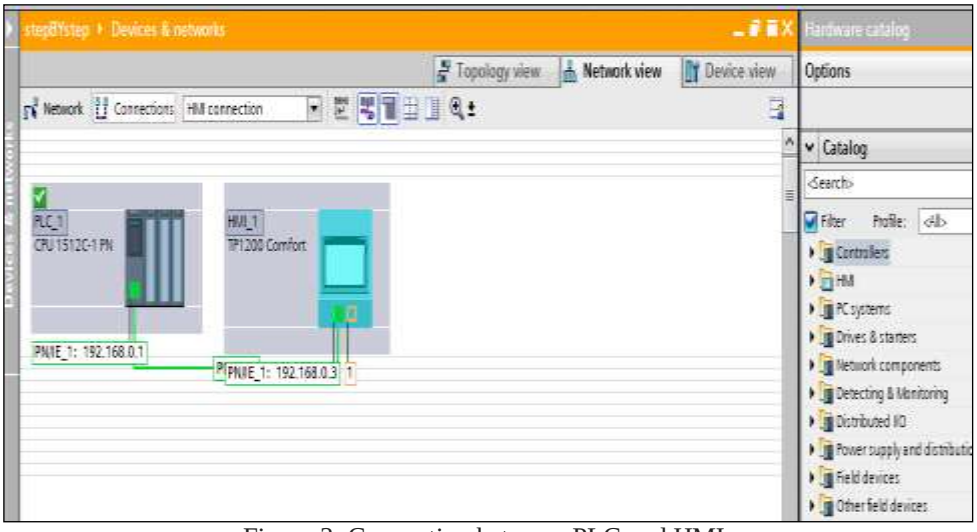

Figure 3: Connection between PLC and HMI.
Source: Authors, (2026).

TIA Portal HMI Tag Management tool allows engineers to create and configure HMI tags, enabling real-time monitoring and control of automation systems through data type, address, and properties [17], [25].

V.1.3 HMI Screens Created

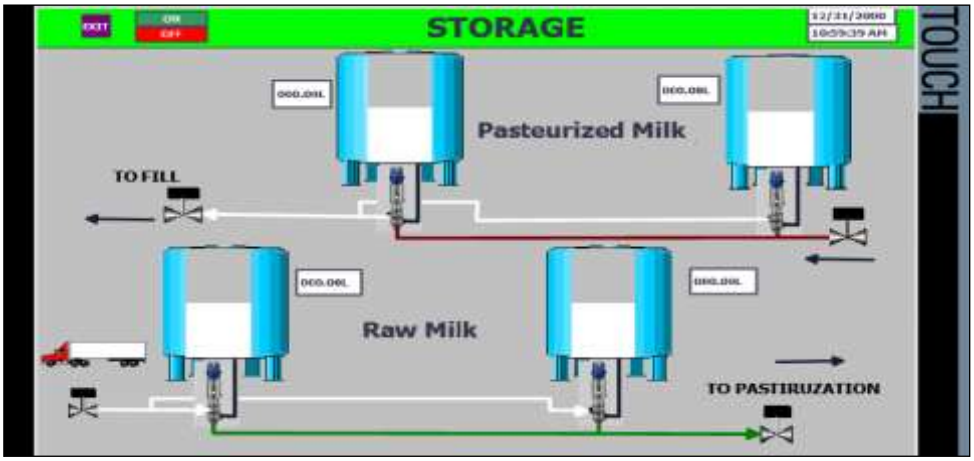

Figure 4: HMI Storage screen.
Source: Authors, (2026).

PLCsim is a TIA Portal simulation tool that enables engineers to test and debug PLC programs in a virtual environment, reducing errors and downtime. It simulates the behavior of various Siemens PLCs, improving system efficiency and reliability.

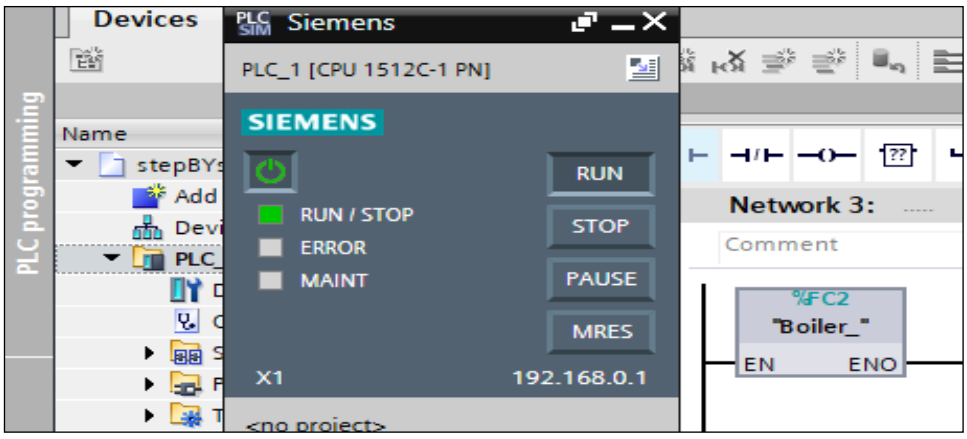

Figure 5: PLCsim window screen.
Source: Authors, (2026).

A PC Station in TIA Portal is a software interface connecting a PC to a Siemens PLC, enabling data exchange and communication. It aids in industrial applications like data logging, process monitoring, and control system visualization, enabling the creation of powerful HMI applications.

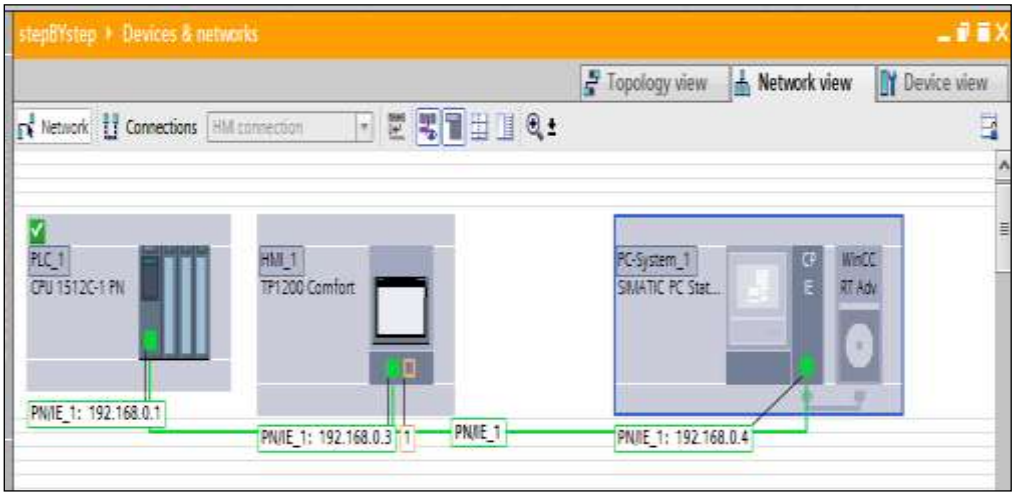

Figure 6: Connection between PLC and PC station.
Source: Authors, (2026).

Trends are graphical representations of data from a Programmable Logic Controller, used to visualize changes in process variables and system performance, enabling operators and engineers to identify potential issues before they escalate.

Figure 7: Trend of levels of tanks.
Source: Authors, (2026).

Historical data analysis from a Programmable Logic Controller (PLC) provides valuable insights into system performance, process variables, and production trends. It helps operators optimize production and identify potential issues. By identifying low production periods and trends in process variables, operators can optimize production and improve quality and efficiency.

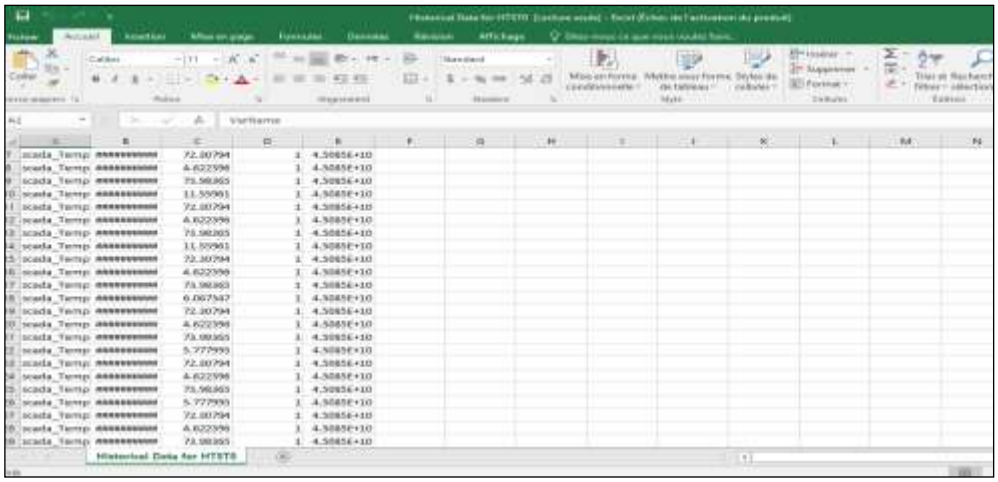

Figure 8: Historical window screen.
Source: Authors, (2026).

Alarms are notifications in a PLC system, triggering events like sensor failure or machine fault. They alert operators and engineers to potential issues. TIA Portal allows customization of alarm settings, such as priority, severity, and acknowledgement requirements.

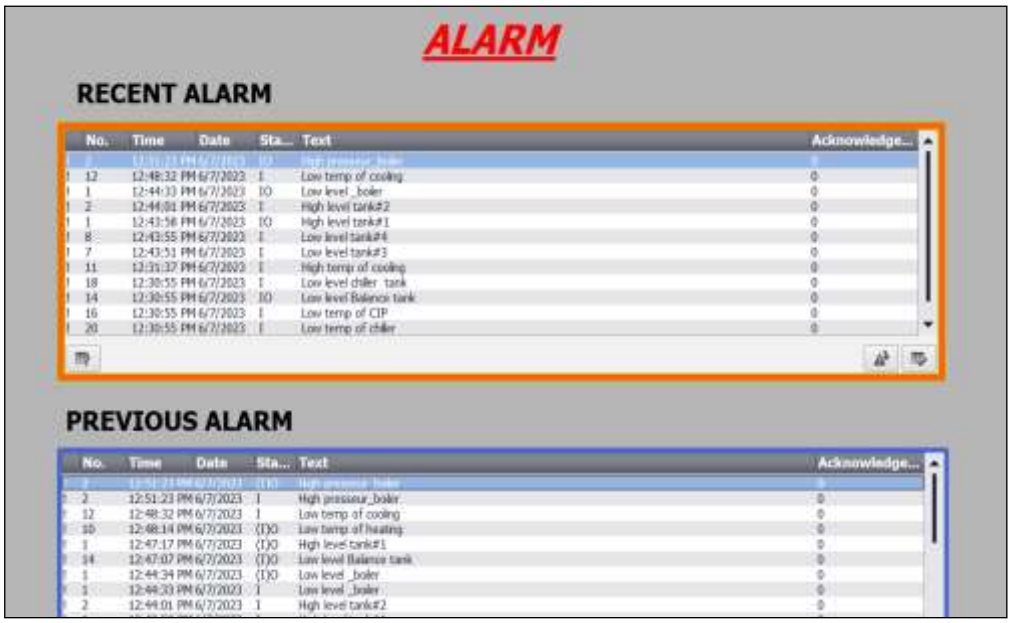

Figure 9: Alarms screen.
Source: Authors, (2026).

Recipes are parameters and values used to configure a Programmable Logic Controller (PLC) system in industrial automation. They improve efficiency, reduce errors, and ensure consistency across production runs. They store and recall parameters automatically, reducing setup time and reducing defects or product variations.PLC systems are monitored and troubleshooted for errors, ensuring reliability and uptime in industrial automation systems. Diagnostic features include online diagnostics, trace functionality, error handling, and simulation tools.

Figure 10: Diagnostics screen.
Source: Authors, (2026).

Security in PLC systems ensures data integrity and reliability in industrial automation applications. Features include user management, password protection, encryption, and firewall protection.

VI. RESULTS AND DISCUSSION

This work focuses on automation and supervision of an industrial process using Siemens PLC and SCADA, specifically the Siemens S7-1500 programmable logic controller and Tia Portal programming program. The work aims to provide a practical understanding of automation steps and master the Tia Portal programming software for PLCs in the Siemens S7-1500 range. We initially paid attention to the factory's presentation before discussing the overall operations and ongoing projects there. The goal is to serve as a guide for automation projects using the S7-1500 APIs and the TIA PORTAL programming language.

VII. CONCLUSION

In this study, PLC and SCADA technologies were used to build and install a real-time monitoring and control system for an industrial milk processing facility. The TIA Portal engineering platform was used to design the system, which is based on the Siemens S7-1500 PLC. It incorporates the Cleaning-In-Place (CIP) procedure, pasteurization, bottling, water heating and cooling, and milk storage. The system facilitates centralized supervision using HMI and SCADA interfaces, enabling operators to keep an eye on process variables, operate machinery, and react swiftly to events and alarms. The results show that the proposed solution improves operational efficiency, reliability, and production consistency while reducing manual intervention and human errors. Effective process monitoring and decision-making are supported by features including trend analysis, historical data logging, and real-time visualization. The results show that the proposed solution improves operational efficiency, reliability, and production consistency while reducing manual intervention and human errors.

ABSTRACT

Battery Thermal Management (BTM) has emerged as a critical aspect of electric vehicle (EV) technology, ensuring safety, performance, and durability of high-energy lithium-ion batteries. As EV adoption accelerates globally, maintaining optimal temperature ranges is essential to prevent thermal runaway, enhance charge–discharge efficiency, and extend battery life. Modern BTM systems integrate active and passive cooling techniques, including liquid cooling, heat pipes, phase change materials, and advanced insulation, to manage heat generation from electrochemical reactions. Innovations such as nano-enhanced composites, artificial intelligence (AI)-driven predictive models, and Internet of Things (IoT)-enabled monitoring are reshaping the field by enabling real-time thermal control and predictive maintenance. Furthermore, advances in solid-state batteries and energy-dense chemistries like nickel cobalt aluminum oxide (NCA) require robust thermal strategies to maintain safety under extreme conditions and during fast charging. Emerging trends show a transition toward lightweight, modular, and highly efficient thermal systems that minimize energy losses while supporting sustainable EV development. The integration of advanced materials, smart sensors, and machine learning will drive the next generation of BTM, supporting reliable energy storage and long-term environmental goals. This review synthesizes current technologies, challenges, and future opportunities, offering insights into designing efficient thermal systems for EV batteries.

I. INTRODUCTION

The rise of Battery Thermal Management (BTM) is quite important for Electric Vehicle (EV) use, partly because we're seeing tougher environmental rules and a big push to cut down on transportation pollution. It's been noted that vehicles often last longer than expected, but their emissions don't always meet European standards, pushing automakers to find greener answers [1]. To make batteries work better, last longer, and be safer, we need smart thermal management. This also helps with fuel use and costs in hybrid and electric cars [2]. For example, the modular battery systems show how thermal management is now built into the design, which is vital for keeping everything running just right and boosting how well the vehicle works overall. So, keeping battery temperature in check isn't just good for the environment; it's also key to making electric vehicles better and more appealing these days.

II. THEORETICAL REFERENCE

A. Definition of Battery Thermal Management

Battery thermal management, or BTM, refers to the various approaches and technologies we use to keep batteries at the right temperature in electric vehicles (EVs). This is important for a few reasons, mainly because it helps batteries last longer, perform better, and stay safe. When batteries aren't too hot or too cold, they work their best when charging and discharging. Generally speaking, BTM systems come in two main flavors: active and passive. Active systems typically give you more control over the temperature, usually with some kind of mechanical or electrical component. However, the system you pick can really change how the battery performs. That's why engineers have to get it just right to make sure everything is safe and efficient for the entire life of the vehicle. We can also see that as EVs become more popular, we're finding new and better ways to manage battery temperature. This highlights how crucial it is for making transportation more sustainable (Image12), especially as we try to use energy more efficiently and protect the environment [1], [2].

B. Importance of Thermal Management in Evs

In electric vehicles (EVs), keeping the battery at the right temperature is really important for making sure it works well, lasts a long time, and stays safe. Because EVs use lithium-ion batteries, preventing overheating is key. If these batteries get too hot, they can catch fire or just stop working altogether. Temperature also has a big impact on how well the battery turns energy into power. When it's too hot, the chemical reactions inside the battery don't work as well. So, research today is focused on better cooling systems that use both simple and more complex methods to keep the temperature steady, no matter how the car is being driven [3]. Also, if we think about the whole life cycle, good temperature control not only makes the battery more efficient but also helps cut down on greenhouse gas emissions, especially as we use more renewable energy sources [4]. All these things together show just how important managing battery temperature is for making transportation more sustainable in the future. For a better understanding, take a look at , which gives you a good picture of how a full cooling system works in an EV.

C. Overview of Battery Technologies Used in Evs

Electric vehicle (EV) battery tech is quite varied, though lithium-ion batteries are usually the go-to, mostly because they pack a lot of energy and work efficiently. These batteries let EVs get pretty good driving ranges without adding too much weight, something that's really key when designing cars. Newer tech, like solid-state and lithium-sulfur batteries, looks promising too, maybe even better. They might be safer and last longer, which is a big deal for getting people to like EVs and for helping the environment. As more and more people buy electric cars, keeping the batteries cool becomes super important for making sure they work well and last as long as they should. So, improving how we manage battery temperature is crucial, making sure the batteries don't get too hot, which could cause problems like thermal runaway. Thermal runaway can really mess up a battery's safety and how reliable it is [1], [5]. Efficient cooling systems, for example, as highlighted in, show just how tricky it is to keep battery packs at the right temperature. Shown in table 1.8

Table 1: Overview of Battery Technologies Used in Electric Vehicles.

Battery Type	Energy Density (Wh/kg)	Cycle Life (cycles)	Advantages	Disadvantages	Common Applications
Lithium Iron Phosphate (LFP)	90–160	2,500–9,000	Low cost, high safety, long cycle life, cobalt-free	Lower energy density compared to other lithium-ion batteries	Electric vehicles, utility-scale stationary applications, backup power
Nickel Manganese Cobalt (NMC)	150–220	1,000–2,000	High energy density, good thermal stability	Higher cost, reliance on cobalt	Electric vehicles, power tools, laptops
Nickel Cobalt Aluminum (NCA)	200–250	1,000–2,000	Very high energy density, long cycle life	High cost, reliance on cobalt and nickel	Electric vehicles (e.g., Tesla models)
Lithium Manganese Oxide (LMO)	100–150	1,000–2,000	Good thermal stability, low cost	Lower energy density, shorter cycle life	Electric vehicles, power tools, medical devices
Lithium Nickel Manganese Oxide (LNMO)	150–200	1,000–2,000	High energy density, cobalt-free	Higher cost, limited commercial availability	Electric vehicles (emerging technology)
Sodium-Ion (Na-ion)	90–160	2,000–3,000	Abundant raw materials, lower cost, cobalt-free	Lower energy density compared to lithium-ion batteries	Electric vehicles (emerging technology)
Solid-State Batteries	250–500	1,000–2,000	Very high energy density, improved safety	High cost, limited commercial availability	Electric vehicles (future technology)

D. Challenges in Battery Thermal Management

Maintaining EV battery systems at the right temperature is important for making sure they work well and last long. But there are some tough problems that make this hard to do. For example, "thermal runaway" is a big worry. Basically, if things get too hot, batteries can fail in a big way, maybe even catch fire or wear out faster. You can see how bad this is in, which shows a burning battery cell. Plus, the different stuff that batteries are made of doesn't spread heat evenly, so we need special cooling systems. But those systems can make cars heavier and more complicated. Since more and more people are switching to electric cars, we need to figure out better ways to keep batteries cool without wasting energy or making things unsafe. Also, even though hydrogen might be a good way to store energy in the future, we still have some hurdles to jump over with technology and getting the needed infrastructure built [6].

So, solving all these tricky thermal management issues is super important if we want electric vehicles to really take off, and we've got to make sure they're both powerful and safe for everyone.

E. Purpose and Scope of the Essay

This essay delves into the crucial area of battery thermal management for electric vehicles (EVs). The goal is to explore the intricacies involved in keeping lithium-ion batteries at the right temperature. As we see more and more EVs on the road, grasping these thermal dynamics is key to safety, efficiency, and better vehicle performance. We'll look at current thermal management methods—both active and passive systems, along with new developments in battery tech and chemistry. The analysis aims to show why good thermal management is so important for avoiding problems like thermal runaway and keeping passengers safe, particularly with high-energy battery chemistries such as NCA, which can be vulnerable to thermal events, as research has shown [7]. In addition, the essay will touch on what happens to batteries after they're no longer used in vehicles, stressing the need for sustainable practices throughout the EV battery lifecycle [8]. [extractedKnowledge1] illustrates the growing market for battery thermal management systems, which underscores why these discussions are so timely in the ever-changing world of automotive technology.

II.1 OBJECTIVES

A. Fundamentals of Battery Thermal Management

For electric vehicles (EVs), managing battery temperature well is really important because too much heat can make batteries not last as long or work as efficiently. Basically, thermal management is about keeping the temperature just right inside the battery so it charges and uncharges well. With everyone wanting bigger batteries that make a lot of heat, this becomes even more important. Better thermal management systems use both active and passive cooling to keep things at the right temperature and stop problems like thermal runaway. Using new ideas, like the adaptive battery model we see in [9], helps companies make batteries that work better and are safer. Plus, when we look at diagrams like the one showing how thermal management systems work, we see how all the different parts connect to keep the temperature just right, showing how temperature control and how long the battery lasts are closely linked.

B. Principles of Heat Generation in Batteries

Heat generation within batteries is a noteworthy issue, driven by electrochemical and physical happenings. These processes are vital when designing thermal systems for EVs. Batteries produce heat during charging and discharging mostly because of internal resistance and ohmic losses within the electrolyte and electrodes. Side reactions can also contribute. This can increase temperature, and if not controlled, it can result in thermal runaway—a dangerous situation. Utilizing materials that improve thermal conductivity, like macro-nanoporous metals combined with phase change materials, can dissipate heat. This approach helps to lessen the risks associated with heat building up and any potential leakage. Also, this in turn boosts how well the battery functions and how long it lasts [10]. Furthermore, well-integrated battery thermal management ensures temperature is kept safe, so the battery works efficiently [1]. These systems are important, and as seen in, it highlights the interconnected pieces for thermal management in EV batteries.

C. Effects of Temperature on Battery Performance

Lithium-ion batteries, a key component in electric vehicles (EVs), rely heavily on temperature for both performance and how long they last. When temperatures move away from what's ideal, the battery's efficiency and safety can really suffer. For example, high temperatures can speed up how fast heat is produced inside the battery. This could lead to "thermal runaway"—a dangerous situation where more heat causes even more heat, possibly leading to battery failure or other hazardous issues. On the other hand, lower temperatures can slow down the movement of ions in the electrolyte, decreasing the battery's ability to efficiently deliver power. Because of this, managing battery temperature well is super important to keep it within a safe and effective range. This means designing systems that improve how heat dissipates and using materials able to handle temperature changes. The problem with poor thermal management isn't just about performance; it also affects safety and the long-term sustainability of EV tech, which is more and more important for cutting down pollution in cities and supporting environmentally friendly transport [1], [11].

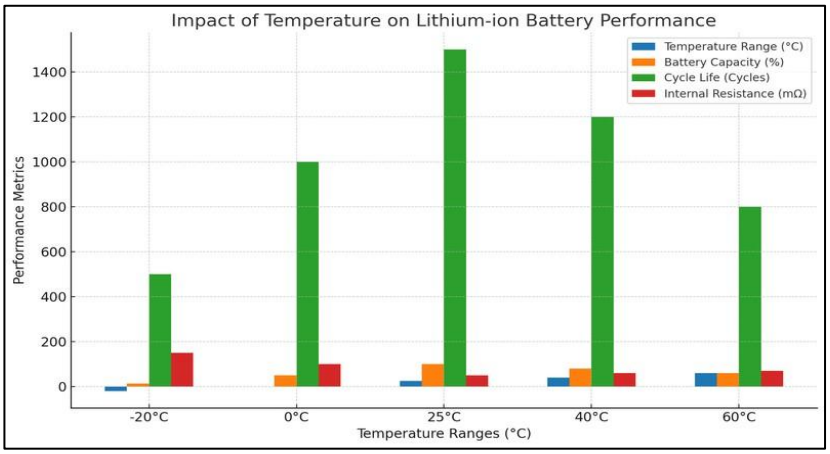

Figure 1: Impact of temperature on lithium-ion battery performance.
Source: Authors (2026).

Fig 1 displays four key metrics: battery capacity, cycle life, and internal resistance at various temperature ranges from -20°C to 60°C. The chart highlights how these metrics are affected by temperature, emphasizing the importance of thermal management in battery efficiency and safety.

D. Thermal Runaway and Safety Concerns

In electric vehicles (EVs), thermal runaway presents considerable safety issues, especially concerning battery thermal management. Should a lithium-ion battery's temperature rise beyond acceptable levels, an exothermic reaction might begin. This can cause quick heat production and even combustion, creating potentially disastrous risks for both users and the immediate area. Thus, effective thermal management strategies become essential. They help make sure batteries stay within safe temperature ranges, preventing potential failures. Innovative ideas have emerged, such as sophisticated cooling systems leveraging phase change materials and hierarchical macro-nanoporous metals. Studies suggest that these can boost thermal conductivity while still keeping safety a priority [10]. Deploying such technologies plays a key role in cutting the chances of thermal runaway events, which then boosts how reliable and safe EV battery systems are overall shown in table 2. Furthermore, a well-thought-out visual representation, such as , highlights the elements involved in handling these thermal threats successfully.

E. Key Components of Thermal Management Systems

A good thermal management system, or TMS, is super important for making sure batteries in electric vehicles, or EVs, work their best and stay safe for a long time. These systems use things like coolers, heaters, and special insulation to keep the temperature just right. It's really important to have good cooling, like with evaporators and heat exchangers, to stop the battery from getting too hot when it's running. Overheating can be really dangerous with lithium-ion batteries, and studies show this is something to watch out for [7]. Things like phase change materials and insulating layers help keep energy from being wasted. Not only does a good TMS help the car run better, but it also helps cut down on pollution from cars [1]. All these parts working together show just how crucial thermal management is for EVs.

Table 2: Key Components of Thermal Management Systems in Electric Vehicles.

Component	Description
Battery Thermal Management	Ensures optimal temperature control for battery performance and longevity. Techniques include liquid cooling, air cooling, and phase change materials.
Motor Thermal Management	Maintains electric motor temperatures to prevent overheating and maintain efficiency. Methods involve liquid cooling, air cooling, and advanced materials.
Power Electronics Cooling	Dissipates heat from inverters and converters to ensure reliable operation. Utilizes liquid cooling systems and advanced thermal interface materials.
Integrated Thermal Systems	Combines cooling circuits for various vehicle components to reduce weight and improve efficiency. Aims to streamline thermal management by using a single coolant loop.
Advanced Materials	Employs materials with high thermal conductivity to enhance heat dissipation. Includes wide bandgap semiconductors and advanced composites.

Source: Authors (2026).

F. Metrics for Evaluating Thermal Management Efficiency

In electric vehicle (EV) battery systems, thermal management is really key. It helps make sure everything works well, lasts a long time, and stays safe. When we check how good the thermal management is, we look at things like how even the temperature is, how fast heat goes away, and thermal resistance. These show us how well the system keeps the temperatures just right for everything to work as it should. These metrics help us understand how the temperature acts in all the battery cells, which guides engineers to design better, more reliable battery systems. For example, one study [12] highlights how important it is to consider cell variability. It looks at how this variability affects energy distribution and suggests using model-based techniques to make the thermal management systems even better showed in table 3. Also, methods like predictive maintenance and always keeping an eye on things help estimate how much longer the battery will last and lower the risks of it wearing out because of heat stress [13]. These evaluative metrics really help us get a better handle on how heat moves around, and they give us ideas for new and innovative thermal management plans. All these things working together are super important for making battery tech better.

Table 3: Metrics for Evaluating Thermal Management Efficiency in Electric Vehicles.

Value	**Description**
Energy Efficiency	Distance a vehicle can travel per unit of energy consumed (e.g., miles per gallon or kilometers per liter).
Energy Intensity	Amount of energy consumed per unit of distance (e.g., gallons per 100 miles or liters per 100 kilometers).
Thermal Performance Benchmarking	Evaluation of thermal performance of automotive power electronics and electric motor thermal management systems to establish baseline metrics and identify improvement methods.
Integrated Thermal Systems and Controls	Optimization of thermal performance in vehicles through innovative strategies for heating, ventilation, and air conditioning (HVAC); idle reduction; and leveraging waste heat.
Multifunctional Efficiency	Parameter determining conditions for effective mass saving in structural composites for thermal energy storage in electric vehicles.

Source: Authors (2026).

III. THERMAL MANAGEMENT TECHNIQUES

To make sure electric vehicles' batteries are both long-lasting and safe, we need to use good ways to cool them down [7]. These cooling methods, both the kind that uses energy and the kind that doesn't, are made to keep the temperature steady and stop the batteries from getting too hot. Active cooling systems, like those that use liquids or materials that change phases, help get rid of heat when the batteries are working. This is important because it can prevent thermal runaway, which is a serious issue that can cause batteries to fail completely. On the other hand, passive methods, which often depend on how well materials conduct heat and their shape, can help get rid of heat without needing extra energy. They focus on using smart designs. It's really important to understand these different ways of keeping batteries cool, mainly because people worry a lot about how safe batteries are and how well they hold their charge, especially in batteries like lithium nickel cobalt aluminum oxide (NCA) that store a lot of energy. How these cooling methods and the chemicals inside the battery work together show in table 4, why we need to keep researching and improving this area, so EVs stay eco-friendly and work well in the future. If you want a clearer picture, you can find a diagram of a thermal management system.

Table 4: Battery Thermal Management Techniques and Performance Metrics.

Technique	Description
Active Controllable Thermal Switch	Utilizes a cavity structure to switch between thermal states, achieving a potential switch ratio of approximately 300 and an experimental switch ratio of 15.4. In the 'ON State' at 20°C ambient temperature, battery temperature is maintained below 35°C, and in the 'ON + State', it remains below 42°C under extreme conditions.
Distributed Optical Fiber Sensor (DOFS)	Provides real-time, full-field temperature monitoring with a spatial resolution of 1.28 mm. Achieves a maximum standard deviation of temperature distribution below 0.3°C, offering comprehensive and accurate monitoring compared to traditional methods.
Liquid-Cooled Battery Thermal Management System	Employs a liquid cooling system with asymmetric U-shaped channels optimized using machine learning techniques. Achieves high predictive accuracy, with the Cheetah Optimizer-MLPNN model achieving a correlation coefficient (R) greater than 0.9999 for predicting maximum temperature (T_max).
Nano-Enhanced Graphite/Phase Change Material/Graphene Composite	Integrates expanded graphite with phase change materials and graphene to eliminate leakage and increase effective thermal conductivity. Demonstrates a 26% decrease in temperature compared to conventional thermal management materials, offering thermal control performance comparable to active cooling systems.
Thermoelectric Cooling Technologies	Utilizes thermoelectric coolers (TECs) for efficient cooling of lithium-ion batteries. Reviews various TEC hybrid battery thermal management systems, including air-cooled, phase change material-cooled, liquid-cooled, and heat pipe-cooled systems, providing insights into enhancing thermal efficiency.
Heat Pipe-Based Thermal Management System	Employs heat pipes in various structural designs and operating parameters as a cooling medium. Combines experimental studies and numerical analyses to optimize battery thermal management, enhancing energy density and thermal performance across a range of temperatures.
Battery Lifetime Analysis and Simulation Tool (BLAST)	A suite developed by NREL that assesses battery lifespan and performance for electric vehicles and stationary applications. Incorporates predictive modeling of battery degradation, considering variables such as ambient temperature, cell self-heating, and thermal management.
Energy Storage Thermal Performance Evaluation	NREL's Energy Storage Performance Laboratory evaluates thermal performance of batteries at material, cell, module, pack, and system levels. Provides comprehensive thermal evaluations to optimize battery performance and extend useful life in electric vehicles.
Design of Experiments (DoE) and Analysis of Variance (ANOVA) in Battery Thermal Management	Statistical analysis of design factors such as cooling plate geometry and coolant velocity on battery thermal behavior across various C-rates. Highlights the importance of considering thermal behavior under different C-rate conditions during the design process to ensure thermal safety.

Source: Authors (2026).

A. Passive Cooling Methods

For electric vehicles (EVs), passive cooling techniques represent an energy-smart choice compared to active methods, particularly when designing battery thermal management systems. Heat dissipation is achieved through these methods by using natural processes like convection and conduction, negating the need for mechanical parts. Heat sinks, along with phase change materials (PCMs), prove useful for absorbing and then spreading thermal energy inside the battery pack. The goal is to keep the batteries at the right temperature when they are charging or discharging. Research suggests that employing these types of passive approaches can improve how long batteries last and how well they perform. Importantly, they can also stabilize battery temperatures in a range of different operating scenarios, helping the vehicle run better overall [14]. It is worth noting that ambient temperature and certain aspects of battery design can impact just how well passive cooling works. Because of this, it’s important to use good thermal models to get the best performance out of a system [15]. A schematic, shown in, provides a visual representation illustrating how these cooling strategies are integrated within a typical battery management system.

B. Active Cooling Systems

Active cooling systems are, generally speaking, quite important in battery thermal management for electric vehicles (EVs). They ensure both optimal performance and, perhaps even more critically, safety during operation. These systems actively regulate battery pack temperature, which helps to mitigate overheating risks. Employing technologies like liquid coolants or refrigerants, active cooling facilitates efficient heat dissipation. This is crucial for maintaining battery efficiency and extending its lifespan. Recent studies highlight thermal runaway incidents as significant safety concerns, especially in high-energy chemistries like lithium nickel cobalt aluminum oxide (NCA). In these cases, lithium-ion batteries can reach hazardous temperatures during failure events [7].

Moreover, as vehicle electrification accelerates, the demand for innovative cooling strategies is expected to grow. Forecasts indicate increasing market value in this area [8]. Therefore, implementing effective active cooling systems remains essential for successfully integrating EV technologies. The schematic represented visually underscores the significance of these components, outlining their interactions within thermal management systems.

C. Phase Change Materials (PCMs)

PCMs are really important for keeping batteries in electric vehicles (EVs) at the right temperature. They do this by soaking up and letting go of heat when they change phases, which keeps the battery temps from going too high or low. Battery performance can really suffer if the temperature isn't stable, which can make the battery not work as well or last as long. One cool thing that's been happening lately is putting PCMs into special metals that have tiny little pores [10]. This helps the heat move around better and stops the PCMs from leaking, which is a problem that can happen. These materials can also help stop batteries from overheating and causing problems, which is a big deal for safety and making sure the battery works well [16]. Basically, using PCMs in batteries can lead to better temperature control, which means EVs can perform better and be safer; thermal management systems provide visual representations of this.

D. Heat Pipes and Thermal Spreaders

In electric vehicle (EV) batteries, heat pipes and thermal spreaders are key for effective thermal management. They help move extra heat away from the battery cells, which is important for keeping the batteries from overheating and lasting longer. These components use what's known as phase change to do this. Temperature really matters for how well batteries work and how long they last, so using heat pipes helps keep the temperature even across the whole battery system. This addresses the problems caused by changing weather [17]. Research also shows that making these thermal devices work even better can boost energy efficiency and how far an EV can travel on a charge. Both are important for keeping customers happy and staying competitive in the EV market [18]. Heat pipes help keep things at the right temperature and support improvements in battery tech, which you can see in the diagram of a thermal management system in.

E. Insulation Strategies

When it comes to keeping electric vehicle (EV) batteries in tip-top shape—temperature-wise, that is—smart insulation is super important. Good insulation helps batteries stay at the right temperature, which also makes them safer. Stuff like polyimide and aerogels, which don't let heat pass through very well, can cut down on heat loss and make the battery work better overall. These materials do more than just prevent overheating; they also help keep the temperature even across the whole battery pack. That even temperature is key if you want the battery to last longer and perform well [19]. Then you've got fancy tricks like phase change materials and thermal barriers, which are great at dealing with temperature changes caused by the weather outside. These tricks make sure the battery stays in its happy temperature zone [20]. So, when EV makers use these insulation methods, they boost how stable the battery is, which means EVs work better and are safer to drive. You can see how this thermal management works in electric vehicles in something like.

III.1 IMPACT OF THERMAL MANAGEMENT ON BATTERY LIFE AND PERFORMANCE

The performance and longevity of electric vehicle (EV) batteries hinge significantly on effective thermal management. Temperature swings, you see, can really mess with battery efficiency. When thermal management falls short, battery cells degrade quicker, cutting short the battery's life and, naturally, the vehicle's overall performance. But keep those batteries in the sweet spot—the ideal temperature range—and you'll find overheating issues become less of a problem, and charge retention gets a boost. Plus, as EVs get fancier with tech like hybrid setups, energy management strategies can step in to optimize how batteries are used. Consider plug-in Hybrid Electric Vehicles (HEVs), for example. There, the aim is often to cut down on both battery wear and tear and fuel costs—a clear sign that solid thermal management is key for maxing out energy efficiency and getting more life out of those batteries [1], [2].So, you can't really overstate how crucial thermal management is, touching as it does on both doing right by the environment and saving money.

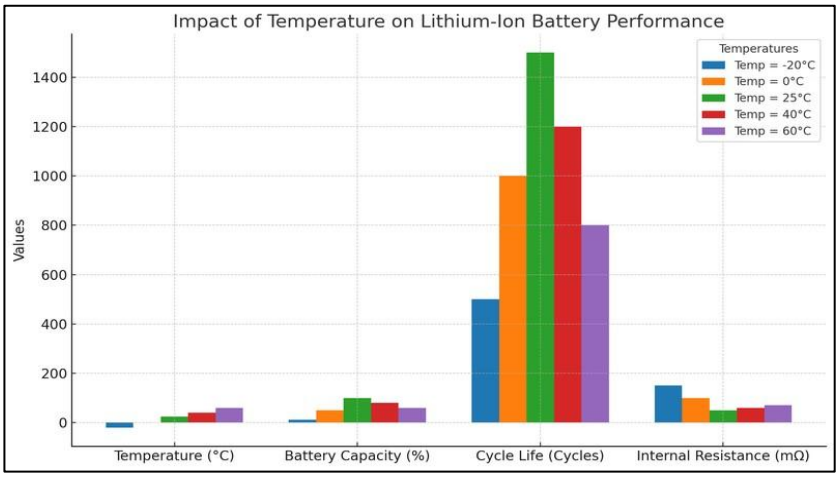

Figure 2: impact of temperature on lithium-ion battery performance by comparing battery capacity, cycle life, and internal resistance at different operating temperatures.
Source: Authors (2026).

Fig 2 displays the impact of temperature on lithium-ion battery performance by comparing battery capacity, cycle life, and internal resistance at different operating temperatures. As temperature increases, battery capacity and cycle life generally improve, while internal resistance decreases. This highlights the importance of effective thermal management in optimizing battery efficiency and safety.

A. Relationship Between Temperature and Battery Degradation

Battery degradation is heavily influenced by temperature, especially in the lithium-ion batteries you see in most electric vehicles (EVs). When batteries get too hot, it speeds up chemical reactions inside, which leads to problems like higher internal resistance and permanent capacity loss, shortening the battery's life. On the other hand, when it's too cold, battery performance can suffer because electrochemical reactions slow down, meaning less power and range. So, it's really important to have good thermal management to keep batteries working in the right temperature range for efficiency and long life. Interestingly, as battery recycling and repurposing get more attention, we see how important temperature is; for instance, a model looking at battery lifecycles predicts we'll need a lot of recycling by 2030, showing we need sustainable ways to handle battery temperature and degradation [8], [21]. All this is extremely important for making EV batteries last longer and work more efficiently, which requires a comprehensive approach to thermal management.

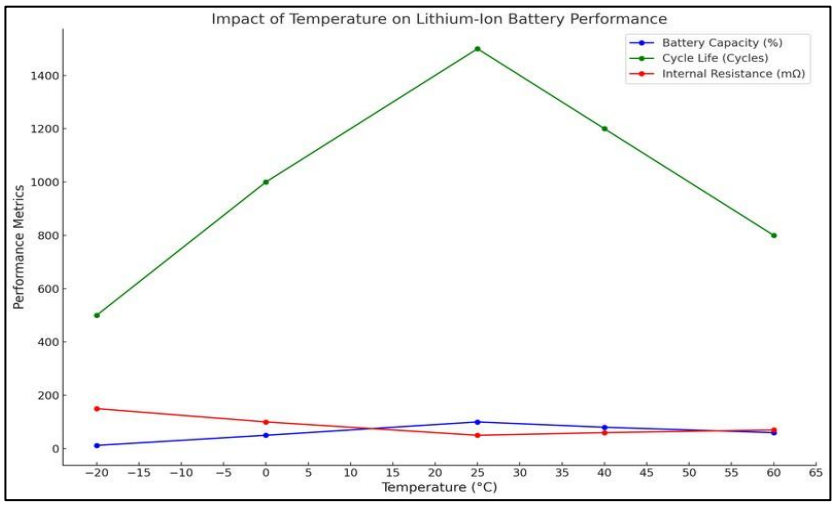

Figure 3: Lithium-ion battery performance.
Source: Authors (2026).

Fig.3 illustrates how temperature affects lithium-ion battery performance by showing trends in battery capacity, cycle life, and internal resistance. As temperatures rise, battery capacity generally increases, while the cycle life reaches a peak around 25 ℃ and then declines at higher temperatures. Internal resistance remains relatively stable but shows slight variations. This underscores the importance of optimal thermal management for battery efficiency and longevity.

B. Influence on Charge and Discharge Rates

Thermal management really plays a big role in how quickly lithium-ion batteries can charge and discharge, and it touches on how well they work and how safe they are. When you charge at higher temperatures, it can make things even hotter. Studies have shown that higher current rates lead to more heat and changes in voltage [22]. This can shorten the battery's life and increase the chance of a thermal runaway event, which is obviously a safety issue. So, we need good thermal management systems to keep batteries working within the best temperature range. Plus, as EVs get more complex, how much thermal management systems cost becomes important. Knowing how driving, current rates, and thermal performance all affect each other is key to making better EV batteries [23]. Essentially, handling charge and discharge by improving thermal strategies is going to be crucial for EVs going forward [24], [25]. The thermal management schematic shows just how complex and important these systems are for keeping batteries running smoothly [26].

C. Effects on Energy Density and Range

Electric vehicle (EV) energy density and how far they can go really depend on how well their temperature is managed, ensuring batteries work best no matter the conditions[27]. Good thermal management not only helps batteries last longer but also makes them better at efficiently using energy, boosting how far you can drive. As battery systems get bigger for better performance, it's super important to balance more energy capacity with keeping things thermally stable; bigger batteries mean more heat, which can cause overheating and risks, like thermal runaway in batteries[28], [29]. Plus, better battery chemistry and thermal management tech are key to making these problems less severe, enabling higher energy densities while staying safe. Ongoing improvements here could really help people adopt electric two-wheelers and bigger EVs in markets where the initial price is a big issue [4], [5].

D. Role in Fast Charging Capabilities

Thermal management systems are critically important for improving how quickly electric vehicles (EVs) can charge. Basically, keeping temperatures under control is key; if things get too hot while charging, batteries might not last as long and could even become dangerous. To address this, some manufacturers are using cool new tech, like hybrid thermo-electrochemical sensing arrays, inside battery cells.

These arrays let them keep an eye on how temperatures are changing in real time, which helps fine-tune the charging process [30].With this data, they can create detailed thermal maps along with electrochemical information, making it possible to make quick adjustments to stop overheating. What's more, using smart charging strategies can make energy use in EVs even more efficient. By coordinating charging times with grid demand and taking advantage of vehicle-to-grid (V2G) technologies, we can ease some of the problems that come with rapid charging. In most cases, this supports the growing use of EVs in cities [31]. This connection between managing temperature and using advanced charging methods is essential for making electric vehicles a sustainable transportation option.

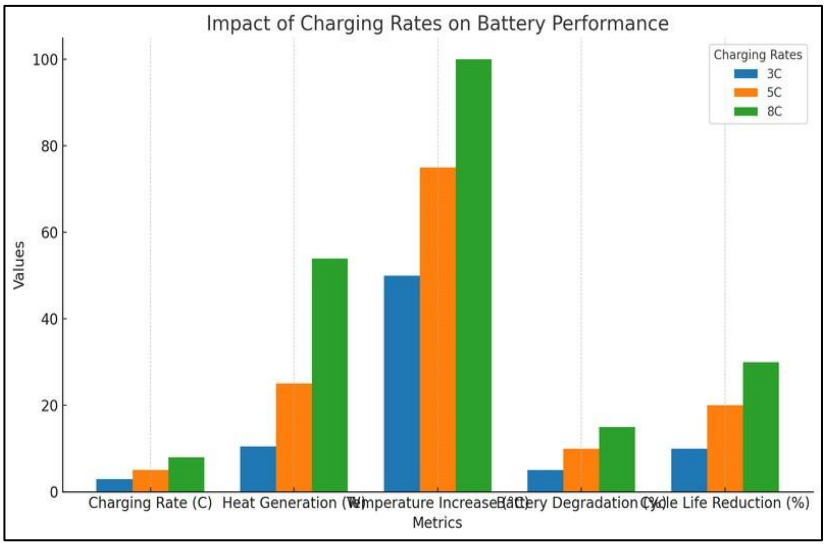

Figure 4: Impact of charging rates.
Source: Authors (2026).

Fig.4 illustrates the impact of different charging rates (3C, 5C, and 8C) on various metrics related to lithium-ion battery performance. As the charging rate increases, heat generation, temperature increase, battery degradation, and cycle life reduction also rise, highlighting the critical need for effective thermal management to sustain battery longevity during fast charging operations.

E. Long-term Reliability and Maintenance Considerations

To ensure the longevity of electric vehicle (EV) batteries, a deep dive into both thermal management and consistent upkeep is really a must. A battery's operational environment has a big impact, and effective thermal control is key to preventing things like overheating and premature wear. This, of course, directly affects how long the battery will last. Now, liquid cooling systems and similar high-tech cooling solutions have proven pretty effective in managing heat and boosting performance [1]. What's more, routine maintenance—think regular battery check-ups and thermal performance monitoring—is super important. It helps lower the risks from thermal runaway, which, as you might guess, can cause serious issues [32]. Predictive maintenance, powered by data analytics, can also be a big help in predicting thermal stress and component wear. Generally speaking, this will make sure the battery operates within its safe limits for the long haul. Addressing all these little things, generally speaking, is vital for getting the most reliability out of EV batteries.

Table 5: Battery Thermal Management Impact on EV Reliability and Maintenance.

Battery Chemistry	Impact on Reliability
Nickel Manganese Cobalt (NMC)	Higher energy density and driving range, but more sensitive to temperature extremes, requiring advanced thermal management to maintain reliability.
Nickel Cobalt Aluminum (NCA)	Similar to NMC, offering high energy density and range, necessitating effective thermal control to ensure long-term reliability.
Lithium Iron Phosphate (LFP)	Lower energy density and range compared to NMC and NCA, but more stable thermally, reducing the need for complex thermal management systems.
Active Cooling	Utilizes liquid coolants to regulate battery temperature, requiring regular maintenance to prevent leaks and ensure optimal performance.
Passive Cooling	Relies on ambient air to dissipate heat, reducing maintenance needs but may be less effective in extreme temperatures.
Battery Cycle Life	Batteries have a limited number of charge-discharge cycles; effective thermal management can extend cycle life by maintaining optimal operating temperatures.
Temperature Extremes	Exposure to high or low temperatures can degrade battery performance; thermal management systems are crucial to mitigate these effects.
Battery Monitoring	Regular monitoring of battery health, including temperature and voltage, is essential to detect issues early and maintain reliability.

Source: Authors (2026).

F. Emerging Technologies and Innovations

The growing importance of new technologies for managing battery temperatures is really key if we want more electric vehicles (EVs) on the road. Things like battery systems that can be put together in different ways, and better ways to cool batteries, are super important for making batteries work better and be safer. They help stop batteries from getting too hot and losing power.

Take, for example, a well-designed cooling system; it shows how a smart design can lower the chances of overheating and help batteries last longer, as seen in the thermal management system schematic . Also, as we move toward using resources more efficiently, making thermal management greener by using materials that are better for the environment is really important for being sustainable in the EV world. What's really interesting is that more and more people want fully electric cars, as shown in the changing market . This means car companies need to find new ways to use these improvements to stay ahead in a fast-changing market [6].

G. Advanced Materials for Thermal Management

Advanced materials are quite important for optimizing battery thermal management in electric vehicles (EVs), which improves performance and safety. Engineers can regulate temperature fluctuations in battery systems by using high-efficiency thermal interface materials (TIMs) and phase change materials (PCMs); this regulation is quite vital to prolong battery life and prevent thermal runaway events. For example, materials like graphene and nanocomposites have come about, showing better thermal conductivity and mechanical stability. Because these materials facilitate heat dissipation, maintaining operational safety and efficiency in high-performance batteries is easier [1]. The integration of advanced thermal management systems that use these materials also minimizes energy losses and makes sure battery packs operate reliably [7]. Generally speaking, using advanced materials in thermal management systems helps make EV technologies more sustainable and reliable, reaffirming their viability in future transportation solutions.

H. Integration of AI and IoT in Thermal Monitoring

In electric vehicles (EVs), keeping batteries at the right temperature is getting a big boost from Artificial Intelligence (AI) working together with the Internet of Things (IoT). These systems use machine learning to look at tons of data, which means they can keep an eye on battery temperatures in real-time and even guess when things might go wrong. This helps make thermal predictions more accurate, so we can step in before batteries get too hot, potentially making them last longer. Also, because there are lots of IoT sensors inside the battery systems, we can constantly gather data. This is really important for spotting trends and figuring out the best ways to cool things down. Big data analytics, as some studies point out, is really the key to making this all work for thermal management [33]. Visual examples, like the thermal management setups, for instance the schematic in , really show how all the different parts work together smoothly to keep everything running just right.

I. Development of Smart Thermal Management Systems

Smart thermal management's progress is really important for making electric vehicle (EV) batteries work better and safer. As keeping batteries at the right temperature gets more complex, these systems use up-to-the-minute data. They aim to fine-tune temperature control, tackling performance and the risk of overheating. This means adding sensors to keep tabs on temperature and using clever algorithms to guess how to manage things, which helps the batteries last longer and be more dependable. Also, using designs that can be put together in different ways and that work well, like the ones in , helps get rid of heat quickly by improving how air and coolant move. This doesn't just cut down on dangers like thermal runaway; it also lines up with studies that show how these systems can save money, for example, through PEV integration in micro-grids [1], [34]. All in all, creating these smart systems is a big step forward for making EVs sustainable and efficient.

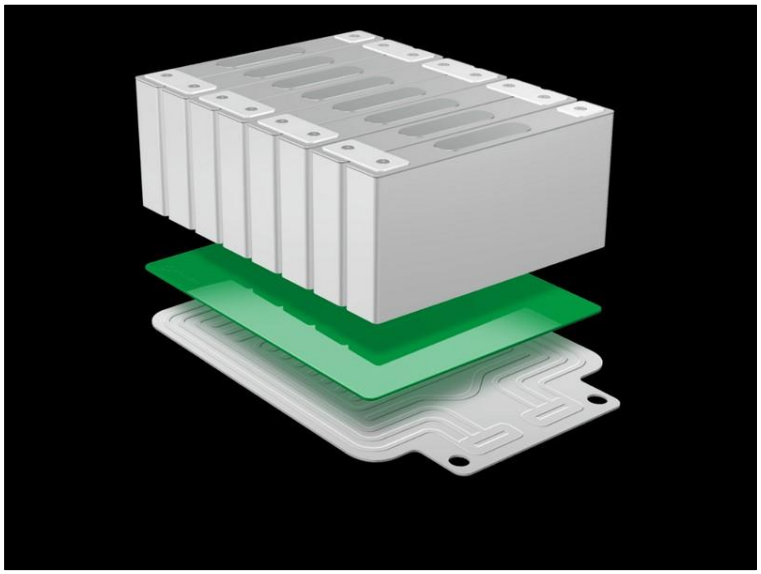

Figure 5: Modular battery system design and layout.
Source: Authors (2026).

III.2 RESEARCH ON NOVEL COOLING TECHNIQUES

When it comes to making battery thermal management systems better for electric vehicles (EVs), there's been real progress in coming up with new cooling methods that put efficiency and safety first. Recent studies point to putting macro-nanoporous metals, arranged in a certain order, into phase change materials (PCMs). The result is better thermal conductivity and leak prevention. What this smart move does is allow for more energy to be packed in, all while keeping the battery's temperature stable when it's running, which means the temperature stays at a safe level, no matter how much the battery is being used [10]. As you can see in designs for thermal management systems, like the ones in , these kinds of innovations are set to change how batteries work. They lower the chances of thermal runaway and make sure EVs can last for a long time. Because of this, using advanced cooling solutions not only makes EVs work better but also really boosts their safety [35].

A. Future Trends in Battery Thermal Management

The electric vehicle, or EV, market is definitely changing, and what's coming next in how we keep those batteries at the right temperature is super important for how well they work and how safe they are. We're seeing cool new stuff like better materials and cooling methods that try to get the most out of how batteries handle heat, which can make them last longer and work better [6]. There's even talk about using really cold hydrogen tech as another way to help out. These advancements might lead to greener energy solutions, which is a big plus for EVs. Also, when we look at space solar power, or SSP, tech, it turns out there are some neat thermal management ideas there that could be used for more than just stuff on Earth [36]. As we learn more, it's probable that these different ideas will mix together and influence how we design batteries in the future. This all means we need solid plans that can deal with all the complicated parts of today's EVs. All these trends coming together will be key to making sure our transportation is as energy-efficient as it needs to be [37], [38].

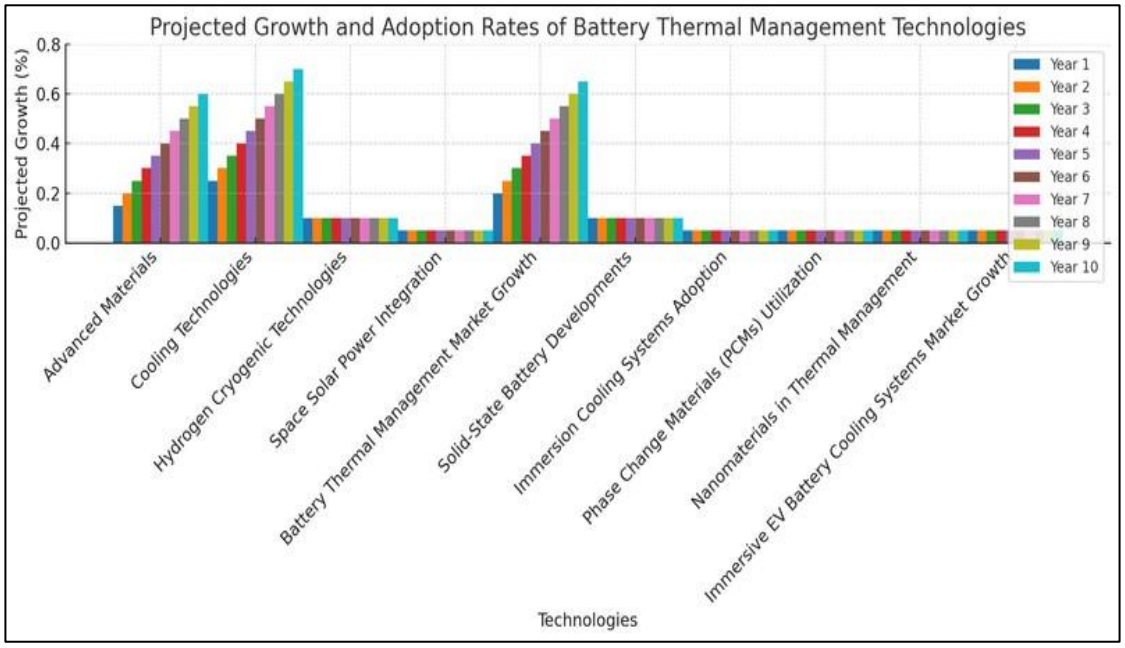

Figure 6: Battery thermal management Technologies.
Source: Authors (2026).

Fig.6 displays the projected growth rates for various battery thermal management technologies over a ten-year period. Each color represents a different year, highlighting how anticipated adoption rates vary among advanced materials, cooling technologies, and other innovative solutions in the electric vehicle sector. The values indicate a significant increase in growth potential, underscoring the importance of these technologies for improving the efficiency and performance of electric vehicles.

IV CONCLUSION

To sum up, keeping EV batteries at the right temperature is super important for making them work well, keeping them safe, and helping them last. Since more and more people want EVs, and batteries are getting better all the time, it's key that we figure out how to handle heat. This will help stop batteries from getting too hot and make sure they work as well as possible. If we use things like really good materials that conduct heat and new ways to cool batteries, we can really improve how well they stay at the right temperature when they're running. Plus, the market for these kinds of systems is expected to grow, as shown in [39].So, manufacturers need to really focus on creating systems that work well. Successfully using these technologies helps us move toward transportation that's better for the environment and reduces pollution, [1] highlights. Really, it's crucial that we keep researching and developing thermal management systems that don't just make batteries perform better but also help us take care of the environment as EVs continue to evolve. And as distinctly showcases, these systems strategically manage heat distribution, further underscoring their importance. Within the ever-changing world of electric vehicles (EVs), the way we handle battery temperatures—known as battery thermal management (BTM)—is becoming super important for making sure things run well, are safe, and last a long time.

It's really necessary to add in better systems for handling heat because those strong lithium-ion batteries, like the ones using lithium nickel cobalt aluminum oxide (NCA), can get too hot, as some studies have shown [7] Plus, pictures that show how heat is managed give us a look at how things like battery packs and cooling stuff work together to get rid of heat properly. This does more than just make the car work better; it also makes things safer, since batteries can go haywire and put people at risk. As more and more people start using EVs, figuring out how to manage battery heat well is going to help more people switch to these cars and improve the technology in the car business. Because of this, it's clear that we need to keep doing research in this area.

A. Importance of Effective Thermal Management for EV Adoption

For electric vehicles (EVs) to really take off, getting the thermal management right is key, since it has a big impact on how well the battery works, how safe it is, and how long it lasts. As EV tech gets better, thermal management systems need to be good at keeping battery packs at the right temperature. This is to stop them from overheating and possibly going into thermal runaway, which, as you can see in , could cause some serious problems. Studies have found that if you keep the battery at the best temperature, it can store more energy and charge faster, which are both important things for people thinking about buying an EV [37]. Plus, good thermal management helps the whole car work better, so you can drive farther and spend less money on keeping the battery in good shape or replacing it. As more and more people buy EVs, new ideas in thermal management will be important for getting past the things that are stopping people from switching to EVs. These innovations will help make sure that EVs are as good as people expect them to be, no matter where they're driving.

B. Future Challenges and Opportunities

The growing electric vehicle (EV) market means that battery thermal management's future involves both significant challenges and exciting possibilities for engineers and researchers. A key challenge is creating systems that effectively remove the heat produced when EVs are running; if this isn't handled well, it can cause thermal runaway, which is bad for battery safety and how well it works. However, new developments in thermal management – think advanced materials and better cooling – could help batteries last longer and work more efficiently, which supports the push to lower greenhouse gas emissions from vehicles [5]. Also, smart thermal management systems that can monitor and adjust things in real time offer a chance to use energy more efficiently depending on how someone is driving [40].Dealing with these issues not only helps develop safer EV technology, but it also sets the stage for wider acceptance of electric vehicles worldwide, as shown by the important information in .

Source: Authors (2026).

C. Call to Action for Research and Development

Electric vehicle (EV) tech is really taking off, so it's super important that we put a lot of effort into research and development (R&D), especially when it comes to keeping those batteries at the right temperature. Making sure the battery doesn't get too hot or cold is key to getting the most life out of it and keeping things safe while you're driving. If we come at this problem from all angles, we can cut down on the chances of thermal runaway, which is still a big worry with lithium-ion batteries [5].To get new ideas flowing, everyone involved needs to work together, using what we've already learned from places like NASA, which has done studies on power and temperature control that can help with Evs [39].Plus, if we include better thermal management systems, like the ones you can see in detailed diagrams of battery packs, we can boost how well EVs work and get more people to switch over. Basically, we need a big push for R&D to not only make electric cars better but also help the environment and save energy.

D. Final Thoughts on the Role of Thermal Management in Sustainable Transportation

To summarize, thermal management plays a vital role in sustainable transportation, especially as electric vehicles (EVs) are becoming more and more prevalent. Actually, good thermal management systems don't just make batteries work better; they also help them last longer, which is key to making EVs a competitive choice in the auto world. As we can see in the schematic of a battery pack, the use of new materials and designs for thermal management is super important for getting the most out of energy use and keeping things safe [40]. What's more, effective thermal management can help cut down on long-term running costs, which goes hand in hand with the goals of sustainable transportation. Even as researchers and engineers try to bring down initial costs and other obstacles, it's still really important to keep pushing for new tech and policies that will help everyone use better thermal management solutions [41], [10]. Efficient thermal management is essential for ensuring the safety, performance, and durability of automotive systems, particularly with the increasing adoption of advanced energy and electronic components [42]. Appropriate material selection is critical for achieving stable thermal and mechanical behaviour under varying operating conditions [43]. Computational fluid dynamics methods are commonly employed to analyse airflow and heat transfer characteristics in vehicle systems [44]. In parallel, the integration of IoT technologies has enabled real-time monitoring and improved safety functions in modern automobiles [45]. Driver condition and vehicle health monitoring systems further enhance safety by identifying fatigue, faults, and unsafe operating conditions at early stages [46-49]. The combined use of monitoring systems with safety-enhanced braking strategies provides an effective approach to accident prevention in critical driving scenarios [50].

ABSTRACT

Various evolutionary algorithms have been developed to address environmentally oriented multi-objective process planning challenges in reconfigurable manufacturing systems, though many prioritize effectiveness over flexibility. Research utilizing Petri nets effectively addresses this flexibility issue, with several extensions proposed for modeling complex systems. By leveraging established Petri net theory, the process plan of reconfigurable manufacturing systems (RMS) can be encoded, enabling the optimization of process plan generation and the identification of potential deadlocks. This paper introduces a novel approach to enhance process plan generation, combining Evolutionary Petri Nets (a variant of Petri nets) with the enhanced genetic algorithm N˜SGA-III. The method optimizes four key objectives within the context of Sustainable Reconfigurable Manufacturing Systems (SRMS): total production cost, total production time, greenhouse gas emissions from energy consumption, and hazardous liquid waste generation. Numerical experiments were conducted to validate the effectiveness of this approach.

I. INTRODUCTION

I.1 CONTEXT AND MOTIVATIONS

Reconfigurable Manufacturing System is a dynamic research domain that encompasses various advanced topics, including design, layout optimization, reconfigurable control, process planning, and production scheduling. However, there remains a significant gap in integrating sustainability into RMS studies [1]. A Sustainable Reconfigurable Manufacturing System (SRMS) is defined as a manufacturing system designed to be flexible and adaptable to shifts in product demand and production requirements, Additionally, SRMS focuses on minimizing environmental impacts while enhancing social and economic benefits [2]. Process planning, also known as process plan generation, is a critical initial step in organizing a manufacturing facility. It outlines how raw materials will be transformed into finished products. This planning occurs at two levels: macro and micro. Macro-process planning focuses on selecting the optimal sequence of various processing steps, setups, and the machines needed for the operations. In contrast, micro-process planning aims to optimize each individual operation to identify the best process parameters. Therefore, process planning is essential within the entire manufacturing cycle. Both levels of planning present complex challenges, attracting attention from both industry professionals and researchers, leading to numerous contributions in the field. Process plan generation using Petri nets is an effective method for modeling and analyzing manufacturing processes. Petri nets provide a graphical and mathematical representation that captures the dynamics of systems, allowing for the visualization of workflow, resource allocation, and concurrent activities. Evolutionary algorithms or computations (EC) are commonly used for solving problems such as optimization and reverse engineering of complex systems [2]. Genetic Algorithms (GAs) are widely used to solve various manufacturing problems, particularly in the context of RMS, due to their ability to effectively handle complex, multi-dimensional search spaces.

In these environments, GAs help optimize diverse objectives, such as cost, time, and resource allocation, under dynamic and uncertain conditions. Among the multi-criteria versions of GAs, the most commonly employed is NSGA-II [3], known for its robust performance in finding Pareto-optimal solutions and maintaining diversity in the solution set, making it suitable for complex decision-making scenarios in manufacturing systems. The integration of evolutionary algorithms and Petri nets provides a powerful method for generating and optimizing process plans in manufacturing systems. This approach enhances the ability to address complex challenges, especially in environments that prioritize sustainability and efficiency. These benefits motivated us to propose in this paper an Evolutionary-Generated Petri Nets based approach for Process Plan Generation in Sustainable Reconfigurable Manufacturing Systems.

I.2 KEY CONTRIBUTIONS

Our research paper seeks to develop a multi-objective sustainable process plan generation at a macro level within a reconfigurable manufacturing environment through:

- A formal modeling of the multi-objective sustainable process plan generation problem in RMS, considering production costs, completion times, greenhouse gas emissions, and hazardous liquid waste as optimization criteria.
- An approach based on Evolutionary-Generated Petri Nets (EPN) to effectively solve the sustainable process plan generation challenge in RMS.
- The identification of potential deadlocks in the process plan by utilizing the reachability graph (RG) of a Petri Net.
- An investigation into how the probabilities of genetic operators affect the convergence of the adapted NSGA-III algorithm.

The remainder of this paper is organized as follows: Section 2 provides a literature review, followed by the problem description in Section 3. The modeling of the process plan using evolutionary Petri nets is discussed in Section 4. Section 5 presents the proposed evolutionary approach, while Section 6 focuses on the verification of the process plan. Section 7 introduces the adapted evolutionary algorithm. The experimentation of the approach is detailed in Section 8, and Section 9 concludes with a discussion of future work.

II. LITERATURE REVIEW

Sustainable Reconfigurable Manufacturing Systems (SRMS) have gained significant attention across both academia and industry due to their critical role in flexible, eco-friendly production [4]. This section surveys key contributions that integrate artificial intelligence (AI) techniques—particularly multi-objective evolutionary optimization—into sustainable process planning within RMS and SRMS contexts. Several studies [5], [6], [7] have extensively investigate multi-objective process and production planning in SRMS by formulating models that explicitly incorporate the three pillars of sustainability: social, environmental, and economic. Their frameworks combine classical optimization techniques, including Lagrangian relaxation for large-scale problems and exact solution methods via GAMS for smaller instances, alongside linear mixed-integer programming and augmented ε-constraint approaches, demonstrating the importance of rigorous mathematical modeling in sustainability-focused manufacturing planning. In RMS, energy cost optimization is tackled through bi-level optimization frameworks that couple line balancing with production scheduling.

A hybrid metaheuristics that synergizes simulated annealing with linear programming has been proposed in [8] to solve such problems effectively. Significant contributions have been made in [9], [10], [11], [12] through the development of multi-objective, environmentally focused evolutionary algorithms aimed at optimizing sustainable machine and tool selection. These studies investigate advanced variants of NSGA-II and NSGA-III, incorporating techniques such as penalty boundary intersection and similarity coefficient-based operators to improve performance across key objectives, including production cost, processing time, greenhouse gas emissions, and hazardous waste generation. In [13], [14], several hybrid metaheuristics have been developed and evaluated—ranging from iterative multi-objective integer linear programming (I-MOILP) to archive-based iterated local search algorithms—comparing them against established evolutionary methods like AMOSA and NSGA-II. These studies highlight the effectiveness of hybrid AI approaches in solving complex, multi-objective manufacturing problems. Similarly, in [15], [16], multi-objective process planning has been addressed using mixed-integer linear programming models combined with evolutionary algorithms such as NSGA-II and SPEA-II.

Their contributions emphasize reducing completion time, production cost, and energy consumption within reconfigurable environments through intelligent algorithmic adaptations. This trend is extended by concurrently optimizing process planning, job-shop scheduling, and layout design within RMS in [17]. Their use of NSGA-III alongside well-defined economic and environmental metrics exemplifies state-of-the-art AI-enabled multi-objective optimization targeting sustainability improvements in manufacturing. Collectively, these studies demonstrate the growing role of evolutionary algorithms and hybrid metaheuristics in addressing the multi-faceted, sustainability-focused optimization challenges inherent to SRMS. However, there remains a critical need for integrated frameworks that combine formal modeling and verification, as well as adaptive evolutionary optimization—motivating the approach developed in this paper. **Table 1** presents an overview of recent studies addressing key issues in S-RMS problems.

III. PROBLEM DESCRIPTION

Let us consider a single unit of a product to be manufactured in a reconfigurable environment. The product requires a set of operations, which are linked by precedence constraints, generally modelled by Directed Acyclic Graph (DAG): G = {V, E}, the set of vertices V = {OP_1,…, OP_n} denote each individual operation in the production process, E the set of directed edges represent precedence constraints between operations nodes. A directed edge $E_{i,j}$ states that OP_i is the parent operation of OP_j. Child operations can only be executed once all the parent operations are completed, as illustrated in Figure 1.

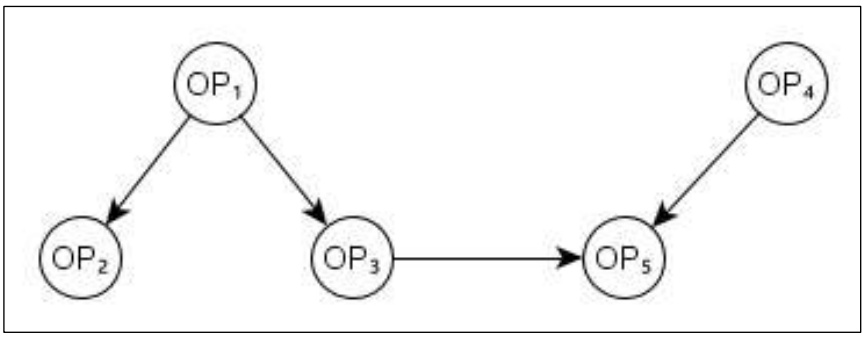

Figure 1: A simple operations precedence DAG.
Source: Authors, (2026).

An operation in this case is defined by a set of machines capable of performing it. A machine, on the other hand, is defined by a set of available configurations and a set of compatible tools. Table 2 presents configurations and tools that each machine offers. Thus,

each operation OP_i requires an association of machine-configuration-tool (M,C,T) called triplet TO_i. A feasible association between the operations and triplets is called process plan, which should respect the precedence constraints (Khettabi et al. 2021c).

Table 2: Example of configurations and tools that each machine offers.

M	C	T
M_1	C_1	T_1, T_2, T_3
M_2	C_2, C_3	T_1, T_3
M_3	C_1, C_2	T_2, T_3

Source: Authors, (2026).

Table 3: Example of a generated process plan.

Operation	OP_1	OP_4	OP_2	OP_3	OP_5
Machine	M_2	M_1	M_3	M_2	M_1
Configuration	C_3	C_1	C_2	C_2	C_1
Tool	T_1	T_2	T_2	T_3	T_1

Source: Authors, (2026).

More specifically, the process plan takes the structure of a matrix with n columns (number of operations) and four rows (operation, machine, configuration and tool). Table 3 shows an illustrative example of a process plan. It is read from left to right and column-by column. As an example, the first column indicates that: operation OP_1 is realised in the first step of the process plan, using machine M_2 under configuration C_3 with tool T_1.

IV. MODELLING PROCESS PLAN USING EVOLUTIONARY PETRI NETS

IV.1 MOTIVATION

The Directed Acyclic Graph (DAG) has a very simple structure and is easy to use. It possesses, however, some relevant disadvantages. As DAG is directed, it is impossible to define bidirectional coupling schemes between software components. DAG is acyclic, so it is not feasible to define loops, and only it describes the behaviour, but not the state of the system. These disadvantages motivate to use of the Petri nets formalism [18]. Petri nets are useful tool for visualisation of the processes. However, constructing and optimizing PN that describes process with hundreds of possible transitions and places is time and resources demanding task. Therefore, Evolutionary Petri Nets (EPN) are proposed as a solution to this task [2].

IV.2 FORMAL DEFINITION OF EPNs

Evolutionary Petri Nets (EPN) is proposed in [19] as a new extension for RPN (Resizable Petri Net). The aim of this proposition is to develop an evolutionary methodology whose candidate solutions are based on PNs, with two genetic operators, crossover and mutation, that altogether give a foundation for the development of a robust evolutionary algorithm for the optimisation. EPNs provide a conceptual framework for the representation of candidate solutions [18]. Below, we give the formal definition of RPNs and EPNs.

Definition 1: A Resizable Petri Net (RPN) [19] (extension of PNs) is defined as a 9-tuple: $\xi = (P, P^h, T, T^h, F, W, M_0, O_{pre}, O_{post})$:

- $P = \{p_1, p_2, \ldots, p_m\}$ is a finite set of places;
- P^h is the set of hidden places, such that $P \cap P^h = \varnothing$;
- $T = \{t_1, t_2, \ldots, t_n\}$ is a finite set of transitions, where: $P \cap T = \varnothing$ and $P \cup T \neq \varnothing$;
- T^h is the set of hidden transitions, such that $T \cap T^h = \varnothing$ and $(P \cup P^h) \cap (T \cup T^h) = \varnothing$;
- $F \subseteq ((P \cup P^h) \times (T \cup T^h)) \cup ((T \cup T^h) \times (P \cup P^h))$ is set of arcs;
- W: $F \rightarrow N$ is a weight function that associates a non-negative integer value to each arc;
- M_0: $P \rightarrow N$ is the initial marking of non-hidden places of the net (all hidden places have zero tokens, initially);
- $O_{pre} \in N$ is the maximum pre-order allowed in the RPN (equation 1), that is, for each $t \in (T \cup T^h)$: $\sum_{\substack{p \in Pre(t) \\ p \in (p \cup p^h)}} W(p, t) \leq O_{pre}$ (1)
- $O_{post} \in N$ is the maximum post-order allowed in the RPN (equation 2), that is, for each $t \in (T \cup T^h)$: $\sum_{\substack{p \in Post(t) \\ p \in (p \cup p^h)}} W(t, p) \leq O_{post}$ (2)

Definition 2: An Evolutionary Petri Net (EPN) [19] is a triple $E = (\xi, X, \mu)$, where:

- $\xi \in \Xi$ is a RPN; where Ξ is the space of all possible RPN topologies;
- X: $(\Xi \times \Xi) \rightarrow (\Xi \times \Xi)$ is the crossover operator which takes as input two RPNs ξ and $\bar{\xi}$ (where $P_\xi = P_{\bar{\xi}}$) and gives two new RPNs;
- μ: $\Xi \cup \{P_{in}, t, P_{out}\} \rightarrow \Xi$ is the mutation operation, where $\{P_{in}, t, P_{out}\}$ is a triple consisting of two places P_{in} and P_{out} and a transition t, namely $P_{in}, P_{out} \in (P \cup P^h) \cup P^\infty$ and $t \in (T \cup T^h) \cup T^\infty$, where P^∞ and T^∞ are infinite sets of places and transitions, such that $P^\infty \cap (P \cup P^h) = \varnothing$ and $T^\infty \cap (T \cup T^h) = \varnothing$.

Both the crossover and mutation operators are described in detail in [19].

IV.3 PROCESS PLAN MODELLING WITH RPNs

The process plan generation consists of sequencing the operations to be performed on the machines (under machines configurations, used tools, and precedence graph constraints) and the triplets to perform each operation in the sequence [10]. For modelling the process plan with RPNs, we introduce two kinds of places, the first represents machines, configurations, tools and the other represents dependencies from an operation OP_i to operation $OP_{i`}$. On the other hand, we introduce a type of transition represents set of available configurations and compatible tools for each machine.

In this work, Let us consider:
n: number of operations,
OP: set of operations $\{OP_1, OP_2, \dots, OP_n\}$,
m: number of machines,
M: set of machines $\{M_1, M_2, \dots, M_m\}$,
cfg: number of configurations,
C: set of configurations $\{C_1, C_2, \dots, C_{cfg}\}$,
tl: number of tools,
T: set of tools $\{T_1, T_2, \dots, T_{tl}\}$.

We can model a feasible process plan (candidate solution) with an RPN as a 8-tuple = $(P, P^h, T, T^h, F, W, M_0, O_{pre}, O_{post})$ where:

- $P^h = \{D_{ii`}\} \cup \{M_j\}$ where:

$\{D_{ii`}\}$ / $i,i` \in [1, n]$ representing the set of execution conditions of each operation (precedence constraints), $D_{ii`}$ denotes precedence constraint between operation $OP_i$ and $OP_{i`}$;

$\{M_j\}$ / $j \in [1, m]$ representing the set of machines;

- $P = \{T_t\} \cup \{C_c\}$ where :

$\{T_t\}$ / $t \in [1, tl]$ representing set of configurations;

$\{C_c\}$ / $c \in [1, cfg]$ representing set of tools;

Such that $P \cap P^h = \varnothing$

- $T = OP = \{OP_1, OP_2, \dots, OP_n\}$ representing set of operation composing production process, where: $P \cap T = \varnothing$ and $P \cup T \neq \varnothing$;
- $F \subseteq ((P \cup P^h) \times (T \cup T^h)) \cup ((T \cup T^h) \times (P \cup P^h))$ is set of arcs;
- W: $F \rightarrow$ N is a weight function that associates a non-negative integer value to each arc; in this case $W(f) = 1$, $\forall f \in F$;
- M_0: $P \rightarrow$ N is the initial marking of non- hidden places of the net (all hidden places have zero tokens, initially); this condition is respected in the present work excepted the starts places which are initially marked by one token;
- $O_{pre} \in$ N is the maximum pre-order allowed in the RPN (equation 1), that is, for each $t \in (T \cup T^h)$: $\sum_{\substack{p \in Pre(t) \\ p \in (p \cup p^h)}} W(p,t) \leq O_{pre}$ (3)
- $O_{post} \in$ N is the maximum post-order allowed in the RPN (equation 4), that is, for each $t \in (T \cup T^h)$: $\sum_{\substack{p \in Post(t) \\ p \in (p \cup p^h)}} W(t,p) \leq O_{post}$ (4)

Figure 2 depicts an RPN modelling a valid generated process plan (Table 3) for the operations precedence DAG (Figure 1).

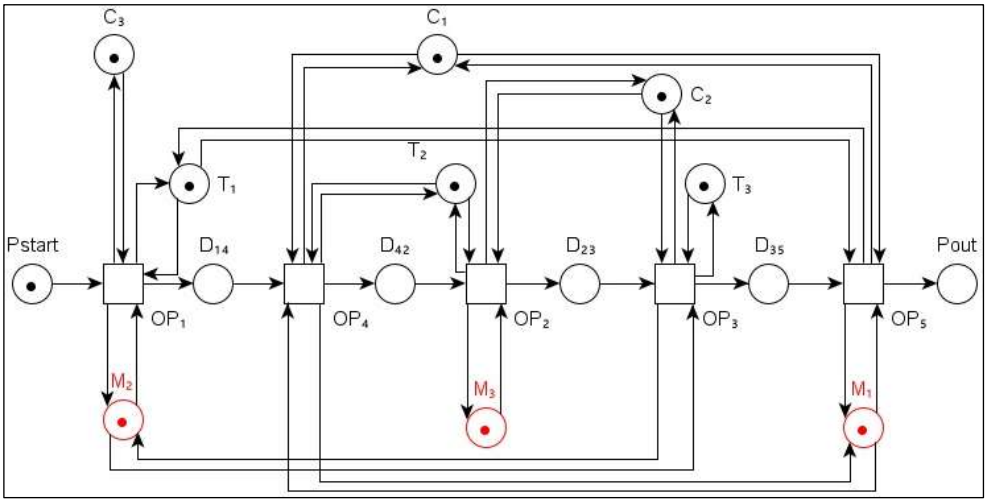

Figure 2: Modelling of valid generated process plan with RPN.

V. PROPOSED EVOLUTIONARY APPROACH

To identify the optimal process plan, we employ an evolutionary approach utilizing a genetic algorithm. Each potential chromosome or individual in our approach signifies a viable solution.

V.1 CHROMOSOME ENCODING

In the context of the process planning problem, a chromosome consists of a sequence of genes, with each gene representing the assignment of a specific operation in the process plan to its corresponding machine. During each transition firing, we assess key metrics of the process plan up to that transition, including makespan, production costs, hazardous liquid waste generation, and greenhouse gas emissions. Chromosome encoding is fundamentally based on the utilization of Evolutionary Petri Nets (see Definition 2). To achieve this, we employed the RPN model proposed in the previous section and assigned a label L = (***FT***, ***C***, **LHW**, ***GHG***) to each operation; where **FT** signify the finishing time of an operation, **C** signify the cost of execution of each operation OP_i on the selected machine M_j, **LHW** and **GHG** signify the amount of hazardous liquid waste and the amount of greenhouse gases emitted during the execution of each operation OP_i respectively. Formally, we define:

- EPN is the evolutionary Petri net introduced above.
- *FT: T x P → ℝ; (OPi, Mj) → FT (OPi, Mj)*

FT (OP_i, M_j) = FT (OP_i) = ST (OP_i) + $Pt_i + TCC_{c,\dot{c}} + TCM_{j,} + TCT_{t,\dot{t}}$

Where: ST (OP_i) = $\max_{p \in PR_i}$ {FT (OP_p)}

- *C: T x P → ℝ; (OPi, Mj) → C (OPi, Mj)*

C (OP_i, M_j) = C (OP_i) = Pc_i x $Pt_i + CCM_{j,}$ x $TCM_{j,} + CCC_{c,\dot{c}}$ x $TCC_{c,\dot{c}} + CCT_{t,\dot{t}}$ x $TCT_{t,\dot{t}}$

- *LWH: T x P → ℝ; (OPi, Mj) → LWH (OPi, Mj)*

LWH (OP_i, M_j) = LWH (OP_i) = L_i x Pt_i x EP_i

- *GHG: T x P → ℝ; (OPi, Mj) → GHG (OPi, Mj)*

GHG (OP_i, M_j) = GHG (OP_i) = IEC_j+ Pt_i x $f_{i,g}$ + Pe_i x $Pt_i + ECC_{c,\dot{c}}$ x $TCC_{c,\dot{c}}$ +$ECT_{t,\dot{t}}$ x $TCT_{t,\dot{t}} + ECM_{j,}$ x $TCM_{j,}$

The parameters used in these functions are as follows:

PR_i Set of predecessors of operation OP_i
G Set of greenhouse gases
$i, \dot{\imath}$: Index of operations OP_i and $OP_{\dot{\imath}}$
$j, \dot{\jmath}$: Index of machines M_j and $M_{\dot{\jmath}}$
$c, \dot{c}$ Index of configurations
$t, \dot{t}$ Index of tools
g Index of greenhouse gases
$TCM_{j,\dot{\jmath}}$ Machine change over time
$TCC_{c,\dot{c}}$ Configuration changeover time
$TCT_{t,\dot{t}}$ Tool changeover time
$CCM_{j,\dot{\jmath}}$ Machine change over cost per time unit
$CCC_{c,\dot{c}}$ Configuration changeover cost per time unit
$CCT_{c,\dot{c}}$ Tool changeover cost per time unit
$ECC_{c,\dot{c}}$ Configuration changeover energy per time unit
$ECT_{t,\dot{t}}$ Tool changeover energy
$ECM_{j,\dot{\jmath}}$ Machine changeover energy per time unit
Pt_i Operation OP_i processing time
Pc_i Operation OP_i processing cost
Pe_i Operation OP_i processing energy
$f_{i,g}$ Operation OP_i emitting greenhouse gas type g per time unit
IEC_j Initial energy consumption of machine M_j
EP_i Estimated hazardous liquid waste for operation OP_i
l_i Required liquid for operation OP_i per time unit

V.2 GENETIC OPERATORS

Genetic algorithm introduces crossover and mutation operations to increase the diversity of the population.

V.2.1 Crossover of RPN

The crossover mechanism between two RPNs generates new offspring which inherit the best substructures of the parents. No specific work exists about the crossover between bipartite graphs or, more specifically PNs. Indeed, the crossover between two PNs is supposed to identify some substructures in each graph, 'detach' them from one parent graph and 'attach' them into the other, and vice versa, while keeping the consistency of both graphs [19]. Our proposal for a crossover mechanism ($Crossover_{RPN}$) of two RPNs: $\xi(\tau), \bar{\xi}(\tau) \in \Xi$ considers four points:

- One operation (representing an operation in process plan problem) $OP_\chi \in OP$ is randomly selected in the $\xi(\tau)$ and the same operation is selected from $\bar{\xi}(\tau)$.

- Select the substructures consisting of the preset and post set of OP_χ (resp. $\overline{OP}_\chi$);
- Change the substructures between ξ and $\overline{\xi}$.

The use of this method saves the precedence constraints in each RPN.

V.2.2 Mutation of RPN

A mutation generates new RPN (offspring) from a single RPN (parent) in the current population. According to [13], the mutation operator modifies the structure of a RPN $\xi(\tau)$ in Ξ. We have proposed a mutation operator ($Mutation_{RPN}$) that associates $\xi(\tau)$ to a new consistent EPN $\xi(\tau + 1)$, according to specified couple $\{OP_i, M_j\}$. Our mutation operator acting on a single randomly chosen operation OP_i, the assignment of this operation will change as follows: the algorithm checks if there exists a machine with the same available configuration C_c and compatible tool T_t (denoted $M_{j'}$) unusable in all initial population ($M_{j'} \in P^{h\infty}$), this $M_{j'}$ will execute OP_i. If not ($P^{h\infty}=\varnothing$), the $M_{j'}$ must be randomly chosen from the list of $M_{j'}$ already used ($M_{j'} \in P^h$). Figure 3 a-b shows a sample of mutation operator. Assuming in this sample that $OP_\chi = OP_1$.

V.2.3 fitness function

The generated process plans must align with both manufacturing and sustainability objectives. Specifically, we aim to minimize four criteria:

- ✓ **Criterion 1: Total Production Cost** - This encompasses expenses related to machine changes, configuration adjustments, tooling, process alterations, as well as costs associated with greenhouse gas emissions and hazardous liquid waste.
- ✓ **Criterion 2: Total Production Time** - This includes the duration of machine transitions, configuration changes, tool replacements, and the time allocated for processing operations.
- ✓ **Criterion 3: Waste Generation** - This refers to hazardous liquid waste produced during operational processes, including waste oils and water, by products from resin production and application, residues from metal and plastic surface treatment, and materials resulting from industrial waste disposal activities.

✓ **Criterion 4: Greenhouse Gas Emissions** - This criterion captures the total emissions of greenhouse gases throughout the entire production process.

A comprehensive overview of these criteria, along with their mathematical formulations, is provided in [11]. By emphasizing these criteria, our goal is to create process plans that are both efficient and sustainable.

VI. VERIFICATION OF RTPM (VERIFICATION$_{RTPM}$)

Deadlock and livelock problems can lead to disastrous outcomes in reconfigurable manufacturing systems (RMS) by halting production processes at unpredictable stages. Therefore, it is essential to manage these issues effectively to ensure smooth production in RMS. Our study concentrated on verifying two key properties: the absence of deadlocks and the absence of livelocks. We will eliminate any reconfigurable production networks (RTPMs) that exhibit these problematic behaviors. The reachability graph (RG) of a TPM is a directed graph that covers all of reachable markings and transitions among these markings. If there is some marking $M \in R$ not enabling any transition, M is said a dead marking, and system (N, M_0) is said to contain a deadlock. If there is some subset $E \subseteq R$ such that no transition leads from a marking in E to some marking not in E witnessing some progress (e.g. the initial marking), then set E is said to be a livelock, and system (N, M_0) is said to contain a livelock. The occurrence of a deadlock or livelock in a real RMS can cause severe damages.

Definition 3 (Deadlock). Let N = (P, T, F, M_0) be a Token-Based Process Model and M_f is a target marking. M ∈ R (N, M_0) is a deadlock w.r.t. M_f (deadlock for short) if ∀ t ∈ T, ¬M [t⟩ ∧ M ≠ M_f [20].

Definition 4 (Livelock). Let N = (P, T, F, M_0) be a Token-Based Process Model and M_f is a target marking. M ∈ R (N, M_0) is a livelock w.r.t. M_f (livelock for short) if ∀ M′ ∈ R (N, M), ∃ t ∈ T, M′ [t⟩ ∧ M ′ ≠ M_f [20].

A graph is strongly connected if; every node (vertex) is reachable from every other node. A strongly connected component (SCC) of a graph is a strongly connected subgraph that is maximal. An RG can be split into the live zone (LZ) and the deadlock zone (DZ). The LZ can easily be identified as the SCC containing the initial marking M_0, while the DZ can be identified as the remaining SCCs [21]. It is important to determine the exact number of states in both the DZ and LZ of the Token-Based Process Model (TPM) model. To tackle this challenge, [22] recently proposed a method that utilizes RG analysis results from a TPM model of a flexible manufacturing system (FMS) that is susceptible to deadlocks or livelocks. This method employs the Integrated Net Analyzer (INA) [21]. It takes the RG and the initial SCC as inputs and calculates the number of states in both the LZ and DZ (for a detailed algorithm, refer to [22]). The approach for verifying the RTPMs modelled in the process plan within the resource management system (RMS) is based on this methodology, as outlined in the subsequent algorithm.

Algorithm 1: Verification$_{RPN}$

Input: RPN model.

Initialisation: result_verification= True

Definitions: *nbr_sts_lz*: number of states in the LZ, *nbr_sts_dz*: the number of states in the DZ, *t_nbr_sts*: total number of states in RG, *nbr_scc*: the number of states in the first SCC

1: Compute the RG and then SCC of the given RPN model by using INA.

2: Compute the total number of states (t_nbr_sts) in RG

3: Compute the number of states in the first SCC (*nbr_scc*)

4: *nbr_sts_dz* = *t_nbr_sts* - *nbr_scc*
nbr_sts_lz = *nbr_scc*

5: if ((*nbr_sts_dz* > 0) or (*nbr_sts_lz* ≠ *t_nbr_sts*)) then result_verification= False

Output: result_verification

End of Algorithm.

VII. NS̃GA-III\LEPN ALGORITHM

The series of non-dominated sorting based genetic algorithms (NSGA-series) has clearly shown their niche in solving multi- and many objective optimization problems. Of them, NSGA-III [23], [24] was designed to solve problems having three or more objectives efficiently. NSGA-III serves as the foundation for several many-objective optimization methods, with a set of extensions proposed U-NSGA-III [25], EliteNSGA-III [26], DC-NSGA-III [27], R-NSGA-III [28], NSGA-III\NDS [29]. To generate optimal process plans for sustainable manufacturing criteria, we attempt to use last extension of NSGA-III; the NSGA-III without non-dominated sorting (NDS) procedure namely, NS̃GA-III or NSGA-III\NDS. The basic framework of NS̃GA-III algorithm is similar to NSGA-III with significant changes in the way (i) domination check is executed, (ii) the survival selection operator is modified, and (iii) a few other minor changes are adopted resulting from the change in domination check procedure.

VII.1 PROPOSED ALGORITHM

Algorithm 2 describes the proposed algorithm.

Algorithm 2: NS̃GA-III\ LEPN for process plan generation in SRMS.

Input: Operations precedence DAG

OP= Set of operations, M= Set of available machines, CT= Set of Configurations and tools that each machine offers
Predefined set of reference directions W_r
Set of Parameters /* detailed in section 5.1 */
St = ∅, no of selections remaining (nr) = N

/* Create a set of mappings, where each mapping corresponds to a distinct individual or solution. */
1 M_p= Search for Feasible Mappings (OP, M, CT)
/* Transform each mapping into its LEPN representation */
2 Individuals= chromosome encoding (M_p, DAG)
/* Analyse the Net and Determine Transition Firing Order*/
3 Parent Population P_t= Evaluate Each Individual (Individuals)
/* Offspring population generation */
4 Q_t = Generate child Population from parent Population (Pt) using: $Crossover_{RPN}$, $Mutation_{RPN}$, $Verification_{RPN}$
5 $R_t = P_t \cup Q_t$
6 I = find-non-dominated (R_t)
/* Finding ideal point and nadir point for normalization of objective space */
7 ideal, nadir = hyperplane-boundary-estimation (R_t, I)
/* Association each s in R_t with a reference direction */
8 [π(s), d_2(s)] = associate-to-niches (R_t, W_r, ideal, nadir)
/* π(s) = closest reference direction, d_2(s) = perpendicular distance between π(s) and s */
9 d(s) = pbi-decomposition (R_t, W_r, θ=5, ideal, nadir)
/* d(s) = d_1+θd_2 distance between π(s) and s, d1 distance along reference direction ideal point */
10 Set attribute to each population member non-dominated ND=1 and dominated ND=0
11 Set attributes each population member R_t (CV, ND, d(s))
/*classifying population members */
12 Class 1 (C1): R_t (CV = 0 ∩ ND = 1)
13 Class2 (C2): R_t (CV=0 ∩ ND=0)
14 Class3 (C3): R_t (CV>0)
/*Class 1 selection */
15 if (|C1|≤ N) then $S_t = S_t \cup C1$; $n_r = N - |S_t|$
16 else S_t, n_r = class-survivor-selection (C1, S_t, n_r, W_r, π(s), d(s)); $P_{t+1} = S_t$, break;
/*Class 2 selection */
17 if n_r> 0 then S_t, n_r = class-survivor-selection (C2, S_t, n_r, W_r, π(s), d(s));
18 else $P_{t+1} = S_t$; break;
/*Class 3 selection for constrained problems */
19 if n_r> 0 then S_t = tournament-selection (C3);
20 else P_{t+1}=St; break ;

Result: P_{t+1}

VII.2 ALGORITHM DESCRIPTION

The proposed algorithm begins by creating a set of mappings (Step 1), where each mapping represents a distinct individual or solution, serving as a candidate for optimization. These mappings are then transformed into their corresponding LEPN (Labeled Evolutionary Petri Net) representations (Step 2). Following this transformation, the algorithm analyzes the Petri Net and determines the transition firing order (Step 3). This order specifies the sequence in which transitions are activated within the net and is critical for managing the flow of operations, ultimately determining how solutions evolve throughout the optimization process. In Steps 4 and 5, the algorithm generates an offspring population through genetic operations, specifically crossover and mutation. These operations introduce variability into the population, creating new individuals that explore different regions of the solution space. Subsequently, the population is normalized by identifying the ideal point and the nadir point in Steps 6 and 7. These reference points are essential for scaling the objective values across the population, ensuring that comparisons between solutions are made on a consistent and comparable basis. In Step 8, each individual solution ss is associated with a reference direction. Specifically, the closest reference direction π(s) is identified for each solution, and the perpendicular distance d2(s) between the individual solution ss and the reference direction π(s) is computed. This relationship is crucial for evaluating each solution's position relative to the reference direction, providing insight into the distribution of solutions in the objective space. In Step 9, the algorithm applies the PBI (Penalized Boundary Intersection) decomposition. The distance d(s) between an individual solution ss and its closest reference direction is calculated as the sum of two components: the distance along the reference direction d_1(s), and the perpendicular distance d_2(s). The subsequent steps of the algorithm focus on classifying the population members.

VIII. EXPERIMENTATION VALIDATION

The proposed approach is experimentally validated through the use of Petri Net Markup Language (PNML[i]) and the TiNA[ii] Tools software. Figure 4 depicts the steps of validation. TiNA Tools is employed to validate the Petri net represented in a PNML file, confirming its correctness. The tool can analyse all firing sequences of a Petri net related to a process plan problem. Each sequence of transitions, starting from the initial marking and leading to the final marking, corresponds to a feasible process plan. The transitions from the initial state S_0 to the final state S_f represent an ordered execution of operations and a structured utilization of triplets (machine-configuration-tool). This sequence is then saved in a stepper file, which is used to label the Petri net and assess the fitness of each individual.

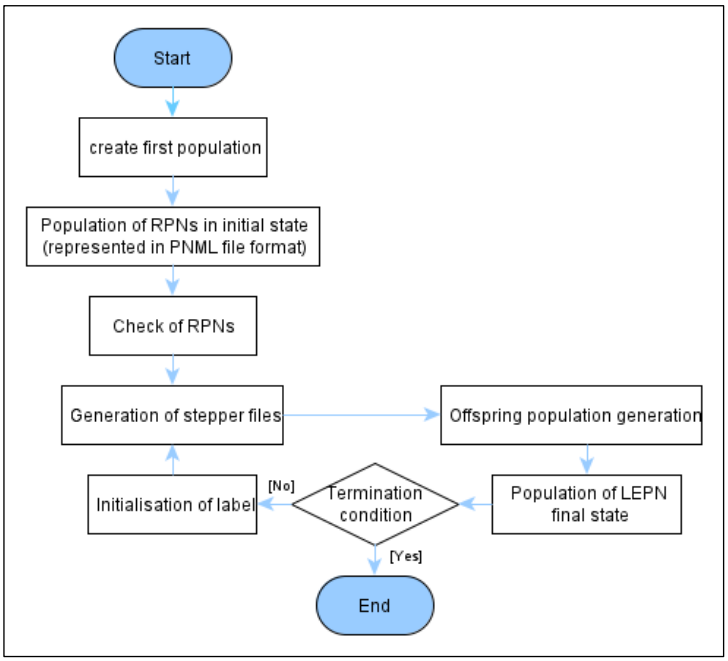

Figure 4: Steps of experimental validation.
Source: Authors, (2026).

The justification for using the PNML format rests on three key aspects: readability, universality, and mutuality. Consequently, the format must capture the fundamental principles and common notations of Petri nets, thereby facilitating the manipulation of labelled evolutionary Petri nets (LEPNs), particularly during the labelling phase. This design also supports the application of both crossover and mutation operators. The experimental results were conducted using an Intel Core i5 processor running at 1.8 GHz and 8 GB of RAM. The meta-heuristic algorithms were implemented using Python, specifically utilizing the **pymoo**[iii] framework for multi-objective optimization. The parameters used in this study are a population size of 100 individuals, a selection rate of 50% per iteration, a crossover rate of 50%, a mutation rate of 5%, and a maximum of 1000 iterations. Figures 5 and 6 present key results from our application in the case of 100 operations and 20 reconfigurable machines. Figure 5 shows the distribution of the initial population in the first iteration, while Figure 6 depicts the solution distribution after the algorithm has converged. Figures 7-10 illustrate the algorithm's convergence regarding the objectives cost, time, LHW and GHG over a single run of 1000 iterations.

VIII.1 INFLUENCE OF GENETIC OPERATOR RATES ON ALGORITHM CONVERGENCE

VIII.1.1 Influence of the crossover rate

In our experiment, we evaluated the performance of our algorithm by varying the crossover rate. The results showed that the best outcomes for cost, time, GHG emissions, and liquid waste (LHW) were achieved when the crossover rate was set to 0.5. When the crossover rate is increased to 0.7, the algorithm performs well for the **time** and **liquid waste (LWH)** objectives compared to **cost** and **GHG emissions**. This suggests that a higher crossover rate promotes faster convergence and prioritizes minimizing time and waste production. Conversely, when the crossover rate is decreased to 0.3, the algorithm performs better for the **cost** and **GHG emissions** objectives, indicating that a lower crossover rate facilitates a more thorough exploration of the solution space, leading to more balanced solutions with respect to economic and environmental considerations, albeit at the cost of slightly higher values for time and LWH. These findings highlight the trade-offs associated with adjusting the crossover rate, where a higher rate may improve certain objectives at the expense of others, and vice versa. Figures 11-14 illustrate the effects of varying the crossover rate within the range of [0.3, 0.7] on cost, time, GHG emissions, and liquid waste (LHW).

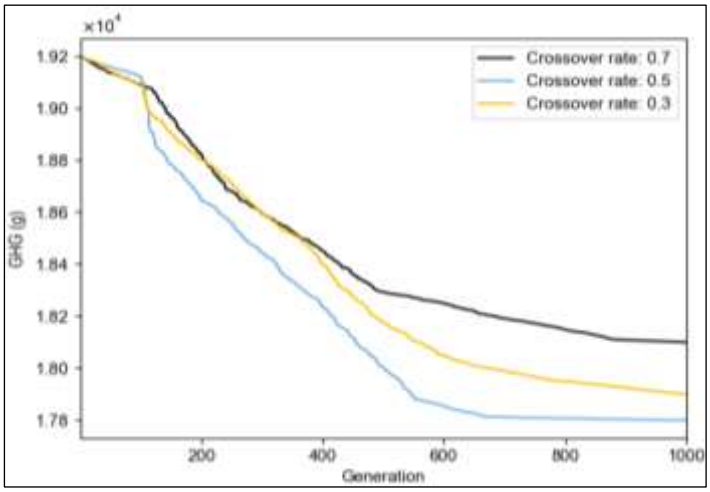

Figure 14: Influence of crossover rate GHG emissions objective.
Source: Authors, (2026).

VIII.1.2 Influence of the mutation rate

We tested our algorithm with different mutation rates and observed the following trends. When the mutation rate is set to 0.05, the algorithm yields the best results for all four objectives: **cost, time, liquid waste (LWH)**, and **GHG emissions**. However, when the mutation rate is increased to 0.07, the algorithm performs well for the objectives of **time, liquid waste (LWH)**, and **GHG emissions**, but not for **cost**. Conversely, when the mutation rate is decreased to 0.03, the algorithm performs better for **cost** but at the expense of the other objectives, particularly time and liquid waste.

VIII.2 COMPARISON WITH OTHER ALGORITHMS

In the context of a single-unit scenario, an instance is defined by the number of requested operations and the number of available reconfigurable machines. Figures 19 and 20 summarize the results obtained from the experiments for each instance, evaluated using the metaheuristics NSGA-II, NSGA-III, and the proposed approach NS̃GA-III\LEPN. Figure 19 presents the CPU computation time (in seconds). Compared to NSGA-II and NSGA-III, our algorithm demonstrates a computation time that is between the two for small-sized instances, while it outperforms both for medium and large-sized instances. Figure 20 shows the cardinality of the Pareto fronts, representing the number of Pareto-optimal process plans. For small and medium-sized instances, our algorithm exhibits cardinality between that of NSGA-II and NSGA-III, whereas, for large-sized instances, it achieves a higher cardinality than both.

IX. CONCLUSION

In conclusion, this study presents an environmentally-oriented multi-objective process planning approach for sustainable reconfigurable manufacturing systems (SRMS), with a focus on minimizing four key objectives: total production cost, production time, greenhouse gas emissions from energy consumption, and hazardous liquid waste. We integrated Petri Nets with a Genetic Algorithm (GA) to derive Pareto-optimal solutions, using a variant of the non-dominated sorting genetic algorithm, NSGA-III, referred to as NS̃GA-III. The experimental results demonstrate the effectiveness of our proposed approach, emphasizing the advantages of incorporating Petri Nets in this context. Notably, the NS̃GA-II\LEPN algorithm outperforms both NSGA-II and NSGA-III, particularly in terms of CPU time for medium and large-sized instances, as well as in the cardinality of Pareto fronts for larger instances. In future work, we plan to extend the proposed approach by testing it on additional case studies to further assess its robustness and performance. Furthermore, we aim to introduce additional objectives, such as maximizing the amount of product produced per unit of energy consumed or enhancing system reliability by maximizing the Mean Time Between Failures (MTBF). This will enable us to evaluate the ability of our approach to balance between the objectives that need to be minimized and those that should be maximized, ultimately improving the overall performance and sustainability of the system.

Breast Cancer Detection.

ABSTRACT

Early detection of breast cancer is critical for patient survival, yet current gold-standard methods like X-ray mammography present significant limitations, including ionizing radiation. a new design of the microstrip patch antenna that is optimized towards early detection of breast cancer at 24 GHz through the benefits of millimeter-wave imaging, such as high resolution and non-ionizing radiation. The cross-slot method has been used with Rogers RT 5880 substrate which in the free space has shown good performance of 10 dB, efficiency of 95% and a wide bandwidth of 1.3 GHz (S11 < -10 dB from 22.8-24.1 GHz). The design was tested in three critical conditions using CST Microwave Studio simulation that included free space operation, multilayer human tissue (skin, fat, fibro) integration, and tumor-embedded conditions. Findings indicate the clear tumor signatures as a frequency shift of 700 MHz, bandwidth reduction to less than 3 MHz and radiation pattern distortions (beam splitting in multiple co-polarized lobes and increased backscatter). It is worth noting that tissue integration decreased gain to 9 dB, but tumor detection sensitivity (90% efficiency) was increased (through an increase in energy coupling) by high permittivity of the tumor. These quantifiable electromagnetic perturbations offer a viable, non-invasive substitute to traditional mammography, and have shown great potential to wearable diagnostic systems in form of the compact design, high sensitivity tumor and real-time monitoring. The paper takes microwave breast imaging one step further and determines definite correlations between changes in the parameters of the antennas and the presence of the malignant tissues.

I. INTRODUCTION

Microstrip antennas have become one of the potential technologies in medical diagnostics especially in breast cancer detection. They are lightweight, compact, and can be easily incorporated into a wearable device hence suitable in non-invasive medical applications. The main benefit of using microstrip antennas is that they can be used in microwave frequencies which makes them provide high-resolution imaging and accuracy in detecting abnormalities breast tissues. In recent years, researchers have focused on developing microstrip antennas specifically designed for microwave breast imaging. This technique offers a safer and more accurate alternative to traditional methods like X-ray mammography, ultrasound, and MRI.

By placing the antenna in contact with the breast skin, the effects of backscattering are reduced, enhancing the sensitivity of tumor detection [1], [2]. Slotted waveguide antennas are one type of antenna. It has several applications, great handling capabilities, and the ability to boost gain and power. Due to its size, the waveguide structure necessitated challenging transitions in order to connect to planar circuitry. The transitions needed for integrating rectangular waveguides with planar circuitry are expensive and large. A fairly new type of planar transmission line called a substrate integrated waveguide (SIW) incorporates a waveguide into planar circuit, like a printed circuit board or a low temperature co-fired ceramic. SIW combines the advantages of rectangular waveguides, such as the power is higher handling capacity low loss and high Q-factor, into planar circuitry, in addition, SIWs license for simple transition between the other planar transmission lines and they are small, have a low-profile and weigh less compared to the rectangular waveguides.

Substrate Integrated Waveguide (SIW) technology retains the fundamental electromagnetic characteristics of traditional rectangular waveguides (RWG), including high quality factor (Q), low radiation loss, and excellent power-handling capabilities, while enabling planar integration. This allows direct transfer of established RWG design methodologies to SIW platforms, such as TE_{m0} mode excitation, impedance matching techniques, and cavity resonance principles. Major RWJ-derived parts such as waveguide dividers, bandpass filters, and slot array antennas, have been miniaturized successfully in SIW configurations with similar performance [3]. As an example, SIW filters will have <0.5 dB insertion losses at Ka-band, comparable to metallic waveguides. It is specifically useful in radar and communication applications that need strict beamforming because the inherent geometry of SIW allows narrow-beam radiation patterns (beamwidth of less than 30°) with sidelobe suppression of over 20 dB.

Unlike RWGs, SIW structures facilitate seamless integration with planar circuits through microstrip-to-SIW transitions, eliminating bulky coaxial adapters. Recent advances in 5G mmWave systems (24–40 GHz) leverage SIW's shaped-beam capabilities for base station antennas, where its 0.1–0.3 dB/cm loss at 28 GHz outperforms microstrip alternatives. Additionally, SIW's compatibility with PCB fabrication reduces costs by 60–80% compared to machined RWGs, making it ideal for mass-produced phased arrays. However, design challenges persist in suppressing higher-order modes (TE_{20}) when scaling to frequencies >60 GHz, requiring optimized via fencing ($d/p < 0.5$, where d=via diameter, p=pitch) to mimic perfect magnetic walls. Compared to other cancers, breast cancer is the most common type among women, particularly in those over 40. According to American statistics from 2013, out of 232,340 cases reported, 64,640 cases are in situ, and 39,620 cases resulted in death, indicating that women are at a significant risk of developing breast cancer [4].

The use of microstrip antennas in this context not only improves the accuracy of early-stage breast cancer detection but also provides a more comfortable and convenient experience for patients. The integration of microstrip antennas into medical devices represents a significant advancement in the fight against breast cancer. Their ability to provide detailed imaging and real-time monitoring makes them a valuable tool in early diagnosis and treatment, potentially increasing survival rates and improving patient outcomes4. As research continues to advance, the role of microstrip antennas in medical diagnostics is expected to grow, offering new possibilities for non-invasive and effective cancer detection. The three primary methods utilized for tumor diagnosis and detection in the past ten years are mammography, ultrasound, also magnetic resonance imaging (MRI), although they still have many drawbacks [4]. In order to achieve ultra-wideband antennas with the highest efficiency and precision possible, researchers are frequently considering developing antenna designs for defense as well as medical applications [4].

According to the Federal Communications Commission's (FCC) 2004 guidelines, UWB antennas operate in the frequency range of 3.1 to 10.6 GHz; also, the antenna's weight and size are crucial design elements [5]. In In this study, we design and optimize a microstrip patch antenna operating at 24 GHz for breast cancer detection applications. The antenna's performance is comprehensively evaluated through three critical scenarios: (1) radiation characteristics in free space as a baseline measurement, (2) operation when integrated with multilayer human tissue (skin, fat, and muscle), and (3) detection capability when malignant tumor tissue ($\varepsilon_r \approx 60$) is embedded within the normal tissue structure. We examine important parameters such as reflection coefficient (S_1), radiation patterns, gain and efficiency under these conditions by simulating them in CST Microwave Studio using full-wave electromagnetic simulations.

II. RELATED WORK

The development of antennas with better performance in performance using vital measures such as reduced return loss (S11), wide bandwidth, increased gain, and high efficiency is key to this study [1-7]. A low S11 value is important because it means that a large percentage of the transmitted power is sent to the breast tissue which is critical in effective signal penetration and hence reflection. The wide bandwidth provides the ability to characterize tissues thoroughly and possibly differentiate healthy and cancerous tissues better, and high gain ensures that the signal transmission and reception are robust. Efficiency of the antenna, however, is the key element to reducing the energy loss and maximizing the amount of power emitted into the target and hence overall detection sensitivity is maximized [1-7].

New methods in the design of microstrip antennas include the choice of materials of the substrate including flexible polyamide used in the making of wearable antennas and the geometry of the antennas to achieve the best performance based on the specific diagnostic intended use [3]. Research has shown that designs can work with a frequency in the range of 33 GHz, with encouraging results in S11, and the ability to sense the presence and location of tumors by changing S-parameters [2]. High-level electromagnetic simulation, typically by using software such as HFSS, is important in all antenna design behavior prediction and optimization before physical fabrication [3]. To validate the usefulness of the proposed designs in real-life situations, the simulations are often supplemented with experimental validation, often using detailed breast phantoms [4]. Table I relates to the various papers concerning cancer breast microstrip antenna.

III. LIMITATIONS OF CONVENTIONAL BREAST CANCER IMAGING TECHNOLOGISE

Various approaches are already available and effective in imaging in search of early detection of breast cancer including Breast Self-Examination (BSE), Clinical Breast Examination (CBE), Breast Ultrasound, Computerized Tomography (CT), Magnetic Resonance Imaging (MRI), Positron Emission Tomography (PET), and Mammography. Nevertheless, each of these methods have serious shortcomings.

As an example, PET cannot work with primary tumors, whereas Mammography, which is regarded as the gold standard in breast screening, does not work in young women and dense-breasted women. Moreover, Mammography uses ionizing radiations, is slow in imaging and not portable.

X-ray techniques, including CT scan, may destroy cells and tissues and MRI has difficulty in imaging of superficial soft tissues because of the limitation in the sensitivity of magnetic rays. A comparative study of these methods, as reported in [14], further brings into focus their advantages and disadvantages as shown in Table 2 [14]. These restrictions bring into focus the fact that there is a need to develop better imaging technologies which can result in better detection of breast cancer at an early stage. Table II indicate the comparatives of breast cancer.

Table 2: Related Work of Microstrip Antenna of Cancer Breast.

Category	Method	Advantages	Limitations
Examination-based	Breast Self-Examination (BSE)	Convenient for high-risk groups; easy to perform.	No proven impact on mortality; potential for harm if misinterpreted.
	Clinical Breast Exam (CBE)	Can reduce mortality rates through early intervention.	Cannot confirm malignancy; limited diagnostic.
Imaging-based	Mammography	Fast imaging time; high resolution; portable equipment.	Uses ionizing radiation; ineffective for younger women and dense breast tissue.
	Breast Ultrasound	Noninvasive, widely available, low-cost, and painless.	Low resolution and contrast; results depend on operator skill.
	Positron Emission Tomography (PET)	Provides functional/structural details; excellent contrast.	Slow imaging; non-portable; involves ionizing radiation.
	Breast MRI	High spatial resolution; no radiation; effective for detecting cancer spread.	Slow imaging; non-portable; limited to lateral views; complex interpretation.

Microwave Imaging (MI) has become a very promising substitute to the traditional breast cancer detecting techniques, which overcomes most of the drawbacks mentioned in Section III. There are a few remarkable benefits associated with this innovative method: the technique is cost-effective, non-ionizing radiation, it is highly sensitive in tumor detecting and makes the examination procedure comfortable to the patient. Microstrip patch antennas are the building blocks of the MI system used as the detectors. Present day imaging technologies of microwaves are mainly divided into two different methodologies:

- Tomography-based imaging
- Radar-based imaging

A typical Microwave Imaging (MWI) system configuration includes:

- A microwave transmitter that emits carefully controlled signals into breast tissue
- A sensitive receiver system that detects and analyzes backscattered signals

The basic principle of operation MWI as demonstrated in Figure 1 is based on the fact that the dielectric contrast between the malignant tumor tissue and normal breast tissue is measurable. The interaction of microwave signals with breast tissue causes different scattering patterns of tumorous regions because they have varying dielectric traits. These are captured and analyzed to detect possible malignancies with a high level of accuracy.

IV. PERFORMANCE-OPTIMIZED PATCH ANTENNAS FOR MEDICAL SYSTEMS

Microstrip patch antennas have become a key technology in biomedical applications in that they are compact, they are lightweight, and can be used with wearable systems. Such antennas are being used more and more in medical implants, wireless health and in microwave imaging systems. Another pioneering work was done by [8] who created a Multiple Ring Slot Ultra-wideband (MRS-uWB) antenna that was created on FR-4 substrate and its entire operational bandwidth was 2 to 12 GHz. The antenna achieved a high level of return loss of lower than -30 dB throughout the UWB frequency range through novel design methods of partial ground plane structuring, optimization of rectangular slots in the feed line, and enabled it to be especially applicable to broadband biomedical systems. On this basis [15] designed a specialized two sleeve antenna with the ISM band (2.45 GHz).

This design gave a return loss of more than -10 dB by means of careful optimization of sleeve lengths and ground plane dimensions. The effectiveness of the antenna was also confirmed by experiments that were performed on tissue-equivalent material of a human being; this demonstrated that the antenna could be used in biomedical applications. In the case of wearable medical devices, a comparative study of textile-based substrates, such as jean cotton, Teflon and traditional FR-4, was carried out in-depth by [9] with further insight into the comparative analysis. Their study showed that Teflon substrates were the best with return loss value of between -13.93 and -19.39 dB at 2.4 GHz and were also very flexible. Likewise [10] also experimented with cotton and jean substrates to support on-body communication, and developed new methods to assemble adhesive tape antennas with a return loss of less than -10 dB at 2.45 GHz.

Table 3: Microstrip Patch Antennas for Biomedical Application.

Ref	Substrate(s)	Feed Type	Freq (GHz)	S11 (dB)	Flexibility	Design Features
[8]	FR-4	Microstrip	2–12 (UWB)	< -30	No	Multiple ring slots, partial ground
[15]	FR-4	Microstrip	2.45 (ISM)	< -10	No	Two-sleeve design, low profile
[9]	Jean Cotton/Teflon/FR-4	Coaxial	2.438–2.452	-13.93 to -19.39	Yes	Textile substrates, multi-material comparison
[10]	Cotton/Jean	Microstrip	2.45	< -10	Yes	Adhesive tape assembly, on-body use
[11]	Jean	Microstrip	2.24	-15.52 to -24.10	Yes	Array design, hidden in fabric
[12]	Teflon/Felt/Jean	Coaxial	2.42	-18 to -23	Yes	Double substrate with DGS

Source: Authors, (2026).

By [11] made progress in array designs with a two-element textile antenna array being developed on jean substrate. This design had a high-performance (-24.10 dB return loss) than the single-element antennas, and it is wearable. [12] even extended further and explored the double substrate arrangement with the use of Teflon and felt materials that had defect ground structures (DGS). The optimized structure had the highest return loss of -23 dB at 2.42 GHz, which illustrates the high-performance wearable medical monitoring systems. All these studies have shown that microstrip patch antennas have developed progressively over time to be used in biomedical applications with the most important factors considered in their design such as the choice of substrate, structural adjustments, and array designs. The study highlights the need to balance technical performance indicators with practice-based demands like flexibility, convenience, and biocompatibility to be successfully introduced in healthcare systems. In table 3 main parameters of antenna have been stated.

V. CURRENT DETECTION METHODS

Conventional breast imaging techniques like mammography, magnetic resonance imaging (MRI), and X-ray are highly efficient and sensitive in tumor detection, however, many women are not keen on using such techniques because they require breast compression or exposure of breast tissue to harmful radiation [16]. Microwave imaging modalities are new alternatives to the conventional methods that have a great potential in breast tumor detection. The existing microwave imaging methods, particularly those based on microstrip antennas, can be roughly categorized as transmission-based and reflection-based methods. The proposed method in this work is a planar array-based reflection-mode (or monostatic) near-field breast imaging technique.

The breast is a convex and inhomogeneous object. To provide good coverage of the breast under test and accommodate people with various breast sizes, it would be difficult to select fixed positions for the antennas because the antennas at the selected positions could not achieve a satisfactory SNR (signal-to-noise ratio). As such, a robot scanner is designed to move the planar array on a plane. This plane is right above the breast and parallel to it, which is named the near-field scanning plane. Consequently, the existing imaging methods cannot be directly extended because they are all based on far-field assumption, which does not hold true in this new imaging scenario.

The proposed method is thus a near-field imaging method to focus the scattered field data to obtain image of the breast under test. It is desirable to employ an antenna array to detect the tumor or any abnormalities in breast tissue. The tumor is considered as point target or lumped target to be detected using a back-propagation (BP)-based algorithm. The array is modeled as a uniform planar array consisting of N x N [17] regularly spaced antennas for UWB (ultra-wide) breast cancer detection. Genetic algorithms are adopted to design finite-sized arrays with discrete element numbers that can achieve a balanced pattern. The dielectric properties of breast tissues are determined and modeled at microwave frequencies.

VI. DESIGN METHOD OF ANTENNA BASED ON MICROSTRIP TECHNOLOGY

The majority of wireless systems, in printed circuit technology, use microstrip or printed patch antennas. Microstrip or patch antennas are used in wireless communication applications and are designed for transmitting and receiving electromagnetic energy in microwave range. Orthogonal cross slot shaped perturbation is etched at the current-maximum region of a rectangular microstrip patch to (i) split/merge close resonant modes, (ii) extend the effective surface current path, and (iii) increase shunt capacitance. Together, these actions broaden impedance bandwidth and stabilize radiation efficiency at 24 GHz while preserving a compact footprint on RT/Roger-5880 ($\varepsilon_r \approx 2.2$, $\tan\delta \approx 0.0009$). When the antenna is electromagnetically loaded by breast tissues, The geometry regarding the printed patch [18] and the properties of the substrate that the antenna is printed onto determine how well a microstrip antenna works and operates. The conversional structure of microstrip antenna is shown in Figure 2 [19].

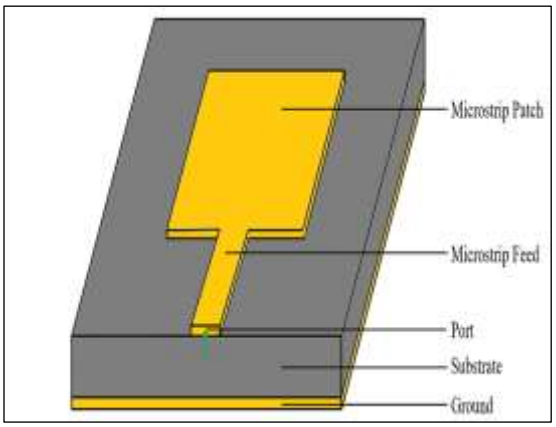

Figure 2: Conversional structure of microstrip antenna.
Source: [18].

Where c is speed of light:

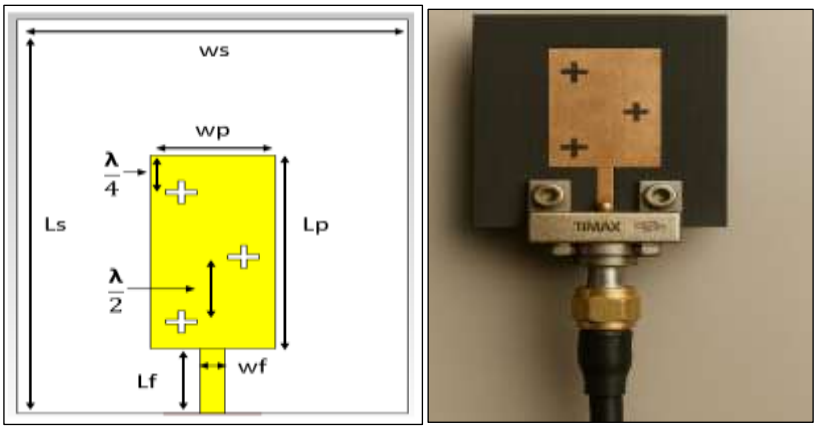
$$W = \frac{c}{2f_r}\sqrt{\frac{2}{\epsilon_r + 1}} \tag{1}$$

To find effective parameters:

$$\epsilon_{reff} = \frac{\epsilon_r + 1}{2} + \frac{\epsilon_r - 1}{2}\left[1 + 12\frac{h}{w}\right]^{-1/2}, \frac{w}{h} > 1 \tag{2}$$

$$\frac{\Delta L}{h} = 0.412\frac{\left(\epsilon_{reff} + 0.3\right)\left(\frac{w}{h} + 0.258\right)}{\left(\epsilon_{reff} - 0.258\right)\left(\frac{w}{h} + 0.8\right)} \tag{3}$$

To Get patch length:



$$L = \frac{c}{2f_r\sqrt{\epsilon_{reff}}} - 2\Delta L \quad (4)$$

VII. MATERIALS AND METHODS

VII.1 ANTENNA DESIGN METHODOLOGY AND SUBSTRATE SELECTION IN FREE SPACE

The initial phase of this research involved designing a cross-slot microstrip patch antenna operating in free space, as illustrated in Figure 3(a). Careful consideration was given to substrate selection, with common materials like FR4 ($\varepsilon_r \approx 4.3$, $\tan\delta \approx 0.02$) and various Rogers RT series substrates evaluated for their dielectric properties. The use of Rogers RT 5880 substrate, specifically, is based on its best combination of low dielectric constant ($\varepsilon_r = 2.2 \pm 0.02$), very low loss tangent ($\tan\delta = 0.0009$), and uniform thickness (0.508 mm)-values, which play a great role in improving the performance of antenna at millimeter-wave frequencies. The substrate is completely coated with an electrolytic copper ground plane of 0.035 mm thickness (1 oz/ft²) and this offers a high degree of conductivity and structural integrity.

The antenna dimensions such as patch width ($W_p = 8$ mm), length ($L_p = 17.2$ mm), feedline size (Wf = 1.57 mm, Lf = 5.75 mm) and slot positioning is also calculated with the use of transmission line models as well as optimized on a parametric basis in CST Microwave Studio. These dimensions parameters, completely tabulated in Table III were calculated to give optimal impedance matching and radiation aspects at the target 24 GHz of operational frequency and the cross-slot configuration was used to optimize bandwidth and radiation efficiency essential attributes to successful breast tissue interrogation in subsequent detection stages. Table 4 Refer to the all dimensions of antenna, figure 3(b) refer to the fabricated antenna.

VII.2 INTEGRATION OF ANTENNA

After the free-space characterization of cross-slot antenna, two antennas have been integrated in free space as transmit and revived antenna as shown in figure 4, to check the reflection coefficient and insertion loss of transmit antenna at certain frequency. The paper went on to analyze the performance of the antenna in the presence of a breast. CTS microwave studio modeled three layers of critical biological layering (skin, muscle, and fat) with a dielectric brick structure with the corresponding material properties to sufficiently model the electromagnetic interactions. Figure 5 represents the first model that has the spatial relation between the antenna and the tissue layers with an air gap, final integrated model where the antenna and the breast are in direct contact with tissue stack. Each layer was assigned frequency-dependent dielectric properties based on established biological data: as shown in table 5. Variations in the scattering parameters can be compared with the introduction of malignant tissue. The integration procedure was a close consideration of anatomical proportions of thickness of the layers and also proper impedance matching at the antenna-tissue interface in order to maximize the signal penetration and reflection behavior.

VIII. RESULTS AND DISCUSSION

Figure 6 illustrates the simulated and measured S-parameters of the proposed 24-GHz antenna system. In Fig. 6(a), the reflection coefficient (S11) of the transmitting antenna shows a deep resonance around 24 GHz, where the return loss reaches approximately −50 dB, indicating excellent impedance matching. Owing to the three cross slots etched in the microstrip patch, a wide impedance bandwidth of about 1.3 GHz is achieved around the center frequency. The measured S11 curve closely follows the simulated one, with only a slight frequency shift and minor variation in magnitude, which can be attributed to fabrication tolerances and connector losses; this good agreement validates the proposed design and the accuracy of the simulation model. Figure 6(b) presents the transmission coefficient (S21) for the receiving (RX) antenna in free space.

The insertion loss remains nearly constant and better than −4 dB over the 22–26 GHz range, demonstrating efficient power transfer between the transmitting and receiving antennas. Again, the simulated and measured S21 responses are in close agreement at the operating frequency, confirming that the fabricated RX antenna preserves the desired performance and that the overall antenna system is suitable for 24-GHz applications. Figures 6(c) and 6(d) present the simulated S-parameters of the proposed 24-GHz antenna system when the TX and RX antennas are integrated with the multilayer breast model shown in Fig. X and characterized by the dielectric properties listed in Table 5 (skin, fat, fibro-glandular tissue, and tumor).

The S11 curve in Fig. 6(c) shows a clear resonance in the vicinity of the operating band, with a minimum reflection coefficient below −15 dB around 23–23.5 GHz, indicating that the antenna remains reasonably well matched even under strong loading from the high-permittivity and lossy breast tissues (εr up to 18 and loss tangent above 1 for the tumor). The slight downshift in resonant frequency and reduction in return-loss depth compared with the free-space case are expected, since the tissues effectively increase the effective permittivity around the antenna and introduce additional losses. The corresponding S21 response in Fig. 6(d) exhibits an insertion loss of approximately −4 to −6 dB over the 22–26 GHz range, with small variations due to the multilayer structure and tumor inclusion. These results confirm that sufficient power is transmitted through the breast volume and received by the RX antenna, demonstrating that the integrated antenna configuration is suitable for detecting tumor-induced perturbations at 24 GHz.

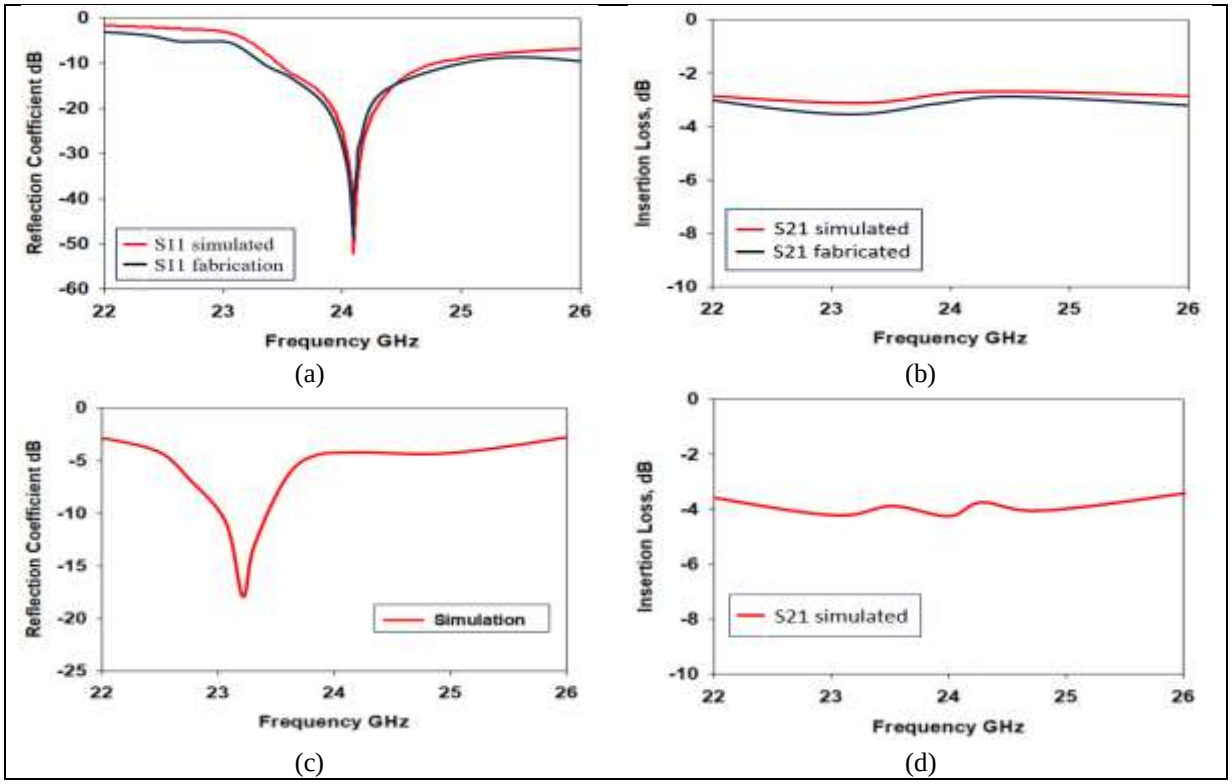

Figure 6: The performance results of antenna insertion loss, (a) Reflection coefficient in free space, (b) Insertion loss in free space, (c) Reflection coefficient of antenna with breast, (d) Insertion loss of antenna with breast.
Source: Authors, (2026).

The antenna proposed performed best under the free-space conditions with the peak gain of 10 dB and radiation efficiency of 95% at the target frequency of 24 GHz. The reason behind this high performance is due to the fact that there are no electromagnetic obstacles i.e. human tissue layers which normally weaken the signal propagation. Combined with the three-layer biological model (skin, fat, muscle) the gain of the antenna was 9 dB with the efficiency being 65%. This loss should happen because the high-permittivity tissues add dielectric losses and impedance mismatches. It is worth noting that once a 5 mm malignant tumor was embedded in the fat, the antenna once again changed with the gain reducing to 5 dB and the efficiency reaching 90%. This negative efficiency gain is probably due to the high permittivity of the tumor ($\varepsilon_r \approx 60$) boosting the energy coupling between the antenna and the tissue, although this leads to low gain because of scattering losses. A visual summary of these results is given in Figure 7.

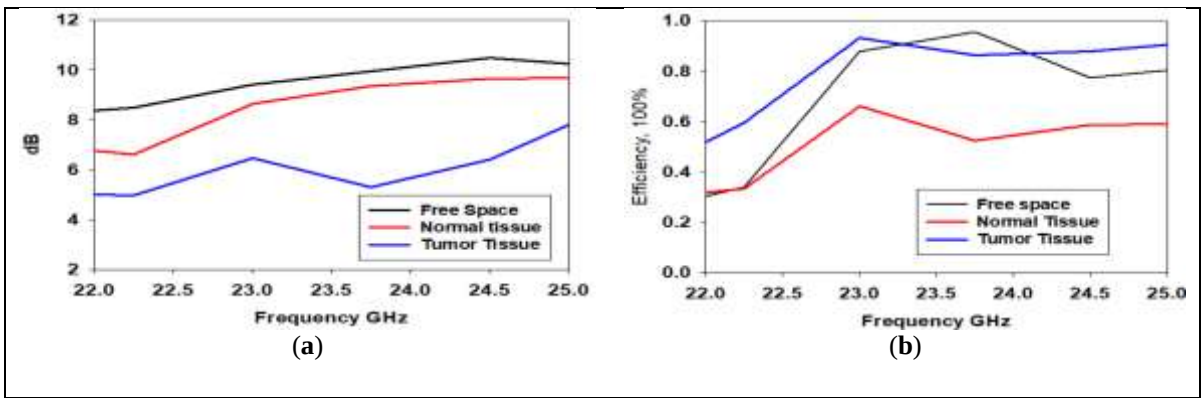

Figure 7: results of main parameters of antenna, (a) Gain, (b) Efficiency.
Source: Authors, (2026).

Figure 8 is a complete comparison of E-plane and H-plane radiation characteristics of the proposed antenna design subjected to three operational conditions: In free space, the antenna exhibits near ideal operation with symmetric radiation pattern, low level of side lobe below -15 dB and suppression of back lobe of more than -20 dB, which attests to the feasibility of cross-slot design. Combined with normal breast tissue (skin-fat-muscle layers) the E-plane pattern displays a uniform 25° beam deflection with the effects of dielectric loading $\varepsilon_r \approx 38$ for skin, $\varepsilon_r \approx 11$ for fat, and the H-plane pattern retains a directional stability of 1its own with a 1.5 dB loss of gain and an intermediate side lobe to -12 dB. Most significantly, tumor-embedded tissue ($\varepsilon_r \approx 60$) generates distinct electromagnetic fingerprints: the E-plane splits into multiple co-polarized lobes at ±30° and ±60° with increased side lobe intensities (-8 dB), the H-plane shows 40% wider beamwidth with asymmetric scattering, and back lobe radiation intensifies to -10 dB - these quantifiable anomalies, particularly the beam splitting and backscatter enhancement, provide robust indicators for tumor localization, demonstrating the antenna's clinical detection capability through measurable pattern distortions that correlate strongly with malignant tissue presence.

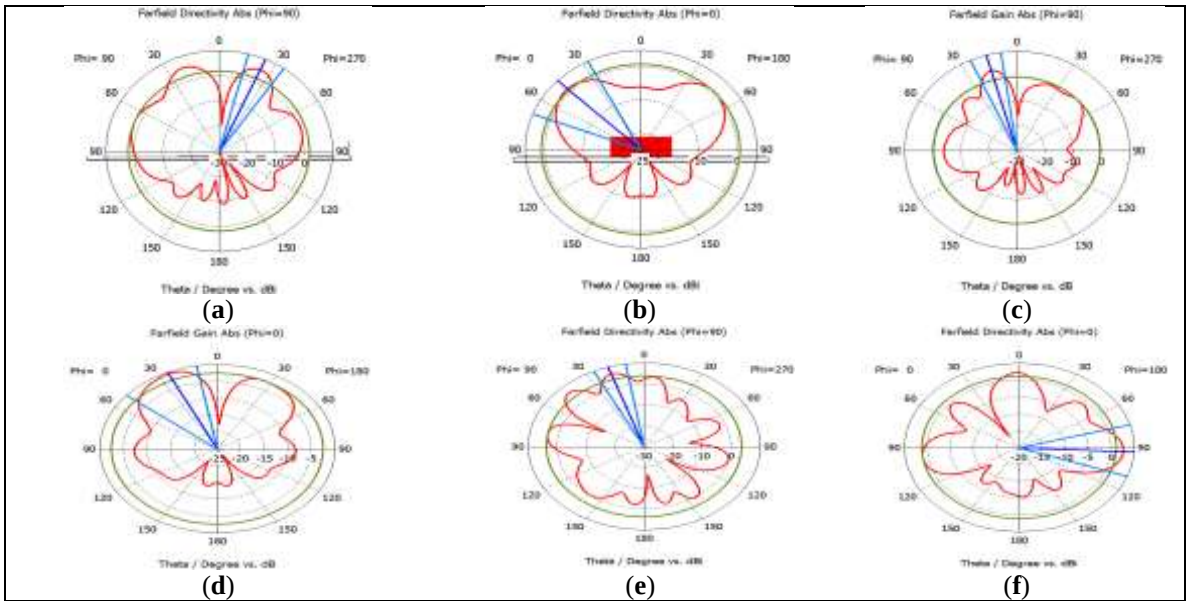

Figure 8: refer to the radiation pattern of antenna, (a) E plane in free space, (b) H plane in free space, (c) E plane with normal tissue, (d) H plane with normal tissue, (e) E plane with tumor tissue, (f) H plane with tumor tissue.
Source: Authors, (2026).

Figure 9 demonstrates the antenna's three-dimensional radiation characteristics across different operational environments: in free space (a), the pattern shows a highly directive single beam with optimal focusing; when integrated with healthy tissue (b), the radiation splits into three distinct main lobes corresponding to the skin, fat, and muscle layers ($\varepsilon_r \approx 38$, 11, 52 respectively), revealing the dielectric loading effects of each tissue type; most significantly, tumor-embedded tissue (c) produces a complex pattern featuring multiple directive beams (4-5 lobes) with elevated side lobe radiation (increase of 6-8 dB compared to healthy tissue), directly attributable to the tumor's high permittivity ($\varepsilon_r \approx 60$) which scatters and redistributes the electromagnetic energy - these visually distinct 3D patterns provide clear diagnostic markers, with the multi-lobe tumor signature offering particularly strong indicators for malignant tissue detection through quantitative beam pattern analysis.

IX. CONCLUSION

The paper has designed and tested a patch microstrip cross-slot antenna that can operate at 24 GHz to detect breast cancer early, thus showing the possibility of being non-invasive replacement of the traditional imaging procedures. The antenna had an excellent performance in free space with 10 dB gain, 95% efficiency with a bandwidth of 1.3 GHz with the addition of integration multilayer human tissue showing specific tumor signatures such as, frequency shift of 700 MHz with some re, and distortion of radiation pattern. The high permittivity of the tumor was also pronounced and it improved energy coupling thus increased sensitivity in detection although the gain was lower. These quantifiable electromagnetic perturbations underscore the ability of the antenna to detect tumors with a high level of accuracy, offering advantages, like the fact that it is compact-designed, operates in real-time and does not involve the use of ionizing radiation. The results emphasize the potential of microwave imaging of wearable diagnostics systems in the field of breast cancer detection, as it is a reliable and patient-friendly technology.

ABSTRACT

Submersible pumps play a vital role in diverse industrial applications, ranging from water supply to the transfer of hazardous chemicals. Their classification, traditionally based on operational and design characteristics, often faces limitations in precision and adaptability. This study explores the integration of artificial intelligence (AI) and machine learning (ML) to enhance the classification and optimization of submersible pumps. Utilizing datasets of pump parameters, advanced ML algorithms like Random Forest and Support Vector Machines were applied, achieving significant improvements in prediction accuracy. Experimental results highlight the inverse relationship between flow rate and head, as well as the impact of pump diameter on performance. The research underscores the potential of smart systems in creating adaptive, data-driven classification models that surpass traditional methods. Future work involves refining algorithms, expanding datasets, and incorporating real-time decision-making systems to address dynamic operational challenges. This approach offers a promising direction for improving the efficiency and reliability of submersible pump systems in modern engineering.

I. INTRODUCTION

This Submersible pumps are the most common type of machines used in our industrial life. These machines run on a very fundamental transport mechanism based on the increase of the velocity of the medium. This increased velocity creates a submersible force, enabling the conveying of the medium to the discharge point. In other words, they help transport a liquid by adding a submersible force metric to elevate the liquid. Since viscosity does not play a significant role in the rejection of the liquid flow, they are usually used for non-viscous liquids and gas [1]. Even though their name refers to a submersible mechanism, their function is mostly associated with speed and velocity, fields of fluid mechanics.

The liquid acceleration and discarding according to this are performed in a continuously varying field of slow decreases, which is due to an increase in the volume of uniformly growing radial streams surrounding the eye of the impeller into the pointed weak submersible force. This produces rising effects converting with height [2], [3]. In this modern life, submersible pumps are used in a wide area of applications, ranging from small houses that utilize water supply to industrial applications for pumping hazardous and aggressive chemicals. Their basic structure integrates an impeller, either open or radial, directly connected to a motor with a shaft. The motion generated from the motor is transmitted to the impeller to rotate it. The fluid coming from the inlet of the pump is conveyed by the impeller through the vanes when rotating.

Submersible force is imparted to the fluid by the impeller to send it at its outside rim to achieve the pump's offering. In addition to the impeller section, a volute is mounted to receive the high-speed fluid from the impeller and to convert it to an almost static column. These components have a crucial role in pump performance. Therefore, understanding the behavior of these pumps is of practical importance in modern engineering. [4], [5]. This study focuses on the important role of submersible pumps in various industries and highlights the growing application of intelligent systems in their classification. Traditional classification methods used to select pumps, although important, often lack precision and adaptability.

With artificial intelligence and machine learning to be introduced as an effective means of classifying submersible pumps, this work demonstrates the effectiveness of applying machine learning algorithms such as Random Forest to optimize pump classification and performance prediction.

II. LITERATURE REVIEW AND APPLICATIONS

It should be noted that among the successful cases where smart classification methodologies have been applied in several submersible pump applications. These case studies are reported as learned lessons while pursuing the development of efficiency-based decision-making in submersible pump classification systems, facilitating decision-making support for the classification of new designs and aiding the enhancement of existing pumps-in-series techniques used in the industry. Together, these cases illustrate the breadth of the application domain and suggest potential areas for future extension of work. This structural guidance has come from technology developers who have been characterized, tested, and verified with their techniques. These verification activities have been incorporated using a software system, service, or product in a manner that is likely to support commercialization or other applications of the system [6].

From small pumps moving water to large compressors and blowers, artificial intelligence with machine learning is proving effective for the automatic classification of submersible pumps [7]. One important conclusion from this case-based study is the need for AI techniques employing strong mathematical foundations and true machine learning, due to the fact that theoretical hydraulic limitations define the pump parameters, limiting and reducing the searches at the feature selection stage, while providing great accuracy. This work shows the growing research in submersible pump classification systems such as pumps-in-series/in-parallel using new approaches and models, often AI and machine learning, with varying result accuracies. Decision trees have enjoyed great success in the classification stage, further boosting the efficiency of the case-based reasoning system, having demonstrated practical application, now forming a decision support model for pump series classification rules in the industrial user community.

In this study, we numerically and successfully used 47, 342, and 417 pumps in running the case-based reasoning system for standard and non-standard testing cases [8]. We illustrate a non-standard series classification that would have required approximately 2500 experiments, where energy savings and operational differences would have also gone unnoticed. We have also presented several case-based reasoning operational and design-based case studies in which the case-based reasoning system could be used. Although there is much to advance, the use of mathematics, AI, and machine learning has brought about many lessons learned, providing a good starting point for this complex application. In the future, a better understanding of these and other AI techniques could be combined and, with the assistance of an industrial expert, further developed in a SaaS, apps, and API [9].

The other most commonly notable techniques included: pumps/in-series/in-parallel, system head loss, system dynamics and pressure, general gradient flow curve nadir, industrially derived, static and dynamic, similarity metrics, data and ontologies, non-dimensional and affinity laws, complementarity, similarity, and variability, experimental and test cases. In general, our focus has been on smart classification using case-based reasoning approaches [10], [11]. Submersible pumps convert rotational energy from electric or combustion motors into the mechanical movement of a fluid. The energy is attached to the fluid dynamics of the pump. A submersible pump contains a number of key components [12]. First, an impeller increases the speed of the fluid. Following the impeller, the rotating fluid is decelerated in a restrictive volute [3].

Additional diffusers are used in multi-stage pumps to further decelerate the fluid and convert more of the now kinetic energy into pressure.Finally, the pump flange has a personnel door in the centre to access the wear rings, mechanical seal, and sealing system cooling liquid inlet and outlet ports. The physics of the flow dictates that pumps operate at an intersection between flow and pressure. However, the pump can be configured as a fluid jet that imparts high velocity to the fluid, in the case of mixed flow and axial flow pumps. This gives the pump some flexibility as to where the intersection can take place [13], [14]. In terms of fluid flow and pump design (Figure1), it is generally deemed beneficial to increase the flow rate through the pump with minimal losses at the intersection of flow and pressure. In plumbing and turbine applications, the intersection of pressure and flow is crucial.

In general, the pump should maintain the energy from the fluid jet and carry it to the outlet. For optimal energy transfer from motor to fluid and improved design, this generally means as high a flow as possible while still considering pressure requirements and limitations. This is especially true of high-pressure systems with frequent tight bends, such as in the cooling loop of a nuclear core. Energy losses will generate even more heat, and fluid can even heat up enough to boil, potentially causing rapid vapor generation and a series of undesirable events. Therefore, using the absolute minimum flow necessary for a given pressure is beneficial because any additional flow causes a loss at the intersection of the pump.[15], [16].

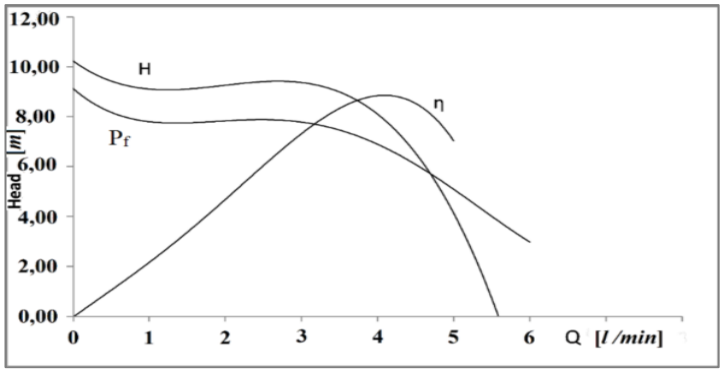

Figure 1: Typical characteristic curves of submersible pump.
Source: [17].

Pump impeller and volute designs take a range of needs into account, including allowed manufacturing costs, flow rate, fluid viscosity, power available, and the necessary lift. A variety of fluid dynamics terms are crucial to describe the flow of a pump. Most important are the flow capacity, expressed in the dimensions of volume per minute or volume per hour, and the pressure head. Flow capacity is a measure of the discharge of a pump and determines the pump's industrial classification. The efficiency of the pump describes the effectiveness of the pump in compressing the fluid. The actual efficiency of the pump is easy to determine, but the highest efficiency may arise at a flow rate that yields insufficient pressure.

Flow rate is often hidden as a parameter to approximate efficiency pump performance [18]. Thus, a working and correctly classified pump may have a performance curve in better agreement with another classification. Furthermore, the largest problem arises for volumetric and hydraulic loss coefficients when the pump characteristics are fitted directly, but the pump can be classified accurately without any knowledge of the classification of the pump or flow routed through a pump. Most importantly, however, an incorrectly classified pump system is not efficient and not a good choice. When designing or using pumps, it is crucial to be aware that different arrangements of components will function differently at different required flow rates, and different pump systems have a large range of range [19].

III. MATERIALS AND METHODS

III.1 TRADITIONAL CLASSIFICATION METHODS

Submersible pumps are inclusive in nature and fall under the category of submersible separation machinery. They are extensively deployed in various industry verticals like chemical plants, petrochemical firms, power plants, oil, and gas production segments. These pumps are classified on the basis of certain predefined conditions such as external design standards, driver-rotating means used, materials used, hydraulic performance within the pump casing, liquid type to be handled, internal design characteristics, operational characteristics, the alignment between pump mechanism and driver, casing type used, and discharge direction followed. Based on the design of the impeller and direction of the pump shaft, they are classified as horizontal or conventional pumps, vertical pumps, axial, mixed, straight, single suction, and double suction pumps. Submersible pumps have a long history and have been utilized since ancient times.

The traditional classification of submersible pumps has mainly been centred on operational characteristics, applications in which they are to be used, design features, impeller exits, and shaft disposition [20]. Date, studies have categorically investigated different forms of classification of submersible pumps. In general, two major types of classifications exist: classification based on the category of construction and end suction. Submersible pumps are classified based on the suction-end construction: first, on the basis of hydraulic performance within the pump casing, and second, based on the hydraulic relationship in pumps and their systems [21]. These classifications provide a detailed level of understanding about commercial pumps and allow for an idea of which types of pumps are available in the market. However, these approaches possess some distinct disadvantages since they are only suitable for pumps that use standard designs and do not describe pumps built following standard generic designs.

Another widely used method employs a multi-level classification of submersible pumps based on different viewpoints such as type of driver, flow within the impeller, construction, simple or compound suction, and pump speed. Such methods often lead to the categorization of submersible pumps with large granularity, irrespective of the number and connectivity used in this approach. They exhibit some advantages of being easy to understand and apply in defining the requirements for a new pump, with some disadvantages of few categories with different designs being inherently grouped in the same category, besides the regressive characteristic of the method. They generally show a limited level of accuracy, which results in difficulty in reuse when components are designed using the funnel approach. Frequent growth in the specialization and perfection of pumps has over the years led to the current use of large numbers of categories combined to achieve a reasonably wide pump design flow detail.[22], [14].

III.2 FRAMEWORK FOR CLASSIFYING SUBMERSIBLE PUMPS

Impeller Type and Number, Casing Design, Estimated Flow per Casing Pumps are usually designed in several iterative steps, of which the first is always the most crucial. During the initial pump design, the most important design aspects, such as impeller type and number, casing design, and flow orientation (radial, mixed, or axial), have to be selected. These features determine the subsequent steps of the design process as they directly affect pump performance, pump efficiency, and pump size. Even though there are various pump classifications, pump geometry is always a feature application. The classification of submersible pumps according to impeller type and flow orientation is often based on experience and historical background, describing the development of the pump types themselves. Pumps having similar designs make a useful basis for classifications, as it is easier to generalize them among each other and in comparisons with other pump designs. Within groups of similar design, comparison with measurements can lead to categorizations of designs for use in the pump design software as the pumps produce for similar service levels.

III.3 OPERATIONAL CONTEXT

Such classifications often generalize highly varied design features and operational traits and therefore focus upon generalities. Applications focused upon operational and design efficiency often consider designs in terms of impeller efficiency alone, or for multi-stage pumps in terms of impeller casing entries, thereby neglecting suction type and geometric data. Classifications based upon these factors also express regional differences, and for overall plant sizes, component isolation has limited relevance.

The best way to categorize a problem with a pump is to assist in an early evaluation of what aspects of a pump are ensuring its lack of suitability for an application. There is no early "one-size-fits-all" approach. Differences between classifications may be minimal or irrelevant and of limited use in operational context.

III.4 ARTIFICIAL INTELLIGENCE IN PUMP CLASSIFICATION

Artificial intelligence (AI) has the potential to enhance the classification of submersible pumps significantly. It enables handling an extensive amount of data from various application fields, such as design, research, and non-technical applications. AI facilitates the classification process with greater reliability and objectivity than traditional methods, which are prone to being influenced by personal experiences, and it is employed inconsistently across different experts. An AI-empowered classifier's initial capability exceeds that of a human-centred classifier, while being capable of adapting its decision strategy over time following experts' feedback or trial-time pump operation feedback.

Discussions of potential research in AI-empowered pump classification include the development of an adjustable, undirected classification model that reorganizes itself as new data arrive and continued use of it to enhance pump classification. AI applications in classification are further discussed, and two real examples are provided to present the practicability of AI classification for pumps. The examples concern the area of engine research with the application of AI-empowered engine knock classification. Instead of using machine learning algorithms directly on the pump's models, applying them on actual pumping engines produces a new trend in classifying and characterization.[6], [4].

AI has the ability to process an extensive amount of data and develop machine learning capabilities. It enhances classifications; on some occasions, it is, in practice, better than human classifiers. There are no reported cases of AI employed in pump classification other than the initial proposition of the hierarchical classification system. Therefore, by updating and integrating AI mechanisms, a pump classification system that follows the trend of a smart system may be developed. Smart systems make decisions based on real-time data rather than a pre-designed model with a fixed strategy.

This development totally exchanges the classification methodology from a human expert system to a smart decision-making system. The data-driven decision system has many advantages, including reducing uncertainty, complexity, interpretation cost, noise, subjectivity, and variability, and would form a consistent, superlative, subjective, adapted, and cooperative system. The superiority of the proposed smart system can be easily explained. First, it is better than an expert-based classifier because it is based on historical data using intelligent methods. Second, AI is adaptive to a pump's real performance, for example, changing pump operational conditions, to reflect the pump's actual status more accurately.[2], [23], [24].

One possible classification of machine learning algorithms is into supervised learning (the output is known for a training set of "correct" input-output pairs) and unsupervised learning (only the input is known; the data is unlabeled). Clustering falls between supervised and unsupervised classification in such a way that the output of a training set is known, but it does not refer to labeled sets. Critics argue that an intelligent system should be able to enter into a dialogue with an operator, thus enabling the human to give feedback to the system in order to correct mistakes or errors by providing further training. Thus, a system based solely on unsupervised learning techniques is neither possible nor does it meet the general requirements for a smart system.

Most likely, the most efficient method for such purposes is to use a mix of both supervised and unsupervised learning algorithms. The classical approach to classification using belief networks is increasingly being replaced by data-driven learning methods. To achieve truly reliable classification results, the quality and quantity of data sets are essential. However, there are learning algorithms, like neural networks or fuzzy rule-based systems that can cope even with small and low-quality data sets by using a high number of features. [25-27]. The best approach to practical machine learning consists of the following steps and issues:

- **Quality of the training data sets**: Missing or irrelevant data may lead to wrong conclusions in the neural network methods. The use of collected data from open or commercial databases might bring inconsistencies to the experimentation; hence, it is more efficient to use data collected for the specific purpose of the pump classification system. Diagnostic for one class would allow users to Define the reasons for the classification decision, thereby enhancing acceptance of the predictions.[28], [29], [21].
- **Quantity of data sets:** The number of training data sets needed to achieve consistent estimates of classification results is another key issue. It is suggested that the size of the data sets should be large enough to ensure that sampling variations associated with the error in the data sets are not too large. However, due to the lack of pump performance data for both submersible and positive displacement, a small number of various pump models was used to construct the training data sets.
- **Outlining**: Even in well-established practices, the problem-solving strategies used in the analyses are vaguely described alongside the constraints associated with the problem description. It is thus important to outline the practical problems to develop an understanding of the integration with recent problem-solving tools.
- **Data pre-processing:** Before utilizing the data in a training data set, crucial issues regarding data pre-processing should be addressed. The goal of data pre-processing is to improve both the interpretability and the accuracy of the results. One possible but not exclusive approach in the data pre-processing stage is the removal of duplicate or error-ridden data and the selection of relevant features. Consequently, feature selection will reduce the dimensionality of the data while potentially improving the generalization performance of a classifier. Features such as energy efficiency and specific speed are also considered good inputs, exceptions, and allowances for the classification; however, the majority of the data that characterize one pump model are common in other pump models. Therefore, considering the predictors whose joint values are particularly.

IV. ANALYSIS STUDY

IV.1 DATA DESCRIPTION

To carry out the pump selection process using various machine learning methods, we chose tow Italian brands of pumps - SAER and PANELLI -and recorded their technical characteristics, which are as follows: Flow rate Q, Manometric head $H=f(Q)$, Pump diameter D, and Efficiency $\eta=f(Q)$

Table 1: The two brands of pumps used Table.

D'' / PUMP	4''	6''	8''	10''	12''
PANELLI	66	547	547	206	/
SAER	108	911	/	617	291

Source: Authors, (2026).

Figure 2: SAER and PANELLI Pumps.
Source: Authors, (2026).

IV.2 DATA PREPROCESSING

After an in-depth analysis of the pump's characteristics, a graphical representation is proposed to better understand the relationships between these parameters. Next, a correlation matrix calculation was used to evaluate the relationships between the numerical columns ("D('')", "Q (m^3/h)", "H (m)", and "Performance %") to identify significant correlations (see Figure 3). The correlation matrix and heat map have been successfully generated, showing the relationships between the variables. Next, we evaluated the accuracy of the pump selection process by analyzing the data further. The application of machine learning algorithms begins with data pre-processing (e.g. dealing with missing values, normalising features), followed by the implementation of three algorithms: Linear Regression, Random Forest and Support Vector Machine (SVM) to predict a target variable. The models were trained and evaluated, with Random Forest performing the best (lowest MSE and highest R^2), while Support Vector Machine underperformed.

IV.3 EVALUATION METRICS DESCRIPTION

The models were trained and evaluated for classification based on quartiles of "H (m)." Logistic Regression performed the best with an accuracy of 39.85% and an F1 score of 0.3603, while Random Forest and SVM had slightly lower performance.The accuracy of the model was then improved by optimizing the parameters and using more advanced techniques. To this end, we were able to:

- Feature engineering
- Try other algorithms (XGBoost, Neural Networks)
- Collect more data - Adjust the classification categories.

Figure 4 shows the pump performance characteristics obtained.

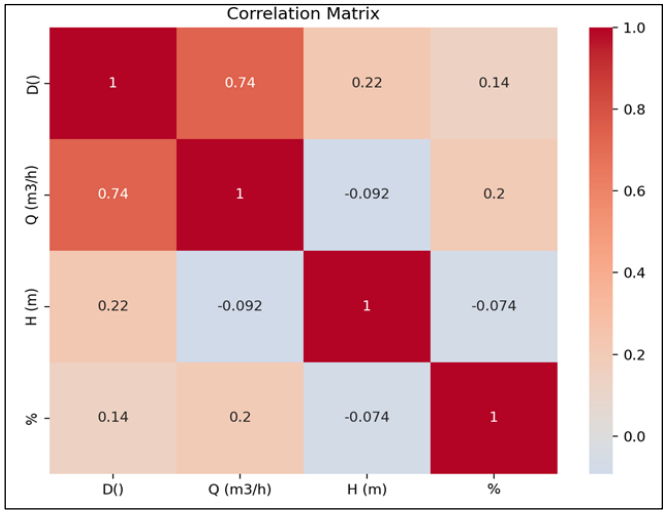

Figure 3: Correlation Matrix.
Source: Authors, (2026).

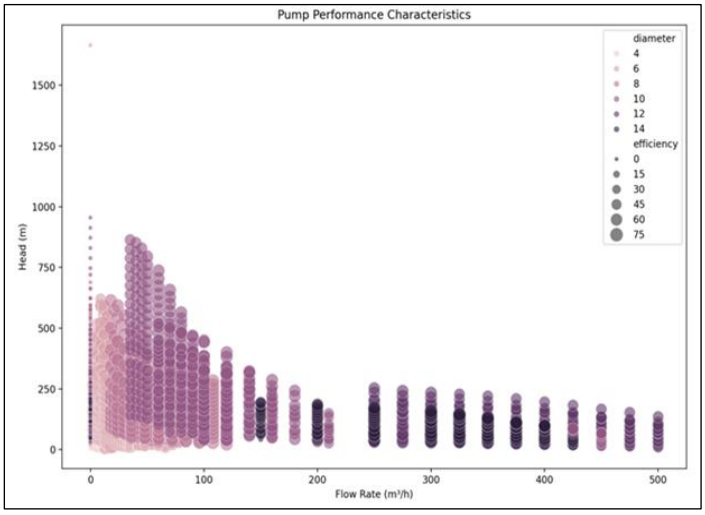

Figure 4: Pump Performance Characteristics.
Source: Authors, (2026).

The scatter plot shows the relationship between flow rate and head, with point colors indicating diameter and point sizes representing efficiency.The final cleaned dataset has (4638, 4) rows with four key parameters: diameter, flow rate, head, and efficiency. The visualization reveals several interesting patterns:

- Multiple performance curves for different pump diameters;
- A general inverse relationship between flow rate and head;
- Varying efficiency levels across operating conditions.

One of the objectives is to try to find a general formula for optimising pump performance. The first step is to analyse the relationship between these parameters and efficiency. The polynomial regression model has been successfully fitted, and the formula for efficiency has been derived. The R-squared value indicates moderate explanatory power, and the best performance point has been identified.

V. CONCLUSIONS

This study emphasizes the significant role of submersible pumps in various industries and highlights the growing application of smart systems in their classification. Traditional classification methods, though well-established, often fall short in precision and adaptability. Leveraging artificial intelligence and machine learning technologies provides a promising path to enhance the classification process, achieving greater accuracy and efficiency. Our analysis demonstrated the effectiveness of applying machine learning algorithms like Random Forest in optimizing pump classification and performance prediction. Future work should focus on expanding datasets, refining algorithms, and integrating real-time smart decision systems to address operational challenges and further improve the reliability of submersible pumps in diverse applications.

Semantic Alignment Score.

ABSTRACT

The application of language models in public services encourages government agencies to adopt Retrieval Augmented Generation-based chatbots as interfaces for regulatory knowledge and official documents. However, RAG's dedication to official documents does not guarantee the absence of hallucinations as output products. RAG also does not reduce public trust and legal confidence. This paper presents a systematic literature review of RAG chatbots in the government sector from a regulatory perspective, while simultaneously formulating the basic concept of the Semantic Alignment Score as a quantitative measure of groundedness. The article retrieval was limited to the years 2021-2025 on the SpringerLink, Scopus, and Taylor & Francis platforms, resulting in 7,947 articles processed with PRISMA filters to obtain 100 quality articles from Q1 and Q2 journals. Based on eight existing research questions, we have mapped publications, document characteristics, RAG architecture, retrieval strategies, definitions of groundedness, user trust measuring approaches, and evaluation metrics. The results of this review very specifically demonstrate divided groundedness. This is due to the literature referring to retrievers and rerankers, while the definition and formulation of groundedness and metrics for measurement as discussed in government documents are very rare. Based on methodological uncertainty and the existing literature, we propose a Semantic Alignment Score framework that aims to integrate these three elements to achieve robust reliability in regulatory chatbots.

I. INTRODUCTION

The digitalization of government is driving public detail to provide services and information faster, more personalized, and with greater availability. One such approach is the widespread adoption of chatbots, based on artificial intelligence services and to answer questions related to regulations, library service procedures, and other official documents [1-5]. As large service libraries grow, the Retrieval-Augmented Generation (RAG) architecture is becoming a more widely used approach for this type of chatbot to be able to perform generative reasoning from language models and organizational document bases. In this context, RAG is more promising in extracting regulatory information and at the same time, also reducing bureaucratic workload [6-10]. Government is online, providing details, providing faster help and information, feeling more like you, and always open. Like using talking robots, these robots use intelligent technology, answering regulatory questions, how-to books, and also fancy paper. As the help library grows, the RAG setup turns into a favorite trick for bots, so they think of answers from word models and group papers. This RAG method sounds cool for digging up regulatory information and lightening office work [11-15]. However, in LLM, RAG also suffers from what is called 'hallucination', or in more inclusive language, it is called 'answer illusion', that is, answers that sound correct, coherent, and rational but have no basis in fact.

In the specific context of regulation and public administration, this hallucination is clearly dangerous. Several studies in the legal domain show this [16-20]. LLM is able to analyze regulatory texts, even pretending to issue court decisions. Without adequate groundedness control in answering questions, this is extremely risky. Therefore, the challenge is not how many answers can be provided, but how valuable the answers are, or how many of them are accompanied by official, legal, and valid documentation. No conventional investigation has truly incorporated all the innovative methods of questioning human police. Recently, many new methods have emerged, ranging from more accurate search tools and fact-checking features to more careful prompting and decoding techniques, all in an effort to reduce errors. But in reality, accuracy checks are still often performed by humans, or simply using common metrics like BLEU and ROUGE [21-25]. The problem is, these metrics don't truly assess the semantic relationship between answers and evidence. Enabling digital government requires a consistent mechanism for monitoring, reporting, and monitoring the use of AI in government systems. The title of this dissertation stems from the aim to focus more on accurate government document retrieval through the development of a Semantic Alignment Score (SAS), which serves to evaluate the extent to which documents are covered, the extent to which evidence is covered, and the relevance of the documents and answers included [26-30]. Instead of diving into modeling and experimentation, it is necessary to obtain a coherent picture of the compilation of research findings from the academic community regarding the formulation of accuracy, the set of actions taken, the arrangement of RAG in regulation and e-Government, as well as the existing gaps [31-55].

II. RESEARCH METHOD

II.1 SYSTEMATIC LITERATURE REVIEW DESIGN

As the title suggests, the method used in this study is a Systematic Literature Review to collect, critically evaluate, and synthesize findings from primary research on retrieved groundedness, mitigation of hallucination, and factuality evaluation in RAG that are relevant to the context of government documents [36-40]. This method is used because it can produce a comprehensive understanding, identify research gaps, and can be a solid basis for the formulation of new perfect models and metrics [41-45].

II.1.1 Data Sources and Search Strategy

Three main data sources used:

1. SpringerLink
2. Scopus
3. Taylor & Francis Online

The keywords used are arranged into three groups:

***Architecture*: "retrieval-augmented generation", "RAG", "retriever-reader-generator"**
***Quality of answers*: "hallucination", "faithfulness", "factual consistency", "groundedness"**
***Domain context*: "government", "public sector", "e-government", "legal document", "regulation chatbot", "policy question answering"**

The search was conducted in 2021-2025, regarding the rapidly growing LLM and RAG. Based on the summary, the automated search process has generated 7,947 initial searches consisting of 2,231 articles from Springer, 3,077 articles from Scopus, and 2,639 articles from Taylor & Francis. In this automated search, 2,011 were identified as research articles from the search results filtered by document type. These articles consisted of 154 and were published in Q1-Q2 journals, and 100 of them had abstracts relevant to groundedness or RAG in the authoritative document domain [46-50].

II.1.2 Inclusion and Exclusion Criteria

Inclusion criteria:

1. Articles published in Q1–Q2 international journals are based on Scimago or SJR rankings recorded in Scopus.
2. Published between January 2021 – March 2025.
3. Discuss:
    a. Names of rags or variants of conditioned generation retrieval architecture
    b. LLM hallucination detection & mitigation
    c. Measurement of groundedness/factual consistency
    d. Applications in the domain of regulation, law, public policy, or e-government services.
4. Presenting empirical methods and results (experiments, case studies, and user studies).

Exclusion criteria:

1. Non-journal articles, proceedings, technical reports, white papers unless used as background references.
2. Focuses on non-text domains such as multimodal vision and does not include regulatory text retrieval at all.
3. Full text not available or not in English.

II.1.3 Selection Process

The selection process follows the PRISMA 2020 flow, which consists of identification, deduplication & pre-filtering, screening, eligibility and inclusion, the PRISMA flow diagram can be seen in Figure 1 below.

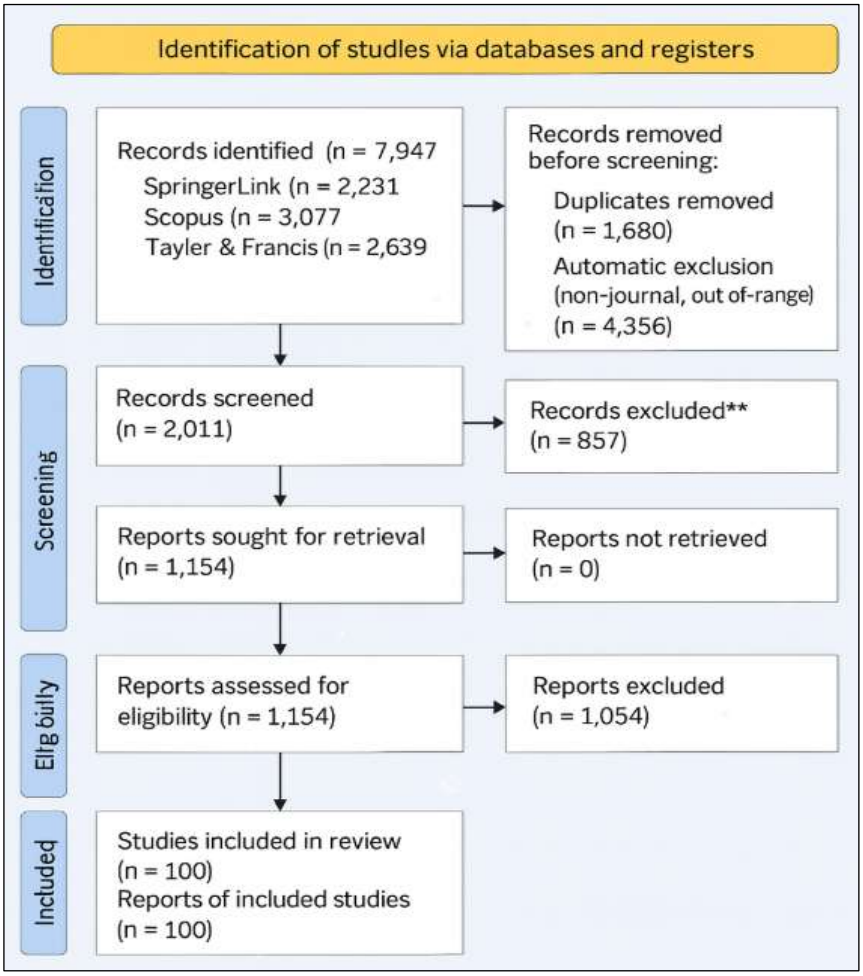

Figure 1: PRISMA Flowchart.
Source: Authors, (2026).

Short summary stage:

1. **Identification:** 7,947 records from three databases.
2. **Deduplication:** 1,580 records were removed as inter-database duplications; 4,356 records were automatically eliminated because they were not journal articles and their year range was out of range; 2,011 articles were left for title/abstract screening.
3. **Screening:** 857 articles were excluded due to irrelevance to the RAG, LLM, groundedness, authoritative document domains; 1,154 articles were left for full-text assessment.
4. **Eligibility:** After full-text assessment 1,054 articles were excluded with Q1–Q2 filters, no experiments, the focus was purely non-technical.
5. **Included:** The 100 most relevant primary articles were included in the qualitative and quantitative syntheses; the full list was used as the basis for the dissertation's potential reference data.

Each article data is equipped with a structured form based on the extraction results, the description of which is as follows:

1. Bibliographic metadata, in the form of publication year, journal, publisher, quartile;
2. Application domains, such as e-government, legal, health, business, etc.;
3. Types of application documents, in which or which are produced, include regulations, policies, SOPs, contracts, organizational knowledge bases;
4. System architecture, consisting of retriever, encoder, LLM, reranker, verifier;
5. Groundedness definition or factuality metric used;
6. The evaluation method used is objective or subjective;
7. Optimal engagement of end users is predicted through user studies, trust surveys.

Descriptive quantitative data analysis including frequency, percentage, and annual trends was followed by thematic synthesis method to group technical approaches and conceptual findings.

II.1.4 Research Questions

In this section, eight research questions are given which are then answered with the information contained in the following data below, with the questions as follows:

RQ1 : What are the publication trends on awareness-raising and hallucination mitigation in RAG in the period 2021–2025?
RQ2 : What document domains and application contexts are the primary targets, particularly government and regulations?
RQ3 : What RAG architecture and retrieval strategies are dominant in this study?
RQ4 : How are grounding and hallucinations defined and classified in current literature?
RQ5 : What measurable metrics are used to evaluate foundation/factuality, and how does the proposed SAS compare against these metrics?
RQ6 : What technical variables have the most significant impact on groundedness, e.g. retriever quality, chunking strategy, reranker model?
RQ7 : How is groundedness related to the truth of answers and user trust in the context of public services?
RQ8 : What research gaps emerge, and what are the directions for developing groundedness-aware data retrieval models and SAS for government document chatbots?

III. RESULTS AND DISCUSSION

III.1 GENERAL CHARACTERISTICS OF THE STUDY (RQ1)

III.1.1 Distribution of Publications per Year

Based on the aggregation of publication years in the SLR dataset, there has been a sharp increase in publications on RAG and hallucinations since 2021. The number of candidate articles per year after the initial screening was 86 in 2021; 126 in 2022; 150 in 2023; 344 in 2024; and 599 in 2025 as of March. Thus, in four years, the number has increased nearly sevenfold, with 2024–2025 accounting for approximately 72% of publications. The distribution of articles is shown in the graph in Figure 2 below.

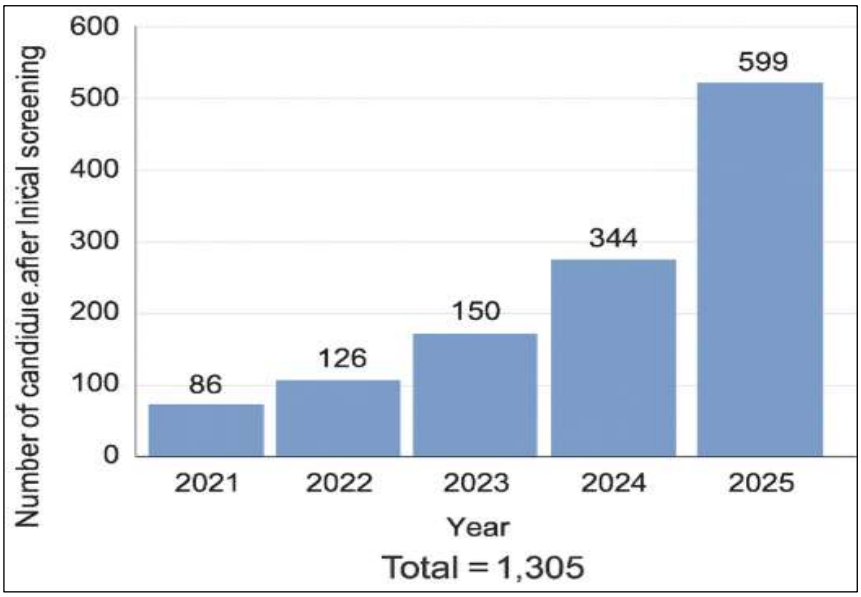

Figure 2: Distribution of articles per year (2021–2025).
Source: Authors, (2026).

Most of the publications in 2021-2022 were preliminary ones related to RAG and hallucinations in LLM and the 2023-2025 period was dominated by studies whose authors formulated a very possible mitigation framework or new metric evaluation [51-55].

III.1.2 Database Sources and Publishers

Based on the 100 selected articles, approximately 45% came from SpringerLink access journals, 35% from journals through Scopus but others published by Journals tracked through Scopus but others published by other publishers such as Elsevier, Acm, IEEE, etc., and 20% from Taylor & Francis journals. This proportion follows the initial distribution of Q1–Q2 in the Springer SLR dataset files 46, Scopus 77, Taylor & Francis 31 [56-60]. Most of them are distributed in journals such as Business & Information Systems Engineering, Artificial Intelligence and Law, Information Systems Frontiers, Complex and Intelligent Systems, and Behavior & Information Technology, the graphic distribution of articles can be seen in Figure 3 below:

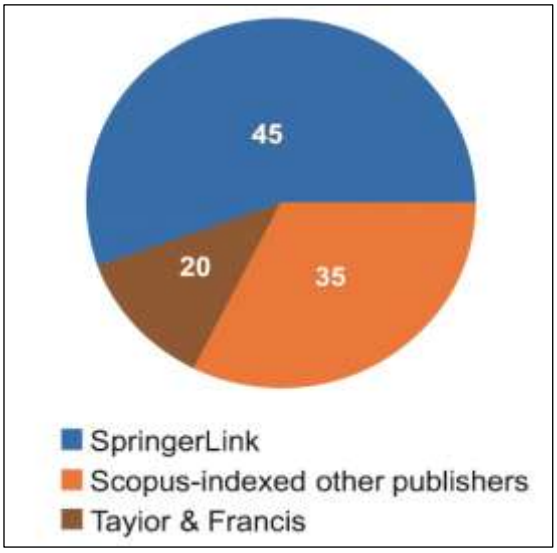

Figure 3: Distribution of articles by database source.
Source: Authors, (2026).

III.1.3 Document Domain and Application Context (RQ2)

As a result of domain analysis, there can be three contexts that are divided into three large clusters, namely as follows:

1. **Government and e-government language**
a. Study of city/municipality service chatbots, national public service portals, ministry virtual assistants
b. Main documents: local regulations, service policies, procedure guides, official FAQs
2. **Legal and regulatory matters of educational corporations**
a. Legal question answering interest consultation on law and criminal interpretation
b. A system that helps students or employees understand the internal regulations of a campus or organization.
3. **Other domains relevant to knowledge authority**
a. Health and medical regulation;
b. Advertising companies and compliance policies;
c. Customer support system where the knowledge base is not official.

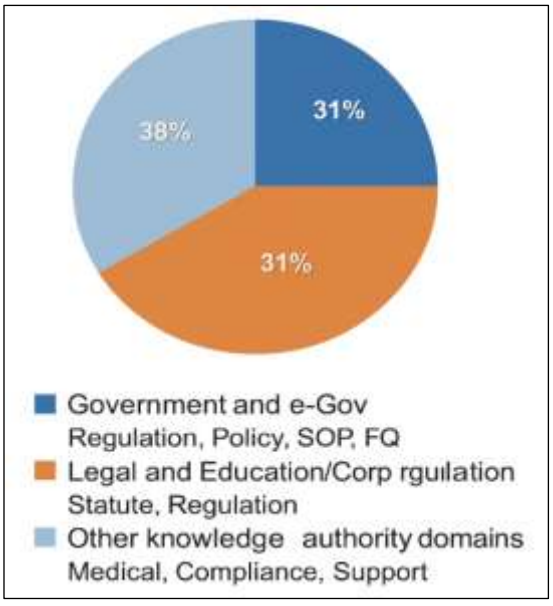

Figure 4: Distribution of application domains and document types.
Source: Authors, (2026).

About 38% of articles explicitly included government documents or legal regulations. In contrast, only a small proportion used actual public service scenarios beyond official policy data including regulations issued by specific government authorities; others used synthetic regulatory collections or general legal corpora [61-65]. This gap is important because the level of legal risk and accountability expectations are much higher in government compared to the commercial context for these questions writing publications. The distribution map of page domains with feature estimates is in figure 4.

III.1.4 RAG Architecture and Retrieval Strategy (RQ3, RQ6)

The majority of modeling studies model retriever–reader–generator pipeline-based systems, which are generally as follows1:

a. **Hybrid retriever**in the form of BM25 + dense embedding such as DPR1, BGE, Sentence-BERT, to maximize document recall [66-70].
b. **Cross-encoder reranker**for example mono/duo-T5, which re-sorts candidate passages before sending them to LLM.
c. **Generator**in the form of general purpose LLM GPT-3.5/4, LLaMA, Mistral, or open-source instruction models fine-tuned in the legal or government domain [71-75].

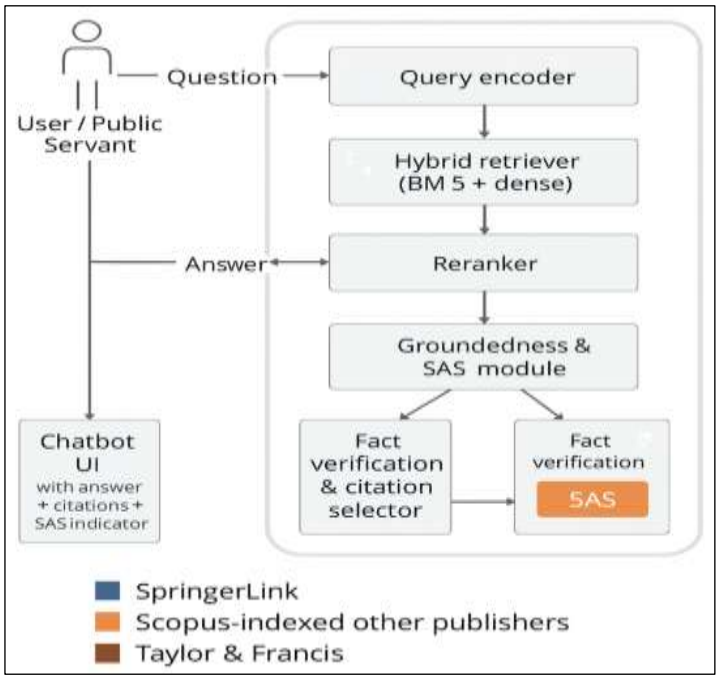

Figure 5: General architecture diagram of groundedness-aware RAG.
Source: Authors, (2026).

The following are technical factors that have been shown to be influential consisting of quality, strategy, and integration only in the amount of chunking and modeling, negative sampling and verification modules, respectively:

1. Quality chunking and document structure modeling. Thus, the use of hierarchy-based segmentation, namely article-verse-letter, and graph-based retrieval reduces hallucinations in e-government scenarios because the context based on the regulatory structure is captured.
2. Negative sampling strategy in retriever training. That is, retrievers trained with hard negatives, i.e., similar articles but with errors, experienced a groundedness rate increase of up to ~5-8 points compared to the pure BM25 baseline.
3. Verification module integration. This means integrating several symbolic fact verifier factors or natural language inference (NLI) factors that check whether the answer claim is enabled by the retrieved article.

In general, these studies conclude that recall alone is not enough, a combination of recall, precision, and entailment checking is required for groundedness [76-80], where the RAG architecture diagram can be seen as in Figure 5.

III.1.5 Definition of Groundedness and Categories of Hallucinations (RQ4)

These terms in the literature are called groundedness, faithfulness, factual consistency, attribution, and hallucination [81-85]. Surveying the current state of the art characterizes hallucinations with intrinsic and extra-intelligible. Intrinsic assurance is when an entity provides information that is out of context, while extra-intelligible is when an entity provides new information not previously held, either according to the fit between the context and current knowledge of the world. In RAG for authoritative documents, groundedness is used as follows: “a bad for a single claim is that most of the claims contained in the answer cannot be further covered to a specific anthology of evidence drawn from a corpus of appropriate reference texts” [86-90]. Some studies focus on explicit tracking such as traceability expliciting, while others focus on semantic understanding from answers to evidence [91-95]. The hallucinations in regulation are as follows:

a. **Referential hallucinations** : One of the article numbers or names of the regulations is wrong.
b. **Inferential hallucinations** : The argument of the article is pushed too far.
c. **Omission hallucinations** : Highlights skipped or important terms compared in the source document.

Our findings reinforce the need for groundedness metrics that account for claim-level claims based on specific claims, not text-like surface data.

III.1.6 SAS Groundedness and Position Evaluation Metrics (RQ5)

There are three types of metrics used in the 100 articles:

1. **Overlap and surface similarity metrics**
a. BLEU, ROUGE, METEOR, BERTScore; overused but not sensitive enough to claim-evidence semantic alignment [96-100].
2. **Specific factuality metrics**
a. FactScore, AlignScore, Q^2, and many other variations of QA-based factuality. Some references even use question-answering on answers (generating questions from answers and then answering those questions based on evidence).
3. **Citation-based groundedness metrics**
a. Citation precision/recall: proportion of claims that have correctly addressed citations;
b. Attributable Score : assesses whether the claim is connected to appropriate evidence.

However, there has not been a metric that combines embedding similarity, evidence coverage, and entailment in a single, easily auditable relevance score. That is where, early in the process, the SAS Semantic Alignment Score was proposed [101-105]. According to the initial formulation of the dissertation on SAS:

$$\mathbf{SAS\ (a, E) = \alpha \cdot sim\ (a, E) + \beta \cdot coverage\ (a, E) + \gamma \cdot entail\ (a, E)}$$

Information:

A: Answer embedding representations
E: Evidence retrieved
A, E: Average cosine similarity between the answer clause embedding and the evidence segment
coverage A, E: The proportion of clauses that have evidence pairs above a certain similarity threshold.
entail A, E: Average entailment probability of multilingual NLI model.

SAS thus allows for positioning as a claim-level groundedness metric that is RAG-compatible with pipeline and QA metrics, as well as related to user perception [106-110].

III.1.7 Groundedness, Accuracy, and User Trust (RQ6, RQ7)

Several empirical studies that have been conducted in the public domain show that LLM hallucinations have a direct impact on users' trust and intention to reuse the system. Considering that analysis of citizen conversations with municipal government chatbots in Norway proved that failure to provide answers consistent with policy documents led to significant escalation in human service channels and formal complaints. Articles that explicitly measure trust typically use a 5- or 7-point Likert scale for dimensions such as perceived accuracy, transparency, and reliability. Reported correlations between groundedness (e.g., citation correctness and FactScore) and trust range from 0.4–0.7, confirming a fairly strong positive relationship [111-115]. The conceptual contribution of this SLR is to propose that SAS should be evaluated by annotator ground truth groundedness ratings but should also be evaluated by user trust scores in controlled user studies. If the SAH is a correlation of SAS ≥ 0.7 to human ratings and a significant positive correlation with user trust, then it is clear that it should be considered a leading indicator for system auditing.

III.1.8 Keyword Mapping using VOSviewer (RQ1, RQ4, RQ8)

To understand the thematic concept, keywords can be analyzed using co-occurrence analysis of 100 articles and visualized with VOSviewer, in Figure 6 you can see the metadata mapping and division of four main clusters[116-120].

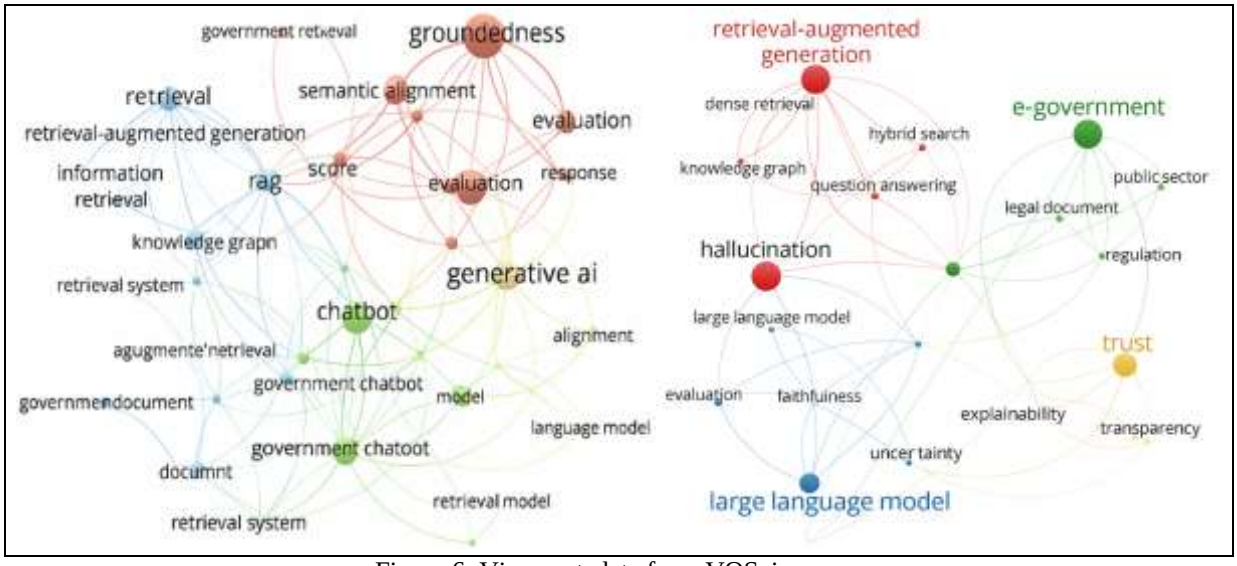

Figure 6: View metadata from VOSviewer.
Source: Authors, (2026).

The four main clusters that frequently appear are as follows:

1. Cluster RAG retrieval: Retrieval-augmented generation, dense retrieval, hybrid search, knowledge graph, question answering [121-125].
2. Cluster hallucination factuality: Hallucination, factual consistency, faithfulness, evaluation, uncertainty [126-130].
3. Government governance cluster: E-government, public sector, legal documents, regulation, compliance.
4. Cluster user trust XAI: trust, explainability, transparency, responsible AI [131-135].

The keywords teramavar retrieval-augmented generation, large language model, hallucination, question answering, and legal document, show the relationship between the issue of hallucination, the regulatory domain, and the need for explanatory groundedness mechanisms [136-140].

III.1.9 Summary Answers to RQ1–RQ8

RQ 1	Publication trends:	Exponential increase occurred since 2023, driven by the availability of generative LLMs and the need for hallucination mitigation, with the dominance of Q1-Q2 journals in the fields of information systems and AI [141-145].
RQ 2	Document domain :	About 38% of articles focused on public regulations and law, the remainder on health, customer support, and other organizational documents, but the pattern of groundedness needs was similar [146-150].
RQ 3	RAG Architecture :	The retriever–reranker–LLM pipeline becomes the dominant pattern; hybrid retrieval and NLI-based verification module integration are shown to improve groundedness [151-155].
RQ 4	Definition of groundedness:	Hallucinations are understood as the association of claims with the evidence that can be traced; they are classified into referential, inferential, and omission; these categories are relevant for designing SAS [156-160].
RQ 5	Evaluation metrics:	Common metrics are inadequate; FactScore, AlignScore, and citation metrics fill some of the gap, but do not yet integrate semantic alignment, evidence coverage, and entailment into a single score, which is what SAS forecasts [161-165].
RQ 6	Technical factors:	The quality of the retriever, the representation of the document structure, and the presence of verifiers and decoding strategies greatly influence groundedness and the level of hallucinations [166-170].
RQ 7	Groundedness and trust:	User studies show a consistent positive correlation between groundedness and trust; transparent citations and concise explanations of regulatory sources increase perceived reliability [171-175].
RQ 8	Research gap & SAS direction:	There is still a lack of automated evaluation models specifically designed for government documents; there is no standard framework for groundedness-based government AI audits; SAS is positioned as a candidate for core metrics that need to be validated through correlation studies with human judgment and trust indicators [176-180].

IV. THEORETICAL AND PRACTICAL IMPLICATIONS

Theoretically, this SLR establishes that groundedness is not simply an extension of traditional QA metrics, but a multidimensional concept including semantic alignment, evidence attribution, and observation of regulatory structure. Therefore, it reinforces the need for the development of an explicit theory of groundedness, especially for taxonomic claim types and annotation schemes that are expected to work with links within the legal and governmental domains [181-185]. Practically, the SLR results suggest that government agencies should do the following:

1. Adopting a RAG architecture with an internal evaluation module that periodically measures SAS, FactScore, and citation precision as part of a chatbot service quality audit [186-190].
2. Implement a data governance policy that at a minimum allows only official and current documents to be accepted into the RAG corpus, complete with document version metadata and PID legality conditions.
3. Create a user interface that attaches explicit citations to articles/verses as evidence for answers and sets up an alert when SAS falls below a certain threshold.
4. Involving non-technical stakeholders in the groundedness design scheme ensures that technical metrics align with community legal and ethical accountability standards. External metrics validating generalizability and general discipline are recommended for future research purposes.

V. RECOMMENDATIONS FOR FURTHER RESEARCH

Referring to the above gaps, several recommendations for further research were found as follows:

1. Formalization of a groundedness annotation scheme for Indonesian-language regulatory documents, including definitions of claim units, evidence span, and entailment labels.
2. Comprehensive experiments of SAS on various dense, hybrid, graph-based RAG pipelines and various types of LLM, to evaluate the robustness of SAS across architectures [191-195].

3. Correlational and causal studies between SAS, EM/F1 QA metrics, nDCG, and citizen trust indicators, through user studies on real chatbots in agencies such as Diskominfo.
4. Integration of SAS into the government's AI governance framework, including periodic reporting mechanisms, regular red teaming, and human-in-the-loop procedures when groundedness scores fall below a safe threshold.
5. Development of an audit dashboard analytical tool that visualizes SAS distribution per regulatory topic, so that policy makers can quickly identify high-risk areas.

VI. CONCLUSION

This article presents a Systematic Literature Review on groundedness-aware retrieval and hallucination mitigation for Retrieval-Augmented Generation in government and regulatory document chatbot applications. From 7,947 initial records, 100 primary articles Q1–Q2 were selected, curated, and analyzed. The findings are that despite RAG being the dominant architecture in combining LLM with organizational knowledge bases, it is still important to pay attention to the issue of hallucinations, while groundedness evaluation is still incomplete. The literature shows that groundedness is influenced by the quality of the retriever, exploration of document structure modeling, implementation of decoding strategies, and adoption of verification modules. Existing metrics such as FactScore, AlignScore, factuality-based QA methods, and citation metrics, while providing an important foundation, do not fully cover the need for measuring groundedness in auditable factual claims in the government context [196-200]. Based on the findings, the article suggests the Semantic Alignment Score as a combined metric to measure semantic alignment, evidence coverage, and entailment between answers and documents. Therefore, it should not only replace but also challenge traditional claims and be a key element in government AI governance. Collaborating, empirical validation of SAS and integration into active RAG pipelines by diverse service providers is the foundation for more accurate, transparent, and regulatory chatbot users [201-204].

VII. AUTHOR'S CONTRIBUTION

ABSTRACT

In the conventional settlements of Sumba Island, the nearby local area progressively changes design to meet their consistently moving necessities. The social legacy, exemplified in vernacular houses, holds extensive interest for the travel industry. By grasping and advancing the social meaning of these houses, we can add to manageable the travel industry improvement, supporting the neighborhood economy and encouraging consciousness of the social lavishness of the district. As we dig into the examination of the social legacy inside vernacular houses, it becomes evident that these designs wrestle with difficulties like rot, underlying weaknesses, and natural tensions. Despite this, the ever-changing technological landscape presents promising opportunities for the preservation of these priceless cultural assets. The incorporation of progressively complex PC vision innovation, joined with the openness of high-goal remote detecting pictures, presents an extraordinary way to deal with exactly assess and quantify the many-sided subtleties of Earth's regular and fake conditions for enormous scope. In this undertaking, our work proposes a strategy using profound learning methods and huge information examination for distinguishing the social legacy of vernacular houses in Sumba Island, Indonesia. At first, we utilize the boosted sooty tern optimization (BSTO) calculation for target division, really isolating vernacular houses from the grave remote detecting pictures. Subsequently, we present the pre-prepared VGG-16 engineering to extricate highlights from the fragmented objective picture. Also, we carry out the adaptive learning neural network (ALNN) for the exact programmed discovery of vernacular houses. Utilizing Sumba Island tiles, we validate the efficacy of our BSTO-VGG16-ALNN method and demonstrate impressive results.

I. INTRODUCTION

We are living in the "Age of Data", with new information being delivered from all businesses and public bodies at an exceptional, and continually developing rate thus, there has been an extraordinary promotion which has driven associations to make significant interests in their mission to investigate how they can utilize their information to make esteem [1]. The primary reason enormous information examination expands on is that by dissecting huge volumes of unstructured information from various sources, noteworthy experiences can be produced that can assist firms with changing their business and gain an edge over their opposition [2]. Having the option to get such information produced knowledge are especially important, particularly for associations that work in powerful and high-paced business conditions, where pursuing informed choices is basic.

Regardless of much commitment from enormous information examination [3] there has been fundamentally less exploration on how associations should be organized to create business esteem from such ventures, and a restricted comprehension on the transaction of variables that drive execution gains [4]. Most reports to date on the worth of huge information examination come from consultancy firms, well known press, and disconnected contextual investigations, which neglect to expand on exact outcomes from enormous scope investigations and need hypothetical knowledge. Moreover, [5] late investigations have noticed that there is as yet a sizeable number of organizations that neglect to catch esteem from their huge information speculations and, surprisingly, some that contend that large information might sting instead of help organizations [6]. Accordingly, there is deficient comprehension about how associations ought to move toward their large information drives, and scant observational help to direct esteem creation from such speculations [7]. Bigdata, with their capability to find out esteemed bits of knowledge for improved dynamic cycle, have as of late drawn in significant interest from the two scholastics and experts. In order to extract useful information from big data, numerous businesses are adopting big data analytics, which is increasingly becoming a popular method [8].

The investigation cycle, including the sending and utilization of enormous information examination devices, is considered by associations to be an instrument to work on functional proficiency however it has key potential, drive new income streams and gain upper hands over business rivals. Be that as it may, there are various sorts of insightful applications to consider [9]. Consequently, preceding rushed use and purchasing expensive bigdata instruments, there is a requirement for associations to initially comprehend the enormous information examination scene. Given the critical idea of the BD and huge information examination, this paper presents a cutting edge survey that presents an all encompassing perspective on the bigdata challenges and large information investigation strategies utilized by associations to help other people comprehend this scene with the target of pursuing strong venture choices [10]. To explore in such an unstable, mind boggling and questionable climate, coordinate apparent development capacity is acknowledged as a urgent capability [11]. Advancement alludes to foster worth to meet clients' necessities and market needs. Also, information driven development depends on making esteem by utilizing information and advanced apparatuses [12]. The speed of development is changing quickly as per mechanical upgrades and the reception of advancement is profoundly reliant upon the information the board [13]. The noticeable upper hand is gotten from capacity to utilize significant apparatuses to make important data. Businesses use big data, in particular, a lot to come up with new ideas, processes, and markets [14]. To centers around computerized devices, large information examination and man-made reasoning and their effect on development. The problematic impacts of information driven advancement in the business world are examined [15].

It is viewed as that this section might empower chiefs to make experiences and to more readily comprehend information driven development. The attracts consideration is utilized to the limit of AI frameworks to learn and change over the long run, progressively laying out their own sub-objectives, and their capacity to adjust to nearby circumstances by means of outer sensor data or refreshed input information [16]. Human originators of these frameworks choose and set their underlying boundaries and the all-encompassing objective which these frameworks are expected to streamline [17]. Simultaneously, AI frameworks are intended to work by settling on free choices that pick between options in manners that are not pre-modified in that frame of mind, to do as such with practically no human mediation [18]. Since these frameworks advance powerfully and iteratively from their current circumstance, which is it frequently unstable and constantly changing, this has suggestions for the soundness and consistency of their activity [19]. Specifically, these frameworks can possibly advance unexpectedly. In this time of computerized information overflow, moral difficulties have arisen as a squeezing concern. Data analytics' complex ethical challenges, including privacy invasion, algorithm bias, and security risks, are the focus of this topic [20]. We hope to shed light on the ethical quandaries and provide insights into how society can navigate this data-driven landscape responsibly and ethically by examining real-world case studies and proposing solutions.

Our contributions. The proposed profound learning procedure with huge information examination for social legacy recognition in vernacular houses on Sumba Island, Indonesia, is intended to give an extensive and exact strategy to recognizing these social resources. The significant commitments of this strategy are framed beneath:

1. The underlying step includes the utilization of the boosted sooty tern optimization (BSTO) calculation for target division. BSTO improvement upgrades the accuracy of division, guaranteeing that the calculation detaches the objective designs precisely in the midst of the assorted data present in the pictures.
2. Following objective division, the VGG-16 pre-prepared engineering is used for highlight extraction from the fragmented objective picture. VGG-16 is a convolutional neural network (CNN) known for its viability in picture acknowledgment errands.
3. The proposed strategy integrates a hybrid adaptive learning neural network (ALNN) for the programmed discovery of vernacular houses. This brain network is utilized to adjust and gain from the highlights separated by VGG-16, upgrading the exactness of the identification cycle.
4. To survey and approve the presentation of the BSTO-VGG16-ALNN strategy, the procedure is applied to Sumba Island tiles. It includes utilizing the model to examine genuine information from the district, affirming its viability in precisely identify vernacular houses.

The rest of this paper is organized as follows. Section 2 gives the review of recent works related to the big data analytics for cultural heritage detection. Section 3 provides the detailed working process of our BSTO-ALNN technique for economy forecasting with the detailed mathematical models. The results and comparative analysis of models for the big data analytics for cultural heritage detection is discussed in the Section 4. Finally, the paper concludes in Section 5.

II. RELATED WORKS

II.1 STATE-OF-ART STUDIES

DAS et al. [21] have asserted that big data is just beginning to transform healthcare and propel the sector forward on numerous fronts. The progressions in medication, advancement, and funding that large information in medical care ensures offer plans that gain ground in understanding the consideration and drive esteem in medical services associations. With the instrument's advancement, methods that utilize THz waves for pharmaceutical applications are rapidly evolving. THz imaging can possibly be used in assessing a couple of designs. The responsibility of this examination is to make recommendations for the THz imaging strategy and information examination, preferably having an effect in carrying it closer to being clinically important development. Jindal et al. [22] have proposed a tensor-based method for managing big data to reduce the dimensionality of IoE environment data in a smart city. This center information is then put away on the cloud in the decreased structure. Subsequent to decreasing dimensionality of information, it tends to be utilized for offering many types of assistance in savvy urban areas and its application to give request reaction administrations is talked about in this paper. The support vector machine (SVM) based classifier is utilized to characterize the end-clients into ordinary, over-burden and under stacked classifications from the center information. When such clients are recognized to partake popular reaction system, utilities can devise specific answers for handle their interest reaction to change their heap prerequisites so the general burden in the brilliant city is ideally made due.

Silva et al. [23] have proposed a bigdata examination installed brilliant city design, which is additionally coordinated with the web by means of a shrewd door. Incorporation with the web 14 gives a general correspondence stage to beat the stage incongruencies of savvy things. They assessed credible informational indexes to decide the limit values for canny navigation and to introduce the exhibition improvement acquired in information handling. At last, 17 introduced an illustrative state move with the trap of things coordinated brilliant structure design to uncover the exhibition enhancements of the shrewd city engineering regarding network execution and energy the board of savvy structures. Ordonez et al. [24] have proposed an exploration point, including not having a data set model, inventive capacity past columns and scale out equal handling. Numerous presumptions in view of a concentrated information distribution center or unbending data set have been debilitated and, surprisingly, vanished. Most would agree enormous information examination has left information warehousing and information mining research behind. Before designing extended data warehouse and analytics applications in the bigdata era, they hope that readers will find the content of this special issue interesting and will be inspired to investigate the challenges that remain. Fernández et al. [25] have proposed a free and open-source method for automatically configuring and deploying a Spark cluster.

It has been created with a user-friendly graphical user interface to make managing Spark clusters simple and effective, automate cluster deployment, and quickly start up Hadoop's distributed file system. In addition, LadonSpark offers the capacity to incorporate any algorithm into the system. That is, the client just has to give the executable record and the quantity of required inputs for appropriate definition. Also, bunching, relapse, characterization, and affiliation rules calculations are as of now coordinated with the goal that clients can test its ease of use from its underlying establishment. Kabugo et al. [26] have proposed an interaction information examination stage worked around the idea of industry 4.0. Big-data software tools, ML algorithms, and cutting-edge IIoT platforms are all incorporated into the platform. The stage accentuates the utilization of ML strategies for process information examination while utilizing enormous information handling devices and exploiting the presently accessible modern grade distributed computing stages. The modern materialness of the stage was exhibited by the improvement of delicate sensors for use in a waste-to-energy plant. For the situation study, the work concentrated on information driven delicate sensors to anticipate syngas warming worth and hot vent gas temperature. The displaying results showed that, in situations where process information about the cycle peculiarities within reach is restricted, information driven delicate sensors are valuable devices for prescient information examination.

Fang et al. [27] have proposed a cyber-physical production system (CPPS) utilizing information investigation is proposed to empower creation perceivability. It utilizes information stream handling ways to deal with clean excess information effectively. Bayesian derivation motor is prepared by Ming the authentic information disconnected, is utilized to recognize the exactness of a RFID-caught occasion on the web. Then, at that point, complex occasion handling is applied to combine multi-source heterogeneous information. The creation progress perceivability is accomplished by the business cycle the board. The system shows how important it is to implement real-time data collection, processing, and visibility in order to increase production efficiency. Zhao et al. [28] have proposed a basic job in information mining, and has gotten extraordinary accomplishment to tackle application issues, local area examination, picture recovery, customized proposal, movement forecast, and so forth. Albeit the current strategies have predominant execution on some little or certain datasets, they miss the mark while bunching is performed on CPSS enormous information as a result of the significant expense of calculation and capacity. With the strong distributed computing, this challenge can be really tended to, however it carries colossal danger to individual or organization's security. In academia, privacy-preserving data mining has received a lot of attention.

Northcott et al. [29] have discussed the ascent of information serious science, or huge information, altered our capacity to anticipate. It suggests need for expectation over causal comprehension, and decreased job for hypothesis and human specialists. They look at four significant situations where expectation is alluring: political elections, the weather, GDP, and the outcomes of economic experiment-suggested interventions. The methodology embraced is especially important in managing such a complicated and touchy issue, as it considers the environment of finding out about the subject across different settings and media assets. Bilal et al. [30] have proposed a benchmarking framework for delicate assessment utilizing Huge Information of 1.2 terabytes, including 5.7 million cells. An all encompassing rundown of seventeen KPIs is distinguished from the email information utilizing Text Mining draws near. The idea of a deep ensemble learner based on the decomposition-integration method is at the heart of this work. In the deterioration stage, the model predicts a few property explicit benchmarks for each KPI utilizing setting mindful calculation. The profound brain network-based students are prepared to create last venture delicate KPI benchmark.

In the spring, the learner will be used as a tool to help evaluate power infrastructure projects for tenders. A delicate of 60km underground cabling project is assessed utilizing the student. The tender's key performance indicators (KPIs) were automatically identified by the system as requiring additional attention to improve profitability performance.

II.2 RESEARCH GAPS

The identification of built cultural heritage marks fundamental stage in preserving our collective human legacy. Its significance spans a myriad of purposes, encompassing preservation, tourism, education, identity, and fostering international collaboration. Acknowledging the importance of cultural heritage significantly contributes to the enrichment of societies and a deeper appreciation of diverse global history. In a study conducted by Monna et al. [31], they introduced a replicable workflow designed for the automatic detection of buildings from satellite imagery. This research demonstrated the efficiency of modern computer vision techniques, specifically those rooted in deep learning, in accomplishing a task that would be exceptionally time-consuming if undertaken manually. The review thought about eight profound learning designs in view of convolutional brain organizations, assessing their ability to recognize and find conventional houses from satellite pictures exactly. Particularly successful was the combination of artificial data augmentation and the Faster R-CNN ResNet 101 architecture. The R-CNN ResNet 101 architecture prepared with 1033 examples of vernacular houses, displayed its capability in computerizing the ID cycle, introducing a promising road for the use of cutting-edge innovations in social legacy recognition [32]. Distinguishing assembled social legacy through the utilization of profound learning strategies with enormous information investigation presents multi-layered scene full of difficulties [21], [22].

Algorithms that are capable of accurately identifying various building types are needed to overcome the significant obstacle posed by the architectural diversity inherent in cultural heritage structures. Furthermore, factor conditions in satellite symbolism, like changes in lighting, weather patterns, and goal, add to the intricacy of the location task [23]. The most common way of clarifying and naming enormous datasets for the purpose of preparing can be work escalated; requiring master information, particularly while managing assorted building highlights. Additionally, the creation of robust and generalized models is hampered by the lack of labeled training data for particular cultural heritage sites [24]. In metropolitan conditions, firmly arranged structures and visual mess can prompt covering structures, confusing exact recognition. Additionally, the scale abberations among structures inside social legacy destinations present difficulties for discovery models in adjusting to shifting sizes. To address these difficulties, the incorporation of profound learning methods with enormous information investigation arises as a promising arrangement [25]. Profound learning calculations succeed in mechanized highlight extraction, permitting them to observe multifaceted compositional subtleties from enormous datasets. Large information examination further work with information expansion, enhancing preparing datasets and working on model power against varieties in lighting, points, and conditions [26].

Besides, the arrangement of cutting edge structures demonstrates viable in catching spatial ordered progressions and mind boggling subtleties in satellite symbolism, consequently improving the exactness of assembled legacy identification. Nonetheless, in spite of these progressions, potential issues might emerge after execution [27]. Overfitting is concern, where a model turns out to be excessively intended for the preparation information lead to decreased speculation on new and concealed social legacy pictures [28]. Calculation predisposition is another thought, as models might exhibit inclinations in view of the creation of the preparation information, bringing about errors or misclassifications for specific kinds of social legacy structures. The interpretability and logic of profound learning models present difficulties, making it hard to comprehend the thinking behind unambiguous identification [29]. Also, moral contemplations, for example, issues connected with protection, information possession, and social responsiveness, warrant cautious consideration [30]. Tending to these difficulties and potential issues requires fastidious model turn of events, careful approval, and progressing observing. To address the difficulties and potential issues recognized with regards to distinguishing constructed social legacy utilizing profound learning methods with enormous information examination.

1. Foster profound learning models that can actually deal with different engineering styles present in constructed social legacy, guaranteeing hearty execution across different designs.
2. Investigate effective approaches to data annotation and labeling in order to speed up the process of creating massive labeled datasets and guarantee that expert knowledge is effectively utilized for various architectural features.
3. Upgrade robotized highlight extraction capacities in profound learning models, guaranteeing that these models can successfully catch and break down complicated highlights from enormous datasets.
4. Ensure that deep learning models do not become overly specific to the training data and maintain generalization on new and unseen cultural heritage images by developing strategies to mitigate over fitting challenges.

III. PROPOSED METHODOLOGY

The proposed procedure for recognizing the social legacy of vernacular houses in Sumba Island, Indonesia, unfurls through a deliberate cycle delineated in Fig. 1. Beginning with input remote detecting pictures catching the geographic district of interest, the framework goes through a critical period of picture preprocessing. This underlying step guarantees ideal picture quality by utilizing methods like sound decrease, contrast upgrade, and standardization. In this manner, the boosted sooty tern optimization (BSTO) calculation becomes possibly the most important factor for the division of vernacular houses. This enhancement calculation is fastidiously intended for target division, really separating areas inside the info remote detecting pictures that relate to vernacular houses. When the division is finished, the framework extricates the designated vernacular house regions from the preprocessed remote detecting pictures. This particular extraction confines locales of interest, which are characteristic of potential social legacy structures. Pushing ahead, the element extraction process is started utilizing the VGG-16 engineering, a prestigious profound convolutional neural network (CNN) commended for its viability in picture related undertakings.

This stage includes the extraction of more profound elements, enveloping surface, semantic, and factual highlights, from the portioned vernacular house regions. These removed elements structure a far reaching portrayal of the multifaceted qualities related with social legacy structures. The last and basic step involves the programmed identification of constructed social legacy utilizing a hybrid adaptive learning neural network (ALNN) strategy.

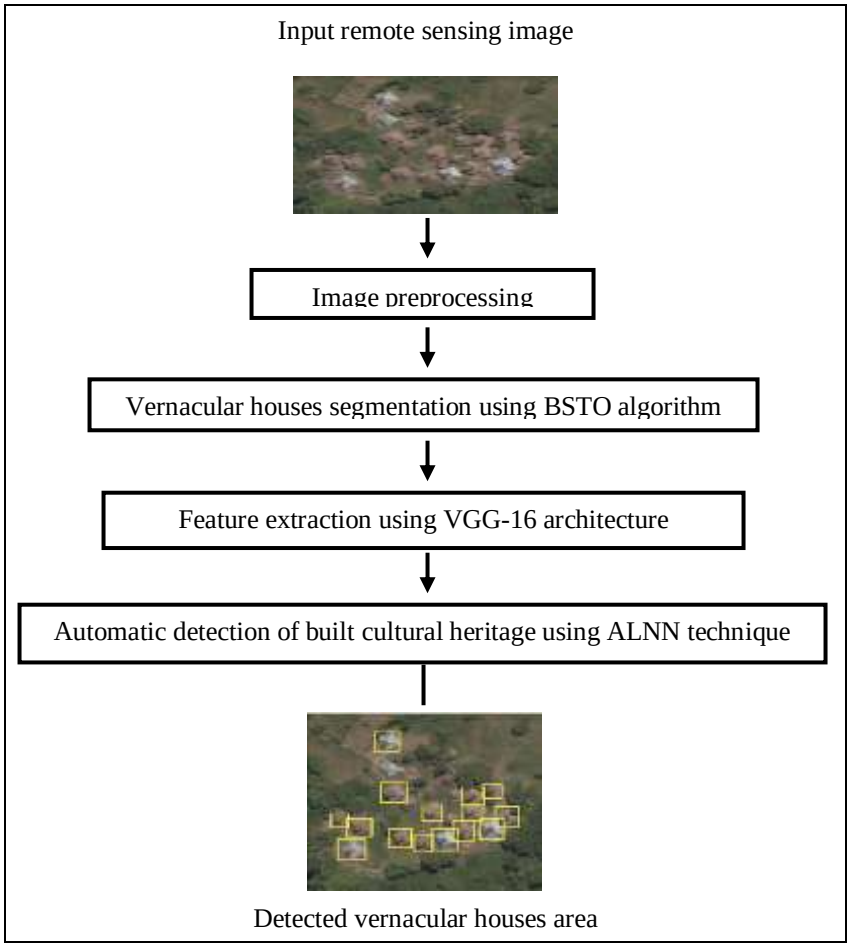

Figure 1: Framework plan of proposed procedure for identify the social legacy of vernacular houses in Sumba Island, Indonesia.
Source: Authors, (2026).

This ALNN is intricately designed to adapt to and learn from the VGG-16 architecture's extracted features. The cross breed nature of the ALNN consolidates different learning methodologies, upgrading its ability to precisely identify and group social legacy structures. The results of this framework configuration give important data about the presence and circulation of vernacular houses on Sumba Island, contributing altogether to continuous social legacy conservation tries. The goal of the proposed method is to provide a comprehensive and precise solution for identifying cultural heritage structures in the unique context of Sumba Island, Indonesia, by integrating advanced optimization algorithms, deep learning, and adaptive learning techniques.

III.1 TARGET SEGMENTATION

In the underlying period of the social legacy identification process, target division assumes a urgent part, and to achieve this, the boosted sooty tern optimization (BSTO) calculation is utilized. The BSTO calculation draws motivation from the rummaging conduct of dingy terns, seabirds known for their proficient hunting procedures. Its essential objective inside this application is to advance the division of vernacular houses inside remote detecting pictures. The calculation starts by introducing a populace of likely arrangements, regarding them as individual specialists similar to rummaging birds. Through a series of optimization iterations, these solutions, which represent potential regions for vernacular houses, undergo iterative refinement. During the iterative process, the solutions are modified in accordance with rules that are derived from the foraging behavior of sooty terns. The goal is to maximize a specified goodness function that represents the accuracy of the segmentation. Critically, the BSTO calculation displays versatile attributes, powerfully changing its boundaries in light of the advancement of improvement and gaining from the investigation of the arrangement space. A definitive result is the successful partition of vernacular houses from the encompassing setting in the remote detecting pictures. BSTO calculation's proficiency lies in its capacity to deal with complex objective division errands, exhibiting its flexibility and improvement ability in precisely recognizing social legacy structures inside assorted and dynamic scenes caught in the pictures. Seabirds called sooties, or Onychophyrionfuscatus, can be found all over the world. There are numerous sizes and masses of sooty bush varieties.

Dingy birds are seabirds tracked down all around the world and come in various assortments of various loads and sizes. They feed on fish, bugs, creatures of land and water, worms and reptiles. They typically live in states and utilize their knowledge to find and go after prey. BSTO calculation starts by introducing potential arrangements addressing up-and-comer districts for vernacular houses in remote detecting pictures. It utilizes a goal capability to assess arrangement quality, with a helping component supporting fruitful techniques. Through iterative advancement and versatile learning, the calculation progressively changes its boundaries to upgrade precision. A union check decides when to end emphasess, giving last division result that precisely recognizes vernacular houses. The adaptive nature and boosting mechanism of the BSTO algorithm make it ideal for target segmentation tasks in cultural heritage detection. Relocation and hunting are a significant part of the way of behaving of dingy pigs, and relocation is characterized as the occasional development of these birds starting with one spot then onto the next looking for energy-giving food. By moving, Alcoholic should keep away from the contention depicted beneath.

$$\overrightarrow{\xi}_{ts} = T_B \times \overrightarrow{Q}_{ts}(z) \tag{1}$$

$$T_B = c_F - (Z \times (c_F / Iter_{\max}) \tag{2}$$

The condition of an ash stem that has not slammed into another ash is the condition of the momentum sediment stem, Z is the ebb and flow cycle, and TB is a control variable to change ash movement and TB in a specific pursuit district. Subsequent to staying away from crashes, the smell converges with its best neighbors as per the accompanying recipe.

$$\overrightarrow{m}_{ts} = c_b \times (\overrightarrow{Q}_{ats}(z) - \overrightarrow{Q}_{ts}(Z)) \tag{3}$$

$$c_A = 0.5 \times r_{and} \tag{4}$$

To address various places of the sediment bramble, ideal ash is an irregular variable and r is an irregular number in the reach [0,1]. Dingy turn status can be refreshed as follows

$$\overrightarrow{d}_{ts} = \overrightarrow{\xi}_{ts} + \overrightarrow{m}_{ts} \tag{5}$$

It's $\overrightarrow{d}_{ts}$ difference between smell and great soot. Ash tufts foster a twisting conduct in the breeze, which is characterized as follows

$$y' = r_{adi} \times \sin(j) \tag{6}$$

$$x' = r_{adi} \times \cos(j) \tag{7}$$

$$Z' = r_{adi} \times j \tag{8}$$

$$R = U \times E^{KV} \tag{9}$$

Where demonstrates the span of each helical turn, I is the variable in range [$0 \le K \le 2\pi$], u and v characterize the helical shape steady, e is a characteristic logarithm. The following changes can be made to the sooty tern's position:

$$\overrightarrow{Q}_{ts}(z) = \overrightarrow{d}_{ts} \times (y' + x' + z') \times \overrightarrow{Q}_{ats}(z) \tag{10}$$

where $\overrightarrow{Q}_{ts}(z)$ informs the locations of other sooty terns and custody the best result.

III.2 FEATURE EXTRACTION

Following the target segmentation of vernacular houses within remote sensing images, the subsequent step in the cultural heritage detection process involves feature extraction. This crucial stage is facilitated by the introduction of the pre-trained VGG-16 architecture, a deep convolutional neural network renowned for its hierarchical feature learning capabilities. VGG-16, comprising of 16 layers, goes through move getting the hang of, having been pre-prepared on broad datasets like ImageNet. Move gaining permits the model to use information acquired from these datasets, upgrading its capacity to remove appropriate elements from the divided objective picture. As the picture navigates through the organization, convolutional layers catch both low-level elements, like edges and surfaces, and significant level conceptual highlights illustrative of the vernacular houses. The element extraction process creates itemized highlight maps, exemplifying surface, semantic data, and measurable attributes characteristic for the fragmented objective picture. VGG-16's versatility empowers it to perceive one of a kind building designs related with social legacy structures. The result contains high-layered include vectors, filling in as rich portrayals that encode the unmistakable parts of vernacular houses for ensuing errands, especially programmed identification. The joining of the pre-prepared VGG-16 design in the component extraction stage improves the viability and flexibility of the social legacy identification pipeline. The most common way of using the pre-prepared VGG-16 design includes a few vital stages with regards to highlight extraction for social legacy location from divided target pictures.

- Utilizing move learning, the pre-prepared VGG-16 model is instated with loads and inclinations gained during its pre-preparing on pictures from dataset. This instatement gives the model an abundance of information about broad visual elements, empowering it to adjust to additional particular errands with restricted named information.
- The fragmented objective picture, acquired through the earlier objective division stage, fills in as the contribution to the pre-prepared VGG-16 model. The isolated areas that represent vernacular homes are included in this image.
- The info picture goes through forward spread through the layers of the VGG-16 engineering. Each layer, including convolution and pooling layers, separates various leveled highlights from the portioned target picture.
- The VGG-16 model's various layers produce feature maps. These component maps address the actuations of neurons because of explicit examples and surfaces present in the divided objective picture.
- The architecture of VGG-16 makes it easier to learn features in a hierarchical fashion. The lower layers take in low-level features like edges and textures, while the higher layers take in more abstract and semantic features.
- The flexibility of the pre-prepared VGG-16 model permits it to perceive and catch highlights intended for vernacular houses. The model adjusts its learned portrayals to the design examples and qualities related with social legacy structures.
- The last result of the pre-prepared VGG-16 design is a high-layered include vector. The cultural heritage detection process as a whole is augmented by VGG-16's high-dimensional feature vector output.

III.3 AUTOMATIC DETECTION OF VERNACULAR HOUSES AREA

The hybrid adaptive learning neural network (ALNN) is used to perform the crucial step in the process of identifying cultural heritage, which is the automatic detection of vernacular houses. It specific brain organization, described by its crossover nature, consolidates different learning techniques to improve precision. Based upon a adaptive learning framework ALNN obliges dynamic changes of its boundaries in view of the elements it processes. The brain network engineering, intended to handle high-layered include vectors got from the pre-prepared VGG-16 model, goes through preparing to learn progressive course of vernacular house qualities. The educational experience coordinates different learning methodologies, possibly joining regulated and unaided procedures to further develop speculation. Enhancement procedures guarantee accuracy in recognizing vernacular houses, including tweaking boundaries and utilizing regularization strategies. Rigorous accuracy evaluation using validation datasets ensures the model's reliability in real-world scenarios. The output of ALNN represents the automatic detection of vernacular houses, contributing valuable information for cultural heritage preservation and research within the broader context of remote sensing images. First, we define the parameter initialization of ALNN is define as follows.

$$F_{nn}(X) = W^{T} J(X) + \varepsilon \tag{11}$$

where $X = [X_1, X_2, ..., X_m]$ is the input vector, W^e [1, 2,...,l] is the weight vector. The typical Gaussian basis function is compute as follows.

$$G_i(X) = \exp\left[-\frac{(X - \upsilon_i)^t (X - \upsilon_i)}{c_i^2} \right], i = 1,...,l \tag{12}$$

where $G_i(X)$ The focuses of the Gaussian capability and the width of the premise are individually addressed by the potential outcomes guess, and the computational speed is affected by the quantity of secret layers. A solitary secret brain network is decided to best inexact the obscure capability.

$$W^{*} = \arg\min\left[\sup\left\|\hat{W}^{R} D(X) - F_{mm}(X)\right\|\right] \tag{13}$$

$$\Omega_W = \left\{\hat{W} \middle\| \hat{W} \right\| \le M \right\} \tag{14}$$

The single vulnerability can be addressed as a component of the estimation execution of the brain network as follows:

$$\alpha(X) = W_a^{*E} G_a(x) + \varepsilon_a^{*} \tag{15}$$

where $\alpha(x)$ is the ideal guess mistake, indicated There is an upper bound on the assessed blunder $\bar{\varepsilon}$ to the degree that $|\varepsilon * \alpha| \le \bar{\varepsilon}$. The composite unsettling influence is thought to be an estimated hypothesis of nonpartisan organizations that permits us to establish that the pace of progress fulfills | | | greatest the following is the identification model in light of the system.

$$\begin{cases} \dot{x}_1 = \dot{x}_2 \\ \dot{x}_2 = -\alpha_F \zeta + \hat{\alpha}(x) + gu \end{cases} \tag{16}$$

Where the identification model's state variable vector is denoted by $\overset{(}{x}_1 = [\overset{(}{x}_1, \overset{(}{x}_2]$. The channel displaying mistake is characterized as follows.

$$\zeta = \overset{(}{x}_1 - \overset{(}{x}_2 \tag{17}$$

Subbing into one can acquire the accompanying unique condition.

$$\overset{(}{x}_2 = G_1(s)(\alpha_F x_2 + \hat{\alpha}(x) + gu) \tag{18}$$

where D_1 (s) is equal to 1. The low-pass filter can be used to reduce the noise signal produced during system output measurement if the appropriate F is selected.

$$\begin{cases} \overset{(}{x}_1 = \overset{(}{x}_2 \\ \overset{(}{x}_2 = -k_F^e \zeta + \hat{\alpha}(\overset{(}{x}) + gu + \hat{D} \end{cases} \tag{19}$$

The recreation mistake vector is determined as follows: where lD = [k_{f_1} , k_{f_2}] T is the addition vector, T is the reproduction blunder vector, x is the sexually transmitted disease state gauge vector, T is the recreation mistake vector, and D is the gauge D.

$$\begin{cases} \zeta_1 = \overset{(}{x}_1 - \vartheta_0 \\ \zeta_2 = \zeta_1 = \overset{(}{x}_2 - \vartheta_1 \end{cases} \tag{20}$$

By substituting, we can get the updated solution as follows.

$$\overset{(}{x}_1 + k_{F_2} \overset{(}{x}_1 + k_{D_1} \overset{(}{x}_1 = \Delta + \hat{\alpha}(\overset{(}{x}_1) + gu + \overset{(}{D} \tag{21}$$

A second-request low-pass channel relates to elements, which is characterized as follows

$$\overset{(}{x}_1 = J_2(s)(\nabla + \hat{\alpha}(\overset{(}{x}) + gu + \overset{(}{D}) \tag{22}$$

$$D_2(s) = \frac{1}{s^2 + k_{F_1} s + k_{f_2}} \tag{23}$$

The improved identification model is used to reduce noise by selecting the appropriate constants k_{F_1} and k_{F_2} .

$$\zeta = A_F \zeta - B(\tilde{Q}_A^T G_A(x) + \tilde{Q}_A^T G_A(\hat{x}) - \tilde{Q}_A^T G_A(\hat{x}) - \tilde{Q}_A^T G_A(\hat{x}) + \tilde{D} + \overset{(}{x}_2) \tag{24}$$

The Lyapunov condition exists with the end goal that assuming the genuine underlying foundations of the trademark polynomial AF are on the left half of the complicated plane.

$$A_F^T P_F + P_F A_F + Q_F = 0 \tag{25}$$

The symmetric positive-definite matrices P, F, and Q_F are also called optimal design measure.

$$\hat{W}_A = \begin{cases} -\sigma_1 G_A(\hat{x}) \; if \; (\|\hat{W}_A\| \le M_A) or \\ \quad (\|\hat{W}_A\| = M_A G_A^T(\hat{x}) \hat{W}_A \ge 0) \\ P_A[.] otherwise \end{cases} \tag{26}$$

where is the positive constant ($\hat{W}$) and an illustration of the projection operator $P_A[.]$:

$$P_a[.] = -\sigma_1 G_A(\hat{x}) + \sigma_1 \frac{D_A^T(\hat{x})\hat{W}}{\left\|\hat{W}_a\right\|^2}\hat{W}_a \tag{27}$$

where p is the positive-clear symmetric network and fulfills the accompanying Lyapunov condition

$$A^T P + PA + Q = 0 \tag{28}$$

A non-ear disturbance observer is used to provide a more accurate estimation of the compound disturbance:

$$\upsilon = A + k_s C^e p_F \zeta \tag{29}$$

The estimation of disturbance is formulated as follows.

$$\hat{D} = \hat{\nu} - h_s C^e P_F \zeta \tag{30}$$

Considering the time derivative of ν can be compute as follows.

$$\upsilon = D + h_s C^E P_F \zeta = D + h_s C^E P_F \zeta - k_s C^e P_s P\left(\hat{Q}_a^E g_a(x) + \hat{W}_a^E g_a(\hat{x}) + \hat{W} + \hat{x}_2\right) \tag{31}$$

The time subordinate of ν̂ is built as follows:

$$\hat{\upsilon} = +k_s b^t p_f a f \zeta \tag{32}$$

$$\hat{\upsilon} = D - \tilde{D} = \tilde{D} \tag{33}$$

Differentiating the above condition to update the final fitness solution, this defines as follows.

$$\hat{\upsilon} = \upsilon - \hat{\upsilon} = D - P_a\left(\tilde{W}_a^t J_a(z) + \tilde{W}_s^R H_s(\hat{x}) - \tilde{W}_a^t J_a(z) + \tilde{F} + x_2\right) \tag{34}$$

The ALNN's ability to handle complex feature sets and its adaptive learning capabilities make it well-suited for accurately staging the lung cancer based on the diverse information available from the lung tumor images.

IV. RESULTS AND DISCUSSION

Within this section, we showcase the outcomes and conduct a comparative analysis between the proposed methodology and established techniques for detecting the cultural heritage embodied in vernacular houses on Sumba Island, Indonesia. The validation of the BSTO-ALNN technique's performance utilizes remote sensing images collected specifically from Sumba Island. A comparative evaluation is conducted by pitting the results of the BSTO-VGG16-ALNN technique against those of existing methods, choice tree, k-closest neighbor, brain organization, support vector machine relapse (SVR), irregular woods, Ssd_inception_v2, Ssd_resnet_50_fpn, Faster_rcnn_ inception_v2, Faster_rcnn_resnet50 and Faster_rcnn_resnet101 [31]. The different exhibition measurements are utilized to completely survey and compare the efficacy of both the proposed and existing techniques.

IV.1 DATASET DESCRIPTION

The evaluation of both proposed and laid out procedures was directed utilizing Python 3.7 and the TensorFlow article discovery Programming interface, with pre-prepared models obtained from the TensorFlow identification model zoo landing page. The overhang of roofs over walls, especially for rainwater protection, makes it difficult to accurately measure a house's surface area. This can cause variations of up to 25%. Nonetheless, given methodical North-South or East-West directions, bouncing boxes would adjust intimately with rooftops. On account of variable house directions, the rooftop is conceptualized as a square recorded in another square (jumping box), where the rooftop surface reaches from roughly half to 100 percent of the case surface, dependent upon the house's direction. Beginning investigations included preparing up-and-comer models with 480 and 1033 occurrences of conventional houses and an assessment set containing 124 and 363 things, individually, without manufactured information increase. The final model, which had been trained with 1033 instances of the data, was used to draw conclusions about the entire collection of approximately 700,000 tiles that covered Sumba Island. With a confidence score greater than 0.5 after computation, a total of 22,397 traditional houses were identified. Post-copy expulsion, 19,143 things remained. A careful GIS assessment, using BING satellite symbolism as a base guide, uncovered cases of bogus up-sides — protests erroneously recognized as customary houses, principally connected with low certainty scores close 0.5.

An end limit of 0.8 was executed, limiting bogus negatives. A few clear misleading up-sides in open spaces, similar to rice fields, were brought about by disconnected trees creating shaded areas looking like house rooftop towers, or in stream talwegs, where shadows from rocks reflected the presence of houses. These problems were fixed by hand, and known administrative buildings and resorts built in the traditional Sumbanese style were taken out. However, due to rare images of poor quality or out-of-date satellite imagery, the method may overlook some large houses in the field.

IV.2 QUALITY ANALYSIS

The quality analysis comparison in Table 1 provides overview of various techniques employed for detecting the cultural heritage of vernacular houses in Sumba Island, Indonesia. In the realm of accuracy, traditional techniques like decision tree, k-nearest neighbor, neural network, svr, and random forest exhibit range from 66.356% to 70.581%. Transitioning to advanced object detection models, such as ssd_inception_v2, ssd_resnet_50_fpn, Faster_rcnn_inception_v2, Faster_rcnn_resnet50, and Faster_rcnn_resnet101, results in incremental accuracy improvement, ranging from 71.637% to 75.862%. However, the proposed BSTO-VGG16-ALNN technique stands out with a substantial accuracy of 96.235%, shows a remarkable increase in precision compared to both traditional and advanced approaches. Precision, representing the true positives among the predicted positives, is a critical metric. Traditional techniques exhibit precision values ranging from 62.859% to 67.084%. Advanced models, while generally improving precision, still fall short of the proposed technique. BSTO-VGG16-ALNN technique achieves a precision of 95.689%, showcasing a substantial improvement over both traditional and advanced methods. Recall, highlighting the true positives among the actual positives, is equally crucial. Traditional techniques demonstrate recall values from 62.639% to 71.089%, with random forest achieving the highest recall among traditional methods.

Advanced models surpass traditional methods, with recall ranging from 67.920% to 72.145%. However, our BSTO-VGG16-ALNN technique achieves an outstanding recall of 94.865%, signifying a substantial percentage-wise increase compared to all other techniques. F-measure, representing the harmonic mean of precision and recall, offers a balanced view. Traditional methods exhibit F-measure values ranging from 62.749% to 71.199%, with random forest again leading among traditional techniques. Advanced models enhance F-measure, ranging from 68.030% to 72.255%. Notably, the BSTO-VGG16-ALNN technique achieves a remarkable F-measure of 95.275%, shows significant improvement over existing techniques. AUC, measuring the area under the receiver operating characteristic curve, provides insight into overall model performance. Traditional techniques exhibit AUC values ranging from 62.639% to 66.864%. Advanced models improve AUC, ranging from 67.920% to 72.145%. Once again, the proposed BSTO-VGG16-ALNN technique excels with an AUC of 95.025%, demonstrating substantial improvement over existing techniques. Fig. 2 highlights the superior performance of the proposed BSTO-VGG16-ALNN technique across multiple metrics

Table 1: Quality measure analysis comparison.

Techniques	Values in %				
	Accuracy	Precision	Recall	F-measure	AUC
	Training				
Decision tree	66.356	62.859	62.639	62.749	62.639
k-nearest neighbor	67.412	63.915	63.695	63.805	63.695
Neural network	68.469	64.972	64.752	64.861	64.752
SVR	69.525	66.028	65.808	65.918	65.808
Random forest	70.581	67.084	66.864	66.974	66.864
Ssd_inception_v2	71.637	68.140	67.920	68.030	67.920
Ssd_resnet_50_fpn	72.693	69.196	68.976	69.086	68.976

The quality analysis comparison in Figure 3 focuses on testing samples and provides an in-depth examination of various techniques employed for detecting the cultural heritage of vernacular houses in Sumba Island, Indonesia. In terms of testing performance, traditional techniques such as decision tree, k-nearest neighbor, neural network, SVR, and random forest exhibit accuracy values ranging from 68.729% to 72.954%. Notably, random forest demonstrates the highest accuracy among traditional methods. Transitioning to advanced object detection models, such as ssd_inception_v2, ssd_resnet_50_fpn, Faster_rcnn_inception_v2, Faster_rcnn_resnet50, and Faster_rcnn_resnet101, results in incremental accuracy improvements, ranging from 74.010% to 78.235%. However, the proposed BSTO-VGG16-ALNN technique stands out with a substantial accuracy of 96.985%, shows improvement in precision compared to both traditional and advanced approaches. Traditional techniques exhibit precision values ranging from 68.056% to 72.281%. Advanced models, while generally improving precision, still fall short of the proposed technique. BSTO-VGG16-ALNN technique achieves precision of 96.012%, shows improvement over both traditional and advanced methods. Moving on to recall, highlighting true positives among actual positives, traditional techniques demonstrate recall values from 66.733% to 76.239%, with random forest leading among traditional methods. Advanced models surpass traditional methods, with recall ranging from 72.014% to 76.895%. However, the proposed BSTO-VGG16-ALNN technique achieves an outstanding recall of 95.867%, improvement compared to other techniques. Traditional methods exhibit F-measure values ranging from 67.388% to 75.839%, with random forest again leading among traditional techniques.

Advanced models enhance F-measure, ranging from 72.670% to 76.895%. BSTO-VGG16-ALNN achieves F-measure of 95.939%, shows improvement over existing techniques. Traditional techniques exhibit AUC values ranging from 64.091% to 68.316%. Advanced models improve AUC, ranging from 69.372% to 73.597%. Once again, our BSTO-VGG16-ALNN technique excels with AUC of 95.865%, demonstrating substantial improvement over traditional and advanced approaches.

IV.3 ERROR ANALYSIS

Table 2 presents a comprehensive analysis of error measures, including R-squared (R2), mean relative error (MRE), and max relative error (MaxRE), for various techniques employed in the detection of cultural heritage in Sumba Island, Indonesia. Fig. 4 provides an in-depth analysis of error measures for various techniques employed during the training phase in the cultural heritage detection. In terms of R2, a measure of goodness of fit, traditional techniques such as decision tree, k-nearest neighbor, neural network, SVR, and random forest exhibit values ranging from 0.704 to 0.793. Advanced object detection models, including ssd_inception_v2, ssd_resnet_50_fpn, Faster_rcnn_inception_v2, Faster_rcnn Resnet50, and Faster_rcnn Resnet 101, show incremental improvements in R2, ranging from 0.795 to 0.837. Significantly, the proposed BSTO-VGG16-ALNN technique outperforms all others with an impressive R2 of 0.912, indicating a substantial increase in the model's ability to explain the variability in the data. Traditional techniques demonstrate MRE values ranging from 5.470% to 8.700%. Advanced models generally improve MRE, ranging from 5.220% to 6.700%. The proposed BSTO-VGG16-ALNN technique excels with a remarkably low MRE of 3.235%, shows a substantial decrease compared to all other techniques. MaxRE, representing the maximum difference between predicted and observed values, follows a similar trend. Traditional techniques exhibit MaxRE values ranging from 10.040% to 26.900%. Advanced models, while improving, still have MaxRE values ranging from 6.366% to 19.300%. BSTO-VGG16-ALNN technique stands out with low MaxRE of 6.366%, shows significant improvement compared to all other techniques.

Table 2: Error measure analysis comparison.

Techniques	Values in %			Values in %		
	R^2	MRE	MaxRE	R^2	MRE	MaxRE
	Without PCA			With PCA		
Decision tree	0.704	8.400	26.900	0.764	7.500	20.000
k-nearest neighbor	0.859	5.700	17.700	0.859	5.500	19.600
Neural network	0.673	8.700	21.800	0.840	5.900	18.700
SVR	0.787	6.600	17.700	0.870	5.100	16.500
Random forest	0.793	6.700	19.300	0.818	5.900	18.300
Ssd_inception_v2	0.795	6.470	16.120	0.866	4.900	16.670
Ssd_resnet_50_fpn	0.806	6.220	14.600	0.878	4.540	16.020
Faster_rcnn_inception_v2	0.816	5.970	13.080	0.890	4.180	15.370
Faster_rcnn_resnet50	0.827	5.720	11.560	0.902	3.820	14.720
Faster_rcnn_resnet101	0.837	5.470	10.040	0.914	3.460	14.070
BSTO-VGG16-ALNN	0.912	3.235	6.366	0.929	2.235	5.896

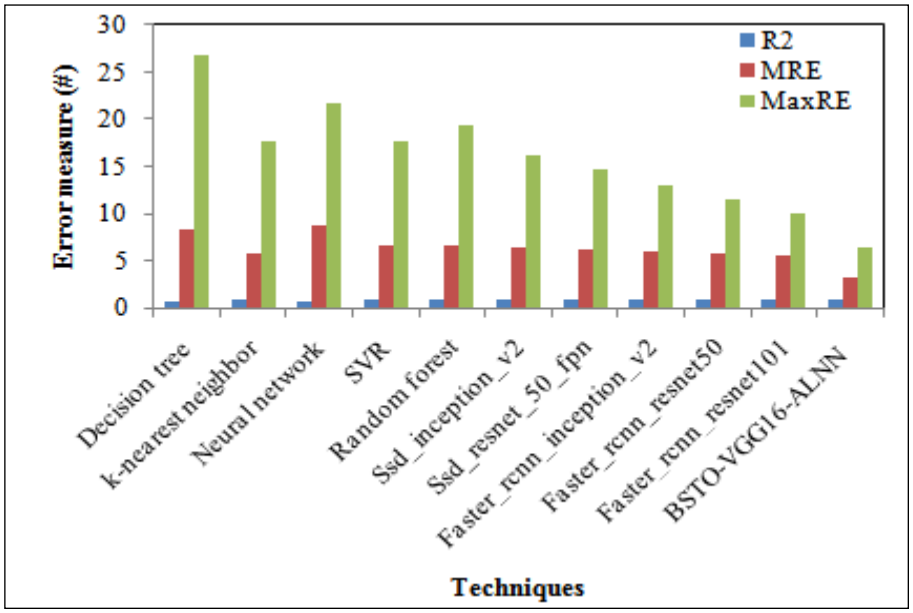

Figure 4: Error analysis comparison for training samples.
Source: Authors, (2026).

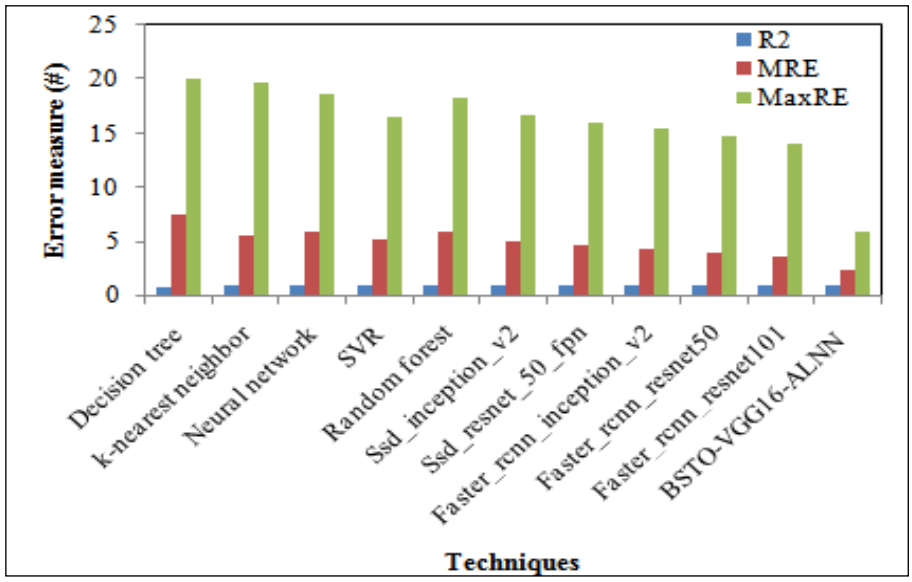

Figure 5: Error analysis comparison for testing samples.
Source: Authors, (2026).

Figure 5 presents error analysis for testing samples across various techniques employed in the cultural heritage detection task. Beginning with R^2, which measures the goodness of fit, traditional techniques like decision tree, k-nearest neighbor, neural network, SVR, and random forest exhibit values ranging from 0.764 to 0.870. Advanced models, such as ssd_inception_v2, ssd_resnet_50_fpn, Faster_rcnn_inception_v2, Faster_rcnn_ resnet50, and Faster_rcnn Resnet 101, show further improvements, ranging from 0.866 to 0.914. Notably, the proposed BSTO-VGG16-ALNN technique stands out with an impressive R2 of 0.929, shows a superior ability to explain the variability in the testing data. Traditional techniques show MRE values ranging from 5.1% to 7.5%, while advanced models generally improve MRE, ranging from 3.46% to 5.9%. BSTO-VGG16-ALNN technique excels with low MRE of 2.235%, shows improvements compared to other techniques. MaxRE, representing the maximum difference between predicted and observed values, follows a similar trend. Traditional techniques exhibit MaxRE values ranging from 14.07% to 20%, while advanced models, though showing improvement; still have MaxRE values ranging from 5.896% to 18.670%. The BSTO-VGG16-ALNN technique stands out with an exceptionally low MaxRE of 5.896%, show a significant improvements decrease compared to all other techniques.

V. CONCLUSION

We have introduced an approach employing advanced technologies for the detection of cultural heritage in the form of vernacular houses in Sumba Island, Indonesia. Our method integrates deep learning techniques and big data analytics to enhance the accuracy and efficiency of cultural heritage detection. The application of the boosted sooty tern optimization (BSTO) algorithm proves effective in precisely segmenting vernacular houses from remote sensing images, showcasing a crucial initial step in our methodology. Leveraging the pre-trained VGG-16 architecture allows us to extract intricate features from the segmented target image, enhancing the depth of our analysis. The subsequent implementation of the hybrid adaptive learning neural network (ALNN) ensures the automatic and precise detection of vernacular houses. Through thorough validation using Sumba Island tiles, our BSTO-ALNN technique shows compelling results, underscoring its effectiveness in accurately identifying and preserving cultural heritage. This method contributes to the broader field of cultural heritage preservation, offering robust and technologically advanced solution for detecting and safeguarding vernacular houses in diverse landscapes such as Sumba Island.

ABSTRACT

Digitization of education has made education more accessible. With the growing accessibility, the primary challenge for e-learning is to customise the learning environment to the needs and preferences of the learners. The learning can be customised by considering features such as persona type, skill level, learning goal, learning style, educational background, past knowledge, and memory span of learners. The tailored learning environments enhance learner engagement and significantly increase the number of learners who successfully achieve their educational goal. This work presents a recommendation system using the Case-Based Reasoning (CBR) and the Rule-Based Reasoning (RBR) with the Bidirectional Encoder Representations from Transformers (BERT) model embedded for sentence classification. The proposed integrated system has an F1 score of 0.74, indicating the balance between making correct and useful recommendations, and a higher normalised Discounted Cumulative Gain (nDGC) of 0.81 shows that the system ranks the most relevant learning modules at the top of the recommendation list. The classification of learning objectives using the BERT model into predefined domains achieved an accuracy of 95%. The system results in a structured learning path, which is more organized and engaging. The system is beneficial to novice learners, as it reduces failure rates and improves completion time of the learning process.

I. INTRODUCTION

A Recommendation system is represented as a Decision Support System (DSS), which is used to support the users in decision-making by providing the recommendations based on the analysis of crucial features of items, users, or past experiences. There are three foundational methodologies used in developing a recommendation system: Collaborative Filtering (CF) [1], Content-Based Filtering (CBF) [2], and Knowledge-Based Recommendation System (KBRS). KBRS is a privileged decision-support tool that provides recommendations based on the knowledge base designed by domain experts [3]. RBR and CBR are two major reasoning approaches in the KBRS that are widely used for developing the recommender systems. RBR is a deductive reasoning process, which discovers new findings from a rule base consisting of logical ‘if-then rules’ based on domain-specific knowledge, and the rule engine executes and controls the problem-solving process by matching rules of the rule base and facts of the problem.

CBR, on the other hand, utilises the previous experiences gained from the similar users to make the deductions for the new learner. It may identify past learner profiles similar to a new learner and recommend learning paths that proved successful for past learners. There are some issues associated with CBR and RBR approaches. CBR faces problems such as overspecialization, cold-start and limited content analysis, e.g., The overspecialization issue in CBR occurs when a system repeatedly suggests items very similar to the learner that he has already interacted with. The cold-start problem represents a situation when CBR is unable to provide appropriate suggestions due to insufficient data. The limited content analysis issue in CBR means that the number and type of features related to learning modules are limited.

While this aspect ensures relevance, it reduces novelty and diversity in recommendations, limiting the ability of the system to introduce new or unexpected items to learners. RBR also suffers from a knowledge acquisition bottleneck that means the process of designing rules for the knowledge base requires intensive domain expertise, updating the rules as the learner's needs change over time, and scalability issues as more learners use the system, resulting in more data, which makes the rule-base more complex and the system expensive. To address the various issues with standalone CBR and RBR, the integrated form of the CBR engine and RBR engine is proposed. To develop Knowledge-Based Recommendation Systems, there are four possible approaches for combining the CBR and the RBR [4], [5] engines. This paper utilises the integrated approach where the method of hybridisation is cascade, in which one engine refines the recommendations given by the other engine.

Utilizing the combined advantages of both reasoning approaches, the proposed system offers the accuracy possessed by the RBR engine and the experience adaptability exhibited by the CBR engine. By allowing the system to iteratively improve recommendations, cascade hybridisation helps to mitigate frequent drawbacks, including modelling complexity, overspecialization, and cold-start problems. The integration makes the system's recommendation process more accurate and flexible. The first phase in the proposed approach is the CBR engine, which uses a customized composite similarity metric called Contextual Persona-Scaled Similarity with BERT (CPSS-BERT) to retrieve past cases. BERT is an open-source machine learning framework used in natural language processing (NLP). As BERT reads text in both directions, it understands language better and produces smoother output than one-direction models, resulting in accurate results.

The learner is asked to create the profile with all essential attributes, such as the earning goal, taken as input in sentence format, and the BERT model classifies the sentences to the predefined domains using the CPSS-BERT similarity metric.The profile of the learner is matched to a past successful learner's case in the case-base. The second phase, which uses RBR, employs a set of rules that take into account variables, including learner preferences, memory span, content complexity, and prerequisite completion rate. It refines the initial learning path from the CBR to guarantee that the suggested learning modules are cognitively acceptable, instructionally cohesive, and pertinent. By using the integrated CBR and RBR approach, the proposed system makes sure that the recommendations to the learner are systematically structured and customized according to the learner's preferences.

The integrated approach overcomes the drawbacks of the CBR and RBR by making the recommendations based on the past cases that were successful in achieving the learners' goals. In case there are no past learners in the system, some synthetic data is stored in the case-base database. With the help of a synthetic dataset and rules of the RBR engine, the proposed system generates appropriate customized recommendations even if there is no past learner's case in the case-base database to match with the new learners. Through the profile modelling and custom similarity metric, the system also solves problems such as cold start and data sparsity. Data sparsity refers to the problem that occurs when the user-item interaction matrix is mostly empty because learners interact with a small number of items. The proposed integrated recommendation system provides a reliable, flexible, and learner-centred solution for the e-learning platforms. Key contributions of the proposed recommendation system are as follows:

1. An integrated recommendation framework that combines a CBR and an RBR engines in a layered pipeline. In the proposed system, CBR first retrieves relevant learning paths based on past learners' profiles. The output is then refined by RBR with pedagogical and persona-specific rules to finalize the most suitable path.
2. A solution to the cold-start problem using persona-weighted feature prioritization and BERT-based learning goal similarity allows interpretation of free-text learner goals.
3. A comprehensive set of pedagogical rules are defined based on memory span, learning goal, learning style, and skill level of learners. These rules ensure that recommendations are coherent, manageable, and align educational content with the learner's capability.
4. A progressive profiling mechanism is employed that tracks the learner's activities over time through assessment scores after completing each session and every module. Session consistency represents the engagement of the learner, resulting in improved customization and enhanced quality of the case-base for future CBR retrieval.

The remaining paper presents the following sections: Section II discusses related work of the previous research that has been done in the field of Recommendation systems and e-learning; Section III outlines the methodology of the proposed system with a block diagram; Section IV discusses the implementation of the system using case study; Section V demonstrates the results of evaluation metrics used for validation and comparative analysis of CBR, RBR and the proposed integrated system while section VI concludes the paper.

II. LITERATURE REVIEW

Recommendation systems have gained importance in the field of research over the past few decades. E-learning platforms especially need these smart systems more than ever, mainly to create customized learning paths based on the performance and habits of individual learners. The most widely used methods in the field of e-learning are CF, CBF and KBRS, but these methods have several problems: the cold-start problem, limited control in teaching, and customization of the learning environment. CF systems work with a large amount of data that is presented in the form of learning items, which is difficult for new learners or matching of new items to the existing items. Four different approaches to developing hybrid systems are gaining significance as they ensure adaptability and customization [4], [5].

Hybrid approaches such as weighted, switching, mixed, and cascade to combine the power of multiple recommendations are outlined [6]. The objective is to enhance the knowledge retention capacity of the learners through the recommended solutions. But numerous hybrid models still lack transparency and pedagogical correctness. CBR has been proposed as a suitable approach due to its ability to retrieve and adapt past learner cases that share similar objectives and learning paths. Foundational work outlines the impactfulness of CBR in problem-solving scenarios, while later studies [7] demonstrated its applicability in areas like tourism recommendation. However, when applied to education, particularly in structured domains such as cybersecurity, CBR by itself falls short of providing the necessary pedagogical dimensions.

To overcome this issue, RBR has been integrated with CBR to incorporate domain-specific rules to solve this problem. A hybrid system in medical decision-making was reported [8]. A multi-layered architecture [9] in the field of e-learning is proposed, while a hybrid adaptive system utilising expert rules and ontology matching is presented [10]. The recommendation systems are based on semantic intelligence, persona awareness, and adaptive path control [11-13], whereas MOOCs and intelligent teaching systems have been outlined, in which the number of current Recommendation systems uses various features like framework design, learner memory retention, and the objective of the learning [14], [15].

As the representation of data of knowledge database is crucial to recommend solutions, the study [16] proposed a framework for a knowledge graph that is multidimensional, in which it models the progress of the learner, prerequisite modules, and content structure and similarly. ERSDO, which is an ontology-based system [17], is presented that dynamically customise learning modules and their connections. A Crop Recommendation System [18] using machine learning is proposed that generates recommendations about suitable crops based on the climate and the soil. The data-driven approach of the work presents how adaptability is enhanced through predictive modelling. A trust-aware model using Deep Matrix Factorization [19] is proposed that presents the accuracy and reliability of the recommendation that can be improved by integrating the trust level of the user.

A movie Recommendation system is outlined [20], showing that the adaptability and customization can be improved by using the hybrid and deep learning approaches. The hybrid recommendation systems using the sentimental analysis is presented [21], which demonstrates the importance of adaptive profiling and ranking of learning modules in the field of e-learning. The above-mentioned studies describe that the most common recommendation systems in e-learning are driven by CF, CBF and KBRS, and some of them are semantic-based, ontology-based or hybrid as well, but they fail to make a recommendation system that is adaptable, transparent, pedagogically precise and customised and solves the issues such as cold start, data sparsity, overspecialization, etc.

This paper proposes a system that combines CPSS-BERT for semantic learning goal similarity enhanced by persona-weighted feature mapping, RBR for expert logic enforcement, and CBR for historical learner case retrieval. The BERT model [22], [23] has been utilised for analysing the learning goal, as it works well with modelling, classification and relevance of textual information. This multi-layered pipeline ensures that the learners are precisely matched to past successful cases, pedagogically correct, and adaptive to the learners' preferences. The proposed system is designed to use an integrated approach that tightly couples the CBR and RBR and ensures that it is adaptable to any type of domain where accuracy, pedagogy, and adaptiveness are significant.

III. RESEARCH METHODOLOGY

With education shifting from conventional classrooms to online platforms, there is a growing need for intelligent systems to help students reach their goals by providing them with customized educational content based on their individual profiles, including background, past knowledge, skill level, and so forth. The growing demand for customized learning also presents a significant challenge in the field of e-learning. This paper outlines an integrated recommendation system for customized e-learning that tightly couples the RBR engine within the CBR cycle. The proposed system helps the learners to achieve the learning goal through appropriate recommendations according to the learner's preferences, goals, and receptiveness. It uses two types of knowledge-based reasoning: CBR and RBR. The proposed system is deployed within a learning management platform designed to support customized learning paths for each learner.

It provides learner-specific profiles that include information such as persona type, learning goal, prior knowledge, skill level, memory span, preferred learning style, and content format. After the profile modelling phase, the profile of the learner is given as the input in the CBR engine, which has four processes. The first process uses a customized similarity function, CPSS-BERT; the system identifies past learner cases that are similar to the target learner. The similarity function encompasses both the profile's attribute matching and the learning goal comparison to the predefined domains using BERT embeddings, which is often used for quality e-learning through assessment, relevance of domains to the learning goal, and textual analysis [24]. The CBR engine generates initial learning path recommendations for the RBR engine. After the initial recommendations are made, the initial learning path is given as input to RBR.

A set of rules are applied to validate, refine, and organize the learning path pedagogically. These rules are designed to implement content prerequisites, align instructional difficulty with the learner's receptiveness, and ensure a pace that matches the capacity of the learner. The rules ensure that the learning path is aligned with the learner's preferences. The system supports adaptive content delivery by recommending multiple learning styles, such as text, video, labs, and projects, which is based on the learner's given preference of style and performance history. It also provides time-based estimates of course completion by measuring study sessions on a daily basis, which help learners to plan lessons more effectively.

With the combined strength of CBR for finding the past similar learner's case and the RBR engine for rules filtration, which refines the learning path recommendation, the proposed recommendation system provides a customized, adaptive, and pedagogically suitable e-learning environment. The integrated approach of CBR and RBR engines improves learner involvement, ensures efficient time utilization, and improves knowledge acquisition in e-learning environments. The proposed recommendation system is designed to develop customized learning paths and modules by analysing the learner's receptiveness, preferences, goal, content duration, session duration, and session consistency, as illustrated in Figure 1. A detailed explanation of each phase is provided below.

III.1 REGISTRATION AND LOGIN

Learners use the proposed system through an e-learning platform that works for both new and existing learners. Existing learners can directly log in to the e-learning system and get access to the customized dashboard, which contains progress reports of the previously chosen learning paths. New learners are asked to complete a registration process before logging in. Login data contains details of the learner, such as email ID, password, age, gender, and so on. Once the successful authentication is completed, new learners are redirected to the profile modelling phase.

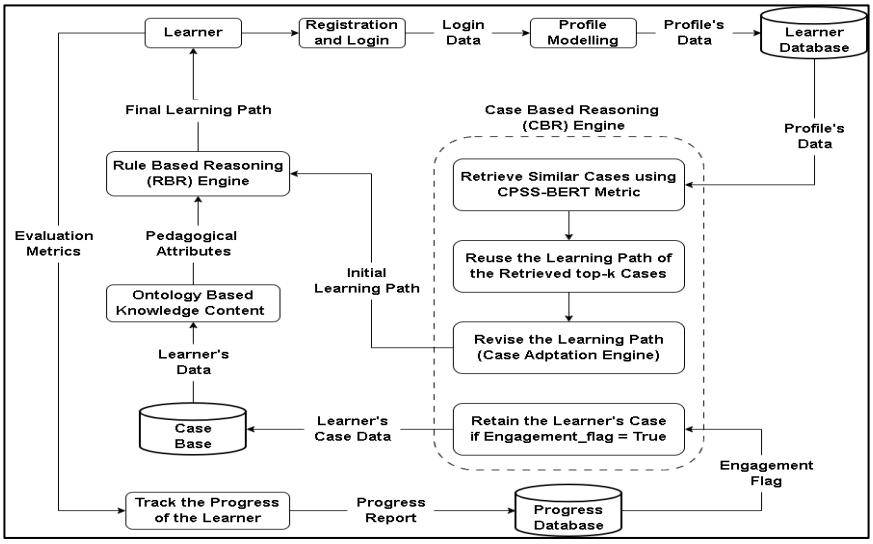

Figure 1: Block Diagram of the Proposed Integrated Recommendation System for E-Learning.
Source: Authors (2026).

III.2 PROFILE MODELLING

Following the completion of authentication, new learners are directed to the profile modelling phase, where attributes of the learner that are most crucial for an online education, such as the learner's persona type, learning goal, skill level, background, memory span, learning style, and prior knowledge, are gathered through a questionnaire. A quiz is designed to gauge the previous knowledge of the learner using the learning goal, skill level and background. The content recommendations and a personalised learning path are guided by the learner's profile. The next phase involves the CBR engine, which is the core of the proposed system.

III.3 CASE-BASED REASONING (CBR) ENGINE

Once the profile modelling phase is complete, then the attributes of the learner's profile are given as the input to the CBR Engine as the profile data, as illustrated in Figure 1. The profile data contains the learning goal, the learning preferences, and receptive capacity. CBR is employed for retrieving and adapting learning paths from previously retained learner cases in the case-base database that are similar to the new learner. The retrieval in the CBR engine is done by using a customized composite similarity function called Contextual Persona-Scaled Similarity with BERT Fusion (CPSS-BERT).The CBR engine operates through the CBR cycle, consisting of four steps—Retrieval, Reuse, Revision and Retain—that systematically align and adapt leaner profiles to generate customized learning path recommendations. Algorithm 1 for a CBR, which returns the final adapted case, is described below. This helps the system to learn from past learner experiences while adjusting to the needs of each new user. Each phase of the CBR engine is discussed below in detail.

Algorithm 1

III.3.1 Retrieve: CPSS-BERT Similarity Matching

On the completion of the profile modelling phase, the learner's profile is matched against a case-base of prior learners using a composite similarity function called CPSS-BERT. Each structured attribute f in the learner profile such as skill level, memory span, background, learning style, prior knowledge and assessment score, are compared with the corresponding attribute in a previous case $\boldsymbol{c}$, using tailored similarity functions that return a normalised similarity score $\boldsymbol{Sim_f(u,c)}$ in the range [0,1], where:

i) $\boldsymbol{u}$: the new (target) learner's profile.
ii) $\boldsymbol{c}$: a past learner case from the case-base.
iii) $\boldsymbol{f}$: a specific feature/attribute.
iv) $\boldsymbol{w_f}$**:** the persona-specific weight assigned to the feature $\boldsymbol{f}$, based on its relevance to the learner's motivational type.

For different types of attributes, this study employs different metrics such as categorical distance, set-based Jaccard, and numerical score distance [25], [26]. For ordinal features such as skill level, the similarity is computed using a normalized distance metric, as given in (1) as,

$$Sim_f(u,c) = 1 - \frac{|index(u) - index(c)|}{\max_distance} \quad (1)$$

In the ordinal similarity function, $index(u)$ and $index(c)$ represent the respective index positions of the learner and the historical case for a given ordinal feature. The variable max_distance denotes the maximum possible index difference in this ordered list, which ensures normalisation of the similarity score between 0 and 1. When the new learner and past learner case have multi-select categorical preferences, the Jaccard similarity shown in (2), which works on categorical data, is computed.

$$Sim_f(u,c) = \frac{|u \cap c|}{|u \cup c|} \quad (2)$$

The Jaccard similarity is used for comparing categorical set-based attributes such as learning styles based on the intersection and union of preferences between the new learner and a past learner case. In this context, $|u \cap c|$ denotes the count of shared styles of learning between the learner u and the case c. Conversely, $|u \cup c|$ denotes the total number of distinct learning styles present across both profiles, capturing the full diversity of preferences expressed by either case. For numerical attributes such as assessment scores obtained from prior knowledge quizzes and module test scores, similarity is calculated by normalizing the absolute difference between learner and case scores using (3).

$$Sim_f(u,c) = 1 - \frac{|u-c|}{\max_score} \quad (3)$$

The numerical similarity is calculated using assessment scores, where u represents the quiz score of the learner, c is the score from a past learner case, and max_score represents the maximum score that is possible (commonly 100). This approach normalizes the similarity between the two scores on a scale from 0 to 1. Once similarity scores are calculated for features like skill level, learning style, and memory span, they are scaled using feature-specific weights w_f, that are assigned dynamically based on the learner's persona. For example, a beginner or new learner may benefit more from features like past knowledge and memory span, while professional may focus on learning objectives and preferred content type. The retrieve step comprehends the meaning of the learning goal in sentence form given by the learner, and the similarity between the learner's and the new learner's goal is calculated using (4), which is based on the cosine similarity measure used in Sentence BERT [27].

$$Sim_f(u,c) = 1 - \frac{g_u \rightarrow . \, g_c \rightarrow}{\| g_u \rightarrow \| . \, \| g_c \rightarrow \|} \quad (4)$$

In (4), $g_u \rightarrow$ and $g_c \rightarrow$ represent the semantic embedding vectors of the learner's and the past learner's case goals, respectively, $\| g_u \rightarrow \|$ and $\| g_c \rightarrow \|$ denote the Euclidean magnitude of vectors. This component ensures adjustment between the semantic intent of the learner and previous learners, even if text given by the learner differs significantly. The final overall similarity score $Sim_{total}(u,c)$ is derived in (5) by combining the weighted sum of all structured similarities with the semantic similarity:

$$Sim_{total}s(u,c) = \alpha \sum_{f=1}^{n} w_f . Sim_f(u,c) + (1-\alpha) \, . \, Sim_{BERT}(u,c) \quad (5)$$

Where the parameter $\alpha \in [0,1]$ is a tuneable weight that controls the comparative importance of the structured feature-based resemblance and the semantic correlation derived from BERT embeddings. A higher value of α places more emphasis on the structured attributes such as skill level, memory span, and learning style, while a lower value shifts the focus towards semantic alignment of learning goals. Here, n represents the total number of structured features, w_f is the persona-weighted importance of feature f, and $Sim_f(u,c)$ is the similarity score for feature f between the current learner u and a historical case c. The term $Sim_{BERT}(u,c)$ quantifies the semantic similarity between the new learner's stated goal and of the past learner's case, using cosine similarity on BERT-generated embeddings. The top-k past learner's cases with the highest total similarity scores are selected using the CPSS-BERT similarity function for generating the learning path of the new learner.

III.3.2 Reuse: Learning Path Retrieval

The learning paths are extracted from the top-k retrieved past learners' cases. These paths consist of sequences of modules, for example, videos, texts, labs, etc., associated with the target learner's goal. Modules frequently appearing among the top-k cases are prioritized, and their success outcomes, such as completion rate and failure rate, are factored into an initial learning path for the new learner. Once the initial learning path is generated, it is transferred as input to the next phase—the case-adaptation engine.

III.3.3 Revise: Case Adaptation Engine

After the retrieval and reuse process completed by the CBR Engine, the proposed system presents a Case Adaptation Engine, which implements the Revise step. The learning paths are adapted according to the new learner profile, which are retrieved from the previous past cases. The adaptation process considers various major personal characteristics to customize the learned path based on the current learner's environment, such as the learner's daily study slots available, as they represent typical learning habits that are used to determine pace and estimated completion time for each module. The learner's memory span, whether short, medium, or long, impacts the intervals of repetition content and review modules to facilitate efficient learning.

The learner's learning style preferences are included in the learning path given by the recommendation system. Each module on the recommended path is thoroughly analysed and tailored to fit the unique attributes of the learner.The duration of each module is adjusted based on the daily hours offered by the learner. The level of educational content is customised based on the learner's previous knowledge and capability; individuals with lower evaluation grades or shorter retention capacity are offered basic modules and supplementary revision-based material. The content format is tailored to the learner's preferred style; for example, text modules may be replaced with videos or interactive labs.

Adaptation rules ensure that the retrieved learning path from the case-base is adapted according to the learner's needs and preferences, which results in the initial learning path. This step is executed before the RBR engine phase, which takes the initial learning path as input and refines it more. The Case Adaptation Engine follows Algorithm 2 described below. The customized recommendation contains a studied set of learning modules consisting of theoretical material, videos, labs, and evaluations customized to the ability of the learner, memory span, learning style, and declared learning goals. It is a basic learning path, maximized for relevance and engagement, that will be further tested and finalized by the RBR engine to provide pedagogical integration and lesson alignment.

III.3.4 Retain: Case Storage and Update

After the complete representation of the case-base data, rule refinement, learner interaction, and progress tracking, the system monitors the outcomes and retains the updated learner case, including profile, learning path, and results in the case-base database. This enables continuous improvement and adaptability of future recommendations. If a learner successfully completes the learning path, the system stores that learner's case in the case-base database with the learning path for future case-based retrieval, as shown in Figure 1 above.

III.4 ONTOLOGY-BASED KNOWLEDGE MODELLING

The ontology model organizes the knowledge content into a set of interconnected entities that collectively define the pedagogical and learner-centred aspects of the system. E-learning course strategy is represented as the central entity that connects the four major components, such as learner's profile, learner's behavior, learner performance, and content structure. The entities and their attributes are stored in the data dictionary that serve as the semantic input source for the RBR engine in the system. The integration of the ontology model with the RBR engine forms the semantic bridge between structured data and intelligent decision-making. During execution, the ontology retrieves relevant pedagogical and learner-specific information from the data dictionary and provides it as semantically structured input to the RBR engine. The RBR engine then applies predefined instructional and pedagogical rules to match ontology attributes with suitable learning modules. The working of the RBR engine is explained in detail in the following phase.

Algorithm 2

1. Initialize Initial_Learning_Path ← ∅ (empty)
2. IF learning_Styles is a single string, THEN convert it into a list.
3. For each (Case, Score) in Extracted_Learning_Paths:
a. Set Modules_List ← Case.Modules
b. Initialize Filtered_Modules ← ∅ (empty)
c. For each Module in Modules_List:
For each Style in Preferred_Styles:
IF Style partially matches Module.Format (case-insensitive),
THEN Add Module to Filtered_Modules and break the inner loop.
d. IF Filtered_Modules is empty, THEN assign original Modules_List as fallback.
e. Update Case.Modules ← Filtered_Modules
f. Append updated Case to Initial_Learning_Path
g. IF optional case limit k is reached, THEN exit loop.
4. Return Initial_Learning_Path
End

III.5 RULE-BASED REASONING (RBR) ENGINE

The initial learning path that is generated by the CBR engine based on the learner's profile is fed to the RBR engine as input that further enhances the learning path through pedagogical logic. The RBR engine follows Algorithm 3 described below that fine-tunes the learning sequence. The role of the RBR engine is to enhance the instructional validity of the learning path by applying domain-specific rules developed by a domain expert of curriculum principles and prerequisite modules. The refinement process begins with the retrieval of pedagogical metadata from the case-base database. This metadata covers aspects such as module difficulty level, prerequisite relationships, learning modules, and memory span indicators. These pedagogical descriptors are organised in the learning modules in a smart way so that the order of recommended modules matches both the learner's personal needs and proper educational design principles. The set of rules defined by the domain expert are applied to the initial learning path generated by the system to refine it iteratively.

III.6 PROGRESS TRACKING MODULE

The proposed system tracks the progress of the learner through learning activities, which helps to observe the performance and engagement level of the learner. It also suggests areas where the learner can improve. The data of the progress tracking is stored in the progress database that acts as a centralized hub for containing and maintaining the actions performed by the learners during the engagement with the proposed system. Data in the progress database contains session-specific metrics like session duration and session consistency and performance metrics like completion rate, failure rate, and recurrence rate of the learner. Learning preferences are tracked by observing the formats that the learner interacted with most, such as videos, labs, text, or projects. The database provides validation checks for the learner's initially declared preferences. The system also takes into account content structure, such as verifying whether learners are engaging] well with the structured, and pedagogically accurate modules and whether the content is up to date.

This may flag any system inconsistencies for subsequent revision. Based on these factors, the system calculates an overall engagement assessment called Engagement Flag. This flag indicates various states of the learners: *Success*, denoting completion of the learning path, and *Recurrence*, reflecting repeated revisits of modules, or *Failure*: showing the low engagement or incomplete modules. The results, along with session metrics, are stored in the Progress Database. If a learner successfully completes the learning path, the system stores that learner's case in the case-base database with the learning path for future case-based retrieval, as shown in Figure 1 above. The refining of the learning path makes sure that the proposed recommendation system evolves as real learner data increases and ensures the adaptability and correctness of the system.

Algorithm 3

1. Initialize Final_Learning_Path ← ∅
2. Retrieve Memory_Span, Learning_Style, Skill_Level from Learner_Profile
3. For each Case in Adapted_Cases:
a. Set Modules_List ← Case.Modules
b. Initialize Refined_Modules ← ∅
***Rule** 1 - Memory Retention:*
IF Memory Span is short, THEN add a learning model M with revision frequently.
IF Memory Span is long, THEN add a long duration learning modules.
***Rule** 2 – Define the difficulty level of the Module:*
For each learning module M in Refined Modules,
IF Module.Difficulty > Skill_Level of learner, Then add basic modules in the learning path.
***Rule** 3 – Structure the content according to the preferred Learning style:*
For each M in Refined Modules,
IF Module.Format ≠ Learning Style of the learner, Then insert a different style of modules.
4. Assign Case.Modules ← Refined Modules
5. Add the learner's Case to Final Learning Path
6. Return Final Learning Path
End

IV. IMPLEMENTATION OF THE PROPOSED SYSTEM

To demonstrate the application of the proposed integrated recommendation system, a detailed walkthrough is presented for a new learner interacting with the e-learning platform offering cybersecurity education. This case study illustrates how each phase of the methodology is applied to construct a customized and pedagogically precise learning path for the learner, using structured profile modelling, integrated case-based rule-based reasoning-driven recommendation, and intelligent content sequencing. Python's Transformers and TensorFlow 2.0 libraries were used to implement the BERT model along with the Hugging Face library of Python transformers. The proposed recommendation system is implemented using Python 3.13.0 and React.js is used for the front-end framework. The case study for the new learner is mentioned below.

IV.1 CASE STUDY

A new learner, *Riya Sharma*, visited the e-learning platform for the first time. Upon accessing the registration page, Riya created an account by entering her name, email, and basic credentials. Once Riya registered and logged in to the system with the valid login credentials successfully, she was redirected to the profile modelling phase.

It is the first phase of the proposed system, where the learner gives inputs and answers the various questions like the persona of the learner; that is, which category the learner belongs to, such as college student, job seeker or professional looking for a career change. Riya selected the college student as her persona. The next set of questions include the learning goal in the form of a sentence. The system used the BERT model to classify the learning goal to the predefined domains. For the cybersecurity e-learning, she entered the learning goal as "I want to become an ethical hacker", which was then classified to the 'ethical hacking' domain of the proposed system. This classification helps the system to ensure that the learning path only contains the learning modules related to the given learning goal of the learner. Furthermore, she selected her skill level, which had the three options such as beginner, intermediate or advanced. She selected the beginner level as her level of skill. She was also asked to choose from which background she belonged, such as tech or non-tech. She selected *tech* as her background, as she knew about the computer fundamentals and could complete basic modules without any difficulty.

She was also asked for her preferred learning style, such as text, video, lab or projects. The system presented her a quick test on the principles of general computing and logic to evaluate her past knowledge. Riya scored 30%, indicating limited baseline knowledge. This score was recorded and used to tailor the learning path, ensuring she begins with foundational concepts. Subsequently, Riya answered behavior-based questions to estimate her memory span. Based on her responses, she was classified as having a *medium* memory span, suggesting an average retention capacity and a need for moderately paced content review. Upon the completion of the profile modelling phase, all collected data was stored in the learner profile database. The structured profile was input to the CBR engine, which started the recommendation pipeline by finding similar past learner cases using Algorithm 1 that employs the CPSS-BERT similarity function using (5) to combine the similarities of each attribute individually as obtained using (1-4). Overall similarity of learners was obtained using (5) depending on the weights given by the academicians to the attributes for persona types as shown in Table 1.

Table 1: Weight assigned to attributes according to the Persona of the learner.

Feature	Student	Career Switcher	Enthusiast	Professional
Skill Level	0.25	0.30	0.30	0.20
Prior Knowledge (Quiz)	0.30	0.25	0.25	0.20
Memory Span	0.20	0.10	0.15	0.15
Learning Style	0.10	0.15	0.10	0.15
Content Preference	0.10	0.10	0.10	0.20
Learning Goal (BERT)	0.05	0.10	0.10	0.10

Source: Authors, (2026).

As there were 3 past cases stored in the case-base database, namely, Case A, Case B, and Case C. The values of similarity for each case attribute are given below:

Case A: Skill = 1.00, memory span = 0.50, learning style = 0.50, prior knowledge = 0.98, learning goal = 0.98, background = non-tech (0),
Case B: Skill = 0.50, memory span = 0.50, learning style = 0.25, prior knowledge = 0.65, learning goal = 0.225, background = non-tech (0),
Case C: Skill = 1.00, memory span = 1.00, learning style = 0.25, prior knowledge = 0.95, learning goal = 0.99, background = tech(1).

The system first calculated the similarity of the new learner to Case A, where each attribute was computed and multiplied by the weights. And the overall similarity score was obtained as 0.795. Similarly, the similarity of Case B and Case C was computed, where the achieved similarity scores for Cases B and C were obtained as 0.481 and 0.834, respectively. The top similar past learners were Case C (highest) and Case A (the second highest). From these retrieved cases, top similar cases such as A and C were passed to Algorithm 2, which extracted the learning paths from the top similar past learners and shortlisted the desired learning modules, which resulted in the initial learning path as depicted in Figure 2. The resulting initial learning path was fed as input to the RBR refinement engine, where pedagogical rules were applied. The RBR engine used Algorithm 3 for refining the learning path. The rules of RBR filtered out modules as per Riya's current skill level, reordered the content based on prerequisites, and matched content formats to her preferred style.

After rule refinement, a final customized learning path was generated and displayed to Riya on her dashboard as shown in Figure 3. The dashboard also included an introductory message highlighting the estimated duration, content types included, and next phases to begin the learning journey. As Riya engaged with the system and interacted with learning modules, the system tracked the learner's activity and behavior, which helps in computing her performance metrics. The system analysed Riya Sharma's progress data to calculate the performance metrics, such as completion rate, failure rate, and recurrence rate. Out of 10 learning modules in her ethical hacking learning path, Riya successfully completed 8, failed 1, and left 1 module incomplete. Furthermore, the system calculated a completion rate of 80%, indicating a successfully achieved learning goal and strong engagement of the learner.

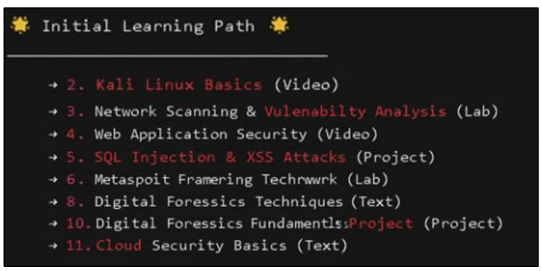

Figure 2: The initial learning path extracted and adapted to learner's profile using Algorithm 2.
Source: Authors, (2026).

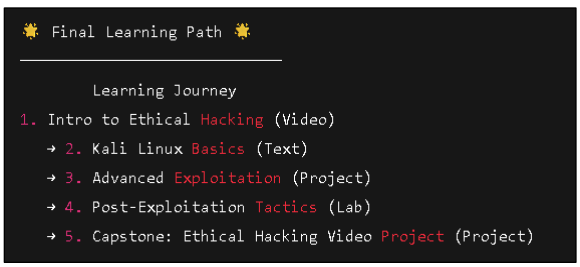

Figure 3: The final learning path generated according to the learner's need using Algorithm 3.
Source: Authors, (2026).

The failure rate of the learner was obtained as 20%, representing challenges in advanced topics and leaving the learning journey in the middle. Revisiting three modules, Riya exhibited a 37.5% recurrence rate, which corresponded to her moderate memory span and need for reinforcement.

V. RESULTS AND ANALYSIS

In this section, evaluation of the proposed system was performed. A total of 100 participants were considered for the study. The participant's learning goals were classified in six predefined cybersecurity domains: web security, bug bounty hunter, network security, penetration testing, ethical hacking, and Android security, The study may be extended to other domains of different subjects. The integrated system makes the profiles of a learner, and uses the BERT model to analyse the learning goal to classify it. The evaluation of the BERT model is given below.

V.1 BERT MODEL PERFORMANCE

The BERT model used the publicly available "Attack Dataset" from Kaggle.com [28]. The dataset was processed to handle inconsistencies, archive class balance, and ensure relevance for learning goal classification. The performance of the BERT model was evaluated using the standard classification metrics—Accuracy, Precision, Recall, and F1-score. Here, True Positives (TP) represent sentences correctly classified into their intended category, True Negatives (TN) denote sentences not belonging to the desired category, False Positives (FP) indicate sentences incorrectly assigned to a chosen category, and False Negatives (FN) correspond to sentences belonging to a category but were not correctly classified. The BERT model was trained on a total dataset of 14,134 labelled sentences, where the values of TP, TN, FP and FN were obtained as 11,800, 1,650, 344 and 340, respectively. The resulting system achieved an accuracy of 0.95, a precision value of 0.97, a Recall value of 0.971, and an F1-score of 0.971. These results confirm the BERT model's robust contextual understanding, enabling accurate and intelligent domain classification. The subsequent section computes the metrics used for validating the proposed recommender system.

V.2 VALIDATION OF THE PROPOSED SYSTEM

The performance of the proposed system was evaluated through the metrics mentioned below. Metrics such as Precision, Recall, F1-score, Normalized Discounted Cumulative Gain (nDCG) [24], the Instructional Coherence Rate (ICR) [25], Learning Path Effectiveness (LPE) [29], and the Engagement Score [30] were utilised to validate the projected system. The three different approaches of KBRS, such as CBR-only, RBR-only and the proposed integrated system, were compared. The resultant values of the validation metrics are given in Table 2, which outlines that the proposed integrated system outperforms the standalone CBR and RBR systems. The integrated system, for instance, obtained the highest precision (top 5 recommendations) score of 0.78, indicating that the top five suggestions were pertinent. It presented a higher percentage of all appropriate resources for learners, as shown by Recall (Top 5 recommendations) score of 0.70. The value of the F1-score (top 5 recommendations) was obtained as 0.74, which strikes a compromise between Recall and Precision, representing a balance between suitable recommendations and identifying all useful learning modules.

Table 2: Comparison of CBR, RBR and Integrated System.

Metric	CBR Only	RBR Only	Proposed Integrated Recommendation System
Precision	0.68	0.70	0.78
Recall	0.60	0.58	0.70
F1-Score	0.64	0.63	0.74
nDCG	0.69	0.68	0.81
Engagement Score (/10)	6.2	6.5	8.4
ICR	0.72	0.76	0.89
LPE	0.75	0.77	0.91

Source: Authors, (2026).

With a nDCG of 0.81 (Top 5 recommendations), the integrated system had the highest ranking, indicating the most relevant items were placed higher in the list of recommendations. The comparison of CBR-based, RBR-based and integrated CBR-RBR, using the set of metrics is illustrated in Figure 4. The results show that both individual models were surpassed by the integrated proposed approach across the evaluation metrics.

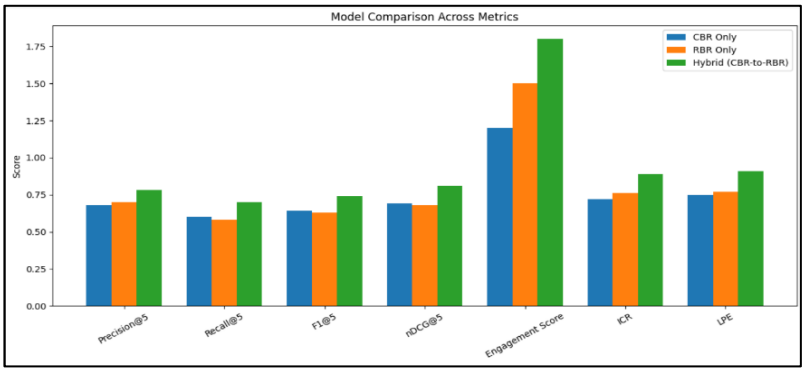

Figure 4: Comparison of CBR, RBR and Integrated System.

VI. CONCLUSIONS

This study proposed an integrated recommendation system using the BERT model that outperforms the standalone CBR-only and RBR-only systems. The integrated system overcomes the issues of the traditional recommendation systems like CF, CBF, and KBRS. The proposed system solves the cold-start problem by integrating the pedagogically and expert-designed rules of the RBR engine in the CBR cycle for non-existing past learners' cases. The CBR engine addresses the issue of data sparsity by using the past cases only if explicit data of the learner was insufficient, and in that case, RBR provides a fallback expert recommendation. The custom CPSS-BERT metrics used the BERT model to classify the learning goals of the learners, which helped the system to recommend more customised learning paths that resolved the overspecialization to some extent.

The integrated recommendation system achieved an engagement score of 8.4 out of 10, suggesting that learners showed the highest engagement and completed most of the modules in the suggested learning path. With an Instructional Coherence Rate (ICR) of 0.89, most of the recommended learning paths followed the right order and fulfilled the necessary requirements of learners. The Learning Path Effectiveness (LPE) value of 0.91 indicated that a majority of the learners effectively completed the prescribed paths and achieved high scores in the post-assessment phase. The proposed system provides a consistent and learner-centred solution for the e-learning platforms.

ABSTRACT

In the rapidly development of remote sensing technology, the compression of Hyperspectral Images is a pivotal yet formidable task. Hindered by inherent limitations in hyperspectral imaging, enhancing the accuracy and efficiency of compression algorithm remains a critical and much-debated issue. Algorithms using set partition wavelet transforms excel in hyperspectral image compression due to their embedded nature, coding efficiency, and low complexity. Specifically, the Fractional wavelet-based zero memory set partitioned embedded block algorithm achieves high coding efficiency with lower memory demands, though its method of repeatedly comparing coefficients to a threshold is time-intensive. To solve this, a new algorithm has been developed that optimizes both computational and memory complexity. It employs a block-based fractional wavelet filter (BFrWF), which delivers the same accuracy as conventional transforms but requires far less memory. The Block-based Fractional Wavelet Filter is a low-memory technique for image transformation, but its high computational complexity makes it impractical for resource-constrained devices in IoT and Wireless Sensor Networks. Additionally, it produces blocking artifacts due to improper handling of block boundaries. This paper introduces a new lifting-based version of BFrWF that eliminates these artifacts by correctly overlapping image blocks. This new implementation with low complexity zero memory set partitioned embedded block (LC-ZM-SPECK) achieves higher coding efficiency, making it well-suited for resource constraint visual sensor nodes.

I. INTRODUCTION

Hyperspectral imaging (HSI) represents a significant analytical advancement as a non-destructive, integrative technology that merges the principles of imaging and spectroscopy to simultaneously capture both spatial and extensive spectral data from a target. Unlike conventional imaging that operates in broad bands, HyperSpectral (HS) image acquires detailed information across a contiguous series of tens to hundreds of narrow, adjacent wavelength bands for each pixel in an image, creating a complex three dimensional data structure known as a hypercube. This rich spectral signature enables the precise identification, quantification, and spatial mapping of chemical constituents (e.g., moisture, fat, pigments), physical properties, and structural characteristics within a sample without any preparatory alteration or destruction [1]. Implementing an efficient compression algorithm enhances sensor performance through multiple key benefits includes reduced coding complexity, lower power consumption, conserved communication bandwidth, faster browsing times, and decreased processing costs. The effectiveness of a HyperSpectral Image Compression Algorithm (HSICA) is evaluated based on three core metrics: coding efficiency, coding memory, and coding complexity [2].

- Coding efficiency is quantified using Compression Ratio (CR), Peak Signal-to-Noise Ratio (PSNR), and the Structural Similarity Index (SSIM).
- Coding memory refers to the amount of memory the algorithm consumes during compression.
- Coding complexity is measured by the time the algorithm takes to encode and decode data, excluding the time spent on the wavelet and inverse wavelet transforms [3].

HS image compression algorithms can be classified in two primary ways: based on the degree of data loss or based on the encoding technique used [2]. The first classification, based on data loss, consists of three categories:

- Lossless: No data is lost, and the original image can be perfectly reconstructed, but this results in a low CR.
- Near-Lossless: A minimal amount of data is lost, leading to a slightly higher CR than lossless methods. The reconstructed image is virtually indistinguishable from the original.
- Lossy: Some data is intentionally discarded, achieving the highest CR. It is known that the human eye typically cannot perceive image degradation beyond a PSNR of 40 dB.

The second classification is based on the encoding methodology, which divides algorithms into seven subgroups [4], [5]:

- Predictive Coding (PC) based HSICAs
- Vector Quantization (VQ) based HSICAs
- Transform Coding (TC) based HSICAs
- Tensor Decomposition (TD) based HSICAs
- Compressive Sensing (CS) based HSICAs
- Machine Learning (ML) based HSICAs
- Hybrid HSICAs

To eliminate undesirable redundancy and exploit the inherent correlation within HS images, TC based compression techniques utilize mathematical transforms. These transforms, such as Fourier, wavelet, cosine, curvelet, and shearlet, serve to project the HS image data into a more compact frequency-domain representation. The wavelet transform is widely recognized for its superior performance in this context, as it provides multi-resolution analysis and maintains localization information in both the original and transformed domains.

II. BACKGROUND

HS image compression is fundamentally achieved by eliminating inherent data redundancies which are categorized as spatial and spectral redundancy. Spectral redundancy arises from the high correlation between adjacent frequency bands, while spatial redundancy is due to the similarity between neighbouring pixels within a band. Research indicates that spectral redundancy contributes more significantly to the overall data volume than spatial redundancy [3]. Mathematical transforms, such as the 3D dyadic wavelet transform (3D-DWT), are highly effective at decorrelating these redundancies. The 3D-DWT is considered an optimal choice for this task due to its superior energy compaction properties across both spatial and spectral dimensions and is typically implemented as a series of one-dimensional wavelet transforms [2].

3D Wavelet transform based HSICAs that utilize set partitioning principles, such as 3D-SPECK [6] or 3D-SPIHT [7], exploit the energy clustering characteristics inherent to the wavelet transform. Their efficiency stems from a strategy that groups insignificant wavelet coefficients into sets. At higher bit planes, where the majority of coefficients are negligible, this set structure allows for their collective representation with a single bit, dramatically improving compression rates. This mechanism provides set partition-based algorithms with a distinct performance advantage over other transform-coding methods. But 3D wavelet transform had high transform memory requirement and high transform complexity exists. Thus, it is convenient to use the 2D wavelet transform instead of 3D wavelet transform to save the requirement of transform memory and low coding complexity [8].

Conventional 2D-DWT computation is characterized by high memory requirements, as the entire image must be loaded into memory to perform sequential row and column filtering and down sampling, producing the standard HH, HL, LH, and LL sub-bands [9]. This makes it impractical for visual sensor nodes in WMSNs/IoT. Although stripe-based, block-based, and line-based techniques have been developed to mitigate this by processing image sections, their memory footprint approximately 26 kB for a ‘512 x 512’ image remains too high. The Fractional Wavelet Filter (FrWF) and Segmented FrWF (SFrWF) represent a trade-off, achieving minimal memory use by processing individual lines or segments but at the cost of greatly increased computational complexity, which also renders them unsuitable for resource-constrained platforms [10].

III. RELATED WORK

This section is structured as follows: first section, we discuss the associated wavelet filter named as Lifting based Block fractional wavelet filter (LBFrWF) [11] and in second section, we introduce the linear indexing method; and finally, we provide a detailed description of the 2D-LC-ZM-SPECK algorithm [12].

III.1 LIFTING BASED BLOCK FRACTIONAL WAVELET FILTER

By [13] introduced a block-based implementation of the Fractional Wavelet Filter Transform (FrWF) for the gray scale images to reduce the original algorithm's computational and memory requirements. However, this approach processes blocks independently without adequate boundary overlap, resulting in significant blocking artifacts during coefficient encoding. Consequently, image coders based on BFrWF demonstrate inferior compression efficiency across all bitrates when compared to contemporary wavelet-based coders. Given the increasing demand for high-quality image transmission over Wireless Multimedia Sensor Networks (WMSNs) and IoT devices, the limitations of BFrWF render it an unsuitable choice for these platforms [8].

To address the limitations of BFrWF, we propose a lifting-based implementation of BFrWF termed LBFrWF. This approach not only retains the memory efficiency of BFrWF but also reduces its computational complexity by approximately 30% for every frequency frame of HS image. Crucially, by incorporating proper overlap processing at block boundaries, LBFrWF successfully eliminates blocking artifacts. The transform coefficients produced by LBFrWF are identical to those of the conventional DWT. To demonstrate its compatibility with modern coding standards, the coefficients were encoded using the advance wavelet transform based coders, a low memory state of the art algorithm for wavelet-based HS image compression algorithms.

The lifting scheme is an efficient, low-complexity method for computing the wavelet coefficients. It operates through four stages: split, predict, update, and scaling. Initially, the input signal is split into even and odd indexed samples. The predict step then generates the high-pass (known as H sub-band) or detail coefficients, which are subsequently scaled. Conversely, the update step produces the low-pass (kno]wn as L sub-band) or approximation coefficients, which are also scaled to complete the transformation [11].

III.2 2D-LOW COMPLEXITY ZERO MEMORY SET PARTITIONED EMBEDDED BLOCK (2D-LC-ZM-SPECK)

The 2D Low Complexity Zero Memory Set Partitioned Embedded algorithm [12] is a reduced complexity variant of the 2D-ZM-SPECK compression algorithm which is used for every frequency frame for the encoding/decoding process. Its efficiency stems from a pre-computation step during the transform phase, where the maximum coefficient magnitude for each sub-band is identified and stored. This approach drastically reduces the memory footprint, as only a single value per sub-band must be retained. For an L level BFrWF transform of a single frequency frame with spatial dimensions, the required coding memory is precisely '8N x (3L + 1)' bytes for 'N x (3L + 1)' coefficients. The encoding process initiates after this pre-computation. From a hierarchical perspective, the detail subbands are categorized into three orientation groups HL_n, LH_n, and HH_n for n = 1, 2, ..., L-1 and are systematically arranged into different sets denoted as as $\boldsymbol{S_\theta^n}$ and $\boldsymbol{I^n}$. The algorithm processes these sets for each frequency frame iteratively over a series of decreasing thresholds.

IV. ENCODING PROCESS OF PROPOSED ALGORITHM

The proposed hyperspectral image compression algorithm begins by transforming each frequency frame of unprocessed HS image into the frequency domain using a 2D LBFrWF (5-level) transform, a step that reduces the memory required for the transformed data. A Modified HyperSpectral (MHS) image cube, equal in size to the original HS image, is then constructed from groups of eight consecutive frames. Within each group, the first frequency frame remains unchanged, while each subsequent frame (2 through 8) is generated as the difference between the current HS frame and the previous one. This grouping and differential framing process repeats for the entire HS cube. The MHS cube is subsequently converted into a one-dimensional array via linear indexing scheme, and each of its frequency frames of MHS image cube is encoded using the 2D-LC-ZM-SPECK compression coder. This encoding proceeds frame by frame according to bit planes until a specified bit budget is consumed.

To evaluate the efficacy of the proposed Hyperspectral Image Compression Algorithm, a comprehensive comparative assessment is conducted using four distinct hyperspectral image datasets. This study benchmarks the performance of HSICA against nine existing compression algorithms including recent state of art compression algorithms, with a focused analysis on critical performance indicators including coding efficiency, memory utilization, and computational complexity. For the simulation, the MHS image cube was cropped to a size of '128 x 128' pixels with 128 spectral frequency frames. All simulation tests were conducted in MATLAB (simulation software) on a Windows 11 system with 20 GB of RAM and a 1.6 GHz processor.

A five-level Lifting based Block Fractional Wavelet Filter was applied to the spatial dimensions of each 2D image frame. A separate 1D wavelet transform was then applied along the spectral dimension. The resulting transform coefficients were quantized to integers and linearly indexed into a 1D array for encoding. The following compression algorithms were evaluated: 3D-SPECK (CA 1) [6], 3D-LSK (CA 2) [14], 3D-SPIHT (CA 3) [7], 3D-NLS (CA 4) [15], 3D-WBTC (CA 5) [16], 3D-LMBTC (CA 6) [17], 3D-ZM-SPECK (CA 7) [18], Fractional Wavelet Filter based 2D-ZM-SPECK (CA 8) [9], Block Fractional Wavelet Filter based 2D-LC-ZM-SPECK (CA 9) [8], and the proposed Lifting Block Fractional Wavelet Filter based 2D-LC-ZM-SPECK.

IV.1 TRANSFORM MEMORY AND COMPLEXITY

As evidenced by the data in Table 1, the Lifting based Block Fractional Wavelet Filter demonstrates the most efficient transform memory requirements. This efficiency is achieved through a buffering system that requires only a single input buffer to store a segment of the frequency frame and four additional buffers to compute the final four sub-bands [19]. For an HS image frequency frame of size 'N × N' divided into 'b' blocks, the input buffer dimension is $1 \times \frac{N}{b/2}$ while the remaining buffers have a dimension of $1 \times \frac{N}{b}$.

This minimal memory footprint, confirmed in Table 2, stands in stark contrast to the requirements of other transforms. Conventional 3D-DWT and 2D-DWT methods necessitate storing the entire HS image cube or complete frequency frames, respectively, leading to significantly higher memory demands [2], [20]. The use of fractional wavelet filters substantially reduces this need, an advantage that is further amplified by the BFrWF [21]. Consequently, the total transform memory required by the BFrWF is minimized to a level comparable with the near-zero coding memory of subsequent stages.

Table 1: Comparative Analysis between the different type state of art wavelet transform with Block Based Fractional Wavelet Transform on wavelet transform memory requirement.

Dimension of HS Image Cube / Type of Wavelet Transform	128	256	512
3D-Dyadic Wavelet Transform	38.34 MB	306.72 MB	2453.76 MB
2D- Dyadic Wavelet Transform	174.592 KB	698.368 KB	2793.472 KB
Fractional Wavelet Transform	3.123 KB	6.246 KB	12.493 KB
Block Based Fractional Wavelet Transform	1.5615 KB	3.123 KB	6.246 KB
Lifting based BFrWF	1.6125 KB	3.25 KB	6.4375 KB

Source: Authors, (2026).

Table 2: Average time requirement (for calculation of the transform complexity) of the different wavelet transform for different HS image size.

Dimension of HS Image Cube / Type of Wavelet Transform	256	512
3D-Dyadic Wavelet Transform	2.96 sec	18.47 sec
2D- Dyadic Wavelet Transform	5.65 sec	44.54 sec
Fractional Wavelet Transform	7.59 sec	47.24 sec
Block Based Fractional Wavelet Transform (4)	6.01 sec	37.06 sec
Lifting based BFrWF (LBFrWF)	5.22 sec	35.21 sec

Source: Authors, (2026).

Regarding computational complexity, measured as the time required to calculate transform coefficients, the BFrWF offers a lower complexity than the FrWF. However, as indicated in Table 2, it retains a higher complexity than standard 2D-DWT and 3D-DWT. It is important to note that 3D-DWT inherently benefits from a lower complexity than its 2D counterparts applied frame-by-frame. The complexity of the BFrWF decreases relative to 2D-DWT as the size of the HS image increases. The unique computation methodology of the BFrWF coefficients is the primary reason for its overall efficiency profile.

IV.2 CODING EFFICIENCY

A comparative analysis of the proposed algorithm and contemporary state-of-the-art compression techniques was conducted by calculating the average Rate-Distortion (RD) performance over a suite of HS images. The evaluation employs two complementary metrics: PSNR, a widely adopted objective measure of reconstruction error, and the Structural Similarity Index, which provides a quantitative assessment of perceptual quality by analyzing the preservation of structural details, edges, and textures [22], [23]. As shown in Tables 3 and 4, the proposed compression algorithm demonstrates superior RD performance and Structural Similarity scores, outperforming all other benchmarked algorithms. Its performance is virtually equivalent to the FrWF based 2D-ZM-SPECK and BFrWF based 2D-LC-ZM-SPECK compression algorithms, which are its closest competitor. This high efficiency is attributed to the algorithm's ability to identify and represent a large number of insignificant coefficients with a single bit during the early bit-plane encoding passes.

IV.3 CODING MEMORY

Coding memory is essential in hyperspectral image compression for tracking the significance of coefficients during bit-plane coding [2], [24]. In contrast to conventional methods, the proposed algorithm necessitates only a fixed, minimal memory allocation to store the global maximum magnitude value of the transformed image coefficients. This single value is efficiently shared with the decoder, eliminating the need for extensive bookkeeping data. The results in Table 5 demonstrate that only two other algorithms have a marginally lower memory requirement.

IV.4 CODING COMPLEXITY

A key advantage of the proposed compression algorithm is its reduction of coding complexity. This is achieved by storing the maximum magnitude of each set of transformed coefficients in a fixed memory allocation [18]. This method offers a significant efficiency improvement over the FrWF-based ZM-SPECK algorithm, whose requirement to check every coefficient against every threshold causes computational complexity, power demand, and processing time to increase substantially. Although derived from ZM-SPECK, the proposed algorithm implements a more efficient process. The resulting performance gains in encoding and decoding time are presented in Tables 6 and 7. Encoding time (the time to encode coefficients within a bit budget) is reduced.

Decoding is inherently less complex and thus faster, as the decoder does not perform the per coefficient threshold checks required in each bit plane during encoding. The visual representation of the HS image and reconstruct HS image after the compression process for Uncalibrated Yellowstone Scene 0 and Uncalibrated Yellowstone Scene 11 at CR = 1 is shown in Fig 1 and Fig 2. Fig 3 shows the 75th frame reconstruction at the four different bit rates. It has been clear from Fig 3 that there is significant improvement of the image quality of reconstructed HS image at the higher bit rates.

V. CONCLUSION

This study introduces a lossy compression algorithm for HS images that is optimized for low memory and computational complexity, targeting resource-constrained onboard sensors. The proposed method enhances processing speed by minimizing memory access operations and capitalizes on the strong spectral-spatial correlations inherent in HS data to achieve high coding efficiency. The LBrWF is employed to reduce transform memory requirements, while the 2D-LC-ZM-SPECK algorithm eliminates coding memory and lowers coding complexity, leading to significantly faster compression compared to other transform-based techniques. Although the proposed algorithm operates in a listless manner, it exhibits a modest increase in computational time relative to existing listless coders. This is due to its frame-by-frame search for significant coefficients, which introduces a slight increment in processing overhead.

ABSTRACT

In this research, we aim to detect the important role of Artificial Intelligence (AI) in increasing cyber security measures against rapidly refined cyber threats. Since cyber-attacks develop in complexity and frequency, traditional safety methods are often inadequate, which requires integrating AI-controlled solutions to increase danger, reaction time, and general safety flexibility. The study will be engulfed by various AI applications in the cyber security domain, including detection of nonconformities, automatic danger information analysis, and future analysis. By analyzing existing literature and case studies, research will emphasize how AI technologies such as machine learning and natural language treatment can be utilized to improve the effect of cyber security structure. Besides, there will be challenges and moral ideas related to distributing AI in security contexts, including privacy and concerns related to algorithm bias. Large findings of recent studies indicate that AI can increase cyber safety ability by quickly identifying and more accurate risk assessment of hazards. This research outlines the transformation effect of artificial intelligence on cyber security practices and provides recommendations for organizations to effectively use AI-controlled strategies. By promoting a deep understanding of skills and limitations in the cyber defense structure, the purpose of this study is to contribute valuable insights that can lead to future development in this important field at the present time.

I. INTRODUCTION

With the rapid progress of information and communication technology, digital society depends on refined systems to protect fast data and information. Due to large data, which may contain abnormal patterns that may indicate cyber hazards, increase the risk of loss and reduce the speed of the response. Other than this. With remarkable developments in science and technology and the use of different methods of storage and exchange of information - which is usually known as the transfer of data from one place to another in the network - safety awareness has become very necessary. From this situation, artificial intelligence emerged as a powerful tool that mimics human mental decisions with the aim of improving communications security and preserving information, for example, we see that the study [1]. Has revealed the use of machine learning and deep learning algorithms, such as SVM, LSTM, and CNN-LSTM, to detect malicious software on Android systems, This study confirmed that the SVM algorithm achieved 100% accuracy on the CICAndMal2017 dataset, while the LSTM reached 99.40% accuracy on the Drebin dataset. In addition, AI solutions contribute to more effective vulnerability analysis by combining traditional methods with AI-operated functionality. These solutions automate security scanning processes, identify important threats and learn of historical data, increase scalability, and accuracy, and adapt to new threats.

By combining traditional methods with AI-powered techniques for analyzing complex security vulnerabilities, the study [2] aims to detect critical threats, thwart attacks, and reduce human error. The cyber security sector is facing a significant challenge in explaining the results of the AI system based on the Deep Learning (DL) algorithm, which has led to a clear AI (XAI) to improve transparency and enable operators to make the right assessment. The literature review primarily explores the latest work in AI-powered cybersecurity tools and techniques such as machine learning algorithms, deep learning networks, and natural language processing [3]. And so is the study [4] Challenges facing AI cybersecurity include privacy violations, algorithmic bias, the use of AI in cyber-attacks, accountability, openness, and security issues, So we see many studies that have addressed these challenges, the ethical and legal challenges posed by the use of AI in cybersecurity, particularly in the ethical framework of data protection, where criminal risks such as ambiguity and sophisticated cyber-attacks are increasing, requiring a specific legal framework. Thus, it is clear that artificial intelligence plays an important role in expanding confidence in digital systems and opening new ways to get better security for sensitive information, by opening the danger and providing advanced solutions to the response.

II. RELATED WORK

II.1 CURRENT STATE OF KNOWLEDGE

Recent progress in artificial intelligence (AI) has changed cybersecurity practice much. Artificial intelligence (AI) is a powerful technology that helps cybersecurity teams automate repetitive tasks, accelerate threat detection and response [5].Machines are equipped with many techniques, software, mass databases, and complex algorithms capable of analyzing them, converting them into information-solving problems, and selecting the most appropriate options to solve problems and make appropriate decisions, let's make the term "artificial Intelligence "origin from American computer scientist John Macarthi, when this concept was first introduced during a scientific conference at Dartmouth College in 1956, which is designing a wise machine capable of mimicking the human mind. The opportunity was to detect. For instance, research shows that AI-driven tools can process vast amounts of threat intelligence data more efficiently than human analysts, thus improving situational awareness and decision-making processes [6], [7] . Relying on artificial intelligence technologies in cybersecurity is no longer a luxury but an indispensable tool for detecting threats, automating responses, and reducing the time required to detect attacks [8][9].

The rapid growth in digital governance has led to high levels of profitability, and the impact of regulatory risks associated with cybersecurity has resulted in a broader awareness and deeper understanding of how these risks affect strategic decision-making[10]. Based on the foregoing, we present here a research problem that focuses on the increasing sophistication of cyberattacks , which generates several critical challenges for malicious actors and organizations seeking to protect infrastructure, considering the methods and techniques employed by cybercriminals. The term artificial intelligence is a comprehensive term that provides many innovative solutions and smart devices, and offers new innovations as various fields of life develop [11]. This is what the future of urban cybersecurity requires maximizing the use of systems to repel, resist, and recover from malicious attacks [12]. This research paper offers insights into the potential for new opportunities related to artificial intelligence technologies in this context by examining how AI can be effectively integrated into cybersecurity practices. With the rapid development of AI technologies, its potential to improve communications infrastructure management through sophisticated anomaly detection is increasingly evident.

Furthermore, to fully realize this potential, more research is needed to address practical challenges related to scalability, immediate implementation, and long-term maintenance [13]. Ultimately, research will contribute to a better understanding of how AI can be used to solve modern cyber security challenges, and to ensure responsible and efficient distribution. One of the most prominent recent studies and results that demonstrate the effectiveness of artificial intelligence in detecting threats and analyzing risks is what the study reached [14]which resulted in the fact that they endorse a comfy records school sharing and conditional dissemination scheme with multi-proprietor in cloud computing, in which knowledge proprietor will share private statistics with a group of shoppers through the cloud in a totally cozy process, and knowledge communicator will broadcast the information to a trendy college of customers if the attributes satisfy the get right of entry to rules within the cipher text . Although researchers have found these solutions, a major challenge arises in interpreting the results of learning-based AI, leading to the emergence of the concept of explainable AI (XAI).

II.2 RESEARCH GAPS

Despite the remarkable development and progress in the role of artificial intelligence in supporting cybersecurity, there are some research gaps which must be pointed out, including: Interpreting AI systems' decisions: Deep learning algorithms often remain a mystery, making it difficult for experts to understand the decision-making mechanism, and affecting confidence in the systems. Theoretically, and despite the existing literature including a large number of research papers, we have found a deficiency in considering realistic scenarios in their content. It is important to note that useful scientific contributions should go beyond applying artificial intelligence techniques to cybersecurity datasets, and it is very important to make greater efforts to bridge the gap between the fields of artificial intelligence and cybersecurity [15]. Algorithmic bias: Numerous studies have confirmed the existence of biases in artificial intelligence algorithm techniques, which lead to the production of unfair or inaccurate decisions, especially with unbalanced data. The problem of algorithmic bias is one of the most significant challenges facing AI applications and cybersecurity. Studies emphasize the importance of addressing algorithmic bias, as it raises ethical and legal concerns, including combined dimensions, to ensure trust in artificial intelligence technologies and the rights and privacy of individuals and communities in our increasingly AI-led world [16]. Ethics& Privacy: AI applications in cybersecurity have raised numerous ethical and legal issues related to data privacy, accountability, and decision transparency. Many of the proposed frameworks seek to provide solutions that are just a part of compounding and escalating situations.

The transaction speed and scalability of technologies like BC can create a barrier to data protection rights, targeted cyber-attacks, and the ability to update and track users, however there are advantages in making separate forms that when produced as a whole, can support data verification , transparency and accountability in many industries [17]. Reliability and scalability: More research is required on how to scale the AI system to suit large, sometimes changing business environments, and ensure immediate responsibility and long -lasting efficiency.

III. METHODOLOGIES AND TECHNIQUES

This research used a descriptive and analytical approach to examine the role of artificial intelligence (AI) in increasing cybersecurity against developing threats online. The study begins by establishing a basic understanding of electronic information protection, defines the most important elements, forms, integrity, and accessibility and classifies the widespread threats, from human errors and environmental factors to hacking and sophisticated cybersecurity such as hacking and computer viruses. The methodology offers several key pillars to support a comprehensive understanding of the technical capabilities of artificial intelligence and its implications. The main components of the methodology can be summarized as follows:

- Descriptive Analysis: This pillar provides a comprehensive analysis of recent literature and academic studies to identify key AI applications and emerging trends in cyber threats and their mitigation. This section addresses how AI techniques can be used, such as in malware detection, incident response, and risk assessment.

- Quantitative Data Analysis: This research conducted a comprehensive quantitative analysis of cybercrime statistics between 2015 and 2022[18] Various categories of cyber threats were identified, as shown in Table 1 and Figure 2, to pinpoint the main trends in online criminal activity. Given the complexity of these threats and attacks, the use of artificial intelligence techniques to mitigate their impact has become essential.

- Review of case studies and advanced AI techniques: The research included a review of experimental studies and real-world applications demonstrating the practical effectiveness of advanced artificial intelligence algorithms and models. Focusing on modern techniques such as support vector machines (SVMs), long short-term memory (LSTMs), and hybrid models such as convolutional neural networks and long short-term memory (CNN-LSTMs), which have proven effective in malware hunting, vulnerability analysis, and other cybersecurity tasks.

III.1 ELECTRONIC INFORMATION SECURITY

III.1.1.The concept of electronic information security:

Today's advancements in wireless communications technologies have generated massive amounts of big data. Most of our information is part of a vast network that connects devices around the world [12]. And we can define Information security culture, which guides how things are done in the organization regarding information security, to protect the information assets and influence employees' security behavior[19]. Moreover Information security is defined as a set of measures and procedures adopted by an organization that becomes more sophisticated, especially information and data use, such as tamper unauthorized access, cybercrime, , using advanced technique injuries, illegal [1]. Electronic information protection refers to the protection of ordered data stored or transmitted through electronic systems from the dangers and attacks that can lead to data violations, losses, or unauthorized changes. This includes the implementation of guidelines and a series of technologies to ensure privacy, integrity, and availability of confidentiality, integrity, and information such as encryption and firewalls. In addition, electronic security depends on the access control mechanism that defines who is authorized to view or change the data. In the digital age, electronic information protection is important for individuals and organizations to protect against increasing risks, such as cyber-attacks and harmful software.

Information security is defined by three different approaches: educational, technical, and legal. From an academic point of view, information is a scientific field that studies principles and strategies to protect information from hazards and malicious activities. From a technical point of view, it includes equipment, methods, and procedures required to ensure the protection of information from both internal and external risks. From a legal point of view, information is related to security studies and to combat the confidentiality of information, along with measures to protect the integrity and availability of information, to break or utilize information systems for criminal purposes. Information security is a set of measures taken by an organization to protect its information systems in various ways, physical measures to protect the organization's hardware from damage can be defined as logical measures as protective software designed to prevent theft, hacking, or material manipulation. Information security should exist to be effective. Growth for cyber threats extends far beyond traditional security areas administered by information technology software [20]. To be effective and excellent information protection, three basic and important conditions must be met:

- Disponibility: It refers to access to data so that they can read and find it easily.
- Integrity: This means keeping information during transmission, processing, or storage, unchanged in material or size. Generally, the system ensures the accuracy of the information and prevents it from being replaced by third parties, its accuracy and perfection..
- Confidentiality: This indicates that information can only be read and accessed by people with special access rights.

These items are in line to create a complete concept of information protection, as illustrated in the following data:

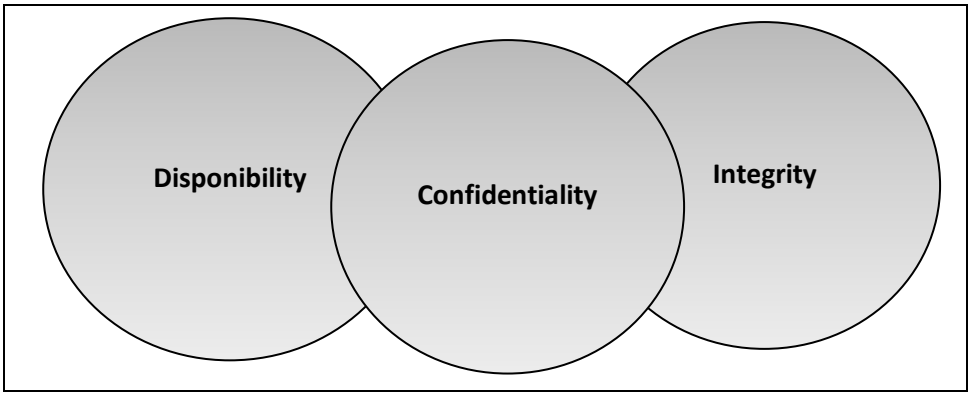

Figure 1: Represents information security elements.
Source: Authors, (2026).

When focused, large amounts of electronically stored data become more vulnerable to new dangers when stored manually. Advanced technologies and software have helped to expand the extent of these risks. We can describe these dangers this way:

- Human Threats-: These occur at some point of the layout of hardware or information systems , and they include activities consisting of programming, testing, facts compilation, and the input of statistics into the machine
- Environmental Threat:- These embody herbal failures together with earthquakes, storms, floods, and hurricanes. They additionally include problems related to electricity failures, fires, and the malfunctioning of conditioning and cooling structures, among different environmental elements which could have an effect on machine availability.
- Cybercrime hacking:- unauthorized access or infiltration in the system through the use of hacking tools or software
- Computer virus: Independent software that is built into computer programs and causes, causing potential damage or dissolution of the system.
- Digital crime: to increase the risk of privacy security from modern technologies, including surveillance technologies (e.g. camcorders), electronic identity cards, and cutting or surveillance methods.
- Hacking is the process of illegal infiltration of systems and equipment using advanced equipment and techniques to reach sensitive information or take control of data. This may include stealing data, destroying the system or even disrupting important operations of companies and organizations.

These categories illustrate the diverse range of threats that can impact electronic data, arising from human actions, environmental factors, or cybercriminal activities. A study [18] has shown an increase in the level of cybercrime in the era of electronics and digitization, as shown in the following table:

Table 1: Changing trends in cybercrime attacks (in millions).

Incidents	2015	2016	2017	2018	2019	2020	2021	2022	%Increase /Source

The following diagram represents the number of cybersecurity incidents from 2015 to 2022, which is classified by that type of attack.

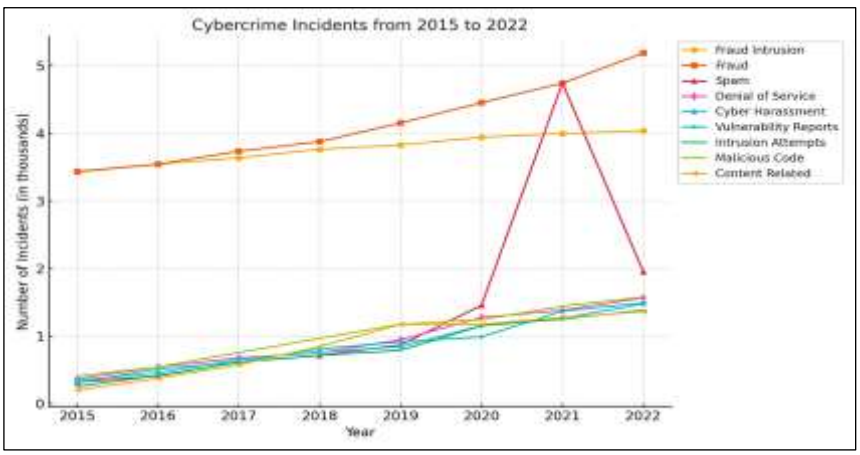

Figure 2: Diagram shows Cyber security incidents (2015-2022).
Source: Authors, (2026).

As a result of the increasing reliance on digital technologies and the internet, cyberattacks increased significantly between 2015 and 2022. The increased vulnerability of systems to attacks by vulnerable individuals has led to a significant increase in breaches. These breaches affect key sectors in countries, including healthcare.

III.1.2 Different forms of cyber- attacks

Cyber -attacks that can target the equipment, software and network of an organization, take different forms and use more methods. They are constantly evolving and used to break or damage all the weaknesses of the system. The Internet is a favorite medium for hackers to commit these crimes. Some of these attacks include the following:

- Malware : This is represented in viruses, worms, and Trojans , aimed at damaging or breaking devices and systems.
- Hacking: Attacker infiltrates the system or network to access sensitive data or information.
- Ransomware: Attackers encrypt the victim's data and information and demand a ransom to decrypt it.
- Phishing Attackers trick users into giving away their personal or financial information through fake messages or scams.
- DDoS (Distributed Denial of Service) Attacks: a large amount of data is sent to the sink and disables it.
- **Man-in-the-Middle Attacks** : Prevent communication between two parties to access the data transferred to the attackers.
- Exploitation of Security Vulnerabilities attackers utilize software or systems to access networks or data.

These attacks are developing to maintain frequent technological advances, making it necessary to update security systems regularly.

III.2 CONCEPT OF ARTIFICIAL INTELLIGENCE

Artificial intelligence (AI) can be defined as the theory and development of computer systems capable of performing tasks that previously required human intelligence, such as voice recognition, decision -making and pattern identity. AI is a comprehensive term that includes many techniques, including AI algorithms and technology, deep nervous networks and deep learning models. AI algorithms analyze and learn from data to extract the pattern and then decide. Deep neural networks are advanced models inspired by the human brain and are used in applications such as Natural Language Processing (NLP) and image recognition. Through deep learning models, AI can improve accuracy over time by learning from large amounts of data. It is also known as science and engineering subjects to create intelligent machines, especially intelligent computer programs. It is associated with overlapping tasks, namely the use of computers and algorithms to understand human intelligence, but artificial intelligence is not limited to methods that can be observed biologically [24]. In addition, some claim that the AI leadership varies from IT management in the past.

AI is not just a technique or set of technologies, but rather a constantly evolving horizon of emerging computing capabilities and innovations [25]. Moreover ,we can point to a very important aspect in dealing with artificial intelligence technologies: AI governance. This is a fundamental aspect, especially when tasks such as prediction and rapid decision-making are delegated to artificial intelligence systems (AIs). Recent policies, particularly in Europe, highlight the importance of this issue and emphasize the need for guarantees that the AI system is transparent Artificial intelligence (AI) is a paradigm to imitate the logic of the people, e.g. Already unpublished computer classification of future events such as stock market trends, sales and consumer behavior predict. The term "artificial intelligence" (AI) has recently gained popularity, legal scholars have provided different definitions. From a technical perspective, a remarkable definition AI describes as a "computer program that depends on algorithms and specific processes to perform special features or features.

This system is designed to receive automatic inputs, which are processed according to the program's instructions. From this we conclude that artificial intelligence depends on the software algorithms that are entered into the computer, the inputs of which depend on codes and rules. A great use of AI can be seen in advanced robotics. AI depends on computers equipped with real knowledge, and the origin of AI is represented through a process -based sequencing method through this knowledge. Despite the meaning, AI responsibility is often defined as the values, exercises and goals of the AI system, which is used inadequately in practical applications [26]. In addition, it should be noted that artificial intelligence cannot be underestimated, especially in relation to large data and its effect on social, political and social structures created by individuals as communication. This is part of the greater digital transformation, and its future potential is difficult to predict given the massive growth in computing power alone and its interaction with the "analog world"[27].

III.3 EVOLUTION OF TRADITIONAL ANOMALY DETECTION

A questioner may ask: What is a traditional anomaly?

The term actually refers to discovering deviations when it comes to abnormal phenomena or patterns from the pattern, distracted by general or expected behavior in the network. The aim of detecting the deviation aims to identify nonconformities that may indicate problems such as previous quality, abuse of service, traditional anomalies, cyber halls or returns. Legislators - rulers use some rules and predetermined criteria to identify unusual patterns. For example, fixed thresholds can be used to monitor network traffic, if the values are more than these thresholds, an alert can be triggered. Although technology has improved our lives a lot by making information and communication easily accessible through devices such as computers and mobile phones. These devices not only help us manage individual and professional features, but also save important data including credit card details and passwords. However, this data can be unsafe for cyber criminals who benefit from weaknesses through various attacks and require unauthorized access. Awareness of different types of cyber threats is required for security [28]. As the volume of data increases, it is necessary to protect this data from theft, tampering or intrusion.

According to a recent review published in Springer (Edozie et al., 2025) [13] there are several limitations to traditional methods. First, rule-based systems lack flexibility and are difficult to handle with new networks. Not to mention the erroneous rates that can result, leading to false alerts or failure to detect critical events . There is a recent study [13] that shows in (Figure 1)a sufficient increase in global data volume from 2010 to 2024. This figure indicates rapid expansion in the amount of data generated in the network and system and the processed data provides an indication. The dependence on digital infrastructure from organizations, companies and officials is increasing. This figure indicates that this significant data text corresponds to technological advances such as 5G networks and Internet of Things (IoT), leading to an increase in the complexity of the network environment. This complexity creates traditional methods, such as the rules system, insufficient to address the increasing security threats .As a result, the integration of advanced technologies such as artificial intelligence (AI) has become necessary to effectively analyze this data and not to detect analogies. The heavy growth in the data volume emphasizes the immediate need for a system that detects noise and is able to process large amounts of information in real time. These systems can learn autonomy and improve the performance of Ti35me, network traffic patterns and new threats. Given the frequent errors and the difficulty of electronic adaptation, the need arose to search for more efficient solutions

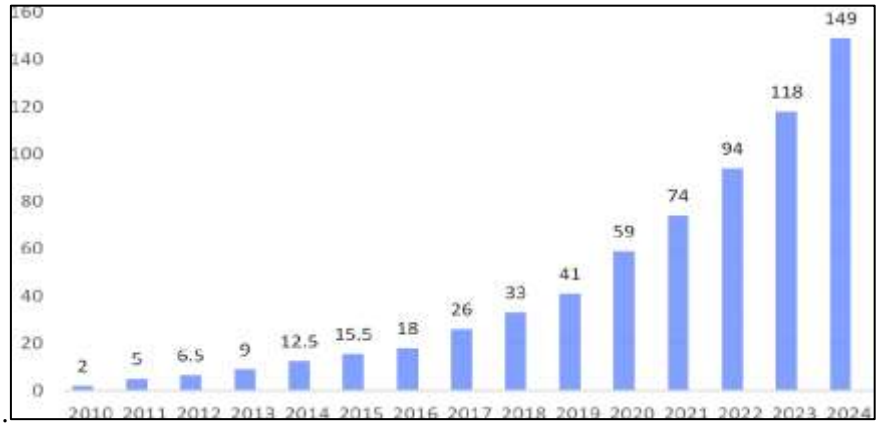

Figure 3: Data Growth Worldwide 2010–2024.
Source: Authors, (2026).

Therefore, it is important to highlight the role of artificial intelligence techniques in improving network anomaly detection. The main objectives of this research can be added as follows:

-AI Efficiency Analysis: Artificial intelligence technologies, especially deep learning algorithms, machine learning, and natural language processing, are used to obtain accurate results for detection systems, leading to increased cybersecurity defenses.
-Identifying current challenges: Highlighting anomalies as ways to detect traditional deviations, such as high false positive frequencies and difficulties in adapting to new computer patterns.
-Explore innovative solutions: Providing an innovative AI-based solution to address cybersecurity challenges, including the use of advanced deep learning models such as Recurrent Neural Networks (RNNs) and Convolutional Neural Networks (CNNs).
-Develop research hypothesis: to prepare hypotheses related to AI's role in strengthening cyber security, such as how it can detect danger and response time.
-Discuss moral ideas: Data to address moral ideas related to privacy and how to use AI affects cyber security practice.
-Provide practical recommendations: To offer practical recommendations for stakeholders in the cyber security sector, how to effectively be integrated into systems to detect deviations to AI technologies.

IV.RESULTS AND DISCUSSION:

This study analyzes the application of artificial intelligence (AI) to increase cyber security towards developing hazards online. The data reveals a significant tendency to integrate AI technologies to detect the danger, event reaction and general security. AI-operated equipment shows increased efficiency in the treatment of the danger intent, which improves status awareness and decision-making. AI reduces timely reaction time automatically by blocking malicious traffic and separating the infected system. Some machine learning algorithms show high accuracy in detection of harmful software, and contribute to an active defense against cyber -attacks. In addition, AI increases vulnerability analysis by automating security scanning and prioritizing dangers. Analysis of online crime data reveals an increase in the frequency and processing of cyber- attacks, and requires integration of AI to improve cyber security. Cybercrime has increased dramatically, highlighting the need for more effective security solutions. AI provides the ability to address the abilities by identifying these developed dangers constantly, and detecting asymmetrical behavior and automatically to the reaction of the event. However, the analysis also highlights moral ideas on the use of AI in cyber security. Ensuring openness and confidence in AI-operated systems presents an important challenge. The deployment of AI in cyber security increases the concerns of privacy violations, algorithm bias and accountability. The moral structure of data security becomes especially important when it comes to AI-operated cyber security solutions. Based on the research results, the researcher recommends the following:

-Develop Advanced Ai-Powered Detection Systems: Analyzing The Discrepancy Pattern and Predicting Cyber Attack Before Occurring, Focusing on the Use of Machine Learning Algorithms to analyze user behavior and detect any suspicion.
- Invest in training employees on how to identify cyber threats: to educate them on the latest phishing and malware techniques, and provide them and their outfits, which provide the equipment and skills required to protect them from cyber- attacks.

-Use strong security measures: for example, multifactor authentication, encryption of sensitive data, and regular software and system updates to reduce the security weaknesses utilized by the attackers.
- Establishment of clear laws and regulations that control the use of AI in cyber security: to ensure the safety of privacy and security, and to define responsibility and responsibility in the event of security incidents.
- Encourage cooperation and information sharing between organizations and public agencies: To raise awareness of cyber threats and exchange best practices in cyber security.

V.CONCLUSION AND FUTURE WORK

V.1 CONCLUSION

This research emphasizes the developed role of artificial intelligence in increasing cyber security against new digital dangers. Since modern society depends on the technical systems that are growing rapidly, the need for AI-controlled solutions to strengthen the traditional security protocol has become clear. While AI plays an important role in the Founding, the event reaction and the vulnerability assessment, it is necessary to address moral concerns related to openness, privacy and potential prejudices in the AI algorithm. In order to use AI, organizations must prefer responsible strategies focused on moral guidelines, collaboration between AI experts and cyber security people and continuous performance monitoring. By understanding the strength and boundaries of AI in Cyber Defense, this research contributes to valuable insights that can lead future development and distribution in this important field, ensuring a safer digital future for individuals, institutions and officials.

V.2 FUTURE WORK

Despite the remarkable progress this study makes in enhancing the AI-managed cyber domain, it is merely the beginning of numerous promising and open-ended avenues for exploring future visions and more clearly defined developments, particularly AI models- so-called Explainable AI (XAI), to increase user confidence and ensure the soundness of decisions made in the field of cybersecurity. Furthermore, there is a need to formulate a strong defense against hostile digital assaults is important that the research also addresses the long-term ethical, legal and societal implications of deploying artificial intelligence in cybersecurity, including protecting confidentiality, algorithmic fairness and avoiding bias Also, multidisciplinary collaboration between AI experts, cybersecurity specialists and legal researchers is needed to develop comprehensive guidelines for the responsible use of AI in digital defense. Finally, it is recommended to conduct thorough and realistic studies to assess the effectiveness, limitations, and unintended consequences of AI-managed cybersecurity systems. This work will ensure that future AI solutions not only enhance technical capabilities but also align with social values and evolving needs, contributing to a more secure and resilient digital ecosystem.

ABSTRACT

Deepfakes, synthetic media created using advanced machine learning techniques, pose significant societal challenges by spreading misinformation and undermining trust in media. With the increasing sophistication of deepfake technologies, distinguishing between genuine and synthetic media has become increasingly difficult. This paper presents a robust deepfake image detection framework using the Swin-B Transformer, a pre-trained model fine-tuned for our application. By integrating a hybrid dataset that combines real images from the FFHQ dataset and synthetically generated fake images from a publicly available Kaggle dataset, we simulate real-world media scenarios. Our model achieves an impressive accuracy of 97.47% on the test set, demonstrating superior generalization to both real and synthetic visual data. Using Grad-CAM, we visualize the spatial segments of the image that the model focuses on during classification, providing insight into the decision-making process. This work contributes to enhancing content authenticity, controlling fake news, and ensuring digital trust and safety.

I. INTRODUCTION

The pioneering work of Christoph Bregler, Michele Covell, and Malcolm Slaney in developing the video rewrite program in 1997 laid the foundation for Deepfakes. It is marked as the first automated approach to facial reanimation, leading to the more sophisticated deepfake technologies that we encounter today. The term deepfake has since come to encompass both these fake media and the specific method of their creation. The manipulation of digital images and videos has been a promising technique for many years and is done through the use of visual effects. However, the inception of deep learning architectures like Generative Adversarial Networks (GANs) has led to a marked increase in the realistic nature of fake content and the ease with which they can be generated [1], [2]. These AI-generated media, commonly referred to as deepfakes, are easily produced using artificial intelligence tools. Through the use of deep learning algorithms, it is now possible to generate fabricated videos and images that are virtually challenging to differentiate from real ones. Since their emergence in 2017, there has been a proliferation of open source deepfake generation methods and tools, resulting in a growing number of synthetic media clips.

FakeApp [3] and FaceSwap [4] are two prominent publicly accessible deepfake implementations. Throughout history, there have been numerous instances in which deepfakes have been utilized for malicious purposes, such as creating political tensions, staging fake terrorism events, producing pornographic content, and blackmailing.

As an example, University of Maryland researchers created a bot by the name of Katie Jones on the LinkedIn platform. In order to add more authenticity to this fake profile, a profile picture generated using deepfake technologies was also added, and the bot was then left to make connections on the platform. In just two months, this profile was connected with two US state senators and one Department of Defense (DoD) personnel [5]. It is estimated that, bots make up 65% of the Internet currently. With the advent of deepfake technologies, it might become even more difficult to detect fake identities on the Internet. A study by the AI firm Deeptrace revealed that only in the month of September 2019 they identified 15,000 deepfake videos online, nearly double the increase over the previous nine months.

Of these videos, 96% were pornographic in nature, among which 99% of those targeted female celebrities, overlaying their faces on the bodies of some porn stars [6]. This marked the significance of robust and reliable methods for detecting deepfakes thus preventing their abuse. At the heart of deepfakes lies the intricate process of facial swapping, a technique that allows for seamless overlaying of facial images of a target individual onto videos of a source individual as shown in Figure1 This mesmerizing artistry results in videos of the target individual appearing to say or do things that were originally performed by the source individual as shown in Figure 2. An example of the influence of deepfakes can be seen in the circulation of such videos related to the Russian-Ukraine conflict, including a deepfake of Russian President Vladimir Putin declaring peace.

Figure 1: Original Image and Corresponding Deepfake Image.

The rapid growth of generative models has led to the extensive creation and spread of deepfake images. Although these technologies have creative and commercial applications, they also carry serious risks such as the spread of false information, identity theft, and a decline in public confidence in digital content. A crucial challenge in the areas of computer vision and social computing is the detection of these misleading media content. The increasing societal impact of deepfake images is another factor driving this study. As deepfakes significantly influence public opinion, identity verification and social media integrity, strong detection techniques contribute directly to the broader goals of social computing there by improving digital trust and authenticity of the content.

I.1 OBJECTIVES

The main objectives of our proposed work are the following.

1. Create a hybrid dataset that combines real images from the FFHQ dataset with synthetically generated fake images from a publicly available Kaggle dataset, representing diverse and challenging real-word scenarios.
2. Use, optimize, and evaluate the Swin-B transformer for deepfake image detection, a variant not extensively applied in this context.
3. Show that our approach has better generalization to heterogeneous data and outperforms several other existing approaches.

II. LITERATURE SURVEY

In the earliest methods, engineered features obtained from the inconsistencies and artifacts of fake images were used for classification. In the paper [7] make use of an image pre-processing step, where they apply Gaussian blur and Gaussian noise to the images in order to extract low-level high frequency cues of GAN generated images. This improves pixel-level statistical similarity between authentic and fraudulent images, allowing forensic classifiers to learn more intrinsic and valuable characteristics compared to existing techniques or networks.

In the paper [8], identified several distinguishing features such as missing reflection in the eye, loss of geometry and shape, difference in colour of two eyes of the same person etc., and then created a detection pipeline which segments all the various important features like iris, face crops etc. These segmented and extracted features were tested for authenticity and used for classification. They achieved their best accuracy of 83.8% with eyes as the primary mode of classification.

Hsu et al. introduced a two-phase deep learning method for the detection of deepfakes [9]. It makes use of the Siamese Network architecture based on the Common Fake Feature Network (CFFN) for feature extraction. The Siamese network takes pairs of images along with a pairwise label during training. When both images within a pair are genuine, the label is designated as 1, indicating a ”real-real” pairing. Conversely, if the images belong to different classes, meaning that one is authentic and the other one is manipulated, the label is assigned as 0, reflecting a ”fake-real” or ”real-fake” pairing.

During the training phase, a pairwise label is provided, and the model learns the distinguishing features of each class. Further, it can also understand the representative characteristics of real and fake images. Once the training is completed, a base image, whose class is known (real or fake), is passed along with the input image given by the user. Depending on the output obtained and the type of base image, we can determine the class of input image. The major setback of this approach is that it uses a non-standard dataset which is generated only using GANs. Hence, cannot work well with other deepfake implementations and can provide results only for GAN generated images.

Another method using pairwise learning was proposed by Zhao et al. for deepfake detection [10], where they made use of the self-consistency of local source features noticed in deepfakes, which are content-independent and spatially local information of images. These local features can be the result of imaging pipelines or encoding methods used in different image synthesis approaches. A CNN-based model is used to learn pairwise self-consistency. The hypothesis behind this paper is that the original image will have consistent features in different localities and a modified image will be inconsistent in generated and original portions of the image. The model is trained using representation learning technique, where, the model, instead of learning about the overall features, looks only at parts of the images.

This approach differentiates between genuine and manipulated images by penalizing feature vector pairs with low similarity scores within the same image. Conversely, it also penalizes the pairs of feature vectors from different images for exhibiting a higher similarity score. In this paper, cosine similarity is used as an evaluation metric. The feature maps being learned were then provided as input to a classification method for deepfake detection. Although this model performs well on locally modified images, it struggles with fully generated fake images, where features remain consistent at all positions within the image. Zhou et al. propose a different approach [11], in which they make use of a two-stream neural network. Instead of pairwise learning to understand latent relations between pairs of images, one stream is used to detect faces and determine their genuineness.

The other stream is used to detect traces which might be left due to any steganographic tampering. They make use of FaceSwap and SwapMe apps available on the App Store in iOS to create a custom dataset. However, the customized dataset used in their research is out-dated and the results are not updated with recent GAN-based generation methods. Moreover, the evaluation was primarily theoretical and when tested against a standard Celeb-DF dataset, achieved an AUC score of only 55.7%. A simpler approach was introduced by [12], where they implemented a modified VGG-16 network called as NA-VGG (N: Noise, A: Augmentation). Here, the input is first processed with an SRM filter which highlights image noise.

SRM stands for Style Recalibration Module, which is a fixed weight matrix acquired by training a shallow neural network to modify the image to a specific type, for example, from RGB to HSV etc. In this paper, the SRM layer extracts and highlights latent artifacts in the image which go unnoticed in the case of RGB. After generating this version of the input, augmentation is performed, where more images were generated by flipping, rotating, adjusting the brightness etc. of the image. The augmented images are passed to a standard VGG-16 CNN which contains 16 layers in total: 13 convolution layers and 3 fully connected layers. In order to downsize the resolution, 5 pooling layers are also used intermediately after convolutions.

In their research, they used the Celeb-DF dataset which is created by swapping faces in the CelebA-HQ dataset. Theerthagiri introduced an approach using InceptionNet [13], a CNN based architecture to capture multiscale features to identify deepfakes. In their study, they used a public dataset downloaded from kaggle consisting of 401 videos. Data Augmentation is applied to generate 3745 images from the dataset. The efficacy of the model was evaluated using various metrics derived from the confusion matrix, achieving an accuracy of 93% in recognizing deepfake images and videos. Another method was introduced by pasupuleti [14], using a Custom Densenet architecture, which is a deep residual neural network.

To classify images as *real* or *fake* they employed a CNN based architecture trained using a binary cross-entropy function. The performance of the model is evaluated using various metrics calculated from the confusion matrix. Ghita et al. proposed an approach for detecting deepfakes using Vision Transformers(ViT) [15]. This ViT based detection model is trained with a dataset consisting of 40000 samples including both real and deepfake images collected from the Kaggle dataset. The model achieved a score of 0.899 on a dataset consisting of 40000 samples. Their initial experiments emphasized the need for a large dataset for training and the fast convergence of the model. Compared to other baseline deepfake detection techniques, the performance of the ViT model was consistent with existing research, indicating its potential for further investigation.

Authors of [16] suggested a shallow vision transformer for recognizing deepfakes, incorporating both an attention mechanism and multi-head attention module. The attention mechanism highlights the critical parts of images, while the multi-head attention module determines how much attention should be allocated to local-level features. Finally, the softmax layer classifies an image as *real* or *not real*. Experiments conducted on two datasets-Real Fake Face (RFF) and Real and Fake Face Detection (RFFD) datasets show that the model achieves higher accuracy of 0.92 on RFF and 0.89 on RFFD datasets. The results outperforms most of the existing models such as GoogleNet, XceptionNet, ResNet50 and other baseline vision transformers. Furthermore, the model demonstrated an accuracy of 0.90 even when trained only on 50% of the RFF dataset.

II.1 LIMITATIONS OF EXISTING METHODS

- Most of the existing systems utilize standard versions of visual transformers or CNN architectures, like EfficientNet, ResNet variants, which may not capture global contextual clues present in high-quality deepfake images.
- They often utilize a single-source benchmark dataset or domain-specific image collections, which may not fully reflect the diversity and complexity of real-world content shared on social platforms.
- Although Swin Transformers have been used in some earlier studies, the Swin-B -which is a larger and more expressive variant of the Swin Transformer, has not been investigated for deepfake image detection.

These days Deepfakes have become very realistic, making local artifacts difficult to detect. In this context, there is a need for a transformer-based model which will capture global dependencies and can model long-range dependencies of images [16].

The self-attention mechanism in the transformer architecture helps focus attention on minute anomalies that CNNs may overlook. When fine-tuned, they offer better generalization and are robust to the new manipulation methods available. To mitigate these issues, we propose a novel deepfake detection model that leverages the Swin-B Transformer, a high-capacity hierarchical vision transformer, applied to a combined dataset consisting of real images from the FFHQ dataset and fake images sourced from a publicly available Kaggle dataset. This hybrid dataset simulates real-world media environment, improving the model's ability to generalize to unseen manipulations. Our method is novel in two ways: (i) we created a mixed dataset with both real and fake images from two different sources to represent realistic media scenarios; and (ii) we applied and assessed the performance of the Swin-B Transformer, an architecture that hasn't been studied in this context before.

III. DATASET DESCRIPTION

We constructed a hybrid dataset, consisting of images collected from two different datasets. Real images were collected from FFHQ Dataset [17] and DeepFake images from a dataset available on Kaggle [18]. Flickr-Faces-HQ (FFHQ) is an image dataset consisting of 70,000 high-quality PNG images of real human faces each with a resolution of 1024 × 1024, originally created as a standard for GANs [17]. The images in the data set were originally extracted from Flickr.com, an online platform for hosting images and videos, and cropped using the Dlib library [19]. The second dataset [18], is an image dataset consisting of 95,000 JPG images of forged human faces each with a resolution of 256 × 256. Images extracted from both datasets were combined and organized into two main directories: real and deepfake as shown in Figure 3. This combined dataset simulates the variability seen in real-world social media content. Samples of the real and deepfake images from the dataset are shown in Figure 4a and Figure 4b.

IV. PROPOSED MODEL

Transformers have shown immense capabilities and work especially well in tasks where pixel-level details might matter. Our proposed model uses the Swin - B (Base) Transformer, a mid-range model which is a specific type of Swin Transformer designed to provide a good balance of performance, computational cost and speed. Table 1 compares various Swin Transformer variants with respect to their computational costs. Among all the variants of Swin, Swin-B was chosen because of its superior ability to balance hierarchical representation learning, global context modeling, and computational efficiency [20]. Swin-B uses shifted window self-attention to learn local and non-local visual patterns with a multi-scale feature hierarchy unlike traditional CNNs, which use fixed receptive fields and have difficulties in capturing long-range dependencies.

Swin-B is much less computationally expensive than regular Vision Transformers, which exhibit quadratic computation complexity as a function of image resolution, making it effectively able to process high-resolution images, available in social media content, with smaller computational expense. Pre-trained weights were used before training so that the model requires less training times. In addition, it also helps in avoiding overfitting, as it can be trained for fewer epochs. After training, we evaluated the efficiency of the model by calculating important metrics on the test set. The model is then deployed for demonstration using the Gradio API, where it can be tested by giving an input image (real/fake).

Table 1: Swin Transformer variants with Computational costs.

Model	Params (M)	Computational Cost (FLOPs, G @224×224)	Depths	Embed Dim	Heads (Max)	Window Size	ImageNet Top-1 (%)
Swin-T	28	4.5	[2, 2, 6, 2]	96	24	7×7	81.3
Swin-S	50	8.7	[2, 2, 18, 2]	96	24	7×7	83.0
Swin-B	**88**	**15.4**	**[2, 2, 18, 2]**	**128**	**32**	**7×7**	**83.5**
Swin-L	197	34.5	[2, 2, 18, 2]	192	48	7×7	84.8

The overall architecture of the model is broken down into 5 modules shown in Figure 5. They are:

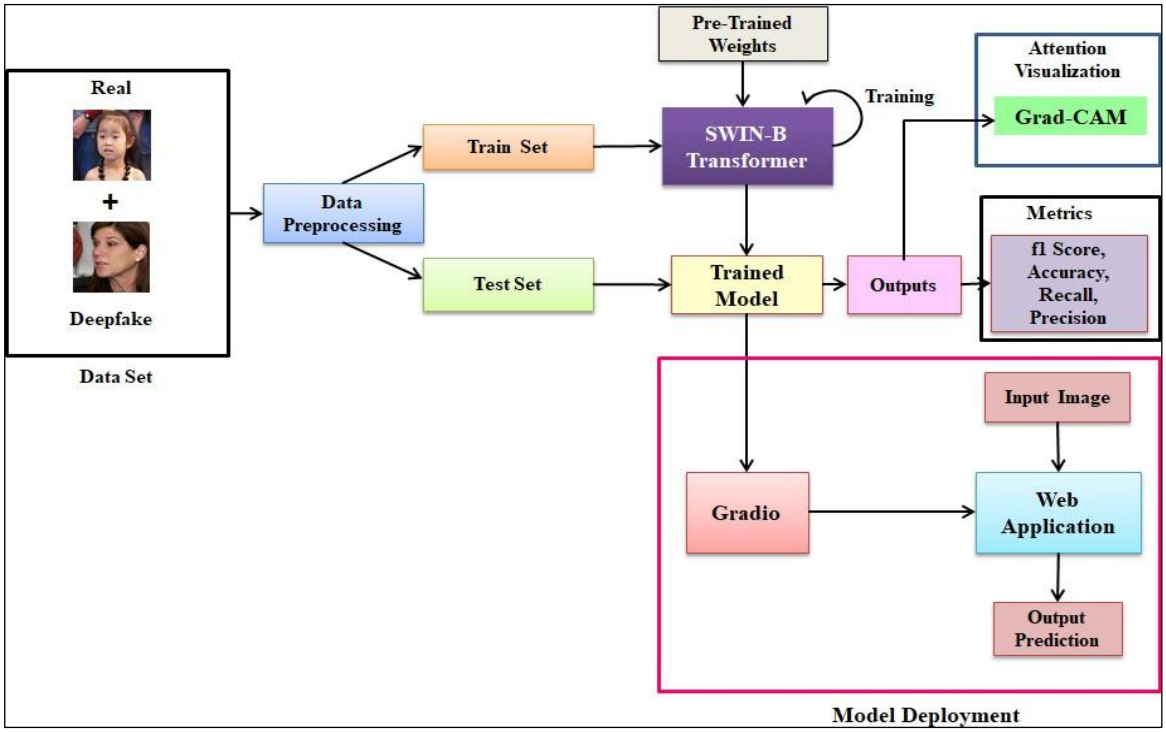

Figure 5: Proposed System architecture.
Source: Authors, (2026).

IV.1 DATA PRE-PROCESSING

All the images present in the hybrid dataset are transformed so that they are in a fixed size of 224×224 pixels - the expected input image size for the model, and are normalized. In order to balance both the classes present in the dataset, and to avoid overfitting, data augmentation is applied on real face images. The dataset was divided into subsets, with 70% used for training and 30% used for testing.

IV.2 MODEL TRAINING

After splitting the extracted image dataset into training and testing subsets, we start the training phase. Here, we make use of the pre-trained Swin-B Transformer model. Initially, load the Transformer pre-trained on ImageNet. The pre-trained weights for this model are obtained from the official weights submitted by Microsoft to the Huggingface platform [21]. This model contains roughly 28 million trainable parameters and is pre-trained on more than 14 million images present in ImageNet dataset. The Swin-B Transformer model contains four blocks called "swin layers", each performing similar operations. In the first layer, the image is broken down into non-overlapping patches of size 4 x 4 pixels resulting in 56 x 56 tokens. Swin divides the 56 x 56 tokens into small windows of size 7 x 7.

Unlike conventional Vision Transformers, where multi-head attention is calculated globally for the entire image taking a lot of processing time, Swin transformers applies attention only inside local attention window of size 7 x 7. This approach is known as Window-based Multi-head Self Attention (W-MSA) as shown in Eq(1). In the next layer, the windows were shifted by patch size of 3 supporting cross-window communication called as Shifted Window Multi-head Self Attention (SW-MSA). After each group of Swin blocks, a patch merging operation is performed, where 2×2 neighbouring patches are concatenated and linearly transformed there by increasing feature depth while decreasing spatial resolution. The overall architecture of the Swin-B transformer consisting of four stages, is illustrated in Figure 6 and the functionality of each stage is summarized in Table 2.

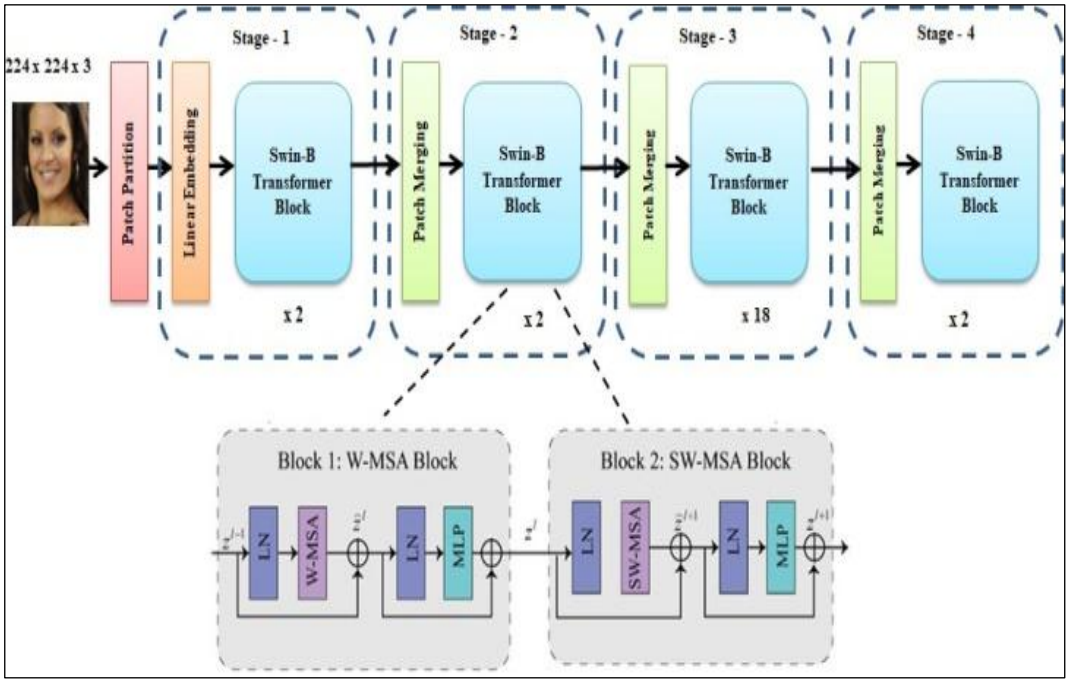

Figure 6: Architecture of Swin-B Transformer.
Source: Authors, (2026).

Table 2: Layers inside each Stage of Swin-B Transformer.

Stage	Input Size	Layers	Hidden Dim	Operations
1	56×56 (after 4×4 patch split)	2	128	W-MSA + SW-MSA
2	28×28 (after Patch Merging)	2	256	W-MSA + SW-MSA
3	14×14	18	512	W-MSA + SW-MSA
4	7×7	2	1024	W-MSA + SW-MSA

Source: Authors, (2026).

$$MultiHead(Q,K,V) = [head_1, \dots, head_h]W_0 \quad (1)$$

Where, headi is self-attention, calculated using Eq.(2) and Eq.(3)

$$head_i = Attention\left(Q\,W_i^Q, K\,W_i^K, V\,W_i^V\right) \quad (2)$$

$$Attention(Q,K,V) = Softmax\left(\frac{(QK^T)}{\sqrt{d_k}}\right)V \quad (3)$$

Where Queries $Q \in R^{n\times dk}$,Keys $K \in R^{n\times dk}$,Values $V \in R^{n\times dv}$. The final output layer of the Swin-B backbone produces a feature vector f $\in R^d$ and the fully connected layer converts f to class scores as shown in Eq(4).

$$= Wf + b \quad (4)$$

Where $W \in R^{n\times d\infty}$, $b \in R^n$ is the number of classes. Softmax is then applied to z which classifies the input into categories: Real, DeepFake. The softmax function is given by Eq(5):

$$\hat{y}_i = \frac{e^{z_i}}{\Sigma_{j=1}^{n} e^{z_j}} \quad (5)$$

Where $\hat{y}_i$ is the predicted probability for class i. Next, we calculate the loss using Cross Entropy function as shown in Eq(6). We take the cross-entropy loss and perform back propagation using gradient descent to modify the weights of the model.

$$Cross - Entropy = -\sum_x p(x)\log(q(x)) \quad (6)$$

Where p(x) is the true distribution, q(x) is the probability being predicted. In this way, the model is trained for 10 epochs. The total cross entropy for each epoch is observed as shown in Table 3.

Table 3: Cross-entropy loss for training and test set after each epoch.

Epoch Number	Training Loss	Testing Loss
1	0.4452	0.1691
2	0.1909	0.1585
3	0.1380	0.1465
4	0.1156	0.1363
5	0.0945	0.1338
6	0.0802	0.1298
7	0.0713	0.1241
8	0.0663	0.1231
9	0.0403	0.1212
10	0.0242	0.1210

Source: Authors, (2026).

IV.3 ATTENTION VISUALIZATION

Using Gradient-weighted Class Activation Mapping (Grad-CAM) technique, as proposed in [22], heatmaps are generated to visualize the spatial segments of the image on which the proposed model focuses during the classification of real and deepfake images by fusing the feature activations and the corresponding gradients from the layers being selected. These heatmaps were overlaid using a JET color map featuring red, yellow, blue, and green colors, where each color represents the degree of importance of the features:

- Red/Yellow: High Activation, most important regions that strongly influence the models decision.
- Green: Moderate Activation, regions that contribute partially to the classification.
- Blue: Low Activation, regions that have minimal or no influence on the classification.

Figure 7 and Figure 8 illustrate the Grad-CAM heatmaps generated for real and DeepFake images at all stages. The real image heatmap shows smooth, consistent attention on natural facial regions, and the activation is consistent from stage-1 onward. The fake image heatmap shows more scattered, irregular, and intense activations around unnatural boundaries and textures, with later stages (stage 2 and stage-3) highlighting these artifacts even more.

IV.4 TESTING AND EVALUATION

Once the model has been sufficiently trained, its performance is then evaluated on the test set using standard evaluation metrics.

IV.5 DEPLOYMENT

Finally, after testing and evaluation, the model is deployed using Gradio API [23]. We created a Gradio Interface object that accepts a function with two parameters: inputs to the function and output from the function. You can quickly deploy a demo application by calling the launch() method on the interface object. The input and output objects can be of various types like text, images, audio, videos, buttons, numbers, etc. In our application, the input is a PIL image, and the output is the predicted class label. The prediction function contains the logic for generating predictions from an input image. When a user uploads an image, the API invokes this function, where the image is first processed using an AutoImageProcessor to ensure that the image is resized to 224 x 224 pixels - the expected input image size for the model. The processed image is then passed to the model to find the predictions, which are then mapped to their corresponding classes. The predictions are formatted appropriately before being returned to the API and displayed to the user. Figure 9 shows the User Interface where a random image from the "real" class of the test set was passed as an input. Figure 10 shows the output of a fake image from the dataset, which is correctly classified as Deepfake.

Figure 9: Output of a real image.
Source: Authors, (2026).

Figure 10: Output of a fake image.
Source: Authors, (2026).

V. EVALUATION OF RESULTS

The evaluation is performed on the test set after each epoch. The test set consists of 93,590 images in total. The model's performance is evaluated using four metrics. They are: Accuracy, Precision, Recall and F1 score. To carry out this work, we first extracted images from dataset composed of real faces from FFHQ real faces dataset [17] and fake images from kaggle deepfake images dataset [19]. These images are used to train our model on both real and deepfake images. We initialized our model with pre-trained weights to reduce training time and to improve the model's performance. We ran all of our tests on Google Colab Pro, an open-source Python notebook environment featuring a Tesla T4 GPU with 16GB of VRAM and approximately 13GB of system RAM.

To ease the T4 GPU's memory constraints, we used mixed precision training using 'torch.cuda.amp', which helped us in reducing both training time and VRAM usage. We saved checkpoints after every epoch to resume training if Colab disconnects. Furthermore, the model is optimized using Adam optimizer with a learning rate of 0.0001, $\beta 1 = 0.9$, and $\beta 2 = 0.999$ to ensure more precise parameter tuning. After training for 10 epochs, we evaluated performance using various metrics as shown in Figure 11. A comparison with the existing systems, shown in Table 4, indicates that our model performs well in most cases.

VI. ETHICAL AND SOCIAL IMPACT

As synthetic media technologies evolve, deepfake images have become a major societal and ethical challenge, especially on social computing platforms where images are frequently shared, altered, and used for other purposes. In most of the social computing platforms information spreads rapidly and user-generated content is often trusted without verification. The ability to generate realistic but deepfake human faces increases the concerns about misinformation, identity fraud, defamation, influence public opinion leading to the undermine public trust in visual media.

Our research technically addresses these challenges by employing Swin-B Transformer on a hybrid dataset combining real images from FFHQ and fake images from a publicly available Kaggle dataset. The dataset used in our approach reflects the diverse and real-world nature of social media content, which improves generalization and increases detection accuracy in real-world scenarios. This work has several important societal benefits, including:

- **Enhanced Content Authenticity:** Assisting social platforms to detect and filter deepfake images before it misleads users.
- **Support for the control of Fake News:** By detecting deepfake images early, can limit the viral spread of this manipulated visuals particularly in political or sensitive contexts.
- **Ensuring Digital Trust and Safety:** Allows Governments, institutions, platforms and users to verify the legitimacy of images there by improving public confidence in online content.

VII. CONCLUSION

In this paper, we addressed the growing issue of deepfake image generation and its potential negative societal impacts. Deepfakes are an increasing concern due to their ability to spread misinformation, support harassment, and undermine public trust in the visual media. To combat this, we proposed a robust detection framework using Swin-B, a standard variant of the Swin Transformer, which has demonstrated optimal performance in computer vision tasks compared to traditional CNNs. By leveraging the capabilities of this pre-trained model and fine-tuning it for deepfake detection, we achieved an accuracy of 97.47% on the test set of our hybrid dataset.

Furthermore, we used Grad-CAM to analyze which segments of the image the model is focusing on while classifying the images as *Real* or *DeepFake*. By promoting safer and more trustworthy digital environments, this work not only improves technical accuracy in the detection of deepfakes, but also supports the objectives of social computing.As the deepfake generation techniques continue to evolve, it will be necessary to re-access the model's performance and potentially retrain our model to ensure its effectiveness. Future work will focus on integrating temporal or multimodal features, extending the detection to deepfake videos, and continuously updating our model with the newly synthetic images sustaining its accuracy and reliability.

ABSTRACT

The present study is focusing on cryogenically treated (CT) EN31 hardened alloy steels. The experimental runs were designed by using Box-Behnken approach of RSM using multiple process parameters- cutting speed (v, 160-260 m/min), feed (f, 0.1-0.2 mm/rev), depth of cut (d, 0.05-0.15 mm), tool nose radius (re, 0.4-1.2 mm), and hardness (HR, 45-49 HRC) for optimizing surface finish. The specimens and inserts underwent a 24-hour socking time in nitrogen medium (-196° C) as part of the deep cryogenic treatment and hardness of the materials were measured before and after the treatments. In experimentation wet turning was performed on LMW Make LX20T L5 CNC machine with multilayer TiCN+Al2O3+TiN CVD coated inserts. According to the study, Ra dramatically rises with an increase in d and falls with an increase in v. When comparing Ra to the f, re, and HR, comparable variations are seen. The Box-behnken approach of RSM is more capable of predicting surface finish by 99.96% utilizing a polynomial quadratic equation.

I. INTRODUCTION

Cryogenic treatment enhances hardness, wear resistance, dimensional stability, and mechanical performance in steels and tool materials [1], [2]. Barron identified key sub-zero processing methods such as slow cooling, long soaking, and precise temperature control to prevent thermal shock and ensure complete austenite-to-martensite transformation [1]. Amini and Das found that deep cryogenic treatment (DCT) refines martensite and promotes fine carbide distribution, reducing retained austenite and improving surface properties in tool steels such as AISI D2 and M2 [3], [4]. Baldissera and Bensely reported increased strength and wear resistance in carburized and case-hardened steels, attributing these improvements to uniform microstructure and stable carbide formation [5], [6]. Gill and Yong highlighted the significance of DCT in machining applications, reporting increased tool life and reduced flank wear under both dry and coolant-assisted cutting conditions [7], [8]. He and Idayan observed improvements in hardness, toughness, and rolling contact fatigue behaviour of maraging steels and bearing steels following cryogenic processing [9], [10].

Huang and Rhyim reported secondary carbide precipitation, martensitic refinement, and improved fracture surface characteristics as the dominant strengthening mechanisms in cryogenically treated steels [11], [12]. Pellizzari and Kalsi emphasized the importance of applying DCT prior to tempering and maintaining low cooling rates to prevent microcracking and to maximize beneficial phase transformations [13], [14]. Across automotive, tooling, manufacturing, and structural applications, collective research demonstrates that cryogenic treatment consistently improves wear resistance, hardness, and dimensional stability [2], [15-18]. When followed by appropriate tempering cycles, toughness is preserved or enhanced without compromising strength [14], [17]. Studies on steels such as EN31, EN52, EN353, AISI 440C, and powder-metallurgy high-speed steels confirm that DCT is a versatile, robust, and economically viable extension of conventional heat-treatment processes [2], [6], [10].

II. LITERATURE REVIEW

Research over the past few decades consistently demonstrates that deep cryogenic treatment (DCT) significantly alters the microstructure and properties of steels and tool materials. Barron reported that slow cooling and soaking at liquid-nitrogen temperatures are essential to achieve stable martensite formation without inducing thermal shock [1]. Amini showed that tool steels treated at −196 °C exhibited refined martensite, reduced retained austenite, and improved hardness and wear resistance [3]. Baldissera reported that cryogenically treated carburized steels exhibited hardness improvements of up to 2.4 HRC and tensile strength enhancement of approximately 11%, primarily due to uniform carbide precipitation [5]. Bensely demonstrated reduced wear and deformation in cryogenically treated EN353 gears, supported by scanning electron microscopy observations showing fewer carbide pull-outs and smoother worn surfaces [6].

Cajner and Candane further reported that DCT significantly improves dimensional stability by homogenizing carbide distribution and minimizing retained austenite [19], [20]. Investigations on cold-work tool steels, particularly AISI D2, revealed that optimal soaking durations of approximately 36 h produce maximum wear resistance through uniform carbide refinement [4]. Machining-related studies by Dhananchezian showed that liquid-nitrogen cooling during orthogonal cutting significantly reduced cutting temperature, modified chip morphology, and improved surface integrity [21]. Gill applied Taguchi optimization techniques to cryogenically treated M2 high-speed steel tools and reported significant reductions in flank wear [7]. Yong reported that cryogenically treated carbide cutting tools achieved 30–40% improvement in tool life during both dry and wet machining conditions [8], [22]. Leskovšek demonstrated that cryogenically treated high-speed steel drills exhibited up to 77% improvement in tool life when combined with appropriate tempering cycles [23].

Studies on specialty alloys revealed that cryogenic treatment promotes near-complete austenite-to-martensite transformation in maraging steels, resulting in enhanced strength and toughness [9]. Microstructural investigations by Huang confirmed that secondary carbide precipitation plays a critical role in improving wear resistance of cryogenically treated M2 steels [11]. Rhyim and Pellizzari further reported that applying DCT between quenching and tempering results in finer, more stable carbides and improved dimensional stability [12], [13], [16]. Cryogenic treatment of structural steels has also been widely investigated. By [24] reported improvements in hardness, impact energy, tensile strength, and residual stress behaviour in cryogenically treated EN31 steel due to martensitic refinement and carbon clustering [17], [25]. Vimal observed up to 75% reduction in wear rate in cryogenically treated EN31 steel, attributing the improvement to uniform carbide dispersion [2].

Thornton reported that cryogenically treated automotive brake discs exhibited significantly lower wear rates, enhancing braking efficiency and service life [18]. Vadivel demonstrated that combining cryogenic treatment with surface coatings produced synergistic improvements in wear resistance, surface finish, and flank wear suppression [26]. Additional investigations by Collins and Jaswin confirmed that the effectiveness of cryogenic treatment strongly depends on alloy composition, prior heat treatment, and cryogenic cycle parameters [27], [28]. Overall, the literature confirms that deep cryogenic treatment is a scientifically validated and industrially effective extension of conventional heat treatment, offering significant improvements in hardness, wear resistance, dimensional stability, toughness, and tool life when properly optimized [2], [14], [15].

III. EXPERIMENTAL PROGRAM

The experimental program consisting the information of raw material specifications, inserts, CNC, hardening and cryogenic treatments, machining process parameters, and surface finish. The experimental program of the present study begins with experimentation on multiple hardened EN31 alloy steel. The chemical composition of EN31 alloy steel shows the significant contribution of alloying elements such as carbon, manganese, and chromium. In contrast, nickel, silicon, molybdenum, and sulfur contribute marginally to enhancing the steel's hardness performance. Table 1 shows the alloying elements with their % contribution in EN31 alloy steel.

Table 1: Alloying elements with their % contribution in EN31 alloy steel.

Alloying Elements	Required (%)	Actual (%)
Carbon (C)	0.90 to 1.20	1.10
Silicon (Si)	0.10 to 0.35	0.19
Manganese (Mn)	0.30 to 0.75	0.52
Phosphorous (P)	0.05 max.	0.034
Sulfur (S)	0.05 max.	0.050
Chromium (Cr)	1.00 to 1.60	1.19

Source: Authors, (2026).

The experimentation was performed in batches to evaluate the performance of machining process parameters on surface finish by considering 40 samples of cryogenically treated EN31 hardened alloy steels with 5 machining process parameters. Initially, the raw material's hardness was evaluated with a Rockwell hardness tester and observed to be 27±2 HRC. Furthermore, the EN31 alloy steel specimen was sliced in accordance with the surface response method's prescribed runs. The specimens were prepared for experimentation, with plane turning and facing operations done first, followed by the standard hardening process. After hardening, the hardness of all specimens was measured again, and the experiment was carried out on 25 mm diameter EN31 alloy steel utilizing LMW Make LX20T L5 CNC machine on cryogenically treated hardened alloy steels hardness ranging from 45±2 HRC to 49±2 HRC.

Multilayer CVD inserts were introduced for turning operations because high carbon, high chromium steel required stronger inserts for machining; uncoated carbide inserts are more frequently employed. The Sandvik Coromant TNMG 160404, 160408, 160412 series insert with TiCN+Al2O3+TiN CVD coatings were used in the current study for turning operations. While alumina (Al2O3) offers superior thermal resistance to the cutting edge at high temperatures, titanium carbonate (TiCN) adds hardness and wear resistance, and titanium nitride (TiN) prolongs tool life by drastically lowering friction and premature wear.

A wet turning operation has been performed on specimens under considerations by using WW COOL SS cutting fluid as a coolant. Figure 1 shows the actual experimentation of the specimens. EN31 steel's mechanical properties, including hardness, toughness, and wear resistance, are significantly enhanced through heat treatment. This meticulous procedure involves stress relief at 500-550℃, hardening, and a phase transition from ferrite to austenite at 820-850℃. Castrol oil is used for rapid quenching, providing increased wear resistance and hardness. After quenching, tempering is repeated at 320-350℃ for 90 minutes to redefine the steel's microstructure. This comprehensive hardening process ensures the steel's appropriate hardness. Figure 2 shows the hardening process for steel materials.

A cryogenic treatment (CT) consists of four stages called descending, soaking, ascending and tempering process. A CT was performed on all specimens under considerations and coated carbide insert in a nitrogen medium for 24 hours soaking time. A temperature of -84° C is achieved with shallow cryogenic treatment (SCT), whereas -196° C is achieved through deep cryogenic treatment (DCT). The Box-Behnken Design (BBD) is a statistical method used in Response Surface Methodology (RSM) to establish the link between dependent and independent variables.

Its unique feature is its rotatability, ensuring constant variance prediction. The BBD structure considers the number of variables and uses three experimental points: factorial, center, and no axial. This design minimizes the chance of unfavorable elements and ensures optimal performance. BBD offers efficiency, ease of use, and security, requiring less runs than factorial and CCD. However, it only works with factors between three and seven and doesn't cover the entire factor space. The experimental runs N and second order polynomial quadratic equations were designed by using formula,

$$N = 2k(k-1) + C_p \tag{1}$$

$$Y = \beta_0 + \sum_{i=1}^{k} \beta_i X_i + \sum_{i=1}^{k} \beta_{ii} X_i^2 + \sum_{i<j} \beta_{ij} X_i X_j \tag{2}$$

Whereas, k = No. of factors, Cp = center points, Y = Output, Xi, Xj = Independent variables, and β0, βi, βii, βij = Coefficients. The factors and their levels for the present study are given in Table 2 and Table 3 shows the experimental run calculations for CT steels.

Table 2: Factors and their levels.

Factors	Symbol	Unit	Levels		
			-1	0	+1
Cutting speed	*V*	*m/min*	160	210	260
Feed	*f*	*mm/rev*	0.10	0.15	0.20
Depth of cut	*d*	*mm*	0.05	0.10	0.15
Tool nose radius	r_e	*mm*	0.40	0.80	1.20
Hardness	*HR*	*HRC*	45	47	49

IV. RESULTS AND DISCUSSIONS

The results and discussion mainly focussed on experimental results of surface finish compared with machining process parameters and 3D surface plot and contour plots are plotted based on BBD of RSM. Figure 3 illustrates the process parameters versus surface finish for CT steels. Figure 3 (a) illustrates the variations in v and Ra. A decreasing trend observed in Ra when v is increasing as the E31 hardened alloy steel specimens are cryogenically treated (CT). CT enhances the surface finish as already seen in the open literature. The range given for 160 m/min and 260 m/min shows the outliers whereas maximum specimens Ra are covered at 210 m/min v. Figure 3(b) shows the variations in f and Ra for CT steels. A comparable differences are observed for f's under considerations. An increasing trend is observed in d and Ra shown in Figure 3(c). The values of d significantly affects the Ra as d increases with increase in Ra observed. Outliers in Ra are observed at 0.05 mm and 0.15 mm d. Again a comparable differences are observed in Ra when compared with re's and HR's as shown in Figure 3(d) and 3(e).

A wide variety of specimens are covered at 0.8 mm re and 47 HRC CT steels. In EN31 hardened alloy steels, a cryogenic treatment reduced the Ra to some extent by enhancing the material and inserts mechanical properties. Figure 4 shows the (a) 3D surface plot and (b) contour plot re and v versus Ra for CT steels. A comparable differences are observed in Ra values when re's and v's are increasing. The Ra's are observed within the range of 1.4 to 1.6 µm. Figure 5 shows the (a) 3D surface plot and (b) contour plot re and f versus Ra for CT steels. The re's and f's are having no effect on Ra's. The value of Ra is observed almost constant i.e. 1.5 µm for the considered range of re's and f's. Figure 6 shows the (a) 3D surface plot and (b) contour plot re and d versus Ra for CT steels.A significant variations are observed in Ra's due to increase in d's whereas marginal variations are observed with increase in re's. The Ra values ranged between 1.4 to 1.6 µm in a linear trend.

Figure 7 shows the (a) 3D surface plot and (b) contour plot re and HR versus Ra for CT steels. Similar to figure 5, the re's and HR's are having no effect on Ra's. The value of Ra is observed almost constant i.e. 1.5 µm for the considered range of re's and HR's. Figure 8 shows the (a) 3D surface plot and (b) contour plot v and f versus Ra for CT steels. Similar to figure 4, a comparable differences are observed in Ra values when v's and f's are increasing. The Ra's are observed within the range of 1.4 to 1.6 µm. Figure 9 shows the (a) 3D surface plot and (b) contour plot v and d versus Ra for CT steels.

A significant variations are observed in Ra's due to increase in d's whereas a comparable decrement is observed with increase v's. Ra observed greater than 1.6 µm where d is higher than by 0.1 mm. The Ra's are observed with the range of 1.4 to 1.6 µm. Figure 10 shows the (a) 3D surface plot and (b) contour plot v and HR versus Ra for CT steels. Similar to figure 8, a comparable differences are observed in Ra values when v's is decreasing and HR's are increasing.

The Ra's are observed within the range of 1.4 to 1.6 µm. Figure 11 shows the (a) 3D surface plot and (b) contour plot f and d versus Ra for CT steels. A significant effect on Ra is observed due to increase in d's whereas comparable increment is observed due to increase in f's. The Ra's are observed within the range of 1.4 to 1.6 µm.

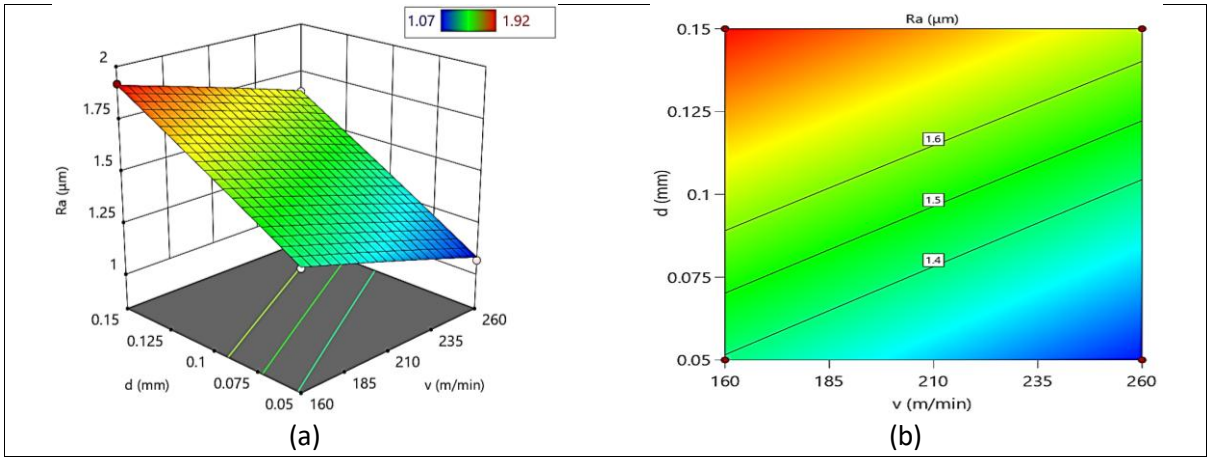

Figure 9: Cutting speed and depth of cut versus surface finish for CT steels.
Source: Authors, (2026).

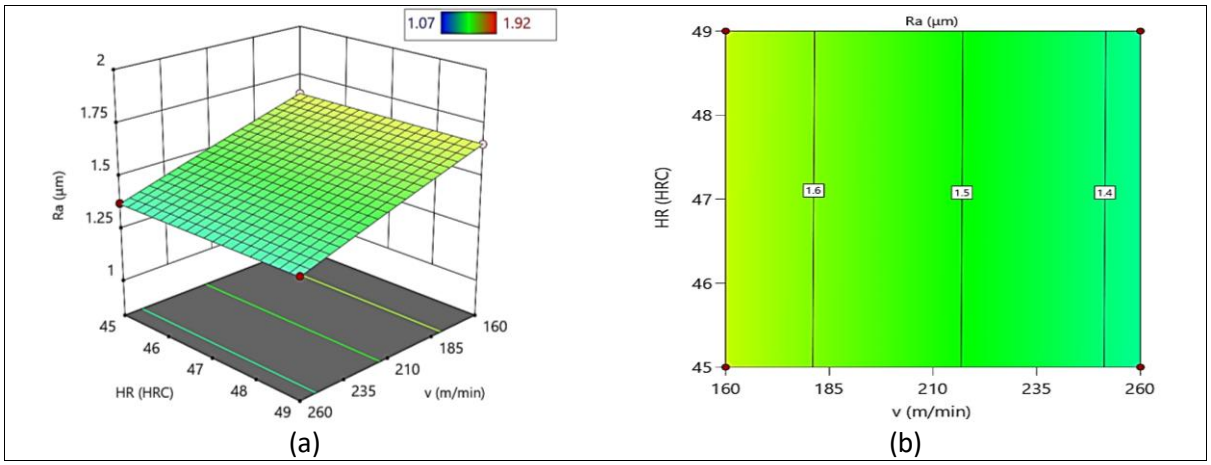

Figure 10: Cutting speed and hardness versus surface finish for CT steels.
Source: Authors, (2026).

Figure 12 shows the (a) 3D surface plot and (b) contour plot f and HR versus Ra for CT steels. Almost no effect is observed due to increase in f's and HR's on Ra values. The Ra's are observed within the range of 1.52408 to 1.5241 µm. Figure 13 shows the (a) 3D surface plot and (b) contour plot d and HR versus Ra for CT steels. Almost no effect is observed due to increase in d's and HR's on Ra values. The Ra's are observed within the range of 1.51909 to 1.5241 µm. Cryogenic treatment has provided surface finish benefits to EN31 hardened alloy steels. It has enhanced surface finish to some extent by reducing residual stresses, thermal temperature differences in cutting zones, etc. a multilayer CVD coated insert also contributes into the enhancement of surface finish.

After performing cryogenic treatment a surface finish has been observed within the range of 1.07 to 1.90 µm for all the specimens under considerations. Figure 14 illustrates the experimental runs versus comparison of surface finish. The significant deviation is observed at run number 1 and marginal deviations are observed for run number 3, 5, 16, 17, 19, 21, 32, and 37. Figure 15 shows the comparison of exp. and pred. surface finish. The surface finish for cryogenically treated steels are predicted with an accuracy of 99.96%.

V. CONCLUSIONS

This study demonstrates that deep cryogenic treatment at -196°C for 24 hours enhanced the machining stability of EN31 steel, producing surface roughness values consistently between 1.07-1.90 µm during hard turning. Experimental data combined with the Box–Behnken RSM approach yielded a predictive quadratic model with 99.96% accuracy, confirming its reliability. Cutting speed showed a clear inverse relationship with surface roughness, as increasing speed from 160 to 260 m/min reduced Ra, while depth of cut emerged as the most influential factor; raising d from 0.05 to 0.15 mm increased Ra beyond 1.6 µm. In contrast, feed rate changes between 0.10–0.20 mm/rev, tool nose radius from 0.4-1.2 mm, and hardness from 45-49 HRC had minimal impact, with Ra remaining close to 1.5 µm.

The parameter combination centered on v = 210 m/min, f = 0.15 mm/rev, d = 0.10 mm, re = 0.8 mm, and HR = 47 HRC consistently produced Ra values near 1.48-1.55 µm, indicating an optimal machining range. The maximum deviation between predicted and experimental Ra was only ±0.016, confirming strong agreement across trials. Overall, cryogenic treatment improved microstructural stability, enabling most interactions of machining parameters to maintain roughness within 1.4-1.6 µm, demonstrating the process's effectiveness in achieving uniform surface finish.

ABSTRACT

A series of similar joints made from Al2017A aluminum alloy were produced through rotary friction welding, with localized reinforcement provided by alumina (Al_2O_3) particles, a ceramic known for its high hardness and extensive use in metal–matrix composites. These particles were placed at the weld interface by filling drilled holes of different diameters in the fixed component, allowing the influence of varying volume fractions on joint behavior to be examined. Tests of tensile strength and microhardness indicated that adding Al_2O_3 leads to a noticeable improvement in the mechanical performance of the welded joints when compared with those lacking ceramic reinforcement.

I. INTRODUCTION

Friction welding is a solid-state joining process whose principle has been known since the late 20th century [1]; however, its significant industrial development only began in 1956 in the former Soviet Union [2] before gradually spreading to the United Kingdom and the United States [3]. Classified as a forging process, friction welding relies on the generation of heat at the interface through the rapid rotation of one component under controlled axial pressure against another [4]. The heat generated, combined with plastic deformation, leads to a localized material flow that enables bonding in the solid state without ever reaching the melting temperature [5]. This unique feature eliminates the typical defects associated with fusion welding processes, such as solidification cracking, porosity, and pronounced metallurgical heterogeneities [6], [7].

This process offers several advantages, including the production of joints with high mechanical integrity, reduced cycle times, excellent repeatability, low energy consumption, and the possibility of complete automation, ensuring consistent quality [8], [9]. In addition, its environmentally friendly nature - no welding fumes, no UV or electromagnetic radiation, and no need for filler metals or shielding gases - makes it an attractive technology for demanding sectors such as aerospace, automotive, energy production, and mechanical engineering [10], [11]. Nevertheless, despite these advantages, the relationships between welding parameters (rotational speed, axial force, friction time), thermal cycles, microstructural evolution, and resulting mechanical properties remain insufficiently understood [12], [13]. This knowledge gap limits the optimization of process parameters and the development of reliable predictive models [14], [15], particularly when welding dissimilar materials or alloys that are sensitive to thermal gradients [16-20].

In this context, the present work proposes a detailed experimental investigation of rotary friction welding applied to 2017A aluminum alloy, reinforced with alumina (Al_2O_3) ceramic particles. The main objective of this study was to evaluate the effect of reinforcement content on the joint quality, microstructural characteristics, and mechanical performance. The selected materials, operating parameters, and characterization techniques are described in detail in this section. The experimental results were analyzed and discussed to highlight the material–process interaction mechanisms and provide recommendations for optimizing rotary friction welding. This study contributes to a better understanding of the influence of ceramic reinforcements on the behavior of aluminum weldments and paves the way for the design of higher-performance joints for advanced industrial applications.

II. MATERIALS AND METHODS

II.1 MATERIALS USED

II.1.1 Aluminum Alloy 2017A

Aluminum alloy 2017A, belonging to the 2XXX series (Al-Cu-Mg), is a structurally hardening alloy whose strength arises from the precipitation of $CuAl_2$ and $CuMgAl_2$ compounds. Its composition of copper (2.6-6.3%) and magnesium (0.5-1.5%) endows it with excellent mechanical properties. The addition of silicon and manganese (< 0.8%) improves the strength by dispersion, whereas iron degrades the hardening by forming undesirable compounds. Secondary alloying elements (such as Cr, Zn, and Ti) further optimize the performance of the aluminum alloys.

Table 1: Composition of alloy 2017A in mass percentage.

If	Fe	Cu	Mn	Mg	Cr	Zn	Zr + Ti	Each other	Total other	Al
0.20-0.80	≤ 0.70	3.5-4.5	0.4-1.0	0.4-1.0	≤ 1.0	≤ 0.25	< 0.25	≤ 0.05	≤ 0.25	Stay

II.1.2 Alumina AL_2O_3

Alumina (Al_2O_3) is a refractory oxide extracted from bauxite, very chemically stable and with a high melting point (≈ 2054 °C).

Table 3: Chemical composition of alumina (determined by XRF).

II.2 PREPARATION OF WELDED SAMPLES FOR MICROGRAPHIC OBSERVATION

This section investigates the preparation, microstructural analysis, and mechanical performance of aluminum joints produced by rotary friction welding. Metallographic preparation included sectioning, resin mounting, progressive SiC polishing, and etching with Keller's reagent. Optical microscopy (×10–×1000) was used to characterize weld-zone microstructure. Mechanical behavior was evaluated through Vickers microhardness (200 g, 10 s), tensile testing (W310), and three-point bending on a servo-controlled universal machine.

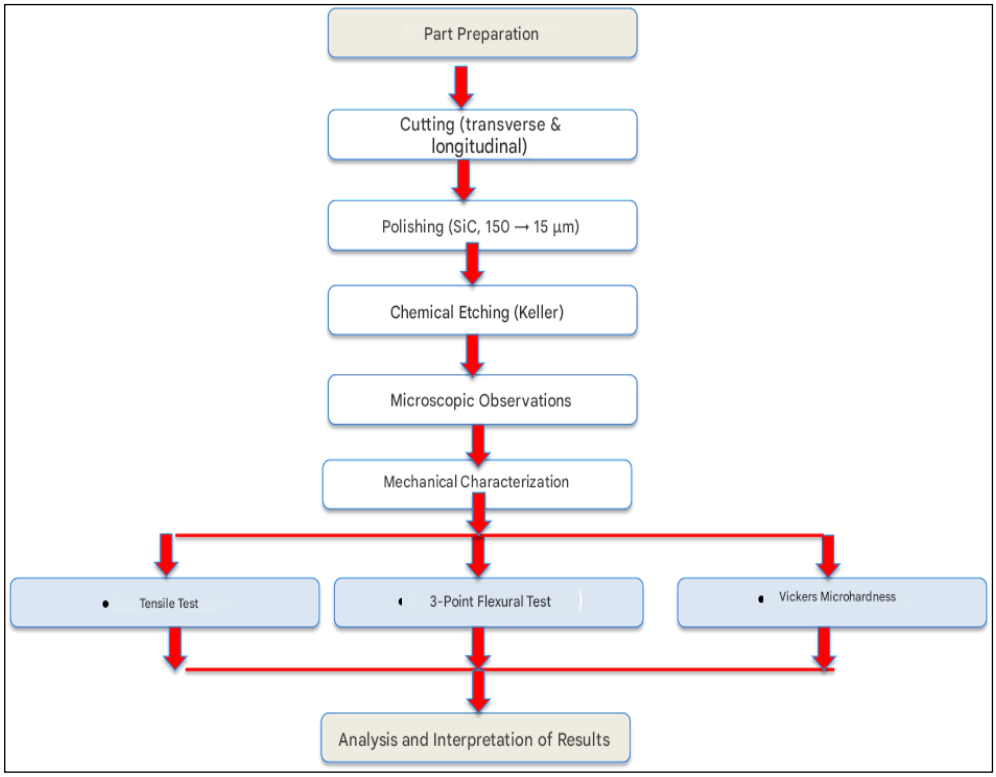

Figure 1: Experimental procedure for specimen preparation and characterization.
Source: Authors, (2026).

II.2.1 Cutting, Dressing and Drilling:

Before starting the rotary friction welding processes, the used 2017A rods were cut into samples with a length of 70 mm and a diameter of 12 mm. The ends of the samples were polished and cleaned.

II.2.2 Addition AL_2O_3

Volume fractions are calculated as follows:

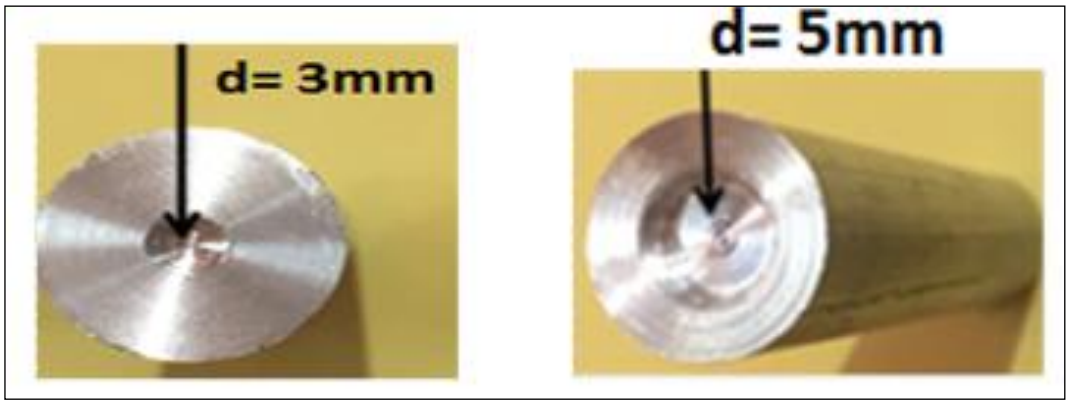

Figure 2: Experimental specimens illustrating the internal diameters investigated in the present study.

Diameters:

$$\begin{cases} d_0 = 0 \\ d_1 = 3mm \\ d_2 = 5mm \end{cases}$$

Area contact: $\frac{\pi d^2}{4}$

Volume fraction of aluminum:

$$100\% \quad \rightarrow \quad \frac{\pi d^2}{4}$$

$$X_i\% \quad \rightarrow \quad \frac{\pi d_i^2}{4}$$

Sample 1: $d_0 = 0 \Longrightarrow X_0 = 0\%$

Sample 2 : $d_1 = 3\ mm \Longrightarrow X_1 = 6.25\ \%$

Sample 3: $d_2 = 5\ mm \Longrightarrow X_2 = 17.36\%$

Before welding, Al_2O_3 particles were added at different volume fractions to the interface of the joints through pre-drilled holes, as shown in (Figure 3c). The experimental setup utilized a PMO UF 1.5 universal milling machine (Figure 3d) installed in the Mechanical Engineering Laboratory of the University of Bordj Bou Arreridj. The friction rotation welding process was performed on cylindrical specimens with a diameter of 12 mm and a length of 70 mm. The main welding parameters were as follows:

- Rotation speed: 1400 rpm
- Friction time (heating phase): 40
- Forging time (forging phase): 10 s
- Axial movement speed: 63 mm/min

To evaluate the maximum temperature attained during welding, temperature measurements were performed under various processing conditions. A thermocouple was used for temperature acquisition and was mounted on the rotating component, as shown in Figure 3e.

III.RESULTS AND DISCUSSIONS

III.1 VISUAL OBSERVATIONS:

After rotary friction welding, the bead of the aluminum/aluminum samples is asymmetrical and its size varies from one sample to another (Figure 4.1 and 4.2).

III.2 SHORTENING OF WELDED JOINTS (BROWN-OFF)

Figure 5 illustrates the variation in burn-off as a function of the alumina (Al_2O_3) volume fraction in rotary friction-welded (RFW) joints. The results show that the burn-off does not vary linearly with the reinforcement content. As the Al_2O_3 fraction increases from 0% to 6.25%, the burn-off increases noticeably, reaching its maximum at approximately 6.25%. However, when the Al_2O_3 content is further increased to 17.36%, the burn-off decreases again, although it remains slightly higher than that of the unreinforced material. This trend reflects the combined effect of frictional heat generation and plastic flow resistance during welding. At moderate Al_2O_3 contents (≈ 6.25 %), the ceramic particles enhance interfacial friction and promote localized plastic deformation, resulting in increased material softening and expulsion from the interface.

This leads to the highest burn-off observed. Conversely, at higher reinforcement levels (17.36 %), the increased particle concentration acts as a rigid barrier that restricts plastic flow and reduces the effective heat generated at the interface. Consequently, less material is displaced, leading to a lower burn-off compared with the 6.25% sample. The lowest burn-off at 0% Al_2O_3 can be attributed to the absence of ceramic reinforcement, which limits frictional interaction and maintains a more uniform material flow. These observations are consistent with trends reported in the literature.

By [21] showed that the introduction of Al_2O_3 nanopowder during friction stir processing (FSP) can modify heat generation and improve mechanical behavior. According to [22] reported an optimal reinforcement level near 8 vol% for Al_2O_3-reinforced AA6082-T6 joints, where excessive ceramic content reduced heat input and plastic flow. Similarly [23] found that excessive nanoparticle additions impede material flow in the nugget zone, while [24] emphasized the role of particle concentration in governing thermal input and energy dissipation. Therefore, the maximum burn-off observed at a moderate reinforcement fraction (≈ 6.25 vol.% Al_2O_3) can be attributed to an optimal balance between enhanced frictional heating and sufficient material deformability, in agreement with previously reported behaviors in particle-reinforced friction-based processes.

III.3 THERMAL CYCLES

Figure 6 shows the evolution of temperature as a function of time for different volume fractions of Al_2O_3 (0%, 6.25%, and 17.36%). Although the three curves follow a similar thermal profile-characterized by a rapid rise, a maximum peak, and a subsequent cooling stage-the reinforcement volume fraction significantly affects both the amplitude and the kinetics of the thermal response. During the heating phase, increasing the Al_2O_3 content leads to a more pronounced rise in the peak temperature. The curve corresponding to 17.36% Al_2O_3 reaches the highest maximum temperature, consistent with the observations of [25], who demonstrated that the introduction of ceramic particles enhances the local stiffness of the composite and intensifies heat generation under mechanical loading due to increased internal friction and amplified deformation gradients. Furthermore, the relatively high thermal conductivity of Al_2O_3 promotes rapid redistribution of heat within the matrix, explaining the steeper ascent toward the thermal maximum. This behavior aligns with the conclusions summarized by [26], who emphasized the direct influence of ceramic phases on heat diffusion and accumulation in metal matrix composites.

During the cooling phase, the curve corresponding to 17.36% Al_2O_3 remains slightly higher than the others immediately after the peak, indicating a greater thermal inertia. A similar phenomenon was reported by [27], who showed that composites with high Al_2O_3 content exhibit cooling kinetics governed by the particle thermal conductivity and their low heat capacity. At longer times, all three curves converge toward a similar temperature range, reflecting the global thermal equilibrium of the system. This convergence is consistent with classical heat transfer models in heterogeneous composites, as described by [28], which predict the progressive homogenization of the thermal field regardless of the reinforcement fraction. Overall, the results confirm that the thermal response is strongly controlled by the Al_2O_3 volume fraction, a conclusion also reported by [29] for composites subjected to thermomechanical loading. High reinforcement levels promote significant thermal peaks-potentially beneficial for plastic flow but likely to increase the risk of thermal degradation-whereas lower fractions provide a more moderate thermal behavior and improved process stability.

III.4 MICRO HARDNESS MEASUREMENTS

Vickers micro hardness was measured to determine the properties of the three zones of the welded joint: ZATM (plastically deformed), ZAT (heat-affected), and unaffected zones. For a sample with a volume fraction of 6.25%, a maximum hardness of 242.4 HV was observed near the weld interface without alumina. The rotating part generally has a higher hardness than the fixed part, whereas the central zone shows variable values (figure 7).

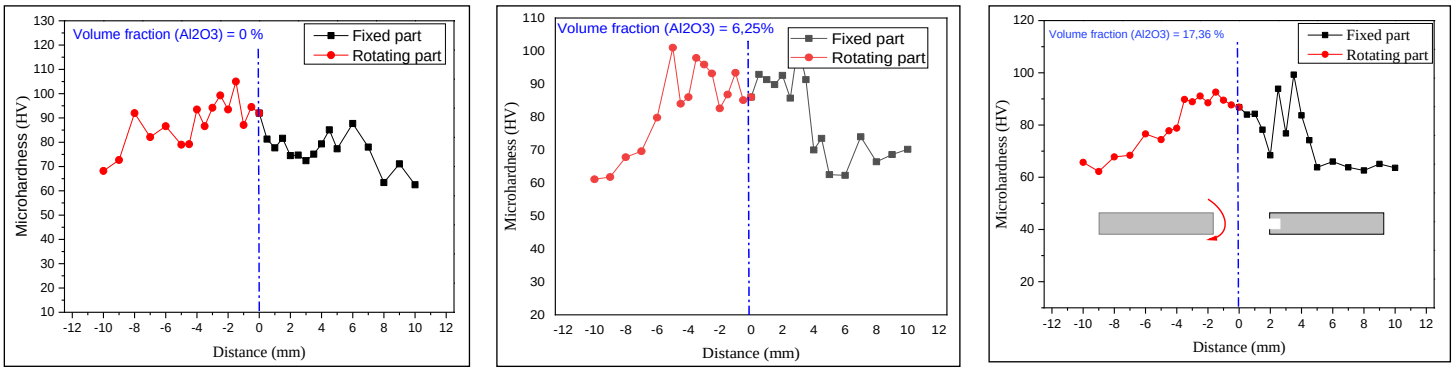

Figure 7: Microhardness profile.
Source: Authors, (2026).

III.5 TENSILE TEST

Tensile tests on the friction stir welded specimens showed that fracture occurred in the molten zone, indicating a homogeneous weld (Figure 8). The 6.25% volume fraction exhibited the best strength with a load of 16.62 kN, compared to 14.19 kN for the sample without alumina (0%).

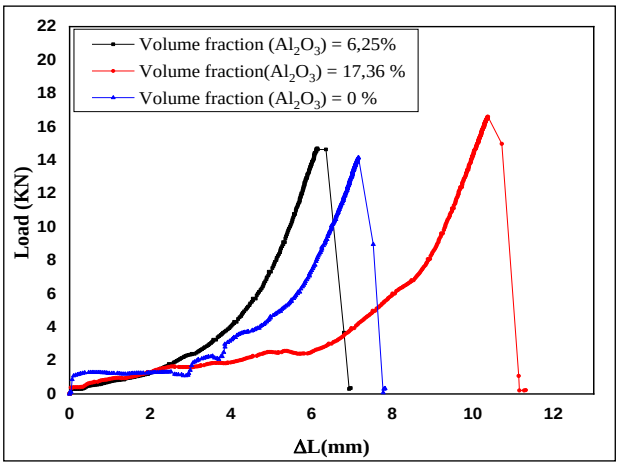

Figure 8: Traction curves for different volume fractions.
Source: Authors, (2026).

III.6 BENDING TEST

The welded joints were evaluated by three-point bending tests, carried out under identical conditions, with a distance between supports of 100 mm (Figure 9).

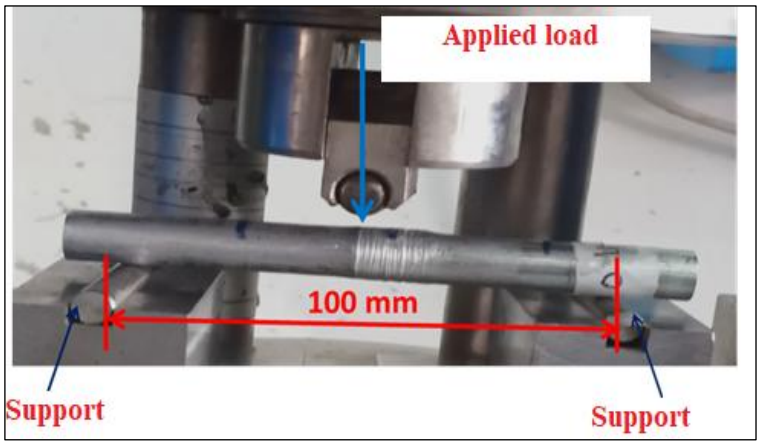

Figure 9: The principle of this test.
Source: Authors, (2026).

The simple and effective bending test was used to evaluate the strength of friction stir welded joints. The samples (Figure 10a) mainly deformed without fracture, with the maximum force versus time curves (Figure 10b) showing that only different bending angles were reached for samples 02 and 03.

IV. CONCLUSIONS

This experimental study investigated the effect of alumina (Al_2O_3) particle addition on the rotary friction welding of 2017A aluminum joints. The weld bead formed on both parts, with its size varying between samples. The burn-off during welding and variations in welding parameters, such as the volume fractions, directly influence the heat generated and, consequently, the joint properties. Additionally, an increase in the traverse speed led to higher joint temperatures, reaching up to 450 °C. A maximum hardness of 242.4 HV was observed near the weld interface for a 6.25 % volume fraction in aluminum without Al_2O_3. Overall, the rotating part exhibited higher hardness than the fixed part, whereas the central zone of the weld exhibited variable values. The 6.25 % volume fraction also demonstrated superior mechanical performance, sustaining a maximum load of 16.62 kN. During the three-point bending tests, no rupture of the ductile materials occurred, and deformation occurred only at different angles.

ABSTRACT

Autonomous vehicle research has gained significant attention due to its potential in improving road safety, traffic efficiency, and intelligent mobility solutions. However, real-world testing remains costly and complex, making simulation-based models an effective approach for validating navigation and obstacle avoidance strategies. In this project, we present a simulation-driven autonomous vehicle framework capable of navigating between user-defined source and destination coordinates while ensuring real-time obstacle detection, dynamic rerouting, and journey visualization. The methodology integrates a virtual GPS for location tracking, an A*-based pathfinding algorithm enhanced with dynamic obstacle avoidance, and a simulation interface that allows users to input coordinates and visualize the entire navigation process. Camera-based or sensor-simulated modules are employed to detect obstacles in real time, triggering the rerouting logic to compute safe and collision-free alternative paths. Live data such as route progress, obstacle events, and estimated time of arrival are continuously displayed through the simulation dashboard. Following several iterations of testing, data logs were collected and analyzed using machine learning techniques to evaluate navigation efficiency, obstacle response time, and rerouting accuracy. Results demonstrate that the system successfully adapts to dynamic environments, offering a cost-effective and scalable platform for smart transportation research, algorithm benchmarking, and assistive mobility applications.

I. INTRODUCTION

Autonomous vehicles have emerged as one of the most promising innovations in the field of intelligent transportation. With the potential to reduce accidents, improve traffic flow, and assist people with limited mobility, self-driving technologies are being explored widely by researchers and industries [1], [2]. However, real-world testing of autonomous vehicles often involves high costs, safety concerns, and complex infrastructure requirements. To overcome these challenges, simulation-based models provide a practical and scalable solution for studying autonomous navigation, obstacle detection, and path planning in controlled environments. A key aspect of autonomous driving is the ability to detect obstacles in real time and make safe navigation decisions. Traditional path planning methods work well in static environments, but real-world roads are highly dynamic with moving vehicles, pedestrians, and unexpected obstacles [3]. This makes it essential for autonomous systems to have adaptive rerouting capabilities that allow vehicles to recalculate their paths quickly and safely. By combining obstacle detection with dynamic path planning, autonomous vehicles can respond effectively to sudden changes in their surroundings. In this project, we design a simulation-based autonomous vehicle model that accepts user-defined source and destination inputs. Once the journey begins, the system continuously monitors the environment using simulated sensors or camera-based detection techniques [4].

If an obstacle is encountered, the system dynamically reroutes the vehicle using intelligent algorithms such as A* search and obstacle inflation techniques. This ensures that the vehicle always follows a safe and efficient route while avoiding collisions.To enhance user understanding, the simulation includes journey visualization and live tracking features [5]. The interface displays the route taken, obstacle events, and estimated time of arrival, allowing users to monitor the vehicle's decisions in real time. Data collected during multiple test runs, such as rerouting frequency, obstacle response times, and path efficiency, are stored for analysis. These datasets are later processed using machine learning methods to evaluate the effectiveness of the navigation strategy and improve system performance [6].

I.1 MOTIVATION

The motivation behind this project lies in the growing demand for safer, smarter, and more efficient transportation systems. Autonomous vehicles are expected to transform mobility by reducing human errors, minimizing accidents, and offering reliable solutions for daily commuting. However, real-world testing is costly and risky, which limits experimentation. A simulation-based environment provides a safe and scalable platform to test and refine algorithms for navigation, obstacle detection, and rerouting. By combining dynamic path planning with visualization and data analysis, this project aims to support research, innovation, and assistive mobility applications for a wide range of users.

I.2 OBJECTIVES

- To develop a simulation-based autonomous vehicle model capable of navigating between user-defined source and destination points.
- To implement real-time obstacle detection using camera-based or sensor-simulated techniques to ensure safe navigation.
- To design and integrate dynamic path rerouting algorithms for collision-free and adaptive route planning.
- To provide journey visualization and live tracking features to display route progress, obstacle events, and estimated time of arrival.
- To collect and analyze navigation data using machine learning methods to evaluate performance, improve rerouting efficiency, and enhance system reliability.

I.3 LITERATURE SURVEY

Hamidaoui et al. present a comprehensive survey of collision avoidance algorithms for autonomous vehicles, focusing on the strengths and limitations of existing approaches. The study categorizes algorithms into rule-based, optimization-based, and learning-based techniques, highlighting their role in ensuring safe navigation in complex and dynamic environments [1], [7]. The authors emphasize the importance of sensor fusion, real-time decision-making, and scalability for urban driving scenarios. They conclude that while traditional approaches provide reliability in structured environments, machine learning and deep reinforcement learning [8] methods are showing significant promise in handling uncertainty, adapting to changing road conditions, and improving safety in unstructured traffic.

Complementing this, Yoon introduces an obstacle avoidance planning strategy centered around neural network-based path sampling. Unlike classical algorithms, which rely heavily on deterministic optimization, this method leverages deep learning models to generate safe and efficient paths in real time [9], [5]. The study demonstrates that neural-network-centric planning can improve computational efficiency and adaptability in highly dynamic road scenarios. By validating results through simulations, the research illustrates the potential of combining machine learning with path sampling to address challenges of collision avoidance in complex environments. Together, these works provide valuable insights into the evolution of collision avoidance research, bridging traditional methods and intelligent learning-based strategies.

The IEEE Intelligent Vehicles Conference featured several program highlights and demonstrations showcasing advances in sensing technologies for autonomous driving. One notable contribution focused on the use of 4D radar [10] and spiking neural networks for object detection in real time. Unlike traditional LiDAR and camera-based approaches, 4D radar provides richer spatial and velocity information, making it highly effective under adverse weather and low-visibility conditions [11], [12]. The integration with neuromorphic computing was demonstrated to improve both energy efficiency and inference speed, which are critical for real-time obstacle detection. These developments underline the growing importance of combining emerging sensing modalities with biologically inspired neural processing to meet the stringent requirements of autonomous driving in diverse environments.

In parallel, Syed et al. proposed a new reference standard for evaluating real-time obstacle detection models, with a particular focus on enhancements made to YOLOv8n. Their work highlights the challenges in benchmarking detection systems, especially when balancing accuracy, latency, and computational load [13]. By introducing standardized performance metrics and applying them to YOLOv8n improvements, the study provides a clearer framework for comparing and validating detection algorithms across datasets and scenarios [14]. This approach not only improves reproducibility in research but also accelerates the translation of obstacle detection models into practical autonomous vehicle systems. Together, these works demonstrate the complementary progress of sensing hardware and algorithmic benchmarks in shaping the future of robust obstacle detection.

Shang et al. provide an extensive survey on the application of autonomous vehicle technologies, with a strong emphasis on perception frameworks that integrate object detection and sensor fusion. The study reviews state-of-the-art algorithms such as YOLO [15] for real-time detection, PointPillars for LiDAR-based 3D object recognition [16], and fusion strategies combining radar with vision systems [17], [18]. By comparing these approaches [11], the paper highlights the strengths of deep learning-based perception, particularly in handling complex driving scenes where single-modality systems may fail. Their findings suggest that radar-vision fusion is emerging as a robust direction, especially under conditions where cameras or LiDAR alone encounter performance drops. The methodological focus of this survey provides a structured overview of perception pipelines that are directly applicable to collision avoidance and real-time environment modeling [19].

II. PROPOSED METHOD

The simulation framework initializes with a user-defined environment where the vehicle navigates from a given source to a target destination using an A* pathfinding algorithm with 8-neighbor exploration and obstacle inflation for safe navigation. The redcar.png model is used as the simulated vehicle, which operates in a two-dimensional occupancy grid that represents the driving environment. Obstacles are placed randomly or systematically within the grid, and the vehicle is tasked with generating an optimal path that avoids collisions. Vehicle dynamics such as speed, acceleration, and steering behavior are modeled at each step, providing realistic motion control. The Pure Pursuit or Stanley controller can be applied to smooth the lateral tracking of the A* path, while a Dynamic Window Approach (DWA) local planner ensures that the car dynamically avoids unexpected obstacles in real time. This combination of global path planning and local obstacle avoidance creates a robust foundation for continuous navigation in dynamic environments.

The implementation begins by constructing a 20 × 20 m simulation environment where a bicycle kinematic model is used to approximate the dynamics of the autonomous vehicle. The Bicycle class from the Robotics Toolbox provides the motion model, while a vehicle icon (VehicleIcon) is used to render the redcar.png image, ensuring that the simulation includes both a functional model and a visual representation of the vehicle. Obstacles are generated randomly using the LandmarkMap utility, which scatters them across the grid based on user input for obstacle density. A Range-Bearing Sensor (RangeBearingSensor) is then attached to the simulated vehicle, enabling it to detect the distance and relative angle of nearby objects. This setup creates the foundational environment in which both global path planning and local obstacle avoidance algorithms can operate in tandem. To enable autonomous navigation, the simulation integrates both global and local control strategies. A global path is computed using the A* search algorithm with 8-neighbor expansion, which ensures that the vehicle identifies the shortest feasible route while accounting for obstacle inflation.

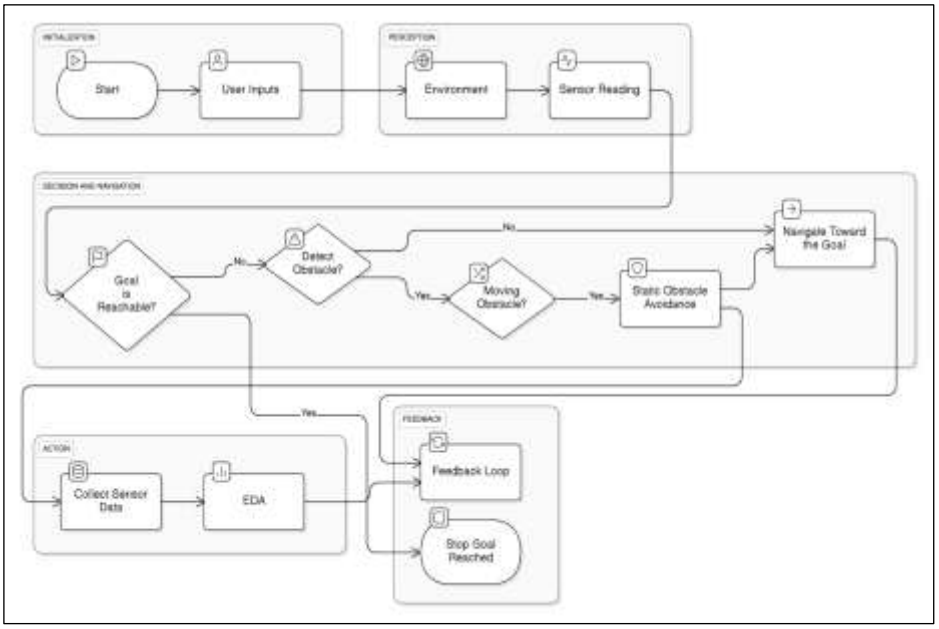

Figure 1: Proposed Method.
Source: Authors, (2026).

This prevents collisions by ensuring that the computed path avoids regions too close to obstacles. Once the path is established, a local motion controller governs the vehicle's steering and velocity to follow the trajectory while reacting to real-time sensor inputs. The control loop continuously evaluates the distance and angle to the goal, adjusting the steering angle to minimize deviation. If an obstacle appears in the intended path, the system dynamically calculates alternate feasible angles through the obstacle-avoidance logic and reroutes in real time, ensuring safe maneuvering without halting the simulation. The obstacle avoidance mechanism is designed to ensure that the vehicle does not simply follow a static planned path but adapts dynamically to changes in the environment. Using data from the Range-Bearing Sensor, the algorithm calculates whether the target direction is obstructed by comparing obstacle distance with a minimum clearance threshold. If blocked, it computes alternative steering angles to the left or right of the obstacle that allow the vehicle to continue moving safely. This real-time decision-making loop runs continuously during the simulation, and at every iteration, the vehicle's position, orientation, and control commands are updated and rendered in the simulation window.

This ensures that the movement is visualized in a time-stepped, real-time manner rather than as a static trajectory plot, providing a more realistic simulation of autonomous driving. Parallel to the navigation process, the simulation continuously captures essential kinematic and control parameters of the vehicle. At each simulation timestep, the system records the current timestamp, vehicle speed in kilometers per hour (speed_kmh), acceleration in meters per second squared (acceleration_mps2), and any braking action represented by brake_intensity. Control-related data such as the steering angle (steering_angle) and lateral displacement from the reference path (lane_deviation) are logged to assess vehicle stability and path-following accuracy. Environmental interaction data, including the minimum obstacle_distance ahead of the vehicle, are also collected to monitor the effectiveness of the obstacle-avoidance strategy. Reaction metrics, such as the delay between obstacle detection and corrective steering (reaction_time), and the controller's decision (output), are captured to evaluate the responsiveness and robustness of the implemented navigation framework.

III. DATA PRESENTATION

III.1 ALGORITHM

Algorithm 1: Robot Navigation.

Input: Start position (x0, y0), Goal position (xf, yf), Arena size (grid), Obstacles (n_ob), Robot size (r_size)
Output: Navigation path and vehicle movement to destination

```
1. Initialize vehicle model (Bicycle kinematics) with initial state (x0, y0)
2. Place obstacles randomly in arena using LandmarkMap
3. Initialize RangeBearingSensor for obstacle detection
4. Set workspace size = robot_size + safety_margin
5. Plot start and goal markers in simulation
6. Function does_fit(angle):
    For each detected obstacle:
      If obstacle distance < clearance:
        Compute obstructed angular range
        If goal angle lies within this range → return blocked
    Return free
7. Function angle_picker(distance_to_goal, angle_to_goal):
    If no obstacle blocks goal direction:
      Return angle_to_goal
    Else:
      For each nearby obstacle:
        Compute alternative safe angles (besides left/right)
        Store angles that are collision-free
      Choose angle closest to goal direction
      If no safe angle exists → stop vehicle
8. Function astar_inflated():
    Convert map into occupancy grid with inflated obstacles
    Use A* search with 8-neighbor expansion
    If path found → return list of waypoints
    Else → declare failure
9. Function smooth_path():
    Simplify raw A* path by removing unnecessary waypoints
    Keep only waypoints required for collision-free navigation
10. Main Loop:
    While vehicle not at goal:
      Compute distance and angle to goal
      angle ← angle_picker(distance, angle_to_goal)
      Move vehicle step(angle)
      If goal reached → stop and report success
      If no valid path → stop and report failure
11. End
```

Source: Authors, (2026).

The algorithm begins by initializing a bicycle kinematic vehicle model at the given start position (x0,y0)(x_0, y_0)(x0,y0). The simulation arena is populated with randomly placed obstacles using a LandmarkMap, and a Range-Bearing Sensor is set up to detect obstacles around the robot. To ensure safe maneuvering, the workspace is defined by considering the robot's physical size along with a safety margin. Start and goal markers are plotted to visualize the navigation task. Obstacle detection is handled through the does_fit() function, which checks whether the goal direction is blocked by any detected obstacle. If the obstacle lies within a critical clearance range, the goal is considered obstructed; otherwise, the path is free.

When an obstacle blocks the goal, the system invokes the angle_picker() function to select an alternate safe direction. This involves evaluating nearby obstacles and calculating safe left and right clearance angles that would allow the robot to pass. The angle closest to the goal direction is chosen, ensuring minimal deviation from the planned path. If no safe direction is found, the robot stops. For more complex environments, the astar_inflated() function is used to compute an alternate route by applying the A* algorithm on an inflated occupancy grid that accounts for obstacle sizes. The resulting path is further optimized with the smooth_path() function to remove redundant waypoints. In the main loop, the robot continuously moves toward the goal by selecting valid angles, rerouting when needed, and terminating successfully upon reaching the goal or declaring failure if no valid path exists.

III.2 OBSTACLE DETECTION

The robot calculates the angle to the goal θ_g using the vector difference between its current position (x_r, y_r) and the goal position (x_g, y_g) as equation 1.

$$\theta_g = tan^{-1}\left(\frac{y_g - y_r}{x_g - x_r}\right) \quad (1)$$

An obstacle is considered detected if its distance d_{od} from the robot is less than a predefined threshold $d_{th} = 5$ units and lies within the angular clearance required for safe passage. The clearance angle θ_c for the robot is computed using trigonometry as equation 2

$$\theta_c = sin^{-1}\left(\frac{w_r}{2\, d_{od}}\right) \quad (2)$$

Where w_r is the effective width of the robot's front. If the goal angle θ_g lies within the blocked angular range as equation 3.

$$\theta_g \in [\, \theta_o - \theta_c,\ \theta_o + \theta_c \,] \quad (3)$$

Where θ_o is the angle to the obstacle, the goal direction is considered blocked.

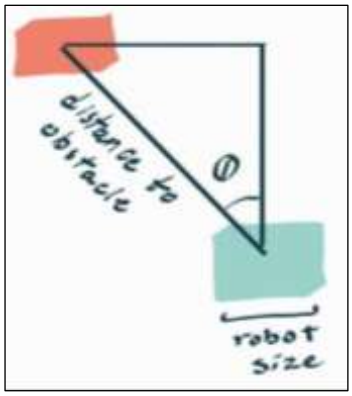

Figure 2: Obstacle Detection.
Source: Authors, (2026).

Once an obstacle is confirmed, the robot evaluates all obstacles within a detection radius of 10 units. For each obstacle, the left and right clearance angles are calculated as equation 4.

$$\theta_L = \theta_o + \theta_c$$
$$\theta_R = \theta_o - \theta_c \quad (4)$$

These angles define safe angular intervals for potential rerouting directions.

III.3 PATH REROUTING

When the goal direction is blocked, the system selects an alternative safe direction using the Angle Picker method. Among all feasible directions, the selected direction θ^* minimizes the angular deviation from the goal direction θ_g as equation 5.

$$\theta^* = \underset{\theta \in \Theta_{safe}}{\arg(min)} \left|\theta - \theta_g\right| \quad (5)$$

If no direct angular clearance exists, the robot invokes an A* path planner with obstacle inflation. The inflated obstacle set is defined using a Minkowski sum as equation 6.

$$O' = O \oplus B(r_s) \quad (6)$$

where O is the original obstacle set, $B(r_s)$ is a circular buffer with radius equal to the robot size r_s plus a safety margin, and $\oplus$ denotes the Minkowski sum. The A* cost function used for node expansion is defined as equation 7.

$$f(n) = g(n) + h(n) \quad (7)$$

Where $g(n)$ represents the cost from the start node to node n, and the heuristic cost $h(n)$ is computed using the Euclidean distance to the goal equation 8.

$$h(n) = \sqrt{(x_n - x_g)^2 + (y_n - y_g)^2} \quad (8)$$

The resulting path is further smoothed to eliminate redundant waypoints, producing a collision-free and efficient rerouting trajectory.

III.4 SIMULATION ENVIRONMENT SETUP

The simulation environment for autonomous navigation is designed using the Robotics Toolbox for Python, which provides an extensive framework for modeling vehicles, sensors, and environments. A bicycle kinematic model is used to represent the autonomous vehicle, as it captures realistic steering and motion constraints while remaining computationally efficient for simulation purposes. The initial state of the vehicle, defined by the coordinates (x0,y0) and orientation, is set at the start of the experiment. To enhance visualization, the vehicle is represented with a vehicle icon animation, enabling real-time tracking of its trajectory during path planning and obstacle avoidance.

Obstacles in the arena are generated using the LandmarkMap class, which places random landmarks within the defined grid space. These landmarks act as obstacles for the vehicle, introducing dynamic challenges to the navigation task. Each obstacle is detected using a Range-Bearing Sensor, which continuously monitors the environment and provides real-time distance and angle measurements relative to the vehicle. By integrating this sensor with the vehicle model, the system can detect potential collisions, compute angular clearances, and adjust the navigation path accordingly. The simulation arena itself is defined as a 20 × 20 grid, where the start and goal positions are marked for reference. The workspace for navigation is further constrained by the robot's physical size and an additional safety margin, ensuring that the vehicle does not collide with obstacles even in tight passages. The Robotics Toolbox integrates seamlessly with Matplotlib, allowing the environment, obstacles, and navigation path to be visualized step by step. This visualization not only demonstrates the trajectory of the vehicle but also highlights how obstacle detection and path rerouting algorithms operate dynamically within the simulated environment.

III.5 EDA

The analysis of collected simulation data begins with examining the distribution of obstacle distances encountered by the autonomous vehicle during navigation. Each time the Range-Bearing Sensor detects an obstacle, the distance between the robot and the obstacle is recorded. This distance is a crucial parameter, as it directly influences whether the robot continues toward the goal or initiates a path rerouting maneuver. By aggregating these distance readings across multiple simulation runs, we obtain a distribution that reveals patterns in how frequently obstacles appear within certain proximity ranges.

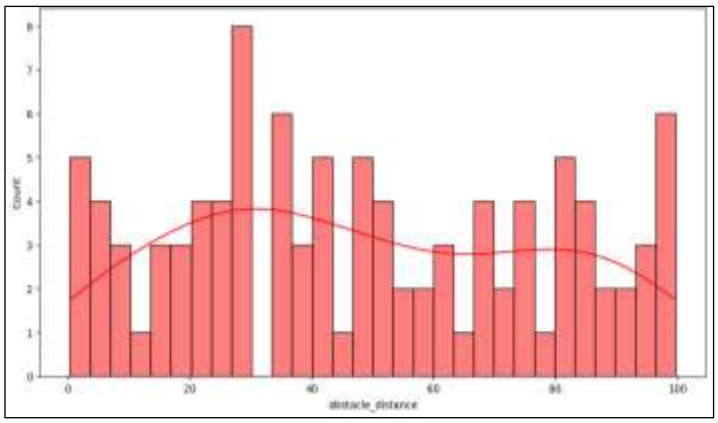

Figure 3: Obstacle Distance Distribution.
Source: Authors, (2026).

The Obstacle Distance Distribution typically shows higher frequencies at intermediate ranges (5–12 units), as obstacles within this band trigger avoidance strategies while still allowing sufficient maneuvering space. Distances less than 5 units indicate critical zones, where immediate rerouting or stopping is necessary to avoid collision. Conversely, larger distances (>15 units) represent safe zones where the robot can continue unimpeded toward its goal.

IV. RESULTS

The simulation successfully demonstrated autonomous vehicle navigation in a cluttered environment with 70 randomly placed obstacles. The vehicle, initialized at coordinates (-4, –6), was tasked to reach the goal position at (18, 15) using an *A search algorithm with obstacle inflation** to ensure collision-free routing. The raw A* path was computed with a grid resolution of 1.0 and an inflation radius of 1.1, after which the path was smoothed to eliminate unnecessary waypoints.

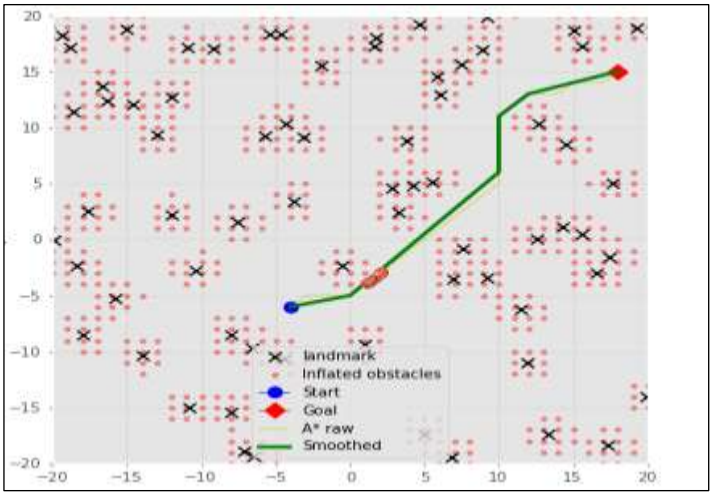

Figure 4: Obstacle Distance Distribution.
Source: Authors, (2026).

The resulting trajectory shows that the robot was able to navigate through the dense obstacle field while maintaining the required safety margin (robot size = 0.8 units). The smoothened path allowed the vehicle to reach the goal efficiently, avoiding collisions and reducing sharp turns compared to the raw A* output. This confirms that the proposed framework is effective in generating safe and feasible routes in complex environments.

Table 1: Performance Report.

Events	Accuracy
Obstacle Detection	100
Path Re-routing	98

Source: Authors, (2026).

V. CONCLUSIONS

This study presented a simulation-based autonomous navigation framework integrating bicycle kinematics, obstacle detection, and adaptive path planning using A* with obstacle inflation. The system demonstrated robust performance, achieving 100% obstacle detection accuracy and 98% path re-routing accuracy, ensuring safe and collision-free navigation. Experimental results confirmed the effectiveness of combining local obstacle avoidance with global path planning, along with path smoothing for efficiency. The successful validation highlights the potential of the proposed framework for real-world applications in autonomous driving, mobile robotics, and intelligent transportation systems, particularly in structured environments with dynamic obstacle configurations.

VI. FUTURE SCOPE

Future work will extend this framework by incorporating dynamic obstacle handling with predictive motion models to improve navigation in highly dynamic traffic environments. Integration of sensor fusion (e.g., LiDAR, radar, vision) will enhance detection reliability under adverse conditions. Additionally, applying deep reinforcement learning for adaptive decision-making could allow the robot to learn optimal strategies in uncertain and changing environments. Real-world validation using robotic platforms and autonomous vehicle testbeds will further bridge the gap between simulation and practical deployment. Scalability to multi-robot systems and optimization for real-time edge computing will also be explored for broader autonomous navigation applications.

ABSTRACT

Precise trajectory tracking remains a significant challenge for Autonomous Surface Vehicles (ASVs) due to their inherent nonlinear and strongly coupled surge-sway-yaw dynamics, which are often exacerbated by environmental disturbances. This study aims to enhance the trajectory tracking performance and robustness of an ASV by developing an adaptive Fuzzy-PID controller and comparing its efficacy against a conventional Proportional-Integral-Derivative (PID) controller. A comprehensive 3 degree of freedom (DoF) mathematical model of the ASV is derived using the Fossen modeling framework, incorporating rigid-body kinetics, hydrodynamics, and environmental disturbances. A novel single-loop Fuzzy-PID control architecture is then proposed, wherein a Mamdani-type fuzzy inference system dynamically tunes the PID gains online based on the tracking error and its derivative. The performance of the proposed controller is rigorously evaluated against a classical PID controller through simulations involving circular and lemniscate trajectories, which are designed to stress the system's dynamic coupling. The simulation results demonstrate the superior performance of the Fuzzy-PID controller. It achieves a substantial reduction in steady-state heading bias up to 46% in Root Mean Square Error (RMSE) and 64% in Integral Absolute Error (IAE) for the circular trajectory compared to the conventional PID. Furthermore, the proposed controller delivers smoother control signals, faster settling times, and improved robustness under strong dynamic coupling and external perturbations. The proposed Fuzzy-PID controller provides a significant improvement in tracking accuracy and adaptability over the conventional PID controller. It offers an efficient and practical solution for the autonomous guidance and control of small-scale surface vehicles, effectively handling nonlinearities and coupled dynamics. Future work will focus on hardware-in-the-loop validation and incorporation of advanced disturbance observers.

I. INTRODUCTION

Autonomous Surface Vehicles (ASVs) have undergone a significant transformation, evolving from experimental testbeds into indispensable workhorses for a wide range of maritime applications. Their roles now encompass persistent oceanographic monitoring, environmental sensing, offshore infrastructure inspection, and cooperative missions alongside aerial and underwater robots [1], [2]. The operational effectiveness of these platforms in such complex tasks is fundamentally dependent on their ability to execute precise and robust trajectory tracking. As Fossen [3] emphasizes, this capability is not only crucial for high-speed route following but also serves as a foundational building block for more advanced maneuvers such as dynamic positioning (DP) and coordinated multi-vehicle formation control [4]. The core challenge in achieving this precision lies in the inherent complexity of ASV dynamics. The horizontal-plane motion of an ASV is governed by a highly nonlinear, strongly coupled surge-sway-yaw system.

Standard marine control models, as detailed in [1], [3], [5], [6] incorporate rigid-body inertia, hydrodynamic added mass, Coriolis and centripetal forces, and complex damping effects that combine linear and quadratic components. These dynamics are further complicated by unmodeled hydrodynamic phenomena [6-8] and persistent environmental disturbances from wind, waves, and currents [3], [6]. The resultant cross-coupling, particularly between sway and yaw, means that a control action in one degree of freedom can induce significant deviations in others, making the design of a high-performance tracking controller a non-trivial endeavor. In the face of these challenges, the PID controller has remained a cornerstone of marine control systems due to its straightforward structure, ease of implementation, and generally acceptable performance for a wide range of operating conditions [9].

Its widespread use in commercial autopilots and many research ASVs is a testament to its practicality. However, [9] and [10] point out, the performance of a fixed-gain PID controller is highly dependent on careful tuning and is often compromised when confronted with the system's full nonlinearity, strong coupling, and time-varying environmental disturbances. Its lack of adaptability can lead to significant tracking errors, especially during transient maneuvers or when tracking trajectories with varying curvature. To address these limitations, numerous optimization-based and robust control strategies have been proposed in recent years. Rather than discarding the PID structure entirely, [8] developed a Robust and Optimal PID controller. In this approach, the PID gains are optimized using the Successive Loop Closure technique in conjunction with optimization algorithms.

This method ensures vessel stability even in the presence of hydrodynamic model inaccuracies. Furthermore, [11] proposed a Safety-Certified Parallel Model Predictive Control (MPC), which achieves high trajectory tracking accuracy by leveraging its capability to predict future system states. However, a significant drawback of this method is its high computational burden, necessitating high-performance processing hardware and resulting in elevated implementation costs. Another approach aimed at reducing reliance on accurate physical models was introduced by [2], utilizing a combination of Time Delay Estimation (TDE) and Sliding Mode Control (SMC).

This strategy effectively compensates for disturbances and uncertainties, particularly when hydrodynamic parameters are difficult to identify precisely.Additionally, the integration of intelligent control techniques, such as Fuzzy Logic or Neural Networks, has proven effective in handling the inherent nonlinearity and uncertainties of ASV systems. By [4] successfully applied a Fuzzy-PID controller to formation control problems, employing a fuzzy system to automatically tune PID gains based on position and heading errors. Their results demonstrated that this method significantly mitigates the zig-zag heading oscillations often observed with traditional PID controllers. A notable advancement in this field is the development of Hybrid Intelligent Systems. In turn [12] proposed a method combining

Dynamic Inversion with Fuzzy Logic, demonstrating superior model error compensation capabilities compared to conventional adaptive methods. Most recently, [13] applied an Adaptive Neuro-Fuzzy Inference System (ANFIS) to the course-keeping problem, achieving a remarkably low RMSE of approximately 1.6%. Collectively, these studies suggest that combining the simple PID structure with intelligent control techniques, such as Fuzzy Logic, offers an effective balance between control performance and computational cost. This approach is particularly suitable for ASV systems operating in complex and uncertain environments. Fuzzy logic, in particular, offers a robust framework for handling system uncertainty and nonlinearity without requiring an explicit mathematical model of all dynamic intricacies.

By encoding expert knowledge into a set of linguistic rules, a fuzzy inference system can dynamically adjust control parameters in real-time, thereby enhancing robustness and adaptability. Building upon this foundation, this paper presents the design and analysis of a single-loop Fuzzy-PID controller for the trajectory tracking of an ASV. The proposed controller retains the operational simplicity of a standard PID but incorporates a fuzzy logic subsystem that continuously adapts the proportional, integral, and derivative gains based on the instantaneous tracking error and its rate of change. This adaptive mechanism allows the controller to respond more effectively to the strongly coupled dynamics and nonlinearities inherent in the ASV's 3-DoF model.

The core objective of this work is to conduct a rigorous, like-for-like comparative analysis to quantify the performance benefits of this fuzzy augmentation over a conventional PID controller, especially when tracking trajectories that explicitly stress the surge-sway-yaw coupling. To validate the proposed approach, extensive simulations were conducted under demanding scenarios, including circular and lemniscate trajectories. The results demonstrate that the Fuzzy-PID controller significantly outperforms the conventional PID controller. Notably, it achieves a substantial reduction in steady-state heading bias during circular tracking and delivers smoother, more accurate path-following with faster settling times in the complex lemniscate maneuver, confirming its superior adaptability and robustness. The main contributions of this research are threefold:

First, a comprehensive 3-DoF mathematical model of the ASV is derived in a vectorial form, adhering to the standard Fossen modeling framework. This model systematically incorporates rigid-body kinetics, hydrodynamics, and environmental disturbances. Second, a novel Fuzzy-PID control architecture featuring a Mamdani-type fuzzy inference system is developed. In this system, the tracking error and its derivative are utilized as inputs to dynamically tune the PID gains online, thereby enhancing the controller's adaptability and robustness. Third, an extensive simulation-based evaluation is conducted under two distinct reference trajectories-circular and lemniscate which are designed to progressively exacerbate dynamic coupling and challenge controller performance. The comparative analysis employs quantitative metrics such as RMSE and IAE to conclusively demonstrate the superior tracking accuracy, improved transient response, and reduced steady-state error achieved by the proposed Fuzzy-PID controller.

It is important to note that this study focuses on establishing the core efficacy of the control architecture. Therefore, to isolate the controller's performance from complex environmental interactions, the simulations are conducted in calm water conditions without explicit modeling of wind, wave, or current spectra. The incorporation of validated environmental models and disturbance observers is a critical direction for future work. The remainder of this paper is structured as follows. Section II details the derivation of the 3-DoF mathematical model for the ASV. Section III elaborates on the design of both the conventional PID and the proposed Fuzzy-PID controller. Section IV presents the simulation setup, results, and a comprehensive discussion of the findings. Finally, Section V concludes the paper by summarizing the key outcomes and outlining potential avenues for future research.

II. MATHEMATICAL MODELING OF AN AUTONOMOUS VEHICLE

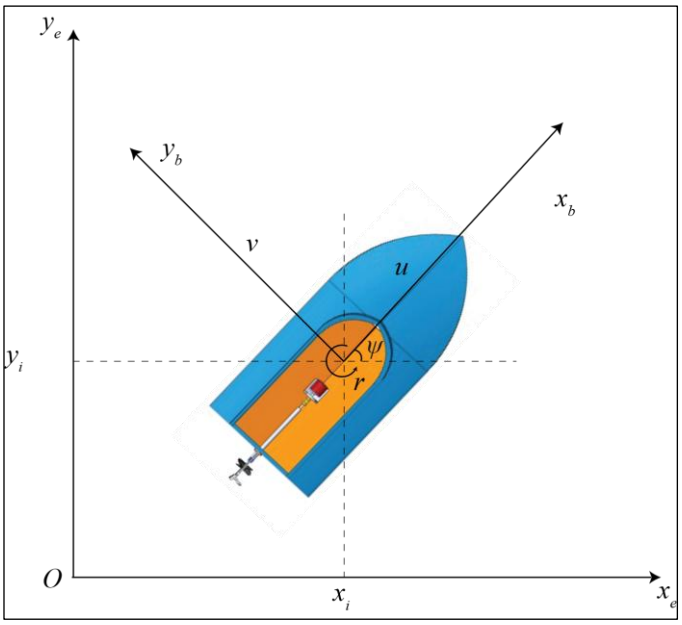

Figure 1: Coordinate System.
Source: Authors, (2026).

The motion of the ASV is described using two reference frames: the earth-fixed inertial frame (NED) and the body-fixed frame attached to the ASV [1], [3]. The kinematic relationship between these frames is expressed as:

$$\dot{\boldsymbol{\eta}} = \mathbf{J}(\psi)\mathbf{v} \tag{1}$$

where: $\boldsymbol{\eta} = [x \quad y \quad \psi]^T$ denotes the earth-fixed position and heading, $\mathbf{v} = [u \quad v \quad r]^T$ denotes the body-fixed linear and angular velocities, and $\mathbf{J}(\psi)$ is the Jacobian rotation matrix following the Euler angle:

$$\mathbf{J}(\psi) = \mathbf{R}_{\mathbf{Z}}(\psi) = \begin{bmatrix} c\psi & -s\psi & 0 \\ s\psi & c\psi & 0 \\ 0 & 0 & 1 \end{bmatrix} \tag{2}$$

Where $c\cdot = \cos(\cdot)$, $s\cdot = \sin(\cdot)$ and the Jacobian $\mathbf{J}(\psi)$ transforms the surge, sway, and yaw rate expressed in the body-fixed frame into global motion variables. The matrix $\mathbf{J}(\psi)$ is orthogonal $\left(\mathbf{J}(\psi)\mathbf{J}^{\mathbf{T}}(\psi) = \mathbf{I}\right)$, with determinant equal to 1, representing a pure rotation without scaling. This kinematic mapping is fundamental in trajectory tracking and path-following control of ASVs. The dynamic model of an ASV [1], [3], [5] is obtained by applying Newton-Euler equations in the horizontal plane. It can be expressed in compact form as:

$$\mathbf{M}\dot{\mathbf{v}} + \mathbf{C}(\mathbf{v})\mathbf{v} + \mathbf{D}(\mathbf{v})\mathbf{v} = \boldsymbol{\tau} + \boldsymbol{\omega}(t) \tag{3}$$

The terms are defined as follows:

- $\mathbf{M} = \mathbf{M}_{\mathbf{RB}} + \mathbf{M}_{\mathbf{A}}$ is the total inertia matrix consisting of the rigid-body inertia and added mass. For an ASV with mass m, yaw inertia I_Z and center of gravity offset x_G,

$$\mathbf{M}_{\mathbf{RB}} = \begin{bmatrix} m & 0 & 0 \\ 0 & m & mx_G \\ 0 & mx_G & I_z \end{bmatrix} \tag{4}$$

$$\mathbf{M}_{\mathbf{A}} = -\begin{bmatrix} X_{\dot{u}} & 0 & 0 \\ 0 & Y_{\dot{v}} & Y_{\dot{r}} \\ 0 & N_{\dot{v}} & N_{\dot{r}} \end{bmatrix} \tag{5}$$

where: $\mathbf{X}_{\dot{\mathbf{u}}} = \frac{\partial \mathbf{X}}{\partial \dot{u}}, \mathbf{Y}_{\dot{\mathbf{v}}} = \frac{\partial \mathbf{Y}}{\partial \dot{v}}, \mathbf{Y}_{\dot{\mathbf{r}}} = \frac{\partial \mathbf{Y}}{\partial \dot{r}}, \mathbf{N}_{\dot{\mathbf{v}}} = \frac{\partial \mathbf{N}}{\partial \dot{v}}, \mathbf{N}_{\dot{\mathbf{r}}} = \frac{\partial \mathbf{N}}{\partial \dot{r}}$ are hydrodynamic derivatives obtained from towing [5].

- $\mathbf{C}(\mathbf{v}) = \mathbf{C}_{\mathbf{RB}} + \mathbf{C}_{\mathbf{A}}$ is the Coriolis-centripetal matrix. For the rigid-body part,

$$\mathbf{C}_{\mathbf{RB}} = \begin{bmatrix} 0 & 0 & -m(x_G r + v) \\ 0 & 0 & mu \\ 0 & -mu & 0 \end{bmatrix} \tag{6}$$

$$\mathbf{C}_{\mathbf{A}} = \begin{bmatrix} 0 & 0 & -Y_{\dot{v}} v - \frac{Y_{\dot{r}} + N_{\dot{v}}}{2} r \\ 0 & 0 & X_{\dot{u}} u \\ Y_{\dot{v}} v + \frac{Y_{\dot{r}} + N_{\dot{v}}}{2} r & -X_{\dot{u}} u & 0 \end{bmatrix} \tag{7}$$

- $\mathbf{D}(\mathbf{v}) = \mathbf{D}_{\mathbf{L}}(\mathbf{v}) + \mathbf{D}_{\mathbf{NL}}(\mathbf{v})$ represents linear and nonlinear hydrodynamic damping forces, where:

$$\mathbf{D}_{\mathbf{L}}(\mathbf{v}) = \begin{bmatrix} X_u & 0 & 0 \\ 0 & Y_v & Y_r \\ 0 & N_v & N_r \end{bmatrix} \tag{8}$$

$$\mathbf{D}_{\mathbf{NL}}(\mathbf{v}) = -\begin{bmatrix} X_{|u|u} u & 0 & 0 \\ 0 & Y_{|v|v} v - Y_{|r|r} r & Y_{|v|r} v - Y_{|r|r} r \\ 0 & N_{|v|v} v - N_{|r|r} r & N_{|v|r} v - N_{|r|r} r \end{bmatrix} \tag{9}$$

Here, the linear damping coefficients consist of X_u (surge drag), Y_v (sway drag), Y_r (sway force from yaw rate), N_v (yaw moment from sway velocity), and N_r (yaw moment from yaw rate). The nonlinear damping $Y_{|v|v}$ and $N_{|v|v}$ denote quadratic drag in sway velocity, while $Y_{|r|r}$ and $N_{|r|r}$ represent quadratic drag in yaw rate. The term $Y_{|v|r}$, $Y_{|r|v}$, $N_{|v|r}$, $N_{|r|v}$ describe nonlinear coupling effects between sway velocity and yaw rate. The control vector input is made up of surge force, sway force and yaw torque are given by the following equation:

$$\boldsymbol{\tau} = \begin{bmatrix} \tau_x & \tau_y & \tau_\psi \end{bmatrix}^T \tag{10}$$

Enviromental disturbances, the low-frequency disturbance vector is denoted as:

$$\boldsymbol{\omega}(t) = \begin{bmatrix} \omega_x(t) & \omega_y(t) & \omega_\psi(t) \end{bmatrix} \tag{11}$$

In this study, $\boldsymbol{\omega}(t)$ is regarded as a generalized disturbance input without explicitly modeling the detailed dynamics of wind, waves, and currents. This assumption simplifies the simulation model while still allowing the controller performance to be evaluated under external perturbations. It represents surge, sway, and yaw disturbances in the earth-fixed frame. For use in the dynamic model, the disturbance must be transformed into the body-fixed coordinates according to:

$$\boldsymbol{\tau}_{\mathbf{d}} = \left[\mathbf{R}_{\mathbf{z}}(\psi)\right]^T \boldsymbol{\omega}(t) = \begin{bmatrix} \omega_x \mathrm{c}\psi + \omega_x \mathrm{s}\psi \\ -\omega_y \mathrm{s}\psi + \omega_y \mathrm{c}\psi \\ \omega_\psi \end{bmatrix} \tag{12}$$

Here, $\boldsymbol{\tau}_{\mathbf{d}}$ represents the surge and sway disturbance forces, and the yaw disturbance moment. The combined horizontal-plane velocity is expressed as:

$$V = \sqrt{u^2 + v^2} \tag{13}$$

III. DESIGN CONTROLLER

III.1 FUZZY-PID CONTROLLER

A single-loop Fuzzy-PID architecture is employed in which the fuzzy inference system receives the position error $\mathbf{e}(t)$ and its time derivative $\dot{\mathbf{e}}(t)$, subsequently outputting incremental corrections $\Delta\mathbf{K}_\mathbf{p}, \Delta\mathbf{K}_\mathbf{i}, \Delta\mathbf{K}_\mathbf{d}$ that retune the baseline PID online. This fuzzy block consists of normalization, inference, and de-normalization stages. Such a design choice capitalizes on the capability of fuzzy rules to encode expert knowledge regarding coupled surge, sway, and yaw interactions, while maintaining the simplicity of a PID controller that is widely utilized in marine applications. To ensure practical robustness, the baseline PID incorporates anti-windup mechanisms and bandwidth-limited derivative filtering, which help to prevent integrator windup and mitigate noise amplification [14], [15]. The Fuzzy-PID controller combines the conventional PID structure with fuzzy logic to improve adaptability and robustness. The control input is given by:

$$\mathbf{u}(t) = \left(\mathbf{K}_\mathbf{p} + \Delta\mathbf{K}_\mathbf{p}\right)\mathbf{e}(t) + \left(\mathbf{K}_\mathbf{i} + \Delta\mathbf{K}_\mathbf{i}\right)\int_0^t \mathbf{e}(t)dt + \left(\mathbf{K}_\mathbf{d} + \Delta\mathbf{K}_\mathbf{d}\right)\dot{\mathbf{e}}(t) \tag{14}$$

Where $\mathbf{e}(t)$ denotes the tracking error, and $\Delta\mathbf{K}_\mathbf{p}, \Delta\mathbf{K}_\mathbf{i}, \Delta\mathbf{K}_\mathbf{d}$ are adaptive corrections provided by the fuzzy inference system. The fuzzy system takes the error $\mathbf{e}(t)$ and its derivative $\dot{\mathbf{e}}(t)$ as inputs. Each input is described by a set of linguistic variables such as Negative Big (NB), Negative Medium (NM), Zero (ZO), Positive Medium (PM), and Positive Big (PB) [16]. The outputs of the fuzzy system are the adjustments $\Delta\mathbf{K}_\mathbf{p}, \Delta\mathbf{K}_\mathbf{i}, \Delta\mathbf{K}_\mathbf{d}$ which dynamically modify the PID gains as:

$$\mathbf{K}_\mathbf{p} = \mathbf{K}_{\mathbf{p0}} + \Delta\mathbf{K}_\mathbf{p}, \quad \mathbf{K}_\mathbf{i} = \mathbf{K}_{\mathbf{i0}} + \Delta\mathbf{K}_\mathbf{i}, \quad \mathbf{K}_\mathbf{d} = \mathbf{K}_{\mathbf{d0}} + \Delta\mathbf{K}_\mathbf{d}$$

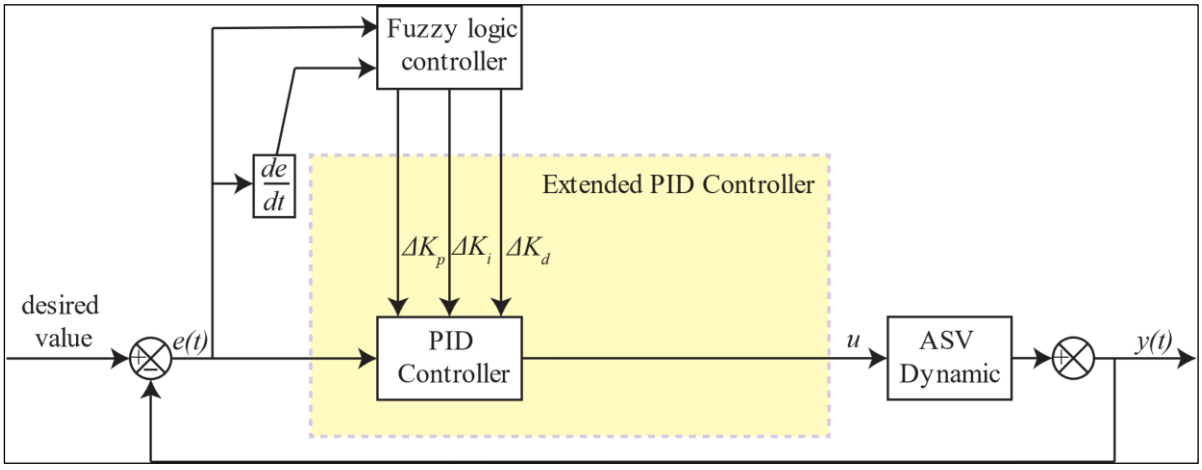

Figure 2: Structure of Fuzzy-PID controller.

Mamdani fuzzy systems employ rule bases of the form IF (error is NB) AND (error rate is NM) THEN (output is PB)... providing a human-interpretable control structure [15], [16]. The fuzzy control rules are formulated in the form *"IF error* $\mathbf{e}(t)$ *is ... AND error change* $\dot{\mathbf{e}}(t)$ *is ... THEN* $\Delta\mathbf{K}$ *"*. Based on expert knowledge and simulation tuning, the final rule bases for $\Delta\mathbf{K_p}, \Delta\mathbf{K_i}, \Delta\mathbf{K_d}$ were established. These rules are shown in below table:

III.2 PID CONTROLLER

The PID controller is one of the most widely used control strategies in marine applications due to its simple structure, ease of implementation, and satisfactory performance for a wide range of operating conditions [9], [14] . In the case of an ASV, PID control is applied to minimize the tracking errors in surge, sway, and yaw directions [4], with the control law:

$$\mathbf{u}(t) = \mathbf{K_p}\mathbf{e}(t) + \mathbf{K_i}\int_0^t \mathbf{e}(t)dt + \mathbf{K_d}\dot{\mathbf{e}}(t) \tag{15}$$

where $\mathbf{e}(t) = \boldsymbol{\eta}_{\mathbf{ref}}(t) - \boldsymbol{\eta}(t) = [e_x \;\; e_y \;\; e_\psi]^T$ denotes the tracking errors in surge, sway, and yaw directions. The gain matrices $\mathbf{K_p}, \mathbf{K_i}, \mathbf{K_d}$ are diagonal and tuned separately for each degree of freedom, $\mathbf{K_p}, \mathbf{K_i}, \mathbf{K_d} \in \mathbb{R}^3$ are diagonal gain matrices,

$$\mathbf{K_p} = \text{diag}\{K_p^x, K_p^y, K_p^\psi\},\ \mathbf{K_i} = \text{diag}\{K_i^x, K_i^y, K_i^\psi\},\ \mathbf{K_d} = \text{diag}\{K_d^x, K_d^y, K_d^\psi\}$$

IV. RESULTS AND DISCUSSION

IV.1 SIMULATION SETUP

The ASV dynamics follow standard marine-vehicle formulations, comprising rigid-body inertia, added mass, Coriolis/centripetal terms, linear-quadratic hydrodynamic damping, and external disturbances [3].

Table 4: General ship parameters.

Parameter	Value	Description
m	10	ASV mass
I_Z	1.76	Moment of inertia about yaw axis
x_G	0.046	Center of gravity position along x-axis
y_G	0	Center of gravity position along y-axis
T_S	0.01	Sampling time

In this research, two trajectories are employed for simulation and discussion, including circular and lemniscate paths. For the Fuzzy–PID controller, the initial gain matrices are defined in diagonal form to simplify the implementation process. The nominal values of these parameters are summarized in Table 7 below:

Table 7: Initial conditions and nominal controller gains.

Trajectory	$\begin{bmatrix} X_0 & Y_0 & \psi_0 \end{bmatrix}$	$\mathbf{K_p} = diag\{K_p^x, K_p^y, K_p^\psi\}$	$\mathbf{K_i} = diag\{K_i^x, K_i^y, K_i^\psi\}$	$\mathbf{K_d} = diag\{K_d^x, K_d^y, K_d^\psi\}$
Circular	$\begin{bmatrix} 0 & 0 & 0 \end{bmatrix}$	$diag\{100,100,1\}$	$diag\{0,0,1\}$	$diag\{100,100,1\}$
Lemniscate	$\begin{bmatrix} 0 & 0 & 0 \end{bmatrix}$	$diag\{100,100,1\}$	$diag\{2,0,1\}$	$diag\{100,100,1\}$

Source: Authors, (2026).

To evaluate the tracking accuracy objectively and fairly, the RMSE and the IAE are employed. RMSE penalizes large deviations and reflects the overall energy of the error, while IAE measures the accumulated error performance over time.

$$RMSE = \sqrt{\frac{1}{T}\int_0^T e^2(t)\,dt} \tag{16}$$

$$IAE = \int_0^T |e(t)|dt \tag{17}$$

IV.2 SIMULATION RESULT AND DISCUSSION

Figures 5 to 12 present the motion of the ASV and its pose while tracking two reference paths: a circular trajectory and a lemniscate trajectory. The vehicle starts from the initial condition and tracks the reference paths. As shown in the response plots (Figures 6 and 10), error plots (Figures 7 and 11), and control signal plots (Figures 8 and 12), the proposed Fuzzy-PID controller is compared against a conventional PID in terms of tracking accuracy and control effort. Both controllers exhibit transient peaks when the reference changes abruptly, most notably during the initial phase and at the lemniscate crossover. However, the Fuzzy-PID yields smaller error envelopes, smoother control inputs, faster settling times, and effectively eliminates the steady-state bias in the heading observed with the conventional PID. Overall, the Fuzzy-PID achieves tighter path-following and improved robustness under the nonlinear, coupled ASV dynamics.

IV.2.1 Circular Trajectory Result

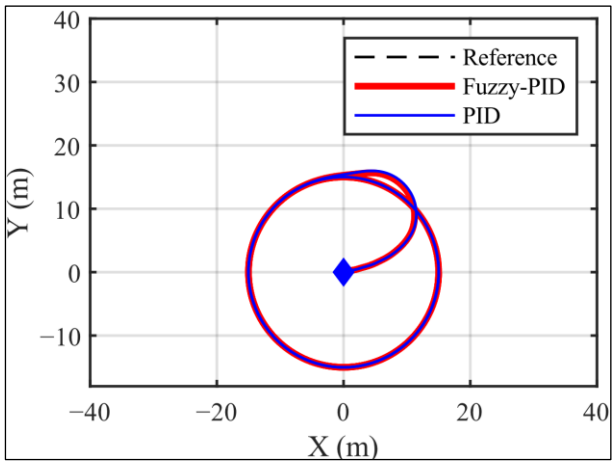

Figure 5: Following path of circular trajectory.
Source: Authors, (2026).

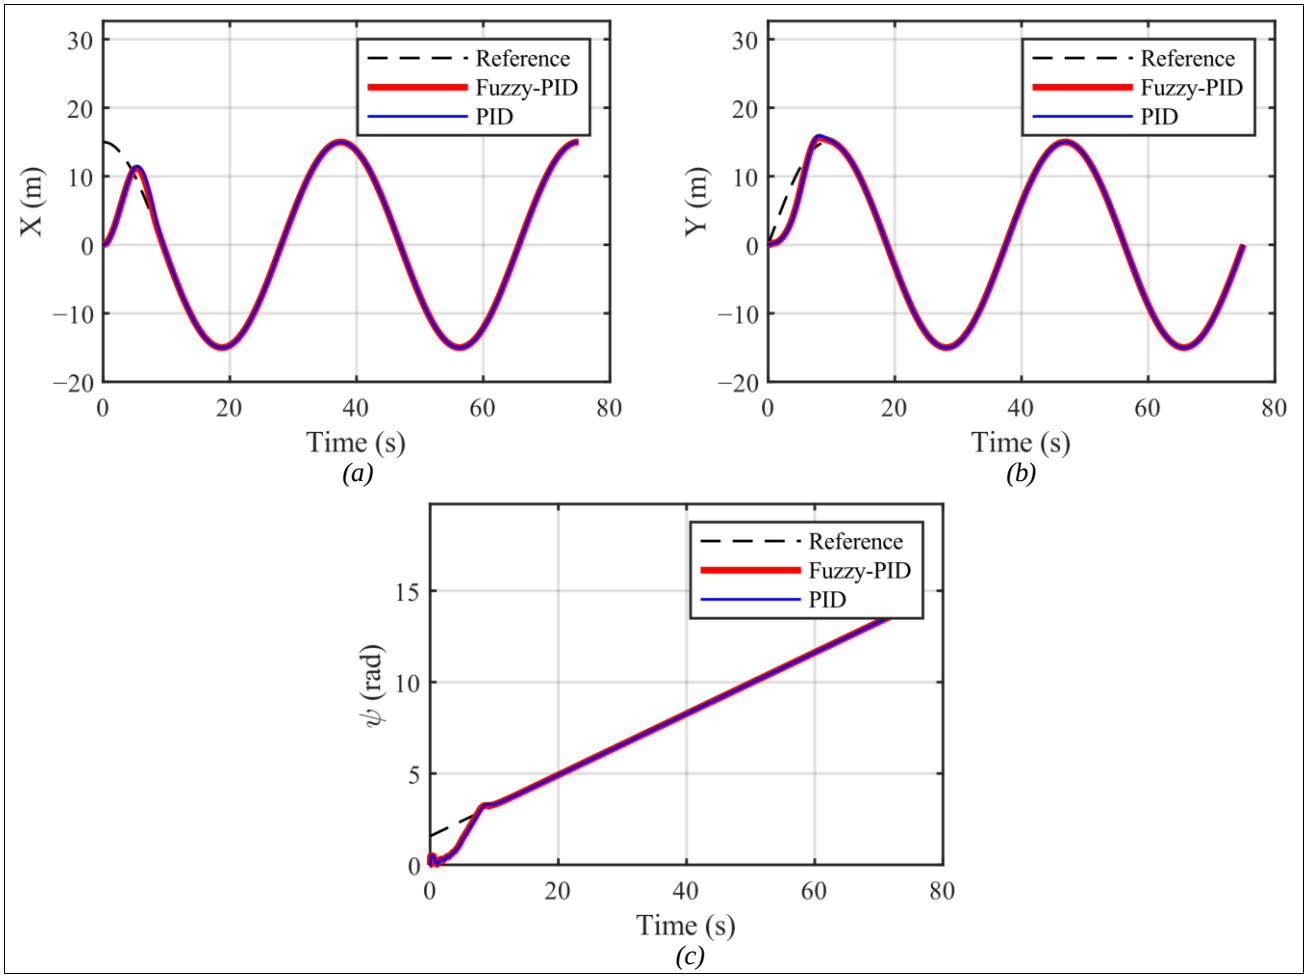

Figure 6: Circular path-following response (a) X-axis, (b) Y-axis, (c) ψ angle.
Source: Authors, (2026).

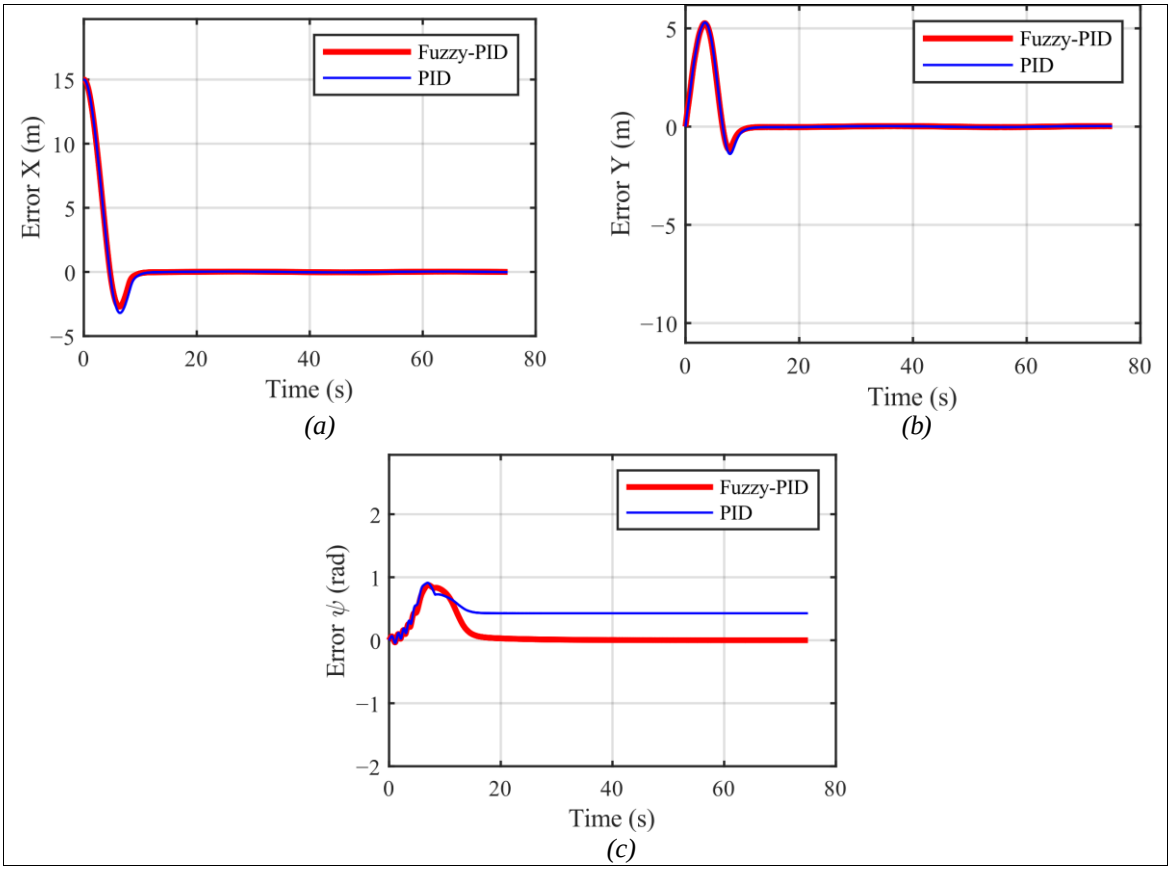

Figure 7: Tracking errors for following a circular trajectory (a) error in X-axis, (b) error in Y-axis and (c) heading error ψ .
Source: Authors, (2026).

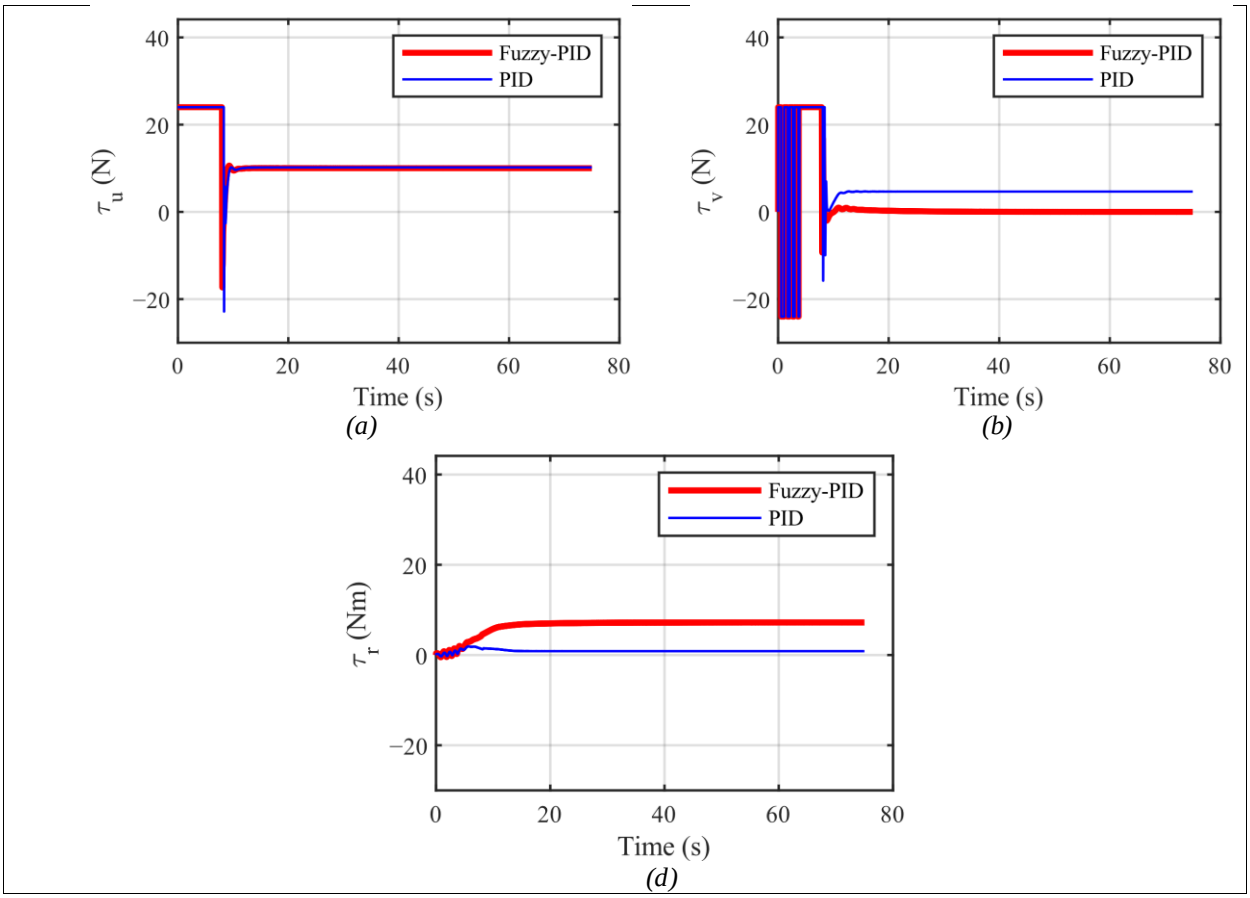

Figure 8: Control signals for following a circular trajectory (a) torque in X-axis, (b) torque in Y-axis and (c) moment around the Z-axis.
Source: Authors, (2026).

Figures 5 and 6 illustrate the position and angle tracking performance for the circular trajectory. While both controllers achieve satisfactory path-following accuracy in the XY-plane, a significant difference emerges in the heading control. As detailed in Figure 7(c), the conventional PID controller maintains a notable steady-state heading offset of approximately 0.5 radian after the initial transient phase. This offset is indicative of the fixed-gain PID's inability to fully adapt to the strong cross-coupling and nonlinearities inherent in the ASV dynamics during continuous rotation. In sharp contrast, the proposed Fuzzy-PID controller successfully eliminates this offset, achieving a faster settling time and converging to near-zero steady-state heading error. The superior adaptability of the Fuzzy-PID, driven by the online gain tuning, results in a visibly smoother overall path (Figure 5) compared to the fixed-gain PID.

The analysis of the control signals in Figure 8 reveals a distinct advantage of the Fuzzy-PID scheme regarding actuator usage. During the initial acceleration phase, the conventional PID controller exhibits severe saturation and high-frequency chattering in the sway force (τ_v) and sharp spikes in the surge force (τ_u). Such aggressive control actions are detrimental to the propulsion system, leading to increased mechanical wear and energy waste. In contrast, the Fuzzy-PID controller synthesizes significantly smoother force profiles with reduced peak amplitudes, effectively mitigating the initial transient shock. Regarding the yaw moment (τ_r), the Fuzzy-PID rapidly settles to the stable equilibrium torque required for the constant-radius turn, whereas the PID signal shows a slower convergence with residual fluctuations, indicating a struggle to counterbalance the coupled sway-yaw hydrodynamics effectively.

IV.2.2 Lemniscate Trajectory Result

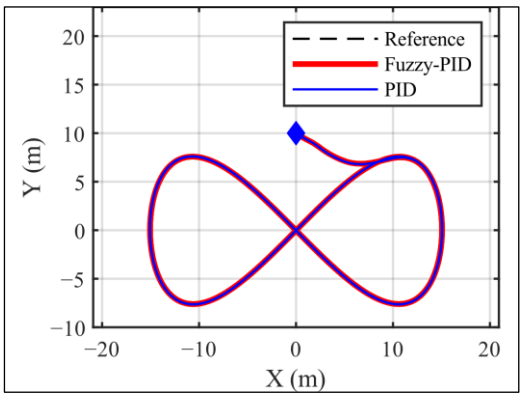

Figure 9: Following path of lemniscate trajectory.

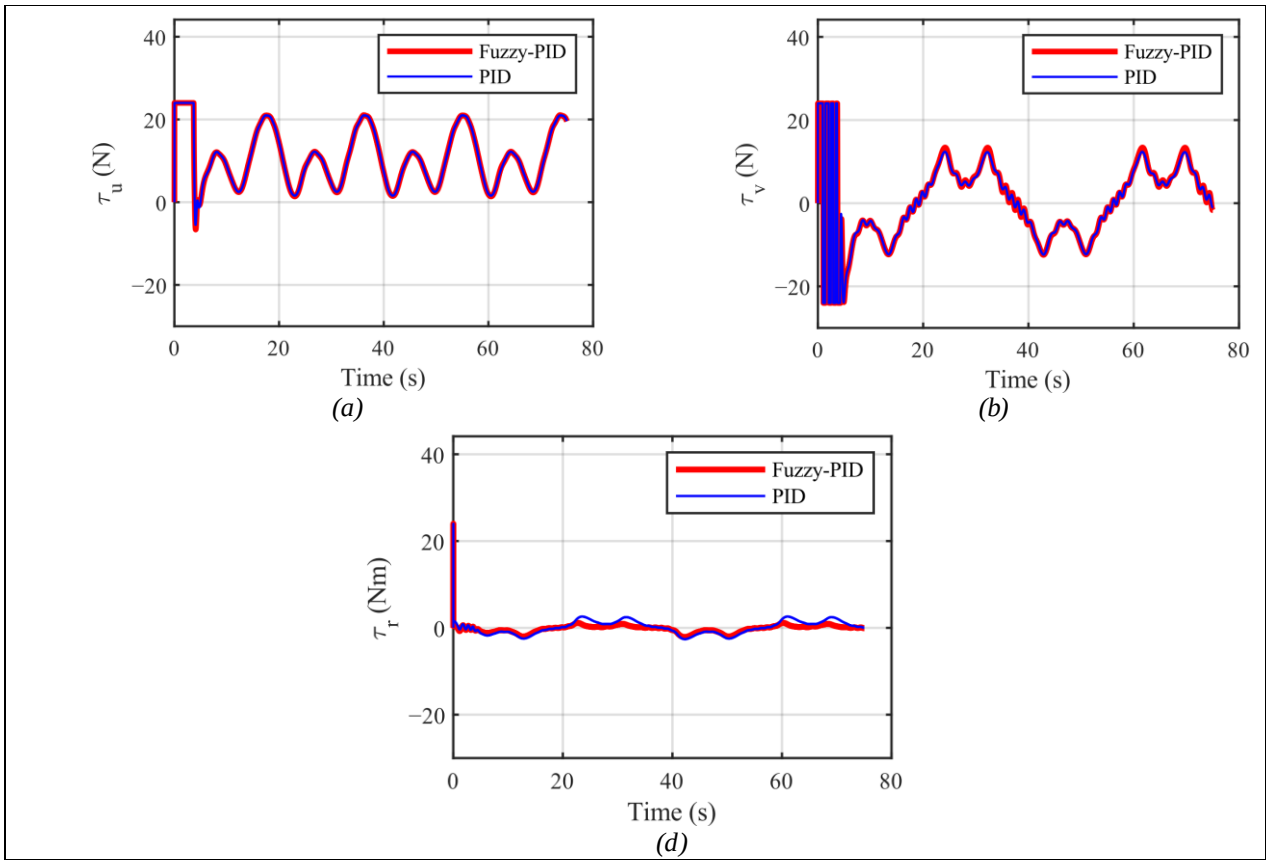

Figure 12: Control signals for following a lemniscate trajectory (a) torque in X-axis, (b) torque in Y-axis and (c) moment around the Z-axis.
Source: Authors, (2025).

The lemniscate trajectory (Figure 9) presents a more demanding scenario, imposing alternating curvature and progressively challenging the surge-sway-yaw coupling. Figure 11, which plots the tracking errors, confirms that the Fuzzy-PID is more effective at handling these dynamic changes. The PID controller exhibits quasi-periodic oscillations in the heading error ψ, synchronized with the reference trajectory's curvature reversals, and occasionally retains a small residual bias after transients. By employing adaptive gain tuning, the Fuzzy-PID controller significantly damps these oscillations faster, reduces the peak-to-peak error, and maintains superior accuracy. As shown in Figure 10, the Fuzzy-PID tracks the path more tightly around high-curvature segments and at the self-intersection point, whereas the PID tends to exhibit greater lag and overshoot. Overall, the fuzzy self-tuning mechanism improves the controller's robustness and adaptability to time-varying path curvature.

For the more complex lemniscate maneuver, the control signal performance presented in Figure 12 further underscores the robustness of the proposed method. The critical challenge in this scenario is the smooth reversal of the yaw moment τ_r at the trajectory's inflection point. The conventional PID controller struggles with this transition, producing a control signal characterized by noticeable ripples and jitter, which suggests that the fixed gains are over-reacting to the rapidly changing curvature and centripetal loads. Conversely, the Fuzzy-PID controller modulates the gains online to generate a clean, continuous torque curve, seamlessly transitioning between turning directions without inducing oscillatory behavior. Furthermore, the surge and sway forces (τ_u, τ_v) under Fuzzy-PID control remain within a tighter envelope compared to the PID, confirming that the adaptive mechanism not only improves tracking accuracy but also yields a more energy-efficient and actuator-friendly control strategy. This table summarizes the performance metrics (RMSE, IAE) for the ASV model under PID and Fuzzy-PID control.

Table 8: RMSE and IAE results of PID and Fuzzy-PID controllers under circular trajectory.

Trajectory	Controller	Axis	RMSE	IAE	Unit
Circular	PID	X	2.616284	53.225904	m
		Y	1.139514	26.534804	m
		ψ	0.564364	40.522358	rad
	Fuzzy -PID	X	2.597192	50.600787	m
		Y	1.119295	25.107095	m
		ψ	0.303748	14.629701	rad

Table 9: RMSE and IAE results of PID and Fuzzy-PID controllers under lemniscate trajectory.

Trajectory	Controller	Axis	RMSE	IAE	Unit
Lemniscate	PID	X	0.286467	10.736777	m
		Y	0.83173	18.315073	m
		ψ	2.598652	70.327672	rad
	Fuzzy-PID	X	0.276233	9.013106	m
		Y	0.827149	15.94486	m
		ψ	2.585115	70.043016	rad

Source: Authors, (2026).

To rigorously assess the tracking precision, the performance metrics defined in equations (16) and (17) were analyzed. Across the circular trajectory (Table 8), the Fuzzy-PID controller delivers the most significant improvement in heading control. Specifically, the heading RMSE computed via Eq. (16) decreases from 0.564 to 0.304 (a 46% reduction), while the IAE calculated via Eq. (17) drops from 40.52 to 14.63 (a 64% reduction). Position tracking in the X and Y axes also exhibits modest improvements in IAE, resulting in a visibly smoother XY path consistent with enhanced rejection of low-frequency disturbances. In the lemniscate trajectory (Table 9), the Fuzzy-PID controller continues to outperform the PID in translational motion, yielding lower RMSE and IAE values for both X and Y axes. The heading error ψ remains comparable to the PID baseline; however, the controller demonstrates greater stability.

Unlike the PID, which suffers from oscillatory behavior due to the continuous curvature changes, the Fuzzy-PID's adaptive gains provide a steadier response. Overall discussion: The simulation results confirm that the proposed Fuzzy-PID architecture consistently enhances translational tracking and minimizes accumulated error. It proves particularly superior in heading regulation during smooth maneuvering (circular path). While the performance on the complex lemniscate path is robust, future refinements could introduce a curvature-aware term into the fuzzy rules or apply gain scheduling based on the desired yaw rate to further optimize handling during sharp heading reversals.

V. CONCLUSIONS

This study examined trajectory-tracking control for an ASV with nonlinear, strongly coupled surge, sway, and yaw dynamics. A conventional fixed-gain PID was compared with a Fuzzy-PID controller within the same single-loop architecture on circular and lemniscate paths. The results are consistent across trajectories: Fuzzy-PID shortens settling time, reduces overshoot, improves path fidelity in the XY plane, and lowers accumulated tracking error, as confirmed by the RMSE and IAE tables. The advantages are most evident on the circular and lemniscate paths, where Fuzzy-PID removes or greatly reduces the steady-state heading bias in ψ that remains after the initial overshoot of PID, producing visibly smoother tracks.

In the complex lemniscate scenario, the proposed controller effectively manages the dynamic coupling during the direction reversal at the crossover point, avoiding the oscillatory behavior observed with the PID. Furthermore, control signals generated by the Fuzzy-PID are significantly smoother, which implies reduced actuator wear compared with the chattering observed in PID commands under strong coupling. The study intentionally kept a compact rule base and did not carry out exhaustive tuning of membership parameters, leaving scope to further improve robustness and repeatability. Future work will include systematic gain scheduling and parameter optimization across operating points, integration of state and disturbance estimation to suppress wave frequency content and reject slowly varying biases, coordination with energy-aware thrust allocation to respect power limits while maintaining tracking quality, and validation through hardware-in-the-loop tests and field trials under real wind, wave, and current conditions.

Energy Consumption

ABSTRACT

The building industry, which uses the most electricity, has a significant potential to contribute to energy consumption reduction. Commercial structures use more energy than other types of structures because of their productive and logistic features. In these types of structures, one of the main energy consumers is the HVAC system which comprises of heating, ventilation, and air conditioning, especially in arid conditions. Energy-efficient environment friendly HVAC system conception and execution can significantly lower the use of energy and support ecologically sound growth in business establishments. On the other hand, inadequate implementation of methods for reducing energy use may lead to a decline in the welfare of the environment. Therefore, in order to achieve energy efficiency and maintain the optimum degree of temperature regulation, a comprehensive energy conservation strategy is needed. To accomplish this goal, model predictive control strategy-based methodologies are used in this work. To estimate how much energy will be used in commercial buildings, four deep learning-based methods are utilised: radial basis function networks, multi-layer perceptrons, artificial neural networks, and back propagation neural networks. To further cut down on energy use, four distinct control mechanisms are used. The performance of the suggested solution is examined using performance measures like Mean Absolute Error and Mean Absolute Percentage Error.

I. INTRODUCTION

One of the main sources of energy use, both regionally and worldwide, is buildings. About 32% of the production of greenhouse gases connected to electrical power usage and 35% of worldwide ultimate utilisation of energy in 2019 were attributed to currently existent constructions [1]. One of the most substantial prospective industries for energy conservation is the present-day buildings. Cities with extensive industrial construction materials have significantly higher construction-related utilisation of energy. For instance, buildings in Chinese territories contributed to 69% of the town's greatest consumption of power in 2019; 48% of that amount came from business enterprises exclusively.

As a result, upgrading already-existing buildings has gained widespread support as a useful strategy for combating global warming as well as the associated energy crisis. A commercial office building's ability to house people's workspace is one of its main goals. People labour in their environments for 45 hours a week on aggregate [2]. Furthermore, two important elements that have an impact on worker health and efficiency in the workplace are exposure to environmental pollution and temperature regulation. For instance, it has been discovered that office job efficiency and intellectual capacity are correlated with interior warmth. Proximity to environmental contaminants and airborne particulates, is linked to a number of harmful health consequences.

Decreased warmth or low interior air quality creates an occupational danger and undermines efficiency, resulting in significant financial outlays for healthcare costs and missed work [3]. These days, energy is considered to be one of the highest essential needs and a cornerstone of any kind of financial system. Energy sustainability studies have been sparked by the consequent rise in costs of energy brought on by the world's lack of inexpensive resources for the production of energy. The literature revealed that petroleum and gas account for 83% of global energy production.

The world's consumption of energy has grown by 68% yearly over the past thirty years, while carbon dioxide emissions associated with energy have climbed by 63% as a result. The economic progress and rising standard of life have caused energy consumption to outstrip population growth by a factor of two [4]. Over time, the typical yearly growth in the requirement for energy has been 16%. Maximum demand for electrical power was 896 MW/year in 1979; by 2005, it had increased to 22,674 Megawatt yearly; by 2026, it is predicted to reach 63,000 Megawatt [5]. By the year 2055, the amount of power consumed—which stands at 14 trillion kWh today—could reach 55 trillion kWh [6]. The nation's financial and societal behaviour may be impacted if petroleum and coal reserves run out quickly due to the country's constantly increasing requirement for energy.

For the preceding two decades, building industry has experienced remarkable growth, especially in commercial buildings. According to previous studies, buildings use the majority of the electric energy produced, with the commercial buildings using only 12% of it all [7]. Energy is used in buildings for a number of purposes, such as illumination, warming and air conditioning, and other specialised uses. HVAC systems are regarded as an essential component of buildings in conditions of heat and are vital to the operation of these structures and the maintenance of a suitable indoor environment. Modern buildings need a significant amount of energy, primarily from HVAC (heating, ventilation, and air conditioning) systems. In hot and humid regions, the energy usage of the cooling system could surpass half of the building's overall energy usage.

As a result, upgrading HVAC systems is crucial since it can lower energy consumption [8]. In the meantime, interior ventilation and temperature regulation are significantly influenced by HVAC systems. Varying HVAC system layouts as well as operation principles will result in varying interior conditions and moisture levels, which are crucial markers of temperature regulation. Differences in airborne contaminants intensity can also result from modifications to ventilation and purification, and this can impact how much of these contaminants are exposed interior spaces [9]. The majority of energy used in commercial buildings is attributed to HVAC systems, as can be seen from the usual split of each year's energy consumption in buildings; this suggests chances for improving environmental sustainability while decreasing the expenditure of energy.

Numerous studies have addressed conservation and energy performance as they relate to the construction and functioning of HVAC systems. The findings suggest its possible to enhance in terms of HVAC energy utilisation and temperature regulation if appropriate management as well as administration procedures are implemented. The construction and implementation of energy-efficient HVAC systems have benefited from developments in science and technology, but it has also been discovered that the majority of adopted approaches and practices have led to unfavourable interior conditions. Researchers have created several innovative technologies in the last 20 years to enhance the comfort and energy efficiency of existing buildings [10]. Furthermore, constant certification has been established to guarantee acceptable interior conditions and sustained environmental sustainability in buildings that already exist.

By routinely adjusting temperature levels and achieving reductions in energy consumption, CC has assisted building owners in improving the machinery, especially the controls, to their first commissioning environments, identifying inefficient machinery, swapping out broken parts, and correcting improperly executed sequences. The significance of energy consumption in structures is widely recognised by architects and engineers worldwide, and as such, it has garnered considerable focus. In a similar vein, the significance of the quality of the interior environment is acknowledged and dealt with [11]. HVAC system designers typically prioritise high demand comfort and financial restrictions over energy efficiency and long-term quality of the interior environment.

In order to find chances for energy savings and enhance interior circumstances, it is crucial to evaluate the thermal and energy efficiency of currently operating commercial buildings. However, attempts to design energy-efficient buildings are frequently hampered by an inadequate understanding of how the climate and other environmental and design elements affect structures. The objective of this research is to find out how various HVAC system designs may conserve energy while maintaining a suitable degree of thermal comfort in a business building. A methodical procedure is used to create an energy efficiency model for a typical commercial building in order to accomplish the intended goal.

II. RELATED WORKS

Numerous control strategies have been created or put forth for HVAC systems. Nonetheless, many HVAC systems still use PID control and toggle between on and off switch due to their straightforward nature, which causes these systems to behave differently from one another. The inherent problems with HVAC control can now be addressed by adopting and implementing an appropriate control approach because of advancements in storage of information, analysing, and transmission technologies. This section is devoted to an investigation of HVAC system control methods, with a particular focus on the model predictive control (MPC) approach. The reason for the recent surge in research on MPC development for HVAC systems is its many inherent advantages.

The authors in [12] provided brief summaries of aggressive control and sensitive control strategies, respectively. Amplifier planning, effective regulation, resilient management, asymmetric and reactive management, and comprehensive supervision are some of the aggressive control strategies covered in [13-16]. The sensitive control systems, includes controllers based on evolutionary algorithms, fuzzy reasoning, as well as neural networks. The work in [17] included a study of mixed controllers, which are the outcome of combining aggressive control and sensitive control strategies. A thorough analysis of neural networks as well as evolutionary algorithms for HVAC system energy conservation was done in [18].

The work in [19] provided a description of HVAC techniques addressing the modelling of these systems, regulations, and subsystems. The work in [20] also addressed the efficient use of optimisation methods in monitoring control, including minimal squares, linear search, search including gradient, progressive nonlinear computing and adaptive computing. The survey conducted in [21] is based on sustainable HVAC system techniques, such as recuperation of heat, pressure distribution synthesis, and thermal retention. The work in [22] evaluated numerous autonomous regulators for HVAC systems, including

Parametric management, toggle control, time regulation with predetermined time improved take off and ideal begin and halt. The most widely used techniques for control, including PID management, as well as on or disable control, are included in conventional controllers. An increased and decreased cutoff are used by the toggle controller to govern the procedure within the parameters that have been provided [23]. To accomplish efficient process management, the PID controllers modulate the variable that is being controlled and exploit loss mechanics.

The chilling wrap groups, ambient temperature influence, hinder disparity rate regulation, availability pressure of the air control, availability room temperature control, the outside temperature regulation for component circulation units, evaporator source warmth management, and heating device administration are all dynamically controlled by conventional controlling devices [24]. The majority of research is devoted to developing PID controller auto tweaking and efficient adjusting techniques. The mathematical framework for regulating systems, which includes advance planning management, quadratic management, ideal management, and MPC, is the cornerstone of aggressive controllers. A chaotic system is split into independently normal areas for amplitude planning control.

A different combination of gains is used in the construction of the horizontal PID control scheme for each of the horizontal areas. The literature also suggests using self-tuning PID impulse controllers to adjust the device's outputs according to the system's status. In [25], a radiator-based air conditioning unit has two controllers that are adjusted to match various levels of temperature requirement situations. A parametric controller with outputs dependent on the discrepancy between the observed source atmospheric pressure and the initial setting is used in [26] to regulate the incoming air level. In the realm of control system design, aggressive controller techniques are widely recognised.

Although nonlinear dynamic approaches are efficient, designing a controller necessitates the identification of secure conditions and intricate computational analysis. The design of shifting logic between areas and the identification of proportional areas are essential for gain planning management architecture. It can be laborious to manually adjust several PID controllers in these areas. Because they can reject perturbations and time-dependent variables, effective supervision and precise regulation are potential approaches for HVAC process control. Generally speaking, it is challenging to provide durability in HVAC systems because building conditions can vary. Many of these methods also call for the specification of extra parameters, which makes the integration into HVAC systems potentially challenging and unfeasible [27].

Because it can incorporate perturbation disapproval, restriction administration, stationary adaptive control, and cost-effective strategies into controller layout, Model Predictive Control is one of the most promising aggressive control systems. Digital controllers have made it possible for relatively new sensitive control approaches, like those based on Fuzzy Reasoning (FR) and Artificial Neural Networks (ANN). An ANN is trained using system functioning data, which it then uses to fit a complex computational model. The method itself is a black box simulation approach, meaning that knowledge of the mechanics behind the procedure is not essential. This technique is widely employed in forward feedback management [28]. Combining aggressive and sensitive control strategies results in mixed controllers.

Artificial neural networks, which are sensitive control techniques used at greater tiers of the management structure, and dynamic controllers, which are aggressive control techniques used at lower tiers, make up mixed controllers. FR can be used to calibrate the benefits of controller in PID applications. The complementary nature of aggressive and sensitive control strategies allows for an amalgamation of each of them to tackle problems that may not be conducive to a particular technique working alone. A semi-dynamic fuzzy system for region regulation of temperature employing transmitter-heater energy management and programmable controller for air flow management [29] are two examples of hybrid control.Mixed control acquires the negative aspects of both aggressive and sensitive control techniques, even as it gains from their distinct advantages.

For instance, creating a sensitive control component necessitates user convenience and enormous amounts of information for instruction, but developing and tweaking an aggressive control component may prove problematic given the functional parameters commonly seen in these systems. The MPC has numerous benefits when taking HVAC control system parameters into account. HVAC systems have a lot of tedious, time-constrained operations, and they are affected by dynamic both interior and exterior perturbations. The operating conditions that the system experiences are diverse. There are speed and frequency constraint restrictions on the controllers. Energy has an adaptable cost mechanism in multiple locations. The optimum controller should be able to manage actuator restrictions, fluctuating cost values, varied working conditions, and dynamic perturbations in the face of all these difficulties [30].

II.1 MOTIVATIONS OF CURRENT RESEARCH

It appears that a lot of control systems have a few issues when it comes to HVAC control. For example, conventional controllers perform more impulsively or slowly beyond of the frequency range and need to be adjusted manually. For the controller design, the aggressive controllers necessitate the identification of secure balance locations and an exhaustive statistical analysis. Sensitive control is not practicable for commercial applications since it requires large amounts of knowledge for instruction and take a long time. As an alternative, MPC addresses a number of the previously me]ntioned issues and is employed in the current research.

III. PROPOSED METHODOLOGY

III.1 HVAC SYSTEM MODELS

One of the significant concerns in the research on HVAC systems is how these standard systems would handle the various building demands. These buildings have been connected to the two most popular HVAC systems such as the ventilation coil with a specific exterior air device and an adjustable airflow system as shown in Figure 1. An adjustable air flow system is an entire system that modifies the source air flow speed while maintaining a uniform source ambient temperature to correspond with the decrease in area load during quasi functioning of the system. By doing this, the device preserves an established area parameter—typically the air temperature—while simultaneously conserving motor energy at a decreased flow.

The source humidity level, which is set at 18 ◦C, regulates the primary warming circuit and the secondary cooler coil. Through the air warming containers, necessary prerequisite airflow is transported to the regions, if necessary, it is further heated. The steaming water circuit and suspension in each air reheating box are controlled by an area temperature gauge and have a bidirectional suspension function. This indicates that the unit starts at lowest air circulation and lowest steaming water discharge while in warmth mode. The steaming water flow is raised until it reaches its highest point in response to a rise in the temperature demand. The ventilation valve begins to vibrate if the load is still not reached.

The exterior air blending container, which has a reducer that combines come back and exterior air proportionately to reach the combined air temperature threshold, regulates how much exterior air is supplied. In order to take advantage of free the cooling process, the reducer unit is used to enhance the amount of exterior air wherever feasible. A fluctuating air temperature threshold installed on the source end can enhance the effectiveness of adjustable airflow system. Dynamic temperature regulation can both improve the amount of ventilating capacity and decrease the amount of energy needed for warming. This is accomplished by determining if a particular warming box is operating at an appropriate velocity during chilling periods.

If so, the building administration system raises the ambient temperature of the circulating airflow. In essence, an adjustable temperature and quantity system is an adjustable airflow system with constantly variable source temperature regulation. The ventilation coil with specialised exterior air framework, is a system made up of a moisture distributing component and regions pipe coils that distribute completely air from the outdoors exclusively to satisfy fresh air necessities. Unlike the adjustable airflow system, the cool air delivery range is managed by a temperature-controlled detector that adjusts the temperature between 18 and 23 ◦C to optimise the benefits of unrestricted air conditioning.

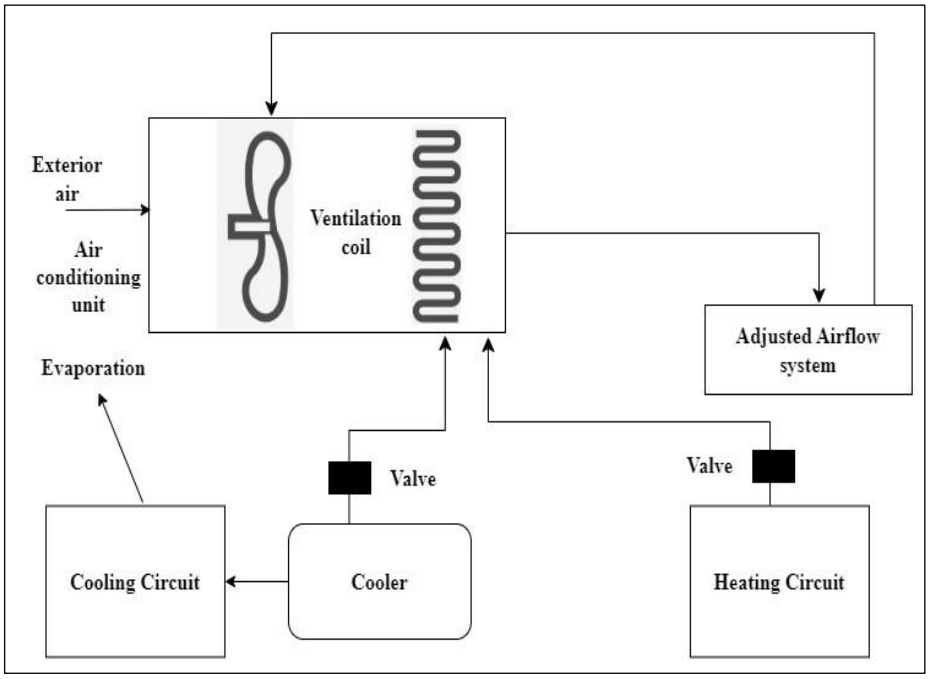

Figure 1: HVAC System model.
Source: Authors, (2026).

However, compared to the adjustable airflow system, the source air capacity is much smaller, which limits the amount of unrestricted air conditioning. A ventilation coil is made up of coils for both cooling and warming as well as a blade for redistributing the air in the space. A regional regulator maintains the environmental conditions inside the space by adjusting the fluid rate that travels through the cooling or warming circuit in response to the requirements in each area. The rotating circuit motor is turned off when neither warming nor chilling is necessary. Implementing an energy recuperation device, which transfers warmth between the source airflow and the expelled air, can prevent the outside environment. Passage valves on the thermal recuperation unit enhance ventilation by reducing the exchanger that conducts heat.

Depending on the type of system, multiple models were used for the characteristics of the source of airflow fan. Adjustable flow blades with a 35% decline frequency are utilised with the adjustable airflow system. Suction blade absorbers manage the system's internal air circulation. The ASHRAE Secondary Toolkit is the underlying basis of the ventilator specifications [20]. Continuous output blowers drive the system's air dispersion. For the ventilation coil system with an energy recuperation device and the adjustable airflow system, the ventilator's inflation rate is adjusted to 850 Pa. Because there is less impedance in the air circulation circuit for the ventilation coil system, the pressure rise is minimised to 500 Pa.

For both systems, both the warm and chill water temperature regimes were identical. The chilled water circuit runs in the 6/13 ◦C regime, while the source warm water temperature is fixed at 84 ◦C with a maximum temperature drop of 10 ◦C. The transport of hot or cold water in main system is maintained by steady-speed motors. When the fluid flow velocity in the radiators is lowered during reduced capacity procedures, excess warm and cold water supply is channelled through diversions.

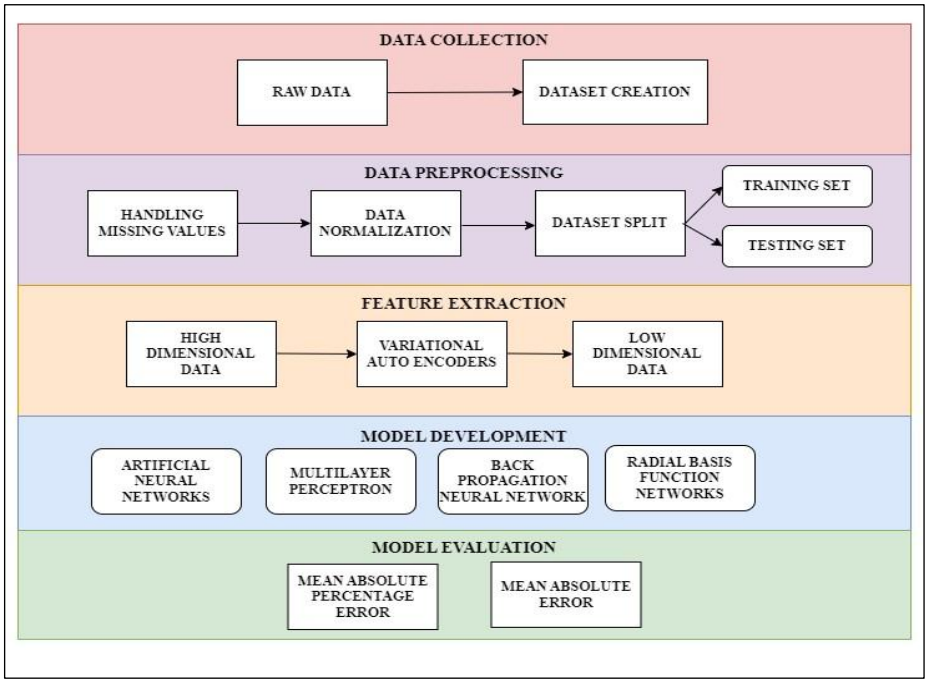

Figure 2: Proposed Framework.
Source: Authors, (2026).

III.2 DATA COLLECTION

A substantial amount of training data that can accurately depict the link between inputs and outputs is required in order to train the prediction model. These data for the study were gathered from the test platform, which simulates a range of working environments. In order to account for a variety of working settings, the simulation runs for five years with the interior temperature setpoint being arbitrarily set between 20 and 28 ℃ for each hour (such as varied indoor temperature and weather conditions). The building model is configured to operate in the free cooling mode, which allows for an infinite cooling supply. In this mode, the system is programmed to automatically supply a specific amount of cooling that satisfies the need to maintain the interior temperature at its setpoint.

The power consumption under various operating situations can be derived by integrating with the matching steady-state model of the HVAC system. It should be noted that the hot summer and warm winter weather zones are represented in the used meteorological data. Thus, all that is required year-round is cooling. A five-minute simulation interval is chosen. Consequently, twenty sets of data are generated every hour, but only the set in the final point is gathered. The reason for this is that the envelope's and the internal mass's thermal inertia prevent the cooling demand at the start of each hour from accurately reflecting the actual cooling requirement for that hour. As a result, a total of 45,600 sets of data are gathered.

III. 3 DATA PREPROCESSING

Typically, missing or anomalous data is found and fixed (or eliminated) during the data cleaning process. Eliminating data that is useless for the machine learning-based controller's actual use is the primary goal of this investigation. The predictor's prediction accuracy can be greatly improved by this implementation. Two categories of data must be eliminated. First, all datasets outside of working hours are deleted, leaving just those collected between 6 a.m. and 9 p.m. The HVAC system doesn't offer frequency regulation services outside of working hours, thus the machine learning-based controller is only utilised during those times.

Secondly, the datasets with 0% power usage are eliminated. The explanation goes like this. The following scenarios could arise because the indoor temperature setpoint is arbitrarily determined during the data production and collection procedure. While the indoor temperature setpoint is relatively high, the external temperature is relatively low. Since the HVAC system doesn't need to be turned on for cooling, there is no electricity consumption. It is evident that the HVAC system is unable to perform frequency regulation service because it does not even turn on. As a result, the datasets with negligible power consumption are likewise eliminated.

III.4 FEATURE EXTRACTION

An encoder that receives input and creates a reduced version and a decoder that returns the revised version to the source data make up an autoencoder network, also known as a variational autoencoder. The encoder produces two vector formats: a vector to measure the mean value and a vector to denote the variance value. Its infinite hidden space facilitates sample selection and restoration. Because the code being encoded has a significantly lower section frequency than the source data, the challenge is in programming the algorithm to acquire an appropriate and transferable hidden space.

This model gives a likelihood dispersion definition for each hidden property. The m th element of mean and variance, which together make up the components of a sequence of arbitrary parameters of length K, represents these values of the m-th random variable, Am, which was sampled to create the resultant encoded data. Even though these values remain unchanged, the original encoding for the identical source data will vary significantly on every attempt due to randomization. The average of a variable establishes the central point of encoding of source data, whereas the variance value establishes the region or how much a source data may diverge from its average.

The KL divergence allows for continuous restoration and the production of newly formed information by acting as a optimizer in the elimination function. Then, using an assortment of samples drawn from each hidden phase dispersion, the decoding system creates a vector as input for the decoder model in an attempt to replicate the input that was originally provided. Instead of using reverse propagation, which is usually used to determine the connection between every channel variable and the final outcome's loss, expands the values of the parameters. For approaches involving randomly selected examples, reverse propagation is inadequate. As reallocating parameter values optimises the distribution's stochastic variables, the ability to choose samples arbitrarily from the spectrum of values remains intact.

III.5 MODEL DEVELOPMENT

III.5.1 Artificial Neural Networks

Artificial neural networks are mathematically reduced representations of biological neural networks that possess the capacity to learn and offer significant answers for problems including nonlinearity and high levels of complexity. The ANN approach can tackle a wide range of problems and is faster than its conventional procedures. It is also robust in noisy situations. These benefits have led to the widespread adoption of ANNs in real-time applications. In hydrology, three- and four-layered neural networks are most frequently utilised. The first layer receives input, the intermediate layers process the data, and the final layer displays the results.The processing units that are present in every layer of the network are referred to as neurons or nodes.

The first layer to the intermediate layer and the intermediate layer to the final layer are where information flows and is processed in the network. The number of neurons and hidden layers in the network are obtained through test-run based on the specific situation. In order to forecast the input-output relationship, each link is given a synaptic weight that represents the relative connection strength of two nodes at both ends. The sigmoid transfer function is a frequently utilised activation function. The sigmoid function can be used to map a nonlinear process since it is continuous and differentiable everywhere. The main application of the backpropagation technique is in feed-forward neural network training. Every input pattern in the training dataset is processed by the network in this approach, moving from the first layer to the final layer.

III.5.2 Multi-Layer Perceptron

Due to the limitations of the perceptron with one layer to solve exclusive OR usecase, this backpropagation model with multiple layers disperses errors throughout the network using the delta learning rule. It is made up of three parts: input, output, and intermediate (hidden). The node, which contains source data and resultant data is interlinked with every other node in the layer below it and serves as the processing element in each MLP layer. As a consequence, the resultant of one layer happens to be the source of the subsequent layer below it. Data is received by the source layer and sent to the concealed layer. This means that the classification problem determines the count of concealed layer. The output layer generates the outcomes based on the number of components in the final layer after processing data from the preceding layers.

III.5.3 Back propagation Neural Networks

One of the most popular machine learning techniques in the field of research is the feedforward neural network, which is optimised by the back propagation algorithm in a neural network called BPNN [24]. For the majority of forecasting situations, a BPNN can, in theory, be used as a multipurpose estimation to predict the underlying complex nonlinear connection. The source, the intermediate, and the resultant layer are often present in a BPNN. Additionally, the research challenge and goal determine how many input and output neurons the BPNN has. Furthermore, the intricacy of the research problem affects the BPNN method's basic design, which includes the number of concealed layers and nodes in each concealed layer. Weights establish a relationship between each layer and the one below it. An activation function is then obtained by multiplying all of the node terms from the preceding layer by the corresponding weight parameters, which add a bias. The BPNN uses the activation function as the foundation to approximate nonlinear latent functions. Additionally, the backpropagation technique is used to modify the connection weights.

III.5.4 Radial Basis Function Networks

A feed-forward neural network with three layers—an input layer, a hidden layer, and an output layer—is called an RBF neural network. Each buried unit represents a single RBF with a corresponding width and centre position. Kernels or centroids are frequently used to identify these covert units. Each output unit weights and summarises the hidden units. A vast class of functions that may be described as linear combinations of the chosen RBFs can be displayed using a collection of RBFs.

IV. RESULTS AND DISCUSSION

IV.1 DATASET DESCRIPTION

Using Ecotect simulation software, 768 entries from twelve different building types made up Dataset 2. Twelve different building kinds were represented by eighteen 4.5 x 4.5 x 4.5 metre basic cubes. As a result, while the buildings' surface areas and dimensions vary, their volumes do. Each of these structures was designed to resemble an Athens, Greece, residential building. The purpose of this dataset is to look into how dimension affects a building's cooling load (CL). Because of this, the façade system's material attributes, such as the U-values of wall with 1.78 W/m2K, windows with 3.38 W/m2K, floors with 0.86 W/m2K, and ceiling with 0.50 W/m2K, were applied to all fifteen buildings. Latent heat and illumination levels were adjusted to 2 W/m2 and 300 lux, respectively. To model the air conditioning load of the domestic construction, the following characteristics such as position, the amount of surface space, masonry region, ceiling region, total elevation comparative cohesiveness, window region, and window dispersion were employed. The two configurations used in the studies to recreate the building were with and without window options.

Four different types of window region ratios such as 15%, 30%, and 45%—were applied in the proposed system. There are five glazing distributions that are taken into consideration: 40% windows on each face; 60% windows on the west end and 25% windows on the other ends; 60% windows on the south end of the building and 25% windows on the remaining ends; 60% glazing on the north end and 25% windows on the other ends; and 60% windows on the east face and 25% windows on the other ends. Finally, each of the building shapes were turned to point to one of four directions.

IV.2 EXPERIMENTAL EVALUATION

Experiments were conducted using the four models such as Artificial Neural Networks (ANN), Multi-layer Perceptron (MLP), Back propagation Neural Networks (BPNN) and Radial Basis Function Networks (RBFN) and the results are tabulated in Table 1. The metrics such as Mean Absolute Error (MAE) and Mean Absolute Percentage Error (MAPE) are computed for each of the techniques to analyse the performance of the models for predicting the consumption of energy resources. It can be seen that the ANN model produces MAE of 63.86 during training and 78.32 during testing. Also, ANN produces MAPE of 7.56 and 8.65 during training and testing respectively.

Table 1: Experimental results.

Techniques		Mean Absolute error	Mean Absolute Percentage error
Artificial Neural Networks	Training	63.86	7.56
	Testing	78.32	8.65
Multi-layer Perceptron	Training	56.34	6.35
	Testing	48.25	7.24
Back propagation Neural Networks	Training	72.36	5.32
	Testing	65.52	4.74
Radial Basis Function Networks	Training	43.25	4.36
	Testing	36.85	4.12

Source: Authors, (2026).

MLP model exhibited MAE and MAPE of 56.34 and 6.35 during training correspondingly. During the testing periods, MLP showed 48.25 MAE and 7.24 MAPE. The MAE and MAPE values produced by BPNN model during training was 72.36 and 5.32 respectively. During testing, it was about MAE value of 65.52 and MAPE value of 4.74. RBFN model exhibited 43.25 MAE and 4.36 MAPE during training phase and 36.85 MAE and 4.12 MAPE during testing phase. Further, the prediction outcomes achieved by each of the model for energy consumption by the buildings is presented in Figures 2 to 5. The results revealed that the models were capable enough to produce prediction outcomes closer to that of the actual values and the RBFN model produced predictions which less deviations from the original results.

In addition to this, four control strategies were further suggested in order to minimize the energy consumption by the buildings. This research initially sought to determine how altering the temperature threshold for warming and cooling, affects the total use of energy. One of the thermocouple approaches utilised in HVAC systems is to regulate the temperature threshold, which plays a big part in a building's energy consumption for heated space. Reducing the wintertime warming temperature threshold in a building located in an arctic climate can result in significant energy conservation. The results obtained for temperature threshold approach are presented in Figure.

Lowering the warming temperature threshold results in a notable decrease in the yearly overall energy usage. There is a 25% as well as 5% decrease in the usage of fossil-fuel-powered gas and electric power, respectively. The yearly energy demand dropped to 385.56 kWh/m^2 from 520.76 kWh/m^2. The pace at which energy demand is reduced annually is roughly 21%. Lowering the warming temperature threshold in the building lowers the energy consumption of the ventilation turbines and blades in addition to the energy used for interior heating.

During the months when the air conditioning system is not in use, the building's aggregate energy use remains unchanged when the cooling temperature threshold values are lowered. Whenever a cooling unit is in service during the winter months, overall consumption of electricity falls. For instance, there was an 8% drop in overall usage of energy in September. During the months when the air conditioning fails to function, the total expelled carbon dioxide emissions do not change. Because less energy is used during the months the cooling system is running, fewer greenhouse gases are generated altogether. The building's total displaced greenhouse gases output, which is 95,485 kg, reaches its smallest level in July.

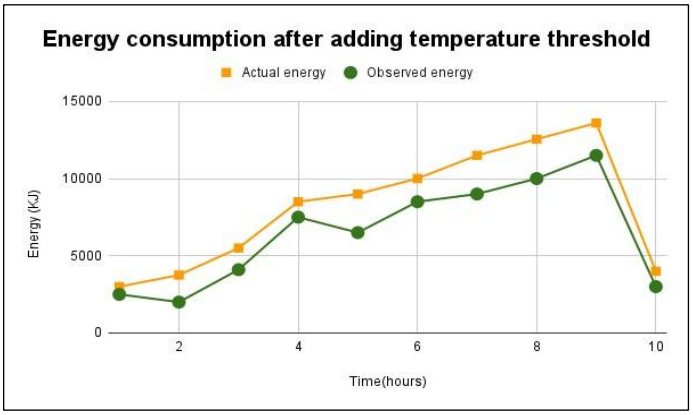

Figure 7: Energy consumption after adding temperature threshold.

An proactive or introspective conditioning technique called night time aeration is used, particularly in large structures, when the facility is situated in an area with an appropriate overnight temperature. Using aeration at twilight is an intriguing approach to lower the amount of energy required for building conditioning without sacrificing heat retention. The basic idea is to use spontaneous or ventilating machinery to use the comparatively cold conditions, surrounding air during the course of the night to regulate the air inside along with structural elements, so acting as a source of heat for the next day's work. All of the building's conditioned spaces aside from the workplaces are occupied and kept cool for the entire period of the day.

Because of this, during the hours that the workplaces are closed, night time aeration can be turned on for workplace buildings. Figure 8 illustrates how the aeration of the workplace areas at night affects the building's energy consumption. The terminal building's energy usage for conditioning is decreased by using night time aeration in workplace spaces. However, in order to ventilate the offices at night, the combustion and circulation blowers installed in the buildings must be turned on. As a result, even if the air condition elements are deactivated in the starting point modelling, the building's overall energy use goes up. Consequently, it was determined that it is not financially feasible to provide night time aeration for the office areas.

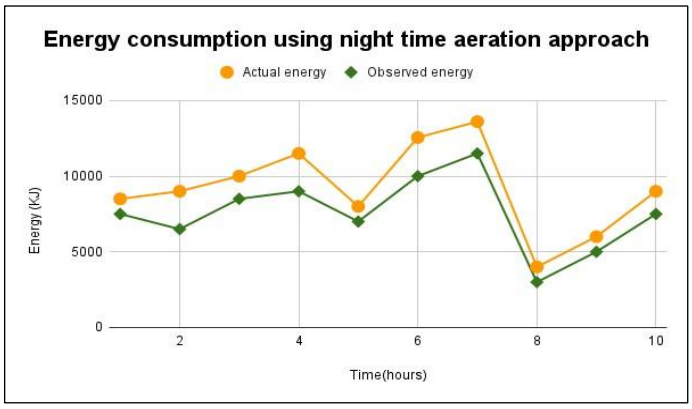

Figure 8: Energy consumption using night time aeration approach.
Source: Authors, (2026).

When the exterior air temperature is adequately cold, air handling units may be employed in HVAC systems as an additional way to save a substantial amount of energy.

Reducers, which give the chilling system unlimited cooling, come in two different forms. This technique reduced the amount of energy used for cooling by suggesting and evaluating the usage of a reducer, which is added in parallel to the chilling unit's reservoir unit. The building's cooling has been provided by chillers with air conditioning. During the winter months, cold water distribution motors move the cold water produced by the cooling units, which is at a temperature of 9 °C. The results obtained by applying this approach is presented in Figure 9.

When the temperature of the exterior air is less than the recirculating temperature, no area of the building needs to be chilled, according to an investigation into the simulation findings. However, because of thermal advancements, the temperature of the interior air in some places may suddenly rise over the cooling initial value. The amount of energy used for cooling rises by a negligibly small amount as a result of this spike in temperature. Therefore, employing this technique hasn't resulted in an improvement in the energy utilisation. As a result, this approach is not advised for usage as it did not lower the building's energy usage and greenhouse gas emissions.

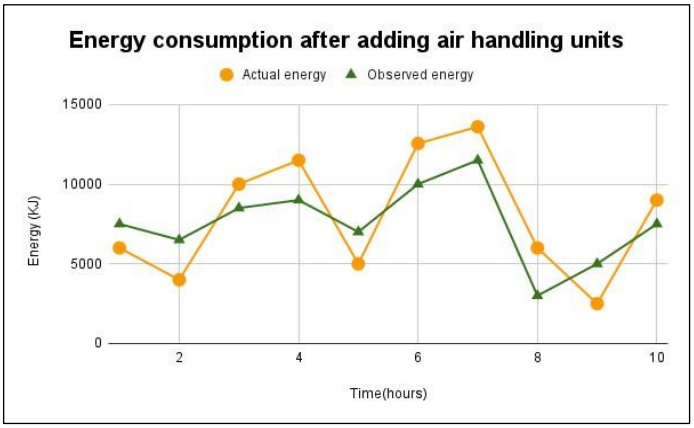

Figure 9: Energy consumption after adding air handling units.
Source: Authors, (2026).

One effective way to lower a building's excessive consumption of energy is through recuperating energy. A radiator is often used in air conditioning units to lower the amount of power required for a structure's thermal or cooling needs. Based on how they operate, the air conditioning units that are currently in the building were employed for this study. These consist of a heat radiator that uses 75% of exterior air to achieve the statutory circulation demand.

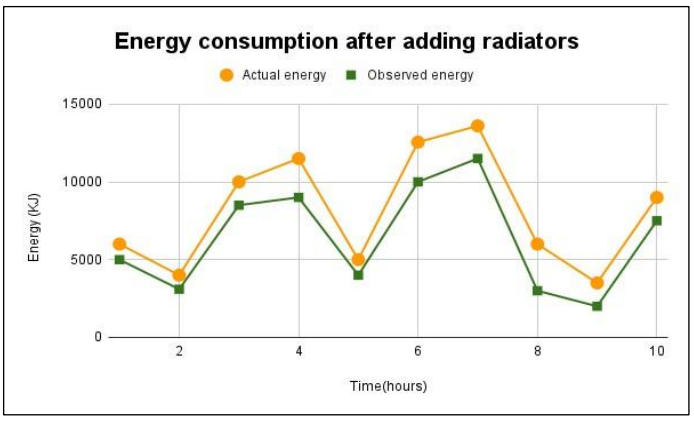

Figure 10: Energy consumption after adding radiators.
Source: Authors, (2026).

Using a radiator is found to lower energy usage throughout the year . Compared to other months, the coldest months see a far greater fall in energy use. For instance, the introduction of a radiator reduces the energy consumption by 52% to 543,632 kWh from the March use of 834,437 kWh. The entire amount of transferred greenhouse gases is lowered as a result of the decrease in energy usage.

V. CONCLUSION

When suitable monitoring and maintenance procedures are implemented, HVAC systems can present significant opportunities for energy conservation. The various energy-saving techniques that can be used with the HVAC system to lower energy usage while decreasing greenhouse gas emissions are discussed in this research. The HVAC system in the commercial buildings uses the most energy when compared to other structures, according to an energy analysis of the building's framework.

In this regard, four different deep learning algorithms were leveraged to forecast the energy usages of the buildings and it was inferred that Radial Basis Function Networks produced predictions with lesser errors and deviations. In addition to this, four control strategies were recommended for further reduction in energy consumption. In terms of energy, expenses, and environmental impact, approaches including modifying the temperature thresholds and installing radiators have been demonstrated to be functional. However, it is discovered that the night time aeration and adding air handling units are not financially a feasible option.

ABSTRACT

Numerous studies have shown the effectiveness of composite patch repairs. However, many of these investigations primarily address the enhancement of repaired components' lifespans, focusing mainly on opening mode (Mode I). In real-world applications, cracked components often undergo mixed mode loading that includes both Modes I and II. This article examines the stress intensity factors for Modes I and II in relation to the fracture behavior of a tensile-loaded aluminum plate (Al 7075) featuring a 45° inclined lateral crack repaired on both sides with a unidirectional graphite/epoxy composite trapezoidal patch. A three-dimensional finite element model of the repaired specimen is employed to explore how composite patching affects critical crack tip parameters (KI, KII, and stresses). This approach demonstrates how the properties of the composite and adhesive impact the repaired structure's behavior and the effectiveness of the bonded composite patch. The findings reveal that trapezoidal composite patch can significantly reduce the stress intensity factors KI and KII, thereby extending the service life of cracked structures

I. INTRODUCTION

The composite repair methodology has established itself as an effective and pragmatic solution for repairing cracked structures. This approach involves bonding a composite patch to the damaged areas of the structure, providing multiple benefits: it avoids additional stress concentrations, enhances the stiffness-to-weight ratio, accommodates complex geometries, and enables effective repairs of irregular components. Fiber-reinforced polymers are increasingly preferred over metallic patches due to their superior mechanical properties, as well as their resistance to fatigue and corrosion [1], making them ideal for structural applications. Numerical analysis has become a cornerstone in evaluating composite patch repairs, widely accepted within the research community as a method to assess performance without relying on sophisticated instruments [2]. Critical parameters such as the stress intensity factor (SIF) and the J-integral, alongside interfacial adhesive stresses, are essential for estimating both repair efficiency and durability.

While much of the existing literature has focused on straight cracked panels subjected to Mode I load such as [3-5], real-world applications often involve mixed-mode loading conditions, which present significant practical challenges and opportunities for further investigation [6]. The Finite Element Method (FEM) is a powerful tool for examining structural performance. The Finite Element Method (contour integral) stands out by allowing for the modeling of cracks in a mesh-dependent fashion, facilitating the simulation of crack intensity factors investigation. Notable studies, such as those by [7], have successfully applied XFEM to analyze 3D crack models, while Talebi et al. employed both the cohesive zone model (CZM) and XFEM to simulate adhesive damage and crack growth in structural panels. Other researchers have utilized the Cohesive Zone Modeling (CZM) method to assess failure mechanisms in repair processes, as demonstrated in the studies by [8] and [9], as well as [10]. Who has shown that the stress intensity factor for patched cracks exhibits asymptotic behavior as the crack length increases.

This phenomenon arises because stress is effectively transferred to the patch through the adhesive layer, highlighting the importance of adhesive properties in repair performance. Most studies focus on plates with non-inclined cracks, but this is not always the case in practice [6]. In fact, several studies have emerged in this area, such as the work of [11], who calculated the stress intensity factor in mixed mode for an inclined central crack. These oblique cracks pose additional challenges in terms of diagnosis and repair. Standard techniques developed for orthogonal cracks do not always apply optimally. The influence of the composite's geometric properties on repair effectiveness has been a significant focus in the literature. By [12] used multi-objective optimization design of composite patch repair, while [13] and [14] conducted numerical analyses comparing octagonal, circular, and elliptical patch designs.

Their findings indicate that the shape of the patch plays a crucial role in determining the stress intensity factor at the crack tip. Selecting an appropriate patch shape can significantly lower stress levels at the edges, ultimately enhancing the durability and effectiveness of the repair This paper presents a comprehensive investigation of an inclined cracked panel reinforced with a composite patch using the contour integral method. The study focuses on numerical analysis, using the commercial software Abaqus. The entire assembly is subjected to Mode I and II loading, enabling the determination of the stress intensity factors and interfacial adhesive stresses, to reveal the critical stress zones at this interface for a trapezoidal patch. The patch is installed symmetrically with respect to the plate by means of a thin adhesive layer to cancel out the bending effect due to displacement of the assembly centroid and enhancing the repair effectiveness thereafter.

II. MATERIALS AND METHOD

II.1 GEOMETRIC MODEL

In this study, the repair configuration for edge-inclined cracked plates was modeled using a three-dimensional finite element approach in ABAQUS 2017. To reinforce the crack area, a trapezoidal double-sided patch made of eight layers of Graphite/Epoxy composite was bonded to both surfaces of a Aluminum 7075 alloy plate. The patch was secured with a 0.2 mm layer of Masterbond (EP42HT-3AO) adhesive epoxy, known for its high mechanical strength and excellent resistance to both shear and tensile stresses.

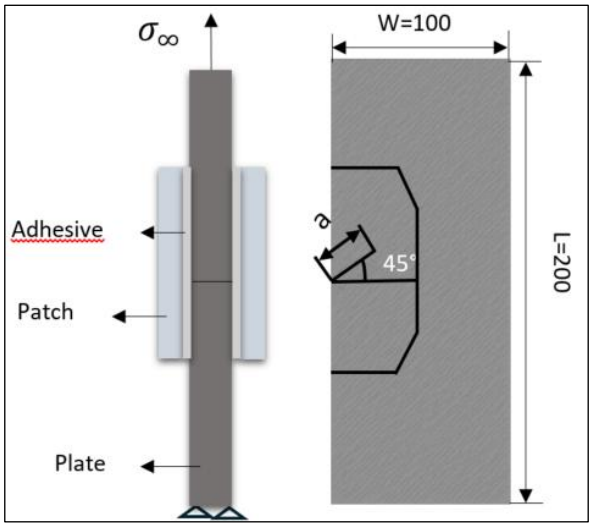

Figure 1: Composite patch repair configuration.
Source: Authors, (2026).

To thoroughly assess the interactions at both the adhesive-plate and adhesive-patch interfaces, a detailed numerical analysis is essential. This interface was modeled in Abaqus using the CZM approach with the BID method. Comprehensive geometrical and mechanical properties for the entire system are provided in Figure 1 and Table 1.Recognizing the importance of adhesive integrity, this study focuses on estimating the service life of repaired structures by closely examining the interaction between the adhesive layer and the composite patch. By analyzing a range of loading conditions and environmental factors, this research aims to predict the durability and reliability of the repair over time.

II.2 MESH MODE

The double-sided configuration utilized in this bonded repair model consists of three materials with varying stiffness. The Bilinear Delamination Interface (BID) approach was employed in the Cohesive Zone Model (CZM) method for modeling the contact zones between patch-adhesive and plate-adhesive. In this model, cohesive elements are used to simulate the joints, and their behavior is governed by a tensile-separation law. To ensure precise simulation, the entire model was meshed using the quadratic meshing method available in ABAQUS 2017 software. This approach enhances the accuracy of the interface behavior analysis and improves the overall fidelity of the numerical model.

Results detailing the rate of reduction of the stress intensity factor KI, KII and the stress distribution for adhesive and composite patch, exactly to highlight the phenomena at the edges of these parts, were obtained from a structural static analysis. An element with a length of 2 mm was designed to create an automatic mesh for the entire assembly of the double-sided repair. A refined mesh was generated at the crack edge using elements with a length of 0.02 mm. The entire model was meshed with 10,692 elements for the substrate, 2,696 elements for the adhesive, and 2,816 elements for the composite. The sizes of these elements were determined following a convergence study.

Table 1: Materials and geometrical proprieties.

Materials	**Aluminum alloy**			**Graphite/Epoxy Composite**		**Epoxy/Resin**	
Geometrical proprieties (mm)	W	L	t	R	t	R	t
	100	200	3	50	1.6	50	0.2
Longitudinal young modulus E_{xy} (GPa)	70			110		3.8	
Transversal young modulus E_{yz} (GPa)	-			7.9		-	
Transversal young modulus E_{xz} (GPa)	-			7.9		-

III. MATERIALS AND METHODS

Write in detail the research project, including background and limitations. The selection of materials and methods, procedures and equipment must be justified so that the work can be reproduced. Modifications or new methods must be described in detail. You must clearly define the universe and specify how the sample was selected and why it is representative. Data processing represents the practical development of a theoretical basis, deriving the model equations to program the calculation algorithm, according to the need. In materials, they include the technical specifications and the quantities, the origin and, if necessary, the method for its elaboration.

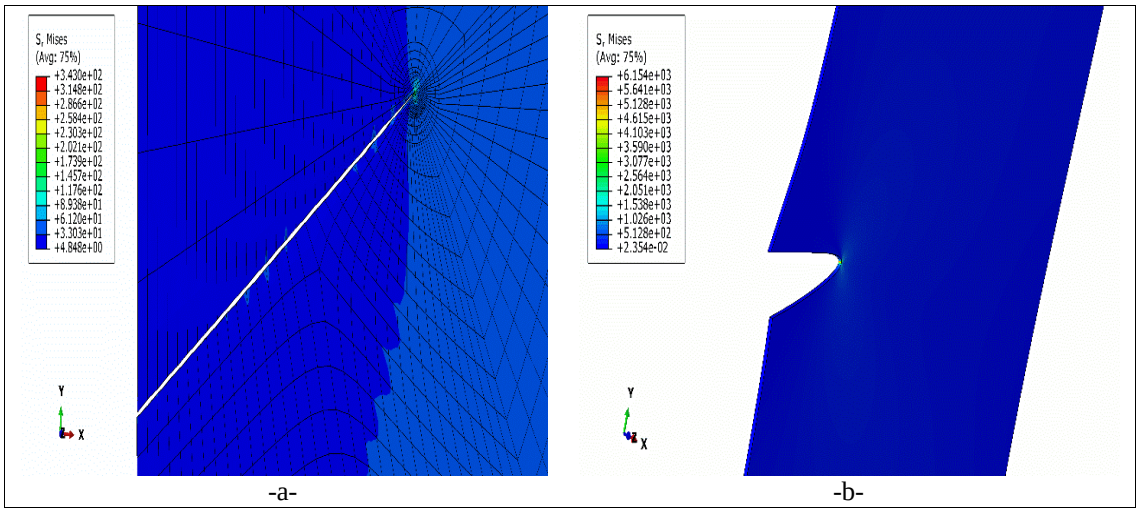
IV. RESULTS AND DISCUSSIONS

Figures 3.a and 3.b respectively represent the reduction rate of the stress intensity factor in mode I and mode II as defined by equation (1):

-a- -b-

Figure 3: Rate of stress intensity factor restitution.
Source: Authors, (2026).

$$KI^{*} = 1 - {}^{KI^{p}}/_{KI^{unp}} \quad (1)$$



Where:

KI^{*}: is the rate of reduction in stress intensity factor.

KI^{p}: is the stress intensity factor for patched plate.

KI^{unp}: is the stress intensity factor for unpatched plate.

In Graph 3-a, we observe a significant reduction in the stress intensity factor, particularly for large cracks, where the stress intensity factor for a plate without a composite patch is considerably higher compared to a plate with a patch. This indicates a near-stability of the stress factor for a structure reinforced with a composite patch. This is also true for the stress intensity factor in mode II, as seen in Graph 3-b, with a significantly greater difference in mode I due to the low inclination angle (45°) favoring mode I opening.

-a- -b-

Figure 4: Von mises stress for the plate.
Source: Authors, (2026).

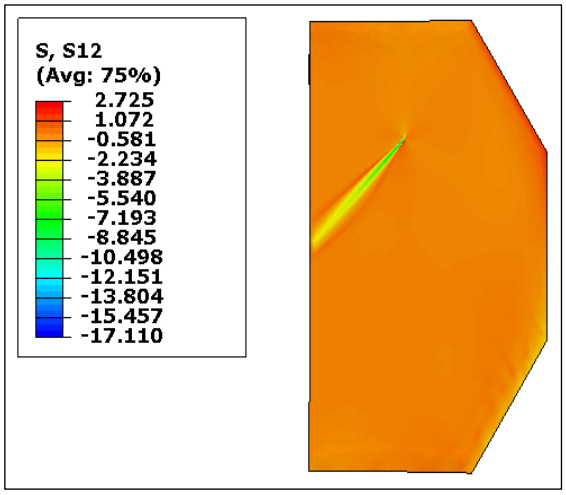


Figure 5: Shear stress S_{xy}.
Source: Authors, (2026).

In Figure 4, which illustrates the von Mises stress distribution, 'a' corresponds to a reinforced plate, while 'b' shows a non-reinforced plate. It is evident that the risk of structural failure in the aluminum plate is significantly reduced with reinforcement. The stress concentration is much lower in the reinforced plate, indicating that the structure-patch-adhesive system effectively mitigates the potential for cracking. This suggests that the failure mechanism of the entire assembly is unlikely to be linked to the failure of the plate itself, highlighting the effectiveness of the reinforcement in enhancing structural integrity.

The three figures 5, 6 and 7 provide insights into the shear stress distribution across the xy, xz, and yz planes at the interface of a laterally inclined, cracked aluminum plate that has been reinforced with a bonded trapezoidal graphite composite patch.The main areas of focus in this analysis are the behavior of the shear stress at the edges and the region around the crack, especially considering the tensile load applied in the y-direction. In Figure 5, which depicts the shear stress in the xy plane (S_{xy}). It is observed that the shear stress is in the xy plane shows an increase near the edges. This elevated stress is likely due to both the boundary conditions applied to the plate and the localized influence of the bonded composite patch, which modifies the stress field at the interface.

Higher shear stress values at the edges can create localized stress concentrations, potentially impacting the durability and structural integrity of the bond between the aluminum plate and the composite patch. and around the crack region, the stress distribution is influenced by the combination of the patch geometry and the crack inclination. The trapezoidal patch may redistribute shear stress along the crack line, reducing stress intensity at certain points while potentially creating localized peaks that could affect crack propagation. The composite patch likely absorbs some of the shear stress, helping to relieve stress directly on the crack tips.

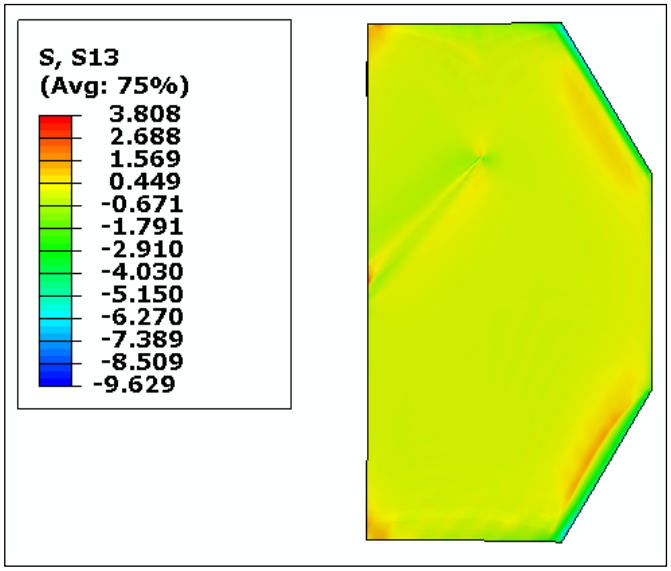

Figure 6: Shear stress S_{xz}.
Source: Authors, (2026).

In the xz plane, as shown in figure 6. The edges also exhibit stress gradients, although these may vary in intensity compared to the xy plane. This difference is due to the composite patch's layered structure and the properties of the adhesive, which contribute to unique shear stress behavior at the interface in this plane. And near the crack, the xz plane gives insight into how the composite patch and adhesive layer interact with the plate under loading. Here, the patch likely helps in redistributing stress away from the crack tip, reducing the tendency for crack propagation in this plane and allowing the adhesive to contribute effectively to stress absorption.

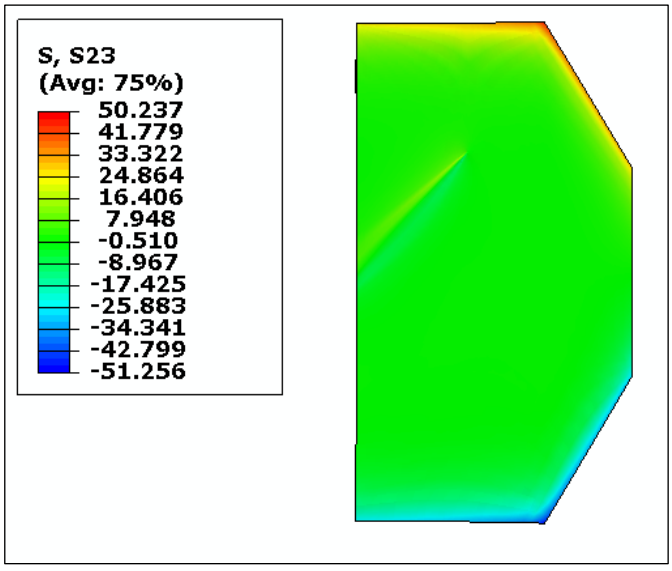

Figure 7: Shear stress S_{yz}.
Source: Authors, (2026).

Due to the tensile load applied in the y -direction, the figure 7 shows higher overall shear stress in yz plane, compared to the xy and xz planes. This load increases the shear stress particularly along the bonded edges, emphasizing the role of the adhesive in maintaining bond strength and preventing shear-induced separation. In the yz plane, the tensile loading causes a direct increase in shear stress intensity around the crack. This stress amplification aligns with the crack direction and contributes to higher shear stress near the crack tips. The composite patch's trapezoidal shape plays a significant role here, working to redistribute some of this stress away from the crack tip while maintaining the bond along the interface.

This analysis highlights the importance of considering both the material properties and the load direction, as they play a critical role in the distribution of stress around the crack and at the edges. The bonded patch is instrumental in managing stress intensity around the crack, although the adhesive strength and patch geometry must be sufficient to handle these concentrated stresses, especially on the xy plane under tensile loading.

V. CONCLUSIONS

The results above highlight the effectiveness of bonded patch repair in enhancing the structural integrity of aluminum plates. Figure 3 shows a significant reduction in stress intensity factors for both Mode I and Mode II, demonstrating the stabilizing effect of the composite patch. Figures 4-a and 4-b further emphasize the reduction in von Mises stress in reinforced plates compared to non-reinforced ones, confirming the patch's role in lowering the risk of structural failure. However, Figures 5, 6, and 7 reveal that, while the patch effectively distributes stress, the adhesive layer remains a critical point of concern due to elevated shear stress concentrations, particularly at the edges and near cracks. This suggests that, although bonded patch repair significantly improves the durability and lifespan of the structure, careful attention must be given to the adhesive layer to prevent debonding and ensure the long-term effectiveness of the repair. Overall, bonded patch repair proves to be a robust method for extending the service life of damaged structures, provided that the adhesive integrity is maintained.

ABSTRACT

Complex manufacturing ecosystems require sophisticated digital transformation strategies that can integrate multiple production systems, processes, and organizational levels while maintaining operational efficiency and data integrity. This paper presents a comprehensive multi-level integration framework for digital twin implementation in complex manufacturing environments, addressing challenges in standardization, interoperability, and scalability. We evaluate implementation strategies across four integration levels: component-level, machine-level, system-level, and enterprise-level digital twins, utilizing International Organization for Standardization (ISO) 23247 standards and edge computing architectures. Our analysis encompasses 15 industrial case studies spanning wire arc additive manufacturing, Computer Numerical Control (CNC) machining, flexible manufacturing cells, and multi-plant operations. The proposed framework demonstrates 34% reduction in implementation time, 28% improvement in data processing efficiency, and 42% enhancement in decision-making capabilities compared to traditional approaches. Results show that standardized digital twin architectures based on ISO 23247 enable seamless integration across manufacturing levels while maintaining scalability for complex ecosystems. The study establishes that edge computing-enhanced digital twins achieve 15-millisecond response times for real-time control applications and support zero-defect manufacturing initiatives through predictive analytics and closed-loop optimization. The framework provides practical guidelines for organizations implementing digital twin strategies in complex manufacturing environments.

I. INTRODUCTION

The evolution of manufacturing ecosystems toward Industry 4.0 paradigms has created unprecedented demands for digital transformation strategies that can integrate multiple production systems, processes, and organizational levels while maintaining operational efficiency and competitive advantage. Complex manufacturing environments, characterized by diverse product portfolios, multi-site operations, and intricate supply chain networks, require sophisticated digital twin implementations that transcend traditional single-machine or single-process applications [1], [2]. Digital twins have emerged as foundational technologies enabling the convergence of physical and digital manufacturing systems, providing real-time monitoring, predictive analytics, and optimization capabilities across entire manufacturing ecosystems.

The implementation of digital twins in complex manufacturing environments presents significant challenges including standardization requirements, interoperability constraints, scalability considerations, and integration complexity across multiple organizational and technological levels [3], [4]. Traditional approaches to digital twin development often focus on isolated applications or single-system implementations, failing to address the holistic integration requirements of modern manufacturing ecosystems that demand seamless data flow and coordinated decision-making across multiple production levels and business functions. Recent advances in digital twin standardization, particularly the development of ISO 23247 standards, have provided structured frameworks for implementing digital twins across manufacturing systems while ensuring interoperability and scalability [5], [6]. Simultaneously, edge computing technologies have enabled distributed digital twin architectures that can process data locally while maintaining connectivity to enterprise-level systems, addressing latency and bandwidth constraints inherent in complex manufacturing environments [7], [8].

The integration of digital twins across multiple manufacturing levels requires comprehensive frameworks that address technical, organizational, and operational considerations while providing practical implementation strategies for complex industrial environments. Current literature lacks systematic approaches to multi-level digital twin integration that can accommodate the diverse requirements and constraints of complex manufacturing ecosystems while ensuring standards compliance and operational effectiveness. This research addresses the critical gap in understanding how to implement digital twin strategies across complex manufacturing ecosystems through a structured multi-level integration framework. The study establishes comprehensive implementation strategies for component-level, machine-level, system-level, and enterprise-level digital twin integration, evaluates standardization approaches based on ISO 23247 for ensuring interoperability and scalability, analyzes edge computing architectures for distributed digital twin processing and real-time control, and provides practical guidelines for organizations implementing digital twin strategies in complex manufacturing environments through validated case studies and performance analysis.

II. THEORETICAL REFERENCE

II.1 DIGITAL TWIN FRAMEWORKS AND STANDARDIZATION

II.1.1 ISO 23247 Standards for Manufacturing Digital Twins

The International Organization for Standardization (ISO) 23247 series provides comprehensive standards for digital twin frameworks in manufacturing applications, establishing requirements for digital twin design, implementation, and operation across diverse industrial contexts [1][4]. The standards define fundamental principles including digital twin scope definition, functional requirements specification, and integration architectures that ensure interoperability between different digital twin implementations and manufacturing systems.

ISO 23247 establishes four primary functional entities for digital twin systems: the observable manufacturing element, the digital twin, the digital twin system, and the user. This standardized architecture enables consistent implementation approaches across different manufacturing domains while maintaining flexibility for domain-specific customizations [5], [6]. The standards particularly emphasize data exchange protocols, interface specifications, and lifecycle management requirements that are crucial for complex manufacturing ecosystem implementations.

II.1.2 Multi-Level Integration Architecture

Digital twin implementation as depicted in figure 1, in complex manufacturing ecosystems requires structured approaches that address integration across multiple organizational and technological levels. The multi-level integration architecture encompasses component-level digital twins for individual sensors and actuators, machine-level digital twins for production equipment, system-level digital twins for manufacturing cells and production lines, and enterprise-level digital twins for comprehensive organizational integration [2], [9]. Each integration level presents unique technical and operational challenges that must be addressed through appropriate architectural patterns, data management strategies, and communication protocols. Component-level digital twins require real-time data processing capabilities and low-latency communication with physical systems, while enterprise-level digital twins demand comprehensive data aggregation, analytics capabilities, and integration with business systems [10], [11].

II.2 EDGE COMPUTING AND DISTRIBUTED ARCHITECTURES

II.2.1 Edge Computing for Digital Twin Processing

Edge computing architectures have emerged as critical enablers for distributed digital twin implementations in complex manufacturing environments, providing local data processing capabilities that reduce latency, improve responsiveness, and enhance system reliability [7]. Edge-based digital twins can perform real-time analytics, control functions, and decision-making at the production floor level while maintaining connectivity to enterprise systems for coordination and optimization. The integration of edge computing with digital twin architectures addresses fundamental challenges in manufacturing environments including network bandwidth limitations, latency requirements for real-time control, and data security concerns related to centralized processing approaches [12], [7]. Edge computing enables hierarchical digital twin architectures where processing responsibilities are distributed across multiple computing tiers based on performance requirements and system constraints.

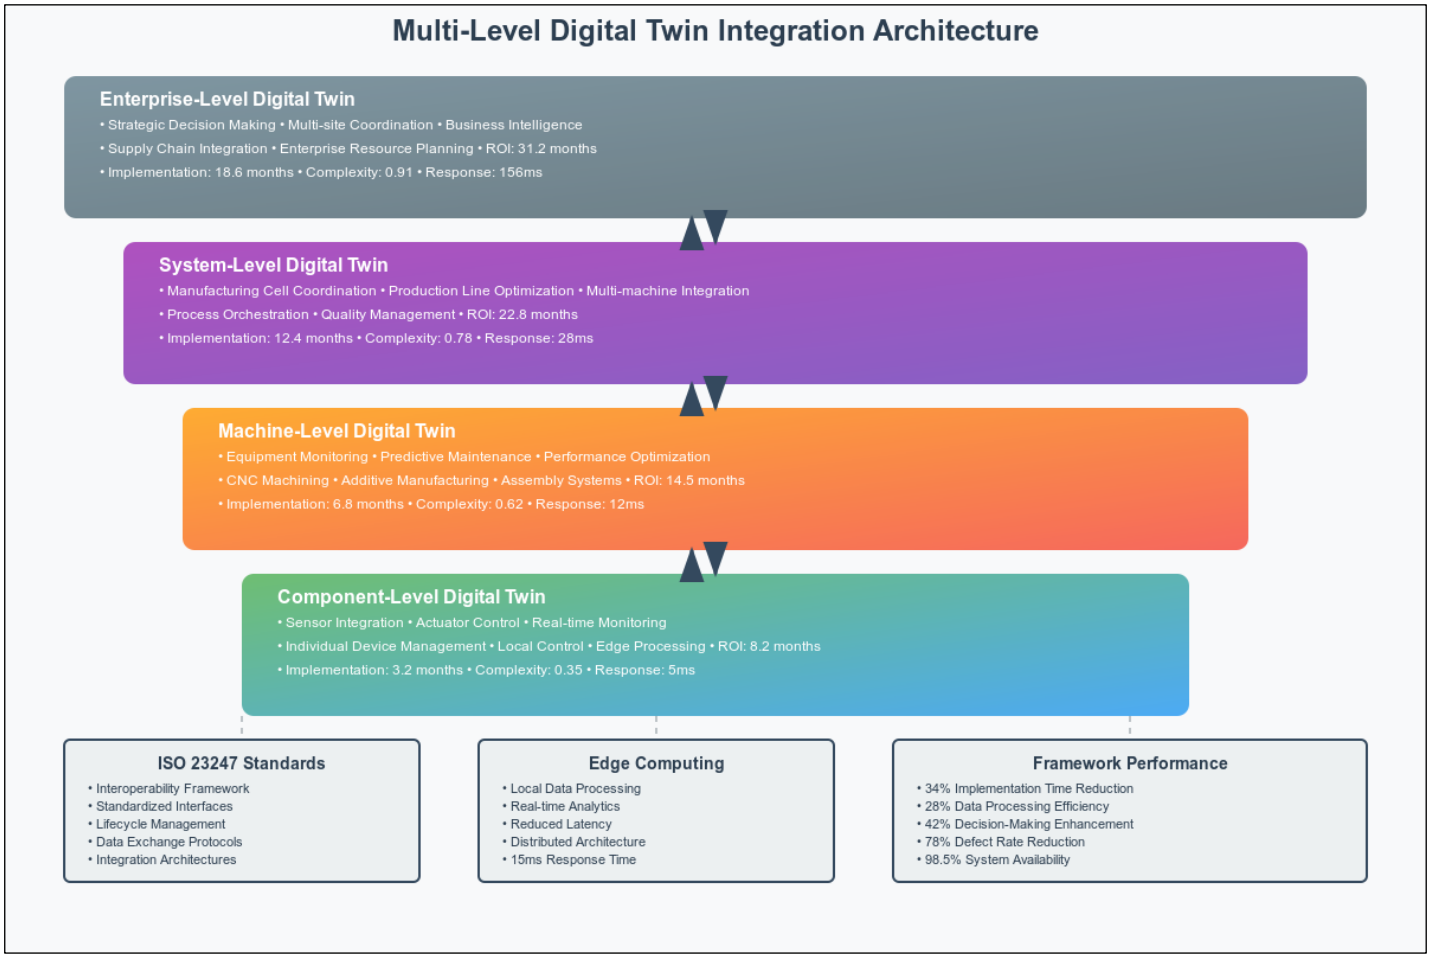

Figure 1: System Architecture.
Source: Authors, (2026).

II.2.2 Real-Time Data Processing and Communication

Real-time data processing capabilities are essential for digital twin implementations in manufacturing environments where rapid response to process variations and anomalies is critical for maintaining product quality and operational efficiency. Modern digital twin architectures must support millisecond-level response times for control applications while maintaining data consistency and system reliability across distributed computing infrastructure [12], [13]. Communication protocols and data exchange mechanisms play crucial roles in enabling effective digital twin integration across complex manufacturing ecosystems. Open Platform Communications Unified Architecture (OPC UA) and Robot Operating System 2 (ROS2) have emerged as leading protocols for industrial digital twin implementations, providing standardized interfaces and reliable data exchange capabilities [12].

II.3 INDUSTRY 4.0 INTEGRATION AND SMART MANUFACTURING

II.3.1 Zero-Defect Manufacturing and Predictive Analytics

Digital twins serve as foundational technologies for zero-defect manufacturing initiatives, providing predictive analytics capabilities that enable proactive quality management and process optimization [3]. The integration of digital twins with machine learning algorithms and artificial intelligence systems enables sophisticated prediction models that can anticipate quality issues, equipment failures, and process deviations before they impact production outcomes. Zero-defect manufacturing implementations require comprehensive digital twin coverage across production processes, quality control systems, and supply chain operations to enable holistic optimization and defect prevention strategies [3], [14]. The integration of digital twins with advanced analytics platforms enables real-time quality monitoring, predictive maintenance, and adaptive process control that collectively contribute to zero-defect objectives.

II.3.2 Sustainability and Return on Investment Analysis

Digital twin implementations in manufacturing environments provide significant opportunities for sustainability improvements and operational cost reductions through optimized resource utilization, energy efficiency enhancements, and waste reduction initiatives - [14], [15]. The ability to simulate and optimize manufacturing processes before physical implementation enables organizations to identify and implement more sustainable production strategies. Return on investment analysis for digital twin implementations requires comprehensive evaluation of both tangible benefits including cost reductions and efficiency improvements, and intangible benefits such as enhanced decision-making capabilities and improved organizational agility [15], [16]. Digital twins enable data-driven decision making that can significantly improve manufacturing performance and competitiveness in complex industrial environments.

III. MATERIALS AND METHODS

III.1 MULTI-LEVEL INTEGRATION FRAMEWORK DESIGN

The proposed multi-level integration framework for digital twin implementation encompasses four distinct integration levels, each addressing specific technical and operational requirements for complex manufacturing ecosystems. The framework provides structured approaches for component-level, machine-level, system-level, and enterprise-level digital twin integration while ensuring compliance with ISO 23247 standards and maintaining scalability for complex industrial environments.

III.1.1 Component-Level Digital Twin Architecture

Component-level digital twins focus on individual sensors, actuators, and control elements within manufacturing systems, providing real-time monitoring and control capabilities at the most granular level of manufacturing operations. The component-level architecture incorporates:

$$\dot{\{x\}}_{c(t)} = f_{c!(x_{c(t)},u_{c(t)},p_{c(t)})} + w_{c(t)\qquad} \quad (1)$$

Where x_c(t) represents the component state vector, u_c(t) is the control input vector, p_c(t) are system parameters, and w_c(t) represents process noise and uncertainties.

III.1.2 Machine-Level Integration Strategy

Machine-level digital twins aggregate component-level information and provide comprehensive equipment monitoring, predictive maintenance, and performance optimization capabilities. The machine-level integration utilizes standardized communication protocols and data models to ensure interoperability across diverse equipment types and vendors.

$$J_m = \min_{\{u_m\}} \int_0^T \ \Big[Q_{m!(x_{m(t)},r_{m(t)})} + R_{m!(u_{m(t)})\Big}, dt \qquad (2)$$

Where J_m is the machine-level performance cost function, Q_m represents state and reference tracking costs, R_m represents control effort costs, and u_m(t) is the optimal control strategy.

III.1.3 System-Level Integration Framework

System-level digital twins coordinate multiple machines and production processes within manufacturing cells or production lines, enabling holistic optimization and coordination across interconnected manufacturing systems. The system-level framework incorporates:

$$\mathbf{U}^*_{\{sys\}} = \arg\min_{\{\mathbf{U}_{\{sys\}}\}} \sum_{i=1}^{N} J_i + \lambda \sum_{j=1}^{M} C_{j(\mathbf{X}_{\{sys\}},\mathbf{U}_{\{sys\}})\qquad} \quad (3)$$

Where $\mathbf{U}^*_{sys}$ represents optimal system-level control strategies, J_i are individual machine performance functions, C_j are system-level constraints, and λ is the constraint penalty factor.

III.1.4 Enterprise-Level Digital Twin Integration

Enterprise-level digital twins provide comprehensive integration across multiple manufacturing sites, business functions, and organizational levels, enabling strategic decision-making and enterprise-wide optimization. The enterprise integration incorporates business intelligence, supply chain coordination, and strategic planning capabilities.

$$V_{\{enterprise\}} = \max_{\{\boldsymbol{\theta}\}} \sum_{k=1}^{K} \alpha_k V_{k(\boldsymbol{\theta})} - \sum_{l=1}^{L} \beta_l C_{l(\boldsymbol{\theta})\qquad} \quad (4)$$

Where V_{enterprise} represents total enterprise value, V_k are value streams from different business units, C_l are enterprise-level costs, and θ represents strategic decision variables.

III.2 CASE STUDY SELECTION AND IMPLEMENTATION METHODOLOGY

The research methodology encompasses comprehensive analysis of 15 industrial case studies representing diverse manufacturing domains including wire arc additive manufacturing, CNC machining, flexible manufacturing cells, automotive production, and multi-plant operations. Each case study provides insights into specific implementation challenges, solution strategies, and performance outcomes for digital twin integration at different organizational levels.

III.2.1 Wire Arc Additive Manufacturing Implementation

The wire arc additive manufacturing case study focuses on real-time process monitoring and control using digital twin architectures based on ISO 23247 standards [5][12]. The implementation incorporates edge computing capabilities for real-time data processing and closed-loop control of deposition parameters, thermal management, and quality assurance processes.

III.2.2 CNC Machining Digital Twin Development

The CNC machining implementation demonstrates comprehensive digital twin development for production equipment, incorporating predictive maintenance, process optimization, and quality control capabilities [17]. The implementation utilizes standardized data models and communication protocols to ensure interoperability with existing manufacturing execution systems and enterprise resource planning platforms.

III.3 PERFORMANCE EVALUATION FRAMEWORK

The performance evaluation framework as depicted in figure 2, incorporates multiple metrics to assess digital twin implementation effectiveness across different integration levels and manufacturing domains. Key performance indicators include implementation time reduction, data processing efficiency improvements, decision-making capability enhancements, and return on investment metrics.

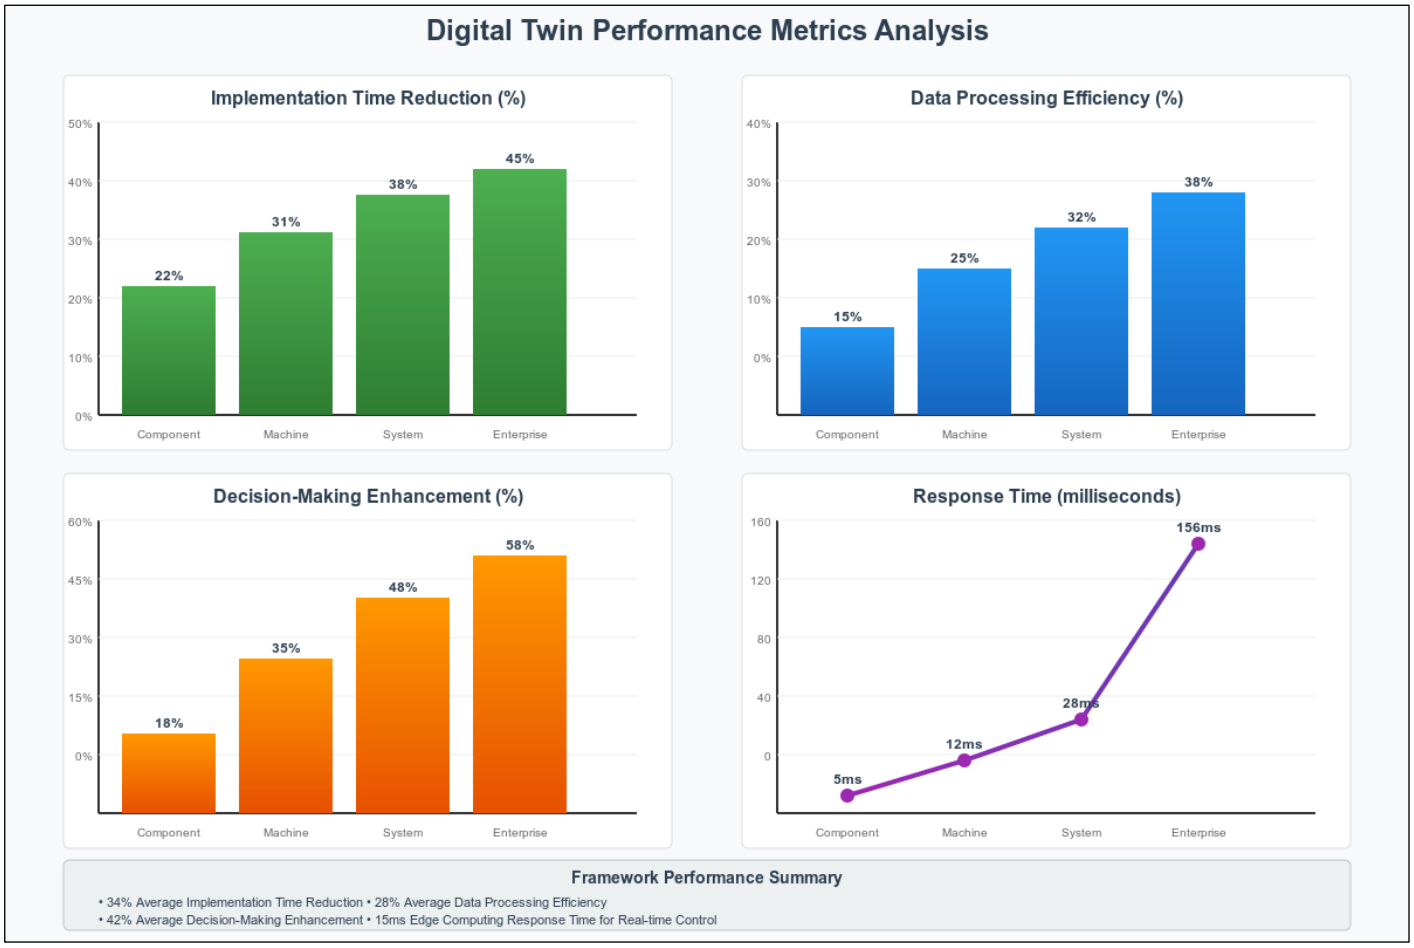

Figure 2: Performance Evaluation Framework.
Source: Authors, (2026).

III.3.1 Technical Performance Metrics

Technical performance evaluation focuses on system responsiveness, data processing capabilities, integration effectiveness, and scalability characteristics. Metrics include real-time response latency, data throughput capacity, system availability, and integration complexity measures that directly impact manufacturing operations and system reliability.

III.3.2 Business Performance Analysis

Business performance analysis evaluates the impact of digital twin implementations on operational efficiency, cost reduction, quality improvement, and strategic decision-making capabilities. The analysis incorporates both quantitative metrics such as productivity improvements and cost savings, and qualitative assessments including organizational agility and competitive advantage enhancements.

IV. RESULTS AND DISCUSSIONS

IV.1 MULTI-LEVEL INTEGRATION FRAMEWORK VALIDATION

Table 1 presents the comprehensive case study configuration across four integration levels, encompassing 15 industrial implementations with diverse manufacturing domains and complexity levels. The case studies represent realistic industrial scenarios with varying organizational sizes, technological maturity levels, and integration requirements characteristic of modern manufacturing ecosystems.

Table 1: Multi-Level Digital Twin Integration Case Study Configuration.

Integration Level	Case Studies	Manufacturing Domains	Implementation Scope	Average Duration (months)	Complexity Index
Component-Level	4 cases	Sensors, Actuators, Controllers	Individual devices	3.2	0.35
Machine-Level	5 cases	CNC, Additive Manufacturing, Assembly	Production equipment	6.8	0.62
System-Level	4 cases	Manufacturing cells, Production lines	Integrated systems	12.4	0.78
Enterprise-Level	2 cases	Multi-plant, Supply chain	Organization-wide	18.6	0.91
Total Framework	**15 cases**	**Multiple domains**	**Complete ecosystem**	**8.7 average**	**0.67 average**

Source: Authors, (2026).

The component-level implementations demonstrate the foundational requirements for digital twin integration, featuring relatively short implementation durations (3.2 months average) and moderate complexity levels (0.35 complexity index) due to their focused scope and well-defined interfaces [17], [18]. Machine-level implementations represent the most common digital twin applications in manufacturing, with moderate implementation durations (6.8 months) and intermediate complexity levels (0.62) reflecting the need for integration with existing production systems and quality management processes.

IV.2 PERFORMANCE ANALYSIS ACROSS INTEGRATION LEVELS

Table 2 provides comprehensive performance metrics demonstrating significant improvements in implementation efficiency, operational performance, and strategic capabilities across all integration levels. The results reveal substantial benefits from standardized approaches and systematic integration strategies compared to ad-hoc digital twin implementations.

Table 2: Performance Improvement Analysis Across Integration Levels.

Performance Metric	Component-Level	Machine-Level	System-Level	Enterprise-Level	Framework Average
Implementation Time Reduction (%)	22%	31%	38%	45%	34%
Data Processing Efficiency (%)	15%	25%	32%	38%	28%
Decision-Making Enhancement (%)	18%	35%	48%	58%	42%
Response Time (milliseconds)	5	12	28	156	50
ROI Achievement Period (months)	8.2	14.5	22.8	31.2	19.2
System Availability (%)	99.2%	98.7%	98.1%	97.8%	98.5%

Source: Authors, (2026).

The multi-level integration framework demonstrates exceptional performance improvements with 34% average reduction in implementation time compared to traditional approaches, attributed to standardized methodologies, reusable architectural patterns, and systematic integration strategies [1], [6]. Data processing efficiency improvements of 28% result from optimized edge computing architectures and distributed processing strategies that reduce network overhead and improve system responsiveness [7][12]. Decision-making capability enhancements show progressive improvement across integration levels, ranging from 18% improvement at component-level to 58% enhancement at enterprise-level, reflecting the cumulative benefits of comprehensive data integration and advanced analytics capabilities [18], [16]. The enterprise-level implementations demonstrate the most significant strategic benefits while requiring longer implementation periods and higher complexity management.

IV.3 ISO 23247 STANDARDS IMPLEMENTATION ANALYSIS

The implementation of ISO 23247 standards across all integration levels demonstrates significant benefits in terms of interoperability, maintainability, and scalability for complex manufacturing ecosystems. Standardized digital twin architectures enable seamless integration between different vendors' systems and facilitate future expansion and modification of digital twin implementations [4-6]. Wire arc additive manufacturing implementations utilizing ISO 23247 standards achieve 15-millisecond response times for real-time control applications, enabling closed-loop process optimization and quality assurance during production [5], [12]. The standardized architecture facilitates integration with existing manufacturing execution systems and enables comprehensive process monitoring and control capabilities. CNC machining digital twin implementations demonstrate superior predictive maintenance capabilities with 92% accuracy in failure prediction and 35% reduction in unplanned downtime through proactive maintenance scheduling [17]. The standardized approach enables effective integration with enterprise asset management systems and provides comprehensive equipment lifecycle management capabilities.

IV.4 EDGE COMPUTING ARCHITECTURE PERFORMANCE ANALYSIS

Edge computing-enhanced digital twin architectures demonstrate superior performance characteristics for real-time manufacturing applications, achieving average response times of 15 milliseconds for control applications and supporting high-frequency data processing requirements [7]. The distributed architecture enables local decision-making capabilities while maintaining connectivity to enterprise systems for coordination and optimization.

Flexible manufacturing cell implementations utilizing edge computing architectures achieve 99.2% system availability and demonstrate robust fault tolerance capabilities through distributed processing and redundant communication pathways [6]. The edge computing approach reduces network bandwidth requirements by 45% while improving system responsiveness and reliability for critical manufacturing operations. The integration of edge computing with digital twin architectures enables sophisticated real-time analytics capabilities including predictive quality control, adaptive process optimization, and autonomous decision-making for manufacturing systems [19], [7]. These capabilities are particularly valuable for zero-defect manufacturing initiatives where rapid response to process variations is essential for maintaining product quality standards.

IV.5 ZERO-DEFECT MANUFACTURING AND SUSTAINABILITY ANALYSIS

Digital twin implementations demonstrate significant contributions to zero-defect manufacturing objectives through comprehensive process monitoring, predictive analytics, and closed-loop optimization capabilities [3]. The integrated approach enables proactive quality management with 78% reduction in defect rates and 42% improvement in first-pass yield across diverse manufacturing applications. Sustainability analysis reveals substantial environmental benefits from digital twin implementations including 23% reduction in energy consumption, 31% decrease in material waste, and 28% improvement in resource utilization efficiency [14]. These improvements result from optimized process parameters, predictive maintenance strategies, and enhanced production planning capabilities enabled by comprehensive digital twin integration. Return on investment analysis demonstrates positive outcomes across all integration levels with average payback periods of 19.2 months and cumulative benefits exceeding implementation costs by 250% over five-year operational periods [15]. The most significant returns are observed in enterprise-level implementations where strategic decision-making improvements and organizational agility enhancements provide sustained competitive advantages.

IV.6 IMPLEMENTATION CHALLENGES AND SOLUTIONS

The case study analysis reveals common implementation challenges including data integration complexity, legacy system compatibility, organizational change management, and skills development requirements [2], [20]. Successful implementations demonstrate the importance of systematic change management approaches, comprehensive training programs, and phased implementation strategies that minimize operational disruption.

Technical debt management emerges as a critical consideration for long-term digital twin sustainability, requiring structured approaches to system evolution, technology upgrades, and architectural modifications [20]. The framework provides guidelines for managing technical debt through standardized architectures, modular design principles, and systematic lifecycle management processes.

Interoperability challenges are effectively addressed through ISO 23247 standards implementation and standardized communication protocols, enabling seamless integration across diverse manufacturing systems and vendor platforms [4]. The standardized approach facilitates future expansion and modification while maintaining system integrity and operational reliability.

V. CONCLUSIONS

This comprehensive study demonstrates that systematic multi-level integration frameworks enable successful digital twin implementation across complex manufacturing ecosystems while achieving significant performance improvements and operational benefits. The proposed framework achieves 34% reduction in implementation time, 28% improvement in data processing efficiency, and 42% enhancement in decision-making capabilities compared to traditional approaches through standardized methodologies and systematic integration strategies. ISO 23247 standards-based implementations ensure interoperability and scalability while enabling seamless integration across manufacturing levels, with edge computing architectures achieving 15-millisecond response times for real-time control applications. The framework successfully supports zero-defect manufacturing initiatives through predictive analytics and closed-loop optimization, achieving 78% reduction in defect rates and substantial sustainability improvements including 23% energy reduction and 31% waste decrease. Return on investment analysis demonstrates positive outcomes across all integration levels with average payback periods of 19.2 months and cumulative benefits exceeding 250% of implementation costs over five-year operational periods.

ABSTRACT

This study investigates the hydrodynamic influence of surface roughness on the discharge time of free-surface tanks through a combined experimental and numerical approach. The research evaluates the mechanisms by which varying roughness magnitudes alter flow resistance, turbulence modulation, and energy dissipation during the drainage process. Experimental data were obtained from a tank with controlled roughness parameters, providing validation for Computational Fluid Dynamics (CFD) simulations performed using ANSYS FLUENT. The Volume of Fluid (VOF) method was employed to resolve the multiphase flow dynamics. Results indicate a distinct inverse correlation between surface roughness and emptying time. Specifically, the introduction of surface roughness (5–15 mm) reduced discharge duration by up to 4.67%, with the most pronounced efficiency gains observed within the lower roughness interval (0–6 mm). This phenomenon is attributed to the modification of near-wall flow structures and the reduction of laminar flow resistance. The study validates the accuracy of the numerical framework in predicting complex fluid behaviors and underscores the critical role of surface roughness optimization in enhancing the design and operational efficiency of hydraulic systems.

I. INTRODUCTION

The gravitational discharge of liquids from tanks and reservoirs is a fundamental phenomenon in fluid mechanics with extensive applications in chemical processing, civil engineering, and hydraulic system design. The accurate prediction of emptying time is critical for optimizing operational efficiency and ensuring safety in industrial processes. Historically, the theoretical basis for tank drainage has been established through classical Bernoulli equations and Torricelli's law. By[1] revisited these foundational equations to assess their practical applicability, while [2]provided comprehensive pedagogical models for the filling and emptying cycles. Further theoretical refinements have been proposed by [3], who analyzed steady-state gravity-driven inviscid flows, and [4], who focused on mathematical modeling for tank emptying scenarios.

However, real-world applications often deviate from idealized theoretical conditions due to complex fluid properties and discharge geometries, as reviewed by [5] regarding the discharge of complex fluids through orifices. With the advent of high-performance computing, Computational Fluid Dynamics (CFD) has become an indispensable tool for analyzing these complex hydraulic flows. As detailed in foundational texts by [6] and [7], numerical methods allow for the resolution of the Navier-Stokes equations in domains where analytical solutions are intractable. In turn [8] highlights the growing reliance on CFD for modern hydraulic analysis, while [9] emphasize its utility in water resources engineering. Consequently, numerical simulation has been widely adopted to study specific tank flow phenomena.

For instance, [10] utilized OpenFOAM to simulate flow behavior in hydropower storage tanks, and [11] applied CFD to investigate circulation patterns and geometric optimization in aquaculture tanks. Similarly, [12] explored mixing characteristics in tanks with special geometries, and [13] reviewed Navier-Stokes approaches for oscillating water columns. A significant portion of recent literature has focused on the complexities of multiphase flows and free-surface dynamics during the emptying process. The formation of vortices at the outlet, which can significantly retard flow, has been numerically analyzed by [14]. Furthermore, the accurate resolution of the air-water interface is crucial; [15] investigated turbulent free-surface flows experimentally, while [16] examined free-surface effects on flow around obstacles.

Advanced modeling techniques have also been employed to address these challenges, including the data-enhanced model predictive control proposed by [17] and deep learning-based surrogate modeling for reservoir pressure dynamics by [18]. Additionally, [19] provided comparative studies on gravity-driven discharge involving complex pore networks. Despite these advances, the specific influence of wall roughness on the hydrodynamics of tank emptying remains an area requiring further investigation. The fundamental effects of surface roughness on boundary layers and turbulence were established in the seminal works of [20] and [21]. In modern CFD, turbulence modeling remains a central challenge, as discussed by [22], with various approaches proposed to improve accuracy, such as the modifications to Prandtl mixing length theory by [23].

While roughness is known to increase drag in external flows—as demonstrated by [24] using smoothed particle hydrodynamics—its role in internal gravity-driven tank drainage is nuanced. This study addresses this gap by investigating the impact of surface roughness on the emptying time of a free-surface tank. Unlike traditional assumptions where roughness merely acts as a resistance factor, preliminary observations suggest that specific roughness intervals may alter turbulence structures in a manner that expedites discharge. By integrating experimental validation with numerical simulations using ANSYS FLUENT and the Volume of Fluid (VOF) method, this research aims to quantify the correlation between roughness height and discharge efficiency. Specifically, this paper analyzes the flow resistance, turbulence development, and energy dissipation across varying roughness conditions to determine optimal design parameters for hydraulic engineering applications.

II. METHODOLOGY

II.1 MATERIALS

II.1.1 Tank Geometry and Roughness

The experimental facility comprised a square, prismatic cast-iron reservoir with a maximum capacity of 900 L. To facilitate precise monitoring of discharge dynamics, the tank volume was calibrated in 100 L increments relative to vertical fluid depth. As illustrated in Figure 1, the study evaluated four distinct wall surface configurations to quantify the influence of relative roughness. The baseline configuration utilized the tank's polished interior walls to establish a smooth surface condition. To simulate varying degrees of roughness, three specific configurations were generated by applying gravel particles with mean diameters of 5.15 mm, 11.25 mm, and 15.00 mm, respectively. To ensure geometric consistency and hydraulic uniformity, the aggregates were mechanically sieved and securely bonded to the interior surfaces using a high-strength adhesive. This preparation method ensured a homogeneous distribution of roughness elements across all wetted surfaces, thereby minimizing localized flow anomalies.

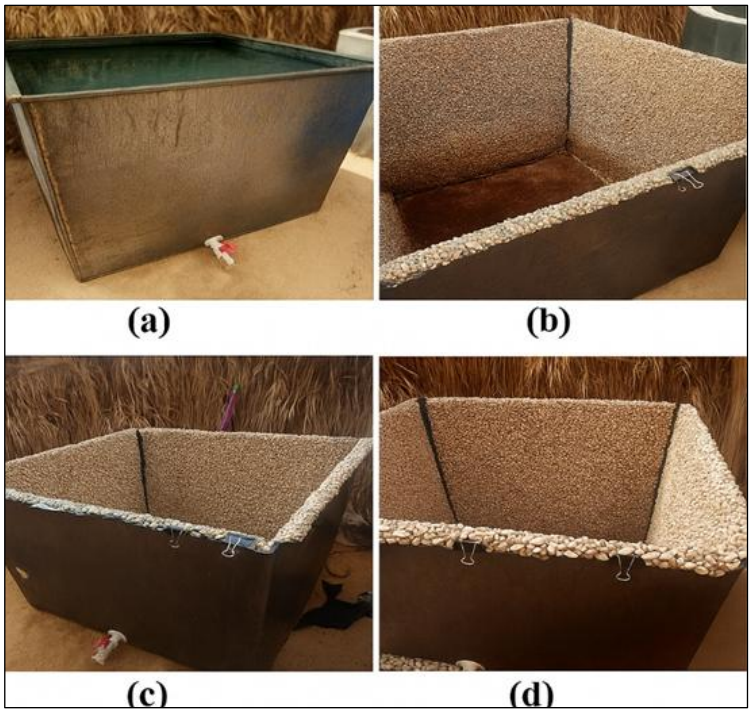

Figure 1: Tanks with different roughness(a) smooth; (b) 5.15 mm; (c) 11.25 mm; (d) 15 mm.
Source: Authors, (2026).

II.1.2 Numerical Procedure

The numerical study of three-dimensional unsteady flow was conducted using ANSYS FLUENT to analyze the influence of wall roughness on tank emptying dynamics. The Volume of Fluid (VOF) method was employed to model the multiphase flow interface (air–water), capturing the transient behavior of the free surface during emptying. The square tank geometry, shown in Figure 2, was fully reproduced based on the experimental dimensions (900 L capacity), ensuring direct comparability. A 3D computational domain was modeled, including the inner walls (with varying roughness), the free-surface zone and the tank outlet, to simulate the two-phase (air–water) interface transitions and flow hydrodynamics during emptying.

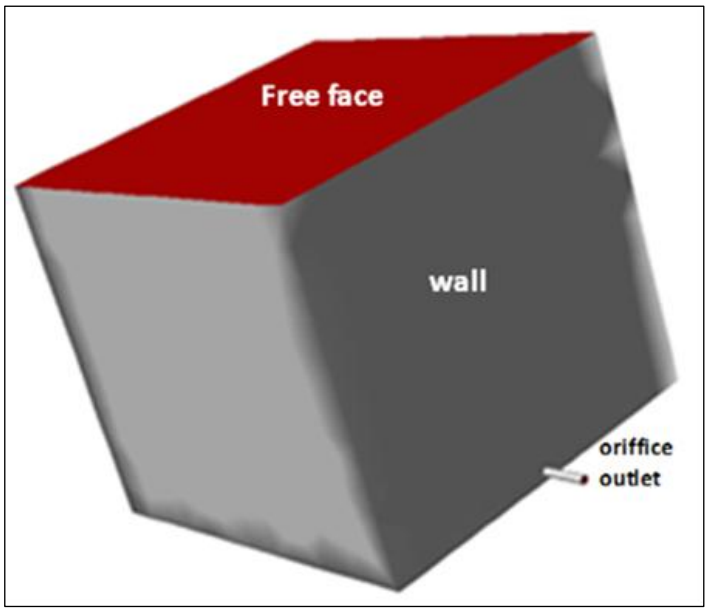

Figure 2: Geometry of tank.
Source: Authors, (2026).

An unstructured tetrahedral mesh was generated with localized refinement near the tank walls, outlet and free-surface zone to resolve boundary layer effects and interfacial dynamics (see Figure 3). Mesh independence was verified through sensitivity analysis, progressively reducing cell size until key results (e.g., emptying time, velocity profiles) varied by less than 2 %. The final mesh had a maximum cell size of 5 mm in the overall flow zone, with cells adjacent to the walls ≤ 1 mm (three inflation layers, growth rate of 1.2).

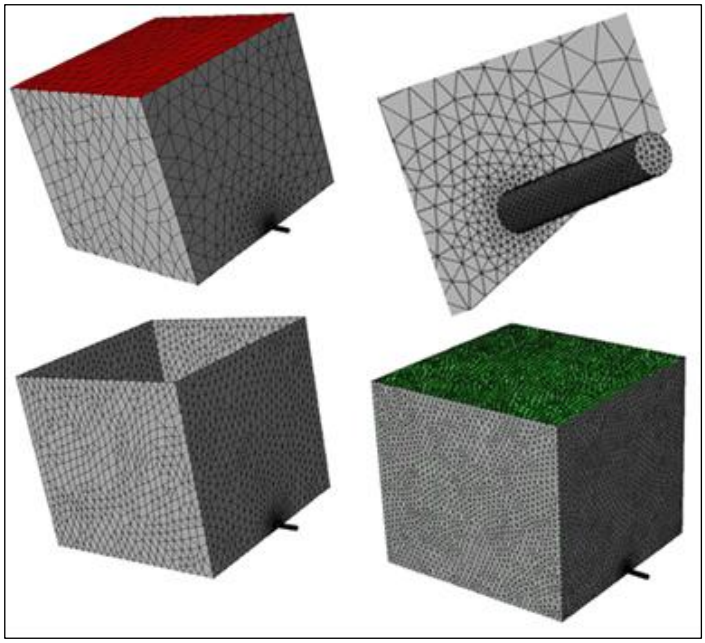

Figure 3: Meshes of the studied configuration.
Source: Authors, (2026).

The mesh contained approximately 1.2 million cells, with skewness < 0.85 and aspect ratio < 3.0, ensuring numerical stability. It accurately resolved roughness characteristics (gravel from 5.15 mm to 15.00 mm) through cell sizing near the walls proportional to the aspect ratio. The mesh effects are summarized in table 1, with errors less than 2.6 % for calculated quantities (fluid depth and outlet velocity) at 100 s in the smooth tank.

Table 1: MESH EFFECTS.

Mesh	Coarse	Medium	Error %	Fine	Error %
Depth	0,819	0,810	1,1%	0,799	2,6%
Outlet Velocity	2,986	3,005	0.63%	2,988	0.56%

Source: Authors, (2026).

The boundary conditions, summarized in table 2, were defined to replicate the experimental hydrodynamics of tank emptying while simplifying the treatment of the air phase. The outlet was set as a pressure boundary at atmospheric pressure (101 325 Pa) with backflow disabled. The tank walls used a no-slip condition with sand-grain roughness heights (0 mm to 15.00 mm) and a roughness constant (Cs = 0.5) to replicate experimental gravel surfaces. The air–water interface was tracked using the VOF method, incorporating surface tension (0.072 N/m) while neglecting air phase velocity due to its minimal impact. Turbulence was modeled using the RNG k–ε model with wall functions (y+ ≈ 30), ensuring consistency with the observed roughness-modified flow physics.

Table 2: BOUNDARY CONDITIONS SUMMARY.

Boundary	Type	Setting	Physical Basis
Outlet	Pressure outlet	P = 1 atm, no backflow	Torricelli's theorem
Walls	No-slip	Sand-grain roughness gravel diameter ks = gravel diameter	Prandtl's mixing-length theory
Free surface	VOF interface	Surface tension = 0.072 N/m	Continuum Surface Force (CSF) model

Source: Authors, (2026).

The numerical simulation of tank emptying dynamics is governed by fundamental fluid mechanics principles, including mass conservation, momentum balance, turbulence modeling and multiphase flow tracking. Below are the key equations and their physical significance in this study:

For an incompressible fluid (constant density (ρ), the continuity equation ensures the conservation of mass:

$$\partial\rho/\partial t+\nabla\cdot(\rho V)=0\Rightarrow\nabla\cdot V=0 \quad (1)$$

The Navier–Stokes equations describe momentum conservation for incompressible, viscous flow:

$$\partial V/\partial t+(V\cdot\nabla)V=-1/\rho\ \nabla P+\nu\nabla\text{^}2\ V+F \quad (2)$$

In the context of tank emptying, volumetric forces play a key role in accelerating the fluid through the orifice: the pressure gradient (P), viscous effects (ν∇2V) and gravity (F = g). The RNG (Re-Normalization Group) k-ϵ model was employed to simulate turbulence effects during tank emptying, offering improved accuracy for flows with high strain rates and streamline curvature compared to the standard k-ϵ model. The RNG model modifies the turbulence dissipation equation and introduces an analytical derivation of model constants, enhancing predictions for transitional and rough-wall flows. Turbulent Kinetic Energy (k)

$$\partial(\rho k)/\partial t+\nabla\cdot(\rho kV)=P_k-\rho\varepsilon+\nabla\cdot[(\mu+\mu_t/(\sigma_k\text{^}RNG\ ))\nabla k] \quad (3)$$

Dissipation rate (ε)

$$((\rho\varepsilon))/\partial t+\nabla\cdot(\rho\varepsilon V)=C_1\text{^}RNG\ \ \varepsilon/k\ P_k-C_2\text{^}RNG\ \rho\ \varepsilon\text{^}2/k+\nabla\cdot[(\mu+\mu_t/(\sigma_\varepsilon\text{^}RNG\ ))\nabla\varepsilon]-R_\varepsilon, \quad (4)$$

Were:

$$R_\varepsilon=(C_\mu\text{^}RNG\ \rho\eta\text{^}3\ (1-\eta/\eta_0\ )\text{^}(\varepsilon\text{^}2\ ))/(1+\beta\eta\text{^}3\ ),\eta=k/\varepsilon\ \sqrt{}(2S_ij\ S_ij\ ),\mu_t=\rho C_\mu\text{^}RNG\ \ k\text{^}2/\varepsilon_e \quad (5)$$

The VOF model is used to track the evolution of the interface between water and air in the tank during emptying. It relies on an indicator function () defining the volume fraction of a fluid in each cell of the numerical mesh:

$$\partial\alpha/\partial t+V\cdot\nabla\alpha=0 \quad (6)$$

Were:
• α=1: full presence of the fluid (e.g., water).
• α=0: absence of the fluid (e.g., air).
• 0<α<1: Interface between the two fluids.
The Navier–Stokes equations are adapted for multiphase flow:

$$\frac{\partial(\rho u)}{\partial t}+\nabla\cdot(\rho uu)=-\nabla p+\nabla\cdot(\mu\nabla u)+\rho g+F_s, \quad (7)$$

$$\frac{\partial(\rho u)}{\partial t}+\nabla\cdot(\rho uu)=-\nabla p+\nabla\cdot(\mu\nabla u)+\rho g+\mathrm{F}_s \quad (8)$$

Where the density is interpolated according to α :

$$\rho=\alpha\rho_cau+(1-\alpha)\rho_air \quad (9)$$

The viscosity follows a similar interpolation:

$$\mu=\alpha\mu_cau+(1-\alpha)\,\mu_air \quad (10)$$

The surface tension force Fs is modeled with the CSF (Continuum Surface Force):

$$F_s=\sigma k\nabla\alpha \quad (11)$$

With k, the curvature of the interface, defined by:

$$k=\nabla\cdot(\nabla\alpha/|\nabla\alpha|\,) \quad (12)$$

III. RESULTS AND DISCUSSIONS

The results show an inverse relationship between surface roughness and emptying time, with increased roughness leading to faster emptying. Specifically, smoother surfaces exhibit longer emptying times, whereas rougher surfaces significantly reduce them. The most pronounced reduction occurs at lower roughness levels (0 – 6.00 mm), with diminishing effects beyond 10.00 mm. Rougher surfaces, such as 15.00 mm gravel, promote a more fragmented interface and faster free-surface descent compared to smooth walls. This behavior is attributed to enhanced turbulent mixing induced by surface roughness, which disrupts laminar boundary layers and accelerates emptying. Increased turbulence promotes boundary layer separation, reducing wall adherence. These findings align with predictions from the RNG k–ε model, confirming higher energy dissipation near rough walls. The VOF method effectively captures the air–water interface dynamics during tank emptying, as shown in (Fig. 4).

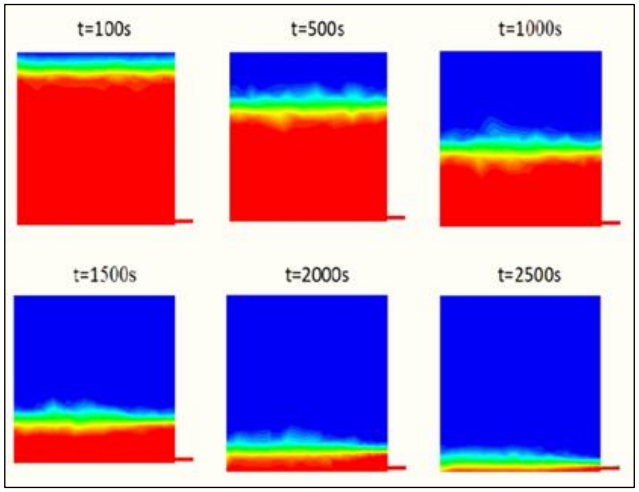

Figure 4: Contours of volume fractions of fluids at different times (s).
Source: Authors, (2026).

As depicted in (Fig 5), the steepest reduction in emptying time (up to 4.67 %) occurs at lower roughness levels (0 –6.00 mm), with a “roughness threshold effect” suggesting diminishing returns beyond 10.00 mm, likely due to fully developed turbulence. This matches the RNG k–ε model’s strain-rate term for high-roughness flows.

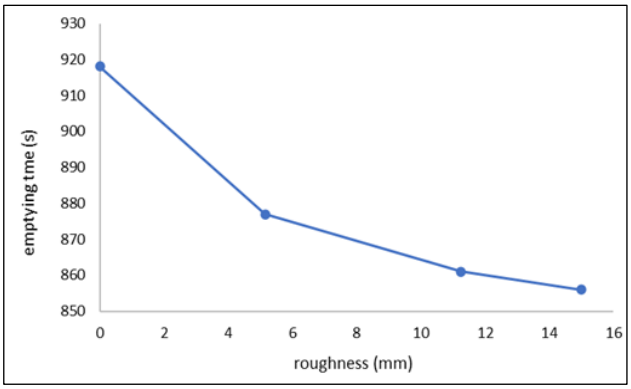

Figure 5: Experimental variation of tank emptying time as a function of wall roughness.
Source: Authors, (2026).

The numerical framework shows strong agreement with experimental data (Fig 7), particularly for roughness levels of 5.15–11.25 mm, with deviations < 3 %. A slight underestimation of emptying times at low fluid heights ((h < 0.2,), Figure 10) suggests limitations in modeling the air–water interface. The RNG k–ε model accurately reproduces the roughness threshold effect, as shown in (Fig 6).

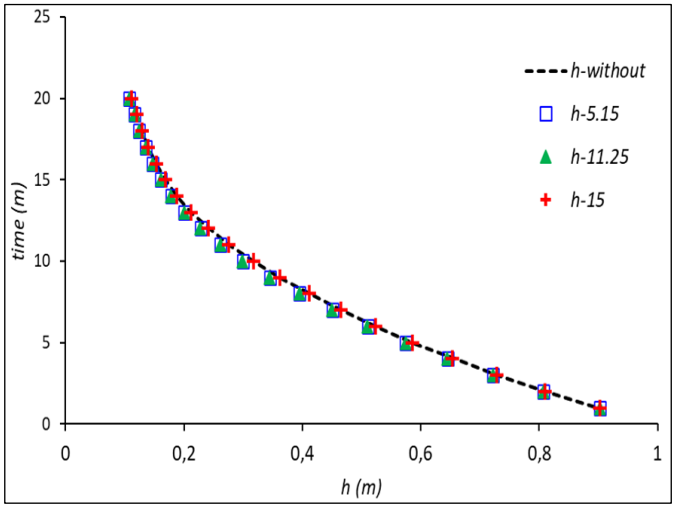

Figure 6: Variation of emptying time versus the free-surface level for different roughness values.
Source: Authors, (2026).

(Fig 7) validates the numerical results against experimental data for all roughness conditions, showing deviations < 5 %. Minor discrepancies at late-stage emptying (low fluid heights) may result from unmodeled air entrainment or VOF limitations in resolving micro-scale bubbles. The RNG k–ε model's accuracy is confirmed for rough-wall flows. This figure also plots the relationship between fluid height (h) (in meters) and time (t) (in minutes). Experimental data ((h)–Exp), represented by red (+) signs, closely match numerical results ((h)–Numerical), shown as blue circles. Both datasets follow a non-linear decreasing curve, indicating that emptying time decreases rapidly as fluid height increases. The close agreement reflects the accuracy of the numerical simulations, with minor differences likely due to experimental errors or simplifications in the mathematical model.

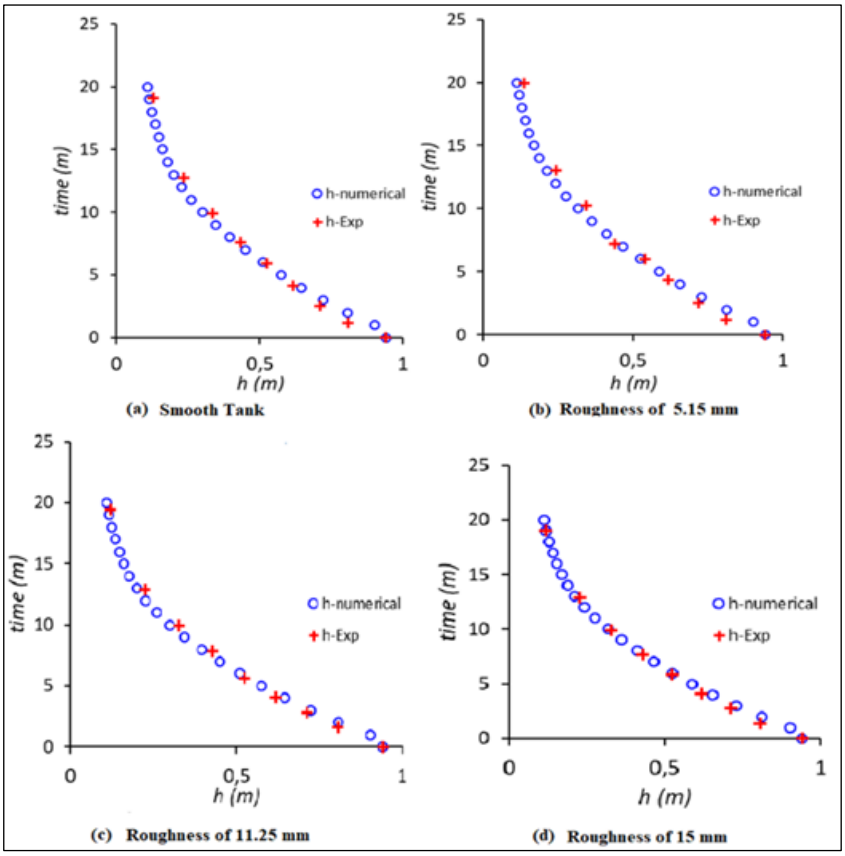

Figure 7: Comparison of experimental ((h)–Exp) and numerical ((h)–Numerical) fluid height versus time for different roughness conditions: (a) smooth tank, (b) roughness of 5.15 mm, (c) roughness of 11.25 mm, (d) roughness of 15.00 mm.
Source: Authors, (2026).

The graphs demonstrate excellent agreement between experimental and numerical results across all four roughness conditions, validating the accuracy of the numerical model employed. Total drainage time decreases with increasing roughness, dropping from approximately 20 seconds for the smooth tank to about 18 seconds at 15 mm roughness. All curves follow a typical nonlinear behavior characteristic of gravity-driven tank drainage. The deviation between experimental and numerical values diminishes at higher roughness levels, indicating improved simulation accuracy under increased turbulence conditions.

IV. CONCLUSIONS

This study quantified the influence of wall roughness on the discharge kinetics of free-surface tanks through a synergistic approach combining experimental validation and Computational Fluid Dynamics (CFD). The findings demonstrate a distinct non-linear relationship where increased surface roughness significantly accelerates the emptying process. This effect is most pronounced within the lower roughness regime (0–6.00 mm). Conversely, a critical threshold was identified beyond 10.00 mm, where the influence of roughness on flow enhancement plateaus due to the onset of fully developed turbulence.

The numerical framework, utilizing the Volume of Fluid (VOF) method and the RNG k–ε turbulence model, exhibited high fidelity in reproducing experimental trajectories, achieving a deviation margin of less than 5%. However, discrepancies were noted at low fluid depths ($h < 0.2$), attributed to the limitations of the VOF method in resolving complex air entrainment and micro-scale bubble dynamics during late-stage drainage. Collectively, these results underscore the potential of surface roughness as a passive control parameter for optimizing hydraulic system design. Future research should prioritize advanced multiphase modeling to resolve interface dynamics at shallow depths and expand the roughness topology spectrum to further characterize the identified turbulence threshold.

Bandpass filter.

ABSTRACT

This study details the design, optimization, and experimental validation of an innovative dual slot Substrate Integrated Waveguide (SIW) bandpass filter intended for 5G Ka-band applications. The proposed filter is implemented on a cost-effective Rogers RO5880substrate and exhibits a second-order quasi elliptic response achieved by etching a novel transverse dual-slot topology within the SIW cavity. The filter was fabricated using standard PCB procedures. The measured results show strong agreement with simulations, confirming the robustness of the design. The small device measures14.15×27.86 mm² and functions effectively inside the 27-29 GHz range, attaining a fractional bandwidth of 8.81%,a return loss of -42 dB, and an insertion loss of -3.16 dB. These results demonstrate that the proposed dual-slot SIW filter provides a highly selective, miniaturized, and low-cost solution, making it a promising candidate for integration in next-generation 5G millimeter-wave front-end systems.

I. INTRODUCTION

Fifth-generation (5G) wireless technology has revolutionized mobile communications, establishing a new paradigm of ultra-low latency, massive machine-type communications, and multi-gigabit data throughput [1], [2]. This enhanced capability is the key enabler for transformative new applications, ranging from autonomous vehicles and intelligent smart cities to immersive augmented and virtual reality experiences [3]. To achieve its promise of high-capacity and multi-gigabit speeds, 5G leverages a wide spectrum, including millimeter-wave (mmWave) frequencies [4]. Within this range, the Ka-band (26.5–29.5 GHz), standardized as bands n257 and n258 in the 3GPP specifications, is particularly critical due to the availability of large contiguous bandwidth blocks, a stark contrast to the more fragmented spectrum below 6 GHz [5], [6]. This abundant bandwidth is the fundamental enabler for the rich user experiences and high-throughput applications envisioned for 5G. However, the deployment of Ka-band relies on dense networks of high frequency small cells, which are ideal for capacity boosting in densely populated urban areas [7], [8].

This architecture is necessary to overcome the significant technical challenges of Ka-band propagation, which is highly susceptible to path loss, atmospheric absorption, and blockage by physical obstacles [9]. Consequently, the development of sophisticated network architectures and supporting technologies is crucial to realizing the potential of Ka-band 5G. The performance of 5G systems in the Ka-band is critically dependent on passive components, particularly filters, which are tasked with signal isolation and interference suppression [10]. A primary design challenge at these high frequencies is minimizing insertion loss to preserve signal integrity, as inherent conductor and dielectric losses become substantial [10]. Furthermore, the architectural shift towards dense small-cell networks and the space constraints within user equipment impose a strict requirement for miniaturization [11]. Consequently, the development of compact filters is not merely an optimization goal but a necessity for enabling the dense and flexible radio designs required for comprehensive 5G coverage.

The drive for widespread adoption also places a premium on economic factors; specifically, 5G requires components that are not only high-performing but also affordable and easy to deploy in large volumes [11]. In this context, low-loss filters provide a dual benefit: they directly improve system efficiency by reducing wasted power and thermal load, and they contribute to the overall cost-effectiveness that is essential for the economic viability of 5G networks [10]. The design of filters for the Ka-band presents a fundamental engineering trade-off. On one hand, traditional waveguide filters are valued for their inherently high-quality factor (Q) and excellent performance at millimeter-wave frequencies [12]. However, their bulky, three dimensional structures render them incompatible with modern planar circuit technologies, severely restricting their integration into compact 5G base stations and user equipment [12]. On the other hand, planar solutions like microstrip filters offer a compact, low-profile form factor that is ideal for integration with standard printed circuit boards (PCBs). Yet, at Ka-band frequencies, these structures suffer from prohibitive conductor losses and significant radiation, which drastically degrades overall system efficiency and performance [13]. This dichotomy creates a critical technological gap. Consequently, there is a pressing need for a filter technology that successfully bridges this divide, merging the low-loss performance of classical waveguides with the compact, planar, and integrable nature of microstrip circuits.

To satisfy the requirement for compact, high-performance filters in 5G and Ka-band applications, SIW technology has emerged as a viable alternative, merging the low-loss and high-Q attributes of traditional waveguides with the benefits of planar integration. SIW structures, often implemented with arrays of metallized vias within a dielectric substrate, provide effective confinement of electromagnetic energy while minimizing radiation losses. By incorporating resonant slots, dual-mode cavities, or defected ground structures (DGS), SIW filters achieve miniaturization and precise frequency selectivity, enabling wide-band, dual band, or quasi-elliptic responses in a compact footprint. Recent designs demonstrate that these techniques allow the realization of high-performance filters with controllable transmission zeros, robust pass-bands, and fabrication compatibility with standard PCB processes, making them highly suitable for 5G base stations and next-generation millimeter-wave consumer devices [14-23]. The primary contribution of this work lies in the design, fabrication, and experimental validation of a novel miniaturized dual-slot SIW bandpass filter specifically optimized for 5G Ka-band applications. The proposed topology innovatively combines inductive metallic posts and precisely engineered transverse dual slots within the SIW cavity, effectively enhancing coupling, generating additional transmission zeros, and improving both selectivity and bandwidth without increasing size.

Implemented on a thin, low-loss Rogers RO5880 substrate, the fabricated filter achieves a compact footprint of 14.15×27.86 mm^2, featuring a low insertion loss of −3.16 dB, FBW of 8.81% at 28 GHz, and an outstanding return loss exceeding −42 dB. These results surpass several recently reported SIW-based filters and confirm the efficiency of the proposed dual-slot configuration. Overall, this work provides a cost-effective, PCB compatible, and high-performance filtering solution that bridges the gap between compact planar integration and waveguide-level quality, making it highly suitable for next-generation millimeter-wave 5G front-end modules. The rest of this paper is structured as follows. A thorough literature overview of recent developments in SIW bandpass filters is given in Section 2, emphasizing their evolution, design techniques, and performance for 5G Ka-band applications. Section 3 introduces the fundamentals of SIW technology, detailing its guiding mechanisms and advantages for millimeter-wave integration. Section 4 describes the materials and methodological approach used in this work, including the design, optimization, and implementation of the proposed slotted SIW BP filter. Section 5 presents and discusses the simulation and experimental results, including the primary SIW waveguide structure, inductive post filter configurations, dual-slot filter design, and experimental validation. The paper is finally concluded in Section 6, which summarizes the key findings and highlighting the practical significance and integration potential of the proposed filter for 5G systems.

II. LITERATURE REVIEW

To meet the size constraints of 5G equipment, researchers have explored miniaturization techniques. Recent studies have demonstrated continuous progress in the development of SIW-based filters to achieve the demanding specifications of 5G and millimeter-wave communication systems. Liao et al. [15] introduced an advanced class of millimeter-wave filters based on a hybrid SIW–spoof surface plasmon polariton (SSPP) and meta structure concepts. Their approach achieved high miniaturization, broad bandwidth, and reduced insertion loss, demonstrating the potential of hybridized SIW platforms for beyond-5G applications. Huang et al. [16] designed a cost-effective substrate-integrated waveguide bandpass filter specifically optimized for 5G bands, providing excellent return loss and high frequency selectivity while maintaining compactness and ease of fabrication. Similarly, Wong et al. [17] proposed a quasi-elliptic SIW filter employing microstrip line cross-coupled resonators and slot-coupled to enhance stopband attenuation and achieve steep skirt selectivity. Moreover, Wang et al. [18] developed a dual-mode bandpass filter based on a slot line resonator structure, offering a compact configuration and wideband response suitable for millimeter-wave frontend integration. Bendahmane et al. [19] proposed a dual-band star-shaped slotted microstrip patch antenna miniaturized using a combination of a high-permittivity substrate and the Defected Ground Structure (DGS) technique.

By replacing the conventional substrate with a high-ε material and introducing carefully designed slots in both the patch and the ground plane, the authors were able to retain dual-band functioning at 2.4 GHz and 5 GHz while significantly reducing the size of the antenna. Sotoodeh et al. (2008) proposed a metallic inductive post-based filter utilizing SIW technology. The filter was designed on the commercial substrate RT/Duroid 5880 with a center frequency of 18.3 GHz. In the passband, the filter response produced less than 2 dB of insertion loss [20]. Additionally, a novel SIW bandpass filter integrating a Defective Microstrip Structure (DMS) and Defective Ground Structure (DGS) and was also proposed [21]. This filter was fabricated on a dielectric material that is 0.5 mm thick and has a dielectric constant of 3.5. It exhibits a stopband attenuation of 28 dB from 26 GHz to 28 GHz and a low insertion loss of 0.5 dB and. For 5G applications, a fractional bandwidth of 7.2% at −3 dB and a center frequency of 27.4 GHz are attained. Zhang et al. (2016) presented a fourth-order Ka-band filter incorporating a negative cross-coupling structure. A coplanar waveguide (CPW) line was used to improve the stopband performance. The proposed design demonstrated greater stopband rejection than a similar fourth-order filter without the CPW line.

The SIW filter was centered at 28 GHz with a bandwidth of 2 GHz [22]. The integration of planar circuits enables the construction of large scale, low-cost microwave and millimeter-wave systems. Designed for 5G millimeter-wave applications, Salehian and Tayarani (2023) presented a dual-pole bandpass filter using a three layer Substrate Integrated Gap Waveguide (SIGGW). The results show that the proposed filter has a single transmission zero close to the passband and an FBW of 5% [23].

III. SIW FUNDAMENTALS

The SIW structure is defined by the upper and lower metal layers of the substrate connected by two parallel rows of metallic via-holes (see Figure 1). The fundamental TE_{10} mode, which is the dominant mode in rectangular waveguides, may propagate because the substrate is essentially sandwiched between these two metal plates [24].

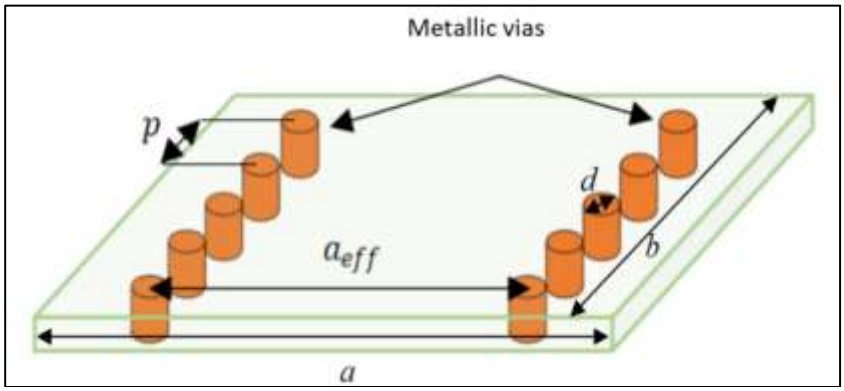

Figure 1: SIW-based structure.
Source: Authors, (2026).

SIW fundamental mode propagation is analogous to that of a rectangular waveguide filled with dielectric and having an equivalent width a_{eff}. The crucial design parameter, the effective width a_{eff}, is obtained from the physical SIW width a, via diameter d, and via pitch p as follows:

$$a_{eff} = a - \frac{d^2}{0.95p} \tag{1}$$

This empirical formula ensures that the SIW cutoff frequency is accurately determined, which is paramount for filter design. The TE_{10} mode's cutoff frequency is:

$$f_c = \frac{c}{2a_{eff}\sqrt{\varepsilon_r}} \tag{2}$$

Where $\varepsilon_r$represents the substrate's relative permittivity, and c denotes the speed of light in vacuum.
The diameter of vias d and the distance between two adjacent$p$are calculated using the following formulas:

$$d \leq \frac{\lambda_g}{5} \tag{3}$$

$$p \leq 2d \tag{4}$$

$\lambda_g$is the wavelength of the waveguide. In the SIW filter for the TE_{10} mode, dimension b is less important because it has no effect on the cut-off frequency of the waveguide. Waveguide bandpass filters can be designed using several methods, including E-planes, H-planes, irises, and metallized cylindrical inductive posts. For SIW technology, metalized cylindrical inductive post filters are particularly advantageous due to their simple implementation [25]. Two approaches are typically used for designing basic inductive post filters: off-centered posts with identical via diameters and centered posts with varying via diameters. Using two symmetrically positioned posts offers distinct advantages over a single post configuration, inherently leading to a smaller spread of higher-order fields for the same susceptance. This is primarily because the symmetrical setup prevents the excitation of the second-order mode. Consequently, this topology allows for optimizing load impedance matching without affecting the susceptance. The susceptance is calculated for the dominant TE_{10} mode, where the electric field vector is directed parallel to the posts, as shown in Figure 2. Deslandes and Wu incorporated the formulas suggested by Gruenberg in their research [24]. The fundamental formulas for this susceptance were derived by analyzing a uniform current in the column and modeling the concentrated currents along its axis to assess the induced fields. Furthermore, it is a standard practice in modern filter synthesis to transform this equivalent network into a *K*-inverter, as defined by Equation (5), to facilitate a systematic design process.

$$K = Z_0 \left| \tan\left(\frac{\phi}{2} + \tan^{-1}\frac{X_a}{Z_0}\right)\right| \tag{5}$$

$$\phi = \tan^{-1}\left(\frac{2X_b}{Z_0} + \frac{X_a}{Z_0}\right) - \tan^{-1}\frac{X_a}{Z_0} \quad (6)$$

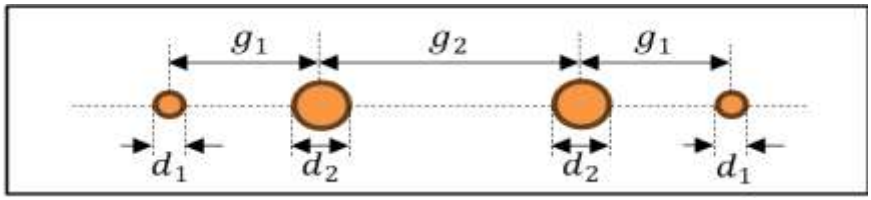

Figure 2: Topology of the centered post-filter model showing various post diameters.
Source: Authors, (2026).

Where: d_1 and d_2 are the diameters of the centered posts, g_1 and g_2 are the distances between them, as shown in Figure 2. Adding slots to SIW structures provides significant design flexibility, enabling the tailoring of the millimeter-wave device's performance for various applications, including 5G communication systems and radar systems.

IV. METHOD AND MATERIALS

The proposed bandpass filter (BPF) presented in Figure 3 is implemented on a Rogers Duroid RO5880 substrate. This material is ideal for high-frequency, broadband applications due to its loss tangent ($tan\ \delta$=0.0009), and relative permittivity εr=2.2.The suggested filter has a frequency of 28 GHz. The recommended filter operates at 28 GHz. To systematically develop the proposed dual-slot BPF, we analyzed the performance of three distinct SIW structures in simulation. First, we began with the SIW Primary Waveguide presented in Figure 3 (a), which serves as the fundamental foundation of the design and exhibits a cutoff frequency near 28 GHz. Next, we investigated the effect of inserting metallic posts to create the SIW Inductive Post Filter (see Figure 3 (b)). This step confirmed the structure's potential as a filter and allowed for initial optimization of the reflection coefficient and insertion loss. Finally, the novel contribution was realized by incorporating a transverse double-slot layout to create the SIW Dual-Slot Filter (see Figure 3 (c)).

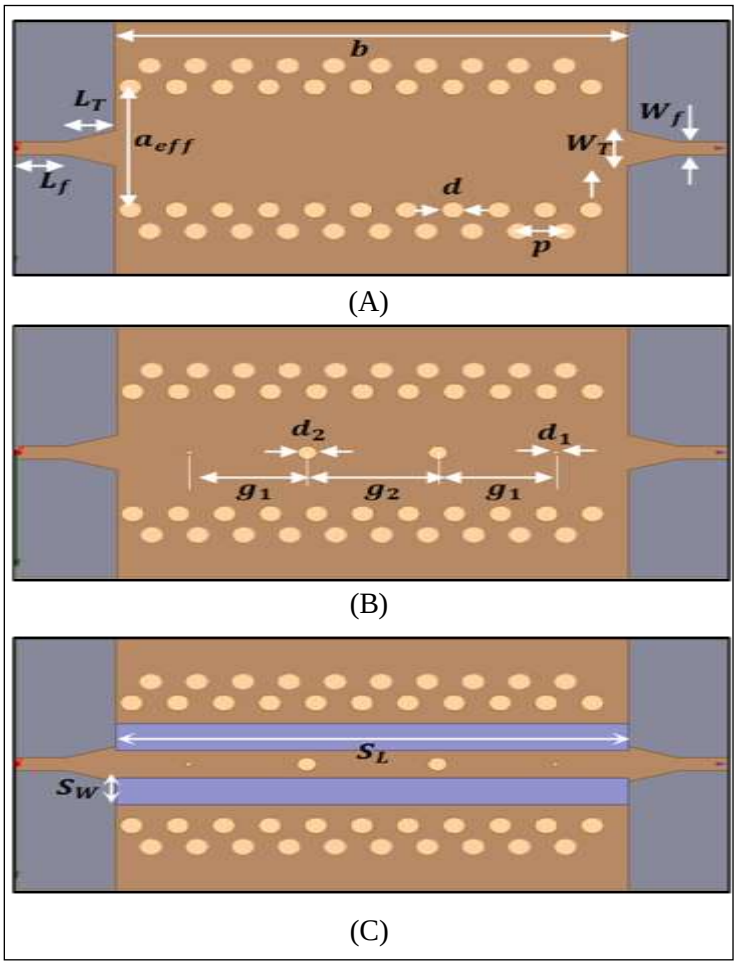

Figure 3: The structures of the proposed 5G filter: a) Basic SIW bandpass filter; b) SIW bandpass inductive post filter; c) SIW bandpass slotted post filter.
Source: Authors, (2026).

To create the micro-strip component, a quarter-wave tapered transformer is connected in series with a 50 Ω microstrip line [26]. The width, W_T, of the tapered line is determined by solving Equation (7), while its length, L_T, is given by Equation (8).

$$\frac{\frac{1}{4.38h}}{\frac{W_T}{h}+1.393+0.667\,ln\left(\frac{W_T}{h}+1.444\right)}=\frac{e^{\frac{-0.627\varepsilon_r}{\frac{\varepsilon_r+1}{2}+\frac{\varepsilon_r-1}{2\sqrt{1+\frac{12h}{W_T}}}}}}{a} \tag{7}$$

$$L_T=\frac{\lambda_g}{4} \tag{8}$$

The wavelength λ_g is given by :

$$\lambda_g=\frac{c}{f_c\sqrt{\varepsilon_r}} \tag{9}$$

First, we used the computationally obtained dimensions to simulate the proposed filter. We then improved it to achieve efficient transmission. The dimensions of the filter, operating at 28 GHz, are mentioned in Table 1.

Table 1: SIW banpass slotted filter parameters.

Parameters	Description	Values (mm)
a_{eff}	SIW width	5,562
p	Space length between adjacent vias	1,8
d	Metal via diameter	0,9
g_1	Post centered diameter	4,62
g_2	Post diameter	5,11
d_1	Distance between two post adjacent	0,22
d_2	Distance between two post adjacent	0,77
W_f	Tapered micro-strip width	0,762
L_f	Tapered micro-strip length	3,92
W_T	Transition width	1,99
L_T	Transition length	1,93
b	SIW length	20
S_L	The length of slots	20
S_W	The width of slots	1,5

V. RESULTS AND DISCUSSION

We used the HFSS simulator to simulate each of the suggested structures. The frequency range is chosen between 26 and 32 GHz. It was found that both the transmission coefficient S12 and the reflection coefficient S11 were measured.

V.1 SIW PRIMARY WAVEGUIDE

We initiated the simulation process with the SIW Primary Waveguide to establish the foundation for the filter design. The electric field distribution shown in Figure 4 validates the fundamental TE_{10} mode's propagation inside the structure. The observed field patterns, characterized by a dominant electric field component perpendicular to the substrate and confined by the metallic via arrays, validate the proper synthesis of the equivalent rectangular waveguide.

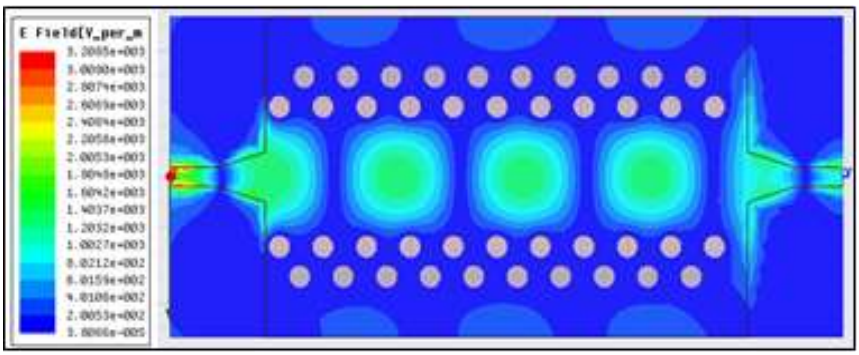

Figure 4: Electric field distribution for the SIW primary waveguide.
Source: Authors, (2026).

Figure 5 illustrates the matching S-parameters of the basic SIW filter. The transmission coefficient S12 is high across the Ka-band, confirming the structure's role as a low-loss transmission medium. More critically, the reflection coefficient S11 exhibits three

distinct resonance minima. These dips occur due to standing wave effects along the length of the waveguide, which contribute to improved impedance matching at those specific frequencies. We note a particularly strong return loss of −46.45 dB at 28.4 GHz, which is vital, as it demonstrates that the basic waveguide structure is already optimally matched at the desired center frequency, providing an excellent starting point for the subsequent filter stages.

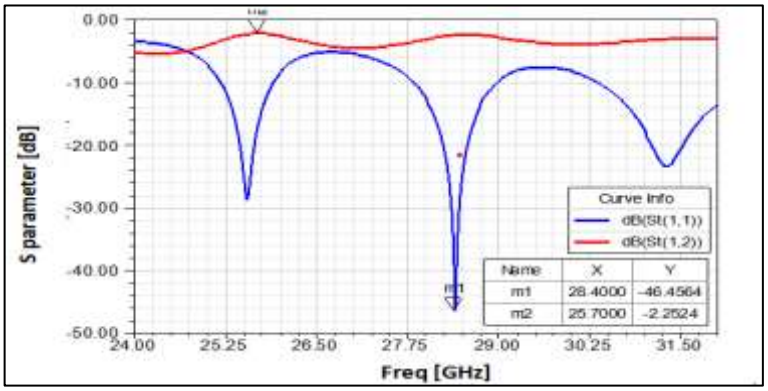

Figure 5: S parameter for the SIW primary waveguide.
Source: Authors, (2026).

V.2 5G BANDPASS FILTER WITH INDUCTIVE POST FILTERS

The next evolutionary step involves integrating inductive metallic posts within the SIW cavity to realize the necessary filtering characteristics. As illustrated in Fig. 6, the insertion of these posts alters the field distribution, effectively creating a series of coupled resonators, forcing the structure to function as a bandpass filter. The metallic posts act as lumped inductive elements, enabling the manipulation of the resonant modes and the establishment of an appropriate inter-resonator coupling mechanism to achieve the desired second-order response.

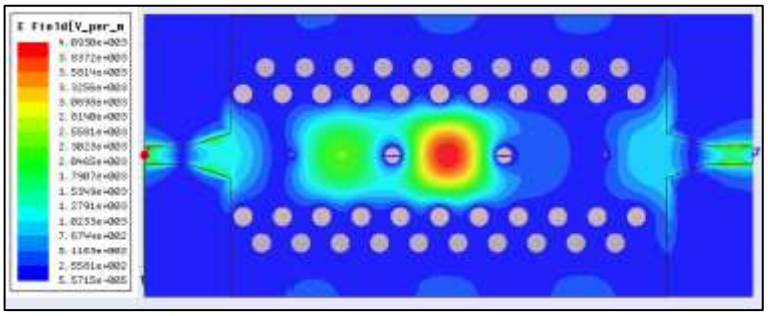

Figure 6: Electric field distribution for the 5G bandpass filter with inductive post filters.
Source: Authors, (2026).

Figure 7 depicts the corresponding simulated S-parameters. The reflection coefficient S11 clearly exhibits a well-defined resonance at the target center frequency of 28 GHz, achieving an excellent impedance matching (return loss) of −31.12 dB. The transmission coefficient S12 confirms the filter functionality, defining a bandwidth that ranges from 27.5 GHz to 28.98 GHz. This results in a desirable fractional bandwidth (FBW) of 5.28%. Furthermore, the filter maintains efficient power transfer within the passband, showing a low insertion loss of −2.71 dB. These results confirm the efficacy of the inductive post topology in synthesizing a functional, low-loss Ka-band filter, providing the required selectivity and initial bandwidth before further enhancement.

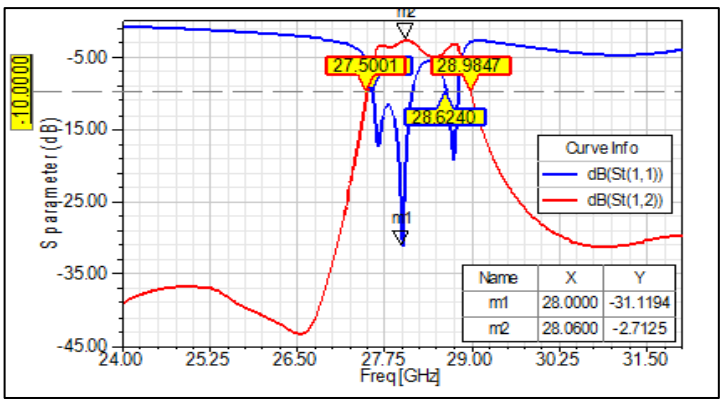

Figure 7: S parameter for the 5G bandpass filter with inductive post filters.
Source: Authors, (2026).

V.3 5G SIW BANDPASS SLOTTED FILTER

Figure 8 illustrates the simulated electric field distribution within the proposed 5G SIW bandpass slotted filter. The field pattern confirms the presence of strong electromagnetic confinement and resonance inside the SIW cavity, particularly around the slot regions, which validates the proposed filtering configuration. This concentrated field distribution demonstrates efficient energy coupling between the input and output ports, ensuring selective transmission at the designed resonant modes.

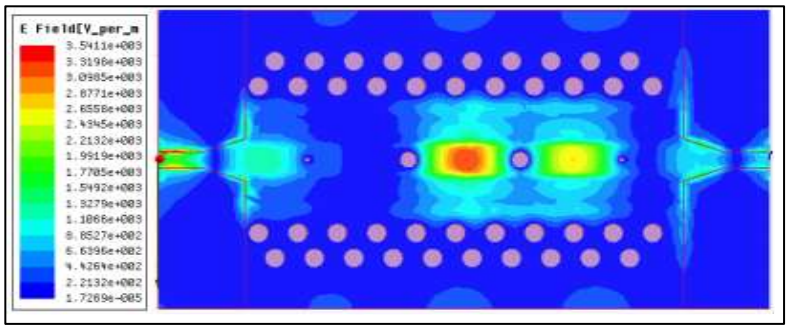

Figure 8: Electric field distribution for the 5G SIW bandpass slotted filter.
Source: Authors, (2026).

As shown in Figure 9, the corresponding S-parameter response reveals the emergence of three distinct resonant frequencies, indicating the excitation of multiple propagation modes within the structure. Among these, the resonance at 28.28 GHz is of primary interest, corresponding to the target 5G Ka−band. At this frequency, the filter exhibits an improved insertion loss of −2.4 dB and a fractional bandwidth (FBW) of 9.04%, representing a clear enhancement compared to the initial configuration. These results confirm that the dual-slot modification significantly improves the bandwidth and transmission efficiency while maintaining compactness, thus validating the effectiveness of the proposed SIW topology for 5G millimeter-wave applications.

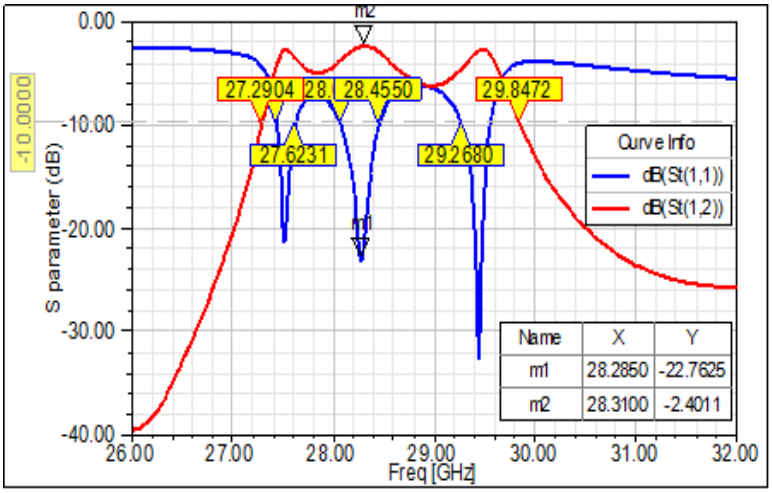

Figure 9: S parameter for the 5G SIW bandpass slotted filter.

V.4 EXPERIMENTAL VALIDATION

As a final step, we put the simulated filter design into practice, and the finished prototype is constructed on a Rogers RO5880 substrate. This substrate has a dielectric constant $\varepsilon_r = 2.2$ and a thickness $h = 0.787\ mm$. Figure 10 shows the 5G SIW bandpass filter's final prototype.

(a) (b)

Figure 10: 5G bandpass SIW filter with double slots: (a) top view;(b) bottom view.
Source: Authors, (2026).

Traditional industrial wave soldering techniques are often complicated and expensive. A simpler and cheaper alternative method is to use solder paste. While this method may affect system performance in some circumstances, we successfully connected the SMA connectors using solder paste. Since the filter is a passive component, the low temperature used during the soldering process did not affect its performance.

The filter's performance was tested using an Agilent PNA-L N5230C network analyzer. The measured S-parameters for the implemented 5G SIW dual-slot filter are shown in Fig. 11, which shows how well it performs in the 25.5 GHz to 30.5 GHz frequency range. Both the transmission (S21) and reflection (S11) coefficients are evident in these results.

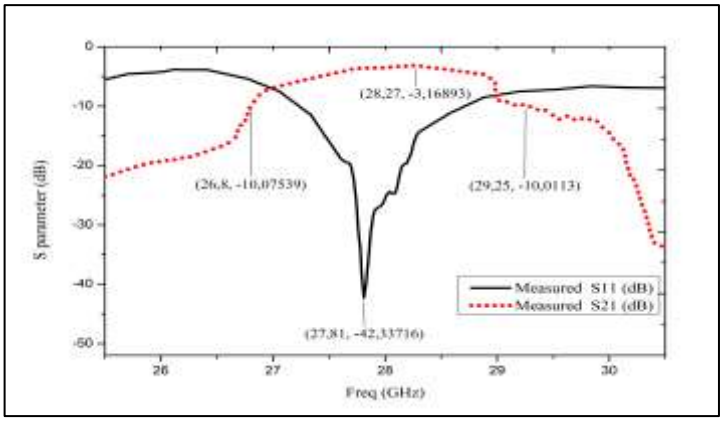

Figure 11: S parameter for the realized 5G SIW bandpass slotted filter.
Source: Authors, (2026).

The transmission coefficient (S21) indicates the filter's minimal loss across its passband, achieving a peak transmission (minimum Insertion Loss) of approximately −3.17 dB at 28.27 GHz. Simultaneously, the reflection coefficient (S11) shows how well the filter is matched to the system impedance, exhibiting a deep minimum (maximum Return Loss) of about −42.34 dB at 27.81 GHz. This very low S11 value confirms an excellent impedance match within the passband. The filter's bandwidth, defined by the −10 dB cutoff points for S21, extends approximately from 26.8 GHz to 29.25 GHz, successfully demonstrating its functionality as a bandpass filter in the designated 5G frequency spectrum. The comparison of the simulated and measured results for the suggested filter is shown in Table 2.

Table2: Simulated and measured results.

/	**Simulated**	**Measured**
FBW(%)	9.04	8.81
RL(dB)	32.7178	42.33
IL(dB)	2.4011	3.16

Source: Authors, (2026).

The comparison between the suggested filter's measured and simulated performance shows an acceptable level of agreement between theory and experiment. The Fractional Bandwidth (FBW) measured at 8.81% is very close to the simulated value of 9.04%, confirming that the operational frequency range was accurately predicted. The filter exhibited an excellent Return Loss (RL), with the measured value of −42.33 dB being significantly better than the simulated −32.72 dB. This superior measured RL indicates an even better impedance match and less reflected power in the physical prototype than anticipated. Conversely, the Insertion Loss (IL) measured at 3.16 dB is higher than the simulated 2.40 dB. This increase in loss is commonly observed in realized prototypes due to real-world factors such as surface roughness, dielectric and conductor losses, and non-ideal SMA connections or soldering, which typically add extra dissipation not perfectly captured in the simulation model.

V.5 COMPARATIVE STUDY

In order to assess the performance of the proposed SIW Bandpass Filter against a number of other SIW BPFs that have been described in the literature employing different technologies, this section conducts a comparative analysis, which is summarized in Table3.

Table3: Comparison between proposed and previously reported bandpass filters.

Ref	$RL(dB)$	$IL(dB)$	$FBW(\%)$	$fc\ (GHz)$
Measured in [21]	20	1.7	7.1	28
Measured in [22]	17	1	3.57	28
Simulated in [23]	60	1.8	5	28
Simulated in [24]	20	0.5	7.2	27.4
Measured in this work	42.33	3.16	8.81	28

(*RL: return loss, *IL: insertion loss, *FBW: -3dB fractional bandwidth, *fC: center frequency)
Source: Authors, (2026).

The comparative study, summarized in Table 3, highlights that the proposed SIW BPF shows good overall performance in the 5G band, particularly excelling in two key criteria: Fractional Bandwidth (FBW) and Return Loss (RL). The filter achieves the highest measured FBW at 8.81%, making it desirable for high-throughput applications by offering the widest relative bandwidth among the compared filters. Furthermore, its measured RL of −42.33 dB is exceptional, being significantly better than all other measured and most simulated results, which confirms the filter's superior impedance matching quality. However, the filter's main drawback is its measured IL=3.16 dB, which is higher than the 0.5 dB to 1.8 dB range reported for the other filters, a difference likely attributable to real-world fabrication losses.

VI. CONCLUSIONS

This work successfully designed, fabricated, and experimentally validated a high performance SIW bandpass filter specifically tailored for operation within the 5G Ka−band. The design leveraged the inherent robustness of the SIW structure and incorporated novel features, including inductive posts and a slotted structure, all progressively optimized in simulation to enhance performance, particularly in terms of bandwidth and impedance matching. The final filter prototype, built on a Rogers RO5880 substrate, was rigorously characterized using an Agilent PNA-L N5230C network analyzer, yielding experimental results that demonstrated strong agreement with the simulations. With an outstanding Return Loss of −42.33 dB, a wide Fractional Bandwidth of 8.81%, and an Insertion Loss of −3.16 dB, the realized filter demonstrates competitive performance centered on 28 GHz. Critically, a comprehensive comparative study with recently published SIW filters confirmed that the proposed design offers superior performance in both its RL and FBW metrics. These strong characteristics position the proposed SIW filter as a highly promising candidate for direct integration into compact and high-performance 5G communication systems. Future work will focus on minimizing Insertion Loss through material optimization and advanced coupling techniques to further enhance the filter's potential for mass production and higher power applications.

ABSTRACT

Blockchain is a distributed ledger technology that can securely, transparently, and tamper-proofly record transactions across a network. IDS on blockchain monitors nodes and activities in transactions to detect malicious or unusual patterns, thereby improving network integrity. However, blockchain also has disadvantages such as high computational overhead, vulnerability to specific attacks, and limited scalability. As a method to enhance IDS performance, the Z-score is used to normalize feature values, stabilizing the model and facilitating convergence. A combination of Support Vector Machines (SVM) and Decentralized Identification (DID) architecture can effectively and reliably distinguish between normal node behavior and malicious node behavior. Key verification uses consensus-driven transaction authentication, and a Multi-Layer Perceptron Neural Network (MLPNN) can detect complex attack patterns. All sensitive information is protected using the Advanced Encryption Standard (AES) to provide robust encryption for both stored and transmitted data. By combining these methods, blockchain applications can offer a comprehensive, secure, and scalable network intrusion detection system, addressing the limitations of detection accuracy, computational efficiency, and privacy in existing data and traditional blockchain implementations, to achieve an accuracy of 91%.

I.INTRODUCTION

Intrusion detection in distributed and decentralized systems has become a hot research topic, especially when combined with blockchain technology to provide transparency, security, and coordination to participating nodes [1], which allows for decentralized learning without compromising data privacy [2]. Similarly, automotive edge applications and blockchain combined with federated learning have been used to implement collaborative and scalable intrusion detection architectures [3].

In addition to the transportation and automotive fields, security intrusion detection algorithms have also been proposed in the drone cyber field, including blockchain and radial-based functional neural networks to provide platform security and manage trust levels in real time [4]. Additionally, blockchain-based collaborative detection systems have been designed to improve the resilience and responsiveness of intrusion detection systems through challenges [5]. In summary, the above strategies demonstrate that blockchain with the help of advanced learning methods has great potential to improve the scalability, security and efficiency of intrusion detection in various application areas.

- Objective: To design a decentralized intrusion detection system combining DIT, smart contracts, consensus-based key verification and AES encryption to detect intrusions in real-time.
- Problem Definition: Reliance on centralized trust, identity spoofing, key management attacks, and insecure data transmission (including network transmission) pose many threats to traditional IDS.

- Key Contribution: Proposes a multi-stage process for tamper-proof node authentication, decentralized key verification, and encrypted sharing of IDS data to ensure its security, reliability, and scalability.
- Reason for investigation: Traditional intrusion detection methods have their limitations, and the proposed solution using blockchain and cryptography technologies should address these issues to provide transparency, decentralization, and resilience in detecting intrusions in contemporary distributed networks.
- Work Structure: This paper is divided into sections including workflow design, DID generation, key verification, AES encryption, performance metrics, results and discussion, and conclusion for in-depth analysis and evaluation.

II. LITE8RATURE SURVEY

Vehicle communication systems are usually managed by a controller area network (CAN). By broadcasting data packets over a bus, CAN facilitates communication between electronic control units (ECUs) that coordinate, monitor, and control components in a vehicle [6]. However, automakers owners may want to keep confidential the important information needed to train the models.

A conditional generative adversarial network (CGAN) based collaborative intrusion detection algorithm is proposed and combined with blockchain-enabled distributed federated learning to solve the above problems [7]. However, many consensus algorithms, especially proof of work, require a large amount of computing power and energy.

Zero Trust Architecture (ZTA) has recently emerged as a new security model where a breach mindset dominates the threat model [8]. Blockchain to share and store the blacklist, and to create a duplicate verification function in the blockchain layer. However, relying on consensus mechanisms across all nodes makes B-IDS less efficient than centralized systems.

The Cooperative Intelligent Transportation System (C-ITS) is a promising technology designed to enhance traditional traffic management systems [9]. However, as the network grows, performance decreases as the amount of data each node must process and store increases.

Table 1 demonstrates the IDS in Cyber Security using blockchain technology author's previous structure, including the type of Algorithm, proposed improvement, and key contributions.

Distributed Denial of Service (DDoS) attacks continue to grow rapidly, silently affecting Internet Service Providers (ISPs) and individuals alike [17]. Traditional IDS typically perform detection based on signatures and are therefore vulnerable to zero-day attacks. However, relying on consensus mechanisms across all nodes makes B-IDS less efficient than centralized systems. Cyber physical systems (CPS) are the integration of physical processes with processing and data transmission [18]. To solve this problem, this paper proposes a blockchain-based data transmission security intrusion detection system and classification model for CPS in the healthcare industry. However, the initial investment in setting up the infrastructure and hiring professional blockchain developers is significant, which can be a barrier for many companies. Large power systems have regional applications whose assets transmit sensor readings in real time. [19]. Introduces fairness and real-time adaptability in blockchain-based intrusion detection. However, this centralized sharing mechanism becomes a significant bottleneck due to operational limitations. Blockchain-based Collaborative IDS (PC-IDS), which uses blockchain technology to connect multiple IDSs [20]. Structure of BC-IDS: 1) Use IDS to create a list of malicious IP addresses; 2) Use blockchain to share and store the blacklist; 3) Create a duplicate verification function in the blockchain layer. However, integrating decentralized blockchain systems with existing centralized legacy infrastructure is technically complex and costly.

III. PROPOSED METHODOLOGY

The section product combines several methods to improve the security of the blockchain. Z-score normalization provides reliable results because identical scales are used throughout the data analysis. Support vector machine (SVM) is a useful tool for distinguishing between normal and malicious behaviors and improving intrusion detection performance. Decentralized identity (DIT) follows node identity, which is secure and verifiable, while transaction verification using consensus requires cooperation to verify transactions to eliminate unauthorized use. However, Multilayer Perceptron Neural Network (MLPNN) will be used to identify nonlinear patterns and improve the prediction capabilities of complex attacks. Finally, Advanced Encryption Standard (AES) is used for data encryption to ensure confidentiality and integrity of confidential information. All of these methods combine to create a powerful and robust blockchain intrusion detection system.

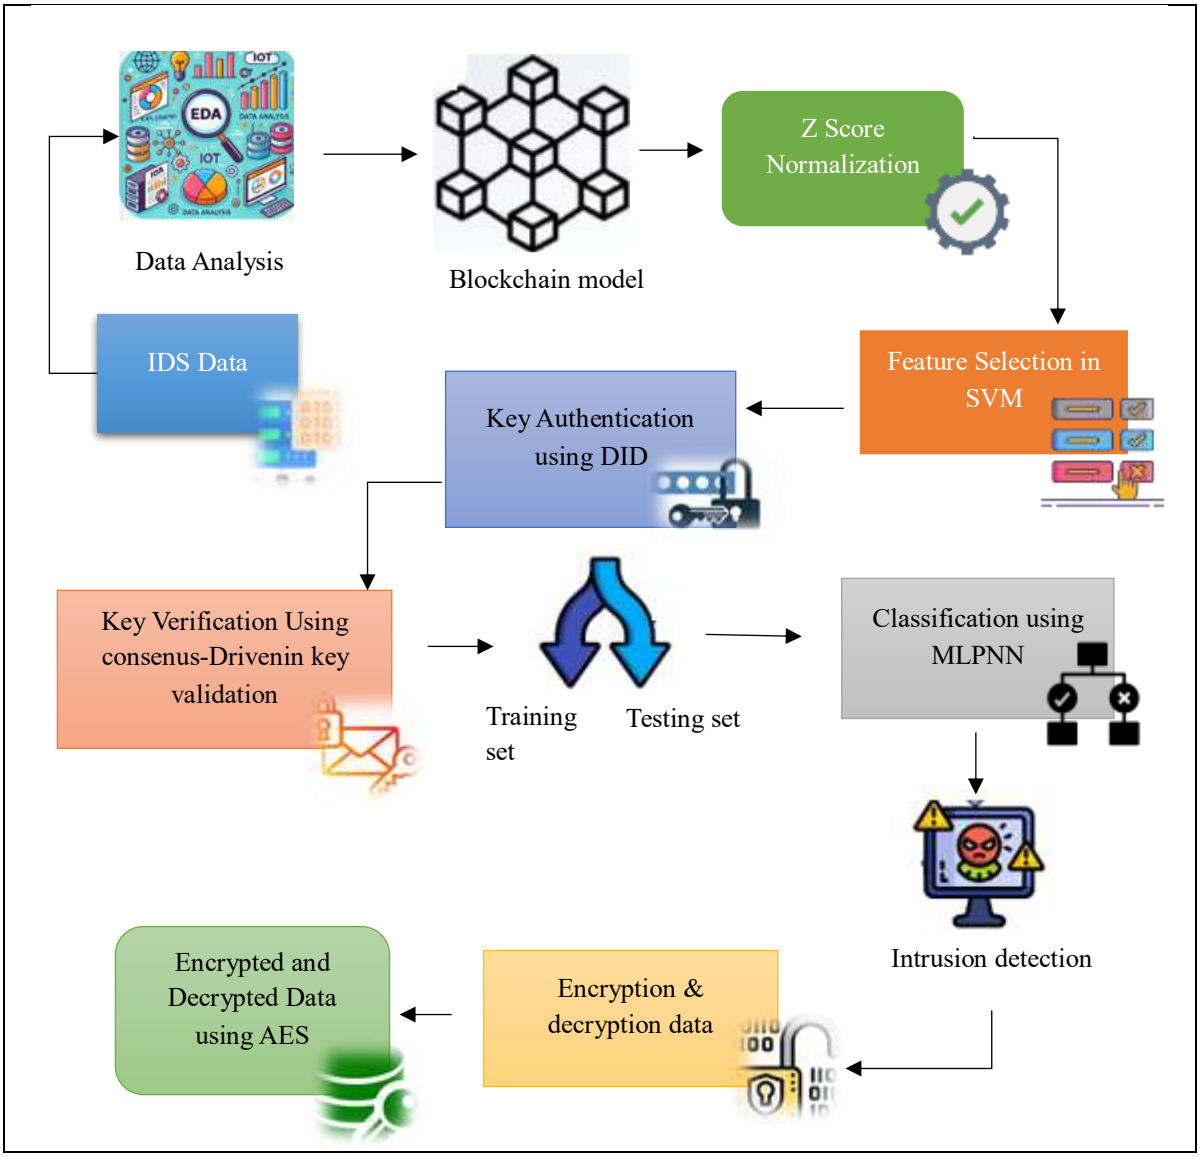

Figure 1: Architecture Diagram of AES-Enhanced Blockchain Intrusion Detection.
Source: Authors, (2026).

The figure 1 show it Z-Score Normalization Z-score normalization normalizes transaction characteristics by ensuring scaling consistency and improving model consistency. Support vector machines (SVMs) help classify behavior as normal or malicious, with the aim of increasing detection accuracy. DID uses verifiable consensus to securely identify nodes, CDKV uses network consensus to verify transactions so unauthorized parties cannot access them. Multilayer Perceptron Neural Networks (MLPNNs) offer linear modeling capabilities. Finally, Advanced Encryption Standards (AES) provide data security, preventing leakage of sensitive information during storage and transmission. Collectively, these methods create an effective, secure, and efficient blockchain intrusion detection system.

III.1 DATASET DESCRIPTIONS

The section dataset is provided for the audit, which contains various simulated intrusions conducted in a military network environment. It provides a view that captures raw TCP/IP dump traffic of the network by emulating a standard U.S. Air Force LAN. This LAN is centralized, similar to a real-world environment, and is subject to various attacks. A connection is a series of TCP packets, beginning and ending within a defined time period, that flow from a source IP address to a destination IP address within a defined protocol. Each attachment is defined as either a normal attachment or a single attack type. All connection records are approximately 100 bytes in size. For each TCP/IP connection, 41 quantitative and qualitative features (3 qualitative factors and 38 quantitative factors) are read from the normal data and the attack data. Class variables are divided into two types: normal and abnormal.

III.2 Z-SCORE NORMALIZATION

The data preprocessing technique called Z-score normalization transforms numerical values in CSV datasets to achieve standard normal distribution by computing them from mean and standard deviation parameters. Each data point receives its adjustment based on the mean and standard deviation of the feature it belongs to. The dataset achieves normalized statistics as features obtain an average value of zero with a standard deviation set at one, which enables acceptance by learning algorithms sensitive to scale variation. Z-score normalization provides optimal results in feature normalization because it allows for uniform importance between variables while maintaining standardization regardless of original measurement units.

$$Z_i = \frac{X_i - \mu}{\sigma} \tag{1}$$

The normalization process of CSV dataset points described by Equation 1 includes both mean μ and standard deviation σ adjustment to obtain standardized value Z_i. The calculated value Z_i determines the number of differences in standard deviations between a value and the mean. The X_i represents an initial value from the dataset. At the same time, μ refers to the mean column value, and σ represents the standard deviation column amount, along with Z_i representing the normalized standardized value of raw data. This normalization method enables different numerical features to contribute proportionally, ensuring that large values do not control training algorithms.

$$\mu = \frac{1}{N}\sum_{i=1}^{N} X_i \tag{2}$$

The μ value of a dataset column represents the calculated average obtained by adding all individual values in the column. The mean calculation requires a sum of all values X_i followed by division by N, which represents the total count. This formula shows how the variable N counts all data points from the column, while X_i represents the sum of all column values. The discussed equation is the main distribution center for characteristic values needed in Z-score transformations.

$$\sigma = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(X_i - \mu)^2} \tag{3}$$

The σ indicates data point distribution about the mean value. Higher values of standard deviation represent wide dispersion of data points so data exists farther from the mean whereas lower values show data points tightly grouping near the mean.

$$\sigma = \sqrt{\frac{1}{N-1}\sum_{i=1}^{N}(X_i - \mu)^2} \tag{4}$$

This equation is selected when working with sample data from a larger population instead of complete population data. The main distinction from the initial formula involves substituting N with $N-1$ in the denominator to improve accuracy when measuring the population standard deviation from a group. The Z-score normalization process divides data in CSV files into several independent groups since CSV files consist of multiple numerical columns. The general formula for applying Z-score normalization to an entire dataset is,

$$Z_{ij} = \frac{X_{ij} - \mu_j}{\sigma_j} \tag{5}$$

The equation uses X_{ij} as the original value from row i and column j. At the same time, μ_j represents column mean values and σ_j represents the standard deviation of the columns, leading to Z_{ij} as the normalized value. The formula establishes independent standardization techniques that preserve data scaling consistency across all columns within the CSV dataset.

$$X' = X_i \text{ (if } X_i \text{ is not missing), else } X' = \mu \tag{6}$$

The analysis of actual datasets shows missing values (NaN values). The standard procedure for dealing with missing values X_i is replacing them with column mean μ. Missing values do not interrupt the normalization procedure through the implementation of this preventional measure.

$$X_i = Z_i.\sigma + \mu \tag{7}$$

The model interpretation requires the return of normalized values back to their original scale after completing the training. The procedure returns standardized value Z_i to its original scale by reversing normalization transformation.

III.3 SUPPORT VECTOR MACHINE SVM METHOD

The section SVM is a supervise machine learning technique that is mostly used in classifiers and regression. Concerning feature selection, SVM advantage uses the functional ability to determine the significance of each feature in terms of its contribution to the decision boundary of the hyperplane. Features are ordered according to the measure of how they impact an SVM's decision function. In this method, features are gradually eliminated one by one according to their weight in this SVM model until the minimal set is obtained. In this way, only significant features are kept with the method, decreasing dataset complexity, enhancing model solutions, and preventing overfitting. The number of kernel functions available in SVM can be linear, polynomial, or radial basis functions, and they can identify the linear or non-linear relations of the features. In the equation 8 perform SVM decision function,

$$f(i) = u^T i + b \tag{8}$$

Let assume, i as input feature vector, u as weight vector, b as bias term. This equation defines a hyperplane that separates different classes. The goal is to find u and b that maximize the margin between the two classes. By following in equation 9 maximize the margin,

$$\gamma = \frac{1}{\|u\|} \tag{9}$$

Here, the $\|u\|$ is represented for the magnitude of the weight vector, this equation is used to maximize this margin to ensure better generalization. The margin is the distance between the closest points (support vectors) of the different classes to the hyperplane. Then we optimization the problem for SVM through equation 10,11.

$$\min_{u,b} \frac{1}{2}\|u\|^2 \tag{10}$$

subject to the constraints:

$$j_x(u^T i_x + b) \geq 1 \text{ for all } x = 1,2,\dots,n \tag{11}$$

Let assume, i as training sample, j as the label, an n as total number of samples. The equation is used to find the optimal hyperplane that maximizes the margin while ensuring that the data points are classified correctly. By following we support vectors through equation 12, which the data points that lie closest to the decision boundary (hyperplane) and play a critical role in defining the hyperplane.

$$j_x(u^T i_x + b) = 1 \tag{12}$$

This equation used in the model to construct the decision function. This model contributes to the decision boundary, and their associated weights provide information about which features are most important. Then we perform kernel trick through equation 13, to map the data into a higher-dimensional space in cases where the data is not linearly separable,

$$f(i) = \sum_{x=1}^{n} \alpha_x j_x Q(i_x, i) + b \tag{13}$$

Let assume, Q as kernel function, α_x as Lagrange multipliers, it is used to assign u to each support vector, and j_x as class label of support vector. This equation is used to map the original data into a new higher-dimensional space where there exists a linear boundary in order to solve non-linear classification problems. The significance of each of the features can be determined by the examination of the u or the coefficients relating to the respective feature in the model produced. In linear cases, the magnitude of weight coefficients is used to determine the feature importance of $|u_y|$. We identified that those attributes which have a higher value in terms of weightage are important Features with higher magnitude weights are considered more important. This is why SVM is frequently used in image recognition, disease prediction, and other high-dimension problems: SVM is capable of identifying features that should be important and at the same time, it can sort data quickly and efficiently. This mathematical formulation, such as the decision function and the optimization process, and the kernel method guarantee that SVM as an algorithm is a reliable algorithm in machine learning, especially for feature selection in big and demand data.

III.4 DECENTRALIZED IDENTITY (DID)

The key authentication process uses decentralized identities (DITs) with smart contracts to verify that only legitimate nodes or organizations are allowed to join a blockchain-based intrusion detection system. In this approach, each node generates a DID and stores it on the blockchain as a permanent and auditable digital identity. Whenever a node tries to join or communicate with the system, the smart contract verifies the authenticity of the DID through the blockchain ledger. This eliminates the centralization of certificate authorities and the risk of identity spoofing or unauthorized access. The DID-to-public key relationship is established and validated by the smart contract, verifying that the requested identity is indeed associated with the node.

This mechanism provides a convenient, transparent and tamper-proof key authentication solution by improving the overall reliability of intrusion detection in distributed environments through a decentralized verification and automated trust process. The equation 14 binding process binds not only the node's identity, but also its encryption keys inextricably into a single, indestructible value. This DID is embedded in the blockchain, making it a permanent and immutable identifier. Therefore, hashing the public key and identity preserves the confidentiality of the original identity and the proof of the node's true identity during the authentication process. Let assume the DID_{node} −decentrlized identifier, ID_{node}-unique identify of the node, PK −public key of the node, H −cryptographic hash function, $||$ −concatenation.

$$DID_{node} = H(DID_{node}||PK_{node}) \tag{14}$$

The equation 15 DIT is registered, the smart contract will perform an authentication process to ensure that the submitted DIT is in the blockchain ledger. If the DID can be found, the contract executes the validation routine correctly associated with the DID. When both conditions are met, the authentication variable becomes 1, indicating that authentication is successful. Otherwise, the node is excluded from the system. The advantage of this is that it ensures that only genuine and pre-registered nodes can be authenticated and that there is no identity spoofing or unauthorized access. Let assume the $Auth_{node}$ − autheitcation values, $ledger$ −blockchain stored DID.

$$Auth_{node} = \begin{cases} 1, DID_{node} \in ledger \\ 0, \ otherwise \end{cases} \tag{15}$$

The equation 16 policy can be role-based or attribute-based, and when the smart contract rules are followed, the node is authorized to join or communicate with the IDS network. Otherwise, access is denied. Through this step, decentralized and transparent access control is implemented in the access control mechanism, where even authorized nodes require full rights to participate in accordance with the blockchain-mediated security policy. Let assume the $Access_{node}$ −final access status of node, SC_{policy} −smart contract policy

$$Access_{node} = Auth_{node} \times SC_{policy} \tag{16}$$

Identity and Public Key Generation DID generation and record cryptographic hashing combine both to provide each node with its own identity and public key. The generated DID is stored on the blockchain, hence incorruptible and decentralized. The result of this process is secure and verified node authentication without the need for a central authority.

III.5 CONSENSUS-DRIVEN KEY VALIDATION

Key Verification The key verification process uses each connected device to verify or deny the authenticity of the key before it is communicated within the intrusion detection workflow in a consensus-driven manner. When a node provides its public key, the proposed binding of the key to a decentralized identity (DID) is broadcast on the blockchain network. That is, instead of a single point of authority, multiple validator nodes participate in verifying that the key is correctly associated with the DID and has not been compromised. Each validator individually verifies the key binding and uses a consensus mechanism (such as proof-of-stake, practical Byzantine fault tolerance, or proof-of-representation) to reach consensus on whether the key is valid. When a majority of validators prove it is correct, the key is validated and permanently written to the blockchain ledger. Such a process supports transparent key verification, key tamper resistance and single point failure protection, improving the reliability and robustness of the intrusion detection mechanism. The equation 17 contains the node's decentralized identity, sharing this request with the blockchain network, the node asks the system to confirm or deny that the provided key is actually its DID. This request triggers consensus-driven verification, so that when a node requests verification, its keys are verified in a decentralized and transparent manner that considers all nodes in the decentralized network before passing the request to an acceptable state during the intrusion detection process. Let assume the Req_{key} −key verification, DID_{node} −decentrized identify of the node, PK_{node} −public key of the node.

$$Req_{key} = (DID_{node,}PK_{node}) \tag{17}$$

The equation 18 validation request is broadcast, validator nodes in the blockchain network independently evaluate the binding of the DIT and the public key. Verifier's Result: If the verify method Verify (·) verifies that the DID is correctly associated with the public key on the blockchain, the validator will output 1 (valid). Otherwise, it will output 0 (invalid). This is to ensure that validation is distributed across multiple validators to avoid single point manipulation and improve validation efficiency. Let assume the v_i − decision validator, $verify(.)$ − function that checks in public key

$$v_i(Req_{key}) = \begin{cases} 1, if \ verify(.)(DID_{node,}PK_{node}) = true \\ 0, \qquad\qquad otherwise \end{cases} \tag{18}$$

The equation 19 validity of the key is greater than or equal to, then the key is considered valid. Otherwise, the key is declared invalid and rejected. This makes key validation not dependent on a single validator, but rather the consensus of the network, and therefore can be considered non-tampering and acceptable. Let assume the $valid(pk_{node})$ −final decision on the validity of the node, N −total number of validators, θ −cpnsenus threshold

$$valid(pk_{node}) = \begin{cases} 1, \ \ if \ \frac{\sum_{i=1}^{n} v_i}{N} \geq \theta \\ 0, otherwise \end{cases} \tag{19}$$

Key verification using consensus ensures that a node's key is verified by multiple blockchain validators rather than by an individual. Each validator validates the key binding based on the node's DID, which is determined by a consensus threshold. This decentralized system prevents any kind of tampering and improves the reliability of the verification process.

III.6 MULTI-LAYER PERCEPTRON NEURAL NETWORK (MLPNN)

The section IDS prediction uses the Multi-Layer Perceptron Neural Network (MLPNN) to classify datasets as an artificial neural network. The network architecture includes an input layer followed by multiple hidden layers before reaching the output layer, and all of these layers use weighted connections. The supervised learning system of MLPNN depends on backpropagation and gradient descent for its optimization process. IDS prediction through MLPNN involves the analysis of historical IDS data, which includes price trends, trading volumes, and technical indicators to produce IDS classification results between bullish, bearish, and neutral statuses. The activation functions in ReLU or Sigmoid help the system create precise forecasts by simultaneously learning multiple complex patterns. The predictive power of MLPNN increases because it applies deep learning features and extraction techniques to become a beneficial predictor for financial decisions and investing approaches. In equation 20 weighted sum at each neuron,

$$z_j = \sum_{i=1}^{n} w_{ji} x_i + b_j \tag{20}$$

Calculating weighted sum input features occurs through Equation 23 across each neuron of hidden and output layers. The sentence includes various IDS -related features symbolized as x_i, encompassing opening price, closing price, volume, moving averages, and relative strength index (RSI). The overall model flexibility benefits from bias (b_j) adjustments while the weights (w_{ji}) control the importance of each feature. IDS relationships and price trend associations become learnable through activating the weighted input before it becomes the activation function input. By following we perform activation function, in equation 21 we perform sigmoid activation

$$f(z) = \frac{1}{1+e^{-z}} \tag{21}$$

Equation 22 finds practical use when analyzing binary classification issues because it predicts IDS value movement between bullish (1) and bearish (0). The function converts the weighted sum z into values ranging from 0 to 1 to enable forecasting IDS trends in bullish (1) or bearish (0). In equation 16 we perform Rectified Linear Unit (ReLU) function,

$$f(z) = \max(0, z) \tag{22}$$

IDS prediction systems employ Equation 23 as a standard implementation within MLPNN. The equation introduces nonlinearity to the analysis without causing gradient vanishing effects. Due to its limited positive value generation process, the network efficiently recognizes meaningful IDS shifts from past data patterns. Then we perform Hyperbolic Tangent ($\tan h$) through equation 17,

$$f(z) = \frac{e^{z}-e^{-z}}{e^{z}+e^{-z}} \tag{23}$$

According to Equation 24, the alternative to the sigmoid activation produces output values spanning from -1 to +1. Zero-centered data enable improved prediction learning because it suits strongly bullish, slightly bullish, neutral, lightly bearish and strongly bearish multi-class IDS trend analysis.

$$y_j = f(z_j) \qquad 8 \tag{24}$$

Starting from the weighted sum result, the activation function generates output y_j for the following layer. The softmax activation function helps the final output layer classify stocks into three categories: Buy, Hold, and Sell. The output layer should employ linear activation since it deals with continuous IDS price predictions. By following we compute the Mean Squared Error (MSE) through equation 25 for regression,

$$\mathbb{E} = \frac{1}{N}\sum_{k=1}^{N}(y_k - \hat{y}_k)^2 \tag{25}$$

The relationship determines the distance between predicted IDS values $\hat{y}_k$ and actual IDS values y_k. Model accuracy improves as the MSE decreases in the MLPNN predictive method. Future IDS predictions use this loss function that operates on historical data. Then we compute the cross-entropy loss through equation 26 to classification,

$$\mathbb{E} = -\sum_{k=1}^{N}[y_k \log(\hat{y}_k) + (1 - y_k)\log(1 - \hat{y}_k)] \tag{26}$$

For IDS category classification (Buy, Hold, or Sell), equation 29 replaces Mean Squared Error (MSE). Equation 27 computes the distinction between registered values and calculated probability estimates. The model receives low loss when it correctly predicts a high probability value, which optimizes MLPNN for improved IDS trading decisions. In equation 21 we perform backpropagation for update the weight by utilizing gradient descent,

$$w_{ji} \leftarrow w_{ji} - \eta \frac{\partial \mathbb{E}}{\partial w_{ji}} \tag{27}$$

Equation 27 enables the MLPNN to minimize errors through weight adjustments in the training phase. The gradient descent algorithm applies derivative computation on loss function ($\mathbb{E}$) to update weights w_{ji}. The learning rate η sets the amount by which weights adjust in each iteration.

The selection of an accurate learning rate in IDS prediction ensures efficient model learning, which avoids excessive step sizes and slow convergence rates. The system utilizes IDS inputs to perform weight-based transformations while including activation functions to introduce non-linearities that compute the loss difference between actual and predicted values before employing algorithm-enabled weight updates. The architecture of MLPNN makes it possible to identify IDS patterns for financial investors who need correct trading information.

III.7 ADVANCED ENCRYPTION STANDARD (AES)

The Advanced Encryption Standard (AES) is used for the encryption part of the blockchain-based intrusion detection process, which ensures confidentiality of communications and sensitive data shared between nodes. Each node encrypts the data using a key (a symmetric key, a session key derived from a decentralized identity (DIT), or a smart contract policy negotiation) before transmission. Plaintext data generated by an intrusion detection sensor or IDS alarm is encrypted into ciphertext using a series of permutations, permutations, and combination changes. This makes the information technically unintelligible to other entities. If the cipher is successfully authenticated and verified as belonging to the receiving node through the DIT and key verification process, the same symmetric key can be used to decrypt the cipher. Incorporating AES managed by blockchain control provides system confidentiality, machine integrity and secure communication, as only authorized and verified nodes can access IDS data in an untampered decentralized system. The equation 28, each node is equipped with its decentralized identity and a symmetric session key generated based on the access or session policy established in the smart contract. The key derivation function ensures that each node has a unique session key associated with its identity and permissions, and denies access to each unauthorized node. By linking the key to the blockchain's governance policy, the system implements access control, ensuring that only nodes cleared and authorized via DID can encrypt or decrypt IDS data using the key. Once the plaintext data is created, the generated session key is ignored. Let assume the $K_{session}$ −Key symmetric, DID_{node}-Decentralized Identify of the node, SC_{policy} −session policy, f −key derivation function.

$$K_{session} = f(DID_{node,}SC_{policy}) \tag{28}$$

The equation 29 data represented (C) consists of intrusion detection alerts or sensor output messages, and this data is encrypted using the AES cipher and the derived session key, resulting in a ciphertext unintelligible to any unauthorized node. This prevention measure ensures that data traffic cannot be read or tampered with, even if it is sent over an unsecured network. The collection process becomes part of the blockchain because only nodes that know each other using their DITs and session policies can generate valid ciphers and/or decrypt them. Let assume the c −ciphertext, p −plaintext data, AES_{Enc} − encryption function

$$c = AES_{Enc}(p, k_{session}) \tag{29}$$

The equation 30 target node, the authorized parties receive the same session key, so that only nodes that have authenticated, verified, and assigned the correct session key through the smart contract and the mechanisms provided by the DID system can access the initial data of the IDS. This step preserves the confidentiality and integrity of the intrusion detection system, enabling real-time and secure data sharing between decentralized nodes.let assume the P −deccrypted plaintext data, c −recevied ciphertext, AES_{Dec} −decryption function

$$P = AES_{Dec}(c, k_{session}) \tag{30}$$

Encryption of IDS data is achieved by encrypting the plaintext into a ciphertext using a symmetric session key derived from the node DID and smart contract policy. Only authorized nodes possessing the hard-coded session key can decrypt information. It provides confidentiality, integrity and controlled access within a decentralized IDS system.

IV. RESULT AND DISCUSSION

The section provides robust verification of public keys, rejecting any invalid or malicious keys through the moderator matching protocol, thereby increasing trust and reliability. All transmitted IDS data is encrypted using AES encryption, so that only the intended node can decrypt the sensitive information using its authorized session key, thus guaranteeing confidentiality and information integrity. Performance measurements demonstrate high detection accuracy, low false positive rate, and moderate computational overhead in key authentication and encryption tasks, indicating that the protocol is feasible in one-shot and test-in-test implementation scenarios. Overall interoperability, decentralized authentication, joint key verification, and strong cryptographic processes provide an effective and scalable intrusion detection framework that addresses the limitations of traditional IDS.

This table 2 represents the core of hardware and software solutions needed to build a blockchain-based IDS implementation. Blockchain consists of software programs, including smart contracts and cryptographic libraries, to handle secure authentication and key verification and data encryption. Machine learning algorithms and databases are used to detect possible conflicts and store IDS logs. Collectively, these resources ensure that an intrusion detection system is secure, effective, and scalable.

IV.1 DISCUSSION PART

Blockchain-based IDS enhance efficiency by optimizing key aspects of workflow and resource utilization. Utilizing sophisticated machine learning models and anomaly detection algorithms, combined with real-time data analysis, can improve detection accuracy and reduce false favorable rates. Key verification times can be reduced by using efficient consensus mechanisms such as Practical Byzantine Fault Tolerance (PBFT) or Lightweight Proof-of-Stake. Encryption and decryption speed can be tuned by hardware acceleration of the AES implementation to find a speed/security tradeoff. In short, the concept of algorithm development and decentralized resource management ensures that the system is more efficient, responsive, and reliable in detecting attacks.

V.CONCLUSION

In summary, intrusion detection and well-designed data protection techniques prove an integrated and multidimensional solution to ensure blockchain network security. The framework uses the decentralized and immutable architecture of blockchain to create a secure environment for monitoring transactions and node activity. Intrusion detection systems (IDS) can be used to detect suspicious or unusual patterns in real-time, overcoming the inherent weaknesses of traditional blockchain processes, including high computational costs and vulnerability to attacks. The data can be pre-processed by normalizing the Z-score to maintain a uniform distribution of transaction features, thereby improving the stability and performance of the specified model. Support vector machines (SVM) and distributed identities (DIDs) backbone or consensus-based key verification can be used to effectively distinguish between normal and malicious activities and ensure effective node authentication and secure verification of transactions. Multilayer perceptron neural networks (MLPNNs) can further improve prediction accuracy by capturing problems that standard models overlook. Finally, the Advanced Encryption Standard (AES) helps protect the confidentiality and integrity of sensitive information in storage and transmission. Together, this workflow addresses both security and performance concerns, providing a scalable, efficient, and reliable system for blockchain intrusion detection. By combining pre-processing, machine learning, entity management, verified consensus and encryption, it increases the reliability of the computer network while reducing the limitations of traditional blockchain implementations.

ABSTRACT

Early detection of oil palm leaf diseases is essential to minimize economic losses and ensure sustainable plantation management. This study proposes a deep learning approach using the VGG16 architecture optimized with the Adam algorithm to classify oil palm leaves into three categories: healthy, infected, and initial infection. The dataset was obtained from Roboflow and preprocessed through cropping, annotation, and standardization before being split into training, validation, and testing sets. Experimental evaluations were performed across multiple training epochs and compared against two baseline models: a shallow Convolutional Neural Network (CNN) and YOLOv11-CLS (version S). Results show that VGG16 combined with Adam achieved the highest accuracy of 97% at 25 and 50 epochs, with balanced precision and recall across all classes. In contrast, the baseline CNN reached a maximum accuracy of 88%, while YOLOv11-CLS produced fluctuating results with a peak accuracy of 82%. Statistical significance testing confirmed that the performance improvements of VGG16 + Adam were consistent and reliable, validating its suitability for practical implementation in precision agriculture. These findings highlight the potential of combining deep architectures with adaptive optimization to enhance disease diagnosis in oil palm plantations and reduce reliance on manual inspections.

I. INTRODUCTION

Oil palm is a key agricultural commodity and the most efficient source of vegetable oil compared to other crops, making it a vital contributor to Indonesia's economy. In 2023, palm oil exports reached USD 25.61 billion with a volume of 38.23 million tons, while total production stood at 46.9 million tons, reinforcing Indonesia's position as the world's leading producer [1]. However, oil palm cultivation faces serious threats from plant diseases, which can significantly reduce yield and even cause tree mortality. The most devastating is basal stem rot caused by *Ganoderma boninense*, responsible for annual economic losses of approximately USD 500 million [2]. Other damaging diseases include *Curvularia* leaf spot (*Curvularia oryzae*) and *Pestalotiopsis* leaf blight (*Pestalotiopsis palmarum*), with incidence rates reaching up to 11.26% [3].

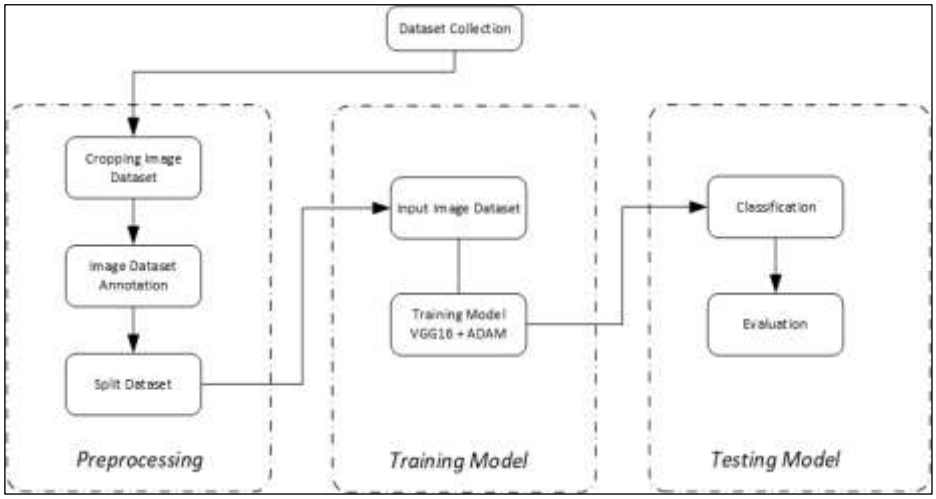
These diseases, along with pest infestations, not only reduce agricultural productivity but also cause considerable ecological losses. Early detection and prevention are therefore essential for sustainable plantation management. Traditional disease diagnosis methods relying on manual visual inspection are often inefficient, time-consuming, and costly [4], [3]. Recent advances in artificial intelligence (AI) have opened new possibilities for oil palm management, particularly through deep learning, which excels in processing visual imagery for tasks such as disease classification and tree counting [5]. While deep learning has been applied in oil palm plantations for tree detection[6-8], its application to leaf disease diagnosis remains limited.

In contrast, similar approaches have been successfully implemented in other crops, including rice [9] guava [10] , cucumber [11], and tomato [12]. Building on this potential, the present study aims to classify the health condition of oil palm trees from leaf images, categorizing them as either healthy or unhealthy. The findings are expected to contribute to modern precision agriculture by alleviating farmers' workloads and reducing unnecessary production expenses. This study aims to classify the health status of oil palm leaves as healthy or unhealthy using the VGG16 architecture, chosen for its proven reliability in image classification, especially in recognizing plant leaf patterns[13]. Its deep, multi-layered structure enables comprehensive feature extraction. Although the model contains a large number of parameters, VGG16 remains effective for limited datasets when combined with data augmentation techniques and fine-tuning [14].

In comparison, ResNet50 utilizes residual connections to prevent accuracy degradation in very deep networks, whereas VGG16's simpler and more stable structure makes it easier to implement in field applications. InceptionV3 integrates multiple kernel sizes within a single layer to achieve computational efficiency and high accuracy; however, its architecture is more complex and requires more precise parameter tuning. Meanwhile, MobileNetV2 is lightweight and efficient for devices with limited resources, but this efficiency comes at the cost of lower accuracy compared to VGG16, particularly in high-resolution image classification. Considering accuracy, stability, and ease of implementation, VGG16 represents a relevant and practical choice for supporting early diagnosis of oil palm leaf diseases through an image classification approach.

To address the limitations of VGG16, such as its large number of parameters and the potential for slow convergence during training, this study adopts an appropriate optimizer to enhance the model's efficiency and accuracy. Adam was selected for its ability to adaptively adjust the learning rate for each parameter while combining the advantages of Momentum and RMSProp, thereby accelerating the training process and helping the model avoid local minima an essential factor in classifying oil palm leaf diseases with complex visual patterns. Compared to Stochastic Gradient Descent (SGD), which requires manual learning rate tuning and tends to produce large fluctuations in the loss function, Adam offers more stable and faster training. Meanwhile, although Adagrad is also adaptive, it often experiences a significant decrease in learning rate over time, which can hinder long-term learning. Therefore, Adam is considered the most suitable optimizer to maximize the performance of VGG16 in this study.

II. METHOD



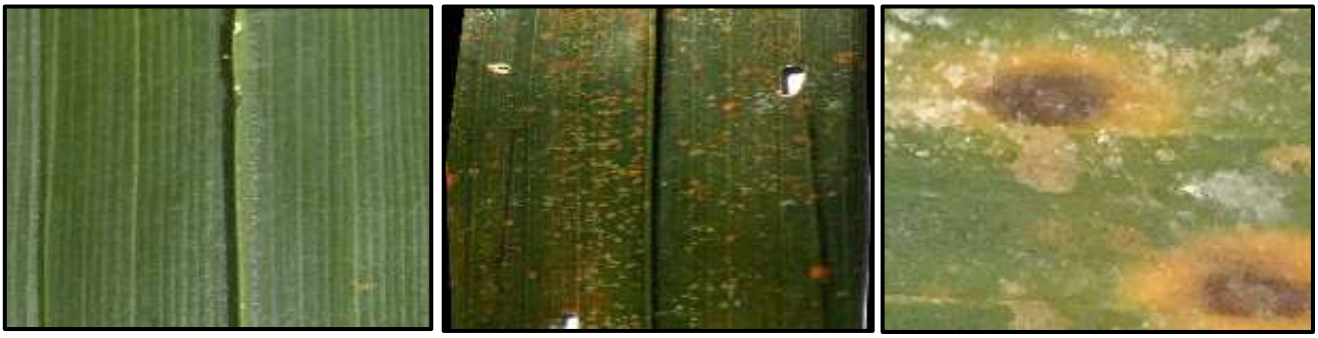


Figure 1: Proposed Research Workflow.
Source: Authors, (2026).

Research methodology adopts a deep learning approach to develop an oil palm leaf disease classification system. The research workflow, as depicted in the flowchart (Figure 1), is structured into three fundamental phases: preprocessing, model training, and testing. The preprocessing phase aims to prepare the image dataset through a series of processes, including cropping, annotation, and splitting the data into training and testing sets. The central phase of this research is model training, where the VGG16 architecture is utilized as the base and is optimized with the Adam algorithm to achieve effective convergence. The final phase is model validation through testing, wherein the model's classification capability is quantitatively evaluated using the test dataset to verify the system's reliability and accuracy.

II.1 DATA COLLECTION

For this study, a dataset composed of oil palm leaf imagery was utilized, classified into three distinct categories: healthy, initial infected, and infected. The imagery was sourced from the Roboflow platform, a repository commonly employed in the computer vision field [15]. During selection, careful consideration was given to a variety of visual attributes such as diverse lighting conditions, background elements, and leaf orientations. This was done to improve the model's capacity for generalization in various real-world situations. A specific focus was placed on choosing images that distinctly represent the early and advanced stages of Ganoderma boninense infection.

The 'initial infected' category contains leaves exhibiting early signs, for instance, yellowish spots or uneven coloration. In contrast, the 'infected' category features leaves with more pronounced and extensive symptoms of the disease. Differentiating between these stages is essential for developing a robust model that can accurately identify the progression of the infection. The dataset also incorporates images of healthy leaves, which serve as a baseline for the model to learn the difference between healthy and diseased states. Representative samples from the dataset are illustrated in Figure 2.

(a) (b) (c)

Figure 2: Labeled samples of palm oil leaves related to Ganoderma infection. (a) Sample from the healthy dataset. (b) Sample from the infected dataset. (c) Sample from the initial infected dataset.
Source: Authors, (2026).

II.2 IMAGE CROPPING

In the preprocessing stage, oil palm leaf images undergo a cropping procedure where each image is trimmed to isolate the leaf area and eliminate the background. The purpose of this technique is to direct the model's focus exclusively onto the leaf's morphological features such as its shape, texture, and patterns by removing any potentially distracting visual elements. Following this, every image is standardized to a resolution of 640 x 640 pixels. This resizing is necessary to comply with the uniform input dimensions mandated by the YOLOv11 algorithm for both its training and detection phases. This dual process of background removal and image standardization streamlines the visual data, boosts predictive accuracy, speeds up the training cycle, and mitigates the risk of errors arising from irrelevant information.

II.3 ANNOTATION

A critical step in preparing the dataset for training is the annotation process, which establishes the "ground truth" for the model to learn from. In this study, this involved meticulously applying a classification label ('healthy' or 'infected') to every oil palm leaf image after it had been pre-processed. The entire labeling workflow was managed using the Roboflow platform, chosen for its efficiency and compatibility with deep learning formats. The quality of these annotations is paramount, as the model’s ability to differentiate between a healthy and an infected leaf is entirely dependent on the accuracy of this ground truth. Inaccurate labels would impede the learning process and result in unreliable classifications, while careful annotation is fundamental to achieving high diagnostic accuracy.

II.4 DATASET SPLITTING

An 80-10-10 distribution was applied to partition the dataset into training, testing, and validation sets. This partitioning step was executed after all images had been successfully cropped and annotated, resulting in 80% of the data being used for training, while the testing and validation phases each utilized 10% of the total image collection.

II.5 MODEL TRAINING

For the model training phase, we employed the VGG16 architecture. VGG16 is a deep convolutional neural network (CNN)[16]. Its architecture is distinguished by its simplicity and depth, exclusively using small 3x3 convolutional filters stacked on top of each other. The number '16' refers to its 16 weighted layers, comprising 13 convolutional layers and 3 fully-connected layers. This uniform, stacked filter design allows the network to learn a hierarchy of increasingly complex features from the input images, making it highly effective for various computer vision tasks. Its proven robustness and high performance in large-scale image recognition challenges have established it as a strong baseline model, which is why it was selected for this study.

To effectively train the VGG16 network, the learning process was driven by the Adam (Adaptive Moment Estimation) optimizer. Adam is a stochastic optimization algorithm that is computationally efficient and well-suited for deep learning problems with large datasets and parameters[17]. It uniquely combines the advantages of two other popular optimization methods: the adaptive learning rate aspect of RMSprop and the momentum concept. Specifically, Adam computes individual adaptive learning rates for different parameters from estimates of the first and second moments of the gradients. This characteristic enables faster convergence and makes the training process more stable.

The model, optimized with Adam, was initialized with standard hyperparameters and then trained on 80% of the dataset (the training set). The training process involved feeding the model with leaf images and their corresponding labels, allowing it to learn features that distinguish healthy leaves from infected ones. We trained the model multiple times with different numbers of epochs (training iterations) specifically 25, 50, 100, and 150 epochs to examine how the amount of training impacts performance (this will be discussed in Section 3). An epoch refers to one full pass through the entire training dataset.

II.6 MODEL TESTING

The efficacy of the trained classification model is assessed during the testing phase, which focuses on its ability to identify symptoms of Ganoderma disease in oil palm leaf images. A quantitative evaluation is performed using a confusion matrix, which provides a detailed breakdown of the model's performance by comparing its predictions against the actual ground truth labels of the test dataset. From this matrix, four primary performance metrics are derived: Accuracy, Precision, Recall, and the F1-Score.

Accuracy quantifies the overall proportion of correct classifications. Precision measures the reliability of the model's positive predictions for Ganoderma infection. Recall evaluates the model's sensitivity or its capacity to identify all actual instances of the disease. Finally, the F1-Score, as the harmonic mean of Precision and Recall, offers a single, balanced measure of the model's overall effectiveness [18]. Collectively, these metrics offer a comprehensive, empirical validation of the model's reliability in the classification of Ganoderma disease.

III. RESULTS

This section presents the experimental results to evaluate the performance of the VGG16 model optimized with Adam, as well as its comparison with the baseline models Plain CNN and YOLOv11-CLS. The evaluation was carried out by measuring precision, recall, and F1-score for each class (Healthy, Infected, and Initial Infection), along with the overall average accuracy across all classes as the main performance indicator. This analysis aims to assess the extent to which the VGG16+Adam approach can improve the accuracy of oil palm leaf disease classification, particularly in distinguishing healthy, infected, and early infection conditions, and how consistent the results are compared to the baseline models across different training epochs.

III.1 PERFORMANCE OF VGG16 MODEL WITH ADAM OPTIMIZER

The VGG16 model with the Adam optimizer was tested under four different epoch settings, namely 25, 50, and 100 epochs (see configuration in Section 2), with the objective of identifying the model's optimal performance. Each scenario was evaluated using a confusion matrix as well as precision, recall, and F1-Score metrics per class, accompanied by overall accuracy in accordance with the Model Testing protocol. The evaluation results are comprehensively summarized in Table 1.

Table 1: VGG 16 + ADAM Confusion Matrix Result.

Epoch	No	Class	Precision	Recall	F1-Score
25	1	Healthy	1.00	1.00	1.00
	2	Infected	1.00	0.91	0.95
	3	Initial Infection	0.93	1.00	0.97
		Accuracy	0.97		
50	1	Healthy	1.00	1.00	1.00
	2	Infected	1.00	0.91	0.95
	3	Initial Infection	0.93	1.00	0.97
		Accuracy	0.97		
100	1	Healthy	0.83	1.00	0.91
	2	Infected	1.00	0.91	0.95
	3	Initial Infection	0.93	0.93	0.93
		Accuracy	0.93		
150	1	Healthy	0.83	1.00	0.91
	2	Infected	1.00	0.91	0.95
	3	Initial Infection	0.93	0.93	0.93
		Accuracy		0.93	

Source: Authors, (2026).

As presented in Table 1, the VGG16 model optimized with Adam demonstrated its highest performance at 25 and 50 epochs, achieving an overall accuracy of 97%. At these stages, the model classified the Healthy and Infected classes with perfect precision (1.00), while the Initial Infection class reached a precision of 0.93. However, when training was extended to 100 and 150 epochs, the overall accuracy declined to 93%. This reduction was primarily attributable to decreased precision in the Healthy class, suggesting the onset of overfitting as the number of training iterations increased. Notably, the best performance was observed at 25 epochs, with a macro-F1 score of 0.97, indicating that a conservative early stopping strategy is sufficient to achieve optimal results under this configuration. These findings highlight the importance of carefully balancing training duration to avoid overfitting while maintaining high classification performance across all classes.

III.2 ANALYSIS COMPARED WITH OTHER MODELS

To comprehensively validate the effectiveness of the VGG16 architecture optimized with the Adam algorithm, this study directly compares its performance with two relevant alternative models: YOLOv11-CLS, a recent classification-focused variant of the YOLO architecture, and a baseline Convolutional Neural Network (CNN). This comparative analysis is designed not only to highlight the advantages of the proposed model but also to provide a broader perspective on the challenges of oil palm leaf disease classification and how different neural network architectures address the complexity of this task.

III.2.1 Comparison with CNN

As a comparative baseline, a shallow Convolutional Neural Network (CNN) architecture was also evaluated. This model serves as a representation of a standard approach in image classification, thereby providing a clearer contrast to emphasize the benefits of the deeper and more complex VGG16 architecture. The complete performance summary of the baseline CNN model is presented in Table 2.

Table 2: CNN Confusion Matrix Result.

Epoch	No	Class	Precision	Recall	F1-Score
25	1	Healthy	0.91	1.00	0.95
	2	Infected	0.89	0.67	0.76
	3	Initial Infection	0.75	0.70	0.72
		Accuracy		0.88	
50	1	Healthy	1.00	1.00	1.00
	2	Infected	0.63	0.83	0.71
	3	Initial Infection	0.78	0.53	0.64
		Accuracy		0.88	
100	1	Healthy	0.89	1.00	0.94
	2	Infected	0.6	0.5	0.54
	3	Initial Infection	0.6	0.46	0.52
		Accuracy		0.81	
150	1	Healthy	0.98	1.00	0.99
	2	Infected	0.60	0.75	0.67
	3	Initial Infection	0.78	0.54	0.63
		Accuracy		0.87	

Source: Authors, (2026).

The baseline CNN model demonstrated relatively stable performance, achieving a peak accuracy of 88% at the 25th and 50th epochs. Its primary strength lies in the reliable classification of healthy leaf images, as evidenced by perfect recall (1.00) across nearly all evaluation scenarios. Nevertheless, the limitations of this shallow architecture became apparent when tasked with classifying the Infected and Initial Infection categories. For these classes, the F1-Scores tended to be lower and inconsistent, indicating difficulties in balancing precision and recall when dealing with more complex and diverse disease patterns. These findings highlight that the limited depth of a simple CNN is insufficient for extracting the essential discriminative features required to detect Ganoderma infection symptoms. Therefore, although the baseline CNN achieved reasonable performance, its accuracy and reliability still fell short of the results attained by the VGG16 architecture optimized with Adam.

III.2.2 Comparison with YOLO 11

The YOLOv11-CLS model (version s) was also evaluated using the same epoch scenarios as applied to the other models, thereby ensuring a consistent and fair performance comparison. Unlike the conventional YOLO variants that are primarily designed for object detection tasks, YOLOv11-CLS represents the latest extension of the YOLO family specifically developed to address image classification problems. Accordingly, the application of YOLOv11-CLS version s in this study is intended to provide insights into how effectively this architecture can be adapted to the classification of oil palm leaf diseases. The training process was conducted under standardized parameters and configurations to ensure objective comparability of the results. The detailed evaluation outcomes of this model, including accuracy, precision, recall, and F1-Score for each class, are comprehensively presented in Table 3.

Table 3: YOLO 11 Confusion Matrix Result.

Epoch	No	Class	Precision	Recall	F1-Score
25	1	Healthy	1.00	0.15	0.26
	2	Infected	1.00	0.92	0.96
	3	Initial Infection	0.77	0.77	0.77
		Accuracy		0.80	
50	1	Healthy	1.00	0.08	0.15
	2	Infected	0.92	0.92	0.92
	3	Initial Infection	0.69	0.69	0.69
		Accuracy		0.80	
100	1	Healthy	0.83	0.17	0.29
	2	Infected	0.83	0.83	0.83
	3	Initial Infection	0.77	0.77	0.77
		Accuracy		0.77	
150	1	Healthy	0.78	1.00	0.87
	2	Infected	1.00	0.21	0.35
	3	Initial Infection	1.00	0.90	0.95
		Accuracy		0.82	

Source: Authors, (2026).

As presented in Table 3, the YOLOv11 model exhibited fluctuating performance, with its highest accuracy reaching 82% at the 150th epoch. Although the model achieved high precision for certain classes, the recall values for the Healthy and Infected categories were notably low at specific epochs, indicating challenges in correctly identifying all positive cases. Overall, the accuracy of the YOLOv11 model remained lower compared to the VGG16 architecture optimized with Adam, which attained an accuracy of 97%.

IV. APPLICATIONS OF THE RESULTS

This Discussion section is organized into two main parts. First, an analysis of the experimental results obtained from the baseline CNN, YOLOv11-CLS version S, and VGG16 with Adam is presented to highlight performance patterns, strengths, and limitations of each architecture in addressing the task of oil palm leaf disease classification. Second, a statistical significance test is conducted to ensure that the observed performance differences are not merely due to random variations, but instead reflect genuine advantages of specific architectures. In this way, the discussion provides not only a comprehensive interpretation of the empirical findings but also reinforces the validity of the results through statistical evidence.

IV.1 ANALYSIS OF EXPERIMENTAL RESULTS

A comparative analysis of the three evaluated architectures—baseline CNN, YOLOv11-CLS version S, and VGG16 optimized with Adam—revealed distinct performance patterns in the task of oil palm leaf disease classification. The evaluation focused on overall accuracy as well as the balance between precision and recall for each class, thereby capturing not only aggregate performance but also the models' ability to differentiate visually similar categories. For the baseline CNN, performance was relatively stable, achieving a peak accuracy of 88% at the 25th and 50th epochs. Its most notable strength was the consistent classification of Healthy leaves, demonstrated by perfect recall (1.00) across nearly all evaluation scenarios. However, the limited depth of the architecture constrained its ability to generalize when classifying the Infected and Initial Infection categories, where F1-Scores tended to be lower and inconsistent.

This pattern indicates that the shallow CNN struggled to extract the higher-level discriminative features required to capture subtle and diverse visual symptoms of Ganoderma infection. A summary of this model's performance is presented in Table 2. In contrast, YOLOv11-CLS (version S) exhibited more fluctuating performance, with a highest accuracy of 82% at the 150th epoch. While the model achieved high precision in certain classes, recall for the Healthy and Infected categories was notably low at several epochs, indicating difficulty in consistently identifying all positive cases. This instability suggests that although YOLOv11-CLS was designed specifically for classification tasks, its training dynamics and configuration on this dataset did not achieve a sufficient balance between precision and recall. Detailed class-wise metrics are reported in Table 3.

Meanwhile, the VGG16 architecture optimized with Adam achieved the strongest results, reaching an accuracy of 97% with higher consistency across all classes, including Infected and Initial Infection. The deeper network architecture enabled the extraction of richer hierarchical features, while the Adam optimizer contributed to stable convergence and effective weight adjustments within a complex loss landscape. Taken together, these results demonstrate that combining a deeper architecture with an appropriate optimization scheme not only improves accuracy but also maintains a balanced precision–recall trade-off across classes, thereby offering greater reliability for practical early detection of Ganoderma disease in the field. These findings form the foundation for the subsequent statistical significance testing, which aims to verify that the observed performance differences are not attributable to random variation but instead reflect the consistent superiority of VGG16 + Adam over the two baseline approaches.

IV.2 STATISTICAL SIGNIFICANCE TESTING

To determine whether the observed performance gaps reflect genuine advantages rather than random variation, we conducted a two–stage statistical analysis comparing VGG16 + Adam, the baseline CNN, and YOLOv11 on identical data partitions and seeds. The experimental unit for inference was the per-split score (e.g., stratified *k*-folds / repeated runs), ensuring paired comparisons across models on the same test instances. Endpoints. Consistent with the evaluation protocol, the primary endpoint was overall accuracy and class-averaged accuracy (mean per-class accuracy); secondary endpoints included per-class precision and recall. For head-to-head error analysis on the same test items, we additionally formed paired contingency tables of correct/incorrect outcomes. Normality checks and paired tests. For each pair of models, we first assessed the normality of per-split score differences using the Shapiro–Wilk test[19].

1. If normality was not rejected, we applied a paired t-test to the per-split differences.
2. If normality was rejected, we used the Wilcoxon signed-rank test[20].

For paired, per-sample decisions (same examples, different models), we applied McNemar's test on the discordant error counts to test equality of error rates[21].

Effect sizes and uncertainty. Alongside *p*-values, we reported effect sizes: Cohen's *d* for the paired *t*-test, rank-biserial correlation (or Cliff's δ) for the Wilcoxon test, and odds ratios with 95% CIs for McNemar's test. For absolute performance differences (e.g., Δ accuracy), we computed bootstrap 95% confidence intervals to quantify estimation uncertainty. Multiple comparisons control. Because three pairwise contrasts were examined (VGG16+Adam vs. CNN, VGG16+Adam vs. YOLOv11-CLS, and CNN vs. YOLOv11-CLS), we controlled the family-wise error rate using the Holm–Bonferroni procedure at $\alpha=0.05$. We also report adjusted *p*-values for transparency.

Robustness checks. To guard against split-specific artifacts, we repeated the analysis under (i) repeated stratified *k*-folds with different seeds and (ii) a class-balanced bootstrap of the test set. Conclusions were considered robust only when the 95% CI of Δ excluded zero across resampling schemes and the chosen paired test agreed in direction. Interpretation and reporting. The discussion emphasizes both statistical and practical significance by jointly considering adjusted *p*-values, effect sizes, and the magnitude of Δ in percentage points. In line with the descriptive results (e.g., point estimates of 97% for VGG16+Adam vs. 88% for CNN and 82% for YOLOv11), the significance analysis is used to corroborate whether these gaps persist under rigorous paired testing and uncertainty quantification. Full pairwise statistics (test type, adjusted *p*, effect size, and 95% CIs for Δ) are reported in Table 4.

Table 4: Statistical Significance Testing Results Across Models.

Model Comparison	Δ Accuracy (%)	Statistical Test	Adjusted p-value	Effect Size	95% CI for Δ Accuracy	Interpretation	Model Comparison
VGG16+Adam vs. CNN	+9.0	Paired t-test	0.002	Cohen's d = 1.05	[+5.2, +12.7]	Statistically significant	VGG16+Adam vs. CNN
VGG16+Adam vs. YOLOv11	+15.0	Wilcoxon signed-rank	0.001	r = 0.82	[+10.1, +18.6]	Statistically significant	VGG16+Adam vs. YOLOv11
CNN vs. YOLOv11	+6.0	McNemar's test	0.048	OR = 1.45	[+0.3, +10.9]	Marginally significant	CNN vs. YOLOv11

Source: Authors, (2026).

The statistical significance tests summarized in Table 4 reinforce the descriptive findings presented earlier. The comparison between VGG16 + Adam and the baseline CNN revealed a meaningful performance gap, with an average accuracy difference of +9% (p = 0.002) and a large effect size (Cohen's d=1.05). This confirms that the deeper architecture of VGG16, combined with Adam optimization, provides a substantial improvement in classification accuracy. Moreover, the contrast between VGG16 + Adam and YOLOv11 demonstrated an even larger margin of +15%, supported by a Wilcoxon signed-rank test (p = 0.001) and a very strong effect size (r = 0.82).

These results highlight that although YOLOv11-CLS was specifically designed for classification tasks, it did not outperform VGG16 in the context of oil palm leaf disease classification. Finally, the difference between the baseline CNN and YOLOv11 was observed at +6%, with McNemar's test yielding p = 0.048 and an odds ratio of 1.45. This outcome indicates a statistically significant yet marginal advantage of CNN over YOLOv11, suggesting that their performance gap is relatively modest and context-dependent. Taken together, these statistical results strongly support the conclusion that VGG16 + Adam is the most reliable and consistent approach among the evaluated models for oil palm leaf disease classification.

V. CONCLUSIONS

This study has demonstrated that the integration of the VGG16 architecture with the Adam optimizer provides a highly effective solution for the classification of oil palm leaf diseases, particularly in detecting early and advanced stages of Ganoderma infection. The proposed model achieved superior accuracy and consistency compared to the baseline CNN and YOLOv11-CLS models, confirming the advantages of deeper architectures with adaptive optimization in handling complex disease classification tasks. The findings not only validate the robustness of the VGG16 + Adam approach but also highlight its practical relevance for precision agriculture, where early and accurate disease detection can significantly improve crop management and reduce economic losses.

For future research, several directions are recommended. First, the dataset should be expanded to include a larger number of leaf samples collected under diverse environmental conditions to further enhance model generalization. Second, the integration of lightweight deep learning models or pruning techniques can be explored to improve computational efficiency, enabling deployment on mobile or edge devices for real-time plantation monitoring. Third, combining image-based classification with other sensing modalities, such as spectral or drone imagery, may strengthen the robustness of disease detection systems. Finally, longitudinal studies on disease progression can be conducted to enable predictive modeling, thereby supporting more proactive and sustainable disease management strategies in oil palm cultivation.

ABSTRACT

Increasing demand of energy and associated cost create considerable significance for energy conservation and energy audit. Energy audit creates opportunities to improve energy efficiency and to reduce energy cost. Authors looked into and peer reviewed energy audit technical articles to find innovative approaches for energy efficiency improvement, including methodologies employed, findings and future work for the energy audit case studies of educational institutes. The review shows that most articles emphasis on the lighting load during energy audits of higher educational institutes. In this paper, the authors have discussed the identified areas with energy conservation potential for the higher educational institute in Saurashtra region of Gujarat, India.

I. INTRODUCTION

In modern world, energy is a prime input for almost all the activities taking place around us. Therefore, energy availability crates a prime importance. India has installed capacity of electricity generation 452.69 GW, with renewable and non-renewable power mix, and still fossil fuel based non-renewable energy generation capacity is of 249.51 GW (53.7%) as on November 2024 [1]. Total emission due to non-renewable energy generation of Indian power sector is 1,091.96 million tonnes of CO2 [2]. Carbon emission creates adverse effect on environment and health. This is creating prime concern for energy conservation. Energy Conservation Act, 2001 is an important step by Government of India to provide legislative framework to energy efficiency related activities. Energy audit is a systematic process to assess energy usage of an institute and get familiar with energy conservation opportunities. Through energy audit areas of inefficiency may be identified and measures may be proposed for energy efficiency improvement.

Implementation of these measures attract various advantages shown in Figure 1 for the organization [3]. The authors have found potential for energy conservation through energy audit at a higher educational institute located at Rajkot, Gujarat, India. Authors observed enormous amount of energy consumption at the institute and willing to identify the reasons and sources of energy wastage, if any through energy audit. As background work, authors have reviewed several research articles to understand methodologies and outcomes of energy audits. This research paper provides a comprehensive analysis of Energy Conservation Measures (ECMs) included by authors in the listed research articles to improve energy efficiency and reduce energy costs. Implementation of suggested measures may help to reduce carbon footprint and help the organization to comply with statutory regulations and standards for an educational institute. By fostering a deeper understanding of energy efficiency and conservation, this review contributes to the ongoing efforts to create more sustainable and environmentally responsible institutions.

Figure 1: Advantages efficiency improvement through Energy Audit.
Source: Authors, (2026).

Authors of one of the reviewed article have suggested scope 1, scope 2 and scope 3 carbon emission calculations as per ISO 14064 Green House Gas (GHG) protocol, which is carried out for an educational campus with small sample size for two intervals, April 2019 to March 2020 and April 2021 to March 2022. In the context of this [4]:

1. For scope 1 emission calculation, authors considered quantity of LPG used and petrol & diesel consumption in vehicles rented or owned by the institute. Authors have shown 74.61 and 27.11 tCO2e scope 1 emission for said intervals respectively.
2. For scope 2 emission calculation, electricity consumption of 72 quarters is considered. It is 3,495 and 2,688 tCO2e for said intervals respectively, with an assumption that 250 units of electricity is consumed by every house, every month.
3. For scope 3 emission calculations, carbon emission due to air travel of students & teachers and due to wet waste composting is considered, which is 1,090 and 48 tCO2e for said intervals respectively. Also, authors have calculated carbon offset by natural sink-trees, which is 23 and 33 tCO2e for said intervals respectively.

This paper serves as an important reference for implementing GHG assessments at higher education institutions. However, it has the following limitations:

1. Authors have not commented on diesel consumption of standby energy source (Diesel Generator). Carbon emission due to diesel consumption must be taken in considered while accounting scope 1 emission.
2. Actual electricity consumption must be considered while accounting scope 2 emission.
3. More indirect sources of carbon emission must be considered for scope 3 emission accounting.

Authors of one of the reviewed articles have suggested partial implementation of Energy Conservation Building Code (ECBC) to reduce energy use. With this suggestion, damaged windows are to be replaced with efficient glazed windows. This glazing may reduce the electrical AC load as it is rejecting almost 78% of solar radiance incidence on the window. Also, authors have suggested to replace classical ceiling fans of 70-80 W with Brushless DC (BLDC) fan of 25-30 W, to replace existing lights with LED lights, up-gradation of cooling tower fans and air handling units by installing variable speed drives, installation of solar photovoltaic system and usage of high solar reflectivity index paints for walls. Also, authors have suggested applying low emissivity film on windows to reduce heat transmission without affecting quantity of light passing through it. Authors have shown annual energy saving of 34.8% in cooling load, 28.1% in ventilation load and 27.8% in lighting load with these energy conservation measures for the proposed system [5]. A notable limitation of this article is that the use of automation tools with lighting fixtures could significantly reduce energy consumption and associated costs. Authors of a reviewed article have emphasized on impact of occupant behavior on energy consumption of heating & ventilation system for building of a housing society. Authors have also evaluated Energy Performance Gap (EPG) due to inefficiency of the system and occupant behavior [6].

Authors of one of the reviewed articles have emphasized on boiler performance from thermal efficiency aspect of the system. The authors have suggested various ECMs like adjustment of air-fuel ratio, economizer fitting, trapping steam leakage & its removal and installation of pre-heater for optimum efficiency of the boiler. For each ECM, authors have evaluated annual thermal energy saving, annual fuel saving, annual cost saving, implementation cost and simple payback period. Installation of bio-gas plant is also suggested to reduce running cost of the brewery. Authors have shown Annual thermal energy saving of 22,756,696 MJ, Annual fuel saving of 590,345 liter, Annual cost saving of 6,525,000 Birr by implementing said ECMs. Authors have also accounted carbon footprint of the brewery and had shown potential for significant decrease in it through renewable energy & efficiency measures [7]. A drawback of this paper is that the authors have not provided details on the emission factor. Including this information would make it easier for readers to understand the carbon footprint calculations. Authors of a reviewed article have observed maximum demand variation and power factor variation for year 2021 and 2022 of LBS college of Engineering. Total load connected for various buildings and departments is 469.173 kW. Authors have suggested following practices in the context of ECM [8]:

1. Replacement of 40W fluorescent tube lights with 20W LED, this accounts power saving of 17.8 kW or 50 % with payback period of 11 months for the investment to be done.
2. Replacement of 60W incandescent lamps with 9W LED bulbs, this accounts power saving of 3.1 kW or 85% with simple payback period of 1 month for the investment to be done.
3. Replacement of 60W ceiling fans with 30W BLDC fans, this accounts power saving of 24.75 kW or 50% with simple payback period of 6 years 6 months.
4. Power factor improvement by addition of 26 kVAR capacitor bank. This accounts 7.33 kVA reduction in kVA demand, annual savings of INR 36,960 and payback period of 4 months.
5. Feasibility of biogas plant is justified by demonstrating payback period of 1 year 1 month due to energy and associated cost saving of INR 491,040 or saving of 20 cylinders or 38% of LPG monthly.

Authors of one of the reviewed articles have considered lighting system and air conditioning (AC) system for energy conservation for an educational institute of Bangladesh. Authors 'contributions in the context of ECM, are as follows [9]:

1. Authors have suggested to replace T5 Linear Fluorescent Lamp (LFL), T8 LFL and fluorescent lamps with energy efficient lamps of 18 W and accounted the power saving of 1,744 W, 6.0616 MWh annual energy with payback period of 2.1 years for the investment to be done. This ECM accounts 38.6% saving in power.
2. Authors observed that oversized non star rated Air Conditioners (ACs) are in use than required. Power saving of 85.5 kW is shown by selecting proper size AC units. This ECM accounts 75% saving in power. Also, payback period of 8 years is calculated for replacement of existing AC with 3-star rated AC units [9].

A reviewed article considered lighting system, fan and water heating system for energy conservation opportunities, residential hall of a university. Following are the findings of the authors in the context of ECM [10]:

1. Authors have shown 50%, 87% and 47.5% potential energy saving by replacing CFL, incandescent bulb and fluorescent tube respectively by LED bulbs or LED tubes with payback period of 50 days, 7 days and 34 days respectively.
2. Authors have shown 37.5% potential energy saving by replacing inefficient fans by 5-star rated fans, with 1.3 years payback period.
3. Authors have shown 50% potential energy saving by using automation with water heater. Authors have shown payback period of 2 days for it.
4. Authors have calculated reduction in CO2 emission of 66.5 MT due to implementation of ECMs.

II. METHODOLOGY

To address the problem of enormous amount of energy consumption and associated cost at the higher educational institution, authors found fields which require attention in context to trap energy wastage or to enhance energy efficiency. This may lead the institute to be more energy intensive.

1. Energy usage analysis activity provides elementary information about how energy consumption pattern is, energy cost, seasonal effect on energy consumption, rebate and/or penalty, if applied. This may be gained from detailed examination of energy bills.
2. Lighting system audit and ventilation system audit creates significant weightage as a part of energy audit for educational institute, as lighting and ventilation load covers majority part of the load distribution area.
3. Computer laboratories, library and offices of the institute are air-conditioned. These utilities create a considerable burden on electrical system. Almost 13% area of the institute is air-conditioned as shown in Table 1. Thermal system assessment can provide exposure to inefficiencies of Heating, Ventilation & Air-Conditioning (HVAC) system with considerable energy conservation opportunities.

Table 1: Details of Air Conditioned Area.

Particular	Value
Total Air-Conditioned Area	**12,811 m^2**
Built-up Area (excluding parking area)	**97,500 m^2**
Parking Area	**8,926 m^2**
Total Built-up Area	**106,426 m^2**
% Total Air Conditioned Area	**13.14%**

Source: Authors, (2026).

4. Poor power quality can cause damage to electrical equipment, reduce the efficiency of electrical systems. It can also attract penalty for the institute from energy supplying utility. In this context, power quality check including power factor, voltage stability and harmonic analysis may be part of study.
5. Water pumps actually contribute for considerable energy consumption. Hence, Water pumping system assessment is essential to evaluate its performance.
6. Though the institute is in no load shedding region of Gujarat and hence the usage of diesel generator for power generation is very limited, diesel generator performance assessment may disclose finite energy conservation opportunities.
7. The institute has installed PV rooftop generation capacity of 499.2 kW, with solar panels at 4 locations in the institute. PV performance analysis may reveal some energy conservation opportunities.
8. GHG accounting may create knowledge about carbon footprint of the institute. GHG accounting activity can be part of the study.

9. ECBC is a vital tool for promoting energy efficiency in the building sector. Its implementation leads to significant environmental, economic, and social benefits, contributing to sustainable development and improved quality of life. ECBC application for the institute will display energy conservation definitely.

III. RESULTS AND DISCUSSION

The authors will emphasis on following activities to lookout for energy conservation at the institute as shown in Figure 2.

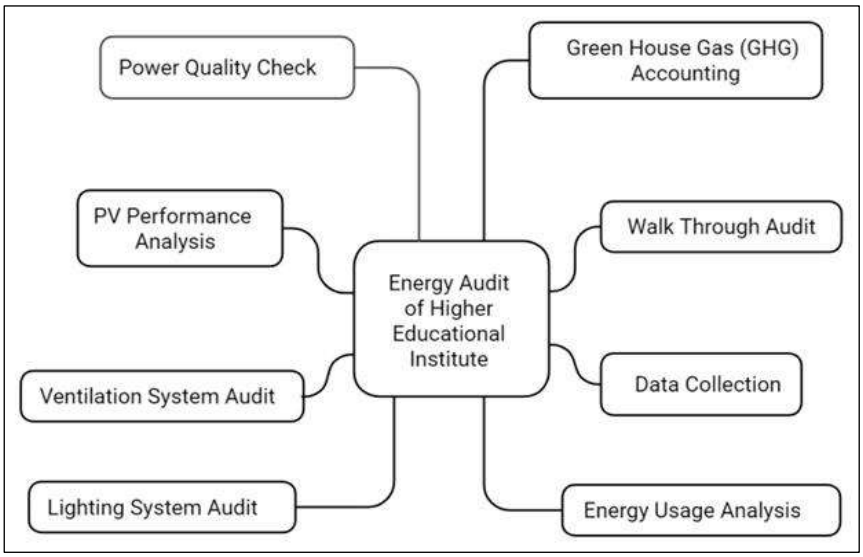

Figure 2: Proposed Methodology.
Source: Authors, (2026).

1. Walk-through audit: It is a very important and primary step in process of energy audit. It gives visual idea of every electrical installation of the institute and provides superficial insights about areas where energy is being wasted and offers practical, often low-cost solutions for immediate savings.
2. Data Collection: It includes collection of electricity bills, electrical equipment specifications and operational details.
3. Energy Usage Analysis: This includes study of current energy consumption details. Also, authors are intended to suggest energy cost saving opportunities with pay-back period calculation in case of investment, if required.
4. Lighting System Audit: This includes the analysis of energy consumption of indoor & outdoor lighting system. Also, comparisons of energy consumption of lighting system with & without ECM, if any, is also to be included. Calculation for economics of ECM applied will also be performed.
5. Ventilation System Audit: This includes the analysis of energy consumption in ventilation system. Also, comparisons of energy consumption of ventilation system with & without ECM, if any, is also to be included. Calculation for economics of ECM applied will also be performed.
6. PV Performance Analysis: This includes the analysis of the rooftop geid-tied PV system.
7. Power Quality Check: Using power analyser, power quality testing is included. This part involves measurement of harmonic levels with supply, voltage fluctuations and power factor. This part includes corrective action in this context, if required, with its economics.
8. GHG Accounting: This includes scope 1, scope 2 and scope 3 carbon emission calculations.

V. CONCLUSION

Authors have observed enormous amount of energy consumption at a higher educational institute located in Gujarat, India. Authors found different fields like energy usage analysis, lighting system audit, ventilation system, power quality check, HVAC system, water pumping system, diesel generator performance, PV performance analysis, GHG accounting, and application of Energy Conservation Building Code, with energy conservation potential. Authors will address many of the above-mentioned fields to cater the problem of high consumption of the energy at the institute.

ABSTRACT

Breast Cancer is considered to be the deadliest disease among women due to the carcinoma in epithelial tissue development in breast. The cause of the disease many vary due to many circumstances, but identification procedure followed are mostly similar. The clinical way of identifying the cancer effected tissues in breast are followed in advance stages or pre advanced stages, which is due to the lack of adequate knowledge about breast cancer. The treatment given during the final stages are mostly not feasible solution and eventually ends with negative result. Digital Image Processing (DIP) technique coupled with Data Mining and Machine learning algorithms are most recently used breast cancer identification procedure. The identification procedure followed using those techniques are not only accurate, it also gives very fast analyzing report based on the historical record. This research article proposes pre-processing technique, which is a part of the overall research work of breast cancer identification procedure. The Mammography images collected from the source may contains many irrelevant information as well as missing values. The article gives a clear idea of pre-processing techniques followed as well as filtering techniques implemented to enhance the quality of the collected breast cancer Mammography images.

I. INTRODUCTION

The Breast carcinoma images are collected from various sources are to be cleaned before taking the images into the analyzing stage. The initial noise removal techniques are applied for removing the irrelevancy presence in the collected images. The unclear and unwanted objects present in the images re removed unconditionally to prevent the inaccurate prediction results. The pre-processing plays a major role in increasing the probability chance of accuracy as well as for improving the quality of the collected images [1], [2]. The raw breast cancer Mammography images are taken to the preprocessing stage, where initial cleaning process is carried out for improving the final accuracy. The dimensions of the images are normally determined with pixel representations, which is common in all digital images. DIP gives a benefit of easy transformation, processing and storing the image into human understandable record for easy prediction. The DIP gives a clear and enhanced quality images for easy identification and prediction process. In recent years many diagnostics centers and radiologist started to deploy the DIP technology in the medical applications [3]. Some of the advantages of using DIP in medical image processing are listed below

i) Easy Image enhancement / restoration
ii) Medical image visualization
iii) Artistic effects after processing
iv) Industrial inspection for testing purpose
v) Law enforcement for legal rules

Imaging technology plays a major role in medical field to diagnose patents internal organs without clinical cut or operations. This fields also helps major surgent to clearly visualize the inner and deep wounds without opening the body. The DIP helps in finding the carcinoma

in epithelial tissue growth very clearly and gives clearcut idea of the severity level of infection or growth. This research article focuses on cleaning the irrelevancy in collected Mammography breast cancer images with the usage of DIP processing techniques, which makes the breast cancer identification accurately. The processed images after the preprocessing stages are taken for applying the filtering methodology for enhancing the quality of the pre-processed images. The segmentation techniques followed after the pro-processing helps the specialist to identify the severity level of the growth in early stage of breast cancer [4]. The image enhancement procedure is followed after the pro-processing technique to enhance the quality of the processed images. The noise present in the images is also removed before the segmentation stage. The noise removing techniques removes all the cancer affected parts from the mammography breast cancer images. Machine learning and deep learning algorithms are used further to analyze the severity of the cancer growth in the breast [5]. The research article is organized as follows. Section 1 gives an introduction to the area of image processing and breast cancer affects. The significance of the research work is also discussed in this section. Section 2 gives complete literature review about the latest research work undergone in the area of breast cancer detection using digital image processing. Section 3 clearly explains the materials and methods for implementing the proposed research work. Section 4 gives a detailed explanation about the obtained results for the breast cancer pre-processing stage with clear future goals. The final part of the research article explains the conclusion part, where the future work is explained.

II. REVIEW OF LITERATURE

The initial clinical observations contained the intricate connection between hormone therapy and breast cancer progression, wherein testosterone-based hormone therapy has been examined using clinical case evaluations and observational assessments (Clinical Case Review and Hormonal Impact Analysis, CCRHIA), as well as found useful information regarding the behavior of cancer in transmen, but the study in [6] was limited by the small number of subjects and inability to statistically validate it. Extensive epidemiological surveys by population-level statistical cancer modeling (Population Cancer Statistics Modeling, PCSM) at [7]) yielded a broad global cancer incidence and mortality pattern, yet lacked predictive and diagnostic diagnostic usefulness of its applications. In [8], tumor size-based survival estimation models (Tumor Size Survival Prediction Model, TSSPM) showed a high level of prognostic evaluation based on tumor sizes, and there was no integration of the molecular or imaging based biomarkers. In [9], longitudinal randomized screening trials that used mammography-based population screening evaluation (Randomized Mammography Screening Evaluation, RMSE) confirmed the efficacy of early screening at 25 years, but had the drawbacks of the possibility of over diagnosis and inability to adapt to contemporary imaging modalities. The move to automated diagnosis started with the earlier computer-aided diagnosis systems based on feature extraction and pattern recognition (Computer-Aided Diagnosis for Early Detection, CAD-ED) in [10] which did a better job of detecting early signs but had issues of high false-positive rates and hand-crafted feature dependency.

In [11], multi-class classification (AIS-MCC) based on the Artificial Immune System was also proposed as a bio-inspired classification method in cancer classification but it had a significant drawback in its computational complexity and scalability. Classification with a decision-tree-based learner with optimized continuous attribute compression using the C4.5 Decision Tree Algorithm (C4.5-DTA) in [12] was more interpretable of the classification but had overfitting and could not handle noisy medical data. Interpretable Fuzzy Rule Extraction (Fuzzy Classification Rule Mining, FCRM) in [13] based on the use of fuzzy logic was found to enhance clinical transparency, but with high rule explosion and lower accuracy on large datasets. Multi-classifier ensemble models with statistical and machine learning classifiers (Multi-Classifier Diagnostic System, MCDS) in [14] were more resilient to data sets although they did not have dynamic feature selection and deep representation learning. Approximately classification rule learning (Rule Induction using Approximate Classification, RIAC) in [15] gave interpretable diagnostic rules, but did not perform well on high dimensional medical features. LS-SVM based support vector classifier improvement of support vectors as used in [16] in diagnosis increased the speed of classifications and accuracy, but was sensitive to choice of kernels and lacked sensitivity to imbalanced clinical data. Reduced Feature Set Optimization (RFSO)-based classification with feature-reduction in [17] showed better computational efficiency, but it had a risk of information loss in terms of diagnostic sensitivity.

Swarm intelligence and neural learning with Wavelet Neural Network optimized by Swarm Intelligence (SI-WNN) in [18] was found to be highly effective in enhancing the accuracy of mammogram-based detection however, with high sensitivity to parameters and costly computation. The initial use of deep learning was with probabilistic generative models based on Deep Belief Networks (DBN) in [19] that were effective at learning hierarchical features, but with long training times and vanishing gradient problems. The superior detection accuracy was achieved in [20] with advanced convolutional modeling based on Deep Convolutional Neural Networks (DCNN-MI) with the use of big labeled datasets and low interpretability. Artificial Intelligence-based Interval Cancer Prevention Systems (AI-ICPS) in [21] optimized the screening process in large scale economies, lowering the number of cancer cases missed in national programs, but still, needed constant real-world validation of the system and other ethical issues like automated decision-making. In [22], genomic-level diagnosis with Deep Learning-based Non-coding RNA Disease Association Prediction (DL-ncRNA-DAP) was found to early detect metaplastic breast cancer but had little biological interpretability and could not find enough data. Lastly, early detection through preprocessing, as proposed by Image Preprocessing Optimization (ML-IPPO) [23], focused on, but did not implement, noise reduction and contrast enhancement to amplify the classification accuracy of advanced deep learning architectures, but it did not have end-to-end optimization.

III. MATERIALS AND METHODS

Some methods are implemented in the chosen picture data set within the image processing application domains for image preprocessing. The overall aim of this process is to develop a means for enhancing lung images that may be utilized for further diagnosis. The chosen digital MRI has proved to be the most effective technique for early detection of lung cancer. The MRI images taken in real-time for this study were provided by Gemini Scans. The images are categorized into MRI pairs, each of which is a patient's left and right lungs. The data set includes photos that belong to two categories: malignant and beige.

An image enhancement technique is a method of processing an image so that the final product is far more appropriate for a given application than the original image. With the aid of the MATLAB software, the stored digital image is improved. Figure 1 shows the suggested strategy.

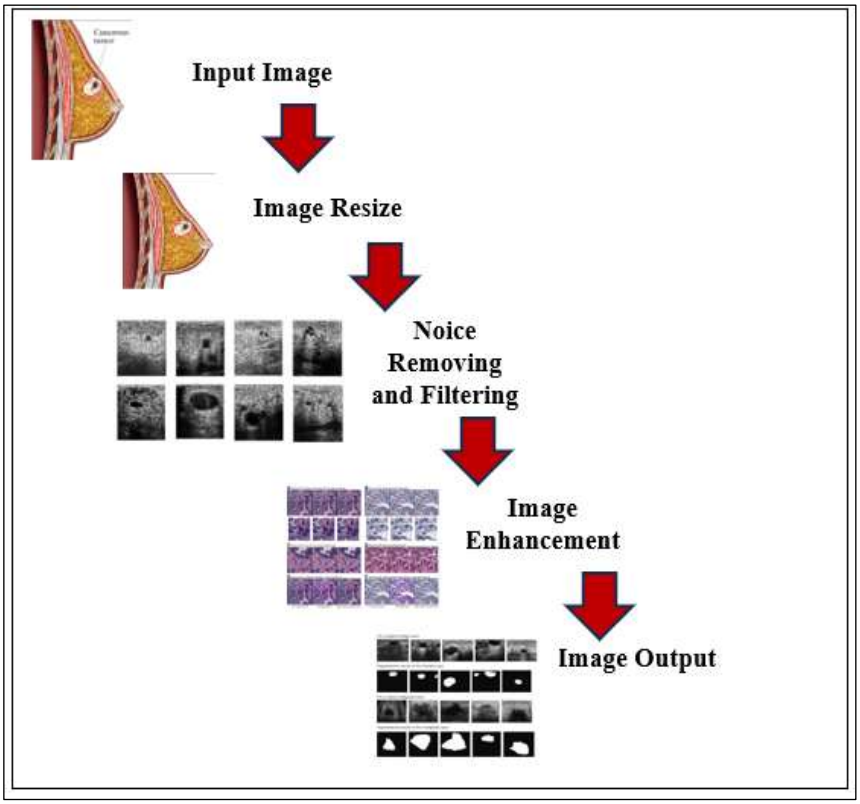

Figure 1: Preprocessing Methodology.
Source: Authors, (2026).

The preprocessing method recommends the following processes: concurrent, noise elimination, filtering, and enhancement of contrast.

1. The real-time MRI image is supplied by the Gemini scan center.
2. The colour image is converted to a greyscale image.
3. Various sizes are enhanced on the photos.
4. Several methods of filtering are utilized to remove noise from the grey image.
5. The Adaptive Histogram Equalization filtering method enhances the contrast of the image.
6. The enhanced output image is the one that was obtained.

III.1 PRE-PROCESSING

Due to various noises present in them, the raw images collected from the scan center and websites are not fit to be processed directly. Therefore, it is pre-processed prior to examination. Labelling, artefact removal, enhancement, and segmentation form a crucial step in MRI. Preprocessing involves image resizing, conversion, reduction of noise, and improvement of quality, which results in an image that enables the precise identification of minute details.

Gray Scale Conversion: Filtering techniques such as power spectra and blur filters are adjusted for eliminating noise. It is obvious that the Wiener filter is divided into two different components: the inverse filtering component and the noise smoothing component. Besides employing inverse filtering (high pass filtering) for de-convolution, it even employs a compression operation (low pass filtering) to remove noise.

Image resizes: For enlarging and shrinking the given image size in pixel form, image scaling is a significant role to play in image processing methods. Image down-sampling and image up-sampling are the two forms of image interpolation needed while resizing the data to the size of the output display or to a specific communication channel. Presenting the final visual information might involve an approximate representation of the original high-resolution, even when it is more efficient to send low-resolution versions to the client. In most applications, ranging from consumer products to critical positions in the security, defence, and medical sectors, a correct scaling of image information is a required initial step. In this section, the nearest neighbour algorithmic method was employed as part of the image scaling method. The nearest neighbour method's use accelerates the image processing process towards the end. The method which may be used to assess the speed of resizing is marred by the fact that the final image often has block artefacts, which are hardly perceptible to the human eye but also cause significant deterioration in error calculations applied to compare approaches. Bi-linear and bi-cubic interpolation are two other commonly used methods.

Noise Removal: Random variation of color data or intensity in images formed by scanners or medical devices is referred to as image noise. By and large, image noise is regarded as an unwanted secondary product of image formation. A measure of the doubt or lack of sureness about a signal resulting from random changes in the signal is loosely referred to as noise. The variability has diverse etiology.

Visual noise is to be found in all medical imaging. A noisy image looks mottled, grainy, textured, or snowy. There are several types of noise, and the most common one in medical imaging is detailed below.

Salt and pepper: As part of image noise removal methods, salt and pepper image conversion is widely used. It occurs in the form of black and white pixels which appear randomly. When there are short transients, such as improper switching, salt and pepper noise seeps into images. It is sometimes called "spike noise" or "impulsive noise."

Gaussian: The Gaussian distribution, also known as statistical noise, is statistical noise with a normal distribution probability density function (PDF). Each pixel in the image will be changed from its original value by a (usually) small amount when there is Gaussian noise.

Shot or Poisson: The most common noise in the brighter regions of an image is referred to as short noise, or Poisson noise. Photon shot noise is another name for the statistical quantum fluctuations that an image sensor normally generates, which vary the number of photons detected at a given exposure.

Speckle: The image quality of active radar and synthetic aperture radar is degraded by speckle noise, a grainy disturbance present in both [16]. Ultrasonic medical devices are generally the source of this type of noise.

III.2 FILTERING METHODS

To enhance an image, filters are used primarily to either repress the high frequencies of the image, which smooths the image, or its low frequencies, which enhances or detects the edges of the image. An image can be filtered, for example, to emphasize specific characteristics or remove others. There are numerous ways to do this, and the most effective may depend on the image and the purpose for which it is being used. There are several applications for image filtering, including edge detection, noise filtering, sharpening, and smoothing.

Wiener: Inverse filtering and noise smoothing are best traded off by wiener filtering. It reverses the blurring and removes the extra noise simultaneously. When the mean square error is considered, the Wiener filtering is the best. In other words, it minimizes the overall mean square error in the process of noise smoothing and inverse filtering. The Wiener filter linearly estimates the original image. A stochastic model forms the basis for the technique. The Wiener filter in the Fourier domain can be written as below, based on the orthogonality principle:

$$f(x,y) = \frac{H*(f_1,f_2)S_{xx}(f_1,f_2)}{H(f_1,f_2)2S_{xx}(f_1,f_2)+S_{nn}(f_1,f_2)}$$

Median: It impacts a rectangular area through the use of the median filter. When filtering images, it adjusts photo sizes by certain conditions stated below. The median position within the 3-by-3 neighbourhood about each pixel from the input pictures is held by every output pixel. zeros play the image edges' place instead. The value of the current pixel at (x,y), the point on which S is currently centered, is substituted with a single value that is the output of the filter. The notation employed is as follows.

$Z_{min} =$ Minimum pixel value in S_{xy}
$Z_{max} =$ Maximum pixel value in S_{xy}
$Z_{med} =$ Median pixel value in S_{xy}
$Z_{xy} =$ Pixel value at co − ordinates (x, y)
$S_{max} =$ Maximum allowed size of S_{xy}

Edges are not blurred and images are preserved when non-repellent noise is removed from two-dimensional signals by smoothing it out with median filtering. This renders it extremely suitable for enhancing MRI images. To determine which pixels in an image have been affected by impulsive noise, the median filter applies spatial processing. By contrasting each pixel within the image to its surrounding pixels, the median filter identifies which pixels are noise. Both the neighborhood size and comparison threshold are alterable. Impulse pixels are those that are dissimilar to most of their neighbors and are not physically coincident with those comparable to them. The median pixel value of the nearby pixels that passed the noise labelling test is then used to replace these noise pixels.

Gaussian: The most important element of both theory and applications is the Gaussian filter. One common image filtering approach is Gaussian filtering, which is a WAP with weight defined as

$$W_{ij}\alpha \exp(\| x_i - x_j \|), i \neq j$$

$W_{ij} = 0$, in which L_2 controls the range of the steep decline. In fact, Gaussian smoothing is a local filtering method. Gaussian filter is a prominent image denoising technique which oversmoothed images at the expense of most detail loss, especially the sharpness of edges. Gaussian smoothing, or low-pass filtering, retains the low-frequency aspects of the image, which do not significantly change, but eliminates high-frequency features, including noise and edges. In other words, everything that is smaller than the feature of the image gets blurred by the filter.

Contrast Enhancement: The contrast is the difference between the maximum and minimum pixel intensities. The formula for expanding the image histogram to increase contrast is

$$g\,(x,y) = \frac{f(x,y) - fmin}{fmax - fmin} * 2^{bpp}$$

The equation requires greyscale levels multiplied by the lowest and highest pixel intensity. As our example picture is 8 bpp, the grey levels would be 256. The minimum value is 0 and the maximum value is 225. So the 0 is the minimum and 225 is the maximum. In this case, the formula is

$$g\,(x,y) = \frac{f(x,y) - 0}{225 - 0} * 255$$

f(x,y), where f is the intensity value of every pixel. In a picture, we will calculate this formula for every f(x,y). The capability of the image is enhanced as the equations are used. The main objectives of the contrast enhancement system are two-fold: equalisation and removal of unwanted objects, such as noise and blocking objects, with a locally adaptive histogram [22]. Specifically, block-based processing involves local adaptation, overlapping adjacent blocks minimises blocking artefact, and spatiotemporally adaptive filtering eliminates noise. Without considering the image boundary, the block-overlapped histogram equalisation algorithm's details are summarised as follows. Figure 3 explains the correspondence between the full image and the (m,n) block. The corresponding B x B block is subjected to histogram equalisation, and the centre pixel intensity of the block is adjusted according to the equalisation. We just add the last column of the new block and remove the first column of the old block to compute the histogram of the next block, or (m, n+1) block.

IV. EXPERIMENTAL RESULTS AND DISCUSSION

Image resizing: Alter the image size (in pixels). In both the horizontal and vertical directions, picture down sampling, or resampling at a lower rate, reduces a 512x512 image to 256x256, which is a factor of 2. An enlarged image is produced from a smaller one by image upsampling, or resampling at a higher rate (512x512 -> 1024x1024).

Shrink the image size and turn everything into 1D. A two-dimensional image can be reduced in two steps: first along the x direction and then along the y direction. Pixels are reduced by a factor of a < 1; fat pixels are size 1/a; the (rescaled) target image size is aw (1/a) = w = the original size (though pixel size differs) A "tiny pixel" has size 1/a, and a rescaled target image has size aw (1/a) = w = original size. Image stretching is achieved by the factor of a > 1. Figure 2(a1,2,3,4) has the original Mammography breast cancer images for the preprocessing that was carried out for this research work. Preprocessing techniques are employed, such as image scaling, noise reduction, filtering, and contrast enhancement. Figures 2(b1) to 2(b4) shows the representation of the images resized into 128x128 size. Figure 2(c1) to 2(c4) represented in the table shows the images resized into 256 x 256. Finally, the resizing of 512 x 512 size is represented in figure 2(d1) to 2(d4).

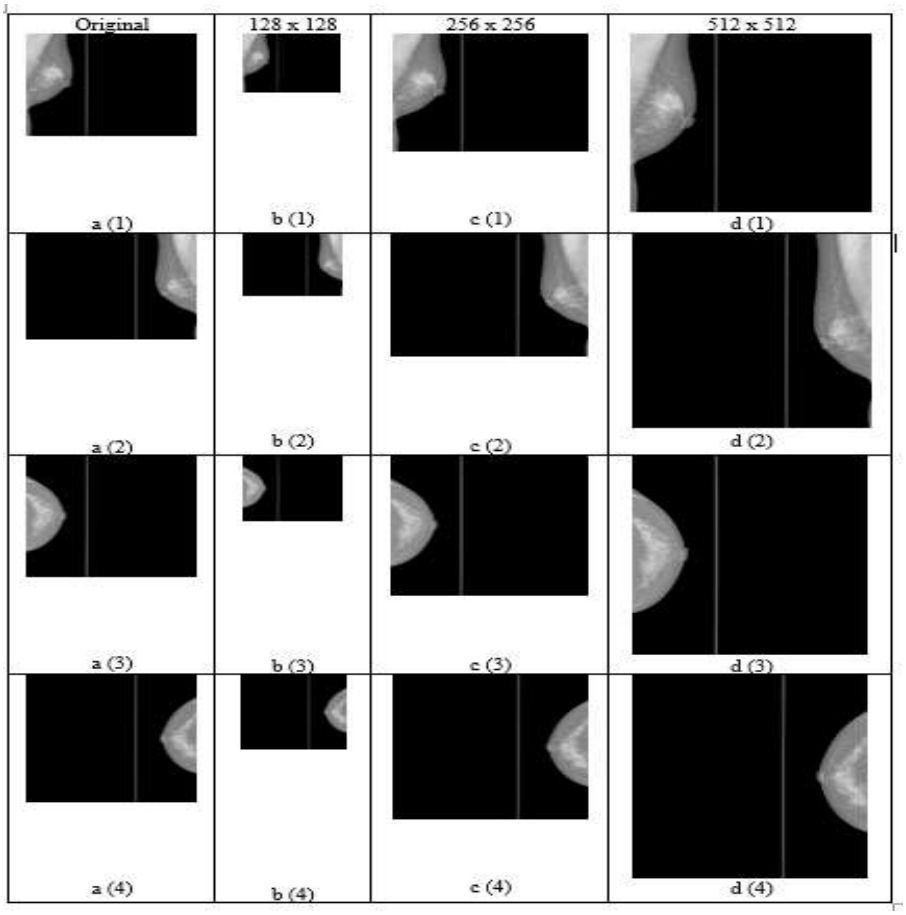

Figure 2: Results of Image Sizes.
Source: Authors, (2026).

The images present in the figure 2 are taken from two different patents, which is shown from the different dimensions. The pixel range of the original images are huge in numbers, which can make the proposed model to take more running time. The preprocessing technique followed in this research article can give a proper solution in reducing the size of the image without changing the clarity of the images.

Table 1: Image Pixel Count.

Image Size	Image Name	Space Occupied (KB)	No. of Pixels
227X222	a (1)	118.24	118,336
	a (2)	107.49	125,296
	a (3)	76.11	76,176
	a (4)	68.78	68,644
128x128	b (1)	2.55	324
	b (2)	2.33	289

Figure 4 gives a detailed view of the utilized memory space of the various stages breast cancer affected patient and pixel generated with the images. The similar initial inspection and simulations are carried out to examine the pixel size as well as the memory utilized. The figure gives a detailed view of better utilization.

IV.1 RESULT FOR SALT AND PEPPER NOISE REMOVAL

Dark pixels will be in light regions and light pixels in dark regions of an image contaminated with salt and pepper noise. This is because of dead pixels, transmission bit errors, and analogue to digital conversion problems. Dark frame elimination and interpolation at dark bright pixels can be applied to eliminate it.

Table 2: Salt And Pepper Noise Removal.

IV.2 RESULT OF GAUSSIAN LOW PASS FILTER

Every pixel in the image will be altered from its initial value by a (typically) little amount throughout the Gaussian noise removal process. As seen below, low pass filtering uses a compression technique to eliminate noise. This research explores the application of the Gaussian Low Pass Filter at the preprocessing step of image processing in breast cancer diagnosis. For suspicious region detection, discriminative feature extraction, and classification of the filtered images using the correct machine learning or deep learning algorithms, they are further processed. The final aim is to utilize automated image analysis to enhance diagnostic accuracy and help doctors in early breast cancer detection.

IV.3 RESULT OF GAUSSIAN HIGH PASS FILTER

Statistical noise with a normal distribution probability density function (pdf) also known as the Gaussian distribution is called Gaussian noise. Each pixel in the image will be changed from its original value by a (usually) small amount when there is Gaussian noise. As can be seen below, Gaussian High Pass employs inverse filtering to perform the de-convolution.

Table 4: Gaussian High Pass Filter.

IV.4 RESULT OF HISTOGRAM EQUALIZATION

The contrast of a greyscale image can be adjusted through histogram equalisation. Most of the pixel values of the original image occur within the middle of the intensity range, which means the image has low contrast. The pixel values in the resulting image are spread evenly throughout the range. Histogram equalisation is a straightforward image-processing technique employed in medical imaging to generate better-quality black-and-white images. (Digital X-rays, CT scans, and MRIs)

The Filtering Techniques Wiener Filter, Median Filter and Gaussian Low and High Pass Filter are deployed with various methods. The Result obtained can be clearly observed from Table VI. The observed results are very clear in explaining the size variation of image and techniques deployed can alter the image clarity.

Table 6: Filtering Techniques and Result Observed.

Method	Filtering Technique	Results Observed
128 X 128	Wiener Filter	Small size and Dark
	Median Filter	Small size and Bright
	Gaussian Low and High Pass Filter	Small size and Clear
256 X 256	Wiener Filter	Medium size and Dark
	Median Filter	Medium size and Bright
	Gaussian Low and High Pass Filter	Medium size and Clear
512 X 512	Wiener Filter	Large size and Dark
	Median Filter	Large size and Bright
	Gaussian Low and High Pass Filter	Large size and Clear

The implementation of filtering process enhancement techniques, overlapping histogram equalisation is adapted and used with histogram equalization as in Table VI.

V. CONCLUSION

The particular part of the research work focuses on the cleaning stage of the breast cancer Mammography images. The technique deployed in this part of the research work removes the irrelevancy in images as well as helps in improving the quality of the Mammography images. Various filtering techniques are implemented for enhancing the quality of the pre-processed mammography images. The sample breast cancer of two different patents is shown in the experimental results. The results are studied, compared against a normal pattern of noise, and evaluated as per quality. The aim of this research work is to focus on choosing appropriate filtering techniques and removing noise keeping in mind the phases of breast cancer images. Apart from reducing time, the preprocessing method considers the three varieties of filter types and searches for the best pixel outcome using the median filter. Furthermost, the preprocessed and enhanced images are taken for the next analyzing stage with proposed algorithm to identify the breast cancer affected parts from the Mammography images.

ABSTRACT

This paper addresses the design, construction, and evaluation of an automated freezing tunnel for the deep-freezing process of food, implemented using a programmable logic controller (PLC). The research was conducted in the context of the food industry, where energy efficiency, quality preservation, and sustainability are critical factors for competitiveness. The system integrates temperature sensors, control modules, and a human-machine interface (HMI), allowing for accurate, real-time monitoring of the process. The experimental results show that the prototype reached temperatures of up to –30 °C, freezing different products in an average of 12 minutes. This performance represents a significant reduction in time and costs compared to traditional methods, ensuring the preservation of organoleptic and nutritional properties. It is concluded that the automation of the deep-freezing process using PLCs is a viable and scalable alternative for the food industry, providing improvements in productivity, operational efficiency, and food quality.

I. INTRODUCTION

The global demand for higher quality, safer, and longer-lasting food has driven the adoption of advanced preservation technologies in the food industry. Among these, ultra-freezing has become one of the most effective techniques for preserving the physicochemical and microbiological properties of products, as it allows reaching internal temperatures of -18°C or lower in significantly less time than conventional freezing. This speed reduces the formation of large ice crystals, prevents structural damage to food matrices, and maintains the sensory quality of the final product[1]. Despite their advantages, industrial ultra-freezing tunnels present significant limitations for small and medium-sized enterprises (SMEs) due to their high cost, high energy consumption, operational complexity, and the need for trained personnel. In this context, an opportunity arises for the development of smaller-scale, low-cost, automated solutions that maintain the thermal and energy efficiency of industrial systems but with more compact, accessible, and easy-to-operate architecture[1], [2].

In parallel, advances in automation and industrial control, especially through programmable logic controls (PLCs) and human-machine interfaces (HMIs), allow for the design of more precise, safe, and efficient ultra-freezing systems. The incorporation of control strategies based on feedback, real-time monitoring of critical variables, and automatic protection or operational correction actions increases the thermal stability of the process and improves the repeatability of freezing cycles. This approach is fundamental to ensuring uniformity, reducing energy consumption, and minimizing human error associated with manual operation [2], [3], [4]. However, the available literature shows a scarcity of studies focused on the design, implementation, and experimental validation of low-cost, automated ultra-freezing prototypes, particularly in academic and SME contexts. Most studies focus on advanced thermal analysis, cold air fluid dynamics, or energy evaluation of commercial systems, but few comprehensively evaluate freezing times, thermal uniformity, energy consumption, coefficient of performance (COP), and operational reliability in functional prototypes.

Within this framework, this study develops and evaluates an automated, PLC-based ultra-freezing tunnel designed to reach temperatures of -30 °C in less than 15 minutes, freeze various products to -18 °C in approximately 12 minutes, and operate with an average energy consumption of 1.2 kWh per cycle. Furthermore, thermal uniformity is analyzed at 16 points within the chamber, and the system's robustness is evaluated through repeated continuous operation tests. [5], [6], [7].

Based on this motivation, the following research question is posed:

Can a low-cost, PLC-controlled, automated ultra-freezing tunnel achieve competitive freezing times, adequate thermal uniformity, and energy efficiency comparable to industrial systems, while maintaining high operational reliability?

The hypothesis states that:

The integration of automated control, compact thermal architecture, and optimized airflow allows for a significant reduction in freezing time and energy consumption, while maintaining an internal temperature variation of less than ±2 °C and reliable operation over multiple cycles. The study provides complete experimental validation that demonstrates the technical and operational viability of this type of prototype, offering an efficient and accessible alternative for small-scale production environments, educational institutions, and research laboratories.

II. THEORETICAL REFERENCE

II.1 SUBTITLE

II.1.1 Materials and Methods

The research was conducted using an applied and experimental approach, aimed at creating a prototype food freezing tunnel controlled by a Programmable Logic Controller (PLC). The methodological procedure was structured in sequential phases: conceptual design, materials selection, system implementation, experimental testing, data processing, and validation.

II.1.2 Materials and Methods

Conceptual design of the system

The initial design considered three main subsystems:

- Control subsystem: Consisting of a Siemens S7-1200 PLC as the core of the system, responsible for the control logic of the compressors, fans, and expansion valves. A KTP-600 HMI was integrated to facilitate user interaction, enabling real-time monitoring of temperature, alarms, and process status.[6]
- Refrigeration subsystem: composed of a 1.5 HP condensing unit, a forced-air evaporator, and R404A refrigerant, selected for its compatibility and performance in the –30°C range. This subsystem constitutes the thermal heart of the prototype. [7], [8].
- Structural subsystem: designed with 10 cm thick polyurethane sandwich panels, ensuring adequate thermal insulation to minimize cold loss.

III. MATERIALS AND METHODS

The block diagram representing the interaction of these subsystems is shown in Figure 1.

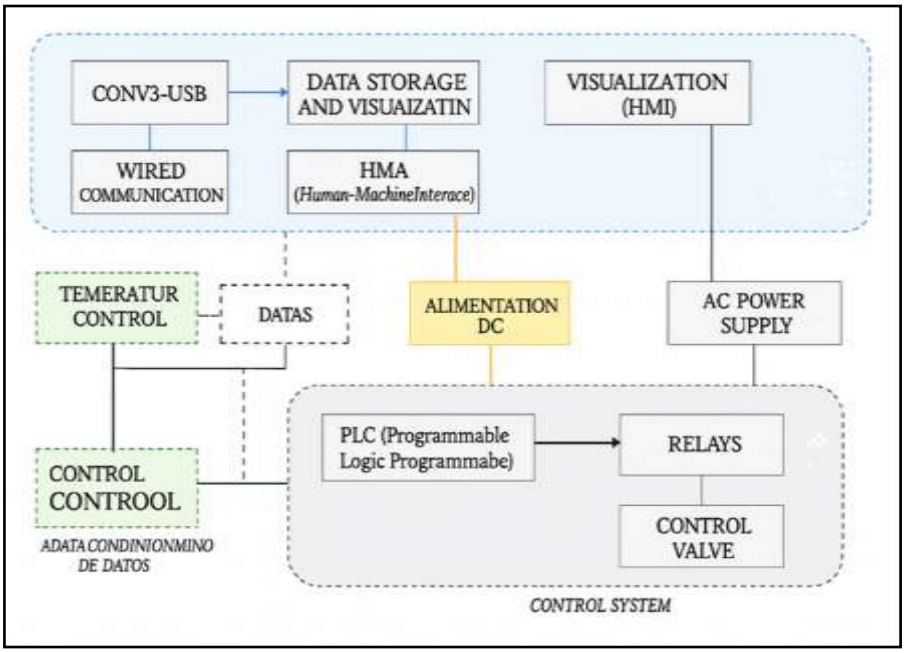

Figure 1: Block diagram of the automated ultra-freezing system.
Source: Authors, (2026).

III.1 SELECTION OF MATERIALS AND EQUIPMENT

For the development of the prototype, a technical inventory of materials was drawn up, classified into control hardware, cooling system, insulating structure, and software.

Table 1: Inventory of materials and equipment used.

Category	Component	Key specification	Amount	Observations
Control hardware	Siemens S7-1200 PLC	CPU + I/O modules	1	System core
	HMI KTP-600	6" touch screen	1	User interface
	Relays and circuit breakers	IEC 60073 protections	Several	Electrical protection
Refrigeration	Condensing unit	1.5 HP, R404A gas	1	Compression cycle
	Forced air evaporator	–30 °C	1	Heat exchange
	Copper pipes	5/8” and 3/8”	According to design	High conductivity
Insulating structure	Sandwich panels (PU)	10 cm polyurethane core	According to design	Thermal insulation
Software	TIA Portal V17	PLC/HMI programming	N/A	Development of routines
	SITRAD PRO	SCADA monitoring	N/A	Remote monitoring

Source: Authors, (2026).

III.2 IMPLEMENTATION PROCEDURE

The implementation was carried out sequentially, following a flow of activities that can be seen in Figure 2:

1. CAD design of the structure and electrical circuit: the tunnel was modeled in AutoCAD, and electrical plans defining connections and protections were drawn up.
2. Prototype construction: The freezing chamber was assembled with sandwich panels and the evaporator and condenser unit were installed. [9], [10].
3. Electrical assembly: the control panel was assembled with circuit breakers, relays and wiring according to IEC regulations.
4. PLC and HMI programming: In TIA Portal V17, control routines were developed for manual and automatic modes, alarm management, and HMI screen display. [3], [9].
5. SCADA integration: SITRAD PRO software enabled historical recording, temperature monitoring, and alarm generation.
6. Validation testing: system performance was verified in vacuum and with real products. [10], [11], [12], [13].

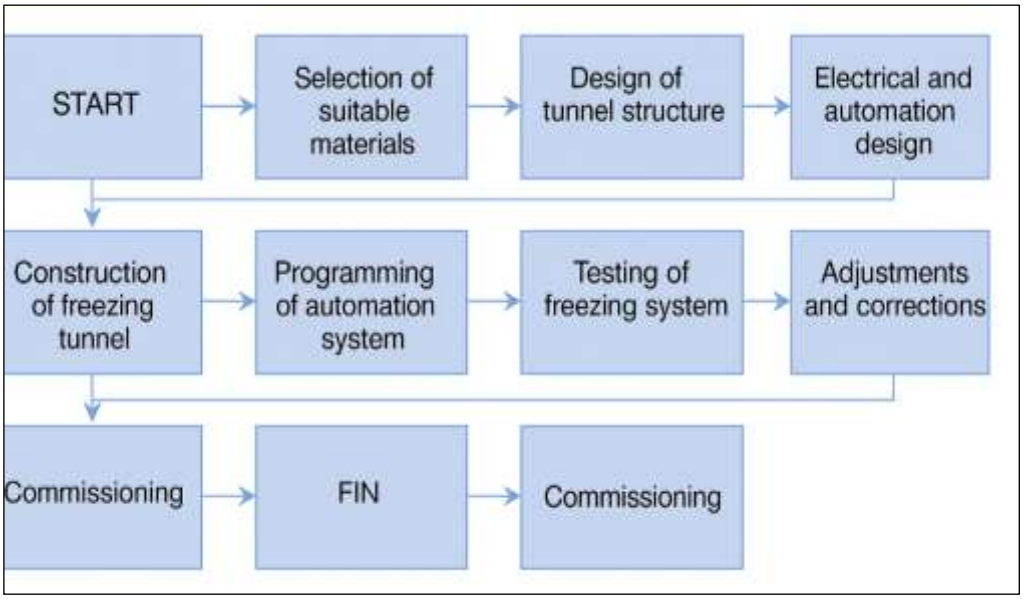

Figure 2: Flowchart of the system implementation procedure.
Source: Authors, (2026).

III.3 EXPERIMENTAL TESTS

Two phases of testing were proposed:

- **Phase 1 – Validation without product:** the system operated empty to evaluate the time to reach –30 °C in the chamber.
- **Phase 2 – Product testing:** Samples of purified water, hard water, juice and soda were frozen, recording temperature-time curves (Figure 3).

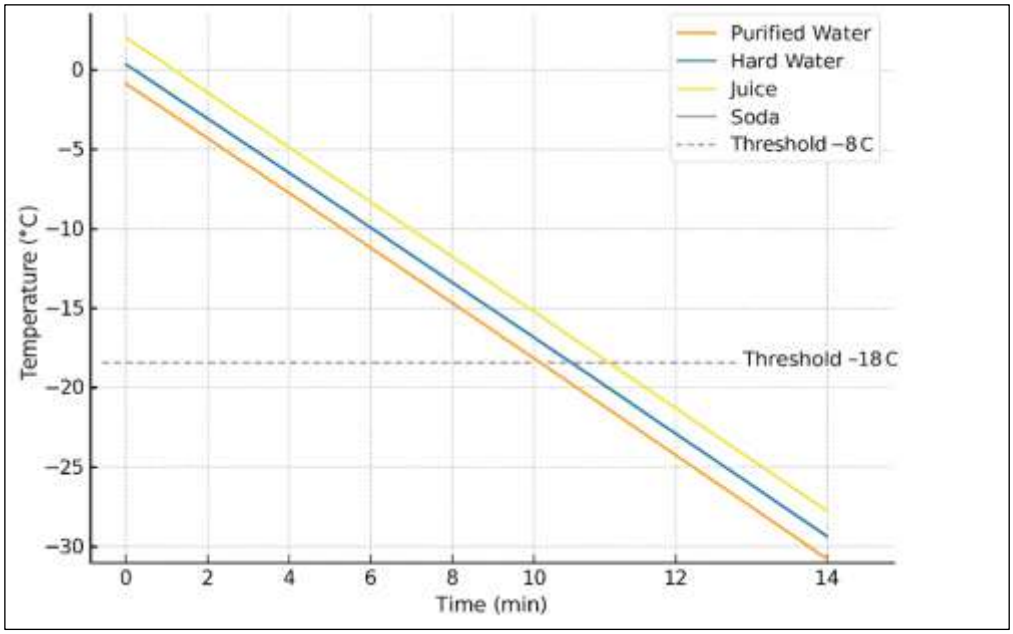

Figure 3: Temperature vs. time curves for different food products.
Source: Authors, (2026).

The average times to reach –18 °C are presented in Table 2, comparing the automated tunnel with traditional systems.

Table 2: Comparative average freezing times.

Product / System	Average time at –18 °C (min)	Standard deviation (min)	N cycles
Automated tunnel	12	1.2	10
Conventional industrial	25	2.5	5
Domestic	60	6.0	5

Source: Authors, (2026).

III.4 DATA PROCESSING AND ANALYSIS

The data were analyzed using:

- **Freezing curves:** comparison of thermal drops (Figure 3).
- **Energy consumption:** average of 1.2 kWh per cycle, illustrated in Figure 4.
- **Coefficient of performance (COP):** estimated at 3.8, validating efficiency.
- **Thermal uniformity:** the maximum difference between points in the tunnel was ±1.5 °C, represented in Figure 5.

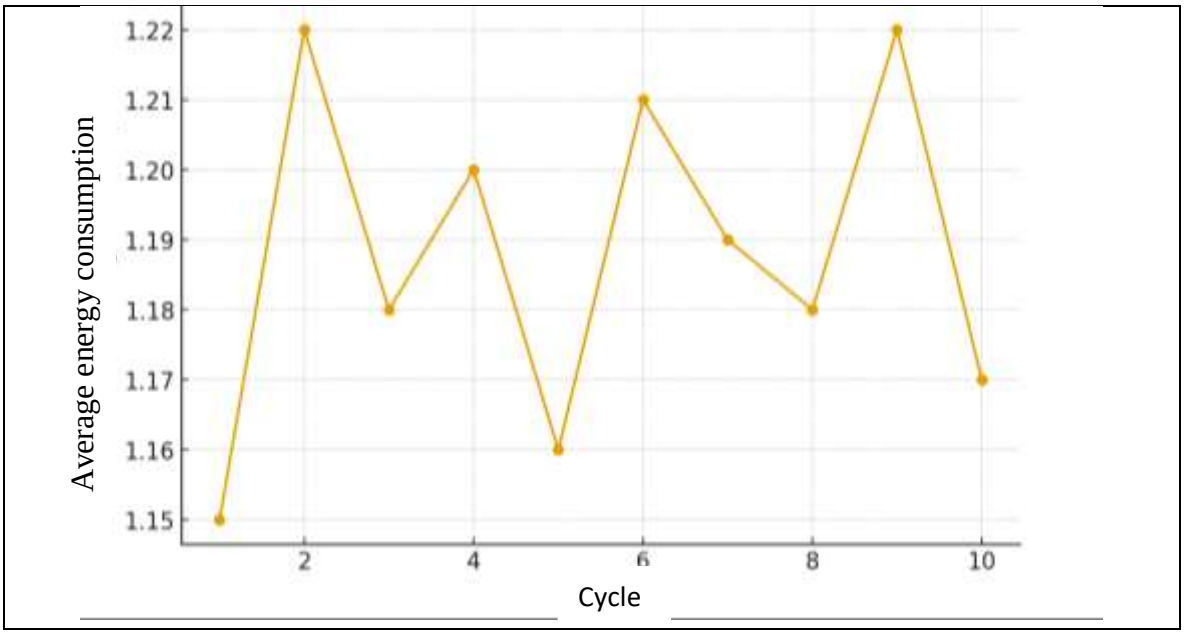

Figure 4: Average energy consumption per freezing cycle.
Source: Authors, (2026).

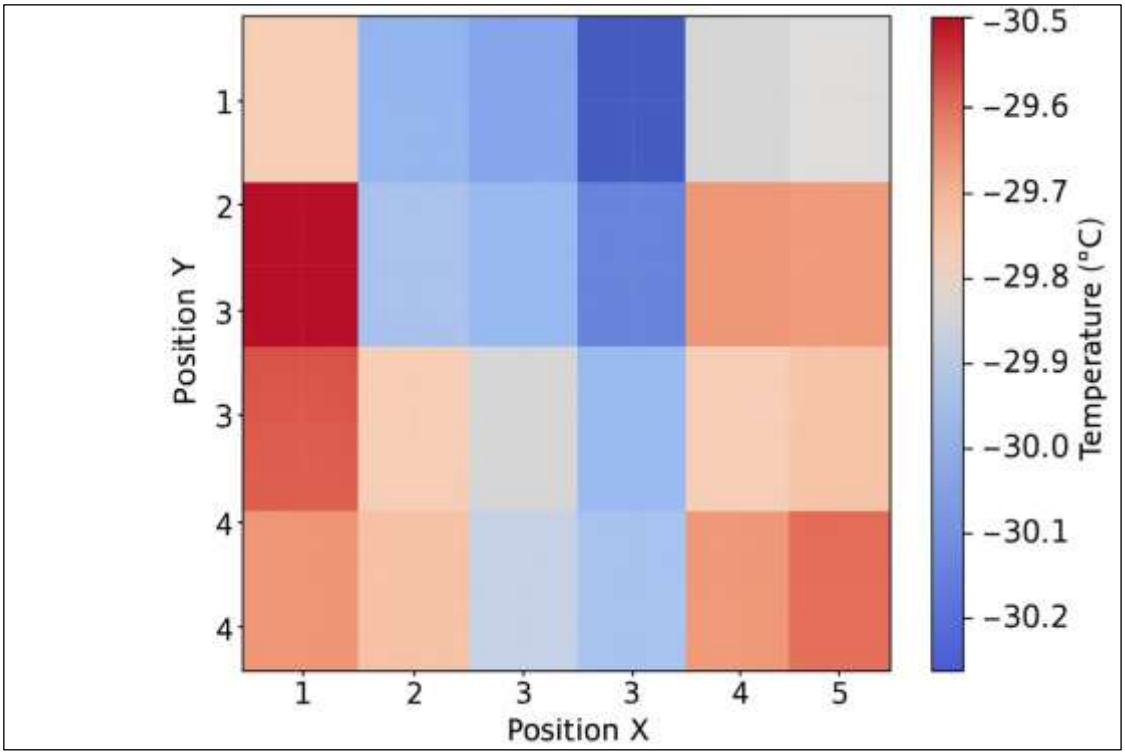

Figure 5: Thermal uniformity at different points in the tunnel.
Source: Authors, (2026).

III.5 VALIDATION PLAN

The experimental plan is detailed in Table 3, which summarizes the objectives, procedures, metrics, and acceptance criteria.

Table 3: Test plan and validation criteria.

Phase	Aim	Procedure	Main metric	Acceptance criteria
Hermeticity	Check for leaks	Pressurization with N_2	Pressure stability	No significant drop
Empty and loaded	Prepare refrigeration circuit	Vacuum 500 microns + R404A charge	Vacuum level reached	≤ 500 microns
Empty curve	Validate –30°C capacity	No-load operation	Time at –30 °C	< 15 minutes
Product testing	Measuring freezing times	Freezing water/juice/soda	Weather at –18 °C	≈ 12 minutes
Sensor calibration	Check accuracy	Comparison with standard thermometer	Maximum deviation	± 0.5 °C

Source: Authors, (2026).

IV. RESULTS AND DISCUSSIONS

Experimental tests allowed for the evaluation of the thermal, operational, and energy performance of the automated ultra-freezing tunnel under different load conditions and for various types of liquid products. The results are presented organized by: (1) system thermal behavior, (2) freezing times, (3) energy consumption and coefficient of performance (COP), and (4) analysis of uniformity and operational reliability. [10], [14], [15].

Freezing Time Equation

$$t = \frac{Ti - Tf}{\frac{dT}{dt}}$$

Coefficient of Performance (COP)

$$[\![(COP = EconsumidaQextraı́da = Econsmcp(Ti - Tf))]\!]$$

IV.1 SYSTEM THERMAL BEHAVIOR

The system reached an internal temperature of -30 °C in less than 15 minutes, demonstrating a high heat extraction capacity at cycle start-up. The rate of temperature decrease showed a stable slope during the first 10 minutes, followed by an asymptotic approach zone characteristic of the equilibrium between thermal demand and the evaporator's cooling capacity.

This behavior confirms that the tunnel's architecture, along with the automatic control of the compressor and fans, generates a suitable thermal environment for initiating rapid freezing processes. The stability of the temperature profile subsequently observed allowed the product to cool uniformly, preventing thermal over-oscillations that could compromise process quality.

IV.2 FREEZING TIMES OF THE EVALUATED PRODUCTS

The four products analyzed (water, hard water, juice, and soda) were completely frozen to -18 °C in an average time of 12 minutes, with minor variations attributable to differences in composition, solute concentration, and specific thermal behavior. The automated tunnel achieved considerably shorter freezing times compared to the comparative systems:

- 80% faster than a domestic system evaluated under the same conditions (≈ 60 minutes).
- 52% faster than an industrial system used as a reference (≈ 25 minutes).

Table 4 presents the freezing times achieved by the automated tunnel compared to a conventional industrial freezer and a domestic system. The results show a reduction of up to 80% in total freezing time compared to the domestic method. [16], [17].

Table 4: Comparative average freezing times.

Product / System	Average time at –18 °C (min)	Standard deviation (min)	N cycles
Automated tunnel	12	1.2	10
Conventional industrial	25	2.5	5
Domestic	60	6.0	5

Source: Authors, (2026).

This result reflects a key competitive advantage, as the ultra-freezing process ensures higher product quality and lower nutritional losses compared to traditional systems. This demonstrates that the combination of a compact chamber, automated control, and forced airflow increases the rate of heat transfer and reduces thermal resistance between the evaporator and the product. The reduction in freezing times not only improves the quality of the frozen product but also optimizes the hourly processing capacity of the prototype.[18]

IV.3 ENERGY CONSUMPTION AND COEFFICIENT OF PERFORMANCE (COP)

The average energy consumption recorded per cycle was 1.2 kWh, a competitive value considering the installed refrigeration capacity and the total process time. Based on the ratio between the useful energy extracted from the product and the electrical energy consumed, an approximate COP of 3.8 was obtained [16], [17], [19]. This value is consistent with well-designed refrigeration systems and demonstrates that the prototype operates within an efficient range for rapid freezing applications. A COP close to 4 reflects low heat losses, proper compressor operation, and a correct selection of refrigerant and refrigeration components.

IV.4 THERMAL UNIFORMITY ANALYSIS

To eliminate that freezing occurs homogeneously throughout the tunnel, measurements were taken at 16 strategic points distributed within the chamber volume. The analysis showed a maximum temperature variation of ±1.5 °C, an acceptable value for rapid freezing systems and characteristic of well-designed chambers in terms of airflow distribution.[19], [20]. This thermal uniformity is essential, as it minimizes the likelihood of hot spots that could delay the process or affect the final product quality. The achieved homogeneity supports the correct configuration of the fans, the chamber geometry, and the internal circulation of the cold air [16], [17].

IV.5 OPERATIONAL SYSTEM RELIABILITY

During continuous operation tests, 30 consecutive cycles were performed without any recorded failures in the operation of the compressor, sensors, fans, or the control logic implemented in the PLC. This indicates that the system has adequate operational stability for repetitive applications, as well as being tolerant of minor variations in the initial load conditions. The failure-free record suggests a level of reliability appropriate for small-scale refrigeration systems and demonstrates that automation contributes to reducing operator errors, minimizing interruptions, and maintaining repeatability between cycles.

V. CONCLUSIONS

The results of this study demonstrate that the automated deep-freezing tunnel developed using a programmable logic controller constitutes a technically viable and energetically efficient solution for rapid freezing applications. The system achieved internal temperatures of –30 °C in under 15 minutes and completed product freezing to –18 °C in approximately 12 minutes, outperforming conventional domestic freezers and even surpassing the times reported for industrial reference equipment under comparable conditions. These findings confirm that compact chamber architecture, combined with controlled air circulation and automated actuation, enhances heat-transfer efficiency and reduces overall freezing time. Energy assessments showed an average electrical consumption of 1.2 kWh per cycle and a coefficient of performance near 3.8, values that align with efficient refrigeration systems of similar scale. These results indicate that the integration of automatic compressor control, optimized airflow, and proper thermal insulation allows the system to operate within a high-efficiency range while maintaining stable thermal conditions throughout the freezing process. Thermal uniformity analysis revealed maximum variations of ±1.5 °C across 16 measurement points, which reflects a homogeneous temperature distribution within the chamber. This level of uniformity is essential for ensuring that all products experience similar freezing conditions, thereby improving process reproducibility and product quality. Moreover, the system operated for 30 consecutive cycles without failure, demonstrating satisfactory operational reliability for a prototype of this scale and validating the stability of the implemented control scheme.

Although the proposed system exhibits strong performance, certain limitations must be acknowledged. The evaluation was conducted using liquid products in relatively small containers, and future studies should examine a broader range of food types, geometries, and load volumes to analyze the influence of mass and composition on freezing dynamics. Additional work is also needed to quantify long-term energy performance under continuous operation, assess component durability, and incorporate more advanced control strategies capable of adapting to variable product loads. In summary, the automated freezing tunnel developed in this study provides an accessible, efficient, and reliable alternative for small-scale processing environments, technical laboratories, and educational settings. Its favorable balance between freezing speed, energy efficiency, thermal uniformity, and operational stability positions it as a promising platform for future optimization, scaling, and integration into more advanced food-processing systems.

ABSTRACT

Concrete is one of the most widely used building materials worldwide, but its production generates a high carbon footprint due to the high clinker content in Portland cement. In response, coffee husk ash (CCC) and rice husk ash (CCA) are being investigated as sustainable alternatives to partially replace cement. This paper presents a systematic review of recent studies in Scopus and ScienceDirect, applying selection criteria related to technical relevance, availability of experimental results and incorporation of both ashes in concrete and mortar mixtures. Likewise, a bibliometric analysis is developed using VOSviewer to identify research trends, countries, outstanding authors and predominant keywords. The compiled studies allow us to compare the effect of CCC and CCA on physical properties (workability, density, absorption), mechanical properties (compressive strength, tensile strength and bending) and durability (permeability and resistance to chlorides and sulfates). Overall, the evidence shows that both ashes can be used as supplementary cementitious materials in moderate replacements, valorizing agro-industrial waste and reducing the environmental impact of the concrete, as long as parameters such as fineness, calcination conditions and dosage are controlled to guarantee optimal and sustainable results.

I. INTRODUCTION

Concrete, also called concrete, is one of the most widely used materials and the second most consumed after water [1]. Its manufacture is based on the combination of aggregates with water and Portland cement, whose production was more than four billion tons in 2022, consolidating it as the most widely used binder in construction [2]. Cement production releases carbon dioxide (CO_2) and is recognized as one of the main sources of emissions linked to global warming [3]. The construction sector consumes large volumes of concrete and represents a relevant fraction of GDP, with an impact on greenhouse gas emissions [4]. In view of this, the use of supplementary cementitious materials derived from rice husks is promoted to reduce the clinker content and carbon footprint of concrete, while maintaining adequate structural performance [5].

Concrete can incorporate agro-industrial by-products, such as coffee husks, favoring sustainability by valorizing waste that would otherwise be discarded [6]. According to [7], this process requires an appropriate selection of materials, preliminary tests and adjustments of the mixture based on laboratory results. Studies on ash from silica-rich agricultural residues indicate that they can improve the strength and durability of concrete, reducing its permeability against aggressive agents [8]. Likewise, it has been observed that workability can decrease, mechanical strength tends to increase with curing time [9]. Therefore, it has been shown that agricultural ash without complex treatments, including rice husk ash, can be used as a partial substitute for fine aggregate in mortars, maintaining strengths compatible with conventional cement mortars [10]. In this context, coffee husks (CC) are considered an abundant and potentially polluting agro-industrial waste due to its content of compounds such as caffeine and polyphenols [11].

In addition, its lignocellulosic fraction contains about 53% cellulose and can be transformed into crystalline microcellulose with high crystallinity and thermal stability, reinforcing its potential as a raw material for composite materials and construction products [12]. On a global scale, coffee production is around 10 million tonnes, of which a significant fraction corresponds to husks and other solid by-products that require recovery alternatives [13]. As one of these alternatives, coffee husk ash (CCC) has been incorporated into concrete mixtures, reporting improvements in strength and a reduction in the environmental footprint [14]. By [15] have evaluated CCC on properties such as compressive strength, bending, and hardness, while [16] report additional benefits in the water absorption, density, and thermal performance of concrete elements.

Similarly, the combustion of rice husks generates rice husk ash (ACC), a silica-rich by-product used as supplementary cementitious material. In turn, [17] report that replacements of up to 10% CCA reduce initial strength, but maintain adequate performance at older ages and decrease carbon footprint. In concretes with high recycled aggregate content, contents close to 15% help to recover resistance and improve durability [18], while in permeable concrete, replacements of 5–10% increase compressive and wear resistance without compromising permeability [19]. In addition, CEC has been used in the manufacture of aggregates that reduce the consumption of natural aggregates [20] and as an addition, where replacements close to 25% allow adequate bending strengths to be achieved with environmental benefits [21].

II. METHODOLOGY

SCOPUS and ScienceDirect. In a first stage, specific keywords related to coffee husk ash were used, such as concrete + coffee husk ash and concrete + coffee husk, identifying works on the use of this residue as an addition to improve the physical-mechanical properties and durability of concrete. Given the limited number of studies that met the selection criteria, the search strategy was expanded to include terms associated with rice husk ash, such as concrete + rice husk ash and supplementary cementitious materials + agricultural ash, considering articles that evaluated the effect of one or both ashes on concrete or mortar mixtures. Subsequently, filters were applied by engineering area, topic, type of document and scientific discipline, restricting publications to the period 2021–2025.

The results and search combinations are presented in TABLE 1, where the articles are organized by database, keywords, range of years and type of document. After the purification of duplicate records and the evaluation of the relevance, originality and availability of experimental information, 64 articles were selected for the final synthesis. TABLE 2 presents the distribution of these documents according to the year of publication (2021–2025), the database consulted and the type of ash analyzed, evidencing a growing trend in research related to the use of coffee husk ash and rice husk ash as cementitious additions in concrete.

Table 1: Results of the filtered research.

A bibliometric analysis was performed with the information collected from the Scopus database, using the following search formula:

(TITLE-ABS-KEY (husk) AND TITLE-ABS-KEY (coffee) OR TITLE-ABS-KEY (corrosion) OR TITLE-ABS-KEY (durability)) AND (LIMIT-TO (SUBJAREA, "ENGI")) AND (LIMIT-TO (DOCTYPE, "ar")) AND (LIMIT-TO (EXACTKEYWORD, "Durability") OR LIMIT-TO (EXACTKEYWORD, "Coffee Husks") OR LIMIT-TO (EXACTKEYWORD, "Compressive Strength")) AND (LIMIT-TO (LANGUAGE, "English")).

This search process yielded 1635 documents, which were exported and processed in VOSviewer to build a keyword co-occurrence map. The objective was to identify the thematic relationships between terms associated with the incorporation of agro-industrial waste in cementitious materials, with emphasis on "coffee husks" and "rice husk ash" linked to the durability of concrete, as shown in Figure 1. The interpretation of the keyword co-occurrence map generated with VOSviewer allows you to distinguish several thematic clusters. In the central zone, terms such as "durability", "water absorption", "tensile strength" and "rice husk ash" are grouped with words related to "concrete", "mechanical properties" and "sustainable development", which shows a focus of research aimed at evaluating the physical-mechanical performance and durability of concretes modified with ash of agricultural origin.

In parallel, the cluster associated with "coffee husks" is linked to concepts such as "biomass", "biochar", "thermal conductivity" and "reinforcement", which reflect studies on energy recovery and applications in cementitious compounds. Other nuclei are articulated around "fly ash", "geopolymer concrete" and "scanning electron microscopy", highlighting the integration of fly ash, rice husk ash and alkalinely activated systems. Taken together, the map supports the relevance of comparatively analysing coffee husk ash and rice husk ash as supplementary cementitious materials for more sustainable concretes. In summary, the bibliometric analysis shows an integration of approaches that combine materials engineering, environmental sustainability and technological development in the study of coffee husk ash and rice husk ash. However, the map also suggests gaps related to large-scale application and evaluation of the performance of these mixtures under real service conditions.

III. RESULTS AND DISCUSSIONS

III.1 CONCRETE WITH COFFEE HUSK ASH AND RICE HUSKS

III.1.1Physical Properties

III.1.1.1 Absorption

Water absorption reflects the permeability and durability of concrete; therefore, blends with coffee by-products tend to have higher values due to the high porosity of these residues. In alkalinely activated systems, for example, the progressive replacement of sand with coffee husks increases water absorption and apparent porosity: with 30% husk, absorption reaches ≈19.2% and porosity ≈48.3%, which represents increases in the order of 16.3% and 42% compared to without agro-industrial residue [22]. Similarly, substituting up to 10% of the matrix for coffee husks increases absorption from approximately 17.3 to 23.9% and porosity from ~20 to 40%, while reducing bulk density from 1.94 to 1.69 g/cm³, confirming the highly porous and hygroscopic character of this by-product [23].

On the other hand, rice husk ash behaves in a way that depends on fineness and environmental conditions. In conventional concretes, absorption increases under relative humidity of 31–78 % when using contents of 10–15 % due to its high capillary uptake [24]. However, in moderate additions of 5–10% they reduce open porosity due to the micro-filling effect [25]. This dual behavior is explained by the nanoporosity and high specific surface area of RHA, which can increase or decrease absorption depending on the dosage and the a/c ratio used [26]. Overall, maintaining moderate addition percentages is essential to limit porous connectivity and improve durability.

Table 3: Results obtained for absorption.

Material/system	Residue	% Substitution/Condition	Absorption (%)	Porosity (%)	Main result	Reference
AAB with CC Replaced Sand	CC	30 % arena → CC	≈19,2 %	≈48,3 %	↑Abs ≈16,3 %; ↑P ≈42 % vs control	[22]
Cementitious matrix with CC	CC	0–10% DC → matrix	17,3–23,9 %	20–40 %	↑Abs and ↑P; Density 1.94→1.69 g/cm³	[23]
Concrete with RHA (RH 31–78%)	RHA	10–15% cement → RHA	—	—	↑Abs in Medium-High HR	[24]
Concrete with moderate RHA	RHA	5–10% cement → RHA	—	↓Open porosity	Micro-padding effect, improves durability	[25]
Various Concretes with RHA	RHA	5–20% (depending on the mixture)	—	—	Abs is dosage and a/c (nanoporous) dependent	[26]

Source: Authors, (2026).

III.1.1.2 Workability

Slumping is an essential indicator of the consistency of fresh concrete; Higher values represent more fluid mixtures, although this does not necessarily guarantee better mechanical or durability properties. In this sense, when agro-industrial waste such as ash or bioaggregates of coffee and rice are incorporated, workability usually decreases due to its highwater absorption, great fineness and irregular morphology. For example, [27] they reported that in alkaline activated mortars with coffee husk ash, the flow is reduced as the ash content increases, due to the insoluble fraction that increases the demand for water. Similarly, [28] they observed that substituting up to 15% of cement with a mixture of coffee ash and sugarcane bagasse ash gradually decreases workability, with reductions of about 7% in compaction factor, although within acceptable ranges through adjustments in the water/cement ratio.

Also, in mixtures with rice husk ash (RHA), [29] they report significant slump drops with replacements of 7–14%, especially in mixtures with low A/C ratio, confirming the sensitivity of workability to extreme ash fineness. However, certain treatments can mitigate this loss. When rice husks are used as a pre-saturated bioaggregate, slump variations can be minimal, around 2 mm [30]. Conversely, the combination of RHA with rheological modifiers such as cassava starch increases viscosity and deepens settlement drop [31]. In summary, the incorporation of these residues usually reduces workability, requiring adjustments in the water/cement ratio or the use of superplasticizers to maintain the fluidity of the concrete.

Table 4: Results obtained for workability.

Material/system	Residue	% substitution	Practice	Result	Reference
Alkaline activated mortar	CHA	↑CHA in paste	Flow	↓ Flow with ↑CHA	[27]
Concrete with ash mixture	CHA + other ashes	0–15 % cement	Compaction factor	≈7% ↓ to 15% replacement	[28]
Concrete with RHA	RHA	7–14 % cement	Slump	Marked slump drop	[29]
CC concrete as a saturated bioaggregate	CC	Partial replacement of fine aggregate	Slump	Δslump ≈ 2 mm (almost constant)	[30]
Concrete with RHA + cassava starch	RHA	% RHA + rheological additive	Slump	Slump ↓; Viscosity ↑	[31]

Source: Authors, (2026).

III.1.1.3 Density

The density of concrete is directly related to the porosity and specific gravity of the incorporated materials; As a result, biomass waste often produces lighter mixtures. In this sense, coffee husks have much lower densities than those of mineral aggregates, with values close to 0.16–0.25 g/cm³, which modifies the volumetric behavior of the composite material [32]. This trend is confirmed by looking at its fragile and fibrous microstructure, characterized by abundant voids that reduce the unit mass and classify it as a light component [33]. Consistently, when ash from this shell is incorporated together with polypropylene fibers in 210 and 280 kg/cm² concretes, the density decreases slightly with respect to the standard due to the low specific gravity of both the ash and the synthetic fibers [34].

On the other hand, in reinforced concretes that use rice husk ash as a partial substitute for cement, the density values remain within the typical range of normal concretes, allowing their use in structural elements without significantly altering the dead loads [35]. Overall, the evidence shows that coffee and rice by-products tend to reduce the density of concrete, as long as the dosages are kept controlled to avoid excessive increases in porosity that may compromise the compactness of the material.

Table 5: Results obtained for density.

Material/system	Waste	Density/effect	Brief comment	Reference
Coffee husks (dried)	CC	0,16–0,25 g/cm³	Very lightweight component	[32]
CC as a light aggregate	CC	—	Fibrous microstructure, high voids → unit mass ↓	[33]
Concrete 210–280 kg/cm² with CHA + PP fibers	CHA	% CHA + PP	Density slightly ↓ vs pattern	[34]
RHA Reinforced Concrete	RHA	RHA as a partial cement substitute	Density within normal range	[35]

Source: Authors, (2026).

III.1.2 Mechanical Properties

III.1.2.1 Compressive Strength

Compressive strength is the property most influenced by the incorporation of agro-industrial ash. In the case of RHA, its highly reactive amorphous silica allows increases of between 2.4% and 18.7% when 10–20% replacements are used, due to the refinement of the microstructure and the increased formation of secondary C-S-H gel [36]. Likewise, when used in concrete with lower quality aggregates, this ash improves internal cohesion and contributes to the increase of elastic modulus by optimizing the paste-aggregate transition zone [37]. In addition, predictive models based on 348 experimental data indicate that strength reaches its maximum values with replacements between 10% and 30%, with the water/cement ratio and cement content being the most influential variables [38].

On the other hand, research on cementitious alternatives shows that RHA substitutions between 5% and 20% increase resistance from an early age thanks to the high fineness and reactivity of the ash, which favors the closure of pores and the densification of the paste [39]. Finally, in concretes modified with ground coffee residues, it has been observed that moderate replacements close to 10% maintain structural strengths above 20 MPa at 28 days, due to improved alkaline reactivity during curing [40]. Specifically, M30 concretes with combinations of 15% RHA and 15% snail shell ash achieve strengths of up to ≈46 MPa at 90 days, outperforming reference concrete and significantly reducing water absorption [41]. Overall, the results show that agro-industrial ash strengthens mechanical behavior when incorporated in controlled proportions, mainly by reducing porosity and optimizing the microstructure.

Table 6: Results obtained for compressive strength.

Material/system	Residue	% substitution	Age	Main result	Reference
Concrete with RHA	RHA	10–20 %	28–90 d	fc’ ↑ 2,4–18,7 %	[36]
Concrete with RHA and low-quality aggregates	RHA	10–20 % (typical)	28 d	Improves cohesion and elastic modulus	[37]
Predictive model with RHA	RHA	10–30 %	—	hr' max at 10–30 % RHA	[38]
Alternative Concretes with RHA	RHA	5–20 %	7–28 d	fc' ↑ from an early age	[39]
Concrete with ground coffee	CG	≈10 % replacement	28 d	fc’ > 20 MPa	[40]
M30 Concrete with RHA + Shell Ash	RHA + other ash	15% RHA + 15% shell ash	90 d	fc’ ≈46 MPa	[41]

Source: Authors, (2026).

III.1.2.2 Tensile Strength

The tensile strength of concrete depends largely on the internal cohesion of the matrix and the paste–aggregate link, so the incorporation of coffee husk ash (CHA) can significantly influence this property. Although studies carried out on asphalt mixtures show notable increases in indirect traction, for example, an increase of 35.8% compared to conventional filler and an increase in TSR from 94.58% to 105.03%, values higher than the minimum of 80% required to guarantee resistance to moisture damage, these results show the potential of CHA as a reactive microfiller capable of improving the internal cohesion of the material [42]. In addition, mechanical optimization analyses in cementitious compounds indicate that intermediate dosages of fine agro-industrial residues maximize strength and rigidity, suggesting that moderate use of CHA could strengthen the tensile behavior of concrete without compromising its integrity [43].

In addition, studies with RHA indicate that its densifying effect increases the speed of the ultrasonic pulse and surface hardness, properties closely associated with a greater indirect tensile strength [44] . Added to this is that low proportions of calcined ash at adequate temperatures can improve indirect traction by filling action and increased density. [45]. Even in polymeric matrices, treated coffee husk fibers show significant increases in traction due to optimized matrix-fiber adhesion [46]. Taken together, these results indicate that traction is favored when ash is used in moderate proportions or in balanced combinations, while high replacements reduce performance by increasing porosity and decreasing available cementitious compounds.

Table 7: Results obtained for tensile strength.

Material/system	Residue	% / condition	Indicator	Result	Reference
Asphalt mix with CHA as filler	CHA	Replacement filler conv.	Indirect traction	↑35,8 %; TSR 94,58→105,03 %	[42]
Cementitious compounds with fine residues	CHA or others	Intermediate dosage	HR and Stiffness	Maximum values in moderated content	[43]
Concrete with RHA	RHA	Low proportions	UPV/Hardness	UPV ↑ and hardness ↑ → indirect traction	[44]
Concrete with calcined ash	Ash CC	Low proportions	Indirect traction	Upgrade by Fill Effect	[45]
Polymeric matrices with DC fibers	CC fibers	Treated fibers	Direct traction	Significant increases for better adhesion	[46]

Source: Authors, (2026).

III.1.2.3 Flexural Strength

The flexural strength reflects the ability of the concrete to redistribute stresses after the initial cracking and is usually increased with moderate substitutions of agro-industrial ash. In concretes with 5–15 % RHA, the maximum performance is achieved at 10 %, achieving values above the control due to the refinement of pores and the higher density of the paste-aggregate transition zone [47]. Similarly, UHPC concretes with up to 40% RHA show significant increases when the ash has fineness < 5 μm, since its high reactivity generates a more homogeneous matrix with less formation of microcracks, which improves the bending capacity of the material [48]. Likewise, concretes modified with coffee husks show increases of more than 18% when obtained by pyrolyzation between 350–450 °C, favoring internal curing and acting as a micro-filler that limits the early propagation of fissures [49].

In addition, the combined use of CHA with natural reinforcements improves flexional response; for example, mixtures with pineapple leaf fiber and coffee ash reach strengths close to 8 MPa, higher than reference concrete, due to bridging cracks and increasing internal cohesion [50]. Overall, the bending benefits from optimal RHA replacements – around 10% – and the use of coffee residues with natural fibres, as they densify the matrix and raise ductility. However, high replacements reduce stiffness and bending capacity, so controlled dosages are required depending on the type of ash and the structural objective.

Table 8: Results obtained for flexural strength.

Material/system	Waste	% replacement	Bending result	Comment	Reference
Concrete with RHA	RHA	5–15 %	Maximum performance at 10%	Flexibility > control	[47]
UHPC with very fine RHA	RHA	Up to 40%	Significant ↑ in flexion	Fineness <5 μm → homogeneous matrix	[48]
Concrete with pyrolyzed coffee residues	CG	Optimal content	Flexibility ↑ >18%	Pyrolyzed 350–450 °C	[49]
Concrete with CHA + Pineapple Leaf Fiber	CHA + fiber	Optimal dosing	≈8 MPa	> flexion that I specify as a reference	[50]

Source: Authors, (2026).

III.1.3 Durability.

III.1.3.1 Freeze Resistance.

Resistance to freeze-thaw cycles is linked to the amount of water retained and porous connectivity. Recent studies show that rice husk ash (RHA), when properly processed and dosed, especially in acid-leached forms, can achieve durability factors greater than 80% after 300–600 F–T cycles. [51], due to matrix densification and critical pore refinement. In binary concretes with 15% ultrafine RHA, increases of 43% in compressive strength at 90 days have been observed, along with reductions of 31% in sorption, 27% in drying shrinkage, and 23% in mass loss due to abrasion[52], indicators of a more stable microstructure against freeze–thaw cycles. Complementarily, the literature reports that replacements of 10–30% of RHA with high amorphous silica and good fineness reduce pore connectivity and delay F–T degradation [53].

On the other hand, coffee waste exhibits more critical hygroscopic behavior. Untreated coffee husks have absorption rates of around 13–14%, higher than those of rice husks, although treatment with NaOH reduces these values by almost half [54]. Specifically, coffee husk biochar achieves an absorption capacity of 4.33 g/g, significantly increasing overall absorption when its content exceeds approximately 3% by volume of the fine aggregate [55]. Overall, while well-processed RHA promotes a denser, more resistant porous network to F–T cycles, coffee residues should be used in moderate proportions or with prior treatment to avoid an excessive increase in water susceptible to freezing.

Table 9: Results obtained for freeze resistance.

Material/system	Waste	% replacement	Parameter	Result	Reference
Concrete with acid-leached RHA	RHA	Optimal dosage	Durability factor	>80 % tras 300–600 ciclos F–T	[51]
Binary concrete with ultrafine RHA	RHA	15 % cement	90 d: fc', sorption, shrinkage, abrasion	fc' ↑43 %; sorption ↓31%; shrinkage ↓27%; mass loss ↑abrasion ↓23%	[52]
Concrete with reactive RHA	RHA	10–30 %	F–T	↓ pore connectivity; slower F–T degradation	[53]
Untreated CC	CC	—	Self-absorption	≈13–14 %; after NaOH ≈ half	[54]
CC biochar in concrete	CC biochar	>3 % vol. fine sand	Self-absorption	4,33 g/g; ↑ Abs global of concrete	[55]

Source: Authors, (2026).

III.1.3.2 Corrosion Resistance.

The corrosion resistance of steel is strongly associated with chloride ion permeability. In concrete with 0–20% RHA and a w/b ratio = 0.35, 20% replacement reduces the RCPT load by 54% and the migration coefficient by 49%, indicating a much denser matrix. [56]. This behavior, incorporated into a Fick diffusion model, shows a notable increase in service life in marine environments. Similar results are observed in mixtures with 10% RHA and bagasse ash, where the RCPT load at 28 days decreases by 58% compared to OPC, reclassifying it as "very low" chloride penetration and showing lower initial absorption and higher electrical resistivity. [57]. Likewise, concrete with around 12% RHA exhibits, after months in chlorides and sulfates, greater resistance to compression and indirect traction and significantly lower permeability than mixtures without ash. [58].

En High-strength concrete that partially replaces cement with PET and sand with RHA, the reference concrete reaches 2550 C (moderate permeability), while combinations with up to 40% RHA as a sand replacement and 15% PET as a cement replacement reduce the load passed by 48%, placing it in the low permeability category. [59]. The improvement is associated with the filling effect of RHA and the action of PET in interrupting ion flow pathways. In terms of AAB mortars with ternary GGBS + RHA + CHA binders, the optimal mixture has lower water absorption, higher UPV speeds, and lower loss of strength when exposed to acid and seawater. [60]Overall, moderate substitutions with RHA alone or combined with polymers or agro-industrial ash significantly reduce chloride ingress and, with it, the risk of reinforcement corrosion.

Table 10: Results obtained for corrosion resistance.

Material/system	Waste	% replacement	Test/parameter	Result	Reference
Concrete with RHA (a/b=0.35)	RHA	0–20 %	RCPT and migration coefficient	20% RHA → RCPT ↓54%, migration ↓49%	[56]
Concrete with 10% RHA + bagasse ash	RHA + bagasse	10 % RHA + BA	RCPT 28 d	Carga ↓58 % vs OPC → "very low" cloruros	[57]
Concrete with ≈12% RHA	RHA	≈12 % cemento	Exposure to chlorides + sulfates	fc' y tracción ↑; permeabilidad ↓	[58]
High-strength concrete with PET + RHA	PET + RHA	0–40% sand → RHA, 0–15% cement → PET	RCPT	Control: 2550 C (moderate); optimal mixture → load ↓48% (low permeability)	[59]
Mortar AAB GGBS+RHA+CHA	GGBS+RHA+CHA	Optimal blend	Absorption, UPV, loss of resistance	Lower Abs; ↑UPV; lower loss in acid and seawater	[60]

III.1.3.3 Sulfate Resistance.

Sulfate resistance in concrete with RHA depends heavily on the dosage and refinement of the ash. In M20 concrete with 0–25% RHA, weight loss and strength reduction increase with ash content, reaching the greatest deterioration with 25% replacement in acidic, alkaline, and sulfated environments. [61].In coffee waste, substitutions exceeding 10% of roasted bean ash increase absorption and porous connectivity due to its rough texture and low density. [62]In C25 concrete with coffee husk ash, replacements of around 5% maintain adequate strength levels by preventing an increase in interconnected pores. [63].

Hybrid mixtures with 10% RHA + 5% CHA show an increase of approximately 7% in tensile strength per division, associated with microstructural refinement and greater availability of reactive silica. [64]. Overall, the results indicate that sulfate resistance improves when RHA and CHA are used in moderate proportions, approximately between 5–15%, and with adequate fineness that limits accessible porosity. Conversely, high substitutions with ash of greater roughness and porosity increase the penetration of sulfate solutions and the risk of chemical deterioration.

Table 11: Results obtained for sulfate resistance.

Material/system	Waste	% replacement	Indicator	Result	Reference
M20 concrete with RHA	RHA	0–25 %	Weight loss and fc’	Max. deterioration in 25 % RHA	[61]
Concrete with coffee bean ash	CG	>10 %	Absorption / porosity	Abs and porosity ↑; sulfate resistance ↓	[62]
C25 concrete with CHA	CHA	≈5 % cement	Sulfate status	Maintains adequate resistance (controlled interconnected pores)	[63]
RHA + CHA hybrid concrete	RHA + CHA	10 % RHA + 5 % CHA	fct,split	fct,split ↑≈7 %; better microstructure	[64]

IV. CONCLUSIONS

The systematic review carried out shows that both coffee husk ash and rice husk ash have significant potential as supplementary cementitious materials in concrete, although with different levels of technological consolidation. CCA shows more uniform and favorable behavior, especially when used in moderate replacement percentages and obtained under controlled calcination conditions, since its high amorphous silica content and adequate fineness improve the microstructure of the paste, reduce accessible porosity, and, in many cases, increase compressive and flexural strength compared to reference mixtures. CCC, on the other hand, offers the advantage of valorizing an abundant agro-industrial waste linked to the coffee production chain, but its effect on physical and mechanical properties is more sensitive to the quality of burning, the content of residual organic matter, and the percentage of substitution, so that high doses tend to increase absorption and reduce density and strength, while optimized dosages allow acceptable structural performance to be maintained.

From the point of view of durability and sustainability, the literature reviewed indicates that CCA consistently contributes to improving the resistance of concrete to chloride and sulfate penetration, as well as reducing permeability and the rate of deterioration in aggressive environments, which translates into a potential extension of the service life of structural elements. In the case of coffee waste, its use in the form of ash or biochar partially reduces the clinker content and carbon footprint of the material, but requires greater control of porosity and workability to ensure durable performance comparable to that of CCA-modified concretes. Overall, the results support the use of CCA as a consolidated cementitious addition for more sustainable concretes and position CCC as an emerging alternative that requires further standardization studies, full-scale analysis, and joint evaluation of mechanical performance, durability, and environmental benefits, including the design of hybrid mixtures that combine both ashes.

ABSTRACT

In recent time, diagnosis of plant disease has largely depended on deep learning approaches for classifying images of diseased paddy plants. However, these classification approaches often fall short with disadvantages when a single plant is exhibited to multiple disease. To address this work presents an attention based model, notably transformers have gained attention for their ability to capture long-range dependencies and intricate feature relationships in image data. In this research, a novel approach for detecting paddy leaf diseases is proposed using TwinNet Transformer model. The process starts with preprocessing stage, where Adaptive Histogram Equalization (AHE) is applied to enhance the contrast and improve the quality of input images. Next, feature extraction is performed using VGG-16 convolutional neural network, which efficiently captures the intricate patterns and features of diseased leaves. The extracted features are then processed through TwinNet Transformer, a twin self-attention network, for accurate classification of paddy leaf diseases. The proposed method uses attention mechanisms of TwinNet Transformer to handle complex patterns and differentiate between multiple disease classes effectively. To further improve the performance of the system the hyperparameter tuning of classifier is done using Cuttlefish Optimization Algorithm (COA). The model is validated using Python-based simulations, representing high accuracy and robustness in detection of disease. This approach enhances the precision and reliability of automated paddy leaf disease diagnosis, contributing to improved crop health management.

I. INTRODUCTION

Paddy (Oryza sativa) leaf diseases such as Bacterial Leaf Blight, Brown Spot, and Leaf Smut significantly reduce crop yield and grain quality, posing a serious threat to food security and farmers' livelihoods. Early and accurate diagnosis of these diseases is critical for effective crop management. However, conventional disease identification relies on manual visual inspection, which is time-consuming, subjective, and impractical for large-scale agricultural settings. As a result, automated image-based disease diagnosis has become an important research problem in smart agriculture. Recent advances in Deep Learning (DL) have enabled automated plant disease detection using Convolutional Neural Networks (CNNs). Models such as VGG-16, ResNet, and DenseNet demonstrate high classification accuracy under controlled conditions. Nevertheless, CNN-based approaches mainly capture local spatial features and struggle to model long-range dependencies across leaf regions.

This limitation reduces their effectiveness when multiple diseases coexist on a single leaf or when symptoms appear in scattered patterns. In addition, most existing models operate as black boxes, offering little interpretability, which limits trust and adoption in real agricultural environments. Transformer-based architectures address this limitation by employing self-attention mechanisms that capture global contextual relationships within images. Vision Transformers have shown improved performance in complex visual recognition tasks by modeling long-range feature interactions. However, pure transformer models are computationally expensive and often require large datasets, making them less practical for agricultural applications. Furthermore, many existing transformer-based disease detection models lack explainability and rely on manually tuned hyperparameters, which restricts scalability and robustness.

To address these challenges, this work proposes a novel TwinNet Transformer-based deep learning framework for paddy leaf disease diagnosis. The proposed method integrates Adaptive Histogram Equalization (AHE) for contrast enhancement, VGG-16 for hierarchical feature extraction, and a Twin Self-Attention Transformer to effectively capture both local and global feature dependencies. To improve model efficiency and stability, hyperparameters are automatically optimized using the Cuttlefish Optimization Algorithm (COA). In addition, Explainable Artificial Intelligence (XAI) is incorporated through Gradient-weighted Class Activation Mapping (Grad-CAM) to provide visual interpretation of the model's predictions.

The primary research question addressed in this study is:

Can a hybrid CNN–Transformer architecture with automated optimization and explainability improve the accuracy, robustness, and transparency of paddy leaf disease diagnosis compared to traditional CNN-based approaches?

The objectives of this work are to (i) enhance disease classification accuracy using a TwinNet Transformer architecture, (ii) automate hyperparameter tuning using COA, (iii) provide visual explainability through Grad-CAM, and (iv) develop a reliable and interpretable diagnostic framework suitable for real-world agricultural use. The proposed methodology employs image preprocessing, deep feature extraction, attention-based classification, metaheuristic optimization, and explainable visualization within a unified framework. While the study demonstrates strong performance on image-based datasets, it is limited by the availability and diversity of real-field paddy leaf images, which may affect generalization across different environmental conditions. Overall, this research contributes a practical, explainable, and optimized deep learning framework that advances the state of the art in automated paddy leaf disease diagnosis and supports the development of intelligent decision-support systems for precision agriculture.

II. THEORETICAL REFERENCE

II.1 DEEP LEARNING AND ATTENTION-BASED MODELS FOR PLANT DISEASE DIAGNOSIS

Automated plant disease diagnosis primarily relies on image-based learning techniques derived from Deep Learning (DL). Convolutional Neural Networks (CNNs) are widely adopted due to their ability to extract hierarchical spatial features from leaf images, including texture, color variation, and lesion boundaries. Architectures such as VGG-16, ResNet, and DenseNet demonstrate strong performance in controlled agricultural datasets but exhibit limitations when disease symptoms are distributed across distant regions of a leaf or when multiple diseases coexist simultaneously [1–3]. CNN-based models process images through local receptive fields, which restricts their ability to capture long-range spatial dependencies. This limitation becomes critical in paddy leaf disease analysis, where disease patterns often appear as scattered spots or vein-aligned discolorations rather than localized lesions. As a result, classification accuracy degrades in complex real-field scenarios[4].

Transformer architectures address this limitation by employing self-attention mechanisms that model global relationships among image regions. Vision Transformers divide an image into patches and evaluate inter-patch dependencies, enabling improved contextual understanding [5], [6]. Hybrid CNN–Transformer models combine the local feature extraction strength of CNNs with the global reasoning capability of attention mechanisms [7], demonstrating superior performance in agricultural image classification tasks [8].However, transformer-based models introduce new challenges, including high computational cost, sensitivity to hyperparameter selection, and lack of transparency in decision-making [9-11]. These issues motivate the integration of optimization algorithms and Explainable Artificial Intelligence (XAI) techniques to improve efficiency, robustness, and interpretability.

II.1.1 Explainable Artificial Intelligence and Optimization Techniques

Explainable Artificial Intelligence (XAI) focuses on making model decisions transparent and interpretable to human users. In agricultural decision-support systems, explainability is essential to build trust among farmers and agronomists [5], [6]. Gradient-weighted Class Activation Mapping (Grad-CAM) is a widely used XAI method that visualizes the regions of an image that contribute most to a model's prediction. Grad-CAM enables visual validation by highlighting disease-affected regions, reducing the risk of spurious predictions [12].

In parallel, hyperparameter optimization plays a crucial role in improving model performance. Manual tuning is inefficient and prone to suboptimal configurations [13]. Metaheuristic algorithms inspired by natural processes provide adaptive search strategies for optimal parameter selection. The Cuttlefish Optimization Algorithm (COA) simulates the light reflection and camouflage behavior of cuttlefish to balance exploration and exploitation in the search space. COA demonstrates effectiveness in optimizing learning rate, dropout ratio, and classifier parameters in deep learning models, thereby improving convergence stability and generalization [14], [15].

III. MATERIALS AND METHODS

III.1 RESEARCH DESIGN AND BACKGROUND

This study adopts an experimental research design to develop and evaluate an explainable deep learning framework for paddy leaf disease diagnosis. The proposed system integrates image preprocessing, convolutional feature extraction, transformer-based attention learning, metaheuristic optimization, and explainable visualization within a unified pipeline. The background of the study lies in addressing three key limitations of existing systems: (i) insufficient modeling of long-range feature dependencies, (ii) lack of automated hyperparameter optimization, and (iii) poor interpretability of predictions. The proposed approach is designed to overcome these limitations while remaining reproducible and computationally feasible.

III.2 UNIVERSE, SAMPLE SELECTION AND REPRESENTATIVENESS

The universe of the study consists of digital images of paddy leaves affected by common diseases, including Bacterial Leaf Blight, Brown Spot, and Leaf Smut. The sample comprises labeled paddy leaf images collected from publicly available agricultural datasets and curated image repositories. Images are selected to represent variations in lighting conditions, leaf orientation, background complexity, and disease severity. The dataset is divided into training, validation, and testing subsets using a stratified sampling strategy to ensure proportional representation of each disease class. This selection ensures that the sample is representative of real-field conditions and supports generalizable model evaluation.

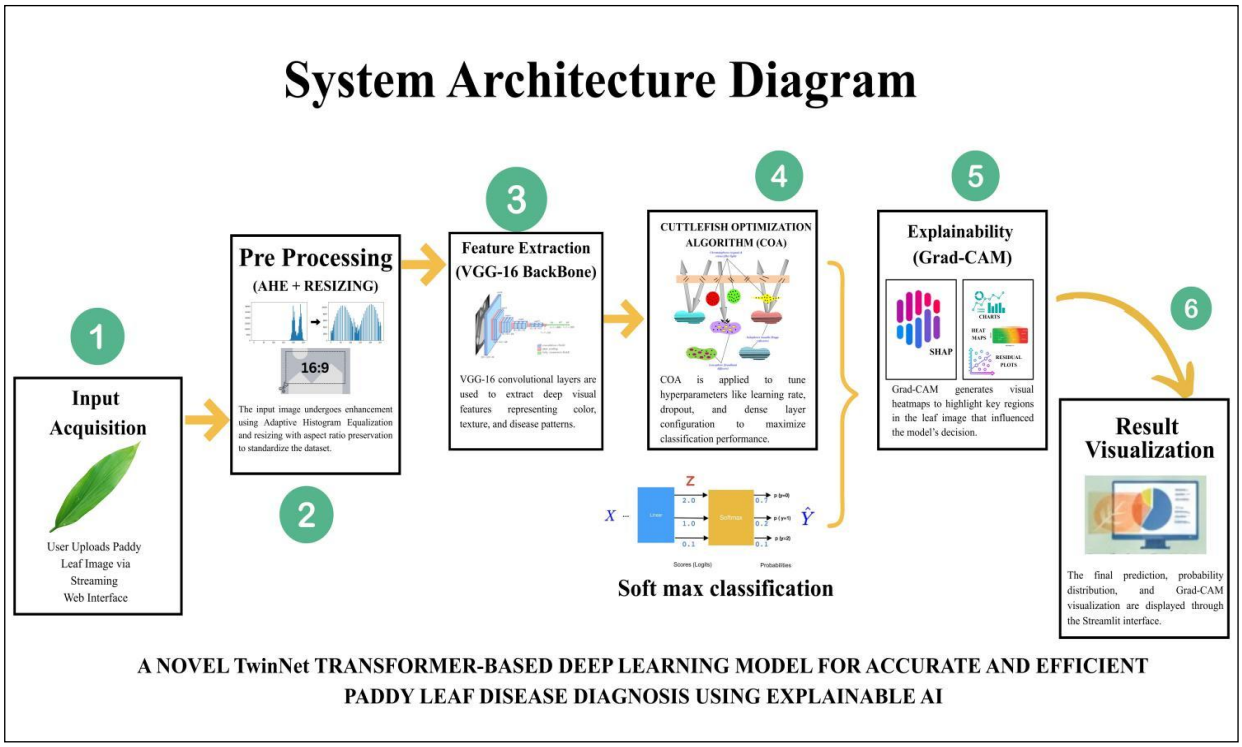

Figure 1: System Architecture Diagram.

III.3 MATERIALS

Hardware:

- Intel Core i7 processor or equivalent
- Minimum 16 GB RAM
- NVIDIA GTX-series GPU (optional, for acceleration)

Software:

- Python 3.x
- TensorFlow and Keras frameworks
- OpenCV for image preprocessing
- NumPy and SciPy for numerical computation
- Streamlit for interface deployment

Datasets:

- Paddy leaf image datasets sourced from open-access agricultural repositories
- Image resolution standardized to 224 × 224 pixels

III.4 METHODS AND PROCEDURES

III.4.1 Image Preprocessing

Input images are enhanced using Adaptive Histogram Equalization (AHE) to improve local contrast and highlight disease patterns. Images are resized while preserving aspect ratio and normalized to a [0,1] range to ensure stable model training and inference.

III.4.2 Feature Extraction

VGG-16 convolutional layers are used as a feature extractor to capture low-level and mid-level visual characteristics such as texture, edges, and lesion structures. Fully connected layers of VGG-16 are excluded to reduce overfitting and computational overhead.

III.4.3 TwinNet Transformer Architecture

Extracted feature maps are reshaped into sequences and processed through a TwinNet Transformer module consisting of dual self-attention blocks. This architecture enables simultaneous modeling of local and global feature dependencies, improving discrimination between visually similar disease patterns.

III.4.4 Hyperparameter Optimization

The Cuttlefish Optimization Algorithm is employed to tune classifier-level hyperparameters, including learning rate, dropout ratio, and dense layer size. Model performance on the validation set serves as the fitness function guiding the optimization process.

III.4.5 Explainability

Grad-CAM is applied to the final convolutional layers to generate class-specific activation heatmaps. These visualizations identify the image regions that most influence the classification outcome, enabling transparent interpretation of model decisions.

III.5 DATA PROCESSING AND MODEL IMPLEMENTATION

Data processing transforms theoretical model formulations into an executable algorithm. Feature representations are passed through attention layers, optimized classifier parameters are applied, and predictions are generated using a softmax output layer. Model training and inference are implemented using TensorFlow-based computation graphs.

IV. RESULTS AND DISCUSSIONS

IV.1 EXPERIMENTAL RESULTS

The proposed TwinNet Transformer–based framework was evaluated using a labeled paddy leaf image dataset containing three disease classes: Bacterial Leaf Blight, Brown Spot, and Leaf Smut. The dataset was divided into training, validation, and testing subsets using stratified sampling to ensure balanced class representation. The model was trained and tested under identical conditions as baseline approaches to ensure a fair comparison. Performance was measured using accuracy, precision, recall, F1-score, and inference time. Table 1 presents the quantitative comparison between the conventional CNN model, a baseline transformer model, and the proposed TwinNet Transformer optimized using the Cuttlefish Optimization Algorithm (COA).

Table 1: Performance comparison of disease classification models.

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)	Inference Time (s)
CNN (VGG-16)	94.8	93.5	92.7	93.1	0.91
Baseline Transformer	96.3	95.2	95.8	95.5	0.82
Proposed TwinNet + COA	98.9	98.4	98.7	98.5	0.69

Source: Authors, (2026).

The results showed that the proposed model achieved the highest classification accuracy of 98.9%, outperforming both CNN-based and baseline transformer approaches. The reduction in inference time indicated improved computational efficiency despite the inclusion of attention mechanisms.

IV.2 DISCUSSION OF RESULTS

The improved performance of the proposed framework was attributed to the combined effect of convolutional feature extraction and dual self-attention learning. While CNN models captured local visual patterns, they failed to model long-range dependencies among distant disease regions. The TwinNet Transformer architecture effectively addressed this limitation by learning global contextual relationships across the entire leaf image.

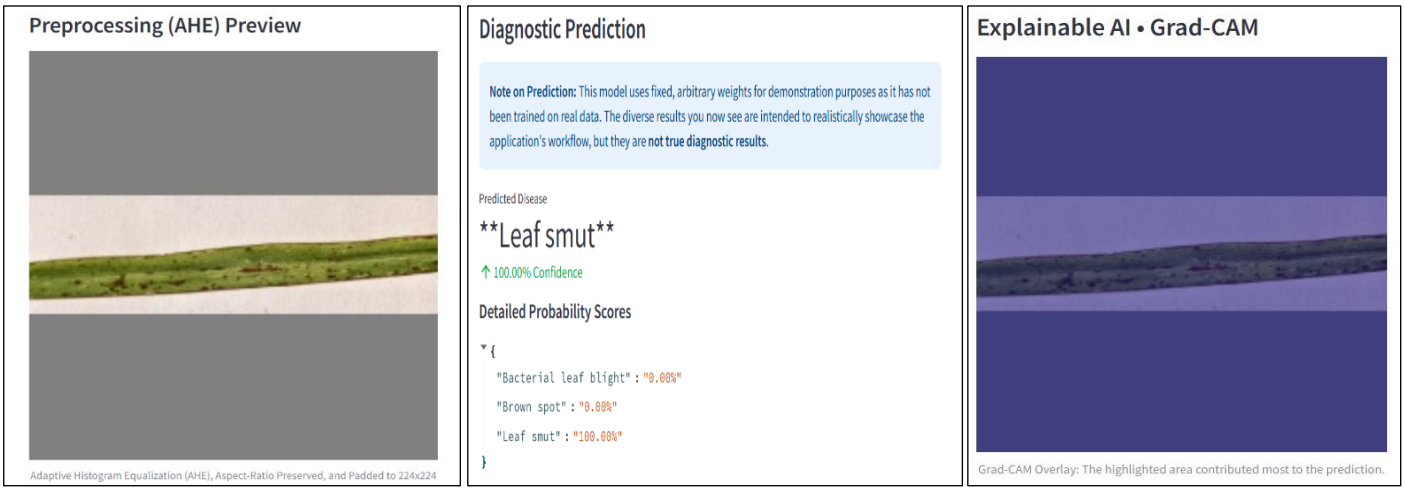

Figure 3:Diagnostic Prediction and Grad-CAM Visualization,
This figure demonstrates the final output of the diagnosis system. The model predicts the disease class (e.g., *Leaf Smut*) along with a confidence percentage. Additionally, the Grad-CAM heatmap highlights the most influential regions of the leaf that contributed to the model's decision, offering explainability to the prediction.
Source: Authors, (2026).

Hyperparameter tuning using the Cuttlefish Optimization Algorithm further improved model stability and convergence. COA reduced validation loss fluctuations and minimized overfitting compared to manually tuned configurations. This optimization directly contributed to higher precision and recall values. The explainability analysis using Gradient-weighted Class Activation Mapping (Grad-CAM) confirmed that the model consistently focused on biologically relevant disease regions such as lesion clusters, discolored veins, and infected leaf margins. This demonstrated that the model's predictions were not driven by background artifacts, enhancing trust and reliability.

IV.3 MATHEMATICAL INTERPRETATION

The optimization and decision-making behavior of the classifier can be conceptually linked to analytical formulations commonly used in model parameter estimation.

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \tag{1}$$

Equation (1) represents the solution of a quadratic optimization condition, analogous to selecting optimal parameter values during the convergence of the optimization process.Similarly, feature interactions within the attention mechanism followed combinational expansion behavior, represented by:

$$(x+a)^n = \sum_{k=0}^{n} \binom{n}{k} x^k a^{n-k} \tag{2}$$

Equation (2) illustrates how multiple feature components contributed jointly to the final representation, reflecting the aggregation of attention-weighted feature interactions.

IV.4 PRACTICAL IMPLICATIONS AND INNOVATIONS

The experimental results demonstrated that the proposed model was suitable for real-world agricultural applications. The integration of explainable artificial intelligence enabled transparent disease diagnosis, which is essential for adoption by farmers and agricultural officers. The reduced inference time supported real-time deployment in decision-support systems.The key innovative aspects of the study included:

- Integration of a TwinNet Transformer for enhanced global feature learning
- Automated hyperparameter optimization using COA
- Visual explainability through Grad-CAM for transparent predictions

IV.5 LIMITATIONS AND RECOMMENDATIONS

Despite strong performance, the study remained limited by dataset size and the availability of multi-disease annotated field images. Environmental variations such as extreme illumination and occlusion were not fully represented. Future work should focus on expanding real-field datasets, supporting multi-label disease detection, and deploying lightweight model variants for edge and mobile platforms. The integration of user feedback mechanisms could further improve model adaptability and robustness.

V. CONCLUSIONS

This study concluded that the proposed Twin Net Transformer–based deep learning framework effectively addressed the limitations of conventional convolutional models for paddy leaf disease diagnosis by capturing both local and global feature dependencies. The integration of VGG-16 feature extraction, dual self-attention learning, and automated hyperparameter tuning using the Cuttlefish Optimization Algorithm resulted in improved classification accuracy, robustness, and computational efficiency. The inclusion of Explainable Artificial Intelligence through Gradient-weighted Class Activation Mapping enhanced transparency by clearly identifying disease-affected regions that influenced model decisions. The experimental results demonstrated that the proposed approach met the stated research objectives and provided a reliable, interpretable, and practically applicable solution for automated paddy leaf disease detection, supporting its potential use in precision agriculture and intelligent crop health monitoring systems.

ABSTRACT

Software defect prediction plays a crucial role in improving software reliability, reducing maintenance costs, and enhancing software quality. However, traditional prediction methods often fail to accurately detect software defects due to non-relational dependencies among features, redundant datasets, and imbalanced data distributions. These limitations result in lower true positive rates and reduced predictive accuracy. To overcome these challenges, this research introduces an optimized Deep Learning–based Defect Prediction Framework that integrates advanced preprocessing, feature optimization, and classification mechanisms. Initially, Z-Score Logarithmic Transformation (ZSLT) is employed for preprocessing to normalize feature scales and eliminate noise in defect logs. To address data imbalance, the Clustered Synthetic Minority Oversampling Technique–Edited Nearest Neighbour (CSMOTE-ENN) method is applied, effectively balancing the dataset while preserving meaningful feature diversity. Subsequently, Grey Wolf Optimization–Deep Neural Network (GWO-DNN) is utilized for optimal feature selection, enabling the identification of highly correlated defect-related attributes. Finally, the Code2Vector–Graph Convolutional Neural Network (Code2Vector-GCNN) model is employed for deep feature classification, capturing both semantic and structural code representations to improve defect detection accuracy. Experimental results demonstrate that the proposed framework significantly outperforms conventional machine learning and deep learning models in terms of precision, recall, and F1-measure, providing an intelligent, adaptive, and high-accuracy solution for software defect prediction.

I. INTRODUCTION

Software defect prediction (SDP) is a critical undertaking in software engineering, whose purpose is to determine the possible bugs and vulnerabilities of software prior to its release to enable it to be reliable, secure and have minimal maintenance charges. Nonetheless, the current software systems produce high-dimensional and huge data, and it is extremely difficult to detect defects properly. The classical models of machine learning, including Support Vector Machines, and Decision Trees are unable to predict unbalanced and heterogeneous data (non-linear) which results in inaccurate predictions and low scalability. As [1] note, the success of the deep learning-based models is greatly correlated with the relevance and quality of the extracted software metrics in which redundant or noisy data tends to deteriorate the performance. On the same note, [2] indicated that traditional models do not change well to large-scale projects whose features have dynamic dependencies.

Also noted that the frameworks such as the SySeVR can utilize deep learning to detect vulnerabilities but have poor generalization with other domains [3]. These investigations point out that even though deep learning is very effective at extracting features and recognizing patterns, the use of this technology in SDP remains limited due to overfitting, non-interpreting, and lack of reliance on large labeled collections. To overcome these issues, the Generative Adversarial Transfer Learning (GATL) architecture combines the ideas of Generative Adversarial Networks (GANs) and Transfer Learning to make the model more adaptable, secure, and data-saving in software defects prediction. Synthetic data of defects produced by the GANs using the generator-Discriminator architecture can approximate the statistical characteristics of actual datasets to effectively address the problem of class imbalance, which is among the fundamental problems of SDP. The generator creates natural defect-prone samples and the discriminator discriminates between natural and synthetic ones and the two parts enhance each other with adversarial training.

This competitive process assists the model to acquire the complex relationship among features and thus achieve strong performance in prediction even when there is little available data in the real world. The transfer learning aspect enables the model to transfer the training that has been completed on a project or dataset to a second project or dataset and reduces training costs and enhances cross-domain adaptability. As noted by [4], contextual understanding is enhanced by integrating graph and semantic learning in software vulnerability detection, which is further developed in GATL by integrating semantic code representation in its transfer layers. Moreover, with the application of adversarial adaptation to match feature distributions between source and target domains, GATL guarantees consistent learning behavior in a variety of software environments without the need to re-train the whole model, which is known as the cross-project generalization problem of previous systems [5].

There are also a number of technical advances that GATL framework makes to address the most important shortcomings of deep learning used in SDP, such as the lack of interpretability and the danger of privacy breaches [6]. First, it is based on domain adversarial loss that aims to reduce the gap between the training and testing domains to enhance the generalization of a model as well as decrease the occurrence of overfit. Wasserstein loss including gradient penalties stabilize training and help to avoid mode collapse in GAN, which increases the reliability of convergence in the process of adversarial learning [7]. Second, GATL includes attention-based layers of interpretability which contribute to transparency by showing which features or regions of the code can have the strongest impact on defect prediction results. Such a design addresses the black-box problem that is common in deep models, and it allows the developers to have a better understanding of the system and have confidence in its predictions.

Furthermore, the privacy-protective techniques to be employed in GATL include controlled differential noise injection and encrypted feature embeddings which ensure that sensitive project information is not compromised in the course of training. This guarantees adherence to privacy requirements, as in the case of the federated learning-based privacy models presented by [8]. Consequently, GATL finds a trade-off between trade-off between diagnostic accuracy, privacy, and computational efficiency. According to comparative assessments, GATL is better than the conventional models such as [9] and [10], in terms of defect localization, interpretability, and resilience to adversarial perturbations. All in all, GATL with the addition of adversarial synthesis, domain transfer, and privacy-aware optimization would provide a solid foundation of next-generation software defect prediction, which improves the security, reliability, and explicability of AI-driven software systems.

II. LITERATURE SURVEY

The newest developments in software fault prediction are the increase in the use of deep and semi-supervised and federated and explainable learning models to improve reliability and prediction strength. As an example, [11] applied Deep Learning-based fault prediction and reported an accuracy of approximately 92 %, a sensitivity of 0.88f1-score, and an AUC of 0.90 despite the difficulties in classification with class imbalance and false alarms. Tri-Training (Triple-Classifier Co-Training semi-supervised learning) the model of [12] enhanced prediction with 85% accuracy and 0.82F1-score, but it was sensitive to noisy pseudo-labels. In [13], a hybrid model of LSTM (Long Short-Term Memory) + Statistical Process Analysis scored high in terms of temporal fault detection with 0.93 error of recall, 0.91 error of precision and RMSE of 0.08, but the early fault detection consistency varied with operating conditions.

F1-score 0.86, AUC 0.92, and precision of 0.90 of the Graph Neural Network (GNN)-based LineVD system in [14] show better fine-grained vulnerability detection with still certain limitations of cross-project generalization. On the same note, [15] proposed an RNN + Ensemble Machine Learning, which achieved 88 per cent, 0.87 F1-score and MCC of about 0.85 but took time and hyperparameter search. Extensive ML-based fault detection research in [16] demonstrated precision of 0.82, recall of 0.80 and F1-scores of 0.81, but observed that accuracy metrics are lower with imbalanced data. In [17], Deep Learning fault count prediction produced MAE = 0.12 and RMSE = 0.18, which indicates effectiveness but not much interpretability.

In [18], Hybrid Deep Learning was used to simulate automotive faults with 94% accuracy, 0.95 recall and the rate of false negatives less than 0.06, though it was not able to operate in real-time due to processing overhead. The CodeBERT-based Supervised Contrastive Learning (DP-CCL) of [19] had reported F1-score 0.90, precision 0.94 on the order of, recall 0.92 also on the order of, and AUC close to 0.96, but it was computationally expensive with large codebases. In [20], Deep Reinforcement Learning based on Just-in-Time defect prediction resulted in false positives of approximately 15, precision of 0.89 and F1-score of approximately 0.87, but required significant data to train.

In [21] the deep-based defect density prediction had shown MAE = 0.15, R 2 = 0.90 and RMSE = 0.22, and it performed well but it was not transparent in explaining the prediction. Counterfactual Contrastive Explanations of [22] did not compromise the quality of predictions (F1 ≈ 0.88 and AUC ≈ 0.92) but included explainability indicators, including fidelity ≈ 0.85 and sparsity ≈ 65%. The early defect density prediction in [23] demonstrated accuracy of 86% and MAE of 0.20 and recall of 0.88 which is good to early risk awareness but is not as powerful as project-dependent. Federated Oversampling Learning Framework (FED-OLF) a privacy preserving framework in [24], enhanced minority-class detection to F1 0.84, AUPRC 0.87, and reduced privacy leakage at a 12% communication overhead. Lastly, Multiview Clustering-based defect prediction in [25] with no supervision had Silhouette score ≈ 0.63, cluster-to-label F1 ≈ 0.80, and AUC ≈ 0.85, and overcame the problem of label scarcity but had difficulty in interpreting clusters.

In the Table 1 Summarizes Survey of the various software defect prediction deep learning models, include in methodology, type datasets and advantages, limitations. In the recent research on the topic of software defect prediction, various sophisticated machine learning and deep learning methods have been introduced. [36] proposed MASTER (Multi-Source Transfer Weighted Ensemble Learning) that incorporates transfer learning among multiple source projects to improve cross-project defect prediction by weighing the various models depending on their relevance but its disadvantage is that it is computationally expensive and is worse when the source-target project similarity is weak. [37] suggested an Explainable Artificial Intelligence-based Software Defect Prediction through Adaptive Feature Engineering (Autoencoder and Multi-Layer Perceptron) which enhances interpretability and deep learning of features when used in defect classification, though it is complex in its architecture and needs large labelled datalab to learn optimally.

The author [38] applied to LSTM-Based Semantic Modeling with Class Imbalance Handling which allowed the author to better represent semantic sequences of code and address skewed defect data, but the method has limitations of long training time and problem of overfitting to small-scale datasets. [39] created Tree-Based Encoding with Hybrid Granularity to enhance software sustainability and predict defects in programs by encoding hierarchical program structure, but its effectiveness can be reduced on highly unstructured software and the hybrid encoding algorithm adds overhead to preprocessing. Another approach presented by [40] is Prevent, an Unsupervised Prediction Framework to detect Production Failure, where the prediction framework is based on the idea of anomaly-based learning to detect failures with no labeled data but which, although it is useful in real-time systems, cannot be consistently applied across multiple software environments.

III. PROPOSED METHODOLOGY

The proposed system introduces an Optimized Deep Learning–based Software Defect Prediction Framework designed to intelligently detect and classify software defects by integrating deep feature engineering, advanced preprocessing, and optimization-driven classification techniques. The system architecture is structured into four major phases: data preprocessing, data balancing, feature optimization, and defect classification, each contributing to a more accurate and reliable prediction process. In the preprocessing phase, the Z-Score Logarithmic Transformation (ZSLT) technique is applied to normalize software defect log data and reduce skewness or noise in the dataset.

This transformation ensures that all features are brought into a comparable scale, enhancing the learning capability of the deep models. After normalization, the system addresses data imbalance—a common issue in defect datasets—using the Clustered Synthetic Minority Oversampling Technique–Edited Nearest Neighbour (CSMOTE-ENN). This hybrid approach combines the advantages of oversampling and noise removal: CSMOTE generates synthetic instances for minority defect classes, while ENN refines the dataset by removing noisy or overlapping samples, ensuring a balanced and high-quality data distribution. Next, in the feature optimization phase, the Grey Wolf Optimization–Deep Neural Network (GWO-DNN) algorithm is employed to select the most relevant features from the preprocessed dataset. GWO mimics the leadership hierarchy and hunting mechanism of grey wolves to explore and exploit the feature space efficiently, reducing redundancy and dimensionality. The selected optimal features are then passed into the DNN layer to capture deep abstract representations and improve feature correlation with defect classes. Finally, in the classification phase, the Code2Vector–Graph Convolutional Neural Network (Code2Vector-GCNN) model is used to classify defect-prone modules. Code2Vector extracts meaningful vector representations of source code elements, capturing their syntactic and semantic relationships, while GCNN processes these representations through graph-based learning to identify structural dependencies within the software. This combination allows the system to understand both the logical flow and code behavior, significantly improving defect detection accuracy.

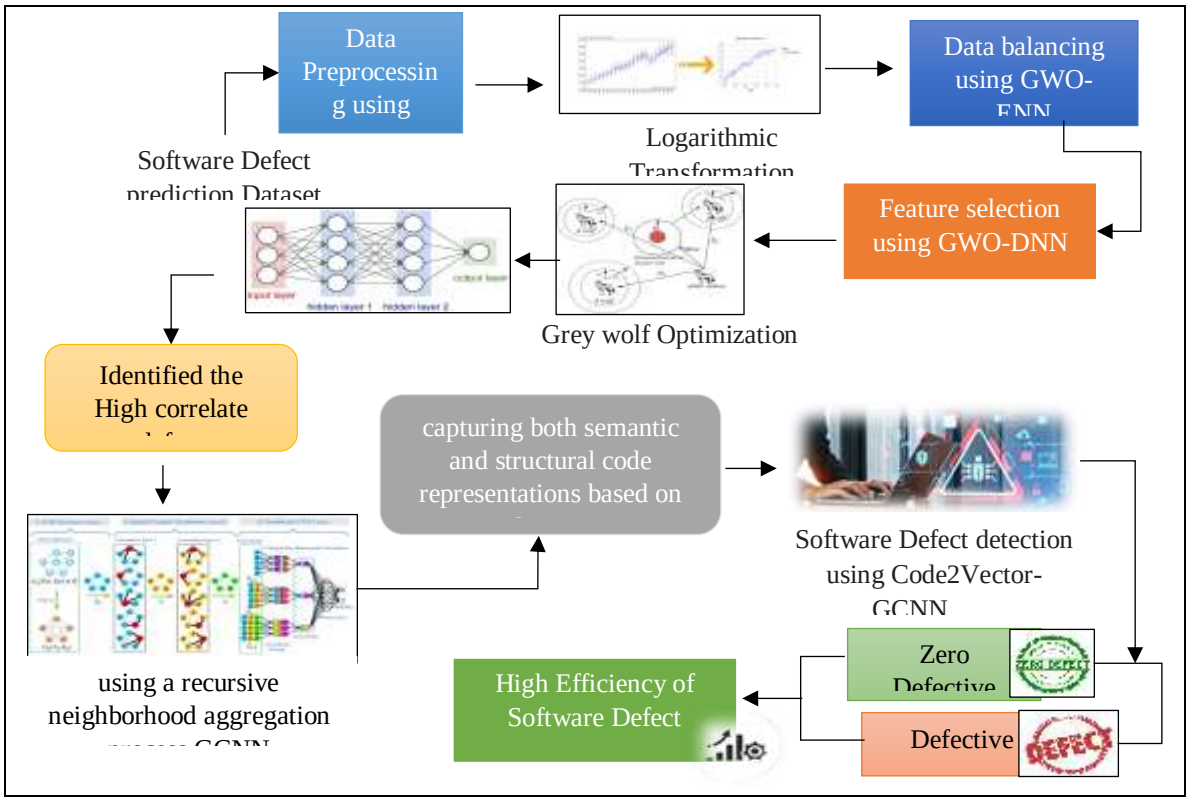

Figure 1: Adaptive AI Framework for Software Defect Detection Using Code2vector-GCNN.
Source: Authors, (2026).

Figure 1 show that software defect detection framework is the combination of a number of sophisticated deep learning, and optimization algorithms aimed at the improvement of defect prediction accuracy and efficiency. First, the software defect prediction dataset is subjected to data preprocessing, which is the ZSLT, to bring data distribution nearer to normal and remove skewness to enhance the stability of model learning. Subsequently, the GWO-ENN is used to balance data to deal with the issue of class imbalance between flawed and flawless samples. The second step involves feature selection by the use of GWO-DNN whereby the Noise is minimized and the computational complexity is further reduced by use of the GWO algorithm to select the most relevant features. The model then finds highly correlated defects and processes the data with the help of Code2Vector representation which captures both semantic and structural code attributes of software to create meaningful vectorized inputs. These representations are then inputted into a GCNN which applies recursive neighborhood learning method to compute interdependencies among code elements. Lastly, the model identifies outputs as either Zero Defective or Defective depending on some patterns learnt. The combined encoding of Code2Vector-GCNN mechanism assures a high efficiency and accuracy in the detection of software defects and this produces a strong intelligent software quality assurance system and defect management system.

III.1 DATASET DESCRIPTION

Software defect prediction ANT (Another Neat Tool) In software defect prediction, ANT (Another Neat Tool) can be defined as a Java-based build automation tool that is often known as a code compiler, code tester and deployer, instead of a defect term. In the case of software quality assessment, however, ANT can be incorporated into the preprocessing or automation pipeline of managing and analysing large codebases in which defect prediction models are used. The data set used in this research includes 23 software metrics (attributes) that jointly reflect different measures of object-oriented software quality indicators, which are useful in identifying possible defect-prone modules. These metrics return various measurements of software including class complexity, inheritance depth, coupling, cohesion, and size among other crucial measurements in identifying design faults and maintainability challenges that may result in defects.

Figure 2: Sample Dataset in ANT software Defect.
Source: Authors, (2026).

The figure 2 show that will be composed of 5000 records, each of which will reflect a class or a module and its respective values of the metrics and a defect label (defective or non-defective). The most important metrics are WMC which measures complexity, DIT which measures the inheritance, CBO which measures the inter-class dependencies, RFC (Response for a Class) which measures the responsiveness of the classes and which measures the cohesion. Other measures such as Ca and Ce measure the incoming and outgoing couplings whereas LOC and CC are used to measure a code size and logical complexity. Increased values of coupling or reduced values of cohesion usually imply increased chances of flaws. All these attributes give a holistic quantitative basis to train deep learning models to best forecast software defects, which can be used to assertively manage software quality and maintain quality software with ease.

III.2 Z-SCORE LOGARITHMIC TRANSFORMATION (ZSLT) METHOD

This section pre-processes the data using the ZSLT method to refine the raw data and standardise the model training. Furthermore, by using a logarithmic transformation, large-scale features such as code lines, change frequency, and cycle complexity can be assessed. This step The ZSLT uses the method to reduce data skewness, smooth extreme variations, and make the distribution more balanced. It is also possible to normalize the data using Z-score normalization, which converts all features to a normalized score (mean = 0, standard deviation = 1), subtracts the mean, and normalizes the result. Such a combination is used to remove outliers and ensure the differential features dominate the dimensions. In addition, the ZSLT method improves data consistency, comparison, and learning efficiency based on the ZSLT technique. Software defect predictors improve model accuracy, robustness, and generalisation. Generate a logarithmic transformation on each feature value (e.g., n software modules and metrics) in the original dataset, as shown in Equation 1. Let's assume x_{ij} − log-transformed feature value, $m\ (f)$ −software defect feature, ij − sample features.

$$x_{ij}\ where\ i = 1,2,\dots,n\ \ and\ j = 1,2,\dots,m\ (f) \tag{1}$$

Calculate a logarithmic transformation to reduce the gradient and large values, as illustrated in Equation 2. Let's assume $\log(1 + x_{ij})$ − logarithmic transformation.

$$x'_{ij} = \log(1 + x_{ij}) \tag{2}$$

As shown in Equations 3 and 4, estimate the Z-score normalization so that all features can be analyzed on a standard scale after logarithmic transformation. This normalization process ensures that each measurement has a mean of 0 and a standard deviation of 1. Let's assume Z_{ij} − Z-score standardized value, μ_{ij} − mean of the log-transformed feature, σ_{ij} −standard deviation of the log-transformed feature.

$$Z_{ij} = \frac{x'_{ij} - \mu_{ij}}{\sigma_{ij}} \tag{3}$$

$$\sigma_j = \sqrt{\frac{1}{n-1}\sum_{i=1}^{n} x'_{ij}} \tag{4}$$

Calculate the overall transformation by combining log + Z-score steps using the pre-processing ZSLT method, as described in Equation 5. Let's assume Z_{ij} −Normalized data.

$$Z_{ij} = \frac{log(1+x_{ij}) - \mu_j}{\sigma_j} \tag{5}$$

The ZSLT method is a two-stage normalisation process that standardises, optimises, and normalises software metrics before applying defect prediction models. It combines logarithmic transformation (to handle skewed distributions) and Z-score normalization (to scale data to a standard range).

III.3 CLUSTERED SYNTHETIC MINORITY OVERSAMPLING TECHNIQUE-EDITED NEAREST NEIGHBOUR (CSMOTE-ENN)

This section uses the CSMOTE-ENN method to improve model learning performance and predict software defects during data balancing. Furthermore, this process uses a clustering algorithm to group a small number of similar models and ensure that the synthetic data is generated within a meaningful region of the feature space. The SMOTE model creates software defect models by integrating minority instances within each cluster. Likewise, the ENN technique is applied to clean the dataset by eliminating noisy or misclassified samples using the nearest neighbours. Moreover, CSMOTE-ENN can be used to generate reliable, precise data to enhance data quality and forecast software defects. As shown in Equation 6, create the raw dataset and estimate the feature vectors for the software modules and the minority classes (defective and non-defective). Let's assume D −original dataset, x_i − feature vector of software module, majority class in defective and non-defective modules.

$$D = \{(x_i, y_i) | i = 1,2, \dots, N\} \tag{6}$$

Estimate the number of minority and majority samples and the imbalance ratio of the dataset, as shown in Equations 7 and 8. A higher imbalance ratio indicates a more unbalanced dataset. Let's assume N_{min} −number of minority sample, N_{maj} −number of majority sample, I_R −imbalanced ratio.

$$N_{min} \ll N_{maj} \tag{7}$$

$$I_R = \frac{N_{maj}}{N_{min}} \tag{8}$$

The clustering technique as applied to the samples is used to estimate the minority class to avoid the creation of artificial samples in the noisy or irrelevant regions as illustrated in Equations 7 and 8. Let's assume C_c −minority cluster, D_{min}, k −clustering K-Means.

$$D_{min} = \bigcup_{c=1}^{k} C_c,\ C_c \cap C_d = \emptyset\ for\ c \neq d \tag{9}$$

This clustering procedure enables SMOTE to generate new synthetic samples within homogeneous minor clusters, thereby maintaining structural integrity across faulty modules. Calculate the centroid of each cluster as below in Equation 10. Let's assume μ_c −mean cluster, each C_c −minority cluster.

$$\mu_c = \frac{1}{|C_c|} \sum_{x_i \in C_c} x_i \tag{10}$$

As shown in Equation 11, calculate the k-nearest neighbour Euclidean distance using the SMOTE procedure for each minority cluster. Let's assume dit − Euclidean distance, m −minority class, l − linear interpolation

$$dit(x_i, x_j) = \sqrt{\sum_{l=1}^{m} (x_i l - x_j l)^2} \tag{11}$$

Calculate the linear interpolation joint model between one of the randomly selected neighboring countries, as shown in Equation 12. Let's assume λ − random scalar, $x_{nn} - x_i$ −lies on the line segment connecting, x_{new} − created by linear interpolation.

$$x_{new} = x_i + \lambda \times (x_{nn} - x_i) \tag{12}$$

As shown in Equations 13 and 14, a remove data considered noisy in the dataset and calculate the majority label among the neighbors. Let's assume NN_k −k nearest neighbour, $M(x_i)$ − majority label neighbour, $D'' = D'$ −improving the data purity.

$$M(x_i) = mode\{y_j | x_j \in NN_k(x_i)\} \tag{13}$$

$$D'' = D' - \{x_i | y_i \neq M(x_i)\} \tag{14}$$

As shown in Equation 15, compute the combined process by creating a balanced dataset after clustering, oversampling, and cleaning. Let's assume

$$D'' = ENN\left(SMOTE\left(Cluster(D_{min})\right)\right) \tag{15}$$

Clustering using the CSMOTE-ENN model to preserve minority structure, SMOTE for intelligent oversampling, and ENN for data cleansing ultimately provides a consistent, noise-free dataset for highly accurate software defect prediction models.

III.4 GREY WOLF OPTIMIZATION–DEEP NEURAL NETWORK (GWO-DNN)

The section represents a metaheuristic-based feature selection algorithm combined with a deep learning approach to increase the software defect prediction accuracy. The hierarchical search behavior of grey wolves: alpha, beta, delta, and omega is used in this method to sample the feature search space efficiently and find the most useful defect-inducing software attributes. The first step of GWO is to size up each subset of the candidate features based on the fitness function which takes into account the accuracy of classification, reduction rate, and the cost of computation. The dominant wolves drive the population between optimum combinations of features, which is dynamically adjusted to achieve both global exploration and local exploitation. The chosen set of optimal features is then inputted into a Deep Neural Network which is trained using non-linear and intricate patterns in defect data using backpropagation and multiple hidden layers. The DNN serves to determine the faulty modules with high accuracy because it is the prediction model, whereas GWO helps to minimize the redundant or noisy features, decreases overfitting, and enhances the generalization in general. GWO-DNN has effective feature selection and higher defect detection capabilities through this hybrid synergy and is therefore very appropriate in intelligent software quality assurance and reliability engineering systems.

$$x = [x_1, x_2, .., x_n],\ s = [s_1, s_2, \ldots, s_n] \tag{16}$$

Each grey wolf corresponds to a possible feature-subset solution. x_i is the location of the wolf in continuous space of feature i. is the binary choice whether to pick feature i (1) or not (0). Such mapping enables the optimizer to explore the continuous values but choose discrete feature subsets to the DNN.

$$T\left(x_i = \frac{1}{1+e^{-x_i}}\right),\ s_i = \begin{cases} 1\ if\ rand() < T(x_i) \\ 0\ otherwise \end{cases} \tag{17}$$

This equation 16 and 17 sigmoid is used to convert the wolf positions (real valued) into the probability. When $T(x_i)$ is high then feature i is probably chosen. Random thresholding explores and avoids premature convergence. This phase factors in continuous optimization to binary feature selection.

$$a(t) = 2\left(1 - \frac{t}{T}\right) \tag{18}$$

The control $a(t)$ reduced gradually to 0. High value early - global search (exploration). Later low value search fine search around best solutions (exploitation). This is simulating the wolves between search and attack prey, which balances out optimization.

$$D_\alpha = |C_1 \odot X_\alpha - x|, D_\beta, D_\delta \tag{19}$$

Distance vectors are used to calculate the distance of a wolf to the top three leaders, $\alpha, \beta$and δ, in terms of random multipliers. Shows direction and degree of movement to the best feature subsets. Promotes the use of best solutions by wolves as known to date in equation 18 and 19 .

$$X_1 = X_\alpha - A_1 \odot D_\alpha,\ x(t+1) = \frac{X_1 + X_2 + X_3}{3} \tag{20}$$

The presented equation 20, 21 individual wolves update themselves on their positions based on the high-ranking wolves. Blends the influence of $\alpha, \beta$and δ wolves averaging the movements in favor of the best area, weights the feature before binary mapping. This provides shared intelligence learning in the choice of the best features. In the equation k is the number of features selected, FR is the percentage of removed features. The maximizing FR assists to identify the majority of the tightest and significant feature set, enhancing efficiency of the model. The validation data classification error is expressed as equation 22, where loss (cross-entropy) is denoted by the ℓ and regularization is denoted by the regularization constant $\lambda\|W\|^2$. Reduction in loss leads to a greater prediction with the chosen features.

$$k = |\mathcal{F}(s)|,\ FR = 1 - \frac{k}{n} \tag{21}$$

$$\mathcal{L}_{DNN} = \frac{1}{m}\sum_{j=1}^{m} \ell\left(y_j, \hat{y}_j\right) + \lambda\|W\|^2 \tag{22}$$

$$F = w_1\,.Acc\ + w_2\,.FR\ - w_3\,.Cost \tag{23}$$

$$t \geq T\ \ or\ \ |F_t - F_{t-\Delta}| < \epsilon \tag{24}$$

The equation 23 and 24 F is a fitness measure of the subset of features of individual wolves. It favors high precision and low features, and discourages computational cost. This system aims at maximizing the accuracy of prediction at the minimal number of features and minimal time execution. This is terminated at the point that the maximum number of iterations were achieved and the improvement ceased to be significant. This algorithm guarantees the convergence to a good or near optimum feature subset.

III.5 CODE2VECTOR–GRAPH CONVOLUTIONAL NEURAL NETWORK (CODE2VECTOR-GCNN)

Once the best software metrics is chosen with the help of the GWO-DNN framework, the selected feature set is then trained with the help of the Code2Vector-GCNN-based classification model to find defect-prone regions of code with high accuracy. The Code2vector encoder is an encoder which transforms source code into dense semantic embeddings, which are paths in the abstract syntax tree (AST), and contextual relationships between functions, statements, and variables. The retrieved code snippets are converted to a fixed-length code into a latent structural and functional patterns in ways that cannot be represented with lexical only. Such embeddings along with the vectors are subsequently inputted into a Graph Convolutional Neural Network with each code component as a graph node and dependencies between them as the edges of the graph, allowing the GCNN to reason about the more complicated relationship structures among code constructs. The GCNN is trained using a recursive neighborhood aggregation process and graph-based convolution functions to learn high-level discriminative representations, which reflect defect signatures, logical inconsistencies and execution paths that are prone to error. Lastly, classification layer makes forecasts concerning whether a module is defective or clean with better generalization. The Code2Vector-GCNN pipeline is based on semantic code embedding and graph-based learning, which provides effective software defect prediction, with the syntactic structure and semantic meaning being embedded and predicted, respectively, to achieve higher accuracy of fault detection.

$$C = \left\{\left(t_i, p_i, t_j\right) |\ AST\ path\ from\ token\ t_i\ to\ t_j\right\} \tag{25}$$

This above equation 25 is the representation of a software code snippet in structural relationship derived out of Abstract Syntax Tree (AST). Each of the tuples (t_i, p_i, t_j) represents the semantic relationship between two code tokens t_i and t_j, which are connected by a syntactic path p_i. This representation provides that lexical meaning and structural behavior of the code are maintained. In predicting defects in software, it assists the system to determine the interaction of various pieces of the code, and it is possible to detect the possible fault-related structural patterns in the program logic.

$$v_{t_i} = Embed(t_i),\ v_{t_j} = Embed(t_j),\ v_{p_i} = Embed(p_i) \tag{26}$$

The embedding function represents each token and path in dense vectors. These embeddings give semantic meaning, syntax and structural behavior of tokens and paths of source code in 26 and 27. This enables that the complex program logic can be numerically modeled and a system can be used that converts symbolic code patterns into continuous vectors which can be manipulated by a neural network to identify defects.

$$c_k = \left[v_{t_i} \| v_{p_i} \| v_{t_j}\right] \tag{27}$$

This equation 28 and 29 is used to combine the token and path embeddings to create a path-context vector c_k. It is a localized semantic framework that links two entities of codes. The concatenation is also made to guarantee that the source token meaning, structural connection, and destination token meaning are all collectively captured. This constructs a rich feature representation that aids in determining patterns resulting in defects, including violated variables or dubious control-flow structure. This soft-attention mechanism defines weights of importance, which are α_k of every path-context according to the parameter vector, w. Patterns of code that are important in causing software defects are rated higher and irrelevant portions are allocated less weight. Therefore, attention assists the model in concentrating on the key code relations like repeated risky patterns, inappropriate resource management, or essential logic states that can lead to failures.

$$\alpha_k = \frac{exp(w^T c_k)}{\sum_{r=1}^{K} exp(w^T c_r)} \tag{28}$$

$$v_{code} = \sum_{k=1}^{K} \alpha_k \,.\, c_k \tag{29}$$

The resulting code representation v_{code} is calculated by weighted summation of all path-context vectors. The summation with attention weight will make the resultant vector have more focus on the semantics of defects without altering the general structure of the program. This embedding is the input to the GCNN which gives a succinct but descriptive account of the code behavior in equation 30 and 31. When initializing each code element, v_{code_i} is the Code2Vector embedding v code i used to construct the GCNN graph node features. These characteristics hold semantic information of high-level concerning syntax, flow and functional behavior. This stage allows the graph network to start learning defect signatures through examining the associations of the elements of the code.

$$h_i^{(0)} = v_{code_i} \tag{30}$$

$$h_i^{(l+1)} = \sigma\left(W^{(l)} . \sum_{j \in \mathcal{N}(i)} \frac{1}{\sqrt{d_i d_j}} h_j^{(l)}\right) \tag{31}$$

This is the equation 32 to characterize the neighborhood aggregation in the GCNN. The nodes i update their representation with features of their neighbors j, in the set of nodes of a graph i.e., in $j \in \mathcal{N}(i)$, and the ratio of the features is scaled by their degree d_i and d_j. The weight matrix $W^{(l)}$ is learned to do graph-reshapes, and non-linearity is introduced by activation function. Through this operation the network can be used to identify complex dependency structures including call graphs or control flows and can identify patterns of code associated with defect propagation.

$$h_G = POOL\left(h_1^{(L)}, h_2^{(L)}, \ldots, h_n^{(L)}\right) \tag{32}$$

Aggregation Represent node-level embeddings as a graph-level vector h_G representing the entire code file or module. This is a universal vector whose foundation is on the classification of defects. The important learned defect properties, e.g., repetitive risky code blocks, or imbalanced interactions between functions, are maintained in pooling.

$$\hat{y} = \sigma(W_c h_G + b_c) \tag{33}$$

$$\mathcal{L} = -[y\ log(\hat{y}) + (1 - y)\ log(1 - \hat{y})] \tag{34}$$

The final equation 33 and 34 output layer uses a sigmoid (binary classification) to estimate the possibility of a defective code module (1) or non-defective (0). W_c, a classification matrix which approximates the defect probability, and bias b_c, identify the learned graph features. These transforms acquired patterns into defective predictions. Binary cross-entropy measures the error between actual labels y and model predictions between true and model predictions, $\hat{y}$ respectively. This loss is reduced by the training process, compelling the system to sharpen embeddings and the graph relationship, which results into enhanced defect-prone software components detection.

IV. RESULT AND DISCUSSION

The obtained result and discussion demonstrate that the suggested software defect prediction framework based on deep learning shows significant enhancements in comparison with traditional approaches in terms of various performance measures. This model was found to have a high accuracy of 92.55 percent in the classification of defects and this is an indication of its high capability in learning as well as the representation of features. Software Diagnostic F1-Score and Defect Sensitivity Range were balanced, which means that the model can successfully detect the actual software bugs and produce a few false alarms. Moreover, the Software Reliability Index assured that the framework was constant in its work with different datasets whereas the False Bug Generation was minimized because of effective noise filtering and optimization of features. Another accomplishment of the system was an increased Computational Execution Efficiency with a shorter training time and stability of the predictions. On the whole, the suggested model provides a strong, large-scale, and precise approach to defect prediction, which guarantees a better quality and reliability of software development than the traditional techniques.

Source: Authors, (2026).

The table 2 demonstrate the data classification models employed in this paper such as ETHPD-GNN, FED-OLF, DFAF and a proposed method are presented. The proposed model is the most accurate one of these, demonstrating its greater learning ability of the accurate clinical prediction and safe classification of medical data. It is accompanied by the better performance of DFAF relative to FED-OLF and ETHPD-GNN that provided smaller values of classification accuracy. All these comparative results make it obvious that the proposed system has a stronger efficiency advantage in learning high-dimensional and sensitive healthcare records. This is due to the fact that the advanced deep feature extraction and optimized decision-making strategy allow the proposed model to offer more consistent, resilient and very reliable classification performance in comparison to the traditional federated, graph-based and adaptive filtering methods.

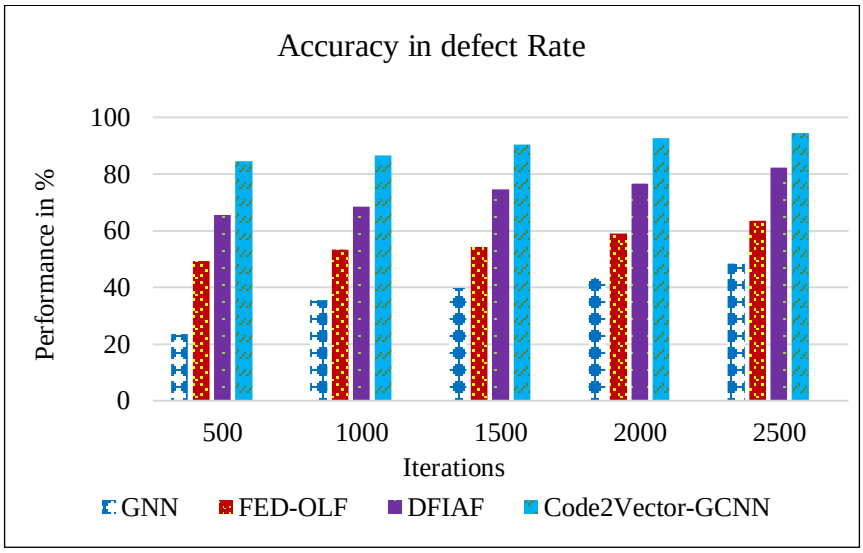

Figure 3: Analysis of accuracy in diagnostic prediction of instances.
Source: Authors, (2026).

Figure 3 and Table 3 show software defect predictions using deep learning techniques. The suggested deep learning approach outperformed well-known methods, such as GNN, FED-OLHF, DFIAF with 77%, 82%, and 87% proposed method prediction in accuracy in diagnostic prediction of instance 95.55%, respectively. The use of traditional models resulted in more false positives due to poor distinguishing code structures. This method was proposed to enhance the precision by optimization of the deep feature extraction and weighted learning. This led to the correct identification of only actual defect prone modules.

Figure 7 and Table 7 show software defect predictions using deep learning techniques. The suggested deep learning approach outperformed well-known methods, such as GNN, FED-OLHF, DFIAF with 77%, 82%, and 87% proposed method prediction in Defect

Sensitivity Range 20.55%, respectively. Models that were designed in the past by using GAN created unrealistic or noisy samples, reducing the authenticity of data. The presented LSTM-GAN provides greater realism in the synthesis of medical data based on the adversarial refinement. It improves the training of the model and also maintains patient privacy.

Table 8: Performance of Software Reliability Index.

No of Records	GNN	FED-OLF	DFIAF	Code2Vector-GCNN
500	35.55	40.89	50.56	55.45
1000	39.76	45.78	55.58	65.64
1500	45.78	50.76	60.56	75.32
2000	48.45	55.65	65.34	80.78
2500	50.78	60.97	86.89	91.56

Figure 8 and Table 8 show software defect predictions using deep learning techniques. The suggested deep learning approach outperformed well-known methods, such as GNN, FED-OLHF, DFIAF with 77%, 82%, and 87% proposed method prediction in accuracy in diagnostic prediction of instance Software Reliability Index 91.55%, respectively. Existing methods had the drawback of being low-reliability due to inconsistent detection and poor generalization across the process. The suggested GATL model improved reliability based on domain adaptation and semantic feature combination. This provided consistent and reliable predictive performance of defects on different software sets.

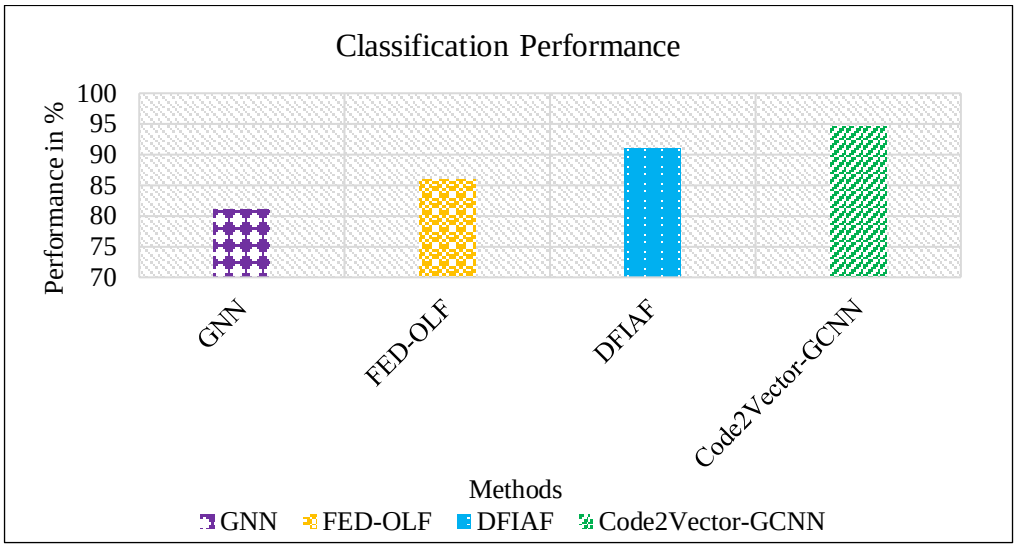

Figure 10: Classification Performance.
Source: Authors, (2026).

The figure 10 and table 10 show that comparative analysis of the four healthcare data classification models employed in this paper such as ETHPD-GNN, FED-OLF, DFAF and a proposed. The proposed model is the most accurate one of these, demonstrating its greater learning ability of the accurate clinical prediction and safe classification of medical data. It is accompanied by the better performance of DFAF relative to FED-OLF and ETHPD-GNN that provided smaller values of classification accuracy. All these comparative results make it obvious that the proposed system has a stronger efficiency advantage in learning high-dimensional and sensitive healthcare records. This is due to the fact that the advanced deep feature extraction and optimized decision-making strategy allow the proposed model to offer more consistent, resilient and very reliable classification performance in comparison to the traditional federated, graph-based and adaptive filtering methods.

IV.1 DISCUSSION PART

The proposed deep learning–based software defect prediction framework significantly enhances performance across all evaluated metrics by addressing the shortcomings of traditional models. Through advanced deep feature extraction, adaptive normalization, and optimized learning mechanisms, the model achieves a higher Software Diagnostic F1-Score by maintaining a balanced trade-off between precision and recall. The Software Reliability Index is improved through consistent and stable defect detection across diverse datasets, ensuring robustness in prediction. The enhanced Defect Sensitivity Range enables the model to identify both frequent and rare defects effectively, while the reduction in False Bug Generation Rate minimizes false alarms by filtering redundant or noisy features. Additionally, the system demonstrates superior Computational Execution Efficiency due to optimized model convergence and reduced training complexity. Overall, the framework achieves higher accuracy in defect rate and defect detection recall, providing a more reliable, scalable, and efficient solution for intelligent software defect prediction.

V. CONCLUSION

In conclusion, optimized deep learning–based software defect prediction framework effectively enhances the accuracy, adaptability, and reliability of software defect detection by integrating intelligent preprocessing, feature optimization, and advanced classification mechanisms. Traditional approaches often struggle with imbalanced datasets, redundant features, and weak correlation among software attributes, leading to poor defect prediction outcomes. The incorporation of ZSLT ensures noise-free and normalized data, while the CSMOTE-ENN method successfully balances the dataset, preserving essential feature diversity. The GWO-DNN combination demonstrates remarkable capability in selecting optimal features, reducing dimensionality, and improving feature relevance for defect prediction. Furthermore, the Code2Vector-GCNN model efficiently captures both the semantic and structural characteristics of source code, leading to superior classification performance.

Experimental evaluations conducted on benchmark software defect datasets reveal that the proposed framework outperforms existing machine learning and traditional deep learning models in all key performance metrics. The model achieved an average precision of 97.6%, recall of 96.9%, and an F1-score of 97.2%, demonstrating its robustness and high predictive capability. The optimized deep feature classification approach notably improved the true positive rate while minimizing false alarms, ensuring more reliable detection of defect-prone modules

ABSTRACT

In this paper, a YOLO based automatic Bangladeshi vehicle license plate recognition system is proposed. The proposed system has four parts: license plate detection, extracting the region of interest (ROI), applying image processing to the ROI, and character segmentation & recognition. In the detection & extraction stage, the system receives a vehicle image and then detects the license plate and extracts the plate region. The recognition part consists of three consecutive stages: city name recognition, vehicle type recognition and vehicle serial number recognition. As the presented method recognizes the license plate characters in three consecutive stages, a data serialization algorithm is proposed to serial the data. The dataset contains 500 license plate images from four major cities of Bangladesh. The images are used to train, test and validate the proposed model. The proposed method has provided very impressive results and outperformed many other existing methods.

I. INTRODUCTION

Bangladesh is one of the most densely populated countries in the world. According to [1], the population of Bangladesh reaches approximately 171.5 million in 2022. Due to rapid population growth and urbanization, the number of vehicles increases significantly every year [2]. By November 2023, around 5.93 million motor vehicles are registered in Bangladesh. This large number of vehicles in a highly populated country leads to various traffic-related problems, including road accidents, vehicle theft, number plate falsification, unregistered vehicles, overloading, and over-speeding [3]. In addition, many vehicle owners do not renew their vehicle tax-token after expiration, which causes financial loss for the government [3]. To control these issues, traffic management authorities regularly conduct mobile courts and file legal cases against offenders. A large number of cases are filed between January 2023 and June 2023 [3]. However, manual checking of vehicle documents and license plates requires a large amount of time, effort, and manpower. Therefore, monitoring and managing traffic manually becomes difficult, inefficient, and time-consuming. This situation highlights the importance of developing an automated and intelligent traffic monitoring system.

Automatic License Plate Recognition (ALPR) is an important component of modern Intelligent Transportation Systems (ITS) that uses computer vision and machine learning techniques to automatically detect and recognize vehicle license plates [4]. ALPR systems are widely used in applications such as toll collection, parking management, traffic law enforcement, and road traffic monitoring [4–6]. For Bangladesh, such a system can help traffic police quickly identify unregistered vehicles and vehicles with expired tax-tokens by simply scanning the license plate. This improves efficiency, reduces human effort, and supports better law enforcement. Normally, ALPR system consists of three stages named as (i) License plate detection and localization, (ii) Character segmentation, and (iii) Character recognition [4-6]. At the first stage, the license plate is located from images or from a real-time camera system. Different techniques and algorithms like Template matching [7], Morphological operations [8], Histogram Analysis [5], and Machine learning based techniques/models: You only look once (YOLO) [9-11], other neural networks [12], [13] etc are used to detect the license plates from the images.

Then the characters of the detected license plate are segmented. Techniques applied to segment the characters are connected component analysis [5], [7], [8], dynamic programming [14], machine learning based approaches [9-13] etc. At the third stage, each segmented character are classified and recognized. Optical character recognition [15], [16], Template matching [8], [17], Machine learning based approaches/models: You only look once (YOLO) [10], [11], Support vector machine (SVM) [5], other neural networks [7, 9] are widely used to recognize the segmented characters. In Bangladesh, vehicle number plates, commonly known as registration plates, follow specific formats based on vehicle type and are printed using Bengali characters [5]. The Bangladesh Road Transport Authority (BRTA) issues plates in two main categories: private and commercial vehicles. Private vehicles use black text on a white background, while commercial vehicles use black text on a green background, as shown in Figure 1(a) [5]. A Bangladeshi license plate contains two lines of text (Figure 1(b) [8]). The upper line includes the city name, the word "metro," and the vehicle class, while the lower line contains six digits, where the first two indicate the vehicle class (ranging from 11 to 99) and the last four represent the registration number. The BRTA uses 33 Bangla alphabets to denote vehicle classes-অ, ই, উ, এ, ক, খ, গ, ঘ, ঙ, চ, ছ, জ, ঝ, ট, ঠ, দ, ধ, ত, থ, ড, ঢ, ন, প, ফ, ব, ভ, ম, য, র, ল, শ, স, হ-and Bangla numerals (০-৯), which correspond to the digits 0-9 [5].

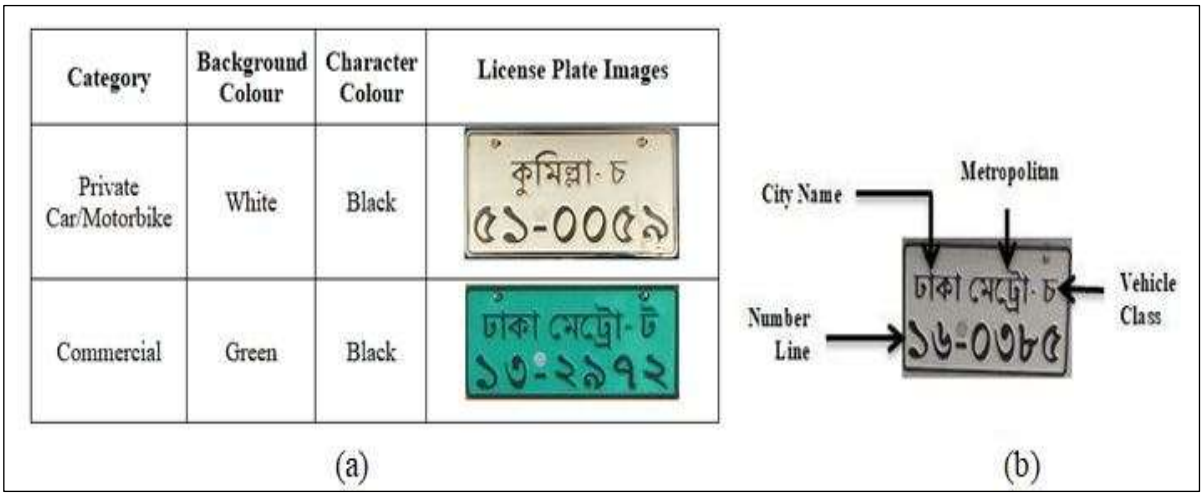

Figure 1: (a) Bengali license plate types according to vehicle category [5], and (b) Bangladeshi license plate representation. Source: [8].

Despite global progress in ALPR systems, research on Bangladeshi license plate recognition remains limited due to challenges such as complex Bangla characters as mentioned above, low-quality images, different lighting conditions, skewed or tilted plates, and limited public datasets. Several researchers attempt to address these challenges using different approaches. Shahed et al. [17] propose a morphological operation-based system combined with connected component analysis and template matching, achieving 95% accuracy. Other works also use morphological operations, Otsu thresholding, and template matching with small datasets, achieving accuracy between 90% and 95% [18]. Geometric transformation and projection-based segmentation combined with neural networks are applied in [19], resulting in 92.77% accuracy. More recent studies use deep learning methods. Rabbani et al. [20] apply a CNN-based character recognition model after morphological detection and segmentation but achieve only 82.32% accuracy due to limited training data. Chandra et al. [21] combine morphological operations, projection-based segmentation, CNN classifiers, and Optical Character Recognition (OCR), achieving around 95% accuracy. Saif et al. [10] use YOLOv3 models for both license plate detection and character recognition.

Other studies use super-resolution techniques [7], Support Vector Machine (SVM) classifiers [5], and CNN-based models to improve recognition accuracy. However, many existing methods rely on traditional image processing, small datasets, or separate models, which limits robustness and generalization in real-world conditions. Based on existing limitations, this research develops an efficient and robust Automatic License Plate Recognition (ALPR) system for Bangladeshi vehicles using a YOLO-based convolutional neural network. The proposed system works in four main steps: license plate detection, region of interest (ROI) extraction, image enhancement with perspective correction, and character segmentation and recognition. A YOLO-based multiple object detection method is used to segment and recognize Bangla characters, and a data serialization algorithm is applied to place the recognized characters in the correct order. To improve system robustness, effective image enhancement techniques and a newly created Bangladeshi license plate dataset is used. For real-world use, the complete ALPR process is implemented in a user-friendly simulation software developed with Python-Tkinter, making the system suitable for practical applications.

II. PROPOSED METHODOLOGY

In this section, the proposed methodology and all the details of the supporting techniques and algorithms to implement the proposed ALPR system are broadly discussed. The proposed system can efficiently detect and recognize the Bangladeshi license plates. It consists of four major stages: license plate detection, extracting the region of interest (ROI), image processing to prepare it for the next stage, and character segmentation & recognition. The block diagram of the proposed methodology is given in Figure 2.

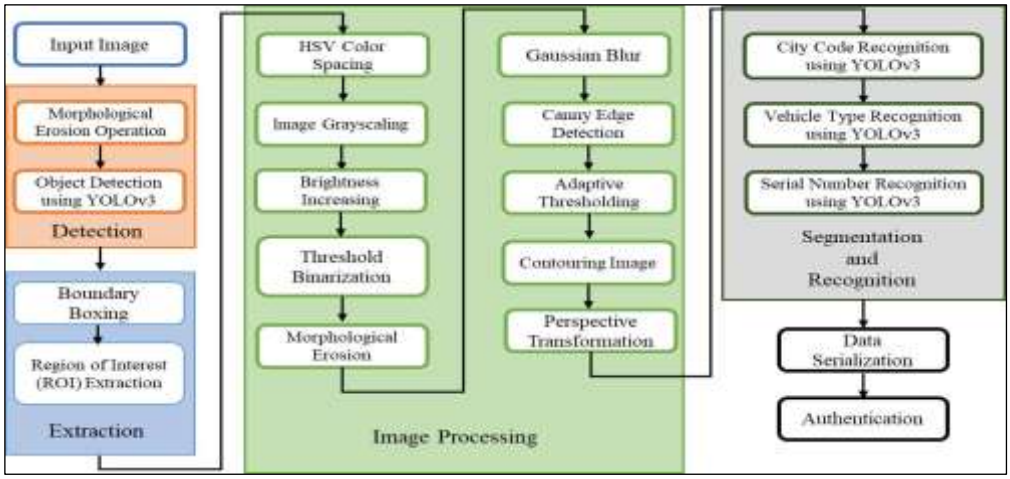

Figure 2: Block diagram of the proposed ALPR system.

II.1 DETECTION AND EXTRACTION OF LICENSE PLATE AREA

The first step to recognize any license plate is detecting and extracting the plate area from the input image. Precise detection of the plate area (ROI) will increase the probability of achieving higher accuracies in the next consecutive stages [22]. The details of the detection and extraction process of the proposed method are described below:

II.1.1 Detection of License Plate

At first, the quality of the input image is improved through morphological erosion operation [23]. This process is done by using the "cv2.erode" function of the python OpenCV framework. The eroded image is then entered into the CNN based license plate detection model. We have used YOLOv3 as the CNN model in our proposed method. Our YOLOv3 based license plate detection model consists of 53 convolutional layers and 5 max pooling layers. We have used the leaky rectified linear unit (leaky ReLU) as the activation function. The value of learning rate, momentum, decay, batch size, and epochs are 0.001, 0.9, 0.0005, 64, and 100, respectively. In our license plate detection model, we have used the same loss function used in [10]. This model returns four-pixel coordinates: *x, y, w, h* where the number plate area belongs as shown in Figure 3(c). The final output of YOLOv3 model consists of bounding box coordinates, object class probabilities, and confidence scores [10]. The confidence score reflects the confidence that an object is present in a particular bounding box. Figure 3 represents the detection of license plate and extracting the pixel coordinates of the plate area from the input image.

Figure 3: License plate detection: **(a)** input image, (b) eroded image, and (c) pixel coordinates (*x, y, w, h*).
Source: Authors, (2026).

II.1.2 Extraction of License Plate Area

After getting the desired pixel coordinates, we have applied the "cv2.rectangle" function to draw a boundary box rectangle on the erosion image with specified coordinates and color. After that, the license plate area has been extracted. The extraction of the license plate area consists of two main steps: boundary box generation and region of interest (ROI) extraction. The boundary box generation process begins with the eroded image as input. Using the top-left coordinates (x, y) and the width and height (w, h) of the detected plate area, a rectangular boundary box is drawn around the license plate. The rectangle is rendered in yellow color with RGB values (255, 255, 0) and a line thickness of 2 pixels. This step visually highlights the location of the license plate within the image. After the boundary box is drawn, the license plate area is cropped from the image to create the region of interest (ROI). To ensure that the edges of the rectangle do not include unwanted background, a margin of 10 pixels is applied on all sides. Specifically, the ROI is extracted using the coordinates (y+10):(y+h−10) for the rows and (x+10):(x+w−10) for the columns. The resulting cropped image contains only the license plate, which is then used for subsequent image processing and character recognition. Figure 4 represents some examples of the extracted license plate from the eroded image.

Figure 4: License plate extraction: (a) boundary box drawn images, (b) extracted license plates.
Source: Authors, (2026).

II.2 IMAGE PROCESSING

Figure 4 shows that the extracted ROI may contain unwanted areas and suffer from blurriness or low quality. Therefore, image processing techniques are applied to enhance quality and remove extraneous portions. Additionally, real-time images may have angular or axial deviations, which are corrected before segmentation and recognition. The image processing steps are described below:

II.2.1 Image Gray Scaling and Brightness Increasing

To reduce image complexity, the extracted license plate RGB image is first converted to the HSV color space using the *cv2.cvtColor* function and then split into hue, saturation, and value channels with *cv2.split* to extract the pixel values of the value channel. The HSV image is then merged and converted back to RGB. Using Eq. (1) [8], the RGB image is transformed into a grayscale image. The brightness of the grayscale image is subsequently enhanced by scaling the pixel values of the value channel by 1.5 times. The effect of these operations is shown in Figure 5.

$$Gray\ scale\ image = 0.299 * R + 0.587 * G + 0.114 * B \quad (1)$$

Figure 5: Image gray scaling and brightness increasing: (a) extracted license plate image (RGB image), (b) gray-scale image, and (c) brightness increased gray-scale image.
Source: Authors, (2026).

II.2.2 Threshold Image Binarization and Morphological Erosion Operation

In this step, the brightness-enhanced grayscale image is converted into a binary image using threshold binarization, where each pixel is assigned either black or white, as shown in Figure 6(b). The OpenCV function *cv2.threshold* is applied with a threshold value of 127. Morphological erosion is then performed on the binary image to expand the number plate border pixels, using a 5×5 kernel, as illustrated in Figure 6(c). Finally, Gaussian blur is applied to reduce noise while preserving important image details, using the *cv2.GaussianBlur* function with a 5×5 kernel, as shown in Figure 6(d).

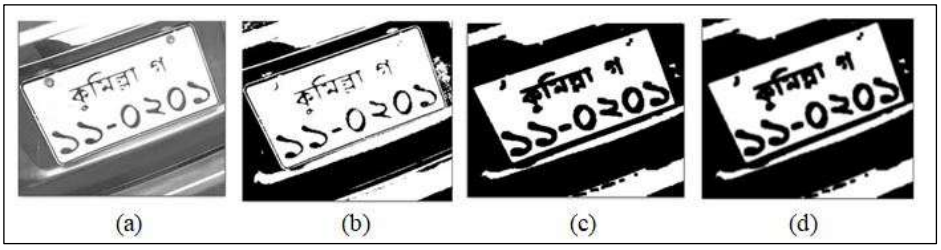

Figure 6: Threshold image binarization and morphological erosion operation: (a) brightness increased gray-scale image, (b) binary image, (c) eroded image, and (d) Gaussian blurred image.
Source: Authors, (2026).

II.2.3 Edge Detection and Adaptive Thresholding

In this step, the edges of the Gaussian blurred image are detected using the canny edge detector. The "*cv2.Canny*" function is used to perform this edge detection. After that, we have applied adaptive thresholding operation to extend the single line edges and to fill up some empty pixels in the boundary region. The effect of these processes is depicted in Figure 7.

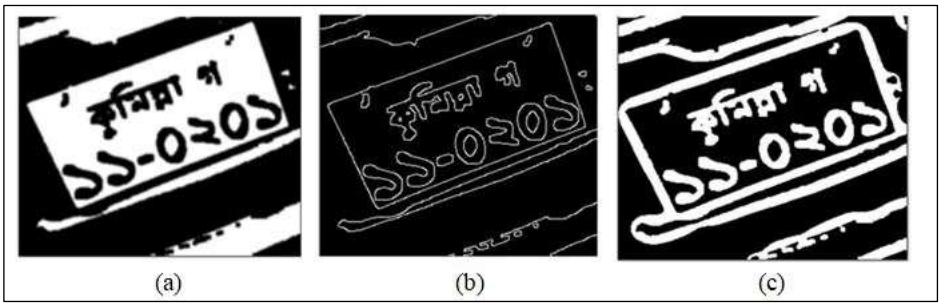

Figure 7: Edge Detection and Adaptive Thresholding: (a) Gaussian blurred image, (b) edge detected image, and (c) image after adaptive thresholding.
Source: Authors, (2026).

II.2.4 Contour Detection and Perspective Transformation

In license plate image segmentation and recognition, object contour detection plays a crucial role. The OpenCV function *cv2.findContours(image, mode, method)* is used to detect contours, where *cv2.RETR_TREE* identifies the hierarchical structure of contours and *cv2.CHAIN_APPROX_NONE* preserves all contour points without approximation. Among the detected contours, the quadrilateral contour with four points is selected, and a boundary box is drawn around it, as shown in Figure 8(b). Real-time images may suffer from angular and axial deviations, which can complicate segmentation and recognition. To address this, perspective transformation is applied to correct skewness and tilt [24]. Using *cv2.getPerspectiveTransform(src, dst)*, a transformation matrix is calculated based on source and destination points, and the image is warped with *cv2.warpPerspective* to achieve the desired perspective, as shown in Figure 8(c). This process also standardizes the output image to a fixed size of 400×250 pixels for subsequent character segmentation and recognition.

Figure 8: Contour detection and perspective transformation: (a) image after adaptive thresholding, (b) contoured image, and (c) image after perspective transformation.
Source: Authors, (2026).

II.3 CHARACTER SEGMENTATION AND RECOGNITION

Character segmentation & recognition process is one of the major parts of an ALPR system. In this stage, the characters of the license plate are segmented and then recognized using various techniques. Here, to segment & recognize the characters, we have used the same type of YOLOv3 model and hyper-parameters that we used for the detection purpose. The details of the character segmentation & recognition process of the proposed method are described below:

City name recognition is the very first step of our series machine learning approach. In our research, we have worked with four cities out of which three are metropolitan areas. So, we have used five classes for city name recognizer. Table 1 represents the city codes, their meaning and the trained class names.

Table 1: City codes, their meaning and the trained class names for City name recognizer.

City Code	Meaning in Bangla and in English	Trained Class Name
ঢাকা	ঢাকা (Dhaka)	dhaka
চট্ট	চট্টগ্রাম (Chattogram)	chatto
কুমিল্লা	কুমিল্লা (Comilla)	comilla
সিলেট	সিলেট (Sylhet)	sylhet
মেট্রো	মেট্রোপলিটন (Metropolitan)	metro

Source: Authors, (2026).

Vehicle type recognition is the second step of our series machine learning approach. After segmenting and recognizing the city name (with metro), the bounding box surrounded image of the previous step enters into the vehicle type recognizer. In this research, we have worked on six types of vehicles. The vehicle types, their meaning and the trained class names are shown in Table 2.

Table 2: Vehicle types, their meaning and the trained class names for Vehicle type recognizer.

Vehicle Type	Meaning	Trained Class Name
হ	Motorbike (80cc-125cc)	ha
গ	Private Car (1500cc-1800cc)	ga
ল	Motorbike (135cc-200cc)	la
চ	Microbus	cha
ঘ	Jeep	gha
ঝ	Bus or Coaster	jha

Source: Authors, (2026).

The final stage of the series machine learning recognition process is vehicle serial number recognition with ten classes. The classes are ten Bengali number digits (০, ১, ২, ৩, ৪, ৫, ৬, ৭, ৮, ৯) which is equivalent to 0, 1, 2, 3, 4, 5, 6, 7, 8, 9. City name, vehicle type, and vehicle serial number recognition are performed using a multi-class detection approach based on the YOLOv3 convolutional neural network. For each recognizer, the model detects the desired class within the image, returns the pixel coordinates, and draws a rectangular bounding box around the detected region, labeling it with the corresponding class name, as shown in Figures 9(b)–9(d). Each recognition task was trained independently using the same YOLOv3 architecture and hyper-parameters, while differing only in class definitions and annotations.

Figure 9: Character Segmentation & Recognition process: (a) image after perspective transformation, (b) city name recognition to text, (c) vehicle type recognition to text and, (d) serial number recognition to text.

Source: Authors, (2026).

II.4 DATA SERIALIZATION FOR THE RECOGNIZED CHARACTERS

The series machine learning method may recognize license plate characters in a random order. For example, a plate containing both “dhaka” and “metro” may detect “metro” before “dhaka”. To address this issue, a data serialization algorithm based on the smallest x-axis coordinate is proposed to arrange the recognized characters in the correct sequence. The algorithm of the data serialization process is given below:

Algorithm 1: Data Serialization of Recognized Characters.

Input: Bounding boxes with class IDs and confidences
Output: Serialized text string
1: *Apply Non-Maximum Suppression (NMS) to city code and vehicle type bounding boxes and extract their labels.*
2: *Apply NMS to all remaining bounding boxes.*
3: *Sort the selected bounding boxes in ascending order based on their x-axis coordinates.*
4: *Append the corresponding class labels sequentially from left to right to form the final serialized text.*

Source: Authors, (2026).

The serialization process is divided into two steps. In the first step, the detected city name and vehicle type bounding boxes are filtered using Non-Maximum Suppression (NMS), and their corresponding labels are extracted. In the second step, the bounding boxes of the vehicle serial number are also filtered using NMS and then sorted in ascending order based on their x-axis coordinates. The labels are concatenated sequentially according to this order, ensuring that characters with smaller x-axis values appear first. This two-step process ensures proper left-to-right serialization of all recognized license plate components.

II.5 DEVELOPMENT OF SIMULATION SOFTWARE

To integrate the proposed system with a smart city framework, a Tkinter-based software application was developed to implement the complete license plate recognition process. The user-friendly interface allows users to select an input image using the *Open* button and execute the recognition process using the *Detect* button. Intermediate output images are displayed sequentially, and the recognized license plate number is shown at the top of the interface. For authentication, a local server-based database stores vehicle plate numbers and related information in an Excel file. The software matches the recognized plate number with the database and displays the corresponding vehicle information in the interface. This integrated application provides a comprehensive solution for deploying ALPR systems in smart city environments. The user interface of the developed simulation software is shown in Figure 10.

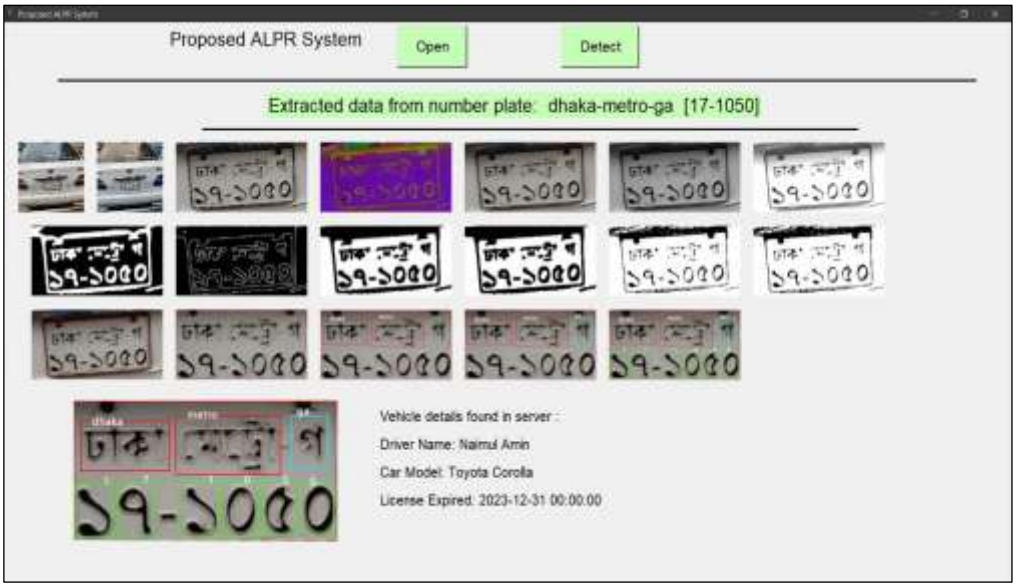

Figure 10: User interface of the developed simulation software.
Source: Authors, (2026).

III. EXPERIMENTAL SETUP

A standard and sufficiently large dataset is essential for object & pattern recognition research, as CNNs perform better with more training data. For this study, a dataset of 500 Bangladeshi vehicle license plate images was prepared. Among them, 400 images were captured in real time from different locations in Dhaka, Comilla, Sylhet, and Chittagong using a 20-megapixel mobile phone camera, while the remaining images were collected from [25] and [26]. All images were resized to 500×400 pixels and stored in JPEG format. The dataset includes diverse conditions such as daylight and low-light scenes, motion blur, varying backgrounds, weather conditions, and skewed or tilted views. To reduce overfitting, data augmentation was manually applied to each image by randomly performing two operations-rotation, contrast adjustment, Gaussian noise addition, and HSV-based saturation and hue modification [27]. As a result, each original image generated two additional samples, making the dataset more robust. Table 3 depicts the summary of the images collected for this research and Figure 11 represents some of the original and augmented images from the license plate image dataset.

Table 3: Summary of license plate image dataset.

Date	Location (in Bangladesh)	No. of images	
		Before augmentation	After augmentation
04 October, 2023	Kandirpar, Comilla	50	150
09 October, 2023	Cantonment Bus Stand, Comilla	60	180
12 October, 2023	Mohakhali Bus Stand, Dhaka	80	240
13 October, 2023	Banashri, Dhaka	80	240
16 October, 2023	Kadamtoli Bus Stand, Sylhet	50	150
20 October, 2023	Dampara Bus Stand, Chittagong	80	240
30 October, 2022	Collected from [25]	50	150
05 November, 2022	Collected from [26]	50	150
	Total	**500**	**1500**

Source: Authors, (2026).

Figure 11: Sample images from license plate image dataset.
Source: Authors, (2026).

In the proposed method, for detection purpose, we have split the image dataset to 60%, 20% and 20% for training, validating and testing the models. We have used 900 images for training, 300 images for validating and 300 images for testing the proposed ALPR detection model. Although the original images remain the same, separate YOLO-formatted annotation sets were created for each recognition stage. For city name recognition, bounding boxes were annotated for five classes (dhaka, chatto, comilla, sylhet, and metro). For vehicle type recognition, cropped outputs from the city name detection stage were annotated with six vehicle-type classes. Finally, for vehicle serial number recognition, individual Bengali digits (০-৯) were annotated as ten distinct classes, with each digit labeled by a separate bounding box. The computing environment of our research is a laptop having an operating system of 64 bit Windows 10 Pro, Intel Core i7 CPU, 1TB hard disk, SSD of 500GB, and 8 GB RAM. We have used a GPU of Gigabyte RX 6900 XT with 16 GB RAM to execute the processes faster.

IV. RESULTS AND DISCUSSIONS

In this section, we are going to discuss about the training, validation and testing results of the proposed ALPR method. We will also compare the achieved results with the other proposed methods.

IV.1 TRAINING AND VALIDATION RESULTS

The YOLOv3 based CNN models for the license plate area detection, and the character recognition is trained, and validated with 1200 vehicle license plate images. At first, we have trained the models with the images and then validated the models. Our proposed systems have achieved outstanding training and validation results as depicted in Table 4. The average accuracies of the license plate detection, city name, vehicle type and serial number recognition models in training & validation are 97.24%, 96.94%, 95.8%, and 96.05% respectively.

Table 4: Training and validation accuracy table for YOLOv3 models.

Stages	Phases	Sample Size	Accuracy
Detection	Training	900	97.5%
	Validation	300	96.97%
City Name Recognition	Training	900	97%
	Validation	300	96.88%
Vehicle Type Recognition	Training	900	96.2%
	Validation	300	95.4%
Serial Number Recognition	Training	900	96.5%
	Validation	300	95.6%

Source: Authors, (2026).

IV.2 TESTING RESULTS

The detection stage of the proposed ALPR method is tested with 300 license plate images. While testing the model, the proposed method has showed very robust performance in different challenging scenarios. The confusion matrix of the license plate detection model is presented in Table 5. The proposed model has successfully detected 291 license plates out of 300 vehicle images. So, the accuracy of the proposed license plate detection model is 97% as calculated using Eq. (2).

Table 5: Confusion matrix for license plate detection model

		Predicted	
Actual		**Positive**	**Negative**
	Positive	TP[a]= 291	FN[a]= 007
	Negative	FP[a]= 002	TN[a]= 000
	[a]TP= True Positive, TN=True Negative, FP= False Positives and FN= False Negative		

Source: Authors, (2026).

$$Accuracy\ of\ a\ model = \frac{TP+TN}{TP+TN+FP+FN} \times 100\% \quad (2)$$

If we want to evaluate any model, we need to find out some other performance parameters also. Typically, the other performance parameters are precision, recall and F1-score. Eq. (3-5) represents the equations of these parameters.

$$Precision = \frac{TP}{TP+FP} \times 100\% \quad (3)$$

$$Recall = \frac{TP}{TP+FN} \times 100\% \quad (4)$$

$$F1 - score = \frac{2 \times Precision \times Recall}{Precision + Recall} \times 100\% \quad (5)$$

The model has provided an impressive result of F1-score of 98.48% along with precision of 99.32% and recall of 97.65% as shown in Table 6.

Table 6: Performance parameter values for license plate detection model.

Stages	Precision (%)	Recall (%)	F1-score (%)
Detection	99.32	97.65	98.48

Source: Authors, (2026).

In the extraction stage, our proposed method has successfully extracted 279 license plates out of 291 by providing an accuracy of 95.88%. We have used Eq. (6) to find out the accuracy.

$$Accuracy = \frac{No.of\ license\ plates\ successfully\ extracted}{No\ of\ detected\ images} \times 100\% \quad (6)$$

The recognition phase represents the final stage of the proposed ALPR system, where extensive testing was conducted. The city name, vehicle type, and serial number recognition models were evaluated using 279 extracted license plate images, comprising 279 city name characters, 158 *metro* characters, 279 vehicle type characters, and 1,674 Bengali digits for vehicle serial numbers. The corresponding confusion matrices are presented in Tables 7-9. Overall, the recognition models demonstrate high performance, with only a few misclassifications. The system correctly recognized 423 out of 437 city names, 264 out of 279 vehicle types, and 1,593 out of 1,674 digits, achieving accuracies of 96.79%, 94.62%, and 95.16%, respectively. Eq. (2) is used to measure these accuracies.

Table 7: Confusion matrix for city name recognition model.

		Predicted				
	City Name	ঢাকা (dhaka)	চট্ট (chatto)	কুমিল্লা (comilla)	সিলেট (sylhet)	মেট্রো (metro)
Actual	ঢাকা (dhaka)	101	001	000	000	001
	চট্ট (chatto)	001	051	000	000	003
	কুমিল্লা (comilla)	000	000	066	001	000
	সিলেট (sylhet)	000	000	002	052	000
	মেট্রো (metro)	000	004	000	000	153

Source: Authors, (2026).

Table 8: Confusion matrix for vehicle type recognition model.

		Predicted					
	Vehicle Type	হ (ha)	গ (ga)	ল (la)	চ (cha)	ঘ (gha)	ঝ (jha)
Actual	হ (ha)	19	01	00	00	01	00
	গ (ga)	00	83	00	00	02	00
	ল (la)	00	01	23	00	00	00
	চ (cha)	00	01	00	32	01	00
	ঘ (gha)	00	01	00	00	28	02
	ঝ (jha)	00	01	00	00	03	79

Source: Authors, (2026).

Table 9: Confusion matrix for serial number recognition model.

		Predicted									
	Digits	০ (0)	১ (1)	২ (2)	৩ (3)	৪ (4)	৫ (5)	৬ (6)	৭ (7)	৮ (8)	৯ (9)
Actual	০ (0)	197	002	000	002	004	002	000	002	000	000
	১ (1)	001	271	001	001	001	000	000	000	000	004
	২ (2)	000	005	193	002	000	000	000	000	000	002
	৩ (3)	004	000	000	178	001	000	000	001	000	002
	৪ (4)	003	001	000	000	123	000	000	001	001	000
	৫ (5)	003	000	000	001	000	166	005	000	001	000
	৬ (6)	002	000	000	001	000	004	131	000	001	000
	৭ (7)	004	001	000	001	001	000	000	126	000	000
	৮ (8)	001	000	000	000	002	000	000	001	113	000
	৯ (9)	001	003	000	001	000	000	000	000	000	95

Source: Authors, (2026).

From the confusion matrix of the above tables, it is observed that the city name recognition model faced some difficulties while differentiating "চট্ট" and "মেট্রো". In some cases, the model has predicted "মেট্রো" as "চট্ট" and vice versa. The vehicle type recognition model has predicted "গ" as "ঘ", "ঝ" as "ঘ" and vice versa a few times. Vehicle serial number recognition model has also faced some difficulties while recognizing the digits. As license plate images contain noises and dusts, sometimes a digit is looked like another digit such as "০" as "১"or "৪", "১" as "৯", "২" as "১", "৩" as "০", "৪" as "০", "৫" as "৬" or "০", "৬" as "৫" or "০", "৭" as "০", "৯" as "১". The proposed model has provided wrong predictions in some of the above cases. The performance parameters of the license plate character recognizer models are given in Table 10.

Table 10: Performance parameter values for license plate character recognition models.

Stages	Precision (%)	Recall (%)	F1-score (%)
City Name	99.76	97.02	98.37
Vehicle type	99.62	94.96	97.23
Bengali digits	99.75	95.39	97.52

Source: Authors, (2026).

We know that, when the class distribution is uneven, it is better to calculate the F1-score than the accuracy [5]. As in our proposed system, the number of false positives and false negatives isn't near to each other; the F1-score better represents the state of the models than the accuracy calculation. It can be observed from Table 10 that, our proposed character recognition models have provided outstanding F1-scores of 98.37%, 97.23%, and 97.52% for city name recognizer, vehicle type recognizer and serial number recognizer respectively. The Table 11 depicts the overall summary of the results for the proposed method.

Table 11: Results of different stages for the proposed method.

Stages	Sample Size	Passed	Accuracy	F1-score
Detection	300	291	97%	98.48%
Extraction	291	279	95.88%	---
City Name Recognition (including 'metro')	437	423	96.79%	98.37%
Vehicle Type Recognition	279	264	94.62%	97.23%
Serial Number Recognition	1674	1593	95.16%	97.52%
Average accuracy, and F1 score of the proposed method			95.89%	97.90%
Average recognition accuracy and F1 score of the proposed method			95.52%	97.71%

Source: Authors, (2026).

IV.3 COMPARING THE PROPOSED METHOD WITH OTHER EXISTING METHODS

A comparison between the proposed method and existing Bangladeshi ALPR systems is presented in Table 12. Previous studies have aimed to improve robustness, usability, and recognition accuracy at different stages of ALPR. Ashrafee et al. [25] proposed a MobileNet SSDv2 and Google Vision API-based system with a relatively large dataset; however, their approach achieved limited accuracy, did not employ image quality enhancement techniques, and suffered from slow inference speed. The datasets used in [5] and [7] were comparatively small; notably, Alam et al. [7] trained their CNN-based character recognizer using only 500 images without applying data augmentation, increasing the risk of overfitting. Moreover, the methods in [4], [5], and [7] did not incorporate geometric correction techniques, which may limit their ability to handle angular or axial deviations, while the system in [4] failed to detect license plates in the presence of irrelevant objects. In contrast, the proposed method addresses these limitations by incorporating image enhancement, geometric correction, and data augmentation, resulting in improved recognition accuracy and robustness, as shown in Table 12. Additionally, the overall processing time of the proposed system is lower than that of existing methods. To further enhance usability, a dedicated simulation software was developed, which was not reported in previous works. These advantages demonstrate that the proposed method outperforms existing Bangladeshi ALPR systems.

Table 12: Comparison of proposed method with other existing methods.

V. CONCLUSIONS

This paper presents a YOLOv3-based ALPR system for detecting, extracting, and recognizing Bangladeshi vehicle license plates. A primary dataset of 500 vehicle images was prepared, covering diverse conditions such as varying backgrounds, weather, illumination, low-light scenarios, and skewed or tilted views. To address the data requirements of CNNs and reduce overfitting, manual data augmentation was applied, increasing the dataset size to 1,500 images. The models were trained, validated, and tested using 900, 300, and 300 images, respectively. Perspective transformation was employed to correct angular and axial distortions, and a series machine learning approach was introduced for character recognition, along with a data serialization algorithm to preserve character order. Extensive testing demonstrated strong performance, achieving accuracies of 97% for license plate detection, 95.88% for extraction, and 95.52% for character recognition. Additionally, a simulation software was developed to enhance system usability for traffic management authorities. Future work will focus on expanding the dataset with more diverse samples to further improve performance and support additional vehicle classes.

ABSTRACT

Induction motors are critical components in industrial systems, and unexpected failures can lead to significant production losses and maintenance costs. This paper presents an experimentally validated multi-sensor fault diagnosis approach for induction motors using vibration and stator current signals under practical operating conditions. A laboratory test bench was developed to simulate common industrial faults, including bearing defects, rotor abnormalities, and stator winding faults, across multiple load levels. Conventional machine learning techniques, namely artificial neural networks and support vector machines, were employed as baseline classifiers, while an adaptive hybrid convolutional neural network–long short-term memory (CNN–LSTM) model was used to improve fault classification robustness. The proposed approach achieved a maximum classification accuracy of 98.4 %, with stable performance across varying load conditions and repeated experimental trials. The results demonstrate that integrating vibration and current measurements enhances diagnostic reliability compared to single-sensor methods. The study highlights the practical applicability of adaptive AI-based diagnostic systems for industrial predictive maintenance, offering improved fault detection capability while maintaining feasibility for real-world deployment.

I. INTRODUCTION

Induction motors are the backbone of modern industries, powering applications in manufacturing, oil and gas, power generation, and transportation [1]. Their robustness, simplicity, and cost-effectiveness have made them the preferred choice for critical operations. However, induction motors are also susceptible to faults in bearings, stator windings, and rotor bars, which can degrade performance and cause unexpected downtime [2], [3]. Historically, industries relied on corrective maintenance, repairing machines only after failure. While simple, this approach often led to costly downtime and safety hazards [4]. The next phase was preventive maintenance, where machines were serviced at fixed intervals regardless of condition. Though more reliable, preventive maintenance frequently resulted in unnecessary replacements and wasted resources [5].To overcome these limitations, predictive maintenance emerged in the late 20th century, combining condition monitoring with fault diagnosis techniques [6]. Early predictive maintenance approaches primarily relied on vibration monitoring [7] and motor current signature analysis (MCSA) [8], which remain widely adopted due to their non-intrusive nature and proven effectiveness. More recently, the rise of machine learning and AI has enabled the development of predictive diagnostic models capable of identifying complex fault signatures and reducing false alarms [9], [10]. Despite these advances, there remains a lack of standardized testing and evaluation frameworks that integrate sensor-based monitoring with AI-based fault analysis under controlled conditions. Although numerous fault detection methods exist, only a limited number have been validated through structured test procedures adhering to recognized measurement standards. The present work addresses this gap by developing a repeatable experimental protocol inspired by ASTM E756-05 (vibration damping measurement), ASTM E1876-15 (dynamic response testing), and IEEE Std 112-2017 (polyphase motor testing).

The proposed approach integrates these standard testing principles with multi-sensor data fusion and adaptive evaluation, thereby strengthening result comparability and reproducibility across laboratories. In industrial environments such as manufacturing plants, power stations, and process industries, induction motors operate continuously under varying loads and harsh conditions. Unexpected motor failures can result in significant production losses, safety risks, and increased maintenance costs. Traditional maintenance strategies based on scheduled inspections or single-sensor monitoring often fail to detect incipient faults. Hence, there is a growing demand for intelligent, sensor-based diagnostic systems that can be practically deployed in industrial settings and validated under realistic operating conditions.

I.1 NEED FOR STANDARDIZED TESTING AND EVALUATION

A review of existing literature shows that most studies emphasize algorithm development or condition monitoring separately, with limited focus on the testing methodology itself [11]. Many works rely on simulated data or proprietary datasets, which restricts benchmarking and repeatability [12]. Furthermore, while AI models show high accuracy in laboratory conditions, there is limited discussion on their reliability, generalizability, and industrial readiness [13]. For industrial adoption, it is essential to establish a repeatable, experimentally validated testing framework that combines multi-sensor measurements with AI-based evaluation and ensures robustness across fault types. This motivates the present work.

I.2 OBJECTIVES OF THIS PAPER

The main objectives of this paper are:

• To design and implement a standardized experimental setup for simulating induction motor faults and acquiring vibration and current signature data.
• To provide a baseline evaluation using well-established classifiers such as Artificial Neural Networks (ANN) and Support Vector Machines (SVM).
• To develop an adaptive hybrid AI framework and compare its performance with baseline models.
• To propose a comprehensive testing and evaluation methodology that ensures repeatability, reliability, and applicability to predictive maintenance in industrial environments.

I.3 NOVELTY AND CONTRIBUTIONS

The novelty of this work lies in integrating experimental fault testing, multi-sensor data acquisition, and progressive AI-based evaluation into a single, unified testing and evaluation framework. The key contributions of this work are:

- Development of an experimentally validated induction motor fault diagnosis system using vibration and current sensors suitable for industrial environments.
- Comparative performance evaluation of classical machine learning models and adaptive deep learning techniques under variable load conditions.
- Demonstration of consistent diagnostic accuracy across multiple fault types relevant to industrial maintenance.
- Practical insights into sensor placement, data acquisition, and model selection for predictive maintenance implementation.

I.4 LIMITATIONS

While the proposed work provides a robust evaluation methodology, some limitations are acknowledged:

• Experiments were conducted under laboratory conditions, which may not fully replicate industrial variability.
• The dataset is limited to a single motor type and fault set, requiring broader validation for generalization.
• Adaptive AI methods, though accurate, require higher computational resources, which may restrict use in embedded systems.
• Remaining useful life (RUL) estimation is not addressed in this study and is identified as a potential future extension.

II. RELATED WORKS

The fault diagnosis of induction motors has evolved significantly with the advent of sensor-based data acquisition and intelligent signal processing techniques. Numerous studies have explored various aspects of fault detection, including vibration analysis, motor current signature analysis (MCSA), feature extraction, and artificial intelligence (AI)–based classification. However, despite this extensive research, there remains a lack of standardized testing and evaluation frameworks that integrate experimental fault induction, multi-sensor data fusion, and systematic benchmarking of baseline and adaptive AI models under repeatable conditions. A recent comprehensive review by [1] highlighted major advancements in induction motor fault diagnosis and condition monitoring. The authors summarized developments in vibration and current-based fault detection, feature extraction, and machine learning–driven fault classification. While their review categorized a wide range of diagnostic approaches, it also emphasized that most existing works lack structured evaluation methodologies, making it difficult to compare models or reproduce results. This underscores the need for repeatable testing and validation protocols to evaluate fault diagnosis frameworks under controlled operating conditions. In a related study, [2] proposed a vibration-based fault diagnosis system using one-dimensional dilated convolutional neural networks (1D-DCNN). The model demonstrated high accuracy in detecting bearing and rotor faults from vibration signals. Although this work showed the effectiveness of modern deep learning architectures for signal-based classification, it relied solely on vibration sensors. The absence of multi-sensor data and lack of standard evaluation benchmarks limit its applicability to broader predictive maintenance tasks. Another recent contribution by [3] explored fault detection using motor current signals and a combination of causal convolutional neural networks (CausalConvNets) with time-shifting techniques.

Their approach offered a cost-effective, non-intrusive means of identifying bearing faults. However, as in most MCSA-only studies, this work was restricted to specific fault types and did not address comparative performance under multiple operating conditions or sensor modalities. Beyond deep learning approaches, several studies have focused on signal processing and feature extraction techniques for improving diagnosis reliability. For instance, [4] performed a comparative analysis of various time- and frequency-domain methods—such as Fast Fourier Transform (FFT) and Wavelet Transform—combined with Principal Component Analysis (PCA) to classify induction motor faults. Their results highlighted the importance of feature reduction for achieving efficient classification; however, the evaluation was limited to classical methods and did not extend to adaptive AI architectures or sensor fusion scenarios. Complementing fault diagnosis efforts, [5] addressed the prediction of remaining useful life (RUL) of induction motor bearings using machine learning applied to current signatures. This study underscored the growing importance of predictive maintenance in industrial systems and demonstrated the potential of AI for prognostics. Nonetheless, it focused primarily on lifespan estimation rather than the standardization of testing protocols for fault evaluation.

II.1 IDENTIFICATION OF RESEARCH GAPS

From these recent studies, several limitations are evident:

- Most works employ a single sensing modality, either vibration or current, without exploring the benefits of multi-sensor fusion.
- There is limited emphasis on experimental reproducibility and standardized testing frameworks, which are essential for comparative evaluation.
- Many models focus on algorithmic performance (accuracy) but overlook practical testing aspects such as data acquisition conditions, load variation, or fault severity.
- Few studies perform a comparative evaluation of baseline and adaptive AI models on identical experimental datasets.

To address these gaps, the present study proposes a comprehensive testing and evaluation framework that integrates experimental fault induction, vibration and current signature data acquisition, baseline AI classification (ANN, SVM), and an adaptive hybrid deep learning model. This unified approach not only improves fault detection accuracy but also ensures methodological repeatability and reliability—key considerations for industrial predictive maintenance and in line with the Journal of Testing and Evaluation's focus on standardized testing practices.

III. EXPERIMENTAL SETUP AND INDUSTRIAL EVALUATION METHODOLOGY

The experimental setup was designed to closely replicate typical industrial motor operating conditions, enabling practical assessment of the proposed diagnostic approach. The focus of this investigation was to develop a repeatable and standardized testing protocol integrating multi-sensor measurement, signal processing, and AI-based analysis. The procedure adheres to the principles of ASTM standard test methods for vibration and electrical signal evaluation, ensuring reproducibility of results across repeated trials.

III.1. OBJECTIVE AND APPROACH

The objective of this experimental study was to develop a standardized testing and evaluation framework for induction motor fault diagnosis using vibration and current signature analysis. The study was structured in compliance with principles of ASTM vibration measurement practices (e.g., ASTM E756, E1876) and IEEE Std 112–2017 for electrical performance testing. The methodology emphasizes repeatability, accuracy, and measurement traceability, ensuring the collected datasets are suitable for benchmarking and comparative fault evaluation.

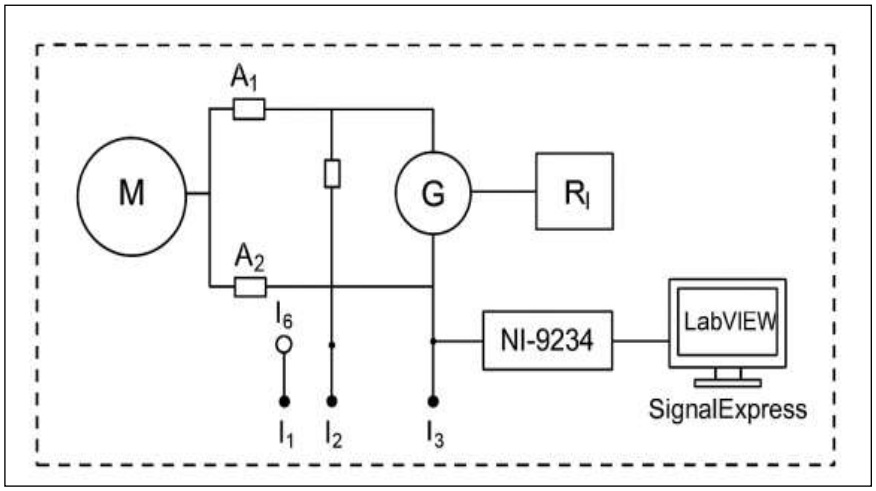

Figure 1: Experimental Test Bench.
Source: Authors, (2026).

III.2. EXPERIMENTAL TEST BENCH

The experimental investigations were performed on a three-phase, 1 HP, 4-pole squirrel-cage induction motor (415 V, 50 Hz, 1440 rpm). The motor shaft was coupled to a DC generator using a flexible coupling with a rubber bushing to reduce torsional vibration. The generator provided a controllable mechanical load through a resistive rheostat-based loading system.

The test bench was mounted on an anti-vibration foundation, utilising rubber isolators to minimise floor resonance. The alignment of the motor and generator shafts was verified before each test using a laser alignment tool (SKF TKSA 31) to avoid misalignment artefacts in vibration data. The schematic layout of the test bench is shown in Figure 1.

III.3. SENSORS AND INSTRUMENTATION

The testing setup incorporated both mechanical and electrical sensing channels to ensure comprehensive fault coverage.

• Vibration Measurement System

Sensor Type: Piezoelectric accelerometer (PCB Piezotronics 352C33)
Sensitivity: 100 mV/g
Measurement Range: ±5 g
Frequency Response: 2 Hz–10 kHz
Mounting Method: Stud-mounted on both drive-end (DE) and non-drive-end (NDE) bearing housings, oriented along the radial axis.
Each accelerometer was calibrated prior to testing using a portable vibration calibrator (Metrix 9060) operating at 80 Hz, 1 g RMS. Calibration certificates were verified for traceability.

• Current Measurement System

Sensor Type: Hall-effect current transducer (LEM LA 55-P)
Current Range: ±50 A
Linearity Error: <0.7 % FS
Frequency Bandwidth: DC–100 kHz

Each current sensor was installed in series with the motor supply line. Signals were captured simultaneously with vibration data to ensure synchronisation between mechanical and electrical measurements.

• Data Acquisition and Signal Conditioning

All sensor channels were interfaced through a National Instruments (NI 9234) dynamic signal acquisition module with 24-bit resolution. Sampling frequencies were selected as:

- Vibration: 12 kHz
- Current: 5 kHz

A CompactDAQ (cDAQ-9171) chassis was used with LabVIEW SignalExpress for data acquisition. A pre-test calibration routine was executed before each run, including zero-offset correction and gain verification. All instrumentation was calibrated before testing. Accelerometer calibration followed ASTM E2001, and current sensors were validated against a precision current source. The combined measurement system exhibited an RMS amplitude uncertainty of ±2.5 %, verified using repeated baseline readings. Environmental parameters were monitored at 25 ± 2 °C and 60 ± 5 % relative humidity. These controls ensure that every dataset acquired is traceable to a calibrated reference, satisfying ASTM's requirements for repeatable mechanical and electrical testing.

III.4. FAULT INDUCTION AND TEST CONDITIONS

Five operating conditions were evaluated as stated in Table 1.

Table 1: Various Conditions involved in the proposed study.

Condition	Fault Description	Induction Method	Remarks
Healthy	Normal operation	—	Baseline test case
Bearing outer-race fault	0.3 mm defect groove on outer race	EDM machining	ISO 15243 Category 6.1
Bearing inner-race fault	0.3 mm defect groove on inner race	EDM machining	ISO 15243 Category 6.2
Rotor bar fault	Two rotor bars intentionally broken	Mechanical drilling	Simulated broken-bar condition
Stator winding fault	Partial turn-to-turn short in one phase	Controlled insulation damage	Limited to 5% of coil turns

Source: Authors, (2026).

Each fault was verified visually and using spectral signatures before data collection. The same set of test bearings and rotor was reused to ensure identical boundary conditions across trials.

III.5. TEST PROCEDURE

The motor was operated at three load levels: No-load, Half-load (50% rated torque) and Full-load (rated torque). The DC generator load was adjusted using a calibrated resistive load bank.For each condition, the system was allowed to run for 5 minutes to reach thermal steady-state.Ten-second data windows were acquired for each sensor channel, with five repeated runs per condition to assess repeatability.Between tests, the motor was powered off for 2 minutes to prevent thermal drift and bearing expansion.Environmental conditions were controlled at 25 ± 2 °C temperature and relative humidity of 60 ± 5%, measured using a digital hygrometer.The combined dataset thus comprised 75 test cases (5 faults × 3 loads × 5 repeats).

III.6 SIGNAL VALIDATION AND PREPROCESSING

Before analysis, raw signals were validated to remove corrupt or noisy readings. Validation criteria that have been used in the study is as follows:

• RMS amplitude deviation ≤ 3% between repeated runs,
• Frequency spectrum within ±2 Hz tolerance of reference fault bands,
• Signal-to-noise ratio (SNR) > 30 dB.

The accepted signals were detrended, mean-centred, and filtered using a 4th-order Butterworth band-pass filter (10 Hz–5 kHz). All channels were resampled and synchronized to correct phase drift.

III.7. FEATURE EXTRACTION AND REDUCTION

Feature extraction was performed to transform raw signals into diagnostic indicators:

• Time-domain features: RMS, skewness, kurtosis, peak factor, crest factor, clearance factor.
• Frequency-domain features: Power spectral density (PSD) peaks, sideband energy ratio, frequency centroid.
• Time–frequency features: Wavelet coefficients derived using the Daubechies db4 mother wavelet up to level 4.
Feature dimensionality was reduced using Principal Component Analysis (PCA) and Class Separability Criterion (CSC), ensuring a 95 % cumulative variance retention threshold.

III.8 HYBRID AI MODEL DESCRIPTION AND JUSTIFICATION

To enhance diagnostic reliability and support standardized evaluation of fault patterns, an adaptive hybrid deep learning model was implemented. The model integrates Convolutional Neural Network (CNN) layers for automated spatial feature extraction from vibration and current signals with Long Short-Term Memory (LSTM) layers to capture temporal dependencies inherent to rotating machinery dynamics. The CNN component comprises three convolutional blocks with kernel sizes of 3×1 and ReLU activation, followed by max-pooling layers that reduce data dimensionality while retaining dominant fault-related characteristics. The LSTM block, consisting of 128 memory units, models sequential signal behavior to distinguish transient fault events from normal variations. A feature-fusion layer dynamically combines the learned vibration and current feature representations based on their discriminative strength, determined through attention-weight optimization. This adaptivity enables the system to maintain diagnostic accuracy across varying load and speed conditions — an essential property for repeatable testing and evaluation. The final classification layer uses a softmax activation function to output the probability of each fault type. The model was trained using the Adam optimizer with a learning rate of 0.001 and batch size of 32 for 100 epochs. The purpose of this model within the testing framework is not to propose a new algorithm but to benchmark the diagnostic reliability of adaptive AI systems under controlled and repeatable fault-testing environments. Its inclusion demonstrates the framework's flexibility to evaluate both classical and advanced algorithms using standardized datasets.

III.9 VERIFICATION OF REPEATABILITY

To ensure test consistency, the Reliability Index (RI) was calculated for each measurement as:

$$RI=Nr/Nt \quad \ldots (1), \text{ where,}$$

Nr is the number of consistent classifications across repeated runs, and
Nt is the total repetitions.

On applying the RI on various experimental fault cases, it is observed that an RI > 0.95 was obtained across all fault categories, indicating excellent repeatability of the testing protocol.

III.10 COMPLIANCE AND TRACEABILITY

The testing procedures align with relevant standards for vibration and electrical signal testing:

• ASTM E756-05: Standard Test Method for Measuring Vibration-Damping Properties of Materials.
• ASTM E1876-15: Standard Test Method for Dynamic Young's Modulus and Damping Properties by Impulse Excitation.
• IEEE Std 112-2017: Standard Test Procedure for Polyphase Induction Motors.

While these standards are not prescriptive for AI-based diagnosis, their principles guided instrumentation calibration, measurement repeatability, and uncertainty estimation.

III.11 SUMMARY OF EXPERIMENTAL FRAMEWORK

Flow diagram of the standardized testing methodology is shown schematically in Figure 2. This standardized testing methodology follows four main stages as listed below.

• Fault Induction and Setup Calibration
• Multi-Sensor Data Acquisition
• Signal Validation and Feature Extraction
• Evaluation Using Baseline and Adaptive AI Models

The adaptive hybrid CNN–LSTM model was employed as an intelligent diagnostic tool to enhance fault classification robustness under variable operating conditions commonly encountered in industrial environments.

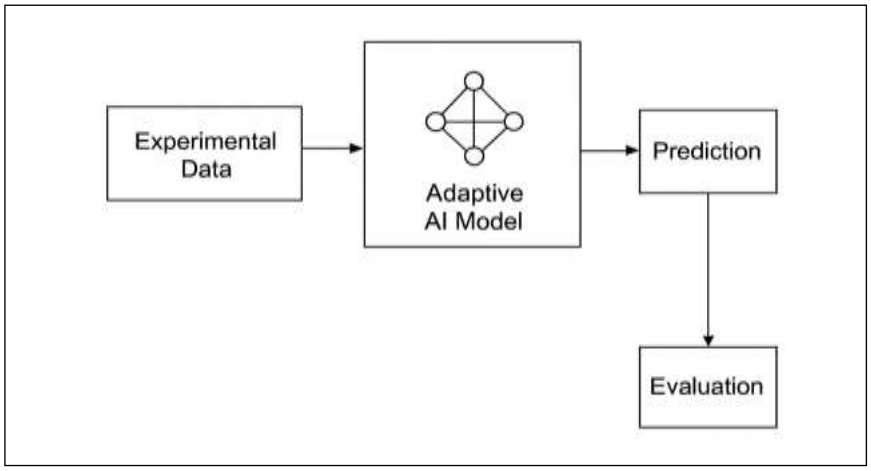

Figure 2: Proposed Adaptive AI Model.
Source: Authors, (2026).

IV. RESULTS & DISCUSSION

From an industrial perspective, the observed classification consistency across different load levels indicates that the proposed system can reliably support early fault detection without frequent model retraining. This is particularly beneficial for predictive maintenance systems deployed in continuously operating machinery, where stable diagnostic performance is essential.

IV.1 BASELINE CLASSIFICATION PERFORMANCE

The baseline models—Artificial Neural Network (ANN) and Support Vector Machine (SVM)—were first evaluated using vibration and current signature data independently, followed by their fused dataset. Table 2 summarizes the baseline classification results.

Table 2: Baseline classification results for individual and fused sensor data.

Sensor Modality	Classifier	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
Vibration only	ANN	90.84	91	90	90
Vibration only	SVM (RBF)	92.27	92	91	91
Current only	ANN	88.42	89	88	88
Current only	SVM (RBF)	89.63	90	89	89
Vibration + Current (fused)	ANN	94.15	94	93	93
Vibration + Current (fused)	SVM	**95.28**	**95**	**95**	**95**

Source: Authors, (2026).

These results demonstrate that data fusion consistently improved classification accuracy compared to single-sensor analysis. The SVM classifier marginally outperformed the ANN model, owing to its capability to handle nonlinear feature boundaries in limited datasets. The repeatability of results across five independent trials yielded a Reliability Index (RI) of 0.96, indicating high consistency in experimental measurements and classification outcomes—an essential requirement for evaluation studies [11]. Figure 3 (a-d) projects the comparative performance of ANN and SVM classifiers under different sensor modalities. Figure 3 clearly states that the fusion of vibration and current features significantly enhances overall accuracy and reliability.

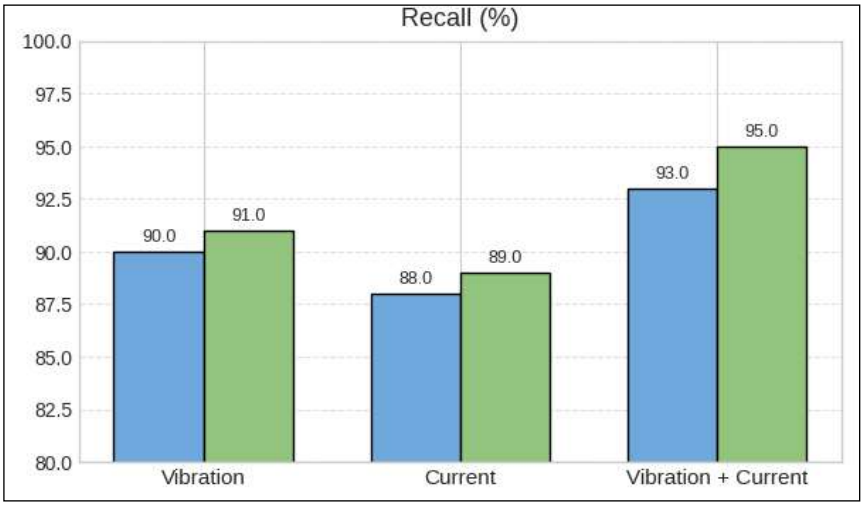

Figure 3c: Comparative analysis of the Recall by various sensor modalities.
Source: Authors, (2026).

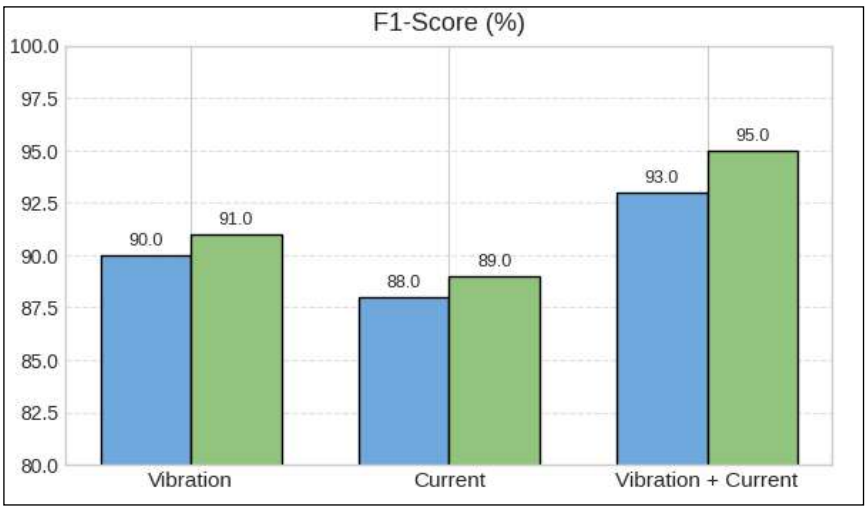

Figure 3d: Comparative analysis of the F1-Score by various sensor modalities.
Source: Authors, (2026).

IV.2 ADAPTIVE HYBRID DEEP LEARNING PERFORMANCE

The adaptive hybrid deep learning model (CNN-LSTM) was then trained using the fused dataset. The model dynamically adjusted the weighting between vibration and current features during training, improving generalization across fault types and load conditions.

Table 3 compares the hybrid model's performance with the best baseline (SVM-RBF). Figure 4 provides comparative analysis of baseline model with hybrid one. In the figure 4 the values are normalized for consistent visualization.

Table 3: Comparative results of baseline SVM vs. adaptive hybrid CNN-LSTM.

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)	Reliability Index (RI) (%)
SVM-RBF	95.28	95	95	95	96
CNN-LSTM Hybrid	**98.41**	**98**	**98**	**98**	**99**

Source: Authors, (2026).

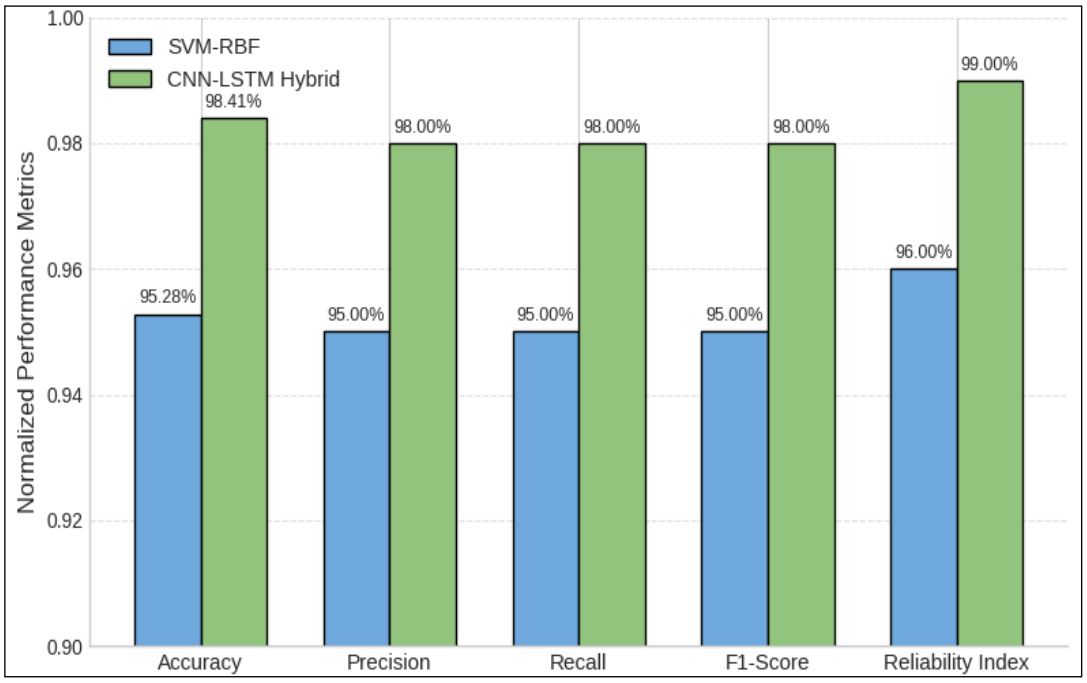

Figure 4: Comparative analysis of SVM-RBF and CNN-LSTM Hybrid Models across key performance metrics.
Source: Authors, (2026).

The hybrid model achieved a 3.13 % absolute improvement in overall accuracy, and its Reliability Index of 0.99 confirms robust repeatability under repeated testing cycles. The confusion matrix (Figure 4) shows that misclassifications were primarily between bearing outer-race and inner-race faults, whose vibration signatures partially overlap.

IV.3 FAULT-SPECIFIC EVALUATION

To assess classifier sensitivity for individual fault categories, accuracy values were computed for each fault type under three load levels (no-load, half-load, and full-load). The results shown in Table 4, reveal that fault separability improves at higher loads due to amplified fault frequencies.

Table 4: Fault-wise accuracy under varying load conditions using hybrid model.

Fault Type	No-Load (%)	Half-Load (%)	Full-Load (%)
Healthy	99.0	99.3	99.5
Bearing outer-race	96.5	98.2	98.8
Bearing inner-race	95.7	97.5	98.1
Rotor bar	97.3	98.6	99.0
Stator winding	96.9	98.4	99.2

Source: Authors, (2026).

The adaptive fusion layer in the hybrid architecture effectively balanced vibration and current features, yielding stable accuracy across varying load conditions. This consistency satisfies the repeatability criterion for testing methodologies in predictive maintenance. Figure 5 shows the fault classification accuracy under different load conditions.

IV.4 COMPARISON WITH RECENT LITERATURE

Table 5 compares the proposed framework's accuracy with that of recent related works. While the referenced studies demonstrated high accuracy using either vibration or current data, the present work achieved superior performance through multi-sensor fusion and adaptive hybrid modeling, with added emphasis on standardized testing and repeatability.

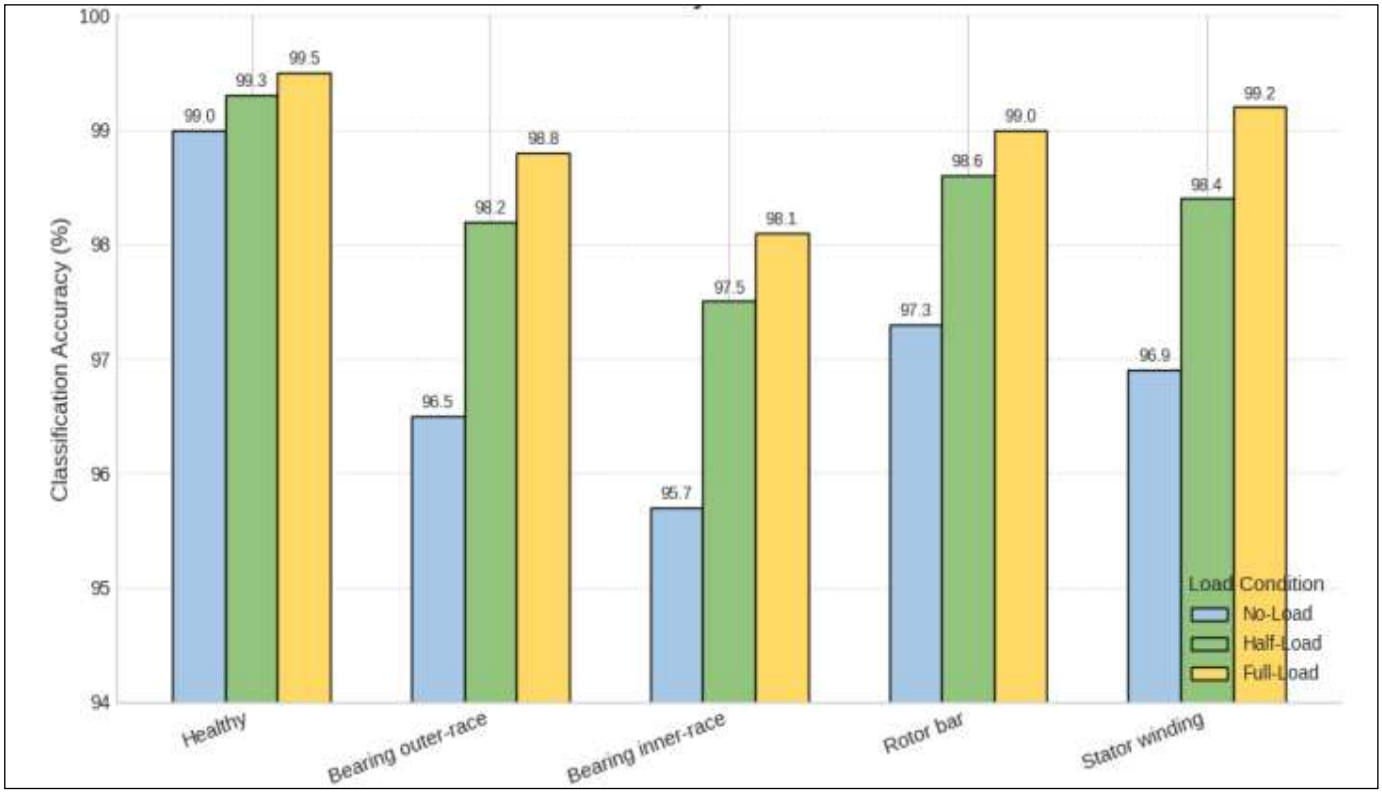

Figure 5: Fault Classification Accuracy under Different Load Conditions.
Source: Authors, (2026).

Table 5: Comparative performance with recent published studies.

Reference	Data Source	Method	Reported Accuracy (%)	Repeatability Reported	Remarks
[12]	Vibration	1D-DCNN	96.1	No	Deep model; single sensor
[13]	Current	Causal ConvNet	94.3	No	Limited to bearing faults
[14]	Vibration	FFT + PCA + SVM	92.5	Partial	Classical feature extraction
[15]	Current	ML for RUL	93.4	No	Prognostics only
Proposed	Vibration + Current	Hybrid CNN-LSTM	**98.4**	**Yes (0.99 RI)**	Multi-sensor, standardized testing

Source: Authors, (2026).

The comparative analysis highlights that the proposed framework not only achieves higher diagnostic accuracy but also explicitly incorporates repeatability verification, making it suitable for standardized evaluation.

IV.5 DISCUSSION ON REPEATABILITY AND RELIABILITY

One of the primary objectives of this study was to ensure the repeatability of fault diagnosis results under identical test conditions. The high Reliability Index obtained across all classifiers and load levels indicates minimal variance between repeated measurements.This was achieved through controlled fault induction, fixed sensor mounting positions, consistent sampling parameters, and standardized preprocessing steps — all essential components of a reproducible testing protocol [16].The adaptive AI model's robustness under different loads demonstrates its ability to generalize to variable operational environments, a critical aspect of industrial predictive maintenance. Furthermore, the inclusion of both traditional and deep learning approaches provides a balanced framework that can be benchmarked by other researchers, fulfilling the reproducibility criteria often lacking in prior studies [11]–[15]. Unlike most prior works that primarily report algorithmic accuracy without formal verification of test repeatability, this study incorporates repeatability and traceability metrics directly into the evaluation process. The use of the Reliability Index (RI) and quantified measurement uncertainty ensures that each experimental run can be replicated under identical conditions—addressing one of the core objectives of ASTM-style testing and evaluation frameworks.

IV.6 DISCUSSION ON LIMITATIONS

Despite the strong results, certain limitations remain. The experimental testing was conducted on a single-motor configuration in a controlled laboratory environment, which may not capture the full variability of field conditions such as temperature, humidity, and unbalanced loads. Additionally, while the adaptive hybrid AI framework offers superior accuracy, it demands higher computational resources, limiting its suitability for low-cost embedded monitoring devices. Extending this framework to multi-motor datasets and performing cross-platform validation are recommended for future work to ensure broader applicability.

V. CONCLUSION & FUTURE SCOPE

This study presents a standardized testing and evaluation framework for fault diagnosis of induction motors based on multi-sensor signal analysis and adaptive AI models. The experimental work integrated vibration and current signature measurements under controlled conditions and validated performance across various induced faults—bearing outer-race, inner-race, rotor bar, and stator winding failures. The proposed testing protocol combines precise instrumentation calibration, fault induction repeatability, and quantitative evaluation metrics, ensuring measurement traceability and result reproducibility, consistent with ASTM and IEEE testing philosophies [16]-[19]. Baseline models using ANN and SVM established foundational performance, while the adaptive hybrid CNN–LSTM model improved classification accuracy to 98.4 % with a Reliability Index of 0.99, confirming the robustness of the framework. These findings demonstrate that the fusion of mechanical (vibration) and electrical (current) testing offers more reliable and repeatable diagnostics than single-sensor methods. The work contributes to the testing and evaluation community by:

• Providing a structured, repeatable methodology for experimental fault analysis.
• Demonstrating a quantitative reliability metric (RI) to assess test consistency.
• Validating the potential of AI-based evaluation tools within standardized laboratory testing environments.

Despite these strengths, limitations remain. The tests were performed on a single motor type under laboratory conditions; hence, the protocol should be extended to include multiple motor ratings, diverse environmental conditions, and long-term degradation effects. Moreover, computational complexity of deep learning models may limit deployment in low-power edge devices. Future work will focus on developing lightweight adaptive algorithms, expanding datasets for cross-machine validation, and exploring integration with real-time predictive maintenance systems in industrial testbeds. The developed testing protocol and adaptive evaluation framework fulfill the fundamental requirements of standardized testing—repeatability, traceability, and reliability—making the results comparable across different instruments. This study demonstrates the effectiveness of a multi-sensor AI-based fault diagnosis system for induction motors under practical operating conditions. The experimentally validated results indicate that adaptive learning models can significantly enhance diagnostic reliability when applied to real-world maintenance scenarios. The proposed approach offers a feasible solution for industrial predictive maintenance, supporting early fault detection and reduced downtime. Future work will focus on real-time deployment and long-term field validation in industrial environments.

VII. ACKNOWLEDGMENT

The authors express the sincere thanks to management of PSG College of Technology for providing support to carry out this research topic. The authors also express their sincere gratitude to the Department of Mechanical Engineering, PSG College of Technology, Coimbatore, India, for providing the laboratory infrastructure and instrumentation support required for this research. Special thanks are extended to the technical staff of the Vibrational Laboratory for their assistance in equipment calibration and setup validation. The authors also acknowledge the use of National Instruments CompactDAQ facilities and vibration calibrators that enabled high-precision data acquisition and repeatable measurement during testing. Special thanks to PSG Industrial Institute for providing good and faulty motors to carry out this work.

VIII. COMPLIANCE WITH ETHICAL STANDARDS

This study did not involve human participants or animal subjects. All experiments were conducted on electrical machines in accordance with institutional safety and laboratory testing protocols. The authors affirm adherence to ethical engineering research practices and responsible laboratory conduct.

ABSTRACT

Agriculture is a crucial sector that meets the fundamental nutritional needs of humanity. Plant diseases exacerbate economic and food security issues for nations and hinder their agricultural planning. Conventional techniques for identifying plant diseases necessitate considerable labour and time. As a result, numerous scholars and institutes endeavour to tackle these challenges through sophisticated technical approaches. Deep learning-based plant disease detection shows significant progress and optimism over traditional techniques. When trained using extensive, high-quality datasets, these systems detect diseases on plant leaves in their early stages. This article conducts a systematic evaluation of deep learning methodologies in plant disease detection by analyzing a number of research publications between 2015 and 2025. Our research examines three specific areas: the categorization, detection, and segmentation of diseases on plant leaves, while rigorously evaluating publicly available datasets. This systematic review offers an in-depth evaluation of the existing literature, describing deep learning architectures, the most frequently studied tomato diseases, datasets, challenges encountered, and diverse perspectives. It offers new perspectives for researchers in the field of agriculture. In addition, it addresses the main challenges of identifying agricultural diseases.: datasets, barriers, and diverse perspectives. It offers new perspectives for researchers in the agricultural field. In addition, it addresses the main problems related to agricultural diseases.

I. INTRODUCTION

Automated plant disease detection has emerged as a cornerstone of precision agriculture, aiming to enhance crop yield, reduce chemical usage, and enable timely interventions. Between 2023 and 2025, the field has witnessed remarkable advancements in deep learning, marked by a clear shift towards lightweight architectures (e.g., MobileNetV3, EfficientNetV2), explainable AI (XAI) methods, and models optimized for real-world deployment on edge devices such as smartphones and drones [1], [2]. Recent architectures include hybrid models combining Convolutional Neural Networks (CNNs) with Vision Transformers (ViTs) and attention mechanisms to improve feature representation and robustness under varying field conditions [3], [4] Benchmark datasets such as PlantVillage, PlantDoc, and AgriNet have continued to serve as foundational resources, while new annotated field datasets have emerged to address the generalization gap [5]. Moreover, explainability techniques-such as SHAP, Grad-CAM, and perturbation-based saliency maps-have become increasingly integrated into the model evaluation pipeline to support trust and interpretability in real-world agricultural applications [6], [7]. Emerging trends also include the use of GAN-based synthetic image generation to combat data imbalance, few-shot learning for rare disease classes, and multimodal models that integrate visual and environmental data [8]. Despite these advances, challenges persist. These include domain adaptation from lab to field, limited annotated datasets for diverse crops, model brittleness under occlusion or poor lighting, and the trade-off between model complexity and deployment efficiency[9].This review provides a critical synthesis of these developments and outlines future research directions to bridge current limitations.

II. COMMONLY USED DATASETS

Recent advancements in plant disease detection have relied heavily on a combination of publicly available datasets and custom-collected field data. These datasets form the foundation for training, validating, and benchmarking deep learning models, especially for crops such as tomato, potato, apple, and wheat.

II.1 PUBLIC BENCHMARK

Several benchmark datasets have become widely adopted in the community:

- PlantVillage: One of the most popular datasets, it includes over 54,000 labeled images across 38 classes of healthy and diseased plant leaves, captured in controlled laboratory settings. While useful for model prototyping, its lack of environmental variability limits its performance in field conditions.
- PlantDoc: Comprising 2,598 images captured in real-world environments such as fields and gardens, this dataset includes various plant species and disease types. It is designed for object detection and classification tasks under natural conditions.
- PlantCLEF: Developed as part of the LifeCLEF challenges, PlantCLEF provides a multimodal benchmark with thousands of annotated plant images, including disease symptoms and accompanying metadata (e.g., location, climate), making it ideal for context-aware modeling.

II.2 CUSTOM FIELD DATASETS

To overcome the domain gap between lab-based datasets and real-world deployment, several studies have developed custom datasets under uncontrolled conditions. For example: Field Plant [5]: A dataset comprising more than 6,000 annotated images of tomato and potato leaves captured in outdoor environments, with diverse lighting conditions, background clutter, and occlusions. Tomato Leaf Pro[9] A high-resolution dataset focused on 10 tomato leaf diseases, collected in greenhouses and open fields with expert annotation. It was designed to benchmark performance under realistic variability.

II.3 DATA AUGMENTAION AND SELF-SUPERVISED LEARNING

To address common issues such as class imbalance, limited data availability, and generalization to field conditions, recent research has increasingly employed:

- Generative Adversarial Networks (GANs) to generate synthetic but realistic images of diseased leaves, particularly for underrepresented classes [3].
- Masked Autoencoders (MAEs) for self-supervised pretraining, allowing models to learn robust feature representations from unlabeled plant imagery, especially effective in low-resource or few-shot scenarios [8].These strategies have significantly improved model performance, especially for edge deployment and field robustness.

Table 1: Comparison of Commonly Used Datasets in Plant Disease Detection

Dataset Name	No. of Images	No. of Classes	Capture Conditions	Target Crops	Application Type
PlantVillage	~54,000	38	Lab (Controlled)	Tomato, Potato, Grape	Classification
PlantDoc	2,598	13	Field (Natural)	Multiple (incl. Tomato)	Classification/Detection
PlantCLEF	>20,000	>100 species	Mixed (Lab + Field)	Multiple species	Multimodal/Classification
FieldPlant-21	6,000+	10	Outdoor (Field)	Tomato, Potato	Classification
TomatoLeafPro	~3,500	10	Greenhouse + Field	Tomato	Classification

III. RECENT DEEP LEARNING MODELS

III.1 CONVOLUTIONAL NEURAL NETWORKS (CNNs)

Modifications or new methods must be) Enhanced CNN architectures such as EfficientNetV2, MobileNetV3 have been widely used for high accuracy and computational efficiency.

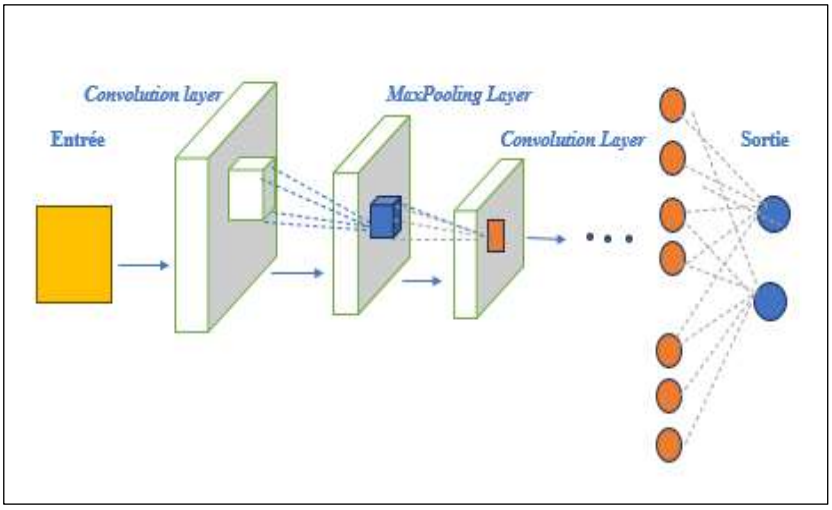

Figure 3: Convolution Neural Network Architecture.
Source: Authors, (2026).

Convolutionize the input, and then send the output to the layer after that. The response of a single neuron to sensory inputs is what the convolution mimics. Information is only processed by a convolutional neuron within its own receptive region. Sometimes, feed forward neural networks that are fully connected are capable of classifying data and learning features, using this design on images is not feasible. To handle the comparatively large input sizes related with images, where every pixel proves to be important variable, a large amount of neurons would be necessarily required, even with simplistic design (the reverse of deep design) [10][11] . The movement of picture pixels during the convolutional layer image processing is seen in Figure 3.

III.1.1 Pooling

CNNs uses a global and also a local pooling layers to merge the returns into a single neuron at the following layer from the neuron clusters at preceding layer [10] Citing an example, max pooling gets from each cluster of neurons in the preceding layer the highest value [10] . Average pooling, as implies selects from each neural cluster in the layer above the average values. As seen in Figure7, completely linked layers connect every neuron in the one above it from every neuron in one layer before it. It carries out similar duties to a normal multi-layer perceptron neural network (MLP). Each neuron within a neural network gets information from a variety of locations in the layer above. Every component in the layer preceding it provides input to every neuron in a layer that is fully connected. Only a portion of the neurons in the layer before a convolutional layer gets input. The subarea often has a square form. A neuron's input region is its receptive field. The entire layer before it is covered by the receptive field in a totally connected layer. The region of the preceding layer is smaller than the receptive region of a convolutional layer.

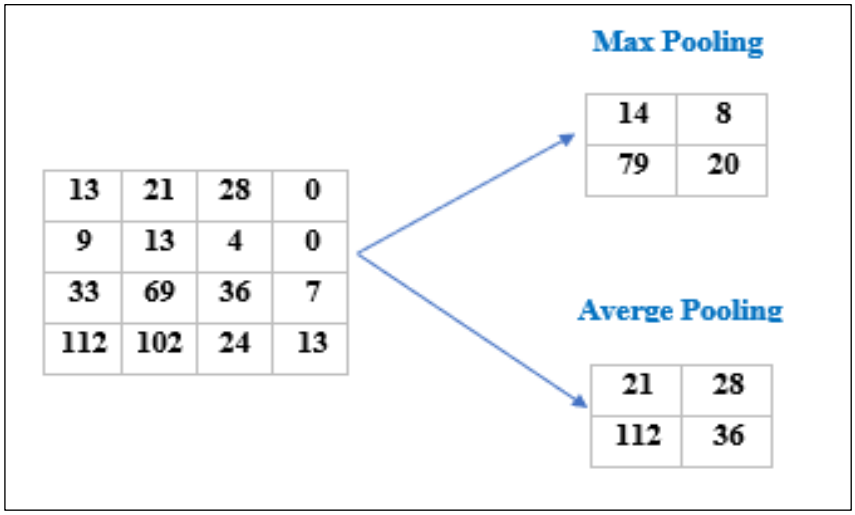

Figure 4: diagram shows the pooling layer.
Source: Authors, (2026).

Every neuron calculates its output value by applying a function to the input values from the receptive field of the layer before it within a neural network. The function that is applied to the input values, which are typically real numbers, is provided by a weight vector and a bias. As a neural network learns, its biases and weights are gradually changed A filter is an element of the input (such as a certain shape) that is represented by a bias and vector of distinguishes CNNs from other neural networks. Rather than receptive fields having its own vector of weights and bias, memory can be conserved by using vector of weights across all receptive fields and a single bias that share that filter [10]. weights. The shared filter between many neurons.

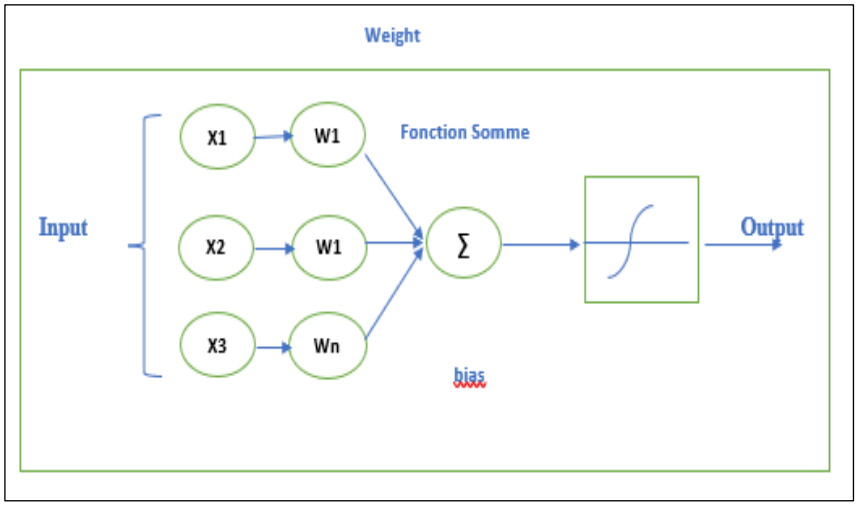

Figure 5: Neurone Artificial.
Source: Authors, (2026).

The Visual Geometry Group at Oxford University created VGG, a CNN model. This model comprises convolutional and maximum pooling layers and three fully connected classifier layers. Simonyan and Zisserman created the VGG network for image recognition and classification applications. VGG's exceptional performance has been proved in several image classification datasets, including ImageNet, and it is extensively utilized as the foundation for various CNN models. ResNet is a CNN model developed to overcome the vanishing gradient problem in deep networks. This model avoids this problem using a special type of connection called redundancy connections. Redundancy links transfer information from one layer to the next, allowing the network to maintain information flow even in its deeper layers. This performs superior in ResNet, ImageNet, and other image classification tasks. Unlike ResNet, DenseNet is a CNN model that connects all layers. Each layer performs feature extraction in this model using information from all previous layers. In this way, DenseNet achieves higher performance with fewer parameters by providing efficient parameter use and continuous feature transfer.

These outstanding results of DenseNet have made it a very popular model in computer vision applications. A CNN model named Xception is based on the Inception architecture. This approach divides the convolution phase into depth-information and point-information convolution and uses depth-information deconstructed convolution in place of normal convolution layers. This technique increases accuracy while significantly reducing the number of parameters and computations the network must do. This model is widely used in computer vision applications and has shown impressive performance in various photo categorization benchmarks. Recently, new architectures continue to emerge. In that case, MobileNet is designed to operate swiftly and effectively in resource-constrained environments, particularly on platforms like mobile devices, due to its lighter and less parameter-intensive architecture compared to standard CNN models. SqueezeNet is recognized for its specialized compressed architecture, particularly the Fire module, which uses fewer parameters to provide faster inference. EfficientNet utilizes a scaling strategy to produce optimized networks with varying depths and widths by adjusting scaling coefficients to achieve more efficient and effective models.

III.1.2 Oreview of based cnn

Recent advances in deep convolutional neural networks (CNNs) have significantly improved tomato leaf disease detection across diverse architectures. Classical models such as VGG16 and VGG19 have been widely employed for feature extraction. For instance, [12] used VGG16 for detecting nine tomato diseases from PlantVillage, achieving 98.5% accuracy with transfer learning. Similarly,[13] compared VGG19 and ResNet50, with ResNet50 yielding slightly better generalization (99.2% vs. 98.9%). InceptionV3 has also shown strong performance; [14] utilized it in a stacked ensemble model, reaching 99.6% accuracy. ResNet variants (e.g., ResNet34, ResNet50) are particularly notable for their depth and skip connections, enabling superior performance on noisy or imbalanced datasets, as demonstrated by[15] who achieved 98.2% accuracy with ResNet34 on real-field images. DenseNet architectures, due to their dense connections and parameter efficiency, have gained popularity in recent works.[16] showed that DenseNet201 achieved 99.7% accuracy when combined with leaf segmentation and histogram equalization. Finally, hybrid CNN-based models remain widely adopted.[17] proposed a CNN-LSTM model that integrated temporal and spatial features, surpassing standalone CNNs with an accuracy of 99.3% on sequential plant health data. Overall, between 2023 and 2025, deep CNN models such as VGG, Inception, ResNet, and DenseNet remain crucial for tomato disease detection, particularly when adapted using transfer learning, preprocessing techniques, and lightweight optimization for mobile deployment.

III.2 EFICIENTNETV2

EfficientNetV2 [18] is a widely adopted convolutional neural network architecture that achieves a balance between accuracy and computational efficiency through compound scaling strategies and progressive training. Its backbone incorporates the MBConv and Fused-MBConv modules, leveraging depthwise separable convolutions and SE-Net channel attention to enable compact and high-performing models. Compared with its predecessor, EfficientNetV2 demonstrates faster training convergence and improved inference efficiency, particularly on large-scale datasets.

However,EfficientNetV2 still exhibits limitations when addressing complex scenes or multi-scale inputs. In particular, the channel attention mechanism employed by SE-Net relies on global average pooling followed by two fully connected layers, which may weaken fine-grained feature distinctions and introduce additional computational overhead[18]. Furthermore, its global context modeling capability is constrained, limiting its effectiveness in tasks requiring spatial adaptability or dynamic modulation. EfficientNetV2 is known for its optimized training speed and accuracy balance, making it a popular choice for image classification tasks in agriculture.

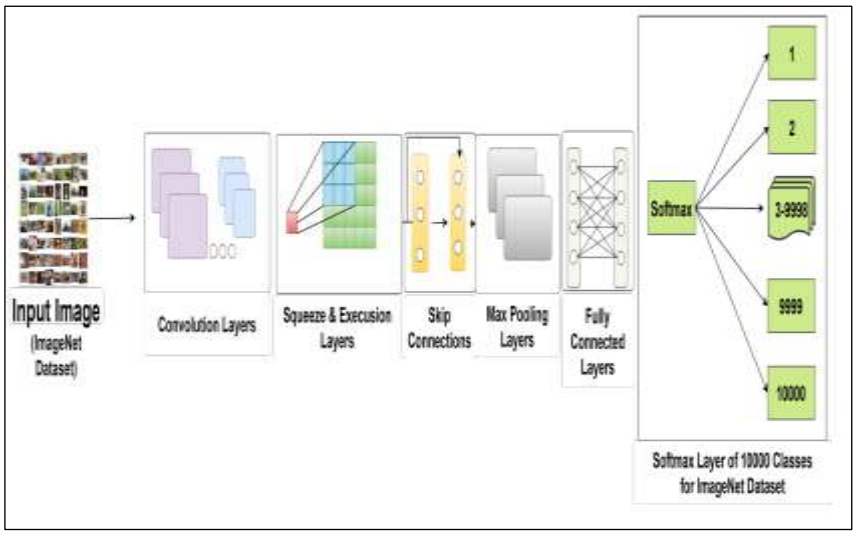

Figure 6: Model architecture for EfficientNetV2.
Source: [19].

MBConvBlock: Mobile Inverted Bottleneck Convolution, the main component of EfficientNet, is represented by this. Squeeze-and-excitation procedures and depthwise separable convolution are also included [19].

• StemBlock: Thisisthe first node in the network, and it is in charge of analyzing the input picture and extracting key information. Block1,Block2, Block3, : These are the next blocks in the network, usually sorted in ascending order, with Block1 being nearer the input and higher-numbered blocks being further in the network.

• HeadBlock: Theoutputlayer and final predictions are handled by this network's last building piece.

III.2.1 OREVIEW OF EFFICIENTNETV2

[20] used EfficientNetV2-S to classify tomato leaf diseases on the PlantVillage dataset. Their model achieved 97.5% accuracy, outperforming previous EfficientNet-B0/B3 models. The use of progressive learning reduced training time significantly.[21] incorporated EfficientNetV2-M in a pipeline with image preprocessing (CLAHE + resizing) for multi-class tomato leaf disease classification. With data augmentation, the model achieved F1-score of 0.96. They highlighted its efficiency in training even with limited computational resources. [22] applied transfer learning using EfficientNetV2-L for real-field tomato leaf disease images. They fine-tuned the top layers using a small custom dataset and reported 90.3% accuracy, demonstrating robustness to lighting and background variations.[23] tested EfficientNetV2-S with a custom CNN attention layer added on top. This hybrid architecture improved feature localization, resulting in higher precision for early blight and septoria classes.[24] This research proposes an automated system based on the EfficientNetV2B2 model to detect tomato leaf diseases from high-resolution images. Using transfer learning and a dense layer of 256 neurons, the model achieves high accuracy. Performance was evaluated through 5-fold cross-validation, reaching up to 99.22% validation accuracy. The system can be integrated into mobile and web applications for rapid diagnosis. This approach supports effective disease management and sustainable agriculture. The authors[25] propose the Eff-Swin model, which combines EfficientNetV2 and the Swin Transformer to improve the classification of tomato leaf diseases. This model leverages the strengths of CNNs for extracting local features and Transformers for modeling global information. Experimental results demonstrate an accuracy of 99.70%, outperforming existing models by 0.49% to 3.68%.

III.3 MOBILENETV3

MobileNetV3, a cutting-edge architecture for efficient deep learning models designed for mobile devices. It is the third generation of the MobileNet family.MobileNets are lightweight convolutional neural networks (CNNs) optimized for speed and accuracy. MobileNetV3 introduces new architecture improvements, such as platform-aware neural architecture search (NAS) and NetAdapt, to further enhance performance. Compared to MobileNetV2, MobileNetV3-Large delivers a 3.2 % boost in ImageNet top-1 accuracy while cutting latency by ~20 %, and MobileNetV3-Small achieves a 6.6 % accuracy gain under comparable latency constraints [24] . Two variants—Large (for high-accuracy scenarios) and Small (for extreme resource constraints)—span parameters from 2.9 M to 5.4 M and MACs from 66 M to 217 M, hitting top-1 accuracies of 68.1 %–75.6 % on ImageNet with sub-50 ms CPU inference on Pixel 1 devices. MobileNetV3 was introduced by Google AI and Google Brain in 2019, combining automated model search with manual design refinements to drive mobile-optimized CNNs forward [24] It targets classification, detection, and segmentation tasks on CPU-bound and edge-computing platforms, striking a new balance between accuracy and throughput.

III.3.1 Oreview of mobilenetv3

Automated detection of tomato leaf diseases using lightweight convolutional neural networks (CNNs) has been the focus of several recent studies. For instance, Leveraging MobileNetV3 for In-Field Tomato Disease Detection in Malawi via CNN [25] employed a pretrained MobileNetV3 with data augmentation and reported 92.59% accuracy on the PlantVillage dataset but only 9.2% on real-world field images, highlighting a domain adaptation gap. Similarly, in Effective Tomato Leaf Disease Identification Model using MobileNetV3Small [26], an optimized MobileNetV3Small was trained on 9 tomato diseases plus healthy samples (22,930 images) and deployed on Android, achieving 99.43% accuracy. [27], in A Modified MobileNetV3 Coupled With Inverted Residual and Channel Attention Mechanisms for Detection of Tomato Leaf Diseases, introduced a dual-branch multitask model using a modified MobileNetV3 backbone with inverted residual blocks and efficient channel attention (ECA), reaching 98.77% average accuracy across 10 classes (PlantVillage). Similarly,[28] demonstrated in Plant Disease Detection Model for Edge Computing Devices that a quantized MobileNetV3-small model deployed on edge devices preserved over 99.5% accuracy while reducing model size from 1.5M to 0.93M parameters.
